## AB0827 HIGH PREVALENCE OF HALLUX VALGUS IN GOUTY PATIENTS REQUIRING URATE LOWERING THERAPY

C. Blandin, M. Forien, P. Dieudé, S. Ottaviani. *Hôpital Bichat, Paris, France*

**Background:** Hallux valgus (HV) is a common pathology leading to pain and deformation of the first metatarsophalangeal joint (MTP1). Gout preferentially affects MTP1 joint and gives disability and pain. It was suggested that gouty patients could have more severe hallux valgus.
**Objectives:** We aimed to determine: 1) the prevalence of HV in gouty patient starting urate lowering therapy (ULT) and 2) the potential factors associated with HV.
**Methods:** In this transversal single center study, we included patient with proven gout (presence of monosodic urate crystal in synovial fluid) requiring ULT. All patients underwent ultrasonography of MTP1s and radiography of the feet. Demographic and clinical characteristics were collected for each patient. Serum uric-acid (SUA) level was assessed at baseline. One trained ultrasonographer, blinded to radiographic measure, assessed at the MTP1 joints, US-evidenced urate deposits (double contour [DC] sign and/or tophi) before starting ULT. HV was analyzed, blinded to clinical and US data, according to the radiographic measure of hallux abductus (HA) angle, and the intermetatarsal (IM) angle. HV was defined by HA angle $\geq 20°$ and/or IM angle $\geq 10°$. Correlation between US findings and different HV angles was estimated by the Spearman coefficient of correlation.
**Results:** A total of 43 patients (93% of male patients) with untreated proven gouty patients were studied. The median age was 63.0 [IQR 57.0–73.0] years old. Median disease duration was 3.0 [1.0–6.0] years. Clinical tophi were found in 24% of patients. The median MDRD creatinin clearance and serum uric acid level were 63.0 [IQR 39.8–78.0] ml/mn/1.73m$^2$ and 507 [IQR 446–601] $\mu$mol/l, respectively. Ultrasound assessment of MTP1 joints revealed a DC sign and tophus in 59.3% and 69.8% of joints, respectively. The median size of US tophi were 11.7 [IQR 9.4–13.7] mm. Radiography found HV in 61.9% of feets (72% of patients). The median IM and HA angles were 8.9 [IQR 7.0–10.0] mm and 20.5 [IQR 15.1–26.0] mm, respectively. The percentage of MTP1 joints with US tophus or DC sign was not significantly higher in patients with HV. No correlation was found between the size of US tophus and HA angle ($P$=0.54). However, IM angle tended to be correlated with the size of US tophus ($P$=0.08). We did not observe any correlation between age, gender, SUA levels, presence of clinical tophus, creatinine clearance, disease duration, number of attacks and presence of HV.
**Conclusions:** Our results suggest a high prevalence of HV in gouty patients requiring ULT. Despite a tendency to have an association between US tophus size and IM angle, we did not observed any correlation between size of tophus and presence of HV. Our patients having a long disease duration, we might hypothesize that a sooner treatment could prevent the apparition of HV in these patients.

## AB0828 CHANGING TRENDS IN RADIOLOGICAL PREVALENCE OF PAGET'S DISEASE OF THE BONE IN LANCASHIRE, UK

S. Jmor[1], A. Chiphang[1], A. Ahmed[1], K. Binymin[1,2]. [1]*Southport and Ormskirk NHS trust, Southport;* [2]*University of Liverpool, Liverpool, United Kingdom*

**Background:** It is widely recognised that the United Kingdom has a very high prevalence of Paget's disease of the bone (PDB) alongside Western Europe, Australia and New Zealand.
In 1980, Barker et al (1), concluded from a meta-analysis of surveys done throughout 31 towns in Britain, that Lancashire showed to be a remarkably localised area of high prevalence of PDB. In 2006, Cooper et al (2) updated the prevalence of PDB in certain British centres and found prevalence rates had fallen by 50%.
**Objectives:** As there have been no further studies around the Lancashire area since, we aim to build on the current literature and present the prevalence of PDB in some local towns within Lancashire, 20 years later.

**Methods:** We began with Southport and Ormskirk the NHS trust whose patients are geographically located within the county of Lancashire. A computer generated random sample was listed for all plain x-rays that include entire lumbar vertebrae, pelvis, sacrum and femoral heads in those aged over 55. We identified 1000 patients whose unique hospital numbers were entered into the PACS system to view each x-ray.
**Results:** Out of 1000 patient x-rays only four were found to have definite evidence of PDB, all confirmed with radiological report. This gives a prevalence rate of 0.4%. Of these, 50% were female and the age ranged from 72–88 years.
**Conclusions:** Southport and Ormskirk towns lie just on the verge of the Lancashire focus (Lancaster, Preston, Bolton, Wigan, Burnley and Blackburn) therefore using the methodology, it was assumed that prevalence rates would be as high (4–8%) as other Lancashire's towns. (1). Consideration to the high socioeconomic status of many –albeit an older population- that live in the studied area and perhaps other environmental factors might explain the low prevalence (0.4%) of PDB. The influence of genetic factors seems less evident.
Additionally, the overall downward trend of prevalence rates in the UK, as hypothesised by Cooper et al (2), could also explain our findings.
This is an area that would be useful to investigate in further studies. An initial plan to re-study a high focus area such as Lancaster town, using the same methodology, might be extremely valuable.

## AB0829 2012 AMERICAN GUIDELINES FOR THE MANAGEMENT OF GOUT AS SEEN BY FAMILY DOCTORS IN FRANCE

C. Mourgues[1], M. Soubrier[1], B. Pereira[2], P. Vorilhon[3], S. Mathieu[1].
*[1]Rheumatology; [2]DRCI; [3]General Medicine, Hopital Gabriel Montpied, Clermont Ferrand, France*

**Background:** Gout is a common and potentially serious rheumatological disease. Its management in France remains inadequate, with target serum uric acid (SUA) levels being reached in 20% of cases. American guidelines for the management of gout were released in 2012.
**Objectives:** Our aim was to assess whether family doctors in Auvergne, France, agreed with the 14 recommendations for managing gout by mailing them a questionnaire.
**Methods:** An anonymous questionnaire was mailed to all the family doctors in our region in November 2014.
**Results:** The response rate was 40% (n=505/1263). Of the 505 family doctor respondents (FDRs), 60% had been in practice for more than 20 years. Some 56.2% were in practice in rural areas, and 53.6% followed on average 5 to 20 gout patients.
Management of acute gout: 90.7% of FDRs agreed with pharmacological management within 24 hours of the attack; 95% of FDRs agreed with using colchicine, 72% short-course nonsteroidal anti-inflammatory drugs, and 16.6% corticosteroids; 81% approved of continuing hypouricemic therapy during the attack.
Management of chronic gout: 61.6% agreed with not treating asymptomatic hyperuricemia. Allopurinol or febuxostat are used as the first-line therapies according to 88.7%. Half of respondents lowered target SUA when gout was tophaceous.
**Conclusions:** The guidelines generally met with the approval of family doctors in Auvergne (72% agreement). They were also confirmed on a European level in 2014. Their use should be disseminated with, however, some additional clarifications, particularly for the management of chronic gout.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3209

## AB0830 IRON METABOLISM: ASSOCIATION OF FERRITIN WITH SERUM URATE AND GOUT

T. Fatima[1], T. Merriman[1], C. Iverson[2], J.N. Miner[2]. *[1]University of Otago, Dunedin, New Zealand; [2]Ardea Biosciences, Inc., San Diego, United States*

**Background:** Iron homeostasis is a tightly regulated set of biochemical processes. Transferrin and its cell-surface receptor regulate iron uptake and ferritin sequesters free iron and acts as a store for excess iron from intra- and extra-cellular pools. Ferritin has been positively associated with serum urate in the National Health and Nutrition Examination Survey III (NHANES III) [1]. There have been observational and interventional studies suggesting a role for iron as a trigger for gout flares, which may be due to a number of pro-inflammatory activities associated with iron [2, 3]. Consistent with this, genetic variation in the transferrin receptor is associated with gout and with an increased likelihood of self-report of an iron-rich food as a trigger of flares [2].
Genetic variation in the transferrin receptor is associated with gout and with an increased likelihood of self-report of an iron-rich food as a trigger of flares [2].
**Objectives:** To replicate the association of ferritin with serum urate and to test for association of ferritin with gout.
**Methods:** For the serum urate association analysis, African-American subjects from the publicly available Jackson Heart Study were included (693 females and 567 males). Subjects who self-reported taking diuretic or urate-lowering medication/s, or who had kidney disease or gout, were excluded. For the gout analysis 93 individuals were included, comprising 60 controls (all males) and 33 gout cases (4 females and 29 males). Linear regression analysis using R 3.2.0 and adjusting for age and body mass index was done to test for association between ferritin and serum urate. An unpaired *t* test was used to test for association between gout and plasma ferritin.
**Results:** A positive association of serum ferritin and urate was found in both males ($\beta$=1.02E-04 pmol/L, $P$=9.6E-03) and females ($\beta$=1.95E-04pmol/L, $P$=7.1E-04) in the Jackson Heart Study. Plasma concentrations of ferritin were elevated in gout cases (Mean±SD; 320.6±167.1 ng/mL) compared to controls (69.45±63.41 ng/mL) ($P<1x10^{-4}$).
**Conclusions:** The associations between ferritin and both serum urate and gout implicate iron metabolism in gout. While it is not possible to assign causality from this observational study, the previously reported association of the transferrin receptor with gout [1] is consistent with iron metabolism having a causal role in gout.

## AB0831 LOW EDUCATION LEVEL AS A PREDICTOR OF GOUT IN WESTERN SWEDEN

V. Sigurdardottir[1], L.T. Jacobsson[2], A. Svärd[1], P. Drivelegka[2], M. Dehlin[2].
*[1]Rheumatology Clinic, Falun Hospital, CKF Dalarna, Falun; [2]Department of rheumatology and inflammation research, Institute of Medicine, Sahlgrenska Academy at the University of Göteborg, Göteborg, Sweden*

**Background:** Gout was previously regarded a disease of the affluent. Knowledge about the association between gout and socioeconomic status in modern times is limited.
**Objectives:** To investigate the association between gout and socioeconomic factors in a population based register study in a large region in Sweden.
**Methods:** All patients receiving ≥2 diagnoses of gout on at least two separate occasions in primary or secondary care or 1 diagnosis by a specialist in Rheumatology in Västra Götaland in the years 2007–2012 were identified by ICD10 codes in a regional database of health-care utilization. 3189 such patients were identified. The date of the first diagnosis was defined as the index date. A previous validation study of cases identified in this manner confirmed that this case definition is highly consistent with a diagnosis of gout as defined by established criteria (PPV >80%)(1).
For each case, up to 5 controls matched for age, gender and place of residence at the time of the first gout diagnosis were chosen by the Statistics Sweden agency (SCB) (N=14946).
Common comorbidities known to be associated with gout (ischemic heart disease, heart failure, atrial fibrillation, hypertension, hyperlipidemia, diabetes and renal failure) prior to the index date were retrieved from the regional database of health-care utilization based on ICD10-codes.
Data on education level and income at the index year was collected from the Longitudinal Integration Database for health Insurance and Labor market studies (LISA). The database holds annual registers since 1990 on all individuals above 16 years of age registered in Sweden.
**Results:** Data on education level and income was analyzed for cases and controls belonging to the working-age population as defined in Sweden (aged 15–74 years). Shorter education, <12 years, was significantly more common among cases. Yearly income was lower among cases irrespective of educational length (Table 1). Cases had significantly more pre-index comorbidities compared to the controls. In a subgroup analysis of 1084 cases and 6117 controls of working age without any cardiovascular- or renal comorbidity, educational level and income was still significantly lower among cases (data not shown).

Table 1. Education and income for individuals aged 15–74 years

| Educational length in years | | | | Mean yearly income in EUR | | |
|---|---|---|---|---|---|---|
| | Cases, N (%) | Controls, N (%) | p-value | Cases | Controls | p-value |
| ≥12 | 406 (20) | 2730 (28) | <0.001 | 22830 | 26230 | 0.037 |
| <12 | 1598 (79) | 6961 (71) | | 11850 | 12930 | 0.021 |

*1% of cases and controls had missing info on educational length.

**Conclusions:** Low education level and income are predictors for gout in the working age population. The effects of education do not seem to be largely/only mediated via cardiovascular- or renal comorbidity, supporting that other factors

possibly related to lifestyle or occupational exposures are of importance for gout development.

## AB0832 INCREASED SERUM URIC ACID (SUA) LEVELS ARE A COMMON FINDING IN PATIENTS WITH HIGH BLOOD PRESSURE, INSULIN RESISTANCE, OBESITY AND CARDIOVASCULAR (CV) DISEASE

I. Tasic[1], S. Kostic[1], V. Skakic[2], A. Đorević[3], D. Djordjevic[1], J. Radicovic[4], M. Nikolic[1], S. Andonov[1], M. Karadzic[2], I. Krstic[1]. *[1]Cardiology; [2]Rheumatology, Institute Niska Banja; [3]Cardiology, Institute for Therapy and Rehabilitation; [4]Faculty of Medicine, Nis, Serbia*

**Objectives:** To evaluate the connection between SUA and severity of coronary heart disease (CHD) assessed by angiography in patients with CHD.

**Methods:** 198 patients (75.8% men) undergoing cardiovascular rehabilitation at the Institute "Niska Banja" from October 1, 2014, to January 31, 2015, were evaluated. Mean (SD) patient age (62.1±10.4), prevalence of patients with 3-vessel coronary artery disease with stenosis >70% (31.3%), coronary artery bypass grafting (CABG) (37.4%), percutaneus coronary intervention (PCI) (38.9%), primary PCI (32.8%), mean ejection fraction (50% ±11). Prevalence of hyperuricemia (>386 μmol/l) 33.3%, hypertension 85.9%, hypelipoproteinemia 81.8%, diabetes mellitus 24%, family history of CHD (47%) and mean number risk factors 2.65. Patients were separated into a normal SUA group (n=132, with SUA <386 μmol/L) and a high SUA group (n=66, with SUA ≥386 μmol/L).

**Results:** Patients with high SUA had significantly higher 3-vessel coronary artery disease with stenosis >70% (40.9% vs. 26.5%; P=0.04), low ejection fraction (EF<34%)(19.7% vs. 8.3%; p=0.021), obesity (27% vs. 14.4; P=0.03), significantly higher triglycerides (2.38±1.7 vs. 1.88±1.44; P=0.028) and serum creatinine (111.5±46 vs. 90±21; p<0.001).

**Conclusions:** SUA levels were independently associated with EF in patients with CHD. Hyperuricemia is associated with severity of CAD- 3-vessel coronary artery disease with stenosis >70%.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.1806

## AB0833 INVESTIGATION ON ALLELE FREQUENCY OF RS9263726 IN SOUTH CHINA

X. Li, Q. Li, J. Gu, Z. Chen. *Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** Gout is caused by chronic elevation of serum uric acid levels above the saturation point for monosodium urate crystal formation. Allopurinol, which can inhibit xanthine oxidase and decrease the formation of uric acid, is widely used as a primary therapy for the treatment chronic gout and hyperuricemia in China. However, some patients may develop allopurinol-induced life-threating severe cutaneous adverse reaction (SCAR). Hung and colleagues [1] in Taiwan reported a strong association between HLA-B*5801 and allopurinol-induced SCAR, and replicated by following studies in different areas and countries, including China [2]. Previously, Tohkin and colleagues [3] in Japan carried out a genome wide association study (GWAS) and indicates that rs9263726 in PSORS1C1, also significantly associated with allopurinol-related SCAR, is in absolute linkage disequilibrium (LD) with HLA-B*5801. Rs9263726 is expected to substitute HLA-B*5801 genotyping in clinical application for predicting the onset of allopurinol-induced SCAR.

**Objectives:** To investigate the allele frequency of rs9263726 in patients with gout or hyperuricemia as well as healthy volunteers from South China. Compare clinical characteristics between different genotype of rs9263726.

**Methods:** We enrolled 171 patients with gout or hyperuricemia which was diagnosed by clinicians. And 191 healthy volunteers with age and sex match were taken as controls in this study. Blood samples were collected and DNA samples were extracted. A pair of specific primers were employed to perform PCR amplification. All PCR products were carried out a Sanger sequencing.

**Results:** Genotype frequencies for rs9263726 polymorphism observed were G/G (88.89%), G/A (9.36%), A/A (1.75%) in patients with gout or hyperuricemis. Rs9263726 A allele was observed in 11.11% of patients, whereas the allele frequency was 6.43%. While in healthy volunteers group, 12.57% was carried rs9263726 A allele, whereas the allele frequency was 7.07%. There was no significant differences between the two groups when compared with the carried rate of rs9263726A allele. Patients were divided into two groups based on whether they carried rs9263726A allele or not. The mean uric acid level is (435.89±129.80)μmol/L in rs9263726A allele group and (419.84±139.45) μmol/L in rs9263726G allele. No significant difference was observed when compared the age, genders as well as uric acid level.

**Conclusions:** The frequency of rs9263726 A allele is relatively high in South China. There is no evidence that the frequency of rs9263726A allele is different in patients with gout or hyperuricemis and healthy volunteers. Further studies should carried out to explore the relationship between rs9263726A allele and allopurinol-related SCAR as well as HLA-B*5801.

## AB0834 ACUTE CALCIUM PYROPHOSPHATE CRYSTAL ARTHRITIS AS A CAUSE OF SUDDEN ONSET OF FEVER AND ARTHRITIS IN GERIATRIC PATIENTS

Y. Yamamura, K. Fujita, N. Shibutou, A. Ueno, M. Yamamura. *Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan*

**Background:** Calcium pyrophosphate (CPP) deposition may give rise to clinical presentations that mimic septic arthritis, polyarticular inflammatory arthritis or osteoarthritis. Of 4 different presentations[1)], acute CPP crystal arthritis crystal arthritis, also known as pseudogout, is characterized by sudden attacks of arthritis frequently with systemic inflammatory features such as fever.

**Objectives:** To determine clinical findings of patients with acute CPP crystal arthritis who was hospitalized due to fever of unknown origin or developed during hospitalization from 2011 to 2015.

**Methods:** Patients were diagnosed as having acute CPP crystal arthritis according to the diagnostic criteria proposed by McCarty DJ[2)] and classification of clinical presentations proposed by EULAR recommendation[1)].

**Results:** We enrolled 26 patients with acute CPP crystal arthritis who were classified as described above, including 9 males and 17 females. All patients presented acute attacks of arthritis. Eight patients were hospitalized due to high fever; and others were for infections in 8 patients, strokes in 6, malignancies in 2 and other medial illnesses in 4, followed by arthritis or fever. The median age at diagnosis was 83.5 years (range 69–102). Fever (>37.5℃) developed in 17 patients and the mean CRP level (± SD) was 14.6±7.2 mg/dL (2.08 - 28.88; n=23). Ten patients were polyarticular or oligoarticular while 16 patients were monoarticular; and affected joints included knee joints in 18 patients, wrist in 6, ankle in 6, elbow in 3, shoulder in 2, cervical in 2, and finger in 2. CPP crystals were demonstrated in synovial fluids in 12 of 15 patients with arthrocentesis. The presence of CPPD deposition-related arthropathy including chondrocalcinosis was found in 24 patients by radiographic studies. All patients responded well to treatment including non-steroidal anti-inflammatory drugs (n=16), joint aspiration and rest (n=5), oral colchicine (n=3), intraarticular injection of glucocorticoids (n=3) and parenteral glucocorticoids (n=2; prednisolone 30 mg/day).

**Conclusions:** The results indicates that acute CPP crystal arthritis develops in not rarely the geriatric population over 75 years of age, often leading to sudden onset of fever and disability. It should be noted that these attacks are often provoked by severe medical diseases such as infections and strokes.

# Infection-related rheumatic diseases

## AB0835 REACTIVE ARTHRITIS: DIAGNOSTIC DIFFICULTIES AND CAUSES OF MISDIAGNOSIS

J. Harisov[1], E. Djuraeva[2], A. Hon[2]. *[1]General Medicine; [2]Cardio-rheumatology, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** Timely diagnostics of inflammatory rheumatic diseases, particularly of Reactive Arthritis (ReA), and the development of reasonable management methods for their course are of a high importance in practice rheumatology, which are needed for early ethiotropic and pathogenetic treatment.

**Objectives:** Study course features of the urogenital ReA and causes of its misdiagnosis.

**Methods:** We have conducted 86 patients being admitted to the rheumatologic department of the 1st Clinic of Tashkent Medical Academy with directional

diagnosis of ReA. 86 patients were divided into 48 men and 38 women aged 19 to 49 years old, with the disease duration of 1 month to 5 years. Acute course was observed in 17 patients, subacute course in 44, and chronic course of the disease in 25 patients. Disease progression after urogenital infection of the urinary tract was established in 58 cases, enterocolitic form in 18 cases, mixed form of ReA in 10 cases. To detect the urogenital chlamydial infection, we used a method of the indirect immunofluorescence of urethral or endocervical smear, and method of DNA diagnostics, when necessary. Patients with enterocolitic form of ReA were conducted with bacteriological stool test.
**Results:** The classic disease presentation, including arthritis, eyes and genital tract impairment was established in 47 of 58 cases. Among them, all 14 patients suffered from acute, 30 of 33 from subacute, 11 of 14 from chronic form of ReA. As to the misdiagnoses at onset of the disease, 1 patient was diagnosed with gout, 3 with rheumatoid arthritis, and 1 patient over 35 years old was diagnosed with osteoarthritis. All patients had involvement of the lower limbs joints in the pathological process. The oligoarthritis prevailed in acute and sub-acute ReA (80% and 92.8% of cases respectively). Monoarthritis was observed only in 20% cases with acute form of the disease. In the chronic disease course, polyarthritis prevailed with symmetric and asymmetric forms, which were observed in 62.8%; and the oligoarthritis in 37.2% cases. All patients during hospitalization or in history mentioned eyes impairment, which, according to our observations, was course independent.
**Conclusions:** Thus, timely diagnosis and adequate management requires distinctive knowledge of ReA clinical presentation and taking into account the course of the disease, and use of existing diagnostic criteria. Difficult diagnostic situations should be extended with case follow-up.

### AB0836 IMPACT OF EPIDEMIOCLINICAL PATIENTS CHARACTERISTICS ON GERM IDENTIFICATION DURING SEPTIC ARTHRITIS

H. Sahli Ep Hedi[1,2], R. Khalfallah[1], R. Tekaya[3], I. Mahmoud[3], O. Saidane[3], L. Abdelmoula[3]. *[1]rhumatology department, mohamed taher maamouri university hospital, nabeul; [2]rhumatology department, hôpital universitaire mohamed taher maamouri de nabeul, Dar Chaabane El Fehri; [3]rhumatology department, charles nicolle hospital, tunis, Tunisia*

**Background:** Septic arthritis may cause damage and inflammation in short period of time. The germ determination must be the first objective to allow targeted treatment. Bacteriological tests remain negative in 7–35% of cases of septic arthritis.
**Objectives:** Our objective is to determine the impact of epidemioclinical patients profile on germ determination during septic arthritis.
**Methods:** This a retrospective study which included medical records of patients treated for septic arthritis during the seventeen past years. Epidemiologic, clinical, biologic, bacteriologic and therapeutic data were recorded and analysed. We made a comparison between patients who had a germ identified with whom who hadn't.
**Results:** Fifty nine cases of septic arthritis were treated during the study period with mean age about 54.6±19 years [range 15 to 95]. The germ was identified in 27 cases (45.77%). The patients with no identified microorganism had a female predominance (sex-ratio M/F=0.77). When germ was identified, there was no sex predominance (sex ratio =1.07) with no differences between the 2 groups (p=0.385). The two groups had same mean age (54.1 and 54.8 years). The maximum of frequency of the disease was for patients aged between 70 and 79 years when germ identified and between 40 and 59 years if not. The percentage of patients with risk factors of septic arthritis was higher if the germ was not identified but with no significant difference (p=0.893). Anorexia, weight loss and lameness were more frequently seen if germ wasn't identified. It was the same ascertainment with fever and inflammatory signs. There was no significant difference between the two groups as regards the arthritis localization and the number of joints involved.
**Conclusions:** This study showed that female sex was the only epidemio-clinical character associated with low chance to identify the germ during septic arthritis.
**Disclosure of Interest:** None declared

## Fibromyalgia

### AB0837 EFFECTS OF VITAMIN D THERAPY ON QUALITY OF LIFE IN PATIENTS WITH FIBROMYALGIA

A. Doğru[1], A. Balkarlı[2], V. Cobankara[3], M. Sahin[1], S.E. Tunc[1]. *[1]Department of Internal Medicine, Division of Rheumatology, Suleyman Demirel University, Faculty of Medicine, ısparta; [2]Department of Internal Medicine, Division of Rheumatology, Antalya Training and Research Hospital, Antalya; [3]Department of Internal Medicine, Division of Rheumatology, Pamukkale University Faculty of Medicine, Denizli, Turkey*

**Background:** The role of vitamin D in the etiopathogenesis of fibromyalgia and non-specific musculoskeletal pain is controversial.
**Objectives:** In our study, we aimed to investigate the effect of vitamin D therapy on quality of life in patients with fibromyalgia.
**Methods:** 70 patients diagnosed with fibromyalgia and 65 age-sex match controls were included in the study. Patients were grouped as deficiency (<20 ng/mL), inadequacy (20–30 ng/mL) and sufficient (>30 ng/mL) according to the levels of vitamin D. Vitamin D replacement was performed for patients with deficiencies and inadequacies. Before and after vitamin D therapy, patients filled in the assessment tools.
**Results:** Vitamin D deficiencies and inadequacies were observed in 60% of the patients (n=42). Social function, mental health and vitality areas in patients' quality of life forms were significantly lower in normal vitamin D group compared with low vitamin D group. In scales examined after Vitamin D replacement therapy, statistically significant differences were observed in the fibromyalgia impact questionnaire, Beck depression inventory, VAS and SF-36 compared to pre-treatment.

Table 1. Baseline and post-treatment scores of Fibromyalgia Impact Questionnaire, Beck depression inventory, VAS, ASEX, sleep VAS

| | Pts with low vit. D (n=42) | Pts with normal vit. D ( n=28) | After vit. D treatment (n=42) | P value |
|---|---|---|---|---|
| Fibromyalgia Impact Questionnaire | 61.2±13.5 | 61.9±15 | 59.7±13.6 | 0.001* |
| Beck Depression Inventory | 15.6±10 | 18.7±11 | 14.8±9.9 | 0.001* |
| VAS | 84.4±12.3 | 85±13 | 79.9±12.7 | 0.001* |
| Arizona Sexual Experience Scale | 18.2±5.2 | 18.7±6 | 17.9±5.2 | 0.176 |
| Sleep Scale (VAS) | 4.9±2 | 5.1±1.6 | 4.7±2 | 0.317 |

Table 2. Baseline and post-treatment scores of SF-36

| SF-36 | Pts with low vit. D (n=42) | Pts with normal vit. D ( n=28) | After vit. D treatment (n=42) | P value |
|---|---|---|---|---|
| 1. Physical Function | 19.7±3.9 | 20.5±4.4 | 20.8±4 | 0.001* |
| 2. Role Physical | 5±1.3 | 4.9±1.1 | 5.5±1.4 | 0.001* |
| 3. Role Emotional | 3.7±1 | 3.6±0.9 | 4.2±1.1 | 0.001* |
| 4. Bodily Pain | 5.2±1.3 | 5.3±1.3 | 6±1.4 | 0.861 |
| 5. Social Function | 6.7±2.2 | 5.9±1.5 | 7.4±2.5 | 0.001* |
| 6. Mental Health | 19.2±5 | 17.7±4.8 | 20.2±4.9 | 0.001* |
| 7. Vitality | 13.1±3.2 | 12.4±3.9 | 13.6±3.8 | 0.003* |
| 8. General Health | 11.3±4 | 11.2±4.1 | 12.5±4.5 | 0.001* |

**Conclusions:** Since, vitamin D deficiency seems to be linked to the pathogenesis of FMS, serum vitamin D levels should be checked routinely as a general health problem and patients should be supplemented.
**Disclosure of Interest:** None declared

### AB0838 A MICRORNA SIGNATURE IN LIQUID BIOPSIES FOR THE DIAGNOSIS OF FIBROMYALGIA

C. Iannuccelli[1], M.P. Guzzo[1], A. Baldassarre[2], A.C. Di Lollo[1], A. Masotti[2], G. Valesini[1], M. Di Franco[1]. *[1]Sapienza, University of Rome; [2]Bambino Gesù Children's Hospital, Rome, Italy*

**Background:** Fibromyalgia (FM) is a syndrome characterized by chronic widespread pain that affects about 2–8% of the general population, especially female gender [1].The pathogenesis of FM is not completely understood and diagnosis is clinical.MicroRNAs, a class of small non-coding RNAs of ~22–24 nucleotides, are involved in different post-transcriptional processes and have been identified as important biomarkers in many diseases [2]. Recently, it has been hypothesized that the modulation of protein expression, potentially mediated by miRNAs, is one of the main characteristic of the central and peripheral sensitization, which is a basic process to development and maintenance of chronic pain, as in FM [3].
**Objectives:** The aim of this study was to analyze the expression of circulating miRNAs in liquid biopsies (i.e. serum and saliva) of a group of selected FM patients.
**Methods:** Consecutive adults FM patients, according to both ACR criteria [4,5], and healthy donors were enrolled. Patients complaining of pain VAS more than 6 (0–10), with positivity of at least 14 tender points at clinical examination and free from drugs at the time of evaluation, were included in the study.Patients and controls completed the following questionnaires: Fibromyalgia Impact Questionnaire, Fibromyalgia Assessment Status, Health Assessment Questionnaire, Zung Self-Rating Anxiety and Depression Scale. After obtaining informed consent, samples from patients and controls were collected.Circulating miRNAs were extracted using miRCURY RNA Isolation Kit-Biofluids (Exiqon) and profiled using the Serum/Plasma Focus microRNA PCR Panel (Exiqon) following the manufacturer's instructions.Data were analyzed by SPSS software.
**Results:** The study population consisted of 14 female patients, without diagnosis of autoimmune diseases, psychiatric or neurological disorders and neuromuscular diseases, and 14 healthy controls matched for sex and age.The exploratory profiling of circulating miRNAs in serum revealed that six miRNAs (miR-23a-3p, miR-1, miR-133a, miR-346, miR-139–5p and miR-320b) were significantly ($p<0.05$) and differentially regulated in FM patients compared to controls, whereas some of these miRNAs were expressed but not significantly modulated in saliva.We found a significant negative correlation ($r=-0.608$; $p<0.05$) between

miR-320b and the score of depression scale.ROC curves for each miRNAs displayed a AUC greater than ~0.7 and the best generalized linear model that can be employed to discriminate FM patients from healthy controls was obtained by taking into account only 5 miRNAs: miR-23a-3p, miR-1, miR-133a, miR-346 and miR-320b (AUC=0.954, sensitivity=100%, specificity=83.3%).
**Conclusions:** Our preliminary work outlines the importance of using circulating miRNAs in liquid biopsies as a powerful diagnostic signature for the diagnosis of FM.Although the expression and the modulation of miRNAs seem to be site specific, we suggested a panel of serum miRNAs that can be used in the future as potential predictors of FM.A wider cohort of patients will be necessary to integrate the results that we obtained in this work and to suggest a more robust predictive model to exploit as an additional diagnostic tool for FM patients.

## AB0839 FIBROMYALGIA SYNDROME IN PREGNANT WOMEN; THE EFFECTS ON PHYSICAL FUNCTIONING AND PSYCHOLOGICAL STATUS

H. Genc[1], M. Atasever[2], B. Duyur Cakit[1], M. Seval[3], A. Koc[3]. *[1]Physical Medicine and Rehabilitation, Ministry of Health, Ankara Training and Research Hospital, Ankara; [2]Gynecology and Obstetrics, Giresun University, Faculty of Medicine, Giresun; [3]Gynecology and Obstetrics, Ankara University, Faculty of Medicine, Ankara, Turkey*

**Background:** There are many unexplored issues related to the presence of fibromyalgia syndrome (FS) in pregnancy such as prevalence of FS, most common symptoms, the impact of FS on physical functioning, psychological status, and treatment of a fibromyalgic pregnant
**Objectives:** To investigate the frequency and most common symptoms of FS among pregnant woman and determine the impacts of FS on physical functioning and psychological status in those patients.
**Methods:** A total of 360 pregnants in the third trimester of pregnancy were included in the study. The pregnants were split into two groups in terms of having or not having FS. Group 1 was consisted of 136 pregnant women with FS. 224 pregnant women without FS were formed control group (group 2). The presence of fibromyalgia was investigated via 2010 ACR classification criteria. Widespread pain index and symptom severity scores of the patients were recorded. The impact of FS on physical functions was evaluated using fibromyalgia impact questionnaire. Psychological status of the patients were evaluated using state-trait anxiety inventory, the Wijma delivery expectancy/experience questionnaire and Beck depression inventory.
**Results:** 136 of 360 pregnants (37.7%) had FS. Mean ages of the 136 pregnants with FS was 27 years and of the 224 without FS was 26.5 years ($p>0.05$). Low back pain is the most common complaint and fatique is the most common symptom in pregnants group with FS. Compared with the pregnants group without FS, pregnants group with FS had higher values of pain severity and higher levels of physical disability ($p<0.001$). Pregnants group with FS had also higher values of anxiety, fear of childbirth and depression ($p<0.001$, for all values). Symptom severity score and physical impairment score were found to be significantly correlated with increased levels of pain, depression, anxiety, fear of childbirth, fatique, increased scores of waking unrefreshed, cognitive symptoms and increased rate of low back pain ($p<0.001$ for all values).
**Conclusions:** FS is common among pregnant women and the existence of FS in pregnancy is a severe factor for maternal stres, anxiety and depression. If we desire a healthy pregnancy and a good child outcome, we need to get therapeutic measures for fibromyalgia syndrome.
**Disclosure of Interest:** None declared

## AB0840 ASSOCIATION BETWEEN CATECHOL-O-METHYL TRANSFERASE GENE POLYMORPHISMS AND FIBROMYALGIA IN A KOREAN POPULATION: A CASE-CONTROL STUDY

J.-H. Kang[1], D.-J. Park[1], S.-H. Kim[2], S.-S. Nah[3], J.H. Lee[4], S.-K. Kim[5], Y.-A. Lee[6], S.-J. Hong[6], H.-S. Kim[7], H.-S. Lee[8], H.A. Kim[9], C.-I. Joung[10], S.-H. Kim[11], S.-S. Lee[1]. *[1]Rheumatology, Chonnam National University Medical School and Hospital, Gwangju; [2]Rheumatology, Inje University Haeundae Paik Hospital, Busan; [3]Rheumatology, Soonchunhyang University, College of Medicine, Cheonan; [4]Rheumatology, Maryknoll Medical Center, Busan; [5]Rheumatology, Catholic University of Daegu, Daegu; [6]Rheumatology, Kyung Hee University; [7]Rheumatology, Soonchunhyang University, College of Medicine; [8]Rheumatology, Hanyang University College of Medicine, Seoul; [9]Rheumatology, Ajou University Hospital, Suwon; [10]Rheumatology, Konyang University Medical School, Daejeon; [11]Rheumatology, Keimyung University, Daegu, Korea, Republic Of*

**Objectives:** Although polymorphisms of the catechol-O-methyl transferase (COMT) gene have been implicated in altered pain sensitivity, results concerning the association between COMT gene polymorphisms and FM are equivocal. We assessed the associations between COMT single-nucleotide polymorphisms (SNP) and FM risk and symptom severity.
**Methods:** In total, 409 FM patients and 423 controls were enrolled. Alleles and genotypes at five positions [rs6269 (A>G), rs4633 (C>T), rs4818 (C>G), rs4680 (C>G) and rs165599 (A>G)] in the COMT gene were genotyped from peripheral blood DNA.
**Results:** Alleles and genotypes of the rs4818 COMT gene polymorphism were significantly associated with increased susceptibility to FM. The rs4818 GG genotype was more strongly associated with FM compared to the CC genotype (OR =1.680, 95% CI: 1.057, 2.672, P=0.027). Although allele and genotype frequencies did not differ among groups, the rs4633 CT genotype was not associated with the presence of FM following adjustment for age and sex (OR =0.745; 95% CI: 0.558, 0.995; P=0.046). However, no association was observed between clinical measures and individual COMT SNPs. In haplotype analysis, there was a significant association between ACG haplotype and FM susceptibility sex (OR =2.960, 95% CI: 1.447, 6.056, P=0.003) and the number of tender points (P=0.046).
**Conclusions:** This large-scale study suggests that polymorphisms of the COMT gene may be associated with FM risk and pain sensitivity in Korean FM patients. However, our results differed to those of previous studies, suggesting ethnic variation in COMT gene polymorphisms in FM.
**Disclosure of Interest:** None declared

## AB0841 PERFECTIONISM IN CHRONIC PAIN: ARE THERE DIFFERENCES BETWEEN FIBROMYALGIA, RHEUMATOID ARTHRITIS AND HEALTHY CONTROLS?

A.M. Pinto[1], A.T. Pereira[2], C. Costa[3], M. Marques[4], J.A.P. da Silva[3], A. Macedo[4]. *[1]Psychological Medicine Department/ Rheumatology University Clinic; [2]Psychological Medicine Department, Faculty of Medicine, University of Coimbra; [3]Rheumatology Department; [4]Psychiatry Department, University Hospital of Coimbra, Coimbra, Portugal*

**Background:** Perfectionism has been associated with a plethora of medical conditions and psychopathological symptoms/disorders.[1] However, the potential impact of perfectionism in different chronic pain conditions is scarcely explored.
**Objectives:** Compare patients with fibromyalgia (FM), rheumatoid arthritis (RA) and pain-free controls regarding mean scores of perfectionism dimensions and cognitions; and test if perfectionism dimensions are significantly associated with the disease group.
**Methods:** Participants were recruited among consecutive attendees with FM, RA and pain-free controls at rheumatology and gynecology practices in Coimbra. Patients with FM and RA satisfied currently accepted classification criteria.[2,3] The absence of chronic pain in healthy controls (HC) was established by a score of zero in the London Fibromyalgia Epidemiological Study Screening[4]. All participants completed the Portuguese versions of the Frost and of the Hewitt and Flett Multidimensional Perfectionism Scales (MPS) and the Multidimensional Perfectionism Cognitions Inventory. To achieve our aims, descriptive analyses, one-way independent ANOVA (followed by *post hoc* tests) and linear multiple regression (LMR) were performed.
**Results:** The total sample comprised 302 participants [103 FM (34.11%), 98 RA (32.45%) and 101 HC (33.44%)]. Differences between samples were found regarding age ($F=30.598$; $p<.001$) and education years ($F=25.883$; $p<.001$).
Results revealed significant differences between the samples regarding: parental criticism (PC), organization (O), Frost-MPS total score, perfectionism cognitions related with concern over mistakes (CoM) and pursuit of perfection (PP). *Post hoc* comparisons indicated that FM patients exhibited higher levels than RA patients and HC in all of these variables (except for PP that did not significantly differ between FM and HC). No significant differences were found between RA and HC, except for PC and O, with RA patients scoring higher. Regarding LMR, the model was significant ($F(8,245)=5,203$; $p<.001$), with PC ($\beta=-.372$; $t=-5.014$; $p<.001$) and O ($\beta=-.161$; $t=-2.567$; $p=.011$) significantly predicting the type of sample.
**Conclusions:** FM patients seem to be noticeably more perfectionistic than RA patients and HC, which in turn, do not differ significantly, in the majority of the perfectionism traits and cognitions. PC and O appear to be the most discriminative perfectionism dimensions. Perfectionism seems a variable of utmost importance, especially in FM, and may deserve consideration as a target for interventions.

### AB0842 RELATIONSHIP OF FIBROMYALGIA SYNDROME, DIFFUSE PAIN, AND SMALL FIBER PERIPHERAL NEUROPATHY

S.J. Wang[1], R.C. Chou[2]. *[1]Internal Medicine; [2]Rheumatology, Dartmouth-Hitchcock Medical Center, Lebanon, United States*

**Background:** The pathophysiology of fibromyalgia syndrome (FMS) remains unclear, but the current predominant hypothesis is that FMS arises from centralized hypersensitivity to pain. Recently, some studies have suggested that a subset of FMS patients may have underlying small fiber peripheral neuropathy (SFPN), a selective degeneration of the cold/pressure and nociceptive nerve fibers (Oaklander et al., 2013). This discovery has challenged the completeness of the "central hypersensitivity" hypothesis.
**Objectives:** Here, we describe a cohort of FMS and/or diffuse unexplained pain patients who have undergone skin biopsy as part of their workup. Our goal was to identify whether these patients have underlying SFPN, and if so, whether the SFPN is idiopathic or secondary to another predisposing condition.
**Methods:** This study is a retrospective review of patients from our medical center. Patients were diagnosed using the 2011 American College of Rheumatology FMS diagnostic criteria. Additionally, a number of patients presented with diffuse, unexplained pain which carried many of the qualities of FMS, but were not formally diagnosed with the disorder. 172 patients have a diagnosis of either FMS or diffuse pain. Of these, 66 had tingling, burning, or numbness for which they underwent skin biopsy.
These patients underwent workup for etiologies of neuropathic pain including fasting glucose, hemoglobin A1C, thyroid-stimulating hormone, vitamin D level, serum protein electrophoresis, hepatitis C, human immunodeficiency virus (HIV), and obstructive sleep apnea (OSA). Additionally, they underwent assessment to search for other conditions which might explain their pain. Patients were referred for skin biopsy whenever possible. Biopsies were analyzed using protein gene product 9.5 (PGP 9.5) immunostaining to determine the epidermal nerve fiber density (EFND). Compared to an internal set of normal controls, the bottom 5 percentile of EFND was reported as diagnostic of SFPN.
**Results:** Overall, 43 patients (65%) had the diagnosis of FMS, while 23 patients (35%) had the diagnosis of diffuse pain. 13 patients were found to have no predisposing condition – their pain syndrome was considered to be idiopathic. 53 were found to have at least one predisposing disease.
Within the group undergoing skin biopsy that did not have predisposing factors for SFPN, 62% were found to have SFPN. Within the group of patients with an identifiable predisposing condition, 72% were found to have SFPN. Overall prevalence of SFPN was 70%. The average age at symptom onset was 35 years old (range 9 to 64 years), and the cohort was 94% female, 6% male. Prevalence of SFPN-predisposing conditions is listed on the table below.

| | |
|---|---|
| Hypovitaminosis D | 40% |
| Connective tissue disease | 32% |
| OSA | 25% |
| Ehler Danlos syndrome 3 | 23% |
| Impaired fasting glucose/diabetes mellitus | 23% |
| Hypothyroidism | 13% |
| Monoclonal gammopathy | 4% |
| Neurotoxic drug exposure | 2% |
| Other inflammatory disease | 2% |
| Other infectious | 2% |
| Hepatitis C | 0% |

**Conclusions:** In our experience, SFPN is highly prevalent among patients who were diagnosed with FMS or diffuse unexplained pain.

## Back pain, mechanical musculoskeletal problems, local soft tissue disorders

### AB0843 TRAMADOL'S RESPIRATORY EFFECTS IN SUBJECTS WITH CHRONIC NON-SPECIFIC LOW BACK PAIN: A RANDOMISED CONTROLLED TRIAL

A.M. Ionescu[1], R. Popa[2], B.N. Manolescu[3], S. Tache[4], M. Berteanu[5]. *[1]Clinical Rehabilitation, Bradet Rehabilitation Hospital, Arges County; [2]IBM; [3]Politehnica University, Bucharest; [4]University of Medicine and Pharmacy Cluj-Napoca, Cluj-Napoca; [5]Clinical Rehabilitation, Elias Emergency University Hospital, Bucharest, Romania*

**Background:** Chronic non-specific low back pain (CNSLBP) is defined as back pain localised at inferior portion of the rachis, without radiating anywhere else, lasting for more than 12 weeks, and whose etiology cannot be assigned to a specific injury, nerve compression, infection, tumor. This is the case in about 90% of all low back pain subjects. Nowadays physicians are aware that altered breathing patterns may be present in a proportion of individuals with CNSLBP. Researchers suggest that breathing patterns should also be evaluated in the presence of low back pain. Guidelines recommend therapeutic physical exercise as a first line treatment option in CNSLBP. That may be because pain itself contributes to loss of functioning, limits the subject's participation to activities of daily living and produces disability among these subjects. As medication, WHO guideline suggests the use of weak opioids. Tramadol is a centrally acting analgesic, which produces its effect by binding to the μ-opioid receptors, and by inhibiting the release of noradrenaline and serotonine. Studies suggest that, despite its part-opioid mechanism of action, tramadol doesn't produce respiratory depression as opioids do.
**Objectives:** Our study goal was to assess tramadol effects on respiratory markers in human subjects with CNSLBP.
**Methods:** A number of 30 subjects with CNSLBP joined this study for a period of 7 days. They were randomised in two groups: control (15 subjects, received placebo capsules twice a day), tramadol (15 subject, received tramadol 50 mg capsules twice a day). All subjects underwent cardio-pulmonary exercise testing using cycle-ergometer with progressive increasing work-rate at baseline and after 7 days of medication. We investigated peak oxygen uptake ($VO_2max$), respiratory reserve (RR), and exercise tolerance expressed as dioxide carbon ventilatory equivalent. All these parameters were investigated in the first and 7th day of study.
**Results:** Peak oxygen uptake significantly raised for tramadol group on last day of the study (p=0.001). RR improved for both groups but the statistical difference came up for tramadol group (p=0.005). Exercise tolerance was better for both groups but it was significantly higher for tramadol group ($p=0.98x10^{-5}$).
**Conclusions:** Tramadol administration to subjects with CNSLBP improved respiratory markers and exercise tolerance.

### AB0844 COMPARING OF THE EFFECTIVENESS OF BOTILINUM TOXIN TYPE-A AND PRILOCAINE INJECTIONS CLINICALLY IN THE TREATMENT OF MYOFASCIAL PAIN SYNDROME

B. Özdemir[1], Ö. Köroğlu[2], T. Dandinoglu[2]. *[1]Physical Medicine and Rehabilitation, Izmir Military Hospital, Izmir; [2]Physical Medicine and Rehabilitation, Bursa Military Hospital, Bursa, Turkey*

**Objectives:** The objective of this study was to compare the effects of botulinum toxin-A (BTX-A) injection and prilocaine injection in the treatment of myofascial pain syndrome (MAS).
**Methods:** Thirty eight patients, having trigger points in the muscles diagnosed as MAS were analyzed in this randomized, single blind, comparative study.
*Setting:* Patients were randomized into two treatment groups namely BTX-A injection group and prilocaine group. Each group consisted of 19 patients.
*Intervention:* In BTX-A injection group, 10 U of BTX was injected to each trigger point. In the prilocaine group 2ml prilocaine was injected to each trigger point. All the patients were asked to do stretching exercises at home.
*Main outcome measure:* Treatment efficacy was evaluated clinically before and 2 and 6 weeks after treatment. Evaluation parameters were during function visual analog scale (VAS), pain score (PS), pain pressure threshold (PPT), general well-being by short form-36 (SF-36) and Beck Depression Inventory (BDI).
**Results:** Statistically significant improvements were observed during function VAS, PS, PPT, SF36 and BDI in both treatment group. Improvement in VAS and PPT at 2 weeks was more significant in the BTX-A group. Improvement in VAS, PPT, PS at 6 weeks was more significant in BTX-A group. There is no difference between two groups in BDI. Borderline improvement was observed in BTX-A group at 6 weeks.
**Conclusions:** BTX-A injections and prilocain injections are the beneficial treatment choices in this syndrome. But we observed the progressive cumulative effect of BTX-A in the course of time. Although cost effectivity limitation we suggest that patients with chronic persistant myofascial trigger points can be convenient candidates for BTX-A injections. Adjuvant appropriate exercises program should be included in primary treatment modality for optimal success.

## AB0845 A RARE CAUSE OF ANTERIOR KNEE PAIN AND LIMITATION OF KNEE EXTENSION: SYMPTOMATIC INFRAPATELLAR PLICA

B. Karslıoğlu[1], Y. Erdem[2], T. Dandinoglu[3]. *[1]Department of Orthopaedic Surgery, Kasımpaşa Military Hospital, Istanbul, Turkey; [2]Department of Orthopaedic Surgery, Girne Military Hospital, Girne, Cyprus; [3]Physical Medicine and Rehabilitation, Bursa Military Hospital, Bursa, Turkey*

**Background:** The synovial plica of the knee is recognized as a structure that represents remnants of synovial membranes in embryonic development of knee. Infrapatellar plica (IP) known as the ligamentum mucosum, arises from the anterior part of intercondylar notch of femur, widens as it descends anteriorly, and runs parallel to and above the anterior cruciate ligament and attaches to the infrapatellar fat.
**Objectives:** In this report, two cases of symptomatic infrapatellar plica which caused anterior knee pain and knee extension limitation were presented. The first case was 23 years old construction worker who admitted with complains of the left anterior knee pain and limitation of knee motion. The second case was a 21 years old amateur footballer with the complaints of knee movement limitation and anterior knee pain while crouching.
**Methods:** Although we detected infrapatellar plica on MR images of the first patient (Fig. 1a and 1b), the second patient showed no evidence of infrapatellar plica on MR sequences. Arthroscopic surgery planned for the patients and plica excision applied.
**Results:** Physical therapy started just right after surgery and there were no pain or knee motion limitation at routine inspection of patients at 1,5–3-6–12 months.

**Conclusions:** These cases demonstrate a potential role for the infrapatellar plica as a cause of anterior knee pain and movement limitation.We emphasize that with the patients who suffer from anterior knee pain and knee motion limitation, one should need to keep in mind the symptomatic infrapatellar plica.

## AB0846 DOES DIABETES MELLITUS CAUSE PROBLEMS IN HAND FUNCTIONS AND QUALITY OF LIFE?

E. Ceceli, S. Gümrük, S. Kocaoğlu, F. Ayhan. *Ministry of Health Ankara Training and Research Hospital Physical Medicine and Rehabilitation, Ankara, Turkey*

**Background:** Diabetes mellitus (DM) is a chronic condition which can effect different systems of the body
**Objectives:** In this study we aimed to determine the impairments in hand and upper extremity functions, pain and quality of life in diabetic patients.
**Methods:** Fifty diabetic patients who attended to physical medicine and rehabilitation outpatient clinics were evaluated. The patients fasting blood glucose levels, hemoglobin A1 C levels, body mass indexes were detected; existing hand deformities were noted; evaluations of hand strength was made by hand grip strength, hand pain by VAS, hand skills by purdue pegboard test and nerve involvement by semmes weinstein monofilaments (SWM). For upper extremity functions Disabilities of Arm Shoulder and Hand scores (DASH) and for quality of life Nottingham Health profile (NHP) test were selected.
**Results:** The mean age of the patients were 62,76±10,99 years. Among our DM patients only 4 patients had normal weight, 14 were over weight, 29 were obese and 4 had morbid obesity. The mean valueof fasting blood gucose was 145,2 and that of HbA1 c was 7,64. In hand evaluations we found trigger finger and dupuytren contracture in 10,6%, restricted hand mobility in 3,4%,crepitation of hand tendons in 55,3% and carpal tunnel syndrome in 38,3%. SWM median nerve mean values were 3,64±0,68 and that of ulnar nerve was 3,77±0,83.In correlation analysis we found hand pain by VAS correlated all evaluation parameters except purdue pegboard test. SWM scores correlated with all subgroups of NHP, purdue pegboard test and hand pain by VAS. DASH scores correlated with HbA1 c levels, abdominal circumference, grip strength and SWM evaluations.
**Conclusions:** In our diabetic patients we found nearly all patients were obese or overweight; had problems both in hand functions and median - ulnar nerves. Involvement of the nerves leads to problems in quality of life and fine skills of hands. Additional upper extremity impairments increase their pain and disability. As a result we suggest the patients to have a strict glucose control for a better life standard.

## AB0847 NON-SPECIFIC CHRONIC LOW BACK PAIN IS COMMON IN SUB-SAHARAN AFRICA: A HOSPITAL-BASED STUDY IN CAMEROON

F. Kemta Lekpa[1], M.S. Doualla[1], M. Singwe-Ngandeu[2], H. Namme Luma[1]. *[1]Rheumatology, Douala General Hospital, Douala; [2]Rheumatology, Yaoundé Central Hospital, Yaoundé, Cameroon*

**Background:** Low back pain is the most frequent cause of rheumatic diseases in Africa (1). However the studies are scarce, especially in sub-Saharan Africa.
**Objectives:** To determine the main characteristics of non-specific chronic low back pain in Cameroon, Central Africa.
**Methods:** We performed a cross-sectional study in all 6804 patients seen in Rheumatology department in a tertiary healthcare centre, the General Hospital of Douala, Cameroon, between January 2004 and December 2013. All patients followed for low back pain (pain experienced in all the lumbar region of the spine) were screened. Patients were classified into acute low back pain (<3 weeks), subacute low back pain (3 weeks - 3 months) and chronic low back pain (>3 months).
Patients with specific low back pain (infection, tumor, fracture, inflammation, ...) were excluded from this study. A $p<0.05$ was considered statistically significant.
**Results:** During the study period, 3008 patients were seen for low back pain. Of these, 220 patients (7.3%) had specific low back pain and 2788 (92.7%) had non-specific low back pain, including 1302 with chronic low back pain. Chronic low back pain were more common than acute and subacute low back pain (p=0.001) without statistical difference in mean age and sex ratio ($p>0.05$) (Table 1).

Table 1. Distribution of patients according to the low back pain duration

| N=2788 | n (%) | Mean age, years [interquartile range] | Sex ratio (F/H) |
|---|---|---|---|
| Acute low back pain | 980 (35.2) | 51.71 (16–90) | 1.14 |
| Subacute low back pain | 506 (18.1) | 52.32 (16–87) | 1.20 |
| Chronic low back pain | 1302 (46.7) | 52.38 (20–81) | 1.67 |

Table 2 shows the distribution of patients according to the radiographic lesions found. The disc disease, particularly the degenerative disc disease were the most common radiographic lesions, found in more than half of the patients.

Table 2. Radiographics findings

| | N (%) | Mean age ± standard deviation | Sex (women/men) |
|---|---|---|---|
| Degenerative disc disease | 1542 (55) | 55.74±14.21 | 985/565 |
| Disc herniation | 383 (13) | 52.46±14.29 | 225/158 |
| Lumbar osteoarthritis | 247 (9) | 52.68±13.94 | 156/76 |
| Facet joint osteoarthritis | 139 (5) | 52.38±14.28 | 105/32 |
| Spinal stenosis | 93 (3) | 61.13±11.99 | 55/37 |
| Spondylolisthesis | 88 (3) | 53.04±13.63 | 68/18 |
| Transitional abnormalities | 116 (4) | 53.32±13.37 | 59/57 |
| Combination of several lesions | 323 (12) | 52.45±14.21 | 230/93 |
| No lesions | 173 (6) | 52.37±14.30 | 105/68 |

**Conclusions:** Non-specific chronic low back pain is the most prevalent musculoskeletal condition in Cameroon. It concerns almost half of the patients seen in Rheumatology department. The degenerative disc disease are the most common radiographic lesions.
The hospital-based study would explain the marked prevalence of chronic low back pain on acute and subacute low back pain. These latter would probably be more often seen in peripheral hospitals by general practitioners.

## AB0848 SPINAL PAIN IS THE MAIN COMPLAINT OF OUTPATIENTS SEEN IN RHEUMATOLOGY IN CAMEROON, SUB-SAHARAN AFRICA

F. Kemta Lekpa, M.S. Doualla, H. Namme Luma. *Rheumatology, Douala General Hospital, Douala, Cameroon*

**Background:** The prevalence of spinal pain or back pain among Africans may be comparable to that reported in research undertaken in developed nations. However, studies evaluating the epidemiological characteristics of spinal pain are rare in sub-Saharan Africa (1).
**Objectives:** To determine the main epidemiological characteristics of spinal pain in a tertiary healthcare center in Cameroon, sub-Saharan Africa;
To describe the profile of specific spinal pain found in Cameroon.
**Methods:** We performed a cross-sectional study among outpatients seen in Rheumatology consultation at Douala General Hospital, Cameroon, between January 2004 and December 2013. All patients followed for spinal pain (pain experienced in all the regions of the spine) were screened.
**Results:** During the study period, 7024 patients were seen in Rheumatology Department but only 6804 cases (4433 women and 2371 men) were selected for analysis because it had a clearly defined rheumatic disease. The mean age of patients was 52.3±14.3 years. The mean body mass index was 29.3 kg/m$^2$±5.1, with 5194 patients with overweight and obesity.
The main reason for consultation concerned the peripheral skeleton in 3230

Table 1. Distribution of patients according to the affected anatomical region

| | Anatomic region | n (%) |
|---|---|---|
| Axial skeleton, n=3574 (52.5%) | Cervical spine | 449 (12.5) |
| | Dorsal spine | 114 (3.2) |
| | Lombar spine | 3011 (84.2) |
| | Sacro-iliac joints | 3 (0.1) |

Table 2. Distribution of patients with specific back pain

| | n (%) |
|---|---|
| Infectious spondylodiscitis | 64 (0.9) |
| Osteoporosis | 59 (0.8) |
| Axial spondyloarthritis | 40 (0.6) |
| Cancer | 36 (0.5) |
| Others | 21 (0.3) |

patients (47.5%) and 3574 (52.5%) in the axial skeleton. The pain was present in all patients with axial involvement and was localized in the lumbar spine in 3008 patients (84.2%) [Table 1].
Most cases are nonspecific, but in 223 (6.2%) of cases a specific cause was suspected, especially of infectious origin (Table 2). Indeed, 64 cases of infectious spondylodiscitis were collected. Tuberculosis was suspected in the majority of patients, but only one case had been documented.
**Conclusions:** Spinal pain, especially in the lumbar region of the spine is the main location of pain in Rheumatology in Cameroon. The infectious and inflammatory etiologies are rare.

