C.X. Maracle[1], R. Agca[2], B. Helder[1], H.W. Niessen[2], M.T. Nurmohamed[2], S.W. Tas[1]. *[1]Amsterdam Rheumatology and immunology Center | AMC; [2]Amsterdam Rheumatology and immunology Center | READE & VUMC, Amsterdam, Netherlands*

**Background:** Patients with chronic inflammatory diseases (CID) have higher risk of developing cardiovascular disease which may be in part due to increased systemic inflammatory burden. In atherosclerosis, extensive neovascularization is associated with plaque instability and increased chance of myocardial infarction (MI). We have established that non-canonical NF-κB signaling, and its central regulator NF-κB inducing kinase (NIK) in endothelial cells (EC) contributes to angiogenesis in synovial tissue of patients with various types of arthritis. Thus, we hypothesized that NIK$^+$ EC may also contribute to neovascularization in atherosclerotic lesions.
**Objectives:** Evaluate the expression of NIK in microvessels in atherosclerotic lesions from patients with and without CID and determine if it is associated with inflammatory cell influx, systemic inflammation or involvement of coronary arteries in MI.
**Methods:** Atherosclerotic lesions from 11 individuals with CID along with 11 matched controls, isolated from parts of the coronary artery implicated in MI (CA+) or not (CA-), were immunohistochemically stained with antibodies against NIK, CD31/34 (EC), myeloperoxidase (neutrophils), CD45 (lymphocytes), CD68 (macrophages) and tryptase (mast cells). NIK vessel density (NIK$^+$VD) and immune cell density (ICD) were subsequently calculated.
**Results:** NIK$^+$EC were present in atherosclerotic lesions of all coronary arteries. NIK$^+$VD significantly correlated with ICD of all characterized immune cells: leukocytes ($r=0.5227$; $p<0.0001$), macrophages ($r=0.3397$, $p<0.0001$), mast cells ($r=0.4205$, $p<0.0001$) and neutrophils ($r=0.2129$, $p=0.0016$). No significant differences were found in NIK$^+$VD in CID patients versus healthy, however, influx of leukocytes and macrophages per NIK$^+$ microvessel was significantly higher in CID lesions. Increased NIK$^+$ microvessels were also noted in CA+ as compared to CA- tissues ($p=0.0139$) in both healthy and CID patients.
**Conclusions:** NIK$^+$ microvessels are present in high numbers in atherosclerotic lesions and are strongly associated with the influx of inflammatory cells. Systemic inflammation is not a prerequisite for activation of this pathway in EC in atherosclerotic lesions, but our findings suggest that non-canonical NF-κB signaling is more pronounced in patients with CID resulting in the attraction of more immune cells that may further enhance progression of atherosclerotic lesions. Since activation of the non-canonical NF-κB pathway in EC induces angiogenesis and NIK$^+$ vessels are increased in coronary arteries associated with MI, non-canonical NF-κB signaling in EC may drive neovascularization and plaque instability, thus increasing the chance of developing a (fatal) MI.

## AB0266 TREAT-TO-TARGET BIOLOGIC THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS HAS A SAFER PROFILE COMPARED TO DELAYED INITIATION OF BIOLOGICS

C.E. Lampropoulos[1], P. Orfanos[2], M. Manoussakis[1], A. Tzioufas[1], H.M. Moutsopoulos[1], P.G. Vlachoyiannopoulos[1]. *[1]Department of Pathophysiology; [2]2Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National University of Athens, Athens, Greece*

**Background:** Rheumatoid arthritis (RA) is a chronic disease with involvement of small and large joints. Treat-to-target strategy aims to improve the outcome and rapidly reduce disease activity by using properly and aggressively all the therapeutic options.
**Objectives:** To estimate the safety of bDMARDs in RA patients, when administered according to international recommendations, compared to delayed initiation of bDMARDs in usual care.
**Methods:** All adverse events (AEs) and their severity were recorded. Cox proportional-hazards models were performed examining the association of treatment groups, with the risk of 1st AE. A separate analysis was performed for new cases of cancer during administration of bDMARDs.
**Results:** There were 250 patients in usual care and 113 patients in T2T group (*Table 1*). Delayed bDMARD administration was accompanied by more frequent and severe AEs, compared to T2T strategy (*Table 2*). In the 1st group 155 patients were recorded with at least one AE (56 patients with serious), of which 80 patients had at least one infection (30 a serious one). In T2T group, there were 47, 9, 11 and 2 patients with at least one AE, serious AE, infection and serious infection respectively. The IRR for the T2T group was 0.78 for the 1st AE, 0.56 for the 1st serious AE, 0.41 for the 1st infection and 0.23 for the 1st serious infection. *Table 3* illustrates the AEs (irrespective of AEs per person) in both groups.
A greater incidence of cancer was noticed in patients of usual care group. There were 15 new cases of cancer (non-melanoma skin=2 lung=2 lymphoma=5 breast=2 urinary tract=3 blood=1) compared with only one (urinary tract) in T2T group. The IR of the 1st group was 1.99/100PY compared to 0.4/100PY of the 2nd group ($p=0.027$). Nine of 16 cases had no risk factors for cancer. Mean

duration of sDMARDs, before bDMARDs, was 113 months and mean duration of bDMARDs 41 months.
The risk of 1st infection (irrespective of severity) was significantly higher for the usual care group compared to T2T group (p=0.002 for 1st infection, p=0.03 for 1st serious infection, *Figure 1*). The risk for 1st AE and serious AE was marginally non-significant (p=0.069 and 0.077 respectively) in usual care group.
After controlling for potential confounders, the risk for a serious AE remained significantly higher for usual care group (HR=0.42, p=0.041) (*Table 4*). Patients in T2T group were more likely to have a reduced risk for infection (HR=0.49 for 1st infection, HR=0.24 for serious one), although the findings were marginally non-significant (p=0.052 and 0.065 respectively).
Extra-articular manifestations increased the risk for any AE (irrespective of severity), progression of age was important for the 1st AE (mild or serious) and 1st serious infection, whereas patients with ESR >40mm/h were more vulnerable to infections.
**Conclusions:** Frequency and severity of AEs, especially infections, were substantially reduced in T2T group. A greater incidence of cancer was noticed in patients with delayed administration of bDMARDs.

## AB0267 NO REMARKABLE DIFFERENCES ON SONOGRAMS OF WRIST, METACARPOPHALANGEAL AND PROXIMAL INTERPHALANGEAL JOINTS BETWEEN RHEUMATOID FACTOR NEGATIVE RHEUMATOID ARTHRITIS AND RHEUMATOID FACTOR POSITIVE RHEUMATOID ARTHRITIS PATIENTS

D.F. Lin[1], Z.Y. Hu[1], X.H. Guo[1], J.Y. Cao[2], Y.F. Pan[1]. [1]*Rheumatology department;* [2]*US department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou, China*

**Background:** It is reported RF-negative Rheumatoid Arthritis (RF-nRA) had distinct genetic background and pathogenesis mechanism leading to different prognosis and therapy response from RF-positive Rheumatoid Arthritis (RF-pRA). Ultrasound (US) of wrist, metacarpophalangeal (MCP) and proximal interphalangeal joints (PIP) which are the classical zone of RA involvement might verify whether the joint destruction would be different in both group.
**Objectives:** To verify whether the joint destruction would be different in RF-negative Rheumatoid Arthritis (RF-nRA) and RF-positive Rheumatoid Arthritis (RF-pRA) patients.
**Methods:** It is a blinded, controlled trial. All cases including RF-nRA group and RF-pRA group satisfied 2009 classification criteria with abnormal swollen or pain in wrists, AMCPs or PIPs. RF-pRA group should have x-ray or MRI evidences The most affected side of joints including the 2nd, 3rd MCPs, Athe 2nd, 3rd PIPs and wrists were examined. US examination and scoring system referred to Backhaus's US7 scoring system related regions. In addition, synovitis in gray-scale US (GSUS) on dorsal side of the 2nd, 3rd MCPs and PIPs (0–3 grade) and bone erosions on dorso-median, ulnar, palmo-median sides (0 or 1 if absent/present) of wrist in GSUS were also counted in to get a total of 0–106 scores. DAS 28 (3 variables) was employed to divide each of the 2 groups into 4 subgroup to assess the sonograms in different disease activity levels.
**Results:** 1) 15 RF-nRA cases and 41 RF-pRA cases were enrolled. Mean age (53.8yrs, 57.2yrs), female-male ratio(29:12,16:9), and disease duration(7.53,7.88) of 2 groups were described as above. DAS-28>5.1 subgroups in both 2 groups had the most cases (RF-nRA/RFpRAremission:low:moderate:high=3:2:4:6/1:5:15:20).
2) DAS-28 had highly positive correlation(r=0.95) to US sum scores while poor positive correlation with synovitis GDUS sum scores or synovial Power Doppler(PD) signals sum scores alone.(r=0.57,0.62)
3) No significant differences between RF-nRA and RF-pRA in aspect of synovitis in GDUS, synovial PD signals, and bone erosions in GDUS in wrists, MCPs, PIPs respectively in different levels.
**Conclusions:** Our study has not found any distinctions in most affected joints between RF-nRA and RF-pRA patients.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2361

## AB0268 CORONARY ARTERY STENOSIS IN PATIENTS WITH RHEUMATIOD ARTHRITIS

E. Gerasimova[1], T. Popkova[1], D. Novikova[1], O. Fomicheva[2], D. Kolmakova[2], E. Nasonov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology;* [2]*Russian Cardiology Research and Production Complex, Moscow, Russian Federation*

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory disease characterized by increased cardiovascular morbidity and mortality. Coronary angiography (CAG) is the gold standard to identify and assess the degree of coronary artery (CA) involvement. CA diseases (CAD) development in RA patients (pts) is associated with the accumulation of traditional risk factors and immunological disorders.
**Objectives:** To determine the incidence and predictors of CA stenosis development in RA pts with suspected CAD.
**Methods:** To analyze 63 RA pts (male/female 25/38, mean age 58 [52; 63] years, with long-standing RA (10,5 [7; 23] years), moderate to high clinical disease activity DAS 28 =4,7 [3,3; 5,8]). All pts underwent CA angiography. Multiple regression analysis was used to determine the risk of CA stenosis in RA pts.
**Results:** CA stenosis was detected in 22 (35%) of the 63 pts, male/female 15/7 (I group), including single vessel involvement - in 15 (68%) pts, three-vessel damage - in 7 (32%) pts, without cases of documented two vessels lesions. The most common stenosis location was the middle segment of the left anterior descending artery (11 (50%) pts), the right coronary artery (RCA) was more rarely involved, and RCA stenosis was observed in 7 (33%) pts, stenosis of the middle RCA segment - in 9 (41%) out of 22 pts. In 41 (65%) out of 63 pts hemodynamically insignificant stenoses (<50%) or intact CA was documented, male/female 10/31 (II group). Groups were comparable in terms of age, disease duration and DAS 28 scores. Males prevailed in Group 1: 68% vs 24% in Group 2 ($p<0,05$). Detection rates of carotid artery atherosclerotic plaques and thickening of the intima-media were similar in Groups 1 and 2 (19/16% and 53/56% pts). The prevalence of traditional risk factors was also similar in both groups: hypertension - 77% and 88%, dyslipidemia - 26% and 33%, diabetes mellitus - 5% and 17%, smoking – 45% and 17%, physical inactivity - 58% and 42%, obesity - 45% and 32% pts in Group 1 and 2, respectively. Serum HDL cholesterol concentrations in Group 1 (1,2 [1,0;1,5]mmol/l) was lower, than in Group 2 (1,55 [1,3;2,0]mmol/l, $p$ =0,03), while concentrations of cholesterol, LDL cholesterol and triglycerides did not differ in between the groups. There were no differences in therapeutic and dosing regiments (disease-modifying antirheumatic drugs (DMARDs), GEBAs and oral glucocorticoids (GCs)), with the only exclusion: the duration of GCs therapy was higher in Group 1 pts (5,3 [4;12] years) vs (3,1 [1,5;8], $p<0,05$) Group 2. The multiple regression analysis did not establish any direct relationship between CA stenosis and gender, age, RA activity, cholesterol and LDL cholesterol concentrations, use of DMARDs and oral GCs. Age was the strongest, but not statistically significant variable predicting stenosis (odds ratio (OR) 0,85; 95% CI [0,72–1,0], $p$ =0,05), with the following HDL-C <1,2mmol/L for women and <1,0 mmol/L for men (OR 0,82; 95% CI [0,64–0,90], $p$ =0,09).
**Conclusions:** Male gender, low HDL cholesterol levels and long-term GCs use seem to increase the risk of coronary artery stenosis in RA pts.
**Disclosure of Interest:** None declared

## AB0269 CARDIOVASCULAR RISK ASSESSMENT IN PERSONS WITH AUTOIMMUNE RHEUMATIC DISEASE: A PILOT STUDY OF NON-INVASIVE ARTERIAL HEALTH TESTING

E.M. Scanlon[1], R. Mankad[2], C.S. Crowson[1,3], I.J. Kullo[2], S.L. Mulvagh[2], E.L. Matteson[1,3], Z. Kvrgic[1], J.M. Davis III[1]. [1]*Division of Rheumatology;* [2]*Division of Cardiology;* [3]*Department of Health Sciences Research, Mayo Clinic, Rochester, United States*

**Background:** Persons with rheumatoid arthritis (RA) have increased mortality attributable to atherosclerotic cardiovascular disease (ASCVD) events. While a heightened risk of ASCVD events exists in patients with RA, we have yet to uncover an accurate method for estimating that risk. It is unknown how the current state of disease activity affects arterial function in early subclinical ASCVD.
**Objectives:** Our goal is to determine the effect of the current state of inflammatory disease activity, as measured by the Simplified Disease Activity Index (SDAI) and Health Assessment Questionnaire (HAQ) score, on arterial health in patients with RA, using an innovative non-invasive testing package developed at Mayo Clinic in Rochester, Minnesota.
**Methods:** We recruited a cohort of 50 patients with RA as defined by the 2010 American College of Rheumatology/European League Against Rheumatism classification criteria, and conducted non-invasive arterial health testing on the same day as a rheumatologic assessment of clinical disease activity, which was classified in terms of tender/swollen joint counts, SDAI score and HAQ score. This arterial health testing package includes measurements of endothelial function (brachial artery reactivity testing, BART), arterial stiffness (pulse wave velocity, PWV), and early atherosclerosis (carotid intima-media thickness, CIMT, and carotid plaque presence).
Statistical analysis was performed with Spearman Correlation Coefficients between the rheumatologic disease activity scores and arterial health testing parameters.
**Results:** Our 50 patients had mean (SD) disease duration of 7.0 (±4.0) years, mean age of 57.2 years, and 38 (76%) were female. The average disease activity was moderate, with mean (SD) SDAI of 21.4 (±17.4); 27 patients had either moderate or high disease activity by SDAI. A statistically significant correlation emerged between the SDAI score and the following measures: corrected aortic augmentation index (r=0.35, p=0.012); and the CIMT of the right common carotid artery (r=0.28, p=0.048). The correlation between SDAI and aortic PWV was borderline (r=0.26, p=0.067). The HAQ score correlated significantly with the corrected aortic augmentation index (r=0.33, p=0.019), but not with PWV or CIMT measures of right and left common carotid artery.
**Conclusions:** We identified significant correlations between SDAI, and measures of arterial stiffness (i.e., corrected aortic augmentation index), and subclinical atherosclerosis (i.e., CIMT). The HAQ score significantly correlated with the corrected aortic augmentation index. This study suggests that the current state of disease activity in RA does significantly influence several measures of arterial health using this testing package.

## AB0270 WORSENING OF DIAGNOSTIC DELAY IN EARLY ARTHRITIS DURING THE LAST 10 YEARS: A SINGLE CENTER EXPERIENCE

F. Benaglio, S. Bugatti, G. Crepaldi, G. Sakellariou, C. Montecucco, R. Caporali.
*Division of Rheumatology, University of Pavia, IRCCS S. Matteo Foundation, Pavia, Italy*

**Background:** The reduction of the diagnostic delay in patients with early arthritis, in order to start treatment as early as possible and to improve outcomes, has required a considerable effort during the last 15 years.
**Objectives:** To evaluate the diagnostic delay, between 2004 and 2015, at our Early Arthritis Clinic (EAC).
**Methods:** 943 patients with rheumatoid arthritis (RA) (according to 1987 and/or 2010 classification criteria) or undifferentiated arthritis (UA) evaluated at our EAC between September 2004 to September 2015 were recruited (disease duration <12 months) and divided into 2 groups according to the time of diagnosis (group 1: 2004–2009; group 2: 2010–2015). A comparison among demographic features, diagnostic delay and disease activity (DAS28) at first evaluation was performed.
**Results:** A total of 943 patients were evaluated: 469 patients into the group 1 (74.4% women, mean age 58 ys) vs. 474 patients into the group 2 (74.7% women, mean age 57 ys). No differences were found in terms of serologic positivity and diagnosis. At baseline, patients in the group 2 showed lower disease activity as for DAS28 (4.86±1.17 vs. 4.32±1.24; p=0.0001), number of tender joints (6 IQR 2–11 vs. 4 IQR 2–8; p=0.0001), swollen joints (6 IQR 4–11 vs. 4 IQR 2–7; p=0.0001), ESR (22 IQR 13–40 vs. 16,5 IQR 8–33; p=0.0001). In contrast, patients in the group 1 showed lower time from the onset of symptoms to the diagnosis (111 days IQR 67–200 vs. 129 IQR 77–228; p=0.008). Data about the diagnostic delay comparing DAS28 categories are showed in figure 1: particularly in the group 2 there was a reduction in the number of patients in high disease activity-DAS28 who have the diagnosis established within the first 90 days after the onset of the disease (p=0,0026). 40% of patients in group 1 vs. 31% in group 2 had the diagnosis established within 90 days (p=0.005); however, the delay from the referral to the first evaluation at our EAC was similar in the two groups (21 days IQR 12–31 vs. 21 IQR 14–29; p=ns).

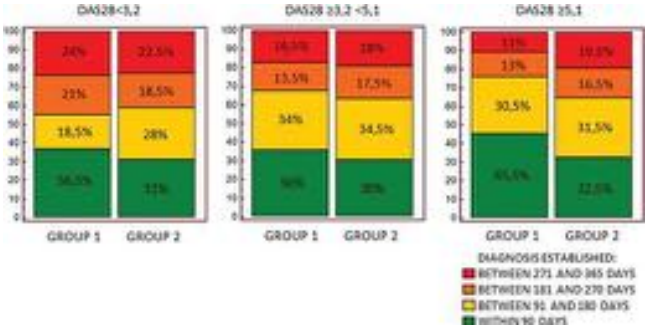

Figure 1

**Conclusions:** Currently, about 70% of the diagnosis is still not made within the so-called window of opportunity (90 days from the onset of symptoms). Moreover, a slight but significant worsening in the diagnostic delay has been observed; the delay doesn't seem to be related neither with time elapsing from referral to the first evaluation at the EAC nor to a lower disease activity at the beginning. Education programs at patients' and general practitioners' level should be implemented in order to reduce the delay and further improve the outcome.

## AB0271 EFFECTS OF GLUCOCORTICOIDS ON ENDOTHELIAL FUNCTION: FOCUS ON RHEUMATOID ARTHRITIS

F. Verhoeven[1,2], C. Prati[1,2], D. Wendling[2,3], C. Demougeot[1]. *[1]EA 4267 "fonctions et dysfonctions épithéliales", UFR SMP, université de Franche Comté; [2]Rhumatologie, CHRU de Besançon; [3]EA 4266 "agents pathogenes et inflammation", UFR SMP, université de Franche Comté, Besançon, France*

**Background:** Rheumatoid arthritis (RA) is the most common systemic autoimmune disease characterized by reduced life expectancy due to accelerated atherogenesis. Endothelial dysfunction (ED) precedes and initiates atherosclerosis, and its correction is associated with reduced CV risk. ED is present in RA and appears as a seminal target for reducing CV risk in RA. Despite the dramatic changes that occurred in the treatment approach in RA, majority of patients still use glucocorticoids (GCs). The potential harmful CV effects of GCs are "well-known" in the general population. In inflammatory diseases such as RA, the effects of GCs on CV risk is still a matter of debate. On the one hand, GC might increase CV risk by increasing CV risk factors but on the other hand, GC might reduce CV risk by decreasing the systemic and/or vascular inflammation.
**Objectives:** To provide the available data regarding the effects of GC on endothelial function, with a special focus on RA.
**Methods:** Systematic review of the literature on the PubMed database with the following keywords: "Glucocorticoids", "rheumatoid arthritis", "endothelial function" and "vascular function".
**Results:** In the vascular system, GC receptors are expressed by intact arteries, cultured vascular smooth muscle cells (VSMC) and endothelial cells. In physiological conditions, experimental data provide evidence of harmful effects of GCs on endothelial function, due to decreased Nitric oxide synthase activity/expression, decreased production of endothelium-derived hyperpolarizing factor (EDHF) and prostacyclin, the three main vasorelaxant endothelium-derived factors, associated with increased production of endothelin-1, an endothelium-derived vasoconstrictor. These experimental data were not unanimously confirmed by the few studies in healthy controls, which reported negative or not effect of GCs on endothelial function. Effect of GCs is totally different in inflammatory conditions in which GC reduced endothelial dysfunction and slowed progression of atherosclerotic plaques in animal models. Only 6 clinical studies were performed in RA. The available data suggested that low dose GC (5 mg/d) did not change endothelial function while a high dose for a short period (7 days) improved endothelial function in RA patient. No harmful effect of GC on endothelial function were reported in RA.
**Conclusions:** Data from experimental models highlighted the Janus face of GCs since they can exert deleterious effects on endothelial function when applied in "normal" cells/animals although they seem to be protective under inflammatory conditions. In RA patients, data are scarce and highly controversial due to methodological weaknesses. However, contrary to common believe that GCs deteriorate CV function, no effect and even positive effect of GCs on endothelial function have been reported. As more RA patients are starting GCs early in their disease course, there is an urgent need to perform clinical trials specifically-designed to define the best GCs strategy to prevent CV risk in RA.
**Disclosure of Interest:** None declared

## AB0272 ANTI-RHEUMATIC TREATMENT IS NOT ASSOCIATED WITH REDUCTION OF PENTRAXIN 3 (PTX3) IN RHEUMATOID ARTHRITIS (RA), PSORIATIC ARTHRITIS (PSA) AND ANKYLOSING SPONDYLITIS (AS)

G. Deyab[1], I. Hokstad[2], S. Agewall[3], T. Lyberg[4], J.E. Whist[1], M.C. Smastuen[5], B.B. Bottazzi[6], G.G. Hjeltnes[7], P.L. Meroni[8], I. Hollan[2,9,10]. *[1]Department of medical biochemistry, Lillehammer Hospital Trust; [2]Lillehammer Hospital for Rheumatic Diseases, Lillehammer; [3]Oslo University Hospital Ullevål and Institute of Clinical Sciences; [4]Medical biochemistry, Oslo University Hospital, Ullevål; [5]Health science, Oslo and Akershus University College, Oslo, Norway; [6]Humanitas Research Hospital, Milan, Italy; [7]Department of Medicine, Lillehammer Hospital Trust, Lillehammer, Norway; [8]Department of Clinical science and Community Health, University of Milan, Milan, Italy; [9]Harvard Medical School; [10]Brigham and Women's Hospital, Boston, United States*

**Background:** PTX3, an important component of the innate immune system,has been proposed as a useful biomarker of inflammation and cardiovascular (CV) risk, but its role in inflammatory rheumatic diseases (IRDs) is still uncertain [1,2].
**Objectives:** The aim of this study was to examine if methotrexate (MTX) and/or anti-tumor necrosis factor treatment (anti-TNF) treatment reduced serum PTX3 (s-PTX3) levels in IRDs (RA, PsA and AS), and if s-PTX3 levels were related to other markers of inflammation and to endothelial function (EF).

| | IRD (n=114) | RA (n= 64) | PsA (n=30) | AS (n= 20) |
|---|---|---|---|---|
| Number of patients treated with MTX monotherapy | 50 | 34 | 16 | 0 |
| PTX3 (ng/ml), Baseline | 3.9 (1.1-22.1) | 3.8 (1.2-22.1) | 4.2 (1.1-14.7) | 4.0 (1.9-8.5) |
| PTX3 (ng/ml), 6 weeks | 3.4 (0.7-11) | 3.3 (0.7-10.3) | 4.1 (0.9-11.1) | 3.2 (1.6-7.4) |
| PTX3 (ng/ml), 6 months | 3.9 (1.2-10.2) | 3.8 (1.2-9.3) | 4.4 (1.3-10.2) | 3.4 (1.5-8.4) |
| CRP (mg/L), Baseline | 8 (1-157) | 8 (1-78) | 5 (1-99) | 10 (1-157) |
| CRP (mg/L), 6 weeks | 2 (1-54) | 2 (1-54) | 3 (1-23) | 1 (1-34) |
| CRP (mg/L), 6 months | 2 (1-67) | 2 (1-67) | 2 (1-20) | 1 (1-14) |
| ESR (mm/h), Baseline | 13.0 (1-87) | 18.5 (1-81) | 8 (2-48) | 11 (2-87) |
| ESR (mm/h), 6 weeks | 7 (1-62) | 10.5 (2-62) | 6 (2-37) | 4 (1-12) |
| ESR (mm/h), 6 months | 7(2-37) | 9.5 (2-37) | 6 (2-22) | 3 (2-23) |

Values are presented as median (range).Reference range for s-PTX3 in serum are 1 ng/ml to 3 ng/ml.

**Methods:** From the biobank of PSARA, an observational study, we examined samples from 114 IRD patients starting with either MTX or anti-TNF with or without MTX (anti-TNF±MTX) due to active disease, who completed a 6 months follow up. s-PTX3 (enzyme-linked immunosorbent assay), EF (finger plethysmography) and established inflammatory biomarkers were evaluated at baseline and after 6 weeks and 6 months of therapy.
**Results:** The s-PTX3 levels in IRD and all the diagnostic subgroups were above the upper limit of the reference range. In contrast to established inflammatory markers, in particular C- reactive protein (CRP) and erythrocyte sedimentation rate (ESR) (all p-values $<0.05$), s-PTX3 levels did not change significantly after 6 weeks and 6 months of anti-rheumatic therapy (all $p>0.2$). The effect of MTX monotherapy and anti-TNF±MTX on s-PTX3 levels was similar. Changes in CRP, ESR and EF were not related to changes in s-PTX3 levels neither in univariate analyses nor in analyses adjusted for potential confounders.
**Conclusions:** IRD patients have increased s-PTX3 levels, which, in contrast to other inflammatory markers, do not seem to improve within 6 months of therapy with MTX and/or anti-TNF. Thus, in theory, s-PTX3 might reflect a persisting immune process, even a causal factor of the inflammation, not inhibited by the standard anti-rheumatic treatment. Furthermore, even though PTX3 is thought to be a strong predictor of CV prognosis, it was not related to EF.

## AB0273 DISEASE CHARACTERISTICS AND CHANGE OF ARTHRITIS ACTIVITY ACCORDING TO TREATMENT IN HEPATITIS B SURFACE ANTIGEN POSITIVE RHEUMATOID ARTHRITIS PATIENTS

H. Kim[1], Y. Eun[1], J.K. Ahn[2], J.-M. Oh[3], H. Jeong[1], J. Lee[1], E.-M. Koh[1], H.-S. Cha[1]. *[1]Department of Internal Medicine, Samsung Medical Center; [2]Department of Internal Medicine, Kangbuk Samsung Hospital, Seoul; [3]Anyang SAM Hospital, Anyang, Korea, Republic Of*

**Background:** Rheumatoid arthritis (RA) treatment may differ according to hepatitis B state and consequently bring about different outcome of arthritis. Only a small number of studies have addressed the differences in disease characteristics and treatment patterns of RA in relation to hepatitis B state. However, it has not yet been elucidated whether hepatitis B affects treatment outcome such as disease activity.
**Objectives:** We investigated possible differences in change of arthritis activity between RA patients according to concomitant hepatitis B virus (HBV) infection.
**Methods:** A retrospective analysis of 40 hepatitis B surface antigen (HBsAg)-positive RA patients and 112 HBsAg-negative RA patients was conducted. The longitudinal relationship between HBsAg-positivity and RA activity/medication use was analyzed using generalized estimating equations in regression models.
**Results:** There were no significant differences in group for baseline characteristics. In regression analysis, RA activity-related outcomes showed follow-up time-dependent improvement during study period. We observed significant interaction between time and HBsAg-positivity for disease activity score in 28 joints with 3 variables (DAS28–3; $P$ =0.026), that means decreases in DAS28–3 with time influenced by HBsAg-positivity. But this interaction did not remain significant after adjustment. For tender joints, erythrocyte sedimentation rate, and C-reactive protein levels, there were no interaction between time and HBsAg-positivity, while swollen joints showed significant interaction ($P$ =0.017). The time-association and group differences were not observed in alanine aminotransferase (ALT) level. Over all visits, HBsAg-positive patients were less likely to receive methotrexate (OR 0.09 [95% CI 0.04–0.19], $P$ <0.0001) and more likely to receive sulfasalazine (OR 3.67 [95% CI 1.94–6.95], $P$ <0.0001). In HBsAg-positive RA patients, initial hepatitis B state was related to use of DMARDs, especially methotrexate ($P$ =0.040). Hepatitis reactivation occurred in 4 patients (10%) in HBsAg-positive RA patients. Among the patients who experienced HBV reactivation, only one patient had received previous antiviral treatment at baseline, but the patient exhibited lower adherence to drug. All patients who experienced HBV reactivation showed positive HBV DNA at baseline. There were no cases of hepatic failure or death.
**Conclusions:** There were no significant differences over time in DAS28–3, tender joints, inflammatory markers, according to HBsAg-positivity, while swollen joints showed significant difference over time. ALT level did not showed time-association and group differences. HBsAg-positive RA patients were less likely to receive methotrexate and more likely to receive sulfasalazine.
**Disclosure of Interest:** None declared

## AB0274 THE INTERDEPENDENCE BETWEEN CLINICAL FEATURES OF RHEUMATOID ARTHRITIS, THYROID GLAND FUNCTION, AND THE ANTI-HORMONAL ANTIBODIES

O.V. Paramonova, I.P. Gontar, A.S. Trofimenko, L.A. Maslakova. *Clinical Immunology Lab, FSBSU Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation*

**Background:** According to the common notions, rheumatoid arthritis (RA) is an immunopathological condition with complex autoimmune response, directed presumably to synovial tissue. Besides that, there are some organ involvements in RA, that can strongly affect the extent of the autoimmune reactions. One of this organs is thyroid gland, because changes of its function, either increase or decrease, modulate activity of immune cells and inflammation level on the whole. Production of antibodies, directed to T3 and T4, is a candidate mechanism of the thyroid involvement.
**Objectives:** The objectives of our study are detection of different thyroid conditions in RA including determination of lesion type and function assessment, as well as searching for interdependence between the clinical features of RA, type of thyroid involvement, and the level of the anti-hormonal antibodies.
**Methods:** The research was carried out in agreement with the principles of the World Medical Association Declaration of Helsinki (1997). Approval for the investigation was got from the Regional Medical Ethics Committee. We enrolled adult patients with RA, verified using ACR/EULAR criteria (2010). RA activity was determined by means of DAS28 index. Thyroid involvement was detected by clinical, ultrasound, and laboratory assessment, including TSH, free T3, free T4, and anti-TPO. Anti-T3 and anti-T4 antibodies were measured using ELISA and calculated in terms of optical density units (ODU). The positive cutoff values, 0.098 ODU for anti-T3 and 0.093 ODU for anti-T4, have been found using healthy controls (n=39). Results were expressed as means±standard errors, the differences were considered significant at $p<0.05$.
**Results:** 75 patients with RA have been enrolled, including 61 (81.4%) women and 14 (18.6%) men, their age was from 25 to 78 years. Mean RA activity was 3.2±1.4 DAS28 points. Different visceral involvements were detected in 20 (26.7%) cases, and 5 (6.7%) of them had an overt clinical picture of thyroid lesions. The signs and symptoms for 4 of them were similar to Hashimoto's thyroiditis with hyperfunction, the remaining one was complied to the mixed toxic goiter. All these 5 patients had low TSH and quite high DAS28 score (4.8±1.9). However, the prevalence of subclinical thyroid disorders in RA was considerably higher. Virtually all the patients (n=73) have been revealed anti-T3 (0.128±0.047 ODU) and/or anti-T4 antibodies (0.152±0.050 ODU). There was no relationship between these antibodies and organ involvement, other than thyroid gland; RF titers also had no significant influence. We found some rather unexpected dependencies of these markers with X-ray RA stages, as well as with RA activity. There was a clear trend of elevation of mean anti-T4 concentration together with higher Steinbrocker stage (p=0.034, ANOVA), the inverse tendency have been observed for anti-T3 (p=0.047, ANOVA). Correlations of DAS28 score with anti-T4 (r=0.525, p=0.031) and anti-T3 (r=-0.391, p=0.040) were also opposite. There was another significant inverse correlation of DAS28 score and TSH concentration (r=-0.330, p=0.046).
**Conclusions:** Our data suggest that though anti-T4 concentration is tended to be elevated, high RA activity can promote hyperthyroidism. This is probably due to either influence of these antibodies to T4 and T3 production, or immune disturbances caused by thyroid hyperfunction itself.

## AB0275 DIFFERENCES IN THE CLINICAL EVALUATION OF JOINTS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SECONDARY SJÖGREN SYNDROME

K. Romanowska-Próchnicka[1,2], M. Olesińska[2], A. Paradowska-Gorycka[3], A. Felis-Giemza[2], M. Mańczak[4], D. Szukiewicz[1]. *[1]Department of General and Experimental Pathology, Warsaw Medical University; [2]Department and Polyclinic of Systemic Connective Tissue Diseases; [3]Department of Biochemistry and Molecular Biology; [4]Department of Epidemiology and Health Promotion, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warszawa, Poland*

**Background:** Secondary Sjögren syndrome (sSS) is classified as a connective tissue disease characterized mainly by xerophthalmia and xerostomia, and accompanied by various autoimmune diseases such as rheumatoid arthritis (RA), systemic lupus erythematosus, scleroderma, vasculitis, mixed connective tissue disease, primary biliary cirrhosis or autoimmune thyroiditis.
**Objectives:** To investigate whether a difference exists between DAS28 from CRP and DAS28 from ESR in patients with rheumatoid arthritis (RA) and secondary Sjögren syndrome (sSS).
**Methods:** The study included patients with rheumatoid arthritis (RA) and secondary Sjögren syndrome (sSS). The inclusion criteria have been specified as follows: radiological confirmation of rheumatoid arthritis, presence of data on DAS28-CRP and DAS28-OB, presence of at least one subjective and one objective symptom of dryness, and also presence of specific antibodies or at least focus score one in biopsy.
**Results:** Disease activity score 28 (DAS28) was assessed using both ESR and CRP in 60 patients with RA and sSS and 59 patients with RA alone. Although concordance between these two methods was good (Cohen's kappa coefficient

κ=0.60, 95% of CI (0.45–0.75) in first group and κ=0,71, 95% of CI (0.56–0.86) in control group). In the group with RA and sSS mean value of DAS28-ESR=5.2, whereas mean value of DAS28-CRP=4.7 ($p<0.0001$). In the group with RA alone mean DAS-ESR=4,7 while mean DAS-CRP=4,6, no significant difference was identified. Moreover, in RA patients with sSS mean ESR=39mm/h compared with mean CRP at 25mg/dl. 79% of all patients demonstrated dysproteinemia. There were connections between higher ESR and dysproteinemia. In control group there were no significant difference between CRP and ESR.

| parameter | RA patients with sSS | RA patients |
|---|---|---|
| age [yr], mean (SD) | 57 (11) | 51,6 (13,7) |
| ESR [mm/hr], median | 34,5 | 15 |
| CRP [mg dl], median | 14 | 16 |
| VAS [mm], median | 51 | 60 |
| tender joints, median | 8 | 8 |
| swollen joints, median | 4 | 3 |
| DAS-28 from ESR, mean (SD) | 5.2 (1.3) | 4,7 (1,3) |
| DAS-28 from CRP, mean (SD) | 4.7 (1.2) | 4,6 (1,4) |

Table 1 Baseline characteristics of the patients with RA and sSS
SD – standard deviation.

**Conclusions:** Both DAS28-ESR and DAS28-CRP are useful outcome measures in RA. However, in patients with RA and sSS DAS28 should be evaluated based on CRP or SDAI.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5422

## AB0276 PSYCHOLOGICAL STATUS IS ASSOCIATED WITH HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Baccouche, L. Mani, S. Belghali, N. Elamri, Z. Alaya, H. Zeglaoui, E. Bouajina. *rheumatology, farhat hached hospital, sousse, Tunisia*

**Background:** Rheumatoid arthritis (RA) as one of the most common autoimmune diseases is known to be one of the leading causes of disability.
**Objectives:** This study aimed to investigate the relationship between psychological disorders (depression, anxiety and insomnia) and quality of life in patients with rheumatoid arthritis patients.
**Methods:** A total of 50 patients were included with the diagnosis of rheumatoid arthritis meeting ACR 1987 criteria, in a prospective study. In a questionnaire, the characteristics of the disease and sociodemographic patient were collected.
Also psychiatric assessment was done using the insomnia severity index score (ISI) and the Hospital Anxiety and Depression scale (HAD). In addition, patients answered a Health Assessment Questionnaire (HAQ) to assess their functional capacity and the SF-12 to evaluate the quality of life.
**Results:** The female was found in 80%, the average age was 52,8 years. The average duration of disease progression was 8,79 years (0,5–30). The mean value of the DAS 28 was 5,03 [1.7 to 7.9].
Extra-articular manifestations were reported in 72% of patients: secondary Sjögrens syndrome in 54%, osteoporosis in 42%, pulmonary fibrosis in 12%. 80% of patients received methotrexate and 38% of patients were treated with biotheraby.
Radiological destruction was observed in 96% of cases. Joint deformities were reported in 56% of cases. The most prevalent comorbidities in this population were anemia (28%), hypertension (18%), and diabetis (18%).
On the psychological level, 12% of patients had an anxiety, 6% had depression. According to the ISI, 34% of patients had Subthreshold insomnia, 40% had moderate insomnia and 6% had severe insomnia. The mean value of the HAQ was 1.49 (0.2–3).
A significant positive correlation was found between the disease activity and the presence of insomnia (p=0.019), the presence of depression (p=0.009) and anxiety (p=0.049). Also, we found a significant positive correlation between the HAQ and depression (p=0,003).
The mean value of the physical health was 40.51 (16–59.2) and for the mental health was 48.13 (26–60).
**Conclusions:** Psychiatric illness is a relatively common disorder in patients with RA, it affects their quality of life. The treatment of those patients must consider psychiatric disorders, as part of a global approach.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1535

## AB0277 COMPARISON BETWEEN INTIMA-MEDIA THICKNESS AND CORONARY ARTERY TOMOGRAPHY IN SUBCLINICAL ATHEROSCLEROSIS DETECTION IN RHEUMATOID ARTHRITIS

L. Riancho-Zarrabeitia[1], A. Corrales[1], J.A. Parra[1], M. Santos-Gómez[1], V. Portilla[1], P. Dessein[2], R. Blanco[1], M.A. González-Gay[1]. *[1]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [2]Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa*

**Background:** Intima media thickness (IMT) and coronary artery calcification (CAC) quantification using multidetector computed tomography (MDCT) scanner are useful in detecting subclinical atherosclerosis and are good surrogate markers of cardiovascular morbidity and mortality in general population and in rheumatoid arthritis (RA)
A good correlation between these methods has been reported in RA, being CAC a slightly more sensitive technique (1)
**Objectives:** Our aim is to determine the value of IMT that better predicts the presence of coronary atherosclerosis, using CAC as reference and assuming CAC value of 100 as the cut-off point indicating high cardiovascular risk.
**Methods:** We evaluated 127 RA patients without previous cardiovascular events. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7–12 MHz linear transducer and the *automated software guided technique radiofrequency – Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). According to data from non-rheumatic patients and also from RA patients, an IMT≥0.90 mm is a good predictor of high cardiovascular risk. To determine CAC score, a CT Imaging of coronary arteries using a 32-slice MDCT scanner (Lightspeed, Pro 32, GE Healthcare, USA) was performed.
**Results:** Patients with IMT below 0.90 mm had CAC values of 88±210 whereas patients with IMT≥0.90 mm had mean CAC values of 190± 272 (p=0.066). We found a positive correlation between IMT and CAC (correlation coefficient 0,303; p=0.001).
The IMT cut-off value ≥0.90 mm had a sensitivity of 32% for detecting CAC ≥100. ROC curve analysis showed and area under the curve of 0.664. The IMT cut-off value of 0.80 mm had a sensitivity of 40% and a specificity of 71.3%. Lowering the IMT cut-off point to 0.70, we reached a sensitivity of 76% and a specificity of 51.5% for CAC ≥100 detection. The positive predictive value for the IMT cut-off point of 0.70 mm was 76% in our population, being the negative predictive value 49.5%

| Variable | | Variable | |
|---|---|---|---|
| Age (mean ± SD) | 58. 57±9.7 | IMT ≥0.7 mm, n (%) | 71 (56) |
| Female sex, n (%) | 92 (72.,4) | CAC score (mean ± SD) | 103.4±222.6 |
| IMT ≥0,9 mm, n (%) | 19 (15) | CAC score ≥100, n (%) | 26 (20.5) |

**Conclusions:** IMT values ≥0.70 mm predict coronary artery calcification score above 100 with a sensitivity of 76%. According to that, the IMT value considered as predictor of high cardiovascular risk would be 0.70 mm instead of 0.90 mm.

## AB0278 ARE THERE DIFFERENCES IN BASAL COMORBIDITIES BETWEEN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT AND THOSE TREATED WITH TUMOR NECROSIS FACTOR INHIBITORS?

M.V. Hernández[1], C.A. Sánchez-Piedra[2], J.E. Inciarte-Mundo[1], F. Sánchez-Alonso[2], F.J. Manero-Ruiz[3], E. Cuende[4], R. Roselló Pardo[5], E. Pérez-Pampín[6], C. Rodríguez-Lozano[7], P. Vela-Casasempere[8], C. Diaz-Torne[9], R. Sanmartí[1], J.J. Gómez-Reino[6] on behalf of Biobadaser 2.0 Study Group. *[1]Arthritis Unit. Rheumatology Dpt., Hospital Clínic, Barcelona; [2]Research Unit, Spanish Society of Rheumatology, Madrid; [3]Rheumatology Dpt., Hospital Universitario Miguel Servet, Zaragoza; [4]Rheumatology Dpt., Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid; [5]Rheumatology Dpt., Hospital General San Jorge, Huesca; [6]Rheumatology Dpt., Hospital Clínico Universitario, Santiago de Compostela; [7]Rheumatology Dpt., Hospital Dr. Negrín, Gran Canaria; [8]Rheumatology Dpt., Hospital Universitario General, Alicante; [9]Rheumatology Dpt., Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

**Background:** Rheumatoid arthritis (RA) patients frequently report concomitant comorbidities that could worsen their prognosis. Tumour necrosis factor inhibitors (TNFi), the most common biological agents used, have shown efficacy in RA patients, although use in RA patients with certain comorbidities warrant caution (1). Abatacept, a biologic agent with a different mechanism of action, inhibiting the co-stimulation of T-lymphocyte, has demonstrated differentiated safety profile (2), that could influence the biological agent prescribed in RA patients with some associated comorbidities
**Objectives:** To analyse differences in the frequency of baseline comorbidities in

RA patients treated with abatacept compared with those treated with TNFi
**Methods:** Patients with RA recruited into the BIOBADASER 2.0 register from January 2008 to December 2014 and treated with abatacept or TNFi with comorbidities were selected. Comorbidity was defined as ≥1 of the following at initiation of biological therapy: ischemic heart disease; malignancy (except lymphoma); diabetes; chronic pulmonary obstructive disease (CPOD); smoking; hypercholesterolemia; hypertension; heart failure; renal failure; lymphoma; osteoporosis; Epstein Barr, hepatitis B or C virus infection; and others. We analysed the frequency of each comorbidity, and differences in the rate of baseline comorbidities in the two groups were compared using t-test
**Results:** From January 2008 to December 2014, 640 and 252 RA patients treated respectively with TNFi or abatacept were included in the BIOBADASER 2.0 register, of whom 51.6% had ≥1 comorbidity at baseline. Frequencies for every basal comorbidity described are shown in Table 1. There was a significantly higher rate of heart failure in abatacept than in TNFi patients. Other comorbidities showed no significant differences.

Table 1

| Comorbidities | Abatacept group | TNFi group | p-value |
|---|---|---|---|
| Ischemic heart disease | 1 (2.27) | 14 (2.11) | 0.940 |
| Malignancy (except lymphoma) | 1 (2.27) | 13 (1.95) | 0.883 |
| Diabetes | 6 (13.64) | 46 (6.92) | 0.098 |
| CPOD | 2 (4.55) | 16 (2.41) | 0.382 |
| Smoking | 8 (18.18) | 109 (16.39) | 0.757 |
| Hypercholesterolemia | 9 (20.45) | 111 (16.69) | 0.519 |
| Hypertension | 10 (22.73) | 148 (22.26) | 0.942 |
| Epstein Barr infection | 0 (0) | 1 (0.15) | 0.797 |
| Heart failure | 4 (9.09) | 6 (0.9) | <0.001 |
| Renal failure | 0 (0) | 8 (1.2) | 0.464 |
| Lymphoma | 0 (0) | 0 (0) | |
| Osteoporosis | 7 (15.91) | 89 (13.38) | 0.635 |
| Hepatitis B virus infection | 1 (2.27) | 13 (1.95) | 0.883 |
| Hepatitis C virus infection | 0 (0) | 1 (0.15) | 0.797 |
| Others | 22 (50) | 292 (43.91) | 0.431 |

**Conclusions:** RA patients treated with abatacept had a higher baseline rate of concomitant heart failure compared with patients treated with TNFi, probably reflecting different recommendations on biological use. Even though abatacept has demonstrated a differentiated safety profile, overall no differences in other baseline comorbidities were found between groups

## AB0279 PERIODONTAL DISEASE AND RHEUMATOID ARTHRITIS – COMPARISON OF TWO ASSESSMENT TOOLS, AND THEIR VALUE IN THE DETERMINATION OF THE ASSOCIATION BETWEEN THE TWO DISEASES

M. Bocskai[1], Z. Zalai[2], M. Antal[2], G. Braunitzer[3], L. Kovács[1]. *[1]Department of Rheumatology; [2]Department of Operative and Esthetic Dentistry; [3]Department of Oral Surgery, University of Szeged, Szeged, Hungary*

**Background:** Periodontitis is involved in the pathogenesis of rheumatoid arthritis (RA), and a worse periodontal status has been proposed to correlate with the inflammatory activity of RA and to have an impact on its responsiveness to therapy. Human studies have been hampered by the lack of well-standardized assessment tools of the severity of periodontal disease (PD).
**Objectives:** The authors' aim was to compare the accuracy of two scoring systems of PD in RA patients, and to correlate the findings with multiple variables of RA activity and severity.
**Methods:** Eighty-one RA patients (mean age: 57 years, range: 28–82) were consecutively recruited. Disease activity was measured with DAS28, ESR, CRP, and swolllen and tender joint counts. Disease severity was assessed by the health assessment questionnaire (HAQ), anti-citrullinated peptide (mutated citrullinated vimentin) antibody and rheumatoid factor titers, and average DAS28 and average corticosteroid dose in the preceding year. The scoring of the severity of PD was assessed by means of the Community Periodontal Index of Treatment Needs (CPI) and the periodontal status classification, proposed by Fernandes et al. CPI scores PD severity on a 0–4 scale according to the presence of calculus and bleeding on probing (BOP) and probing depth, whereas the other index categorizes the severity as healthy-early-moderate-severe on the basis of clinical attachment level (CAL) and probing depth. Smoking status was also recorded.
**Results:** RA patients had a median score of 3 on the CPI index, and the median severity was moderate according to the periodontal status scale. The two systems had excellent correlation (Spearman r=0,966, p<0.0001), and there was also a negative correlation between the number of teeth and the CPI score (r=0,254, p<0.05) and the periodontal status score (r=0,210, p=0.059). A worse periodontal status (assessed with higher CPI score) was associated with a higher average DAS28 (despite therapy) measured during the year before the dental examination (r=0,376, p=0,022), with smoking (Kruskal-Wallis: p=0.014), and with higher DAS28 at the time of the examination (r=0.198, p=0.07). When assessed with the 4 staged periodontal status score, the association between PD severity and current DAS28 was significant (r=0.409, p=0.01).
**Conclusions:** CPI seems to have better performance than the periodontal status score proposed by Fernandes et al for the examination of the severity of PD in RA patients, and confirms the correlation between the severity of PD and RA activity and severity. This method is recommended for the research on the impact of periodontal status and of its correction on RA outcome.

## AB0280 DEPRESSION AFFECTS NEGATIVELY QUALITY OF LIFE RELATED TO HEALTH OF COLOMBIAN PATIENTS WITH RHEUMATIC ARTHRITIS

M. Peña. *Rheumatology, Universidad Nacional de Colombia, Neiva, Colombia*

**Background:** Rheumatic arthritis (RA) causes deterioration on the health-related quality of life (HRQOL) and a negative impact on the emotional sphere of the affected individuals (1).
**Objectives:** Owing to scarce information existing in Colombia on the subject we decided to know the prevalence of depression on patients with RA and quantify its impact as well as the impacts of other variables on the HRQOL.
**Methods:** Design of Study: analytical cross sectional study.
Population of study: 100 individuals with ages 18 years or more, diagnosed with RA according ACR/EULAR 2010 criteria (2), which attended to outpatient service of the University hospital in the city of Neiva (Colombia) during 2013.
Gathering of information (data): through personal surveys that included socio-demographic and clinics variables; evaluation of depression prevalence using the Zung questionnaire (3) and HRQOL using the QOL-RA scale in spanish version (4).
Statistical analysis: summary measures, mean with standard deviation were used. An analysis of multiple lineal regression to identify predicter variables of HRQOL was made. For data analysis IBM SPSS 19. version was used. The research project was approved by the bioethical committee of the Universidad Surcolombiana in Neiva.
**Results:** 84% of participants were women, with mean age 53 years. 85% belong to 1 and 2 (lower) social strata, and 61% live with stable partners, depression prevalence of 23% was found. The mean outcome was 6.38. According dimension, the higher outcomes were familiar support (8.34), social interaction (8.24), and mood (6.49), while the lower outcome were perceived pain (4.97), arthritis (5.01) and physical ability (5.57). Likewise, the patients with depression had significantly lower outcomes of HRQOL (4.94) than those without depression (6.82) (p<0.001). With the multiple lineal regression model the only variable that predicted the HRQOL outcome was depression.
**Conclusions:** Colombian RA patients have high HRQOL outcomes in social interaction and familiar support dimensions and low in pain and arthritis dimensions; likewise patients with depression had lower HRQOL outcomes than those without depression, indicating that depression affects negatively all dimensions that comprise the QOL-RA scale.
HRQOL of Colombian RA patients are negatively influenced by depression, which stresses the importance of early detection and treatment of depressive symptoms in that population.

## AB0281 BODY IMAGE DISTURBANCE IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO REQUIRES SURGICAL INTERVENTION

M. Horita[1], D. Kaneda[1], A. Takeshita[1], T. Machida[1], R. Nakahara[1], Y. Nasu[2], K. Hashizume[3], K. Nishida[4], T. Ozaki[1]. *[1]Department of Orthopaedic surgery; [2]Department of Medical Materials for Musculoskeletal Reconstruction, Okayama University Graduate School of Medicine, Density and Pharmaceutical Sciences; [3]Department of Orthopaedic Surgery, Okayama Rosai Hospital; [4]Department of Human Morphology, Okayama University Graduate School of Medicine, Density and Pharmaceutical Sciences, Okayama, Japan*

**Background:** Recent effective treatment with disease-modifying anti-rheumatic drugs (DMARDs) including biologic DMARDs (bDMARDs) improved the disease control of patients with rheumatoid arthritis (RA), and the change of body image

of the patients might influenced the surgical indication. Body image assessment tool (BIAT) has been reported to be a reliable and valid tool[1)]. Patients with RA had a worse body image than individuals without RA[2)], however, there are no evidence showed the body image of patients who requires surgical intervention.
**Objectives:** The current study aimed to investigate the body image of patients who requires surgical intervention and to examine the correlation with depressive condition.
**Methods:** 163 patients (16 male, 147 female) with RA were divided into two groups of patients who didn't require the surgical intervention (non-operative group) and who underwent surgery (operative group). The non-operative group and operative group included 88 and 75 patients, respectively. The mean age of the non-operative and operative group were 64.8 and 64.4 years, and the mean disease duration were 17.5 and 22.7 years, respectively. The clinical evaluation included the use of bDMARDs, pain VAS (0–100mm), Health Assessment Questionnaire Disability Index (HAQ-DI), disease activity (DAS28-CRP), depression assessed by Beck Depression Inventory-II (BDI-II), and body image assessed by BIAT. Statistical analyses were performed using the Mann-Whitney U test, and Fisher's exact test.
**Results:** The rate of use of bDMARDs was not significant between non-operative and operative group. In the operative group, pain VAS, HAQ-DI, DAS28-CRP and BDI-II were significantly higher ($p<0.01$, $p<0.01$, $p<0.01$ and $p=0.02$, respectively) and BIAT was significantly lower ($p=0.02$) when compared with non-operative group. Higher BDI-II significantly correlated with lower BIAT in both non-operative ($r=-0.69$, $p<0.01$) and operative group ($r=-0.61$, $P<0.01$).

Comparing the non-operative and the operative groups

| | Non-operative group (n=88) | Operative group (n=75) | P value |
|---|---|---|---|
| Pain VAS (mm) | 22.0 (0~88) | 39.1 (0~100) | <0.01 * |
| HAQ-DI | 0.75 (0~2.75) | 1.39 (0~3.00) | <0.01 * |
| DAS28-CRP | 2.24 (1.03~5.31) | 2.64 (1.11~5.14) | <0.01 * |
| BDI-II | 9.1 (0~32) | 12.0 (0~49) | 0.02 * |
| BIAT | 3.2 (1.6~4.0) | 3.0 (1.5~4.0) | 0.02 * |

* Mann-Whitney U test

**Conclusions:** The result of this survey found the body image of patients in operative group was disturbed than that of non-operative patients. Body image disturbance was highly correlated with depressive condition in both operative and non-operative patients. To assess the body image might be useful to understand the patients' expectation and proper indication of the surgery.

## AB0282 PREDICTING THE RESPONSES TO BIOLOGICAL THERAPY BY TWO KINDS OF ANTIBODIES TITERS AGAINST PORPHYROMONAS GINGIVALIS IN RA PATIENTS

M. Matsushita[1], M. Okada[2], T. Kobayashi[2], H. Yoshie[2], K. Kuzuya[1], H. Matsuoka[1], T. Shimizu[1], T. Nii[1], S. Teshigawara[1], E. Tanaka[1], S. Tsuji[1], S. Ohshima[3], J. Hashimoto[1], Y. Saeki[4]. *[1]Rhuematology, Osaka Minami Medical Center, Osaka; [2]Oral Biological Science, Niigata University, Graduate School of Medical and Dental Sciences, Niigata; [3]Clinical Research, Osaka Minami Medical Center; [4]Clinical Research, Osaka Minami Medical Center, Osaka, Japan*

**Background:** There is little evidence on prediction of clinical response to biologics in patients with RA. Recently, it has been suggested that clinical response to tumor necrosis factor (TNF) inhibitors was related to periodontal conditions, which might be affected by infection with *Porphyromonas gingivalis* (*P.g.*). Additionally, serum antibody responses to *P. g* were associated with RA and periodontitis.Newly established test of antibody against hemin binding protein 35 (HBP) of *P.g.*, which has an ability specifically bind to *P.g.* containing protein HBP, can be available.
**Objectives:** To evaluate whether serum antibody responses to *P.g.* antigens and periodontal conditions are associated with clinical response to biologics in patients with RA.
**Methods:** 20 patients with severe RA enrolled in this study were treated with biologics according to the usual regimen. Clinical background and disease parameters were assessed at entry. DAS28-CRP was evaluated at 6 months (reassessment) after the initiation of biologics. Periodontal conditions were also assessed at entry. Serum levels of antibodies against *P.g.* sonicated extracts (SE) and HBP of *P.g.* were determined by enzyme-linked immunsorbent assay, respectively.
**Results:** Their mean (SD) age was 57.2 (13.4) years. Patients were predominantly women (85%) with mean disease duration of 8.2 (6) years.10 patients were treated with TNF-i, 7 with IL-6 blocker and 3 with CTLA4-Ig, respectively. Most patients had active disease with DAS28-CRP 4.2 (0.9) at baseline, and showed an improvement of DAS28-CRP 2.87 (0.82) at reassessment. Seven patients (35%) achieved remission (DAS28-CRP $<2.3$) at reassessment. The mean serum levels of anti-CCP antibodies were 270.2 (221.9), and the mean serum levels of antibodies against *P.g.* SE and HBP were 15.9 (52.3) and 0.632 (0.276), respectively at baseline. Periodontal conditions of the patients were as follows; mean PD was 2.62 (0.51) (mm), mean CAL was 2.85 (0.77) (mm), mean PCR was 0.37 (0.23) (%), and mean BOP was 0.21 (0.17) (%) at baseline. No associations were observed between changes in DAS28-CRP (delta-DAS28-CRP) and serum and periodontal parameter values (serum levels of antibodies against *P.g.* SE and HBP, PD, CAL, PCR, and BOP). Antibody titers against *P.g.* SE gradually decreased, on the other hand, anti-*P.g.* HBP was increased during 6 months.
**Conclusions:** Antibodies titers against *P.g.* and periodontal conditions could not predict the responses to biologics, but further studies are required to evaluate this hypothesis. And to our knowledge, this is the first report describing the change of serum level of antibodies against *P.g.* after treatments with biologics except infliximab.

## AB0283 EFFICACY AND SAFETY OF RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS-RELATED BRONCHIECTASIS (RA-BR): RESULTS FROM A MULTICENTRE COHORT

M.Y. Md Yusof[1,2], K. Iqbal[3], P. Emery[1,2], S. Dass[1,2], C. Kelly[3]. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; [3]Rheumatology, Queen Elizabeth Hospital, Gateshead, United Kingdom*

**Background:** Bronchiectasis (BR) is a significant pulmonary morbidity associated with Rheumatoid Arthritis (RA). Patients with RA-BR are susceptible to infection and this poses a challenge in the treatment of articular disease. Evidence of efficacy and safety of biological therapy is scarce as these patients are often excluded from clinical trials.
**Objectives:** To evaluate the efficacy and safety of B cell depletion therapy with rituximab in a large RA-BR cohort of patient drawn equally from two centres.
**Methods:** We conducted a retrospective observational study of consecutive patients with RA-BR (detected by HRCT prior to rituximab) using identical data collection methodology between centres. Each cycle (Cn) of rituximab consisted of 2x1000mg infusions, repeated on clinical relapse. Disease activity was assessed using DAS-28 at baseline and every 6 months after each cycle and EULAR responses were calculated. Safety assessments included the number and severity of acute exacerbations of lung disease per year, together with five year survival and causes of death.
**Results:** 61 sero-positive patients were studied (43 female, median age 67 years (range 38–91)), median RA duration 9 years (range 1–23) years and BR duration 6 years (range 1–67). 36/61 (60%) were non-smokers. 20 patients were TNF-IR (8 primary non-response, 5 secondary non-response and 7 had side effects). 67% were on concomitant DMARDs. Total follow up duration was 321 patient-years.
At baseline, median DAS-28 was 5.7 (IQR 4.3–7.6). In C1, 53/61 (87%) achieved moderate-good EULAR response with a median reduction in DAS28 scores of 2.1 (IQR 0–3.4) $p=0.007$ at 6 months. EULAR responses were maintained at C2 and C3; 91% and 86% respectively. Median duration of response for C1, C2 and C3 were 54, 50 and 52 weeks respectively. In the 12 months prior to RTX, there was a median of 3 (0–7) infective exacerbations per patient. After RTX, 13 patients (21%) had fewer exacerbations compared to baseline; 40 patients (66%) remained stable and 8 patients (13%) had increased exacerbations. Overall, the number of exacerbations rose in the first year to a median of 4 (0–10) but then fell in years 2 and 3 to 2 (0–6) and 1 (0–4) respectively. Rituximab was discontinued in 8 patients (4 were due to increased exacerbations and 4 were due to inefficacy). 6 patients (10%) subsequently required alternative biologics for the treatment of RA. Of the 9 (15%) deaths, 3 (5%) died from respiratory disease.
**Conclusions:** Rituximab is effective and has an acceptable safety profile in the treatment of RA-BR. A temporary increase in acute exacerbations of lung disease may occur in the first year following rituximab. After subsequent treatment cycles, pulmonary symptoms stabilised or improved in most patients. Rituximab may therefore be a particularly appropriate therapeutic choice for this group of patients.

## AB0284 REPRODUCTIVE HEALTH IN ADULT WOMEN WITH JIA AND RA

M.E.B. Clowse, G. McDaniel. *Medicine, Duke University, Durham, United States*

**Background:** Building a family is an important part of a full life for many women with rheumatoid arthritis (RA) and juvenile inflammatory arthritis (JIA).

**Objectives:** Our goal was to identify the differences and similarities between the reproductive health choices and practices of women with RA and JIA.
**Methods:** A cross-sectional survey was completed by women between age 18–39 with a diagnosis of RA and/or JIA seen in a university rheumatology clinic. Descriptive statistical methods were used.
**Results:** Of the 33 women that completed the survey, 22 were diagnosed with RA at or after age 18 and 11 were diagnosed with JIA. The average age at diagnosis and the time of the survey was higher for women with RA (see table). The majority of participants were white. Methotrexate (MTX) had been used by all women with JIA and 73% of women with RA. The average total lifetime dose and duration of MTX dose was significantly higher among women with JIA.
Contraception: 4 women with RA were trying to conceive at the time of the survey. Among the other women, the rates of effective contraceptive use was similar, but more women with RA used an IUD or surgery and more women with JIA were taking daily birth control pills.
Pregnancy: Women in both groups reported a similar ideal number of children. About 2/3 of the women had either tried to conceive or been pregnant. The average age of first attempted pregnancy was similar between women with RA and JIA. Of the women who had tried to conceive or been pregnant, both groups had a similar number of pregnancies and the rates of live births, miscarriages, ectopic pregnancies, and elective terminations were not significantly different between the groups.
Fertility: Of the women who tried to get pregnant or had a pregnancy, 19% with RA and 40% with JIA reported infertility (p=0.3) and 12.5% with RA and 60% with JIA had used a fertility treatment to attempt pregnancy (p=0.03). The age of menarche, the frequency of menstrual irregularities, and the number of menses per year were similar between the groups.

| | RA | JIA | p-value |
|---|---|---|---|
| Number of women | 22 | 11 | |
| Age at survey | 33.9 (range 24–39) | 28.3 (range 20–38) | 0.005 |
| Age at diagnosis | 26.7 (sd 4.1) | 8.3 (sd 6.2) | 0.000 |
| Duration of disease | 7.2 (sd 3.8) years | 20 (sd 8.4) years | 0.000 |
| Race | 64% white/23% black | 100% white | 0.02 |
| Effective contraception | 56% | 82% | 0.34 |
| IUD or surgery | 44% | 9% | 0.05 |
| Oral contraceptives | 33% | 82% | 0.01 |
| Tried to conceive and/or had a pregnancy | 73% | 45% | 0.12 |
| Age 1st tried to conceive | 27.2 | 26.6 | 0.8 |
| Ideal number of children | 2.5 (sd 1.0) children | 2.4 (sd 0.8) children | 0.7 |
| Number of pregnancies | 1.7 pregnancies | 1.8 pregnancies | 0.4 |

**Conclusions:** The reproductive goals of women with JIA and RA appear to be similar. The majority of sexually active women were using effective contraception, with women with RA using long-acting options and women with JIA relying on birth control pills. Pregnancy outcomes appeared to be similar. Infertility was increased, particularly among women with JIA.

## AB0285 EFFECT OF ANTI-RHEUMATIC TREATMENT ON PERIODONTAL STATUS IN RHEUMATOID ARTHRITIS PATIENTS: A PILOT STUDY

M.J. de Smit[1], M.D. Posthumus[2], A.-M. van Brenk[2], L. Oosting[2], G. Springer[3], E. Brouwer[4], M. Bijl[2], J. Westra[4]. *[1]Dentistry, University Medical Center Groningen; [2]Internal Medicine and Rheumatology; [3]Oral and Maxillofacial Surgery, Martini Hospital; [4]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Overlapping molecular pathways of inflammation have been implicated in periodontitis and rheumatoid arthritis (RA). The presence of shared underlying inflammatory pathogenesis mediating the progression of periodontitis and RA could provide potentially important common therapeutic targets.
**Objectives:** The primary purpose of this observational study was to determine the effect of methotrexate (MTX) and anti-TNFα (etanercept) on clinical parameters of periodontitis. Influence of periodontitis on efficacy of medical treatment of RA was a secondary endpoint.
**Methods:** Fourteen treatment-naïve patients starting with MTX and 12 patients starting with anti-TNFα therapy, fulfilling the ACR/EULAR classification criteria for RA (2010), older than 18 years, and with natural dentition were included. One patient was excluded because of antibiotic use for oral infection <3 months prior to the study. Four patients stopped treatment with etanercept after the first follow up visit because of patient related factors. Before starting medical treatment for RA and after 2 months (MTX) or 3 months (anti-TNFα), periodontal inflammatory burden was quantified with the periodontal inflamed surface area (PISA) (Nesse et al. 2008). Subgingival presence of *P. gingivalis* was determined by anaerobic culture. In addition, radiographic intra-oral pathologies (furcation involvement, peri-apical pathology and cariës) were assessed on panoramic radiographs. Oral hygiene was measured using full mouth plaque scores. Efficacy of anti-rheumatic treatment was measured by change in RA disease activity (DAS28-ESR).
**Results:** Treatment with MTX of anti-TNFα significantly improved DAS scores (both $p<0.001$) and erythrocyte sedimentation rates (ESR) (both $p<0.05$). PISA did not change significantly after starting with treatment with MTX or anti-TNFα. Also, PISA or presence of other intra-oral pathologies were not associated with changes in DAS scores and ESR
**Conclusions:** Anti-rheumatic treatment did not have significant impact on clinical periodontal parameters. Within the limitations of this study (PISA scores were rather low) PISA and presence of other intra-oral pathologies were not of associated with efficacy of anti-rheumatic treatment.

## AB0286 CLINICAL FEATURES AND THERAPEUTIC CONSIDERATIONS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS; A CROSS-SECTIONAL STUDY

N. Alpay Kanıtez[1], S. Çelik[1], Ö. Pehlivan[2], S. Yılmaz Öner[1], C. Bes[1]. *[1]Internal Medicine, Rheumatology, Bakırköy Dr. Sadi Konuk Training and Research Hospital; [2]Internal Medicine, Rheumatology, Ümraniye Traning and Research Hospital, Istanbul, Turkey*

**Background:** Rheumatoid arthritis (RA)'s prevalence increases with age. The average life expectancy is getting longer and global population is becoming older. Physicians will be challenged with the recognition and treatment of RA patients who may have different physical conditions, comorbid diseases and using multi-drugs.
**Objectives:** The aim of this study was to evaluate the clinical characteristics and treatment modalities in elderly RA patients.
**Methods:** We assessed elderly RA patients (≥65 years) diagnosed according to 2010 American College of Rheumatology (ACR) criteria. Clinical and laborotary findings, treatment durations, dose of drugs and treatment related adverse effects were recorded into a pre-defined protocol. "Disease Activity Score" (DAS-28), "Physician Global Assessment" (PGA) and "Health Assessment Questionnaire" (HAQ) scores were used as composite indices for RA activity evaluation.
**Results:**
Seventy-four RA patients [54 patients (73%) were female] with a mean age of 71±5 (65–86) years were included into the study,. The mean total disease duration of these patients was 97±104 (9–600) months. Disease onset was in the elderly period for 40 (55%) patients. Small joints of hands were the most frequently involved joints (95%). Seropositivity rate was 66% and 56% of the patients had erosive disease. DAS-28 and HAQ scores were correlated with PGA scores (p:0,001). The proportion of patients with high and moderate disease activity was found as 79% according to DAS-28 scores. There was no association between age and antibody titers or activity indices. Non-steroidal antiinflammatory drugs (NSAIDs) were part of the treatment in 53 patients (71%) and no severe side effects associated with NSAIDs were observed. The mean cumulative prednisolone dose was 7617±10602 mg. Hypertension and osteoporosis were the most frequent comorbidities (64% and 48%, respectively). The most commonly used disease modifying antirheumatic drug (DMARD) was methotrexate (76%) and the rate of compliance was found high for all drugs except sulfasalazine (Table 1). While 60% of all patients were treated with DMARD monotherapy, combination DMARD therapy were used in 37% of patients. The rate of biologic theraphy was found as 12% (9 patients) in all study population.

Table 1. The anti-rheumatic treatments in elderly RA patients

| Drugs | n (%) | Mean ages | Starting in ≥65 age n (%) | Mean dose | Treatment duration* | Maintanence of the theraphy n (%) |
|---|---|---|---|---|---|---|
| Methotrexate | 58 (79) | 70,9±5 | 42 (73) | 11,2±4,7mg/w | 38,1±51 | 41 (72) |
| Hydroxychloroquine | 35 (48) | 71,9±5 | 25 (74) | 206±37mg/d | 30,8±37 | 31 (91) |
| Leflunomide | 28 (39) | 72±6 | 20 (74) | 18,4±3,5mg/d | 29,5±29 | 20 (77) |
| Sulfasalazine | 13 (18) | 71,3±5 | 7 (53) | 1,8±0,3g/d | 47,1±69,2 | 5 (45) |
| Rituximab | 5 (6,7) | 72,6±6 | 5 (100) | 1000mgx2/2w | 6,2±3 | 5 (100) |
| Etanercept | 2 (2,7) | 65,5 | 21 (50) | 50mg/w | 13,5±14,8 | 1 (50) |
| Abatacept | 1 (1,3) | 66 | 1 (100) | 125mg/w | 6 | 1 (100) |
| Adalimumab | 1 (1,3) | 71 | 1 (100) | 40mg/d | 24 | 1 (100) |

*The mean treatment duration as months.

**Conclusions:** In this preliminary data from our ongoing study, elderly RA patients had remarkable compliance with NSAIDs and DMARDs. Although patients treated with biologic agents constituted a small group, no serious side effect that required cessation of the treatment was observed. By the increasing numbers of elderly RA patients in our cohort, we expect to obtain more powerful data on compliance and safety issues of the treatment and particularly biologic agents.

## AB0287 PSYCHIATRIC DISORDERS IN RA PATIENTS: RELATION WITH FATIGUE, SLEEP QUALITY AND QUALITY OF LIFE

D. Durmus[1], G. Sarisoy[2], C. Aslan[1], Y. Doydu[2], G. Alayli[1], E. Unverdi[2], A. Bilgici[1], O. Kuru[1]. *[1]Physical Medicine and Rehabilitation; [2]Psychiatry, Ondokuz Mayis University Medical Faculty, Samsun, Turkey*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that predominantly affects the synovial joints and the periarticular structures, leading to persistent pain, functional deterioration, disability, sleep disturbance, and lower quality of life. Psychiatric disturbances are frequently observed in these patients.
**Objectives:** The aim of this trial was to investigate I) the psychiatric disorders in RA and II) the effect of concurrent psychiatric disorders on pain, fatigue, disease activity, sleep quality and health-related quality of life (HRQOL).
**Methods:** The patients who fulfilled the American College of Rheumatology (ACR) criteria for RA were recruited. All the patients were interviewed by a psychiatrist. The psychiatric disorders were evaluated with the Turkish Structured Clinical Interview for DSM-VI Axis I Disorders (SCID-I). Sociodemographic data, disease activity (DAS 28 score) and disease duration were reported. Pain was evaluated with visual analogue scale (VAS), fatigue with Multidimensional Assessment of Fatigue (MAF), and quality of life with 36-item Short Form Health Survey (SF-36), and sleep quality with Pittsburgh Sleep Quality Index (PSQI).
**Results:** One hundred patients with RA were studied (90% women, mean age 52.02±12.74 years; disease duration 10.29±8.99 years). Forty-six (46.0%) patients were diagnosed with a psychiatric disorder. Adjustment disorder (n=15) and major depressive disorder (n=12) were frequently observed in these patients. When we divided the groups as the RA patients with psychiatric disorders and the RA patients without psychiatric disorders, RA patients with psychiatric disorders had significantly higher pain scores (p=0.035) and fatigue scores (p=0.005). There was no difference between groups regarding disease activity. The scores of all domains of the SF-36 were significantly lower in RA patients with psychiatric disorders ($p<0.05$ for all). While there was no significant difference between groups regarding sleep duration, usual sleep efficiency and sleeping aid use, significant differences in sleep quality, sleep latency, sleep disturbance, daytime sleepiness and PSQI total score were observed. These scores were higher in RA patients with psychiatric disorders ($p<0.05$).
**Conclusions:** The rate of psychiatric disorders in RA patients was found to be 46% in the present study. We also determined that concomitant psychiatric disorders in RA patients were associated with significantly lower sleep quality and HRQOL and higher fatigue. Early identification of psychiatric disorders in RA patients and early referral to a multidisciplinary psychiatric team are necessary to improve the quality of life, sleep quality, and to reduce fatigue.

## AB0288 THE 24-MONTH STUDY OF TREATMENT WITH MONOCLONAL ANTIBODY TO RANKL ON BONE MINERAL DENSITY AND STRUCTURAL DAMAGE IN PATIENTS WITH OSTEOPOROSIS AND RHEUMATOID ARTHRITIS

P. Kovalenko, I. Dydykina, E. Petrova, A. Smirnov, L. Alexeeva, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Chronic synovitis and RANKL-dependent osteoclastogenesis in rheumatoid arthritis (RA) lead to bone damage, such as local and systemic bone destruction (osteoporosis (OP), erosions and joint space narrowing). RANK-ligand is essential for osteoclast development, activation, and survival. The addition of an anti-RANKL antibody (denosumab) to the traditional scheme of RA treatment is a potentiality to control and prevent joint destruction as well as inhibit systemic osteoporosis.
**Objectives:** The aim is to evaluate the effects of continuous treatment with denosumab on bone mineral density and structural damage in patients with RA and OP.
**Methods:** 27 postmenopausal women (mean age 58,4±7,4 years) with RA (mean duration of RA 19,5±11,8 years) and OP received subcutaneously denosumab 60 mg every 6 months pro 2 years. According to X-ray 8 (29,6%) patients had the 2nd, 8 (29,6%) – the 3rd and 11 (40,8%) – the 4th stage of RA. 17 patients (62,9%) continued glucocorticoids (GC). The primary end points were the change from baseline in BMD (by dual energy x-ray absorptiometry at three sites: lumbar spine (L1-L4), hip neck (HN) and distal forearm (DF), the change in Sharp/van der Heijde (SVH) score by X-ray of hands and feet and the change in X-ray morphometric analysis of deformations in vertebrae (Genant method). The change of pain severity in spine was assessed using VAS. The Statistica 6.0 was used.
**Results:** At L1-L4 the significant increase of BMD was noted both at 12- and 24-month point in comparison with baseline: 0,789±0,079 g/cm$^2$ vs 0,818±0,077 g/cm$^2$ ($p<0.001$) and 0,789±0,079 g/cm$^2$ vs 0,836±0,078 g/cm$^2$ ($p<0.001$), respectively. The same was noted at DF – the increase of BMD at 12- and then at 24-month: 0,480±0,102 g/cm$^2$ vs 0,493±0,095 g/cm$^2$ (p=0.01) and 0,480±0,102 g/cm$^2$ vs 0,511±0,104 g/cm$^2$ ($p<0.001$), respectively. At HN it was noted the stabilization in BMD (statistically nonsignificant improvement) at both points. After separation on groups based on GC intake, this trend was also seen at both points in both groups: increase of BMD at L1-L4 and DF, stabilization of BMD at HN.
The erosion and total SVH score were increased at 12- and 24-month ($p<0.05$), while the narrowing score was not changed significantly at both points.
The index of vertebral deformations was not changed after 24-month compared with baseline: 0,79±0,01 for lumbar site and 0,76±0,04 for thoracic site, respectively.
At baseline 13 patients had pain in thoracic site of spine, while after the treatment their number significantly decreased (p=0.019) more that 2-fold – 4 (mean VAS 41.1±16.9 and 31.2±8.5 mm, respectively), at lumbar spine pain was also reduced (p=0.09): 15 and 8 patients (44.3± 23.3 and 35.6±14.7 mm, respectively).
**Conclusions:** Throughout the 24 months of therapy with denosumab it was shown the continued increase of BMD at L1-L4 and distal part of forearm - the significant increase was observed both at the first and the following year of therapy regardless of GC intake. At HN it was observed the stabilization of BMD. The erosion and total SVH score were increased, but the narrowing score didn't change after two years of observation. The index of vertebral deformations remained stable. The frequency and severity of pain in spine were decreased.

## AB0289 ANALYSIS OF JOINTS SUSCEPTIBLE TO RHEUMATOID ARTHRITIS (RA) AND THEIR RECOVERY SEQUENCE BASED ON DAS28 WITH SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) IN CHINA: A PROSPECTIVE COHORT STUDY

R. Mu[1], J. Yang[2], H. Wang[3], X. Xin[4], H. Wei[5], F. Zhang[6], X. Li[7], J. Dong[2], Y. Jia[8], Y. Liu[8], F. Xiao[8], Z. Li[1]. *[1]Department of Rheumatology and Immunology, People's Hospital, Beijing University Medical School, Beijing; [2]Central Hospital of MianYang, MianYang; [3]JiaXing First Hospital, JiaXing; [4]Ningbo First Hospital, Ningbo; [5]Northern Jiangsu People's Hospital, Yangzhou; [6]Hebei General Hospital, Shijiazhuang; [7]The Second Affiliated Hospital of Shanxi Medical College, Taiyuan; [8]Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China*

**Background:** The disease activity score in 28 joints (DAS28)[1] and health assessment questionnaire (HAQ) [2] are guides the treatment of rheumatoid arthritis (RA). Smart System of Disease Management (SSDM) is a series of mobile phone applications for chronic diseases management, which includes interfaces of both doctors' and patients' applications. After entry data of lab test, treatment regiments, and executing DAS28 evaluation entry by patients, all data can be synchronized automatically to the authorized rheumatologist' mobile tool. The rheumatologist can adjust treatment regiments base on patients' profile. We have confirmed that the results of self-assessment in DAS28 by RA patients with SSDM were consistent with professionals' assessment in our previous study[3].
**Objectives:** To evaluate the susceptible joints and the recovery sequence of swollen joint counts (SJCs) and tender joint counts (TJCs) based on DAS28 which self-assessed by Chinese RA patients with SSDM, and to describe the association between DAS28 and HAQ.
**Methods:** Since August 31, 2014, thirty-one rheumatologists from twenty-five hospitals participated in the study. Adult patients fulfilling the 1987 ACR (formerly the American Rheumatism Association) criteria for RA were recruited. Patients were taught to self-assess DAS28 and HAQ with SSDM at the baseline, and were asked to repeat the assessment once a month during the treatment.
**Results:** As of January 14, 2016, 636 RA patients self-assessed for 2,306 times. At the baseline, 1,628 joints were swollen and 2,761 joints were tender. The top five swollen joints were right wrist, right middle proximal interphalangeal, left wrist, right knee and left knee joints, and the top five tender joints were right wrist, left wrist, right knee, left knee and right shoulder joints. Table1 shows the proportion of different joint involvement at the baseline and the last assessment. After treatment, the top five recovery joints were left little metacarpophalangeal, left ring metacarpophalangeal, right index proximal interphalangeal, right little metacarpophalangeal and right middle proximal interphalangeal in tender, and

left little proximal interphalangeal, left little metacarpophalangeal, right little proximal interphalangeal, right little metacarpophalangeal and left index proximal interphalangeal in swelling.
HAQ score showed that the top two difficult functions of RA patients were "reaching" and "hygiene" at the baseline. At the last assessment, the degree of recovery about "hygiene", "dressing and grooming" function were quicker than "reaching" and "walking", which was matched with DAS28's joints recovery characteristic (Detailed see Table 2).
**Conclusions:** In this study, most involved joints in tender and swelling are hand and wrist joints, which co-related to the physical activity function of "hygiene" and "dressing and grooming". After treatment, hand joints recovered more quickly than other joints, which matched with HAQ assessment results.

## AB0290 LYMPHOCYTE RESTORATION AND TRANSITION OF PERIPHERAL LYMPHOCYTES SUBSETS ASSOCIATES WITH SPONTANEOUS REGRESSION OF METHOTREXATE-ASSOCIATED LYMPHOPROLIFERATIVE DISORDER (MTX-LPD)

S. Saito[1], K. Suzuki[1], K. Yamaoka[1], T. Shimizu[2], T. Mori[2], S. Okamoto[2], K. Amano[3], M. Tokuhira[4], T. Takeuchi[1]. *[1]Department of Internal Medicine, Keio University School of Medicine, Division of Rheumatology; [2]Department of Internal Medicine, Keio University School of Medicine, Division of Hematology, Tokyo; [3]Saitama Medical Center, Saitama Medical University, Division of Rheumatology; [4]Saitama Medical Center, Saitama Medical University, Division of Hematology, Saitama, Japan*

**Background:** Methotrexate-associated lymphoproliferative disorder (MTX-LPD) is a relatively rare but well known complication among patients under MTX treatment. Spontaneous regression of LPD after MTX withdrawal is regarded as a distinct character of MTX-LPD. Although detection of Epstein-Barr virus encoded small RNAs (EBER) in the pathological tissue is reported as a predictor of regression, although it is not necessarily specific [1)].
**Objectives:** To investigate the factors involved in spontaneous regression of LPD following MTX withdrawal.
**Methods:** We retrospectively reviewed 43 rheumatoid arthritis (RA) patients complicated with MTX-LPD from January 2000 to October 2015 in our institution. Age, sex, RA duration matched 76 control MTX-treated patients were selected. MTX-LPD patients were divided into two groups regarding to the status of LPD after MTX cessation; regressive LPD (R group) and persistent LPD (P group), and clinical parameters were compared. Flowcytometric analysis of the whole blood was underwent in a part of the MTX-LPD patients (N=10, 7 regressive, and 3 persistent LPD) and controls (N=10). The time of MTX cessation (= time of LPD diagnosis) was defined as week 0, and whole blood sample was collected at week 0, 4 and 12. Epstein Barr Virus antigen specific CD8+ T cells (EBV specific CD8+) was defined as MHC/EBV peptide tetramer positive CD8+ T cells.
**Results:** At the time of MTX cessation (week 0), number of peripheral lymphocytes was significantly decreased in LPD group, compared to control group. Among the LPD group, significant increase of lymphocyte number following MTX withdrawal was observed only in the R group, but not in P group while MTX dose, EBER positivity rate and pathological phenotypes did not show significant difference. Flowcytometric analysis revealed significant decrease in proportion of effector memory CD8+ T cells (EM CD8+), EBV specific CD8+ and T helpler 1 (Th1) subset in R group compared to control group. Following MTX cessation, significant increase in proportion of these subsets were observed only in the R group, but not in P group. On the other hand, proportion of CD14-CD15+ cells in lymphocyte fraction, which include myeloid derived suppressor cells [2)] (MDSC) was significantly increased in LPD group at week 0, and significantly decreased following MTX cessation only in the R group, but not in P group. Proportion of CD14-CD15+ cells negatively and significantly correlated with the proportion of EM CD8+T cells.
**Conclusions:** Our study suggested that decreased lymphocytes at the time of LPD diagnosis and restoration following MTX withdrawal are associated with pathogenesis and clinical course of "regressive" MTX-LPD. Proportion of Th1 cells, EM CD 8+, EBV specific CD8+ and CD14-CD15+ cells was restored following MTX cessation, indicating their involvement in regression of MTX-LPD.

## AB0291 AN ANALYSIS OF THE RELATIONSHIP BETWEEN CLINICAL ACTIVITY, MODE OF THERAPY AND DEPESSION IN RHEUMATOID ARTHRITIS

S.K. Stojanovic, J. Nedovic, B.N. Stamenkovic. *rhematology, Institut for prevention and rehabilitation Niska banja, Nis, Serbia*

**Background:** An ever increasing body of research confirm that rheumatoid arthritis is associated wuth depression.
**Objectives:**
- Assessment of presence and severity of depression in patients suffering from RA.
- Determination of the connection between depression with the activity of the disease, functional status, and radiological stage of the disease.
- To examine the effect of therapy on the severity of depression.

**Methods:** The examination was conducted with 276 patients with RA (82.24% women and 17.76% men), with the average age of 5563±14.46 years. The average duration of the disease was 48.4±20.3 months. The control group comprised 145 healthy examinees homogenous with the examined group in age and sex distribution. The activity of the disease was determined using the DAS 28 SE index, the functional status was determined on the basis of an HAQ questionnaire, while the degree of radiological damage was determined using the Larsen score (0–200).
The intensity of pain was determined by the examinees themselves on the visual-analog pain scale VAS (0–100mm). The degree of depressivity was determined through application of the Beck scale for depression.
The statistical data processing was performed in the SPSS package, version 15.0.
**Results:** The symptoms of depression were registered in 73.19% of patients, significantly more than in CG (21.34%), $p<0.01$. Mild depressivity was registered in 37.62% of patients, moderate in 28.71%, pronounced in 14.76%, and major depression in 8.91% of patients.
Out of the total number of examinees, 34.78% received combined therapy (MTX + biological therapy). 65.22% of patients were treated using monotherapy (MTX). The mean value of the Beck index of the patients receiving biological therapy was significantly lower than the value of the Beck index of the patients receiving monotherapy MTX (11.8±7.16 vs.16.86±8.09).
The connection between the ages of patients, the duration of the disease, DAS 28 SE, VAS of pain, Larsen score and HAQ index with the Beck index of depressivity was studied. The results of the univariant logistic regression show that the degree of depression is separately affected by the duration of the disease and the functional status of the patient. The multivariant model of logistic regression emphasizes the functional status as the most dominant predictor of depressivity (coef. Beta 0.764), $p<0.001$.
**Conclusions:** Depression is a frequently present manifestation of RA which is most prominently influenced by the degree of functional disability of RA patients. Apart from the medication therapy, the treatment of RA requires an individual psychosocial approach and wider social support.

## AB0292 LOW SERUM ALBUMIN, GLUCOCORTICOID AND LEFLUNOMIDE USE WERE ASSOCIATED WITH PERMANENT DISCONTINUATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Chaiamnuay, P. Limpawittayakul. *Medicine, Phramongkutklao Hospital, Bangkok, Thailand*

**Background:** Methotrexate (MTX) is the first line therapy for treatment of rheumatoid arthritis (RA) because of high efficacy and saved cost. MTX has toxicities such as GI irritation, hepatitis, pneumonitis and cytopenia. However,

MTX toxicities usually mild and does not lead to discontinuation. MTX toxicities have never been studied in Thailand, which prevalence of hepatitis B infection was high (26%).
**Objectives:** To examine the prevalence and reasons of discontinuation of MTX in RA and to determine factors, especially previous hepatitis B infection, associated with MTX discontinuation.
**Methods:** All 197 RA patients according to American College of Rheumatology (ACR) 1987 and/or ACR and European league of Rheumatology 2010 between 2000 and 2015 were studied. Anti-hepatitis B core antibody (anti-HBcAb), hepatitis B surface antigen (HBsAg), chest film were revealed prior to start methotrexate. Patients with positive HBsAg were excluded. Measurements of aspartate aminotransferase (AST), alanine aminotransferase (ALT), complete blood counts, signs and symptoms of methotrexate toxicities were recorded. Potential risk factors for toxicity were recorded. Univariable and multivariated analyses were performed to identify associated factors for permanently discontinuation of MTX.
**Results:** One hundred and ninety-seven RA patients were followed for 2142 person-years of MTX exposure. MTX was discontinued permanently in 47 patients (24%). Reasons for discontinuation were as followed: leucopenia 12 patients (26%), anemia8 patients (17%), thrombocytopenia3 patients (6%), pneumoitis11 patients (23%), GI irritation8 patients (17%), mild hepatitis (AST40–80 IU/mL) 8 patients (17%), severe hepatitis (AST>80 IU/mL) 8 patients (17%), mucositis 5 patients (10%), alopecia1 patient (2%). Mean time (standard deviation) to discontinuation was 522 (26.9) days. Multivariate logistic regression analyses found that serum albumin level less than 3.5 mg/dL, leflunomide use of more than 10 mg/d and prednisolone use of more than 10 mg per day were significantly associated with methotrexate discontinuation (odd ratio and 95% confidence interval of 15.33 (1.37–171.23), 5.33 (1.40–20.27)2.97 (1.14–7.77), respectively). Previous resolved hepatitis B infection defined as patients with positive anti-HBcAb was not associated with methotrexate discontinuation.
**Conclusions:** MTX discontinuation occurred in almost one-fourth of patients. Low serum albumin, glucocorticoid and leflunomide use were associated with permanent discontinuation of methotrexate in patients with rheumatoid arthritis.

## AB0293 CAROTID INTIMA MEDIA THICKNESS AND INTERLEUKIN -17 LEVEL IN RHEUMATOID ARTHRITIS PATIENTS

S.S. Shaharir[1], N. Sulaiman Sahari[2], A. Abdul Wahab[3], M.S. Mohamed Said[4], M.R. Ismail[5]. *[1]Internal Medicine, National University of Malaysia (UKM), Kuala Lumpur; [2]Internal Medicine, Universiti Putra Malaysia, Serdang; [3]Immunology, National University of Malaysia (UKM); [4]Internal Medicine; [5]Radiology, National University of Malaysia, Kuala Lumpur, Malaysia*

**Background:** Rheumatoid Arthritis (RA) patients are at risk of cardiovascular disease (CVD) and carotid intima media thickness (cIMT) is an excellent marker of subclinical atherosclerosis. However, cIMT and the CVD biomarkers among RA patients with low disease activity and remission are not well studied.
**Objectives:** To assess the carotid intima media thickness (cIMT) in RA patients who were in low disease activity state and lacking concomitant co-morbidities potentially influencing cIMT. This study was also aimed to determine the correlation between serum IL-17 with cIMT.
**Methods:** Rheumatoid Arthritis patients who were in low disease activity or remission (DAS28<3.2) from Rheumatology Clinic, National University of Malaysia Medical Centre were recruited. Patients with traditional CVD risk factors were excluded. Carotid ultrasound was performed in RA patients and their age and gender-matched healthy controls to determine the cIMT thickness. Serum IL-17 was measured using ELISA method.
**Results:** A total of 76 patients were screened and 22 RA patients who were in low disease activity or remission were included. Patients with RA had significantly higher median cIMT, 0.53 (IQR0.13) mm compared to controls, 0.47 (IQR 0.14) mm, p=0.01. In RA patients, the cIMT had significant positive correlation with age ($r_s$=0.84, p=0.00), systolic BP ($r_s$=0.45, p=0.04), waist circumference ($r_s$=0.43, p=0.04), total cholesterol ($r_s$=0.54, p=0.01), BMI ($r_s$=0.45, p=0.04) and serum IL-17 ($r_s$=0.45, p=0.03) but negative correlation with total HDL ($r_s$=-0.43, p=0.05).
**Conclusions:** Patients with RA had significantly higher cIMT as compared to healthy controls despite minimal disease activity and lack of traditional CV risk factors, suggesting that the vascular injury due to previous inflammation may not be reversible. Serum IL-17 was also found to be correlated significantly with cIMT, suggesting that it may play a role in atherogenesis among RA patients.

## AB0294 LYMPHOCYTE RECOVERY AFTER METHOTREXATE DISCONTINUATION RELATE TO SPONTANEOUS REGRESSION OF MTX-LPD IN RA PATIENTS

T. Kameda[1], H. Dobashi[1], M. Inoo[2], I. Onishi[2], N. Kurata[2], M. Izumikawa[1], S. Nakashima[1], H. Shimada[1], H. Ozaki[1], R. Wakiya[1], N. Kadowaki[1]. *[1]Department of internal medicine division of hematology, rheumatology and respiratory medicine, Kagawa University; [2]Internal medicine, Utazu hospital, Kagawa, Japan*

**Background:** Rheumatoid arthritis (RA) patients have a high risk of onset of lymphoproliferative disorders (LPD). Especially, LPD develop in patients treated with methotrexate (MTX) is known as MTX-associated LPD (MTX-LPD). MTX-LPD is classified among the "immunodeficiency-associated lymphoproliferative disorders (ID-LPD)" as an "other iatrogenic ID-LPD" in the 2008 WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues (1). We previously reported that MTX is an independent risk factor for LPD onset in Japanese RA patients (2). Characteristic of MTX-LPD is that MTX withdrawal possibly results in spontaneous regression of the LPD. Furthermore, there are some reports that the Epstein-Barr virus (EBV) infection is related to spontaneous regression of MTX-LPD. However, enough evidence about the relation with EBV infection and spontaneous regression of MTX-LPD is not presented. In addition, biomarker predicting a spontaneous regression of MTX-LPD has not been clarified.
**Objectives:** We examined the clinical characteristics of MTX-LPD in Japanese RA patients and attempted to determine the predictive marker for spontaneous regression of MTX-LPD.
**Methods:** We enrolled 33 RA patients who developed MTX-LPD from Kagawa Prefecture, Japan between June 2010 and December 2015. Patients were diagnosed according to American College of Rheumatology 1987 classification criteria, and treated with disease modifying antirheumatic drugs (DMARDs) including MTX. We divided into patients who were followed-up after the discontinuation of MTX alone (MTX withdrawal group) and patients who were performed chemotherapy after one month or more of the MTX discontinuation (chemotherapy group). The following differences between the two groups were examined: 1) serum LDH; 2) serum CRP; 3) sIL-2 receptor; 4) lymphocyte counts before and after MTX discontinuation; 5) hemoglobin; 6) histological findings related to LPD; 7) EBV association; 8) number of LPD lesions and 9) outcome.
**Results:** There were 28 patients in the MTX withdrawal group and 5 patients in the chemotherapy group. Laboratory data such as LDH, CRP, sIL-2R, lymphocyte counts and hemoglobin showed no significant difference in two groups. Furthermore, there is no difference between two groups about EBV infection and number of LPD lesions. However, significant differences were found in the change ratio of lymphocyte between the two groups.
**Conclusions:** We revealed that the change of lymphocyte before and after the MTX discontinuation relate to spontaneous regression of the MTX-LPD. This data suggest that the recover of lymphocyte after the MTX discontinuation may become a predictive marker for MTX-LPD treatment strategy.

## AB0295 ABNORMAL CENTRAL RETINAL VEIN EQUIVALENT FOUND IN ACTIVE RHEUMATOID ARTHRITIS: A DIFFERENT PERSPECTIVE OF MICROVASCULAR HEALTH

H. Babaoglu[1], S. Kadayifcilar[2], A. Erden[3], A. Baytaroglu[2], U. Kalyoncu[3]. *[1]Department of Internal Medicine; [2]Department of Ophthalmology; [3]Department of Internal Medicine, Division of Rheumatology, Hacettepe University, Ankara, Turkey*

**Background:** Patients with rheumatoid arthritis (RA) have increased risk of cardiovascular disease. Retinal vascular caliber (RVC) is one of the new tools to determine the cardiovascular risk. RVC includes central retinal artery and vein equivalents (CRAE and CRVE). It is well known that CRVE is closely related with chronic inflammation (1).
**Objectives:** The objective of this study was to assess RVC score in RA patients and compared the data with those of SLE patients and age-sex-comorbidity equivalent population.
**Methods:** Forty-seven RA patient were enrolled in this study between July 2014 and January 2015. Demographic data of patients were recorded. Before the measurement of RVC, disease activity was measured by Disease Activity Score-

28 (DAS-28). Functional capacity assessed by Health Assessment Questionnaire (HAQ). Disease activity was categorized according to DAS-28 (DAS-28<3.2 low disease activity, DAS-28>5.1 high disease activity). Thirty-two SLE patients and 45 healthy controls constituted the control groups. RVC was measured from the dilated fundus photographs, and summarized as the central retinal artery and vein equivalents (CRAE- CRVE) using a semi-automated computer-assisted method (IVAN, Wisconsin University-Figure 1). Measurement of the retinal vascular caliber performed in between the 0,5–1 disc distance from the optical disc margin (Zone B, figure 1). Arterioles and venules were marked semi-automatically by the software (Red=arterioles, Blue=Venules). The largest 6 vessels width used in the previously accepted formula for calculating the CRAE and CRVE. Retinal photography was performed in all patients at baseline and 24 of RA patients were re-evaluated 5.2±2.1 months later.

**Results:** The mean age of RA, SLE patients and healthy controls were 52.1±11.9, 41.4±14.5, and 47.2±17.3 (p=0,008), respectively. Female sex (83%, 84%, and 80%, p>0.05), hypertension (40%, 31%, and 27%, p>0.05) and diabetes mellitus (8%, 3%, and 11%, p>0.05) frequencies were similar in all groups. CRAE score was similar in RA, SLE, and healthy controls (147.8±11.7 μm, 148.3±12.8μm, and 147.4±17.6μm), respectively. CRVE score was also similar (213.3±17.8 μm, 209.2±14,1μm, and 217.5±26.2μm). There was no correlation between DAS-28, HAQ score with RVC scores. At baseline, ten (21%) of patients had active disease, and 22 (47%) patients had low disease activity. CRVE score was higher in active RA patients than low disease activity patients (222.8±10.1 vs. 207.3±17.8, p=0.004). There was no correlation between the changes of DAS-28 and HAQ with the RVC changes during follow-up period.

**Conclusions:** CRVE is associated with systemic inflammation and possibly increased CV risk (1,2). Although, CRVE and CRAE were similar in RA, SLE and healthy control groups, however especially active RA patients had worse CRVE level. Measurement of retinal vein caliber is a sensitive methods for assessment of microvascular circulation. Further studies should be focused to importance of abnormal CRVE and cardiovascular status in rheumatic diseases.

### AB0296 CLINICAL CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS ACHIEVING NO DEPRESSION WITH 6 MONTHS OF BIOLOGIC TREATMENT

Y. Miwa[1], M. Hatano[1], A. Nishimi[1], S. Nishimi[1], T. Hayashi[1], R. Yanai[1], H. Furuya[1], M. Umemura[1], T. Kasama[1], M. Hosaka[2], K. Sanada[3]. *[1]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo; [2]Department of Psychosomatic Medicine, Katsuyama Clinic, Yamanashi; [3]Department of Psychiatry, Showa University School of Medicine, Tokyo, Japan*

**Background:** It is known that rheumatoid arthritis (RA) is comorbid with various diseases and especially concomitant depression is common with a high prevalence of approximately 20%. Even if RA disease activity is controlled, patients with persistent depression result in decreased activity of daily life (ADL) and quality of life (QOL).

**Objectives:** To study predictive factors for no depression status after using biologic agents for 6 months.

**Methods:** The study was 333 RA patients treated with biologic agents. The following patient's characteristics were investigated: age, gender, the number of previous drugs, disease duration, the type of biologic agents, baseline steroid dosage, MTX dosage, serum rheumatoid factor (RF), serum matrix metalloproteinase-3 (MMP-3), anti-cyclic citrullinated peptide antibody (anti-CCP antibody), tumor necrosis factor (TNF)-α, and interleukin (IL)-6. For evaluation we used Simplified Disease Activity Index (SDAI) for RA disease activity, Health Assessment Questionnaire (HAQ) for ADL, Short Form (SF)-36 for QOL, and Hamilton Depression Rating Scale (HAM-D) or Self-rating depression scale (SDS) for depression status. No depression was defined by HAM-D≦7 or SDS≦39 after 6 months of treatment. The subjects were divided into two groups according to the presence or absence of depression, and a retrospective study was performed. We excluded 101 patients due to loss to 6-month follow-up and 39 patients due to incomplete data; therefore, we included 193 patients in the analysis.

**Results:** Compared with a group of RA patients with depression (n=130), a group of patients without depression (n=63) had younger age (52.7± 14.8 vs. 59.8±14.3, p=0.002), more males (p=0.046), lower baseline steroid dosage (3.2±3.1mg vs. 5.0±4.4mg, p=0.002), lower SDAI (22.9±12.8 vs. 29.5±15.2, p=0.002), lower HAQ (0.43 ±0.47 vs. 0.75±0.62, p<0.001), higher SF-36 (p<0.05 in all categories), lower SDS (38.2±8.5 vs. 46.7±9.6, p<0.001), and lower HAM-D (5.0±4.0 vs. 9.3±6.0, p<0.001) were detected based on univariate analysis. On the other hand, younger age (p=0.0352), more males (p=0.0048), lower baseline steroid dosage (p=0.0459), lower titer of serum RF (p=0.0114), lower HAQ (p=0.0485) and lower "pain (p=0.0222)", "general health perception (p=0.0364)" and "social functioning (p=0.0078)" item of the SF-36 were detected based on logistic regression analysis.

**Conclusions:** It was suggested that RA patients with more male, lower disease activity, lower dosage of steroid, younger age, and higher ADL and QOL at baseline are more likely to achieve no depression status with biologic treatment.

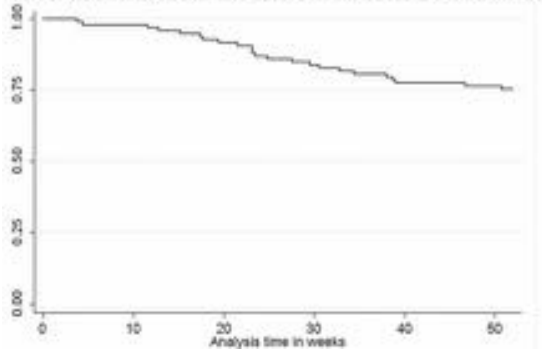
## Rheumatoid arthritis - anti-TNF therapy

### AB0297 REAL-LIFE EFFECTIVENESS OF GOLIMUMAB IN BIOLOGIC-NAÏVE RHEUMATOID ARTHRITIS PATIENTS – DATA FROM REUMA.PT, A PORTUGUESE REGISTRY

A.F. Mourão[1], C. Ribeiro[2], J. Borges[3], M.J. Gonçalves[4], M. Bernardes[5], S. Fernandes[3], R. Dezerto[6], P.A. Laires[6], P. Machado[6], M. Eusébio[7], M.J. Santos[8], H. Canhão[4] on behalf of REUMA.PT Investigators. *[1]CHLO, Egas Moniz, Lisbon; [2]CHAlgarve, Faro; [3]IP Reumatologia; [4]CHLN, Santa Maria, Lisbon; [5]CHP, São João, Oporto; [6]Merck Sharp & Dohme, Paço de Arcos; [7]Sociedade Portuguesa Reumatologia, Lisbon; [8]H Garcia Orta, Almada, Portugal*



**Background:** Registries are becoming an increasingly important source of data, providing additional information on the use of biologics in clinical practice. The real-world clinical data currently available regarding the use of SC anti-TNFs is still limited. Therefore, it is of utmost importance to increase the knowledge of Golimumab (GLM) effectiveness in the clinical practice.

**Objectives:** This study was designed to access the effectiveness of SC GLM 50 mg/monthly + MTX through 52 weeks of treatment in biologic-naïve RA patients. The primary objective was to investigate the proportion of patients achieving clinical remission (DAS28ESR<2.6). The secondary objectives were the evaluation of: the treatment persistence rates; the proportion of patients achieving functional response (ΔHAQ>0.22); and the effect of treatment on DAS28 individual components.

**Methods:** This was a retrospective non-interventional study based on the Rheumatic Diseases Portuguese Register (Reuma.pt). It was conducted in a cohort of patients aged >18 years with active RA despite previous treatment with conventional DMARDs, biologic-naïve, who started SC GLM+MTX, from March 2011 to August 2015. The cumulative incidence of achieving clinical remission, treatment persistence and functional response/remission were estimated using survival analysis. Cox regression was used to calculate the hazard ratios.

**Results:** A total of 109 patients (86.3% female, mean age 55.5±13.2 years; mean age of diagnosis 45.5±13.5 years, rheumatoid factor 78% positive) met the study criteria. Ninety-three had a follow up of at least 52 weeks (i.e. all patients who started treatment before August 2014). At week 52, 38.3% of patients were on clinical remission, 91.9% achieved functional response and 35.2% were on functional remission (HAQ<0.5). The treatment persistence rate was 75.3% for the individuals who were in the study for ≥52 weeks (Figure 1). For functional remission, high CRP levels at baseline seem to be a determining factor (HR=0.54, *p*=0.026).

Figure 1: Kaplan-Meier survival estimate for Golimumab treatment persistence through 52 weeks

**Conclusions:** This is the first Golimumab data analysis generated from the Portuguese registry Reuma.pt. Our results are in agreement with data from other national registries and demonstrate the long-term effectiveness and the high treatment persistence rates of GLM through 52 weeks.

## AB0298 CURRENT STATUS OF CLINICAL DEVELOPMENT OF ANTI-TNF BIOSIMILARS: MAIN CHARACTERISTICS AND CURRENT TRENDS OF PHASE III TRIALS

A. La Noce[1], Z. Lai[2]. [1]*Worldwide Clinical Trials, Roma, Italy;* [2]*GlaxoSmithKline, Collegeville - PA, United States*

**Background:** The global development of a biosimilar product is methodologically complex, presenting potential design pitfalls and operational challenges with the risk of failing to demonstrate equivalence. The clinical development of anti-TNF biosimilars presents an additional challenge of selecting the most appropriate therapeutic indication(s) for the pivotal clinical trial(s) among those approved for the originator molecules.
**Objectives:** By reviewing the clinical development programs of biosimilars of adalimumab, etanercept and infliximab, we aimed to highlight the key features of pivotal clinical trials in terms of both study design and most suitable indications.
**Methods:** We performed a search of completed or ongoing Phase III global clinical trials for anti-TNF biosimilars in different clinical trials databases[1–3] as well as a search of literature on Medline for anti-TNF biosimilar clinical trials, and summarized the main features of study design of the retrieved trials.
**Results:** The pivotal efficacy and safety trials for anti-TNF biosimilars were either in rheumatoid arthritis (RA) or in psoriasis (PsO). In only a few cases, both indications were pursued for the same product in two pivotal trials. For etanercept and infliximab biosimilars, the most frequent indication of the pivotal trial was RA. For adalimumab either RA or PsO indications were investigated in approximately the same number of trials, with the most recent trials being all in PsO. All studies have an equivalence and not a non-inferiority design. However, considerable differences exist among these studies regarding key design elements such as the target patient population, background therapy, blinding, stratification, switch from originator to biosimilar product, primary dependent variable, and selection of equivalence margin. The differences of the study design of the Phase III biosimilar studies are summarized and discussed regarding the potential impact on demonstrating comparability and operational feasibility.
**Conclusions:** Most of the sponsors are conducting or have conducted the pivotal Phase III studies of anti-TNF biosimilars in one disease indication only, with a preference for PsO in most recent trials. This may suggest that PsO has become the indication of choice for pivotal trials for anti-TNF biosimilars. Potential advantages include 1) the greatest placebo-adjusted response rate is in PsO for the various TNF inhibitors among the licensed therapeutic indications[4,5], consistent with the need for a smaller sample size to demonstrate equivalence; 2) the primary study endpoint at week 16 or Week 12 for PsO compared to week 24 of RA allows for a shorter study duration; 3) a more favorable competitive environment leading to a faster trial execution; and 4) a more sensitive model to investigate immunogenicity compared to RA since PsO patients do not receive any immunosuppressive drug for the duration of the study.

## AB0299 THE REASONS FOR WITHDRAWAL OF BIOLOGICAL DMARDS ACCORDING TO THE RUSSIAN REGISTRY OF PATIENTS WITH RHEUMATOID ARTHRITIS

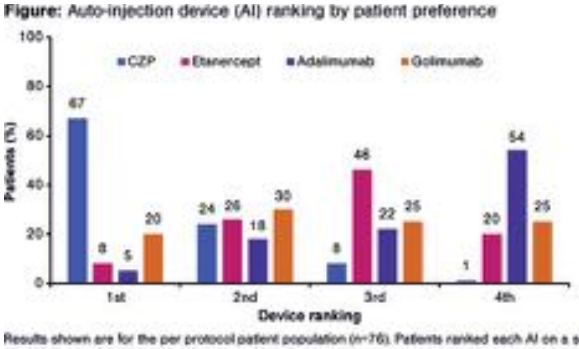
A. Satybaldyev, D. Karateev, E. Nassonov, E. Luchikhina, G. Lukina, M. Nikolenko, M. Bilinskaya, M. Dmitrieva, L. Bogoderova, N. Lapkina, N. Chichasova, V. Sorotskaya, D. Abdulganieva, R. Mukhina, G. Gafurova, V. Mazurov, D. Chakieva, R. Samigullin. *V.A. Nassonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Russian register of patients with inflammatory arthritis started in 2012 as a register of RA ("All-Russian register of Rheumatoid Artritis"- ARRA) now transformed into "Observational REgister of arthritis in cLinical practice" (OREL), including patients with rheumatoid arthritis (RA), psoriatic arthritis and adults with juvenile arthritis. (RA), psoriatic arthritis and adults with juvenile arthritis.
**Objectives:** To study reasons for withdrawal of biological DMARDs in patients with RA in clinical practice in Russia.
**Methods:** Data of 1398 pts with RA (286 men, 1112 women, medium age of 50,5 years), treated of biological DMARDs, were included in OREL registry from 01 Mar 2012 to 30 Mar 2015.
**Results:** 320 pts (22.8%) had withdrawals of biologics during this period. In 77 pts (23.4%) the reason for withdrawal was primary lack of efficacy or secondary loss of response; in 54 pts (16.9%) - adverse events (AE) or serious adverse events (SAE). In 80 pts (25.0%) biologic therapy has been stopped due to continuous remission; 109 pts (32.5%) had administrative reasons (lack of funding etc.).

Table 1. Main reasons for withdrawal biological DMARDs

| Biological DMARD | n | All reasons n (% )* | Continuos remission n (% )* | Lack of efficacy or loss of response n (%)* | AE/SAE n (%)* | Lack of funding n (% )* |
|---|---|---|---|---|---|---|
| Infliximab | 207 | 28 (13.5) | 0 | 11 (5.3) | 10 (4.8) | 7 (3.4) |
| Adalimumab | 253 | 64 (25.3) | 2 (0.8) | 25 (9.9) | 11 (4.3) | 26 (10.3) |
| Etanercept | 230 | 125 (54.3) | 74 (32.2) | 12 (5.2) | 8 (3.5) | 31 (13.5) |
| Certolizumab pegol | 47 | 12 (25.5) | 1 (2.1) | 1 (2.1) | 2 (4.3) | 8 (17.0) |
| Abatacept | 211 | 44 (20.9) | 0 | 17 (8.1) | 16 (7.6) | 11 (5.2) |
| Tocilizumab | 120 | 27 (22.5) | 1 (0.8) | 2 (1.7) | 6 (5.0) | 18 (15.0) |
| Rituximab | 330 | 20 (6.1) | 2 (0.6) | 9 (2.7) | 1 (0.3) | 8 (2.4) |

% relative to the total number of patients in the subgroup of drug.



**Conclusions:** Frequencies of withdrawals due to lack of efficacy or loss of response among biological DMARDs were comparable. Etanercept has been withdrawn due to long term remission more often than other biologics. Lack of funding is still an important cause of withdrawal of biological therapy of RA.
**Disclosure of Interest:** None declared

## AB0300 COMPARATIVE USABILITY STUDY FOR A CERTOLIZUMAB PEGOL AUTO-INJECTION DEVICE IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Domanska[1], L. Peterson[2], I. Mountian[1], M.H. Schiff[3]. [1]*UCB Pharma, Brussels, Belgium;* [2]*UCB Pharma, Raleigh;* [3]*University of Colorado School of Medicine, Denver, United States*

**Background:** Impaired manual dexterity is common in patients (pts) with rheumatoid arthritis (RA), often resulting in difficulties with drug self-administration when using pre-filled syringes.[1,2] Auto-injection devices (AIs) have been shown to provide a number of benefits, including reduced discomfort and greater ease of use compared with manual injections.[2,3] A new certolizumab pegol (CZP) device was created, based on pt insights and capitalizing on the benefits of existing AIs.
**Objectives:** To compare the usability of a new CZP AI with alternative anti-tumor necrosis factor (anti-TNF) devices (adalimumab, etanercept and golimumab) in patients with moderate to severe RA.
**Methods:** Eligible pts had moderate to severe RA (fingers, hands and/or wrists affected) and no prior experience of using an AI for RA. Each pt tested 4 AIs (CZP, golimumab, etanercept and adalimumab) in a randomized order by performing a simulated self-injection on a training skin pad strapped to the upper thigh or lower abdomen. All identifications were removed from the AI devices and respective instructions for use. Pts were provided with instructions for use for each of the AIs, but were not trained on device use prior to testing. Following utilization of all four AIs, pts were asked to rank them in order of preference from 1–4 (1=the most preferred) and to provide feedback on their usability (easy to use, easy to start the injection, easy to tell when injection was finished and willingness to use).
**Results:** Overall, 76 pts took part in this study. 67.1% pts ranked the CZP AI as their most preferred device; 23.7% ranked it as their second most preferred (Figure). The preference in the overall ranking of the CZP AI over each of the other devices was statistically significant ($p<0.001$). The majority of pts agreed, strongly agreed or very strongly agreed that the CZP AI was easy to use, easy to start the injection and that it was easy to determine when the injection was finished. Pts were significantly more willing to use the CZP AI compared with each of the other devices tested ($p<0.001$).

**Figure:** Auto-injection device (AI) ranking by patient preference

Results shown are for the per protocol patient population (n=76). Patients ranked each AI on a scale of 1–4 (1=the most preferred and 4=the least preferred).

**Conclusions:** In pts with moderate to severe RA, the CZP AI was the preferred

choice compared to the golimumab, etanercept and adalimumab AIs, and was associated with a high level of patient satisfaction.

## AB0301 COMPARISON OF THE BIOAVAILABILITY OF A SINGLE DOSE OF CERTOLIZUMAB PEGOL INJECTED EITHER BY A PRE-FILLED SYRINGE OR BY AN AUTO-INJECTION DEVICE

B. Astruc[1], S. Watanabe[2], G. Parker[2], R. Hulhoven[2]. [1]*Biotrial, Rennes, France;* [2]*UCB Pharma, Brussels, Belgium*

**Background:** Evaluation of the pharmacokinetic (PK) properties of certolizumab pegol (CZP) has shown a linear relationship between the dose administered (intravenous and subcutaneous [sc] routes), the maximum plasma concentration ($C_{max}$), and the area under the plasma concentration versus time curve (AUC).[1] In multiple clinical studies, the half-life ($t_{1/2}$) was approximately 14 days for all CZP dosage levels tested. CZP has also been demonstrated to have good bioavailability (approximately 80%) when given sc.[1]

**Objectives:** To compare the bioavailability of a single CZP 400 mg dose given as 2 x 200 mg injections injected by either a pre-filled syringe (PFS) or by an auto-injection device (AI), and to investigate the safety and tolerability of both methods of administration.

**Methods:** In this open-label phase I study, healthy volunteers were randomized into two parallel groups. On Day 1, study participants were injected with either 2 x 200 mg CZP via a PFS or 2 x 200 mg CZP via an AI. CZP plasma concentrations were measured pre-dose, and post-dose at 12h, 24h and Days 2, 3, 4, 5, 6, 7, 10, 14, 21, 28, 42, 56 and 84. Safety and tolerability were assessed by recording adverse events (AEs) and serious AEs (SAEs). In addition, the tolerability of the injection was assessed by a pain visual analog scale (VAS) and an injection site reaction questionnaire.

**Results:** 98 healthy volunteers were randomized to the PFS (n=49) and AI (n=49) groups. The mean plasma CZP concentration vs time profile of the AI was similar to that of the PFS. PK parameters were similar between the two modes of administration (Table). The 90% confidence intervals (CI) for the test/reference geometric mean ratios in $C_{max}$, $AUC_{(0\text{-}t)}$, AUC and $t_{1/2}$ were all contained in the bioequivalence range of 80–125%, and no statistically significant difference was found for $t_{max}$ between the two modes of administration (Table). Safety assessments showed that both methods of administration were equally well-tolerated. Injections performed with the AI appeared to be less painful immediately after administration than injections given by the PFS, as well as being associated with less burning and redness.

**Table:** Results of the bioequivalence analysis

| Parameter (unit) | Reference [a] | Test [a] | Test/Reference [c] | | CV (%) [d] |
|---|---|---|---|---|---|
| | CZP 400mg [b] PFS | CZP 400mg [b] AI | Point estimate | 90% CI | |
| $C_{max}$ (µg/mL) | 61.7 | 60.1 | 97.5 | 87.3–108.9 | 33.9 |
| $AUC_{(0\text{-}t)}$ (µg d/mL) | 1269.0 | 1239.9 | 97.7 | 89.1–107.2 | 28.1 |
| AUC (µg d/mL) | 1308.4 | 1325.8 | 101.3 | 92.8–110.6 | 25.9 |
| $t_{1/2}$ (days) | 10.4 | 11.3 | 108.9 | 96.4–123.0 | 36.7 |
| $t_{max}$ (days), median | 5.0 | 5.0 | 0.0 | 0.0–1.0 | n/a |

[a] Geometric least squares mean, unless otherwise noted; [b] CZP 400 mg dose was given as 2 x 200 mg injections; [c] Point estimate (90% CI) for the test/reference geometric least squares mean ratio (%) derived from the ANOVA; for $t_{max}$, median point estimate (90% non-parametric CI) of the difference test-reference; [d] ANOVA residual error, representing inter-subject variability. CI: confidence interval; CV: coefficient of variation.

**Conclusions:** CZP 400 mg dose is bioequivalent whether administered by AI or PFS. Overall, CZP injections were safe and well-tolerated for both administration methods.

## AB0302 INFLUENCE OF TAPERING BIOLOGICAL THERAPIES IN IMMUNOGENICITY IN A COHORT OF RHEUMATOID ARTHRITIS WITH LOW DISEASE ACTIVITY

B. Paredes, C. Plasencia, A. Balsa, I. Monjo, C. Plasencia, D. Pascual-Salcedo, I. Monjo, A. Pieren, E. Moral, C. Tornero, P. Bogas, G. Bonilla, L. Nuño, A. Villalba, D. Peiteado, S. Ramiro, T. Jurado, J. Díez, E. Martin-Mola, A. Balsa. *Rheumatology, Hospital Universitario La Paz, Madrid, Spain*

**Background:** Recent studies propose the use of a tapering strategy (dose reduction or discontinuation) of tumor necrosis factor inhibitors (TNFi) in rheumatoid arthritis (RA) patients (pts) in low disease activity (LDA) or clinical remission (R) without losing the disease control. One concern, when lower doses are used, is the appearance of anti-drug antibodies (ADA) with the consequent loss of efficacy.

**Objectives:** To evaluate the clinical influence of the tapering strategy of TNFi in a cohort of RA pts in LDA or R.

**Methods:** Of a total of 283 RA pts under TNFi, 52 patients treated with Infliximab (Ifx), Adalimumab (Ada) or Etanercept (Etn) were selected. All pts were in LDA or R (DAS28 $<$3.2 or $<$2.6, respectively) for at least 6 months prior to start the tapering strategy. Clinical activity (DAS28), drug levels (DL) and ADA were evaluated at baseline before tapering (pre-visit) and at the last available visit after 4 years follow-up (final-visit), this parameters were also evaluated at flares (DAS28$>$3,2 and $\Delta$DAS28$>$0.6). At flare, the biologic and non-biologic therapy could be intensified.

**Results:** In our cohort of 52 pts, 26 (50%) pts were treated with Ada, 16 (31%) with Etn and 10 (19%) with Ifx. Forty one (79%) were women and 41 (79%) pts were ACPA+ and RF+. Most patients received methotrexate concomitantly (69%), 25 (48%) pts other DMARDs and 22 (42%) prednisone. The mean follow-up was 43.76±8months, without statistically significance among TNFi (p=0.595). At pre-visit, 40 (77%) pts were in R and 12 (33%) LDA. The majority of patients remained in LDA or R at final-visit: 26 (50%) in R, 14 (27%) in LDA, 12 (23%) with DAS28$>$3.2, p=0.97). When a subanalysis in each TNFi was performed, it was confirmed that most pts were in LDA or R at final-visit (p=0.59 in Ada, p=0.26 in Ifx and p=0.78 in Etn). No differences in CRP levels between visit-pre and final visit were seen. 25 patients (48%) had flares during follow-up (13 (52%) had 1 flare, 10 (40%) had 2 flares and 2 (8%) had 3 flares. Most patients with flares were in LDA or R at final-visit (R=9 (36%), LDA=5 (20%)). Only 2 pts with flares dropped out the TNFi and were ADA + at final visit. All patients were ADA negative at the pre-visit and only 6 (11%) were positive at final-visit, 4 of them withdrawed therapy for maintaining clinical remission. A statistically significant decrease was observed in drug levels between the pre-visit and post-visit (Ada: 5251.9±1205.9 vs 1507.2±322.7, p=0.001; Etn: 2735.2±347.4 vs 1114.9±283.2, p=0.002; Ifx: 2358.4±728.5 vs 650.4±290.1, p=0.008).

**Conclusions:** The tapering strategy seems feasible in RA pts in LDA treated with TNFi, reducing the amount of drug administered with low incidence of ADA and without deterioration of disease activity. In most patients, flares appear to be controlled by changing the drug administration interval without the necessity of changing or stopping treatment.

## AB0303 IDENTIFYING IMMUNOLOGICAL BIOMARKERS TO PREDICT TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS - PRELIMINARY RESULTS OF A PILOT STUDY

B. Mulhearn[1], S. Viatte[2], T. Hussell[1], A. Barton[2] on behalf of BRAGGSS Consortium (K Hyrich, Manchester; A Morgan, Leeds; AG Wilson, Sheffield; J Isaacs, Newcastle). [1]*Manchester Collaborative Centre for Inflammation Research (MCCIR);* [2]*Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom*

**Background:** Good evidence shows that treating the inflammation of rheumatoid arthritis (RA) early leads to less disability and improved patient outcomes [1]. However, for patients receiving biologic therapies, only ~30% will have a good response to the first drug tried [2]; currently there is no way to predict which drug will be effective in each individual patient. As RA is an autoimmune disease, we hypothesise that the immunophenotype can be used to inform selection of the treatment most likely to be effective in individual patients.

The first step is to identify immunophenotypic differences between RA patients with very active disease and controls in order to inform hypotheses as to which immune markers may be important in informing selection of effective biologic therapy.

**Objectives:** 1) To compare the immunophenotype of RA patients about to start biologic therapy with controls.

2) To characterise the involvement of novel cell types such as invariant natural killer T (iNKT) cells and co-stimulatory pathways (CD200/CD200R) in RA compared to healthy controls.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were collected from patients about to be started on a biologic drug as part of the BRAGGSS study [3]. PBMCs were stimulated under a number of different conditions and analysed by 16-parameter flow cytometry for:

a) Cell surface profiles (major T and B cell subsets, classical and non-classical

monocytes, natural killer cells, dendritic cells, markers for iNKT cells and the expression of CD200 and CD200R), and
b) Intracellular cytokine quantification, following a stimulation assay (IFNγ, TNFα, IL-13, IL-10, IL-17A, GM-CSF, IL12-p40, IL-6).
**Results:** 7 RA patients and 9 healthy control samples were examined in this pilot study.
There were large differences in the number of IFNγ-producing T cells in all samples, in both RA patients and healthy controls (range 8.19% to 65.1% in RA and 17.9% to 49.0% in controls,). There were also differences in the number of IL-17A-producing T cells, although absolute numbers were lower (range: 1.2% to 12%). Samples could be placed into four phenotypes: 1) "IFNγ", 2) "IL-17A", 3) "double-hi", and 4) "low".
Interestingly, there was also a large range in number of IFNγ-producing B cells in all samples (mean fluorescence intensities (MFI) ranged from 202 to 1197).
Follow up data was available for 7 patients. Five had been started on an anti-TNF, one on tocilizumab and one on rituximab. Four had a good EULAR response, had been started on an anti-TNF, and had either the "double-hi", "IFNγ", or "low" phenotypes. One non-responder had been started an anti-TNF but had the "IL-17" phenotype. The other non-responder had been started on rituximab and had both the "IL-17" phenotype and a low IFNγ B cell signature.
**Conclusions:** RA patients may have very different B and T cell cytokine profiles on *ex vivo* stimulation of their PBMCs. This may be important in selecting the first biologic drug choice: For instance, a high IFNγ B cell phenotype might make rituximab a more attractive first choice, and so forth. These results require validation with larger sample numbers.

## AB0304 ADHERENCE TO DMARD AND SUBCUTANEOUS BIOLOGICAL THERAPY AMONG RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS AT BASURTO UNIVERSITY HOSPITAL

C. Gómez [1], M.L. García [1], E. Galindez [1], O. Fernández [1], E. Ruíz [1], I. Calvo [1], E. Guerrero [1], J.M. Blanco [1], I. Torre [1], J.F. García [1], I. Gorostiza [2], M.M. Alvarez [3], M. Alonso [3]. *[1]Rheumatology; [2]Research Department; [3]Pharmacy, Basurto University Hospital, Bilbao, Spain*

**Background:** Combination therapy with DMARDs and Biological drugs is a common practice in the management of peripheral arthritis. The addition of Methotrexate to Biological agents provides better clinical response and decreased anti-drug antibodies production. This is well proved for patients with rheumatoid arthritis (RA), especially under therapy with anti-TNF antibodies, but not so clear for psoriatic arthritis (PsoA). Nevertheless a high percentage of patients may be non adherent, especially to DMARDs (Disease Modifying Antirheumatic Drugs), and this fact could have a negative effect on the course and management of the disease.
**Objectives:** To assess the adherence to subcutaneous Biological drugs and DMARDs in our patients with RA and PsoA under combination therapy, and to assess the relationship between the degree of adherence and different demographic and clinical aspects.
**Methods:** 179 clinical records of patients with PsoA and RA on Biologic treatment were reviewed. 61 patients on Biological monotherapy were excluded from the analysis. Demographic, clinical characteristics and comorbidities were collected. The level of adherence to DMARDS was obtained from the PRESBIDE monitoring system that estimates external pharmacy drug picking up for the last 8 months, and data of adherence to Biologicals from the Hospital Pharmacy registry (FARHOS). SPSSv22 software was used for statistical analysis.
**Results:** 109 patients included, 76% women, mean aged 57 years (range 19–86). 70% had RA and 30% PsoA. Disease evolution was longer than 10 years in 63% of the patients. 32% presented more than two comorbidities. Concerning DMARDs, 76% of patients received Methotrexate, 15.6%Leflunomide and 8.4% others. Average adherence to DMARDs was 65.5%, being good (>80%) in 49.5%, fair (60–80%) in 22% and low (<60%) in 28.4%. In 13 patients (11.92%) DMARD collection at the pharmacy was 0. Evaluated Biological drugs were mainly Adalimumab (30%) and Etanercept (39.5%). Adherence to Biologicals was excellent, average 91.8% (SD 9.78), significantly higher than the adherence to DMARDs (average 65.53, SD 32.79). ($p<0.001$, WR test). Disease activity estimated by DAS 28 was<2.6 in 57% of patients, 2.6–3.2 in 19,6% and >3.2 in 23.4%. There was no correlation between lack of adherence and resulting DAS 28. 47.7% of patients had received more than one DMARD previously, fact not being related to the current adherence. No relationship between the number of previous Biological drugs and adherence to DMARD was found.
**Conclusions:** Adherence to subcutaneous Biologic agents was good and statistically superior to Methotrexate. A high proportion of our patients (1/3) is non adherent to DMARDs, so that more than 10% are under unexpected monotherapy with Biological drugs because of noncompliance or withdrawal of the treatment. The reasons for this may be various, and the impact on the disease activity must be evaluated, as far as both negative and neutral effect had been described in the literature. The implementation of tools to monitor adherence and identification of non-compliant patients is useful in the search of solutions and clinical decision making.

## AB0305 INFLUENCE OF DRUG LEVELS DURING THE FIRST ANTI-TNF THERAPY ON THE CLINICAL RESPONSE TO A SECOND BIOLOGIC IN RHEUMATOID ARTHRITIS PATIENTS

C. Plasencia-Rodriguez [1], M.D. Pascual-Salcedo [2], G. Bonilla [1], V. Navarro-Compán [1], A. Martinez-Feito [2], C. Diego [2], A. Villalba [1], D. Peiteado [1], L. Nuño [1], E. Martin-Mola [1], A. Balsa [1]. *[1]Rheumatology; [2]Immunology, La Paz University Hospital-Idipaz, Madrid, Spain*

**Background:** The anti-tumor necrosis factor (anti-TNF) therapy has shown to be effective in rheumatoid arthritis (RA). Recent publications have shown the association between drug levels (DL) and clinical response to the anti-TNF therapies. For now it is not clear if the DL monitoring to the 1st anti-TNF in patients who discontinued due to inefficacy, can be useful to evaluate the clinical efficacy to the 2nd anti-TNF.
**Objectives:** To evaluate in a RA cohort (who stopped to the 1st anti-TNF due to inefficacy), the influence of the presence/absence of DL [infliximab (Ifx) y adalimumab (Ada)] at discontinuation, on the clinical response to the 2nd anti-TNF during the 1st year of therapy.
**Methods:** Seventy seven out of 182 RA patients who discontinued the Ifx or Ada therapy were recruited. All these patients dropped out the first anti-TNF due to inefficacy and switched to a 2nd anti-TNF (48 patients: 2 with Ifx, 4 with Ada, 40 with etanercept and 2 with certolizumab) or other biologics (OB) different to anti-TNF (29 patients: 17 with rituximab, 6 with tocilizumab and 6 with abatacept). Clinical activity was measured by DAS28 and clinical improvement by Delta-DAS28 adjusted to baseline clinical activity (baselineDAS-DAS (24weeks or 52weeks)/baselineDAS) at baseline, 24 weeks (24w) and 52 weeks (52w). DL were measured prior to drug administration at 24w and 52w by ELISA.
**Results:** Of the 77 RA patients, 82% (63/77) were women and the mean disease duration was 21±13 years. At the end of the 1st antiTNF, 54/77 (70%) had undetectable DL and 23/77 (30%) had detectable DL. At w24 of the 2nd biologic, patients treated with OB tended to be less active than patients treated with a 2nd anti-TNF but these differences were not significant at w52 (*DAS28 at w24:* 3.5±1.3 with OB vs 4.1±1.1 wirh 2nd anti-TNF, p=0.053; *Delta-DAS28 at w24:* 0.3±0.3 with OB vs 0.2±0.3 with 2nd anti-TNF, p=0.326; *DAS28 at w52:* 3.3±1.2 with OB vs 3.8±1.1 with 2nd anti-TNF, p=0.166; *Delta-DAS28 at w52:* 0.3±0.2 with OB vs 0.2±0.3 with 2nd anti-TNF, p=0.501). Patients with undetectable DL to first anti-TNF treated with a 2nd anti-TNF had better clinical response during the first year of therapy (*DAS28 at w24:* 3±1.1 with non DL vs 4.3±1.2 with DL, p=0.004; *Delta-DAS28 at w24:* 0.3±0.3 with non DL vs 0.2±0.3 with DL p=0.074; *DAS28 at w52:* 2.9±1.1 with non DL vs 4±1.2 with DL, p=0.015; *Delta-DAS28 at w52:* 0.4±0.2 with non DL vs 0.2±0.3 with DL, p=0.210). However, no differences in the clinical activity were observed between patients with undetectable or detectable DL who switched to OB (*DAS28 at w24:* 4.4±1.4 with non DL vs 3.8±1 with DL, p=0.247; *Delta-DAS28 at w24:* 0.2±0.2 with non DL vs 0.2±0.2 with DL, p=0.382; *DAS28 at w52:* 4.1±1.2 with non DL vs 3.5±0.7 with DL, p=0.122; *Delta-DAS28 at w52:* 0.2±0.2 with non DL vs 0.3±0.1 with DL, p=0.376).
**Conclusions:** In our cohort of RA patients with inefficacy to the 1st anti-TNF, a high proportion of patients discontinued the therapy with undetectable DL. The DL monitoring during the 1st anti-TNF seems to be a useful tool to define what patients have a better clinical response to the 2nd anti-TNF, although this effect does not influence on those patients who switch to OB.

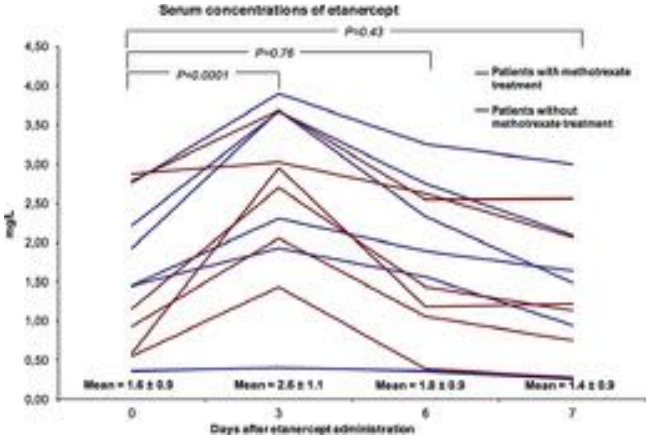
## AB0306 THE TIME WINDOW TO DETERMINE TROUGH VALUES OF ETANERCEPT IS IMPORTANT IN PERSONALIZED MEDICINE REGIME INDEPENDENTLY OF METHOTREXATE COADMINISTRATION

C. Hornshoj-Sorensen [1,2], B. Brock [1], U. Tarp [2], M. Pfeiffer-Jensen [2]. *[1]Department of Clinical Biochemistry; [2]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark*



**Background:** Several studies show correlation between trough serum concentrations of TNF-alpha inhibitors and treatment efficacy (1,2). In spite of this, patients are treated with standard dosages as in "one size fits all". Individualised treatment based on trough value of etanercept might optimise treatment and reduce risk of adverse events. However, the time window to determine the trough value of etanercept in patients on standard dosing is not known. Based on the pharmacokinetics of etanercept ($t_{max}$ approx. 69 h, $t_{1/2}$ approx. 102 h) the purpose of this study was to challenge the window to determine trough values in patients treated with etanercept with and without concomitant methotrexate.
**Objectives:** To explore the time window to determine trough values of etanercept and whether concomitant treatment with methotrexate influence the width of the window.
**Methods:** Six arthritis patients with concomitant methotrexate and six arthritis patients without were included. Serum concentrations of etanercept were measured

before dosing, at day 3 ($t_{max}$), at day 6, and before next dosing at day 7 thus focusing on trough rather than peak values. Serum concentrations of etanercept were assessed by ELISA technique (3).

**Results:** The study included 12 female patients (10 diagnosed with rheumatoid arthritis and 2 with juvenile arthritis equally distributed between groups) treated with etanercept, with or without concomitant methotrexate. In the methotrexate group the average dosage was 15.4 mg/week (SD=6.4). For the whole study population, the age was 59.5 years (SD=15.4) with disease duration of 23.5 years (SD=7.4), and an average DAS28CRP of 2.2 (SD=0.6). There were no differences between the two subgroups in regard to age, disease duration, and years of treatment with etanercept, while the group treated without methotrexate tended to have a lower DAS28CRP (1.9 vs 2.5, p=0.06).

In a mixed-effect logistic regression model, methotrexate did not influence the serum levels of etanercept (P=0.6).

As expected there was a significant increase in serum level of etanercept on day 3 ($t_{max}$), while no difference was seen between day 0 and day 6 or 7 (compatible with the t½ of approx. 4 days), thus allowing considering extension of the window to determine trough values. However, a post hoc analysis confirmed a decline in concentrations from day 6 to day 7 of 0.32 mg/l (SD=0.29). In light of the rather narrow concentration ranges found in patient populations (1,2) it can not be ruled out as clinical irrelevant.

**Conclusions:** Concomitant methotrexate did not influence the serum levels of etanercept.

The day to day decrease in serum concentrations of etanercept at the end of a dosing interval must be considered when designing an algorithm for serum-concentration based personalized medicine.

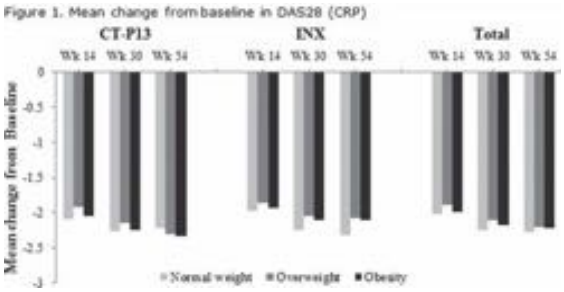
## AB0307 NO CORRELATION BETWEEN BODY MASS INDEX AND CLINICAL RESPONSE TO INFLIXIMAB: POST-HOC ANALYSIS OF PLANETRA

D.H. Yoo[1], W. Park[2], S.C. Shim[3], C.H. Suh[4], S.J. Lee[5], S.Y. Lee[5], S.H. Lee[5], J.H. Suh[5]. *[1]Hanyang University Hospital, Seoul; [2]Inha University Hospital, Incheon; [3]Chungnam National University Hospital, Daejeon; [4]Ajou University Hospital, Suwon; [5]Celltrion, Inc., Incheon, Korea, Republic Of*

**Background:** Rheumatoid Arthritis (RA) patients with high body mass index (BMI) have been known to respond less well to anti-tumor necrosis factors (TNFs), especially infliximab. The post-hoc analysis of PLANETRA [1], a randomized controlled trial, was carried out to evaluate the influence of BMI on clinical response to infliximab (both infliximab originator and its biosimilar) in a large number of patients with RA.

**Objectives:** To investigate the association between BMI and clinical response to infliximab in patients with RA.



**Methods:** BMI was calculated before initiation of infliximab treatment in 606 patients with RA in PLANETRA. Patients were classified into 3 groups as normal weight (<25 kg/m$^2$), overweight (≥25-<30 kg/m$^2$) and obesity (≥30 kg/m$^2$) according to the WHO BMI categories. Changes in disease activity were assessed at weeks 14, 30 and 54 with the Disease Activity Score in 28 joints (DAS28 [CRP]), Health Assessment Questionnaire (HAQ), and Short Form Health Survey (SF-36) based on BMI categories.

**Results:** The proportion of patients with normal weight, overweight and obesity were 43.1%, 36.1% and 20.8%, respectively. Baseline characteristics were comparable among BMI subgroups in gender, height and weekly MTX dose given to patients. The mean DAS28 (CRP) at baseline was significantly higher in obesity group (5.80±0.87, 5.72±0.86 and 6.15±0.78 for normal weight, overweight and obesity, respectively; $P<0.0001$). But no significant differences were observed when comparing the mean change from baseline at Week 14 (-2.02 vs. -1.89 vs. -1.99), Week 30 (-2.25 vs. -2.10 vs. 2.17) and Week 54 (-2.27 vs. -2.20 vs. -2.22) among BMI subgroups. Similar results were observed when analysing biosimilar infliximab (CT-P13) and innovator infliximab (INX) separately up to Week 54 [Figure 1].

HAQ score was significantly higher in obese patients at baseline (1.55±0.55, 1.56±0.62 and 1.71±0.50, for normal weight, overweight and obesity, respectively; $P$=0.0278). However, there was no significant difference of mean change from baseline in HAQ at Week 14 (-0.56 vs. -0.48 vs. -0.55), Week 30 (-0.56 vs. -0.54 vs. -0.56) and Week 54 (-0.59 vs. -0.56 vs. -0.57) when assessed by BMI categories. In addition, improvements from baseline in both physical and mental component summary (PCS and MCS) scores were similar at weeks 14, 30 and 54 regardless of BMI (Table 1).

Table 1. Mean (SD) change from baseline in PCS and MCS of SF-36

| | <25kg/m$^2$ (n=261) | ≥25–<30kg/m$^2$ (n=219) | ≥30kg/m$^2$ (n=126) | P-value |
|---|---|---|---|---|
| Physical component summary (PCS) | | | | |
| Week 14 | 6.82 (7.36) | 6.25 (6.72) | 6.34 (7.57) | 0.6751 |
| Week 30 | 7.35 (7.75) | 6.76 (8.06) | 6.56 (7.68) | 0.6260 |
| Week 54 | 7.31 (8.48) | 7.56 (8.17) | 6.89 (8.57) | 0.8205 |
| Mental component summary (MCS) | | | | |
| Week 14 | 6.72 (10.82) | 5.61 (9.95) | 6.70 (9.84) | 0.4818 |
| Week 30 | 6.92 (10.10) | 6.41 (10.80) | 7.50 (9.95) | 0.6774 |
| Week 54 | 7.33 (10.79) | 6.31 (11.34) | 7.84 (10.22) | 0.4917 |

**Conclusions:** The BMI does not affect the clinical response to infliximab in patients with RA. No significant association was found between BMI and clinical response by DAS28 (CRP), HAQ and SF-36. Therefore, the weight-based dosing of infliximab is appropriate in RA patients.

## AB0308 A PHASE I PHARMACOKINETIC STUDY COMPARING PRE-FILLED PEN AND PRE-FILLED SYRINGE OF SB5, AN ADALIMUMAB BIOSIMILAR IN HEALTHY SUBJECTS

D. Shin[1], Y. Lee[1], J.W. Kang[2], R. Ellis-Pegler[3]. *[1]Samsung Bioepis Co., Ltd., Suwon; [2]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of; [3]Auckland Clinical Studies, Ltd., Auckland, New Zealand*

**Background:** SB5 is developed as a biosimilar of the Adalimumab reference product (ADL). Equivalence in the pharmacokinetics (PK) between pre-filled syringe (PFS) of SB5 and PFS of ADL was demonstrated in a phase I study conducted in healthy subjects[1] and equivalent efficacy and comparable safety between PFS of SB5 and PFS of ADL up to week 24 were demonstrated in the phase III study conducted in patients with rheumatoid arthritis[2].

**Objectives:** To investigate and compare the PK, safety, and tolerability of the pre-filled pen (Pen) and PFS of SB5 in healthy subjects.

**Methods:** This study was a randomised, open-label, single-dose, 2-arm, parallel group study in healthy subjects. Subjects were randomised in a 1:1 manner to receive a single 40 mg dose of SB5-Pen or SB5-PFS by subcutaneous injection on Day 1 and then were observed for 57 days during which the PK, safety, and tolerability measurement were made. The serum concentration of adalimumab was measured using an enzyme-linked immunosorbent assay. The primary PK parameters were area under the concentration-time curve from time zero to infinity ($AUC_{inf}$), area under the concentration-time curve from time zero to the last quantifiable concentration ($AUC_{last}$), and maximum concentration ($C_{max}$). Equivalence for the primary PK parameters was to be concluded if the 90% confidence intervals (CIs) for the ratio of geometric least squares means (LSMeans) of the groups compared were completely contained within the pre-defined equivalence margin of 0.8 to 1.25 using an analysis of variance.

**Results:** Of 190 randomised subjects, 1 subject was excluded from the PK population in each arm (non-compliance with medication dosage in SB5-Pen and exclusion criteria met in SB5-PFS) and 188 subjects were analysed as PK population (n=94 in SB5-Pen and SB5-PFS each). Following single dose, the mean of $AUC_{inf}$, $AUC_{last}$, and $C_{max}$ were 2743.2 μg·h/mL, 2329.2 μg·h/mL, and 3.803 μg/mL for the SB5-Pen and 2503.3 μg·h/mL, 2182.2 μg·h/mL, and 3.673 μg/mL for the SB5-PFS. 90% CIs for the geometric LSMeans ratios of primary PK parameters for SB5-Pen and SB5-PFS were within the pre-defined equivalence margin of 0.8 to 1.25 (Table), confirming the bioequivalence between SB5-Pen and SB5-PFS. The proportion of subjects who experienced treatment-emergent adverse events (TEAEs) was comparable between the SB5-Pen and SB5-PFS (68.4% in SB5-Pen vs 60.6% in SB5-PFS). The most frequent TEAEs were upper respiratory tract infection (15.8% in SB5-Pen vs 19.1% in SB5-PFS). The majority of TEAEs were mild in severity. Only one subject in SB5-PFS experienced a moderate injection site reaction.

Table 1. Comparison of primary PK parameters between the treatments

| Comparison | PK parameters | Ratio | 90% CI |
|---|---|---|---|
| SB5-Pen vs SB5-PFS | $AUC_{inf}$ (μg·h/mL) | 1.104 | 0.9953; 1.2240 |
| | $AUC_{last}$ (μg·h/mL) | 1.070 | 0.9802; 1.1687 |
| | $C_{max}$ (μg/mL) | 1.021 | 0.9503; 1.0968 |

**Conclusions:** This study demonstrated PK equivalence between SB5-Pen and SB5-PFS in healthy subjects. Both SB5-Pen and SB5-PFS were generally well tolerated with similar safety profiles.

## AB0309 VALUE OF THE CLINICAL MEETINGS FOR AN ACCURATE BIOLOGICAL THERAPY ASSESSMENT IN RHEUMATIC DISEASES. THE EXPERIENCE OF THE BIOLOGICAL THERAPY ASSESSMENT COMMITTEE AT A TERTIARY HOSPITAL

E. Grau Garcia[1], J. Ivorra Cortés[1], L. González Puig[1], I. Chalmeta Verdejo[1], C. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz Sanjuan[1], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Fragio Gil[1], I. Martínez Cordellat[1], J. Valero Sanz[1], C. Alcañiz Escandell[1], G. Poveda Marín[1], C. Nájera Herranz[1], E. Monte Boquet[2], V. Fornes Ferrer[3], J. Román Ivorra[1]. *[1]Rheumatology Department; [2]Pharmacy Department, HUP la Fe; [3]Biostatistics Unit, IIS la Fe, Valencia, Spain*

**Background:** Given the increasing use of biological therapies in rheumatologic diseases and the importance of their secondary effects, it has been promoted clinical Meetings for an accurate Biological Therapy Assessment (BTAM). In the BTAM rheumatologists consider the need to initiating biological therapy, changes in biological therapeutic targets, sustained biological treatment or their suspension.

**Objectives:** To assess the BTAM effectiveness in patients with rheumatic diseases in a Rheumatology Department in a tertiary-level hospital.

**Methods:** Prospective study including all consultations to BTAM between 2013 and 2015 in the Rheumatology Department of La Fe Hospital. Consultations were classified as: "therapeutic target modification", "route of administration modification", "dose treatment modification", "new biological treatment", "treatment continuation" and "treatment suspension". In order to evaluate disease activity, we used DAS28, BASDAI, serum C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). Biostatistical analysis was performed using R software 3.2.3.

**Results:** We included 1683 BTAM consultations, corresponding to 517 patients with rheumatic diseases with a mean age of 39.94±14.88 and 13.37±8.75 years of disease progression. 51.6% of patients were rheumatoid arthritis, 27.9% spondyloarthritis, 15.3% psoriatic arthritis and 5.2% other diagnosis. 116 patients received a prior biological treatment. Disease activity evaluation of the 1683 BTAM consultations for the main categories is shown in the table.

| | Therapeutic target modification n (%) | Dose treatment modification n (%) | New biological treatment n (%) | Treatment continuation n (%) |
|---|---|---|---|---|
| TOTAL | 88 (5.2%) | 79 (4.7%) | 52 (3.1%) | 1405 (83.5%) |
| DAS28 | 4.32±1.68 | 2.74±1.39 | 4.78±0.97 | 2.8±1.23 |
| BASDAI | 6.3±1.71 | 3.03±1.89 | 6.74±1.28 | 4.29±2.36 |
| ESR | 26.12±28.13 | 17.47±18.43 | 17.26±11.99 | 13.79±12.54 |
| CRP | 10.21±15.23 | 4.15±4.41 | 8.22±9.04 | 3.88±6.41 |

Biostatistic analysis shows significant differences in Das28, BASDAI, CRP and ESR values between BTAM consultations for initiating new treatment or modify therapeutic target, and treatment continuation consultations ($P<0.0001$). There was also a significant association between the number of biological targets administered and the increase of DAS28 ($P<0.0001$) and BASDAI ($P=0.014$).

**Conclusions:** We observed a increased disease activity in cases where a new biological treatment or different therapeutic target is administrated, and values of disease activity in treatment continuation are compatible with low activity. In the 5.2% of consultations it has prescribed modification treatment, in order to avoid treatment ineffectiveness. Moreover, some continuation treatment consultations showed low activity scores, leading to a therapeutic optimization. BTAM consultations are useful for optimal management of these patients with biological therapy

## AB0310 PROSPECTIVE STUDY OF 78 PATIENTS TREATED WITH INFLIXIMAB BIOSIMILAR REMSIMA®

E. Rubio[1], A. Ruiz[1], J. López[2], J.M. López-Chozas[3], L. Bermudez[4], C. Aguilera[1], J. Povedano[1]. *[1]Rheumatology; [2]Primary Care Medicine; [3]Internal Medicine, Hospital Universitario Virgen del Rocio Sevilla, Sevilla; [4]Kern Pharma, Barcelona, Spain*

**Background:** In 2015 it began to be used in many EU countries the first biosimilar antiTNF (Infliximab) approved by the EMA. The Korean company owns the molecule under the trademark Remsima® was widely used for replacing existing treatments with infliximab molecule marketed since 1999 as Remicade in the approved indications in sheet for this purpose, RA, AS and PsA.

**Objectives:** Control the security and survival of the drug in patients Remsima® in which replaced the molecule Remicade infliximab. Settled visits every 3 months to monitor the occurrence of adverse events with possible association to the drug. Patients were followed in routine clinical practice for 8 different doctors.

**Methods:** 78 patients began treatment with Remsima® since March 2015. Of these, 25 were suffering from Rheumatoid Arthritis, Psoriatic Arthritis 8, SpA 41 and severe uveitis 2. 53 of these patients had already been treated with Remicade and 25 were "naive" to IFX, having been previously treated with other biological therapy or were naive to this.

**Results:** 37 patients, less than half have associated a DMARD in the 9th month of follow-up (70'2% MTX). 11 patients with Remsima not reached 37 weeks of follow-up and were removed (5 of these patients had replaced Remicade). None of them was removed for serious adverse effect. Overall 86% survival at 9 months. No patient dropped the sheet approved for disease Remsima 3mg/kg body weight or Remsima 5mg/kg dose before 6 months of treatment.

The reasons for medication discontinuation were in the 5 cases of replacement Remicade by Remsima: 4 loss efficacy and cutaneous leishmaniasis.

For patients naive to Remicade, 1 case of possible photosensitivity, 1 case of bronchospasm during infusion, one case of urticaria, 1 case of hip replacement surgery, one transfer to another country of residence and a loss of effectiveness.

The reasons for medication discontinuation were in the 5 cases of replacement Remicade by Remsima: 4 loss efficacy and cutaneous leishmaniasis.For patients naive to Remicade, 1 case of possible photosensitivity, 1 case of bronchospasm during infusion, one case of urticaria, 1 case of hip replacement surgery, one transfer to another country of residence and a loss of effectiveness. 4 patients showed in repeated infusions dizziness, headache or neck stiffness within 48 hours of infusion Remsima. However they asked to continue with medication.

Overall 86% survival at 9 months.Only 23% of patients needed glucocorticoid use at 9 months. 22% of patients required to reduce the infusion period IFX-Remsima 7 weeks or less. Finally in 4 patients an optimization of treatment extending to more than 8 weeks was achieved infusions. It is worth drawing attention to the small variation of CRP level ($\Delta$ <5mg/dl) at 9 months of initiation of Remsima treatment.

**Conclusions:** The results of safety and survival of biosimilar infliximab Remsima® are similar to those shown in their pivotal trials PLANETRAS and PLANETAS, both in patients with prior use of infliximab as another patient who has not used this. Although the follow-up period is too short, averaging 8.3 months and a standard deviation of 2, these data support an increasingly widespread use of this biosimilar in any patient profile.

## AB0311 CLINICAL RESPONSES AND SYNOVIAL VASCULARITY IN OBESE RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ADALIMUMAB AND METHOTREXATE

G.S. Kaeley[1], V.K. Ranganath[2], D.K. MacCarter[3], A.L. Pangan[4], X. Wang[4], J. Kalabic[5]. *[1]Univ of Florida, Jacksonville, FL; [2]Univ of California, Los Angeles, CA; [3]North Valley Hospital, Whitefish, MT; [4]AbbVie, N Chicago, IL, United States; [5]AbbVie, Ludwigshafen, Germany*

**Background:** Obese rheumatoid arthritis (RA) patients (pts) may have higher levels of inflammatory mediators, greater joint swelling and tenderness, and suboptimal response to therapy.

**Objectives:** We assessed disease activity and treatment response in obese RA pts, using ultrasonography (US) and clinical measures.

**Methods:** This *post hoc* analysis used observed data from the MUSICA trial[1] which evaluated the efficacy of high [20 mg/week (wk)] or low (7.5 mg/wk) doses of methotrexate (MTX) in combination with adalimumab (ADA) for 24 weeks (wks)

in RA pts with previous inadequate response to MTX who initiated ADA. Pts were grouped according to body mass index (BMI) at baseline (BL): normal BMI <25; overweight BMI ≥25-<30; obese BMI ≥30. Synovial vascularity and hypertrophy were measured by Power Doppler US and Greyscale respectively, bilaterally, at metacarpophalangeal (MCP) joints 2, 3, 5, metatarsophalangeal joint 5 (MTP5) and wrists. Swollen joint count (SJC) of 66 joints, tender joint count (TJC) of 68 joints, 28-joint count Disease Activity Score using C-reactive protein (DAS28-CRP), and numbers of pts reaching American College of Rheumatology (ACR) criteria, Clinical Disease Activity Index [CDAI] low disease activity (LDA,<10), DAS28-CRP low disease activity (LDA; DAS<3.2), were assessed at wks 12 and 24.

**Results:** Out of 308 pts at BL, 69 pts (22.4%) had BMI <25,102 pts (33.1%) had BMI ≥25-<30 and 137 pts (44.5%) had BMI ≥30. Disease characteristics and ultrasound disease assessments were similar for the 3 BMI subgroups at BL. At wks 12 and 24, compared with pts in the normal and overweight categories, obese pts tended to have numerically smaller mean changes from BL in SJC66, TJC68, DAS28-CRP, synovial hypertrophy and synovial vascularity (table). Compared to pts in the normal and overweight categories, significantly fewer obese pts reached ACR20/50 at wks 12 and 24. Significantly fewer obese pts reached CDAI LDA and DAS28-CRP LDA at wk 12; this difference was driven by those obese pts receiving low dosage of concomitant MTX (7.5 mg/wk), although by wk 24, the differences were no longer significant. There was low to no correlation between synovial vascularity/hypertrophy and clinical findings of swelling and tenderness. The proportion of pts with synovial vascularity=0 in the 3 BMI subgroups at wks 12 and 24 was not statistically different.

*P* values for comparison between BMI subgroups. *p <.05, ** <.001. Chi-squared test was used for categorical variables, ANCOVA adjusting for baseline, treatment and BMI group was used for continuous variables.

**Conclusions:** Among obese RA pts initiating ADA, those on low dosage of concomitant MTX had poorer responses than pts in the normal and overweight categories, as measured clinically and by ultrasound imaging, although this effect was partly overcome by wk 24. Obese RA pts may have an improved clinical benefit if ADA is initiated with high (20 mg/week), rather than low dosage of concomitant MTX.

## AB0312 PREDICTORS OF DISEASE COURSE AFTER THE DISCONTINUATION OF BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS PATIENTS WITH LONG-TERM REMISSION

G. Kádár[1], Á. Czibula[2], B. Szalay[3], K. Nagy[4], A. Pusztai[5], A. Balog[1], É. Monostori[2], B. Vásárhelyi[6], Z. Szekanecz[5], L. Kovács[1]. *[1]Department of Rheumatology, University of Szeged; [2]Biological Research Centre, Institute of Genetics, Szeged; [3]Department of Laboratory Medicine, Semmelweis University, Budapest; [4]Markhot Ferenc Hospital, Eger; [5]Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen; [6]Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary*

**Background:** The increasing number of patients treated with biologic therapies, the extending duration and costs of these treatments necessitate the development of strategies to the tapering or discontinuation of biologics in rheumatoid arthritis (RA) patients with long-standing remission on these agents. As flares occur frequently in patients in whom biologics are stopped, the identification of predictive markers for the preservation of long-standing remission after discontinuation is an important need. Several microRNA-s (miRNA) and SuPar (soluble urokinase plasminogen activator receptor) have been found to correlate with disease activity, and to be sensitive biomarkers of treatment response.

**Objectives:** The authors' aim was to prospectively follow the disease course after the permanent cessation of biologics, and to identify clinical and biochemical predictors of sustained biologic-free remission.

**Methods:** In this prospective, multicentre, controlled trial, eligible RA patients were treated with anti-TNF or IL6R-blocker, had a minimum of one-year remission (DAS-28<2.6), and no corticosteroid therapy. After discontinuation of the biologics, DAS28, HAQ, ESR and CRP were recorded at baseline, month 1, 3 and every 3 months thereafter. SuPar and soluble miRNA146a, miRNA16, miRNA155, miRNA223 and miRNA346 levels were measured by ELISA or QRT-PCR, respectively at baseline, month 1, 3, 6 and at relapse, if occurred. In the control group (n=5), patients had sustained remission on biologics, and had similar demographic and serological parameters, but the biologic therapy was not stopped.

**Results:** At present 23 patients with RA have been enrolled (average age: 59,95/35–79/ years).The mean duration of biologic therapy was 54,04 (25–84) months, and was started an average of 62,3 months (1–240 months) after the diagnosis. After the discontinuation, 14 patients are in biologic-free remission for an average of 5,21 (1–16 months). Relapse occurred in 9 cases an average of 5,20 (2–12) months after the discontinuation. miRNA146a levels at stop were higher in relapsers than in those with sustained remission (relative expression to cel miR39: -3,08 vs -7,87, p=0.009) (n=8 stopped patients, n=1 control). Circulating miRNA223, miRNA16, miRNA155 and miRNA346 levels were comparable in the two drug-cessation groups. SuPar levels were not different in the 12 patients in remission and 7 relapsers, in whom the measurements have been performed so far.

**Conclusions:** In RA patients with long-term remission on anti-TNF or IL6R-blocker, elevated level of miRNA146a may indicate a higher risk of relapse after stopping biologics. Further follow-up and the involvement of more patients are currently underway, and this may identify further predictive markers.

## AB0313 SHORT-TERM EFFECTS OF TNF INHIBITORS ON BONE TURNOVER MARKERS AND BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

G. Orsolini, G. Adami, O. Viapiana, L. Idolazzi, A. Fassio, M. Vitiello, D. Gatti, M. Rossini. *Rheumatology Section, Department Medicine, University of Verona, Verona, Italy*

**Background:** TNFα inhibitors (TNFαI) exert positive effects on disease activity in rheumatoid arthritis (RA). Bone involvement is a major determinant of functional impairment in this disease.

**Objectives:** Here we investigated the short-term effects of TNFαI therapy on bone metabolism and density.

**Methods:** We studied 54 patients with RA starting a TNFI biologic drug, in whom any factor known to interfere with bone metabolism was excluded or rigorously accounted for. We measured at baseline and after 6 month therapy bone turnover markers (BTM): N-propeptide of type I collagen (P1NP), and bone alkaline phosphates (bAP) for bone formation and serum C-terminal telopeptide of type I collagen (CTX) for bone resorption. We also evaluated bone mineral density (BMD) at hip and lumbar by dual energy X ray absorptiometry (DEXA).

| | Absolute changes | P value | % changes | P value |
|---|---|---|---|---|
| P1NP (ng (ml) | 8.5±18 | 0.001 | 30.6±64.3 | 0.001 |
| bAP (μg/l) | 1±2.38 | 0.003 | 8.6±20.7 | 0.003 |
| CTX (ng/ml) | 0.047±0.188 | 0.07 | 44.9±130.6 | 0.01 |
| BMD Lumbar spine (mg/cm$^2$) | 4.1±50.7 | >0.1 | 0.2±5.2 | >0.1 |
| BMD Femoral neck (mg/cm$^2$) | −14.1±34.6 | 0.004 | −1.8±4.6 | 0.005 |

**Results:** All bone markers rose significantly and these changes were not dependent on steroids dosage; a significant decrease in femoral neck BMD was also observed (see Table).
**Conclusions:** These results indicate that TNFαI therapy in RA over 6 months is associated with an early increase in bone turnover and a decline in hip BMD.

## AB0314 AWARENESS AND ACCEPTANCE OF BIOSIMILARS BY RHEUMATOLOGISTS IN ELEVEN EU COUNTRIES

H. Kellner[1], E. Domènech[2], P.L. Lakatos[3], J. Marsal[4], C. Agboton[5], M. Cassese[6], N. Georgitseas[7], S. Anwar[7], A. Venugopal[6], P. Audhya[5].
*[1]Schwerpunktpraxis für Rheumatologie und Gastroenterologie Munich, Munich, Germany; [2]Trias i Pujol University, Barcelona, Spain; [3]Semmelweis University, Budapest, Hungary; [4]Lund University, Lund, Sweden; [5]Hospira, a Pfizer Company, Maidenhead, United Kingdom; [6]Life Sciences, Navigant, New York, United States; [7]Life Sciences, Navigant, London, United Kingdom*

**Background:** The first infliximab biosimilar was approved in Europe in Sept. 2013 for all indications authorised for originator infliximab, including those in rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Confusion exists around differences between biologics and biosimilars, the definition of a biosimilar and the process by which they are manufactured. In addition, there are varying levels of comfort in the types of patients to whom biosimilars could be prescribed.
**Objectives:** We aimed to understand rheumatologists' current perspectives and knowledge on biosimilars, including regulatory aspects and manufacturing principles, as well as comfort with prescribing.
**Methods:** 222 rheumatologists chosen randomly across 11 countries (Finland, France, Germany, Hungary, Ireland, Italy, Norway, Portugal, Spain, Sweden, and UK) participated in a web-based survey from Jun. to Aug. 2015. Key eligibility criteria: being in a practice with at least 30% of patients with Rheumatoid Arthritis or 5% with Ankylosing Spondylitis; at least 15% of these treated with a biologic; physicians in the survey prescribed infliximab (originator or biosimilar) to at least one patient and have access to biosimilar infliximab (able to prescribe biosimilar infliximab). Most (72%) had prescribed biosimilar infliximab to at least one patient.
**Results:** 97% of rheumatologists indicated being familiar or very familiar with biosimilars. Despite a high level of familiarity, only 48% correctly identified the EMA definition of a biosimilar; the remainder incorrectly defined biosimilars as the equivalent of generics for biologics (16%) or as similar biologics having the same mechanism of action as the originator (36%). 65% of rheumatologists cited either limited or no knowledge of biologic manufacturing processes.
Most rheumatologists preferred to prescribe biosimilars to naïve patients or those who stopped responding to their current biologic. On a scale of 1 to 10 (10 = extremely comfortable), rheumatologists rated their level of comfort in prescribing biosimilars as 6.5 (significantly lower than gastroenterologists answering an identical question in a parallel survey; mean = 6.9, *p=0.002*). There was a general correlation between the length of exposure to biosimilars and willingness to prescribe, although exceptions were noted (e.g., Portugal, Spain). Knowledge regarding biosimilar manufacturing standards and comfort in prescribing were not correlated.
**Conclusions:** Knowledge and awareness of biosimilars is growing among EU rheumatologists and there are high levels of comfort in prescribing biosimilars; however, confusion still exists with regard to definitions, regulations and manufacturing standards.

## AB0315 REDUCTION OF CONCOMITANT ORAL METHOTREXATE OR CORTICOSTEROIDS IN COMBINATION TREATMENT WITH ADALIMUMAB DOES NOT AFFECT EFFECTIVENESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Keystone[1], F. Breedveld[2], A. Kavanaugh[3], Y. Zhang[4], I. Sainsbury[4], J. Kalabic[5]. *[1]Univ. of Toronto, Toronto, Canada; [2]Leiden Univ. Medical Center, Leiden, Netherlands; [3]Univ. of California San Diego, La Jolla, CA; [4]AbbVie, N. Chicago, IL, United States; [5]AbbVie, Ludwigshafen, Germany*

**Background:** In rheumatoid arthritis (RA) patients (pts) receiving corticosteroids (CS) or methotrexate (MTX) with an anti-TNF, such as adalimumab (ADA), the concomitant CS or MTX dose may be reduced if pts respond well or have side-effects.
**Objectives:** To assess treatment effectiveness in pts whose MTX or CS oral dose was reduced over 10 years (y) of open label (OL) ADA treatment.
**Methods:** This was observed data from OL extensions (OLE) of the PREMIER and DE019 trials.[1,2] In PREMIER, MTX-naïve, early RA pts received ADA/MTX/ADA+MTX for 2y, and optional OL ADA for upto 8y. In DE019, biologic-naïve, established RA pts received 20 mg ADA+MTX/ 40 mg ADA+MTX/PBO+MTX for 1y and optional OL ADA+MTX for upto 9y. In both OLEs, MTX could be added/adjusted at the investigator's discretion, and oral CS dose could be tapered in pts who responded. Effectiveness at final visit (FV) was assessed by the numbers of pts achieving TJC68 =0, SJC66 =0, improvement from baseline in HAQ-DI $\geq$0.5 (HAQ-DI 0.5), ACR20/50/70 criteria and 28-joint disease activity score based on C-reactive protein (DAS28-CRP)$<$2.6. Additionally, in PREMIER, modified EULAR remission (REM) criteria [DAS28-CRP $<$2.6, TJC68 $\leq$1, SJC66 $\leq$1], "Good EULAR response" [DAS28-CRP $<$3.2 with a change from baseline $\leq$-1.2] were used.
**Results:** In *PREMIER*, by the pt's FV, out of 375 pts who had any oral CS, 220 (58.7%) were on ongoing CS; 155 (41.3%) had stopped. Among the 375 pts, 32% had a stable CS dose and 26.1% had a CS dose reduction. Dose reduction did not affect the proportion of pts reaching ACR criteria, HAQ-DI 0.5, and DAS28-CRP $<$2.6 by FV (table). Out of 497 pts in the OLE, 261 (52.5%) used concomitant MTX in the OLE, 236 pts did not. With/without MTX, the number of pts with DAS28-CRP$<$2.6 increased from 2 to 10y, and the proportion of pts with SJC or TJC=0, good EULAR response, or modified EULAR REM criteria, and the HAQ-DI scores were comparable in the +/– MTX groups. In *DE019*, by the pt's FV, out of 352 pts who received any oral CS, 207 (58.8%) were on ongoing CS and 145 (41.2%) had stopped CS. Among the 352 pts, 141 (40%) had a stable CS dose and 82 pts (23.3%) had a dose reduction. Out of 550 pts on MTX during the study, 497 (90.4%) were receiving MTX, and 53 (9.6%) had stopped by FV; 345/550 pts (62.7%) had stable MTX and 158 (28.7%) had a reduction. Reduction of CS or MTX did not affect the proportion of pts who reached the ACR criteria, HAQ-DI 0.5 and DAS28-CRP $<$2.6 by FV.

Table: Impact of dose changes in concomitant oral corticosteroids or MTX on effectiveness by final visit, n/N (%)

| | | |
|---|---|---|
| **PREMIER** | | |
| | **Stable CS dose** | **Decreased CS dose** |
| ACR20 | 66/117 (56.4) | 71/98 (72.4) |
| ACR50 | 44/117 (37.6) | 55/98 (56.1) |
| ACR70 | 26/117 (22.2) | 42/98 (42.9) |
| HAQ-DI 0.5 | 48/118 (40.7) | 48/98 (49.0) |
| DAS28-CRP <2.6 | 47/119 (39.5) | 57/98 (58.2) |
| | **With MTX use** | **Without MTX use** |
| TJC68=0 | 97/261 (37.2) | 115/234 (49.1) |
| SJC66=0 | 114/261 (43.7) | 129/234 (55.1) |
| Modified EULAR REM criteria | 87/261 (33.3) | 113/239 (48.5) |
| "Good" EULAR-CRP | 169/259 (65.3) | 177/232 (76.3) |
| Mean HAQ-DI at final visit | 0.7 (0.7) | 0.6 (0.7) |
| **DE019** | | |
| | **Stable CS dose** | **Decreased CS dose** |
| ACR20 | 164/323 (50.8) | 98/153 (64.1) |
| ACR50 | 109/323 (33.7) | 75/153 (49.0) |
| ACR70 | 63/323 (19.5) | 57/153 (37.3) |
| HAQ-DI 0.5 | 137/342 (40.1) | 75/158 (39.5) |
| DAS28-CRP <2.6 | 100/323 (31.0) | 188/524 (35.9) |
| | **Stable MTX dose** | **Decreased MTX dose** |
| ACR20 | 57/128 (44.5) | 45/78 (57.7) |
| ACR50 | 31/128 (24.2) | 38/78 (48.7) |
| ACR70 | 18/128 (14.1) | 26/78 (33.3) |
| HAQ-DI 0.5 | 54/139 (38.8) | 37/82 (45.1) |
| DAS28-CRP <2.6 | 29/128 (22.7) | 35/80 (43.8) |

MTX, methotrexate; CS, corticosteroid; ACR, American College of Rheumatology; HAQ-DI, health assessment questionnaire- disability index; DAS28-CRP, 28-joint count disease activity score based on c-reactive protein; TJC68, tender joint count at 68 joints; SJC, swollen joint count at 66 joints.

**Conclusions:** Overall, effectiveness associated with continuous ADA treatment was not sacrificed in pts in whom concomitant oral CS or/and MTX doses were reduced or discontinued, although many of these pts were likely responding well at the time of taper.

## AB0316 AN EXAMINATION OF DOSE ESCALATION AMONG INFLIXIMAB USERS IN THE US CORRONA RA REGISTRY

J.R. Curtis[1], Y. Shan[2], K.C. Saunders[2], D. Parenti[3], S. Kafka[3], J.M. Kremer[4]. *[1]University of Alabama, Birmingham; [2]Corrona, LLC, Southborough; [3]Janssen Scientific Affairs, LLC, Horsham; [4]Albany Medical College and Center for Rheumatology, Albany, United States*

**Background:** Limited data are available about infliximab (IFX) dose escalation.
**Objectives:** This analysis examines the frequency of dose escalation among IFX patients using data from the US CORRONA RA registry and describes the characteristics of patients who dose escalate vs those who do not.
**Methods:** RA patients initiating IFX at a dose of $\leq$5 mg/kg on or after 6/1/2009 with at least 1 follow-up visit with dose information were eligible for analysis. Subgroup analysis was performed among patients with follow-up at 1yr to compare characteristics between those who dose escalated vs those who did not. Dose escalation was defined as an increase of $>$1mg/kg in dose and/or a decrease in the frequency of dosing by at least 1 wk (e.g. q 8 wks to q7 wks). Censoring occurred if patients switched to another biologic or left the registry. Descriptive statistics were used to compare baseline characteristics of infliximab patients stratified by number of biologics, and also comparing those who dose escalated vs those who did not within the 1st yr after initiating therapy.
**Results:** A total of 716 patients initiated IFX after June 2009. Common characteristics included mean age (61yrs), women (78%), mean weight (83 kg), RF+ (70%) and CCP+ (67%), baseline CDAI (22.5), and insurance status (Medicare 46%, Medicaid 6%). Differences between those who initiated IFX as their 1st, 2nd, or 3rd biologic included RA duration (7.0, 9.6, 11.0 yrs, respectively, $p<0.001$), college education (50, 61, 66%, respectively, p=0.002), number of prior DMARDs (1.6, 1.8, 2.0; $p<0.001$), proportion receiving monotherapy (12, 15, 26%), and prednisone use (31, 29, 35%).
Over 3 yrs follow-up, the proportions of patients escalating IFX significantly differed, ranging from a low of 21% at 1 yr for patients using IFX as 1st line to a high of 81% at 3yrs for patients using it as 3rd line (Table, p=0.0024 for between-group differences). In patients with follow-up data at 12mo (n=608), there were some baseline characteristics associated with dose escalating vs not in the 1st yr of therapy including shorter RA duration (p=0.03), greater number of prior biologics (p=0.04), monotherapy (p=0.03), greater prednisone use (p=0.01), and higher CDAI (p=0.04) and related disease activity measures.

Table 1. proportion of patients increasing infliximab dose over time according to its use as a first, second, or third line biologic agent

| Follow-up time | First line (N=373) | Second line (N=210) | Third line (N=133) |
|---|---|---|---|
| 12 months, % | 21 | 31 | 30 |
| 24 months, % | 35 | 46 | 58 |
| 36 months, % | 49 | 62 | 81 |

**Conclusions:** Dose escalation of IFX is relatively frequent over time. Patients with more severe RA undergo dose escalation more commonly than those with less severe disease. Understanding long term benefits and persistence and related factors following dose escalation may help optimize dose escalation as a treatment strategy compared to switching.

## AB0317 DRUG SURVIVAL OF BIOLOGIC AGENTS IN RHEUMATOID ARTHRITIS USING 10 YEARS OF DATA FROM THE NATIONAL HEALTH INSURANCE IN KOREA: A POPULATION-BASED STUDY AND COMPARISON WITH A SINGLE-INSTITUTION COHORT

J.S. Lee[1], J.W. Park[1], H.Y. Lee[2], E.Y. Lee[1], J.K. Park[1], E.B. Lee[1], Y.W. Song[1], E.Y. Lee[1]. *[1]Internal Medicine, Division of Rheumatology, Seoul National University Hospital, Seoul; [2]Center for Preventive Medicine and Public Health, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea, Republic Of*

**Background:** Since 2004, Korean national health insurance began to cover the cost of biologic agents in rheumatoid arthritis (RA) patients experiencing treatment failure by conventional disease modifying antirheumatic agents. However, real-world issues such as selecting or switching among biologic agents in clinical practice became more complicated as types of the agents increased.
**Objectives:** To evaluate 1) first choice among biologic agents, 2) drug retention rate and duration and 3) switching rate and duration before switching of each biologic agent in RA.
**Methods:** We used prospective cohort data by the National Health Insurance Service (NHIS) in Korea, which consisted of more than one million subjects representing age, sex and income status of whole Korean population followed from 2004 to 2013. All RA patients with any experience of biologic agents were checked by the code of each drug and KCD9 code of diagnosis including all types of RA. To supplement the results of the population based study, we also compared and validated with the independent cohort of biologic agent users in Seoul national university hospital (SNUH).
**Results:** One hundred and seventy three patients were found to experience any of TNFa inhibitors from Jan. 2004 to Dec. 2013. Etanercept was the most frequent choice as first TNFa inhibitor (43.4%), followed by adalimumab (35.3%), infliximab (20.2%), golimumab (0.6%) and abatacept (0.6%). Among TNFa inhibitors, retention rates of etanercept (73.1%, 62.7%) at month 12 and 24 were significantly higher (p=0.039, both) than adalimumab (57.7%, 44.2%) and infliximab (45.5%, 36.4%). In SNUH cohort, etanercept (79.8%, 67.0%) also had better retention rate than adalimumab (51.3%, 48.7%) and infliximab (58.6%, 34.5%) at month 12 and 24 respectively. Mean duration of retention was almost twice longer in etanercept (3.42 years) than adalimumab (1.83 years, p=0.004) and infliximab (1.71 years, p=0.011). Similarly, etanercept (3.24 years) prescribed longer than adalimumab (1.98 years) and infliximab (1.63 years) with statistical significance in SNUH cohort. Etanercept also had lower switching rate (20.9%) than adalimumab (32.1%) and infliximab (38.5%, p=0.040) and the tendency were similar in SNUH cohort. Preferred biologic agents after switching were adalimumab (27.4%) and rituximab (24.2%). Etanercept users (1.35 years) had longer duration of use before switching than infliximab (0.60 years, p=0.050) but no significant difference was shown comparing with adalimumab (0.73years, p=0.483).
**Conclusions:** As golimumab, abatacept, tocilizumab were available relatively later than existing TNFa inhibitors and rituximab, more follow up period would be required to evaluate their value in treating RA. This research can be a pilot study before analyzing nationwide population cohort encompassing whole population of Korea. Conclusively, etanercept has been prescribed longer in general and the rate of retention till 2 years was also better then adalimumab and infliximab for 10 years after national insurance coverage.

## AB0318 DOES CONCENTRATION OF ANTIBODIES TO ETANERCEPT AND ADALIMUMAB CORRELATES WITH PARAMETERS OF DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS?

J. Nedovic, B. Stamenkovic, S. Stojanovic, V. Zivkovic. *Institute for rheumatology Niska Banja, Nis, Serbia*

**Background:** Introduction of tumor necrosis factor alpha (TNF) inhibitors has revolutionized therapy of rheumatoid arthritis (RA). Immunogenicity with consequent formation of antidrug antibodies (ADAb) is most responsible factor for secondary resistance. Adalimumab (ADA) as a fully humanized monoclonal antibody and Etanercept (ETN) as a fusion protein, are considered less immunogenic compared to other TNF inhibitors. In spite of this, various studies detected ADAb to ETN from 0% to 18% and for ADA from 0.04% to 87%.
**Objectives:** Our objectives were to determine the prevalence of ADAb to ETN and ADA in patients with RA and to evaluate correlations of ADAb with concentration of ETN and ADA and with parameters of disease activity.
**Methods:** Consecutive patients with established RA treated with ETN (25 patients) and ADA (20 patients) were enrolled in our cross-sectional study. Patients treated with ETN were older compared to patients treated with ADA (53.09±13.20 versus 47.06±12.54 years), had longer duration of disease (13.78±6.88 versus 9.11±6.91 years) and had longer duration of treatment (58.76±22.53 versus 20.3±14.11 years). Drug levels and concentration of ADAb were measured with commercially available ELISA kits from blood samples taken before next injection (trough values), and these levels were correlated with parameters of disease activity and compared between two groups.
**Results:** Both drugs had comparable efficacy according to DAS 28 SE (3.32±0.93 for ETN and 3.86±1.43 for ADA). Mean trough concentration of both drugs was satisfactory with values sevenfold greater than referent values: 240.23±502.64 ng/mL for ETN (referent values 0.0–35 ng/mL) and fourfold greater for ADA: 94.86±25.56 ng/mL (referent values 0.0–24.0 ng/mL). In spite of this, a more than a double concentration of ADAb was recorded in both groups: 326.96±292.51 IU/mL for ETN (referent values 0.0–142.06 IU/mL) and 23.21±56.87 IU/mL for ADA (referent values 0.0–10.00 IU/mL). Eight from 25 patients (32.4%) in ETN group and 8/20 (40%) in ADA group had elevated concentration of ADAb and this difference was not significant. Pearson correlation coefficient (r) showed weak negative correlation (r=-0.338) between concentration of ADAb to ETN and concentration of ETN and no correlation between ADAb to ADA and concentration of ADA. There were positive correlation of ADAb to ETN and Erythrocyte Sedimentation Rate (r=+0.482) and CRP (r=+0.411) but not with DAS 28 SE nor with the levels of RF and CCP Ab. The concentration of ADAb to ADA shoved only weak correlation with CCP Ab (r=+0.366) but not with any other parameter of disease activity.

**Conclusions:** Our data suggest that formation of ADAb after prolonged time of therapy is common even in the patients treated with TNF inhibitors considered as less immunogenic. But, a weak or even absent correlation with disease activity also suggest that not all of these ADAb are neutralizing with clinical consequences. These results also suggest that methodological aspects are of even more significance. There is a need for assay standardization and validation and consensus on the interpretation of serum drug and ADAb cut-off values with evidence based treatment algorithm useful for clinical practice.

## AB0319 ANALYSIS OF LARGE JOINT DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED BY GOLIMUMAB

K. Kanbe, K. Oh, J. Chiba. *Department of Orthopaedic Surgery, Tokyo Women's Medical University, Medical Center East, Tokyo, Japan*

**Background:** There is no investigation of large joint destruction treated with golimumab in rheumatoid arthritis. Especially what clinical factors related to the inhibition of large joint destruction was not reported so far.
**Objectives:** In order to investigate the inhibition of large joint destruction for rherumatoid arthritis in treated with golimumab, 450 large joints were assessed at baseline and 52 weeks after treatment with golimumab.
**Methods:** 450 large joints from 45 patients including elbow, shoulder, hip, knee and ankle by using ARASHI (Assessment of rheumatoid arthritis by scoring of large joint destruction and healing in radiographic imaging) scoring system (1) at baseline and 52 weeks after treatment with golimumab. Baseline data were mean age of 61.29±14.71 years, 91.1% of female, mean disease duration of 12.6±12.48 years, stage/class of I:7,II:10,III:9:,IV:19/2:18,3:26,4:1, mean MTX of 6.44±1.78 mg/weeks, mean PSL of 1.078±1.871 mg/day, 44.4% of 100 mg for golimumab, mean DAS28 (CRP) of 4.431±1.044. Rapid radiographic progression (RRP) and rapid radiographic improvement (RRI) were calculated and analysis of correlation for large joint destruction and clinical factors between baseline and 52 weeks.
**Results:** RRP was 21.9% in 450 large joints treated with golimumab. Therefore 78.1% were inhibited large joint destruction treated with goimumab in RA. RRI was 35.7% showing large joint improvement were obtained by golimumab. In clinical factors, baseline CRP affects ARASHI change score of knee at 52 weeks after treatment of golimumab.
**Conclusions:** Inhibition of large joint destruction were obtained in 78.1% for the patients treated with golimumab in RA.

## AB0320 FACTORS ASSOCIATED WITH ACTIVE AND LATENT TUBERCULOSIS, TUBERCULIN SKIN TEST CONVERSIONS DURING ANTI-TUMOUR NECROSIS FACTOR THERAPY IN PATIENTS WITH RHEUMATIC DISEASES IN A MEXICAN COHORT

L.D. Fajardo Hermosillo on behalf of Fajardo-Hermosillo Luis Daniel. *Rheumatology, IMSS, Guadalajara, Mexico*

**Background:** The Anti Tumour Necrosis Factor (aTNF) therapy in Rheumatics Diseases (RD) had changed the prognosis of theses conditions in the last decade. Unfortunately, aTNF therapy is associated a high-risk rate of infections, especially active tuberculosis (TB) [1]. The use of tuberculin skin test (TST) to detect and treat latent tuberculosis (LTBI) before to initiate aTNF therapy had reduced the risk of TB by 75 to 95% [2]. However, multiple factors as prevalence of TB by country, malnutrition, anergy, immunosuppressors, advanced age, BCG vaccination between others compromise the sensitivity and specificity (falsely negative and positive results) of the test to distinguish between remote and recent disease. These factors are also associated with frequency and progression of LTBI to TB and differ between populations [3]. Few studies have been performed in Mexicans with RD under aTNF therapy [4].
**Objectives:** To determine the frequency of TB and LTBI, TST conversions and associated factors during aTNF therapy in patients with RD from a Mexican cohort.
**Methods:** 151 patients ($\geq$14 years) from a Mexican cohort from 2011 to 2016 were examined. Ankylosing Spondylitis (AS), Juvenile idiopathic arthritis (JIA), Psoriatic Arthritis (PsA) and Rheumatoid Arthritis (RA) cases fulfilled Amor, ILAR, CASPAR and ACR/EULAR 2010 criteria respectively. TB and LTBI (TST induration $\geq$5 mm recorded to 72 hours) diagnosis occurred before to start aTNF therapy. Conversions happened in the second TST. Demographic factors, comorbidities and pharmacologic treatments were examined for patients without and with TB, LTBI and TST conversions under aTNF therapy. Variables were examined by univariable and multivariable analyses.
**Results:** Of 151 patients, 71 had AS, 68 had RA, 9 had JIA and 3 had PsA; of them 53% were women. The mean age [standard deviation (SD)] was 47.1 (12.5) years. The mean of time at onset of RD [standard deviation (SD)] was 12.3 (8.7) years. A total of 5 patients had TB for a crude prevalence of 3.3% and three of them used infliximab. TB was more common in patients with first TST negative and after TST conversion (OR 6.97, 95% CI 1.36–35.5, p=0.019). LTBI was detected in 57 (37.7%) patients and was more associated with lower wage (OR 0.2, 95% CI 0.52–0.98, p=0.047), to be healthcare workers (OR 57.1, 95% CI 2.67–1219.50, p=0.010), and smoking (OR 30.1, 95% CI 5.40–167.24, p$\leq$0.005). TST Conversions were presented in 43 (28.5%) cases and were more associated with treatment with $\geq$15 mg/d of prednisone (OR 3.7, 95% CI 1.54–9.21, p$\leq$0.005). No differences were found for patients with BCG vaccination and previous TB before aTNF therapy
**Conclusions:** This study suggests that patients with RD in this cohort from Mexico have a high prevalence of TB, LTBI and TST conversions compared to other studies. Also lower wage, to be healthcare workers and smoking were associated with LTBI, and TST conversion occurred more associated to use higher dose of glucocorticoids. The clinical significance of these TST conversions is unclear at the moment.

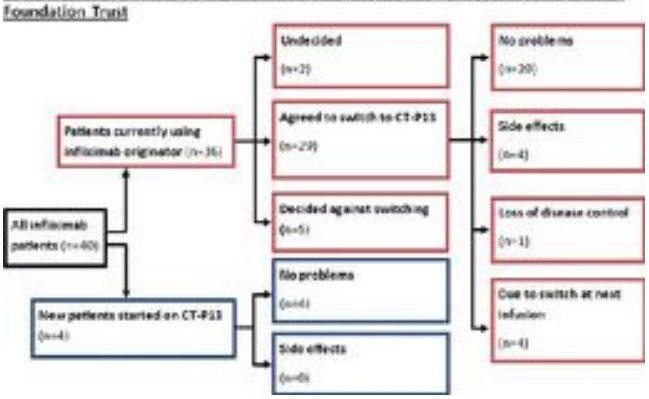
## AB0321 A TOTALITY-OF-THE-EVIDENCE APPROACH TO THE DEVELOPMENT OF GP2015, A PROPOSED ETANERCEPT BIOSIMILAR

M. McCamish[1], A. DaSilva[1], R. Ernst Mayer[2], C. Fritsch[3], M. Schiestl[2]. *[1]Hexal AG, Holzkirchen, Germany; [2]Sandoz Biopharmaceuticals, Kundl, Austria; [3]Novartis Pharma AG, Basel, Switzerland*



**Background:** Assessment of biosimilarity uses the "totality-of-the-evidence" concept, whereby a complete data package, comprising physicochemical, biological, nonclinical and clinical data, is used to evaluate and confirm biosimilarity between a proposed biosimilar and an approved originator (reference) product. A stepwise approach, using comparative analytical characterisation to inform next steps, is recommended. The totality-of-evidence derived from these data should demonstrate that the active substance of a biosimilar and its originator are essentially the same.
**Objectives:** To describe the development of a proposed etanercept biosimilar (GP2015).
**Methods:** To define the development target, multiple batches of the originator were characterised over time to understand quality attributes relating to protein structure, function, and amino acid modifications. An iterative, target-directed development process was used to design and produce a potential biosimilar product (GP2015) that fell within the variability range of the originator. Biosimilarity between GP2015 and the originator was confirmed at analytical, functional, nonclinical, pharmacokinetic (PK) and clinical levels using a stepwise approach. Biochemical attributes and functional properties were assessed using a comprehensive and sensitive state-of-the-art panel of analytical tools. Bioequivalence between GP2015 and the originator was assessed in vivo and in four PK studies in healthy volunteers. To confirm there were no clinically meaningful differences between GP2015 and the originator, a study of efficacy, safety and immunogenicity was performed in patients with moderate-to-severe chronic plaque-type psoriasis. This confirmative study assessed the Psoriasis Area and Severity Index response rate at Week 12 and at long-term timepoints.
**Results:** GP2015 was developed at the same dosage and strength as the originator. Multiple orthogonal analytical methods showed high similarity between GP2015 and the originator. The amino acid sequence was confirmed to be identical and protein folding was indistinguishable. Other attributes, such as glycosylation and product-related impurities, were highly-comparable with the originator. In vitro assays reflecting mechanisms of action and pharmacological properties showed GP2015 and the originator had similar bioactivity. PK bioequivalence between GP2015 and the originator was established in nonclinical and human studies. The study in patients with psoriasis confirmed similar efficacy and safety and comparable immunogenicity in a highly-sensitive indication. In all studies, no clinically meaningful differences between GP2015 and the originator were observed.
**Conclusions:** Analytical, functional, nonclinical and clinical data provide a comprehensive understanding of both GP2015 and the originator and demonstrate a high level of similarity between the two products in accordance with regulatory requirements. The totality-of-the-evidence is therefore believed to justify the use of the biosimilar in the same indications as the originator.

## AB0322 PRELIMINARY DATA ON THE INTRODUCTION OF THE INFLIXIMAB BIOSIMILAR (CT-P13) TO A REAL WORLD COHORT OF RHEUMATOLOGY PATIENTS

M. Sheppard, S. Hadavi, F. Hayes, J. Kent, B. Dasgupta. *Southend University Hospital NHS Foundation Trust, Westcliff-on-Sea, United Kingdom*

**Background:** Infliximab is a chimeric monoclonal antibody against tumour necrosis factor alpha (TNF-α), used to treat autoimmune diseases such as rheumatoid arthritis, ankylosing spondylitis and psoriatic arthritis.[1] In 2015 NICE recommended the use of a new less expensive biosimilar CT-P13 (Remsima™; Inflectra™), based on its efficacy, safety and quality comparable to the reference infliximab product.[2] At Southend University Hospital NHS Foundation Trust, the use of CT-P13 has reduced treatment costs and allowed significant cost savings compared with reference infliximab.
**Objectives:** To review patient outcomes and estimate the cost savings of using CT-P13 as compared with reference infliximab.
**Methods:** Information packs were sent out to patients to inform them of the intended switch from Infliximab to CT-P13. Their understanding was further reinforced in a face-to-face session with the biologics pharmacist and any concerns were addressed. Additionally patients had access to a dedicated email account which was set up to deal with their queries. Written consent was obtained from patients prior to the switch. Patients were carefully monitored during the first infusion of CT-P13 and were advised to contact the rheumatology department if they developed any undue side-effects or loss of disease control. All eligible patients were offered a chance to recruit to BSR Biologics Register. All side-effects were reported to MHRA.
**Results:** 25 patients consented to the switch from infliximab to the biosimilar CT-P13. 20 patients reported no new side-effects or loss of disease control (80%, ±15.68). 4 patients developed side-effects after switching to CT-P13. 1 developed flu like symptoms, 1 developed inflamed foreskin and 2 developed pruritic rashes, (one patient after the first dose and the other patient after the 4th dose). All patients who developed side-effects were successfully switched back to reference infliximab. 1 patient reported loss of disease control and is due to switch back at their next infusion. None of the patients initiating CT-P13 first line have developed any side-effects to date. A paired t-test has revealed no statistically significant difference in CRP values taken before and after the switch (n=21, p=0.151). £70k is expected to be saved based on this reported use of CT-P13 in our rheumatology department over 12 months.

Flow diagram to demonstrate patient outcomes from CT-P13 usage at Southend NHS Foundation Trust

**Conclusions:** In our cohort of patients, switching from Infliximab to CT-P13 appeared to be safe for the majority of patients and represents a significant opportunity to provide a more cost effective service in rheumatology. The immunogenic nature of infliximab highlights the importance of having a robust safety net strategy when switching patients to biosimilars. Further multi-centre studies are needed to corroborate our findings.

## AB0323 PERSISTENCE OF BIOLOGIC THERAPY AND LONG TERM OUTCOMES AT 14 YEARS: OBSERVATIONAL DATA IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM A SINGLE CENTRE

M.A. Fernandes[1], I. Figueiredo[1], N. Riso[2], A. Panarra[1], M.F. Moraes-Fontes[1]. [1]*Unidade de Doenças Auto-imunes;* [2]*Unidade de Doenças Autoimunes, Hospital Curry Cabral, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

**Background:** Current recommendations for Rheumatoid Arthritis (RA) treatment focus on a treat to target approach [1, 2]. Long term individual drug persistence has been associated to factors such as type of biological agent and higher disease activity [3, 4]. Here we present data from a tertiary referral centre.
**Objectives:** To determine factors associated to drug persistence, switch or withdrawal of first-line biological therapy.
**Methods:** Retrospectively collected data (01/2002 to 12/2015) from our Unit included patients classified as RA according to ACR 1987 [5] and 2010 [6] criteria. The analysis included 288 patients, 29% (n=85) of which were lost to follow-up and 15% (n=44) of which were deceased. The present study was restricted to current biological therapy. We extracted baseline characteristics (age, gender, presence of RF and anti-CCP, duration of RA, year of initiation of therapy), first biologic and causes of switch or withdrawal, adverse events and treatment efficacy (according to DAS28). Data were collected through to December 2015. Outcomes were compared using the Man-Whitney test comparing those that maintained the same biologic to those that switched. We limited the analysis to patients treated with Etanercept (ETN), Adalimumab (ADA), Rituximab (RTX) and Tocilizumab (TCZ).
**Results:** A total of 85 patients (53%) were started on biological therapy (bDMARD), instituted after methotrexate (MTX) failure or intolerance (mean peak MTX dose 17 mg/week). Mean age [±SD]=59 [±10.2] years,79% female (n=65), mean disease duration 11.3 [±7.2] years (ranging from 1 to 37 years), 6 (7%) non-white, the majority positive for rheumatoid factor and/or anti-CCP (n=61, 72%). These patients were originally treated with ETN (n=56), Infliximab – INFLIX (n=3), ADA (n=12), RTX (n=6), TCZ (n=7) and Golimumab (n=1) (Graph I). After mean 4 [±2.9 [±SD] years of follow-up, ranging from 1 to 14 years (Graph II), 70 of 85 patients are currently still on bDMARD, mostly on ETN (n=34), TCZ (n=13), RTX (n=11) and ADA (n=9). Abatacept has been started on one patient. The median time of receiving ETN, ADA, RTX and TCZ was 5.0, 3.5, 2.0 and 4.0 years and retention rates were 71%, 67%, 83% and 86%, respectively. Overall, more than 95% of treatment switch was due to drug inefficacy. Severe infections occurred with ETN (one Pneumocystis pneumonia) and ADA (one genitourinary tuberculosis). Lack of efficacy due to TCZ was only seen in a single patient. There was no statistically significant differences between retention and non-retention groups.

**Conclusions:** Biological drugs for RA treatment in our Unit were determined by drug development and National Authority of Medicines and Health Products authorization. ETN was the most frequently used and for the longest duration with a 71% retention rate. Overall we found that the other agents were also well tolerated and effective in patients between 50 and 70 years of age. This information may be useful for clinicians with an ageing population.

## AB0324 TAPERING OF ADALIMUMAB BASED ON THERAPEUTIC DRUG MONITORING IN RHEUMATOID ARTHRITIS

M.J. l'Ami [1], A.F. Marsman [1], C.L. Krieckaert [1], J. Ruwaard [1], E.L. Kneepkens [1], M.T. Nurmohamed [1], G.J. Wolbink [1,2]. *[1]Amsterdam Rheumatology and immunology Center – Reade; [2]Immunopathology, Sanquin Reasearch and Landsteiner Laboratory Academic Medical Center, Amsterdam, Netherlands*

**Background:** Treatment with biologicals is based on the principle of "one size fits all" without taking differences in dosing schemes, patients characteristics and pharmacokinetics into account.
**Objectives:** To compare disease activity 26 weeks after dose interval prolongation versus continuation of the regular dose in rheumatoid arthritis (RA) patients with high serum adalimumab concentration[1].
**Methods:** In the interim analysis of this open randomised controlled trial, patients with an adalimumab concentration >8 mL/L were randomly (1:1) assigned to continuation of adalimumab every other week (continuation group) or prolongation of the dosage interval to once every 3 weeks (tapering group), independently of disease activity score in 28 joints (DAS28). Patients were treated with adalimumab 40 mg subcutaneous every other week for at least 28 weeks before start of the study. Visits were scheduled at baseline, 13 and 26 weeks thereafter. The change in DAS28 (∆DAS28) after 26 weeks compared to baseline was taken as outcome measurement and a clinical relevant difference was defined as a ∆DAS28 >0.6. Based on an intention to treat analysis, an independent t-test was used to compare mean ∆DAS28 between the two groups. A total of 102 patients was calculated as a priori sample size.
**Results:** Fifty-three patients out of 142 screened patients (37%) had adalimumab concentrations >8 mL/L and were included in the study. All patients completed follow up. Twenty-six patients were randomly assigned to continuation group and 27 patients were assigned to tapering group. Patients characteristics at baseline did not differ significantly between the two groups. After 26 weeks, mean ∆DAS28 did not meet the criteria for a clinically relevant difference in both continuation group (0.29± 0.58 standard deviation (SD)) and tapering group (-0.06±0.58 SD) and did not significantly differ (p=0.06) between groups (see figure). Six patients in the continuation group developed active inflammation (defined as an increase of ≥1 swollen joint compared to baseline) during follow-up. In the tapering group, two patients developed active inflammation of whom one returned to standard dose of adalimumab. Despite the absence of inflammatory signs, eight other patients in the tapering group returned to standard dose on request of patient or treating rheumatologist.

**Conclusions:** This interim analysis shows that disease activity remains stable in RA patients with adalimumab concentrations >8 mL/L who prolonged their dose interval to once in the three weeks compared to patients who continued adalimumab every other week.

## AB0325 COMPARISON OF THE EFFICACY OF SECOND TNF INHIBITOR VERSUS ALTERNATIVE BIOLOGICAL AGENT (RITUXIMAB/ TOCILIZUMAB/ABATACEPT) AFTER SECONDARY FAILURE TO INITIAL ANTI TNF THERAPY IN RHEUMATOID ARTHRITIS – A RETROSPECTIVE OBSERVATIONAL ANALYSIS

M.R.A. Shipa, M. Di Cicco, E. Roussou. *Department of Rheumatology, Barking, Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom*

**Background:** Treatment of rheumatoid arthritis (RA) has been revolutionized by the introduction of tumor necrosis factor inhibitors (TNFi). Nonetheless a significant proportion of patients fails to respond (primary failure) or may lose the initial response over time (secondary failure). Subsequent treatment for the patients who experienced secondary failure yet needs to be defined, particularly, as to whether a second TNFi or an alternative biological agent (non- TNFi), should be used.
**Objectives:** With the aim to assess and compare the efficacy of second TNFi versus non-TNFi after secondary failure to the first TNFi, we obtained data from patients with secondary failure who had started treatment with biologics from 2010 to 2015.
**Methods:** A pro-forma has been given to patients with secondary failure who were on either second TNFi or non-TNFi either in clinic or sent by post. Patients were excluded if they had missing or incomplete data, if the nature of the failure was unclear or if the treatment was changed due to infection, cancer, hepatitis, tuberculosis (TB) or Multiple Sclerosis (MS). Response was assessed by ACR20. Additionally, the clinical notes were reviewed and scrutinised aiming to gather as accurate as possible information on patients' clinical assessments. The response to treatment following secondary failure was further analysed according to the presence or absence of Rheumatoid Factor (RF) and Anti-CCP Antibodies (aCCP).
**Results:** Data from a total of 109 patients were obtained. 43 patients (M:F =1:3) were included in the analysis. Patient's mean age was of 61 years (SD ±10). From those patients excluded, 16 patients had incomplete data, 13 had unclear data, 19 patients had infection, 11 had cancer, 4 had hepatitis, 2 had TB, and 1 had MS. From the 43 patients analysed 20 were on a second TNFi [6 on Adalimumab (ADA), 5 on Certolizumab (CZP), 5 on Etanercept (ETA), 4 on Golimumab (GLM)] while 23 were on non-TNFi [12 on Rituximab (RTX), 6 on Tocilizumab (TCZ), 5 on Abatacept (ABT)].
A total of 24 of 43 patients (46.5%) responded to treatment after secondary failure. Of these, 8 patients (of 20; 40%) were from the TNFi group and 16 (of 23; 70%) from the non- TNFi group (p=0.05). Among the TNFi group, the response rate was 16% (1/6) for ADA, 60% (3/5) for CZP, 40% (2/5) for ETA, 50% (2/4) for GLM. In the non-TNFi group, the response rate was 75% (9/12) for RTX, 67% (4/6) for TCZ and 60% (3/5) for ABT.
When stratifying the response according to the presence or absence of RF or aCCP, seropositive patients showed significantly better response to non-TNFi compared to TNFi (70% vs 33%; p=0.03). Looking at responses according to drugs used after secondary failure, all patients who were seronegative responded to CZP and ABT (100% response) while seropositive patients showed 90% response to RTX.
**Conclusions:** Secondary failures to TNFi overall respond better to non-TNFi compared to second TNFi, especially if they are seropositive.Further studies are needed in order to guide the accurate pharmacological interventions.
**Disclosure of Interest:** None declared

## AB0326 THREE-YEAR STUDY OF TNF-ALFA INHIBITORS USE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND CONCOMITANT CHRONIC HEPATITIS B OR C

Y. Pak, I. Menshikova, A. Pogromov, I. Kolosova, N. Michlina. *First Moscow State Medical University, moscow, Russian Federation*

**Background:** Managing patients with rheumatoid arthritis (RA) and concomitant hepatitis B virus (HBV) or hepatitis C virus (HCV) infections represents a major challenge in modern rheumatology.Due to a high risk of HBV, HCV infection reactivation and potential hepatotoxity the use of disease-modifying antirheumatic drugs (DMARDs) and corticosteroids is limited in such patients. Since biologic agents have been increasingly employed in patients with chronic inflammatory rheumatic diseases, their efficacy and safety need to be further investigated in patients with chronic HBV and HCV infection.
**Objectives:** To assess the safety and efficacy of TNF-alfa inhibitors (TNFi) in RA patients with concomitant chronic HBV and HCV infection.
**Methods:** From 2012 to 2015 we have been observing 10 RA patients (5 male, 5 female, mean age 45,4 years) with chronic HBV (6 patients) and HCV (4 patients) infection who were undergoing therapy with TNFi. Mean duration of the disease before initiating biologic agents was 8 years, mean follow-up period was 18,2 months. Criteria for starting biologics included high disease activity score (DAS28 - 6,7) with little response to non-biologic DMARDs (methotrexate, leflunomide, sulfasalazine) and/or low-dose corticosteroids (4–8 mg/day); intolerance of DMARDs or contraindications to them. 2 patients with RA and chronic HBV infection were given a preventive treatment with ribavirin and a concomitant treatment with alfa-inetrferon. One patient with RA and chronic HCV

infection recieved an antiviral preventive treatment with alfa-interferone. Hepatitis activity was monitored with viral load and liver function tests, RA activity was monitored with ESR, CRP, pain assessment with visual analogue scale (VAS) and disease activity score in 28 joints (DAS28). All tests were performed every 3 months during the first year and every 6 months beyond the first year of study. Patients were given standard doses of TNFi – adalimumab (2 patients with hepatitis C), etanercept (8 patients with hepatitis B, 2 patients with hepatitis C).
**Results:** Disease activity reduction was observed in all patients: mean pain VAS score decreased from 80 to 26.5 mm ($p<0,001$), mean ESR decreased from 32,8 to 12,5 mm/h, mean CRP level decreased from 4.2 to 0.3 mg/dl ($p<0,001$), mean DAS28 decreased from 6.25 to 3.36 ($p<0,001$). No viral load or liver enzymes increase was observed in our study. One patient with chronic hepatitis B and one patient with chronic hepatitis C had leukopenia on while being on etanercept and concomitant or preventive alfa-interferon therapy, which was successfully reversed with Leucostim
**Conclusions:** After 3 years of study TNF-alfa inhibitors (adalimumab and etanercept) appear to be effective and quite safe in patients with RA and concomitant chronic HBV and HCV infection. During the mean follow-up period of 18.2 months no viral load increase or signs of hepatitis virus reactivation have been noted. Althigh, TNFi-based treatment requires regular monitoring of HBV and HCV activity using PCR test.

## AB0327 AN AUDIT OF THE USE OF BIOLOGIC THERAPIES AND DOSAGE TAPERING IN STABLE INFLAMMATORY ARTHRITIS PATIENTS: A REAL LIFE LOOK AT A DISTRICT GENERAL HOSPITAL'S PATIENTS

R. Rabbitts. *Rheumatology, North Devon District Hospital, Devon, United Kingdom*

**Background:** Rheumatology department at a South West England District General Hospital.
**Objectives:** To audit our use of biologic therapies in patients with inflammatory arthritis. To establish how many patients we are increasing the dosage interval, which patients we are choosing to do this for and what are the success rates from this. Evaluate what the financial implications are in doing this.
**Methods:** Using the "Homecare Patient List" patients with any inflammatory arthritis who were on a biologic medication were identified. Patients with a firm diagnosis of Rheumatoid Arthritis (RA) or Psoriatic Arthritis (PsA) were identified from this. Patients on one of 6 biologic medications (abatercept, adalimumab, certolizumab, etanercept, golimumab, and tocilizumab) were then included. Further inclusion criteria for the audit included being on a biologic medication for over 6 months (ie. Started before April 2015) and having regular follow up with our service (at least every 6 months).
148 patients were identified as suitable (108 Rheumatoid arthritis, 40 Psoriatic arthritis). Demographics were collected from hospital electronic records and then information regarding biologic medications and clinical status was taken from clinic letters using Epro records. Clinic letters prior to 2013 were not viewed. Results were collected in MS Excel template.
**Results:** Of the 108 RA patients; 76 female and 36 male, mean age was 61 years with a range of 32 years to 78 years. In 40 of these patients we attempted to taper the interval of their biologic medication. 87% of these patients were on methotrexate as an anchor medication. Biologic medications that were tapered included adalimumab, etanercept and certolizumab. In the 40 patients tapered this change has been maintained or increased in 28 patients, giving a success rate of 70%. 12 patients have returned to the original dosing regimen due to increased disease activity.
In the Psoriatic Arthritis patient group, there were 21 females, 19 males, with a mean age of 52 years (age range 31 years to 73 years). In 5 of these patients we have attempted to taper the interval of their medication. The majority of those tapered were on monotherapy adalimumab. The changes were maintained in 80% of patients.
**Conclusions:** In total we have attempted to taper 30% of RA and PsA patients on biologic therapies, 71% of these attempts have been maintained or increased. We are increasing the dosage intervals successfully by varying amounts, with a range from 16% to 55%, and by a mean of 30.58% over all medications included. Etanercept has successfully had the largest increase in interval with dosing intervals increasing by a mean of 55% compared to once every 7 day dosing. This has significant financial implications with an annual savings of £72,108.60 based on the data in this audit.
**Disclosure of Interest:** None declared

## AB0328 WHAT COULD WE LEARN FROM THE SUB-ANALYSIS OF A SINGLE NATION COHORT IN A WORLDWIDE STUDY? LESSON FROM THE RESULTS OBSERVED IN THE ITALIAN COHORT OF THE GO-MORE TRIAL

R. Giacomelli [1], P. Ruscitti [1], V. Liakouli [1], P. Cipriani [1], M. Mecchia [2] on behalf of the Italian GO-MORE Investigators. *[1]Division of Rheumatology, University of L'Aquila, L'Aquila; [2]MSD Italy, Rome, Italy*

**Background:** GO-MORE Trial investigated the use of Golimumab (GLM) in rheumatoid arthritis (RA) in 3280 patients worldwide [1]. At present, the burden of arthritis is greater in poorer countries than in developed countries due to socioeconomic disparities [2], thus suggesting the usefulness of subgroup investigations.
**Objectives:** We evaluated the GLM as add-on therapy for RA patients in the Italian cohort of GO-MORE trial and we compared the baseline characteristics and efficacy after 6 months between Italian patients and the enrolled patients worldwide. A limit of these analyses is that they are *post hoc* in nature and many tests were performed without adjustments for multiplicity.
**Methods:** Ninety-eight Italian patients with active RA, fulfilling the 1987 ACR criteria, naïve for biologic drugs were enrolled. Statistical analyses were performed to assess: i. the differences in baseline characteristics; ii. the efficacy after 6 months; between Italian and Rest of the World GO-MORE populations.
**Results:** The majority of Italian patients were older than the worldwide patients ($p=0.01$). Compared to Rest of the World population, Italian patients showed a lower value of DAS28-ESR ($p=0.045$), DAS28-CRP ($p=0.0001$), and a significantly short disease duration ($\leq$2 years) ($p=0.045$). Differently from the Rest of the World patients, the large majority of Italian patients received biologic therapy after the failure of the first sDMARD ($p<0.0001$). Furthermore, a lower percentage of Italian patients were treated by high MTX dosage ($p<0.0001$). After 6 months of GLM treatment, the therapeutic response of the Italian patients did not differ from those observed in Rest of the World cohort. More than 90% of patients reported that the overall autoinjection experience was favourable and these results mirrored those observed worldwide [3].
**Conclusions:** The analysis of the Italian GO-MORE subset confirms that differences among patients may be shown, depending from different approaches in different health systems. The Italian cohort (early onset of the disease and already fulfilling the 1987 ACR criteria) is probably affected by a more severe disease with poor outcome [4], but the efficacy in this subset response rate of Italian subset did not differ from worldwide patients. GLM in the Italian patients showed a favourable benefit/risk profile and the positive autoinjection experience may help for patient's compliance and survival of the treatment.

## AB0329 ULTRASOUND 7 VERSUS ULTRASOUND12 IN MONITORING THE RESPONSE TO ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Tropea, I. De Andres, P. Santonocito, A.A. Russo, E. Battaglia. *U.O. Rheumatology, Arnas Garibaldi, Catania, Italy*

**Objectives:** This study aimed to assess the responsiveness of ultrasonography (US)-7 in patients with psoriasic arthritis (RA) non responders at only MTX terapy recruided with baseline ecographic positivity per disease activity. Sixty-two RA patients were recruited and followed up for 24 weeks.
**Methods:** The clinical, laboratory, and X-ray assessments, along with grayscale US (GSUS) and power Doppler US (PDUS) examinations were performed at baseline, 6, 14, and 24 weeks after adalimumab treatment GSUS for synovitis and PDUS for synovitis and paratendinitis/tenosynovitis were assessed by a semi-quantitative (0 to 3) score, while GSUS for paratendinitis/tenosynovitis and bone erosion was qualitatively assessed as absent or present (0 or 1). US scores in both 7-joint (US7) and 12-joint (US12) systems were evaluated.
**Results:** After 6, 14, and 24weeks of treatment with adalimumab, indices such as US scores in both 7-joint (US7) and 12-joint (US12) systems were evaluated. After 6, 14, and 24 weeks of treatment with adalimumab indices such as US scores, 28-joint disease activity (DAS28) score, and tender and swelling joint count were

all significantly improved compared to baseline. US7 scores were significantly correlated with that of US12. Strong correlations were identified between most US7 scores with DAS28, health assessment questionnaire (HAQ), and C-reactive protein (CRP) levels. When DAS28 was used as a reference, the US7 cutoff for disease remission was less than 35 for GS+PD and also less than 29 for GS and 1 for PD, respectively

**Conclusions:** Additionally, the positive percent agreement, negative percent agreement, and overall percent agreement for GS+PD were 77.78, 76.19, and 76.67%, respectively, which were all higher than that of GS or PD. US7 may be a feasible tool to assess the therapeutic response in RA patients.

## AB0330 ETANERCEPT ALTERNATIVE STORAGE AT AMBIENT TEMPERATURE

S.M. Vicik[1], J. Daffy[1], H. Jones[2], A. Paulson[1], E. Shannon[1]. *[1]Pfizer Biotech, Andover, United States; [2]Pfizer, Collegeville, United States*

**Background:** Introduction of biological disease-modifying antirheumatic drugs (DMARDs) that began with the approval of the tumour necrosis factor (TNF) inhibitor etanercept has revolutionized the management of patients with rheumatic diseases[1] and other inflammatory diseases.[2] Use of biological therapy, including TNF inhibitors, has improved outcomes for patients with RA, with sustained remission now considered the optimal treatment goal to prevent joint damage.[1] Therefore, flexible and convenient treatment options that are compatible with modern lifestyles are important aspects in helping patients maintain treatment and manage their disease. Since the introduction of etanercept, Pfizer has aimed to provide this through innovation in the form of lyophilized powder for solution injection, pre-filled syringe and pre-filled pen formulations.[3] Regulation of the manufacture of etanercept and other biologic drugs is governed by a requirement to perform robust analytical and stability testing to ensure quality is maintained.[4] Due to its structural complexity, etanercept, as with many other biologics, is typically stored under refrigerated conditions.[3] Here we describe the stability testing data that support an alternative storage condition for etanercept at ambient temperature, representing further innovation in the product lifecycle aimed at enhancing patient convenience.

**Objectives:** To generate a comprehensive analytical data package from stability testing of key quality attributes consistent with regulatory requirements that determine if the product profile of etanercept is maintained at an alternative storage condition of ambient temperature.

**Methods:** Test methods assessing the key attributes of purity (Size Exclusion High Performance Liquid Chromatography, Hydrophobic Interaction Chromatography), quality (appearance, pH, etanercept concentration by ultraviolet absorbance spectroscopy, particulate matter, reconstitution time, functionality), potency (cell-based TNF alpha-induced apoptosis bioassay) and safety (sterility, container closure integrity).

**Results:** Results and statistical analysis from stability testing across all etanercept presentations showed key stability indicating parameters were within acceptable limits through the alternative storage condition of 25℃ ±2℃ for a period of 1 month.

| Presentation | Stability study temperature (period in specification) | | |
|---|---|---|---|
| | 5℃ ±3℃ | 25℃ ±2℃ | 30℃ ±2℃ |
| 25mg PFS, 50mg PFS, 50mg PFP | 36 months | 1 month | ≥4 weeks |
| 25mg/vial | 36 months | 6 months | ≥4 weeks |
| 10mg/vial | 36 months | 24 months | ≥4 weeks |

PFS, pre-filled syringe; PFP, pre-filled pen.

**Conclusions:** Stability testing performed in line with regulatory requirements supported a single period of storage for etanercept at an alternative storage condition of 25℃ ±2℃ for up to 1 month within the approved expiry of the product. This alternative storage condition for etanercept provides greater flexibility for patients, particularly whilst travelling with etanercept, reflecting Pfizer's commitment to offer enhanced overall patient convenience.

## AB0331 EARLY IMPROVEMENT OF MUSCULOSKELETAL ULTRASOUND FINDINGS CAN PREDICT FUTURE CLINICAL RESPONSE TO CERTOLIZUMAB PEGOL IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Fujimura, T. Fujimoto, H. Kawashima, T. Kira, R. Hara, N. Shimmyo, Y. Kobata, A. Kido, Y. Akai, Y. Tanaka. *The Center for Rheumatic Diseases, Nara Medical University, Kashihara, Japan*

**Background:** Certolizumab pegol (CZP) is a PEGylated Fab' fragment of a humanized anti-TNF antibody and it brings rapid improvement of the signs and symptoms of RA. Musculoskeletal ultrasound (US) has been proved to be useful at assessing synovitis precisely in patients with RA. There are few reports, however, that verify the early response to CZP in RA patients by US. Moreover, it remains to be ascertained whether early US assessment of synovitis can predict future clinical response in treatment with CZP.

**Objectives:** In the present study we investigate whether US is useful for predicting future clinical response to CZP in RA patients.

**Methods:** Twenty patients with RA were treated with subcutaneous CZP 400 mg at weeks 0, 2, 4 followed by 400 mg every 4 weeks or 200 mg every 2 weeks. The mean age of patients was 55.2 years old and the mean disease duration was 5.9 years. The mean disease activity at baseline (week 0) was 4.91 for 28-joint disease activity score (DAS28). Fifteen (75%) patients were naïve to biologic agents. Seventeen (85%) and 9 (36%) patients were treated with methotrexate and glucocorticoids concurrently. At baseline and weeks 2, 4 and 12, US examination was performed at bilateral MCP, PIP, IP, and wrist joints. Gray-scale (GS) and pulse Doppler (PD) signal was recorded in each joint using semi-quantitative score (0 to 3). The sum of these scores obtained from each joint was used as GSUS and PDUS score.

**Results:** At weeks 0, 2, 4, and 12, mean GSUS score was 24.1, 20.4, 17.5, and 16.7, respectively. Mean PDUS score at weeks 0, 2, 4, and 12, was 14.6, 10.8, 10.8, and 9.9, respectively. Both GSUS and PDUS score were improved significantly as early as 2 weeks after treatment ($p=0.031$ and 0.011) and reduced by degrees during study period. At weeks 0, 4, 8, 12, and 24, mean DAS28 was 4.91, 3.61, 3.55, 3.50, and 3.05, respectively. DAS28 was significantly improved as early as 4 weeks after treatment ($p<0.001$). Clinical response was evaluated as achievement of DAS remission (DAS $<2.6$), and we classified 10 patients (50%) who achieved DAS remission at week 24 as "responders". The improvement in US assessment at week 2 was compared between responders and non-responders. Four patients showed a $>50\%$ reduction in PDUS score from baseline (PDUS 50 response) at week 2. At week2, none achieved a $>50\%$ reduction of GSUS score from baseline, whereas 8 patients indicated a $>20\%$ reduction in GSUS score from baseline (GSUS 20 response) at week 2. There was a marked high responder rate (80%: 4 out of 5) in the patients showing PDUS 50 response at week 2. Similarly, the responder rate (88%: 7 out of 8) of the patients showing GSUS 20 response at week 2 was remarkably high and significantly higher than that (25%: 3 out of 12, $p=0.020$) of the patients without GSUS 20 response.

**Conclusions:** Early response to CZP was confirmed by US examination and the early assessment of synovitis by US is useful to predict future clinical response to CZP in patients with RA.

**Disclosure of Interest:** None declared

Caporali[1,2] on behalf of LORHEN Registry. *[1]Department of Rheumatology, IRCCS Policlinico San Matteo Foundation; [2]University of Pavia, Pavia; [3]Spedali Civili, Brescia; [4]University Hospital L Sacco, Milano; [5]Ospedale Mauriziano; [6]Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Torino; [7]Santa Chiara Hospital, Trento; [8]Struttura di Reumatologia A.S.O. "SS.Antonio e Biagio e C. Arrigo", Alessandria; [9]Department of Rheumatology, Gaetano Pini Institute, Milano, Italy*

**Background:** The efficacy of Golimumab (GLM) treatment in rheumatoid arthritis (RA) has been widely documented in clinical trials. Data are still needed to assess its efficacy and tolerability in everyday clinical practice.

**Objectives:** To assess the efficacy of the treatment with GLM in RA previously treated with conventional synthetic disease modifying antirheumatic drugs (cs-DMARDs) or biological DMARDs (bDMARDs) from a multicentric observational cohort (the LORHEN Registry).

**Methods:** All patients with a diagnosis of RA in the LORHEN database who started GLM from october 2010 up to september 2015, with at least one reported visit, were included.
We reviewed the data regarding the first 24 months of treatment, focusing on clinical efficacy.
The efficacy of GLM was assessed with DAS28, DAS28(CRP), SDAI and EULAR response criteria.
We executed intention-to-treat (ITT) and per-protocol analysis (PP).
We repeated the analysis for the subgroups of patients who received GLM as first or second bDMARD.
**Results:** We retrieved the data regarding 180 patients, with a mean (sd) age of 54,57 (13,62) years and a mean (sd) disease duration of 9,52 (9,32) years. Methotrexate was the concomitant csDMARD for 123 (68,3%) patients, while leflunomide, sulfasalazine and cyclosporine were given to 13 (7,2%), 5 (2,8%) and 4 (2,2%) patients respectively. 35 (19,4%) patients were treated with GLM monotherapy. 137 (76,1%) and 5 (2,8%) patients were given low dose (≤10mg prednisone equivalent a day) and medium dose (≥10 and ≤25) corticosteroid at baseline, with following tapering.
A total of 79 patients stopped the treatment with GLM due to inefficacy or adverse events before 24 months of treatment.
With the ITT design 55 (30,6%) and 44 (24,4%) patients achieved good or moderate EULAR response respectively at 6 months. The mean (sd) DAS28, DAS28(CRP) and SDAI progressively reduced, reaching 2,61 (1,11), 2,41 (0,72) and 4,62 (3,80) respectively at 24 months.
Within the PP scenario, 32 (66,7%) and 9 (18,8%) patients reached and maintained good or moderate EULAR response respectively to the end of the follow-up.
The clinical response to GLM therapy resulted slightly reduced when given as a second line bDMARD treatment, but the data did not met statistical significance.