## AB0849 SPINAL BRUCELLOSIS: A STUDY OF 40 CASES IN A TUNISIAN HOSPITAL

H. Ajlani, S. Rekik, S. Boussaid, H. Sahli, E. Cheour, M. Elleuch. *regional hospital of Ben arous, tunis, Tunisia*

**Background:** Brucellosis is a major health problem in Mediterranean countries, including Tunisia. The clinical presentation of this zoonosis varies considerably, but osteoarticular involvement and spinal brucellosis particularly, is the commonest complication.
**Methods:** This study was carried out between 2006 and 2013. Forty patients with infectious spondylodiscitis hospitalized in the department of Rheumatology were analyzed. All patients were thoroughly interrogated, subjected to a rigorous clinical examination and a battery of investigations including: complete blood count, urine analysis, blood culture, erythrocyte sedimentation rate, C-reactive protein (CRP) and serology for brucellosis. The imaging ordered including: plain X-ray of the lumbosacral spine, bone scan and magnetic resonance imaging (MRI) with contrast enhancement of the spine.
**Results:** Ten of the forty patients (25%) proved to have spinal brucellosis. The mean age of this patients was 51 years (range 15 – 68 years) and female/male ratio: 1,5. The mean delay of diagnosis was 7 months. The following symptoms were observed: fever in 9 patients and back pain in all patients. Other symptoms were less frequently observed, such as splenomegaly (one patient), peripheral adenopathy (two patients) and diarrhoea (one patient). Laboratory exams showed elevated erythrocyte sedimentation rate in most of them (8 patients), high levels of CRP in all patients and leukocytosis in 7 cases. Wright serology was positive in all of them. Brucella melitensis was isolated in blood cultures in 2 cases. Standard X-rays were performed in all patients; they showed signs of spondylodiscitis in the lumbar spine in 5 cases, cervical in one case and dorsal in two cases. CT-scan and MRI confirms the diagnosis and showed associated epiduritis (3cases) or abscess (4 cases). Bone biopsy and histopathological examination were performed in three cases. A combination of cycline and rifampicin was given to all patients. The duration of therapy was between 6 and 8 weeks.
**Conclusions:** Brucellosis is present with various clinical signs in endemic areas and may simulate many diseases. The need for prompt diagnosis and treatment of spinal brucellosis is of the utmost importance to prevent serious bone destruction and severe neurologic sequelae.

## AB0850 PREVALENCE OF MUSCULOSKELETAL DISORDERS IN FIREFIGHTERS AND ITS ASSOCIATION WITH INSOMNIA

M. Abbasi[1], Z. Yazdi[2], M.M. Mahdavifar[3]. *[1]metabolic disease research center, Qazvin University of medical sciences; [2]Social Determinants of Health Research Center, Qazvin University of Medical Sciences; [3]Qazvin University of Medical Sciences, Qazvin, Iran, Islamic Republic Of*

**Background:** Musculoskeletal disorders (MSDs) are among the main underlying reasons for decreased productivity at workplace. Awkward working posture, forceful movements, and unexpected events are main reasons for high prevalence of MSDs in firefighters. According to previous research, there is a significant contribution between MSDs and other co-morbidities such as insomnia.
**Objectives:** The present study aimed to evaluate the prevalence of MSDs in firefighters and its relation with severity of insomnia.
**Methods:** A cross sectional study was conducted on firefighters in Qazvin. Demographic information was collected for the participants. A self-administered questionnaire including Nordic question, body map, and insomnia severity index were completed by the firefighters. Descriptive statistics, student t-test, and Chi-square were used for data analysis.
**Results:** Prevalence of MSDs was 54.2% amongst the firefighters, and low back pain was the most common complaint with 30.5%. The highest intensity of pain was in the middle of lumbar region. 20.3% of firefighters had subclinical insomnia, and 30% of them had moderate to severe insomnia. Severity of insomnia was significantly more in subjects with MSDs (12.4±7.9) compared to those without MSDs (7.1±6.6) ($P<0.05$). Among different parts of body, significant association was solely found between back pain and severity of insomnia.
**Conclusions:** The results showed that MSDs, especially around the lumbar region is associated with the severity of insomnia in firefighters. In addition, the prevalence of MSDs and insomnia was significantly higher in firefighters compared to similar studies in general population which calls for preventive activities.

## AB0851 IMPROVEMENT OF WORK CAPACITY IS DEPENDENT OF A DECREASE IN THE KINESIOPHOBIA

M. Norberg[1], L. Belgrand[2], M. Norberg[3], M. Norberg[4]. *[1]Rheumatology, CHUV, Lausanne; [2]Rheumatology, Lavey-les-bains; [3]occupation therapy, Lavey Medical, Lavey les Bains; [4]Gymnase de Beaulieu, Lausanne, Switzerland*

**Background:** The avoidances of movement is a key structure in the chronic pain patient. In this situation the kinesiophobia has a great importance. It could be evaluated using different questionnaires (Tampa, TSK, but also the Fabq).According to Vlayen, the kinesiophobia is the most important prognostic factor when evaluating the return to work.
**Objectives:** In this situation, we wanted to evaluate the evolution of the kniesiophobia before and after a functional restoration program, and its relationship to the work capacity in a group of chronic lumbar back pain patients.
**Methods:** We included 702 patients who had followed an outpatient program of functional restoration during 3 weeks. The program was composed of physical exercices, occupational therapy and psychologcial follow. The patientes were followed on questionnaires (Tampa (3), Fabq, Pact (2) -subective work capacity-) their work capacity and their physical performances (using different tests as Shirado, Biering-Sörensen, Bruce, lumbar mobility)
**Results:** There were a clear relationship between a decrease in kinesiophobia and an increase of work capacity. In fact in patient were the Tampa score decreased with more than 10 points, there were a still staying increased work capaciry. On the other side, none of he physical characteristics were associated with an increase or decrease of work capacity.
**Conclusions:** We have confirmed the observation of Vlayen from 1996, saying that the kinesiophobia is an important prognostic factor for work capacity. This observation is important in functional restoration programs.

## AB0852 RESIDUAL PAIN IN THE INFECTIOUS SPONDYLODISCITIS, WHEN TO EXPECT IT?

R. Dhahri, I. Gharsallah, N. Boussetta, R. Abid, L. Metoui, F. Laajili. *Internal Medicine, Military Hospital of Tunis, Tunisia, Tunis, Tunisia*

**Background:** Residual pain after Infectious spondylodiscitis can result in a major handicap in social and professional life. The aim of the present work was to describe predictive factors of Residual pain after Infectious Spondylodiscitis according to the experience of an internal medicine department in Tunisia.
**Methods:** Patients with SDI either confirmed or presumed and hospitalized in the internal medicine department of The Principle Military Hospital Of Tunis, Tunisia have been included in the Study. Factors correlated with later pain are gathered in this study.
**Results:** See Table 1.

Table 1

| | | Residual pain | | P |
|---|---|---|---|---|
| | | yes | No | |
| Pain at initial examination (ie) | Yes | 4 | 8 | **0.026** |
| | No | 20 | 67 | |
| Neurological compression signs (ie) | Yes | 7 | 9 | **0.049** |
| | No | 17 | 5 | |
| Cutaneous infection | Yes | 10 | 7 | **0.03** |
| | No | 9 | 0 | |
| Germ identified | Yes | 1 | 7 | **0.008** |
| | No | 23 | 7 | |
| SD group | SDT | 9 | 12 | **0.003** |
| | SDP | 15 | 2 | |
| MRI signs of compression | yes | 11 | 13 | **0.048** |
| | no | 5 | 1 | |

Fourty-four patients met the inclusion criteria. They have been gathered over 20 years-period. They were 24 men and 20 women with an average age at 52.5 years. The diagnosis was a Tuberculous Spondylodiscitis in 22 cases (50%): among them 10 patients had a concomitant extra spinal TB. The diagnostic delay was 231 days for TB SDI and 40.5 days for SDP.
Treatment duration was 13 months for SDT and 18 weeks for SDP. The outcome was favorabl Regular monitoring was observed in 38 patients (17 SDP, SDT 21) with an average duration of 20 months (5–48 months).
**Conclusions:** Neurological signs at first examination and MRI are main factors of residual pain in SDI.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5742

## AB0853 ELECTROACUPUNCTURE TREATMENT OF MERALGIA PARAESTHETICA

R.E. Alexander. *Edgware Community Hospital, London, United Kingdom*

**Background:** Meralgia Paraesthetica (MP) (meros = thigh, algos = pain) is an under diagnosed fairly condition caused by entrapment of the lateral femoral cutaneous nerve. Paraesthesiae, numbness or burning typically affect the thigh. I noticed that acupuncture produced a rapid improvement and invited referrals from rheumatology consultants.
**Objectives:** I had treated several rheumatology patients [1] and decided to do a case series of MP, using a series of tender and traditional Chinese acupuncture points. I found that all patients were tender over GB31 acupuncture point on the affected lateral thigh (7 inches proximal to the popliteal crease).
**Methods:** A series of 10 patients, including two who had refused surgery (excluding those with significant lumbar spine problems), were treated. Xray/MRI scans were taken if relevant. Acupuncture points used were UB25, GB30, GB34, Ex21 lumbar facet trigger points, GB31+ “Ah chi” tender buttock and Chinese points using an infra-red lamp. Electro-acupuncture (using a dense-disperse mode), was used after the first treatment if significant benefit was not obtained. VAS pain scores were collected weekly from patients prior to treatment by a nurse or receptionist Analgesic intake was recorded.
**Results:** Without exception patients were tender over GB31 point on the thigh.
The pain scores improved for all 10 patients by at least 50% with an average of 3–4 treatments. At follow up (3–36 months), improvement was nearly 100%. They were all able to reduce or stop their medication
**Conclusions:** A series of 10 patients all improved, including a patient with a 20 year history. Two patients had refused surgery and three were misdiagnosed. The patients had no signs of radiculopathy. Nerve conduction studies were considered to be non feasible. Electroacupuncture appears to be a good treatment for this debilitating condition.
A Cochrane review in 2008 found observational studies only, not RCTs [1]. Many patients appear to improve spontaneously but 10–15% may need local steroid/anaesthetic injections. Decompression or resection of the nerve may be necessary [2]. In this series 50% of patients needed surgery. I found one paper only discussing two case reports of the treatment of MP with acupuncture [1]. Acupuncture is a safe non-invasive treatment for this debilitating condition. Tenderness of GB31 acupuncture point on the lateral side of the thigh was consistently present, which may aid diagnosis.

## AB0854 BODY ADIPOSITY MEASURES AND THEIR ASSOCIATION WITH LOW BACK PAIN: RESULT FROM A PROSPECTIVE COHORT STUDY

S.M. Hussain[1], D.M. Urquhart[1], Y. Wang[1], J.E. Shaw[2], D.J. Magliano[2], A.E. Wluka[1], F.M. Cicuttini[1]. *[1]Monash University; [2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia*

**Background:** Although obesity is associated with low back pain (LBP) prevalence in adults, the mechanism how obesity causes LBP remained unexplored. Since, our current understanding on how obesity causes other joint pain i.e. pain in hand joints suggest that, there must be additional systemic effect of obesity in the pathogenesis of LBP. Thus, clarifying the role of body composition on the risk of LBP is important as it will help in the understanding of likely pathological mechanisms.
**Objectives:** To examine the relationship between adiposity measures and LBP intensity and disability in community based population.
**Methods:** 5,058 participants (44% men) of the Australian Diabetes, Obesity and Lifestyle Study recruited at 1999–2000 were included. Their body mass index (BMI), waist circumference, and waist-to-hip ratio were obtained from direct anthropometric measurements. The fat mass and percentage fat were estimated from bioelectrical impedance analysis. LBP intensity and disability assessed in 2013–2014 using the Chronic Pain Grade Questionnaire.
**Results:** All the adiposity measures were associated with LBP intensity, independent of fat free mass, for both men and women. The odd ratios (OR) of men for high intensity LBP were BMI OR 1.41 (95% CI 1.17–1.70), waist OR 1.25 (95% CI 1.07–1.46), waist-to-hip ratio OR 1.33 (95% CI 1.03–1.71), percent fat OR 1.45 (95% CI 1.19–1.77), fat mass OR 1.23 (95% CI 1.05–1.44). For women the ORs were - BMI OR 1.39 (95% CI 1.22–1.59), waist OR 1.36 (95% CI 1.22–1.52), waist-to-hip ratio OR 1.49 (95% CI 1.21–1.84), percent fat (10%) OR 1.39 (95% CI 1.22–1.57), fat mass OR 1.27 (95% CI 1.15–1.40). Similarly all adiposity measures were associated with LBP disability. The risk of LBP intensity and disability increased in a linear manner in sex-specific quartiles of all adiposity measures such that the individuals in the highest quartile had the highest risk of developing LBP.
**Conclusions:** All adiposity measures were significantly associated with LBP intensity and disability. This suggests a role for metabolic mechanisms associated with adiposity contribute to the risk of LBP. The rise in the obesity epidemic throughout the world is likely to increase the burden of LBP, as such understanding the mechanism of action will be important in effective prevention of the disease.

## AB0855 FOOT INVOLVEMENT IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS AND ITS EFFECT ON FUNCTIONAL STATUS AND QUALITY OF LIFE

S. Acer[1], A. Bal[1], O.Z. Karaahmet[1], Ö. Başaran[2], H.H. Gezer[1], B. Acar Celikel[2], N. Cakar[2], A. Cakci[1]. *[1]Physical Treatment and Rehabilitation Clinic Disertation, Diskapi Yildirim Beyazit Training and Research Hospital, Ankara; [2]Department of Pediatric Nephrology and Rheumatology, Ankara Children’s Hematology and Oncology Hospital, Ankara, Turkey*

**Background:** Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children that often results in persistent and disabling foot impairments (1). Foot and ankle problems are common but relatively neglected manifestations of JIA (2). Ultrasound examination is beneficial for detecting subclinical disease, especially in foot and ankle, which are otherwise difficult to examine in children (3). Therefore, in this study, we evaluated the involvement of foot and ankle in JIA patients using both ultrasonography and physical examination.
**Objectives:** The aim of the study was to investigate the foot and ankle involvement in JIA patients and determine the relationship between this involvement and disease activity, functional status, and quality of life.
**Methods:** We evaluated those children who attended the Pediatric Rheumatology Department between December 2014 and April 2015. Thirty two JIA patients, aged between 6–16 years, participated in this study. Along with the demographic characteristics, the Disease Activity Score-28 (DAS-28), Childhood Health Assessment Questionnaire (CHAQ), and Pediatric Quality of Life (PEDsQoL) scores were recorded for the measurement of disease activity, physical functional status, and quality of life, respectively. The involvement of foot and ankle was investigated by both physical examination (tenderness, swelling and deformities) and detailed gray-scale ultrasonographic evaluation.
**Results:** Of the total included JIA patients, 17 patients (53%) showed foot and ankle involvement. Foot or ankle tenderness was detected in eight patients, swelling in four patients, pes planus in four patients, calcaneal valgus in four patients, limited ankle joint range in two patients, and hallux valgus was detected in three patients. The ultrasonographic investigation revealed tenosynovitis in five patients, ankle joint effusion in four patients, synovial hypertrophy in one patient, bursitis in one patient, and plantar fasciitis in one patient. There was no difference between the group with foot and ankle involvement and the group with no such involvement in terms of demographical data or disease activity ($p>0.05$).

A lower physical functional state was detected in the patients of the foot and ankle involvement group compared to the patients who had no such sign ($p<0.05$). However, this difference was not reflected in the quality of life of the patients ($p>0.05$).

**Conclusions:** This study showed that foot and ankle disorders are not rare in children with JIA. Appropriate evaluation and management of the foot and ankle are important for better functional status of JIA patients.

## AB0856 EVALUATION OF CARDIAC CAPACITY PARAMETERS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

S. Acer[1], O.Z. Karaahmet[1], A. Bal[1], Ö. Başaran[2], A. Cakci[1]. [1]*Physical Treatment and Rehabilitation Clinic Disertation, Diskapi Yildirim Beyazit Training and Research Hospital, Ankara;* [2]*Department of Pediatric Nephrology and Rheumatology, Ankara Children' s Hematology and Oncology Hospital, Ankara, Turkey*

**Background:** Children with juvenile idiopathic arthritis (JIA) are believed to have a lower cardiopulmonary capacity and functional ability. This means that they face more problems in performing daily activities compared with healthy children (1). Anaerobic capacity is important because most daily activities performed by children are anaerobic in nature (2). The association between anaerobic physical fitness and functional ability emphasized the importance of anaerobic physical fitness in children with JIA (3).

**Objectives:** The purpose of this study is to examine whether children with JIA have lower cardiac capacity compared to healthy children and determine the clinical features that might be related to low aerobic capacity in children with JIA.

**Methods:** 32 JIA patients and 11 healthy children aged between 6–16 years old participated in this study. The age, sex, height, weight, body mass index, disease duration, disease subtype, and medications of the participants were noted. Disease activity, functional disability and quality of life were measured with Disease Activity Score-28, Childhood Health Assessment Questionnaire and Pediatric Quality of Life scores, respectively. Knee or hip involvement in the patients was detected with physical examination. The ergospirometry stress test with bicycle was applied to all the participants to determine their cardiac capacity. The participants began the test with a load of half of their weight and a speed of 100 rpm (rapid per minute) and continued with a load that increased by 1 watt per 3 minutes. They were asked to pass the anaerobic threshold (respiratory exchange ratio). The VO2peak (the maximum volume of the oxygen consumed per minute) values were recorded to assess the aerobic capacity. The time passed after the thresholds (anaerobic capacity) and the total test time were also recorded to measure the whole (aerobic and anaerobic) cardiac capacity.

**Results:** The averages of the cardiac capacity parameters (VO2peak level for the aerobic capacity and the total test time for the cardiac capacity) of the JIA group were significantly lower than those of the control group (p=0.00, p=0.00). There was no significant difference between the JIA (5.88 ±4.13 min) and the control groups (10.50±5.40 min) in terms of the time passed after the threshold (p=0.15). The investigations of the parameters that affect the VO2peak level revealed that women had a lower VO2peak level (p=0.02) compared to men and the participants with knee or hip involvement had a lower VO2peak level (p=0.01) compared to the ones who had no such a sign. Sex and CHAQ were identified as the most determinant factors on VO2peak level when the other probable risk factors were corrected (p=0.00, p=0.04).

**Conclusions:** This study shows that JIA patients have lower aerobic capacities. In JIA treatment, the lower limb involvement, physical functional state, and sex should be considered when targeting to increase the cardiopulmonary capacity of the patients In addition, customized treatment programs should be designed for the JIA patients.

## AB0857 SPONTANEOUS REGRESSION OF EBV-ASSOCIATED LYMPHOPROLIFERATIVE DISORDER IN A JUVENILE IDIOPATHIC ARTHRITIS PATIENT AFTER DISCONTINUATION OF METHOTREXATE AND ETANERCEPT

A. Klein[1], H. Reinhard[1], A. Mueller[2], G. Horneff[1]. [1]*Asklepios, Sankt Augustin;* [2]*University Bonn, Bonn, Germany*

**Background:** The risk for malignancies especially lymphoma seems higher for JIA patients. So far, treatment with TNF-inhibitors, especially with Etanercept has not been described to further enhance the malignancy rate. The association of EBV induced lymphoproliferation/lymphoma has been described in adult patients with rheumatoid arthritis upon treatment with several immunosuppressive drugs including Methotrexate and may not be related to Etanercept.

**Results:** A case of a 16-year-old female patient with polyarticular JIA since the age of 4 years is reported. The patient also suffers from a complex congenital cardiac and several other congenital abnormalities including mental retardation, sensoneurinal hearing loss, growth retardation and pubertas tarda. Microdeletion 22q was ruled out and a microarray assay in search of an underlying genetic disorder was normal. When diagnosed with JIA at the age of 4 years treatment with methotrexate was started but discontinued due to elevated liver enzymes 10 months later. At the age of 13 years, JIA relapsed with multiple joint involvement and treatment with methotrexate and Etanercept was initiated leading to acceptable clinical condition, with functional impairment due to restricted joint movements. Complete remission of JIA was not reached.

After 3 years on combination treatment, the patient reported multiple subcutaneous nodules on the lower extremities. On palpation such nodules were 0.5 to 2.0 cm of size and the largest one was slightly tender. No overlying skin changes such as erythema were noted. Laboratory analysis revealed normal blood counts, normal CRP, but elevated lactate dehydrogenase and uric acid. Ultrasound investigation showed several round lesions with a maximum diameter of 1.7 cm with enhanced signal of capsules and in some of the lesions hypoechoic centers. Thoracic CT detected a mediastinal lesion suggestive of a mediastinal lymphoma.

Biopsy of the largest nodule revealed diffuse large B-cell lymphoma (DLBCL). EBV-RNA (EBER-in-situ-hybridization) could be detected in the nuclei of the blasts. While IgG antibodies to EBV VCA and EBNA were positive, EBV VCA IgM was negative and in the patient's peripheral blood EBV DNA PCR gave negative results. The patient was classified as clinical stage IIIA due to a mediastinal lesion. Immunosuppressive treatment was discontinued immediately, which led to regression of remaining nodules, mediastinal lymphoma and normalization of lactate dehydrogenase. So far, no recurrence of DLBCL or JIA could be detected, 9 months after discontinutation of immunosuppressive treatment.

**Conclusions:** The clinical course with spontaneous regression of the lymphoproliferative lesions and normalization of LDH after discontinuation of antirheumatic treatment lead to the assessment of the neoplasm as lymphoproliferative disorder (LDP) associated with iatrogenic immunosuppression rather than manifest lymphoma. The patient was considered to have iatrogenic lymphoproliferative disorder classified as "other iatrogenic immunodeficiency-associated lymphoproliferative disorders" by the WHO. This is the first case-report of a JIA patient with EBV-positive DLBCL following administration of Etanercept and Methotrexate showing spontaneous regression of lymphoproliferation after discontinuation of antirheumatic treatment.

## AB0858 RARE NOD2 VARIANTS IN PATIENTS WITH GRANULOMATOUS UVEITIS

C. Galeotti[1], G. Sarrabay[2], O. Fogel[3], I. Touitou[2], B. Bodaghi[4], C. Miceli-Richard[5], I. Koné-Paut[1]. [1]*Pediatric Rheumatology, CHU Bicêtre, le Kremlin Bicêtre;* [2]*Genetics, CHU Montpellier, Montpellier;* [3]*Rheumatology, CHU Toulouse, Toulouse;* [4]*Ophtalmology, CHU Pitié-Salpêtrière;* [5]*Rheumatology, CHU Cochin, Paris, France*

**Background:** Blau Syndrome is a rare autosomal dominant inflammatory disease characterized by early-onset granulomatous arthritis, dermatitis and recurrent uveitis (1). Mutations in the nucleotide-binding domain (NBD) of *CARD15/NOD2* gene (mainly R334W, R334Q and L469F) have been identified in Blau syndrome (2). Polymorphisms in the leucine-rich repeats (LRR) of *CARD15* are associated with Crohn's Disease, and mutations in the NBD domain are observed in Blau syndrome (3).

**Objectives:** We describe two patients with granulomatous uveitis carrying rare genetic variants of NOD2.

**Methods:** The analysis of the coding exons of the *NOD2/CARD15* gene was performed in our two patients because they had a granulomatous uveitis.

**Results:** The first patient, a 14 years old boy, had an isolated bilateral granulomatous uveitis since he was 10 years old. He was treated by steroids and methotrexate. He carried the A725G variant of *NOD2* (rs5743278 MAF 0.018). The second patient, a 15 years old girl had an isolated bilateral granulomatous panuveitis since she was 5 years old. She was treated by azathioprine and steroids. She carried two other rare genetic variants of *NOD2:* H287Y and L682F (MAF=0.0002).

**Conclusions:** NOD2 is composed of three domains: a C-terminal LRR domain involved in ligand recognition, a central NBD and an N-terminal CARD domain.

Our two patients carried a rare genetic variant located between the LRR and the NBD domains (A725G and L682F). The A725G variant has been previously described in patients with Crohn disease's (CD) phenotype by Hugot et al (3) but our first patient had no clinical symptom related to CD. The second patient carried another rare variant located in the NBD domain (H287Y), compatible with the diagnosis of Blau syndrome. According to these observations, genetic variations located between the LRR and the NBD domains of NOD2 might be associated with the occurrence of granulomatous uveitis. It should be thus recommended to screen NOD2 mutations in patients with isolated granulomatous uveitis.

## AB0859 EFFICACY AND SAFETY OF ANTI-TNFα THERAPIES IN CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS (CRMO): AN EXTENSIVE REVIEW OF THE LITERATURE

C. Campochiaro, L. Rovati, G. Cavalli, P. Aiello, A. Berti, M.G. Sabbadini, E. Baldissera, L. Dagna. *Unit of Internal Medicine and Clinical Immunology, IRCCS San Raffaele, Milan, Italy*

**Background:** CRMO is an autoinflammatory disease characterized by relapsing and remitting episodes of pain related to the presence of foci of sterile bone inflammation [1]. TNFα levels are elevated in the serum of patients affected by CRMO and in bone-biopsy specimens [2]. NSAIDs and steroid afford symptomatic relief of pain and swelling in approximately 80% of patients [1]. Some recent reports have shown that anti-TNFα agents lead to clinical and radiological improvement in refractory cases of CRMO.
**Objectives:** We provide a review of the literature concerning the efficacy and safety of anti-TNFα in CRMO.
**Methods:** We searched the MEDLINE database and selected articles published in the English language with the headings "CRMO" and "anti-TNFα". We only included unambiguous CRMO cases. We added a patient from our cohort.
**Results:** A total of 13 patients met our inclusion criteria (see Table 1). Etanercept (ETN) was the anti-TNFα most commonly used (7 pts). In 6 cases ETN was used at a dosage of 0.8 mg/kg/week. In 5 cases the dosage was modified after 6 months to 0.8 mg/kg every 2 weeks. In 1 case the drug was used at a dosage of 0.4 mg/kg twice a week. In 2 cases MTX was added to ETN. Infliximab (IFX) was used in 4 pts. It was administered at a dose of 5 mg/kg in 3 pts. In 2 cases a loading dose similar to the one recommended for the treatment of RA was used. In our case, due to the recurrence of bone pain after 4 years with IFX 5 mg/kg every 8 weeks, we reduced the administration interval to 6 weeks. In another patient with worsening bone pain after an initial administration of IFX at a dosage of 5 mg/kg every 8 weeks, a loading dose of 6.7 mg/kg was used for three times every 2 weeks. The patient was then treated with an IFX 6.7 mg/kg every 4 weeks. In 1 pt, an initial regimen of IFX every 4 weeks was modified after 1 year to an 8-weeks regimen. 1 pt was instead treated with IFX at a dosage of 3 mg/kg every 8 weeks. IFX was used as a monotherapy in all cases. Adalimumab (ADA) was used in 2 pts. No data about ADA dose or administration interval were recorded in the published article. Of note, all patients underwent remission after starting an anti-TNFα therapy. In 3 cases a disease flare occurred during the anti-TNFα treatment. In 1 case the flare occurred after increasing the administration interval of ETA from one to two weeks. In the 2 remaining cases the disease flare occurred without any previous therapy modification. In all cases increasing the anti-TNFα agent dosage allowed to achieve remission of CRMO. No adverse events were recorded during the anti-TNFα therapy. No pt required a switch to a different anti-TNFα agent. Attempts to discontinue etanercept therapy were performed in 4 pts, but were followed by disease relapses within a month in 3 cases; in the remaining case, ETA was successfully discontinued after 4.5 years of treatment.
**Conclusions:** Our experience and the review of the literature indicate that anti-TNFα agents represent an effective and possibly safe option in the treatment of refractory CRMO.

## AB0860 JIA ASSOCIATED UVEITIS IN GREEK ADULT PATIENTS: PROFILE AND LONG-TERM OUTCOME

D. Dimopoulou[1], M. Trachana[2], P. Pratsidou[2], P. Sidiropoulos[3], F. Kanakoudi-Tsakalidou[2], A. Garyfallos[1]. *[1]4th Department of Internal Medicine; [2]1st Department of Pediatrics, Aristotle University, Thessaloniki; [3]Department of Rheumatology, University of Heraklion, Heraklion, Greece*

**Background:** JIA-associated uveitis is an important cause of ocular morbidity overtime.
**Objectives:** To evaluate the risk factors of uveitis development and describe its characteristics and outcome in a cohort of Greek adult patients with JIA. No relevant Greek data have been published so far.
**Methods:** Medical charts were reviewed in terms of gender, current age, ILAR category, age and ANA titer at disease onset. For patients with an established uveitis, the type of uveitis, date of diagnosis, uveitis complications (synechiae, cataract, glaucoma) were also recorded. The final ocular outcome was the Best Corrected Visual Acuity (BCVA) at the last follow up visit and was ranked in 3 levels: a) good visual acuity: BCVA $\geq$20/40, b) impaired visual acuity: BCVA 20/50–20/100, c) legal blindness: BCVA $\leq$20/200.
**Results:** A total of 102 (72 females) patients were enrolled with a disease age of onset (mean ±SD) 7.7±4 years, a disease course 17.2±6.7 years and patients' current age 25±5.9 years. The JIA subtypes were systemic (12.7%), oligoarthritis (29.4%), polyarthritis (29.4%, 10.8% RF positive), psoriatic (8.8%), enthesitis-related arthritis (17.6%) and unclassified arthritis (1.9%). Uveitis developed in 11 patients (10.8%), mainly in females (10/11 females, p=0.224). In 90.9% of the patients, uveitis was diagnosed within the first 3.5 years of the disease (mean time 2.2, range 0–13 years). In none of these patients uveitis was diagnosed prior to JIA, while in only one, concurrently. Uveitis was mainly bilateral than unilateral (81.8% vs 18.2%). Patients with oligoarticular type of onset had the highest rate of uveitis (9/30, 30%). Patients with uveitis were significantly younger at onset than those free of uveitis ($p<0.001$) and had a higher rate of ANA positivity (81.8% vs 27.3%, p=0.001). Five of these 11 patients (45.5%, 4.9% of the cohort) developed at least one ophthalmologic complication. Cataract was detected in 4/11 patients (36.3%), synechiae in 4/11 (36.3%) and glaucoma in 4/11 patients (36.3%). Three of the 11 (27.3%) developed all the aforementioned complications. The visual outcome at the study visit revealed unilateral legal blindness in 18.2% and the rest (81.8%) had a bilateral good visual acuity. Predictors of uveitis development were early disease onset [OR (95%) 0.562 (0.381, 0.829), p=0.004] and ANA positivity at onset [OR (95%) 10.703 (1.821, 62.899), p=0.009]. Oligoarticular onset was positively associated with uveitis development only in the univariate analysis (p=0.01).
**Conclusions:** The majority of adults with JIA-associated uveitis had a good visual bilateral acuity after a -17 year disease onset. ANA positivity and younger age at disease presentation have been proved to be independent risk factors for uveitis development in Greek patients, too.

## AB0861 PROGNOSTIC VALUE OF ANA POSITIVITY IN GREEK ADULT JIA PATIENTS

D. Dimopoulou[1], M. Trachana[2], P. Pratsidou[2], P. Sidiropoulos[3], V. Tzimouli[2], F. Kanakoudi-Tsakalidou[2], A. Garyfallos[1]. *[1]4th Department of Internal Medicine; [2]1st Department of Pediatrics, Aristotle University, Thessaloniki; [3]Department of Rheumatology, University of Heraklion, Heraklion, Greece*

**Background:** Antinuclear antibodies (ANA), one of the biomarkers of ILAR JIA classification, has been proposed to be associated with a protracted disease course overtime, regardless of JIA subtype. However, their role in the disease outcome is still debated.
**Objectives:** To investigate the impact of ANA positivity in the long-term outcome of JIA patients.

**Methods:** Patients ≥18 years with an established JIA, a minimal disease duration of 5 years and no history of a >6–month care from external rheumatologists, were enrolled in the study. Data were retrieved from the patients' charts, including ANA titers at onset (2 measurements, 3 months apart). The ANA were measured by indirect immunofluorescence (cut-off value ≥1:160). Clinical, laboratory -including ANA- and radiographic assessment were performed at the last follow-up visit, 17.2 years post-diagnosis. The outcome variables defined were: radiographic damage assessed by the total modified Sharp/van der Heijde Score (TmSvdHS), articular and extra-articular damage by Juvenile Arthritis Damage Index (JADI-A and JADI-E), physical ability by the Health Assessment Questionnaire-Disability Index (HAQ-DI) and the cumulative % times spent in a state of disease activity and of clinical remission off medication (CR).
**Results:** Hundred two patients (72 females) were enrolled. The disease age of onset (mean ±SD) was 7.7±4 years, the interval from onset to last visit 17.2±6.7 years and the patients' current age 25±5.9 years. Thirty three (32.4%) patients were ANA positive at onset. At the last follow-up, there was no significant difference between ANA positive and ANA negative patients in terms of TmSvdHS (p=0.982), JADI-A (p=0.699), JADI-E (p=0.235), HAQ-DI (p=0.234), cumulative % time spent in disease activity (p=0.583) or CR (p=0.175). There was no statistical gender difference among ANA positive patients (F:M 36.6%:25%, p=0.385), but they had an earlier disease onset (p=0.038), mostly oligoarticular (p=0.004) and were more prone to uveitis development (p=0.001). In the multivariate analysis ANA positivity was found to be the single independent risk factor for uveitis development [OR (95%) 10.703 (1.821, 62.899), p=0.009].
**Conclusions:** Patients with ANA positive had predominantly an earlier and oligoarticular disease onset and a higher risk of uveitis development. However, ANA positivity was not found to influence the final disease outcome in terms of articular and extra articular degree of damage, radiographic abnormalities, physical disability and cumulative % time spent in disease activity or CR.

## AB0862 ARTICULAR AND EXTRA-ARTICULAR DAMAGE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

D. Dalia, N.E. Carmen, M.E. Aritina, P. Ileana. *UMF Craiova, Craiova, Romania*

**Objectives:** The objective of this study was to asses the damage present in patients with JIA using the JADI-A and JADI-E scores, as well as their correlation to various clinical, lab and functional parameters.
**Methods:** The study was prospective and it took place between 2009 and 2014, involving 45 Romanian patients with JIA:15 patients with the systemic form, 15 patients with the polyarticular form and 15 patients with the oligoarticular form, in which the clinical, lab and radiological factors at the onset of the disease were assessed. The reevaluation of the patients was done 3 years later, following a special protocol that included the assessment of the general state, the disease activity score (DAS 28), joint involvement, radiological modifications (according to the Dale scoring system), CHAQ, the JADI-A and JADI-E scores. The correlation between the JADI scores and other parameters was made with the help of Spearman's correlation coefficient.
**Results:** The articular damage highlighted by the JADI-A score was present in 15 patients (33.33%). Extra-articular damage was present in 24 patients (53.33%) and the most affected form was the systemic one – 12 patients (80%). The most frequent extra-articular impairment was growth hypotrophy, which was present in 15 patients (33.33%). In the entire subject group of patients with JIA, the JADI-A score is correlated ($p<0.01$) with the articular score (0.62), CHAQ (0.41), and the parents (0.56) and physician (0.52) visual analogue scale. The JADI-E score is positively correlated ($p<0.01$) with the Steinbrocker classification (0.56), the DAS 28 score (0.53), ESR (0.3) and CHAQ (0.52).
**Conclusions:** The articular and extra-articular damage JADI scores can represent a useful instrument for the monitoring of damage in children with JIA.

## AB0863 HIGH FREQUENCY OF CAPS AND TRAPS IN RUSSIAN PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

E. Alexeeva [1,2], K. Savostyanov [1], T. Sleptsova [1], A. Pushkov [1], T. Bzarova [1,2], S. Valieva [1], R. Denisova [1], K. Isayeva [1], E. Chistyakova [1,2], O. Lomakina [1], M. Soloshenko [1], E. Kaschenko [1]. *[1]Scientific Centre of Children's Health; [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** The main clinical manifestations of monogenic autoinflammatory syndromes and polygenic Systemic juvenile idiopathic arthritis (sJIA) are similar and presented with fever, migratory erythematous rash, arthritis/arthralgia and eye manifestations. The right diagnosis is reached using gene analysis and prognosis depends on correct personified therapy.
**Objectives:** To evaluate frequency of CAPS and TRAPS in Russian systemic JIA pts.
**Methods:** 170 pts (61 boys, 109 girls) at the age from 1 to 17y. (6.9 (3.9;9.4) followed with a diagnosis of sJIA were selected according to the clinical manifestations, with subsequent obligatory genetic counseling in the Department of Rheumatology of the Scientific Center for Children's Health. The median age of disease onset was 2.9 (1.2;6.0)y., disease duration – 4.0 (2.6;5.4)y. The commonest features were fever (100%), arthritis/arthragia (100%), rash (163 pts/96%), hepato- and splenomegaly (160/94%), lymphadenopathy (136/80%), headache (88/52%), abdominal pain (98/58%) and eye manifestations (42/25%). Patients' DNA was sequenced in all coding exons and intronic flanks of the TNFRSF1A and NLRP3 genes.
**Results:** In 18/130 (10.6%) pts genetic autoinflammatory syndrome was established. In 12 pts we found mutations in TNFRSF1A: In 9/12 pts - the most frequent mutations c.362G>A (p.R92Q) located in exon 4 and associated with the mild progression of TRAPS. One pt revealed a TNFRSF1A mutation c.374G>A (C96Y). Two pts identified mutations which were not previously described in the databases. They had TNFRSF1A deletion c.337_339del (p.Glu113del) and frameshift mutation c.792delT (p.Lys265Serfs*87) located in exons 04 and 09 of TNFRSF1A gene, respectively. The median age of disease onset was 5.3 y. Pts had a median 85 symptomatic days per year, attacks were recurrent in 78%. A family history was present in 3 pts: 2 girls with R92Q and one – with C96Y mutation. Four pts identified mutations in NLRP3 gene. One pt had mutation c.598G>A (p.Val200Met). Three pts had mutations which were not previously described in the databases. One pt had a mutation c.796C>T (p.Leu266Phe) in exon 04 of NLRP3 gene. Two other pts had mutations c.2861C>T and c.2173C>A, respectively. Pts with c.2173C>A and c.796C>T mutations have CINCA/NOMID phenotype and dramatic effect of canacinumab.
2 pts presented changes in both genes. They had R92Q mutation in TNFRSF1A and polymorphism Q705K in NLRP3 gene.
In 15 (7.6%) pts we identified NLRP3 gene polymorphism Q705K associated with elevated levels of IL1.
**Conclusions:** Our results suggests for a relatively frequent incidence of CAPS and TRAPS in Russian systemic JIA pts. The number of genetically confirmed pts with periodic fever syndromes in Russia is very low. It is important to establish a network for genetic testing of periodic fever syndromes.

## AB0864 PEDIATRIC ACUTE-ONSET NEUROPSYCHIATRIC SYNDROME (PANS): CLINICAL EVALUATION IN A GROUP OF ITALIAN CHILDREN. A DIFFERENT ENTITY FROM PANDAS?

F. Falcini [1], G. Lepri [1], A. Ferrari [2], M. Matucci-Cerinic [1], A. Meini [2]. *[1]Department of Internal Medicine, Section of Rheumatology, University of Florence, Florence; [2]Pediatric Clinic University of Brescia and Spedali Civili di Brescia, Brescia, Italy*

**Background:** PANDAS (Pediatric Autoimmune Neuropsychiatric Disorders associated with Streptococcal Infections) identifies a subgroup of pts with unusually abrupt and dramatic TIC/OCD onset GAS infection related. PANS "Pediatric acute-onset neuropsychiatric syndrome" is a term proposed to describe a clinically distinct presentation of OCD/TIC with post infectious origin. Differently from PANDAS, in PANS other agents may trigger the disease, including *Mycoplasma pneumonia*, Influenza viruses, Epstein Barr virus, *Borrelia Burgdorferi*, Herpes simplex and Varicella viruses. Clinical presentation is characterized by an abrupt dramatic onset of OCD and additional neuropsychiatric symptoms nor explained by known neurologic or medical disorders[1].
**Objectives:** To describe clinical features of 23 Italian children with OCD/TIC diagnosed as PANS in comparison to our PANDAS group.
**Methods:** Between May 2009 through January 2016 we recruited 23 pts (13 M, 10 F) with OCD/TIC starting before puberty. The mean age at onset 77 mnths±35.6SD.
**Results:** 19 (86.4%) were full-term born, 3 (13.6%) from Caesarean section (no information in 1 adopted child). 8/21 (38.1%) had familiars with OCD/tics or other neurologic diseases (2 pts without data). At onset, clinical signs were OCD in 3 (13%), OCD and motor tics in 7 (30.4%), motor tics in 5 (21.7%), vocal tics in 1 (4.3%), motor/vocal tics in 5 (21.7%), motor/vocal tics and OCD in 2 (8.7%), Mean age at diagnosis 106.8 months±36.9 SD. Antistreptolysin O and antiDNaseB titers were negative in all pts. In all *EBV*, *Mycoplasma pneumoniae*, *CMV*, *Borrelia Burgdorferi* were tested: 2 pts had history of tick bite and *Borrelia Burgorferi* Ab+, 6 pts Mycoplasma pneumoniae Ab+, 1 EBV Ab+; in 2 pts a VZV infectionAb+ was found. In 1 child Rotavirus infection was suspected and 12 had a viral pharyngitis before OCD/Tics onset. All underwent neuropsychiatric evaluation, none had deficit of psychological development; in all autoimmunity (ANA; antiDNA and ENA Ab) was negative as well as cerebral MR and EEG. All received antibiotic therapy according to the specific infection: pts with *Mycoplasma* macrolide, pts with *VZV* antiviral, pts with *Borrelia* amoxicillina. All showed benefit during and after the treatment. Pts, with no specific agent, received amoxicillina and benzathine benzylpenicillin with benefit after a more prolonged period than PANDAS pts.

**Conclusions:** Our data show that PANS as PANDAS prediliges males with higher familiar predisposition in PANS. The age at onset is comparable to PANDAS, while OCD are more common and severe than in PANDAS. All pts had an infectious event, as PANDAS pts, but the trigger agent was different from GAS, and all responded to the specific therapy. PANDAS and PANS mainly differs from the trigger agent. The knowledge of PANS and PANDAS is mandatory to early recognize children at the disease onset avoiding to delay the diagnosis and the beginning of therapy.

## AB0865 VITAMIN D RECEPTOR POLYMORPHISMS ARE NOT ASSOCIATED WITH THE RISK OF KAWASAKI DISEASE (KD) IN A GROUP OF ITALIAN CHILDREN

F. Falcini[1], F. Marini[2], S. Stagi[3], D. Rigante[4], G. Lepri[1], M. Matucci-Cerinic[1], M.L. Brandi[2]. *[1]Department of Internal Medicine, Section of Rheumatology, Transition Clinic; [2]Dept. of Surgery and Translational Medicine, University of Florence; [3]Health Sciences Department, University of Florence, Anna Meyer Children's University Hospital, Florence; [4]Institute of Pediatrics, Università Cattolica Sacro Cuore, University of Rome, Rome, Italy*

**Background:** Kawasaki disease (KD) is an acute multisystemic vasculitis, affecting primarily infants and children, and it is the most common cause of acquired heart disease in Western countries. The exact pathogenesis of KD has not been clearly identified, but infections caused by one or more pathogens are strongly suspected as major cause of the disease. Our previous study demonstrated that KD patients have highly reduced 25(OH)-vitamin D levels in comparison with healthy controls and also with other immunological disorders, suggesting a hypothetical role of vitamin D deficiency in the development of coronary artery damage in KD, and low vitamin D levels might contribute to the severity of chronic vascular abnormalities. Specific polymorphisms of vitamin D receptor (*VDR*) gene have recently been associated with different biologic response to vitamin D itself.

**Objectives:** 1.To analyze the possible associations of these polymorphisms in a series of Italian children affected by KD. 2. To evaluate a possible influence of VDR polymorphism in enhancing the risk of the disease.

**Methods:** We recruited 50 Italian infants and children affected by typical KD (38 males, 12 females), age ranging from 2 through to 62 months.

Genomic DNA was extracted from peripheral blood leukocytes to analyze *VDR* polymorphisms by PCR-based sequencing (*CDX2* in the promoter region) and PCR-based enzymatic digestions (*FokI* in exon 2, *BsmI* and *ApaI* in intron 8, and *TaqI* in exon 9).

An Italian population of 2221 unrelated individuals without KD or other immunological disorders was used as healthy controls. The distribution of polymorphism genotypes and alleles was evaluated in patients vs healthy controls.

**Results:** The distribution of all Cdx2, *FokI, BsmI, ApaI*, and *TaqI* polymorphisms (both as genotypes or alleles) did not show significant differences between affected subjects and healthy controls.

**Conclusions:** In conclusion, this pilot study evidence that *VDR* polymorphisms seem not to have any influence in determining the risk of KD. Anyway, future larger studies are needed to unravel the exact relationship between *VDR* genotype and KD development and/or clinical characteristics.

**Disclosure of Interest:** None declared

## AB0866 CROSS-SECTIONAL EVALUATION OF VITAMIN D LEVELS IN A LARGE COHORT OF PATIENTS WITH PEDIATRIC AUTOIMMUNE NEUROPSYCHIATRIC DISORDERS ASSOCIATED WITH STREPTOCOCCAL INFECTIONS (PANDAS)

F. Falcini[1], G. Lepri[1], S. Stagi[2], E. Casalini[1], M. Matucci Cerinic[1]. *[1]Department of Internal Medicine, Section of Rheumatology, Transition Clinic; [2]Health Sciences Department, University of Florence, Florence, Italy*

**Background:** Vitamin D (vitD) is known for its essential role in calcium homeostasis and bone health. It is now considered as a potent neurosteroid hormone, with a pivotal role on the brain development and normal brain function. VitD ligand-receptor, a receptor that mediates the majority of vitamin D biological actions, has been found throughout the body including the central nervous system (CNS). Vitamin D deficiency is commonly observed in patients with severe mental illness such as schizophrenia. PANDAS is an autoimmune disorder characterized by obsessive-compulsive symptoms and/or tics triggered by group-A beta-hemolytic Streptococcus infections with relapsing/remitting course due to recurrence of infections itself. Despite the action of 25-hydroxyvitamin D [25(OH)D] on immune and CNS system, to our knowledge, no studies have been performed in patients with PANDAS.

**Objectives:** To evaluate 25(OH)D levels in a large cohort of children and adolescents with PANDAS 2. To compare the results with a healthy control group.

**Methods:** We measured plasma 25(OH)D levels in one hundred seventy-nine patients with PANDAS (49 females, 132 males, mean age at diagnosis 101.4 ±30.1 months) and an age, sex, and body mass index-matched control group of 179 subjects.

**Results:** Patients with PANDAS showed a higher percentage of reduced 25(OH)-vitamin D levels ($<$30 ng/mL) in comparison with controls (94.6% *vs.* 82.5%; $p<0.005$). In addition, PANDAS patients have lower levels of 25(OH) D than controls (20.4±6.9 *vs.* 24.8±7.3 ng/mL, $p<0.0001$). This difference has been confirmed also considering the winter (13.7±3.25 vs. 21.4±5.9) and summer (21.8±6.5 *vs.* 32.5±8.7) period. Yet, serum 25(OH)-vitamin D levels correlated with the number of streptococcal infections before the diagnosis ($p<0.005$) and with their recurrences ($p<0.005$).

**Conclusions:** PANDAS patients have reduced 25(OH)D values that seem to be associated with streptococcal infections, and the probability of its recurrences. So, reduced 25(OH)D levels may be a cause significantly important in PANDAS etiopathogenesis. A regular supplementation of VitD in PANDAS patients is recommended as it should improve the course of the disease and prevent or reduce the recurrences of infections and the relapses of neurological symptoms. This hypothesis should be further explored in future studies.

**Disclosure of Interest:** None declared

## AB0867 EXPERIENCE OF ETANERCEPT USE IN TREATMENT OF JUVENILE IDIOPATHIC ATRTRITIS IN CHELYABINSK REGIONAL CHILDREN HOSPITAL

G.A. Glazyrina[1], N.A. Kolyadina[2]. *[1]South Ural Governmental Medical University; [2]Chelyabinsk regional children hospital, Chelaybinsk, Russian Federation*

**Background:** Recently due to application of genetically engineered biologic drugs (GEBD) prognosis for juvenile idiopathic arthritis (JIA) has significantly improved. 558 children with JIA are under monitoring in Chelyabinsk region. If basic therapy with Methotrexane is inefficient Etanercept is the drug of choice for JIA treatment. Etanercept is registered within the Russian Federation for use in children older than 2 years. In Chelyabinsk regional children hospital Etanercept has been used during 5 years.

**Methods:** 23 children aged from 2 to 17 (mean age 9.2 years) diagnosed with JIA were under monitoring (10 boys, 13 girls). Disease duration was from 6 months to 14 years (mean duration 4.5 years). JIA was diagnosed based on ILAR diagnostic criteria. Oligo arthritis was diagnosed in 8 children, sero-negative polyarthritis was diagnosed in 8 children. Five patients had systemic JIA (without active systemic presentations), two children had enthesitic JIA. X-ray stage 1–2 was observed in 22 children and stage 3 in one. Enhancement antigens HLA B 27 were found in 7 children. In all children Methotrexate was ineffective in dose of 15 mg/m$^2$ during 6–12 months. Etanercept was introduced in dose of 0.4 mg s/c biweekly, or 0.8 mg QW. Therapy duration was from 3 months to 5 years (mean duration 17 months). Assessment of disease activity and therapy efficiency was conducted in accordance with ACR pedi criteria. Nonparametric statistical methods were used to compare results.

**Results:** Prior to etanercept use high disease activity was observed in all children. Mean number of joints with active arthritis was 6 [3, 8] (Me [25; 75%]). Mean number of joints with functional impairments – 4 [2, 8]. Mean ESR (according to Panchenkov) – 31 [18.40] mm/h, CRP 19.7 [8.37] g/L. Assessment of functional activity according to CHAQ questionnaire- 1 [0.75; 2]. Activity assessment according to VAS by doctor – 70 [70,80]. Assessment of parents/patients according to VAS 80 [65,90]. No active systemic presentations and eye lesions were found in children under monitoring.

On the background of eternacept therapy a decrease in disease activity was observed in 21 patients. Mean number of joints with active arthritis was 0 [0, 1] (Me [25; 75%]) (P=0.0004). Mean number of joints with functional impairments – 1 [0.2] (P=0.0006). Mean ESR was 4 [3.7] mm/h (P=0.00008), CRP 3 [1; 4.1] g/L (P=0.0001). Assessment of functional activity according to CHAQ questionnaire was 0.25 [0; 0.5] (P=0.0004). Activity assessment according to VAS by doctor – 10 [10, 30] (P=0.0004). Assessment of parents according to VAS 20 [10, 30] (P=0.0004).

Clinical disease remission (according to ACR pedi criteria– $\geq$90%) was observed in 11 patients after 6–12 months of treatment. Remission duration up to now is from 3 months to 4 years. Efficiency according to ACR pedi criteria is 70% in 8 children, 50% in 1, 30% in 2.

The drug was well-tolerated. Drug was cancelled only in 2 patients due to change in disease presentations: one patient developed bilateral uveitis, the other one experienced recurrence with expressed systemic presentations.

**Conclusions:** Etanercept therapy was highly effective and safe in patients with JIA. Clinical remission was achieved in 47.8% children. Decrease in disease activity was observed in 91.3% of children. No serious undesirable effects were reported.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.2726

## AB0868 A DESCRIPTIVE RETROSPECTIVE STUDY OF JUVENILE IDIOPATHIC ARTHRITIS PATIENTS WITH TREATED BIOLOGICAL

H. Moruno-Cruz[1,2], M.L. Romero Bogado[1], P. Pretel Ruiz[1], A. Pérez Gómez[1], D. Clemente Garulo[2], A. Turrión Nieves[1], A. Movasat[1], C. Bohorquez[1], E. Cuende[1], F. Albarrán[1], A. Sánchez[1], J.C. López Robledillo[2], M. Álvarez-Mon[1]. *[1]Immune System Diseases - Rheumatology Service, "Principe de Asturias" Universitary Hospital, Alcalá de Henares; [2]Pediatric Rheumatology Service, "Niño Jesús" Universitary Children's Hospital, Madrid, Spain*

**Background:** Biologic drugs are a mainstay in the treatment of juvenile idiopathic arthritis (JIA). The early use of these drugs allows controlling disease activity avoiding its consequences and improving the quality of life of patients. We know the main characteristics of our cohort of JIA patients treated with biologics.
**Objectives:** To describe the main characteristics of patients and biological treatments received during the last 5 years (2010–2015) in a pediatric unit of a children's hospital.
**Methods:** Retrospective descriptive analytical study of patients diagnosed with JIA (as proposed by ILAR nomenclature) receiving biological treatment from 1 January 2010 to 30 June 2015. Data from medical records collected from patients who biological treatment received. Statistical analysis performed on SPSS.19.0 program.
**Results:** Total 105 patients treated with biological drugs in the last 5 years, 2/3 female (67 girls, 64%), 1/3 male (38 boys, 36%), mean age at diagnosis 5.3 years (DE ±3.95años). The distribution of JIA: Oligoarticular arthritis 40% (42 patients). Polyarticular RF negative arthritis 22.9% (24 patients). Enthesitis-Related arthritis 15.2% (16 patients). Systemic 14.3% (15 patients). Polyarticular RF positive arthritis 3.8% (4 patients). Psoriatic arthritis 3.8% (4 patients).
Patients with positive antinuclear antibodies (ANA) 24.8% (26 of 105 patients).
Of the patients 32.2% (34 patients), i.e. 1/3 had uveitis, of these 41% (14 patients) had positive ANA.
Initial treatment with methotrexate 78.1% (82 patients), methotrexate maintained 56.2 (59 patients), with adalimumab 37.1% (39 patients), etanercept 16.2% (17 patients), tocilizumab 2.9% (3 patients).
Total received 123 biological treatments: adalimumab 49 (39.8%), etanercept 47 (39.2%), tocilizumab 16 (13%), anakinra 8 (3.5%) and canakinumab 3 (2.4%). Overall median time of monitoring 33.3 months (SD ±22.4 months). Continue with the drug 54 (43.9%), decrement regimen 50 (40.7%), replaced by inefficiency 15 (12.2%) (adalimumab 3, etanercept 4, anakinra 3, tocilizumab 5), suspended for toxicity 4 (3.3%) (anakinra 3, adalimumab 1). No deaths recorded.
**Conclusions:** The clinical features in this cohort of JIA patients treated with biologics are similar to those described in other "general series" that do not distinguish the type of treatment.
The biological treatments used most often are etanercept and adalimumab, both with similar percentages (mainly in non-systemic JIA). The most commonly used drugs in systemic JIA are anakinra, tocilizumab and canakinumab.
The biological treatments appear to be safe based on what has been described: few drugs had to be replaced by toxicity, and was not recorded death by the treatment or the disease itself.

## AB0869 THE CONTENT OF ADIPONECTIN IN THE BLOOD OF CHILDREN WITH RHEUMATIC DISEASES

I. Chyzheuskaya[1,2], L. Belyaeva[3], R. Filonovich[1], H. Khrustaleva[2], L. Zajtseva[1], T. Yuraga[4]. *[1]Pediatrics, 4th City Children's Hospital; [2]Pediatrics; [3]Pediartics; [4]biochemical laboratory, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus*

**Background:** The hormone adiponectin is an indispensable component in the regulation of energy homeostasis and maintaining optimal lipid profile. It was found that low levels of adiponectin may be regarded as a predictor of metabolic syndrome. Despite the fact that adiponectin has an effect on energy homeostasis and is an anti-inflammatory agent, its main role is antiatherogenic effect and influence on the lipid profile body.
**Objectives:** to study the contents of adiponectin in the blood of children with rheumatic diseases.
**Methods:** Indicators serum lipid spectrum (total cholesterol, triglycerides, and HDL cholesterol) were studied at a biochemical analyzer. The concentration of adiponectin and serum CRP levels determined by ELISA.
Statistical analysis was performed using the software package Statistica 8.0 ("StatSoft, Inc.", USA).
**Results:** The study involved 54 children with juvenile idiopathic arthritis (JIA), 18 children with systemic lupus erythematosus (SLE) and 24 children with juvenile scleroderma (JS). Most of the children receiving long-term glucocorticoid and immunosuppressive therapy. 28 children with JIA, 9 children with SLE and 11 children with JS were overweight. Obesity is defined in 13 children with JIA, 8 children with SLE and 5 children with JS. When comparing the average concentrations of adiponectin according to the body mass index (BMI) found that with an increase in this index decreased adiponectin content in blood. Adiponectin level was significantly lower in obese children (10,8±4,6 mg/ml) compared with children with overweight (13,2±5,3 mg/ml) and children with normal body weight (16,4±4,1 mg/ml). In healthy children adiponectin content was 21,3±5,7 mg/ml. There was a significant negative correlation of adiponectin with body mass index (r=-0,36), glucose concentrations (r=-0,29), C-reactive protein (r=-0,31), the levels of blood pressure (r=-0.34) and positive to the level of high density lipoprotein (r=0.26).
**Conclusions:** The negative correlation between the level of adiponectin blood concentration of C-reactive protein and a positive correlation with the level of HDL indicates the probable anti-inflammatory properties of adiponectin and its protective effect against the development of atherosclerosis in children with rheumatic diseases.
**Acknowledgement:** This study would not have been possible without the collaboration of numerous Belarusian pediatric rheumatologists, patients and their parents.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5593

## AB0870 LIPID DISORDERS IN CHILDREN WITH RHEUMATIC DISEASES

I. Chyzheuskaya[1,2], L. Belyaeva[2], R. Filonovich[1], H. Khrustaleva[2], L. Zajtseva[1], T. Yuraga[3]. *[1]4th City Children's Hospital; [2]Pediatrics; [3]Biochemical Laboratory, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus*

**Background:** Lipid metabolism disorders is one of the most studied problems in adult patients with rheumatic diseases in the world of rheumatology in connection with proven dyslipidemia in these patients, and raises the question of the genesis of atherosclerosis in the background of autoimmune disease.
**Objectives:** To examine the state of lipid metabolism in children with rheumatic diseases.
**Methods:** The survey included: the collection of family history, anthropometry, instrumental and laboratory examination, including the study of lipid profile (total lipids, total cholesterol, triglycerides, HDL, LDL, apolipoproteins: ApoA, ApoB, ApoE).
**Results:** The study involved 96 children, suffering from rheumatic diseases - 54 children with juvenile idiopathic arthritis (JIA), 18 children with systemic lupus erythematosus (SLE) and 24 children with juvenile scleroderma (JS). Additionally it was examined 50 healthy children. Children with SLE found a significant increase in the content of total lipids, total cholesterol and triglycerides when compared with the control group ($P<0.001$). Children with JIA, there was a significant increase in total lipids and triglycerides ($P<0.001$) when compared with the control group. In children with JS found a significant increase in serum total lipids ($P<0.05$), as well as the reduction of HDL cholesterol ($P<0.05$) when compared with the control group. Increased levels of total lipids in serum>7.0 g/l are set at 61.1% of children with SLE, in 44.4% of patients with JIA and in 62.5% of JS. Elevated triglycerides >1.4 mmol/l were detected in 50% of children with SLE, 20.4% of patients with JIA and 25% of patients with JS. Elevated levels of total cholesterol >5.2 mmol/l is set at 16.7% of children with JIA, and reduced levels of HDL cholesterol <0.96 mmol/l was found in 29.6% of patients with JIA and in 25% of children with JS.
During the correlation analysis established a direct correlation between the level of total cholesterol in blood serum and disease duration ($r_s$=0,71; $P<0.01$), as well as between the degree of disease activity and the content of total lipids ($r_s$=0,63; $P<0$ 01).
Apolipoprotein A is the major protein component of HDL. The significant (P 0.05) decrease in the concentration of ApoA patients clinical groups compared with the control group.
ApoA1 ratio and ApoB is a valuable indicator for assessing the atherogenic shift and the risk of cardiovascular disease. Normally ApoA1/ApoB >1 and is seen as a low atherogenic risk factor. Among children with rheumatic diseases indicator ApoA1/ApoB <1 is set at 16.7% of patients with SLE, in 14.8 patients with JIA and in 12.5% of patients with JS. An inverse correlation between the ratio ApoA1/ApoB and the concentration of serum cholesterol ($r_s$=-0,31; $P<0.01$).
Apolipoprotein E (ApoE) is a part of the fat particles of chylomicrons and very low density lipoproteins, initiating their capture and removal of blood by interacting with specific cell surface receptor on the liver. The study established an elevated level of ApoE in the serum of children with rheumatic diseases compared to the control group. Established correlation ($r_s$=0,37; $P<0.05$) between the content of ApoE and total cholesterol in the blood serum.
**Conclusions:** For children suffering from rheumatic diseases characterized by atherogenic disorders of lipid metabolism.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5820

## AB0871 IMPACT OF FAMILIAL MEDITERRANEAN FEVER, MKD/HIDS, AND TRAPS ON PATIENTS AND FAMILIES, DATA FROM PATIENT INTERVIEWS

J. Hausmann[1], K.G. Lomax[2], A. Shapiro[3], K.L. Durrant[4]. *[1]Boston Children's Hospital and Beth Israel Deaconess Medical Center, Boston, MA; [2]Immunology and Dermatology Medical Affairs, Novartis Pharmaceuticals Corp, East Hanover, NJ; [3]Flince Research, Brooklyn, NY; [4]Autoinflammatory Alliance, San Francisco, CA, United States*

**Background:** Patients with the rare autoinflammatory diseases of Familial

Mediterranean Fever (FMF), mevalonate kinase deficiency (MKD)/Hyperimmunoglobulin D syndrome (HIDS), and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) often have long diagnostic journeys. Patient and family experiences along this path to diagnosis are poorly understood.
**Objectives:** To understand the experiences of patients and families with autoinflammatory diseases through diagnosis and treatment.
**Methods:** We employed 90-minute semi-structured qualitative interviews and 5-day written/video diaries of patients and families with autoinflammatory diseases.
**Results:** Twelve US families participated in the fall of 2015 including 4 TRAPS patients, 5 MKD/HIDS patients, and 5 FMF patients. The patients' ages ranged from 1–28 years. Caregivers reported an insidious onset of symptoms, but were initially reassured by their healthcare providers (HCPs) that symptoms were related to normal childhood illnesses. Most parents in this study (86%) realized that something was seriously wrong only after medical crises and hospitalizations. The diagnostic path began in earnest then, including many specialist visits (often with long waits for appointments), extensive testing, and many misdiagnoses including Lyme disease, meningitis, H1N1 influenza, systemic lupus erythematosus, systemic juvenile idiopathic arthritis, atypical Kawasaki's disease, leukemia, lymphoma, bone cancer, and Crohn's disease. Most parents (92%) lost faith in the medical system's ability to find an answer to their children's symptoms, while they also struggled with unsupportive school officials and dismissive friends and relatives. Parents and patients frequently felt a loss of self-confidence and increasing alienation in the face of criticism and disbelief. Patients and caregivers report holding onto a memory of what normal life was like prior to the onset of symptoms, and mourning their subsequent loss of normalcy. Receiving the diagnosis of an autoinflammatory disease provided vindication and relief, as well as a focus for further education and treatment. Even after diagnosis, patients and caregivers reported continuing confusion about what to expect in the future. Many (64%) reported disease symptoms between flares that were rarely recognized as such by their HCPs. Uncertainties about their diseases led patients and caregivers to seek online support communities, but struggled finding patients whose symptoms mirrored their own.
**Conclusions:** Patients with autoinflammatory diseases often encounter long diagnostic delays, causing significant stress and confusion for the patient and their families. Distrust of the medical establishment may persist even after diagnosis. Loss of normalcy is a core tragedy for many families. Confusion and uncertainty continue to mark these families' lives, even after diagnosis. Initiatives that improve the speed and accuracy of diagnosis, provide more comprehensive patient education, and support patients and their families through their illness have the potential to greatly improve the lives of patients with autoinflammatory diseases.

## AB0872 SWITCHING OF BIOLOGIC TREATMENT IN ONE PAEDIATRIC RHEUMATOLOGY CENTRE. RETROSPECTIVE REVIEW

K. Khawaja, B. Ayyash, M. AlMaini. *Mafraq Rheumatology Allergy and Immunology, Mafraq Hospital, Abu Dhabi, United Arab Emirates*

**Background:** The treatment of children with rheumatic and musculoskeletal diseases (RMD) have changed significantly with biologic treatment.
**Objectives:** To look at reasons for switching from one biologic to another.
**Methods:** Patients with confirmed RMD identified in our centre using The International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM), from 1st January 2011 to 31st December 2015. Retrospective review of electronic records and paper case notes of patients presented to the centre reviewed using pre-specified Clinical Research Form (CRF).
**Results:** We identified 181 paediatric patients on continuous follow up. The distribution as follows; juvenile Idiopathic Arthritis (JIA) 78, Systemic Lupus (JSLE) 19, Juvenile Scleroderma (Scl) 5, vasculitis 7, Juvenile Dermatomyositis (JDM) 6, Familial Mediterranean Fever (FMF) 9, Macrophage Activation Syndrome (MAS) 3 and Uveitis only in 2. Other diagnoses of non-inflammatory nature 52 including juvenile osteoporosis, mechanical pain syndromes and vitamin D deficiency.
The total number of patients on biological therapy is 35 patients including 33 JIA and 2 JSLE. The number of patients still on the same biologic agent is 25.
The following are the biologics with numbers of patients still on the same therapy (25): Etanercept 7 (JIA), Infliximab 3 (JIA), Adalimumab 1 (Uveitis), Abatacept 1 (JIA), Tocilizumab 7 (JIA), Anakina 4 (JIA 3, FMF 1), Rituximab 2 (JSLE).
The number of patients who switched their treatment to a second or third agent is 10. The reason for switching biological treatment was lack of efficacy in 7 out of the 10 patients and side effects in the other 3 patients (table 1). Average follow up on current treatment of 36.6 months (range 0.5 to 81 months).
**Conclusions:** The percentage of patients who switched biological treatment is 28.6% although numbers are small. Reasons for switching biologic treatment in our experience in children with RMD is:
-lack of efficacy with persistent inflammation in 7 out of 10.
-Side effects of treatment in 3 out of the 10 (Uveitis while on etanercept (2) and one developed MAS twice on canakinumab.
**Acknowledgement:** To all the children and their families for allowing us to use their data.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5826

**Abstract AB0872** – Table 1

| Case Number | Diagnosis | 1st biologic | 2nd Biologic | 3rd Biologic | Reason for switching |
|---|---|---|---|---|---|
| 1 | Oligo JIA + Uveitis | Adalimumab | Infliximab | | Persistent eye inflammation |
| 2 | Extended JIA | Etanercept | Tocilizumab | | Persistent joint inflammation |
| 3 | Polyarticular JIA | Adalimumab | Abatacept | | Persistent joint inflammation |
| 4 | Polyarticular JIA | Adalimumab | Tocilizumab | Abatacept | Persistent joint inflammation in 2nd and 3rd |
| 5 | Polyarticular JIA | Etanercept | Adalimumab | | Uveitis with etanercept |
| 6 | Extended Oligo JIA | Abatacept | Tocilizumab | | Persistent inflammation |
| 7 | Systemic JIA | Tocilizumab | Canakinumab | Anakinra | Persistent inflammation with 1st biologic MAS twice on Canakinumab |
| 8 | Enthesitis Related JIA | Etanercept | Adalimumab | | Uveitis on Etanercept |
| 9 | Poly JIA | Adalimumab | Tocilizumab | | Persistent joint inflammation |
| 10 | Systemic JIA | Etanercept | Tocilizumab | | Persistent inflammation |

## AB0873 COMPREHENSIVE MEDICAL AND PSYCHOSOCIAL CARE TO REDUCE THE BURDEN OF CHRONIC RHEUMATIC DISEASES IN CHILDREN: TWO-YEAR EXPERIENCE OF THE FRENCH NETWORK RESRIP

L. Rossi-Semerano[1], P. Dusser[2], C. Hascoët[3], I. Koné-Paut[4]. *[1]Paediatric Rheumatology, National Reference Centre for Auto-inflammatory Diseases; [2]Paediatric Rheumatology; [3]RESRIP (Réseau Rhumatismes Inflammatoires Pédiatriques), Bicêtre Hospital; [4]Paediatric Rheumatology, National Reference Centre for Auto-inflammatory Diseases, Bicêtre Hospital, University Paris Sud, le Kremlin Bicêtre, France*

**Background:** Chronic rheumatic diseases (CRD) in children are associated with significant morbidity and disability, poor quality of life and impact on families. In the region of Paris (France), CRD affect around 2000 children. Management of CRD involves different physicians and health professionals, in a multidisciplinary approach that is particularly valuable in paediatric patients. The RESRIP (Réseau pour les Rhumatismes Inflammatoires Pédiatriques) network has been created to improve coordination between health professionals and personalize patient care for paediatric patients affected by CRD
**Objectives:** To describe demographics, socioeconomic features and diseases characteristics of patients enrolled in the RESRIP network in a 2-year period
**Methods:** Retrospective study involving patients included in the network (September 2013-December 2015). Inclusion criteria were $\geq$2 of the following: disease severity (defined as a disease impacting on $\geq$1 of the following: physical/psychological status, school attendance, growth/development; complexity of treatment); association of $\geq$2 diseases; necessity of $\geq$3 different health professionals; socioeconomic frailty; demand of support expressed by the patient/parents; transition to adult health care; patient followed in a peripheral hospital
**Results:** 147 patients (103F, 44M, median age at disease onset 4.2 y (0.42–15.2) were included. Median time to diagnosis was 4 months (0–134). Median disease duration at enrolment in the network was 14 months (1–172). Main diseases were: juvenile idiopathic arthritis (JIA) (49.7%) (polyarticular 38%, oligoarticular 29%, enthesitis-related arthritis 18%, psoriatic arthritis 11%, systemic arthritis 4%); connective tissue diseases (CTDs) (19%) (overlap-syndrome: 43%, systemic lupus erythematosus: 32%, dermatomyositis 21%, systemic sclerosis 4%) and auto-inflammatory diseases (AIDs) (14.3%) (FMF 52%, Mevalonate Kinase deficiency 4.8%, PFAPA 4.8%, CRMO 28%, other 9.5%). Inclusion criteria were: disease severity (82%), necessity of $\geq$3 different health professionals (80%), demand of support expressed by the patient or the parents (28%), socioeconomic frailty (24%), association of $\geq$2 diseases (20%), patient followed in a peripheral hospital (8%), transition to adult healthcare (7%). Inclusion criteria differed according to the disease: for JIA, it was the necessity of several health professionals (96%), mostly physiotherapists and nurses, while disease severity was the main criterion for CTDs (100%) and for AIDs (72%). For AIDs, the demand of support by patient/parents was a frequent reason for enrolment (53%)
**Conclusions:** RESRIP enrolled mostly patients with JIA, CTDs and AIDs. Disease severity and the necessity of multiple health professionals were the main identified reasons to be followed in the network. These data confirm that CRD patients and their families are in need of support for everyday care. Health networks can provide help by improving care coordination and treatment adherence

## AB0874 JUVENILE IDIOPATHIC ARTHRITIS. FOLLOW-UP IN ADULTHOOD: A DESCRIPTIVE STUDY

L. Expósito Pérez[1], J.J. Bethencourt Baute[1,2], F. Álvarez Reyes[3], M. García González[1], H. Sánchez Pérez[1], S. Bustabad Reyes[1]. *[1]Servicio de Reumatología; [2]Hospital Universitario de Canarias, San Cristóbal de la Laguna; [3]Servicio de Reumatología, Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain*

**Background:** Juvenile Idiopathic Arthritis (JIA) is the most prevalent clinical entity between childhood rheumatic diseases. Treatment and follow-up in adulthood of patients diagnosed with JIA is not well defined, it is therefore important to define the clinical features and complications during adulthood of these patients, and thus achieve better management of the disease.
**Objectives:** To describe the clinical features and complications in adult patients diagnosed with JIA.
**Methods:** Cross-sectional descriptive study where the evolution of 44 patients older than 18 years diagnosed with JIA in current monitoring Services Rheumatology two tertiary hospitals is determined.
**Results:** The current average age of the patients is 31.06 years (18–64); sex: 34 woman,10 men; average age of diagnosis was 9.9 years (1–16); mean duration of disease 21.2 years (4–53). The patient characteritics and their complications are specified in Table 1.
During follow-up the number of relevant infections occurred in 9 patients (20.5%): 4 polyarticular JIA (community-acquired pneumonia, pyelonephritis E. coli, catheter-related sepsis and repeat UTI), 2 in JIA Oligoarticular 2 with systemic JIA and another in psoriatic way; and they have required hospitalization at some point in the evolution of his illness 80% of systemic JIA, 71.4% of polyarticular JIA and 66.6% of oligoarticular JIA. Orthopedic surgery was performed in 14 patients (32%); JIA subtypes with higher number of surgeries were systemic and polyarticular RF positive. The most common surgeries: total knee and hip prosthesis. All patients have been treated with FAME (especially LFN and MTX), except for one patient with psoriatic JIA and 2 ERA B27+. Biological treatment has been used in 23 patients (52.3%): polyarticular JIA (47.6%), systemic onset JIA (100%), oligoarticular JIA (50%), arthritis-entesistis (50%). 25% received a biological; 16% received two biological and 10% three or more biological.
**Conclusions:** Despite the small number of patients in our series, we have determined the following:1)The most frequent form of JIA on follow-up in adulthood is polyarticular (47.7%). 2)93.2% of patients received FAME treatment. 3) More than half of patients (52.3%) received treatment with biologics. 4) Relevant infections occurred in 20.5% of patients, especially in subtype polyarticular JIA. 5)The vast majority of orthopedic surgeries were performed in the pre-biological age. JIA subtypes that needed more systemic way were systemic JIA and polyarticular RF positive, the most common surgeries total hip and knee prosthesis.

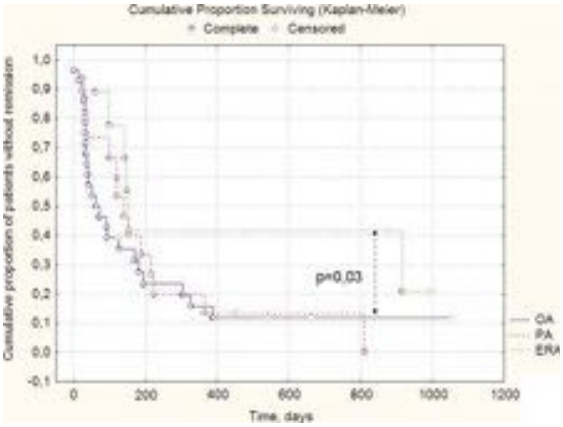
## AB0875 ANALYSIS OF JOINT FUNCTION IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS AGAINST THE BACKGROUND OF STANDARD THERAPY



M.A. Abiodun[1], E.A. Adegoke[1], N. Panko[1], N. Shevchenko[2]. *[1]Department of Pediatrics, V.N. Karazin Kharkov National University; [2]Department of cardiorheumatology, SI "Institute for Children and Adolescents Health Care of NMSA of Ukraine", Kharkov, Ukraine*

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic and socially significant disease as it leads to quick disability in childhood despite treatment
**Objectives:** To study the development of joint dysfunction in patients with JIA against the background of standard therapy with methotrexate
**Methods:** The study involved 83 children within 2–18 years with JIA: oligoarthritis in 39,6%, polyarticular form – 37,7%, systemic form – 20,8%, enthesitis-related arthritis – 1,9%. Changes in the joints were assessed depending on the duration of disease: 1–2 years (25 patients), 3–5 years (23 patients), 5–10 years (35 patients). There were 51 females, 33 males. Criteria of decreased function of joints include: amplitude of motion of hands less then 110°; elbows, knees, ankles and wrists – less then 50°, shoulder and hip joints - less than 70°. For the statistic processing of the material, Stagraphics 3.0 was used.
**Results:** With an increase in the duration of the disease despite standard care, the joint tenderness according to Ritchie index and joint pain according to *Visual Analogue Scale* were decreased, especially after 5 years of illness ($p<0,0\ 5$). The most significant signs of joint determination were limitation of motion and function of articular apparatus. It was found that frequency limited to function of joints among our patients was 77.11%, which was a prerequisite of patients' disability. With an increase in duration of disease, frequency of limited function of joints constantly grew and probably greater in comparison with the initial stages of the disease ($p<0.05$). The most common joints, which lost motion, were knee, radio-wrist, ankle and hip. In stages over three years of course of JIA, limited motion were found in all of the affected joints. Cervical spine lesion was determined in 33.3% of patients typically after 2 years of duration of JIA. In term from one to two years despite treatment in 50% of patients, affection of hip joints were presented. It was determined during the first two years, the changes that correspond to 0 (27,3%) and I stage of the disease by Steinbrocker (72,7%), from 3 year in 45,5% of children II stage was found, from 4th year 15,4% - III, after 6th year 14,7% persons had IV stage. The main stage of deterioration of the radiological changes is the term disease for more than 5 years, when significantly the frequency of the III stage in comparison with the previous period is increased ($p<0,01$) and the IV stage is appeared.
**Conclusions:** It reflected steadily progressive destructive changes of the musculoskeletal system with limited motion of joints function despite therapy with methotrexate and independent of activity of disease and symptom load.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2197

## AB0876 ACHIEVEMENT REMISSION IN DIFFERENT JUVENILE IDIOPATHIC ARTHRITIS CATEGORIES DURING ADALIMUMAB THERAPY: DATA OF RETROSPECTIVE ANALYSIS

M.M. Kostik, M. Dubko, E. Isupova, I. Chikova, E. Gaidar, V. Masalova, L. Snegireva, O. Kalashnikova, V. Chasnyk. *Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation*

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic rheumatic disease with onset before 16 years. According ILAR classification there are several categories based on number of joints, clinical and laboratorial features. Patients with JIA without systemic features who fall or not tolerated to methotrexate (MTX) or sulfasalasine (SSZ) usually treated by biologics, especially TNFα-inhibitors. Currently only 2 TNFα-inhibitors approved in JIA: etanercept and adalimumab (ADA).
**Objectives:** The aim of study was to evaluate the efficacy of ADA in children with JIA without systemic features and ability to induce remission.
**Methods:** In the retrospective observation study were included 53 children (67.9% girls) with active JIA without systemic features, who were resistant to previous therapy with MTX alone (or SSZ in enthesytis-related arthritis) or with combination with other non-biologic DMARDs and were treated with subcutaneous ADA injections every 2 weeks. The onset age was 3.9 (1.7–7.8) years, the interval between onset of JIA and start of ADA was 4.2 (0.3–15.2). Uveitis was detected in 32 (60.3%) patients. According number of active joints and clinical features all patients were divided into 3 groups: oligoarthicular course (OA) – 4 active joints or less, polyarthricular course (PA) – 5 active joints or more and enthesitis-related arthritis (ERA) with any active joints. We evaluated routine clinical and laboratorial test for JIA and ability and time to achieve inactive disease, according to C. Wallace criteria (2004).

**Abstract AB0874** – Table 1

| Subtype of JIA | Number of patients (n=44) | Sex | Time evolution (mean in years) | ANA | Uveitis | MAS | Infections | Ortopedic Surgery | Synovectomy/synoviorthesis |
|---|---|---|---|---|---|---|---|---|---|
| Sistemic-onset | 5 (11.3%) | 3♀: 2♂ | 24.8 | ND | No | 2/5 | 2/5 | 4/5 | No |
| Oligoarticular | 12 (27.3%) | 10♀: 2♂ | 21.7 | 10+/2– | 7/12 | No | 2/12 | 2/12 | 3/12 |
| Poliarticular | 21 (47.7%) | 17♀: 4♂ | 23.9 | 10+/11– | 1 (ANA–) | No | 4/21 | 7/21 | 3/21 |
| FR+ | 9 (42.9%) | | | | | | 3/9 | 4/9 | 2/9 |
| FR– | 12 (57.1%) | | | | | | 1/12 | 3/12 | 1/12 |
| Psoriatic | 2 (4.5%) | 2♀ | 7 | ND | No | No | 1/2 | 1/2 | No |
| ERA B27+ | 4 (9.1%) | 2♀: 2♂ | 14,2 | ND | No | No | No | No | No |

**Results:** Number of active joints (NAJ) and erythrocyte sedimentation rates significantly decreased, while levels of C-reactive protein, WBC, Hb and platelets still unchanged. In 12 months after start of ADA median of NAJ was equal 0. During the trial 44 (84.6%) patients reached the status of inactive disease (ID) according the C. Wallace criteria in median time 122.0 (36.5–220.0). We have not found any significant differences of initial JIA parameters between patients who achieved and not achieved status of ID. We have found differences in JIA groups in achievement ID: patients with OA similar to PA faster and frequently get into remission than patients with ERA (p=0.03, Log-Rank test, OA vs ERA). During the trial 26 (50.0%) have experienced the flare throw the median time 551.0 (317.0–809.0) days after 1st ADA injection. Patients with flare had less NAJ [1.0 (0,0; 2,0) vs 4.0 (1,0; 8,0), p=0.007]. The main predictors of JIA flare during the ADA trial were calculated with Cox-regression models: JIA duration ≥4 years before start of ADA (HR=2.4, p=0.055), presence of concomitant uveitis (HR=4.8, p=0.0008) and discontinuation of MTX (HR=3.2, p=0.19). During the trial 1 SAE was detected: disseminated tuberculosis in patient who received ADA near 3 years (unrecognized family contact).
**Conclusions:** In our study the efficacy of ADA was shown. Further trials required for evaluation long-term outcomes.
**Disclosure of Interest:** None declared

## AB0877 DYNAMICS OF PARAMETERS CHANGES OF ANTIOXIDANT DEFENSE AND LIPID PEROXIDATION IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

N. Panko, I. Khadzhynova, S. Shukrey. *department of pediatrics, V.N. Karazin Kharkov National University, Kharkov, Ukraine*

**Background:** The dependence of intensity of carbonyl stress and its correlation with the pathogenic inflammatory and erosive process of joint tissue were determined in adults with rheumatoid arthritis. These issues in patients with juvenile idiopathic arthritis (JIA) were not studied.
**Objectives:** It was to determine the role of content in the blood of carbonylated proteins (CP), the intensity of induced lipid peroxidation (LPO), the activity of superoxidedismutase (SOD), glutathioneperoxidase (GPO) and the correlations between them and the early immunological markers of the disease, such as anti-cyclic citrullinated peptide antibodies (a-CCP) and *modified* citrullinated *vimentin antibody (a-MCV),* at different stages of the disease development in patients with JIA.
**Methods:** The study included 29 patients with oligoarticular and polyarticular forms of JIA within 2 – 18 years old. 12 healthy children of identical age and gender with the studying patients were present in the control group. For the statistic processing of the material Stagraphics 3.0 was used.
**Results:** Investigated group included 21 female and 8 - male. Patients under 10 years predominated. In children with JIA increase of the intensity of induced LPO in comparison with persons of control group was presented ($p<0.001$) and did not depend on the duration of JIA, number of affected joints and inflammatory activity. Patients with oligoarthritis had higher values of induced LPO than with polyarthritis ($p<0.05$). The level of CB had a significant decrease in patients with JIA in comparison with persons of control group ($p<0.05$). It is presented in the first 6 months of the onset of the disease, mostly by patients with III degree of inflammatory activity. Variations of GPO activity in patients and the children of control group were not different, and did not depend on the form of arthritis, duration of disease, inflammatory activity. Rate of activity of SOD was lower in children with JIA in comparison with persons of control group ($p<0.05$). Among patients with positive a-CCP in comparison with children with positive a-MCV decrease of SOD activity was determined ($p<0.05$). A similar pattern was typical for JIA in the first 6 months of illness, during 6–12 months of pathological process development it was marked increase in SOD activity ($p<0.05$), and the longer history of the disease level of SOD activity was not different in comparison with control group. Level of SOD activity was authentically lower among patients with polyarthritis and with high degree of activity ($p<0.05$).
**Conclusions:** Increasing of level of induced LPO was presented at early stage of JIA, with increasing duration of the disease it was also increased. For the first 6 months of JRA development level of CB in serum was decreased, especially in patients with high (III) degree of disease activity. Decreasing of SOD activity was determined in the first year of the disease's development, mainly in patients with polyarthritis, with II-III degree of inflammatory activity and positive titers of a-CCP. Activity of GPO was not different between patients and persons of control group. Reasonability and methods of correction of above-noted changes of parameters of antioxidant defense and lipid peroxidation in patients with juvenile idiopathic arthritis should be investigated further.
**Disclosure of Interest:** None declared

## AB0878 LIVER CONDITION AND SIGNS OF THE FIBROSIS FORMATION IN SLE IN ADOLESCENTS

L. Bogmat, N. Shevchenko. *department of cardiorheumatology, SI Institute for children and adolescents health care of the NAMS of Ukraine, Kharkiv, Ukraine*

**Background:** The liver damage in SLE usually occurs in 60% of cases. Histological investigation shows plethora, blood stagnation in the vessels, fat infiltration and necrosis in the portal system. The data on the liver pathology in SLE in children and adolescents are quite poor. Clinical and laboratory instrumental signs of the liver damage lack both in diagnostic criteria of SLE and in SLICC/ACR damage index. Together with that, liver is a hidden target organ, the pathological changes in which can be registered at the fibrosis formation stage.
**Objectives:** To determine the liver function tests and determination of the stage of fibrosis in the adolescents with SLE at the onset of disease.
**Methods:** The study involved 48 patients with SLE (mostly female (90,00%). The mean age of the patients was 14,4 years (172,9±4,72 months). The diagnosis was based on SLICC, 2012 criteria. The functional state of liver was examined with a complex of clinical laboratory, biochemical and instrumental methods (objective examination, ultrasound investigation of liver and gallbladder, the levels of bilirubin and its fractions, general cholesterol, the activities of alanine transferase (ALT), aspartate transferase (AST), alkaline phosphatase (AP). De Ritis's coefficient (AST/ALT) and APRI index (Aspartate-aminotransferase-to-Platelet Radio Index) have been estimated.
**Results:** At the onset of SLE an increase in size and an increase in transaminase activity were registered in 11 of 48 patients (22,9%). The SLE onset age in this group was 14,1 years (169,09±5,91 months), the mean SLE duration was 4,63±1,90 months, 54,5% of the patients had subacute onset and 63,6% had an increased activity of pathological process. 81,1% had liver cytolysis manifestations (increase in ALT (115,66±5,42 IU/l), AST (60,6±3,47 IU/l), decrease in De Ritis's coefficient (down to 0,79 with its normal values 1,3–1,4). 37,4% of the patients of this group had De Ritis's coefficient higher than 1,0 (AST prevailing) that is more typical for "cardiac" cytolysis. 63,6% of the patients of this group had De Ritis's coefficient lower than 1,0 (ALT prevailing) that is an evidence of liver changes. Activity of AP and pigment metabolism did not have changes. The level of cholesterol in the serum was decreased in 30,0%. USI data showed an increase in the size of liver in 81,81% of the patients, an increase in parenchyma echogenicity and fading of ultrasound signal in deep layers. AST positively correlated with CRP ($r=0,67$, $p<0,05$), sialic acids ($r=0,66$, $p<0,05$), glycoproteins ($r=0,62$, $p<0,05$); ALT positively correlated with the level of circulating immune complexes ($r=0,81$, $p<0,001$). Tests for fibrosis showed an increased risk of its formation in 27,3% of patients at the onset of SLE, and its reliable probability in 9,1% (APRI index 1,1).
**Conclusions:** Liver is involved in SLE, with high occurrence of liver damage manifested as cytolisis, a decrease in synthetic activity, signs of fibrogenesis activation and the presence of the initial stage of fibrosis in some patients at adolescent age. The degree of changes depends on SLE activity and the presence of cardiac and renal syndromes. The examination of the patients should take into account the markers of functional state of liver, including inflammatory activity and fibrosis formation. A timely discovery of such changes can benefit the therapy able to decrease their progress.
**Disclosure of Interest:** None declared

## AB0879 PHARMACOKINETICS, SAFETY, AND TOLERABILITY OF TOFACITINIB IN PAEDIATRIC PATIENTS FROM TWO TO LESS THAN EIGHTEEN YEARS OF AGE WITH JUVENILE IDIOPATHIC ARTHRITIS

N. Ruperto[1], H.I. Brunner[2], A. Hazra[3], R. Wang[4], C. Mebus[4], C. Alvey[4], M. Lamba[4], S. Krishnaswami[4], U. Conte[5], M. Wang[5], N. Tzaribachev[6], I. Foeldvari[7], G. Horneff[8], D. Kingsbury[9], E. Koskova[10], E. Smolewska[11], R.K. Vehe[12], Z. Zuber[13], A. Martini[1], D. Lovell[2]. *[1]Istituto G. Gaslini, Pediatria II, PRINTO, Genoa, Italy; [2]Pediatric Rheumatology Collaborative Study Group, Cincinnati Children's Hospital Medical Center, Cincinnati; [3]Pfizer Inc, Collegeville; [4]Pfizer Inc, Groton; [5]Pfizer Inc, New York, United States; [6]Pediatric Rheumatology, Bad Bramstedt; [7]Hamburger Zentrum für Kinder- und Jugendrheumatologie, Hamburg; [8]Asklepios Klinik, Sankt Augustin, Germany; [9]Randall Children's Hospital, Portland, United States; [10]Institute of Rheumatic Diseases, Piestany, Slovakia; [11]Department of Pediatric Cardiology and Rheumatology, Medical University of Lodz, Lodz, Poland; [12]University of Minnesota Masonic Children's Hospital, Minneapolis, United States; [13]St Louis Children's Hospital ODS Rheumatology and Neurology, Krakow, Poland*

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).
**Objectives:** Report the pharmacokinetics (PK), safety and taste acceptability of tofacitinib following multiple oral doses in patients (pts) 2-<18 years (yrs) old with active juvenile idiopathic arthritis (JIA).
**Methods:** Data were obtained from an open-label, non-randomised, multicentre, Phase I study (NCT01513902) where JIA pts were given 5 mg adult equivalent (based on body weight) of tofacitinib (tablet or solution) twice daily (BID) for 5 days (Table). There were 3 cohorts (COH) based on pt age, COH1: 12-<18 yrs, COH2: 6-<12 yrs, and COH3: 2-<6 yrs, with a target enrolment per group of ≥8 JIA pts for N=≥24 evaluable pts completing the study. Pts were enrolled in a step-wise approach beginning with the older age COH first. Subsequent younger age COH were enrolled following confirmation of safety and PK from the previous COH. PK parameters of tofacitinib were calculated using non-compartmental analysis of plasma concentration (conc)-time data. Taste acceptability of the solution formulation was listed and categorically summarised (frequency and %).

**Results:** 26 pts (COH1 [N=8], COH2 [N=9] and COH3 [N=9]) were included in this analysis. Pts' age ranged from 2–17 years; all were white race except for one; there were 17 females and 9 males. Baseline disease characteristics were similar across all COH. All exposure metrics including geometric mean (GM) area under the conc-time curves ($AUC_{tau}$), maximum ($C_{max}$), minimum ($C_{min}$) and predose ($C_{trough}$) conc were lower in COH2 relative to those in COH1; however, due to higher doses in COH3 (modified after interim analysis of COH1 and 2), the mean $AUC_{tau}$ in COH3 was comparable to COH1. GM apparent volume of distribution ($V_z$/F) decreased with age (COH1=104.9L, COH2=71.0L, COH3=51.4L). Average terminal half-life ($t_{1/2}$) were COH1=2.62h, COH2=1.95h and COH3=1.77h. GM tofacitinib CL/F were 53%, 39% and 11% higher in COH1, COH2 and COH3 pts, respectively, vs adult RA pts (18.4L/h) receiving tofacitinib 5 mg BID. GM CL/F and V/F parameters were similar between males and females. Tofacitinib, administered over 5 days as multiple dose tablets or solution formulation, was well tolerated and taste for the solution formulation was found acceptable in children with active JIA. No serious adverse events or new safety signals were identified.

| Body Weight (kg) | Tofacitinib Dose BID (mg) | Volume (mL) |
|---|---|---|
| Dosing Scheme for Age 6 to <18 years | | |
| 5-11 | 1 | 1 |
| 12-18 | 1.5 | 1.5 |
| 19-24 | 2 | 2 |
| 25-31 | 2.5 | 2.5 |
| 32-39 | 3 | 3 |
| ≥40 | 5 | 5 |
| Dosing Scheme for Age 2 to <6 years | | |
| 5-6 | 1 | 1 |
| 7-9 | 1.5 | 1.5 |
| 10-12 | 2 | 2 |
| 13-15 | 2.5 | 2.5 |
| 16-19 | 3 | 3 |
| 20-22 | 3.5 | 3.5 |
| 23-26 | 4 | 4 |
| 27-29 | 4.5 | 4.5 |
| ≥30 | 5 | 5 |

BID, twice daily

**Conclusions:** PK results from this study established dosing regimens for pts aged ≥2 years to be used in the upcoming efficacy and safety studies of tofacitinib in JIA pts. Tofacitinib was well tolerated in this study in JIA pts. Overall, pts found the taste of the tofacitinib solution formulation to be acceptable.

## AB0880 MACROPHAGE ACTIVATION SYNDROME – AN INDIAN EXPERIENCE

P.P. Giri[1], P. Pal[2]. *[1]Pediatric Medicine; [2]Pediatric Rheumatology, Institute of Child Health, Kolkata, India*

**Background:** Macrophage activation syndrome is a deadly complication of systemic rheumatic disease namely Systemic Juvenile Idiopathic arthritis (SJIA). But many other rheumatic diseases like SLE and Kawasaki disease (KD) can be complicated by MAS due to immune deregulation and extreme hypercytokinemia. Here we present a series of 24 cases of MAS that we have encountered in last 7 and half years.

**Objectives:** 1.To evaluate the clinical and laboratory characteristics of MAS
2.To assess the treatment responsiveness to different therapies
3. To identify the poor prognostic factors

**Methods:** Children fulfilled the recent 2014 diagnostic criteria of MAS that has been admitted in the time period of July 2008 to November 2015 has been included in the study. The details of clinical features, laboratory results and outcome were noted down.

**Results:** The total number of patient was 24 among them, Systemic JIA was 18, SLE was 5 and rest one had KD as a primary illness. The male: female ratio was 17:7 and the mean age at presentation was:7.9 years. CNS, cardiac and respiratory involvement were present respectively in 78, 52 and 35% of cases. 20 patients needed ICU admission, 10 needed mechanical ventilation. 16 survived and 7 expired with a mortality rate of around 30%. All of them received Pulse Methylprednisolne (30mg/kg) for 5–7 days +/– Intravenous immunoglobulin. 12 needed Cyclosporine.

**Conclusions:** 1. MAS is a deadly complication of pediatric rheumatological diseases with a high mortality rate of 30% in our series.
2. Features of acute liver failure along with CNS and cardiac involvement with extreme hyperferritenemia (ferritin >50,000ng/ml) was associated with bad prognosis.
3. The effectiveness of IV pulse methylprednisolone was only 40%.

## AB0881 ANTI-ADALIMUMAB ANTIBODIES IN JUVENIL IDIOPATHIC ARTHRITIS AND LOSS OF RESPONSE. PRELIMINARY STUDY

S. Masegosa, S. Copete, R. Jimenez, E. Collantes, R. Roldan. *Department of Rheumatology, University Hospital Reina Sofí, Córdoba, Spain*

**Background:** The longterm use of adalimumab (ADL) is limited by the formation of neutralizing antibodies. To the best of our knowledge, immunogenicity in juvenile idiopathic arthritis (JIA) has not been investigates in depth.

**Objectives:** Our main objective was to evaluate the prevalence of adalimumab immunogenicity in JIA and the association of anti-adalimumab antibodies (AAA) with response to treatment. Secondary objectives were to assess the association between AAA and ADL treatment time, and the influence of use of concomitant immunosuppressive therapy in the formation of AAA.

**Methods:** Twenty consecutive patients with JIA treated with ADL >6 month participated in our cross-sectional study. The demographic and clinical characteristics, disease activity and use of methotrexate (MTX) were collected. Until now, were evaluated drugs levels (ELISA) and AAA (Brindgind ELISA) in ten of these patients, before the next injection. Serum samples with ADL concentrations >2mg/L were not analysed for AAA.

**Results:** A total of 10 patients with JIA were recruited, with a mean age of 12.2 years (range 8.15–18.76 yrs), 50% women. 60% of the patients were concomitantly treated with MTX. Altogether, 70% of the patients demonstrated therapeutic drug levels. Of the 10 patients studied, 3 (30%) had AAA coinciding with the relapse of the disease despite treatment. Also, these 3 patients had undetectable levels of drug. Note that 2 patients (66.6%) who have developed AAA and 4 patients (57.14%) who have not developed AAA also received MTX, there were no significant differences. The duration of JIA was 6.6 years (range 2.54–13.04 yrs) and half time ADL treatment was 2.6 years (range 0.95.5.79 yrs). Half time to ADL treatment before AAA development was 3.62 years (range 1.6–5.44 yrs) and in patients who do not develop AAA was 2.19 years (0.95–5.79 yrs), there were no significant differences.

**Conclusions:** - Significant levels of AAA were present in up to 30% of patients with JIA treated with ADL.
- In our patients, the formation of AAA during treatment with ADL is associated with a loss of clinical response.
- In our preliminary study, the development of AAA was not associated with ADL treatment time.
- In principle, not appear to be significant using combination therapy with MTX and the development of antibodies.
- To consider that this is a preliminary study with a sample size too small, so these results should be confirmed once the study is completed.

## AB0882 ACUTE RHEUMATIC FEVER: A EVER PRESENT DISEASE IN THE WESTERN WORLD WITH POSSIBLE INSIDIOUS INVALIDATING HEART INVOLVEMENT

S. Pieropan[1], D. Degani[2], S. Picassi[2], I. Dal Forno[1], F. Caldonazzi[2], G. Piacentini[2], A. Boner[2], D. Biasi[1], S. Adami[1], M.A. Prioli[3]. *[1]Rheumatology; [2]Paediatric unit, Policlinico gb rossi; [3]Cardiology, Ospedale b.go Trento, Verona, Italy*

**Background:** Rheumatic Fever (RF) is a systemic inflammatory disease following pharyngeal infection by goup A beta–hemolytic Streptococcus (GAS).
**Objectives:** to describe the characteristics of rheumatic Fever in a pediatric population of Verona between the 2005–2015.
**Methods:** Clinical presentation of 44 patients with diagnosis of Rheumatic Fever was investigated. Patient age, sex, age at diagnosis as well as Jones criteria fulfilled were reported. The presence/absence of familiarity of Rheumatic Fever, therapy prescibed, pophylaxis' adhesion and primary cardiac involvement with it's evolution after therapy were evaluated.
**Results:**
Incidence of RF in Verona is increasing according to our data Age at diagnosis ranged from 2 to 17 years old (mean age 9-+4 years). Among Jones criteria carditis is most frequently encountered and its severity is not correlated with the values of antistreptolysin o titer (ASO). Heart murmur Was present in 57% of cases at diagnosis. 2 cases had a grade 1 AV blockade and two children underwent pacemaker implantation due to complete not reversibile AV blockade; no case of pericarditis was diagnosed and valvular involment (according to WHF classification) included mitral rigugitation (46,5%), aortic rigurgitation (7%) and bivalvular aortic-mitral rigurgitation (46.5%).
**Conclusions:** RF has not disappeared in the western world; cardiac involvement, which is not correlated with the absolute value of ASO, is the most worrysome clinical condition due to its possible severe sequaela; regular cardiac US and EKG togetherwith thorough physical examination should always be performed in order to identify subclincal cases. While prompt high dose steroids and NSAIDS administration prevent severe evolutions, antibiotics rappresent the main instrument in the primary and secondary prevention of the chronic reumatic Heart disease.Individual susceptabilty is a point of concern for the outbrake of RF as well as the need to identify "rheumatic" streptococci in order to elaborate a specific vaccination.

## AB0883 CRYOPYRINOPATHY DETECTED IN 10 FAMILY MEMBERS OF 4 GENERATIONS: IMPORTANCE OF INTERDISCIPLINARY COLLABORATION

S. Fingerhutova[1], J. Franova[2], L. Prochazkova[3], P. Dolezalova[1]. *[1]Department of Paediatrics and Adolescent Medicine, General University Hospital in Prague, Czech Republic, Prague; [2]Department of Paediatric Rheumatology, University Hospital Brno; [3]Department of Rheumatology, St Ann's Hospital Brno, University Hospital, Brno, Czech Republic*

**Background:** Cryopyrin-associated periodic syndromes (CAPS)are autoinflammatory disorders with autosomal dominant inheritance. Although Muckle-Wells Syndrome (MWS) stands in the middle of theCAPS severity spectrum, it is associated with the high risk of severe late complications that include hearing loss, vision impairment and AA amyloidosis affecting about 26% of individuals. Early diagnosis and appropriate treatment with interleukin-1 (IL-1)blockade may prevent their development
**Objectives:** Analysis of a single paediatric patient trajectory leading to the revelation of multiple members of his family suffering with MWS, description of evolving disease phenotype in patients from different generations. To stress an importance of disease awareness as well as interdisciplinary collaboration in detecting familiar conditions affecting both children and adults.
**Methods:** Multiple-case study.
**Results:** A 3-years old Caucasian boy was referred to the allergologyclinic by his primary care paediatrician for recurrent flares of non-pruritic urticarial rash from about 4 months of age. There were no other symptoms of note. Detailed family history suggested presence of rash in other family members.Working together, paediatric and adult rheumatologist detected additional 9 individuals suffering with variable combinations of fever episodes with rash (all), episodic arthritis, eye inflammation, hearing loss, headache and proteinuria (Graph 1, Table 1). Patient's great grandmother died in 52 years of age from renal failure. Although renal biopsy was not performed at the time, presence of other symptoms as reported by her children made clinical diagnosis of MWS and amyloidosis very likely.
Genetic analysis of exon 3 of NLRP3 gene in affected individuals revealed heterozygous mutation c.1322C>T causing change of amino acids p.Ala441Val and prompted referral to the autoinflammatory disease centre for biologic therapy.

| Patient | Age (yrs) | Onset (yrs) | Fever | Rash | Eyes | Arthritis | Hearing loss | Headache | Proteinuria |
|---|---|---|---|---|---|---|---|---|---|
| 1 | 3 | 0.3 | – | + | – | – | – | – | – |
| 2a | 31 | 2 | + | + | + | + | – | + | – |
| 2b | 31 | 3 | + | + | + | + | – | – | ? |
| 2c | 27 | 7 | + | + | + | + | – | – | – |
| 2d | 24 | ? | + | + | + | + | – | – | – |
| 2e | 21 | 6 | + | + | + | + | – | – | – |
| 3a | 51 | 2 | + | + | + | + | + | + | + |
| 3b | 52 | 4 | + | + | + | + | + | – | + |
| 3c | 43 | ? | – | + | + | – | ? | ? | ? |
| 4a | 52 | ? | ? | + | + | + | + | ? | + |

**Conclusions:** In this family medical care was not primarily seeked by adults who have got used to their long-term and relatively mild symptoms. The diagnostic procedure was initiated by the paediatric referral. Detailed analysis of the symptoms suggests presence of the high risk of severe complications. Hearing loss and/or proteinuria have only been noticed in individuals older than 50 years of age. Importantly, younger members below 30 years have not yet developed any of these symptoms which may now be prevented with long-term biologict herapy. This multi-case report illustrates importance of the high degree of suspicion as well as close collaboration between paediatric and adult specialists in order to establish timely diagnosis and initiate appropriate investigations and treatment.

## AB0884 DIAGNOSTIC VALUE OF PROCALCITONIN FOR DIFFERENTIATION BETWEEN BACTERIAL INFECTION AND NON INFECTIOUS INFLAMMATION IN FEBRILE CHILDREN WITH SYSTEMIC AUTOIMMUNE DISEASE

S. Kumar, S.K. Loganathan. *Pediatric Rheumatology Unit, Department of Pediatrics, Christian Medical College, Vellore, Vellore, India*

**Background:** Systemic autoimmune disease children presents with fever during disease flare and systemic infection. It is very difficult for clinician to decide the diagnosis clinically, acute phase reactants helps in this situation. Hence we decided to determine the diagnostic value of procalcitonin to differentiate bacterial infection and non infectious inflammation.
**Objectives:** To determine the clinical value of procalcitonin (PCT) in differentiating bacterial infection from disease activity in children with systemic autoimmune disease.
**Methods:** This was a cross-sectional study of children with systemic autoimmune disease presented with fever recruited over 9 months. Baseline demographic variables were recorded and measurements of PCT, CRP, ESR and blood cultures were done. The disease activity for SLE was determined by SLEDAI score and for JIA by Wallace criteria. During the study period, 24 children with systemic autoimmune disease were recruited and analysed. Children were divided in 2 groups: Fever due to disease flare and due to infections.
**Results:** Out of 24 children recruited as per inclusion criteria, 16 had SLE (11 in disease flare group and 5 in infection group) and 8 had disease flare of Systemic JIA. 2 children in SLE infection group died. As for infections, serum PCT concentration (cut-off value >1.2 ng/ml) gave a sensitivity of 83% (95% CI 43.6 - 0.97), a specificity of 72% (95% CI 49.1–87.5), a positive predictive value of 50% (95% CI 23.6- 76.3) and a negative predictive value of 93% (95% CI 68.5 - 98.7).To achieve the same sensitivity (as of PCT) of 83%, the cut off value for CRP was 34 mg/dl and ESR was 76 mm/hr. Mean PCT was 92.2 ng/ml in SLE infectious group and 3.50 ng/ml in SLE flare group which was statistically significant (p=0.009). But mean CRP was 98 mg/dl in SLE infectious group and 52 mg/dl in SLE flare group which was not statistically significant (p=0.25). Similarly mean ESR level (38 mm/hr) in SLE infectious group and in SLE flare group (66 mm/hr) was not statistically significant (p=0.35).
**Conclusions:** Our results suggested that the procalcitonin level was the most discriminatory parameter, followed by CRP in children with SLE presenting with fever between disease flare and infection. Procalcitonin levels>1.2 ng/ml in febrile SLE patients should point to bacterial infection, whereas procalcitonin levels less than <1.2 ng/ml might indicate non-infectious inflammation that could reduce unnecessary antibiotic use.

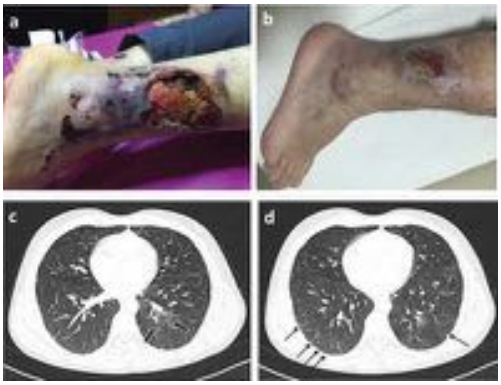
## AB0885 CHILDHOOD-ONSET EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: A RARE CHILDHOOD VASCULITIS MIMICKING ANTHRAX AND EOSINOPHILIC LEUKEMIA



S. Sahin[1], A. Adrovic[1], K. Barut[1], D.E. Toprak[2], T. Celkan[3], O. Kasapcopur[1]. *[1]Department of Pediatric Rheumatology; [2]Department of Pediatrics; [3]Department of Pediatric Hematology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey*

**Background:** Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare small-vessel vasculitis most commonly presents in adults with the average age of diagnosis is being 50 years. After the long-standing prodromal phase (asthma,

allergic rhinitis, nasal polyposis) patients progress to eosinophilic phase which is marked by eosinophilia and pulmonary infiltrates and then to the vasculitic phase (1,2).

**Objectives:** Herein, we present a child in the vasculitic phase of EGPA with a severe skin involvement, who was initially diagnosed and treated for cutaneous anthrax.

**Results:** A 14-year-old male previously misdiagnosed as cutaneous anthrax was referred with a 2-month history of multiple wide and deep ulceronecrotic lesions in lower extremities, started after contact with animals (1a). Complete blood count (CBC) revealed anemia (hemoglobin: 8.5 g/dl, hematocrit: 26.9%), eosinophilia (4100/$mm^3$) and thrombocytopenia (34000/$mm^3$). Peripheral blood smear also revealed marked eosinophilia (42%). Infectious etiologies such as cutaneous anthrax, leishmaniosis, aspergillosis and nonspecific agents were excluded by gram staining, wound-blood-bone marrow cultures and serological investigations. Bone marrow aspiration was performed owing to the prominent eosinophilia, anemia and thrombocytopenia. However, the result was also pointing out eosinophilia without signs of eosinophilic leukemia. Although ANCAs were negative, the robust clinical manifestations concordant with EGPA (e.g. eosinophilia, increased Ig E level, history of asthma, vasculitic lesions) had led us to repeat the skin biopsy and search for lung involvement. Pulmonary high resolution computed tomography (HRCT) demonstrated bilateral ground glass opacity (figure 1c) and millimetric subpleural nodules (figure 1d). Skin biopsy revealed necrotizing inflammation without apparent granulomas and marked eosinophilic infiltrations in the extravascular areas. On the second day of hospitalization he developed deep vein thrombosis (DVT). A diagnosis of EGPA was established and intravenous methylprednisolone with low–molecular weight heparin were administered. Patient showed remarkable improvement of cutaneous lesions and DVT (Figure 1b).

**Conclusions:** Lack of awareness for EGPA among paediatricians as a consequence of limited childhood cases, results with diagnostic delay. Diagnosis of EGPA is challenging in the vasculitic phase and necessitates a detailed history that specifically questions the patient for asthma history. Coexistence of vasculitic lesions and eosinophilia associated with a prior history of asthma should lead to the consideration of EGPA in differential diagnosis.

## AB0886 A QUALITY OF LIFE (QOL) STUDY OF 100 CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) FROM NORTHERN INDIA

M. Agarwal, S. Sawhney, S. Mittal. *Institute of Child Health, Sir Ganga Ram Hospital, New Delhi, India*

**Background:** JIA affects many domains of a child's life. The patient with JIA has a lot to cope with: Physical pain, medicine intake (both parenteral and oral), clinic appointments, phlebotomy, exclusion from school and social activities during disease flares and anxiety about disease.JIA has an impact on the child's physical, mental and psychosocial health. There is a lacuna in the assessment of Pediatric QoL in these children from our country,we thus undertook this study.

**Objectives:** 1) To assess the QoL score of JIA patients using i) Pediatric rheumatology quality of life (PRQL) score [1] and ii) Pediatric quality of life 3.0 rheumatology module(PedsQL) score [2]. 2) To assess the clinical and socioeconomic factors that may impact the QoL. 3) To correlate PRQL and PedsQL

**Methods:** 100 consecutive children with JIA, 2–18 yr,attending Ped rheumatology unit during a 8 week period were evaluated for QoL. PRQL (parent & child version) PedsQL (parent & child version) & CHAQ (Childhood Health Assessment Questionaire) [3] were completed. Entry criteria was JIA patients with at least 6 months of disease.

**Results:** 46 girls & 54 boys with a median age of 11 yrs (2–18 yrs). Median age:6.2 yrs at disease onset,7.62yrs at diagnosis. 28 children had clinically active disease on the day of QoL assessment. Age:2–4 yr:8, 5–7 yr.:18, 8–12 yr.:35 and 13–18 yr.:39.Diagnosis: SOJIA: 31,ERA: 42,PJIA:14,OJIA:13.Socio economic indicators: Mother's literacy status: Unlettered 4,primary schooling 10,High school 12,Senior school 7,Graduates 37,Post graduates 30.Stay at home mothers:85,working 15. 19 children belonged to lower socioeconomic strata. Children with clinically active disease had poorer QoL as compared to clinically inactive group (Mann-Whitney test: $p<0.00$).QoL indicators and CHAQ had no statistical correlation. PRQL and PedsQL were in agreement with each other (Spearman's rho,r=0.72) and both parent and child versions were in concordance.

**Conclusions:** Both PRQL and PedsQL are appropriate tools to assess QOL in JIA. Clinical disease activity status impacts QoL adversely.There was no difference in QoL of children from various socioeconomic strata, nor did the parental education or professional status impact it.

## AB0887 DYNAMICS OF GROWTH IN CHILDREN WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS TREATED WITH TOCILIZUMAB

V. Seraya, E. Zholobova, A. Vitebskaya. *I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** systemic juvenile idiopathic arthritis (sJIA) is an arthritis with systemic manifestations (fever, rash, lymphadenopathy, hepatosplenomegaly) in children up to 16 years. In juvenile arthritis often occur growth disorders. Prior to the widespread use of biologic agents in 10–20% of children with sJIA was noted growth retardation. Currently it is of importance to investigate the influence of biologic agents on growth.