**Conclusions:** GLM is effective in treating RA in everyday clinical practice. The efficacy increases significantly over the first 6 months and slightly during the following 18 months.
Interestingly enough, patients treated with GLM after a first bDMARD can still achieve low disease activity and clinical remission, with an overall efficacy of the treatment not statistically different to the first line.

## AB0333 DRUG SURVIVAL OF TNF-α INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS IN DAILY CLINICAL PRACTICE: A RETROSPECTIVE COHORT RESEARCH

Y. Veenstra[1], I.E. van der Horst[2], M.L. Becker[3], O.N. van Hall[2], S. ten Wolde[1].
*[1]Spaarne Gasthuis, Haarlem; [2]VU University Medical Centre, Amsterdam; [3]SAHZ, Haarlem, Netherlands*

**Objectives:** The aim of this study was to examine the frequency and reasons of discontinuation of TNF-α inhibitor treatment in rheumatoid arthritis (RA) patients in daily practice. We focused on (serious) infections, (skin) malignancies, (local) allergic reactions, inefficacy and remission. Furthermore, we investigated if the discontinuation was temporarily or permanent, if there were differences between the five TNF-α inhibitors (etanercept, adalimumab, infliximab, golimumab, certolizumab pegol), if there was dose reduction during treatment and if there were differences between men and women.
**Methods:** This is a retrospective cohort study of RA patients treated with TNF-α inhibitors of the Rheumatology department Spaarne Gasthuis in Haarlem between January 2012 until January 2015. The variables of the database were tested with Kaplan Meier, Cox-regression and Chi-square test.
**Results:** In total 274 patients were included of whom 184 (67.2%) used etanercept, 63 (23%) used adalimumab and the groups treated with infliximab, golimumab and certolizumab pegol had each nine patients (3.3%). Of the 274 patients, 93 (33.9%) continued with the same TNF-α inhibitor treatment without interruption. The mean treatment duration in these patients was 30.1 months. Furthermore, 101 patients (36.9%) stopped treatment temporarily, of whom 95 stopped for less than 6 months. The reasons for the temporary stops were mild infections (64), newly diagnosed malignancies (2), local allergic skin reactions (1) and remission (6). Finally the first treatment episode in the study period was stopped permanently in the remaining 80 patients (29.2%), of whom 19 switched to another TNF-α inhibitor, 13 switched to another biological and 48 stopped biological treatment permanently. In table 1 reasons for stopping TNF-α inhibitor treatment are shown. Dose reduction of TNF-α inhibitor treatment was observed in 50 patients (18%), resulting in a relapse of RA in only 5 patients. Etanercept showed significantly more interruptions than the other TNF-α inhibitors. Other differences between the five TNF-α inhibitors and between men and women were not significant.

Table 1. Reasons for stopping TNF inhibitor treatment permanently (80 patients)

| | |
|---|---|
| Infections | 13 (11 mild and 2 serious) |
| Malignancies | 4 |
| Allergic skin reactions | 5 (3 local and 2 systemic) |
| Other side effects | 13 |
| Inefficacy | 21 |
| Remission | 5 |
| Lost to follow-up | 5 |
| Deceased | 5 |
| Other reasons | 9 |

**Conclusions:** Concluding, 71% of the RA patients stayed on the same TNF-α inhibitor, of whom 34% without interruptions and 37% with mostly short interruptions. This is in line with the literature (1). The remaining 29% of the patients stopped TNF-α inhibitor treatment permanently. Short treatment interruptions were found significantly more in the etanercept group. A plausible explanation for this finding is the higher injection frequency (once per week) of etanercept leading to more frequent interruptions. In conclusion, TNF-α inhibitor treatment in RA patients is safe and effective in more than 70% of the patients. Dose reduction may be an option in some patients, but stopping because of remission is rare and half of the patients flared within six months.

## AB0334 CLINICAL EFFICACY OF CERTOLIZUMAB PEGOL THERAPY IN PATIENTS WITH JAPANESE ACTIVE RHEUMATOID ARTHRITIS 52 WEEK RESULT ～A MULTICENTER REGISTRY STUDY～

Y. Kanayama[1], A. Kaneko[2], N. Takahashi[3], T. Kato[4], Y. Hirano[5], Y. Hattori[2], N. Asai[3], N. Ishiguro[3], T. Kojima[3] on behalf of TBCR Study Group. *[1]Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [2]Orthopedic Surgery and Rheumatology, Nagoya Medial Center; [3]Orthopedic Surgery, Nagoya University Graduate school of Medicine, Nagoya; [4]Orthopedic Surgery, Kato Clinic, Okazaki; [5]Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan*

**Background:** Certolizumab pegol (CZP) is a polyethylene glycol (PEG)ylated Fc-free new anti-TNF α agent. However few data still reported clinical efficacy of CZP treatment in the routine practice.
**Objectives:** To evaluate the clinical efficacy of CZP in patients with Japanese active RA for 52 weeks.
**Methods:** Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed CZP from Tsurumai Biologics Communication Registry (TBCR) between May 2013 and October 2014 were enrolled.The final study cohort of 80 RA patients. We reviewed the methods about the improvement of CRP, MMP3, DAS28-ESR and SDAI which was an index of disease activity of RA using Wilcoxon signed-rank, test and the rate of remission patients at Week4,8,12,24 and 52 by LOCF method.
**Results:** The group of patients included 15 males and 65 females. The mean age was 60.1±14.2 years old; the disease duration was 9.7±9.3 years; the patients of receiving methotrexate (MTX) was 59 cases (74%); the MTX dose was 11.0±3.5 mg/week and b-DMARD naïve patients was 51 cases (64%). Clinical findings related to RA were as follows: mean tender joint count, 5.7±4.9; swollen joint count, 5.4±4.2; patient's and physician's global assessment of disease activity, 51.7±26.5 and 44.7±23.2mm; CRP, 1.9 ±2.2 mg/dL; ESR, 48.9±34.0 mm/h; MMP3, 224±172 ng/ml; the rate of rheumatoid factor positive patients was 77%; DAS28 (ESR), 5.01±1.31; and SDAI, 22.7±11.3. The mean CRP improved to 1.0±1.4, 0.8±1.3, 0.7±1.1 and 0.5± 1.0 at Week 4, 12, 24 and 52 ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$), mean MMP3 improved to 153±132, 165±169, 119± 131 and 105±96 at Week 4, 12, 24 and 52 ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$), the mean DAS-ESR improved to 3.70±1.35, 3.47±1.43, 3.47±1.46 and 3.41±1.45 at Week 4, 12, 24 and 52 ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$) and the mean SDAI improved to 12.3±9.2, 10.6±9.1, 10.7±9.4 and 9.9±9.6 at Week 4, 12, 24 and 52 ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$) significantly (Fig.1). At Week 4, 12, 24 and 52 the rate of patients who achieved remission were each 22.7, 28.9, 30.0, 31.3% and 7.4, 26.0, 30.2, 31.8% in DAS-ESR and SDAI criteria (Fig.2). Also at Week 4, 12, 24 and 52 the rate of patients who achieved low disease activity (LDA) were each 41.3, 47.3, 48.6, 55.2% and 55.9, 58.9, 60.4, 71.2% in DAS-ESR and SDAI criteria. We used logistic models in order to determine predictive factors to achieve remission and LDA at Week52. Even after adjusting for other risk factors, b-DMARD naïve and MTX combination

remained significant and independent to achieve remission at Week52 (HR 3.88; 95%CI 0.95–15.89; p=0.059)(HR 4.06; 95%CI 0.79–20.88; p=0.094), and b-DMARD naïve and DAS-ESR at baseline remained significant and independent to achieve LDA at Week52 (HR 6.41; 95%CI 1.41–29.17; p=0.016)(HR 0.47; 95%CI 0.25–0.87; p=0.017) in the multivariate logistic analysis.

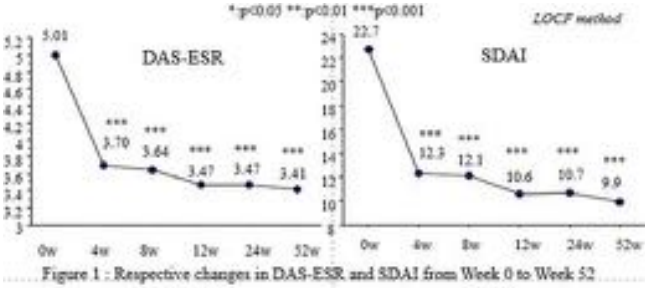

Figure 1 : Respective changes in DAS-ESR and SDAI from Week 0 to Week 52

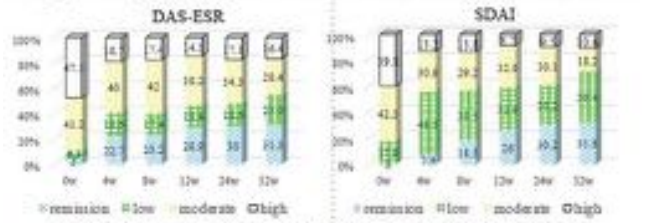

Figure 2: Time course of disease activity criteria using DAS-ESR and SDAI (Cut-off value was 5.1-3.2-2.6 and 23-11-3.3)

**Conclusions:** This study suggested that the new TNF-antagonist therapy of CZP was effective early and rapidly in patients with active Japanese RA. Especially lower DAS-ESR at baseline, MTX combination and b-DMARD naïve patients could expect higher efficacy of CZP treatment.

## AB0335 PREVALENCE OF RESIDUAL INFLAMMATION IN RHEUMATOID ARTHRITIS PATIENT AFTER ONE YEAR OF ADALIMUMAB THERAPY

Y.-C. Chen, J.-F. Chen, T.-T.C. Tien-Tsai Cheng. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

**Background:** Studies have previously demonstrated that ultrasound detected power Doppler (PD) activity (implying active synovial inflammation) may be present in a proportion of patients in clinical remission[1,2] and this can be used to accurately predict subsequent radiographic structural progression.[3] It may be hypothesised that such continued subclinical inflammation despite apparent remission as determined by traditional criteria may trigger a subsequent disease flare.

**Objectives:** Our study aimed to determine subclinical joint inflammation in patients with rheumatoid arthritis by power Doppler ultrasound in patients with rheumatoid arthritis at 12 months of adalimumab therapy.

**Methods:** Patients with RA who had received adalimumab therapy were enrolled. Patients underwent clinical, laboratory, and ultrasonographic assessment with power Doppler assessment of bilateral elbows (posterior recess), wrists (radiocarpal), second and third MCP joints (dorsal recess), MCP II and III, PIP II and III (dorsal recess), knee, ankle and MTPII and MTP V joint at 12th month.

**Results:** Power Doppler ultrasound was performed in 62 patients (87 females and 18 males; mean age: 57.09±9.96 years). The mean baseline DAS28 were 8.13±9.52. Baseline PD score (mean ±SD) were 0.852 ±1.051 and after 12 month of adalimumab therapy, the PD score decreased to 0.23±0.42. Ultrasound was performed 12th month at various parts, with the mean GS score: most prominent at right wrist (.810±.924) and left wrist (.774±.909) (Table).Logistical regression confirmed diabetes, positive anti-CCP, high DAS28 had more sonographic inflammation, while hypertension and positive rheumatoid factor (RF) had less sonographic inflammation. MTX, glucocorticoid and cyclosporin therapy had increased inflammation.

Table 1. Distribution of PD ultrasound score at various joints

| Joints | Mean score | SD | 95% Confidence interval |
|---|---|---|---|
| R't Elbow | 0.536 | 0.7854 | 0.325–0.746 |
| Left Elbow | 0.464 | 0.7126 | 0.273–0.655 |
| R't Wrist | 0.810 | 0.9246 | 0.608–1.010 |
| L't Wrist | 0.774 | 0.9098 | 0.576–0.971 |
| R't 2nd MCP | 0.268 | 0.5557 | 0.119–0.416 |
| L't 2nd MCP | 0.179 | 0.6062 | 0.016–0.340 |
| R't 3rd MCP | 0.125 | 0.3844 | 0.022–0.227 |
| L't 3rd MCP | 0.071 | 0.3223 | 0.015–0.157 |
| R't PIP II | 0.143 | 0.4013 | 0.035–0.250 |
| R't PIP IV | 0.071 | 0.2599 | 0.001–0.141 |

**Conclusions:** Our data confirm the evidence that even after 1 year of biological therapy, there were still persistent subclinical synovitis, more severe at wrist joints. Baseline high DAS28 and high PD activity had more prone to residual inflammation. So we recommended serial ultrasound follow up of PD ultrasound in patients with rheumatoid arthritis after adalimumab therapy.

## AB0336 ANTI-ATHEROSCLEROTIC EFFECTS OF BIOLOGIC AGENTS, TOCILIZUMAB AND ETANERCEPT, IN RHEUMATOID ARTHRITIS PATIENTS

Y. Suzuki, Y. Mitsuke, N. Ootsuki, H. Tsutani. *Internal Medicine, National Hospital Organization Awara Hospital, awara-city, Japan*

**Background:** Epidemic studies have shown that endothelial dysfunction and accelerated atherosclerosis lead to increased cardiovascular morbidity and mortality in patients with rheumatoid arthritis (RA). Cardio ankle vascular index (CAVI) measures arterial stiffness independent of blood pressure and it is superior to brachial ankle pulse wave velocity as an index of arterial stiffness. The aim of our study was to examine inhibitory effects on atherosclerosis of RA patients by biologic agents.

**Objectives:** We studied 36 RA patients with moderate or more disease activity as defined by the European League Against Rheumatism (EULAR) disease activity score (DAS28-ESR) in spite of MTX treatment.

**Methods:** We measured their CAVI before and after treatment with biologic agents (tocilizumab (TCZ) plus methotrexate (MTX)(n=11), etanercept (ETN) plus MTX (n=12), or MTX alone (n=13)) for one year.

**Results:** Each groups of characteristics (DAS 28, CRP, age, gender, disease duration) at baseline are no significantly different. Treatment with TCZ (9.62±1.56 and 9.05±1.42%, $P<0.05$), ETN (9.72±1.68 and 9.18±1.34%, $P<0.05$), but not MTX (9.88±1.63 and 9.79±1.87%; P=0.77) attenuated the CAVI significantly from baseline to 1 year follow-up.

**Conclusions:** TCZ and ETN but not MTX therapy may have a beneficial effect on preventing the progression of subclinical atherosclerosis and arterial stiffness. It remains unknown whether this effect is specific to TNF-alpha antagonists or relates to better control of inflammation irrespective of the disease modification strategy by which this is achieved.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4643

## AB0337 INCIDENCE RATE OF TUBERCULOSIS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TNF-α INHIBITORS-DATA FROM THE SLOVENIAN NATIONAL BIORX.SI REGISTRY

Ž. Rotar, M. Tomsic on behalf of Slovenian Rheumatologists. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

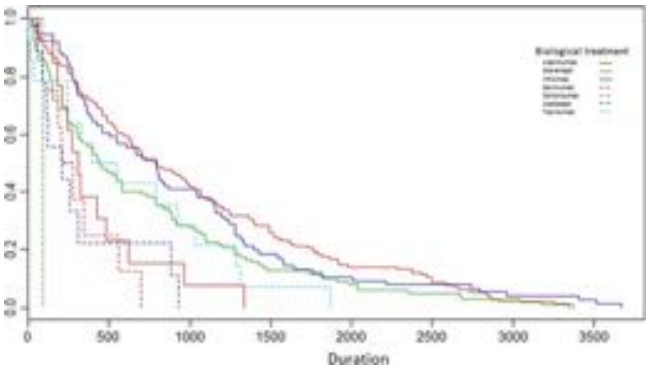
**Background:** Treatment with TNF-α inhibitors (TNFi) is associated with an increased incidence rate (IR) of tuberculosis (TB).[1] Proper screening can reduce TB IR.[2,3] Recent reports suggest comparable TB IR for certolizumab (CZP) and monoclonal TNF-α inhibiting antibodies adalimumab ADA, golimumab (GOL) and infliximab (IFX) (0.47–0.69 vs 0.29–0.50 per 100 person years (PY), respectively).[4] Etanercept (ETA) was associated with a TB IR of 0.009–0.08 per 100 PY.[5–7] In February 2012 we showed that in our setting with a background annual TB IR of 8.4 per $10^5$ persons and stringent screening for latent tuberculosis infection prior to the initiation of the first TNFi since 2002 a TB IR of 0.16 (95% CI 0.02–0.58) per 100 PY in RA patients treated with TNFi.[8]

**Objectives:** To compare the TB IR in patients treated for RA with different TNFi.
**Methods:** In February 2015 we cross-linked the data from the mandatory BioRx.si and the national TB registries to identify cases of TB in patients who were ever treated with TNFi to avoid underreporting. TB IR for RA patients were calculated and compared for different TNFi.
**Results:** At the time of data extraction the BioRx.si contained data for 1693 RA, ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients treated with at least one TNFi for 4574 PY. There were no TB cases among the patients with AS and PsA. In 945 RA patients treated with TNFi for 2453 PY (41% ADA, 9% CZP, 36% ETA, 4% GOL, 10% IFX) 5 cases of TB were identified (Table 1) which translates into an overall IR of 0.20 (95%CI 0.07–0.47) in RA patients. There were no TB cases in RA patients on GOL or IFX, but 3 on CZP, 1 on ADA, and 1 on ETA. The TB IR for CZP was 1.39 (95% CI 0.29–4.02) per 100 PY which is significantly higher than TB IR for ADA at 0.10 (95% CI 0.002–0.55; p=0.002) per 100 PY or ETA at 0.11 (95% CI 0.003–0.63; p=0.005) per 100 PY or all TNFi other than CZP combined at 0.09 (95% CI 0.01–0.32; p=0.006) per 100 PY.

Table 1

| Age (years) | Sex | TST (mm) | CXR | QF | CP | TNFi | MP ever | MP (mg qd) |
|---|---|---|---|---|---|---|---|---|
| 54 | F | 18 | – | – | yes | ETA | yes | 8 |
| 57 | F | 20 | – | + | yes | CZP | yes | 4 |
| 62 | M | 0 | – | ND | no | ADA | yes | 4 |
| 70 | F | 10 | – | – | no | CZP | no | 0 |
| 80 | F | 0 | – | ND | no | CZP | yes | 4 |

F, female; M, male; MP, methylprednisolone; ND, not done; WNL, within normal limits; pts, patients; TNFi, tumor necrosis factor inhibitor; ADA, adalimumab; CZP, certolizumab; ETA, etanercept; RA, rheumatoid arthriti;, CP, tuberculosis chemoprophylaxis; TST, tuberculin skin test; QF, Quantiferon TB Gold test; CXR, chest X-ray suggestive of tuberculosis.



**Conclusions:** In our TNFi treated observational RA cohort, admitting all the shortcomings of the registry data, we observed a very strong signal suggesting a significantly higher TB IR in patients treated with CZP than those treated with any other TNFi.

## Rheumatoid arthritis - other biologic treatment

### AB0338 SURVIVAL OF BIOLOGICAL DRUGS IN THE TREATMENT OF CHRONIC INFLAMMATORY ARTHROPATHIES

A. Martin Vila[1], R. Melero Gonzalez[2], N. Martínez López de Castro[1,3], M. Álvarez Payero[1], M.R. Rodriguez[1], F. Maceiras Pan[2,3], C. Mouriño[2,3], M. Rodríguez López[2,3], I. Hernández Rodriguez[2], C. Barbazán Álvarez[2], M. Samartin Ucha[1,3], V. Balboa Barreiro[4], J. De Uña Álvarez[4], G. Piñeiro Corrales[1], J.M. Pego Reigosa[2,3]. *[1]Pharmacy; [2]Rheumatology, Eoxi Vigo; [3]Iridis Group, IBI; [4]Statistic, U.Vigo, Vigo, Spain*

**Objectives:** To analyze the survival of treatment lines with different biologics in a cohort of patients diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (AP), ankylosing spondylitis (AS) and other spondyloarthropathies (O).
**Methods:** Retrospective observational study.All patients who had been treated with a biological drug for at least six months during the period between 01/01/2009 and 31/08/2014, for any of the previously specified indications were included.In addition to demographic data, all lines of treatment received from the diagnosis and the duration of them were collected.It has been analyzed whether there were differences in the duration of treatment depending upon the drug and the disease. A survival analysis of all lines of treatment was performed using the Kaplan-Meier curves for each drug, including those who had not finished.It was represented on the vertical axis the percentage of patients who had each treatment and in the other axis, duration in days.It was analyzed whether there were differences between these curves using the log-rank test.
**Results:** We studied 484 patients with a mean age of 56 years (SD 14.4), 54.3% women. 742 lines of treatment were analyzed. Drug distribution: Adalimumab 344, etanercept 219, infliximab 96, golimumab 20, certolizumab 6, abatacept 20 and tocilizumab 26. In the cutoff point of the study (31.AUG.2014) had completed 342 of these lines.
The average duration of treatment in days (± SD) was calculated with the following results: Adalimumab: 1034 (±864)days; Etanercept: 735 (±768)days; Infliximab: 959 (±845) days; Golimumab: 302 (±225)days; Certolizumab: 90±0 days; Abatacept: 429 (±360)days; Tocilizumab: 328 (±337)days. The average length of treatment depending on the pathology (± SD) was also calculated. AR: 989 (±853)days; AP: 975 (±843)days; EA: 766 (± 677)days and O: 912 (±920)days.Given the standard deviations found, a survival analysis was performed using the Kaplan-Meier curves.Significant difference were observed when comparing the drugs 2–2 for the following pairs:adalimumab and infliximab have longer lines comparing to golimumab, certolizumab, abatacept and tocilizumab ($p<0.05$) and etanercept longer than golimumab, certolizumab and tocilizumab ($p<0.01$).

**Conclusions:** The duration of treatment lines is variable in all drugs and for all conditions tested. No differences were found with regard to the length of the lines between the three drugs analyzed with a longer time since its commercialization: adalimumab, etanercept and infliximab.
Supported by an unrestricted grant from Pfizer.

### AB0339 CORRELATION BETWEEN CLINICAL AND ANTI-DESTRUCTIVE EFFECTS OF RITUXIMAB (RTM) AND B-CELLS COUNT IN RHEUMATOID ARTHRITIS (RA) PATIENTS

A.V. Pivanova, G. Lukina, Y. Sigidin, A.V. Smirnov, K.Kh. Kuzikyants, A.Yu. Kuznetsova. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Rheumatoid arthritis is a chronic autoimmune disease characterized by inflammation of the synovial tissue and destruction of the cartilage and bone. Antirheumatic treatment plays a important role in controlling the inflammation of rheumatoid arthritis and in minimizing joint damage. Rituximab has been successfully used to treat rheumatoid arthritis. It is a chimeric monoclonal antibody that targets the CD20 molecule expressed on the surface of B cells. Noteworhty, clinical and antidestructive effects often did not coincide.
**Objectives:** To study the impact of B-cells depleting therapy (RTM) on joint destruction in correlation with clinical effects and B-cells counts.
**Methods:** The study included 61 RA pts (average disease duration 10,1±7,7 y., mean DAS28 6,3±0,94, RF-positive 87%, ACCP–positive 93%) undergoing RTM therapy. Clinical effect was scored by EULAR criteria, radiographic progression was assessed using Sharp/van der Heijde (SvH) modified scoring method. B-cell level was measured with flow cytometry.
**Results:** By Week 48 after 2 RTM courses good response was documented in 29,7% pts, good and satisfactory in 85,3%; remission was achieved in 14,6% pts. There was no radiographic progression in remission pts., in 83% of pts with low disease activity and in 33% - with moderate disease activity. Of note, further progression in joint space narrowing was more pronounced than bony tissue destruction - in 32% and 25%m respectively. Clinical and anti-destructive effects were often dis-matching: bone destruction was abrogated without any clinical improvement in 54% of pts. There was no significant difference in clinical effects of RTM dosing regimens (1000mg x2 or 500mg x2). More potent anti-destructive effect was documented in pts getting higher RTM dose values. No significant influence of B-cells depletion on radiographic progression of the disease was noticed. Although, in RA pts achieving remission B-cell depletion was more notable (Median, IQR 0% (0–1.133) as compared to pts with active disease (Median, IQR 0.8% (0.2–4.8, p 0.001).
**Conclusions:** Clinical and anti-destructive effects of B-cell depletion therapy are not always equivalent. Therapeutic effect of two dosing regimens was similar, but the anti-destructive one was more pronounced with higher RTM doses. Radiographic progression did not show any correlation with the degree of B-cells depletion. Most pronounced B-cells depletion was documented in pts achieving remission.

## AB0340 TAPERING STRATEGY IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TOCILIZUMAB

C. Tornero[1], C. Plasencia[1], D. Pascual[2], T. Jurado[2], I. Monjo[1], M.B. Paredes[1], E. Moral[1], A. Pieren[1], L. Nuño[1], G. Bonilla[1], D. Peitedo[1], E.M. Mola[1], A. Balsa[1]. *[1]Rheumatology; [2]Immunology, Hospital La Paz, Madrid, Spain*

**Background:** Clinical trials have demonstrated the efficacy of Tocilizumab (TCZ) for patients with rheumatoid arthritis (RA). Several studies have demonstrated that dose tapering of TNF-inhibitors is a feasible therapeutic option in rheumatic patients with low disease activity (LDA). Nevertheless, few reports analyse the effectiveness of dose-tapering of TCZ.
**Objectives:** To evaluate the clinical outcome and incidence of flares in patients with RA in remission or LDA under a tapering strategy with TCZ and to analyse the influence of the tapering on serum drug levels.
**Methods:** Of a cohort of 34 adult patients with RA under therapy with TCZ, 13 patients with sustained LDA or remission (DAS 28-ESR <3,2) under a tapering strategy were included. Clinical disease activity (DAS-28-ESR, CDAI and SDAI), serological data (C-reactive protein, erythrocyte sedimentation rate) and serum TCZ levels were evaluated at the visit prior to starting tapering strategy (V0) and at the last visit available during a three-year follow-up period (LV). The tapering strategy consisted in a progressive interval prolongation and/or dose reduction. A flare was defined as an increase of the DAS28 greater than 3.2 plus a delta-DAS28 (related to pre-tapering DAS28) lower than -0.6. The number of flares, time to first flare and the activity in the worst flare were collected. In the case of a flare, the concomitant therapy and TCZ dose could be intensified. Blood samples were collected just before the infusion and serum drug levels were measured by ELISA.
**Results:** The baseline demographic and clinical characteristics are shown in Table 1. No differences in the clinical activity (DAS28: 2,28± 0,8 at V0 vs 2,5±0,7 at LV, p=0,25; CDAI 4,71: ±5,1 at V0 vs 5,71±5,1 at LV p=0,08; SDAI (4,99±5,3 at V0 vs 5,0 ±4,8 at LV, p=0,052), number of swollen joints (1,69±3,2 at V0 vs 1,46±1,8 at LV; p=0,091) and tender joints (0,69± 1,1 at V0 vs 0,62±0,96 at LV; p=0,243) and acute-phase reactants (CRP: 0,48±0,6 at V0 vs 0,54±0,6 at LV, p=0,219; ESR: 7,69±3,1 at V0 vs 10,3±5,4 at LV, p=0,152) between V0 and LV were observed. The decrease of drug levels between V0 and LV was not significant (15,4±9,31 vs 3,02±5,99, p=0,867). During the follow-up period, 6 (43%) patients presented flares. The number of flares after the tapering strategy was 1,2±1,6 and the time to the first flare was 1±0,4 years. The following clinical and disease activity data and serum TCZ levels were registered at the worst flare: STJ: 6,7± 7,4 and TJC: 1,83±1,2; DAS28: 3,99±0,6, CDAI: 14,7± 8,2 and SDAI: 14,5±9,08; TCZ levels: 0,86±1,78. Most patients after having a flare (4/6) reached remission or LDA at the end of the study, and no significant differences in LDA were observed between those with or without flares (DAS-28 LV<3,2:4/11 (36,4%) vs 7/11 (63,6%), p=0,097; CDAI LV <10: 4/10 (66,7%) vs 6/10 (85,7%), p=0,42; SDAI LV <11: 4/11 (36,4%) vs 7/11 (63,6%), p=0,097, respectively). All of the patients continued on tapering strategy and no patients dropped out because of inefficacy.

## AB0341 FAVORABLE EFFECTS OF SIRUKUMAB TREATMENT ON PHYSICAL FUNCTION AND REDUCTIONS IN MORNING STIFFNESS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

C. Thorne[1], T. Takeuchi[2], G. Karpouzas[3], K. McQuarrie[4], S. Sheng[4], W. Xu[4], S. Peterson[4], R. Ganguly[5], C. Han[4], K. Fei[4], B. Hsu[4]. *[1]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [2]Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan; [3]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA; [4]Janssen Research & Development, LLC, Spring House, PA; [5]GlaxoSmithKline, King of Prussia, PA, United States*

**Background:** Improvement in physical function and morning stiffness are important goals of rheumatoid arthritis (RA) treatment. Sirukumab, a selective human anti-IL6 monoclonal antibody, has recently been evaluated in a global, Phase 3 study for the treatment of RA in patients (pts) with active disease that did not respond adequately to conventional, synthetic disease-modifying antirheumatic drugs (DMARDs).
**Objectives:** To evaluate the effects of sirukumab treatment on physical function and morning stiffness in pts with active RA refractory to DMARDs.
**Methods:** In this study, eligible pts with active RA and inadequate response to DMARDs were randomized (1:1:1) to treatment with sirukumab SC 50mg q4w, sirukumab SC 100mg q2w, or placebo SC q2w. In the placebo group, pts with insufficient (<20%) improvement at Wks 18 or 40 or still on placebo at Week 52 were re-randomized to receive 1 of the 2 sirukumab doses. Pts completed the HAQ-DI at baseline (BL) and 16 subsequent study visits from Week 2 to 52. A clinically meaningful improvement in HAQ-DI from BL was defined as a change (reduction) of 0.22 in HAQ-DI,[1] and a normal HAQ-DI score was defined as ≤0.5. The average duration of daily morning stiffness during the previous week in minutes (0–1440 minutes) was evaluated at the same visits as the HAQ-DI.
**Results:** A significantly greater improvement from BL in the mean HAQ-DI score was observed for both doses of sirukumab compared with placebo at all time points from Wk 2 through to Wk 52 (all $P \leq 0.006$; Table). Improvements from BL in the HAQ-DI score were clinically meaningful (change of –0.22) for a significantly greater proportion of pts with sirukumab (both dose regimens) compared with placebo from Wk 4 onwards (all $P<0.001$). At Wks 24 and 52, a significantly greater proportion of pts achieved a HAQ-DI score of ≤0.5 with both doses of sirukumab compared with placebo (all $P<0.001$). In addition, there was a significantly greater reduction from BL in the duration of morning stiffness with both doses of sirukumab compared with placebo at Wks 16, 24, and 52 (all $P \leq 0.022$).

Table 1. HAQ-DI and morning stiffness outcomes at week 52[a]

| Outcome | Placebo (n=556) | Sirukumab 50mg q4w (n=557) | Sirukumab 100mg q4w (n=557) |
|---|---|---|---|
| HAQ-DI, mean (SD) change from BL | –0.23 (0.57) | –0.45 (0.61)[b] | –0.47 (0.60)[b] |
| Clinically meaningful improvement from BL in HAQ-DI, n (%)[c] | 263 (47.1) | 353 (63.4)[b] | 359 (64.5)[b] |
| HAQ-DI ≤0.5, n (%) | 69 (12.4) | 153 (27.5)[b] | 163 (29.3)[b] |
| Duration of daily morning stiffness (min), mean (SD) change from BL[d] | –67.3 (196.98) | –99.1 (233.82)[e] | –97.7 (231.53)[e] |

[a]n values are based on initial treatment assignment. [b]$P<0.001$ vs placebo. [c]Minimum clinically meaningful improvement, change of –0.22 from BL. [d]Placebo, n=552; sirukumab 50 mg q4w, n=552; sirukumab 100 mg q2w, n=555. [e]$P \leq 0.022$ vs placebo.

**Conclusions:** Sirukumab treatment in pts with active RA refractory to DMARDs was associated with early, sustained, and clinically meaningful improvement in both physical function and morning stiffness, which are key treatment goals for pts with RA.

## AB0342 STUDY ON ABATACEPT AND TOCILIZUMAB ATTENUATION (SONATA) IN RHEUMATOID ARTHRITIS PATIENTS: A RETROSPECTIVE, EXPLORATIVE COHORT STUDY

C. Bouman[1], L. Tweehuysen[1], D. Haverkort[1], C. van den Ende[1], J. Fransen[2], A. van der Maas[1], A. den Broeder[1]. *[1]Rheumatology, Sint Maartenskliniek; [2]Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Disease activity guided tapering of tumor necrosis factor inhibitors (TNFi) has been shown to be feasible, safe and cost-effective in rheumatoid arthritis (RA) patients with stable low disease activity. However, data on biologics with another mode of action, like abatacept (ABA) and tocilizumab (TCZ), is scarce. Moreover, most studies are clinical trials, leaving uncertainty on the feasibility of tapering in daily clinical practice.
**Objectives:** To assess the difference in mean change (∆) between baseline and 12 months follow-up in DAS28 and HAQ-DI between eligible RA patients that attempted to taper ABA or TCZ compared to eligible patients that did not attempt to taper.
**Methods:** In this retrospective, explorative cohort study, data on clinical outcome measures were collected from all patients eligible to taper ABA or TCZ at the outpatient clinic of a specialized rheumatology hospital. Patients were eligible when fulfilling the 1987 and/or 2010 ACR RA criteria and/or clinical diagnosis by the treating rheumatologist, and when reaching low disease activity (DAS28 $<3.2$) after $\geq 6$ months of treatment with ABA or TCZ. Patients that attempted to taper were included in the tapering group and patients that did not attempt to taper were included in the control group. Tapering was done according to the local protocol, in which the dose was stepwise reduced or the injection interval was prolonged until discontinuation. Successful tapering was defined as using ABA or TCZ on lower than baseline dose and having low disease activity at 12 months. Outcome measures were mean ∆DAS28 and mean ∆HAQ-DI (positive figures mean increase) and differences between groups were tested using an (unpaired) t-test.
**Results:** From January 2007 until June 2015, 320 patients were treated with ABA and/or TCZ of whom 58 patients could be included (figure 1). Tapering was successful in 37% of ABA patients and 35% of TCZ patients. Mean ∆DAS28 at month 12 was 0.92 (95% CI -0.46 to 2.31) in the ABA tapering group versus 1.32 (95% CI 0.00 to 2.65) in the control group (p=0.05)and 0.31 (95% CI -0.24 to 0.85) in the TCZ tapering group versus 0.28 (95% CI -0.59 to 1.16) in the control group (non-significant (NS)). Mean ∆HAQ-DI at month 12 was 0.16 (95% CI -0.48 to 0.89) in the ABA tapering group versus -0.41 (95%CI -0.51 to 0.69) in the control group (NS) and 0.02 (95% CI= -0.40 to 0.44) in the TCZ tapering group versus 0.24 (95% CI= -0.31 to 0.79) in the control group (NS).

**Figure 1.** Flow chart with patient disposition

**Conclusions:** Tapering of ABA or TCZ appears to be feasible in RA patients in daily clinical practice, with no significant difference in change of disease activity or functioning between patients that tapered and patients that did not taper, although confidence intervals are relatively large in this small study. However, the percentage of successful tapering is lower compared to studies on tapering of TNFi. Also, numbers of patient that start tapering are suboptimal, possibly explained by the perception of a more refractory patient population in which treatment is continued longer, since ABA and TCZ are reserved for patients that fail on TNFi in our clinic.

## AB0343 TREATMENT OF RHEUMATOID ARTHRITIS PATIENTS WITH PARENTERAL STAPHYLOCOCCAL PROTEIN A (PRTX-100): AN OPEN-LABEL SINGLE-SITE EXTENSION TRIAL

C. Wiesenhutter[1,2]. *[1]Rheumatology, Coeur d'Alene Arthritis Clinic, Coeur d'Alene; [2]Department of Family Medicine, University of Washington, Seattle, United States*

**Background:** Staphylococcal protein A (SpA) is a bacterial B-cell superantigen that binds with high affinity to the Fc region of most immunoglobulins (Igs) and to the Fab framework region of Igs in the $V_H3$ gene family. PRTX-100, a highly purified form of SpA, has exhibited an acceptable safety profile when administered intravenously to small numbers of subjects at doses of up to 12 μg/kg.[1] SpA forms multimeric Ig complexes (MIgCs) with human antibodies which interact with and modulate cells of the monocytic lineage via FcR1 receptors.[2] However, the effects of SpA in rheumatoid arthritis (RA) are not fully understood.
**Objectives:** To expand the safety experience of parenteral PRTX-100 given to patients with RA, including retreatment. To describe PRTX-100 immunogenicity and pharmacodynamics as well as the feasibility of ultrasound joint count measurements.
**Methods:** This open-label trial enrolled 11 seropositive patients with RA who had previously participated in a Phase I trial[1] and responded (n=9) or had been given placebo (n=2). Patients were treated with 6 μg/kg PRTX-100 with four weekly intravenous infusions followed by five monthly infusions. Safety and disease activity were monitored monthly. Anti-PRTX-100 antibodies were measured. Patients were evaluated by standard clinical assessments and by ultrasound power Doppler joint counts (UPD).[3] Pharmacodynamic alterations in MIgC concentrations were assessed via cryoglobulin levels.
**Results:** The preliminary results indicated that PRTX-100 exhibited an acceptable safety profile. Adverse events (AEs) included fatigue (9% of patients), and headache (9%). Worsening of RA following initial infusions were observed in 82% of patients but diminished with subsequent infusions of PRTX-100. One patient discontinued therapy due to worsening of RA symptoms. One patient discontinued treatment due to perceived lack of improvement. No serious AEs were reported. At study day 196, 1 month after final infusion, all 11 patients demonstrated a reduction of DAS28CRP. There was a reduction in the UPD score of 26% (p=0.0054) and a correlation between the UPD and DAS28CRP of r=0.630 ($p<0.0001$). In addition, 55% of patients demonstrated increases in their MIgCs during treatment
**Conclusions:** Treatment with PRTX-100 in nine patients for the second time and two patients for the first time demonstrated an acceptable safety profile. A single subject discontinued the trial due to worsening of RA symptoms, although RA disease activity was improved in the majority of patients by the end of the study compared to baseline levels. Some subjects exhibited an increase in MIgCs after infusion of PRTX-100. The incorporation of ultrasound joint count methodology into small open-label trials might offer enhanced assessment of clinical efficacy.

## AB0344 A RETROSPECTIVE NON-INTERVENTIONAL STUDY ON THE USE OF BIOLOGICS IN THE TREATMENT OF AUSTRALIAN PATIENTS WITH RHEUMATOID ARTHRITIS-THE REAL STUDY

D. Nicholls[1], H. Griffiths[2], R. Barrett[3], P. Button[3], M. Truman[3], P. Bird[4], L. Roberts[5], K. Tymms[6], G. Littlejohn[5]. *[1]Coast Joint Care, Maroochydore; [2]Barwon Rheumatology Service, Geelong; [3]Roche Products, Pty. Limited, Dee Why; [4]University of NSW, Sydney; [5]Monash Rheumatology Clayton, Clayton; [6]Canberra Rheumatology, Canberra, Australia*

**Background:** Medication choices offered to rheumatoid arthritis (RA) patients are based in part on results from randomised controlled trials (RCTs). While

these trials form a valuable evidence-base for rational prescribing, extrapolation of RCTs data to every day clinical practice is hampered by the highly selected patient (pt) groups that are accepted into RCTs. The comparative effectiveness of biologic treatment regimens in a real world Australian population is unknown.
**Objectives:** To assess effectiveness of biologic (b) DMARDs, as monotherapy, in combination with conventional (c) DMARDs other than MTX and in combination with cDMARDs regimens including MTX in the Australian OPAL database.
**Methods:** A retrospective non-interventional study. Data was extracted from participating Australian rheumatology centres using point of care software. Pts ≥18 years (yrs) with probable/definite RA, who had been prescribed a bDMARD and have had a visit recorded 12 months prior to and at least 12–40 weeks (wks) after commencement of a bDMARD were included. Bouts of treatment (BTs) refer to cycles of continuous, individual biologics prescribing in individual pts; if pts change biologics then this was defined as a new BT. Wk12 (-4/+8) analyses included any measurement between wk8 and wk20 post bDMARDs initiation and wk24 (-4/+8) included any measurements between wk20 and wk32.
**Results:** 2971 pts met criteria; median age 60 yrs (min 19, max 94) and median disease duration prior to 1st bDMARD of 6.1 yrs (min 0.2, max 58.3). Median number of bDMARDs per pt was 1 (min 1, max 8). At least 1 bDMARD was taken by 2971 pts, 1177 received 2 bDMARDs and 507 received 3 or more. There were 4923 bDMARD BTs recorded for this population with median treatment duration of 0.7 yrs (min 0, max 11.8). Median duration of 1st bDMARD (n=2971 pts)=0.8 yrs (min 0, max 11.8); 2nd bDMARD (n=1177)=0.6 yrs (min 0, max 9.9) and 3rd bDMARD (n=507)=0.6 yrs (min 0, max 6.4). The most commonly used bDMARDs were etanercept (n=1358), adalimumab (n=1098), abatacept (n=642) and tocilizumab (n=629); median duration of BTs=0.7 (min 0, max 11.8), 0.8 (min 0, max 10.5), 0.7 (min 0, max 6.1) and 1.0 (min 0, max 7.4) yrs respectively. bDMARD monotherapy (no cDMARD overlap) was administered in 10% BTs (n=488); bDMARDs + MTX +/– other cDMARD(s) were administered in 74% BTs (n=3639) and bDMARDs + cDMARD(s) other than MTX were administered in 16% BTs (n=796). Median CDAI and DAS28 by biologic presented in Table 1.

**Conclusions:** The majority in this cohort of Australian RA pts receive 1 line of bDMARD. Pts tend to persist longer on 1st bDMARD than subsequent biologics. bDMARDs as monotherapy or in combination (+/– MTX) are valid treatment strategies in the real world.

## AB0345 COMPARATIVE EFFECTIVENESS OF BIOLOGIC AGENTS FOR PATIENTS WITH RHEUMATOID ARTHRITIS – PRIMARY ANALYSIS FROM THE US CORRONA CERTAIN STUDY

D.A. Pappas[1,2], A. John[3], J.M. Kremer[2,4], G.W. Reed[2,5], T. Sommers[2], J.D. Greenberg[2,6], J.R. Curtis[7]. *[1]Columbia University, New York; [2]Corrona, LLC, Southborough; [3]Genentech, Inc, South San Francisco; [4]Albany Medical College and The Center for Rheumatology, Albany; [5]University of Massachusetts Medical School, Worcester; [6]NYU School of Medicine, New York; [7]University of Alabama at Birmingham, Birmingham, United States*

**Background:** Comparative effectiveness research (CER) can inform decisions regarding the choice of biologics for the treatment of RA.
**Objectives:** To compare the efficacy of tumor necrosis factor inhibitors (TNFis) and non-TNFis (nTNFis) in real-world patients with RA previously treated with ≥1 TNFi.
**Methods:** CERTAIN was a CER study nested within the US Corrona registry.[1] Adult patients with RA with moderate to high disease activity (CDAI >10) starting a TNFi or nTNFi (physician-driven choice of agent) were enrolled. For the primary analysis, only patients previously treated with ≥1 TNFi were included. The primary outcome was achievement of low disease activity (LDA) at 12 months (CDAI ≤10). A propensity score (PS) for the probability of treatment with a TNFi vs nTNFi was generated; patients outside the common area of support in the PS were excluded. Response rate was modeled using a mixed-effect logistic regression model with start of a biologic as the unit of analysis, adjusting for a priori and imbalanced baseline factors and to account for the clustering of patients within practice sites. As a sensitivity analysis, patients were matched 1:1 on the PS within each site.
**Results:** Of the 2795 biologic starts captured, 1142 biologic naive and 562 nTNFi experienced were excluded, leaving 1091 biologic starts in 998 patients for analysis of response after a TNFi. After PS trimming, 1081 starts (566 [52.4%] nTNFi and 515 [47.6%] TNFi) remained. Patients who started nTNFis were significantly more likely to have longer disease duration, higher patient fatigue scores, Medicare insurance and more prior TNFi use. At 12 months, 29.4% of nTNFi and 24.3% of TNFi initiators were in LDA. In the adjusted analysis (Table), patients on nTNFis were significantly more likely to achieve LDA. However, when adjusting for site clustering, the results were no longer significant.

Table 1. Adjusted ORs of achieving LDA after failure of ≥1 prior TNFi

| nTNFi vs TNFi Initiation* | OR (95% CI) | *P* Value |
|---|---|---|
| Partially adjusted logistic regression model (n=963) | 1.55 (1.12–2.13) | 0.008 |
| Fully adjusted mixed model with adjustment for site q clustering (n=963) | 1.17 (0.82–1.67) | 0.382 |
| Sensitivity analysis, 1:1 matching on PS within site (n=292) | 0.81 (0.48–1.36) | 0.428 |

LDA, low disease activity; nTNFi, non-TNFi; OR, odds ratio; PS, propensity score; TNFi, tumor necrosis factor inhibitor. *Adjusted for number of prior TNFis, duration of RA, seropositivity, fatigue, baseline CDAI, insurance status, baseline methotrexate and steroid use.

**Conclusions:** In this large, real-world study, after ≥1 TNFi failure, switch to a nTNFi was favored over treatment with a subsequent TNFi, but was not statistically significant after adjusting for site clustering. Results warrant further study.

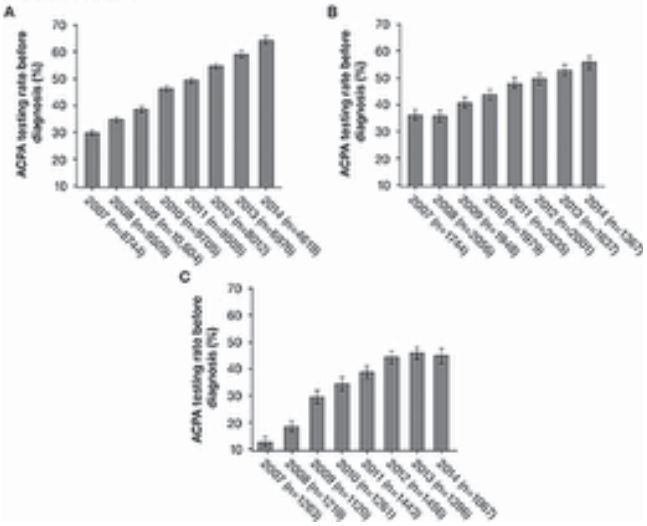
## AB0346 TESTING FOR ANTI-CITRULLINATED PEPTIDE ANTIBODIES IN US CLINICAL PRACTICE SETTINGS IN PATIENTS NEWLY DIAGNOSED WITH RA – DATA FROM THREE DATABASES BETWEEN 2007–2014



E. Alemao, Z. Guo, L. Burns. *Bristol-Myers Squibb, Princeton, United States*

**Background:** Current clinical guidelines recommend testing for anti-citrullinated protein antibodies (ACPA) at the time of RA diagnosis.[1] However, there is a lack of information about the frequency of ACPA testing at RA diagnosis or thereafter.
**Objectives:** To describe the frequency of ACPA testing over time and to investigate the potential differences in demographics, co-morbidities and hospitalizations between patients who received ACPA tests versus those who did not.
**Methods:** Data from the three following US commercial healthcare claims databases were analysed: IMS PharMetrics Plus (database A), Optum Clinfor-

matics Data Mart (database B) and Optum Clinformatics Data Mart Medicare (database C). Patients with two diagnosis codes for RA from 1 January 2007 to 31 December 2014, treatment with a DMARD, and continuous enrolment for at least 12 months before and 6 months after the index date were included. ACPA and RF testing claims identified by current procedural terminology codes were included in the analysis. ACPA testing rates were evaluated as number of patients with tests divided by total number of patients with and without tests. Multinomial logistic regression was used to evaluate baseline covariates associated with single ACPA test before the index date, single ACPA test after the index date and multiple ACPA tests.

**Results:** A total number of 67,674 patients newly diagnosed with RA in database A (age 18–64 years), 14,767 in database B (age 18–64 years) and 10,225 in database C (age ≥65 years) met the study inclusion criteria. The overall ACPA testing rate (95% CI) was 70.6% (70.3, 70.9) in database A, 72.2% (71.5, 72.9) in database B and 63.5% (62.5, 64.4) in database C. The ACPA testing rates increased from 2007 to 2014 for all three databases (Figure). The corresponding RF testing rates were 75.4% (75.1, 75.7), 85.1% (84.5, 85.6) and 77.8% (77.0, 78.6), respectively. Patients tested and not tested had similar characteristics, with a standardized difference of >0.10 in only a few co-morbidities. The odds ratio (OR) for pre-diagnosis testing for each year increase from 2007 to 2014 was 1.26 (95% CI: 1.25, 1.28) in database A, 1.19 (1.17, 1.22) in database B and 1.27 (1.23, 1.31) in database C. Women were more likely to have multiple tests in database A (OR: 1.15; 95% CI: 1.08, 1.21) and in database B (OR: 1.29; 95% CI: 1.14, 1.45), but not in database C (OR: 0.93; 95% CI: 0.80, 1.08). Patients who received ACPA tests, versus those who did not, had a lower rate of 1-year hospitalization; the hazard ratio (95% CI) after adjustment for covariates was 0.76 (0.71, 0.80) in database A, 0.86 (0.75, 0.98) in database B and 0.76 (0.68, 0.85) in database C.

**Figure 1.** ACPA Pre diagnosis Testing Rate 2007-2014 (A=PharMetrics; B=Optum; C=Optum Medicare

**Conclusions:** The ACPA testing rate, especially pre-diagnosis testing, increased significantly from 2007 to 2014. Women aged 18–64 years were more likely to have multiple tests. A slightly lower rate was seen in RA patients ≥65 years old.

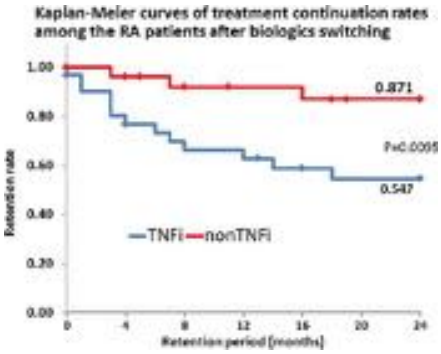
## AB0347 THE RETENTION RATES OF THE SECOND BIOLOGIC AGENTS IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO TNFα INHIBITORS, SINGLE-CENTER, RETROSPECTIVE, OBSERVATIONAL STUDY

E. Kikuchi, K. Uekubo, N. Aoki, T. Yoshioka, T. Okai. *Center for Rheumatology and Joint Surgery, Kawakita General Hospital, Tokyo, Japan*

**Background:** There are few data about the safety of biologics switching for rheumatoid arthritis in clinical practice conditions.



**Objectives:** To analyze the retention rates of biologics switch therapies for rheumatoid arthritis patients after inadequate response to TNFα inhibitors.

**Methods:** Data was collected retrospectively from medical records of RA patients in our center. We divided the RA patients with inadequate response to TNFα inhibitors into the two groups. The first group is consists of the patients who switched to other TNFα inhibitors. The other is consists of the patients who switched to non-TNFα inhibitors. We analyzed the retention rate of each group by Kaplan-Meier curves and log-rank test.

**Results:** In the "*another TNFα inhibitor*" group (31 cases, 59.4±14.8 years, women: 90.3%, ACPA-positive 74.2%, MTX use 93.3%, oral steroid use 30.0%), infliximab (IFX): 11, etanercept (ETN): 7, adalimumab (ADA): 9, golimumab (GLM): 2 and certolizumab pegol (CZP): 2 are administered as the first biologics, discontinued due to adverse events: 4, inadequate efficacy:26 and other: 1 respectively), IFX: 4, ETN: 17, ADA: 3, GLM: 2 and CZP: 5 were chosen as the second biologics. The cumulative retention rates of the second biologics in 12 and 24 months were 0.628 and 0.547 respectively. The reasons for discontinuation of secondary used TNFα inhibitors were adverse events: 4 and inadequate efficacy: 9.

In the "*non-TNFα inhibitor*" group (27 cases, 64.0±14.2 years, women: 83.3%, ACPA-positive 92.6%, MTX use 57.7%, oral steroid use 30.8%, IFX: 8, ETN: 13, ADA: 4, GLM: 1 and CZP: 1 are administered as the first biologics, discontinued due to adverse events: 7, inadequate efficacy: 20 respectively), tocilizumab (TCZ): 8 and abatacept (ABT): 19 were chosen as the second biologics. The cumulative retention rates of the second biologics in 12 and 24 months were 0.920 and 0.871 respectively. Three TCZ used patients were discontinued biologics within 24 months due to adverse events: 2 and inadequate efficacy: 1.

There was a significant difference in the retention rates in the two groups (log-rank test, p=0.0095) (figure). In the "non-TNFα inhibitor" group, the cumulative retention rates of TCZ and ABT in 24 months are 0.822 and 1.000 respectively. There is no significant difference (log-rank test, p=0.277).

**Conclusions:** Our data suggested that non-TNFα inhibitors can be used for a long period for the RA patients with inadequate response to TNFα inhibitors.

## AB0348 A RETROSPECTIVE REVIEW OF DISPENSING OF CONCOMITANT GLUCOCORTICOIDS WITH BIOLOGICS PRESCRIBED FOR THE TREATMENT OF RHEUMATOID ARTHRITIS IN THE AUSTRALIAN POPULATION

G. Jones[1], S. Hall[2], G. Littlejohn[3], E. Chung[4], R. Barrett[5], P. Button[5]. *[1]Royal Hobart Hospital, Hobart; [2]Cabrini Medical Centre, Malvern; [3]Monash Medical Centre, Clayton; [4]Prospection, Eveleigh; [5]Roche Products, Pty. Limited, Dee Why, Australia*

**Background:** The treatment of Rheumatoid arthritis (RA) in Australia is consistent with the current international guidelines of starting a biologic (b) DMARD in combination with methotrexate (MTX) where possible and/or other synthetic DMARDs with or without glucocorticoids (GCs). There is limited data available on the effects of various bDMARDs on oral GCs consumption in a real world data setting and in the same patient population.

**Objectives:** The objective of the study was to investigate the usage of concomitant GCs with bDMARDs for the treatment of RA patients over time.

**Methods:** Concessional (government subsidised) RA patients ≥18 years of age for whom bDMARDs were first dispensed for their RA (between 01August 2010 and 31July 2013), and who were in the Australian Medicare 10% sample database provided by the Department of Health and Aging through an Australian healthcare consulting company (PROSPECTION) were followed for a period of 2 years (until 31 July 2015). bDMARDs included: abatacept (IV and SC), adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, and tocilizumab. Data were analysed using descriptive statistics for continuous variables and frequency counts for categorical variables. Individual anti-TNFs were equivalent in all analyses and therefore were combined for simplicity.

**Results:** Data from 269 patients were analysed. Of the patients who received oral GCs at some point during the study period (86%; n=230), 49% were ≥65 years old and 51% were 18–64 years old. The majority (81%) were females. For all patients, median dose of oral GCs was 4.1 (min 0, max 21) mg/day at one year prior to initiation of a bDMARD, 2.9 (min 0, max 22.2) mg/day and 2.0 (min 0, max 17.3) mg/day at 1 and 2 years, respectively, post-bDMARDs initiation. Daily GCs doses across the analysis time points and by drug group are presented in Table 1. Daily dose changes at 1–2 years post initiation of bDMARDs from 1 year before initiation of bDMARDs were statistically significant for all bDMARDs

(p<0.0001), all anti-TNFs (p<0.0001) and tocilizumab (p=0.0002). Percentage of patients who stopped GCs at any time post initiation of a bDMARD was 43% for all RA bDMARDs, 44% for all anti-TNFs, 27% for abatacept and 39% for tocilizumab. 31 percent of patients who remained on biologics for the observation period in the "all RA bDMARDs" group had an increase in GCs dose and 60% had a decrease after 1-year and 65% after 2 years; percentage increase and decrease in GCs doses for all groups are listed in Table 2.

**Table 1:** Daily glucocorticoids dosage

| Drug group | Time period | N | Mean (mg/day) | SD | Median (mg/day) | Min | Max |
|---|---|---|---|---|---|---|---|
| All RA bDMARDs | 1 yr before | 230 | 4.4 | 3.5 | 4.1 | 0 | 21.0 |
| | 1 yr after | 230 | 3.5 | 3.6 | 2.9 | 0 | 22.2 |
| | 1-2yr after | 230 | 2.8 | 3.1 | 2.0 | 0 | 17.3 |
| All RA anti-TNF | 1 yr before | 145 | 4.7 | 3.7 | 4.1 | 0 | 21.0 |
| | 1 yr after | 145 | 3.5 | 3.6 | 2.9 | 0 | 22.2 |
| | 1-2yr after | 145 | 2.5 | 2.9 | 1.8 | 0 | 15.2 |
| Abatacept | 1 yr before | 45 | 4.8 | 3.6 | 4.1 | 0 | 14.0 |
| | 1 yr after | 45 | 4.3 | 3.4 | 4.1 | 0 | 15.7 |
| | 1-2yr after | 45 | 4.8 | 3.9 | 4.9 | 0 | 17.3 |
| Tocilizumab | 1 yr before | 62 | 5.4 | 5.7 | 3.8 | 0 | 32.1 |
| | 1 yr after | 62 | 4.4 | 4.5 | 3.2 | 0 | 18.1 |
| | 1-2yr after | 62 | 3.2 | 3.9 | 1.9 | 0 | 18.2 |

**Table 2:** Proportion of patients with glucocorticoids dose changes from 1 year before to 1 and 1-2 years after initiation of bDMARDs.

| | Time period | N | Increased N (%) | Decreased N (%) | No change N (%) |
|---|---|---|---|---|---|
| All RA bDMARDs | 1 yr after | 230 | 72 (31) | 137 (60) | 21 (9) |
| | 1-2yr after | 230 | 63 (27) | 149 (65) | 18 (8) |
| All RA anti-TNF | 1 yr after | 145 | 46 (32) | 90 (62) | 9 (6) |
| | 1-2yr after | 145 | 34 (23) | 101 (70) | 10 (7) |
| Abatacept | 1 yr after | 45 | 19 (42) | 21 (47) | 5 (11) |
| | 1-2yr after | 45 | 18 (40) | 23 (51) | 4 (9) |
| Tocilizumab | 1 yr after | 62 | 23 (37) | 34 (55) | 5 (8) |
| | 1-2yr after | 62 | 14 (23) | 43 (69) | 5 (8) |

**Conclusions:** In the Australian setting, the majority of RA patients who were taking oral GCs had reductions in their daily GCs doses after initiation of bDMARDs; which continued for up to 2 years post treatment initiation.

## AB0349 DENOSUMAB VERSUS BISPHOSPHONATES FOR TREATMENT OF RHEUMATOID ARTHRITIS

H. Kinoshita[1], N. Miyakoshi[2], S. Miyamoto[3], S. Abe[1], Y. Sugimura[4], Y. Shimada[2] on behalf of Akita Orthopedic Group on Rheumatoid Arthritis.
*[1]Orthopaedics, Ugo Municipal Hospital, Ogachi-gun, Ugo-machi; [2]Orthopaedics, Akita University Graduate School of Medicine; [3]Orthopaedics, Nakadori General Hospital, Akita; [4]Orthopaedics, Minamiakita Orthopedic Clinic, Katagami, Japan*

**Background:** Rheumatoid arthritis (RA), caused by upregulation of proinflammatory cytokines, is characterized by overexpression of receptor activator of nuclear factor kappa-B ligand (RANKL) in the synovial membrane, which promotes osteoclast differentiation and thus increases bone resorption. Denosumab, an antibody against RANKL, prevents RANKL/RANK interactions and inhibits osteoclast-mediated bone resorption. This study investigated whether denosumab can prevent the inflammation caused by excessive bone resorption in RA patients in comparison with bisphosphonates, which directly prevent osteoclast-mediated bone resorption.

**Objectives:** RA patients in the Akita Orthopedic Group on Rheumatoid Arthritis (AORA) registry included 58 and 49 newly denosumab-treated and bisphosphonate-treated patients, respectively.

**Methods:** For RA, the Steinbrocker classification was measured at pretreatment and use of glucocorticoid, methotrexate, and biological agents, DAS28-ESR, simplified disease activity index (SDAI), erythrocyte sedimentation rate, and matrix metalloproteinase 3 were measured at pre-treatment and 6 and 12 months post-treatment. For bone metabolism, bone-specific alkaline phosphatase (BAP), indicating bone formation, tartrate-resistant acid phosphatase 5b (TRACP-5b), indicating bone resorption, and bone mineral density (BMD) of the lumbar and femoral neck were measured at pre-treatment, and 6 and 12 months post-treatment.

**Results:** For RA, the Steinbrocker class and stage were significantly higher in the denosumab group compared with the bisphosphonate group (p<0.0001 and p=0.0004, respectively). Use of biological agents was also significantly higher in the denosumab group compared with the bisphosphonate group at pre-treatment and 12 months post-treatment (p=0.006 and p=0.0467, respectively). There were no significant differences in DAS28-ESR and SDAI between the periods for denosumab or bisphosphonates (Figure). For bone metabolism, denosumab reduced BAP at 6 and 12 months post-treatment compared with pre-treatment (p=0.006 and p=0.0132, respectively) (Figure). There were no significant differences in BMD of the lumbar and femoral neck between the periods for denosumab or bisphosphonates, but denosumab revealed a tendency toward increases and bisphosphonates revealed a tendency toward decreases.

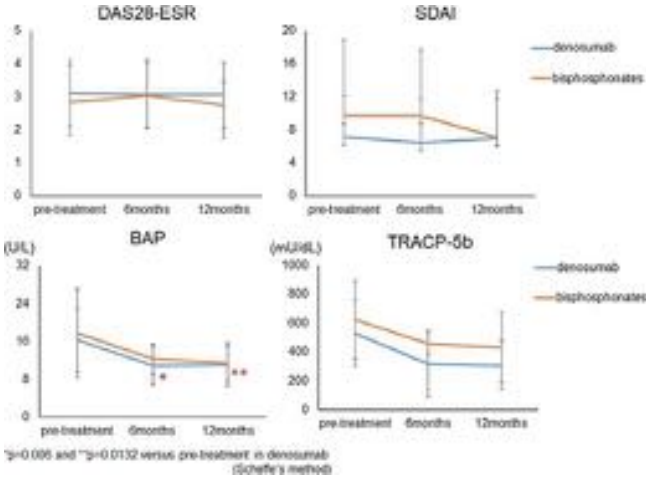

Figure 1

**Conclusions:** Denosumab and bisphosphonates did not suppress RA activity, but denosumab prevented excessive bone turnover more effectively than bisphosphonates.

## AB0350 RITUXIMAB SEEMS OUTSTANDING BIOLOGICAL OPTION IN LATE ONSET RHEUMATOID ARTHRITIS: HUR-BIO REAL LIFE RESULTS

L. Kilic, A. Erden, A. Sari, B. Armagan, O. Karadag, A. Akdogan, S. Apras Bilgen, S. Kiraz, I. Ertenli, U. Kalyoncu. *Department of Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey*

**Background:** Rheumatoid arthritis (RA) can be categorized into late-onset RA and young-onset RA. Age at disease onset may implicate on disease activity, disease severity, comorbidity and also may have an impact on physicians' treatment choices.

**Objectives:** The aim of this study was to assess clinical and laboratory features, disease activity, response, and biological treatment choices according to late-onset RA and young-onset RA patients.

**Methods:** Hacettepe University Biologic Registry (HUR-BIO) is a single center biological registry since 2005. HUR-BIO biological dataset included demographic and clinical data and disease activity parameters. A total of 1087 (79.4% female) patients from the HURBIO registry were analyzed. Patients were categorized into two groups: young-onset RA (n=990, <60 years of age) and late-onset RA (n=97, ≥60 years of age) at disease onset. DAS-28 remission (<2.6) and low disease activity (<3.2) were assessed at last outpatient visit.

**Results:** The female gender was similar in both age group (77.3% vs. 79.6%, p>0.05). Mean age of patients were 71.4±6.0 years in late-onset RA and 51.6±11.7 years in young-onset RA group. The median age at diagnosis of patients were 64 (range 60–85) years in late-onset RA and 40 (range17–59) years in young-onset RA patients. Mean disease duration between diagnosis of RA and first biologic therapy was longer in young-onset RA patients [7.7±7.3 vs. 2.7±2.6 years, p<0.001], but mean biologic duration was similar in both groups [29.9±27.5 vs. 38.4±37.1 months, p>0.05]. Rheumatoid factor and anti-citrullinated peptides positivity in late-onset RA and young-onset RA patients were; 56.2% vs. 63.8% (p>0.05) and 45.9% vs. 63.2%, p=0.008, respectively. At the baseline level, anti-TNF (61 (61.9%) vs. 827 (73.6%), p=0.014) drugs were less frequently used in late-onset RA, rituximab (21 (21.6%) vs 111 (11.3%), p=0.003) was more frequently used in late-onset RA, and abatacept (16 (16,5%) vs. 148 (15,1%), p>0.05) was used similar in both group. Change in DAS-28 score was similar [1.55±1.14 vs. 1.79±1.45 (p>0.05)], in late-onset RA and young-onset RA patients. Remission (29.5% vs. 38.6%, p>0.05) and low disease activity (52.5% vs. 55.4%, p>0.05) were similar in late-onset RA and young-onset RA patients. Biological switch ratio was significantly lower in late-onset RA group, 18.6% vs. 35.2%, p<0.001.

**Conclusions:** Age may influence the clinician choice based on the efficacy and

safety profile. Biologic drugs are effective in late-onset RA, as well. Rituximab was relatively more preferred in late-onset RA patients; may be related with administration of every 6 months and safety profile in malignancy risk. Patient and physician opinion on these choices should be evaluated in further studies.
**Disclosure of Interest:** None declared

## AB0351 BIOLOGIC TAPERING IN RHEUMATOID ARTHRITIS: INITIAL EXPERIENCES IN AN ENGLISH DISTRICT GENERAL HOSPITAL

J. Trickey, C. Holloway, H. Robinson, J. McDowell, S. Andrews, V. Jolliffe, A. Joshi, D. Rees, A. Peall. *Hereford County Hospital, Hereford, United Kingdom*

**Background:** Biologics are effective therapies in the treatment of Rheumatoid arthritis (RA)[1]. However, they are expensive and may have potentially serious side effects including infection[2]. There is growing evidence that biologic doses may be tapered down in patients with well-controlled RA, and good disease control may be retained[3].
**Objectives:** To ascertain if biologic tapering in patients with RA retain good disease control when biologic doses are tapered down, in a small district general hospital rheumatology department.
**Methods:** Patients taking biologics and with quiescent RA were selected prospectively on attendance to rheumatology follow up clinics, commencing in June 2015, and consented to participation in dose tapering. Eligible patients must not be taking corticosteroids. They must have disease remission for at least 2 years (defined as DAS28CRP $<2.6$). Alternatively, they may have disease remission for 12 months and no evidence of synovitis on ultrasound. Rituximab dose was decreased to one 1g infusion every 6 months. Infliximab, Abatacept and Tocilizumab infusion doses were reduced by 25%. Frequency was prolonged by 50% in subcutaneous TNF inhibitors. Patients were followed up at 6-monthly intervals with support from rheumatology help line in between for flares of disease.
**Results:** Between June 2015 and January 2016, 25 patients with RA have had biologic doses tapered. 6 month follow up appointment data is currently available for 10 patients. One female patient was found to have active disease at 6 month follow up, and one male patient had a flare up 1 month before his clinic appointment, so both have reverted back to standard dose biologic.
Mean DAS change for the 9 patients seen 6 months after dose tapering was +0.39 (-0.24: +2.03), which was skewed largely by the one female patient who had a flare at follow up. Median DAS change was +0.1. Mean GVAS before tapering was 29.8, and 33.7 at 6 month follow up. Mean CRP pre-tapering was 5.75 and at 6 months was 4.7. Two patients had a DAS 28 $>3.2$ at 6 months: one of whom had recent surgery which was felt to have contributed to disease flare so reduced dose Rituximab was continued. 6 out of the 9 patients had no swollen joints at 6 month follow up
**Conclusions:** So far 2 out of 25 patients have needed to revert back to original dose of biologic after tapering, which is promising. 7 of the 9 patients followed up on tapering had static disease activity. This suggests that dose tapering can be successfully achieved in a majority of RA patients who have achieved disease remission.

## AB0352 THE CHANGING FACE OF SEPTIC ARTHRITIS COMPLICATING RHEUMATOID ARTHRITIS IN THE ERA OF BIOTHERAPIES. RETROSPECTIVE SINGLE-CENTER STUDY OVER 35 YEARS

J.-J. Dubost[1], B. Pereira[2], A. Tournadre[1], Z. Tatar[1], M. Couderc[1], M. Soubrier[1]. *[1]rheumatology department; [2]Biostatistics Unit, CHU Clermont-Ferrand, Clermont-Ferrand, France*

**Background:** Rheumatoid arthritis (RA) is a risk factor for septic arthritis (SA), and anti-TNF therapy doubles the risk of SA.
**Objectives:** The purpose of this study was to see whether the frequency and features of SA complicating RA have changed over the last 35 years.
**Methods:** This retrospective single-center study included the full register of all patients hospitalized at the rheumatology department of Clermont-Ferrand – CHU between 1979 and 2013 for septic arthritis bacteriologically documented by synovial fluid and/or blood culture samples. The periods 1979–2002 (period before biotherapies) and 2003–2013 (last decade in the era of biotherapies) were compared.
**Results:** Between 1979 and 2013, 64/514 (12.5%) SA presented with a RA – 21/153 (13.7%) in the 2003–2013 period and 43/361 (11.9%) in the 1979–2002 period. Over the past decade, median age of SA–RA patients increased (61 *vs* 68 years; $p<0.02$) and predominant gender became males (52% *vs* 40%). The features of the RA remained unchanged: history (18 years (8–29) *vs* 16 (8–25)), rheumatoid factor (95% *vs* 87%), and corticosteroids (91% *vs* 81%) at the same mean dose (10 mg/d). 71% in the period before biotherapies and 63% in the last decade received a DMARD. Over the last decade 24% (*vs* 0; $p<0.003$) of patients received a biologic DMARD: etanercept (n=2), adalimumab (n=1), rituximab (n=1), tocilizumab (n=1). Proportion of polyarticular infection had decreased (9.5% *vs* 37%; $p<0.02$), down to the same level as SA-non-RA cases (8%). Proportion of *S. aureus* infections had stabilized (62% *vs* 74%) in SA-RA patients but was higher than SA-non-RA (47% and 53%). MRSA infections became more frequent in SA-RA (31% *vs* 6%; $p<0.05$) in contrast to SA-non-RA cases (8% *vs* 16%; ns). Gram-negative bacilli infections have tended to become more frequent (19% *vs* 5%; $p=0.08$). Blood cultures less often tested positive (29% *vs* 47%; ns). Mortality rates has fallen slightly (5% *vs* 9%; ns), in contrast to SA-non-RA cases (7% *vs* 6%; ns).
**Conclusions:** This study brings reassuring findings – in the era of biotherapies, the frequency of septic arthritis complicating rheumatoid arthritis has stabilized, and the most severe septic polyarticular forms are on the decline.
**Disclosure of Interest:** None declared

## AB0353 SURVIVAL AND EFFECTIVENESS OF RITUXIMAB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS IN DAILY CLINICAL PRACTICE

J.A. Gómez-Puerta[1,2], L. Uribe Botero[1], J. Urrego[1], L.A. González[1,3], C. Cerón[1], C. Ochoa[4], M.A. Saldarriaga[1], A. Uribe Toro[1], O.J. Felipe Diaz[1]. *[1]Medicarte IPS, Medellín; [2]Grupo de Inmunología Celular e Inmunogenética; [3]Sección de Reumatología, Universidad de Antioquia, Medellín; [4]Medicarte IPS, Bogotá, Colombia*

**Background:** Recently registry data provide evidence about long-term safety and efficacy of TNF inhibitors. However, data on Rituximab (RTX) treatment in daily clinical practice is limited.
**Objectives:** Our aim was to describe survival rate and effectiveness of RTX therapy in real-life practice conditions in a big cohort of patients with RA from Colombia
**Methods:** We included patients with RA treated at Medicarte IPS from May 2008 and November 2015. Medicarte is a referral center for the integral medical care and pharmacosurveillance of patients under biologic therapies in 13 cities in Colombia. Only those patients with systemic rheumatic diseases were enrolled. We only included those patients with at least 1 complete cycle of RTX treatment. Clinical information was obtained from electronic clinical records and medical claims. We defined survival of RTX treatment only those cases who started RTX treatment before 2015 and persist on RTX during the last visit.
**Results:** From a total of 1064 patients treated with Rituximab, 901 patients had a systemic rheumatic disease. 754 (86%) of patients had a diagnosis of RA. The majority of patients were female (87%); mean age was 55.0± 14.1 years and mean disease duration was 14.7±9.1 years. 57 patients were excluded as they had received less than 1 cycle, leaving 697 patients valid for full analysis. Of these, 80.2% received RTX as a first biological therapy. The mean number of cycles was 1.8 cycles (range 1–8). Adverse effect was reported in 85 (11.2%) patients. 318 patients received only 1 cycle, 185 patients 2 cycles, 91 patients 3 cycles, 30 patients 4 cycles, 18 patients 5 cycles and 8 patients 6 or more cycles. A total of 193 (25.5%) of patients remain on RTX treatment. At the last visit, mean DAS-28 score was 2.9± 1.4 and mean HAQ 0.97±0.71. 66% of patients had a low disease activity (DAS-28 $<3.2$) and 49% of patients were on remission (DAS-28$<2.6$). A 64% of patients had a good index of functionality (HAQ $<1.0$). We did not find differences in terms of clinical response or functionality among patients who used RTX as a first line therapy vs patients with previous biologic treatment (Table).

Table 1. Comparison among patients with RTX as a first agent vs patients previously treated with biologic therapy

| | RA treated with with RTX N=754 | RTX as a first agent N=605 | Previous treatment with biologic agents N=147 | P value |
|---|---|---|---|---|
| Female gender (%) | 87 | 88 | 85 | NS |
| Age (years) | 55±14 | 53±14 | 55±13 | NS |
| Mean disease duration (years) | 15. ±9.6 | 15.13±9.8 | 14.7±9.47 | NS |
| BMI | 25.2±3.9 | 25.2±3.8 | 24.9±4.4 | NS |
| Number of cycles | 1.8±1.1 | 1.7±1.0 | 2.0±1.4 | 0.002 |
| Duration of RTX treatment (years) | 1.55±1.70 | 1.35±1.36 | 3.24±1.9 | 0.001 |
| Last DAS-28 | 2.93±1.43 | 2.93±1.44 | 2.93±1.39 | NS |
| Last HAQ | 0.97±0.71 | 0.98±0.70 | 0.95±0.76 | NS |
| Remission (DAS28$<2.6$ )% | 48 | 49 | 47 | NS |

In 2 patients no information about previous biologic treatment was available.

**Conclusions:** In our cohort with more than 700 Colombian patients with RA treated with RTX, the rate of survival-on-drug in those with more than 1 cycle was 25%. Around half of patients under RTX treatment were on remission with an adequate physical function.

## AB0354 SUBCUTANEOUS ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-LIFE EXPERIENCE

J.C. Sarmiento-Monroy, C. Villota-Eraso, M.J. Mantilla-Ribero, N. Molano-González, M. Rodríguez-Jiménez, A. Rojas-Villarraga, R.D. Mantilla. *Center for Autoimmune Diseases Research (CREA), School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia*

**Background:** Therapeutic guidelines draw heavily on evidence from randomized controlled trials undertaken in well-characterized, highly-selective populations and managed in tightly-controlled settings. As such, the extent to which therapeutic efficacy in real-life populations and routine care settings is often unclear [1–2].
**Objectives:** To assess subcutaneous (SC) abatacept (ABA) efficacy and safety in a real-life setting.
**Methods:** This was a retrospective and single center study in which 94 patients (1987 ACR) were assessed from April 2014 to January 2016. The patients were stratified according to their treatment background: (n=39) biologic-naïve, (n=22) switched from IV to SC ABA administration (125mg-wk), and (n=33) inadequate response to TNF inhibitor (TNF-IR). The primary and secondary endpoints were change in DAS28-CRP, and Routine Assessment of Patient Index Data (RAPID3) from baseline to 6 months, respectively. A linear mixed effects model was made to account for correlation among repeated measures. Adverse events (AEs) were assessed and recorded at each visit to the rheumatology center.
**Results:** Baseline characteristics of patients were as follows: female gender 86%, mean age 55.2±12.3 years, median disease duration 12.5 (IQR 14) years, Rheumatoid Factor positive 94%, Anti-Cyclic Citrullinated Peptide Antibodies 84%, mean DAS28-CRP 5.4±0.72, and mean RAPID3 15.6±5.0. SC ABA monotherapy, concomitant use of methotrexate (MTX), and leflunomide were reported in 10%, 48%, and 27%, respectively. Demographics and disease characteristics were similar in all groups, except for baseline DAS28-CRP ($p<0.0001$), and RAPID3 ($p<0.0001$) in switch group. After 6 months of administration, the DAS28-CRP score change was statistically significant irrespective of group. The scores changed from 5.4±0.9 to 3.8±1.3 ($p<0.0001$, biologic-naïve group), from 3.1±1.2 to 2.7±1.2 (p=0.002, switch IV-SC group), and from 4.6±1.9 to 3.2±1.4 (p=0.0305, TNF-IR group). The RAPID3 scores changed from 18.1±5.4 to 12.1±6.3 ($p<0.0001$, biologic-naïve group), from 10.4±6.6 to 9.2±7.0 (p=0.0114, switch IV-SC group), and from 16.1±5.7 to 11.8±7.1 (p=0.284, TNF-IR group). No patients relapsed or needed to return to the IV administration. Infections, headache, and constitutional symptoms, occurred in 48%, 37% and 32% of patients, respectively. Serious infections were reported only in 2% of patients (i.e., herpes zoster). Local injection-site reactions occurred in 13% of patients. Most of AEs reported were reversible and mild. There were no treatment discontinuations. No deaths and malignancies were reported.
**Conclusions:** Our results disclose an improvement in RA disease activity and physical function, during 6 months administration of SC ABA. Patients switching from IV to SC formulation of ABA had lower activity and functional impairment at baseline, and efficacy was maintained through follow-up. SC ABA demonstrated a good safety profile, consistent with previously published data.

## AB0355 REAL CLINICAL EXPERIENCE WITH ABATACEPT, FROM INTRAVENOUS TO SUBCUTANEOUS

J.C. Nieto-González, I. Janta, J.G. Ovalles-Bonilla, B. Serrano, C. Mata, R. González-Benítez, L. Valor, F.J. López-Longo, C.M. González-Fernández, I. Monteagudo, E. Naredo. *Rheumatology, Hospital G.U. Gregorio Marañón, Madrid, Spain*

**Background:** Abatacept, a fusion protein CTLA4Ig1 that selectively modulates coestimulation of T lymphocites, was approved for the treatment of active rheumatoid arthritis (RA) in 2010 as an endovenous (e.v.) biologic therapy. Three years later was approved the subcutaneous (s.c.) abatacept for RA. The efficacy and safety of both types of administration of abatacept is similar[1]. Also switching from e.v. to s.c. administration of abatacept is effective and safe according to clinical trials[2]. Real clinical practice sometimes differs from clinical trials results. To the best of our knowledge, there is a lack of studies based on real clinical experience about RA patients who switched from e.v. to s.c. abatacept.
**Objectives:** To describe the efficacy of switching from e.v. to s.c. abatacept in our RA patients, evaluated by clinical and ultrasound examination
**Methods:** This observational study was conducted at the rheumatology department of Hospital Gregorio Marañón, Madrid, Spain. Patients diagnosed with RA under treatment with e.v. abatacept in whom rheumatologist and patient consensually decided to switch to s.c. abatacept were included in the study.
Subcutaneous abatacept was started one month later to the last e.v. administration, corresponding to baseline in the study. At baseline and three months later, all patients were clinically assessed and underwent to ultrasound (US) examination. US examination consisted on a reduced joint count (elbows, wrists, 2nd and 3rd metacarpophalangeal, knees and ankles) and tendon examination (2nd, 4th and 6th extensor compartments and tibialis posterior and peroneal tendons). Global synovitis was calculated on B mode and Power Doppler (SBM and SDM), also for tenosynovitis (TBM and TBM). After one year from the switching, clinical reports were reviewed to collect clinical data.
All patients signed an informed consent before to be included. This study was approved by our ethics committee.
**Results:** We included 23 RA patients, from them 21 (91.3%) are still on s.c. abatacept. Twenty-two from 23 (95.7%) were females, mean age 60 years old (range 44.1–82.4) and mean time on e.v. abatacept was 2 years (range 0.8–7.1). SBM was greater at 3 months after switching in 81.9% (18/22) of patients. No differences between SDM, TBM nor TDM were seen at three months. One patient had active synovitis on US both at baseline and three months. She stopped abatacept after US at three months.
Four patients were receiving half dose of e.v. abatacept (5 mg/kg every month) and switched to s.c. abatacept 125 mg every other week. All four patients are still on the same regimen.
Table 1 shows clinical and ultrasound data at baseline and follow-up.

| | Baseline (n:23) | 3 months (n:22) | 12 months (n:21) |
|---|---|---|---|
| DAS28crp (median, IR) | 2.87 (2.24, 4.12) | 2.28 (1.59, 3.1) | 2.37 (1.96, 3.79) |
| ESR mm/1ªh (median,IR) | 15 (9, 27) | 9.5 (6, 16.3) | 11 (3.5, 17.3) |
| CRP mg/dl (median, IR) | 0.46 (0.26, 0.74) | 0.3 (0.2, 0.6) | 0.4 (0.2, 0.6) |
| VAs global (mean, SD) | 4 (2.4) | 3,8 (2.3) | 2,8 (2.2) |
| TJC (median, IR) | 1 (0, 5) | 0.5 (0, 2) | 0 (0, 7.5) |
| SJC (median, IR) | 1 (0, 1) | 0 (0, 1) | 0 (0, 1) |
| SBM (median, IR) | 2 (2, 5) | 9 (4.75, 11) | NA |
| SDM (median, IR) | 0 (0, 1) | 0 (0, 1.25) | NA |
| TBM (median, IR) | 0 (0, 0) | 0 (0, 1) | NA |
| TDM (median, IR) | 0 (0, 0) | 0 (0, 0) | NA |

**Conclusions:** Switching from e.v. to s.c. abatacept in our RA patients was succesful at 12 months. Ultrasound on B mode showed more synovitis at 3 months after swiching, without relation with flares at 12 months.

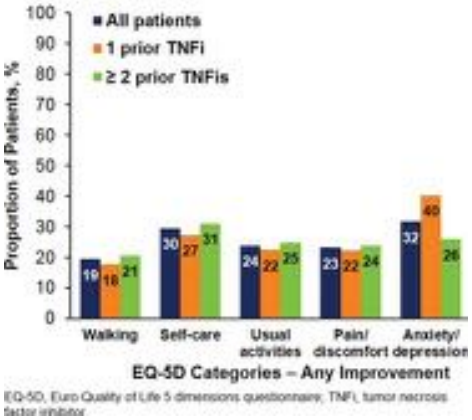
## AB0356 HOW DOES FIRST-LINE ABATACEPT COMPARE TO OTHER BIOLOGICS? DATA FROM A RHEUMATIC DISEASE REGISTRY

K. Michaud[1,2], S. Pedro[2], T. Simon[3], F. Wolfe[2]. *[1]University of Nebraska Medical Center, Omaha; [2]National Data Bank for Rheumatic Diseases, Wichita; [3]Brystol-Myers Squibb, New Brunswick, United States*

**Background:** Observational studies are critical in assessing medication safety and effectiveness in the real world. Non-random assignment can provide insight to how and when medications are prescribed. Since the US introduction of TNF inhibitors (TNFi) in 1998, several newer biologics with varying mechanisms of action are available to patients and physicians. Most physicians prescribe TNFi prior to another biologic, however this trend may be changing.
**Objectives:** To compare the characteristics and outcomes (serious infections and malignancies) of patients who receive abatacept (ABA) vs TNFi as a first biologic.
**Methods:** Participating patients with RA in the National Data Bank for Rheumatic Diseases (NDB) provided treatment and other characteristics (sociodemographics and comorbidities) through self-reported biannual questionnaires. Only responses from 2005–2014 were used for greater comparability. Initiators of biologics were stratified by type (ABA vs. TNFi) and by number of previously exposed biologics. All patient-reported outcomes were verified by medical record review except non-melanoma skin cancer. Patients who had an outcome in the 180 days before treatment initiation were excluded from the analysis for that outcome. Marginal structural models were used to estimate the effect of treatment on the outcome by an appropriate control for the effects of time-dependent confounders using stabilized weights. Variables included sex, employment, marital status, smoking, education, income, select comorbidities, and medications prescribed. These results are reported as adjusted hazard ratios (HR). We repeated the analysis comparing ABA with all other biologics.
**Results:** A total of 3,088 RA patients initiated a first biologic during the study. Of these, 348 received ABA without any prior biologics, having a mean (median) time in the study of 2.6 (1.9) years with a total of 900 patient-years of follow-up. For patients who initiated a TNFi, 3.4 (2.4) years was the mean (median) time in the study with a follow-up of 9296 patient-years. The ABA patients were older, smoked more, and used more prednisone and less MTX compared to those starting their first non-ABA biologic. They also tended to have worse disease activity measured by HAQ and PAS. The crude and adjusted HR of hospitalized infections were: 0.7 (0.2–2.3) and 0.5 (0.2–1.6) and for all malignancies: 1.5 (0.84–2.8) and 1.1 (0.7–2.0), respectively. The results were similar when compared to all biologics (N=2,900).

| | ABA (N=348) | TNFi (N=2740) |
|---|---|---|
| Age, yrs - mean (SD) | 62.5 (13.1) | 57.9 (12.9) |
| Male sex - % | 17 | 20 |
| Education, yrs – mean (SD) | 13.8 (2.2) | 13.8 (2.4) |
| RA duration, yrs – mean (SD) | 11.9 (11.2) | 12.2 (11.1) |
| HAQ (0-3) - mean (SD) | 1.2 (0.7) | 1.0 (0.7) |
| Pain VAS (0-10) - mean (SD) | 4.5 (2.9) | 3.8 (2.8) |
| Global VAS (0-10) - mean (SD) | 4.2 (2.4) | 3.7 (2.6) |
| PAS (0-10) - mean (SD) | 4.2 (2.2) | 3.6 (2.2) |
| Cancer ever - % | 19 | 18 |
| Current smoker - % | 14 | 13 |
| Past smoker - % | 59 | 51 |
| IV antibiotics - % | 4.0 | 3.5 |
| Methotrexate (MTX) - % | 54 | 64 |
| DMARDS not MTX - % | 35 | 33 |
| Hydroxychloroquine - % | 19.5 | 19.8 |
| Prednisone - % | 37.6 | 29.9 |
| Any NSAID - % | 39.6 | 46.3 |
| Hypertension - % | 39.5 | 34.3 |
| Diabetic - % | 13.8 | 11.5 |



The table shows baseline characteristics comparing Abatacept and TNFi initiators.
**Conclusions:** In this RA cohort receiving a first biologic therapy, there appears to be a trend of channeling with ABA. Patients starting ABA tended to be older and have worse disease outcomes. Despite the baseline differences, there was no difference in hospitalized infections and cancers between the groups. This was still true when the comparison was made between ABA and other biologic initiators.

## AB0357 IMPACT OF RITUXIMAB ON PATIENT-REPORTED OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE US CORRONA REGISTRY

L.R. Harrold[1,2], A. John[3], C. Karki[1], Y. Li[2], J.D. Greenberg[1,4], J.M. Kremer[5]. *[1]Corrona, LLC, Southborough; [2]University of Massachusetts Medical School, Worcester; [3]Genentech, Inc, South San Francisco; [4]NYU School of Medicine, New York; [5]Albany Medical College and The Center for Rheumatology, Albany, United States*

**Background:** Patients with rheumatoid arthritis (RA) experience diminished quality of life, including increased disability and RA-related comorbidities. Patient-reported outcomes (PROs) are increasingly being recognized as important measures in determining response to therapy in patients with RA.
**Objectives:** To examine the impact of rituximab on PROs in the Corrona registry, a national US observational cohort of >40,000 patients with RA.
**Methods:** Between March 1, 2006, and September 1, 2015, patients with RA who had prior exposure to ≥1 tumor necrosis factor inhibitor (TNFi) and newly initiated rituximab while not in remission (Clinical Disease Activity Index [CDAI] >2.8) with a follow-up visit at 1 year (± 3 months) were identified. Changes in PROs, assessed 1 year from baseline and stratified by prior TNFi use, included patient global assessment of disease, pain and fatigue (visual analog score; 0–100); morning stiffness (hours); modified Health Assessment Questionnaire (mHAQ; 0–3) and Euro Quality of Life 5 dimensions questionnaire (EQ-5D). Improvement in EQ-5D domains was defined as patients reporting improvement or resolution of impairment among patients who reported impairment at baseline. Outcomes between the 1 and ≥2 prior TNFi groups were compared using $\chi^2$ or *t*-tests, as appropriate.
**Results:** Of the 667 patients initiating rituximab included, 284 (43%) had received 1 prior TNFi and 383 (57%) had received ≥2 prior TNFis. Overall, the median (IQR) age was 59 (50–66) years; 79% of patients were female. Baseline mean (SD) CDAI was 25.6 (13.9). Baseline PROs showed that patients were substantially impaired by their disease and were mostly similar between the 1 and ≥2 prior TNFi groups, although patients in the 1 prior TNFi group tended to have longer duration of morning stiffness and greater fatigue scores. At baseline, patients reported median (IQR) global assessment, pain, fatigue and mHAQ scores of 50 (35–73), 60 (31–75), 65 (40–80) and 1 (0.6–1.6), respectively, and a median (IQR) of 1 (0.5–2) hour of morning stiffness. Of the 667 total patients, 63% received rituximab retreatment and persisted on rituximab through 1 year. At 1 year, improvements were reported in all PROs with no significant difference between patients with 1 or ≥2 prior TNFis. Median (IQR) improvements in patient global assessment, pain and fatigue were 7 (–10 to 25), 7 (–5 to 25) and 9 (–5 to 20), respectively. Improvement in EQ-5D categories is shown (Figure). 51.7% of patients reported no improvement in morning stiffness, 28.5% reported improvement of 1–60 minutes and 19.8% reported improvement of >60 minutes.
**Conclusions:** Real-world data showed that quality of life in this cohort of patients with long-standing, refractory RA was substantially impacted by the disease. One year after initiation of rituximab, improvements were reported in all PROs, such as self-care and usual activities, and were similar between patients with exposure to 1 or ≥2 prior TNFis.

## AB0358 EFFICACY AND SAFETY OF INTRAVENOUS AND SUBCUTANEOUS TOCILIZUMAB IN A COHORT OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS IN REAL-LIFE

L. Manfredi[1], D. Benfaremo[1], S. Tedesco[1], M.G. Danieli[1], M.M. Luchetti[1], A. Gabrielli[1], G. Pomponio[2]. *[1]Clinica Medica, Dipartimento di Scienze Cliniche e Molecolari, Università Politecnica delle Marche; [2]Clinica Medica, Azienda Ospedaliero-Universitaria "Umberto I- Lancisi-Salesi", Ancona, Italy*

**Background:** Tocilizumab (TCZ) is a humanized monoclonal anti-interleukin-6 receptor antibody, used for the treatment of moderate to severe rheumatoid arthritis (RA). Although TCZ has been proved to be highly effective and safe in RA patients in large clinical trials, few data are available from real-life practice [1].
**Objectives:** To evaluate efficacy, safety and retention rate of intravenous (IV) and subcutaneous (SC) TCZ in a real-world setting.
**Methods:** We evaluated patients affected by moderate-to-severe RA and treated with TCZ from April 2010 to December 2015. Data of patients treated with IV-TCZ until December 2014 were collected retrospectively, while patients treated with either IV or SC-TCZ from January 2015 were included in a prospective cohort

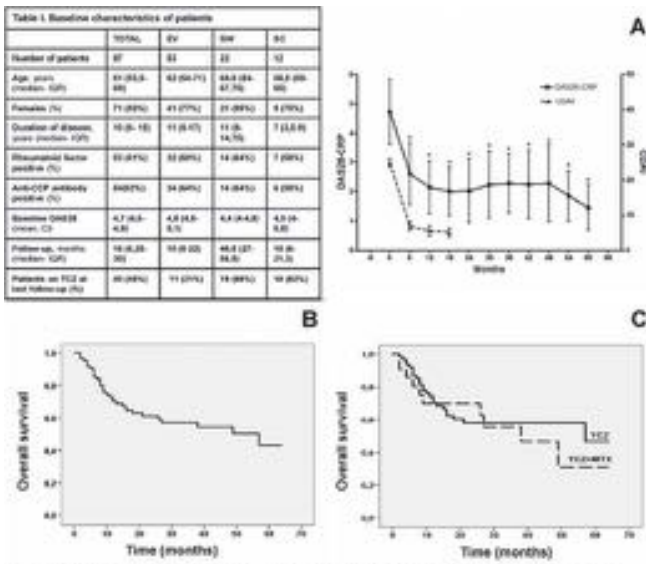

**Figure. Table I** shows baseline characteristics of the patients enrolled in the study. **Panel A** shows mean DAS28 of all the patients during a follow-up of 60 months (continuous line) and mean CDAI of 12 patients treated with SC-TCZ in the prospective phase (dashed line). **Panel B** shows the overall TCZ survival curve estimated by means of Kaplan-Meier method. **Panel C** shows the survival curve of patients treated with TCZ in monotherapy (continuous line) vs patients treated with TCZ in combination with MTX (dashed line). *p<0.001

and assessed for disease activity, quality of life, treatment discontinuation and/or onset of adverse events (AEs). DAS28-CRP, CDAI and SDAI were used for activity assessment. Treatment retention rate was estimated by Kaplan-Meier method.
**Results:** We evaluated 87 patients, 53 treated with IV-TCZ (8 mg/kg every 4 w), 12 with SC-TCZ (162 mg every week) and 22 patients who switched from IV to SC during follow-up (71 females, median age 61 y, median duration of disease 10 y, median follow-up 16 months). Sixty-six patients (76%) were treated in monotherapy and 21 (24%) in combination with methotrexate; 16 (18%) patients were naïve for previous biologic drugs.
At baseline, disease activity was severe in 36% of patients, moderate in 59% and mild or inactive in 5%; at month 6, 49% of patients achieved a clinical remission. The mean overall DAS28 was 4.72 at baseline and 2.61 at 6 months ($p<0.001$ for all comparisons between baseline and subsequent assessments, see Figure).
Thirty-three patients (38%) discontinued TCZ because of inefficacy (67%), AEs (24%) or other reasons (9%). Seventy-three infectious AEs occurred in 38 patients (45.1/100 person-years), 3 cases of pneumonia were severe and only one required treatment discontinuation. Other AEs were mild neutropenia (29%), mild hypertransaminasemia (22%), hypercholesterolemia (39%) and hypertriglyceridemia (10%). Infusion reactions were reported in 5/75 IV-TCZ patients, while injection site reactions in 8/34 SC-TCZ patients.
We observed an overall high retention rate (85.2%, 70.2%, 61.3%, 54.6%, 43.2% at 6, 12, 24, 48 and 60 months respectively); no significant difference was found between combination or monotherapy (p=0.58) or between IV or SC at 22 months (p=0.51). In multivariate Cox regression analysis longer duration of disease (HR 1.06, 95%CI 1.02–1.11), presence of ≥1 comorbidities (HR 2.25, IC95% 1.39–3.64) and previous treatment with ≥2 biologic drugs (HR 1.55, IC95% 1.04–2.31) were associated with treatment discontinuation.
**Conclusions:** TCZ is effective, well tolerated and safe in a population of RA patients followed in a real-life setting.

## AB0359 TREATMENT EFFECTIVENESS FOR RHEUMATOID ARTHRITIS AFTER SWITCHING FROM A TUMOR NECROSIS FACTOR INHIBITOR TO ANOTHER AGENT

M. Bonafede[1], J.R. Curtis[2], D. McMorrow[1], P. Mahajan[3], C. Chen[4]. *[1]Truven Health Analytics, Cambridge MA; [2]University of Alabama at Birmingham, Birmingham AL; [3]Sanofi, Bridgewater NJ; [4]Regeneron Pharmaceuticals, Inc., Tarrytown NY, United States*

**Background:** When tumor necrosis factor inhibitor (TNFi) therapy fails in rheumatoid arthritis (RA), a majority of patients switch to another TNFi instead of a non-TNFi biologic disease-modifying antirheumatic drug (bDMARD).[1] The effectiveness of TNFi cycling compared with switching to a non-TNFi agent is not well established.
**Objectives:** This study examined treatment effectiveness among patients with RA in a large, commercially insured population who cycled to another TNFi ("TNFi cyclers") compared with those who switched to a non-TNFi agent ("non-TNFi switchers").
**Methods:** Administrative claims from January 2010 to September 2014 were analyzed from the Truven Health MarketScan Commercial database. Eligible patients received a TNFi in the 12 months before the "index" drug (a different TNFi or non-TNFi [bDMARDs or tofacitinib]). The study included adults ages 18 to 64 years with ≥12 months of continuous medical and pharmacy enrollment pre- and post-index, and ≥1 claim for RA (ICD-9-CM 714.0x) pre-index or 30 days post-index with no other autoimmune condition. Treatment effectiveness was defined using a validated algorithm[2] that was applied to medical and pharmacy claims for 12 months post-index for each patient. Treatment was considered to be effective if the patient satisfied all 6 algorithm criteria in this period: (1) ≥80% adherence (subcutaneous medication possession ratio or number of intravenous infusions); (2) no increase in dose; (3) no switch to another bDMARD; (4) no new conventional DMARD; (5) no new/increased oral glucocorticoid; and (6) less than 2 glucocorticoid injections in the first 90 days after the index date. Logistic regression was used to compare effectiveness rates by treatment cohort, controlling for baseline demographic and clinical characteristics, including number of prior biologic therapies.
**Results:** Of the 6,945 patients who switched from a pre-index TNFi, 5,020 (72.3%) were TNFi cyclers and 1,925 (27.7%) were non-TNFi switchers. Achievement rates for all 6 algorithm criteria combined and for individual criteria in the 12 months post-index are shown in the table. In the logistic regression model, non-TNFi switchers were 1.25 times as likely as TNFi cyclers to achieve all algorithm criteria for effectiveness (odds ratio, 1.248; 95% CI, 1.103–1.414; $P<0.001$).

| Achievement of treatment effectiveness criteria 12 months post-index | TNFi cyclers (n=5,020) | Non-TNFi switchers (n=1,925) | *P* value |
|---|---|---|---|
| Achieved all criteria | 24.0% | 27.8% | 0.001 |
| ≥80% Adherence | 40.0% | 41.7% | 0.182 |
| No dose increase | 88.3% | 96.7% | <0.001 |
| No switch to another bDMARD | 65.4% | 70.3% | <0.001 |
| No new conventional DMARD | 84.7% | 85.6% | 0.353 |
| No new/increased oral glucocorticoid | 85.7% | 84.7% | 0.285 |
| <2 Glucocorticoid injections in first 90 days | 90.6% | 90.6% | 0.968 |

**Conclusions:** On the basis of a claims-based algorithm of treatment effectiveness for RA, it appears that patients who switch from TNFi to non-TNFi agents are more likely to achieve treatment effectiveness criteria for 12 months after switching than patients who cycle to another TNFi.

## AB0360 IMPACT OF ABATACEPT ON DISEASE ACTIVITY AND FUNCTIONAL STATUS IN PATIENTS WITH DIFFERENT DURATION OF RHEUMATOID ARTHRITIS

M.A. Kanonirova[1], G. Lukina[1], Y. Sigidin[1], E. Aronova[1], S. Glukhova[2], E. Luchihina[3], D. Karateev[4], E. Nasonov[5]. *[1]Laboratory of Clinical Pharmacology, Department of Early Arthritis; [2]Laboratory of Information Technologies; [3]Department of Early Arthritis; [4]Department of Early Arthritis; [5]Nasonova Reserch Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Abatacept (ABA) is a selective co-stimulation modulator, which is widely used in treatment of RA. There isn't enough data about its effectiveness and impact on functional status in patients with early (ERA) and long-standing (LS) rheumatoid arthritis (RA).
**Objectives:** To assess the impact of ABA on disease activity and functional status in patients with different duration of RA.
**Methods:** 85 patients (pts) with active RA and an inadequate response to synthetic DMARDs or biologics were enrolled in the study. They were grouped into 2 arms based on RA duration: less than three years (early RA) and more than three years (LS RA), i.e. 51% and 49% pts in each group, respectively. Most of them were middle aged females (48,8±13,5 years) with high disease activity (DAS28=5,25±1,15), RF-positive (76,7%) and ACPA-positive (73,1%). ABA (10 mg/kg) was administered intravenously following the adult intravenous dosing regimen. Disease activity was assessed by DAS28, functional status by HAQ-DI and results by EULAR criteria every 12 weeks.
**Results:** Before treatment DAS28 in ERA pts was 5,1±0,9, in LS RA – 5,3±1,3 and HAQ-DI in ERA pts was 1,3±0,6, in LS RA - 1,6±0,9. In three months after ABA therapy initiation a significant improvement in DAS28 and HAQ-DI was achieved in both groups ($p<0,05$). Improvement by EULAR response criteria was registered in 80% of pts with ERA and 67% of pts with LS RA. There was no significant difference between two groups after 3 and 6 months of treatment in achieving a good EULAR response: 27,5% and 43,75% – in early RA pts, 28,57% and 38,4% – in LS RA pts. There was a comparable percentage of non-responders after 3 and 6 months of therapy in both groups (at 3 months – 20% in early RA group, 31,4% – in LS RA group; at 6 months – 18,7% and 19,2% respectively). After 3 months and 6 months the improvement of HAQ-DI in ERA group was significantly higher, than in LS RA group ($p<0.05$). 28 adverse events (AEs) in 17 (20%) pts were registered. The most frequent AE were upper respiratory tract infections – 10 (11,8%) pts. Serious AEs (SAEs) occurred in 4 (4,7%) pts.
**Conclusions:** ABA has shown significant improvement in reduction of disease activity and improvement in functional status in pts with RA. No significant difference was seen between the groups of ERA and LS RA by EULAR criteria. However, pts in ERA group had significant improvement of HAQ-DI comparing with LS RA group. ABA has good safety profile, adverse events were registered only in 20% of patients.

## AB0361 EVALUATION OF BASELINE CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT OR TUMOR NECROSIS FACTOR INHIBITORS IN CLINICAL PRACTICE IN SPAIN

M.V. Hernández[1], C.A. Sánchez-Piedra[2], J.D. Cañete[1], F. Sánchez-Alonso[2], J. Manero-Ruiz[3], A. Ortiz-García[4], R. Rosello Pardo[5], E. Pérez-Pampín[6], C. Rodriguez-Lozano[7], R. Sanmarti[1], J.J. Gomez-Reino[6] on behalf of BIOBADASER 2.0 Study Group. *[1]Arthritis Unit. Rheumatology Dept., Hospital Clinic, Barcelona; [2]Research Unit, Spanish Society of Rheumatology, Madrid; [3]Rheumatology Dept., Hospital Universitario Miguel Servet, Zaragoza; [4]Rheumatology Dept., Hospital de la Princesa, Madrid; [5]Rheumatology Dept., Hospital General San Jorge, Huesca; [6]Rheumatology Dept., Hospital Clínico Universitario, Santiago de Compostela; [7]Rheumatology Dept., Hospital Dr. Negrín, Gran Canaria, Spain*

**Background:** Biological therapies have demonstrated efficacy in patients with rheumatoid arthritis (RA) improving the prognosis. The most widely used biological agents are tumor necrosis factor inhibitors (TNFi), although other biological agents with different mechanisms of actions, such abatacept, have been approved. Although all these drugs are indicated in RA, there is limited data on their use and whether differences in baseline characteristics of RA patients treated with different biologics

**Objectives:** To analyze differences in baseline characteristics of RA patients treated with abatacept, a T-cell co-stimulation inhibitor, compared with those treated with a TNFi

**Methods:** All BIOBADASER 2.0 register patients diagnosed with RA and treated with abatacept from January 2008 to December 2014 were selected. Baseline sociodemographic and clinical characteristics were analyzed compared them with RA patients treated with TNFi during the same period. Variables analyzed: age; gender; disease duration; positivity of rheumatoid factor; disease activity at initiation of biological measured by the DAS-28 score; number of previous biological agents (0, 1, ≥2); and concomitant glucocorticoid treatment. Differences between abatacept and TNFi patients in baseline DAS28 were analyzed according to the number of previous biological drugs received

**Results:** From January 2008 to December 2014, 252 RA patients treated with abatacept and 640 with TNFi were included in the BIOBADASER 2.0 register. Baseline characteristics are shown in Table1. At baseline, patients treated with abatacept were significantly younger; had a longer disease duration; had received a greater number of previous biologics; and had a higher DAS-28 (significant in patients who had received 1 previous biologic) than those treated with TNFi

| Variable | Total (n=892) | Abatacept group (n=252) | TNF inhibitor group (n=640) | p-value |
|---|---|---|---|---|
| Age at initiation of first biologic (years), mean (SD) | 55.3 (13.5) | 52.2 (13.1) | 54.6 (13.7) | **0.018** |
| Women, n (%) | 705 (79.0) | 208 (82.5) | 497 (77.6) | 0.107 |
| Disease duration (years), mean (SD) | 8.7 (8.3) | 12.1 (8.15) | 7.3 (8.0) | **<0.001** |
| Number of previous biological agents | | | | |
| 0 | 605 (67.8) | 27 (10.7) | 578 (90.3) | **<0.001** |
| 1 | 151 (13.6) | 71 (28.2) | 50 (7.8) | |
| ≥2 | 166 (18.6) | 154 (61.1) | 12 (1.9) | |
| Concomitant glucocorticoids (%) | 512 (57.4) | 134 (53.2) | 378 (59.1) | 0.109 |

| Basal DAS28 score, mean (SD) | | | | |
| Clustered | 4.74 (1.63) | 4.86 (1.74) | 4.73 (1.63) | 0.597 |
| Number of previous bDMARD = 0 | n=667* | n=44* | n=623* | 0.495 |
| | 4.70 (1.63) | 4.86 (1.74) | 4.69 (1.63) | |
| Number of previous bDMARD = 1 | n=490* | n=71* | n=419* | **<0.001** |
| | 4.28 (1.93) | 5.20 (1.53) | 4.09 (1.95) | |
| Number of previous bDMARD >2 | n=484* | n=137* | n=347* | 0.412 |
| | 4.74 (4.17) | 4.99 (1.46) | 4.59 (5.17) | |

*Number of treatments available to calculate DAS28 mean.

**Conclusions:** Patients with RA treated with abatacept have more active disease and a poorer prognosis that those treated with TNFi, significantly longer disease duration, have failed more previous biological agents and have higher baseline inflammatory activity

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4551

## AB0362 SERUM LIPID LEVEL CHANGES ASSOCIATED WITH TOCILIZUMAB TREATMENT: OUR EXPERIENCE IN TWO UNIVERSITY HOSPITALS

B. García-Núñez[1], S. López-Salguero[2], F. Sivera[3], M. Andrés[2]. *[1]Servicio de Medicina Interna, Hospital General Universitario de Elda, Elda; [2]Seccion de Reumatologia, Hospital General Universitario de Alicante, Alicante; [3]Seccion de Reumatologia, Hospital General Universitario de Elda, Elda, Spain*

**Background:** Tocilizumab (TCZ) is a humanised monoclonal antibody against the Interleukin-6 (IL-6) receptor effective in patients with rheumatoid arthritis (RA) with an inadequate response to conventional DMARDs or an anti-TNF biologic. Among its side effects, a change in the serum lipid profile due to an increase of low density lipoproteins (LDLc) and of high density lipoproteins (HDLc) has been previously described. Its impact and proper management is still uncertain.

**Objectives:** To analyze the changes in serum lipid levels in patients under TCZ treatment.

**Methods:** Retrospective review. Patients treated with TCZ and complete serum lipid profile (total cholesterol, LDLc, HDLc, triglycerides) in two different rheumatology units were selected. Three time-points were established: 1) baseline; 2) one month after the start of TCZ; 3) six monthts after the start of TCZ. Epidemiologic and clinical data on al patients and laboratory findings (C reactive protein – CRP, erythrocyte sedimentation rate – ESR) at the given time-points were also recorded. A before-after comparative anlaysis using Wilcoxon's test, an a correlational analysis with inflammation laboratory parameters using Spearman's Rho test were performed.

**Results:** Thirty-five patients were included: 34 patients with rheumatoid arthritis and one with idiopathic retroperitoneal fibrosis. Patients were a mean (p25–75) of 57.5 years (51.8–63.3) old, and 30 (86%) were women. Table 1 shows the variations in lipid parameters at the different timepoints. A mild increase in HDLc levels was observed after one month of treatment which was maintained at 6 months later, but with no statistical significance (p=0.36). A significant elevation was observed in the remaining lipid paramenters (total cholesterol, LDLc, triglycerides) after one month of treatment, which dissapeared after 6 months of treatment. Inflammatory markers decreased significantly and persistently after the beginnig of TCZ treatment. In the correlation analysis no association was found between lipid levels and inflammatory markers (p>0.05 for all comparisons).

| | Baseline | Month 1 | p | Month 6 | p |
|---|---|---|---|---|---|
| Total cholesterol | 213.0 (193.5–47.0) | 242.5 (199.7–273.5) | **0.002** | 214.0 (179.0–37.0) | 0.36 |
| HDLc | 60.5 (46.0–78.0) | 64.0 (42.5–79.0) | 0.54 | 63.0 (53.0–81.0) | 0.36 |
| LDLc | 124.5 (97.0–150.2) | 143.5 (107.2–170.7) | **0.008** | 116.0 (79.0–140.0) | 0.66 |
| Triglycerides | 118.0 (74.5–170.5) | 137.5 (78.0–211.0) | 0.06 | 123.0 (82.0–209.0) | 0.15 |
| CRP | 2.6 (0.9–7.1) | 0.9 (0.9–1.75) | **0.002** | 0.9 (0.7–0.9) | **<0.001** |
| ESR | 29.0 (10.5–56.0) | 7.0 (3.0–18.0) | **<0.001** | 6.0 (2.0–12.0) | **<0.001** |

Units en mg/dL (unless mm/h for VSG). Data shown as median (p25–75). HDLc: high density lipoproteins, LDLc: low density lipoproteins, CRP: reactive C protein, ESR: erythrocyte sedimentation rate.

**Conclusions:** With TCZ, most lipid parameters show a significant but transitory increase. A mild though non-significant increase in HDLc levels was also observed. The antiatherogenic benefit of TCZ might be mediated by qualitative changes in the HDLc molecule. Prospective and larger studies are needed to characterize these results better.

## AB0363 THE POSSIBILITY OF ESTIMATING THE THERAPEUTIC OUTCOME OF ABATACEPT FROM CHANGES IN CD4+/CD25+HIGH FRACTION

M. Sato[1], M. Takemura[2]. *[1]Rheumatology; [2]Reserch Park, Matsunami General Hospital, Hashimagunn, Gifu, Japan*

**Background:** Cytotoxic T-lymphocyte antigen (CTLA) 4 is a molecule that suppresses T-cell activation and is expressed on the surface of regulatory T cells. Abatacept (ABT), a fusion protein fused to CTLA-4, is used in the treatment of rheumatoid arthritis (RA).

**Objectives:** The purpose of this study was to analyze the effect of ABT therapy on the CD4+/CD25+$^{high}$ fraction, which is thought to include regulatory T cells in the peripheral lymphocyte fractions of RA patients, and to elucidate whether this can be correlated to therapeutic outcome.

**Methods:** The subjects were 32 RA patients who were currently being treated with ABT therapy. The patients' background characteristics were as follows: age ranging from 39 to 81 years (mean: 62±12 years.), stage II disease in 8 patients, stage III disease in 14 patients, and stage IV disease in 10 patients. Sixteen patients were switched from other biological preparations, and 16 patients were ABT naive. Changes in CD4+/CD25+ and CD4+/CD25+$^{high}$ expression levels in blood tests prior to ABT administration were determined by using fluorescein isothiocyanate and phycoerythrin double stain, and measured by using flow cytometry in 5 points: 0 (prior to first ABT administration), 4, 12, 24, and 52 weeks.

**Results:** CD4+/CD25+ (%) showed a slight elevation at week 12 with subsequent decline followed by a slight elevation at week 52, although no significant differences were observed. Measured values at weeks 0, 4, 12, 24, and 52 were 26.4±1.6, 26.7±1.5, 28.9±1.7, 26.8±1.6, and 28.1±1.6, respectively. No significant differences in these values were observed between the switched and naive groups. However, our analysis of the CD4+/CD25+$^{high}$ distribution revealed that in the naive group, an interim decline occurred at week 52, but significant elevations were observed in the switched group starting at week 12. Analysis of the responders (10 cases) and non-responders (6 cases) to ABT in the switched group indicated that the responders showed significant declines in CD4+/CD25+$^{high}$ levels between weeks 12 and 52, as did the cases in the naive group. However, the non-responders showed significant elevations in this fraction from initial ABT administration until week 52.

**Conclusions:** Based on the fact that CTLA-4 is expressed on the surface of regulatory T cells, considering that ABT is a fusion protein that fuses CTLA-4 and immunoglobulin and regulatory T cells are present in the CD4+/CD25+$^{high}$ fraction, as well as the results of this study, we believe that in cases in which satisfactory

therapeutic effects were obtained through the use of ABT, the expression level of regulatory T cells declined. However, patients who were refractory to ABT therapy experienced CTLA-4 deficiency, which we believe caused regulatory T cells to be expressed. Based on these results, changes in the CD4+/CD25+$^{high}$ fraction can be used to measure the therapeutic efficacy for RA from the perspective of CTLA-4.

**Disclosure of Interest:** None declared

Bettini[8], N. Ravenni[8], J. Wilton[8], P. Zufferey[9], G. Ferraccioli[10], R. Caporali[11], C. Specker[12], J. Wollenhaupt[13], D. Neri[14]. *[1]Rheumatology Unit, University Hospital of Siena, Siena, Italy; [2]Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany; [3]Rheumatology Unit, San Camillo-Forlanini Hospital, Rome; [4]Rheumatology Unit, University Hospital of Pisa, Pisa; [5]Rheumatology Unit, University Hospital of Verona, Verona, Italy; [6]Rheumatology Unit, Hospital of Freiburg, Freiburg, Switzerland; [7]Rheumatology Unit, Hospital Luigi Sacco, Milan; [8]Clinical Research Unit, Philogen S.p.A., Siena, Italy; [9]Rheumatology Unit, University Hospital of Vaud (CHUV), Lausanne, Switzerland; [10]Rheumatology Unit, University Hospital A. Gemelli, Rome; [11]Rheumatology Unit, University Hospital IRCCS San Matteo, Pavia, Italy; [12]Rheumatology Unit, University Hospital Essen Sud, Essen; [13]Rheumatology Unit, University Hospital Schön Klinik Hamburg Eilbek, Hamburg, Germany; [14]Department of Chemistry and Applied Biosciences, Swiss Federal Institute of Technology Zurich, Zurich, Switzerland*

**Background:** F8-IL10 (Dekavil) is a human immunocytokine composed of the vascular targeting antibody F8, specific to the extradomain A of fibronectin, fused to the cytokine interleukin-10. F8-IL10 is being investigated in a dose-finding, PK phase Ib study and in a randomized, double blind, placebo-controlled phase II study, as a new therapeutic strategy for rheumatoid arthritis (RA).

**Objectives:** The primary objective of the phase Ib study is to determine the safety, tolerability and MTD of Dekavil in combination with methotrexate (MTX). The primary objective of the phase II study is to assess the superiority of Dekavil plus MTX over MTX by measuring the mean change from baseline of DAS28-CRP. Immunogenicity of F8-IL10 and its PK and PD profile will also be explored.

**Methods:** Patients with active RA despite MTX therapy and who failed anti-TNF$\alpha$ treatment are the target population of both studies. In the phase Ib, cohorts of 3–6 patients are treated with escalating doses of Dekavil (6, 15, 30, 60, 110, 160, 210, 300, 450 and 600 $\mu$g/kg) in combination with a fixed dose of MTX (10–15 mg). In the phase II, patients are randomized to Dekavil 30 or 160 $\mu$g/kg plus MTX or placebo plus MTX. Dekavil is administered by s.c. injection once weekly for a maximum of 8 weeks in both studies.

**Results:** The first 9 cohorts of the phase Ib study have been completed, 32 patients were treated and 31 are evaluable for DLT. One DLT (G2 purpura) was observed in one patient of the 9th cohort. The same patient had G1 thrombocytopenia and G3 ALT increase. Both events were considered related to the study drug and resolved within ten days. Neither SUSAR nor treatment-related deaths occurred. Mild injection site reactions were reported in 59% of patients and 2 cases of anemia (G2 and G3) were considered related to the study drug. All adverse reactions resolved after the end of treatment. Currently, the MTD has not been reached and the 600 $\mu$g/kg dose is ongoing. To date, 59.3% of the 27 patients analyzed for efficacy had ACR and EULAR responses, 29.6% and 11.1% had ACR50 and ACR70, respectively, at the low dosages of 15, 30 and 60 $\mu$g/kg. Two patients benefited from ACR70 response for 12 months after the last drug administration. In the phase II study, 13 out of 87 patients have been enrolled so far. To date, neither SUSAR nor treatment-related deaths were recorded.

**Conclusions:** The promising safety and efficacy results, even at low dosages, of Dekavil in the phase Ib study led to the start of the phase II study to verify the efficacy of Dekavil in combination with MTX in the same patient population. The currently available data suggest that the targeted delivery of IL-10 to the sites of inflammation is a promising therapeutic approach for RA.

## AB0365 THE EFFICACY AND SAFETY OF ABATACEPT AS A FIRST BIOLOGICS IN JAPANESE RHEUMATOID ARTHRITIS PATIENTS COMPLICATED BY PULMONARY INVOLVEMENT

M. Takata[1,2], S. Tsunoda[2], C. Ogita[2], Y. Yokoyama[2], T. Abe[2], M. Maruoka[2], T. Furukawa[2], T. Yoshikawa[2], K. Tanaka[2], A. Saitou[2], A. Nishioka[2], M. Sekiguti[2], N. Azuma[2], M. Kitano[2], K. Matsui[2], E. Shimizu[1], H. Sano[2]. *[1]Depertment of Multidisciplinary Internal Medicine, Faculty of Medicine, Tottori University, Tottori; [2]Department of Internal Medicine, Hyogo College of Medicine, Hyogo, Japan*

**Background:** In clinical practice, it is not rare that we encounter patients with rheumatoid arthritis (RA) complicated by lung involvement. Clinically, lung involvement that accompany RA can be divided into: 1) lung lesions developing as extra-articular symptoms of RA, 2) drug-induced lung lesions caused by the drugs used for RA treatment, 3) opportunistic infection developing during RA treatment, and 4) others including lung lesions without causal relationship to RA. Then, starting the treatment, lung involvement is an important factor to select the disease-modifying anti-rheumatoid drugs (DMARDs) including biologics. There are many unfavorable reports to use tumor necrosis factor-$\alpha$ inhibitor, tocilizumab and rituximab in RA patients with lung involvement. Until now there are few reports whether or not abatacept induced serious respiratory adverse events (SRAE) and exacerbated RA associated ILD (RA-ILD).

**Objectives:** To compare the efficacy and safety of abatacept as a first biologics in RA patients between complicated with and without pulmonary involvement.

**Methods:** This is a prospective observation study. Thirty eight RA patients, who have never used biologics, were enrolled in this study. Pulmonary involvement was evaluated by high resolution computed tomography (HRCT). At 48 weeks after the enrollment of the study, clinical efficacy, safety, and continuation rate were compared between RA patients with pulmonary involvement and without pulmonary involvement.

**Results:** All patients are Japanese and eight patients were male and thirty patients were female. The mean age was 59.0±14.1 year-old, the mean prednisolone dose was 3.89±3.35 mg/day, and the mean methotrexate dose was 5.37±3.78 mg/week. DAS28-CRP was 4.24±1.33 and SDAI was 24.01±12.32 at enrolment. Eleven patients showed pulmonary involvement (8 patients: airway disease, 3 patients: interstitial lung disease). At 48 weeks, SDAI was significantly improved in both group (patients with pulmonary involvement: 25.3±14.56 to 14.23±12.31; p=0.023, patients without pulmonary involvement: 23.48±11.55 to 7.69± 6.70; $p<0.001$). $\triangle$DAS28-CRP was no significant difference between patients with pulmonary involvement and without pulmonary involvement (mean change, -1.20 vs -1.81; p=0.47). There was no change in LDH and KL-6 level in both group. Continuation rate was 81.6% and there was no difference between patients with pulmonary involvement (90.0%) and without pulmonary involvement (77.8%). There were no patients with exacerbating interstitial lung disease.

**Conclusions:** Abatacept as a first biologics is safe and effective in RA patients regardless of the presence or absence of pulmonary involvement. Furthermore abatacept did not lead the exacerbation of the existing pulmonary involvement.

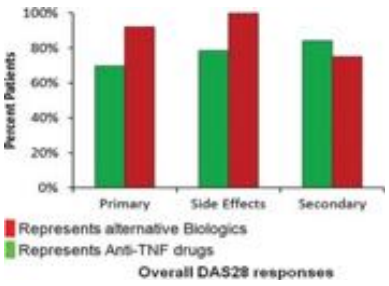
## AB0366 SWITCHING IN 1ST ANTI-TNF FAILURES TO 2ND ANTI-TNF AND OR ALTERNATIVE BIOLOGIC

M. Sharif, D. Scott. *Rheumatology, King's college Hospital, London, United Kingdom*



**Background:** When patients fail 1st anti-TNF & continue to have high disease activity, clinicians face a choice of switching to 2nd anti-TNF or alternative biologic. We set out a study using real world data from a clinical cohort in secondary care hospital in the United Kingdom

**Objectives:** To assess DAS response between the patients who have failed the 1st anti-TNF & compare switching to 2nd anti-TNF & or alternative biologic

**Methods:** We undertook a retrospective, observational study using a routine care biologics database. RA was diagnosed by consultants based on ACR criteria. The patients who failed to respond to a first anti-TNF were selected (including primary & secondary non-responders). Patients were dichotomised into either those who received either 2nd anti-TNF & or an alternative biologics (rituximab, abatacept or tocilizumab). The primary outcome measure was DAS response at 6 months following at dose initiation. A secondary outcome was safety. Statistical analysis compared rates in 2 groups by using Fischer's exact test

**Results:** 136 adult patients, who failed their 1st anti-TNF were included from January 2012 to December 2014. 56 (41.2%) patients received a 2nd anti-TNF & 13 (23.2%) had DAS non-response whereas 43 (76.8%) had DAS response. 19 patients failed second anti-TNF & had alternative biologic (including 6 with adverse events), whereas 37 continued. 99 (72.8%) received the alternative biologic in total. DAS response rates were 54%, 77% & 85% in the 3 groups. We further looked into the reasons for failure. Primary inefficacy was seen in 52 (38.2%), 23 (41%) & 38 (38.3%) patients in each of the cohorts respectively. Failure due to adverse

events were seen in 24 (17.6%), 14 (25%) and 13 (13.1%) patients in each of the cohorts respectively. Secondary inefficacy was seen in 60 (44.1%), 19 (33.9%) & 48 (48.4%) patients. Further analysis of 61 patients of primary inefficacy, 23 patients received 2nd anti-TNF, 16 responded & 7 did not, 38 received alternative biologic, 35 responded & 3 did not. Fischer's exact test showed P-value of 0.032 for the patients on alternative biologic, which is statistically significant. The adverse events group had 27 patients, 14 received 2nd anti-TNF, 11 responded and 3 did not.13 patients received alternative biologic with DAS response. P-value was 0.222 which is statistically not significant. Out of 67 secondary inefficacy patients, 19 received 2nd anti-TNF, 16 responded and 3 did not. 48 patients received alternative biologic, 36 responded & 12 did not with P-value of 0.527.
Overall, when the responses were compared for primary inefficacy, adverse events & secondary inefficacy, 2nd anti-TNF group had a total response of 77% (70%, 79% & 84% respectively), whereas alternative biologic group had 85% (92%, 100% & 75% respectively).There were no observed differences in safety signal between any of the groups

**Conclusions:** The study suggested that primary inefficacy patients respond better to alternative biologic, whereas 2nd anti-TNF group did not have statistically significant result. Adverse events group respond well to alternative biologics but the numbers were small. The disease duration and smoking status has shown to correlate with the biological treatment as well. Over all, this study should be repeated with large number of patients

## AB0367 ADHERENCE TO THE BIOLOGICAL THERAPY (BT) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

N. Mena-Vazquez, S. Manrique Arija, M.C. Ordóñez Cañizares, M. Rojas Giménez, C. Domic Bueno, C. Fuego Varela, I. Ureña Garnica, C.M. Romero Barco, L. Cano García, G. Diaz Cordovés, F.G. Jimenez Nuñez, M.A. Belmonte Lopez, M.V. Irigoyen Oyarzabal, A. Fernández Nebro. *Department of Rheumatology at the University Regional Hospital of Malaga (HRUM). Institute for Biomedical Research in Malaga (IBIMA). Malaga Regional Hospital Virgen de la Victoria in Malaga. Malaga University., MALAGA, Spain*

**Objectives:** To study the adherence to biologic therapy (BT) in patients with RA.
**Methods:** *Design* :Cross-sectional study. *Patients:* Consecutive sampling stratified by route of administration in the biological therapy unit (UTB). *Protocol:* Patients with sc BT are alternately reviewed every 3 months in general and specific (only BT pts) outpatient clinic. Iv BT patients are checked each time the drug is infused. Both groups of pts are reviewed according to a predetermined protocol of data collection. At the start of BT all subjects are interviewed by a nurse who explains the mode of application of drugs and emphasizing the importance of adherence to the effectiveness and safety of BT. *Outcome variables:* (1) level of adherence evaluated by Morisky-Green Test (MGT) and withdrawal drug in hospital pharmacy or drugstore (medication possession ratio [MPR]). Good adherence was considered when 4 responses indicative of adherence were given in MGT and a MPR>80%. The attendance rate to infusions was handled as equivalent to the medication possession ratio. *Other variables:* Demographics, comorbidities, clinical-analytical and synthetic DMARDs reclaim in the drugstores using "XXI electronic prescription"(a software used to control the dispensations in the public health system in Andalusia) in the last 6 months. *Statistical analysis:* Bivariate analyses were performed using T student test, Mann Whitney U test and Ji square test, followed by binary logistic regression (BLR).
**Results:** The main characteristics of the patients (n=178) are shown in the table. One hundred and twelve (63%) were with sc BT, 66 (37%) with iv BT and 49 patients (27.5%) were in monotherapy. 123/178 (69%) showed good adherence to BT and 67/129 (52%) took correctly concomitant synthetic DMARDs. Good adherence to BT was associated in the bivariate analyses with better control of the disease measured by DAS28 ($p<0.001$) and HAQ (p=0.006), fewer comorbidities (p=0.061), lower multimorbidity (p=0.014) and iv administration.However, in the multivariate analysis of poor adherence to BT as dependent variable identified only moderate to high activity DAS28 (OR [95% CI] = 4.51 [1.78 to 11.38]; p=0.001) and poor adherence to DMARDs (OR [95% CI] = 5.42 [2.18 to 13.24]; $p<0.001$) as independent predictors.

| Variables | Value |
|---|---|
| Sex (woman), n (%) | 138 (77,5) |
| Any comorbidity, n (%) | 111 (62,4) |
| Multimorbidity, n (%) | 76 (42,7) |
| Some traditional cardiovascular risk factors, n (%) | 113 (63,5) |
| Positive rheumatoid factor, n (%) | 153 (86,0) |
| Positive anti–cyclic citrullinated peptide antibodies, n (%) | 142 (79,8) |
| DAS28 at protocol, mean (DE) | 2,99 (1,3) |
| DAS28 average, mean (DE) | 3,04 (1,2) |
| HAQ at protocol, mean (DE) | 1,20 (0,7) |
| HAQ average, mean (DE) | 1,19 (0,7) |

**Conclusions:** Adherence to BT of patients with RA in a specific unit is moderate (69.1%) and adherence to the concomitant synthetic DMARDs is bad (52.7%).Patients with moderate or high activity in the previous 6 months, have 4.5 odds of having a bad adherence to FAMEb compared to those who are in remission or have low activity. Likewise, patients who do not take in proper manner associated biological DMARDs are 5.4 times more likely to have bad adherence to FAMEb.

## AB0368 AC-CUTE: AN OPEN-LABEL STUDY TO EVALUATE NON-PROGRESSION OF STRUCTURAL JOINT DAMAGE IN PATIENTS WITH MODERATE TO SEVERE ACTIVE RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB

P. Bird[1], C. Peterfy[2], J. DiCarlo[2], F. Joshua[3], S. Hall[4], H. Griffiths[5], P. Youssef[6], R. Barrett[7], P. Button[8]. *[1]University of New South Wales, Kogarah, Australia; [2]Spire Sciences, Inc., Boca Raton, United States; [3]Combined Rheumatology Practice, Kogarah; [4]Cabrini Medical Centre, Malvern; [5]Barwon Rheumatology Service, Geelong; [6]Royal Prince Alfred Hospital, Camperdown; [7]Medical Affairs; [8]Roche Products, Pty. Ltd, Dee Why, Australia*

**Background:** Clinical efficacy of subcutaneous tocilizumab (SC-TCZ) has been demonstrated in rheumatoid arthritis (RA); however the effect of SC-TCZ on joint damage has not yet been assessed. AC-CUTE (NCT01951170) aimed to evaluate the effects of weekly SC-TCZ on structural change in patients (pts) with moderate-severe active RA, who were inadequate responders to MTX/MTX-intolerant or inadequate responders to a single anti-TNF.
**Objectives:** To assess radiographic and MRI progression at week 24, in pts receiving SC-TCZ as monotherapy or in combination with MTX and/or conventional (c) DMARDs.
**Methods:** An open-label, multi-centre, prospective, single-arm study. Pts received TCZ 162mg weekly, single fixed dose SC injection, monotherapy or in combination with MTX or other cDMARDs. Primary endpoint was absolute change in radiographic Genant-modified Sharp Score (mTSS) between screening and week-24. Secondary endpoints were absolute change from baseline in RAMRIS of MRI erosions, synovitis and osteitis, and MRI cartilage loss (CARLOS). Efficacy parameters included change from baseline (initiation of SC-TCZ) in mTSS, DAS28, CDAI, SDAI and ACR20/50/70. The full analysis set population included pts who received at least 1 dose SC-TCZ, and was used for reporting safety, tolerability and efficacy. Subgroup analyses were split into SC-TCZ monotherapy [SC-TCZM: SC-TCZ monotherapy or SC-TCZ+cDMARDs other than MTX] and SC-TCZ in combination [SC-TCZC: SC-TCZ+cDMARDs including all MTX regimens].
**Results:** 52 pts enrolled from 10 Australian sites; majority females (79%), median age 59 yrs (min 28, max 79) and 5 yrs (min 0, max 31) median duration of RA. Pts in SC-TCZM had longer disease duration at baseline and higher mTSS score. 29 pts completed 24 weeks of treatment. Mean change from baseline for erosion/JSN/mTSS was 0.162/0.485/0.647 in SC-TCZM and 0.124/0.238/0.362 in SC-TCZC respectively; changes relative to baseline and between subgroups were not significant ($p>0.05$). Mean changes from baseline in MRI erosion/cartilage loss/synovitis/osteitis were 0.794/0.0882/-1.56/-2.88 for SC-TCZM and 0.955/0.1439/-1.68/-3.77 for SC-TCZC. Change from baseline for each MRI measure within SC-TCZC was significant ($p<0.05$); however no significant differences were observed between the 2 subgroups ($p>0.1$). At 24 weeks, decrease in DAS28 from baseline was significant for both subgroups (p=0.004 for SC-TCZC; $p<0.0001$ for SC-TCZM); however no significance was observed between subgroups (p=0.3). The proportion of pts achieving DAS28 remission (<2.6) over 24 weeks ranged from 65% for SC-TCZC to 89% for SC-TCZM. 3 pts reported serious adverse events, asthma, anaemia and Weber B Ankle Fracture; deemed unrelated to study medication.
**Conclusions:** There was no significant radiographic progression during the study period across groups. Mean changes in MRI variables were not significant in SC-TZM. MRI changes in SC-TCZC were significant for joint damage progression, as well as regression of synovitis and osteitis.

## AB0369 COMPARATIVE EFFECTIVENESS ABATACEPT, ADALIMUMAB AND RITUXIMAB IN PATIENTS WITH LONG-STANDING RHEUMATOID ARTHRITIS IN A REAL-LIFE SETTING

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Rheumatology; [2]Psychology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Clinical response in patients with rheumatoid arthritis (RA) using biologics is well-known. However, there is no direct comparison between biologics in cohorts of patients with long-standing RA in real-life settings, which could have implications in treatment decisions and health economics.
**Objectives:** The aim of this study was to describe a direct comparison in effectiveness between three different biological agents in their mechanism of action and its application in patients with long-standing RA in a cohort of real-life.
**Methods:** A descriptive retrospective study was performed. Were included 242 patients with at least 12 visits to rheumatologist in last 24 months. Clinical follow-up was according to DAS28: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. We divided patients in two groups: remission-low disease activity (Rem/LDA) patients and moderate-severe disease activity (MDA/SDA) patients and the aim of the study was to analyze of patients who were in MDA/SDA disease activity how many reached a Rem/LDA status. Patients with diagnosis of RA and using Abatacept, Adalimumab and Rituximab were involved. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
**Results:** 242 patients were included, 201 (83%) women and 41 (17%) men. Mean age was 58±10 years; patients with RA and using Abatacept, Adalimumab and Rituximab were involved and treatments were distributed as follows: Abatacept 72 (30%), Adalimumab 96 (40%) and Rituximab 74 (30%); At 24 months was observed an increase in percentage of patients in Rem/LDA and a decrease in percentage of patients in MDA/SDA disease activity statistically significant. For Abatacept at beginning the mean DAS28–3.8 and 24 months later DAS28–2.7; for Adalimumab at beginning the mean DAS28–3.2 and 24 months later DAS28–2.6; for Rituximab at beginning the mean DAS28–3.7 and 24 months later DAS28–2.5; although the HAQ reduction had clinical relevance there was no statistically significance. Between these biologics were not differences statistically significant in effectiveness. A very important issue was that at the end of the follow-up there was no patients in severe disease activity.

DISEASE ACTIVITY (DA) AT BEGINNING (AB) AND 24 MONTHS LATER (24 ML)

| | Remission AB n(%) | Remission 24 ML n(%) | Low DA AB n(%) | Low DA 24 ML n(%) | Moderate AB n(%) | Moderate 24 ML n(%) | Severe AB n(%) | Severe 24 ML n(%) |
|---|---|---|---|---|---|---|---|---|
| Abatacept | 20 (30) | 21(27) | 11 (15) | 25 (35) | 25 (34) | 27(38) | 15 (21) | 0 (0) |
| Adalimumab | 44 (46) | 45 (47) | 13(13) | 34 (35) | 27(28) | 18 (19) | 11(12) | 0(0) |
| Rituximab | 17 (23) | 21(29) | 10 (14) | 29 (39) | 30(40) | 24 (32) | 17(23) | 0(0) |

**Conclusions:** Study shows no significant differences in effectiveness between three different biological agents in their mechanism of action and its application analyzed, but there was a clear improvement in all patients with respect to basal disease activity, which proves effectiveness of implementation of a T2T strategy in patients with long-standing RA independent of biological.

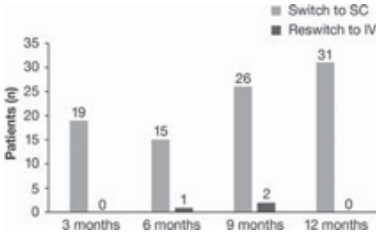
## AB0370 REAL LIFE EXPERIENCE WITH ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM A REGIONAL CENTRE IN UK



P. Joshi, T.P. Sheeran, S. Venkatachalam, S. Roskell. *Rheumatology, Cannock Chase Hospital, Cannock, United Kingdom*

**Background:** Abatacept is a biologic option for patient with Rheumatoid arthritis who have not responded to conventional disease modifying drugs as well as to TNF alpha inhibitors. It has been approved by the National Institute of Health and Clinical Excellence in UK.
**Objectives:** We share our experience with Abatacept in patients with Rheumatoid arthritis (RA) in routine clinical practice focussing on clinical response, disease remission and drug survival.
**Methods:** A retrospective analysis of RA patients on Abatacept from November 2012 to November 2014 was performed. Data collected included baseline demographics, number of previous synthetic and biologic DMARDs (Disease modifying drugs), baseline DAS 28 (Disease activity score) and change in DAS28 at 6 months.
**Results:** Total patients: 138 (100 females and 38 males, F: M ratio 2.63:1). Mean age of population was 63 years. Mean disease duration prior to abatacept was 12.8 years. Mean number of conventional DMARDs used before abatacept were 3.1 and biological DMARDs were 1.8. Abatacept was the first biological therapy used in 10 (7.2%) patients. At last follow up 59 (42.8%) and 57 (41.3%) patients were on intravenous and subcutaneous abatacept.
Mean DAS score before starting abatacept 5.89. Clinical response with a change in DAS 28 >1.2 was seen in 76% patients on Abatacept at 6 months. 15.9% Abatacept patients achieved remission at 6 months. 22 (15.9%) patients discontinued abatacept. Drug survival over 6 months was seen in 102 (73.9%) patients.
**Conclusions:** Abatacept showed response rate of 76% similar to reported in literature. Drug survival beyond 24 weeks was higher compared to other studies. Abatacept is safe, well tolerated and clinically effective in RA patients in real life.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6154

## AB0371 IS SWITCHING FROM IV TO SC ABATACEPT THERAPY SUSTAINABLE IN THE REAL WORLD? 1-YEAR ANALYSIS OF THE PROSPECTIVE, INTERNATIONAL ACTION STUDY

R. Alten[1], H. Nüßlein[2], M. Galeazzi[3], H.M. Lorenz[4], X. Mariette[5], A. Cantagrel[6], M. Chartier[7], Y. Elbez[8], C. Rauch[9], M. Le Bars[10]. *[1]Schlosspark-Klinik University Medicine, Berlin; [2]University of Erlangen-Nuremberg, Nuremberg, Germany; [3]University of Siena, Siena, Italy; [4]University Hospital, Heidelberg, Germany; [5]Université Paris-Sud, Paris; [6]Hôpital Purpan, Toulouse; [7]Chiltern International, Neuilly; [8]Excelya, Boulogne-Billancourt, France; [9]Bristol-Myers Squibb, Munich, Germany; [10]Bristol-Myers Squibb, Rueil-Malmaison, France*

**Background:** Open-label clinical trials have shown that patients with RA can switch from IV to SC abatacept therapy with no efficacy loss or safety concerns;[1,2] however, findings from single-centre, real-world studies are unclear.[3,4]
**Objectives:** To examine characteristics at baseline and before switching, and reasons for switching, in patients who switched from IV to SC abatacept in the real-world ACTION study.
**Methods:** ACTION is a 2-year, prospective, observational study of patients with moderate-to-severe RA who initiated IV abatacept across Europe and Canada. Enrolment periods: May 2008–Dec 2010 (biologic naïve or failed prior biologics); Sept 2010–Dec 2013 (biologic naïve); Oct 2011–Dec 2013 (failed prior biologics). This was an interim analysis of 1-year data. Assessments: baseline characteristics; reasons for switching; efficacy at the time of switch measured by EULAR response, DAS28 (ESR), DAS28 (CRP), CDAI and SDAI.
**Results:** 2364 patients were enrolled and 2350 were evaluable. A total of 91 patients (3.9%) switched from IV to SC abatacept during their first study year: 19 were biologic naïve and 72 had failed prior biologics at study entry. Compared with non-switchers, the switch group had numerically higher percentages of patients with BMI ≥35 kg/m$^2$, ≥1 co-morbidity and ≥2 prior anti-TNF failures, and lower mean disease activity, at baseline. Most patients (62.6%) who switched did so after >6 months in the study (Figure). Reasons for switching from IV to SC abatacept were available for 86 patients (94.5%; some patients had >1 reason): patient wish (53.5%), physician's preference (24.4%), safety (9.3%), poor compliance (4.7%), efficacy (2.3%), remission (2.3%), surgery (1.2%) and other (16.3%). Only 3/91 (3.3%) patients re-switched to IV abatacept; reasons were: patient wish, safety, efficacy (1 patient each). Prior to switching to SC abatacept, 64% of patients had a good/moderate EULAR response. According to mean (SD) values, disease activity before switching was moderate: DAS28 (ESR) 3.85 (1.09), DAS28 (CRP) 3.46 (1.07), CDAI 12.49 (7.70) and SDAI 13.6 (8.13).

**Conclusions:** Few patients switched from IV to SC abatacept and most who did so switched after >6 months allowing them to first achieve stable disease activity. Switching from IV to SC abatacept was primarily driven by patient or physician preference for the SC formulation. The very low rate of return to IV (3.3%) suggests that switching from IV to SC abatacept had no adverse clinical impact.

## AB0372 TREATMENT TO TARGET FOLLOWING INITIATION OF TREATMENT WITH RITUXIMAB IN RHEUMATOID ARTHRITIS: REAL LIFE EXPERIENCE

R. Ionescu[1,2], M. Ismajli[1], S. Moore[1], G. Cambridge[1,3], M. Leandro[1,3].
*[1]Rheumatology, University College London Hospitals, London, United Kingdom; [2]Rheumatology and Internal Medicine, Sfanta Maria Hospital, Bucharest, Romania; [3]Rheumatology, University College London, London, United Kingdom*

**Background:** Rituximab (RTX) is an effective and relatively safe treatment for rheumatoid arthritis (RA). Following treatment initiation there is still controversy on how best to optimise further retreatment while limiting risks of cumulative immunosuppression and cost. There is evidence that retreatment at 6 months in patients with initial response but still have active disease can lead to further improvement[1,2].
**Objectives:** Evaluate how often is retreatment with RTX at 6 months associated with further improvement in disease activity in patients with RA that responded to 1 cycle of RTX.
**Methods:** Retrospective study of patients in the UCLH/UCL cohort:RA patients retreated with RTX (2x1000mg) at 6 months for improvement of initial response were selected and divided into 2 groups:patients that improved further (group A), and patients that did not (group B). Clinical and laboratorial data were assessed.
**Results:** Out of 40 selected patients, 32 (80%) improved further while 8 (20%) did not. Median age was 54 years with median disease duration (MDD) of 13 years in group A, and 51 years with 19 years MDD in group B. In both groups:75% were female, more than 87% were seropositive and more than 75% anti-cyclic citrullinated peptide antibody positive. In group A:10 received RTX alone, 11 with Methotrexate (MTX), 4 MTX and prednisolone, and 7 other immunosuppressants/immunomodulators. In group B:3 received RTX alone, 4 with MTX, and 1 with Etanercept. At baseline, group A presented a mean swollen joint count (mSJC) of 7.81, mean tender joint count (mTJC) 15.56, mean erythrocyte sedimentation rate (mESR) 41.5 and mean C-reactive protein (mCRP) 25.5, giving a median baseline DAS28 of 6.13 (IQ 5.23–7.21). Group B recorded:mSJC of 8.5, mTJC 16.9, mESR 44.25, mCRP 42.25, giving a median DAS28 of 6.49 (IQ 5.32–7.6). After the 1st RTX cycle group A recorded a median DAS28 decrease of 1.83 (IQ 1.11–2.5):4 (12%) achieving low disease activity, 22 (69%) moderate activity and 6 (19%) still high activity scores. While group B also presented improvement, the decrease in DAS28 was only a median of 1.07 (IQ 0.76–1.94): 1 patient (13%) achieving remission,2 (25%) moderate activity and 5 (62%) remaining with high disease activity. After the 2nd RTX cycle,in group A median DAS28 decreased a further 0.6 (IQ-0.12–1.3): 11 (35%) achieving remission or low disease activity, 19 (59%) moderate activity and 2 (6%) remaining with high disease scores. In group B DAS28 recorded a median decrease of 0.04 (IQ 0.72–0.67): 6 (75%) presenting high disease scores, 2 (25%) moderate and none remission or low disease activity.
**Conclusions:** Not all patients treated with RTX will achieve remission or low disease activity, but the majority that improve after 1 RTX cycle will improve even further after a 2nd cycle[1,2]. In our group 80% of patients improved further after a 2nd RTX cycle, with more than a third achieving remission or low disease activity and more than half moderate activity. There was a suggestion that patients who responded less well to their 1st cycle were less likely to improve further

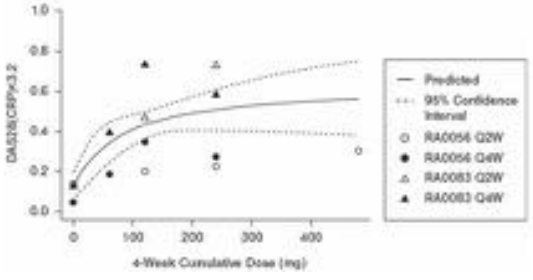
## AB0373 DOSE RESPONSE MODELING IS A USEFUL TOOL TO DETERMINE DOSES FOR PHASE 3: EXPERIENCE FROM OLOKIZUMAB



R. Reeve[1], A. Krotkova[2], D. Weilert[3], S. Fatenejad[4]. *[1]Quintiles Inc., Durham, United States; [2]R-Pharm CJSC, Moscow, Russian Federation; [3]Quintiles Inc., Kansas City; [4]Fatenejad Consultancy, Miami, United States*

**Background:** Olokizumab (OKZ) is an anti-interleukin-6 (IL-6) monoclonal antibody in development for the treatment of rheumatoid arthritis (RA). In phase 2 studies, treatment with OKZ+MTX resulted in significant improvements in disease activity compared to placebo (PBO)+MTX.[1,2] Here, we used dose-response modeling based on efficacy and safety data from phase 2 to determine the most appropriate OKZ doses for phase 3 development. This modeling approach utilizes all available data, and ensures that the decision is scientifically-based.
**Objectives:** To test the dose-response relationship of OKZ with clinical efficacy and safety, and identify the optimal doses for phase 3.
**Methods:** The nonparametric Jonkheere-Terpstra (JT) test was fitted to DAS28(CRP) data obtained from two double-blind, randomized, phase 2 dose-ranging (60 to 480mg 4-week cumulative dose [cd]) studies (RA0056 [NCT01242488] and RA0083 [NCT01463059]) to test for a monotonic dose-response curve without any assumptions on curve shape. The JT tests indicated that a dose-response model was statistically significant, allowing the Hill parametric model to be used, with study as a categorical covariate that affected both the $ED_{50}$ and $E_{max}$ parameters. Mean and 95% confidence intervals for the response were calculated. The Hill model was used since it fit the data adequately, and allowed estimation of the response curves using all available information. To select an appropriate dose, safety as well as efficacy must be included, and a balance between the two achieved. Thus, a dose-response model for the incidence of adverse events (AEs) was also required. A logistic regression model was fitted to the 17 most commonly observed preferred terms across pooled phase 2 data.
**Results:** The JT test indicated a statistically significant monotonic dose-response relationship: $p<0.005$ for all dosing regimens (every 2 weeks [wks; Q2W] and every 4 wks [Q4W]) in each study, and across pooled data from the two studies. Categorical DAS28(CRP) endpoints also indicated a monotonic dose-response relationship (Table). A parametric dose-response curve fitted using a Hill model[3] to combined data from the studies (Figure) adequately described the data, with an inflection point of 120mg 4-wk cd. This is the smallest dose that attains a response near the maximum. Dosing frequency had a small, non-statistically significant effect on categorical DAS28(CRP) response.
Logistic regression analysis of AEs did not indicate any evidence of a dose-related increase in AEs examined vs PBO+MTX, with the exception of injection site reaction.

**Table:** Probability of a monotonic dose-response relationship, based on the Jonkheere-Terpstra test

| Categorical endpoint | Dosing frequency | JT p-value |
|---|---|---|
| DAS28(CRP) < 2.6 | Q4W | 0.0001 |
| DAS28(CRP) < 2.6 | Q2W | 0.0003 |
| DAS28(CRP) < 3.2 | Q4W | <0.0001 |
| DAS28(CRP) < 3.2 | Q2W | 0.0020 |

**Figure:** Model for proportion of patients with DAS28(CRP)<3.2 at Week 12 as a function of 4-week cumulative dose, based on the Hill model

**Conclusions:** Efficacy increased with dose, without an increase in safety events, and plateaued at approximately 120mg cd. Modeling data were robust, with comparable results for individual studies vs pooled data, and continuous vs categorical responses. Thus a dose at the inflection point (128mg 4-wk cd given as 64mg Q2W) and a dose below the inflection point (64mg 4-wk cd) were selected for inclusion in the phase 3 program.

## AB0374 ANALYSIS OF SPACING OF THE INTRAVENOUS ADMINISTRATION OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Ito[1], D. Kobayashi[1], C. Takai[1], T. Nemoto[1], H. Lee[1], A. Abe[1], H. Otani[1], H. Ishikawa[1], A. Murasawa[1], I. Narita[2], K. Nakazono[1]. *[1]Department of Rheumatology, Niigata Rheumatic Center, Shibata City; [2]Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata City, Japan*

**Background:** Although the biologic disease modified anti rheumatic drugs (bDMARDs) are the most effective treatment of rheumatoid arthritis (RA), the costs are much higher than those of conventional synthetic DMARDs (csDMARDs). A number of studies on discontinuation, dose reduction or spacing of bDMARDs have been performed, but there is almost no report of the spacing of tocilizumab (TCZ) so far.
**Objectives:** To analyze the efficacy of spacing of the intravenous (iv) administration of TCZ in patients with RA.
**Methods:** Enrolled were 63 patients (11 male, 52 female) who were administrated iv TCZ for more than 1 year. Eleven patients had shifted to subcutaneous injection and the data at the last iv infusion were analyzed.
**Results:** Mean age was 57.4 years old (30–78), mean body weight was 55.5kg (37–85.5), mean duration of illness was 10.7years (0–32), Steinbrocker's Stage were 4/12/20/27, Class were 0/41/22/0, and the number of the former biologics were 0.9 (0–3), and duration of TCZ was 46.9 months (13–83). The intervals of administration were 4 weeks: 28.6%, 5 weeks: 38.1%, 6 weeks: 17.5%, 7 weeks: 6.0%, 8 weeks: 7.9%, 10 weeks: 1.6%. Tender joint count, swollen joint count, erythrocyte sedimentation rate (ESR), C-reactive protein, matrix metalloproteinase-3, patient's visual analogue scale (VAS), doctor's VAS, disease activity score (DAS) 28-ESR, simplified disease activity index (SDAI), and clinical DAI (CDAI) were significantly ameliorated. The remission rats were DAS28-ESR 90.5%, CDAI 44.4%, SDAI 42.9%, respectively. The number of patients with prednisolone (PSL) wer decreased from 50 patients at the initiating TCZ treatment to 38 patients ($p=0.031$), 4.2 (0–10) to 1.7 (0–5) mg/day ($p<0.0001$). Methotrexate (MTX) were used in 46 to 32 patients ($p=0.017$), 6.0 (0–18) to 3.3 (0–14) mg/weeks ($p<0.0001$). There were no changes in the usage of other csDMARDs.
**Conclusions:** Spacing of the TCZ administration were done in 71.4% of the patients,even though it significantly reduced disease activity and reduced PSL and MTX. TCZ is the most inexpensive bDMARDs in Japan, but with spacing, it is possible to reduce more cost with a good control of RA. Further study of the analysis of the prevention of joint destruction by spacing is necessary.

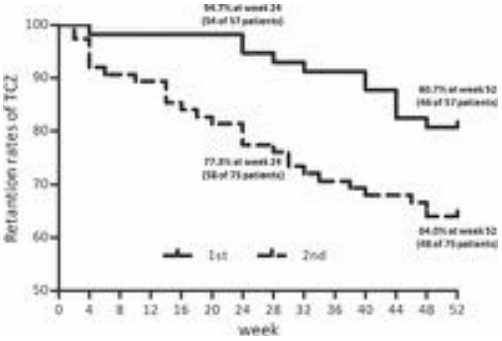
## AB0375 BIOSIMILARS IN RHEUMATOLOGY CLINICAL PRACTICE-GAINING ACCEPTANCE IN DEVELOPING WORLD-EXPERIENCE FROM SOUTH INDIA

S. Nallasivan. *Assistant Professor and Consultant, Dept of Rheumatology, Velammal Medical College Hospital and Research Institute, Madurai, India*

**Background:** Biologic disease modifying anti-rheumatic drugs (DMARD) have revolutionized the management of several rheumatic disorders. A decade of experience in the west has gained insights in to the safety and efficacy of these cytokine inhibitors in inflammatory rheumatological disorders. However, the access to biologics has been restricted by the cost, in the developing world.
Bio-similars [(1)] have been developed in the Far East including India and the efficacy and safety have been comparable to their reference products, with affordable cost, with huge benefit to the patients.
**Objectives:** To review the use of synthetic DMARDs- Biosimilars in two centres of Rheumatology in south India and assess the efficacy/safety profile among the patients.
**Methods:** All Biologic users for a period of one year in the Rheumatology centre in Velammal Medical College Hospital, Madurai and Aruna Hospitals, Tirunelveli were reviewed (Oct 14-Oct 15). All patients should satisfy ACR criteria for diagnosis and would have failed classic DMARDs. They were all screened for TB, Hepatitis as per UK-NICE guidelines. All had 3 months review and are under regular follow up.
**Results:** Data from 15 patients were collected in this retrospective review. (Indications below)



| Indications | No. of patients | Bio similar drug |
|---|---|---|
| Rheumatoid arthritis | 7 (6+1) | Intacept and Ritux (1) |
| Spondyloarthritis | 5 | Exemptia |
| SLE | 1 | Mabtas |
| ANCA associated vasculitis | 1 | Ritux RA |
| Psoriatic arthritis (but CCP positive) | 1 | Exemptia |

All 7 patients with RA were Bio-naive, received the biosynthetic DMARDS and achieved remission in 3 months. Pre treatment average DAS score was 5.65 and 3 months following treatment, the average DAS 28 score was 2.01, which shows significant improvement. The girl with SLE has responded dramatically following Mabtas therapy. In the Spondyloarthropathy group, all but one had spinal disease only. Pre treatment average BASDAI was 6.64 and 3 months following biosimilars BASDAI was 2.6. To date no infective complications were reported. All are maintained on oral DMARDS either Methotrexate or Leflunomide without steroids.
**Conclusions:** Biosimilars have been developed in the developing world with affordable cost. They are increasingly being used in different complex inflammatory rheumatologic diseases. It has gained reasonable acceptance. The rheumatologist should be aware of safety and use in a diligent manner.

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5521

## AB0376 RETENTION RATES AND CLINICAL EFFICACY OF TOCILIZUMAB AS FIRST-LINE BIOLOGICS COMPARED TO SECOND-LINE IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Okano[1], K. Inui[1], M. Tada[2], Y. Sugioka[3], K. Mamoto[1], T. Koike[3], H. Nakamura[1]. *[1]Departmento of Orhopedic surgery, Osaka City University Graduate School of Medicine; [2]Departmento of Orhopedic surgery, Osaka City General Hospital; [3]Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka, Japan*

**Background:** To date, biologic disease-modifying anti-rheumatic drugs (bDMARDs) targeting cytokines such as tumor necrosis factor (TNF)-$\alpha$ or interleukin (IL)-6 have been established as a standard therapy for rheumatoid arthritis (RA) patients with insufficient responses to conventional synthetic DMARDs such as methotrexate (MTX). The IL-6 receptor blocking monoclonal antibody, tocilizumab, is included as one of the first-line bDMARD in the latest European League against Rheumatism (EULAR) recommendations [1]. However, there has been few data as the retention rates of tocilizumab.
**Objectives:** This study aimed to investigate the retention rates and clinical efficacy of tocilizumab as first-line bDMARD compared with second-line treatment in patients with RA.
**Methods:** This is a retrospective study. All RA patients who treated with tocilizumab were included this analysis. These patients were divided into two groups. In the first group, tocilizumab was used as a first-line bDMARDs (1st group). Patients in the other group received tocilizumab as a second-line or more treatment (2nd group). Retention rates and clinical efficacy assessed by disease activity score in 28 joints (DAS28; on the basis of the erythrocyte sedimentation rate, ESR) and clinical disease activity index (CDAI) from week 0 to week 52 were assessed. The discontinuation ratio of glucocorticoid and MTX was also evaluated. Moreover, the effect of tocilizumab for bone was assessed by bone mineral density (BMD) of lumber spine and hip, and bone metabolic marker (BMM) of urinary type I collagen cross-linked N-telopeptide (NTX) and bone-specific alkaline phosphatase (BAP).
**Results:** Fifty-seven patients in 1st group and 75 patients in 2nd group were analyzed in this study. Retention ratio at week 24 and 52 was 94.7 and 80.7% in 1st group and 77.3 and 64.0% in 2nd group, respectively. Of 11 discontinued patients in 1st group, only 2 patients were withdrawal due to inadequate response. DAS28 remission rates were 17.4, 45.7, 50.0, 41.3 and 39.1% in 1st group and 8.3, 22.9, 29.2, 33.3 and 37.5% in 2nd group at week 4, 12, 24, 36 and 52, respectively. CDAI remission rates were 8.7, 10.9, 13.0, 23.9 and 15.2% in 1st group and 0, 6.3, 10.4, 14.6 and 10.4% in 2nd group at week 4, 12, 24, 36 and 52, respectively. The dose of MTX was reduced in 11 patients and MTX was withdrawal in 4 patients among 34 patients of 1st group using MTX at week 0. The dose of glucocorticoid was reduced in 16 patients and glucocorticoid was withdrawal in 10 patients among 20 patients of 1st group using glucocorticoid at week 0. BMM was not significantly changed and BMD was kept in both groups.

**Conclusions:** High retention rates and clinical efficacy of tocilizumab as first-line biologic treatment was found in retrospective research. Moreover, dose reduction and withdrawal of MTX or glucocorticoid was achieved in some patients with tocilizumab.

## AB0377 DIFFERENCES IN BASELINE PREDICTIVE FACTORS FOR REMISSION AT 52 WEEKS BY CONCOMITANT MTX USE DURING TOCILIZUMAB TREATMENT USING PROPENSITY SCORE MATCHED GROUPS

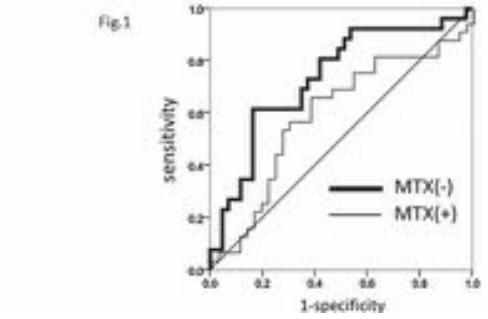
T. Kojima[1], S. Asai[1], N. Takahashi[1], Y. Yabe[2], Y. Hirano[3], Y. Kanayama[4], A. Kaneko[5], T. Takemoto[1], N. Asai[1], T. Watanabe[1], K. Funahashi[1], M. Hayashi[6], N. Ishiguro[1] on behalf of TBCR Study Group. *[1]Orthopedic Surgery, Nagoya University Hospital, Nagoya; [2]Rheumatology, JCHO Tokyo-Shinjyuku Medical Center, Tokyo; [3]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [4]Rheumatology, Toyota Kosei Hospital, Toyota; [5]Orthopedic Surgery, Nagoya Medical Center, Nagoya; [6]Rheumatology, Nagano Red Cross Hospital, Nagano, Japan*

**Background:** In the treatment of rheumatoid arthritis, concomitant use of methotrexate (MTX) should be a critical factor for decision of treatment now. Tocilizumab, IL-6 receptor antibody has been reported to have good efficacy even without concomitant MTX in clinical trials and observational study. However, there is an important clinical question that concomitant MTX use could have any impacts on predictive factors of achievement of good clinical goal.

**Objectives:** To explore the differences in predictive factor for achievement of remission by concomitant MTX use during TCZ treatment. In observational study, it is important to match background of the patients for comparison. We used propensity score matching, which is useful statistical tool for comparison in clinical practice.

**Methods:** This study included 240 RA patients who received TCZ (concomitant MTX use: MTX(+) 117: no use: MTX(–) 123) in the multicenter observational cohort (Tsurumai Biologics Communication Registry; TBCR, 2827cases treated with biologics were registered until 2014). We prepared matched groups by concomitant MTX use using propensity score (matched factors, age, sex, previous biologics use, glucocorticoid use, Steinbrocker stage and class, disease duration, DAS28 at baseline). We determined the baseline predictive factors for remission (DAS28) at week 52 by the matched groups using multivariate logistic regression analysis. Especially, association of DAS28 at baseline to achievement of remission was compared using area under the curve (AUC) of ROC curve.

**Results:** Sixty-nine patients were matched between groups. Baseline characteristics were shown in Table 1. Rate of remission was 55.2% in MTX(+) group and 44.8% in MTX(–) group (p=0.39). Independent predictive factors at baseline for remission were disease duration [OR:0.90, 95%CI (0.83–0.97)] in MTX(+) group while DAS [OR:0.49, 95%CI (0.29–0.83)] in MTX(–) group based on multivariate analysis. We also showed significant difference in association of DAS at baseline to remission between groups using AUC of ROC curve (AUC 0.59 vs 0.73, Fig. 1). Interestingly, after matching baseline characteristics, achievement of remission in MTX(–) group depended on disease activity at baseline while that in MTX(+) group did not. The cut-off value of DAS28 at baseline for achievement of remission was 4.87 (sensitivity 0.61, specificity 0.84) in MTX(–) group.



**Conclusions:** There is significant difference in baseline predictive factors for good clinical results by concomitant MTX use during TCZ treatment. The results should be taken into consideration to predict clinical response in clinical practice.

## AB0378 IMPROVEMENTS IN MEASURES OF WORK PRODUCTIVITY/INTERFERENCE AND GENERAL HEALTH STATUS WITH SIRUKUMAB TREATMENT IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE DISEASE-MODIFYING ANTI-RHEUMATIC DRUG TREATMENT

T. Takeuchi[1], G. Karpouzas[2], C. Thorne[3], K. McQuarrie[4], S. Sheng[4], W. Xu[4], S. Peterson[4], R. Ganguly[5], C. Han[4], K. Fei[4], B. Hsu[4]. *[1]Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan; [2]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, United States; [3]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [4]Janssen Research & Development, LLC, Spring House, PA; [5]GlaxoSmithKline, King of Prussia, PA, United States*

**Background:** Treatment-related improvements in the ability to perform work and general health status are key outcomes from the perspective of a patient with rheumatoid arthritis (RA). Sirukumab is a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity and is under development for RA and other diseases.

**Objectives:** To evaluate the effects of sirukumab on work productivity/interference and general health status in patients with active RA refractory to conventional, synthetic disease-modifying anti-rheumatic drugs (DMARDs).

**Methods:** In a randomized, double-blind, Phase 3 global study, patients with active RA and inadequate response to DMARDs were randomly assigned (1:1:1) to treatment with sirukumab SC 50 mg q4w, sirukumab SC 100 mg q2w, or placebo SC q2w. Patients on placebo with insufficient (<20%) improvement at Weeks 18 or 40 or who remained on placebo at Week 52 were re-randomized to receive treatment in 1 of the 2 sirukumab groups. The Work Limitations Questionnaire (WLQ) was used to evaluate health-related job limitations and productivity loss. The 3-level EuroQol-5 Dimension (EQ-5D) questionnaire was used to measure 5 dimensions of health status (mobility, self-care, usual activities, pain or discomfort, and anxiety or depression). The changes from baseline in the WLQ scores, EQ-5D index score (based on UK TTO), and EQ-5D health state visual analog scale (VAS) scores at Weeks 24 and 52 were evaluated as secondary endpoints.

**Results:** Mean WLQ production loss scores improved significantly from baseline for both sirukumab 50 mg q4w and 100 mg q2w compared with placebo at Weeks 24 and 52 (all $P<0.001$). In addition, significantly greater improvements from baseline were also observed in all 4 mean WLQ domain scores (mental-interpersonal, output, physical demands, time management) for both doses of sirukumab compared with placebo at Weeks 24 and 52 (all $P<0.05$). Both the mean EQ-5D index and health state VAS improved significantly from baseline with both sirukumab doses compared with placebo at Weeks 24 and 52 (all $P\leq0.002$).

Table 1. Mean (SD) change from baseline in WLQ and EQ-5D scores at week 52[a]

| Outcome | Placebo | Sirukumab 50 mg q4w | Sirukumab 100 mg q2w |
|---|---|---|---|
| *WLQ* | *(n=227)* | *(n=223)* | *(n=221)* |
| Production loss (total) score | –0.73 (5.03) | –3.06 (4.53)[b] | –2.94 (4.39)[b] |
| Domain scores | | | |
| Mental-interpersonal | –1.39 (21.09) | –8.45 (19.23)[b] | –8.69 (19.37)[b] |
| Output | –2.47 (24.17) | –12.39 (23.03)[b] | –12.18 (22.38)[b] |
| Physical demands | –4.70 (23.29) | –12.91 (22.27)[b] | –8.70 (21.00)[c] |
| Time management | –5.75 (25.52) | –16.54 (24.41)[b] | –16.38 (23.79)[b] |
| *EQ-5D* | *(n=556)* | *(n=557)* | *(n=557)* |
| Index[d] | 0.13 (0.34) | 0.20 (0.33)[b] | 0.20 (0.33)[b] |
| Health state VAS | 8.30 (26.14) | 16.80 (28.60)[b] | 17.14 (28.33)[b] |

[a]n values are based on initial treatment assignment and varied slightly for WLQ domain scores. [b]$P<0.001$. [c]$P=0.047$. [d]Based on UK TTO.

**Conclusions:** In patients with active RA refractory to DMARDs, sirukumab treatment was associated with significant improvements in work-related productivity and general health status, consistent with disease improvement demonstrated with sirukumab treatment.

## AB0379 TAPERING OR STOPPING OF METHOTREXATE IN NON-TUMOR NECROSIS FACTOR THERAPY (TOCILIZUMAB AND ABATACEPT) IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Hirano[1], S. Hirabara[1], M. Isono[1], Y. Oishi[1], N. Ishiguro[2], T. Kojima[2]. [1]*Rheumatology, Toyohashi Municipal Hospital, Toyohashi;* [2]*Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Non-tumor necrosis factor (TNF) agents, such as tocilizumab (TCZ) and abatacept (ABT), were widely used in the treatment of rheumatoid arthritis (RA). It seems that non-TNF agents are slightly different from anti-TNF agents in respect to dependency on methotrexate (MTX). Although MTX is a very important concomitant drug in anti-TNF therapy, MTX may not be so in non-TNF therapy for majority of patients. MTX have many severe adverse events (AE) such as interstitial pneumonia, severe infection, and myelosuppression. Tapering or stopping of MTX have been tried in our institute to avoid AE of MTX when RA patients treated with non-TNF agents reached at sustained remission. We report the preliminary results of MTX tapering in non-TNF therapy in this study.

**Objectives:** This retrospective study evaluated tapering or stopping of MTX in non-TNF therapy (TCZ and ABT) and impact of it to RA treatment in clinical practice.

**Methods:** 27 RA patients who initiated TCZ or ABT with concomitant MTX and continued non-TNF agents for 2 years were used. Time-course of disease activity (DAS28-CRP and CDAI), arthritis marker (serum MMP-3), activity of daily living (mHAQ), joint destruction ($\Delta$mTSS per a year) and tapering concomitant drug (MTX and prednisolone) were investigated. MTX was tapered depending on physicians decisions and stopped if possible.

**Results:** 20 females and 7 males with mean age of 60 years were used in this study. Mean RA duration was 11.8 years. TCZ was continued for 2 years in 16 cases and ABT in 11 cases. MTX of mean dosage of 9.0mg/week (4.0–16.0 mg/w) was prescribed in all patients at baseline. Mean DAS28-CRP was 4.57 at baseline, 2.26 at 1 year and 2.00 at 2 years. There were significant decreases not only from baseline to 1 years ($p<0.0001$) but also from 1 year to 2 years ($p=0.04$). Significant decrease and sustainment were also observed in CDAI, serum MMP-3 and mHAQ) (Fig. 1). Although $\Delta$mTSS at baseline was )10.0, it was significantly improved to 1.5 from baseline to 1 year ($p=0.0001$) and to 0.5 from 1 year to 2 years ($p<0.0001$). Mean MTX dosage was significantly decreased from 9.0mg/w at baseline to 4.8mg/w at 1 year ($p=0.0003$) and to 2.9mg/w at 2 years ($p<0.0001$). There was a significant difference of MTX dosage between at 1 year and 2 years ($p=0.049$). Although MTX was concomitant in all patients at baseline, it was used in only 66.7% at 1 year and only 40.7% at 2 year. Mean PSL was also tapered from 3.5mg/day at baseline to 1.2mg/d at 2 years (Fig. 2). Similar trends were observed in both patients treated with TCZ and ABT.

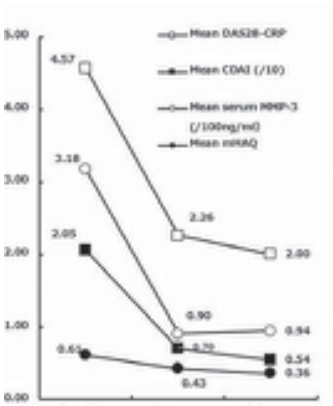

Fig1. Time courses of evaluated parameters

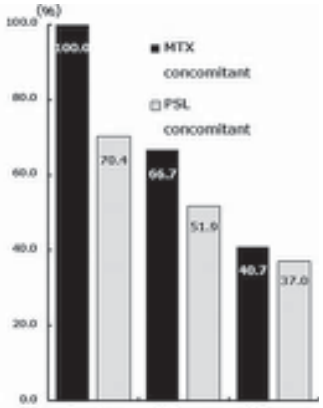

Fig2. Rates of concomitant MTX & PSL

**Conclusions:** This study suggested that concomitant MTX may be tapered or stopped in RA patients treated with TCZ or ABT and reached to sustained remission without worsening disease activity and joint destruction. Information of prospective large studies was necessary in the future.

**Disclosure of Interest:** None declared

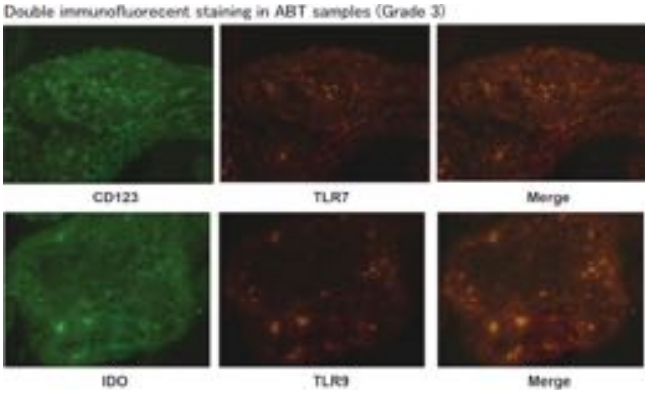
## AB0380 EXPERIENCE WITH RITUXIMAB IN THE MANAGEMENT OF RECURRENT TOCILIZUMAB INDUCED MACROPHAGE ACTIVATION SYNDROME IN AN ADULT PATIENT WITH SYSTEMIC-ONSET JUVENILE IDIOPATHIC ARTHRITIS (STILL'S DISEASE)

Y. Muraviev, V. Lebedeva, S. Soloviev, N. Nokanorova, E. Nikolaeva, V. Khlaboschina, L. Bozhieva. *Federal State Budgetary Institution "Research Institute of Rheumatology" under the Russian Academy of Medical Sciences, Moscow, Russian Federation*

**Background:** Macrophage activation syndrome (MAS) is a potentially fatal complication of Still's disease (SD). The use of *biologic disease-modifying antirheumatic drugs* (bDMARDs) has significantly improved the prognosis in SD pts, although most recent reports on MAS linked to use of bDMARDs in SD patients raise certain concern.

**Objectives:** To share the experience from the use of bDMARD for management of MAS, induced by other bDMARDs in an adult patient with SD.

**Methods:** Description of a case of successful rituximab therapy for MAS, induced by tocilizumab in an adult SD patient.



**Results:** In a patient Sh.,18 yo, the onset of SD occurred in December 2008y (at the age of 14 y.o.), manifesting with fever 39°C, arthralgia, lymphadenopathy, hepatosplenomegaly, neutrocytosis, maculopapular rash, ESR up to 40 mm/h, CRP 48 mg/L. Prednisone (50 mg/day) was discontinued shortly due to emergence of multiple duodenal ulcers (EFGDS), which resulted in increasing CRP up to 154 mg/L, anemia (nv-89 g/L), neutrocytosis up to $14{,}7x10^9$, elevated ALT and AST >120 EU/L, LDH 735 U/L, and ferritine >12000 μg/L. This condition progressed to tonic-clonic seizures and coma, leucopenia ($4{,}5x10^9$), and thrombocytopenia ($33x10^9$). MAS was documented. GCs were re-administered (prednisone 50 mg/day, methylpred pulse-therapy), sandimmun was also commenced at 200 mg/day dose. By 2013 y. the dose of prednisone was down-titrated to 2,5 mg/day and of sandimmun - to 100 mg/day. At this dose level a relapse of fever 38,5° C, arthralgia, pharyngalgia and rash on the forearms occurred. The dose of prednisone was up-titrated to 20 mg/day, but arthralgia and ubnormal lab parameters of active disease persisted (ferritine, CRP, ESR), necessitating administration of tocilizumab (8 mg/kg). But second infusion of tocilizumab caused severe adverse reaction (dyspnea, drop of BP, nausea, dizziness) with MAS reoccurrence (fever 39,5° C, thrombocytopenia, anemia, elevated liver

enzymes, ferritine, hypofibrinogenemia, hypertriglyceridemia), necessitating up-titration of methylpred dose up to 40 mg/day, pulse therapy with methylpred and dexamethasone, IVIG (2.5 g/kg total dose), SAMe. Associated pneumonia was successfully cured with antibiotics (CT verified). Rituximab 1000 mg was administered i/v by drop infusion, and repeated after 6 mo. Currently the patient does not voice any specific complaints, her lab parameters are constantly normal (remission), the methylpred dose was down-titrated to 4 mg/day.
**Conclusions:** Presented case, on one side, raises the appropriateness of updating the summary of product characteristics&directions for tocilizumab use in package circular/prescribing info, and on the other side, confirms the usefulness of rituximab for refractory Still's disease, complicated with MAS.
**Disclosure of Interest:** None declared

### AB0381 EXPRESSION OF TOLL-LIKE RECEPTORS AND DISTRIBUTION OF IMMUNE-CELLS IN RHEUMATOID SYNOVIAL TISSUES OF THE PATIENTS TREATED BY ABATACEPT

Y. Takakubo, Y. Naganuma, H. Oki, S. Yang, K. Sasaki, M. Takagi. *Department of Orthopaedic Surgery, Yamagata University Faculty of Medicine, Yamagata, Japan*

**Background:** Rheumatoid arthritis (RA) is a progressive chronic autoimmune and autoinflammatory disease affecting multiple joints simultaneously[1]. Abatacept (ABT) which is cytotoxic T-lymphocyte-associated protein (CTLA) 4-Ig agent is one of biologics[2].
**Objectives:** The aim of this study is to examine the effect of ABT for evaluating immune-reactive cells with toll-like receptors in the synovial tissue samples of RA patients with ABT therapy (ABT groups) compared to them with non-biological therapy (Non-BIO groups).
**Methods:** Synovial tissue samples of 20 RA (10 ABT and 10 Non-BIO samples) were immunohistochemically stained with TLR+ and immune-reactive cells including T cells (CD2), B cells (CD20), macrophage (CD68), conventional dendritic cells (cDC; S100, DC-LAMP), regulatory T cells (FoxP3) and indoleamine 2,3-dioxygenase+ cells (IDO). Positive cells were counted per 10 fields (x 200) by microscopy. TLR positive cells were analyzed by double Immunofluorescent methods with T cell, B cell, macrophage, cDC and plasmacytoid DC (pDC; CD123)-markers and IDO. Synovial inflammation was estimated by Krenn grading score.
**Results:** ABT and non-BIO group was shown the similar grading scores (2.3 vs 2.0), DAS28CRP4 (5.1 vs 4.3) and CRP (1.3 vs 0.9). IDO+ and FoxP3+ cells, not CD3+, CD20+ and CD68+ cells were correlated significant with DAS28CRP (4) in lymphoid aggregation in ABT groups ($p<0.01$). TLR immunoreactivity was also confirmed in pDCs and IDO+ cells by immunofluorescent staining (Fig. 1).

**Conclusions:** ABT was reported the similar remarkable effect with other biologics. We have already shown the residual inflammation of synovitis with TLR expressions in the RA patients who were received TNF-blockers[3]. TLR+ cells were observed with T cells and B cells related local inflammatory grading in ABT groups, however regulatory immune-cells might be increased and regulate inflammatory simultaneously. CTLA-4 and IDO was recently revealed the generation of osteoclast [4,5]. IDO+ cells increased in synovial tissues of ABT group compared to no-BIO group. ABT may not only regulate the immunosuppression but also suppress the activation of osteoclast in RA.

## Rheumatoid arthritis - non-biologic treatment and small molecules

### AB0382 PREVENTION OF VENOUS THROMBOEMBOLISM (VTE) AFTER TOTAL KNEE REPLACEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Rybnikov[1], E. Byalik[1], T. Reshetnyak[2], S. Makarov[1], M. Makarov[1], V. Pavlov[1], A. Khramov[1], E. Naryshkin[1]. *[1]Orthopaedic; [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** In this study, we analyzed incidences of VTE in patients with rheumatoid arthritis (RA) and osteoarthritis (OA) after total knee or hip arthroplasty, compared schemes of drug prevention and evaluated their efficiency.
**Objectives:** To evaluate the efficiency of prevention of VTE in patients with rheumatoid arthritis and osteoarthritis after total knee replacement under comparable conditions
**Methods:** We studied 151 patients operated in V.A. Nasonova Research Institute of Rheumatology for the period 2014–2015. Of these, 72 patients with RA (47.7%) and 79 patients with OA (52.3%). For a comparative analysis of the efficiency of anticoagulant therapy, each patient group was divided into 2 subgroups by type of drug therapy. The first - nadroparin calcium (the drug therapy was started for 12 hours after the operation at a dose of 0.1 ml per 10 kg of body weight one time per day), the second - nadroparin calcium with transfer to dabigatran etexilate (the first stage of 4 hours after the operation was started therapy by nadroparin calcium, and then after the removal of the epidural catheter moved to the dabigatran etexilate).Doppler ultrasonography (DUS) was routinely performed preoperatively and on postoperative day 7, 14, then 1 time a month for diagnosing a deep venous thrombosis (DVT). Time of observation was 6 months.
**Results:** VTE were reported in 6 (3.9%) patients, 1 of them (0.7%) with RA and 5 (3.3%) with OA. Distal deep vein thrombosis developed on 15 days after total knee replacement in RA patient. He received nadroparin calcium only. 4 patients with VTE after surgery from OA group used nadroparin calcium and 1 patient was on combined drug therapy. Of the 6 cases of VTE 4 (66.7%) were asymptomatic and 2 (33.3%) with development of clinical and laboratory picture. The case of thrombosis in a group of RA was asymptomatic. In a perioperative period of clinically significant bleeding was not seen.
**Conclusions:** Cases of VTE in patients with RA, despite the large number of risk factors, under comparable conditions is significantly lower than patients with OA. The number of asymptomatic deep vein thrombosis prevails over the development of clinical and laboratory complex of symptoms in both groups. In patients with RA and OA who were from the first group have reported 5 cases of VTE and only 1 case of VTE have reported in patients who were from second group. Combined drug VTE prevention in patients with RA and OA has been most effective and safe.
**Disclosure of Interest:** None declared

### AB0383 WHAT'S DIFFERENT ABOUT RHEUMATOID PATIENTS ON LONG TERM STEROIDS?

A. Sathiyakeerthy[1], S. Burton[2], H. Jones[3], S. Sukumaran[4], R. Britten[5], T. Ahmed[5], R. Hughes[6], J. Wajed[2], J. Galloway[1], S. Kaushik[1], M. Lloyd[2]. *[1]Rheumatology, Kings College Hospital, London; [2]Rheumatology, Frimley Park Hospital, Frimley; [3]Rheumatology, Kingston Hospital, Kingston; [4]Rheumatology, William Harvey Hospital, East Kent; [5]Rheumatology, Croydon University Hospital, Croydon; [6]Rheumatology, Ashford and St Peter's Hospital, Chertsey, United Kingdom*

**Background:** Corticosteroids have been in and out of fashion as treatment in rheumatoid arthritis (RA) since their introduction in the 1940s. Current EULAR recommendations suggest using oral prednisolone at initiation and then for up to 6 months (1). However, studies suggest up to 30% of RA patients remain on prednisolone for much longer periods (2). We were interested in the characteristics of these long term current prednisolone users, and aimed to compare them to a cohort of RA patients not currently using oral prednisolone using data from our regional audit group.
**Objectives:** To describe the characteristics of RA patients currently taking oral prednisolone for more than 12 months (COP), and to compare to them to a cohort of RA patients not taking prednisolone (NOP).
**Methods:** 7 centres in our regional audit network submitted consecutive RA patients until we had achieved 100 patients in each group. We analysed demographics, duration of RA, use of second line medication, total number of medications, co-morbidities (ischaemic heart disease, hypertension and type 2 diabetes), bone density and RA activity measures.
**Results:** The table below shows key results. The mean daily steroid dose in the COP group was 6.6mg and the mean duration of current steroid use was 4.9 years. Similar numbers of patients in the COP and NOP groups were also using a conventional DMARD and/or biologic (85% and 86% respectively). 39% of both groups had one or more of the 3 comorbidities we looked for. 4% of the COP group had all 3 comorbidities compared to none of the NOP group and 5% of the COP group had 2 out of 3 comorbidities compared to 8% in the NOP group.

DEXA scans were available for 61% of COP and 31% of NOP patients. The mean T score in the COP group was -1.2 compared to -1.05 in the NOP group.

| | Current users | Non-current users |
|---|---|---|
| Number | 100 | 100 |
| Average Age (years) | 64.7 | 61.5 |
| Female (%) | 71 | 78 |
| Mean duration of RA (years) | 11.3 | 8.9 |
| Mean DAS28 score | 3.8 | 3.4 |
| Mean ESR (mm/hr) | 27 | 16 |
| Mean CRP (mg/L) | 21.5 | 9.2 |
| Mean total number of current medications | 8 | 5 |
| Total number on non-biologic DMARDs | 50 | 67 |
| Total number on biologic DMARDs | 12 | 3 |
| Total number on both non- biologic and biologic DMARDs | 23 | 17 |

**Conclusions:** This study provides a snapshot of an important group of 'real world' steroid-using RA patients who are perhaps under-represented in the literature. In our audit RA patients on long term prednisolone tended to be a little older, have a longer duration of RA, greater polypharmacy and greater disease activity. Interestingly, the prednisolone users were taking at least as much other second line medication as the non users, suggesting prolonged steroid use may suggest difficult to control RA rather than avoidance of polypharmacy. Co-morbidities seemed similar between groups. The relatively long duration of prednisolone treatment suggests that RA patients on steroids for more than one year are likely to stay on steroids longer term.

## AB0384 THE EFFECTS OF PENTOXIFYLLINE ON RHEUMATOID ARTHRITIS ACTIVITY ACCORDING TO THE DAS28 CRP DISEASE ACTIVITY SCORE

D.S. Bublikov, A.V. Andrienko, V.G. Lychev, D.A. Anchugina. *Department of Hospital Therapy, Altay State Medical University, Barnaul, Russian Federation*

**Background:** Treatment of rheumatoid arthritis (RA) prior to "Treat to target" is difficult enough, forcing researchers around the world look for ways to improve the effectiveness of RA treatment.

**Objectives:** To explore the possibilities of reducing RA activity on the disease activity score DAS28 CRP by adding pentoxifylline to the methotrexate treatment.

**Methods:** This study included women (n=101) with RA longer than 1 year in duration, have a seropositive rheumatoid factor, and DAS28 CRP activity score of 3.2–5.1. Middle aged – 45.04±5.24 years old. All patients received a 15.50±2.50 mg oral dose of methotrexate per week. Patients were divided into two groups - those who only had methotrexate (n=50) and those who were treated with an oral dose of methotrexate and 1200 mg of pentoxifylline per day (n=51).

**Results:** The baseline for both groups of RA patients did not differ significantly in terms of the level on the DAS28 CRP (p=0.812). On 14th day of the group who were taking pentoxifylline, the DAS28 CRP disease activity score was significantly lower by 12.5% ($p<0.001$). After 28 days, the users had a DAS28 CRP disease activity score index difference. The difference between two groups is statistically significant. In the group that were treated with pentoxifylline in addition to methotrexate (p=0.001) the index was found to be 8.3% lower. For 28 days, the methotrexate group's disease activity according to the DAS28 CRP activity score significantly decreased by 14.3% from the baseline ($p<0.001$). For 28 days, the pentoxifylline + methotrexate group also achieved a statistically significant reduction in the index according to the DAS28 CRP activity score by 20.5% ($p<0.001$)

The disease activity index for the two groups for 14 and 28 days is shown in the table.

DAS28 CRP Index in the two groups of RA patients

| Groups of patients and observation time | Group Methotrexate (n=50) | Group Methotrexate + Pentoxifylline (n=51) | Statistical significant differences between the two groups |
|---|---|---|---|
| Baseline | 3.11±0.05 | 3.13±0.05 | p=0.812 |
| For 14 days | 3.06±0.05 | 2.69±0.06 | $p<0.001$ |
| For 28 days | 2.71±0.04 | 2.48±0.06 | p=0.001 |

**Conclusions:** Thus, converting the monotherapy methotrexate to pentoxifylline will significantly reduce the activity of RA, while avoiding many of the adverse effects of the other combination therapies. This data requires further long-term research.

## AB0385 TOFACITINIB IN RHEUMATOID ARTHRITIS: RESULTS OF POST-APPROVAL INVESTIGATOR INITIATED TRIAL

D. Karateev[1], E. Luchikhina[1], D. Abdulganieva[2], S. Lapshina[2], A. Baranov[3], N. Lapkina[3], D. Petrov[3], O. Ivanova[4], T. Salnikova[5], V. Sorotskaya[5], O. Semagina[6], V. Mazurov[7], R. Samigullina[7], D. Chakieva[7], A. Babaeva[8], E. Kalinina[8], A. Sizikov[9], O. Chumasova[9], N. Demidova[1], A. Misiyuk[1], E. Nasonov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Moscow; [2]Kazan State Medical University, Kazan; [3]Yaroslavl State Medical University, Yaroslavl; [4]Voronezh Regional Clinical Hospital, Voronezh; [5]Tula Regional Clinical Hospital, Tula; [6]Samara Regional Clinical Hospital, Samara; [7]North-western State Medical University named after I.I.Mechnikov, Saint-Petersburg; [8]Volgograd State Medical University, Volgograd; [9]Scientific Research Institute of Clinical immunology, Siberian Branch, Russian Academy of Sciences, Novosibirsk, Russian Federation*

**Background:** Tofacitinib (TOFA) was approved in Russia for treatment of patients with rheumatoid arthritis (RA) in 2013, but published information about its post-approval use limited to some individual clinical observations.

**Objectives:** To study the efficacy and safety of TOFA in patients with severe active RA in clinical practice.

**Methods:** We present the preliminary results of ongoing investigator initiated study "Local open label multicenter observational study of efficacy and safety of Tofacitinib in patients with active rheumatoid arthritis with insufficient response to DMARDs", a part of a research program "Russian investigation of methotrexate and biologics in early active inflammatory arthritis" (REMARCA). We included 120 patients (pts) with severe active RA (97 females, 23 males), with median age 51,0 [41,25; 59,0] years and disease duration 60,0 [24,25; 120,0] months, 92 (76,7%) RF positive, 91 (75,8%) ACPA positive, who were non-responders to methotrexate (MTX) at least 15 mg/week and/or other synthetic DMARDs, and biological DMARDs (b-DMARDs). 9 of 30 b-DMARDs non-responders had 2–4 biologics in history. Tuberculin test and chest X-ray were performed in all pts before TOFA prescription. We use TOFA in all the pts in starting dose 5 mg BID per os with possibility to increase the dose to 10 mg BID if needed. The use of TOFA in combination or as monotherapy was a prerogative of the rheumatologist. By January 2016, 91 patients received TOFA for 3 months and 55 pts – for 6 months.

**Results:** TOFA used in combination with MTX in 84 (70%) pts, with Leflunomide in 12 (10%), as monotherapy – in 24 (20%) pts. Dose escalation to 10 mg BID was carried out in 25 (20,8%) pts. Results presented in the table. 20 episodes of adverse events (AEs) in 14 pts observed: liver test 2-fold elevation – 4 cases, Herpes simplex – 3, skin rash – 2, erysipelas – 1, Herpes zoster – 1, latent TB activation – 1, bronchitis – 1, nasopharyngitis – 1, cystitis – 1, hemorrhoids – 1, headache – 1, nausea – 1. No serious AEs were reported. TOFA has been withdrawn in 4 pts: three due to lack of efficacy, one due to allergic skin rash.

Table 1

| | Baseline (n=120) | Month 3 (n=91) | Month 6 (n=55) |
|---|---|---|---|
| DAS28-ESR | 5,92 [5,15; 6,62] | 4,53 [3,47; 5,44]* | 3,88 [2,93; 4,44]* |
| DAS28-ESR remission/LDA | 0/0 | 10 (11%)/11 (12,1%)* | 10 (18,2%)/3 (5,5%) |
| SDAI | 32,2 [25,9; 43,8] | 15,7 [10,2; 23,8]* | 16,5 [11,1; 26,2]* |
| SDAI remission/LDA | 0/0 | 7 (7,7%)/20 (22%)* | 3 (5,5%)/10 (18,2%)* |
| CDAI | 28,3 [21,0; 37,9] | 12,0 [7,0; 19,0]* | 9 [5,0;16,0]* |
| CDAI remission/LDA | 0/0 | 7 (7,7%)/29 (31,9%)* | 3 (5,5%)/25 (45,5%)* |

*$p<0,01$ in comparison with the baseline values in the same pts.

**Conclusions:** TOFA was effective in clinical practice for control of disease activity in patients with severe RA with multiple resistance to synthetic and biological DMARDs during short-term follow up. Safety was satisfactory; there were no cases of serious AEs.

## AB0386 EFFECTIVENESS OF TRIPLE THERAPY USING TACROLIMUS, MIZORIBINE AND METHOTREXATE (MTX) FOR RHEUMATOID ARTHRITIS PATIENT RESISTANCE TO MTX – COMPARISON TO BIOLOGIC AGENTS

E. Torikai, M. Suzuki, Y. Matsuyama. *Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan*

**Background:** The advancement in biological agents and improvement in treatment strategy enabled many patients with rheumatoid arthritis to achieve remission or low disease activity. On the other hand, the cost of biological agents has become major problem in health economics and for some patients biological therapy is not affordable. Therefore recently, combination of conventional disease-modifying anti-rheumatic drugs (DMARDs) therapy have been reconsidered and some studies proved that triple therapies could be as efficacious as biologic agents.

**Objectives:** To compare retrospectively the triple therapy consisting of methotrexate (MTX), tacrolimus (TAC) and Mizoribine (MZR) with biologic agents in patients with established rheumatoid arthritis with no improvement despite the treatment with MTX.

**Methods:** Fifty one established RA patients with a disease duration more than 2 years were included. They showed no improvement the despite treatment with MTX for at least 3 months. We classified patients in 2 groups, one group with the addition of TAC and MZR (csD group) and the other with TNF inhibitor (bD group). There were no significant differences between the backgrounds of the two groups. We evaluated DAS28CRP scores, the van der Heijde-modified total sharp scores [1] and ARASHI change scores [2] which is a scoring system of large joint destruction and compared them between both groups for 2 years. Moreover we performed questionnaire of patient's satisfaction for the therapies.
**Results:** There were no significant differences of DAS28CRP at baseline. Both groups had significant improvement of the scores at final evaluation. There was a significant difference of the improvement rate in DAS28CRP of the bD group in comparison with the csD group at 1 month after treatment. However, no significant difference was observed between the two groups at 3 months and beyond after the treatment (Figure). There was a significant difference in the radiographic progression of small joints between both groups at the final evaluation (csD 0.53/year and bD 0.19/year). Main reasons for the discontinuation the treatment was the adverse events in csD group (csD 23.1% and bD 6.9%), as opposed to patient's intension in bD group. Although patient's satisfaction for improvement of disease activity was simila between the two groups, patient's intension to continue the therapy in csD group was higher than in the bD group. Many patients in bD group complained of the treatment expense.

**Conclusions:** Triple therapy using TAC, MZR and MTX enabled good clinical benefit even in comparison with the biologic agents. Moreover the triple therapy showed rapid effect which was significant within 3 months. However we should also focus on the mechanism for inferior effect on preventing the small joint destruction.

## AB0387 EFFICACY OF 12-MONTH THERAPY WITH METHOTREXATE SOLUTION FOR SUBCUTANEOUS INJECTION (SC MTX) IN PATIENTS WITH EARLY RA WITH DIFFERENT BODY MASS INDEX (BMI)

G.I. Gridneva, Y. Muraviev. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The levels of inflammation markers, specifically C-reactive protein (CRP), are known to be elevated in patients with excessive body weight.
**Objectives:** To evaluate the efficacy of 12-month therapy with SC MTX in patients with recently emerged RA with different BMI.
**Methods:** MTX-naive patients with active early RA (<6 months) diagnosed in accordance with ACR/EULAR 2010 or ACR 1987 (DAS28>3.2) before inclusion were eligible for the 12-month open study. Patients were divided into 3 groups depending on the BMI: I ≤25 kg/m$^2$, II =25–30 kg/m$^2$, III ≥30 kg/m$^2$. Monotherapy with SC MTX once weekly was administered to all patients; starting dose – 10–15 mg per week with escalation of 5 mg every 1–2 weeks (maximum dose – 30 mg per week) until treatment targets were reached (DAS28≤2.6) or adverse events (AE) appeared. Given that patients received almost identical single doses of SC MTX, but had different BMI, we have calculated the dose in mg per m$^2$, calling it the actual dose (AD). Folic acid was administered at the dose of at least 5 mg per week on any day(s) except for the date of SC MTX administration. Disease activity was determined using $DAS28_{ESR}$, $DAS28_{CRP}$ and SDAI. Remission was determined in accordance with ACR/EULAR 2011 criteria.
**Results:** 47 patients (38 female, 9 male) with mean RA duration of 4.2±1.7 months and mean age of 51.0±13.2 years were included. There were no differences between groups defined on the basis of BMI in gender, disease duration, rheumatoid factor, baseline disease activity. The majority of patients have not received DMARD or glucocorticoids (GC) before. After 3, 6 and 12 months of monotherapy with SC MTX we received different results between groups (see table). AE were similar in all groups at each time point.
**Conclusions:** Treatment effect of SC MTX in patients with recently emerged RA correlates with BMI and is significantly increased in patients with normal BMI (≤25 kg/m$^2$) than in patients with excessive body weight or obesity.

Txagorritxu, Araba, Vitoria, Spain*

**Background:** Lack of adherence to medication in rheumatoid arthritis (RA) can worsen disease activity.
**Objectives:** To evaluate the risk of non-adherence to disease modifying antirheumatic drugs (DMARD) in RA patients treated with subcutaneous (SC) biological therapy.
**Methods:** ARCO was a retrospective study in RA patients ≥18 years-old from 42 Spanish hospitals on SC biological therapy. The risk of non-adherence to oral DMARD was evaluated using the Compliance Questionnaire in Rheumatology (CQR), a questionnaire validated against an electronic medication-monitoring system, for a cut-off point of taking ≤80% of the doses. Patients completed the Beliefs About Medicines Questionnaire (BMQ) and the Carbonell satisfaction

Risk of non-adherence to DMARD according to socio-demographic characteristics

| | | Risk of non-adherence | p |
|---|---|---|---|
| Age (years) | Q1: (≤48) | 37.4% | <0.001 |
| | Q2 (>48–56) | 15.0% | |
| | Q3 (>56–63) | 11.1% | |
| | Q4 (>63) | 21.7% | |
| Gender | Men | 26.5% | 0.361 |
| | Women | 20.3% | |
| Ethnic group | Caucasian | 20.5% | 0.107 |
| | Others | 38.1% | |
| Risk of alcoholism (AUDIT) | No | 21.0% | 0.429 |
| | Yes | 30.4% | |
| Educational level | Primary | 16.0% | 0.143 |
| | Secondary | 24.2% | |
| | Professional | 21.6% | |
| | University | 30.5% | |
| Employed | No | 17.8% | 0.039 |
| | Yes | 27.2% | |
| Comorbidities | No | 29.6% | 0.050 |
| | Yes | 18.5% | |

**Abstract AB0387** – Table 1. Efficacy of 12-month therapy with SC MTX in patients with recently emerged RA with different BMI

| Necessity of bDMARDs usage, % ($p_{1-2}$=0.02; $p_{1-3}$=0.002) | 23% | 60% | 60% |
| Remission according to ACR/EULAR 2011 ($p_{1-2}$=0.1; $p_{1-2}$=0.07; $p_{1-2}$=1) | 12 (60%) | 5 (30%) | 3 (30%) |

questionnaire (Spanish validated questionnaire on satisfaction with medication).
**Results:** 364 patients were included (mean age 54.9 years [SD 12.5]; 77.5% women median RA duration 7.8 years). Complete CQR was available for 304 patients, of which 21.7% showed risk of non-adherence to oral DMARD (95% CI: 17.4 – 26.7%). The percentage was similar in men and women, and greater in extremes of age (>63 and ≤48 years-old), in those currently working and in patients with no comorbidities (Table). There was a trend to a higher percentage at risk of non-adherence in non-Caucasian patients, those with higher educational level and in those with risk of alcoholism (AUDIT questionnaire) (Table). The percentage with risk of non-adherence was similar in patients with 1, 2 or >2 oral drugs for RA, and in those treated or not with SC methotrexate, and it was higher in those who considered that the effect of their treatment for RA on the symptoms had been less than expected (38.1% vs 17.9% in those who thought it had been greater, p=0.029). No differences were seen with regard to the result of the BMQ.
**Conclusions:** In patients with RA treated with SC biological therapy, 21.7% showed risk of non-adherence to DMARD according to the CQR (taking ≤80% of the doses). The percentage was higher in extremes of age, patients with university degree, employed, without comorbidities and in those who considered that the treatment effect on RA had been lower than expected.

## AB0389 METHOTREXATE TREATMENT FOR RHEUMATOID ARTHRITIS IN POLAND: RETROSPECTIVE ANALYSIS OF PATIENTS IN ROUTINE CLINICAL PRACTICE

J. Świerkot[1], B. Batko[2], M. Stajszczyk[3], M. Jedrzejewski[4], P. Wiland[1].
*[1]Department of Rheumatology and Internal Medicine, Wroclaw Medical University, Wroclaw; [2]Department of Rheumatology, J. Dietl Specialist Hospital, Krakow; [3]Reumatology and Autoimmune Diseases Unit, Silesian Rheumatology Center, Ustron; [4]Gfk Polonia, Warsaw, Poland*

**Background:** Methotrexate (MTX) is a folic acid antagonist which has both an antiproliferative and an anti-inflammatory action. It is the most commonly prescribed DMARD (disease-modifying antirheumatic drug) and is considered the "anchor drug" in rheumatoid arthritis (RA).
**Objectives:** Our study reviews RA treatment with MTX in Poland.
**Methods:** Presented study was based on a retrospective analysis of a cohort of 1957 patients with RA in routine clinical practice. The study was conducted among 100 rheumatologists from different centers that have been selected to reflect the structure of the treatment of RA in Poland. Each physician received 20 questionnaires that were filled on the nearest visit of consecutive 20 patients with RA. Data was collected using pre-defined questionnaire.
**Results:** MTX was taken by 91% of patients and 80% of them continued the treatment both as monotherapy (65%) or concomitantly with other DMARDs. In general, the therapy was initiated within 6 months after diagnosis in 60% of cases. However, MTX was introduced at the very beginning of the treatment for the majority of patients diagnosed after 2009. Methotrexate was given mostly orally, nevertheless in case of 18% of patients it was administered subcutaneously. During MTX treatment dose modifications could be observed in 76% cases and were contingent on different factors. Lack of efficacy was the major reason for increase, while the most common cause of reduction the dose was intolerance of MTX or presence of adverse events, like the most prevalent nausea and vomiting, weakness, increase in activity of liver enzymes and hair loss. Initial dose of MTX was mostly 10 or 15 mg/week. An increase in dosage to 25 mg/week was observed in 36% cases and was continued for 27% of patients. Medium maximum dose that was achieved during treatment was 20.2 mg/week (median 19.3 mg/week). Patients who currently take MTX primarily use a dose of 25 mg/week (27%), 20 mg/week (24%) or 15 mg/week (21%). Treatment interruption was noted in 21% patients predominantly due to intolerance to MTX, however in 13% of cases it was patient's decision. More than half of patients (61%) treated for 3–6 months with MTX achieved remission or low disease activity based on DAS-28.
**Conclusions:** MTX when used according to current recommendations is a effective drug, taking into account the efficacy and adverse effects.
To optimize the MTX therapy regular control visits are required

## AB0390 SAFETY AND EFFICACY OF ABT-494, A NOVEL SELECTIVE JAK1 INHIBITOR, IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE OR INTOLERANCE TO ANTI-TNF BIOLOGIC THERAPY

J.M. Kremer[1], E.C. Keystone[2], P. Emery[3], H.S. Camp[4], A. Friedman[4], L. Wang[4], A.A. Othman[4], N. Khan[4], S. Jungerwirth[4]. *[1]Albany Medical College, Albany, United States; [2]Mount Sinai Hospital, University of Toronto, Toronto, Canada; [3]National Institute for Health Research Leeds Musculoskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom; [4]AbbVie, Inc., North Chicago, United States*

**Background:** ABT-494 is a novel selective JAK1 inhibitor.
**Objectives:** The safety, efficacy, and dose response of ABT-494 were characterized vs placebo (PBO) in patients (pts) with moderately to severely active RA and an inadequate response to ≥1 anti-TNF biologic therapy (TNF-IR).
**Methods:** This was a phase 2b, 12-week, double-blind PBO-controlled study; TNF-IR pts receiving stable background methotrexate (MTX) were randomized 1:1:1:1:1 to ABT-494 3, 6, 12, and 18 mg twice daily (BID) or matching PBO. The primary efficacy endpoint was the proportion of pts who achieved an ACR20 response at week 12.
**Results:** All 276 pts had failed ≥1 anti-TNF therapy prior to enrollment; 28% had received ≥2 anti-TNF biologics and 20% had also received non–anti-TNF biologics. Baseline (BL) characteristics were similar in all treatment groups. The proportion of pts achieving ACR20 at week 12 was significantly higher for all ABT-494 groups vs PBO (Table 1). There was a significant ($P<0.01$) dose response between PBO and all ABT-494 treatment groups for ACR20 response rates (non-responder imputation) at week 12. ACR50 and ACR70 responses were statistically significantly higher at doses of ≥6 mg BID. Changes in DAS28(CRP) from BL were significantly greater for all doses of ABT-494 vs PBO. Onset of action was rapid, with significant differences in ACR20 and change in DAS28(CRP) from BL at week 2 ($P\leq0.007$) for 6, 12, and 18 mg BID vs PBO. Low disease activity and clinical remission per DAS28(CRP) criteria were achieved statistically significantly more often in the 12-mg BID dose group vs PBO. The incidences of AEs were numerically higher in ABT-494 dose groups, with some trend towards dose dependency (Table 2). The majority of infections were mild. There was one serious infection ("bronchiectasis") in the PBO group and none in the ABT-494 treatment groups were reported. Five pts had non-serious events of herpes zoster: 1 pt each in the ABT-494 3 mg, 12 mg, and 18 mg BID treatment groups, and 2 pts in the PBO group. One pt in the 6-mg BID dose group reported 2 events of non-melanoma skin cancer (basal cell and squamous cell carcinomas). There was 1 report of anemia in the 18-mg BID dose group. No deaths were reported during the study.

**Table 1. Efficacy Endpoints at Week 12**

| | PBO (n=66) | ABT-494 3 mg BID (n=66) | ABT-494 6 mg BID (n=65) | ABT-494 12 mg BID (n=66) | ABT-494 18 mg BID (n=66) |

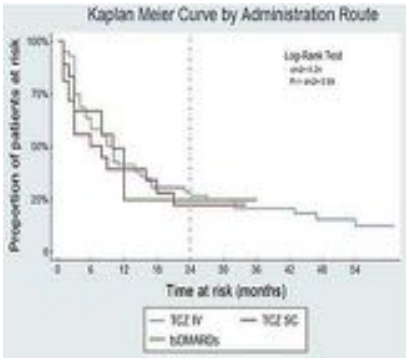
AE, adverse event; BID, twice daily



**Conclusions:** This phase 2b study demonstrated the clinical efficacy of ABT-494 vs PBO when dosed in combination with MTX in TNF-IR pts with active RA. ABT-494 had an acceptable safety and tolerability profile.
**Acknowledgement:** The design, study conduct, analysis, and financial support of the clinical trial (NCT01960855) were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the content. All authors had access to all relevant data. Mariana Ovnic and Michael J. Theisen of Complete Publication Solutions, LLC, provided medical writing support paid for

by AbbVie. This presentation contains information on the investigational product ABT-494.

## AB0391 SUSTAINED REMISSION AND RATE OF RELAPSE AFTER WITHDRAWAL OF BIOLOGIC OR NON-CONVENTIONAL DMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

J.D. Castillo-Ortiz[1], J.J. Castaneda-Sanchez[1], A. Ramirez-Gomez[1], J.M. Sanchez-Gonzalez[2], C. Ramos-Remus[2]. *[1]Unidad de Investigacion en Enfermedades Cronico-Degenerativas; [2]Vicerrectoria Academica, Universidad Autonoma de Guadalajara, Guadalajara, Mexico*

**Background:** Rheumatoid arthritis (RA) treatment has changed considerably over the last decade with the introduction of biologics and target synthetic non-conventional DMARDs. In spite of algorithms about when to begin using these drugs, data about when to stop them are scant.
**Objectives:** To assess the length of remission in patients with RA who had to discontinue a biological or a non-conventional DMARD because a clinical trial ended, and to compare survival remission curves.
**Methods:** A prospective cohort study of RA patients assembled at the time of their last dose of any of the following drugs: tocilizumab subcutaneous (TCZ-SC), TCZ intravenous (TCZ-IV), or targeted synthetic oral drugs (tsDMARDs) tofacitnib or baricitinib p.o. All patients were in RA remission (DAS-28 $<2.6$ and absence of swollen joints). Patients were followed at our clinic in the following way: 1) each patient had a structured telephone interview based on the COPCORD questionnaire every eight weeks by a senior medical student; 2) each patient was instructed to communicate with our center immediately if they were experiencing swollen joints, and 3) All patients had in-office assessments with the same rheumatologists every four months. The primary outcome was RA relapse, defined as the time (months) when the patient presented at least one swollen joint. Survival remission curves were calculated per type of drug (TCZ vs. tsDMARDs) and per route of administration (PO, SC or IV). A Long Rank Test was used to assess differences among survival curves and $p<0.05$ was considered significant. A Cox analysis was used to assess baseline predictors for relapse times.
**Results:** 99 patients were included, 88% female, with a mean age of 47±13 years. Sixty patients were treated with TCZ-IV, 18 with TCZ-SC and 21 with tsDMARDs-PO. Over the following 165 person-years, 27 (27%) remained in RA remission and 73% developed flare-ups (9 months was the median period for a flare-up). There were no significant differences among the three types of administration (IV, SC, and PO) or between the two classes of drugs (biological vs. tsDMARD). None of the baseline variables were significant as predictors of flare-ups.

**Conclusions:** Long-term clinical remission is possible in a number of patients with RA after suspending a biological or non-conventional DMARD. This feature has also been reported with other biological agents, but not with tsDMARDs. Additional data are required to support recommendations for discontinuing a biological agent after achieving remission.
**Disclosure of Interest:** None declared

## AB0392 SAFETY AND TOLERABILITY OF IGURATIMOD IN RHEUMATOID ARTHRITIS WITH COMORBID ILLNESSES

K. Takasugi, M. Okada, C. Min, A. Kitada, Y. Kataoka, S. Kaneshita, M. Suda, Y. Ohara, R. Rokutanda, H. Shimizu, T. Tsuda, K. Yamaguchi, K. Yamaguchi, M. Kishimoto. *Immuno-Rheumatology center, St. Luke's International Hospital, Tokyo, Japan*

**Background:** Iguratimod, a member of the family of methanesulfonanilide, is a relatively new oral anti-rheumatic medication. Although most of the members of this family act as cyclooxygenase 2 inhibitor, iguratimod has been considered to be a novel immunomodulator agent. Little data exists regarding its safety and tolerability in patients with comorbid illnesses.
**Objectives:** To determine the safety and retention rate of Iguratimod in high risk patients.
**Methods:** For the period from December 2012 to July 2015, a retrospective review of medical records was performed at our institution for all patients who had been treated with Iguratimod for rheumatoid arthritis (RA). Baseline characteristic and clinical course were reviewed. For the analysis, using Kaplan-Meier curves, a comparison of adverse events and the number of treatment switches by each risk category (history of malignant neoplasms, latent tuberculosis infection (LTBI), underlying pulmonary disease, and estimated glomerular filtration rate (eGFR $<60$ mL/min/1.73m$^2$)) was conducted.
**Results:** A total of 173 patients were included in this study. The mean age was 68.7 yrs, and the disease duration was 12±10 yrs. Positivity of ACPA was 79% (the mean titer was 127.3 U/mL). Thirty nine patients (22.5%) have history of neoplasms (over 5 years before: n=13, within 5 years: n=14, on current treatment or on best supportive care (BSC): n=12). Thirty eight patients (22%) have LTBI, 46 patients have underlying pulmonary disease (Interstitial pneumonia: n=30, others: n=16). Estimated eGFR$<$60ml/min were seen in 28 patient.
Adverse effects (AE) include rash (n=4), gastrointestinal symptoms (n=10), liver function test abnormality (n=12), renal impairment (n=9), and interstitial pneumoniae (n=3).
None of the patients developed tuberculosis or HBV reactivation during the follow-up period. During the study period, 8 out of the 12 patients with current neoplasms were able to continue Iguratimod. Three patients who currently had neoplasms died during the study (all of whom were BSC patients at the baseline, and the follow-up periods were 199, 378, and 610 days, respectively). One patient was taken off Iguratimod due to an abnormality in the liver function test.
There was no statistical significance on the log-rank analysis for AE, and the number of treatment switches was LTBI (p=0.183), neoplasms (p=0.185), underlying pulmonary disease (p=0.136), and eGFR $<$60ml/min (p=0.373). For AE, LTBI (p=0.239), neoplasms (p=0.953), underlying pulmonary disease (p=0.158), and eGFR $<$60ml/min (p=0.322).
**Conclusions:** This study demonstrated the safety and tolerability of Iguratimod for established high-risk RA patients.

## AB0393 METOTHREXATE PLUS LEFLUNOMIDE STEP-UP THERAPY IN EARLY RHEUMATOID ARTHRITIS PATIENTS WITH NON RESPONSE TO INITIAL METHOTREXATE IN MONOTHERAPY

L.R. Carlevaris. *Reumatologia, El Hospital B. Rivadavia, Ciudad Autónoma de Buenos Aires, Argentina*

**Background:** Treatment of patients with rheumatoid arthritis (RA) must be directed to remission, and in some patients minimum activity, can be an option. The strategy most studied is the early and intensive treatment, associated with a strict monitoring. Half of these patients respond to initial monotherapy with methotrexate (MTX), and in non-responders, additive treatments with other synthetic DMARDs are an option.
The utility of the combined and additive strategy (Step-up) of MTX and Leflunomide (LEF) is not well defined in early RA.
**Objectives:** The objectives of this study was to estimate theproportion of clinical remission achieve by the Step-up strategy with LEF in patients with early RA that did not respond to initial monotherapy with MTX, the time to achieve remission, and estimate the state of remission in the last follow-up evaluation.
**Methods:** An observational study of consecutive case series was performed by including a cohort of patients from Early Arthritis Argentine Consortium (CONAART) with RA of less than 2 years of disease duration, with no response to MTX in monotherapy according to medical judgment, and in whom treatment was additive with LEF. Assessment and data collection was performed every 3 months. Sociodemographic characteristics, functional status, disease activity and treatment were included. "Time to result" was assessed since the date of the beginning with the combination of MTX plus LEF to remission or last control. The

state of remission was evaluated by DAS28. The Kaplan-Meier method was used to estimate the probability of each outcome.
**Results:** A total of 106 patients were included. The mean duration of the disease at the time of inclusion was 4 months (IQR 2–8). The average age was 50±12 years and 83% were women. 68% were positive for RF and 65% for CCP. Median follow-up was 34±18 months (300 patient-years). After addition of LEF, 95 (90%) patients weren't in remission. The mean DAS28 was 4.61 (±1.61), HAQ =0.9 (±0.76), dose of prednisone =7.31 (±4.25). The median time in months of use of MTX was 6.7 (IQR 3.4–14.4), and 64% had doses greater than 20 mg of MTX during follow-up, 47 (50%) of patients achieved clinical remission in an average time of 8 months. The remaining patients did not achieve remission. The overall probability of remission for patients-month follow-up was 0.49. Twenty-seven of the 47 patients (58%) were still in remission at the last visit. Median follow-up after achieving remission was 20 months (IQR 3–29).
**Conclusions:** In this early RA cohort study, 50% of patients with lack of response to MTX who added LEF achieved remission assessed by DAS28 at a median time of 8 months. 6 out of 10 of these patients were in remission at 2 years of follow-up.
**Disclosure of Interest:** None declared

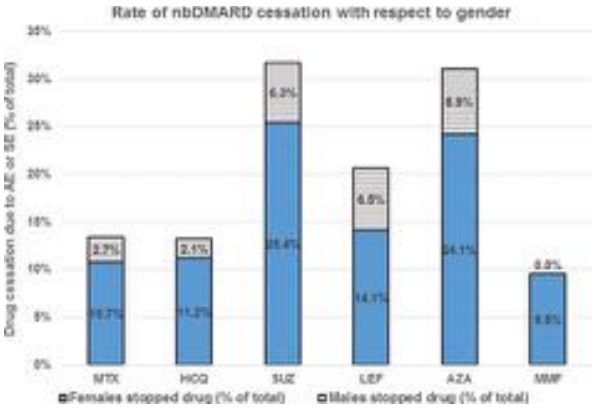
## AB0394 EARLY EFFECT OF TOFACITINIB ON OSTEOCLAST REGULATOR IN RHEUMATOID ARTHRITIS



M. Kitano[1], S. Kitano[1], M. Sekiguchi[1], N. Azuma[1], N. Hashimoto[2], S. Tsunoda[1], K. Matsui[1], H. Sano[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo; [2]Hashimoto Rheumatology Clinic, Osaka, Japan*

**Background:** The selective Janus kinase (JAK) inhibitor tofacitinib has demonstrated excellent efficacy for rheumatoid arthritis (RA). These results suggest the possibility that tofacitinib improves osteoclastic bone destruction of RA. However, the detailed mechanism of tofacitinib for osteoclastogenesis in RA is pooly understood. In this study, we investigated the effect of tofacitinib on serum biomarkers related to osteoclast regulation such as soluble receptor activator of NF-kappa B ligand (sRANKL) and osteoprotegerin (OPG) in patients with RA.
**Objectives:** To clarify the effect of tofacitinib on osteoclast regulator in RA.
**Methods:** Fourteen patients with active RA who inadequate response to disease-modifying antirheumatic drugs (DMARDs) (mean age: 54.6 years, mean disease duration: 4.1 years, mean simplified disease activity index: 26.9, ACPA positive: 86%, oral steroid use: 29%, mean oral steroid dose: 10mg/day, MTX use: 93%, mean MTX dose:10.9mg/week, biologic DMARDs naïve: 57%) were started on treatment with tofacitinib 5mg twice daily (BID). Disease activity was assessed using the 28-joint count disease activity score-C-reactive protein sedimentation rate (DAS28-CRP) and simplified disease activity index (SDAI). Next, circulating levels of sRANKL and OPG were examined by enzyme-linked immunosorbent assay (ELISA) (sRANKL: human RANKL ELISA kit, Biomedica, OPG: human osteoprotegerin ELISA kit, Biomedica respectively) at the baseline, week 2, 4 and 12.
**Results:** After treatment of tofacitinib, SDAI score among all fourteen patients decreased significantly from 26.9±12.4 (mean±SD) at the baseline to 14.7±9.9 at week 4 ($p<0.0001$), to 8.3±6.1 at week 12 ($p<0.0001$). Baseline levels of sRANKL were significantly correlated with the levels of CRP (Spearman $r^2=0.488$, P=0.0054). Average of sRANKL levels decreased immediately from 0.15±0.11 pmol/L at the baseline to 0.09±0.05 pmol/L at week 2 ($p=0.0097$), to 0.11±0.10 pmol/L at week 4 ($p=0.0311$), to 0.08±0.05 pmol/L at week 12 ($p=0.0014$). On the other hand, statistically significant changes in OPG levels were not observed during 12 weeks. Consequently, average of sRANKL/OPG ratio decreased significantly from 4.81±4.82 at the baseline to 2.62±1.84 at week 2 ($p=0.0186$), to 3.11±2.81 at week 4 ($p=0.0191$), to 2.11±1.72 at week 12 ($p=0.0052$). Interestingly, decreasing effects of sRANKL levels or sRANKL/OPG ratio were greater in patient with high sRANKL level at the baseline.
**Conclusions:** Here, we show for the first time that tofacitinib has improved inflammatory bone destruction immediately through the regulation of sRANKL levels and sRANKL/OPG balance in RA. This mechanism might be a control of RANKL induction via JAK pathway inhibition in activated CD4+ T cells and synovial fibroblasts
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1413

## AB0395 ONE YEAR RETROSPECTIVE ANALYSIS OF SIDE EFFECTS OF NON-BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS

N.L. Maddox[1], C.I. Gut[2], R. Bhatt[2], O.A. Moore[2]. *[1]Peninsula College of Medicine and Dentistry (Universities of Exeter and Plymouth); [2]Rheumatology, Derriford Hospital, Plymouth, United Kingdom*

**Background:** Non-biologic disease modifying anti-rheumatic drugs (nbDMARDs) (e.g. Methotrexate (MTX), Sulfasalazine (SUZ) and Leflunomide (LEF)) are used as initial treatment for autoimmune conditions; such as rheumatoid arthritis and psoriatic arthritis. However, there is limited evidence upon the proportion of patients who have to stop medication due to side-effects. Infoflex (CIMS) is an electronic system implemented at Derriford Hospital, May 2014. This system was used to record Rheumatology drugs started and stopped and causes for drug cessation[1].
**Objectives:** Our aim was to determine the proportion of patients who had to stop taking nbDMARDs due to adverse events (AE) or side-effects (SE), document the commonest reactions and examine whether there were gender differences in drug cessation.
**Methods:** A retrospective search was performed using Infoflex for all Rheumatology patients at Derriford Hospital for patients who had been started on nbDMARDs for a one year period between 01/12/2014–30/11/2015. Patients were selected for inclusion if they were continuing on the drug or had stopped it due to AE or SE. Patients were excluded if they had stopped their drug due to inefficacy.
**Results:** 1424 patient records were documented from a total of 1080 patients that met the inclusion criteria. Patients included were treated for a variety of rheumatological conditions with the following nbDMARDs; MTX (n=588), Hydroxychloroquine (HCQ) (n=385), SUZ (n=303), LEF (n=92), Azathioprine (AZA) (n=29), Mycophenolate Mofetil (MMF) (n=21), Cyclophosphamide (n=2), Gold (n=2), Cyclosporine (n=1), Tacrolimus (n=1).
The percentage and number of patient records that ceased medication due to AE or SE was; MTX 13.44% (n=79), HCQ 13.25% (n=51), SUZ 31.68% (n=96), LEF 20.65% (n=19), AZA 31.03% (n=9), MMF 9.5% (n=2). The nbDMARD dosage did not have any relationship to the rate of SE or AE.
Mean length of usage for each drug before stopping due to AE or SE was: MTX (95.9 days), HCQ (57.2 days), SUZ (57.1 days), LEF (68.2 days), AZA (69.8 days), MMF (175.5 days).
The most common AE or SE was found to be gastrointestinal for all drugs, except MMF.
The female to male ratio for those who discontinued MTX, HCQ and SUZ was increased in comparison with the female to male ratio for overall drug usage.

**Conclusions:** SUZ had the highest percentage of patients stopping medication (31.68%) with the shortest duration of usage (57.1 days). MMF had the lowest percentage of patients stopping medication (9.5%) with the longest duration of usage (175.5 days).
The commonest reported AE or SE for all drugs (except MMF) were within the gastrointestinal category; principally gastrointestinal intolerance and nausea.
The strengths of our data lie in the amount of information captured and its real world setting. Its weakness is the characterisation of SE is insufficiently specific and we have been unable to classify by disease. Future data collection is required to fully capture the patients who will discontinue nbDMARDs within the current study population. However, these data could potentially aid clinicians in advising rheumatology patients of the potential risks of different nbDMARDs.

## AB0396 SAFETY OF TOFACITINIB FOR THE TREATMENT OF RHEUMATOID ARTHRITIS IN PATIENTS FROM LATIN AMERICA AND THE REST OF THE WORLD

O. Castañeda[1], J. Jaller[2], G. Citera[3], S.C. Radominski[4], M.H. Cardiel[5], C.A.F. Zerbini[6], R. Guzmán[7], G. Solano[8], M. Belini[9], A. Maniccia[10], K. Kwok[10], R. Rojo[11], D. Ponce de Leon[12]. *[1]Clínica Angloamericana, Lima, Peru; [2]Centro de Reumatología y Ortopedia, Barranquilla, Colombia; [3]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina; [4]Universidade Federal do Paraná and CETI, Curitiba, Brazil; [5]Centro de Investigación Clínica de Morelia, Morelia, Mexico; [6]Centro Paulista de Investigação Clinica, São Paulo, Brazil; [7]Immunology Department, Fundación Universitaria Juan N. Corpas and IDEARG, Bogotá, Colombia; [8]Pfizer Inc, San José, Costa Rica; [9]Pfizer Inc, Buenos Aires, Argentina; [10]Pfizer Inc, New York; [11]Pfizer Inc, Groton, United States; [12]Pfizer Inc, Lima, Peru*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA).
**Objectives:** To assess the safety of tofacitinib in patients from Latin America (LA) and the rest of the world (ROW).
**Methods:** Data were pooled from patients who received tofacitinib 5 or 10 mg twice daily ± conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) from two Phase 1, nine Phase 2, six Phase 3 and two long-term extension (LTE) studies (one LTE was ongoing at time of analysis, data as of March 2015). Incidence rates (IR; patients with events/100 patient-years) and 95% confidence intervals (CI) for safety events of special interest pooled for both tofacitinib doses were calculated and compared between LA and ROW patient populations. LA countries that enrolled patients were: Argentina, Brazil, Chile, Colombia, Costa Rica, the Dominican Republic, Mexico, Peru and Venezuela.
**Results:** The analysis included 1037 LA patients (91.2% female; mean age 49.5 years; 7.5 years mean RA duration; 67.1 kg mean weight; 6.5 mean baseline Disease Activity Score for 28-joint counts based on erythrocyte sedimentation rate [DAS28-4(ESR)]; 71.3% baseline concomitant steroid use) and 5157 ROW patients (81.0% female; mean age 53.7 years; 8.1 years mean RA duration; 71.9 kg mean weight; 6.3 mean baseline DAS28-4 [ESR]; 63.8% baseline concomitant steroid use). IRs for safety events of special interest were generally similar for LA and ROW populations with overlapping 95% CIs (Table).

Table. Number of patients with events, IR and 95% CIs for safety events of special interest for all tofacitinib-treated patients

| Patients with events (IR, patients with events/100 patient years [95% CI]) | Latin America N=1037 (3251.3 patient-years total exposure) | Rest of the world N=5157 (16254.4 patient-years total exposure) |
|---|---|---|
| Discontinuations due to AEs | 211 (6.6 [5.7, 7.5]) | 1229 (7.5 [7.0, 8.2]) |
| Serious infection events (all patients) | 80 (2.5 [2.0, 3.1]) | 447 (2.8 [2.5, 3.1]) |
| Serious infection events (patients without baseline corticosteroid use) | 14 (3.7 [2.0, 6.2]) | 100 (3.8 [3.1, 4.6]) |
| Tuberculosis | 4 (0.1 [0.0, 0.3]) | 12 (0.1 [0.1, 0.1]) |
| Opportunistic infections (excluding tuberculosis) | 13 (0.3 [0.2, 0.5]) | 46 (0.3 [0.2, 0.4]) |
| Herpes zoster (serious and non-serious) | 111 (3.7 [3.0, 4.4]) | 592 (4.0 [3.6, 4.3]) |
| Serious herpes zoster | 5 (0.2 [0.1, 0.4]) | 48 (0.3 [0.2, 0.4]) |
| Malignancies (excluding NMSC) | 9 (0.3 [0.1, 0.5]) | 164 (1.0 [0.8, 1.2]) |
| Lymphoma | 0 (0.0 [0.0, 0.1]) | 19 (0.1 [0.1, 0.2]) |
| MACE[1] | 6 (0.2 [0.1, 0.4]) | 65 (0.4 [0.3, 0.5]) |
| All-cause mortality[1] | 13 (0.4 [0.2, 0.7]) | 38 (0.2 [0.2, 0.3]) |

[1]Adjudicated events; [2]deaths occurring within 30 days of the last dose of study drug
AE, adverse event; CI, confidence interval; IR, incidence rate; MACE, major adverse cardiovascular event; NMSC, non-melanoma skin cancer

**Conclusions:** In this analysis of pooled data from tofacitinib RA trials, the safety profile of tofacitinib in the LA and ROW populations was similar.

## AB0397 TREATMENT REFRACTORY RHEUMATOID ARTHRITIS: IS REPOSITORY CORTICOTROPIN INJECTION (RCI) AN EFFECTIVE OPTION IN PATIENTS RESISTANT TO BIOLOGIC THERAPIES? (A PILOT STUDY)

P. Fischer[1], R. Rapoport[2]. *[1]Sturdy Memorial Hospital, Attleboro; [2]Southcoast Health, Fall River, United States*

**Background:** Despite the availability of therapeutic options for RA, including DMARDs and biologic agents, there are many patients who are resistant to current therapy and remain inadequately controlled. We hypothesized that 12-week repository corticotropin injection (RCI) treatment may provide relief of RA and acute exacerbations in patients refractory to treatment with DMARDs and at least three biologics (including 1 tumor necrosis factor inhibitor).
**Objectives:** The objective of this study was to assess the efficacy and safety of RCI in this patient population.
**Methods:** This was a 12-week prospective, multicenter, open-label study with 9 patients. Patients were maintained on stable doses of a biologic, other DMARD therapies and prednisone of at least 7.5 mg daily; RCI was adjunctive therapy. RCI 40 U was given subcutaneously daily for 7 days. If an adequate response (>1.2 point reduction in the Disease Activity Score 28 using C-Reactive Protein [DAS28-CRP]) was achieved, the dose was decreased to 40 U twice weekly through week 12. If the response was inadequate, patients received 80 U once daily for 7 days, followed by 80 U twice weekly through week 12. The primary endpoint was >1.2 point reduction in DAS28-CRP at week 12. Secondary endpoints included improvements in American College of Rheumatology 20%, 50%, and 70% (ACR20, 50 and 70), decrease in Health Assessment Questionnaire Disease Index (HAQ-DI) score, and improvement in Functional Assessment of Chronic Illness Therapy (FACIT) and health-related quality of life (HRQOL) questionnaires.
**Results:** We report results for 9 patients (44–60 years). A total of 66% (6/9) of patients met the primary endpoint. The mean DAS improvement at 12 weeks on 40 U of therapy was numerically greater than that in patients increasing their dose to 80 U. Improvements were also noted in secondary endpoints, particularly over the first 4–8 weeks of treatment. Five of 9 patients maintained improvement in HAQ-DI and in the FACIT fatigue scale at week 12 (Table). There did not appear to be a clear pattern or association between cortisol levels and RCI response. No serious adverse events (AEs) occurred. Mild AEs included Cushingoid features (n=2), mild hyperglycemia (n=1), herpes zoster (n=1), and pedal edema (n=1).

Table 1

| Measure | Dose (U) | n | Mean baseline value | Mean change from baseline | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | | Week 1 | Week 2 | Week 4 | Week 8 | Week 12 |
| DAS28-CRP | 40 | 5 | 5.43 | –1.99 | –2.32 | –1.94 | –2.08 | –1.99 |
| | 80 | 4 | 5.26 | –0.73 | –1.63 | –1.53 | –0.56 | –1.64* |
| HAQ-DI | 40 | 5 | 1.05 | –0.20 | –0.25 | –0.17 | –0.03 | –0.10 |
| | 80 | 4 | 1.85 | 0.06 | –0.34 | –0.12 | –0.17 | –0.19* |
| FACIT | 40 | 5 | 29.60 | 4.80 | 9.40 | 6.20 | 4.00 | 5.60 |
| | 80 | 4 | 22.00 | 5.75 | 10.0 | 6.25 | –0.75 | 0.50* |

A decrease in DAS28-CRP and HAQ-DI, and an increase in FACIT indicate improvement. *Data for 2 patients are not reported here as they dropped out due to inadequate response. DAS28-CRP, the Disease Activity Score 28 using C-Reactive Protein; HAQ-DI, Health Assessment Questionnaire-Disease Index; FACIT, Functional Assessment of Chronic Illness Therapy.

**Conclusions:** RCI produced a rapid and clinically meaningful reduction in markers of disease activity and improved quality of life. RCI demonstrated a favorable safety profile; there were no serious adverse events and cortisol levels did not increase for most patients. For patients who are refractory to common RA therapies, the response rate to RCI was substantial and shows great promise in this difficult to treat population.

## AB0398 EFFICACY OF ADALIMUMAB AND TOFACITINIB IN RHEUMATOID ARTHRITIS: POST-HOC ANALYSES FROM A PHASE 3 STUDY

R. van Vollenhoven[1], S. Cohen[2], A. Mendelsohn[3], E. Bananis[3], H. Fan[3], L. Takiya[3], R. Fleischmann[2]. *[1]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [2]Metroplex Clinical Research Center, Dallas; [3]Pfizer Inc, Collegeville, United States*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). In a Phase 3, 12-month (Mo) study (ORAL Standard) including RA patients (pts) on stable background methotrexate (MTX), tofacitinib and adalimumab (ADA) demonstrated significant improvements in efficacy outcomes compared with placebo (PBO).[1]

**Objectives:** To evaluate the efficacy of tofacitinib and ADA based upon American College of Rheumatology (ACR) component scores in a post-hoc analysis of ORAL Standard.

**Methods:** ORAL Standard (NCT00853385) was a randomised, multicentre, Phase 3 study investigating the efficacy of oral tofacitinib 5 and 10 mg twice daily (BID) or ADA 40 mg administered subcutaneously (SC) every two weeks vs PBO in MTX inadequate responders. All pts received background MTX. Effects of tofacitinib 5 mg BID vs ADA 40 mg SC were evaluated in exploratory, post-hoc analyses at Mo 3, 6, 9 and 12 of the proportion of pts achieving ACR 20/50/70 response as well as the change from baseline in each of the following ACR components: Health Assessment Questionnaire-Disability Index (HAQ-DI), tender and swollen joint counts (TJC and SJC), Patient's Global Assessment (PtGA), erythrocyte sedimentation rate (ESR), Physician's Global Assessment (PGA), C-reactive protein (CRP) and Pain. For ACR response rates, pts who withdrew before Mo 12 were considered non-responders from that visit onward. The normal approximation approach to binomial proportions was used to analyse the ACR response. A mixed-effect model was applied to analyse the change from baseline data. Treatment differences for tofacitinib 5 mg BID vs ADA 40 mg SC were reported along with 95% confidence intervals. All analyses were descriptive and were not adjusted for multiplicity.

**Results:** Overall, ACR20/50/70 response rates were numerically higher for tofacitinib 5 mg BID vs ADA over the 12 mo. At Mo 6 ACR20/50/70 rates for tofacitinib were 60.6%, 38.9%, 19.7% vs 57.9%, 28.9%, 9.1%, for ADA. At Mo 12 ACR20/50/70 rates for tofacitinib were 59.6%, 43.5%, 24.9%, vs 61.4%, 38.6%, 16.8% for ADA. Comparable changes from baseline were reported for tofacitinib vs ADA in HAQ-DI, ESR, TJC, SJC, CRP, PtGA, PGA and Pain over time, with numerically higher improvements observed for tofacitinib in the majority of ACR components (Table). Previously published safety data from this study showed that infections and infestations were the most frequent AEs reported over 12 mo in both tofacitinib and ADA treatment groups.[1] Serious infection events were more frequent in tofacitinib 5 and 10 mg BID treatment groups (3.4% and 4.0%, respectively) compared with ADA (1.5%), over 12 Mo.[1]

LS mean change from baseline (difference from comparator) [95% CI treatment differences for tofacitinib 5 mg BID vs ADA 40 mg SC] in efficacy parameters at Months 3, 6, 9 and 12 for tofacitinib 5 mg BID and ADA 40 mg SC (FAS, longitudinal model).

| Efficacy | Month 3 | | Month 6 | | Month 9 | | Month 12 | |
|---|---|---|---|---|---|---|---|---|
| Parameter | Tofacitinib 5 mg BID (N=185) | ADA 40 mg SC (N=188) | Tofacitinib 5 mg BID (N=172) | ADA 40 mg SC (N=178) | Tofacitinib 5 mg BID (N=156) | ADA 40 mg SC (N=169) | Tofacitinib 5 mg BID (N=147) | ADA 40 mg SC (N=157) |

ADA, adalimumab; BID, twice daily; CRP, C-reactive protein; CI, confidence interval; ESR, erythrocyte sedimentation rate; FAS, full analysis set; HAQ-DI, health assessment questionnaire-disability index; LS, least square; PtGA, patient global assessment; PGA, physician global assessment; SJC, swollen joint count; TJC, tender joint count. N' number of patients given in the column headers are based on HAQ-DI analysis, other endpoints could have slightly different numbers of patients due to data collection and availability. Analyses were based on the full analysis set (FAS) which includes all patients who were randomised and received ≥1 dose of study drug, with the exclusion of data from two study sites (one site was identified after completion of the study report) due to GCP violation. A negative value of treatment difference indicates the effect is in favour of tofacitinib.

**Conclusions:** These post-hoc analyses show that efficacy was generally similar in comparing tofacitinib with ADA, with numerical differences in favour of tofacitinib in some efficacy parameters. The ORAL Standard study was not designed or powered for statistical comparisons between ADA and tofacitinib. Prospective studies to investigate the effect of tofacitinib compared with ADA are under way.

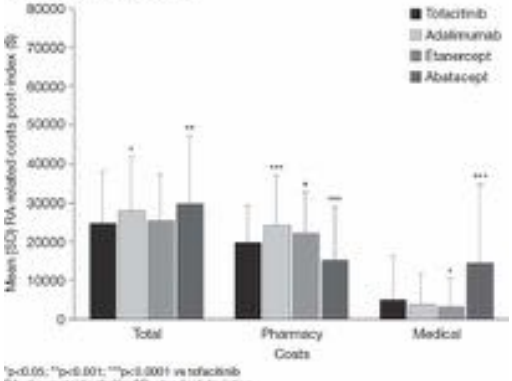
## AB0399 REAL-WORLD EXPERIENCE WITH TOFACITINIB VS ADALIMUMAB (ADA), ETANERCEPT (ETN) AND ABATACEPT (ABA) IN BIOLOGIC-EXPERIENCED PATIENTS WITH RHEUMATOID ARTHRITIS (RA): DATA FROM A US ADMINISTRATIVE CLAIMS DATABASE

J. Harnett[1], R. Gerber[2], D. Gruben[2], A. Koenig[3], C. Chen[1]. *[1]Pfizer Inc, New York; [2]Pfizer Inc, Groton; [3]Pfizer Inc, Collegeville, United States*



**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of RA. Limited real-world data exist comparing tofacitinib with biologic DMARDs (bDMARDs) in biologic-experienced (BE) RA patients (pts).

**Objectives:** To compare pt characteristics, treatment patterns and costs in BE RA pts receiving tofacitinib vs ADA, ETN and ABA using US claims data.

**Methods:** This retrospective cohort study included pts aged ≥18 years with RA (ICD9: 714.0x–714.4x; 714.81) and ≥1 tofacitinib (identified first) or bDMARD claim in the Truven MarketScan® Commercial and Medicare Supplemental healthcare claims database (01/11/2012–31/10/2014). Pts were continuously enrolled for ≥12 months (mos) pre- /post-index and had 1 bDMARD pre-index (due to greater imbalance in number of tofacitinib/bDMARD pts with ≥2 prior bDMARDs). Monotherapy was defined as absence of select conventional synthetic DMARDs within 90 days post-index. Outcomes were treatment persistence (index refills without a 60-day gap after prescription/administration days' supply expiration), adherence (proportion of days covered [PDC]), and 12-mo pre-/post-index RA-related costs. Adjusted analyses were performed using generalized linear models, which included demography, disease status/duration and pre-index therapy variables; 12-mo pre-index costs were included for cost-related dependent variables.

**Results:** 392 tofacitinib, 178 ADA, 118 ETN and 191 ABA pts met selection criteria. 12-mo pre-index bDMARD use was most common for tofacitinib (78%) vs ADA (60%), ETN (49%) and ABA (48%) pts (all $p<0.0001$). TNFi were the most common prior bDMARDs for tofacitinib (74%), ADA (92%), ETN (86%) and ABA (93%) pts. Pts who received tofacitinib at index had greater RA-related total/pharmacy costs vs ADA, ETN and ABA pts (all $p<0.05$) and medical costs vs ADA and ETN pts (both $p<0.0001$) in 12 mos pre-index, and highest percentage of index monotherapy use (53%) vs ADA (48%), ETN (48%) and ABA (41%; $p<0.05$) pts. The proportion of pts persistent with index therapy was similar for tofacitinib (43%), ADA (38%), ETN (42%) and ABA (44%) pts and remained so in adjusted analyses. Mean (SD) PDC was 0.55 (0.30) for tofacitinib pts vs 0.57 (0.30) for ADA, 0.59 (0.31) for ETN and 0.44 (0.39) for ABA ($p=0.0003$) pts. In adjusted analyses, ABA use vs tofacitinib was associated with lower mean PDC; increasing age and commercial insurance coverage were associated with higher PDC. Tofacitinib pts had lower post-index RA-related total costs vs ADA and ABA pts, pharmacy costs vs ADA and ETN pts, and medical costs vs ABA pts (all $p<0.05$) (Figure). In adjusted analyses, ABA, ETN and ABA use, commercial insurance coverage and number of pre-index rheumatologist visits were associated with higher total RA-related costs; North Central/Southern regions were associated with lower costs.

**Figure.** Mean (SD) RA-related total, pharmacy and medical costs in the 12-month post-index period

*p<0.05; **p<0.01; ***p<0.0001 vs tofacitinib
RA, rheumatoid arthritis; SD, standard deviation

**Conclusions:** More BE pts started tofacitinib vs ADA, ETN and ABA after recent (prior 12 mos) bDMARD use; BE tofacitinib pts had the highest proportion of monotherapy use. Persistence and adherence were at least similar for tofacitinib and bDMARD pts. Tofacitinib pts had lower adjusted RA-related total costs post-index vs bDMARD pts.

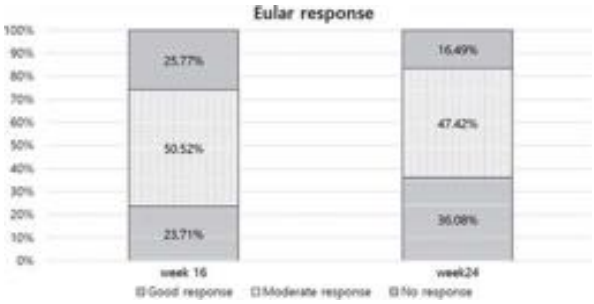
## AB0400 OPEN LABELED, MULTICENTER 24-WEEK STUDY TO ASSESS THE EFFICACY AND SAFETY OF TACROBELL® IN ACTIVE RHEUMATOID ARTHRITIS PATIENTS

S.-J. Hong[1], J.-Y. Choi[1], S.-S. Kim[2], Y.S. Kim[3], S.-H. Kim[4], G.-T. Kim[5], S.J. Choi[6], M.S. Lee[7], J.-W. Hur[8]. *[1]Kyung Hee University, Seoul; [2]Ulsan University and Gangneung Asan Hospital, Ulsan; [3]Chosun University, Gwanju; [4]Keimyung University, Daegu; [5]Kosin University, Busan; [6]Korea University Ansan Hospital, Ansan; [7]Wonkwang University, Iksan; [8]Eulji University, Daejeon, Korea, Republic Of*

**Background:** Rheumatoid arthritis (RA) is chronic inflammatory disease characterized by persistent synovitis and structural joint damage with T cell-driven inflammation. Tacrolimus suppress activation of T cells through the inhibition of calcineurin.



**Objectives:** We evaluated the efficacy and safety of Tacrobell® (Tacrolimus from Chong Kun Dang Pharma Inc.) in Korean active RA patient who had inadequate response to disease-modifying anti-rheumatic drugs (DMARDs) including Methotrexate (MTX).

**Methods:** During the study period from Aug. 2012 to Jun. 2015, in this open labeled, multicenter study, 111 patients were enrolled. Patients were in active disease state with Disease Activity Score28 (DAS28) $\geq$3.2 despite previously taken at least one conventional DMARD including MTX. Patients had wash out period with DMARDs, except MTX. Patients received Tacrobell® during 24 weeks. The initial dose was 1 mg once daily and was increased to 3mg once daily by 1mg, every 4 weeks.

The disease activity was measured by the DAS28-ESR at 4, 8, 16, 24-week after the add on Tacrobell®. Simplified Disease Activity Index (SDAI), Korean Health Assessment Questionnaire (KHAQ)-20, Erythrocyte Sedimentation Rate (ESR), C-Reactive Protein (CRP) and the safety was assessed.

**Results:** Data from 97 patients were evaluated in full set analysis. At week-24, EULAR response rate were 83.5% (81 of 97) with improvements from week-16 in 74.2% (72 of 97). Mean DAS28-ESR was continuously decreased of 5.64 at baseline, 4.14 (±1.22, $p<0.001$) at week-16 and 3.66 (±1.39, $p<0.001$) at week-24. Efficacy rates according to SDAI were 89.7% (87 of 97) and KHAQ-20 score decreased -2.42 (±4.37, $p<0.001$) from baseline 7.27 (±4.59) at week-24. Mean ESR was decreased -10.97 (±24.16, $p<0.001$) at week-16, -14.77 (±24.57, $p<0.001$) at week-24 from baseline 46.05 (±23.22). Mean CRP was decreased from 2.86 (±7.85, $p=0.0578$) at baseline to 1.34 (±3.02, $p=0.0367$) at week-24.

The most common adverse events were in gastrointestinal (18 of 108; 16.679%) and respiratory disorder (12 of 108; 16.67%). In serious adverse events (6 of 108, 5.56%), two cases (pneumonia, high glucose level) were related with Tacrobell® and recovered with treatment. At laboratory exam, no abnormal findings with increased BUN or Cr as known common Tacrolimus side effect. Systolic blood pressure increased 2.12 mmHg at week-8.

**Conclusions:** This study demonstrated the efficacy of add on Tacrobell® therapy to MTX in patients with active RA.

## AB0401 COMPARATIVE EFFICACY OF INJECTION AND TABLET METHOTREXATE FORMS IN RHEUMATOID ARTHRITIS TREATMENT

L. Myasoutova[1], S. Lapshina[1], R. Mukhina[2]. *[1]Kazan State Medical University; [2]Clinical Hospital # 7, Kazan, Russian Federation*

**Objectives:** To evaluate comparative efficacy of injection and tablet methotrexate forms in rheumatoid arthritis treatment.

**Methods:** 23 patients were included in study group (19 women, 4 men) with moderate (47.8%) and high activity (52.2%), receiving methotrexate subcutaneously in a dose of 10 -15 mg (average dose - 11 1±5,21) 1 time per week: 11 patients were switched from methotrexate tablet form, 2 patients received leflunomide previously, 10 patients received methotrexate initially. Comparison group - 20 patients (17 women, 3 men) taking methotrexate (10 -15 mg/week, the average dose 11,6±4,89) in tablets. The groups were comparable on key parameters. Effectiveness evaluation (ACR and EULAR criteria) and tolerability of treatment was carried out every 4 weeks for 6 months.

**Results:** Significant clinical and laboratory improvement (ACR 20) was achieved in 23 patients (main group) and in 14 patients - the control group. The appearance of the first effect (ACR 20) of methotrexate subcutaneously was observed after 2 weeks of treatment in 8 (34.8%), one month therapy - 17 (73.9%) patients, in the control group at 2 weeks - in 1 (5%), after 1 month at 7 (5%) patients respectively. After 6 months of methotrexate subcutaneously treatment decrease in activity ($DDAS28_{ESR}$ 2,3±0,9, initial $DAS28_{ESR}$ 5,3±2,9) corresponds to good effect, and treatment was significantly ($p<0.05$) better compared to the group receiving methotrexate in tablet form ($DDAS28_{ESR}$ 1,3±1,0, initial $DAS28_{ESR}$ 5,2±2,6). Adverse events occurred in 5 (21.7%) patients of the main group (alopecia, itching at the injection site, increased transaminases less than 1.5 normal) did not require discontinuation of the drug, in the control group - in 11 (55%) patients: dyspepsia, alopecia, increased transaminases, 2 (10%) patients refused from therapy

**Conclusions:** Subcutaneous administration of methotrexate in RA patients demonstrated more rapid and pronounced effect, better tolerability compared with taking the drug inside.

**Disclosure of Interest:** None declared

## AB0402 EFFICACY OF IGURATIMOD ALONE OR IN COMBINATION WITH METHOTRXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Kawamoto, T. Umibe, S. Iida. *Rheumatology, Matudo City Hospital, Matsudo, Japan*

**Background:** It has reported that Iguratimod (IGU), one of methanesulfonanilide of anti-inflamamatory agents, can inhibit anti-arthritic activity of rheumatoid arthritis (RA). IGU was approved for rheumatoid arthritis patients with inappropriate response to conventional treatments in Japan in September 2012.

**Objectives:** We aimed to assess the efficacy of IGU alone or in combination with Methotrxate (MTX) in patients with rheumatoid Arthritis

**Methods:** Patients who had an inadequqte response to MTX were enrolled. From December 2012, forty nine patients treated with IGU were analyzes retrospectively; 17 of 49 patients were treated with only IGU, 32 of 49 patients were treated with add-on IGU in combination with MTX. Disease activity and clinical response were assessed by disease activity score 28/ESR (DAS28-ESR) and EULAR response criteria, respectively. The DAS28-ESR, CRP, SDAI, CDAI at 1, 2, 3, 6, 12, 24 months from administration of IGU were examined.

**Results:** The average amount of IGU is 40.7mg in MTX group and 41.3mg in non-MTX group. The average amount of MTX was 7mg. After follow up 24 months, escape cases was six cases. The DAS28-ESR. After 12 months of treatment, The DAS28-ESR was decreased from4.32 to 2.37 significantly in MTX group ($P<0.01$), and also decreased from4.23 to 2.37 significantly in non-MTX group ($P<0.01$). According to EULAR response criteria at 12 months, The DAS28-ESR remission was observed in 46.9% of patients in MTX group and 52.9% in non-MTX group. CRP decreased from1.9 to 0.7 significantly in MTX group ($P<0.01$), and also decreased from 2.1 to 0.8 significantly in non-MTX group ($P<0.05$).There was no significant difference between the two groups.

**Conclusions:** Based on these results, we can conclude that the treatment of IGU is effective and well tolerated, and represents a new option for RA patients, including patient with inadequqte response to MTX.

## AB0403 WHAT IS THE PLACE OF CORTICOSTEROIDS IN THE TREATMENT OF PATIENTS WITH EARLY ARTHRITIS?

T. Serban[1,2], I. Satulu[1], O. Vutcanu[1], A. Circiumaru[1], M. Milicescu[1,2], C. Mihai[1,2], M. Bojinca[1,2]. *[1]"Dr. I. Cantacuzino" Hospital; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*

**Background:** While the 2013 EULAR recommendations for the management of rheumatoid arthritis (RA) mention that low-dose corticosteroids (CS) should be considered as part of the initial treatment strategy in association with DMARDs and should be tapered as soon as possible (1), the 2015 ACR Guidelines for the treatment of RA recommend CS for early RA (ERA) patients only if the disease flares (2).
**Objectives:** The aim of this study is to determine what forms of CS are used for patients with ERA and if the use of CS influences the outcome of this patients.
**Methods:** We have evaluated data obtained from patients with early arthritis (duration of less than 12 months), either ERA or early undifferentiated arthritis not classifiable as other disease, referred to the Early Arthritis Research Center of "Dr. I. Cantacuzino" between 2010 and 2014. Patients were treated according to the current guidelines. Parameters were evaluated at baseline and after 1 year of follow up.
**Results:** 73 patients were enrolled in this study and 60.3% were female. The mean age was 49.81±15.93 years. The mean duration of symptoms was 3.39±3.42 months. The parameters evaluated at baseline and after 1 year of follow up (median value and interquartile range) are described in Table 1.

Table 1. Parameters evaluated during the study

| Parameter | Baseline Median (Interquartile range) | 12 months Median (Interquartile range) |
|---|---|---|
| CRP (mg/l) | 8.63 (2.63–18.44) | 1.91 (0.91–4.19) |
| ESR (mm/h) | 27.00 (11.00–47.00) | 12.00 (7.00–17.00) |
| VAS patient (mm) | 64.00 (52.50–76.00) | 15.50 (0.00–26.00) |
| VAS physician (mm) | 50.00 (30.00–60.00) | 10.00 (0.00–10.00) |
| DAS28 | 4.75 (3.63–5.35) | 1.61 (1.17–2.59) |
| SDAI | 26.12 (14.94–32.13) | 2.67 (0.31–5.32) |

61.7% of patients received treatment with DMARDs and 56.2% of patients received CS, associated with DMARDs. The types of CS used at baseline and the percent of patients who received each type were: Prednisone (42.5%), Dexamethasone i.m. (4.1%), Betamethasone administered intra-articularly (8.2%) and pulse therapy with Methylprednisolone (1.4%). At 12 months only 10 patients (13.7%) still received CS and the only form of CS used was low-dose Prednisone. The number of patients who required CS decreased significantly during the study ($p<0.001$ – Wilcoxon test). All the parameters evaluated decreased significantly during the study ($p<0.001$ – Wilcoxon test), but CS didn't influence any of them ($p>0.05$ – linear regression) regardless of dose or mode of administration.
**Conclusions:** In a relatively small cohort of patients with early arthritis, there was no significant influence of CS treatment on the variation of parameters reflecting disease activity at 12 months. The doses and modes of administration at baseline varied, but that didn't influence the outcomes. On short-term, patients who receive CS, at baseline, have an subjective improvement of symptoms assessed by VAS, but at 12 months there is no significant difference between those who received at baseline DMARDs associated with CS and those who received DMARDs monotherapy. The number of patients who required treatment with CS decreased significantly during the follow up period and the few patients who still required CS at 12 months were receiving only low-dose Prednisone.

## AB0404 ULTRASONOGRAPHIC EVALUATION OF IGURATIMOD THERAPY IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS

Y. Kanayama[1], H. Nagasaka[2], M. Shimotake[2], F. Miyachi[2], K. Fujita[2], Y. Ishii[2], A. Nagata[2]. *[1]Orthopedic Surgery and Rheumatology; [2]Clinical technology, Toyota Kosei Hospital, Toyota, Japan*

**Background:** Iguratimod (IGU) is a small-molecule antirheumatic drug that was approved in Japan in September 2012. IGU suppressed tumor necrosis factor-alpha-induced production of interleukin (IL)-6, IL-8, and monocyte chemoattractant protein 1 via inhibition of nuclear factor kappa B activation in cultured human synovial cells and human acute monocytic leukemia cells. We reported the clinical efficacy of IGU at ACR2014 and EULAR2015. However there is still few studies of improvement of ultrasonographic findings in RA treated with IGU.
**Objectives:** To evaluate the clinical efficacy of IGU therapy patients with rheumatoid arthritis (RA) using ultrasonography (US).
**Methods:** Participants comprised 51 Japanese RA patients who had recently received IGU. All patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments every 4 weeks from baseline to 24 weeks, and US assessments at baseline, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 26 (0–78) synovial sites (22 joints) in the following joints: bilateral first to fifth metacarpopharangeal (MCP) joints (dorsal recess); first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) (dorsal recess) joints; and the wrists (dorsal radial, median and ulnar). We evaluated the improvement of GS and PD score from baseline to week 24.
**Results:** The patients included 15 males and 36 females. The mean age was 65.4±11.6 years; the mean disease duration was 9.1±11.0 years; and the number of MTX combination, other DMARD excluded combination, IGU monotherapy and Biologics combination were each 30, 9, 8 and 4 cases.
Clinical findings related to RA were as follows: tender and swollen joint count, 4.2±2.9 and 3.2±2.2; patient's and physician's global assessment of disease activity, 39.7±23.3 and 39.7±18.9mm; CRP, 1.1±1.3 mg/dL; ESR, 31.4±18.6 mm/h; DAS-ESR, 4.37±0.85; DAS-CRP, 3.80±0.74; CDAI, 15.3±6.4 and SDAI, 16.4±6.8. The mean CRP improved to 0.7±1.0 and 0.5±0.8 at Week 12 and 24 ($p<0.001$, $p<0.001$), mean MMP3 improved to 147.7±140.4 and 161.8±254.5 at Week 12 and 24 ($p<0.001$, $p=0.003$), the mean DAS-ESR improved to 3.39±0.93 and 2.91±0.83 at Week 12 and 24 ($p<0.001$, $p<0.001$) and the mean SDAI improved to 8.6± 6.0 and 5.8±4.8 at Week 12 and 24 ($p<0.001$, $p<0.001$) significantly. The mean GS score changed from 16.8±12.4 at baseline to 15.7±11.0 ($p=0.158$) and 14.5±9.8 ($p=0.043$) at week12 and 24. The mean PD score changed from 7.9±6.8 at baseline to 6.0±6.1 ($p=0.001$) and 5.3±5.5 ($p=0.006$) at week12 and 24 (Fig.1).
In the with MTX (n=30) and monotherapy or with csDMARD patients (n=17), the respective changes in GS and PD scores from baseline to 12 or 24 weeks were as follows: ΔGS score: -2.3±7.0 vs 1.3±5.8 ($p=0.118$) at 12 weeks and -3.9±9.2 vs 0.3±8.8 ($p=0.158$) at 24 weeks; and ΔPD score: -2.8±6.7 vs -0.5±2.6 ($p=0.053$) at 12 weeks and -4.0±6.8 vs 0.1±5.0 ($p=0.016$) at 24 weeks (Fig.2).

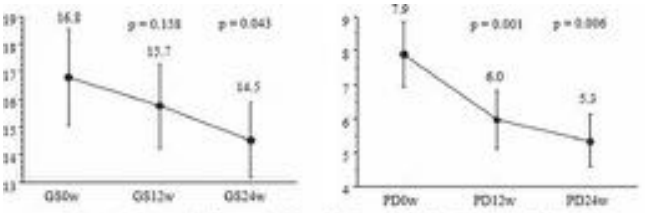

Figure 1 : Respective changes in GS and PD score from baseline to Week 24

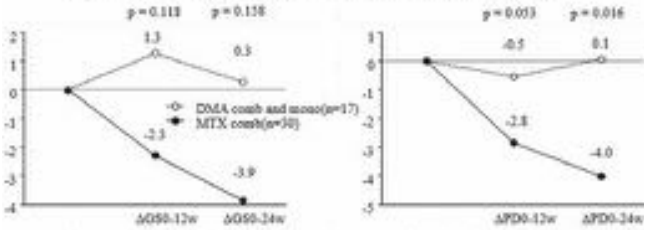

Figure 2 : Respective changes in ΔGS and ΔPD score from baseline to Week 24 in MTX combination and csDMARD combination or IGU monotherapy patients

**Conclusions:** The present study provides evidence supporting the IGU therapy improved not only the disease activity not also the inflammatory synovitis. Especially MTX combination patients could expect higher efficacy of IGU treatment.

## AB0405 EFFECTS OF ATORVASTATIN ON DYNAMICS OF BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Akhverdyan, B. Zavodovsky, J. Polyakova, L. Seewordova, M. Kuznetsova, A. Zborovsky. *Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology" Under the Russion Academy of Medical Sciences, Volgograd, Russian Federation*

**Background:** There are some data indicating that statins produce a pleiotropic effect and can increase bone mineral density. It is also known that some statins (pravastatin, simvastatin) have an anti-inflammatory effect. Simvastatin has been shown to be effective in the treatment of rheumatoid arthritis (RA) in humans. We failed to find any research data indicating that atorvastatin has anti-inflammatory effects.

**Objectives:** To study the effect of Atorvastatin on the dynamics of bone mineral density and inflammatory markers of osteoporosis (OP) in patients with RA.
**Methods:** We examined 170 RA patients aged 22 – 75 years (128 females (75.3%) and 42 males (24.7%)). Bone mineral density was measured with dual-energy X-ray absorptiometry (DEXA) (Lunar DPX-Pro, GE, USA). Additionally, we measured serum osteocalcin levels and urine CrossLaps with ELISA test.
We divided the patients into two groups to study the effectiveness of Atorvastatin in the treatment of patients with RA/OP and osteopenia. Group 1 included 38 individuals who received Atorvastatin for 6 months at a dose of 20–40 micrograms per day. The experimental group included 29 patients with OP and osteopenia. They received calcium supplements at a dose of 1000 mg per day.
**Results:** We revealed that 84 (51.5%) out of 170 patients with RA had significantly lower Z- and T-scores values. We noted that 17 (20.2%) patients were diagnosed as having osteoporosis, while 67 (79.8%) had osteopenia. The most common manifestations of OP in RA patients included fractures, bone and back pain, as well as decreased muscle strength.
We measured biochemical markers of bone turnover at baseline and after 6-month of the treatment. There was significant positive dynamic of clinical and laboratory parameters during a 6-month treatment with Atorvastatin in OP patients with RA. In this patients we observed BMD and muscle strength increasing, reducing of bone and back pain, decreasing of C-reactive protein. Urinary CrossLaps were significantly decreased. Atorvastatin was well tolerated. There were few of insignificant side effects which were reduced after the drug dose decreasing. Symptomatic improvement occurred within 2–3 months after starting of atorvastatin therapy. Second group patients who received calcium monotherapy showed signs of progressive OP: bone mineral density continued to decrease (mean -2.7±0.18%), while bone pain and biochemical markers of bone metabolism remained unchanged.
**Conclusions:** We concluded that Atorvastatin may be used in the treatment of RA patients and can help to stabilize bone mineral density and improve the OP symptoms.

## SLE, Sjögren's and APS - treatment

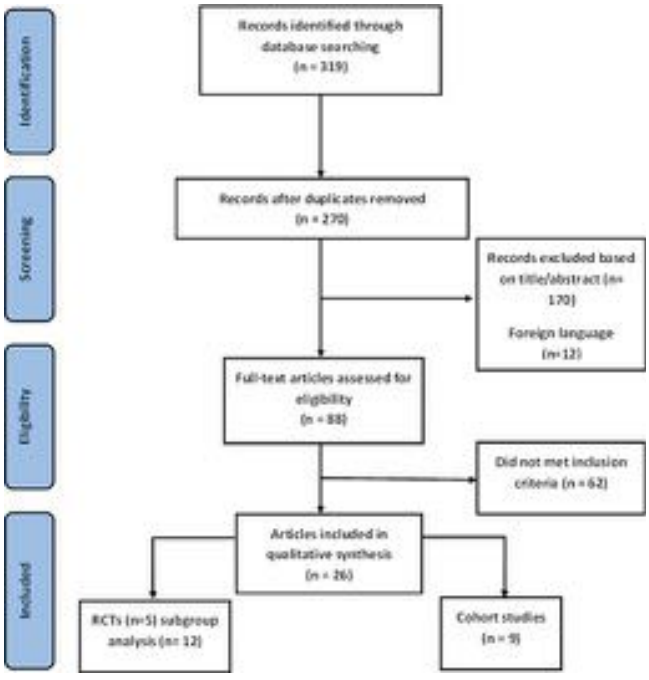
### AB0406 CLINICAL EXPERIENCE FROM ABATACEPT USE IN SYSTEMIC LUPUS ERYTHEMATOSUS: EFFECTIVENESS AND SAFETY

B. Serrano-Benavente, N. Bello, J.C. Nieto-González, J.G. Ovalles-Bonilla, I. Janta, R. González-Benítez, C. Mata, D. Hernández-Flórez, F.J. López-Longo, E. Naredo, C.M. González-Fernández, I. Monteagudo. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** Biologicals therapies have been used for the treatment of Systemic Lupus Erythematosus (SLE) but only Belimumab has been approved by the European Medicines Agency. Abatacept (ABA), a T-cell co-stimulation blocker, has been proposed as an effective treatment for SLE due to its mechanism of action. Three randomised clinical trials have been performed with ABA in patients with SLE. Although any of these trials met the primary outcome of efficacy, it is still considered as an "off-label" option when none of the other conventional therapies have worked.
**Objectives:** To assess effectiveness and safety of ABA in patients diagnosed of SLE in a Rheumatology service from a tertiary care hospital in Madrid, Spain.
**Methods:** We performed an observational retrospective study in patients with SLE (according to the 1997 American College of Rheumatology classification criteria) who received treatment with ABA. We recorded demographic, clinical and laboratory parameters at the beginning of treatment, and after 6 and 12 months of treatment. We also recorded adverse events.
**Results:** We included 8 patients, all of them women. The median age was 45.13 years (range 30–67 years) and the median time from SLE diagnosis to ABA treatment was 12.12 years (range 3–21 years). Three patients had an overlap disease with Rheumatoid Arthritis. The most frequent symptoms were arthritis (n=5), cutaneous (n=3) and neurological symptoms (n=5), specifically organic brain syndrome (n=4) and lupus headache (n=3). None of the patients had renal disease. In all patients ABA was use after anti-TNFα or Rituximab treatment. One patient discontinued ABA after 2 months due to inefficacy, so she was excluded from statistical analysis.
Table 1 shows clinical and laboratory parameters at the beginning of treatment and after 6 and 12 months of treatment. After 6 months of treatment, disease activity according to SLEDAI decreased. One patient persisted with organic cerebral syndrome. After 12 months of treatment neurological symptoms showed a substantial improvement in every patient that presented them at the beginning. Four patients showed significant improvement of arthritis. Two patients experienced serious infections that required hospitalization.

Table 1. Clinical and laboratory parameters

| | 0 months (n=7) | 6 months (n=7) | 12 months (n=7) |
|---|---|---|---|
| SLEDAI (median) | 13.71 | 3.71* | 1.43* |
| Prednisone dose (mg/ day) (median) | 6.78 | 5.71 | 3.57 |
| Anti-DNA antibody levels (UI/ml) (median) | 80.61 | 22.77* | 20.21 |
| C3 (mg/dl) (median) | 95.94 | 94.13 | 98.94 |
| C4 (mg/dl) (median) | 11.63 | 15.13* | 14.88 |



*Wilcoxon's Signed Rank Test, *p<0.05. Baseline vs 6 months after treatment and baseline vs 12 months after treatment.

**Conclusions:** ABA was effective in our SLE patients. Clinical response was evident at 6 months and persisted at 12 months. ABA may be a therapeutic option in SLE patients with inadequate response to conventional therapies, specially if arthritis or neurological symptoms are present.

### AB0407 CAN WE IDENTIFY WHO BENEFITS FROM MYCOPHENOLATE MOFETIL IN SYSTEMIC LUPUS ERYTHEMATOSUS? A SYSTEMATIC REVIEW

C. Mendoza Pinto[1,2], C. Pirone[2,3], B. Parker[2], I. Bruce[2]. *[1]Department of Rheumatology, HGR 36-CIBIOR Instituto Mexicano del Seguro Social, Puebla, Mexico; [2]ARUK Centre for Epidemiology, CfMR, Institute of Inflammation and Repair, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom; [3]Department of Internal Medicine and Medical Specialties, Rheumatology Unit, Sapienza University of Rome, Rome, Italy*

**Background:** Mycophenolate mofetil (MMF) has been shown to be a good therapeutic option in systemic lupus erythematosus (SLE), particularly lupus nephritis (LN). There is, however, evidence of variation in the response. Knowledge of predictors of response could aid patient selection for this therapy.
**Objectives:** The aim of this systematic review was to summarize the evidence examining factors measured at baseline and during treatment associated with a response to MMF in SLE.
**Methods:** We searched Medline, Embase, Web of Science and Cochrane Central Registers for Controlled Trials until November 2015 for relevant studies (Fig. 1). Studies included were randomized clinical trials (RCTs) with subgroup analysis and cohort studies involving SLE patients administered MMF with factors measured at baseline and during treatment that may predict treatment outcome. The overall quality of studies included was assessed independently by two reviewers. The quality of RCTs and cohort studies was assessed using the Cochrane Collaboration risk of bias tool and the QUality In Prognosis Studies (QUIPS) assessment tool, respectively. The quality of subgroup analysis was also evaluated. The Grading of Recommendations Assessment, Development, and Evaluation working group approach summarized the quality of evidence (QoE).
**Results:** Although the methodological quality of RCTs was good for primary outcome, most were compromised by lack of power for subgroup analyses and lack of an explicit test of the interaction. Very-low to low QoE suggested a comparable efficacy and safety of MMF among White, Black, Hispanic and Asian patients. Very- low to low QoE indicated that adolescent patients had neither a better LN response at 24 weeks or treatment failure rates at 36 months compared with adults. Patients with membranous LN or poor renal function (<30 mL/min/1.73 $m^2$) may have a renal improvement at 6 months with MMF according to low QoE. Moderate QoE suggested patients with extrarenal manifestations

may show control of disease activity and significant reduction in corticosteroid dose at 6 and 12 months. One moderate QoE study showed that LN patients with a mycophenolic acid area under the curve (MPA AUC) ≥30 mg/h/L-1 may have a better renal response at 1 year. Several studies of varying quality indicated a better response to therapy at 6 and 12 months in LN patients with an early reduction in proteinuria or early normalization of C3 and C4. However, an early reduction in anti–double-stranded DNA was not predictive of the renal response at 6 months.

**Conclusions:** In SLE patients, evidence for predictors of outcomes with MMF is limited. The results of this review should be treated with caution due to the heterogeneity of studies, and the risks of bias identified. Future studies of predictors measured at baseline and during treatment should be designed with "a priori" hypotheses and adequate statistical power.

## AB0408 FACTORS THAT INFLUENCE THERAPY IN PATIENTS WITH UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE

D.P. Pena[1], A.D. Askanase[2]. *[1]Universidad Militar Nueva Granada, Bogotá/Colombia, Bogota, Colombia; [2]Rheumatology, Columbia University College of Physicians & Surgeons, New York, United States*

**Objectives:** To compare clinical and immunological characteristics in patients with undifferentiated connective tissue disease (UCTD) treated with hydroxychloroquine (HCQ) in a large academic clinical practice.

**Methods:** This cross-sectional study included all patients diagnosed with UCTD according to the preliminary classification criteria (1), that seen at the Columbia University Lupus Clinic in New York, from January to December 2015. Clinical and immunological variables were ascertained by clinical evaluation and chart review. Chi squared tests were used to compare the following characteristic between treated and untreated patients: demographic characteristics, number of ACR criteria, SLICC criteria, individual symptoms and laboratory values.

**Results:** Eighty-three patients were identified; 93% were female, mean age at diagnosis of 44 years ±14.9; 67% were Caucasian, 20% Hispanic and 11% Black/African American; median disease duration of 3.91 years ±5.35. The most prevalent symptoms that required medical attention were arthralgia (81%), arthritis (46%), Raynaud (41%), fatigue (32%) and sicca symptoms (30%). All patients had positive antinuclear antibody (ANA) titers, 87% had titers above 1:640, with speckled pattern in 71% of patients. Interestingly, 16% of the patients studied met SLICC SLE criteria. Half of the patients, 42 (51%) were treated with HCQ and 41 (49.3%) were not treated.

The patients treated with HCQ were more likely to meet SLICC criteria (10 vs. 3, respectively; p=0.03), have a history of arthralgia (38 vs. 29; p=0.02), arthritis (28 vs. 10; p=0.0001), and fatigue (25 vs. 14; p=0.02). A history of low complement was more prevalent in the treated group (12 vs. 3, p=0.01).

**Conclusions:** Data from this single-center cohort of patients with UCTD show that patients treated with HCQ by their rheumatologist are more likely to have multiple clinical criteria and low complement compared to those that were not treated. These data suggest that rheumatologist treat pre-clinical autoimmunity in the setting of clinical symptoms. None of patients were treated based on serologies alone. Longitudinal studies are needed to evaluate the long-term impact of HCQ on outcomes in patients with UCTD.

## AB0409 MODIFIED HOMA-IR INDEX IN PATIENTS WITH RHEUMATIC DISEASES RECEIVING GLUCOCORTICOID THERAPY

G. Nurullina, F. Valeeva. *Kazan Medical State University, Kazan, Russian Federation*

**Background:** HOMA-IR index is widely used in current clinical practice for the evaluation of insulin resistance (IR). Elevation of HOMA-IR index is an indirect marker of IR progression.

**Objectives:** To evaluate the role of modified HOMA-IR index in patients with rheumatic diseases receiving glucocorticoid (GC) therapy.

**Methods:** The study included 98 patients with rheumatic diseases, including systemic lupus erythematosus (SLE) - 53 patients and systemic vasculitis (SV) – 45 patients. The first group included 52 patients receiving GC pulse-therapy (GC-PT) (prednisolone 10–15 mg/kg a day i/v, on 3 consecutive days), the second group included 46 patients receiving oral prednisolone 15–30 mg/day. The first group included 31 (59.6%) women and 21 (40.4%) men aged 18–69 years. Control group included 27 (58.7%) women and 19 (41.3%) men aged 19–63 years. All patients underwent standard clinical evaluation and an oral glucose tolerance test (OGTT): patients receiving GC-PT underwent OGTT 72 hours after the end of PT course, patients receiving oral GC – during the time of inpatient treatment. According to OGTT results patients were divided into 4 groups: no carbohydrate metabolism disturbance (CMD), impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and diabetes mellitus (DM). IR calculation according to HOMA-IR index was performed according to a formula proposed by X. Li et al. (2004): Homa-IR =1,5 + fasting blood glucose (mmol/l) x fasting C-peptide level (pmol/l) /2800.

**Results:** CMD developed in 10 (33.3%) patients in SLE group receiving GC-PT, compared to 18 (81.8%) patients receiving oral GC (p=0.002). In SV patients CMD was more prevalent in those receiving oral GC compared to GC-PT (4 (19.1%) vs. 19 (79.2%) patients, respectively (p=0.035). HOMA-IR index, reflecting the degree of IR, was elevated in patients with IGT and DM at baseline, during maximal blood glucose level and after GC-PT, compared to patients without CMD and IFG ($p<0.05$). IR was more pronounced in patients receiving oral GC and IGT and DM after OGTT ($p<0.05$), which demonstrates that a more pronounced IR during GC therapy predisposes to the development of more pronounced CMD.

**Conclusions:** GC therapy results in the development of IGT and DM in patients with elevated IR after GC-PT or prolonged oral GC treatment. CMD is more prevalent among patients receiving prolonged oral GC therapy.

**Disclosure of Interest:** None declared

## AB0410 THE INFLUENCE OF MAGNETIC PROPERTIES OF THE ADSORBENTS ON EFFICIENCY OF EXTRACORPOREAL THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH ANTIPHOSPHOLIPID SYNDROME

I.P. Gontar[1], O.I. Emelyanova[1], L.A. Maslakova[1], O.V. Paramonova[1], I.A. Zborovskaya[2]. *[1]Clinical Immunology Lab; [2]FSBSU Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation*

**Background:** Due to magnetic properties an installation which creates physiological magnetic field holding granules in suspension to prevent particle adhesion of sorbent and contribute to better blood contact was used.

**Objectives:** To remove pathogenic antibodies to cardiolipin in patients with systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS), constant hemocompatible antigenic drugs with magnetic properties (immobilized granulated antigen drugs – IGAD) were created.

**Methods:** To determine antibodies level to cardiolipin (AKA) the indirect ELISA was used. Magnetic adsorbents were created using technique of 3D oriented antigen fixation.

**Results:** When carrying out sorption of antibodies to cardiolipin (CL) in vitro, its decrease in all cases of EGAD use was observed (before sorption of antibodies to CL – 0.390±0.021, after – 0.141±0,006, $p\leq0.001$) unlike hemosorption with activated coal (before coal hemoadsorbent (HSC) – 0.52±0.05, after – 0.44±0.04, $p>0.05$). The use of activated carbon was accompanied by significant damage of formed blood elements: erythrocytes ($10^{12}$ /l) 3.8±0.02 – prior to sorption, 3.3±0.02 – after sorption; leukocyte count ($10^9$ /l) 5.4±0.12 before sorption, 4.0±0.09 after sorption; platelets ($10^9$/l) 203±1.14 – prior to sorption, 146±0.97 – after sorption that wasn't observed when IGAD used (erythrocytes ($10^{12}$ /l) – prior to sorption 3.8±0.03; after sorption 3.8±0.03; leukocytes ($10^9$ /l) – prior to sorption 5.4±0.12; after – 5.3±0.14; platelets ($10^9$/l) – prior to sorption 203±1.17; after 200±1.53.

Thrombosis frequency in the column free of magnetic field made 8 cases out of 20, and in 4 of them prevented blood flow. When carrying out immunoadsorbtion procedure in installation mentioned, 1 case out of 20 microclots were detected, which were not an obstacle to successful completion of immunoadsorbtion ($\chi^2$ =7.03, p=0.009). As a result of sorption procedure a significant decrease in circulated immune complexes (CIC) concentration from 12.4±1.2 to 4.6±0.5% was observed, at the same time changes in the concentration of total protein, immunoglobulin G, A, M classes were insignificant ($p<0.05$).

**Conclusions:** Thus, the adsorbent magnetic properties allow to avoid formed blood elements destruction as well as to increase extracorporal immunoadsorbtion efficiency, especially in cytopenic syndrome often observed in patients with SLE with APS.

## AB0411 RAPID REDUCTION OF ANTIBODIES AND IMPROVEMENT OF DISEASE ACTIVITY BY IMMUNOADSORPTION IN CHINESE PATIENTS WITH SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS

J. Huang[1], G. Song[2], Z. Yin[3], W. He[3], L. Zhang[1], W. Kong[3], Z. Ye[3].
*[1]Rheumatology, The University of Hong Kong-Shenzhen Hospital; [2]The Third People's Hospital of Shenzhen; [3]Rheumatology, The Fourth People's Hospital of Shenzhen, Shenzhen, China*

**Background:** Immunoadsorption (IAS) has been used to treat patients with SLE for many years. Efficacy was proved for case report or series with SLE after IAS treatment, while case-control studies are so far lacking.
**Objectives:** We aim to evaluate the efficacy and safety of IAS as an addition to aggressive immunosuppressive treatment in Chinese SLE patients with severe disease activity.
**Methods:** Patients with SLE disease activity index 2000 (SLEDAI 2k) >15 were enrolled. The number of patients in IAS group and non-IAS group was 52, including 22 with lupus nephritis (LN), 10 with severe thrombocytopenia (<10 platelets/$\times 10^9$/l), 10 with neuropsychiatric lupus and 10 with a large pericardial effusion, respectively. Observation study was performed for every individual in either group for 3 months. Corticosteroid pulse therapy (CSPT, intravenous methylprednisolone 250 mg/day for 3 days) was given to each patient consecutively, followed by a daily oral dose of 1 mg/kg bodyweight of corticosteroid. Corticosteroid were tapered by 10% every 1~2 weeks after 4 weeks. IAS was initiated on the second day of CSPT. Other immunosuppressant included intravenous cyclophosphamide pulse therapy (IVCY, targeting 0.5 g/m$^2$ body surface area) every 2 weeks for 3 months. IVCY was initiated after 3 days' of CSPT.
**Results:** In total 52 SLE patients, the improvement of C3 level, dsDNA and AnuA titer after treatment at different visits compared with baseline was discovered in both groups, while the overall changes of these markers in IAS group were all more significant than those in non-IAS group. Similar results were observed in subgroup analysis. SLEDAI score dropped significantly after 1 week of treatment both in IAS group (from 24.46±4.14 to 12.65±3.85, p=$1.13\times10^{-27}$) and non-IAS group (from 24.46±4.07 to 14.67±3.42, p=$5.41\times10^{-24}$), while the significance was more prominent in IAS group (p=0.004). The dosage of steroids used at 3 months was significantly lower in IAS group (13.46±4.12mg) than that in non-IAS group (15.10±3.77mg) (p=0.037). No severe side effect occurred in our study.
**Conclusions:** This is the first report of the application of phenylalanine immunoadsorption to treating patients with SLE in China. In combination with corticosteroid therapy and immunosuppressant, IAS would appear to be an effective and safe treatment optimal for SLE, without consideration of its high cost.

## AB0412 EXPLORATORY RESULTS FROM THE BLISS AND ILLUMINATE TRIALS SUPPORT THE DESIGN OF THE CHABLIS-SC1 TRIAL, A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 3 STUDY TO EVALUATE THE EFFICACY AND SAFETY OF BLISIBIMOD ADMINISTRATION IN SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.T. Merrill[1], V. Strand[2], C. Hislop[3], M. Gangal[3], R.S. Martin[3], K.C. Kalunian[4].
*[1]Head, Clinical Pharmacology, Oklahoma Medical Research Foundation, Oklahoma; [2]Division of Immunology/Rheumatology, Stanford University, Palo Alto; [3]Anthera Pharmaceuticals, Hayward; [4]UC San Diego School of Medicine, San Diego, United States*

**Background:** Targeted, biologic inhibitors of B-cell Activating Factor (BAFF) have been evaluated in 4 large Phase 3 clinical trials in nearly 4000 patients with Systemic Lupus Erythematosus (SLE). Data from these studies identify that greatest treatment effect is discernable using more stringent endpoints in patients who enter with higher disease activity scores, taking more corticosteroids, and/or have anti-double-stranded DNA (dsDNA) and low complement C3 or C4[1,2,3].
**Objectives:** The CHABLIS-SC1 study (NCT01395745) has completed enrollment and will be the first trial to prospectively evaluate the impact of treatment on the above "responder populations" using the BAFF inhibitor, blisibimod.
**Methods:** CHABLIS-SC1 enrolled subjects positive for anti-nuclear and/or anti-dsDNA antibodies with SELENA-SLEDAI≥10 despite corticosteroid therapy. Subjects were randomized to have blisibimod or placebo added to their background medications. Efficacy will be evaluated using the SLE Responder Index-6 (SRI-6) at Week 52, defined as: ≥6 point reduction in SELENA-SLEDAI; no new BILAG A or 2 new BILAG B organ domain scores; and no worsening in Physician's Global Assessment.
**Results:** Table 1 identifies that the baseline characteristics of the 442 subjects enrolled into the CHABLIS-SC1 study more frequently meet all descriptions of "responder populations" identified previously[2–7]. In previous studies, the SRI-6 was associated with lower placebo responder rates and greater benefit of BAFF inhibitors over placebo.

Table 1. Estimated baseline disease characteristics of subjects in the CHABLIS-SC1 study and in Phase 3 trials with other BAFF inhibitors

| | Blisibimod (CHABLIS-SC1) | Belimumab (BLISS Trials) | Tabalumab (ILLUMINATE Trials) |
|---|---|---|---|
| Total randomized (N) | 442 | 1664 | 2288 |
| Mean age (years) | 36.3 | 35.3 | 40.7 |
| Female (%) | 93.9 | 94.1 | 91.9 |
| Mean SELENA- SLEDAI | 13.6 | 9.7 | 10.3 |
| Receiving corticosteroids (%) | 100 | 86.3 | 75.3 |
| ANA ≥1:80 (%) | 98.9 | 93.0 | – |
| +Anti-dsDNA (%) | 85.5 | 69.4 | 59.2 |
| Low C3 <90mg/dL (%) | 53.9 | 45.0 | 39.4 |
| Low C4 <16mg/dL (%) | 48.2 | 56.1 | 22.5 |
| +Anti-dsDNA & Low C3/C4 (%) | 59.7 | 52.6 | 35.0 |
| Protein:Creatinine ≥1g/g (%) | 19.7 | 13.1 | [Pr:Cr ≥0.4 10.4%] |
| Protein:Creatinine >2g/g (%) | 9.5 | 5.9 | – |

**Conclusions:** BAFF inhibitors are known to be at least modestly effective in SLE and impact B Cell-driven immunopathology such as autoantibodies. The CHABLIS-SC1 study design will determine whether enrichment for the hypothesized "responder population," patients with more severe, immunologically active SLE, will robustly discriminate treatment impact of blisibimod when background therapy is maintained.

## AB0413 SYSTEMIC THERAPY IN PRIMARY SJÖGREN SYNDROME PATIENTS

M. Fernandez Castro[1], J.L. Andreu[2], C. Sanchez-Piedra[3], V. Martinez Taboada[4], A. Olive[5], J. Rosas[6] on behalf of members of the Sjögren-SER Study Group (EAS-SER). *[1]H. Infanta Sofía; [2]H. Puerta de Hierro; [3]Unidad de Investigación de la SER, Madrid; [4]H. Marqués de Valdecilla, Santander; [5]H. Germans Trias i Pujol, Barcelona; [6]H. Marina Baixa, Alicante, Spain*

**Background:** Primary Sjögren syndrome (pSS) is a systemic autoimmune disease involving mainly the exocrine glandular system. Nevertheless, its clinical spectrum includes the development of multiple extra-glandular manifestations which will be determinant for the use of systemic therapy.
**Objectives:** The aim of our study was to describe the systemic therapy in a pSS cohort assisted in Spanish Rheumatology Departments and its association with the involvement of different organs.
**Methods:** This is a multicenter descriptive transversal study of pSS patients fulfilling European/American consensus criteria. Patients were included by randomization from thirty-three Rheumatology departments. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians, and rates. Chi-square was used to establish the statistical associations, being considered a p<0,05 as significant.
**Results:** Four hundred and thirty-seven patients were included. Ninety-five percent of them were women. The median age of the cohort was 58 years. Eighty-four percent of the patients have been treated (currently or previously) with non-steroidal anti-inflammatory drugs (NSAID), 49% had been treated with glucocorticoids (GC), 7% with boluses of GC, 51% with antimalarial, 13% with methotrexate (MTX), 10% with azathioprine (AZA), 4% with mycophenolate mofetil (MM) and 3% with cyclophosphamide (CF). NSAIDs were significantly used more frequently in patients with joint involvement. GC were significantly used more frequently in patients with joint, pulmonary, central and peripheral nervous system (CNS and PNS) involvement and cytopenia. GC boluses were used significantly

more frequently in patients with musculoskeletal, pulmonary and nervous system involvement. Antimalarials were significantly used more frequently in patients with joint involvement. MTX was significantly used more frequently in patients with joint, CNS involvement and cytopenia. AZA was significantly used more frequently in patients with lung and CNS involvement and cytopenia. MM was significantly used more frequently in patients with renal, lung and PNS involvement, and cytopenia. CF was significantly used more frequently in patients with joint, pulmonary, CNS and PNS involvement.

**Conclusions:** Despite the absence of clinical controlled studies demonstrating efficacy and safety, systemic therapy use in SSp patients is very frequent. Its use is mainly associated with the presence of musculoskeletal, neurological, pulmonary and haematological manifestations.

**Disclosure of Interest:** None declared

## AB0414 MYCOPHENOLATE MOFETIL AND DEFLAZACORT IN NEUROPSYCHIATRIC LUPUS: A RETROSPECTIVE STUDY

N. Gupta[1], S.K. Mandal[1], J. Mathew[1], S. Pulukool[1], R. Goel[1], A.J. Mathew[1], A. Nair[1], T. Sebastian[2], D. Danda[1]. *[1]Clinical Immunology & Rheumatology; [2]Biostatitics, CHRistian Medical College, Vellore, India*

**Background:** Mycophenolatemofetil (MMF) is an effective therapeutic agent with high safety profile in the management of lupus nephritis.

**Objectives:** This retrospective study was conducted to assess the efficacy and side effect profile of MMF and deflazacort in patient with neuropsychiatry lupus (NP SLE).

**Methods:** Patients of SLE by SLICC 2012 between January 2005 and May 2015 satisfying ACR 1997 criteria for NP SLEwere recruited from department of Clinical immunology & Rheumatology, Christian Medical College, Vellore, India. Patients consistently using MMF as the second line agent were enrolled. Clinical response, SLEDAI and side effect profile were noted from electronic medical records. Clinical improvement was defined as remission of presenting neurological symptom with no new neurological symptom.

**Results:** Of the 140 patients with NP SLE, 88 fulfilled the inclusion criteria. Mean age of the cohort was 25.51±7.82 years with female to male ratio of 84: 4. Median duration of neurological symptoms prior to presentation was 90 (17.5 – 317.5) days. Median duration of follow up was 33 (3–129) months. Among the various NP SLE manifestations, seizure was the most common presentation (n=37, 42.05%). Renal involvement was seen in 49 (55.7%) patients. MRI findings varied from white and grey matter hyper -intensities to ventricular dilatation and brain atrophy. Of the 88 patients on MMF, 13 were pulsed with 1 gm methylprednisolone for 3 days and 8 were pulsed with oral dexamethasone pulse of 40 mg/day for 5 days. Subsequently, oral steroids was started at a dose of 1 mg/kg & tapered after 8–12 weeks to mean deflazacortdose (prednisoloneeqyuivalent) of 11.07±7.77 (9.33±5.88) mg at the end of 1 year.

IMAGE: Showing various parameters at baseline and follow up as below.

Major adverse events included lower respiratory tract infection in 2 patients and 1 fatality due to sepsis from gastroenteritis.

Of 68 patient with median duration of follow up of 33 (3–129) months, 17 were only on MMF without any steroids, 14 not on either steroids or MMF and 6 were only on maintenance low dose steroids.

Table 1. Comparing side effect profile of patients on deflazacort and prednisolone (n=88)

| | Deflazacort | Prednisolone | P value |
|---|---|---|---|
| Number of patients | 70 | 18 | 0.001 |
| Cushingoid habitus | 7 | 16 | 0.000 |
| Serious Infections | 0 | 3 | 0.006 |
| Steroid induced hypertension | 1 | 4 | 0.000 |
| Steroid induced diabetes | 4 | 6 | 0.001 |

Deflazacort was equally efficacious and had better toxicity profile than prednisolone.

| Parameters | Baseline | Follow up at 3 months (%) | Follow up at 1 year (%) | Last follow up (%) |
|---|---|---|---|---|
| Number of patients | 88 | 78 (88.6%) | 76 (86.4%) | 68 (77.3%) |
| Mean steroid dose – deflazacort ( prednisolone equivalent) | 49.82 ± 14.65 ( 41.51 ± 12.21) | 33.42 ± 13.80 ( 27.85 ± 11.50) | 11.07± 7.77 ( 9.33 ± 5.88) | 3.63± 1.27 ( 3.03 ± 1.06) |
| Patients with clinical improvement (%) | NA | 68 (87.2%) | 71 (93.4%) | 66 (97.1%) |
| Patients with relapse or new onset neurological symptoms (%) | NA | 3 (4.42%) | 1 (1.3%) | 2 (2.9%) |
| Patients with unchanged neurological status | NA | 7 (8.98%) | 4 (5.3%) | 0 |
| Mean SLEDAI score | 21.99 ± 7.52 | 4.29 ± 2.81 | 2.27± 1.22 | 1.19± 0.82 |

**Conclusions:** In patients of NP SLE, MMF is efficacious in inducing remission and preventing relapse of disease with a good safety profile. Deflazacort was found to have superior toxicity profile with equal efficacy as to prednisolone in NP SLE patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.5461

## AB0415 THE EFFECT OF VITAMIN D SUPPLEMENTATION ON ANTIPHOSPHOLIPID ANTIBODIES LEVEL IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

N. Soroka, T. Talako. *Internal Medicine, Belarusian State Medical University, Minsk, Belarus*

**Background:** Vitamin D is regarded as modulator of the immune response [1]. Treatment with $1,25(OH)_2D$ can ameliorate autoimmune disorders in rodent models of experimental allergic encephalitis, nephritis, inflammatory bowel disease, and diabetes mellitus [2,3]. Vitamin D deficiency is common among patients with antiphospholipid syndrome (APS) and is associated with clinically defined thrombotic events [4].

**Objectives:** To evaluate the effects on antiphospholipid antibodies level of an oral Cholecalcipherol supplementation for 3 months in APS patients.

**Methods:** The study included 16 patients (men - 4, women - 12) with APS (Sidney, 2006) mean age 34±6,4 years treated with warfarin – 5,0–7,5 mg/day and acetylsalicylic acid – 75 mg/day. 3 patients were diagnosed with vitamin D insufficiency, 13 – with deficiency [5]. Cholecalciferol - 1000 IU/day was added to the therapy for 3 months. Anticardiolipin (aCL) and anti-β2-glycoprotein I (aβ2GPI) IgG and IgM antibodies, serum 25(OH)D level were tested using commercially available ELISA kits before and after treatment with Cholecalciferol. Lupus anticoagulant was not investigated due to possibility of false positive results in warfarine-treated patients.

**Results:** Baseline level of aCL IgG was median 6,21 intarquartile range 2,72–65,77 GPL, aCL IgM – 85,30 (12,66–154,26) MPL, aβ2GPI IgG –16,40 (7,99–44,32) U/ml, aβ2GPI IgM – 15,89 (6,24–67,60) U/ml, serum 25(OH)D - 15,04 (13,00–19,00) ng/ml. After treatment with Cholecalciferol for 3 months the levels of antiphospholipid antibodies and vitamin D were the following: aCL IgG – 4,69 (2,91–12,42) GPL, aCL IgM – 7,38 (4,42–110,35) MPL, aβ2GPI IgG – 9,43 (5,42 - 13,04) U/ml, aβ2GPI IgM – 29,97 (8,13–71,30) U/ml, serum 25(OH)D - 27,16 (23,06–32,90) ng/ml. We found significant increase in serum 25(OH)D level (p=0,007) and decrease in aβ2GPI IgG level (p=0,038) after treatment with Cholecalciferol. The level of other antiphospholipid antibodies did not differ significantly ($p>0,05$) before and after Cholecalciferol treatment.

**Conclusions:** Our preliminary results indicate that vitamin D supplementation might be associated with decreased serum aβ2GPI IgG level. This can indicate a possible correlation between vitamin D status and thrombotic risk in APS.

## AB0416 RELIABILITY AND SAFETY OF A NOVEL AUTOINJECTOR FOR SELF-ADMINISTRATION OF SUBCUTANEOUS BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

S.Z. Sheikh[1], N.L. Fox[2], A.E. Hammer[3], H. Struemper[4], J. Groark[5], D. Roth[5], D. Gordon[5]. *[1]University of North Carolina, Chapel Hill, NC; [2]GlaxoSmithKline, MD; [3]GlaxoSmithKline, RTP, NC; [4]PAREXEL, Durham, NC; [5]GlaxoSmithKline, Philadelphia, PA, United States*

**Background:** The ability to self-administer subcutaneous (SC) belimumab would enhance treatment options for patients with SLE.

**Objectives:** The reliability and safety of a novel autoinjector for self-administration of belimumab SC was examined in patients with SLE.

**Methods:** Study 200339 (NCT02124798) enrolled adults with SLE who had received at least three prior intravenous (IV) doses of belimumab 10 mg/kg plus standard care, or who had completed the open-label continuation phase of a randomised, controlled trial of belimumab SC (prefilled syringe). Open-label belimumab 200 mg SC (1 mL) was self-administered weekly (thigh or abdomen) using an autoinjector, under clinic observation at Weeks 1, 2, 4, 8 and at home at Weeks 3, 5, 6, 7. Patients assessed and recorded injections using a diary. Investigators assessed clinic injections. The primary endpoint was the proportion of patients who successfully administered the first two injections. Secondary endpoints included success at Weeks 4 and 8 within the clinic and success at Weeks 3, 5, 6, and 7 at home.

**Results:** 95 patients enrolled: 91 completed the study (3 withdrew due to AEs, 1 patient was lost to follow-up). 88 (93%) patients were female; mean (SD) age was 44.8 (12.5) years. Overall, 94% (89/95) of patients successfully administered belimumab at Weeks 1 and 2 using the autoinjector. Five patients completed their 1st injection with assistance from clinic personnel.

Of 736 attempted injections 720 (98%) were considered to be successful. Of the 16 injections reported to be incomplete, 14 (4 from 1 patient) were associated

| | Self-injection success or failure | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | Week 1 | Week 2 | Week 3 | Week 4 | Week 5 | Week 6 | Week 7 | Week 8 |
| Was the drug successfully injected?[a] | | | | | | | | |
| n | 95 | 90 | 93 | 88 | 90[b] | 93 | 90 | 92 |
| Yes | 95 (100) | 89 (99) | 92 (99) | 87 (99) | 89 (99) | 90 (97) | 87 (97) | 91 (99) |

[a] Five patients had a successful 2nd injection after an unsuccessful 1st attempt; the 2nd attempt is included in this summary. [b] For 1 patient, injection was performed at Week 5 per patient recall but no patient diary was available and no record was entered into the Interview Guide.

with use errors, 13 of which were concluded to be related to not holding the autoinjector in place until the injection was completed. Use errors were repeated by only 1 patient.

Reported pain levels were low and diminished over time. A total of 39 (41%) patients reported at least one adverse event (AE) and 15 (16%) patients reported an AE considered to be drug related. Four (4%) patients reported 7 serious AEs: anaemia/neutropenia/pneumonia/pyrexia, postoperative abscess, pulmonary embolism and deep vein thrombosis. Four (4%) patients reported injection site reactions: erythema (2), pruritus, rash, injection-related reaction and site reaction. No serious systemic reactions or deaths were reported.

**Conclusions:** Patients with SLE successfully administered belimumab SC using a novel autoinjector.

## AB0417 PREVALENCE AND CLINICAL MANIFESTATIONS OF PULMONARY AND EXTRAPULMONARY TUBERCULOSIS IN A COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

O. Vera Lastra, M. Cameras-Orantes, J. Sepulveda-Delgado, L.F. Pineda-Galindo, S.A. Mendoza-Alvarez, L.J. Jara, M.D.P. Cruz-Dominguez, G. Medina. *Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disease of unknown etiology affecting different organs and systems, and requiring the use of immunosuppressors (IS), which increases the risk of infections such as tuberculosis (TB) and its deliberate search is mandatory. Patients with SLE are prone to infections as a consequence of either intrinsic immunologic defects or the IS mainly steroids. The prevalence of TB is higher in SLE patients compared with the general population and has been reported in endemic areas up to 5%.

**Objectives:** To determine the prevalence of pulmonary TB - extrapulmonary and associated factor in SLE patients.

**Methods:** we performed a retrospective study in a cohort of 328 SLE patients between 2010–2015 in tertiary level hospital. We included SLE patients with TB diagnosis which was made by PCR, culture, histopathology (HP), acid fast bacillus (AFB) and therapeutic trial (TT). We investigated associated factors for TB: IS drugs 6 months prior diagnosis of Tb (steroids, cyclophosphamide pulse (CY), azathioprine, mycophenolate mophetil (MM) and rituximab), comorbidities (diabetes mellitus, chronic renal disease, arterial hypertension). We also investigated previous exposure and vaccination for TB, type of TB: pulmonary and extra pulmonary. Time evolution, organ involved and SLEDAI at time of diagnosis of Tb were analyzed. Descriptive statistics were performed descriptive statistical.

**Results:** We found 13 SLE patients with TB (mean age 43.5± 9.06 years, mean disease evolution of SLE: 6.6±3.2 years). SLE organ involvement: Renal: 7, hematological: 4 Neuropsychiatric: 2; joint -mucocutaneous 6. Active SLE: 9 (SLEDAI 11.5±4.9), inactive SLE: 4. Use of IS: MM 6, Azathioprine: 7, Cy: 5, steroid: 13 (prednisone: median 2.5, range 2.5 to 50 mg/day and methylprednisolone pulse 3g bimonthly in 2 patients), Rituximab: 3. Prevalence of TB was 13 of 328 (4%) patients, extrapulmonary:10 (77%) renal: 4, meningeal: 3, cerebral tuberculoma: 1 peritoneal: 1 disseminated: 1, and pulmonary TB: 3 (23%). Manifestation associated with TB: Fever 12 (92%) appetite loss: 3 (23%), weight loss 5 (38%), asthenia 8 (61%) headache: 3 (23%), hematuria: 2 (15%). TB diagnosis: AFB: 9 (69%), HP: 1 (7.5%), culture and PCR: 2 (15%), TT: one patients with miliary TB who died.

**Conclusions:** The prevalence of TB in SLE patients was about 4% and its main form was extrapulmonary. The presence of tuberculosis in patients LES constitute a chalence and should be identified in promptly in order to initiate an adequate treatment. TB diagnosis in patients with active SLE is difficult because both diseases share clinical and laboratory manifestations.

## AB0418 SECONDARY SJÖGREN'S SYNDROME AND SICCA SYNDROME IN SYSTEMIC SCLEROSIS IN MEXICAN POPULATION

O. Vera-Lastra, J. Pelaez-Montiel, F. Treviño-Tello, M.D.P. Cruz-Dominguez. *Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

**Background:** Systemic sclerosis (SSc) and Sjögren's syndrome (SS) are autoimmune diseases, which can coexist with sicca syndrome due to accumulation of collagen or chronic inflammation of the exocrine glands (salivary and endocrine). The prevalence of secondary SS to SSc ranges from 4 to 60%.

**Objectives:** To determine the prevalence of SS and sicca syndrome in Mexican patients with SSc.

**Methods:** Cross-sectional study. Seventy seven patients with SSc were studied at a tertiary hospital. SS and sicca syndrome were investigated according to the 2002 revised international criteria for Sjögren's syndrome by the American European Consensus Group (AECG). All patients underwent minor salivary gland biopsy, and the results of fibrosis andinflammation were classified according to Tarpley's classification with a score $\geq$1. Anti-Ro/SSA and Anti-La/SSB antibodies were quantified in 34 patients with positive histological findings for SS. All patients with ocular symptoms were also performed Schirmer's I test to evaluate the ocular manifestations.

**Results:** Infiltration characteristic of SSc, and 21 (27%) revealed SS lymphocytic infiltrate. Isolatedxerostomia was found in 17 (22%) patients, and isolated xerophthalmia in 5 (7%) patients.Five (6.5%) patients referred parotid glands swelling. Anti-Ro/SSA and/or anti-La/SSBautoantibodies were found in 28.5% (6/21) of patients with SS. 21 (27%) patients met the2002 revised criteria for classification for SS by the AECG, Schirmer's I test revealed dryeye severity level 2 in 4 (19%) patients, level 3 in 12 (57%) patients and level 4 in 5 (23.8%) patients.

**Conclusions:** The prevalence of sicca syndrome was 71%, 44 per cent related to systemic sclerosis's collagen infiltration, and 27% due to Sjögren's syndrome's lymphocytic infiltrate. It is important to give a treatment to improve symptoms and considering the high frequency of non Hodgkin lymphoma in patients with SSc and SS.

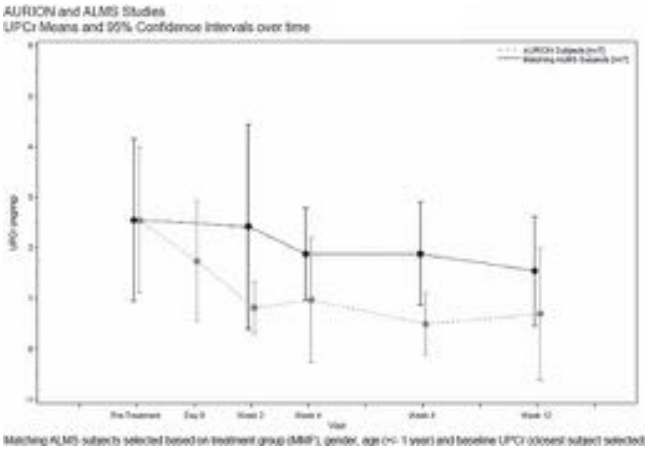
## AB0419 AURION STUDY: PRELIMINARY RESULTS OF VOCLOSPORIN IN LUPUS NEPHRITIS

R. Yahya[1], A.H.B.A. Gafor[2], R. Huizinga[3], T.M. Chan[4], N. Solomons[3]. *[1]Nephrology, Hospital Kuala Lampur; [2]Nephrology, Universiti Kebangsaan Malaysia Medical Centre Cheras, Kuala Lampur, Malaysia; [3]Clinical, Aurinia Pharmaceuticals, Victoria, Canada; [4]Medicine, University of Hong Kong, Hong Kong, Hong Kong*

**Background:** In lupus nephritis (LN), complete or partial remission (PR) is associated with better patient and renal survival. However, studies demonstrate that subjects who did not achieve a 25% reduction in proteinuria within 8 weeks of starting induction immunosuppression were unlikely to achieve even a PR. Recent studies suggest that a combination of calcineurin inhibitors (CNi's), MMF and low dose steroids may be effective in LN patients. Voclosporin (VCS) is a next generation CNi intended for the treatment of autoimmune diseases and prevention of transplant rejection, with a predictable pharmacokinetic-pharmacodynamic profile. An ongoing study (AURA-LV) is a global double-blind, prospective study comparing 2 doses of VCS with placebo. This study, AURION, is an exploratory study of VCS in active LN in combination with MMF and steroids.



**Objectives:** The AURION study assesses the ability of biomarkers measured at 8 weeks to predict clinical response over 24 and 48 weeks. In addition complete remission is assessed at week 24, defined as a protein/creatinine ratio of $\leq$0.5 mg/mg and estimated glomerular filtration rate (eGFR,CKD-EPI equation) $\geq$60 mL/min/1.73 $m^2$ or no decrease from baseline in eGFR of $\geq$20%.

Participating subjects with active lupus nephritis will take voclosporin 23.7 mg BID in combination with standard of care. We report preliminary biochemistry data.
**Methods:** Eligibility criteria includes: renal biopsy within 2 years of screening; SLE by ACR criteria; laboratory features consistent with active LN; and eGFR >45ml/min/1.73m$^2$. VCS 23.7 mg po BID is administered in combination with MMF 1–2g/day and a reducing course of corticosteroids. UPCr assessments are made at each visit, together with biomarker (C3, C4 and anti-dsDNA) data at regular intervals. Proteinuria reduction over time is presented for the first 7 subjects enrolled in this pilot study, together with renal function, C3, C4 and anti-dsDNA plots.
To understand the impact of MMF/steroids alone, UPCr data is presented below with historical data from age/sex/UPCr matched patients from ALMS[1].
**Results:** (Mean±SD) Pretreatment UPCr was 2.5±1.6 mg/mg and eGFR was 115±34 ml/min. By week 8 mean UPCr had fallen to 0.5±0.5 mg/mg; a reduction in mean UPCr of 81%. eGFR at the same time-point was 113±10 ml/min. Expected increases in C3, C4 and decreases in anti-dsDNA were seen in this population.

Baseline demographics

| Demographics | (n=7) |
|---|---|
| Age (years) | 29.0±4.8* |
| Race | Asian |
| Sex (F/M%) | 100/0 |
| Time from SLE to LN diagnosis (years) | 1.6±2.6* |
| Time from SLE to study entry (years) | 6.1±3.0* |
| LN Class at study entry (n,%): Class III | 2 (29%) |
| Class IV | 2 (29%) |
| Class V | 3 (42%) |
| MMF Naïve (%) | 57.1 |
| eGFR at study entry (ml/min/1.73m$^2$) | 115±34* |
| Urine Protein/Creatinine Ratio | 2.54±1.56* |

*Mean ± SD.

**Conclusions:** Preliminary data from this this pilot study indicates that MTT using VCS, in combination with MMF and steroids, produced consistent reductions in proteinuria with preservation of renal function in the first 7 subjects enrolled with active LN. The results of the confirmatory global AURA-LV study using similar treatment patterns will be available later this year.

## AB0420 SATISFACTION AND UNMET NEED AMONG SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS TAKING STANDARD OF CARE MEDICATIONS (SOC) IN A REAL WORLD SETTING

S. Ramachandran[1], K. Pascoe[2], B. Hoskin[3], S. Lobosco[3], D. Bell[3], B. Pobiner[4], Y. Asukai[5]. *[1]Value Evidence & Outcomes, GlaxoSmithKline, King of Prussia, United States; [2]Value Evidence & Outcomes, GlaxoSmithKline, Middlesex; [3]Adelphi Real World, Cheshire, United Kingdom; [4]US Medical Affairs, GlaxoSmithKline, Research Triangle Park, Philadelphia, United States; [5]Value Evidence Analytics, GlaxoSmithKline, Middlesex, United Kingdom*

**Background:** Limited data exists to assess drivers of treatment satisfaction and areas of unmet need among patients with SLE.
**Objectives:** Primary: Assess physician and patient reported treatment satisfaction and unmet need amongst SOC patients treated ≥3 months. Secondary: Describe factors associated with satisfaction among SLE patients treated with SOC. SOC is defined as ≥1 of the following treatments: anti-malarials [AMs], corticosteroids, [CS] immunosuppressants [IMs] or non-steroidal anti-inflammatory drugs [NSAIDs].
**Methods:** Cross-sectional study of 88 US rheumatologists and their next five, SLE patients. Patient record forms (PRFs) were completed by physicians and patients provided data via self-completion forms (PSCs). Clinical burden, quality of life and satisfaction data were collected from both parties. Descriptive and bivariate analysis was used to profile SOC patients. Backwards stepwise logistic regression was used to assess drivers of physician and patient reported treatment satisfaction.
**Results:** Rheumatologists provided 369 SOC PRFs; 228 corresponding PSCs were completed by SOC patients (mean age 44.0, majority female [86%], Caucasian [56%] and working/studying [63%]).
Current SLE disease severity for a majority of SOC patients was described as mild by their physician, however 25% were described as moderate/severe. Current SLE status was described by physicians as deteriorating/unstable for 12% of SOC patients and physicians reported dissatisfaction with treatment in 18% (a figure matched by PSC patients).
A significant correlation existed between decreased satisfaction (patient & physician) and increased disease severity ($p<0.001$) and/or deteriorating disease status ($p<0.001$).
Significant associations with physician satisfaction were observed in the following covariates; musculoskeletal involvement (vs. no involvement) (OR: 0.05, $p<0.001$), disease status (deteriorating vs. improving/stable) (OR: 0.06, $p<0.001$), reduction in activities of daily living (ADLs) (vs. no reduction) (OR: 0.14, $p<0.001$), improvement in general symptomatology (vs. no improvement) (OR: 10.66, $p<0.001$).
Significant associations with patient satisfaction were observed in the following covariates; Number of symptoms (OR per additional symptom: 0.88, p=0.020), reduction in ADLs (vs. no reduction) OR: 0.34, p=0.030, improvement in general symptomatology (vs. no improvement) (OR: 3.44, p=0.017), frequency of medication administration (satisfied vs. dissatisfied) (OR: 7.07, $p<0.001$).
**Conclusions:** Clinical burden (disease severity/disease deterioration) continues to impact over a quarter of current patients on SOC. This burden has a significant bearing on both physician and patient satisfaction with treatment, particularly among moderate/severe & deteriorating patients. These findings are worthy of further exploration to ensure best clinical practice and ways to enhance physician and patient communication.

## AB0421 EVALUATION OF THE EXPERIENCE, SATISFACTION AND OUTCOMES OF AN AUTOINJECTOR FOR SELF-ADMINISTRATION OF SUBCUTANEOUS BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

E. Dashiell-Aje[1], G. Harding[1], K. Pascoe[2], J. DeVries[2], P. Berry[3], S. Ramachandran[3]. *[1]Evidera, Inc., Bethesda, United States; [2]GlaxoSmithKline, London, United Kingdom; [3]GlaxoSmithKline, Philadelphia, United States*

**Background:** A US, phase IIb study (#200339) found the belimumab autoinjector (BAI) was reliable and well-tolerated for home administration. This separate follow-up study (#201816) was conducted at the end of the phase IIb study to capture patient experiences with the various delivery devices-the BAI, intravenous belimumab (BIV) and belimumab prefilled syringe (BPS).
**Objectives:** To assess patient experiences with the BAI, with belimumab in general, and with switching to the BAI from BIV or BPS. Preference for administration route and the impact on activities of daily living were also explored.
**Methods:** Patients were recruited at their final week 8 study visit. The study consisted of a 43 item online (or paper) questionnaire followed by qualitative telephone interviews in a subset of patients. IRB approval was obtained and patients gave informed consent. The telephone interview captured further information from the patients' online survey responses. Quantitative data were analyzed using descriptive statistics and the qualitative data were transcribed and analysed using a content analysis approach.
**Results:** This study included a total of 43 patients who were representative of those that completed the phase IIb BAI study. Patients reported a high level of confidence in their ability to use the BAI correctly the first time they used it on their own. Overall satisfaction and satisfaction with the frequency of administration was higher for the BAI compared with BIV, and 76% preferred the BAI. The BAI was considered more convenient than BIV due to shorter administration time, less travel time, less interference with work, portability, and less/no pain. In telephone interviews, 62% (n=13) reported some disadvantages with the BAI (discomfort, inconvenience, not ergonomic). Patients reported a high level of satisfaction with belimumab regardless of administration route; 74% were satisfied or very

satisfied. All patients stated they would have preferred to initiate belimumab at an earlier stage of their disease and all patients wanted to continue receiving belimumab. The majority of patients reported improvements in overall symptoms, flare frequency and severity, and fatigue, since starting belimumab; many reported improvements in activities of daily living. Of those patients who worked, 59% reported the BAI had a positive impact on their ability to work and 40% of all patients reported the BAI improved their ability to carry out daily activities.
**Conclusions:** Patients were positive regarding their experience with adding belimumab to standard of care therapies, and favoured the BAI over BIV administration. Given only 2 patients were on the BPS, it was hard to draw any meaningful conclusions for this group. Self-selection bias, recall bias and small sample size should be considered limitations of this study design. The results of this study suggest that the availability of the BAI will be a welcome treatment option. The potential benefits of the BAI identified in this study should be explored in a long-term evaluation of the device to assess clinical and patient reported outcomes.
**Role of the study sponsor statement:** The research presented in this abstract was conducted by Evidera Inc. and was funded by GlaxoSmithKline.

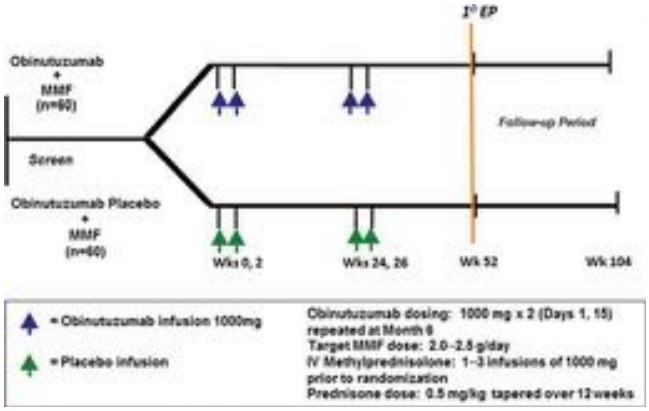
## AB0422 SELECTIVE FACTOR XA INHIBITORS IN TREATMENT AND PREVENTION OF THROMBOSES IN PATIENTS WITH RHEUMATIC DISEASES



N. Seredavkina[1], T. Reshetnyak[1], M. Satybaldyeva[1], L. Kashnikova[2], E. Nasonov[1]. *[1]Department of Systemic Connective Tissue Diseases; [2]Department of laboratory diagnostics, Nasonova Scientific Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Due to the smaller size of the molecule and low affinity for platelet factor (f) 4, fondaparinux (F) does not cross react with heparin-induced-thrombocytopenia- antibodies [1]. Also F has some more beneficial mechanisms: reduction of aPl-production (BAFF/Blys) and tissue f expression, C3/C5-inactivation, fXa-C3 cleavage blocking, increase of angiogenic process [2]. This can lead to classify F as pathogenic treatment option for rheumatic diseases (RD) as well as anticoagulant.
**Objectives:** To evaluate the affectivity and safety of F in treatment and prevention of thromboses in patients (pts) with RD.
**Methods:** The study included 54 pts suffered from the next RD: 8 systemic lupus erythematosus (SLE), 7 rheumatoid arthritis (RA), 4 antiphospholipid syndrome (APS), 25 SLE+APS, 4 systemic sclerosis, 1 osteoarthritis, 2 ANCA-associated vasculitis and 1 Behcet's disease. All the pts were treated with anticoagulants - 24 pts with F, 25 pts with nadroparin, 1 pts with enoxaparin and 4 pts with rivaroxaban - for different reasons: deep vein thrombosis (DVT), trophic ulcer, thrombotic cerebral microangiopathy, postthrombotic pulmonary hypertension, hypercoagulability due to nephritis, thrombosis prevention in SLE+APS pts with low platelets. Incidences of thrombosis, bleeding events and platelets levels were monitored. 10 pts (RA + vasculitis) had initial high fibrinogen levels. 12 pts with SLE+APS had baseline aPTT elevation from lupus anticoagulant (LA). Direct anti-fXa level monitoring (anti-Xa) was performed.
**Results:** All the pts demonstrated clinical improvement. Low anti-Xa was registered in 6 (12%) pts, normal anti-Xa – in 37 (69%) pts and high anti-Xa – in 11 (19%) pts. Pts with low anti-Xa underwent dose correction and none of them had new incidence of thrombosis. Most of pts did not have bleeding complications. Only 1 pt with SLE+APS treated with F developed multiple cutaneous haemorrhages. We discharged F for 24 hours and started again in a half dose. anti-Xa monitoring showed level decrease from 1.73 to 1.3 units/mL. In pts with APS and/or SLE F did not influence on aPL, fibrinogen and aPTT. 3 SLE+APS pts who had distal gangrene and cutaneous necrosis intentionally were treated with high dose of F with anti-Xa ~2 units/mL. That led to a good clinical response and blood flow recovery in ischemic tissues. There were no any signs and symptoms of bleeding.
**Conclusions:** Fondaparinux is an effective and save drug for the treatment and prevention of thrombosis in pts with RD. During the therapy routine coagulation monitoring is not representative because of LA and inflammation. We recommend to monitor signs of bleeding and anti-Xa and to expand its normal rate up to 2 units/mL in pts with distal gangrene and cutaneous necrosis due to SLE and APS.

## AB0423 NOBILITY, A PHASE 2 TRIAL TO ASSESS THE SAFETY AND EFFICACY OF OBINUTUZUMAB, A NOVEL TYPE 2 ANTI-CD20 MONOCLONAL ANTIBODY (MAB), IN PATIENTS (PTS) WITH ISN/RPS CLASS III OR IV LUPUS NEPHRITIS (LN)

T. Schindler[1], B. Rovin[2], R. Furie[3], M. Leandro[4], M. Clark[5], P. Brunetta[6], J. Garg[6]. *[1]F. Hoffmann-La Roche AG, Basel, Switzerland; [2]The Ohio State University Wexner Medical Center, Columbus; [3]Northwell Health, Great Neck, United States; [4]University College London, London, United Kingdom; [5]University of Chicago, Chicago; [6]Genentech, South San Francisco, United States*

**Background:** B cells infiltrate the kidneys of LN pts, and leukocyte-rich tubulointerstitial infiltrates are associated with greater risk for progression to renal failure. High-sensitivity flow cytometry (HSFC) analysis suggests incomplete B-cell depletion in systemic lupus erythematosus (SLE) is associated with nonresponse to rituximab (RTX). Obinutuzumab (Obi) is a glycoengineered type 2 anti-CD20 mAb that binds CD20 differently from RTX, a conventional type 1 anti-CD20 mAb, and depletes B cells to a greater degree than RTX. In preclinical studies, Obi displayed significantly increased antibody-dependent cellular cytotoxicity and enhanced direct cell death over type 1 anti-CD20 mAbs. In the CLL11 trial, which led to FDA breakthrough designation and its licensing in chronic lymphocytic leukemia, Obi demonstrated greater progression-free survival and greater minimal residual disease negativity over RTX even in protected microenvironments such as bone marrow. Double-blind randomized controlled trials demonstrated that type 1 anti-CD20 mAbs added to mycophenolate mofetil (MMF) or cyclophosphamide (CYC) increased the proportions of pts achieving partial renal response (PRR) but had no impact on complete renal response (CRR) rates at 12 months. Although these studies with RTX and ocrelizumab did not meet their respective primary endpoints, EULAR and ACR LN guidelines recommend RTX if treatment with CYC or MMF fails.
**Objectives:** The phase 2 study NOBILITY is designed to test the hypothesis that Obi may generate superior CRR rates in pts with active proliferative LN based on its ability to deplete B cells to a greater degree than type 1 anti-CD20 mAbs. The primary objective of this study is to evaluate the effect of Obi compared with placebo (PBO) when added to MMF in pts with class III or IV LN as assessed by the proportion of pts who achieve CRR at wk 52. Key secondary objectives relate to overall response (CRR + PRR), PRR, change in biomarkers of LN disease activity, and time to CRR.
**Methods:** Randomized, double-blind, PBO-controlled study to evaluate safety and efficacy of Obi added to MMF and corticosteroids (CS) in pts with ISN/RPS 2003 class III or IV LN.
**Results:** The study design is as follows: NOBILITY is a global multicenter study enrolling ~120 pts with biopsy-proven ISN/RPS 2003 class III or IV LN in the United States, Mexico, Columbia, Argentina, Spain, Israel, Brazil, and France. All pts will be on MMF up to 2.5 g/d and a combination of IV and oral CS to be tapered to 7.5 mg/d by wk 12. All pts will be followed up until wk 104, with the primary endpoint evaluation at wk 52 (figure). NOBILITY also features interim analyses at wk 4 for depletion of peripheral $CD19^+$ B cells by HSFC, centralized evaluation of the renal biopsy, and repeat renal biopsy on the basis of clinical status and local practice.

**Conclusions:** NOBILITY, a phase 2 trial evaluating Obi in LN, is grounded on the hypothesis that a type 2 anti-CD20 mAb will induce greater B-cell depletion in the kidneys and associated secondary lymphoid structures, translating to significant CRR rates.

## AB0424 RETROSPECTIVE EVALUATION OF MYCOPHENOLATE MOFETIL INFECTIOUS SIDE EFFECTS ON LUPUS NEPHRITIS PATIENTS

T. Meirinhos[1], E. Mariz[2], I. Castro Ferreira[3], R. Neto[3], E. Pereira[4], L. Costa[5]. *[1]Rheumatology, Chbv - Aveiro, Valongo; [2]CHSJ, Porto, Portugal; [3]Nephrology; [4]Internal Medicine; [5]Rheumatology, CHSJ, Porto, Portugal*

**Background:** Systemic lupus erythematosus (SLE) is a multifaceted autoimmune disease driven by auto-reactive immune cells, in particular B cells that target multiple organ systems leading to severe complications. A main complication of SLE is nephritis, formally known as lupus nephritis (LN). MMF is a selective, non-competitive and reversible inhibitor of inosine monophosphate dehydrogenase. MMF provided to be useful in the treatment of patients affected by SLE, especially in those with LN. MMF demonstrated a more favorable safety profile compared with cyclophosphamide, especially in terms of alopecia and infertility rates. Nonetheless, the use of MMF in LN has not been extensively evaluated in terms of safety and infection rates.
**Objectives:** To study the prevalence of infections complications in a cohort of adult LN patients under MMF maintenance therapy.
**Methods:** Retrospective study, enrolling patients attending a Rheumatology/Nephrology department, diagnosed with SLE (American College of Rheumatology criteria) and LN, under MMF maintenance therapy. Drug variables: dose of MMF, time of exposure. Clinical variables: age, gender, race, disease duration, histological classification (renal biopsy), specific organ involvement, other therapeutics for SLE, serum urea and creatinine, 24h proteinuria, and urinary sediment. Statistical analysis with Microsoft Excel 2010; appropriate statistical tests were used; $p$ value$<0.05$ with a 95% confidence interval will be assumed.
**Results:** 44 SLE patients were enrolled, 37 were female (84.1%); mean age was 38.4±11.9 years and mean disease duration was 122.9±108 months. All the patients were white. 35 patients (80%) had class 4 LN, 5 had class 5 and histological classification was unknown in 4 patients. 34 (77%) patients had extra renal disease, 23 with joint disease and 14 with cutaneous involvement. Mean MMF dose was 1018±876mg. 35 (79%) patients were doing steroid therapy, mean dose 5.58±3.87mg and 39 (88.6%) patients under Hidroxicloroquine therapy. We identify 25 infectious events, 4 (16%) needing hospitalization, none death. Mean time to infection after MMF introduction was 12.16±16.3 months. The most frequent infections include urinary tract infections (UTI) (8 patients), cutaneous Herpes Zoster (4 patients) and respiratory tract infections (4 patients). We found a positive correlation between the occurrence of infection in the first 8 months of therapy and 24h Proteinúria and dsDNA in the beginning of therapy (p=0.04 and p=0.03, respectively). Hidroxicloroquine seem to have a protective effect against infections, but no statistic association was found. We found no association between infections and MMF/steroid dose or renal function.
**Conclusions:** We found significant morbidity associated with an increase incidence of infection after introduction of MMF, especially in the first months of therapy and patients with more active disease in the beginning of MMF. No mortality was associated with these infectious complications, and the hospital admission rate was low.

## AB0425 TAC-TIC USE OF TACROLIMUS-BASED REGIMENS IN LUPUS NEPHRITIS

T. Kraaij[1], O.W. Bredewold[1], T. Huizinga[2], T. Rabelink[1], O. Teng[1]. *[1]Nephrology; [2]Rheumatology, LUMC, Leiden, Netherlands*

**Background:** Current guidelines do not mention tacrolimus as a treatment option and no consensus has been reported on the role of tacrolimus in active LN. Recent clinical trials have reported positive effects of tacrolimus-based (TAC) regimens for treatment of lupus nephritis (LN).
**Objectives:** With this systematic review and meta-analysis, we aimed to translate recent outcomes on tacrolimus-based regimens for LN treatment into clinical practice.
**Methods:** We identified from various databases every clinical studies investigating TAC regimens in LN. Studies were summarized on the basis of treatment target (induction or maintenance), concomitant immunosuppression and quality of the data. A meta-analysis was performed for the efficacy of TAC regimen as induction treatment, maintenance treatment as well as safety.
**Results:** 239 studies were identified from which 24 were clinical studies performed in LN patients: 6 case series, 9 cohort studies, 3 case-control studies (CCS) and 6 randomized controlled trials (RCTs). Further analysis of the 9 controlled trials showed that 7 studies investigated tacrolimus in combination with steroids and 2 tacrolimus with mycophenolate plus steroids. 4 RCTs investigated TAC regimens as induction treatment and 2 RCTs as maintenance treatment. Strikingly, there was no consensus in any of the studies regarding tacrolimus dosing and target trough levels. Importantly, all the studies were performed in LN patients of Asian ethnicity. A meta-analysis of TAC regimens for induction treatment showed a significantly higher complete response (RR 1.18, 95% CI 1.04–1.34, p=0.01) and a significantly lower no response rate (RR 0.71, 95% CI 0.56–0.90, p<0.01). With respect to safety, no clear differences between TAC regimens and conventional treatment were observed.
**Conclusions:** Current studies on TAC regimens for LN are limited, heterogenous and predominant uncontrolled studies in patients of Asian ethnicity. A significant, clinical efficacy of TAC regimens as induction treatment was found however cannot be extrapolated beyond Asian LN patient groups. Clearly, these results mandate further confirmation in multi-ethnic, randomized trials.

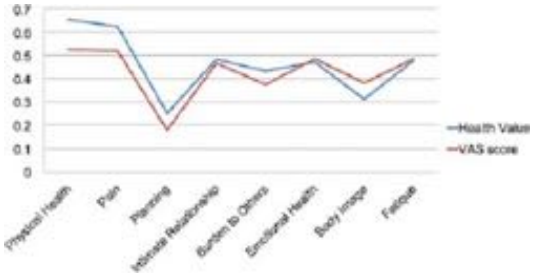
## AB0426 RISK OF PNEUMOCYSTIS CARINII PNEUMONIA INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE POPULATION COHORT STUDY

W.H. Wang[1], C.-C. Lai[2], Y.-S. Chang[3]. *[1]Kuanshan Tzu Chi Hospital, Taitung; [2]Taipei Veterans General Hospital, Taipei City; [3]Shuang Ho Hospital, New Taipei City, Taiwan, Province of China*

**Background:** Pneumocystis carinii pneumonia (PJP) infection often affects immunocompromised patients may cause severe morbidity and mortality. PJP may be preventable by prophylactic antibiotics in high risk patients. However, the epidemiology and risk factors for PJP in patients with systemic lupus erythematosus (SLE) are not full studied.
**Objectives:** This nationwide population-based study aimed to evaluate the risk of PJP in patients with systemic lupus erythematosus in Taiwan.
**Methods:** We identified 23,378 SLE patients from the National Health Insurance research database between 1997 and 2012 and compared the incidence rate (IR) of PJP infection with that of 93,512 age- and gender-matched non-SLE cohort. A Cox multivariable proportional hazards model was applied to evaluate the risk of PJP infection in the SLE cohort. Risk factors of PJP infection were also analyzed.
**Results:** The SLE cohort had a significantly higher IR of PJP infection (SLE IR=2.49, control IR=0.10, incidence rate ratio = 26.06, p<0.001). Male (Hazard ratio [HR] = 2.05, p=0.039), end stage renal disease (HR=1.88, p=0.035), use of mycofenolate mofetil (HR=5.11, p<0.001), intravenous steroid pulse therapy (HR=96.23, p<0.001).

Table 1. Risk factors of PJP infection in patients with SLE

| Variable | Univariate analysis | | | Multivariable analysis | |
|---|---|---|---|---|---|
| | HR (95% CI) | *P*-value | | HR (95% CI) | *P*-value |
| Male | 2.61 (1.33–5.13) | 0.005 | | 2.05 (1.04–4.04) | 0.039 |
| Comorbidity | | | | | |
| Diabetes mellitus | 0.55 (0.20–1.53) | 0.251 | | | |
| End-stage renal disease | 3.80 (2.15–6.72) | <0.001 | 1.88 (1.05–3.39) | 0.035 | |
| ILD | 2.02 (0.80–5.09) | 0.137 | | | |
| Stroke | 1.77 (0.92–3.40) | 0.088 | | | |
| Malignancy | 0.71 (0.40–1.25) | 0.237 | | | |
| Medications | | | | | |
| Hydroxychloroquine | 0.622 (0.35–1.12) | 0.108 | | | |
| Azathioprine | 1.86 (1.01–3.42) | 0.043 | – | - | |
| Mycofenolate mofetil | 14.58 (7.23–29.41) | <0.001 | 5.11 (2.48–10.50) | <0.001 | |
| Cyclosporine | 7.55 (3.21–17.77) | <0.001 | – | - | |
| Cyclophosphamide | 7.26 (3.80–113.89) | <0.001 | – | - | |
| MTX | 0.619 (0.09–4.49) | 0.632 | | | |
| Steroid | | | | | |
| Intravenous | 182.3 (65.31–508.8) | <0.001 | 96.23 (33.46–276.82) | <0.001 | |
| Oral daily dose over 7.5m† | 15.87 (7.07–35.64) | <0.001 | 3.83 (1.66–8.82) | 0.002 | |



**Conclusions:** Higher risk of PJP infection was observed in SLE patients. Risk factors for PJP infection include male, end stage renal disease, use of mycofenolate mofetil, intravenous steroid pulse therapy and an oral daily steroid dose over 7.5mg.

## SLE, Sjögren's and APS - clinical aspects (other than treatment)

### AB0427 HEALTH-RELATED QUALITY OF LIFE IN THAI LUPUS PATIENTS. COMPARISON OF THE EUROPEAN QUALITY OF LIFE SCALE (EQ-5D) AND THE LUPUS QUALITY OF LIFE QUESTIONNAIRE (LUPUSQOL)

A. Koolvisoot[1], N. Thongthap[2]. [1]*Medicine, Siriraj Hospital;* [2]*Phrajomklao Hospital, Bangkok, Thailand*

**Background:** SLE mostly affects the working-age population. The disease burden has a significant impact to the quality of life.
**Objectives:** To assess the HRQoL in SLE patients by using the EQ-5D and the LupusQoL and to evaluate their correlation.
**Methods:** 248 patients were recruited. Demographic and clinical data including the SLEDAI were collected. We also evaluated the patients' preference in terms of the language, the precision of questions, and time consume. The correlation was examined by Pearson's correlation.
**Results:** 94.6% of patients were female. Mean age was 37.5±11.9 with the median disease duration of 5.1 years. The mean SLEDAI score was 3.6±0.4. The mean of EQ-5D health value and VAS scores were 0.65±0.20 and 78.1±20.2. Most patients reported that SLE had mild effect to their health status. 28.1 and 18.3% of patients reported moderate to severe problems in the mental components of pain/discomfort and anxiety/depression. The mean LupusQoL score was 78.9±16.3. Both EQ-5D health value and VAS were significantly correlated with all LupusQOL domains, strongly correlated with physical health and pain but poorly correlated with planning and body image. The patients preferred to use the EQ-5D over LupusQoL.

**Conclusions:** HRQoL in most SLE patients was generally good. The EQ-5D score was significantly correlated with the LupusQoL score particularly in the domains of physical health and pain. The EQ-5D is a simple and more convenient tool to assess the general health and can be used as a brief evaluation of lupus-specific HRQoL in daily practice.

### AB0428 CARDIAC INVOLVEMENT IN SYSTEMIC SCLEROSIS – A PORTUGUESE REALITY

A.C. Duarte, I. Cordeiro, S. Sousa, L. Teixeira, A. Cordeiro, M.J. Santos. *Rheumatology, Hospital Garcia de Orta, Almada, Portugal*

**Background:** Systemic sclerosis (SSc) has a wide spectrum of cardiovascular manifestations, being pulmonary hypertension (PH) one of the most lethal complications. Echocardiography is a pivotal screening test for patients at risk for PH that allows prompt identification of those with high estimated pulmonary artery systolic pressure (PASP).
**Objectives:** We conducted a retrospective analysis of patients with SSc followed in our Rheumatology department aiming to characterize those with estimated PASP≥35 mmHg.
**Methods:** Clinical and laboratory features, including dyspnea according to New York Heart Association (NYHA) classes, N-terminal pro-Brain Natriuretic Peptide (NT-proBNP) serum levels, uricemia, anti-nuclear antibody (ANA) specificities, 6-minute walk test (6MWT), and right heart catheterization (RHC), if required, were assessed.
**Results:** In total, 87 out of 103 SSc patients had available echocardiography results (females 93.1%; mean age 57.8 years; mean disease duration 10.3 years). Eight patients were classified as having NYHA class≥3. The median value of NTproBNP was 104 pg/mL (19 to 15902). Twenty one (24%) had estimated PASP≥35 mmHg (in 16 patients PASP could not be estimated), of whom16 performed RHC. PH (mPAP≥25 mmHg) was confirmed in 7 (44%) cases; 3 were classified as group 1, 1 as group 2, 2 as group 3 and 1 as group 5, according to the ERS/ECS 2013 classification. The group with elevated PASP included 11 patients with limited SSc, 7 with diffuse SSc, 1 sine scleroderma and 2 overlap syndromes. Comparison of patients with PASP≥35 mmHg with those with PASP<35 mmHg put in evidence the following differences (Table bellow).

| | PASP≥35 mmHg N=21 | PASP <35 mmHg N=66 | p-value |
|---|---|---|---|
| Age | 64.9 | 45.3 | 0.595 |
| Disease duration (years) | 10.1 | 11.5 | 0.571 |
| NYHA ≥3 | 35% | 0% | <0.001 |
| Mean NTproBNP (pg/mL) | 2549 (35–15,902) | 225 (19–3,042) | 0.083 |
| Mean uricemia (mg/dL) | 5.2 | 4.8 | 0.446 |
| Anti-Scl70 antibody | 42.1% | 18% | 0.055 |
| Raynaud phenomenon | 80% | 82% | 0.507 |
| Carbon monoxide diffusion (DLCOsb) <75 | 66.7% | 76.4% | 0.359 |
| Restrictive pulmonary disease (FVC <70%) | 44.4% | 4.8% | <0.001 |
| Mean distance in 6MWT (m) | 345 (150–530) | 398 (310–610) | 0.349 |

**Conclusions:** PASP is elevated in one quarter of SSc patients. This subgroup present more frequently higher NYHA classes, elevated NTproBNP levels and Scl70 positivity. About 44% of them had restrictive pulmonary disease. It is essential to closely monitor cardiorespiratory function in order to rule out cardiac involvement as early as possible.
Our results suggest that there is still need to increase physicians' awareness of systematic cardiovascular screening, since fewer patients than are nowadays recommended had a complete evaluation.

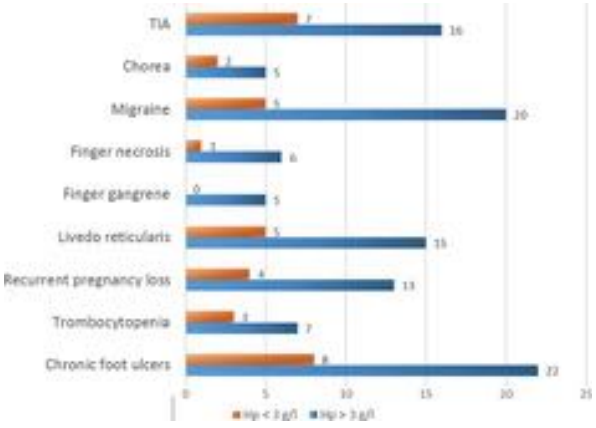
Marañon;* [8]*H 12 Octubre, Madrid;* [9]*EOXI;* [10]*IBI, Vigo, Spain*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune systemic rheumatic disease that, in our area, presents hematologic manifestations in approximately 70% of cases[1]. Some of them are very rare, there are no large series whose analysis could provide relevant information.
**Objectives:** To study the characteristics of patients with Pure Red Cell Aplasia (PRCA) in a large sample of SLE patients.
**Methods:** SLE patients from RELESSER database were studied. We analysed the clinical and analytical SLE manifestations at 12 different domains (mucocutaneous, renal, musculoskeletal, constitutional, haematologic, vascular, cardiac, respiratory,

**Abstract AB0429** – Table 1



| | Patient 1 | Patient 2 | Patient 3 | Patient 4 | Patient 5 |

| Number of organ systems affected by SLE before PRCA diagnosis | Not applicable | 6 | 6 | 4 | 7 |
| Number of organ systems affected by SLE at PRCA diagnosis | Not applicable | 1 | 1 | 1 | 6 |
| Number of organ systems affected by SLE until last assessment | 3 | 3 | 5 | 1 | 2 |
| Haemoglobin levels at PRCA diagnosis (g/dl) | 7 | 4.9 | 4.9 | 4.5 | 6.3 |
| Bone Marrow biopsy or aspirate | Selective aplasia/hypoplasia of the red series, without changes in other series | | | | |
| SLEDAI / SLICC-ACR DI at PRCA diagnosis | Not applicable | 4 / 1 | 2 / 1 | 0 / 0 | 20 / 0 |
| SLEDAI / SLICC-ACR DI 1 year after PRCA | Not applicable | 0 / 1 | 2 / 1 | 2 / 0 | 4 / 0 |
| SLEDAI / SLICC ACR DI at last assessment | 0 / 0 | 6 / 3 | 0 / 2 | 0 / 0 | 0 / 0 |
| Number of treatment lines | 2 | 2 | 2 | 1 | 4 |
| Treatments administered | 1st: Oxitosona<br>2nd: Inmunoglobulins | 1st: Glucocorticoids<br>2nd: Inmunoglobulins & RBC transfusion | 1st: Glucocorticoids<br>2nd: Ciclosporin A | Glucocorticoids | 1st: Glucocorticoids<br>hydroxicloroquine<br>3rd: Rituximab<br>2nd: Belimumab<br>erythropoietin<br>4th: Darbepoetin α |
| Total number of treatments administered | 2 | 3 | 2 | 1 | 6 |
| Relapse | No | | | | |
| Death | No | | | | |

neuropsychiatric, gastrointestinal, ophthalmic and serological) before, during and after PRCA diagnosis and until the last available assessment. We also studied activity (SELENA-SLEDAI) and damage (SLICC/ACR DI)indices at each of those times.
We evaluated the treatment received, PRCA recurrences and the number of deaths by this entity.
**Results:** 3,656 patients from 45Rheumatology Units across Spain were studied. 5 cases of PRCA were found (<0.5%of total)
There were not viral infections in relation with the PRCA.
All patients had a good response to treatment, reaching complete remission without relapses or deaths. The mean number of treatment lines (± SD)that were necessary was 2.2 (±1.01)and the mean (± SD)number of treatments used was 2.8 (±1.92). Except for the patient diagnosed with PRCA before SLE, all of them received glucocorticoids as initial treatment. Of these 4patients only 1achieved complete remission without requiring immunosuppressive therapy.
The following table shows the characteristics of each patient:
**Conclusions:** PRCA is a very rare cause of anemia in SLE. In most cases it appears several years after the diagnosis of SLE. It is a serious manifestation but in our series, with a proper management showed a favourable response.

## AB0430 CARRIAGE FREQUENCY OF HAPTOGLOBIN PHENOTYPES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME AND THEIR ASSOCIATION WITH CLINICAL MANIFESTATIONS

M. Sultanova[1], A. Hon[2]. *[1]Rheumatology Department; [2]Cardio-rheumatology Department, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** At present, in 30–35% systemic lupus erythematosus (SLE) patients antiphospholipid antibodies (aPL) are associated with the development of secondary antiphospholipid syndrome (APS), including venous and/or arterial thrombosis and other systemic disorders. Practitioners still face certain difficulties in differential diagnosis of the APS positive SLE and are in need for efficient tests to verify the diagnosis. Hp (haptoglobin) is a hemoglobin-binding glycoprotein of α2-globulin serum proteins fraction induced by seromucoids at the early stages of an inflammatory process. There are three phenotypic variants of Hp: Hp 1–1, Hp 2–1 and Hp 2–2. The practical value of Hp test in SLE patients is the possibility to diagnose a genetic predisposition to APS to predict severity of the disease.
**Objectives:** Determine the carriage frequency of different Hp phenotypes in SLE patients with APS, and reveal a correlation between the level of serum Hp and clinical manifestations of APS in SLE patients.
**Methods:** The study is based on the follow-up results of 103 SLE patients under treatment at the Republican Centre of Rheumatology, Tashkent Medical Academy. Entry criteria of patients in the study: reliable diagnosis of SLE, verified in accordance with SLICC (2012) criteria and the informed consent to participation. The secondary APS (SAPS) was based on the Sydney (2006) Classification Criteria for APS. Haptoglobin test was performed using disc polyacrylamide gel electrophoresis (PAGE).
**Results:** We have defined APS in 44 of 103 (42.7%) SLE patients. In 29 of 44 (65%) cases the APS diagnosis was based on major manifestations, and in 15 of 44 (35%) – by the presence of two or more additional signs. Distribution of SLE patients with APS, depending on the Hp phenotype: 38 (86.4%) patients with APS had Hp 1–1, 6 (13.6%) – Hp 2–1, 0 (0%) - Hp 2–2 phenotype (P<0.01, 95% CI). Distribution of SLE patients without APS depending on the Hp phenotype: 23 (39%) patients – Hp 1–1, 27 (45.8%) – Hp 2–1, 9 (15.3%) – Hp 2–2 phenotype. After distribution of the patients into groups by the Hp level, more than 3 g/l (I group) and less than 3 g/l (II group), we have analysed the correlation between Hp and clinical manifestations of APS: thrombocytopenia: I – 7 (22,5%), II – 3 (23,07%), HM – I – 13 (41,9%), II – 4 (30,7%), livedo reticularis: I – 15 (48,3%), II – 5 (38,4%), finger gangrene: I – 5 (16,1%), II – 0 (0%); finger necrosis: I – 6 (19,3%), II – 1 (7,6%); migraine: I – 20 (64,5%), II – 5 (38,4%); chorea: I – 5 (16,1%), II – 2 (15,3%); transitory ischemic attack (TIA): I – 16 (51,6%), II – 7 (53,8%); chronic ulcers of lower extremities: I – 22 (70,9%), II – 8 (61,5%) (P<0.05, 95% CI).

**Conclusions:** Results of our investigation showed that development of SLE and APS is characteristic for Hp 1–1 phenotype, apparently, being a predisposing factor to the autosensitisation and a genetic marker for APS. Furthermore, there is an expressed correlation between Hp level and clinical manifestations of APS.

## AB0431 ANTIBODIES TO THE ENZYME OF ADENINE BRANCH OF PURINE METABOLISM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A.V. Aleksandrov[1], I.Y. Alekhina[2], V.A. Aleksandrov[2], L.N. Shilova[3], N.V. Aleksandrova[2]. *[1]Volgograd State Medical University; [2]FSBSU Research Institute for Clinical and Experimental Rheumatology; [3]Chair of hospital therapy, Volgograd State Medical University, Volgograd, Russian Federation*

**Background:** In the pathogenesis of SLE an important place is given to immune mechanisms with many uncertain aspects. Adenosine deaminase (ADA), 5-nucleotidase (5-NT), adenosine kinase (ADK) and xanthine oxidase (XO) are the main enzymes of adenine branch of purine metabolism (PM), the activity of which is closely related to the immunological processes in the body. The role of antibodies to enzymes PM in systemic lupus erythematosus (SLE) is not defined and poorly studied.
**Objectives:** The purpose of our work was to study antibodies to enzymes of adenine branch of PM in SLE patients and to detect correlations between studied antibodies and clinical and laboratory indices of pathological process.
**Methods:** 30 healthy individuals aged 18 to 40 years (20 women and 10 men) and 60 SLE patients aged 22 to 58 years (55 women and 5 men) were included into the research. The diagnosis of SLE was verified using the ACR criteria of the 1997. The object of research was blood serum. IgG antibodies to ADA (anti-ADA), 5-NT (anti-5NT), ADC (anti-ADC) and XO (anti-XO) were determined in the method developed by us for indirect ELISA-assay using an immobilized form of the correlative enzyme as antigen matrix. Positive results were considered greater than 2 standard deviations of figures obtained during the examination of healthy persons (0.106 Unit for anti-ADA; 0.1 Unit for anti-5NT; 0.47 Unit for anti-ADC; 0.097 U for the anti-XO). The results were expressed as mean ± σ, differences were considered significant when p<0.05. Person correlation coefficient (r) was also used.
**Results:** According to the results of the research the number of SLE patients with elevated levels of anti-ADA was 51.6%, anti-5NT - 41.7%, anti-ADK - 46,7%, the anti-XO - 53.3%. Comparison between the positive and negative for the presence of anti-ADA groups of patients with SLE showed a statistically significant increase in the detection rate of chronic headaches (p=0.01), lymphopenia (p=0.025) and the definition of increased values of antibodies to phospholipids (p=0.014).
Comparison between the positive and negative for the presence of blood serum anti-5NT groups of SLE patients showed an increase in the frequency of kidney damage (p=0.031) and vessels (p=0.053). Analysis of anti-5NT in relation to laboratory data allowed to identify a number of statistically significant correlations: with proteinuria (r=0,27; p=0,039), leukocyturia (r=0,35; p=0,012) and red blood cell (r=0,29; p=0,026). These data allow us to consider the anti-5NT as an additional indicator of lupus nephropathy.
Among patients with the presence of anti-ADK a significant number of patients with vascular disease (p=0,023) was revealed. A bit more often, but not statistically significant, patients with the presence of anti-ADC pulmonary injury (p=0,113) and the autonomic nervous system (p=0,124) were observed.
Comparison between the positive and negative for the presence of anti-CA groups of patients with SLE demonstrated a statistically significant increase in the frequency of signs of kidney (p=0.032) and blood vessels injury (p=0.042).
**Conclusions:** Determination of antibodies to enzymes PM can be used as additional laboratory tests in the diagnosis of complex SLE to characterize the clinical variants of the disease.

## AB0432 HIGH PREVALENCE OF METABOLIC SYNDROME IN SOUTH AFRICAN SLE PATIENTS

A.N. Nkabane[1], I. Okpechi[2], B. Hodkinson[3]. *[1]Internal Medicine; [2]Division of Nephrology and Hypertension, Groote Schuur Hospital and University of Cape Town; [3]Internal Medicine, University of Cape Town and Groote Schuur Hospital, CapeTown, South Africa*

**Background:** Against a background of urbanisation and widespread poverty, the prevalence of the metabolic syndrome (MetS) is increasing in South Africa, and atherosclerotic cardiovascular diseases are emerging as a major cause of mortality. Patients with systemic lupus erythematosus (SLE) are at increased risk of the MetS and its complications, but there are no published studies of the prevalence or associations of the MetS amongst sub-Saharan Africans with SLE.
**Objectives:** To investigate the prevalence and associations of the MetS amongst recent-onset SLE patients.
**Methods:** A cross-sectional study of baseline features of an inception cohort of recent onset (<5 years' disease duration) SLE patients. All patients met the SLICC SLE classification criteria and were attending the rheumatology clinic in a state-sector tertiary academic hospital. The MetS was defined by Joint Interim Statement criteria[1].
**Results:** Of 90 patients, the mean (SD) age was 36.7 (12.2) yrs, disease duration was 24.7 (22.9) months, 81 (87.8%) were female, and of these 67 (82.7%) were premenopausal. In terms of ethnicity, 70.0% were of mixed ethnic ancestry and 25.6% were Black Africans. Patients were of poor socio-economic status: 31.1% were unemployed, with a mean (SD) schooling of 10.2 (2.6) yrs. The mean (SD) SLEDAI score was 5.9 (3.4), and 94.4% were ANA positive, and 15 (16.7%) had lupus nephritis. The majority of patients were prescribed chloroquine (97.8%) and low dose corticosteroids (67.1%). The mean (SD) BMI was 26.2 (6.8) kg/m$^2$, and 53.3% were smokers. The overall prevalence of MetS in this cohort was 33.3%, and increased waist circumference and reduced HDL- C were the most frequently observed features (Table). There was a trend toward more females having MetS (OR 0.2 (95%CI 0.02–1.4, p=0.09), but there was no association between the MetS and age, menopausal status, disease duration, ethnic group nor with SLEDAI score, presence of dsDNA, hypocomplementaemia, or with organ involvement including nephritis. Surprisingly, neither the use of corticosteroid or their dose was associated with MetS.

| Frequency of the MetS components (n, %) | Overall cohort (n=90) | Patients with MetS (n=30) |
|---|---|---|
| Hypertension | 37 (41.1) | 21 (70.0)) |
| Increased waist circumference | 62 (68.9) | 30 (100.0) |
| Hypertriglyceridemia | 22 (24.4) | 17 (56.7) |
| Low HDL-cholesterol | 50 (55.6) | 24 (80.0) |
| Diabetes | 6 (6.7) | 5 (16.7) |

**Conclusions:** South Africans with recently diagnosed SLE are at particularly high risk of atherosclerotic cardiovascular disease due to the high prevalence of the MetS and cigarette smoking. This calls for aggressive primary prevention strategies.

## AB0433 DISEASE CHARACTERISTICS, SURVIVAL ANALYSIS AND MORTALITY IN A SINGLE CENTRE COHORT OF 240 PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

B. Artim-Esen[1], Y. Şahinkaya[1], T. Yüce[1], O. Pehlivan[1], M. Bektaş[2], B. Toz[1], B. Erer[2], S. Kamali[1], A. Gül[1], L. Ocal[1], M. İnanç[1]. *[1]Department of Internal Medicine, Division of Rheumatology; [2]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey*

**Background:** Antiphospholipid syndrome (APS) is an autoimmune disease characterized mainly by thrombosis and/or pregnancy morbidity in the presence of antiphospholipid (aPL) antibodies. Significant mortality and morbidity has been reported in patients with APS.
**Objectives:** To characterize a single center cohort of patients with APS (including non-criteria manifestations) and to assess their survival rates, causes of mortality and associations with disease characteristics.
**Methods:** Records of 240 patients with APS were studied. Demographic characteristics, cumulative clinical and laboratory features, autoantibody profiles were retrieved from the existing database. Unattending patients were contacted by telephone and were searched on the national death information system (NDIS). Patients who were non-responsive to telephone calls, not seen in the outpatient clinic within the last 6 months and could not be traced on the NDIS were considered lost-to follow-up.
**Results:** There is a total of 240 patients in this cohort 118 of whom had primary APS and 122 had APS associated with SLE. 83% of the patients were female. The mean age at diagnosis was 41±12, duration of disease and follow-up were 110±85 and 92±82 months respectively.
Of 240 patients, 65% had vascular thrombosis (VT), 24% had pregnancy morbidity (PM), 10% had both VT and PM and 3 had catastrophic antiphospholipid syndrome. Overall 29% patients had thrombotic risk factors among which smoking followed by homozygous factor V Leiden mutation were the most prevalent. Of patients with VT 49% had arterial (a), 38% had venous (v) and 13% had both a and v thrombosis. 95 patients experienced a single thrombotic episode whilst 62 had more than once, most commonly v followed by a thrombosis. In the PM group, there were 31 patients with fetal deaths beyond 10 weeks, 39 with 3 or more abortions before 10 weeks, 18 with premature labour and 14 with pre-eclampsia. Overall, 46% of patients had aCL IgG, 36% had IgM and LA was present in 54%. Anti-β2GPI was tested in 117 patients and 38% were positive for IgG and 25% for IgM. Of the non-criteria manifestations of APS, the most common presentation was heart valve lesions followed by thrombocytopenia.
In total there were 25 deaths and 19 patients were lost to follow-up. Survival rates were 94, 86, 78 and 71% at 5, 10, 15 and 20 years respectively. Comparison of survival between patients with VT and PM displayed a marked reduction in the VT group (p=0.04) whilst primary and lupus associated APS patients had similar rates. Causes of death could be identified in 19 patients. Myocardial infarction, alveolar hemorrhage and pulmonary hypertension were the leading causes of death. Mortality was significantly associated with LA positivity (p=0.02).
**Conclusions:** In this cohort, the most prevalent manifestation of APS was arterial thrombosis. Long-term follow up revealed that patients with APS had significant mortality and APS-related manifestations dominated the causes. Thrombotic patients had a reduced survival relative to PM patients. No single aPL test was sufficiently sensitive in the evaluation of APS. LA positivity was a risk factor for reduced survival.

## AB0434 THE ROLE OF IGG ANTI β2-GPI IN THE CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS

B. Mahendran, R. Sankalingam, K. Mohanasundaram, S. Sankaran, M. Mani, B. Chilukuri. *Rheumatology, Madras Medical College, Chennai, India*

**Background:** Beta 2 GPI is an important antigenic target for antiphospholipid antibodies. The role of IgG antibodies to β2 glycoprotein I [Anti-β2-GPI] has been well defined in antiphospholipid antibody syndrome but its role in the clinical manifestions of SLE remains elusive.
**Objectives:** To investigate the role of Anti-β2-GPI in the clinical manifestations of SLE
**Methods:** IgG Anti-β2-GPI was measured in 184 patients with SLE (93% women, mean age 28 years). IgG Anti-β2-GPI (>18 GPL units) was found in 19 patients (10.3%). Associations were determined with clinical manifestations of SLE and with components of the Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index
**Results:** Of the patients with SLE who demonstrated IgG Anti-β2-GPI, 31% had at least one thrombotic event (OR 4.2, p=0.01), 26% had pulmonary hypertension (OR 3.2, p=0.02) and 26% had recurrent abortions (OR 4.1, p=0.02). IgG Anti-β2-GPI was protective against lupus nephritis (OR 0.31, p=0.02). No other manifestations were significantly higher in patients with IgG Anti-β2-GPI positivity

| Clinical Manifestation | | Anti-β (2)-GPI | | |
|---|---|---|---|---|
| | | Positive | Negative | |
| Recurrent abortions | Present | 5 | 13 | OR 4.1 p=0.02 |
| | Absent | 14 | 152 | |
| Thrombotic events | Present | 6 | 16 | OR 4.2 p=0.01 |
| | Absent | 13 | 149 | |
| Pulmonary hypertension | Present | 5 | 15 | OR 3.2 p=0.02 |
| | Absent | 14 | 150 | |
| Lupus nephritis | Present | 6 | 98 | OR 0.31 p=0.02 |
| | Absent | 13 | 67 | |

**Conclusions:** In SLE, IgG Anti-β2-GPI is associated with thrombotic events and pulmonary hypertension, but may have a protective effect against lupus nephritis. Large scale studies are required to confirm these findings.

## AB0435 IMMUNOSIGNATURE TECHNOLOGY IDENTIFIES SYSTEMIC LUPUS ERYTHEMATOSUS FROM A DROP OF SERUM

B.P. Nayak[1], C. Putterman[2], R. Gerwien[1], K. Sykes[3], T.M. Tarasow[1].
*[1]HealthTell, San Ramon, CA; [2]Albert Einstein College of Medicine, Bronx, NY; [3]HealthTell, Chandler, AZ, United States*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic inflammatory autoimmune disease characterized by production of pathogenic autoantibodies. These autoantibodies form immune complexes that can deposit in tissues causing organ damage. The clinical heterogeneity of SLE, and its manifestations that overlap other diseases, pose a diagnostic challenge (1–3). Early identification of disease and disease activity is key to curtailing permanent organ damage (3–5). More accurate diagnosic tools than those in current clinical use would have a significant impact on patient care.
HealthTell has developed a high density peptide array platform to diagnose a disease based on differential Ab binding called ImmunoSignatures (IS). The IS technology uses arrays of hundreds of thousands of unique peptides designed to survey an individual's Ab repertoire from a drop of blood, plasma, or serum (6). Differential binding profiles of the Ab on the array between patients with the disease of interest and control groups are selected as input to develop classification algorithms. The technology holds promise for detecting the presence of any disease that generates a specific B-cell response. Furthermore, for autoimmune diseases the technology has the potential to provide accurate differential diagnosis as well as detection of disease activity and progression.
**Objectives:** To establish the feasibility of the IS technology in identifying subjects with SLE.
**Methods:** Two well-annotated cohorts of serum samples were used representing i) 45 SLE cases and ii) 45 age, gender and race-matched normal donors. All SLE patients met ACR criteria, and as their primary clinical manifestation had joint (53%), renal (38%), skin (2%), or inactive disease (7%). Serum samples were diluted and applied on to the arrays. Ab-peptide binding was detected with fluorescently-labeled goat anti-human IgG. Peptide binding signal was quantified and features with significant differences in intensity between cases and controls were identified by Bonferroni adjusted t-test and log odds ratios. Support vector machine classification algorithms were trained using the most distinguishing peptides. Classifier model performance was evaluated by applying 100 iterations of a four-fold cross-validation routine that included feature selection, model training, and model testing.
**Results:** The cross-validated performance metrics of the 500-peptide IS classifier included an area under the Receiver Operator Curve of 0.99 (95% confidence interval (CI) 0.98–0.99) and an overall accuracy of 93% (95% CI 91%>96%) at equal sensitivity and specificity.
**Conclusions:** ImmunoSignature identification of SLE is feasible and highly accurate based on the preliminary cross-validated performance. These results need verification in larger cohorts and validation in blinded studies. Future studies will include control samples relevant to SLE differential diagnosis such as inflammatory and non-inflammatory rheumatic diseases, as well as active and inactive SLE.

## AB0436 ALL THE "HISPANICS" ARE NOT EQUAL. THE SEVERITY AND ACTIVITY OF PATIENTS WITH SLE IS HIGHER IN MESTIZOS LATIN AMERICAN VS. EUROPEAN CAUCASIAN. LESSONS FROM RELESSER

B. Hernández-Cruz[1], F. Alonso[2], J. Calvo Alén[3], J.M. Pego-Reigosa[4], F.J. López-Longo[5], M. Galindo Izquierdo[6], A. Olive[7], E. Tomero[8], Í. Rúa-Figeroa[9] on behalf of RELESSER Group. *[1]UGC Reumatología, HUVM, Seville; [2]Unidad de Investigación, Sociedad Española de Reumatología, Madrid; [3]Reumatology, Hospital Universitario Araba, Vitoria, País Vasco; [4]Reumatology, University Hospital Complex, IBIV, Vigo; [5]Reumatology, Hospital Gregorio Marañón; [6]Reumatology, Doce de Octubre University Hospital, Madrid; [7]Reumatology, Germans Trías i Pujol University Hospital, Badalona; [8]Reumatology, la Princesa University Hospital, Madrid; [9]Reumatology, Hospital Dr. Negrín, Gran Canaria, Spain*

**Background:** SLE is a known disease for the study of ethnic and gender minorities. In Spain, from 1998 to 2011, occurred a significant immigration from Latin American people. The English speakers consider "Hispanics" as the same ethnic group. But there are differences between the Hispanics from Spain (with ethnicity European Caucasian) and the Hispanics from Latin America (with ethnicity Mestizo Latin American).
**Objectives:** To know the demographic, clinical, severity, activity, damage, mortality and comorbidity of SLE in Hispanics with ethnicity European Caucasian (EC) and in Hispanic Mestizos from Latin American (MLA) residents in Spain. To identify differences between the groups.
**Methods:** Design: observational, multicentric, crossover study. Patients with SLE (ACR 1987) and <16 years old were included in 45 rheumatology Units in Spain. The RELESER methodology has been informed. Statistical analysis: we grouped the patients from the registry in two groups: EC and MLA and descriptive, univariate and multivariate statistics were done.
**Results:** 3,490 patients with SLE were included, 90% females; 3,305 (92%) Hispanics EC y 185 (5%) Hispanics MLA. The Table shows the main variables. Patients MLA had higher levels of activity (SLEDAI), severity (KATZ INDEX) and number of admissions to the hospital for SLE activity. The damage index (SLICC), mortality, and comorbidity Index showed no differences. In the multivariate analysis several models were constructed with adjusted for age, sex and disease duration. The patients MLA had a higher risk for Severity (Katz Index >3) OR 1,45 (1,038 – 2, 026, p=0,02. This differences were not found for activity: OR 0,98 (0.30 - 1.66), may be for collinearity.

Table 1

| Variable | European Caucasian n, % | Mestizos Latin American n, % | p |
|---|---|---|---|
| Total | 3.305, 92 | 185, 5 | |
| Women | 2.891, 90 | 176, 95 | 0.02 |
| Myositis | 113, 3 | 15, 8 | 0.001 |
| Hemolytic anemia | 271, 8 | 24. 14 | 0.01 |
| Lupus nephritis | 952, 29 | 79, 44 | <0.0001 |
| Serositis | 49, 1 | 9, 5 | <0.001 |
| Admissions related to LES activity | 1.741, 54 | 120, 67 | 0.0001 |
| | Median (IQR) | Median (IQR) | |
| Age at SLE diagnosis (years) | 35.5 (24.3–44.5) | 30.5 (22.6–36.9) | 0.001 |
| Age at the study inclusion | 32.8 (22–42) | 28.6 (21–36) | <0.001 |
| SLA disease duration (years) | | | |
| 1st symptom to diagnosis | 12.5 (5.7–17.5) | 7.9 (2.5–10.7) | <0.0001 |
| Activity (SLEDAI) | 2.5 (0–4) | 3.8 (0–4) | 0.01 |
| Severity (KATZ) | 2.6 (1–3) | 2.9 (2–4) | 0.01 |
| Damage (SLICC) | 1.1 (0–2) | 0.9 (0–1) | 0.6 |
| Comorbidity (Charlson) | 2.3 (1–3) | 1.7 (1–2) | 0.2 |

**Conclusions:** The SLE of Hispanics MLA patients had clinical differences when it was compared with Hispanics EC patients, mainly higher severity and activity. This shows that all the Hispanics are not equal.
**Disclosure of Interest:** None declared

## AB0437 COMPLICATIONS OF THE MINIMALLY INVASIVE BIOPSY OF THE MINOR SALIVARY GLAND

C. Galisteo, M. Garcia Manrique, J. Calvet, C. Orellana, M. Arevalo, M. Moreno, M. Larrosa. *Rheumatology, Parc Tauli Sabadell Hospital Universitari, Sabadell, Spain*

**Background:** The diagnosis of Sjogren Syndrome (SS), requires fulfillment of the American- European classification criteria, which include the obligatory presence of antibodies or a compatible histology. Numerous labial salivary gland biopsy techniques have been described, with variations in the size and shape of incision, as well as the need for suturing. Nowadays, the tendency is to use less invasive techniques
**Objectives:** To evaluate the frequency of complications of the minimally invasive biopsy of minor salivary glands
**Methods:** Transversal study of 159 biopsies of the minor salivary gland. *Inclusion Criteria:* patients with dry syndrome. *Biopsy technique:* anesthesia with ultracain and epinephrine, vertical incision (≤5 mm) of the internal surface of the lower lip using a scalpel and whitout suture, followed by the application of a gauze with topical procoagulant for 30 minutes. *Variables studied:* 1) clinical: age, sex, presence and duration of the symptoms; 2) diagnostic: Schirmer test, salivary scintigraphy, ANA, RF, anti-SSA and anti-SSB. 3) biopsy complications: a) immediate: bleeding and lipothymia; b) acute (<1 month): dysesthesia, hematoma, swelling, infection, pain, speaking and eating difficulties, scarring disorders (granuloma, keloid) and c) chronic (>1 month): dysesthesia, scarring disorders (granuloma, keloid), 4) histological: a) degree of atrophy: absent, light, moderate and severe b) Chisholm-Mason scale (I-IV)
**Results:** The characteristics of the sample group were; age 59.9 ±12.43 years, 91% women, 88% xerostomia, 89% xerophthalmia for a period of 49±37 months, 45% positive salivary scintigraphy, 54% positive Schirmer, 54% ANA, RF 22%, anti-SSA and anti-SSB of 28% and 6.2%, respectively. The complications were: immediate (n=16; 8%): bleeding (n=13; 81%), lipothymia (n=3; 18%); b) acute (n=93; 58%): dysesthesia (n=2; 1.2%) for a period of 2.5±0.7 days, hematomas (n=23; 14%)) for a period of 4±2.5 days, swelling (n=69; 43%) for a period of 3±2.4 days, infection (0%), 37% pain (26% mild, 9% moderate, 2% severe) for a period of 3±2.5 days, speaking difficulties (n=13;8.1%) for a period of 3±3.6 days, eating difficulties (n=20; 12%) for a period of 2.3±2.8 days and granuloma (n=10; 6.2%); c) chronic (n=4; 2.5%): dysesthesia (0%) and granuloma (n=4; 2.5%) without clinical repercussion. Material for histology was obtained in 92.5%. The development of chronic complications (granuloma) was not related to the presence of acute complications except temporal dysesthesia (18% vs 1%;

p<0.001). Also chronic complications was not related to the degree of histological atrophy or age, but a tendency was observed in younger patients (49±4.5 vs 60±12.4; p<0.09)
**Conclusions:** The minimally invasive biopsy of the minor salivary gland is a technique which is easy to carry out and complications are rare. Moreover, it also offers success rates to obtain material which are similar to those of other techniques. Given the ease of the technique and the fact that complications are rare, it is worth evaluating its incorporation into those centres where it is not being used and it should be performed by rheumatologists.

## AB0438 CHEMOKINES AND RENAL COMPLICATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

C.P. Lee [1], D.Y.H. Yap [2], P.H. Li [1], A.W.K. Chan [1], L.H. Lee [1], V.S.F. Chan [1], C.S. Lau [1]. *[1]Division of Rheumatology and Clinical Immunology, Department of Medicine, Li Ka Shing Faculty of Medicine; [2]Division of Nephrology, Department of Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, -*

**Background:** We and others have performed cluster analyses of patients with systemic lupus erythematosus (SLE) and revealed several prognostically distinct clinical patterns. Certain clusters of patients present with lupus nephritis (LN) while others remain LN free in the course of their disease. [1] This observation suggests different immunopathogenic mechanisms may be in play in the various disease manifestations of lupus. Chemokines recruit immune cells and have been proposed as biomarkers for LN.
**Objectives:** This study aimed to investigate if changes in the serum levels of various chemokines were abnormal in patients with a clearly defined history of LN and non-LN (NLN). Chemokines, including interferon-γ-induced protein-10 (IP-10), RANTES and macrophage inflammatory protein-1α (MIP-1α) were examined.
**Methods:** Patients were said to have LN if they had at least 1 episode of biopsy-confirmed Class III, IV or V (or any combination of these 3 classes) nephritis, while those who had not exhibited any renal diseases after at least 10 years of follow up were designated NLN. The LN patients were further divided into those with inactive LN (ILN) and active LN (ALN). ALN patients were recruited at the time of renal biopsy before immunosuppressive drug treatment. Enzyme-linked immunosorbent assay (ELISA) was used to measure the concentration of RANTES, MIP-1α and IP-10 in serum of the 3 groups of patients.
**Results:** 80 patients were studied. 32 had ILN, 8 ALN and 40 NLN. Preliminary data show the serum levels of RANTES and MIP-1α were significantly lower in the LN group (including ALN and ILN) when compared with NLN SLE patients. (LN vs NLN: RANTES 3.3±5.7 ng/ml vs 7.6±9.9 ng/ml, p=0.0003; MIP-1α 39±106 pg/ml vs 86±158 pg/ml, p=0.03; IP-10 284±342 pg/ml vs 300±534 pg/ml, p=n.s.) There were no significant differences in the serum concentrations of RANTES and MIP-1α between the ALN and ILN subgroups (ALN vs ILN: RANTES 4.3±8.3 ng/ml vs 3.0±5.0ng/ml, p=n.s.; MIP-1α: 27±23 pg/ml vs 42±112 pg/ml, p=n.s.) For IP-10, no significant differences were found among the ILN, ALN and NLN groups. (ILN: 256±264pg/ml, ALN: 398±569pg/ml, NLN: 300±534pg/ml, all p =n.s.)
**Conclusions:** LN patients had lower serum levels of RANTES and MIP-1α when compared with patients with clearly no LN disease. These chemokines may have an immunopathogenic role in the development of renal complications in SLE. That no differences in the serum levels of RANTES, MIP-1α and IP-10 were observed between ILN and ALN patients may suggest these chemokines are not implicated in LN disease progression although a larger cohort study with serial follow-up of patients before and after the development of LN and the use of immunosuppressive treatment is needed. This is underway. In addition, more candidate chemokines and related cytokines will be studied.

## AB0439 ADVERSE EVENTS AFTER SURGERY IN PEDIATRIC PATIENTS WITH SLE: A NATIONWIDE STUDY

C.-C. Liao, T.-L. Chen. *Department of Anesthesiology, Taipei Medical University Hospital, Taipei City, Taiwan, Province of China*

**Background:** Little was know about the outcomes after surgery in pediatric patients with systemic lupus erythematosus (SLE).
**Objectives:** Our purpose is to investigate the postoperative adverse events among surgical pediatric patients with preoperative SLE in a nationwide population-based study.
**Methods:** We used Taiwan's National Health Insurance Research Database to identify pediatric inpatients with SLE and 258294 controls receiving major surgery. Sociodemographic characteristics, preoperative comorbidities, postoperative 30-day in-hospital major complications and mortality were analysed among surgical patients with and without SLE.
**Results:** Pediatric patients with SLE had a higher prevalence of preoperative coexisting medical conditions and postoperative major complications. The OR of 30-day postoperative mortality for surgical patients with SLE was 8.55 (95% CI 2.65–27.6) after adjustment. Among pediatric patients, SLE was associated with postoperative pneumonia (OR 8.79, 95% CI 5.54–13.9), acute renal failure (OR 30.6, 95% CI 14.8–63.2), admission to intensive care unit (OR 2.16, 95% CI 1.55–3.00), prolonged length of stay (OR 2.45, 95% CI 1.78–3.38) and increased medical expenditure (OR 2.64, 95% CI 1.92–3.63).
**Conclusions:** Among pediatric population, SLE significantly increased the risks of surgical complications and mortality after major surgery. Our findings demonstrated the need for integrated care and revised protocols for perioperative management to improve outcomes for pediatric patients with SLE.

## AB0440 SERUM URIC ACID LEVELS PREDICT NEW RENAL DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

C. Reátegui-Sokolova, M. Ugarte-Gil, R. Gamboa-Cardenas, F. Zevallos, J.M. Cucho-Venegas, J. Alfaro-Lozano, M. Medina, Z. Rodriguez-Bellido, C. Pastor-Asurza, R. Perich-Campos. *Rheumatology, Hospital Guillermo Almenara Irigoyen - EsSalud, Lima, Peru*

**Background:** Renal involvement is one of the most serious and frequent manifestations of systemic lupus erythematosus (SLE) and is associated with increased morbidity and mortality. Uric acid levels have been associated with the progression to subsequent end-stage renal disease in patients with chronic kidney disease [(1)]. Uric acid has been reported to be associated with new onset lupus nephritis [(2)]; however, the association between uric acid levels and renal damage has not been reported in SLE patients.
**Objectives:** To determine whether uric acid level predicts new renal damage in SLE patients after adjusting for known confounding factors.
**Methods:** This longitudinal study was conducted in consecutive SLE patients seen in our Rheumatology Department since 2012. Every patient had a baseline visit; follow-up visits were conducted every 6 months. For the purpose of this study, patients with at least two visits were included. Patients with end-stage renal disease (regardless of dialysis or transplantion) were excluded for this analysis. Renal damage was ascertained using the SLICC/ACR damage index (SDI). Uric acid was measured in mg/dl. Survival analyses using univariable and multivariable Cox-regression models were performed to determine the risk of new renal damage. The multivariable model was adjusted for age at diagnosis, gender, disease duration, socioeconomic status, SLEDAI, SDI, serum creatinine, use of prednisone, antimalarials and immunosuppressive drugs at baseline.
**Results:** One hundred and eighty-six patients were evaluated; their mean (SD) age at diagnosis was 36.8 (13.7) years; nearly all patients were Mestizo. Disease duration was 7.7 (6.8) years. Time of follow-up was 2.3 (1.1) years. At baseline, uric acid levels were 4.5 (1.3) mg/dl, the SLEDAI was 5.2 (4.3) and the SDI 0.8 (1.1). Sixteen (8.6%) patients had one point in renal domain at baseline and 2 (1.1%) had two. During the follow-up 16 (8.6%) patients developed at least one new point in the renal domain of the SDI. In univariable and multivariable analyses uric acid level at baseline predicted the development of new renal damage [HR: 2.24 (1.50–3.34), p<0.001; HR: 3.21 (1.39–7.42), p=0.006; respectively].
**Conclusions:** Higher uric acid levels predict the development of new renal damage in SLE patients even after adjusting for other well-known risk factors.

## AB0441 NEUROPSYCHIATRIC MANIFESTATIONS OF ADULT-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

D. Ivanova [1], G. Milev [2], S. Nacheva [3], I. Petrova [3], G. Angov [3], J. Petrova [3], K. Stoyanova [3]. *[1]University Hospital Sofiamed, Department of Rheumatology; [2]Department of Rheumatology, MU Kliment Ohridski, Sofia; [3]Department of Neurology, MU Sofia, University Hospital Alexandrovska, Sofia, Bulgaria*

**Background:** Evaluation of the diversity of Neuropsychiatric (NP) manifestations of adult-onset Systemic Lupus Erythematosus (SLE) for the period 2012–2014 (extended 2014–2015) is presented. The most common complications are migraine, cognitive and motor disorders, seizures, cerebrovascular disease
**Methods:** Complete clinical, rheumatological and neurological evaluation was performed using SLEDAI-2K, BILAG 2004, SLICC/ACR Damage Index test batteries. Immunological blood tests include C3, C4, Serum Cryoglobulins, ANA, anti-β2 GP I-Ig G, anti-β2 GP I-Ig M, Anti-double stranded DNA, anti-RNP/Sm, anti-His., Ro (SSA), La (SSB), anti-CENT B, anti-ribosomal P, ANCA followed by lumbal puncture, neuropsychological testing, Doppler sonography, EMG and EEG, brain MRI/CT.

**Results:** A total of 220 patients were longitudinally observed in 4 years period - 185 female, (84%), 35 men (16%). 82 (37%) patients presented NPSLE during the first 6 months. Consequent NP manifestations include: central vertigo (73.5%), headache (66.5%), cognitive impairment (33.2%), psychiatric disorders (18.7%), seizures (7.3%), cerebrovascular disease (10.6%), and polyneuropathy (3.5%). Positive anti-DNA antibodies (50%), anti-ribossomal P (20%), anticardiolipin antibodies (50%) were identified in NPSLE patients.
**Conclusions:** Patients with SLE present with different NP manifestations. It is still difficult to provide accurate differential diagnosis between NPSLE and chronic cerebrovascular disease or MS especially when NP manifestations are the first symptoms of SLE.
**Disclosure of Interest:** None declared

## AB0442 SPECTRUM AND DRUG RESISTANCE OF BACTERIA ISOLATED FROM HOSPITALIZED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

D. Chen, Z. Zhan. *The first affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** In recent decades, the leading cause of death in patients with *systemic lupus* erythematosus (SLE) has changed from active disease to infection. The spectrum of infectious agents in SLE patients varies significantly among different ethnic groups. Furthermore, multiple drug resistance (MDR) pathogens have become the biggest concern worldwide, and the situation is even more serious in China.
**Objectives:** To investigate the spectrum and antibiotic resistant pattern of bacterial infection in patients hospitalized with SLE.
**Methods:** We collected the clinical and microbiological data from hospitalized SLE patients with bacterial infection between June 2005 and June 2015 and then conducted retrospective analyses.
**Results:** Among our sample of 3815 hospitalized patients, 258 episodes had microbiological defined bacterial infection. In terms of isolated microorganisms, gram-negative bacteria (GNB) were predominant over gram-positive bacteria (GPB) (178 isolates vs. 90 isolates). In the GNB, Escherichia coli (24.6%) was the most common isolate, followed by Acinetobacter baumannii (13.4%) and Klebsiella pneumoniae (9.0%). For GPB, coagulase negative Staphylococcus (CNS, 13.4%) was most commonly documented followed by Staphylococcus aureus (11.2%) and other GPB. Overall, MDR bacteria were detected in 26.9% of the isolates. Extended-spectrum beta-lactamase (ESBL) producers were expressed mainly in Escherichia coli (30/66, 45.5%) and Klebsiella pneumoniae (7/24, 29.2%). The proportion of multi-drug resistant acinetobacter baumannii (MDR-AB) in the sample was 36.1%. Eight of Staphylococcus aureus (8/30, 26.7%) were found to be methicillin-resistant Staphylococcus aureus (MRSA), and fourteen of CNS (14/36, 38.9%) were considered methicillin-resistant CNS (MRSCNS).
**Conclusions:** Predominance of GNB with emerging of MDR isolates was the notable features of bacterial infection in Chinese SLE patients. Therefore rational use of antibiotic will be urgently needed to reduce the morbidity and mortality of patients with SLE.
**Disclosure of Interest:** None declared

## AB0443 RELATION BETWEEN ACCUMULATIVE DAMAGE AND DISABILITY RECOGNICED BY THE INSS* IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

E. Grau Garcia[1,2], M. Fernández Matilla[2], G. Poveda Marín[1], C. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz Sanjuan[1], N. Fernández-Llanio[3], D. Hervás Marín[4], V. Fornes Ferrer[4], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortés[1], J. Fragio Gil[1], I. Martínez Cordellat[1], J. Valero Sanz[1], I. Chalmeta Verdejo[1], L. González Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], J. Castellano Cuesta[3], J. Román Ivorra[1]. *[1]Rheumatology Dept., HUP La Fe; [2]Rheumatology Research Group, IIS la Fe; [3]Rheumatology Dept„ Hospital Arnau de Vilanova; [4]Biostatistics Unit, IIS La Fe, Valencia, Spain*

**Background:** Systemic Lupus Erythematosus (SLE) in a multisystemic and autoimmune disease that specially affects young women during the second and third decade, and is able to injure different organs and or systems, being the most common one affected the musculoskeletal system. Events attributed to SLE itself and other related to the disease may impact negatively in the quality of life, unemployment, disability and mortality. Recent data show that 3.8% of SLE patients have comorbidities and 59.2% of them were receiving a disability pension. In Spain, the evaluation of disability and the assignation of the mentioned pension is given by the National Social Security Institute of Spain (INSS: Instituto Nacional de la Seguridad Social).
**Objectives:** To assess the relationship between cumulative damage regarding to the affected organ and the percentage of disability recognized by the INSS in SLE patients in Spain.
**Methods:** Cross-sectional prospective study of SLE patients according to the SLICC-2012 criteria, from the Rheumatology Service of Arnau de Vilanova Hospital and La Fe Hospital. We collected clinical and demographic data through personal interview and the SLIC-ACR questionnaire.
**Results:** A total of 140 patients were evaluated; of them, 95% were women with 33.39±13.63 year-old average at the diagnosis time with a 10.05±1.42 year-evolution of SLE. Clinical characteristics of each group are described in the table.

| | Without disability | With disability |
|---|---|---|
| N | 98.00 | 42.00 |
| Disability (%) | 0 | 53.14±23.7 |
| SLICC | 0.75±0.98 | 1.8±1.10 |
| Age at SLE diagnosis | 34.6±14.8 | 30.7±10.4 |
| SLE evolution (years) | 13.9±10.7 | 20.7±8.10 |
| Nervous system damage (%) | 12.24 | 28.57 |
| Musculoskeletal damage (%) | 88.78 | 90.48 |
| Mucocutaneus damage (%) | 72.45 | 76.19 |
| Serositis (%) | 7.14 | 14.29 |
| Cardiovascular damage (%) | 13.27 | 19.05 |
| Cytopenia (%) | 42.86 | 47.62 |
| Renal damage (%) | 13.27 | 19.05 |
| Raynaud's (%) | 29.59 | 47.62 |
| Antiphospholipid synd. (%) | 7.14 | 11.90 |
| Sjögren synd. (%) | 16.33 | 23.81 |
| Vasculitis (%) | 1.02 | 4.76 |

**Conclusions:** We observed a positive correlation between percentage of recognized disability and the SLICC-ACR index score. Musculoskeletal system is, in general, the most affected one, without differences between both groups; but we found a higher proportion of damage in nervous system, renal and vasculitis in patients with a recognized disability.
**Disclosure of Interest:** None declared

## AB0444 EVALUATION OF CUMULATIVE DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AS A NEW CARDIOVASCULAR RISK FACTOR

M. Fernández Matilla[1], E. Grau Garcia[1,2], G. Poveda Marín[2], C. Feced Olmos[2], E. Labrador Sánchez[2], F.M. Ortiz Sanjuan[2], N. Fernández-Llanio[3], D. Hervás Marín[4], V. Fornes Ferrer[4], K. Arévalo Ruales[2], R. Negueroles Albuixech[2], J. Ivorra Cortés[2], J. Fragio Gil[2], I. Martínez Cordellat[2], J. Valero Sanz[2], I. Chalmeta Verdejo[2], L. González Puig[2], C. Alcañiz Escandell[2], C. Nájera Herranz[2], J. Castellano Cuesta[3], J. Román Ivorra[2]. *[1]Rheumatology Research Group, IIS la Fe; [2]Rheumatology Department, HUP la Fe; [3]Rheumatology Department, Hospital Arnau de Vilanova; [4]Biostatistics Unit, IIS la Fe, Valencia, Spain*

**Background:** The first cause of mortality in patients with Systemic Lupus Erythematosus (SLE) is cardiovascular disease (CVD). Accelerated atherosclerosis that occurs in SLE is considered one of the fundamental mechanisms of the increase of cardiovascular mortality in this group of patients. Among the factors that contribute to the accelerated atherosclerosis process, we include the classical CVD risk factors, as well as the inflammatory and specific SLE factors.
**Objectives:** To assess the CVR in SLE patients and the possibility of modifying it based on the accumulative damage and the disease activity.
**Methods:** Cross-sectional prospective study of SLE patients according to the SLICC-2012 criteria, from the Rheumatology Service of Arnau de Vilanova Hospital and La Fe Hospital. All patients had a complete blood-test with autoimmunity markers, and clinical, biometrics and treatment data were collected. Biostatistical analysis was performed with the *R* software version 3.2.3.
**Results:** 140 patients were evaluated; (95% women) with 33.39±13.63 year-old average at the diagnosis time with a 10.05±11.42 year-evolution of SLE. 15% of patients had had some kind of CVD; in them, we observe an increase of the classical cardiovascular risk factors comparing to the group who hadn't had any CVD manifestation.
We found a statistically significant association between high scores in the SLICC-ACR index ($P<0.001$), dyslipemia (P=0.04), diabetes (P=0.02) and the presence of CVD in our patients. In addition, though it didn't get statistical significance, we observed a tendency to the association between CVD with the presence of hypertension, high levels of LDL-cholesterol and high scores in the SELENA-SLEDAI activity index.
Finally, and also without statistical significance, we observed a marked difference between levels of IgM anticardiolipin and IgM beta2-glicoprotein, finding higher levels in the group of patients that had suffered any manifestation of CVD.
**Conclusions:** The CVD rate among our group of patients is 15%, clearly higher than the general Spanish population (8.53%). We confirm the weight of classical cardiovascular risk factors as a trigger of CVD in SLE; however, the accumulative damage of the disease calculated with the SLIC-ACR index has a determinant paper in the cardiovascular risk of our patients. Therefor it could be proposed as an additional factor of cardiovascular risk in SLE patients.
On the other hand, the disease activity calculated with the SELENA-SLEDAI index seems to have a tendency of correlation between higher scores and the presence of CVD, though the years of disease evolution don't seem to influence in CVD. Nevertheless, more independent studies are needed to confirm this hypothesis.

## AB0445 OCULAR POSTERIOR SEGMENT FINDINGS IN ANTIPHOSPHOLIPID SYNDROME

E. Kucukkomurcu[1], A.U. Unal[2], F. Esen[3], G. Ozen[2], H. Diresekeneli[2], H. Kazokoglu[1]. *[1]Department of Ophthalmology; [2]Division of Rheumatology, Marmara University Medical Faculty, Istanbul; [3]Ophthalmology Clinic, Zonguldak Devrek State Hospital, Zonguldak, Turkey*

**Background:** Antiphospholipid Syndrome (APS) can affect all vessels in the body. Ocular complications are seen most commonly in posterior segment of the eye in these patients. The purpose of this study is to evaluate the posterior segment signs in APS patients and to compare these signs between Primary APS, Secondary APS and Systemic Lupus Erythematosus (SLE) patients without APS.
**Methods:** We have included 11 Primary APS, 2 Sjogren's Syndrome/ 27 SLE patients diagnosed as Secondary APS and 29 SLE patients without APS followed at Marmara University, Division of Rheumatology Outpatient Clinics in this study. All of the patients had a detailed ophthalmological examination, including dilated fundus examination and color fundus imaging. 10 patients with Primary Antiphospholipid Syndrome, 23 patients with Secondary APS and 23 patients with SLE had fundus fluorescein angiography imaging.
**Results:** Mean age of the patients was 34.8±12.5 years in Primary APS, 38.3±11.1years in Secondary APS and 38.3±10.9 years in SLE group. In Primary APS 45.5% of patients had venous thrombosis, 45.5% had arterial thrombosis and 72.7% had obstetric complications. In Secondary APS, 44.8% patients had venous thrombosis, 27.6% had arterial thrombosis and 72.4% had obstetric complications. Venous tortuosity was observed in 6 eyes of 3 patients in Primary APS group and 8 eyes of 4 patients in Secondary APS group. One patient with Secondary APS had bilateral branch retinal arterial occlusion. The most common ocular finding of the FFA was pigment epithelial window defect and was observed totally in 19 eyes of 12 patients. There was no statistically significant difference of ocular findings between the Primary APS, Secondary APS and SLE patients.
**Conclusions:** In this study, ocular posterior segment findings of Primary APS had been observed less commonly than previous studies. The lower prevalence of ocular complications in this study can be the result of early diagnosis and better control of relapses in these patients.
**Disclosure of Interest:** None declared

## AB0446 CONTRACEPTIVE PRACTICES AND KNOWLEDGE AMONG WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN A PORTUGUESE TERCIARY CARE HOSPITAL

F. Aguiar, R. Fonseca, I. Brito. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Systemic Lupus Erythematosus (SLE) is a disease that primarily affects women of reproductive ages. Unplanned pregnancy in women with SLE can have various complications both for the child and the woman, due to the disease itself or to eventual exposure to teratogenic medications. Most of these patients are candidates for extremely effective contraceptive methods, including implants, intrauterine devices (IUD) or permanent sterilization. However, some of these patients do not receive proper counseling and these methods are often underutilized.
**Objectives:** To determine contraceptive use, knowledge and counseling among patients with SLE attending a portuguese terciary care hospital.
**Methods:** Cross-sectional study in which women aged 15–50 followed in our Rheumatology Department with a diagnosis of SLE were approached to complete a researcher-administered survey.
**Results:** 74 women were included, median age 34 years (range 15–50), with median disease duration of 9.0 years (range 0.50–30.0). 8 patients were in menopause, 2 were pregnant at the time of the survey, and 18 had not been sexually active with a man in the 3 months prior to the survey. 46 women (62.1%) were sexually active and were considered to be at risk for unintended pregnancy. 41.3% (n=19) of these patients were using extremely effective contraceptive methods with a typical use failure rate of $\leq$3% (10 of them using (IUD), 7 permanent sterilization, and 2 implants), 32.6% (n=15) were using highly effective contraceptive methods with a typical use failure rate of $\geq$3% but $\leq$10% (combined oral contraceptive in 7 and progestatin-only oral contraceptive in 8) and 26.1% (n=12) were using either no method, or low effective methods with a typical use failure rate of $>$10% (masculine condom in 11 and one patient was not using any method).
52.2% (n=24) of the sexually active women were taking one or more of methotrexate, mycophenolate mofetil, cyclophosphamide or warfarin. Amongst these soubgroup of patients one third was using extremely effective contraceptive methods, one third was using highly effective methods and another third was using low effective methods either or no method.
Among women at risk for unintended pregnancy 13% (n=6) were not aware of the complications associated with pregnancy in their medical condition, and in patients using teratogenic medications 8.3% (n=2) were not aware of the the risks and 37.5% (n=9) had never been counseled about contraception. In women using teratogenic medications and low effective methods, 87.5% (n=7) were aware of the risks of pregnancy but 87.5% (n=7) had never been counseled about contraception.
**Conclusions:** In this study, most women with SLE who are at risk for unintended pregnancy were aware that their medical condition increases the health risks for themselves and their fetuses. However a significant number of patients, especially those under potencially teratogenic medications did not receive any contraceptive counseling. It is essential to educate these women about their reproductive health and contraceptive options and risks.

## AB0447 ANTI-PHOSPHOLIPID POSITIVITY IN HEALTHY SUBJECTS: EVALUATION OF RISK FOR THROMBOTIC EVENT AFTER A 5 YEARS FOLLOW-UP

F. Ceccarelli[1], L. Massaro[1], F. Morello[1], C. Perricone[1], A. Palermo[1], F.R. Spinelli[1], C. Alessandri[1], A. Chistolini[2], G. Valesini[1], F. Conti[1]. *[1]Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche; [2]Dipartimento di Biotecnologie Cellulari ed Ematologia, Sapienza Università di Roma, Rome, Italy*

**Background:** Antiphospholipid syndrome (APS) is defined by the presence of thrombosis and/or pregnancy morbidity in combination with the persistent positivity of antiphospholipid antibodies (aPL): lupus anticoagulant (LA), anticardiolipin (aCL) and anti b2glycoprotein I antibodies (anti-b2GPI). These autoantibodies could be detected in other pathological conditions, such as autoimmune diseases (i.e. Systemic Lupus Erythematosus - SLE -), infectious diseases or cancer. Moreover, aPL could be identified in asymptomatic subjects (aPL carriers). Concerning this group, several questions are still unsolved, such as the risk of developing thrombotic events and the need of a prophylactic treatment. To date, the aPL carriers who are considered at higher risk of thrombosis are those with LA positivity, with triple positivity (LA+aCL+anti-$\beta$2GPI) and those with persistently positive aCL at high/medium titer. Data from the literature reported a risk ranging from 0 to 3.8% after a mean follow-up period of 2.3–8.7 years. It should be considered that 70% of the evaluated aPL carriers showed a concomitant autoimmune disease, which represents a risk factor for thrombotic events.
**Objectives:** In this prospective study, we evaluated a cohort of aPL positive healthy subjects, in order to define the risk of developing thrombotic events, in comparison with a group of primary APS (PAPS) patients.
**Methods:** In this longitudinal study, we consecutively enrolled 29 aPL carriers (M/F 3/26; mean age±SD 45.0±10.9 years) and 21 PAPS (M/F 5/16; mean age±SD 41.8±12.1 years). According with the study protocol, all patients underwent clinical assessment (collection of anamnestic data and traditional risk factors for cardiovascular disease) and laboratory evaluation (aCL, anti-$\beta$2GPI, LA, antinuclear antibody – ANA –, C3 and C4 serum levels; thrombophilic screening). Data concerning the familial cardiovascular history were collected. All subjects were evaluated every 6 months.
**Results:** The comparison between aPL carriers and PAPS patients demonstrated as LA was significantly more frequent in aPL carriers (P=0.0001) while a similar percentage of triple positive patients was identified. Seventeen (58.6%) aPL carriers were treated with low dose aspirin (LDA), 2 (6.9%) with hydroxychloroquine. After a mean follow-up of 67.0 months (range 12–228), we identified an absolute risk to develop a thrombotic event of 0.03 (95% CI 0.001–0.238) and a relative risk of 0.7 (95% CI 0.02–6.44). In particular, a 55 years old female, treated with LDA, developed a thrombotic event after 84 months of follow-up, consisting in a minor stroke. The patient, without other risk factors, tested positive for LA and aCL at high/medium titer.
**Conclusions:** To the best of our knowledge, this is the first study specifically designed to evaluate only aPL positive healthy subjects. The longitudinal evaluation identified, after a mean follow-up higher than 5 years, an absolute risk for thrombotic events of 0.03, with a relative risk of 0.7. As suggested by the case described, the presence of multiple aPL positivity, with high/medium titer antibodies, requires particular attention.
**Disclosure of Interest:** None declared

## AB0448 REAL TIME SONOELASTOGRAPHY IN PRIMARY SJÖGREN'S SYNDROME CORRELATES WITH MORPHOLOGICAL ULTRASONOGRAPHIC FEATURES AND GLANDULAR ACTIVITY BUT NOT WITH MINOR SALIVAR GLAND FIBROSIS

G. Hernandez-Molina[1], S. Criales[2], L. Azpeitia[2], C. Pacheco[3], E. Reyes[4], G. Lima[1], L. Llorente[1], E. Kimura-Hayama[2]. *[1]Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran; [2]Radiology, Instituto Nacional de Cardiologia; [3]Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran; [4]Pathology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico*

**Background:** Real time sonoelastography (RTS) is a novel imaging option involving tissue stiffness assessment that might be a useful in primary Sjögren's syndrome (PSS).
**Objectives:** To evaluate the stiffness of parotid and submandibular glands using RTS, and to correlate with a morphologic ultrasonographic (US) score, profibrotic chemokines and cytokines, and gland fibrosis among patients with PSS.
**Methods:** We included 26 PSS patients with salivary gland biopsy within 5

years previous the US evaluation. B-Mode US and RTS (ARFI technique) were performed by a trained radiologist. Parotid and submandibular glands were individually rated for parenchymal echogenicity, homogeneity, hypoechogenic areas, hyperechogenic reflections and clearness of borders using the Hocevar scale (Global B-mode sum score 0–48 points). RTS was conducted at both parotid and submandibular glands (8 areas of each gland to obtain a median value) and then reported a median global RTS score in m/seg. We assessed the ESSDAI, ESSPRI, non-stimulated whole salivary flow rate (NSWSF), C3 and C4 levels, RF, anti-Ro/La antibodies and salivary levels of CXCL14, CCL28, TRAIL and TGb measured by ELISA. We also evaluated the presence of fibrosis in biopsies with the Masson's trichrome staining.

**Results:** The mean age was 51.1±11 years, median disease duration of 6.1 years, 92.8% were females and 92.8% had oral symptoms. The global B-mode score was 22.2 points (13–44) and the RTS global score 2.5 (1.64–3.28) m/seg. We found a correlation between the RTS global score and the global B-mode score (t=0.53, p=0.001), the RTS global score between both parotids (t=0.58, p=0.0001) and both submandibulars (t=0.50, p=0.0001); but not between parotids and submandibular glands. The RTS global score correlated with the NSWSF (t=-0.53, p=0.001), ESSDAI (t=0.31, p=0.03), glandular ESDDAI domain (t=0.36, p=0.02), C4 levels (t=-0.32, p=0.04), but not with the rest of serological variables, chemokines and cytokines levels.

We found fibrosis in 7 patients (26.9%), and these patients were not different when compared to the group without it, regarding the RTS global score, B-mode global score, age and chemokine and cytokines levels, but tended to have a longer disease duration. At the linear regression analysis, the glandular ESSDAI domain (B=0.49, p=0.04), the C4 level (B=-0.02, p=0.05) and the disease duration (B=0.04, p=0.04) were associated with the RTS global score.

**Conclusions:** The elastrographic evaluation correlated with the US morphologic score and glandular activity but not with fibrosis.

## AB0449 COUPLING ANTI-SM ANTIBODY DETECTION AND ANTI-CHROMATIN ANTIBODY DETECTION IMPROVES THE DIAGNOSIS AND PROGNOSIS OF SYSTEMIC LUPUS ERYTHEMATOSUS

G. Carvajal Alegria[1], C. Capaldo[2], A.-M. Roguedas-Contios[3], C. Hanrotel-Saliou[4], M. Pluchon[5], E. Pasquier[6], S. Jousse-Joulin[1], Y. Renaudineau[2]. *[1]Rheumatology, CHRU Cavale Blanche; [2]Immunology; [3]Dermatology, CHRU Morvan; [4]Nephrology, CHRU Cavale Blanche; [5]Obstetric and gynecology, Polyclinique Keraudren; [6]Internal medicine, CHRU Cavale Blanche, Brest, France*

**Background:** Autoantibody (Ab) detection including anti-nuclear Ab (ANA) plus anti-dsDNA/Chromatin Ab and/or anti-Sm Ab is central in the diagnosis and prognosis of systemic lupus erythematosus (SLE) and several methods can be used to detect them.

**Objectives:** Our objective was to compare diagnostic accuracy for several anti-dsDNA Ab, anti-chromatin Ab and anti-Sm Ab detection.

**Methods:** Accordingly, we compared different methods for anti-dsDNA Ab [indirect immunofluorescence using *Crithidia Luciliae* (CLIFT), anti-dsDNA by ELISA, anti-dsDNA by chemiluminescence (CLIA; IDS-ISYS, IDS) and anti-chromatin Ab (dsDNA-NCX, Euroimmun)] and anti-Sm Ab by ELISA (Immuno concept) and by CLIA (IDS-ISYS, IDS)]. The evaluation was performed in 49 SLE and 98 autoimmune disease controls including rheumatoid arthritis, scleroderma, vasculitis and Sjögren's syndrome.

**Results:** In SLE patients, Ab sensitivity (and specificity) was 97.9% for AAN, 61.2% (92.9%) for anti-chromatin Ab, 36.7% (93 9%) for anti-dsDNA Ab by CLIA, 32.6% (95.9%) for anti-dsDNA Ab by ELISA, and 30.6% (100%) by CLIFT. For anti-Sm Ab, CLIA improved its detection (sensibility 18.4% versus 8.2% by ELISA; specificity 100% both). The best associations were found for anti-chromatin Ab and CLIFT (sensitivity 67.3% and specificity 91.8%), and for anti-chromatin and anti-Sm Abs by CLIA (sensitivity 53.1% and specificity 95.2%). Several associations were identified, including, for anti-chromatin Ab, articular [Odds ratio (OR)=28,41; p=0,002] and cardio vascular disease [OR=9,47; p=0,032], plus leucopenia [OR=13,72; p=0,049]; and for anti-Sm Ab by CLIA lupus glomerulonephritis [OR =5.0, p=0.05], and pleuropulmonary manifestations [OR =25.3; p=0.004].

**Conclusions:** Combining anti-chromatin Ab detection by ELISA and anti-Sm Ab detection by CLIA contribute to improve the diagnosis and the prognosis of SLE.

**Disclosure of Interest:** None declared

## AB0450 SYSTEMIC LUPUS ERYTHEMATOSUS: A FRENCH EXPERIENCE FOR 6 YEARS OF MULTIDISCIPLINARY CONSULTATION IN BREST

G. Carvajal Alegria[1], C. Capaldo[2], A.-M. Roguedas-Contios[3], C. Hanrotel[4], M. Pluchon[5], E. Pasquier[6], Y. Renaudineau[2], S. Jousse-Joulin[1]. *[1]Rheumatology, CHRU Cavale Blanche; [2]Immunology; [3]Dermatology, CHRU Morvan; [4]Nephrology, CHRU Cavale Blanche; [5]Obstetric and gynecology, Polyclinique Keraudren; [6]Internal Medicine, CHRU Cavale Blanche, Brest, France*

**Background:** Systemic lupus erythematosus (SLE) is a complex disease and its diagnosis and treatment can require multiple capabilities easily available for the patients.

**Objectives:** Our objective was to set up a multidisciplinary consultation enabling patient support in occidental Brittany.

**Methods:** Given the complexity for the management of patients with systemic lupus erythematosus (SLE), a multidisciplinary consultation was set up to ensure optimal care for SLE patients at Brest University Medical School. This consultation was set on a quarterly base and gather rheumatologists, dermatologists, nephrologists, gynecologists and internal medicine physicians. A close collaboration with the immunology laboratory for biological diagnosis and follow-up was also set up. Clinical and biological data were collected.

**Results:** Of the 49 SLE patients followed since 2009, 45 were women (91.8%). The mean age was 47.1±17.7 years. Eighteen patients had malar rash (37.5%), 21 (43.8%) photosensitivity, 7 (14.6%) oral ulcers, 6 (12.5%) alopecia, 43 (89.6%) diffuse articular pain or arthralgia, 10 (20.8%) tenosynovitis, 15 (31.25%) lupus glomerulonephritis, 7 (14.3%) pericarditis, 2 (4%) cardiac vegetations, and 3 (6.1%) pleurisy. The mean SLEDAI score was 2.7±3.5, with values ranging from 0 to 17. Twenty patients were referred for diagnostic opinions (40.8%), 31 (63.3%) for therapeutic advice, 3 (6%) for pregnancy monitoring, and 16 (32.6%) for comorbidities management. The main comorbidities were cardiovascular risk factors and osteoporosis.

**Conclusions:** In conclusion, the multidisciplinary consultation helps to provide diagnostic and therapeutic aid due to the presence of experts from several disciplines. Patient enrollment for several services enables the creation of a valuable database whose analysis is ongoing.

## AB0451 CLINICAL AND SEROLOGICAL FEATURES OF SJÖGREN'S SYNDROME ASSOCIATED WITH SSB/LA

G.G. Bartel[1], M.M. Mayer[1], S.D. Velez[1], F. Zazzetti[1], G. Andrea[1], N.I. Daciuk[2], H. Laborde[1], J.C. Barreira[1]. *[1]Rheumatology Section; [2]Buenos Aires British Hospital, Buenos Aires, Argentina*

**Background:** Sjögren's syndrome (SS) is an autoimmune disease associated with focal lymphocytic infiltration in the epithelium of exocrine glands, and may develop systemic manifestations in about 80% of the patients. Typical antibodies present in SS are antinuclear antibody (ANA), rheumatoid factor, SSA/Ro and SSB/La. SS classification criteria includes SSA/Ro and SSB/La, and their presence is associated with extra-glandular manifestations. The prevalence of SSA/Ro in SS is 30–70%, and is related to increased frequency of dermatologic symptoms, scleritis and interstitial lung disease. The relationship between SSB/La and clinical manifestations has not been previously well established, though it can be found in 5–50% of SS, and may co-exist with SSA/Ro half of the times. SSB/La is found isolated in a very low percentages of SS.

**Objectives:** To evaluate the correlation between the presence of SSB/La antibody with distinct clinical, demographic and serological characteristics of SS.

**Methods:** Adult patients evaluated in the Rheumatology Section (Buenos Aires British Hospital) who fulfilled American European Consensus Group (AECG) SS criteria were included. Three groups were compared according to the antibodies present: 1. Positive SSA/Ro and negative SSB/La 2. Both positive 3. Negative SSA/Ro and positive SSB/La. Mann-Whitney and Fisher tests were used according to variables; those with $p<0.05$ were introduced in a multivariable analysis by logistic regression.

**Results:** Among 195 patients with SS, 93.8% (n=183) were female. Mean age was 54.7 years and the mean total disease duration was 68.5 months. We excluded from analysis 16/8.2% patients due to missing data, and 29/14.9% patients that were negative for both antibodies. Two groups were finally compared (Group 3

| Features | Group 1 n=67 (%) | Group 2 n=80 (%) | p |
|---|---|---|---|
| Sialoadenitis | 9 (13.4) | 30 (37.5) | **0.0019** |
| Palpable purpura | 1 (1.5) | 13 (16,3) | **0.0058** |
| Neuropathy | 8 (11.9) | 10 (12.5) | 0.56 |
| Interstitial lung disease | 4 (6) | 5 (6.3) | 0.6 |
| Raynaud phenomenon | 12 (17.9) | 12 (15) | 0.63 |
| Arthritis | 27 (40) | 35 (43) | 0.79 |
| Hypocomplementemia | 9 (13.4) | 39 (48.8) | **0.00001** |
| Hypergammaglobulinemia | 22 (32.8) | 55 (68.8) | **0.00003** |
| Rheumatoid factor | 28 (41,8) | 55 (68,8) | **0.0018** |
| ANA | 61 (90) | 80 (100) | 0.05 |
| Leucopenia | 7 (10.4) | 18 (22.5) | 0.08 |
| Cryoglobulinemia | 2(3) | 4 (5) | 0.42 |

**Group 1: Positive SSA/Ro and negative SSB/La; Group 2: Both positive**

excluded due to low prevalence, n=3/1.5%): 80/41% patients with positive SSA/Ro and negative SSB/La; and 67/34.3% positive SSA/Ro and SSB/La. In the univariate analysis, positive SSA/Ro and SSB/La was statistically found to be associated with recurrent sialoadenitis and palpable purpura. Serological findings associated with this group included positive rheumatoid factor, hypocomplementemia and hypergammaglobulinemia. Poor prognosis features such as palpable purpura (OR 9.5 IC 95% 1.1–79 p 0.037), recurrent sialoadenitis (OR 3.1 IC 95% 1.2–7.7 p 0.011), hypocomplementemia (OR 3.6 IC 95% 1.4–9.4 P 0.0075) and hypergammaglobulinemia (OR 2.7 IC 95% 1.2–6.1 p 0.01) were also statistically significant in the multivariate analysis. Cryoglobulinemia and leucopenia were not found to be associated in both of the analysis.
**Conclusions:** In our population, the presence of SSB/La in patients with positive SSA/Ro was related to recurrent sialoadenitis, palpable purpura, hypocomplementemia, hypergammaglobulinemia and reumathoid factor. Although previous studies are contradictory, our study might justify the systematic search of this antibody due to its clinical relevance and link to poor prognosis factors in SS.
**Disclosure of Interest:** None declared

## AB0452 ANALYSIS OF CLINICAL MANIFESTATIONS, COURSE OPTIONS, OUTCOME OF SLE ACCORDING TO THE PROSPECTIVE STUDY AMONG RESIDENTS OF KYRGYZSTAN

G. Koilubaeva[1], E. Aseeva[2], S. Soloviev[2], E. Nasonov[2], T. Reshetnyak[2], A. Djumagulova[1], V. Eralieva[1], E. Karimova[1]. *[1]Rheumatology, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Bishkek, Kyrgyztan; [2]Rheumatology, Federal State Research Institution (FSRI) named after V. A. Nasonova, Moscow, Russian Federation*

**Background:** Systemic lupus erythematosus (SLE) is a devastating disease affecting different organs, ultimately leading to organ failure and death. To date, there are no data regarding the real-life picture of SLE in Kyrgyzstan.
**Objectives:** To study of clinical symptoms, course and outcome of SLE according to the prospective study among residents of Kyrgyzstan.
**Methods:** An 2-year prospective analysis of patients with SLE with a specially developed research base (BLIPS 8, ADS-Limathon). 60 patients with definite diagnosis of SLE (ACR, 1997; SLICC, 2012), were treated in the department of rheumatology of NCCIM and observed from 2012 to 2015. They were evaluated by sex, age, disease duration, activity of SLE according the SLEDAI-2K, irreversible organ damage by SLICC Damage Index (SDI), quality of life using the SF-36 questionnaire, LupusQoL, HADS, FACIT, therapy, with monitoring of all parameters every six months for 2 years. From the data of the immunological studies immune linear (immunoblot) “ANA-LIA-Max 17” were analyzed with a purpose of detecting the antibodies of double-stranded DNA, Sm D1 antigen and antibodies of double-stranded DNA-linked immunosorbent analyisis (ELISA), C3-C4 components complement, indirect immunofluorescence of the antinuclear antibody cells of line Hep-2.
**Results:** Patients were mainly from the northern region of the republic (81.7%). The vast majority were women (86.7%), with average age 30 years old, with disease duration of about 1.0 years. Periods to verify the diagnosis ranged from 1 month to 9 years. The clinical course was dominated by patients with acute version (47%) and high activity (57%). In the debut of the disease most common clinical symptoms were cutaneous and articular syndrome (84.2% and 72.3%, respectively), the defeat of the serous membranes (88%) and kidney (68%). All patients received glucocorticoids (GC), 79% of them in the form of pulse therapy with methylprednisolone. From immunosuppressive drugs most commonly were used CP (48%), AZA (21%), MTX (10.4%) and plaquenil (11%), to a lesser extent MMF (8%). The proportion of patients receiving biologic therapy (rituximab) was only 2%, IVIG (Octagam) - 3.3%.The development of irreversible organ damage was recorded in half the patients (46%), at average of 6 months from the onset of the disease, mostly with low (36.7%) and the average SDI (21.7%). During the period of 2-year prospective study not only a significant reduction in the activity of the pathological process in many patients ($p<0,001$) is noted, but also the lack of clinical activity in 18% of patients. In 35% of cases minimal disease activity represented immunological activity. At 2-year follow-up there were 14 fatal cases (19.4%). They were mostly women (72%) with average age 37.9 years, with disease duration around 4 years. The main causes of death were active SLE and its complications: kidney disease (29%), central nervous system (CNS)-21.4% and combined CNS and lung (21.4%).
**Conclusions:** In the debut of the SLE acute onset and high disease activity, which led to the rapid development of organ damage in half the patients was recorded. In the structure of mortality among Kyrgyz cohort of SLE patients with renal involvement prevailed, CNS and CNS combined with lungs.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1619

## AB0453 THE QUALITY OF LIFE OF THE KYRGYZ COHORT OF PATIENTS WITH SLE ACCORDING TO THE PROSPECTIVE STUDY

G. Koilubaeva[1], E. Aseeva[2], S. Soloviev[2], E. Nasonov[2], T. Reshetnyak[2], A. Djumagulova[1], V. Eralieva[1], E. Karimova[1]. *[1]Rheumatology, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Bishkek, Kyrgyztan; [2]Rheumatology, Federal State Research Institution (FSRI) named after V. A. Nasonova, Moscow, Russian Federation*

**Background:** Systemic lupus erythematosus (SLE) is a devastating disease affecting different organs, ultimately leading to organ failure and death. To date, there are no data regarding the real-life picture of SLE in Kyrgyzstan.
**Objectives:** The goal of the study is evaluation of the quality of life among Kyrgyz cohort of patients with SLE according to the prospective study.
**Methods:** 60 patients with definite diagnosis of SLE (ACR, 1997; SLICC, 2012) were treated in the department of rheumatology of NCCIM and observed from 2012 to 2015. They were evaluated by sex, age, disease duration, activity of SLE according the SLEDAI-2K, irreversible organ damage by SLICC Damage Index (SDI), quality of life using the SF-36 questionnaire, LupusQoL, HADS, FACIT, therapy, with monitoring of all parameters every six months for 2 years. From the data of the immunological studies immune linear (immunoblot) “ANA-LIA-Max 17” were analyzed with a purpose of detecting the antibodies of double-stranded DNA, Sm D1 antigen and antibodies of double-stranded DNA-linked immunosorbent analyisis (ELISA), C3-C4 components complement, indirect immunofluorescence of the antinuclear antibody cells of line Hep-2.
**Results:** Patients were mainly from the northern region of the republic (81.7%). The vast majority were women (86.7%), with average age 30 years old, with disease duration of about 1.0 years. Dates of illness onset to verify the diagnosis ranged from 1 month to 9 years. The clinical course dominated patients with acute one (47%) and high activity (57%). The clinical symptoms of were cutaneous and articular syndrome (84.2% and 72.3%, respectively), the defeat of the serous membranes (88%) and kidney (68%). Before the treatment, according to the overall SF-36 questionnaire all SLE patients had lower QOL revealed. Marked limitation of life activity of patients was due to the presence of physical and emotional problems with severe anxiety and depression affects on their social functioning. After 2 years significant improvement in quality of life on many scales, except for the scale of mental health is noted. Attention is drawn to the deterioration of quality of life on the scale of “viability”, which characterizes the patient a sense of lack of strength and energy for the period of the disease. The lowest quality of life is reported among Kyrgyz patients in the comparative analysis to QOL of patients with SLE in other 3 countries of Europe (UK, France and Italy) and Russia. Despite the reduction of disease activity ($p<0,001$) among Kyrgyz cohort of patients the baseline QOL of Russian SLE patients for a period of two years of careful clinical supervision was not achieved.
**Conclusions:** The low quality of life among Kyrgyz cohort of patients with SLE is associated with poor physical, emotional and social functioning. Despite the reduction of disease activity during the treatment, quality of life on the scale of “viability, lack of improvement of mental health component is identified as declining”.

## AB0454 THE OUTCOME OF SLE RESIDENTS OF KYRGYZSTAN ACCORDING TO THE PROSPECTIVE STUDY

G. Koilubaeva[1], E. Aseeva[2], S. Soloviev[2], E. Nasonov[2], T. Reshetnyak[2], A. Djumagulova[1], V. Eralieva[1], E. Karimova[1]. *[1]Rheumatology, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Bishkek, Kyrgyztan; [2]Rheumatology, Federal State Research Institution (FSRI) named after V. A. Nasonova, Moscow, Russian Federation*

**Background:** Systemic lupus erythematosus (SLE) is a devastating disease affecting different organs, ultimately leading to organ failure and death. To date, there are no data regarding the real-life picture of SLE in Kyrgyzstan.
**Objectives:** To study the outcomes of SLE according prospective study among residents of Kyrgyzstan.
**Methods:** An 2-year prospective analysis of patients with SLE with a specially developed research base (BLIPS 8, ADS-Limathon).60 patients with definite diagnosis of SLE (ACR, 1997; SLICC, 2012), were treated in the department of rheumatology of NCCIM and observed from 2012 to 2015. They were evaluated by sex, age, disease duration, activity of SLE according the SLEDAI-2K, irreversible organ damage by SDI, therapy, with monitoring of all parameters every six months for 2 years. From the data of the immunological studies immune linear (immunoblot) “ANA-LIA-Max 17” were analyzed with a purpose of detecting the antibodies of double-stranded DNA, Sm D1 antigen and antibodies of double-stranded DNA-linked immunosorbent analyisis (ELISA), C3-C4 components complement, indirect immunofluorescence of the antinuclear antibody cells of line Hep-2.
**Results:** The vast majority were women (86.7%), with average age 30 years old, with disease duration of about 1.0 years. Periods to verify the diagnosis ranged from 1 month to 9 years. The clinical course was dominated by patients with acute version (47%) and high activity (57%). In the debut of the disease most common clinical symptoms were cutaneous and articular syndrome (84.2% and 72.3%, respectively), the defeat of the serous membranes (88%) and kidney (68%). The

development of irreversible organ damage recorded in half the patients (46%), on average of 6 months from the onset of the disease, preferably with low (36.7%) and the average SDI (21.7%). Among the irreversible organ damage leading place is occupied by respiratory failure (53.5%) of them with pulmonary fibrosis (21.4%) and pulmonary hypertension (25%). Second place takes kidney disease (50%) with severe forms of nephritis (nephrotic syndrome and chronic renal failure). Irreversible changes in the central nervous system were observed in 21% of patients. Over the whole period there were 14 fatal cases (19.4%). They were mostly women (72%) with average age 37.9 years, with disease duration around 4 years. The main causes of death were active SLE and its complications: kidney disease (29%), central nervous system (CNS)-21.4% and combined CNS and lung (21.4%). During the two-year observation, despite the significant decrease in disease activity ($p<0,001$), the progression of SDI ($p<0,0001$), deterioration of whom are independent from both the activity and the variant of the disease ($r=0.18$, $p=0.2$; $r=0.03$, $p=0.8$ respectively) is noted. However, the degree of organ damage depended on the duration of illness ($r=0.27$, $p<0,03$) and the age of patients ($r=0.29$, $p=0.02$).

**Conclusions:** Irreversible organ damage of the respiratory organs (pulmonary fibrosis, pulmonary hypertension), renal, and CNS were the main predictors of adverse outcome of SLE among the residents of Kyrgyzstan.

**Disclosure of Interest:** None declared

## AB0455 DYSLIPIDEMIA AND ATHEROGENIC RISK IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

H.A. Radillo[1], J.A. Batún[1], E. Hernández[2]. *[1]Internal Medicine; [2]Hospital de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez, Villahermosa, Mexico*

**Background:** Dyslipidemia is a common comorbidity in patients with systemic lupus erythematosus, it is favored by central obesity, nephrotic syndrome, glucocorticoids and immunosuppressants.

**Methods:** 51 patients, who were determined the lipid profile were included. Variables associated with the disease and the drugs used were recorded. Atherogenic risk was calculated. Chi square was used for categorical variables. ANOVA was performed to determine the relationship between mean lipid profile and a logistic regression model to determine the association of the variables with the presence of dyslipidemia.

**Results:** 68.6% had dyslipidemia. Significant difference between the presence of dyslipidemia and Activity index measured by SLEDAI ($p=0.021$) was found, the presence of lupus nephritis ($P=0.021$), use of prednisone $\geq$20 mg/day ($p=0.0009$), evolution disease $<$3 years ($P=0.027$). Significance between the absence of dyslipidemia and use of hydroxychloroquine ($P=0.021$) was found. Activity index $\geq$4 (RR 6.34; $p=0.038$) and the use of prednisone $>$20 mg/day (RR 6.67; $p=0.036$) were independently associated with the presence of dyslipidemia. The average of Castelli rate was 5.02±1.8, the Kannel index was 2.97±1.4 and triglyceride/HDL-C ratio was 5.24 ±3.3.

**Conclusions:** Patients with systemic lupus erythematosus have a high prevalence of dyslipidemia and a high atherogenic rate, which increases cardiovascular risk significantly.

## AB0456 COMPARATIVE STUDY OF RISK FACTORS FOR VENOUS AND ARTERIAL THROMBOSIS IN CARRIERS OF ANTIPHOSPHOLIPID ANTIBODIES

I. Les, C.J. Vidal, P. Anaut, C. Sánchez, A. Andía. *Department of Internal Medicine, Hospital Universitario Araba, Vitoria-Gasteiz, Spain, Vitoria-Gasteiz, Spain*

**Background:** Previous studies on factors predicting thrombosis in antiphospholipid syndrome (APS) show that vascular risk factors impact mainly on arterial thrombosis, while antiphospholipid antibodies (aPL) exert more influence on pure vein thrombosis or mixed thrombosis (venous and arterial).

**Objectives:** To investigate and compare factors associated with occurrence of venous and arterial thrombosis in carriers of aPL.

**Methods:** Prospective observational study of a cohort of patients with medium-high titers of aPL according to current recommendations on APS, enrolled in the outpatient clinic of a tertiary care hospital. Association between venous or arterial thrombosis and several factors such as age, sex, arterial hypertension, hypercholesterolemia, diabetes mellitus, smoking, obesity, oral contraceptives, platelet count, mean platelet volume (MPV), lupus anticoagulant (LA), IgG/IgM anticardiolipin antibodies (aCL), IgG/IgM anti-β2-glycoprotein I and partial aPL-score was assessed by univariate analysis (Pearson's $X^2$ and Fischer exact tests if qualitative variables, *T*-student and *U* Mann Withney tests if quantitative variables), following by a logistic regression.

**Results:** Seventy-one patients (50 females, baseline age 51±17 years), of which 40 fulfilled definite classification criteria for APS (29 primary APS, 11 secondary APS), were followed for 4.2±4 years. Thirty-two patients developed 46 thromboses (24 in venous bed, 22 in arterial bed), of which 14 were recurrences. In univariate analysis, patients with venous thrombosis showed a higher prevalence of diabetes mellitus (3/5 vs 15/66, $p=0.06$) and LA (14/40 vs 4/31, $p=0.05$) and a lower platelet count (134.8±71.0 vs 168.1±73.3x$10^3$/$mm^3$, $p=0.09$), whereas patients with arterial thrombosis were more frequently men (8/20 vs 9/51, $p=0.04$) of advanced age (59±14 vs 50±15 years, $p=0.04$), and had a higher prevalence of diabetes mellitus (3/5 vs 14/66, $p=0.08$) and higher levels of IgG aCL (72.7±122.2 vs 34.8±58.2 GPL, $p=0.08$) and MPV (10.8±2.0 vs 9.8±1.3 fL, $p=0.02$). The logistic regression identified male sex, age, diabetes mellitus and IgG aCL as predictors of arterial thrombosis, while positivity to LA as the only predictor of venous thrombosis (Table 1).

Table 1. Odds ratio (95% CI) of independent factors associated with venous and arterial thrombosis ($p\leq0.05$)

| | Male sex | Age | Diabetes | LA positive | IgG aCL |
|---|---|---|---|---|---|
| Venous thrombosis | | | | 4.46 (1.12–17.73) | |
| Arterial thrombosis | 5.25 (1.36–20.27) | 1.05 (1.001–1.098) | 7.54 (1.00–59.05) | | 1.008 (1.001–10.160) |

**Conclusions:** In carriers of aPL, vascular risk factors such as male sex, age and diabetes predispose to arterial thrombosis together with IgG aCL, while the presence of LA is more specific of patients who experience venous thrombosis.

## AB0457 HOW MUCH DIFFERENT IS JUVENILE ONSET SYSTEMIC LUPUS ERHYTEMATOSUS? DATA FROM A ROMANIAN COHORT

I. Saulescu, T. Gudu, D. Opris, L. Groseanu, A. Borangiu, S. Daia-Iliescu, C. Constantinescu, R. Ionescu. *Internal Medicine and Rheumatology, Umf Carol Davila, Sf. Maria Hospital, Bucharest, Bucharest, Romania*

**Background:** Systemic Lupus Erhytematosus (SLE) is a multiorgan disease in which pattern of evolution is linked to activity and damage. When the disease starts at an early age, all the outcomes might be influenced by this.

**Objectives:** The main focus of this study is to describe the differences between juvenile and adult onset SLE in a Romanian cohort.

**Methods:** 101 SLE patients were evaluated between March 2015 and December 2015. Patients were diagnosed with SLE according to ACR classification criteria and splited in 2 groups, taking into account age at disease onset: before and after 18. All patients agree to participate in this study. Data about demographic, clinical or serological characteristics, activity (SLEDAI) or damage (SLICC damage index SDI), treatment were collected. Statistical analisys was performed with SPSS 20.0.

**Results:** Our cohort was made from 18 patients with juvenile onset SLE and 83

with adult onset SLE. Mean age at diagnosis was 14.05 versus 37.89. The juvenile onset SLE group had significant more autoimmune disease as family background, mainly SLE and rheumatoid arthritis (33.3% versus 12.04%, p 0.025), significant more severe organ involvement during the disease evolution: SLE related neurologic involvement 33.3% versus 12% (p 0.025) and renal involvement 50% versus 16.8% (p 0.023), more frequent anti dsDNA Ab positives 88.8% versus 60.24% (p 0.021). This more severe pattern of evolution is also reflected by immunosuppressant therapy, Cyclophosphamide being used in juvenile subgroup in 66% cases versus 35.3% in adults (p 0.014). Interesting, there were no differences between cumulative damage between groups, as measured by SDI (p 0.24), with the mention that in juvenile onset patients, SDI>1 was more frequent SLE related. This is in line with the fact that side effects of the corthicotherapie were identified more in adult onset SLE 61.44% versus 33.3% in juvenile onset (p 0.029).

**Conclusions:** Our data clearly show that juvenile onset SLE has more genetic background and it is more prone to a severe disease, renal and neurologic involvement being more frequent than in adult onset form. Severity seems to be related both to the activity, but also to fast damage accrual over time. Controlling the disease activity must be our goal, since cumulative irreversible damage is mainly SLE related for our patients.

## AB0458 SERUM FERRITIN AS A BIOMARKER OF CLINICAL AND HISTOPATHOLOGICAL RESPONSE TO TREATMENT IN LUPUS NEPHRITIS

I. Parodis[1], H. Ding[2], A. Zickert[1], L. Arnaud[1], C. Mohan[2], I. Gunnarsson[1].
*[1]Department of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [2]Department of Bioengineering, University of Houston, Houston, United States*

**Background:** Lupus nephritis (LN) is a major organ manifestation of Systemic Lupus Erythematosus (SLE). Renal biopsy is the current gold standard for assessment of renal pathology in LN, as non-invasive reliable markers are lacking. Ferritin is found in most tissues as a cytosolic protein that stores iron. Small amounts are secreted into the serum, where ferritin functions as an iron carrier. Ferritin is considered an acute phase protein, as it increases in response to stresses. Studies have reported elevated serum concentrations in patients with active compared to patients with inactive SLE, and also associations with LN.

**Objectives:** We assessed serum ferritin levels in patients with LN, in order to clarify its role in this SLE subset.

**Methods:** Serum levels of ferritin were determined by ELISA (Raybiotech Inc.) in 64 patients with biopsy-proven active LN (52 proliferative LN, PLN; 12 membranous LN, MLN), before and after completion of induction treatment. Post-treatment renal biopsies were performed after a median time of 7.7 months. Clinical responders (CR) were defined by $\geq$50% reduced proteinuria, normal or $\geq$25% improved estimated glomerular filtration rate, and inactive urinary sediment. Histopathological responders (HR) were defined by $\geq$50% improvement of renal Activity Index in post-treatment biopsies.

**Results:** Serum levels of ferritin decreased following induction therapy for LN in the entire cohort ($p<0.001$) and in patients with PLN ($p<0.001$), but not in patients with MLN (p=0.35). In the entire cohort, ferritin levels decreased in both CR ($p<0.001$) and clinical non-responders (CNR; p=0.030). They also decreased in HR ($p<0.001$), but remained stable in histopathological non-responders (HNR; p=0.06). In PLN, ferritin levels decreased in CR ($p<0.001$) and in CNR (p=0.003), as well as in HR ($p<0.001$) and HNR (p=0.011). In MLN, ferritin levels decreased in CR (p=0.03) and HR (p=0.046), but neither in CNR (p=0.69) nor in HNR (p=0.89). In patients with MLN, both baseline and post-treatment ferritin levels were higher in CNR (baseline median: 172.9 ng/mL, range: 15.9–486.3; post-treatment median: 309.7 ng/mL, range: 8.4–714.8) than in CR (baseline median: 59.8 ng/mL, range: 24.4–200.9; post-treatment median: 32.3 ng/mL, range: 4.9–43.2; p=0.03 and p=0.005, respectively); however, they did not differ between HR and HNR (p=0.79 and p=0.43, respectively).

**Conclusions:** Our data suggest ferritin as a marker of histopathological response to induction treatment in patients with LN. In patients with MLN in particular, high baseline ferritin levels predicted unfavourable clinical response to induction treatment, and, despite being initially lower, baseline ferritin levels decreased in CR. This implies a role of ferritin in the pathogenesis of this LN subset and warrants further investigation.

## AB0459 TUBERCULOSIS AMONG SYSTEMIC LUPUS ERYTHEMATOSUS MEXICAN MESTIZO PATIENTS

I.J. Colunga-Pedraza[1], R.I. Arvizu[2], A. Martínez-Moreno[3], D.O. Treviño-Montes[1], D.A. Galarza-Delgado[2], M.A. Garza-Elizondo[1].
*[1]Rheumatology; [2]Internal Medicine; [3]Cardiology, Hospital Universitario, UANL., Monterrey, Mexico*

**Background:** Tuberculosis (TB) represents a major global health problem. TB has a higher incidence among patients with autoimmune rheumatic diseases than in the general population. The incidence and severity of TB in patients with systemic lupus erythematosus (SLE) varies greatly among different series (2.5–13.8%).

**Objectives:** To investigate the frequency and characteristics of TB in Mexican mestizo patients with SLE.

**Methods:** We reviewed the charts of 123 patients with SLE in our lupus clinic. Patients who developed TB after the diagnosis of SLE were identified. Data of all SLE patients followed up in our clinic were retrospectively analyzed. Clinical and demographic characteristics and treatment before diagnosis of TB were recorded.

**Results:** A total of 123 SLE patients were analyzed, 89.43% (n=110) woman. Seven cases (5.69%) of TB infection developed after the diagnosis of SLE. Pulmonary TB was reported in 3 patients (2.44%). Extra-pulmonary TB infecction was reported in 3 (2.44%) patients (one case of tuberculous pleurisy, one case of meningeal TB, and 1 case of cutaneous TB). Also, we found 1 SLE patient (0.81%) with latent TB infection. All patients had good response to treatment. No one received biologic therapy at the time of the diagnosis of TB infection. We did not found any case of disseminated infection or mortality related to TB infection.

**Conclusions:** These results suggest that in a country with high TB burden, TB screening and treatment of latent TB would be useful since the diagnosis of SLE is made.

## AB0460 CAUSES OF EARLY AND LATE DEATH OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS OVER A 10-YEAR PERIOD

I. Padjen[1], M. Erceg[2], M. Cerovec[1], M. Mayer[1], R. Stevanović[2], B. Anić[1].
*[1]Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, University Hospital Centre Zagreb and University of Zagreb, School of Medicine; [2]Croatian Institute of Public Health, Zagreb, Croatia*

**Background:** Causes of death (CODs) of patients with systemic lupus erythematosus (SLE) comprise active SLE and comorbidities that develop as a result of SLE and immunosuppressive therapy: infections, cardiovascular disease and malignant tumors. Active disease and infections are typical causes of early death, while cardiovascular disease typically causes late death. However, COD frequencies depend on the source population and data ascertainment method.

**Objectives:** To identify and compare causes of early and late death of SLE patients deceased during a ten-year period.

**Methods:** We retrospectively identified SLE patients followed-up by our Department, deceased between 2002 and 2011, and included patients with $\geq$4 classification criteria of the American College of Rheumatology (ACR), $\geq$18 years of age and Croatian residency at the time of death. Death and causes of death were retrospectively identified using patient medical records, as well as death certificates and autopsy reports, when available. We also matched data on all SLE patients that visited our Department from 2002 to 2011 with the National Mortality Database. We classified CODs into five categories: active SLE, cardiovascular disease, infection, malignant tumor and other. More than one COD category was possible in a single patient. We compared the frequencies of each COD category between patients deceased within and after 5 years following diagnosis (early vs. late death). Frequencies were compared using the $\chi^2$ and Fisher's exact test, and continuous variables using the t-test and Mann-Whitney U test. The study was approved by the local ethics committee.

**Results:** We identified 90 deceased patients (68 females, 22 males; 21 in the

| Cause of death | Patients deceased (N=90) | % | Early death (N=21) | Late death (N=69) |
|---|---|---|---|---|
| Active disease (SLE) | 26 | 29 | 8 | 18 |
| Infection | 30 | 33 | 9 | 21 |
| a) Sepsis | 20 | 22 | 6 | 14 |
| b) Pneumonia | 18 | 20 | 5 | 13 |
| c) Urinary tract infection | 8 | 9 | 3 | 5 |
| Cardiovascular disease | 36 | 40 | 6 | 30 |
| a) Myocardial infarction + ischemic heart disease | 12 (7+5) | 13 | 1 | 11 |
| b) Myocardial infarction | 5 | 6 | 1 | 4 |
| c) Stroke | 8 | 9 | 0 | 8 |
| d) Pulmonary embolism | 3 | 3 | 1 | 2 |
| Malignant tumor | 15 | 17 | 1 | 14 |
| Other | 10 | 11 | 4 | 6 |
| Unknown | 8 | 9 | 1 | 7 |

early death group (EDG), 69 in the late death group (LDG)). EDG patients were older than LDG patients at diagnosis (mean age±SD: 56±15 vs. 46±17 years; p=0.005), but there was no difference between the age at death (mean age±SD: 58±15 years for all patients). Patients were followed-up for a median of 10 years (IQR: 5–15 years). LDG patients fulfilled a higher number of ACR criteria compared to EDG patients (median, IQR: 6, 5–7 vs. 5, 4–6; p=0.018). No difference between COD category frequencies was detected between EDG and LDG. Nevertheless, infections and active SLE were leading causes of early death (9/21 and 8/21, respectively), while cardiovascular disease was the most frequent cause of late death (30/69), followed by infection and active SLE (21/69 and 18/69, respectively)(Table). SLE was mentioned in the death-related medical records of only 41/90 patients.

**Conclusions:** Infections and active SLE are leading causes of early death, while cardiovascular disease is the most frequent cause of late death in SLE. Lack of recording of SLE in death-related medical records requires matching of clinical data with a complementary source, such as a population-based mortality database, to identify deceased SLE patients.

## AB0461 A RETROSPECTIVE STUDY OF PRIMARY SJOGREN'S SYNDROME PATIENTS WITH CANCER IN CHINESE POPULATION: A SINGLE-CENTER EXPERIENCE

J. Qi, Q. Li, Z. Hu, P. Zhang, Y. Jiang, Z. Chen, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** With the development of modern therapies, better care of patients with primary Sjogren's syndrome has been achieved. However, primary Sjogren's syndrome may share an association with risk of lymphoproliferative disease or other malignancy.

**Objectives:** To investigate the clinical features of primary Sjogren's syndrome (pSS) patients with malignancies.

**Methods:** We studied clinical features of the pSS patients coexist with malignancies in the Third Affiliated hospital of Sun Yat-sen University from 2002 to 2015. Thirteen out of 918 patients with pSS developed malignancies, both solid tumors and lymphomas. Student's t test was used to compare patients'age and age of onset.

**Results:** The ratio of pSS with malignancies was 1.4% (13/918) in these patients. 6 were lymphoma, including 5 diffuse large B-cell lymphoma (DLBCL) and one mucosa associated lymphoid tissue type (MALT) Lymphoma. 7 were solid tumors, including one Colon cancer, one Hepatocellular carcinoma, one cervical carcinoma, one ovarian cancer, and one breast cancer, one cervical lymph nodes of squamous cell carcinoma and one peritoneal metastasis of unknown origin. The onset age of pSS was 44.5±19years,and onset age of malignancies was 47±18.4years. it seems that the age of pSS patients with solid tumors (53.6±18.9 years) was older than the age of pSS patients with lymphoma (34±13.9 years),but there was no significant difference.

**Conclusions:** The most frequent cancer associated with pSS is Lymphomas. the age of pSS patients with solid tumors might be older than the age of pSS patients with lymphoma.

## AB0462 THE RISK OF CANCER IN SYSTEMIC LUPUS ERYTHEMATOSUS IN CHINESE POPULATION: A SINGLE-CENTER EXPERIENCE

J. Qi, P. Zhang, Z. Hu, Z. Chen, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** It was reported that incidence rate of malignant tumor in general population was 0.24% in China in 2010. Cyclophosphamide is widely used in the treatment of systemic lupus erythematosus. Long term use of CTX may lead to increase the risk of tumor. However, whether the Cyclophosphamide risk of cancer will increase is not clear.

**Objectives:** To investigate the risk of cancer in systemic lupus erythematosus patients.

**Methods:** We studied retrospectively systemic lupus erythematosus patients coexist with malignancies hospitalized in the Third Affiliated hospital of Sun Yat-sen University from 1999 to 2015. The study included 2530 systemic lupus erythematosus patients.

**Results:** The ratio of systemic lupus erythematosus with malignancies was 0.24% in these patients (6/2530). Compared to general population, no increase in tumor incidence was found in systemic lupus erythematosus. The onset age of SLE was 47±17.8years,and the age of the patients with cancer were 50.7±14.9years.There were 6 solid tumor in our study, including three thyroid carcinoma, one nasopharyngeal carcinoma, one nerve glioma, and one meningioma.

**Conclusions:** The incidence of tumor in SLE patients was similar to the general populations.

## AB0463 CLINICAL CHARACTERISTICS OF ELDERLY PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

K. Nakanishi, M. Kinjo. *Rheymatology, Okinawa CHUbu Hospital, Uruma, Japan*

**Background:** Sjögren's syndrome is a common autoimmune disorder with the majority of cases occurring in midlife. Although the clinical presentation of primary Sjögren's syndrome (pSS) is known to differ by age, clinical characteristics of elderly patients with pSS have not been well described.

**Objectives:** To identify clinical characteristics of patients with pSS based on age group.

**Methods:** We retrospectively identified all patients with biopsy-proven lymphocytic sialadenitis and/or positive anti-SSA/Ro antibody who were treated at a tertiary medical center in Japan between 2005 and 2015. Data were collected on their clinical and laboratory features. Definite pSS was defined by the fulfilled American-European Consensus (AEC) criteria for pSS and probable pSS was determined by any 3 of the 6 AEC criteria without other collagen diseases. Clinical and laboratory characteristics of patients aged 60 years or older were compared with those of their younger counterparts.

**Results:** We identified 402 Japanese patients with biopsy-proven lymphocytic sialadenitis and/or positive anti-SSA/Ro antibody. 147 (37%) had pSS, 36 (9%) were undifferentiated, and 219 (54%) had at least one or more antinuclear antibody-associated collagen diseases. The median age of the pSS patients was 52 years (range 17–89); 41% (60 patients) were aged 60 years or older, and 91% were female (Table). Compared to the younger age group, the older patients were more likely to have dry mouth, primary biliary cirrhosis, lymphoma and thrombocytopenia. The younger patients had a greater likelihood of arthritis and a photosensitive rash ($p<0.05$).

| | Younger group | | Older group | | | Total |

## AB0464 THE RATE OF AND RISK FACTORS FOR FREQUENT HOSPITALIZATION IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM THE KOREAN LUPUS NETWORK REGISTRY

K.-E. Lee, J.-W. Lee, D.-J. Park, Y.-R. Yim, J.-E. Kim, L. Wen, S.-S. Lee.
*Rheumatology, Chonnam National University Medical School, Gwangju, Korea, Republic Of*

**Objectives:** The survival rate of patients with systemic lupus erythematosus (SLE) has improved in the last few decades, but the rate of hospitalization and health care costs for these patients remain higher than in the general population. Thus, we evaluated the rate of hospitalization and associated risk factors in an inception cohort of Korean patients with lupus.
**Methods:** Of the 507 patients with SLE enrolled in the KORean lupus NETwork (KORNET registry), we investigated an inception cohort consisting of 196 patients with SLE presenting within 6 months of diagnosis based on the ACR classification criteria. We evaluated the causes of hospitalization, demographic characteristics, and laboratory and clinical data at the time of SLE diagnosis of hospitalized patients and during a follow-up period. We calculated the hospitalization rate as the number of total hospitalizations divided by the disease duration, and defined "frequent hospitalization" as hospitalization more than once per year.
**Results:** Of the 196 patients, 117 (59.6%) were admitted to hospital a total of 257 times during the 8-year follow-up period. Moreover, 22 (11.2%) patients were hospitalized frequently. The most common reasons for hospitalization included disease flares, infection, and pregnancy-related morbidity. In the univariate regression analysis, malar rash, arthritis, pericarditis, renal involvement, fever, SLE disease activity index >12, hemoglobin level <10 mg/dl, albumin level <3.5 mg/dl, and anti–Sjögren's syndrome A (SS-A) positivity were associated with frequent hospitalization. Finally, multivariate analysis showed that arthritis, pericarditis, and anti–SS-A antibody positivity at the time of diagnosis were risk factors for frequent hospitalization.
**Conclusions:** Our results showed that frequent hospitalization occurred in 11.2% of hospitalized patients and arthritis, pericarditis, and anti–SS-A antibody positivity at the time of diagnosis were risk factors for frequent hospitalization.

## AB0465 IS IT POSSIBLE TO ESTABLISH A PREDICTIVE PROFILE FOR LUPUS NEPHRITIS?

L. Maldonado-Romero, A. Zea-Mendoza, M. Gámir-Gámir, A. Boteanu, M. García-Villanueva, J. Bachiller, M. Vázquez-Díaz. *Rheumatology, Hospital Ramon y Cajal, Madrid, Spain*

**Background:** Lupus nephritis (LN) is one of the most common and serious complications of Systemic Lupus Erythematosus (SLE). There are several factors that are considered related to the development of LN like malar erythema, anti-dsDNA and low serum complement. However not all patients with high level of anti-dsDNA or low level of serum complement present LN.
**Objectives:** To determine if patients with low serum complement, high level of anti-dsDNA and malar erythema are more likely to have NL and analyze other clinical and immunological characteristics associated with NL.
**Methods:** This is an observational, retrospective study in which 30 patients with LN, diagnosed with renal biopsy are compared with 61 SLE patients without LN, followed in the Rheumatology Unit of the University Hospital Ramón y Cajal in the last 15 years. We excluded the patients diagnosed with other non lupus nephropathy or other associated autoimmune disease. The triad we've studied was the simultaneous presence of malar erythema, low level of serum complement (C3 and/or C4, <90 mg/dl and <10 mg/dl respectively) and high level of anti-dsDNA title (more than 3 times the normal limit as the standard technique >45 IU/ml by EliAUniCAP). Clinical and immunological data were collected following a review of medical records and analyzed using bivariate and multivariate methods in SPSS version 20.
**Results:** Patients with NL were significantly younger at diagnosis of SLE than the control group (26.4±10.7 years vs 32.7±12.5 years), p=0.022. There were no differences between gender, ethnicity and time of evolution of SLE. In bivariate analysis, significant associations between NL and malar erythema (OR 6.25, p=0.0001), oral ulcers (OR 2.68, p=0.029), leukopenia (OR 2.97, p=0.034), lymphopenia (OR 5.5, p=0.001), serositis (OR 3.4, p=0.013) and fever (OR 2.56, p=0.045) were observed. Among the immunological parameters that are associated with NL were anti-dsDNA>45 U/ml antibody (Cramer's V =0.360, p=0.001), anti-U1RNP (OR 3.2, p=0.013), and low level of complement (OR 10.3, p=0.008). Chronic cutaneous lupus erythematosus and rheumatoid factor had a negative association with LN (p=0.02; p=0.049 respectively). The LN type IV was significantly associated with the studied triad (p=0.013). In the multivariate analysis the patients who had the triad were more likely to have LN (OR 42.5, 95% CI 7.7 to 233, p=0.0001); in 75% of these patients the time from the onset of the triad to the onset of LN was equal to or less than 10.2 months. The triad has higher specificity than anti-dsDNA alone (93.4% vs 55%), but lower sensitivity (76.6% vs 96%), the positive predictive value of the triad was 85% and the negative predictive value was 89%.
**Conclusions:**
The presence of the triad (malar erythema, low level serum complement and anti-DNAds) is an important predictive factor for the development of lupus nephritis and more specific than the presence of each of these alterations separately. Given these results, although larger studies are needed to confirm this profile, special care must be taken to the patients with this clinical and analytically features.