**Objectives:** To evaluate the effect of tocilizumab (TCZ) the growth of children with sJIA.

**Methods:** the study included 25 children with sJIA, all children with high clinical and laboratory activity. All patients received active anti-rheumatic therapy, including therapy with glucocorticoids (GC): all patients (100%) – pulse therapy; oral - 12 children (48%). The age of the onset was 6,2±2,4years (from 9 months to 13,6years). 9 children (36%) before tocilizumab received anti-rheumatic therapy, 5 (20%) children – another biological agent. The duration of such therapy was 2,9±2,9 years (1 month to 12 years), 11 children (44%) began receiving tocilizumab during the year from the onset of the disease. The average age of initiation: 9,4±3,4 years (4 to 14 years old). The study evaluated growth SDS, growth rate and growth rate SDS prior of the therapy with tocilizumab after 6 months, after 1 year and after 2 years of therapy.

**Results:** In 22 children (88%) with sJIA prior TCZ growth SDS was normal: -0,03±1,2 (-1,4 to 2,6). In 3 patients (12%) identified growth retardation: growth SDS from -2,6 to -6,0. These children were transferred tocilizumab via 7,6±3,0 years from the onset of the disease.

After 6 months of TCZ therapy in all children the average rate of growth amounted to 5,0±2,4 cm/yr, growth rate SDS was -0.2±2,4 (from -4,8 to 6,4). After 1 year growth rate was 6,5±3,2cm/yr, growth rate SDS was 2,5±2,8 (6,61 to -2.9). After

**Abstract AB0886** – Table 1. QoL in JIA patients

| Domain | No. of patients | Range | Result |
|---|---|---|---|
| Clinically active disease | 100 | – | 28 |
| MD global score (median IQR) | 100 | 0–100 | 0 (IQR 0–10) |
| Patient global score (median IQR) | 100 | 0–100 | 0 (IQR 0–10) |
| CHAQ (median IQR) | 100 | 0–3 | 0 (IQR 0–0.25) |
| PRQL – Parent (median IQR) | 100 | 0–30 (higher scores indicating poorer QoL) | 0 (IQR 0–3) |
| PRQL – Child (median IQR) | 92 (not assessable in 8 very young children) | 0–30 (higher score indicating poorer QoL) | 0 (IQR 0–2) |
| PedsQL 3.0 Rheumatology module – Parent (median IQR) | 100 | 0–100% (higher scores indicate better QoL) | 98.25 (IQR 86.6–100) |
| PedsQL 3.0 Rheumatology module – Child) (median IQR) | 92 (not assessable in 2–4 years old) | 0–100% (higher scores indicate better QoL) | 100 (IQR 89.7–100) |

2 years of therapy growth rate amounted 6,5±2,5 cm/yr. Growth rate SDS on the 2nd year amounted to 2,8±2,8 (6,4 to -2,1).
In children previously treated with anti-rheumatic therapy and other biological agent, the average rate of growth prior to the TCZ initiation was 4,3±2,3 cm/year, growth rate SDS was -2,3±2,3 (-5,5 to 0,06). After 6 months of TCZ therapy growth rate was 5,9±2,8cm/year, growth rate SDS was 0,9±1,9 (-2,2 to 3,9). After 2 years of therapy growth rate was 6,1±3,1cm/year, growth rate SDS was 2.9±2,7 (from 1,7 to 6,2). Growth rate SDS was significantly higher than the previous one as after 6 months as after 2 years of TCZ therapy.
Growth SDS in all children after 2 years of TCZ therapy was -0,1±1,5 (-4,3 to 2,3). In children with growth retardation growth SDS has improved significantly -2,6 up to -1,7, -3,5 to -3,2, and -6,0 to -4,2 respectively.
**Conclusions:** Treatment with tocilizumab increases growth rate not only in the first year, but in the subsequent period of treatment. Timely therapy sJIA with TCZ prevents growth retardation in children with normal growth and reduces existing growth retardation.

## AB0888 CHILDHOOD ARTHRITIS AS THE FIRST MANIFESTATION OF INFLAMMATORY BOWEL DISEASE

V. Bittermann[1], E. Quesada-Masachs[1], A. Remesal[2], S. Murias[2], C. Modesto[1]. *[1]Pediatric Rheumatology, Hospital Vall d'Hebron, Barcelona; [2]Pediatric Rheumatology, Hospital La Paz, Madrid, Spain*

**Background:** Joint involvement is the most common extraintestinal manifestation in children with inflammatory bowel disease and it may appear years before its diagnosis.
**Objectives:** To describe the characteristics of arthritis associated with inflammatory bowel disease (IBD) in children.
**Methods:** A retrospective, cross sectional, descriptive study was performed including patients of two Pediatric Rheumatology Units from tertiary hospitals with arthritis as the first manifestation of an inflammatory bowel disease.
**Results:** Data for all JIA patients controlled in 2 tertiary centers were analyzed. 14 patients met the inclusion criteria (10 females/4 males). Median age of onset of joint manifestation was 7 years (3–14.3 years). Median age of onset of gastrointestinal symptoms was 17.1 years (8.8–29.8 years). Musculoskeletal manifestations preceded the intestinal manifestations about 12 years (0.3–21.8 years). Most frequent JIA subtype was extended/persistent oligoarticular form (36% of all cases). Polyarticular type of JIA was present in 3 patient, enthesitis related arthritis in 2 patients and undifferentiated JIA in 2 patients. One patient had reactive arthritis. The most common type of IBD was Crohn's disease (60%). The most frequently affected joint was the knee (57%). In 2 patients the initial affected joint was the hip. ANA were positive in 6 children (40%) and 3 had HLA B27 positive (20%). Fecal calprotectin was normal in 10 patients studied. All patients have received systemic corticosteroids and 70% needed articular infiltration. 85% of patients required biological treatment to control the articular symptoms and/or gastrointestinal (mostly adalimumab) associated with DMARDs in a high percentage.
**Conclusions:** It isn't common that the joint involvement precede the digestive symptoms in IBD. In our series the most frequent category was the oligoarticular form with negative ANA and this presented later than usual. They present an evolution with difficult control of the flares. A large number of patients needed biological treatment to control the articular manifestations. These results support the need for new biomarkers that could detect subclinical intestinal disease in children.

## AB0889 TRANSITIONAL CARE UNIT FOR PATIENTS WITH PEDIATRIC-ONSET RHEUMATIC DISEASES: 4 YEARS EXPERIENCE IN A SPANISH TERTIARY HOSPITAL

W.A. Sifuentes Giraldo, C. Sobrino Grande, M. Llop Vilaltella, C. Bouruncle Alaluna, S. Garrote Corral, M. Teran Tinedo, M.L. Gámir Gámir. *Rheumatology, University Hospital Ramon y Cajal, Madrid, Spain*

**Background:** The transition of patients with childhood-onset rheumatic diseases from pediatric to adult rheumatology care providers requires a gradual and effective approachment given the chronic and complex nature of these disorders. The transition units play an important role to facilitate this step. Several models have been proposed to manage this process in a multidisciplinary way, but there is no consensus on which is the best model.
**Objectives:** To describe the epidemiological and clinical characteristics of patients treated in a transition care unit for pediatric-onset rheumatic diseases in a Spanish tertiary center.
**Methods:** We performed a descriptive and retrospective study of patients seen in the transition unit of our center between January 2011 and December 2014. All patients with age range 16–24 years (target population of the unit) were included. Demographics, diagnosis and treatment data were collected through review of their medical records. The consultation of the transition unit is carried out once a week and has a continuous model in which the pediatric rheumatologist is the same responsible of the transition consultation and coordinates the multidisciplinary team, attending patients of our own center as well as other patients referred to the unit.
**Results:** During the period studied a total of 109 patients were attended, the majority of them women (62.4%) with a mean age at beginning of follow-up by the unit of 17 years. The origin of the patients was the pediatric rheumatology consultation of our center in 47%, primary care 13%, the department of Pediatrics of our center 4%, departments of pediatric rheumatology of other centers 4%, other non-pediatric rheumatologists 8% and pediatric orthopedics 5%. The patients came from the area assigned to the hospital in 54%, other areas 32% and other regions in 14%. The most frequent diagnoses were juvenile idiopathic arthritis (JIA) in 32.7%, juvenile systemic lupus erythematosus 13.1%, juvenile dermatomyositis 2.8%, juvenile systemic sclerosis 2.8%, primary Raynaud's phenomenon 5%, Behcet's disease 2.8%, Scheuermann's disease 2.8% and mechanical low back pain 2.8%. The management of the patients required participation of other medical specialties in 53%. At the end period studied 62% of patients were still in follow-up, 22% were discharged, 15% lost follow-up and 1% died. With regard to treatment 43% of patients received DMARDs (methotrexate, sulfasalazine, hydroxychloroquine), 13.7% immunosuppressants (azathioprine, cyclosporine, mycophenolate mofetil, cyclophosphamide) and 21% biologic drugs (anti-TNF 14, tocilizumab 4, rituximab 3, anakinra 3, belimumab 1).
**Conclusions:** The diseases most frequently treated in the transition unit of our center were JIA and systemic autoimmune diseases and more than half of the cases require a multidisciplinary management with involvement of other departments. A high percentage of patients were still active at the end of follow-up by the unity and required treatment with DMARDs and biologic drugs. Due to the characteristics of the population treated at our center, the current operating model of the unit allows the continuity of proper management of these patients.

## AB0890 NEUROPSYCHIATRIC MANIFESTATIONS IN PEDIATRIC-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: EXPERIENCE OF A SPANISH TERTIARY CENTER

W.A. Sifuentes Giraldo, S. Garrote Corral, A.L. Boteanu, M.L. Gámir Gámir, A. Zea Mendoza. *Rheumatology, University Hospital Ramon y Cajal, Madrid, Spain*

**Background:** The neuropsychiatric (NP) manifestations are an important cause of morbidity and mortality in patients with pediatric-onset systemic lupus erythematosus (pSLE). The prevalence of these manifestations ranges from 29% to 44% in different series, but data in the spanish pediatric population are scarce.
**Objectives:** To analyze the clinical and immunological features of patients with pSLE and NP followed in a Spanish tertiary center.
**Methods:** We performed a retrospective study of 49 patients with pSLE diagnosed between 1985 and 2005 in our center. The ACR NPSLE case definitions were used for classification. Demographic, clinical and immunological data were obtained through review of their medical charts.
**Results:** Twenty six patients (53%) developed NP manifestations. Mean age was 13.6 years and female:male ratio was 2.7:1. NP manifestations were present at the beginning of the disease in 7 cases (26.9%) and the mean time to

Table 1. Comparison of clinical and immunological features in patients with and without NPSLE

| | Total | NPSLE | Non-NPSLE | p-value |
|---|---|---|---|---|
| Number of patients | 49 (100%) | 26 (53%) | 23 (47%) | – |
| Females:males | 42:7 | 19:7 | 23:0 | 0.0072* |
| Age at diagnosis (years) | 13.2±3.1 (2–18) | 13.6±3.3 (2–18) | 12.9±2.9 (7–17) | 0.4179 |
| Disease duration (months) | 19.6±10.8 | 18.9±11.8 | 20.2±9.6 | 0.5287 |
| Secondary antiphospholipid syndrome | 8 (16.3%) | 5 (19%) | 2 (8.6%) | 0.0557 |
| ANA $\geq$1/1280 | 10/40 (25%) | 8/21 (38.1%) | 2/19 (48.6%) | 0.0443* |
| Anti-DNA antibodies (IU/mL) | 117.1 | 196.2 | 49.9 | 0.0042* |
| Anti-Ro/SSA antibodies | 14/46 | 10/23 | 4/23 | 0.0545 |
| Antiphospholipid antibodies | 11/40 | 6/20 | 5/20 | 0.7233 |
| Anti-cardiolipin antibodies | 4/40 | 3/20 | 1/20 | 0.2918 |
| Anti-$\beta_2$GPI antibodies | 5/40 | 5/20 | 0/20 | 0.0168* |
| Lupus anticoagulant | 11/39 | 6/20 | 5/19 | 0.7982 |
| Cryoglobulins | 6/18 | 6/12 | 0/6 | 0.0339* |
| ESR (mm/h) | 23.2 | 25.1 | 13.5 | 0.0108* |
| C reactive protein (mg/L) | 3.5 | 5 | 2.6 | 0.2077 |
| C3 (mg/dL) | 66.1 | 54.4 | 75.7 | 0.0042* |
| Low C3 ($<$80 mg/dL) | 32/46 | 20/23 | 12/23 | 0.0104* |
| C4 (mg/dL) | 11.7 | 7.2 | 15.4 | 0.0037* |
| Low C4 ($<$16 mg/dL) | 14/46 | 20/23 | 11/23 | 0.0046* |

develop them was 30.5 months. The most common presentations of NPSLE were seizures (50%), headache (26.9%), mood disorder/depression (26.9%), psychosis (19.2%), cerebrovascular disease (15.3%) and aseptic meningitis (15.3%). There was more than one NP manifestation in 15 cases (57.7%), with an average of 2.4 manifestations/patient. The comparison of patients with and without NPSLE demonstrated significant diffences ($p<0.05$) in the number of males, titers of antinuclear antibodies (ANA) and anti-DNA antibodies, positivity for anti-$\beta_2$-glicoprotein I ($\beta_2$GPI) and cryoglobulins, high erythrosedimentation rate (ESR) and low complement (C3, C4) (Table 1). There were 2 cases of mortality in NPSLE (7.7%) during follow-up period, one as a result of infection of the central nervous system and another due to sepsis associated with intestinal thrombosis.

**Conclusions:** In our series >50% of patients had NPSLE manifestations and frequently occurred early during the course of the disease. The clinical spectrum of NPSLE was wide in our cases and most of them had more than one manifestation. Patients with NPSLE showed a higher disease activity as measured by levels of autoantibodies, increased acute-phase reactants and low complement. Although NPSLE has been associated with antiphospholipid antibodies in other series, specifically anticardiolipin antibodies and lupus anticoagulant, we only found significant association with anti-$\beta_2$GPI antibodies. Mortality in patients with NPSLE was high.

## AB0891 DYNAMICS OF PARAMETERS OF CONNECTIVE TISSUE METABOLISM IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS BY THE FOLLOW-UP STUDY

Y. Zaytseva, I. Lebec. *Department of Cardiorheumatology, SI "Institute for Children and Adolescents Health Care of NMSA", Kharkiv, Ukraine*

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic and socially significant disease as it leads to quick disability in childhood. Metabolic processes of connective tissue are important part of pathogenesis of JIA.

**Objectives:** It was to study dynamics of parameters of connective tissue metabolism in children with JIA against the background of standard therapy with methotrexate by the follow-up study.

**Methods:** The study involved 65 children within 2–18 years with JIA: oligoarthritis in 39,6%, polyarticular form - 37,7%, systemic form - 20,8%, enthesitis-related arthritis – 1,9%. In serum the total level of glucosaminoglycans (GAG) and chondroitinsulfate (CS), level of chondroitin-6-sulfate as I fraction of GAG, level of chondroitin-4-sulfate as II fraction of GAG, level of heparansulfate as III fraction of GAG, calcium, phosphorus and in urine level of oxyproline, uronic acid, calcium, phosphorus were determined. Parameters were assessed depending on the duration of disease: till 1 years (19 patients), 1–2 years (17 patients), 2–3 years (29 patients). They had being evaluated over the following 3 years.

**Results:** 77.78% of patients had decreased level of GAG in the serum. Decrease of I fraction of GAG was determined in 11.11% of patients, of II fraction of GAG -92.59% and III fraction of GAG – 96.3% of patients. Increased level of I fraction of GAG was presented in 48.15% of children. Mean general level of GAG was not difference in comparison with persons of control group and did not depend on duration of disease. Mean level of I and II fractions of GAG in patients with JIA was higher in comparison with persons of control group, beginning from 1st year of diseases development and for next 3 years ($p<0.001$). Mean level of III fraction of GAG was not difference in comparison with persons of control group and did not depend on duration of disease. 51.85% of patients had increased level of CS. Mean level of CS in patients with JIA was higher in comparison with persons of control group, beginning from 1st year of diseases development and for next 3 years ($p<0.001$). 59.26% of children with JIA had increased urinary excretion of oxyproline. The mean levels of oxyproline, uronic acid, phosphorus in urine in patients with JIA were not different in comparison with children of control group and did not depend on duration of disease. The level of serum calcium in the majority of patients (96.3%) was within the limits of norm, in urine – in 74.07% of patients was increased. The average level of calcium in urine was reliably below, than at group of the control ($p <0, 01$), irrespective of duration of disease.

**Conclusions:** Changes in the exchange of connective tissue metabolism are occurred already during the first year of JIA development and presented in subsequent years, despite treatment.

## AB0892 THE FEATURES OF CHRONIC RHEUMATIC HEART DISEASE IN SAINT-PETERSBURG

A.M. Shulman, A.M. Shulman, E.N. Ushakova, T.G. Shemerovskaya, O.V. Inamova. *City Rheumathology Centre, Saint-Petersbug, Russian Federation*

**Background:** Chronic rheumatic heart disease (CRHD) is a pathology characterized by valve anomaly formed after acute rheumatic fever. The adequate management of CRHD is important for prognosis, necessity of surgical intervention, and life quality of patients.

**Objectives:** The purpose of the study was to analyze the patterns of CRHD in adults with different valve anomalies together with the role of tonsillectomy and secondary prevention.

**Methods:** 150 patients (16 males, 134 females) were examined. The age was 19–80. The anamnesis (the age of disease manifestation, number of rheumatic fevers, the age of heart failure manifestation, the period from the disease manifestation to the first symptoms of heart failure, the age of permanent atrial fibrillation manifestation, the period from disease manifestation to permanent atrial fibrillation, cardiac operation, tonsillectomy, bicillin secondary prevention, chorea), examination, ECG, echocardiography was assessed.

**Results:** The period from disease manifestation to the first symptoms of heart failure and the first symptoms outbreak period of heart failure were more in the group of non operated patients ($P<0.01$). There were no differences in functional class (NYHA) between operated and non operated patients ($P=0.06$). The operated patients had higher level of pulmonary hypertension ($P<0.001$). Chorea was observed more often in the group of non operated patients. In the non operated group the age of permanent atrial fibrillation manifestation and the period from disease manifestation to permanent atrial fibrillation was observed more than in operated group ($P<0.01$). The permanent atrial fibrillation was seen more often in operated group ($P<0.001$). Operated patients had more damaged valves ($P<0.001$). There were no differences in age of disease manifestation in operated and non operated groups.

There were no differences between the group which had 1–2 rheumatic fevers and the group that had 3–5 rheumatic fevers in the period from disease manifestation to the first symptoms of heart failure, the age of permanent atrial fibrillation manifestation and the period from disease manifestation to permanent atrial fibrillation and in functional class (NYHA).

The patients with the history of chorea had a smaller number of damaged valves and the longer period from disease manifestation to the first symptoms of heart failure outbreak.

There were also no differences in the group which had secondary prevention in comparison with other patients in the period from disease manifestation to the first symptoms of heart failure outbreak, in functional class (NYHA), the age of permanent atrial fibrillation manifestation and the period from disease manifestation to permanent atrial fibrillation, number of damaged valves.

There were also no differences in patients with tonsillectomy and without it on the same signs.

The age of first symptoms of heart failure was more in the group without secondary prevention.

**Conclusions:** The operation was performed in patients with more severe variant of CRHD. The operated patients have acceptable quality of life in comparison with the other patients. The quantity of rheumatic fevers does not affect the rate of progression and severity of the disease in future. Tonsillectomy and secondary prevention do not affect the rate of progression and severity of CRHD, which requires to be analyzed more.

## AB0893 COMPARISON OF ANTI-INFLAMMATORY EFFECTS OF THE GEL INCLUDED DICLOFENAC SODIUM AND THE MIXTURE OF ZINGIBER OFFICINALE, HYPERRICUM PERFORATUM, EUGENIA CARYOPHYLLATA AND LAURUS NOBILIS OIL IN COLLAGEN-INDUCED ARTHRITIS MODEL IN RATS

Y. Vural[1], Y. Ugan[2], A. Yigit[3], A. Doğru[2], M. Deryal[4], E. Uz[5], H. Vural[5], S.E. Tunc[2]. *[1]Department of Internal Medicine; [2]Department of Internal Medicine, Division of Rheumatology; [3]Department of Medical Genetics, Suleyman Demirel University, Faculty of Medicine; [4]Suleyman Demirel University; [5]Department of Medical Biochemistry, Suleyman Demirel University, Faculty of Medicine, Isparta, Turkey*

**Background:** Phytotherapy is a therapeutic option which aims to prevent and treat diseases with using the herbal preparations prepared by the whole or some parts of plants.

**Objectives:** We aimed to investigate the anti-inflammatory effect of Herbal cream on experimentally induced arthritis model in rats.

**Methods:** 60 Wistar-albino rats were divided into 5 groups as Control, Freund's Complete Adjuvant (FCA), Arthritis, Arthritis + Diclofenac gel, Arthritis + Herbal cream. A single dose of saline 300 $\mu$L for Control group, a single dose of FCA + acetic acid 300 $\mu$L for FCA group, a single dose of collagen Type II + CFA emulsion for other 3 groups injected to induce arthritis intradermally to 5–6 separate sites around the tail. Treatments (diclofenac gel or herbal cream) were given as b.i.d. after day 14, for five consecutive days. Blood samples were collected from all animals at the end of the experiment by cardiac puncture. IL-1$\beta$, IL-6, TNF-$\alpha$, COX-1, COX-2 and hsCRP levels were measured by an ELISA method.

**Results:** HsCRP levels was found significantly elevated in the Arthritis group when compared to Control group ($p<0,0001$). In comparison between Arthritis group and Arthritis + Herbal cream groups, there was no significant differences between them according to the levels of hsCRP.In the model of collagen induced arthritis and FCA groups the levels of IL-6 were significantly higher then Control group ($p<0,0001$). When we compared the Arthritis group to the Arthritis +

Diclofenac group IL-6 level was found significantly lower in the latter ($p<0,0001$). In comparison between Arthritis group and Arthritis + Herbal cream group, significantly lower concentration of IL-6 was found also in Arthritis + Herbal cream group ($p<0,0001$). Despite COX-1 and COX-2 levels were both significantly lower in Arthritis + Diclofenac group, only COX-2 levels were found significantly low in Arthritis + Herbal cream group. However, no significant difference was found between each group in IL-1β and TNF-α levels.
**Conclusions:** In our study, we concluded that topical herbal cream has a weak antiinflammatory efficacy via lovering IL-6 but not hsCRP and this efficacy is formed by COX-2 inhibition. However, designing new studies in the future would be valuable to determine the effective dose and mixture to achieve evident improvement.

## AB0894 THE SIGNIFICANCE OF URINARY BETA-2 MICROGLOBULIN LEVEL FOR DIFFERENTIAL DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER AND ACUTE APPENDICITIS

Y. Ugan[1], H. Korkmaz[2], A. Doğru[1], Y.S. Koca[3], A. Balkarlı[4], F. Aylak[5], S.E. Tunc[1]. *[1]Department of Internal Medicine, Division of Rheumatology, Suleyman Demirel University, Faculty of Medicine, Isparta; [2]Department of Internal Medicine, Division of Endocrinology, Gaziantep University, Faculty of Medicine, Gaziantep; [3]Department of General Surgery, Suleyman Demirel University, Faculty of Medicine, Isparta; [4]Department of Internal Medicine, Division of Rheumatology, Antalya Training and Research Hospital, Antalya; [5]Department of Medical Biochemistry, Suleyman Demirel University, Faculty of Medicine, Isparta, Turkey*

**Background:** The clinical and laboratory parameters widely used are not specific to discriminate the abdominal pain due to FMF attack from that of acute appendicitis.
**Objectives:** The present study aims to investigate the urinary beta-2 microglobulin (U-$\beta_2$M) level as a potential parameter to identify these two diseases mimicking each other.
**Methods:** A total of 51 patients with established FMF diagnosis due to Tel Hashomer criteria on colchicine treatment (1–1.5mg/day), 15 patients with acute appendicitis who had appropriate clinical picture and were also supported pathologically after the surgery, and 20 healthy controls were enrolled in the study. Of the 51 patients with FMF, 25 were at an attack period, while remaining 26 were not. For the diagnosis of acute attack, as well as physical examination, laboratory tests including white blood cell count, C-reactive protein, and erythrocyte sedimentation rate were performed. From urine specimens urinary Beta-2 Microglobulin, microalbumin, and N-acetyl glucosaminidase (U-NAG) were measured.
**Results:** U-$\beta_2$M levels were significantly higher in acute appendicitis group compared to FMF group during attack period, FMF group during attack free period, and control groups ($p<0.001$, $p<0.001$, and $p<0.001$ respectively). U-NAG and microalbuminuria were significantly higher in acute appendicitis, FMF group during attack period, and FMF group during attack free period compared to controls (U-NAG $p<0.001$, $p=0.016$, $p=0.004$, microalbuminuria $p<0.001$, $p<0.001$, $p<0.001$ respectively). Microalbuminuria was significantly higher in acute appendicitis group compared to the FMF group during attack period ($p=0.004$).
**Conclusions:** Determination of U-$\beta_2$M levels may be helpful for differential diagnosis of peritonitis attacks of FMF patients on colchicine treatment, and acute appendicitis. However, this finding should be substantiated with other studies.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2629

## AB0895 EFFECTS OF COLCHICINE ON NEUTROPHIL APOPTOSIS IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

E. Kaya[1], M. Nazıroglu[2], Y. Ugan[3], M. Sahin[3], A. Doğru[3], M. Aykur[4]. *[1]Department of Internal Medicine; [2]Neuroscience Research Center; [3]Department of Internal Medicine, Division of Rheumatology, Suleyman Demirel University, Faculty of Medicine, Isparta; [4]Department of Microbiology, Gaziosmanpasa University Faculty of Medicine, Tokat, Turkey*

**Background:** Familial mediterranean fever (FMF) is an autoinflammatory disease associated with a self-limiting attacks of fever and serositis.
**Objectives:** We aimed to investigate the assessment of apoptosis during acute attack and the effect of colchicine on apoptosis in patients with familial mediterranean fever (FMF).
**Methods:** This study was performed on 7 FMF patients during acute attack period and 7 age-sex matched healthy persons. Caspase 3 and caspase 9 were studied as the markers of apoptosis. Caspase 3–9 were studied again after neutrophils were incubated with colchicine in cell culture.
**Results:** Apoptosis level (0.21±0.009 versus 0.17±0.009, $p<0.05$) and markers of apoptosis (caspase 3 and 9) was significantly higher in FMF group during attack period than the control group ($p<0.001$). After the incubation with colchicine, apoptosis markers were found to provide a significantly decrease in comparison with attack period ($p<0.001$).

Table 1. Apoptosis, caspase 3 and caspase 9 levels in between groups

| Parameters | FMF (n=7) | Control (n=7) | P |
|---|---|---|---|
| Apoptosis | 0.21±0.009 | 0.17±0.009 | <0.05 |
| Caspase 3 | 14.33±0.69 | 8.01±0.18 | <0.001 |
| Caspase 9 | 12.54±1.57 | 6.17±0.83 | <0.001 |
| | FMF (n=7) | FMF + Colchicine (n=7) | P |
| Apoptosis | 0.21±0.009 | 0.15±0.014 | <0.01 |
| Caspase 3 | 14.33±0.69 | 9.16±1.99 | <0.001 |
| Caspase 9 | 12.54±1.57 | 7.11±1.99 | <0.001 |

**Conclusions:** Changing the structure of pyrin after mutation can cause failure in the regulation of inflammation and apoptosis. We suggest that defects in the regulation of apoptosis may play a role in the pathogenesis of FMF. Colchicine may reduces apoptosis as well as other mechanisms of action. More studies are needed to clarify the pathogenetic mechanisms of apoptosis in FMF.

## AB0896 COGAN SYNDROME: DIFFERENTIAL RESPONSE TO BIOLOGIC AGENTS AND ROLE OF PET-CT IN THE INCREASED DIAGNOSIS OF AORTITIS

B. Toz[1], B. Erer[1], S. Kamali[1], I. Tugal-tutkun[2], L. Ocal[1], A. Gul[1]. *[1]Division of Rheumatology Istanbul School of Medicine, Istanbul University; [2]Department of Ophthalmology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey*

**Background:** Cogan syndrome (CS) is a rare inflammatory disorder typically characterized by interstitial keratitis and audiovestibular symptoms. Patients may also develop other inflammatory ocular symptoms, progressive sensorineural hearing loss and systemic manifestations including aortitis, aortic insufficiency, and cerebral vascular manifestations. It has been classified as “variable vessel vasculitis”, and autoantibodies against inner ear and endothelial antigens has been claimed in its pathogenesis. There is no diagnostic test, and classification of patients as CS is still problematic due to variability of clinical findings. Glucocorticoids are the mainstay of CS treatment. Also, azathioprine, methotrexate, and biological agents including TNF and IL-6 inhibitors have been tried in the treatment of CS.
**Objectives:** We herein report the diagnostic and therapeutic findings of eight patients diagnosed with CS or CS-like illness with an aim of characterisation of the spectrum of CS.
**Methods:** We retrospectively reviewed the charts of the eight patients diagnosed with CS or CS-like illness according to their clinical manifestations. All of the clinical findings, laboratory and imaging results and treatment responses were recorded using a standard form. Because of the sample size, no statistical analysis was carried out. Results are summarized as descriptive findings.
**Results:** The mean age of the patients diagnosed with CS was 36 years, and the mean follow-up duration was 5.6 years. Demographic and clinical characteristics of CS patients are summarized in Table 1. Sensorineural hearing loss and intraocular findings were present in all patients. We observed variability in ocular findings, which included typical interstitial keratitis in three, scleritis in four patients, and occlusive retinal vasculopathy in one patient. Although aortitis has rarely been reported previously, diagnostic work-up included PET-CT imaging in three patients, and it revealed positive findings compatible with aortitis. One of our patients needed aortic valve replacement due to severe aortic regurgitation. All patients responded well to high dose corticosteroids initially. Partial or complete remission could be achieved in three patients with a mild disease course with azathioprine or methotrexate. Remaining 5 patients required biologic agents to control inflammatory activity. One patient with polyarthritis responded adalimumab and methotrexate combination. However, no response or even exacerbation of findings were observed with anti-TNF agents in two patients. In four patients, a partial, near-complete, or complete remission could be achieved with IL-1 blockade.

**Conclusions:** Patients with CS comprise a heterogeneous group, which may include some yet undiagnosed hereditary autoinflammatory conditions. Aortic involvement has rarely been reported in CS patients, but PET-CT imaging may help diagnosing asymptomatic patients with inflammatory imaging findings in

aorta. Early and effective treatment may prevent organ damage, and a differential response to IL-1 blocking biologic agents requires further investigation for both understanding its pathogenesis and better management of refractory patients.

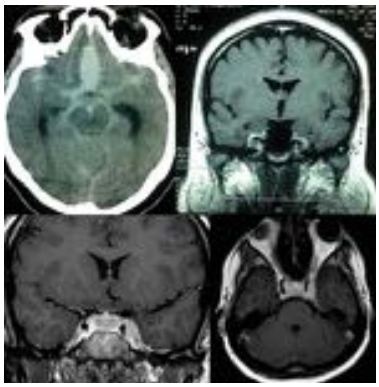
## AB0897 EVALUATION OF CLINICAL FACTORS AFFECTING THE DIAGNOSIS TIME IN FAMILIAL MEDITERRANEAN FEVER



C. Bes[1], N. Alpay Kanıtez[1], S. Yılmaz Öner[1], B. Yılmazer[1], S. Çelik[1], M. Soy[2].
*[1]Rheumatology, Bakırköy Dr Sadi Konuk Training and Research Hospital; [2]Rheumatology, Kemerburgaz University, Istanbul, Turkey*

**Background:** Familial Mediterranean fever (FMF) is the most frequent periodic febrile syndrome among the autoinflammatory disease, characterized by recurrent, self-limiting episodes of fever and serositis. FMF is a common disease in mediterranean countries although the diagnosis may be delayed due to especially patients-related reasons.
**Objectives:** In this study, we aimed to investigate the relationship between the diagnosis time and clinical features in patients with FMF.
**Methods:** Consecutively 44 patients diagnosed with FMF were recruited for this cohort study. The diagnosis time, clinical features, genetic mutations of MEFV genes and disease severity calculated with the Tel-Hashomer Severity Score were recorded retrospectively. The period from disease onset to diagnosis was named as undiagnosed time (UT). Correlation coefficients and significance were calculated by Pearson's test to assess the differences between groups. For all the tests, a two-tailed p value of $<0.05$ was considered statistically significant. Statistical analysis were performed using the software package SPSS 17 running on Windows NT.
**Results:** The mean age was 27.25±5.83 years, (59% female). The mean disease severity score was 6.25±2.06. Patient's clinical features included fever (79.5%), peritonitis (95.4%), arthralgia and/or arthritis (36.6%), pleuritis (13.6%), and erysipelas-like erythema (13.6%). Genetic analysis of 44 patients revealed that M694V was the most frequent mutation (63.6%). The mean UT was found 12.72±7.08 years. Amyloidosis was diagnosed in 3 (6.8%) patients with UT of up to 27 years. There was a negative correlation between UT and disease severity ($p<0.05$).
**Conclusions:** Our study, although a small patient group, suggested that the time from disease onset to diagnosis may still be longer in FMF. Disease severity is seen as an important factor for diagnosis time. Mild attacks or the lack of any symptom in the attack intervals may be reasons for late admission to physician. We have considered that emphasizing of patient education is substantial especially in countries which have high FMF prevalence.

## AB0898 IDIOPATHIC HYPERTROPHIC PACHYMENINGITIS: CLINICO-RADIOLOGICAL FEATURES AND OUTCOME IN MEXICAN PATIENTS

E. Martín Nares[1], V.C. Martínez Mayorquín[2], J.L. Ruiz Sandoval[3], G.D.J. Parra Romero[3], E. Sardá Inman[4]. *[1]Internal Medicine; [2]Ophthalmology; [3]Neurology, Hospital Civil de Guadalajara "Fray Antonio Alcalde", Guadalajara; [4]Head and Neck Radiology, DEI, Diagnóstico Especializado por Imagen, Zapopan, Mexico*

**Background:** Idiopathic hypertrophic pachymeningitis (IHP) is a rare chronic inflammatory disease characterized by fibrous thickening of the cerebral and/or spinal dura matter, with a clinical presentation depending on the topography of the dural thickening. Prevalence of IHP is not known due to its rarity. Case series come mainly from Asian countries and only a handful of case reports from Latin American countries can be found in the literature.
**Objectives:** We aimed to elucidate the clinical, laboratory, and radiological features, treatment and outcome of a cohort of Mexican patients with IHP.
**Methods:** Consecutive patients with the final diagnosis of IHP seen between November 2002 and January 2016 at *Hospital Civil de Guadalajara "Fray Antonio Alcalde",* a tertiary referral center in western Mexico, were included. Known causes of secondary hypertrophic pachymeningitis were ruled out. All patients gave informed consent to be included in this study. We analyzed demographic, clinical, laboratory, neuroimaging and therapeutic data.
**Results:** Five patients were included (1 male and 4 female). Mean age of beginning of symptoms was 32.2 years (range: 13–59); mean age at diagnosis of IHP was 36.8 years (range: 20–63); mean duration of symptoms before diagnosis was 55.4 months (range 2–132). All patients presented with headache and visual complaints. One presented with ataxia and 2 with encephalopathy. Main cranial nerve (CN) affected was CN II (4/5, 80%), followed by CN IV, CN VI and CN VII (3/5, 60% each). Multiple cranial neuropathy was the presentation in 4 patients (4/5, 80%). One patient presented with bilateral proptosis and one patient with the Tolosa-Hunt syndrome. Mean C-reactive protein (CRP) level of 4.05 mg/dl ($N=<0.80$) (range: 0.78–6.63). Mean erythrocyte sedimentation rate (ESR) was 77 mm/hr ($N=<10$) (range: 35–109). Mean CSF cell count was 58 cells/ml (range: 2–169) and mean CSF protein was 98 mg/dl (range: 25–254). Contrast-enhanced brain MRI showed diffuse dural thickening in 4 patients and focal in one; other MRI findings were: cavernous sinus involvement (1), hypophysitis (1), orbital pseudotumor (1), pansinusitis (1), cerebral edema (3), involvement of internal auditory canals and optic canals (1). Biopsy of orbital pseudotumor was performed in one patient showing non-specific chronic inflammation. Corticosteroids were used in 4 patients. Other immunosuppressants were used as corticosteroid-sparing agents, mainly methotrexate (MTX) (4/5 patients). Mean duration of follow-up was 18.4 months (range: 2–38). Mean pre-treatment clinical score was 8.2 (range: 5–10) and mean post-treatment clinical score was 2.6 (range: 0–5).

**Conclusions:** IHP in Mexican patients seem to occur more commonly in female patients and at a younger age compare to other populations. Main symptoms were headache and multiple cranial neuropathies and main CN affected was CN II, consistent with other series. Corticosteroids and MTX were used successfully as first line treatment with an evident decline in the HP clinical score. IHP should be consider in the differential diagnosis of headache associated with visual complaints, even in younger patients.

## AB0899 SERUM LEVELS OF CALPROTECTIN IN ACTIVE NON INFECTIOUS ENDOGENOUS UVEITIS. COMPARISON WITH HEALTHY CONTROLS

E. Valls Pascual[1], E. Vicens Bernabeu[1], J.J. Alegre Sancho[1], I. Martínez Ibáñez[2], D. Acevedo León[2], M.C. Guixeres Esteve[3], L. Martínez-Costa[3], J.A. Román Ivorra[4], C. Vergara Dangond[1], D. Ybáñez García[1], M.À. Martínez Ferrer[1], M. Aguilar Zamora[1]. *[1]Rheumatology; [2]Clinical analysis; [3]Ophthalmology, Hospital Universitari Doctor Peset; [4]Rheumatology, Hospital Universitari i Politècnic la Fe, Valencia, Spain*

**Background:** Calprotectin is a highly immunogenic molecule principally expressed in the cytosol of granulocytes and monocytes. Serum calprotectin levels are increased in different inflammatory conditions such as bacterial infections, inflammatory joint diseases and cystic fibrosis.
It has been suggested that measurement of serum calprotectin levels may be a sensitive indicator of disease activity in patients with endogenous posterior uveitis and that this molecule could play a role in the clearance of inflammatory cells at the late phase of uveitis.
**Objectives:** *Main objective:*To determine serum calprotectin levels in patients with active non infectious endogenous uveitis.
*Secondary objectives:* To compare serum calprotectin levels with those of a control cohort of healthy volunteers.
**Methods:** Study type: transversal study.
Patients: Uveitis cohort: patients with active non infectious endogenous uveitis. Control cohort: healthy volunteers.
Stadistic analysis: Proportions for categorical variables and average ± SD (or median if appropiate) for continuous variables were calculated. Categorical variables were compared by chi-square test (applying continuity correction if necessary). T-test (or Kruskal-Wallis if appropiate) was used to compare averages. Spearman coefficient was calculated in order to stablish correlation between continous and ordinal variables.
**Results:** 22 uveitis patients and 8 healthy volunteers were included.
From 22 patients with uveitis, 14 were diagnosed with anterior uveitis, 1 with intermediate uveitis, 5 with posterior uveitis and 2 with panuveitis. 17 patients had received corticosteriods (topical, systemic or periocular) previously to the serological determination. 9 were diagnosed with another inflammatory disease: spondyloarthritis (4), Crohn's disease (2), pulmonary sarcoidosis (1), psoriasis (1), systemic sclerosis (1).
No statistically significant differences were observed between both cohorts regarding age (p=0.156) and gender (p=0.554).
The median of calprotectin levels was higher in the uveitis cohort than in the control cohort (637.5 vs 396 mg/kg), although the difference didn't reached statistically significance (p=0.174).
No statistically significant differences were found between patients who were diagnosed with another inflammatory disease and those who weren't (p=0.548).

Taking into account anterior uveitis, a moderate-good correlation was observed between Tyndall degree and serum calprotectin levels (Spearman $\rho$=0.627, p=0.016).
**Conclusions:** In our study, serum calprotectin levels were higher in patients with active non infectious endogenous uveitis than in healthy volunteers, although this difference didn't reach statistical significance. A moderate-good correlation was observed between Tyndall degree and serum calprotectin levels.
This work is limited by the small sample size. Results are probably influenced by previous use of corticosteroids in the most part of patients.
**Disclosure of Interest:** None declared

## AB0900 EVOLUTION AND OUTCOMES OF PREGNANCIES IN PATIENTS WITH SYSTEMIC INFLAMMATORY RHEUMATIC DISEASES

E. Vicens Bernabeu, M. Aguilar Zamora, D. Ybáñez García, È. Valls Pascual, C. Vergara Dangond, À. Martínez Ferrer, M. Robustillo Villarino, G. Albert Espí, J.J. Alegre Sancho. *Rheumatology Department, Hospital Universitari Dr. Peset, Valencia, Spain*

**Background:** Rheumatic diseases are prevalent in women of childbearing age who want to have offspring. Hormonal and immunologic changes during pregnancy may influence the course of the inflammatory disease and could carry maternal or fetal complications.
**Objectives:** To describe the characteristics of a cohort of pregnant patients with rheumatic diseases being controlled in a specific consultation of pregnancy.
**Methods:** Descriptive observational study. All patients controlled in this consultation from 2011 to 2015 were included. The following data were collected: age at the conception, diagnosis, treatment during pregnancy, weeks of gestation, type of birth, breastfeeding, complications affecting the mother and the fetus, and autoantibodies profile (antinuclear antibodies (ANA), anti-Ro, anti-La and antiphospholipid antibodies [aPL]). Statistical analysis was done using SPSS 17.0.
**Results:** Twenty-five patients having Rheumatoid Arthritis [RA] (4), Psoriatic arthritis [PsA] (2), Ankylosing spondylitis [AS] (4) (two associated with Crohn's disease [CD]), Palindromic rheumatism (1), chronic oligoarthritis (1), Systemic Lupus Erythematosus [SLE] (6) (2 having antiphospholipid syndrome (APS) and 1 showing anti-Ro and aPL), APS (1), Behcet's disease [BD] (2); Systemic Sclerosis [SSc] (1); Sjögren's Syndrome [SS] (1); Mixed connective tissue disease [MCTD] (1) and psoriasis [Ps] plus ANA, anti-Ro and anti-La antibodies (1) were studied. All the patients were in remission or low disease activity.
The mean age of the patients was 33.32±3.7 years, mean pregnancy duration was 38.5±2.2 weeks and 24% of the patients had two pregnancies during the follow-up period. Thirty-one pregnancies were recorded. 93.6% were term pregnancies (75.9% vaginal delivery, 24.1% caesarean). Two patients had a miscarriage at 8 weeks. Regarding previous abortions, 2 were reported in APS, 2 in BD, 1 in MCTD, 7 in CD-AS and 2 in RA patients. 64.5% of the patients chose breastfeeding. No hypertension, eclampsia, pre-eclampsia or thrombosis were observed as maternal complications. As for fetal complications, intrauterine growth restriction (16.1%) and fetal distress (12.9%) occurred in mothers with anti-Ro antibodies and in one RA patient. A patient having Ps and anti-Ro antibodies reported a case of fetal heart block in their 1st pregnancy, but she had a second pregnancy with no complications. A case of neonatal lupus without cardiac affection was recorded in a SS patient.
No treatment was needed during pregnancy in 22.6% of the patients. Patients having SLE, SS and MCTD had antimalarial drugs (along with salicylic acid and heparin in case of APS). Sulfasalazine and antimalarials were used in patients with inflammatory arthritis. Adalimumab and azathioprine (AZA) were maintained until week 30th in a CD-AS patient. AZA was also used in a BD patient. 25.8% needed low-dose corticosteroids.
**Conclusions:** Our results confirm that optimal treatment of diseases, before conception and during pregnancy, minimize complications during and after pregnancy. Patients having anti-Ro and aPL have higher frequency of complications. Better results can be achieved by means of the creation of specific pregnancy consultations.

## AB0901 THE ROLE OF ALCOHOL RELATED FACIAL FLUSHING RESPONSE ON THE RELATIONSHIP BETWEEN RISK OF HYPERURICEMIA AND ALCOHOL CONSUMPTION

E. Kim. *Health promotion center, Daejeon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, DaeJeon, Korea, Republic Of*

**Background:** Alcohol is known to be associated with the occurrence of hyperuricemia. Facial flushing responses to drinking appears to be due to the intelerance to alcohol. This study assessed the role of the facial flushing response in the relationship between alcohol consumption and hyperuricemia.
**Objectives:** The subjects were 845 Korean adult males (463 non-flushers, 382 flushers) who had undergone a health check-up at an university hospital.
**Methods:** Data were collected from the subjects' medical records. After Adjusted for high density lipoprotein cholesterol, hypertension, diabetes, log-transformed triglyceride, log-transformed estimated glomerular filtration rate, body mass index, a logistic regression analysis was used to calculate the risk of hyperuricemia with drinks per week as compared with non-drinkers of each group.
**Results:** In non-flushing group, the risk of hypeuricemia was significantly increased when non-flushers consumed more than 8 drinks per week (odds ratio [OR], 2.61; 95% confidence interval [CI] 1.05–6.51). In contrast, a higher risk of hyperuricemia was associated with flushers who consumed even <2 drinks (OR, 3.33; 95% CI, 1.01–10.98) per week.
**Conclusions:** These findings suggest that the amount of drinking associated with the risk of hyperuricemia in flushers was lower than in non-flushers.

## AB0902 GENETIC CHARACTERIZATION OF HEREDITARY PERIODIC FEVER SYNDROMES: A RETROSPECTIVE COHORT OF 25 PATIENTS

A. Ruiz [1], E. Rubio [1], I. Porras [2], S. Garcia-Morillo [2], J. Povedano [1]. *[1]Rheumatology; [2]Internal Medicine, Hospital Universitario Virgen del Rocio Sevilla, Sevilla, Spain*

**Background:** This is a descriptive study of the epidemiological, clinical and genetic characteristics of a cohort of adult patients of a health area of 975,000 inhabitants in the south of Spain, diagnosed with hereditary periodic fever syndrome features. We contrast the mutations found in the genetic study of these with previously published data.
**Objectives:** A retrospective analysis of medical records of patients was performed. Sex, age, ethnicity, family history, clinical manifestations, time of evolution, genetic testing, final diagnosis, treatment and therapeutic response: the following information was collected. For the diagnosis of FMF clinical criteria such Hashomer (TH) and Livneh (ACR) was choosen, besides the usual genetic study.
**Methods:**
A total of 25 patients, 13 women and 12 men, of whom 21 had altered marenostrin gene (MEFV) (11 women and 10 men) and 4 TRAPS (2 women and 2 men) were studied.
Regarding the FMF; 8 patients had mutations associated with familial Mediterranean fever (6 women and 2 men); while 13 patients (8 males, 5 females) showed mutations in MEFV protein polymorphisms considered by high high frequency in healthy population.
The mean age at diagnosis was 30 years and 8 patients (38%) debuted with less than 20 years. All patients met clinical criteria.
A total of 25 patients, 13 women and 12 men, of whom 21 had altered marenostrin gene (MEFV) (11 women and 10 men) and 4 TRAPS (2 women and 2 men) were studied.
Regarding the FMF; 8 patients had mutations associated with familial Mediterranean fever (6 women and 2 men); while 13 patients (8 males, 5 females) showed mutations in MEFV protein polymorphisms considered by high high frequency in healthy population.
Two of the patients are ethnic predisposing (an Armenian Jew and a citizen of the Middle East). Genetic testing was performed in all patients. Exons 1 to 10 of MEVF gene (marenostrin) were sequenced. Total 15 patients (71%) of patients had received sometime in the course of the disease treatment with colchicine, with good response in most cases.
In the case of TRAPS, 4 patients (2 men and 2 women) were diagnosed by clinic. The genetic study was performed in all patients. Exons 2, 3 and 4, encoding the extracellular domains of TNF receptor I, being the pR92Q mutation in exon 4 in 3 patients, and pP46L homozygous mutation in exon 3 in the fourth patient were sequenced, who turn pR202Q had homozygous mutation in the gene MEVF.
**Results:** In 8 patients (38%) recurrent mutations (M694V, E148Q and I591T, I640 M), in previous publications associated with FMF found. However, the most frequent mutation was the pR202Q detected in more than half of patients. This mutation is often associated with the pE148, but only 1 of the patients had both. Because of its high prevalence in the population (>1%) is considered a polymorphism.
Regarding TRAPS, both mutations found (pR92Q and p46L) are common, but with low penetrance and a controversial clinical significance, and are thought to TNFRSF1A gene variants, although not directly responsible for the syndrome.
**Conclusions:** Genetic studies in patients with a clinical diagnosis of FMF reveal heterogeneity. This may be due to the existence of genes at present unknown. They are generated by mutating genes similar to that seen in the FMF clinical phenotype, but in some cases, as with mutations pR202Q, pR92Q and p46L are considered polymorphisms.

## AB0903 BEHCET'S DISEASE IN THE MIDWEST REGION OF IRELAND: PATIENT ACCESS AND RESPONSE TO ANTI-TNF BIOLOGICS

F. Adeeb[1,2], W.L. Ng[1], A. Stack[2,3], A.D. Fraser[1,2]. *[1]Rheumatology Department, University Hospital Limerick; [2]Graduate Entry Medical School, University of Limerick; [3]Renal Department, University Hospital Limerick, Limerick, Ireland*

**Background:** Current literature shows promising data for efficacy of anti-tumor necrosis factor (anti-TNF) biological therapy in Behcet's disease (BD) patients.
**Objectives:** The aim was to investigate a cohort of BD patients in Midwest Region of Ireland, current prescription practice for anti TNF biologics in this cohort, patient response & the risk of serious infections or other serious side effects.
**Methods:** All BD patients attending our rheumatology service & satisfying the ISGBD or ICBD criteria were included in the study. Response was evaluated on patient's new/worsening clinical features & improvement/resolution of clinical symptoms. Management was benchmarked against current European League Against Rheumatism (EULAR) guidelines published in 2009. Serious infection was defined as the requirement for intravenous antimicrobial therapy and hospitalization.
**Results:** From a cohort of 22 patients, 18 (81.9%) received anti-TNF (6 males, 12 females) with mean age 38.9 years. 14 patients (77.8%) achieved complete remission & 4 patients (22.2%) achieved low disease activity on anti-TNF. Among this 3 patients (16.7%) were successfully switched to a different agent due to secondary failure, 6 patients (33.3%) needed 3 different anti-TNFs and one patient required a fourth anti-TNF therapy to achieve remission. Indications to start anti-TNF among our cohort include severe mucocutaneous lesions with significant impact to quality of life (15/18), ocular manifestations (7/18), destructive laryngeal disease (5/18), vascular manifestations (3/18) & resistance or intolerance to conventional treatments (8/18). Anti-TNF was extremely effective in suppressing the mucocutaneous oral & laryngeal manifestations, significantly improving patient's quality of life. However resistant genital ulcers was often a difficult symptom to control with 3 patients achieving partial remission.5 allergic reactions were encountered, all with administration of infliximab. 5 serious infections were documented involving 3 patients (16.7%) and all in patients aged 50 years or above. No other serious side effects were noted.

| 22 | F | 24 | + | + | - | + | - | - | - | - | ETA | - | - | - |

**AOU**: Recurrent aphthous oral ulcers; **GU**: Genital ulcers; **OL**: Ocular lesions **CL**: Cutaneous lesions; **PP**: Positive pathergy test; **VI**: vascular involvement; **GI**: GI involvement; **ENT**: ENT manifestations; **B**: Anti-TNF Biologics; **IFX**: Infliximab; **IFX-r**: revital with infliximab **ADA**: Adalimumab; **ETA**: Etanercept; **GOL**: Golimumab; **CER**: Certolizumab

**Conclusions:** Anti TNF-α biological therapy is an important alternative option for first line therapy in severe BD as many conventional treatments failed to maintain clinical remission and prevention of life-threatening complications. Response rates to anti-TNF-α therapy were excellent and treatment was well tolerated but should be used with caution in patients age 50 or above. BD patients who fail one anti TNF-α due to intolerance, ineffectiveness or secondary failure may still benefit from switching to another drug from this group or even re-trial of a previously administered anti-TNF.

## AB0904 PERICARDITIS AS A POSSIBLE PREDICTOR FOR BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS NEED IN ADULT ONSET STILL'S DISEASE

F. Dall'ara[1], M. Frassi[2], A. Tincani[1], P. Airò[2]. *[1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia; [2]Rheumatology and Clinical Immunology, Spedali Civili of Brescia, Brescia, Italy*

**Background:** Adult onset Still's disease (AOSD) is a rare systemic inflammatory disorder of unknown aetiology, which is considered to be similar to systemic-onset juvenile idiopathic arthritis (SOJIA). Peculiar clinical and laboratory features of SOJIA and AOSD led some authors to propose that these diseases should be included among the family of autoinflammatory diseases related to abnormalities in innate immune system. The optimal treatment strategy of AOSD is difficult to determine because of the absence of large-scale prospective studies. Predictive factors of outcome would be useful to draw guidelines for patient management.
**Objectives:** To look for clinical or serological markers able to predict the use of biological disease modifying anti-rheumatic drugs (bDMARDs) in patients with AOSD. To evaluate the efficacy and safety of bDMARDs in AOSD.
**Methods:** In a single-center retrospective study, 42 patients with AOSD were divided into two groups according to whether they were ever treated with bDMARDs (n:20) or not (n:22). Literature was searched for articles dealing with possible predictors of the use of bDMARDs in AOSD.
**Results:** Among 20 AOSD patients who received at least one bDMARDs, the prevalence of pericarditis was higher than in the other patients (8/20 vs 1/22; p:0.008; OR, 14.0, 95% CI 1.56 to 126). Literature search retrieved another paper dealing with predictors of bDMARDs need in AOSD (1): the analysis pooling data from our series and literature confirmed pericarditis at disease onset as a predictor of bDMARDs need (p:0.018; OR, 3.81, 95% CI 1.31 to 11.1). A complete remission was observed in 17 out of 18 evaluable patients treated with bDMARDs, allowing withdrawal or tapering of corticosteroid therapy ($p<0.001$), but, because of inefficacy or adverse events, some patients received more than one bDMARD during the course of the disease, and 33 different trials of bDMARDs were needed.
**Conclusions:** Pericarditis is a possible marker of the auto-inflammatory process that may underlie the pathogenesis of AOSD. Pericarditis at disease onset may be a predictor of bDMARDs need. Biological DMARDs have a good efficacy and safety profile in AOSD, and should be considered for patients not responding to conventional therapy.