## AB0466 DAMAGE INDEX IN PATIENTS WITH THROMBOTIC ANTIPHOSPHOLIPID SYNDROME: RETROSPECTIVE COHORT STUDY

L.A. Martinez-Martinez[1], M.J.N.N. Chacon-Perez[1], M.C. Amigo[2].
*[1]Rheumatology, National Institute of Cardiology; [2]Rheumatology, ABC Medical Center, Mexico city, Mexico*

**Background:** The antiphospholipid syndrome is an autoimmune-acquired thrombophilia, the thrombotic manifestations are associated with an important risk of organ damage.[1] A new index for assessment of thrombotic accumulative damage in APS has been proposed, it is called *Damage Index in patients with Thrombotic Antiphospholipid Syndrome* (DIAPS).[2]
**Objectives:** Explore the DIAPS change in patients with primary and secondary APS in a long-term retrospective cohort.
**Methods:** Clinical records of patients with APS according to the Sapporo[3] classification criteria and/or Sydney[4] were reviewed. The DIAPS instrument with 38 items was applied. Comparison of the initial and final DIAPS was performed using the Wilcoxon test and the changes in the follow up were analyzed with T Student. The main treatments were analyzed before and after with the NcNemar test.
**Results:** Fifty clinical charts were reviewed, 12 had to be excluded for not fulfill classification criteria or incomplete information. Initial and final DIAPS was recorded in 38 patients (13±5 years of follow up), 78.9% were female, with a mean age at diagnosis 44.2±12.4 years. A total of 57.9% had primary APS. Thirty four patients remain alive with 3 to 23 years of follow up. The initial DIAPS was 3±2 and the final score was 5±3 ($p$ <0.0001). The magnitude of change in the DIAPS was similar in primary and secondary APS ($p$ =0.243). During follow up, 31/38 patients had oral anticoagulation at the beginning and 33/35 at the end ($p$ =0.687). At the beginning of the study hydroxychloroquine was recorded in 14/38 patients and in 24/38 at the end ($p$ =0.021). Aspirin was used by 17/38 patients during the follow up ($p$ =1.000).
**Conclusions:** The change in DIAPS suggests cumulative damage in patients with APS despite treatment. The DIAPS is a useful tool to estimate accrued damage in patients with primary and secondary APS.

## AB0467 ANTIBODIES TO DOUBLE STRANDED DNA: COMBINED STANDARD ELISA AND HIGH-SALT ELISA ASSAYS FOR THE DETECTION OF SLE DISEASE ACTIVITY

L. Durcan[1], J.L. Thomason[1], D. Kuo[2], M.H. Wener[3]. *[1]Rheumatology; [2]Medicine; [3]Laboratory Medicine, Divisions of Immunology and Rheumatology, University of Washington, Seattle, United States*

**Background:** Serological markers in systemic lupus erythematosus (SLE) are crucial objective measures included in disease activity indices. Antibodies to double stranded DNA (anti-dsDNA) are included in composite outcomes, and changes in titers in response to therapy are frequently reported in clinical trials. Despite this, there are multiple disparate methods to evaluate anti-dsDNA. The classic Farr immunoassay for anti-dsDNA employs high concentrations of ammonium sulfate, detecting only high-avidity antibodies, binding in high ionic strength. The salt-resistant anti-dsDNA assay is considered highly specific for the diagnosis of SLE and reliable as a disease activity marker. In contrast, most ELISAs are performed with buffers of relatively low ionic strength, detecting both low-avidity and high-avidity antibodies. We screen for anti-dsDNA using the standard ELISA, and follow-up with a modified high salt ELISA which detects only higher avidity antibodies. Use of both forms of anti-dsDNA has not been evaluated as an additive tool for the assessment of disease activity.
**Objectives:** To evaluate the sensitivity and specificity of anti-dsDNA measurement

by standard and high-salt ELISA assays for SLE disease activity (SLEDAI ≥4). To gauge the additive value of the high salt assay, performed as a reflex, in those with a positive ELISA evaluation, for the assessment of disease activity.
**Methods:** Patients fulfilling ACR classification criteria for SLE were identified in rheumatology clinic. Demographic data and disease activity (SLEDAI) were recorded. Anti-dsDNA titers were evaluated initially by standard ELISA. With a positive ELISA, a high salt assay was performed reflexively. Those with disease activity (SLEDAI≥4) were compared to those with quiescent disease. Statistical analysis involved the calculation of sensitivity, specificity, positive and negative predictive value of each assay.
**Results:** Seventy-seven encounters were evaluated (69 patients), mean age 41 (SD 14) years, 64 (92.8%) were female. The group was mostly Caucasian, 39 (56.5%), 10 (14.5%) were African-American, 9 (13.0%) Asian and 8 (11.6%) were Hispanic. Forty-two (54.5%) assessments were of active disease, 26 (33.7%) had active renal disease.
The sensitivity of antibodies to dsDNA for disease activity, by standard ELISA, was 90.5% with a specificity of 35.1%. The high salt avid assay resulted in a lower sensitivity (47.6%) and higher specificity, (78.4%). When considered in combination, given that both are performed, the sensitivity of our protocol was 90.5% with a specificity of 78.4% for disease activity.
The correlation between the standard and high-salt anti-dsDNA assay taking all cases where both was performed was moderate (r=0.53), often with substantial discordance in results in individual patient specimens.
**Conclusions:** With an increasing focus on novel markers to evaluate SLE disease activity, there has been little focus on the optimal use of pre-existing tools. Here we demonstrate the clinical utility of a screening ELISA followed by a reflex high salt anti-dsDNA assay. We show high sensitivity and specificity for SLE disease activity through the use of a standard anti-dsDNA ELISA, and a high-salt modified assay which avoids the need for radioactivity and can be readily employed.

## AB0468 CARACTERISTICS OF RENAL INVOLVEMENT IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

L. Belhaj, A. Hariz, I. Boukhris, S. Azzabi, E. Cherif, I. Kechaou, L. Ben Hassine, N. Khalfallah. *Internal medecine B, Charles Nicolle hospital, Tunis, Tunisia*

**Background:** Renal involvement is one of the most common manifestations of primary Sjögren's syndrome (pSS) and has no specific symptoms.
**Objectives:** - Identify the clinical and biological characteristics of patients with renal involvement in pSS.
- Identify the immunological profile of these patients.
- Specify the adequate treatment.
**Methods:** Fourty five patients with pSS admitted inCharles Nicolleuniversity Hospital from 2005 to 2015 were enrolled. All the patients met the validated European-American co-criteria of 2002 for pSS. No patients with secondary SS were included.
**Results:** Fourty five patients were enrolled in our study. Nine of them had renal involvement: eight women and 1 man. The mean age was 44,5 years. Time from onset to diagnosis was about 2,33 years. Concerning the kidney damage, 4 of the patients developed renal tubular acidosis (RTA), 3 of them developed others tubulo-interstitial disorders and 2 were diagnosed with glomerular disorder withhigh proteinuria. One of the nine patients had diabetis insipidus. Laboratory examinations showed 3 cases of hyperchloremia and 6 cases of hypokaliemia. One patient had hypokaliemic paralysis. Six patients had creatinincleranceunder 50 ml/mn.
All patients received symptomatic treatment. Seven patients were treated with corticosteroids and 3 patients received hydroxylchloroquine.
**Conclusions:** Patients with pSS commonly present with renal impairment.Tubular disorders are the main renal involvementespecially RTA. Glomerular lesions might be predominant. Morbidity of chronic renal failure might account for a certain proportion of pSS. Corticosteroids therapy might improve the prognosis.

## AB0469 EVOLUTION OF ANTHROPOMETRIC PROFILE AND HABIT FOOD AFTER 10 YEARS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

L.S. Souza[1], J. Calzza[1], É. Cassol[2], R.M. Xavier[3], O. Monticielo[3]. *[1]Rheumatology and Nutrition; [2]Rheumatology, Universidade Federal do Rio Grande do Sul; [3]Rheumatology, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune inflammatory disease that affects various organs and systems. Cardiovascular disease is a common complication and is associated with factors inherent to the SLE and environmental factors such as overweight and poor eating habits. In addition, obesity has been speculated as a contributing factor to the onset and progression of autoimmune diseases.
**Objectives:** Evaluate the anthropometric profile and food habit after 10 years of follow-up of a group of patients with SLE and identify possible association with chronicity index and disease activity.
**Methods:** We evaluated 55 patients with SLE in two moments with an interval of 10 years, coming from a care referral center for SLE in Hospital de Clínicas de Porto Alegre, Brazil. For chronicity and activity was used Systemic Lupus International Collaborating Clinics (SLICC) index and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), respectively. Body Mass Index (BMI), Body Fat Percentage (BFP) and waist circumference (WC) were the anthropometric data collected in accordance with the standards of the World Health Organization (WHO). The total cholesterol, LDL, HDL and triglycerides were performed as routine care. The study was approved by the Ethics Committee of the Universidade Federal of Rio Grande do Sul (UFRGS) and all patients who agreed to participate in the study met the consent and informed.
**Results:**

| Variables | First | After 10 Years | p |
|---|---|---|---|
| BMI (kg/m$^2$) | 26.8±5.4 | 28.3±6. | 0.096 |
| BFP (%) | 25.7 (21.1, 33.5) | 33.8 (27.8, 39.6) | 0.054 |
| WC (cm) | 83.9±11.2 | 96.2±14.3 | 0.001 |
| Consumption of sweets (portion/day) | 0.143 | 0.286 | 0.286 |
| HDL cholesterol (mg/dL) | 56.0 (43.7, 72.3) | 48.5 (41.0, 55.0) | 0.026 |

**Conclusions:** Our study revealed a worsening in the lipid profile and a higher concentration of abdominal fat in patients with SLE after 10 years of follow-up, although diet has remained stable. Factors related to disease or treatment may have influenced these results, but were not assessed in this study. These findings serve as a warning to us take better care of the nutritional status and lipid profile of our patients.

## AB0470 SEROLOGICAL EVOLUTION IN FERTILE WOMEN WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODIES

L. Riancho-Zarrabeitia, G. Daroca, M. López Hoyos, P. Muñoz, A. Haya, M. González, R. Del Barrio, V. Martínez-Taboada. *Hospital Universitario Marqués de Valdecilla, Santander, Spain*

**Background:** Antiphospholipid syndrome (APS) is an autoimmune disease characterized by the presence of aPL and at least a clinical event defined as recurrent venous thrombosis, arterial thombosis or pregnancy morbidity. The titers of aPL usually fluctuate, they frequently decrease and eventually become negative during follow-up period, thus reducing the risk of thrombotic events.
**Objectives:** The aim of this study was to explore the clinical and serological course of fertile women with positive aPL, as well as the factors and the potential therapeutic implications associated with aPL negativization.
**Methods:** We conducted a retrospective study including women attending the obstetric autoimmune pathology clinic of a tertiary-facility serving a population in about 350,000 in Northern Spain. We included 105 women with a confirmed positive APL serology according to Sydney Criteria between October 1995 and December 2013. Patients were classified into 3 different groups: A) patients with primary APS (49), B) patients with a positive serology for APL, not meeting clinical criteria (42) and C) patients with systemic lupus erythematosus and a positive serology for APS (14). They were also classified, according to the serological APL evolution: patients with persistently negative aPL, transiently

positive serology and persistently positive serology according to previously established criteria.
**Results:** After a mean follow up of 114,4±37,2 months, 59% patients had persistently negative antibodies, while 25,7% patients presented persistently positive aPL serology. After the multivariate analysis only the tobacco use (OR 3,5 p=0,013) was confirmed as an independent risk factor. The load of antibodies, specially the presence of triple positivity (OR: 2,4; IC: 0,16–2,36), was close to statistical significance (p=0,162). No other factors, including traditional cardiovascular risk factors, treatments or clinical manifestations reached statistical significance. Persistent positivity was associated with higher risk for further pregnancy morbidity (41 vs 52%; p=0,328). In 17 patients, with persistently negative serology who were asymptomatic, treatment with low dose aspirin was discontinued. No clinical events related to APS were reported after treatment withdrawal, during a 119,9 months follow-up period.
**Conclusions:** Our study suggests that among fertile women, antiphospholipid antibodies remain persistently positive only in one quarter of patients, being tobacco use an independent risk factors for its persistence. Among patients with persistently negative serology and with a low-risk profile discontinuation of antiplatelet therapy could be considered a safe choice.
**Disclosure of Interest:** None declared

## AB0471 RISK FACTORS FOR PREGNANCY MORBIDITY IN PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES WITHOUT A DEFINED CLINICAL ANTIPHOSPHOLIPID SYNDROME

R. Demetrio Pablo, P. Muñoz, L. Riancho-Zarrabeitia, V. Calvo-Río, M. López-Hoyos, V.M. Martínez-Taboada. *Hospital Universitario Marqués de Valdecilla, Santander, Spain*

**Background:** Antiphospholipid syndrome (APS) is an autoimmune disease characterized by the presence of either thrombosis or pregnancy morbidity and antiphospholipid antibodies (aPL), such as anticardiolipin (ACL), anti b2 glycoprotein (AB2GLP1) and lupus anticoagulant (LA). The prevalence of aPL is around 10% in the general population, increasing up to 50% in lupus patients. However, the frequency of pregnancy morbidity and the influence of the antibody profile in patients with positive APL serology without a defined APS is not well established.
**Objectives:** 1) To define the frequency of pregnancy morbidity in women with positive aPL who do not fit the clinical criteria for APS; 2)To analyze the influence of the serological profile and the load of antibodies associated with these complications, and 3) To determine the efficacy of prophylactic treatment in preventing adverse pregnancy outcome.
**Methods:** We retrospectively analyzed 92 pregnancies in 39 women with a confirmed positive serology for aPL (ACL, AB2GLP1 and LA) according to Sydney criteria. Then, we analyzed a subgroup of 15 women who had 38 pregnancies after a positive serology was confirmed.
**Results:** Overall, 54% of the 39 pregnant women suffered morbidities: one early pregnancy loss (7), two pregnancies losses (7), fetal death* (1), premature birth* (1), preeclampsia (2) and intrauterine growth restriction (3). After a mean follow-up of 146±60,3 months, only 2 patients developed obstetric APS* and none of them developed thrombotic APS. We found no association between the antibody profile and pregnancy morbidities. There was no association between pregnancy complications and the load of antibodies either. Regarding prophylactic treatment, only 8 women received AAS, combined with LWH in 3 of them, we found a non-significant tendency to prevent obstetric events.
When analyzing the 92 pregnancies, we found 28 obstetric events in 26 pregnancies. Mean age for pregnant women was 29,9±5,8 years, gestational age was 38,2±1,8 weeks, birth weight was 3108±482 g and mean Apgar was 8,7±1,1. Regarding treatment influence there was a non significant tendency to prevent obstetric events (OR 0,32, CI 95% 0,87–1,20; p=0,081), that reached statistical significance when analyzing early pregnancy losses (OR 0,12; IC 0,02–0,95; p=0,019). When we restricted the analysis to the 38 pregnancies that were posterior to the positive serology result, we found a significant protective effect of prophylactic treatment (OR=0,15; CI 95% 0,02–0,85; p=0,021), thus conferring a 6.5-fold higher risk of pregnancy complications in the untreated women (IC 95% 1,2–36,33; p=0,032).
**Conclusions:** a) Pregnancy morbidity rate in women with positive antiphospholipid antibodies was 54% when analyzing the total number of pregnancies, and 32% when analyzing the pregnancies after confirmed positive serology. b) We didn't find a profile of antibodies specifically related with obstetric complications. c)Prophylactic drug therapy is effective in preventing early pregnancy losses and achieving a higher live birth rate.

## AB0472 ASSESSMENT OF MEAN PLATELET VOLUME AS A MARKER OF DISEASE ACTIVITY IN SLE PATIENTS

L.T. Hartmann[1], A.P. Alegretti[2], A.B.M.P. Machado[2], E.F. Martins[1], R.M.D.S. Chakr[1], A.A. Gasparin[1], O.A. Monticielo[1]. *[1]Rheumatology Clinic; [2]clinical pathology service, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

**Background:** Systemic lupus erythematosus (SLE) is a multisystem inflammatory autoimmune disease that evolves with periods of remission and exacerbation activity, whose intensity can be measured by the SLEDAI. This tool is complex and has limitations. The mean platelet volume (MPV) is a marker of platelet activation and has been shown to be associated with inflammation, which makes it a potential biomarker to aid in the assessment of disease activity in SLE.
**Objectives:** To evaluate VPM in SLE patients at the active and inactive stages according SLEDAI and assess a possible correlation between VPM with SLEDAI, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), complement 3 (C3), and complement 4 (C4).
**Methods:** This cross-sectional study consisted of 40 patients with SLE, according to American College of Rheumatology (ACR) classification criteria, that were evaluated in Rheumatology Clinic of the Hospital de Clínicas de Porto Alegre in the second half of 2015. Interview during medical consultation and medical chart review were used to collect demographic, clinical and laboratory data. Disease activity was assessed with SLEDAI and chronicity was assessed with SLICC damage index (SDI). The blood count and platelets are measured in automation equipment Sysmex XE 5000. Platelets are analyzed by impedance, and the mean platelet volume is an index calculated by the machine when the examination of platelets. VSG was carried out by automated method by capillary photometry kinetics, PCR and C3 and C4 complement were determined in automation by immunoturbidimetry with intensification of reaction particles. Comparisons between groups were made with t-test or Mann-Whitney test.
**Results:** All patients studied were female, 25 (62.5%) were classified as European-derived, mean age was 42.7±12.6 years and the average age at diagnosis was 29.9±9.9 years. At the time of the study, the median (IQR) for SLEDAI was 1.50 (0.0,4.0) and for SDI was 0.0 (0.0,1.0). Patients were divided into two groups (SLEDAI=0 and SLEDAI>0). The VPM had an inverse significant correlation with SLEDAI ($r$=-0.38; p=0.01). However, the MVP did not correlate significantly with ESR, CRP, C3 and C4. Patients were divided into two groups (SLEDAI=0 and SLEDAI>0) and the results for classification criteria were similar, but lymphopenia was most prevalent in group SLEDAI>0.
**Conclusions:** There is a correlation between the VPM and the SLEDAI in our SLE patients, making it a possible tool to be used in the evaluation of disease activity.

## AB0473 QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS MEASURED BY THE SF36

M.I. Acosta Colman[1], L. Roman[1], S. Cabrera[1], G. Avila Pedretti[1], M.E. Acosta Colman[2], E. Rojas[1], Y. Yinde[1], J. Losanto[1], M. Duarte[1]. *[1]Reumatologia, Hospital de Clinicas; [2]Departamento de Producción, Instituto de Investigación en Ciencias de la Salud, San Lorenzo, Paraguay*

**Background:** Systemic Lupus Erythematosus (SLE) and rheumatoid arthritis (RA) are autoimmune diseases that mainly affect people in the reproductive stage of their life; it is interesting to investigate the impact of both diseases have in patient's quality of life.
**Objectives:** The main objective of this study was to evaluate the quality of life of patients diagnosed with SLE and RA using the SF36 questionnaire and the factors that influence it
**Methods:** Analytical, observational cross-sectional study of a cohort of SLE and RA patients. A large number of clinical and epidemiological variables were recorded (i.e. years of evolution, the age at diagnosis, disease activity, gender, marital status, etc). Quality of life was determined by SF36 questionnaire. Statistical analysis was performed with SPSS19.0 program. Qualitative variables were expressed as percentages and frequencies while quantitative were informed as mean and standard deviation. Association was analyzed with X2 test and Student T test. Pearson's test was used for correlation analysis.
**Results:** 112 patients were studied, 50.9% (57/112) patients had SLE and

49.1% (55/112) RA. 69.6% (78/112) of patients came from the capital city and metropolitan area. 87.5% (90/112) were female, 57.14% (64/112) were living in couple and 49.1% (55/100) had basic education. 43.8% (49/97) perceive less or equal to the minimum wage monthly income. 42% (47/98) were living with 3 or fewer inhabitants in the house and 58.9% (66/108) had ≥40 years old at disease onset. The mean value of physical (PCS) component of SF36 questionnaire in SLE and RA was 45.13±12.5 and 47.7±12.5 respectively and the difference between them was significantly (p=0.01). On the other hand, the mean value of mental (MCS) component was 47.7±12.5 and 46.4±12 respectively but no significant difference was found (p=0.58). In relation to the 8 SF36 components we found significant difference between them, principally in the components that measures body pain (p=0.0001) and health perception (p=0.047). In SLE patients, a significant negative correlation it was found between PCS and HAQ (p=0.00018) and SLEDAI (p=0.0020). No significantly correlation with MCS was found. Regarding the SLICC Score, a statistically negative correlation was found with MCS (p=0.036). In RA patients, a significant negative correlation was found between PCS and HAQ (p=0.0001), no association with the DAS28 was found. But, a negative correlation between the MCS and DAS28 (p=0.03) was found. No significant correlation was observed with HAQ.

**Conclusions:** In this cohort revealed that physical and mental component of SF36 are influenced by the disease activity and functional impairment.

## AB0474 A PROSPECTIVE EVALUATION OF ENDOTHELIAL DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITHOUT PREVIOUS CARDIOVASCULAR EVENTS: PRELIMINARY RESULTS

M. Taraborelli[1], E. Sciatti[2], I. Bonadei[2], V. Terlizzi[3], M. Fredi[1], R. Zani[4], G. Cancarini[3], A. Tincani[5], F. Franceschini[1], E. Vizzardi[2], I. Cavazzana[1].
*[1]Rheumatology and Clinical Immunology, Spedali Civili of Brescia; [2]Cardiology; [3]Nephrology, Spedali Civili and University of Brescia; [4]Nephrology, Spedali Civili of Brescia; [5]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy*

**Background:** Cardiovascular disease (CVD) due to premature atherosclerosis is a leading cause of morbidity and mortality in Systemic Lupus Erythematosus (SLE) patients. Early identification of patients with subclinical disease and tight control of cardiovascular risk factors are essential to reduce such complication [1,2].

**Objectives:** To assess the prevalence of endothelial dysfunction (ED) by a non invasive procedure in SLE patients with early disease without history of CVD.

**Methods:** SLE patients, according to 2012 Classification Criteria, with a disease duration less than 5 years, followed in the Rheumatology and Nephrology Unit of our Hospital were proposed to perform a cardiologic evaluation. Exclusion criteria were represented by: history of CVD, diabetes, chronic renal disease (creatinine clearance<60 ml/min), not controlled systemic arterial hypertension, current smoking or smoking in the last 3 years, hypercholesterolemia (total cholesterol>240 mg/dl), obesity (body mass index ≥30), statin or beta-blocker use. Each patient underwent a clinical and serological evaluation, a transthoracic doppler echocardiogram and an evaluation of endothelial function by endoPAT technique. Patients with ED, defined as reactive hyperemic index ≤2, were compared to those without ED by Fisher, T student or Mann-Whitney tests as appropriate.

Table I Disease characteristics and treatment of 17 SLE patients

| | |
|---|---|
| Cutaneous, n (%) | 9/17 (53) |
| Mucosal, n (%) | 5/17 (29) |
| Renal, n (%) | 7/17 (41) |
| Articular, n (%) | 12/17 (71) |
| Neurological, n (%) | 1/17 (6) |
| Serositic, n (%) | 5/17 (29) |
| Hematological, n (%) | 12/17 (71) |
| Antiphosphslipid Syndrome, n (%) | 1/17 (6) |
| Antinuclear antibody positivity, n (%) | 17/17 (100) |
| Anti-double stranded DNA positivity, n (%) | 7/17 (41) |
| Anti-extractable nuclear antigen positivity, n (%) | 10/17 (59) |
| Anti-cardiolipin IgG positivity, n (%) | 1/16 (6) |
| Anti-cardiolipin IgM positivity, n (%) | 4/16 (25) |
| Anti@2Glycoprotein I IgG positivity, n (%) | 1/16 (6) |
| Anti@2Glycoprotein I IgM positivity, n (%) | 2/16 (12) |
| Lupus anticoagulant positivity, n (%) | 5/17 (29) |
| C3 mg/dL, mean (SD) | 86,5 (20,7) |
| C4 mg/dL, mean (SD) | 13,2 (6,8) |
| Systemic Lupus Erythematosus Disease Activity Index 2K, mean (SD) | 4,06 (3,13) |
| Systemic Lupus International Collaborating Clinics Damage Index., median (range) | 0 (0-3) |
| Steroids, n (%) | 16/17 (94) |
| Antimalaric, n (%) | 15/17 (88) |
| Disease Modifying Antirheumatic Drugs, n (%) | 10/17 (59) |
| Belimumab, n (%) | 1/17 (6) |
| Low dose aspirin, n (%) | 8/17 (47) |
| Oral anticoagulant, n (%) | 2/17 (12) |
| Anti-hypertensive drugs, n (%) | 7/17 (41) |

**Results:** We enrolled 17 SLE patients (100% female, 88% caucasian) with a median disease duration of 14 months (0–68), a mean age of 41 years (±16), and a mean age at diagnosis of 39 years (±17). Five patients (29%) had a systemic hypertension that was well controlled by treatment. No other cardiovascular risk factors were present. Disease characteristics and treatment are shown in Table I. Echocardiogram showed diastolic dysfunction in 3 patients. EndoPAT identified 7 patients (41%) with ED. We did not find any significant association between the presence of ED and demographic-clinical-serological characteristics of patients or treatments or echocardiografic findings. A tendency for an association with an history of renal disease was observed (57% versus 0%, p:0.058).

**Conclusions:** A significant proportion of SLE patients showed signs of ED despite a recent disease and the absence of significant cardiovascular risk factors.

## AB0475 SHRINKING LUNG SYNDROME IN SYSTEMIC LUPUS ERYTHEMATOSUS – A RARE COMPLICATION

M.A. Blazquez Cañamero[1], A.L. Boteanu[2], M.J. García Villanueva[2], A. Zea Mendoza[2], A.F. Cruz Valenciano[1]. *[1]Rheumatology, Severo Ochoa Hospital; [2]Rheumatology, Ramón y Cajal Hospital, Madrid, Spain*

**Background:** Pleuropulmonary involvement in Systemic Lupus Erythematosus (SLE) occurs in 60 to 80% of patients. Shrinking lung syndrome (SLS) is a non-exclusive, rare manifestation of SLE. The pathogenesis and treatment of SLS are not well established.

**Objectives:** We describe the clinical, immunological and radiological features and the therapeutic management of a series of 8 cases of SLS.

**Methods:** This study is a retrospective, descriptive study of a series of 8 cases of patients diagnosed with SLE in the Rheumatology Unit of Ramón y Cajal Hospital and Severo Ochoa Hospital.

**Results:** Of the 8 patients, 7 were women with a mean age at diagnosis of 40 years. Only 2 patients had severe visceral involvement. All patients had a history of serositis. All patients had positive ANA, 87.5% anti-DNA positive and 100% had low complement at some point in the evolution of the disease. 62.5% had anti-Ro and 50% had anti-RNP. 37.5% of patients were already in treated with low or intermediate doses of corticosteroids at the time of diagnosis, 37.5% received dolquine, 25% were treated with azathioprine and one patient had epratuzumab.In relation to diagnostic studies, 100% of patients had elevating one hemidiaphragm or both on chest radiography and basal atelactasis. The most common findings on the CT scan were: elevation of the diaphragm, pleural effusion and the presence of basal atelectasis. All cases had a restrictive pattern in PFT and in the cases in which the results were available, the carbon monoxide gas transfer capacity was reduced. Regarding the therapeutic management, 62.5% were treated initially with intermediate-high doses of oral corticosteroids (mean dose 17.5 mg/day), in 25% was added Chloroquine, in 25% of cases Azathioprine and MMF in one patient. Only one patient received treatment with Beta-2 agonists. The evolution was favorable only in the patient receiving MMF with clinical and radiological improvement of stabilization on clinical and radiological findings over the time. In 62.5% of patients the pleuritic chest pain persisted and 37.5% presented later infectious respiratory complications.

**Conclusions:** SLS is a rare complication in patients with SLE. The pathogenesis of SLS is unknown. It was suggested the possible involvement of the anti-Ro antibody. In our series, 62.5% had anti-Ro positive and 50% anti-RNP positive. The SLS must be suspected when a SLE patient star with unexplained dyspnea and/or pleuritic chest pain and a loss of lung volume in the imaging studies and development of a restrictive pattern in PFT. The treatment is not well established. In most published series, as in our case, the initial treatment is represented by the oral corticosteroid (30–60 mg/day). In several studies it has been proposed the use of Beta-2 adrenergic agonists and Theophylline, although their effectiveness has not been well demonstrated. In refractory cases the use of other immunosuppressive has been successfully reported. In our series, the addition of Chloroquine or Azathioprine was not associated with radiological improvement but with clinical stabilization in time. The MMF was associated with clinical and radiological improvement but a conclusion cannot be taken. The clinical outcome in most of the series is usually favorable, with subjective improvement in pain and dyspnea and with progressive improvement in lung function tests.

**Disclosure of Interest:** None declared

## AB0476 SERUM LEVELS OF PROLIFERATION-INDUCING LIGAND, B-CELL ACTIVATING FACTOR, ANTINUCLEAR AUTOANTIBODIES AND MARKERS OF INFLAMMATION IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME COMPARED TO PATIENTS WITH SICCA SYMPTOMS WITHOUT DIAGNOSIS OF PSS AND WITH HEALTHY SUBJECTS

M. Maslinska[1], E. Kontny[2]. [1]*Early Arthritis Clinic;* [2]*Department of Pathophysiology and Immunology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*

**Background:** The proliferation-inducing ligand (APRIL) and B-cell activating factor (BAFF) are associated with primary Sjögren's syndrome (pSS), because they affect B-cell activity – possible key factor in the pSS pathogenesis.
**Objectives:** The study aimed at determining the correlation between serum concentrations of APRIL /BAFF and markers of pSS and of systemic inflammation.
**Methods:** We evaluated 3 groups: (i) 41 patients with established pSS diagnosis (according to AECG criteria and ACR criteria 2012); [the mean age 51±15.3; 82,9% female (F), 17.1% males (M)]; (ii) 32 subjects with symptoms of dryness (other connective tissue diseases were excluded)[the mean age 56±12,46; (93,75%) F, 2 (6,25%) M], and (iii) 24 healthy volunteers [the mean age 43±12,4; 19 (79,2%), F and 5 (20,8%)M]. Laboratory tests were performed, including establishing inflammatory parameters: erythrocyte sedimentation rate (ESR), serum concentration of C-reactive protein (CRP) (range 0–10 mg/l), concentrations of gamma globulins (g/dl). ANAs titers and patterns were determined by an indirect immunofluorescence method with HEp2 slides. Anti-SSA and anti-SSB antibodies were detected by a dot-blot method allowing semi-quantitative evaluation. Serum concentration of APRIL and BAFF were measured using an enzyme-linked immunosorbent assay. Minor salivary gland biopsies evaluating the number of inflammatory infiltrates foci [focus score (FS) of mononuclear cells above 50] were performed. The study was approved by the Ethics Committee of NIGRR. Differences between groups were analyzed using U Mann-Whitney test (continuous variables). Correlations between variables were assessed with the Spearman correlation coefficient. Statistical significance was set at $p<0.05$
**Results:** pSS patients had significantly higher serum concentrations of BAFF and ANAs (Mann Whitney test $p<0,015$, $p<0,000$ respectively), but not of APRIL, compared to the healthy control (HC) group. There were no differences in serum concentration of BAFF and APRIL between pSS and sicca (S) group. Positive correlation between BAFF and APRIL serum concentrations was found in HC group ($r=0,469$;$p<0,05$), but not in pSS and S groups. In S group BAFF positively correlated with CRP ($r=0,446$;$p<0,05$) and ANAs positively correlated with a presence of anti-SS-A, anti- SS-B antibodies and a level of gamma globulins. In pSS group there was a statistically significant positive correlation between the concentration of APRIL and: (i) ANAs ($r=0,569$), (ii) anti-SS-A ($r=0,313$), (iii) anti -SS-B ($r=0,424$) and (iv) gamma globulins level ($r=0,408$). In pSS group ANAs positively correlated with FS ($r=0,455$).
**Conclusions:** 1. BAFF correlates more closely with an inflammatory reaction, while APRIL with a prolonged autoimmune response, that favoures the production of autoantibodies. 2. Lack of statistically significant differences in the concentrations of BAFF and APRIL between pSS and S group may be explained, based on other studies, by a local BAFF overexpression in salivary glands in pSS group or by an influence of EBV infection or reactivation in both groups (data not shown). 3. Positive correlation between FS and ANAs may suggest a role of ANAs in a local inflammation.

## AB0477 ARTERIAL STIFFNESS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS NEPHRITIS PATIENTS AS A POTENTIAL PREDICTOR OF EARLY ATHEROSCLEROSIS

M. Schubertová[1], A. Smržová[1], Z. Heřmanová[2], F. Mrázek[2], M. Skácelová[1], P. Horák[3], J. Zadražil[1]. [1]*Department of Internal Medicine III - Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacky University Olomouc, University Hospital;* [2]*Department of Immunology, Faculty of Medicine and Dentistry, Palacky University Olomouc;* [3]*Department of Immunology, Faculty of Medicine and Dentistry, Palacky University Olomouc, University Hospital, Olomouc, Czech Republic*

**Background:** Cardiovascular disease (CVD) is one of the major cause of death in patients with SLE. Arterial stiffness is considered to be an independent risk factor of development CVD and a strong predictor of all-cause mortality. Increased arterial stiffness, due to premature vascular ageing, can be observed in patients with SLE as well as in patients with chronic kidney disease.
**Objectives:** To evaluate arterial stiffness determined as carotid – femoral puls wave velocity in systemic lupus erythematosus patients. The comparison of traditional risk factor of CVD and markers of subclinical atherosclerosis in SLE, patients with histologically proven Lupus nephritis (LN) and healthy controls.
**Methods:** We evaluate the data from 41 SLE patients, (37 females, 4 male, mean age 37, mean duration of the SLE of 8years). 21 of these patients with histologically proven Lupus nephritis and chronic kidney disease (CKD). Arterial stiffness, measured as carotid – femoral puls wave velocity (PWV) was established with the SphygmoCor system. This non-invasive technique uses the principle of applanation tonometry. Our control group counted 20 heathy male and female with no history of CVD, CKD or autoimmune disease. We evaluate the influence of traditional CV risk factors as age, smoking, BMI, diabetes mellitus, dyslipidemia, previous history of CV and cerebrovascular morbidity to PWV in SLE patients. Disease activity score (SLEDAI), the level of C3, C4 complement component and anti-dsDNA antibodies, renal function and antifosfolipid antibodies were measured at the same timepoint, correlated with PWV and carotid artery intima media thickness.
**Results:** Mean PWV in Lupus nephritis patients was numerically higher (6,5m/s) than that in other SLE patients (5,7m/s) and healthy controls but it lacked the statistical significance. PWV in LN was positively associated with carotid artery intima media thickness (IMT), hsCRP level, serum creatinine level, C4 complement component ($p<0,05$), presence of antiphopholipid syndome and SLICC score ($p<0,02$).
**Conclusions:** SLE patients are in increased risk of CV disease. PWV is considered as an independent risk factor of CVD and CKD. Despite we did not prove statistical significant difference in PWV in patients with Lupus nephritis in comparison to other SLE patients, there was a trend to increased PVW in this pilot study. The correlation to creatinin levels indicates relation of this parameter to renal function. It seems to be associated more with the fact of renal insufficiency that the pure presence of lupus nephritis. The PVW correlates with another test for early atherosclerosis and with the IMT. Further investigation is needed to establish the role of evaluation of PWV in SLE patients.

## AB0478 GLUCOCORTICOID PREVENTS THE PROGRESSION OF ATHEROSCLEROSIS IN JAPANESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL PROSPECTIVE COHORT STUDY (NTMC-COHORT STUDY)

M. Iwasaki[1,2], M. Ushikubo[1], K. Izumi[1], K. Akiya[1], H. Oshima[1]. [1]*Connective tissue disease, Tokyo Medical Center;* [2]*Nephrology, Toho University Ohashi Medical Center, Tokyo, Japan*

**Background:** Several cross-sectional studies have shown a progression of atherosclerosis in systemic lupus erythematosus (SLE) was associated with the activity of SLE but not with glucocorticoid therapy. However, a few evidence showed the correlations between the progression of atherosclerosis in SLE and glucocorticoid therapy in longitudinal studies. Moreover, races and regions are known to be important in atherosclerosis.
**Objectives:** We conducted a longitudinal prospective cohort study to clarify relevant clinical factors to influence the progression of atherosclerosis in Japanese patients with SLE.
**Methods:** In our cohort of the patients with SLE who regularly visit our department, the patients who underwent echography of the carotid arteries twice or more, with an interval of two years or more, were enrolled into the present study.
Atherosclerosis was evaluated with echography of the carotid arteries. A mean of the bilateral intimal carotid artery media thickness (mIMT) was measured with the three-point method (TOSHIBA Xario200, Aplio400). The annual progression rate of mIMT (mIMT/y) was calculated from the difference between the baseline and the subsequent echo studies.
We analyzed clinical factors associated with mIMT and mIMT/y using multiple regression analysis. For mIMT, clinical factors assessed in the analysis were as follows: age, disease duration, smoking habits, comorbid conditions, total cumulative prednisolone dosage (tPSL), history of other medications, SLICC/ACR damage index (SDI), Ankle-Brachial Index, Cardio-Ankle Vascular Index, HbA1c, C-reactive protein, serum creatinine, high density lipoprotein cholesterol, and low density lipoprotein cholesterol at baseline. For mIMT/y, in addition to the factors above, we assessed mean daily prednisolone dosage during the follow-up period (mPSL) and other medications during the follow-up period.
The analysis was performed by SPSS version 20.
Data were represented as median (25–75 percentile).
**Results:** Thirty-nine Japanese patients with SLE were recruited in our study. Of these, 35 were women; age, disease duration, tPSL at baseline, and daily prednisolone dosage during the follow-up period (mPSL) were 60 (48–65) years, 25 (12–32) years, 58 (36–82) g and 5.0 (4.0–7.5) mg/day, respectively. The intervals of echo studies were 4.0 (2.7–6.1) years.
At baseline, the mIMT was 0.60 (0.50–0.75) mm. Age ($B=0.005$, $SE=0.002$, $p=0.011$) and SDI ($B=0.05$, $SE=0.02$, $p=0.019$) were selected as positive contributory factors for mIMT, while tPSL was selected as a negative factor ($B=-0.002$, $SE=0.001$, $p=0.007$).
For mIMT/y, mPSL ($B=-0.005$, $SE=0.002$, $p=0.004$) was a negative contributory

factor, and diabetes mellitus requiring medical therapy was a positive factor (B=0.032, SE=0.014, p=0.035).
**Conclusions:** These results suggested that glucocorticoid therapy might be protective against the progression of atherosclerosis in Japanese patients with SLE.
**Disclosure of Interest:** None declared

## AB0479 MUSCULOSKELETAL MANIFESTATIONS ARE MAJOR DETERMINANTS OF IMPAIRED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Piga[1], M. Congia[1], A. Floris[1,2], A. Gabba[1], A. Cauli[1], A. Mathieu[1].
*[1]Rheumatology, University Clinic, Cagliari, Italy; [2]Rheumatology, Oxford's University, Oxford, United Kingdom*

**Background:** Musculoskeletal (MS) manifestations are among the most frequent expressions of Systemic Lupus Erythematosus (SLE) being present in up to 90–95% of patients during disease course and in 60% of disease flares. They have been associated with impaired quality of life (QoL) in SLE patients. However, the role of different subtype of MS manifestations has not been investigated.
**Objectives:** To investigate the impact of different MS manifestations in SLE patients as major determinants of impaired health related QoL (HRQoL) in SLE.
**Methods:** One hundred twelve consecutive SLE patients (age 47.6± 16.8 years, disease duration 115.5±84.0 months; 6 male) diagnosed according to the 1997 ACR classification criteria were recruited in this cross-sectional study; 87 patients were sub-classified as affected by non-deforming non-erosive arthritis (NDNE), 15 as Jaccoud's arthropathy (JA) and 10 as rhupus syndrome (RS) according to clinical and radiographic features. Thirty-five patients affected with Rheumatoid Arthritis (RA) and 38 healthy controls (HC) were recruited as control groups. HRQoL was evaluated using three validated self-administered questionnaires: the Short Form 36 (SF36) health survey questionnaire, the Heath Assessment Questionnaire (HAQ) and the Fatigue scale v4 (FACIT-4).
The search for factors independently associated with low QoL included univariate analyses and stepwise multiple regression models. Explanatory variables tested were: age, disease duration, gender, occupation, arthropathy subtypes, SLEDAI, SLICC damage index, Body Mass Index, arthritis, discoid LE, neuropsychiatric symptoms, active nephritis, depression, fibromyalgia, osteoporosis with fractures, osteonecrosis. Multivariate models were fitted with covariates with $p<0.1$ to predict outcomes; Bonferroni's corrected $p<0.05$ was considered significant.
**Results:** SLE patients had worse results ($p<0.01$) than HC in SF36, HAQ, and FACIT-4. Patients classified as affected by JA and RS had worse results ($p<0.01$) in SF36, HAQ, and FACIT-4 than patients with NDNE and RA, but no differences were recorded between these two groups.
Factors independently associated with lower score in the physical summary components of SF36 were: JA ($p=0.01$), arthritis ($p<0.01$) and fibromyalgia ($p<0.01$). Factors independently associated with lower score in the mental summary components of SF36 were: JA ($p<0.01$), RS ($p<0.01$) and fibromyalgia ($p<0.01$). Factors independently associated with lower HAQ results were: JA ($p<0.01$), arthritis ($p<0.01$) and osteoporosis with fracture ($p<0.01$). Factors independently associated with lower FACIT-4 score were JA ($p<0.01$) and arthritis ($p<0.01$).
**Conclusions:** MS manifestations were confirmed as one the major factors associated with lower QoL in patients with SLE. In particular active arthritis, JA and fibromyalgia were associated with low levels of patient's perception in physical function evaluated with the HAQ and SF36, whereas JA and fibromyalgia were determinants of impaired mental health. Active arthritis and JA were associated with increased fatigue perception evaluated with FACIT-4.

## AB0480 CANCER INCIDENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. Fernández Matilla[1], E. Grau Garcia[1,2], G. Poveda Marín[2], C. Feced Olmos[2], E. Labrador Sánchez[2], F.M. Ortiz Sanjuan[2], N. Fernández-Llanio[3], D. Hervás Marín[4], V. Fornes Ferrer[4], K. Arévalo Ruales[2], R. Negueroles Albuixech[2], J. Ivorra Cortés[2], J. Fragio Gil[2], I. Martínez Cordellat[2], J. Valero Sanz[2], I. Chalmeta Verdejo[2], L. González Puig[2], C. Alcañiz Escandell[2], C. Nájera Herranz[2], J. Castellano Cuesta[3], J. Román Ivorra[2]. *[1]Rheumatology Research Group, IIS la Fe; [2]Rheumatology Dept., HUP la Fe; [3]Rheumatology Dept., Hospital Arnau de Vilanova; [4]Biostatistics Unit, IIS la Fe, Valencia, Spain*

**Background:** In the latest study published by the SEOM (Spanish Society of Medical Oncology) in 2012, the most prevalent types of cancers in Spanish women are breast, colorectal, corpus uteri, lung and ovary. In addition, in Systemic Lupus Erythematosus (SLE) patients a higher incidence of cancer has been described, about 15–20% higher. Today, there is some controversy around the activity on SLE or even drugs employed such as cyclophosphamide could be an extra risk factor for cancer development in these patients. In fact, there are not many studies regarding cancer incidence in SLE.
**Objectives:** To analyze the cancer incidence in a series of SLE patients, as well as their clinical characteristics.
**Methods:** Cross-sectional retrospective study of SLE patients according to the SLICC-2012 criteria, coming from the Rheumatology Service of Arnau de Vilanova Hospital and La Fe Hospital. In all patients clinical and disease activity data were collected, using personal interview and medical history.
**Results:** A total of 140 patients were evaluated; of them, 95% were women with 33.39±13.63 year-old average at the diagnosis time with a 10.05±11.42 year-evolution of SLE. Of them, 6 patients (4.3%) have had some type of cancer, whose clinical characteristics are presented in the table.
**Conclusions:** The percentage of SLE patients who have developed any type of cancer was 4.3%, which doubles the rate for Spanish general population (2.12%). The types of found cancer are heterogeneous and don't correspond to the usual pattern described for general population in our country.
**Disclosure of Interest:** None declared

## AB0481 DESCRIPTION OF A LATE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

M. Fernández Matilla[1], E. Grau García[2], G. Poveda Marín[2], C. Feced Olmos[2], E. Labrador Sánchez[2], F.M. Ortiz Sanjuan[2], D. Hervás Marín[3], N. Fernández-Llanio[4], V. Fornes Ferrer[3], K. Arévalo Ruales[2], R. Negueroles Albuixech[2], J. Ivorra Cortés[2], J. Fragio Gil[2], I. Martínez Cordellat[2], J. Valero Sanz[2], I. Chalmeta Verdejo[2], L. González Puig[2], C. Alcañiz Escandell[2], C. Nájera Herranz[2], J. Castellano Cuesta[4], J. Román Ivorra[2]. *[1]Rheumatology Research Group, IIS la Fe; [2]Rheumatology Department, HUP la Fe; [3]Biostatistics Unit, IIS la Fe; [4]Rheumatology Department, Hospital Arnau de Vilanova, Valencia, Spain*

**Background:** The late-onset Systemic Lupus Erithematosus (SLE) has been defined as that one beginning after 50 years old, and supposes around 6–18% of the SLE patients. According to the literature, the most common clinical manifestations are interstitial lung disease, serositis, Sjögren's syndrome and cytopenias. Though the illness activity is lower in these patients, this population usually stands with more accumulative damage and has a higher mortality than the early-onset SLE patients.
**Objectives:** To study the differences between the late-onset SLE patients and the conventional-onset ones, regarding to the debut and actual manifestations, biomarkers of autoimmunity, accumulative damage and disease activity.
**Methods:** Cross-sectional prospective study of SLE patients according to the SLICC-2012 criteria, coming from the Rheumatology Service of Arnau de Vilanova Hospital and La Fe Hospital in Valencia, Spain. All patients had a complete blood-test with autoimmunity markers, and clinical and activity data were collected using the SLICC-ACR and SELENA-SLEDAI questionnaires.
**Results:** A total of 140 patients were evaluated; (95% were women) with 33,39±13,63 year-old average at the diagnosis time with a 10,05±11,42 year-evolution of SLE. Of them, 12% had a late-onset of the disease (diagnosis at >50 years old). In this group of patients we found a higher incidence of SS and Raynaud's phenomenon as the initial symptom (5,9% and 11,8% respectively), compared to the early-onset patients (2,4% and 4,1%). However, regarding to the actual manifestations, this group has a lower incidence of Raynaud's, as well as renal damage or cytopenias. We observe a higher proportion of SS between the late-onset group, although the ENAs levels are lower than in the early-onset group. In addition, the late-onset group has an incidence of cardiovascular events 4 times higher than the early-onset one.
**Conclusions:** We observe a concordance between the debut symptoms in our late-onset series and other series described previously in the literature, where SS presents with a higher proportion in these patients. On the other hand, we cannot distinguish if the higher proportion of cardiovascular events in this groups is due to the late-onset SLE characteristics itself, or to other factors regarding to the older age.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4145

**Abstract AB0480** – Table 1

| Case | Gender | SLE-onset age | SLE evolution (years) | Cancer type | Time from SLE-onset to cancer diagnosis (years) | Anti-dsDNA | ANAs | Anti-RO | Anti-LA | Anti-SM | Anti-RNP |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | Female | 17 | 30 | Ovarian adenocarcinoma | 21 | – | + | + | – | – | – |
| 2 | Male | 47 | 18 | Thymoma | –2 | – | – | – | – | – | – |
| 3 | Female | 40 | 18 | Liposarcoma right leg | 3 | + | + | – | – | – | – |
| 4 | Female | 45 | 25 | Invasive ductal carcinoma left breast | 25 | – | + | + | – | – | – |
| 5 | Female | 29 | 10 | Cervical intraepithelial neoplasia (CIN-1) | 7 | – | + | + | + | – | – |

## AB0482 EVALUATION OF CURRENT AND AT THE ONSET CLINICAL MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. Fernández Matilla[1], E. Grau García[2], G. Poveda Marín[2], C. Feced Olmos[2], E. Labrador Sánchez[2], F.M. Ortiz Sanjuan[2], D. Hervás Marín[3], N. Fernández-Llanio[4], V. Fornes Ferrer[3], K. Arévalo Ruales[2], R. Negueroles Albuixech[2], J. Ivorra Cortés[2], J. Fragio Gil[2], I. Martínez Cordellat[2], J. Valero Sanz[2], I. Chalmeta Verdejo[2], L. González Puig[2], C. Alcañiz Escandell[2], C. Nájera Herranz[2], J. Castellano Cuesta[4], J. Román Ivorra[2]. *[1]Rheumatology Research Group, IIS la Fe; [2]Rheumatology Department, HUP la Fe; [3]Biostatistics Unit, IIS la Fe; [4]Rheumatology Department, Hospital Arnau de Vilanova, Valencia, Spain*

**Background:** Systemic Lupus Erythematosus (SLE) in a multisystemic autoimmune disease that specially affects young women during the second and third decade, and is able to injure different organs and or systems, being the most common one affected the musculoskeletal system.
**Objectives:** To analyse the influence of the time of evolution and age of the patient in the current clinical manifestations and the debut of the disease in patients with SLE.
**Methods:** Cross-sectional prospective study of SLE patients according to the SLICC-2012 criteria, coming from the Rheumatology Service of Arnau de Vilanova Hospital and La Fe Hospital. All patients had a complete blood-test with autoimmunity markers, and clinical, biometrics and treatment data were also collected from the personal interview and the medical history. Biostatistical analysis was performed using the *R* software version 3.2.3., using a simple, binomial and logistic lineal regression.
**Results:** A total of 140 patients were evaluated; of them, (95% were women) with 33.39±13.63 year-old average at the diagnosis time with a 10.05±11.42 year-evolution of SLE. We can find the clinical manifestations at the onset disease on the table.

| Onset manifestation | (%) | Onset manifestation | (%) |
|---|---|---|---|
| Musculoskeletal | 73.6 | Sjogren synd. | 2.9 |
| Skin | 39.3 | Raynaud's | 5 |
| Kidney | 5 | Other | 27.1 |
| Cytopenia | 7.9 | | |

We observe statistically significant differences in the musculoskeletal system involvement (P=0.008), and in the presence of vasculitis (P=0.01) in patients with a shorter time of disease evolution. There is also a direct relationship between cardiovascular (P=0.002) and renal (P=0.03) affection in younger patients. Finally, cytopenias are correlated both in young patients (P=0.0009) as well as with a shorter time of evolution (P=0.02).
**Conclusions:** We observe a concordance between our SLE series and those already described at the literature, where renal involvement occurs at younger ages, and the musculoskeletal system involvement occurs early in disease or even as the onset symptom.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5044

## AB0483 RISK FACTORS ASSOCIATED WITH GREATER DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: AN EGYPTIAN MULTICENTER STUDY

M. Eissa[1], M. Hammad[2], S. Fathi[2]. *[1]Department of Rheumatology and Rehabilitation, Cairo University, Cairo; [2]Department of rheumatology and rehabilitation, Zagazig University, Zagazig, Egypt*

**Background:** Systemic lupus erythematosus (SLE) is a prototypic multisystem autoimmune disorder. The total damage in a patient with SLE may result from SLE itself or any other pathologic process. The management of SLE targets immediate control of disease activity, but also it should include the prevention of organ damage from treatment and comorbidity by minimizing or controlling risk factors of organ damage.
**Objectives:** The aim of this study was to assess risk factors of greater damage in a sample of Egyptian SLE patients.
**Methods:** This is an Egyptian multicenter retrospective study. The study included 100 SLE patients: 64 patients from Cairo University Hospital and 36 patients from Zagazig University Hospital. The patients are classified according to the Systemic Lupus International Collaborative Clinics (SLICC) criteria for SLE. Systemic Lupus International Collaborative Clinics/ACR Damage Index (SLICC/ACR-DI) was used to measure damage in each patient. The period of data collection took 4 months. The collected data included demographic, clinical, serologic data and medications.
**Results:** 100 SLE patients (93% females and 7% males with mean age 33.44±8.6 and disease duration 6.25 (1–17) were included. The most frequent item in the damage index in our patients was retinal changes or optic atrophy (12%), followed by osteoporosis (11%). The total SLICC/ACR Damage Index Score ranged from 0 to 8. There was a significant positive correlation between the Damage Index and the patient's age, SLEDAI-2k at the onset and at the last visit ($P<0.05$). A higher Damage Index score was found in hypertensive patients compared to normotensive patients and among those with positive anti-phospholipid antibodies compared to those with negative anti-phospholipid antibodies and the difference was statistically significant ($P<0.01$). A statistically significant higher Damage Index score was found in cyclophosphamide users compared to non-users, and in those with proteinuria & seizures compared to those without ($P<0.05$). Comparing all variables; seizures was by far the most important predictor of Damage Index in the regression model (Beta=0.279, P=0.028), followed by SLEDAI at last visit (Beta =0.234, P=0.062) and then Antiphospholipid Syndrome (Beta =0.335, P=0.064).
**Conclusions:** Damage in SLE cannot be prevented completely as SLE is an aggressive disease treated by aggressive medications. Frequent ophthalmologic follow up is necessary for all SLE patients. SLE patients with hypertension and positive antiphospholipid antibodies develop higher damage scores so they need closer observation and control of these factors if possible. Rheumatologists should try to minimize damage as much as possible to maintain patients' health, functioning, and general wellbeing.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2728

## AB0484 IDENTIFICATION OF CLINICAL AND SEROLOGIC FACTORS ASSOCIATED WITH NEUTROPENIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M.K. Chung[1], H. Jeon[1], S.H. Kim[1], I.J. Kim[2], J. Lee[2]. *[1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea; [2]Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of medicine, Seoul, Korea, Republic Of*

**Background:** Hematologic manifestations are common in systemic lupus erythematosus (SLE). Lymphopenia is most commonly found among leukopenia, but neutropenia is also found in about 50–60% of SLE patients. Most patients experience mild neutropenia while less than 5% of those experience moderate to severe neutropenia which can increase susceptibility to recurrent infection. Although it is crucial to understand risk factors associated with neutropenia in SLE patients, there is a paucity of clinical data regarding neutropenia in patients with SLE.
**Objectives:** This study was performed to identify the clinical and serologic factors that are associated with neutropenia in patients with systemic lupus erythematosus (SLE).
**Methods:** A total 160 admissions of 85 SLE patients between 2006 and 2013 were retrospectively reviewed. Neutropenia was defined as absolute neutrophil count (ANC) below 1,500/mm$^3$. Baseline characteristics of the patients were compared between patients who experienced neutropenia and those without. Clinical and serological factors related to neutropenia episode during admission were analyzed using generalized estimating equation (GEE) and multivariate analysis.
**Results:** Thirty two (37.6%) patients experienced neutropenia, and neutropenia episode was found in 35 (21.9%) of admissions. Most of the neutropenia episodes were mild to moderate. Severe neutropenia of ANC$<$500/ mm$^3$ occurred in 14.3% of the cases. Patients with neutropenia had higher frequencies of ANA (100.0 vs 86.8%, *P*=0.042) and anti-dsDNA (87.5 vs 60.4%, *P*=0.008), and satisfied more SLE classification criteria at the time of the diagnosis than those without (4.8 vs 4.1, *P*=0.014) Clinical characteristics at admission such as comorbidities, concomitant medications, and SLEDAI were not different between admissions with and without neutropenia episode. Anemia, leukopenia, thrombocytopenia and low complement levels were frequently associated with neutropenic episodes. Co-existence of chronic kidney disease (OR,16.91; 95% confidence interval (CI), 2.09–136.6; *P*=0.008) and Sjögren's syndrome (OR, 6.48; 95% CI, 1.46–28.66; *P*=0.014) was associated with increased risk of developing neutropenia.
**Conclusions:** This study demonstrates that most of neutropenia in SLE patients occur as part of hematologic and immunologic abnormalities. SLE patients with renal damage and Sjogren's syndrome should be closely monitored for development of neutropenia.

## AB0485 ANTI-C1Q ANTIBODIES IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION WITH RENAL PATHOLOGY OF LUPUS NEPHRITIS

M. Qiu, Z. Hu, X. Guo, J. Qi, Q. Lv, J. Gu. *Rheumatology, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** There is a lack of serum markers for effective evaluation of renal lesion severity of systemic lupus erythematosus (SLE). Recent studies show that anti-Clq antibody has been associated with SLE and lupus nephritis (LN), but there were few data about the relationship between anti-Clq antibody and renal pathology of LN.
**Objectives:** To investigate the relationship between serum anti - Clq antibody and the disease activity of SLE as well as renal pathological characteristic.
**Methods:** Anti-C1q Ab were measured by enzyme-linked immunosorbant assay (ELISA) in 128 patients with SLE (including 58 cases with LN and 70 cases without LN), 103 patients with other autoimmune diseases (disease control group) and 60 healthy individuals (healthy control group). Renal biopsy was conducted in all LN patients.

**Results:** Prevalence of anti-C1q was 31.3% (40/128) in patients with SLE, significantly higher than that in disease control group and healthy control group (31.3% vs.4.9% (5/103), $P<0.01$; 31.3% vs. 0 (0/60), $P<0.01$). And the positive rate of anti-C1q Ab was significantly higher in patients with active SLE (37/54,68.5%), LN (35/58, 60.3%) and active LN (32/36, 88.9%) in comparison with patients with inactive SLE (3/64,4.7%), non-LN (5/60,8.33%) and inactive LN (3/22,13.6%), respectively. The incidence of renal involvement in SLE patients with positive anti-C1q Ab was higher than that in anti-C1q Ab negative group (87.5% vs 29.5%, $P<0.05$). 12 cases of renal biopsies were classified as WHO Class II. 13 cases Class III,18 cases Class IVCand 15 cases Class V. The serum anti-C1q Ab level in Class IV LN patients (63±10 RU/ml) was higher than that in Class II/III/V LN patients ($P<0.01$). There was no significant difference of the anti-C1q Ab level among the other pathological types of LN.The serum C1qAb level was significantly higher in the LN patients with renal deposition of C1q (++), IgG positive and C3 positive, in comparison with the deposition of C1q (+/–), IgG negative and C3 negative, respectively ($P<0.05$). The elevated levels of anti-C1qAb was significantly positively correlated with the deposition of C1q, IgG and C3 in the kidney.

**Conclusions:** The serum anti-C1q antibody, a simple and non-invasive marker, can reflect the disease activity of SLE, especially with regard to renal involvement. It is useful for SLE to predict renal lesion, particularly diffuse proliferative LN (iclass IV).

## AB0486 PRESENTING MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN A COHORT OF 100 SLE PATIENTS FROM A SINGLE CENTER

M. Sefik Bukilica[1,2], N. Terzic Stanic[2], L. Kovacevic[2], O. Pajic[2], N. Vujasinovic Stupar[2]. *[1]Medical Faculty, University of Belgrade; [2]Institute of Rheumatology, Belgrade, Serbia*

**Background:** Systemic lupus erythematosus (SLE) is a multiorgan disease with protean manifestations and its diagnosis can pose a considerable challenge.

**Objectives:** The aim of the study was to analyze clinical and laboratory manifestations at the onset of SLE and to compare ACR and the SLICC criteria for the classification of SLE.

**Methods:** A retrospective study of a well characterized SLE cohort of 100 patients was undertaken. All patients met four or more updated ACR criteria (range 4–8). The following data were collected: age, gender, initial manifestations, time from the first symptom or disorder to definite diagnosis and clinical and laboratory features at the time of SLE diagnosis.

**Results:** Of the 100 patients analyzed 91 were women, the mean age at the time of diagnosis was 36.56±11.61 years. The most common presenting features were mucocutaneous (77%) and musculoskeletal (76%) manifestations, fatigue (74.6%), fever (52%) and non-scarring alopecia (34%). Median time from the first symptom/disorder to diagnosis was 10 months (range 1–120 months). At diagnosis most of the patients had elevated inflammatory markers ESR and CRP (87.4% and 50% respectively). Anemia and leukopenia was detected in 61% and 48% patients respectively. Serositis was observed in 24%, renal manifestations in 15% and psychosis or seizures in 7% of patients. Positive ANA were present in 97% of patients, anti-dsDNA antibodies in 66%, anti-Sm antibodies in 29.8%, aCL in 18.2%, aB2GPI in 13.8%, LA in 27% and low complement levels in 44.3%. All patients met also SLICC criteria (range 4–11), and significant number of them fulfilled items not contained in updated ACR criteria (non-scaring alopecia, low complement and other neuropsychiatric manifestations).

**Conclusions:** The prevalence of various clinical and laboratory features associated with SLE in our patients is comparable to findings of most major studies. We have shown that some patients could be diagnosed earlier using SLICC criteria. Furthermore, elevated inflammatory markers support SLE diagnosis.

## AB0487 ANTIPHOSPHOLIPID SYNDROME AND EPILEPSY: WHERE DO WE STAND?

M.A. Noureldine[1], G. Harifi[2], A.A. Haydar[1], A. Berjawi[1], M. Nader[3], R. Elnawar[4], A. Sweid[5], J. Al Saleh[2], M.A. Khamashta[6], I. Uthman[7]. *[1]Gilbert and Rose-Marie Chagoury School of Medicine, Lebanese American University Medical Center-Rizk Hospital, Beirut, Lebanon; [2]Dept. of Rheumatology, Dubai Hospital, Dubai, United Arab Emirates; [3]Dept. of Neurology, Lebanese American University Medical Center-Rizk Hospital, Beirut, Lebanon; [4]Dept. de Neurologie, Universite Paris Diderot, Paris, France; [5]Dept. of Neurosurgery, Lebanese American University Medical Center-Rizk Hospital, Beirut, Lebanon; [6]Lupus Research Unit, The Rayne Institute, Division of Women's Health, St Thomas Hospital, London, United Kingdom; [7]Division of Rheumatology, American University of Beirut, Beirut, Lebanon*

**Background:** Epilepsy and seizures are commonly reported among the neurological manifestations of Antiphospholipid Syndrome (APS).

**Objectives:** To discuss the epidemiological, pathophysiological, laboratory, clinical, radiological, and therapeutic aspects of epilepsy/seizures in APS/ antiphospholipid antibody (aPL)-positive patients.

**Methods:** We searched the literature through Google Scholar and PubMed for all publications reporting on the epidemiology, pathogenesis, laboratory, imaging and associated clinical findings, and management of epilepsy/seizures in APS/aPL-positive patients. The following keywords were used: antiphospholipid, Hughes syndrome, anticardiolipin, lupus anticoagulant, anti-β2-glycoprotein I, partial, complex, generalized, and idiopathic epilepsy, seizure, and convulsion. All reports published between 1971 and 2015 were included.

**Results:** Temporal lobe epilepsy is particularly prominent in many APS cases. The prevalence of epilepsy/seizures in APS patients is approximately 8%, which is nearly 10 times the prevalence of epilepsy in the general population (0.5–1%). The pathogenesis is complex and may involve micro-thrombosis and/or immune-mediated neuronal damage. The association of seizures with aPL is more significant in the presence of SLE. Seizure patients with positive aPL tend to develop thrombocytopenia and livedo racemosa more frequently than those without aPL. The presence of SLE and the presence of neurological symptoms significantly correlate with the presence of white matter changes on MRI. In contrast, the correlation between aPL positivity and the presence of white matter changes is very weak. However, MRI can be normal in more than 30–40% of patients. New MRI techniques can better elucidate the pathology of brain damage in neuro-APS. The theurapeutic management of epileptic APS patients relies on anti-epileptic treatment and anticoagulant agents when there is evidence of a thrombotic event. The anti-thrombotic benefit of hydroxychloroquine and statins is supported by several studies.

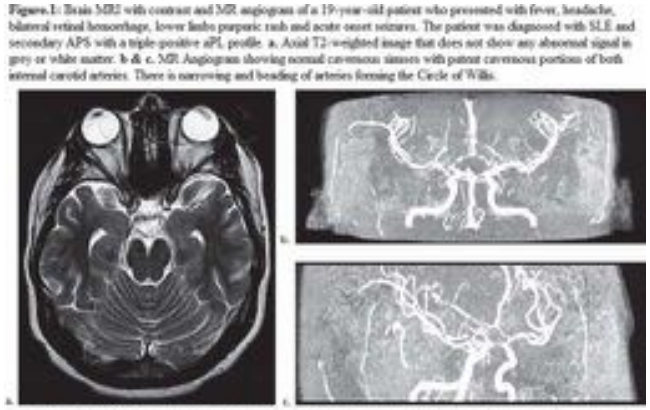

Figure.1: Brain MRI with contrast and MR angiogram of a 19-year-old patient who presented with fever, headache, bilateral retinal hemorrhage, lower limbs purpuric rash and acute onset seizures. The patient was diagnosed with SLE and secondary APS with a triple-positive aPL profile. a. Axial T2-weighted image that does not show any abnormal signal in grey or white matter. b & c. MR Angiogram showing normal cavernous sinuses with patent cavernous portions of both internal carotid arteries. There is narrowing and beading of arteries forming the Circle of Willis.

Legend: MRI, Magnetic resonance imaging; MR, Magnetic resonance; SLE, Systemic lupus erythematosus; APS Antiphospholipid syndrome; aPL, Antiphospholipid antibodies.

**Conclusions:** MRI remains the imaging modality of choice. aPL testing is recommended in young patients presenting with atypical seizures and multiple hyper-intensity lesions on brain MRI in the absence of other possible conditions. In the absence of consensual recommendations, the decision of lifelong anticoagulation in epileptic APS patients is discussed on a case-by-case basis.

## AB0488 CLINICAL, BIOLOGICAL AND IMMUNOLOGICAL FEATURES OF SYSTEMIC LUPUS ERYTHEMATOSUS IN A GROUP OF TUNISIAN PATIENTS

T. Ben Salem, M. Tougorti, I. Naceur, M. Lamloum, M. Khanfir, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease with wild spectrum manifestations. Disease severity and outcome are variable in different ethnic groups. The aim of this study was to describe clinical, biological and immunological features of SLE in a group of Tunisian patients.

**Objectives:** A retrospective study, including patients with SLE (Revised criteria of the American College of Rheumatology), followed in a department of Internal Medicine from 2000 to 2013. Data for demographic, clinical, biological and immunological characteristics of patients were recorded and analyzed. Treatment and outcome were described.
**Results:** Two hundred and forty six patients with SLE were included. The sex-ratio M/F was 0.14. The mean age at the disease onset was 32.96 years (ranges 6–72 years). The mean delay to diagnosis was 20±40. 3 months. Arthralgia, arthritis and cutaneous manifestations were noted in 90.2, 46.3 and 76% of cases respectively. Pleural effusion was observed in 25.6% of cases and pericarditis in 37% of patients. Lupus nephritis was diagnosed in 104 patients (42.3%). In the 81 patients who underwent renal biopsy, class IV nephritis was the most frequent (27 cases). Neuropsychiatric manifestations were observed in 20.6% of cases and 7.3% patients had peripheral neuropathy. Biological data revealed anemia in 73.2% of cases (Among them, 83.4% had a positive Coombs test), leucopenia (44.7%), lymphopenia (78%) and thrombocytopenia in 24% of cases. Antinuclear antibodies were positive in 97.2% of cases. Anti-dsDNA antibody was positive in indirect immunofluorescence and in ELISA in 141/190 and 76/91 patients respectively. Autoantibodies to extractable nucleair antigens were positive in 165/194 cases; anti-Sm antibodies were positive in 96/152, anti-nucleosome in 26/31, anti-histone in 48/82 and anti-ribosome in 16/67 cases (they weren't systematically screened). Low rate complement was observed in 83/140 cases. Chloroquine or hydroxychloroquine were given to 234 patients and 91.4% of patients were treated with corticosteroids (mean treatment duration: 64.13±50.83 months). Immunosuppressive drugs were added in 59.3% of patients; Cyclophosphamide (n=80), Azathioprine (n=52), Methotrexate (n=11) and Mycophenolate mofetil (n=3). The mean treatment duration of immunosuppressive therapy was 37.1±33.17 months. Relapses occurred in 62.8% of cases with a mean delay of 33.4±34.45 months. Mean follow up duration was 75.65±57.26 months. Remission was noted in 133 (54%) of patients. Twenty four patients died and 43 patients were lost to follow up. End stage renal disease was observed in five patients. Infections occurred in 143 cases. SLE was associated to Sjogren syndrome (n=41), antiphospholipid syndrome (n=29), systemic sclerosis (n=10), primary biliary cirrhosis (n=5), celiac disease (n=4) and to Kikuchi disease in 3 cases.
**Conclusions:** In our series, SLE patients had a high prevalence of cutaneous and articular manifestations. Nephritis lupus prevalence was similar to other African, Afro-american and Hispanic groups and lower than Asians. Global outcome was good with more than a half remission. Infections were frequent in our group (58%) because most of our patients had poor socio-economic conditions, in addition to their immunosuppression.

## AB0489 CENTRAL NEUROLOGICAL MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

T. Ben Salem, M. Tougorti, I. Naceur, M. Lamloum, M. Khanfir, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

**Background:** Central neurological manifestations are a serious and common complication of systemic lupus erythematosus (SLE).
**Objectives:** The aim this study was to determine the prevalence of central neurological manifestations in a group of Tunisian patients and to describe their clinical, imaging findings, their treatment and outcome
**Methods:** A retrospective study conducted in an Internal Medicine department over a period of 14 years (from 2000 to 2013). SLE patients with central neurological manifestations (criteria of the American College of Rheumatology) were included. Clinical, laboratory data and imaging features of these patients were analyzed.
**Results:** Fifty one patients had central neurological and /or psychiatric manifestations (20.7%). The mean age at diagnosis was 33.6±14.16 years. Sex ratio M/F was 0.10. Neurologic manifestations revealed the disease in 3.2% of SLE patients. The mean delay from SLE diagnosis to neurological manifestations was months 11.7±47.9 months. Clinically, headache was reported in 42.1% of cases and seizures in 39.4% of cases. Physical exam found: pyramidal syndrome (n=12), reflecting meningeal irritation (n=9), paraplegia (n=4) and chorea (n=2). Psychiatric manifestations were associated to neurological manifestations in 23.07% of patients: depression (n=8), anxiety disorder (n=7) and catatonia (n=2). Thirteen patients had only psychiatric manifestations: depression (n=9), anxiety disorder (n=5), catatonia (n=1). Antinuclear antibodies, anti-Sm and anti-Ribosome were positive in 49/50, 17/31 and 2/16 respectively. Aseptic meningitis was found in nine patients; lymphocytic (n=7) or polynuclear predominance (n=2). Magnetic resonance imaging (MRI) confirmed central nervous system involvement in 31 cases. Demyelinating aspect with high intensity signals were found in different localizations: periventricular (n=9), frontal (n=6), parietal (n=5), centrum semiovale (n=5), occipital (n=3). Cortical atrophy was observed in two patients. Two patients presented with stroke and one patient had cerebral venous thrombosis. MRI was normal in three patients. Antiphospholipid syndrome and Sjogren syndrome were associated to SLE in six and nine patients respectively. Patients had also arthralgia (96.1%), cutaneous manifestations (80.4%), pericarditis (31.4), pleural effusion (17.6) and lupus nephritis (37.2%). Patients were treated with antimalarial drugs (90.2%), corticosteroids (88.2%) and antiplatelet drugs (23.5%). Thirty two patients received immunosuppressive therapy: Cyclophosphamide (n=22), Azathioprine (n=9) and Methotrexate (n=1). Neurologic relapses were noted in 23, 7% of cases with a mean delay of 42.2 months. Remission was noted in 68.4% of patients with sequel in 38.4% of cases. Mean follow duration was 74.8±52.3 months.
**Conclusions:** Prevalence of central neurological and psychiatric manifestations in systemic lupus erythematosus varies widely in different studies (20 to 97%), depending on the studies style and the including criteria. They are a real challenge for clinicians because they need to exclude other related conditions (infections, drugs, ...) and primitive psychiatric disorders.

## AB0490 PLASMA VITAMIN D LEVEL IN PRIMARY SJOGREN'S SYNDROME – TUNISIAN COMPARATIVE STUDY OF 66 PATIENTS

M. Tougorti[1], A. Kallel[2], M.K. Ben fradj[2], I. Ben Ghorbel[1], M. Feki[2], J. Riadh[2], M.H. Houman[1], N. Kaabechi[2]. [1]*Internal Medicine;* [2]*Biochemistry, Rabta university hospital, Tunis, Tunisia*

**Background:** Beyond its critical function in calcium homeostasis, vitamin D has recently been found to play an important role in the modulation of the immune/inflammation system. Increasing numbers of study have established that vitamin D insufficiency contributes to a number of diseases, suggesting a range of physiological functions of vitamin D. Recent findings seem to show that low vitamin D levels in patients with Sjogren Syndrom could be associated with severe complications such as peripheral neuropathy.
**Objectives:** The purpose of this study was to evaluate plasma vitamin D level in Primary Sjogren's Syndrome (PSS) and comparing it with healthy controls.
**Methods:** North Africans patients (Tunisian patients) with PSS were diagnosed in an internal medicine department. All patients with PSS meet the revised AECG criteria 2002 and/or ACR proposed criteria 2012. We proceed in this prospective study with a comparison of plasma vitamin D between two groups, with a matched age and sex, one of patients with a Primary Sjogren's Syndrome (PSS) and a second of healthy control subjects. Sixty six patients with PSS were enrolled. Sex ratio was 0.11 (59 female (89.4%) and 7 male (10.6%)).Mean age at diagnosis was 49.07 years ±12.56 (range 26 -73years). Forty eight healthy controls were included. Sex ratio was 0, 14 (42 females (87.5%) and 6 males (12.5%). Registration and statistical analysis of data were done with SPSS. Plasma 25-hydroxyvitamin D (25-OHD) concentrations were measured by a competitive chemiluminescence immunoassay using the Liaison Analyzer (DiaSorin Inc., Stillwater, MN). The inter-assay CV was below 10%. Vitamin D deficiency was defined according to the most recent cut-points defined by The Institute of Medicine as 25-OHD concentrations $<10$ $\mu$g/L.
**Results:** Plasma vitamin D level of PSS patients was insufficient in 42.2% of cases (plasma vitamin D level $<30$ $\mu$g/L) and in 57.8% of cases plasma vitamin D level was lower than 10 $\mu$g/L. Plasma vitamin D was lower than 10 $\mu$g/L in 66.66% of healthy controls. There is no significant variation of plasma vitamin D levels according to sex, in the PSS group. Plasma vitamin D levels are not significantly decreased in patients with central and/or peripheral neurological manifestations compared to patients with no neurological symptoms. Plasma vitamin D levels are, however; significantly lower in male patients than controls.
**Conclusions:** The incidence of vitamin D deficiency seems more important for PSS patients than healthy controls. It might be interesting to study these patients to examine the outcome of the disease and its severity after a vitamin D supplementation therapy.
**Disclosure of Interest:** None declared

## AB0491 PLEURAL AND PULMONARY INVOLVEMENTS IN SYSTEMIC LUPUS ERYTHEMATOUS

T. Ben Salem, I. Naceur, M. Tougorti, M. Lamloum, M. Khanfir, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

**Background:** Pleural and pulmonary involvements (PPI) occur in almost half of the patients with systemic lupus erythematous (SLE). The aim of the study was to determine prevalence of these manifestations in a group of Tunisian SLE patients and to describe their clinical, biological, and immunological characteristics.
**Methods:** We conducted a retrospective study of patients who fulfilled the revised ACR criteria of SLE admitted in an Internal Medicine department over a period time of 14 years. Patients with PPI related to SLE were included. Infectious states were excluded. Respiratory involvements were evaluated using chest x-ray, computed tomography (CT) and pulmonary function tests.
**Results:** Sixty six SLE patients had PPI (27%). The mean age was 36 years (ranges 14 to 69 years). The sex-ratio M/F was 0.1. Clinical symptoms were dyspnea (6 cases), chest pain (4 cases) and fever (32 cases). The chest X-Ray was abnormal in 66 cases: pleural effusion (n=65), atelectasis (n=2) and parenchymal opacities (n=1). CT showed parenchymal bands in three cases and fluctuating multifocal opacities in one patient. Pleural fluid was lymphocytic in all cases. Pulmonary function tests showed restrictive syndrome in two cases.
PPI was found in 44 cases (67%) at the time of SLE diagnosis and revealed the

disease in 18 cases. In other cases, PPI occurred after mean disease duration of 44 months. Pleural effusion was confirmed in 65 patients. Two patients had Shrinking syndrome. Bronchiolitis obliterans was diagnosed in one patients and organizing pneumonia in another one. Pulmonary hypertension was noted in 4 patients. Other involvements were noted in all patients: pericardial effusion (77%), cutaneaous manifestations (74%), lupus nephritis (36%), neurological involvements (14%) and myositis (9%). Comparison of patients with and without PPI involvements showed that pericarditis was significantly more frequent in patients with PPI (76.2% vs 22.6%; $p<0.001$). Antibodies to extractable antigens and anti-SSB/La antibodies were more frequent in these patients (94% vs 82.6%; p=0.049 and 57.9% vs 28.4%; p=0.001 respectively).
Patients received steroids and immunosuppressant drugs in 88% and 51% of cases respectively. Pleural effusion was recurrent in 7 patients. Mean duration of follow up was 69 months (range 0–187).
**Conclusions:** SLE had a wide spectrum pulmonary manifestations; pleural effusion is the most frequent. PPI can be due to lupus itself or to other associated conditions. In all cases, possible infectious and drug-induced causes should be ruled out.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5502

## AB0492 MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CAUSES AND RISK FACTORS IN A GROUP OF TUNISIAN PATIENTS

T. Ben Salem, M. Tougorti, I. Naceur, M. Lamloum, M. Khanfir, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

**Background:** Mortality risk in patients with (SLE) is higher than in general population.
The aim of this study was to determine mortality causes in a group of SLE patients.
**Methods:** A retrospective study of patients who fulfilled the revised ACR criteria of SLE and admitted in an Internal Medicine department from 2000 to 2013. Data were recorded and analyzed for clinical, biological manifestations, infections and complications. Mortality causes were noted.
**Results:** Twenty three patients out of 246 SLE patients died (9.3%). They were 22 female and 1 male. Mean age at disease onset 33.5±16.1 years. During SLE course, patients presented with arthralgia (n=21), pericardial effusion (n=15), lupus nephritis (n=14), pleural effusion (n=9), hepatitis (n=7), neurologic manifestations (n=6) and pulmonary hypertension (n=2).
Patients were given corticosteroid in 95.6% of cases and immunosuppressive drugs in 60.8% of cases. Immunosuppressive treatment were based on cyclophosphamide (n=10), azathioprine (n=7), mycophenolate Mofetil (n=2) and cyclosporine (n=1). SLE was in remission in 82.6% of cases when death occurred and four patients were in relapse without other conditions.
Death was related to infections in 13 cases: pneumonia (n=5), urinary tract infection (n=4), skin infection (n=2), tuberculosis (n=1) and pulmonary aspergillosis (n=1). Three patients had cancer (one lung cancer, one cecum cancer and one still indeterminate). Death occurred in two patients because of heart failure and was related to a severe pulmonary hypertension. Pericarditis (65.2% vs 36.9%; p=0.01), anti-histone antibodies (83.3% vs 49%; p=0.031) and infections (91.3% vs 60.1%; p=0.004) were statistically more frequent in dead patients. Lupus nephritis was also more frequent in these patients (63.6% vs 43%; p=0.068).
**Conclusions:** Pericarditis and lupus nephritis were a poor factor prognosis in our series. Infection was the main cause of mortality in our patients. In addition to immunosuppression, poor socioeconomic status and lack of health care access in some patients can explain this high prevalence.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5615

## AB0493 RETINAL VASCULOPATHY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. Gao, M. Li, Y. Li, S. Zhang, S. Zhang, L. Zhao, L. Wang, F. Zhang, Y. Zhao, X. Zeng. *Peking Union Medical College Hospital, Beijing, China*

**Background:** Systemic lupus erythematosus (SLE) is one of the most common autoimmune diseases affecting multiple systems and organs. Retinal vasculopathy (RV) in SLE patients has a reported incidence of 3–29%[1–2]and often leads to poor visual outcome. However, there are limited data to date on this condition in Chinese patients, which might underestimate the importance of SLE with RV in daily practice.
**Objectives:** To analyze medical records of SLE inpatients from January 2006 to January 2016 and compare the clinical characteristics of SLE patients with and without RV.
**Methods:** All patients admitted to Peking Union Medical College Hospital from January 2006 to January 2016 fulfilled the revised ACR classification criteria for SLE (1997)[3]. For each case, two controls were randomly selected from contemporaneous SLE patients without clinical ophthalmic complaints.
**Results:** (1) The prevalence of RV was 0.66% (35/5298) in our cluster of SLE patients. The median duration of SLE before clinical retinal vascular disease was 12 months (range 0–168months). Seven out of 35 (20%) SLE patients with RV complained of ophthalmic disorders before they were diagnosed with SLE. Two patients presented ophthalmological disorder as initial manifestation. A total of 60 eyes were involved in these patients. Most (48/60, 80%) eyes presented with a decrease of visual acuity, 7/60 eyes had visual field loss, and 3/60 eyes presented diplopia.
The ophthalmic examination revealed cotton-wool spots (30/60, 50%), retinal vascular stenosis (31/60, 51.6%), vaso-occlusion (16/60, 26.7%) and hemorrhage (41/60, 68.3%)(Fig. 1).
(2) The nervous system involvement (51.4 vs. 24.3%, P=0.005) and hematological disturbance (62.9% vs. 34.3%, P=0.005) presented more frequently in patients in the case group than the control group.Patients in the case group presented a much lower frequency of positive anti-SSA antibodies than the control group (34.3% vs. 67.1%, P=0.001).
The patients in the case group had a more active SLE disease index. The mean (± SE) SLEDAI score was 19.9±0.9 points in cases compared to 10.2±0.7 points in controls ($P<0.001$).
(3)Nervous system disturbance (OR =4.340, 95% CI 1.438, 13.094, P=0.009) and leukocytopenia (OR =6.385, 95% CI 1.916, 21.278, P=0.003) were the independent risk factors, while anti-SSA antibody positive (OR =0.249, 95% CI 0.087, 0.710, P=0.009) was a protective factor for RV in SLE patients.

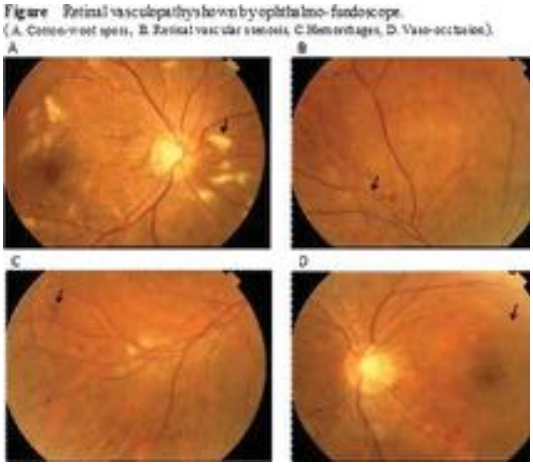

**Figure** Retinal vasculopathy shown by ophthalmo-fundoscope.
(A. Cotton-wool spots, B. Retinal vascular stenosis, C. Hemorrhages, D. Vaso-occlusion).

**Conclusions:** RV is one of serious ocular lesions in SLE patients not received enough attention yet in our Chinese clinical work. Fundus examination is recommended to be performed as soon as a patient is diagnosed with SLE to screen potential cases of RV in SLE patients. On the other hand, all RV patients with uncertain causes should be referred to a rheumatologist for further screening of SLE.

## AB0494 RISK FACTORS OF HEART DISEASE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N.A. Ganiyeva, M.B. Kasymova, F.K. Ziyayeva, E.R. Djurayeva, D.U. Berdiyeva. *Internal Disease, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** Cardio vascular diseases are caused by premature development of atherosclerotic vascular lesions and thrombotic complications and the third leading cause to death in patients with systemic lupus erythematosus (SLE).
**Objectives:** Identify associated risk factors of cardiovascular disease in patients with SLE.
**Methods:** A total of 92 patients (9 men and 83 women) with a documented diagnosis of SLE according to the ARA criteria. The age of patients ranged from 18 to 55 years of age, disease duration ranged from 3 to 24 years. More than half part of patients with SLE have a subacute course of the disease (78.6%) and the average level of activity (80.2%). In clinical surveys were taken into account family history of cardiovascular disease, smoking, hypertension, diabetes mellitus (DM), body mass index, menopause in women, stress. It was detected biochemical blood tests to determine the lipid profile - total cholesterol, VLDL cholesterol, LDL cholesterol, HDL cholesterol, triglycerides. Also surveyed cerebral circulation according to Doppler ultrasound of the brachiocephalic vessels (SPL cylinder head).
**Results:** Classical cardiovascular risk factors (one or more) occurred in 85 (92.3%) patients. Thus, were the predominant dyslipidemia (78.7% of patients), mainly due to triglyceridemia, increase the level of total cholesterol and low

density lipoprotein. Hypertension was detected in 32.7% of patients, smoking - 13.6%, overweight - at 45.4%, family history of cardiovascular disease - at 27.2%, diabetes - at 4.5%, menopause in women - 15.8%, stress - 35% of patients. During the cylinder head ultrasound carotid artery vasoconstriction by type was detected in 77.2% of patients.

**Conclusions:** The results of this study confirm the high probability of the development of atherosclerosis and related complications in SLE patients, which calls for the timely detection and correction of modifiable risk factors.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4951

## AB0495 BIOMARKERS ASSOCIATED WITH INCREASED RISK OF THE PRESENCE OF ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

N.M. Khalil[1], A.I. Badawi[1], A. Abdelhamid[1], E.M. Darwish[1], M. Wassef[2]. *[1]Internal Medicine; [2]Clinical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt*

**Background:** Systemic lupus erythematosus is a common autoimmune disease occurring predominantly in women during reproductive age. Antiphospholipid syndrome (APS) is a prothrombotic, systemic autoimmune disease. Tumor necrosis factor (TNF)-like weak inducer of apoptosis (TWEAK) is a recently identified proinflammatory cytokine of the TNF superfamily. The available evidences have indicated that TWEAK might be a target for therapeutic intervention in renal, vascular injury and neuropathy in systemic lupus erythematosus SLE. Hyperleptinaemia in the general population is also associated with atherosclerosis, hypertension and metabolic syndrome.

**Objectives:** Aim of the study was to evaluate the correlation between IMTand serum level of soluble TWEAK (sTWEAK), adipokine Leptin and traditional risk factors of atherosclerosis. Comparison between (sTWEAK) and Leptin in different studied groups.

**Methods:** The study is a case control study which conducted on 30 patients with SLE (A), 26 patients with secondry antiphospholipid syndrome (B), 14 patints with primary antiphospholipid syndrome (C) and 20 healthy volunteers with matched age and sex (D). All the study persons underwent full clinical assessment and investigations including Complete blood picture, ESR, kidney function tests, Lipid profile,body mass index.carotid duplex measuring intima media thickness (IMT). Serum soluble TWEAK and leptin using ELISA.

**Results:** The results showed high statistically signficant difference (P value $<0.001$) between group C and D, group B and C amd high statistically signficant difference (P value: 0.006) between group A and C as regards IMT. High statistically signficant difference (P value $<0.001$) between all groups as regards sTWEAK and leptin. With high level in those with antiphospholipid syndrome. There was no significant correlation btween (sTWEAK) and Leptin and IMT in different studied groups.

**Conclusions:** sTWEAK and leptin with other traditional risk factors can be a useful markers to predict and evaluate the presence of atherosclerosis in SLE and antiphospholipid patients.These findings should be taken into consideration as leptin contributes to increased oxidation, but further studies are required to determine whether hyperleptinaemia in patients with SLE contributes directly to increased oxidative stress.

## AB0496 OCCURRENCE OF VASCULAR ACCESS THROMBOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ON HEMODIALYSIS

N.O. El-Azizi, M. Abd El-Baky, A.B. Abd El-Aziz, E.S. Atwa. *Internal Medicine & Rheumatology, Facilty of Medicine- Ain Shams University, Cairo, Egypt*

**Background:** In patients with lupus nephritis, the presence of antiphospholipid antibodies (aPL) is considered to be an indication of increased risk of thrombotic microangiopathy, a serious complication of SLE [1].

**Objectives:** To assess the occurrence of vascular access thrombosis in SLE patients on regular hemodialysis & its relation to the presence of antiphospholipid antibodies.

**Methods:** The study included 50 SLE female patients on regular hemodialysis; patients further subdivided into; *group A* included 34 patients with thrombotic history and/or fetal loss and *group B* included 16 patients without thrombosis and *group C* 20 female patients on regular hemodialysis with end stage renal disease caused by diseases other than SLE with age matching as a control group. All recruited from the dialysis units in Ahmed Maher Teaching Hospital, and Ain Shams University Hospital. After informed consent all the study population underwent full history taking, detailed clinical examination, measurement of anti-ds DNA, ANA, anticardiolipin IgG & IgM and lupus anticoagulant in addition to CBC, PT, PTT, Creatinine, ALT & AST and duplex on A-V fistula with measurement of intima media thickness.

**Results:** Age & dialysis duration matched groups were selected (37.24±8.88, 35.69±10.91 vs 37.15±9.21 yrs & 5±3.06, 5.06±3.04 vs 5.65±3.17 yrs respectively). We found that the level of anticardiolipin IgG & IgM and lupus anticoagulant were highly significantly higher in patients of group A than group B than group C (62.18±8.84 vs 20.74±5.73vs 13.41±5.70 u/ml, 46.96±9.72 vs 9.99±3.85 vs 7.12±2.68 u/ml, 63.26±12.05 vs 38.31±6.33 vs 2±0 respectively) ($p<0.001$). Also there was a highly significant thrombocytopenia in group A (132.41±15.10 vs 270.56±64.78 vs 264.05±67.80x$10^3$/$\mu$l) with prolonged PT and PTT (17.14±1.74 vs 13.47±1.55 vs 12.40±2.33 sec. and 45.24±6.32 vs 33.25±4.71 vs 29.55±3.62 sec) than group B & group C ($p<0.001$). There was a highly significant increase in intima media thickness of A-V fistula in group A than group B & group C (119.94±22.22 vs 51.19±15.58 vs 61.91±34.55 mm) ($p<0.001$).

**Conclusions:** SLE patients on regular hemodialysis with positive antiphospholipid antibodies have higher incidence of occurrence of vascular access thrombosis.

## AB0497 THE PREVALENCE OF AUTOANTIBODIES IN LYMPHOPROLIFERATIVE DISEASES AND THEIR CLINICAL IMPORTANCE

O.N. Pamuk[1], M. Maden[2], G.E. Pamuk[2]. *[1]Rheumatology; [2]Trakya University Medical Faculty, Edirne, Turkey*

**Background:** The association between lymphoproliferative diseases, like chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphoma (NHL), and autoimmunity is well-known. The risk of development of lymphoproliferative diseases, primarily lymphomas, is higher in autoimmune diseases, like systemic lupus erythematosus (SLE), Sjogren's syndrome (SS) and rheumatoid arthritis (RA). Until now, various studies evaluated markers of autoimmunity, like antinuclear antibody (ANA).

**Objectives:** We evaluated the frequency of some autoantibodies in CLL and NHL; and investigated their association with clinical findings.

**Methods:** Onehundred-and-ninetynine NHL patients (113 males, 86 females, mean age: 55.1+16.4) and 64 CLL patients were included into the study (36 males, 27 females, mean gae: 62.4+12.4). Blood samples were taken from the patients at the time of diagnosis. ANA, ANCA tests and ENA profile when deemed necessary were assessed by the immunofluorescence method by same technician. Rheumatoid factor (RF), anti-CCP were evaluated by the nephelometry method. The demographic and clinical features and outcome of patients were obtained from medical charts. In addition, the frequency of CLL and NHL in our RA and SLE cohort were evaluated.

**Results:** In NHL group, ANA was positive in 44 (22.1%); RF in 13 (6.5%); anti-CCP in 3 (1.5%); and ANCA in one patient. In CLL group, ANA was positive in 20 patients (31.7%), and RF in 7 (11.1%) patients; ANCA was positive in 3 patients; and anti-CCP was positive in 2 patients. Our NHL group included 3 RA (1.5% 3/199), one SLE (0.5%, 1/199) and one SS (0.5%, 1/199) patients. Our CLL patients included one RA (1.6%, 1/63), one SS (1.6%, 1/63) and one ANCA-associated vasculitis (1.6%, 1/63). In NHL patients, the frequencies of ANA positivity (29.1% vs. 16.8%) and RF positivity (11.6% vs. 2.7%) were higher in female patients (p values, 0.039 and 0.011). In CLL group, there was a trend to more frequent ANA positivity (40.7% vs. 25%); and less frequent RF positivity (3.7% vs. 16.7%) in female patients (p values$>$0.05). ANA positivity in NHL patients was at least at a titer of at least 1/100 in 25 cases; in 19 patients, it was positive at higher titers. In CLL patients, on the other hand, ANA was positive at a 1/100 titer in 11 cases; in 9 cases, it was positive at a higher titer. The frequencies of ANA and RF positivity were most common in subtypes of marginal zone lymphoma (30.8% vs. 23.1%). The mean age in NHL group was also significantly higher in RF- positive patients than in other patients (64.3±12.5 vs. 54.4±16.5, p=0.036). In CLL patients, the frequency of lymphadenopathy was significantly higher in RF-positive (15.6% vs. 0%, p=0.05) and ANA-positive (42.2% vs 5.6%, p=0.005) groups than in others.

**Conclusions:** ANA was the most commonly encountered autoantibody in both CLL and NHL patients. RF positivity was more frequent in CLL. RF and ANA were associated with the presence of lympadenopathy. The most common autoimmune disease in patients with lymphoproliferative diseases was RA.

## AB0498 ETHNIC ASPECTS OF CHILDREN WITH SYSTEMIC LUPUS ERITHEMATOSUS

P. Ishuova, R. Maitbasova. *Scientific Center of Pediatrics and Children's Surgery, Almaty, Kazakhstan*

**Background:** Clinical, genetic aspects of rheumatic diseases with a relation to the patients' ethnicity have increasingly become the subject of wide discussion in recent years. The significance of this problem is clearly seen in systemic lupus erythematosus (SLE).
**Objectives:** Explore ethnic, genetic features in children with SLE.
**Methods:** The basis of this work was aimed to survey results and data of archival materials of 153 SLE patients observed in the clinic of the Scientific Center of Pediatrics and Pediatric Surgery, the Republic of Kazakhstan. We studied the course and outcome of systemic lupus erythematosus in children of Kazakh and Russian population and features of distribution of HLA-class I loci in children Kazakh population.
**Results:** We observed 153 patients with SLE at the age from 3 to 15 years and older, including 120 children of Kazakh nationality (78.4%), and 33 - of Russian nationality (21.6%). Evaluating the activity of pathological processes, depending on the ethnicity, revealed that the highest activity (74.1% vs. 24.2%) and acute (69.2% vs. 33.3%) were in Kazakh children. In assessing the overall disease activity by SLEDAI scale, the children of the Kazakh population had 38,9±5,1 against Russian 22,1± 4,1 points. Thus, acute and the high degree of activity of SLE prevailed in Kazakh children ($P<0.05$).
Given the severity and outcome of SLE in the indigenous children, we studied the association between SLE and HLA - class I antigens in Kazakhs children. This study was carried out for the first time in Kazakh children. Antigens of HLA system loci A, B and C were determined in 62 Kazakh children between the 7–16 years with SLE. The control group included 277 healthy test donors of the same nationality. The most common alleles in locus HLA-A SLE was HLA-A1 ($p<0.001$); the highest rate in the locus B was found in: HLA-B5 ($p<0,01$), HLA-B7 ($p<0.01$), HLA-B15 ($p<0.01$), HLA-B35 ($p<0.01$); in the locus C: HLA-CW3 ($p<0.01$). Among them the increase of the frequency of antigen HLA-A1 and HLA-CW3 were significant (Pcorr.=0.01–0.08).
Compared with donors, the positive level of association was found in HLA - A1 ($\chi^2$=14,62, RR=3,04, $p<0,001$), HLA-B7 ($\chi^2$=6,16, RR=2,30, $p<0, 01$), HLA-B15 ($\chi^2$=6,61, RR=2,51, $p<0,01$), HLA-CW3 ($\chi^2$=7,91, RR=2,91, $p<0.01$) and negative association in HLA-B5 ($\chi^2$=6,29, RR=0,41, p=0,01), HLA-B35 ($\chi^2$=7,06, RR=0,26, p=0,01).
As a result of the studies, four tentatively called "risk" antigens were found and the severity of its clinical manifestations - HLA-A1, HLA-B7, HLA-B15 and HLA-CW3. HLA-B5 and HLA-B35 had the protective nature of SLE. Given the fact that the studies discovered four tentatively called "risk" antigens – HLA-A1, HLA-B7, HLA-B15, HLA-CW3 and two protector antigens – HLA-B5, HLA -V35, they were compared with the position of the risk attribute (etiologic and preventive fraction). It was found that the greatest contribution to the development of the disease was brought by the antigen HLA-A1 (RR=3,04, EF=0,32), and vice versa, a contribution to the resistance of the disease was made by HLA-B5 (RR=0,41, PF=0, 21).
**Conclusions:** Acute and the high degree of activity of SLE prevailed in children of Kazakh population. Determination of loci HLA- A1, HLA -B15, HLA-B7 and HLA-CW3 has a great importance in the prediction of severity and related tactics of management and treatment of patients.

## AB0499 BONE MINERAL DENSITY IN POSTMENOPAUSAL MEXICAN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

P. Soto-Santillan [1], C. Mendoza-Pinto [2], S. Mendez-Martinez [2], L. Leon-Vazquez [2], I. Etchegaray-Morales [2], J.-C. Solis-Poblano [2], M.-A. Enriquez-Guerra [3], A. Montiel-Jarquin [4], A. Lopez-Colombo [5], M. Garcia-Carrasco [2]. *[1]Medicine School, Department of Immunology and Rheumatology, Benemérita Universidad Autónoma de Puebla, Puebla, México; [2]Systemic Autoimmune Diseases Research Unit, Hospital General Regional No. 36, Instituto Mexicano del Seguro Social, Puebla, Mexico; [3]edical Sciences, Medicine School, Benemérita Universidad Autónoma de Puebla, Puebla, México; [4]Division of Health Research, UMAE, HTO, Instituto Mexicano del Seguro Social, Puebla, México; [5]Direction of Health Education and Research, UMAE, HEP, Instituto Mexicano del Seguro Social, Puebla, México, Puebla, Mexico*

**Background:** It is accepted that patients with SLE exhibit an increased risk for low BMD and bone fractures; nevertheless, few studies have evaluated bone disorders in Latin American population. It is the first study that has evaluated frequency and correlations of low BMD in postmenopausal mestizo Mexican women with SLE
**Objectives:** To determine the frequency of osteoporosis and possible risk factor for low bone mineral density (BMD) in postmenopausal mestizo Latino American women with systemic lupus erythematosus (SLE)
**Methods:** A cross-sectional study was conducted among 100 postmenopausal patients with SLE. Patients were evaluated using a questionnaire about the follow variables: age at the time of the study, age at menopause, disease duration, disease activity, damage of the disease, cumulative corticosteroid dose, and history of fracture. Lumbar spine and hip measurements of BMD were performed by dual absorptiometry. Univariate and multivariate statistical analyses were used to assess relationship between risks factor and BMD.
**Results:** The mean age was 53.8±9.56 years and the mean SLE duration was 73.2±65 months. The mean BMD of the lumbar spine was 0.944±0.178 g/cm$^2$ and the hip was 0.915±0.135 g/cm$^2$. Osteopenia was present in 63% and osteoporosis in 31%. In the univariate analysis, age at the time of the study and menopause duration were associated with low BMD at the hip while age at the time of the study, menopause duration and damage of the disease were associated with low BMD at the lumbar spine. In the multiple regression analysis, low BMD in lumbar spine and hip were associated only with age (B= -0.0004, P=0.017; B= -0.0006, P= <0.05).
**Conclusions:** Osteopenia was found in 63% and osteoporosis in 31%. Risk factor for low BMD in both total hip and lumbar spine in postmenopausal SLE women was age.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5154

## AB0500 A NOVEL DNA-PEPTIDE COMPLEX DETECTS ANTI-DSDNA ANTIBODIES IN SLE SERA

P. Migliorini [1], F. Panza [1], M.C. Alcaro [2], F. Petrelli [1], F. Angelotti [1], F. Pratesi [1], P. Rovero [3]. *[1]Clinical Immunology Unit; Departement of Clinical and Experimental Medicine, University of Pisa, Pisa; [2]Toscana Biomarkers, Siena; [3]Department of Neurosciences, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy*

**Background:** The detection of anti-dsDNA antibodies is critical for the diagnosis and follow-up of SLE patients. The presently available assays are characterized by a non-optimal specificity (solid phase assays) or sensitivity (CLIF test).
**Objectives:** To overcome the limits of CLIFT and solid phase chromatin assays, we explored the diagnostic potential of an assay based on plasmid DNA containing a highly bent fragment of 211 bp from *Crithidia Luciliae* microcircles, complexed with histone peptides.
**Methods:** Electrically neutral complexes of PK201/CAT plasmid (PK) DNA and histone (H) 4 peptides were evaluated by electromobility shift assay. Complexes of H4 peptides and PK were absorbed to the solid phase to detect IgG antibodies in sera. Sera from 109 SLE patients, 100 normals and 69 disease controls (systemic sclerosis, Sjogren's syndrome, unclassified connective tissue disease) were tested.
**Results:** H4 (14–34) containing the consensus sequence for DNA binding interacts with PK retarding its migration. H4 (14–34)-PK complexes were used to test sera by ELISA; inhibition assays show that sera react with epitopes present on DNA or on the complex, not on the peptide. Anti-H4-PK antibodies were detected in 56% SLE sera (more frequently in patients with skin or joint involvement) vs 12% disease controls; antibody titer is correlated with ECLAM score and anti-C1q antibodies, negatively with C3 levels. Anti-H4-PK antibodies compared with CLIFT and solid phase dsDNA assays display moderate concordance.
**Conclusions:** The H4-PK assay is a simple and reliable test, endowed with high specificity and sensitivity, useful for the differential diagnosis and evaluation of disease activity of SLE patients. This assay increases the variety of anti-DNA antibodies that can be measured, complementing the assays currently used for the detection of anti-DNA antibodies.

## AB0501 SJÖGREN SYNDROME, CANCER INCIDENCE AND MORTALITY IN VIGO AREA

R. Lorenzo [1], A. Argibay [1], A. Sousa [1], N. Val [1], A. Baroja [1], B. Maure [2], M. Freire [1], A. Rivera [1]. *[1]Thrombosis and Vasculitis Unit, Hospital Alvaro Cunqueiro. University hospital of Vigo, Vigo (Pontevedra); [2]Internal Medicine, Hospital of Salnes, Vilagarcia de Arousa (Pontevedra), Spain*

**Background:** Sjögren's syndrome (SS) is a systemic autoinflammatory disease with a well known epidemiological and laboratory characteristics. Its main symptoms are derived from exocrine glands affectation. Like other inflammatory diseases presents an increased incidence of malignancies. The diagnosis of this entity and subsequent identification of factors associated with the occurrence of tumors is important for early detection and management
**Objectives:** To analyze the epidemiological, clinical and laboratory characteristics and the occurrence of lymphoma and mortality in a cohort of patients in a tertiary hospital diagnosed with SS
**Methods:** Descriptive analysis of data collected retrospectively of patients with SS (criteria American-European 2002) between November 1989 and November 2012 the Hospital of Vigo
**Results:** We describe 58 patients with SS of which 86% were women with a mean age of 53±15 years.Mean follow-up time was 69 months (range5–343). Mean age at diagnosis was 50 years (range 26–87 years).Only 6 (10%) had a secondary SS associated with Lupus Erythematosus Systemic, Rheumatoid Arthritis, Scleroderma, Mixed Connective Tissue Disease and Sarcoidosis. We do not find any autoimmune disease associated with organ-specific.The 84.5% and 93% had ocular and oral symptoms respectively.The parotid scintigraphy

was performed in 25 (43%), which was pathological in 37 (68%).Salivary gland biopsy was performed in 30 (52%), 28 were diagnostic (93%).The most common extraglandular involvement was the joint (50%),followed the skin and lymph nodes (both 12%).24% have Raynaud's phenomenon with capilaroscopia nonspecific. Others, were central and peripheral nervous system (8.6% each one), respiratory (7%) and kidney (3%). None had muscle involvement. Anti-Ro was positive in 83% (59% also had anti-La) and anti-La was positive in only 48%.Antinuclear antibodies and rheumatoid factor were positive in 95% and 67% respectively. 22 (38%) had low C4 and 10 (17%) had low C3. Cryoglobulins were positive in 2 (3%). Only two patients have anti-Ro and anti-La negatives (they had xerostomia and xerophthalmia, parotid scan and biopsy compatible with the diagnosis). The cancer incidence was 10%, 2 were solid tumors (one pancreatic adenocarcinoma and another invasive ductal breast cancer) and 4 were hematologic (diffuse B lymphoma, angioimmunoblastic T lymphoma, Hodgkin's lymphoma and nodal MALT). All those who developed lymphoma they had previous lymphadenopathy. The mortality rate was 12%: 4 neoplasia (2 lymphomas, 1 pancreas and 1 breast), 2 infections, 1 cerebral hemorrhage.

**Conclusions:** The 89.6% of our series had a primary SS with the same collected clinical and serological features literature. The development of a neoplasm was the leading cause of death (57.1%). In our cohort over half the patients who had lymphadenopathy developed a hematologic malignancy. SS patients have a higher risk for hematologic malignancy, so based on our data, the occurrence of lymphadenopathy it is a warning sign which requires us to actively seek a lymphoproliferative process

## AB0502 PREVALENCE AND CLINICAL CHARACTERISTICS OF SECONDARY SJÖGREN'S SYNDROME AND SICCA SYMPTOMS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN DAILY CLINICAL PRACTICE

R. Moerman[1], S. Arends[1], F. Kroese[1], F. Spijkervet[2], E. Brouwer[1], A. Vissink[2], H. Bootsma[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Department of oral and maxillofacial surgery, University Medical Center Groningen, University of Groningen, the Netherlands, Groningen, Netherlands*

**Background:** Patients with rheumatoid arthritis (RA) can develop sicca symptoms which may be related to secondary Sjögren's syndrome (sSS).

**Objectives:** To assess the prevalence and clinical characteristics of sSS in RA patients.

**Methods:** In this cross-sectional study, 96 consecutive established RA patients referred to our outpatient clinic were submitted to a complete diagnostic work-up for the presence of sSS according to the American-European Consensus Group criteria.[1] Patients underwent clinical examination including DAS-28 score, Schirmer's test and sialometry of submandibular/sublingual (SM/SL) glands and parotid (PAR) glands. In addition, patients were asked to complete the Health Assessment Questionnaire (HAQ), RAND-36 and Multidimensional Fatigue Inventory (MFI). Clinical characteristics were compared between RA patients fulfilling the criteria for sSS, RA patients with at least one sicca symptom of the eyes or mouth but no sSS and RA patients without sicca symptoms.

**Results:** Of the 96 included RA patients, 75 (78%) were female, mean age was 54±10 years and median disease duration of RA was 10 years (IQR 5–17). In total, 38 patients (39.6%) reported to have at least one sicca symptom of the eyes or mouth. Six patients (6.3%) were diagnosed with sSS. RA patients with sSS had higher disease activity, lower tears production and lower salivary flow rates compared to patients with and without sicca symptoms. Patients with sicca symptoms used more often xerogenic drugs, had higher disease activity and lower salivary flow rates than patients without sicca symptoms. No differences were found in the proportion of patients that were anti-SSA/SSB antibody positive between the groups. Furthermore, both patients with sSS and patients with sicca symptoms experienced worse physical functioning, lower health-related quality of life and more fatigue than RA patients without sicca symptoms (Table 1).

**Conclusions:** The prevalence of sicca symptoms and sSS was 39.6% and 6.3%, respectively, in our study group of established RA patients in daily clinical practice. Both the presence of sicca symptoms and sSS was associated with higher disease activity, impaired health-related quality of life and fatigue in RA patients.

Table 1. Clinical characteristics of RA patients with sSS, with sicca symptoms but no sSS, and without sicca symptoms.

| | sSS (n=6) | Only sicca (n=32) | Non-sicca (n=58) | P-value (overall) |
|---|---|---|---|---|

## AB0503 LARGE VESSEL VASCULITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS - A CASE SERIES FROM A SINGLE CENTRE IN SOUTH INDIA

R.V.P. Irlapati, A.R. Sabella, L. Rajasekhar. *Department of Rheumatology, Nizams Institute of Medical Sciences, Hyderabad, India*

**Background:** In Systemic lupus erythematosus (SLE), vasculitis is seen in 11% to 36% of patients. Small vessel vasculitis is seen in upto 86% and medium vessel vasculitis in the rest, and rarely large vessels are involved. We present a series of 4 such patients which is unique in that aortitis and lupus were diagnosed at the first presentation.

**Objectives:** To study the clinical profile of SLE patients presenting with Large vessel vasculitis (LVV).

**Methods:** Patients presenting to Rheumatology department between January 2012 and February 2015 fulfilling ACR criteria for SLE with evidence of large vessel involvement clinically and by Doppler ultrasound, CT angiography or MR angiography were included and followed prospectively. Demographic, clinical, laboratory and imagelogy data were studied.

**Results:** All patients were females, between 21–37 years of age. All had clinical features suggestive of SLE with a positive serology for ANA and double stranded DNA. Mean age of the patients was 25.25±4 years, with median duration of disease of 34.5 (range 4 -60) months with mean SLEDAI of 22±7.

All patients had history of claudication of extremities. Imaging findings are described in table 1.

Patients 1, 2 and 4 had subclavian artery and aortic bruit. Patient 3, who presented with cerebrovascular accident had MR angiography showing multiple focal intracranial vessel stenosis along with large vessel involvement. Three patients had nephritis, one had CNS lupus. Three patients had high ESR 68,106,70 mm after one hour. One patient had a positive Anticardiolipin antibodies (1/3). Three had low complements (3/3). Patient 2 underwent renal biopsy, and found to have class V lupus nephritis.

Patient 1,2 and 3 received intravenous pulse cyclophosphamide therapy, Patient 4 was treated with azathioprine. Patient 1 underwent PTCA to aorta and subclavian artery in view of persistent claudication. After a mean follow up of 29±22 months all patients are stable.

**Abstract AB0503** – Table 1

| Patient 1 | Patient 2 | Patient 3 | Patient 4 |
|---|---|---|---|
| CT angiogram | CT angiogram | CT angiogram | Doppler ultrasonogram |
| Circumferentially thickened descending aorta and left subclavian artery | Segmental stenosis (7cm) of descending thoracic aorta, upto level of aortic hiatus with post stenotic dilatation, stenosis of second part of left subclavian artery with irregularity of the wall. | Narrowing of the 1st and 2nd part of subclavian artey and entire left radial artey | Doppler showed reduced flow b/l subclavian brachial, radial, femoral, dorsalis pedis and posterior Tibial.A |

**Conclusions:** Large vessel involvement in SLE predominantly involves aorta and subclavian arteries and is associated with high disease activity.

## AB0504 HTR2A POLYMORPHISMS INFLUENCE IN SYSTEMIC LUPUS ERYTHEMATOUS CLINICAL, IMMUNOLOGICAL MANIFESTATION AND DAMAGE ACCRUAL

R. Faria[1,2], R.R. Dias[3], R. Ferreira[4], P.G. Pereira[1], I. Inácio[1], B.G. Leal[4], A.I. Tavares[4], A. Bettencourt[4], C. Carvalho[4], I. Almeida[1], A. Marinho[1], B. Martins da Silva[4], C. Vasconcelos[1] on behalf of Unit for Multidisciplinary Research in Biomedicine - ICBAS-UP. *[1]Unidade Imunologia Clinica, CHP, Porto; [2]Unit for Multidisciplinary Research in Biomedicine - ICBAS-UP; [3]Medicine Department, Centro Hospitalar do Porto; [4]Laboratório de Imunogenética - ICBAS-UP, Porto, Portugal*

**Background:** Serotonin receptor 1A and 2A genes polymorphisms (HTR1A and HTR2A) have been associated to increased risk of depression and suicide. Hypomethylated HTR1A has been associated to Systemic Lupus Erythematosus (SLE) patients manifestations. Preliminary results in our cohort showed an association between HTR2A polymorphisms and SLE manifestations development risk and depression risk in SLE patients.

**Objectives:** To investigate the association of 5-HTR2A polymorphisms (rs6314, rs6313) and clinical organ involvement, specific antibodies expression and damage accrual and time to damage accrual in SLE patients.

**Methods:** 75 SLE patients were evaluated for 5-HTR2A polymorphisms rs6314 and rs6313, by a Taqman assay and PCR-RFLP methodology, respectively. SLE diagnosis was based in ACR 1999 criteria, the organic involvement and specific antibodies were reviewed in the charts (Cumulative SLE manifestations for genetic studies) and damage was assessed by SDI (Systemic Lupus International Collaborating Clinics - Damage Index). Statistical analysis was made with SPSS 22.0.

**Results:** 75 SLE patients (70 female) with a mean age of diagnosis of 29.55 years old (SD 12.0) and mean follow-up time of 17,39 years (SD 7,70). Mucocutaneous involvement occurred in 88%, articular 85,3%, renal 46,7%, 30,7% neuropsychiatric. 38 patients (50,7%) had organ damage acrrual with a mean time to first damage accrual of 3,75 years (SD 6,88). 7 (9,3%) accrued renal damage and 15 (20%) neuropsychiatric. Polymorphism distribution was rs6313 (CC 22,7%, CT 54,7% e TT 14,7%) and rs 6314 (CC 86,7%, CT 13,3%). No association was found between these polymorphisms and any clinical involvement, cytopenias, antibodies, damage accrual or time to damage. Neuropsychiatric damage accrual was earlier in patients carrying CC rs6314.

**Conclusions:** Contradictory results are a very common phenomena in studies of complex diseases mainly due to the interaction fo several genes. Although poorly studied the serotonin receptor and transporter genes have been linked to SLE development and depression in SLE patients. In our study, there was no relation between any clinical or serological manifestations and the rs6313 and rs6314 HTR2A polymorphism but the earlier neuropsychiatric damage accrual opens a window of doubt of what might be the role of serotonin in SLE heterogeneity.

## AB0505 PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC LUPUS ERYTHEMATOSUS

R. Dhahri, I. Gharsallah, N. Boussetta, S. Sayhi, L. Metoui, F. Laajili. *Internal medicine, Military Hospital of Tunis, Tunisia, Tunis, Tunisia*

**Background:** Pulmonary arterial hypertension (PAH) is a rare disease characterized by the progressive increase in pulmonary artery pressures, leading to right heart failure. Systemic lupus erythematosus (SLE) is the second connectivity after Scleroderma can be complicated by PAH. This study aims to estimate the prevalence of PAH in SLE, detected by echocardiography.

**Methods:** This is a retrospective study of ten years about 80 patients with SLE fulfilling the criteria of the ACR (American College of Rheumatology), followed in our department of internal medicine. Echocardiography with measurement of pulmonary artery pressure was performed in 72 patients. Above 30 mmHg mean arterial pressure was used to define PAH.

**Results:** Ten patients (7% of cases) had pulmonary arterial pressure greater than 30mmHg. Two of them had lung disease (the first with emphysematous lung and the other a lupus interstitial lung disease). Three patients had mitral insufficiency. A syndrome of anti-phospholipid antibodies (APS) was noted in four patients (40% of cases). Five other lupus patients had isolated PAH (50% of cases). We noted a positive anti-Sm antibody in three patients (40% of cases).

**Conclusions:** PAH is a rare and severe complication of SLE and is a bad prognostic factor. Its detection is based on echocardiography. PAH lupus may be the expression of APS or secondary to pulmonary fibrosis or left valvulopathy. The treatment is based on corticosteroids and immunosuppressive association. Anticoagulants are indicated in cases of APS.

Due to the severity of PAH in SLE, a screening echocardiography should be systematically offered to patients with SLE to treat early this serious complication and to enhance prognosis.

## AB0506 SYSTEMIC LUPUS ERYTHEMATOSUS: NEUROPSYCHIATRIC MANIFESTATIONS

S. Monov[1], D. Monova[2], R. Rashkov[1], R. Shumnalieva[1]. *[1]Clinic of Rheumatology; [2]Medical Institute – MVR, Medical University - Sofia, Sofia, Bulgaria*

**Background:** Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by autoantibody production, complement activation and deposition of immune complexes in tissues and organs. According to different authors about 25–79% of the SLE patients have neuropsyhiatric involvement (NPSLE) at same point of the disease course. The latter could be the only and single disease manifestation but often NPSLE is present in patients with active disease.

**Objectives:** Our objective is to present the results from our study about the neuropsychiatric manifestations in patients with SLE. Based on its results we propose a new set of criteria for NPSLE. The use of these criteria for the last 5 years in Bulgarian patients with SLE proved their high sensitivity and specificity.

**Methods:** In order to determine the type and incidence of nervous system (NS) damages clinical, laboratory, and instrumental examinations were performed in a total number of 225 patients with SLE for a total period of 9 years. Depending on the specific features of the clinical course the patients were divided into three groups: with clinically manifested NS damages, without clinically manifested NS damages and with incomplete SLE. Patients with rheumatoid arthritis and healthy controls matched for age and gender were used as control groups.

**Results:** The study showed high percentage (64,44%) of neuropsychiatric manifestations in the SLE patients. Cognitive dysfunctions were found in 49,33% of the SLE patients. According to this set of criteria the NPSLE diagnosis should be made in the presence of at least one indicator from the first group of criteria (seizures, psychosis, cerebrovascular event, lesion of cranial nerves, motor disturbances, quantitative alterations of consciousness) and at least two indicators from the second group of criteria (cognitive dysfunction, headache due to lupus, peripheral neuropathy, MRI changes, EEG changes, ENMG changes, positive aRPA, positive aPL) after excluding other causes than SLE for their occurrence.

**Conclusions:** The use of the proposed criteria of NPSLE with high specificity and sensitivity is of practical value allowing earlier detection of NS damages and introduction of adequate pathogenic treatment.

**Disclosure of Interest:** None declared

## AB0507 EARLY DETECTION OF ASYMPTOMATIC PLEUROPULMONARY MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS BY HIGH RESOLUTION CT AND PULMONARY FUNCTION TESTS

S.M. Ghanem, M.M. Ghanem, M.A. Hegazy, E. Abo Elftouh, A. Negm, S. Daabous. *Rheumatology, Faculty of Medicine, Cairo, Egypt*

**Background:** (SLE) is a prototype of an autoimmune disease with a broad variety of clinical manifestations, particularly affecting the kidneys and the central nervous

system. Autoantibodies against double strand DNA (Anti ds DNA) and a number of other nuclear and cytoplasmic antigens as well as spontaneous immunoglobulin producing cells are characteristic of SLE, reflecting an aberrant immune response (1). Patients may manifest serious and life threatening complications of the disease with relapses and remissions (2). Thoracic manifestations of the rheumatic diseases (RDs) are a significant cause of morbidity and mortality worldwide. The five RDs most frequently associated with pleuropulmonary disease are: Rheumatoid arthritis (RA), (SLE), Progressive systemic sclerosis (PSS), Polymyositis/dermatomyositis (PM/ DM), Sjogren syndrome (SS). The clinical presentation is highly variable, ranging from pleuritic pain alone to slowly progressive breathlessness accompanied by cough. On occasion RD may present acutely with overwhelming respiratory failure as the first pulmonary manifestation (3). Asymptomatic involvement is more common and abnormalities in pulmonary function tests have been cited in up to two thirds of patient with SLE in some studies.

**Objectives:** The aim of this study is the early detection of asymptomatic pleuropulmonary manifestation of systemic lupus erythematosus using high resolution CT and pulmonary function tests.

**Methods:** During study period (May 2013 to June 2015), 30 SLE patients (29 female and 1 male) were included in this prospective study. The patients were diagnosed according to the American College of Rheumatology criteria for the classification of SLE. All patients were asymptomatic for any pulmonary manifestations. Plain chest X-ray, HRCT and pulmonary functiontests (PFTs) were performed for all patients. Analysis of data was done by Compaq computer using SPSS (statistical program for social science version 14).

**Results:** The high resolution CT findings in the studied patients were positive in 12 (40%) out of 30 patients and negative in 18 (60%) out of 30 patients. The plain x-ray finding in the studied patients were positive in 3 (10%) out of 30 patients. The pulmonary function tests were as the following: restrictive disease in 5 (16.7%) out of 30 patients, the rest of patients were normal and no obstructive disease

**Conclusions:** The pulmonary manifestations are present in SLE patients even in asymptomatic cases, at some point of time during the course of the disease. Some of these manifestations may remain asymptomatic. The use of CT scan and pulmonary function tests will help in early recognition and introduction of the therapy will help in preventing the morbidity and mortality in such cases.

## AB0508 SERUM AND URINARY INTERFERON-GAMMA-INDUCIBLE PROTEIN 10 IN LUPUS NEPHRITIS

S.I. Nasef[1], A. El-Gohary[2], A. Hegazy[3], M.A.F. Abbas[4], N. Kamel[3].
*[1]Rheumatology and Rehabilitation, Faculty of Medicine, Suez Canal University, Ismailia; [2]Clinical Pathology, Egypt-Japan University of Science and Technology, Cairo; [3]Clinical Pathology; [4]Community Medicine, Faculty of Medicine, Suez Canal University, Ismailia, Egypt*

**Background:** Lupus nephritis (LN) is one of the serious complications of systemic lupus erythematosus (SLE). Finding reliable non-invasive biomarkers for LN will help to improve disease outcomes. IFN-γ-inducible protein 10 (IP-10) is a pro-inflammatory chemokines which is involved in the immunopathogenesis of LN. Thus, we investigated the role of IP-10 as a potential marker of LN.

**Objectives:** To identify the sensitivity, specificity and cut-off value of serum and urinary IP-10 level in LN patients compared to albumin/creatinine ratio and anti-dsDNA.

**Methods:** We included 30 female SLE patients and 10 age-matched healthy female controls. SLE disease activity index (SLEDAI) was calculated. Active SLE was defined as SLEDAI $\geq$4. Patients were divided into 10 SLE patients with LN, 10 active SLE without LN and 10 inactive SLE patients. Serum and urinary levels of IP-10 were measured by ELISA. Anti-dsDNA and urine albumin/creatinine ratio were measured. Renal biopsy was performed to LN patients.

**Results:** Mean age of patients was 30±10 years versus 32±9 years in controls. Mean disease duration was 52±16 months. Mean SLEDAI was 10.2±3.6.

Active SLE patients had significantly increased serum IP-10 (324±224 pg/dl) and urinary IP-10 (172±206 pg/dl) as compared to inactive SLE (215±188 pg/dl and 121±150 pg/dl respectively) ($P<0.01$) and healthy controls (103±28 pg/dl and 32±13 pg/dl respectively) ($P<0.008$).

No significant difference was found in serum and urinary IP-10 levels between active LN and active non-renal patients, even in biopsy-proved proliferative LN patients.

Serum and urinary IP-10 positively correlated with SLEDAI ($r=0.416$; $P<0.02$) and ($r=0.448$, $P<0.01$) respectively.

By receiver operating characteristics (ROC) analysis, serum and urinary IP-10 could be used to diagnose SLE with serum IP-10 being better [p=0.011, AUC, 95% confidence interval (CI) = 0.772 {0.629–0.915}, P=0.018, AUC 95% CI = 0.753 (0.606–0.901) respectively].

A value of serum IP-10 116.5 pg/ml as a cut-off value is best in differentiating SLE patients from healthy controls with 76% sensitivity and 70% specificity. A value of urinary IP-10 37.9 pg/ml is best in indicating SLE with 70% sensitivity and 70% specificity.

Serum IP-10 could differentiate active from inactive SLE [P=0.007, AUC (95% CI = 0.753 (0.594–0.911)]. It is better than urinary IP-10, albumin/creatinine ratio and anti-dsDNA [AUC {95% CI = 0.654 (0.467–0.841); {0.529 (0.317–0.742)} {607 (402–812)}].

A value of serum IP-10 136 pg/ml is best in differentiating active from inactive SLE with 81% sensitivity and 71% specificity.

Serum and urinary IP-10 did not significantly differentiate either LN from SLE without LN [AUC 95% CI = 0.633 (0.430–0.837), 0.610 (0.397–0.823)], nor active renal SLE from active non renal SLE (AUC [95% CI = 0.533 (0.230–0.837), 0.700 (0.431–0.969)].

Albumin/creatinine ratio is a better marker in differentiating between SLE with LN and SLE without LN [P=0.008, AUC (95% CI = 0.803 (0.610–0.995)]

Any of the serum and urinary IP-10, albumin/ creatinine ratio, and anti-dsDNA didn't correlate with the class of lupus nephritis (P=0.658, 0.647, 0.807 and 0.069 respectively).

**Conclusions:** Serum and urinary IP-10 are useful markers of lupus activity; however, they are not indicative of renal activity. Albumin/creatinine ratio is superior in identifying LN and renal activity.

**Disclosure of Interest:** None declared

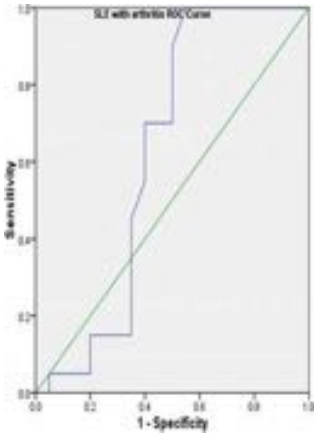
## AB0509 SERUM DICKKOPF-1 (DKK1) AND ARTHRITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS



S.I. Nasef[1], H.H. Omar[2]. *[1]Rheumatology and Rehabilitation; [2]Clinical Pathology, Faculty of Medicine, Suez Canal University, Ismailia, Egypt*

**Background:** Systemic lupus erythematosus (SLE) is a chronic multi-organ autoimmune disease. Among the various clinical manifestations, arthritis is one of the most common features. Arthritis in SLE is usually considered mild and non-erosive; however, chronic pain and deformities are frequently reported by patients with longstanding disease. The underlying mechanism for arthritis and joint damage in SLE is not very clear. It is increasingly recognized that Wnt pathway is considered as a key signalling pathway in bone homeostasis. Dickkopf-1 (DKK-1) is an inhibitory molecule that regulates the Wnt pathway. The potential role of DKK1 in the pathogenesis of arthritis in SLE patients is not clearly understood. Therefore, we are investigating the relationship between serum DKK-1 and arthritis in patients with SLE aiming at finding new therapeutic targets in SLE patients.

**Objectives:** To identify the sensitivity, specificity and cut-off value of serum DKK1 in SLE patients with arthritis.

**Methods:** We recruited 84 subjects (44 SLE patients and 40 age and gender-matched healthy control subjects). SLE patients were divided into 2 groups; the first group included 22 SLE with arthritis and the second group included 22 SLE patients without arthritis or joint involvement. Arthritis was based on the American college of rheumatology (ACR) definition in the classification criteria for SLE.To be included in the analyses, the arthritis must have been documented by the treating physician and have been present for at least the two weeks preceding the clinic visit. We used SLE disease activity index (SLEDAI) for assessment of disease activity. Active lupus was defined as SLEDAI $\geq$4. Serum DKK1 was measured using ELISA. We measured anti-dsDNA, C3, C4, CRP and ESR. Plain X-ray was done to all patients.

**Results:** Mean age of the patients was 34.6±4.7 and mean age of the controls was 32.07±8.1. Most of the study groups were females (88.6% of the patients and

87.5% of the controls). Mean disease duration was 8.4±4.5 years. Mean SLEDAI was 10.7±6.8.
Patients with SLE had significantly increased serum DKK1 (2749±1675 pg/ml) compared to controls (2020±771 pg/ml) ($P<0.019$). SLE patients with arthritis had significantly higher levels of serum DKK1 than SLE patients without arthritis (2748±199 pg/ml and 2462±331 pg/ml respectively) ($P<0.042$).
Serum DKK1 didn't show any correlations with SLEDAI, CRP, ESR, C3, C4 or anti-dsDNA levels. No correlation was found between serum DKK1 and disease duration or age of the patients.
By receiver operating characteristics (ROC) analysis, serum DKK1 could be used to diagnose SLE patients with a diagnostic cut-off value of 1560 pg/mL [area under curve (AUC) 0.631 (95% CI, 0.509- 0.755)], sensitivity 82.5%, and specificity 45.5%. A value of serum DKK1 1920 pg/mL as a cut-off value is best in differentiating SLE patients with arthritis from SLE patients without arthritis with sensitivity 70%, and specificity 50% [(AUC) 0.622 (95% CI, 0.432- 0.813)]. Serum DKK1 couldn't differentiate between active and inactive SLE patients.
**Conclusions:** High serum DKK1 level is associated with arthritis in SLE patients. Therefore, DKK1 could have a role in the pathogenesis of arthritis in SLE patients and strategies that block DKK1 may be of potential therapeutic interest.

## AB0510 CHRONIC DAILY HEADACHE DETERIORATES THE QUALITY OF LIFE IN KOREAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S.-H. Kim[1], H.-J. Jeong[1], J.-M. Kim[1], Y.S. Kim[2], H.-S. Kim[3], S.-J. Hong[4], S.-S. Kim[5], C.-N. Son[1]. *[1]Department of Internal Medicine, Keimyung University School of Medicine, Dongsan Medical Center, Daegu; [2]Department of Internal Medicine, Chosun University Hospital, Gwangju; [3]Department of Internal Medicine, Soonchunhyang University Seoul Hospital; [4]Department of Internal Medicine, Kyung Hee University School of Medicine, Seoul; [5]Department of Internal Medicine, Ulsan University School of Medicine, GangNeung Asan Hospital, Gangwon-do, Korea, Republic Of*

**Background:** Headaches is common in patients with systemic lupus erythematosus (SLE) [1]. However, the lack of specific clinical distinctions for headache in SLE has made it difficult to elucidate its pathophysiology. Chronic daily headache (CDH) is a category of headache disorders that occurs more than 15 days per month and is associated with a profound decline in the quality of life [2].
**Objectives:** The aim of this study is to investigate the clinical characteristics of CDH in patients with SLE and their association with disease severity and the quality of life.
**Methods:** A total of 40 consecutive patients with SLE participated in the survey. We investigated headache characteristics, visual analogue scale (VAS) for pain, and six-question headache impact test (HIT-6) to evaluate the impact of headache on the quality of life. The patients underwent required blood tests for assessment of disease activity using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI).
**Results:** Six patients (15%) met the criteria for CDH. The total score of HIT-6 is significantly higher in SLE patients with CDH than in those patients who suffered from headache without CDH (P=0.027). SLE patients with CDH in particular had a higher prevalence of "wish could lie down" than those who suffered from headache without CDH (P=0.017). The multivariate regression analysis indicates that the headache days per month was a predictor for headache-related disabilities.
**Conclusions:** As far as we know, this is the first study of its kind to evaluate the correlation of CDH and the quality of life in Korean patients with SLE. CDH may deteriorate the quality of life in patients with SLE.

## AB0511 MINOR SALIVARY GLAND (MSG) BIOPSY FINDINGS IN INDIAN PATIENTS WITH SJÖGREN'S SYNDROME AND THEIR CORRELATION WITH EXTRA-GLANDULAR MANIFESTATIONS

S. Kumar[1], D. Puttegowda[2], P. Kamate[3], S. Pai[4]. *[1]Rheumatology; [2]Pathology, Columbia Asia Hospitals, Bangalore; [3]Medicine, Jawaharlal Nehru Medical College, Belgaum; [4]Pathology, Columbia Asia Hospitals, Bangalore, India*

**Background:** Minor salivary gland (MSG) biopsy has assumed greater importance in the classification of patients with Sjögren's syndrome fter publication of the ACR criteria[1]. In addition, germinal center (GC) like structures on MSG biopsy, have been reported to predict future risk of lymphoma[2]. Sjögren patients in India are younger and have more extraglandular features compared to western cohorts.[3] There has been no data regarding biopsy findings and ACR criteria utility in Indian patients.
**Objectives:** Determine utility of MSG biopsy in Indian Sjögren patients. Determine correlation of biopsy findings with extraglandular manifestations of Sjögren's syndrome.
**Methods:** After Institutional Ethics Committee approval, a retrospective review was done to determine all minor salivary gland biopsies in our hospital from July 2013 to Sept 2015.Among the biopsy specimens, patients diagnosed as Sjögren's were selected and their slides were reviewed by pathologist.Clinical characteristics were determined by retrospective chart review.
**Results:** A cohort of 26 patients emerged. Nearly all were female (25/26) and fulfilled the ACR criteria (25/26). The mean age was 56.9 years.Twenty one patients had an extra glandular manifestation.Arthritis was seen in 14 patients,2 patients had renal involvement 2 patients had vaculitis,3 patients had interstitial lung disease,1 patient had pulmonary artery hypertension, and hematological involvement was seen in 7 patients.Salivary gland biopsy was positive in 20. ANA was positive in 23 of 26 patients, RF in 16/25, anti-Ro antibody in 8/18 & anti-La in 7 of 18 patients.The mean focus score was 1.7/mm$^2$ with a maximum score of 9.57/mm$^2$.There was no statistical difference in proportion of positivity of biopsy (4/5) or mean focus score (2.01/mm$^2$)between patients with extra glandular involvement and those without (16/21 and 1.71/mm$^2$).Mean focus score and proportion of positive MSG biopsy was also similar between patients with arthritis and those without. Only 2 patients (7.7%) had germinal centers (GC) like structures in the biopsy.Both patients with GC like structures had extra glandular features, were biopsy positive and had a focus score of 6.175/mm$^2$. Among patients without GC like structures 19 out of 24 had extra articular features, 18 out of 24 were biopsy positive and the mean focus score was 1.41/mm$^2$. These patients are under follow up for possible progression to lymphoma.
**Conclusions:** In this small cohort of Indian Sjögren's patients who had undergone biopsy the ACR criteria was sensitive enough to be fulfilled in nearly all patients.Similar to previous Indian series, extra glandular features were more frequently observed compared to western cohort. Only two patients had germinal centers.(c.f. ~25% in Theander et al.[2]).Among patients with GC like structures there seemed to higher focus score and more extraglandular features.However, biopsy findings did not appear to correlate with extraglandular manifestations.

## AB0512 USE OF NOMINAL GROUP TECHNIQUE TO FACILITATE ITEM REDUCTION FOR SLE CLASSIFICATION CRITERIA DEVELOPMENT

S. Johnson[1], D. Khanna[2], R. Cervera[3], N. Costedoat-Chalumeau[4], D.D. Gladman[1], B.H. Hahn[5], F. Hiepe[6], J. Sanchez-Guerrero[1,7], E. Massarotti[8], D. Boumpas[9], K. Costenbader[8], D. Daikh[10], D. Jayne[11], T. Dorner[12], D. Kamen[13], M. Mosca[14], R. Ramsey-Goldman[15], J.S. Smolen[16], D. Wofsy[10], M. Aringer[17]. *[1]University of Toronto, Toronto, Canada; [2]University of Michigan, Michigan, United States; [3]Hospital Clinic, Barcelona, Spain; [4]Hôpital Cochin, Paris, France; [5]University of California Los Angeles, Los Angeles, United States; [6]Charite University Hospital, Berlin, Germany; [7]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [8]Harvard Medical School, Boston, United States; [9]University of Athens, Athens, Greece; [10]University of California, San Francisco, United States; [11]Addenbrooke's Hospital, Cambridge, United Kingdom; [12]Charite University Hopsital, Berlin, Germany; [13]Medical University of South Carolina, Charleston, United States; [14]University of Pisa, Pisa, Italy; [15]Northwestern University, Chicago, United States; [16]Medical University of Vienna, Vienna, Austria; [17]University Medical Center Carl Gustav Carus, Dresden, Germany*

**Background:** Criteria for the classification of SLE are being developed with the support of EULAR and ACR. Two independent exercises (expert-based Delphi exercise and data-driven cohort evaluation of early SLE and controls) were undertaken to generate candidate criteria, and then reduce them to a smaller set.
**Objectives:** To select a set of items that maximizes the likelihood of SLE in a person with an uncertain diagnosis.
**Methods:** A panel of seven international SLE experts (reflecting practice in Spain, France, Germany, United States, Canada and Mexico) was asked to rank 41 candidate criteria nominated in the Delphi and cohort studies. The rankings were presented at a face-to-face meeting of the expert panel and steering committee. A consensus meeting using nominal group technique (NGT) was conducted to reduce the list of criteria for consideration. Redundant or poorly performing criteria were removed.
**Results:** This expert panel NGT exercise reduced the candidate criteria for SLE classification from 41 to 21. The panel distinguished potential "entry criteria", which would be required for classification, from other potential "additive criteria", summarized in Table 1. Entry criteria were ANA by hep 2 immunofluorescence ≥1:80, and low C3 and/or low C4.
Additional work is needed to refine definitions*, to evaluate their independence and relationships within domains, and to ascertain item weights.
**Conclusions:** This expert panel NGT exercise resulted in 21 candidate SLE

Table 1. Additive criteria

| Lupus nephritis by renal biopsy with immune deposits |
|---|
| Rash with dermoepidermal interface changes and/or immunoglobulin and/or complement deposition on immunofluorescence |
| Anti-dsDNA antibody |
| Anti-Smith antibody |
| Presence of multiple autoantibodies* |
| Antiphospholipid antibodies (*LA, anti-Cardiolipin, anti-beta2GPI, or prolonged RVVT*) |
| Leukopenia (<4000/mm$^3$on 2 or more occasions) |
| Thrombocytopenia <100,000 on 2 or more occasions |
| Autoimmune hemolytic anemia |
| Active urine sediment (without UTI) |
| Persistent proteinuria (>0.5g/day) |
| Acute cutaneous lupus: SLICC definition |
| Chronic cutaneous lupus: SLICC definition |
| Alopecia with associated scalp inflammation |
| Arthritis (inflammatory arthritis tender or swelling)* |
| Serositis *(pleural, pericardial effusion, pleurisy, pericarditis, peritonitis)* |
| Oral mucosal lesions on the hard palate |
| CNS manifestations *(seizures, psychosis, chorea, myelitis, optic neuritis, stroke or acute confusional state*) |
| Fever* |

classification criteria. Refinement of definitions, ability to cluster criteria into domains and weighting of criteria will be ascertained in the next phase.

## AB0513 PREGNANCY OUTCOME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

O.N. Pamuk[1], M.A. BAlci[1], N. Yilmaz[2], S. Yavuz[2]. *[1]Rheumatology, University of Edirne, Edirne; [2]Rheumatology, Istanbul Bilim University, Istanbul, Turkey*

**Background:** Systemic lupus erythematosus (SLE) is associated with increased pregnancy complications. In addition, pregnancy may lead to disease exacerbations in SLE. Another problem is infertility and early menopause caused by drugs, like cyclophosphamide.

**Objectives:** In this study, we aimed to evaluate pregnancy complications and menstrual problems in SLE patients.

**Methods:** Out of 400 regularly followed SLE patients, 73 patients with 86 pregnancies during the last 5-year period from 2 centers were included. SLE patients were questioned about the presence of pregnancy, history of menstrual cycle, the method of contraception, status of fertility and exacerbation of SLE during pregnancy. Their medical records were evaluated to retrieve data about the pre-mentioned questions

**Results:** During this period, 10 SLE patients had come to hospital for the treatment of infertility. 7 of them became pregnant by in vitro fertilization. 52 of SLE patients planned pregnancy before conception. Fetal loss developed in 18 patients, 6 patients experienced preeclampsia during pregnancy. Premature delivery developed in 5 patients. The frequency of fetal loss tended to be higher in SLE patients with unplanned pregnancy (38.5 vs. 25%, p>0.05). Fetal loss was significantly higher in anti-phospholipid syndrome group (35% vs. 4.2%, p=0.002) and in SLE patients with hypocomplementemia (47.1% vs. 20.9%, p=0.059).

SLE flares were observed in 15 patients and nephritis (8 patients) was the most common finding of exacerbation. SLE flare group during pregnancy had a significantly higher rate of hypocomplementemia (84.6% vs. 30.8%, p=0.001), premature delivery (27.3% vs. 2.3%, p=0.023), and APS (27.3% vs 7%, p=0.056).

**Conclusions:** In our cohort, fetal loss and SLE flares were relatively higher. APS and hypocomplementemia were associated with fetal loss and disease flares.

**Disclosure of Interest:** None declared

## AB0514 ASSOCIATION OF ANTI-RO (SSA) SPECIFICITY WITH CLINICAL MANIFESTATIONS IN A SPANISH POPULATION

T. Rodriguez[1], P. Cossio[1], S. Rojas[1], V. Moreno[2], R. Veroz[1], M. León[1], J.J. Aznar[1], M. Espárrago[2], E. Chamizo[1]. *[1]Rheumatology; [2]Immunology, Hospital de Merida, Merida, Spain*

**Background:** The Ro/La system is considered as an heterogeneous antigenic complex, constituted by three different proteins (52 kDa Ro, 60 kDa Ro and La) and four small RNAs particles. Anti-Ro are the most prevalent specificity among many autoimmune diseases. There is controversy regarding the relation between the different subunits of Ro antibody and the appearance of certain clinical aspects both in patients with autoimmune diseases and in healthy people[1].

**Objectives:** To analyse antiRo Ab subtypes of people with or without autoimmune diseases criteria and determine whether there is a relation with any type of involvement.

**Methods:** We reviewed patients medical records who had more than one positive determination of anti-Ro, between 2010 and 2012 in the hospital of Merida, Spain. We collected data to support the existence of xerophthalmia and xerostomia, mucosal ulcers, Raynaud's phenomenon, arthritis, interstitial lung disease (ILD), serositis, neurological involvement (polyneuropathy, mononeuritis multiplex and central involvement), nephritis and cutaneous lesions (SCLE, DLE, photosensitivity, malar rash and alopecia). We use Xi2 and, when necessary, Yates correction, to determine if there exist significative relation between the described pathologies and antibodies to 52 kDa Ro, 60 kDa Ro and La.

**Results:** Data of the relation of each pathology with the anti Ro subunits are represented in Table 1. From the 131 patients, the frequency of antibodies was found: 11 anti-Ro52 Ab, 33 antiRo 60 Ab, 73 antiRo52/60 Ab, 14 patients with unknown pattern and 47 also had associated anti-La Ab. We found statistically significant in the following cases: Xerophthalmia and xerostomía with anti-La (p<0.01), mucosal ulcers with anti-La (p<0.05), ILD with antiRO52 (p<0.05), neuropathy anti-Ro52/60 (p<0.01) and antiLa (p<0.05); skin lesions with the abscence of anti-Ro52 (p<0.01) and the presence of anti-La (p<0.01). Of the 10 cases of ILD, three of them progressed to pulmonary fibrosis, all of them with antiRo 52, therefore with a relation statistically significant (p<0.01).

Table 1

| | Anti Ro antibody (n=285) | | | | Anti La & anti Ro Ab (n=121) | All patients (n=285) |
|---|---|---|---|---|---|---|
| | Ro 52+ (n=21) | Ro 60+ (n=63) | Ro52/60+ (n=177) | Unknow n=24 | | |
| Xerophtalmia-Xerostomia | 6 (9.4%) | 12 (18.7%) | 41 (64.1%) | 5 (7.8%) | 31 (48.4%) | 64 (100%) 48.8% |
| Mucosal ulcers | 3 (7.1%) | 8 (19.1%) | 28 (66.7%) | 3 (7.1%) | 21 (50%) | 42 (100%) 32.1% |
| Raynaud | 4 (12.1%) | 8 (24.2%) | 19 (57.6%) | 2 (6.1%) | 9 (27.3%) | 33 (100%) 25.2% |
| Artritis | 4 (10%) | 8 (20%) | 21 (52.5%) | 7 (17.5%) | 15 (37.5%) | 40 (100%) 30.5% |
| ILD | 3 (30%) | 3 (30%) | 4 (40%) | 0 | 3 (30%) | 10 (100%) 7.6% |
| Serositis | 1 (7.1%) | 2 (14.3%) | 8 (57.1%) | 3 (21.4%) | 5 (35.7%) | 14 (100%) 10.7% |
| Neuropaty | 0 | 0 | 10 (22.2%) | 0 | 7 (77.8%) | 10 (100%) 7.6% |
| Nephritis | 0 | 4 (26.7%) | 10 (66.7%) | 1 (6.7%) | 6 (40%) | 15 (100%) 11.5% |
| Skin involvement | 0 | 18 (31.6%) | 36 (63.2%) | 3 (5.3%) | 24 (42.1%) | 57 (100%) 43.5% |

**Conclusions:** We found that the anti-La Ab, was associated with sicca symptoms, mucosal ulcers, neuropathy and skin lesions. Ro52 subunit had a positive association with the occurrence of ILD and its progresion to fibrosis and negative association with skin lesions. Anti-Ro60 positivity was unrelated to any involvement. AntiRo52/60 positivity were associated with the onset of neurological symptoms. Studies bigger and with a larger sample of patients to confirm these results are needed.

## AB0515 VITAMIN D, IL-10, IL-17, AND IL-23 AS BIOMARKER FOR DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

T. Senturk[1], B. Genc Cetin[2], G. Sargin[1], N. Aydin[3]. *[1]Rheumatology; [2]Internal Medicine; [3]Clinical Microbiology, Adnan Menderes Universty, Aydin, Turkey*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic, autoimmune, inflammatory disease and the prototype of multisystem autoimmune diseases. Several cytokines such as interleukin (IL)-10, IL-17, IL-23, and vitamin D have been suspected in the pathogenesis of SLE. However, the association between these cytokines, vitamin D and disease activity is unknown.

**Objectives:** We aimed to determine the association between IL-10, IL-17, IL-23, vitamin D and SLE disease activity index (SLEDAI) score.

**Methods:** We included 40 patients with SLE (mean age: 35.5±13.41 years, 95% female) and 20 healthy controls (mean age: 36.1±14.76 years, 70% female) in the study. Clinical and laboratory parameters and, SLEDAI score were evaluated. Serum IL-10, IL-17 and IL-23 were measured by nephelometry and vitamin D by HPLC (high-performance liquid chromatography). Mann-Whitney U and Kolmogorov-Smirnov test were used for statistical analysis. P<0.05 was accepted as statistically significant.

**Results:** The level of vitamin D was significantly lower (p=0,003), and IL-23 was significantly higher (p=0,001) in SLE patients compared to healthy controls. There was no significant difference for IL-10 and IL-17 between both group (p>0,05). However, a significant correlation between vitamin D and disease duration (p=0,02), and between IL-23 and vitamin D (p=0,019) were found among SLE patients. Vitamin D levels were correlated with SLEDAI score and IL-23 in patients group.

**Conclusions:** Although there are studies suppporting the role of IL-10 and IL-17 in the pathogenesis of SLE in the literature, there was no significant difference between patients and healthy controls in our study. IL-23 levels were significantly higher, whereas vitamin D levels were significantly lower in SLE patients than in the control group. Also vitamin D levels were negative correlated with duration of

disease and IL-23. Levels of IL-23 may be used to evaluated the disease activity, or may be a promising therapeutic approach for SLE patients.

## AB0516 SERUM LEVELS OF FAS/APO-1 AND FAS LIGAND (FASL) IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

T.A. Panafidina, M.A. Sokhova, T.V. Popkova, M.A. Cherkasova, A.A. Novikov, E.N. Aleksandrova, E.L. Nasonov. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Apoptotic defects have been proposed to explain the pathogenesis of systemic lupus erythematosus (SLE). Fas/APO-1 and FasL, members of the tumor necrosis factor (TNF) families, are involved in apoptosis. They are expressed in membrane-associated as well as soluble forms (sFas/APO-1 and sFasL).
**Objectives:** The aim of this study is to determine serum levels of sFas/APO-1 and sFasL in patients with SLE.
**Methods:** The study included 48 pts (90% females, age 30,0 [27,0–44,5] years (median [interquartile range 25%>75%]) with SLE (ACR criteria, 1997) and 10 controls (100% females without any rheumatic and infectious diseases, age 39,5 [31,0–45,0] years, $p>0,05$). SLE-related factors, including disease duration, clinical features, SLE Disease Activity Index (SLEDAI 2K) and Systemic Lupus International Collaborating Clinics (SLICC) damage index were evaluated in parallel with relevant laboratory findings (blood and urine tests, CRP, immunoglobulins G, A and M, complement C3 and C4 fragments and others), autoantibodies (ANA, antiDNA, ENA-SSA, -SSB, -Sm, -RNP-70, aPL). Serum levels of sFas/APO-1 (pg/ml) and sFasL (ng/ml) were measured by ELISA (Bender MedSystem GmbH, Austria). Statistical analyses were performed with STATISTICA program, version 8.0.
**Results:** Mean SLE duration was 5,0 [1,0–12,0] years, SLEDAI 2K score - 9 [4–15], SLICC damage index score - 0 [0–1]. SLE pts had lower levels of sFas/APO-1 vs control (669,65 [487,90–791,40] vs 1456,90 [426,50–2060,80] pg/ml, $p<0,01$) and higher levels of sFasL vs control (0,10 [0,01–0,03] vs 0,07 [0,05–0,10] ng/ml, $p<0,05$). In SLE pts serum sFas/APO-1 level correlated with platelets absolute count (r=-0,292, $p<0,05$), creatinine (r=0,538, $p<0,0001$), urea (r=0,431, $p<0,01$), uric acid (r=0,698, $p<0,000000$), proteinuria (r=0,311, $p<0,05$), cylindruria levels (r=0,365, $p<0,05$), glomerular filtration rate (r=-0,341, $p<0,05$) and systolic blood pressure (r=0,327, $p<0,05$), SLEDAI 2K (r=0,342, $p<0,05$), antiSSA (r=-0,467, $p<0,001$), antiSSB (r=-0,338, $p<0,05$), ACL IgG (r=0,434, $p<0,01$), CRP concentrations (r=0,446, $p<0,01$) and ESR (r=0,428, $p<0,01$). We divided SLE pts into two groups: Group 1 included pts with lupus nephritis (n=24 (50%)), Group 2 – SLE pts without nephritis (n=24 (50%)). Pts from Group 1 had higher, but not statistically significantly, levels of sFas/APO-1 as compared to Group 2 levels (706,15 [601,35–974,05] vs 591,90 [464,25–754,85] pg/ml, $p>0,05$).
**Conclusions:** The increased level of sFasL (a marker of apoptosis) and reduced level of sFas/APO-1 (apoptosis inhibitor that blocks binding of sFas/APO-1 to sFasL) in the study group is indicative of up-regulated apoptosis in SLE patients. Established correlation of sFas/APO-1 concentration with indicators of kidney damage and SLEDAI 2K score allows us to consider sFas/APO-1 as a marker of lupus nephritis and high SLE activity.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4053

## AB0517 SEASONAL DISEASE ACTIVITY IN LUPUS NEPHRITIS IN NORTHERN PORTUGAL – RETROSPECTIVE STUDY

T. Meirinhos[1], E. Mariz[2], I. Castro Ferreira[3], R. Neto[3], E. Pereira[4], L. Costa[2]. [1]*Rheumatology, CHBV - Aveiro, Valongo;* [2]*Rheumatology;* [3]*Nephrology;* [4]*Internal Medicine, CHSJ, Porto, Portugal*

**Background:** Systemic lupus erythematosus (SLE) is a multifaceted autoimmune disease driven by auto-reactive immune cells that target multiple organ systems leading to severe complications. A main complication of SLE is nephritis, formally known as lupus nephritis (LN) that is classified as a secondary form of glomerulonephritis. Exposure to sunlight is one of the environmental factors involved in the pathogenesis of systemic lupus erythematosus. Previous studies of a seasonal influence on SLE activity have conflicting results, suggesting that there was only an increased incidence of photosensitive rashes in the summer months, whereas others found more articular pain in the winter and spring. A study of renal biopsies found that the prevalence of class V lupus nephritis was significantly higher in Winter and Spring.
**Objectives:** To determine, in a cohort of adult LN patients, whether there is any seasonal variation in the activity of LN, and possible correlations between specific organ involvement, gender and disease duration.
**Methods:** Retrospective study, enrolling patients attending a Rheumatology/Nephrology outpatient department, diagnosed with SLE (according to the American College of Rheumatology criteria) and LN. Fixed variables: age, gender, race, disease duration, LN treatment phase, histological classification (renal biopsy), specific organ involvement and therapeutics for SLE, including glucocorticoids. Clinical variables evaluated 2 times for year (one in winter; one in summer, without change in therapeutics): anti-dsDNA antibodies, serum urea and creatinine, urinary sediment and protein-to-*creatinine* ratio (UPr/Cr). Statistical analysis with Microsoft Excel, version 2010; appropriate statistical tests was used, and a $p$ value$<0.05$ with a 95% confidence interval will be assumed.
**Results:** 73 SLE patients were enrolled in the study, 61 were female (84%); mean age was 40±11.5 years and mean disease duration was 118±102 months. All the patients were white. 51 patients (70%) had class 4 LN. 58 (79%) patients had extra renal disease, 34 with joint disease and 23 with cutaneous involvement. Mean UPr/Cr was superior in summer than winter (0.443±0.66mg/g Vs 0.401±0.84mg/g), this increase being statistically significant (p=0.04). Patients with SLE cutaneous involvement had higher renal activity in summer and higher seasonal variation (p=0.02). Mean dsDNA was superior in summer, but this difference wasn't statistically significant. No association was identified between seasonal disease activity and sex or disease duration.
**Conclusions:** Despite the reduced size of our cohort, we confirmed a seasonal pattern for Lupus Nephritis and renal disease activity in Northern Portugal, being higher in summer time, in possible correlation with an increase in temperature and duration of sunshine, expecially in SLE patients with cutaneous envolvement.

## AB0518 CLINICAL THROMBOTIC MANIFESTATIONS IN SLE PATIENTS WITH AND WITHOUT ANTIPHOSPHOLIPID ANTIBODIES: A TEN-YEAR FOLLOW-UP

T. Tarr[1], N. Nagy[1], E. Cserép[2], M. Zeher[1]. [1]*Division of Clinical Immunology;* [2]*Division of Psychiatric, University of Debrecen, Debrecen, Hungary*

**Background:** Systemic lupus eyrthematosus can bge associated with antiphospholipid syndrome. Years ago our study team investigated the thrombotic risk factors and complications in 272 lupus patients with and without antiphospholipid antibodies. At baseline, three groups were created, an aPL- group with 107 aPL negative patients, an aPL+ group with 81 aPL positive patients without clinical manifestations and a secondary antiphospholipid syndrome (APS) group with 84 aPL+ patients who met the Sapporo criteria.
**Objectives:** The objective of this study was to investigate of new thrombotic events, SLE activity,.co-morbidities, and mortality in total of 272 lupus patients for ten years of follow up.
**Methods:** The above mentioned 272 patients with SLE registererd in the Division of Clinical Immunology, University of Debrecen have been followed up prospectively for ten years.
**Results:** A total of 28 out of the 272 patients were lost to follow up. A total of 22 new thrombotic complicatons occurred, two in the aPL negative group, three in the aPL+ group. New antiphospholipid antibodies appeared in these patients. 77.3% of the new thrombotic complicatins reoccurred in the APS group despite the adequat anticoagulant and/or anti-platlet therapy. SLE activity was the most common in the APL+ group but the difference was not significant. A total of 27 out of 84 APS (32%), 14 out of 81 aPL positive and 10 out of 107 aPL negative patients died during the follow up. The causes of death were thrombotic events or complications in 40.7% in patients with APS.
**Conclusions:** Our data confirm recurring thrombotic events in lupus patients with antiphospholipid syndrome. Antiphospholipid syndrome seems to negatively influence the survival of the patients with systemic lupus erythematosus.
**Disclosure of Interest:** None declared

## AB0519 QUALITY OF LIFE OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION WITH DISEASE ACTIVITY AND ORGAN DAMAGE

V. Zivkovic[1], B. Mitic[2], B. Stamenkovic[1], S. Milenkovic[1], I. Aleksic[1]. [1]*Institute for Treatment and Rehabilitation "NIška Banja", Niska Banja;* [2]*Clinic of Neprhrology, Clinical Center, Nis, Serbia*

**Background:** In order to assess adequately the success of treatment of patients with systemic lupus erythematosus (SLE), the patient's individual perception of his physical and mental health and degree of integration into the community is required. The most commonly used standardized quality of life questionnaire, involving physical, mental and social acpects, is The Medical Outcome Survey Short Form 36 (SF-36). The results regarding the correlation of activity index and degree of organ damage in SLE patients with quality of life have so far been contradictory.
**Objectives:** Our aim was to evaluate the quality of life of SLE patients using the SF-36 questionnaire, and to establish the correlation of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), organ damage index - SLICC/ACR Damage Index (SDI) with quality of life.
**Methods:** The study enrolled 85 SLE patients aged 45.3±9.7 years on the

average, out of which 78 (91.8%) women and 7 (8.2%) men, with average disease duration of 10.4±8.0 years, hospitalized at the Clinic of Rheumatology, "Niška Banja" Institute, in whom the diagnosis was made based on the revised 1997 ACR criteria. Disease activity was assessed using the SLEDAI questionnaire, organ damage using the SDI, and quality of life using the SF-36 questionnaire. The control group consisted of 30 healthy examinees. Both groups were homogenous as to the factors of gender and age.
**Results:** Our results showed that there was significantly worse quality of life in all SF-36 domains in SLE patients compared to controls ($p<0.001$). The domain of physical functions in SLE patients had poorer results compared to mental functions (36.68 vs. 49.14), and average results were below 52% in all SF-36 domains. There were no significant differences in the values of all SF-36 domains between the group with lupus nephritis and those without it. The mean value of SLEDAI was 11.38±7.55, median was 8, minimum value 0 and maximum value 36. In the assessment of correlation between the SLEDAI and quality of life represented via the SF-36 questionnaire, we found only a negative correlation between limitations due to physical difficulties and SLEDAI ($r=-0.216$; $p<0.05$). The mean SDI value was 1.81±1.98, median 1, minimum value 0, maximum value 9. Our study demonstrated a negative correlation between all SF-36 domains and SDI ($p<0.001$ in most domains), with the exception of emotional status and SDI, where a correlation was not found.
**Conclusions:** Quality of life of SLE patients measured by the SF-36 index was significantly worse compared to healthy individuals. There was no difference in quality of life in any of SF-36 domains between those with and without lupus nephritis. Quality of life measured by the SF-36 index was not correlated with disease activity measured by the SLEDAI in most of the domains. Poorer quality of life was associated with a higher SDI, except for the emotional status domain.

## AB0520 MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS IN A ARGENTINIAN COHORT

V. Juarez[1], M. Aciar[1], N. Cucchiaro[2], R. Rojas Tessel[1], E. Picco[2], E. Buschiazzo[1], M.V. Lencina[1], M.D.L.A. Aciar[3], I. Artes Rocha[2], M.E. Crespo Espindola[1]. *[1]Rheumatology; [2]Internal Medicine, Hospital Señor del Milagro; [3]Endocrinologia, Hospital Arturo Oñativia, Salta, Argentina*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease associated with a high morbidity and mortality. The specific causes of death may vary among ethnic groups.
**Objectives:** To examine mortality rates related to SLE in a single Argentinian population.
**Methods:** A retrospective cohort study was designed. Clinical Record of SLE patients treated between 2000 and 2005 and followed until 2015 in a tertiary no academical hospital that does not attend pediatric population were reviewed, including demografic and clinical data. The cause of death was searched from the medical records and deaths certificates from the Public Health Archives. Continuous data was expressed in median and interquartile range (IQR), categorical data in frequency and percentage. Chi-square test or Fisher's test was used to analyse categorical data and Mann-Whitney or Student's T-Test for continuous data. Kaplan – Meier survival curves were calculated. A p value $<0.05$ was considered as significant.
**Results:** Fifty- five patients were enrolled, 48 women (87%), with a median age of 37 years (IQR:29–44.5), median disease duration of 9 years (IQR:3–12.3) and a total follow-up of 500 patients- years.Thirty- five patients (63%) were diagnoses after the first visit. Two (3.6%) were smokers, 16 (29.1%) had hypertension, 8 (14%) were diabetics and 9 (16.7%) has dyslipidemia. Treatments included glucocorticoids ($>10$ mg/ day of prednisone) in 47 (85%), immunosuppressive therapy 27 (49.1%) and anti-malarial 44 (80%). Renal involvement was found in 30 (54%) patients.
**Conclusions:** Long-term survival in a single center of SLE argentinian patients was low in comparation with oteher studies. An cumulative survival from diagnosis of 81% at 5 years and 61% at 10 years was observed. Infection and SLE activity were the main causes of death
**Disclosure of Interest:** None declared

## AB0521 QUALITY OF LIFE IN PATIENTS WITH SLE AND CUTANEOUS INVOLVEMENT

V. Sadovici-Bobeica[1], M. Cebanu[1], L. Mazur-Nicorici[1], V. Salaru[2], M. Pasali[1], M. Mazur[1]. *[1]Rheumatology; [2]Family Medicine, State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

**Objectives:** To establish the relationship between cutaneous involvement and Quality of Life (QoL) in patients with systemic lupus erythematosus
**Methods:** Cross-sectional study of SLE patients with cutaneous involvement, fulfilling SLICC/ACR 2012 classification criteria. Cutaneous involvement was assessed by Cutaneous Lupus Erithematosus Disease Area and Severity Index (CLASI), disease activity – by SLEDAI and SLAM and QoL by SF-8 questionnaire. The Pearson correlation coefficient was calculated between the variables.
**Results:** The study included 92 Caucasian SLE female patients with a mean age of 40,0±12,6 yrs and a mean disease duration of 5,1±5,8 yrs. The mean age at the disease onset was 33,5±11,4 yrs and the mean SLICC/ACR criteria number – 6,1±2,8 points. The disease activity by SLEDAI and SLAM was appreciated as high with 1,24±10,4 and 12,1±8,6 points, respectively. The SLICC/ACR DI constituted 1,47±1,6 points. The cutaneous involvment by CLASI showed a mean activity of 4,7 points and a damage of 3,0 points, mean CLASI score being appreciated with 7,2 points. The QoL by SF-8 demonstrated low indices, compared to general population, in both domains: Physical Component Summary (PCS) and Mental Component Summary (MCS) with a mean value of 37,74 and 38,72 points, respectively. The analysis of Pearson coefficient between the QoL and CLASI did not show significant correlation ($r\leq0,2$, $p>0,05$). The PCS og the QoL correlated inversely with the disease activity ($r=-0,58$ for SLAM and $r=-0,45$ for SLEDAI, $p<0,05$) and the MCS correlated inversely with SLICC/ACR classificatino criteria ($r=-0,45$, $p<0,05$). CLASI activity index correlated with SLAM and SLEDAI ($r=0,45$ for SLAM and $r=0,37$ for SLEDAI).
**Conclusions:** The QoL is dicreased in SLE patients by both components: physical and mental. The severity of cutaneous involvment did not correlate with the QoL's indices. Meantime, CLASI activity score correlated with disease activity and the MCP pf the QoL correlated with the number of SCLICC/ACR 2012 classification criteria.

## AB0522 ON THE POSSIBLE PROTECTIVE ROLE OF COMPLEMENT SYSTEM IN IMMUNE COMPLEX LUPUS NEPHROPATHY

V.I. Shishkin, Y.A. Malenkov, V.V. Shishkin, G.V. Kudriavtseva. *Saint Petersburg State University, Saint Petersburg, Russian Federation*

**Background:** The links between complement and SLE are complicated and fascinating. After many years of study, hypotheses are developing which may begin to explain these apparent paradoxical findings.
**Objectives:** To assess correlation between complement? Circulating immune complexes and organ pathology in SLE.
**Methods:** Of 277 patients enrolled, 252 were female (91%) and the mean age of the patients was 46.6 years (range 18 to 70). 194 patients (70%) had active disease defined as SLEDAI score. All patients met $\geq$4 ACR SLE criteria. Complement activity in serum was detected by hemolytic method in CH50 units. For the assay of immune complexes (CIC), polyethylene glycol (PEG) precipitation method was used. As a control we used sera from 100 healthy donors.
**Results:** During a long observation of SLE patients we identified variants of hypocomplementemia dynamics. In the group 1 there was almost continuous and increasing hypocomplementemia (75 patients). In the group 2 hypocomplementemia arose during exacerbation of the disease and the complement level was restored under the influence of treatment (67 patients). In the group 3, the activity of complement constantly corresponded to the normal level (135 patients). Glomerulonephritis was diagnosed in 50% of patients in the first group and 46% in the 2nd and in 35.3% in the third group. Renal failure was more frequent among patients in groups 1 and 2. In the group 3, it appeared significantly less often, because of long course of the disease. The average activity of the complement, depending on the group of patients differed, and the average concentration of CIC was highest in the group 3 and in groups 1 and 2 it was statistically less high and was almost the same in both groups. However, signs of inflammation, such as fever and ESR, CRP were higher in patients of the group 3. The activity of complement was the most low and CIC levels were high in patients with renal insufficiency. A decrease of complement activity in patients with the maximum degree of activity of SLE in 56% and 57%, respectively. When calculating the number of units of CH50 per number of units of CIC we get a new integral indicator of the activity of the disease in more than 89% of cases.
**Conclusions:** According to the activity of the complement system in SLE represents a heterogeneous group. The low level of activity of the complement system, characteristic for a certain group of patients contributes to the appearance of glomerulonephritis. High level of complement has a protective effect against renal pathology. The ratio of activity of the complement system and the level of circulating immune complexes has a specific pathogenic role in SLE.

## AB0523 CUTANEOUS MANIFESTATIONS IN PRIMARY SJOGREN'S SYNDROME

V. Durigan, C. Troitiño, V. Duarte, A. Secco, M. Mamani. *Hospital Bernardino Rivadavia, Buenos Aires, Argentina*

**Background:** Cutaneous manifestations are one of the most common extraglandular manifestations of Sjogren's syndrome (SS). Entities such as as Annular erythema, Sweet syndrome, erythema nodosum and vasculitis have been described. Vasculitis was reported in approximately 10% of SS patients, with histologically characterized by lymphocytic or leukocytoclastic vasculitis.
**Objectives:** Describe cutaneous manifestations in patients with primary SS, registered in the GESSAR (Argentine Study Group for the Sjogren Sydrome) database and determine their association with systemic and laboratory clinical manifestations.

**Methods:** Observational, analytical case-control study. Patients aged 18 years and older with a diagnosis of primary SS. Demographic, clinical and serological data about patients included in the GESSAR database was collected, from the moment of joining until June 2015. Cases (patients with cutaneous manifestations) and controls (patients without cutaneous manifestations) were included with a relationship 1:4. Cutaneous manifestations were described. In addition, patients with purple were compared to the rest of the patients included in the study. For the analysis of continuous variables t or Mann Whitney tests were used, according to distribution and sample size. Categorical variables were analyzed using chi-square or Fisher exact test, according to the expected frequency distribution table. Multivariate logistic regression analysis was performed.
**Results:** 335 patients were included, 67 with cutaneous manifestations, with an average age of 53 years (SD 15). 95% are female and the average diagnosis age is 47 years (SD 17). In the group of patients who had cutaneous manifestations, 60% had purple, 19% urticaria, 19% petechiae, 16% ulcers, 7% erythema multiforme, 4% erythema nodosum and 9% subcutaneous nodules. No statistically significant differences in age, sex and time of evolution of the disease between the two groups were found. In univariate analysis differences were found in: arthritis (47% vs 31%, p=0.01), neuropathy (21% vs 9%, p<0.01), decrease in C4 levels (34% vs 18%, p<0.01), decrease in C3 levels (25% vs 10%, p<0.01) and positive cryoglobulins (27% vs 9%, p<0.01). In the multivariate analysis no independent association of these variables was found. With respect to purple, significant differences were found with: arthritis (49% vs 31%, p=0.02), neuropathy (9% vs 25%, p<0.01), anemia of chronic disorders (34% vs 17%, p<0.01), decreased C3 (37% vs 10%, p<0.01) decrease in C4 level (49% vs 15%, p<0.01), anti LA (66% vs 47%, p<0.03) and positive cryoglobulins (37% vs 10%, p<0.01). In multivariate analysis, the decrease in C4 levels (OR 4.5; 95% CI 1.6–12.9, p<0.05) and positive cryoglobulins (OR 5.6; 95% CI 1.7–18.6, p<0.05) were independently associated with the presence purple.
**Conclusions:** No independent associations were found regarding demographic, clinical and serological characteristics between patients with and without cutaneous manifestations. Purple is the most common cutaneous manifestation. The group of patients with Purple is most often associated with decreased C4 levels and the presence of cryoglobulins.

## AB0524 INCIDENCE AND RISK ANALYSIS OF OSTEOMYELITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A NATIONWIDE COHORT STUDY

Y.F. Huang, C.C. Lai. *Division of Allergy, Immunology, and Rheumatology, Department of Medicine, Taipei Veterans General Hospital, Taiwan, Taipei City, Taiwan, Province of China*

**Background:** Fever and musculoskeletal pain are manifestations of systemic lupus erythematosus (SLE). These symptoms might be confused with the presentations of osteomyelitis, especially in SLE patients. On the other hand, SLE patients may have higher risk to get infection, including osteomyelitis, due to immunodeficiency.
**Objectives:** This study aimed to investigate the epidemiology and risk factors of osteomyelitis in SLE patients.
**Methods:** We conducted this population-based cohort in entire Taiwanese by using Taiwan National Health Insurance Research Database. Patients with SLE and age- and sex-matched control group without SLE were enrolled. The primary endpoint was the first occurrence of osteomyelitis. The risks of osteomyelitis in SLE patients were analyzed with Cox proportional hazards regression models, including age, sex, comorbidities and medications.
**Results:** From 2000 to 2012, we identified 18472 SLE patients (88.6% women, mean age of 37.5 years) and 73888 control patients. Compared with the controls, the osteomyelitis incidence rate ratio (IRR) (95% CIs) among all SLE patients were 8.23 (6.76–10.05). The IRR between young SLE patients (18–40 years) and their controls was 22.87 (15.59–34.44). Multivariable Cox regression analyses in SLE patients indicated that older age, being male, with disease of peripheral artery disease (PAOD), chronic kidney disease (CKD), bone fracture, performing orthopedic surgery in recent 6 months, and daily prednisolone equivalent to or more than 7.5 mg are strongly related to osteomyelitis. In contrast, the use of hydroxychloroquine was a protective factor for osteomyelitis.

Table 1. Risk factors of osteomyelitis in patients with systemic lupus erythematosus

| Variables | Univariate analysis | | Multivariable analysis[a] | |
|---|---|---|---|---|
| | HR (95% CI) | p value | HR (95%CI) | p value |
| Age | 1.029 (1.020–1.039) | <0.001 | 1.027 (1.017–1.037) | <0.001 |
| Male, n (%) | 2.014 (1.436–2.825) | <0.001 | 1.766 (1.255–2.484) | 0.001 |
| Comorbidity | | | | |
| Diabetes mellitus | 4.25 (1.735–10.409) | 0.002 | | |
| Chronic kidney disease | 4.300 (2.429–7.613) | <0.001 | 2.750 (1.536–4.921) | 0.001 |
| PAOD | 5.408 (1.988–14.710) | 0.001 | 3.628 (1.342–10.102) | 0.011 |
| History of septic arthritis | 3.755 (0.526–26.828) | 0.187 | | |
| Orthopedic surgery | 4.277 (2.681–6.823) | <0.001 | 2.047 (1.165–3.597) | 0.013 |
| Bone fracture | 6.991 (4.256–11.482) | <0.001 | 4.327 (2.387–7.843) | <0.001 |
| Drugs | | | | |
| Steroid (day dose≥7.5)[b] | 1.931 (1.505–2.477) | <0.001 | 2.639 (2.017–3.454) | <0.001 |
| Hydroxychloroquine | 0.516 (0.393–0.677) | <0.001 | 0.579 (0.437–0.766) | <0.001 |
| Azathioprine | 0.735 (0.574–0.942) | 0.015 | 0.721 (0.547–0.949) | 0.02 |

**Conclusions:** SLE patients had a higher incidence rate of osteomyelitis, especially those who were older, male, had history of PAOD, CKD, bone fracture and orthopedic surgery and used a high dose of corticosteroid.

## AB0525 CORRELATION ANALYSIS OF SERUM CYSTATIN C AND LIPIDS LEVELS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Z. Ye, Y. Zhang, X. Luo. *Rheumatology Institute of Guangdong Medical College, Shenzhen, China*

**Objectives:** To discuss the correlation between the level of serum cystatin C and lipids in patients with systemic lupus erythematosus.
**Methods:** Used automatic biochemical analyzer to detect serum cystatin C (CysC), triglyceride (TG), total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), low density lipoprotein (LDL-C) and hsCRP levels in 136 cases of SLE patients and 113 cases of healthy people. Data obtained using SPSS13.0 software to carry on statistical analysis.
**Results:** Outcome of SLE patients group comared with healthy controls, hsCRP (13.5±4.85 mg/L vs 2.03±0.88 mg/L), CysC (2.63±1.95 mg/L vs 0.85±0.37 mg/L), LDL-C (3.06±1.21 mmol/L vs 2.33±0.41 mmol/L), TC (5.32±2.63 mmol/L vs 4.02±1.67 mmol/L) and TG (1.92±0.83 mmol/L vs 1.44±0.8 mmol/L) were significantly different between the two groups. Compared with healthy controls, HDL-C (1.12±0.31 mmol/L vs 1.52±0.85 mmol/L) was decreased (P<0.01). In SLE patients group, the serum CysC level and hsCRP, TC, TG and LDL-C were positively correlated, and the level of HDL-C was negative to the level of CysC. The health control group was no significant corretation.
**Conclusions:** Serum lipid levels of SLE patients were positive to the level of CysC. Suggest that joint detection of SLE patients serum CysC and blood lipids index is helpful to the diagnosis of SLE treatment and condition monitoring.

# Vasculitis

## AB0526 SERUM FERRITIN AS A MARKER OF ACTIVITY IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

H. Küçük, Ö. Varan, B. Bitik, M.A. Öztürk, B. Göker, S. Haznedaroğlu, A. Tufan. *Department of Rheumatology, Gazi University, Ankara, Turkey*

**Background:** ANCA-associated vasculitides (AAVs) are a group of systemic inflammatory disorders with substantial morbidity and mortality. Alveolar hemorrhage and gastrointestinal involvement are major causes of death in these disorders. Markers that measure activity and predict prognosis are needed. Serum ferritin levels are shown to be associated with activity and prognosis of certain rheumatic diseases such as antiphospholipid syndrome, dermatomyositis and systemic lupus erythematosus.
**Objectives:** To investigate association between serum ferritin with acute phase reactants and major disease manifestations in AAV.To investigate association between serum ferritin with acute phase reactants and major disease manifestations in AAV.
**Methods:** Retrospective charts of 40 patients (22 males, mean age 49±15 years) with AAV were utilized. Patients fulfilling Chapel hill classification criteria for AAV and those with at least 6 months of follow up were included. Disease activity of AAV was assessed with Birmingham vasculitis activity score (BVAS). Serum ferritin, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and creatinine values were obtained from hospital records. Creatinine clearance (CrCl) was calculated with MDRD formula. Association between serum ferritin

with acute phase reactants and major disease manifestations were analyzed with Spearman rank and Mann Whitney U tests.
**Results:** Among 40 patients with AAV, 14 had pulmonary hemorrhage, eight had end stage renal disease, three mesenteric ischemia and four died in the follow up (two due to alveolar, one cerebral and one GI hemorrhage). Serum ferritin was not correlated with ESR and CRP. However, there was a significant correlation between BVAS and initial CrCl ($r=0.61$, $p<0.001$ and $r= -0.59$, $p<0.001$, respectively). Serum ferritin values were higher in patients with pulmonary hemorrhage (median (IQR), 65.8 (207) vs 1041 (1281) ng/mL, $p<0.001$) and in those four patients who died in the initial six-moths follow up period (206.8 (556) vs 1362 (1292) ng/mL, $p<0.014$).
**Conclusions:** Serum ferritin could be used as a marker of activity because of its ability to reflect disease severity which has already been shown in other systemic inflammatory disorders. Association between serum ferritin with other manifestations of AAVs remain to be elucidated in the large population studies.

## AB0527 COMPARISON OF TWO INITIAL PREDNISONE DOSE REGIMENS IN GIANT CELL ARTERITIS

A. Sousa, A. Martínez-Vidal, A. Soto-Peleteiro, R. Lorenzo, A. Baroja, C. Vázquez-Triñanes, A. Argibay, M. Freire, A. Rivera. *Thrombosis and Vasculitis Unit, Complejo Hospitalario Universitario de Vigo, Vigo, Spain*

**Background:** Giant cell arteritis (GCA) is a vasculitis affecting large vessels and it is the most frequent type in patients over 50 years old. Although glucocorticoids (GC) still remain the mainstay of treatment in all these cases there is no yet clear evidence about optimal initial dose, regimen and relapses predictors and treatment [1, 2].
**Objectives:** To assess the characteristics of treatment, relapse and outcomes of a biopsy-proven GCA patients and to compare these items between groups based on initial oral prednisone dose.
**Methods:** We performed a retrospective review of all patients diagnosed of biopsy-proven GCA in our institution (Complejo Hospitalario Universitario de Vigo) between 1 January 2000 and 31 December 2014. Additionally, they fullfilled at least 2 of other 4 1990 ACR classification criteria. Epidemiological, clinical and laboratory data, treatment and outcome of all these patients at diagnosis and during follow-up were analysed. We also compared groups by initial oral prednisone dose ($\leq$40mg/day vs $>$40mg/day) using Cox models.
**Results:** During study period 70 patients were identified and analysed. Mean age at diagnosis was 77±7 years old and fifty-one (73%) were female. Charlson index was $\leq$1 in 83% of cases. Most frequent presenting symptoms were headache (87%), polymyalgia rheumatica (57%) and jaw claudication (48.6%). Ischaemic manifestations at diagnosis were seen in ten patients (14.3%). Median ESR and CRP was 88±26mm/h [31–140] and 92±88mg/dL [4–326] respectively. Median delay time from first symptom until diagnosis was 2 months [0–72]. We also analysed patients divided in two groups based on initial oral predisone dose ($\leq$40mg/day [17 patients] vs $>$40mg/day [53 patients]). No differences was seen in sex, age, comorbidities (including cardiovascular risk factors), antiagregants/ immunosupressive therapy use or laboratory markers. Nevertheless prednisone dose at first month (30.2mg/day vs 48.6mg/day; p=0.001), time to reach $\leq$5mg/day of prednisone (11.8 vs 16 months; p=0.045) and total prednisone dose (7.2 vs 11.5 grams; p=0.001) were significantly higher in $>$40mg/day group although we did not see more GC-related adverse effects in this group (p=0.38). During follow-up period (median 29 months [3–140]) 18 patients had at least one relapse, however we did not observe statiscal differences between both groups (18% in $\leq$40mg/day vs 28.8% in $>$40mg/day; p=0.35). Time to first relapse (12±11.3 months in $\leq$40 vs 16±12.9 months in $>$40; p=0.67) and total treatment time (28±23.5 in $\leq$40 vs 35±25.1 months in $>$40) were similar in boths groups. We could not identified any factor that was related to relapses in our multivariate analysis. Twenty-two patients died during follow-up period but none were related with GCA.
**Conclusions:**
- High-dose prednisone was the most frequent initial treatment of GCA patients.
- Lower doses regimen could be as safe and effective as the high-dose regimen.
- Relapses were seen in ¼ of patients but we could not identified any factor associated with them.

## AB0528 ORGAN INVOLVEMENT WITH SYSTEMIC VASCULITIS OF AUTOIMMUNE AND OF SEPTIC ORIGIN – A COMPARATIVE POSTMORTEM STUDY OF 38 RHEUMATOID ARTHRITIS PATIENTS

Á. Apáthy[1], M. Bély[2]. [1]*Department of Rheumatology, St. Margaret Clinic;* [2]*Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, Budapest, Hungary*

**Background:** In rheumatoid arthritis (RA) circulating immune complexes lead to systemic vasculitis of autoimmune origin (A-SV) which may involve various organs. RA as well as autoimmune diseases may be complicated by septic infections (SI) and accompanied with systemic vasculitis of infectious origin (S-SV). In case of systemic vasculitis the identification of its origin is of crucial importance because of the basic differences in therapy.
**Objectives:** The aim of this study was to compare the prevalence, average incidence and severity of A-SV and S-SV in various organs of RA patients.
**Methods:** At the National Institute of Rheumatology 12138 patients died between 1969 and 2000; among them 234 with RA and all of them were autopsied. Lethal septic infection (SI) was observed in 31 (13.25%) of 234 patients. SI was accompanied in 5 patients with S-SV. The clinically identified pathogenic agents and the strong, significant and positive correlation between S-SV and SI (association coefficient: 1, $c^2=26.1881$, $p<0.00007$) supported the infectious origin of SV.
The prevalence, average incidence and severity of S-SV in twelve organs of these 5 RA patients was determined histologically and compared with 33 RA patients with A-SV of our previous study [1].
**Results:** The prevalence in % and the average incidence and severity of A-SV (n=33) and S-SV (n=5) in various organs of 38 RA patients are summarized in the table.

| RA | A-SV | | | | S-SV | | | |
|---|---|---|---|---|---|---|---|---|
| Organs | A-SV/ organ (n=33) | Prevalence/ organ in % | Average incidence/ organ | Average severity/ organ | S-SV/ organ (n=5) | Prevalence/ organ in % | Average incidence/ organ | Average severity/ organ |
| Heart | 22 of 33 | 66.67 | 0.303 | 0.566 | 5 of 5 | 100.0 | 0.400 | 0.567 |
| Lung | 15 of 31 | 48.39 | 0.194 | 0.349 | 2 of 5 | 40.0 | 0.167 | 0.267 |
| Liver | 12 of 32 | 37.50 | 0.115 | 0.214 | 2 of 5 | 40.0 | 0.200 | 0.300 |
| Pancreas | 9 of 25 | 36.00 | 0.160 | 0.320 | 1 of 5 | 20.0 | 0.133 | 0.267 |
| Kidney | 17 of 33 | 51.52 | 0.197 | 0.313 | 3 of 5 | 60.0 | 0.300 | 0.600 |
| Adrenal gland | 12 of 28 | 42.86 | 0.149 | 0.280 | 1 of 4 | 25.0 | 0.125 | 0.208 |
| G-I tract | 11 of 29 | 37.93 | 0.161 | 0.293 | 4 of 5 | 80.0 | 0.333 | 0.567 |
| Spleen | 12 of 28 | 42.86 | 0.155 | 0.292 | 1 of 5 | 20.0 | 0.167 | 0.300 |
| Skeletal muscle | 15 of 28 | 53.57 | 0.190 | 0.375 | 5 of 5 | 100.0 | 0.400 | 0.740 |
| Nerve | 12 of 23 | 52.17 | 0.138 | 0.254 | 2 of 3 | 66.67 | 0.167 | 0.333 |
| Skin | 8 of 23 | 34.78 | 0.072 | 0.094 | 1 of 3 | 33.33 | 0.056 | 0.056 |
| Brain | 3 of 32 | 9.38 | 0.021 | 0.042 | 0 of 5 | 0.0 | 0.0 | 0.0 |

**Conclusions:** The involvement (prevalence in %) of various organs, the average incidence and severity of A-SV and S-SV are basically determined by the systemic circulation and blood supply of various organs, by circulating immune complexes and other agents, furthermore by their possible elimination. The source of infection may have a modifying effect regarding the organ manifestation of S-SV.
**A-SV** was most dominant in the heart, skeletal muscles, lung, pancreas, and kidneys, the main targets of circulating immune complexes in RA. In septic RA patients the S-SV dominated in the heart, skeletal muscles, kidneys, and gastrointestinal tract, which may be due to the complex effect of circulation and source of septic infection (e.g. high prevalence of urogenital and gastrointestinal infections in our autopsy population).

## AB0529 LONG-TERM GLUCOCORTICOID MONOTHERAPY CAN LEAD TO REMISSION IN JAPANESE PATIENTS WITH POLYMYALGIA RHEUMATICA WITHOUT NOTABLE ADVERSE EFFECTS

A. Aoki[1], A. Senuma[2], A. Osada[3], S. Nagaoka[3]. [1]*Dept. of Rheumatology, Tokyo Medical University Hachioji Medical Center, Tokyo;* [2]*Dept. of Rheumatology, Yokohama City University Medical Center;* [3]*Dept. of Rheumatology, Yokohama Minami Kyosai Hospital, Kanagawa, Japan*

**Background:** Polymyalgia rheumatica (PMR) is a common inflammatory condition of elderly persons. Clinical symptoms are improved by low-dose glucocorticoids (GCs). However, most patients require long-term GC therapy, because relapses are common. The recent recommendations for the management of PMR[1)] suggested early introduction of methotrexate (MTX) in addition to GCs in patients with a relapse, and/or without a significant response to GC, or experiencing GC-related adverse events.
**Objectives:** The aim of this study was to evaluate the duration of GC monotherapy until remission of PMR patients, and the adverse events of long-term GC treatment.

**Methods:** We conducted a retrospective study of 29 PMR patients who had achieved remission in 3 hospitals in Japan. All patients met EULAR/ACR classification criteria. None of the patients had clinical symptoms or signs of giant cell arteritis. Patients who had been treated with methotrexate in addition to GCs were excluded. Remission was defined as the absence of symptoms and normal levels of Erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) after the discontinuation of GC. Treatments to prevent GC related adverse event, especially osteoporosis, were left up to each physicians.
**Results:** 20 (69%) were women. The mean (SD) age at the diagnosis was 75.7 (8.14) (range 61–90) years. The median and mean (SD) of initial prednisolone (PSL) dose was 15 and 13.1 (4.15) mg daily. The median duration of GC treatment until remission was 21 months (range 7–88). Three patients achieved remission after longer than 5 years of GC treatment (66, 69, and 88 months)(Figure). For analysis, patients were divided into 2 groups; those who achieved remission within 24 months (early remission group; 17) and those who required GC treatment for more than 25 months (long treatment group; 12). A comparison of the 2 groups was done. No difference was observed in clinical features and laboratory data at diagnosis. Furthermore, there was no significant difference in the starting dose of GCs or GCs tapering speed. Most female patients received vitamin D and/or bisphosphonate. Serious GC adverse events, such as osteoporosis associated fractures, and infections, were rare, and the frequencies of adverse events did not differ between the 2 groups.

Figure Duration of glucocorticoid therapy until remission in 29 patients of polymyalgia rheumatica

**Conclusions:** Most patients have achieved a remission within two years. However, some patients required longer-term treatment. The risk factors for prolonged therapy were reported; female sex, elevated ESR, and peripheral inflammatory arthritis. In this study, any clinical factors at diagnosis were not associated with the duration of PSL treatment until remission.
Our results indicate that low-dose GC therapy might be safer than was previously reported, as long as efforts are made to prevent GC-related adverse events. The rate of MTX adverse events in elderly is not low. Further studies are necessary to determine the risk and benefit of GC monotherapy

## AB0530 25-HYDROXYVITAMIN D3 DEFICIENCY: PREVALANCE AND ITS IMPACT ON DISEASE ACTIVITY IN SMALL-MEDIUM VESSEL VASCULITIS

F.N. Korkmaz[1], G. Ozen[2], A.U. Unal[2], M. Can[3], S. Tuglular[4], H. Direskeneli[2]. *[1]Internal Medicine; [2]Department of Rheumatology, Marmara University Faculty of Medicine; [3]Department of Rheumatology, Medipol University; [4]Department of Nephrology, Marmara University Faculty of Medicine, istanbul, Turkey*

**Background:** Growing evidence suggests that vitamin D has important immunomodulatory effects and plays key roles in endothelial dysfunction, atherosclerosis and pathogenesis/progression of some of the inflammatory rheumatic diseases such as rheumatoid arthritis and systemic lupus erythematosus. Although recent data indicated that vitamin D deficiency is quite prevalant and affects endothelial dysfunction in Behcet's Disease and Takayasu's arteritis, vitamin D levels in small/ medium vessel vasculitis and its effects on disease course have not been evaluated.
**Objectives:** To determine the prevalance of 25-hidroxyvitamin D3 [25(OH)D3] deficiency and to investigate its effects on disease activity in patients with small and/or medium vessel vasculitis.
**Methods:** In this cross-sectional study, 25(OH)D3 levels were measured in adult patients with systemic small-medium vessel vasculitis including ANCA-associated vasculitis (AAV), cryoglobulinemic vasculitis (CryV), IgA vasculitis (IgAV) and polyarteritis nodosa (PAN), and sex-matched healthy subjects (HS). All patients' baseline demographics, disease characteristics, acute phase reactants, medications and disease extents (DEI), disease activities (BVAS) and damage scores (VDI) were determined. 25(OH)D3 level <30ng/ml and <20ng/ml were regarded as insufficiency and deficiency, respectively.
**Results:** Forty five patients (29% new diagnosis) with systemic vasculitis and 63 HS were included (*Table 1*). The mean 25(OH)D3 level was 21.8±14.3 ng/mL in patients with vasculitis and 56.7±23.9 ng/mL in HS ($p<0.001$). Vitamin D insufficiency and deficiency were significantly higher in patients with vasculitis compared to HS (*Table 1*). Thirty eight patients (84.4%) were active (BVAS≥1) at the time of recruitment. 25(OH)D3 levels were not different in active (21.6±14.8) and inactive (23.1±12.1) patients (p=0.79). Of the 24 vitamin D deficient patients 23 (95.8%) had renal involvement. Vitamin D deficient patients had slightly higher BVAS (6.5±6.7 vs 3.7±3.7), VDI (3.8±1.4 vs 3.2±1.3) and DEI (3.0±2.8 vs 1.8±2.4) scores at recruitment but the differences were not statistically significant ($p>0.05$). Likewise there was no difference in acute phase reactants according to vitamin D status.

Table 1. Baseline characteristics of patients with vasculitis and healthy subjects*

| | Patients with vasculitis* (n=45) | Healthy subjects (n=63) | P value |
|---|---|---|---|
| Age, years | 51.9±16.0 | 38.3±6.1 | <0.001 |
| Male, n (%) | 39 (86.7) | 32 (50.8) | 0.10 |
| Disease duration, years | 4.8±4.7 | - | - |
| Organ involvement | | | |
| Cutaneous | 25 (55.6) | - | - |
| Upper airway | 18 (40) | - | - |
| Ocular | 5 (11.1) | - | - |
| Pulmonary | 25 (55.6) | - | - |
| Renal | 39 (86.7) | - | - |
| Gastrointestinal | 5 (11.1) | - | - |
| Neurologic | 12 (26.7) | - | - |
| Cardiovascular | 1 (2.2) | - | - |
| BVAS, median (range) | | | |
| BVAS new/worse (0-63) | 0 (0-22) | - | - |
| BVAS persistent (0-33) | 1 (0-31) | - | - |
| DEI (0-23), median (range) | 2 (0-9) | - | - |
| VDI (0-59), median (range) | 4 (1-6) | - | - |
| 25-Hydroxyvitamin D3 level, ng/mL | 21.8±14.3 | 56.7±23.9 | <0.001 |
| <30ng/mL, n (%) | 35 (77.8) | 8 (12.7) | <0.001 |
| <20ng/mL, n (%) | 24 (53.3) | 2 (3.2) | <0.001 |

*The values are presented as mean±SD, unless indicated otherwise ¶ Systemic vasculitis included AAV (n=34, GPA=23, MPA=11), CryV (n=3), IgAV (n=7), PAN (n=1)

**Conclusions:** Vitamin D insufficiency and deficiency are quite common in patients with small/medium vessel systemic vasculitis. In this preliminary study we could not demonstrate any association with vitamin D deficiency and disease activity in patients with vasculitis. However, prospective followup of a larger sample would better clarify the role of vitamin D on disease activity. Considering also the use of high dose glucocorticoid treatment, these patients should be adequately evalauted and treated for vitamin D deficiency.
**Disclosure of Interest:** None declared

## AB0531 THE ROLE OF HYDROXYCHLOROQUINE IN ANCA POSITIVE AND NEGATIVE VASCULITIS

A. Casian, S. Sangle, D. D'Cruz. *Lupus Unit, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom*

**Background:** There is an unmet need for a less toxic, corticosteroid sparing therapy in ANCA vasculitis (AAV), as up to 50% of patients relapse by 5 years and 20% have sub-optimal disease control. Hydroxychloroquine (HCQ) has been effective and safe in autoimmune diseases such as systemic lupus erythematosus and rheumatoid arthritis. There is mechanistic rationale for the effectiveness of hydroxychloroquine in vasculitis, considering its effect on immune mediators involved in pathogenesis, including B cell activating factors, Toll-like receptors, autoreactive T cells and cytokines.
**Objectives:** To assess retrospectively the efficacy and safety of hydroxychloroquine (HCQ) in patients with systemic vasculitis
**Methods:** Patients were identified by searching our departmental vasculitis database including 248 patients in total and electronic clinical records. Twenty-six patients received hydroxychloroquine along with corticosteroids and immunosuppressants. We assessed the effect of hydroxychloroquine on clinical symptoms and the median dose of corticosteroids required.
**Results:** Twenty six patients with various vasculitides were treated with hydroxychloroquine (median dose 200 mg OD): 6 patients with Henoch Schonlein

purpura (HSP), 6 urticarial vasculitis, 6 with ANCA+ vasculitis (AAV) (4 PR3-ANCA, 2 MPO-ANCA), 1 Eosinophilic Granulomatosis with Polyangiitis (EGPA), 2 Takayasu arteritis, 2 Behcet's disease, 1 adult Still's disease (AOSD), 1 relapsing polychondritis, 1 polyarteritis nodosa (PAN). The female: male ratio was 21:5. Median age was 53 years. The median duration of HCQ treatment was 3 years. Sixteen patients experienced a reduction in arthralgia, skin rashes improved in 8 patients and completely resolved in a further 4. Eight patients could reduce corticosteroid doses (from 9 mg to 6 mg) and 3 discontinued corticosteroids. Four patients developed fewer vasculitic relapses, 6 felt less fatigued, 2 patients no longer experienced abdominal pain and diarrhoea, 2 improved their mood and ability to think clearly. The 6 patients with AAV experienced improvement in arthralgia, reduced their prednisolone doses by a third, had fewer relapses and felt less tired. One patient developed asymptomatic QT prolongation and stopped the hydroxychloroquine, with no other adverse events reported.

| Additional immunosuppressive therapy | Patient No. | Diagnosis |
|---|---|---|
| Nil | 8 | 3 Behcet 2, HSP, 1 AAV, 1 PAN,1 urticarial vasculitis |
| Methotrexate + prednisolone | 5 | 2 HSP, 1 AAV, 1 AOSD, 1 polychondritis |
| Azathioprine + prednisolone | 3 | 1 HSP, 1 AAV, 1 urticarial vasculitis |
| Mycophenolate mofetil + prednisolone | 2 | 1 urticarial vasculitis, 1 EGPA |
| Mycophenolate mofetil | 2 | 1 AAV, 1 Takayasu |
| Methotrexate | 2 | Urticarial vasculitis |
| Azathioprine | 1 | Takayasu |
| Prednisolone | 1 | AAV |
| Mepacrine | 1 | HSP |
| Rituximab | 1 | AAV |

**Conclusions:** All 26 patients reported symptomatic benefits associated with hydroxychloroquine treatment, especially improvement in joint pains, fatigue, rash. Vasculitic relapses were less frequent, with a reduction in corticosteroid doses. Hydroxychloroquine was generally well tolerated.
**Disclosure of Interest:** None declared

## AB0532 PROFILE OF HENOCH SCHONLEIN PURPURA (HSP) NEPHRITIS: 23 YEARS EXPERIENCE AT A TERTIARY CARE CENTRE IN NORTH INDIA

A. Gupta[1], A. Jindal[1], A. Gupta[1], R. Nada[2], R.W. Minz[3], D. Suri[1], A. Rawat[1], S. Singh[1]. *[1]Pediatric Allergy Immunology Unit; [2]Department of Histopathology; [3]Department of Immunopathology, Post Graduate Institute of Medical Education and Research (PGIMER), Chandigarh, India*

**Background:** HSP is one of the most common vasculitides of childhood. Glomerulonephritis is seen in approximately 30–50% of the patients and is the principal cause of morbidity and mortality in HSP patients.
**Objectives:** We describe our experience of managing children with HSP Nephritis (HSPN).
**Methods:** 314 children were registered in Pediatric Rheumatology Clinic, Advanced Pediatrics Centre, PGIMER, Chandigarh with a diagnosis of HSP based on EULAR/PRINTO/PRES criteria during the period from January 1993 to June 2015. A retrospective case review of all patients with HSPN with respect to clinical features, pathological findings and treatment was done. HSPN was defined based on urine erythrocyte >5/HPF and/or proteinuria >150mg/24 hr. Patients were divided into four clinical types according to the laboratory results: (1) isolated hematuria (urine erythrocyte >5/HPF and proteinuria <150 mg/24hr); (2) minimal proteinuria (150 mg/24hr ≤ proteinuria <25 mg/kg); (3) moderate proteinuria (25 mg/kg ≤ proteinuria <50 mg/kg); (4) massive proteinuria (≥50 mg/kg). The severity of the renal pathological findings was determined based on the classification of the International Study of Kidney Disease (ISKDC), from grades I – VI [(1)].
**Results:** Renal involvement was seen in 64 patients (20.4%) after a mean duration of 32.3 days from the onset of symptoms of HSP. Renal manifestations developed in 57.8% of the patients within 4 weeks of symptom onset, in 84.4% within 8 weeks and in 100% within 6 months. Massive proteinuria was the most common clinical feature seen in 56.7% of the patients followed by minimal proteinuria in 21.7%, moderate proteinuria in 15% and isolated hematuria in 6.7% of cases. Hypertension was seen in 24 patients. 4 patients had deranged renal function tests.13 patients developed a clinical relapse of the renal disease after a mean interval of 551.5 days from the remission of first episode. Albuminuria with microscopic hematuria was the most common presentation of second episode (77%) followed by isolated albuminuria (23%).
Kidney biopsy was done in 48 patients. Three fourth of the patients had histological grade II or IIIa. 75% of patients with grade ≥ IV had gross hematuria at presentation. 25 patients received prednisolone alone, 31 received azathioprine in addition to prednisolone, while cyclophosphamide and mycophenolate mofetil were used in 5 and 1 patient respectively. Patients were followed up for a mean period of 3.6 years during which 13 were lost to follow up, 1 expired while 3 patients each are currently on prednisolone and azathioprine. Nephritis resolved in 48 patients (75%) with mean duration of renal involvement being more in patients with nephritis at presentation (429 days) as compared to patients who develop nephritis in follow up (321 days).
**Conclusions:** In our cohort of HSPN, 100% of the patients developed renal involvement within 6 months of the onset of symptoms of HSP with massive proteinuria being the most common clinical feature. Grade II and IIIa were the most common renal pathological grades seen in 75% of the patients.

## AB0533 SYSTEMATIC REVIEW: "EFFICACY AND SAFETY OF BIOLOGICAL THERAPY COMPARED TO IMMUNOSUPPRESSIVE THERAPY VS PLACEBO IN THE TREATMENT OF UVEITIS ASSOCIATED WITH BEHÇET'S DISEASE"

A. Urruticoechea-Arana[1], T. Cobo-Ibáñez[2], V. Villaverde Garcia[3], M. Santos-Gómez[1], F. Diaz-González[4], L. Fariñas-Padrón[5], K. Vargas-Osorio[5], V. Calvo-Río[6], R. Blanco Alonso[6]. *[1]Rheumatology, Hospital Can Misses, Ibiza; [2]Rheumatology, Hospital Universitario Reina Sofía; [3]Rheumatology, Hospital Universitario de Móstoles, Madrid; [4]Rheumatology, Hospital Universitario de Canarias, Canarias; [5]Family and Community Medicine, Hospital Can Misses, Ibiza; [6]Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Spain*

**Background:** Systemic treatments used in ocular involvement in Behçet's disease are corticosteroids, synthetic and biological immunosuppressants. Because of irreversible ophthalmic complications, it's a priority to know the efficacy of these drugs.
**Objectives:** To analyze the efficacy and safety of biological therapy vs cyclosporine A (CyA), azathioprine (AZA) or placebo in reducing the rate of uveitis and improving the visual prognosis of Behçet's.
**Methods:** A systematic search of literature on MEDLINE,EMBASE,and Cochrane Central Register of Controlled Trials was conducted from inception to July 2015.A hand search was performed by reviewing the references of the included studies and the international congress.Criteria for study selection:1)adults with Behçet's-uveitis,2)Biological therapies,3)placebo or active comparator with CyA or AZA,4)outcome measures to evaluate effectiveness as a number (no) of recurrence of uveitis,visual prognosis,cystic macular edema, retinal vasculitis,vitritis,hypopyon,etc; and/or adverse events.Meta-analyses,systematic reviews,clinical trials and observational studies of>10 patients with comparator were included.The selection,review and evaluation of quality of the articles was independently conducted by 2 reviewers.The Oxford Level of Evidence scale was used to determine the quality of the studies.
**Results:** Of 195 articles,5 met the inclusion criteria:2retrospective observational studies and 3randomized clinical trials in 235 patients with Behçet and refractory uveitis.Age range was 12–69 years with male dominance,and follow up was 1–72 months.Evidence with infliximab (IFX) (2 studies) is weak and suggests more effective than CyA in reducing the rate of uveitis in short-term (6m) and more effective than CyA+AZA or methotrexate (MTX) to reduce the no. of retinal vasculitis relapse,and severe complications and to improve visual acuity in long term (LE4).The weak and insufficient evidence of rituximab (RTX) associated with MTX (1study) suggested similar efficacy to cyclophosphamide (CYM) associated with AZA, improving the total adjusted rate of disease activity without improvement in short-term visual acuity (6m)(LE 3b).Regarding secukinumab and daclizumab vs placebo (1 study respectively), the small but acceptable level of evidence suggests ineffectiveness in reducing relapses and in the improvement of visual acuity,with sparing effect on immunosuppressants in short-term for secukinumab (LE2a-2b). Available evidence reveals few significant adverse events. All studies could be applicable in clinical practice.
**Conclusions:** With the limited evidence found, IFX appears to be safe and more effectiveness than CyA alone or in combination with other immunosuppressants in reducing short term uveitis relapse and the number of severe long-term complications.RTX is similar to CYM paired with AZA in improving rates of inflammatory activity in short term.Secukinumab as well as daclizumab is not effective in reducing relapses of uveitis but could spare immunosuppressants.The results of this review support the benefit of carrying out further well-designed comparative studies with IFX and RTX.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3255

## AB0534 THE RELATIONSHIP OF PENTRAXIN-3 LEVELS IN BEHCET DISEASE WITH IL-17, DISEASE ACTIVITY AND ATHEROSCLEROTIC RISK FACTORS

S. Sağ[1], A. Kamanlı[1], I. Tekeoğlu[1], K. Nas[1], M.S. Sağ[1], H. Harman[2], M. Altındiş[3]. *[1]Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya; [2]Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Abant Izzet Baysal University, Bolu; [3]Department of Microbiology, Faculty of Medicine, Sakarya University, Sakarya, Turkey*

**Background:** Several factors have been implicated as contributing to the risk of atherosclerosis in patients with BD. (1) These include inflammatory mediators

such as cytokines and adhesion molecules and traditional cardiovascular risk factors such as age, high blood pressure, and dyslipidemia.(2) PTX3 also acts as a modulator of inflammatory processes and is involved in the development of atherosclerotic lesions. It is produced by endothelial cells in atherosclerotic plaques.
**Objectives:** With this study we aimed to identify the levels of the proteins like Pentraxin and Fetuin-A which are thought to have a role in the progress of atherosclerotic and cardiovascular disorders in Behçet disease and the relationship of these with disease activity, inflammatory cytokine, insulin resistance and dyslipidemia.
**Methods:** This study included 58 patients (36 female, 22 male) with Behçet disease and 20 healthy controls. Serum pentraxin-3, fetuin-A, IL-17 and insulin concentrations were determined. Also, HOMA-IR values were calculated. Disease activity was assessed with Behcet's Disease Current Activity Form (BDCAF).
**Results:** PTX3 and fetuin-A levels were not correlated with ESR, CRP, and any domains of BDCAF scores. IL-17 levels were significantly positively correlated with arthritis of BDCAF scores. there wasn't any significant relationship between the lipid profile and PTX3, IL17 and fetuin-A levels. There wasn't any correlation between PTX and IL 17, fetuin-A, insulin, HOMA IR levels ($p>0.05$).
**Conclusions:** Just like CRP, PTX3 is an acute-phase reactant and it is considers as an inflammatory and atherosclerotic biomarker. In this study, we presented that PTX3 can increase like IL-17 but there aren't any relation between the disease activity and coronary risk factors such as serum lipids, glucose intolerance and obesity. Since this is a cross sectional study, to determine higher levels of pentraxin in BD patients who also have higher cardiovascular disease incidences, the patients have to be followed in the longer run. To identify these long-term studies to quantified atherosclerosis are required.

## AB0535 ASSESSMENT OF CARDIOVASCULAR RISK IN PATIENTS WITH GRANULOMATOSIS WITH POLIANGIITIS USING THE SCORE RISK INDEX

B. Bitik[1], H. Kucuk[2], O. Varan[2], M.A. Ozturk[2], S. Haznedaroglu[2], B. Goker[2], A. Tufan[3]. *[1]rheumatology, Ankara Training and Research Hospital; [2]Gazi University, Ankara, Turkey; [3]rheumatology, Gazi University, Ankara, Turkey*

**Background:** anulomatosis with Poliangiitis (GPA) is an inflammatory disease characterized by destruction of small vessels. Patients with rheumatic diseases particularly with high inflammatory activity such as rheumatoid arthritis have increased morbidity and mortality due to cardiovascular (CV) disease.
**Objectives:** To analyze the prediction index of 10-year risk of a fatal cardiovascular disease events in GPA patients versus controls using the systematic coronary risk evaluation (SCORE) risk index.
**Methods:** Thirty-five GPA patients older than 40 years (18 males, mean age 54.7±9.8 years) and thirty age and sex matched healthy controls seen at the rheumatology clinic were studied. The American College of Rheumatology and Chapel Hill Consensus Conference criteria were used for the diagnosis of GPA. Information on demographics, classic CV risk factors, and clinical features of GPA were obtained by standardized forms. Disease activity of GPA was calculated with Birmingham vasculitis activity index/Wegener (BVAS/WG). Disease and control groups were compared with non-parametric tests.
**Results:** Calculated SCORE values of GPA patients were significantly higher compared to age and sex matched control group (Median (IQR) 2 (3) vs 1 (0), p==0.022). Seven GPA patients (20%) were above the threshold of high risk for the Turkish population. 30 out of thirty seven (81%) patients were newly diagnosed when the SCORE was calculated. There was no correlation between initial BVAS values and SCORE index.
**Conclusions:** We found that GPA patients have a higher 10-year risk of a fatal cardiovascular disease event than healthy controls. However, the use of additional tools or modifications in the SCORE might be considered to fully identify the GPA patients with high CV risk.

## AB0536 CAN RHEUMATOLOGISTS DIAGNOSE AND MANAGE GIANT CELL ARTERITIS BETTER THAN NON RHEUMATOLOGISTS

C. Mercieca, M. Galea, R. Galea, A.A. Borg. *Rheumatology, Mater Dei Hospital, Msida, Malta*

**Background:** Giant cell arteritis (GCA) is the commonest vasculitis affecting large and medium vessels. GCA presents with varying symptomatology which makes timely diagnosis and management challenging. A number of guidelines for the management of GCA have been published.[1,2] In clinical practice, patients present to various specialists including general practitioners, general physicians, neurologists, rheumatologists and ophthalmologists which may result in wide variations in clinical care.
**Objectives:** To establish the incidence of GCA in the Maltese population and whether rheumatologists are able to diagnose and manage giant cells arteritis better than non rheumatologists.
**Methods:** This was a population observational study of Maltese patients between 2012 and mid 2015. All patients who underwent a temporal artery biopsy (TAB) were recruited and their case notes reviewed.
**Results:** There were 122 patients (80 females) who underwent a TAB over 3.5 years for suspected GCA and out of these, 29 were positive. The incidence of biopsy proven temporal arteritis in Malta was 6.4 per 100,000 inhabitants aged over 50 years. Mean age was 72.6 (SD 10.5) years. An additional 27 patients were treated for GCA on clinical grounds. Median CRP was 31 mg/L (IQR 6–87) and ESR 81 mm/hr (53.5–102.5).
A total of 53 patients presented to the rheumatologists and 69 patients to non rheumatologists, and a positive TAB was obtained in 32% and 11.6% of patients respectively. Glucocorticoids were initiated before taking a TAB in 39.6% by rheumatologists and 34.7% and non rheumatologists. Overall (including TAB negative patients) 60.4% of patients presenting to the rheumatologists and 33% of patients presenting to non rheumatologists were treated as GCA.
The starting dose of Prednisolone was between 40–60mg in 82% of rheumatologist treated patients compared to 65% by non rheumatologists. The tailoring regimes varied widely and documentation was poor for many patients treated by non rheumatologists. Rheumatologists treated 50% of patients with a Prednisolone dose of 40 mg or greater for at least a month, 37.5% were given lower doses while the treatment regimen was unclear in 12.5%. Non rheumatologists treated 20.8% with a Prednisolone dose of 40 mg or greater for at least a month, 33.3% were given lower doses and in 45.8% regimen was unclear. The main differential diagnoses were sepsis/infection (7 cases), PMR (4 cases), pyrexia of unknown origin (4 cases) and cluster headache (2 cases).
**Conclusions:** Malta seems to have a low incidence of GCA comparable to other Mediterranean countries but lower than northern European countries.[3]
GCA presents to a wide variety of specialists leading to a broad variation in treatment regimens. Non rheumatologists seem to have a lower threshold for TABs and possibly perform a number of unnecessary TABs.
In order to ensure timely and appropriate management rheumatologists should take the lead and set up interspecialist pathways based on international guidelines that work in the local context. These pathways should include guidance about access, diagnosis, investigations and treatment and be disseminated to other clinical colleagues in both primary and secondary care.

## AB0537 ISOLATED AORTITIS OR AORTITIS RELATED WITH RETROPERITONEAL FIBROSIS: A SINGLE CENTER EXPERIENCE OF 12 PATIENTS

D. Üsküdar Cansu[1], I. Ak Sivrikoz[2], M. Kebapçi[3], C. Korkmaz[4]. *[1]Rheumatology, Associated Proff; [2]Nuclear medicine; [3]Radiology; [4]Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey*

**Background:** Aortitis is the inflammation of aortic wall and it can result from infectious or non-infectious conditions. Retroperitoneal fibrosis (RPF) may be accompanied by idiopathic aortitis.
**Objectives:** In this report, we aimed to retrospectively evaluate in terms of clinical course, treatment and outcomes of 12 patients with isolated aortitis or aortitis related with RPF.
**Methods:** We reviewed files of our patients diagnosed with non-infectious aortitis or aortitis with RPF between Jan-1998-Dec-2015. Their clinical presentations, co-morbidities, location of aortic involvement, treatment features and outcomes were recorded. The diagnosis of aortitis and RPF were based on positron

emission tomography (FDG-PET-CT) scan and/or computed tomography. The presence of RPF was confirmed by biopsy in 4 patients.
**Results:** The study group consisted of 12 patients (8 M, 4 F). The mean age at the time of diagnosis was 60 yrs (42–70 yrs). Isolated aortitis was found in 5 patients, RPF plus aortitis in 6 patients, pure RPF in 1 patient. 6 patients with RPF plus aortitis presented with hydronephrosis and 1 patient with pure RPF presented with cystocele. In patients with isolated aortitis, 4 patients had subclavian and thoraco-abdominal involvement, 1 patient had bilateral subclavian and abdominal aorta involvement. 5 patients with RPF plus aortitis had only abdominal aorta involvement, 1 patient had thoraco-abdominal involvement. 1patient with abdominal aorta involvement had aortic aneurysm. Constitutional symptoms including fever, weight loss, and fatigue existed in all patients at the first admission. Hydronephrosis and post-obstructive renal failure were treated with double J stent and steroid treatment in 6 patients with RPF. Acute phase reactants increased in all patients. Ig G4 levels were determined in 8 patients and only 1 patient had increased level of Ig G4. All patients were given only prednisolone or prednisolone plus immunosuppressive drugs such as azathioprine or methotrexate. Clinical manifestations and increased acute phase reactants resolved in a reasonable time. 2 patients passed away due to sepsis and intra-cerebral infection, respectively. One of these 2 patients had many co morbidities.
**Conclusions:** While constitutional symptoms were a dominant complaint in isolated aortitis, hydronephrosis and acute renal failure as well as back pain were the chief manifestations of RPF. The presence of co-morbidities may play a role in mortality.

## AB0538 ASSESSMENT OF NEUROLOGICAL MANIFESTATIONS IN TEMPORAL ARTERITIS

C. Aranda-Valera[1], S. García[2], I. Monjo[2], M.J. Rodríguez[1], E. Martín-Mola[2], E. De Miguel[2]. *[1]Rheumatology, University Hospital Jerez, Jerez de la Frontera; [2]Rheumatology, University Hospital La Paz, Madrid, Spain*

**Background:** Temporal Arteritis (TA) is a vasculitis characterized by systemic and ischemic symptoms that concern fundamentally supraaortic blood vessels. The neurological clinic can be expressed as: headache, visual alterations, affection of cranial nerves, transient ischemic attack (TIA) or ischemic stroke in carotid or vertebrobasilar territory. The ocular affection is the most frequent but other neurological ischemic affections, not retinals, are not rare but they often occur unnoticed and are attributed to atherosclerosis given the age of the patients. Being a treatable and preventable process, there is an opportunity to improve the diagnosis of this affection.
**Objectives:** Assess the vascular events of supraaortic blood vessels, ocular vessels and non ocular vessels in our vasculitis surgery.
**Methods:** A retrospective study was carried out on the clinical history of the patients sent to our vasculitis surgery on suspicion of TA. The diagnosis of arteritis or nonarteritic neurological affection was realized in agreement with usual clinical criteria. The variables registered were age and sex, cardiovascular risk factors (CVR), clinical manifestations,VSG and PCR values, the final diagnosis and the results of the biopsy and the ultrasound examination, as well as the number of affected branches, brain TAC and MRI. The statistical analysis was realized by means of the software program SPSS Statistics version 20.0.
**Results:** Of the 163 patients studied, 112 were women and 51 men (31,3% vs 68,7%). One hundred thirteen patients (59,32%) had definite diagnosis of TA while 50 (30,68%) presented other diagnoses. Of the total of the patients, 59 (24 men and 35 women) presented neurological clinic: diplopía 10, loss of vision 48, TIA 7 and ACVA 4. Of these 42 were diagnosed with arteritic neurological affections (secondary to TA): 6 diplopía, 35 loss of vision, 4 TIA and 2 ACVA. Among the patients with nonarteritic and arteritic neurological events no differences were found for sex, VSG, PCR, blurry vision, fever, loss of vision, diplopía, TIA, ACVA, CVR, smoking and atrial fibrillation (AF): there was only significant differences for age. The analysis of the patients diagnosed with TA, withand without neurological events, appear in the table.

| | AT with neuroischemic events (n=42) | AT without neuroischemic events (n=71) | P< |
|---|---|---|---|
| Age (mean) | 81.29 | 71.29 | 0.001 |
| Sex ♀/♂ | 20/22 | 51/20 | 0.030 |
| VSG (mean) | 58.58 | 55.53 | 0.845 |
| PCR (mean) | 35.86 | 25.04 | 0.435 |
| Headache (no/yes) | 25/17 | 21/49 | 0.002 |
| Constitutional syndrome (no/yes) | 37/5 | 58/12 | 0.322 |
| Fever (no/yes) | 40/2 | 61/9 | 0.143 |
| Jaw claudication (no/yes) | 36/6 | 61/9 | 0.521 |
| Pulse temporal arteries (no/yes) | 15/2 | 20/1 | 0.419 |
| Polymyalgia rheumatica | 39/3 | 60/10 | 0.203 |
| Cardiovascular risk (no/yes) | 11/31 | 6/11 | 0.140 |
| Smoking (no/yes) | 28/12 | 56/10 | 0.196 |
| Number of affected branches | 2.88 | 3.43 | 0.018 |

**Conclusions:** Non ocular central neuroischemic events are frequent and affect 10,62% of the patients with TA. Among the patients with TA the neuroischemic risk associates to being a male, advanced age, a greater number of affected branches in ultrasound examination and to the presence of headache.

## AB0539 TOFACITINIB FOR POLYARTERITIS NODOSA – A TAILORED THERAPY

D. Rimar[1], A. Alpert[2], E. Starosvetsky[3], I. Rosner[1], G. Slobodin[1], M. Rozenbaum[1], L. Kaly[1], N. Boulman[1], A. Awisat[1], S.S. Shen Orr[3]. *[1]Rheumatology, Bnai Zion Medical Center; [2]Immunology, Rappaport Faculty of Medicine, Technion – Israel Institute of Technology; [3]Immunology, Rappaport Faculty of Medicine, Technion – Israel Institute of Technology, Haifa, Israel*

**Background:** Tofacitinib is a novel inhibitor of Janus kinase (JAK) 3 and JAK1 [1]. The JAK inhibitors are in the focus of research in myriad of other inflammatory diseases as it seems the JAK- (signal transducer and activator of transcription) STAT pathway has a central role in cytokines' signal transduction. We herein describe a case of refractory polyarteritis nodosa (PAN) successfully treated with tofacitinib.Preliminary evidence for the role of JAK-STAT pathway in vasculitis has been recently published [2].
A 28 years-old man had been diagnosed with PAN at the age of 14. He presented with livedo reticularis, arthritis and skin nodules with fibrinoid necrosis, as confirmed by biopsy. Immunologic panel at the time of diagnosis was negative for ANCA, ANA, SSA, SSB, RF, and complement levels were normal. He was treated with azathioprine and methotrexate for several years and was in complete remission. Three years prior the initiation of tofacitinib his disease flared and he began suffering from necrotizing vasculitis of the scrotum and calves, abdominal pain and polyarthritis with high CRP levels (160–300 mg/l) for which he received recurrent intravenous solumedrol pulses and oral prednisone therapy of 40–60 mg daily in between pulses. Numerous treatments including, infliximab, adalimumab, rituximab, etanercept, tocilizumab, potassium iodide and cyclophosphamide intravenous and oral failed to achieve remission. Subsequently, he was hospitalized for reevaluation and was treated by plasma exchange for 3 weeks with partial remission, but had to discontinue the treatment due to central line sepsis. At this point he was in severe long standing inflammatory state for 3 years with high CRP levels low albumin (3 mg/dl) and ongoing leukocytosis.
**Objectives:** To evaluate the activity of the JAK-STAT pathway guiding the treatment with tofacitinib.
**Methods:** We have profiled his peripheral blood cells using mass cytometry (CyTOF), a single cell proteomics platform capable of simultaneously measuring the expression up to 45 proteins on each cell and on millions of cells. This provided a high-dimensional immune cell type profile of his immune system, both in cell abundance as well as the activity of the JAK1 and 3 along with STAT 3 pathways in response to stimulation with interleukin 6, specifically in CD4+ and CD8+ T cells subsets (figure 1).
**Results:** We initiated treatment with tofacitinib 10 mg BID that resulted in prompt normalization of his CRP, albumin and leukocyte count, resolution of skin ulcers and relief of pain. Prednisone therapy was soon tapered from 60 mg to 10 mg daily. Reevaluating the response of the JAK-STAT pathway to IL-6 stimulation after treatment confirmed attenuated response of the CD8+T and CD4+T cell (figure 1). After one year of follow-up the patient remained in complete remission.

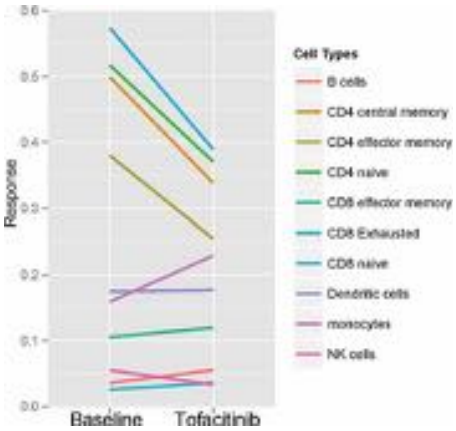

Figure 1

**Conclusions:** In conclusion, this is the first report in the literature of treatment of refractory PAN vasculitis with tofacitinib. Using high resolution mass cytometry technology we were able to tailor and monitor therapy.

## AB0540 POST-THROMBOTIC SYNDROME AND VENOUS DISEASE SPESIFIC QUALITY OF LIFE IN PATIENTS WITH VASCULAR BEHÇET'S DISEASE

F. Alibaz-Oner[1], B. Aldag[1], M. Aldag[2], A.U. Unal[1], A. Mutis[1], T. Toptas[3], T. Ergun[4], H. Direskeneli[1]. *[1]Rheumatology, Marmara University, School of Medicine; [2]Cardiology, Siyami Ersek Cardiovascular Surgery Research and Training Hospital; [3]Hematology; [4]Dermatology, Marmara University, School of Medicine, Istanbul, Turkey*

**Background:** Behçet's disease (BD) is a systemic disease characterized by oral aphthosis, genital ulcers, ocular lesions and systemic involvement including major vessels. Vascular Behçet's disease (VBD) is observed in up to 40% of BD. It is one of the major causes ofmorbidity and mortality in BD. Deep venous thrombosis (DVT) is the most common form of vascular involvement in Behcet's disease (BD). Post-thrombotic syndrome (PTS) develops in up to one-half of patients with DVT and is associated with impaired quality of life (QoL). There is no data on severity of DVT related PTS and its impact on quality of life in patients with Vascular Behçet's Disease (VBD).
**Objectives:** We aimed to evaluate frequency of PTS and venous disease spesific QoL in VBD and to compare it with patients having DVT associated with non-Behçet's disease (NBD) causes.
**Methods:** This study included 50 patients (Male/Female: 41/9) with VBD and 31 age and gender-matched individuals (Male/Female: 22/9), with DVT associated with non-BD causes. Villalta scale was used to assess of PTS. Venous Disability Score (VDS) and Venous Clinical Severity Score (VCSS) were used for the assessment of venous disease. Venous disease-specific QoL was measured through Venous Insufficiency Epidemiological and Economic Study Quality of Life/Symptom questionnaire (VEINES-QoL/Sym). Behçet Syndrom Activity Score (BSAS) questionnaire was used to assess disease activity.
**Results:** We observed significantly lower risk of PTS together with significantly better VEINES-QoL, VEINES-Sym and VDS in VBD group compared to NBD group. When VBD patients with PTS were compared to patients without PTS; VEINES-QoL, VEINES-Sym VCSS were significantly worse. BSAS was also significantly higher in patients with PTS. An inverse correlation was found between VEINES-QoL and BSAS in multivariate analysis. There were no differences between anticoagulant users and non-users regarding the presence of PTS and scores of all venous assessment tools.

Table 1. Venous assessment and quality of life parameters in study groups

| | Vascular Behçet disease (n=50) | Non-Behçet group (n=31) | P value |
|---|---|---|---|
| VEINES-QoL | 85.6±17.1 | 74.9±18.6 | 0.01 |
| VEINES-Sym | 37.7±9.4 | 33.1±10.1 | 0.04 |
| VCSS | 5.2±5.1 | 6.2±4.5 | 0.346 |
| CEAP | 2.4±1.7 | 2.3±1.5 | 0.747 |
| VDS | 1.1±0.6 | 1.5±0.5 | 0.002 |
| SF-36 MCS | 45.3±9.6 | 41.9±10.8 | 0.163 |
| SF-36 PCS | 42.1±10.7 | 41.2±9.6 | 0.726 |

VEINES-QoL/Sym: Venous Insufficiency Epidemiological and Economic Study Quality of Life/Symphtom questionnaire, VCSS: Venous Clinical Severity Score, CEAP: Clinical, Etiologic, Anatomic, Pathophysiologic) classification, VDS: Venous Disability Score MCS: Mental component of SF-36, PCS: Physical component of SF-36.

**Conclusions:** We found lower PTS risk and better venous disease spesific QoL, symptom severity and venous disability scores in VBD compared to NBD group. Venous disease spesific QoL negatively correlated with disease activity. Effective control of vascular inflammation through treatment in VBD might explain lower PTS and better venous QoL outcomes in VBD patients. Our results suggest that successful control of disease activity might decrease development of PTS, improve venouse disease spesific QoL as well as preventing the relapses in VBD.

## AB0541 THE PROGNOSTIC SIGNIFICANCE OF THE BIRMINGHAM VASCULITIS ACTIVITY SCORE (BVAS) IN PATIENTS WITH SYSTEMIC VASCULITIS TRANSFERRED TO THE INTENSIVE CARE UNIT (ICU)

F. Biscetti, A. Carbonella, F. Parisi, F. Cianci, S.L. Bosello, B. Tolusso, E. Gremese, G. Ferraccioli. *Rheumatology, Catholic University School of Medicine, Rome, Italy*

**Background:** Systemic vasculitides represent a heterogeneous group of diseases that share clinical features including respiratory distress, renal dysfunction, and neurologic disorders. These diseases may often cause life-threatening complications requiring admission to an intensive care unit (ICU) [1]. Birmingham Vasculitis Activity Score (BVAS) is the most widely used generic tool to quantify disease activity in systemic vasculitis. Acute Physiology And Chronic Health Evaluation (APACHE II) is a simple and accurate assessment scale of the severity of disease in critically ill patients newly admitted to ICU.
**Objectives:** The aim of this study was to identify possible prognostic biomarkers for patients with vasculitis admitted to ICU.
**Methods:** A retrospective study was carried out from 2004 to 2014 in patients with systemic vasculitis admitted to the Rheumatology division and transferred to ICU due to clinical worsening, with a length of stay beyond 24 hours. An additional group of patients admitted to ICU, and without history of systemic vasculitis, were used as a matched-control group. A total of 25 patients were included in the analysis.
**Results:** ICU mortality was significantly associated with higher BVAS scores performed in the ward ($p<0.01$) and at the admission in ICU (p=0.01), regardless of the value of APACHE II scores (p=0.50). We used receiver-operator characteristic (ROC) curve analysis to evaluate the possible cutoff value for the BVAS in the ward and in ICU and we found that a BVAS $>8$ in the ward and that a BVAS $>10$ in ICU were significantly related to the mortality in ICU ($p<0.01$).
**Conclusions:** BVAS appears to be an excellent tool for assessing ICU mortality risk of patients with systemic vasculitides admitted to specialty departments. Our experience has shown that performing the assessment at admission to the ward is more important than determining the evaluation before the clinical aggravation causing the transfer to ICU.

## AB0542 DO AGE-RELATED VARIATIONS REMAIN IN HENOCH-SCHÖLEIN PURPURA CURRENTLY?

F. Rey, A. Rubio, C. Peña, C. Bonilla, A. Cruz, P. Collado. *Rheumatology, Hospital Severo Ochoa, Madrid, Spain*

**Background:** Henoch-Schölein purpura (HSP) is a generalised vasculitis characterised by various combinations of skin, joint, gastrointestinal and renal involvement. The diagnosis HSP is based on clinical and histological features. HSP can occur at any age, but is most common in childhood. The etiology remains unknown, although it is quite common upper respiratory tract (URT) infections as a precedent.
**Objectives:** To describe the prevalence of the clinical manifestations in adults and children at the time of diagnosis of HSP.
**Methods:** A retrospective study of the case records of all admitted patients identified by the HSP diagnosis in the Hospital Universitario Severo Ochoa (Madrid, Spain) between January 1976 and June 2015 was undertaken. Classification criteria proposed by Michel et al were used for the diagnosis - including age $<20$ years at onset (1). Demographic, clinical and laboratory data at the time of diagnosis of the patients with HSP were extracted from their clinical records according to a specifically designed protocol and stored in a computerized file. Continuous data were described as mean and standard deviation (mean, SD), or median and interquartile range (IQR) and categorical variables as percentages. Means and incidence rates were compared using the Student t test. To compare categorical data we performed the chi-square test.
**Results:** We identified 51 patients, mainly male (64.7%), with a median age at the onset of symptoms of 18 (IQR 13–41) years old. Thirty nine were younger than 20 years old. In 51% a history of URT infection before the onset of HSP was found, particularly in children (56.4%), without statistical significance (p=0.19). Palpable purpura was the initial manifestation of the disease in all patients. Differences in the distribution of cases by joint and abdominal manifestations between adults and children were not statistically significant. Joint involvement was presented in 66.7% (34 patients), where arthritis was recorded up to 41.2%, mostly children having arthritis in 84.21% (p=0.5). Abdominal manifestations were presented in 60.8% (47% adults and 13% children) (p=0.8). Renal manifestations were hardly recorded at onset, whereas up to 66.7% had no renal involvement described (31 children and 3 adults) (p=0.001). Hematuria and proteinuria were observed in 3.9% and 2% of the study population respectively, while the association of both renal manifestations was observed in 21.6%.
**Conclusions:** Although the simple size is small, our study shows several differences at the onset of HSP between adults and children. The disease is observed predominantly in childhood, where joint involvement was frequent. Renal involvement, generally manifested as hematuria either isolated or in association with proteinuria, constitutes the most serious feature of HSP in adulthood.

## AB0543 RISK FACTORS FOR MORTALITY IN ANCA-ASSOCIATED VASCULITIDES

G.B. Bae, J.S. Eun, N.R. Kim, E.J. Nam, Y.M. Kang. *Kyungpook National University Hospital, Daegu, Korea, Republic Of*

**Background:** Antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitides (AAV) are necrotizing small-vessel vasculitides in conjunction with autoantibodies to neutrophil constituents. Diffuse alveolar hemorrhage (DAH) and

renal involvement are the most serious manifestations, and higher five factor score (FFS) has been associated with higher mortality rate. Although the introduction of cyclophosphamide and corticosteroids has changed the natural history of disease from an almost fatal condition to a relapsing and remitting one with greatly increased survival, patients with AAV still have a 9-fold increased risk of death in the first year of disease. Furthermore, reported causes of death (COD) and risk factors for mortality vary between studies, which indicate the need of further investigation.

**Objectives:**

To investigate the COD and risk factors for mortality in patients with AAV.

**Methods:** A retrospective study was conducted in 44 patients with microscopic polyangiitis (MPA) and 12 granulomatosis with polyangiitis (GPA) from January 1999 to December 2011. All patients fulfilled the Chapel Hill Consensus Conference 1992 definition and Sorensen's diagnostic criteria for MPA and GPA. We reviewed medical records of patients including basic demographic characteristics, cumulative clinical features, treatment agents, and causes of death. The primary COD was defined as the main clinical and pathological process directly responsible for death and then categorized into 3 groups: vasculitis-related, vasculitis-unrelated, and unknown.

**Results:** Renal involvement and DAH were observed in 73.2% (41/56), and 30.4 (17/56), respectively, in all the patients with MPA or GPA. The mortality rate was 41.1% (23/56) with 5 deaths (41.6%) in patients with GPA and 18 (40.9%) with MPA. Among the significant risk factors for mortality on univariate analysis, which include DAH, renal involvement, $\geq$4 organ involvements, $\geq$2 FFS scores, and $\geq$4 treatment modalities, a multivariate regression analysis identified DAH as an independent predicting factor (HR, 10.28; 95% CI, 2.58–40.56; $p<0.001$). In an analysis of COD, two deaths (8.6%) were related to vasculitis, while 19 (82.6%) were related to infection. The most common COD was pneumonia (17/23, 73.9%) which, in turn, was associated with DAH (OR, 27.18; 95% CI, 4.30 - 171.80; $p<0.001$) and $\geq$4 organ involvement (OR, 7.62; 95% CI, 1.54 - 37.71; $p=0.013$) as independent risk factors. Bacteria were the most frequent microorganisms causing pneumonia (n=43, 68.2%), followed by fungi (n=8, 12.7%) and *Pneumocyctis jirovecii* (n=7, 11.1%). Most frequently isolated bacteria were *Acinetobacter baumanii* (6 cases), and *Staphylococcus aureus* (MRSA, 6 cases). The mean number of isolated pathogens in patients with pneumonia was 3.33 ±2.11. There were no significant difference in the mean number of pathogens between patients who survived and dead (3.00±0.00 vs. 3.37±2.24).

**Conclusions:** The result of present study implicated that early intervention of pulmonary infection may be critical to increase survival rates in AAV patients with DAH and or severe disease.

## AB0544 SERUM BETA 2-MICROGLOBULIN LEVELS IN BEHÇET'S DISEASE

I.A. Choi[1], S.J. Lee[1,2], E.Y. Lee[1], E.B. Lee[1], Y.W. Song[1,2]. *[1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital; [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Center, Seoul National University, Seoul, Korea, Republic Of*

**Background:** Behçet's disease (BD) is a systemic vasculitis characterized by oral ulcer, genital ulcer, skin lesion and uveitis. Because there is no reliable biomarker, the evaluation of BD disease activity is dependent on the extent of clinical manifestation and usually assessed by questionnaires, such as Behcet's Disease Activity Score (BSAS) or Behcet's Disease Current Activity Form (BDCAF).

**Objectives:** This study was performed to investigate the association of serum beta 2-microglobulin level and clinical manifestation or disease activity in BD.

**Methods:** The study population consisted of 63 patients with BD and 21 healthy controls. Patients with BD were assessed by disease duration, currently involved organ, BSAS, BDCAF, ESR and CRP.

**Results:** Serum beta 2-microglobulin levels of patients with BD were found to be significantly higher than those in the healthy controls (median 1.67 mg/L and 1.44 mg/L, p=0.003). In further analysis in BD patients, it was significantly correlated with ESR (rho =0.289, p=0.025) and CRP (rho =0.364, p=0.004) but not correlated with BD activity represented by BSAS (rho = -0.039, p=0.761) and BDCAF (rho =0.011, p=0.929). Serum beta 2-microglobulin levels were significantly increased with age (rho =0.459, $p<0.001$) but did not have correlation with BD duration (rho =0.161, p=0.212). There was no difference in the serum beta 2-microglobulin levels according to the presence of oral ulcer, genital ulcer, skin lesion, uveitis and arthritis.

**Conclusions:** Serum beta 2-microglobulin was elevated in patients with BD and correlated with ESR and CRP, but was not correlated with BD clinical manifestation or disease activity.

**Disclosure of Interest:** None declared

## AB0545 INTERFERON ALPHA2A VERSUS CYCLOSPORIN A FOR THE TREATMENT OF SEVERE OCULAR BEHCET'S DISEASE – A PROSPECTIVE, RANDOMISED, SINGLE BLIND, NATIONAL MULTICENTER TRIAL (INCYTOB)

I. Kötter[1], R. Vonthein[2], B. Schoenfisch[3], T. Xenitidis[4], D. Doycheva[5], J. Henes[4], N. Stübiger[6], E. Feist[7], A. Heiligenhaus[8], T. Rath[9], R. Max[10], F. Mackensen[11], A. Altenburg[12], L. Krause[13], C. Zouboulis[12], S. Blaschke[14], M. Horn[15], T. Neß[16], S. Goldacker[17], C. Deuter[18]. *[1]Internal Medicine 4, Asklepios Clinic Altona, Hamburg; [2]Institute for Medical Biometry and Statistics, Lübeck; [3]Gynaecology and Obstetrics; [4]Internal Medicine 2, University Hospital; [5]Uveitis Clinic, University Eye Hospital, Tübingen; [6]Eye Hospital; [7]Rheumatology and Clinical Immunology, Charite University Hospital, Berlin; [8]Ophthalmology; [9]Internal Medicine, St. Franziskus Hospital, Münster; [10]Internal Medicine V, Rheumatology; [11]Ophthalmology, University Hospital, Heidelberg; [12]Dermatology; [13]Ophthamology, Städtisches Klinikum, Dessau; [14]Rheumatology, Nephrology; [15]Ophthalmology, University Hospital, Göttingen; [16]Ophthalmology; [17]Rheumatology, University Hospital, Freiburg; [18]Ophthalmology, Uveitis Clinic, University Hospital, Tübingen, Germany*

**Background:** Behcet's disease (BD) is a variable vessel vasculitis. To date, there are only retrospective case series showing efficacy of interferon alpha for ocular BD. This trial was started in 2007.

**Objectives:** To prove that interferon alpha2a is at least as effective as cyclosporin A.

**Methods:** Maintenance dosage of IFN was 3 to 9 Mill iU 3x/week, CSA dosage 3 to 5 mg/kg, adapted to response every two weeks. In case of nonresponse, the patients were switched to the alternative treatment arm after week six. Efficacy was measured by Posterior Uveitis scoring system (PUS), Behcet's disease current activity form (BDCAF), Health assessment questionnaire (HAQ) and Beck depression Inventory (BDI) were also used. Primary endpoints were time to remission by PUS and number of cross over from one arm to the other.

**Results:** The study was stopped in 2013 after 37 patients due to slow recruitment. 13 patients per treatment arm (n=26, 65% male, 35% female, 38% German, 50% Turkish, 12% other, mean age 30.5 years) were evaluated. All 13 patients with primarily IFN achieved remission of their ocular disease, 9 of 13 in the CSA arm (p=0.096). The median time to complete PUS remission was 84 vs. 72 days, p=0.899. The probability to achieve remission after one year was 0.92 for IFN (95% CI 0.49–0.99) and 0.62 for CSA (95%CI 0.24–0.81). There were significantly more switches from CSA to IFN (n=7) than vice versa (n=1) (p=0.030). The main reasons were inefficacy (n=4 for CSA) and/or side effects (n=3 for CSA). PUS of the affected eyes improved significantly in both arms during the first year ($p<0.001$). Visual acuity at baseline was significantly better in the CSA arm than in the IFN arm, hence a significant improvement over time could only be shown in the IFN arm ($p<0.003$ week 30). BDCAF improved in both arms ($p>0.001$), as did HAQ (p=0.047). Safety analysis revealed more hair loss (p=0.004) and cytopenia ($p<0.001$) in the IFN and hypertension (p=0.048) in the CSA arm.

**Conclusions:** Both treatments are effective for ocular and extraocular BD. There is a tendency towards superiority of interferon alpha considering that there were more switches from CSA to IFN due to inefficacy and side effects. Due to the small sample size, this did not reach significance. A prospective international multicenter trial may help to overcome these limitations.

**Acknowledgement:** This trial was supported by the German Ministry of Health (BMBF/DLR, No. 01KG0706) and by Roche (supply of interferon alpha2a)

**Disclosure of Interest:** None declared

## AB0546 SHOULD A RHEUMATOLOGIST MANAGE PATIENTS WITH GIANT CELL ARTERITIS?

I.A. Onac[1], M. Sharif[2], E. Sames[3]. *[1]Rheumatology, Eastbourne District General Hospital, Eastbourne; [2]Rheumatology, King's College Hospital, London; [3]Rheumatology, St. Peter's hospital, Surrey, United Kingdom*

**Background:** Temporal arteritis (TA) is the commonest vasculitis characterised by inflammation of large and medium vessels. It predominantly affects the cranial arteries arising from the aortic arch and requires early recognition and treatment to ensure the avoidance of ischaemic neuro-ophthalmic complications.

**Objectives:** 100% compliance with the British Society of Rheumatology guidelines for TA: Ø Diagnosis criteria Ø Urgent referral for specialist evaluation Ø Inflammatory markers checked before steroid started Ø Temporal artery biopsy (TAB) advised for all the patients with a suspicion of TA Ø Analyse the correlation between inflammatory markers and TAB results Ø and the complex management of this patients.

**Methods:** Retrospective analysis of electronic records of patients that were discharged from acute services with a diagnosis of TA from Brighton and Sussex University Hospital between 1st August 2012 and 31st July 2015.

Patients' blood and TAB results were checked. Specialist letters (Rheumatology, Ophthalmology, Care of the Elderly, TAB clinic) were reviewed electronically. We analized the discharge medication and the advice following specialist review and investigations performed.

**Results:** There were a total of 39 patients with a proposed diagnosis of TA 37 of which had data available for analysis. The average age was 77, 74% were female. Two patients (5%) were referred by the GP for TAB. One of them (50%)

had a positive TAB but was not referred for a rheumatology review. Only 62% had TAB from which 46% were positive. 91% of positive biopsies had an ESR>50 and 100% had a CRP>5. All the patients seen in hospital were immediately started on steroids. Only 79% were on Calcium and Vitamin D3, 67% were on Bisphosphonates, 27% were on Antiplatelet treatment and 74% were on a proton pump inhibitor (PPI). 54% of the patients were seen by a Rheumatologist with the diagnosis being confirmed in 86%, even though 44.5% did not have a TAB and 11% had a negative result. One third of the patients had no evidence of secondary care follow up, 13% were seen by Ophthalmology and 2.5% by Elderly Care. From the 46% not seen by a Rheumatologist 11% had a positive TAB and 33% did not undergo TAB. From 8 patients seen by Ophthalmogist 37% were referred for a rheumatology review and only 50% of those with a positive biopsy.
**Conclusions:** In order to achieve 100% standards as set by BSR guidelines based on ACR criteria we need to reinforce GP's to directly refer to Rheumatologist. We recommend that all those patients seen by the medics in hospitals should be referred for Rheumatology review directly as well as those patients seen by an ophthalmologist. Rheumatology review should focus more on the supportive medical management to ensure the BSR guidelines are appropriately implemented. We have proposed a pathway for the investigation, management and specialist review for those patients suspected of Giant Cell Arteritis that will be attached to the discharge letter from the hospital and from the TAB clinics.

## AB0547 DIAGNOSTIC DELAY FOR GIANT CELL ARTERITIS (GCA). A SYSTEMATIC REVIEW AND META-ANALYSIS

J.A. Prior[1], H. Ranjbar[1], J. Belcher[1], S. Mackie[2], C.D. Mallen[1]. [1]*Research Institute for Primary Care and Health Sciences, Keele University, Keele;* [2]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

**Background:** The diagnosis of giant cell arteritis (GCA) remains difficult, with patients often presenting with non-specific and atypical symptoms. Such ambiguity can lead to delays in the diagnosis of GCA, which in-turn may result in the patient experiencing preventable and life-altering outcomes, including blindness. Despite the seriousness of such diagnostic delay, the extent of this, though frequently highlighted, has seldom been the primary focus of GCA research. Without a clear understanding of the extent to which GCA diagnosis is delayed, it is difficult to quantify the current problem and how this may then impact on patient outcomes.
**Objectives:** To determine the average time-period between the onset of GCA symptoms and receiving a GCA diagnosis.
**Methods:** We conducted a systematic review and meta-analysis to identify research literature which has examined diagnostic delay of GCA and to determine the extent of this delay. Literature searches were conducted in the following bibliometric databases; MEDLINE, EMBASE, CINAHL, PsycInfo and ISI web of knowledge. A single reviewer (HR) initially performed a title screen; abstracts were then reviewed by two reviewers (HR & JP) and finally, two reviewers (JP & CM) assessed the remaining articles in full. Final article selection was based on pre-specified inclusion criteria and from these data on a multitude of factors was extracted. The primary outcome of interest was the "average number of weeks between onset of GCA symptoms and GCA diagnosis", with other extracted data including; lead author, year of publication, sample size, gender, age, country, healthcare setting, method of GCA diagnosis and the definition of diagnostic delay. Where diagnostic delay was reported as 'days" or "months", data were converted to "weeks" to provide a standardised dataset for analysis. Standard deviations were also converted to standard errors (SE) for use in a meta-analysis. Random-effects meta-analysis was used to report the mean number of weeks (95% confidence interval (CI)) between symptom onset and GCA diagnosis.
**Results:** 4,128 articles were initially identified, 185 were reviewed in full and 34 articles were included in the final systematic review. Of these, the average age ranged from 65.2 to 81.6 years and GCA samples from 31 articles were recruited from secondary care. GCA diagnosis was defined by a positive temporal artery biopsy in 25 articles, using the 1990 ACR criteria in 4 articles, with the remaining articles either using clinical judgement or not providing a definition. Delay was determined by the article reporting "how many days, weeks or months had occurred between GCA symptom onset and receiving a diagnosis of GCA". 16 articles were included in the meta-analysis, resulting in a mean number of weeks between symptom onset and GCA diagnosis of 8.87 (95% CI 6.4 to 11.3) ($I^2$ =95.8%, p<0.001).
**Conclusions:** On average, patients experience approximately a 9-week delay between the onset of their symptoms and receiving a diagnosis of GCA. The reasons for this are yet to be understood, but could provide important insight and inform future strategies to improve outcomes for patients. Our research provides the current benchmark for diagnostic delay of GCA for which future efforts to reduce this problem can be measured against.

## AB0549 ANCA TESTING IN A COHORT OF PATIENTS FROM A SINGLE CENTRE

J. Loureiro-Amigo[1], R. Pujol-Borrell[2], A. Marín-Sánchez[2], R. Solans-Laqué[1], J. Mestre-Torres[1]. [1]*Internal Medicine – Autoimmune Diseases Department;* [2]*Immunology Department, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

**Background:** Antineutrophil cytoplasmic antibodies (ANCA) are autoantibodies directed against constituents of primary granules of neutrophils. ANCA are the serological marker of some idiopathic systemic vasculitides, predominantly involving small and medium-sized blood vessels, such as granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), which are known as the ANCA-associated vasculitis (AAV). Although ANCA are the serological hallmark of AAV, ANCA have been reported in a number of other conditions including infections, malignancies, connective-tissue diseases, liver and gastrointestinal diseases, renal diseases, and other vasculitides. Many studies have evaluated the clinical value of ANCA testing, but few analyze ANCA utility under actual routine conditions in unselected patients with the usual laboratory techniques.
**Objectives:** Our aim was to evaluate the positive predictive value (PPV) of ANCA testing in a cohort of unselected patients from a Spanish tertiary hospital.
**Methods:** We reviewed the clinical charts of patients with positive ANCA testing between January 2014 and December 2014 at the Immunology Department from a 1.000-bed tertiary teaching hospital from Barcelona (Spain). Detection methods included indirect immunofluorescence (IIF) for all testing request and chemiluminescent immuno-assay (CLIA) for antibodies against mieloperoxidase (MPO) and proteinase 3 (PR3) in patients with positive IIF.
**Results:** Out of 1615 patients with ANCA testing request, 298 (18.5%) tested positive. Atypical pattern (X-ANCA) was the most frequent (50.3%) over perinuclear pattern (P-ANCA) (27.5%) and cytoplasmatic pattern (C-ANCA) (22.1%). 35.4% of P-ANCA and 36.4% of C-ANCA were positive for MPO-ANCA and PR3-ANCA, respectively, whereas 97.3% of X-ANCA tested negative by CLIA. 53 (18.2%) patients with positive ANCA had a diagnosis of ANCA-associated vasculitis (AAV). Other diagnosis were the following: 26 (8.9%) connective tissue diseases, 13 (4.5%) vasculitides non-AAV, 13 (4.5%) autoimmune liver diseases and 11 (3.8%) inflammatory bowel disease. The combination of IIF and CLIA showed the best diagnostic accuracy. P-ANCA with anti-MPO had a PPV of 75% for AAV, and PPV of C-ANCA with anti-PR3 was 70.8% for GPA.
**Conclusions:** This study proves that ANCA testing with modern commonly commercially available methods has an elevated PPV for AAV in routine clinical practice.

## AB0550 HUGHES-STOVIN SYNDROME: SUCCESSFUL USE OF INFLIXIMAB IN LIFE THREATENING BEHCET'S, WITH PULMONARY INVOLVEMENT IN 3 CASES IN AN UNIVERSITY HOSPITAL

M. Prathapsingh[1], S. Bagguley[1], S. Jones[1], B. Hope-Gill[2], A. Gordon[3], J.T. Nash[1]. [1]*Rheumatology;* [2]*Respiratory medicine;* [3]*Radiology, University Hospital of Wales, Cardiff, United Kingdom*

**Background:** Hughes-Stovin Syndrome (HSS) is described as a very rare vascular manifestation of Behcet's disease in medical literature. HSS is a very rare clinical disorder and around 40–60 published cases of HSS have been described in medical literature so far.
**Objectives:** To illustrate the use of Infliximab in three cases.
**Methods:** Case1: A 25 year old male presented with optic nerve emboli, oral ulcers and CT scan revealed pulmonary artery aneurysms within the right lower lobe and pulmonary emboli (image). This was treated with Endovascular coiling, pulsed cyclophosphamide, mycophenolate and prednisolone. He had ongoing episodes of haemoptysis that were treated with Infliximab. The patient is now well controlled on Infliximab, mycophenolate and prednisolone.
Case2: A 34 year old male with history of genital and mouth ulcers, presented with haemoptysis and CT scan showed multiple pulmonary emboli with aneurysms. He was treated with pulsed Methyl-prednisolone and infliximab 5mg /kg at weeks 0,4,6 and 8, followed by every 8 weeks and Methotrexate. He later developed a DVT, therefore the methotrexate was switched to Azathioprine 2.5mg/kg/day

and he received Methyl-prednisolone. Infliximab dose was increased to every 2 weeks. After ongoing review he was switched from Infliximab to Adalimumab and he is now in remission.
Case3: A 19 year old male admitted with haemoptysis and respiratory compromise and was intubated in ICU. His CTPA showed bilateral pulmonary emboli with aneurysms. He had erythematous macules, follicular papules, oral ulcers and weight loss with positive pathergy. He was treated with IV methyl prednisolone and infliximab 5mg/kg every 2 weeks.He was extubated 24 hrs after starting treatment and he was discharged home within 9 days of treatment.He is maintained on Adalimumab and Azathioprine and he is now in remission.
**Results:** Although case 1 did not fulfill the ISG criteria for Behcet's disease, case 2&3 fulfilled the criteria. Case1 had a protracted course although managed as per Behcet's pathway by Behcet's centres of excellence in UK and Infliximab was used as a step up treatment. Case 3 presented very unwell, but he was extubated 24 hrs after starting treatment and Infliximab was used as an induction treatment.

**Conclusions:** Early diagnosis and timely intervention is crucial in improving the prognosis of patients with HSS. Our experience of these 3 rare cases suggests that Infliximab should be used as induction treatment in managing life threatening HSS.

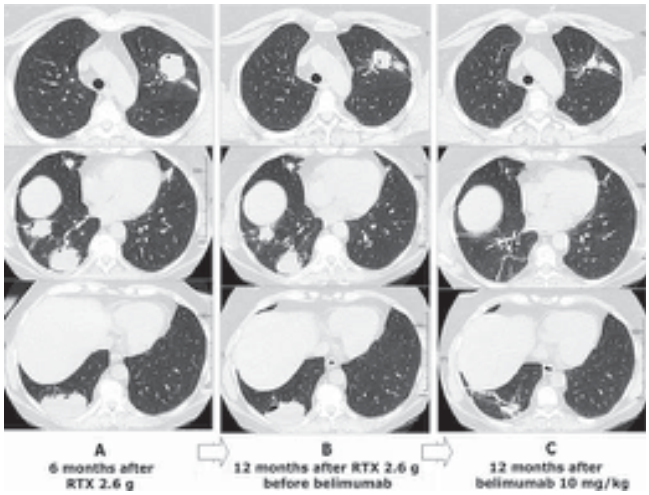
## AB0551 CLINICAL APPLICATION OF TWO DIFFERENT DISEASE ACTIVITY SCORES FOR ENT INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS



M. Felicetti[1], D. Cazzador[2], C. Faccioli[2], R. Padoan[1], E. Emanuelli[2], E. Zanoletti[2], A. Martini[2], F. Schiavon[1]. *[1]Operative Unit of Rheumatology; [2]Department of Neuroscience, Operative Unit of Otolaryngology, University of Padova, Padova, Italy*

**Background:** In the management of Granulomatosis with Polyangiitis (GPA), is critical to assess correctly the disease activity in each organ to define the better therapeutic approach and follow up strategy. This statement is also valid for ENT involvement, that we decide to assess with two different organ specific disease activity scores, the already validated Del Pero ENT/GPA DAS[1] and a new ENT score developed by our Otolaryngology Unit (Padova,ENT/GPA DAS), composed by 8 items: nasal crusting, reported bloody rhinorrhea, nasal inflammation, laryngoscopy inflammation, objective stridor, inflamed TM/middle ear, siero-mucous otitis and hearing loss.
**Objectives:** Compare the accuracy of two different ENT scores (ENT/GPA DAS and Padova ENT/GPA DAS) and correlate them with the most commonly used GPA Activity Indexes and identify if they are effective to predict relapses that require therapeutic changes.
**Methods:** We selected retrospectively the GPA patients with ENT involvement followed by Rheumatology and Otolaryngology Units from 2006 to 2015. Each ENT evaluation of our patients were matched with temporally nearest Rheumatologic visit to assess the ENT/GPA DAS, the Padova ENT/GPA DAS, the Birmingham Vasculitis Activity Scores (BVAS v3, BVAS-WG), the Physician Global Assessment (PGA), the Vasculatis Damage Index (VDI), the serological biomarkers (ESR and CRP) and treatment strategy.
For statistical analysis, we used Mann Whitney test, Spearman test and Fisher test.
**Results:** The selected ENT/GPA patients were 25 (41.6% of all GPA patient cohort), mainly middle aged (51.7±14.9 years), women (64%) and ANCA positive (80%) with PR3 specificity (75%). The total of ENT assessment were 67, so some patient were seen more than once (mean 2.68, min 1, max 8). The two considered ENT scores presented a significant difference ($p<0.0004$) from each other and the correlation analysis showed that ENT/GPA DAS was directly correlated to ESR ($p<0.0001$), CRP ($p=0.03$), BVAS v3 ($p=0.005$), BVAS-WG ($p=0.004$) and PGA ($p<0.0001$), while our Padova ENT/GPA DAS presented a significant correlation only with VES ($p<0.0001$) and PGA ($p=0.027$).
The therapeutic strategies analysis observed that, in all cohort, the change of the immunosuppressive drug (32/67) presented higher BVAS v3 ($p<0.0001$), BVAS-WG ($p<0.0001$) and PGA ($p<0.0001$). Furthermore, in follow up visits of patient in maintenance therapy or induction of remission therapy, excluded those with Cyclophosphamide or Rituximab (25/44), we observed a significant increased rate of therapeutic change in those with ENT/GPA DAS higher than 0 ($p=0.025$, OR 5.8 IC95% 1.16–24.9)
**Conclusions:** Our analysis showed that ENT/GPA DAS is more performing than Padova ENT/GPA DAS to reflect the disease activity. This is probably a consequence that some items considered in our ENT/GPA DAS, such as all type of hearing loss, express better the damage than active disease. Moreover, the data showed that ENT/GPA DAS could identify patients with an active disease worthy of therapeutic changes, especially in particular patient subsets. This data should be confirmed with further evidences on larger GPA patients cohorts and prospective studies.

## AB0552 SUCCESSFUL EXPERIENCE WITH BELIMUMAB IN THE TREATMENT OF REFRACTORY GRANULOMATOSIS WITH POLYANGIITIS

T.V. Beketova, M.Y. Volkov, M.N. Chikina, N.O. Nikonorova, T.M. Novoselova. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Anti-CD20 antibody rituximab (RTX) has proved beneficial in ANCA-associated vasculitis (AAV). However, granulomatous features typical for the granulomatosis with polyangiitis (GPA) can be resistant to RTX, primarily after a single course. Local production of B-cell activating factor (BAFF) in granulomatous lesions and elevated levels of serum BAFF in AAV provide a rationale for BAFF-targeted therapies. The anti-BAFF monoclonal antibody (belimumab) has shown efficacy in SLE, and its role as a relapse prevention agent in AAV is being assessed in a randomized trial (BREVAS), but whether BAFF-neutralization can be used to induce remission of AAV remains unsolved.
There is some evidence for increasing of BAFF levels after RTX treatment (Holden et al., 2011) and high levels of BAFF are associated with a shorter duration of the RTX-induced B-cell depletion. Thus, addition of belimumab should potentially enhance B-cell suppression.
**Objectives:** Here we present the first clinical case report of effective belimumab use for remission induction in GPA with severe pulmonary granulomatous inflammation, which was refractory to cyclophosphamide (CYC) and one course of RTX.
**Results:** A 56-year-old woman with 6-month history of fever, rhinitis, otitis, cough, polyarthralgia and cranial nerve affection was admitted to hospital. A chest X-ray revealed bilateral nodules. Fiberoptic bronchoscopy revealed infiltration in the subglottic area and ulcerated lesions along the tracheobronchial tree. She also had elevated inflammatory markers (ESR 24 mm/h, CRP 48 mg/dL), thrombocytosis (PLT $781\times10^3$/mm$^3$) and cytoplasmatic pattern positive ANCA by indirect immunofluorescence screening. GPA was diagnosed. Induction therapy included prednisolone (40 mg/day) and pulses of CYC and methylprednisolone.
6 mo later CYC total dose (TD) was 6.2 g, prednisolone 15 mg/day. A CT scan revealed new focuses of granulomatous inflammation in lungs. Birmingham Vasculitis Activity Score (BVAS)=8. ESR 45 mm/h, CRP 13 mg/dL, platelets $323\times10^3$/mm$^3$, ANCA was negative. RTX (TD 2.6 g) was administered due to the refractory GPA and resulted in B-cell depletion.
After 6 mo of RTX clinical improvement was achieved, however, a CT scan

revealed persistence of pulmonary lesions (A). BVAS=6. CRP 2 mg/dL, CD19+ B-cells 0%. Mycophenolate mofetil 1 g/day was initiated but soon discontinued due to nausea and replaced by azathioprine 100 mg/day. As there was no significant improvement after 12 mo of RTX (B), treatment with belimumab was initiated (800 mg/wk N2, then 800 mg/mo).

CT monitoring showed consistent improvement of pulmonary lesions after administration of belimumab (C), but at 12 mo the lesions failed to resolve completely, necessitating the prolongation of Belimumab to total 18 mo, then due to poor tolerability (emerging stomatitis) it had to be discontinued. Thus, RTX was restarted at 500 mg twice with 6 mo interval, providing further improvement in CT images.

**Conclusions:** Belimumab can be useful in treatment of patients with GPA, who are refractory to CYC and RTX. Combined approach to B-cell targeting with both anti-CD20 and anti-BAFF treatment can represent promising strategy for patients with severe refractory GPA.

## AB0553 SYSTEMIC VASCULITIS OF AUTOIMMUNE AND SEPTIC ORIGIN – A COMPARATIVE POSTMORTEM STUDY OF 38 RHEUMATOID ARTHRITIS PATIENTS

M. Bély[1], Á. Apáthy[2]. *[1]Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God; [2]Department of Rheumatology, St. Margaret Clinic, Budapest, Hungary*

**Background:** Systemic vasculitis of autoimmune origin (A-SV) is of critical importance in the pathogenesis of rheumatoid arthritis (RA). RA may be complicated by septic infections (SI) accompanied with systemic vasculitis of septic origin (S-SV). The correct clinical diagnosis of A-SV and S-SV is essential because of essential differences in therapy.

**Objectives:** The aim of this study was to characterize the A-SV and S-SV by the type, incidence and severity of vasculitis involving blood vessels of different caliber.

**Methods:** At the National Institute of Rheumatology 12138 patients died between 1969 and 2000; among them 234 with RA and all of them were autopsied. RA was confirmed clinically according to the criteria of the ACR. Lethal septic infection (SI) was observed in 31 (13.25%) of 234 patients. SI was accompanied in 5 patients with S-SV. The clinically identified pathogenic agents and the strong, significant and positive correlation between S-SV and SI (association coefficient: 1, $c^2$=26.1881, $p<0.00007$) supported the infectious origin of SV.

The average incidence and severity of S-SV in twelve organs of these 5 RA patients was analyzed and compared with 33 RA patients with A-SV of our previous study [1]. The negative value of association coefficient and the lack of significant correlation between A-SV and lethal SI (association coefficient: -0.3249 $c^2$=0.6052, $p<0.44$) supported the direct autoimmune origin of SV in patients without SI [1].

The incidence (existence), severity, and the types of vasculitis (non- specific – Ns, fibrinoid necrotic – Fn, granulomatous – Gr) in blood vessels of different calibers (arteriole – a, small artery – A, medium size artery – AA, venule – v, small vein – V, medium size vein – VV) were determined visually in histological slides [1]. Severity of vasculitis was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale (based on the number of involved vessels/light microscopic field x40).

**Results:** The incidence and severity of A-SV and S-SV in absolute number is summarized in Table.

| N of RA patients with SV | Type of vasculitis | | | Size of involved blood vessels | | | | | | Total |
|---|---|---|---|---|---|---|---|---|---|---|
| | Ns | Fn | Gr | a | A | AA | v | V | VV | |
| A-SV (n=33) | | | | | | | | | | |
| A-SV incidence | 216 | 64 | 45 | 169 | 106 | 32 | 6 | 9 | 3 | 325 |
| A-SV severity | 395 | 119 | 80 | 322 | 191 | 55 | 9 | 13 | 4 | 594 |
| S-SV (n=5) | | | | | | | | | | |
| S-SV incidence | 50 | 17 | 0 | 27 | 23 | 15 | 0 | 0 | 2 | 67 |
| S-SV severity | 87 | 27 | 0 | 53 | 40 | 18 | 0 | 0 | 3 | 114 |

**Conclusions:** The clinical course of RA characterized by acute exacerbations and relapses corresponds to the relapsing nature of autoimmune vasculitis. A-SV and S-SV may exist in different stages of inflammation at the same time [1]. A-SV is more severe and shows variegated histologic changes, versus S-SV which is less severe and more monotonous.

Non-specific and fibrinoid necrotic vasculitis may exist in A-SV and S-SV as well. Granulomatous vasculitis was never detected in S-SV; the presence of granulomatous vasculitis refers to A-SV.

Arteries of all calibers may be involved in both systemic vasculitis with more pronounced involvement of medium size arteries in S-SV. Veins were never involved in S-SV; the inflammation of veins supports A-SV.

Histological differences may help in identification of autoimmune or septic origin of vasculitis.

## AB0554 AN AUDIT OF THE PREVENTION OF LONG TERM COMPLICATIONS IN PATIENTS WITH AN ANCA-ASSOCIATED VASCULITIS

M. Naushad Amin[1], N. Brown[2], M. Venning[2], S. Haque[3]. *[1]Manchester Medical School, University of Manchester; [2]Renal Medicine, Central Manchester University Hospital; [3]Department of Rheumatology, University Hospital of South Manchester, Manchester, United Kingdom*

**Background:** ANCA–associated vasculitis (AAV) is a potentially life threatening condition which requires immediate intervention with immunosuppressive treatment. Although patient survival from disease had improved, unfortunately patients survive to experience long term complications of both the disease and the treatment. The major cause of early mortality in this population is infection with increased later risks of malignancy and cardiovascular disease. Patients are also at risk of other treatment related morbidity such as impaired fertility. These complications are a major cause of morbidity and mortality in these patients, therefore it is vital to implement all the available preventative measures when indicated

**Objectives:** The aim for this audit was to assess whether patients were receiving the correct adjuvant treatment and counselling in order to protect them against the long term complications of ANCA-associated vasculitis and the side effects from treatment.

**Methods:** Patients under the Rheumatology/Renal vasculitis clinic at the University Hospital of South Manchester (UHSM), with a diagnosis of an AAV, were identified. Audit standards were set using 2008 EULAR recommendations and BSR/BHPR guidelines for management of patients with vasculitis, therefore patients diagnosed before the publication of the 2008 EULAR recommendations (April 2008) were excluded from this audit. Standards were set at 100% unless stated otherwise. Data was collected retrospectively from patient's medical records and electronic secondary care records.

**Results:** We identified 22 patients diagnosed with AAV at UHSM after April 2008, comprising of 12 male and 10 female patients, ranging from 23 to 70 years of age. The median age is 51 and the interquartile range is 22.5. Of these patients, 25% were assessed for their risk of tuberculosis prior to treatment and 77.2% and 72.7%, were given the influenza and pneumococcal vaccines respectively. Only 4.76% of patients had a full cardiovascular risk assessment in the 12 months prior to this audit. This comprised of monitoring the patients' blood pressure (95.24%), weight (90.48%), cholesterol (80.95%) and HbA1c/ fasting glucose levels (76.19%) and counselling patients about smoking cessation (0% documented) and exercise (23.81% documented). Of the 13 patients treated with intravenous cyclophosphamide, 87.5% received Mesna, 91.6% were monitored for bladder cancer with a urinalysis and 40% of women were documented to have been advised to have cervical smears. 37.5% of patients were informed about the risk of infertility; however, no male patients had a documented offer of sperm banking.

**Conclusions:** Optimal preventative management for the complications of disease and treatment were not uniformly applied to patients with AAV. Awareness and screening for cardiovascular risks were good however areas for improvement include counselling these patients about possible risks associated with treatment of the disease, such as infertility and encouraging uptake of protective measures

## AB0555 AMOUNT OF PROTEINURIA IS RISK OF FLARE FROM BVAS REMISSION AMONG MICROSCOPIC POLYANGIITIS PATIENTS IN JAPAN

M. Watanabe[1], Y. Fujita[2], H. Shimizu[3], M. Terashita[3], Y. Haji[1]. *[1]Rhuematology, Daido hospital; [2]Rheumatology; [3]Nephrology, Chuburosai hospital, Nagoya, Japan*

**Background:** Microscopic polyangiitis (MPA) is a common form of ANCA associated vasculitis in Japan. Renal involvement is frequent in MPA and an important factor with respect to therapeutic methods and outcomes.

**Objectives:** To determine the association between renal characteristics at diagnosis and the relapse.

**Methods:** A retrospective review was conducted in 28 patients who were newly diagnosed as MPA. (January 2007 to August 2015) Baseline characteristics are collected include urine profile and renal pathology. The primary endpoint is the first flare. Disease flare is defined an increase in at least one major Birmingham vasculitis activity score (BVAS) items. Furthermore, analysis on other outcomes, such as end stage renal failure, induction of hemodialysis and death has been conducted.

**Results:** Of the 28 patients with MPA, all patients had renal vasculitis. 18 achieved BVAS remission, and relapse occurred among 5 patients (19.2%). Cox

multivariate analysis showed that amount of proteinuria on admission was a predictor of relapse (HR 4.2; 95% CI, 0.13–10.5). In renal biopsy, those relapsed five cases tend to have more intensive glomerulonephritis, according to the European Vasculitis Study Group (EUVAS) classification, though no statistical significance was performed.

**Conclusions:** Amount of proteinuria is a risk factor for relapse in MPA.

## AB0556 HLA REVISITED IN EGYPTIAN PATIENTS WITH BEHÇET'S SYNDROME:NEW ASSOCIATIONS OF HLA ALLELES WITH SUSCEPTIBILITY, PROTECTION, PRESENTATION AND SEVERITY OF THE DISAESE

M.M. Elfishawi[1], F.T. Elgengehy[1], G.I. Mossallam[2], S.M. Elfishawi[2], M.M. Alfishawy[3,4], I.M. Metwally[1]. *[1]Rheumatology Department, Kasr Alainy Hospital, Cairo University; [2]Clinical Pathology Department, National Cancer Institute, Cairo University; [3]Internal Medicine, Kasr Alainy Hospital, Cairo University, Giza, Egypt; [4]Internal Medicine, Icahn School of Medicine at Mount Sinai, Queens Hospital Center, New york, United States*

**Background:** Behçet's syndrome is a multisystem autoimmune syndrome that has a male predominance. Its manifestations usually start in the young adulthood with target organ damage affecting mainly the skin, eyes, Brain and blood vessels [(1)]

**Objectives:** The aim of the study was to investigate HLA class I genotyping in a cohort of Egyptian patients with Behçet's syndrome and comparing them with HLA genotyping in healthy population (control group) to estimate possible association between HLA and syndrome susceptibility as well as syndrome presentations.

**Methods:** Fifty-seven Egyptian patients with Behçet's syndrome fulfilling the International study group criteria for Behçet's syndrome[(2)] were recruited from the Rheumatology department, Cairo University teaching hospitals.HLA class I genotyping was done for all patients via sequence specific oligonucleotides probes at the National Cancer Institute. HLA class I genotyping data of normal control group was obtained from case control studies done on Egyptian population with a total of 221 individual. [(3–4)]

**Results:** The studied 57 patients were divided into 50 males and 7 females. The mean age of patients was 35.28±9.73 years with mean disease duration of 9.26±7.36 years. The main clinical features were oral ulcers (100%), genital ulcers (100%), eye involvement (54%) neurological involvement (29%) and vascular involvement (36%) furthermore (33%) had bilateral visual acuity $\leq$6/60 fulfilling the diagnosis of legal blindness.

Certain HLA genotypes were significantly associated with susceptibility for Behçet's syndrome, the odds ratio (OR) for HLA-A68 was 8.4 (CI=2.9–25.9), HLA-B15 was 6.7 (CI=2.9–15.6), HLA-B51 was 6.6 (CI=3.4–13.0), HLA-A24 was 4.0 (CI=1.5–10.2) and HLA-A2 was 2.1 (CI=1.1–3.8). On the other hand HLA A3 genotype was found to be significantly protective with odds ratio of 0.003 (CI=0.01–0.6).

HLA B51 was significantly associated with ocular disease with odds ratio of 3.47. Furthermore HLA B51 was associated with legal blindness with a significant odds ratio of 5.21.

**Conclusions:** HLA A68, B15, B51, A24 and A2 are associated with Behçet's syndrome susceptibility in the present cohort of Egyptian patients and A3 was found to be protective.

HLA B51 is associated with ocular involvement and more important the blinding eye disease and can be considered as a poor prognostic marker for ocular disease.

## AB0557 BEHÇET'S DISEASE IN WOMEN: A TUNISIAN SERIES OF 135 PATIENTS

T. Ben Salem, M. Tougorti, I. Naceur, I. Ben Ghorbel, M. Lamloum, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

**Objectives:** The aim of this study was to describe clinical and genetic characteristics of Behçet's disease (BD) in women and to compare them with those in men.

**Methods:** 430 cases of patients with BD (fulfilling criteria of the International Study Group for BD) were studied. Clinical and genetic characteristics of women with BD were noted, than compared to those observed in male BD patients. Data were compared using the Chi2 test and the Fisher exact test.

**Results:** 135 women were studied; the mean age at the onset of the BD was at 28.7 years. The average age at BD diagnosis was 34.64 years. Genital aphtosis was noted in 71.9% of patients and skin lesions in 83% (pseudofolliculitis: 63.7%, erythema nodosum: 28.9% and positive pathergy test: 56.6%). Ocular involvement in type of uveitis was noted in 43% of patients and retinal vasculitis in 23.7% of them. 65% of women complained of arthralgia while only 7.4% of them presented arthritis. Neurological manifestations were objectified in 31.9% of patients. Deep vein thrombosis (DVT) and arterial disease were noted respectively in 15.6% and 0.7% of cases. HLA B51 was present in 47.7% of women with BD in our series. Compared to male patients, women had significantly less genital aphtosis (71.9% vs 83%, p=0.008), pseudofolliculitis (63.7% vs 79.6%, $p<0.0001$), DVT (15.6% vs 33.2%, $p<0.0001$) and arterial disease (0.7% vs 9.2%, p=0.001). On the contrary, arthralgia (65% vs 47.5%, p=0.007) and erythema nodosum (28.9% vs 11.6%, $p<0.0001$) were significantly more frequent in women.

**Conclusions:** Our results were similar to other BD series regarding the high incidence of erythema nodosum and joint manifestations in women, and the lower frequencies of genital aphtosis and vascular involvements compared to men.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.1104

## AB0558 JUVENILE-ONSET BEHÇET'S DISEASE: CLINICAL AND GENETIC FEATURES COMPARED WITH ADULT ONSET-DISEASE

T. Ben Salem, I. Naceur, M. Tougorti, I. Ben Ghorbel, M. Lamloum, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

**Background:** Behçet's disease (BD) is are in children.

**Objectives:** The aim of this study was to describe clinical spectrum of BD in childhood in comparison to adult onset-disease.

**Methods:** We conducted a retrospective study over 10 years including 430 patients with the diagnosis of BD according to the criteria of the International Study Group. The patients were placed into two groups based on the age of the disease onset: group1: juvenile-onset ($\leq$16 years) and group 2: adult-onset disease (age $>$16 years). Clinical, genetic and therapeutic characteristics of juvenile patients were analyzed and compared with adult patients

**Results:** There were 38 cases with juvenile onset disease (24 males, 14 females; gender ratio M/F: 1.7). A family history of BD was found in 3 patients. The mean age of the disease onset in this group was 12.8 years ±2.9 and the average age at BD diagnosis was 21.55 years ±7.47. Genital ulcers were observed in 71% of cases. Skin lesions were found in 76.3% of patients and positive pathergy test in 70.4%. Nineteen patients (50% of cases) had ocular involvement (uveitis: 18 cases, retinal vasculitis: 10 patients) which was complicated of blindness in 2 cases. Neurological involvement was observed in 8 patients (21% of cases). Eight patients presented vascular lesion (superficial venous thrombosis: 5 cases, deep venous thrombosis: 3 cases), no cases of arterial involvement was noted. HLA B51 was found in 62.5% of cases. Comparative study of the 2 groups showed that children with BD had significantly less deep venous thrombosis and more superficial venous thrombosis. The ocular involvement was relatively less severe in children (blindness: 15.4% vs 32.5%). Treatment was based in colchicine, corticosteroids (73.7%) and immunosuppressant agents. Cyclophosphamides were more used in adults (45.6% vs 26.3%; p=0.02) and azathioprine in children (46% vs 33%; p=0.08).

**Conclusions:** Behçet's disease in children is characterized in our series by the frequency of superficial venous thrombosis and seems to run a less severe course (less DVT and blindness, no arterial involvement and less use of cyclophosphamide). An appropriate and early treatment would prevent the occurrence of serious visceral complications in these patients.

## AB0559 RELIABILITY AND VALIDITY OF THE TURKISH TRANSLATION OF THE BELIEFS ABOUT MEDICINES QUESTIONNAIRE (BMQ-T) IN PATIENTS WITH BEHÇET'S DISEASE

M. Cinar[1], F.I. Cinar[2], C. Acikel[3], S. Yilmaz[4], M. Cakar[1], R. Horne[5], I. Simsek[6]. *[1]Division of Rheumatology, Gulhane Military Medical Academy, School of Medicine; [2]Gulhane Military Medical Academy, School of Nursing; [3]Department of Biostatistics; [4]Gulhane Military Medical Academy, School of Medicine, Ankara, Turkey; [5]Centre for Behavioural Medicine, UCL School of Pharmacy, University College, London, United Kingdom; [6]Division of Rheumatology, Güven Hospital, Ankara, Turkey*

**Background:** Behçet's disease (BD) is a multisystem vasculitis with unknown etiology characterized by the heterogeneous nature of organ involvement and a fluctuating disease course. There are various effective treatment alternatives, while, the first and essential step for a successful treatment is patients' adherence to therapy. Efforts to improve treatment outcomes require a better understanding of the particular barriers to and facilitators of adherence to therapy, and of patient experiences of taking treatment. Treatment adherence is influenced by many factors, among them: i) route of administration, ii) psychosocial factors, iii) fear of side effects, iv) lack of an immediate feeling of benefit, and v) patient attitudes to health and disease and beliefs about medicines.
**Objectives:** The aim of this study was to evaluate the reliability and validity of the Turkish translation of the Beliefs about Medicines Questionnaire (BMQ-T)© for patients with Behçet's disease.
**Methods:** This methodological study enrolled a sample of 125 patients. The scale was adapted to Turkish through a process including translation, comparison with versions in other languages, back translation, and pretesting. Construct validity was evaluated by factor analysis. Medication adherence evaluated as poor, moderate and good according to the Morisky Medication Adherence Scale (MMAS). BMQ-T scores compared along medication adherence status groups.
**Results:** In our study, as in the original scale, the factor analysis confirmed that the BMQ-T had a four-factor structure explaining 54.73% of the total variance. The BMQ-T had acceptable internal consistency (Cronbach's alpha coefficient: Specific Necessity = 0.812; Specific Concerns = 0.672; General Harm = 0.677; General Overuse = 0.656), adequate test–retest reliability (intraclass correlation coefficients: Specific Necessity = 0.715; Specific Concerns = 0.680; General Harm = 0.678; General Overuse = 0.327). Specific Necessity and Specific Concerns scores were significantly different between medication adherence status groups.
**Conclusions:** The psychometric properties of the BMQ-T were consistent with those reported in the original study. The BMQ-T was found to be a valid and reliable tool for evaluating beliefs about medicines in patients with Behçet's disease.

## AB0560 CLINICAL FEATURES OF ARDIOVASCULAR INVOLVEMENT IN BEHCET'S DISEASE

N. Gao, T. Wang, H. Liao, W. Ci, Y. Guo, J. Du, W. Han. *Anzhen Hospital, Capital Medical University, Beijing, China*

**Background:** Behcet's disease is a kind of systemic vasculitis. Multiple organs including derma, mucosae, articulation, neurologic system, gastrointestinal tract and cardiovascular system might be involved. Vital organ complications lead to poor outcomes. Cardiovascular involvement in Behcet's disease is estimated to range from 7% to 40%, with fatality rate reaches up to 29% [1–3].The characteristics of Chinese Behcet's disease patients with cardiovascular lesions were rarely reported before.
**Objectives:** To investigate the clinical characteristics of cardiovascular involvement in Behcet's disease.
**Methods:** We reviewed 35 medical records of patients of Behcet's disease with cardiovascular lesions in Anzhen Hospital, Capital Medical University between January 2002 and January 2014. All the patients fulfilled the international Behcet's disease study group criteria [4].
**Results:** (1) The mean (±SD) age when the cardiovascular disorders flare-up was 36.9±9.6 years. 27/35 (77.1%) of the patients were male.
(2) The clinical spectrum of cardiovascular abnormalities included valvular regurgitation (20,57.1%, among these patients, two patients complicated with infectious endocarditis, and five patients had perivalvular leakage after primary valvular surgery), conduction system disturbances (10,28.6%), intracardiac thrombosis (1,2.9%), aneurysms of the arteries (13,37.1%), artery stenosis or occlusion (5,14.3%), pulmonary vascular diseases (3,8.6%), venous thrombosis (4,11.4%). 20 patients had more than one of these lesions simultaneously.
(3) Clinical manifestations were varied from shortness of breath (17,48.6%), febrile (9,25.7%), chest pain (5,14.3%), dizziness (4,11.4%), cough (4,11.4%), limb ischemia (4,11.4%), palpitation (3,8.6%), hemoptysis (3,8.6%), seroperitoneum (2,5.7%), facial edema (1,2.9%), dysphagia (1,2.9%), to asymmetric blood pressure (1,2.9%).
(4) Inflammatory indicators erythrocyte sedimentation rate and C-reactive protein were not significantly different between the different subgroups (P=0.26 and P=0.972, respectively).
(5) Ten patients received corticosteroids and immunosuppressive drugs treatment. Intervention therapy (aortic coated stent lumen isolation) was administered on one patient. Operations (including valve replacement, valular annulus reconstruction, Bentall, aorta replacement and heart transplantation) were performed on 12 patients. One patient (2.9%) died from multiple organ dysfunction during hospital stay.
**Conclusions:** Cardiovascular involvement in Behcet's disease is a serious systemic lesion deserved attention. Corticosteroids and immunosuppressive drugs together with intervention therapy or operations are effective remedies for Behcet's disease patients with cardiovascular lesions.

## AB0561 HEART INVOLVEMENT IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

N. Nikitina[1], O. Aleksandrova[1], I. Nam[2], N. Rodionova[3], A. Rebrov[1]. *[1]GBOU VPO "Saratov State Medical University name Rasumovskogo", Saratov, Russia; [2]Rheumatology Department, Regional Clinical Hospital, Saratov; [3]Rheumatology Department, Clinical Hospital, Tambov, Russian Federation*

**Background:** Cardiac involvement is factor of poor prognosis in eosinophilic granulomatosis with polyangiitis (EGPA). Due to current data, heart lesions in EGPA are associated with higher peripheral eosinophilia. However, data about cardiac manifestations of EGPA are limited.
The aim of the study was to evaluate the frequency of occurrence of heart involvement in patients with EGPA, and to study interrelation of heart lesion and peripheral eosinophilia and other signs of the disease.
**Objectives:** Were analyzed 19 case histories of patients with EGPA (13 women and 6 men, mean age ± SD – 49.8±14.8 years, mean disease duration – 4.6±3.76 years). The patients were treated in Saratov regional hospital, rheumatology department.
**Methods:** Were used clinical tests and echocardiography.
**Results:** 7 (36.8%) patients had features of heart damage. In 2 patients were found clinical signs of myocarditis, confirmed with echocardiography (ejection fraction 48 and 50%, respectively). In 1 patient was found fibrosis of atrioventricular valves, in 3 patients – signs of valvular insufficiency, in 1 – was diagnosed coronariitis.
Eosinophils number was increased in 11 patients: in 4 from 7 patients with cardiac involvement and in 8 from 11 without heart lesion. The highest number of eosinophils was found in 2 patients with miocarditis (40 and 43%, respectively). Improvement in miocarditis and ejection fraction under the treatment was associated with decrease of eosinophils count.
In other patients during the treatment (12–24 month of follow-up) eosinophils count was normalized. There were no new features of cardiac involvement under the treatment.
**Conclusions:** Patients with EGPA frequently have cardiac involvement. Miocarditis is associated with high eosinophils' count. Heart involvement is reversible and has no trend to progression under the treatment.

**Disclosure of Interest:** None declared

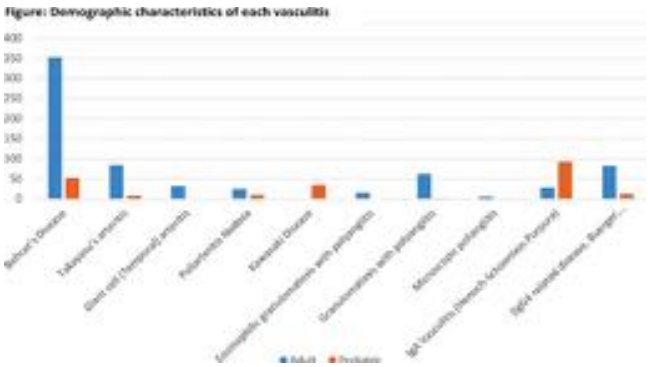
## AB0562 DEMOGRAPHIC CHARACTERISTICS AND DISTRIBUTION OF THE VASCULITIDES FREQUENCIES: A REAL- LIFE EXPERIENCE OF VASCULITIS CENTER FROM EASTERN MEDITERRANEAN

O. Karadag, A. Erden, E. Bilgin, E.D. Batu, B. Armagan, A. Sarı, E. Fırat, Z.S. Arıcı, A.O. Uyaroğlu, E. Seyhoglu, E.C. Bolek, U. Kalyoncu, A. Akdoğan, S.A. Bilgen, S. Kiraz, I. Ertenli, S. Ozen. *Hacettepe University Vasculitis Center (HUVAC), Ankara, Turkey*

**Background:** Vasculitides are a heterogeneous group of diseases. The distribution of the type of vasculitis changes not only with age and sex but according to the geographic area as well. The prevalence of each vasculitis is important in guiding the local medical education and raising awareness of doctors and policy makers etc.
**Objectives:** This study is aimed to present the distribution of vasculitides in the Pediatric and Adult Vasculitis patient Groups.
**Methods:** Hacettepe University is one of the main referral centers in the country. Executive committee of our Vasculitis center consist of physicians from Pediatric



and Adult Rheumatology, Nephrology, Radiology and Pathology Departments. Multidisciplinary approach improves management of our patients. All patients starting from October 2014 have been included and defined according to the 2012 revised Chapel Hill nomenclature criteria.

**Results:** A total of 882 patients had been newly diagnosed/followed in this period. 205 (23.2%) of them were pediatric patients. The leading vasculitis among adult patients was Behcet's Disease whereas in pediatric patients it was HSP (Figure). More than half of the adult Behcet's patients (58.4%) had uveitis/neurologic/vascular involvement.

Takayasu arteritis was more frequent than giant cell arteritis among the adult patients. There was a female predominance in patients with large vessel vasculitis. Granulomatous polyangiitis was the most common small vessel vasculitis in adults. Finally 23 adult cases of Immunglobulin G4 related disease have been seen.

Table 1. Demographic characteristics of each vasculitis

| | Adult patients Mean age (SD) | Pediatric patients Mean age (SD) |
|---|---|---|
| Behçet's disease | 42.8 (12.9) | 11.8 (4.0) |
| Female, % | 52.5% | 46.1% |
| Takayasu's arteritis | 38.9 (14.2) | 14.3 (4.1) |
| Female, % | 91.6% | 100% |
| Giant cell (temporal) arteritis | 69.5 (8.2) | – |
| Female, % | 74.2% | |
| Poliarteritis nodosa | 40.1 (15.3) | 11.3 (7.3) |
| Female, % | 39.1% | 50.0% |
| Kawasaki disease | – | 4.7 (3.0) |
| Female, % | | 26.4% |
| Eosinophilic granulomatosis with polyangiitis | 52.9 (19.3) | 10 |
| Female, % | 60% | 100% |
| Granulomatosis with polyangiitis | 54.1 (15.9) | 8.5 |
| Female, % | 46.5% | 50% |
| IgA Vasculitis (Henoch-Schoenlein purpura) | 38.3 (18.5) | 7.3 (4.9) |
| Female, % | 46.1% | 47.7% |
| IgG4related disease | 47.8 (17.8) | – |
| Female, % | 52.2% | |
| Others (secondary vasculitis, Buerger, cryoglobulinemic vasculitis, aortitis, etc.) | 47.4 (15.6) | 13 (5.1) |
| Female, % | 50% | 50% |

**Conclusions:** We describe the demographic characteristics and distribution of vasculitides in the eastern Mediterranean. Behcet's disease has a high frequency as expected. Also Takayasu arteritis is more frequent than Giant cell arteritis. Microscopic polyangiitis is very rare. Among children Kawasaki was less and Behçet disease markedly more when compared to western Europe figures. The observed differences may be due to genetic modifiers or environmental factors.

## AB0563 TAKAYASU'S ARTERITIS: EXPERIENCE FROM A TERTIARY CARE CENTRE IN WESTERN INDIA

P.S. Sagdeo, R. Samant, C. Balakrishnan, G. Mangat, T. Parikh, Y. Gc.
*Rheumatology, P.D Hinduja Hospital and Medical Research Center, Mumbai, India*

**Background:** Takayasu's arteritis (TA) is a rare, granulomatous panarteritis of aorta and its major branches, most commonly presenting before the age of 40 years. There is limited data regarding epidemiology of TA from India.

**Objectives:** To describe the clinical profile and outcome of patients with Takayasu arteritis from a tertiary care centre in western India.

**Methods:** We analysed medical records of TA patients satisfying the 1990 Criteria of American College of Rheumatology for the Classification of Takayasu Arteritis attending Rheumatology Department from 2009 to 2014.Demographic, clinical, laboratory, imaging features and intervention done were noted.

**Results:** Forty Eight patients were included. Mean ESR at first visit of patients was 51mm/hr and last visit was 28 mm/hr. Mean ITAS at first visit was 10.9 and last visit was 0.6.CT angiography was used in 41%, PET was done in 70% and repeat PET was done in 35%.

Table 1. Disease characteristics

| | |
|---|---|
| Female:Male ratio | 2.69:1 |
| Mean age at diagnosis (mean±SD) (years) | 34.18±11.65 |
| Fatigue | 20 (41.6%), |
| Malaise | 18 (37%), |
| Headache | 12 (25%), |
| Hypertension | 10 (20%), |
| Pulse loss | 33 (68%). |
| Bruit | 35 (72%), |
| Aortic incompetence | 4 (8%) |
| Renal artery stenosis | 5 (10%) |
| Most common pulse loss | Brachial |
| Most common bruit | Carotid |
| Most common class of disease (as per angiographic classification) | Class V |
| Most common steroid sparer used | Methotrexate 28 (58%) |
| Change of steroid sparer required in patients due to lack of efficacy | 13 (27%) |
| Surgical intervention required. | 13 (27%) |
| Patients suffered stroke during the course of illness | 7 (14%) |
| Patients diagnosed in pre pulseless stage of disease | 12 (25%) |
| Uneventful pregnancy | 4 |

**Conclusions:** 1. 12 (25%) patients were diagnosed in pre pulseless stage of disease. 2. As per angiographic classification class V disease was most common seen in our cohort. 3. 27% patients were refractory to treatment requiring surgical intervention.

## AB0564 SHORT-TERM RESULTS OF THE NEW ANTI-TNF TREATMENT WITH CERTOLIZUMAB PEGOL IN REFRACTORY TAKAYASU'S ARTERITIS

P. Novikov[1], I. Smitienko[2], E. Zhiliaev[3], A. Elonakov[4], S. Moiseev[1]. *[1]Sechenov First Moscow State Medical University; [2]Russian Peoples' Friendship University; [3]European Medical Center; [4]Moscow's regional research clinical institute n.a. M.F. Vladimirskiy, Moscow, Russian Federation*

**Background:** Takayasu's arteritis (TAK) has a prolonged chronic course and requires long-term immunosuppressive treatment with different results. Tumor necrosis factor (TNF) alpha is a promising target for treatment in patients with TAK, though clinical experience is limited. Certolizumab pegol (CER) is a pegylated Fab' fragment of a humanized TNF inhibitor monoclonal antibody.

**Objectives:** To evaluate the efficacy and safety of treatment with CER in patients with TAK refractory to standard immunosuppressive treatment.

**Methods:** Four patients with type 5 [generalized] TAK (all females, median age 30.5 years [20–33]) were treated with CER for the average of 10.5 months (8–12). TAK was diagnosed according to the ACR criteria and CHCC2012. CER was administered subcutaneously at a dosage of 400 mg every 4 weeks (with loading dose 400 mg every 2 weeks for the first month). Prior to CER administration all patients were treated with combination of immunosuppressive drugs (PRED + median 3 cytotoxic agents [MTX=4, MMF=3, CYC=2, LEF=1, AZA=1] and 1 biologic agent [INFL=2, TOCI=1] for 7.5 years [1–12]). Criteria of efficacy included complete and incomplete remission and relapse of arteritis. Activity of disease was evaluated using the NIH criteria and the Indian Takayasu Clinical Activity Score (ITAS2010).

**Results:** Median duration of disease before CER administration was 12 years (11–16). High activity of TAK was confirmed by standard laboratory tests (median ESR 38 mm/h, CRP 21 mg/L) and MR-angiography/US. All patients improved, including complete and partial remission in 3 (75%) and 1 (25%) patients, respectively. Median PRED dose was reduced from 15 mg (10–25) to 5 mg daily (≤5 mg daily in 3 patients, discontinuation in 1). 2 patients discontinued MTX and MMF, in 1 patient MTX dose was decreased from 20 to 10 mg/wk, 1 patient continued CER monotherapy for 6 months. After treatment average ESR and CRP were 10 mm/h and 1.2 mg/L, respectively. Repeated US and MRA confirmed low or absence activity of disease in all patients. Median ITAS score decreased from 4 (2–10) to 0 (0–2) and median Kerr index decreased from 2 (1–3) to 0 (0–1). CER administrations were well-tolerated; we observed 1 case of community-acquired pneumonia (after 4 months of CER) and 1 case of post-operative abscess of foot (after 5 months of CER). During treatment with CER there were no relapses of TAK. All patients continue CER treatment.

**Conclusions:** CER is effective in case of active systemic inflammation in patients with TAK that was refractory to other immunosuppressive therapies, including biologic agents (INFL, TOCI). In one case CER monotherapy was sufficient to control disease activity for at least 6 months. As in case of other TNF inhibitors the risk of infections should be taken into account. Long-term results with clinically important end-points (surgical interventions, occlusions or stenosis progression, long-term survival etc.) are awaited.

**Disclosure of Interest:** None declared

## AB0565 DIFFUSE ALVEOLAR HEMORRHAGE, DIAGNOSIS, TREATMENT AND 3-YEAR PROGNOSIS IN A GROUP OF 32 CASES OF TERTIARY CENTRE

P. Bradna[1], J. Manak[2], T. Soukup[1], J. Toms[1], M. Kodeda[1]. *[1]II. GE department of medicine; [2]III.department of medicine, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic*

**Objectives:** Diffuse alveolar hemorrhage (DAH) is severe, life-threatening syndrome, affecting the patients with systemic vasculitis and other systemic connective tissue diseases. It can be often the first manifestation of systemic disease. Frequently DAH is the acute incident, which often leads to the rapidly emerging respiratory and/or renal failure with requirement of ventilatory support and with high mortality rate.
**Methods:** Diffuse alveolar hemorrhage was diagnosed on the basis of bronchoscopy and CT examination in patients with rapidly progressive respiratory insufficiency or newly emerged hemoptysis. Artificial ventilation was started in majority of cases.Therapeutically were used high doses of steroids i.v. (1000 mg 3–5 times in the iv infusion), Cyclophosphamide pulse, and plasmapheresis in some cases.
**Results:** The group of patients consisted of 32 cases; the average age of patients was 54 years (20–71) years. In half of patients was the episode of DAH the first manifestation of the disease. 16 patients were pro3 ANCA-positive, 7 patients MPO-ANCA positive, 6 patient had known systemic connective tissue disease 46.8% of patients survive 3 years from the acute episode of DAH, including two with repeated hemorrhage. 15 patients died during the acute phase of the disease, 3 more died during next 3 years, two of them on an opportunistic infection. Steroids were used for all patients, cyclophosphamide in 71, plasmapheresis in 56%, and i.v. immunoglobulins for 6.25 percent of patients. Patients who survive 3 years after the acute episode, had significantly lower necessity of artificial ventilation (40 vs. 93%) against the fatal cases, unfavorable prognostic sign was long term connective tissue disease. Residual lung impairment is present in 53% of the surviving patients; the signs of pulmonary arterial hypertension are present in 20% of the surviving group.
**Conclusions:** Diffuse alveolar hemorrhage is a sudden life-threatening event with a high mortality rate (46%) in the acute phase and during the first 3 years after the acute episode (20% of survivors). Up to half of patients the episode of DAH may be the first manifestation of the disease. Survival of patient depends on rapid diagnosis and the initiation of intensive immunosuppressive therapy. Respiratory failure is the major negative quoad vitam prognostic factor.
Suspect the diffuse alveolar bleeding is necessary always in the case of a rapidly progressive respiratory failure. Acute bronchoscopy and x-ray examination give diagnosis of DAH, which further specify the acute examination of ANCA antibodies (71% of the report was ANCA antibodies positive.
**Disclosure of Interest:** None declared

## AB0566 OUTCOMES OF TAKAYASU'S ARTERITIS IN CHILDREN AND ADOLESCENTS

R. Maytbasova, P. Ishuova. *Scientific Center of Pediatrics and Children's Surgery, Almaty, Kazakhstan*

**Background:** Takayasu's arteritis (AT) in children and adolescents is ranked number third in frequency among the vasculitis and is one of the common causes of renovascular hypertension. It is believed that the sickness rate of AT is more common in Asian ethnic group. In this disease, vascular stenosis has been found in 90% of cases and 45% of them is the aneurysm. In this regard, early diagnosis and adequate treatment are important to avoid the development of stenosis, aneurysms, vascular thrombosis, ischemia of organs and an adverse outcome.
**Objectives:** To conduct a retrospective analysis of the course and survival in children and adolescents with Takayasu's arteritis.
**Methods:** A retrospective analysis of the course and survival in patients with Takayasu's arteritis observed in the clinic of the Institute since 2005 was conducted. Total: 9 patients. Age: 10–17 years. The ratio of girls/boys was 3.5:1. Takayasu's arteritis was diagnosed according to the diagnostic criteria recommended by the EULAR/ PRINTO/ PRES (2010).
**Results:** All patients were patients of Kazakh nationality. None of relatives of the 1st and 2nd relationship degree had any cases of vasculitis or autoimmune diseases. Chronic nasopharyngeal infection, carious teeth were identified in all patients, which could be a trigger factor for the occurrence of Takayasu arteritis. But, no any cases of relation between Takayasu arteritis and TB infection were identified. On average, from the appearance of disease symptoms and before diagnosis of the disease 14 months had left (8 months ÷ 2 years 2 months). In all patients, Takayasu's disease was diagnosed at advanced stage, characterized by lesions of the arteries extending from the aorta, which was confirmed by angiography. Vascular disease Type III was revealed in 7 patients, type IV in 2. Secondary shrinkage of both kidneys due to a complete occlusion of the renal arteries developed in one 13 years old patient. All patients had undertaken active anti-inflammatory (glucocorticoids) and immune suppressive therapy (methotrexate 10–15mg/m$^2$, tocilizumab 12 mg/kg), symptomatic therapy. During the therapy, unstable and partial regression of general inflammatory symptoms were observed, hypertension was not completely stopped in 8 patients (88.9%), including a patient with end-stage of renal failure. Given the nature (III and type IV) of vascular lesions, unstable and partial anti-inflammatory effect of the therapy, the prognosis for life was unfavorable. Since diagnosis, survival rate in patients under 7 years was 22.2% (2), under 5 years – 44.4% (4) under 2 years – 22.2% (2) and at one year – 11.1% (1). The cause of death was: end stage of renal disease – 11.1% (1), stroke – 55.5% (5), myocardial infarction – 22.2% (2) and aortic aneurysm rupture of 11.1% (1).
**Conclusions:** Thus, the diagnosis of AT in children and adolescents was revealed late, which delayed an early prescription of adequate immunosuppression and contributed to the development of severe complications and death
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5830

## AB0567 AORTIC INVOLVEMENT IN A RETROSPECTIVE COHORT OF LARGE VESSEL VASCULITIS PATIENTS

M. Bellan[1,2], R. Bonometti[2], A. Rossini[2], A. Gibbin[2], D. Sola[1,2], R. Pedrazzoli[2], M. Tran Minh[2], M. Pirisi[1,2], P.P. Sainaghi[2]. *[1]Translational Medicine, Università del Piemonte Orientale UPO; [2]Internal Medicine Division, AOU Maggiore della Carità, Novara, Italy*

**Background:** Large vessel vasculitis include Giant cell arteritis (GCA) and Takayasu's disease. Both these conditions can be associated with aortic inflammatory involvement, detectable by FDG-PET. Aortitis is an indicator of a more severe clinical course of disease.
**Objectives:** We aimed to evaluate the different clinical phenotypes of large vessel vasculitis in a retrospective cohort of patients followed-up at our immunorheumatology outpatient clinic. We further aimed to identify predictors of aortic disease.
**Methods:** We retrospectively reviewed all the clinical records of patients receiving a diagnosis of large vessel vasculitis from 1st January 2010 to 1st January 2016. Clinical, laboratory, hystopathological and imaging data were collected. Non-parametric statistical analysis was performed.
**Results:** We recorded 42 diagnosis of large vessel vasculitis along a 5-year follow-up. Out of them 6 patients were not included in the analysis because of the lack of clinical informations. Median age of general population was 72.5 [64.0–76.0]; at onset, median ESR was 56 mm/h [44–75], while CRP was 6.9 mg/dl [3.4–12.1]. Median follow-up was 12 months [6–28]. 25/36 patients were female (69.4%); headache was the commonest onset symptom (28 cases, 77.8%), while polymyalgia rheumatic was diagnosed in 10 patients (27.8%). Half of the patients underwent a PET to rule out aortitic involvement, which was detected in 14/18 patients. The prevalence of aortic involvement was higher in male (7/11, 63.6%) than in female (7/25, 28%; p=0.04). Headache was always reported in uncomplicated GCA, while it was less frequent in aortitic patients (6/14 patients, 42.8%; p=0.0007). No differences were found with respect to age and laboratory data between patients with and without aortic involvement.
**Conclusions:** Large vessel vasculitis are quite common diseases in elderly people. A subset of patients, characterized by aortic involvement and a more severe prognosis can be detected. The absence of headache and male sex are risk factors for aortitis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4891

## AB0568 GIANT CELL ARTERITIS AND MALIGNANCY – MORE THAN JUST A COINCIDENCE?

R. Ješe, A. Hočevar, Ž. Rotar, S. Praprotnik, M. Tomšič. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** Malignancy associated vasculitis represents 2–5% of systemic vasculitides. While there have been reports of increased incidence of malignancy in patients with giant cell arteritis (GCA) no definite association has yet been established.
**Objectives:** To determine the proportion patients with GCA and past/concurrent/subsequent malignancy.
**Methods:** We conducted a prospective longitudinal analysis of patients diagnosed with GCA from September 2011 to December 2015 at a single secondary/tertiary rheumatology centre. The proportion of patients with past, concurrent, and successive malignancy (diagnosed within 1 year of follow-up) was determined. Crude incidence rate (CIR) of malignancy in general population aged 50 years and above from the same geographical region in year 2011 and 2012 (final accessible reports based on complete yearly data) was acquired from Slovenian Cancer Registry for comparison.
**Results:** During the observation period 106 new GCA cases were identified (Table 1). Nineteen patients (17.9%) were diagnosed with a malignancy at any point in time (Table 2). In 7 patients (6.6%) malignant disease was found concomitantly with GCA (4/7) or within one year of follow-up (3/7). With respect to location of these 7 newly diagnosed malignancies, there were 4 cases (3.8%) of urinary bladder cancer (Table 2). There was 1 death due to cancer during the follow-up. None of the 12 patients with a history of past malignant disease had a recurrence of cancer at GCA diagnosis or during the follow-up. CIR for malignancy in comparably aged population of the same geographical region was 1.51%, with cumulative CIR for urinary tract malignancy of 0.08% and specific CIR for bladder cancer of 0.04%.

Table 1. Characteristics of GCA patients

| | |
|---|---|
| Age, years (median (IQR)) | 73.9 (67.3–78.8) |
| Gender (female/male) (%) | 75/31 (71/29) |
| Smoking (current and/or past), # (%) | 42 (39.6) |
| General symptoms, # (%) | 78 (73.6) |
| – in patients with concurrent/successive malignancy, # (%) | 1/7 (14.3) |
| – in patients with past history of malignancy, # (%) | 2/12 (16.7) |
| – in patients without known malignancy, # (%) | 16/87 (18.4) |
| Positive temporal artery biopsy, # (%) | 71/88 (80.7) |
| Positive temporal artery ultrasound, # (%) | 81/105 (77.1) |
| Large vessel vasculitis, # (%) | 42/97 (43.3) |

Legend: IQR, interquartile range.

Table 2. Location of malignancy and temporal relationship to GCA

| Location | P | C | S |
|---|---|---|---|
| Renal | 1 | 0 | 0 |
| Bladder | 0 | 3 | 1 |
| Stomach | 0 | 0 | 1 |
| Colon | 3 | 0 | 0 |
| Ovarian/uterine | 3 | 0 | 0 |
| Haematologic | 1 | 1 | 0 |
| Breast | 2 | 0 | 0 |
| Prostatic | 1 | 0 | 0 |
| Melanoma | 1 | 0 | 1 |
| Total | 12 | 4 | 3 |

Legend: P, past; C, concurrent; S, successive.

**Conclusions:** In our study, 6.6% of GCA patients were found to have a concurrent malignant disease compared to 1.5% of similarly aged general population. Additionally, we detected an increased incidence of urinary bladder cancer in our GCA cohort.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2845

## AB0569 DOES THE AGE AT DISEASE ONSET INFLUENCE THE CLINICAL PRESENTATION AND LONG-TERM OUTCOME OF ANCA-ASSOCIATED VASCULITIDES? RESULTS FROM A SINGLE-CENTRE COHORT

S. Monti, S. Balduzzi, L. Cavagna, C. Montecucco, R. Caporali. *Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, Pavia, Italy*

**Background:** ANCA associated vasculitides (AAV) are a group of diseases that can transversally affect all age groups (1).
**Objectives:** To identify peculiar characteristics in clinical presentation and long-term outcome of patients with AAV according to age at diagnosis.
**Methods:** Medical records of patients followed at our Department up to December 2015 with a diagnosis of AAV were analysed. Patients were stratified according to age at diagnosis $<65$ or $\geq 65$ years old.
**Results:** A total of 96 patients with AAV were identified. General characteristics of the study population are presented in table 1. 72.91% of patients were diagnosed before the age of 65 (group A), while 27.09% presented with an elderly-onset disease (group B). Mean age at symptoms onset was 43.09±12.55 and 68.49±8.03, respectively ($p<0.0001$). Mean follow up was 70.19±73.41 without significant differences between the two groups. The diagnosis of granulomatosis with polyangiitis (GPA) was more frequent in group A (33.33% Vs 9.37%; p=0.03). Accordingly, c-ANCA (PR3) were significantly more detectable in group A (p=0.03). Eosinophilic granulomatosis with polyangiitis (EGPA) and microscopic polyangiitis (MPA) were more represented in group A without reaching statistical significance. The clinical presentation at disease onset was characterised by a higher rate of ocular and musculoskeletal involvement in group A (p=0.004) and more frequent systemic symptoms (p=0.01) and peripheral nervous system involvement (p=0.008) in group B. A compromised renal function due to the vasculitic process was more reported in the elderly-onset group (p=0.007). Comorbidities were more relevant in group B ($p<0.0001$). Treatment approach did not differ between the two groups, except for a lower mean corticosteroid (CS) dosage in the elderly group at induction, counterbalanced by a lower rate of CS suspension at the end of follow up. Rituximab was only prescribed to 3 female patients of group A. Despite the different organ involvement, indices of disease activity, prognosis and damage did not differ between the two groups. Outcome was generally favorable in both groups, with a 2% mortality rate in group B.
**Conclusions:** Elderly-onset AAV shows some peculiar characteristics of organ involvement at disease onset, a higher rate of comorbidities, and slightly different therapeutic approach compared to younger-onset patients; nevertheless, long-term outcome is generally equally favorable.

Table 1. General characteristics of the study population

| Clinical characteristics N (%) | Total population N=96 | Group A (<65 yrs) N=70 | Group B (≥65 yrs) N=26 | p |
|---|---|---|---|---|
| Sex: (M/F) | 43/53 (44.79%/55.21%) | 31/39 (44.28%/55.71%) | 12/14 (46.15%/53.84%) | ns |
| Type of AAV: | | | | |
| EGPA | 55 (57.29%) | 38 (39.59%) | 17 (17.71%) | ns |
| GPA | 38 (39.58%) | 29 (41.43%) | 9 (9.37%) | 0.006 |
| MPA | 3 (3.12%) | 3 (4.29%) | 0 | ns |
| p-ANCA (MPO) | 33 (34.37%) | 22 (40.43%) | 11 (42.31%) | ns |
| c-ANCA (PR3) | 28 (29.17%) | 25 (35.71%) | 3 (11.54%) | 0.03 |
| FFS positivity | 37 (38.54%) | 28 (40%) | 9 (34.61%) | ns |

## AB0570 IGG4 RELATED DISEASE: PROTEAN CLINICAL MANIFESTATIONS AND A DIAGNOSTIC CONUNDRUM

S. Chittalae[1], V. Singh[1], P. Efthimiou[2,3]. *[1]Medicine, New York Methodist Hospital, Brooklyn; [2]Medicine, Weill Cornell Medical College, New York; [3]Rheumatology, New York Methodist Hospital, Brooklyn, United States*

**Background:** -
Immunoglobulin G4-related disease (IgG4-RD) is a multisystemic fibro-inflammatory condition characterized by tumefactive lesions, dense lympho-plasmacytic infiltrate, storiform fibrosis and obliterative phlebitis. Serum IgG4 levels are usually elevated in 70–90% of cases. The mean age at diagnosis is 60 years with a striking male preponderance. (Male:Female – 8:3)
**Objectives:** To present a single center experience with IgG4-RD and the diagnostic and therapeutic challenges encountered.
**Methods:** A retrospective case review at an urban teaching hospital was done over a year after the availability of quantitative assessment of IgG4 levels and tissue immuno-histological staining techniques. This revealed four cases of IgG4-RD involving the pancreas, retroperitoneum, kidney and meninges demonstrating its multi-systemic nature.
**Results:** We encountered a M:F ratio of 3:1 with mean age at presentation being 66 year
Case 1: A 76-year-old male with significant weight loss, erroneously diagnosed with pancreatic tail malignancy, underwent distal pancreatectomy and was subsequently diagnosed with AIP on biopsy.
Case 2: A 71-year-old male s/p left partial nephrectomy 4 years ago with an incidental finding of right kidney mass (2x2x2cm). After undergoing right partial nephrectomy, he was diagnosed with IgG4-related kidney disease.
Case 3: A 56-year-old male with abdominal pain and worsening renal function had MRI findings of a heterogeneous retroperitoneal mass attached to the right kidney. Biopsy revealed a diagnosis of IgG4-retroperitoneal fibrosis.
Case 4: A 57-year-old female presented with headache, bilateral lower extremity weakness and gait abnormality. Elevated serum IgG4, leptomeningeal enhancement on MRI and dural biopsy all suggested IgG4-related pacchymeningitis.
**Conclusions:** IgG4-RD often presents as a diagnostic conundrum. There is a need to increase clinician awareness of IgG4-RD, since early identification and subsequent treatment with immunomodulators may prevent disease progression and prevent complications and/or unnecessary surgeries. PET/CT may prove to be a useful adjunctive imaging technique to investigate for multi-system involvement. Over reliance on serum IgG4 levels for screening may result in missed diagnosis in a significant percentage of patients.

## AB0571 A CROSS-SECTIONAL STUDY OF HEALTH-RELATED QUALITY OF LIFE ASSESSED BY THE SF-36 AND THE EQ-5D-5L IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

S. Hirahara, Y. Katsumata, M. Harigai, Y. Kawaguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** Health-related quality of life (HRQoL) is an important outcome of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), and the Medical Outcomes Study Short Form-36 (SF-36) is usually used as a generic measure of HRQoL. However, there are only several published reports focusing on HRQoL among patients with AAV. In addition, another popular measure of HRQoL, the 5-level EuroQoL 5-Dimensions Questionnaire (EQ-5D-5L), which is often used for the calculation of quality-adjusted life years (QALYs) has received less attention in the field of AAV.
**Objectives:** We aimed to cross-sectionally investigate the relationship between HRQoL assessed by the SF-36 and the EQ-5D-5L, and clinical background and indices among AAV patients.
**Methods:** Patients with AAV were defined and classified according to the European Medicines Agency algorithm. Patients were approached during their outpatient attendance in our university clinic from July through December 2015. Some of the hospitalized patients during the study period were also eligible to

the study. Patients were asked to complete the SF-36, the EQ-5D-5L, and other related demographic questionnaires. The SF-36 contains 36 items scored in 8 domains. Using the national norm score and its SD, the "0–100 score" of each domain of the SF-36 was transformed to the norm-based score (NBS) so that each had a mean of 50 and a SD of 10 in the national population sample. In addition, 2 summary scales were calculated based on NBS: physical (PCS) and mental (MCS) component summary scores. A lower score in SF-36 indicates poorer health or greater disability. The EQ-5D-5L comprises the 5 dimensions of HRQoL, and each dimension has 5 levels. An EQ-5D-5L health state was converted to a single summary index by applying the formula and ranges from 0 to 1; 0 meaning death and 1 complete health. Physicians were asked to complete the Birmingham Vasculitis Activity Score (BVAS) and the Vasculitis Damage Index (VDI) simultaneously and record other medical information.

**Results:** A total of 34 Japanese patients with AAV (microscopic polyangiitis 23, granulomatosis with polyangiitis 8, and eosinophilic granulomatosis with polyangiitis 3) participated. In the study population, the mean age was 66, 29 were women, the mean disease duration was 7 years, the mean prednisolone dosage was 10.9 mg/day, the mean BVAS was 5.2, and the mean VDI was 2.7. The mean scores in 7 out of the 8 domains of the SF-36 were significantly lower than those of the age- and sex-matched national norms ($p<0.05$). The mean PCS and MCS scores of the SF-36, and the mean EQ-5D-5L index value were 29.4, 48.0, and 0.72, respectively. The mean PCS score and the mean EQ-5D-5L index value were significantly lower than those of the age- and sex-matched national norms ($p<0.05$), whereas the mean MCS score was not. The PCS score and the EQ-5D-5L index value had moderate inverse correlation with age, the prednisolone dosage, the BVAS, and the VDI ($r$= -0.41 to -0.62), whereas the MCS score did not. Sex and AAV classification were not significantly associated with the PCS and MCS scores or the EQ-5D-5L index value.

**Conclusions:** In the study population, the PCS score and the EQ-5D-5L index value in patients with AAV were lower than the national norm and inversely correlated with age, the prednisolone dosage, the BVAS, and the VDI, whereas the MCS score was not.

## AB0572 IMPACT OF AGING ON THE CLINICAL FEATURES AND TREATMENT OF ANCA ASSOCIATED VASCULITIS IN THE ELDERLY

S. Sato, T. Asano, H. Kobayashi, H. Watanabe, H. Ohira. *Gastroenterology and Rheumatology, Fukushima Medical University School of Medicine, Fukushima, Japan*

**Background:** ANCA associated vasculitis (AAV) usually occurs in elderly patients, but only a few studies regarding clinical features and treatment of elderly onset AAV have been reported so far[1,2].

**Objectives:** To compare clinical features and treatment of AAV between elderly patients (≥75) and younger patients (<75) in Japanese patients.

**Methods:** Patients who met the criteria for granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and Churg-Strauss syndrome (CSS) were included in this study. AAV patients (N=31) who were initially treated at Fukushima Medical University Hospital (Fukushima, Japan) from 2004 to 2015 were retrospectively reviewed. These patients were divided into 2 groups (elderly, N=9 and younger, N=22) and compared for the following clinical features, laboratory data and treatment: age at diagnosis, sex, Birmingham Vasculitis Activity Score (BVAS), symptoms, liver and renal function, hemoglobin, serum ferritin levels, IgG, ANCA (MPO/PR3) positivity, and therapy (prednisolone and immunosuppressive therapy).

**Results:** Following 31 AAV patients were identified: 8 cases of GPA, 20 cases of MPA, and 3 cases of CSS. Elderly group showed significantly lower frequency of skin manifestation and significantly higher frequency of kidney symptoms. In laboratory data, elderly group showed significantly lower serum AST, LDH and Ferritin levels. As to therapy, elderly patients received significantly lower prednisolone doses and frequency of cyclophosphamide (CYP) administration. Mortality rates (1 year) were significantly higher in elderly group (33.3%) than younger group (4.6%). Four patients died: all patients were MPA and the main causes of death were vasculitis progression (alveolar hemorrhage) and infection.

| Clinical features | Elderly, N = 9 | Younger, N = 22 | *p* value |
|---|---|---|---|
| Age (years old) | 78.2 | 61.1 | - |
| Sex (Female, %) | 77.8 | 45.5 | 0.053 |
| BVAS | 17.9 | 17.3 | N.S |
| Symptoms (%) | | | |
| ENT | 33.3 | 40.9 | N.S |
| Lung | 77.8 | 40.9 | N.S |
| **Kidney** | **88.9** | **50.0** | **0.023** |
| Nervous system | 33.3 | 54.5 | N.S |
| **Skin** | **0** | **27.3** | **0.043** |
| Laboratory Data | | | |
| **AST (IU/L)** | **27.2** | **44.8** | **0.049** |
| ALT (IU/L) | 25.3 | 46.5 | 0.081 |
| **LDH (IU/L)** | **181** | **264** | **0.028** |
| CRP (mg/dL) | 11.37 | 9.33 | N.S |
| Creatinine (mg/dL) | 1.03 | 1.02 | N.S |
| Hemoglobin (g/dL) | 9.77 | 10.6 | N.S |
| **Ferritin (ng/mL)** | **257** | **486** | **0.009** |
| IgG (mg/dL) | 1885 | 1802 | N.S |
| ANCA (MPO/PR3) positivity (%) | 100 | 81.8 | N.S |
| Therapy | | | |
| **PSL doses (mg/day)** | **34.4** | **45.9** | **0.028** |
| **CYP therapy (%)** | **0** | **27.3** | **0.043** |
| **Mortality rates (1 year, %)** | **33.3** | **4.6** | **0.016** |

**Conclusions:** This study shows that the clinical features of elderly AAV patients are comparable to those of younger patients in Japan, except for lower skin manifestations and higher kidney symptoms. Lower AST, LDH, and ferritin levels in elderly AAV may indicate that elderly patients show milder organ damage on admission. Higher mortality rates in elderly AAV may be associated with lower PSL doses and frequency of CYP administration. Proper immunosuppressive therapy should be considered to reduce mortality rates for vasculitis progression or severe infection in elderly AAV.

## AB0573 THE DISEASE ASSOCIATIONS OF TAKAYASU'S ARTERITIS

S.N. Esatoglu[1], A.M. Celik[2], D. Ucar[3], A.F. Celik[4], S. Ugurlu[1], G. Hatemi[1], M. Melikoglu[1], I. Fresko[1], V. Hamuryudan[1], H. Ozdogan[1], S. Yurdakul[1], H. Yazici[1], E. Seyahi[1]. *[1]Istanbul University, Cerrahpasa Medical Faculty, Depatment of Internal Medicine, Rheumatology; [2]Istanbul University, Cerrahpasa Medical Faculty, Depatment of Internal Medicine; [3]Istanbul University, Cerrahpasa Medical Faculty, Depatment of Ophthalmology; [4]Istanbul University, Cerrahpasa Medical Faculty, Depatment of Internal Medicine, Gastroenterology, Istanbul, Turkey*

**Background:** Case reports or small case series suggest that Takayasu arteritis (TA) can co-exist with various chronic inflammatory disorders. Inflammatory bowel disease [(IBD; Crohn's disease (CD) or ulcerative colitis (UC)] has been the most common association.

**Objectives:** We conducted a formal study to look specifically at the frequency of association of such chronic inflammatory disorders in a large cohort of patients with TA followed at a single tertiary center.

**Methods:** There were 226 (200 F/26 M) patients registered with a diagnosis of TA at the Rheumatology Department of Cerrahpasa Medical Faculty, between 1977 and December 2015. Of these, 17 (8%) had died and 15 (7%) were lost to follow-up. The remaining 194 patients were called back at the outpatient clinic for an interview and for a physical examination. A standardized form sought whether the patient was also diagnosed as IBD, ankylosing spondylitis (AS), Behçet's syndrome (BS), amyloidosis (AA), uveitis, rheumatoid arthritis (RA), systemic lupus erythematosus, systemic sclerosis, Sjögren syndrome, psoriatic arthritis, myositis, small vessel vasculitis, a demyelinating or any other autoimmune or inflammatory disorder. The presence of skin-mucosa lesions ascribed to BS and inflammatory back pain were also specifically sought for. In addition to the self-reported information, patient charts and all medical documentation available such as hospitalization reports, imaging studies and blood work were used as a source of information.

**Results:** One hundred and fifty-three (136 F/17 M) patients were studied. The mean age at the onset of symptoms was 31±11 years and at the time of TA diagnosis was 34±12 years. Subclavian artery was the most common involved artery (83%), followed by common carotids (75%) and aorta (64%). Currently, while 25 (16%) patients were off treatment, 72 (47%) patients were using glucocorticoids, 47 (31%) azathioprine, 32 (21%) methotrexate and 44 (29%) biological agents.

We identified 11 (7%) patients with IBD (CH/UC:7/4), 11 (7%) with AS, and 9 (6%) with BS. Ten patients (6 IBD and 4 BS) were diagnosed simultaneously. The onset of TA preceded AS in 6 patients, IBD in 2, and BS in 1 as shown in Table. Among the remaining 122 patients, when the 31 patients with IBD, AS and BS were excluded, recurrent oral ulcers were present in 19 (16%), erythema nodosum in 13 (11%), arthritis in 12 (10%), papulopustular lesions in 5 (4%), uveitis in 5 (4%), and genital ulcer in 1. Inflammatory back pain was reported by 44 (36%) patients; this was usually in the dorsal spine level alone (n=30), less commonly in both dorsal and lumbar spine (n=10) and in the lumbar spine alone (n=4).

Table. Demographic features of 31 TA patients with IBD, AS or BS

| Concomitant disease | F/M | Mean age at TA diagnosis (SD) | Mean age at concomitant disease (SD) | The time of TA diagnosis in relation to concomitant disease |
|---|---|---|---|---|
| AS (n=11) | 9/2 | 31 ±8 | 27±11 | TA preceded (n=6)<br>AS preceded (n=5) |
| IBD (n=11) | 10/1 | 33±9 | 31±9 | Simultaneous (n=6)<br>TA preceded (n=2)<br>IBD preceded (n=3) |
| BS (n=9) | 7/2 | 35±13 | 32±13 | Simultaneous (n=4)<br>TA preceded (n=1)<br>BS preceded (n=4) |

In addition, 3 patients had secondary amyloidosis, 1 had RA and 1 morphea. We also observed 2 patients with autoimmune hepatitis and 2 with psoriasis, all having onset after anti-TNF treatment.
**Conclusions:** This survey shows that TA co-occur with IBD, AS or BS in about 1/5 of the patients, at least in a hospital setting and this seems to be without a clear temporal pattern. The rather high prevalence of inflammatory back pain in the dorsal spine in TA needs further scrutiny.

## AB0574 FECAL CALPROTECTIN LEVEL LOOKS PROMISING IN IDENTIFYING ACTIVE DISEASE IN BEHÇET'S SYNDROME PATIENTS WITH GASTROINTESTINAL INVOLVEMENT: A CONTROLLED AND PILOT STUDY

S.N. Esatoglu[1], I. Hatemi[2], Y. Ozguler[1], G. Hatemi[1], A.F. Celik[2], H. Yazici[1]. *[1]Istanbul University, Cerrahpasa Medical Faculty, Depatment of Internal Medicine, Rheumatology; [2]Istanbul University, Cerrahpasa Medical Faculty, Depatment of Internal Medicine, Gastroenterology, Istanbul, Turkey*

**Background:** The fecal calprotectin (FC) level is widely used as a non-invasive method for identifying patients with active Crohn's disease (CD) and ulcerative colitis. Gastrointestinal involvement of Behçet's syndrome (GIBS) shows clinical and endoscopic similarities to CD. A previous study in a small number of Behçet's syndrome (BS) patients with mainly mucocutaneous lesions showed that serum calprotectin levels did not differ between active and inactive patients (1). Another study suggested that FC may help to diagnose GIBS patients (2). We are not aware of studies addressing whether FC levels help to distinguish active GIBS patients from those in remission.
**Objectives:** To determine whether FC levels help predict active disease in GIBS patients.
**Methods:** We collected fecal specimens from 23 GIBS (11 M, 12 F and mean age 44±9 years) patients before colonoscopy. The reasons for colonoscopy were assessing active disease in patients presenting with abdominal pain (with or without diarrhea) (n=9) or confirmation of a remission in asymptomatic patients (n=16). Four symptomatic and 3 asymptomatic patients had active ulcers by endoscopy. On the other hand, 5 symptomatic and 13 asymptomatic patients did not have ulcers by endoscopy. We also included 22 active and 25 inactive CD patients as controls. We used 150 μg/g as the cut-off for a positive FC level. We also looked at the correlation between FC and serum CRP levels, Crohn's disease activity index (CDAI) and disease activity index for intestinal Behçet's disease (DAIBD) scores.
**Results:** FC was >150 μg/g in all of the 7 GIBS patients with ulcers compared to 4/16 of GIBS patients without ulcers (OR, 95%CI: 42 to 888). The mean FC was 1125±800 μg/g (95%CI: 341 to 1908) among symptomatic patients with ulcers (n=4) and 209±213 μg/g (95%CI: 22 to 396) among symptomatic patients without ulcers (n=5). On the other hand, the mean FC was 243±73 μg/g (95%CI: 158 to 328) among asymptomatic patients with ulcers (n=3) and 95±160 μg/g (95%CI: 0.4 to 189) among asymptomatic patients without ulcers (n=11). Among CD patients, 16/25 active patients and 3/22 patients in remission had FC level >150 μg/g (OR, 95%CI: 11 to 49). There was a low correlation between FC and serum CRP levels (r=0.3, p=0.1), a moderate correlation between FC levels and CDAI scores (r=0.5, p=0.02) and very low correlation between FC and DAIBD scores (r=0.01, p=0.9). Among the 4 GIBS patients who had high FC levels despite being in remission for gastrointestinal involvement, 1 had active mucocutaneous lesions, 1 had concomitant macrophage activation syndrome, and 1 had polycythemia vera with trisomy 8. None of the patients were receiving NSAIDs that could increase FC levels.
**Conclusions:** Pending the study of more number of patients, FC may turn out to be a useful non-invasive tool for ruling out active gastrointestinal lesions in asymptomatic GIBS patients. A high FC level demands caution for the presence of active ulcers especially in symptomatic patients, but whether the presence of other BS manifestations can cause false positive results remains to be studied.

## AB0575 STEROID USE IS PROTECTIVE OF OSTEOPOROSIS IN POLYMYALGIA RHEUMATICA PATIENTS: A CASE-CONTROL STUDY

S.F. Ling, R. Sinha, M. Bukhari. *Department of Rheumatology, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom*

**Background:** The treatment of polymyalgia rheumatica (PMR) requires long-term corticosteroid therapy, which is known to induce bone mineral density loss and predispose patients to fracture. Therefore, we hypothesise that patients with PMR are more likely to suffer from osteoporosis (OP), as defined by a T-score threshold of ≤-2.5.
**Objectives:** To ascertain whether steroid use in PMR patients is associated with an increased propensity to OP, and whether other factors increase the propensity.
**Methods:** Study subjects were recruited from patients attending for DEXA scan at a scanner in the North West of England from 2004–2014. Patients with PMR were identified from this cohort for a case-control study: cases were defined as OP on DEXA scan, and controls were patients with T-score >-2.5; the exposure was steroid use (current, previous or ever). Odds ratios within the case-control study were estimated using Stata v13.1, which was used for all statistical analysis. A logistic model was fitted with OP as the dependent variable and age, gender, co-morbidities, medication predisposing to OP and risk factors for OP as the explanatory variables. Following univariate analysis, variables with p<0.2 were fitted into a multivariate logistic model, which was stratified by OP overall, and OP of either the femoral neck or lumbar spine.
**Results:** 649 patients with PMR were identified. There were 108 patients with OP (cases), of whom 95 patients (87.96%) were female, and 541 controls, of whom 388 patients (71.72%) were female (p=4.11E-04). Mean age in cases was 74.59 years (SD 8.78) and 70.18 years (SD 8.49) in controls (p=1.23E-06).
"Current" and "ever" use of steroids were associated with reduced odds of OP: OR 0.62 (95% CI 0.26–1.10, p=0.07) and OR 0.16 (95% CI 0.04–0.58, p=3E-04), respectively. There was no association with "previous" steroid use.
Following multivariate logistic regression, any history of steroid use ($OR_{adj}$ 0.14 [95% CI 0.04–0.44]), age >70 years ($OR_{adj}$ 2.37 [95% CI 1.51–3.72]) and female gender ($OR_{adj}$ 3.05 [95% CI 1.64–5.66]) were significantly associated with OP overall. This model retained significance in lumbar spine OP: steroid use $OR_{adj}$ 0.24 (95% CI 0.08–0.78), age >70 years $OR_{adj}$ 1.72 (95% CI 1.08–2.75) and female gender $OR_{adj}$ 2.83 (95% CI 1.46–5.48). Steroid use was not associated with femoral neck OP, whilst age>70 years ($OR_{adj}$ 7.01 [95%CI 2.93–16.79]) and female gender ($OR_{adj}$ 2.68 [95% CI 1.11–6.49]) retained their significant association.
**Conclusions:** This study demonstrates that steroid use is protective of OP in PMR patients, despite the increased risk of OP with chronic steroid use. This may be because clinicians are more diligent in prescribing bone protection in these patients, due to awareness of the increased iatrogenic risk of OP that long-term corticosteroid use predisposes to.

## AB0576 OPHTALMOLOGIC FINDINGS IN PATIENTS WITH TAKAYASU'S ARTERITIS

A.B. Kelesoglu[1], A. Baytaroglu[2], A. Sari[1], A. Erden[1], L. Kilic[1], O. Tatar[2], O. Karadag[1], U. Kalyoncu[1], I. Ertenli[1], S. Apras Bilgen[1]. *[1]Hacettepe University Vasculitis Center (HUVAC); [2]Department of Ophtalmology, Hacettepe University, Ankara, Turkey*

**Background:** Takayasu's Arteritis (TA) is a large vessel vasculitis of young females. Ophtalmologic findings as wreath-like arteriovenous anastomosis around the optic disc are the firstly described clues for TA. Opthalmologic pathologies could have negative impact on quality of life but, there are limited data about ocular manifestations of TA.
**Objectives:** To investigate the ophthalmologic manifestations of TA.
**Methods:** In this cross-sectional study 33 TA (F/M: 29/4) patients were evaluated. Demographic and clinical findings were recorded from hospital files. Addition to routine examination, anterior segment and fundus of eyes were assessed.
**Results:** The median age at the time of ocular examination was 38 (min-max:19–62) years and mean disease duration was 5.7±5.5 years. Two (6.1%) patients had diabetes mellitus, 13 (39.4%) patients had hypertension. Only one patient had cranial involvement of TA. Most of the patients had been taking immunosuppressive agents addition to corticosteroids [Methotrexate (n=11, (33.3%)), cyclophosphamide (n=9, (27.3%)), azathiopurine (n=5, (15.2%)), one patient for each mycophenolate mophetil, infliximab, tocilizumab]
Of patients 15 (45.4%) had pathologic findings in opthalmologic examinations. Twelve patients (36.4%) had anterior segment pathology, 10 (30.3%) patients had posterior segment pathology. Of these patients 7 (21.2%) had both anterior and posterior segment pathology. Distribution of anterior segment pathologies were; 9 (27.2%) patients had cataract, 2 (6.1%) patients had dry eyes and one patient had congenital disgenesis.
In fundoscopic examination of posterior segment, hypertensive retinopathy was the most frequent pathologic finding as 12.1% (n=4) Three of these patients have had diagnosis of essential hypertension and were treated with anti-hypertensive medication One patient had ocular ischemic syndrome which is typical for TA (Table 1).

Table 1. The Fundoscopic Examination Findings of 33 patient with TA

| Fundoscopic Examination Findings | N | % |
|---|---|---|
| Normal | 23 | 69.7 |
| Stage 1 hypertensive retinopathy | 4 | 12.1 |
| Foveal pigment epithelial alterations | 1 | 3.0 |
| Ocular ischemic syndrome | 1 | 3.0 |
| Hard exudate and microhemorrhage | 1 | 3.0 |
| Delayed mfERG (multiphocal electroretinography) responses | 1 | 3.0 |
| Drusen formation | 1 | 3.0 |
| Exudate and subretinal fluid | 1 | 3.0 |

**Conclusions:** In the early results of our study, disease or treatment related ocular pathologic findings were frequent in TA. Periodic consultation and ophthalmologic

examination of TA patients might be rational approach in follow up of these patients.

## AB0577 SLEEP QUALITY IN BEHCET'S DISEASE IS ASSOCIATED WITH DISEASE ACTIVITY, DEPRESSION, AND QUALITY OF LIFE IN KOREAN POPULATIONS

S.-S. Kim[1], J. Lee[2], Y.S. Kim[3], H.-S. Kim[4], S.-J. Hong[5], H.-J. Jeong[2], C.-N. Son[2], J.-M. Kim[2], S.-H. Kim[2]. *[1]Department of Internal Medicine, Ulsan University School of Medicine, Gangwon-do; [2]Department of Internal Medicine, Keimyung University School of Medicine, Daegu; [3]Department of Internal Medicine, Chosun University Hospital, Gwangju; [4]Department of Internal Medicine, Soonchunhyang University Seoul Hospital; [5]Kyung Hee University School of Medicine, Seoul, Korea, Republic Of*

**Background:** Behcet's disease is a chronic, systemic vasculitis that can involve all sizes of blood vessels. Those complicated symptoms lead to the patient's impairment of life quality as well as psychological problems. Sleep disturbance is one of the most particular concerns in patients with Behcet's disease. It has been known that the disease activity of rheumatoid arthritis and ankylosing spondylosis is associated with the sleep quality. However, studies about the sleep quality of patients with Behcet's disease in Korean population are limited.
**Objectives:** The purpose of this study was to find out the effects of sleep quality on Behcet's disease in Korean population. We also investigated the relationship between depression, quality of life, other clinical findings of Behcet's.
**Methods:** The study was performed by cross-sectional design in two tertiary hospitals. We met one hundred patients with Behcet's disease, surveyed them face-to-face and conducted the chart review for more clinical informations. Sleep quality was assessed by the Korean version of Pittsburgh sleep quality index (PSQI). Disease activity of Behcet's disease was evaluated by Behcet's disease current activity form (BDCAF). Depression was assessed by the Korean version of Beck depression inventory second edition (BDI-2). Quality of life was assessed by the Korean version of the Leeds Behcet's Disease Quality of Life Measure (BDQoL).
**Results:** Among 100 patients, median age was 51 [44.5–56.0] years, median disease duration was 77.5 [24.0–136.0] months and 31% were male. Those who met the diagnostic critera of fibromyalgia were 28 patients. The frequency of poor sleep quality (PSQI $>5$) was 67%. Patients with poor sleep quality tend to have higher BDI2, BDCAF and pain VAS score ($P<0.001$, $P=0.028$, and $P=0.011$). Female rate was significantly higher, and BDQoL was lower in poor sleeper group ($P=0.004$ and $P<0.001$). Among 7 PSQI components, daytime dysfunction was higher in patients with high disease activity ($P=0.03$). Total PSQI score were strongly correlated with BDCAF score, BDI-2 score, BDQoL score, and pain VAS score ($P=0.02$, $P<0.001$, $P<0.001$, and $P<0.001$, respectively).
**Conclusions:** The low quality of sleep is associated with disease activity, depression and quality of life in Korean patients with Behcet's disease. We expect better disease control will improve the sleep quality.

## AB0578 SUCCESSFUL TOTAL HIP ARTHROPLASTY IN PATIENTS WITH SEVERE ANCA- ASSOCIATED VASCULITIS: SINGLE- CENTER EXPERIENCE

T.V. Beketova, S.A. Makarov, E.I. Byalik, E.A. Naryshkin, A.L. Logunov, M.M. Lipina, A.A. Roskidaylo. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Objectives:** We evaluated the postoperative morbidity in patients with severe ANCA- associated vasculitis (AAV) undergoing primary total hip arthroplasty (THA).
**Methods:** Retrospective analysis of interventional case series, single referral center study. Four patients with severe AAV due to destructive hip damage (5 affected hips) were selected for 5 THA.
**Results:** The mean age of our cohort was 45 years (27- 66 years), 75% female. Two patients had microscopic polyangiitis (MPA), 1- granulomatosis with polyangiitis (GPA) and 1- eosinophilic granulomatosis with polyangiitis (EGPA). All patients had severe AAV and Five-Factor Score (FFS)=1. Short course of hemodialysis was required in one patient with MPA and rapidly progressive glomerulonephritis. In another case was the age of MPA onset $>65$ years. The GPA patient had a history of nephrectomy for hydronephrosis, which complicated afterwards with kidney and ureter granulomatous vasculitis and occlusive thrombosis of the femoral veins in the active phase of the disease. EGPA patient was overweight (BMI 28) and had EGPA-associated cardiomyopathy. Destructive hip damage was caused by osteonecrosis in 3 patients, and fracture of the proximal femur in 1 patient with osteoporosis. At the time of THA procedure all patients were in remission phase (BVAS=0) with normal serum creatinine levels, all comorbidities were controlled by medications. In two cases AAV remission was induced by rituximab.
All implants were radiographically stable without osteolysis. In all cases THA has been clinically effective, with functional gain such as improved mobility as well as pain reduction and was not associated with postoperative serious complications (except for blood transfusion requirements) or AAV relapse.
**Conclusions:** Elective THA is a safe and effective procedure for destructive hip damage in the AAV patients, including cases with the history of severe vasculitis and unfavorable prognostic factors (FFS=1). AAV remission must be achieved and comorbidities identified and treated to minimize postoperative complications.

## AB0579 NON-INFECTIOUS AORTITIS ASSOCIATED WITH POLYMYALGIA RHEUMATICA: WHAT IS THE BEST DIAGNOSIS AND THERAPEUTIC OPTION? EXPERIENCE IN A LOCAL HOSPITAL

V. Aldasoro Cáceres[1], J.J. Inchausti Irazábal[2], O. Maíz Alonso[3], J.R. De Dios Jiménez de Aberasturi[4]. *[1]Rheumatology, Hospital Alto Deba, Mondragon; [2]Rheumatology, Hospital de Mendaro, Mendaro; [3]Rheumatology, Hospital Universitario Donostia, San Sebastián; [4]Rheumatology, Hospital Universitario Arava, Vitoria, Spain*

**Background:** Non-infectious aortitis associated with polymyalgia rheumatica (PMR) is a rare entity (1). Sometimes the conventional immunosuppressive therapy is not enough, forcing us to find new therapeutic options (2,3). We present our experience in a local hospital.
**Objectives:** To evaluate symptoms, clinic, diagnosis and therapeutic options.
**Methods:** During the years 2010–2015 we search for patients diagnosed with PMR which at the same time were diagnosed with non infectious aortitis. Their medical records were reviewed and the following data were collected: initial clinical diagnosis, diagnosis method used, time elapsed since the onset of symptoms to diagnosis, ESR and CRP at diagnosis and after the use of treatment.
**Results:** 5 patients were found: 4 women and 1 man. The average age onset of initial symptoms was 67.2 (74–58) years and the average delay in the diagnosis of the disease was 26 (1–50) months.
The most common onset clinic was classic PMR symptom. Patients 2, 3, 4 and 5 also showed parietooccipital or parietal headache. Other symptoms were lower limb claudication, temporomandibular joint pain, dyspnea, fatigue and pseudofibromyalgia.
All patients underwent temporal artery biopsy. In patient 5 bilateral temporal artery biopsy was performed.
The definitive diagnosis test was PET (4). In patient 2 PET was compatible with aortitis being angioMRI negative.
The average ESR at the beginning and after the treatment was 87.4 (114–65) and 10.2 (15.6) respectively. The initial and final average CRP (mg /dL) was 8.03 (14.54–1.86) and 1.2 (3 to 0.5) respectively.
All patients underwent autoimmune analytical battery, being this study negative.
1,2,3 and 4 patients performed concomitant weekly methotrexate (MTX) with maximum dose of 25 mg weekly sc. Patients 1 and 5 made concomitant treatment with steroids and azathioprine at doses of 100 and 150 mg daily, respectively.
Patients 1,2,3 and 5 were treated with tozilizumab which was well tolerated and without adverse effects to date. The average time from diagnosis of the disease until the start of treatment was 9.75 months (2,3). Patient 4 at the time of publication of these data remained asymptomatic with weekly MTX 15 mg sc and 5 mg of prednisone.
**Conclusions:** Non-infectious aortitis associated with PMR may go unnoticed due to high variability of presentation. This can make, sometimes, a delayed diagnosis (1). PET seems to be a good tool for the diagnosis (4) and tozilizumab seems to be a suitable treatment for those patients refractory to steroids and DMARDs (2,3). More patients are needed to generalize these data.

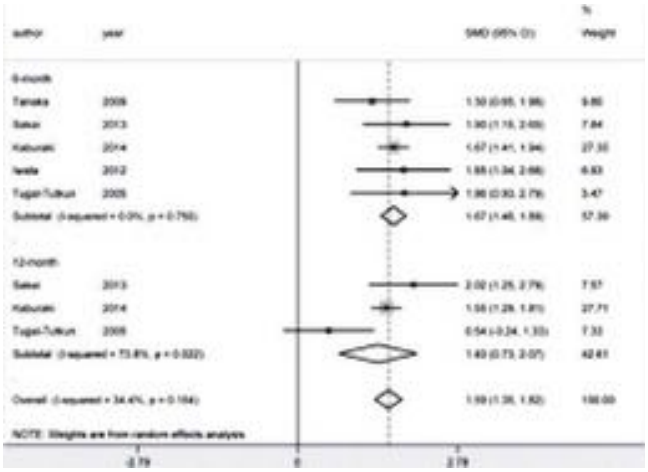
AB0580 **A PROSPECTIVE OPEN-LABEL SINGLE CENTER STUDY OF ADALIMUMAB IN BEHCET ARTHRITIS**



Y. Braun-Moscovici, Y. Tavor, D. Markovits, M. Naffaa, K. Toledano, A. Rozin, R. Beshara-Garzoz, M.A. Nahir, A. Balbir-Gurman. *B Shine Rheumatology Unit, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Haifa, Israel*

**Background:** Behcet's disease is a multisystemic chronic relapsing inflammatory disease, classified among the vasculitides. The clinical manifestations include mucocutaneous lesions, articular, ocular, vascular, gastrointestinal and/or central nervous system involvement. The aetiology of Behcet's disease is unknown. TNF-α may play an important role in the pathogenesis of the disease. Short term studies reported the efficacy of anti-TNFα therapy, particularly regarding ocular and mucocutaneous involvement in Behcet's.
**Objectives:** The primary end point was to assess efficacy and safety of Adalimumab (ADA) in patients with active Behcet's arthritis not responding to one or more DMARDS. The secondary end point was to assess the impact of treatment on other disease manifestations.
**Methods:** Eligible patients with active arthritis were enrolled in a 24 weeks single center prospective open-label study. Patients who relapsed within 12 weeks following ADA discontinuation could enter a 3 year extension study. The efficacy was assessed by 68 tender and 66 swollen joint count, patient visual analogue scale (VAS) for pain, physician overall disease activity VAS, health assessment questionnaire (HAQ), Behçet's Disease Current Activity Form (BDCAF), C reactive protein (CRP) and erythrocyte sedimentation rate (ESR). Statistical methods: descriptive statistics, T test, Mann-Whitney U test.
**Results:** Ten patients (6 females),age (mean, standard deviation – SD) 45 (8.4) years, with a disease duration of 11.6 (10) years, met the inclusion, exclusion criteria and were treated with subcutaneous ADA 40mg every 2 weeks for 24 weeks. The clinical manifestations included arthritis, oral and urogenital aphtae in all patients, erythema nodosum (3 patients) and other skin involvement (3 patients), uveitis (1 patient) and deep vein thrombosis (1 patient). Prior to ADA therapy they failed treatment with3.2 (1.3) different DMARDs. A statistically significant improvement was observed in swollen joint count (mean (SD) at baseline 4.6 (4.2) vs 0.4 (0.6) at 24 weeks, p=0.006), physician VAS (51.5 (18.5) vs 24.5 (16), p=0.002) and BDCAF (5.4 (1.6) vs 2.1 (1.4), p=0.001), but not in tender joint count (19 (18.7) vs 10.9 (12.6), p=0.14) or HAQ (1.76 (0.85) vs 1.59 (0.99), p=0.14). Resolution of oral and urogenital ulcers was achieved in all patients. Significant reduction of pain was reported by 40% of patients. No relapse of uveitis or other disease manifestations occurred during the study. The treatment was well tolerated: there were no serious adverse events; there were no injection related site reactions. Four infective episodes (2 cases of pneumonia and 2 of sinusitis), were treated ambulatory and did not require ADA withdrawal. The disease relapsed in 9 out of 10 patients, within 4–6 weeks following ADA interruption, 7 patients enrolled into the extension study.
**Conclusions:** ADA treatment was well tolerated and achieved a significant improvement in arthritis and mucocutaneous manifestations in all study patients but only 40% reported significant pain reduction. A subset of patients with insufficient improvement in joint tenderness and generalized pain may require comprehensive pain management besides anti-inflammatory therapy.

AB0581 **INFLIXIMAB THERAPY IN PATIENTS WITH REFRACTORY UVEITIS OF BEHÇET'S DISEASE: A META-ANALYSIS**

Y. Qin[1,2], X. Zhang[1], P. Geng[3], R. Luo[1], G. Zhang[1]. *[1]Department of Rheumatology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou; [2]Medical Affair Department, XiAn Janssen; [3]Center for Evidence-Based and Translational Medicine, Zhongnan Hospital of Wuhan University, Wuhan, China*

**Background:** Behçet's disease is a chronic inflammatory vasculitis that can affect multiple systems. Ocular involvement is common and often cause significant morbidity, such as loss of sight, and offering challenge to management due to relapse. Off-label use of anti-tumor necrosis factor (TNF) agents for Behçet's disease (BD) is increasing. Especially for refractory uveitis
**Objectives:** To assess the effect of infliximab on refractory uveitis caused by Behçet's disease, we conducted a meta-analysis.
**Methods:** A comprehensive search of multiple databases was performed. Weighted Mean Difference (WMD) or standardized mean difference (SMD) and 95% confidence intervals (95%CI) were calculated to assess the efficacy. Q test was used to examine the inter-study heterogeneity, and the robustness of the results was tested through sensitivity analysis. Begg's funnel plot and Egger's test were operated to check the publication bias.
**Results:** A total of 9 articles were included in this meta-analysis. We observed that infliximab treatment significantly reduced uveitis attack in Behçet's disease patients (WMD=2.35, 95% CI: 1.74–2.96), which was confirmed by subgroup analysis on 6- and 12- month after treatment (WMD=2.51, 95% CI: 1.81–3.21; WMD=2.11, 95% CI: 0.62–3.60). Visual acuity was greatly improved by infliximab therapy (SMD=-0.31, 95% CI: -0.59 to -0.03). Moreover, infliximab therapy also decreased the macular thickness of Behçet's disease patients (SMD=1.75, 95% CI: 1.35–2.15).

**Conclusions:** Infliximab therapy is effective in the treatment of Behçet's disease patients with refractory uveitis.

## Scleroderma, myositis and related syndromes

AB0582 **MORTALITY IN PATIENTS WITH SYSTEMIC SCLEROSIS – A SINGLE CENTER EXPERIENCE**

A. Balbir-Gurman[1,2], H. Attamna[2], M.A. Nahir[1,2], Y. Braun-Moscovici[1,2]. *[1]B.Shine Rheumatology Unit, Rambam Health Care Campus; [2]Rappaport Faculty of Medicine, Technion, Haifa, Israel*

**Background:** Patients (pts) with systemic sclerosis (SSc) experience higher mortality rates.
**Objectives:** To assess the mortality and causes of death in SSc pts' cohort at our center.
**Methods:** The data were retracted from the Rambam EUSTAR database (220 pts, years 2004–2013) and completed from pts' files; demographic, clinical and laboratory data, malignancy cases, the reason of death were analyzed. Comparisons were made between the deceased pts and surviving pts with similar disease duration. Proportional hazards models of Kaplan-Meier survival analysis and student's T-test were used for statistical analysis. Data found to significantly affect survival in a first univariate analysis were entered in a multivariate Cox proportional hazards model. Causes of death were analyzed using standard descriptive statistics. Data characterized pts with malignancy were incorporated in the logistic regression model.
**Results:** 47 (21.4%) pts deceased (age 53±15 years, disease duration 9.8±11 years, females 76.6%, diffuse disease 27.6%). Causes of death were: pulmonary

fibrosis (PF), pulmonary arterial hypertension (PAH), right and left heart failure (CHF, 27.7% and 19.1%); infections (17.0%), malignancies (17.0%), renal crisis (6.4%), gastrointestinal complications (GIT) (2.1%), and others (10.64%). Survival was significantly affected by: older age at diagnosis (P=0.011), male gender (P=0.049), reduced lung volumes and diffusing capacity (P=0.014 and p=0.001), PF (P=0.002), PAH (P<0.001), CHF (P<0.001), use of diuretics (P<0.001), arrhythmias (P<0.001), malignancy (P=0.003), proteinuria (P=0.003), and GIT complications (P=0.027). Malignancy was reported in 14/47 (29.8%) pts: lungs 23.5%, GIT 17.7%, genitourinary tract 17.7%, other 41.2%. Malignancy was not an independent predictor of mortality.
**Conclusions:** In this study the leading cause of death in SSc pts was cardiopulmonary complications, followed by malignancy and infections; renal and GIT complications were less frequent. High index of suspicion and early diagnosis of main SSc complications will allow early intervention and may hopefully change the fate of SSc pts.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2460

## AB0583 LONG-TERM INTEGRATED TREATMENT WITH BOSENTAN AND ILOPROST INCREASES, INDEPENDENTLY FROM OTHER CLINICAL CHARACTERISTICS, THE ABSOLUTE NUMBER OF CAPILLARIES IN SYSTEMIC SCLEROSIS PATIENTS: A NAILFOLD CAPILLAROSCOPIC ANALYSIS

A.C. Trombetta[1], A. Sulli[1], C. Pizzorni[1], S. Paolino[1], E. Alessandri[1], V. Smith[2], B. Ruaro[1], M. Cutolo[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology Department of Internal Medicine, University of Genova, Genova, Italy; [2]Department of Rheumatology, Ghent University Hospital, Faculty of internal medicine, Gent University, Gent, Belgium*

**Background:** Iloprost (ILO) and bosentan (BOSE) integrated therapy was demonstrated to improve microvascular structure in systemic sclerosis (SSc) patients, in two long-term follow up studies [1].
**Objectives:** Since the alterations in capillary number seem to predict the incidence of clinical SSc complications [2], present study aimed to quantify, by nailfold videocapillaroscopy (NVC), long-term effects of BOSE treatment on nailfold capillary absolute number and their possible correlation with clinical parameters of the disease.
**Methods:** Thirty SSc patients entered the study, with a follow up of for 4 years. Fifteen patients were treated with ILO mono-therapy (80 μg/day, for 5 continuous days, every 3 months), while other 15 patients, because of the onset of systolic pulmonary hypertension (sPAP) or digital ulcers (DUs) were treated with BOSE (125 mg twice/day) and ILO integrated therapy (ILO+BOSE). Nailfold capillaries absolute number, DU incidence, diffusing capacity of the lung for carbon monoxide (DLCO), sPAP and renal artery resistive index (RI) were evaluated yearly. Friedman test, Cochran's q test, Marginal homogeneity and mixed modelling were used to study variables with repeated measures. A p value lower then 0.05 was considered significant.
**Results:** In the ILO+BOSE group, capillary absolute number was found to have a significant increase (p=0.01) from T0: 6.8±1.3 to T4: 7.8±1.5 (14.7%), whereas in the ILO group, a non-significant decrease in capillary number from T0: 7.18±0.5 to T4: 6.5±1.1 (9.4%) was found. According to multivariate analysis, the most significant associations, other then BOSE treatment, were observed between capillary number increase and baseline capillaroscopic "Early" pattern (p<0.0001), lcSSc subtype (p=0.001), while it was independent from other clinical characteristics. In the ILO+BOSE group there was a significant reduction in the annual incidence of new DUs from T0 (10/15 patients) to T4 (2/15 patients) (80%; p=0.0042) and no further negative significant changes were observed in DLCO and sPAP. On the contrary, in the ILO group, DLCO was significantly reduced (8.1%, p=0.039) and sPAP increased (15%, p=0.04) during the follow up. RI did not change significantly in both groups.
**Conclusions:** Capillary absolute number count seems a reliable parameter to evaluate long-term effects of BOSE on microvasculature in SSc. A significant reduction in the annual incidence of new DUs and stabilization of lung function was observed and appeared to be associated to the increased number of capillaries during a four-years integrated treatment with BOSE and ILO.

## AB0584 SYSTEMIC SCLEROSIS SINE SCLERODERMA: AN INFRA-DIAGNOSED DISEASE?

A.I. Martinez-Vidal, M. Freire, A. Soto-Peleteiro, A. Sousa-Dominguez, I. Villaverde-Alvarez, C. Vázquez-Triñanes, R. Lorenzo-Castro, A. Argibay, A. Rivera. *Internal Medicine, Thrombosis and Vasculitis Unit, Alvaro Cunqueiro Hospital, University Vigo's hospital, Vigo, Spain*

**Background:** Systemic sclerosis (SSc) is a connective tissue disease of unknown origin, with heterogeneous clinic presentation and chronical and progressive evolution. There is a subtype of SSc without cutaneous presentation designated as systemic sclerosis sine scleroderma (ssSSc) that is difficult to diagnose with a delay on it producing worse prognosis.
**Objectives:** The objective of this study was analyzing demographic features, clinical presentations, the treatment and evolution of ssSSc patients from our hospital.
**Methods:** There were analyzed in a retrospective way the patients diagnosed of SSc in our center between 1990 and May 2015, selecting those with ssSSc.
**Results:** Among the 106 patients diagnosed of SSc in this period, only 5 patients (4.7%) had ssSSc. All of them were women with an average of 51 years. 3 patients (60%) had additionally an autoimmune hypothyroidism, other a polyglandular autoimmune syndrome and the other one had no autoimmune disease. Only one patient (20%) was HTA, another was smoker and another one had dyslipidemia. None of the 5 patients had suffered exposure to toxic elements. Average time delay for diagnosis was 10 years. For 3 patients initial diagnosis was in one case primary Raynaud phenomenon, other case pulmonary arterial hypertension (PAH) essential and in another one polyglandular autoimmune syndrome. 2 of the ssSSc diagnosis were done in 2006 (coincident with the opening of our monographic office of autoimmune systemic diseases). The reason for consultation in 4 of the patients (80%) was Raynaud phenomenon (RP) that was present in all of the patients during the tracking. Only one patient (20%) had digital ulcers, 2 patients (40%) esophagitis and 1 tendinopathy. 1 patient (20%) had PAH confirmed by right coronary angiography. All patients had antinuclear antibodies (ANA) positive, 80% anticentromere. A patient presented positivity to Anti Ro and another one to anticardiolipin antibodies. Nailfold capillaroscopy was made to 4 patients (80%), being all of them pathologic (Cutolo's pattern 3 active and 1 early). Spirometry was made in 4 patients (80%) founding diffusion alteration in 3 of them. The transthoracic echocardiogram performed to all patients was pathologic in the 3 of them (60%) (1 patent ductus arteriosus, 1 PAH and 1 valvular heart disease). Regarding treatment, 3 patients (60%) were treated with calcium antagonists and 2 (40%) received bosentan, without presenting none of them any serious adverse effect. It is important to highlight that 2 patients (40%) developed limited scleroderma after 9 and 4 years of diagnosis respectively. The patient with PAH died during the tracking because of right heart failure.
**Conclusions:** ssSSc diagnosis is difficult due to the absence of the main presentation, the cutaneous one. The most frequent beginning symptom is the RP, so including this symptom in the anamnesis and stablishing screening measures in patients with RP with detection of ANAs and periungual capillaroscopy is important for an early detection to allow diagnosis improvement.

## AB0585 INTIMA MEDIA THICKNESS AND ATHEROSCLEROTIC PLAQUES ARE ASSOCIATED WITH SUBCLINICAL ATHEROSCLEROSIS AND DEPRESSION IN SYSTEMIC SCLERODERMA

A. Smržová[1], M. Schubertová[1], J. Vymětal[1], M. Skácelová[1], A. Petráčková[2], E. Kriegova[2], F. Mrázek[2], Z. Heřmanová[2], P. Horák[1]. *[1]3Rd Department of Internal Medicine – Nephrology, Rheumatology and Endocrinology; [2]Departement of Immunology, Faculty of Medicine and Dentistry, Palacký University Olomouc, Olomouc, Czech Republic*

**Background:** Atherosclerosis is a common cause of mortality and morbidity in many autoimmune diseases. There is not much evidence about the role of atherosclerosis in increase mortality in systemic scleroderma.
**Objectives:** The aim of study is detection of subclinical atherosclerosis measured by ultrasound detected intima media thickness in a group of systemic scleroderma patients and finding relation to traditional risk factors, clinical manifestation, immunological profile and selected laboratory markers.
**Methods:** From March 2015 to January 2016 55 patients with systemic scleroderma were included in the study. (9 men. 46 women, mean age - 59±10.5y., age of diagnosis 51.2±12.3y., duration of disease 5±8.5y., duration of Raynaud's phenomenon 8±12.1y.). In these patients data were collected on traditional atherosclerosis risk factors (smoking, BMI, arterial hypertension, Diabetes, lipid profile, family history of cardiovascular event), on the phenotype of scleroderma disease (lung manifestation, pulmonary hypertension, digital ulceration, involvement of gastrointestinal tract, myositis, renal crisis). The immunological profile of the disease was assessed by analysis of autoantibodies. All patients were tested by complex psychological test - MMPI-II (The Minnesota Multiphasic Personality Inventory test, standardized psychometric test of adult personality and psychopathology) and BDI-II test (Beck Depression Inventory test of depression). The presence of subclinical atherosclerosis was assessed by ultrasound measurement of intima media thickness (IMT) and by assessment of presence carotic plaque. Echocardiography aimed for detection of pulmonary hypertension, left ventrical function and valvlular disease was done. Statistical tests (descriptive statistic, Student t-test, Spearman test and ANOVA) were

performed to describe eventual relation of findings, p-value $\leq$0.05 considered as significant.
**Results:** Pathological IMT was detected in 31 (56.3%), plaques in 19 patients (34.5%). In this group was low incidence of cardiovascular events – 1 ischemic heart disease, 1 myocardial infarction and one stroke, prevalence presence of valvuvar disease (16 patients, 29.1%). IMT correlated with disease duration (p=0.01), positivity of anti Scl 70 (p=0.02), TC/HDL ratio (p=0.02), hsCRP (p=0.05), presence of PH (p=0.002), digital ulceration (p=0.007), gastrointestinal damage (p=0.04), but also with MMPI-II scale of depression (p=0.03) and hypochondria (p=0.01) and BDI-II summary score (p=0.04). Presence of plaques correlated with disease duration (p=0.05), diffuse form (p=0.01), TC and HDL ratio (p=0.02), hsCRP (p=0.02), digital ulceration (p=0.03) and MMPI-II measured scale of conversion hysteria (p=0.01) and BDI-II summary score (p=0.03).
**Conclusions:** Patients with scleroderma in our study had low presence of cardiovascular manifestation. Nevertheless prevalence of latent atherosclerosis detected by increase IMT and presence of atherosclerotic plaques of carotic artery is high and correlates with some organ manifestations (pulmonary hypertension, digital ulceration). Presence of atherosclerosis correlates also with subclinical depression assessed by complex psychological tests.

## AB0586 PREDICTORS OF INTERSTITIAL LUNG DISEASE IN 79 PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE

A. Felis-Giemza[1], E. Kontny[2], E. Haładyj[1], K. Walkiewicz-Pielaszek[3], Z. Czuszyńska[4], Z. Zdrojewski[4], A. Paradowska-Gorycka[5], M. Olesińska[1]. *[1]Connective Tissue Disease Department; [2]Department of Pathophysiology and Immunology; [3]Department of Rheumatology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw Poland, Warszawa; [4]Clinic of Internal Medicine, Connective Tissue Disease&Geriatrics, Medical University of Gdansk, Gdansk; [5]Biochemistry and Molecular Biology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw Poland, Warszawa, Poland*

**Background:** Interstitial lung disease (ILD) is a common complication of various connective tissue diseases, like scleroderma, polymyositis or mixed connective tissue disease (MCTD). The development of ILD is in many cases asymptomatic, although autopsy found lesions typical for the ILD in 90–100% [1]. In the case of MCTD ILD is the most common pulmonary involvement with incidence of 47,1% (active form- 66% of them) and its severe type - progressive fibrosis characterize 20.8% after 4.2 years mortality rate [2].
**Objectives:** The aim of the study was to estimate the prevalence of ILD and pulmonary fibrosis in a cohort of MCTD patients, and to identify clinical and immunological predictors of this complication.
**Methods:** The study included 79 patients (the median age =44 years, 83.5% of women), who fulfilled Alarcon-Segovia and Kasukawa sets of criteria for MCTD. Clinical features of MCTD, autoantibody profile and serum cytokine (IL-1, IL-10, IL-21, IL-23, TNF$\alpha$, IFN$\gamma$, VEGF) concentrations were assessed. Screening chest X-ray, and if needed pulmonary function tests and high resolution computed tomography (HRCT) were performed additionally.
ILD was defined as active, reversible interstitial lung disease with symptoms such as dyspnoea and dry cough, proven radiologically by presence of interstitial lesions in X-ray or ground-glass opacity in HRCT ± decrease in pulmonary function tests by 10% in forced vital capacity (FVC) or diffusing capacity of the lungs for carbon monoxide (DLCO).
**Results:** ILD and pulmonary fibrosis were present in 19% of MCTD patients and this group was characterized by older age, longer disease duration, more frequent systemic damage, and higher disease activity comparing to the rest of study group. The most common findings among patients with ILD were abnormal FEV1 (80% vs 15,4%) and oesophageal involvement (4,4 vs 19,7%). Concomitance of pulmonary arterial hypertension (PAH) and ILD in MCTD were observed in only 2,5% of examined patients. Moreover, patients with ILD were less often positive for anti-SmB antibody than the ILD-free subjects (11.1 vs 37.7%), but similar cytokine concentrations was stated in both groups.
**Conclusions:** In MCTD pulmonary involvement (ILD and/or pulmonary fibrosis) develops mostly in patients with long lasting, clinically severe disease, accompanied by low frequency of anti-SmB antibody presence.

## AB0587 PULMONARY ARTERIAL HYPERTENSION AS A RISK FACTOR FOR MORTALITY IN CONNECTIVE TISSUE DISEASE WITH BIOPSY PROVEN INTERSTITIAL LUNG DISEASE

A.L. Svensson[1], N. Tvede[1], J. Carlsen[2], M. Iversen[2], A.S. Jensen[2], S. Jacobsen[1]. *[1]Department of Rheumathology; [2]Department of cardiology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark*

**Background:** Connective tissue diseases (CTD) are a heterogeneous group of autoimmune systemic diseases characterized by circulating autoantibodies and varying degrees of organ involvement including interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH).[1–2] PAH in CTD is known to be associated with increased mortality. Whether ILD alone is associated with increased mortality is uncertain, but lung infections have been suggested to accelerate the development of ILD and impair the prognosis.
**Objectives:** To investigate a cohort of CTD patients with biopsy verified ILD and examine whether histopathologic ILD patterns, PAH and/or lung infections requiring hospital admission are independent predictors of mortality.
**Methods:** A retrospective cohort study of CTD patients with lung biopsy verified ILD. Data regarding ILD patterns were obtained from lung biopsies, PAH was evaluated with transthoracic echocardiography (TTE) using tricuspidal regurgitation $\geq$36 mmHg as a parameter for PAH. Data regarding lung infections requiring hospital admission and death were obtained from medical records. Survival was analyzed by age and gender adjusted multiple cox-regression analysis using SPSS version 22.
**Results:** Fifty-six CTD patients had ILD verified CTD, 21 (37%) with systemic sclerosis, 14 (25%) with polymyositis, 14 (25%) with undifferentiated connective tissue disease and 7 (13%) with mixed connective tissue disease. At the time of lung biopsy, the 56 CTD patients (50% females) had a mean (SD) age of 53.5 (11.3) years and disease duration of 4.4 (9.1) years. The follow-up after biopsy consisted of 203 person-years. Eight patients (14%) died during follow-up translating to a mortality rate of 39.4 per 1000 person years. Non-specific interstitial pneumonia (NSIP) histopathological pattern was observed in 15 (27%), fibrosis in 16 (29%), while 25 (44%) had other histopathological patterns. Thirteen (23%) patients had PAH which was associated with increased mortality with a HR=5.3 [95% CI 1.2–24.2], p=0.03. The patients with histopathological NSIP and fibrosis patterns had a higher mortality than other types of ILD, nevertheless the histopathologic pattern of ILD and hospital admission requiring infections did not predict increased mortality.
**Conclusions:** PAH predicts poor outcome in CTD patients with ILD, irrespective of the histopathological ILD pattern. In CTD with interstitial lung disease early PAH screening and initiation of treatment is paramount for optimizing survival among patients with CTD and ILD.

## AB0588 RISK FACTORS FOR THROMBOEMBOLIC EVENTS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

A. Notarnicola[1], L. Näsman[1], Q. Tang[1], A. Tjärlund[1], K. Elvin[2], L. Berg[1], J. Norkko[1], I.E. Lundberg[1], A. Antovic[1]. *[1]Department of Medicine, Rheumatology Unit; [2]Department of Clinical Immunology and Transfusion Medicine, Karolinska University Hospital and Karolinska Institutet, Solna, Stockholm, Sweden*

**Background:** Patients with Idiopathic Inflammatory Myopathies (IIM) have an increased risk of thrombotic event (TE) compared with the general population (1). The role of traditional thrombotic risk factors, IIM disease activity, presence of antiphospholipid antibodies (aPL) and adhesion molecules, in the pathogenesis of TE is unknown.
**Objectives:** *We* aimed to investigate the prevalence of TE (pulmonary embolism (PE), deep venous thrombosis (DVT), myocardial infarction (MI), stroke, transitory ischemic attack (TIA) or peripheral arterial thrombosis (PAT)) in IIM patients. We also compared clinical and serological characteristics of IIM patients with and without TE.
**Methods:** 286 IIM patients followed between 1993–2014, with and without TE, were identified. Information on traditional risk factors for TE, autoantibody profiles, disease activity and medical treatment was retrieved from registries and medical records. Serum levels of anti-$\beta$2-glycoprotein I (anti-$\beta$2-GPI) and anticardiolipin antibodies (aCL) as well as serum levels of adhesion molecules i.e. vascular cell adhesion molecule 1 (VCAM), intercellular adhesion molecule 1 (ICAM) and e-selectin were analysed on stored sera. Sera of patients with TE were screened for levels of adhesion molecules at the time of IIM diagnosis and at the time of TE. Levels of adhesion molecules were also analysed in 40 healthy individuals.
**Results:** Sixty-seven (23.4%) of the 286 IIM patients suffered from at least one TE, 33 presented with arterial thrombosis (MI, Stroke, TIA, PAT), 31 with venous

thrombosis (DVT, PE), 3 with both. Among traditional risk factors for TE, higher age at diagnosis ($p<0.001$), male gender ($p<0.05$) and hypertension ($p<0.05$) occurred more frequently in patients with TE than in those without. No other significant differences in terms of prevalence of risk factors, disease activity, medical treatment or autoimmune profile were found. Significantly higher levels of VCAM, ICAM and E-selectin ($p<0.001$, $p<0.001$ and $p<0.05$, respectively) were found in patients with IIM compared to controls. However, there was no significant difference in the levels of any of the investigated adhesion molecules between IIM patients with TE and those without. Moreover, no significant difference in the levels of adhesion molecules at the time of IIM diagnosis and at the time of TE was observed.

**Conclusions:** The main finding of this study is the striking prevalence of thrombotic events in patients with IIM. The fact that 1 out of 5 patients suffered from a TE should alert the clinician to screen for TE when clinically indicated as well as to consider prophylactic treatment in risky situations, including surgery, immobilisation or pregnancy. Male gender, higher age at IIM diagnosis and hypertension should be taken into account when estimating TE risk. High disease activity or aPL positivity were not specific features of IIM patients with TE, nor were elevated serum levels of adhesion molecules. The mechanisms leading to increased risk of TE in patients with IIM need further investigations.

## AB0589 HYPERCOAGULABLE STATE MIGHT BE INDUCED BY ALVEOLAR-ENDOTHELIAL DAMAGES IN INTERSTITIAL LUNG DISEASE ASSOCIATED WITH POLYMYOSITIS/DERMATOMYOSITIS

A. Kawano, K. Umekita, M. Matsuda, K. Kubo, S. Miyauchi, M. Komura, I. Takajo, Y. Nagatomo, A. Okayama. *Division of Rheumatology, Infectious Diseases and Laboratory Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan*

**Background:** Polymyositis and dermatomyositis (PM/DM) are often complicated by interstitial lung diseases (ILD), which is an important cause of death. It has been reported that endothelial damages are likely to exist in PM/DM patients with ILD (PM/DM-ILD). Endothelial damages and oxidative stress induced hypercoagulable state in many connective tissue diseases (CTD) such as rheumatoid arthritis, systemic lupus erythematosus and systemic scleroderma. Recent evidence suggested that anticoagulation therapies might contribute to improve the disease activity of pneumonia related to CTDs.

**Objectives:** The purpose of this study was to clarify the association between the disease activity of ILD and blood coagulation disorders in patients with PM/DM.

**Methods:** This study is retrospective observation study. The medical records of 22 patients who were diagnosed as having PM/DM admitted to our hospital from April 2012 to March 2015 were reviewed in present study (median age: 50.5, female ratio: 81.8%). Diagnosis of ILD was evaluated by chest high-resolution CT. We reviewed the laboratory findings and autoantibody profile associated with PM/DM.

**Results:** Eighteen of 22 (81.8%) patients with PM/DM were diagnosed as having ILD. Autoantibodies associated with PM/DM were evaluated in 14 patients among 18 patients with PM/DM-ILD. Anti-aminoacyl-tRNA synthetases (ARS) and anti-MDA5 antibody was positive in 8/14 patients (57%) and 4/14 patients (29%), respectively. Anti-Jo-1 antibody was detected in 3 patients (38%), anti-PL7 in 3 patients (38%), anti-OJ in one patient (12%), and anti-EJ in one patient (12%) in 8 patients with anti-ARS antibody positive PM/DM-ILD. The levels of creatinine kinase (CK) in anti-ARS antibody positive PM/DM-ILD patients was higher than those in anti-ARS antibody negative PM/DM-ILD patients (median CK 2464 v.s 106 IU/ml, p=0.01). The levels of serum KL-6 and plasma D-dimer in anti-ARS antibody positive PM/DM-ILD patients tended to be higher than those in anti-ARS antibody negative PM/DM-ILD patients (median KL-6 691 v.s 489 IU/ml, D-dimer 2.57 v.s 1.96 ug/ml). Additionally, there is significantly positive correlation in the levels of between serum KL-6 and plasma D-dimer (R=0.58, p=0.0008). However, there is no correlation between the levels of serum KL-6 and blood coagulation tests, such as prothrombin time (%) and activated thromboplastin time.

**Conclusions:** These results suggest that anti-ARS antibody, especially anti-Jo-1 and anti-PL7, seems to be associated with the severity of muscular manifestation and alveolar-endothelial damages. The level of plasma D-dimer reflects the disease activity of ILD in patients with PM/DM. The hypercoagulable state might be induced by alveolar-endothelial damages and oxidative stress in PM/DM-ILD.

## AB0590 EVALUATION OF DERMAL THICKNESS BY THREE DIFFERENT TECHNIQUES IN SYSTEMIC SCLEROSIS PATIENTS

B. Ruaro, A. Sulli, S. Paolino, C. Pizzorni, M. Cutolo. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy*

**Background:** Skin involvement is critical for sub-classification of systemic sclerosis into different subsets (1).

**Objectives:** The aim of this study was to identify possible correlations between modified Rodnan skin score (mRSS), high frequency skin ultrasounds (US) and plicometer skin test (Plicometry) in the evaluation of dermal thickness (DT) in patients with (SSc).

**Methods:** 63 SSc patients (mean age 63±12SD years, mean SSc duration 6±5 years) and 63 healthy subjects (mean age 65±15SD years) were enrolled. The three methods were employed in the seventeen areas of the skin usually evaluated by mRSS (face, fingers, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs and feet) and the total score calculated, as previously reported (2,3). US was performed by a 18 MHz probe (Esaote, Italy) reporting DT as millimetres, and Plicometry (Gima, Italy) adopting a 0–3 score as for mRSS assessment (4). Nailfold videocapillaroscopy (NVC) was performen in SSc patients to assess the proper pattern of microangiopathy.

**Results:** A statistically significant positive correlation was found between the three methods to evaluate DT in the SSc patients (mRSS vs US $r=0.53$, $p<0.0001$; mRSS vs Plicometry $r=0.98$, $p<0.0001$; US vs Plicometry $r=0.53$, $p<0.0001$). In particular, US showed that all SSc patients had a statistically significant higher DT in the 17 areas when compared with control subjects ($p=0.0001$). DT measurements were found progressively higher in patients with “Early”, “Active” and “Late” NVC pattern of microangiopathy.

**Conclusions:** This study demonstrates a significant relationship between mRSS, US and Plicometry in dermal thickness evaluation in SSc patients. At the level of the seventeen skin areas analyzed by US, all SSc patients showed a statistically significant higher DT than controls.

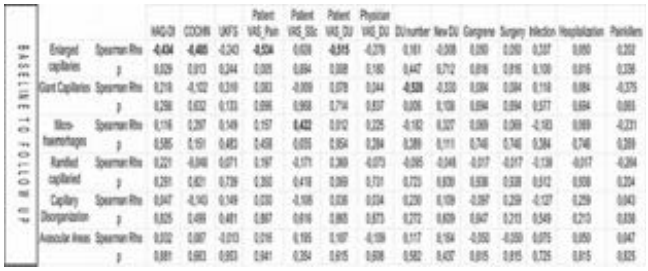
## AB0591 NAILFOLD VIDEOCAPILLAROSCOPY MAY NOT REFLECT CHANGE OF DIGITAL ULCERS STATUS IN A SHORT TERM EVALUATION OF SYSTEMIC SCLEROSIS PATIENTS

C. Bruni[1], T. Ngcozana[2], F. Braschi[1], T. Barskova[1], S. Guiducci[1], S. Bellando-Randone[1], L. Tofani[3], C.P. Denton[2], D.E. Furst[4], M. Matucci-Cerinic[1]. *[1]Department of experimental and clinical medicine, division of Rheumatology, University of Firenze, Firenze, Italy; [2]Centre for Rheumatology and Connective Tissue Diseases, UCL Division of Medicine, London, United Kingdom; [3]Department of Neurosciences, Psychology, Drug Research and Child Health, University of Firenze, Firenze, Italy; [4]Department of Medicine, Division of Rheumatology, University of California at Los Angeles, Los Angeles, United States*



**Background:** Nailfold videocapillaroscopy (NVC) is a useful tool in systemic sclerosis (SSc) patients, useful not only for the diagnosis but also to predict the development of organ and vascular complications, such as the utility of the recently proposed semi-quantitative scoring for digital ulcers (DU) [1].

**Objectives:** to prospectively evaluate the change of prevalence of NVC microvascular alterations and their possible correlations with changes in patients-reported outcomes (PROs) and clinical-reported outcomes (CROs) and prevalence of clinical characteristics related to DU in SSc patients.

**Methods:** SSc patients presenting at least one DU and attending the Rheumatology Wound Care Clinic of the Florence University Hospital or the London Royal Free Hospital were enrolled. Patients were assessed with PROs (HAQ-DI, UKFS, Cochin scale, VAS for pain, DU status and general disease status) and CROs (VAS for DU status) at baseline and after 16 weeks. DU number, appearance of new DU, presence of gangrene, infection, need for hospitalization or surgery procedures, painkillers use were recorded at each visit. NVC was performed at both visit and the presence of micro-haemorrhages, giant capillaries, irregularly enlarged capillaries, ramified capillaries, capillary disorganization and loss of capillaries was scored according to the previously proposed score (0 = no changes, 1 = from 0 to 33%; 2 = from 33% to 66%, 3 = more than 66%). Correlations were tested through Spearman test.

**Results:** twenty-five SSc patients were eligible for the study. No significant correlation was seen at baseline; when analysing changes between baseline and follow-up, a negative correlation was seen between irregularly enlarged capillaries and the majority of PROs; moreover, changes of number of DU showed negative correlation with changes of giant capillaries, possibly reflecting the evolution of microvascular damage.

**Conclusions:** NVC is useful tool to predicting DU development, but may not reflect short term change in DU status; therefore a longer-term evaluation may be necessary to detect NVC modifications paralleling DU changes in SSc patients.

## AB0592 EVALUATION OF ARTERIAL STIFFNESS IN A COHORT OF SYSTEMIC SCLEROSIS PATIENTS: A CASE-CONTROL STUDY

E. Bartoloni[1], F. Battista[2], A. Alunno[1], F. Cannarile[1], V. Valentini[1], G. Pucci[2], G. Schillaci[2], R. Gerli[1]. *[1]University of Perugia, Rheumatology Unit, Perugia; [2]University of Perugia, Internal Medicine Unit, Terni Hospital, Italy*

**Background:** Systemic sclerosis (SSc) patients are characterized by premature cardiovascular (CV) mortality. In this setting, the disease represents an intriguing model to evaluate premature endothelial damage. Indeed, both macrovascular and microvascular damage characterizes subclinical atherosclerosis (ATS) in these patients (1). Traditional CV risk factors, SSc-related inflammatory and autoimmune mechanisms may contribute to accelerated ATS. Among indirect measures of subclinical ATS, aortic stiffness (AS), measured by carotid-femoral pulse wave velocity (cf-PWV), and augmentation index (Aix@75) are independent predictors of CV morbidity and mortality in several diseases. To date, studies evaluating subclinical ATS in SSc provided conflicting results. Moreover, factors influencing atherosclerosis in SSc have not been well defined.

**Objectives:** To evaluate cf-PWV and Aix@75 measures of AS in SSc patients and analyze relationship between disease-related features and AS.

**Methods:** Thirty-four consecutive female SSc patients (mean age 61±15 years) with mean disease duration of 17±12 years since Raynaud phenomenon and 34 healthy sex, age and arterial pressure (AP) matched controls (HC) were enrolled. Traditional CV risk factors, disease-specific clinical, metabolic and immunologic features were collected. Disease activity and severity were assessed by Valentini Disease Activity Index (VDAI) and Medsger Disease Severity Scale (MDSS), respectively. Cf-PWV was determined by means of applanation tonometry (SphygmoCor). AIx@75 was calculated as difference between the 2nd and 1st wave systolic peaks and standardised to 75 beats/min. The relationship between cf-PWV, AIx@75 and all variables was investigated with univariate (one-way ANOVA) and multivariate models.

**Results:** Mean blood AP was similar in patients and HC. About 1/3 patients were receiving immunosuppressive therapy, 33% iloprost, 41% calcium-chanel blockers, 9% beta-blockers, 9% angiotensin receptor blockers and 3% ACE-inhibitors. Mean VDAI was 1,37±1,32 and 15% of patients were characterized by high activity (score >3). Mean MDSS was 0,35±0,65 with 9% of patients who had a moderate-severe disease. Both absolute AIx (16,1±8 *vs* 11,5±7 mmHg; p=0,014) and AIx@75 (30,9±16 *vs* 22,2±12%; p=0,012) resulted significantly higher in SSc compared to HC, while cf-PWV was similar in the two populations. At multivariate analysis, age, mean AP and mean C-reactive protein resulted independent predictors of cf-PWV, while only age and mean AP of AIx@75. Of interest, limited SSc and anti-centromere positive patients were characterized by significantly higher AIx@75 in comparison to diffuse SSc and anti-Scl70 positive (p=0.045 and p=0.04, respectively).

**Conclusions:** Subclinical atherosclerotic damage in SSc seems to be mainly characterized by increased AIx, a measure of arterial stiffness that encompasses peripheral vascular reflectance and left ventricular ejection, thus reflecting a prevalent peripheral microvascular involvement. Moreover, several factors, including inflammatory state, may contribute to AS in these patients. Intriguing, the significant increase of AIx in limited SSc may suggest a more severe peripheral microvascular involvement in these patients.

## AB0593 CHOROIDAL INVOLVEMENT IN SYSTEMIC SCLEROSIS: COMPARISON BETWEEN SKIN BLOOD PERFUSION AND CHOROIDAL THICKNESS BEFORE AND AFTER ILOPROST TREATMENT

E. Bernero[1], A. Sulli[1], B. Ruaro[1], A.C. Trombetta[1], S. Paolino[1], C. Pizzorni[1], M. Nicolò[2], C.E. Traverso[2], C.A. Cutolo[2]. *[1]Department of Internal Medicine, University of Genova, Research Laboratory and Academic Division of Clinical Rheumatology; [2]DINOGMI, University of Genova, Ophtalmology Clinic, Genova, Italy*

**Background:** Systemic sclerosis (SSc) is characterized by progressive diffuse microvascular damage and decreased blood perfusion (BP) at skin and internal organs (1). Laser speckled contrast analysis (LASCA) evaluate skin BP in different areas of body (2). Histological studies and fluorescein angiography demonstrated choroidal involvement in SSc, and recently optical coherence tomography (OCT) measurement showed significantly thinner choroid thickness (CT) in SSc patients (3–5). Iloprost, a prostacycline analogue, is effective in the treatment of microvascular manifestations in SSc (7).

**Objectives:** To study skin BP and ocular CT in patients with SSc, before and after iloprost treatment.

**Methods:** After informed consent was obtained, twelve SSc patients according to ACR/EULAR classification criteria (8) (mean age 58±13 years, mean disease duration 5±3 years) underwent ophthalmologic evaluation by OCT and BP evaluation by LASCA, before after 8 hours of continuous iloprost i.v. infusion (0.5 ng/kg/min). OCT images were recorded by 3D-2000 OCT (Topcon, Japan) using protocol "line" that averages 50 B-scans and generates a horizontal 6 mm line. CT area measurements were performed manually using image J software. BP was assessed by LASCA at the level of fingertips, periungueal, whole face, perioral and periorbital area, and the average BP calculated as perfusion units (PU)(1). Statistical analysis was performed by non parametric tests.

**Results:** Both before and after iloprost therapy (T0-T1), statistically significant positive correlations between BP and CT were found at periorbital (T0 r=0.55, p=0.022, and T1 r=0.91 p=0.0002), fingertips (T0 r=0.69, p=0.004, and T1 r=0.63, p=0.01), and perioral skin areas (T0 r=0,75, p=0.002, and T1 r=0,61, p=0.012). Further correlations were observed at periungueal (T0 r=0.54, p=0.02, and T1 r=0.50, p=0.04) and whole face (T0 r=0.49, p=0.04, and T1 r=0.47, p=0.05). BP was found significantly increased after iloprost therapy in all examined areas (p=0.002). Patients did not show any visual/ocular symptom during and after iloprost infusion.

**Conclusions:** LASCA and OCT seem concordant tools in assessing the functional microvascularization status in SSc patients. Since LASCA is a reliable tool to assess skin BP, its observed correlation with the CT and the effects of iloprost treatment, suggest that the OCT evaluation could be included in periodical instrumental evaluation of SSc progression and effects of microvascular targeted treatments.

## AB0594 ANTI-RNA POL III ANTIBODIES IN SYSTEMIC SCLEROSIS - THE PREVALENCE AND USEFULNESS

E. Wielosz, M. Dryglewska, M. Majdan. *Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Lublin, Poland*

**Background:** Anti-RNA Polimerase III (a-RNA Pol III) antibodies are markers antibodies which are detected in sera of patients with systemic sclerosis (SSc). They are found in approximately 20% of SSc, particularly with diffuse subtype. According to literature a-RNA Pol III antibodies are strongly associated with scleroderma renal crisis (SRC). They are also correlated with higher rate of SSc-related mortality. Additionally, there are many data which reported that, a-RNA Pol III antibodies are associated with an increased risk of malignancy in patients with SSc.

**Objectives:** The aim of the study was assess the prevalence of a-RNA Pol III antibodies in patients with systemic sclerosis and to identify differences in the picture of the disease in patients with the presence of a-RNA Pol III.

**Methods:** The study was performed in 126 (98-female and 28-male) consecutive SSc patients treated in Department of Rheumatology. Patients fulfilled the ACR classification criteria of SSc (60 have diffuse SSc-dcSSc and 66 limited SSc – lcSSc). The subtype of SSc, incidence of internal organ involvement, the prevalence of malignancy, death and serological profile were determined in the whole data group. The study group were studied according to the presence of antibodies applying commercial test – EUROLINE Systemic Sclerosis Profile. Detection and interpretation of results was carried out electronically using the specific program Euroimmun– EUROLINEScan. Due to the presence of a-RNA

Pol III antibodies, patients were divided into two groups a-RNA Pol III(+) SSc – 19 pts and a-RNA Pol III(–) SSc – 107 pts.
**Results:** According to our data a- RNA Pol III antibodies were present in 19/126 patients with SSc (15%), including the a-RNA Pol III 11 were present in 16 and a-RNA Pol III 155 in 14. In this group of 13 (68,4%) pts had no other marker to SSc antibodies as a anticentromere, anti-topoisomerase I. Moreover, in our study group, a-RNA Pol III antibodies were more common in patients with dcSSc (p=0,049), compare to lcSSc. We also showed a significant positive association with a-RNA Pol III antibodies and occurrence of malignancy (p=0,007), SRC (p=0,001) and decreased DLCO (p=0,007). There was no relationship between the presence of a-RNA Pol III and other organ involvement, digital ulcerations or calcinosis.
**Conclusions:** 1. Anti- a-RNA Pol III antibodies are quite common in patients with systemic sclerosis, particularly with diffuse subtype.
2. In more than 50% of patients a-RNA Pol III antibodies may be present as the sole marker to SSc antibodies.
3. In SSc a-RNA Pol III antibodies are frequently associated with malignancy occurrence, kidney and lung involvement.

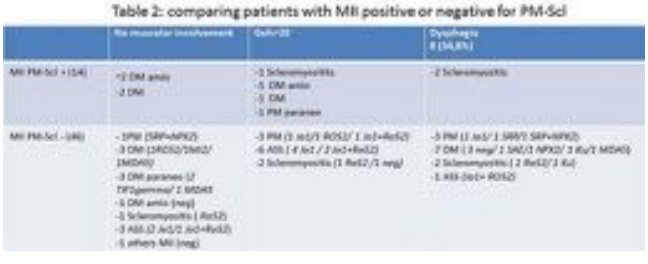
## AB0595 DESCRIPTIVE ANALYSIS OF A SINGLE CENTER SERIES OF 23 PATIENTS WITH POSITIVE PM-SCL ANTIBODY



F. Furini[1], E. De Stefani[1], A. Lo Monaco[1], R. La Corte[1], A.L. Giuliani[2], F. Di Virgilio[2], M. Govoni[1]. *[1]Rheumatology Unit, Department of Medical Sciences, University of Ferrara and Azienda Ospedaliera-Universitaria Sant'Anna - Ferrara (Italy); [2]Dept of Morphology, Surgery and Experimental Medicine, University of Ferrara, Section of Pathology, Oncology and Exerimental Biology, Ferrara, Italy*

**Background:** PM-Scl antibodies (abs) belong to the group of myositis-associated antibodies and typically determine a nucleolar or speckled pattern on immunofluorescence. These abs found in patients (pts) with Scleromyositis and, less frequently, in isolated forms of Systemic sclerosis (SSc), Polymyositis (PM) and Dermatomyositis (DM). In SSc pts PM-Scl +, pulmonary involvement seems less severe, while they show more frequent arthritis. Raynaud's phenomenon (RP), digital ulcers (DU) and gastroesophageal involvement appear to be less frequently expressed. In myositis the association with esophageal and lung involvement is well known.
**Objectives:** To characterize demographic and clinical features of a single center series of PM-Scl positive patients.
**Methods:** Sera from 48 SSc and 60 idiopathic inflammatory myophaties (MII) attending local outpatient clinic, detected with EUROIMMUNE Myositis Profile 4 kit, were tested to search PM-ScL antibodies. Demographic, laboratory and clinical data (RP, arthritis, DU, muscular involvement, disphagia) were retrospectively retrieved from available clinical charts. The presence of interstitial lung disease (ILD), was evaluated by HRCT (measured by using score of Goh for the extension) and functional respiratory testing (FVC and DLCO). Severe ILD was defined by: Goh score of>20 and FVC and DLCO <75%.
**Results:** 23 Pts (18 F) resulted positive for PM-Scl. The mean age was 60.5±9.4 years and the mean disease duration was 145.9± 76.3 months. 1 patient had negative ANA, 1 showed ANA anticentromere and 1 dot pattern; the remaining 20 patients (86,9%) were ANA+ showing nucleolar pattern. By applying available formal classification criteria 5 (21.7%) pts were diagnosed as DM, 2 (8.7%) as DM amyopathic, 3 (13.05%) as overlap Scleromyositis, 3 (13.05%) as PM, 1 (4.4%) as cancer associated PM, 9 (39.1%) as SSc (2 diffuse, limited 6, intermediate 1). 13 (56.5%) pts had no evidence of cytopathic muscle involvement (defined as normal CPK, myoglobin and LDH). 5 pts (21.7%) presented a Goh score >20, 1 FVC <75%, and 7 (30.4%) DLCO <75%.
4 pts presented arthritis. 14 (60.8%) had RP, 6 (26%) DU, 8 (34.8%), dysphagia (see images 1). When compared with patients with SSc and MII negative for PM-Scl, MII PM-Scl + pts did not show significant greater risk of developing ILD (Goh>20)dysphagia or minor muscle involvement. SSc PM-Scl + pts seem to have a greater risk of developing arthritis and DU than their corresponding SSc PM-Scl negative pts (p<0.05) while no differences did emerged about ILD (Goh>20) and dysphagia.

Table 1: comparing patients with SSc positive or negative for PM-Scl

Table 2: comparing patients with MII positive or negative for PM-Scl

**Conclusions:** The role of PM-Scl as a risk factor for ILD in MII pts is not confirmed, but should be considered the positivity in the control group of Jo1, representing per se a major risk factor for this complication (image 2). For patients with SSc is confirmed the role of PM-Scl as a risk factor for arthritis and digital ulcers but not for ILD.

## AB0596 ASSESSMENT OF PULMONARY FUNCTION IN PATIENTS DIAGNOSED OF EARLY SYSTEMIC SCLEROSIS

F.M. Ortiz Sanjuan[1,2], J. Ivorra Cortés[2], L. González Puig[2], I. Chalmeta Verdejo[2], E. Grau Garcia[2], M. Fernández Matilla[1], C. Feced Olmos[2], E. Labrador Sánchez[2], K. Arévalo Ruales[2], R. Negueroles Albuixech[2], J. Fragio Gil[2], I. Martínez Cordellat[2], J. Valero Sanz[2], C. Alcañiz Escandell[2], C. Nájera Herranz[2], G. Poveda Marín[2], J. Román Ivorra[2]. *[1]Rheumatology Research Group, IIS la Fe; [2]Rheumatology Department, HUP la Fe, Valencia, Spain*

**Background:** Interstitial lung disease (ILD) is a frequent complication of systemic sclerosis (SSc) and is often progressive and has a poor prognosis. A restrictive ventilatory defect could suggest ILD either alone or in combination with pulmonary arterial hypertension. Nowadays, Early-SSc is well defined as preliminary stage of SSc. Patients who meet criteria for Early-SSc could benefit from an early diagnosis of pulmonary involvement.
**Objectives:** Our aim was to assess the pulmonary function in patients diagnosed of Early SSc.
**Methods:** Retrospective observational study of a wide and unselected series of patients diagnosed as Early-SSc from a single university hospital from June 2012 to August 2015. Patients were classified as Early-SSc following Le Roy criteria. In spite of this, patients already did not met 2013 ACR/EULAR classification criteria for SSc. We reviewed pulmonary function through conventional spirometry and diffusing capacity of lung for carbon monoxide (DLCO). Interpretation of the results of spirometry and DLCO was made according European Respiratory Society (ERS) and American Thoracic Society (ATS) standards
**Results:** We included a total of 41 patients with a mean age of 53±15.6 years (97.6% women; 2.4% men). No one of our patients evidenced a restrictive ventilatory pattern. DLCO was under normal limits in 11 patients (26.8%). Small airway obstruction expressed according decreased maximal (mid-) expiratory flow (MMEF) 25–75 was present in 13 patients (31.7%).
After a mean follow-up period of 26.1±16.6 months, 20 (48.8%) patients fulfilled 2013 ACR/EULAR criteria. The remaining 21 patients continued classified as Early-SSc following Le Roy criteria. The analysis of the subgroup of patients who progressed to SSc showed that DLCO was decreased in 7 of those 20 patients (35%) and also 8 of 20 patients (40%) presented decreased maximal (mid-) expiratory flow (MMEF) 25–75. Comparing with the subgroup of patients which not progressed to SSc no were significant differences (Decreased DLCO: 35% vs 26.8%; p=0.8 and Decreased MMEF 25–75: 40% vs 31.7%; p=0.9).
**Conclusions:** In our study, about a quarter of the patients classified as Early-SSc presented abnormal values of DLCO and/or signs of small airway obstruction without the presence of a restrictive ventilatory pattern. Moreover, the expression of this pulmonary dysfunction tends to be more frequent in patients who progressed to definitive SSc, although this was not statistically significant. An early assessment of pulmonary function in this context should be highly recommended.

## AB0597 ADAPTATION OF UCLA SCLERODERMA CLINICAL TRIAL CONSORTIUM GASTROINTESTINAL TRACT 2.0 QUESTIONNAIRE INTO TURKISH

M.Y. Tas[1], P. Keskinoglu[2], G. Kenar[3], H. Yarkan Tugsal[3], B. Zengin[3], G. Dervis Hakim[1], G. Can[3], F. Onen[3], N. Akkoc[3], M. Akarsu[1], M.A. Birlik[3]. *[1]Internal Medicine; [2]Biostatistics and Medical Informatics; [3]Rheumatology, Dokuz Eylul University, Izmir, Turkey*

**Background:** Nearly 90% of patients with scleroderma (SSc) have gastrointestinal tract (GIT) involvement in variable severities and is a challenging process for clinicians.
The University of California Scleroderma Clinical Trial Consortium Gastrointestinal Tract 2.0 (UCLA SCTC GIT 2.0) is a questionnaire including 34 items, 7 multi-item scales: reflux, distention/bloating, diarrhea, fecal soilage, constipation, emotional well-being and social functioning. By these parameters, a total GIT score is calculated (1). This scale translated in German, Italian, French, Polish, Spanish, Swedish, Dutch before, they are available in http://www.uclascleroderma.researchcore.org/ website (1–3). There is no Turkish version of this scale yet.
**Objectives:** Our aim is to make translation, cultural adaptation of the UCLA SCTC GIT 2.0 into Turkish, and assess reliability of the scale in patients speaking Turkish.
**Methods:** UCLA SCTC GIT 2.0 scale was translated into Turkish according

to international guidelines and applied to 97 SSc patients. The questionnaire repeated in 29 patients after an interval of 15 days for determining reliability. For internal consistency, Cronbach's alpha was calculated, reliability coefficient if item deleted and test-retest reliability also determined. External consistency was measured by comparing with the Short Form (SF)-36 by Spearman's correlation analysis (rho: ≤0.29 weak, 0.30–0.49 middle, ≥0.50 strong).

**Results:** 97 scleroderma patients were included in this study (female:87.6%, mean age:55.4±11.4). Internal consistency Cronbach's alpha was calculated as 0.89, reliability coefficient if item deleted was 0.89–0.90. External consistency of UCLA SCTC GIT 2.0 was measured by comparing with the SF-36, correlation was meaningful in medium level (Table 1,2).

Table 1. Descriptive statistics and internal consistency statistics

| UCLA SCTC GIT 2.0 scale | n | Mean score (SD) | Minimum score | Maximum score | Cronbach alpha | Floor effect % | Ceiling effect % |
|---|---|---|---|---|---|---|---|
| Reflux | 97 | 0.64 (0.54) | 0.0 | 2.6 | 0.83 | 17.5 | 0.0 |
| Distension | 97 | 1.02 (0.75) | 0.0 | 3.0 | 0.58 | 7.2 | 1.0 |
| Soilage | 97 | 0.30 (0.72) | 0.0 | 3.0 | 0.68 | 82.5 | 3.1 |
| Diarrhea | 97 | 0.28 (0.47) | 0.0 | 1.5 | 0.36 | 69.1 | 0.0 |
| Social Functioning | 97 | 0.17 (0.32) | 0.0 | 1.3 | 0.47 | 67.0 | 0.0 |
| Emotional Wellbeing | 97 | 0.30 (0.43) | 0.0 | 2.2 | 0.73 | 41.2 | 0.0 |
| Constipation | 97 | 0.63 (0.69) | 0.0 | 2.5 | 0.56 | 34.0 | 0.0 |
| Total GIT score | 97 | 0.45 (0.37) | 0.0 | 1.6 | 0.82 | 3.1 | 0.0 |

All scales are scored from 0.00 (better HRQOL) to 3.00 (worse HRQOL) except the diarrhea and constipation (range from 0.00–2.00 and 0.00–2.50, respectively). The UCLA GIT 2.0 provides a total score of GIT severity and calculated by summation of all scales (except constipation) and ranges from 0.00 to 2.83.

Table 2. External Consistency Statistics: Correlation Between SF-36 Items and Component Summaries and UCLA SCTC GIT 2.0 Items

| UCLA SCTC GIT 2.0 / SF-36 | PF | RP | RE | VT | MH | SF | BP | GH | PCS | MCS |
|---|---|---|---|---|---|---|---|---|---|---|
| Reflux | -,300** | -,436** | -,296** | -,421** | -,376** | -,285* | -,417** | -,312** | -,386** | -,318** |
| Distension | -,461** | -,422** | ,238* | -,465** | -,474** | -,340** | -,427** | -,408** | -,437** | -,354** |
| Soilage | -,237* | -,160 | ,001 | -,170 | -,165 | -,131 | -,328** | -,114 | -,254* | -,027 |
| Diarrhea | -,265** | -,258* | -,180 | -,214* | -,215* | -,146 | -,325** | -,083 | -,296** | -,176 |

| Constipation | -,163 | -,101 | -,199 | -,047 | -,063 | -,166 | -,299** | -,065 | -,167 | -,132 |
| Total GIT score | -,482** | -,453** | -,321** | -,492** | -,493** | -,369** | -,560** | -,395** | -,482** | -,349** |

p<0.05 * and p<0.01 ** PF: physical functioning, RP: role limitations due to physical health, RE: role limitations due to emotional problems, VT: vitality, MH: mental health, SF: social functioning, BP: bodily pain, GH: general health, PCS: physical component summary, MCS: mental component summary.

**Conclusions:** UCLA SCTC GIT 2.0 scale had strong internal consistency, good reliability and acceptable validity when adapted into Turkish. Turkish-speaking patients with scleroderma, this scale will be useful to assess GIT symptoms. The basic constraint of our study was, not using image procedures for objective GIT involvement evidences.

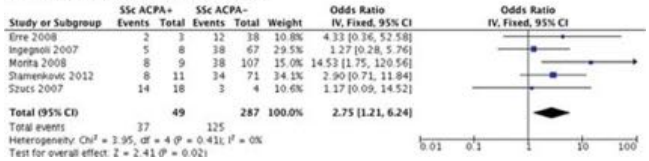
## AB0598 DOES THE PRESENCE OF ANTI-CITRULLINATED PROTEIN ANTIBODIES CHANGE THE PRESENTATION OF SYSTEMIC SCLEROSIS?

G. Laustriat[1], Y. Degboe[2], A. Ruyssen-Witrand[2], A. Constantin[2], T. Barnetche[3], D. Adoue[2], A. Cantagrel[2]. *[1]Rheumatology Resident, Toulouse Hospital; [2]Rheumatology, Toulouse Hospital, Toulouse; [3]Rheumatology, Bordeaux Hospital, Bordeaux, France*



**Background:** Systemic sclerosis (SSc) is one of the most complex and heterogeneous systemic disease. The diagnosis can be helped by the positivity of different characteristic auto-antibodies steered toward topoisomerase I, centromeric protein, RNA polymerase and fibrillarin. Different presentations of the disease can be associated with some specificities of auto-antibodies. Recently, some studies have reported the presence of anti-citrullinated protein antibodies (ACPA) in patients with SSc.

**Objectives:** We have conducted a systematic literature review in order to define the prevalence of ACPA in SSc, and to observe their influence on clinical and paraclinical presentation of the disease.

**Methods:** Literature search was performed in PubMed Medline database on 15 february 2015. Publication were identified through a search that used the terms: ("systemic sclerosis"(MeSH) and "ACPA or anti-CCP or rheumatoid factor or cohort or value diagnostic"). In a first step, we have selected all cohorts over 50 patients with SSc and ACPA identification. In a second step we have included all studies in which the clinical profile of scleroderma was detailed according to their ACPA status. Meta-analyses were performed when there were two or more studies with similar clinical description.

**Results:** For the first question, we identified 13 observational studies merging 1231 patients with SSc. ACPAs were positive for 113 patients, giving a prevalence of ACPA in SSc of 9.2%. In a second step, we identified 9 studies reporting clinical and paraclinical aspects according to their ACPA status. Information was enough to perform a meta-analysis for arthralgia, arthritis, joint erosions, skin sclerosis, pulmonary arterial hypertension, pulmonary fibrosis and gastrooesophageal reflux. We found a significant association between ACPA positivity and the presence of arthritis (OR: 25.48 [11.82–54.47]), joint erosions on X-rays (OR: 13.06 [4.68–36.43]), pulmonary arterial hypertension (OR: 7.72 [2.38 – 25.5]), and pulmonary fibrosis (OR: 2.75 [1,21–6.24]) (Fig 1).

Figure 1 – Meta-analysis assessing the impact of presence of ACPA on pulmonary fibrosis in patients with SSc.

**Conclusions:** ACPA prevalence in scleroderma is 9.2%. Our systematic literature review shows a significant increased risk for erosive arthritis, pulmonary hypertension and pulmonary fibrosis in ACPA positive SSc. ACPA should be systematically included in the check-up of systemic sclerosis.

## AB0599 INTERLEUKIN-35 IN IDIOPATHIC INFLAMMATORY MYOPATHIES

H. Mann[1], O. Krystufkova[1], H. Hulejova[1], J. Zamecnik[2], J. Hacek[2], M. Filkova[1], J. Vencovsky[1], L. Senolt[1]. *[1]Experimental rheumatology, Institute of rheumatology; [2]Pathology and molecular medicine, 2nd Medical faculty, Charles University, Prague, Czech Republic*

**Background:** Interleukin-35 (IL-35) is a newly described heterodimeric cytokine that belongs to the IL-12 family and consists of p35 (IL-12a) and EBI3 (IL-27b) subunits. IL-35 exerts immunomodulatory activities in several autoimmune inflammatory diseases.

**Objectives:** The aim of this study was to assess IL-35 expression in muscle tissue of patients with idiopathic inflammatory myopathies (IIM) and to compare serum levels of IL-35 in patients with IIM to healthy controls and asses potential association with activity of IIM.

**Methods:** The expression of IL-35 was studied in a series of 19 muscle biopsy samples of idiopathic inflammatory myopathies (9 dermatomyositis, 10 polymyositis) and 10 non-inflammatory control muscle biopsies from patients with myasthenia gravis.Serum levels of IL-35 were measured in 23 PM, 28 DM and 15 cancer associated myositis patients as well as in 40 healthy controls.Disease activity was evaluated by the Myositis Disease Activity Assessment Tool (MYOACT) and by serum muscle enzymes.

**Results:** Both IL-35 subunits were found in immune cells of the inflammatory infiltrates in IIM muscle biopsies, no immunoreactivity was observed in muscle tissue of control patients.IL-35 serum levels were increased in all IIM patients compared to healthy controls ($p<0.001$). There were no differences in IL-35 serum levels between myositis subgroups. Serum IL-35 levels correlated with the overall MYOACT score, with extramuscular and muscle domains of MYOACT, with physician's global activity assessment and lactate dehydrogenase levels.

**Conclusions:** IL-35 subunits are overexpressed in inflammatory infiltrates in muscle tissue of IIM patients and elevated circulating IL-35 levels correlate with several disease activity parameters. These data suggest potential role of IL-35 in the pathogenesis of inflammatory myopathies.

## AB0600 HIGH PREVALENCE OF REDUCED BONE MINERAL DENSITY AND UNDERTREATMENT OF OSTEOPOROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

M.J. Spanjer, A.E. Voskuyl, W.F. Lems, I.E.M. Bultink. *Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Amsterdam, Netherlands*

**Background:** Systemic sclerosis is a systemic inflammatory rheumatic disease with a very low prevalence, that has been associated with an increased risk of

low bone mineral density (BMD)[1], but data on risk factors associated with bone loss in systemic sclerosis are scarce.
**Objectives:** The objective of this study was to investigate the prevalence of and risk factors for low BMD in patients with systemic sclerosis.
**Methods:** Demographic and clinical data of 61 patients with systemic sclerosis were collected. BMD measurements of the lumbar spine, total hip and femoral neck were performed using DXA. Osteoporosis was defined as a T score less than -2.5 SD and osteopenia as a T-score between -1.0 and -2.5 SD, according to WHO definitions. Systemic sclerosis disease severity was defined by the Rodnan skin score and by the Medsger disease severity score[2]. Multiple linear regression analyses was used to assess factors associated with BMD.
**Results:** Patients were on average 56.7±12.4 years old and 72% were female of whom 77% postmenopausal. BMD measurements revealed osteopenia or osteoporosis in at least one measurement site in 67% of the patients, of whom 30% had osteoporosis. Low body mass index and postmenopausal state were significantly associated with low BMD in all skeletal sites. No significant associations were found between age, Rodnan skin score, Medsger disease severity score, glucocorticoid treatment and BMD. Of the 30% of patients who had an indication for anti-osteoporosis treatment, 91% did not receive anti-osteoporosis medication.

Table 1. Multiple linear regression analysis of BMD in the total hip, femoral neck and lumbar spine

| | Covariates | β | *p*-value | $r^2$ |
|---|---|---|---|---|
| Total hip | Postmenopausal state | –0.326 | 0.003 | 43% |
| | BMI | 0.406 | <0.001 | |
| | Medsger score general | –0.150 | 0.251 | |
| | Proteinuria | –0.229 | 0.085 | |
| Femoral neck | Postmenopausal state | –0.280 | 0.02 | 33% |
| | BMI | 0.351 | 0.004 | |

BMI = body mass index, DcSSc = diffuse cutaneous systemic sclerosis, ESR = erythrocyte sedimentation rate, β = standardized regression coefficient.

**Conclusions:** The results of this cross-sectional study demonstrate a high frequency of osteoporosis or osteopenia in 67% of our patients with systemic sclerosis and low body mass index and postmenopausal state were identified as the most important risk factors. No relationship between disease severity and BMD was found, which could be related to the sample size, although it can be argued that low BMI is, at least partly, a marker of disease severity. This study also shows a high frequency (91%) of undertreatment of osteoporosis in this patient group. These results underline the importance of monitoring and treatment of low BMD in systemic sclerosis.

## AB0601 SIGNIFICANT CARDIOLOGICAL CHANGES IN SYSTEMIC SCLEROSIS: AN ELECTROCARDIOGRAPHIC AND ECHOCARDIOGRAPHIC EVALUATION

I. Sciarra, D. D'Aluisio, G. Onelli, M. Vasile, K. Stefanantoni, S. Morelli, G. Valesini, V. Riccieri. *Internal Medicine and Medical Specialties, Sapienza, University of Rome, Rome, Italy*

**Background:** Cardiac involvement in Systemic Sclerosis (SSc) is rather common and it can be considered a bad prognostic feature.
**Objectives:** In this study we aimed to evaluate this involvement performing electrocardiogram (ECG) and echocardiogram in a group of SSc patients, comparing their data with those of healthy volunteers (NC).
**Methods:** Seventy-one consecutive SSc patients (Group A) were compared to 60 NC (Group B), matched for age and sex. Both patients and NC were evaluated by anamnesis, physical examination, ECG and trans-thoracic echocardiogram, with Doppler and tissue-wave Doppler.
**Results:** Ten SSc patients and 3 NC were excluded (Group A: 4 patients for increased basal heart rate, 2 for TAPSE <17 mm, 3 for valvular disease and 1 patient for severe pulmonary hypertension. Group B: 3 subjects for high basal heart rate). Among SSc patients 22 (36.1%) had a diffuse cutaneous form (dcSSc), and 39 (73.9%) had a limited cutaneous form (lcSSc). In table 1 clinical-demographic and laboratory features of patients are described. QT dispersion (QTd) and QTc dispersion (QTcd) were significantly higher in Group A respect to Group B (QTd 49.83 vs 27.85 msec, p<0.0001; QTcd: 51.39 vs 29.73 msec, p<0.0001). Patients with dcSSc showed longer QTc values than controls (440.58±18.23 vs 427.64±23.12 msec, p=0.02). Left ventricular mass index (LVMI) mean values were significantly increased while left ventricular ejection fraction (LVEF) mean values were significantly reduced in Group A compared with Group B respectively (LVMI: 80.5 vs 61.54 g/$m^2$, p<0.0001; LVEF: 63.55 vs 68.42%, p=0.0001). No patient with LVEF<55% was found. In addition left atrial volume index for body surface (LAVI) mean values were higher in Group A (27.67 vs 18.78 ml/$m^2$, p<0.0001). The percentage of patients with left ventricular diastolic dysfunction (LVDD) was higher in Group A (70.5 vs 21.8%, p=0.0001). In Group A QTc prolungation, increased levels of QTcd and P wave duration were associated with LVDD. An increase of P-wave duration was also associated with higher values of LAVI (p=0.04).

Table 1. Main clinical-demographic and laboratory features of 61 SSc patients

| Features | |
|---|---|
| Age (years)(median, 25°p–75°p) | 66.5 (55–74.5) |
| Sex (F/M) | 57/4 |
| Disease duration (years)(median, 25°p–75°p) | 5.5 (4–12) |
| lcSSc/dcSSc | 39/22 |
| Modified Rodnan Skin score (median, 25°p–75°p) | 8.5 (4.75–14.25) |
| Active digital ulcers (n/%) | 8/13 |
| Interstitial lung disease (n/%) | 26/42.6 |
| Anti-nuclear antibodies positivity (n/%) | 58/95 |
| Anti-centromere antibodies positivity (n/%) | 23/37.7 |
| Anti-topoisomerase I antibodies positivity (n/%) | 22/36 |

**Conclusions:** Significant cardiological differences can be found in SSc, even in asymptomatic patients, respect to NC, thus confirming how ECG and echocardiogram are relevant instruments able to detect morpho-functional abnormalities suggestive of an early myocardial involvement in this disease.

## AB0602 INCREASED STIFFNESS OF MEDIAN NERVE IN SYSTEMIC SCLEROSIS

I. Yagci[1], O. Kenis Coskun[2], T. Ozsoy[1], G. Ozen[3], H. Direskeneli[3]. *[1]Department of Physical Medicine and Rehabilitation, Marmara University School of Medicine; [2]Department of Physical Medicine and Rehabilitation, Kartal Training and Research Hospital; [3]Department of Rheumatology, Marmara University School of Medicine, Istanbul, Turkey*

**Background:** The frequency of peripheral nerve involvement has been debated in systemic sclerosis (SS). Despite the patients have clinical symptoms such as numbness and paresthesia the electrodiagnostically proven neuropathy incidence is low.
**Objectives:** The aims of this study are to document peripheral neuropathies in a cohort of SS and compare the sonoelastrographic measurements of median nerves in systemic sclerosis, idiopathic carpal tunnel syndrome and healthy controls.
**Methods:** The clinical, electrophsiological and ultrasonographic assessments were done by three masked researchers. Patients with SS and CTS were assessed with nerve conduction studies. The sonoelastography and sonographic assessments of the median nerve were perfomed with 6–18 Mhz lineer transducer. The measurements of cross sectional areas (CSA)were performed at psiform and forearm level from axial US images. The sonoelastrography was performed with same transducer and same sonographer. The median nerve was visualized in axial view and kept in center of the screen. Seven-10 slight compressions were made periodically by the sonographer until the device determined that the proper elastographic view was obtained. The elastic ratio is the ratio of strain distribution in two selected region of interests (ROI). A round ROI was positioned in the center median nerve, while a same size of ROI was positioned in a homogeneously soft anatomical structure, which was considered as internal control. Second ROI was positioned on the flexor carpi radialis for the wrist level and flexor digitorum superficialis for the forearm level. The ROIs were fixed to 2 mm. By using this method, a higher elastic ratio reflects a lower elasticity of median nerve.
**Results:** The study was completed with 47 hands of 24 patients with SS, 53 hands of patients with CTS and 38 hands of health controls. According to electrodiagnostic testing 17 patients were normal, 4 patients were diagnosed as CTS and 3 patients were diagnosed as polyneuropathy in patients with SS. The CSA of CTS group was significantly higher than systemic sclerosis and control groups. The elastic ratio at psiform level and forearm levels of systemic sclerosis

| Group | Mean | SD | ANOVA | Tukey |
|---|---|---|---|---|
| Median nerve cross sectional area at psiform level | | | | |
| Control | 9.13 | 2.18 | F: 11.15 p=0.001 | Control/systemic sclerosis p=0.325 |
| Systemic sclerosis | 10.27 | 3.36 | | Control/CTS p=0.001 |
| CTS | 12.64 | 4.61 | | CTS/systemic sclerosis p=0.004 |
| Elastic ratio at psiform level | | | | |
| Control | 1.63 | 1.15 | F: 7.09 p=0.001 | Control/systemic sclerosis p=0.001 |
| Systemic sclerosis | 3.02 | 2.56 | | Control/CTS p=0.27 |
| CTS | 2.19 | 0.93 | | CTS /systemic sclerosis p=0.04 |
| Elastic ratio at forearm level | | | | |
| Control | 9.16 | 1.71 | F: 9.93 p=0.001 | Control/systemic sclerosis p=0.001 |
| Systemic sclerosis | 8.3 | .94421 | | Control/CTS p=0.24 |
| CTS | | | | CTS /systemic sclerosis p=0.001 |

SD, standard deviation.

group were significantly higher than the CTS and control groups. There was no statistical difference between CTS and control groups.
**Conclusions:** The frequency of peripheral neuropathy is increased in SS. The median nerves loose the elasticity in both wrist and forearm level where the CSA's are in the normal range. These results suggested that the increased peripheral nerve involvement in SS is about the increased stiffness of the nerves.
**Disclosure of Interest:** None declared

## AB0603 MAJOR COMORBIDITIES OF IDIOPATHIC INFLAMMATORY MYOSITIS AFFECTING SURVIVAL AND FUNCTIONAL IMPAIRMENT: A POPULATION-BASED STUDY USING 11 YEARS OF FOLLOW UP FROM THE NATIONAL HEALTH INSURANCE IN KOREA

J.S. Lee[1], M.J. Kim[1], H.Y. Lee[2], S.Y. Ahn[3], Y.W. Song[1], E.B. Lee[1], E.Y. Lee[1], Y.J. Lee[4], E.H. Kang[4]. *[1]Internal Medicine, Division of Rheumatology, Seoul National University Hospital, Seoul; [2]Center for Preventive Medicine and Public health, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do; [3]Medical Research Collaborating Center; [4]Internal Medicine, Division of Rheumatology, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

**Background:** Patients with idiopathic inflammatory myositis (IIM) suffer from comorbidities such as interstitial lung disease (ILD), cancer, and infections related to immunosuppressive agents.
**Objectives:** To evaluate 1) incidence rate ratio (IRRs) of major comorbidities in IIM compared to non-IIM Koreans, and 2) impact of the comorbidities on survival and functional impairment.
**Methods:** A retrospective cohort study was performed using the 2002–2013 National Health Insurance Service (NHIS) database of weighted probability sampled one million cohort. IIM was identified by at least two visits to the tertiary hospitals under ICD9 code of IIM. Age- and sex-matched twenty subjects per patient, who never had ICD9 code at least for 1 year, were included as the unexposed. The occurrence of ILD, cancer, herpes zoster, and tuberculosis, severely disabled status, and death was captured using ICD9 code, disease-specific medication, and/or government-approved qualification for co-payment reduction on these outcomes.
**Results:** Ninety-one patients were newly diagnosed as IIM from 2003 to 2013. Most patients (>90%) defined as such were found to have muscle biopsy, electromyogram, or multiple laboratory examinations on muscle enzymes. Their incidence rate of the above outcomes was significantly elevated (Table); IRRs of ILD 31.8 [95% confidence interval: 13.2 – 76.7], cancer 2.36 [1.61–3.48], herpes zoster 1.75 [1.20–2.54], tuberculosis 2.08 [1.15–3.77], severely disabled status 4.79 [2.55–9.01], and mortality 3.47 [1.96–6.12]. Among IIM patients, the presence of ILD or cancer greatly deteriorated survival; mortality IRR of 73.2 [9.58–559.9] in ILD and 63.2 [17.6–226.7] in cancer. The occurrence of zoster and tuberculosis did not influence on the mortality. ILD and cancer also worsened functional impairment of IIM patients; IRR of 12.0 [2.64–54.9] for severely disabled status in ILD and 13.2 [4.19–41.6] in cancer.

Table 1. Incidence rate and incidence rate ratios of major comorbidities, severely disabled, and death in patients with idiopathic inflammatory myositis versus the matched control

| | Incidence rate (# of cases/1,000 person-year) | | Incidence rate ratio [95% Confidence interval] |
|---|---|---|---|
| | Myositis (n=91) | Control (n=1820) | |
| Interstitial lung disease | 33.0 (13/394.3) | 1.04 (8/7714.3) | 31.8 [13.2–76.7] |
| Cancer | 73.6 (29/394.3) | 31.1 (240/7714.3) | 2.36 [1.61–3.48] |
| Herpes zoster | 76.1 (30/394.3) | 43.6 (336/7714.3) | 1.75 [1.20–2.54] |
| Tuberculosis | 30.4 (12/394.3) | 14.6 (113/7714.3) | 2.08 [1.15–3.77] |
| Severely disabled | 30.4 (12/394.3) | 6.35 (49/7714.3) | 4.79 [2.55–9.01] |
| Death | 35.5 (14/394.3) | 10.2 (79/7714.3) | 3.47 [1.96–6.12] |

**Conclusions:** This is the first report of the nation-wide population based evaluation of IIM in Korea. The incidence of ILD, cancers, zoster, and tuberculosis was exceptionally higher in IIM than non-IIM. ILD and cancers significantly affected prognosis of IIM. More detailed analysis of comorbidities and their risk factors using the whole national database is underway.

## AB0605 RIDAI.ORG/SSC: THE PORTUGUESE NATIONAL SYSTEMIC SCLEROSIS REGISTRY – FOCUS ON QUALITY OF LIFE AND DATA CONFORMITY

J. Matos-Costa[1], I. Almeida[2,3], L. Santos[4,5], J. Delgado Alves[6,7,8], S. Pinheiro[9], M. Santos[10], C. Dias[11], E. Serradeiro[12], G. Alves[13], J. Vedes[14], H. Brito[15], P. Ferreira[16], N. Oliveira[17], J. Garcia[18], E. Pinelo[19], A. Ferreira[20], A. Marinho[2,3] on behalf of NEDAI – Study Group of Autoimmune Diseases of SPMI – Portuguese Society of Internal Medicine. *[1]Autoimmunity Clinic - Internal Medicine III, Hospital Distrital de Santarém, Santarém; [2]Clinical Immunology Unit - Internal Medicine Department, Hospital de Santo António; [3]Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto; [4]Faculdade de Medicina, Universidade de Coimbra; [5]Department of Internal Medicine, Centro Hospital e Universitário de Coimbra - Polo HUC, Coimbra; [6]Medicine IV, Hospital Fernando Fonsea, Amadora; [7]CEDOC - Chronic Diseases Research Center; [8]NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa; [9]Medicine II, Centro Hospitalar de Lisboa Central - Hospital dos Capuchos, Lisboa; [10]Internal Medicine, Centro Hospitalar de Entre Douro e Vouga, Feira; [11]Internal Medicine, Centro Hospitalar do Funchal - Hospital dos Marmeleiros, Funchal - Madeira; [12]Internal Medicine, Centro Hospitalar de Trás os Montes e Alto Douro, Vila Real; [13]Internal Medicine, Centro Hospitalar do Alto Ave, Guimarães; [14]Internal Medicine, ULS da Guarda - Hospital Sousa Martins, Guarda; [15]Internal Medicine, Centro Hospitalar do Algarve, Faro; [16]Internal Medicine, Centro Hospitalar de Gaia/Espinho, Vila Nova de Gaia; [17]Internal Medicine, Centro Hospitalar do Tâmega e Sousa - Hospital Padre Américo - Vale do Sousa, Penafiel; [18]Internal Medicine, Hospital de Braga, Braga; [19]Internal Medicine, ULS do Nordeste, Bragança; [20]Internal Medicine, ULS de Matosinhos - Hospital Pedro Hispano, Matosinhos, Portugal*

**Background:** Registries have a major role in patient follow-up, prospectively collecting real life data, they help us to better understand rare diseases like scleroderma. These atabases allow standardization of daily clinical practice, introducing decision support tools and improving quality and health outcomes. They also allow drug and device surveillance; scientific societies, academia and regulatory authorities can analyze their selected core set of data.
**Methods:** Our web-based registry - RIDAI (Informatic Registry of Autoimmune Diseases; www.ridai.org), was created in 2003 by the Portuguese Society Internal Medicine to support all Autoimmunity Clinics in Portugal; currently collecting data from 40 centres, with 4825 patients with different diseases. It has been constantly developped to comprise all the updated tools to measure important domains in autoimmune diseases. Demographic and clinical data were collected and analysed in Microsoft Excel 2013.
**Results:** Short presentation and demonstration of RIDAI, online since 2013. The scleroderma cohort has 326 patients, 227 limited and 99 diffuse subtypes, 43 (13.2%) males, mean age 56.4 (range 3–90), longest follow-up since 1993.
Comorbidities are highly prevalent in our cohort: dyslipidemia in 46 patients, hypertension in 40, peripheral vascular disease in 22, osteoporosis in 20, heart failure in 13, diabetes in 10 and coronary heart disease in 3 patients.
Most frequently used tools include Modified Rodnan Skin Score (mRSS), Visual Analogic Scale (VAS), Joint Count, EUSTAR Systemic Sclerosis Activity Scale (EUSTAR SSAS), the UCLA Scleroderma Clinical Trials Consortium Gastrointestinal Scale (SCTC GIT), Health Assessment Questionaire (HAQ) and Short Form-36 (SF-36). MRSS has a mean value of 9.1. Patient VAS has a mean 39.6; physician VAS mean 38.6. Painful Joint Count has a mean value of 3.0; tender Joint Count mean 1.6. The EUSTAR SSAS has a mean value of 1.27. SCTC GIT mean value is 0.52. HAQ mean value is 1.0; SF-36 mean is 103.9.
Biological disease modifying drugs were prescribed off-label in 10 patients, for severe skin and joint disease.
**Conclusions:** The RIDAI is the largest portuguese scleroderma registry. It's a versatile application and can be articulated with other platforms, with direct contribution to international multicentric studies. The presentation of the first 326 patients illustrates the complexity and heterogeneity of systemic sclerosis and of this cohort of patients. Treating to target and using standardized monitoring tools, Portuguese Internal Medicine physicians confirm good treatment performance, with a positive impact on indexes, specially mean mRSS and quality of life (HAQ, SF-36); enabling comparision with best practices.

## AB0606 FACTORS RELATED WITH THE DEVELOPMENT OF ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

J.J. Alegre Sancho[1], M. Robustillo Villarino[1], C. Vergara Dangond[1], G. Albert Espi[1], D. Ybáñez García[1], E. Valls Pascual[1], À. Martínez-Ferrer[1], E. Vicens Bernabeu[1], M. Aguilar Zamora[1], J.A. Román Ivorra[2]. *[1]Rheumatology, Hospital Universitario Dr. Peset; [2]Rheumatology, Hospital Universitari i Politècnic la Fe, Valencia, Spain*

**Background:** Different studies and meta-analysis have shown that subclinical atherosclerosis (AS) and vascular complications (VC) are higher in patients with Systemic Sclerosis (SSc) than in healthy population, a fact that has been fundamentally related to non traditional vascular risk factors (VRF).
**Objectives:** To identify VRF which shows to be independently related to the

existence of macrovascular affection (carotid ultrasound, ankle-braquial index [ABI]) in patients with SSc.
**Methods:** Transverse descriptive study with analytical components. Study population: cohort of 115 patients with SSc controlled in the Rheumatology Department of a tertiary hospital. Variables: 1) *Clinical variables*; 2) *Questionnaires and indices:* global VAS, HAQ, SF-36, CHFS (Cochin Hand Function Scale),MHISS (Mouth Handicap In Systemic Sclerosis scale), HOMA and SCORE; 3) *Analytical variables:* hemogram, classic vascular risk biomarkers, activity/inflammation biological markers, autoantibody profile, hemostasis/vascular disease markers; 4) *Vascular study:* ABI and carotid doppler ultrasound (ESAOTE MyLab XV70, 7–12 MHz linear transducer, software $^{RF}$QIMT) measuring intima-media thickness (IMT) and the presence of atheroma plaques (Mannheim Consensus); 5) *Other variables:* acro-osteolysis, ECG, functional pulmonary tests, lung HRCT and doppler echocardiography. A vascular surgeon measured ABI and the carotid doppler ultrasound was done by a vastly experienced rheumatologist, blind to the rest of findings, in a term of 3 months after the initial evaluation. Statistical analysis: IBM-SPSS Statistics v22.0 package.
**Results:** 115 patients where included, of which 108 were studied; with a mean age of 60,16 years (SD ±15,16); 99 women (91.7%) and 9 men (8.3%.) Mean SSc evolution time was 11.45 years (SD ±8,84). LSSc was most frequently diagnosed (50%), followed by SSc without scleroderma (18.5%), DSSc (16.7%), overlap syndrome (9.3%) and pre-SSc (5.6%). 38.9% of patients were hypertensive, 46.3% suffered a DL, and 6.3% were diabetic. 37% had a pathological carotid ultrasound and 39.8% had macrovascular damage (atheroma plaque and/or IMT$>$0.9 mm and/or ITB$<$0.9). The bivariate analysis showed a relation between macrovascular disease and several traditional and non traditional (related to the disease) VRF. In the multivariate analysis, age, HTA, DL, systolic pressure, glycaemia, renal function,VC history, SCORE values, SF36, duration of the SSc, coexistence of an inflammatory disease, diastolic dysfunction of the LV, ESR, D-dimer values, estimated PsAP values, and the use of different drugs (statins, ACEI, ARBs, endothelin receptor antagonists, rituximab) maintained a significant relationship with the different macrovascular disease variables.
**Conclusions:** Macrovascular disease in patients with SSc associates with traditional VRF (age, HTA and DL) as well as VRF related to SSc (prolonged duration, greater inflammatory load, elevated PsAP values, diastolic dysfunction of LV). A strict control of blood pressure values and the use of statins should be part of the regular protocol for treating selected, elderly patients.

## AB0607 DETERMINANTS OF UNEMPLOYMENT AMONGST AUSTRALIAN SYSTEMIC SCLEROSIS PATIENTS

K. Morrisroe[1], M. Huq[2], W. Stevens[3], C. Rabusa[2], S. Proudman[4], M. Nikpour[3] on behalf of Australian Scleroderma Interest Group (ASIG). *[1]Rheumatology and Medicine, St Vincent's Hospital, Melbourne; [2]Rheumatology, St VIncents Hospital; [3]Rheumatology, St Vincent's Hospital, Melbourne; [4]Rheumatology, Royal Adelaide Hospital, Adelaide, Australia*

**Background:** The ability to work is a fundamental component of everyday life.
**Objectives:** To assess employment status, risk factors for unemployment and the associations of unemployment with patients' health related quality of life (HRQoL).
**Methods:** All patients completed in a systemic sclerosis (SSc) longitudinal cohort study, completed an employment questionnaire on enrolment. Clinical manifestations were defined based on presence at the time of enrolment. Summary statistics, chi-square tests, univariate and multivariable logistic regression were used to determine the associations of various risk factors with employment.
**Results:** Among 1587 SSc patients, 160 (20%) were unemployed at the time of cohort enrolment excluding retired patients. Of these, 63% had limited disease subtype. Mean (±SD) age at enrollment was 51.9 (±10.4) years; 13 years below the average retirement age in Australia. Mean (±SD) disease duration at recruitment was 11.1 (±10.9) years. Multivariable regression analysis revealed the presence of digital amputation (OR 3.9, 95%CI 1.7–9.1, p=0.002), diffuse disease subtype (OR 2.2, 95%CI 1.3–3.5, p-value=0.002), sicca symptoms (OR 2.7, 95%CI 1.6–4.4, p$<$0.001), a physical job (OR 1.8, 95%CI 1.1–3.1, p=0.03) and pulmonary arterial hypertension (OR 2.2, 95%CI 1.1–4.5, p=0.02) to be associated with unemployment. Unemployed patients had consistently poorer HRQoL scores in all domains (physical, emotional and mental health) of the SF-36 form than those who were employed.

Table 1. Risk factors associated with unemployment in multivariable analysis

| Characteristic | OR (95% CI) | p value |
|---|---|---|
| Physical job | 1.8 (1.1–3.1) | 0.03 |
| Diffuse disease subtype | 2.2 (1.3–3.5) | 0.002 |
| PAH | 2.2 (1.1–4.5) | 0.02 |
| Sicca | 2.7 (1.6–4.4) | $<$0.001 |
| Digital amputation | 3.9 (1.7–9.1) | 0.002 |

Abbreviation: OR = odds ratio; PAH = pulmonary arterial hypertension; 95% CI = 95% confidence interval.

**Conclusions:** SSc is associated with substantial work disability and unemployment, which is in turn associated with poor quality of life. Raising awareness, identifying modifiable risk factors and implementing employment strategies and work place modifications are possible ways of reducing this burden.

## AB0608 CHARACTERISTIC ADVERSE EVENTS AND DEVELOPMENT OF DIGITAL ULCERS IN BOSENTAN-TREATED JAPANESE PATIENTS WITH DIGITAL ULCERS SECONDARY TO SYSTEMIC SCLEROSIS

K. Takehara. *Dermatology, Kanazawa University, Kanazawa, Japan*

**Background:** Only a few medications have been approved for the prevention and treatment of digital ulcers in Japan. Ethnicity has been reported to affect the severity and occurrence rate of digital ulcers, which are potentially caused by more common autoantibody prevalence in the systemic sclerosis (SSc) patients of some ethnic groups; however, information on Japanese and Asian patients is limited. In the present study, the adverse events and development of digital ulcers were investigated when bosentan was administered to Japanese SSc patients. We focused on liver function test abnormalities, which are one of the characteristic adverse events of bosentan, baseline patient characteristics, and the onset/resolution time of the associated adverse events. The occurrence and healing of digital ulcers over time in each patient were also examined.
**Methods:** Twenty-eight (28) patients were enrolled in 9 study sites in Japan. This was a multi-center, single arm, open-labeled study conducted in order to investigate the safety and efficacy of bosentan in Japanese patients who had or had a previous history of SSc-related digital ulcers. The safety of the drug was monitored and the clinical course of digital ulcers was assessed up to Week 52 of the treatment.
**Results:** The adverse events observed in $\geq$5% of patients, i.e., at least two patients during the 52-week treatment period, were upper respiratory tract infections (14/28, 50.0%), liver function test abnormalities (12/28, 42.9%), the development of new digital ulcers (7/28, 25.0%), anemia (5/28, 17.9%), peripheral edema (4/28, 14.3%), diarrhea (3/28, 10.7%), urinary tract infections (2/28, 7.1%), arthralgia (2/28, 7.1%), constipation (2/28, 7.1%), and herpes zoster (2/28, 7.1%). Of the 12 patients (42.9%) with liver function test abnormalities, 4 (14.3%) showed AST and/or ALT elevations $>3\times$ the upper limit of normal, occurring before Week 16 for two patients and after Week 16 for the other two. All elevated liver enzymes normalized upon withdrawal of the drug. During the 52-week observation period, 25% (7/28) of patients developed new digital ulcers, the mean (± SD) number of which was 0.6±1.3.
**Conclusions:** The adverse events observed in the present study were similar to those previously reported with the use of bosentan, demonstrating the safety of the drug for Japanese patients; however, 4 out of 28 patients had adverse events associated with liver function disorders, which are one of the characteristic adverse effects of bosentan. These results indicate that liver function needs to be monitored regularly in patients treated with bosentan.

## AB0609 RADIOGRAPHIC FINDINGS IN HAND X-RAY IN PATIENTS WITH SYSTEMIC SCLEROSIS

K. Sakata, Y. Kaneko, H. Yasuoka, K. Yamaoka, T. Takeuchi. *Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Musculoskeletal involvement is major complication for patients with systemic sclerosis (SSc). Many radiographic abnormalities are observed, especially in hands, however, the detailed prevalence and the association with clinical features is still unclear.
**Objectives:** To clarify the characteristics of radiographic findings in hand X-ray and their association with clinical features in SSc.
**Methods:** Japanese SSc patients without rheumatoid arthritis who visit our hospital from 2011 to 2015 were included. Two directional hand X-ray was taken to evaluate joint and soft-tissue changes. Clinical and serological parameters were collected retrospectively from their medical records. The prevalence of abnormal findings in X-ray was examined, and the associations with clinical features, SSc subtypes and autoantibodies were analyzed.
**Results:** Sixty four patients including 16 diffuse cutaneous (dc) SSc and 49 limited cutaneous (lc) SSc were enrolled. The mean age was 66.7 years (range 31–88years), 87.5% were female and the mean disease duration was 13.9 years (range 1–37 years). Thirty four patients (53.1%) were positive for anticentromere antibody, 21 (32.8%) for anti-Scl-70 antibody, and 3 (4.7%) for anti-RNA polymerase III antibody. Fifteen (24.6%) were positive for rheumatoid factor (RF), and 1 (1.6%) for anti-cyclic citullinated peptide (CCP) antibody. Finding of hand X-ray showed acroosteolysis in 18.4%, erosive hand osteoarthritis in 15.4%, flexion contracture in 13.8%, and calcinosis in 10.8%. Acroosteolysis was significantly associated with digital tip ulcer (p$<$0.01), digital pitting scar (p$<$0.01), interstitial

lung disease ($p<0.05$), gastrointestinal involvement ($p<0.05$), and longer disease duration ($p<0.01$). Flexion contracture also showed the association with digital tip ulcer, digital pitting scar, and gastrointestinal involvement ($p<0.01$, $p<0.01$, and $p<0.05$, respectively). While acroosteolysis and flexion contracture were more frequent in dcSSc than lcSSc (43.8% vs 10.4%, $p<0.01$ and 31.3% vs 8.3%, $p<0.05$, respectively), erosive osteoarthritis was observed only in lcSSc (dcSSc 0% vs lcSSc 20.4%, $p>0.05$). Calcinosis and erosive osteoarthritis were not related with any other clinical features including age, sex, and disease duration. Assessing the relation between X-ray findings and autoantibody, acroosterolysis were associated with positivity for anti Scl-70 ($P<0.05$,), and flexion contracture with anti-RNA polymerase III ($P<0.05$), but no association was found between X-ray findings and RF/anti-CCP antibody positivity.

**Conclusions:** Various abnormal findings in hand X-ray were observed in patients with SSc. Of these, acroosteolysis was most prevalent. Both acroosteolysis and flexion contracture were associated with peripheral circulatory disturbance and the distinct characteristics of dcSSc, whereas erosive osteoarthritis was observed only in lcSSc. These results suggest that the difference of X-ray findings reflects the underlying pathogenesis of each patient with SSc.

## AB0610 PLATELET FACTOR 4 AS A BIOMARKER IN KOREAN PATIENTS WITH SYSTEMIC SCLEROSIS

K.H. Jung, W. Park, S. Kwon, M.J. Lim. *Division of Rheumatology, Department of Internal Medicine, Inha University, Incheon, Korea, Republic Of*

**Background:** Systemic sclerosis (SSc) is a complex multi-organ autoimmune disease with chronic and heterogeneous clinical manifestations. There is an unmet need for a new biomarker for early diagnosis and classification of SSc. Recent technical advancements have indicated several biomarkers for SSc; among these, platelet factor 4 (PF4), also known as CXCL4, was suggested by a large-cohort proteomic study [1]. PF4 is a chemokine released from activated platelets and is involved in coagulation, inflammation, and angiogenesis, which are influential in SSc pathogenesis. Therefore, PF4 may be an effective biomarker for SSc.

**Objectives:** To investigate the efficacy of PF4 as a biomarker for the diagnosis, activity and severity of patients with SSc.

**Methods:** Thirty-nine SSc patients (36 female and 3 male; mean age, 58.8±10.42 years; mean disease duration, 7.15±3.92 years; 11 diffuse cutaneous SSc cases and 28 limited cutaneous SSc cases) and 30 healthy controls (HC; 25 female and 5 male; mean age, 46.43±14.43 years) were enrolled. To estimate the circulating PF4 level, levels of platelet poor plasma (PPP) PF4 as well as serum PF4 were measured using an ELISA kit (R&D, Minneapolis, USA). SSc patients were divided into 2 subgroups according to disease activity and based on the presence/absence of interstitial lung disease (ILD), pulmonary hypertension, digital ulcers, and autoantibodies (anti-centromere Ab and anti-Scl70 Ab). Differences between SSc and HC groups were compared by Student's *t*-test, and the subgroups were compared using the Mann-Whitney test. Predictive values of serum PF4 and PPP PF4 for SSc diagnosis were evaluated by the area under the receiver operating characteristic curve (AUROC).

**Results:** Serum PF4 levels of SSc were lower than those of HC (SSc, 5143.3±1777.5 ng/mL; HC, 5927.4±1348.5 ng/mL; $p$ =0.048) but no significant differences were observed PPP PF4 levels (SSc, 407.2±486.6 ng/mL; HC, 297.3±141.5 ng/mL; $p$ =0.187) between SSc patients and controls. Moreover, no significant differences were observed between active and inactive SSc subgroups and between subgroups with/without ILD, pulmonary hypertension, digital ulcers, and autoantibodies. The AUROC for serum PF4 and PPP PF4 levels was 0.628 (0.497–0.76, cuff of value 3998.5 ng/mL) and 0.491 (0.367–0.65, cuff of value 511.1 ng/mL), respectively.

**Conclusions:** In Korean patients with SSc, both serum PF4 and PPP PF4 levels are not efficient biomarkers for SSc diagnosis and do not appear to be associated with clinical activity and severity.

## AB0611 ULTRASOUND EVALUATION OF HAND ARTICULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS COMPARED TO PHYSICAL EXAMINATION

O. Kaloudi, C. Nannini, L. Niccoli, E. Cassaràì, F. Cantini. *Department of Rheumatology, Hospital of Prato, Prato, Italy*

**Background:** Musculoskeletal involvement, preferentially affecting hands and feet, represents a frequent feature and may lead to disability in patients with systemic sclerosis (SSc). The most common manifestations are arthralgia, stiffness, synovitis, and tenosynovitis. In a large multicentre study, synovitis, tendon friction rubs, and joint contractures were found in 16%, 11%, and 31% of 7286 SSc patients assessed by clinical examination [1]. However, several ultrasound (US) studies revealed a higher frequency of hand joint involvement [2].

**Objectives:** To investigate the frequency and severity of hand joint involvement in a cohort of SSc patients evaluated by US, and to compare the results of US synovitis detection with those of physical examination.

**Methods:** Over a 6-month period, all consecutive (new and old diagnosis) SSc patients (ACR/EULAR 2013 criteria) currently followed in our center underwent clinical and US hand examination. One rheumatologist expert in musculoskeletal US performed all examinations by using Esaote Technos MPX, MyLab 40, employing high frequency (12–18 MHz) transducers. Power Doppler (PD) parameters were adjusted (range of pulse repetition frequency 400–800 Hz; frequency 7–11.1 MHz). Patients were scheduled to be examined at the same hour of the day in the same room with an ambient temperature of 21°C. Hand and wrist joints were evaluated for synovitis, tenosynovitis, calcinosis, acro-osteolysis and distal vascularization. An independent rheumatologist made the clinical examination and US examiner was blind to clinical findings. US assessment of synovitis was scored according to the OMERACT–EULAR PD composite semiquantitative scale (0–3).

**Results:** 89 patients, 79F/10M, mean age 61.11±15.1, median disease duration 160 months (min: 2,max: 492), 83 (93%) with limited SSc and 6 (7%) with diffuse SSc were recruited. Synovitis was detected in 15 (16.8%) and in 35 (40.2%) of the cases by clinical examination and US, respectively ($p=0.019$). PD revealed grade 1 synovitis in 19/35 (54.3%) patients, grade 2 in 14 (40%) and grade 3 in 2 (5.7%). Tenosynovitis, calcinosis and acro-osteolysis were found at US 19 (21.3%), 14 (15.7%), acro-osteolysis in 11 (12.3%) and 8 (9%), respectively. Distal vascularization was detected in 60 patients (67%).

**Conclusions:** Confirming previous studies, our results show that hand synovitis in SSc may be underestimated by clinical examination only, while US examination provides an accurate assessment of the frequency and the degree of severity of synovial inflammation. However, synovitis in our cohort of SSc patients resulted mild in the majority of the cases.