## AB0905 THE EXPANDING SPECTRUM OF INFLAMMATORY DISEASES ASSOCIATED WITH MEFV GENE MUTATIONS

F. Cosan[1], Z.A. Cetinkaya[2]. *[1]Department of Internal Medicine, Division of Rheumatology; [2]Department of Internal Medicine, Bahcesehir University, Faculty of Medicine, Istanbul, Turkey*

**Background:** Familial Mediterranean fever is an autoinflammatory disease with recurrent inflammatory attacks. The genetic cause of FMF is the mutations in the MEFV gene coding pyrin, which has role in the activation of inflammasome, acitvation of caspase 1 and production of IL-1B. The impaired function of MEFV gen results increased systemic inflammation. It is shown that MEFV mutations can have effect on some other inflammatory diseases as contributing the disease development or increased inflammation or severe disease duration.
**Objectives:** It is reported several articles about the association between MEFV mutations and different inflammatory diseases. We aimed in this study to analyse the MEFV gene associated diseases with a systematic review.
**Methods:** We searched databases for articles about MEFV gene mutations

Table 1. MEFV gene associated diseases

| Disease | Number of articles | Increased frequency | Disease modulating effect |
|---|---|---|---|
| IBD | 12 | 5 | 4 |
| BD | 11 | 7 | 3 |
| HSP | 8 | 7 | 5 |
| AS | 7 | 5 | 3 |
| PFAPA | 6 | 4 | 4 |
| JIA | 4 | 4 | 2 |
| RA | 3 | 0 | 3 |
| AOSD | 3 | 1 | 0 |
| SLE | 3 | 0 | 3 |
| Ischemic heart disease | 2 | 2 | 1 |
| SNA | 2 | 2 | NA |
| Fibromiyalgia | 2 | 2 | 1 |
| Dismenorrhea | 2 | 1 | NA |
| Hematolymphoid malignancies | MM (2), AML (2), MDS (2), PV (1), ALL (2) | 2 | NA |
| Seizure | 2 | 2 | NA |
| PAN | 1 | 1 | NA |
| ROA | 1 | 1 | NA |
| Chronic renal failure | 1 | 1 | NA |

(MEFVm). We excluded the articles including FMF patients. 92 research articles were included our study which analysed the MEFV gene mutations in inflammatory diseases except FMF.
**Results:** Inflammatory bowel disease (IBD), Behçet's disease (BD), HSP, ankylosing spondylitis (AS), PFAPA, JIA, ischemic heart disease (IHD) were disorders which are associated increased MEFV gene mutation rate and it is shown in these diseases that MEFVm have disease modifying effect. Rheumatoid arthritis and SLE studies have shown no significant difference in MEFVm rates, but MEFVm are related with some clinical findings. The MEFVm carrier frequency was increased in seronegative arthritis, adult onset Still disease (AOSD), fibromiyalgia, dismenorrhea, chronic renal failure, hematolymphoid neoplasms (ALL, MM, MDS, PV). The study design of these disorders doesn't include to investigate the relationship of MEFVm with the disease activity. It was found any association with MEFVm in gouty arthritis, rheumatic heart disease, uveitis,idiopatic pericarditis, tip I Diabetes Mellitus and osteoarthritis. The detailed data is shown in Table-1.
**Conclusions:** MEFV mutations may have effect in the develeopment of inflammatory diseases and may modify the clinical findings. This modifying effect may be important especially in countries with high MEFVm mutation carrier rate.
**Disclosure of Interest:** None declared

## AB0906 ANTI-INTERLEUKIN-1 THERAPY IN FAMILIAL MEDITERRANEAN FEVER AMYLOIDOSIS: A SINGLE CENTER EXPERIENCE

H. Ozdogan, S. Ugurlu, A. Hacioglu, B. Ergezen. *Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

**Background:** Recently there is increasing number of reports pointing out the efficacy of anti-interleukin 1 (anti-IL1) therapy to control AA amyloidosis secondary to autoinflammatory diseases.
**Objectives:** Here we report our experience in IL-1 blockade in patients with AA amyloidosis secondary to Familial Mediterranean fever (FMF)
**Methods:** Eighteen FMF patients with histologically proven secondary AA amyloidosis treated with anti-IL1 agents (canacinumab and anakinra). Creatinine, creatine clearance, 24-hour urine protein, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) parameters were measured before and throughout the treatment period in order to evaluate the response. Patients were closely monitored and adverse events were also reported.
**Results:** Eighteen (8 female, 10 male) patients with AA amyloidosis secondary to FMF who were also on colchicine (mean dose: 1.4±0.7 mg/day) were started on anti-IL1 agents (8 on canakinumab, 13 on anakinra, 3 on both). The mean age was 41.9±11.4 years, while the mean duration of FMF was 21.5±8.9 years. The mean follow-up period on anti-IL1 was 16.5±11.7 months (10.9±7.3 months on anakinra; 18.8±10.7 months on canakinumab).
Ten patients are still on anti-IL-1 therapy (7 on anakinra, 3 on canakinumab). Renal functions remained stable after therapy for 5 out of 10 patients (creatinine from 1.2±0.6 mg/dl to 1.1±0.6 mg/dl; creatine clearance from 82.3±49.5 ml/min to 87.7±53.2 ml/min; 24-hour urine protein from 1094.2±995.4 mg/dl to 885.0±725.0 mg/dl), while CRP (from 15.7±9.5 mg/L to 1.3±0.9 mg/L) and ESR (from 41.8±15.5 mm/h to 15.5±3.7 mm/h) decreased. Renal functions and acute phase reactants improved with therapy (creatinine from 0.7±0.7 mg/dl to 0.7±0.7 mg/dl; creatine clearance from 81.9±79.4 ml/min to 93.3±65.9 ml/min; 24-hour urine protein from 6963.9±7514.0 mg/dl to 304.8±81.5 mg/dl; CRP from 29.6±18.1 mg/L to 28.0±46.8 mg/L; ESR from 63.8±45.7 mm/h to 32.3±44.7 mm/h) for four patients. Renal functions deteriorated after anakinra and it was switched to other biological agents for the remaining patient. However since he progressed to end stage renal disease and started hemodialysis, anakinra was re-introduced to take control over attacks. Global patient assessment score of the whole group decreased significantly (from 8.6±1.6 to 1.2±1.8) with IL-1 blockade.
Anti-IL-1 therapy was discontinued in 8 patients, 3 of them were on anakinra (due to unresponsiveness in 2 and allergic reaction in 1), 5 were on canakinumab (due to increase in proteinuria during the course of treatment in 3, lichen plans in 1 and one was lost to follow up although showed improvement during the follow-up period, then the treatment was terminated since he developed lung adenocarcinoma). Anakinra was switched to canakinumab due to allergic reaction in one and unresponsiveness in two patients
**Conclusions:** Anti-IL1 therapy can improve renal functions and stabilize patients with AA amyloidosis secondary to FMF. The efficacy and safety of anti-IL1 therapy in this group of patients are needed to be verified by further researched.
**Disclosure of Interest:** None declared

## AB0907 NECK PAIN MAKES NO ODDS ON CERVICAL ALIGNMENT IN PATIENTS WITH TEMPOROMANDIBULAR DISORDERS

I. Coskun Benlidayi[1], R. Guzel[1], U. Tatli[2], F. Salimov[2], O. Keceli[2]. *[1]Department of Physical Medicine and Rehabilitation, Cukurova University Faculty of Medicine; [2]Department of Maxillofacial Surgery, Cukurova University Faculty of Dentistry, Adana, Turkey*

**Background:** Despite the extensive research on the possible link between cervical posture and temporomandibular disorders (TMDs), it still remains as a highly controversial issue. The inconclusive results derived from the previous studies, might be in part due to the ignorance of neck pain, which usually accompanies TMDs.
**Objectives:** In the present study, we aimed to elucidate the impact of neck pain-if any-on cervical alignment in patients with TMDs.
**Methods:** °Patients diagnosed with TMDs according to the research diagnostic criteria for TMDs (RDC/TMD) between November 2013-November 2015 were included in the study. All subjects underwent lateral cervical x-ray evaluation and were asked to complete the RDC/TMD Axis II Biobehavioral Questionnaire for TMDs. Pain, disability and depression scores for TMD were calculated. Computerized measurement of the cervical lordosis angle was performed according to the C2-C7 cobb method. Additionally, disability score for neck pain was measured through Neck Disability Index (NDI) in patients with concomitant neck pain. The study sample was divided into two groups according to the presence of neck pain and a comparative analysis for cervical lordosis angle was carried out between groups. The relation of cervical malalignment with neck disability, TMD-associated pain, depression and disability was evaluated via Pearson's correlation analysis.
**Results:** The study sample was consisted of 60 patients with a mean age of 31.2±10.8 years. The mean value for cervical lordosis angle in the whole group was 10.9±12.7°, which was consistent with hypolordosis. Cervical lordosis angle did not differ between patients with (n=28) and without (n=32) neck pain (12.2±12.8° versus 9.8±12.7°, respectively; p=0.46). Cervical alignment was correlated with neither neck disability nor TMD-related variables including pain intensity, depression and disability.
**Conclusions:** Patients with TMDs have hypolordotic cervical malalignment regardless of neck pain. The presence of neck pain makes no odds on patients' cervical alignment.
**Disclosure of Interest:** None declared

## AB0908 A NOVEL MUTATION IN PROTEOGLYCAN-4 UNDERLIES CAMPTODACTYLY-ARTHROPATHY-COXA-VARA-PERICARDITIS SYNDROME IN A CHINESE FAMILY

Q. Jun, Z. Hu, Q. Li, P. Zhang, Q. Lv, Z. Lin, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** Camptodactyly-arthropathy-coxa-vara-pericarditis (CACP) syndrome is an autosomal recessive condition characterized by the association of congenital or early onset camptodactyly and noninflammatory arthropathy, it can also affect the pericardium. CACP syndrome is caused by mutations in proteoglycan 4 (PRG4), a chondroitin sulfate proteoglycan that acts as a lubricant for the cartilage surface. Several cases were described in the literature from ethnically different populations including Caucasian, Egyptian, Saudi Arabian, Pakistani, Indian and Korean.
**Objectives:** We undertook this study to genetically screen a Chinese family segregating CACP in an autosomal recessive manner.
**Methods:** To screen for mutation in PRG4 gene, all coding exons and exon-intron junctions were sequenced using ABI prism 3730 automated DNA sequencer.
**Results:** Sequence analysis of PRG4 gene in affected individual of the family presented here revealed one base insertion (exon 9, c.3755_3756insT) predicting a frame shift mutation (p.Lys1253fs*1). Sequencing of PRG4 exon 9 in the parents showed that the father was a heterozygous carrier of the c.3755_3756insT mutation, but the mother did not have this alteration. To our knowledge, this is probably the first mutation identified in PRG4 gene in Chinese population.
**Conclusions:** We described a novel insertion mutation in PRG4 gene in a Chinese family with CACP.

## AB0909 EFFECTS OF COMBINED THERAPY WITH PREDNISONE AND METHOTREXATE ON B CELL SUBPOPULATIONS IN PATIENTS WITH IGG4-RELATED DISEASE

M. Lanzillotta[1], R. Milani[2], C. Campochiaro[1], E. Bozzalla[1], A. Berti[1], M.G. Sabbadini[1], E. Della Torre[1]. *[1]Unit of Internal Medicine and Clinical Immunology; [2]Unit of Immunohematology, San Raffaele Scientific Institute, Milan, Italy*

**Background:** IgG4-Related Disease (IgG4-RD) is a systemic fibro-inflammatory condition characterized by oligoclonal expansion of IgG4+ class-switched plasmablasts (PBs) (1). PBs swiftly decline together with clinical improvement after rituximab, suggesting a role for B cells in the pathogenesis of IgG4-RD (2). Studies with alternative effective non B-cell depleting therapies (3) are needed in order to confirm the pathogenic importance of PBs and their utility as disease biomarkers.
**Objectives:** To assess the impact of combined therapy with prednisone (PDN) and methotrexate (MTX) on B cell subpopulations in patients with IgG4-RD.
**Methods:** Five patients with active biopsy proven IgG4-RD were treated with PDN (0.6–1 mg/kg) and MTX (10–20 mg per week). PDN was gradually tapered and withdrawn in 6 months. Disease activity, partial (PR) and complete response (CR) were assessed through the IgG4-RD Responder Index (IgG4-RD RI) (4). Serological, immunological and radiological studies were performed according to the clinical presentation. Flow cytometry was used to measure PBs (CD19+CD20-CD27+CD38+bright cells), naïve (CD19+CD20+CD27-CD38+ cells), and memory (CD19+CD20+CD27+CD38- cells) B cells at baseline, after 3 and 6 months of therapy. Nine age and sex matched subjects were used as healthy controls (HC).
**Results:** At disease onset, the median IgG4-RD RI was 9 (normal $<3$). The median serum IgG4 level was 534 mg/dl (normal $<135$mg/dL). Circulating PBs were increased (median 7000 cells/mL) compared to HC (median 605 cells/mL; $p<0.004$). PBs showed a positive correlation with the number of organs involved ($r=0.77$), with serum IgG4 level ($r=0.87$), and with disease activity ($r=0.73$). The number of circulating memory B cells was comparable between IgG4-RD patients and HC ($p=0.57$). Naïve B cells were significantly lower in IgG4-RD patients compared to HC ($p<0.05$). After 6 months of therapy 4 patients achieved CR (IgG4-RD RI $<3$) and 1 PR. Serum IgG4 level decreased in all patients but normalized only in one patient at 6 months. Circulating PBs declined to levels comparable to HC (median 230 cells/mL, $p=0.3$). Memory B cells were unaffected by the therapy, while naïve B cells showed a declining trend, yet not statistically significant compared to baseline levels ($p>0.05$)
**Conclusions:** PBs and naïve B cells are expanded and reduced, respectively, in patients with active IgG4-RD compared to HC. Combined therapy with PDN and MTX leads to clinical improvement and to normalization of circulating PBs. Naïve B cells slightly decrease, while memory B cells are not affected by immunosuppressive treatment

## AB0910 INVESTIGATION OF THE ARTERIAL STIFFNESS AND RELATED FACTORS IN PATIENTS WITH ACROCYANOSIS

M. Cakar[1], M. Cinar[2], S. Yilmaz[2]. *[1]Gulhane Military Medical Academy, School of Medicine, Ankara, Turkey; [2]Division of Rheumatology, Gulhane Military Medical Academy, School of Medicine, Ankara, Turkey*

**Background:** Acrocyanosis is a disorder of the peripheral circulation and often arises due to cold, and describes the situation with diffuse blue-purplish discoloration of the hands and feet. Although its etiology is unknown, infections, malignancies, hematological disorders, neurological, psychiatric, autoimmune and metabolic status have all been suggested to contribute. It is more frequent in women and usually starts during the third decade. Unless there is another underlying disease, there is no data regarding whether these patients have increased risk of mortality and morbidity or not, compared to a healthy people. Arterial stiffness measurements have long-term high predictive value, accessibility, cost-effectiveness and repeatability for representing cardiovascular risk.
**Objectives:** To investigate long-term cardiovascular risk, determine factors that may play a role in the etiology and measure arterial stiffness in patients with acrocyanosis.
**Methods:** The study included 23 consecutive patients who were diagnosed as acrocyanosis and agreed to participate in the study (F/M: 1/22) and 17 healthy controls (F/M: 1/16) were included. Tensiomed Arteriograph device used for measuring arterial stiffness of the cases. T he demographic and clinical features, blood counts and routine laboratory tests were recorded and their relationships with arterial stiffness measurements were investigated. Correlation and regression analysis were used for the evaluation of the data.
**Results:** The mean age of the patient and control groups were similar (22.83±4.7 and 25.0±0.5 years, respectively, $p=0.066$). The average body mass indexes of the patient and control groups were also similar (21.6±2.6 and 22.7±1.3 kg/m 2). The average pulse wave velocity measurements were lower in acrocyanosis patients compared to controls, but the difference did not reach statistical significance (6.87 ±1.11 and 7.15±1.37 m/s, $p=0.508$). Pulse wave velocity measurements were associated with erythrocyte sedimentation rate ($r=0.551$, $p=0.012$). Ankle-brachial index (ABI) was associated with serum glucose levels ($r=0.896$, $p<0.001$). Serum calcium levels were associated with aortic and brachial augmentation indexes ($r=0.477$ and 0.474; $p=0.045$ and 0.047, respectively). Patient and control groups had similar aortic and brachial augmentation indexes, and there was no significant difference between the groups in terms of central aortic pressures.
**Conclusions:** According to our study, arterial stiffness indexes representing cardiovascular risk were similar in patients with acrocyanosis compared to healthy population of the same age. However, the lower average pulse wave velocity measurements in acrocyanosis, need to be further investigated in a larger group.

## AB0911 SARCOPENIA ASSESSMENT IN CHRONIC KIDNEY DISEASE PATIENTS

N.O. El-Azizi, H.M. Farouk, M.A. Abdel-Rahman, S.A. Shalaby. *Internal Medicine & Rheumatology, Facilty of Medicine- Ain Shams University, Cairo, Egypt*

**Background:** Sarcopenia is a syndrome characterized by progressive and generalized loss of skeletal muscle mass and strength with a risk of adverse outcomes such as physical disability, poor quality of life and death. Uremic sarcopenia causes a high morbidity and mortality and consequently a high priority for muscle wasting prevention and treatment in these patients.
**Objectives:** To assess sarcopenia (muscle state and power) in CKD patients with & without hemodialysis.
**Methods:** In this study there were three studied groups: Group I: 20 CKD patients on regular hemodialysis. Group II: 20 CKD patients on conservative treatment. Group III: 20 normal persons. After informed consent all patients recruited from dialysis unit, inpatient and outpatient clinics of Internal Medicine Department at Ain Shams University Hospital. Diabetic, patients with hemoglobin $\leq$10 g/dl, aged $\geq$50 years or have chronic diseases that may cause secondary sarcopenia had been excluded from the study. All subjected to full medical history and clinical examination. The muscle power assessed using the hand grip dynamometer[1], physical performance through using 4 Meter Walk Gait Speed Test[2]. CBC, serum creatinine, BUN, serum electrolytes & PTH. Dual-energy X-ray absorptiometry (DEXA)[3] was used to assess bone loss and total body mass loss (lean mass, fat mass, BMD). Assessment of nutritional status by using subjective global assessment (SGA) score[4].
**Results:** There is high significant positive correlation between age and 4 meter walk test. Group I & II had a higher mean time of 4 meter walk test & weaker hand grip strength compared to the control. There is positive correlation between 4 meter walk test and SGA score & clinical symptoms of sarcopenia (asthenia, easy fatigability, weakness & muscle cramps), negative correlation with hand grip strength. Also there is positive correlation between hand grip strength with lean mass & BMD and negative correlation with clinical symptoms of sarcopenia, fat mass & SGA score. There is negative correlation between SGA score with lean mass, fat mass & BMD. 4 meter walk test is the most specific & sensitive test to diagnose sarcopenia in CKD patients.
**Conclusions:** Sarcopenia was present in CKD patients with hemodialysis more than without hemodialysis than normal people. Asthenia, weakness, easy fatigability & cramps are warning symptoms for sarcopenia. 4 meter walk test was the most specific & sensitive test to assess sarcopenia in CKD patients.

## AB0912 REVISITING THE DIFFERENTIAL DIAGNOSIS OF PANNICULITIS

O.N. Egorova, B.S. Belov, Y.A. Karpova, N.M. Savushkina, S.G. Radenska-Lopovok. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Panniculitis (Pn) is a group of heterogeneous inflammatory diseases characterized by involvement of the subcutaneous fat (SF), locomotor system and viscera. Challenges in identification of Pn are associated with multiplicity of clinical and pathomorphological types alongside with the absence of specific Pn markers.
**Objectives:** to identify and analyze the diagnostic features of lipodermatosclerosis (LDS) as one of lobular Pn (LPn) varieties.
**Methods:** 550 patients with referral diagnosis of "erythema nodosum" (EN), "panniculitis", or "vasculitis" were thoroughly evaluated according to the in-house diagnostic algorithm.
**Results:** LPn was verified in 132 patients after through examination. LDS with disease duration 18,97±7,4 mo was found in 53 (9,6%) out of them (M-3, F–50, age 18- 80 y.). 32 patients were overweight with average body mass 91.5±21.8 kg. Inflammation in predominantly lower inner leg subcutaneous fat was documented in 37 pts (54,7%) resulting in the inverted coke bottle appearance of the lower leg (79,2%) ($p$=.00556). All main types of Pn clinical course were present: acute (up to 3 mo), subacute (3 to 6 mo) and chronic (>6 mo). Acute disease was diagnosed in 20 pts (37,7%) aged 51,8±15,7 y., with indurated non-demarcated pink nodules existing for 1,47±0,3 mo.($p$=.001). Subacute disease was found in 12 pts (22,6%) aged 57,50±12,1 y. with average disease duration 4,7±1,3 mo., dark red nodules and inverted coke bottle appearance of the lower leg in 91,67% cases. Chronic Pn with disease duration 43,3±24,0 mo was documented in 21 pts (39,6%) aged 56,1±11,9 y, with demarcated red-brownish nodules and inverted coke bottle appearance of the lower leg in 17 cases (80,95%). The risk of lower leg deformity was increased 2,3-fold in pts with chronic disease vs acute (95%, CI 1,2–4,4,$p$=.003). Asymmetric pattern of nodules was present in 70% of acute and subacute disease, symmetric pattern was found in 50% of chronic cases ($p$=.003). ROC-analysis showed with 86% sensitivity and 58% specificity that palpatory evaluation of pain in LDS using VAS corresponded with 40 mm cut-off value. In 46% of cases skin lesions were accompanied by polyarthralgia (in 15 pts), and myalgia (in 12 pts) with insignificant increase of inflammation activity markers. Chronic venous insufficiency lasting for 10,2±1,3 years and verified by US Doppler scanning of the lower extremities veins was found in 28 pts (including 19 with chronic LDS) ($p$<0,05). Pathomorphological examination of skin and subcutaneous fat biopsy samples in 7 pts confirmed lobular Pn-LDS with sclerosis of borderline fatty tissue and of small arteries in hypoderma.
**Conclusions:** LDS is a variation of LPn. Identified predisposing factors include female gender, middle age, increased body mass and chronic venous failure in lower extremities. Asymmetric nodules of specific color on the inner leg and inverted coke bottle appearance of the lower leg are established diagnostic criteria for LDS. Successful diagnosis is possible with detailed history case, adequate evaluation of clinical, laboratory and instrumental modalities.

## AB0913 CLINICAL UTILITY OF MBDA PANEL VECTRA-DA IN THE MANAGEMENT OF ADULT ONSET STILL'S DISEASE

O. Petryna, X. Gao. *Rheumatology, Mount Sinai Beth Israel Medical Center, New York, United States*

**Background:** Adult Onset Still's disease (AOSD) is an inflammatory disorder with an expansive and heterogeneous presentation that can often be mistaken for infectious or malignant etiology. The diagnosis is largely based on clinical manifestations with corroborating laboratory features, such as elevated acute inflammatory markers, ferritin, and leukocytosis. The long-term management of AOSD can be difficult due to the limited amount of reliable biomarkers used to predict and manage disease activity.
**Objectives:** We present two cases with the diagnosis of AOSD and the use of Vectra DA to track clinical progression and response to therapy wit a goal to assess clinical utility of MBDA pannel *Vectra DA* in the management of Adult Onset Still's Disease
**Results:** *Case One:* 68-year-old male with history of hypothyroidism was evaluated for fever of unknown origin associated with generalized malaise, fatigue, and a maculopapular rash in bilateral upper extremities for 3 weeks. The patient was pan-CT scanned with results only remarkable for bladder thickening. He denied any familial history of rheumatological disorders, and was found to have negative ANA and RF. Further infectious and malignant work-up inpatient was negative. Patient was found to have ferritin level of 15,599 ng/mL, ESR 82 mm/hr, and CRP 18 mg/dL; and was diagnosed with Adult-Onset Still's Disease (AOSD). Vectra DA score was 77 at time of diagnosis. He was started on pulsed steroid and then discharged home to complete a tapered steroid regimen with the addition of Rilonacept with a good response; repeat Vectra DA score at three-month follow-up was 15. Delta of Vectra correlated with normalized CRP <0.9 and ESR 6.
*Case Two:* 25 year-old female with history of JIA that achieved remission for the past 14 years presented with recurrent fevers, sore throat, generalized malaise, arthralgias, and a new-onset maculopapular rash of the inner forearms and thighs bilaterally for one-month duration. Her blood work revealed WBC 20.8 k/uL but further infectious work-up was negative. She was found to have negative RF, ANA but elevated ferritin level of 321 mg/mL, ESR 75 mm/hr, CRP 138 mg/dL. Patient was diagnosed with AOSD, and started on pulsed oral steroid with methotrexate but failed treatment. Her Vectra DA score was 72 at the peak of her symptoms. Eventually received pulsed IV corticosteroids and started on Rilonasept with symptomatic improvement. A repeat Vectra DA score at three-month follow-up was 17. Delta of Vectra correlated with normalized CRP <0.1 and ESR 2.
**Conclusions:** Vectra DA is a 12-biomarker disease activity pannel commonly employed in the management of rheumatoid arthritis (RA). Vectra DA is not routinely employed in the management of AOSD and, here, we have illustrated two examples demonstrating the clinical utility of Vectra DA as an assessment tool in the diagnosis and management of AOSD. As such, this should prompt to reconsider the value of Vectra DA as a diagnostic tool in AOSD and other inflammatory disorders where there are limited biomarkers utilized to reliably track disease progression.

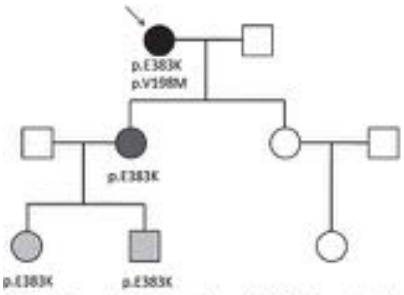
## AB0914 HEMARTHROSIS AS GRAFT VERSUS HOST DISEASE IN A PATIENT AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION FOR CHRONIC MYELOGENOUS LEUKEMIA (CASE REPORT)

O. Teplyakova[1], T. Dotsenko[2], G. Shlykova[2]. [1]*Ural State Medical University;* [2]*Medical Association "New Hospital", Ekaterinburg, Russian Federation*



**Background:** The following manifestations of graft-versus-host disease damaging the musculoskeletal system were described: fasciitis, stiffness, myositis, arthralgia and arthritis. But we did not find any descriptions of the hemarthrosis.
**Objectives:** We present a case report.
**Results:** A 43-year-old man presents in June 2015 with pain in his left knee and left hip, swelling of left knee, subfebrile temperature.
Chronic myelogenous leukemia (CML) was diagnosed in July 2014, Imatinib therapy started. In 12.19.2014 an allogeneic bone marrow transplantation was made, and then the patient receives calcineurin blockers (cyclosporine A), and prednisone. In the early postoperative period cytopenia (the lowest level of white blood cell was 0,9 × 103/μL, platelets was 27 × 103/μL,) and diarrhea were recorded. In February 2015 appeared the pain in the joints, first they were weakly expressed, but to May 2015 pain had reached 70–80 mm by VAS.
Hematologist assumed the reactive arthritis, amoxicillin/clavulanate (14 days) and metamizol were given. The treatment was ineffective, and the patient referred to rheumatologist.
On examination, his temperature was 37.2 ℃. Skin and mucosa were pale with no rash. Mucosa is wet. Physical examination confirmed swelling in the knee, as well as tenderness in the areas, left knee flexion was limited to 110°. Also there was a significant movement limitation of the left hip joint. His lungs are clear to auscultation. His cardiac is unremarkable. He has palpable hepatomegaly but no splenomegaly. There is no clinical evidence of ascites
Initially we excluded septic arthritis especially tuberculosis. The initial laboratory analysis reveals white blood cell count of 9.06 × 103/μL, platelets of 30 × 103/μL, hemoglobin of 7,6 g/dL Procalcitonin serum <0.5 ng/ml (normal level). Blood cultures twice - negative result. Results of the left hip MRI were alarming. There were established the thickening of the synovial membrane, increased number of non-uniform fluid in the joint and cartilage plates damages which should have been differentiated between the previous osteoarthritis and secondary lesions on the background of a septic (tuberculosis) process. MRI results of the left knee: synovium cover thickening with areas of hemorrhagic impregnation. Synovitis.
Enzyme immunoassay serum to M.tuberculosis, also as QuantiFERON test - negative.
The synovial fluid tests show: white blood cell count of 4625 cells/ml, polymorphonuclear leukocyte 74%, erythrocytes of 50–70 in sight, crystals and culture isolation were not found.
**Conclusions:** Thus, we excluded septic genesis of arthritis. Considering hemorrhagic content (date of MRI and synovial fluid), and in our opinion the platelet count has not reached critical level for the development of hemarthrosis, we have assumed the existence of graft-versus-host desease. During the further observation for 3 months with continued cyclosporine A and prednisolone therapy, CML did not relapse, and joint complaints completely regressed.
This is one of the first cases which describe hemarthrosis as graft versus host desease.

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1147

## AB0915 A LOW-PENETRANCE NLRP3 VARIANT IN A NOD2 CARRIER POSSIBLY WORSENS THE PHENOTYPE OF BLAU SYNDROME

P. Galozzi[1], P. Sfriso[1], D. Basso[2], A. Scanu[1], F. Oliviero[1], M. Plebani[2], L. Punzi[1]. *[1]Rheumatology Unit, Dept. of Medicine; [2]Laboratory Medicine, Dept. of Medicine, University of Padova, Padova, Italy*

**Background:** Blau syndrome (BS) is a rare autosomal dominant autoinflammatory syndrome that primarily affects skin, joints, and eyes, with varying severity of inflammation, and results from mutations in the *NOD2* gene[1]. NOD2 bears highly conserved residues and structural similarities to the NLRP3 protein, a key component of the inflammasome which mutations underlie some autoinflammatory disorders, named cryopyrinopathies.
**Objectives:** This study assessed the potential contribution of *NLRP3* mutations to the inflammatory BS phenotype in an Italian affected family carrying p.E383K *NOD2* mutation (Fig. 1).
**Methods:** Genomic DNA was isolated from blood samples of the four affected family members and sequence analyses of *NLRP3* were performed by an ABI 3730XL DNA sequencer (Applied Biosystems). A genotype/phenotype correlation of the carriers of *NLRP3* variations was also assessed.
To explain the differences in inflammatory phenotype severity, peripheral blood mononuclear cells (PBMC) were isolated from patients and healthy subjects and their ability to activate NF-κB and inflammasome pathways was measured by an array-based assay (reverse phase protein array).
**Results:** A heterozygous genetic variant of *NLRP3* was found only in the proband's sample. The p.V198M mutation was known in literature as a low-penetrance mutation associated with cryopyrinopathies in symptomatic patients (Infevers database data). The proband with combined mutations presented the worsened BS phenotype (severe chronic bilateral uveitis with glaucoma, cataracts and visual impairment), whereas the three subjects with only p.E383K variant had a much milder disease.
Concerning the activation of NF-κB pathway, all BS patients have raised levels of signalling key molecules (phosphorylated NF-κB $p<0.05$; phosphorylated IkB-α $p<0.05$) compared to the controls. However, the components of inflammasome pathway presented a pattern of activation related to individual patients rather than to the whole disease. Enhanced level of cleaved caspase-1, the key component of inflammasome, was noticed only in proband PBMCs (p=0.03), potentially promoted by the additional presence of p.V198M *NLRP3* mutation.

Blau syndrome family carrying p.E383K BS-associated mutation.
The proband (arrowed) with the most severe phenotypes (black circle), inherited both *NOD2* (p.E383K) and *NLRP3* (p.V198M) mutations. The other three subjects with only *NOD2* variant, have milder symptomatology, even if proband's daughter have more severe phenotype than her children.

**Conclusions:** Our data strongly suggest that severe phenotype in BS may result from co-existence with mutations in genes associated with other autoinflammatory diseases, and are consistent with recently reported findings in hereditary periodic fever syndromes[2]. The synergistic effect of dual mutations can also explain the differential activation of the inflammatory pathways and may lead to appropriate targeted drug development.

## AB0916 ADULT-ONSET STILL'S DISEASE-EXPERIENCE OVER LAST FIVE YEARS

P.S. Sagdeo, C. Balakrishnan, T. Parikh, G. Mangat, Y. Gc. *Rheumatology, P.D Hinduja Hospital and Medical Research Center, Mumbai, India*

**Background:** Adult onset still's disease (AOSD) is a rare systemic inflammatory disorder of unknown etiology seen by a rheumatologist. There is limited data about this disease especially from our country.
**Objectives:** To study the clinical profile of AOSD patients in a tertiary care hospital.
**Methods:** A 5 year (2009–2014) retrospective analysis was done of patients with AOSD (Diagnosed using the Yamaguchi criteria). Their clinical features, laboratory findings at presentation, disease course, treatment and outcomes were analyzed.
**Results:** 14 patients with AOSD according to Yamaguchi criteria were enrolled. The mean age at disease onset was 43.57±16.91 years and the male to female ratio was 4:3. The mean duration of symptoms prior to diagnosis was 2.2 months (range 1–6 months). The most common clinical manifestations were fever (n=14), articular symptoms (n=14), rash (n=7), weight loss (n=7), sore throat (n=4), Lymphadenopathy (n=8), hepatomegaly (n=5), splenomegaly (n=3) and serositis (n=4). Most common joints involved were knee (n=9) followed by wrist (n=7).Neutrophilic leucocytosis was seen in 13, thrombocytosis was seen in 4 patients. Elevated ESR and Ferritin levels were present in all, with a mean of 70±35.18 mm/hr and 3966.35±2988 ng/ml respectively. Hepatic enzymes were elevated in 6. The mean duration of follow up was 18.71±16.99 months. Prednisolone was used in all while methotrexate was used in 12 patients; one patient each required sulfasalazine and cyclosporine. Tender joint and swollen joint counts displayed a progressive reduction on follow up. During treatment, we observed a resolution of fever in all patients. On first follow up mean ferritin levels decreased from 3966.35±2988 to 3018±699 ng/ml. Course of the disease was monophasic in 7 intermittent in 4 and chronic in 3 patients.
**Conclusions:** 1.Fever and joint symptoms were the most common presenting symptom.
2.Steroids and methotrexate was most commonly used for treatment.
3.Majority of patients had clinical improvement with resolution of systemic and joint symptoms.

## AB0917 PULMONARY MANIFESTATIONS IN PATIENTS WITH IGG4-RELATED DISEASE AT A TERTIARY CARE INSTITUTE

R. Banka[1], Y. Gc[2], C. Balakrishnan[2], R. Samant[2], L. Pinto[1], P.S. Sagdeo[2]. *[1]Respiratory Medicine; [2]Rheumatology, P.D Hinduja Hospital and Medical Research Center, Mumbai, India*

**Background:** IgG4-Related Disease (IgG4 RD) is a rare immune-mediated disease with multi-organ involvement.
**Objectives:** To describe pulmonary manifestations of patients with IgG4-RD.
**Methods:** Chart review was performed of consecutive patients diagnosed with IgG4 RD between 2009–2014 at the PD Hinduja National Hospital, Mumbai. Included patients fulfilled diagnostic criteria of Japanese Ministry of Health, Labour and Welfare guidelines, 2011.Their clinical features, laboratory findings were noted down.
**Results:** 8 of 11 patients with IgG4 RD had pulmonary manifestations. Ages of presentation ranged from 15–73 years.6 patients were female. Average delay in diagnosis was 9 months. Prior to diagnosis, 3 patients received empiric antituberculous drugs and bronchoalveolar lavage performed in 3 patients was non-diagnostic. The right mainstem bronchus was found to be narrowed in 1 patient. The serum IgG4 levels were elevated in all patients. Median IgG4 level was 4.76 mg/dl (IQR 3.26, 6.1).Presenting symptoms, thoracic CT and histopathological findings are summarized below

Table 1. Feature (number of patients)

| | |
|---|---|
| Symptoms | Fever (6), Cough (5), Shortness of breath (5), Weight loss (4), Stridor (1) |
| Thoracic CT findings (8 of 8 pts) | Multiple small nodules <1cm with an upper lobe predominance (5), ill-defined patchy areas of consolidation (4), cervical and mediastinal homogeneously enhancing lymphadenopathy (4), ground glass opacities (3,) peribronchial wall thickening (2), interlobular septal thickening (2), subglottic stenosis (2), mass-like lesion (1), bronchial stenosis (1). |
| Histopathological findings (4 of 8 pts) | Subglottic biopsy (2) – non-diagnostic. Transbronchial lung biopsy (1) – minimal interstitial fibrosis. Lymph node biopsy (1), – minimal inflammation and mild fibrosis. |

**Conclusions:** Pulmonary involvement in IgG4 RD is common and should be sought for in patients diagnosed with the disease.

## AB0918 PREVALENCE OF PREVIOUS PFAPA SYNDROME IN BEHCET'S DISEASE

P. Ene[1], L. Damian[1], A. Maniu[2,3], O. Serban[4], S.-P. Simon[1,2], S. Rednic[1,2]. *[1]Emergency Clinical Hospital Cluj, Rheumatology Dept; [2]Iuliu Hatieganu" University of Medicine and Pharmacy; [3]Emergency Clinical Hospital Cluj, ENT Dept; [4]Emergency Clinical Hospital Cluj, Internal Medicine Dept, Cluj Napoca, Romania*

**Background:** Marshall's syndrome or PFAPA (periodic fever, aphtous stomatitis, pharyngitis, cervical adenitis) is a pediatric diseases characterized by recurrent febrile episodes associtaed with head and neck symptoms, improved or cured after tonsillectomy. Differential diagnosis includes infectious angina, Behcet's disease, cyclic neutropenia, TRAPS syndrome and other autoinflammatory syndromes. However, part of the patients with Behcet's disease may have PFAPA as part of their disease onset.
**Objectives:** We aimed to investigate the reported prevalence of PFAPA symptoms in patients with Behcet's disease.
**Methods:** The patients in the evidence of the Rheumatology Dept, a tertiary referral unit, with confirmed Behcet's syndrome (according to ISSG) presenting in the last year, were taken into the cross-sectional study, after informed consent. A questionnaire (AMAB) was developed and employed, with regard to the presence of diagnostic Marshall/ PFAPA features (Thomas 1998), familial history, tonsillectomy, fever presence and pattern and other possible features of BD appearing in childhood. Cyclic neutropenia was ruled out as part of clinical investigations, and data regarded the pathergy, eye examination and thrombotic events were obtained from the medical records.
**Results:** We enrolled 21 patients (11 F, 12 M), average age 47.6 yrs, that agreed to answer the questionnaire. In the whole responder BD group, fever was present in 38.1%. We found that 23% of the responder BD patients reported symptoms compatible with a PFAPA diagnosis, with a medium age of onset of 8.2 years. BD was diagnosed at 40±12.8 yrs (15–56), but in the patients with PFAPA symptoms the onset was earlier (28±12.3 yrs). In the 3 patients with tonsillectomy, the symptoms improved for several years, only to reappear milder after adolescence, along with other features of BD. Most patients (76.19%) recalled ulcers since childhood, and isolated oral ulcers generally remained as such until occurrence of other diagnostic BD features. We found no differences in the severity of the disease, eye involvement or thrombosis prevalence in the patients with or without PFAPA features.
**Conclusions:** PFAPA may co-exist as an associated disease in BD and is not necessarily an exclusion diagnosis. Although many patients with BD suffer from oral ulcers since childhood, BD symptoms appear in most after adolescence.

## AB0919 H-FERRITIN AND CD68+/H-FERRITIN+ CELLS ARE INCREASED IN THE SKIN OF ADULT ONSET STILL'S DISEASE PATIENTS AND CORRELATE WITH THE DISEASE ACTIVITY

P. Ruscitti[1], P. Cipriani[1], F. Ciccia[2], P. Di Benedetto[1], V. Liakouli[1], O. Berardicurti[1], F. Carubbi[1], G. Guggino[2], S. Di Bartolomeo[1], G. Triolo[3], R. Giacomelli[1]. *[1]Division of Rheumatology, University of L'Aquila, L'Aquila; [2]Division of Rheumatology, University of Palermo; [3]Division of Rheumatology, University of Palermo, Palermo, Italy*

**Background:** Adult onset Still's disease (AOSD) is an inflammatory disease, characterized by high spiking fevers, arthritis, salmon-pink erythema and multi-visceral involvement [1]. During AOSD, exceptionally high serum levels of ferritin may be observed and they might contribute to production of proinflammatory molecules [2]. Ferritin is composed by 24 subunits, heavy (H) subunits and light (L) subunits. The ferritin enriched in L subunits (L-ferritin) and the ferritin enriched in H subunits (H-ferritin) may be recognized in different tissues [3].
**Objectives:** To investigate the skin tissue expression of both H-and L-ferritin and the number of macrophages expressing these molecules, in the inflammatory cutaneous infiltrate from 10 AOSD patients with persistent (more than 24–36 hours) cutaneous lesions. In addition, we performed statistical analysis to evaluate whether these results might correlate with the severity of the disease.
**Methods:** We obtained skin samples from 10 consecutive patients with active AOSD with persistent cutaneous lesions and 10 healthy controls (HC). An immunofluorescence analysis was performed evaluating the tissue expression of both H- and L-ferritin and the number of macrophages expressing these moleculkes. Serum levels of ferritin, ESR, CRP, Pouchot's score were also recorded.
**Results:** We observed an increased H-ferritin expression in the skin samples of AOSD patients, when compared with HC ($p<0.001$). On the contrary, no differences were observed for L-ferritin when compared to HC. Furthermore, a significant increase of H-ferritin was detected when compared with L-ferritin in AOSD patients ($p<0.001$) and when compared with both H-ferritin and L-ferritin in HC ($p<0.001$; $p<0.001$). Furthermore, a positive correlation between H-ferritin and the Pouchot's score was observed ($p<0.01$). We also reported a positive correlation among the tissue expression of H-ferritin and both serum ferritin ($p<0.05$) and CRP ($p<0.05$). The double staining between the H-ferritin and CD68 showed an increased presence of macrophages expressing H-ferritin in the inflammatory infiltrate when compared with HC ($p<0.001$). In the same samples, we did not observe any co-localization between CD68 and L-ferritin. However, our analysis failed to show any positive correlation among the number of CD68+/H-ferritin+ in the skin and disease activity, serum ferritin and inflammatory markers.
**Conclusions:** Our data show an imbalance between the production of L- and H-ferritin in the skin of AOSD patients, associated with a strong infiltrate of CD68+/H-ferritin+ cells in the same samples suggesting a possible pathogenic role. Furthermore, a correlation between the levels of H-ferritin in the skin of these patients and the disease activity was observed.

## AB0920 ANY PREDICTIVE FACTORS OF THERAPEUTIC RESPONSE IN INFECTIOUS SPONDYLITIS?

I. Gharsallah, R. Dhahri, N. Boussetta, R. Abid, L. Metoui, F. Laajili. *Internal Medicine, Military Hospital of Tunis, Tunisia, Tunis, Tunisia*

**Background:** The aim of the present work was to describe predictive factors of good or bad outcome Infectious Spondylodiscitis according to the experience of an internal medicine department in Tunisia.
**Methods:** Patients with SDI either confirmed or presumed and hospitalized in the internal medicine department of The Principle Military Hospital Of Tunis, Tunisia have been included in the Study.
**Results:** Fourty-four patients met the inclusion criteria. They have been gathered over 20 years-period. They were 24 men and 20 women with an average age at 52.5 years. The diagnosis was a Tuberculous Spondylodiscitis in 22 cases (50%): among them 10 patients had a concomitant extra spinal TB. The diagnostic delay was 231 days for TB SDI and 40.5 days for SDP.
Length of hospital stay was 48.6 days (6–225 days): with a mean of 48.9 days in SDT and 45.3 days in SDP.
Regular monitoring was observed in 38 patients (17 SDP, SDT 21) with an average duration of 20 months (5–48 months). Three were lost views and three died. Evolution was considered positive if there was a clinical and biological improvement and no recurrence or death.
The analytical study objectified that existence of a immunosuppression, a longer diagnosis period, or hospitalization period and the follow-up duration were associated with a longer duration of treatment ($p=0.038$, $p<0.001$).
The absence of orthopedic complications initially or during the evolution and treatment duration were the only factors associated with good favorable change ($p<0.001$, $p=0.004$), the existence of bacteriological evidence of multifocal involvement, the presence of epidural or spinal compression showed no significant association.
**Conclusions:** Earlier treatment with effective duration and follow up are predictive factors of favorable outcome in SDI either due to TB or regular germs.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5696

## AB0921 INFECTIOUS SPONDYLODISCITIS FEATURES: ABOUT 44 CASES

R. Dhahri, I. Gharsallah, N. Boussetta, R. Abid, L. Metoui, F. Laajili. *Internal medicine, Military Hospital of Tunis, Tunisia, Tunis, Tunisia*

**Background:** Spinal infections can be described aetiologically as pyogenic, granulomatous (tuberculous, brucellar, fungal) and parasitic. Its early diagnosis is crucial to the establishment of adequate treatment in order to get favorable outcomes.
The aim of the present work was to describe clinical, diagnostic and therapeutic aspects of Infectious Spondylodiscitis according to the experience of an internal medicine department in Tunisia.
**Methods:** Patients with SDI either confirmed or presumed and hospitalized in the internal medicine department of The Principle Military Hospital Of Tunis, Tunisia have been included in the Study.
**Results:** Fourty-four patients met the inclusion criteria. They have been gathered over 20 years-period. They were 24 men and 20 women with an average age at 52.5 years. The diagnosis was a Tuberculous Spondylodiscitis in 22 cases (50%): among them 10 patients had a concomitant extra spinal TB. The diagnostic delay was 231 days for TB SDI and 40.5 days for SDP.

Revealing symptoms were dominated by pain:, often mixed (61%). Radicular pain was noted in 15 cases. Fever was found in 17 cases. On examination: spinal syndrom was present in 65.9% of cases, spinal cord compression signs were found in 8 patients. MRI was contributive in all cases showing a disc enhancement in 50% (SDP in 67%, TSDI in 33%), epiduritis in 63.5% (SDP 60%, TSDI 67%). The disc biopsy was contributive in 71% of cases. The diagnosis was certain in 15 cases, highly probable in 18 cases and presumptive in 11 cases.
Treatment duration was 13 months for SDT and 18 weeks for SDP. The outcome was favorable in 30 cases (SDP 13, TSDI 17).
**Conclusions:** Infectious sondylodiscitis remains a diagnostic and therapeutic problem in our country. Only an early care can enhance its prognosis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5707

## AB0922 FDG-PET/CT IS A VALUABLE TOOL FOR RELAPSING POLYCHONDRITIS

R. Wakiya, H. Ozaki, H. Shimada, S. Nakashima, Y. Takeuchi, M. Izumikawa, T. Kameda, H. Dobashi. *Kagawa University, Kita-gun, Japan*

**Background:** Relapsing polychondritis (RP) is a comparatively rare inflammatory disorder t in which recurrent episodes of inflammation occur in the external ear, nose, and joints. Although the pathogenesis of RP is unclear, it is believed to involve autoimmune mechanism such as autoantibody to type II collagen. Clinically, diagnosis in early stages of RP is difficult because of few typical physical findings. Furthermore, airway involvement is the most important complication of RP, and is associated with significant morbidity and mortality. Therefore it is important to diagnosis and treat RP in early stages. On the other hand, fluorine-18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) has been an established in a field of oncology. Recently, FDG-PET/CT is used as diagnostic tool for inflammatory disorder such as infection or collagen vascular disease.
**Objectives:** We investigate the features and the usefulness of FDG-PET/CT in the diagnosis of RP.
**Methods:** We enrolled the five RP patients (M/F: 1/4) who fulfilled the RP criteria by Damiani and Levine, and treated in our facility between 2005 and 2015. All patients had undergone FDG-PET/CT before treatment. Inflammatory lesion was evaluated by using the maximum standardized uptake value (SUV max). Furthermore, we performed follow-up FDG-PET/CT due to evaluate the efficacy of treatment for RP.
**Results:** FDG-PET/CT findings revealed abnormal FDG accumulation in the cartilages for all five patients. The lesions of abnormal FDG accumulation were tracheal/bronchial in 3 cases, auricular cartilage in 2 cases. The mean SUV max in tracheal/bronchial was 4.84 and in auricular cartilage was 2.53. All RP patients received glucocorticoid (GC) treatment. 3 patients were performed methylprednisolone-pulse therapy. All RP patients had well responce to initial GC treatment. However three patients were refractory for GC treatment. In these patients, one treated with methotrexate combined with GC and another 2 cases cyclophosphamide. The follow-up FDG-PET/CT was undergone in 2 patients. These findings revealed that FDG accumulation was significantly decreased or disappeared.
**Conclusions:** In RP patients, FDG-PET/CT is useful for the early diagnosis. Additionally, we suggest that FDG-PET/CT is valuable for monitoring response to treatment.

## AB0923 PREVALENCE OF RHEUMATOLOGIC SYMPTOMS AND SPECIFIC RHEUMATIC DISEASES IN PATIENTS WITH HISTORY OF BREAST IMPLANTS

R. Rojas Tessel, D. Alonso Lopez, E. Buschiazzo, R.V. Juarez, M. Aciar, M.E. Crespo Espindola. *Hospital Sr del Milagro, Salta, Argentina*

**Background:** The Autoimmune Syndrome Induced by Adjuvant (ASIA) includes several clinical conditions as siliconosis, gulf war syndrome, miofasciitis macrophagic syndrome and post vaccination phenomenon. Acting as an adjuvant the Breast implants (BI) could be potentially linked with several autoimmune diseases.
**Objectives:** The purpose of this study was to describe the rheumatological characteristics of a group of patients with the history of previous BI, that assisted to a rheumatologist, and to compare them with age matched controls.
**Methods:** A retrospective, descriptive study was designed. Patients with the history of BI, that assisted to a rheumatologist, where included. The data was collected from clinical registries, including socio-demographic data and comorbidities, kind and duration of symptoms, development of a specific rheumatologic syndrome/disease, fulfilment of ASIA proposed criteria and type of clinical evolution. All the patients and their controls attended private practice rheumatology outpatient clinics.
For each case, 2 controls were randomly selected from clinical registries if they had: ±2 years of age compared with the cases at the first visit, had no history of BI or pre-existing rheumatological disease and had attended at least 2 followup visits.
Statistical Analysis – Categorical data were expressed in frequency and percentage, continuous data in median and interquartile range (IQR). Chi$^2$ and Fisher test were used to analyse categorical data and Student T test or Mann-Whitney for continuous data based in its distribution. A p value $<0.05$ was considered as significative.
**Results:** Twenty-two female patients with history of BI (all met ASIA classification criteria) and 44 female controls were included. Median age was 44.5 years (IQR 38–53), without difference between groups (44.3 vs 44.9, p=0.8). The median time between the BI and the beginning of the rheumatologic symptoms was 4 years (IQR 1–10) since all the patients developed the symptoms after the BI surgery. The cases had significantly more frequency of arthritis (31.8% vs 11.4%, p=0.042), less myalgias (18.2% vs 75%, $p<0.0001$) and less fatigue (18.2% vs 47.7%, p=0.03) than the controls. Though it was not statistically significative, the group of patients had more frequency of specific rheumatic diseases (36.4% vs 19%, p=0.1), with more rheumatoid arthritis (13.6% vs 4.5%, p=0.1) and fibromyalgia (13.6% vs 9.1%, p=0.5) than controls. Overall, the frequency of any specific rheumatic disease (including fibromyalgia) was higher in patients than in controls (50% vs 29.5%, p=0.1).
**Conclusions:** In our group of patients with history of BI we found more prevalence of arthritis, and less of myalgia and fatigue. Maybe arthritis could be a characteristic symptom of ASIA. The weaknesses of this study relies in its retrospective design and the small sample size. Prospective studies could be helpful to answer the question of the possible link between BI and rheumatic diseases.

## AB0924 SERUM ADIPOKINES LEVELS IN PATIENTS WITH SARCOIDOSIS

S. Kobak[1], M. Akyildiz[2], A. Gokduman[2], T. Atabay[3], H. Vural[2]. *[1]Rheumatology; [2]Biochemistry; [3]Physiology, Sifa University Faculty of Medicine, Izmir, Turkey*

**Background:** Adipokines are different proteins synthesized by adipose tissue who have an influence on angiogenesis, hemostasis, lipid metabolism and immune system regulation. Sarcoidosis is a chronic inflammatory disease characterized by non-caseating granuloma which etiology is unknown yet. Adipokines may play an important role in the pathogenesis of sarcoidosis.
**Objectives:** To determine the serum adipokines levels in patients with sarcoidosis and to determine a possible correlation with clinical and laboratory signs of disease.
**Methods:** Forty-four biopsy proven sarcoidosis patients followed at a single center and age and sex matched 41 healthy volunteers were included in the study. Demographic, clinical, laboratory and radiological data were recorded and body mass index (BMI) was calculated in all patients. Routine laboratory tests (blood glucose, liver and kidney function test) were measured. Serum adiponectin and leptin levels were measured by ELISA method.
**Results:** Among 44sarcoidosis patients 13 (29.5%) were male and 31 (70.5%) were female. Twenty-one (47.7%) patients had erythema nodosum, three (6.8%) had uveitis, 40 (90.9%) had arthralgia, 23 (52.3%) had ankle arthritis, 15 (34.1%) had enthesitis. Laboratory evaluation showed increased serum ACE level in 24 (54.5%) patients, increased serum calcium level in 11 (25%) patients, increased serum D3 level in 5 (11.4%) patients, increased ESR and CRP levels in 22 (50%) and 23 (52.3%) patients, respectively. Compared with the control group serum adiponectin levels were significantly higher in patients with sarcoidosis (p=0.007). Serum adiponectin level were associated with arthralgia and ankle arthritis (p=0.007, p=0.006 respectively). Serum leptin levels were similar in sarcoidosis patients and controls (p=0.327). There was no relationship between serum leptin level and disease features ($p>0.05$).
**Conclusions:** In this study, high serum adiponectin level was detected in patients with sarcoidosis while serum leptin level were similar in the sarcoidosis and control group. Adiponectin, an anti-inflammatory protein may play an important role in the pathogenesis of sarcoidosis. Studies are needed to shed light on this topic.

**DOI:** 10.1136/annrheumdis-2016-eular.1655

## AB0925 SERUM GALECTIN-3 AND TGF-BETA LEVELS IN PATIENTS WITH SARCOIDOSIS

S. Kobak[1], M. Akyildiz[2], A. Gokduman[2], T. Atabay[3], H. Vural[2]. *[1]Rheumatology; [2]Biochemistry; [3]Physiology, Sifa University Faculty of Medicine, Izmir, Turkey*

**Background:** Sarcoidosis is a chronic granulomatous disease characterized by non-caseating granuloma formation. Galectin-3 is a multifunctional protein involved in many biological processes such as fibrosis, angiogenesis and immune activation.
**Objectives:** To determine the serum galectin-3 and transforming growth factor-beta (TGF-beta) levels in patients with sarcoidosis and to determine a possible correlation with clinical findings.

**Methods:** Forty-four biopsy proven sarcoidosis patients followed at a single center and age and sex matched 41 healthy volunteers were included in the study. Demographic, clinical, laboratory and radiological data were recorded in all patients. Serum galectin-3 and TGF-beta levels were measured by ELISA method.
**Results:** Among 44sarcoidosis patients 13 (29.5%) were male and 31 (70.5%) were female. Average patient age was 47.4 years, mean disease duration was 3.2year. Twenty-one (47.7%) patients had erythema nodosum, three (6.8%) had uveitis, 40 (90.9%) had arthralgia, 23 (52.3%) had ankle arthritis, 15 (34.1%) had enthesitis. Laboratory evaluation showed increased serum ACE level in 24 (54.5%) patients, increased serum calcium level in 11 (25%) patients, increased serum D3 level in 5 (11.4%) patients, increased ESR and CRP levels in 22 (50%) and 23 (52.3%) patients, respectively. Serum galectin-3 level were similar in the sarcoidosis patients and the control group (p=0.977). No relationship were found between serum galectin-3 level and clinical and laboratory findings ($p>0.05$). Serum TGF-beta level were higher in patients with sarcoidosis compared with the control group (p=0.005). Serum TGF-beta level was associated only with enthesitis and arthralgia (p=0.006,p=0.02), while no correlation were detected with other disease features ($p>0.05$).
**Conclusions:** We found high level of serum TGF-beta, but normal level of galectin-3 in patients with sarcoidosis. These findings suggest that TGF-beta play an important role in the pathogenesis of sarcoidosis. to, there is a need for new Multicenter prospective studies are needed to illuminate the possible relationship between serum galectin-3 and sarcoidosis.