## AB0612 MULTICENTER REGISTRY ON INFLAMMATORY MYOPATHIES IN MADRID (REMICAM): DESCRIPTIVE ANALYSIS

L. Nuño [1], M.J. García [2], F.J. López Longo [3], V. Maldonado [4], I. Llorente [5], C. Barbadillo [6], P. García de la Peña [7], L. Ruiz [8], H. Moruno [9], T. Cobo [10], R. Almodovar [11], L. Lojo [12], B. Joven [13] on behalf of REMICAM Study Group. *[1]H. La Paz; [2]Instituto de Salud Musculoesquelética; [3]H. Gregorio Marañón; [4]H. Ramón y Cajal; [5]H. La Princesa; [6]H. Puerta de Hierro; [7]H. Madrid Norte Sanchinarro; [8]H. Niño Jesús, Madrid; [9]H. Príncipe de Asturias, Alcalá de Henares; [10]H. Infanta Sofía, San Sebastián de los Reyes; [11]H. F. Alcorcón, Alcorcón; [12]H. Infanta Leonor; [13]H. Doce de Octubre, Madrid, Spain*

**Background:** Clinical manifestations, evolution and prognosis of idiopathic inflammatory myopathies (IIM) are very heterogeneous which, together with its low prevalence, limits the study of the disease.

**Objectives:** To analyze the clinical characteristics of patients diagnosed of IIM in a multicenter study.

**Methods:** A multicenter retrospective descriptive study from REMICAM[1] myositis study group was performed. All patients were diagnosed with IIM according to Bohan and Peter[2] criteria, were followed up sometime between January 1980 and December 2014 and were classified into 7 different clinical subgroups: primary dermatomyositis (DM), primary polymyositis (PM), juvenile dermatomyositis (JuvM), cancer associated myositis (CAM), overlap myositis (OM), inclusion body myositis (IBM) and necrotizing myositis (NM).

**Results:** 478 IIM cases were included. 74% of the cases was women, with an age at diagnosis of 43.7±22.6 years, and an average follow-up time of 9.7±8.3 years. The main IIM subgroups were primary myopathies (PM 28%, DM 22%, OM 19.9%, JuvM 19.2%, CAM 8.4%, NM 1.3%, BMI 1.3%). The connective tissue diseases more frequently associated in OM subgroup were MCTD (30%), systemic sclerosis (27%) and SLE (18,9%). The main extramuscular manifestations were cutaneous lesions (65%), arthritis (43%), general symptoms (39%) gastrointestinal complications (33%), and interstitial lung disease (ILD) (30%). Patients with OM had a higher prevalence of ILD (46.8% vs. 25.8%;$p<0.001$), Raynaud (67% vs. 19.4%;$p<0.001$), arthritis (70% vs. 35.8%;$p<0.001$) and cytopenias (55.9% vs. 21.5%; $p<0.001$), whereas JuvM patients developed more calcinosis (30.4% vs. 5.7%;$p<0.001$) but fewer serious infections (4.7% vs. 29.3%;$p<0.001$). During the period of study 114 patients died (24%), and the main causes of death were infections (24%), cancer (24%) and cardiovascular events (22%).

**Conclusions:** In this multicenter REMICAM registry 478 IIM cases have been included. The most common subtypes were primary myopathies, and the most frequent extramuscular manifestation were typical cutaneous lesions. Overlap myositis patients presented with more extramuscular manifestations than the other subgroups.

## AB0613 ANTI-C1Q AUTOANTIBODIES ARE FREQUENTLY DETECTED IN PATIENTS WITH SYSTEMIC SCLEROSIS AND LUNG FIBROSIS

C. Liaskos[1], S. Rentouli[2], T. Simopoulou[1], A. Mavropoulos[1], G.L. Norman[3], I. Alexiou[1], C.G. Katsiari[1], D.P. Bogdanos[1], L.I. Sakkas[1]. *[1]Rheumatology, Medical School, University of thessaly; [2]Faculty of Biotechnology and Biomedical Sciences, Larissa, Greece; [3]Inova Diagnostics, San Diego, United States*

**Background:** Anti-C1q autoantibodies are associated with systemic lupus erythematosus (SLE) but their presence in other rheumatic diseases has not been investigated in great detail.
**Objectives:** We aim to assess the clinical significance of anti-C1q autoantibodies in systemic sclerosis (SSc).
**Methods:** Seventy five patients with SSc (median age 59 years; females, 61; diffuse cutaneous SSc 35, limited cutaneous SSc, 40) were studied. Thirty eight patients with SLE, 25 patients with Sjögren's syndrome (SjS), 19 with rheumatoid arthritis (RA), and 31 healthy individuals (NC) were also included. IgG anti-C1q antibodies were tested by ELISA. Anti-nuclear antibodies (ANA), and SSc-specific autoantibodies were also tested.
**Results:** A receiver operator characteristic curve (ROC) confirmed that the cut off at 20 RU/mL for the anti-C1q test (specificity, 0.94, 95% CI, 0.79 to 0.99, LR: 5.0) was appropriate. Anti-C1q antibodies were present in 32.0% of SSc patients compared to 16.0% SS, 10.5% RA patients ($p<0.05$, for all) and in 6.5% NC ($p<0.01$). The frequent presence of anti-C1q antibodies in SLE was confirmed (13/38, 34.2%). Amongst the 24 anti-C1q (+) SSc patients, 15 had high/moderate levels (>40 RU/mL). There was no association between anti-C1q antibodies and anti-topoisomerase I, anti-centromere, or anti-RNA polymerase III antibodies. Anti-C1q antibodies were associated with male sex (p=0.04) and lung fibrosis (LF) (p=0.008), and co-occurrence of LF and skin ulcers (p=0.006). Ulcers were more prevalent in anti-C1q(+) than anti-C1q(–) patients (64% vs 44%), but the difference did not reach statistical significance (p=0.1).
**Conclusions:** Anti-C1q antibodies were frequently detected in SSc, were associated with PF and co-occurrence of PF and skin ulcers and may contribute to the autoimmune process in SSc.

## AB0614 A COMPHEHENSIVE ANALYSIS OF 12 DISEASE-SPECIFIC AUTOANTIBODIES IN GREEK PATIENTS WITH SYSTEMIC SCLEROSIS

C. Liaskos[1], E. Marou[1], T. Simopoulou[1], M. Barmakoudi[1], T. Scheper[2], W. Meyer[2], C.G. Katsiari[1], D. Bogdanos[1], L.I. Sakkas[1]. *[1]Rheumatology, Medical School, University of thessaly, Larissa, Greece; [2]Institute of Immunology, Euroimmun, Luebeck, Germany*

**Background:** Patients with systemic sclerosis (SSc) are characterized by ANAs against various autoantigens, none of which is 100% sensitive for the disease. The need for profiling testing based on a combination of the most important SSc-related autoantigens has led to the development of commercial SSc-profile assays.
**Objectives:** To determine the diagnostic and clinical relevance of systemic sclerosis (SSc)-related autoantibodies tested by a line SSc-profile assay in a well defined cohort of Caucasian SSc patients, all from Central Greece.
**Methods:** 98 consecutive patients with SSc (80 female, 18 male, mean age 57,9±14,9 y) including 60 patients with diffuse cutaneous SSc (dcSSc) and 38 with limited cutaneous SSc (lcSSc) were analyzed by a profile SSc line assay (Euroimmun) for autoantibodies against 12 autoantigens: Scl-70, Centromere (A, B), RNA polymerase III (subunits 11 & 155), fibrillarin, NOR90, Th/To, PM/Scl 100, PM/Scl75, Ku and PDGFR.
**Results:** ANA by indirect immunofluorescence was present in 98 (98%) patients with SSc. Overall, 81 (82.6%) patients had abs against at least one of the 12 autoantigens. Anti-Scl-70 abs were present in 49 (49.4%) SSc patients, anti-centromere A in 22 (22.5%), anti-centromere B in 22 (22.5%, all anti-centromere A positive) anti-RNA polymerase III RP155) in 18 (18.3%) anti-RNA polymerase III RP11 in 14 (14.3%), anti-fibrillarin in 3 (3.1%), anti-Ku in 5 (5.1%), anti-NOR90 in 7 (7.1%), anti-PM/Scl100 in 4 (4.1%), anti-PM/Scl75 in 7 (7.1%), anti-Th/To in 4 (4.1%) and anti-PGDFR in 1 (1%) SSc patients. Overall, the most frequent anti-Scl-70, anti-centromere or anti-RNA polymerase III abs were present in 81 (81%) SSc patients while 6 (6.1%) lacked those antibodies and were positive for at least one of the other 9. Anti-Scl-70 were associated with diffuse SSc and ACA with limited SSc ($p<0.001$ for both). Positivity of Scl-70 was also correlated with the presence of lung fibrosis (p=0.004) and tended to be associated with the presence of digital ulcers (p=0.073). Anti-centromere abs were less prevalent in SSc patients with lung fibrosis (p=0.004). Anti-PM/Scl75 abs tended to be associated with the presence of digital ulcers (p=0.055). Anti-NOR90 abs were more frequent in male SSc patients (p=0.019).
**Conclusions:** Anti-Scl70, anti-centromere and anti-RNA polymerase are by far the most dominant autoantibodies in SSc but other disease-related autoantibodies can also be present in SSc patients lacking those three autoantibodies. The presence of anti-Scl-70 abs identifies patients with lung fibrosis and along with anti-PM/Scl75 tend to be associated with the presence of digital ulcers.

## AB0615 IS INCREASED SERUM INTERLEUKIN-35 LEVELS A DISEASE ACTIVITY MARKER IN DERMATOMYOSITIS AND POLYMYOSITIS?

L. Yin[1], G. Wang[2], Y. Ge[2]. *[1]Peking University China-Japan Friendship School of Clinical Medicine; [2]Rheumatology, China-Japan Friendship Hospital, Beijing, China*

**Background:** Idiopathic inflammatory myopathies (IIMs) are a group of heterogeneous, systemic disorders [1].DM and PM are two main clinical subtypes of IIMs in Chinese population. The pathogenesis underlying myositis is complicated and yet not well clarified. In IIM, cytokines are secreted by immune cells, endothelial cells and muscle cells, and can exert pro-inflammatory or anti-inflammatory effects [2–3].Interleukin-35 (IL-35) is a heterodimeric cytokine composed of two subunits, p35 and EBI3 [4].To date, IL-35 has been studied in several kinds of autoimmune disease but its role remains controversial under the pathology conditions. Therefore, we measure IL-35 expression in circulation of IIM patients and to evaluate its association with myositis-related features.
**Objectives:** The purpose of this study was to assess the level of serum IL-35 in indiopathic inflammatory myopathies (IIMs) patients and to evaluate its association with IIM-related features.
**Methods:** Clinical data and serum samples were collected from76 DM, 28 PM and 43 healthy controls. Follow-up of 34 patients was also conducted. Serum IL-35 levels were detected by enzyme linked immunosorbent assay (ELISA). Disease activity of myositis patients was assessed according to the myositis disease activity assessment visual analogue scale (MYOACT).
**Results:** IL-35 serum levels were increased in myositis patients compared to healthy controls ($P<0.001$). No differences in IL-35 serum levels were found between DM and PM (P=0.468). Serum level of IL-35 with IIM was negatively correlated with disease duration (r =-0.231, P=0.019). Patients with dysphagia had higher IL-35 levels than those without (P=0.001). But, there was no statistically significant difference between IIM patients with interstitial lung disease (ILD) and without (P=0.997). Cross-sectional correlation analysis showed a positive correlation of serum IL-35 with CK (r=0.285, P=0.004), ESR (r=0.235, P=0.02), serum ferritin (SF) (r=0.471, P=0.001), LDH (r=0.401, $P<0.001$) and MYOACT scores (r=0.227, P=0.021). Serum IL-35 levels were significantly higher in ANA (P=0.026), anti-HMGCR (P=0.038) and anti-SRP (P=0.009) antibody positive patients than that in negative respectively. Follow-up study showed the change of IL-35 levels after treatment correlated with the change of MYOACT scores (r=0.375, P=0.029).
**Conclusions:** Serum IL-35 was elevated in both PM and DM patients and increased serum IL-35 was associated with dysphagia of myositis patients but not ILD. The serum levels of IL-35 also correlated with disease activity. These data suggest the increased serum IL-35 is a marker of disease activity and the risk for esophagus involvement in IIM. Finally, IL-35 may participate in the pathophysiological process of IIM.

## AB0616 ADAPTATION INTO SPANISH OF THE HAND MOBILITY IN SYSTEMIC SCLEROSIS TEST (HAMIS) IN A GROUP OF PATIENTS WITH SYSTEMIC SCLEROSIS

M.M. Mayer[1], G. Alsina[2], J.A. Maldonado Cocco[2], M. Rivero[1], M.E. Lara[1], P. Maldonado Alsina[1], A. Gallacher[3], M. Khoury[4], G. Earsman[3], J.C. Barreira[3]. *[1]Rheumatology, Hospital Britanico; [2]Rheumatology, Consultorios Reumatológicos Pampa, Buenos Aires; [3]Rheumatology, Hospital Britanico de Buenos Aires; [4]Statistics Section, Teaching and Research Department, Hospital Britanico de Buenos Aires, Capital Federal, Argentina*

**Background:** Hand function in scleroderma patients can be assessed by specific instruments such as the Cochin scale and the Scleroderma Health assessment questionnaire (SHAQ), both self administrated. Sanqvist and Eklun designed the Hand Mobility in Systemic Sclerosis test (HAMIS), which is performed by the evaluation of a health professional. The original instrument was designed in English.
**Objectives:** The aim of this study was to adapt into Spanish the HAMIS test in

order to assess hand function in patients with systemic sclerosis and to evaluate its reliability and validity.
**Methods:** The study included 28 patients that met ACR/EULAR 2013 classification criteria for systemic sclerosis, who attended the Rheumatology Service from March 2014 to March 2015; 21 were diffuse and 7 limited. Patients with overlapping and sclerodermiform syndromes were excluded. Demographic data, clinical manifestations, laboratory studies including ANA by IIF (Hep2) were recorded. Different scores were performed: modified Rodnan, Medsger and Cochin. HAMIS was translated into Spanish and back translated into English. Four translators did not know the original English version of the test. A pilot test was conducted in 5 systemic sclerosis patients and adaptations were performed in order to obtain the final Spanish version. HAMIS test was assessed by an occupational therapist. Two weeks later, the study was repeated in 10 patients chosen randomly to assess stability (test-retest) and concordance according to Bland&Altman. Values of HAMIS and Cochin test were correlated (Spearman's Rank correlation coefficient).
**Results:** All 28 patients (27 female) had mean age at diagnosis of 49.6±13 years and median disease duration of 5 years (range=0–25). All patients developed Raynaud's phenomenon (mean age at onset of Raynaud of 45±17 years), 3 patients had puffy hands, 11 presented digital ulcers, 9 pitting scars and 23 telangiectasia. Through capillaroscopic evaluation, early pattern was found in 11 patients, active in 7 and late in 8 patients. When analyzing severity by Medsger score, such was normal in 1 patient, 11 presented mild involvement, 13 moderate and 3 severe. Median for Rodnan score was of 6 (range=2–27) and 8 for Cochin (range=0–38). Median for HAMIS was of 6 (range=0–21) with Cronbach's alpha of 0.81; in test-retest: mean of the difference was of 0.091 (range= -5 to +5). Correlation between HAMIS and Cochin was significant (r=0.65; p=0.0002)
**Conclusions:** An adapted Spanish version of HAMIS was developed, showing an acceptable reliability (Cronbach and stability) and criterion validity (correlation with Cochin test).
**Disclosure of Interest:** None declared

## AB0617 CYCLOPHOSPHAMIDE VS MYCOPHENOLATE MOFETIL IN SCLERODERMA INTERSTITIAL LUNG DISEASE (SSC-ILD) AS INDUCTION THERAPY: A SINGLE CENTER, RETROSPECTIVE ANALYSIS

M.K. Bavliya[1], P. Shenoy[2]. *[1]Rheumatology and Clinical Immunology, Amrita Institute of Medical Science, Kochi; [2]Rheumatology and Clinical Immunology, Centre of Arthritis and Research Excellance, Kochi, India*

**Background:** Scleroderma is an autoimmune disease characterized mainly by skin manifestations and various visceral organs involvement especially lungs. Lung involvement is the leading cause of mortality in this patients.Various studies have demonstrated efficacy of cyclophosphamide (CYC) and mycophenolate mofetil (MMF) in SSc-ILD but no head to head comparative data is available till date.
**Objectives:** To compare efficacy of CYC & MMF in patients with SSc-ILD in terms of improvement in lung function.
**Methods:** Patients more than 18 years of age fulfilling ACR 2012 classification criteria for Systemic sclerosis with significant ILD as defined by Forced vital capacity (FVC) $\leq$80 and Presence of ILD on thoracic high resolution computerized tomography were included.MMF group received upto 3gm daily and CYC group received 600mg/m$^2$ (Max 1.2 gm) for total duration of 6 months.Monthly clinical assessment and 3 monthly lung function (spirometry-FVC) were done for 6 months.Response was evaluated as per American Thoracic Society recommendations (improvement when increase in FVC $\geq$10%, stabilization when change in FVC $<$10% and worse reduction in FVC was $\geq$10%).Appropriate statistical tests were applied to analyse the data.
**Results:** 23 patients (18 female/5 male) in CYC and 44 patients (40 female/4 male) in MMF group were included with mean age of 46±10.34 years (mean disease duration of 6.04±5.96 years) and 45.54± 13.74 years (mean disease duration of 4.84±4.08 years) in respective groups.After 6 months of induction therapy,increase in mean percentage of FVC observed was 10.84±13.81% (p=0.003) in CYC and 6.07±11.92% (p=0.006) in MMF group.When the change in FVC at 6 months in both groups were compared to each other,no significance difference was found (p=0.373).
**Conclusions:** We support the use of mycophenolate for the patients for whom CYC is contraindicated or not tolerated, given the substantial toxicities and modest benefit of CYC as alternative.A prospective multicenter controlled trial of mycophenolate in SSc-ILD patients is warranted to support the above data.

## AB0618 NAILFOLD CAPILLAROSCOPY CHANGES DURING PREGNANCY IN CONNECTIVE TISSUE DISEASES

M. Meroni[1], V.L. Ramoni[2], A.L. Brucato[2], M. Limonta[3], C. Pizzorni[4], M. Cutolo[4]. *[1]Rheumatology Unit, Internal Medicine Unit, Papa Giovanni XXIII Hospital; [2]Internal Medicine Unit, Papa Giovanni XXIII Hospital; [3]Rheumatology Unit, Papa Giovanni XXIII Hospital, Bergamo; [4]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*

**Background:** Nailfold videocapillaroscopy (NVC) changes early appear in connective tissue diseases (CTDs): besides the "scleroderma pattern" of systemic sclerosis (SSc), abnormalities have been reported in mixed connective tissue disease (MCTD) and undifferentiated connective tissue disease (UCTD) [1]. Pregnancy can modify the course of of CTDs [2]. NVC changes during pregnancy have been described in healthy women [3], but no data are available regarding CTD subjects during pregnancy.
**Objectives:** Our study aimed to investigate if there is an impact of pregnancy on NVC changes, and of which kind, among CTDs patients.
**Methods:** After Local Ethic Committee approval and informed consent signature, we prospectively enrolled 29 consecutive pregnant women, with an established diagnosis of CTD (either SSc, MCTD or UCTD) and RP from at least 12 months. Pregnant women underwent a NVC examination at conception (defined as T0) and, after that, to a second one (T1), between the beginning and the end of the third trimester of gestation. The pregnant subjects are referred as "cases". In parallel, 29 non-pregnant women with the same diagnosis, comparable underlying disease duration and similar age of cases were matched in retrospect ("controls"). NVC was performed in all 29 couples of patients by the same operator, at baseline (T0) and follow-up (T1) (Videocap, DS MediGroup, Milan, Italy). The following capillaroscopic parameters were considered: number of capillaries per area; presence of ectasic capillary and megacapillaries; haemorrhages (hemosiderin deposits); loss of capillaries, disorganization of the microvascular array and capillary ramifications (combined, their constitute the "microangiopathy evolution score"-MES); tortuosity; edema. A semiquantitative rating scale was adopted to score each capillary abnormality (0=no changes; 1=less than 33% of capillary alterations/reduction; 2=33–66% of capillary alterations/reduction; 3=more than 66% of capillary alterations/ reduction) [4]. Statistical analysis was conducted by non-parametric tests.
**Results:** Among 29 cases (and 29 matched controls), we collected 14 UCTD, 10 MCTD and 5 SSc. Regarding capillaroscopic abnormalities, the two groups were homogeneous at T0, whereas statistically significant differences (excepted for ectasias and tortuosity scores) were observed at T1. Capillary number increased only among cases (pregnant women; $p<0.001$). Hemosiderin deposition and architectural subversion scores were reduced in cases and increased in controls (both, $p<0.05$). Megacapillary, MES, ramifications and edema scores progressed only in controls (all, $p<0.05$), while capillary number reduction score (consistently with absolute capillary number per mm$^2$) was abated in pregnant cases.
**Conclusions:** Our work investigated for the first time pregnancy influence on NVC aspects in CTDs; considering the number of statistical differences in capillaroscopic abnormalities between the two groups at the follow-up, it suggests that pregnancy could play a protective role against microvascular damage progression in CTDs subjects.

## AB0619 AUTOLOGOUS NON-MYELOABLATIVE HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR SYSTEMIC SCLEROSIS: THE BENEFIT OF QUANTITATIVE CHEST-CT ANALYSIS FOR RESPONSE OF LUNG INVOLVEMENT AND COMPARISON WITH RESULTS OF PULMONARY FUNCTION TESTS AND CLINICAL TESTS

M.S. Marius[1], T. Xenitidis[2], I. Koetter[3], N. Konstantin[1], J. Henes[2], C. Kloth[1]. *[1]Radiology; [2]Internal Medicine II, Eberhard-Karls-University Tuebingen, tuebingen; [3]Internal Medicine Rheumatology, Asklepios Klinik, Hamburg, Germany*

**Background:** Lung disease represents the leading cause of mortality and

morbidity in patients with systemic sclerosis (SSc). In patients with rapid progressive disease immunoreset by high-dose chemotherapy accompanied by autologous stem cell transplant (auto-SCT) represents a possible rescue. For accurate evaluation and monitoring of lung parenchymal changes in patients undergoing treatment for SSc, different modalities (clinical examination, respiratory functional tests) are used, but these are all prone to some inaccuracies. Quantitative-CT represents a novel, fully automated technique able to exactly quantify lung volume and changes in CT-attenuation of lung parenchyma induced by SSc. Parameters like high attenuation value (HAV) and mean lung density (MLD) as well as percentile ranges 200–300/and300–400 Hounsfield units (HU) reflect at best lung involvement with this disease.

**Objectives:** The aim of this study was to evaluate the course of SSc-related pulmonary changes following high-dose therapy & auto-SCT using quantitative chest-CT analysis and compare its results with those of established clinical and pulmonary function tests.

**Methods:** Non-enhanced chest-CT examinations were performed before, directly after (0.49±0.20y) and at mean 2.2±2.1y after auto-SCT in 26 patients with SSc that were enrolled between March 2001 and March 2015. Chest-CT quantitative analysis was performed using fully automated software calculating inspiratory total lung volumes (TLV), mean lung densit (MLD), high attenuation values (HAV) and their distribution in the lung core vs. peel. All patients underwent pulmonary functional tests. The course of cutaneous SSc was evaluated by modified Rodnan skin score (mRSS). Classification of response to auto-SCT was performed at mean 6mo after auto-SCT based on the course of forced vital capacity (FVC) into responders 10% increase or stabilisation of FVC and non-responders >10% decrease in FVC.

**Results:** The FVC course at 6mo classified the patients into responders 20 (76.9%) and 6 (23.1%) non-responders. Correspondingly, FVC, forced expiratory volume in 1s (FEV1s), vital capacity (VC) as well as single-breath diffusion capacity for carbon monoxide ($DLCO_{cSB}$) significantly improved (p=0.03/0.001/0.001/0.013). Mean modified Rodnan skin score (mRSS) improved from 27.35±9.25 before to 10.81±8.64 after auto-SCT (p=0.003) in responders. In non-responders no statistically significant improvement were registered. At CTD, total lung volume increased (p=0.018) whereas MLD (p=0.026) and HAV decreased (p=0.020) after auto-SCT only in responders. Improvement of CTH-parameters was stronger in the lung peel reflecting the typical localisation of SSc-fibroalveolitis. Changes of mRSS 6 months after auto-SCT correlate significantly with those 24 months after transplantation (r=0.575; p=0.031). Percental changes in MLD correlated well with FEV1 (r=0.733; p=0.016) in responders.

**Conclusions:** Quantitative-CT analysis of lung parenchymal attenuation and volume in SSc-patients presenting lung involvement is accurate, can be easily and quickly accomplished being less dependent on patient's compliance and results match those of pulmonary function and clinical tests.

## AB0620 EVALUATION OF USEFULLNESS OF KLEBS VON DEN LUNGEN-6 AS A BIOMARKER OF INTERSTITIAL LUNG DISEASE WITH POLYMYOSITIS AND DERMATOMYOSITIS INCLUDING THAT IN THE SHORT TIME COURSE AFTER TREATMENT

M. Hanaoka, Y. Katsumata, Y. Kawaguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** Because of the extremely variable incidence and outcome of interstitial lung disease (ILD) in polymyositis/dermatomyositis (PM/DM), exploration and validation of biomarkers for diagnosis, prognosis, and response to treatment is mandatory. Lung epithelium-derived proteins such as Krebs von den Lungen-6 (KL-6) and surfactant protein-D (SP-D) are used as serum biomarkers for ILD. However, their usefulness in patients with PM/DM is not fully established.

**Objectives:** We aimed to evaluate the usefulness of KL-6 as a biomarker of ILD with PM/DM, including that in the short time course after treatment.

**Methods:** A total of 42 patients with active PM/DM who were admitted to our hospital from April 2010 through March 2015 were included: 22 with PM, 14 with classical DM, and 6 with clinically amyopathic dermatomyositis (CADM). PM/DM and CADM were diagnosed according to Bohan and Peter's criteria and Sontheimer's criteria, respectively. Overlap patients with other collagen tissue diseases were excluded to avoid potential confounding. ILD was defined as presence of a diffuse parenchymal lung disease on high-resolution CT such as reticular opacity, ground-glass opacity, and honeycombing. Clinical, radiological, and laboratory data were retrospectively collected from the medical records and statistically analyzed.

**Results:** Of the 42 study subjects, 30 patients had ILD on high-resolution CT: 24 with PM/classical DM, and 6 with CADM. There was no significant difference in age, sex, or disease duration between patients with and without ILD. On admission (pre treatment), % vital capacity (%VC) and % diffusing capacity of the lungs for carbon monoxide (%DLCO) were not significantly different between patients with and without ILD ($p$ =0.11 and 0.06, respectively). However, serum KL-6 and SP-D levels were already significantly higher in patients with ILD than in those without ($p$ <0.01 in both comparisons). In addition, levels of serum KL-6 and SP-D showed moderate inverse correlations with %VC and %DLCO ($r$ = -0.45 to -0.51). All the patients with ILD were treated with glucocorticoid. In addition, calcineurin inhibitors, namely cyclosporine and tacrolimus, and intravenous cyclophosphamide were administered simultaneously in 22 and 8 patients, respectively. Although 12 patients showed some clinical and/or radiological improvement in 4 weeks, levels of serum KL-6 were not significantly different between those at pre treatment and at 2 or 4 weeks post treatment ($p$ =0.78 and 0.81, respectively). Concordance rate between clinical or radiological amelioration and decrease in serum KL-6 levels after treatment was low (Cohen's $\kappa$ = -0.39).

**Conclusions:** The present study validated that serum KL-6 is a useful biomarker for the diagnosis of ILD associated with PM/DM. However, the levels of serum KL-6 did not respond immediately by treatment even in the cases with clinical improvement. Serum KL-6 should be used as a biomarker for ILD with PM/DM while understanding these strengths and limitations.

## AB0621 FROM VEDOSS TO ESTABLISHED SYSTEMIC SCLEROSIS DIAGNOSIS ACCORDING TO THE NEW ACR/EULAR 2013 CLASSIFICATION CRITERIA: A FRENCH-ITALIAN CAPILLAROSCOPIC SURVEY

M. Vasile[1], J. Avouac[2], I. Sciarra[1], K. Stefanantoni[1], N. Iannace[1], Y. Allanore[2], V. Riccieri[1]. *[1]Department of Internal Medicine and Medical Specialities, Sapienza Università di Roma, Roma, Italy; [2]Rheumatology A Dpt, Cochin Hospital, Paris Descartes University, Paris, France*

**Background:** NailfoldCapillaroscopy (NC) is a diagnostic and sensitive tool in order to investigate Raynaud's phenomenon (RF) that is the hallmark of both Systemic Sclerosis (SSc) and Very Early Diagnosis Of ScS (VEDOSS) patients. Thus NC is largely used in patients with these conditions and NC specific abnormalities have become a minor criteria in ACR/EULAR SSc Criteria in 2013.

**Objectives:** Aim of our study was to monitor NC changes in a group of 66 VEDOSS patients, enrolled in two EUSTAR center.

**Methods:** We selected those patients who developed SSc at the follow-up. Moreover, we compared the NC features of these patients with NC of those VEDOSS patients who did not move to SSc, in order to find out NC features, if any, suitable as predictive risk factor for SSc at the time of VEDOSS diagnosis.

**Results:** In our 66 VEDOSS patients, 21 of them (19 females, mean age 55 yrs) shifted to SSc in a mean follow-up time of 31 months (range 6–60 months). Table 1 shows the main features of matched VEDOSS patients: Group A with unchanging diagnosis and Group B progressing into SSc. Table 2 shows the progression of NC abnormalities from VEDOSS to established SSc diagnosis in Group B patients.

Table 1

| Features | Group A (n=21) | Group B (n=21) |
|---|---|---|
| Age, yrs (range) | 50 (28–70) | 55 (27–77) |
| Sex (M/F) | 1/20 | 2/19 |
| Disease duration, month (range) | 51 (14–70) | 50 (21–70) |
| Follow up, months (range) | – | 31 (6–60) |
| Anti-centromere Ab (n) | 11 | 14 |
| Anti-Scl70 Ab (n) | 3 | 5 |
| ANA positivity (n) | 7 | 2 |
| NC Pattern | Normal = 11 (52.3%)<br>Early = 7 (33.3%)<br>Active = 2 (9.6%)<br>Late = 1 (4.8%) | Normal = 8 (38.1%)<br>Early = 8 (38.1%)<br>Active = 4 (19%)<br>Late = 1 (4.8%) |

Table 2

| NC Parameter | NC at baseline (VEDOSS diagnosis) | NC at follow-up (SSc diagnosis) |
|---|---|---|
| Loop diameter | 86 μm | 98 μm |
| Apex width | 176 μm | 187 μm |
| Capillary distribution | Slighty irregular = 11 (52.4%)<br>Disorganized = 4 (19%) | Slightly irregular = 14 (66.6%)<br>Disorganized = 6 (28.6%) |
| Capillary density (n/mm$^2$) | Normal = 12 ( 57.1%)<br>Reduced = 9 (42.8%) | Normal = 9 ( 42.8%)<br>Reduced = 12 (57.1%) |
| Capillary enlargement (enlarged = 20–50 μm; giant >50 μm | Enlarged loops = 10 (47.6%)<br>Giant loops = 10 (47.6%) | Enlarged loops = 6 (28.6%)<br>Giant loops = 11 (52.4%) |
| Avascular areas (n pts/%) | 2/9.5% | 6/28.6% |
| NC Pattern (n) | Early = 8 (38%)<br>Active = 4 (19%)<br>Late = 1 (4.7%) | Early = 5 (23.8%)<br>Active = 7 (33.3%)<br>Late = 2 (9.5%) |
| Score >1 (n pts) | 13 | 15 |

When we compared basal NC of Group A and Group B patients, in former VEDOSS developing SScwe found a significantly higher NC score (>1), 13 versus 5 cases (p<0.03) and a larger mean apex width, 177 μm (range 50–640) versus 104 μm (range 10–280) (p<0.005).

**Conclusions:** Our study describes a progression of NC changes during the evolution of early SSc. Moreover we identified some NC features, such as higher NC score and larger apex width, whose presence at the very early diagnosis of SSc may suggests its development in an established disease, thus underlying the relevance of specific NC abnormalities as possible predictive risk factors.

## AB0622 ASSESSMENT OF OUALITY OF LIFE IN SYSTEMIC SCLEROSIS PATIENT WITH TRANSLATION, CROSS-CULTURAL ADAPTATION, AND VALIDATION OF THE SYSTEMIC SCLEROSIS QUESTIONNAIRE (SYSQ) INTO THE TURKISH LANGUAGE

F. Temiz[1], M. Saganak[1], N. Enginar[1], G. Ozen[2], A.U. Unal[2], Y. Sahinkaya[2], H. Direskeneli[2]. *[1]Marmara University School of Medicine, Istanbul, Turkey; [2]Division of Rheumatology, Marmara University School of Medicine, Istanbul, Turkey*

**Background:** Systemic Sclerosis (SSc) is a multisystem connective tissue disorder which decreases the life-expectancy and quality of life (QoL) of the patients.
**Objectives:** To determine the effects of SSc on physical and mental health of the patients as well as their QoL and translation, cross-cultural adaptation, and validation of the Systemic Sclerosis Questionnaire (SySQ) to the Turkish language.
**Methods:** We evaluated 88 SSc patients (F/M=77/11, mean age 49.8±12.4 and mean disease duration 7.2±6.0 years, limited/diffuse=60/28) and 81 healthy subjects (HS)(F/M=70/11, mean age 46.8±11.2 years) without a history of malignancy and infection. QoL, functional capacity, fatique, anxiety and depression were assessed by SF-36, SySQ, HAQ, UK SSc functional score (UKFS), FACIT-F and HADS, respectively. The SySQ was translated according to international guidelines and administered to all patients and controls. Internal consistency was tested by computing Cronbach's alpha. Test-retest reliability was determined by computing the intraclass correlation coefficient (ICC). Correlation of SySQ with SF-36, HADS, FACIT-F was assessed by using Pearson test.
**Results:** The internal consistency of SySQ was similar to the original study (1) and ranged from 0.812–0.937 for items. The interobserver reliability was also very good for each item (ICC: 0.88–0.97). QoL assessed by SySQ, anxiety and depression and fatique scores were significantly worse in SSc patients than healthy subjects (Table 1). All items of SySQ positively correlated with UKFS, HAQ, HADS scores, patient and physician global assessments of disease activity and negatively correlated with all parameters of SF-36 and FACIT-FT.

**Table 1:** Comparison of SF-36, SysQ, HAQ, HADS and FACIT-FT scores between SSc patients and healthy subjects*

| | SSc patients (n=88) | Healthy subjects (n=81) | *P* value |
|---|---|---|---|
| **SF-36 components** | | | |
| Physical functioning | 38.9±12.6 | 50.6±7.6 | <0.001 |
| Physical role functioning | 39.3±12.2 | 49.0±10.3 | <0.001 |
| Bodily pain | 43.3±13.2 | 52.0±12.0 | <0.001 |
| General health perceptions | 35.7±12.0 | 45.8±9.6 | <0.001 |
| Vitality | 45.2±12.1 | 52.5±10.4 | <0.001 |
| Social role functioning | 41.0±14.9 | 49.4±11.0 | <0.001 |
| Emotional role functioning | 38.6±13.6 | 41.5±13.6 | 0.17 |
| Mental health | 39.8±11.4 | 47.1±9.4 | <<0.001 |
| Physical component summary | 37.6±11.9 | 49.6±10.5 | <0.001 |
| Mental component summary | 42.3±11.6 | 45.3±12.0 | 0.09 |
| **Systemic Sclerosis Questionnaire (SysQ)** | | | |
| SysQ-General symptoms (0-24) | 10.3±5.7 | 2.3±3.8 | <0.001 |
| SysQ-Gastrointestinal system (0-21) | 6.3±5.3 | 1.5±1.9 | <0.001 |
| SysQ-Musculoskeletal system (0-33) | 8.7±7.9 | 1.0±1.9 | <0.001 |
| SysQ-Cardiopulmonary system (0-18) | 5.4±4.3 | 1.9±2.5 | <0.001 |
| **Hospital anxiety and depression scale (HADS)** | | | |
| HADS-Depression | 8.3±5.3 | 5.1±4.1 | <0.001 |
| HADS-Anxiety | 8.3±4.7 | 5.5±3.6 | <0.001 |
| **HAQ** | 1.13±0.94 | 0.13±0.26 | <0.001 |
| **Fatigue (FACIT-FT) score** | 94.0±29.0 | 124.2±22.3 | <0.001 |

**The values are presented as mean±SD, unless indicated otherwise*

**Conclusions:** Disease-specific QoL, mental and physical health of the SSc patients were significantly worse than healthy individuals in our study. Turkish version of SySQ is reproducible and valid for Turkish SSc patients.

## AB0623 TREATMENT OF SCLERODERMA-RELATED DIGITAL ULCERS WITH ILOPROST: A COHORT STUDY

M. Colaci[1], F. Lumetti[1], D. Giuggioli[1], S. Guiducci[2], S. Ballando Randone[2], G. Fiori[2], M. Matucci-Cerinic[2], C. Ferri[1]. *[1]University of Modena and Reggio Emilia, Rheumatology Unit, Modena; [2]University of Florence, Division of Rheumatology, Florence, Italy*

**Background:** SSc is characterized by diffuse microangiopathy leading digital ulcers (DU) in almost 50% of patients. The treatment of non-healing DU is often very difficult. It includes both systemic (prostanoids, bosentan) and local (wound care) therapies. In clinical practice, therapy of DU should be tailored mainly on clinical symptoms and according to specific clinician's experience. At the moment, no guidelines for the use iloprost, a stable prostacyclin-analogue used for the management of DU in SSc, are not yet available.
**Objectives:** We report the therapeutical effects of our regimen for the use of iloprost in a cohort of SSc patients during a long-lasting follow-up period.
**Methods:** Fifty consecutive SSc patients recruited at two Rheumatology Units since January 2003, who received iloprost infusions for a time period >2 years were included in the analysis. Patients' features were: males/females ratio 7/43; mean age at SSc diagnosis 43.5±12.7SD years; median disease duration at the beginning of therapy 2 years (range 0–18); mean follow-up with iloprost treatment 10±4.2SD years; diffuse SSc cutaneous subset in 13/50 (30%) patients; anti-Scl70 and anticentromere autoantibodies in 25 (50%), and 14 (28%) subjects, respectively. For all patients epidemiological, clinical, laboratory, and instrumental data were available for the study period. Iloprost schedule consisted in monthly i.v. infusion at 0.8–1 ng/kg body weight/min with average cumulative dosage per each session of 25 μg, according to patients' tolerance. At the beginning of the treatment and in the presence of recent onset, severe and/or multiple DU at high risk of gangrene, patients were hospitalized for continuous infusion of iloprost (3 days, average 0.2 mg).
**Results:** 31/50 (62%) patients showed DU at the beginning of iloprost therapy: among them, 22 (71%) resolved during the follow-up, while the other 9 presented recurrent or chronic DU, despite the treatment. With regards the 19/50 patients without DU at baseline, only one developed skin lesions at the end of very long follow-up (8 years), when a general deterioration of clinical conditions, in particular severe pulmonary hypertension, lead to exitus.
Considering the 31 SSc patients with DU at baseline, a diffuse skin subset was present in 3 out of 22 patients with healed DU, and in 5 out of 9 who did not (13.6% vs 55.5%, Fisher's p=0.027); no other significant correlations were observed as regards visceral organ involvement and serological alterations. Finally, the concomitant administration of other vasoactive therapies seems to be scarcely relevant on the DU outcome.
**Conclusions:** Our data suggest that long term administration of iloprost seems to be effective for DU healing in SSc. Comparative studies with different treatment regimens are warranted to reach a consensus on standardized guidelines for the use of Iloprost for DU healing in SSc.
**Disclosure of Interest:** None declared

## AB0624 CLINICAL CONSEQUENCES OF GLUCOCORTICOIDS (GCS) DISCONTINUATION IN PATIENTS WITH PERSISTENTLY INACTIVE SYSTEMIC SCLEROSIS (SSC)

M. Iudici, S. Vettori, B. Russo, V. Giacco, D. Capocotta, G. Valentini. *Rheumatology Section, Department of Clinical and Experimental Medicine, Second University of Naples, Naples, Italy*

**Background:** Glucocorticoids (GCs) are widely used in the management of patients with systemic sclerosis (SSc), but are frequently discontinuated because of patient and/or physician concern. Clinical consequences of GCs discontinuation have never been investigated in SSc patients.
**Objectives:** To identify factors hampering GCs discontinuation in SSc patients with inactive disease who had been chronically (i.e. more than 3 months) treated with oral GCs.
**Methods:** Consecutive SSc adult patients fulfilling the 2013 ACR/EULAR criteria for SSc (1) were evaluated for the following inclusion criteria: - stable lung function and skin thickening during the previous year; - non inflammatory joint involvement; - no puffy fingers; - no serositis; - no CK increase; - no cutaneous vasculitis; - inactive disease, i.e. European Scleroderma Study Group Activity Index score<3 during the previous 6 months (2); - no co-morbidities requiring GCs. A slow GCs tapering regimen (reduction of 10% of weekly dose each week) was prescribed to achieve GCs discontinuation within 6 months (T6) from enrollment. At study entry, and at last evaluation the following self-administered patient outcomes were recorded: Short-Form-36 (SF-36), Health Assessment Questionnaire – Disability Index (HAQ-DI), VAS fatigue, VAS pain, VAS general health. Moreover, at study entry, after 3 and 6 months a complete history and clinical assessment were performed.
**Results:** Forty-eight SSc patients (46 females, 9 dcSSc, 17 anti-Scl-70 positive), with a mean±SD age of 56±14 years and a median disease duration of 10 years (range 2–22) satisfied the inclusion criteria and were enrolled in the study. Median baseline daily GCs dose was 5 mg (range 5–10).
At T6, 33 (68.7%) patients were free from GCs. In the remaining 15 patients, GCs were not discontinued because of the occurrence of inflammatory arthralgias

in 8, arthritis in 2, puffy fingers in 2, increase of CK in 2, and subacromial bursitis in 1 patient. At univariate logistic regression analysis baseline VAS-GH (OR 1.03, 95% CI 1.00–1.06; p=0.03), VAS-pain (OR 0.97, 95% CI 0.95–0.99; p=0.02), HAQ-DI score (OR 0.34, 95% CI 0.13–0.81;p=0.010), heart severity score (OR 0.28, 95% CI 0.08–0.97; p=0.018) resulted to be associated with the achievement of a GCs-free regimen. At multiple logistic analysis, baseline HAQ-DI resulted to be the only indipendent factor hampering GC discontinuation (OR 0.33, 95% CI 0.13–0.83; p=0.01). At ROC curve analysis, a HAQ-DI score$\leq$0.5 identified patients in whom discontinuation was successfully obtained with 77.5% sensitivity and 55% specificity; a HAQ-DI score $\leq$0.125 with 9.7% sensitivity and 86.7% specificity (positive likelihood ratio=5.23; negative likelihood ratio 0.35; AUC=0.764).

**Conclusions:** About one-third of SSc patients with inactive disease were not able to achieve a GC-free regimen. Disability as assessed by HAQ-DI was the leading factor hindering GCs discontinuation. A low HAQ-DI score can drive the physician choice to completely discontinue GCs in SSc patients.

## AB0625 THE CLINICAL SIGNIFICANCE OF ANTIPHOSPHOLIPID ANTIBODIES IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Merashli[1], P. Ames[2]. [1]*Rheumatology, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK, Leeds, United Kingdom;* [2]*Vascular Disease Unit, Nova University, Lisbon, Portugal, Lisbon, Portugal*

**Background:** The association between antiphospholipid antibodies (aPL) and systemic sclerosis (SSc) and its clinical manifestations is controversial, but owing to some shared pathogenetic pathways one expects that SSc patients with aPL will have more severe vascular manifestations that SSc without aPL.

**Objectives:** To evaluate whether different aPL are associated with SSc and some of its clinical manifestations and if so, whether aPL titre impact on the severity of those clinical manifestations.

**Methods:** Systematic review of EMBASE and PubMed databases from inception to October 2015 followed by meta-analysis according to the PRISMA guidelines.

**Results:** The relationship between between aCL (anticardiolipin) of IgG/IgM isotype and SSc was addressed in 8 studies yielding 725 controls and 484 SSc participants. The pooled prevalence of IgG aCL was 1.6% in controls and 15.4% in SSc patients with an odds ratio (OR) of 10.895 (95% CI 5.853, 20.282, $I^2$ =19.5%, p=0.003) and that of IgM was 0.6% and 5.1% respectively with an OR of 7.843 (95% CI 2.981, 20.633, $I^2$ =21.5%, p=0.002). The relationship between between IgG a$\beta_2$GPI of IgG/IgM isotype and SSc was addressed in 8 studies yielding 725 controls and 484 SSc participants. The pooled prevalence of IgG a$\beta_2$GPI was 1.6% in controls and 15.4% in SSc patients (OR 11.121, 95% CI 2.587, 47.812, $I^2$ =35.6%, p=0.0003) while that of IgM was 0.6% and 5.1% respectively (OR 12.185, 95% CI 1.563, 94.948; $I^2$ =67.5%, p=0.02). The relationship between aPL and thrombosis was addressed in 6 studies yielding 428 aCL negative and 88 aCL positive SSc: the pooled prevalence of thrombosis was 3.7% in the aCL negative group and 25% in the aCL positive group with a relative risk (RR) of 7.344 (95% CI: 4.089–13.191; $I^2$ =29.5%, $p$ =0.0001). The relationship between aPL and pulmonary arterial hypertension (PAH) was addressed in 7 studies yielding 1171 aCL negative SSc patients and 166 aCL positive SSc: the pooled prevalence of PAH in aCL negative patients was 11% and in aCL positive patients was 24.6% for a RR of 6.8 (95% CI: 3.110–12.280; $I^2$ =4.18; $p$ =0.0001). The relationship between aPL and renal involvement was investigated in 5 studies yielding 264 aCL negative and 83 aCL positive SSc patients: the pooled prevalence of renal involvement in aCL negative patients was 17% and in aCL positive patients was 40% for a RR of 1.993 (95% CI: 1.359–2.923; $I^2$ =0%, $p$ =0.0001).

**Conclusions:** There is a strong association between aPL and SSc; within SSc per se, aPL, with varying heterogeneity, relate to some vascular manifestations of SSc, such as thrombosis, DI, PAH and renal involvement. The analysis was carried out on the percentage of positive aPL per group, as very few studies reported aPL titres, precluding further assumptions on the relationships found

## AB0626 CLINICAL PREDICTORS FOR DEVELOPMENT OF INTERSTITIAL LUNG DISEASE IN MCTD

N. Narula[1], T. Narula[2], B. Wang[1], A. Abril[1]. [1]*Rheumatology, Mayo Clinic;* [2]*Pulmonary and critical care medicine, Respiratory Critical Care & Sleep Medicine Associates, Jacksonville, United States*

**Background:** Mixed connective tissue disease (MCTD) is an immune-mediated systemic disorder characterized by serum autoantibodies against U1-ribonucleoprotein and diverse multi-systemic clinical manifestations. Approximately 50% of patients with MCTD develop a radiological pattern of interstitial lung disease (ILD). In this study, we explore the phenotypic and clinical features in patients with MCTD that are associated with development of ILD.

**Objectives:** To explore the association of demographics, clinical features and serologic markers with the development of ILD in patients with MCTD.

**Methods:** We performed a retrospective case control study utilizing data from patients evaluated at a single tertiary care center between 2007–2014. Twenty-eight patients who met validated criteria for diagnosis of MCTD were included in the study. Out of these, 14 patients had high-resolution computed tomography or biopsy-proven ILD, and the remaining 14 had MCTD without any evidence of ILD. We performed a multivariate logistic regression with multiple demographic, clinical and serological predictor variables, and ILD as the outcome variable.

**Results:** Two clinical variables were found to have an association with development of ILD in patients with MCTD: 1. Dyshpagia with a $R^2$ value of 0.33 (p value $<$0.001); 2. Raynaud's phenomenon with $R^2$ value of 0.28 (p$<$0.001). We did not find a significant association between any other demographic, clinical or serological variables and development of ILD in patients with MCTD.

**Conclusions:** Dysphagia is one of the symptoms of esophageal involvement in patients with autoimmune connective tissue disorders. An association of dysphagia with the development of ILD in our study is in harmony with the existing literature, wherein esophageal dysmotility has been described in a cluster of patients with MCTD and ILD.

Scant data, primarily case reports, suggest an association of Raynaud's phenomenon with development of ILD in patients with undifferentiated CTD. To our knowledge, this is the first study highlighting the association of Raynaud's phenomenon with development of ILD in a subset of patients with MCTD.

This study is limited by its small size and retrospective nature. Additionally, the mechanistic aspects of this association between Raynaud's phenomenon and ILD remain unexplored.

The association of easily elicited historical and clinical features of MCTD with subtle, but worrisome, pulmonary pathology carries the promise of sensitizing the unsuspecting clinician about the entity of ILD in MCTD.

## AB0627 PREDICTORS OF ILD AND ITS PROGRESSION IN A COHORT OF SCLERODERMA PATIENTS FROM WESTERN INDIA: A PROSPECTIVE OBSERVATIONAL COHORT STUDY

Y. Gc[1], R. Samant[1], A. Mahashur[2], P.S. Sagdeo[1], G. Kakade[1]. [1]*Rheumatology;* [2]*Respiratory Medicine, P.D Hinduja Hospital and Medical Research Center, Mumbai, India*

**Background:** Pulmonary involvement, including both interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH), has become the primary cause of Scleroderma-related death. Little data has been published from India regarding the progression of ILD and Pulmonary arterial hypertension in Scleroderma.

**Objectives:** 1) To identify baseline factors predictive of ILD and its outcome in patients with Scleroderma. 2) To study the progression of ILD and PAH in scleroderma patients 3) To study the demographic and clinical profile of scleroderma patients from Western India.

**Methods:** Prospective observational study involving 68 patients. Patients were evaluated at 0,3,6,9 and 12 months. Patient's demographic and clinical details were recorded at baseline. Other than routine tests, Anti-nuclear antibodies (ANA), Spirometry, diffusing capacity of lung for carbon monoxide (DLCO) measurement, high resolution computed tomography (HRCT) of thorax, 6-minute walk test and echocardiography were done.

**Results:** Study included 68 individuals with Scleroderma (according to the American College of Rheumatology classification criteria for SSc) with majority of cases being females n=64 (94.1%). ILD was seen in 53 (77.9%) patients with a mean duration of 4.17 years. When we compared the mean change in FVC, DLCO and PAH from the time of onset of ILD/PAH to the values at last follow up, there was no significant change. ILD patients with UIP pattern on HRCT, showed a significant progression in terms of $>$10% fall in FVC as compared to NSIP subgroup. None of the baseline parameters were predictive of ILD and its progression. Older age predicted onset of PAH.

**Conclusions:** 1) None of the studied baseline variables were predictive of ILD and its progression. 2) Only age had statistically significant effect as a predictor for

Table 1. Disease characteristics

| Variables | No (%) |
|---|---|
| Raynaud's phenomenon | 62 (91.2) |
| Sclerodactyly | 49 (72.1) |

## AB0628 LUNG CANCER IN SYSTEMIC SCLEROSIS: CASES IN A HOSPITAL COHORT

P. Corzo[1], A. Pros[1], L. Polino[1], E. Balcells[2]. *[1]Rheumatology Department; [2]Respiratory Department, Hospital de Mar, Barcelona, Spain*

**Background:** Systemic sclerosis (SS) is a rare disease that leads to greater morbidity and mortality than in general population, but due to its unfrequency there are very few clinical and epidemiological data. Some meta-analysis[1] about the increased incidence of cancer in SS compared to the average population (Relative risk (RR) 1.75[1]) were published; even more relevant when it refers to lung cancer (RR 4.35[1]), compared to the general population; suggesting that interstitial lung disease (ILD) may be the cause of this increased incidence

**Objectives:** To provide our cases of lung cancer in patients with SS, describe the clinical, epidemiological and pathological features and assess the possible risk factors associated

**Methods:** Retrospective review of lung cancer cases of a 115 patients hospital cohort with SS. Clinical and epidemiological characteristics, timeline, SS subtype, histology and likely associated risk factors are described.

**Results:** The prevalence of cancer in our 115 patients serie with SS is 10.4% (12/115), lung cancer was the most frequent neoplasia (4/12, 33%)

Case 1. Woman, 36 years old, nonsmoker, diagnosed at 23 year old of diffuse SS (DSS) Scl70+, with recurrent ulcers. ILD (HRCT and biopsy: desquamative interstitial pneumonia, DIP) at 29 years old. Treatment: prednisone (7.5 mg/ average dose), azathioprine 100mg, calcium antagonists, bosentan and alprostadil. She presented intercostal pain and was diagnosed by biopsy and HRCT of well defined adenocacinoma with mucosecretory pattern and acinar areas, T3N0M0. Pneumonectomy was performed with good results.

Case 2. Woman, 72 years old, nonsmoker, diagnosed at 58 years old of DSS Scl70+ with recurrent ulcers and ILD (HRCT: nonspecific interstitial pneumonia, NSIP) at 64 years old. Treatment: calcium antagonists, bosentan and alprostadil. She presented abrupt clinical and PFT deterioration, biopsy and HRCT showed poorly differentiated non-small cell carcinoma T4N0M1b. Dyed six months after diagnosis.

Case 3. Male, 47 years old, nonsmoker, diagnosed at 43 years old of DSS and ILD (HRCT: NSIP) with recurrent ulcers. Treatment: prednisone (7.5 mg/d), calcium antagonists, bosentan and alprostadil. He presented constitutional syndrome and respiratory clinical worsening, diagnosed by biopsy and HRCT of large cell neuroendocrine carcinoma of the lung, T3N0M1b. Stable after 18 months of palliative chemotherapy.

Case 4. 57-years-old male, smoker, ESD diagnosis with rapid Raynaud's syndrome onset, HRCT and lung biopsy evidenced lung adenocarcinoma T2aN3M0. Improvement of skin symptoms after chemoradiation.

**Conclusions:** Lung cancer is the most common malignancy in our cohort. All of them had DSS. Most of them (3/4) had a previous diagnosis of ILD and were nonsmokers, with a mean time of evolution from the SS diagnosis to neoplasia of 9.6 years and 6.3 years from diagnosis of ILD. The other case, had simultaneous diagnosis of SS and lung cancer. Only one case had been previously treated with non-steroid immunosuppressant. These results force us to strictly control the risk of neoplasia in patients with SS, predominantly those with diffuse involvement and ILD diagnosis.

## AB0629 DESIGN OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 2 CLINICAL TRIAL OF THE TOLL-LIKE RECEPTOR ANTAGONIST IMO-8400 IN PATIENTS WITH DERMATOMYOSITIS

P. Gordon[1], R. Cooper[2], H. Chinoy[3], D. Isenberg[4], I.E. Lundberg[5], V. Werth[6], K. Gruis[7], M. Hurtt[7], J. Brevard[7], L. Granlund[7], D. Fiorentino[8]. *[1]Department of Rheumatology, King's College London, London; [2]MRC/ARUK Institute for Ageing and Chronic Disease, University of Liverpool, Liverpool; [3]National Institute of Health Research, Manchester Musculoskeletal Biomedical Research Unit, Centre for Musculoskeletal Research, University of Manchester, Manchester; [4]Department of Rheumatology, University College London Hospitals, London, United Kingdom; [5]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden; [6]Division of Dermatology, Corporal Michael J. Crescenz Veterans Affairs Medical Center (Philadelphia), Philadelphia; [7]Idera Pharmaceuticals, Inc., Cambridge; [8]Department of Dermatology, Stanford University School of Medicine, Redwood City, United States*

**Background:** Dermatomyositis (DM) is a rare idiopathic inflammatory myopathy characterized by an auto-inflammatory immune response in muscle and skin. Multiple lines of evidence suggest Toll-like receptors (TLRs), central components of the innate immune system, play a key role in DM pathogenesis. A retrospective study evaluating muscle biopsy samples showed that TLR9, TLR4 and TLR2 were significantly over-expressed in skeletal muscle and infiltrating cells in DM subjects compared to controls. Over-expression of type I and type II interferons and other cytokines has been demonstrated in DM, suggesting involvement of the NF-κβ pathway. Expression of certain cytokines also had significant positive correlations with expression of TLR9 and TLR4. IMO-8400 is an investigational oligonucleotide-based antagonist of TLRs 7, 8 and 9 that has demonstrated clinical activity in patients with psoriasis. We hypothesize that inhibition of TLR activity in patients with DM with IMO-8400 has the potential to reduce chronic inflammation in affected tissue.

**Objectives:** Our objective was to design a Phase 2 clinical trial of IMO-8400 in DM patients using the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) as the primary efficacy endpoint. Specifically, we wished to estimate the placebo response for the CDASI and calculate optimal treatment effect in order to estimate optimal subject numbers and length of trial.

**Methods:** Retrospective analyses were conducted using longitudinal CDASI assessments for 115 unique DM patients seen at the Stanford University outpatient dermatology clinic. Patients with multiple assessments approximately 12 or 24 weeks apart were grouped by the first visit CDASI activity score ($<$15, 15–19, 20–24 and $\geq$25), and the change in CDASI activity score between the visits was assessed.

**Results:** Over 24 weeks, a 5 point or greater decrease in CDASI activity score was observed at 31.8% of patient visits, with the change in CDASI activity score ranging from -23 to +27 points across all patients. Because some patients experienced clinically meaningful changes of 4 to 5 points on the CDASI following treatment with standard of care therapies, a 7 point treatment effect was targeted for the IMO-8400 trial. Sample size calculations resulted in 10 patients per treatment group, assuming a standard deviation of 8.5 points over 24 weeks using a Repeated Measures Mixed Model analysis of change from baseline on monthly CDASI assessments ($>$80% power on a 1-sided test; alpha=0.05).

**Conclusions:** Based on these analyses, we initiated a double-blind, placebo-controlled, 24-week Phase 2 clinical trial in DM patients (NCT number: NCT02612857). Key entry criteria include adults with DM aged 18–75 years, CDASI activity score $\geq$15, clinical symptoms of active muscle disease, and abnormal serum CK or ALD, EMG, muscle biopsy or MRI. Additional outcome measures include MMT-8, timed function tests including 10-meter run walk, and exploratory biomarkers of disease activity.

## AB0630 CARDIAC MAGNETIC RESONANCE IMAGING WITH PHARMACOLOGICAL STRESS PERFUSION IN ASYMPTOMATIC PATIENTS WITH SYSTEMIC SCLEROSIS

P. Ruscitti[1], E. Di Cesare[2], P. Cipriani[3], A. Di Sibio[4], V. Liakouli[1], A. Gennarelli[4], F. Carubbi[1], A. Splendiani[4], O. Berardicurti[1], P. Di Benedetto[1], F. Ciccia[5], G. Guggino[5], G. Radchenko[6], G. Triolo[5], C. Masciocchi[4], R. Giacomelli[1]. *[1]Division of Rheumatology, University of L'Aquila; [2]Divison of Radiology, University of LAquila; [3]Divison of Rheumatology, University of L'Aquila; [4]Division of Radiology, University of L'Aquila, L'Aquila; [5]Division of Rheumatology, University of Palermo, Palermo, Italy; [6]Institute of Cardiology of Ukrainian National Academy of Medical Science, Kyiv, Ukraine*

**Background:** Systemic Sclerosis (SSc)-heart disease (SSc-HD), although often clinically silent, significantly reduces the life-expectancy in these patients [1]. The cardiac magnetic resonance (CMR) is recognized useful tool for the diagnosis of SSc-HD and cardiac stress tests might be a helpful technique to highlight the occult myocardial involvement, which cannot be detected at rest due to compensatory mechanisms [2,3].
**Objectives:** To evaluate the possible occult cardiac involvement in asymptomatic SSc patients by pharmacological stress, rest perfusion and delayed enhancement CMR, to identify as earlier as possible those patients at higher risk of cardiac related mortality and needing specific cardiovascular treatments.
**Methods:** Sixteen consecutive patients with definite SSc fulfilling the ACR/EULAR 2013 classificative criteria [4] in less than 1 year from the onset of Raynaud's phenomenon underwent pharmacological stress, rest perfusion and delayed enhancement CMR. No enrolled patient showed signs and/or symptoms suggestive for cardiac involvement, confirmed by both the 12-lead ECG examination and echocardiography. No patient showed traditional cardiovascular risk factors. Patients, in which CMR technique showed occult cardiac involvement, underwent to heart computed tomography (CT) scan to evaluate a possible coronary disease.
**Results:** Stress perfusion defects, in the left ventricle, were detected in 6 out of 16 (37.5%) patients. A sub-endocardial defects and/or a ventricular mid-myocardial layer stress perfusion defects were observed. Our results confirmed, in these 6 patients, a normal flow distribution of the explored coronary arteries by CT scan. The presence of CMR stress perfusion defects did not correlate with any clinical feature of patients.
**Conclusions:** Myocardial stress perfusion defects may be early detected, by pharmacological stress perfusion CMR, a reliable and sensitive technique for the non-invasive evaluation of SSc-HD, in patients with SSc of recent onset. These defects seems to be independent from traditional risk factors and associated comorbidities, suggesting that are a specific hallmark of the disease. An early detection of myocardial involvement might suggest starting of vasodilatative therapies in these patients.

## AB0631 PREVALENCE, SEVERITY AND CLINICAL SIGNIFICANCE OF PAIN IN PATIENTS WITH SYSTEMIC SCLEROSIS

P. Ostojic[1,2], K. Jankovic[2], N. Djurovic[1], B. Stojic[1], S. Knezevic-Apostolski[3], D. Bartolovic[4]. *[1]Institute of Rheumatology; [2]School of Medicine, University of Belgrade; [3]Outpatient neurological clinic "Apostolski"; [4]Clinic for Medical Biochemistry, Clinical Centre of Serbia, Belgrade, Serbia*

**Objectives:** To assess prevalence, severity and type of pain in patients with systemic sclerosis (SSc), and relationship with disease status, depression and quality of life.
**Methods:** 42 consecutive patients with SSc (38 women and 4 men), mean age 56.5 years, mean disease duration 9.5 years, were included in this study. 31 (73.8%) of patients had limited SSc (lSSc) and 11 (26.2%) diffuse form of disease (dSSc). ACA were positive in 15 (35.7%) and ATA in 17 (40.5%) patients. We assessed prevalence and severity of different types of pain (during attacks of Raynaud's phenomenon, pain caused by ischemic ulcers, odynophagia, arthralgia, headache, back pain and chest pain) in our patients. Presence of manifestations of neuropathic pain was assessed using the PainDetect questionnaire. Relationship among different types of pain with disease status, symptoms of depression and quality of life was estimated. Disease status was assessed using the Scleroderma Assessment Questionnaire (SAQ), occurrence of depressive symptoms by the Beck's Depression Inventory (BDI), whilst quality of life was evaluated using the EQ-5D index.
**Results:** Thirty nine patients (92.9%) reported different types of pain. 19 (45.2%) patients experience some form of pain every day. Arthralgia is the most common type of pain, present in 78.6% of patients, followed by pain during attacks of Raynaud's phenomenon (69%), back pain (47.6%), headache (31%), chest pain (23.8%), odynophagia (21.4%) and painful ischemic ulcers (19%). Pain caused by ischemic ulcers was reported as most severe (median 8.5 on a 0–10 scale). All types of pain were equally frequent in patients with lSSc and dSSc. However, joint pain was more intense (p=0.02) in patients with dSSc (7.6 vs. 5.5). The Index of Disease Statuts (IDS) positively correlated with severity of joint pain ($\rho$=0.66, $p<0.001$), but not with severity of other types of pain. Moreover, a significant correlation was noticed only between joint pain and the EQ-5D index ($\rho$=-0.52, p=0.009). On the other hand, a significant correlation between BDI index and intensity of pain during attacks of Raynaud phenomenon ($\rho$=0.49, p=0.007), pain caused by ischemic ulcers ($\rho$=0.81, p=0.016), odynophagia ($\rho$=0.73, p=0.026) and arthralgia ($\rho$=0.59, $p<0.001$) was observed. Compared to patients with intermittent pain, patients suffering from chronic pain have a significantly lower mean value of EQ-PD index (0.52 vs 0.79, z=-4.12, $p<0,001$) and a higer mean value of IDS (1.21 vs. 0.53, z=-3.32, p=0.001). Patient with manifestations of neurpathic pain have significantly higher mean values of IDS, BDI an EQ-5D index, than patients without neuropathic pain.
**Conclusions:** Pain is present in 92.9% of patients with SSc. Arthralgia is the most common type of pain. Although less frequent, pain caused by ischemic ulcers was reported as most severe. Intense joint pain, chronic pain and neuopathic pain are associated with more severe form of the disease and poorer quality of life. All types of pain have impact on development of depressive symtoms in patients with SSc.

## AB0632 ASSOCIATION BETWEEN INTERSTITIAL PULMONARY INVOLVEMENT AND MICROVACULATURE CHANGES IN SYSTEMIC SCLEROSIS

R. Bečvář[1], M. Tomcik[1], S. Skacelova[1], J. Stork[2], A. Slovakova[3]. *[1]Institute of Rheumatology; [2]Department of Dermatovenerology; [3]Department of Pulmonology, Praha 2, Czech Republic*

**Background:** Pulmonary disease is the leading cause of mortality in patients with systemic sclerosis (SSc). Baseline gas transfer (DLCO) and FVC levels have traditionally been used as measures of disease severity and reductions in both parameters have been associated with increased mortality in the interstitial lung disease of SSc. In SSc the reduced capillary density leads to a reduced blood flow, to tissue ischemia. Tissue hypoxia usually initiates the formation of new blood vessels from the pre-existing microvasculature. Nailfold capillaroscopy is a safe, noninvasive routine way for the microvascular investigation
**Objectives:** The aim of this study is to assess the association between capillaroscopic abnormalities and parameters of interstitial lung involvement in patients with SSc.
**Methods:** All patients underwent routine clinical examination (dyspnea, cough, crepitus), pulmonary function tests, DLCO (alveolitis grade and fibrosis), blood gases and HRCT scan of chest (1). Microvasculature changes were assessed using nailfold videocapillaroscopy (NVC) which was performed by two independent examiners. The obtained images were analysed anonymously by two investigators blinded for the clinical and serum status of SSc patients and classified as early, active and late pattern, non specific or normal picture (2). For statistical evaluation Poisson's correlation coefficient and T-test were used.
**Results:** Total 42 patients (38 females) were investigated: 30 individuals with limited form, 7 with diffuse, 3 patients with scleroderma sine scleroderma, 1 with overlap syndrome and 1 with undifferentiated connective tissue disease. The mean age ± standard deviation (SD) of the whole cohort was 51±22 years and the mean disease duration ± SD was 10±7 years. 3 patients (7.5%) had early NVC pattern, 12 patients (30%) had active, 10 (58%) late pattern, and 17 (37.5%) had nonspecific changes or normal picture. The patients with late NVC pattern exhibited more often mild to moderate alveolitis, decreased FEV1 and FVC and DLCO. When correlating NVC patterns with clinical findings, pulmonary function test and HRCT scans we found only an association of low significance with dyspnea and alveolitis grade (both $p<0.1$).
**Conclusions:** In our study NVC patterns did not seem to correlate with severity of interstitial lung disease in SSc patients

## AB0633 PERFORMANCE OF THE EULAR/ACR 2013 CLASSIFICATION CRITERIA IN A PORTUGUESE SYSTEMIC SCLEROSIS POPULATION

R. Fonseca[1], D. Rosa-Gonçalves[1], F. Aguiar[1], T. Meirinhos[2], T. Martins-Rocha[1], E. Mariz[1], M. Bernardes[1], L. Costa[1]. *[1]Rheumatology, São João Hospital Centre, Oporto; [2]Rheumatology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal*

**Background:** The 1980's ACR classification criteria for systemic sclerosis (SSc) show low sensitivity, especially in early or mild forms. A new set of classification criteria has been developed by ACR/EULAR in 2013. Applicability of the new criteria in clinical practice remains to be shown.
**Objectives:** To evaluate the performance of both set of classification criteria for SSc in a Portuguese SSc population.
**Methods:** Cross-sectional study including consecutive patients with clinical diagnose of SSc (based on expert opinion) followed in our rheumatology department. Clinical and demographic characteristics were collected by consulting the clinical files and national data base – Reuma.pt. The two sets of criteria were applied to all patients, sensitivity was calculated and Kappa coefficient was used to evaluate the agreement between them. Patients not fulfilling the old but fulfilling the new criteria were compared with those that fulfilled ACR criteria using Mann-Whitney, qui-square and fisher test (SPSS 23.0). Significance level was set as $<0.05$.
**Results:** 108 patients were included, 96 (88.9%) were female with mean age of 58.21 (±12.8) years and a median disease duration of 6 years (0–38). 96 (88.9%) had localized and 12 (11.1%) had diffuse disease form. The most prevalent criteria items were: Raynaud's phenomenon (93.5%), sclerodactyly of the fingers (85.2%) and antinuclear antibodies (94.4%).
For overall cohort, 53 patients (49.1%) fulfilled the old ACR criteria. These 53 patients and more 44 patients (97) fulfilled the new ACR/EULAR criteria, showing a sensitivity of 89.9% compared to 49.1% of the old ones. Kappa coefficient was 0.197 (p=0.01).
In patients with localized forms, the sensitive of ACR/EULAR criteria was 88.5% compared with 43.8% of ACR 1980 criteria and Kappa coefficient was 0.183 (p=0.02).
In diffuse forms, all 12 patients fulfilled both criteria set, showing an almost perfect agreement.
Patients not fulfilling the old but fulfilling the new criteria presented more frequently with capillaroscopic abnormalities (p=0.04) and anticentromere antiboy (p=0.01), but low incidence of anti-Scl70 antibodies ($p<0.001$) and interstitial lung disease ($p<0.001$).
**Conclusions:** Our study confirmed a greater sensibility of the new ACR/EULAR 2013 criteria compared with ACR 1980 criteria, especially in mild and localized SSc disease forms. In our patients with SSc not fulfilling the old criteria, the presence of capillaroscopic abnormalities and anticentromere antibodies among the new set of classification criteria were of the utmost importance in their reclassification as SSc patients. The application of the new criteria in clinical scenario allows an early classification and timely management of more SSc patients, ensuring a better prognosis.

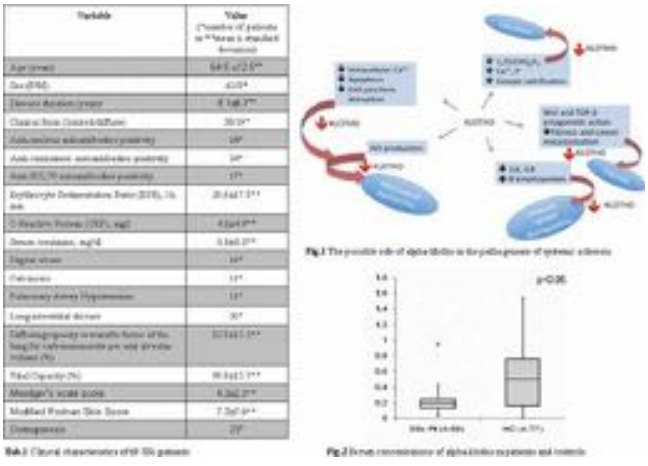
## AB0634 SURVIVAL AND CAUSES OF DEATH IN A PORTUGUESE POPULATION WITH SYSTEMIC SCLEROSIS



R. Fonseca[1], D. Rosa-Gonçalves[1], F. Aguiar[1], T. Meirinhos[2], T. Martins-Rocha[1], E. Mariz[1], M. Bernardes[1], L. Costa[1]. *[1]Rheumatology, São João Hospital Centre, Oporto; [2]Rheumatology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal*

**Background:** Systemic sclerosis (SSc) is known for its poor prognosis. However, it is apparent that subsets of patients have bad outcomes sometimes after a short time of disease duration whether some others will remain stable with a milder disease. The factors that have impact in the prognosis and mortality are yet to be determined.
**Objectives:** To study the causes of dead and survival predictors in a Portuguese SSc population.
**Methods:** Observational retrospective cohort study was performed including consecutive patients with clinical diagnosis of SSc (based on expert opinion), followed in our rheumatology department since 1990. Clinical and demographic characteristics were retrospectively collected by consulting the clinical files.
Patients who have died were compared with the others using Student t-test, Mann-Whitney test, Chi-square or Fisher test. Kaplan-Meier survival analysis and log rank were used to compare survival (SPSS 23.0). Significance level was set as $<0.05$.
**Results:** 114 patients were included, 99 (86.8%) females and 15 (13.2%) males, with a mean age of 57.61 (±11.3) and a median disease duration of 7 years (0–38). 100 (87.7%) had localized and 14 (11.1%) had diffuse disease form.
The mortality rate observed was 1.1 cases per 100 person-years. Among the 10 patients that have died, 60% (6) were female, 60% (6) had diffuse and 40% (4) had limited skin involvement, and 20% (2) had overlap syndromes (1 overlap with rheumatoid arthritis and 1 with systemic lupus erythematosus). The median age was 63.5 [57 – 84] years and median disease duration was 10 [1–20] years.
The causes of death were: infections in 5 (3 sepsis, 1 septic arthritis, 1 pneumonia), cardiovascular events in 3 (right heart failure secondary to pulmonary arterial hypertension) and neoplasia in 2 (1 brain metastases of occult tumour and 1 gastric adenocarcinoma).
Mortality occurred more frequently in male patients (26.7% compared to 6% in females, p=0.03), in patients with diffuse skin involvement (40% compared to 4% in limited forms, $p<0.001$), digital ulcers (16.7% compared to 5%, p=0.04), pitting scars (20.6% compared to 3.8%, p=0.007), pulmonary arterial hypertension (50% compared to 6.5%, p=0.009), interstitial lung disease (19.2% compared to 5.7%, p=0.04) and anti-Scl70 antibodies (20.8% compared to 5.6%; p=0.03).
Kaplan-Meier univariate analysis showed a lower survival in patients with diffuse skin involvement (log rank 14.2 $p<0.001$), interstitial lung disease (log rank 6.3 p=0.04) and positive anti-Scl70 antibodies (log rank 6.4 p=0.04).
**Conclusions:** Our results are in accordance with previous studies that show a high frequency of infections and cardiovascular events as major causes of death, but we also find malignancy as an important factor too. Diffuse skin disease, interstitial lung disease and positive anti Scl70 unfavourably influenced the survival and these patients are the ones in need for carefully evaluation and aggressive treatment.

## AB0635 MEASUREMENT OF SERUM ALPHA-KLOTHO IN SYSTEMIC SCLEROSIS PATIENTS: RESULTS FROM A PIVOTAL STUDY

R. Talotta[1], F. Atzeni[1], S. Bongiovanni[1], M.C. Ditto[1], T. Letizia[2], T. Vago[2], V. Varisco[1], F. Rigamonti[1], A. Batticciotto[1], M. Antivalle[1], P. Sarzi Puttini[1]. *[1]Rheumatology Unit, University Hospital "Luigi Sacco"; [2]Endocrinology and Rheumatology Laboratory, University Hospital "Luigi Sacco", Milan, Italy*

**Background:** Systemic sclerosis (SSc) is a connective tissue disease characterized by microangiopathy and fibrosis involving skin and inner organs. Furthermore, an aberrant activation of the immune system may contribute, at least in part, to the pathogenesis of the disease. Klotho, expressed both as transmembrane and soluble protein, contributes to prevent ageing, hyperphosphatemia, fibrosis, arteriosclerosis, inflammation, and cancer development. Mice lacking klotho gene expression develop an accelerated ageing, with different phenotypes ranging from atherosclerosis and hyperphosphatemia to skin atrophy and emphysema. A deficiency in klotho expression could be responsible for microangiopathy, calcinosis and fibrosis, which represent common characteristics of systemic sclerosis (fig. 1).
**Objectives:** To evaluate the serum concentration of a-klotho in a group of SSc patients compared to healthy controls and to correlate its levels with the degree and the kind of organs involvement, assessed through Mesdger's scale score.
**Methods:** We enrolled 69 patients affected by SSc, according to ACR/EULAR 2013 criteria, and 77 matched HC. Blood samples obtained from both patients and controls were collected and analysed by an ELISA test for the determination of human soluble a-klotho by using an anti-human Klotho Mouse IgG (My Biosource, CA, USA). Scleroderma patients were assessed for disease activity through Mesdger's scale. Moreover, modified Rodnan Skin Score (mRSS), pulmonary function tests, 2D echocardiography, chest high resolution computerized tomography, serum creatinine level, ESR, and CRP were also assessed. Subjects suffering from uncontrolled diabetes, lung obstructive diseases or renal impairment not depending on systemic sclerosis were excluded.
**Results:** Our cohort consisted of 69 SSc patients (61 females, mean age 64.5±12.5 years, mean disease duration 9.1±6.7 years) and 77 healthy controls (28 females, mean age 49,7±10,2 years). Demographic data are reported in tab.1. Patients were treated with calcium channels blockers (21 cases), i.v.prostanoids (all), immunosuppressive drugs (prednisone in 22 cases; hydroxychloroquine in 14 cases; mofetilmycophenolate in 3 cases; methotrexate in 6 cases; cyclosporin A in 1 case; azathyoprine in 5 cases). Overall, SSc patients have lower serum

klotho concentration than healthy controls (0.45 + 0.43 ng/ml vs 0.59 + 0.39 ng/ml; p=0.023197; fig.2). However, in SSc patients Spearman test did not reveal a significant association between the serum concentration of klotho and Mesdger's scores. Furthermore, we did not find any association among klotho levels and mRSS, DLCO/AV, serum creatinine, disease duration, age of the patients, ESR and CRP.
**Conclusions:** To our knowledge, this is the first study aiming to investigate the serum concentration of klotho in SSc patients. Our data showed a lower concentration of klotho in the serum of SSc patients compared to healthy controls. However, klotho levels were not related to the severity of the disease, assessed through Mesdger scale, neither to lung or kidney functional impairment, skin fibrosis or systemic inflammation.

## AB0636 INTERSTITIAL LUNG DISEASE IN SCLERODERMA PORTUGUESE PATIENTS

S.I. Sousa[1], A. Duarte[1], I. Cordeiro[1], L. Teixeira[1], J. Canas da Silva[1], A. Cordeiro[1], M.J. Santos[1,2]. *[1]Rheumatology, Hospital Garcia de Orta, Almada; [2]Rheumatology Research Unit, Instituto de Medicina Molecular, Lisboa, Portugal*

**Background:** Systemic sclerosis (SSc) is a rheumatic disorder characterized by inflammation and fibrosis involving the skin as well as internal organs, including the lung.
**Objectives:** This study was conducted to characterize SSc patients with ILD and determine predictor features for the presence of ILD.
**Methods:** A retrospective evaluation of SSc patients from our Rheumatology department was undertaken. ILD was defined according to imaging findings in high-resolution CT (HRCT) combined with functional parameters. Demographic features, auto-antibodies, spirometry, diffusion capacity for carbon monoxide (DLCO) measurement, echocardiography and 6-minute walk test were compared between groups with and without ILD using parametric tests and non-parametric tests. Predictor factors were established by logistic regression analyses.
**Results:** One hundred and three SSc patients with current mean age of 60.2±14.1y and mean disease duration of 10.0±9.6y were evaluated. Thirty-four (35.8%) patients were diagnosed with ILD, of whom 13 had limited cutaneous SSc, 14 had diffuse cutaneous SSc, 2 sine sclerodema and 5 overlap syndroms. ANA was positive in 100% cases, anti-Scl70 was found in 55% and anti-centromere antibody positivity was found in 15% of patients. HRCT revealed diffuse parenchymal lung disease involvement >20% in 18 (53%) cases, with the majority showing a predominant honeycombing pattern. Spirometry showed a restrictive pattern in 8 patients and 1 had obstruction. The DLCOsb was abnormal in 7 patients. Three patients had pulmonary hypertension confirmed by right heart catheterization, 2 patients classified as group 1 and 3 and 1 patient of group 5. About 63% of ILD patients were ever treated with corticosteroids and 27% with cyclophosphamide, which were the most common drugs used. Two patients were also treated with rituximab. In this ILD-group, 5 deaths were recorded, 2 due to cancer, 1 abdominal sepsis, 1 pulmonary hypertension and 1 of unknown cause. Comparison of these ILD patients with non-ILD patients revealed some significantly differences (Table 1).

Table 1. Statistically significant distinctions between patients with and without ILD

| | ILD patients (n=34) | No-ILD patients (n=61) | *P* |
|---|---|---|---|
| Current mean age (years) | 61.8±14.5 | 58.6±13.2 | 0.330 |
| Mean disease duration (years) | 11.6±9.8 | 9.2±9.3 | 0.250 |
| Anti-centromere antibody (%) | 5 (15) | 48 (79) | **<0.001** |
| Anti-Scl70 antibody (%) | 18 (55) | 4 (7) | **<0.001** |
| Diffuse cutaneous disease (%) | 14 (41) | 5 (8) | **<0.001** |
| Digital ulcers (%) | 19 (54) | 11 (18) | **<0.001** |
| NYHA Functional Classification (%) | 23 (67) | 30 (49) | **0.017** |
| Tricuspid regurgitation (%) | 26 (84) | 24 (45) | **0.001** |
| DLCOsb <60 (%) | 7 (64) | 0 (0) | 0.056 |
| Hypoxemia at rest (%) | 8 (27) | 4 (7) | **0.013** |
| Gastrointestinal involvement (%) | 10 (48) | 9 (24) | 0.060 |
| Death (%) | 5 (16) | 1 (2) | **0.020** |

Multivariate analysis showed that digital ulcers (OR=31.6, 95% CI 3.09 to 321.91), Anti-Scl70 antibody positivity (OR=10.1, 95% CI 1.19 to 85.74) and anti-centromere antibody negativity (OR=0.08, 95% CI 0.01 to 0.83) were independently associated with the presence of ILD.
**Conclusions:** This study is one of the first studies carried out in Portugal regarding lung involvement in SSc. About one third of the patients had ILD, whose main characteristics are in accordance with other European cohorts. We confirmed that anti-SCL70 positivity, presence of digital ulcers as well as the absence of anti-centromere antibody is independently associated with ILD
**Disclosure of Interest:** None declared

## AB0637 ILOPROST (ILO) IN SYSTEMIC SCLEROSIS (SSC): THE SAFETY EXPERIENCE OF TWO ITALIAN CENTRES

S. Guiducci[1], S. Bellando-Randone[1], C. Bruni[1], D. Giuggioli[2], M. Colaci[2], F. Lumetti[2], G. Lepri[1], G. Fiori[1], F. Bartoli[1], C. Ferri[2], M. Matucci-Cerinic[1]. *[1]Department of experimental and clinical medicine, division of Rheumatology, University of Firenze, Firenze; [2]Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy*

**Background:** Iloprost (ILO) is a synthetic analogue of prostacyclin $PGI_2$ with a potent vasodilator action, an anti-proliferative effect on smooth muscle cells and inhibition of platelet aggregation. ILO is employed intravenously for the control of Raynaud Phenomenon and digital ulcers. Up to now, no agreement has been reached on the regimen (dosage and frequency) to be used in SSc patients.
**Objectives:** To identify the most common side effects that are developed during ILO infusion in SSc.
**Methods:** 81 SSc patients, classified according to ACR EULAR criteria, derived from two Italian centers, were submitted to ILO infusion: patients were subclassified according to the edematous or fibrotic/atrophic phase of the disease. ILO was infused (6–8 hour infusion, dose ranging from 0.5 to 1.0 ng/kg/ min) (1) with a progressive increase of the dosage up to the achievement of patient's tolerance: the infusion on pump was started at 5 ml/hour and increased every half an hour up to 20 ml/hour (a dose of 4 mcg/h which corresponds to 1ng/kg)according to patients tolerance and appearance of side effects.
**Results:** Out of 81 patients, 16 were in the *edematous phase* with puffy fingers (digital edema). In this cohort, 5 individuals (31.2%) developed diarrhea and 9 (56.2%) developed hypotension during the infusion. When the drug was withdrawn patients had an immediate amelioration but when ILO was restarted, they again developed diarrhea or hypotension that led to definitive interruption of the treatment. Moreover, 10/16 patients (62.5%) experienced significant and painful digital swelling which led to the tapering of the infusion dosage below 10 ml/hr (which corresponds to 0.5 ng/kg per min); out of 10 patients, only one could continue the treatment while the other 9 had to be withdrawn due to the maintenance of the intense digital pain due to vasodilation. Finally, 11 patients (68.7%) reported flushing and 7 (43.7%) headache, but they were always controlled with the reduction of the infusion below 10 ml/hr. Out of 81 patients, 65 were in the *atrophic/ fibrotic phase:* 10 patients (15.3%) developed diarrhea and 24 pts (37%) hypotension that led to temporary withdrawal: when ILO was restarted and kept below 10 ml /hr, no side effects were experienced. In 23 cases (35.3%) flushing and in 8 cases (12.3%) headache were experienced, but were well controlled with infusion reduction below 10 ml/hr.
**Conclusions:** ILO was well tolerated in SSc patients characterized by fibrotic phase, where side effects could be managed by reducing/modulating the infusion rate. In edematous patients, ILO infusion should be decided in case where the severity of Raynaud's phenomenon or the presence of digital ulcers strongly suggests its use.

## AB0638 A REDUCED LOWER ESOPHAGEAL SPHINCTER PRESSURE PREDICTS A HIGHER GASTROESOPHAGEAL REFLUX DISEASE QUESTIONNAIRE SCORE IN SYSTEMIC SCLEROSIS PATIENTS

S. Vettori[1], D. Capocotta[1], V. Giacco[1], R. Chieffo[1], S. Tolone[2], L. Docimo[2], G. Valentini[1]. *[1]Internal and Experimental Medicine; [2]Surgery, Second University of Naples, Naples, Italy*

**Background:** A reduced basal lower esophageal sphincter (LES) pressure (LES<15 mmHg) is recognized as an early finding of esophageal involvement in systemic sclerosis (SSc) patients (1).
**Objectives:** We aimed to investigate potential associations of a reduced basal LES pressure at first observation with the development of new gastrointestinal symptoms and with self-administered questionnaires devoted to assess the impact of gastrointestinal involvement on quality of life during follow-up (FU) in SSc patients.
**Methods:** SSc patients meeting the 2013 ACR/EULAR criteria for disease classification with measurement of basal LES pressure at the first observation and at least one FU visit with complete clinical evaluation were enrolled. The gastroesophageal reflux disease questionnaire (GerdQ) (2, 3) was administered to explore the impact of esophageal symptoms on patient's disease perception and to estimate the risk for GERD. Associations between reduced basal LES pressure and new onset gastrointestinal symptoms at FU were analyzed by Fisher's exact test, while the GerdQ score in SSc patients with or without a reduced basal LES pressure was analyzed by Mann-Whitney U test.
**Results:** Fifty-nine SSc patients, aged 47±13 years, were investigated (75% females; median disease duration 7 years, range 0.5–43). Eighty % of patients had a limited SSc subset (lcSSc); 20% had a diffuse subset (dcSSc). All patients were ANA positive (36% had anti-centromere antibodies, 39% anti-Scl70+; 5% anti-RNApolymerase III; 1.7% anti-PmScl; 1.7% anti-U1RNP). All patients were

under proton pomp inhibitors ± prokinetics during FU. Forty-two % of patients had already esophageal symptoms at baseline; 32% developed new esophageal symptoms and 40% new gastric and/or intestinal symptoms during observation (median FU 4 years; range 0.5–15.5). Baseline basal LES pressure was reduced in 63% of patients. Out of these, 49% had also esophageal symptoms. Median GerdQ score at the end of FU was significantly higher in patients with baseline reduced LES pressure (7, range 3–14 versus 6, range 2–11; $p<0.001$). However, even though patients with baseline reduced LES pressure had a higher prevalence of a GerdQ score higher than 7, indicating an impact of esophageal symptoms on their quality of life (12/37 versus 4/22), this difference was not statistically significant.

**Conclusions:** Our data suggest that evaluation at baseline of esophageal involvement in SSc patients by esophageal manometry can predict the development of more severe symptoms over time, as evaluated by the association with a higher score at GerdQ also in initially asymptomatic patients. Larger studies need to be carried out to confirm this association.

## AB0639 BONE MINERAL DENSITY IS DECREASED IN PATIENTS WITH SYSTEMIC SCLEROSIS AND CORRELATES WITH SERUM IPTH LEVELS: A CROSS SECTIONAL STUDY

S.K. Sharma, S.K. Sharma. *Internal Medicine, post graduate institute of medical education and research, Chandigarh, Chandigarh, India*

**Background:** Systemic sclerosis is a multisystemic disease with devastating consequences. It is believed that osteoporosis is common in systemic sclerosis with causation being ascribed to the altered GI motility, malabsorption, immobility, use of glucocorticoids among other factors. A few studies have looked at osteoporosis and associated factors in patients with systemic sclerosis, however results are conflicting [1–2].

**Objectives:** The aim was to study the bone mineral density (BMD) in patients with systemic sclerosis and its correlation with organ involvement.

**Methods:** Patients attending the Rheumatology Clinic at PGIMER, Chandigarh were screened and 100 patients meeting the American College of Rheumatology (ACR) criteria for systemic sclerosis were recruited for the study. In all such patients, BMD was measured using dual energy xray absorptiometry (DXA). Serum Vitamin D and iPTH levels were estimated.

**Results:** Most of the participants were females (8:1). The mean age of the participants was 42±12 years. The median disease duration prior to recruitment was 5 years (3–8 years). Thirty four of eighty nine women were post menopausal at the time of conducting the study. 48% of patients had interstitial lung disease while 18% had pulmonary arterial hypertension. 56% had received corticosteroids while 16% had received cyclophosphamide. Most patient received 7.5 mg of corticosteroids intitially and the dose was tapered to 5mg once a day and then to alternate days and subsequently was stopped. Cyclophosphamide was given as a monthly pulse for 6 months when indicated. Among patients included, 72% of patients had a low bone mass at the spine while 42% had a low bone mass at the femoral neck. In all, 28% had osteoporosis of the lumbar spine while 6% had osteoporosis of the femoral neck. 41 patients exhibited hypocalcemia. Serum iPTH levels were elevated with a median value of 76.24 (50.26–102.675) pg/ml. Serum iPTH correlated inversely with low bone mass at the hip ($p=0.023$, $r^2=0121$). We did not find a correlation with increasing age, postmenopausal status, low BMI, corticosteroid use, serum 25(OH) Vitamin D levels, disease duration, presence of ILD or PAH.

**Conclusions:** Low bone mass is highly prevalent in patients with systemic sclerosis and correlates inversely with Serum iPTH levels. Serum iPTH levels may be an important marker for early diagnosis of osteoporosis in these patients and may help in timely institution of anti resorptive measures, hopefully, before the occurrence of fragility fractures

## AB0640 CAROTID INTIMA MEDIA THICKNESS IS INCREASED IN PATIENTS OF SYSTEMIC SCLEROSIS: CROSS SECTIONAL, CASE-CONTROL STUDY

S.K. Sharma, A. Dhooria, V. Kumar, S. Singh. *Internal Medicine, post graduate institute of medical education and research, Chandigarh, Chandigarh, India*

**Background:** Atherosclerosis is a leading cause of cardiac and non-cardiac related morbidity and mortality in SSc[1]. It is believed to occur secondary to chronic inflammation, altered lipid profiles and function, development of autoantibodies, and endothelial dysfunction. There is increasing evidence that atherosclerosis occurs prematurely in systemic sclerosis [2–3].

**Objectives:** The aim was to describe the parameters of subclinical vascular changes [Carotid Intima Media Thickness (cIMT), Flow Mediated Dilatation (FMD), Ankle Brachial Pressure Index (ABPI)] in patients with systemic sclerosis and compare them with age and sex matched controls.

**Methods:** 50 patients of systemic sclerosis aged 20–50 years were selected and compared with the same no. of age and sex matched controls. Patients with diabetes, hypertension, dyslipidemia, smoking and thyroid disorders were excluded. cIMT was calculated using a linear probe (L 12–5 MHz) on a Philips iU 22 ultrasound machine at a distance of 2 cm from the carotid bulb. A mean of the left and right cIMT was calculated. Endothelium-dependent FMD of brachial artery was expressed as the percentage change in brachial artery diameter from baseline. The average of the right and left brachial artery FMD was studied. ABPI of both right and left lower limb was measured (using Doppler) and the average value of ABPI was considered.

**Results:** The cases and controls were well matched in terms of age, blood pressure, B.M.I, renal and liver functions, and lipid profiles. 16 patients had limited cutaneous SSc while 36 had diffuse cutaneous SSc. cIMT was significantly more in SSc patients as compared to controls (0.585 mm *vs* 0.571 mm; p=0.001). FMD measurements in SSc patients were lower when compared to controls, but they did not achieve statistical significance (7.61% *vs* 8.03%; p=0.608). ABPI values were similar in SSc patients and controls (1.056 vs 1.036; p=0.398). cIMT did not show any correlation with age or duration of illness. ABPI showed significant inverse correlation with duration of illness (Rho= -0.385; p=0.006). However, none of these parameters varied as per the pattern of skin involvement (diffuse vs limited), presence or absence of digital infarcts or pulmonary fibrosis.

**Conclusions:** cIMT is increased in patients with systemic sclerosis as compared to matched controls and may serve as a useful marker for detection of subclinical atherosclerosis in these patients. ABPI varies inversely with disease duration in patients with systemic sclerosis.

## AB0641 THE ROLE OF ORO-PHARYNGEAL-ESOPHAGEAL SCINTIGRAPHY IN THE EVALUATION OF THE SWALLOWING FUNCTION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: SHORT-TERM RESULTS OF AN ONGOING PROSPECTIVE STUDY

S. Barsotti[1,2], G. Puccini[3], A. Tripoli[1], R. Talarico[1], D. Volterrani[3], M. Mosca[1], R. Neri[1], M. Grosso[3]. *[1]Rheumatology Unit - University of Pisa, Pisa; [2]GenOMeC Doctorate - University of Siena, Siena; [3]Regional Center of Nuclear Medicine - University of Pisa, Pisa, Italy*

**Background:** Dysphagia represents a major burden in IIM patients. OPES is a safe, reliable and repeatable technique, which allow a semi-quantitative scoring of oropharyngeal (OP) and esophageal (E) involvement. OPES is widely used in neuromuscular diseases and could replace other traditional imaging techniques, such as esophageal x-ray, which is difficult to repeat, allows only qualitative examination and exposes patients to risk of aspiration pneumonia.

**Objectives:** The primary aim of our study was to explore prevalence of upper gastrointestinal abnormalities in IIM using OPES. Secondary aim was to correlate the presence of alterations detected by OPES with disease activity and dysphagia in IIM patients.

**Methods:** Twenty-eight IIM patients were enrolled (M:F=3:25; 11 dermatomyositis, 15 polymyositis, 2 inclusion body myositis; mean age: 60±14.7 years; mean disease duration: 52±44 months). Each patient underwent a disease activity evaluation: physician's and patients' visual analogue scale (phVAS and ptVAS), health quality assessment questionnaire, manual muscle test 8 (MMT8) and serum creatine kinase. Dysphagia was assessed by a validated patients reported outcome questionnaire, the "MD Anderson dysphagia inventory" (MDADI), which classifies dysphagia as not present, mild, moderate, severe and total disability.

Dysphagia parameters, assessed by OPES after 10 ml liquid (L) or semi-solid (SS) bolus labelled with 99mTechnetium-nanocolloid intake, were: pre-deglutition penetration, aspiration, OP and E transit time and retention index (RI). OP-RI was classifiable by a 4 grade scale: no retention (<8% of the swallowed bolus), mild (9–20%), moderate (21–40%) and severe retention (>40%), while E-RI was classifiable by a 3 grade scale: no retention (<20%), mild (20–45%) and severe retention (>45%).

**Results:** According to MDADI score, 10 patients (36%) presented no dysphagia, 12 (43%) mild, 4 (14%) moderate and 2 (7%) severe disability.

OPES showed a normal OP and E transit time in all patients.
OP-RI or E-RI were altered in almost all patients, and, both after L and SS bolus, RI was altered in 25 patients. In the 10 patients with no dysphagia symptoms, IR alterations for L and SS bolus were detected respectively in 9 and 7 patients.
Correlations with statistical significance between disease activity parameters and MDADI index were found for phVAS and ptVAS ($p$=0.032 and $p$=0.017) and MMT8 ($p$=0.014), while E-RI correlated with MMT8 ($p$=0.007).
Moreover, 13 patients presented uncoordinated movement at proximal and medium esophagus and 2 patients presented SL bolus inhalation. No patients presented pre-deglutition penetration.
**Conclusions:** Dysphagia represents a major disabling feature in 64% of IIM patients and is associated with disease activity. From the clinical point of view, OPES allows to identify subclinical involvement in almost all patients examined, even if no symptoms were reported by the patients. Greater sample size and, above all, prospective clinical follow-up will clarify the clinical meanings of the alterations detected by OPES and their prognostic value.

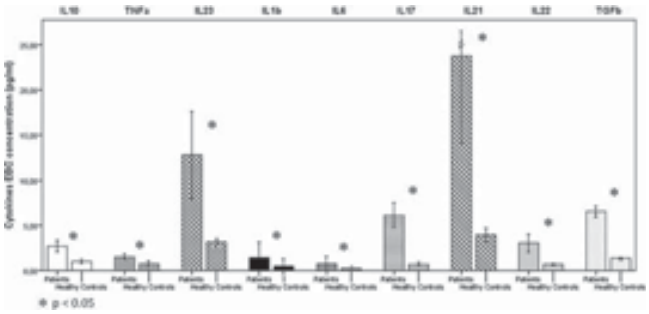
## AB0642 LARGE VESSEL INVOLVEMENT IN LIMITED AND DIFFUSE SYSTEMIC SCLEROSIS: A PULSE WAVE VELOCITY STUDY



S. Parisi[1], C. Ballini[1], M. Priora[1], A. Milan[2], F. Tosello[2], C.L. Peroni[1], F. Veglio[2], E. Fusaro[1]. *[1]Rheumatology Unit; [2]Internal Medicine Division and Hypertension Unit – Department of Medical Sciences – University of Turin, Azienda Ospedaliero Universitaria Città della Salute e della Scienza, Turin, Italy*

**Background:** Systemic Sclerosis (SSc) is a chronic inflammatory autoimmune disease of the connective tissue characterized by vasculopathy and progressive fibrosis thickening of the skin and internal organs. Vascular damage is recognized as a diagnostic landmark in SSc, both in its limited and diffuse form. Micro- and macro-vascular damage have been involved in the pathology; early detection may be helpful in therapeutic planning and management. Subclinical cardiac damage can be detected with transthoracic echocardiography (TTE) while arterial stiffness can be measured by Pulse wave velocity (PWV). Both have been shown to have an independent predictive value in cardiovascular risk stratification. However it is not yet clear whether they are actually present and detectable in SSc patients, or if an association with a specific subtype exists (1).
**Objectives:** to evaluate the presence of subclinical cardiac organ damage in patients with limited and diffuse SSc, in comparison with a cohort of healthy individuals.
**Methods:** Patients with limited and diffuse SSc referred to the Rheumatology Unit in our Hospital, in according to 2013 ACR/EULAR Classification Criteria, were enrolled. The study was conducted in accordance with the Declaration of Helsinki and approved by our Ethics Committee. All patients underwent a complete transthoracic echocardiogram, and PWV evaluation, which were performed in agreement with the last International Guidelines (2). Past medical history and risk factors, clinical and biochemical data were collected. 23 healthy subjects, similar for demographic characteristics, were used as controls.
**Results:** 41 patients (35 female,age 56.9±13.6 years), 21 with diffuse and 20 with limited SSc were recruited. Past medical history, cardiovascular risk factors, gender distribution and disease duration were similar in the two subgroups with no statistically differences. Patients with limited SSc were mean of 10 years older than patients with diffuse SSc. TEE parameters – left ventricular remodeling, atrial enlargement, diastolic disfunction - and hemodynamic indexes – PWV (6.5 [6;6.8] vs 7.0 [6.2;8.5], p=0.24) and Augmentation index (145.6±14.2 vs 149±20.6,p=0.52) did not show significant difference. Indeed, in the regression analysis, PWV was correlated to age (rho=0.60,p<0.001). When compared with healthy controls, again no significant difference emerged, considering echocardiographic and hemodynamic indexes.
**Conclusions:** In SSc, PWV seems to increase in according to age, with no additional impact of the specific pathology nor subtype. Vascular damage in the SSc population is likely not reflected in increased arterial stiffness or subclinical cardiac damage. Evaluation of SSc patients with PWV and TEE should not be routinely performed.

## AB0643 TH-17 CYTOKINES AND INTERSTITIAL LUNG INVOLVEMENT IN SYSTEMIC SCLEROSIS

S. Nicola[1], E. Fusaro[2], G. Rolla[3], C. Bucca[1], C. Peroni[2], E. Heffler[4], M. Cassinis[5], A. Ferraris[5], M. Boita[1], S. Parisi[2], L. Brussino[1]. *[1]Medical Science, University of Turin; [2]Rheumatology Unit, AOU Città della Salute e della Scienza; [3]Medical Science, Università degli studi di Torino; [4]University of Turin, Turin, Italy; [5]Department of Radiology, University of Turin, Turin, Italy*

**Background:** T Helper 17 (Th17) cytokines play an important pathogenetic role in most of autoimmune diseases, but their role in lung impairment in systemic sclerosis (SSc) is still poorly known.
**Objectives:** We aim to evaluate whether Th17-related cytokines are detectable in serum and in exhaled breath condensate (EBC) of patients affected by SSc and whether their concentrations are related to clinical parameters of lung impairment in diffuse SSc.
**Methods:** The outpatients with SSc according to ACR criteria attending Clinic of Rheumatic Disease, Città della Salute e della Scienza in Turin, between May 2014 and March 2015 were enrolled into the study, as well as a group of healthy non-smokers subjects, enrolled as controls. The study was approved by ethical committee and each patient released his informed consent; smokers, patients with asthma, COPD, history of cancer or other autoimmune diseases, current corticosteroids or immunosuppressive drugs therapy, recent (last 8 weeks) or current airway or systemic infection were excluded from the study. All patients underwent pulmonary function tests: spirometry, flow-volume curves, residual volume and diffusing capacity of the lung for carbon monoxide (DLCO), thoracic CT-scan analysed according to Global Warrick score and six minutes walking tests (6MWT). EBC and blood samples were collected in all the patients and controls. Serum and EBC Th-17 related cytokines (IL-17A, IL-21, IL-22, IL-23, IL-1β), TGF-β, TNF-α, IL-6 and IL-10 were measured using an xMAP technology and analysed by a multiplex immunoassay.
**Results:** 29 outpatients affected by SSc were enrolled, as well as 20 healthy controls.
17 patients (1 male) were affected by limited SSc (lSSc) and 12 (no men) were affected by diffuse SSc (dSSc); the mean age was 64.5±15.5 yrs. All serum cytokines were significantly higher in patients than in controls ($p<0.05$), except for IL-1β (p=0.063) and TGF-β (p=0.900); all EBC cytokines were significantly higher in patients than controls ($p<0.05$). No difference in serum cytokines concentrations was observed between lSSc and dSSc, while all Th17-related cytokines in EBC were significantly higher in dSSc than in lSSc ($p<0.05$).
In dSSc, serum IL-10 levels were significantly correlated with CT Global Warrick score (p=0.007, r=0.730), with DLCO (r=-0.664, p=0.018) and with 6MWT (r=-0.857, p=0.001).
Serum TNF-α and IL-23 levels significantly correlated with the CT Global Warrick score (r=0.699, p=0.011 and r=0.659, p=0.020 respectively) and IL-23 also correlated with FVC (r=-0.578, p=0.049). In EBC, IL-1β significantly correlated with CT Global Warrick score (r =0.434, p=0.016) and with DLCO (r=-0.492, p=0.007), while IL-17 negatively correlated with DLCO (r=-0.394, p=0.042).

**Conclusions:** In conclusion, our results show a correlation between Th-17 cytokines measured in serum and in EBC, with interstitial lung involvement of patients with diffuse SSc, underlining the importance of targeting these cytokines in the development of new therapeutic approaches against lung fibrosis.

## AB0644 SUBCLINICAL HEARING LOSS IN SYSTEMIC SCLEROSIS PATIENTS: RELATION TO DISEASE SEVERITY

T.A. Gheita[1], H. Fathi[2], M. El-Akkad[3]. *[1]Rheumatology and Clinical Immunology, Faculty of Medicine, Cairo University, Cairo; [2]Rheumatology; [3]Audiology, Faculty of Medicine, Fayoum University, Fayoum, Egypt*

**Background:** Systemic sclerosis (SSc) is one of the most complex systemic autoimmune diseases[1]. Ear involvement is not uncommon and should be taken into consideration during diagnostic and therapeutic procedures of SSc[2]
**Objectives:** The aim of the present study was to assess hearing in asymptomatic SSc patients and correlate the findings with clinical characteristics and disease severity.

**Methods:** The study included 35 female SSc patients and 35 matched controls. Skin thickness was assessed using modified Rodnan skin score (mRSS) and disease activity by Medsger severity score (MSS). Audiological tests including pure tone audiometry, speech audiometry, impedance audiometry and auditory brainstem response (ABR) were performed
**Results:** The mean age of patients was 40.3±6.2 years, and disease duration 7.3±4.6 years. Mild bilateral symmetrical sensorineural hearing loss (SNHL) was present in 27/35 (77.1%) mostly at high frequencies. Hearing thresholds, pure tone average and speech reception threshold were significantly higher (p=0.001) in SSc patients than in control. In those with hearing loss, word discrimination score (WDS) was lower and ABR-I delayed compared to those without (p=0.001,p<0.0001 respectively) with consequently shorter inter-peak interval (IPI) I-III (p=0.01) and IPI I-V (p=0.004). In patients with hearing loss there was an increased frequency of acro-osteolysis (51.9%), telangiectasia (59.3%), arthralgia (70.4%) and peripheral neuritis (44.4%) compared to those with normal hearing. The MSS and mRSS significantly correlated with the high frequency hearing threshold and negatively with WDS. Audiometric parameters were comparable between patients with diffuse (n=14) and limited (n=21) cutaneous SSc.
**Conclusions:** Audiometric tests may detect subclinical SNHL mostly cochlear in SSc patients. The significant association between SNHL with telangiectasia and neuritis raises the likelihood that the SNHL may be due to an underlying vasculopathy or neuritis.

## AB0645 ANTI-SSA/RO ANTIBODIES IN A COHORT OF SYSTEMIC SCLEROSIS PATIENTS: THE ASSOCIATION WITH INTERSTITIAL LUNG DISEASE

T. Martins Rocha, R. Fonseca, D. Rosa-Gonçalves, F. Aguiar, T. Meirinhos, M. Bernardes, A. Bernardo, L. Costa. *Rheumatology, Centro Hospitalar de São João, Porto, Portugal*

**Background:** Anti-SSa/Ro antibodies are among the common antibodies found in Systemic Sclerosis (SSc) patients (prevalence range 15–38%). Recent studies have suggested the association of anti-SSa/Ro with interstitial lung disease (ILD) as well as their prognostic role in SSc patients, however its definitive importance is yet to be determined.
**Objectives:** To determine the prevalence of anti-SSa/Ro antibodies in a cohort of SSc patients and its association with clinical and serological features.
**Methods:** Observational retrospective cohort study was performed including consecutive patients with clinical diagnosis of SSc (based on expert opinion) followed in our Rheumatology Department. Demographic, clinical and laboratorial data were obtained from clinical records. Lung involvement was considered if ILD was detected by an experienced radiologist in high-resolution computed tomography. Extractable Nuclear Antigen Antibodies, including ant-SSA/Ro, were measured in all the patients included, using enzyme-linked immunosorbent assay (ELISA) method. Patients with positive anti-SSa/Ro were compared with the other patients using Mann-Whitney, t-student, $\chi^2$ and Fisher tests (SPSS 23.0). Significance level was set as $<0.05$.
**Results:** 108 patients were included, 96 (90%) were females with a mean age of 58.2±12.8 years and a median disease duration of 6 years [0–38]. 12 (11%) patients had diffuse SSc and 96 (89%) limited SSc. Anti-SSa/Ro antibodies were present in 13 (12%) patients and were the third most common antibodies after anti-centromere (57%) and anti-Scl70 (20%). In the anti-SSa/Ro group, 11 (84.9%) were females and the mean age was of 61.1±12 years. Comparing to non-anti-SSa/Ro patients, both groups were similar regarding demographical data, disease duration and type of skin involvement. Anti-SSa/Ro group had more frequent SSc-Overlap syndromes (SSc-OS) (54% vs 15%, p=0.003). Anti-SSa/Ro group had significantly more frequent ILD (54% vs 18%, p=0.01) with no differences regarding the pattern of lung disease. No statistically significant differences were found regarding frequencies of myopathy, pulmonary hypertension, gastrointestinal, renal and cardiac involvement. There was a greater proportion of neoplasia and joint involvement in the anti-SSa/Ro group (23% vs 6% and 54% vs 27%, respectively), not reaching statistical significance. Anti-SSa/Ro patients had significantly more frequent anti-Scl70 antibodies (46% vs 17%, p=0.02) and Rheumatoid Factor (31% vs 6%, p=0.018), without differences regarding other antibodies. No differences in mortality were found between the groups.
**Conclusions:** Anti-SSa/Ro antibodies were among the most common antibodies in our cohort of SSc patients. Consistently with previous data, our study supports their association with SSc-OS and ILD without evidence for other clinical features. Finally, our study also demonstrates a greater proportion of anti-Scl70 antibodies in these patients.

## AB0646 THE ROLE OF SERUM YKL-40 IN SYSTEMIC SCLEROSIS (SSC)

T. Furukawa, K. Matsui, M. Kitano, S. Kitano, Y. Yokoyama, M. Sekiguchi, N. Azuma, H. Sano. *Division of Rheumatology, Department of Internal Medicine, Hyogo college of Medicine, Nishinomiya, Japan*

**Background:** SSc is a refractory of connective tissue disease that causes fibrosis of the skin and various organs. 2013 ACR/EULAR classification criteria of SSc can diagnose early phase of skin involvement. Thus we considered that YKL-40 is known to be involved in inflammation, tissue fibrosis and remodeling, is an useful marker for evaluating early diagnosis and complications in SSc. YKL-40 is expressed in the synovial membrane and cartilage fibroblast cells in Rheumatoid Arthritis. However the relationship between SSc and YKL-40 is unclear.
**Objectives:** To clarify YKL-40 is useful marker in early diagnosis in the presence or absence of complications in Japanese SSc patients.
**Methods:** Study I: We measured serum level of YKL-40 by ELISA (Quantikine ELISA (R&D systems) ®) in 16 healthy controls and 26 SSc patients without complications: such as asthma, infection, diabetes, malignant disease, interstitial pneumonia (IP), pulmonary arterial hypertention (PAH), arthritis and other collagen disease. These complications may be increased YKL-40 levels. Study II: We measured serum level of YKL-40 by ELISA in 76 SSc patients: 42 patients without IP or PAH,17 patients with IP, 4 patients with PAH, 13 patients with IP and PAH. We were attention to IP and PAH complications as a factor involved in the prognosis in SSc.
**Results:** Study I: Serum YKL-40 levels were significant higher in SSc patients without complications than in healthy controls (77.3±15.8 vs 35.0±4.5ng/ml, P=0.01). On the other hand, there is no difference of YKL-40 levels due to gender, disease duration and disease type of SSc. Study II: Serum YKL-40 levels were significantly higher in SSc patients with IP and PAH than in SSc patients without IP and PAH (66.5±15.3 vs 193.4±45.3 ng/ml, P=0.01). Serum YKL-40 levels in SSc patients with IP was 92.9±28.5 ng/ml, and with PAH was 157.5±60.2 ng/ml.
**Conclusions:** We could show increase in serum YKL-40 levels with SSc excluding complications in Japan. In contrast, Montagna reported that serum YKL-40 levels in 40 SSc patients was median 75.5ng/ml (24.2–584) including the organ complications such as heart, lung, kidney, arthritis and high CRP cases (median 0.4mg/dl, 0.3–7.5). The Complications and other factors may be influent to level of serum YKL-40. And, Nordenbaek reported SSc patients with elevated serum YKL-40 had shorter survival than patients with normal serum YKL-40 and died more often due to extensive interstisial or vascular fibrosing processes. However, there is no report on YKL-40 in SSc patients with PAH. We thought that the measure of serum YKL-40 levels in SSc patients with organ complications such as IP and/or PAH is very useful marker. We showed that YKL-40 levels are useful marker in early diagnosis of SSc with or without complications.

## AB0647 DISEASE SUBSETS, AUTOANTIBODIES AND CLINICAL FEATURES IN 176 ADULT ITALIAN PATIENTS WITH SYSTEMIC SCLEROSIS: A CROSS SECTIONAL STUDY

T. Schioppo [1], L. Cesana [2], F. Ingegnoli [1], C. Bentow [3], M. Mahler [3], S. Vettori [4], P. Meroni [1], G. Valentini [4]. *[1] University of Milan; [2] Immuno-rheumatology research laboratory, Istituto Auxologico, Milan, Italy; [3] Research and Development, Inova Diagnostics, San Diego, CA, United States; [4] Second University of Naples, Naples, Italy*

**Background:** Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by vascular changes and progressive fibrosis of skin and various internal organs. A variety of circulating autoantibodies have been detected in SSc. Some of them are well-established tools strongly associated with SSc and useful for diagnosis and management of the disease (e.g. ANA, anti-centromere, anti-topoisomerase I, anti-RNA polymerase III – RNAP III). Other autoantibodies are less frequent and non-specific for SSc even if potentially useful to better assess clinical subsets and prognosis (e.g. anti-Th/To, anti-Ku, anti-PM/Scl).
**Objectives:** To investigate the prevalence of anti-Th/To, anti-Ku, anti-RNAP III and anti-PM/Scl antibodies as well as to study the associations between these antibodies and clinical features in Italian SSc patients.
**Methods:** Sera from 176 consecutive patients with SSc collected at two Italian sites were tested for anti-Th/To (anti-Rpp25 and anti-Rpp38), anti-Ku, anti-RNAP

III, anti-PM/Scl, and anti-centromere antibodies (anti-CENP-A and B) using QUANTA Flash chemiluminescence immunoassays (CIAs) on the BIO-FLASH instrument (Inova Diagnostics, San Diego, USA). Additionally, ANA screening was performed using QUANTA Flash CTD Screen Plus which includes the most relevant nuclear/cytoplasmic antigens. The Italian cohort included: women 162 (92%), limited cutaneous (lc-SSc) subtype 137 (78%), patients with present or past history of digital ulcers 56 (32%), calcinosis 25 (14%), lung fibrosis 69 (39%), heart involvement 22 (12.5%), pulmonary arterial hypertension 11 (6%) and esophageal involvement 84 (48%).
**Results:** 152 (86.4%) patients were CTD Screen Plus positive, 8 (4.5%) anti-Th/To positive, 8 (4.5%) anti-Ku positive, 20 (11.4%) anti-RNAP III positive, 0 (0%) anti-PM/Scl positive, 70 (39.8%) anti-CENP-A positive, and 87 (49.3%) anti-CENP-B positive. Anti-CENP-A, anti-CENP-B and anti-Ku antibodies were significantly associated with the lc-SSc subtype ($p<0.0001$, $p<0.0001$ and $p=0.0469$, respectively). None of patients positive for anti-Ku antibodies displayed digital ulcers ($p=0.0075$). Anti-Th/To (Rpp25) antibodies were associated with the presence of calcinosis ($p=0.0399$) while anti-RNAP III antibodies with its absence ($p=0.0353$). All patients positive for anti-Th/To were positive for the Rpp25 component while only one of them was also positive for the Rpp38 component.
**Conclusions:** The present study points out the low prevalence of anti-RNAP III and highlights a lower prevalence of anti-Th/To in Italian SSc patients. Several known associations between autoantibodies as SSc subsets have been confirmed while others could not be verified in the study. This supports the potential utiliy of autoantibodies to stratify SSc into clinical subsets. Large international multi-center studies are required to define and validate rare autoantibodies such as anti-Th/To, anti-Ku and anti-PM/Scl antibodies.

## AB0648 ANTICENTROMERE ANTIBODIES: CLINICAL SIGNIFICANCE IN A LARGE COHORT OF PATIENTS WITH A LONG FOLLOW-UP

V. Alende[1], E. González[2], C. Vázquez-Triñanes[3], L. González[4], A. Lorenzo[2], I. Villaverde[3], M. Alonso[4], S. Rodríguez[5], M.J. Isorna[6], P. Eiras[7], B. Sopeña[1] on behalf of Working Group of Autoimmune Diseases of Galicia (CEAG).
*[1]Medicine Department. Faculty of Medicine. University of Santiago de Compostela (Spain), Hospital Clínico Universitario de Santiago de Compostela (CHUS), Santiago de Compostela (A Coruña); [2]Autoimmunity, Hospital Universitario de Ourense, Ourense; [3]Thormbosis and Vasculitis Unit, Hospital Universitario of Vigo; [4]Autoimmunity, Hospital Povisa, Vigo; [5]Autoimmunity, Hospital Barbanza, Santiago de Compostela (A Coruña); [6]Autoimmunity, Hospital Universitario de Coruña, A Coruña; [7]Immunology, Hospital Clínico Universitario de Santiago de Compostela (CHUS), Santiago de Compostela (A Coruña), Spain*

**Background:** The presence of anti-centromere antibodies (ACA) has been associated with limited cutaneous systemic sclerosis (lcSSc), primary biliary cirrhosis (PBC), Sjogren's syndrome and less frequently with other autoimmune diseases (AID). However, given the low prevalence of ACA (<3% of positive ANA), the series published to date have included few patients and with little follow-up, so there have been mixed results (1, 2).
**Objectives:** The aim of the study was to establish the clinical significance of ACA in a large group of patients with a long follow-up.
**Methods:** The study was conducted at six affiliated University hospitals on all patients with positive ACA by indirect immunofluorescence on Hep-2 cells, between January 2011 and December 2014. Subsequently, the date of the first positive determination to ACA was identified in the patient's electronic file. Low titers of ACA were considered when the highest value was 1/320. Only those who have 2 or more positive determinations were included. All laboratory tests, echocardiography, CT of the chest and the final diagnosis were carefully reviewed.
**Results:** A total of 308 patients were studied, 269 were women (87%). The mean age was 70.21±13.5. The mean follow-up from the first determination of positive ACA was 125.43 months (range 11–276). High titers of ACA (>1/1280) were recorded in 94.5% of patients. The ACA was the only positive antibody in 219 patients (71.1%). On the other patients the associated antibodies were: AMA 15%, anti-Ro 6%, ASMA 2.2%, anti-Scl 70 1.5% and anti-gastric parietal cell in 2.9%. Regarding the diseases diagnosed in ACA patients: 57% had systemic sclerosis most of them lcSSc, 11% PBC, 6.6% Raynaud without systemic manifestations, 3% Sjogren's syndrome, 3% Arthritis, 2% Autoimmune hepatitis (AIH). Also, there was a 5.9% (17 patients) with overlap syndromes (lcSSc + PBC; AIH + PBC; AIH + Rheumatoid arthritis). Of the 175 patients with lcSSc 16% had pulmonary arterial hypertension, 10% interstitial lung disease and 5% suffered from digital ulcers. No autoimmune disease was diagnosed during the follow-up in 65 patients (21%). Among the 14 patients with low titers of ACA only 28.6% had AID.
**Conclusions:** The presence of anticentromere antibodies were associated with a high likelihood of developing anautoimmune dise ase (80%) mainly limited cutaneous systemic sclerosis, so these patients should be adequately evaluated and followed. However, low titers of ACA decrease the frequency of associated autoimmune diseases.

## AB0649 CLINICAL AND IMMUNOLOGICAL FEATURES OF PATIENTS WITH ANTI-PM/SCL ANTIBODIES: A RETROSPECTIVE STUDY OF 17 CASES

W.A. Sifuentes Giraldo[1], C. Bouruncle Alaluna[1], G. Roy Ariño[2], M.J. García Villanueva[1], C. de La Puente Bujidos[1]. *[1]Rheumatology; [2]Immunology, University Hospital Ramon y Cajal, Madrid, Spain*

**Background:** The PM/Scl autoantigen, which is currently known as the 'human exosome', is a macromolecular complex that consist of up to 16 proteins located primarily in the nucleolus and is involved in RNA processing and degradation. It has 2 major antigenic determinants called PM/Scl-100 and PM/Scl-75 based on their molecular weights. Anti-PM/Scl antibodies were initially reported in patients with systemic sclerosis (SSc)-polymyositis (PM) overlap syndromes but they are associated with a wide variety of autoimmune diseases including isolated SSc, PM, dermatomyositis (DM) and interstitial lung disease (ILD), and less frequently with systemic lupus erythematosus, primary Sjögren's syndrome (pSS) and undifferentiated connective tissue disease (UCTD).
**Objectives:** To describe the clinical and immunological features of PM/Scl-positive patients treated in a Spanish tertiary center.
**Methods:** We performed a retrospective study of patients with PM/Scl-100 and PM/Scl-75 positive antibodies seen in our center during the period 2007–2015. Positivity for these antibodies was detected by line immunoassay and confirmed by indirect immunofluorescence. Demographic and clinical data were obtained through review of their medical records.
**Results:** 17 anti-PM/Scl-positive patients were found during the study period, 12 of them women (70.6%) with a mean age at diagnosis of 57.5 years (range: 38–82). Positivity PM/Scl-75 was detected in 8 cases, for PM/Scl-100 in 4 cases and simultaneously for both antibodies in 5 cases. The diagnoses of these patients were: limited cutaneous SSc in 3 cases, SSc-PM overlap 2, SSc-DM overlap 1, isolated PM 1, isolated DM 1, unspecified myositis 3, isolated ILD 2, pSS 1, UCTD 1 and mitochondrial myopathy 1. The most common clinical manifestations were dyspnea (41.2%), Raynaud's phenomenon (RP) (35.2%), muscle weakness (29.4%), hand edema (23.5%) and arthralgia (23.5%). Three patients developed digital ulcers, 2 'mechanic's hands' and Gottron's papules and 1 calcinosis. No differences in clinical manifestations between PM/Scl-75 and PM/Scl-100 were found. ILD was diagnosed in 8 cases (47.1%) with radiological pattern of usual interstitial pneumonia in 2 cases, nonspecific interstitial pneumonia 2, organizing pneumonia 1, lymphocytic interstitial pneumonia 1 and no characteristic pattern 2. The acute phase reactants (erythrosedimentation rate, C-reactive protein) were elevated in 58.8% and muscle enzymes in 41.2% (creatine kinase mean value 658 IU/L, range: 184–1758), 4 cases had lymphopenia and 6 hypergammaglobulinemia. The antinuclear antibodies were positive in 13 patients, anti-Ro/SSA in 4 and anti-centromere, anti-SRP, and anti-Ku in 1 case each. None of the patients died or developed malignancy (mean follow-up: 70.6 months).
**Conclusions:** The patients in our series presented a heterogeneous clinical profile similar to other series in the literature and the most common manifestations were ILD, RP and myositis. Anti-PM/Scl antibodies have been traditionally associated with overlap syndromes, but we found a wide variety of diagnoses in our cases. Despite the high incidence of ILD in anti-PM/Scl-positive patients, the presence of these antibodies seems to be associated with good prognosis and infrequent development of malignancies.

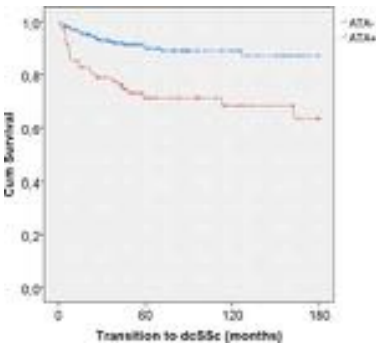
## AB0650 SURVIVAL AND ORGAN INVOLVEMENT IN PATIENTS WITH LIMITED CUTANEOUS SYSTEMIC SCLEROSIS AND ANTI-TOPOISOMERASE ANTIBODIES

P. Kranenburg, W.M.T. Van Den Hombergh, H.K. Knaapen-Hans, F.H. van den Hoogen, J. Fransen, M.C. Vonk. *Department of Rheumatology, Radboud University Medical Centre, Nijmegen, Netherlands*



**Background:** In systemic sclerosis (SSc) there are two main subgroups based on skin involvement: limited cutaneous systemic sclerosis (lcSSc) and diffuse cutaneous systemic sclerosis (dcSSc). LcSSc is associated with the presence of anti-centromere antibodies (ACA) and a more subtle disease course, whereas dcSSc is associated with anti-topoisomerase antibodies (ATA) and often a more severe disease course. Nevertheless, despite the associations between clinical subtype and autoantibodies, there are quite a number of SSc patients who have limited skin involvement and antibodies associated to diffuse skin involvement (ATA). The question is whether these patients have a disease more like lcSSc or more like dcSSc.
**Objectives:** The aim of this study is to determine whether survival and organ involvement in lcSSc patients who are ATA positive are similar to lcSSc ATA negative patients or to dcSSc ATA positive patients. Furthermore, the relation between ATA positivity and time to transition from lcSSc to dcSSc was evaluated.

**Methods:** Data from The Nijmegen Systemic Sclerosis cohort were used. Survival analysis was performed to show cumulative survival and time to event for Interstitial Lung Disease (ILD), Pulmonary Arterial Hypertension (PAH), cardiac involvement, Scleroderma Renal Crisis (SRC), and transition to lcSSc. Cox proportional hazard modelling was performed to adjust for confounders.
**Results:** Survival up to 15 years of follow-up was highest in lcSSc ATA positive patients, whereas dcSSc ATA positive patients had lowest survival (table 1). Interstitial Lung Disease (ILD) occurred more frequently in lcSSc ATA positive patients compared to lcSSc ATA negative patients. However, a higher frequency of ILD was seen dcSSc ATA positive patients. No significant differences were seen between the four (table 1) subgroups in occurrence of PAH, cardiac involvement and SRC. At the moment of diagnosis, 343 patients were classified as lcSSc and 48 of these patients evolved from lcSSc to dcSSc, 24 (9%) in the ATA negative subgroup and 24 (29%) in the ATA positive subgroup (figure 1).

Table 1. Organ involvement and death during follow up

| | Total | lcSSc | | dcSSc | | p-value |
|---|---|---|---|---|---|---|
| | | ATA+ | ATA– | ATA+ | ATA– | |
| Death (%) | 85 (18.5) | 6 (10.3) | 44 (18.6) | 17 (21.8) | 18 (20.7) | 0.334 |
| Death or ASCT (%) | 102 (22.2) | 6 (10.3) | 44 (18.6) | 30 (38.5) | 22 (25.3) | <0.001 |
| ILD (%) | 131 (35.9) | 20 (48.8) | 48 (24.7) | 35 (60.3) | 28 (38.9) | <0.001 |
| PAH (%) | 32 (7.5) | 4 (7.0) | 21 (9.8) | 5 (6.7) | 2 (2.5) | 0.199 |
| Cardiac Involvement (%) | 49 (11.0) | 6 (11.1) | 19 (8.2) | 13 (17.1) | 11 (13.3) | 0.158 |
| SRC (%) | 14 (3.1) | 0 (0.0) | 3 (1.3) | 4 (5.3) | 7 (8.5) | 0.003 |

ILD: interstitial lung disease, PAH: pulmonary arterial hypertension, SRC: Scleroderma renal crisis, ASCT: autologous stem cell transplantation.

**Conclusions:** This study showed that lcSSc ATA positive patients differ from lcSSc ATA negative patients and dcSSc ATA positive patients concerning both survival and occurrence of ILD. Therefore, in everyday clinical practice, the prognosis of lcSSc ATA positive patients should be considered separately.

## AB0651 USEFULNESS OF NEUTROPHIL TO LYMPHOCYTE RATIO IN PREDICTION OF LUNG INVOLVEMENT IN PATIENT WITH SYSTEMIC SCLEROSIS

W.S. Lee[1], Y.-M. Lee[1], M.-J. Hong[2], C.-H. Lee[3], M.S. Lee[3], S.-I. Lee[4], W.-H. Yoo[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Research Institute of Clinical Medicine of Chonbuk National University-Biomedical Research Institute of chonbuk national university hospital; [2]Division of Rheumatology, Department of Internal Medicine, Presbyterian Medical Center, jeonju; [3]Division of Rheumatology, Department of Internal Medicine, Shool of medicine, wonkwang University, Iksan; [4]Division of Rheumatology, Department of Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of*

**Background:** Both neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte (PLR) are reported to be increased in various inflammatory diseases, but there clinical significance in systemic sclerosis (SSc) remains unclear
**Objectives:** The aim of the study is to evaluate usefulness of neutrophil to lymphocyte ratio in diagnosis of systemic sclerosis and in prediction of lung involvement such as pulmonary fibrosis.
**Methods:** The medical records of 88 SSc patients and 50 healthy controls were retrospectively reviewed. NLR, PLR between SSc patients and healthy controls were compared, and correlation between these indexes and lung involvement were analyzed. Exclusion criteria included active infection and/or the presence of any hematological, cardiovascular or metabolic disorder.
**Results:** The NLR and PLR were found to be significantly higher in SSc patients when compared to the healthy control (NLR: 3.95±6.59 vs 2.00±1.07, $p<0.01$, PLR: 163.87±101.12 vs 126.33 ±42.31, $p<0.05$). SSc patients with lung involvement had higher NLR and PLR levels than those without lung involvement ($p<0.01$, $p<0.05$). NLR was negatively correlated with forced vital capacity (FVC)(r=-0.341, $p<0.01$) but not diffusing capacity for carbon monoxide (DLCO). Receiver-operating characteristics analysis (ROC) of NLR to predict lung involvement in SSc showed that the area under the curve (AUC) was 0.763. The cut-off NLR value for prediction of lung involvement was determined as 2.59. (sensitivity, 0.700;specificity, 0.729; $p<0.01$)
**Conclusions:** NLR may be a promising marker that reflects lung involvement in patients with SSc and values greater than 2.59 were useful in prediction of lung involvement.
**Disclosure of Interest:** None declared

## AB0652 GRANULOMATOSIS AND INFLAMMATORY MYOPATHY: CLINICAL SEROLOGICAL PATHOLOGICAL FEATURES AND PROGNOSIS

Y. Dieudonne[1], D. Wendling[2], C. Von Frenckell[3], N. Poursac[4], A. Echaniz-Laguna[1], J. Sibilia[1], A. Meyer[1]. *[1]CHRU Strasbourg, Strasbourg; [2]CHU Besancon, Besancon, France; [3]CHU Liège, Liege, Belgium; [4]CHU Bordeaux, Bordeaux, France*

**Background:** Case reports and short series ($n<7$) suggested that granulomatosis may be found in various inflammatory myopathies (IM) subtypes [1] but the clinical significance of this association is unanswered.
**Objectives:** To study clinical significance of granulomatosis in IM patients.
**Methods:** Patients with non-caseating granuloma (muscle or other tissue) were first identified among a monocentric cohort of 291 patients diagnosed with IM. 20 rheumatology and internal medicine practitioners were also contacted by electronic letters and asked to report their observations. Clinical, biological, histological features and evolution were retrospectively studied using a standardized questionnaire and compared with a control group of 14 randomly selected patients suffering from IM without identified granulomatosis.
**Results:** 14 IM patients with granulomatosis with a median follow-up of 77 months were included. Age at IM diagnostic was 54 years (16 to 70). Granuloma was identified 44 months before IM (23 years before to 4 after) in muscle (n=5), lymph node (n=5), skin (n=2), liver or spleen (n=1) tissues. Angiotensin converting enzyme amount was 114U/l (48 to 168).
7 patients (4 women, 57±14 years at IM diagnosis) were categorized as a defined IM subset because of typical histological and/or immunological features: antisynthetase syndromes (n=3), polymyositis (n=1), scleromyositis (n=1), dermatomyositis (n=1), inclusion body myositis (sIBM, n=1). These patients mostly presented with proximal weakness (n=6/7). Mean CK level was 780±390U/l. None had granumola in muscle biopsy. Extra-muscular involvements were arthralgia (n=4), interstitial pneumonia (n=4), mechanic's hand (n=1) and Raynaud's phenomenon (n=1). Patients received corticosteroids and meanly one another immunological drug (n DMARDs=1±0,8) with effectiveness except for the sIBM patient. None of these features was significantly different from the control group.
7 patients (4men, 54±12 years) did not met definitive criteria of a specific myopathy. As compared with the control group, they presented more often with distal weakness (n=3/7, p=0.002) and had lower CK level (260±56 vs. 2028±600U/l, p=0.006). Muscle biopsy most frequently revealed granuloma (n=5). Other lesions were endomyosial inflammatory cell infiltration (n=4), fibers atrophy (n=4), rimmed vacuoles (n=2). The patients experienced polyarthralgia (n=4), interstitial pneumonia (n=3), Raynaud (n=2). Despite a higher number of DMARDs as compared with the control group (2.7±0.4 vs. 1.3±0.2, $p<0.05$) and the patients with granolumatosis and defined IM ($p<0.05$), absence of muscle improvement was more frequent (n=5/7).
**Conclusions:** Half of IM patients with granulomatosis match diagnostic criteria for IM subtypes without clinical particularity aside from the granuloma. The unclassified others patients are characterized by an sIBM-like phenotype with distal weakness, low CK level and frequent unfavorable response to immunomoduling therapy despite not meeting criteria for definite sIBM. Clinicians should pay attention to auto-antibodies and muscle histology to tailor the care of IM patients with granulomatosis, which do not represent a homogeneous group.

## AB0653 GASTRIC ANTRAL VASCULAR ECTASIA IN SYSTEMIC SCLEROSIS PATIENTS: LONG-TERM PROGNOSIS AND TREATMENT

Y. Braun-Moscovici[1], M. Braun[2], I. Hermesh[3], Y. Tavor[1], M. Naffaa[1], R. Beshara-Garzoz[1], K. Toledano[1], A.P. Rozin[1], A. Balbir-Gurman[1]. *[1]B Shine Rheumatology Unit, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Haifa; [2]Liver Institute, Beilinson Hospital, Sackler School of Medicine, Tel aviv University, Petach Tikva; [3]Institute of Gastroenterology, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Haifa, Israel*

**Background:** Gastric antral vascular ectasia (GAVE) is characterized by a pathognomonic endoscopic pattern, mainly represented by red spots either organized in stripes radially departing from pylorus, defined as "watermelon stomach", or arranged in a diffused-way, the so called "honeycomb stomach". In

our previous work we found a prevalence of GAVE in 35% of systemic sclerosis (SSc) patients that had an upper gastrointestinal (GI) endoscopy for evaluation of symptoms. The main complication of GAVE is symptomatic anemia due to GI bleeding requiring blood transfusion. As the pathogenesis is unknown, the aim of the therapy is to decrease GI bleeding. Endoscopic therapy (endotherapy) is the mainstay of treatment with surgery reserved for severe refractory cases. The data on the efficacy of endotherapy and treatment requirements of SSc patients with GAVE is very limited.
**Objectives:** The aim of our study is to assess the treatment requirements of SSc patients with GAVE and the efficacy of endotherapy in particular.
**Methods:** Retrospective analysis of a prospectively maintained database of SSc patients followed in a tertiary referral center for SSc. Our cohort is part of the EUSTAR cohort. Statistical analysis: descriptive, student's T test, Mann-Whitney test.
**Results:** Fifty SSc patients were diagnosed with GAVE. Seventeen patients (34%) suffered of symptomatic anemia and were treated with argon plasma coagulation (APC) for a mean (SD) of 4.5 (4.3) sessions per patient. The mean (SD) hemoglobin was 9.4 (1.7) gr% in the group who required endotherapy compared to 11.5 (1.3) in the group which did not need any intervention. Four patients needed more than 6 sessions of treatment. Mean (SD) follow up was 4.1 (2.4) years. Nine patients required a total of 73 packed blood cells units and another 4 had intravenous iron replacement. Four patients died during the first 2 years after diagnosis, none of them due to bleeding complications. None of the patients that survived more than 2 years required further endotherapy or blood transfusions. No significant complications of APC occurred. Interestingly, all those who survived,had received immunotherapy with cyclophosphamide or mycophenolate mofetil due to multisystem involvement and disease activity.
**Conclusions:** Long term survivors among SSc patients with GAVE had an excellent response to APC and did not require blood transfusions or endotherapy after 2 years follow up. All the long term survivors received immunotherapy. This observation might hint to the pathogenesis of GAVE in SSc.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5458

## Spondyloarthritis - treatment

### AB0654 DRUG SURVIVAL AND SWITCHING RATE OF TNF INHIBITORS IN A COHORT OF PATIENTS WITH ANKYLOSING SPONDYLITIS WITH LONG TERM FOLLOW UP

K. Klavdianou, A. Lazarini, C. Koutsianas, C. Tsalapaki, K. Thomas, C. Hatzara, K. Antonatou, D. Vassilopoulos. *Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National University of Athens Medical School, Athens, Greece*

**Background:** Although the efficacy of TNF inhibitors (TNFi) in ankylosing spondylitis (AS) is well established, their long term survival (>5 years), baseline prognostic factors for their discontinuation and switching rate have not been adequately studied in daily clinical practice.
**Objectives:** To estimate the long-term survival, switching rate of TNFi as well as to identify baseline predictors for drug survival in a cohort of patients with AS in real life settings.
**Methods:** A retrospective systematic chart review of all AS patients treated with TNFi in our Rheumatology Unit from 1/1/2003 to 31/12/2015 was performed. Demographic, clinical and laboratory data were collected and analyzed. Drug survival was estimated by Kaplan-Meier analysis. The impact of several covariates on drug survival was analysed by Cox regression.
**Results:** 103 AS patients who had received etanercept (ETN, n=41), infliximab (INF, n=33), adalimumab (ADA, n=21), golimumab (GOL, n=7) or certolizumab pegol (CZP, n=1) were included. Patients were predominantly males (67%, n=69) with a mean age of 45±11.8 years and a median disease duration of 7 years. The patients were followed for a median time of 5 years (mean: 5.1±2.6 years). Peripheral arthritis was present in 42% (n=43) and extra-articular manifestations in 26.5% (n=27) of patients. The majority (94%, n=97) received TNFi as monotherapy. The mean overall survival of the first TNFi was 81.2±6.7 months (40% survival after 7 years). ADA demonstrated a longer survival (84±8.5 months) compared both to ETN (53±6 months, p=0.04) and INF (76±11 months, p=0.063). 43 patients (42%) discontinued the 1st TNFi due to adverse events (37%), inadequate response (35%) or other reasons (28%). 10% of patients were lost to follow up. No difference in discontinuation reasons was found among the different TNFi (p=0.125). 33 patients (32%) switched to a second TNFi (ADA: n=23, ETN: n=3, INF: n=3, GOL n=2, CZP n=1). Overall the retention to therapy was better for non-switchers compared to switchers' to a second TNFi (81.2±6.7 months vs. 42.8±7 months, p=0.086). Specifically for ADA, this difference was statistically significant (p=0.03). Among several baseline variables (age, disease duration, extra-articular manifestations, peripheral arthritis, HLA B27 status), none was predictive for therapy discontinuation. Although lower baseline CRP (HR=0.7, 95% CI: 0.5–1.3), longer disease duration (HR=1.1, 95% CI: 0.9–1.3), concurrent smoking (HR=4.9, 95% CI: 0.9–25) and male gender (HR=4.8, 95% CI: 0.8–26) were associated with higher risk for drug discontinuation, these did not prove to be statistically significant by multivariate analysis.
**Conclusions:** Only 40% of AS patients remain on their 1st TNFi 7 years after starting treatment. ADA demonstrated longer survival compared to ETN and INF as the 1st TNFi. Approximately one-third of patients switched to a 2nd TNFi which had a shorter survival compared to the 1st. In our patient cohort we did not identify any baseline predictors for longer drug survival.

### AB0655 ANTI-TNF ALPHA DOSE REDUCTION IN ANKYLOSING SPONDYLITIS PATIENTS

A. Ortolan[1], M.S. Chimenti[2], M. Lorenzin[1], P. Frallonardo[1], F. Sunzini[2], P. Conigliaro[2], R. Perricone[2], L. Punzi[1], R. Ramonda[1]. *[1]Rheumatology Unit, Department of Medicine DIMED, University of Padova, Padova; [2]Rheumatology, Allergology and Clinical Immunology Department of "Medicina dei Sistemi", University of Rome "Tor Vergata", Rome, Italy*

**Background:** Anti-Tumor Necrosis Factor (TNF)alpha drugs play a fundamental role in Ankylosing Spondylitis (AS) therapy. Nevertheless their use is associated to potential side effects, such as a higher frequency of infection, and high healthcare costs. On these bases, a dose reduction strategy (lengthening drug administration interval) is often attempted in clinical practice.
**Objectives:** 1) to retrospectively compare the features of anti-TNFalpha-treated AS patients who could lengthen the administration interval (group A) with those of patients who needed to maintain standard dosage (group B); 2) to evaluate the impact of dose reduction on infection frequency; 3) to evaluate cost-savings in group A.
**Methods:** All AS patients attending the spondyloarthritis outpatients clinic-Rheumatology Unit of University of Padova and of University of Rome "Tor Vergata" between January 2011 to April 2015 who were treated with anti-TNFalpha (infliximab, adalimumab, etanercept) at a standard dose for at least 6 months with a good control of disease activity (ASDAS <2.1) were prescribed a dose reduction regimen. Some patients were able to maintain the new regimen (group A), while others were not because of symptom flare-up (group B). Disease activity (ASDAS, BASDAI), inflammatory (CRP), functional and (BASFI) and metrologic (BASMI) indexes were recorded at baseline (t0), after 6 months (t6), then once a year (t12, t24, t36, t 48) for a 4-year follow-up.
**Results:** Data from 96 AS patients (25 females, 26.04%; mean age 47.62±13.39 years) were examined. Drug administration interval, which could be lengthened in 66 (68.75%) patients (group A) without flare-ups or functional worsening, was associated to an improvement in ASDAS [t0=2.1 (1.49) vs t48=1.00 (0.29); p<0.0001]; BASDAI [t0=39 (49.6) vs t48=9.5 (14); p<0.0001]; BASFI [t0=22 (35) vs t48=1 (11); p<0.0001]. At the end of the observation period (t48), group A showed better physical functioning and lower disease activity compared to group B [BASFI A vs B =1 (36.18) vs 17.5 (7.3), ASDAS 1 (0.3) vs 1.6 (1.15); CRP 2.15 (2.1) vs 3.1 (7.3) mg/L]. At t0 group A had a less severe inflammatory status [CRP A vs B 2.9 (3.3) vs 4.7 (6.4) mg/L; p=0.0134], and a negative family history for spondiloarthritis (p=0.0318), while no significant difference was observed for smoking, psoriasis, peripheral arthritis, dactylitis, uveitis, enthesitis in more than 4 sites and HLA B27. The number of patients who developed infections during the observation period was significantly lower in group A (p=0,007); the average cost saving at t48 for group A vs group B was: 7.060 vs 14.820 € for infliximab; 6357 vs 13.260 € for etanercept; 11840 vs 12.917 € for adalimumab.
**Conclusions:** Lenghtening anti-TNFalpha administration interval appears to be a valid approach in patients with a less severe inflammatory status, and a negative family history of spondyloarthritis. Dose reduction regimen is associated to lower infection frequency and less expense for National Health Care System.

### AB0656 CLINICAL RELEVANCE OF MEASURING FREE VERSUS TOTAL ANTI-INFLIXIMAB ANTIBODIES IN PATIENTS WITH SPONDYLOARTHRITIS

A. Ruiz del Agua[1], J. Pascual[1], N. Torres[1], D. Pascual-Salcedo[2], A. Martínez[2], T. Jurado[3], C. Plasencia[3], A. Balsa[3], B. Ruiz-Argüello[1], A. Maguregui[1], A. Ametzazurra[1], A. Martínez[1], D. Nagore[1]. *[1]R&D, Progenika-Grifols, Derio; [2]Immunology; [3]Rheumatology, Hospital La Paz, Madrid, Spain*

**Background:** Antibodies to infliximab (ATI) are associated to loss of response, adverse effects and discontinuation of treatment in rheumatic patients[1]. However, the clinical relevance of measuring free versus total anti-drug antibodies (free plus drug-complexed antibodies) remains to be established.
**Objectives:** To analyse the association between the clinical response and ATI measured as free and total content of immunoglobulins in a cohort of patients with spondyloarthritis.
**Methods:** A retrospective pilot study was conducted including 12 patients with

spondyloarthropathies (9 ankylosing spondylitis (AS) and 3 spondyloarthritis (SpA)) under maintenance infliximab (IFX) therapy (3–5 mg/kg every 8 weeks). Disease activity was assessed by BASDAI score every 6 months. Trough serum samples were consecutively collected every two months during a follow up period of 1±0.1 years. In total 75 samples were collected (average of 6.3 per patient). Ten patients (83%) received concomitant therapy with methotrexate. IFX levels were measured with *Promonitor®-IFX* (Progenika-Grifols, Spain). Free and total-ATI were measured with *Promonitor® Anti-IFX* (Progenika-Grifols, Spain) (PR) and *IDKmonitor® Infliximab total ADA* (IDK) (Immundiagnostik, Germany) ELISA kits, respectively. Cut-point of PR and IDK ATI assays is 5 and 10 AU/mL, respectively. FDA guidance for comparing two diagnostic tests in the absence of a gold standard was followed[2].

**Results:** Five (41.7%) and (83.3%) patients were positive for free and total-ATI using PR and IDK assays, respectively. Overall, positive (PPA) and negative (NPA) percent agreements between the two assays were 52%, 16% and 100%, respectively. All samples with positive free-ATI (7) had undetectable IFX levels (0.0±0.0 μg/mL); however, 72% of total-ATI positive samples (43) were also positive for IFX levels (1.7±1.7 μg/mL, min 0.035 μg/mL and max 6.4 μg/mL). Both outcomes are coherent with the intended use of each kit, which also explains the low PPA. However, total-ATI are positive in 40% of the samples even when the patient responds (BASDAI<4), which questions the utility of total-antibodies in a clinical setting. This evidences a low clinical specificity of total-ATI measurement using the cut-off of 10 AU/mL recommended by the manufacturer and therefore that the presence of total-ATI in the presence of detectable drug has little utility. Patients without free-ATI had significantly lower BASDAI than patients with free-ATI (2.7±2.0 without antibodies vs 5.0±0.9 with antibodies, $p$=0.049), whereas no statistically significant difference was observed between patients when total-ATI were used (3.1±2.2 without antibodies vs 2.9±2.0 with antibodies, $p$=0.969) (Fig. 1).

**Conclusions:** Total-ATI do not correlate with disease activity in spondyloarthritis. The fact that many samples are positive to total-ATI even in patients with low disease activity makes very difficult interpretation of results. The explanation is that the fraction of ATI bound to IFX is not clinically relevant as long as there is free therapeutic drug in circulation.

## AB0657 DISCONTINUATION OF ANTI-TNF THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS IN CLINICAL PRACTICE: PREVALENCE AND CAUSES

E. Moral[1], C. Plasencia[1], V. Navarro-Compán[1], D. Pascual Salcedo[2], T. Jurado[2], C. Tornero[1], A. Pierens[1], M.B. Paredes[1], P. Bogas[1], I. Monjo[1], E. Martin Mola[1], A. Balsa[1]. *[1]Rheumatology; [2]Inmunology, La Paz University Hospital, Madrid, Spain*

**Background:** The majority of patients with axial spondyloarthritis (SpA) response to anti-TNF therapy. However, discontinuation of this therapy due to different reasons is still a relevant problem. Currently, there is not enough data to know exactly which is the prevalence and causes of interruption of anti-TNF therapies in clinical practice.

**Objectives:** First, to evaluate the frequency and causes of discontinuating adalimumab or infliximab as the first anti-TNF in patients with axial SpA in clinical practice. Second, to investigate the influence of anti-drug antibodies (ADA) on these causes.

**Methods:** A total of 326 patients with axial SpA who had received adalimumab (34%) or infliximab (66%) as a first anti-TNF therapy were included in this retrospective, observational study performed in a tertiary hospital. Disease activity (BASDAI, ASDAS, CRP and ESR) was measured before starting anti-TNF therapy, after 6 months and when interrupting the therapy to assess properly whether the reason for discontinuation was primary or secondary failure. Serum drug levels and/or ADA were measured at 6 months visit and at the end of anti-TNF treatment.

**Results:** A total of 99 (30.4%) patients discontinued treatment. Mean (SD) under anti-TNF therapy until discontinuation was 2.5 (2.9) years. Characteristics of these patients when initiating anti-TNF therapy are shown in Table 1. The reason to interrupt treatment was: primary failure in 22.2%, secondary failure in 36.4%, side effects 32.3%), and other reasons in 9.1%. Serum drug levels and ADA were available in 83 patients. In most patients with ADA positive (14/17), the reason for discontinuation was secondary failure. Out of those patients who discontinued due to secondary failure, 38.9% had ADA positive.

| Demographic characteristics | Total (n=99) |
|---|---|
| Age (years) | 49.9 ± 11.9 |
| Sex (female) | 45 (45.5%) |
| BMI | 28.2 ± 5.1 |
| HLA-B27 positive | 50 (50.5%) |
| Disease duration (years) | 14.2 ± 8.5 |
| Drug levels 6 months | 39 (39.4%) |
| ADA levels 6 months | 12 (12.1%) |
| Drug levels endpoint | 53 (53.5%) |
| ADA endpoint | 25 (25.3%) |
| DMARDs | 50 (50.5%) |
| Baseline CRP | 10.2 ± 16.3 |
| Baseline ESR | 21.5 ± 18.9 |
| Baseline ASDAS | 3.1 ± 0.9 |
| Baseline BASDAI | 6,1 ± 1.9 |

**Conclusions:** In our cohort of patients with axial SpA treated with adalimumab/infliximab, 30% of patients discontinued anti-TNF therapy. The main reason to discontinue treatment was secondary failure, which was related to the presence of ADA in almost 40% of patients.

## AB0658 INFLUENCE OF KNOWN RISK FACTORS ON SPINAL RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS PATIENTS RECEIVING LONG-TERM TREATMENT WITH TNF INHIBITORS: RESULTS FROM THE GLAS COHORT

F. Maas[1], S. Arends[1,2], F.R. Wink[2], E. van der Veer[3], R. Bos[2], H. Bootsma[1], E. Brouwer[1], A. Spoorenberg[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Laboratory Medicine, University Medical Center Groningen, Groningen, Netherlands*

**Background:** In ankylosing spondylitis (AS), the most important prognostic factor for spinal radiographic progression is the presence of syndesmophytes at study entry. In addition, male gender, older age, longer symptom duration, smoking, HLA-B27 positivity, and increased inflammatory markers were found to be associated with radiographic progression in AS.[1]

**Objectives:** To investigate the influence of known risk factors on spinal radiographic progression in AS patients receiving long-term treatment with TNF inhibitors.

**Methods:** Consecutive patients from the GLAS cohort receiving TNF inhibitors with baseline and biannual spinal radiographs untill 6 years of follow-up were included. Radiographs were scored in chronological time order by two independent readers according to the mSASSS. Single linear imputation of radiographic data was used in case patients had missing data at one or more intermediate follow-up visits. The influence of the earlier mentioned risk factors for radiographic progression was investigated using univariable and multivariable generalized estimating equations (GEE). Subsequently, radiographic progression

was modeled with different time functions (linear and non-linear) to provide the best fit for the data in patients with and without risk factors. A time function with $p \leq 0.05$ contributed significantly to the model and the estimated mean progression rates of the 2-year time intervals were calculated.

**Results:** Eighty patients were included; 70% were male, 78% HLA-B27+, mean age was 41±10 years, median symptom duration 14 (IQR: 8–24) years, mean BASDAI 6.0±1.7, mean ASDAS 3.8±0.8, and mean mSASSS 8.7±13.3.

During 6 years of follow-up, mean progression was 4.2±4.8 mSASSS units. GEE revealed that baseline syndesmophytes, gender, age, and symptom duration were significantly associated with radiographic damage over time. No significant associations were found for smoking, HLA-B27 status, and elevated CRP levels. The presence of baseline syndesmophytes was the only independent predictor for progression.

Baseline mSASSS was highest in AS patients with baseline syndesmophytes, male gender, age ≥40 years, and symptom duration ≥10 years. In these patients, mSASSS progression followed a non-linear course showing a reduction in estimated progression rates over time (Table 1). Most patients with syndesmophytes also had one or more other risk factors (e.g. male gender and symptom duration ≥10 years). A linear course with low estimated progression rates was found in patients without these risk factors (Table 1).

**Table 1.** Estimated mean spinal radiographic progression rates based on the best time model of AS patients (n=80) stratified for baseline risk factors.

| | | n | Baseline mSASSS | Best time model (linear or non-linear) | mSASSS progression scores 0-2 year | 2-4 year | 4-6 year |
|---|---|---|---|---|---|---|---|
| **Syndesmophytes** | **Yes** | 37 | 15.8 ± 14.9 | Non-linear | 2.8 | 2.5 | 1.6 |
| | **No** | 43 | 0.4 ± 0.8 | Linear | 0.4 | 0.4 | 0.4 |
| **Gender** | **Male** | 56 | 10.9 ± 14.6 | Non-linear | 1.8 | 2.1 | 1.2 |
| | **Female** | 24 | 3.5 ± 7.4 | Linear | 0.7 | 0.7 | 0.7 |
| **Age** | **≥40 years** | 43 | 12.3 ± 15.2 | Non-linear | 2.3 | 2.0 | 1.3 |
| | **<40 years** | 37 | 4.5 ± 9.1 | Linear | 0.9 | 0.9 | 0.9 |
| **Symptom duration** | **≥10 years** | 52 | 12.3 ± 15.2 | Non-linear | 2.3 | 2.0 | 1.3 |
| | **<10 years** | 25 | 2.1 ± 3.1 | Linear | 0.6 | 0.6 | 0.6 |

Values are presented as mean ± standard deviation; mSASSS: modified Stoke AS Spine Score.

**Conclusions:** In our cohort of AS patients receiving long-term treatment with TNF inhibitors in daily clinical practice, patients with known risk factors for radiographic progression (especially the presence of baseline syndesmophytes) showed the highest radiographic damage scores at baseline and the highest but reducing radiographic progression over time. In contrast, patients without these risk factors showed less baseline damage and low linear progression rates.

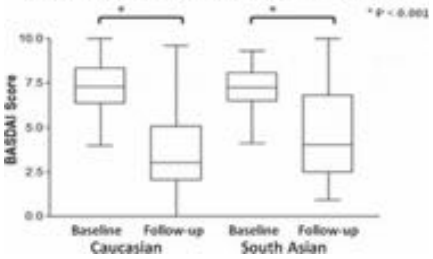
## AB0659 EFFECT OF ETHNICITY ON RESPONSE TO ANTI-TNF BIOLOGIC THERAPY IN SEVERE ANKYLOSING SPONDYLITIS

G. Aggrey-Fynn[1,2], D. Chagadama[2], A. Jawad[1,2]. *[1]Barts and The London School of Medicine and Dentistry Queen Mary University of London; [2]Rheumatology Department, Barts Health NHS Trust, London, United Kingdom*

**Background:** Anti-TNF biological therapy has revolutionised management of Ankylosing Spondylitis (AS) however, variability in treatment response within the AS population exists and may possibly be influenced by ethnicity.

**Objectives:** To investigate the effect of ethnicity on treatment response to anti-TNF biologics by analysis of patient disease activity scores of severe AS patients by ethnicity.

**Methods:** Severe AS patients defined by a persistent Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) of >4 and poor response to non-steroidal anti-inflammatory drugs (NSAIDs) were identified retrospectively from an anti-TNF therapy clinic database of patients treated by the Rheumatology Department between 2004 and 2014. Prescribed biologics were Infliximab, Etanercept, Adalimumab, Golimumab and Certolizumab. Patient clinical demographics and baseline BASDAI and spinal pain Visual Analogue Scale (VAS) scores from electronic records were collected pre-biologic treatment initiation and from 12 weeks post treatment follow-up. Data was analysed by non parametric descriptive statistics for changes in disease activity levels and compared by ethnicity. Adequate treatment effect was determined as a follow-up BASDAI score reduction with respect to the baseline of ≥2 units or 50% of the pre-treatment baseline score (BASDAI50) with a reduction of the spinal pain VAS by ≥2 cm. 99 of 256 available electronic records were complete at baseline and follow-up for BASDAI and corresponding VAS scores and were selected for analysis.



**Results:** Overall 59/99 (59.6%) of the 99 selected records achieved an adequate response. Interrogation of records by database ethnicity classifications showed the following groups to be present in the data set:

49: Caucasian – English, Scottish, Welsh, Irish, Any Other White Background
44: South Asian – Bangladeshi, Indian, Pakistani
3: Other Asian
1: Other Mixed
2: Other

By ethnicity an adequate response was achieved in:
36/49 (73.5%) of Caucasians,
20/44 (45.5%) of South Asians,
2/3 (66.7%) of the Asian other group,
1/2 (50%) of the Other group and 0/1 (0%) of the other mixed group.

Kruskal-Wallis multiple comparison testing showed statistical differences between baseline and follow-up mean BASDAI scores within Caucasian and South Asian ethnicities (*Figure 1).* Within the Caucasian group the baseline median=7.28 (IQR 6.3, 8.35), mean=7.31 (CI 6.92–7.70) versus follow-up median=3 (IQR 2, 5.1), mean=3.79 (CI 3.05–4.54). Within the South Asian subgroup the baseline median=7.25 (IQR 6.45, 8.06), mean=7.25 (CI 6.88–7.63) versus follow-up median=4.04 (IQR 2.45, 6.8) mean=4.62 (CI 3.8–5.44), both comparisons $P<0.001$. No significance was returned for comparisons between all ethnic groups at baseline and all at follow-up. "Other" group data subsets were too small to draw conclusions.

**Figure 1. Comparison of treatment response by ethnicity at baseline and 12 weeks post treatment initiation**

**Conclusions:** Therapy was efficacious in 59.6% of patients analysed. By ethnicity statistically significant BASDAI score improvements were achieved within Caucasian and South Asian populations respectively. Baseline scores between these ethnicities were similar however the patient proportion within each of these groups that achieved an adequate response was higher among Caucasians 73.5% versus 45.5% of South Asians. This preliminary study may suggest as yet undiscovered ethnic influences affecting treatment response that merits further investigation.

## AB0660 PREDICTORS OF FLARE AFTER TAPERING ANTI-TNF THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

I. Monjo Henry, C. Plasencia, V. Navarro-Compán, B. Paredes, G. Bonilla, L. Nuño, D. Peiteado, A. Villalba, D. Pascual-Salcedo, S. Ramiro, E. de Miguel, E. Martín-Mola, A. Balsa. *University Hospital La Paz, IdiPaz, Madrid, Spain*

**Background:** In most patients with axial spondyloarthritis (axSpA) achieving a clinical response after receiving standard dose of anti-TNF therapy, it seems possible to decrease anti-TNF dose without leading to flare of the disease. However, a minority of patients fails to this strategy and need to maintain standard dose of anti-TNF therapy in order to keep disease activity under control.

**Objectives:** To identify prognostic factors of flare after tapering anti-TNF therapy in patients with axSpA who achieve sustained clinical response with standard dose of this therapy.

**Methods:** This was a restrospective, observational study performed in a tertiary hospital. All patients with axSpA who had achieved sustained low disease activity for at least 6 months after receiving standard dose of a first anti-TNF drug and who had later decreased the dose of anti-TNF therapy were included. Low disease activity was defined as BASDAI <4 plus normal value of CRP. All patients were followed-up during 2 years after starting on tapering strategy. Collected data included: demographic (age, gender) and disease characteristics (HLA-B27, disease duration, peripheral involvement), smoking status, clinical disease activity measures (BASDAI, ASDAS, CRP) before starting and before decreasing anti-TNF therapy, time under anti-TNF therapy, concomitant treatment, and time in remission before tapering. Patients were followed-up during 2 years after tapering anti-TNF therapy. Flare was defined as BASDAI ≥4 plus elevated CRP (>5mg/L) and/or delta-BASDAI ≥2. To identify possible predictors of flare, univariable and multivariable logistic regression analyses were employed including all variables described within the collected data as independent factors.

**Results:** Fifty-three patients with axSpA receiving a tapering strategy after achieving low disease activity were included. Characteristics for these patients are presented in table 1. Four patients interrupted anti-TNF due to adverse effect before ending the study. In total, 8/49 patients (16%) had a flare during the 2-year follow-up period. In the univaribale analysis, only the age (OR=1.06; p=0.05), BASDAI before tapering (OR=2.64; p=0.01) and ASDAS before tapering (OR=4.12; p=0.08) were significantly associated with the occurrence of flare. In

| Characteristic | Mean ± SD/n (%) |
|---|---|
| Age years | 50.9±13.2 |
| Gender, males | 39 (74) |
| Smoking habit | |
| Non-smoker | 29 (57) |
| Smoker | 8 (16) |
| Past smoker | 14 (27) |
| Anti-TNF therapy | |
| Infliximab | 18 (34) |
| Adalimumab | 17 (32) |
| Etanercept | 14 (26) |
| Golimumab | 4 (8) |
| Time in remission before tapering, months | 16.9±12.6 |
| MTX pre-tapering | 13 (25) |
| SSZ pre-tapering | 18 (34) |
| BASDAI pre-tapering | 1.7±1.2 |
| ASDAS pre-tapering | 1.2±0.6 |
| CRP pre-tapering | 3.5±7.6 |

the multivariable analysis, only the BASDAI before tapering remained statistically significantly associated with flare (OR=2.39; p=0.03).
**Conclusions:** In patients with axSpA and sustained clinical response to anti-TNF therapy, a tapering strategy leads to flare in less than 20% of patients. The value of BASDAI before tapering anti-TNF therapy predicts the occurrence of flare. This may help us to select the appropriate patients and moment to implement a tapering strategy in patients with axSpA.

## AB0661 PREDICTORS OF RESPONSE IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH INFLIXIMAB OR GOLIMUMAB IN A REAL-WORLD SETTING

L. Bessette[1], S. Kapur[2], M. Zummer[3], M. Starr[4], D. Choquette[5], M. Sheriff[6], W. Olszynski[7], E. Rampakakis[8], E. Psaradellis[8], B. Osborne[9], K. Maslova[9], F. Nantel[9], A.J. Lehman[9], C.M. Tkaczyk[9]. *[1]Université Laval, Quebec; [2]Ottawa Hospital, Nepean; [3]Hôpital Maisonneuve-Rosemont; [4]McGill University; [5]IRM, Montreal; [6]Nanaimo Regional Hospital, Nanaimo; [7]University of Saskatchewan, Saskatoon; [8]JSS Medical Research, Montreal; [9]Janssen, Toronto, Canada*

**Background:** Recent studies have suggested that early and aggressive treatment of spondyloarthritis, including ankylosing spondylitis (AS) and psoriatic arthritis (PsA), may be associated with favorable patient outcomes, reducing synovial inflammation, delaying joint damage, and maintaining functional status.
**Objectives:** The objective of this analysis was to determine the predictive factors of ASDAS remission in AS patients treated with infliximab (IFX) or golimumab (GLM) in a Canadian routine clinical care setting.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis, or psoriatic arthritis with IFX or GLM. Eligible patients for this analysis included AS patients treated with IFX or GLM between 2005 and 2015. Variables associated with ASDAS remission (<1.3) were examined using univariate analysis and those showing a statistical trend (P<0.150) were considered in multivariate logistic regression analysis to identify independent predictors.
**Results:** A total of 582 patients were included in the analysis with a mean (SD) age of 45.8 (12.2) years and a disease duration of 8.3 (10.2) years. The majority of patients were male (57.2%). Upon 12 months of treatment statistically significant and clinically meaningful improvements were observed in ASDAS (3.6 vs. 2.3; P<0.001), BASDAI (6.2 vs. 3.8; P<0.001), BASFI (5.6 vs. 3.9; P<0.001), morning stiffness (74.2 vs. 42.8; P<0.001), and HAQ-DI (1.12 vs. 0.77; P<0.001). The proportion of patients who achieved ASDAS remission was 22.3% and 22.2% at 6 and 12 months, respectively. Sustained remission was achieved by 16.0%. In univariate analysis, male gender (male vs. female: 25.2% vs. 14.1%; P=0.073), previous use of a biologic (experienced vs. naive: 37.5% vs. 20.9%; P=0.129), lower ESR (P=0.096), lower BASFI (P=0.003), lower BASDAI (P=0.002), lower morning stiffness (P=0.120) and lower HAQ-DI (P=0.001) showed a statistical trend in their association with ASDAS remission at 12 months of treatment. Age, disease duration, CRP, psoriasis, peripheral arthritis, inflammatory bowel disease, uveitis, HLA-B27 and presence of enthesitis did not have an impact of ASDAS remission. Multivariate logistic regression analysis showed that, upon adjusting for covariates, non-exposure to a previous biologic (OR=3.40; P=0.078) approached statistical significance and lower HAQ-DI (OR=0.36; P=0.004) was a significant independent predictor of ASDAS remission.
**Conclusions:** Twelve-month treatment with IFX or GLM in a real-world setting was associated with significant improvements in disease parameters. Prior exposure to a biologic and lower HAQ-DI were identified as independent predictors of ASDAS remission upon adjusting for potential confounders.

## AB0662 INDIRECT COMPARISON OF TNF INHIBITORS FOR ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: META-ANALYSIS OF RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIALS

M. Fan[1], J. Liu[2], B. Zhao[2], M. Zhao[1], X. Wu[1], J. Gu[1]. *[1]the third affiliated hospital of Sun Yat-Sen University; [2]the first affiliated hospital of sun yat-sen university, Guangzhou, China*

**Background:** For ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA) patients, tumor necrosis factor (TNF) inhibitors are recommended when disease activity persists despite non-steroidal anti-inflammatory drugs.
**Objectives:** To evaluate the efficacy and safety of TNF inhibitors in patients with AS and nr-axSpA.
**Methods:** Searching PubMed, Embase, Cochrane Library, CNKI and WanFang databases, we included all double-blind randomized controlled trials (RCTs) that compared a TNF inhibitor with placebo in AS/nr-axSpA patients. The efficacy endpoints included the proportions of patients reaching Assessment in Ankylosing Spondylitis 20% response (ASAS20), ASAS5/6, partial remission, and Bath Ankylosing Spondylitis Disease Activity Index 50% improvement (BASDAI50). We used adverse events (AEs), withdrawals due to AEs and severe AEs to evaluate the safety of biologics. TNF inhibitors were pooled to perform comparison with placebo and among themselves, calculating odds ratios (OR) with associated 95% credible intervals (CrI), probability of being best ($P_{best}$) and the surface under the cumulative ranking curve (SUCRA) as well as numbers needed to treat (NNT).
**Results:** Twenty-nine double-blind RCTs with 5200 patients were included in the analysis focusing on 6 TNF inhibitors, including etanercept, intended copies of etanercept, adalimumab, infliximab, golimumab and certolizumab. Compared with placebo, TNF inhibitors were efficacious in achieving ASAS20, ASAS5/6, partial remission and BASDAI50 responses, but with an increased risk of AEs and withdrawals due to AEs. No significant differences in efficacy were found among biologics, except that etanercept had a higher rate of ASAS20 response compared with golimumab in the Chinese patients (OR 4.78, 95% CrI 1.20–17.84). Among the Chinese population, etanercept was ranked the most efficacious therapy for ASAS20 with NNT of 2 ($P_{best}$ 93.6%, SUCRA 0.97).
**Conclusions:** Compared to placebo, TNF inhibitors are efficacious in controlling disease activity for AS and nr-axSpA patients without a higher risk of severe AEs. Although no significant differences in efficacy among biologics were found, the Chinese population had a better ASAS20 response to etanercept.

## AB0663 EFFICACY AND SAFETY OF ADALIMUMAB IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS - AN INVESTIGATOR-INITIATED RANDOMIZED PLACEBO-CONTROLLED TRIAL

S. Krabbe[1], M. Østergaard[1], I.J. Sørensen[1], B. Jensen[1], O.R. Madsen[1], G.P. Eng[2], K.H. Asmussen[1], J. Møller[3], L. Balding[3], S.J. Pedersen[1]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Frederiksberg, Gentofte and Hillerød; [2]Department of Rheumatology, Køge Sygehus; [3]Department of Radiology, Herlev and Gentofte Hospitals, Denmark*

**Background:** This study investigates the effect of adalimumab (ADA) in patients with axial spondyloarthritis (axSpA).
**Objectives:** In an investigator-initiated randomized, placebo-controlled, double-blinded trial (NCT01029847) the efficacy of adalimumab was investigated in patients with axSpA according to the Assessment of Spondyloarthritis International Society (ASAS) criteria.(1,2)
**Methods:** 49 patients with axSpA, BASDAI≥4.0 despite treatment with NSAID and clinical indication for TNFα inhibitor treatment were randomized to s.c. placebo (PLA) or ADA 40 mg eow from baseline to week 6. All patients received ADA from weeks 6 to 24. At week 24, patients with a BASDAI reduction >50% or 2.0 were considered responders. MRI of the spine was scored according to SPARCC Spine Inflammation Index by an experienced reader blinded to all other data. Data from the randomized period (week 0–6) were analysed by Chi-square, unpaired t-tests and Mann-Whitney U tests as appropriate.

**Abstract AB0663** – Table 1

| | Adalimumab | | | Placebo | | | Comparison of treatment groups at week 6, p-value* | Comparison of treatment groups for change from baseline to week 6, p-value* |
|---|---|---|---|---|---|---|---|---|
| | Baseline | Week 6 | Change from baseline to week 6 | Baseline | Week 6 | Change from baseline to week 6 | | |
| BASDAI | 6.3 (1.2) | 3.9 (2.4) | –2.4 (2.2) | 6.4 (1.5) | 5.8 (2.2) | –0.6 (1.8) | 0.007 | 0.005 |
| BASFI | 5.2 (1.9) | 2.9 (2.1) | –2.3 (1.9) | 5.0 (2.1) | 4.9 (2.3) | –0.2 (1.3) | 0.005 | 0.000 |
| BASMI | 2 (1; 4) | 2 (1; 3) | 0 (–1; 0) | 3 (2; 4) | 2 (1; 5) | 0 (–1; 1) | 0.64 | 0.46 |
| VAS pain | 68 (19) | 36 (25) | –33 (31) | 65 (19) | 63 (24) | –2 (25) | 0.001 | 0.001 |
| VAS patient global | 70 (18) | 40 (28) | –32 (30) | 68 (19) | 63 (27) | –5 (26) | 0.007 | 0.002 |
| VAS physician | 55 (46; 78) | 26 (11; 53) | –18 (–44; –7) | 72 (48; 80) | 56 (35; 72) | –5 (–22; 8) | 0.004 | 0.028 |
| SPARCC spine | 7 (1; 15) | 1 (0; 12) | –2 (–12; 0) | 5 (2; 8) | 3 (2; 7) | 0 (–3; 1) | 0.21 | 0.046 |

Mean (SD) or median (IQR). *Unpaired t-tests for BASDAI, BASFI, VAS pain and VAS global. Mann-Whitney U tests for BASMI, VAS physician and SPARCC MRI spine score. P<0.05 is considered significant.

**Results:** Mean (range) age was 38 years (20–61), symptom duration 12 years (0–45) and time since diagnosis 3 years (0–38). 51% were males, 74% HLA-B27 positive, 20% had a history of uveitis, 4% of psoriasis and 6% of inflammatory bowel disease.
At week 24, a BASDAI reduction >50% or 2.0 was attained by 32 of 49 (65%) patients (58% and 72% in the PLA and ADA groups, respectively). 61% of patients achieved ASAS 20 response and 61% ASAS 40 response. From baseline to week 6, the SPARCC MRI spine score improved significantly more in the ADA group than in the PLA group, as did clinical variables (Table):
Treatment was discontinued in 5 patients due to adverse events during ADA treatment, due to rash (1), unspecified allergic reaction (1), paresthesia and reduced sensibility of 2 fingers (1), back pain worsening (1), and hospitalization due to myalgia and malaise (1).
**Conclusions:** Adalimumab significantly improved clinical and MRI measures of disease activity already at week 6 compared to placebo. 2/3 of patients achieved the clinical endpoint at week 24, confirming the clinical efficacy in axSpA.

## AB0664 HIGHER EXPRESSION OF MICRORNAS IN PERIPHERAL BLOOD MONONUCLEAR CELLS IN ANKYLOSING SPONDYLITIS

X. Li, Q. Li, J. Gu. *Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease characterized by inflammatory back pain and enthesis. MicroRNA (miRNA) are an abundant class of small RNA that can play an important role in gene regulation and participate in many physiological and pathological process[1]. According to the microarray results previously, our group found that the expression levels of miR-17–5p, miR-27a, miR-29a and miR-126–3p were higher in AS group than in healthy group. Moreover, the expression levels of miR-17–5p downregulated significantly after regular etanercept treatment, while the other 3 microRNAs slightly upregulated. Another study also reported elevated miR-29a expression in PBMCs of patients with AS[3], while no further study on investigating the treatment effect on miRNA expression.
**Objectives:** To investigate the expression level of the four miRNAs mentioned before in AS and healthy controls. The changes of microRNAs expressions after regular therapies are also the focus of our study.
**Methods:** We initially validated the expression levels of miR-17–5p, miR-27a, miR-29a, miR-126–3p in the PBMCs of AS (n=99) and healthy controls (n=39) using real-time quantitative reverse transcription PCR (qRT-PCR). Patients with AS were divided into 4 groups according to their different therapies, including 12-week Celecoxib/Etanercept /combination therapy and 24-week rh TNFR:Fc therapy (n=16, n=23, n=22 and n=38 respectively). Fold change for each reaction was calculated as $2 - \Delta\Delta Ct$.
**Results:** Significantly higher expression of the four miRNAs (miR-17–5p, miR-27a, miR-29a and miR-126–3p) were observed in AS ($\Delta Ct$ value: 4.40±2.02, 6.75±1.58, 1.52±1.12 and 2.34±1.58, $p<0.001$, respectively) than in healthy controls ($\Delta Ct$ value: 6.15±1.41, 8.05±0.86, 4.29±1.16, and 4.17±1.01, $p<0.001$, respectively). The corresponding fold changes were 3.34 (0.61–18.37), 2.47 (0.71–8.59), 6.82 (2.24–20.79) and 3.55 (0.96–13.06). Moreover, expressions of miRNAs were dramatically downregulated after 24-week etanercept therapy except miR-29a ($p$=0.013, $p$=0.043, $p$=0.025 and $p$=0.262 respectively). A 12-week celebrax therapy or combination therapy can significantly reduce the expression level of miR-126–3p ($p$=0.006 and $p$=0.016). There were no significant difference between AS patients before and after treatment in miR-17–5p, miR-27a as well as miR-29a.
**Conclusions:** We validated the 4 elevated miRNAs expression in PBMCs of patients with ankylosing spondylitis. Different treatments can reduce the expression of microRNAs to some extent.

# Spondyloarthritis - clinical aspects (other than treatment)

## AB0665 IMPACT OF DISEASE ACTIVITY ON PSYCHOLOGICAL STATUS IN PATIENTS WITH SPONDYLOARTHRITIS

A. Ben Tekaya, I. Mahmoud, R. Tekaya, O. Saidane, L. Abdelmoula.
*Rheumatology charles Nicolle, Tunis, Tunisia*

**Background:** Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a standard instrument regularly used to assess disease activity of patients with spondyloarthritis (SpA). However, the well-being of a patient is also affected by impairment of function as well as psychological status especially depression and anxiety.
**Objectives:** The aim of this study was to investigate the relationship between disease activity measured by the BASDAI and psychological variables.
**Methods:** This was a cross-sectional study at a rheumatology department over a twelve months period. Patients with diagnosis of SpA (ASAS 2009) were recruited. Respectively, disease status and psychological status were assessed by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Hospital Anxiety and Depression Scale (HADS). A statistical analysis was performed.
**Results:** A total of 100 patients were enrolled; mostly male (71%). The mean age of the sample was 41,72 (±13,57) years; the mean disease duration at study baseline was 11,87 (±10,3) years. Mean morning stiffness 30,26 minutes. The mean score on VAS pain was 60,3mm (±28,66). At baseline, the mean BASDAI score was 4,5 (±2,3); 57% have BASDAI greater than or equal to 4. The mean (SD) scores by the study participants on the HADS-Anxiety (HASD-A) and HADS-Depression (HADS-D) were 8,9 (±5,08) and 7,23 (±5,27), respectively. The prevalence of anxious symptomatology based on the HADS-A was 39%, 18% were classified as possible anxiety cases. Based on HADS-D scores, 31% of the patients presented symptoms of depression and 15% possible depression. BASDAI was positively correlated with both HADS-D ($r$=0.505, $p<0.0001$) and HADS-A ($r$=0.425, $p<0.0001$). The multivariate logistic regression analysis revealed that patients' whose BASDAI>4 at baseline was an independent risk factor associated with the risk of both depression (OR=4.9, 95%CI [1.7–13.9], p=0.002) and anxiety (OR=2.7, 95%CI [1.1–6.7], p=0.027).
**Conclusions:** This study underscore that high disease activity increased significantly the risk of depression and anxiety in SpA.

## AB0666 PROGRESSION OF AORTIC AND VALVE ABNORMALITIES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Godzenko[1], Y.O. Korsakova[2], A. Bochkova[2], O. Rumyantseva[2], V. Badokin[1], S. Erdes[2]. *[1]Russian medical academy of postgraduate education; [2]Nasonova research institute of rheumatology, Moscow, Russian Federation*

**Background:** Aortic and valve abnormalities are systemic inflammatory manifestations of ankylosing spondylitis (AS). Data on the prevalence, clinical significance and evolution are discrepant.

**Objectives:** To assess the dynamics of aortic and valve abnormalities detected by transthoracal echocardiography (TTE) in AS pts according to the results of prospective study.
**Methods:** 45 pts with AS (The New-York criteria) age <60 years, with the initial TTE - changes of aorta and valves and without concomitant cardiac diseases were assessed at the Institute of Rheumathology from 2008 to 2015. At baseline 15 pts had aortic root dilatation, 21 – aortic wall thickening, 32 – aortic valve thickening, 15 – mitral valve thickening. 5 pts had valve prosthesis (including 2 with both aortic and mitral prosthesis). 19 pts had aortic regurgitation (AR), 15 of them – 1–2 degree, 4 – 3–4 degree), 20 pts had mitral regurgitation (MR) 1–2 degree. Subaortic thickening ("bump") was detected in 10 pts. 16 of 45 pts used anti-TNF drugs during the observation period, 14 pts – only NSAID, 15 – NSAID and DMARD, including sulfaslazine (11 pts) and metotrexate (4 pts). All pts were underwent re-TTE after 1–4 years
**Results:** Negative dynamics was detected in 27 (60%) pts in total. Progression of aortic root dilatation from 1 to 6mm was detected in 12 of 15 pts (80%), in 2 - dilatation was first identified. 14 pts had first identified valve thickening (9 – aortic, 4 – mitral, 1 – both). 5 pts were underwent valve replacement: 4 – aortic, 1 – mitral. AR progression was detected in 10 pts (in 2 – of 2 degree, in 8 – of 1 degree), MR progression – in 6 pts of 1 degree). A negative correlation was found between anti-TNF- therapy and progression of aortic root dilatation (R=-0,329, P=0,03). "Subaortic bump" was first identified in 3 pts. Among 10 pts with subaortic bump initially, decrease from 8mm to 3mm was found in 1 pts, complete regression – in 2, all used biologics.
**Conclusions:** Aortic root and valve abnormalities tend to progression in most AS pts. Subaortic bump is able to regress if it is due to inflammatory edema and not fibrosis. Active anti-inflammatory therapy can protect in cardiac disease progression.

## AB0667 HLAB27 ASSOCIATED UVEITIS TRENDS AND PATTERNS OF A MULTIETHNICITY COHORT: NEED FOR COMBINED RHEUMATOLOGY AND EYE SERVICES?

A. Pradeep[1], P. Kumar[1], A. Moorthy[2]. *[1]ophthalmology; [2]Rheumatology, university hospitals of leicester, leicester, United Kingdom*

**Background:** Uveitis is associated with systemic autoimmune disease and often present to Eye Department as an emergency. Uveitis can be a first presenting symptom of systemic autoimmune disease and often not followed up in Rheumatology services. Approximately 40% of patients with acute anterior uveitis (AAU) have undiagnosed spondyloarthritis (1). Previous studies in UK by Hamilton et al showing delay in diagnosing spondyloarthropathy (SpA) up to 8 years (2). Delay in referral of HLA B27 positive Uveitis by primary care and secondary care physicians to Rheumatology may be a reason for the delayed diagnosis (3,4).This can be better avoided if inter-speciality referral and pathways are established. To enable the best effective care delivered for Uveitis patients,we attempted to review the current trends of our own cohort of patients with HLAB27 Associated Uveitis
**Objectives:** - To review the cohort of HLA B27 positive uveitis in a busy tertiary care hospital serving multi ethnic patients.
- To observe the pattern and association of systemic autoimmune disease particularly spondyloarthropathy.
- To see how many cases been referred to Rheumatology services and how best they are managed with systemic immunosuppressive therapy.
**Methods:** The methodology includes retrospective analysis of data captured from the Uveitis Data Base maintained by ophthalmology department. The consecutive new cases of HLAB27 uveitis were identified for three-year period from 2011 to 2014. The clinical records, ophthalmology examination records, demographic details, ethnicity were reviewed. The type of uveitis, presenting symptoms and systemic associations were explored. Modes of treatment, complications and pattern of referral and input from other specialties were assessed as well treatment plans were collected. The data were captured by using standardized proforma. The captured data was analysed using excel spreadsheet.
**Results:** Total of 624 Uveitis patients 73 cases (105 eyes) of HLAB27 positive uveitis (11.7%) were identified.The most common systemic association in our cohort was Ankylosing Spondylitis (31.8%). 34%of the affected eyes did not develop anycomplications.88% had anterior uveitis with 38% showing chronicity.79% of the patients had better than 0.3LogMar acuity in the affected eye on presentation.
**Conclusions:** The data collected emphasizes the higher incidence of Ankylosing Spondylitis in patients, who presents with uveitis associated with positive HLA B27. Our result reiterates the need for establishing combined clinics to avoid delay in referrals enhancing patient management and experience.
**Disclosure of Interest:** None declared

## AB0668 EFFECTS OF INFLIXIMAB TREATMENT IN TERMS OF METABOLIC PARAMETERS AND INSULIN RESISTANCE IN ANKYLOSING SPONDYLITIS PATIENTS

A. Cefle, D.T. Karadag, M. Bilen, S.Y. Sener, O.O. Isik, A. Yazici. *Division of Rheumatology, Kocaeli University, Kocaeli, Turkey*

**Background:** Risk of cardiovascular mortality is increased in patients with ankylosing spondylitis (AS). Chronic inflammation plays a crucial role in the development of accelerated atherosclerosis. TNFa is a pro-inflammatory cytokine which may be a key mediator in the pathophysiology of atherogenesis. This cytokine reduces the activity of insulin and causes insulin resistance (IR).
**Objectives:** We assessed the effect of infliximab treatment on insulin sensitivity and metabolic parameters in patients with AS.
**Methods:** In this prospective study, 20 consecutive AS patients (11 men and 9 women, mean age 39±10 and mean disease duration 12±7 years) fulfilling the modified 1984 New York criteria for AS were investigated. All patients were treated with iv infliximab (5 mg/kg, 0, 2, 6. week and ewery 8 weeks). A complete biochemical profile was obtained before and after 24 weeks of infliximab therapy (BASDAI, BASFI, ESR, CRP, hsCRP, lipid parameters, fasting glucose, insulin, HbA1C, waist circumference, weight, BMI, blood pressure). No patients were taking medications known to affect glucose, lipid metabolism and blood pressure. The Homoeostasis Model Assessment of Insulin Resistance Index (HOMA-IR) and Quantitative Insulin Sensitivity Check Index (QUICKI) were used to measure IR.
**Results:** After 24 weeks of infliximab treatment there was no statistically significant difference in fasting glucose levels, fasting insulin, HOMA-IR, QUICKI, HbA1C and blood pressure. Weight (84±18 vs. 87±16, p=0.002), body-mass index (29±6 vs. 30±5, p=0.001), waist circumference (101±12 vs. 104±11, p=0.014) and LDL level (112±42 vs. 127±36, p=0.014) increased significantly from baseline.
**Conclusions:** Infliximab treatment caused an increase in weight, BMI, waist circumference and LDL level but no change in IR. Cytokines associated with inflammation reduce appetite. Amelioration of anorexia with anti-TNF therapy may explain these results. Further studies are needed to clarify the role of factors that contribute to accelerated atherosclerosis in AS.
**Disclosure of Interest:** None declared

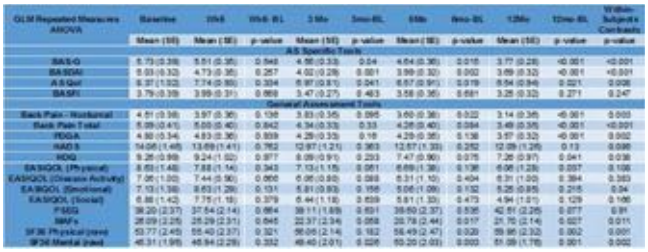
## AB0669 12 MONTH FOLLOW-UP OF PATIENT SATISFACTION AND OUTCOMES OF A NOVEL ANKYLOSING SPONDYLITIS PATIENT CENTERED EDUCATION PROJECT

C.A. Inderjeeth[1,2], J. McQuade[3], C. Johnson[3], K. Briffa[4], J. Edelman[5], N. Cook[3], W. Raymond[6]. *[1]Rehabilitation & Aged Care, Sir Charles Gairdner Hospital; [2]School of Medicine & Pharmacology, The University of Western Australia; [3]Arthritis & Osteoporosis Foundation of WA; [4]Physiotherapy & Exercise Science, Curtin University of Technology; [5]Rheumatology; [6]Sir Charles Gairdner Hospital, Perth, Australia*



**Background:** Ankylosing Spondylitis (AS) specific patient centred interventions are rare. Following educational needs assessment, focus group consultation, and execution of a *Plan, Do, Study, Act* (PDSA) model, we developed and delivered a 6 weekly AS *education for Ankylosing Spondylitis* (AS-P) program to patients diagnosed with AS (New York criteria)
**Objectives:** Determine participant satisfaction and response to the AS-P intervention at 12 months.
**Methods:** Seventy-nine participants, mean age 43.5±14.5 years, diagnosed with AS were recruited for this study (AS-P). Intervention: 6-week group education program facilitated by health professionals. Program content included disease process, medication, pain management, stretches and strategies to cope with depression and fatigue. The program using patient centred approach is based on adult learning techniques and uses self-efficacy and self-management constructs. The SMAS was delivered in a small group setting delivery by interactive teaching and group discussions. The outcomes were measured post-intervention at 3, 6 and 12 months, 42 (of 79) patients completed the 12 month evaluation.
**Results:** At 12 months, 83.3% of patient made behaviour changes after the AS-P program, predominantly, increased exercise (n=7) and lifestyle modifications (n=6), with 94.3% of these patients sustaining these changes. 69% of patients continued to set and achieve goals related to their AS. 71.4% of patients felt that the AS-P gave them all the information they required to manage their condition. 95.2% of patients felt that attending the AS-P was worthwhile. 64.3% of patients reported never forgetting to take their medication, 23.8% forgot to take their medication a couple of times a month, 4.8% forgot to take their medication most of the time, and 7.1% didn't respond.
**Conclusions:** We have developed a program that is effective in improving patient related outcomes with high levels of satisfaction up to 12 months. Improved clinical outcomes are described in a separate abstract. The program is portable and sustainable and can be delivered in community or hospital settings. "Train the trainer program" workshops are planned for health professionals wanting to deliver this program.

## AB0670 ANKYLOSING SPONDYLITIS (AS-P) PATIENT CENTRED EDUCATION PROGRAM IMPROVES DISEASE ACTIVITY AND QUALITY OF LIFE UP TO 12 MONTHS

C.A. Inderjeeth[1,2], W. Raymond[3], C. Connor[4], J. Edelman[5], N. Cook[4], K. Briffa[6], J. McQuade[4]. *[1]Rehabilitation & Aged Care, Sir Charles Gairdner Hospital; [2]School of Medicine & Pharmacology, The University of Western Australia; [3]Sir Charles Gairdner Hospital; [4]Arthritis & Osteoporosis Foundation of WA; [5]Rheumatology, Sir Charles Gairdner Hospital; [6]Physiotherapy & Exercise Science, Curtin University of Technology, Perth, Australia*

**Background:** Patient centered education interventions are rare. After a needs assessment, focus group consultation, and execution of a *Plan, Do, Study, Act* (PDSA) model, we developed and delivered a multidimensional *Ankylosing Spondylitis Education Program* (AS-P) to patients referred via a rheumatologist (meeting the New York criteria for AS).
**Objectives:** To examine the benefits of AS-P for people with Ankylosing Spondylitis (AS) in regards to health status, quality of life and disease activity.
**Methods:** 79 people were recruited in the intervention. Exclusion criteria: <18yo; non-English speaking; comorbid inflammatory musculoskeletal disease; and/or visual, auditory, or cognitive impairment. Participants attended a weekly 2.5 hour patient centered education session facilitated by same two health professionals over 6 weeks. The scripted content included multidimensional strategies including stretches; self-efficacy and self-management constructs and optional 7th week supervised exercise class.
Data collection included demographic, AS disease management characteristics, medication patterns, and outcomes, measured at baseline, 6 weeks, 3 months, 6 months and 12 months using GLM repeated measures ANOVA. Additional outcomes included the: BAS-G, BASDAI, AS-QoL, BASFI, back pain (VAS), PDGA, anxiety (HADs), health distress (HDQ), quality of life (EASIQoL), perceived health (GPH), pain (PSEQ), MAFs and SF-36.
**Results:** At baseline, 43.3% were male and the mean age was 43.5 ±14.5 years. The median time to AS diagnosis from the index symptom experience was 4 years IQR (1–11). The only significant change in medication usage occurred between Month 3 to Month 6 (p=0.018).
The BAS-G, BASDAI and the AS-QoL had improved between baseline to 3, 6 and 12 months (all $p<0.05$). Nocturnal and total back pain had improved between baseline and 12 months (all $p<0.05$). The PDGA and HDQ had improved between baseline and 12 months (all $p<0.05$). The EASI-QOL (physical health composite) had improved at 3 and 12 months ($p<0.05$). There was also a positive trend in the EASIQOL disease activity, emotional state and social composite scores ($p>0.05$). MAFs demonstrated a sustained improvement over 12 months (p=0.011). Similarly, the SF-36 physical (p=0.001) and mental (p=0.002) composite scores had improved 12 months post-intervention.
BASFI (p=0.271) and HADs (p=0.086) demonstrated no improvement 12 months post-intervention.

**Conclusions:** AS-P for AS is effective in improving AS specific disease activity, pain and QOL scores for up to 12 months.

## AB0671 DEGRADATION OF ISOMERIZED TYPE II COLLAGEN MAY SERVE AS A DISCRIMINATIVE BIOMARKER OF INFLAMMATION MEDIATED JOINT DESTRUCTION IN RHEUMATIC DISEASES

C.S. Thudium[1], Y. He[1], N.S. Gudmann[1], K. De Vlam[2], R. Lories[3], S. Hirata[4], Y. Tanaka[4], M.A. Karsdal[1], A.-C. Bay-Jensen[1]. *[1]Nordic Bioscience A/S, Herlev, Denmark; [2]Katholieke Univ.it Leuven; [3]Div. of Rheumatology, Univ. Hosp. Leuven, Leuven, Belgium; [4]Univ. of Occupational and Environmental Hlth., Kitakyushu, Japan*

**Background:** Collagen isomerization is a non-enzymatical process associated with tissue aging, and changes in levels of isomerized peptide fragments may reflect unique changes during pathological conditions. The D-G sequence in C2M is likely to undergo beta-isomerization over time, and may be altered in tissue turnover diseases affecting the joint. We therefore hypothesize that pathological conditions, such as ankylosing spondylitis (AS) or rheumatoid arthritis (RA), which affects the general turnover of cartilage may result in altered levels of isomerized collagen type II.
**Objectives:** The aims of this investigation were to develop a novel assay measuring an isomerized form of MMP degraded collagen II and to investigate whether it can be used as a clinical marker of joint deterioration in inflammatory joint diseases.
**Methods:** A solid phase competitive ELISA was developed applying a specific monoclonal antibody targeting an isomerized type II collagen fragment, C2Mβ. The biomarker was characterized by measuring its generation in vitro by cleavage of bovine cartilage with a range of proteases. Furthermore, the release of C2Mβ into the supernatant of bovine explants cultured ex vivo were measured under normal (without cytokines) and catabolic (TNF-α and oncostatin M) conditions. Serum samples from AS patients (n=28, age 25–76) or RA patients (n=149, age 15–86) were collected and C2Mβ measured. The change in C2Mβ after TNF-alpha treatment for 52 weeks was analyzed in AS patients. ROC curves were generated and the area under the curve calculated (AUC) to assess the assays capacity to distinguish between the diseases. Multivariable logistic regression was employed to correct for age and gender.
**Results:** The antibody against C2Mβ was specific towards the neo-epitope and did not recognize the non-isomerized form. C2Mβ was released from bovine cartilage when cleaved with MMP2 or MMP9 but not Cathepsin S. Levels of C2Mβ was increased in the supernatant of *ex vivo* cultured bovine cartilage explants in response to the catabolic cytokines TNF-α and Oncostatin M ($p<0.001$), compared to unstimulated explants which did not release C2Mβ. The addition of the MMP inhibitor GM6001 to catabolically activated explants completely abrogated the release of C2Mβ. C2Mβ was slightly decreased in AS patients treated with TNF-α inhibitors (10%), although the effect was not significant. C2Mβ was able to distinguish AS from RA with an AUC of 0.785, which increased to 0.905 when including age and gender
**Conclusions:** The C2Mβ neoepitope is released from catabolically activated cartilage and is measurable in human serum. C2Mβ is elevated in AS patients compared to RA patients and the marker can discriminate AS from RA with high diagnostic accuracy. Anti-inflammatory treatment in AS patients resulted in a trend towards a decrease in the marker compared to baseline. These findings suggest that systemic levels of C2Mβ may potentially serve as a joint specific biomarker for monitoring joint turnover and destruction as well as treatment efficacy in rheumatic diseases

## AB0672 PREVALENCE AND RISK FACTORS OF OSTEOPOROSIS AND LOW BONE MINERAL DENSITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN HONG KONG: A CROSS-SECTIONAL STUDY

C.Y.S. Ho. *Department of Medicine & Geriatrics, Princess Margaret Hospital, Kowloon, Hong Kong*

**Background:** The disease process of ankylosing spondylitis (AS) is characterized by chronic inflammation. Osteoporosis is now known to be associated with chronic inflammation. Bone loss occurs early in AS increasing the risk of fracture, and is related mainly to the inflammatory process. This study aims to determine the relationship between AS and osteoporosis.
**Objectives:** To determine the prevalence and risk factors of low bone mineral density (BMD) in a local Hong Kong Chinese cohort of ankylosing spondylitis (AS) patients. Dual X-ray absortiometry (DXA) scan at different sites were compared and evaluated.
**Methods:** Ninety-two patients with AS were enrolled in this study. Clinical, demographic and radiological data were collected. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI), Ankylosing Spondylitis Disease Activity Score (ASDAS), Patient and Physician global scores, Health Assessment Questionnaire (HAQ) and Bath AS Metrology Index (BASMI) were evaluated. BMD at the lumbar

spine via antero-posterior (AP) and lateral projections, neck of femur (NOF) and total hip were measured.
**Results:** Low BMD was found in half of the 92 Chinese AS patients. Factors associated with low BMD were BASDAI, BASMI, post-menopausal status, body mass index (BMI), alcohol use and family history of AS. Multiple logistic regression analysis by backward selection revealed that BASDAI (odds ratio (OR) 1.03, 95% confidence interval (CI)1.00–1.06; $p$ =0.031), post-menopausal status (OR 6.11, 95% CI 1.07–34.81; $p$ =0.041), BMI (OR 0.81, 95% CI 0.71–0.93; $p$ =0.003) and alcohol use (OR 4.79, 95% CI 1.49–15.38; $p$ =0.008) were significantly associated with low BMD. Total hip BMD was more sensitive than AP lumbar BMD in detecting low BMD in AS.
**Conclusions:** Low BMD in AS is not uncommon and often underdiagnosed. BASDAI, post-menopausal status, alcohol use and BMI were independently associated with low BMD in this study.

## AB0673 ARTERIAL STIFFNESS, DISEASE ACTIVITY AND FUNCTIONAL IMPAIRMENT IN ANKYLOSING SPONDYLITIS PATIENTS

C. Avram[1], R.G. Dragoi[2], E. Amaricai[2], M. Dragoi[2]. *[1]Department of Physical Therapy and Special Motricity, West University of Timisoara; [2]Department of Rehabilitation, Physical Medicine and Rheumatology, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania*

**Background:** Cardiovascular risk is an important factor for increased morbidity and mortality in patients with ankylosing spondylitis. Currently, it is estimated that the cardiovascular risk from atherosclerotic origin in patients with ankylosing spondylitis is twice as high compared with aged-matched controls [1–4]. Arterial stiffness appears to contribute to the complex aetiology of cardiovascular disease and is regarded as a predictor of increased cardiovascular risk and all-cause mortality [5].
**Objectives:** To assess arterial stiffness in relation to the disease activity and functional limitation in patients with ankylosing spondylitis.
**Methods:** Twenty four patients (mean age: 45.8±11.7 years) suffering of ankylosing spondylitis (disease duration: 11.1±5.1 years) and twenty four gender and age-matched healthy controls were included in the study. Clinical, biological and functional status of ankylosing spondylitis patients was recorded. Arterial stiffness was assessed by measuring pulse wave velocity (PWV) and pulse wave analysis was performed using applanation tonometry.
**Results:** We found significant differences between ankylosing spondylitis patients and healthy controls in regard to PWV (p=0.047), aortic augmentation pressure - AP (p=0.028), augmentation index - AIx (p=0.038) and aortic augmentation index adjusted for heart rate - AIx75 (p=0.011). PWV and AIx75 were significantly associated with the disease functioning score - BASFI (p=0.012, r =0.504; p=0.041, r=0.421). Aortic AP and augmentation indexes (AIx and AIx75) were all associated to ASDAS score (p=0.028, r=0.448; p=0.005, r=0.549; p=0.025, r=0.455).
**Conclusions:** Our study showed that ankylosing spondylitis patients have a higher arterial stiffness than the age-matched controls, leading to an increased cardiovascular risk. We found that arterial stiffness is positively associated with disease activity and functional impairment. Chronic spondiloarthropaties should be screened for arterial stiffness, even in the absence of traditional cardiovascular risk factors, in order to benefit from primary prevention measures.

## AB0674 SECRETORY IGA: NEGATIVE CORRELATION WITH DISEASE ACTIVITY MEASURES IN HLA B27 POSITIVE SPONDYLOARTHRITIS PATIENTS

C. Romero-Sanchez[1], F. Salas-Cuestas[2], J. Bello[1], I. Arias[3], W. Bautista-Molano[2], V. Parra I[4], D. Herrera[3], R. Valle-OÑAte[1]. *[1]Rheumatology Department, Hospital Militar Central; [2]School of Medicine, Universidad Militar Nueva Granada; [3]Instituto de Genética Humana, School of Medicine, Pontificia Universidad Javeriana; [4]School of Medicine, Universidad de la Sabana, Bogota, Colombia*

**Background:** The human Major Histocompatibility Complex (*MHC*) encompasses a group of genes located in chromosome 6 (6p21.3); it encodes proteins expressed on the cell surface. The HLA-B27 is a MHC class I molecule associated with spondyloarthritis (SpA); many theories related to its natural function have been postulated to explain its pathogenic role.[1–2] Relevance of HLA-B27 molecule in the mucosal immune system, the gut mucosa inflammation, and secretory IgA (SIgA) production remains unresolved.
**Objectives:** The purpose of this study was to evaluate the correlation between serum SIgA levels and disease clinical activity in a cohort of HLA B27 positive and negative SpA patients with ReA and USpA, in a clinical center in Bogota Colombia.
**Methods:** The concentration of SIgA in serum was measured by an enzyme linked immunosorbent assay and the HLA-B27 was assessed by flow cytometry, followed by Polymerase Chain Reaction with sequence specific primers, in 46 patients with USpA and ReA. Clinical gastrointestinal manifestations and activity indices (BASDAI, ASDAS x CRP and ASDAS x ESR) were collected from each patient. Statistical analysis was performed using Stata 11.2 ® software for Windows; Pearson correlation was used to measure the degree of relationship between SIgA and clinical activity depending on the HLA B27 status. The study was approved by local hospital's ethics committee.
**Results:** 46 SpA patients completed the study with mean age of 34,8 ±12,3 years; 78,2% were men, 52,17% were HLA B27 positive, 60.9% of patients reported gastrointestinal symptoms such as diarrhea, abdominal pain, abdominal swelling and hematochezia. 63,6%, 88,6% and 100% of patients had disease activity evaluated by BASDAI, ASDAS-CRP and ASDAS-ESR scores, respectively, and 71,7% of patients had SIgA concentration above the upper normal range. The SIgA concentration was correlated with disease activity measures: BASDAI, ASDAS-CRP and ASDAS-ESR (-42% (0.0046), -37% (0.014) and -45% (0.0021) respectively); the negative coefficient correlation between SIgA and BASDAI, ASDAS-CRP and ASDAS-ESR was higher in HLA-B27 $^{+}$ patients -70% (0.0009), -58% (0.0093) and -57% (0.0083) than in HLA-B27 $^{-}$ patients.

| Correlation | HLA-B27 positive | | HLA-B27 negative | |
|---|---|---|---|---|
| | Pearson Coefficient | P value | Pearson Coefficient | P value |
| SIgA vs BASDAI | –70% | 0.0009 | –21% | 0.3397 |
| SIgA vs ASDAS-CRP | –58% | 0.0093 | –20% | 0.3579 |
| SIgA vs ASDAS-ERS | –57% | 0.0083 | –35% | 0.0992 |

**Conclusions:** These results suggest that SIgA levels in patients with ReA and USpA might be a correlate of disease activity measures based upon HLA-B27 status and might reflect an immunomodulatory role in these pathologies.

## AB0675 IS THE PERIODONTAL CLINICAL AND MICROBIOLOGICAL CONDITION IN SPONDYLOARTHRITIS SIMILAR THAN RHEUMATOID ARTHRITIS?

S. Giraldo Q[1], C. Romero-sanchez[1,2,3], W. Bautista-Molano[1], J.M. Bello-Gualtero[1], J. De-Avila[2], L. Chila M[2], D.M. Castillo[2], G.I. Lafaurie[2], J. Londoño[3], R. Valle-Oñate[1,3]. *[1]School of Medicine, Universidad Militar Nueva Granada; [2]Unit of Oral Basic Investigation, Universidad El Bosque; [3]Spondyloarthropathy Group, Rheumatology Department, Hospital Militar Central/Universidad de la Sabana, Bogotá, Colombia*

**Background:** The periodontal disease (PD) generates systemic impact given the increase in acute phase reactants related to the inflammatory. The relationship between Rheumatoid arthritis (RA) and PD is supported by pathological and immunological data but is not clear this association in Spondyloarthitis (SpA). The association between their respective disease activities and severities are less documented. Periodontal inflammation may affect disease activity and severity on patients with SpA.
**Objectives:** To evaluate the association between clinical indices of PD and markers of disease activity in SpA patients and compare these markers in patients with RA and controls.
**Methods:** The rheumatologic condition and periodontal status of 79 individuals with SpA, 59 patients with RA and 79 matched-controls were evaluated. *Porphyromona gingivalis (Pg)*, IgG1, and IgG2 to *Pg* were determined. The C-reactive protein-, erythrocyte sedimentation rate-, HLA B 27, rheumatoid factor-

RF, anti-citrullinated protein antibodies, and disease activity measures for SpA and RA were assessed. The rheumatologic Scores and periodontal condition were evaluated by two experienced and calibrated periodontists and rheumatologist. The groups were compared with Kruskal Wallis, Mann-Whitney U and Wilcoxon test's test and a paired t-test. The chi-square test was used to evaluate periodontal variables and SpA disease activity. The institutional Ethics Committee approved the study.

**Results:** 79 SpA patients with the following subtypes were included: Ankylosing Spondylitis (AS) (19), undifferentiated SpA (46), and reactive arthritis (ReA) (14). SpA patients had a considerable frequency of periodontitis (55.7%). Of them, 39.2% were classified as moderate and 2.5% as severe periodontal condition. No differences was found in frequency of periodontal condition between subtypes. SpA patients showed lower levels of insertion loss compared to RA patients and the control group ($p<0.05$). A significant association was observed in microbiological variables of SpA patients. The frequency of (*P gingivalis)* in the control group was 51.9% compared to 30% in SpA (p=0.015), especially in those with good response to NSAIDS ($p= <0.05$). Significant associations between the severity of periodontal involvement in RA patients was observed. 63.8% of RA patients had moderate severity disease (49.2%) and severe periodontitis (13.6%) (p=0.035) but not in SpA group. There were not association between disease activity measures in SpA, periodontal and severity condition.

**Conclusions:** As compared to RA and healthy controls, periodontal condition in SpA patients was similar. Lower grades of severity and bacterial load were found. This suggests that an interdisciplinary treatment between periodontists and rheumatologists may help to modulate periodontal condition and prevent systemic impact

## AB0676 EVOLUTION OVER THIRTY YEARS OF THE PROFILE OF INPATIENTS WITH REACTIVE ARTHRITIS IN A TERTIARY RHEUMATOLOGY UNIT

A. Brinster, X. Guillot, C. Prati, D. Wendling. *Rheumatology, CHU Jean Minjoz, Besançon, France*

**Background:** Reactive arthritis (ReA) are sterile arthritis occurring after extra articular bacterial infection, mainly located in gut or genito urethral mucosa

**Objectives:** The aim of this study was to analyze, over 30 years, frequency as well as clinico-biological and therapeutic characteristics of ReA, comparing two periods.

**Methods:** In this retrospective monocentric study, the charts of all the patients followed in our unit between January 1st 1984 and April 2014 with the diagnosis or ReA, according to International Classification Criteria (1), were recorded and clinic biological features, management and outcome were analyzed, and compared between two periods: from January 1984 to December 1993, and from January 2004 to December 2013.

**Results:** 62 patients fulfilling international diagnosis criteria were analyzed. We found no significant differences (Table) between the two periods in incidence of new cases, clinical presentation (rheumatologic and extra articular features), biological and microbiological data or outcome. Change in therapeutic management was obvious with occurrence of anti TNF use in the recent period.

**Conclusions:** Reactive arthritis is still a current rheumatologic problem, with an apparently stable incidence in a developed country, with a need of early and tailored rheumatologic management.

## AB0677 COMPARATIVE CHARACTERISTICS OF RADIOGRAPHIC AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS (NR-AXSPA) BASED ON DATA FROM 12 MONTH FOLLOW UP OF CORSAR COHORT

T. Dubinina, D. Rumyantseva, O. Rumyantseva, A. Demina, E. Gubar, S. Erdes. *VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Clinical similarity of nr-axSpA and ankylosing spondylitis (AS) has been well established, but whether nr-axSpA is an initial stage of AS, or these two subtypes are nosologically self-determined entities is still being debated.

**Objectives:** To study the evolution of early axial spondyloarthritis (axSpA) in the Moscow axSpA cohort of patients (pts) - CoRSaR (Russian acronym from CohoRt of early axSpA pts).

**Methods:** Currently the CoRSaR cohort includes 94 axSpA pts with <5 years of inflammatory back pain duration (ASAS 2009y.criteria). 54 out of them with at least 12 months (mo) follow up pts (FUP) were included into preliminary analysis of axSpA evolution study. Evaluation of all pts at inclusion (Mo0) and FUP (Mo12) visits was similar and included: medical case history, clinical examination, X-ray of pelvis (and other segments of the back bone and joints, when necessary) - following ASAS guidelines, MRI of sacroiliac joints. Pts' mean age at Mo0 visit was 27,1±5,5 y., average disease duration - 22,4±15,1 mo, 49 (90,7%) pts were HLA-B27 positive.

**Results:** Pts were grouped into 2 arms to analyze axSpA evolution: Group 1 – nr-axSpA, Group 2 – AS. The table shows pts' baseline and FUP Mo12 visit characteristics. No significant difference has been found between the two groups – radiographic AS and nr-axSpA - in terms of prevalence of arthritis, enthesitis, BASDAI, ASDAS CRP, and BASFI scores. Radiographic sacroiliitis, i.e., AS, has developed in 9 (39%) out of 23 nr-axSpA pts during 12 Mo FUP.

**Conclusions:** No clinical differences between radiologically confirmed axSpA (i.e., AS) and nr-axSpA were established. AS has developed in 9 (39%) out of 23 nr-axSpA pts during 12 Mo.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3399

## AB0678 A COMPARISON OF DEPRESSION AND ANXIETY LEVELS IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHROPATHY WITH THOSE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Solmaz [1], E. Barisan [2], T. Yildirim [3], S. Akar [4]. *[1] Rheumatology, Namik Kemal University School of Medicine; [2] Internal Medicine, Namik Kmeal University School of Medicine; [3] Physical therapy and rehabilitation, Namik kemal University School of Medicine, Tekirdağ; [4] Rheumatology, Izmir Katip Celebi University School of Medicine, Izmir, Turkey*

**Background:** The concept of axial spondyloarthropathy (SpA) recently recommended by the ASAS includes patients comprising the early and late stages of the disease. This concept also includes patients not meeting the criteria for ankylosing spondylitis (AS) but classified as non-radiographic SpA on the basis of chronic lumbar back pain and other characteristics of SpA. Although this group is more heterogeneous and distinct from AS in terms of some characteristics, it still has a similar burden in terms of disease activity. Psychiatric symptoms can often

be seen in patients during the course of AS. Depressive symptoms are seen at levels of 27.4–55.5% and anxiety symptoms at levels of 19.5–60.9%. Few studies have investigated this situation in the non-radiographic SpA group.
**Objectives:** To assess depression and anxiety levels in AS and non-radiographic SpA groups and to review potentially associated factors.
**Methods:** One hundred fifty-five (114 AS, 41 non-radiographic SpA) patients with axial SpA according to the ASAS definition were included in the study. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was used to assess activity, visual anolog scale (VAS) for spinal pain, the Bath Ankylosing Spondylitis Functional Index (BASFI) for functional capacity and the Ankylosing Spondylitis Quality of Life (ASQOL) for quality of life. The State-Trait Anxiety inventory (STAI), Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI) were used to determine psychiatric symptoms.
**Results:** The AS patient group (mean age 39±10.8, male 73.4%) was older than the non-radiographic SpA group (mean age 35±10.1, male 54.8%), and had a greater preponderance of males.
No difference was determined between the two groups in terms of BASDAI, VAS spinal pain, ASQOL or BASFI scores. Psychiatric measurements were also similar between the AS and non-radiographic SpA groups.
The STAI, BDI and BAI exhibited good correlated with BASDAI, BASFI, ASQOL and VAS spinal pain (Table).

Table 1. Correlations between psychiatric symptoms and disease, functional capacity and quality of life scales

| | | BASDAI | BASFI | VAS spinal pain | ASQOL |
|---|---|---|---|---|---|
| STAI-I (state anxiety) | r | 0.432 | 0.343 | 0.373 | 0.481 |
| | p | <0.001 | <0.001 | <0.001 | <0.001 |
| STAI-II (trait anxiety) | r | 0.375 | 0.342 | 0.234 | 0.420 |
| | p | <0.001 | <0.001 | 0.005 | <0.001 |
| Beck anxiety inventory | r | 0.430 | 0.375 | 0.326 | 0.508 |
| | p | <0.001 | <0.001 | <0.001 | <0.001 |
| Beck depression inventory | r | 0.427 | 0.432 | 0.410 | 0.595 |
| | p | <0.001 | <0.001 | <0.001 | <0.001 |

**Conclusions:** Despite the presence of some clinical differences between the AS group and the non-radiographic SpA group, regarded as the early stage of the disease, the two group exhibit similar features in terms of psychiatric symptoms and disease activity. Psychiatric symptoms are closely associated with disease activity, functional capacity and quality of life.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5390

## AB0679 MARDRID SONOGRAPHIC ENTHESIS INDEX SCORING SYSTEM IS SENSITIVE FOR ASYMPTOMATIC PERIPHERAL ENTHESITIS IN EARLY AXIAL SPONDYLOARTHRITIS

D.F. Lin[1], Z.Y. Hu[1], M.J. Zhao[1], J.Y. Cao[2], J.R. Gu[1]. *[1]Rheumatology department; [2]US department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou, China*

**Background:** Mardird sonographic enthesis index (MASEI) was one of the most wide used scoring systems for enthesitis not only used in spondyloarthropathy (SpA) but also in the other disease such as enthesitis in Behcet's disease. However, no articles mentioned its role in early diagnose in the early axial SpA without peripheral syndromes yet.
**Objectives:** Our study is to find out the role of MASEI in diagnosis of early axial SpA.
**Methods:** Ultrasound was performed by 2 observers blinded to the other examinations and the final diagnosis. All cases were diagnosed as early axial SpA fulfilling 2009 classification criteria but not 1996 New York Criteria with sacroilliac X-ray and MRI.US examination referred to MASEI related regions. BASDI, ASDAS were employed to assess disease activity. MRI was synchronized done for the position with positive findings by ultrasound to make sure the accuracy of the enthesitis.
**Results:** 1) 168 early axial SpA subjects without proof for peripheral enthesitis including physical examination or past history were screened by ultrasound.47 (28.0%) were made diagnosis as perpheral enthesitis by US and 45 (25.6%) were comfirmed by MRI. Mean age of 45 was 29.3 yrs, female-male ratio was 0.36:1, and disease duration was 0.89 yr. Positive HLA-B27 patients were more than HLA-B27negative ones (4:1).
2) The average of MASEI scores were low level (7.26±2.36). No significant differences between HLA(+) and HLA(–) groups. However, the scores for male patients group was higher than female ones (Sig=0.002), especially in respect of tendon thickness, tendon structure disturbance and bone erosion (Sig=0.000,0.001, 0.011).
3) The most common US findings were the chronic presentations as bone erosion, bone calcification. (75.6%, 84.4%) which suggested the enthesis aggression in asymptomatic patinets is a long-term slow change.
**Conclusions:** Our study found MASEI assessment is good tool for early diagnosis and follow up for peripheral enthesitis in early axial SpA and the US positive findings might be earlier than the clinical presentations.

## AB0680 WHAT PATIENTS CLAIM TO BE HIP PAIN DOES NOT ALWAYS REFER TO THE ACTUAL HIP JOINT. RESULTS FROM A CLINICAL AND RADIOLOGICAL EVALUATION COHORT IN CLINICAL PRACTICE

M. Karela[1], L. Rickard[2], A. Georgiou[1], A. Khan[1], E. Roussou[1]. *[1]Rheumatology, BHRUT; [2]Queens Mary's University of London, Medical school, London, United Kingdom*

**Background:** The hip joint is a site of involvement in a number of rheumatic conditions. Patients are often complaining of hip pain. The "Hip" as a complaint or a joint involved in disease is being used, as a metric in a number of indices or questionnaires, to evaluate IBP (1) or Spondyloarthropathies (such as BASDAI question 2) (2). However, what patients are describing as "hip" pain is not always referred to the actual hip joint.
**Objectives:** To assess which structure(s) patients indicate when they are referring to hip pain.
**Methods:** A diagram has been developed which has been used as a proforma to design on the site of "hip pain" from patients (new and/or follow up) when seen in clinic. After detailed history and examination, an accurate description of the site referred to as "hip" was recorded. Radiological imaging was utilised, for those patients with either multiple sites or clinically unclear causes of "hip" pain, to confirm or exclude the clinical diagnosis for the pain. The study classified as an audit and took place at a single centre between August 2014 and September 2015.
**Results:** A total of 54 patients (M:F 10:44) have been assessed [mean age of 57.6 years (sd ±14.1)]. Total sites identified and evaluated were 72 as 14 patients of 54 (25.9%) indicated more than 1 site when describing their hip pain [10 patients:2 sites (18.5%), 4 patients (7.4%) 3 sites]. A total of 8 structures have been described by patients as the site of their hip pain. These (in addition to the hip joint) were: trochanterum, iliac crests (including anterior superior, posterior superior and anterior inferior) lumbar spine, sacroiliiac joint. Radiological evaluation performed on 40/54 patients (74%). From those, 23 patients had X-rays (57.5%), 13 patients had ultrasound (32.5%), 4 patients (10%) had MRI.
Following clinical and radiologic evaluation the structures identified and confirmed as the source of the hip pain were: Trochanterum (n=19; 26.3%), followed by hip joint (n=15; 20.8%), Iliac crest (n=13; 18%), Lumbo-sacral spine (n=6; 8.3%), posterior superior iliac crest (n=6; 8.3%), anterior superior iliac crest (n=5; 6.9%), Sacro-iliac joint (n=5; 6.9%), and anterior inferior iliac crest (n=3; 4.1%).
**Conclusions:** A total of 80% of patients presented with "Hip pain" were referring to a different structure than the hip joint in our study. The greater trochanter was the most commonly reported anatomical structure of pain from patients when they were referring to hip pain. The hip joint itself was 2nd in the frequency of reported hip pain, seen in only 1 in 5 patients coming to clinic complaining of hip pain. We therefore suggest the "hip pain" item, used in questionnaires that do not include clinical evaluation, has to be interpreted with caution.

## AB0681 CAN CONVENTIONAL AND NON-CONVENTIONAL CARDIOVASCULAR MARKERS IDENTIFY DIFFERENT TYPES OF CARDIOVASCULAR INVOLVEMENT IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

F. Atzeni[1], L. Gianturco[2], S. Bongiovanni[1], L. Boccassini[1], P. Sarzi-Puttini[1], M. Turiel[2]. *[1]Rheumatology Unit, L. Sacco University Hospital; [2]Cardiology Unit, Department of Biomedical Sciences for Health, IRCCS Galeazzi Orthopedic Institute, Milan, Italy*

**Background:** Cardiovascular (CV) mortality is increased in patients with ankylosing spondylitis (AS) and psoriatric arthritis (PsA) but there are very few publications concerning CV morbidity. Furthermore, the findings of a number of studies indicate that AS and PsA are associated with different CV manifestations.
**Objectives:** The aim of the study was to use conventional and unconventional CV markers such as common carotid IMT (ccIMT), carotid pulse wave velocity (PWV), ejection fraction (EF) and global longitudinal strain (GLS) assessed by means of speckle tracking echocardiography (STE) to identify the different types of CV involvement in AS and PsA.
**Methods:** The study involved 30 outpatients satisfying the New York diagnostic criteria for AS (14 males and 16 females; mean age 53.07±10.73 years; mean disease duration 5.03±4.06 years), and 30 outpatients satisfying the CASPAR criteria for PsA (15 males and 15 females; mean age 54.27±9.63; mean disease duration 5.73±4.07 years), matched in terms of age, gender and other anthropometric characteristics. None of the participants had smoked cigarettes during the previous ten years or showed any signs or symptoms of CV disease, pulmonary involvement, or any other complication. All of the patients were treated with DMARDs and anti-inflammatory drugs, but none had received any biological or steroid therapy at baseline. They were therefore normal in terms of basal

ECG tracking, blood pressure (BP) values and glyco-lipid profiles (hypertension, dyslipidemia, diabetes and hyperuricemia were exclusion criteria). All of the patients underwent a clinical and standard echocardiographic examination, a carotid ultrasound study (including IMT and PWV assessment), and STE of the left ventricle (LV) using commercial QLAB Philips software.
**Results:** There were no differences between the AS and PsA groups in terms of EF and traditional echocardiographic parameters such as ccIMT (right: median right 0.64 mm, IQR 0.48–0.78 mm *vs* 0.64 mm, IQR 0.50–0.79 mm; $p$=0.07; and left: 0.64 mm, IQR 0.49–0.80 mm *vs* 0.64 mm, IQR 0.50–0.80 mm; $p$=0.08). However, PWV was higher in the PsA group (right: median 7.82, m/sec:, IQR 7.05–8.45, m/sec *vs* 7.08, m/sec, IQR 6.92–7.92, m/sec; $p$=0.04; and left: median 7.80 m/sec, IQR 6.99–8.41 m/sec *vs* 7.07 m/sec, IQR 6.93–7.92 m/sec; p=0.04), and GLS was lower in the AS group (median 19.83, IQR 16.00–24.40 *vs* 20.03, IQR 18.12–24.82; p=0.02).
**Conclusions:** The study findings show that our AS patients had impaired GLS in comparison with those with PsA, thus suggesting a myocardial alteration, and our PsA patients had higher PWV values than the AS patients, thus indicating endothelial dysfunction. There were no differences in ccIMT, EF or other conventional echocardiographic indexes between the two groups, but these findings suggest that AS and PsA patients are affected by different types of CV alteration, and the importance of identifying them in order to prevent CV events.