## AB0926 INCREASED CIRCULATING INTERLEUKIN-23 IN PATIENTS WITH SARCOIDOSIS

S. Kobak[1], M. Akyildiz[2], A. Gokduman[2], T. Atabay[3], H. Vural[2]. [1]*Rheumatology;* [2]*Biochemistry;* [3]*Physiology, Sifa University Faculty of Medicine, Izmir, Turkey*

**Background:** Sarcoidosis is Th1-mediated chronic granulomatous disease characterized by non-caseating granulomas formation. Interleukin-23 (IL-23) is a protein encoded by the IL-23 gene in humans and is produced by dendritic cells and macrophages. IL-23 and IL-12 share a common p40 subunit and are important proinflammatory cytokines.
**Objectives:** This study aim to determine the serum IL-23 level as well as serum IL-6, IL-12, IL-17 levels in patients with sarcoidosis, and to determine a possible correlation with clinical and laboratory findings of the disease.
**Methods:** Forty-four biopsy proven sarcoidosis patients followed at a single center and 41 healthy volunteers were included in the study. Demographic, clinical, laboratory and radiological data of all patients were recorded. Serum samples from all the patients and the control group were taken and IL-6, IL-12, IL-17, IL-23 were measured by ELISA method.
**Results:** Among 44sarcoidosis patients 13 (29.5%) were male and 31 (70.5%) were female. Average patient age was 47.4 years, mean disease duration was 3.2year. Twenty-one (47.7%) patients had erythema nodosum, three (6.8%) had uveitis, 40 (90.9%) had arthralgia, 23 (52.3%) had ankle arthritis, 15 (34.1%) had enthesitis. Laboratory evaluation showed increased serum ACE level in 24 (54.5%) patients, increased serum calcium level in 11 (25%) patients, increased serum D3 level in 5 (11.4%) patients, increased ESR and CRP levels in 22 (50%) and 23 (52.3%) patients, respectively. Compared with the control group higher serum IL-23 level were found in patients with sarcoidosis (p=0.01). Serum IL-23 were associated with ankle arthritis (p=0.02). Serum IL-6, IL-12 and IL-17 levels were similar in sarcoidosis patients and control group (p=0.128, p=0.212, p=0.521 respectively).
**Conclusions:** In our study we found increased serum IL-23 in patients with sarcoidosis, while serum IL-6, IL-12 and IL-17 were detected as normal. Despite our results are somewhat contradictory to other studies in literature, sarcoidosis still should be discussed if is Th1/Th17 disease or not? Multicenter studies are needed in this regard.
**Disclosure of Interest:** None declared

## AB0927 BIOLOGICAL DRUGS USE IN PRIMARY IMMUNODEFICIENCIES

A. Robles-Marhuenda[1], T. Cobo-Ibáñez[2], J.J. Ríos-Blanco[1], F. Arnalich-Fernández[1]. [1]*Internal Medicine, Hospital La Paz, Madrid;* [2]*Rheumatology, Hospital Infanta Sofía, San Sebastián de los Reyes, Spain*

**Background:** Many patients with primary immunodeficiencies develop immune-mediated diseases that require biological treatment. For some time it has been denied the use of biological treatment to patients with immunodeficiencies, because of the theoretical risk of serious infections.
**Objectives:** To analyze our experience in the use of biological agents in patients with primary immunodeficiency.
**Methods:** Retrospective analysis of 8 patients over 18 years, diagnosed with primary imunodeficiency, by WHO classification, that have received biological treatment. Demographic data, type of immune-mediated disease, biological treatment used, response to treatment and rate of infection were record.
**Results:** We present 8 patients that have received biological drugs. The mean age was 23 years, all of whom were male,except one woman. The time evolution of the priamry immunodeficiency was on average 10.2 years. Five patients have a common variable immunodeficiency, two chronic granulomatous disease and one of them agammaglobulinemia-X. Patients with chronic granulomatous disease and agammaglobulinemia received anti-TNF, for the treatment of inflammatory bowel disease. While patients with common variable immunodeficiency received rituximab; two of them for immune-mediated thrombocytopenia, two for lymphoid interstitial pneumonitis and another by transverse myelitis. Agammaglobulinemia-X and one patient with chronic granulomatous disease precised the use of various anti-TNF (infliximab, adalimumab, certolizumab). All patients had disease improvement in which biological treatment was indicated. The rate of infection was lower along the use of biological drugs (median follow up 1.2 years) than along the treatment with other immunosuppressants. There was only one episode of serious infection that required hospitalization, a patient with agammaglobulinemia-X who presented a herpes zoster, while being trated with steroids and certolizumab for inflammatory bowel disease. The perceived quality of life was better when using biological agents than previously to it.
**Conclusions:** Our experience could open the prudent use of biological drugs for patients with primary immunodeficiencies, always under close monitoring and appropriate prescription.
**Disclosure of Interest:** None declared

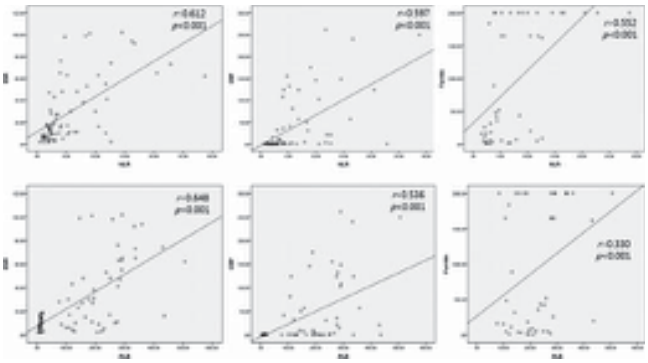
## AB0928 SOME GENETIC MARKERS IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE IN COMPARISON WITH SYSTEMIC LUPUS ERYTHEMATOSUS, SYSTEMIC SCLEROSIS AND RHEUMATOID ARTHRITIS PATIENTS



V. Dostanko[1], N. Dostanko[2], V. Yagur[2], K. Chizh[2]. [1]*Infomed;* [2]*2-d Department of Internal Medicine, BSMU, Minsk, Belarus*

**Background:** Mixed connective tissue disease or Sharp syndrome (MCTD) was described in 1972 [1] as a connective tissue inflammatory syndrome with overlapping features of systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), polymyositis/dermatomyositis (PM/DM) and systemic sclerosis (SS) associated with antibodies to U1 small ribonuclear protein (U1 RNP). The long-term follow-up studies revealed a tendency for MCTD to evolve into SLE or SS over time [2].
**Objectives:** To reveal genetic markers associated with MCTD and to estimate their discriminating and prognostic value.
**Methods:** For the twenty-five year period (1980–2005) MCTD was diagnosed in 29 patients (25 women and 4 men) observed at Byelorussian Republican Rheumatologic Center. There were 17 cases of overlapping SLE and RA, 7 patients had features of SLE and SS, and combination of SS and RA was revealed in 5 patients. A number of some genetic markers as HLA-A; (8 loci) and HLA-B (17 loci) antigens, AB0 and Rhesus ($Rh_0^+$, $Rh_0^-$) blood groups and haptoglobin phenotype ($Hp_{1-1}$, $Hp_{2-1}$, $Hp_{2-2}$) were investigated in patients with MCTD as well as in patients with RA (n=260), SLE (n=182), SS (n=52) and healthy individuals of the control group (n=120) for the comparison. All the patients fulfilled the ACR criteria for the corresponding diseases.
**Results:** The least differences in A and B loci were revealed between patients with MCTD and SLE (locus A: $\chi^2$=5.3, df=8, p=0.725; locus B: $\chi^2$=10.9, df=16, p=0.813) and the greatest differences – between patients with MCTD and healthy individuals of the control group (locus A: $\chi^2$=11.7, df=8, p=0.165; locus B: $\chi^2$=15.5, df=17, p=0.557). The differences in pairs MCTD vs RA and MCTD vs SS had the intermediate significance level of $\chi^2$ criterion. HLA-$A_1$ antigen was determined in patients with MCTD more often than in the control group (40.9% vs 18.3%, $p_{2\text{-}t}$=0.0231, two-way Fisher's exact test) as well as HLA-$B_8$ (31.8% vs 10.8%, $p_{2\text{-}t}$=0.017) and phenotype $A_1B_8$ (27.3% vs 8.3%, $p_{2\text{-}t}$=0.0198). The same significant differences of HLA phenotype were revealed between MCTD patients and RA and SS patients in contrast to the SLE patients, characterized by the HLA profile similar to MCTD patients. The following frequency of erythrocyte antigens and haptoglobin phenotypes in MCTD patients was determined: I(0) 41.7%; II(A) 16.7%; III(B) 33.3%; IV(AB) 8.3%; $Rh_0^+$ 100.0%; $Hp_{1-1}$ 22.2%; $Hp_{2-1}$ 44.5%; $Hp_{2-2}$ 33.3%. II (A) blood group was determined rarer in MCTD than in RA (40.1%), SLE (42.0%) and SS (50.8%) and in the control group (37.2%). The only significant difference of erythrocyte antigens was between MCTD and SS patients (p=0.043, one-way Fisher's exact test, and $p_{2\text{-}t}$=0,073).
**Conclusions:** HLA-$A_1$, HLA-$B_8$ and phenotype $A_1B_8$ were associated with MCTD. The findings agree with recently published data identified HLA-B8 as risk allele for MCTD [3] and highlight the genetic and clinical similarity between MCTD and SLE in Byelorussian MCTD cohort.

AB0929 **NEUTROPHIL/LYMPHOCYTE RATIO (NLR), PLATELET/LYMPHOCYTE RATIO (PLR) WERE USEFUL MARKERS IN ASSESSMENT OF INFLAMMATORY RESPONSE IN AOSD PATIENTS**

W.S. Lee[1], Y.-J. Choi[1], M.-J. Hong[2], C.-H. Lee[3], M.S. Lee[3], S.-I. Lee[4], Y.-H. Cheon[4], W.-H. Yoo[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Research Institute of Clinical Medicine of Chonbuk National University-Biomedical Research Institute of chonbuk national university hospital; [2]Division of Rheumatology, Department of Internal Medicine, Presbyterian Medical Center, jeonju; [3]Division of Rheumatology, Department of Internal Medicine, Shool of medicine, wonkwang University, Iksan; [4]Division of Rheumatology, Department of Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of*

**Background:** Both neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte (PLR) are reported to be increased in various inflammatory diseases, but there clinical significance in adult onset still disease (AOSD) remains unclear.
**Objectives:** The aim of the present study was to evaluate NLR and PLR as a inflammatory marker in AOSD.
**Methods:** The medical records of 23 AOSD patients and age, sex-matched 25 healthy individuals were retrospectively reviewed. NLR, PLR between AOSD patients and healthy controls were compared, and correlation between these indexes and clinical characteristics were analyzed. Exclusion criteria included active infection and/or the presence of any hematological, cardiovascular or metabolic disorder.
**Results:** The NLR and PLR were found to be significantly higher in AOSD patients when compared to the healthy control (NLR: 10.67± 6.73 vs 2.05±1.07, $p<0.001$, PLR: 255.78±107.22 vs 128.10 ±42.60, $p<0.001$). The NLR and PLR were decreased significantly after treatment (4.67±3.22, 196.84±78.54). NLR was positively correlated with erythrocyte sedimentation rate (ESR)($r=0.612$, $p<0.001$), C-reaction protein (CRP)($r=0.597$, $p<0.001$) and ferritin ($r=0.552$, $p<0.001$). PLR was positively correlated with ESR ($r=0.648$, $p<0.001$), CRP ($r=0.536$, $p<0.001$) except ferritin ($r=0.33$, $p=0.025$).

**Conclusions:** NLR, PLR, together with other serum inflammatory markers, were proving as significant clinical tools which could be used as biomarkers for inflammatory response of disease activity in AOSD patients.
**Disclosure of Interest:** None declared

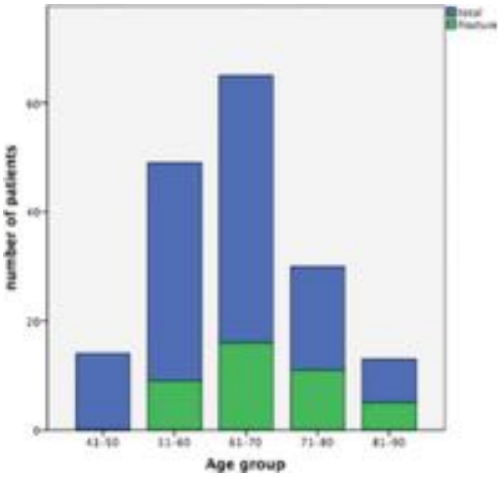
## Diagnostics and imaging procedures

AB0930 **QUANTITATIVE CHEST CT IN ILD-SSC PATIENTS WITH DIVERGENT RISKS OF MORTALITY**

A. Ariani[1], M. Silva[2], V. Seletti[2], E. Bravi[3], M. Saracco[4], S. Parisi[5], F. De Gennaro[6], F. Lumetti[1], L. Idolazzi[7], P. Caramaschi[7], C. Benini[7], F.C. Bodini[8], C.A. Scirè[9], V. Alfieri[10], E. Bonati[10], G. Lucchini[1], M. Aiello[10], D. Santilli[1], F. Mozzani[1], D. Imberti[3], E. Arrigoni[3], G. Delsante[1], E. Michieletti[8], R. Pellerito[4], E. Fusaro[5], A.A. Chetta[10], N. Sverzellati[2]. *[1]Dipartimento di Medicina, Unità di Medicina Interna e Reumatologia, Azienda Ospedaliero Universitaria di Parma; [2]Department of Clinical Sciences, Section of Radiology, University of Parma, Parma; [3]Department of Medicine, Internal Medicine and Rheumatology Unit, Ospedale G. Da Saliceto, Piacenza; [4]Rheumatology Unit, Ospedale Mauriziano - Umberto I di Torino; [5]Rheumatology Department, Azienda Ospedaliera Cittá della Salute e della Scienza di Torino, Torino; [6]Rheumatology Unit, Azienda Ospedaliera "Istituti Ospitalieri" di Cremona, Cremona; [7]Rheumatology Section, Department of Medicine, University of Verona, Policlinico Borgo Roma, Verona; [8]Radiology Unit, Ospedale G. Da Saliceto, Piacenza; [9]Epidemiology Unit, Italian Society for Rheumatology, Milano; [10]Department of Clinical & Experimental Medicine, Respiratory Disease and Lung Function Unit, University of Parma, Parma, Italy*

**Background:** Quantitative analysis of chest CT (QCT) is increasingly applied to characterization of Interstitial Lung Disease (ILD) associated to Systemic Sclerosis (SSc). However, there is no prognostic evidence for QCT in predicting lung detrimental evolution or death. Many Authors proposed composite clinical indexes to predict 1-year mortality. Recently the ILD-GAP index and du Bois index were proven to stratify ILD-SSc patients in outcome-related subgroups.
**Objectives:** The main aim of this study was to compare QCT assessment of SSc-ILD and composite clinical indexes in the selection of patients with high risk of mortality.
**Methods:** Chest CT, anamnestic data and pulmonary function test of 146 patients with SSc were retrospectively collected and ILD-GAP and DuBois score were calculated. Each chest CT underwent a quantitative assessment. Correlation between clinical prediction models and QCT parameters was tested. $p<0,05$ was considered statistically significant.
**Results:** All QCT parameters had a statistically different distribution in patients with diverging mortality risk according to both clinical prediction models. The cut-off of QCT parameters were calculated by ROC curve analysis, with statistically significant value as compared to clinical prediction models (AUC $>0.7$, $p<0.0001$).
**Conclusions:** QCT assessment of SSc-ILD can distinguish between different mortality risk categories, therefore it yields prognostic value. These findings, together with the operator-independence, strengthen the accuracy of QCT for assessment of SSc-ILD.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2995

AB0931 **QUANTITATIVE CT IN ILD-SSC: FEASIBILITY OF AN OPERATOR INDEPENDENT METHOD BASED ON FREE OPEN SOURCE DICOM VIEWER**



A. Ariani[1], M. Ronconi[1], M. Matucci-Cerinic[2], D.E. Furst[3]. *[1]Dipartimento di Medicina, Unità di Medicina Interna e Reumatologia, Azienda Ospedaliero Universitaria di Parma, Parma; [2]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy; [3]David Geffen School of Medicine, University of California, Los Angeles, United States*

**Background:** Quantitative chest CT (QCT) is a promising procedure to assess the extent and severity of interstitial lung disease (ILD) in systemic sclerosis (SSc) patients. OsiriX and its 64-bit version, Horos, are two free open source software that make it possible to put to use a CT post-processing procedure that is definitely operator independent.
**Objectives:** The main aim of this study is to investigate the feasibility of the operator independent method based on OsiriX/Horos as described by Ariani et al. [1] and hereafter abbreviated as ARIANI.
**Methods:** To explore the feasibility, we address the following areas of focus: a) Demand ("Can ARIANI fill a gap in the field of ILD-SSc studies?"); b) Implementation ("Can ARIANI improve the current way to evaluate ILD-SSc?"); c) Acceptability ("Can ARIANI be used by a newbie after a one-hour training?"); d) Practicality ("How long does ARIANI take to give the QCT of a patient's ILD-SSc?"); e) Dissemination ("Does ARIANI require special equipment? Is it expensive and/or barely available?"). All the answers were extracted from the most current literature (only Pubmed and Academia.edu indexed papers or abstracts about ARIANI were reviewed) and from our own practice-based experience.
**Results:** We selected four papers and five abstracts. Also taking into account our four year experience in performing QCT with ARIANI, we answered to all focus areas chosen. In summary, ARIANI can be extremely useful because the current ways to assess ILD-SSc are not completely satisfying for their inter/intra-observer variability (Demand). Conversely, an operator independent algorithm can represent a starting point to develop a new standard evaluation (Implementation). All the rheumatologists (two) and medical students (two) that were trained, learned how to successfully complete the QCT assessment without requiring any other explanation even after three years (Acceptability). ARIANI requires 1.8 min (range from 0.5 to 3.2 min); this time interval is mainly influenced by the computer configuration (Practicality). The use of Apple (R) computers (which are quite widespread hardware) is mandatory because of the OsiriX/Horos software architecture running only on MacOs X. ARIANI performance is virtually possible on every Mac now available for sale and on the majority of those built in the last seven years (Dissemination).
**Conclusions:** Taking into account the previous close examination, the use of OsiriX/Horos with ARIANI appears potentially useful in ILS-SSc assessment and limited only in those few centers in which there is no availability of the required equipment (i.e. computed tomographies and Mac computers). Thus, ARIANI feasibility seems to be good and ready for a world-wide spread.

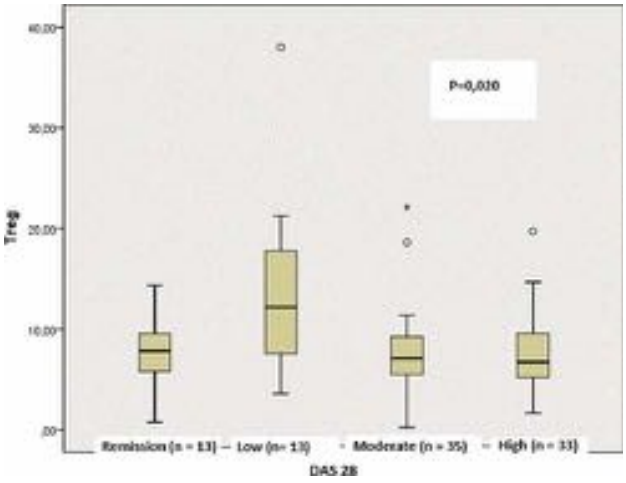
## AB0932 FREQUENCY OF VERTEBRAL FRACTURE ON LATERAL VERTEBRAL ASSESSMENT IN PATIENTS WITH OSTEOPENIA UNDERGOING DXA SCANNING

A. Alshamsi[1], M. Barry[2], E. Murphy[3], C. Corry[4], T. Duffy[3]. *[1]Rheumatology, St. Vincent HOSPITAL; [2]Rheumatology, Connolly HOSPITAL, Dublin; [3]Rheumatology, Connolly Hospital; [4]Radiolology, Clane Hospital, Dublin, Ireland*

**Background:** Previous low trauma fracture is a strong predictor of future fracture. Lateral Vertebral Assessment (LVA) is useful to screen for preexisting but undiagnosed vertebral fracture. It is however commonly not performed at the time of DXA scanning. Anti resorptive therapy is frequently withheld in patients with Osteopenia on DXA as fracture risk is perceived not to be high. This perception might change if LVA performed at the time of DXA scanning demonstrated previous fracture.
**Objectives:** The aim of this study was to measure the frequency of vertebral fracture on LVA in patients found to have Osteopenia on DXA.
**Methods:** DXA scans from 170 female patients from two centers in Ireland (Connolly Hospital/Clane Hospital) performed in 2013/2014 were analyzed retrospectively. Patients ranged in age from 40 to 90 years. All patients had T-score between -1.0 and -2.5. They underwent Lateral Vertebral Assessment at the same session following BMD measurement.
All patients are scanned by the same certified densitometry technologist at both centers, using quantitive (vertebral morphometry) and semiquantitative (visual assessment). The scans were reported by a consultant Rheumatologist and Rheumatology registrar. A vertebral fracture was diagnosed if identified by all 3 reviewers.
**Results:** 41 out of 170 Osteopenic patients i.e 24% had vertebral fractures seen on LVA. 51 fractures in total were identified, involving 32 thoracic and 19 lumbar vertebrae. They all occurred in those above 50 years of age, and the frequency of fractures increased with age. 43 of the fractures were classified as mild, 3 as moderate and 5 as severe fractures according to Genant et al. [4].



**Conclusions:** Our study emphasizes the importance of LVA in identifying vertebral fractures in osteopenic patients. In view of its advantages, we suggest that any patient undergoing DXA assessment should have an LVA performed regardless of age.

## AB0933 TREG/TH17 CELLS AND HIGH RESOLUTION ULTRASOUND INFLAMMATORY FINDINGS IN ESTABLISHED RHEUMATOID ARTHRITIS: A CROSS SECTIONAL STUDY

A.D. Do Prado[1,2], T.S. Baptista[3], L. Petersen[3], M.E. Bauer[3], M.C. Bisi[2], M. Bredemeier[1], D.M. Piovesan[2], I.G. da Silveira[2], J.A. Mendonça[4], H.L. Staub[2]. *[1]Rheumatology Unit, Grupo Hospital Conceição (GHC); [2]Rheumatology Unit, Hospital Sao Lucas da Pontifícia Universidade Católica do Rio Grande do Sul (PUCRS); [3]Laboratory of Immunosenescence, Institute of Biomedical Research, Pontificia Universidade Católica do Rio Grande do Sul (PUCRS), Porto Alegre; [4]Rheumatology Unit, Hospital da Pontifícia Universidade Católica (PUC) de Campinas, Campinas, Brazil*

**Background:** Imbalance and disfuntion in regulatory T-cells (Tregs) and IL-17 producer lymphocytes (Th17) have been implicated in the pathogenesis of rheumatoid arthritis (RA). Gray scale synovial proliferation (GS), power Doppler signal (pD) and bone erosions seen on high resolution muskuloskeletal ultrasound (MSUS) are hallmarks of destructive articular disease.
**Objectives:** The present study was undertaken to evaluate the association of peripheral Tregs and Th17 with MSUS findings in RA.
**Methods:** 90 RA patients (1987 ACR criteria) treated with disease-modifying antirheumatic drugs (DMARDs) were included in this prospective cross-sectional study. A blood sample was taken just before clinical and ultrasonographic evaluation. Lymphocytes were isolated and immunophenotyped by flow cytometry to investigate regulatory FoxP3+ T cells and IL-17+ cells. MSUS (MyLab 60, Esaote, Genova, Italy, linear probe 6–18 MHz) was performed consecutively by two ultrassound-trained rheumatologists on the wrists, 2th and 3th metacarpophalangeal and 2th and 3th proximal interphalangeal joints of both hands. GS and pD were searched using a semi-quantitative scale (0–3). Bone erosions were classified as present or absent. The sum of the individual joint scores for GS and pD (score 10) was calculated and used to correlate with clinical and laboratory data. Disease acitivity and disability were measured using Disease Activity Score in 28 joints (DAS28) and Health Assessment Questionnaire (HAQ), respectively. Mann-Whitney test, Kruskal-Wallis test and Spearman correlation coefficient ($r_S$) were used for statistical analysis. Inter-rater agreement was tested using the weighted *kappa* statistic (WKS) and intraclass correlation (ICC).
**Results:** Clinical and demographic features were: mean age, 55.8 ±11 years; female gender, 79%; Caucasians, 84%; positive rheumatoid factor by nephelometry, 63%; median (interquartile range) disease duration 6 (2–13) years; mean ± SD DAS28, 4.28±1.64; mean ± SD HAQ score, 1.11±0.85. WKS for erosions was 1, and ICC for GS- and pD-score10 were 0.964 (95%CI 0.899 to 0.986) and 0.859 (0.646 to 0.941), respectively. There was no significant association of bone erosions, GS- and pD-score10 with peripheral Tregs and Th17 cells ($P>0.25$ for all tests). Tregs but not Th17 cells were significantly associated with DAS28 level of disease activity (figure 1).

**Conclusions:** In this first study addressing MSUS features and lymphocytes subtypes in established RA, data did not support an association of circulating Tregs and Th17 lymphocytes with inflammatory and structural damage findings on MSUS.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1180

## AB0934 BLOOD PRESSURE IS NOT CHANGED BY TOPICAL NSAID – A PILOT CONTINUOUS AUTOMATED BLOOD PRESSURE MONITOR STUDY

M.S. Trandafir, A.M. Nicu, F. Berghea, M. Abobului, R. Ionescu, D. Predeteanu. *Saint Marry Clinical Hospital Bucharest, Bucharest, Romania*

**Background:** Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used by rheumatic patients for both acute and chronic conditions. A certain increase

in blood pressure of 3–5 mmHg seems to be a NSAID class effect. Although the effect appears from the beginning of the treatment, due to his"modest" amplitude, it was largely ignored both by patients and physicians. However, new epidemiological data suggest that such a small increase in BP could produces in USA about 21.000 deaths per year (higher than in case of gastrointestinal deaths produced by the unprotected usage of nonselective NSAID). For the time being we do know that topical and systemic NSAID have similar therapeutic effect on superficial exposed joints (e.g. knee, wrists, elbows etc).
**Objectives:** The aim of the study was to evaluate whether or not the use of topical NSAIDs in rheumatic patients affects blood pressure or pulse rate values.
**Methods:** This was a prospective study which included patients diagnosed with various rheumatic diseases using a continuous Automated BP Monitoring (ABPM): both BP and pulse rate have been continuously recorded for 48 hours at baseline (24 hours without topical NSAID use) and day1 (24 hours with topical NSAID use). Same NSAID (namely Aceclofenac) in same dose was used in all cases. Subjects that changed their concomitant medication have been excluded from the analyses. Daytime (0700–2200), nighttime (2201–0659) and all-day (24h) systolic and diastolic BP along with pulse rate values have been analyzed. Difference between Baseline and Day1 have been tested by using ANOVA and Fisher exact test; a $p<0.05$ was considered significant.
**Results:** 15 subjects have been evaluated between October 2015 to January 2016. The meanSystolic BP varied between 101.75 and 147.9 in Baseline respectively between 103.9 and 132.25 during D1. The mean diastolic BP varied between 55.5 – 88.1 in Baseline and respectively between 56.4–82.5 during D1. Pulse varied between 60.2 and 95.9 in Baseline and respectively 59.3 and 90.2 during Day1. No difference between baseline and Day1 have been identified for Systolic or DiastolicBP, cardiac pulse; same results have been obtained for all-day, nighttime and daytime subanalysis.
**Conclusions:** Although this study has certain limitations our data suggest no significant change in BP or cardiac pulse associated to topic use of NSAID (in our case Aceclofenac). Larger studies should be made to confirm the conclusion of this pilot study.

## AB0935 RHEUMATOLOGISTS AND MUSCULOSKELETAL ULTRASOUND: DISCREPANCY BETWEEN ATTITUDES, DESIRE AND REALITY IN ROUTINE PRACTICE IN SOUTH EAST ENGLAND

A. Grigoriou, P. Kiely. *Rheumatology, St George's Healthcare NHS Foundation Trust, London, United Kingdom*

**Background:** The use of musculoskeletal ultrasound (MSK US) in routine care is expanding. The number of rheumatologists using or seeking to learn the technique is also increasing, though it is unclear how US is being incorporated into routine work practices (RWP).
**Objectives:** This survey sought to gain an insight into the use of MSK US in a region of Southern England.
**Methods:** A questionnaire was designed by the authors to collect information on training, access & service delivery, indications and attitudes towards use of MSK US in RWP. All rheumatology consultants (RC), trainees (RT) and specialist nurses (SN) working in 19 Hospitals (Hs) (4 Medical School Universities, 15 District General) in London South, Kent, Surrey and Sussex regions of England were invited to complete the survey. Data were analysed using simple descriptive and summary statistics.
**Results:** A total of 70 questionnaires (51%) were returned (RC 61%, RT 27%, SN 12%) with at least one response from all 19 Hs.
*Training:* Of the 70 responders (Rs), 42% report having had formal training in the use of US, however only 12% had support for this and 10% have a formal MSK US certificate.
*Access & service delivery:* MSK US scans are most usually performed by radiologists (64%). In 11 Hs there are also US machines in the rheumatology department, of which 8/11 are currently used for routine care. The routine waiting time for a MSK US is up to 6 weeks.
10 of the 29 Rs who have had training (34%) perform US scans themselves. They report greatest confidence scanning the hands (90%), followed by feet (70%) and 20% are confident to scan all joints. US guided injections are given by 50% and US guided synovial biopsies performed by 20%.
The maximum number of joints scanned in one session varies from 5 – 40 joints, taking an average time of 20 minutes per scan.
*Indications:* MSK US are requested for diagnostic purposes by 92%, guided injection by 80%, assessment of treatment response by 52%, research purposes by 8% and 75% request a scan at least 1 – 5 times a week. The proportion of Rs requesting MSK US per disease groups is: Inflammatory Arthritis (IA) >85% and soft tissue 63%.
*Attitudes:* More than 60% of the Rs report that MSK US results often lead to a change in their management plans and that it enhances patients' satisfaction. 82% think it appropriate that RC should perform MSK US scans as part of their RWP. 50% of the RC and 72% of the RT think that proficiency in use of US should be a mandatory part of the rheumatology training curriculum. 51% of the Rs indicated a willingness to learn the technique.
Free text responses revealed concerns about available time and proper training but others commented that MSK US is beneficial in an early IA setting.
**Conclusions:** This cross-sectional, observational, multicentre survey demonstrates widespread use of MSK US by rheumatologists in routine care in the South East Coast region of England. 82% of Rs think it appropriate that RC should perform MSK US in RWP and 57% believe training in this should be a mandatory part of the curriculum. In contrast 42% of Rs have had formal training, but only 14% of them have incorporated MSK US into RWP, the majority relying on radiology colleagues to do the scans. This illustrates a discrepancy between attitudes, desire and reality of MSK US use in routine rheumatological practice.

## AB0936 USEFULNESS OF SALIVARY GLANDS ULTRASONOGRAPHY IN THE DIAGNOSIS OF SJÖGREN SYNDROME

B. Paredes[1], E. De Miguel[1], G. Bonilla[1], A. Pieren[1], C. Plasencia[1], I. Monjo[1], A. Pieren[1], E. Moral[1], C. Tornero[1], A. Rosell[2], E. Ruiz-Bravo[2], E. Martin-Mola[1], A. Balsa[1], E. De Miguel[1]. *[1]Department of Rheumatology; [2]Department of Pathology, Hospital La Paz-IdiPAZ, Madrid, Spain*

**Background:** Sjögren syndrome (SS) is a chronic autoimmune disease characterized by lymphocytic infiltration of the lacrimal and salivary glands resulting in clinical symptoms of keratoconjunctivitis sicca and xerostomia. Recent studies have shown that salivary gland ultrasonography (SGUS) is a valid tool to evaluate the involvement of major salivary glands in SS.
**Objectives:** To assess the utility and accuracy of the USGS for diagnosis of SS.
**Methods:** Single-center experimental study in a cohort of patients with suspected SS in whom a salivary gland biopsy (SGB) would be performed as requested by their usual physician.
SGUS examination of the parotid and submandibular salivary glands was preformed prior to the realization of minor salivary gland biopsy. Changes in the echostructure of the glands were scored according to the scoring system of de Vita et al., which mostly focuses on the inhomogeneity of gland tissue with scores ranging from 0 to 3 (0: homogenous glands, 1: isolated hypoechoic areas, 2: scattered hypoechoic areas with variable size, not uniformly distributed, and/or to multiple punctate or linear non-shadowing densities and 3: large round or confluent hypoechoic areas, and/or to linear densities, and/or to multiple cysts or multiple calcifications). The SGB was considered as Gold standard. The definitive diagnosis of SS was made according to the AECG criteria.
**Results:** From a sample of 24 patients with suspected SS, SGUS was performed in 20 patients before the SGB. All the patients were women with a mean age of 58±14. Eleven patients (46%) fulfilled AECG criteria, 4 (17%) did not met criteria and in 9 of them (37%) was not possible to classify because of insufficient data (at least two unregistered criteria). Eleven patients (55%) had a normal SGUS while 9 (45%) had some degree of changes in the gland's echostructure.
In the group of patients who met AECG criteria, four (36%) had a negative biopsy, four (36%) positive biopsy and 3 (28%) had nonspecific biopsy. Of the 9 patients with an uncertain diagnosis for lack of data, 7 (78%) had a nonspecific biopsy. 5 patients (56%) with changes in the SGUS met AECG criteria. Of the 6 patients with positive biopsy for SS, 4 (67%) had ultrasound abnormalities. Of the 7 patients with pathological salivary scintigraphy, 5 (71%) had alterations in USGS. Taking biopsy as the gold standard, the sensitivity of the SGUS was 100%, specificity was 68.75%, PPV 44.4% and NPV of 100%; the sensitivity of scintigraphy was 80%, specificity was 44%, PPV 44% and NPV 44%. Considering the scintigraphy as the gold standard, sensitivity of ultrasound was 71.4%, specificity was 100%, PPV 100% and NPV 60%. As limitations of this study is important to remark that these are preliminary results from a small sample in early stages of the disease.
**Conclusions:** Our findings suggest the potential of SGUS as a diagnostic tool for distinguishing SS. Although data is preliminary we found high sensitivity and NPV of SGUS compared to biopsy and high specificity of SGUS compared to scintigraphy.

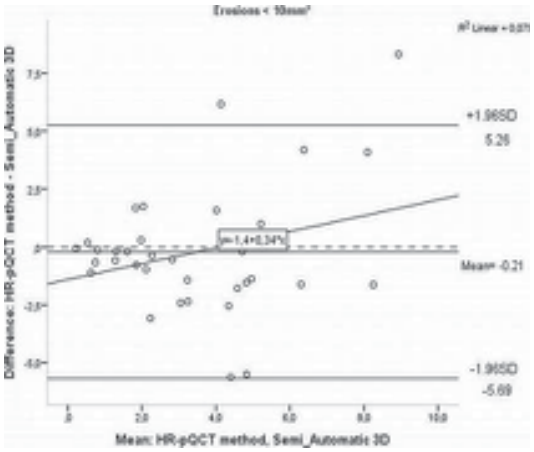
## AB0937 THE COMPARISON OF SYNOVIAL DEGREE INFLAMMATION BETWEEN SYSTEMIC SCLEROSIS AND RHEUMATOID ARTHRITIS BY MAGNETIC RESONANCE IMAGING OF HANDS



B.N. Stamenkovic[1], A.M. Stankovic[2], J.M. Nedovic[1], S.K. Stojanovic[1], V. Zivkovic[1], S.B. Milenkovic[1], I. Aleksic[1], N. Damjanov[3]. *[1]Rheumatology, Institute for treatment and rehabilitation Niska Banja, Medical Faculty of Nis, Serbia; [2]Rheumatology, Intermedica, Nis; [3]Rheumatology, Institute of Rheumatology, Medical Faculty of Belgrade, Belgrade, Serbia*

**Background:** MRI is a usefull tool for assessing subclinical synovial inflammation and joint damage in rheumatic diseases. There are no references clarifying the problem of distinguishing arthritis in systemic sclerosis (SSc) and rheumatoid arthritis (RA) so far
**Objectives:** The aim of our investigation is to compare the degree of inflamatory changes of the hand (bone edema, synovitis, bone erosion and tenosynovitis) in SSc and RA.
**Methods:** 82 SSc pts, mean age 54,5y and 35 RA pts (EULAR/ACR 2010 criteria), mean age 54,3y underwent low field MRI with gadolinium at the dominant hand including wrist and MCP joints 2–5. Assessment of bone marrow edema, synovitis, bone erosions and tenosynovitis was performed by the OMERACT RA MRI scoring system. Images were evaluated independently by two blinded readers. The mean scores of the two readers were analyzed.
**Results:** Anti-citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) were found in 89% and 74,3% of RA pts and 13,4% and 14,6% of SSc pts. Synovitis was more frequently detected on MRI with significantly higher score in RA compared to SSc (wrist:4,37±1,31 vs 2,69±2,29,p<0,001; MCP joints:5,26±2,09 vs 3,15±2,95, p<0, 001). MRI erosion score in the wrist and MCP was significantly higher in RA compared to SSc (wrist:20,57±10,23 vs 6,58±10,89,p<0,001; MCP joints:10,51±7,90 vs 3,99±9,82, p<0,001). MRI bone edema score was also significantly higher in RA compared to SSc (wrist:18,60±5,01 vs 6,84±7,43, p<0,001; MCP joints:9,09±4,27 vs 4,04±4,76, p<0,001).
**Conclusions:** The present data suggest great frequency of inflammatory changes on the hands in SSc and RA using MRI. Inflammation scores were significantly higher in RA compared to SSc. MRI may be helpful in differentiating arthritis in RA and SSc, specially in subclinical inflammation.
**Disclosure of Interest:** None declared

## AB0938 A COMPARISON OF TWO METHODS TO SEGMENT BONE EROSIONS IN THE METACARPOPHALANGEAL JOINTS OF RHEUMATOID ARTHRITIS PATIENTS

C. Figueiredo[1,2], D. Simon[1], F. Stemmler[1], A. Weissenfels[3], D. Weishaeupl[3], O. Museyko[3], A. Friedberger[3], J. Rech[1], A.J. Hueber[1], J. Haschka[4], G. Schett[1], K. Engelke[3], A. Kleyer[1]. *[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [2]Bone Metabolism Laboratory, Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [3]Institute of Medical Physics (IMP), Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [4]Medical Department II, The VINFORCE Study Group, St. Vincent Hospital, Vienna, Austria*

**Background:** Bone erosions are a central feature of rheumatoid arthritis (RA). In particular small erosions not yet detectable on radiographs or even MRI, but already well depicted in high-resolution quantitative computed tomography (HR-pQCT) are a sign for early RA and may guide intervention before major bone destruction and functional impairment.
**Objectives:** To compare standard segmentation tools implemented on the HR-pQCT scanner (XCT) with MIAF (Medical Image Analysis Framework) software in their ability to quantify erosion shape and size in metacarpophalangeal (MCP) joints. MIAF runs on external PCs and requires DICOM export of XtremeCT images.
**Methods:** 2D threshold based contouring of bone is a standard feature of the XtremeCT software to segment the distal radius and tibia. These contouring algorithms along with the manual editing options were applied to segment erosions of MCP joints. In contrast MIAF uses more sophisticated 3D algorithms to separately segment periosteal bone surface and erosions. In particular the cortical break and (for larger erosions) the border between bone marrow and erosion can be better defined. HR-pQCT scans of the 2nd and 3rd MCP joints of ACPA positive RA patients, which represent a homogeneous subgroup with high level structural damage, were analyzed. Based on volume, erosions were categorized into 2 groups: $<10mm^3$ (MIAF measurement) and $>10mm^3$. Based on their shape, they also were visually classified into “regular” or “Irregular”. This classification was compared with sphericity (0–1), which can be obtained with MIAF but not with XCT.
**Results:** 76 erosions of 65 (46F; 19M) patients were analyzed. Irregular erosions were larger ($>10mm^3$) than regular erosions ($\chi(1)^2$=20.52, p<0.001). Irregular erosions had lower sphericity (0.53±0.08); than regular ones (0.63±0.09, $t_{(74)}$= -4.645, p<0.001). Irregular erosions were considered smaller in MIAF than XCT (49.9±70.7 vs. 52.2±79.4; p=0.013), while regular erosions were larger than for XCT (7.0±9.4 vs. 4.0±4.5; p=0.002). There was a 47% absolute difference in size between MIAF and XCT. The differences could be largely explained over-segmentation of irregular erosions and under-segmentation of regular erosions in the XCT. The main reason was the under-segmentation of the cortical break.

**Conclusions:** Standard tools implemented on XtremeCT scanners can be applied for measurement of erosion size but compared to MIAF the segmentation of the cortical break is less accurate resulting in differences in the determination of erosion volume. MIAF performs a separate bone and erosion segmentation, avoiding under/overestimating volume. The visual classification of erosions according to their shape could be useful to infer the amount of bone damage in RA patients but an operator independent quantitative parameter such as sphericity may be preferable as precision will likely increase.

## AB0939 SHOULDER PAIN ACCORDING TO TIME OF ONSET OF SYMPTOMS: AN ULTRASONOGRAPHIC FEATURES COMPARISON

C.A. Guillen-Astete[1], G. Silvestre-Egea[2], M. Villarejo-Botija[1], A. Boteanu[1]. *[1]Rheumatology Department; [2]Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** Ultrasonographic features in shoulder pain have been extensively described in many series. Most epidemiological studies have focused on ultrasonographic findings without considering time of onset of symptoms. In our experience with patients with shoulder pain of recent onset (less than a week) we find ultrasonographic features which proportions are discordant with global epidemiological data especially in terms of prevalence of subacromial bursitis and supraspinatus tendinosis.
**Objectives:** To describe and compare ultrasonographic findings on patients with shoulder pain who consulted to our emergency department and underwent an ultrasonographic shoulder assessment.
**Methods:** The registries of the musculoskeletal and rheumatologic urgencies unit of our A&E department, from 2013 to 2015 were consulted. The known ratio of ultrasonographic assessment of our unit is close to 95% of all shoulder pain cases. Two rheumatologists with full ultrasonographic training and at least 3 years of experience performed the studies following Eular shoulder ultrasonographic definitions. Findings were grouped according to time of onset of symptoms using an arbitrary definition of hyperacute (<7 days), acute (1 to 6 weeks) and chronic (>6 weeks) of shoulder pain.
**Results:** 474 registries of shoulder ultrasonographic assessments were reviewed. Average age of patients was 59 SD 17 years old. Male proportion was 67%. Global findings showed that supraspinatus tendon was affected in 86.7% of all records, while subscapularis tendon in 26.8% and biceps tendon in 11.8%. 67, 47 and 20 registries were classified as hyperacute, acute and chronic shoulder pain, respectively. 38.6% of all supraspinatus tendinosis was present in hyperacute, 25.1% in acute and 36.3% in chronic shoulder pain. 50% of all subacromial bursitis detected were present in hyperacute shoulders, 35.1% in acute and 14.9% in chronic shoulder pain. 34.2% of all supraspinatus tears were present in hyperacute shoulders, 47.4% in acute and 18.4% in chronic

| Ultrasonographic shoulder findings | Time since onset of symptoms: Less than a week | | 1 to 6 weeks | | More than 6 weeks | |
|---|---|---|---|---|---|---|
| | N | Row N % | N | Row N % | N | Row N % |
| Subacromial bursitis | 67 | 50.0 | 47 | 35.1 | 20 | 14.9 |
| Supraspinatus tendinosis[a] | 103 | 38.6 | 67 | 25.1 | 97 | 36.3 |
| Supraspinatus tear | 52 | 34.2 | 72 | 47.4 | 28 | 18.4 |
| Supraspinatus calcification | 8 | 12.7 | 20 | 31.7 | 35 | 55.6 |
| Subscapularis tendinosis[b] | 28 | 70.0 | 12 | 30 | - | - |
| Subscapularis tear | 8 | 66.7 | 4 | 33.3 | - | - |
| Bicipital tendinosis | 8 | 22.2 | 16 | 44.4 | 12 | 33.3 |
| Bicipital synovitis | 8 | 40.0 | 4 | 20.0 | 8 | 40.0 |
| Bicipital tear | 4 | 50.0 | 4 | 50.0 | - | - |

[a] Excluding calcificant tendinosis.
[b] Including a single case of calcificant tendinosis.

shoulder pain. 70% of all subscapularis tendinosis were present in hyperacute and 30% in acute shoulders. 12.7% of all subscapularis calcifications were present in hyperacute shoulders, 31.7% in acute and 55.6% in chronic shoulders. All of these distributions had differences statistically significant. Supraspinatus calcification distribution was not statistically different in the three groups.
**Conclusions:** Subacromial bursitis and subscapularis tendinosis seems to be the most frequent finding in patients with hyperacute shoulder pain. Our results, in patients with less than a week of symptoms, do not agree with most epidemiological ultrasonographic studies of the shoulder. It is possible that differences could be explained by the fact that most studies have not been performed in patients with hyperacute shoulder pain. In our opinion, a better comprehension of shoulder ultrasonographic features in shoulder pain should be linked to the time of onset of symptoms.

## AB0940 COMPARISON OF US7 AND US10 RISK SCORES IN EARLY INFLAMMATORY ARTHRITIS (EIA)

C. Rawlings, R. Davies, E. Choy. *Division of Infection and Immunity, Cardiff University, Cardiff, United Kingdom*

**Background:** Ultrasound (US) can anticipate joint damage better than DAS28 [1], correlates well with MRI [2] and can be of value determining persistence of EIA [3].
US scoring systems aim to standardise risk assessment. US10 risk score showed clinical utility in predicting benefit from early biologic therapy [4]. The US7 score reflects arthritis therapeutic response [5]. No study has directly compared these US scores.
**Objectives:** Compare measurement performance of US7 and US10 scores in assessing EIA.
**Methods:** 32 EIA patients were examined by 2 trained musculoskeletal US Rheumatologists. 52 DAS28 scores and US7/US10 risk assessments were completed. Inter-observer variability was assessed by intraclass correlation coefficient (ICC). Criterion validity assessed by Pearson correlation with DAS28.
**Results:** Mean age 57 (SD=14), 24/32 (75%) female, 28/32 (87.5%) anti-CCP positive, 27/32 (84%) RF positive. Inter-observer variability (ICC) for US10 and US7 were 0.57 ($P<0.0001$) and 0.73 ($P<0.0001$) respectively. DAS28 correlation with US7 (r=0.335, P=0.018) and US10 (r=0.095, P=0.514). US7 and US10 correlated with swollen joint count (r=0.499, P=0.000) and (r=0.368, P=0.006). The addition of wrist US improved DAS28 correlation with US10 (r=0.255, p=0.077).

Table 1. Correlation coefficient between US7/US10 and DAS28

| Risk score | P value | Correlation coefficient with DAS28 |
|---|---|---|
| US7 | 0.018 | 0.335 |
| US10 | 0.514 | 0.095 |
| US10 with wrist | 0.077 | 0.255 |

**Conclusions:** Inter-observer variability is moderate to good with US7 and US10. US7 and US10 correlates with SJC. US7 score in comparison with US10, correlates with the DAS28. Addition of wrist US score to US10 improved correlation with DAS28. This could be a more time effective method to stratify patients if feet assessment is not feasible.

## AB0941 SYSTEMATIC LITERATURE REVIEW OF ULTRASOUND IN LARGE VESSEL VASCULITIS FOR ESTABLISHING OMERACT DEFINITIONS

C. Duftner[1], C. Dejaco[2], A. Iagnocco[3], W.A. Schmidt[4] on behalf of OMERACT US Large Vessel Vasculitis Group. *[1]Department of Internal Medicine, Clinical Division of Internal Medicine VI, Medical University Innsbruck, Innsbruck; [2]Department of Rheumatology, Medical University Graz, Graz, Austria; [3]Department of Rheumatology, Sapienza Università di Roma, Rome, Italy; [4]Medical Centre for Rheumatology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin, Germany*

**Background:** Ultrasound (US) is increasingly used for the diagnosis of large vessel vasculitis (LVV), as this imaging technique enables the visualization of the inflammatory vessel wall swelling. A consensus about the definition of US lesions for diagnosis of LVV has not yet been accomplished.
**Objectives:** 1) To identify definitions of US lesions in LVV; 2) to evaluate the role of US in monitoring disease response; and 3) to assess the value of identified US lesions for diagnosis of LVV.
**Methods:** A systematic literature search was conducted in PubMed, Embase and the Cochrane Library (till 23rd November 2014). Research articles enrolling at least 20 patients with suspected cranial giant cell arteritis (GCA) or large-vessel GCA (LV-GCA), Takayasu arteritis (TAK), published in English or German were selected. The study design, subjects, methods, imaging protocols and diagnostic values were evaluated, as well as the US definitions of vasculitis. The quality of the included studies was assessed by the QUADAS2 tool.
**Results:** Of 2960 articles identified, 34 studies were included in the review for the extraction of definitions of vasculitis in US. Thirty-two reports addressed the role of US in diagnosis of cranial GCA, whereas only 6 studies evaluated US in the settings of LV-GCA. The role of US in disease monitoring was evaluated in 11 articles on cranial GCA and in 2 articles on LV-GCA. No studies assessing the role of US in TAK fulfilled the inclusion criteria. Most studies investigated the value of the "halo sign" (32 articles), whereas "compression sign", "stenosis", "occlusion" or "decreased vessel wall pulsation" as signs of vasculitis were addressed in 1, 22, 19, and 1 paper(s), respectively.
**Conclusions:** US is a valuable diagnostic tool in patients with suspected GCA. In this systematic literature review we identified "halo sign", "stenosis", "occlusion", "compression sign" and a "decreased vessel wall pulsation" as possible key US lesions for vasculitis. Based on these results future research on the role of US in LVV is now being performed by the OMERACT US group.

## AB0942 DIAGNOSTIC VALUE OF ANTI-RA33 ANTIBODY IN COMPARISON WITH ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODIES AND RHEUMATOID FACTOR IN PATIENTS WITH EARLY ARTHRITIS AND INDIVIDUALS WITH FIRST-DEGREE RELATIVES OF PATIENTS WITH RA

S. Giraldo[1,2], C. Romero-Sanchez[1,2,3], D.M. Castillo[3], D. Gordillo[4], W. Bautista-Molano[2], J.M. Bello-Gualtero[1,2], L. Chila M[3], R. Valle-Oñate[1,2] on behalf of Hospital Militar Central - Unit of Oral Basic Investigation. *[1]Department of Rheumatology and Immunology, Hospital Militar Central; [2]School of Medicine, Universidad Militar Nueva Granada; [3]Unit of Oral Basic Investigation, Universidad El Bosque; [4]Faculty of Health Sciences, Universidad Colegio Mayor de Cundinamarca, Bogota, Colombia*

**Background:** Rheumatoid Arthritis (RA) is an inflammatory autoimmune disease characterized by joint involvement, pain and inflammation with or without extra-articular joint commitment. Serological markers can guide early diagnosis before that clinical activity takes place, optimizing early diagnosis, less activity and functional disability. RA 33 is considered a diagnosis-marker in RA patients related to prognosis and therapeutic response compared with conventional markers. RA 33 is common in patients with negative conventional markers and with few clinical symptoms.
**Objectives:** Evaluated the frecuency of RA33 in individuals with first-degree relatives of patients with RA and patients diagnosed with early rheumatoid arthritis as a good prognosis marker
**Methods:** A transversal study was conducted evaluated rheumatologic and periodontal condition of 112 individuals with first-degree relatives of patients with RA and 46 patients diagnosed with early rheumatoid arthritis, according to classification criteria for RA (ACR-EULAR 2010). In addition, 47 healthy individuals were included. RA patients and control group were matched for age and gender. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), rheumatoid factor RF, ACPAs, and RA 33 were performed. VAS Pain Scale, SDAI Index, HAQ and DAS28 were evaluated. *Porphyromona gingivalis (Pg)* by CRP, IgG1, and IgG2 were determined. The data included in the study were analyzed using STATA 11.1. Associations were determined by the statistical test Chi 2, and Comparisons between groups of rheumatologic diagnosis and median values for continuous variables was performed using Mann-Whitney Test. Approved by the Ethics Committee of the Institution.
**Results:** 112 healthy individuals with first-degree relatives of patients with RA were assessed. Of them 78.3% has periodontal disease, presence of painful joints (30.63%). 36.94% patients had *Pg* in subgingival plaque samples. In the control

group the presence of periodontal disease was 71.74%, tender joints (19.57%), swollen joints (6.52%). Disease activity measures were not representative. Only a woman in the group of family related RA patients was positive for RA 33 (49 years old, without treatment, painful and swollen joints and the presence of periodontal disease and *Pg*, ESR and CRP positives but RF and ACPAs negative). No patient with RA of less than two years of diagnosis was positive for RA 33.

**Conclusions:** The diagnostic value of anti RA33 was low in this population, with regard of worst prognosis markers and higher disease severity. Ra33 should be more follow-up clinical and paraclinical to subjects with risk factors who could have positive markers, without symptoms.

## AB0943 RELIABILITY OF MUSCULOSKELETAL ULTRASOUND TO DETECT ELEMENTARY LESIONS IN JUVENILE IDIOPATHIC ARTHRITIS

C. Hernández Díaz[1], L. Ventura-Ríos[1], L. De la Cruz Becerra[2], L. Barzola[3], A. Rodríguez García[4], G. Sanchez Bringas[5], E. Faugier[4], J. Roth[6].

*[1]Laboratorio de Ultrasonido Musculoesquelético y Articular, Instituto Nacional de Rehabilitación, Distrito Federal; [2]Servicio de Reumatología, Hospital Universitario "Dr. José Eleuterio González", Monterrey, Mexico; [3]Servicio de Reumatología, Hospital de Niños Ricardo Gutiérrez, Buenos Aires, Argentina; [4]Servicio de Reumatología, Hospital Infantil de México; [5]Servicio de Columna, Instituto Nacional de Rehabilitación, Distrito Federal, Mexico; [6]Rheumatology Department, Children's Hospital of Eastern Ontario, University of Ottawa, Ontario, Canada*

**Background:** Clinical evaluation has limitations to detect inflammation in JIA. Musculoskeletal ultrasonography (MSKUS) is a useful tool to detect inflammation in various arthropathies, but in children has not been validated for detection of elementary lesions such as synovitis [effusion (SE) and synovial hypertrophy (SH)], erosions, tenosynovitis (TNS) and cartilage damage.

**Objectives:** To evaluate the reliability of MSKUS to detect carpal and metacarpal joint synovitis in patients with JIA.

**Methods:** Seven patients with JIA diagnose according to ILAR criteria were included; they were evaluated by MSKUS for 5 ultrasonographers to evaluate synovitis, erosions, TNS and cartilage in the carpal joint, 2nd and 3rd metacarpophalangeal joints bilaterally; in 2 rounds in one day. Intra- and interobserver variability was established with Cohen's kappa, according to Landis and Koch classification.

**Results:** The mean age of the children was 9 years old; disease duration of 5 years. The inter-observer DS, HS, TNS and erosions agreement was good to excellent (k=.88 0.5889–1.0 95%, p=0.0000) and moderate for cartilage (k=0.43, 95% CI 0.0545 to 0.8964, p=0). The intra-observer variability was good (0.71, IC95% from 0.591 to 0.8498, p=0.0000).

**Conclusions:** The US is reliable for assessing the presence of synovitis, tenosynovitis, erosion and cartilage in hands, in patients with JIA.

**Disclosure of Interest:** None declared

## AB0944 AUTOMATING EVALUATION OF SALIVARY GLAND ULTRASOUND IMAGES IN PSS PATIENTS USING THE SCATTERED TRANSFORM ALGORITHM – A PILOT STUDY

D.S. Hammenfors[1,2], P.G. Nes[3], V. Milic[4], K. Delli[5], B. Hofauer[6], C. Baldini[7], V. Devauchelle-Pensec[8], E. Theander[9], J.G. Brun[1], M.V. Jonsson[10].

*[1]Department of Rheumatology, Haukeland University Hospital; [2]Broegelmann Research Laboratory, Department of Clinical Science, University of Bergen, Bergen; [3]Department of Mathemathics, Sogn and Fjordane University College, Førde, Norway; [4]Department of Rheumatology, University of Belgrade, Belgrade, Serbia; [5]Department of Oral and Maxillofacial Surgery, University of Groningen, Groningen, Netherlands; [6]Department of Otorhinolaryngology/Head and Neck Surgery, Technical University Munich, Munich, Germany; [7]Department of Rheumatology, University of Pisa, Pisa, Italy; [8]Centre Hospitalier Universitare de Brest, Brest, France; [9]Department of Rheumatology, Malmö University Hospital, Malmö, Sweden; [10]Department of Clinical Dentistry, University of Bergen, Bergen, Norway*

**Background:** Primary Sjögren's syndrome (pSS) is an autoimmune inflammatory disease predominantly affecting the salivary and lacrimal glands. The main symptoms are dryness of the mouth and eyes. The diagnosis of pSS is based on 6 items according to the American-European consensus group (AECG) classification criteria. Interest regarding ultrasonography (US) as a diagnostic tool for pSS has increased over the last years. However, the applied scoring-systems vary and as of yet international consensus on how to perform the evaluation are lacking. Consequently, the examination and evaluation depends on the examiners skill and experience. In both clinical work and a scientific setting there is a need to use objective methods with as little inter- and intra-examiner variation as possible.

**Objectives:** The aim of this study was to develop a software able to analyze changes in digitally stored US images of the major salivary glands.

**Methods:** Digitally stored US images of glandula parotis (n=94) were blindly evaluated and scored as "normal" or "SS-like" by three independent clinical researchers. At least 2/3 evaluations had to be in agreement to classify the image. All images were from patients fulfilling the AECG criteria. Images had been obtained by six clinical investigators using similar protocols on different US machines. For the analysis, images were divided into databases of SS-like changes and normal-appearing morphology. The image classification and analysis was performed using the ScatNet (v.02) algorithm (Ref: http://www.di.ens.fr/data/software/) for MatLab, which is an algorithm for advanced pattern recognition. Images from the databases were randomly selected to be used as either "training" images or "test" images. Each database of "training" images was analysed, and features of pathological and non-pathological morphology were identified by the software. For the software test, the algorithm analyses which of the databases of training images are most similar to the test images and decides in which group the test images belong. This selection was then compared to the manual scoring.

**Results:** Out of the 94 images evaluated, 40 were classified as normal-appearing and 54 as corresponding to SS-like pathological changes. In the preliminary simulations we have used the following training: test ratios 84:10 (90%), 70:24 (75%) and 47:47 (50%), to respectively train the classification algorithm, and then test the algorithm. The best result with 9/10 correctly classified (92% accuracy) was obtained using 90% of the images to train the software and 10% to test the software. Using 75% or 50% of the images to train the software, the accuracy was reduced to 21/24 (88%) and 25/36 (78%), respectively.

**Conclusions:** Preliminary results indicate that the success rate of the algorithm is closely dependent on the number of images used to train the algorithm. The results are promising and indicate possible clinical use in the evaluation of SGUS images. We will further focus on expanding the image database to achieve more precise results.

## AB0945 AN ATLAS BASED AUTOMATIC SEGMENTATION OF THE HUMAN THIGH MUSCLES: A PROMISING APPROACH FOR MUSCLE VOLUME QUANTIFICATION IN LONGITUDINAL STUDIES

A. Le Troter[1], A. Fouré[1], M. Guye[1], S. Confort-Gouny[1], J.-P. Mattei[2], S. Guis[2], J. Gondin[1], E. Salort-Campana[3], D. Bendahan[1]. *[1]CRMBM/CEMEREM CNRS UMR 7339; [2]CRMBM/CEMEREM CNRS UMR 7339, Department of Rheumatology 1, Aix-Marseille University; [3]Department of Neurology, Aix-Marseille University, AP-HM, Marseille, France*

**Background:** Atlas segmentation is a powerful method for automatic structural segmentation of several sub-structures in many organs. However, so far, very few studies have assessed this method for skeletal muscle segmentation.

**Objectives:** In this study, we present an atlas-based pipeline we have developed for segmentation of quadriceps muscles from magnetic resonance images obtained in twenty five young healthy males and illustrate the potential of this approach for a longitudinal follow-up in a group of 7 subjects.

**Methods:** T1-weighted axial MR images from the thigh were recorded once in a group of 25 subjects (G1) and twice (a few days apart) in another group of 7 subjects (G2). The multi-atlas library was built from G1. In order to do so, MR images were initially automatically segmented for bone, muscle and fat tissues and each muscle of the thigh anterior compartment was manually delineated. The same process was applied to G2 in order to obtain the ground-truth set of images. Then each MRI dataset from G1 was registered to each MRI dataset of G2 using a non-linear registration process. An optimal fusion method was then used applied in order to obtain the highest DICE index, a similarity index between the atlas-based manual segmentation and the ground-truth set of images. A single-atlas version of the pipeline was used without the fusion process and a similar validation was performed for a longitudinal follow-up study.

**Results:** In control subjects, the results for each quadriceps muscle show a mean DICE similarity coefficient higher than 0.85. While the multi-atlas pipeline did not provide sensitive enough for muscle volume quantification, the single-atlas version proved to be far better.

**Conclusions:** In the present study we reported two segmentation pipelines based on atlases. The examples provided in a control population demonstrated a robust method which could be useful for muscle quantification in the fields of neuromuscular disorders, sports medicine and rehabilitation.

## AB0946 S100A8 BUT NOT S100A9 LEVEL IS RELATED TO THE EXTENT OF EROSIVE BONE DAMAGE IN PSORIATIC ARTHRITIS PATIENTS

D. Simon[1], K. Nas[2], F. Faustini[3], A. Kleyer[1], J. Haschka[1,4], M. Englbrecht[1], A.J. Hueber[1], R. Kocijan[4], M. Sticherling[5], G. Schett[1], J. Rech[1]. *[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [2]Division of Rheumatology, Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Sakarya University, Sakarya, Turkey; [3]Department of Medicine, ClinTRID, The Karolinska Institute, Stockholm, Sweden; [4]Medical Department II, The VINFORCE Study Group, St. Vincent Hospital, Vienna, Austria; [5]Department of Dermatology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany*

**Background:** Psoriasis and psoriasis arthritis are associated with bone damage [1–3]. However, little is known about markers associated with structural bone damage in patients with psoriasis (PsO) and psoriasis arthritis (PsA). C-reactive protein is of limited use in PsO and PsA and therefore development of new markers is needed to identify patients with higher level structural bone damage. The calcium-binding proteins S100A8 and S100A9, which are predominantly produced by myeloid cells and elevated in certain forms of inflammatory diseases are interesting candidates.
**Objectives:** To analyse whether S100A8 and S100A9 serum levels are related to structural bone damage in patients with PsO and PsA.
**Methods:** Both PsO and PsA patients (according to the CASPAR criteria) were analysed. Demographic and disease-specific variables were recorded. Bone architecture was assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT, Scanco, Switzerland) of the metacarpal heads 2 and 3. Number and size of bone erosions were quantified as described previously [1]. Levels of S100A8 and S100A9 were measured by enzyme-linked immunosorbent test. Serum markers were correlated to the extent (volume) of bone erosions, respectively using Spearmans correlation.
**Results:** 94 patients were included into this combined imaging and serum analysis, 42 of them had PsO (18 female, mean age 48.4±12.8 years) and 52 had PsA (29 female, age 48.3±14.8 years). Duration of skin disease was 14.7±16.1 years in PsO and 13.3±13.6 years in PsA. Duration of joint disease in PsA was 4.6±5.9 years. Mean time between blood collection and HR-pQCT measurement was 0.3±1.7 days (maximum 10 days). Mean±SD S100A8 level was 11.8±15.3 ng/ml in PsO patients and 12.8±13.8 ng/ml in PsA, while mean ±SD S100A9 level was 66.8±51.1 ng/ml in PsO and 75.9±58.3 ng/ml in PsA. Mean±SD erosion volume was 0.7±1.8 $mm^3$ in PsO patients and as high as 2.2±3.6 $mm^3$ in PsA. Serum levels of S100A8 were significantly correlated to erosion volumes ($\rho$=0.327 (p=0.019)) in PsA but not in PSO. No significant correlation for S100A9 was found.
**Conclusions:** S100A8 but not S100A9 level is significantly correlated to the extent of structural bone damage in patients with PsA. Hence, S100A8 may emerge as an interesting biomarker for determining the severity of psoriatic disease, especially the extent of structural bone damage.

## AB0947 THE ROLE OF MUSCULOSKELETAL ULTRASOUND IN MANAGING SYSTEMIC LUPUS ERYTHEMATOSOUS AND SJOGREN'S SYNDROME IN A REAL LIFE CLINIC

E. Ntatsaki[1], B. Gracia-Tello[2], C. Ciurtin[1]. *[1]Rheumatology, University College London, London, United Kingdom; [2]Rheumatology, Internal Medicine. Lozano Blesa Universitary Hospital, Zaragoza, Spain*

**Background:** Musculoskeletal Ultrasound Assessment (US) is increasingly used as a valid and reliable tool for guiding the management of inflammatory arthritides. However its use in Systemic Lupus Erythematosous (SLE) and Sjogren's Syndrome (SS) in clinical practice remains limited[1], thus potentially missing an opportunity to appreciate severity of joint involvement and optimise management[2].
**Objectives:** To analyse a real life cohort of SLE and SS patients referred for US assessment on clinical grounds, to review their characteristics and whether US assessment led to a change in treatment.
**Methods:** Retrospective analysis of real life data from a dedicated rheumatology US clinic at a tertiary referral hospital. The OMERACT scoring system was used for the US examination of 22 hand joints in every patient (wrists, metacarpophalangeal and proximal interphalangeal (PIP) joints bilaterally).
**Results:** Over a 2 year period (01/2014–12/2015) a total of 604 patients were scanned including 19 with SLE and 17 with SS. Patient characteristics and differences between their US outcomes are shown in table 1. US assessment prompted treatment change in 84% of SLE patients and 82% of SS cohort. ESR showed a better association with swollen joint count in SS (r=0.29) than SLE (r=0.17), however this did not reach statistical significance. A subanalysis of the SLE cohort showed poor correlation of the MSK BILAG items scores with active joint disease defined as PD presence on US (r=0.189, p=0.5).

Table 1. Patient characteristics and US features

| Patients characteristics and US features | | SJögren | SLE | Significance |
|---|---|---|---|---|
| Age at scan | | 56 | 47 | p=0.03** |
| Gender | Male/female | 0/17 | 0/19 | NS |
| Duration of symptoms (years) | | 12.5 | 14.6 | NS |
| ANAs | | 29.4% | 76.5% | p=0.006** |
| dsDNA | | 11.8% | 33.3% | NS |
| ENAs | | 70.6% | 70.6% | NS |
| ESR (mm/h) | | 22.47 | 29.29 | NS |
| CRP (mg/L) | | 3.7 | 3.5 | NS |
| Mean number of joints with power Doppler (PD) | | 0.18 | 2.06 | p=0.013** |
| Mean number of joint with synovial hypertrophy | (Grade 2) | 0.47 | 4.32 | p=0.002** |
| Mean number of joints with erosions | | 2.18 | 3.44 | NS |
| Mean number of joints with effusions | | 0.47 | 1.06 | NS |
| Mean number of joints with osteophytes | | 2.24 | 3.11 | NS |
| Swollen Joint Count | PD negative | 1.75 | 2.14 | NS |
| | PD positive | 1.41 | 4.29 | NS |
| PIP involvement | | 5.9% | 52.6% | p=0.02** |
| Tendon abnormalities | | 5,9% | 15,8% | NS |
| Treatment | HCQ | 47.1% | 68.4% | NS |
| | Prednisolone | 5.9% | 52.6% | p=0.003** |

NS = non-significant.

**Conclusions:** US assessment led to significant change in management for both cohorts. The SLE group had more active disease on US than SS, despite similar swollen joint count and increased prednisolone. There was poor correlation of US disease activity and MSK BILAG in SLE patients, suggesting that US can provide additional information in identifying active joint disease. US proves a useful and reliable tool to monitor musculoskeletal features and therapeutic outcomes in both SLE and SS patients that can be used routinely in real life clinical practice.

## AB0948 SIGNAL PEPTIDE-CUB-EGF DOMAIN-CONTAINING PROTEIN (SCUBE); A NOVEL MARKER IN RELATION WITH ANJIOGENESIS IN RHEUMATOID ARTHRITIS?

E. Capkin[1], M. Arslan[2], A. Mentese[2], M. Karkucak[2], S. Özer Yaman[3], N. Cilesizoglu[2], D. Altay[2]. *[1]Pm&r and Rheumatology; [2]Karadeniz Technical University, Trabzon; [3]Biochemistry, Karadeniz Technical University, Trabzon, Turkey*

**Background:** Rheumatoid Arthritis (RA) is a multifactorial, systemic, progressive, inflammatory disease which is characterized with bone and cartilage destruction. Synovial angiogenesis is important at the etiopathology. Recently with the better understanding of RA pathogenesis, the target specific treatment approaches come up with better results.
**Objectives:** The purpose is to study levels of newly identified plasma signal peptide-CUP-EGF domain containing protein (SCUBE) 1and 3 in RA patients. Moreover, to determine whether there exists any correlation between these proteins, other angiogenesis parameters and disease activities
**Methods:** This study covers 106 patients diagnosed with RA associated with 2010 American Collage of Rheumatology (ACR) diagnosis criteria matched with healthy controllers who are equivalent of RA patients in terms of age and gender. All necessary data such as age, gender and body mass index of all participants were recorded. Detailed background information and examination of the patients are recorded and disease activity scores (DAS28) were figured out. The levels of SCUBE 1–3, Vascular Endotedial Growth Factor (VEGF), Matrix metaloproteinaz-9 (MM-9), Interlökin-6 (IL-6), CD40L are evaluated with the method of Enzyme-Linked Immuno-Sorbent Assay (ELISA) in both patients and control group
**Results:** This study covers 201 individuals 106 of whom were diagnosed with RA (82 women, 24 men) and 95 of them were healthy controllers (64 women, 31 men). Age, body mass index (BMI) and gender distribution of both groups were very similar to one another. Significant differences were observed between RA patients and healthy controller groups in terms of SCUBE 1 (respectively1.28±1.41ng/mL, 0.94±0.67ng/mL p=0.002) and CD40L MMP-9 levels ($p<0.001$, p=0.012). Any significant difference was not detected between disease activity and SCUBE 1–3 and other angiogenesis markers. Any significant correlation was not determined between disease activities, SCUBE 1–3 and other parameters.
**Conclusions:** Levels of SCUBE might be considered as a significant marker in the disease pathogenesis independent from other parameters in the RA diagnosed patients.

## AB0949 ENTHESITIS IN RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS: AN ULTRASOUND STUDY

E. Maman, V. Masson-Behar, B. Coustet, E. Palazzo, P. Dieude, S. Ottaviani.
*Hôpital Bichat, Paris, France*

**Background:** Enthesitis is a common clinical feature of spondyloarthritis (SpA) that could be evaluated by ultrasound (US). Some studies suggested that US assessment of enthesitis might be sensitive and specific of SpA diagnosis. However, others studies found similar prevalence of US enthesitis in rheumatoid arthtitis (RA) and SpA (1) or that US assessment of heels could not differentiate SpA to controls (2).
**Objectives:** We aimed to determine the prevalence of US enthesitis in SpA and RA patient.
**Methods:** In this transversal single center study, we included patient with RA (ACR/EULAR 2010 criteria) and SpA (ASAS criteria). All patients underwent clinical and ultrasonographic evaluation of both upper and lower limbs at seven sites (quadriceps tendon enthesis, proximal and distal patellar tendon enthesis, Achilles tendon enthesis, plantar aponeurosis enthesis, triceps tendon enthesis, lateral epicondyle enthesis). Two US scores were calculated for each patient using the Glasgow Ultrasound Enthesitis Scoring System (GUESS) and the Madrid Sonographic Enthesitis Index (MASEI). US assessment of tendon thickness and structure, bone erosion, bursitis, power Doppler, calcifications and enthesophytes was performed for all patients by a sonographer blinded to clinical data. Demographic and clinical characteristics were collected for each patient.
**Results:** A total of 30 RA (mean age: 45.3±15.4 years old, 17% of male patients, mean disease duration: 10.5±7.9 years) and 41 SpA (mean age: 55.7±14.8 years old, 68% of male patients, mean disease duration: 9.2±8.7 years) patients were analyzed. In SpA patients, 67% of them were HLAB27 positive. ACPA and rheumatoid factor were found in 93% and 83% of RA patients, respectively. Clinical examination found painful enthesis in 98 (17%) of 574 examined sites in SpA patients and in 59 (14%) of 420 sites in RA ($P$=0.2). SpA and RA patients had 2.4 and 1.96 painful enthesis sites per patients, respectively ($P$=0.81). The mean MASEI score was 8.5±7.3 in RA and 7.8±6.5 in SpA patients ($P$=0.87). A MASEI score $\geq$18 was found in 6 (20%) RA patients and in 4 (10%) of SpA patients ($P$=0.22). The mean GUESS score was 5.8±3.1 in RA and 6.3±3.9 in SpA patients ($P$=0.67). At least one enthesis abnormality was found by US in 264 (46%) of 574 sites in SpA patients and in 200 (48%) of 420 sites in RA ($P$=0.61).
**Conclusions:** Our results suggest that entheseal abnormalities are frequent in RA and SpA without difference in the population. We could hypothesize that the US assessed entheseal features have low specificity in inflammatory conditions affecting joints and enthesis as SpA and RA.

## AB0950 LEUCINE-RICH ALPHA-2 GLYCOPROTEIN (LRG) AS A POSSIBLE URINARY MARKER FOR LUPUS NEPHRITIS

H. Lee[1,2], M. Fujimoto[1], Y. Hosono[3], K. Suzuki[4], H. Honda[1,5], H. Urushima[1], T. Ohkawara[1], S. Serada[1], T. Takeuchi[4], T. Mimori[3], T. Naka[1]. *[1]Laboratory of immune signal project, National Institute of Biomedical Innovation, Health and Nutrition; [2]Graduate School of Frontier Biosciences, Osaka University, Osaka, Ibaraki city; [3]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto; [4]Division of Rheumatology, Department of Internal Medicine, School of Medicine, Keio University, Tokyo; [5]Graduate School of Medicine, Osaka University, Osaka, Ibaraki city, Japan*

**Background:** Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE). Its accurate evaluation is dependent on renal biopsy. A search for other non-invasive methods such as urinalysis is warranted. Recently, we identified a novel acute phase protein, LRG[1,2] whose expression is induced at the site of inflammation by various inflammatory cytokines.
**Objectives:** To investigate whether LRG can be a new urinary biomarker of LN.
**Methods:** We determined LRG levels in serum and urine of SLE patients (n=46, M:F=3:43, age: 37.1 (22–66)) with or without LN by ELISA. We divided SLE patients into four groups according to the results of renal biopsy (group 1: no LN [n =19], group 2: LN class 5 [n =3], group 3: LN class 1 or 2 [n =4], group 4: LN class 3 or 4 [n =20] (ISN/RPS)), and analyzed the relationship between urinary LRG levels and renal pathology. Also, we analyzed NZ B/W F1 mice, a lupus model, to study the mechanism of LRG expression in LN. Mouse urinary LRG levels were determined by western blot. Also, we evaluated the expression of LRG and several cytokines in kidney by real-time PCR, immunohistochemistry (IHC) and immunofluorescence (IF). In vitro, we investigated the expression and secretion of LRG in primary tubular epithelial cells (PTEC) obtained from NZ B/W F1.
**Results:** Urinary LRG levels were significantly higher in group 4 patients, and tend to be high in group 2 and 3 patients compared with group 1. In kidney of NZ B/W F1 mice with LN-like alteration, mRNA expression of LRG and IL-1 beta was significantly up-regulated, compared with NZ B/W F1 mice without LN-like alteration and B6 mice. By IHC and IF analysis, LRG protein was detected in renal tubular epithelia of NZ B/W F1 mice with nephritis. Additionally, macrophage infiltration and IL-1beta production was detectable around of the LRG-positive tubules in NZ B/W F1 mice. In vitro, LRG expression and secretion was induced by IL-1beta in PTEC of NZ B/W F1 mice.
**Conclusions:** Urinary LRG may be a useful biomarker which reflects the active inflammation of LN.

## AB0951 ULTRASONOGRAPHIC DIFFERENTIATION BETWEEN PSA AND RA BASED ON FINGER FLEXOR TENDON PULLEY ENTHESEAL COMPLEX

I. Tinazzi[1], P. Macchioni[2], A. Marchetta[1], M. Catanoso[2], D. Mc Gonagle[3]. *[1]Unit of Rheumatology, Ospedale Classificato Equiparato Sacro Cuore – Don Calabria, Negrar (Verona); [2]Unit of Rheumatology, Arciospedale Santa Maria Nuova, Istituto di Ricovero e Cura a Carattere Scientifico, Reggio Emilia, Italy; [3]Muscoloskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom*

**Background:** Both RA and PsA are associated with hand involvement including synovitis and tenosynovitis. Differentiation between RA and PsA can sometimes be impossible using existing serological, genetic and imaging biomarkers.
At the micro anatomical level PsA is strongly linked to disease localisation to entheses and other sites of high mechanical stressing. Recently high resolution MRI has shown prominent abnormalities at the mini-entheses of the flexor tendon pulleys may be common (1).
**Objectives:** This study tested the hypothesis that that mini-entheses disease of the hand including the A1,3, and 5 pulleys and flexor tendon insertion could be used to differentiate between RA and PsA.
**Methods:** 46 cases of seropositive RA and 37 PsA patients were consecutively recruted. Cases were matched for disease duration, age and BMI with the majority being under therapy with conventional DMARDs (table1). Patients underwent completely rheumatological examination (AM, MC) and CRP and ESR determination. US examination was done with ESAOTE MyLabClass equiped with 18–6 linear probe. The 2nd to 4th dominant finger were scanned both on the dorsal and palmar surface. The sonograraphers (IT, PM) were blinded to the clinical details. The following changes were recorded as present (1) or absent (0): tendon flexor tenosynovitis, flexor pseudotensynovitis (peritendinous oedema), bone formation and the DIP flexor tendon insertion enthesophyte or calcifcations. A1, 3 and 5 pulley tendon thickness was measured at the level of maximal thickness in longitudinal or transverse way. The ecogenicity of the pulley was recorded as normal (if anecogen) or abnormal (no complete anecogenicity).
**Results:** Flexor tenosynovitis was evident in 25/108 digits in PsA versus 8/135 in RA ($p<0.001$). Peritendinous oedema was evident in 23/108 PsA digit compared to only 8/135 RA digit ($p<0.001$) despite the fact that the magnitude of tenosynovitis was the same in RA and PsA. The A1, A3 and A5 pulleys were *not* significantly thicker in PsA compared to RA. Flexor tendon enthesopathy as determined by intra tendinous new bone was evident in 78/108 PsA cases, 21/135 RA and 2/30 health control ($p<0.001$ for both comparisons.

Table 1

| | PsA (n=37) | RA (n=46) | HC (n=10) |
|---|---|---|---|
| Age, mean±SD years | 59.2±9.7 | 60.1±11.8 | 55.9±16.9 |
| Women, number (%) | 22 (60) | 33 (72) | 6 (60) |
| BMI, mean, kg/m$^2$ (SD) | 25.0±3.6 | 24.4±3.5 | 23.8±1.7 |
| DAS 28 CRP | 2.9±0.6 | 3.2±0.9 | nd |

**Conclusions:** This study suggests that PsA cases have a much higher burden of abnormalities in the min-entheses of the hand flexor tendons. With the improving resolution and capabilities of MKUS these findings may be relevant for defining the phenotype of joint swelling as RA (synovial centric) or SpA (entheseal like).

## AB0952 SERUM VISFATIN AND RESISTIN, BUT NOT ADIPONECTIN OR LEPTIN, ARE ASSOCIATED WITH ULTRASOUND SYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Hurnakova[1], R. Horvath[2,3,4], K. Danova[3,4], J. Zavada[1], H. Mann[1], L. Palova Jelinkova[3,4], H. Hulejova[1], P. Hanova[1], M. Klein[1], O. Sleglova[1], M. Komarc[5], M. Olejarova[1], S. Forejtova[1], O. Ruzickova[1], R. Spisek[3,4], J. Vencovsky[1], K. Pavelka[1], L. Senolt[1]. *[1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Czech Republic; [2]Department of Pediatric and Adult Rheumatology, University Hospital Motol in Prague, Czech Republic; [3]Department of Immunology, University Hospital Motol and 2nd Faculty of Medicine, Charles University in Prague, Czech Republic; [4]Sotio a.s., Prague, Czech Republic; [5]Department of Methodology, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic*

**Background:** Adipocytokines are soluble mediators secreted by adipose tissue and immune cells with potent immune regulatory functions. Some adipocytokines have been previously associated with disease activity and radiographic progression in patients with rheumatoid arthritis (RA)[1].
**Objectives:** To investigate associations between adipocytokines, clinical and traditional laboratory markers as well as with ultrasound synovitis in patients with RA.
**Methods:** A total of 82 patients with RA (62 females, median disease duration 4.2 years) were enrolled into this study. All patients underwent clinical examination (swollen joint count - SJC, tender joint count – TJC, Disease activity score - DAS28-ESR and DAS28-CRP, Clinical disease activity index - CDAI, Simplified disease activity index - SDAI). Moreover, ultrasound examination of 7 selected joints mostly affected in RA (wrist, second and third metacarpophalangeal and proximal interphalangeal, and second and fifth metatarsophalangeal joints) was performed to measure synovial hypertrophy in Grey Scale (GS) and pathological neovascularization in Power Doppler (PD) using semi-quantitative grading 0–3[3]. Blood samples were taken at the same day as clinical and ultrasound assessments. Serum concentrations of adiponectin, resistin, visfatin, leptin and CRP were measured. Clinical and laboratory measures were correlated with ultrasound findings using Spearman's correlation coefficient.
**Results:** Serum visfatin and resistin levels were associated with the disease activity (Figure 1) and correlated significantly with DAS28-ESR ($r=0.473$, $p<0.001$; $r=0.363$, $p<0.001$, resp.), DAS28-CRP ($r=0.443$, $p<0.001$; $r=0.348$, $p<0.005$, resp.), SDAI ($r=0.431$, $p<0.001$; $r=0.344$, $p<0.005$, resp.), CDAI ($r=0.419$, $p<0.001$, $r=0.344$, $p<0.005$, resp.) and with CRP levels ($r=0.456$, $p<0.001$; $r=0.364$, $p<0.001$, resp.). Moreover, visfatin and resistin levels significantly correlated with GS ($r=0.430$, $p<0.001$, $r=0.273$, $p<0.05$, resp.) and PD synovitis scores ($r=0.309$, $p<0.01$, $r=0.283$, $p=0.01$, resp.). Neither leptin nor adiponectin correlated with parameters of disease activity in patients with RA.

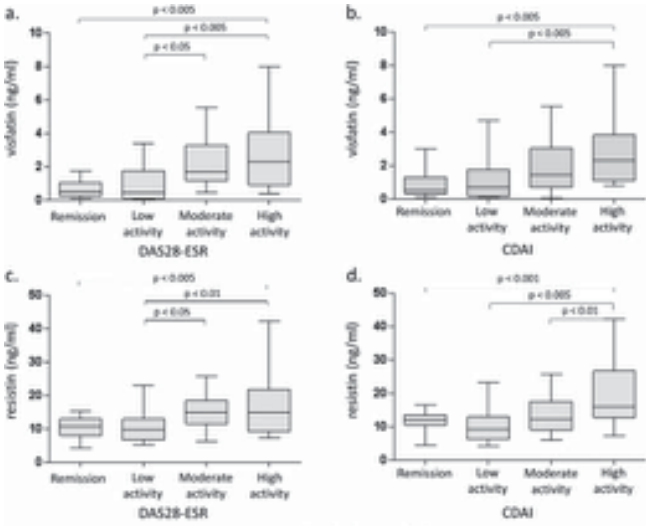

Figure 1. Box plots showing associations between visfatin (a,b), resistin (c,d) and DAS28-ESR and CDAI, respectively

**Conclusions:** Our study supports circulating visfatin and resistin as promising serum pro-inflammatory biomarkers reflecting clinical, laboratory as well as ultrasound parameters of synovial inflammation in RA.

## AB0953 CONTRIBUTION OF ULTRASONOGRAPHY TO ASSESS DISEASE ACTIVITY IN PATIENTS WITH INFLAMMATORY MYOPATHIES

J. Sousa Neves, D. Santos Faria, M. Cerqueira, J.A. Costa, M.C. Afonso, F. Teixeira. *Rheumatology, Hospital Conde de Bertiandos, ULSAM, Ponte de Lima, Portugal*

**Background:** Inflammatory myopathies (IM) comprise a group of rare and heterogeneous diseases, challenging to diagnose, treat and follow-up. Monitoring patients with IM is difficult as there is a lack of precise measures for assessing disease activity. Ultrasonography (US) is a non-invasive, relatively inexpensive technique that is increasingly being used to evaluate muscular system.
**Objectives:** To assess the utility of US evaluation in the monitoring of patients with IM.
**Methods:** Patients diagnosed of IM from 2005 to 2015 followed up at a Rheumatology Department were included. Fourteen patients (11 female) with a mean age of 50.1±21.4 years and mean disease duration of 4.8±3.2 years were evaluated. The different diagnosis were as follows: 6 dermatomyositis (DM), 3 polymyositis (PM), 2 myositis associated with Systemic Lupus Erythematosus, 1 inclusion body myositis (IBM), 1 recurrent focal myositis (RFM) and 1 undifferentiated IM. Physical examination, including muscle strength tests, laboratorial tests (comprising levels of serum muscle enzymes) and a selective muscle US assessment were performed to each patient. For US evaluation a General Electric LOGIQ S8 equipment with a 6–15 MHz linear transducer was used. Muscles were subjectively evaluated for echogenicity (determined by gray-scale) and muscle morphology. Power Doppler (PD) was used to assess vascularity.
**Results:** Nine of the 14 patients evaluated were on clinical remission, with absence of symptoms or signs of disease, preserved muscle strength, normal muscle enzyme levels and conserved muscle pattern on US assessment. One female with DM presented with an acute exacerbation of disease, with proximal muscular weakness of the upper limb and US findings of increased muscle echogenicity of biceps revealing a muscle oedema pattern. The patient with IBM also experienced a flare which was associated with proximal muscle weakness and asthenia; US assessment showed focal oedema through right biceps muscle but also proximal lower limb muscle atrophy characterized by increased echogenicity with diminished volume of the quadriceps compartment and change of normal architecture of tibialis anterior muscle of both legs. These findings are consistent with a long term disease with acute flare. Another patient with longstanding PM in remission revealed no signs or symptoms of active disease, normal muscle strength but low creatine phosphokinase levels and symmetrical proximal muscle atrophy pattern in US evaluation. On the other hand, the patient with shorter duration of disease, recently diagnosed as myositis (undifferentiated IM), revealed proximal weakness and elevated serum muscle enzymes; in this case, US assessment showed diffuse increased echogenicity of proximal muscle compartment and increased PD signal. Finally, the patient with RFM presented with left arm swelling and weakness and US evaluation showed enlargement and diffuse increased echogenicity within the left carpal extensor compartment.
**Conclusions:** US findings in patients with IM seem to correlate well with disease activity suggested by clinical and laboratory data. As a result, US imaging may be a useful tool to assess disease activity and damage in these patients as well as to monitor disease progression.

## AB0954 A NEW ULTRASONOGRAPHY PROTOCOL FOR THE ASSESSMENT OF PRIMARY KNEE OSTEOARTHRITIS

J.L. Gomes[1], A. Sepriano[1,2], S. Falcao[1,2], J. Polido-Pereira[3,4], F. Saraiva[3,4], H. Canhao[3,4], F. Pimentel-Santos[1,2], J.C. Branco[1,2]. *[1]Rheumatology, Hospital Egas Moniz - CHLO, Lisbon; [2]CEDOC, NOVA Medical School - UNL; [3]Rheumatology, Lisbon Academic Medical Center; [4]Rheumatology Research Unit, Instituto de Medicina Molecular, Lisboa, Portugal*

**Background:** There is a lack of adequate outcome measures of treatment response in Knee Osteoarthritis (KOA). The role of Ultrasonography (US) in the management of inflammatory articular and periarticular diseases is well established, but it has been less extensively used in OA.
**Objectives:** To develop a new high-resolution US protocol for the assessment of structural and inflammatory changes in primary KOA and to evaluate its inter-observer reliability.

**Methods:** A scanning protocol was developed by consensus among 3 senior Rheumatologists with similar high levels of experience in musculoskeletal US. The protocol includes both inflammatory elementary lesions (synovitis, power Doppler, Baker's cyst) and structural damage lesions (medial collateral ligament bulging, meniscal lesions and osteophytes) measured as dichotomous variables (present/absent). Cartilage thickness (in millimeters) is assessed at the notch and 10mm towards the lateral and medial condyles (mean value of 3 measurements). The OMERACT definitions for elementary lesions were used whenever available. In addition, global scores were calculated for joint inflammation (range: 0–3) and structural damage (range 0–11). Patients with primary KOA according to the American College of Rheumatology classification criteria underwent Knee US assessment in the same day by the 3 experts using the same device. For dichotomous parameters, Inter-observer agreement was estimated by the free-marginal multirater Kappa and the proportion of agreement (Agt). For continuous parameters two-way mixed effects models were used and absolute-agreement Intraclass Correlation Coefficients (ICC) was measured between individual ratings and global scores.
**Results:** In total, 7 patients were included (14 knees), corresponding to 42 US assessments by the 3 readers. Patients were 6 females and 1 male, with a mean age of 58.6 years. Concerning inflammatory lesions, agreement was good for synovitis $\kappa$=0.714; Agt=85.7%) and Baker cyst $\kappa$=0.714;Agt=85.7%). All power Doppler analysis were negative, thus achieving excellent agreement $\kappa$=1; Agt=100%). As a result, agreement was good for the inflammatory score (ICC: 0.774; 95% CI). Results were not as homogenous for structural damage lesions. In one hand, agreement was excellent for medial meniscus cyst $\kappa$=0.810; Agt=90.5%), good for lateral and medial femoral osteophytes [$\kappa$=0.619; Agt=80.9%) and $\kappa$=0.714; Agt=85.7%) respectively] and for lateral meniscus extrusion and cyst $\kappa$=0.619 and 0.619; Agt=81.0%). On the other hand, it was poor for lateral meniscus fracture $\kappa$=0.143; Agt=57.1%). For cartilage thickness, agreement was good for notch and medial condyle (ICC=0.652 and 0.619). Finally, the overall structural score agreement was moderate (ICC: 0.484).
**Conclusions:** The proposed protocol has shown to be reliable in patients with KOA, therefore a promising tool to be used both in clinical practice and for research purposes. Long-term reproducibility and responsiveness to change is needed to become a valid outcome measure, thus filling in an important gap in OA assessment.

## AB0956 ATYPICAL PATTERNS OF ANTINUCLEAR ANTIBODIES IN COLOMBIAN GENERAL POPULATION

J.A. Gómez-Puerta[1,2], A. Londoño[1], V.E. Estrada[1], S.L. Puerta[1], S.M. Osorno[1], J.A. Carmona[1]. *[1]Dinamica IPS; [2]Grupo de Inmunología Celular e Inmunogenética, Universidad de Antioquia, Medellín, Colombia*

**Background:** Since more common patterns of antinuclear antibodies (ANAs) such as homogeneous or nucleolar patterns are well recognized, the prevalence of uncommon or atypical pattern is not well described
**Objectives:** Our aim was to describe the prevalence of atypical ANAs patterns in a big cohort of ANA measurements in general Colombian population.
**Methods:** We included all ANAS determinations done during 2 consecutive years (2013 and 2014) from Dinamica IPS in 8 different cities in Colombia. We defined such as uncommon patters the following: anti MSA-2 (mitotic spindle apparatus), cytoplasmatic fibers, lysosomal, Golgi, multiple dots, NuMA1 (MSA-1), anti MSA-3, PCNA, centrosome and nuclear envelope. All patient sera submitted for ANAs testing were tested by conventional indirect immunofluorescence using Hep-2 cells (AESKU.DIAGNOSTICS, Wendelsheim, Germany). We use 3 images for sample and in some cases several dilutions were needed. Parametric test were used for comparison among groups.
**Results:** The overall sample included 113,491 consecutive samples for ANAs, being positive in 62,501 (55%) cases. 912 (1.45%) samples in 838 patients were classified as atypical pattern. Mean age for atypical positive pattern patients was 47±16.8 years and 80% of patients were female. The most common atypical patterns are summarized in Table. We did not find any difference among sex according atypical patterns. In subgroup analysis, centrosome pattern was more common in younger patients ($<$18 years) than in older than 18 years (27.84% vs 11.5%; Chi2, p=0.001), anti MSA-2 pattern was significantly more common in patients $>$18 years than in $\leq$18 years (23.6% vs 11.3%; Chi2, p=0.038), and cytoplasmic fibers was more prevalent in patients older than 55 years (14.7 vs 9%, p=0.013).

Table 1. More common atypical ANA patterns in Colombian population

| | N=843 | % |
|---|---|---|
| NuMA | 294 | 35.0 |
| Midbody (MSA-2) | 190 | 22.5 |
| Centriosome | 106 | 12.5 |
| Cytoplasmatic fibers | 93 | 11.0 |
| Multiple dots | 82 | 9.7 |
| Lysosomal | 28 | 3.3 |
| Golgi | 21 | 2.5 |
| PCNA | 19 | 2.3 |
| MSA-3 | 8 | 1.0 |
| Nuclear envelope | 2 | 0.2 |

**Conclusions:** In this large cohort of almost 130.000 samples of ANAs from a Colombian general population, the prevalence of atypical ANAs was around 1.5%. That prevalence is in concordance with some other series (1). Anti NuMa and MSA-2 patterns were the most common atypical ANAS. Anti centrosome were more common in young people, anti MSA in middle age patients and anti cytoplasmic fibers in elderly population.

## AB0957 ULTRASOUND MEASURES OF SYNOVITIS ARE INDEPENDENT OF CLINICAL PARAMETERS IN THE SETTING OF RHEUMATOID ARTHRITIS REMISSION: A CROSS-SECTIONAL ANALYSIS

K.F. Baker, B. Thompson, D.W. Lendrem, A.G. Pratt, J.D. Isaacs. *Musculoskeletal Research Group, Newcastle NIHR Biomedical Research Centre, Newcastle University and Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

**Background:** Musculoskeletal ultrasound (MSUS) is a useful tool for the diagnosis of rheumatoid arthritis (RA), and can be used to help guide treatment escalation in patients with active disease. At the opposite end of the spectrum however, the relationship between clinical and ultrasound measures of remission remains poorly understood.
**Objectives:** To define the relationships between clinical and ultrasound parameters in the setting of RA low disease activity and remission.
**Methods:** Patients with a clinical diagnosis of established RA were recruited as part of an ongoing study of RA clinical remission. Patients who were taking biological therapies or who had received corticosteroids within the past 3 months were excluded. At the baseline visit, a 7-joint ultrasound scan (US-7 scan) was performed blinded to the clinical disease activity assessment. All scans were performed by the same trained operator (KB) using the same ultrasound machine. Greyscale (GS) and power Doppler (PD) synovitis was scored on a 4-point semi-quantitative scale (0–3); erosions were scored as either present (1) or absent (0). MSUS images were then re-scored in a blinded fashion by KB and BT, with intra- and inter-observer reliability assessed by Cohen's Kappa statistic with linear weighting. Multivariate ordinal logistic regression was used to analyse the significance of relationships between total GS, PD and erosion scores with age, sex, disease duration, seropositivity for rheumatoid factor (RhF) and/or anti-citrullinated peptide antibody (ACPA), smoking history, and clinical remission as defined by the 2011 ACR/EULAR Boolean criteria.
**Results:** 29 patients were assessed in this preliminary cross-sectional analysis (19 [66%] female, 22 [76%] RhF and 20 [69%] ACPA positive) of median (IQR) age 67 (53–72) years and 6 (4–13) years following RA diagnosis. Methotrexate, sulfasalazine and hydroxychloroquine were prescribed to 25 (86%), 8 (28%) and 5 (17%) patients respectively. The median (IQR) DAS28-CRP score was 1.18 (0.97–1.81) and 16 (55%) patients satisfied ACR/EULAR remission. Median (range) total GS, PD and erosion MSUS scores were 5 (1–10), 0 (0–2) and 0 (0–8) respectively. Intra- and inter-observer MSUS score agreement ranged from good to excellent; intra/inter $\kappa$: GS 0.72/0.43, PD 0.92/0.83, erosions 0.70/0.65. In multivariate analyses, disease duration ($p<0.001$) and male sex (p=0.038) were independent predictors of a higher total erosion score only. Patients who were seropositive for either RhF and/or ACPA tended to have higher GS and PD scores though this was not statistically significant (p=0.053 and p=0.063 respectively).
**Conclusions:** Joint erosions were more frequently seen in male patients with a longer duration of disease, the latter in keeping with increased cumulative inflammatory joint damage. Substantial levels of synovitis, particularly GS, were visualised by MSUS despite low clinical measures of disease activity. Whether such ultrasound findings provide added value in predicting subsequent disease course following the withdrawal of DMARD therapy is an important focus of our ongoing prospective study.

## AB0958 SERONEGATIVE EARLY ARTHRITIS. MAY POWER DOPPLER ULTRASONOGRAPHY PREDICT PROGRESSION TO RHEUMATOID ARTHRITIS?

L. Mayordomo[1], C. Jurado[2], M.L. Velloso[1], L.M. Jimenez Liñan[1], J.L. Marenco[1], C. Almeida[3]. *[1]Rheumatology; [2]Radiology; [3]Research and Statistics Unit, Hospital Universitario Valme, Sevilla, Spain*

**Background:** The presence of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) are classic risk factors used for the diagnosis and classification of rheumatoid arthritis (RA) patients. Seropositive patients are at higher risk of developing RA, although in early arthritis RF/ACPA may be within the range of normality.
**Objectives:** To assess if the presence of basal Power Doppler (PD) signal in patients with negative baseline status for RF and ACPA may predict the risk of final diagnosis of RA according ACR criteria 1987, at 12 months of follow up.

**Methods:** We included 48 patients remited to an early arthritis consulting with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with <12 months of duration of the symptoms and negative for RF and ACPA, not previously treated with esteroides or DMARDs, without previous diagnose of RA or other inflammatory chronic articular disease. The presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, knees) and 44 joints (28 joints and in addition hips, tarsus, ankles and MTPs), was studied with an ultrasound equipment GE L5 by an expert rheumatologist. Presence of basal CRP and ESR and basal erosions (score ≥2 in at least one joint by modified Sharp method) for each patient were registered (only 44 patients with complete radiology sets available) by and independent trained radiologist. The patients who met criteria for RA according 1987 ACR during first 12 months of follow-up and did not have any exclusion criteria were classified as definite rheumatoid arhtritis. Statistical study: Chi-square, Fisher exact test, p univariant, Odds Ratio and Post-Test Probability calculation.
**Results:** The presence of basal power doppler signal in ≥1 joints of 44 (PD44) at baseline shows statistically significant association with the RA diagnosis at 12 months by ACR 1987 classification criteria, with p=0.002, OR=19,46 (2,25–168,27) but the presence of at least one joint with power doppler signal of 28 joints (PD28) did not (p=0.111). Presence of basal radiographic erosions (RXERb) were associated to RA with p<0.0005 and OR 12,04 (2,87–50,45) as well as high CRP p=0.019, OR 4,20 (1,23–14,36). Elevated ESR was not associated to RA diagnosis. The presence of PD44 and RXERb together is greater in patients with final diagnose of RA, p<0.0005 OR 45,71 (5,08–410,92). The combined presence of PD28 and RXERb is also associated to RA diagnose p<0.0005, OR 31,11 (3,53–274,11). Post-test probability of RA (considering a given pretest probability of 10% for seronegative patients obtained in our study) was 61% (19,1–91,8) for PD44+RXERb, 58% (16,9–90,8) for PD28+RXERb and 30% (15–51.8%) for RXERb.

| Basal variables n=48 | | AR (ACR 1987) YES | p (univariant) | OR | 95% CI |
|---|---|---|---|---|---|
| PD28 | yes | 20/34 (58,8%) | NS | - | - |
| | NO | 4/14 (28,6%) | 0,111 | | |
| PD44 | yes | 23/36 (63,9%) | 0,002 | 19,46 | (2,25-168,27) |
| | NO | 1/12 (8,3%) | | | |
| PD28+EROS BASAL n=44 | yes | 14/15 (94,1%) | < 0,0005 | 31,11 | (3,53-274,11) |
| | NO | 9/29 (31%) | | | |
| PD44+EROS BASAL n=44 | yes | 16/17 (94,1%) | <0,0005 | 45,71 | (5,08-410,92) |
| | NO | 7/27 (25,9%) | | | |
| EROSION BASAL n=44 | yes | 17/21 (81 %) | <0,0005 | 12,04 | (2,87-50,45) |
| | NO | 6/23 (26,1%) | | | |
| CRP | yes | 18/28(64,3%) | 0,019 | 4,20 | (1,23-14,36) |
| | NO | 6/20(30%) | | | |

**Conclusions:** The presence of at least one joint with power doppler signal on 44 joints (PD44) at baseline may help to predict progression to RA at 12 months according to ACR 1987 criteria in seronegative patients. Combined presence of PD44 or PD28 associated to basal radiographic erosions was able to select seronegative patients with higher risk of progression to RA at 12 months according to ACR 1987 criteria.

## AB0959 THE AUTOMATED SOFTWARE-GUIDED ULTRASOUND ASSESSMENT OF BILATERAL COMMON CAROTIDS INTIMA-MEDIA THICKNESS FOR INVESTIGATION OF CARDIOVASCULAR RISK: COMPARISON BETWEEN PSORIATIC AND RHEUMATOID ARTHRITIS PATIENTS

L. Pereira Jr[1], G.M. Soares[1], M.A. Dias[1], P. Ribeiro[1], M.M. Pinheiro[2], K. Luz[1]. *[1]UNINOVE - SP; [2]UNIFESP, Sao Paulo, Brazil*

**Background:** Recent studies have shown the relationship between psoriatic and rheumatoid arthritis and subclinical atherosclerosis. Currently, a new automated ultrasound software, based on radio frequency, called RF-QIMT technology, proved to be a useful method for assessing subclinical atherosclerosis with the measurement of the intima-media thickness (IMT) in carotid arteries.
**Objectives:** To compare the carotid IMT in patients with ordinary psoriatic arthritis (PsA) and rheumatoid arthritis (RA) through the RF-QIMT.
**Methods:** Total of 28 patients with APs (n=14) and RA (n=14) were enrolled in this case-control study. Patients with diabetes mellittus, dyslipidemia and previous cardiovascular events excluded. We evaluated the body mass index (BMI) and disease activity, including DAS28 score. The patients underwent a US assessment of the IMT of the posterior wall of common carotids using a My Lab 60 (Esaote SpA, Genoa, Italy) equipped with a 4–13 MHz linear probe adopting an automatic software-guided technique (named RF-QIMT technology).
**Results:** Mean age was 42.5. ±7.7 years and 46,6± 11.6 years in patients with APs and RA with no statistical difference between the groups (p>0.05). The mean disease duration was 14.1±9,5 and 6.17±4.4 years (p<0.05) in patients with APs and RA, respectively, with a predominance of men in those with APs (50% vs. 0%) (p<0.05). In addition, there was no statistical difference (p>0.05) between the groups regarding BMI (26.3±5.7 vs. 26.6±4.5 kg/m$^2$) and DAS28 score (3.93±0.7 vs. 2.8±0.63). There was no statistical difference (p>0.05) in relation to the average values of IMT (0.744± 0.244 in APs vs. 0.626 mm ±0.113mm in RA), the standard deviation (SD) of the six average values indicated by the system, were ranging from 12,7μm to 21μm, respectively. In addition, it was found that 64.3% of the patients with APs and 78.6% of those AR had higher IMT measurement than expected (p>0.05). There was no statistically significant correlation between IMT and the DAS28 score. However, there was a moderate statistically significant correlation (r =0.51; p<0.05) between the higher IMT measurement than expected and the DAS28 score.
**Conclusions:** The results show that patients with APs and AR have high rates of subclinical atherosclerosis, which can be measured by the new adopting an automatic software (called RF-QIMT) of evaluating the IMT, moreover there was correlation and validation with disease activty score.

## AB0960 RELIABILITY OF ULTRASOUND TO DETECT GOUT ELEMENTARY LESIONS

L. Ventura-Rios[1], C. Hernández-Díaz[1], C. Gómez-Ruíz[2], S. Gallegos-Nava[3], P. Rodríguez Henríquez[4], J. Vázquez-Mellado[2]. *[1]Laboratorio de Ultrasonido Musculoesquelético, Instituto Nacional de Rehabilitación; [2]Servicio de Reumatología, Hospital General de México; [3]Servicio de Reumatología, Hospital General "Dr. Dario Fernandez Fierro" ISSSTE; [4]Servicio de Reumatología, Hospital General "Dr. Manuel Gea Gonzalez", Distrito Federal, Mexico*

**Background:** The double contour (DC) seen by ultrasonography (US) was recently included in the classification criteria of gout, but this injury and other ones like tophi, hyperechoic aggregates Intra -articular and/or intra-tendinous, and bone erosions have not been validated.
**Objectives:** To evaluate the reliability of US to detect gout elementary lesions
**Methods:** Nine patients with Gout were included; diagnosis established by demonstration of monosodium urate crystals; patients were evaluated by 5 ultrasonographers in 2 rounds to detect tophi, hyperechoic aggregates, DC and bone erosions according to OMERACT definitions (1) in knee joint recesses and 1st metatarsophalangeal (MTP) joint, quadriceps, patellar and Achilles tendons bilaterally. Cohen's Kappa was used to establish Intra and inter-observer variability; the Kappa values were assigned as follows: poor (below 0.2), just (0.21 to 0.40), moderate (0.41 to 0.60), good (0.61 to 0.80) and excellent (0.81 to 1).
**Results:** Patients were 48+10 years old and 10+6 years of disease evolution. The inter-observer Kappa was good for DC in the knee and 1st MTP joint (0.87, 95% CI 0577–1170, p=0.000), good for hyperechoic aggregates in parapatellar recess, quadriceps and patellar tendon (distal insertion) and 1st MTP joint (0.71, -1064 to 2834, 95%, p=0.0001), moderate to proximal insertion of patellar tendon (0.46, 95% CI NA-NA, p=0.168), excellent for tophi in all tendons and in 1st MTP joint (0.82, 95% CI 0366–1270, p=0.000) and the same for erosion in 1st MTP joint (0.83, 95% CI 0349–1000, p=.0003). The intra-observer reliability was good (K=0.80; 95% CI 0758–0852, p=0.0000)
**Conclusions:** The US is reliable for detecting gout elementary lesions in the knee and the 1st MTP joint.

## AB0961 COMPARISON BETWEEN ULTRASOUND B-FLOW, COLOUR DOPPLER AND MAGNETIC RESONANCE IMAGING FOR ASSESSMENT OF TENOSYNOVITIS IN THE HAND OF RHEUMATOID ARTHRITIS PATIENTS - A PILOT STUDY

M. Ammitzbøll-Danielsen[1], D. Glinatsi[1], M. Østergaard[1], S. Torp-Pedersen[2], L. Terslev[1]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, University of Copenhagen; [2]Department of Diagnostics, Rigshospitalet, Copenhagen, Denmark*

**Background:** Ultrasound (US) B-flow imaging (BFI) is a new technique for vascular imaging, based on US grey scale physics [1]. Therefore, Doppler artefacts such as aliasing, blooming and reverberations are not seen. Whether it is an alternative to Doppler for depicting inflammatory flow in the tendon sheath in rheumatoid arthritis patients (RA) is unknown.

**Objectives:** To evaluate US BFI for assessment of inflammatory activity in the tendon sheath compared to grey scale (GS), colour Doppler (CD) US and magnetic resonance imaging (MRI).
**Methods:** Ten RA patients with US-verified tenosynovitis were included. GS, CD and BFI assessment were performed using a GE Logiq E9 US unit with a high frequency linear 6–15 ML probe. BFI settings were adjusted to maximum sensitivity of 50, frequency at 12 MHz and dynamic range at 66. GS frequency was 15 MHz and CD settings according to published recommendations (ref). All settings were identical in all examinations. Axial T1-weighted pre- and post-contrast fat-saturated MR image sets (0.8mm slice thickness) were obtained using a Philips 1T MRI scanner (figure 1). One tendon sheath per patient was scored, in either the wrist or at the metacarpophalangeal joint level. CD, GS and MR images were scored for tenosynovitis 0–3 as proposed by the OMERACT US group and the OMERACT MRI in arthritis working group. BFI was scored peritendiniously as: 0: No flow, 1: Focal flow, 2: Multifocal flow, 3: Diffuse flow. Descriptive statistics were used for comparison of BFI, GS, CD and MRI scores.
**Results:** The mean (SD) score for the patients were 0.89 (0.74), 2.10 (0.74), 2.20 (0.92) and 2.30 (0.95) for BFI, GS, CD, and MRI, respectively. The difference between CD vs GS and MRI was never larger than ±1. The difference between CD and BFI was 1 in 5 patients and ≥2 in 3 patients (table 1).

Table 1. Baseline scores (0–3) and Δ scores with CD as reference, for BFI imaging, CD, GS and MRI

| Patient No. | Tendon sheath | BFI | GS | CD | MRI | ΔCD; BFI | ΔCD; GS | ΔCD; MRI |
|---|---|---|---|---|---|---|---|---|
| 1 | Extensor carpi ulnaris | 1 | 3 | 3 | 3 | 2 | 0 | 0 |
| 2 | Flexor carpi radialis | 1 | 2 | 2 | 3 | 1 | 0 | –1 |
| 3 | Flexor tendon of the 4th digit | 2 | 2 | 3 | 3 | 1 | 1 | 0 |
| 4 | Flexor tendons of the 5th digit | 0 | 2 | 3 | 3 | 3 | 1 | 0 |
| 5 | Flexor tendon of the 2nd digit | 1 | 2 | 2 | 1 | 1 | 0 | 1 |
| 6 | Extensor carpi ulnaris | 2 | 3 | 3 | 3 | 1 | 0 | 0 |
| 7 | Extensor carpi ulnaris | 0 | 1 | 0 | 1 | 0 | –1 | –1 |
| 8 | Extensor carpis radialis brevis/longus | 0 | 1 | 2 | 2 | 2 | 1 | 0 |
| 9 | Extensor pollicis longus | 1 | 2 | 2 | 1 | 1 | 0 | 1 |
| 10 | Extensor digitorum communis/ indicis proprius | 1 | 3 | 2 | 3 | 1 | –1 | –1 |

Note: Number (n), B-flow imaging (BFI), grey scale (GS), colour Doppler (CD), magnetic resonance imaging (MRI).

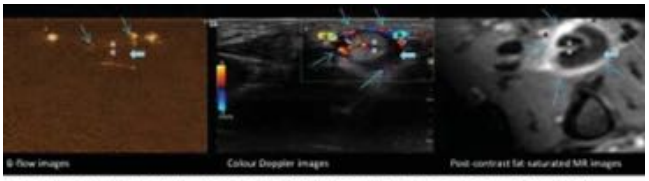

**Figure 1.** Tenosynovitis at the *flexor tendons (**) of the 4th finger* in 3 imaging modalities; BFI, CD and MRI, respectively. The pathological flow/enhancement is marked with thin *arrows and a peritendinous effusion is marked with a thick arrow. Interdigital arteries are marked with one (*) asterisk.*

**Conclusions:** BFI is a new imaging modality for visualization of perfusion. However, the presented results indicate that BFI is less sensitive to detect inflammation in the tendon sheath than CD, GS and MRI in RA patients. Further studies are required, in order to increase image optimization and flow sensitivity, but also to evaluate further use of BFI in diagnosis of inflammatory conditions.

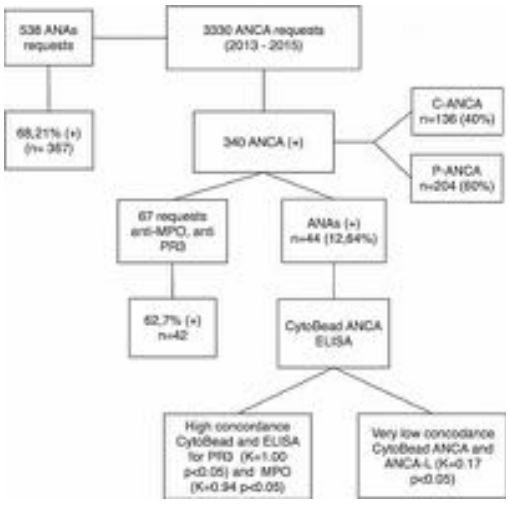
## AB0962 VALIDITY AND SENSITIVITY TO CHANGE OF THE SEMI-QUANTITATIVE OMERACT ULTRASOUND SCORING SYSTEM FOR TENOSYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRIT

M. Ammitzbøll-Danielsen[1], M. Østergaard[1,2], E. Naredo[3], L. Terslev[1].
*[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, University of Copenhagen; [2]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [3]Department of Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** Tenosynovitis is frequent in rheumatoid arthritis (RA) patients. In 2012 the Outcome Measures in Rheumatology (OMERACT) US group proposed a new tenosynovitis scoring system with a good inter-observer reliability. However, its interreader agreement longitudinally and the sensitivity to change during treatment have not been tested.
**Objectives:** In a 6-months follow-up study of RA patients with US tenosynovitis, initiating treatment intensification with synthetic and/or biological disease-modifying anti-rheumatic drug (DMARD), to validate the semi-quantitative OMERACT US-scoring system of tenosynovitis by testing its interreader reliability, sensitivity to change, and comparison to clinical evaluation.
**Methods:** US (by grey-scale (GS) and color Doppler (CD)) and clinical assessment of the flexor and extensor tendon sheaths of the clinically most affected hand and foot was performed at baseline and after 3 and 6 months. Tenosynovitis was assessed using the semi-quantitative scoring system (0–3) proposed by the OMERACT US group for GS and CD calculating a sum score (0–39 for the hand and 0–21 for the foot) for each patient. In 20 patients, US was done independently by 2 physicians at baseline and 6 months, to assess the inter-observer agreement. A GE Logiq E9 with a linear 6–15 ML probe was used. CD frequency was 7.5 MHz, a pulse repetition frequency =0.4 and gain just below the noise limit. The same Doppler settings were used for all examinations. A binary score for clinical tendon involvement (0–1) was also performed at the same locations as the US score, with reference to published recommendations (3), calculating a sum score (0–13 for the hand and 0–7 for the foot)
**Results:** Fifty-one RA patients, planned for treatment intensification, were included: 43 women (age: mean 55.6; standard deviation (SD) 13.1) and 8 men (mean 49.1; SD 9.34). Thirty-four patients were anti-rheumatoid factor positive and 30 had early RA (duration <1 year). The interreader agreement, as assessed by the intra-class correlation coefficient (ICC) was very good at baseline and for change for GS sum scores (ICC Baseline=0.89; Change=0.89) and CD (ICC Baseline=0.95; Change=0.90) tenosynovitis. The smallest detectable change for change in scores was 0.97 for GS and 0.93 for CD. Tenosynovitis scores had decreased significantly at months 3 and 6 (Table 1 and figure 2). The sensitivity to change, as expressed by the standardized response mean from month 0–6, was high for GS and CD tenosynovitis (0.90 and 0.76, respectively), and moderate (0.59) for the clinical score (Table 1).