## AB0682 CORRELATION BETWEEN DISEASE ACTIVITY AND CARDIOVASCULAR PARAMETERS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

F. Atzeni[1], L. Gianturco[2], S. Bongiovanni[1], R. Talotta[1], P. Sarzi-Puttini[1], M. Turiel[2]. *[1]Rheumatology Unit, L. Sacco University Hospital; [2]Cardiology Unit, Department of Biomedical Sciences for Health, IRCCS Galeazzi Orthopedic, Milan, Italy*

**Background:** As cardiovascular (CV) involvement is frequent in patients with rheumatic diseases, it is important to implement strategies of early diagnosis, treatment and follow-up and to understand the relationship between this complication and disease activity.
**Objectives:** To investigate the correlations between the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and a series of conventional and unconventional CV markers in a group of patients with ankylosing spondylitis (AS).
**Methods:** We studied 30 patients with AS diagnosed using the New York criteria (14 males and 16 females with a mean age of 53.07±10.73 years), all of whom underwent a standard echocardiographic examination, a carotid ultrasound study (including IMT and PWV assessment), and speckle tracking echocardiography (STE).
**Results:** Our AS patients had impaired STE-measured LV myocardial longitudinal ε(median 19.83%, IQR 16.00–24.40% *vs* 21.46%, IQR 18.35–25.69%; $p<0.05$) and higher PWV (right: median 7.81 m/sec, IQR 7.03–8.45 m/sec *vs* 6.86 m/sec, IQR 6.42–7.99 m/sec; $p$=0.07: left: median 7.77 m/sec, IQR 6.97–8.38 m/sec *vs* 6.85 m/sec, IQR 6.28–7.88 m/sec; $p$=0.06) compared to healthy controls. Stepwise regression analysis revealed a weak correlation between BASDAI values and right (p=0.04) and left carotid PWV (p=0.05), whereas LV global longitudinal strain (GLS) assessed by means of STE very significantly correlated with disease activity (p=0.001). There was no correlation with common carotid IMT (cIMT) or ejection fraction (EF).
**Conclusions:** PWV and (especially) GLS are very important markers of CV damage and may identify CV involvement in AS patients earlier than conventional indices such as EF or cIMT, furthermore the are a correlation between these markers and disease activity. However, these findings need to be confirmed in a larger series of patients.

## AB0683 HIP INVOLVEMENT IN SPONDYLOARTHRITIS PATIENTS: A FREQUENT AND SERIOUS MANIFESTATION

F. Aguiar, T. Martins-Rocha, R. Fonseca, A. Bernardo, I. Brito. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** The prevalence of hip involvement in spondyloarthritis (SpA) patients varies from 7–50%. It is a cause of significant functional impairment and a marker of poor prognosis.
**Objectives:** The aim of this study was to compare demographic, clinical, laboratory and treatment data among SpA patients with and without hip involvement.
**Methods:** Cross-sectional study including 187 SpA patients that fullfilled the modified New York criteria. The patients completed a questionnaire assessing age at diagnosis, disease subtype, clinical presentation, disease-activity (BASDAI, ASDAS) and functional-indices (BASFI) and BASMI was calculated. The patients' records were consulted to asses the following parameters: presence of HLA-B27 antigen, inflammatory markers (ESR, CRP), radiographs of spine, hip and sacroiliac joints. Hip involvement was considered based on the BASRI-hip scoring system (hip involvement if $\geq$2). The statistical analysis was performed using SPSS 21.0 software, and $p<0.05$ was taken to indicate statistical significance. To compare the differences between the groups, Mann-Whitney U, $\chi^2$ and Fisher tests were used.
**Results:** 187 patients were included, with 55.6% males, median age 46.0 (range 21.0–79.0) years. In this study 75 (40.1%) patients had hip involvement, which was significantly more frequent in males (46.1% vs 32.5%, p=0.041). There were no statistically significant differences in age at diagnosis, age at evaluation, time of diagnosis, smoking habits, subtype of SpA, extra-articular manifestations or HLA-B27 positivity. Ankylosis of bilateral sacroiliac joints and syndesmophytosis were significantly more frequent in patients with hip involvement (56.2 vs 28.8% p<0.001 and 57.3% vs 38.7% p=0.009). Median disease duration was significantly greater in SpA patients with hip involvement (19.0 vs 14.0 years, p=0.001). BASMI, BASFI and ASDAS-CRP were significantly higher in patients with hip involvement (median 5.0 vs 3.8, p<0.001; median 5.1 vs 3.3, p=0.001 and 2.4 vs 2.0, p=0.038, respectively). Median BASDAI and ASDAS-ESR were also higher in these patients but this difference was not statistically significant (3.3 vs 2.8, p=0.361 and 2.3 vs 2.1 p=0.318, respectively). There were no differences in what concerns SpA treatment between the two groups.
**Conclusions:** This study shows that radiographic hip involvement is a frequent disease manifestation in SpA, and that it could be more common in male patients with long-standing disease. It also confirms that hip involvement reflects more severe disease, as it is associated with more axial damage and functional impairment.
**Disclosure of Interest:** None declared

## AB0684 GENDER SPECIFIC DIFFERENCES IN ANKYLOSING SPONDYLITIS AT TREATMENT INITIATION IN PATIENTS TREATED WITH INFLIXIMAB OR GOLIMUMAB

M. Starr[1], M. Zummer[2], D. Choquette[3], B. Haraoui[3], P. Rahman[4], M. Sheriff[5], E. Rampakakis[6], E. Psaradellis[6], B. Osborne[7], A.J. Lehman[7], K. Maslova[7], F. Nantel[7], C.M. Tkaczyk[7]. *[1]McGill University; [2]Hôpital Maisonneuve-Rosemont; [3]Institut de Rhumatologie de Montreal, Montreal; [4]Memorial University, St John's; [5]Nanaimo Regional Hospital, Nanaimo; [6]JSS Medical Research, Montreal; [7]Janssen, Toronto, Canada*

**Background:** The prevalence of ankylosing spondylitis (AS) is 2–3 times higher in men compared to women. Recent studies have suggested that clinical differences exist between both genders with women experiencing a higher burden of disease.
**Objectives:** This analysis examined gender-specific differences with respect to patient and disease parameters at initiation of infliximab (IFX) or golimumab (GLM) for the treatment of AS in a Canadian routine clinical practice setting.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or psoriatic arthritis with IFX or GLM. Patients with AS treated with IFX who were enrolled since 2002 or with GLM enrolled since 2010 were included in this analysis. Between group differences were assessed with the Fisher's Exact test or the independent samples t-test, while linear regression was used to assess the independent association of gender with HAQ-DI, ASDAS, BASDAI, and BASFI improvements at 12 months.
**Results:** A total of 539 AS patients were included in this analysis; 188 (34.9%) patients were treated with GLM and 351 (65.1%) with IFX. The majority of patients were male (61.8%). Mean age and disease duration were comparable between genders for both GLM and IFX, (Table 1). Overall, disease parameters (ESR, PtGA, MDGA, HAQ-DI, ASDAS, and BASFI) were similar for GLM with the exception of BASDAI where higher disease severity was observed among females. Among patients treated with IFX, between gender differences were observed for CRP with significantly lower levels in female patients; however BASDAI and HAQ-DI where significantly higher in females compared to males. Other parameters (ESR, PtGA, MDGA, ASDAS, and BASFI) were similar for IFX between genders. Regression analysis showed that, upon adjusting for baseline levels, female gender (ΔBASDAI=0.603; P=0.035) was associated with increased BASDAI at 12 months of treatment as compare to males. HAQ-DI, ASDAS, and BASFI, on the other hand, at 12 months were comparable between genders.

Table 1. Patient characteristics at baseline by gender

| AS-GLM, mean (SD) | Male (n=115) | Female (n=73) | P-value |
|---|---|---|---|
| Age, years | 46.3 (15.2) | 44.4 (11.8) | 0.498 |
| Disease duration, yrs | 5.2 (10.0) | 6.0 (10.6) | 0.704 |
| CRP, mg/L | 12.6 (15.2) | 17.5 (50.5) | 0.389 |
| BASDAI | 5.6 (2.3) | 6.5 (1.7) | **0.007** |
| **AS-IFX, mean (SD)** | **Male (n=218)** | **Female (n=133)** | **P-value** |
| Age, years | 45.1 (12.0) | 47.0 (10.8) | 0.163 |
| Disease duration, years | 9.6 (10.3) | 8.8 (9.6) | 0.505 |
| CRP, mg/L | 19.2 (26.9) | 12.5 (17.6) | **0.012** |
| HAQ-DI | 1.11 (0.58) | 1.27 (0.63) | **0.019** |
| BASDAI | 6.0 (2.1) | 6.6 (2.1) | **0.013** |

**Conclusions:** Overall, at anti-TNF initiation, female AS patients experience greater disease activity relative to men at initiation of biologic therapy. Whether this represents a gender bias in prescribing, or a gender based difference in the acceptance of biologic treatment or disease assessment, requires additional research.

## AB0685 NOVEL USE OF PULMONARY FUNCTION TESTING IN MEASUREMENT OF DISEASE STATUS IN ANKYLOSING SPONDYLITIS

I.T.D. Thomson [1], G.T.D. Thomson [1], J.L. Johnston [2]. *[1]CIADS; [2]Dept of Medicine and Ophthalmology, University of Manitoba, Winnipeg, Canada*

**Background:** Chest wall restriction is a common outcome in patients with ankylosing spondylitis (AS). Pulmonary function testing (PFT's) demonstrates a restrictive pattern of impairment. This impairment may be exacerbated when the subject is recumbent particularly when sleeping. It is not clear to what extent the specific FVC and FEV1 standing or lying values correlate with other commonly employed physical exam and functional outcome measures.We postulate that critical diminution of recumbent pulmonary function may have an adverse effect on sleep quality and functional outcome measures.
**Objectives:** To determine the utility of PFT testing in AS patients. To determine if FVC and FEV1 values in standing and recumbent postures correlate with other physical and functional outcome measures in AS patients.
**Methods:** 48 consecutive patients with AS had routine history and physical exams including the EDASMI (Edmonton Ankylosing Spondylitis Metrology Index). Standard AS questionnaires were administered BASG, BASDAI, BASFI and Epworth Sleepiness Scale was used to determine degree of daytime sleepiness as a measure of sleep quality. PFT's were performed in standing and recumbent posture. Statistical analysis was performed with SPSS software and included age, sex and smoking adjusted analysis of correlation of FVC standing, FVC lying, FVC difference between standing and lying (FVC delta), FEV 1 standing, FEV 1 lying and FEV1 difference between standing and lying (FEV1 delta).
**Results:** The population consisted of 15 women 10 of whom were smokers and 34 men 24 of whom were smokers. The mean age for the females was 50 years with a mean disease duration of 29.2 years. The mean age of the males was 51 years with a mean disease duration of 28.7 years. Mean BMI for the females was 29.4 and for the males 28.3.
There is a statistically significant correlation in men between FVC and FEV1 with chest expansion, EDASMI, BASFI and BASDAI. Tragus to wall measurement also correlated with FVC measurements. These relationship were observed even when controlling for age and smoking history. FVC delta did not correlate with measurements of AS outcome or the Epworth Sleepiness Scale. BASFI correlates with the Epworth Sleepiness Scale.
In the female cohort, FVC correlation with EDASMI almost reached statistical significance. The FVC in female smokers correlates with the age of onset and duration of disease. However, there was no correlation of FVC or FEV 1 with measurement of chest expansion, tragus to wall measurement, BASFI or BASDAI. The FVC delta did correlate with BASFI in females who have smoked. Correlation between FEV1 delta (but not FVC delta) with the Epworth Sleepiness Scale almost reached statistical significance in the female smoking group.
**Conclusions:** FVC and FEV1 are objective and reproducible measures of pulmonary function. In men, these correlated well with the standard physical examination measurements including chest expansion, tragus to wall measurement and the EDASMI. In turn all of these physical measurements correlated with the patient function as measured by BASFI and to a lesser extent BASDAI. Further study of this patient population is required to determine the utility of PFT testing as an independent outcome variable.

## AB0686 CROSS SECTIONAL COHORT OF INFLAMMATORY BOWEL DISEASE RELATED ARTHRITIS IN RHEUMATOLOGY SECONDARY CARE

H.D. Morrison, R. Sengupta, W. Tillett. *Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom*

**Background:** Joint involvement associated with inflammatory bowel disease (IBD) is well recognised within the concept of spondyloarthritis (SpA). There are two groups of articular manifestation in IBD: an axial arthropathy, including inflammatory back pain, sacroiliitis and ankylosing spondylitis (AS); and a lesser-studied peripheral arthritis, which is broadly divided into type 1 (oligoarthritis) and type 2 (polyarthritis). Previous data comes largely from cohorts of patients studied in gastroenterology secondary care, and identifies IBD related arthritis as a common and poorly understood condition.
**Objectives:** To describe the demographic characteristics, clinical features and current assessment and treatment of patients with Crohn's Disease (CD) or Ulcerative Colitis (UC) related arthritis in rheumatology secondary care.
**Methods:** One hundred consecutive patients with a physician diagnosis of IBD related arthritis were selected for inclusion. Data was collected retrospectively from patient notes, hospital electronic records and imaging software. Demographic, patient reported, clinical and treatment data was collected.
**Results:** In this group of 100 patients, mean age 48.8 years (range 22–86), mean disease duration 7.8 years was an equal proportion of men (54) and women (46) and IBD subtype (CD=53, UC=41, Indeterminate=5, other=3). Disease phenotype and radiographic damage are described in table 1. At the last clinic assessment only 36% of patients had a tender and swollen joint count documented. The burden of peripheral symptoms was small with an average tender joint count of 1.43 (range 0–12) and swollen joint count of 0.67 (range 0–14). Frequency of axial and peripheral symptom assessment was similar at 72% and 75% respectively. Gut symptoms were only assessed in 50% of patients. 21% of patients had a documented history of uveitis and 22% a history of enthesitis. In patients with axial symptoms the mean outcome measures were as follows: BASDAI =4.4 (range 0.9–7.1), BASMI =3.7 (range 0–7.4) BASFI =4 (range 0–8.6), back pain =4 (range 0–9), patient global assessment =3.3 (range 1–9). 79% of patients had a current or prior treatment history with one or more disease modifying anti rheumatic drugs (DMARD), and 37% with anti-TNF therapy. At least 11% had a history of non-steroidal anti-inflammatory use.

Table 1. Demographics and clinical features of 100 patients with IBD related arthritis patients in rheumatology secondary care

| | |
|---|---|
| **Demographics** | |
| Age (years) | 48.8 |
| Disease duration (years) | 7.8 |
| **Clinical features** | |
| HLA-B27 positive | 46.4% |
| Axial disease | 62% |
| Radiographic | 84% |
| Non-radiographic | 16% |
| Peripheral disease | 56% |
| Type 1 | 31% |
| Type 2 | 17% |
| Other | 8% |
| Arthralgia | 10% |
| Erosive disease | 7.6% |
| Radiograph not done | 36.4% |
| History of uveitis | 21% |
| History of enthesitis | 22% |

**Conclusions:** We report data describing a distinct but heterogeneous clinical phenotype of IBD associated arthritis in rheumatology secondary care. We found high rates of DMARD and anti-TNF use, little erosive peripheral disease and variable clinical assessment. We suggest there is a need for improved assessment of IBD associated arthritis to better quantify the burden of disease and natural history.

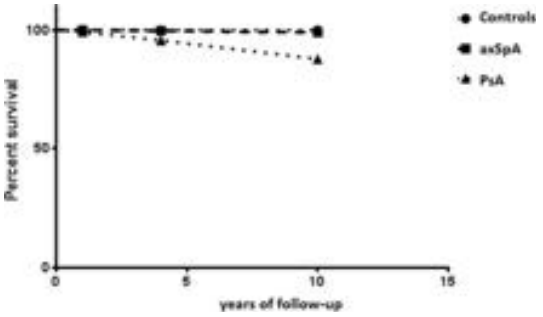
## AB0687 CARDIOVASCULAR MORBIDITY AND MORTALITY OF PATIENTS WITH SPONDYLOARTHRITIS, RESULTS OF 10-YEAR PROSPECTIVE CONTROLLED STUDY

I. Gaydukova, A. Rebrov, A. Akulova, A. Aparkina, E. Khondkaryan. *Hospital therapy, Saratov State Medical University, Saratov, Russian Federation*



**Background:** Cardiovascular events are the leading cause of mortality in arthritis. However, data of cardiovascular (CV) morbidity and mortality in spondyloarthritis (SpA) are contradictory. Current data about CV mortality and morbidity in SpA in Russian population are limited.
**Objectives:** The aim of the study was to evaluate CV morbidity and mortality in patients with SpA.
**Methods:** 676 patients with SpA without CV diseases were involved, 160 healthy individuals included as controls. In 10 years of follow-up CV events (cardiac death, angina, myocardial infarction (MI), stroke, arterial hypertension (AH), arrhythmias or conduction disturbances) were recorded. Statistical analysis was performed using SPSS17.
**Results:** 313 patients and 10 controls had loss the follow-up. From 363 patients with 10-year results 278 had axial SpA (axSpA), 85 – psoriatic arthritis (PsA)). Mean age±SD was 40.1±14.1 years in SpA, 40.0±11.4 in axSpA, 40.55±10.6 in PsA, 39.0±11.2 in controls, $p \geq 0.05$ for all. Prevalence of male was recorded in axSpA compared with PsA (p=0.02), other groups were matched in gender, $p \geq 0.05$ (69.7% males in SpA, 76.3% in axSpA, 48.2% in PsA, and 56% in controls). Smoking was frequently occurred in axSpA (68%, $p < 0.05$ with all the other groups). Frequency of CV events is presented in table.

Table 1. Cardiovascular events in SpA during 10-years of follow-up

| | Angina, n | MI, n | AH, n | Cardiac death, n |
|---|---|---|---|---|
| SpA, n=363 | 57 | 41 | 188 | 9 |
| axSpA, n=278 | 36 | 28 | 132 | 2 |
| PsA, n=85 | 21 | 13 | 56 | 7 |
| Controls, n=150 | 13 | 3 | 32 | 0 |

Arrhythmias were recorded in 55 (15.2%), conduction disorders – in 48 (13.22%), stroke – in 9 (2.47%) SpA patients.

Odds ratio (OR) of death in SpA as compared to controls was 4.6 (95% confidential interval (CI) 0.4–10.6), $p>0.05$, in PsA OR=8.0 (CI 5.7–16.1) compared to controls and 9.9 (CI 6.0–18.1), compared to axSpA, $p<0.0001$ for all, image.
Relative risk (RR) of MI in axSpA was 1.77 (CI 1.5–2.1), in PsA – 4.3 (CI 2.5–14.5), compared to controls, $p<0.0001$ for all. In controls risk of MI was comparable with expected population level (RR 1.24, CI 0.96–1.59).
In axSpA RR for AH = 2.23 (CI 1.6–3.1), in PsA RR = 3.09 (CI 2.19–4.35), $p<0.0001$ compared to controls.

**Conclusions:** CV mortality in SpA and axSpA is comparable to population level, in PsA is higher, than in healthy controls and in ax-SpA. The incidence of angina, MI, AH in patients with ax-SpA and PsA exceeds the incidence in healthy controls.

## AB0688 DISEASE ACTIVITY AND INFLAMMATORY MRI LESIONS IN PATIENTS WITH AXIAL AND PERIPHERAL SPONDYLOARTHRITIS

I. Shynkaruk, O. Iaremenko, D. Fedkov. *Department of Internal Medicine of Dental Faculty, Bogomolets National Medical University, Kyiv, Ukraine*

**Background:** Relationship between inflammatory lesions on magnetic resonance imaging (MRI) and clinical disease activity measures is still unclear in patients (pts) with spondyloarthritis (SpA). In some studies MRI sacroiliac joints (SIJ) scores correlated negatively with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) [1], but correlated neither with the Ankylosing Spondylitis Disease Activity Score (ASDAS) nor C-reactive protein (CRP) level. Another study showed a positive correlation between BASDAI and Spondyloarthritis Research Consortium of Canada (SPARCC) score [2].
**Objectives:** To evaluate the disease activity and correlations between clinical indices, CRP, erythrocyte sedimentation rate (ESR) and SPARCC MRI score in SpA.
**Methods:** 67 SpA pts (23 - axial (according to Assessment of Spondyloarthritis International Society (ASAS) 2009 criteria) and 44 – peripheral (according to ASAS 2011 criteria)) consulting a clinic for the first time were included. Mean age of pts (68.7% male) was 36.6+10.7, 88.4% of 43 pts were HLA-B27 positive. BASDAI (mm), Bath Ankylosing Spondilitis Functional Index (BASFI, mm), ASDAS, CRP (mg/l), ESR (mm/hr) and SPARCC MRI SIJ score (0–72, n=32) were evaluated. Spearman coefficients for correlation were calculated.
**Results:** In all SpA pts mean value ($M\pm\sigma$) of indices and laboratory parameters were: BASDAI – 4.76±1.89, BASFI – 3.3±2.2, ESR – 26.21±19.63, CRP – 27.48±54.83, ASDAS-CRP 3.11±1.02 and ASDAS-ESR 3.07±0.97.
ASDAS-CRP, ASDAS-ESR and BASDAI were higher in peripheral SpA than in axial SpA: 3.32±1.05 vs 2.72±0.83 (p=0.016), 3.29±1.01 vs 2.66±0.75 (p=0.005) and 5.12±2.02 vs 4.07±1.4 (p=0.01) respectively. The level of inflammatory lesions of SIJ was high: SPARCC MRI SIJ score was 25.97±12.89, without significant differences between axial (27.83±12.92) and peripheral (23.57±12.92) SpA.
The correlation analysis revealed that for all SpA pts BASFI positively correlated with the both, ESR (r=0.388, p=0.01) and CRP (r=0.357, p=0.003), but BASDAI was only with CRP (r=0.428, p=0.001). All disease activity and functional indices for all SpA showed a high correlation with each other: ASDAS-CRP and ASDAS-ESR with BASDAI and BASFI (r value from 0.502 to 0.745, p=0.001), and BASDAI with BASFI (r=0.426, p=0.015).
In pts with axial SpA ASDAS-CRP and ASDAS-ESR but not BASDAI and BASFI were correlated with laboratory activity: ASDAS-ESR with ESR (r=0.620, p=0.002) and CRP (r=0.516, p=0.012), ASDAS-CRP only with CRP (r=0.785, p=0.001). All clinical indices of pts with the involvement of peripheral joints showed significant ($p<0.05$) correlation with ESR and CRP (r value from 0.302 to 0.779).
SPARCC MRI SIJ score showed correlation with CRP (r=0.358, p=0.004) in all SpA, with CRP (r=0.496, p=0.036) in axial SpA and with BASFI (r=0.556, p=0.039) in peripheral SpA pts.
**Conclusions:** Disease activity according to ASDAS-CRP, ASDAS-ESR and BASDAI was significantly higher in pts with peripheral comparison with axial SpA. Clinical indices of pts with peripheral SpA showed better correlation with laboratory activity in comparison with axial SpA. SPARCC MRI score correlated with disease activity (only CRP level) of axial SpA pts and functional status (BASFI) of peripheral SpA pts.

## AB0689 COMOPARISON BETWEEN MALES AND FEMALES WITH SPONDYLOARTHRITIS

J. Essouiri[1], N. Benaicha[2], F.E. Abourazzak[1], T. Harzy[1]. *[1]rheumatology; [2]Epidemiology, CHU hassan II, Fez, Morocco*

**Objectives:** The aim of our study is to describe the characteristics of women with spondyloarthritis though a comparison with men.
**Methods:** This is a retrospective observational study, conducted in the rheumatology department at CHU Hassan II Fez, analyzing the records of patients diagnosed spondyloarthritis during the period extending from January 2009 to June 2014.
We realized a descriptive study of our patients then we compared clinical and epidemiological profil of spondyloarthritis in both sex to emphasize the characteristics of morrocan women spondyloarthritis.
**Results:** A 136 patients were included, 86 men and 50 women. The mean age was 38,44±13,5 years with an average diagnostic delay of 4,71±5 years. Clinical symptomatology was dominated by axial involvement dorsolombalgie in 90,4% of cases.
Uveitis was the extra-articular manifestation most common in 5,1% of cases. 61,8% of patients had active disease, and 46,3% had severe disease.10,3% of patients had juvenile-onset, 24.1% patients had a hip involvement.
The comparison of women and men objectified significant association between female sex and late onset of disease ($p<0,001$), illiteracy (p=0,021), family antecedent of spondyloarthrtitis (p=0,025), arthritis (p=0,049), the use of sulfasalzine and methotrexate (p=0,042, p=0,006 respectively)
After logistic regression analysis the female sex was associated with late onset of disease ($p<0,001$, OR=0,93; IC=0,89–0,96) and the use of methotrexate (p=0,018, OR=0,14;IC=0,02–0,71) whereas male sex was associated with hip involvement (p=0,02, OR=3,3; IC=1,18–13,03) and tabac (p=0,004, OR=22,47; IC=2,76–182)
**Conclusions:** Women with AS appear to have both similarities and differences in disease expression when compared with men with spondyloarthritis. The causes of the differences are still unknown, although both sex and gender factors may explain some of them.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5724

## AB0690 PROFILE OF JUVENILE-ONSET COMPARED TO ADULT-ONSET SPONDYLOARTHRITIS

J. Essouiri, F. Awassi, F.E. Abourazzak, T. Harzy. *rheumatology, CHU hassan II, Fez, Morocco*

**Objectives:** the aim of our study is to analyze the differences and similarities between a group of juvenile-onset spondyloarthritis (JOSpA) ($\leq$16 years) and a group of adult-onset spondyloarthritis (>16 years) (AOSpA).
**Methods:** This is a retrospective observational study, conducted in the rheumatology department at CHU Hassan II Fez, analyzing the records of patients diagnosed spondyloarthritis during the period extending from January 2009 to June 2014.
We realized a descriptive study of our patients (clinical and epidemiological parameters) then we compared JOSpA and AOSpA to emphasize the characteristics of juvenile onset spondyloarthritis.
**Results:** A 84 patients were included 22 with JOSpA and 62 with AOSpA. The mean age was 30,90±10,5 years with the average diagnosis delay of 5,68±5,74 years. Diagnosis according to ASAS criteria was in 73,8% of cases, according to AMOR criteria in 21,4% of cases and 4,8% according to NYM criteria. Clinical symptomatology was dominated by axial involvement dorsolombalgie in 89,3%.
Uveitis was the extra-articular manifestation most common in 8,3%.
The average Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was 4,62±1,907, the average Bath Ankylosing Spondylitis Functional Index (BASFI) was 4,56±2,485. 34.5% patients had a hip involvement.
The variables associated with JOSpA were lower limb arthritis (p=0.04), hip involvement (p=0,001), enthesitis chest pain (p=0,04) and the use of anti TNF alpha (p=0,008).
After logistic regression analysis the JOSpA was associated with enthesitis chest pain (p=0,011; OR=8,2, IC=1,62–41,34) and the use of anti TNF alpha (p=0,001; OR=9,1; IC=2,39–34,69)
**Conclusions:** Our study showed that JOSpA is associated with enthesitis and the use of anti TNF alpha. This characterization will help to understand the characteristics of the JOSpA patients and their needs in the long-term follow up.

## AB0691 OBLIQUE VIEWS HAVE ADVANTAGES OVER ANTERO-POSTERIOR VIEW RADIOGRAPHS IN ASSESSING SACROILIITIS: AN IMAGING STUDY

Z. Hu, P. Zhang, J. Qi, M. Qiu, X. Guo, J. Gu. *Third Affiliated Hospital of Sun Yat-Sen Universit, Guangzhou, China*

**Background:** Radiograph of antero-posterior (A-P) view of pelvis is usually used to diagnose sacroiliitis. Magnetic resonance imaging (MRI) can detect lesions early in the disease course before they can be seen on radiography. The severity of sacroiliitis may be different as detected by MRI or by A-P view X-ray. The oblique view of pelvis may provide additional information that makes it closer to the finding of MRI than A-P view X-ray.
**Objectives:** To record lesions of sacroiliac joint (SIJ) seen on A-P view and oblique views radiographs and MRI in patients with axial Spondyloarthritis (SpA), and to analyze whether oblique views have advantages over A-P view radiographs in assessing sacroiliitis.
**Methods:** Three readers blinded graded the sacroiliitis according to the modified New York criteria seen on A-P view, oblique views and MRI from 182 patients with axial SpA. We summarized the characteristics of scores assessed by three kinds of imaging methods and calculated the sensitivity, specificity, positive and negative likelihood ratio of A-P view and oblique views radiographs for diagnosing axial SpA with MRI as the gold-standard.
**Results:** The total accuracy of oblique views was higher than that of A-P view in assessing sacroiliitis as referred to the data of MRI (82.8% vs. 71.6%, $p<0.01$). The agreements were higher between oblique views and MRI than that between A-P view and MRI in the SIJs graded $\leq 2$, especially in patients with symptom duration less than 2 years (all $p<0.01$). But in the SIJs graded $>2$ and in patients with symptom duration more than 2 years, there were no differences using A-P view or oblique views to assess sacroiliitis (all $p>0.05$). Oblique views had high sensitivity, while A-P view had moderate sensitivity for diagnosing axial SpA in the SIJs graded $\leq 2$.
**Conclusions:** We recorded and analyzed the sacroiliitis assessed by A-P view, oblique views radiographs and MRI and found that oblique views had some advantages over A-P view radiographs in assessing sacroiliitis.

## AB0692 PARAMETERS ASSOCIATED WITH SEVERE AXIAL STRUCTURAL INVOLVEMENT: DATA FROM THE BAMBOO SPINE COHORT ON 133 SPONDYLOARTHRITIS PATIENTS

J. Gross[1], S. Ramiro[2], A. Etcheto[1,3], A. Molto[1,3], A. Van Tubergen[4], R. Landewée[5], D. van der Heijde[2], M. Dougados[1,3], C. Miceli-Richard[1,6] on behalf of French Society of Rheumatology. *[1]Paris Descartes University, Rheumatology Department, Cochin Hospital, AP-HP, 75014, Paris, France; [2]LUMC, Leiden, Netherlands; [3]Inserm (U1153), Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, 75013, Paris, France; [4]MUMC, Maastricht, Netherlands, MUMC, Maastricht, Netherlands, Maastricht; [5]ARC, Amsterdam, Netherlands, Amsterdam, Netherlands; [6]Pasteur Institute, Immunoregulation Unit, 25 rue du Dr Roux, Paris, France*

**Background:** Several factors have been associated with the structural severity of axial SpA: older age, disease duration, HLA-B27 positivity, elevated C-reactive protein (CRP) levels, male gender and cigarette smoking status.
**Objectives:** This study aimed to depict the characteristics of the patients with severe axial involvement in 2016 in France, after a long disease duration, and their exposition to NSAIDs, and biologics during the course of their disease.
**Methods:** Patients with severe axial involvement were defined by the presence of at least one of the following criteria: two intervertebral adjacent bridges and/or fusion at lumbar spine and/or at cervical spine; three inter-vertebral adjacent bridges and/or fusion at thoracic spine. Patients have been identified through a nationwide effort involving 19 departments of rheumatology located in France and in Monaco (the ACTSPA network). Data have been retrospectively collected through a structured questionnaire.
**Results:** In the current study, 133 patients have been included between February 2015 and January 2016. Mean (±SD) age was 54 yrs ± 13 at inclusion and 32 years (±12.5) at diagnosis. The patients were mainly males (n=123), sex ratio male/female was 12/1. Mean duration since the diagnosis was 22 yrs (±12.6), but was 28 yrs (± 12.3) since the first axial symptoms. 73% were ever smokers, and 37% were active smokers (n=49; men 38%, women 20%). Mean BASDAI was 2.9/10 (±1.9) and mean BASFI 3.7/10 (±2.0). 42% of the patient reported chest wall pain, 75% buttock pain, 43% peripheral arthritis, 37% enthesitis, and 8% dactylitis. Most patients were HLA-B27 positive (n=96; 72%). 80% had increased CRP during the course of the disease. Anterior uveitis prevalence was 28%, of psoriasis 19%, of IBD 9.8%. 91% of the patients were exposed to NSAIDs during the course of their disease, for a mean exposure duration of 17 years (range 1- 42 yrs). Patients were exposed to biologics in 79% of cases; all of them with at least one TNF-Blocker (mean number of anti-TNF per patient 1.57; mean exposure to the treatment 7.5 yrs). 5 patients were exposed to other biologics (ustekinumab or tocilizumab)
**Conclusions:** This crude data analysis of patients with axial structural lesions shows patients' characteristics that were previously associated with disease severity such as high HLA-B27 prevalence, sex ratio biased toward male gender and systemic inflammation. Nevertheless, these data also demonstrate the potential huge impact of tobacco on disease severity since 73% of the patients from this cohort were ever smokers compared with 36% in DESIR cohort and 52% in the French male population (1). When considering the potential role of NSAIDs or TNF-blockers, further studies are required in particular by comparing this population to other existing cohorts of SpA patients with less structural damage. Moreover, among other mechanisms, epigenetic deregulation induced by smoking should be investigated as a potential disease severity paramer.

## AB0693 GENDER AS A DETERMINANT OF FUNCTIONAL STATUS AND DISEASE ACTIVITY MEASURES IN PATIENTS WITH LONGSTANDING ANKYLOSING SPONDYLITIS

J. Nossent[1,2], G. Bakland[2]. *[1]School of Medicine, University of Western Australia, Crawley, Australia; [2]Rheumatology, Arctic University Norway, Tromso, Norway*

**Background:** Increasing evidence points to gender differences in disease presentation and course in Ankylosing Spondylitis (AS). This could reflect female specific AS characteristics or inequalities in health care provision.
**Objectives:** To investigate the impact of gender and remoteness on functional outcome, quality of life (QOL) and disease activity measures in an AS cohort with longstanding disease.
**Methods:** Cross sectional cohort study in TNFi naïve AS patients (n=227) in the Arctic region of Norway. Spinal function and functional indices (BASFI, Dougados Index), QOL measures (MHAQ, SF36) were obtained simultaneously with a range of biomarkers (ESR, CRP, IL-6, TNFa, IL-17, IL-23) during a research visit. Remoteness definition was living in a community with <10000 inhabitants. Associations between clinometric, QOL and serological findings were analysed by non-parametric methods.
**Results:** Despite similar age at and disease duration since symptom onset (280 vs 265 months, p=0.5) female patients (n=66) had better spinal flexion (median 40 vs. 36°, p=0.035) and finger floor distance (7 vs. 16 cm, p=0.015) compared to male patients (n=161). While global disease scores (BASFI, Dougados Index, MHAQ and ASDAS-CRP) and comorbidity prevalence were comparable, female patients were more often work disabled (61 vs 49%, p=0.01). IL-6 levels correlate with ASDAS (Rs 0.4, p=0.005), occiput wall distance (Rs 0.32,p=0.012) and inversely with Schober (Rs -0.36 p=0.004), spinal flexion (Rs -0.27, p=0.03) and lateral movement (Rs= -0.31, p=0.013) in female patients only.
**Conclusions:** While remoteness has little impact on the disease severity of AS in Northern Norway, the gender based variation in disease course in AS may be underpinned by differential activation of inflammatory cytokines.

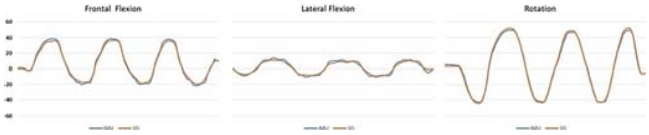
## AB0694 INERTIAL SENSOR FOR THE ASSESSMENT OF CERVICAL RANGE OF MOVEMENT IN AXIAL SPONDYLOARTHRITIS

J.L. Garrido-Castro[1], C. Gonzalez-Navas[1], J. Castro-Jurado[1], P. Font-Ugalde[2], E. Collantes-Estevez[2]. *[1]Maimonides Institute of Biomedical Research of Cordoba; [2]Reina Sofia University Hospital, Cordoba, Spain*

**Background:** Axial Spondyloarthritis (AxSpA) affects mainly the spine reducing patient mobility including neck. Several tools have been used to evaluate range of motion in AxSpA, but these tools have problems of reliability and accuracy. Motion capture [1], has been recently developed and validated, however a dedicated laboratory of movement is needed. IMU sensors (Inertial Measurement Unit) are a new and cheap kind of technology that allows knowing 3D orientation. These sensors could provide equivalent results to motion capture, with lower requirements, although validation processes are needed.
**Objectives:** To evaluate reliability of an inertial sensor IMU to assess cervical range of movement in patients with AxSpA.
**Methods:** 7 male patients with AxSpA (age 55.9±11.9, time of evolution 14.37±10.74) were included. An IMU sensor (Shimmer3©) placed on the patient's forehead was used. 4 reflective markers were attached to the head using a band (one above the sensor, two over the tragus, and one in the occiput). To detect movement of the trunk, 4 more markers were used (2 over the shoulders, 10 cm below C7 and average distance between L4 and C7). 3D reconstruction



**Abstract AB0694** – Table 1

| | IMU1 | IMU2 | 3D | ICC-A* | ICC-B* | SME-A* | SME-B* | RMSE-A* | RMSE-B* | CV-A* | CV-B* |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Frontal flexion (°) | 74.0 (51.0) | 74.1 (52.3) | 72.5 (53.4) | 0.999 (>0.995) | 0.994 (>0.975) | 2.53 | 5.36 | 2.35 | 5.21 | 3.42% | 7.29% |
| Lateral flexion (°) | 49.2 (44.5) | 50.6 (44.8) | 45.1 (43.5) | 0.999 (>0.998) | 0.995 (>0.978) | 1.39 | 4.21 | 1.87 | 5.72 | 2.82% | 8.60% |
| Cervical rotation (°) | 89.2 (62.5) | 91.3 (67.9) | 93.2 (63.2) | 0.993 (>0.967) | 0.996 (>0.981) | 7.88 | 5.73 | 7.64 | 6.67 | 8.90% | 6.45% |

IMU 1, IMU 2: results obtained by the IMU tests (mean (SD)) test/retest. 3D: results obtained by UCOTrack. ICC: intraclass correlation coefficient (value and >95% IC). SME: systematic mean error. RMSE: root mean square error. CV: coefficient of variation. A: comparison test/retest. B: Comparison IMU/3D.

was performed using the UCOTrack© system [1]. 3D orientation was obtained by the sensor and by the UCOTrack, both at 50 Hz. Patient made three bend movements (frontal, lateral and rotation). Measurements were repeated 5 minutes after. PRO questionnaires and structural damage (mSASSS) were also evaluated. Several statistical tests were performed to assess reliability of the sensor and its comparison with the Gold Standard.

**Results:** Affectation level was widely spread among the study participants (BASDAI: 3.4±2.9; BASFI 4.2±3.9; BASMI 5.3±2.2; UCOASMI: 6.1±2.5; mSASSS: 39.9±22.4; cervical mSASSS: 17.9±8.8). Table shows the measurements in the three ranges of cervical motion and statistical parameters analyzed.

**Conclusions:** Test/retest values were very similar, with excellent ICCs and low errors. Motion capture system detected some variations from 3° to 13° at the trunk. To place another IMU sensor at C7 to compensate it is recommended. Number of patients were very small and a model that analyzes the entire spine, not only the cervical part, must be developed. This pilot study shows that IMU sensor could be used, with results very similar to gold standard and with good reliability, improving metrology for AxSpA patients.

## AB0695 BONE QUALITY ASSESSMENT BY THE TRABECULAR BONE SCORE IN SPONDYLOARTHRITIS

K. Boussoualim, H. Marotte, T. Thomas. *Rheumatology, Centre Hospitalier Universitaire Nord Saint-Etienne, Saint-Priest-en-jarez, France*

**Background:** Many patients affected by spondyloarthritis are at risk of fracture due to the bone's fragility although their bone mineral density (BMD) is not significantly decreased. Other tools are needed to assess changes in the bone of these patients. The Trabecular Bone Score (TBS) is a bone quality assessment tool that analyses variations of the grey level of a densitometric image. It was evaluated among post-menopausal women and in secondary osteoporosis. It may help to discriminate patients with osteoporosis fractures.

**Objectives:** To evaluate the TBS in a population of spondyloarthritis as a bone quality indicator and look for the clinical and biological factors correlating to the values of the TBS.

**Methods:** Patients who met the criteria of a spondyloarthritis diagnosis and who had a measure of BMD were selected. All these patients came for the setting up or the changing of a biotherapy. Clinical and laboratory data were collected at the same time as the BMD measurement.The TBS measurements were obtained immediately from dual-energy X-ray absorptiometry spinal images. A TBS was considered normal above 1.34, distorted between 1.34 and 1.2 and very distorted below 1.2.

**Results:** Ninety-eight patients participated in the study. The average age was 40.2 years and the average duration of the disease's evolution was of 8.2 years. A spinal BMD lower than -1 and -2.5 T-score was respectively observed in 17% and 3% of patients. The average TBS was lowered to 1.34. The spinal BMD correlated positively to the values of TBS (r=0.61), whereas the duration of the disease's evolution (r = -0.24), its activity level (r= -0.33) and the serum PTH levels (r= -0.27) correlated negatively to the TBS. This association persisted in multivariate analysis. More than half of patients with a BMD above the threshold of a -2.5 T-score had an altered TBS. The relashionship observed between the rates of the PTH and the TBS, which we do not find with the BMD, suggests that a part of the changes of the bone structure in inflammatory rheumatism such as the spondyloarthritis, would be under the dependence of the PTH regardless of the BMD.

**Conclusions:** This study shows that TBS provides additional and independent information from the simple BMD measure on bone status of patients with inflammatory rheumatism. It appears necessary to carry out studies on a larger scale to analyse the discriminating power of the TBS in the prediction of fragility fracture to a greater extent.

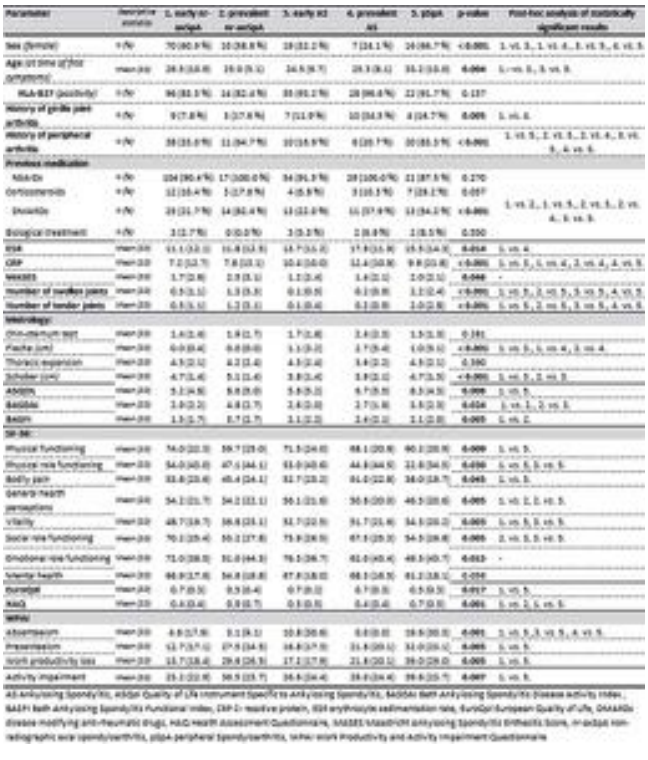
## AB0696 CLINICAL CHARACTERISTICS OF SPONDYLOARTHRITIS IN THE CZECH REPUBLIC: A SINGLE CENTRE COHORT



K. Grobelná[1], Š. Forejtová[1], M. Urbanová[1], K. Zegzulková[1], M. Hušáková[1], T. Philipp[2], J. Gatterová[1], J. Hořínková[1], K. Hejduk[3], L. Šenolt[1], K. Pavelka[1]. *[1]Rheumatology Institute in Prague; [2]Thomayer Hospital, Prague; [3]Institute of Biostatistics and Analyses, Brno, Czech Republic*

**Background:** Spondyloarthritis (SpA) is an inflammatory rheumatic disease with predominantly axial or peripheral involvement.

**Objectives:** To present baseline characteristics of different groups of SpA patients.

**Methods:** 244 patients diagnosed with SpA were examined between 2012–2015 and divided into 5 subsets: early non-radiographic axial SpA (nr-axSPA), prevalent nr-axSpA, early ankylosing spondylitis (AS) prevalent AS, peripheral SpA (pSpA), according to the time of diagnosis (more or less than 3 years from baseline examination) and according to the imaging arm of ASAS criteria for axSpA and for pSpA. The analysis included: gender, age/type of first symptoms, age at diagnosis, family history, inflammatory back pain, history of peripheral or girdle arthritis and extraarticular manifestations, previous/present medication (NSAIDs, DMARDs, glucocorticoids, biological agents), smoking, BMI, spinal mobility, *MASES*, swollen/tender joints, physician global assessment (MDGAS), ASDAS-CRP, BASDAI, BASFI, quality of life outcomes (ASQol, SF-36, EuroQol, HAQ, WPAI), HLA-B27, ESR, CRP. Kruskal-Wallis test and post-hoc analysis were used, data are presented as mean±SD.

**Results:** We found a significant difference in gender: majority of nr-axSpA patients as well as pSpA were females in contrast to subsets of AS patients. Patients with early AS developed first symptoms earlier compared to patients with early nr-axSpA and pSpA. Prevalent subsets had higher occurrence of girdle and peripheral arthritis compared to early subsets. Previous treatment with DMARDs was significantly higher in patients with prevalent nr-axSpA and pSpA compared to the remaining subsets. Patients in AS subsets compared to nr-axSpA subsets had significantly worse spinal mobility (fleche, modified Schober distance). BASDAI was significantly higher in prevalent nr-axSpA compared to early nr-axSpA and early AS. BASFI was significantly higher in prevalent nr-axSpA compared to early nr-axSpA. ASQol values were significantly higher in prevalent nr-axSpA and pSpA compared to early nr-axSpA. Almost all SF-36 values and EuroQol were significantly lower in pSpA compared to axSpA (especially early subsets). WPAI values showed worse work conditions (absenteeism, presenteeism, work productivity and activity impairment) in pSpA compared to all subsets of axSpA, especially nr-axSpA with significant differences in all parameters. CRP levels

were significantly higher in AS subsets compared to nr-axSpA subsets. We did not find significant difference in HLA-27 positivity across analyzed subsets, however nr-axSpA groups had tendency to lower percentage of HLA-B27 positivity compared to the remaining groups.
**Conclusions:** The results of our study are comparable to other SpA cohorts described in the literature. In addition, we demonstrated worse quality of life and work limitations in patients with pSpA than in those with axSpA.

## AB0697 DOES VITAMIN D AFFECTS THE SEVERITY OF THE DISEASE IN PATIENTS WITH ANKYLOSIS SPONDYLOARTHRITIS IN A SUNNY COUNTRY?

M. Djennane. *medicine, university mouloud mammeri, Tizi ouzou, Algeria*

**Background:** Vitamin D has been found to have a role in immune system function. It there's been many studies on the relationship between vitamin D and disease activity in ankylosing spondyloarthritis (AS). However, studies have concerned the groups based on vitamin D levels and determined the differences between these patients in terms of disease activity, functional status, quality of life, and others clinical parameters. The aim of this study was to compare 25-hydroxyvitamin D (25 (OH) D) in patients with AS and healthy subjects and to determine the relationship between 25 (OH) D and activity disease, functional status and quality of life.
**Objectives:** The aim of this study is to compare 25-hydroxy-vitamin D3 (25(OH)D3) levels in AS patients with those in normal healthy subjects and to determine the relationship between 25(OH)D3 levels and AS disease activity, functional status, and quality of life.
**Methods:** hundred twenty-five consecutive patients and 76 healthy volunteers were included in this study. After a comparison between the patient group and the control group, the group of patients was divided into normal subgroups, deficient and inadequate function of plasma 25 (OH) D3 levels for another comparison
**Results:** Level differences 25 (OH) D between the patients and controls were statistically significant. The number of patients with AS whose rates 25 (OH) D were classified as normal, insufficient and deficient were respectively 32, 51 and 38.
The sedimentation rate (ESR), C-reactive protein (CRP) and the scores Bath AS Disease Activity Index (BASDAI) were higher in the subgroup deficiency and 25OHD deficiency ($P<0.05$). Bath functional scores (BASFI) and the quality of life (ASQoL) were significantly different between the subgroup with normal 25OHD levels and deficient subgroups ($P<0.05$). Finally the level of pain, BASDAI, ESR and CRP were inversely correlated with 25OHD ($P<0.05$)
**Conclusions:** Plasma levels of 25 (OH) D may be reduced in patients with ankylosing spondyloarthritis and this can negatively affect the activity of the disease, the functional status and quality of life.

## AB0698 CLINIMETRIC PROPERTIES OF THE ASAS HEALTH INDEX IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: VALIDATION IN AN ITALIAN COHORT

M. Di Carlo[1], V. Lato[1], M. Carotti[2], F. Salaffi[1]. *[1]Rheumatology Departement, Polytecnic University of the Marche, Jesi; [2]Radiology Department, Polytechnic University of the Marche, Ancona, Italy*

**Background:** Over the last decades, many efforts have been conducted to develop useful tool for the evaluation of disease activity. However, since the development of Assessment of SpondyloArthritis international Society Health Index (ASAS HI), no specific freely available questionnaires to describe the overall picture of impairments, limitations and restrictions in activities or social partecipation.
**Objectives:** The aims of this study were to test the feasibility, reliability, and construct validity of the ASAS HI, in order to compare its clinimetric properties with the current available measures of disease activity, functional limitation and health status assessments in patients with axSpA.
**Methods:** A cohort of 140 consecutive axSpA has been the object of study. The feasibility has been determined by the percentage of patients who were able to complete the questionnaire by themselves and by the time employed to fill the ASAS HI. The reliability has been evaluated performing a test-rerest of the questionnaire within a week. The construct validity was examined in three ways. First, we examined construct convergent validity by correlating the scores of the ASAS HI with ASDAS-CRP/ESR, SASDAS, BASDAI, BASMI, BASFI, the ASQoL and EQ-5D. Secondly, we have created patient groups based on the patients' activity ranks (ASDAS-CRP and SASDAS categorisation) within the cohort to assess discriminative accuracy. Additionally, to distinguish patients with active and non-active disease and to assess their respective cut-off points values, the receiver operating characteristic (ROC) curve analysis was used. Thirdly, we analyzed the contribution of demographic (age, sex, and disease duration) and clinical variables (number of comorbidity and disease activity by ASAS-CRP) to the attainment of an ASAS HI condition by stepwise logistic regression.
**Results:** The mean time to complete the ASAS HI was 114.9± 45.2 seconds (range 48 – 210 seconds). Coefficients of agreement between ASAS HI scores on first and second administrations were excellent and all items showed very good agreement (ICC =0.976; range 0.966 to 0.982). The ASAS HI was correlated significantly with all other comparator scores ($p<0.0001$). The highest correlations were seen with ASQoL (rho 0.784; $p<0.0001$), BASFI (rho 0.671; $p<0.0001$) and SASDAS (rho 0.640; $p<0.0003$). On categorizing patients into different cut-off point of disease activity, with respect to the both ASDAS-CRP and SASDAS, ASAS HI scores were highly significantly different between the four categories ($p<0.0001$). An ASAS HI value of 4.0 resulted the cut-off with the highest combination of sensitivity and specificity (82.6% and 86.3%, respectively) to distinguish the inactive disease.
**Conclusions:** The results reported in this study confirm the feasibility, reliability and validity of the ASAS HI in Italian patients with axSpA. Of particular interest appears the cut-off value of 4.0, under which could be identified the inactive disease. This value could represent an easily applicable starting point in daily clinical practice.

## AB0699 ENTHESITIS AND SACROILIITIS PREVALENCE DETERMINED BY DOPPLER ULTRASONOGRAPHY AND MAGNETIC RESONANCE IMAGING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Aparicio[1], A. Ruiz-Cerulla[2], J.A. Narváez[3], C. Moragues[1], M. Peñalva[2], X. Michelena[1], J.M. Nolla[1], J. Guardiola[2], X. Juanola[1]. *[1]Rheumatology; [2]Gastroenterology; [3]Radiology, Hospital Universitari de Bellvitge, Barcelona, Spain*

**Background:** Patients with inflammatory bowel disease (IBD): Crohn disease (CD) and ulcerative colitis (UC) can develop extraintestinal manifestations and ones of the most important are musculoskeletal affections. In published studies, the prevalence of Spondyloarthritis (SpA) stands from 10 to 20% but with a wide range of variation. These differences are related to the methods used for its determination.
**Objectives:** 1) To determine the prevalence of sacroiliitis with X-ray or magnetic resonance imaging (MRI) and of enthesitis with Doppler ultrasonography in patients with active IBD without following an immunosuppressant therapy 2) To check the prevalence of patients with positive ASAS criteria for axial and peripheric SpA.
**Methods:** Cross-sectional study in which a sample of patients diagnosed of active IBD, without previous diagnosis of rheumatic inflammatory disease and without any previous immunosuppressant therapy, underwent a comprehensive rheumatologic examination addressed to detect musculoskeletal SpA features. Data collected comprised: demographics, family medical history, IBD characteristics and comorbidities, axial symptoms, swollen and tender joint counts (44/46 joints), entheses and dactylitis examinations, BASDAI and BASFI questionnaires and CRP and HLAB27 blood tests. The following image techniques were also applied: cervical, lumbar column and pelvis X-ray, sacroiliac MRI with T1 and STIR sequence and ultra-sound exploration of entheses.
**Results:** 30 patients (16 women) with a mean age 39.8 (9,8) years have been studied. 16 had CD and 14 UC. 16% tested positive for B27. 14 patients referred chronic lumbar pain, 4 of them with inflammatory characteristics. 10 patients referred arthralgias, without joint swelling o redness and 3 patients had history of heel pain, although they were not explored for any physician. None of the patients did not refer past medical history of uveitis or psoriasis (family or own history). 36% of the patients had MRI signs of sacroiliac inflammation that met ASAS criteria. One of the patients had grade 3 radiographic sacroiliitis and one patient with inflammatory signs in sacroiliac joints by MRI did not refer chronic lumbar pain. Ultrasound alterations were found in at least one enthesis within 97% of the patients: entheses calcifications (72%), bursitis (61%) and erosion (5%).
**Conclusions:** In patients with active IBD not previously diagnosed with SpA, the existence of sacroiliitis and ultrasound alterations in entheses is frequent (36% and 97%, respectively). The prevalence of patients meeting axial SpA ASAS criteria is 32% and for peripheral criteria is 10%. The lower frequency of peripheral SpA can be attributed to an earlier diagnose of this form of presentation or to a lack of sensitivity of the peripheral SpA ASAS criteria on patients with IBD. Addition of ultrasound results in classification criteria could take into account patients with enthesitic signs earlier.

## AB0700 BASELINE CLINICAL CHARACTERISTICS OF THE LEEDS SPARRO EARLY PSORIATIC ARTHRITIS COHORT: HIGH DISEASE AND RADIOGRAPHIC INVOLVEMENT ARE SEEN EARLY EVEN IN THE PRESENCE OF PRESERVED QUALITY OF LIFE

M. Merashli, G. De Marco, A.L. Tan, P. Emery, D. Mcgonagle, P. Helliwell, H. Marzo-Ortega. *NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Data are mounting on the need to treat PsA early to improve long term outcome and prevent disability. There are few cohorts of early untreated PsA reported in the literature with variable characteristics and outcomes which may reflect different geographical and health economic backgrounds.
**Objectives:** To describe the baseline clinical characteristics of the early PsA cohort recently initiated as part of the Leeds SpARRO (Spondyloarthropathy Register for Research and Observation) study to assess how change in practice implemented through dedicated early synovitis and SpA clinics may affect outcome in SpA.
**Methods:** Observational study describing baseline clinical characteristics of the first 55 patients recruited to the Leeds SpARRO register with a new diagnosis of PsA. Data are presented as descriptive statistics including demographics, clinical disease activity measures, treatment and patient reported outcomes.
**Results:** Subjects recruited fulfilled CASPAR criteria [mean disease duration from symptom onset is 1.5±0.6 years]; F:M ratio 1.4; 66% white British; mean BMI 29±6 kg/m$^2$ and were DMARD naïve (90%) at presentation. The majority were negative for both RF and CCP antibodies (96% [n=53]; with an asymmetrical (67%), polyarticular joint phenotype (73%). Axial involvement was seen in 29% (n=16). As expected, the majority of the cohort was negative for HLA-B27 (76%, n=42). Prevalence of current skin psoriasis was high (91%) although extent and severity were mild (PASI median (IQR) 4 (0–27). Nail involvement was recorded in 50% (mNAPSI mean± SD 8±11). No extra-articular manifestations were seen apart from 1 case with Crohn's disease. Quality of life scores for skin and joints showed mild impairment [DLQI median (IQR) 4 (1–9)] and PsAQoL [median (IQR) 7.5 (3–12)] however, the PASDAS was consistent with high disease activity mean ±SD (5.6±1.2). Furthermore, baseline radiographic assessment (n=44) showed established change in 25% (n=11) [juxta-articular new bone formation (n=7) and erosions (n=4; all in MTP joints)] of subjects whilst 50% of the total population were smokers (22% n=12 current; 27% n=15 previous). HAQ score (median [IQR] was 0.75 [0.25–1.4]).

Table 1. Baseline clinical characteristics of early PsA patients

| Clinical characteristics | Values | Pt number |
|---|---|---|
| Age, mean ± SD years | 42±12 | 55 |
| Skin psoriasis duration (yrs) | 10±11 | 47 |
| Family history of psoriasis, n (%) | 32 (61%); unknown in 2 (4%) | 55 |
| Family history of PsA, n (%) | Yes 5 (9%); unknown 3 (5%) | 55 |
| DIP prominent disease, n (%) | 6 (11%) | 55 |
| Arthritis mutilans, n (%) | 0 (0%) | 55 |
| Dactylitis score, mean ± SD | 1±1 | 55 |
| MASES, mean ± SD | 2±3 | 55 |
| SJC76, mean ± SD | 4±6 | 55 |
| TJC78, mean ± SD | 12±15 | 55 |
| Early MS, mean ± SD | 101±167 | 54 |
| CRP level mg/L, mean ± SD | 11±22 | 55 |

**Conclusions:** Our cohort of early, untreated PsA shows relatively preserved quality of life at baseline highlighting the successful and timely identification of these patients through early arthritis clinics. Still, composite measures of disease activity and radiographic assessment confirm highly active disease and established damage in 25% of cases, emphasizing the need for prompt intervention to achieve immediate disease control and prevent disability and development of co-morbidities in this disease.

## AB0701 THE DIAGNOSTIC VALUE OF SACROILIAC PROVOCATION TESTS IN SPONDYLOARTHRITIS AND THEIR RELATIONSHIP WITH MAGNETIC RESONANCE IMAGING FINDINGS

S. Yilmaz[1], M. Cinar[1], H.T. Sanal[2], M. Cakar[1], S.A. Dilmen[3], I. Simsek[4]. *[1]Division of Rheumatology; [2]Department of Radiology, Gulhane Military Medical Academy, School of Medicine; [3]Department of Physical Therapy and Rehabilitation, Physical Therapy and Rehabilitation Ankara Training and Research Hospital; [4]Division of Rheumatology, Guven Hospital, Ankara, Turkey*

**Background:** Sacroiliac provocation tests are used in cases with a suspected diagnosis of spondyloarthritis (SpA). However, all of the studies on the diagnostic value of these physical examination tests have been carried out in non-inflammatory sacroiliac (SI) joint pathologies, and the data about the contribution of these tests in the diagnosis of SpA is poor.
**Objectives:** To investigate the role of sacroiliac provocation tests in the diagnosis of SpA, and their relation with inflammatory findings in magnetic resonance imaging (MRI).
**Methods:** 51 patients (F/M=7/44) with chronic low back and/or hip pain admitted to the rheumatology clinic were included in the study. The history of patients participating in the study were taken by a rheumatologist, and another experienced rheumatologist who is unaware of the patient's medical information performed 5 different challenge tests for SI joints (sacroiliac compression test, sacroiliac distraction test, FABER-Patrick test, sacral thrust test, drop test) within a certain protocol. All patients were evaluated with sacroiliac MRI for the presence of acute inflammation. The sensitivity, specificity, positive predictive value, negative predictive value, positive and negative likelihood ratio (LR) and diagnostic accuracy of each physical examination methods were calculated with taking clinical diagnosis and sacroiliac MRI as the standard evidence of acute inflammation (2 different comparisons).
**Results:** 30 patients included in the study met the diagnostic criteria for SpA. Calculations related to diagnostic value of each examination method are summarized in Table 1.When data was analyzed for the diagnosis of SpA, the positive LR value of provocation tests ranged between 1.4–2.24.For the relationship between the examination findings and acute changes in SI joint MRI, LR values ranged positively between 1.1–2.79.Inflammatory back pain in history was associated with a positive LR value of 1.17 in predicting the diagnosis of SpA and a positive LR value of 1.37 in predicting acute changes in MRI.

Table 1. The diagnostic features of sacroiliac joint provocation tests (acute inflammation in MRI are taken as standard)

| | Sacroiliac compression test | | Sacroiliac distraction test | | FABER-Patrick | | Sacral thrust test | | Drop test | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Dx | MRI | Dx | MRI | Dx | MRI | Dx | MRI | Dx | MRI |
| Prevalance | 0.41 | 0.41 | 0.65 | 0.65 | 0.61 | 0.35 | 0.76 | 0.76 | 0.43 | 0.43 |
| Sensitivity | 0.43 | 0.53 | 0.71 | 0.77 | 0.46 | 0.43 | 0.79 | 0.87 | 0.61 | 0.53 |
| Spesifity | 0.61 | 0.76 | 0.43 | 0.52 | 0.78 | 0.76 | 0.26 | 0.38 | 0.78 | 0.71 |
| PPV | 0.57 | 0.76 | 0.61 | 0.70 | 0.72 | 0.72 | 0.56 | 0.67 | 0.77 | 0.73 |
| NPV | 0.47 | 0.53 | 0.56 | 0.61 | 0.55 | 0.48 | 0.50 | 0.67 | 0.62 | 0.52 |
| LR+ | 1.10 | 2.24 | 1.26 | 1.61 | 2.14 | 1.82 | 1.06 | 1.40 | 2.79 | 1.87 |
| LR- | 0.94 | 0.61 | 0.66 | 0.45 | 0.68 | 0.74 | 0.82 | 0.35 | 0.50 | 0.65 |
| Accuracy | 0.51 | 0.63 | 0.59 | 0.67 | 0.35 | 0.57 | 0.55 | 0.67 | 0.69 | 0.61 |

Dx, diagnosis; PPV, Positive predictive value; NPV, negative predictive value; LR, likelihood ratio.

**Conclusions:** These results show that the contribution of SI provocation tests for predicting the findings of inflammation in MRI or SpA diagnosis is extremely limited.When compared to the diagnostic accuracy of similar tests in non-inflammatory conditions of SI joint in the literature, the predictive value of provocation tests in the diagnosis of inflammatory conditions seems to be lower.
**Disclosure of Interest:** None declared

## AB0702 MEDIAL OLIVOCOCHLEAR REFLEX IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Serdaroğlu Beyazal[1], A. Özgür[2], S. Terzi[2], M. Çeliker[3], E. Dursun[2]. *[1]1 Department of Physical Medicine and Rehabilitation, Recep Tayyip Erdogan University, Medical Faculty; [2]Department of Otorhinolaryngology, Recep Tayyip Erdogan University, Medical Faculty; [3]Department of Otorhinolaryngology, Recep Tayyip Erdogan University Research and Training Hospital, Rize, Turkey*

**Background:** Ankylosing spondylitis (AS) is a chronic systemic inflammatory disease. Via autoimmune mediators, AS can damage the auditory system similar to other systems. Otoacoustic emissions studies in patients with AS showed that the damage that causes hearing loss was in the outer hair cells. The medial olivocochlear (MOC) reflex is used to evaluate the medial olivocochlear efferent system (MOES), which includes the outer hair cells.
**Objectives:** The aim of this study was to evaluate the presence of subclinical damage in the inner ear with the aid of the MOC reflex test in patients with AS with no hearing complaints.
**Methods:** Thirty-four patients with AS and a control group of 30 healthy volunteers with similar demographic characteristics were evaluated in the study. Otoacoustic emission responses, MOC reflex results, and frequency-specific and total suppression findings were compared between the groups. The relationship between the clinical and laboratory findings for the patients with AS and the MOC reflex data were also investigated.
**Results:** Reduced MOC reflex response ($p$=0.04) and suppression ($p$=0.019) were detected in patients with AS. When the clinical and laboratory findings for the patients with AS and the MOC reflex test results were compared, a significant correlation was found only between the MOC reflex and the erythrocyte sedimentation rate (ESR).
**Conclusions:** The results showed that AS can damage the inner ear, especially the MOES, and can reduce the MOC reflex response without clinical hearing loss.

## AB0703 PREVALENCE OF AXIAL AND PERIPHERAL SPONDYLOARTHRITIS IN A SAMPLE OF LEBANESE PATIENTS WITH PSORIASIS

Z. Mechref[1], N. Ziade[2]. *[1]Medicine, Saint-Joseph University; [2]Rheumatology, Hotel Dieu de France, Beirut, Lebanon*

**Background:** Spondyloarthropathies (SpA) are a group of frequent inflammatory rheumatic disorders with usually delayed diagnosis. Extra articular manifestations such as psoriasis are frequently observed, therefore it is crucial to detect SpA at the dermatologist's clinic.
**Objectives:** The main objective is to evaluate the prevalence of axial SpA in a sample of Lebanese patients with psoriasis. Secondary objectives include evaluating the prevalence of inflammatory back pain (IBP) and peripheral SpA.
**Methods:** We evaluated a sample of consecutive patients, with cutaneous or nail psoriasis, diagnosed by a dermatologist at Hotel-Dieu de France hospital, and a control sample of patients consulting for other dermatologic symptoms. Patients and controls responded to a questionnaire including items corresponding to different sets of SpA criteria. Biology and imaging data were retrieved from the medical file.
**Results:** 80 patients were included, 48 psoriasis and 32 controls. Mean age was 39.3 years (SD 17.66), sex ratio was 1. Mean psoriasis duration was 12.9 years (SD 12.37). 14.6% of psoriasis patients were on systemic treatment, 0% had HLA B27 available, 4.2% had imaging and 12.5% had CRP results. In the psoriasis patients, the prevalence of axial SpA according to the ASAS criteria was 4.2% compared to 0 in the control group. However, according to Amor criteria, where imaging or HLA B27 are not mandatory, the prevalence of SpA was 29.2%, significantly higher than in the control group 0% (p 0.01). The prevalence of peripheral SpA (ASAS criteria) was 27.1%, higher than the control group 0%. The prevalence of IBP according (ASAS criteria) was numerically higher 14.6% in the psoriasis group compared to 3.1% in the control group (p 0.135). No significant correlation was found between age, gender, psoriasis duration and diagnosis of SpA. A statistically significant difference was found between psoriasis duration and IBP prevalence (p 0.049), between family history of SpA and axial SpA (OR 2.18, p 0.003) and IBP (OR 2.38 p 0.027). Nail psoriasis seemed to be associated with peripheral SpA (OR 2.5), however the association was not statistically significant (95% CI 0.62–10.05). The same trend was found for generalized psoriasis: OR 2.47 (95% CI 0.65–9.34).
**Conclusions:** The expected significantly higher prevalence of SpA in the psoriasis sample indicates the importance of raising the awareness of Lebanese dermatologists to early detection of SpA. From simple clinical hints (IBP, family history of SpA, nail psoriasis), the index of suspicion should be high enough to prescribe the appropriate tests and/or refer the patient to a rheumatologist.

## AB0704 DIFFERENTIAL EVALUATION OF SPONDYLOARTHRITIDES RADIOGRAPHIC FEATURES

N. Soroka, A. Teteryukov. *Internal Medicine, Belarusian State Medical University, Minsk, Belarus*

**Background:** Diagnosis and differential diagnosis of various forms of spondyloarthritides is primarily based on the clinical manifestations and radiographic features analysis. Clinical manifestations though can be quite similar, so imaging studies data play an important role in diagnosis.
**Objectives:** To evaluate the differences of certain forms of spondyloarthritides in terms of radiographic features and also the opportunity to establish differential diagnosis and prognosis of the disease on this basis.
**Methods:** The study enrolled 100 patients with spondyloarthritides. The first arm included 50 patients with ankylosing spondylitis (AS). The second arm included 50 patients with Chlamydia-induced spondyloarthritis (HiSPA). The diagnosis of AS was made on the basis of the modified New York criteria (1984). Mean patients' age was 34.0±10.9 years in the AS arm and 27.1±6.9 years in the HiSPA arm. All patients in both arms were males. Mean disease duration was 6.4±4.5 years [1.9; 10.9] in the AS arm and 5.6±4.7 years [0.9; 10.3] in the HiSPA arm. Patients underwent radiography of the sacroiliac joints (SIJ), lumbar, thoracic and cervical spine. We evaluated and compared the frequency of the following radiographic features: erosions/pseudodilation or irregular narrowing of the SIJ, SIJ ankylosis, symmetrical syndesmophytes in any region of the spine, asymmetrical syndesmophytes in any region of the spine.
**Results:** Our study showed the following rate of the individual radiographic features: erosions/pseudodilation or irregular narrowing of the SIJ: 11 (22.0%) in the first arm and 32 (64.0%) in the second arm ($p<0.05$); SIJ ankylosis: 28 (56.0%) in the first arm and 2 (4%) in the second arm ($p<0.05$); symmetrical syndesmophytes: 34 (68%) in the first arm and 3 (6.0%) in the second arm; asymmetrical syndesmophytes: 5 (10.0%) in the first arm and 21 (42.0%) in the second arm ($p<0.05$). Furthermore, in the AS arm radiography significantly more often revealed simultaneous involvement of all 3 spine regions (cervical, thoracic, lumbar): 17 (34.0%) vs. 2 (4.0%) in the HiSPA arm ($p<0,05$).
Thus, despite the general similarity of radiographic features, we have identified significant differences, which, in our opinion, are due to diversity of pathogenesis and can be considered predictors of structural disease progression rate. This observation can help in the diagnosis and disease prognosis establishment, as well as in the prediction of the skeletal dysfunction course in patients with spondyloarthritides.
**Conclusions:** Our findings suggest differences in AS and HiSPA radiographic features. In the first arm they were of more pronounced proliferative and progressive nature, and in the second had distinct inflammatory features with less progression while disease duration in both groups was quite comparable.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2985

## AB0705 FATIGUE, PAIN AND PATIENT GLOBAL ASSESSMENT ARE UNSTABLE IN SPONDYLOARTHROPATHY PATIENTS WITH STABLE DISEASE ACCORDING TO BASDAI

E. Egsmose[1], O.R. Madsen[1,2]. *[1]Department of Rheumatology, Copenhagen University Hospital Gentofte, Hellerup; [2]DANBIO Registry, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

**Background:** The use of patient-reported outcome measures has become routine in clinical practice and in clinical trials. In order to use a specific outcome measure in the daily clinic, the natural variation of the outcome measure must be known. Natural variation may also be characterized as measurement error and is assessed in individuals who are considered to be in "steady state".
**Objectives:** To examine natural variation of BASFI, patient global assessment (PaGl), pain, fatigue in patients with stable spondyloarthropathy (SpA).
**Methods:** 107 SpA patients treated in the daily clinic with a TNF-inhibitor and characterized by stable disease were identified in the Danish rheumatology registry (DANBIO). According to ASAS response criteria for biological treatment in SpA [1] and to previous reports on BASDAI measurement errors [2], stable disease was defined as a change in BASDAI $\leq$20 between two consecutive visits. Paired data from a single set of such two visits were extracted for each patient. Data comprised BASDAI, BASFI, PaGl, pain and fatigue scored on 0–100 VAS scales. Natural variation was examined using the Bland-Altman method with calculations of lower and upper 95% limits of agreement (LLoA;ULoA) between two consecutive assessments and the corresponding bias (mean of individual differences). Associations between intra-individual inter-visit differences ($\Delta$) were described by linear correlation (r) and stepwise multiple regression analyses (partial regression coefficients (rp) and standard errors of estimation (SEE)).
**Results:** Mean age was 44±14 years, mean inter-visit time duration 16±13 weeks (range 3 – 91) and mean $\Delta$BASDAI 0.0±10.5 (range -20 – 20, ns). Biases were close to 0 for all the variables indicating stable conditions on the group level between the two consecutive visits. On the individual level, differences were more pronounced (Table). LoA for BASFI corresponded to the predefined accepted limits for BASDAI (±20). However, LoA for fatigue, pain and PaGl approximated ±35. No significant correlations were found between the absolute $\Delta$values of BASDAI, BASFI, fatigue, pain or PaGl and the inter-visit time duration (r range -0.1 – 0.2, ns). $\Delta$BASFI, $\Delta$fatigue, $\Delta$pain and $\Delta$PaGl were weakly correlated with $\Delta$BASDAI (r range 0.30 – 0.60, $p<0.01$). In multiple regression analyses, $\Delta$BASFI was best predicted by $\Delta$pain, and $\Delta$fatigue, $\Delta$pain and $\Delta$PaGl by $\Delta$BASDAI (rp range 0.40 – 0.49, $p<0.0001$, SEE). Although the associations were highly significant, SEEs were high (range 10.8 – 15.6) illustrating poor agreement in individuals.

Table 1. Agreements between two consecutive measurements in SpA patients with stable disease (change in BASDAI $\leq$20)

| Level | Group (mean ± SD) | | | Individual | |
|---|---|---|---|---|---|
| | Visit 1 | Visit 2 | Bias | LLoA | ULoA |
| BASFI | 33.0±24.8 | 32.7±25.2 | –0.3±11.7 (ns) | –23.2 | +22.6 |
| Fatigue | 49.3±28.2 | 48.7±28.7 | –0.6±18.8 (ns) | –37.4 | +36.2 |
| Pain | 35.6±26.9 | 34.8±25.7 | –0.8±17.0 (ns) | –34.1 | +32.5 |
| PaGl | 40.8±27.9 | 39.4±27.9 | –1.4±17.5 (ns) | –35.7 | +32.9 |

**Conclusions:** Independently of time duration, fatigue, pain and PaGl fluctuated substantially and unpredictable in SpA patients with stable BASDAI. In the daily clinic, a change in these outcome measures of at least 35 may be considered as natural variation or "measurement error" with no clinically important relation to the disease activity.

## AB0706 LIPID PROFILE AND ACTIVE SYSTEMIC INFLAMMATION MAY DIFFERENTLY AFFECT THE PATHOMECHANISM OF CARDIOVASCULAR DISORDERS IN ANKYLOSING SPONDYLITIS (AS) AND IN PSORIATIC ARTHRITIS (PSA)

P. Gluszko[1], K. Bonek[1], R. Rupinski[1], J. Wronski[1], W. Maslinski[2]. *[1]Department of Rheumatology; [2]Department of Pathophysiology and Immunology, National Institute of Geriatrics, Rheumatology and Rehabilitation. Warsaw, Poland, Warszawa, Poland*

**Objectives:** To investigate lipid profile, inflammatory mediators, markers of endothelial activation and other clinical factors associated with cardiovascular risk in AS and PsA.
**Methods:** Lipid profile, atherogenic index (AI –the TC: HDL)), CRP level, disease activity (BASDAI and ASDAS), patients BMI and risk factors like smoking and hypertension were evaluated in 21 AS patients (6 female, 15 male, mean age 41,6±7,4 years, with disease duration of 6,5 ±10,1 years) and in 18 PsA patients (8/f, 10/m, mean age 46,1± 10,6 y., disease duration 6.1±7,5 y.). Serum concentrations of ICAM-1, RANTES, CD40 Ligand were measured using ELISA. The SCORE calculator was used for CV risk estimation.
**Results:** Mean values of BMI for AS and PsA patients, mean age and the disease duration did not differ significantly between the study groups. There were 9 smokers, 6 patients with hypertention and 3 patients with a coronary heart disease (CHD) in AS group and 5 smokers, 11 patients with hypertension, 3 with CHD in PsA. Mean values of BASDAI 5,9±1,9 SD in AS and 4,4±2,2 in PsA indicated active diseases. The SCORE CV risk above 5% was found in 4 patients (19%) with AS and in 3 PsA patients (16%). In AS AI (3.6±1) was significantly lower and HDL/LDL (0.51 ±0,1) higher vs. AI (4,4±1) and HDL/LDL (0,46± 0,1) in PsA ($p<0,03$).
14 (AS + PsA) smokers revealed higher serum levels of ICAM-1 (17,9± 7,7 ng/ml) comparing to 25 non –smokers (12,8±2,5 p=0.004). In AS we found significant ($p<0,05$) positive correlations between BASDAI values and HDL levels (r=0,4) and ASDAS and HDL (r=0,55) and negative correlations between BASDAI and AI (r= -0,60), ASDAS and AI (r= -0,50), BASDAI and CD 40 Ligand (r= -0,5). In PsA only BASDAI positively correlated with HDL levels (r=0,56). In non –smokers AI positively correlated with CD40 Ligand and CD40 Ligand negatively correlated with BASDAI. In smokers BASDAI and ASDAS positively correlated with HDL and BASDAI negatively with AI. We did not find any correlatinons between SCORE risk, disease activity, markers of inflammation and vascular injury.
**Conclusions:** In our opinion the SCORE calculator underestimates CV risk in AS and PsA. Higher activity of the disease is associated with elevated HDL levels and decreased AI (a lipid paradox), which may suggest, that mostly in active AS, factors other then cholesterol-related are associated with the pathogenesis of CV disorders.
Neither lipid alterations nor inflammatory mediators but smoking seems to be the strongest factor associated with a direct vascular injury.

## AB0707 CHECKLISTS (MINIMUN AND EXCELLENCE) FOR THE EVALUATION OF PATIENTS WITH AXIAL SPONDIYOARTHRITIS IN DAILY PRACTICE: PERSONALIZA PROJECT

R. Almodóvar[1], E. Batlle[2], E. Collantes[3], E. de Miguel[4], S. González[5], A. Hernández[6], X. Juanola[7], L.F. Linares[8], E. Loza[9], M. Moreno[8], M. Moreno[10], V. Navarro-Compán[11], J. Sanz[12], P. Zarco[1]. *[1]Rheumatology Unit, Hospital Universitario Fundación Alcorcón, Madrid; [2]Rheumatology Unit, Hospital Universitario Sant Joan d'Alacant, Alicante; [3]Rheumatology Unit, Hospital Universitario Reina Sofía, Cordoba; [4]Rheumatology Unt, Hospital Universitario idiPaz, Madrid; [5]Rheumatology Unit, Hospital de Cabueñes, Gijón; [6]Rheumatology Unit, Hospital Virgen de la Salud, Toledo; [7]Hospital Universitario de Bellvitge, L'Hospitalet de Llobregat, Barcelona; [8]Rheumatology Unit, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia; [9]INMUSC, Madrid; [10]Rheumatology Unit, Hospital Universitario Parc Taulí, Sabadell; [11]Rgeumatology Unit, Hospital Universitario idiPaz; [12]Rheumatology Unit, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain*

**Background:** Currently there is great workload in rheumatologic clinics and a lot of variability in the type and number of potential measures for patients with axial SpA.
**Objectives:** To standardize axial SpA evaluation in daily practice through the generation of two checklists (one for minimum and another of excellence).
**Methods:** A qualitative study was performed. First, an expert panel was set up (8 rheumatologists with interest and experience in axial SpA). A focal group with patients was organized. Barriers and facilitators in the evaluation and management of patients with axial SpA was analyzed. A systematic literature review was performed in order to identify measures for axial SpA and methodological characteristics as their validity or impact in daily practice. All of this information was presented to the experts and discussed. As a result, a draft of variables for a proper evaluation of patients with axial SpA was proposed. Then, the experts evaluated different characteristics of these variables (validity, feasibility, impact, etc) and selected a feasible and relevant list of variables (minimum checklist, in case of busy clinics or less skilled professionals) and added some other interesting variables (excellence checklist, the ideal evaluation) to cover all the domains of the disease. With these variables an electronic and paper checklists were designed.
**Results:** Two checklists were generated. The minimum checklist includes a) Personal history (date of symptoms start, date of diagnosis, family history of Crohn disease/ulcerative colitis, psoriasis, reactive arthritis, uveitis, spondyloarthritis, smoking status, peripheral disease, enthesitis, dactylitis, extra-articular manifestations, profession, physical activity, inflammatory low back pain; b) Comorbidity (arterial hypertension, Diabetes Mellitus, hypercholesterolemia, cardiovascular disease, gastric ulcers, depression, osteoporosis, others); c) Physical examination (enthesis, synovitis, hips, dactylitis, modified Schöber, thoracic expansion, cervical rotation); d) Activity control (ASDAS, BASDAI, physician VAS, d) Function: BASFI; e) Labs and imaging (hemogram, ESR, biochemistry, CRP, urine, axial and sacroiliac x-ray, HLA B-27); f) Treatments (NSAID, biologic therapy, cessations and reasons, other treatments, physical activity). In the excellence checklist along with the previous, the following variables were included: blood pressure, cardiac frequency, weight, height, BMI, abdominal perimeter, BASMI, lipids, 25-OH Vitamin-D, glicohaemoglobina, microalbuminuria, DEXA.
**Conclusions:** These checklists for patients with axial SpA might help evaluate rheumatologists in daily practice in order to early recognition and management of comorbidities, disease activity and other outcomes.

## AB0708 DELAY TO DIAGNOSIS IN ANKYLOSING SPONDYLITIS: A LOCAL PERSPECTIVE

S.P. Moran[1], C. Longton[2], M. Bukhari[1], L. Ottewell[1]. *[1]Rheumatology; [2]Physiotherapy, Royal Lancaster Infirmary, Lancaster, United Kingdom*

**Background:** The diagnostic delay in axial spondyloarthritis is reported to be improving after campaigns by ASAS and the rheumatology community to educate primary care physicians to refer patients for early assessment[1]. MRI scanning has also been in widespread use since 2000. We conducted a local study to assess if diagnostic delay was improving in our well-defined cohort of ankylosing spondylitis (AS) patients who are reviewed in our physiotherapy-led service, and to compare this with national trends.
**Objectives:** We set out to determine the time to diagnosis of AS in our cohort and to assess if this has changed over time. Our aim is to reduce diagnostic delay by educating local primary care clinicians about inflammatory back pain (IBP) and the importance of early recognition and referral.
**Methods:** Patients were identified from the physiotherapy database of 53 patients currently reviewed under the AS service at a district hospital in the North West of England. We assessed mean and median delay to diagnosis, gender, family history of AS, those diagnosed pre- and post-2000, patient age and date of first presentation to primary care with IBP, and date of first rheumatology review. Only those fulfilling diagnostic criteria for AS were included in the dataset.
**Results:** 44 males and 9 females with age range 28–83 years.
Mean delay to diagnosis was 8.94 years. Median delay to diagnosis: 8 years.
1962–1999 (10 patients) Mean 6.7 years. Median 7 years
2000–2004 (13 patients) Mean 9.5 years. Median 7 years
2005–2009 (15 patients) Mean 9.8 years. Median 8 years
2010–2015 (16 patients) Mean 9.1 years. Median 7 years
Range of diagnostic delay was 0 to 40 years. 15% were diagnosed in <2 years. 42% diagnosed in <5 years. 58% diagnosed in <10 years. The pre-2000 mean delay to diagnosis was 6.7 years, Post-2000 mean delay was 9.45. However, 81% of our AS patients were diagnosed post-2000.
42% of patients were on biologic therapy, the remainder were on NSAIDs. No significant difference was seen between the sexes. 19% of patients had a clear family history of AS, and no difference was seen in delay to diagnosis compared to those without family history.
**Conclusions:** Our findings closely reflect those of national data obtained in recent studies[2]. Diagnostic delay has not improved in the time frame of this local study, although AS diagnoses have proportionally increased, likely due to increased use of MRI. Why is the delay not improving? Back pain remains a common presenting complaint in primary care, with lack of recognition of associated extra-articular features. In conclusion, there remains a need for education on when to suspect axial spondyloarthritis and refer to secondary care.
To follow up this study we are holding a series of AS targeted educational meetings with primary care colleagues, a local AS patient support group and regional special interest group. We will assess this intervention and subsequent referrals with the aim of improving confidence in suspected AS cases.

## AB0709 NEUROPATHIC PAIN COMPONENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

K. Gok, G. Cengiz, K. Erol, S. Ozgocmen. *Erciyes Univ. Sch. Med. Div. Rheum. Kayseri, Kayseri, Turkey*

**Background:** Axial spondyloarthritis (axSpA) comprises a heterogeneous group of diseases which predominantly involve the axial skeleton and have many overlapping clinical features. The axial SpA spectrum ranges from non-radiographic axial SpA (nr-axSpA) at one end to ankylosing spondylitis (AS) at the other. Chronic low back pain (LBP) is the presenting symptom in the majority of patients with axSpA. Different studies have revealed that 16 to 54% of patients with chronic LBP may have neuropathic pain (NeP) component. Although there is no gold standard for the diagnosis of NeP, use of neuropathic pain screening tools, and quantitative sensory testing may offer the reliable way to diagnose NeP.
**Objectives:** The aim of this study was first to assess NeP component in patients with axSpA, including nr-axSpA and AS; and secondly to assess potential interactions between NeP component and other variables and outcome measures.
**Methods:** Adult patients who met Assessment of SpondyloArthritis International Society (ASAS) axSpA classification criteria were consecutively recruited. Patients with a previous diagnosis or under treatment for NeP, or having diseases causing increased risk to develop neuropathic disorders like uncontrolled diabetes, neuroendocrine or neuro-vascular disorders were excluded. Patients were examined and evaluated for disease specific and generic outcome measures including disease activity parameters, physical functions, psychological status and health related quality of life measures. Neuropathic component of pain was evaluated using the DN4 interview and PainDetect questionnaire which were applied by the same experienced physician who was unaware of patients' other clinical and outcome data. Patients with a score $\geq$4 in DN4 were considered as "probable NeP" and $\geq$13 in PainDetect were considered as "possible or likely NeP". Clinical variables and outcome measures were compared patients with NeP and without NeP component according to two different criteria.
**Results:** One hundred and seven patients (51.4% male, 48.6% female) with axSpA (36 nr-axSpA, 71 AS) were included (mean age 35.9±10.2). The first presenting symptom was LBP in 80% of the patients. NeP component was present in 31.8% of patients with axSpA categorized according to DN4 (33.3% in nr-axSpA vs 31.0% in AS, p=0.805) and in 34.6% of patients categorized according to PainDetect (36.1% in nr-axSpA vs 33.8% in AS, p=0.813). Pain characteristics like burning, electric shock, tingling, pins and needles, itching, numbness and painful cold as well as pain course were quite similar between patients with nr-axSpA and AS. Patients with NeP component according to two assessment tools had significantly higher scores in VAS-pain, fatigue, BASDAI, ASDAS-CRP and poorer QoL and physical functions compared to patients with nonNeP. However after adjusting for confounding variables in a multivariable logistic regression analysis NeP was associated only with ASQoL (OR 1.14; 95% CI 1.05–1.25) in DN4 categorized and VAS-fatigue (OR 1.32; 95% CI 1.07–1.62) in PainDetect categorized patients.
**Conclusions:** This is the first study showing that nearly one third of patients with axSpA may have NeP component regardless of having nr-axSpA or AS. NeP component may contribute worsened QoL and fatigue and should be kept in mind while targeting the management.

## AB0710 PLATELET DISTRIBUTION WIDTH AS AN ADJUNCTIVE INFLAMMATORY MARKER IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S.-J. Byun, S.-W. Lee, J.J. Song, Y.-B. Park, S.-K. Lee. *Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

**Background:** With the recent introduction of biological drugs, remarkable improvements have been reported in treatment of ankylosing spondylitis (AS). Since those are most effective for delaying the progression when started sufficiently early in the disease course, more aggressive interventions are necessary at that time through evaluation of disease activity. Usually three methods for disease activity assessment are available for use in patients with AS: BASDAI (Bath AS Disease Activity Index), BASFI (Bath AS Disease Functional Index), and ASDAS (Ankylosing Spondylitis Disease Activity Score). However, these activity score have problem of depending too much on subjective assessment. Laboratory findings such as ESR and CRP also are not the good biomarkers since they have possibility of false positive and false negative. Thus, there is a high *demand* for additional and complementary marker that correlate with disease activity. Platelet distribution width (PDW) is specific marker of platelet activation. It can represent the heterogeneity of thrombocyte volume. Mean value of PDW was significantly higher in patients with preterm labor with asserted platelet activation compared to healthy persons suggesting the possible high grade inflammation in the pathology. In addition, an association between elevated platelet (PLT) counts and several autoimmune diseases is well known.
**Objectives:** We investigated whether PDW and PLT counts correlated with disease activity indices of AS and laboratory inflammatory markers and compared them between active and inactive AS patients.
**Methods:** We evaluated the disease activity in the 78 AS patients by using the BASDAI, ASDAS-ESR, and ASDAS-CRP. Laboratory inflammatory marker as acute-phase reactants, including ESR, and CRP levels were also measured in these AS patients. We divided all patients into 2 groups according to disease activity indices of AS: active groups were defined as BASDAI $\geq$3.7 (the median), ASDAS-ESR $\geq$2.1 (60.2%) and ASDAS-CRP $\geq$2.1 (43.6%).
**Results:** The mean (±SD) PDW was 11.0 (±1.3) %. The means (±SD) of PLT counts, ESR, CRP, BASDAI, ASDAS-ESR, and ASDAS-CRP level were respectively 263±57 x $10^9$/L, 21 (±18.6) mm/hr, 5.17 (±8.0) mg/l, 3.6 (±1.8), 2.39 (±1.03), and 2.08 (±1.02)] in the patients with AS (not shown). PDW significantly correlated with BASDAI, ASDAS-ESR, and ASDAS-CRP (r =0.390, p<0.01; r =0.287, p<0.05; r =0.295, p<0.001, respectively). On the other hand, PLT count showed no significant correlation with these parameters, but there was significant correlations with CRP (r =0.346, p<0.05) (Table). The Mean of PDW of patients with higher BASDAI were significantly higher when compared with that with lower activity (11.4±1.4 vs 10.6± 1.0%, p=0.007) (Figure).

| | ESR | CRP | BASDAI | ASDAS-ESR | ASDAS-CRP |
|---|---|---|---|---|---|
| PDW | 0.084 | 0.043 | **0.390*** | **0.287**# | **0.295*** |
| PLT count | 0.193 | **0.346*** | –0.060 | 0.117 | 0.084 |

PDW, platelet distribution width; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; ASDAS, Ankylosing Spondylitis Disease Activity Score. r is determined by Spearman's rank correlation test Bold characters indicates a statistically significant difference with a *p*-value <0.05. #Statistical significance p<0.05. *Statistical significance p<0.01.

**Conclusions:** To conclude, we suggest PDW as supplementary novel marker to detect active AS that shows conventional inflammatory marker in normal range.

## AB0711 BODY MASS INDEX IS RELATED WITH THE PRESENCE OF SYNDESMOPHYTE IN AXIAL SPONDYLOARTHRITIS: DATA FROM KOREAN COLLEGE OF RHEUMATOLOGY BIOLOGICS (KOBIO) REGISTRY COHORT

S.-K. Kim[1], J.-Y. Choe[1], S.-S. Lee[2], K. Shin[3]. *[1]Division of Rheumatology, Department of Internal Medicine, Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu; [2]Department of Rheumatology, Chonnam National University Medical School, Gwangju; [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

**Background:** Given that obesity might have a potent role in the regulation of the inflammatory response of spinal or peripheral joints in axial spondyloarthritis (axSpA), the detailed relationships between obesity and disease symptoms and activity should be addressed in patients with SpA
**Objectives:** We cross-sectionally investigated whether body mass index (BMI) is associated with parameters of disease activity and clinical manifestations in axSpA.
**Methods:** Demographic, clinical, and radiological features and disease activity indexes from 789 axSpA patients (619 males and 170 females) were obtained from the Korean College of Rheumatology Biologics (KOBIO) registry cohort. BMI (kg/m$^2$) was classified into normal (BMI <23.0), overweight (23.0 $\leq$ BMI <25.0), and obese (BMI $\geq$25.0). Disease activity indexes included ESR, CRP, ASDAS, BASDAI, and BASFI.

**Results:** The mean BMI in patients with axSpA was 23.8± 13.3. 50.2% of all patients were overweight or obese. Overweight/obese female patients showed higher ESR, CRP, ASDAS-ESR, and ASDAS-CRP than normal patients (p=0.045, p=0.011, p=0.035, and p=0.029, respectively). Patients with ASDAS score ≥2.1 showed higher BMI than patients with ASDAS score <2.1 (p=0.019). A greater increase in BMI was noted in patients with syndesmophyte than in those without syndesmophyte (p<0.001). Multivariate regression analysis showed that increased BMI was closely related with presence of syndesmophyte (β=0.932, p=0.002). In addition, syndesmophyte was found to be influenced by BMI (OR=1.087, 95% CI 1.033–1.145, p=0.007)

**Conclusions:** Our results imply that increased BMI was related with presence of syndesmophyte and in part associated with disease activity in axSpA.

## AB0712 ANALYSIS OF DIFFERENT MANIFESTATIONS IN THE CERVICAL SPINE INVOLVEMENT OF LONGSTANDING ANKYLOSING SPONDYLITIS: ATLANTOAXIAL ANKYLOSIS (AAA) AND ATLANTOAXIAL SUBLUXATION (AAS)

S. Lee[1], T.-H. Kim[2], Y. Song[3], Y.B. Joo[4], J.-B. Jun[5]. *[1]Radiology; [2]Hanyang University Hospital for Rheumatic Disease; [3]Radiology, Hanyang Univeristy Hospital for Rheumatic disease; [4]Rheumatology, Hanyang University Hospital for rheumatic disease; [5]Rheumatology, Hanyang Univeristy Hospital for Rheumatic disease, Seoul, Korea, Republic Of*

**Background:** Atlantoaxial ankylosis (AAA) is another late manifestation of cervical spine involvement in longstanding AS and suggest that higher cervical mSASSS is more related with the development of AAA than atlantoaxial subluxation (AAS). AAA does not cause as much cervical instability as AAS.

**Objectives:** To analyze radiologic and clinical findings of atlantoaxial ankylosis and atlantoaxial subluxation in ankylosing spondylitis

**Methods:** A total of 150 AS patients (145 men, 5 women, mean age, 36.8 years) who had AAA (60 men and 2 women, mean age, 60 years) or AAS (85 men and 3 women, mean age, 34 years) were randomly gathered and underwent at least two plain radiographs of lateral cervical spine on flexion. The atlantodental interval more than 3mm was considered as AAS. Loss of atlantodental interval was considered as AAA. The plain radiographs of lateral cervical spine were independently analyzed by two radiologists. Interobserver reliability between reader 1 and 2 in scoring mSASSS in AS was analyzed. We compared the results of mSASSS between AAS and AAA to see if it was related to severity or duration of the disease.

**Results:** The mean mSASSS of AS patients with AAA and AAS were 40.1 and 16.5 respectively and the mean duration of AS patients with AAA and AAS were 19.3 and 13.7 years each. There was a significantly (p<0.05) higher total mSASSS, especially cervical spine mSASSS, for AS patients with AAA than those with AAS after mSASSS was corrected for age and duration. But, disease duration was not significantly related with the development of AAA compared with that of AAS.

**Conclusions:** We found that it has incidence as high as AAS and both are similar in that they are late presentation of AS and occur in patient with long duration. We found that AAA is another manifestation of cervical spine involvement in longstanding AS and is related to severity of the AS reflected by higher cervical mSASSS.

## AB0713 SPECTRUM OF ATLANTOAXIAL ANKYLOSIS (AAA) IN THE ANKYLOSING SPONDYLITIS (AS): IS IT REALLY CHRONOLOGICAL CHANGES THAT OCCUR WITH DISEASE PROGRESSION OR ARE THERE TWO COMPLETELY DIFFERENT PATHWAYS?

S. Lee[1], T.-H. Kim[2], Y. Song[1], Y.B. Joo[2], J.-B. Jun[2]. *[1]Radiology; [2]Rheumatology, Hanyang University hospital for rheumatic disease, Seoul, Korea, Republic Of*

**Background:** The morphologic characteristics of atlantoaxial ankylosis in AS patient and suggests different pathways of involvement resulting in atlantoaxial subluxation in AS patients

**Objectives:** To evaluate morphologic characteristics of AAA in AS patient and classify them into categories which reflects the end-stage manifestations of two differents disease pathways.

**Methods:** Plain radiographs of cervical spine in 62 AS patients with AAA were reviewed. We classified AAA in AS patients into three subtypes: loss of atlantodental interval (type I), ankylosis of facet joint (type II) and ankylosis of anterior longitudinal ligament or anterior atlantooccipital membrane with cervical spine (type III).

And then, we categorized 62 AS patients with AAA into two subgroups: group A (21 patients) with only synovial joint involvement of AS (type I or type II or both) and group B (41 patients) with enthesis involvement of AS with additional synovial joint involvement (type III plus type I or type II or both).

We compared the results of mSASSS and disease duration between group A and B.

**Results:** The mean cervical mSASSS of patients in group A and B were 27.3 and 16.0 each (p value, 0.196). The mean duration of AS patients in group A and B were 23.7 and 23.6 years each. There was no siginificant differences in cervical, lumbar and total mSASSS or disease duration between the two groups.

**Conclusions:** We propose that atlantoaxial joint involvement in the AS patients is not chronological changes that occur with disease progression, but rather it is end-stage manifestation of two different pathways: one only involving synovial joint and the other one involving both synovial joint and enthesis.

## AB0714 NSAID PRESCRIBING PRACTICE IN PATIENTS WITH SPONDYLOARTHRITIS

S. Habibi[1], R. Sengupta[1,2]. *[1]Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath; [2]University of Bath, Bath, United Kingdom*

**Background:** NSAID's are widely prescribed for patients with active spondyloarthritis. All NSAID's have the risks of adverse cardiovascular, GI, renal and thrombotic toxicity.

The Medicines and Healthcare Products Regulatory Authority (MHRA) as well as National Institute of Clinical Excellence (NICE) have issued guidance that applies to all traditional NSAIDs and selective COX-2 inhibitors.

**Objectives:** To review the prescribing of NSAID's in line with the MHRA/NICE recommendations.

**Methods:** This is a Trust-wide audit, looking into the NSAID prescribing practice in spondyloarthritis at the Royal National Hospital for Rheumatic Diseases.

The "AS database" was interrogated to define the total number of patients prescribed an NSAID to be taken continuously, from 1st Sept 2014 till 31st Aug 2015. Data was retrospectively collected from the database as well as the case records. Information regarding the definite indication for NSAID prescribed, contraindications and risk factors was collected. Pathology systems were accessed to check if renal function had been performed in the past 12 months of prescription.

**Results:** 69 patients with SpA taking regular NSAIDs were identified. A clear indication was identified in 44/69 (63.7%) patients (Table 1). No patients with

Table 1. Indications for prescribing NSAID's

| Indication | Number of patients |
|---|---|
| Inflammatory backache | 26 |
| Peripheral arthritis | 7 |
| Enthesitis | 3 |
| Osteoarthritis | 7 |
| Others | 7 |
| Fatigue | 2 |
| Greater trochanteric bursitis | 2 |
| Hip pain | 2 |
| Fracture | 1 |

Table 2. Risk factors for NSAID's

| Risk factor | Number of patients |
|---|---|
| Age >65 years | 15 |
| Ischemic heart disease | 3 |
| CVA | 0 |
| Peripheral vascular disease | 0 |
| CKD | 0 |
| Diabetes mellitus | 2 |
| Hypertension | 18 |
| Drugs which could increase the risk of bleeding when co-prescribed with NSAID's (SSRI) | 1 |
| Drugs increasing nephrotoxicity when co-prescribed with NSAID's | 17 |

contra-indications were prescribed the drugs. 22/69 (31.8%) had one or more risk factors for the drugs (Table 2). 49/69 (71.01%) patients were at risk of adverse GI effects. Of these, 27 (55.1%) were prescribed PPI's.
Renal function in the last 12 months was assessed in 40/69 (57.97%) patients. 8 patients who were receiving other concomitant nephrotoxic drugs had not had their renal function assessed in the past 12 months.
**Conclusions:** The proportion of patients with a documented indication for NSAID was moderately high. No patients with contra-indications to the drugs were prescribed the medication, which is in keeping with the guidance. The most common risk factors were age>65 years, hypertension and drug interactions involving ACE-I and ARB's, which increase the risk of nephrotoxicity. Only 55% of those at risk of adverse GI side effects were prescribed a PPI. Monitoring of renal function in addition, was moderate, being done in just over a half of the patients. Strategies to improve routine assessment of risk factors prior to commencing NSAIDs in AxSpA patients need to be addressed.

## AB0715 CORRELATION OF CLINICAL SYMPTOMS AND INSTRUMENTAL FINDINGS IN AS COXITIS

S. Erdes, T. Dubinina, O. Rumyantseva, A. Starkova, M. Podryadnova, S. Krasnenko, A. Demina, M. Urumova, E. Agafonova. *VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Involvement of the hip joint (coxitis) is one of distinctive manifestations of ankylosing spondylitis (AS), resulting total hip arthroplasty in 5%>7% of cases.
**Objectives:** To correlate the clinical features of coxitis in AS pts with radiographic and ultrasonographic findings.
**Methods:** A total of 63 patients (mean age 31,7±12,7 years) with a diagnosis of AS (at the modified New York criteria 1984), having of pain in the hip joints, sequentially admitted for treatment at the clinic. Mean age of disease onset was 30,8±9,6 y. Hip pain was scored using VAS 100 mm. Coxitis was established on the basis of clinical symptoms - the presence of pain and/or limitation of motion in the hip joints at the time of admission of the patient to the clinic. Pelvic radiographs were taken in all pts to determine the severity of hip involvement using BASRI hip scale, and ultrasound examination was made using Sono Diagnost 360 (Philips) with linear (7,5 MHz) and convex (5,0 MHz) transducers. Joint effusion was set when the distance between the signals from the joint capsule and the inner part of the femoral neck was more than 7 mm.
**Results:** Synovitis on ultrasonography found in 53 (81%) pts out of 61. Pts were grouped into 2 arms based on radiologic findings, i.e. Group with radiographic signs of coxitis and Group without radiographic abnormalities. Two groups comparison data are presented in the Table

| Parameters | Pts with US verified coxitis | | P |
|---|---|---|---|
| | BASRI-hip 0–I (n=20) | BASRI-hip II–IV (n=33) | |
| Gender (M/F), n | 18/2 | 23/10 | 0,04 |
| AS duration, mo, Me [25%; 75%] | 93.95 [77–111.5] | 221 [176–321] | 0.03 |
| Age | 35.5 [25.7–43.2] | 46.3 [37.2–49.1] | 0.02 |
| US confirmed trochanteritis | 3 (15%) | 5 (12.1%) | 0.4 |
| BASDAI, Me [25%; 75%] | 4.85 [3.7–6.75] | 4.3 [3.3–5.4] | 0.2 |
| BASFI, Me [25%; 75%] | 4.8 [2.3–5.7] | 5.3 [4.3–6.9] | 0.03 |
| HLA-B27. n (%) | 19 (95%) | 30 (93.9%) | 0.6 |
| ASDAS (CRP) Me [25%; 75%] | 3.3 [2.95–3.85]* | 3.7 [2.4–4.7] | 0.6 |
| VAS mm Me [25%; 75%] | 60 [40–80]* | 40 [20–60] | 0.002 |
| ESR, mm/h, Me [25%; 75%] | 14.5 [10–35] | 20.5 [25–45] | 0.02 |
| CRP, mg/mL, Me [25%; 75%] | 22.52 [4.75–33.9] | 17.4 [5.3–27.5] | 0.03 |
| Bilateral coxitis, n (%) | 15 (75%) | 20 (60%) | 0.5 |
| Intermalleolar distance with maximally spread legs <100 cm | 1 (5%) | 3 (6%) | 0.8 |

**Conclusions:** Ultrasound allows hip joint to clarify the cause of pain with similar clinical and radiographic manifestations, localized in this area, as well as to determine if the patient has synovitis in the early stages of the coxitis. Patients with radiological coxitis have a longer duration of the disease, severe functional disorders of the index BASFI, with the defeat of the peripheral joints is less common.

## AB0716 SOME CAUSES FOR DELAYED RECOGNITION OF ANKYLOSING SPONDYLITIS IN REAL CLINICAL PRACTICE IN RUSSIA: RESULTS OF A SINGLE MULTICENTER NON-INTERVENTIONAL STUDY – EPIKA 2

S. Erdes[1], T. Dubinina[1], O. Rumyantseva[1], D. Abdulganieva[2], I. Vinogradova[3], L. Evstigneeva[4], A. Yelonakov[5], E. Otteva[6], T. Raskina[7], T. Salnikova[8], R. Samigullina[9], V. Sorotskaya[8], L. Shkil[10]. *[1]VA Nasonova Research Institute of Rheumatology, Moscow; [2]KSMU, Kazan; [3]District Clinical Hospital "1", Ulianovsk; [4]District Rheumatology Center, Ekaterinburg; [5]MONIKI, Moscow; [6]Regional Clinical Hospital "1" named after Prof Sergeev S.I., Xabarovsk; [7]District Clinical Hospital of War Veterans, Kemerovo; [8]District Clinical Hospital, Tula; [9]NWSMU named after Mechnikov, St. Peterburg; [10]MHCI Municipal Clinical Hospital "20" named after Berzon I.S., Krasnoyarsk, Russian Federation*

**Objectives:** Recognition of ankylosing spondyloarthritis (AS) in current real clinical practice is often delayed. Identification of main causes of this peculiarity would help to propose administrative interventions to improve practices.
**Methods:** A single multicenter non-interventional study was conducted in spring 2015 y in order to ascertain the clinical features of AS in the real practice of a rheumatologist. 402 consecutive AS pts (meeting modified N-Y criteria) referred to a rheumatologist were evaluated following accepted standards during 2 mo at 10 clinical centers of Russia. All pts were evaluated, including those who attended because of deterioration, and pts coming for scheduled check-ups within the disease monitoring program. Patients' mean age was 40,8±11,5 y,. 292 (72,6%)-males, 82,6% were HLA-B27- positive.
**Results:** Time to establishing the AS diagnosis from the disease onset was 85,2±86,2 mo. In 32,3% of cases the diagnosis was made within 2 years from the onset, in 52,5% - within 5 years, and in 25,8% of pts the diagnosis was established in >10 years after AS onset. Association with specific clinical AS features at disease onset, such as axial or joint involvement (location, spatial extent of pain and synovitis) was not established. The AS diagnosis in 351 (87,3%) pts was established by rheumatologist, in 25 (6,2%) – by general practitioner, in 14 (3,5%) – by neurologist, and in remaining pts – by other specialists. During the first reference to a doctor the AS diagnosis was established in 3,7% (15 pts) cases, during 2–5 visits – in 25,1% (101), during 6–10 visits – in 25,1% (113), while 43,0% (173) of cases required >10 visits to establish the AS diagnosis. Probably due to established practices and pts' mentality in Russia all cases with back pain would be referred initially to neurologists and GPs, and only after multiple visits they may be referred to rheumatologists, which explains the fact of establishing AS during the first visit by neurologists and GPs, and only 6% input in AS verification from rheumatologists during Visits 2–5–6%. Generally before recognizing AS physicians were inclined to name it as spine degenerative disease (58%), reactive arthritis (21%), hernia of inter-vertebral disk (34%), osteoarthritis (6%), non-differentiated arthritis (10%), and oths. In almost half (42%) cases pts had to undergo 2–3 other diagnoses (not associated with spondyloarthritis) before AS was verified.
**Conclusions:** In real clinical practice the final AS diagnosis is usually established in 7 years average after AS onset. Pts are usually attended for quite a long period of time by other specialists, who are not sufficiently familiar with AS, therefore, AS is missed and other disease are being treated instead. Therefore, GPs and neurologists require improved and adjusted training, enabling them to suspect AS and timely refer a patient to a rheumatologist.

## AB0717 CLINICAL CHARACTERISTICS OF ANKYLOSING SPONDYLOARTHRITIS IN REAL CLINICAL PRACTICE IN RUSSIA: RESULTS OF A SINGLE MULTICENTER NON-INTERVENTIONAL STUDY – EPIKA 2

T. Dubinina[1], S. Erdes[1], O. Rumyantseva[1], D. Abdulganieva[2], I. Vinogradova[3], L. Evstigneeva[4], A. Yelonakov[5], E. Otteva[6], T. Raskina[7], T. Salnikova[8], R. Samigullina[9], V. Sorotskaya[8], L. Shkil[10]. *[1]VA Nasonova Research Institute of Rheumatology, Moscow; [2]KSMU, Kazan; [3]District Clinical Hospital "1", Ulianovsk; [4]District Rheumatology Center, Ekaterinburg; [5]MONIKI, Moscow; [6]Regional Clinical Hospital "1" named after Prof Sergeev S.I., Xabarovsk; [7]District Clinical Hospital of War Veterans, Kemerovo; [8]District Clinical Hospital, Tula; [9]NWSMU named after Mechnikov, St. Peterburg; [10]MHCI Municipal Clinical Hospital "20" named after Berzon I.S., Krasnoyarsk, Russian Federation*

**Objectives:** Recognizing the clinical picture of ankylosing spondylitis (AS) in real practice would help to optimize healthcare services provided to this group of pts.
**Methods:** A single multicenter non-interventional study was conducted in spring 2015 y in order to ascertain the clinical features of AS in the real practice of a rheumatologist. 402 consecutive AS pts (meeting modified N-Y criteria) referred to a rheumatologist were evaluated following accepted standards during 2 mo at 10 clinical centers of Russia. All pts were evaluated, including those who addressed because of deterioration, and pts coming for regular check-ups within the disease monitoring.
**Results:** Patients' mean age was 40,8±11,5 y,. 292 (72,6%)- males, 82,6% were HLA-B27- positive. Age at AS onset was 27,6±12,3 y., in 65,4% AS onset occurred before the age of 30 y.o., and in 16,9% – before 16 y.o. Time to establishing the AS diagnosis was 85,2±86,2 mo. By the moment of evaluation inflammatory

back pain was present in 55,7% pts, peripheral arthritis - in 33,1%, enthesitis – in 37,1%, dactylitis – in 1,2%. Average BASDAI disease activity score was 4,3±2,1 (in 54,2% of pts it was >4, in 12,7% - >7, and in 18,2% - <2), and BASFI score – 4,1±1,8 (in 48,0% of pts it was >4,in 17,1%,- >7, and in 26,1% - <2). Extraskeletal manifestations were documented in 13,2% AS pts (including uveitis – in 45,3%, psoriasis – in 28,3%, Chrons disease – in 7,5%, IgA-associated neuropathy – in 5,7%, aortitis – in 3,8%). Such complications as amyloidosis were registered in 6 (1,5%) pts, cardiac arrhythmias – in 10 (2,5%) pts, aortal defect – in 1 (0,2%) patient. Most common comorbidities (verified by corresponding specialists) in this population were: arterial hypertension - in 25,1% AS pts, gastric ulcer – in 9,7%, ischemic heart disease – in 4,0%, diabetes mellitus – in 3,0%, chronic bronchitis – in 2,2%, bronchial asthma – in 2,0%, HCV hepatitis – 1,7%, HBV hepatitis – in 1,5%, tuberculosis – in 1,0%, oncologic diseases – in 0,2%, demyelinating conditions – in 0,2% pts. Comorbidities were not found in more than 50% (52%) of pts. Total arthroplasty procedures were documented in 19 (4,7%) pts, including 15 (3,7%) cases of hip replacement, and knee replacement in the rest. By the moment of evaluation another 6,7% of pts required total hip replacement procedure. 92% of pts were taking NSAIDs, sulfasalazine – 31,2%, methotrexate – 11,2%, peroral GCs s - 9,3%, TNF-α inhibitors– 19,1%.
**Conclusions:** In real clinical practice the final AS diagnosis is usually established in more than 7 years after AS onset, by that moment the disease has already reached high activity and pronounced functional impairments occurred. Various comorbidities are found in >40% of AS pts, but with much lower incidence as compared to other systemic rheumatoid diseases.

## AB0718 IS THERE A RISK OF SERIOUS RHYTHM AND CONDUCTION DISTURBANCES, REQUIRING THE INSTALLATION OF A PACEMAKER, IN PATIENTS WITH SPONDYLOARTHRITIS?

S. Lapshina[1,2], M. Mangusheva[1,2], F. Chuvashaeva[2], A. Nigmatyanova[1], S. Eremin[2], L. Myasoutova[1,3]. *[1]Kazan State Medical University; [2]Republic Clinical Hospital; [3]Clinical Hospital # 7, Kazan, Russian Federation*

**Background:** There is a lot of conflicting data about the defeat of the cardiovascular system in patients with spondyloarthritis (SpA).
**Objectives:** Rate the frequency of pacemakers setting in patients with SpA compared with the frequency of pacemakers implanted in the population
**Methods:** A database of patients with established heart pacemakers in 2013–2014 years, residing in the territory of the Tatarstan Republic was analyzed, the results correlated with the number of population. The frequency of cardiac pacemakers establishing the Tatarstan Republic is 2 per 10,000 population. The population of Tatarstan Republic in 2014 - 3,855,258 people, of whom at the age of 18 to 50 years - 1,831,719 people. 2958 patients with SpA are observed in Rheumatology clinics in Tatarstan, 2355 from them - with ankylosing spondylitis (AS).
**Results:** Young working age patients with implanted pacemakers without heart disease history were selected from the database. Those aged 18 to 50 years - 123 people (0.7 per 10,000 population), of whom 59 (47.9%) had congenital heart disease and conduction abnormalities, 5 (4.1%) patients had rheumatic disorders, (2 (1.6%) - a history of acute rheumatic fever, 3 (2.4%) - SpA. Among patients with an established diagnosis of SpA, AS was established in 1 person, in 2 diagnosis of SpA was set retrospectively: in the history of the disease low back pain was found and further examination was conducted. Thus, the frequency of cardiac pacemakers implanted in patients with SpA in Tatarstan is 0.1% or 10 cases per 10,000 patients, and 0.04% or 4 cases per 10,000 in patients with AS.
**Conclusions:** In patients with SpA there is a risk of serious rhythm and conduction disturbances, in some cases requiring the establishment of a permanent pacemaker. The frequency of pacemaker implantation is higher than in the whole population.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4645

## AB0719 THE EFFECTIVENESS OF THERAPEUTIC STRATEGIES TO ACHIEVE THE GOAL (T2T) ON THE EXAMPLE OF KAZAN (RUSSIA) COHORT OF PATIENTS WITH SPONDYLOARTHRITIS

S. Lapshina[1,2], L. Myasoutova[2,3], S. Erdes[4], R. Mukhina[3], A. Vasilyev[3]. *[1]Republic Clinical Hospital; [2]Kazan State Medical University; [3]Clinical Hospital # 7, Kazan; [4]Institute of Rheumatology, Moscow, Russian Federation*

**Objectives:** To rate the effectiveness of therapeutic strategies to achieve the goal (T2T) on the example of Kazan cohort of patients with spondyloarthritis (SpA) compared with routine practice
**Methods:** The main group of active observation by rheumatologist and regular correction of therapy according to the T2T criteria for spondyloarthritis included 42 patients: 27 (64.3%) with ankylosing spondylitis (AS) - New York criteria, 15 (35.7%) with axial SpA and positive MRI osteitis. High and very high activity (ASDAS) was at 54.8%, moderate - at 45.2% of patients. The comparison group - 40 patients (65% - AS, 35% - axial SpA) observed in the routine practice with a rheumatologist consultation as needed (just about once in 6 months). Patients were comparable for demographic and clinical characteristics, disease activity, duration of symptoms was not more than 10 years, the average 5,1±2,7. All patients received nonsteroidal anti-inflammatory drugs (NSAIDs), if necessary on a long constant reception. At baseline and after 3, 6 and 12 months BASDAI, ASDAS, BASFI, remission criteria (ASAS) were determined, adherence to treatment was evaluated.
**Results:** During the observation period in two groups a decrease ($p<0.05$) of mean values BASDAI, BASFI, $ASDAS_{CRP}$ was noticed. For the year of observation in the main group 95.2% of patients showed improvement on ASAS40 criteria, partial remission ASAS criteria was reached at 3 months - 47.6% of patients, at 6 months - 73.8%, at 12 months - 80, 9%, periods of exacerbation were observed in 19.1% of patients.
In the comparison group - 55% of patients showed improvement on ASAS40 criteria, after 3 months partial remission ASAS criteria was reached in 17.5% of patients, at 6 months - 35%, 12 months - 47.5% patients, periods of exacerbation were observed in 57.5% of patients.
The number of patients, regulary performed physical exercises, in the study group was 73.8%, in the control group - 35%. In the study group 76.1% of patients received NSAIDs continuously, in the control group - 37.5% of patients - only on request
**Conclusions:** The treatment strategy T2T SpA is an effective tool for the management of patients with this pathology, improves adherence to therapy, helps to control disease activity, improves functional status.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5752

## AB0720 THE CHARACTERISTICS OF ANDERSSON LESIONS (SPONDYLODISCITIS) BASED ON WHOLE SPINE MAGNETIC RESONANCE IMAGING IN ANKYLOSING SPONDYLITIS

S.-K. Kim[1], K. Shin[2], Y. Song[3], S. Lee[3], T.-H. Kim[4]. *[1]Division of Rheumatology, Department of Internal Medicine, Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu; [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine; [3]Department of Radiology; [4]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of*

**Background:** Andresson lesions could cause debilitating pain and functional impairment in ankylosing spondylitis (AS) patients.
**Objectives:** The objective of this study was to identify the characteristics of Andersson lesions using whole spine magnetic resonance imaging (MRI) in AS.
**Methods:** A total of 62 patients with AS who had taken whole spine MRI were retrospectively enrolled in this study. Regional distribution in the entire spine and within the individual discovertebral unit (DVU) including the central, peripheral, and diffuse disc types of Andersson lesion was assessed. We compared the number of DVUs with Andersson lesion with clinical and radiographic indicies such as erythrocyte sediment rate (ESR), C-reactive protein (CRP), BASDAI, BASFI, and modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).
**Results:** Fifty-three patients (85.5%) had at least one Andersson lesion. We found a total of 129 DVUs with Andesson lesions (9.0%) in the entire spine levels. Andersson lesion at the lower thoracic spine (from T7–8 to T12-L1) was most commonly detected than other spine levels. Among the total 151 Andersson lesions, 41 lesions were identified at the central, 26 lesions at the anterior peripheral, 44 lesions at the posterior peripheral, and 40 lesions at the diffuse disc types. However, the number of Andersson lesions did not correlate with ESR, CRP, BASDAI, BASFI, and mSASSS in AS patients ($p>0.05$ of all).
**Conclusions:** Our study indicates that presence of Andersson lesion in AS patients is clearly underestimated. MRI provides more increased opportunity to detect earlier Andersson lesions than conventional radiography.

## AB0721 THE CLINICAL CHARACTERISTICS AND ASSOCIATED FACTORS OF CHINESE ANKYLOSING SPONDYLITIS PATIENTS

X. Zheng, Q. Li, L. Tu, Q. Lv, M. Yang, Y. Zhang, Z. Lin, Z. Liao, S. Cao, Q. Wei, J. Qi, R. Yuan, J. Gu. *Department of Rheumatology and Immunology, The Third Affiliated Hospital of Sun Yat-sen Universiy, GuangZhou, China*

**Background:** Ankylosing Spondylitis (AS) is the prototype of spondyloarthritis, with inflammatory back pain (IBP) as its most typical clinical characteristic and others including peripheral arthritis, anterior uveitis, dactylitis and so on. Human leucocyte antigen B27 (HLA-B27) status, gender and some other factors have been reported to be related with the disease clinical characteristics.

**Objectives:** We aim to describe the clinical spectrum of Chinese AS patients and investigate the influence of HLA-B27 status, gender and age at disease onset factors on the clinical features.
**Methods:** Chinese AS patients with complete clinical data and fulfilling the 1984 Modified New York criteria are studied. The recorded parameters include age, sex, HLA-B27 status, family history, age at AS onset, symptom at onset, disease pattern and presence of IBP, peripheral arthritis, hip joint involvement, anterior uveitis, dactylitis and enthesitis. Chi-square test and independent samples t-test are applied between groups of categorical and continuous variables respectively, using SPSS version 13.0 software.
**Results:** (1) A total of 1630 Chinese AS patients with a gender ratio of 3.36:1, average age of 27.84±9.07 and age at disease onset of 22.03±7.62 are included.17.2% have positive family history and 18.3% have juvenile onset AS (JoAS). (2) The overall HLA-B27 prevalence is 84.2%. HLA-B27 positive group has a younger age at onset (21.86±7.48 vs 22.92±8.31,p=0.041), higher presence of IBP (86.62% vs 78.35%, p=0.001) and hip joint involvement (53.12% vs 43.25%, p=0.004) than B27 negative group. (3) However, HLA-B27 positivity still shows some differences within different gender cohort. In the male group HLA-B27 positivity only shows higher prevalence of family history and IBP (86.62% vs 78.35%, p=0.001), while in the female B27 positivity has higher prevalence of hip joint involvement (48.98% vs 32.43%, p=0.011). (4) From the aspect of age at onset, although the JoAS and AoAS group have similar B27 positive rate and gender ratio, JoAS group has obviously higher prevalence of peripheral symptom at onset (52.70% vs 24.00%), enthesitis (34.38%vs23.17%) and peripheral pattern (68.56% vs 42.07%), with all P value $<0.001$.
**Conclusions:** HLA-B27 status, gender as well as age at disease onset are associated with the clinical manifestations of AS patients, which indicates the disease complexity and requires further attention in disease diagnosis. Larger scale studies and immunogenetic technology development are needed for better understanding of disease spectrum and mechanism.

## Psoriatic arthritis

### AB0722 PSORIATIC ARTHRITIS PATIENTS WITHOUT SYMPTOMS OF CORONARY ARTERY DISEASE MAY HAVE HIGHER PRESENCE AND EXTENT OF CORONARY PLAQUES COMPARED TO CONTROLS BY CORONARY CT ANGIOGRAPHY

A. Szentpetery[1], D. Brady[2], G. Healy[2], C. Redmond[2], H. Fleming[2], J. Duignan[2], M. Haroon[1], J.D. Dodd[2], O. FitzGerald[1]. *[1]Department of Rheumatology; [2]Department of Radiology, St. Vincent's University Hospital, Dublin, Ireland*

**Background:** Patients with psoriasis and psoriatic arthritis (PsA) have an increased prevalence of cardiovascular (CV) risk factors, metabolic syndrome (Metsy), and higher risk for subsequent major CV adverse events[1]. Previous studies in rheumatoid arthritis have shown higher coronary plaque vulnerability in patients with coronary artery disease (CAD) compared to controls[2]. Far less is known about CAD in PsA. The extent and composition of coronary plaques have not been studied yet in PsA.
**Objectives:** (1) Study the presence, extent and type of coronary plaques as measured by coronary CT angiography (CCTA) in PsA without symptoms of CAD as compared to controls. (2) To compare plaque measurements between patients with Metsy to those without Metsy (NMetsy) and to controls. (3) Investigate the effect of disease related variables on coronary plaques.
**Methods:** 50 PsA patients (25 Metsy - 25 NMetsy) and 25 controls without CAD (age and sex-matched) underwent 64-slice CCTA. Scans were analysed by 2 readers, blinded to the patients' characteristics. Plaque localisation within the coronary tree, the number of patients with plaque and of affected coronary vessels were assessed. Plaque type was classified into calcified (CP), mixed (MP) and non-calcified plaque (NCP)[3]. Plaque volume was measured for each plaque type and was added to give a total volume (PV) in $mm^3$. The number of segments with plaque per patient (segment involvement score (SIS 0–15)) and segment stenosis score (SSS 0–60) were calculated. Kruskal-Wallis test, rank correlations and linear regression analyses were used to study the effect of Metsy and PsA related variables on coronary plaques.
**Results:** Mean age of PsA patients and controls was 58 (±8.3) and 57 (±5.6) years. PsA disease duration was 19 (±7.8) years. 4 (16%) controls had Metsy. 78% of PsA vs 44% of controls had plaques (P=0.007) and the number of affected coronary vessels were higher in PsA (P=0.015). There were more PsA patients with MP and MP volume was higher compared to controls (P=0.006). Mean PV, SIS and SSS were higher in patients with PsA (P=0.002, P=0.032, P=0.004; respectively). Skin and joint related parameters, and CCTA measurements were similar in Metsy vs NMetsy. Plaque presence, PV and SSS were significantly higher in both Metsy and NMetsy compared to controls. SIS (P=0.034) and MP volume (P=0.004) were higher in NMetsy vs controls.
Max CRP correlated with PV (r=0.39 P=0.006), SIS (r=0.41 P=0.003) and SSS (r=0.4, P=0.004). Disease duration, max TJC and max CRP had significant effect on the number of affected coronary vessels (P=0.034, P=0.049, P=0.022, respectively). Linear regression analyses revealed no significant relationship between PV and Metsy, whilst diagnosis of PsA (B=0.324 (CI95% 0.05–0.597) P=0.021) and max CRP (B=0.01 (CI95% 0.004–0.019) P=0.006) were independent predictors of PV.
**Conclusions:** This pilot study is the first to assess coronary plaques in PsA using CCTA. PsA patients asymptomatic for CAD had a higher presence and extent of plaques, particularly MP, compared to controls. Our results suggest that PsA may result in accelerated coronary plaque formation independent of metabolic disease.

### AB0723 THE CLINICAL ASSESSMENT OF ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODIES IN PSORIATIC ARTHRITIS

O. Ozdemir Isik, F. Cosan, A. Yazici, A. Cefle. *Department of Internal Medicine, Division of Rheumatology, Kocaeli University Medical Faculty, Kocaeli, Turkey*

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disease in the spondyloarthropathy group with the history of psoriasis. Although some PsA findings are similar to rheumatoid arthritis (RA), RF negativity, some radiological and clinical findings are different in PsA. There is no spesific laboratory examination for diagnosis of PsA. On the other hand, anti-CCP antibody positivity is a spesific finding for the diagnosis of RA.
**Objectives:** We aimed in this study to analyse the frequency of anti-CCP positivity in PsA and the asscіaton with clinical and radiological findings.
**Methods:** The study group is consisted of 100 PsA patients, who fulfilled the CASPAR cirteria for PsA and 100 healthy controls (HC). We filled a form for all patients, which included clinical and laboratory findings of patients. We analyzed anti-CCP antibody with microELISA in the sera of patients.
**Results:** In our study, the anti-CCP positivity (40,9±63,5 IU/ml) was detected in 15% of PsA group and 4% of healthy controls. The difference was statistically significant (p=0,014; OR=4.24, 95% CI=1.35–13.25).Nine out of 15 anti-CCP positive patients were female, the remaining 6 were male. Thirteen patients (86,7%) had peripheral arthritis, 1 patient (6,7%)had sacroiliitis, 1 patient (6,7%) had peripheral arthritis and sacroiliitis. 42,8% of PsA patients with peripheral arthritis had asymetric olygoarthritis (6/14), 28,5% had monoarthritis (4/14) and 28,5% had symetric polyarthritis (4/14). Anti-CCP antibody positivity had no effect on the involvement of peripheral arthritis. Sacroiliitis and dactilitis were more frequent in the anti-CCP negative group. No patient with dactylitis had anti-CCP positivity (p=0.005). While, 43,5% of RF positive patients were detected anti-CCP positivity, 6,5% of RF negative patients were detected anti-CCP positivity (p=0,000).

Table 1. The frequency of disease findings in anti-CCP positive and negative groups

| | CCP(–) (n=85) | CCP(+) (n=15) | p | OR | 95% CI |
|---|---|---|---|---|---|
| Sex: Female / Male | 64.7% / 35.3% | 60% / 40% | 0.071 | 2.75 | 0.889–8.47 |
| Increased ESH | 32.9% | 46.7% | 0.178 | 1.78 | 0.587–5.4 |
| Increased CRP | 34.1% | 40% | 0.771 | 1.29 | 0.417–3.97 |
| RF >20 | 15.3% | 66.7% | 0.00 | 11.08 | 3.25–37.7 |
| Deformity | 21.2% | 26.7% | 0.736 | 1.35 | 0.385–4.76 |
| Sacroiliitis | 21.2% | 13.3% | 0.729 | 1.75 | 0.361–8.15 |
| Radiographic changes | 15% | 0% | 0.207 | 0.828 | 0.752–0.911 |
| Anti-TNF treatment | 31.8% | 26.7% | 0.077 | 0.78 | 0.228–2.67 |
| PSARC responce | 84.7% | 86.7% | 1 | 0.852 | 0.172–4.23 |

**Conclusions:** Our data reveals that anti-CCP positivity is more frequent in PsA compared to HC. We found no statisticall association between anti-CCP positivity and clinical or radiological findings.

## AB0724 THE FREQUENCY OF THE METABOLIC SYNDROME AND COMPARISON OF HE RISK FACTORS FOR CARDIOVASCULAR DISEASE IN PSORIASIS, PSA AND RA GROUPS

O. Ozkul[1], A. Yazici[2], A. Akturk[3], D. Karadag[2], O. Ozdemir[2], S. Tekeoglu[2], A. Cefle[2]. *[1]Department of Internal Medicine; [2]Department of Internal Medicine, Division of Rheumatology; [3]Department of Dermatology, Kocaeli University Medical Faculty, Kocaeli, Turkey*

**Background:** Metabolic syndrome (MetS) increases the risk of developing cardiovascular disease at least two-fold. Various studies have suggested that MetS is associated with a state of chronic, low-grade inflammation (1).
**Objectives:** Our aim is to show relationships between MetS and chronic low grade inflammatory diseases, to determine frequency of MetS in psoriasis and psoriatic arthritis (PsA) against romatoid arthritis (RA).
**Methods:** 155 patients were included in this cross-sectional study. Fifty patients were psoriasis, 55 patients were PsA who was diagnosed according to the CASPAR criteria. Fifty patients were seropositive RA who was diagnosed according to the ACR/EULAR 2010 classification criteria. MetS was diagnosed by the 2005 criteria of IDF (2). Cardiovascular risk factors and MetS associated parameters were evaluated.
**Results:** Patients mean age, age at onset disease and diagnosing age of disease in the RA group were significantly higher compared with the psoriasis and PsA (p=0,002–0,000–0,000; respectively). Duration of psoriasis was 14,7±10,2 years in the PsA group and 12,1±11,7 years in the psoriasis group (p=0,000). Duration of arthritis were significantly longer in the RA group compared with the PsA group (p=0,000).
Insulin resistance showed no significant difference between the three groups (%70, %64, %66). Elevated triglyceride levels were higher in the psoriasis and PsA compared with the RA groups (%34, %32,7, %16; respectively; p=0,045). Hypertension ratio was higher in RA than PsA and psoriasis (p=0,011) (Table 1). CRP and HAQ which are parameters for used in the follow up disease activity were higher in the RA group.

Table 1. The frequency of the metabolic syndrome and the risk factors for cardiovascular disease in Psoriasis, PsA and RA groups

| n (%) | Psoriasis | PsA | RA | P |
|---|---|---|---|---|
| Sex (F/M) | 24/26 (48/52) | 39/16 (71/29) | 39/11 (78/22) | 0,04* |
| Smoking | 20 (40) | 17 (30,9) | 7 (14) | 0,04* |
| Alcohol Consumption | 4 (8) | 4 (7,3) | 1 (2) | 0,201 |
| Increased Fasting Glucose | 10 (20) | 14 (25,5) | 16 (32) | 0,172 |
| Increased HbA1c | 11 (22) | 17 (30,9) | 12 (24) | 0,82 |
| Increased Triglycerides | 17 (34) | 18 (32,7) | 8 (16) | 0,045* |
| Increased Total Cholesterol | 21 (42) | 32 (58,2) | 23 (46) | 0,69 |
| Increased LDL | 21 (42) | 22 (40) | 18 (36) | 0,54 |
| Decreased HDL | 3 (6) | 9 (16,4) | 16 (32) | 0,016* |
| Increased VLDL | 18 (36) | 14 (25,5) | 8 (16) | 0,023* |
| Increased Uric Acid | 5 (10) | 6 (10,9) | 5 (10) | 0,984 |
| MetS | 18 (36) | 16 (29,1) | 18 (36) | 0,684 |
| Insulin Resistance | 35 (70) | 35 (64) | 33 (66) | 0,785 |
| Hypertension | 8 (16) | 11 (20) | 19 (38) | 0,011* |

**Conclusions:** In all three groups, the MetS was shown to be higher than the general population. The differences between the groups could not be detected because of the small number of patients, and not equal distribution of population by age and gender.

## AB0725 ANTI-TNF-α THERAPY IMPROVES ENDOTHELIAL FUNCTION AND ARTERIAL STIFFNESS IN PATIENTS WITH MODERATE-TO-SEVERE PSORIASIS: A 6-MONTH PROSPECTIVE STUDY

C. Fernández-Díaz[1], T. Pina[1], A. Corrales[1], R. López-Mejías[1], S. Armesto[2], M.A. González-López[2], I. Gómez-Acebo[3], B. Ubilla[1], S. Remuzgo-Martínez[1], C. González-Vela[4], R. Blanco[1], J.L. Hernández[5], J. Llorca[3], J. Loricera[1], M.Á. González-Gay[1]. *[1]Rheumatology; [2]Dermatology, Hospital Universitario Marqués de Valdecilla, IDIVAL; [3]Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL; [4]Pathology; [5]Internal Medicine, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*

**Background:** The risk of CV events is closely related to the severity of the psoriasis. The presence of severe psoriasis confers an additional 6.2% absolute risk of a 10-year rate of CV events compared with the general population. Studies on anti-TNF-α therapy indicate that these agents yield a reduction in the incidence of CV events in patients with psoriasis.
**Objectives:** To determine if the use of the anti-TNF-α monoclonal antibody adalimumab could improve endothelial function and arterial stiffness in patients with moderate-to-severe psoriasis.
**Methods:** Prospective study on a series of consecutive patients with moderate-to-severe psoriasis who completed 6 months of therapy with adalimumab. Patients with history of cardiovascular events, diabetes mellitus, kidney disease, hypertension or body mass index $\geq$35 kg/m$^2$ were excluded. Assessment of endothelial function by brachial artery reactivity measuring flow-mediated endothelial dependent vasodilatation (FMD%), and carotid arterial stiffness by pulse wave velocity (PWV) was performed at the onset of treatment (time 0) and at month 6.
**Results:** 29 patients were studied. Anti-TNF-α adalimumab therapy yielded a significant improvement of endothelial function. The mean±standard deviation (SD) FMD% values increased from 6.19±2.44% at the onset of adalimumab to 7.46±2.43% after six months of treatment with this biologic agent (p=0.008). Likewise, following the use of adalimumab, PWV levels decreased from 6.28±1.04 m/s at the onset of adalimumab to 5.69±1.31 m/s at 6 months (p=0.03).
**Conclusions:** Patients with moderate-to-severe psoriasis exhibit improvement of endothelial function and arterial stiffness following anti-TNF-α therapy. These findings are of potential relevance due to increased risk of cardiovascular disease in patients with severe psoriasis.
**Acknowledgement:** The study was supported by a research grant from Abbvie Inc.
**Disclosure of Interest:** None declared

## AB0726 SEVERE OBESITY IS FREQUENT IN PATIENTS WITH PSORIATIC ARTHRITIS AND IS ACCOMPANIED BY INCREASED CARDIOVASCULAR RISK

D. Huscher[1], K. Albrecht[1], S. Bischoff[1], K. Thiele[1], F. Behrens[2], G. Hoese[3], W. Ochs[4], A. Zink[1]. *[1]Epidemiology, German Rheumatism Research Centre, Berlin; [2]CIRI/Rheumatology & Fraunhofer TMP, Goethe-University, Frankfurt; [3]Rheumatologist, Stadthagen; [4]Rheumatologist, Bayreuth, Germany*

**Background:** It is known that patients with psoriatic arthritis (PsA) are at increased risk of obesity and associated cardiovascular comorbidity, in particular those with severe and long-standing disease (>10 years). There is less information on the frequency of obesity and cardiovascular risk in patients with incident or medium-term disease.
**Objectives:** To investigate the prevalence of obesity compared to the population, disease presentation and the cardiovascular morbidity at onset of disease and after a mean of five years disease.
**Methods:** We selected two discrete groups of patients with a PsA diagnosis (M07.0-M07.3) enrolled in the national database of the German Collaborative Arthritis Centres between 2003 and 2014: patients with either short ($\leq$0.5 years) or longer disease duration (between 4 and 6 years). Stratified by BMI classes, disease activity and cardiovascular comorbidity, as well as the deviation of the BMI from the age- and sex-matched normal population were analysed.
**Results:** 421 patients were enrolled with incident disease (mean disease duration 3.0 months) and 965 with medium-term PsA (mean 5.0 years). Both the BMI distribution in general and the portion of patients with severe obesity (BMI$\geq$35, ~8%) were similar in incident and medium-term PsA. In comparison to the age- and sex-matched population, obesity was more frequent in patients with incident (23.5% vs. 16.1%) as well as in medium-term PsA (24.7% vs. 17.4%). Obesity was associated with higher disease activity, higher patient-reported burden and substantially higher prevalence of cardiovascular risk factors already in early PsA except for significantly lower smoking rates (Table1). In medium-term PsA, 23.6% of all patients (mean age 52 years) and 36.1% of the obese patients (mean age 54 years) presented with any cardiovascular risk factor (diabetes, hypertension, hypercholesterolemia or heart disease); in obese patients the prevalence of coronary heart disease (10.1%) was doubled compared to incident patients.
Table 1 shows patient characteristics in incident PsA.
**Conclusions:** One quarter of the patients with PsA are obese, already at the onset of the disease, and they present with more severe obesity than the age and

| | BMI 18.5-<25 | BMI 25-<30 | BMI≥30 |

## AB0727 INCREASED RATES OF HYPERTENSION IN PATIENTS WITH PSORIATIC ARTHRITIS COMPARED TO PSORIASIS ALONE: RESULTS FROM THE UK BIOBANK

E. Bellou[1], S.M.M. Verstappen[2], M. Cook[2], J.C. Sergeant[2,3], R.B. Warren[4], A. Barton[1,3], J. Bowes[1]. *[1]Arthritis Research UK Centre for Genetics and Genomics, Manchester Academic Health Science Centre; [2]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre; [3]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust; [4]Dermatology Centre, Salford Royal NHS Foundation Trust, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom*

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with the presence of psoriasis. Lifestyle factors such as body mass index (BMI), smoking and alcohol consumption have been reported to contribute to the risk of both diseases. These risk factors also contribute to cardiovascular disease (CVD) which is a major cause of morbidity and mortality in patients with psoriasis and PsA.

**Objectives:** To compare lifestyle factors between individuals with PsA, psoriasis and a control group and to assess the association between these inflammatory diseases and CVD outcomes utilising the UK Biobank resource.

**Methods:** UK Biobank recruited 502,664 people aged 40–70 years in the UK between 2006 and 2010. Data on lifestyle, sociodemographics, health and medical history were collected at the assessment visit by questionnaire and interview by research nurse. Participants were asked if they have ever been diagnosed by a physician with a disease. Lifestyle factors including alcohol (current or past drinker) and smoking status (ever or never) were recorded and height and weight measured to calculate BMI. In this cross-sectional study, the frequency of these factors was compared between PsA, psoriasis and healthy controls using logistic or linear regression analyses depending on the outcome, adjusting for age and gender. Comparison between disease groups was performed by linear combinations of coefficients post estimation. Three CVD outcomes: heart attack, angina and hypertension, were tested for association with disease group using logistic regression including BMI, smoking, alcohol, age and sex as covariates. Odds ratios (OR) and β coefficients are reported with 95% confidence intervals (CI).

**Results:** 862 people with PsA, 4,761 with psoriasis and 465,371 control participants were included in the study (Table). Compared to the control group; both the PsA and psoriasis groups had higher BMI (β 1.43 (95% CI 1.11:1.75) and 0.72 (0.58:0.85) respectively), the psoriasis group smoked more (OR 1.63 (1.54:1.72)) and patients with PsA were less likely to be current drinkers (OR 0.68 (0.55:0.85)). Compared to patients with psoriasis, patients with PsA had higher BMI (β 0.69 (0.32:1.06)) and were less likely to be ever smokers and current drinkers (OR 0.70 (0.61:0.81) and 0.65 (0.51:0.83), respectively). Finally, hypertension was more prevalent in PsA compared to the control and psoriasis cohorts (OR 1.71 (1.48:1.97) and 1.55 (1.33:1.82), respectively).

Table 1. Characteristics of patients

| | Control (n=465,371) | Psoriasis (n=4,761) | PsA (n=862) |
|---|---|---|---|
| Age, mean (sd) | 56.4 (8.1) | 56.3 (8.1) | 56.1 (7.4) |
| Males (%) | 45.1 | 52.9 | 48.1 |
| BMI, mean (sd) | 27.3 (4.8) | 28.1 (5.0) | 28.9 (5.4) |
| Current drinkers (%) | 92.1 | 92.6 | 88.9 |
| Ever smokers (%) | 44.6 | 57.3 | 47.8 |
| Hypertension (%) | 26.9 | 29.2 | 37.7 |
| Heart attack (%) | 2.2 | 2.9 | 2.8 |
| Angina (%) | 3.1 | 4.0 | 4.3 |

**Conclusions:** Using a large population based cohort we show that self-reported CVD outcomes, in particular hypertension, are significantly higher in PsA compared to psoriasis independently of known CVD risk factors. The results contribute to our understanding of the lower quality of life reported by patients with PsA.

## AB0728 RENAL DISORDERS IN PATIENTS WITH PSORIATIC ARTHRITIS

E. Koraboev. *Rheumatologic Department, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Objectives:** To study clinical and laboratory changes in kidney patients with psoriatic arthritis (PA).

**Methods:** The study included 60 patients. The age of patients ranged from 22 to 60 years. All patients underwent clinical and laboratory study: functional kidney tests, general analysis of blood, Zimnitsky test, Reberg test, creatinine and urea levels.

**Results:** Kidney disease was diagnosed in 25 (41,7%) patients. Nephropathy is directly related to the underlying disease, was detected in 18 (30.0%) patients, including chronic glomerulonephritis in 10 cases and renal amyloidosis in 6 cases. We failed to verify the nature of kidney impairment in 2 patients. There was the prevalence of men among patients with psoriatic nephropathy (in 17). Renal disease is seen in patients with other systemic manifestations of the PA, including the expressed trophic disorders (in 9), prolonged fever (in 5), lymphadenopathy (in 2), heart disease (in 6) and liver (in 3).

Urinary syndrome was characterized by transient proteinuria and small haematuria (in 19 cases), a significant and persistent haematuria (red blood cells up to 30–40–50 in sight with episodes of gross haematuria) at extremely low values of proteinuria (in 5), regularly or occasionally high proteinuria above 3g/day (in 5). Extrarenal symptoms was presented with persistent oedema (in 4), hypertension (in 5). Nephritic syndrome was diagnosed in 12 patients. Reduced concentration ability of the kidneys was observed in 17 patients, and expressed presentation of chronic renal failure in 5 cases. Bladder syndrome was usually observed at the beginning of the PA, in exacerbations of joint syndrome with generalization process or the development of an advanced stage of dermatosis. In some cases, slight proteinuria and haematuria accompanied by acute syndromes was a comorbidity of main PA for many years without any development of kidney damage or azotaemia. Renal amyloidosis was characteristic for being accompanied by the nephritic syndrome. Daily protein loss reached 6–8g, and the amount of protein in a disposable examination of urine - 10,5 g/l. The total protein content in the serum was reduced to 49 g/l. Changes in urine, except for proteinuria, characterized microhaematuria (in 5 patients), small leukocytes (in 6), granular and wax cylinders.

**Conclusions:** Patients with PA in 41,7% cases had a variety of manifestations of the urinary syndrome. This represents the role of immediate diagnosis and correction of renal dysfunction; thus, chronic renal impairment may adversely affect prognosis of the disease.

**Disclosure of Interest:** None declared

## AB0729 BASELINE LEVELS OF CTX-II AND GLUCOSYL-GALACTOSYL-PYRIDINOLINE IN PATIENTS WIH EARLY PSORIASIC ARTHRITIS: ASSOCIATION WITH DISEASE SEVERITY,DISABILITY, QUALITY-OF-LIFE, BIOLOGICAL TREATMENT REQUIRED AND PROGRESSION OF JOINT DESTRUCTION AT 5 YEARS OF FOLLOW UP

E. Trujillo[1], M. Garcia[1], H. Sanchez[1], L. Exposito[1], A. Monroy[1], M.D.M. Trujillo[2]. *[1]Servicio de Reumatologia, Hospital Universitario de Camarias; [2]Servicio de Planificacion y Evaluacion de Tecnologia Sanitaria, Servicio Canario de Salud, la Laguna, Spain*

**Background:** Although many efforts have been made to identify Psoriasic Arthritis (PsA)-specific biomarkers, none of the putative ones identified so far has resulted in a clinically relevant outcome and patient benefit.

In other diseases of the joints, elevated levels of urinary CTX-II (C-telopeptide fragments of type II collagen) and Glc-Gal-PYD (glucosyl-galactosyl-pyridinoline) have been associated with progression of damage.

**Objectives:** To analyze the association between the baseline levels of urinary CTX-II and Glc-Gal-PYD in patient with early PsA with disability, quality of life, biological treatment required and radiological damage at 5 years of follow up.

**Methods:** We included 36 patients who came to the service with some of the suggestive information of PsA and who later completed five years of follow-up and they fulfill nowadays PsA according to classification of psoriatic arthritis (CASPAR) criteria.

Urine samples were taken from all patients attending for the first time with suspected early PsA. Urinary excretion of CTX-II was determined by immunoassay

(ELISA) (ng/ml). Urinary excretion of Glc-Gal-PYD was determined by High performance liquid chromatography (HPLC). Because urinary levels were not normally distributed, all data were transformed into logarithms for analysis.
Association analysis was performed with the following five variables at 5 years:
- Disease Severity for the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA): mild, moderate and severe.
- Health Assessment Questionnaire (HAQ).
- Study Short Form 36 (SF-36).
- Anti-TNF therapy: Yes/No.
- Sharp-van Der Heijde modified scoring method for PsA.

**Results:** Baseline levels of urinary excretion of CTX-II and Glc-Gal-PYD in patients presenting for the first time with suspected early SpA were significantly higher in those who had HAQ and SF-36 scores significantly worse, required biological treatment and in those due to moderate and severe disease severity at five years of follow up.
In a multivariable linear regression analysis, Baseline levels of urinary excretion of CTX-II and Glc-Gal-PYD in patients presenting for the first time with suspected early SpA were an important predictor of worse radiological score at the age of 5 (erosions, joint space narrowing, (subluxation, ankylosis, gross osteolysis, and pencil in cup phenomena).
**Conclusions:** Baseline levels of urinary excretion of CTX-II and Glc-Gal-PYD in patients with early SpA may be a prognostic biomarker since in our series it was associated with worse disease severity, disability, quality-of-life and progression of joint destruction at 5 years of follow up.
**Disclosure of Interest:** None declared

## AB0730 PSORIATIC ARTHRITIS PATIENTS WITH WORK DISABILITY HAVE WORSE QUALITY OF LIFE COMPARED TO THOSE WHO ARE EMPLOYED

F. Farkas, A. Szentpetery, P. Gallagher, O. FitzGerald. *Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland, Dublin, Ireland*

**Background:** Work disability (WD) is an important functional outcome measure in inflammatory arthritis, which has been studied comprehensively in rheumatoid arthritis and ankylosing spondylitis, however limited data is available in psoriatic arthritis (PsA). A variety of WD measurement tools are available, but there are no validated and specific guidelines in PsA [1,2].
**Objectives:** In PsA patients with and without WD: (1) to compare patient-reported outcomes (PROs) and physician-assessed measures and (2) to assess whether there are gender-specific differences associated with WD.
**Methods:** Consecutive patients with PsA fulfilling the CASPAR criteria were enrolled. Patients on disability pension, those with early retirement due to arthritis, those unemployed, away from work due to sick leave were considered as having WD. Disease activity measures (TJC/68, SJC/66, ESR, CRP, PASI), economic data, patient-reported outcome measures (HAQ, EQ-5D, SF-36, BASDAI, BASFI, ASQoL, DLQI, pain VAS, average level of fatigue), radiographic damage, medication history and comorbidities were compared between employed and work-disabled patients in both genders using Mann-Whitney pairwise and chi-square test.
**Results:** 81 patients completed the economic questionnaire. Thirty-eight (17 male and 21 female) participations of working age had work disability versus forty-three (20 male, 23 female) employed patients. Out of 81 patients, 27 were biologic-naïve and 54 had ever been on biologic agents. We have found no significant differences in disease activity measures or in the number of erosions between work-disabled and employed patients. On the other hand patients with WD had significantly worse self-reported values in both gender groups, especially in females. The total number of comorbidities (p=0.020) and coexistent rheumatic diseases (p=0.025) were significantly higher among patients with WD. Work-disabled patients had more healthcare-related appointments and required more help (p=0.001), including home care and assistance travelling to the hospital.
**Conclusions:** Consistent with previous studies, in this cross-sectional cohort we have observed that rates of WD are high (46.9%) among patients with PsA with no difference between males and females. Despite similar disease activity and structural damage measures, patients with WD had worse physical function and overall reduced quality of life compared to employed patients. These differences were more pronounced in females, who had more physical and social limitations related to PsA.

## AB0731 MUSCULOSKELETAL BUT NOT SKIN DISEASE ACTIVITY INFLUENCE RHEUMATOLOGISTS DECISION TO CHANGE DMARDS OR BIOLOGIC THERAPY IN PSORIATIC ARTHRITIS

G. Porru[1], A. Marchesoni[2], I. Olivieri[3], R. Scarpa[4], C. Salvarani[5], E. Lubrano[6], S. D'Angelo[3], M. Piga[1], M.G. Catanoso[5], R. Peluso[4], W.J. Parsons[6], A. Mathieu[1], A. Cauli[1]. *[1]University of Cagliari, Cagliari; [2]Istituto Ortopedico G Pini, Milan; [3]San Carlo Hospital of Potenza, Potenza; [4]University "Federico II", Naples; [5]University of Modena, Reggio Emilia; [6]Università del Molise, Campobasso, Italy*

**Background:** Psoriatic arthritis (PsA) is a systemic inflammatory disease mainly characterised by arthritis, dactylitis, enthesitis and skin involvement. Recently issued therapeutic guidelines (1) suggest that treatment decisions should be driven by as many manifestations of disease as possible.
**Objectives:** The aim of this study was to determine, in a multicentre Italian cohort of PsA patients, which clinical or patient reported disease outcome influence physician decision to change DMARD or biologic treatment.
**Methods:** 173 consecutive patients with PsA (103 males and 70 females, mean age 52±12 years) were enrolled in a longitudinal observational study. Seven tertiary referral clinics with expertise in PsA and SpA were involved. Detailed clinical examination, including ACR joint count, presence or absence of dactylitis and enthesitis, PASI, were recorded. Patient perception of disease was evaluated by means of global, joint and skin specific VAS scales. Detailed treatment information were also recorded. According to study protocol clinical assessment was performed at baseline and after twelve weeks in order to identify two distinct groups: changed and unchanged DMARD or biologic therapy.
**Results:** A higher number of tender joints ($p<0.007$) and an higher number of swollen joints ($p<0.0003$) but not an higher PASI score (p=ns) were observed in the group of patients which were prescribed a change in DMARD or biologic treatment. Enthesitis and dactilytis were more frequent in the group with changes in treatment (p=0.001 and p=0.02 respectively). Patient global and joint perception of disease resulted more severe in the group where a change of therapy was decided, as shown by VAS global ($p<0.001$) and VAS joint ($p<0.02$) while no differences in the distribution in the two groups were observed considering patient perception of skin involvement. A significant difference was observed in the following joints: wrist (p=0.05), distal interphalangeal ($p<0.002$) and knee (p=0.03) involvement.
**Conclusions:** The results of this study, performed in an Italian cohort of PsA patients, suggest that rheumatologists, when they decide to change DMARD or biological treatment in PsA patients, are influenced by both objective evidence of musculoskeletal involvement and by patient reported global and joint outcomes. They do not seem to be influenced by the extent of skin dermatitis, possibly because of the generally low extent of skin involvement in PsA patient and/or because of a musculoskeletal orientated approach of rheumatologists.

## AB0732 PERSISTENCE ON TREATMENT AND OPTIMIZATION AMONG ANTI-TNFα AGENTS IN PSORIATIC ARTHRITIS PATIENTS IN CLINICAL PRACTICE

J. Pinto-Tasende[1], E. Alonso[2], C. Bejerano[2], J. Gromaz[2], B. Acasuso[2], C. Fernandez-Lopez[1], N. Oreiro[1], M. Acasuso[3], J. De Toro[1], F. Blanco[1]. *[1]Rheumatology; [2]INIBIC, Complejo Hospitalario Universitario A Coruña; [3]CS San José, SERGAS, A Coruña, Spain*

**Background:** As in rheumatoid arthritis some patients with psoriatic arthritis (PsA) can be refractory to anti-TNF-α therapy, may lose responsiveness, or develop drug intolerance over time and a switch to another TNFα antagonist can often restore therapeutic response.
**Objectives:** The study aim was to determine treatment persistence and to identify causes of discontinuation in PsA patients in clinical practice.
**Methods:** Patients with PsA (classified on the basis of CASPAR criteria) and treated with blockers of the TNF-α (following EULAR recommendations) adalimumab (ADA), etanercept (ETA), golimumab (GOL), infliximab (INF) or certolizumab (CTZ), between 2011–2015, were retrospectively included. Treatment persistence was analyzed and differences between therapies were assessed by means of an analysis of variance model (ANOVA), while a chi-square test was used to evaluate relationships between therapies and causes of treatment discontinuation and the administration of concomitant disease-modifying antirheumatic drugs (DMARDs) among therapies and types of disease.
**Results:** One hundred and ninety-six patients received: 98 ETA, 63 ADA, 22 GOL, 10 INF and 3 CTZ, with an age mean of 51.7±12.4 years old without differences among groups of therapies (p 0.993), and 111 were men (56.6%). Combination treatment with DMARDs was in 126 patients (64.3%) and no differences were observed among five anti-TNF therapies. One hundred and forty-three patients (73.0%) had persistence in first anti-TNF, mean 61.2 (12.8) months, and by groups was: 84.7% ETA, 60.3% ADA, 59.1% GOL, 70% INF and 66.7% CTZ, p 0.007,

without differences among clinical subtypes (p 0.978). Combination therapy with DMARDs was associated with a higher persistence in first anti-TNF, 67.8% vs 55.9%, but without statistical significance (p 0.108). Change of first anti-TNF occurred in 53 patients: failure to treatment was in 33 patients (62.3%) and discontinuation by adverse event was in 20 patients (37.7%) without differences among groups (p 0.535). Discontinuation by failure to treatment has happen with a mean of 66.1 (43.1) months and by adverse event in 53.4 (30.2) months (p0.235). In 68 (34.7%) patients without clinical activity dosing interval of treatment was increased and we have not observed differences among the groups (p 0.265).
**Conclusions:** In this cohort, anti-TNFα therapy was associated with high persistence at first anti-TNF therapy, mainly etanercept. Switching to another anti-TNF-α agent occurred in a quarter of patients, when treatment was suspended because of failure to response or an adverse event. Furthermore, treatment was optimized in one third of patients.

## AB0733 MASEI SHOWS SUBSTANTIAL CHANGES IN THE ENTHESES OF YOUNG HEALTHY VOLUNTEERS – AMENDING ITS PD SCORE AND EXCLUDING KNEE ENTHESES THICKNESS PROVIDES BETTER DISCRIMINATION OF ENTHESITIS IN PSORIATIC ARTHRITIS PATIENTS

K. Wervers[1], N. Rasappu[1], M. Vis[1], I. Tchetverikov[2], M.R. Kok[3], A.H. Gerards[4], J.M.W. Hazes[1], J.J. Luime[1] on behalf of DEPAR Study Group. *[1]Rheumatology, Erasmus Medical Centre, Rotterdam; [2]Rheumatology, Albert Schweitzer Hospital, Dordrecht; [3]Rheumatology, Maasstad Hospital; [4]Rheumatology, Vlietland Hospital, Rotterdam, Netherlands*

**Background:** Tendon complaints are common in both healthy adults and patients with psoriatic arthritis (PsA). Ultrasound (US) could be used to investigate whether these are located at the enthesis and of inflammatory origin, as it is able to detect structural changes and inflammatory changes using Power Doppler.
**Objectives:** We aim to describe the difference in ultrasound abnormalities in the entheses of patients with recently diagnosed PsA, patients with established PsA and young healthy volunteers (20–30 years). using the MASEI US score
**Methods:** Consecutively newly diagnosed PsA patients participating in the Dutch south west Psoriatic Arthritis Registry (DEPAR), patients with >2 years PsA and healthy volunteers (aged 20–30 years) were asked to participate. An ultrasound was performed by one examiner unaware of clinical findings using an Esoate Mylab 60 (probe LA-435 and LA-523). The triceps, quadriceps, proximal and distal patellar and Achilles tendon insertion, plantar fascia (i.e. the locations of the Madrid Sonographic Enthesis Index; MASEI) and the tendon insertion at the lateral epicondyle of the elbow were investigated (1). In each location structural changes, erosions, calcifications, increased thickness and Power Doppler signal and is some locations bursitis were evaluated, resulting in a total score (range 0–158).
**Results:** In total, 25 newly diagnosed PsA patients (A), 25 established PsA patients (B) and 25 healthy volunteers (C) participated. The median of the MASEI+ score was for A 18 (IQR 15–30), for B 22 (IQR 15–27) and for C 10 (IQR 5–15) (Table 1).
Of note, the reference values for thickness of the Quadriceps tendon at the superior pole (6.1 mm), the inferior pole (4.0 mm) and the insertion at the tuberosity of the tibia (4.0 mm) were exceeded by 50%, 58% and 70% of the entheses of healthy volunteers (50 tendons). Also the degree of Power Doppler signal varied from one spot of signal to a confluent signal in large section of the enthesis, suggesting different levels of inflammation or possibly even false-positive findings. The images were re-evaluated for PD signal (assigning 1 point for one spot of signal, 1.5 for 2 or 3 spots, 2 for confluent small area or 3 points for confluent large area). When excluding increased thickness of knee entheses and using the re-evaluated PD scores the median MASEI was resp. 13 (IQR 10–22.5), 13.5 (IQR 9.5–18) and 3 (IQR 1.5–8) (Table 1).

**Table 1. Scores of the ultrasound evaluation in the three participant groups**

| | new PsA (n=25) | established PsA (n=25) | healthy volunteer (n=25) |
|---|---|---|---|
| MASEI | | | |
| MASEI + lateral epicondyle (median, IQR) | 18 (15-30) | 22 (15-27) | 10 (5-15) |
| MASEI* (median, IQR) | 13 (10-22.5) | 13.5 (9.5-18) | 3 (1.5-8) |
| PD | | | |
| 0 enthesis with PD (%) | 6 (24) | 1 (4) | 11 (44) |
| 1 enthesis with PD (%) | 7 (28) | 7 (28) | 3 (12) |
| 2 enthesis with PD (%) | 7 (28) | 9 (36) | 5 (20) |
| 3 enthesis with PD (%) | 1 (4) | 4 (16) | 3 (12) |
| >3 enthesis with PD (%) | 4 (16) | 4 (16) | 3 (12) |

PsA = psoriatic arthritis; IQR = interquartile range; MASEI = Madrid Sonographic Enthesis Index added with the lateral epicondyle score bilaterally (range 0-158);* MASEI and lateral epicondyle score, excluding increased thickness in knee entheses and using new scoring system to award points for PD: 1 point for one spot of signal, 1.5 for 2 or 3 spots, 2 for confluent small area or 3 points for confluent large area; PD = Power Doppler signal.

**Conclusions:** US structural changes and inflammation in the entheses are common in both early and established PsA patients using the MASEI. In healthy young adults US enthesitis was only observed around the knee. MASEI ultrasound score differentiated PsA patients from healthy volunteers when dropping the knee tendon enthesis thickness and applying a refined Power Doppler score. Our findings need to be confirmed in a larger cohort of healthy controls and patients.

## AB0734 QUALITY OF LIFE AT BASELINE IN EARLY PSORIATIC ARTHRITIS RELATED TO INITIAL PRESENTATION OF MONO-, OLIGO-, AND POLYARTHRITIS AND TENDER ENTHESIS: RESULTS FROM THE DEPAR STUDY

K. Wervers[1], J.J. Luime[1], I. Tchetverikov[2], A.H. Gerards[3], M.R. Kok[4], C.W.Y. Appels[5], W.L. van der Graaff[6], J.H.L.M. van Groenendael[7], L.-A. Korswagen[8], J. Veris[7], J.M.W. Hazes[1], M. Vis[1] on behalf of DEPAR Study Group. *[1]Erasmus Medical Centre, Rotterdam; [2]Albert Schweitzer Hospital, Dordrecht; [3]Vlietland Hospital; [4]Maasstad Hospital, Rotterdam; [5]Amphia Hospital, Breda; [6]Beatrix Hospital, Gorinchem; [7]Reumazorg Zuid West Nederland, Roosendaal; [8]Sint Franciscus Gasthuis, Rotterdam, Netherlands*

**Background:** Little data is available on quality of life in newly diagnosed psoriatic arthritis (PsA) patients and its relation to the extent of the disease.
**Objectives:** To describe quality of life in newly diagnosed PsA related to the extent of the disease as defined by the number of swollen joints and the presence or absence of tender enthesis.
**Methods:** Baseline data of consecutively recruited incident PsA patients was used from the Dutch south west Psoriatic Arthritis Registry (DEPAR) study between August 2013 to November 2015. Health-related quality-of-life (HRQoL) was assessed by the 8 subscales of the Short-Form 36 (SF-36) questionnaire (0–100, higher score represents a better HRQL) and the PsA-specific quality-of-life (PsAQoL) questionnaire (0–20, lower score represents a better HRQL). Patients were classified in the three arthritis subtypes (i.e. mono-, oligo- or polyarthritis) based on evaluation of the rheumatologist. A tender enthesis was defined as having at least one tender enthesis using the Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES).
**Results:** 209 patients with arthritis at time of inclusion completed the SF-36 questionnaire. Average age was 51.4 years (SD 13.7) and 55% were male. Of these patients 49 had monoarthritis, 92 oligoarthritis and 68 polyarthritis. At least one tender enthesis was present in 45%, 38% and 53% of the patients.
Mean scores of the subdomains in the SF-36 were similar across the different arthritis-groups, with better scores for monoarthritis compared to oligo and polyarthritis. However, when separating the groups based on the presence of a tender enthesis HRQoL decreased substantially for all groups across all subdomains of the SF-36, with a mean difference of 15 points (Figure 1). Mean scores of all subdomains were significantly lower in the tender enthesis group (n=106) compared to the non-tender enthesis group (n=131). Comparable results were observed for the PsAQoL scores (mono: 7.09 (SD 6.24) vs. 2.15 (SD 2.85); oligo: 7.11 (5.21) vs 4.18 (5.65) and 8.52 (6.04) vs 2.16 (2.90)

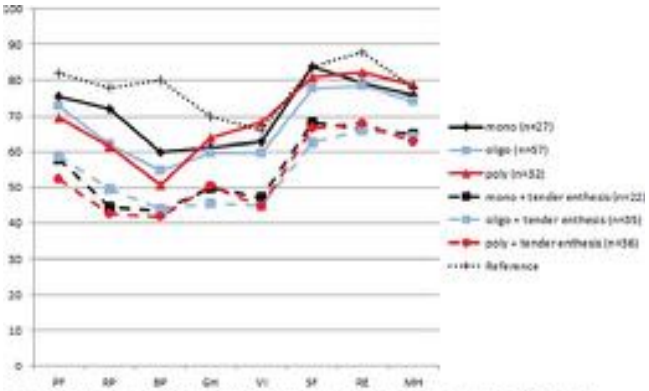

Figure 1. Health-related quality of life in patients with monoarthritis (mono), oligoarthritis (oligo), and polyarthritis, with and without presence of a tender enthesis, as measured by physical functioning (PF), physical role functioning (PR), bodily pain (BP), general health (GH), vitality (VI), social functioning (SF), emotional role functioning (ER), and mental health (MH) (SF-36).

**Conclusions:** Stratifying the HRQoL for the presence of tender enthesis, present in about half of newly diagnosed PsA patients, showed lower levels of health-related quality-of-life across both physical and mental scales, independent of arthritis classification, emphasizing the importance of the enthesis in PsA.
**Disclosure of Interest:** None declared

## AB0735 THE ANNUAL INCIDENCE OF NEWLY DIAGNOSED PSORIATIC ARTHRITIS IN RUSSIAN PATIENTS WITH PSORIASIS IS SUSPECTED TO BE HIGHER THAN OFFICIALS REPORT: A POPULATION-BASED STUDY

M. Olesya[1], K. Tatyana[2], S. Vladimir[1], N. Evgeniy[2]. *[1]Federal Research Institute of Health Organization and Informatics of Ministry of Health of the Russian Federation; [2]Research Institute of Rheumatology n. a. V. A. Nasonova, Moscow, Russian Federation*

**Background:** Psoriatic arthritis (PsA) occurs in 6.2–42% of patients (pts) with psoriasis (PsO). The results range widely among different populations due to some difficulties in performing epidemiological studies, heterogeneous clinical presentations of PsA, and the lack of world accepted criteria and questionnaires and low awareness of the risk PsA in PsO pts among dermatologists.
**Objectives:** to estimate the mean annual incidence of PsA in Russian pts with PsO according to medical statistics record and to compare with direct interview results of pts with PsO in dermatologic clinics across Russian Federation.
**Methods:** Analysis of the number of newly diagnosed PsA among the adult and children above 14 years Russian pts with PsO coding in official medical records as L40.5+ by International Statistical Classification of Disease and Related Health Problems (ICD-10) between 2009 - 2013 years. 1091 pts with different clinical types of PsO at the same age were called to the dermatological offices to be direct interviewed by dermatologists and responded to follow questions: Do you have any joint pain? Do you have PsA confirmed by rheumatologists? The mean annual incidence of PsA in PsO pts were calculated by formula.
**Results:** Between 2009 - 2013 the mean annual incidence of newly diagnosed PsA in Russian pts with PsO estimated at 2.5% or 1.9/100.000 cases for whole Russian population. Among 1091 interviewed PsO pts in dermatologic offices 27.9% of pts have joint complaints and 8% of pts have PsA confirmed by rheumatologists.
**Conclusions:** The mean annual incidence of PsA in the Russian pts with PsO is lower than reported before in other populations due to under diagnosis, heterogeneous clinical presentations of PsA and coding problems in dermatological clinics. Iinterdisciplinary collaboration with rheumatologists is needed.

## AB0736 THE BEPAS COHORT: A REAL-LIFE MULTICENTER PROSPECTIVE COHORT OF PSORIATIC ARTHRITIS IN BELGIUM: DEMOGRAPHICS AND BASELINE CHARACTERISTICS

K. De Vlam[1], R. Lories[1], S. Steinfeld[2], F. Van Den Bosch[3], A. Nzeusseu Toukap[4], M. Malaise[5], V. Taelman[1], F. Van Bruwaene[6], M. Van Den Berghe[7], J. Lenaerts[8], R. Joos[9], P. Geusens[10], S. Dall'Armellina[11], I. Peene[12], G. De Brabanter[13], M. Van Den Berghe[14], J. Qu[15], M. Maertens[16], H. Leroi[17] on behalf of BEPAS. *[1]rheumatology, University Hospitals Leuven, Leuven; [2]Clinique St Jean, Bruxelles; [3]Ugent, Gent; [4]rheumatology, UCL St Luc, Brussels; [5]rheumatology, CHU Sart Tilman, Liege; [6]rheumatology, Heilig Hart Ziekenhuis, Roeselaere; [7]rheumatology, Algemeen Stedelijk Ziekenhuis, Aalst; [8]Reuma instituut, Hasselt; [9]rheumatology, ZNA, Antwerpen; [10]ReumaClinic, Genk; [11]rheumatology, Clinique Notre Dame de Grace, Gosselies; [12]AZ St Jan; [13]rheumatology, AZ St Lucas, Brugge; [14]rheumatology, Grand Hopital de Charleroi, Charleroi; [15]rheumatology, Iris sud, Brussels; [16]AZ Damiaan, Oostende; [17]Medical Affairs Immunology, MSD Belgium, Brussels, Belgium*

**Background:** Psoriatic arthritis (PsA) is a common form of chronic arthritis with major impact on the physical and psychosocial integrity of the patient. BEPAS (Belgian Epidemiological Psoriatic Arthritis Study) is a large prospective multicenter cohort set up in 17 Belgian rheumatology practices based in secondary and tertiary referral centers (private practice, non-academic and academic hospitals).
**Objectives:** (1) To generate a comprehensive database to characterize the clinical presentation and the frequency of the distinct PsA subtypes; (2) to estimate the severity of disease based on disease activity scores and structural damage; (3) to estimate the impact in terms of health-related quality of life of PsA in Belgium and (4) to evaluate progression of structural damage and loss of function in patients with PsA over time.
**Methods:** Patients with an existing or a new clinical diagnosis of PsA and fulfilling the CASPAR classification criteria were recruited. All patients gave informed consent. In the prospective study, patients are followed every year during the first 2 years with a possible extension for an additional 5 years. Demographics,clinical parameters, and data about QoL and disability were collected. X-rays of hands and feet are performed every year and axial X-rays every 2 years.
**Results:** 461 patients (mean age: 52.79 years (±12.29), male 57%) were recruited from December 2012 to July 2014. N = number of patients with data available.
**Conclusions:** This large cohort paints a real-life heterogeneous presentation of PsA in academic and non-academic centers in Belgium and contrast with other cohorts which are mainly academic cohorts. Further data collection will facilitate clinical and outcome studies iabout the impact and natural history of PsA in Belgium.

## AB0737 CLINICAL AXIAL INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS IS UNDERESTIMATED: IMPACT ON BURDEN OF THE DISEASE. DATA FROM THE BEPAS COHORT

K. De Vlam[1], R. Lories[1], S. Steinfeld[2], F. Van Den Bosch[3], A. Nzeusseu Toukap[4], M. Malaise[5], V. Taelman[1], F. Van Bruwaene[6], M. Van Den Berghe[7], J. Lenaerts[8], R. Joos[9], P. Geusens[10], S. Dall'Armellina[11], I. Peene[12], G. De Brabanter[13], M. Van Den Berghe[14], J. Qu[15], M. Maertens[16], H. Leroi[17] on behalf of BEPAS Study Group. *[1]rheumatology, University Hospitals Leuven, Leuven; [2]Clinique St Jean, Bruxelles; [3]Ugent, Gent; [4]rheumatology, UCL St Luc, Brussels; [5]rheumatology, CHU Sart Tilman, Liege; [6]rheumatology, Heilig Hart Ziekenhuis, Roeselaere; [7]rheumatology, Algemeen Stedelijk Ziekenhuis, Aalst; [8]Reuma instituut, Hasselt; [9]rheumatology, ZNA, Antwerpen; [10]ReumaClinic, Genk; [11]rheumatology, Clinique Notre Dame de Grace, Gosselies; [12]AZ St Jan; [13]rheumatology, AZ St Lucas, Brugge; [14]rheumatology, Grand Hopital de Charleroi, Charleroi; [15]rheumatology, Iris sud, Brussels; [16]AZ Damiaan, Oostende; [17]Medical Affairs Immunology, MSD Belgium, Brussels, Belgium*

**Background:** Psoriatic Arthritis is often considered to be predominantly peripheral presenting with arthritis, dactylitis and enthesitis. Consequently randomized controlled trials, screening procedures for early detection and treatment strategies largely focus on peripheral disease. Axial involvement is considered less common. The BEPAS cohort (Belgian Epidemiological Psoriatic Arthritis Study) is a prospective multicenter real life cohort set up in 17 Belgian large academic and non academic rheumatology practices that offers a unique opportunity to study the axial involvement in this patient group.
**Objectives:** (1) To estimate the prevalence of axial involvement in patients with PsA in general (2) to estimate the prevalence of inflammatory back pain in patients with PsA; (3) to estimate the influence of disease duration on spinal manifestations.

| SF36 Phys Comp Sum | 42.25 | 10.12 | 35.81 | 9.27 | <0.01 |
| SF36 Mental Comp Sum | 47.10 | 12.43 | 40.39 | 13.28 | <0.01 |

**Methods:** Patients included in the BEPAS cohort were evaluated for the presence of a clinical phenotype indicating axial involvement, the specific presence of spinal complaints (reported by patients) and the presence of inflammatory back pain according the Rudwaleit criteria. Demographics and clinical features were recorded. BASDAI and BASMI were calculated.
**Results:** Among the 461 recruited patients (mean age: 52.79 years (±12.29), male 57%) 157 patients (34,1%) fulfilled the Berlin Criteria for inflammatory back pain with a higher prevalence in female patients (40,5% vs 28,9%, p=0.007) at inclusion.A family history of ankylosing spondylitis is reported in 3.3% of the patients. Clinical characteristics and demographics are listed in table 1.
**Conclusions:** The BEPAS cohort reports a substantial contribution of inflammatory axial involvement to the clinical and inflammatory burden of disease in PsA patients. Inflammatory axial involvement is a common clinical phenotype in PsA patients reporting higher disease activity and worse health status occurring more frequent in female patients, contrasting with other spondyloartropathies.

## AB0738 ASSOCIATION BETWEEN ENTHESOPATHIC CHANGES AND BONE TURNOVER MARKERS IN PATIENTS WITH PSORIATIC ARTHRITIS

M. Cerqueira[1], M. Robustillo Villarino[2], C. Vergara Dangond[2], À. Martínez-Ferrer[2], G. Albert Espí[2], E. Vicens Bernabeu[2], D. Ybáñez García[2], È. Valls Pascual[2], M. Aguilar Zamora[2], J.J. Alegre Sancho[2]. [1]*Rheumatology, Hospital Conde de Bertiandos ULSAM, Ponte de Lima, Portugal;* [2]*Rheumatology, Hospital Universitario Dr. Peset, Valencia, Spain*

**Background:** In patients with Psoriatic arthritis (PsA) there are changes in bone remodeling, not well established, that lead to a loss in bone mineral density (BMD) and to bone formation in the form of syndesmophytes and enthesophytes.
The enthesis, one of the most pathological findings that characterize PsA, can be studied with ultrasonography in a more sensitive and specific way than by clinical examination. Enthesopathic structural and inflammatory changes, which can be diagnosed by ultrasonography, are described in the OMERACT consensus and can be quantified by exploration indices such as MASEI.
**Objectives:** To evaluate the association between enthesopathical changes measured by MASEI index and bone remodeling markers in a population of patients with PsA.
**Methods:** Patients diagnosed with peripheral PsA and had been followed in a tertiary hospital, excluding those treated with vitamin D were included. Demographic, clinical, analytical (vitamin D (25OHD), bone turnover markers P1NP and βCTX, BMD (done with a maximum of 24 months before) data was collected. The entheseal affection count was determined by ultrasonography according to the MASEI index, which was re stratified in inflammation index and structure index, and by anatomical areas. Statistical study was done with the SPSS 17.0 program.
**Results:** 66 patients were included, 62.1% (41) were women, with a mean age of 56.8±11.9 years and mean duration of disease of 108.1 ±102.5 months; 84.8% (56) were treated with methotrexate and 33.3% (22) were receiving biological therapy (anti-TNF). Mean MASEI index was 13±9.7; mean structure index was of 9.3±5.9; and mean inflammation index 3.7±4.5. The quadricipital and achilles enthesis had higher mean MASEI indexes (4.2±3.4 and 2.9±2.1, respectively). MASEI and the structure index were positively associated with age ($r=0.31, p<0.05$ and $r=0.42$, $p<0.01$, respectively); contrary to the inflammation index.
Patients with osteoporosis had a mean age significantly greater than the rest of the sample.
No association was found between the results of BMD (stratified as normal, osteopenia and/or osteoporosis) and total MASEI index, structure score, inflammation score or each of the anatomical areas that were studied. As to bone turnover markers, P1NP and βCTX showed a tendency to an inverse relation with age. βCTX was inversely related to MASEI index of quadriceps and achilles ($p<0.05$). Likewise, when excluding patients treated with antiresorptive and anabolic agents the tendency maintains the same but is not statistically significant (p=0,078 and 0,076, respectively).No other associations were found between these bone remodeling markers and the rest of ultrasound indexes of enthesis.
**Conclusions:** Structural changes seen in the enthesis of our group of patients with PsA associate with a reduction of the bone turnover marker βCTX.
**Disclosure of Interest:** None declared

## AB0739 ASSESSMENT OF SKIN INVOLVEMENT IN PATIENTS WITH POLYARTICULAR PSORIATIC ARTHRITIS AFTER 30 MONTHS OF BIOLOGICAL THERAPY OPTIMIZATION

M.J. Rodriguez Valls[1], J. Marquez Enriquez[2], C. Aranda-Valera[1], Y. Cabello Fernandez[1], M.D. Toledo Coello[1], J.J. Perez Venegas[1]. [1]*Rheumatology;* [2]*Dermatology, Hospital de Jerez, Jerez de la Frontera, Spain*

**Background:** Some patients with psoriatic arthritis (PA) in optimizing biological therapy present joint and/or skin activity, and they need to return to the standard dose of the drug. We present the articular and skin Activity Data in our cohort of patients with polyarticular psoriatic arthritis (PPA) in therapeutic optimization
**Objectives:** Assessment of the cutaneous activity by the PASI (Psoriasis Area Severity Index) and NAPSI (Nails Psoriasis Severity Index) scales and the analysis of the joint clinical course by DAS28 in PPA patients with biological treatment followed in the Rheumatology section of an university hospital of Jerez (Cadiz, Spain), which are undergoing therapeutic optimization.
**Methods:** An observational, descriptive, longitudinal and retrospective study by reviewing medical records, between January 2013 and January 2016, of PPA patients carrying at least 6 months in remission (DAS28 <2.6) or minimal activity (DAS28 2.6–3.2) and those who underwent optimization of biological therapy. Demographics, duration of PPA before the use of biological, biological time optimization, clinical evaluation by DAS28 pre and post-optimization, therapeutic strategy and assessment of skin activity by the PASI and NAPSI scales. Statistical analysis with the SPSS Statistics 22.0 software version is performed.
**Results:** From a total of 120 patients with PA in biological treatment, 26 of them with only polyarticular involvement (20.83%) were performed optimization of the therapy. 61.5% are male. Mean age 50±13 years. Average time optimized treatment dose: 31±14 months. 11 patients (42%) performed adalimumab 40 mg/15 days optimizing his administration every 21 days; 15 (57%) patients initially performed etanercept 50 mg/7 days were optimized to 25 mg/7 days (9 patients (34%)), 50 mg/10 days (2 (7%)) or 50 mg/15 days (4 (15%)). At the time of optimization, 25 (96.2%) patients presented remission DAS28 and 1 (3.8%) low activity, continuing in the same situation at the time of the end of the study (30 months after optimization). However, 5 patients (19.2%) (4 from etanercept group and 1 from adalimumab group) required to return to full doses of biologic drug for clinical worsening, agreeing worsening skin, remaining stable clinical joint. The skin evaluation was average PASI 1.95±2.13 (0–72) and medium NAPSI 11.19±11.38 (0–160), presenting patients who required back to initial biological dose PASI values between 1.6 and 5.8 and NAPSI values between 20 and 32, with prevalence of nail disease in the lower limbs. One patient (3.8%) required changing biological undesirable effects (anal fistula)
**Conclusions:** 77% of patients with PPA in remission or low activity subject to therapeutic optimization in our center remained stable at an average of 31 months of optimization, allowing continued the biological treatment in optimized doses. The main cause of return to full doses of biologic therapy in the remaining 33% of cases was worsening cutaneous involvement, remaining stable clinical joint in 100% of patients of our study

## AB0740 THE EFFECT OF PREGNANCY ON DISEASE ACTIVITY OUTCOMES IN PSORIATIC ARTHRITIS PATIENTS

M. Berman, D. Paran, J. Wollman, O. Elkayam. *Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

**Background:** Psoriatic arthritis often affects patients at a childbearing age. The relationship between pregnancy and psoriatic arthritis (PsA), in terms of pregnancy outcomes and its effect on disease activity, has not been well studied.
**Objectives:** The aim of this study is to evaluate the effect of pregnancy on disease activity in psoriatic arthritis
**Methods:** A retrospective review of files of female patients followed at the Psoriatic arthritis clinic at the Tel Aviv Medical center was performed and patients with at least 1 pregnancy during follow up and one visit during or soon after pregnancy were included in this descriptive study. A thorough review of the files was performed which included the following data: age, disease duration, pattern of PsA, disease activity before during and after pregnancy, and record of treatment, including intra-articular injections before and during pregnancy. Postpartum period was defined as up to 1 year after pregnancy. PsA as well as psoriasis activity was defined by the treating physician as follow: no disease activity (no active synovitis), mild disease (up to 1 joint involved), moderate to severe disease (more than 2 joints involved). Accordingly, the follow up during and after pregnancy was classified as: improvement, worsening or stable
**Results:** 13 PsA women and 20 pregnancies were identified. 19 resulted in live healthy babies. The mean age at pregnancy was 31.6 years. Table 1 summarizes the status of disease activity before, throughout pregnancy and during the post partum period in the whole group. No significant change in disease activity was noticed throughout pregnancy while a significant proportion of patients flared at post partum
Before 12 pregnancies, the patients were treated with TNF α blockers. In 10, the biologic treatment was discontinued close to pregnancy or during the first trimester. In this group, 4 (40%) of patients were classified as mild to severe activity prior to pregnancy. This number increased up to 6 (60%), 7 (70%) and 10

(100%) during the 1st, 2nd trimester and postpartum period respectively. In the 2 patients in whom biologics were not stopped pregnancy, no change in the degree of disease activity was noticed.
Interestingly, in the group of non-TNFα treated patients, an improvement in disease activity was observed – the proportion of patients with mild to severe disease activity decreased from 100% close to pregnancy to 71% in the 1st and 2nd trimester and 43% in the 2rd one while an increase to 86% was observed after pregnancy.
During 5 pregnancies, corticosteroids (CS) were initiated or the dosage increased - all in pregnancies where TNF α blockers were stopped before pregnancy.

Table 1. Disease activity during pregnancy

| No (%) | Before pregnancy | 1st trimester | 2nd trimester | 3rd trimester | Post partum |
|---|---|---|---|---|---|
| No disease activity | 7 (37%) | 6 (32%) | 6 (32%) | 8 (42%) | 2 (10%) |
| Mild dis. Activity | 4 (21%) | 5 (26%) | 5 (26%) | 5 (26%) | 6 (32%) |
| Moderate to severe dis. activity | 8 (42%) | 8 (42%) | 8 (42%) | 4 (21%) | 11 (58%) |

**Conclusions:** Patients with PsA definitively flare after pregnancy. Our results suggest that stopping treatment with TNF α blockers before pregnancy is associated with flare during pregnancy and the post partum period. It seems that in terms of PsA disease activity, it is recommended to continue treatment with TNF α blockers throughout pregnancy
**Disclosure of Interest:** None declared

## AB0741 DETECTION OF PSORIATIC ARTHRITIS IN PATIENTS WITH PSORIASIS IN DAILY ROUTINE CARE USING QUESTIONNAIRES FOR DIAGNOSIS OF PSORIATIC ARTHRITIS AND FLUORESCENCE-OPTICAL IMAGING TECHNIQUE: DIAGNOSTIC VALUE FOR DETECTION OF SUBCLINICAL SIGNS OF MUSCULOSKELETAL INFLAMMATION IN PSORIASIS?

M. Köhm[1,2], T. Rossmanith[2], H.-E. Langer[3], G. Burmester[4], S. Wassenberg[5], U. Kaesser[6], M. Backhaus[7], H. Burkhardt[1,2], F. Behrens[1,2] on behalf of XCiting Study Group. *[1]Rheumatology, Goethe-University; [2]Clinical Research, Fraunhofer IME Project group TMP, Frankfurt; [3]Rheumatology, RHIO Düsseldorf, Düsseldorf; [4]Rheumatology, Charité Universitätsklinik Berlin, Berlin; [5]Rheumatology, Evangelisches Fachkrankenhaus Ratingen, Ratingen; [6]Rheumatology, Internistische Praxisgemeinschaft am Krankenhaus Balserische Stiftung Gießen, Gießen; [7]Rheumatology, Park-Klinik Weissensee, Berlin, Germany*

**Background:** Psoriasis (Pso) is one of the most common chronic inflammatory skin disease in Europe. Psoriatic arthritis (PsA) is closely associated to Pso; the skin manifestation appears usually years before PsA-related symptoms emerge. Up to 30% of Pso patients develop PsA; its concrete prevalence is still unclear. Questionnaires for detection of PsA (PASE, PEST, GEPARD) are validated tools for use in dermatology practice with different sensitivity and specificity levels. Fluorescence-optical imaging technique is a new method to detect changes in microvascularisation of the hands as potential early marker for subclinical musculoskeletal inflammation. Positive results of screening questionnaires in patients without current detection of PsA in rheumatological examination might have a diagnostic value to reflect subclinical disease activity of PsA.
**Methods:** This interims analysis includes 151 Pso patients (diagnosis confirmed by dermatologist) without pre-existing diagnosis of PsA but risk factors for its development (nail psoriasis and/or joint pain or swelling within the last 6 months) from a prospective, multicentre study (XCITING) in Germany. Patients are examined by rheumatologist (clinical examination and ultrasound) to determine PsA-diagnosis. FOI is performed additionally and analysed by an independent central reader. Results for PASE, PEST and GEPARD questionnaires as well as for FOI in comparison to the diagnosis of PsA by rheumatologist are compared to survey their value for clinical performance.
**Results:** In 81 out of 151 (53.6%) psoriasis patients with risk of development of PsA (as defined in inclusion criteria) PsA was diagnosed by rheumatologist using clinical examination and ultrasound. PsA confirmed patients were positive in 71.6% when using PASE, 32.1% when using PEST and 44.4% by GEPARD. Positive results in questionnaires despite negative results in rheumatologists assessment were seen in 28.4 – 67.9% of the used tools (67.9% PASE, 28.4% PEST, 55.6% GEPARD). In addition to PsA confirmed by rheumatologists, in 23.2% of Pso patients without clinical verified PsA a positive FOI-signal could be detected. In this group PASE was positive in 47.1%, PEST in 14.3% and GEPARD in 25.7% of the patients.
**Conclusions:** In this cohort of patients with active Pso and newly diagnosed PsA but with pre-defined risk of development of PsA, more than 50% of the patients were classified as PsA by rheumatologist. The sensitivity of detection of PsA by using questionnaires in early disease seems to be limited. False positive results in questionnaires in patients without clinical evident PsA might be influenced by signs of subclinical inflammation measured by FOI.

## AB0742 EVOLUTION OF BIOLOGIC TREATMENT, SATISFACTION WITH CONTROL OF DISEASE, AND PATIENT-REPORTED OUTCOMES IN EUROPEAN PATIENTS WITH PSORIATIC ARTHRITIS: A REAL-WORLD STUDY

J. Lucas[1], R. Wood[1], J. Piercy[1], J.C. Cappelleri[2], B. Kola[3], A. Chhabra[4], R. Vasilescu[5], M.-A. Hsu[2]. *[1]Adelphi Real World, Cheshire, United Kingdom; [2]Pfizer, Groton, United States; [3]Pfizer, Tadworth, United Kingdom; [4]Pfizer, New York, United States; [5]Pfizer, Brussels, Belgium*

**Background:** Patients with psoriatic arthritis (PsA) commonly receive therapy with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), either alone or in combination with biologics such as tumour necrosis factor inhibitors.[1]
**Objectives:** To assess the evolution of real-world biologic treatment patterns in patients with PsA by comparing patient data from two distinct patient surveys from 2014 and 2011.
**Methods:** This was a retrospective, cross-sectional analysis of data from two independent surveys (Adelphi Real World PsA Disease Specific Programmes) conducted in Q1 2011 and Q3 2014. Rheumatologists provided patient demographics, clinical details, treatment history and levels of satisfaction with disease control. Patient-reported outcomes included satisfaction with disease control, EuroQol-5 Dimension, Work Productivity and Activity Impairment (WPAI) and Alternative Health Assessment Questionnaire Disability Index (without aids/devices, HAQ-DI). Statistical differences were assessed using Mann-Whitney-U tests and Fisher's exact tests for quantitative and categorical outcomes, respectively. Missing data were not imputed.
**Results:** Patients with PsA receiving biologic treatment were similar in age, sex and body mass index in 2014 (n=325) and 2011 (n=326). The two independent cohorts showed no difference in time since diagnosis, severity of PsA prior to initiation of current treatment, disease progression prior to initiation of current treatment and time on current biologic treatment. The 2014 cohort had milder PsA vs the 2011 cohort (mild/moderate/severe: 72.6%/24.9%/2.5% vs 59.8%/35.0%/5.2%, respectively; P=0.0004), fewer patients who had ever experienced an acute episode (36.4% vs 56.6%, respectively; P<0.0001) or experienced an acute episode in the last 12 months (21.9% vs 31.4%, respectively; P=0.0074) and more patients with better current disease status (improving/stable/deteriorating slowly/deteriorating rapidly/unstable: 31.4%/56.7%/1.6%/7.2%/3.1% vs 27.3%/52.2%/14.4%/3.1%/3.1%, respectively; P=0.045). Patients did not receive biologic treatment any earlier in 2014 (median [interquartile range]; 36 [12, 72] months in 2014 vs 33 [15, 63] in 2011, P=0.2261). The number of csDMARDs received prior to initiation of biologic treatment did not differ significantly in 2014 vs 2011 (P=0.1551). Both physicians and patients were more satisfied with control of PsA in 2014 vs 2011 (81.5% vs 71.8%, P=0.0016 and 90.9% vs 67.3%, P=0.0002, respectively). The HAQ-DI score was significantly lower, indicating better health, in 2014 vs 2011 (0.38 [0.00, 0.88] vs 0.63 [0.27, 1.00], respectively; P=0.0065). WPAI scores showed nonsignificant improvements in outcomes in 2014 compared with 2011.
**Conclusions:** There were no significant differences in severity of PsA at initiation of treatment or treatment patterns in the patient samples analysed in 2014 vs 2011; however, patients' disease status was improved and both patients and physicians were more satisfied with the control of PsA in 2014 than in 2011. Further investigation is required to elucidate the reasons behind the improved outcomes observed over time.

## AB0743 CHARACTERIZATION OF PSORIATIC ARTHRITIS PATIENTS BY SKIN AND JOINT SEVERITY: RESULTS FROM THE CORRONA SPONDYLOARTHRITIS REGISTRY

P.J. Mease[1,2], M. Skup[3], C. Karki[4], C.J. Etzel[4], W. Malley[4], J.D. Greenberg[4], A. Joshi[3]. *[1]Swedish Medical Center; [2]University of Washington School of Medicine, Seattle, WA; [3]AbbVie, Inc., Chicago, IL; [4]Corrona, LLC, Southborough, MA, United States*

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory condition affecting the skin and joints, and can lead to significant joint damage, disability and reduced quality of life. Disease severity varies among patients and is not well characterized in a real world setting.
**Objectives:** To characterize the PsA patients by skin severity (defined by body surface area, BSA) and joint (defined by modified disease activity score, mDAS)

in the Corrona PsA/Spondyloarthritis (SpA) registry, a large cohort of PsA-SpA patients in the US.

**Methods:** PsA patients enrolled in the registry between 4/2013 and 7/2015 were included. Patients were categorized by the level of skin involvement measured by BSA (low:BSA≤3%; moderate: BSA>3% & BSA≤10%; high:>10%) and joint severity as measured by mDAS (low:mDAS≤2.7; moderate:mDAS>2.7 & mDAS≤4.1 & high:mDAS>4.1). Patient characteristics at registry enrollment and biologic use were evaluated and one-way analysis of variance/Chi-square tests were used for continuous and categorical variables to evaluate differences.

**Results:** 1613 PsA patients were included, of which 1281 were categorized by BSA severity (low=64%, moderate=22%, high=14%) and 1331 by mDAS severity (low=21%, moderate=53%, high=26%). Overall, there were 53% females, mean (SD) age of 54 (13) yrs, mean (SD) disease duration of 12 (10) yrs. Majority of patients were referred by a primary care provider (40%) followed by self-referral (23%) or a rheumatologist (19%); 5% were referred by a dermatologist. Presence of dactylitis (10%, 13% and 22% in low, moderate and high resp.), and enthesitis (18%, 23% and 40% in low moderate and high resp.) were highly correlated with mDAS categories ($p<0.0001$), however similar correlation were not observed with categories of BSA. 61% of patients had prior biologic use and differences were observed in current biologic use by severity of BSA and mDAS categories: 62%, 59% and 97% ($p<0.001$) and 64%, 62% and 97% ($p<0.0001$) with low, moderate and high respectively, where app. one-third of the patients were on monotherapy. Among patients with moderate/high mDAS only 15% had high BSA (table).

| Skin involvement (BSA) | Joint severity (mDAS) | | | |
|---|---|---|---|---|
| | mDAS: Low (≤2.7) | mDAS: Moderate (2.7–≤4.1) | mDAS: High (>4.1) | Total |
| BSA: Low (≤3%) | 151 (67.4%) | 399 (70%) | 133 (47.8%) | 683 |
| BSA: Moderate (>3–≤10%) | 47 (21%) | 111 (19.5%) | 80 (28.8%) | 238 |
| BSA: High (>10%) | 26 (11.6%) | 60 (10.5%) | 65 (23.4%) | 151 |
| Total | 224 | 570 | 278 | 1072 |

**Conclusions:** Majority of PsA patients present to the rheumatologist with moderate/severe joint symptoms and mild skin symptoms, and are primarily referred by PCPs, self-referred, or other rheumatologists. mDAS severity was correlated with presence of dactylitis/enthesitis and the number of enthesitis sites. The majority of PsA patients (60%) were treated with biologic agents regardless of joint or skin severity; however over 90% of patients with high joint or skin severity were treated with biologic therapy.

## AB0744 DEVELOPING THAI SIRIRAJ PSORIATIC ARTHRITIS SCREENING TOOL AND VALIDATED THAI PSORIASIS EPIDEMIOLOGY SCREENING TOOL AND THE EARLY ARTHRITIS FOR PSORIATIC PATIENTS

P. Chiowchanwisawakit[1], L. Wattanamongkolsil[2], V. Srinonprasert[1], C. Petcharat[1], W. Katchamart[1]. *[1]Medicine; [2]Office of Research and Development, Siriraj Hospital, Bangkok, Thailand*

**Background:** Majority of PsA patients present with Ps before onset of arthritis up to 10 years. Ps patients are generally taken care by general practitioners or dermatologists therefore they play a key role for early detection of PsA. There are a few screening tools available; however, it has been reported that they have a wide range of sensitivity and specificity around 24- 90% and 40–94%, respectively, in the different studies [1]. There is no screening tool which has been verified in Thai content. Furthermore, it would be essential to have a simple tool with good discriminating property.

**Objectives:** To validate Thai version of the Psoriasis Epidemiology Screening Tool (PEST)[2] and the Early ARthritis for Psoriatic patients' questionnaire (EARP)[3], and to develop the new tool for screening psoriatic arthritis (PsA) among psoriasis (Ps) patients.

**Methods:** This was a cross-sectional study. Ps patients visiting psoriasis clinic at Siriraj Hospital were recruited. They filled out EARP, and PEST, and were evaluated full musculoskeletal history, examination and radiography. Diagnosis of PsA was based on a rheumatologist's evaluation and fulfilled ClASsification criteria for Psoriatic Arthritis. Receiver operator characteristic (ROC) curves, sensitivity, and specificity were used to determine the performance of tools. Siriraj Psoriatic Arthritis screening Tool (SiPAT) was composed from the most relevant questions regarding peripheral arthritis, axial inflammation, enthesitis selected from multivariate analysis.

**Results:** A total of 159 patients, prevalence of PsA was 78.6%. The ROC curve analyses of the Thai EARP, PEST, and SiPAT were 0.90 (95%CI: 0.84, 0.96), 0.85 (0.78, 0.92), and 0.89 (0.83, 0.95), respectively. The sensitivities of SiPAT, Thai EARP and PEST were 91.0, 83.0, and 72.0%, respectively while the specificities were 69.0, 79.3, and 89.7%, respectively.

**Conclusions:** Thai EARP and SiPAT have diagnostic performance better than Thai PEST. SiPAT could be proposed as a simple and effective tool for screening PsA among Ps patients.

## AB0745 DAPSA WITH TWENTY-EIGHT JOINT COUNTS MAY BE USEFUL FOR THE ASSESSMENT OF PSORIATIC ARTHRITIS

U. Kalyoncu, A. Erden, L. Kilic, A. Sari, B. Armagan, O. Karadag, A. Akdogan, S.A. Bilgen, S. Kiraz, I. Ertenli. *Department of Internal Medicine, Division of Rheumatology, Hacettepe University, Ankara, Turkey*

**Background:** Disease Activity index for Psoriatic Arthritis (DAPSA) originally developed from patients with reactive arthritis (1). Subsequently, validation of DAPSA was also shown on psoriatic arthritis (PsA) patients (2). DAPSA includes swollen joint count (SJC) (66 joint), tender joint count (TJC) (68 joint), CRP (mg/dl), patient global assessment, and pain. However, it is well known that assessment of 28 joint is feasible than 66/68 joints especially in the rheumatoid arthritis trials.

**Objectives:** Objective of this study was to assess construct validity and sensitivity to change of DAPSA-28 in a single center biological registry.

**Methods:** Hacettepe University biological registry (HUR-BIO) is a single center biological registry. Since 2012, consequently all PsA patients with new started anti-TNF treatments were recorded. HUR-BIO included sex, age, PsA disease duration, education, body mass index (BMI). Before anti-TNF treatments, baseline disease activity parameters were recorded: SJC and TJC (28 joints), health assessment questionnaire (HAQ), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath ankylosing spondylitis activity index (BASDAI), visual analog scale 0–100 mm (VAS) of patient's global assessment of disease activity (PGA), pain, and fatigue. Original DAPSA calculated to sum of CRP (mg/dl), pain VAS (cm), PGA VAS (cm), SJC (66 joints), and TJC (68 joints). We used 28 TJC/SJC instead of 66/68 joints for calculation of DAPSA, which called DAPSA-28. At baseline, all DAPSA items completed in 78 patients. The subsequent clinical visit recorded in 53 patients (4.6±3.0 months after baseline). *Statistical analysis:* Internal consistency was evaluated using Cronbach's $\alpha$ coefficient. Construct validity was assessed by Spearman's correlation between the DAPSA-28 scores and other measures. Sensitivity to change assessed with standardised response mean (SRM). A SRM >0.8 is considered large.

**Results:** Overall, 58 of 78 (74.4%) were female, mean age was 43.1 (11.8) years, mean PsA duration was 6.4 (5.1) years. Mean DAPSA-28 score was 20.1 (8.1). Patients with low educational level (primary scholl 22.8 (9.6) vs high scholl 16.8 (5.7), p=0.009), and high BMI (BMI >30 kg/m$^2$ 22.4 (8.4) vs BMI <30 kg/m$^2$ 17.8 (7.2), p=0.011) had higher DAPSA-28 score. Mean of all DAPSA items were followed; PGA 5.8 (1.7), pain 6.3 (2.3), CRP 2.0 (2.8), SJC 1.9 (2.2), TJC 4.0 (3.6). DAPSA-28 domains had moderate internal consistency (Cronbach's $\alpha$ 0.61). Correlation of DAPSA-28 with other outcome measures followed; DAS-28 (r=0.86), TJC (r=0.78), SJC (r=0.73), PGA (r=0.48), pain VAS (r=0.47), CRP (r=0.44), fatigue VAS (r=0.38), HAQ (r=0.36), ESR (r=0.35), and BASDAI (r=0.31). DAPSA-28 had excellent SRM (1.14).

**Conclusions:** DAPSA domains are almost universal for all kind of inflammatory arthritis. Simple sum of those domains seem valid and feasible in PsA patients. Although assessment of 66/68 joints may be rational particularly patients with distal interphalangeal involvement, it has feasibility issue. Our results demonstrated that DAPSA-28 had excellent capacity at sensitivity to change for clinical trials. Unfortunately, we could not compare DAPSA with DAPSA-28, future studies are needed for these comparison.

## AB0746 HIGH PREVALENCE OF CARDIOVASCULAR COMORBIDITY IN PATIENTS WITH PSORIATIC ARTHRITIS AND MODERATE-TO-SEVERY PLAQUE PSORIASIS: A RETROSPECTIVE DERMATOLOGICAL CLINIC-BASED STUDY

N. Batkaeva[1], T. Korotaeva[2], E. Batkaev[1]. *[1]Department of dermatology, Peoples ' Friendship University of Russia; [2]Department of early arthritis, Research Institute of Rheumatology n.a. V. A. Nasonova, Moscow, Russian Federation*

**Background:** An association between inflammation, psoriasis (PsO), psoriatic arthritis (PsA) and increased cardiovascular comorbidity has still limited data.
**Objectives:** to evaluate the prevalence of cardiovascular comorbidity in patients (pts) with PsA and PsO without arthritis in the dermatological hospital cohort.
**Methods:** 592 pts (Male-348/Female-244) with moderate-to-severy plaque PsO, mean age 49.2±0.6 years, mean PsO duration 11.8±0.6 were included. PsO and PsA pts with cardiovascular disease (CVD), including coronary heart disease (CHD), arterial hypertension, (AH), atherosclerosis and cerebrovascular accident (CVA) were identify in the hospital Database reporting and coding by International Statistical Classification of Disease and Related Health Problems (ICD-10) between 2010 - 2011 years. M±m, t-test, (%) were calculated. All $p<0.05$ were considered to indicate statistical significance.
**Results:** 220 out of 592 pts (37.2%) had PsA and 372 out of 592 pts (62.8%) had PsO alone. PsA pts were older then PsO pts – 53.3±0.9 and 46.9±0.9 ($p<0.001$). In PsA pts CVD coding as I 00 – I 99 were found in significantly more cases than in PsO pts – in 155 out of 220 pts (70.5%)/in 200 out of 372 pts (53.5%) accordingly ($p<0.05$). In PsA pts AH coding as I 10 - I 15 was found in significantly more cases than in PsO pts - in 138 out of 220 pts (62.7%) and in 178 out of 372 pts (47.9%) accordingly ($p<0.001$). In PsA pts CVA coding as I 65 – I 66 found significantly often than in PsO pts - in 48 out of 220 pts (22%) and in 57 out of 372 pts (15.3%) accordingly ($p<0.05$). CHD and Atherosclerosis coding as I 70 were registered significantly often in PsA pts compared to PsO pts – in 40 out of 220 pts (18%) and in 35 out of 372 pts (9.3%) accordingly ($p<0.001$).
**Conclusions:** Cardiovascular comorbidity is common for PsA and PsO without arthritis pts. High frequency of CVD in PsA than PsO could be due to share inflammation pathways with atherosclerosis and age. Screening and accurate management of CVD risk factors in both diseases are needed.
**Disclosure of Interest:** None declared

## AB0747 PSORIATIC ARTHRITIS REGISTRY OF TURKEY (PSART): RESULTS OF A MULTICENTER REGISTRY ON 1081 PATIENTS

S.Z. Aydin, O. Bayindir, M.F. Oksuz, A. Dogru, G. Kimyon, E.F. Tarhan, A. Erden, S. Yavuz, M. Can, G.Y. Cetin, L. Kilic, O. Kucuksahin, A. Omma, C. Ozisler, D. Solmaz, A.M. Onat, B. Kisacik, D.E. Ersozlu Bozkirli, M.A. Tufan, L. Akyol, M. Cinar, S.M. Pehlevan, A. Tufan, F. Yildiz, A. Balkarli, F. Erbasan, R. Mercan, E.K. Gunal, F. Arslan, T. Kasifoglu, S. Senel, S. Kobak, B. Yilmazer, S. Yilmaz, T.M. Duruoz, A. Kucuk, E.O. Gonullu, K. Aksu, Y. Kabasakal, M. Sahin, N. Cakir, S. Erten, M. Sayarlioglu, E. Dalkilic, S. Akar, C. Acikel, N. Atakan, U. Kalyoncu. *Psoriatic Arthritis Registry of Turkey (PsART), Ankara, Turkey*

**Background:** PsART (PsA registry of Turkey) is a multicenter web-based registry.
**Objectives:** The objective of this registry is to assess characteristics of PsA and compare the differences among genders in our population.
**Methods:** PsART was established in 2014 including 32 rheumatology centers. Detailed data regarding demographics for the skin and joint disease, disease activity assessments and treatment choices were collected.
**Results:** One thousand and eighty-one patients (64.7% women) with a median (range) PsA duration for 3.7 (0–45) years were enrolled. Median psoriasis duration was 13 (0–59) years. The most frequent type of PsA was polyarticular 437 (40.5%) followed by oligoarticular 407 (37.7%) and axial disease 372 (34.4%). Patients with a combination of axial and peripheral disease had a longer disease duration than patients with one type of joint disease (52 (0–545) vs 42 (0–486) months, p=0.008). Mean (SD) swollen and tender joint counts were 1.7 (3) and 3.6 (4.8). 38.6% of patients were on csDMARD monotherapy, 7.1% were anti-TNF monotherapy and 22.5% were using anti-TNF plus csDMARD combinations. Within items included in the minimal disease activity, only 17.6%>67% of patients had inactive disease state. The major differences among genders were women being older (48.3 (12.8) VS 44.4 (12.5), $P<0.001$), more fatigue and higher HAQ scores (Table). Women also had more frequent peripheral arthritis than men and less axial disease (only peripheral vs axial vs combined, n (%): women: 479 (68.5%), 62 (8.9%), 158 (22.6%) respectively; men: 222 (59.4%), 41 (11%), 111 (29.7%) respectively; p=0.011). Women had significantly more history of psoriasis in their family compared to men (34.8% vs 25.7%, p=0.003).
**Conclusions:** PsART had similarities with the previously published registries, supporting its external validity. Women having more fatigue and worse functioning and as well as the high percentage of active disease state point out to the unmet need in treatment of PsA.

| | All patients (n=1081) | Female (n=702) | Male (n=379) | p |

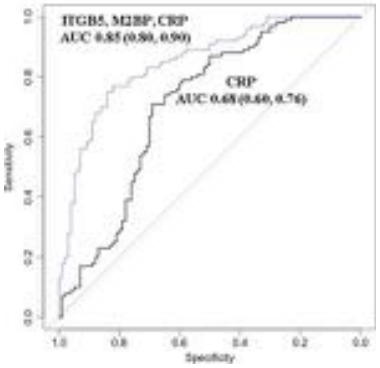
## AB0748 NOVEL BIOMARKERS DISTINGUISH PSORIATIC ARTHRITIS FROM PSORIASIS



V. Chandran[1,2], D. Cretu[3], L. Gao[4], K. Liang[4], E.P. Diamandis[3]. *[1]Medicine, Laboratory Medicine and Pathobiology, Institute of Medical Science, University of Toronto; [2]Krembil Research Institute; [3]University of Toronto, Toronto; [4]University of Waterloo, Waterloo, Canada*

**Background:** There is a high prevalence of undiagnosed psoriatic arthritis (PsA) in psoriasis patients. Therefore identifying soluble biomarkers for PsA will help in screening psoriasis patients for appropriate referral to a rheumatologist.
**Objectives:** Our purpose was to investigate whether serum levels of novel markers discovered by quantitative mass spectrometry (MS) of synovial fluid and skin biopsies, differentiate PsA patients from those with psoriasis without PsA (PsC).
**Methods:** Serum samples were obtained from 100 patients with PsA, 100 with PsC, and 100 healthy controls. Subjects were group matched for age and sex. No patient was undergoing treatment with biologics at the time of serum collection. Using enzyme-linked immunosorbent assays, four high-priority markers, previously discovered by quantitative MS of synovial fluid and skin biopsies, were analyzed in the serum: Mac-2-binding protein (M2BP), CD5-like protein (CD5L), Myeloperoxidase (MPO), and Integrin-β 5 (ITGB5), as well as previously established markers Matrix metalloproteinase-3 (MMP3) and C-reactive protein (CRP). Data were analyzed using logistic regression (LR), and receiver operating characteristic (ROC) curves were plotted.
**Results:** The 100 PsA patients (41 females, mean age 51 years) had mean psoriasis duration of 22.9 years, PsA duration of 14.6 years, swollen joint count 3.2, tender joint count 6, and PASI score of 4.7. The 100 PsC patients (45 females, mean age 50 years) had mean psoriasis duration of 20.3 years and PASI score of 4. The 100 controls (52 females) had a mean age of 35 years. Polychotomous LR showed that ITGB5, CRP and M2BP are markers that are significantly different between the three groups. The analyses also showed that CD5L, ITGB5, M2BP, MPO, MMP3 and CRP are independently associated with PsA, while CD5L, M2BP and MPO are independently associated with PsC. When comparing PsA to PsC, ITGB5, M2BP, and CRP were found to be independently associated with PsA (Table 1). ROC analysis (Figure 1) of this model showed an

Table 1. Logistic regression analysis comparing patients with PsA to PsC

| | Univariate | | Multivariate | |
|---|---|---|---|---|
| Biomarkers | OR[a] (95% CI) | P-value | OR[a] (95% CI) | P-value |

area under the ROC curve of 0.85 (95% CI [0.80, 0.90]) that was superior to CRP only model (AUC 0.68 [0.60, 0.76]).
**Conclusions:** CD5L, ITGB5, M2BP, MPO, MMP3 and CRP are soluble PsA markers. However, only ITGB5, M2BP and CRP, differentiate PsA from PsC, and is superior to CRP alone.

## AB0749 IMPACT OF PATIENT PERCEPTION OF PSORIASIS AND PSORIATIC ARTHRITIS SEVERITY ON PATIENT-REPORTED OUTCOMES: AN ANALYSIS FROM THE ADELPHI DATABASE

W.-H. Boehncke[1,2], J. Piercy[3], S. Chen[4], M. Hojnik[5], F. Ganz[6]. *[1]University of Geneva; [2]Geneva University Hospital, Geneva, Switzerland; [3]Adelphi Real World, Cheshire, United Kingdom; [4]AbbVie Inc, North Chicago, United States; [5]AbbVie, Ljubljana, Slovenia; [6]AbbVie AG, Baar, Switzerland*

**Background:** Patients (pts) with psoriatic arthritis (PsA) report experiencing different levels of skin involvement (psoriasis, PsO). The impact of pt perception of PsO and PsA severity on pt-reported outcomes (PROs) in PsA pts is not clearly understood.
**Objectives:** To examine the impact of perception of PsO and PsA severity (assessed by self-completion questionnaires) in PsA pts on PROs in real world setting.
**Methods:** This retrospective analysis extracted data from the Adelphi 2014 Rheumatology disease-specific programme (DSP).[1] The DSP is a large multi-center, multi-country, cross-sectional survey of pts with a physician confirmed diagnosis of PsA. Pts filled out a self-completion form providing an assessment of their symptoms, satisfaction with disease control and quality of life. Pts reported their perception of PsA severity as mild, moderate or severe, both at diagnosis and at the time of survey. Pts reported their perception of PsO severity on a numeric rating scale of 0–10 (0, No PsO; 1–3, Mild; 4–7, Moderate; 8–10, Severe) only at the time of survey. The self-assessment questionnaires also included Dermatology Quality of Life (DLQI), alternative Health Assessment Questionnaire – Disability Index (HAQ-DI), Work Productivity and Activity Impairment (WPAI), and Euro Quality of Life 5 Dimensions (EQ5D). Pts with PsA diagnosis were stratified by self-reported severity of both PsA and PsO. Statistical differences between the groups were evaluated using $\chi^2$ test (categorical variables) or analysis of variance (ANOVA, continuous variables).
**Results:** Of the 329 PsA pts analyzed from the Adelphi database, similar number of pts reported either mild (164, 50%) or moderate-to-severe PsA (165, 50%) symptoms, at the time of survey (Table 1a). At the time of PsA diagnosis, majority of pts (292, 88%) reported experiencing moderate-to-severe PsA symptoms. At the time of survey, greater number of pts reported mild-to-moderate PsO (223, 68%) and the remaining pts reported no PsO (69, 21%) or severe PsO (37, 11%) symptoms. There was a significant association between the perception of PsA and PsO severity at the time of survey (P<0.001). The frequency and severity of itching increased significantly with increasing perception of PsO and PsA severity (P<0.001, Table 1b). However, the severity of itching was much more pronounced in pts with severe PsO. DLQI and WPAI scores were significantly impacted by increasing severity of both PsA and PsO (P<0.001). The HAQ-DI and EQ5D scores were significantly influenced by severity of both PsA (P<0.001 for HAQ-DI and EQ5D) and PsO (HAQ-DI: P<0.05; EQ5D: P<0.01); however, a larger effect on HAQ-DI and EQ-5D scores were observed in pts with severe PsA.

Table 1a. PsA severity at diagnosis or at present stratified by PsO severity at survey[a]

| PsO Severity | PsA severity at diagnosis | | | Total | PsA severity at survey*** | | | Total[b] |
|---|---|---|---|---|---|---|---|---|
| | Mild | Moderate | Severe | | Mild | Moderate | Severe | |
| No PsO | 8 (2.4) | 33 (10.0) | 27 (8.2) | 68 (20.5) | 45 (13.7) | 19 (5.8) | 5 (1.5) | 69 (21.0) |
| Mild | 11 (3.3) | 49 (14.9) | 43 (12.4) | 101 (30.5) | 61 (18.5) | 34 (10.3) | 7 (2.1) | 102 (31.0) |
| Moderate | 13 (3.9) | 75 (22.7) | 34 (10.3) | 122 (36.9) | 42 (12.8) | 70 (21.3) | 9 (2.7) | 121 (36.8) |
| Severe | 7 (2.1) | 16 (4.8) | 17 (5.1) | 40 (12.1) | 16 (4.9) | 15 (4.6) | 6 (1.8) | 37 (11.2) |
| Total | 39 (11.8) | 173 (52.3) | 119 (36.0) | 331 (100) | 164 (49.8) | 138 (41.9) | 27 (8.2) | 329 (100) |

# Osteoarthritis

## AB0750 ANALGETIC EFFECT OF NSAIDS IN CHRONIC KNEE OSTEOARTHRITIS WITH A "CLINICAL" CENTRAL SENSITIZATION

E. Turovskaia[1], L. Alekseeva[1], E. Filatova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology; [2]I.M.Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** NSAIDs are widely used for therapy nociceptive pain in osteoarthritis (OA) patients. But in 27% - 61% case this treatment fails to reduce mean pain levels beyond minimal clinically important thresholds [1]. Recent studies have demonstrated that chronic knee OA mechanisms besides nociceptive pain also include central sensitization (CS) (neuroplastic changes in the posterior horn) [2]. CS characterized with neuropathic (NP) phenomena spontaneous and evoked (34% cases), referred hyperalgesia and neurophysiological changes (low pressure pain threshold).
**Objectives:** to evaluate the efficacy of NSAID in patients with "clinical" CS.
**Methods:** 40 women (age 55±75), II-III grade by Kellgren-Lawrence with chronic knee OA were included. Patients were divided in groups in accordance with the results of neuropathic test DN4 (screening test for CS): patients with positive DN4 (n=11) and patients with negative DN4 (n=29) and accordance with presence of spontaneous NP phenomena (for ex. burning, tingling, current rush): patients with spontaneous NP phenomena (n=29) and patients without spontaneous NP phenomena. Dynamic of OA severity by WOMAC (mm) and pain intensity by VAS (mm) were assessed between groups.
**Results:** There was no difference between sociodemographic factors in groups. Statistically and clinically significant reduction in pain score after one-month treatment (n=20) in patients with negative DN4 score was seen (mean pain relief 26mm vs 17 mm, p<0,05). Significant decrease of WOMAC from baseline to final evaluation in patients without spontaneous NP phenomena (mean WOMAC redaction 315 mm vs 199 mm, p<0,05) was demonstrated.
**Conclusions:** Patients with clinical signs of CS have suboptimal pain control. Targeting treatment including anticonvulsants or antidepressants to symptoms of CS in people with OA could lead to benefit.

## AB0751 THE DEPENDENCE OF OSTEOARTHRITIS PROGRESSION FROM GLYCEMIC CONTROL IN PATIENTS WITH DIABETES

E. Trifonova, O. Sazonova, E. Zonova. *Novosibirsk State Medical University, Novosibirsk, Russian Federation*

**Background:** The influence of type 2 diabetes mellitus (T2DM) on development and progression of osteoarthritis (OA) has been proved. However, there is a lack of data from more detailed researches in such category of patients.
**Objectives:** To estimate the proinflammatory serum cytokine levels and the clinical features in patients with knee OA and T2DM depending on glycemic control.
**Methods:** Patients (n=45) who had bilateral knee OA according to ACR criteria and T2DM were divided into two groups according to the compensation degree T2DM taking into account parameters of glycated hemoglobin concentrations (HbA1c) which were assessed using liquid chromatography. Blood glucose level was also estimated. Group 1 (n=26) had control T2DM. Group 2 (n=19) had no control T2DM. All patients were comparable by age, sex and duration of OA. Serum cytokine levels (IL-1b, IL-6, IL-10, IL-18), NO, and adypokines

(adiponectin, leptin) using ELISA were assessed. Intensity of pain, general health, stiffness, physical functions were measured by visual analog scale (VAS),Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Knee injury and Osteoarthritis Outcome Score – (KOOS) and short form 36 (SF-36). U-Mann-Whitney test was applied to detect differences between groups. Correlation was assessed using Spearman correlation coefficient (rs).
**Results:** No significant difference has been found in parameters reflecting the functional disorders. Serum cytokines levels also were not different between the studied groups. Correlation analysis identified the relationships between clinical parameters and cytokines in OA patients with control and non-control T2DM. Certain data are presented (Table).

Table. Correlation between clinical parameters and serum cytokine levels in studied groups

| Cytokines | OA patients with control T2DM n=26 | | | OA patients with non-control T2DM n=19 | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | Pain (KOOS) | Physical Function (WOMAC) | General health (SF-36 GH) | Pain (VAS) | Physician's assessment of disease (VAS ) | Pain (KOOS) | Physical Functioning (SF36-PF) | Bodily pain (SF36-BP) | Physical health (SF36-PH) |
| IL-1b (pg/ml) | 0.56 | 0.44 | 0.45 | 0.95 | 0.41 | 0.64 | **0.0002*** | **0.0001*** | **0.002*** |
| IL-6 (pg/ml) | 0.70 | 0.62 | 0.58 | **0.002*** | **0.02*** | **0.03*** | 0.13 | 0.13 | 0.30 |
| IL-10 (pg/ml) | 0.83 | 0.51 | 0.74 | 0.33 | 0.18 | 0.85 | 0.42 | 0.21 | 0.30 |
| IL-18 (pg/ml) | **0.03*** | **0.04*** | 0.61 | 0.62 | 0.23 | 0.61 | **0.04*** | 0.95 | 0.80 |
| NO (pg/ml) | 0.38 | 0.07 | **0.02*** | 0.54 | 0.18 | 0.78 | 0.35 | 0.95 | 0.80 |
| Leptin (ng/ml) | 0.73 | 0.87 | 0.67 | **0.003*** | **0.002*** | **0.01*** | **0.001*** | **0.04*** | **0.01*** |

Table legend: * - p<0.005;

**Conclusions:** The results show that depending on the glycemic control may change clinical and immunology parameters of OA in patients with T2DM, especially in group with non-control T2DM. These data should be verified by larger studies and may be useful for the development of a personalized approach to patients with comorbid disorders such as OA and T2DM in future.

## AB0752 THE ASSOCIATION BETWEEN CLINICAL SYMPTOMS AND SERUM CYTOKINES LEVELS IN PATIENTS WITH KNEE OSTEOARTHRITIS AND COMORBIDITY

E. Trifonova, O. Sazonova, E. Zonova. *Novosibirsk State Medical University, Novosibirsk, Russian Federation*

**Background:** A number of factors influence development and progression of osteoarthritis (OA), including comorbid diseases. Such factors as obesity, impaired glucose tolerance, raised blood glucose level can affect clinical processes and also have similar mechanisms of immunopathogenesis with OA.
**Objectives:** To explore the symptoms and the proinflammatory serum cytokine levels in patients with knee OA and obesity, metabolic syndrome (MS) and type 2 diabetes mellitus (T2DM) and to estimate association between clinical and immunological features.
**Methods:** A study was performed on 128 persons with bilateral knee OA according to the ACR criteria who were divided into four groups. Group 1 (n=17) had obesity, group 2 (n=17) had MS, group 3 (n=56) had T2DM and group 4 (n=38) had only knee OA without comorbid diseases. All patients were comparable by age, sex and duration of OA. We assessed serum cytokine levels (IL-1b, IL-6, IL-10, IL-18), NO including adipokines such as adiponectin and leptin using ELISA. Intensity of pain, general health, stiffness, physical functions were measured by visual analog scale (VAS),Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Knee injury and Osteoarthritis Outcome Score – (KOOS) and with short form 36 (SF-36). U-Mann-Whitney test was applied to detect differences between groups. Correlation was assessed using Spearman correlation coefficient (rs).
**Results:** In the course of the comparative analysis of the groups of OA patients and concomitant diseases with a group of OA patients without comorbidity there were found many statistically significant differences in such scales and indexes as VAS, WOMAC, KOOS, SF-36. Patients with OA and obesity are characterized by the prevalence of symptoms OA of KOOS scale (median (Me) 61.1; interquartile range (IQR) 55.5–70.8; $p<0.001$). Patients from group 2 (MS) and 3 (T2DM) were significant worse parameters of general health and high levels of pain, morning stiffness and functional disoders of the knees. Differences in serum cytokine levels were found in patients with OA and T2DM (IL-6 p=0.0018; IL-18 p=0.0006; NO $p<0.001$). Patients with OA and obesity had high leptin level (p=0.03). Group 3 with OA and T2DM had significant differences in leptin (p=0.0002). Correlation analysis identified relationships between clinical parameters and cytokines in OA patients with obesity and T2DM. Some data is presented (Table).

Table. Correlations between clinical parameters and serum cytokine levels in studied groups

| Cytokines | OA patients with obesity n=17 | | | | | | OA patients with T2DM n=56 | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Physician's assessment of disease (VAS ) | General health (VAS) | Total score WOMAC | Sport's activity (KOOS) | Bodily pain (SF36-BP) | Physical health (SF36-PH) | Pain (VAS) | General health (VAS) | Symptoms OA (KOOS) | Physical Functioning (SF36-PF) | General Health (SF36-GH) | Physical health (SF36- PH) |
| IL-1b (pg/ml) | 0.49 | 0.49 | **0.02*** | 0.05 | 0.41 | 0.10 | 0.79 | 0.69 | **0.03*** | 0.66 | 0.46 | 0.28 |

| IL-10 (pg/ml) | 0.20 | 0.80 | 0.35 | **0.01*** | 0.49 | 0.29 | 0.62 | **0.007*** | 0.42 | 0.13 | 0.08 | 0.13 |
| IL-18 (pg/ml) | 1.0 | 0.41 | 0.38 | 0.29 | 0.17 | **0.01*** | 0.02 | 0.80 | 0.41 | 0.45 | 0.25 | 0.47 |
| NO (pg/ml) | 0.41 | **0.03*** | 0.29 | 1.00 | 0.13 | 0.49 | 0.71 | 0.66 | 0.42 | 0.96 | **0.03*** | 0.73 |
| Adiponectin (pg/ml) | **0.01*** | 1.0 | 0.65 | 0.29 | 0.29 | 0.65 | 0.91 | 0.70 | 0.57 | 0.57 | 0.84 | 0.45 |
| Leptin (pg/ml) | 0.80 | 0.35 | 1.0 | 0.56 | 0.13 | 0.49 | **0.003*** | **0.03*** | **0.04*** | 0.05 | 0.05 | **0.01** |

Table legend: * - p<0.005;

**Conclusions:** According to the study, patients with obesity, MS and T2DM have special clinical and laboratory features of progression of OA. Such immunological parameters as serum cytokine concentrations may also be linked with symptoms of OA in patients with aforecited comorbidity. These data should be verified by larger studies.

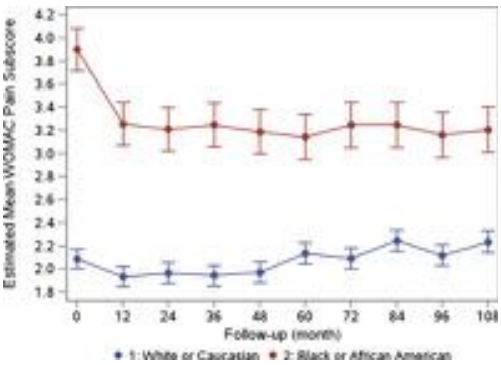
## AB0753 LONGITUDINAL STUDY ON CLINICAL WORSENING OF OSTEOARTHRITIS IN THE KNEE AND HIP OVER 2 YEARS: WORSENING AFTER STANDARDIZED NON-SURGICAL TREATMENT FOR 3 MONTHS IS A STRONG PREDICTOR FOR WORSENING AT 2 YEARS



E.A.M. Mahler[1], A.A. den Broeder[1], J.W.J. Bijlsma[2], G.F. Snijders[1], F.H.J. van den Hoogen[3], C.H.M. van den Ende[1]. *[1]Department of Rheumatology, Sint Maartenskliniek, Nijmegen; [2]Department of Rheumatology and Clinical Immunology, University Medical Centre Utrecht, Utrecht; [3]Department of Rheumatology, Radboud University Medical Centre, Nijmegen, Netherlands*

**Background:** Despite the high incidence of clinically established knee and hip osteoarthritis (OA), few data are available on risk factors for clinical worsening.
**Objectives:** The aims are 1) to estimate the proportion of symptomatic knee and hip OA patients showing worsening at 2 years, after 3 months standardized conservative treatment, 2) to estimate the additional value of clinical criteria at 3 months in prediction worsening at 2 years compared to baseline values only.
**Methods:** All 302 patients in this longitudinal study in secondary care (CONTROL-PRO: patients fulfilling clinical ACR criteria for knee or hip OA and not yet deemed eligible for arthroplasty), received conservative treatment (the first 3 months standardized) which comprised education, physical therapy, step up analgesics and advice on weight reduction if indicated. The Western Ontario and McMaster Universities of Osteoarthritis Index (WOMAC) was used to measure pain and physical functioning as well as a numeric rating scale measuring patient global assessment. Measurements were performed at baseline, 3 months and 2 years. Worsening at 2 years was operationalized as fulfilling recently validated clinical worsening criteria for knee and hip OA or total joint replacement (TJR) in the index joint. Logistic regression was used to estimate the additional value of the determinant fulfilling clinical worsening at 3 months as predictor for worsening at 2 years.
**Results:** Baseline characteristics were 66% female, a mean age of 55.0 (SD 9.8) years, and median BMI of 27.9 kg/m$^2$ (IQR 25.3–32.9). Median duration of symptoms was 3.8 years (IQR 1.6–10.4), the majority addressed the knee joint (84.8%) as index joint and 211 patients (69.9%) had Kellgren and Lawrence scores $\geq$2. A total of 79 (27.8%) and 181 patients (59.9%) clinically worsened at 3 months and 2 years respectively. 75 Out of 181 patients (41.4%) who worsened at 2 years, had undergone a TJR in the index joint on average 1.1 years (SD 0.5) after inclusion. Of these 181 patients who worsened over time, a lower proportion of patients underwent a TJR of the knee than a TJR of the hip in their index joint (34.5% versus 72.7% respectively, $p<0.0001$). Patients who clinically worsened at 3 months showed an increased odds ratio of 5.8 to clinically worsen at 2 years as well (95% CI 2.2–15.6, $p<0.001$). Similar results were obtained when only TJR at 2 years as outcome measure was used.
**Conclusions:** A high proportion of knee and hip OA patients in secondary care who are not deemed yet eligible for surgery at inclusion, showed clinical worsening over 2 years, even after conservative treatment. At 2 years, we observed relatively less TJRs for knee OA than for hip OA. Our results show that clinical worsening at 3 months is a strong independent risk factor for worsening at 2 years. A short conservative treatment trial could thus be used in clinical practice to select patients in whom TJR should be considered.

## AB0754 RACIAL DIFFERENCES IN KNEE OSTEOARTHRITIS PAIN, SYMPTOMS AND DISABILITY REPORTING

E.R. Vina[1], D. Ran[2], E. Ashbeck[1], C.K. Kwoh[1]. *[1]Rheumatology; [2]Biostatistics, University of Arizona, Tucson, United States*

**Background:** Manifestations and severity of knee osteoarthritis (KOA) vary across racial groups. Characterizing this variability allows identification of vulnerable groups and customizing interventions accordingly. Pain and functional limitations tend to be greater among African-Americans (AAs) than Whites (WHs) with KOA. Differential progression in KOA symptoms by race has not been well-described.
**Objectives:** To compare progression over 9 years in reported pain, disability and other symptoms of AAs and WHs with or at high-risk of KOA
**Methods:** Data from baseline to 108 months were gathered from the Osteoarthritis Initiative (OAI). The study rationale and inclusion criteria for OAI (people ages 45–79 with symptoms of and/or radiographic KOA, or with risk factors for developing KOA) have been described (http://oai.epi-ucsf.org/datarelease/). All AA and WH subjects were included in the study. Knee pain, disability and other OA symptom trajectories were based on: 1) WOMAC pain subscale score [range: 0–20], 2) Knee pain severity in the past 30 days based on a numerical rating scale (NRS) [range: 0–10], 3) WOMAC disability subscale score [range: 0–68], and 4) Knee Injury and Osteoarthritis Outcome (KOOS) other symptoms score [range: 0–100]. Higher scores indicate greater OA-related pain/disability in all measures, except for KOOS symptoms score. Mixed effect models for repeated measures were used to test for racial differences in mean values and mean change during follow-up. All models were adjusted for age, sex, body mass index [BMI], and education.
**Results:** A total of 3790 WH and 874 AA OI participants were included, and the majority (58.4%) were female. Mean (SD) age at baseline was 61.2 (9.2) years, and mean (SD) BMI was 28.7 (4.9) kg/m$^2$. Baseline WOMAC pain subscale score was higher in AAs (mean 3.90 [95% CI: 3.72 to 4.08]) in comparison to WHs (mean 2.09 [95% CI: 2.00 to 2.18]) ($p \leq 0.0001$). After the second administration of the questionnaires 1-year post-baseline, there was a significantly greater decline in mean WOMAC pain score among AAs compared to WHs (-0.64 [95% CI: -0.79 to -0.50] vs. -0.15 [95% CI: -0.22 to -0.08]; $p < 0.0001$), while the mean pain levels remained relatively stable between the 1 year and 9 year follow-up visits (Figure 1). Trajectories of mean pain severity measured with a NRS, WOMAC disability, and KOOS symptom score had similar patterns, with a significantly greater decline among AAs from baseline to the first year of follow-up, followed by relatively stable group means. Change in mean scores over the first year of follow-up for AAs, in comparison to WHs, were as follows: pain severity (-0.70 [95% CI: -0.83 to -0.56] vs. -0.14 [95% CI: -0.20 to -0.08]; $p < 0.0001$), WOMAC disability score (-1.70 [95% CI: -2.15 to -1.25] vs. -0.79 [95% CI: -0.99 to -0.58]; p=0.0003) and KOOS other symptoms score (2.16 [95% CI: 1.52 to 2.80] vs. 1.18 [95% CI: 0.89 to 1.48]; p=0.0064).

**Conclusions:** The results suggest that AAs report a precipitous drop in KOA-related symptoms between first administration at baseline and second administration 1 year later. Self-reported measures of symptoms are accepted as primary endpoints in randomized controlled trials (RCTs) and commonly used in observational studies. The implications for RCTs that rely on changes in these measures to demonstrate drug efficacy include obscured treatment effects among AAs, as well as biased selection for trial eligibility.

## AB0755 THE PREDICTIVE ROLE OF HIGH SENSITIVE C-REACTIVE PROTEIN AND HIGH DENSITY LIPOPROTEIN IN DEVELOPMENT OF ROTATOR CUFF TEAR IN PATIENTS WITH HAND OSTEOARTHRITIS

H.-O. Kim[1], Y.S. Suh[1], Y.-H. Cheon[2], K.S. Park[3], S.-H. Kim[4], S.-I. Lee[2]. *[1]Internal Medicine, Changwon Gyeongsang National University School of Medicine, Changwon; [2]Internal Medicine; [3]Preventive Medicine, Gyeongsang National University School of Medicine, Jinju; [4]Internal Medicine, Dongsan Medical Center, Keimyung University, Daegu, Korea, Republic Of*

**Background:** Rotator cuff tear (RCT) and hand osteroarthritis (HOA) are commonly accompanied because they share a similar pathogenesis. However, there was no previous study investigating the relationship between RCT and HOA.
**Objectives:** To estimate the prevalence and associated factors of RCT in patients with HOA.
**Methods:** In this study, we enrolled 1150 farmers who lived in Gyeongnam province in Korea from June 2013 to December 2015. Physical examinations were performed by rheumatologists and orthopedists. Plain radiography of hands and magnetic resonance imaging (MRI) of shoulders were performed in all participants. Serum levels of high sensitive C-reactive protein (hsCRP) and high density lipoprotein (HDL) were checked. RCT was diagnosed by clinical examination and MRI findings. Diagnosis of HOA was made by the 1990 American College of Rheumatology classification criteria. Severity of HOA was defined as Kellgren–Lawrence (KL) grade $\geq$3 on plain radiographs. Erosive HOA was defined as having eroded 'E' or remodelled 'R' phase of the Verbruggen.
**Results:** The prevalence of RCT was higher in patients with HOA group (192/307, 62.5%) than those without HOA (410/827, 49.5%, $p < 0.010$). Among 307 with HOA, patients with RCT were older (62.69±7.04 vs. 59.11 ±7.69, $p < 0.001$) and showed higher hs-CRP (1.51±3.78 vs. 0.67±0.70, p=0.004) and lower HDL levels (55.66±15.46 vs. 60.48±12.45, p=0.003) compared to those without RCT. There were no significant differences in gender, smoking, comorbidities, work period, body mass index, number of affected joints, HOA severity, and prevalence of erosive HOA between both groups. Multiple logistic regression analysis showed significant associations of age (odds ratio [OR] 1.06; 95% confidence interval [CI] 1.02 - 1.10), serum levels of hsCRP (OR 1.37, CI 1.04 - 1.80), and HDL (OR 2.13, CI 1.14 - 3.98) with RCT in HOA patients.
**Conclusions:** The prevalence of RCT is high and age and serum levels of hsCRP and HDL have predictive roles in the development of RCT in HOA patients.

## AB0756 LIVING WITH OSTEOARTHRITIS: REAL LIFE PERCEPTION UPON PAIN AND FUNCTION

I. Saulescu[1], C. Coltoiu[2], A. Neagu[1], A. Borangiu[1], D. Opris[1], S. Daia-Iliescu[1], V. Bojinca[1], A. Balanescu[1], R. Ionescu[1]. *[1]Internal Medicine and Rheumatology, UMF Carol Davila, Sf. Maria Hospital, Bucharest; [2]Internal Medicine and Rheumatology, UMF Carol Davila, Bucharest, Romania*

**Background:** Osteoarthritis (OA) is a prevalent condition for which treatments are based on analgesia and physical therapies. Despite that, most of the patients continue to have pain and limited function influencing there day by day life.
**Objectives:** Our objective was to evaluate pain perception in a cohort of participants, diagnosed with osteoarthritis.
**Methods:** 75 patients with osteoarthritis were enrolled in this study, conducted in Sf. Maria Hospital between 1 June and 30 December 2015. All patients signed an informed consent approved by local ethic committee. Data about demographics, joint involvement and treatment were collected. All patients completed a HAQ evaluation and a Visual Analogue Scale (VAS) for pain (0–10). We developed a questionnaire in order to capture patient perception about osteoarthritis symptoms and how this disease impact there life. They were asked about how pain interfere with usual activity (work, preparing meal, house kipping), with social activity (family interaction, friends) or how they perceived pain or efficacy of the treatment in the last month. They were also asked about there expectations related to this disease. Statistical analysis was made with SPSS.
**Results:** Mean age at evaluation was 63 with a female predominance (83%). 89.3% were taking NSAIDs and 73.3% acetaminophen. Functional status evaluated by HAQ showed that 24% patients had a score of 0, with 57% having a score of 1 and 19% a score of 2. VAS for pain was at least 5 for more than 80% of patients, despite treatment. Higher VAS was significant more frequent in female patients (p 0.001), in patients with family history of osteoarthritis (p 0.023) and in the one with sedentary life style (p 0.035). Most of the patients considered that pain interfere with daily activity, the impact being evaluated as moderate for 46.67% of patients and severe for 32%. Pain also had a negative impact on their social life, the percentage for moderate disturbance being of 38.67% and 18.67% for severe one. Only 11% of patients consider that the pain control is well managed. Despite these results, 40% of the patients do not expect that there quality of life will improve in the future.
**Conclusions:** Residual pain after treatment is present in most of the patients with osteoarthritis and these interfere significantly with daily living and quality of life. These patients enter in a vicious cycle related to worsening pain – low physical activity. Although this findings, there is a resumption of these patients in front of the disease.

## AB0757 CLINICALLY IMPORTANT IMPROVEMENT THRESHOLDS FOR HARRIS HIP SCORE AND ITS ABILITY TO PREDICT REVISION RISK AFTER PRIMARY TOTAL HIP ARTHROPLASTY

J.A. Singh [1], C. Schelck [2], S. Harmsen [2], D.G. Lewallen [2]. *[1]Birmingham Veterans Affairs Med Ctr and University of Alabama at Birmingham, Birmingham; [2]Mayo Clinic, Rochester, United States*

**Background:** Harris Hip Score (HHS) is the most commonly used instrument in the assessment of total hip arthroplasty (THA). Clinically meaningful thresholds for HHS have not been defined; limited data exist on responsiveness.
**Objectives:** To examine the clinically meaningful change thresholds, responsiveness and predictive ability of the Harris Hip Score (HHS) questionnaire.
**Methods:** We included a cohort of patients who underwent primary total hip arthroplasty (THA) and responded to HHS preoperatively and/or at 2- or 5-year post-THA to examine the clinically meaningful change thresholds (Minimal clinically important improvement, MCII; and moderate improvement), responsiveness (effect size (ES) and standardized response mean (SRM)) based on pre- to post-operative change and its predictive ability at 2- and 5-years post-THA for future revision.
**Results:** 2,667 patients with mean age of 64 years completed baseline HHS; 1,036 completed both baseline and 2-year and 669 both baseline and 5-year HHS. MCII and moderate improvement thresholds ranged 15.9–18 points and 39.6–40.1 points, respectively. ES was 3.12 and 3.02 at 2- and 5-years; respective SRM was 2.73 and 2.52. Compared to patients with HHS scores of 81–100 (score range, 0–100), patients with scores $<55$ at 2- and 5-years had higher hazards (95% confidence interval) of subsequent revision, 4.34 (2.14, 7.95; $p<0.001$) and 3.08 (1.45, 5.84; p=0.002), respectively. Compared to HHS score improvement $>50$ points from preoperative to 2-years post-THA, lack of improvement/worsening or 1–20 point improvement were associated with increased hazards of revision, 18.10 (1.41, 234.83; p=0.02); and 6.21 (0.81, 60.73; p=0.10), respectively.
**Conclusions:** HHS is a valid measure of THA outcomes, is responsive to change and predictive of revision risk post-primary THA. We have defined MCID and moderate improvement thresholds for HHS in this study.

## AB0758 THE RELATIONSHIPS BETWEEN BONE MINERAL DENSITY AND RADIOGRAPHIC FEATURES OF HAND OR KNEE OSTEOARTHRITIS IN OLDER ADULTS: DATA FROM THE DONG-GU STUDY

K.-E. Lee, L. Wen, Y.-R. Yim, J.-E. Kim, J.-W. Lee, D.-J. Park, S.-S. Lee. *Rheumatology, Chonnam National University Medical School, Gwangju, Korea, Republic Of*

**Objectives:** The relationship between osteoarthritis (OA) and osteoporosis has exhibited contradictory features over the past four decades. The aim of this study was to evaluate this relationship using separate analysis of the radiographic features of OA whether various radiographic features of OA were associated differently with bone mineral density (BMD) in the Korean elderly.
**Methods:** Data were derived from the Dong-gu cohort; 2,354 subjects were enrolled in the present cross-sectional study. Baseline characteristics, the BMDs of the lumbar spine and femoral neck which was measured by DXA, and X-rays of knees and hands, were collected. A semi-quantitative grading system was used to estimate the severities of individual radiographic features. We adjusted for confounders using multiple linear regression modeling to analyze the relationships.
**Results:** After adjustment for confounders, hand and knee OA total scores were negatively associated with the BMDs of the lumbar spine and femoral neck, except for the total knee OA score and lumbar spine BMD. In detail, hand osteophytes and sclerosis exhibited positive relationships with the BMDs of the lumbar spine and femoral neck, except for hand osteophytes and femoral neck BMD. On the contrary, however, knee joint space narrowing (JSN), hand JSN, and hand subchondral cysts were negatively associated with the BMD of the lumbar spine and femoral neck. Knee JSN and hand subchondral cysts exerted the greatest effects on BMD.
**Conclusions:** Separate analysis of the radiographic features of OA better reveals associations of OA with the BMD of the lumbar spine and femoral neck.
**Disclosure of Interest:** None declared

## AB0759 RELATIONSHIP BETWEEN COMORBIDITY INDEX AND HEALTH RELATED QUALITY OF LIFE IN SYMPTOMATIC KNEE OSTEOARTHRITIS PATIENT

M. Tarigan [1], B. Setiyohadi [2], E. Dewiasty [1], H. Shatri [1]. *[1]Internal Medicine; [2]Internal Medicine, Rheumatology Division, University of Indonesia, Jakarta, Indonesia*

**Background:** Knee osteoarthritis (OA) is the most prevalent symptomatic OA among adults and is the leading cause of disability.[1] The ultimate treatment goal in such chronic disease is to achieve a good health related quality of life (HRQoL).[2,3] Since knee OA prevalence is increasing throughout age, comorbidity become common condition.[4,5] Comorbidity is presumed as contributing factor unto health related quality of life in knee OA patient.
**Objectives:** To evaluate the relation between comorbidity index and health related quality of life in symptomatic knee OA patient.
**Methods:** This was a cross-sectional study conducted in Rheumatology Policlinic Cipto Mangunkusumo Hospital, Jakarta. HRQol was measured with a self-assessment generic instrument Medical Outcome 36- Items Short Form (SF-36) Health Status Survey (figure 1).[6] Comorbidity index was measured by researcher with Cumulative Illness Rating Scale (CIRS).[7] Bivariate analysis was performed by using Chi-square test and its alternative Fisher Exact Test.
**Results:** Most subjects were woman with mean age of 62,62 years (SD8,02). The most prevalent risk factor was overwight or obesity. Mean value for body mass index in this study was 27,54 kg/m$^2$ (SD 4,44). Eighty six percent of subjects were having poor physical component summary (PCS) of HRQoL. Whereas 72,2% of subjects waere having good mental component summary (MCS) of HRQoL. Ninety eight point seven percent subjects were having $\geq$1 comorbidity(ies). The three top positive comorbidity system were endocrine- metabolic, vascular, and musculosceletal and integument. The median value of comorbidity index was 1,68 (0–2,33) which is resembled moderate comorbidity index. There was no relation has been found in bivariate analysis between comorbidity index and PCS (OR=1,11; CI95%=0,26–4,75), neither with MCS (OR=1,21; CI95%=0,41–3,61).

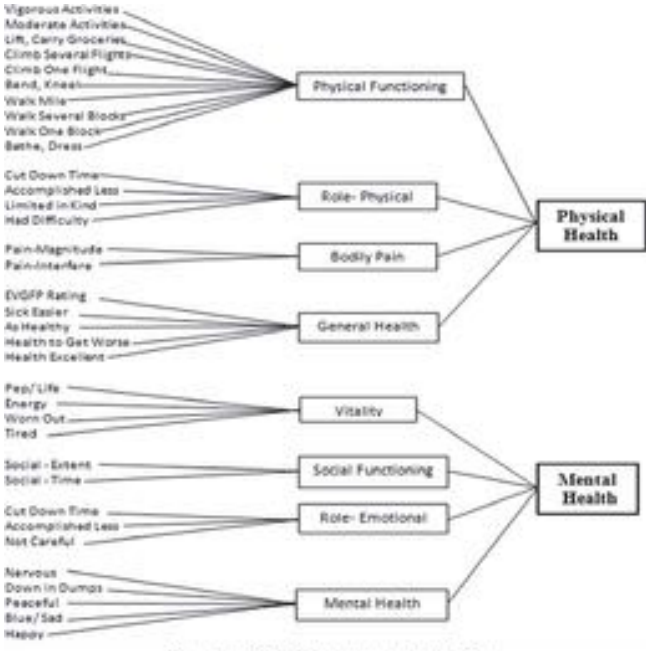

**Figure 1. SF-36 *Measurement Model**
*Ware JE, Sherbourne CD 1992*

**Conclusions:** There is no relation between comobidity index and HRQoL, both physically and mentally component in symptomatic knee OA patients. The homogenicity of comorbidity condition and HRQoL in subjects may contributed to the result.

## AB0760 COMPARISON OF LIFE QUALITY, PAIN INTENSITY AND FATIGUE WITH PATIENTS SUFERRING FROM RHEUMATOID ARTHRITIS AND KNEE OSTEOARTHRITIS

M.S. Karadzic, J.V. Jovanovic. *Rheumatology, Institute of Reheumatology "Niska Banja", Nis, Serbia*

**Background:** It is well known that chronical rheumatoid diseases have negative impact on life quality. Pain and joint swelling, limited motion, stiffness and deformity from one side, as well as fatigue, poor sleep quality and depression, on the other hand, significantly reduce life quality.
**Objectives:** Comparison of life quality, pain intensity and fatigue intensity of patients with rheumatoid arthritis (RA) and knee osteoarthritis (knee OA).
**Methods:** 150 patients have been examined: 75 patients with RA and 75 patients with knee OA. Groups were homogenous regarding gender and age. Life quality has been estimated by means of questionnaire- Short Form Medical Outcomes Instruments (SF 36) SF 36F-physical sphere and SF 36M-mental sphere. Pain and fatigue intensity was estimated by scale VAS.
**Results:** Average value of SF 36F with patients suferring from RA was 35.62±21.73 in regard to patients suffering from knee OA 61.72±18.85, $p<0001$. Average value of SF 36M with patients suffering from RA was 44.79±24.18 compared to patients with knee OA having 68.12±20.77, $p<0001$. Pain intensity with patients with RA was 47.79±24.66 compared to patients with knee OA ranging 46.08±18.82, $p=0.622$. Fatigue intensity with patients suffering from RA was 48.28±25.64 compared to patients with knee OA having 29.23±15.58, $p<0001$.
**Conclusions:** Patients with RA have significantly less quality of life and greater fatigue intensity compared to patients with knee OA. Pain intensity was not statistically significantly different. Although patients with RA have poorer values of quality of life, taking into account a big number of patients with knee OA, a significant implication of this disease is recognized. Pain is significant predictor of poor quality of life.

## AB0761 EFFICACY OF PER-CUTANEOUS ULTRASOUND GUIDED DRAINAGE OF DEGENERATIVE MENISCAL CYSTS IN KNEE OSTEOARTHRITIS PATIENTS

M. Mortada, N. Ezzeldin, M. Hammad. *Rheumatology & Rehabilitation, Faculty of Medicine Zagazig University, Zagazig, Egypt*

**Background:** Meniscal cysts presented in about 4% of patients with knee osteoarthritis [1]. Meniscal cysts may result in pain and disability in the knee. Ultrasound may be used for therapeutic aspiration of the cyst [2].
**Objectives:** To evaluate the efficacy of ultrasound guided percutaneous drainage of symptomatic meniscal cysts in patients with knee osteoarthritis.
**Methods:** Ultrasound guided percutaneous drainage of symptomatic meniscal cysts were performed in 38 patients with Knee osteoarthritis in the period between January 2013 and December 2015. Thirty cysts were related to the medial meniscus and 8 cysts were related to the lateral meniscus. Cysts were injected with local anaesthetic before completion of procedure. All 38 patients were subsequently followed up one month and 6 months after the aspiration with the primary outcome measures were the Western Ontario and McMaster Universities OA Index total pain score WOMAC (a Likert scale), patient global assessment (PGA) questionnaires and musculoskeletal ultrasonography assessment.
**Results:** In every case the procedure was well tolerated. Complete aspiration of the cyst were performed in 15 patients (39.5%) and partial aspiration were performed in 23 patients (60.5%). Before aspiration US meniscal cyst measurements 29.5±9.2 mm * 13.6±4.5 mm. At the end of the 1st month, there was a reduction of 50% in the WOMAC pain score. 89.4% (34 patients) felt that their knee pain had improved compared to baseline. At this time point just US meniscal cyst measurements 19.5±5.2 mm * 11.6±4.1 mm. At the end of the 6th month post aspiration, there was a reduction in the WOMAC pain score of 30%. At this time point just 78.9% (30 patients) felt that their knee pain had improved compared to baseline. At this time point just US meniscal cyst measurements 25.5±6.2 mm * 13.6±3.6 mm. Patient outcomes did not significantly correlate with any meniscal cyst characteristic. Complete aspiration was associated with better outcomes.
**Conclusions:** Ultrasound-guided percutaneous aspiration of degenerative meniscal cysts is a well-tolerated, simple, and safe procedure for patients with knee osteoarthritis.

## AB0762 FFICACY AND SAFETY OF NEM® ARTRO(NEM®-STRATUM NUTRITION) BRAND EGGSHELL MEMBRANE IN PATIENTS WITH KNEE OSTEOARTHRITIS ACCOMPANYING WITH JOINT PAIN AND STIFFNESS. A MULTI-CENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, CROSSOVER STUDY

N. Eskiyurt[1], M. Saridogan[2], K. Senel[3], R. Gunaydin[4], A. Erdal[3], U. Akarirmak[2], O.F. Sendur[5], K. Barut[5], G. Akyuz[6], T. Ozsoy[6], T. Tuncer[7], O. Karatas[7], J. Irdesel[8], A. Ketenci[1], C. Aydagan[9]. *[1]Istanbul University, Istanbul School of Medicine; [2]Istanbul University Cerrahpasa School of Medicine, Istanbul; [3]Ataturk University School of Medicine, Erzurum; [4]Ordu University School of Medicine, Ordu; [5]Adnan Menderes University School of Medicine, Aydın; [6]Marmara University Pendik Training and Research Hospital, Istanbul; [7]Akdeniz University School of Medicine, Antalya; [8]Uludag University School of Medicine, Bursa, Turkey; [9]Pyhtonet, Schindellegi, Switzerland*

**Background:** Traditional treatments for pain and stiffness in osteoarthritis attempt to address only the symptoms associated with the diseases.
**Objectives:** To investigate the efficacy and safety of natural eggshell membrane Natural Eggshell Membrane (NEM) in patients with knee osteoarthritis having joint pain and stiffness.
**Methods:** This study is a Efficacy and Safety of NEM®ARTRO(NEM®-Stratum Nutrition) Brand Eggshell Membrane in Patients With Knee Osteoarthritis Accompanying With Joint Pain and Stiffness. A Multi-center, Randomized, Double-blind, Placebo-controlled, Crossover Study. This study was planned to include 200 female or male patients, however a total of 166 patients were screened and all the 166 patients were enrolled to the study. Median age of the medication group was 53 and in the placebo group was 57. The study was conducted as a multicenter, randomized, double blind, placebo controlled and crossover study. Patients aged $\geq$40 years having osteoarthritis complaints for 1–5 years and grade 2 or 3 knee osteoarthritis were included as 166 patients in total (32 male and 134 female). They were randomly assigned to receive either Natural Eggshell Membrane (NEM®) (drug group) or placebo (placebo group) for 30 days. After the evaluations on day 30, the placebo group was also initiated to Natural Eggshell Membrane (NEM®). Thus, at the end of 90 days, two groups (the 60-day and 90-day Natural Eggshell Membrane (NEM®) treatment groups) were evaluated. For pain and stiffness in patients, VAS and WOMAC scales and for quality of life SF-36 scale was used. The degree of pain and stiffness was evaluated at baseline and days 7, 30, and 90. Quality of life scales were evaluated in the baseline and in the end of treatment.
**Results:** There was no difference between the drug (n=83) and placebo (n=83) groups regarding demographics, baseline clinical findings, and pain (VAS, WOMAC) and stiffness (WOMAC) scores. At the end of 7- and 30-day treatment, the pain and stiffness scores were significantly lower in the drug group than in the placebo group.
A total of 8 adverse events in the medication group and 15 adverse events in placebo group were observed. It was seen that none of the conditions in medication group are serious.
WOMAC pain score has decreased 30% in the first month and 40% in the third month for medication group. VAS score was decreased 22% in the first month and 42% in the third month for medication group. WOMAC stiffness score has decreased 34% in the first month and same in the third month for medication group. SF-36 score was 39 for the first month and 46 for the third month for medication group.
**Conclusions:** In the treatment of patients with knee osteoarthritis, Natural Eggshell Membrane (NEM®) reduces pain and stiffness in early period and provides a significant progress in quality of life and maintains its efficacy in long-term.

## AB0763 DOES DECREASED BONE MINERAL DENSITY AFFECT CLINICAL MANIFESTATION IN KNEE OSTEOARTHRITIS WOMEN?

T. Tarasenko[1], N. Shuba[2]. *[1]polyclinic, Regional Clinical Hospital named after I.I. Mechnikov, Dnipropetrovsk; [2]National Medical Academy of Postgraduate Education named after P.L. Shupyk, Kyiv, Ukraine*

**Background:** Current studies and research support the role of bone mineral density (BMD) in knee osteoarthritis (KOA). However, few studies have focused on its impact on KOA parameters.
**Objectives:** The aim of this study was to investigate if decrease of BMD affect the intensity of pain, functional disability, and radiographic severity in KOA women.
**Methods:** We conducted a cross sectional study including confirmed radiographic knee osteoarthritis according to Kellgren and Lawrence scale, with normal and reduced BMD according to the classification of Report of a WHO Study Group. The two groups were compared on pain Visual Analogue Scale (VAS), Lequesne index, Womac function, and radiological grade after adjusting for significant covariates. Multiple regression analysis was used to identify the independent effects of each specific component for decrease of BMD on knee osteoarthritis parameters.
**Results:** One hundred forty women were included. The mean age was 55,28±8,08 [37–75] years, and the mean BMI was 30,18±2,43 [23–37] kg/m$^2$. The prevalence of decrease of bone mineral density was 55,7%. Women with and without osteoporosis had similar KOA parameters. Multiple regression analyses showed, after adjusting for all covariates, that decrease of BMD had a positive impact on pain VAS (p=0,002) and WOMAC (p=0,003), an indicator of restrictions on daily activity WOMAC (p=0,08), Lequesne index (p=0,001). Noted that lower parameters BMD was significantly associated with high level of CRP (p=0,04).
**Conclusions:** In patients KOA with a concomitant decrease in BMD revealed a distinct pain in the knee by VAS and index WOMAC, a strong indicator of restrictions on daily activity WOMAC, more high Lekena index and a higher level of CRP.
**References:**
[1] In addition to anti-inflammatory therapy, appropriate treatment of osteoporosis needs to become an important management strategy for knee pain and functional impairment.

## AB0764 RADIOGRAPHIC CHARACTERISTICS OF THE HIP MAY PREDICT RESPONSE TO VISCOSUPPLEMENTATION IN PATIENTS WITH HIP OSTEOARTHRITIS. RESULTS OF A PROSPECTIVE OBSERVATIONAL, MULTICENTER, OPEN-LABEL, PILOT STUDY

F. Eymard[1], B. Maillet[2], H. Lellouche[3], T. Conrozier[4] on behalf of OA group of the French Society of Rheumatology and Groupe de Recherche en Rhumatologie Interventionnelle Français. *[1]Rheumatology, Henri Mondor university Hospital, Créteil; [2]Rheumatology, Saint Odilon Clinic, Moulins; [3]Rheumatology, Lariboisière University Hospital, Paris; [4]Rheumatology, Nord Franche Comté Hospital, Belfort, France*

**Background:** Viscosupplementation by intra-articular injections of hyaluronic acid (HA) is used to alleviate pain and improve function in patients with hip osteoarthritis (HOA). However patients the more likely to be satisfied with the treatment are not well defined because predicive factors of success are still lacking.
**Objectives:** To identify radiological predictive factors of response to viscosupplementation (VS) in patients with hip osteoarthritis (HOA).
**Methods:** Prospective, multicenter, open-label trial, performed in daily practice conditions. Patients with hip OA were treated with a single IA injection of crosslinked HA+mannitol (CHAM), using fluoroscopy or ultrasonography guidance. Hip radiographs at baseline were scored by a single experienced observer using Kellgren-Lawrence (KL) grade and OARSI score for joint space narrowing (JSN), osteophytes and subchondral changes. Hips were classified according radiographic features such as JSN location (supero-lateral, supero-medial, axial, diffuse, posterior) and architectural abnormalities (dysplasia, coxa profunda, femoro-acetabular impigement FAI). Pain and function were assessed at baseline and day 90 using WOMAC index. Satisfaction with the treatment, decrease in analgesics consumption throughout the follow-up, and treatment efficacy were self-assessed by the patients at day 90. Association between these features and response to treatment (pain improvement>50% versus baseline) were assessed in univariate analysis, and then using logistic regression, adjusting confounded variables
**Results:** One hundred patients (59 females, 41 males, mean age 62) were included in the trial. Hip OA was bilateral in 39 patients. The median (range) WOMAC pain and function at baseline were 26 (7–42) and 79 (9–134) respectively. Response to treatment was obtained in 60 patients without any difference regarding gender, age and BMI but was better in the most symptomatic patients (p=0.014). In the 80 patients who completed the trial with fully available radiographic and clinical data, efficacy was inversely related to KL grade (p=0.02). Furthermore the percentage of success was highly dependent on the radiographic features. Regarding JSN severity, response was obtained in 100%, 59%, 55%, 41% of the cases for grade 0,1, 2 and 3 respectively. Regarding the femoral head migration, better results were obtained in axial (65%) and supero-medial (62%) JSN than in supero-lateral JSN (50%). Response was also more likely to be obtained in case of FAI (62%) and coxa profunda (69%) than in hip dysplasia (40%).
**Conclusions:** This pilot study, which need further confirmation by larger scale trials, suggests that radiological features might be of high importance for the decision of viscosupplementation in patients with hip OA.

## AB0765 IDENTIFICATION OF NEUROPATHIC PAIN COMPONENT IN PATIENTS OF VARIOUS AGE WITH KNEE OSTEOARTHRITIS

V. Povoroznyuk, U. Pryimych. *D.F. Chebotarev Institute of Gerontology Nams Ukraine, Kyiv, Ukraine*

**Background:** Osteoarthritis-induced pain is a result of nociceptor stimulation, associated with local tissue damage and inflammation. Resent data suggest the presence of neuropathic pain symptoms in patients with osteoarthritis.
**Objectives:** The aim of this study was to estimate the structure of pain syndrome, reveal the presence of neuropathic pain (NP) component, symptoms and signs of NP in patients suffering from knee osteoarthritis.
**Methods:** We've examined 44 patients with knee osteoarthritis of the II-III stages by the Kallgrene-Lawrence scale aged 47–85 years (average age 66,1±1,5 years). Patients were divided according to age into next groups: 47–60, 61–74, 75–85 years. To assess the NP component, we used screening scales painDETECT, LANSS, DN4 questionnaires. To assess intensity of pain, visual analogue scale (VAS) was used. Besides WOMAC and EuroQol-5D questionnaire were applied. For statistical analysis of results, ANOVA, correlation and regression analysis, chi square ($\chi^2$) were applied.
**Results:** 72,7% of patients with knee osteoarthritis examined by painDETECT were unlikely to have the NP component, 22,7% might possibly, 4,6% – probably. LANSS scale: 25% were probably to have NP. DN4 scale: 31,2% probably had NP. Moderate to significant correlations were found between intensity of pain by VAS data and Neuropathic Pain Scales (painDETECT, LANSS, DN4) data (p<0,05). It was established than higher results of screening by painDETECT and DN4 positively correlate with a disturbance of physical function tested by WOMAC (p<0,05). PainDETECT data have moderate to significant correlations with EuroQol-5D questionnaire (p<0,01). Verbal descriptors as pins and needles, tingling, numbness and allodynia, pain from light touch which are revealed by 3 screening scales can significantly contribute to the likely neuropathic component in patients with knee osteoarthritis (p<0,05). Burning pain (p<0,01), pins and needles (p<0,05) can be associated with a more severe pain in patients with knee osteoarthritis.
**Conclusions:** Thus, in patients with osteoarthritis the pain syndrome may reveal NP features. Identification of these would promote a targeted treatment strategy.

## AB0766 BAKERS' CYST AND TIBIOFEMORAL ABNORMALITIES ARE MORE DISTINCTIVE MRI FEATURES OF SYMPTOMATIC OSTEOARTHRITIS THAN PATELLOFEMORAL ABNORMALITIES

W. Visser[1], B. Mertens[2], M. Reijnierse[3], J.L. Bloem[3], R. de Mutsert[4], S. le Cessie[4], F.R. Rosendaal[4], M. Kloppenburg[1]. *[1]Rheumatology; [2]Medical Statistics and Bio-informatics; [3]Radiology; [4]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** In knee osteoarthritis (OA) structural abnormalities can be present in all joint tissues and compartments. These abnormalities are not OA specific and co-occur in different joint locations. Which structural abnormalities can identify symptomatic OA is unclear.
**Objectives:** We investigated magnetic resonance (MR) abnormalities in the knee that can discriminate best between individuals with and without symptomatic OA.
**Methods:** The Netherlands Epidemiology of Obesity (NEO) study is a population-based cohort including 6671 individuals aged 45–65 years, of which 1284 participated in a MR imaging sub-study. Structural abnormalities (osteophytes, cartilage loss, bone marrow lesions (BMLs), subchondral cysts, meniscal abnormalities, effusion, Baker's cyst) at 9 patellofemoral and tibiofemoral locations were scored using the knee OA scoring system. Symptomatic OA in the imaged knee was defined following the ACR criteria.
The relation between structural abnormalities on different locations within the joint was visualized by network graphs, constructed using R, by estimating a sparse inverse covariance matrix using a lasso penalty, based on the pooled variance-covariance matrix across the entire study population. Logistic ridge regression analyses using a double cross-validatory approach were used to investigate which MR abnormalities discriminate best between individuals with and without symptomatic OA, taking co-occurrence of all abnormalities into account. Higher

regression coefficients reflect better discrimination between presence or absence of symptomatic OA. Analyses were performed crude and adjusted for age, sex and BMI.
**Results:** In the sub-study (55% women, median age 56 years (IQR 50–61), BMI 30.0 kg/m$^2$ (27.9–33.0)) 177 participants had symptomatic knee OA.
All MR abnormalities except for subchondral cysts were highly frequent both in individuals with and without OA. The network graphs showed relations between osteophytes within all compartments of the knee and between cartilage defects on different locations. Within the same compartment, osteophytes and cartilage defects were related.
Baker's cysts showed the highest regression coefficient (0.293) for presence of symptomatic OA, followed by osteophytes and BMLs in the medial tibiofemoral compartment (0.185–0.279), osteophytes in the medial trochlear facet (0.262), and effusion (0.197). After adjustment for age, sex and BMI, the same abnormalities identified OA best. The area under the curve of the logistic ridge regression model including all assessed abnormalities was approximately 0.7. The figure illustrates which abnormalities best identify symptomatic OA (A: Baker's cyst, effusion, osteophyte in medial trochlear facet, B: osteophytes in medial femoral condyle and medial tibial plateau, C: BMLs in medial femoral condyle and medial tibial plateau).

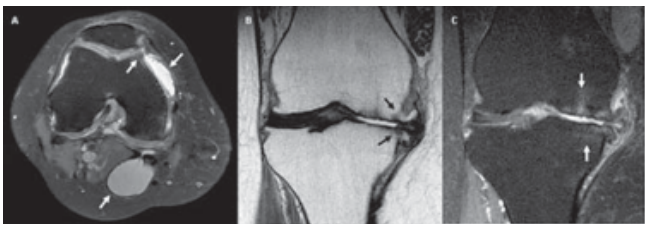

Figure 1

**Conclusions:** Baker's cysts discriminate best between individuals with and without symptomatic knee OA. Especially structural abnormalities as osteophytes and BMLs in the medial side of the tibiofemoral joint and effusion add further in discriminating symptomatic OA. Presence of Baker's cysts may present as a target for treatment.

### AB0767 EFFECT OF CHONDROITIN SULFATE ON SOLUBLE BIOMARKERS OF OSTEOARTHRITIS: HOW TO ANALYZE AND INTERPRET THE RESULTS FROM AN OPEN-LABEL TRIAL IN UNILATERAL KNEE OSTEOARTHRITIS PATIENTS

I. Möller[1], M. Gharbi[2], H. Martinez[3], M. Herrero[3], J. Verges[3], Y. Henrotin[4]. *[1]Poal Institute of Rheumatology, Barcelona, Spain; [2]Artialis SA, GIGA Tower, CHU Sart-Tilman, Liège, Belgium; [3]Clinical R&D Area, Bioiberica S.A., Barcelona, Spain; [4]Bone and Cartilage Research Unit, Arthropôle Liège, Institute of Pathology, CHU Sart-Tilman, Liège, Belgium*

**Background:** Changes in the level of biomarkers specific of osteoarthritis (OA) could help not only for the diagnosis but also for the monitoring of the disease progression and efficacy of a therapeutic intervention.
**Objectives:** The aim of this study was to investigate the effects of chondroitin sulfate (CS) on the serum levels of biomarkers in patients with knee OA.
**Methods:** Seventy two patients with unilateral symptomatic knee OA were involved in a post-authorization open-label study. Patients treated with CS (800 mg/day) were evaluated 5 times from D-30 to 6-month. The primary outcome was the % relative change in serum biomarkers (Coll2–1, Coll2–1NO2, Fib3–2). Secondary outcomes were the evaluation of pain (VAS) and function (Lequesne's Index). Responders and non-responders were classified according to OMERACT-OARSI recommendations. Finally, an original cut-off method was applied to categorize patients and interpret variations in serum levels of Coll2–1.
**Results:** Patients from either ITT or PP populations showed no difference in the serum biomarkers levels at baseline. Most of the biomarkers levels decreased after 1 month of treatment but no significant differences were reported. However when considering responders and non-responders from the ITT population, a significant difference was found for Coll2–1 at 3 months (p=0.030) and 6 months (p=0.038) (ACA approach). A decrease in pain (VAS) and an improvement in function (LI) were recorded throughout the visits ($p<0.01$). The decrease in pain was significant at 1, 3 and 6 months in ITT and PP populations when compared to baseline. The improvement of function was shown to be significant after 6 months. Finally, an intra-batch cut-off of 22% was determined for Coll2–1 assay based on the variation of Coll2–1 between two blood collections in non-arthritic adult subjects. This value allowed the definition of metabolic responders as patients with variation of Coll2–1 by more than 22%.This means that a variation of 22% or less in the serum level of Coll2–1 consisted in a variation related to homeostasis. In contrast, a variation over this limit revealed either an increase or a decrease in cartilage catabolism. Considering these categories, CS decreased Coll2–1 serum levels between baseline and 1-month visit compared to the value of Coll2–1 before treatment (screening visit) which can be interpreted as a drastic reduction of the proportion of patients with an increase of Coll2–1 over 22% (reduction from 13% to 3). It also consisted in a more important proportion of patients with a decrease in Coll2–1.
**Conclusions:** CS was effective modulating the metabolic status of KOA patients trough the reduction of Coll2–1 levels in responders and the disease's symptoms. Biomarkers are important tools for the monitoring of OA disease and of treatment. The main goal in biomarker research is to qualify them as surrogate endpoints in clinical trials. This study proposes a new approach for the analysis and the interpretation of the variation in biomarker levels and introduces the notion of metabolic responders.

## Osteoporosis

### AB0768 PREVALENCE OF LOW BONE MASS IN PATIENT WITH EARLY INFLAMMATORY ARTHRITIS PRESENTING TO EARLY ARTHRITIS CLINIC

A.M. Al Marzooqi, J. Al Saleh. *Dubai Health Authority, Dubai, United Arab Emirates*

**Background:** Low Bone Mineral Density (BMD) was described in patients with inflammatory arthritis. The data on its occurrence at preliminary phase of arthritis onset is insufficient. This study looks into the prevalence of low BMD in patients with early inflammatory arthritis (EIA).
**Methods:** We reviewed the medical records and electronic files of all patients with synovitis who attended rheumatology clinic between 1st December 2012 and 1st June 2015. Cases with features of synovitis less than two years were only included in the study. The following data was captured; demographics, time of symptom's onset, results of Dual-energy X-ray absorptiometry (DEXA) scan, and 25-hydroxyvitamin D level (ng/ml). Data are presented as the median values and interquartile range (IQR). The prevalence was described as a fraction. Mann-Whitney test was used to compare those with low BMD and those with normal BMD.
**Results:** We identified 83 patients with inflammatory arthritis for less than two years only 31 (37.3%) patients underwent DEXA scan. 26 (83.8%) were Emirati's, 27 (87.0%) were females, and median age was 61 (IQR 57 -65 years). 9 (29%) patients had normal BMD (T-score $>$-1.0 S.D), 13 (41.9%) patients had osteopenia (T-score between -1.0 and -2.5 S.D), and 9 (29%) patients had osteoporosis (T-score$<$- 2.5 S.D). Among osteoporotic patients, 4 (12.9%) had osteoporosis at the lumbar spine only, 1 (3.2%) had osteoporosis at neck of the femur, and 4 (12.9%) patients had osteoporosis at both the lumbar spine and neck of the femur. Age was a significant predictor of low BMD in patients with EIA (Z-Score is 2.357, p-value less than 0.02). However, ethnicity, gender, time lag before the initiation of therapy, and vitamin D level did not predict the occurrence of low BMD.
**Conclusions:** Low BMD is a frequent manifestation in patients with EIA, especially in the elder age group. Prospective studies are required to evaluate the long term significance of low BMD in EIA.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2563

### AB0769 ASSESSMENT OF SEQUELS OF POLIOMYELITIS IN HIPS BY 3D-DXA

A. Erra[1], D. Grados[1], L. Lopez-Vives[1], Y. Martelli[2], L. Humbert[2], A. Pasarin[3], N. Allue[3], S. Di Gregorio[4], L. del Rio[4]. *[1]rheumatology, Hospital Sant Rafael; [2]Galgo medical; [3]Rehabilitation, Hospital Sant Rafael; [4]Cetir Grup Medic, Barcelona, Spain*

**Background:** Polio is a devastating infectious disease that causes paralysis and severe muscular atrophy. When any of the legs is affected, a low aBMD at the corresponding hip is a common finding in DXA measurement.
**Objectives:** to study the influence of polio consequences on volumetric bone density and cortical thickness using the 3D-DXA technology.
**Methods:** 22 patients of both sexes suffering post-polio syndromes (mean age 57±uffering pos were scanned using a GE iDXA system and both proximal femurs were reconstructed using the 3D-DXA technology. 3D-DXA is based on the registration of a 3D statistical model of the femoral shape and density onto the 2D DXA image and provides measurements of volumetric BMD (vBMD) and BMCof the trabecular and cortical bone as well as a quantification of the cortical thickness. The measurements at the leg affected by polio were compared by t-test with those at the non-affected leg.
**Results:** Trabecular BMC was 22% lower (-1.8 g, $p<0.01$) and cortical BMC 19% lower (-2.9 g, $p<0.01$) at the polio leg (total hip region). Similar findings were observed for the vBMD: 18% decrease (-0.020 g/cm$^3$, $p<0.01$) at the trabecular region and a 2.3% decrease for the cortical bone (-0.024 g/cm$^3$, $p<0.01$). The proximal femur volume was also inferior (-12%, -9 cm$^3$, $p<0.01$). The cortical thickness was thinner at the polio leg (-12%, -0.2 mm, $p<0.01$).
**Conclusions:** A long period of decreased of mechanical charges, low muscle strength, postural imbalance has dramatic consequences on bone development. The analyses performed using the 3D-DXA technology indicates an overall

impairment of cortical and trabecular BMD and a significant decrease of the cortical thickness.
**Disclosure of Interest:** None declared

## AB0770 SERUM CALCIDIOL, DUAL-ENERGY X-RAY ABSORPTIOMETRY AND LUNG RESPIRATORY TESTS IN PATIENTS WITH INTERSTITIAL LUNG DISEASES

A. Pieren, C. Tornero. *Rheumatology, Hospital Universitario La Paz, Madrid, Spain*

**Background:** Vitamin D plays an essential paper in the regulation of the bone metabolism. Its role in the modulation of the autoimmune system is better known every day as well as its involvement in the pathogenesis of the autoimmune diseases. Some studies have shown a possible implication of the vitamin D in the development of lung diseases, as the interstitial lung diseases (ILD) through the inhibition of the fibroblasts' profibrotic phenotype. Likewise, it's been described a possible association between serum calcidiol levels and a decreased pulmonary function.
**Objectives:** Analyze the prevalence of vitamin D insufficiency. Evaluate a possible relationship between calcidiol levels and lung respiratory tests. Asses the prevalence of low bone mineral density (BMD) and its correlation with risk factors.
**Methods:** Retrospective study of a cohort of patients with ILD referred from the pulmonary consultation. We analyzed demographic and analytics aspects, dual-energy x-ray absorptiometry (DXA), spinal column radiographies, and lung respiratory tests. The statistical study was performed with SPSS.
**Results:** 44 patients were recruited, 68% women with median age 66 years. 45.5% presented an idiopathic ILD (Usual Interstitial Pneumonia (UIP), Nonspecific IP and Cryptogenic Organizing Pneumonia) and 40.1% sarcoidosis. The 20% left was composed by patients with ANCA-Vasculitis (2), Extrinsic Allergic Alveolitis (6) and ILD related to connective tissue diseases (3 Rheumatoid Arthritis). 79.5% had received corticosteroids with a median dose of 5 grams.
The prevalence of vitamin D insufficiency (<30ng/dl) was 81.3%, 42.9% presented calcidiol levels under 20 ng/dl and 6.80% <10ng/dl. The creatinine clearance rate, age and ESR were correlated with calcidiol levels. Upon the studied factors, we found no statistically association between vitamin D levels and lung respiratory tests and neither with the DLCO. By contrast, we did find an indirect association between FVC and trochanteric BMD which was removed by adjustment for sex, age and smoking status.
About the bone density measures, 33.3% presented a normal BMD, 47.6% osteopenia and 19% osteoporosis. BMD was related to the renal function in total hip, wards triangle, trochanter and intertrochanteric region. We established an inverse association between BMD and ESR too. In the subgroup analysis, we found a younger population in the sarcoidosis group with a greater BMD in total hip, trochanter and intertrochanteric region as well as a smaller FRAX index. There were no statistically significant differences in the prevalence of osteoporosis or osteopenia and the subtype of pneumopathy, middle levels of calcidiol and the other bone metabolism parameters.
**Conclusions:** In our patients with ILD, we found a high prevalence of vitamin D insufficiency. Nonetheless, there was no association between calcidiol levels and a worse obstructive pattern as it has been described in other chronic lung diseases. It is especially interesting the indirect correlation established between BMD and ESR, concluding the own disease activity can play a determinant role in the regulation of the bone metabolism.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6038

## AB0771 OSTEOPOROSIS AS A PROGNOSTIC FACTOR FOR SURGERY TREATMENT FAILURE IN HIP FRACTURE PATIENTS TREATED WITH INTERNAL SCREW FIXATION

Ø. Berg[1], G. Haugeberg[2,3], A. Diamantopoulos[4,5]. *[1]Orthopedics, Hospital of Southern Norway Trust, Kristiansand S; [2]Rheumatology, Martina Hansen Hospital, Oslo; [3]Neuromedicine, Norwegian University of Science and Technology (NTNU), Trondheim; [4]Rheumatology, Hospital of Southern Norway Trust, Kristiansand S; [5]Rheumatology, Hospital for Rheumatic Diseases in Haugesund, Haugesund, Norway*

**Background:** Arthroplasty has become the method of choice for the treatment of displaced femoral neck fractures. This because the previous treatment standard using internal fixation had an unacceptable failure rate ranging from 33–45%. One explanation may have been the presence of osteoporosis which is highly prevalent in elderly patients with hip fracture. Less is known about how osteoporosis influences bone healing and the risk of treatment failure in hip fracture patients treated internal screw fixation.
**Objectives:** The aim of this study was to investigate whether osteoporosis may predict failure of displaced femoral neck fractures treated with internal fixation.
**Methods:** Individuals over 60 years of age with a displaced fracture of the femoral neck (Garden 3 and 4) in 2004 and 2005 were retrospectively identified at the Department of Orthopedics, Hospital of Southern Norway Trust in Kristiansand. All patients were operated with two cannulated screws. All patients assessed in the present study had participated in a cross sectional study on hip fracture in southern Norway in 2004 and 2005 (1). The bone mineral density of the non-fractured femoral neck as well as the bone mineral density of the lumbar spine was measured within three days post-operatively by dual-energy x-ray absorptiometry (DEXA). Osteoporosis was defined according to the WHO definition (T-score <-2.5 SD at hip and/or lumbar spine). Potential predictors of hip fracture mortality were tested using univariate and multivariate logistic regression analysis.
**Results:** 145 patients were identified (100 females, 45 males) with a mean age of 80.9 years (females 80.5 years, males 81.6 years). 63 patients (43.4%) suffered of internal fixation failure, 51 (81.0%) of them had osteoporosis. The univariate and multivariate logistic regression analysis including gender, osteoporosis and age groups and the dependent variable of the study (internal fixation failure) are presented in the table 1.

| | Univariate model | | Multivariate model | |
|---|---|---|---|---|
| | OR (95% CI) | P values | OR (95% CI) | P values |
| Gender (ref. male) | 2.46 (1.16–5.23) | 0.02 | 2.27 (1.04–4.92) | 0.04 |
| Osteoporosis (ref no) | 3.01 (1.40–6,48) | <0.01 | 2.79 (1.26–6.15) | 0.01 |
| Age group (ref ≤80 years) | 1.35 (0.68–2.67) | 0.40 | 1.09 (0.52–2.24) | 0.82 |

OR: odds ratio, CI: confidence interval, ref.: reference.

**Conclusions:** Osteoporosis appears to be strongly associated with increased risk of treatment failure in hip fracture patients treated with internal screw fixation. In adjusted analysis, only gender and osteoporosis but not age was associated with treatment failure. Thus, patients suffering of osteoporosis should not be offered internal fixation after a hip fracture. Our results should be confirmed in a large scale prospective study.

## AB0772 PREVELANCE OF OSTEOPOROSIS IN ADULT HOMOCYSTINURIA PATIENTS

A. Mohamed Sathathulla[1], T. O'Neill[1], R. Sharma[2]. *[1]Rheumatology Department; [2]Mark Holland Metabolic Unit, Salford Royal NHS Foundation Trust, Salford, United Kingdom*

**Background:** Homocystinuria is an inborn error of metabolism associated with elevated plasma and urine homocysteine levels. Osteoporosis is a recognised feature of the disease and is thought to be related to defective collagen cross-linkage. Limited data exists, however, concerning levels of bone health in unselected patients with homocystinuria.
**Objectives:** The aim of this analysis was to determine the prevalence of osteoporosis in a cohort of adult homocystinuria patients.
**Methods:** 46 adult homocystinuria patients, mean age 36.9 years, (Standard deviation [SD]=12.9) attending a specialist metabolic medicine clinic at Salford Royal Hospital NHS Trust (Salford, United Kingdom) were identified and retrospective analysis of their medical records performed. Information obtained included data on previous medications, and bone mineral density (BMD) scans which had been performed using Dual energy x-ray absorptiometry (DEXA). Also, when available information about plasma homocysteine levels was obtained.
**Results:** 78% of patients (n=36) had had at least one DEXA scan. The mean lumbar spine BMD Z-score was -0.51 (SD=1.20) and for the total hip site, mean Z-score was -0.36 (SD=1.40). Mean level of plasma homocysteine was 96.6 μmol/Litre (normal range: <16μmol/Litre), (SD=69.7). Using the International Society of Clinical Densitometry (ISCD) criteria (Z-score < -2.0), five (10.9%) patients had evidence of osteoporosis; while using the World Health Organisation (WHO) criteria (T-score < -2.5), only three (6.5%) patients had evidence of osteoporosis. There was no association between either total hip or lumbar spine BMD Z-score and levels of plasma homocysteine.
**Conclusions:** In this cohort of patients with homocystinuria attending hospital clinics, the prevalence of osteoporosis was relatively low.

## AB0773 THE TREATMENT WITH DENOSUMAB PLUS BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATIC CHRONIC DISEASES SHOWED EFFICACY AND SAFETY. A CASE SERIES

B. Hernández-Cruz[1], P. León Rubio[2], E. Rubio[2], M. Lisbona[2], M. Fernández[2], M.J. Valenzuela[2], D. Decán[1], C. Ojeda García[1], M. León[2], A. Ruiz[2], J. Povedano Gómez[3]. *[1]UGC Reumatología, HUVM; [2]UGC COT y Reumatología, HUVR; [3]UGC COT Reumatología., HUVM y HUVR, Seville, Spain*

**Background:** The T2T strategy of treatment in severe inflammatory rheumatic diseases includes the use of biologic DMARDs (bDMARDs). However, the combination of two or more bDMARDs is not recommended due to toxicity, mainly infections. These patients had high risk of osteoporosis (OP) and its treatment is at least as important as the rheumatic disease. For this, the use of the combination of denosumab (DNS) plus bDMARD is increasing.
**Objectives:** To know the prevalence of patients in treatment with DNS + bDMARD. To describe the inflammatory rheumatic disease and the OP. To know the frequency of severe adverse events of the combination.
**Methods:** Design: An observational, retrospective, case series in common clinical practice.
Methods: Nine rheumatologists were trained about design, protocol and data management. They reviewed all the clinical charts of patients with bDMARDs and identified those with at least one prescription of DNS. Of each case 53 variables were filled in a database, and the database was re-reviewed in order to verify the data. The statistical analysis was done with descriptive statistic. The incidence density rate for adverse events was calculated.
**Results:** 1,540 clinical charts were reviewed (569 of the HUVM and 971 of the HUVR), 38 cases of patients with DNS+bDMARD were found. The prevalence was 2.46%. They were female (36, 95%), with RA (28, 74%), SLE (2, 5%), and APs (2, 5%) and others. The mean (p25-p75) age at the rheumatic disease diagnostic was 49 (35–62) years old; the mean age at the OP diagnostic was 61 (54 - 68). The bDMARD were ETN (16, 42%), RTX (9, 24%), ADA (4, 10%), INF (3, 8%), ABA (3, 8%), TCZ (2, 5%) y GOLI (1, 3%) and the duration of the bDMARD treatment was of 60 (25–120) months. In addition, the most common synthetic DMARD used was MTX in 15 (40%) cases, and the dose was 15 mg/week (7.5 – 20). In 26 (67%) cases corticosteroids were used and the dose was 5 mg/day (5–10). Most of them had a mixed OP (glucocorticoid related and postmenopausal), n=26, 72% and in 5 cases the OP was postmenopausal. Fragility fractures (FF) previous to DNS were found in 9 cases (23%). The FF were peripheral (5, 13%); 2 (5%) vertebral FF and 2 (5%) with both of them. The patients received a mean of 3 (2–6) doses of DNS, with a duration of DNS treatment of 14.7 (6 – 37.9) months. The baseline FRAX score calculated without BMD for major osteoporotic FF was 13 (5.6 – 31) and for hip FF was 3.8 (0.7 – 16). The BMD showed T-score of femoral neck of -2.5 (-1.3 - -3.1) and total lumbar of -2.4 (-1 - -3.5). There were three cases of incident FF (5.07 FF x 100 patient/year). The adverse events were three urinary tract infections, and one of soft tissue. The infections were mild and treated with PO antibiotics. The rate was 6,75x 100 patients/year. There were not severe infections, admissions to the emergency room, neither deaths.
**Conclusions:** The frequency of the combination of DNS + bDMARD is low. This combination is used in patients with inflammatory rheumatic disease of a major length, damage and long treatment with steroids. The efficacy of DNS was the expected with no increased in toxicity.

## AB0774 THE EFFECT OF 1 YEAR ORAL IBANDRONATE ON BONE MINERAL DENSITY AND HR QOL – AN OUTPATIENT STUDY IN A SPECIALITY CLINIC IN ALBANIA

B. Hebibasi. *Rheumatology, Policlinic of Specialities No 2, Tirana, Albania*

**Background:** Biphosphonate use is expected to increase Bone Mineral Density (BMD) and reduce the risk of vertebral and non-vertebral fractures. This may also lead to an improvement of Health Related Quality of Life (HR QoL) in the treated patients.
**Objectives:** To confirm the efficacy and safety of 1 year oral Ibandronate, 150 mg monthly. To analyze its effect on patients' quality of life.
**Methods:** 140 postmenopausal patients (average age 65.2 yrs, avg age of menopause 46.8 yrs, avg years from menopause 18.3yrs) diagnosed with osteoporosis (T-score $<$2.5 SD) during 2014 – 2015, were given 150mg of oral Ibandronic Acid monthly and supplements of Calcium and Vitamin D daily. BMD was measured with DXA HOLOGIC at baseline and after 1 year of treatment. HR QoL was assessed through EQ – VAS at baseline and after 1 year.
**Results:** 132 patients completed the study. 5 patients (3.5%) withdrew from the study because of G-I complications, 3 patients (2.1%) did not repeat the DXA. A statistically significant increase of BMD was noted in the lumbar spine, (4.7%, $p<0.001$) and in the hip region (2.9%, $p<0.001$). Patients' perceived health also improved on a Visual Analogue Scale. Median 74 IR 60: 89 compared to median 70 IR 51:86 at the beginning of the study.
**Conclusions:** Oral Ibandronate is safe and effective in increasing BMD in both Hip and lumbar spine. Apart from reducing the risk of fractures, it helps to improve the patients' perceived Health Related Quality of Life.

## AB0775 EFFECTIVENESS OF THE USE OF TRANSDERMAL BUPRENORPHINE THERAPY IN AXIAL PAIN RELATED TO NON-ACUTE VERTEBRAL FRACTURE IN COMPARISON TO OTHER PHARMACOLOGICAL MANAGEMENTS: A RETROSPECTIVE ROUTINE PRACTICE-BASED STUDY IN TERMS OF REDUCTION OF URGENT RECIDIVISM

C.A. Guillen-Astete[1], A. Tentor-Viñas[2]. *[1]Rheumatology Department; [2]Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** Previous studies demonstrated that lumbar and dorsal pain episodes are two to three times more frequent in patients of the same age when a documented vertebral fracture is present. Many treatments have been tested in musculoskeletal pain with different results. There are no studies conducted to compare different therapeutic strategies in back pain treatment related to non-acute vertebral fractures in terms of recidivism in an urgency enviroment.
**Objectives:** To compare the effectivenes of buprenorphine transermal therapy with other level of OMS pain control therapies in terms of urgency recidivism.
**Methods:** A retrospective observational study was conducted. Data was retrieved from the database of registries of A&E department of our hospital and the follow up registries of the rheumatologic and musculoskeletal urgencies unit. No identity data was gathered. Registries included had the following criteria: (1) Al least 60 years old, (2) Radiological demonstration of a previous known vertebral fracture/collapse since at least 3 months, and (3) chief complain related to dorsal or back pain. Patients were grouped according to the treatment at discharge: First scale of the WHO pain treatment ladder (Group I), second scale (Group II) and Transdermal buprenorphine (Group III). Main outcome variable was the time until the need of a further urgent assessment (Kaplan-Meier curve).
**Results:** 180 registries were analyzed. Group I, II and III contained 39, 74 and 67 cases. No demographic statistically significant differences were founded between groups. Group I consisted by patients who underwent treatment with metamizol, paracetamol or both (24), NSAID alone or associated with metamizol or paracetamol (15). Group II consisted by patients who underwent treatment with an average dose of 155mg/day of tramadol (range 37.5–300mg/day) and patients treated with codein (2). Group III consisted by patients treated with 35 mcg/72h of transdermal buprenorphine, 50 mcg/72h (2) and 70 mcg/72h (1). 50% of patients of group III had to be assessed after the 50th day since the first urgent visit (ICR 41–60), while same proportion of patients from group I and II consulted at the 28th (ICR 21–53)and 19th (ICR 10–37) day, respectively. Patients from group I drugs increase their re-assessment rate 4.19 fold (CI95% 2.57–6.80; $P<0.001$) while patients from group II have a 1.91 fold re-assessment rate (CI95% 1.22–2.99, $P=0.005$) compared with group III patients. 3/39, 10/74 and 1/67 patient from groups I, II and III, respectively requested a new urgent assessment due to what was finally interpreted as a prescription side effect. Tramadol users (Group II) had a significantly higher proportion of side effects than transdermal buprenorphine by the first month ($P=0.01$). There were no statistically significant differences between proportions of side effects in patients from group I compared to group III ($P=0.14$)
**Conclusions:** Treatment with transdermal buprenorphine in patients with non-acute vertebral fracture seems to reduce the ratio of further need of urgent re-assessments compared to tramadol or first scale drugs of the WHO-pain treatment ladder.
**Disclosure of Interest:** None declared

## AB0776 IMPROVING ADHERENCE TO OSTEOPOROSIS TREATMENT BY PROMOTING PATIENT INVOLVEMENT IN PHYSICIAN/PHARMACISTS COOPERATION

D. Poivret[1], C. Wilcke[2], V. Noirez[3], C. Goetz[3]. *[1]Unité ETP, Chr Metz Thionville; [2]URPS pharmacist; [3]Chr Metz Thionville, Metz, France*

**Background:** The management of osteoporosis requires multi-years drug treatment and lifestyle changes: maintenance of adapted physical activity, adequate dietary calcium intake, maintaining balance on the ground. It is admitted that adherence to medication does not exceed 50% at one year
**Objectives:** To improve patients follow-up, we have created cooperation between their family doctor and the City pharmacist initiated by the patient himself.
**Methods:** We proposed participation to therapeutic session education to each osteoporotic patient at the end of which we give him a logbook that contains 6 doctor questionnaires and 6 pharmacist questionnaires. The patient remains the owner of the diary, he transmit it to his doctors and his pharmacist twice a year over 3 years. The doctor questionnaire covers the changes in lifestyle; the pharmacist questionnaire covers the medication. Once a year, doctors and pharmacists meet to develop the protocol and addressing diagnostic and therapeutic innovations. The inclusions began in January 2013. We have been able to study the results of the questionnaires one (2014) and two (2015). A nurse and a secretaress call many time ech patient to remain them the project. We conducted a semi led interview with 10 doctors and 10 pharmacists to detect the brakes and levers of successful interprofessional cooperation.
**Results:** Cooperation physicians/pharmacists: the patient initiates cooperation

doctors/pharmacists by providing logbook at regular intervals to both health professionals. Patients play a role in the initiation and continuation of their collaboration. We undertook an exploration work with the anthropological laboratory to investigate the change in the perception of its role by the patient over program. We included 48 patients in 2013. 36/48 continue their treatment at 2 years. Only 1 patient has stopped his treatment without medical reason.
4 patients discontinued treatment for dental care side, 2 for intolerance to any treatment. 9 continue their treatment althougt their physician or pharmacist don't full the questionnaire. 5 don't give any news about them.
The analysis of 73 questionnaires received at one year and 32 questionnaires received at 2 years shows sufficient dietary calcium intake at 2 years to 81% against 84% at one year and a satisfactory for ground balance 75% against 90% at one year. All patients knew at one year the name of their treatment and 96% meet the conditions of the drug taken. 69% do not forget their treatment at two years against 86% at one year thank pharmacist intervention. Only 6% wanted to stop the treatment at 2 years because of side effects, of excessive stresses, lack of noticeable effect, against 17% at 1 year, but they have not stopped after consulting the doctor and/or pharmacist. 25% improved their level of physical activity at 2 years against 14% at one year, 69% were held against 76% at one year.
**Conclusions:** 75% patients continue their treatment at 2 years: the cooperation between doctor and pharmacist induced by the patient has a positive effect on adherence.
**Disclosure of Interest:** None declared

## AB0777 BONE METABOLISM AND OSTEOPOROSIS RISK FACTORS ANALYSIS IN SPINAL CORD INJURY PATIENTS

E. Grau Garcia [1], I. Martínez Cordellat [1], J. Valero Sanz [1], F. Torralba Collados [2], C. Grao Castellote [2], J. Ivorra Cortés [1], L. González Puig [1], I. Chalmeta Verdejo [1], C. Feced Olmos [1], E. Labrador Sánchez [1], F.M. Ortiz Sanjuan [1], K. Arévalo Ruales [1], R. Negueroles Albuixech [1], J. Fragio Gil [1], C. Alcañiz Escandell [1], G. Poveda Marín [1], C. Nájera Herranz [1], V. Fornes Ferrer [3], J. Román Ivorra [1].
*[1] Rheumatology Department; [2] Spinal Cord Injury Unit, HUP la Fe; [3] Biostatistics Unit, IIS la Fe, Valencia, Spain*

**Background:** It is noticed that spinal cord injury (SPI) is a difficult process associated to patient immobilization which leads to bone mass decrease, osteoporosis risk and high risk of bone fracture. In these patients a low bone mass and bone resorption is observed, even in the six months after SPI, and this situation stabilizes over the next 22–26 months after injury. Moreover there is an increased bone fracture risk due to the high risk of osteoporosis.
**Objectives:** To assess bone metabolism and bone fracture incidence in SPI patients.
**Methods:** Prospective study of SPI patients from the Spinal Cord Injury Unit of La Fe Hospital. In all cases lower backs and hips densitometry, spinal cord plain x-ray image, bone metabolism biomarkers and clinical evaluation have been performed. Statistical techniques was carried out using R software 3.2.3.
**Results:** We studied 37 patients with SCI, 46% of them women, with a mean age at SPI of 54.38±24.77 years. The 58.9% of patients showed thoracic injuries, 48.6% paraparesis and 46.7% presented level C in Asia scale. Results from biochemical markers of bone turnover and densitometry are showed in the table.

| | Mean (SD) | | Mean (SD) |
|---|---|---|---|
| Calcium | 9.06 (0.48) | Body-mass index (BMI) | 27.22 (4.2) |
| Phosphorus | 3.84 (0.62) | Lumbar spine DXA (g/cm$^2$) | 2.04 (0.29) |
| Alkaline phosphatase | 202.89 (68.34) | Lumbar spine t-score | –0.39 (2.72) |
| 25-OHVitamin-D | 26.6 (20) | Femoral neck DXA (g/cm$^2$) | 0.82 (0.26) |
| PTH | 34.93 (22.52) | Femoral neck t-score | –0.79 (2.33) |
| P1NP | 70.5 (74.75) | Hip bone DXA (g/cm$^2$) | 0.88 (0.29) |
| bCTX | 0.89 (0.42) | Hip bone t-score | –0.82 (2.33) |

We observed a statistically association between decreased vitamin D values and increased values of bCTX (P=0.002) and PTH (P=0.03). In addition, altered PTH and vit D values are associated with thoracic location of the SCI (P=0.03), total loss of mobility (P=0.02) and high levels in Asia Scale (P=0.004). Also, classic osteoporosis risk factors were evaluated, and they were significantly and inversely related to alcohol consumption (P=0,022), frequent falls in the last year (P=0.02), long-term use of anticoagulants (P=0.006), and altered values of PTH and vitamin D.
**Conclusions:** A high proportion of our SCI patients showed serum vitamin D deficit, associated to high levels of bCTX and PTH. Moreover, patients with the lowest vitamin D levels were more likely to have higher limitation of movement and higher Asia Scale levels.
**Disclosure of Interest:** None declared

## AB0778 TRABECULAR BONE SCORE IS SEVERELY AFFECTED IN MALE PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

E. Casado [1], L. Del Rio [2], M. Gallego [3], M. Arévalo [1], M. Larrosa [1].
*[1] Rheumatology, University Hospital Parc Taulí, Sabadell; [2] CETIR Medical Center, Barcelona; [3] Pneumology, University Hospital Parc Taulí, Sabadell, Spain*

**Background:** Patients with chronic obstructive pulmonary disease (COPD) have a high risk of osteoporosis and fractures. We reported 27% of vertebral fractures in COPD male patients with normal bone mineral density (BMD)[1]. TBS has been described as an index of bone microarquitecture, and could be a new assessment tool to detect bone quality impairment.
**Objectives:** Analysis of TBS in a sub-cohort of male patients with COPD and its possible association with BMD,corticoid use, COPD severity or vertebral fractures.
**Methods:** Male patients, older than 50 years, with COPD were included.Exclusion criteria: Other concomitant pulmonary disease, rheumatologic and/or vertebral disease that may lead to missinterpretation of BMD by DXA.
Exclusion criteria: Other concomitant pulmonary disease,rheumatologic and/or vertebral disease that may lead to missinterpretation of BMD by DXA. BMD wasdetermined by dual-energy X-ray absorptiometry (DXA) at lumbar spine and proximal femur. Vertebralfractures were assessed by thoracic and lumbar X-ray. Corticosteroid use in the previous five years andnumber of hospitalizations were recorded in all patients.
**Results:** We included 98 patients. Mean age 67.8±7.5 years. 38% patients had a mild pulmonar disease, 39% moderate and 23% had a severe disease ((FEV1/FVC<30%). 29 patients (30%) had morphometric vertebral fractures. Mean BMD T-score at lumbar spine -1.67±1.55, at femoral neck -1.81±1.04, and al total hip -1.31±1.14. Mean TBS was 1.035±0,135 (T-score -2.85±1.18). TBS was lower in fractured patients (T -2.59±1.16 vs -2.34±1.22; p=NS). According to COPD severity TBS was lower in patients with modereate disease (T-2.57±1.34) and severe disease (T -2.54±1.34) than in patients with mild disease (T -2.19±1.32), although without reaching significant differences. We didn't find any significant assotiation between TBS and corticosteroid use.
98 patients were included. Mean age 67.8±7.5 years. 41% of patients had mild lung disease and 22% had severe disease (FEV1/FVC <30%). 58% of patients had received corticosteroid therapy in the past 5 years. 29 patients (30%) presented morphometric vertebral fractures. BMD values were: lumbar spine T-score -1.67±1.55, femoral neck T-score -1.81± 1.04, total hip T-score -1.31±1.14. 91% of patients had a degraded or very degraded microarchitecture according to TBS, with a mean value of 1.035±0.135 (T-score -2.85±1.18). Microarchitecture (TBS) was more deteriorated in fractured patients (2.59±1.16 vs T - 2.34 ±1.22; p = NS). TBS was lower in patients with moderate pulmonary disease (2.57±1.34 T) and severe disease (T -2.54±1.34) than in patients with mild disease (T -2.19±1.32, p<0.05). Both, use of corticosteroids and high cumulative dose were associated with lower TBS (p=0.002 and p=0.015 respectively).
**Conclusions:** TBS is severely impaired in male patients with chronic obstructive pulmonary disease, especially in patients with moderate and severe pulmonary disease and those who have received corticosteroids. Although patients with vertebral fractures have a lower value of TBS, this technique does not detect many cases with fracture.

## AB0779 MULTIDISCIPLINARY OUT-PATIENT CLINIC (REUMATOLOGY-ENDOCRINOLOGY) FOR PATIENTS WITH COMPLEX METABOLIC BONE DISEASE: 2 YEARS EXPERIENCE

E. Casado [1], O. Giménez [2], M. Arévalo [1], M. Rigla [2], M. Larrosa [1].
*[1] Rheumatology; [2] Endocrinology, University Hospital Parc Taulí, Sabadell, Spain*

**Background:** Osteoporosis (OP) is a highly prevalent metabolic bone disease and may be secondary to endocrine diseases. In these cases the assessment of a rheumatologist and an endocrinologist may be complementary and beneficial for both the patient and the hospital.
**Objectives:** To describe the experience of two years of a multidisciplinary out-patient consultation Rheumatology-Endocrinology in the care of patients with metabolic bone diseases.
**Methods:** A multidisciplinary outpatient clinic Rheumatology-Endocrinology was set in December 2013 to assess patients coming from one or another specialty with some metabolic bone disease that could benefit from both a rheumatologist and an endocrinologist. The consultation takes place between 12–14h, on a monthly basis. Demographic characteristics, department of origin, diagnosis, complementary tests, and implemented changes in both the diagnosis and treatment were recorded. Data collected during the years 2014 and 2015 are presented.
**Results:** In these 2 years there have been 20 consultation sessions (10 per year), with a total of 103 visits. 54 patients (43 women and 11 men) were treated as first visit. Age 57±15 years (range 29–88). There have been 27 successive visits (ratio first/successive 2/1) and in 22 cases the patients did not attend the appointment. 63% of patients (34) came from Endocrinology and 31% (17) from Rheumatology.

Three patients came from other services (Internal Medicine, Primary Care and Physical Therapy).
Pathologies in order of frequency derived from Endocrinology were OP in the context of primary hyperparathyroidism (29%), hypogonadism (26%), bariatric surgery (15%) and glucocorticoid induced OP (6%). In 6 patients the inquiry was not related to bone metabolism and the diagnoses were: gout, psoriatic arthritis, osteoarthritis, fibromyalgia, among others. The pathologies most frequently derived from Rheumatology were primary hyperparathyroidism (41%), hypogonadism (18%) and adrenal insufficiency in patients with chronic corticosteroid therapy (12%). In 62% of patients referred from Endocrinology and in 65% of patients from Rheumatology underwent some change, either diagnosis or treatment.
**Conclusions:** A multidisciplinary consultation Rheumatology-Endocrinology improves communication between the two specialties and facilitates the standardization of diagnostic and therapeutic criteria. It also represents a convenience for the patient and savings for the hospital, as the number of visits and complementary tests are reduced.

## AB0780 THE INFLUENCE OF DXA INACCURACIES ON THE EVALUATION OF A NEW ULTRASOUND METHOD FOR PROXIMAL FEMUR DENSITOMETRY

F. Conversano[1], M. Muratore[2], A. Greco[3], P. Pisani[1], M. Peccarisi[3], M. Aventaggiato[3], M. Di Paola[1], D. Costanza[2], A. Grimaldi[2], S. Casciaro[1].
*[1]Institute of Clinical Physiology, National Research Council; [2]O.U. of Rheumatology, "Galateo" Hospital, San Cesario di Lecce, ASL-LE; [3]Echolight srl, Lecce, Italy*

**Background:** According to the operational definition provided by the World Health Organization, osteoporosis is diagnosed when bone mineral density (BMD) measured at lumbar spine or proximal femur is at least 2.5 standard deviations lower than the young adult mean. Currently, dual X-ray absorptiometry (DXA) is the most widely adopted method for osteoporosis diagnosis, since it is considered the gold standard for BMD measurements. Therefore, DXA outcomes are often used as the ground truth reference to assess the diagnostic performance of novel alternative approaches that are undergoing clinical validation. However, very recent literature [1] documented that high percentages of clinical routine DXA investigations are typically affected by specific errors altering the final measurement result. This may also have significant effects on the comparative evaluation of the effectiveness of the innovative diagnostic methods under validation.
**Objectives:** To assess the actual diagnostic performance of the Osteoporosis Score (OS), a recently introduced ultrasound (US) parameter for osteoporosis diagnosis on the femoral neck, through a retrospective analysis of the DXA reports of the enrolled patients.
**Methods:** In a previous study [2], we directly assumed the outcome of DXA investigations as the gold standard reference to assess the OS performance for osteoporosis diagnosis on the femoral neck in a population of 170 patients aged in 55–80 years, obtaining an overall accuracy of 84.7% in patient classification (osteoporotic, osteopenic, or healthy) coupled with a good correlation between DXA-measured BMD and corresponding OS-derived values ($r$ =0.71, $p<0.001$). In the present work, we performed a retrospective check of the 170 DXA reports, excluding all those cases presenting a typical DXA error as identified by recent literature (e.g., incorrect patient positioning, presence of artefacts, improper image segmentation, etc.) [1] and re-assessing the actual diagnostic accuracy of our US approach by considering only those patients having a reliable DXA report.
**Results:** 57 patients out of the initial 170 (33.5%) were excluded because of clear DXA inaccuracies. The overall agreement between DXA and OS-based diagnoses on the remaining 113 patients was 93.8% ($r$ =0.79, $p<0.001$), ranging from a minimum of 85.7% ($r$ =0.79, $p<0.001$) to a maximum of 95.6% ($r$ =0.82, $p<0.001$) when single 5-year age intervals were considered. Therefore, undetected DXA errors had resulted in a significant underestimation of OS accuracy in our previous study.
**Conclusions:** The actual potential of the OS-based approach for osteoporosis diagnosis on the femoral neck was previously underestimated. The adopted method for retrospective analysis of DXA reports could be also used to re-assess the performance of different US methods that assumed routine DXA investigations as the gold standard reference.

## AB0781 EFFECTS OF TERIPARATIDE FOR BONE LOSS AND PAIN-RELATED BEHAVIOR IN THE HIND LIMB-UNLOADED MOUSE MODEL OF DISUSE OSTEOPOROSIS

G. Miyamura, H. Wakabayashi, S. Kato, T. Nakagawa, Y. Naito, A. Sudo.
*Department of Orthopaedic Surgery, Mie University Graduate School of Medicine, Tsu City, Japan*

**Background:** Factors of chronic pain due to hemiplegia or prolonged immobility are varied, there is osteoporosis (a rarefaction due to bone atrophy) as the cause. Osteoporotic patients with no evidence of fractures sometimes experience vague lower back pain. However, there have been few reports regarding the correlation between osteoporosis and pain-related behavior. Our previous studies have indicated that hindlimb-unloading induced bone loss and mechanical hyperalgesia in hindlimb of mice. We investigated the effects of teriparatide (PTH) on bone mass and pain-related behaviors in osteoporosis model mice with hindlimb unloading.
**Objectives:** The objective of the current study was to investigate the effect of PTH on bone mass and pain-related behaviors in hindlimb-unloaded mice model of disuse osteoporosis.
**Methods:** Male ddY mice (8 weeks old) were tail-suspended for 2 weeks and assigned to 3 groups; hindlimb-loaded mice treated with vehicle (control), hindlimb-unloaded mice treated with vehicle (HU), hindlimb-unloaded mice treated with PTH (HU-PTH)
(n=8/group). Starting immediately after tail-suspension, vehicle or 40μg/kg PTH was injected subcutaneously twice a week for 2 weeks. The bilateral distal femoral metaphyses and proximal tibial metaphyses were analyzed three-dimensionally by micro-computed tomography (μCT) 2 weeks after tail-suspension. Mechanical sensitivity was also tested using von Frey filaments 2 week after the tail suspension. The withdrawal threshold, the 50% withdrawal threshold and the frequency of the withdrawal response to the application of von Frey filaments to the plantar surface of the hind paws was examined. Measurement of pain-related behavior with von Frey filaments was interpreted as indicative of mechanical allodynia.
**Results:** μCT analysis of the distal femoral metaphysis and the proximal tibial metaphysis showed that significantly decreased bone volume/tissue volume (BV/TV) and trabecular thickness (Tb.Th) in HU compared with HL was significantly increased by PTH treatment. (Fig.1) Similarly, decreased trabecular number (Tb.N) in HU compared with HL was increased, and increased trabecular separation (Tb.Sp) in HU compared with HL was decreased by PTH treatment, but not significant. The paw withdrawal threshold and the 50% paw withdrawal threshold were significantly lower in the HU than in the control, whereas it was significantly higher in the HU-PTH than in the HU group. (Fig.2) The paw withdrawal frequency stimulated by von Frey filaments with strength of 0.4–2.0 g was significantly higher in the HU than in the control. Whereas it was significantly lower in the HU-PTH than in the HU.
**Conclusions:** In this study, treatment of PTH prevented bone loss and mechanical hyperalgesia in disuse osteoporotic animal models by hindlimb-unloading. The results suggest that low bone volume itself is one of the causes of osteoporotic pain.
**Disclosure of Interest:** None declared

## AB0782 TWO-YEAR STUDY OF BONE METABOLISM IN LIVER TRANSPLANT PATIENTS. INFLUENCE OF ANTIRESORPTIVE TREATMENT AND EVALUATIONS BEFORE SURGERY

J. Valero Sanz[1], E. Grau Garcia[1], J. Ivorra Cortés[1], L. González Puig[1], I. Chalmeta Verdejo[1], C. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz Sanjuan[1], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Fragio Gil[1], I. Martínez Cordellat[1], C. Alcañiz Escandell[1], G. Poveda Marín[1], C. Nájera Herranz[1], D. Hervás Marín[2], D. Moya Nájera[3], A. Moya Herraiz[4], J. Román Ivorra[1]. *[1]Rheumatology Department, HUP la Fe; [2]Biostatistics Unit, IIS la Fe; [3]Health and Sport Research Group, UV; [4]Hepatology Department, HUP la Fe, Valencia, Spain*

**Background:** Osteoporosis is a frequent complication in patients with chronic liver disease, especially in end-stage and when there is a history or evidence of chronic cholestasis. But even more important is that liver transplant patients, in the first few months after the transplant there may be an accelerated loss of bone mass, which also means greater osteopenia and osteoporosis incidence and fracture risk.
**Objectives:** To study the effect in bone metabolism of antiresorptive treatments in patients undergoing liver transplantation (LT), as well as an evaluation prior to transplant to decrease the risk of osteoporosis.
**Methods:** We collected patients undergoing LT, where data is available at transplant (month 0) and 6–12–18–24 month follow-up after surgery. We collected data of bone metabolism biomarkers, densitometric and antiosteoporotic treatment. Statistical analysis was carried out using R software 3.2.3.
**Results:** We selected 172 patients with LT, and 56 of them had completed the 24 months follow-up. Of the total cohort, 89.7% are men, with a mean age at transplantation of 57.7±6.7 years. The 89% of patients were supplemented with 25-OHVitamin-D after surgery and during follow-up, the 6.4% initiated treatment with bisphosphonates and 2.3% with denosumab.

Improved vitamin D levels and normalization of the values of PTH, beta-CTX and P1NP were observed. The t-score densitometric value for the first 12 months of follow-up dropped slightly, to increase again at 24 months of follow-up. This situation is still more pronounced in lumbar spine (t-score -1.49±1.29 after surgery and -1.29±1.1 at 24 months of follow-up).
Statistical analysis yield a significant influence of antiresorptive treatment ($P<0.0001$) on the normalization densitometric values, as well as on the normalization of vitD (P=0.003), bCTX (P=0.03) and P1NP (P=0.02). In contrast, obesity correlates with altered densitometric (P=0.003). Finally, there is a clear difference in bone metabolism biomarkers between LT patients evaluated and treated before surgery and those evaluated after surgery ($P<0.0001$).
**Conclusions:** In general, there is a normalization of serum vitamin D levels and biomarkers of bone metabolism in two years after surgery. The use of antiresorptive treatment is crucial to reach with stage, as well as to establish an evaluation before surgery and treat the patient if is required.

## AB0783 OSTEOPOROTIC FRACTURE AS THE MAIN RISK FACTOR IN THE DETECTION OF OSTEOPOROSIS IN MEN UNDER 70 YEARS

J.M. Blanco Madrigal[1], M.L. Garcia Vivar[1], I. Torre Salaberri[1], I. Calvo Zorilla[1], E. Guerrero Basterretxea[1], E. Galindez Agirregoikoa[1], C. Gómez Arango[1], O. Fernández Berrizbeitia[1], E. Ruiz Lucea[1], J.F. García Llorente[1], I. Gorostiza[2]. *[1]Rheumatology; [2]Medical Research, Basurto University Hospital, Bilbao, Spain*

**Background:** Osteoporosis (OP) in male under 70 years is less common than postmenopausal and senile OP, but causes important social and health costs associated with morbidity and mortality from fractures. It's common in patients with inflammatory rheumatic diseases, enteric and endocrine diseases, also in COPD patients and in those undergoing chronic corticosteroid therapy.
Sometimes clinical risk factors of male OP go unnoticed, so the diagnosis is done when one or more low energy mechanism fractures have already occurred (failure in early detection).
Bone Metabolism Unit at Basurto University Hospital values from years ago male patients referred from different specialties with suspected OP.
**Objectives:** To describe main demographic and clinical characteristics of men aged 70 years or less, visited in our monographic OP consultation, with previous to 2013 protocols established with Primary Care (PC) and rheumatology (derivation according to risk factors).
**Methods:** Retrospective descriptive study based on a review of medical records and database of these patients. We analyze origin of derivation, risk factors, presence of fractures at moment of diagnosis, primary diagnoses and occurrence of refractures.
The analysis was performed using statistical system SPSSv22.
**Results:** 127 patients, mean aged 58.17 years (18–70), up to 74% of the total derived from PC (47), and general rheumatology (47); 10 patients (7.9%) from traumatology; 8 from endocrinology (6.3%); 7 from gastroenterology (5.5%).
55.9% were smokers or former smokers, 22% kept drinking habit. 19.7% had received prednisone doses $\geq$7.5 mg for more than 3 months.
9 patients had family history of fracture (6.3%), and 46 themselves presented with one or more fractures (36.2%): 36 with one or more vertebral fractures, 4 hip fracture and 12 wrist fracture. 64 patients were diagnosed of OP with treatment indication by bone agent.
61% have secondary OP, the main cause (19%) enteric disorders (malabsorption syndromes and inflammatory bowel disease); 13% endocrine disorders and rheumatic inflammatory diseases by 13%. No primary cause was found in 39% of cases.
The presence of fractures was associated with decreased DXA lumbar spine (p=0.027) and DXA hip (p=0.004). A very weak correlation between higher fracture FRAX and number of risk factors was detected, on the other hand a moderate correlation was observed with the number of fractures (Spearman Rho =0.472; $p<0.001$). So does to the hip FRAX (Spearman Rho =0.417; $p<0.001$).
Of the 46 patients with previous fractures, only 12 (26%) had received prior treatment with bone agent. Only 5 patients suffered refracture after starting treatment and during follow-up (94.06 months) (25–129).
**Conclusions:** Almost 1/3 of men were referred for fractures caused by low energy impact, what means a late diagnose of male OP.
It's important to establish protocols with other medical specialties for men at risk to be identified and referred, in order to make an early diagnose.
It highlights the lack of patients derived from pneumologists, although vertebral fractures in chronic respiratory patients worsen their functional status and mean a frequent cause of hospitalization in this group.

## AB0784 A STUDY OF SERUM ELECTROLYTE LEVELS AFTER DENOSUMAB ADMINISTRATION

K. Nakaseko, T. Asano. *Kuwana City Medical Center, Kuwana Mie, Japan*

**Background:** Denosumab is a fully human monoclonal antibody that targets the receptor activator of nuclear factor kappa B ligand (RANKL) and blocks its binding to RANK, preventing osteoclasts from resorbing bone mass and significantly reducing the risk of vertebral, non-vertebral, and proximal femoral fractures. One of the major and critical adverse events of denosumab injection is hypocalcemia, which is most often observed in the one-week period following administration. Examination of albumin-adjusted calcium (Ca) level after one week is recommended to exclude the presence of hypocalcemia. Although hypophosphatemia has been reported to be an adverse event with a frequency of more than 1% in patients subcutaneously administered 120mg of denosumab for tumor treatment, there have been no reported data regarding its frequency in patients administered 60mg for osteoporosis. The purpose of the present study was to evaluate the occurrence of denosumab adverse events, focusing on serum electrolyte levels soon after administration, as well as to confirm its efficacy.
**Objectives:** Thirty-one women between the ages of 55 and 91 years with post-menopausal osteoporosis were enrolled and treated with a 60mg subcutaneous injection of denosumab and an oral calcium tablet combined with native vitamin D and magnesium.
**Methods:** Serum Ca and phosphorus (P) were measured at baseline and at 1,2,3,and 4 weeks after administration. The bone resorption marker intact serum procollagen type 1 N-terminal propeptide (P1NP) and bone formation marker tartrate-resistant acid phosphatase-5b (TRAP-5b) were also evaluated at baseline and 4 weeks after administration. Laboratory investigations after a second injection were performed in three patients in the same manner. Bone mineral density (BMD) was measured at baseline and 6 months after administration.
**Results:** Both serum Ca and P electrolyte levels significantly decreased soon after administration. Hypocalcemia was detected in 2 patients: one patient 1 week after administration, and the other 2 weeks after. Hypophosphatemia was observed in 7 patients: 5 patients 1 week after administration and 2 patients after 2 weeks. Hypocalcemia was observed 1 week after the second administration in 1 of the 3 patients. Patients with hypocalcemia and/or hypophosphatemia tended to have a body mass index (BMI) of less than 22.There were no patients who discontinued the treatment due to adverse events in the present study. All serum electrolyte levels recovered within 4 weeks of each administration. At 4 weeks, P1NP level was decreased by 31.7% and TRAP-5b was decreased by 71.3%. At 6 months, BMD of the lumbar spine was increased by 2.0%, the femur by 1.5%, and the distal radius by 0.6%.
**Conclusions:** Hypocalcemia and hypophosphatemia were observed within 1 or 2 weeks after the first and/or second administration of denosumab. Therefore, measuring serum electrolyte levels of Ca and P within in 1 or 2 weeks is strongly recommended for the detection of hypocalcemia and hypophosphatemia. Adverse events were not observed clinically throughout the duration of the study period. However, denosumab administration to individuals with a BMI less than 22 may carry a risk of hypocalcemia and /or hypophosphatemia. Furthermore, denosumab administration resulted in a low bone remodeling ratio reflected by decreases in both P1NP and TRAP5b levels, and increase in BMD, which may reduce fracture risk.

## AB0785 RELATIONSHIP BETWEEN METABOLIC SYNDROME AND ITS COMPONENTS WITH BONE DENSITY IN MENOPAUSE WOMEN

M. Abbasi[1], Z. Yazdi[2], S.A. Farzam[1], Z. Mamaghani[1]. *[1]metabolic disease research center, Qazvin University of Medical Sciences, Qazvin, Iran; [2]social determinanats of health, Qazvin, Iran, Islamic Republic Of*

**Background:** Prevention of osteoporosis and bone fracture and the relationship between metabolic syndrome and bone density are controversial issues.
**Objectives:** The present study aimed to investigate metabolic syndrome and its components and the association with bone mineral density in post menopausal women referring for bone mineral density (BMD) test.
**Methods:** A total of 143 postmenopausal women with at least one year of menopause experience participated in this cross-sectional study. Demographic and anthropometric characteristics for all participants were collected. Biochemical parameters including fasting blood sugar, Cholesterol (HDL and LDL), triglyceride were also measured prior to BMD test. Afterwards, association between the components of metabolic syndrome and bone densitometry were analyzed using statistical methods.
**Results:** In this study, 72% of participants did not have metabolic syndrome. Among them, 43.4% and 28.7% had osteoporosis and normal density, respectively. Of the remaining28% with metabolic syndrome 12.6% had osteoporosis and 15.4% had normal density. Among the metabolic syndrome components, waist circumference, HDL cholesterol, and waist to hip ratio were found to be significantly associated with bone mass ($P<0.05$). Osteoporotic women had lower waist circumference and waist to hip ratio and higher HDL than women without osteoporosis. In contrast, women with metabolic syndrome did not have significant differences with women without metabolic syndrome in terms of lumbar and femoral neck densitometry ($P>0.05$).
**Conclusions:** Results from this study showed that metabolic syndrome and its components did not induce bone mass loss. Due to discrepancies of the studies in this area, it seems that more studies are needed so as to make it possible to take some preventive measures in large scale.

## AB0786 ARE WE MANAGING MALE OSTEOPOROSIS ADEQUATELY?

M. Rogers[1], J.S. Gauci[2], J.M. Gauci[2], M. Azzopardi[2], A. Borg[1].
*[1]Rheumatology; [2]Medicine, Mater Dei Hospital, Msida, Malta*

**Background:** Osteoporosis is becoming increasingly recognized as an important public health problem in men, with one in four men over the age of 50 years developing at least one osteoporosis-related fracture in their lifetime.[1]
**Objectives:** The primary aim of our project was to evaluate whether male patients with osteopenia or osteoporosis are being investigated and managed according to the Endocrine Society Guidelines[2] published in June 2012. We also assessed the indications for bone mineral density (BMD) measurements in our cohort.
**Methods:** Patients who had a BMD measurement done at Mater Dei Hospital, Malta, between September and December 2012 were recruited in this study. Information on patient demographics, indication for BMD measurement and other investigations carried out were obtained from the patients' medical notes and iSoft Clinical Manager®.
**Results:** A total of 116 patients had a BMD scan done during the study period. Mean age was 56 years (SD ±15.28). 75.86% (n=88) had at least one documented risk factor for osteoporosis and therefore an indication for BMD measurement. The commonest risk factors were smoking (34.5%), history of long-term corticosteroid use (33.6%) and age above 70 years (18.1%).
49.1% (n=57) had their BMD result recorded in their medical notes. Of these, 24.6% (n=14) were osteoporotic at the hip, and 14.0% (n=8) at the spine. From the cohort of patients with osteoporosis or osteopenia, 40.9% (n=18) had testosterone levels, 27.3% (n=12) had Vitamin D levels, and none had 24-hour urinary calcium levels checked. All patients had a full blood count, calcium, phosphate, renal and liver function tests checked.
77% (n=34) were prescribed calcium supplements and 75% (n=33) also received Vitamin D supplementation. Advice on weight bearing exercise was documented in 22.7% (n=10), whilst advice on smoking cessation was only documented for 12.5% of smoking patients.
Of all cases where bisphosphonate therapy was indicated, 55.6% (n=15) were on treatment. 46.7% (n=7) of patients had a dental assessment prior to starting treatment.
**Conclusions:** Our study has identified that a high proportion of BMD scans are being requested in concordance with guidelines. However, a significant number of patients with osteoporosis remain untreated. This stresses the need of increasing awareness amongst clinicians of current guidelines together with improving our patients' education on lifestyle measures and smoking cessation, in order to avoid potential complications which can result in significant morbidity and also mortality.

## AB0787 SCALES ELDERLY PATIENT GLOBAL ASSESSMENT APPLIED TO ELDERLY PATIENTS WITH HIP FRACTURE

A.M. Gómez Mosquera[1], R.B. Melero González[2], T. Parajes Vázquez[1], C. Barbazan[2], M. Rodríguez López[2]. *[1]Geriatric Service; [2]Rheumatology, Vigo University Hospital (CHUVI), Vigo, Spain*

**Objectives:** Analyze the potential relationship between the risk of hip fracture and the results of the scales Elderly Patient Global Rating geriatric patients.
**Methods:** Retrospective and descriptive study of a random series of 120 patients over 75 years attending emergencies in the University Hospital of Vigo in the year 2013 with a diagnosis of hip fracture. Data collected from medical records that refer to the functional, mental and social value at the time of the event are analyzed.
**Results:** Of the 120 patients analyzed in the study, 92 were women (76.6%) and 28 males (23.3%) with a mean age of 84.53 years. Considering the Elderly Patient Global Assessment in the functional area, according to the scale of disability of the Red Cross in terms of ambulation is concerned, we classified our patients in 6 degrees: grade 0 (normal walking) on 30.83% of patients; Group 1 (wanders with some difficulty) 27.5%; Grade 2 (roams using cane or similar) 17.5%; Grade 3 (roams helped at least one person) 10.83%; Grade 4 (roams helped with extreme difficulty, two people) 6.67%; and grade 5 (immobilization in bed or chair) 6.67%). Regarding the mental sphere in 75% of our patients any cognitive decline is not evidence. Only 10% of them were institutionalized at the time of the fracture.
**Conclusions:** In this series of 120 elderly patients a direct relationship between hip fracture by low-impact crash, and functional, mental and social situation is evident; being at greatest percentage of fractures, those elderly who have difficulty walking or in need of a single support, without any cognitive impairment and who live in residence.
**Disclosure of Interest:** None declared

## AB0788 PREDICTORS OF FRACTURES IN EXCESSIVE CONSUMPTION OF ALCOHOL: AN OBSERVATIONAL STUDY

M. Papp, R. Sinha, M. Bukhari. *University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom*

**Background:** High alcohol intake is a known risk factor for fractures.[1] This association is mediated by a combination of factors including muscle atrophy, unsteadiness and loss of bone mineral density (BMD). Chronic alcohol consumption is common, and predictors of fractures in these patients have not been the object of many studies.
**Objectives:** We used data from a large observational cohort to determine predictors of fractures among chronic heavy drinkers.
**Methods:** A dual X-ray absorptiometry (DEXA) database from a district general hospital in Northwest England was used to identify patients drinking more than the maximum recommended amount of alcohol. Patient demographics, presence of other risk factors and bone mineral density (BMD) at the femoral neck, total proximal femur and L1-L4 lumbar vertebrae were recorded. Univariate logistic regression models predicting fracture risk were fitted using traditional FRAX risk factors for osteoporosis. These include age at scan, female gender, total hip BMD (left and right), femoral neck BMD (left and right), L1-L4 BMD, presence or absence of smoking, rheumatoid arthritis, family history of fracture, steroid exposure and body mass index (BMI). Subsequently a multivariate model was fitted with a cut off value of $p<0.05$ for individual variables.
**Results:** 1794 patients were referred between 2004–2014; of these, 737 (41.1%) had sustained a fracture. Median age at scan was 59.6 years, and 1221 (68.1%) were female. Results of univariate analysis are shown in Table 1.

| Risk factor | Odds ratio | 95% CI |
|---|---|---|
| Age at scan (years) | 1.02 | 1.01, 1.03* |
| Female gender | 1.06 | 0.87, 1.30 |
| Femoral neck BMD (right) | 0.036 | 0.016, 0.079* |
| Femoral neck BMD (left) | 0.046 | 0.022, 0.095* |
| Total hip BMD (right) | 0.036 | 0.017, 0.074* |
| Total hip BMD (left) | 0.035 | 0.017, 0.070* |
| Lumbar spine BMD | 0.094 | 0.054, 0.16* |
| Body mass index (kg/m$^2$) | 0.99 | 0.97, 1.01 |
| Smoker | 1.24 | 1.01, 1.48* |
| Rheumatoid arthritis | 0.71 | 0.40, 1.21 |
| Family history of fracture | 0.85 | 0.65, 1.09 |
| Steroid exposure | 0.58 | 0.46, 0.74 |

In the multivariate model, age at scan, total hip BMD (left), lumbar spine BMD, BMI and steroid exposure were predictors of risk. As in the univariate model, steroid exposure in this cohort appears to reduce the risk of fractures.
**Conclusions:** In the univariate analyses, bone mineral density measured at any site, age and smoking status were predictors. In the multivariate model, the strongest predictors were lumbar spine BMD, BMI and steroid exposure ($p<0.001$), with age and total left hip BMD also significant. In this population, lumbar spine BMD may be a better predictor than hip BMD used in the FRAX risk assessment tool. There may well be an as yet undetermined role of unmeasured confounders, and further research is needed to guide the development of a more accurate risk assessment tool in this population.
Steroid exposure reduces the risk of fractures in both models, which is difficult to explain. Steroid exposure indicates engagement with medical care, which may be less likely amongst the heaviest drinkers, thus creating confounding. Our data does not quantify alcohol consumed, and it is possible that those with significant steroid exposure consume less alcohol overall. Further work is needed to clarify the role of steroid exposure in fracture risk prediction in chronic drinkers.

## AB0789 BMD CHANGE AROUND PROSTHESIS AFTER UNCEMENTED TOTAL HIP ARTHROPLASTY IN RA PATIENTS: 15-YEAR FOLLOW UP

M. Makarov, S. Makarov, E. Byalik, A. Logunov, G. Vardikova, M. Lipina, V. Kolomatsky, V. Pavlov. *orthopaedic department, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** In previous studies we noted that maximum bone loss around total hip prosthesis occurs in first six months after surgery. After six months bone loss becomes slower and in some cases BMD even can increase.
**Objectives:** To study the 15-year follow up changes of BMD in patients with RA.
**Methods:** 282 RA patients were examined at the baseline. At the end of investigation we analyzed 43 patients. DEXA was used for BMD assessment around stem (7 ROIs) and cup (3 ROIs) of prosthesis. First examination was conducted 2 weeks after the operation and repeated at 3, 5, 10 and 15 year after surgery.
**Results:** 3 years after decrease of BMD was -5,8% and -4,9% around stem and cup respectively ($p<0,01$). By 5 and 10 year the bone loss was not significant (-6,1% and -5,5%; -7,1% and -6,3% around stem and cup respectively). 15 years after surgery we observed significant increase of bone loss (-18,9% and -22,7% around stem and cup respectively ($p<0,01$))
**Conclusions:** These data supports our opinion of stress remodeling of bone around hip prosthesis. This phenomenon doesn't stop after 1 year but keep on even 15 years after surgery. This means that all RA patients after THA need to use medication to normalize bone remodeling
**Disclosure of Interest:** None declared

## AB0790 DESCRIPTIVE STUDY OF ZOLEDRONIC ACID TREATMENT IN A HOSPITAL OF THIRD LEVEL. OUR EXPERIENCE

M. Retuerto[1], L. Sierra[2], C. Moriano[1], M. Martín[1], A. García[1], M. Garijo[1], C. Iniguez[1], A. Lopez[1], C. Álvarez[1], E. Díez[1], T. Pérez[1]. *[1]Rheumatology Department; [2]Pneumology department, University Health Care Complex of León, León, Spain*

**Background:** The zoledronate is a bisphosphonate widely used in the treatment of bone pathologies such as the Paget's disease and the osteoporosis, due to its convenient dosage (annual infusion), its rate of therapeutic compliance and its excellent safety profile.
**Objectives:** Our objective in this study is to describe the clinical and demographic features of the patients treated with zoledronate in our hospital over the past five years, according to the different therapeutic indications.
**Methods:** This is a retrospective observational study that has included 186 patients treated with zoledronate at the University Health Care Complex of Leon since January 1st, 2011 to December 31st, 2015. Two of the main therapeutic indications of the drug have included in the study: osteoporosis and Paget's disease of bone. Clinical and analytical data have been obtained from the information reported in the medical record.
**Results:** 186 patients were included, 76.9% female and 23.1% male, with a mean age at the moment of the first infusion of 73,77±10,451 |43–97|. Forty-six of the treatments were indicated for active Paget's disease of bone (26.3%), 136 for osteoporosis (76.1%) and one for osteogenesis imperfecta.
Among the patients treated for Paget's disease of bone, 51% were male and 49% female, presenting the 48% of them monostotic fibrous dysplasia and the 52% of them polyostotic fibrous dysplasia. The mean Alkaline Phosphatase levels (ALP) at baseline was 444.82±292.85 IU/L, receiving an average dose of infusions of 1.12 with SD 0.389. The ALP levels after the infusion of zoledronate decreased to an average value of 91.98±41.94 IU/L within a year. Two of the patients needed reinfusion 4 years after the first infusion. 2% of them had flu-like symptoms and only one patient had post-infusion pathological fracture as complication.
In the group treated for osteoporosis, 18 patients were men and 118 women. 59.1% of the patients required infusion due to abnormal DXA results with -2.5 SD or less, 31.4% of the patients required it due to previous fractures and 7% due to a concomitant use of high dosage of oral steroids (prednisone>10mg/day). The mean dose of infusion in these patients was 2,63±1,38 with a mean bone mass density at the beginning of the treatment of 0,804±0,116 in the lumbar spine and of 0,73±0,128gr/cm$^2$ in the hip. The mean bone mass density after 2 years of treatment was of 0,831±0,114 in the lumbar spine and of 0,767±0,141 in the hip. 54.8% of all patients included in the study had not received prior treatment with oral bisphosphonates, while the remaining 45.2% did receive it (33.3% for <5 years and 11.8% for>5 years).
7 patients had side effects after infusion: 4 mild adverse reactions and 2 severe reactions. Therefore, these patients required the discontinuation of the treatment due to uncomplicated osteonecrosis of the jaw and due to severe hypocalcaemia. Other causes for suspension of treatment were post-infusion fractures in the 2.2% of the cases and no improvement of bone mass density according to the DXA in the 1.1% of the patients.
**Conclusions:** Zoledronic acid has been shown to improve the levels of ALP in the Paget's disease with a single dose, and in the bone mineral density of both the lumbar spine and the hip, presenting few complications and being a good therapeutic option.
**Disclosure of Interest:** None declared

## AB0791 A COMPARISON BETWEEN COMBINATION TREATMENT WITH ALENDRONATE AND VITAMIN K AND ALENDRONATE ALONE ON BONE MINERAL DENSITY IN PATIENTS WITH POSTMENOPAUSAL OSTEOPOROSIS? THE RESULTS OF A PILOT STUDY

M.H. Jokar, Z. Mirfeizi, M. Khamoshi. *Mashhad University of Medical Sciences, Mashhad, Iran, Islamic Republic Of*

**Background:** Osteoporosis is the most common metabolic bone disease. It affects a significant number of postmenopausal women and elderly people. Standard treatment of osteoporosis is the use of oral calcium and vitamin D in combination with one of the following drugs: bisphosphonates, raloxifene, parathyroid hormone, calcitonin, denosumab and strontium ralenate [1]. Numerous studies have investigated the effects of vitamin K in bone health. These studies have shown conflicting results [2]. There isn't any human study about adding of vitamin k to alendronate to treat osteoporosis.
**Objectives:** The purpose of the present study was to compare the vitamin K and alenddronte versus alendronate alon on the bone mineral denity in postmenopausal osteoporosis.
**Methods:** Forty - seven patients were introduced to the study from our Rheumatology Clinics. All patients had postmenopausal osteoporosis ($T\leq$ -2.5). The patients were randomly assigned into two groups: one group (n=23) received calcium pills (500 mg twice daily), vitamin D pills (400 IU daily) and alendronate pills (70 mg weekly). The other group (n=24) received the same combination plus vitamin K1 pills (10 mg daily). The duration of treatment was one year in both groups. At the enrollment and the end of the study, bone mineral density was measure for all patients by the same scanner. Data were analyzed using SPSS software.
**Results:** There was no significant difference in the baseline characteristics between the two groups. In the Vitamin K+ Alendronate group, the mean bone mineral density (BMD) of femoral neck before and after the intervention was 0.56±0.08 mg/cm$^2$, that the difference was not significant (P=0.93). The mean BMD of femoral neck in the alendronate group before and after treatment were 0.61±0.09 mg/cm$^2$ and 0.58±0.09 mg/cm$^2$, that the difference was not significant (P=0.93). There was no significant difference between two groups regarding to the mean change of BMD of femoral neck before and after treatment (P=0.31). In the Vitamin K+ Alendronate group, the mean BMD of lumbar spine before and after the intervention were 0.76±0.11 mg/cm$^2$ and 0.76±0.12 mg/cm$^2$ and there was not significant change. In the alendronate group, the mean BMD of lumbar spine before and after were 0.71±0.06 mg/cm$^2$ and 0.76±0.04 mg/cm$^2$, that the change was significant (P=0.009). There was also no significant difference between two groups regarding to the mean change of BMD of lumbar spine before and after treatment (P=0.24). There was not any osteoporotic fracture in two groups.
**Conclusions:** Adding vitamin K pills (10 mg daily) to Alendronate, calcium and vitamin D regime had no more effect on the increasing of BMD in patients with postmenopausal osteoporosis.

## AB0792 KNOWLEDGE ABOUT OSTEOPOROSIS AND IT'S RISK FACTORS AMONG ELDERLY PARTICIPANTS OF HEALTHY AGING ACADEMY

O. Brzezinska-Pawlowska[1,2], T. Budlewski[3], A. Wardzynska[1], A. Lewandowska-Polak[1], M. Kowalski[1], J. Makowska[2,3]. *[1]Department of Immunology, Rheumatology and Allergy, Medical University of Lodz; [2]Healthy Aging Research Centre; [3]Department of Rheumatology, Medical University of Lodz, Lodz, Poland*

**Background:** Osteoporosis and osteoporotic fractures are among the major problems of elderly population. Although deaths related to bone disease usually have indirect causes it is assessed that approximately 20% patients dies due to complications within first year after hip fracture and another 30% need permanent care. Some of the risk factors of osteoporotic fracture can be modified by lifestyle (diet, habits, exercise) intervention. To introduce this modifications elderly people need to be aware of the burden, risk factors and preventive measures of osteoporosis. Healthy Aging Academy is an initiative of Healthy Aging Research Center at Medical University of Lodz, which one of the aims is to educate local community of elderly people.
**Objectives:** The aim of the study was to assess the knowledge of elderly patients

about osteoporosis, its risk factors, prevention measures and available treatment.
**Methods:** The study group included 177 students (34 men and 143 women, mean age 69±10 years old) of Healthy Aging Academy. Students were asked to answer 22 questions grouped in 4 domains: questions regarding symptoms and burden of osteoporosis (6 questions), risk factors (8 questions), preventive measures (5 questions) and treatment (3 questions).
**Results:** In total 177 participants filled questionnaire. The mean percentage of correct answers was 63±13% (range from 31% to 82%). The mean percentage of correct answers in the group of questions on symptoms and burden of osteoporosis was 54±14±13%. The mean percentage of correct answers on risk factors, preventive measures and treatment was 84±22%, 63±18% and 53±25% respectively. It has to be noticed that only 1/3 patients were aware about prevalence of osteoporosis and were convinced that bone pain is a symptom of osteoporosis preceding fracture. The sources of vitamin D and calcium were correctly identified only by 62% and 70% of students.
**Conclusions:** Despite fact that our questionnaire was filled by group of relatively well educated and active elderly a significant proportion of subjects did not present adequate knowledge on treatment and preventive measures in osteoporosis.

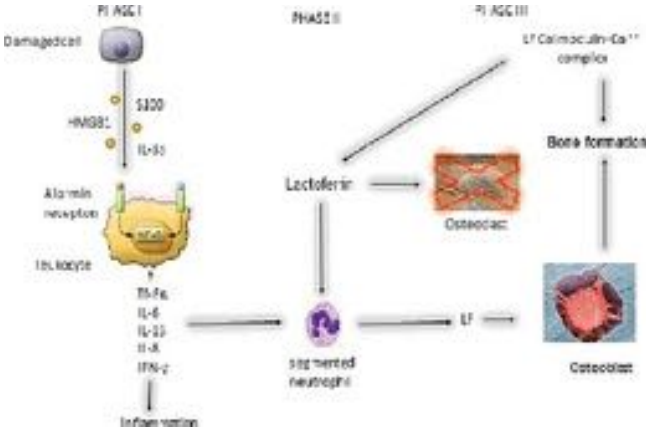
## AB0793 RHEUMATIC DISEASES WITH EMPHASIS IN OSTEOPOROSIS IN A COHORT OF PATIENTS WITH BREAST ADENOCARCINOMA



B. Hernández-Cruz[1], P. González[1], P. León Rubio[2], G. López[1], C. Prieto[3], J. Povedano Gómez[4]. *[1]UGC Reumatología, HUVM; [2]UGC COT y Reumatología; [3]Urgencas de Traumatología, HUVR; [4]UGC COT y Reumatología., HUVM y HUVR, Seville, Spain*

**Background:** The osteoporosis (OP) and the breast cancer (BC) are diseases with increasing prevalence. The BC treatment includes total and early castration. In addition to surgical treatment and chemotherapy, they had lower levels of 25-OH-D vitamin, reduced physical activity and sun exposure, with effects in the bone health.
**Objectives:** To know the prevalence of rheumatic diseases in a cohort of patients with BC attended in clinical practice in two hospitals. To identify the characteristics of the OP and their treatment.
**Methods:** Setting: The Oncology Services and OP Unit of the Rheumatology Departments of the Hospital Virgen del Rocío (HUVR) and the Hospital Virgen Macarena (HUVM) in Seville, Spain. A prospective case series was design. Consecutive patients with BC who attended the Oncology Service (September to December of 2014) were evaluated. The patients were reviewed by 5 rheumatologists, previously trained about design, variables, data management, and the study protocol in order to collected 152 clinical variables. Descriptive statistics and univariate and multivariate statistics were done. The work was conducted in according to GPC and approved for the local ethical committee.
**Results:** 151 patients were included, all them women. The mean age (p25-p75) was 64.3 years (40.0 – 81.2). The menopausal was at 48 (34–56) years; in 44% it was before than 45 years. There were 11% smokers; 34% with regular sun exposure; 5% on corticosteroids and 2% drinkers. The rheumatic diseases were: OP in 103 (68%), chronic musculoskeletal pain 16%, osteoarthritis 16%, fibromyalgia 9%. The most frequent comorbidities were depression (16%), hypothyroidism (9%), Secondary hyperparathyroidism 9%, and Diabetes (8%). The comorbidity Index (Charlson) was 2 (2–5). The mean OP duration was 3.3 (0.19 – 9.8) years. The OP diagnostic was done with FF in 26 (23%) cases, 7 of them without OP by BMD. The FF were vertebral in 15 (10%), peripheral in 10 (7%) and one case with both. The baseline FRAX was 5.1 (1.4 -26) for major FF and 1.3 (0.1 – 10) for hip FF. The OP was diagnosed with BDM of femoral neck in 31 (24%) and in total lumbar column in 57 (45%), and in both in 15 (12%). The patients were treated with Calcium plus 25-OH-VitD 89%, PO bisphosphonates 51%, denosumab 26%, IV bisphosphonates 11%, teriparatide 3%, and 36% received 25-OHVitD. None of the multiple regression models was able to predict FF. In the best of cases the models predicted 20% of the FF ($R^2$). The model with the FRAX as predictor of major FF was poor: $R^2$ 0,15, $p<0,0001$; OR 1.15 (1.06 – 1.2). The FF were best predicted by the comorbidity index, SLE, RA or drinker; but with significant collinearity, and was impossible calculate statistics.
**Conclusions:** Patients with BC had an elevated prevalence of rheumatic diseases and comorbidity. The OP was severe with a high prevalence of FF. The classical risk variables of FF cannot predicted it. In this group of patients, the FRAX was not a good tool of prediction.
**Disclosure of Interest:** None declared

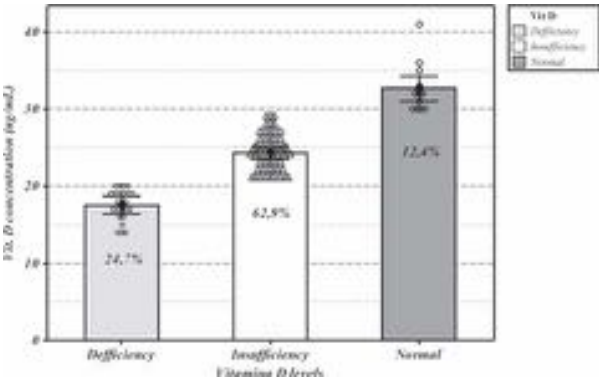
## AB0794 POSSIBLE MOLECULAR MECHANISM OF LACTOFERRIN ACTION ON BONE FORMATION

P. Sadchikov[1], I. Goldman[2], A. Chernousov[2], E. Sadchikova[2]. *[1]Faculty of Fundamental Medicine, Lomonoso Moscow State University; [2]Transgenebank, Institute of Gene Biology, Moscow, Russian Federation*

**Background:** Lactoferrin (LF) is a multifunctional protein, for which several biological activities were determined, among which the main are antimicrobial, antiviral, antifungal, anti-inflammatory and antioxidant effects. LF takes an active part in stimulation of tissue regeneration processes. LF's active role in the stimulation of tissue regeneration processes was established. In the last decade LF has also been shown to play the role in bone formation.
**Objectives:** In experiments carried out in different countries, it was found that the ovariectomized experimental animals, when giving LF per os, achieved relief of symptoms of osteoporosis, occurring at similar postmenstrual osteoporosis in women and human aging. Accumulating facts are showing a decrease in physiological serum LF in patients under pathological conditions of bone formation. In molecular genetic studies the identical mechanisms, resulting in reduced expression of LF and the emergence of bone desorption were determined.
**Methods:** We present a possible model of bone formation under the LF influence (Fig).
**Results:** According to our conception in osteoporosis, various injuries, or surgical impacts associated with the bones, the involvement of LF in the regenerative processes of the bone formation, apparently, is implemented as follows: as a result of damage of different tissues are released risk molecules – alarmins (high-mobility group protein B1 (HMGB1), S100 protein, IL-α, IL-33), which are necessary to repair damaged tissues, including bone. They interact with alarmins receptors on the surface of leukocytes, thus there is a release of proinflammatory cytokines (TNFα, IL-6, IL-1β, IL-8, INFγ) (Fig. Phase I). Further, under the action of IL-8, which is a chemotactic factor for neutrophils in the bone defect area segmented leukocytes migrate from granules which stands LF (Fig. Phase II). Then LF immerses in osteoblasts (OB), activating them, and osteoclasts (OC), inhibiting their activity (Fig. Phase III).



**Conclusions:** According to the presented model, the LF is simultaneously a factor of implementing the calcium transfer. The ability of LF to bind calcium is well known. The transfer of calcium in the bone tissue due to the complex LF-Calmodulin-Ca ++ (Fig.).
It is possible that the expansion of research of the role of LF in bone formation will help create new and effective drugs to combat osteoporosis.

## AB0795 HYPOVITAMINOSIS D AND CALCIUM INTAKE OF ADULT POPULATION IN BOGOTA (DICAVITD)

R.A. Guzman Moreno[1], L.G. Piñeros[2], A. Teheran[2], J. Flechas[2], M. Mejia[2]. *[1]Immunology; [2]Research Group, Fundación Universitaria Juan N Corpas-IDEARG, Bogota, Colombia*

**Background:** The calcium intake on the diet below normal daily requirements is related with low levels of vitamin D. The available scientific evidence supports a key role of calcium and vitamin D in skeletal health. We analyzed this relationship in healthy colombian population and describe this association.
**Objectives:** The main objetive is to Assess the prevalence of hypovitaminosis D and the relationship with the daily calcium intake in a healthy Colombian population. Furthermore it is crucial to estimate the impact of key mineral elements such as Calcium and Vitamin D in bone health.
**Methods:** In a prospective cohort of general population we measure the prevalence of hypovitaminosis D and the calcium intake, (mg/dl) following demographic, antropomethric, biochemical characteristics and sun exposure of the population evaluated. We used a model of multiple regresion to predict the

levels of vitamin D regarding the factors analysed. We excluded patients with secondary conditions that affect the absorption of calcium and vitamin D.
**Results:** We included 97 patients, average age 23 yrs, 61% women, average weight 65 kg, Height 165 cm, average BMI 22.8. The calcium intake was 393,7 mg/d, levels of vitamin D were 23.71. We identified hypovitaminosis D in 87% of the patients, 24.7% had vitamin D defficiency and 63% had insufficiency (Figure 1, Levels of Vitamin D in the population study).
The concentration of Vitamin D was calculated in quadratic function, for the relationship between sex, sun exposure and habitual calcium intake. (R:>90%).

**Conclusions:** We found a strong relationship between low calcium intake and hypovitaminosis D in the study group. In a healthy colombian population we saw an important low intake of calcium on the diet and high prevalence of Hypovitaminosis D. These findings have enormous impact on public health policy in our country. Effective and imperative strategies are required to prevent future complications such as Osteoporosis and secondary fractures.

## AB0796 THE PREDICTORS OF FRACTURE IN PATIENTS WITH HYPERPARATHYROIDISM: AN OBSERVATIONAL STUDY

S. Ashraf[1], B. Khan[1], R. Sinha[2], M. Bukhari[2]. *[1]Lancaster University; [2]Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom*

**Background:** Hyperparathyroidism and other endocrine disorders have been associated with a low bone mineral density. The FRAX ™ tool uses the femoral neck to predict fractures on a population basis and ignores the lumbar spine.
**Objectives:** We set out to determine the predictors of fragility fractures in a large cross sectional study of 508 patients diagnosed with Hyperparathyroidism.
**Methods:** Patients referred for bone mineral density (BMD) estimation in a scanner in the North West of England with a history of Hyperparathyroidism were identified from a dual X-ray absorptiometry (DEXA) database. Demographics and other risk factors were recorded as well as fragility fractures. Initially, Univariate logistic regression models were modelled predicting fractures in the data set and a multivariate model was subsequently fitted. Variables included age at scan, gender, body mass index (BMI), family history of fracture, alcohol intake, smoking, glucocorticoid exposure, rheumatoid arthritis, in addition to BMD in the lumbar spine and femoral neck.
**Results:** 508 patients were scanned in the referral period. Mean age at scan was 65.0 (SD 12.4). 411 (80.9%) of the patients were female and 97 were male. Results of the univariate analysis (adjusted for age and gender) are shown in table 1. Significant predictors are denoted with an asterisk.

Table 1

| Predictor | Odds ratio | 95% CI |
|---|---|---|
| Lumbar spine BMD | 0.18 | 0.31, 1.04* |
| Femoral neck BMD | 0.70 | 0.72, 6.80 |
| Rheumatoid arthritis | 0.65 | 0.73, 5.77 |
| Smoking | 0.84 | 0.50, 1.42 |
| Excess alcohol | 1.30 | 0.34, 5.00 |
| Family history of fracture | 1.43 | 0.57, 3.64 |
| Steroid exposure | 1.55 | 0.82, 2.93 |
| Body mass index kg/m$^2$ | 1.04 | 0.99, 1.09 |

In the multivariate model, the only variable that predicted fractures in this cohort was Lumbar spine BMD OR 0.18 (95% CI 0.31,1.04)
**Conclusions:** In the univariate analysis, many risk factors are associated with fracture. However in the multivariate analysis conducted, the best predictor was Lumbar Spine BMD. This is not included in the FRAX ™ tool and would make estimating the fracture risk in this cohort difficult. Further modelling in other cohorts is needed to validate this finding.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4410

## AB0797 ANKLE FRACTURES AND ITS RELATIONSHIP BETWEEN OSTEOPOROSIS, DIABETES AND OBESITY

S. Rodríguez-Muguruza[1], A. Prior[1], A. Florido[2], J. Sanint[1], Y. García Mira[1], I. Casas[3], M. Martinez-Morillo[1], L. Mateo[1], J. Canellas[1], X. Tena[1], A. Olive[1], S. Holgado[1]. *[1]Rheumatology; [2]Orthopedic Surgery; [3]Epidemiology, Germans Trias I Pujol Hospital, Barcelona, Spain*

**Background:** Osteoporosis is a major health problem worldwide and leads to several million fractures every year. Diabetes mellitus (DM) and obesity are an increasing threat for global health. While the pathophysiology of diabetic bone disease is unknown, some recent studies have demonstrated an increased fracture risk related to type 2 DM. Type 1 DM has also been associated with a decreased bone mineral density (BMD).
**Objectives:** To investigate the relationship between DM and obesity, and their relation to osteoporosis and ankle fractures.
**Methods:** Retrospective study 2008–2014. Center: tertiary academic hospital with a referral area of 850,000 inhabitants. The medical charts, dual-energy X-ray absorptiometry (DXA), radiographs and electronic data bases were retrospectively reviewed of patients seen for ankle fractures. Patients were classified in 4 groups: obesity (IMC>30), non-obesity, diabetic and non-diabetic. We compared demographic data (age, gender), mechanism of injury (high or low energy trauma), pattern of fracture (single malleolus, bimaleollar and trimalleolar), treatment of the fracture, presence of new fracture (in other localizations) and osteoporosis treatment
**Results:** We compared a total of 65 diabetic patients (32.3% male and 67.7% female, mean age 61.8 years [DS 17.6]) with 234 non-diabetic patients (52.9% male, 47.1 female, mean age 31.5 [DS 41.7]) and 40 obese patients (37.5% male and 34.7% female, mean age 42 years [DS 21.2]) with 76 non obese patients (38.2% male, 61.8% female). The main characteristics of the study groups are presented in Table 1. There were no differences in fracture pattern, mechanism of injury, BMD and fracture treatment among all groups. Bimaleolar fracture was the most common pattern in all groups. Diabetic group had higher frequency of a low energy trauma, osteoporosis and new fracture. New fracture was reported in 12 patients, between 3 and 48 months (after the ankle fracture). There was 5 Colles'fracture, 3 hip, 2 in other localization. One patient had two fractures (Colles and vertebral) Obese group had higher frequency of osteopenia compared with non obese.

Table 1

| | Diabetic (%) | Non diabetic (%) | p | Obese (%) | Non obese (%) | p |
|---|---|---|---|---|---|---|
| Female | 53 | 67.7 | 0.03 | 61.8 | 62.5 | 0.9 |
| Bimaleolar | 61.5 | 51.7 | 0.4 | 52.6 | 52.5 | 0.8 |
| Trimaleolar | 10.8 | 17.5 | 0.4 | 20 | 17.1 | 0.8 |
| Low energy trauma | 52.3 | 43.2 | 0.3 | 47.5 | 56.6 | 0.6 |
| Conservative treatment | 13.8 | 11.1 | 0.5 | 7.5 | 7.9 | 0.9 |
| Osteopenia | 25 | 62.5 | 0.2 | 60 | 42.9 | 0.2 |
| Osteoporosis | 50 | 37.5 | 0.2 | 20 | 57.1 | 0.2 |
| New fracture | 18.5 | 15 | 0.4 | 15 | 19.7 | 0.5 |

**Conclusions:** We did not found statistical differences between diabetic and obese compared with non diabetic or non obese patients. Ankle fracture in diabetic group could have features of osteoporotic injury including the high frequency of new fracture.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5529

## AB0798 CAN ANTI-OSTEOPOROTIC THERAPY REDUCE ADJACENT FRACTURE IN MAGNETIC RESONANCE IMAGING-PROVEN ACUTE OSTEOPOROTIC VERTEBRAL FRACTURES?

Y.-C. Chen. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

**Background:** Adjacent fracture of the cemented vertebrae may result from unfilled space left during the procedure or from crushed fragile trabeculae underneath the cement during follow-up, suggesting impaired bone marrow integrity of the injured vertebrae. Anti-osteoporotic therapy is reported to increase spinal, total hip, and femoral neck bone mineral density[1]. If treating osteoporosis does have a positive impact on adjacent fracture among patients who have undergone vertebroplasty, there will be several important potential implications for managing skeletal health specifically and for the health care of the elderly in general.
**Objectives:** This study aimed to determine if anti-osteoporotic therapy can decrease the risk of adjacent fracture in patients with acute vertebral fracture after vertebroplasty.
**Methods:** This retrospective study reviewed of cases of osteoporosis patients with magnetic resonance imaging (MRI)-proven acute vertebral fractures between 2001 and 2007. Osteoporotic patients were investigated as determined by pre-operative MRI with subsequent adjacent fracture of the cemented vertebrae and for the possibility of anti-osteoporotic therapy decreasing the progression of collapse after a minimum of 6 months follow-up. All associated co-morbidities were

recorded, as well as the use of anti-osteoporotic drugs (i.e., alendronate, raloxifen, calcitonin, and teriparatide). Cox regression analysis was also performed.
**Results:** The 192 patients with acute vertebral fractures who underwent vertebroplasty and anti-osteoporotic therapy had a mean age of 74.40±6.41. The basic characteristics of patients with and without adjacent fracture differed in age, body mass index, rheumatoid arthritis, and use of glucocorticoids and anti-osteoporotic drugs (Table 1). Using the Kaplan-Meier curve, anti-osteoporotic therapy after vertebroplasty had a significant effect on adjacent fracture ($p$=0.037, by log rank text). After adjusting for potential confounders, patients with anti-osteoporotic therapy still had a lower adjacent fracture rate than patients without anti-osteoporotic therapy ($p$=0.006; HR: 2.137, 95% CI: 1.1238–3.690). The adjacent fracture rate also increased in old age ($p$=0.019; HR: 1.049; 95% CI:1.008–1.039) and among smokers ($p$=0.026; HR: 3.891; 95% CI: 1.175–12.890).

Table 1. Multivariable Cox regression analysis of the hazard ratios for adjacent fracture

| Variables | Regression coefficient | p value | HR (95% CI) |
|---|---|---|---|
| Age | 0.048 | 0.019 | 1.049 (1.008–1.093) |
| Body mass index (kg/m$^2$) | –0.055 | 0.126 | 0.946 (0.882–1.016) |
| Sex | –0.595 | 0.248 | 0.551 (0.201–1.513) |
| Smoking | 1.359 | 0.026 | 3.891 (1.175–12.890) |
| Glucocorticoid use | –0.304 | 0.492 | 0.737 (0.310–1.756) |
| Anti-osteoporotic therapy | 0.759 | 0.006 | 2.137 (1.238–3.690) |

Abbreviations: HR, hazard ratio; SE, standard error.

**Conclusions:** In this study, adjacent fracture of cemented vertebrae is inevitable after vertebroplasty but can be mitigated by anti-osteoporotic therapy to increase bone mass.

## Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis

### AB0799 GOUT MANAGEMENT: AUDIT FOR BEST PRACTICE IN GOUT

A.-W. Al-Allaf[1], H. Mohiaddin[2], O. Al-Allaf[3]. *[1]New Cross Hospital, Wolverhampton, Wolverhampton; [2]imperial College, London; [3]Exeter Medical school, Exeter, United Kingdom*

**Background:** Gout is well known old disease, with still increasing prevalence. We are not in short of well-established clear guidelines for its management. However, it is still not well managed even in developed countries.
**Objectives:** We share our experience of auditing the gout management in our out-patient clinic with the completion of our audit cycle. The aim is to improve gout service in line with 2006 EULAR guidelines, using the ethos of treat-to-target approach.
**Methods:** We audited randomly selected 101 patients seen in our well established gout clinic. All patients should be in that clinic for a minimum of 6 months, ensuring sufficient time for prophylactic therapy to take effect. Records from patients attending the gout clinic between 07/07/2014 and 29/06/2015 were accessed & information was collected on serum urate and the treating medications, gouty attacks & presence of tophi. Patients' comorbidities were recorded. Recent serum uric acid levels were specifically scrutinized against both BSR and EULAR targets of $\leq$300 and $\leq$360 mmol/L respectively
**Results:** Female (27%), males (73%). Average age: 64. Acute attack management: NSAID (42%), Colchicine: (82%), Oral Steroid (10%), IA Steroid (27%).
42% and 69% of patients acieved the BSR & EULAR s. uric acid target as compared with 9.3% for BSR target in 2010 and 29% & 60% for 2012 audit respectively. 64% of patients were under the BSR target reported no acute gout episodes since their last appointment, which is almost the same (66%) of patients achieving EULAR target.
70%, 20% & 10% of patients in the sample were on allopurinol, Febuxostat and Benzbromarone respectively. For Allopurinol treated patients 36.6% & 67.6% were under BSR and EULAR targets respectively. For Febuxostat these figures were much better at: 61.9% and 85.7% and for Benzbromarone 54.5% achieved EULAR & BSR target. Patients on Febuxostat had a significantly lower average urate (290) than allopurinol (351) (P=0.015). Patients prescribed Febuxostat if they had experienced side-effects to allopurinol (in concordance with NICE guidelines) or if allopurinol found it to be ineffective (31%).
However, for patient with tophi s. uric acid target of $<$300 (BSR) was achieved in 33.3% and of $<$360 (EULAR) in 59.3%.
100% of patients received lifestyle advice on diet, exercise & alcohol (NICE recommendation) as compared to only 9% in 2010. In CHD patients, 71% reduced their Cholesterol/HDL ratio to $<$5.0. In hypertensive patients, 60% reduced systolic blood pressure to $<$160 & in obese patients 7.84% were able to significantly reduce their weight ($>$5 kg).
**Conclusions:** The proportion of patients achieving BSR & EULAR targets, in comparison to 2010 and 2012 were increased significantly on adapting gout speciality clinic. A greater proportion of patients on Febuxostat reached their targets compared to other urate lowering agents. No significant benefit (in terms of stopping further acute attacks with the meeting of the BSR target of $<$300 over the EULAR target of $<$360 were seen. Tophaceous gout has not been treated well when compared to the rest of the cohort. The impact of the clinic on improving and managing other co-morbidities associated with gout has much improved. We recommend that all gout patients should be treated with target to treat stratigy & this will be best achieved in specialized gout clinic
**Disclosure of Interest:** None declared

### AB0800 NEUTROPHIL: LYMPHOCYTE RATIO AND MEAN PLATELET VOLUME IN PATIENTS WITH GOUT

A. Balkarli[1], A. Dogru[2], Y. Ugan[2], G. Dogan[3], S.E. Tunc[2], M. Sahin[2]. *[1]Rheumatology, Antalya Training and Research Hospital, Antalya; [2]Suleyman Demirel University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Isparta; [3]Rheumatology, Pamukkale University, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Denizi, Turkey*

**Background:** Gout is a clinical syndrome with increased uric acid concentration, which is caused by inflammatory response against mono sodium urate (MSU) crystals. In gout, neutrophils are involved in inflammatory response and neutrophil activation is dependent to local cytokine production. Mean platelet volume (MPV) and neutrophil:lymphocyte ratio (NLR) are considered as inflammatory markers in several diseases and it is reported that they may have prognostic significance.
**Objectives:** According to current literature, there is no study evaluating MPV and NLR in gout. In this retrospective study, we investigated role of MPV and NLR in determination of inflammation in gout disease.
**Methods:** In this retrospective study, 106 patients with gout (91 men and 15 women) meeting inclusion criteria by patients records and 148 age- and sex-matched healthy controls (128 men and 20 women) were included. Laboratory data during attacks (group I) and intercritical period (group II) were collected in the patient group.
**Results:** Mean age was 59.46±12.93 years in the patient group whereas 59.00±11.33 years in the control group. Age at first attack was 52.00±12.77 years and mean time interval between first 2 attacks was 6.00±5.52 months. There was tophus in 9 patients (8.5%) and family history of gout in 17 patients (16.0%). Compared to group 2 (intercritical period) and control, no significant difference in MPV levels was found in the group 1 (during attack). MPV was similar among three groups. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were found to be significantly higher in the group I compared to group II. There was significant difference in NLR among three groups. When classified according to presence of tophus, it was seen that MPV and NLR were similar in both groups.

Table 1. Parameters evaluated in the groups

| Parametre | Group I (during attack period) n=106 | Group II (during intercritical period) n=106 | Control n=148 | p |
|---|---|---|---|---|
| MPV (f/L) | 8.1 (5.9–10.7) | 8.2 (5.4–12) | 8.3 (6.7–12.9) | 0.054 |
| NLR | 2.88 (1.21–21.16) | 2.19 (0.69–21.82) | 1.72 (0.78–11.25) | **<0.001**† |
| ESR (mm/h) | 36 (24–65) | 12.5 (2–30) | – | **<0.001** |
| CRP (mg/dL) | 35 (19–60) | 3.2 (1.6–4.7) | – | **<0.001** |

CRP: C-reactive protein, Normal reference range: 0–10 mg/dL. ESR: erythrocyte sedimentation rate, MPV: mean platelet volume; NLR: neutrophil:lymphocyte ratio; †There are statistically significant differences in all groups.

**Conclusions:** The finding of increased NLR during attacks and intercritical period shows that patients with gout are subjected to chronic inflammation. Thus, NLR can be simple, inexpensive and useful diagnostic marker in gout. Studies comparing cytokine levels with NLR will be helpful in elucidating this topic.
**Disclosure of Interest:** None declared

### AB0801 OSTEOPOROSIS FREQUENCY AND THE ASSOCIATION OF RANK, RANKL, OSTEOPROTEGERIN GENE POLYMORPHISMS WITH OSTEOPOROSIS IN GOUT PATIENTS

C.C. Karatay[1], A. Balkarli[2], L. Elmas[3], B. Can[1], E. Tepeli[3], V. Cobankara[4]. *[1]Internal Medicine, Pamukkale University School of Medicine, Denizli; [2]Rheumatology, Antalya training and research hospital, Antalya; [3]Department of Medical Biology; [4]Rheumatology, Pamukkale University School of Medicine, Denizli, Turkey*

**Background:** Gout is a disease characterized by acute arthritis as a result of increased serum uric acid concentration and deposition of monosodium urate crystals into tissues. In recent times the significant role of RANK- RANKL- OPG network in bone remodeling and osteoclastogenesis was proven. In patients with osteoporosis and in rheumatoid arthritis patients, genetic variations in the genes encoding RANK, RANKL and OPG was investigated and conflicting results were obtained. Also the role of these genes in the pathogenesis of psoriasis, psoriatic arthritis and ankylosing spondylitis has been researched. There is not any study that evaluates RANK, RANKL, Osteoprotegerin gene polymorphisms and their

association with the susceptibility to osteoporosis in gout patients. To the best of our knowledge, this is the first study to investigate this subject.
**Methods:** 69 gout patients, 50 RA patients and 51 healthy controls were recruited for this study. BMD of lumbar spine and femoral sites were measured using DEXA. After acquisition of the BMD T- score, the patients and controls divided into normal, osteopenic and osteoporotic groups according to WHO criteria. We studied 7 SNP in the genes of RANK gene (2 SNP: rs1805034, rs35211496), OPG gene (2 SNP: rs3102735, rs 2073618) and RANKL gene (3 SNP: rs9533156, rs1054016, rs2277438) using real time PCR.
**Results:** There was no significant difference for BMD scores between three groups. The 7 SNP genotypes showed no significant difference between three groups. The 7 SNP allel frequencies showed no significant difference between three groups. Gout patients with rs1805034 wild genotype had lower incidence of osteoporosis at the femoral sites. Gout patients with rs1805034 heterozygous genotype had higher incidence of normal BMD scores at the femoral sites than other gout patients. Controls with rs2277238 wild genotype, had lower incidence of osteoporosis and those with mutant genotype had higher incidence of osteoporosis at any sites than other controls. Controls with normal BMD at lumbar spine, frequency of rs35211496 wild genotype was higher than other controls.
**Conclusions:** As a result it is seen that the C allel of the RANK SNP rs1805034 is protective against osteoporosis at femoral site in gout patients. The A allel of the RANKL SNP rs2277438 is protective against osteoporosis at either femoral sites or lumbar spine in healthy people. BMD in patients with Gout, RA and healthy population unexpectedly is not different from each other which may be related to low number of cases. Genotype distribution and genetic diversity varies between ethnic groups. There is a need for more studies with larger patient populations to explain the subject.
**Disclosure of Interest:** None declared

## AB0802 EFFECT OF ALLOPURINOL AND FEBUXOSTAT IN PROLONGING THE FLARE-FREE TIME IN GOUTY PATIENTS WITH OR WITHOUT PROPHYLACTIC TREATMENT WITH COLCHICINE: A RETROSPECTIVE KAPLAN-MEIER ANALYSIS

C.A. Guillen-Astete[1], M. Villarejo-Botija[2], L. Fuertes[2], G. Silvestre-Egea[2].
*[1]Rheumatology Department; [2]Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** Among inflammatory joint diseases, gout is a main cause of recidivism in urgency departments due to insufficient pain control or development of arthritis flares. This burden produces time and resources consumption and time of work off. New and old hypouricemic treatments are not only intended to control uric acid level below 6mg/dL but to reduce the number of flares per year. It is well known that their activity removing uric deposits could trigger new flares so prophylactic treatment is always recommended when those treatments are initiated. There are many studies conducted to compare hypouricemic effectiveness with those treatments, however, their impact in flare-free survival is a topic not previously studied.
**Objectives:** To compare the effectiveness of Allopurinol and febuxostat in terms of recidivism in patients with gout flares.
**Methods:** A descriptive retrospective study was performed. Electronic registries of patients diagnosed by gout and treated with Allopurinol (100–200mg/d and 300–600mg/d) and febuxostat (80mg/d and 120mg/d) with at least a gout flare were included. Prophylaxis treatment was considered as positive in patients on treatment with colchicine 0.5–1mg/día or NSAIDs according to the 2012 ACR Guidelines for management of gout (Khanna et al. Arthritis Care & Research, 2012: 64 (10); 1447–61). Follow up period was 2013–2015. Only patients with flares were included. Kaplan Meier curves were built considered censored any flare which took place after 6 months since the treatment started. Data recovered from electronic registries were: demographic and clinical data, number of consultations and work off time where appropriated. Comparisons were made according to hypouricemic treatment and colchicine prophylaxis treatment. No data about treatment compliance were considered.
**Results:** 90 registries of different patients were identified: 18 were under treatment with febuxostat (14 on 80mg/day and 3 on 120mg/day) and 72 under treatment with allopurinol (22 on 100–200mg/day, 50 on 300–600mg/day). Difference on average of age, proportion of males and proportion of tophus were not statistically significant between both groups. Mean of time until the first flare after starting treatment with allopurinol was 132.4 SD 6.8 days (CI95% 119.0–145.8) and 142.6 SD 11.63 (CI95% 119.8–165.4) with febuxostat (Chi-squared 0.304; *P*=0.581, Hazard ratio 0.806; 95%CI 0.3935–1.654). Excluding patients without prophylaxis treatment (2 on febuxostat and 26 on allopurinol), the mean of time until the first flare was 116.4 SD 8.0 days (CI95% 100.7–132.1) in the group on allopurinol and 153.8 SD 9.9 days (CI95% 134.3–173.3) in the group on febuxostat (Chi-squared 5.984; *P*=0.0144, Hazard ratio 0.356 (CI95% 0.183–0.692). No differences statistically significant were observed when Kaplan Meier curves were built groping patients according to the doses of Allopurinol or febuxostat.
**Conclusions:** Our observations point that there is a tendency to higher surveillance without flares in gouty patients on febuxostat than on allopurinol. This tendency becomes statistically significant when only patients on colchicine treatment were compared, so it seems that prophylaxis treatment benefits specially this group of patients prolonging the period of time free of flares.

## AB0803 CHRONIC KIDNEY DISEASE DOES NOT AFFECT THE NUMBER OF THE ATTACKS AND THE ATTACK DURATIONS IN GOUT PATIENTS

Y. Özdem İnan, N. Alpay Kanıtez, S. Çelik, S. Yılmaz Öner, B. Yılmazer, C. Bes.
*Rheumatology, Bakırköy Dr Sadi Konuk Training and Research Hospital, Istanbul, Turkey*

**Background:** Gout is one of the most severe and frequent rheumatic diseases. Clinical manifestations of gout arise from uric acid crystal deposition in the musculoskeletal tissue. Many patients with gout have co-morbidities, including hypertension and chronic kidney disease (CKD).
**Objectives:** The goals when treating gout are no different in these patients, but the choice and dosage of drugs may need to be modified. In this study, we aimed to determine whether the chronic kidney disease affects or not the number of the gout attacks.
**Methods:** Consecutively 31 gout patients with CKD (group 1, n=31) and 46 gout patients without CKD (group 2, n=46) were enrolled in the study. The gout attack durations and the number of the gout attack in the last one year were compared among groups.
**Results:** The clinical, demographical and anthropometric variables were presented on table 1. There were no statistical differences in body mass index, use of diuretics and history of nephrolithiasis between two groups ($p>0.05$ for all). Compared to group 2, group 1 had statistically similar levels of the gout attack durations and the number of the gout attacks in the last one year (both $p>0.05$). In Bivariate Pearson correlation analysis; gout attack durations and the number of the gout attacks in the last one year were not correlated in any parameters in group 1 ($p>0.05$ for all).

Table 1. Comparison of the demographic and anthropometric and biochemical characteristics of all patients

| Variables | Group 1 (n=31) | Group 2 (n=46) | *p* |
|---|---|---|---|
| Gender, male/female | 20/11 | 42/4 | 0.004 |
| Age, years | 62.64±12.75 | 53.00±12.40 | 0.002 |
| BMI, kg/m$^2$ | 29.89±5.18 | 29.99±4.20 | 0.925 |
| Creatinine, mg/dL | 1.55±1.08 | 0.97±0.17 | 0.001 |
| GFR, ml/min | 64.96±24.05 | 112.59±30.26 | <0.001 |
| Uric acid, mg/dL | 8.43±1.80 | 7.69±1.42 | 0.064 |
| Use of diuretics, +/– | 11/20 | 11/35 | 0.310 |
| History of nephrolithiasis, +/– | 12/19 | 12/34 | 0.317 |
| Disease duration, months | 72.00±100.25 | 74.08±106.97 | 0.931 |
| Number of the attacks, in the last one year | 2.38±2.10 | 2.78±2.24 | 0.434 |
| Attack durations, days | 8.54±7.64 | 14.30±16.56 | 0.075 |

**Conclusions:** The present study revealed that CKD does not affect the number of the attacks and the attack durations in gout patients. Future large scale multicenter randomized controlled studies are needed and warranted to clarify our results.
**Disclosure of Interest:** None declared

## AB0804 THE EFFICACY AND TOLERABILITY OF FEBUXOSTAT IN HYPERURICEMIC PATIENTS UNDERGOING DIALYSIS

D.-H. Lim[1], J.S. Oh[2], S.M. Ahn[1], S. Hong[1], W.J. Seo[3], Y.-G. Kim[1], C.-K. Lee[1], S.W. Choi[2], B. Yoo[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul; [2]Division of Rheumatology, Department of Internal Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Korea, Ulsan; [3]Division of Rheumatology, Department of Internal Medicine, Seoul Veterans Hospital, Seoul, Korea, Republic Of*

**Background:** Febuxostat is metabolized mainly in the liver and is excreted through both urine and feces, suggesting that it may be an alternative choice for the treatment of hyperuricemia and gout in chronic kidney disease (CKD) patients. However, there are insufficient data on the use of febuxostat in patients undergoing dialysis.
**Objectives:** The aims of our study were to investigate the efficacy and tolerability of febuxostat in hyperuricemic patients on dialysis.
**Methods:** We retrospectively reviewed clinical and laboratory data from two tertiary referral centers from January 2012 to December 2015. We included 49 patients with underlying CKD on dialysis who started febuxostat treatment in the two hospitals.
**Results:** The mean age of the study patients was 54.4±12.5 year and follow-up duration was 12.7±10.2 months (Table 1). Among 41 patients who were treated with febuxostat for over 3 months, the mean serum uric acid level at 3 months after treatment (4.97±1.84 mg/dL) was significantly reduced compared with the pretreatment level (9.61± 2.18 mg/dL) ($p<0.001$). And the serum uric acid level stayed significantly lower for 12 months without deterioration in eGFR. Of the 49 patients, only 2 stopped the medication due to adverse event. The two patients who stopped taking febuxostat were on peritoneal dialysis.

Table 1. Baseline characteristics of the study patients at the time of febuxostat initiation

| Characteristic | Dialysis patients (n=49) |
|---|---|
| Age, years | 54.4±12.5 |
| Sex, male (%) | 41 (83.7) |
| Follow-up duration, months | 12.7±10.2 |
| Renal disease | |
| Diabetic nephropathy (%) | 8 (16.4) |
| IgA nephropathy (%) | 8 (16.4) |
| Primary glomerulonephritis (%) | 6 (12.2) |
| Polycystic kidney (%) | 5 (10.2) |
| Lupus nephritis (%) | 1 (2.0) |
| Others (%) | 21 (42.8) |
| Comorbidity | |
| Hypertension (%) | 35 (71.4) |
| Gout (%) | 36 (73.5) |
| Diabetes (%) | 9 (18.4) |
| Malignancy (%) | 4 (8.2) |
| Initial dose of febuxostat | |
| 40 mg/day (%) | 38 (77.6) |
| 80 mg/day (%) | 11 (22.4) |

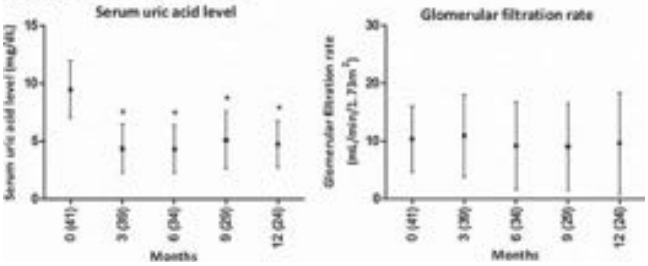

**Figure 1** Changes in serum uric acid levels and eGFR during the 12-month period after febuxostat initiation (number in parentheses indicates number of patients). Data are shown as mean ± SD. * $p<0.05$ versus month 0 (paired *t* test).

**Conclusions:** Febuxostat is efficacious and well tolerated in hyperuricemic patients undergoing dialysis. Close observation for adverse events might be needed for patients on peritoneal dialysis.
**Disclosure of Interest:** None declared

## AB0805 CONCORDANCE BETWEEN CLINICAL FINDINGS AND ULTRASOUND IN GOUT

E. Norkuviene[1], M. Petraitis[1], I. Apanaviciene[1], D. Virviciute[2], A. Baranauskaite[1]. *[1]Rheumatology, Lithuanian university of health sciences; [2]Rheumatology, Institute of Cardiology of Kaunas Medical University, kaunas, Lithuania*

**Background:** Ultrasound (US) evidence of double contour (DC) sign has been incorporated to new ACR/ EULAR gout classification criteria. Other specific US symptoms like tophus (T) and unspecific features like synovial hypertrophy (SH), synovial effusion (SE) are still under investigation. Which joints should be investigated – only symptomatic or more - still a matter of debate [1]. The US studies with rheumatoid arthritis showed that US adds information to clinical findings [2]. The concordance between clinical symptoms and ultrasound in gout still needs to be investigated.
**Objectives:** to evaluate concordance between clinical examination, patient reported gout symptoms and ultrasound findings in gout patients.
**Methods:** observational, prospective, controlled single centre study has been performed. 50 crystal proven gout patients with different disease duration, activity and treatment and 36 healthy controlls has been included. 36 joints were systematically investigated by experienced rheumatologist, blinded to patients clinical data and complaints. The concordance between clinical signs, such as tender joints and swollen joints defined by other rheumatologist, joints with previous gout flares, reported by the patient and presence of ultrasonographic SE, SH, DC and T was assessed by computing the kappa coefficient.
**Results:** the concordance between patient reported gout flare (PRGF) and SH, SE was poor with kappa 0,125 (95% CI 0,070–0,179) and 0,136 (95%CI 0,082–0,190) accordingly. The concordance between (PRGF) and T, DC and combination of T plus DC was fair – kappa 0,325; 0,275 and 0,376 accordingly. There was negative kappa (-0,053) between reported joint flare in I MTF and DC sign, poor concordance between knee, ankle PRGF and DC sign. Negative kappa (-0,005) between PRGF and T in wrist joints. The concordance between US T and DC and patient reported flare stayed fair in untreated (33) group. The strongest concordance between PRGF and T, considered as moderate (kappa 0,420; 95% CI 0,296- 0,544) was found in early gout group (16 patients), with fair agreement according DC sign in this subgroup. Poor agreemant was found between SE, SH, T and DK and objectively found tender and swollen joints, ultrasound was found to be much more sensitive - SH in 92% (195/211) cases, T in 93% (211/228) of cases and DC in 92% (268/290) of cases was found in non swollen joints. The overall specificity of DC, T and SH according controls was 86% ($p<0,0001$), 81% ($p<0,0001$) and 64% ($p<0,0001$).
**Conclusions:** The concordance between patient reported gout flare in the joint and US tophus or double contour sign was poor to fair in total gout group and moderate in early gout according tophus. We found no agreement according clinics and tophus sign in wrist and double contour sign in I MTF. Ultrasound added information to clinical examination with good specificity for tophus and double contour sign.

## AB0806 HOW OFTEN DO GOUT PATIENTS REACH TARGET IN A RHEUMATOLOGY PRACTICE?

E. Corbett[1], P. Pentony[2], N. McGill[3]. *[1]Royal Prince Alfred Hospital, Camperdown; [2]Rheumatology, Canberra Hospital, Canberra; [3]Rheumatology, Royal Prince Alfred Hospital, Camperdown, Australia*

**Background:** Achieving the target serum urate has been repeatedly emphasized in published guidelines as a key determinant of successful gout management. Success rates are low in general practice and community audits but few studies have assessed results in a gout-orientated rheumatology practice
**Objectives:** To determine the frequency of achieving target urate levels and the drugs required.
**Methods:** Consecutive patients with gout who attended the private rooms between Jan 2010 and Sept 2014, in whom rheumatologist (NMcG) and patient agreed that urate-lowering therapy (ULT) was indicated and who commenced therapy were included. Serum urate targets: no tophus $\leq$0.36mmol/L; tophi $\leq$0.30mmol/L. Allopurinol was used initially. Due to limited access to febuxostat, for allopurinol intolerant patients with adequate renal function, probenecid was used next, then febuxostat.
**Results:** Of 168 patients (148 male), 123 (83.1%) achieved target. The average;standard dev;range of serum creatinine were 98;31.9;21–231. Of patients able to tolerate allopurinol, 103/145 (71.0%) achieved target with an average dose of 393mg/day. Included in the 103 patients were 40 who did not achieve target on allopurinol 300mg/day, but did achieve target with a higher dose (400–900mg/day). For the remaining 42 of 145 patients, 35 were deemed to be non-compliant (did not attempt $>$3 dose increases or a change to another medication and failed to achieve target). For 7/145 patients, allopurinol was ineffective. 3/7 reached target on combination of allopurinol and probenecid. 2 did not increase beyond allopurinol 400mg/day and failed to reach target, 1 increased to allopurinol 900mg/day but failed to reach target, 1 changed to febuxostat 80mg/day without reaching target. 23/168 (13.7%) were unable to use allopurinol (due to concurrent azathioprine or intolerance). Of the 23, 8 reached target on probenecid, 1 on benzbromarone, 8 on febuxostat and 1 on combination of probenecid and febuxostat. 5 did not reach target (4 increased only to febuxostat 40mg/day, 1 attempted probenecid without reaching target and was unable to attempt febuxostat due to supply difficulties).
Of 18 patients on probenecid (12 due to inability to use allopurinol), target was achieved by probenecid alone (7) or in combination with allopurinol (4) or with febuxostat (1). 2 attempted probenecid unsuccessfully, but then reached target on a retrial of allopurinol (1) or benzbromarone (1).
Of 19 patients on febuxostat, target was reached on febuxostat alone (10) or on a combination of febuxostat and probenecid (1). 1 reached target on a re-trial of allopurinol, and 7 did not reach target. Of those 7, only 1 failed febuxostat 80mg daily, with 2 non-compliant and the others on febuxostat 40mg/day by end of the study period.
In total (considering any ULT), 37/168 (22.0%) were non-compliant. No patient was intolerant or allergic to all ULTs.
**Conclusions:** Even in a gout-oriented rheumatology practice, non-compliance was by far the commonest reason for not achieving the serum urate target. For compliant patients able to tolerate allopurinol, failure to achieve target was uncommon (4.8%). Although potent newer ULTs are of benefit in specific patients, if advances in ULT availability are going to have a major impact on overall treatment success, they will need to be associated with improved compliance.

## AB0807 GOUT IN RURAL AREA IN SUB-SAHARAN AFRICA: A COMPARISON BETWEEN PATIENTS COMING FROM RURAL AND URBAN AREAS, IN AN URBAN TERTIARY HEALTHCARE CENTER IN CAMEROON

F. Kemta Lekpa[1], M.S. Doualla[1], M. Singwe-Ngandeu[2], H. Namme Luma[1].
*[1]Rheumatology, Douala General Hospital, Douala; [2]Rheumatology, Central Hospital, Yaoundé, Cameroon*

**Background:** Gout, the disease of kings is seen today in both urban and rural areas. However, few data are available on the characteristics of gout in the rural area, especially in sub-Saharan Africa.
**Objectives:** To evaluate the differences between gouty patients in rural and urban areas in Cameroon, Central Africa.
**Methods:** We performed a cross-sectional study in all 511 patients (96 women and 415 men) seen at General Hospital, Douala, Cameroon, between January 2004 and December 2013. The main demographic and clinical features of gouty patients living in rural and urban were compared. A $p< 0.05$ was considered statistically significant.
**Results:** The baseline characteristics of patients are presented in Table 1. Patients living in rural areas were older, had an oligoarticular clinical presentation, more hyperuricemia and higher serum uric acid levels and a more frequent chronic inflammation compared to patients living in urban areas.
Chronic kidney disease and dyslipidemia were more frequent in rural areas while obesity and hypertension were more frequent in urban areas.

Table 1. Main baseline characteristics of patients

| Variables | | Rural area (n=49) | Urban area (n=462) | *p* |
|---|---|---|---|---|
| Age (years), mean ± SD | | 60±12.05 | 56±10.63 | 0.001 |
| Sex | Men | 34 | 381 | <0.001 |
| | Women | 15 | 81 | |
| Obesity | | 24 | 297 | 0.01 |
| Arthritis | | 16 | 182 | 0.001 |
| Tophi | | 9 | 183 | 0.01 |
| Presentation at diagnosis | Acute gout | 25 | 230 | <0.001 |
| | Chronic gout | 24 | 232 | <0.001 |
| Clinical presentation, n | Monoarticular | 25 | 230 | <0.001 |
| | Oligoarticular | 22 | 173 | <0.001 |
| | Polyarticular | 2 | 59 | 0.12 |
| Fever, n | | 2 | 19 | 0.21 |
| Elevated uric acid levels, n | | 26 | 231 | <0.001 |
| Serum uric acid, mean ± SD, mg/dL (μmol/L) | | 84.68±3.22 | 82.21±1.07 | <0.001 |
| MSU cristal (synovial fluid)†, n | | 2 | 20 | 0.21 |
| Acute phase reactants, n | Elevated CRP | 13 | 151 | <0.001 |
| | Elevated ESR | 28 | 223 | <0.001 |
| Urate arthropathies, n‡ | | 6 | 62 | <0.001 |

**Conclusions:** Gout is characterized in patients living in rural area by a late age at onset and hyperuricemia higher compared to patients living in urban area. Cardiovascular risk factors are common. Further studies are needed to evaluate lifestyle changes in rural area.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2481

## AB0808 COMORBIDITIES ASSOCIATED WITH GOUT ARE ALSO COMMON IN SUB-SAHARAN AFRICA THAN IN DEVELOPED COUNTRIES: A CROSS-SECTIONAL STUDY IN CAMEROON

F. Kemta Lekpa[1], M.S. Doualla[1], M. Singwe-Ngandeu[2], H. Namme Luma[1].
*[1]Rheumatology, Douala General Hospital, Douala; [2]Rheumatology, Central Hospital, Yaoundé, Cameroon*

**Background:** Comorbidities associated with gout are frequently described in developed countries. Data are scarce in sub-Saharan Africa.
**Objectives:** To identify the main comorbidities associated with gout in Cameroon, Central Africa.
**Methods:** We performed a cross-sectional study on patients seen in the Rheumatology department of the Douala General Hospital, Douala, Cameroon, between January 2004 and December 2013. We have included the records of patients with diagnosis of gout according to ACR criteria 1977. The main comorbidities of gouty patients were recorded. A $p<0.05$ was considered statistically significant.
**Results:** We included 511 patients (415 men and 96 women). The mean age was 55.9±10.8 years. The main comorbidities associated with gout in our study are summarized in Table 1.
Metabolic syndrome was present in 101 patients (19.7%). Chronic kidney disease and dyslipidemia were more frequent in rural areas while the obesity and hypertension were more frequent in urban areas ($p<0.05$) [Table 2]. The association between gout and components of metabolic syndrome were all significant ($p<0.001$), particularly for obesity and dyslipidemia in men and hypertension and diabetes in women.

Table 1. Main comorbidities associated with gout

| Comorbidities | n (%) |
|---|---|
| Obesity | 256 (52.2%) |
| Hypertension | 208 (40.7%) |
| Osteoarthritis | 111 (21.7%) |
| Dyslipidemia | 80 (15.9%) |
| Digestive diseases (epigastralgia, gastroduodenal ulcer, upper gastrointestinal haemorrhages) | 74 (14.5%) |
| Diabetes | 52 (10.2%) |
| Chronic kidney diseases | 42 (8.2%) |
| Heart failure | 16 (3.1%) |
| HIV infection | 10 (2%) |
| Others | 13 (2.6%) |

**Conclusions:** Comorbidities are common in Cameroonians with gout like in developed countries. These data should encourage seeking and treating gastrointestinal adverse events and cardiovascular risk factors in gouty patients to reduce morbidity and mortality linked to gout.
**Disclosure of Interest:** None declared

## AB0809 EFFICACY AND SAFETY OF A PERSONALIZED NUTRITIONAL DIET IN GOUTY PATIENTS IN CAMEROON: A PILOT STUDY

F. Kemta Lekpa[1], H.D.G. Mbiatat[2], M.S. Doualla[1], H. Namme Luma[1].
*[1]Rheumatology; [2]Nutrition and Dietetics, Douala General Hospital, Douala, Cameroon*

**Background:** Many guidelines from different parts of the world mention the impact of diet on gout (1). However, data are scarce in sub-Saharan Africa.
**Objectives:** To evaluate the efficacy and safety of a gouty apurinic personalized diet based on ethnic origin, dietary habits and patient comorbidities.
**Methods:** Gout (177 ACR preliminary criteria) patients with serum urate levels >70g/dL were recruited. Patients were randomized to receive a standard diet apurinic gout or a personalized diet. At 1 month, all patients in the standard diet group were put under the personalized diet.
The primary endpoint was the reduction of serum uric acid at 1 month (M1) and 3 months (M3). Secondary outcomes were the number of gout attacks and changes in anthropometric measures at M1 and M3. A $p<0.05$ was considered statistically significant.
**Results:** Of the 30 patients randomized, 12 patients have not respected their diet. Only 18 were retained in the final analysis: 10 patients on personalized diet group and 8 on standard diet group. The baseline characteristics of both groups were similar at baseline ($p>0.05$). At M1, we have observed a significant decrease in serum uric acid in the personalized diet group compared to the standard diet group (p=0.0001). We have observed 5 acute gout attacks in the standard diet group against 2 acute gout attacks in the personalized diet group (p=0.03). A trend of decrease was observed for all other parameters without significance ($p>0.05$) [Table 1].
At M3, all patients received personalized diet. Initial efficacy was maintained in all the patients of the personalized diet group. For patients of the standard diet group, we observed a significant decrease in serum uric acid (p=0.02). There was no difference in the number of acute gout attacks (p=0.08). A trend of decrease was also observed for all other parameters without significance (Table 1).

**Abstract AB0809** – Table 1. Comparison of personalized diet group and standard diet group at baseline and at 1 month

| | | Baseline | Month 1 | *p** | Month 3** | *p**** |
|---|---|---|---|---|---|---|
| Weight | Standard diet | 90.12±16.72 | 89.37±16.31 | 0.46 | 88.02±52.31 | 0.31 |
| | Personalized diet | 89.30±24.66 | 87.40±23.35 | 0.33 | 86.76±53.46 | 0.06 |
| BMI | Standard diet | 32.63±5.11 | 32.35±8.52 | 0.45 | 30.95±8.23 | 0.12 |
| | Personalized diet | 31.49±8.52 | 30.88±8.25 | 0.43 | 28.74±6.21 | 0.08 |
| Waist-to-hip ratio | Standard diet | 0.89±0.14 | 0.88±0.10 | 0.63 | 0.87±0.21 | 0.09 |
| | Personalized diet | 0.90±0.17 | 0.89±0.13 | 0.44 | 0.88±0.15 | 0.08 |
| Uricemia | Standard diet | 87.37±8.68 | 88.30±12.68 | 0.57 | 75.56±5.97 | 0.02 |
| | Personalized diet | 89±19.21 | 65.32±41.19 | 0.0001 | 59.05±17.13 | 0.0001 |

**p*: baseline vs. Month 1. **Only 7 patients of Standard diet group and 9 patients of Personalized diet group ended the study. ***p*: baseline vs. Month 3.

No adverse events related to both diet group were observed.
**Conclusions:** This study shows that the diet should be personalized in gouty patients according to socio-cultural environment, lifestyle, and comorbidities of each patients. Efforts should be made to improve compliance to diet like other non-pharmacological and pharmacological treatment.

## AB0810 MACROPHAGE MIGRATION INHIBITORY FACTOR IN GOUTY ARTHRITIS

H.-R. Kim[1], K.-A. Lee[1], K.-W. Kim[2], B. Kim[2], S.-H. Lee[1]. *[1]Konkuk University School of Medicine; [2]Catholic univeristy of Korea, Seoul, Korea, Republic Of*

**Background:** Macrophage migration inhibitory factor (MIF) is proinflammatory, angiogenic and tissue degrading cytokine.
**Objectives:** This study aimed to determine monosodium urate (MSU)-induced MIF production and the role of MIF in gouty arthritis.
**Methods:** Peripheral blood and clinical data were obtained from 98 patients (31 patients with acute gouty arthritis and 67 patients with intercritical gout). Synovial fluid (SF) was obtained from patients with acute gouty arthritis and SF white blood cells and neutrophils were counted. SF and serum levels of MIF, interleukin (IL)-1, IL-8 and leukotriene B4, were measure using enzyme-linked immunosorbent assay (ELISA) and their relationship was analyzed. Peripheral blood mononuclear cells (PBMC) were isolated and cultured with MSU crystal, the production of MIF was determined.
**Results:** SF MIF level was higher in acute gouty arthritis than osteoarthritis. Serum MIF was higher in patients with intercritical gout than patients with acute gouty arthritis or healthy volunteers. SF MIF level was positively correlated with SF WBC and neutrophil counts, IL-1b and IL-8 levels in acute gouty arthritis. Serum MIF level was correlated with IL-1b and IL-8 levels in patients with intercritical gout. MSU crystal induced MIF production in PBMC with maximal effect at 100mg/ml.
**Conclusions:** MIF was highly produced in gouty arthritis and MSU induced MIF production. MIF could be involved in early inflammatory process in acute gouty arthritis.

## AB0811 MTHFR C677T POLYMORPHISM IS ASSOCIATED WITH INCREASE IN HOMOCYSTEINE BUT NOT WITH URIC ACID

I.W. Sohn[1], S.W. Nam[1], C.-B. Choi[1], Y.S. Kim[2], J.-B. Jun[1]. *[1]Rheumatology, Hanyang University Hospital for Rheumtic diseases; [2]Neurology, Hanyang University Hospital, Seoul, Korea, Republic Of*

**Background:** Serum homocysteine (sHcy) is currently well recognized as an independent risk factor for cardiovascular and cerebrovascular diseases. Hyperhomocysteinemia is reportedly associated with high serum uric acid (sUA) levels. MTHFR C677T polymorphism is associated with increase in sHcy. Some studies have suggested a positive correlation between MTHFR C677T polymorphism and sUA, but it remains unclear.
**Objectives:** We aimed to evaluate the association between sHcy and sUA as well as MTHFR C677T polymorphism and sUA.
**Methods:** Patients with memory impairment who visited neurology outpatient clinic were enrolled excluding those who were taking medication for the control of hyperuricemia. Hyperuricemia was defined as $>7.0$ mg/dl for male and $>5.6$ mg/dl for female. Hyperhomocysteinemia was defined as $>15$ μmol/l. Clinical laboratory examinations and genotyping for MTHFR C677T polymorphism was performed. Statistical analyses were performed using chi-square, Pearson's correlation coefficients, and ANOVA.
**Results:** Data from 861 subjects (264 male and 597 female) were analyzed. The mean age was 73.2±11.3 years in male and 75.3±10.3 years in female. Male showed significantly higher smoking, alcohol intake, LDL cholesterol, sUA, and sHcy levels, whereas HDL cholesterol, vitamin B12, folic acid were significantly lower compared to female. The prevalence of hyperhomocysteinemia was 38.6% (n=102) in male and 21.4% (n=128) in female. Hyperuricemia was also more common in male with prevalence of 13.3% (n=35) compared to 18.8% (n=112) in female and the mean sUA level was significantly higher in male (5.7±1.4 mg/dl vs 4.6±1.3 mg/dl, $p<0.001$).
sHcy was significantly associated with both folic acid ($r=-0.307$, $p<0.001$) and vitamin B12 ($r=-0.197$ $p<0.001$). Subjects with elevated sHcy levels had an odds ratio (OR) of 2.7 (95% CI 1.4–5.4) in male and 2.0 (95% CI 1.4–3.1, $p=0.001$) in female for hyperuricemia. The genotype frequency of MTHFR C677T was 32.8% (n=282) for CC, 49.8% (n=429) for CT, and 17.4% (n=150) for TT. TT genotype showed association with hyperhomocysteinemia when both gender were analyzed. In male, TT genotype ($r=0.399$, $p=0.007$) was associated with positive correlation between hyperhomocysteineima and hyperuricemia. In female, CT ($r=0.289$, $p<0.001$) and CC ($r=0.240$, $p<0.001$) was associated with positive correlation between hyperhomocysteineima and hyperuricemia. MTHFR C677T polymorphism was not associated with hyperuricemia.
**Conclusions:** Low serum folic acid and vitamin B12 are significant risk factors for hyperhomocysteinema, which reflects the influence of alcohol consumption and vitamin deficiencies on sHcy level. TT genotype of the MTHFR C677T was associated with hyperhomocysteinemia.
A positive association was observed between sHcy levels and sUA levels for both males and females which is in agreement with previous studies. Male having the TT genotype and female having the CT and CC genotype with hyperhomocysteinemia are likely to have higher sUA level.
MTHFR C677T polymorphism is not associated with sUA level, which is inconsistent with recent studies.

## AB0812 AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA: REVIEW OF 63 CASES

D. Amri[1], K. Baccouche[1], K. Zahra[2], B. Monia[1], S. Belghali[1], N. Elamri[1], Z. Alaya[1], H. Zeglaoui[1], E. Bouajina[1]. *[1]Rheumatology; [2]Hematology, Farhat Hached Hospital, Sousse, Tunisia*

**Background:** Multiple myeloma is a malignant disorder in which plasma cells accumulate in the bone marrow and produce an entire immunoglobulin (usually IgG or IgA) or only immunoglobulin light chains (kappa or lambda). Multiple myeloma accounts for approximately 10% of hematologic cancers and 1% of all cancers. In recent years there is huge improvement in treatment of patients with multiple myeloma. The milestone of these improvement is the Autologous hematopoietic stem cell transplantation
**Methods:** We analyzed results of 63 consecutive patients (16 male and 47 female) of MM who underwent Autologous hematopoietic stem cell transplantation (ASCT).
**Results:** A review of 63 cases of multiple myeloma seen from 2006 through 2015 revealed that The median age was 59,1 years (range: 38–80) and that 25% of them were male. Inital findings were bone pain in 73,8% of patients, anemia in 14%, renal insufficiency in 11% and hypercalcemia in 34,9%. Proteinuria was noted in 10% and Bence Jones proteinuria was identified in 5,2%. Skeletal roentgenographic abnormalities were seen in 78%. Serum proteinelectrophoresis showed a spike in 83% and hypogammaglobulinemia in 17%. Immunoelectrophoresis of the serum revealed a monoclonal heavy chain in 80% and a monoclonal light chain in the serum, in 5.2% (Bence Jones proteinemia). ASCT was performed in 15 patient (age <65ans); Post ASCT 47,1% of patients achieved complete reponse, 24,2% had very good partial response (VGPR), and 38.7% had partial response (PR).
**Conclusions:** Multiple myeloma is still an incurable disease with pattern of regression and remission followed by multiple relapses raising from the residual myeloma cells surviving even in the patients who achieve complete clinical response to treatment.
**Disclosure of Interest:** None declared

## AB0813 HIGH PREVALENCE OF UROLITHIASIS DUE TO EXCESS URINARY URIC ACID CONCENTRATION AND CALCIUM EXCRETION IN SOUTH CHINESE GOUT PATIENTS

Q.-H. Li, Y.-H. Li, D.-H. Zheng, J.-J. Liang, Y.-Q. Mo, X.-N. Wei, L. Dai. *Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** Urolithiasis greatly impact urate lowering therapy in Chinese gout patients. Benzbromarone is contraindicated and Chinese is high risk of allopurinol hypersensitivity syndrome. Febuxostat is too expensive for many patients. Few study about urolithiasis in Chinese gout patients are presented.
**Objectives:** To investigate the prevalence and risk factors of urolithiasis in south Chinese gout patients.
**Methods:** Patients with primary gout were recruited in the present cross-section study. Urolithiasis was defined as positive stone history and/or ultrasonography. All inpatients with estimated glomerular filtration rate (eGFR) over 30 ml/min/1.73 $m^2$ underwent 24 hours urinary chemistry assay including uric acid (UA), UA concentration, clearance of UA, Cr, calcium, phosphorus, potassium, sodium and chloride. Logistic regression were performed to examine association of urolithiasis with independent variables including age, gender, duration of gout, sUA, previous urate lowering therapy, serum creatinine, eGFR, body mass index, urine pH and 24 hours urinary chemistry assay.
**Results:** (1) Two hundred and nighty-four patients were recruited. Mean age of male (N=255) and female (N=39) were 54.4±16.4 and 67.2±15.3, respectively. Average serum UA was 9.0±2.5mg/dl and 25.9% of patients presented tophi.

Allopurinol, benzbromarone, or a combination of these two drugs had been prescribed in 97 patients (33.0%), 18 patients (6.1%) and 36 patients (12.2%), respectively. The rest 143 patients (48.6%) had not received urate lowering therapy before. (2) One hundred and eleven gout patients (37.8%) complicated with urolithiasis and urolithiasis was observed in 69 of them (62.1%) on ultrasonography. Compared with non urolithiasis group, urolithiasis group had significant higher serum creatinine (1.6±0.6 VS 1.3±0.3 mg/dl], lower eGFR (56.3±18.0 VS 64.1±18.4 ml/min/1.73m$^2$) and higher alcohol overuse (38.7% VS 26.2%) (P<0.05). (3) Among 102 patients performed 24 hours urinary chemical assay, 45 patients complicated with urolithiasis. Urolithiasis group had significantly higher 24 hours urine UA concentration than non-urolithiasis group (30.4±13.1 VS 23.9±11.9 mg/dl, P=0.01). There were no significant difference of other variables between two groups. Prevalence of urolithiasis increased significantly across increasing quartiles of urinary UA concentration (P=0.012, Table 1). (4) Logistic regression suggested that risk factors of urolithiasis were urinary UA concentration grouped by quartile (P=0.05) and urinary calcium excretion [OR 1.26 (1.01, 1.57), P=0.04]. Urinary UA concentration over 24.4mg/dl was associated with increasing risk of urolithiasis (Table 1).

Table 1. Prevalence of urolithiasis among quartiles of urinary UA concentration

| | Quartiles of urinary UA concentration (mg/dl) | | | |
|---|---|---|---|---|
| | I (<17.6) | II (17.6–24.3) | III (24.4–34.9) | IV (≥35.0) |
| Median (mg/dl) | 12.8 | 20.8 | 30.0 | 42.5 |
| Prevalence* | 13.3% (6) | 22.2% (10) | 33.3% (15) | 31.1% (14) |
| Adjusted OR# | 1 | 2.47 (0.66, 9.24) | 5.5 (1.50, 20.72) | 4.58 (1.24, 16.92) |
| P# | – | 0.18 | 0.01 | 0.02 |

*Test for a linear trend P=0.012. #By logistic regression.

**Conclusions:** Prevalence of urolithiasis in Chinese gout patients were high and predicted by excess urinary UA concentration and urinary calcium excretion.

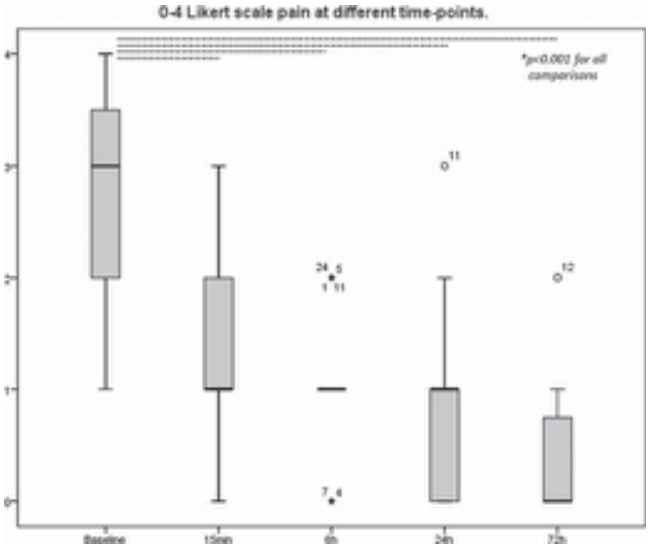
## AB0814 ONLINE PATIENT INFORMATION RESOURCES ON GOUT PROVIDE INADEQUATE INFORMATION AND MINIMAL EMPHASIS ON POTENTIALLY CURATIVE URATE LOWERING TREATMENT



L. Jiménez-Liñán[1], L. Edwards[2], A. Abhishek[1], M. Doherty[1]. [1]*Rheumatology;* [2]*Rehabilitation Medicine, Academic Rheumatology, University of Nottingham, Clinical Sciences Building, Nottingham City Hospital, Nottingham, United Kingdom*

**Background:** Nowadays patients use the internet to find more about their disease and its management. The accuracy of online gout patient information resources has not been examined before.
**Objectives:** To assess the content, accuracy and readability of freely available online patient information resources against the current understanding of gout.
**Methods:** An internet search was carried out to identify online gout patient information resources from the United States of America (USA), United Kingdom (UK), Australia and Canada in October 2015. Websites aimed at healthcare professionals, those requiring a paid subscription, or focussed on a specific aspect of gout were excluded. Information provided in the websites was compared against 15 key points. If information on a key point was regarded as present, it was classified on a 1–3 Likert Scale (1-inaccurate, 2-acceptable information with some inaccuracy and 3-acurate). Readability was assessed using Flesch-Kincaid Reading Ease score. Fifteen randomly selected websites were reviewed by a binder second reviewer.
**Results:** Eighty-five websites (30 provided by a medical and/or healthcare organisation were selected). Information was provided for a mean (SD) 7.73 (2.85) of 15 key points overall. The websites were more likely to contain information on risk-factors than on treatment of gout (p<0.001). More than 50% provided no information, or had inaccuracies regarding the pathogenesis of gout and over 75% of websites had no or inaccurate information on the role of ULT. Most websites highlighted information on dietary and lifestyle modifications for treating gout and did not emphasise ULT and its potential for cure. The two raters agreed in 80% of occasions on whether information on a particular question was present or not (*k* 0.60). The majority of websites were difficult to read, with information in 68% websites rated as at least fairly difficult.
**Conclusions:** Most of the patient information on gout available online is inaccurate and commonly over emphasises the use of dietary and lifestyle changes as a way of managing gout. The importance of ULT in managing gout and the potential for gout being curable with long-term ULT are not explained well. Moreover, most websites were difficult to read and most on-line resources had inaccuracies regarding the pathogenesis and treatment of gout.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5392

## AB0815 INTRAARTICULAR TRIAMCINOLONE PLUS MEPIVACAINE PROVIDES A RAPID AND SUSTAINED RELIEF FOR ACUTE GOUTY ARTHRITIS

M. Andrés[1], A. Begazo[1], F. Sivera[2], P. Vela[1,3], E. Pascual[1,3]. [1]*Seccion de Reumatologia, Hospital General Universitario de Alicante, Alicante;* [2]*Seccion de Reumatologia, Hospital General Universitario de Elda, Elda;* [3]*Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain*

**Background:** Gout attacks are often considered as especially painful. Effective treatments for gout attacks - colchicine, NSAIDs, systemic or intra-articular corticosteroids, IL-1 blockers -result in a rapid subsidence of the attacks, but it usually requires 1–3 days (1–3) to relieve the symptoms. Our standard procedure in clinics is to add 2% mepivacaine to intra-articular triamcinolone, as we have repeatedly observed a very rapid and persistent subsidence of pain. Here we aimed to document this outcome in a prospective way.
**Methods:** Consecutive patients with crystal-proven gout and an acute, monoarticular attack were recruited. All cases were treated with an intra-articular injection of triamcinolone plus 2% mepivacaine, according to our clinical practice. Joint pain was registered using a 0–4 Likert semiquantitative scale (0=absent; 4=severe) at baseline and 15min, 6h, 24h, and 72h after the injection. Presence of joint swelling and erythema was also collected at baseline and after 72h. Treatment response after 72h was evaluated by both the physician and the patient on a 0–4 Likert scale (0=no effect; 4=complete resolution). Between-after comparisons were analyzed using Wilcoxon signed-rank test.
**Results:** A total of 24 patients were recruited, median (±SD) aged 64.8 years (±12.7), 22 males. Involved joints were 16 first metatarsophalangeal (1MTP), 5 knees, 2 wrists, and one ankle. Triamcinolone doses ranged from 10mg (1MTP) to 20–40mg (others). Median (p25–75) pain at baseline was 3 (2–3.8), joint swelling was present in all cases, and in 13 cases (54.2%) erythema was observed. After the intra-articular injection, a significant pain reduction was observed at all time-points, even at 15min after the injection, as shown in the Figure. No symptoms rebounds between time-points were reported. Treatment was effective as assessed by both patients and rheumatologists (3 (3–4) and 3.5 (3–4), respectively).

**Conclusions:** This small study confirms a rapid relief of gout attacks with adding mepivacaine to intra-articular corticosteroids, with a significant response even at 15min after the injection. Large, controlled studies should confirm these results.

## AB0816 GOUTY FLARES AND ATHEROGENIC SERUM LIPID PROFILE IN PATIENTS WITH GOUT

M. Radak-Perovic[1], M. Zlatkovic-Svenda[2]. [1]*Institut of Rheumatology, School of Medicine, Belgrade University;* [2]*Clinical Department IV, School of Medicine, Belgrade University, Belgrade, Serbia*

**Background:** Atherogenic serum lipid profile is prevalent in gouty patients.Recently conducted *in vitro,in vivo and clinical studies* of gout have evidenced proinflammatory effects of LDL-C and antiinflammatory properties of HDL-C (1–3).

**Objectives:** To investigate if atherogenic serum lipid profile in gouty patients predicts gout activity.
**Methods:** A total number of 69 patients (97,1% male) were divided into two groups with regard to the frequency of their gouty flares: group 1 (up to 1 flare per year) and group 2 (2 or more flares per year, with the maximum flare number of 20). Logistic regression model was used to identify the set of metabolic items able to predict frequent flares in gout. The following variables were included in the model: total cholesterol level (border set up at 5,2 mmol/L), HDL cholesterol level (1,03 mmol/L for men and 1,3 mmol/L for women), LDL cholesterol level (3,37 mmol/L) triglicerydes (1,68 mmol/L) and serum uric acid (359 mmol/L). The fit of the selected model to the actual outcome was determined with a set of goodness of fit tests. All analyses were carried out using statistical program SPSS 20.0.
**Results:** Logistic model was acceptable, by showing 74% of correctly predicted cases in a classification table with a cut off value of p=0.5. Hosmer and Lemeshow goodness of fit test was found to be nonsignificant (p=0,881), suggesting that model fit to data well. Two additional goodness-of-fit tests which confirmed those results were Cox and Snell $R^2$ (p=0,195) and Nagelkerke $R^2$ (p=0,275). According to the logistic regression model, the only significant predictor of the gouty flares frequency in patients with gout was the high LDL cholesterol level (p=0,008).
**Conclusions:** More frequent flares in patients with gout were predicted by the higher LDL cholesterol level only. Surprisingly, gouty flares were not predicted by serum uric acid level, as it was commonly thought. HDL cholesterol level, total cholesterol level and level of triglycerides were not found to be the predictors of the frequent gout attacks.

## AB0817 ANALYSIS OF INTERLEUKIN-1β INHIBITOR (CANAKINUMAB) IMPACT ON ENDOTHELIAL DYSFUNCTION

M. Eliseev, O. Zhelyabina, S. Vladimirov, E. Markelova, D. Novikova, O. Korsakova, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** It is supposed that IL-1β inhibition may be associated with cardiovascular risk reduction [1, 2], but it isn't known what effect of it is on endothelial function.
**Objectives:** To assess canakinumab effects on structural and functional parameters of vasculature.
**Methods:** Open-label prospective study of 20 pts (17 (85%) males and 3 (15%) females) with chronic gout was performed in 2014–2015 y. at the V. A. Nasonova Research Institute of Rheumatology. All patients received one dose of canakinumab 150 mg subcutaneously. Lab parameters (uric acid, cholesterol, triglycerides, hsCRP and interleukin-6 (IL-6) levels), 24 hour BP monitoring, comprehensive Echo-CG, duplex scanning of carotid arteries the intima-media thickness (TIM) measurements of near and far wall were taken from both common carotid arteries (CCA), vascular wall stiffness was evaluated before injection of canakinumab and on days 14 and 120 after. The quantification of serum hsCRP levels was done with highly sensitive immune turbidimetric test, serum IL-6 levels was detected using of "xMAP" technology (Human Grp I Cytokine 27-plex panel) and on the analyzer "BioPlex-200" (Bio-Rad, the USA). Lipid-lowering and antihypertensive therapy was not modified during the study. Statistical analysis was performed using the application package STATISTICA 10.0 (StatSoft.Inc., USA). Differences were considered significant at $p<0.05$.
**Results:** Baseline TIM in the CCA was 0,83 [0.71; 0.94] mm, while by the end of the study it dropped to 0,74 [0.69; 0.84] mm (p=0.022). Median baseline pulse wave velocity (PWV) in the aorta was 14,12 [10; 17] m/s, dropping during the study to 13,1 [11; 14] (p=0,79). Falling down of baseline arterial stiffness index was documented in 13 (65%) pts, and by the end of the study in 7 out of them not a single joint was tender or swollen, hsCRP levels >5 mg/l was in 5 out of 13 pts, who was statistically significantly more rare as compared to pts without positive changes of this index (in 6 out of 7 pts (86%)) ($p$=0.043). Median of serum hsCRP level and IL-6 level in pts who had reduction of PWV was significantly smaller then in others pts at 120 days (respectively, hsCRP level – 2.7 [2.3; 7.7] mg/dl vs 11.5 [6.9; 17.7] mg/dl (p=0.0084) and IL-6 level – 5,9 [3,9; 7.7] pg/ml vs 12,6 [10,8; 22,4] pg/ml) (p=0,44). Based on BP monitoring data no changes from baseline BP measured before injection of Canakinumab, and on Day 14 or Day 120, occurred. Mean levels of cholesterol and triglycerides didn't change as well
**Conclusions:** IL-1β inhibitor Canakinumab may have positive effect on TIM parameters. Effects of Canakinumab on arterial stiffness parameters depend on the potency of anti-inflammatory effect.

## AB0818 ULTRASONOGRAPHY SIGNS OF MSU URATE DEPOSITION IN PATIENTS WITH HYPERURICEMIA AND EARLY DIAGNOSIS OF GOUT

M. Eliseev, O. Zhelyabina, S. Vladimirov, M. Severinova, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The role of ultrasonography (US) in diagnosis of gout is not clearly established [1].
**Objectives:** The detection of monosodium urate (MSU) crystals depositions in pts with asymptomatic hyperuricemia (ASHU) and in pts with gout by US examination for early diagnostics of gout.
**Methods:** The study included 84 pts with either ASHU (n=34), or gout (n=50), 72 males and 12 females. The diagnosis corresponded all pts with gout to the criteria developed by S.L. Wallace, and were subjected to joint puncture (1st metatarsophalangeal joint (MTPJ), knee, elbow, ankle) with further synovial fluid analysis under polarized microscopy. Mean age of gout pts was 48,1±12,6 y., disease duration <1 years was established in 12 out of 50 pts (24%); mean age of ASHU pts was 47,21±11,57 y., with mean level of uric acid – 473,71±73,7μmol/l. All pts were subjected to 1st MTPJ US examination with linear 7–17 MHz multi-frequency ultrasonic transducer. Statistica 10.0 package and Biostatistics were used for statistical processing of data. *P* values <0.05 were considered statistically significant.
**Results:** Based on US examination data the "double contour" (DC) sign in the 1st MTPJ was found in 36 (72%) out of 50 gout pts, intra-articular or soft tissue gouty tophi – in 27 (54%) pts, both signs – in 24 (48%) pts. MSU were found in 45 (90%) gout pts by synovial fluid analysis. 1st MTPJ arthritis was established in past medical history in 41 gout pts. In subjects with disease duration <1 years DC sign was found more frequently as compared to pts with disease duration ≥1 years, respectively in 30 (79%), and 6 (50%) ($p$=0,045), same refers to the presence of US tophus signs: in 22 (58%), and 5 (42%) pts ($p$=0,33) respectively; one of the two signs - in 36 (95%), and 6 (50%) pts, respectively ($p$=0,0002). In 4 out of 50 gout pts with only one attack of arthritis in past medical history the DC sign was found in 1 patient, as well as intra-articular or soft tissue tophus - also in 1 patient. The US DC sign in ASHU subgroup was found in 12 (35%) pts, US tophus sign – in 5 (15%) pts, both sings – in 2 (6%) pts. In 17 pts with UA level >420 μmol/l and ≤480 μmol/l the US DC sign was found in 4 (24%) pts. In 12 pts with UA level >480 μmol/l and ≤540 μmol/l the DC sign was found in 5 (42%) pts, and both signs – US DC and US tophus were present in 2 (17%) pts. Elevated uric acid levels >540 μmol/l were detected in 5 pts, the US DC sign was found in 3 out of them, while both signs – in 2 pts. Energy Doppler scanning identified synovitis in 15 (44%) out of 34 ASHU pts.
**Conclusions:** Serum UA levels may predefine US detection of MSU deposition in ASHU pts and in 44% of cases US signs of MSU depositions are combined with subtle signs of inflammation, detected with energy Doppler scanning. Detection rates of US gout signs grow in parallel with disease duration.

## AB0819 INDIRECT COMPARISON OF URATE-LOWERING THERAPIES FOR HYPERURICEMIC PATIENTS WITH OR WITHOUT GOUT: META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

M. Fan[1], J. Liu[2], B. Zhao[2], X. Wu[1], J. Gu[1]. *[1]the third affiliated hospital of Sun Yat-Sen University; [2]the first affiliated hospital of sun yat-sen university, Guangzhou, China*

**Background:** Hyperuricemia is the most significant risk factor for the development of gout, defined as a serum concentration of uric acid at 6.8 mg/dl or greater. Long-term maintenance of serum urate levels below its saturation threshold can reduce the frequency of acute gout flares and resolve the existing tophi.
**Objectives:** To assess the urate-lowering efficacy and safety of febuxostat, allopurinol and benzbromarone in hyperuricemic patients with or without gout.
**Methods:** We included all the randomized controlled trials (RCTs) that compared any urate-lowering medication with placebo or head to head. The efficacy outcomes included the proportions of achieving the target urate level (<6.0 mg/dl) at final visit or last 3 visits and the percentage of gout flares during the first 8 weeks. The safety outcomes included total adverse events (AEs), withdrawals due to AEs and serious AEs. A Bayesian network model was used to compare all interventions simultaneously.

**Results:** Sixteen RCTs (6645 patients) were included in the analysis. All urate-lowering therapies were more likely to achieve the target urate level at final visit and last 3 visits than placebo, but had an inconclusive higher risk of gout flares. Furthermore, all of the febuxostat doses (40, 80, 120, 240 mg/day) had a higher proportion of achieving the target urate level at final visit than allopurinol. With febuxostat dosages increased, more patients achieved the target urate level. Febuxostat 240 mg/day was the most effective drug for serum urate normalization. Regarding safety, there were no significant differences among urate-lowering therapies and placebo for total AEs, withdrawals due to AEs and serious AEs, except that allopurinol had a higher risk of total AEs than febuxostat 120mg/day.

**Conclusions:** Compared to placebo, all urate-lowering therapies are effective in achieving the target urate level for hyperuricemic patients. Febuxostat is more efficacious than allopurinol for serum urate normalization.

## AB0820 CALCIUM PYROPHOSPHATE DIHYDRATE AND HYDROXYAPATITE CRYSTAL INDUCED METABOLIC DISEASES – SAME OR DIFFERENT?

M. Bély[1], Á. Apáthy[2]. [1]*Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God;* [2]*Department of Rheumatology, St. Margaret Clinic, Budapest, Hungary*

**Background:** Arthropathy induced by calcium pyrophosphate dihydrate [$Ca_2P_2O_7.2H_2O$] (CPPD) crystals (chondrocalcinosis, pseudogout, pyrophosphate arthropathy) and arthropathy induced by hydroxyapatite [$Ca_5(PO_4)_3(OH)$] (HA) crystals (apatite rheumatism, Milwaukee syndrome) are regarded as distinct clinical entities [1–3].

This distinction is justifiable clinically by the different localization and symptoms of CPPD and HA crystal depositions, and is supported by the observation of the crystals in conventional hematoxylin-eosin (H-E) stained histological sections. In H-E stained sections viewed under polarized light in case of chondrocalcinosis the CPPD crystals are detectable, while the more soluble HA crystals in case of apatite rheumatism are not.

The probability of identifying crystals is much higher in unstained sections viewed under polarized light, than in H-E stained ones [4,5].

**Objectives:** The aim of this study was to detect and compare the prevalence of CPPD and HA crystals in H-E stained and unstained sections in clinically diagnosed chondrocalcinosis and apatite rheumatism.

**Methods:** Eighteen (18) tissue samples of 10 patients with clinically diagnosed chondrocalcinosis, and ten (10) tissue samples of 3 patients with clinically diagnosed apatite rheumatism were studied in serially cut histologic sections of formalin fixed and paraffin embedded tissue blocks. The sections stained with H-E and unstained sections were viewed under polarized light with an Olympus BX51 polarization microscope.

**Results:** The H-E stained sections were examined under polarized light; CPPD crystals were detected in all 10 patients with clinically diagnosed chondrocalcinosis, and HA crystals were detected in 1 of 3 patients with clinically diagnosed apatite rheumatism.

In unstained sections viewed under polarized light CPPD and HA crystals were present in all 13 patients with different prevalence (dominance).

| Clinical diagnosis | Stained with HE | | Unstained | |
|---|---|---|---|---|
| | CPPD | HA | CPPD | HA |
| Chondrocalcinosis n=10 | 10 | 0 | 10 | 10 |
| Apatit rheumatism n=3 | 0 | 1 | 3 | 3 |
| Total n=13 | 10 | 1 | 13 | 13 |

In unstained sections CPPD dominated the crystal deposits in 6 of 13 patients (with sporadic presence of HA). The presence of HA crystals was absolutely dominant in crystal deposits in 4 of 13 patients (with sporadic presence of CPPD). The presence of CPPD and HA crystals was equal in 3 of 13 patients.

**Conclusions:** There is a difference in the shape, size, and intensity of birefringence of CPPD and HA crystals, furthermore in their solubility in conventional fixatives (formalin) and other aqueous solutions (e.g. dyes).

The presence of CPPD and the absence of HA crystals in H-E stained histologic sections supports the distinction between chondrocalcinosis and apatite rheumatism.

In unstained histologic sections variable amounts of CPPD and HA crystals were demonstrated in clinically diagnosed cases. Based on these findings the chondrocalcinosis and apatite rheumatism may represent different clinical manifestations and symptoms of the same metabolic disorder.

## AB0821 EVOLUTION OF THE VALUES OF ALKALINE PHOSPHATASE (ALP) IN PATIENTS TREATED WITH ZOLEDRONIC ACID AND DIAGNOSED WITH THE PAGET'S DISEASE OF BONE

M. Retuerto[1], L. Sierra[2], M. Martín[1], C. Moriano[1], A. García[1], M. Garijo[1], C. Iniguez[1], A. Lopez[1], C. Álvarez[1], E. Díez[1], T. Pérez[1]. [1]*Rheumatology Department;* [2]*Pneumology department, University Health Care Complex of León, León, Spain*

**Background:** The indication or use of zoledronic acid on the Paget's disease of bone was approved in 2005. Recent studies point out the administration of a single intravenous dose of this medicine as the first therapeutic option.

**Objectives:** The aim of this study is to determine whether there is improvement in the ALP values among the patients with Paget's disease of bone after the administration of the zoledronic acid and to analyze whether this improvement is greater in the group previously treated with oral bisphosphonates or in the group who have not received prior treatment.

**Methods:** This is a retrospective study which included 49 patients with Paget's disease of bone that were examined by the rheumatology department and that have been registered in a retrospective database since 2010.

The independent variables included were age, gender, smoking habits, presence of diabetes mellitus, date of first treatment, doses received, corticosteroid therapy, presence of concomitant inflammatory disease, complications after treatment, fractures after the administration of the drug and pretreatment with oral bisphosphonates.

**Results:** The mean age of patients was 75±9,84 years [53–97]. 25 patients (51%) were male and 24 (49%) were female. 29 patients (59.2%) non-smokers, 10 (20.4%) former smokers, and 10 (20.4%) current smokers. 9 patients (18.4%) were diabetic. 26 patients had not received prior treatment with oral bisphosphonates, while 23 had been previously treated. 2 patients were treated with corticosteroids. 7 patients had active cancer, one patient had rheumatoid arthritis and one patient had another type of inflammatory disease. One patient developed fever as a post-infusion complication; however, this side effect did not require the discontinuation of therapy. Two patients required reinfusion due to the resurgence of the Paget and due to the high levels of ALP after the first dose. The mean dose received was 1.12± 0.389. One patient had a fracture after the administration of the drug.

There is a statistically significant difference between the average ALP prior to the initiation of treatment with zoledronic acid and after the treatment in both groups of patients. Nevertheless, when comparing both subgroups of patients (treated or not previously with bisphosphonates), there is a greater difference in the subgroup of patients who had not received prior treatment compared to those that had been treated with oral bisphosphonates.

**Conclusions:** * Zoledronic acid treatment is effective in reducing the ALP levels in patients with Paget's disease of bone.

* The difference in ALP levels after the zoledronic acid administration with respect to the previous ones is higher in the group of patients not previously treated with oral bisphosphonates.

## AB0822 HOSPITALIZATION TRENDS OF GOUT AND RHEUMATOID ARTHRITIS IN THE UNITED STATES: A TALE OF TWO ARTHRITIDES

N. Lu[1], S.Y. Lim[1], A. Oza[1], M. Fisher[1], S.K. Rai[2], M.E. Menendez[3], H.K. Choi[1]. [1]*Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, United States;* [2]*Arthritis Research Canada, Vancouver, Canada;* [3]*Department of Orthopaedic Surgery, Massachusetts General Hospital, Boston, United States*

**Background:** Gout and rheumatoid arthritis (RA) are the two most common

inflammatory *arthritides*. As hospitalizations for these conditions are known to incur substantial resource use, hospitalization trends and associated costs provide key benchmarks of disease burden. Varying levels of perceived success in their care and changing epidemiology (mainly for gout) may have made a substantial impact over recent years; however, relevant data are scarce.
**Objectives:** To examine hospitalization trends of gout and rheumatoid arthritis in the US.
**Methods:** We examined trends in the annual hospitalization rate of gout and RA using the US Nationwide Inpatient Sample (1993–2011).
**Results:** From 1993 to 2011, the annual hospitalization rate for patients with a principal diagnosis of RA declined by 67% from 13.9 to 4.6 per 100,000 US adults ($p<0.001$), whereas that for gout doubled from 4.4 to 8.8 per 100,000 US adults ($p<0.001$), reversing the hospitalization rates between the two conditions over the past two decades. These trends persisted among subgroups by age, sex, race, and geographic region (all p-values $<0.001$). Approximately 60% of RA admissions and 2% of gout admissions were associated with total joint replacement or other major joint surgeries; the frequency trend of these surgeries paralleled the declining trend in RA hospitalizations (all p-values $<0.001$). The hospital costs also reflected the hospitalization trends, resulting in $58,003 (2011 USD) per 100,000 US adults for gout and $55,988 per 100,000 US adults for RA in 2011.

Figure 1. Annual Rate of Hospitalization for Patients with a Principal Diagnosis of Gout and Rheumatoid Arthritis

**Conclusions:** These nationally representative inpatient data indicate that both primary hospitalization rates and the inpatient economic burden for gout have increased substantially over the past two decades, whereas those for RA have declined considerably. These trends reflect both suboptimal gout care in addition to its increasing prevalence; these data also provide a key reassuring benchmark for the perceived improvement in RA care, thereby preventing joint replacements. These data support the critical need to improve gout prevention and care.

## AB0823 HOW CURABLE IS GOUT? EXPERIENCES FROM A RHEUMATOLOGY CLINIC

O. Slot. *Center for Rheumatology and Spine Diseases, Rigshospitalet Glostrup, University of Copenhagen, Glostrup, Denmark*

**Background:** In spite of good treatment options results in surveys of gout have been disappointing. In general practice only 50% of gout pt.s are put on urate lowering treatment (ULT) and of these less than 50% reach the curative treatment target (TT)(p-Urate $<0.36$ mmol/l) rendering many pt.s prone to experience continuous disease activity or repeating flares. In order to improve gout treatment EULAR and ACR have elaborated guidelines based on the treat to target concept with gradually intensified ULT combined with flare prophylaxis.
**Objectives:** To evaluate the eligibility and effectiveness of the EULAR/ACR guidelines in clinical practice.
**Methods:** 100 consecutive pt.s diagnosed with crystal proven gout were offered personal disease information and a standardized treatment regime. ULT was started with allopurinol (ALL) 100 mgs daily and the dose was gradually increased at follow up visits typically every 6 weeks until TT was reached. Pt.s with known or new incident ALL intolerance were treated with/changed to febuxostat (FEB) or benzbromaron (BEN). All pt.s were unless contraindicated offered flare prophylaxis with colchicine (COL) 0.5 mgs bid as long as they had clinical symptoms or were dose escalated in ULT. The pt.s were offered to be followed until their reached "Clinical Remission" defined as TT reached for 3 months and no flares and no flare prophylaxis for the last month.
**Results:** 88 males (62,1±13,6 (SD) yr) and 12 females (74,1±6,9 yr) were included. Mean disease duration was 8,6±6,9 years. 18 had mon-, 37 oligo-, 25 polyarticular, and 20 had tophaceous gout. Recently affected joints included MTPs: 63%, midfoot/ankles: 57%, knees: 57%, hands/wrists/elbows: 47%. Most patients had comorbidity in the form of CVD: 36%, Hypertension: 80%, DM2: 28%, and nephropathy: 29%. 72% had Metabolic Syndrome. At entry 15 pt.s were on ALL treatment. P-urate was initially 0.53±0.11 mmol/l in untreated pt.s and 0.46±0.10 mmol/l in ALL treated pt.s.
93 pt.s started/continued ULT (ALL: 86, FEB: 12, BEN: 7). 85% reached TT after mean 4.7±3.9 months. 40% reached p-Urate $<0.40$ mmol/l. Median ALL dose was 300 mgs daily, 17% and 11% needed 450 and 600 mgs respectively. 90% received COL prophylaxis with mean treatment duration of 7.6±5,8 months. "Clinical Remission" was reached in 82 of 100 gout pt.s after mean treatment duration of 10.4±5.6 months. The mean number of visits were 5.5±2.4 and follow up timewas11.1±5.6months. The 18 patients who did not reach "Clinical Remission" either did not want any treatment (n=3), did not want ULT due to previous experience with flares (n=4), had bad compliance (n=6), could not reach TT due to co-morbidity with nephropathy (n=2), or were due to AEs satisfied with insufficient ULT and continuous COL treatment (n=3).
**Conclusions:** Reaching a good treatment result in gout still is challenging due to extensive morbidity and co-morbidity. This study shows that a good clinical response can be achieved in the majority of patients when given personalized disease information and long term follow up with long term flare prophylaxis in compliance with the EULAR/ACR guidelines. It is suggested that rheumatologists assume the role of following gout patients until they have reached TT and clinical remission and subsequently can be followed in general practice.

## AB0824 SYNOVIAL FLUID ANALYSIS IN A RHEUMATOLOGY DEPARTMENT. PAST AND PRESENT

P. Cuevas, S. Rodriguez, J. Inciarte, P. Peris, A. Monegal, N. Guañabens. *Rheumatology, Hospital Clinic, Barcelona, Spain*

**Background:** For decades the Departments of Rheumatology have used synovial fluid analysis for the differential diagnosis of various arthropathies, especially microcrystalline diseases. However, it is possible that access to new diagnostic techniques and new treatments has changed the frequency and characteristics of synovial fluid analysis.
**Objectives:** To compare the frequency and findings in synovial fluid analyses in two periods 10 years apart.
**Methods:** Retrospective cross-sectional study evaluating the synovial fluid analysis reports from a Rheumatology Department (including outpatient, inpatient and emergency departments) carried out for a 4-year period (2012- 2015). The results were compared with those obtained in a previous study conducted between 1998–2005.
**Results:** During the last 4 years we have analyzed a total of 440 samples of synovial fluid, with an average of 110±24.8 samples per year (range: 135–78), while in the previous study (1998–2005) 1,881 synovial fluid samples were analyzed, with an average of 235±54.8 samples per year (range: 326–162), decreasing the number of fluid analysis evaluations by 53%. In 31.8% of the current samples and in 18.8% of samples of the previous study microcrystals were detected. The identification of monosodium urate crystals (MSU) were observed in 50% and 49.1% of the current vs. the previous analysis of the samples, respectively, whereas calcium pyrophosphate dihydrate crystals (CPPD) were present in 44.2% and 47.4%, respectively. The identification of both crystals in the same sample (UMS + CPPD) was reported in 6% and 1% of the analyses in the current and previous study, respectively. In both studies, MSU crystals were more frequent in males (83% vs. 89% in the current and previous study), whereas in women CPPD crystals were observed in 48% and 64% of current and previous analyses, respectively.
**Conclusions:** In recent years a decrease in the number of synovial fluid analysis is observed. Although the proportion of synovial fluid analyses from pathologies other than crystal-induced arthritis has decreased, the proportion of detectable UMS and CPPD crystals has not changed.

## AB0825 SURVEY ON MANAGEMENT OF GOUT AND HYPERURICEMIA AMONG THAI PHYSICIANS

P. Chiowchanwisawakit, K. Charoenhongthong, W. Katchamart, V. Srinonprasert. *Medicine, Siriraj Hospital, Bangkok, Thailand*

**Background:** Gout is the most common inflammatory arthritis in men. Suboptimal treatment of gout has been reported[1]. To improve quality of care, it is essential to identify problems.

**Objectives:** To assess management of gout among physicians in Thailand.
**Methods:** A cross-sectional survey was conducted among physicians in Thailand. A questionnaire designed to evaluate knowledge regarding management of hyperuricemia and gout was sent to 3,916 doctors between December 1, 2011 and January 1, 2012. Only doctors having experience in taking care patients with hyperuricemia and gout were included in this study.
**Results:** A total of 742 (19.1%) questionnaires were returned. Six hundreds and seven (81.8%) participants had experience of hyperuricemia and gout management. Of total, 271 (44.6%) advised patients on non-pharmacologic management of hyperuricemia, as follows: stop alcohol drinking, 262 (43.2%); weight reduction, 223 (36.7%); stop entrails and gut, 216 (35.6%); stop purine rich vegetables, 198 (32.6%); and stop poultry, 196 (32.3%).
Regarding treating acute gout, colchicine was the most frequently used, 582 (95.9%) and 157 (27.0%) managed with high dose regimen, followed by non-steroidal anti-inflammatory drugs (NSAIDs) (88.8%), corticosteroid (47.1%), physiotherapy (33.9%), and topical NSAIDs (25.3%). Five hundreds and ten (84.0%) physicians used colchicine as the first medication for arthritis prophylaxis while only 36 (5.9%) doctors chose NSAIDs.
Three hundred and sixty nine (67%) of 575 respondents set the target of SUA of urate lowering therapy (ULT) less than 6 mg/dl. Among uric lowering agent, allopurinol was the most well-known, 592 (97.5%), followed by probenecid, 426 (70.2%), benzbromarone 244 (40.3%), and sulfinpyrazone, 140 (23.1%). Four hundred and eighty eight (80.4%) of respondents would hold or stop allopurinol sometimes along the course of allopurinol treatment. Ninety five (15.7%) and 58 (9.6%) held allopurinol when having gouty attack and acute illness, respectively. Reasons for stopping allopurinol were, as follows: normal serum uric acid for 5 years, 324 (53.4%); no tophi for 5 years, 206 (33.9%); no symptoms for 5 years, 224 (36.9%); no arthritis, no tophi, and normal serum uric acid for 5 years, 86 (14.2%); and no arthritis and normal serum uric acid for 5 years, 55 (9.1%).
**Conclusions:** In Thailand, physicians gave patient education less than 50%, and some of advice was not correct as evidence-based studies. Colchicine was commonly used to control acute gout; however, some of doctors still used a high dose regimen which may result in more toxicity. Approximately 30% of physicians did not keep the target of SUA when treating with ULR as the general accepted target. To improve overall quality of care for gout and hyperuricemia patients, education should focus on specific problems.

## AB0826 DEVELOPMENT AND PILOT TESTING OF AN ONLINE GOUT EDUCATION TOOL – MYGOUTCARE®

P.P. Khanna, A. Rankin, L. An, D. Khanna. *University of Michigan, Ann Arbor, United States*

**Background:** Recent management guidelines for gout have identified unmet educational needs in patients with gout. Qualitative studies have documented that there is a paucity of patient-focused materials to facilitate ongoing patient-physician communication.
**Objectives:** To develop and test a web-based interactive educational resource for patients with gout tailored to improve their knowledge. This electronic platform has the potential to educate patients about gout and help facilitate communication with their physician to improve long term outcomes.
**Methods:** The website was developed in four phases. 1. Two advisory panels - 30 gout patients and 10 gout experts iteratively reviewed pre-identified content areas of modifiable gaps in pathogenesis, natural history and treatment goals from previously conducted focus groups[1]. They evaluated the design (graphics and lay out) of the website and provided written input. 2. Incorporation of a validated knowledge questionnaire[2] on gout and a 5-minute post-survey to assess knowledge about critical take-home messages and satisfaction with their physician's care. 3. With a team of web designer and health informatics expert content areas were tailored in the website so the patient could walk through their own journey to learn various aspects of gout including triggers of flares, comorbidities, pharmacologic and non-pharmacologic treatment, healthy gout diet, and lifestyle choices. 4. Beta testing by patients with gout in clinics for clarity and usability. The website is called MyGoutCare® and in the pilot study, the patient completes a baseline survey of demographics and gout knowledge, reviews the website and generates a list of customized questions (Mygoutreport®) to discuss at the upcoming visit with their physician. They next complete a post-survey within two weeks of the physician visit. Data was analyzed using a paired t-test and presented as mean change in scores between post and baseline surveys.
**Results:** 10 patients beta-tested the website for clarity, format, and flow. In the ongoing pilot study 22 subjects (mean age of 57 years, disease duration of 9.5 years, and 3–5 flares per year) were recruited from general medicine, podiatry, and rheumatology clinics and have completed MyGoutCare®. They were extremely receptive of an e-learning tool that was accessible 24/7. Pre-survey scores (0–10) on knowledge questions improved significantly (20%) when compared to post-survey scores with mean (SD) at -1.95 (1.76), $p<0.001$. All subjects reported satisfaction with the discussion on the natural history of disease and treatment choices. Most importantly they reported actionable changes moving forward, such as decision to continue lifelong urate-lowering therapy, compliance with monitoring serum urate, and dietary changes to achieve flare-free status.
**Conclusions:** Our preliminary data suggests web-based patient-focused materials can serve as a practical tool to positively impact ongoing educational needs of patients in busy clinical practice. It remains to be seen if this will lead to better long term outcomes and improve patient-physician interactions.