**Table 1** Changes in ultrasound and clinical evaluation sum score over 6 month and standardized response mean (SRM) for each score

| | | Baseline | 3 months | 6 months | Δ 0-3 months | Δ 1-6 months | Δ 0-6 months | SRM 0-3 months | SRM 3-6 months | SRM 0-6 months |
|---|---|---|---|---|---|---|---|---|---|---|
| Grey scale | Mean (Std Dev) | 3.5 (2.6) | 2.1 (1.6) | 1.4 (1.4) | -1.4 (2.2) | -0.7 (1.3) | -2.1 (2.4) | 0.6 | 0.5 | 0.9 |
| | Median (25;75 pctl) | 3.0 (2;4) | 2.0 (1;3) | 1.0 (0;2) | 1.0 (-2;0) | 0.0 (-1;0) | -2.0 (-3;-1) | | | |
| | p | | | | P<0.0001 | P=0.0001 | P<0.0001 | | | |
| Colour Doppler | Mean (Std Dev) | 3.4 (3.5) | 1.4 (1.9) | 0.8 (1.7) | -2.0 (3.3) | -0.6 (1.7) | -2.8 (3.4) | 0.6 | 0.3 | 0.8 |
| | Median (25;75 pctl) | 3.0 (1;4) | 1.0 (0;2) | 0.0 (0;1) | -1.0 (-3;0) | 0.0 (-1;0) | -2.0 (-3;0) | | | |
| | p | | | | P<0.0001 | P=0.0211 | P<0.0001 | | | |
| Clinical | Mean (Std Dev) | 2.4 (1.8) | 1.8 (1.6) | 0.9 (1.4) | -0.6 (1.8) | -0.6 (1.6) | -1.4 (2.4) | 0.4 | 0.3 | 0.6 |
| | Median (25;75 pctl) | 2.0 (1;3) | 1.0 (0;3) | 0.0 (0;1) | 0.0 (-2;0) | 0.0 (-1;0) | -1.0 (-3;0) | | | |
| | p | | | | P=0.0043 | P=0.0181 | P<0.0001 | | | |



Note - P = Wilcoxon Pratt tests

**Conclusions:** The present study demonstrated an excellent interreader agreement for the OMERACT US scoring system for tenosynovitis and a high ability to detect changes over time. The high reproducibility and responsiveness of both GS and CD scores indicate that the OMERACT US scoring system is useful for diagnosing and monitoring of tenosynovitis in RA clinical trials and practice

## AB0963 INTEFERENCE OF ANAS IN ANCA ANALYSIS AND COMPARISON TO CLINICAL OUTCOME OF VASCULITIS

M.F. Benavides Solarte[1,2], M.C. Romero S.[1,2,3,4], A. Castro[1], I. Angarita[5], A.I. Ospina[1,2], V. Parra[5], I. Galindo[6], L. Chila[4], L. Rey[1], A. Villa[3], S. Pineda[1], M. Casas[3], J.M. Bello[1,2], R. Valle[1,2]. *[1]Rheumatology and Immunology Department, Hospital Militar Central; [2]School of Medicine, Universidad Militar Nueva Granada; [3]Instituto de referencia Andino; [4]UIBO Institute (Oral Basic Research Unit), Universidad El Bosque; [5]Faculty of Medicine, Universidad de la Sabana; [6]School of Health science, Universidad Colegio Mayor de Cundinamarca, Bogotá, Colombia*

**Background:** Anti-neutrophil cytoplasmic antibodies (ANCAs) are directed against the primary granules of neutrophils and monocytes and are essential in the diagnosis of vasculitis pauciimmune. The positivity of anti nuclear antibodies (ANAs) interferes with the interpretation of ANCAs leading to false positives.
**Objectives:** Evaluate the interference of ANAs in the interpretation of ANCAs in a population with manifestations of autoimmune disease
**Methods:** 3330 patient data involving ANCA requests between 2013 and 2015 were analyzed. Indirect immunofluorescence (IIF) was used to determine whether the samples had interference with ANAs through the L-ANCA system

(Inmmunoconcepts®). Results were evaluated by the Generic assay kit ELISA® and CytoBead® ANCA (Generic Assays) to confirm positivity to MPO and/or PR3.The technical performance was evaluated by correlation analysis with Kappa values for data in which ANCAs was assessed at least by two techniques. Subsequently positivity of ANCAs was determined in a small sample of patients with clinical manifestations of autoimmune disease

**Results:** Positive ANCAS were found in 10.21% (340/3330) of the data, 40% (136/340) were C-ANCA and 60% (204/340) P-ANCA. Only 67 requests included specific anti-MPO and anti-PR3 assays, and 62.7% of these (42/67) were positive for ANCAs. ANAs were requested in 538 data resulting positive in 68.21% (367), predominantly homogeneous pattern. 12,64% of ANCAs positive data were also positive for ANAs, with P-ANCA in 83.72% of cases. The technique comparison included 44 samples positive for ANCAs evaluated by L-ANCA, CytoBead ANCA and ELISA. The correlation analysis showed high concordance between *CytoBead* and ELISA for PR3 (K=1.00 $p<0.05$) and MPO (K=0.94 $p<0.05$). However, in the evaluation between *CytoBead* ANCA and ANCA-L, a very low concordance (K=0.17 $p<0.05$) was observed

**Conclusions:** The results suggest there is interference of ANAs in the positive P-ANCA results. IIF is an excellent technique for screening the presence of ANCAs while other methods such as anti-PR3 and anti- MPO by ELISA or microparticles assays are required for confirmation

## AB0964 SYNOVIAL INFLAMMATION ANALYSED BY 3 TESLA MAGNETIC RESONANCE IMAGING IN ETANERCEPT-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS INDICATES PERSISTENT DISEASE ACTIVITY DESPITE OF CLINICAL REMISSION

M. Oleszowsky[1], M. Marinova[2], W. Willinek[3], M. Seidel[1]. *[1]Department of Onkology, Hematology of and Rheumatology, University Hospital of Bonn, Medizinische Klinik III; [2]Department of Radiology, University Hospital of Bonn, Bonn; [3]Department of Radiology, Neuroradiology, Sonography and Nuclear Medicine, Krankenhaus der Barmherzigen Brüder Trier, Trier, Germany*

**Background:** Treatment efficacy of conventional disease-modifying anti-rheumatic drugs (DMARDs) is insufficient in some patients with rheumatoid arthritis (RA). These patients require TNF-a antagonists that demonstrate excellent remission rates confirmed by clinical scores and conventional radiographs. Magnetic resonance imaging (MRI) is a more detailed diagnostic tool and furthermore, the 3 Tesla technique provides a higher spatial resolution compared to 1.5 Tesla. Especially early and thus prognostically relevant subchondral bone lesions might be detected more precisely using 3 Tesla MRI.[1]

**Objectives:** The aim of this study was to evaluate a reduction of joint inflammation in RA patients treated with DMARDs as compared to etanercept (ETA) over a period of 12 months.

**Methods:** This epidemiologic clinical pilot MRI study examined 10 ACR/EULAR-positive RA patients with inadequate response to two DMARDs with an indication for ETA using the RA MRI system (RAMRIS). The control group consisted of 10 patients adequately responding to DMARDs. 3 Tesla MRI (PDSPAIR; T1 with and without contrast agent) using a multi-channel hand coil was performed at baseline, four (only ETA) and 12 months following initiation of ETA. RAMRIS scoring included analysis of synovitis, effusion, subchondral erosion, and also bone marrow edema. Additional analysis consisted of the visual analogue scale (VAS) and the Disease Activity Score 28-joint count (DAS28) at baseline and after 12 months in DMARD patients and at baseline, four and 12 months in ETA-patients.

**Results:** In DMARD-patients, the VAS averaged 21.0±11.3 and 20.2±24.6 (p=0.9). In ETA-patients, the VAS decreased from 46.3±7.9 (baseline) to 23.9±7.1 (p=0.04) and 24.0±6.3 (p=0.04). In DMARD-patients, the DAS28 remained at 2.1±0.6 and 2.9±1.0 (p=0.06). In ETA-patients, however, it decreased from 3.8±0.4 (baseline) to 2.8±0.3 (p=0.08) and then significantly to 2.5±0.3 (p=0.01). In DMARD-patients, the RAMRIS did not change between baseline and 12 months (11.0±2.3 vs. 11.8±2.8, respectively, p=0.8). Similarly, in ETA-patients, the RAMRIS did not change significantly (28.9±5.0 vs. 25.8±4.7, p=0.7 and 24.6±4.5, p=0.5). In contrast, the RAMRIS was significantly higher at baseline in ETA-patients as compared to DMARD-patients (28.9±5.0 vs. 11.0±2.3 p=0.005) and after 12 months (24.6±4.5 vs. 11.8±2.8, p=0.03). Separate analysis of synovitis, erosion and bone marrow edema did not change after 12 months.

**Conclusions:** The data show a significant higher RAMRIS and thus more actively diseased patients prior to ETA treatment as compared to DMARD-patients at baseline and after 12 months despite of adequate DAS28 remission ($<2.6$). Persistence of 3 Tesla MRI synovial inflammation and DAS28 remission are thus separate entities. MRI scoring before starting a treatment may indicate the requirement for anti-TNF-a agents.

## AB0966 COLOUR DOPPLER ULTRASONOGRAPHY IS SPECIFIC BUT NOT SENSITIVE IN DIAGNOSIS OF CARPAL TUNNEL SYNDROME

O.Z. Shehata, D.M. Sharaf, M.A. Mortada, F.A. Elsayed. *Rheumatology & Rehabilitation, Faculty of Medicine Zagazig University, Zagazig, Egypt*

**Background:** Carpal tunnel syndrome (CTS) is the most common form of peripheral entrapment neuropathies. Ultrasonography (US) has been used to diagnose CTS with a good sensitivity and specificity.There is no consensus about the role of colour Doppler US in diagnosis of CTS (1).

**Objectives:** To assess the diagnostic role of color Doppler ultrasonography in idiopathic CTS.

**Methods:** This study included 2 groups. The first group included 35females middle aged (32.1±4.8) patients with idiopathic CTS. The second group included 35 healthy middle aged (40.1±7.6) females. The diagnosis of CTS was done clinically and by nerve conduction studies.Ultrasonography of the median nerve was performed to find colour Doppler signals, wrist cross sectional area, forearm cross sectional area, flattening ratio, flexor retinaculum bowing and pronator quadratus ratio by use of high frequency (5–12MHz) linear probe diagnostic ultrasound.

**Results:** There was a statistical highly significant difference between control group and patients with CTS regarding colour Doppler signal (p=0.00).the specificity of CDUS in diagnosis of CTS was excellent (100%) but its sensitivity was poor (22.9%) with an accuracy of 61.4%. As regards the other US parameters, flattening ratio was the most accurate method (86.4%) with a senstivity (88.7%) and a specificity of (83.3%).There was a statistical highly significant positive correlation between nerve conduction study grading and Color Doppler ultrasonography (p=0.005).

**Conclusions:** CDUS is a highly specific test in evaluation of idiopathic CTS. It represents a useful confirmatory tool in diagnosis. Flattening ratio is the most accurate grey scale US parameter and highly correlated with CT severity.

## AB0967 ULTRASONOGRAPHIC FEATURES OF NEUROPATHIC (CHARCOT) ARTHROPATHY OF ANKLE JOINT

M. Mortada, M.A.H. Hammad, N. Ezzeldin. *Rheumatology & Rehabilitation, Faculty of Medicine Zagazig University, Zagazig, Egypt*

**Background:** neuropathic osteoarthropathy (Charcot arthropathy) is a progressive condition that is characterized by joint dislocations, pathologic fractures, and debilitating deformities. It occurs most commonly in the lower extremity, at the foot and ankle. Although magnetic resonance imaging (MRI) is the modality of choice to examine patients with suspected neuropathic osteoarthropathy, for its ability to depict bone and soft tissues changes, ultrasonography (US) may be able to identify pathological changes in cases of Charcot arthropathy.

Up to the best of our knowledge this the first study of ultrasonographic feature of neuropathic ankle joint.

**Objectives:** Our aim was to characterize the ultrasonographic features of patients with neuropathic (Charcot) arthropathy of ankle joint.

**Methods:** In this retrospective study, all 26 patients between January 2013 and December 2015 with neuropathic (Charcot) arthropathy of ankle joint proved by X ray and/or MRI were enrolled. We collected and analyzed 26 patients, on whom high-resolution (5–15 MHz) muculoskeletal US of ankle and small joints of the affected feet had been carried out.

**Results:** Ages of our patients ranged from 38 to 67years (57.3± 6.4). Most of our patients (25 patients) 96.2% had diabetes mellitus and all of our patients had peripheral neuropathy. According to the modified Eichenholtz classification system; 3 patients (11.5%) were in grade 0, 11 patients (42.3%) were in grade 1, 10 patients (38.5%) were in grade 2, and 2 patients (7.7%) were in grade 3.

Ultrasonographic findings were: Effusion/synovitis of ankle joints (100%), High Doppler activity (grade 2 or 3) in ankle joint was present in 92.3% of our patients, bone irregularities in distal fibula 73.1%, bone irregularities in distal tibia were found in 34.6%, tendonitis of tibialis posterior 65.4%, proneal tendonitis were found in 50%. Double contour sign were present in 2 ankle joints (7.7%). Arthritis (effusion/synovitis) in mid tarsal joints were found in 92.3% of patients with high Doppler activity in 65.4% and bone irregularities in57.7%.

**Conclusions:** The main US features of neuropathic (Charcot) arthropathy of ankle joint are: effusion, synovitis, high grade Doppler activity, bone irregularities of the distal fibula and involvement of mid tarsal joints (synovitis, high Doppler activity and bone irregularities).

**Disclosure of Interest:** None declared

## AB0968 HIGH-FRAME RATE POWER DOPPLER IMAGING IS MORE SENSITIVE THAN CONVENTIONAL POWER DOPPLER IN DETECTING LOW BLOOD FLOWS IN A FLOW-PHANTOM AND IN HEALTHY VOLUNTEERS

M. van der Ven[1], J.J. Luime[1], L.L. van der Velden[2], J.G. Bosch[3], N. de Jong[3], J.M. Hazes[1], H.J. Vos[3]. *[1]Rheumatology, Erasmus MC, University Medical Center, Rotterdam; [2]Technical Medicine, University of Twente, Enschede; [3]Biomedical Engineering, Erasmus MC, University Medical Center, Rotterdam, Netherlands*

**Background:** Early detection of inflammation at diagnosis of rheumatoid arthritis (RA) or in remission of RA is important to optimise treatment in order to prevent joint damage and disability. Recent studies in ultrasound (US) indicate that US, especially power Doppler (PD), is more sensitive to detect inflammation than physical examination. Early diagnosis and treatment monitoring could be achieved by a more sensitive power Doppler (PD) method to detect early increased vascularisation. Inspired by recent breakthrough work in high-frame rate Doppler US imaging that was shown to be more sensitive to low flows associated with vascularisation [1], we systemically explored this method for its application in diagnosing and monitoring RA.
**Objectives:** (i) To compare the minimal flow velocity that can be detected with the high-frame rate Doppler US technique and a conventional clinical US machine using a flow phantom. (ii) To show visual differences between high-frame rate PDUS and conventional PDUS in healthy volunteers assuming that high-frame rate PDUS would detect more vascularisation in MCP2 joints.
**Methods:** In a flow phantom filled with tissue mimicking material [2] and a vessel diameter of 700 μm, we tested the PDUS performance of conventional PDUS (Esaote MyLab60) and a custom high-frame rate PD imaging technique (Verasonics Vantage). Settings for both methods were optimised to detect lowest flows (continuous PDUS signal) by adjusting pulse repetition frequency (PRF), velocity range, wall filters, frequency and gain. Subsequently we included six healthy volunteers and we performed conventional PDUS and high-frame rate PDUS of the MCP2 joint. The US images were graded on power Doppler (PD; 0–3) according to a semi-quantitatively scoring system of Naredo et al.
**Results:** In the flow phantom we could detect a flow velocity of 2.5 mm/s with the conventional PDUS. With the high-frame rate PDUS the lowest detectable flow was 0.5 mm/s. Results in healthy volunteers (n=6) showed no PD signal in MCP2 joints using conventional PDUS (Figure 1A). With high-frame rate PDUS (Figure 1B) the median PD grade was 2 (IQR: 2 - 2).

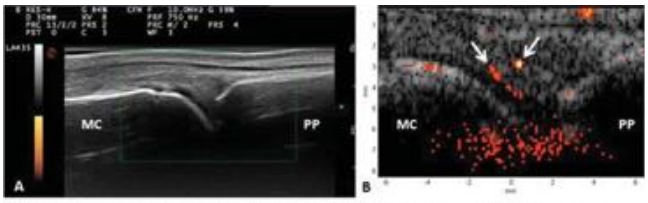

Figure 1. Power Doppler ultrasound (PDUS) of a MCP2 joint of a healthy volunteer; A) Conventional PDUS; B) High-frame rate PDUS (arrows: positive PD signal); MC: metacarpal; PP: proximal phalanx

**Conclusions:** In a flow phantom we could detect five times lower flows with the high-frame rate PDUS technique than with conventional PDUS. Contrary to conventional PDUS, we detected a positive PD signal in all healthy volunteers with high-frame rate PDUS. Therefore, high-frame rate PDUS is more sensitive to vascularisation. Further evaluation whether this will facilitate early diagnosis and monitoring in RA is needed.

## AB0969 THE ROLE OF HIGH RESOLUTION CT SCANNING IN THE ASSESSMENT OF PATIENTS WITH INFLAMMATORY JOINT DISEASE (IJD) ON BIOLOGICS

M. Nisar, N. Sayed, J. Whitmore. *Dept of Rheumatology, Burton Hospitals NHS Foundation Trust, Burton on Trent, United Kingdom*

**Background:** Biologic therapy (BT) in the treatment of IJD is now well established. The risks and potential complications of this modality of the treatment including infections and interstitial lung pathology have been described previously including in reports from several national registry databases such as the BSRBR. Furthermore the prevalence of lung disease in rheumatoid IJD is estimated at 5%. HRCT scanning for lung disease is therefore an important but under-utilized means of objective assessment of patients with IJD particularly in later stages of disease and when medical treatment is escalated to include immunomodulatory and biologic therapies.
**Objectives:** Our data examines the role of HRCT in the assessment of IJD patients before and after introduction of biologic therapies to consider the merits of this investigation in the intermediate and long term surveillance of IJD and biologic therapies.
**Methods:** Hospital records of patients with IJD under the care of one rheumatologist (MN) submitted for assessment for biologics were assessed. Specific diagnosis, treatment regimens and progression to biologic therapy were documented along with a record of submission for HRCT. Outcome and changes in treatment over time as well as follow up scan results were documented and analysed.
**Results:** Of the 130 patients assessed for BT in the 5 year period up to 2015, 106 (82%) had HRCT prior to commencing BT. 92 (71%) had normal scans. A total of 116 patients were submitted for BT (93 anti TNF and 23 other) of these 70 (60%) were also on MTX. Thus 10 patients had BT without HRCT. 14 (11%) had abnormal scans (including ground glass change, bronchiectasis, COPD) and were not commenced on anti TNF, Rituximab or other BT. Of the 130 patients 87 (67%) had RA of which 71 (81.6%) were seropositive. Of the 14 with abnormal scans, 8 were seropositive and 8 were on MTX. Of the 93 patients started on Anti TNF, 35 (37.6%) were discontinued/switched to another BT for a variety of reasons including inefficacy and side effects. Of the anti-TNF start-ups, 29 (31%) had progressive changes on repeat HRCT within 0 to 12 months. Of these 14 were switched to Rituximab with no further change in HRCT. Repeat HRCT scan data is available in only 5 of 15 patients switched to a second anti TNF, in three of which progression of lung changes was noted.
**Conclusions:** These preliminary data reveal the importance of HRCT scanning in the pre-assessment and monitoring of patients requiring BT for IJD. Progression of lung disease was seen in 31% patients on anti TNF. We recommend early repeat scans if any adverse effects are experienced or a change in BT planned due to lack or loss of efficacy. As lung disease is now recognised as the main non-infective cause of mortality in IJD, consideration should be given to routine review HRCT at 12 months after introduction of BT and then at regular (no longer than 3 year) intervals to monitor change even in asymptomatic patients controlled on biologics.

## AB0970 ULTRASONOGRAPHY IN DIAGNOSIS AND MANAGEMENT OF ILIOLUMBAR SYNDROME: CASE SERIES

N. El Khoury[1], S.H. Zebouni[2], M. Revel[3], F. Fayad[1]. *[1]Rheumatology Departement; [2]Radiology Departement, Hotel Dieu de France Hospital, Saint Joseph University, Beirut, Lebanon; [3]Spine disorders and rehabilitation medicine, Cochin Hospital, Paris Descartes University, Paris, France*

**Background:** The iliolumbar ligament may be an important cause of acute and chronic Low Back Pain (LBP). The diagnosis of iliolumbar ligament inflammation is based on clinical history and physical examination which lack sufficient specificity. The treatment consisted of the standard care used in common LBP. Nowadays, ultrasonography (US) is used in routine practice in rheumatology for diagnostic purposes and to guide local injections but this technique is generally confined to assess peripheral joints and peri-articular structures.
**Objectives:** To describe the role of ultrasonography in the diagnosis and treatment of LBP related to an inflammation of the iliolumbar ligament.
**Methods:** From December 2012 till December 2015, all patients with clinically suspected iliolumbar syndrome were included in this study. Patients underwent an ultrasonography to confirm the diagnosis. For this technique, the patient is in the prone position and the probe is positioned almost horizontally for L5 and in slightly oblique direction for L4. To confirm the diagnosis, we should have a swollen hypoechoic iliolumbar ligament with reproduction of the usual back pain during the passage of the probe above the ligament[1]. Also, the thickness of the inflamed ligament should be higher than 1mm. The US was always performed bilaterally so we can compare both sides. Patients who failed standard treatment were injected under US-guidance or in clinic with 80mg of methyl-Prednisolone and 5cc of local xylocaïne. The patient's assessment of usual LBP was recorded 20mn after the injection of xylocaïne.
**Results:** 30 consecutive patients with clinically suspected iliolumbar syndrome (LBP with presence of tenderness on palpation of the posterior/ medial aspect of the iliac crest) were evaluated by US. Patients included in this study were relatively young with a mean age 38.87 years (22–65 years). The sex ratio is 5/1 (female/male). As suspected, X-ray and/or MRI of the lumbar spine and pelvis, when performed, were normal in most cases. Few cases of mild degenerative disc disease are noted. US showed, in all patients, an inflammation of the iliolumbar ligament (fig.1). In four patients, the iliolumbar ligament was inflamed at both sides. The mean thickness of the ligament was 2.64 mm (1.5–6mm). There was an associated tendonitis of the gluteus medius muscle in 5 patients, diagnosed also on US. The patients received a treatment with NSAIDs and a 12-session course of physical therapy, but this standard therapy was insufficient in 67% of cases. Twenty one (70%) patients received injection of 80 mg of methyl-Prednisolone and 5cc of local xylocaïne, 11 patients under US-guidance and 10 in clinic. All

patients noted the disappearance of the usual LBP 20mn after the injection (effect of local anesthesia).

*Fig 1. Ultrasound image of iliolumbar ligament. Note the thickened hypoechoic iliolumbar ligament at right (2.2mm) versus a small thickening of this ligament at left without an hypoechoic area. SC= subcutaneous tissue, IL= iliolumbar ligament, IC= iliac crest, PM= paravertebral muscle.*

**Conclusions:** Ultrasonography allows the diagnosis of iliolumbar syndrome in patients with LBP. It is a useful tool to guide infiltrations of corticoids as an effective therapy for this pathology. Prospective randomized trials are needed to confirm our conclusions.

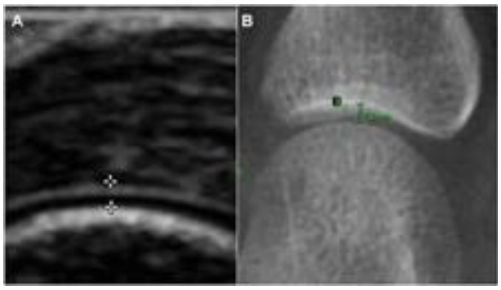
## AB0971 CHANGE IN SONOGRAPHIC CARTILAGE THICKNESS CORRELATES WITH CHANGE IN RADIOGRAPHIC JOINT SPACE NARROWING IN THE METACARPHALANGEAL JOINTS OF PATIENTS WITH RHEUMATOID ARTHRITIS

P. Mandl[1], H. Radner[1], G. Supp[1], D. Aletaha[1], J.S. Smolen[1,2]. *[1]Division of Rheumatology, Medical University of Vienna; [2]Rheumatology, Krankenhaus Hietzing, Vienna, Austria*



**Background:** It was previosly shown that metacarpal cartilage thickness (MCT) as assessed by ultrasound (US) correlates with both radiographic joint space width (JSW) and joint space narrowing (JSN) in the metacarpophalangeal joints (MCP) of patients with rheumatoid arthritis (RA).

**Objectives:** To correlate change in MCT with change in radiographic JSW and JSN in a longitudinal study of patients with RA.

**Methods:** We performed US examination of 19 consecutive outpatients with RA fulfilling the 2010 ACR/EULAR classification criteria with recent hand X-rays. Metacarpal cartilage of MCP 2–5 was assessed bilaterally by US at baseline and after 3 years in mm with an integrated caliper on static images (Figure 1A). JSN was evaluated on X-rays taken $<1$ year before the sonographic assessment as well as within 6 months of the second sonographic assessment by the van der Heijde modified Sharp method (vdHS). In addition, JSW was measured on the very same hand X-rays using an integrated calliper (Figure 1B). The relationship between sonographic and radiographic measures was investigated by Spearman correlation.

**Results:** Over the study period of 3 years a mean change of MCT of 0.00±0.01mm, was paralleled by a mean change of JSW of -0.08±0.20mm and a change of 0.12±0.37 in the JSN component of the vdHS. Change in MCT correlated with change in JSW (r: 0.37; p:$<$0.001) as well as with change in JSN (r:-0.26; p:$<$0.001). We could also demonstrate correlation between the two radiographic measures (r: 0.33; p:$<$0.001). Change in erosion did not correlate with either sonographic MCT or with the radiographic measures.

**Conclusions:** Change in sonographic cartilage thickness correlates with radiographic measures of joint space narrowing in the MCP joints of RA patients over time. Thus, ultrasound may be a valid tool for the longitudinal assessment of metacarpal cartilage in RA patients, but also the radiographic assessments appear to reflect "true" cartilage dimensions.

## AB0972 UTILITY OF THE ULTRASOUND FOR THE EVALUATION OF ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REMISSION OR LOW CLINICAL ACTIVITY IN TREATMENT WITH BIOLOGICAL IN OPTIMIZATION PHASE

R. Martínez Pérez[1], E. Rubio[1], M.D. Fernández Alba[1], B. Hernández[2], R. Menor[1], J. Povedano[2]. *[1]Rheumatology, Virgen del Rocío University Hospital; [2]Rheumatology, Virgen Macarena University Hospital, Seville, Spain*

**Background:** In rheumatoid arthritis (RA), the activity is correlated with radiological damage. Our therapeutic goal is clinical remission. The concept of clinical remission may be insufficient due to persistent subclinical inflammation, which can be determined by ultrasound.

**Objectives:** Our goal is to determine the frequency of subclinical synovitis by ultrasonography in patients with RA in low activity or remission of the disease measured by CDAI, in biological treatment optimization phase.

**Methods:** Transversal and longitudinal study describing the ultrasonographic changes in gray scale and Doppler in parallel with blind clinical evaluation. We included 23 patients (16 women and 7 men) with RA according to ACR criteria/EULAR under low activity/remission measured by CDAI, under biological treatment and optimized at least for 6 months. They were sent by their usual clinician, making a random selection. They were evaluated in the same day by a rheumatologist and blind sonographer. VAS, VGP, VGM, HAQ, number joints painful, joints swelling, ESR, CRP and CDAI were evaluated. Regarding the ultrasound, were evaluated; Synovitis and Doppler in 12 joints (wrists, second to fifth MCF and fifth bilateral MTF).

**Results:** All patients were in low activity/remission in accordance with their rheumatologist. The baseline characteristics and different variables are described in Table 1B, 1B. After the blind rheumatologist evaluation, the percentage of patients in remission/low activity was lower, 65.2% (15 patients, 2 in remission, 13 in low activity), p$<$0.005 compared to regular clinician. 8 patients had CDAI $>$10. The presence of subclinical synovitis in ultrasound was 69.6% (16 patients) with an average of 2.02± 1.9 of joints and 15 patients with Doppler. Therefore, only the 47.8% (11) of patients in remission/low activity was classified, compared to 100% and 65.2% of the regular and blind clinical respectively. 14 of the 23 patients were under optimization dose for 6–8 months, while 9 of them exceeded the 8 months. No differences were observed in the clinical status of both groups.

Table 1

| | Total (n=23 patients) |
|---|---|
| **A. Basal characteristics** | |
| Average age ± DE (years) | 57.7±9.7 |
| Average time of disease progression (years) | 11.57±5.86 |
| Immunology | |
| RF positive/CCP positive (%) | 87 |
| RF positive/CCP negative (%) | 4.3 |
| RF negative/CCP negative (%) | 8.7 |
| Treatment with DMARDs (%) | 60.9 (methotrexate 65.2%) |
| Biological treatment (optimization) (%) | 100 |
| Optimization average time (months) | 9.6±4.26 |
| **B. Clinical and functional characteristics** | |
| VAS | 48.26±24.80 |
| VGM | 18.48±15.62 |
| VGP | 45.22±24.65 |
| Joints painfull (number) | 2.62±2.85 |
| Joints swelling (number) | 2.65±2.82 |
| ESR | 10.74±6.78 |
| CRP | 3.37±7.32 |
| HAQ | 1.184±0.682 |
| CDAI usual rheumatologist | 3.2±3.04 |
| CDAI blind rheumatologist | 11.56±8.11 |

**Conclusions:** Our study shows how the exploration performed by a rheumatologist blind to the patient's clinical situation brings a lower percentage of remission compared to outpatient valuation. As well, with the ultrasound we can observe a greater sensitivity for the detection of the disease than with physical examination. The detection of subclinical joint damage is often undertreated, showing ultrasound as a noninvasive technique of great help reducing joint damage.

## AB0973 THE 8-JOINT ULTRASOUND SCORE IS USEFUL FOR MONITORING RESPONSE TO TREATMENT FOR RHEUMATOID ARTHRITIS

R. Yoshimi[1], Y. Toyota[1], N. Tsuchida[1], Y. Sugiyama[1], Y. Kunishita[1], D. Kishimoto[1], R. Kamiyama[1], K. Minegishi[1], M. Hama[1], Y. Kirino[1], S. Ohno[2], A. Ueda[1], H. Nakajima[1]. *[1]Department of Hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine; [2]Center for Rheumatic Disease, Yokohama City University Medical Center, Yokohama, Japan*

**Background:** Musculoskeletal ultrasonography (US) is one of the standard tools for the diagnosis and monitoring of rheumatoid arthritis (RA). Although we and other groups have proposed several sets of US assessment procedures in arbitrary combinations of selected joints,[1–3] there is still no consensus in defining the joints to evaluate.
**Objectives:** To investigate whether US assessment in the selected 8 joints which we advocate as a routine assessment is useful for monitoring response to treatment for RA.
**Methods:** Power Doppler (PD) US was performed in 24 joints, including all PIP, MCP, bilateral wrist and knee joints, as comprehensive evaluation in 15 RA patients treated with certolizumab pegol (CZP). Before and after treatment with CZP, PD signals were scored semiquantitatively from 0 to 3 in each joint, and total PD oscore-24 and total PD score-8 were calculated by summing up PD scores of the 24 joints and the selected 8 joints (bilateral second and third MCP, wrist, and knee joints), respectively.[1]
**Results:** Amount of change of total PD score-24 by treatment with CZP correlated highly with the changes of disease activity indices, SDAI ($r_s$ =0.91, $p$ <0.01) and DAS28-CRP ($r_s$ =0.86, $p$ <0.01). Although it correlated well with the changes of some components of disease activity indices, including swollen joint count ($r_s$ =0.74, $p$ <0.01), tender joint count ($r_s$ =0.86, $p$ <0.01), CRP ($r_s$ =0.85, $p$ <0.01) and ESR ($r_s$ =0.62, $p$ <0.01), there were no significant correlations between the changes of total PD score-24 and the changes of patient's global assessment ($r_s$ =0.42, $p$ >0.05) and evaluator's global assessment ($r_s$ =0.27, $p$ >0.05). Amount of change of total PD score-8 exhibited stronger correlations with the changes of SDAI ($r_s$ =0.92, $p$ <0.01) and DAS28-CRP ($r_s$ =0.89, $p$ <0.01) as compared to that of total PD score-24 (Figure 1). The change of total PD score-8 correlated more highly with the changes of swollen joint count ($r_s$ =0.81, $p$ <0.01) and tender joint count ($r_s$ =0.91, $p$ <0.01), while it showed lower correlation coefficients with the changes of patient's global assessment ($r_s$ =0.39, $p$ >0.05) and evaluator's global assessment ($r_s$ =0.22, $p$ >0.05) as compared to that of total PD score-24.

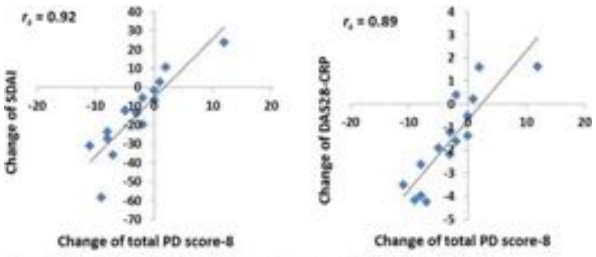

Figure 1 Correlation diagrams between the change of total PD score-8 and the change of disease activity indices.

**Conclusions:** This study suggests that total PD score-8 is useful for monitoring response to treatment in RA patients.

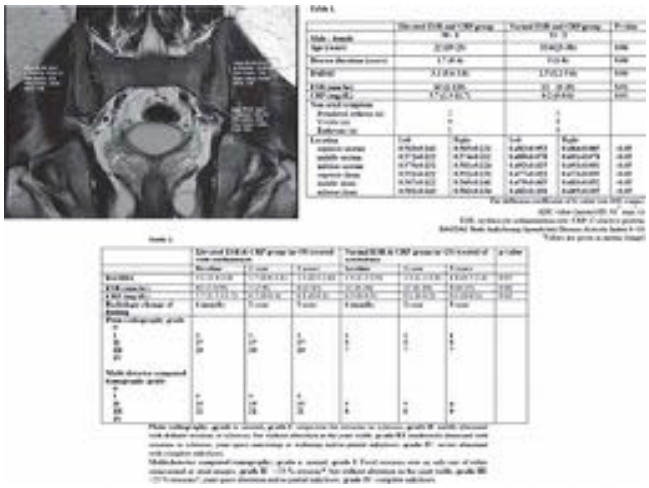
## AB0974 HIGH-FIELD MRI: INFRA-RADIOLOGICAL STRUCTURAL ABNORMALITIES DETECTION IN WRIST OF PATIENTS WITH SPONDYLOARTHRITIS AND EARLY RHEUMATOID ARTHRITIS



S. Guis[1], P. Souteyrand[2], D. Militianu[3], C. Chagnaud[2], Y. Le Fur[4], J.-P. Mattei[5], M. Rozenbaum[6], I. Rosner[6], H. Boudinet[1], M. Bernard[4], D. Bendahan[4]. *[1]Department of Rheumatology, Aix-Marseille University, AP-HM; [2]Radiology, AP-HM, Conception, Aix Marseille University, Marseille, France; [3]Musculo-Skeletal MRI, Rambam Health Care Campus, Haifa, Israel; [4]CRMBM/CEMEREM UMR CNRS 7339, CNRS, Aix Marseille University; [5]Department of Rheumatology, Aix-Marseille University, AP-HM, Marseille, France; [6]Department of Rheumatology, Bnai Zion Medical Center, Haifa, Israel*

**Background:** Previous studies have showed that structural abnormalities such as erosions and geodes could be detected in wrist of patients with Rheumatoid Arthritis (RA) using high-field MRI whereas corresponding anomalies were invisible using conventional 1.5 T MRI. Similar observations have not been reported so far for patients with either an early form of RA or patients with axial and peripheral forms of spondyloarthritis (SpA).
**Objectives:** In the present study, we compared wrist MRI investigations performed at 1.5 and 3 T in SpA and early RA patients (less than one-year disease evolution). We aimed at determining whether synovitis, geodes and erosions are similarly observed in both cases.
**Methods:** The study was conducted in the wrist of 9 SpA patients (6 with ankylosing spondyloarthritis (AS) and 3 with psoriatic arthritis) and in 7 early RA patients. Age in the RA group ranged from 35 to 54 (6 females, 1 male) while it ranged between 22 and 64 in the SpA group (7 females, 2 males). All the patients provided their written informed consent before their inclusion in the protocol which was approved by the local ethics committee.
MRI investigations were performed at 1.5T (Philips Achieva) using a Flex-M coil and at 3T (Siemens Verio) using a 4-channel flexible coil. In both cases, subjects were asked to lie down in the supine position inside the scanner and wrist was scanned at 1.5T using a T1-SE and a PD-FS-SE and at 3T using both a VIBE and a DESS sequences. MR images were analyzed by one senior radiologist (CC).
**Results:** In the RA group, we identified more abnormalities at 3T as compared to 1.5T for 1 patient while for 5 patients the number of abnormalities was identical in both cases. 1 patient did show no abnormality. Similarly, in the SpA group, more abnormalities were observed at 3T as compared to 1.5T for 2 patients. In those cases, more erosions were identified whereas geodes, synovitis and oedema were similar. These two patients had AS with peripheral and axial pain without psoriasis. For 1 patient with structural abnormalities, the results at both fields were similar. In 6 patients, (including 2 patients with psoriatic arthritis), we did not detect any structural abnormality.
**Conclusions:** In the present study, we illustrated that for both RA and SpA patients, MRI investigations performed at high-field can detect wrist abnormalities which were not detectable at 1.5T.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2459

## AB0975 DIFFUSION WEIGHT MAGNETIC RESONANCE IMAGING MAY PREDICT A TREATMENT RESPONSE IN ANKYLOSING SPONDYLITIS

S.Y. Lee, W.T. Chung, S.W. Lee. *Rheumatology of Internal Medicine, Dong-A University Hospital, Pusan, Korea, Republic Of*

**Background:** With the today's advanced magnetic resonance imaging (MRI) techniques, the pathologic features of ankylosing spondylitis (AS) can be detected early and promptly treatment.
**Objectives:** This study aimed to determine the value of diffusion-weighted MR imaging (DWI) in determined of AS treatment strategy and assess the role of quantitative MRI in the evaluation of AS treatment outcome.
**Methods:** 52 patients with the diagnosis of early AS were included in this study. Disease activity was measured according to clinical instruments and laboratory tests. For each patient, both inflamed sacroiliac (S-I) joint lesion was checked quantitatively at first diagnosis by diffusion-weighted MR imaging (DWI) and measured the apparent diffusion coefficient (ADC). Based on ADC value, low ADC value group were treated with conventional NSAIDs and high ADC value group were treated with TNF-α inhibitor. all subjects were revaluated continuously by pelvis multi-directional computer tomography (MDCT) for bone change in sacroiliac joint, after treatment.
**Results:** The high ADC value patient had higher BASDIA score, ESR and CRP than low ADC value patients relatively. The clinical parameters diminished significantly with regression of the inflammatory activity after treated with TNF-α

inhibitor or NSAIDs. But paradoxically, one patient who was low ADC value and treated with NSAID had radiologic change of S-I joint and no change of ADC value in follow up MRI.
**Conclusions:** The ADC value measured by DWI maybe predicted treatment response.

## AB0976 ACHILLES TENDON INJURY AND COMPLEX PATELLAR FOR OVERUSE IN SOCCER PLAYERS: ULTRASOUND INVESTIGATION BEFORE AND AFTER THE MATCH

S. Tropea[1], C. Trovato[2], A. Tropea[1]. *[1]reumatologia, CMPSA Center; [2]Sport Medicine, ASP 3, Catania, Italy*

**Background:** Football is one of the most popular sports in the world. Many players are suffering from disease of the Achilles tendon and the complex of the patellar tendon during periods of intense training with characteristics painful conditions of the tendons. Football players use their tendons to the limit because of the 'intensity of your workouts and frequent games. They participate in tournaments with echographic signs of underlying disease, and most of them play with a certain degree of pain.
**Objectives:** To investigate the changes in the players ultrasound at baseline and after participating in a youth football tournament.
**Methods:** 72 players were interviewed. 64 of the respondents underwent ultrasound examination before the game. 45 of the 64 players (70%) were scanned again at follow-up after the match. The interviews were conducted by the same person and all scans were done by the same doctor. The players were chosen randomly among those controlled interview Scanning was performed with a 15 MHz linear transducer. E 'was performed a careful examination grayscale and Doppler of the Achilles tendon and patellar complex. Ultimate goal was to determine the amount and distribution of activities Doppler with a score of 0–4.
**Results:** Sixty-two players (86%) had severe damage to tendons 80 over the past three years. 45 (50%) covered the whole patellar and 34 (37%) the Achilles tendon. In 60% of the problems they had started slowly and the mean duration of symptoms was 4 months (0–36). The '86% accepted the pain, 21% took painkillers, especially NSAIDs, to be able to play.
At baseline, the Doppler activity was evaluated in most players. After the match, these changes were not significantly changed in most investigated regions. However, a very significant increase was observed in the tendons on the non-dominant side: quadriceps (Willcoxon $p<0.001$), patellar tendon ($p<0.05$), and Achilles tendon central portion ($p<0.05$).
**Conclusions:** Doppler activity was found in all the tendons of soccer players examined to indicate a high degree of tension of these tendons. An increase in the fraction of color Doppler was significant only at the non-dominant leg. This can be explained by the fact that players load more frequently on this side. Changes Doppler correspond to the highest number of accidents on this side and a possible prognostic value of Doppler information is to be tested in a prospective study.

## AB0977 ULTRASONOGRAPHY-DETECTED SUBCLINICAL INFLAMMATION IN PATIENTS WITH HAND OSTEOARTHRITIS AND ESTABLISHED RHEUMATOID ARTHRITIS: EVALUATION OF DIFFERENT ULTRASOUND HAND JOINT SCORES

S. Hussain[1], P. Sivakumaran[1], A. Gill[2], D. Dhas[3], J. Manson[4], C. Ciurtin[4]. *[1]University College London Medical School; [2]Department of Rheumatology, North Middlesex University Hospital NHS Trust; [3]Department of Biomedical Sciences, Royal Holloway University; [4]Department of Rheumatology, University College London Hospitals NHS Foundation Trust, London, United Kingdom*

**Background:** Despite the interest in validating ultrasound (US) as an outcome measure in rheumatology, progress has been achieved only in defining the pathological US abnormalities associated with rheumatoid arthritis (RA). A recent review of US studies in osteoarthritis (OA) showed very limited data about hand OA (1). Patients with OA have been previously described as having synovial thickening (SH), erosions, osteophytes and rarely positive Power Doppler (PD) signal on US examination (2). These findings suggest a possible overlap between US features of hand OA and RA.
**Objectives:** This study aimed to investigate the usefulness of a standardised US examination protocol for hand joints in differentiating subclinical RA from OA, in patients with equivocal clinical examination. In addition, we explored which simplified hand US scores perform better for every disease taken separately.
**Methods:** A retrospective, observational study was conducted in patients with inflammatory hand joint pains referred to the US clinic with suspected subclinical inflammation. We compared patients with established RA (n=224) and hand OA (n=73), with respect of several demographic, clinical, laboratory and US parameters. We used a 22 hand joint US examination protocol (wrists, metacarpophalangeal and proximal interphalangeal joints bilaterally - OMERACT scoring system) for all patients, and compared it with a range of smaller, pre-defined US joint scores.
**Results:** Significant statistical differences were found for age at the time of scan, US parameters and clinical examination between the two groups. Subclinical joint inflammation in the context of equivocal clinical examination was found in 9.6% OA patients compared to 46.4% in RA ($p<0.05$). The comparison between several joint scores in OA patients suggested that for detecting subclinical inflammation, multiple finger joints should be examined (20 joint score, comprising MCPs and PIPs was significantly more informative than the 12, 10 and 4 joint scores, ($p<0.05$)), whereas in RA, the 4 joint scores (assessing wrists and MCP 5 or MCP 2 and 3 bilaterally) detected inflammation just as well as the 22 joint score ($p<0.05$).
**Conclusions:** Our study findings reflected differences between the incidence and characteristics of subclinical inflammation in patients with RA and OA. The attractiveness of using US scores assessing a smaller number of joints may pose limitations, despite being of benefit in a time-constrained clinical setting. Our study assessed comparatively the utility of several US hand scores, however, further research is need to validate their use in practice.

## AB0978 THE ASSOCIATION OF POWER DOPPLER SIGNAL GRADES WITH THE SERUM INFLAMMATORY MARKER LEVEL

J.-E. Park[1], H.-S. Lee[1], H.-D. Cho[2], T. Kang[1]. *[1]Department of Rheumatology, Yonsei University Wonju College of Medicine, Wonju, Gangwon-do; [2]Cho Hyung-Do Internal Medicine Clinic, Seoul, Korea, Republic Of*

**Background:** Power Doppler can show the degree of hyperemia in inflamed synovium. Serum inflammatory markers also reflect the arthritic activity in various rheumatic disease including rheumatoid arthritis. However, no report has been published regarding an association between them.
**Objectives:** We investigated an association between power Doppler semiquantitative signal grade and all the 5 serum inflammatory markers of white blood cell (WBC), hemoglobin (Hb) and platelet (PLT) count which possibly can be used in the practical field as well as commonly used ESR and CRP.
**Methods:** Rheumatic disease patients initially presenting with objective joint tenderness or swelling were evaluated with ultrasound and blood test was done to determine serum inflammatory marker level. A total of 827 ultrasound examined joints (112 metacarpophalangeal, 85 metatarsophalangeal, 82 proximal interphalangeal, 13 knee, 46 tendons, 136 ankle, 53 elbow, 15 hip, 255 wrist, 29 shoulder) from 2009 to 2014 were analyzed in this study. According to rheumatic disease classification, rheumatoid arthritis was most common and undifferentiated arthritis, ankylosing spondylitis and gout followed. ANOVA, two sample T-test, Spearman correlation test, multiple linear regression and logistic regression analysis were performed for statistics using SAS 9.2 version. $p<0.05$ were considered as significant.
**Results:** The presence of positive Doppler signal itself was associated with elevated ESR, CRP and PLT number but not Hb level at the time of ultrasound examination (ESR, CRP: $p<0.0001$, WBC: $p=0.0116$, platelet: $p=0.0246$). Spearman correlation coefficients showed positive linear association between power Doppler grade and serum levels inflammatory markers (ESR: $r=0.21$, CRP: $r=0.30$, WBC: $r=0.13$, platelet: 0.11, p-value $<0.05$) except Hb level. However, multiple linear regression test after adjusting confounding variables showed that only the CRP level among the 5 variables showed a positive relationship with power Doppler grade ($p=0.0022$). Furthermore, logistic regression test showed one step increase of Doppler grade resulted in 1.3 mg/dL increase of serum CRP level. Post hoc (Scheffe) analysis showed rheumatoid arthritis was the most correlated disease among the rheumatic diseases we included.
**Conclusions:** In a patient with presenting objective joint tenderness or swelling, if there is a positive power Doppler signal, it is associated with elevated serum markers of inflammation. Especially, the CRP is the only marker that have positive correlation with the Doppler signal semi-quantitative grade. One grade up of Power Doppler signal is expected to elevate CRP as amount of 1.3 mg/dL. Rheumatoid arthritis is the most associated disease that can be applied this result.

## AB0979 A COMPARISON OF PHYSICAL AND JOINT ULTRASONOGRAPHY FINDINGS OF THE MTP JOINT IN RHEUMATOID ARTHRITIS

T. Kashiwagura[1], Y. Kimura[2], I. Wakabayashi[2], Y. Yuasa[2], S. Miyamoto[3], M. Kobayashi[4], Y. Sugimura[5], N. Miyakoshi[6], Y. Shimada[6]. *[1]Department of Rehabilitation Medicine; [2]Department of Orthopedic Surgery, Akita City Hospital; [3]Department of Orthopedic Surgery, Nakadori Genaral Hospital, Akita; [4]Department of Orthopedic Surgery, Hiraka General Hospital, Yokote; [5]South Akita Orthopedic Clinic, Katagami; [6]Department of Orthopedic Surgery, Akita University Graduate School, Akita, Japan*

**Background:** Rheumatoid arthritis (RA) causes a variety of foot lesions, but the feet and ankles are not included in disease activity indices such as the Disease Activity Score (DAS). The spread and usefulness of joint ultrasonography in RA diagnosis and treatment have recently been reported. Many disease activity indices use tender (painful) joints and swollen joints, but few reports have examined the association between synovitis on joint ultrasonography and physical findings. This study evaluated joint ultrasonography of the metatarsophalangeal (MTP) joint in RA patients and examined the results in conjunction with physical findings.
**Objectives:** This study evaluated joint ultrasonography of the metatarsophalangeal (MTP) joint in RA patients and examined the results in conjunction with physical findings.
**Methods:** The subjects were 65 RA patients (82 feet) visiting our department on an outpatient basis. Surgical patients were excluded. Their mean age was 64.1 (27–84) years, and the disease stage was Stage I in 19 subjects, II in 11 subjects, III in 10 subjects, and IV in 25 subjects. The degree of functional disability according to the Steinbrocker classification was Class I in 45 subjects, Class II in 16 subjects, and Class III in four subjects. Disease activity according to the DAS28-ESR was complete response in 16 subjects, low disease activity (LDA) in 27 subjects, moderate disease activity in 14 subjects, and high disease activity in 7 subjects. Twenty-two subjects were taking a combination of biological agents. After interviewing subjects about any foot-related complaints, pain and swelling were evaluated, and joint ultrasonography was performed. The same examiner examined all subjects in the same room using the same diagnostic equipment. Grade 1 or higher on power Doppler ultrasonography was defined as synovitis.
**Results:** The detection rates of pain, swelling, and synovitis in all 410 toes were 33.9%, 14.1%, and 13.4%, respectively. Forefoot-related complaints were cited in 13 feet, and pain was observed in all subjects. However, synovitis was only detected in 38.5%, and many cases had asymptomatic synovitis. The detection rates of synovitis in subjects taking biological agents and subjects not taking biological agents were 11.0% and 24.4%, respectively, with no significant difference (Pearson's chi-squared test). When examined according to disease activity, synovitis was observed in 27.9% of those with LDA or less, which was the treatment objective. During the evaluations, joint swelling had to be differentiated from edema in a large number of cases.
**Conclusions:** Out of pain, swelling, and synovitis, the detection rate was highest for pain. This was likely due to the inclusion of pain other than that from arthritis, such as from subluxation and dislocation of the MTP joint and plantar calluses. There was a high prevalence of asymptomatic synovitis, suggesting the utility of evaluating synovitis by joint ultrasonography.

## AB0980 VALUE OF ULTRASOUND IN THE FOLLOW-UP OF PATIENTS AFTER NEEDLING AND LAVAGE OF CALCIFIC TENDINOPATHY

T. Garraud, C. Darrieutort-Lafitte, Y. Maugars, B. Le Goff. *Hopital Hotel Dieu Et Hme, NANTES CEDEX 1, France*

**Background:** Calcific tendinopathy is a frequent cause of shoulder pain. Needling and lavage of the calcification is considered as the first line treatment after failure of NSAID or physiotherapy. X-ray remains the best imaging modality to diagnose and follow-up calcification changes after treatment. Ultrasound (US) has also shown its interest in the diagnosis of calcific tendinopathy and to guide the needling. It allows an evaluation of the calcification aspect and size. However, the value of US to follow-up calcification changes after needling is currently unknown.
**Objectives:** The goal of our study was to evaluate the value of US in the follow-up of patients after needling and lavage of shoulder calcifications.
**Methods:** Patients undergoing a needling and lavage of a shoulder calcific deposit were followed prospectively. Calcification size was measured on X-Ray and their aspect classified according to the French Arthroscopy Association (type A (sharp contours and a homogeneous structure); type B (sharp contours and a nonhomogeneous structure). Measurements were performed at the same time with US and calcifications were classified according to their echogenicity (arc-shaped; fragmented with or without shadowing, nodular). Changes in the X-ray and US at 3 months were studied.
**Results:** Thirty patients were included, 20 female (66%), mean age 50 years (±11). On X-ray, calcifications were type A in 11 patients (36%) and type B in 19 patients (64%). Calcific deposits were mostly in the supraspinatus tendon (96%). Mean length, width and height of the calcific deposit were 15 mm (±6), 12 mm (±5.7) and 5.2 mm (±1.9) respectively. On US, calcification were arc shaped in 12 cases (40%), fragmented with shadowing in 15 (50%), without shadowing in one case and nodular in 2 cases (6.7%). Type A calcification on X-Ray were mainly arc shaped on US (80%) whereas type B on X-ray were fragmented or nodular on US in 79% of the cases. Bursitis was associated in 12 patients (40%). A significant correlation was found between the size of the calcification recorded on US and X-Ray (length (r=0.78), width (r=0.65) and height (r=0.59); $p<0.01$). A 3 months, 12 calcifications (40%) had completely disappeared on X-Ray, 3 (10%) were reduced between 50 and 90%, 9 (30%) reduced by less than 50% and (20%) had not changed. In contrast, only two patients had a complete disappearance of their calcific deposit on US. Calcifications became most of the time fragmented with (9; 30%) or without (12; 40%) acoustic shadowing. Calcific deposit remained arc shaped in only 2 patients. Bursitis was still present in 12 patients at 3 month.
**Conclusions:** US seems a good imaging modality to follow-up patients with calcific tendonitis. Indeed, we found a good correlation between the sizes of the calcification assessed by US and X-ray as well as their radiological and US pattern. Three months after needling and lavage of the calcification, US was able to depict changes in morphology of the calcific deposit and could still detect calcifications even in patients with a complete disappearance of the calcification on X-Ray. In view of the lack of radiation for the physician and the patients, US could be of value in the follow-up of patients after treatment of a calcific tendinopathy.

## AB0981 HAND JOINT INFLAMMATION IN EARLY RA: CLINICAL ULTRASOUND AND FLUORESCENCE OPTICAL IMAGING DIAGNOSTICS

Y. Kisten[1], E. af Klint[1,2], N. Györi[1], A. Karlsson[1], A. Levitsky[1], H. Rezaei[1,2], L. Arnaud[1], R. van Vollenhoven[1,3]. *[1]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska Institute; [2]The Rheumatology Unit and Clinic, Karolinska University Hospital, Stockholm, Sweden; [3]Departments AMC, READE and VUmc, Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam, Netherlands*

**Background:** Altered microcirculation (abnormal perfusion/capillary leakage) of synovial tissue can be detected early using Fluorescence Optical Imaging (FOI). FOI utilizes an intravenous fluorophore[1,2] that displays high-resolution hand images that can be analyzed visually (FOI-v) in real-time, or by using digital Disease ACTivity (DACT) scoring methods. We previously reported FOI's sensitivity and specificity in detecting silent synovitis in various rheumatic diseases[1].
**Objectives:** Here, we test the diagnostic performance of FOI-DACT in detecting subtle hand joint inflammation in early rheumatoid arthritis (eRA), as compared to clinical evaluation and MusculoSkeletal UltraSound (MSUS).
**Methods:** Fingers and wrists of patients with eRA were assessed by clinical examination, MSUS and FOI-DACT imaging. Inflammation was defined as having synovial hypertrophy/effusions and intra-articular Doppler signaling on MSUS, and as increased optical intensities on FOI-v. Scores of DACT$\geq$1 were considered indicative of disease activity.
**Results:** 1326 joints of 39 eRA patients [72% females, 56% previous/current smokers, 54% RF(+) and 69% ACPA(+)] were studied. The incidence and mean number ±SD of joints inflamed by clinical, MSUS and FOI-v were 23% (7.8±8.1), 29% (9.7±7.7) and 30% (10.3±7.2), respectively. Using MSUS as a reference, FOI-DACT was 95% (35/37) accurate in identifying patients with active disease, 24% (9/37) of whom had erosive RA. High correlations and agreements emerged between MSUS and FOI-v (r=0.803, $p<0.001$; kappa±SE:0.70±0.02 [95% CI 0.67–0.75]), clinical and FOI-v (r=0.732, $p<0.001$; kappa±SE:0.56±0.03 [95% CI 0.51–0.61]) and MSUS and clinical (r=0.793, $p<0.001$; kappa±SE:0.59±0.03 [95% CI 0.54–0.64]). The sensitivity, specificity, NPV and PPV of inflammation

by FOI-v was 81% (308/380), 90% (854/946), 61%, and 96% respectively. Of the clinically negative but MSUS positive (145/1023) joints, 68% (Subclinical: 98/145) were also FOI positive. Remarkably, one patient had 15 joints that were FOI-DACT positive and MSUS negative, but a month later, the same joints became MSUS positive. Although the wrists and MCPs were frequently inflamed, DIP joint inflammation was noted in 12 patients by FOI-DACT and MSUS. Nine of these patients had osteoarthritis by conventional radiography.

**Conclusions:** In early RA, Fluorescence Optical Imaging (FOI) coupled with digital Disease ACTivity (DACT) scoring correlates well with MSUS, and has a high positive predictive value. FOI-DACT emerges as a useful automated quantitative scoring method for synovial inflammation, and may be used in monitoring the effects of therapy.

## AB0982 DICHOTOMOUS SCORING OF RA ULTRASOUND INFLAMMATION DEMONSTRATES GOOD RESPONSIVENESS COMPARED TO SEMI-QUANTITATIVE SCORING WHEN USING NOVEL JOINT SELECTION METHODS

Y.K. Tan[1,2,3], J.C. Allen Jr[4], W.K. Lye[4], P.G. Conaghan[5,6], L.C. Chew[1,2,3], J. Thumboo[1,2,3]. *[1]Department of Rheumatology and Immunology, Singapore General Hospital; [2]Duke-NUS Graduate Medical School; [3]Yong Loo Lin School of Medicine, National University of Singapore; [4]Office of Clinical Sciences, Centre for Quantitative Medicine, Duke-NUS Graduate Medical School, Singapore, Singapore; [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [6]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*

**Background:** Novel joint selection methods using semi-quantitative scoring (SQS) of ultrasound (US) joint inflammation (power Doppler (PD) vascularity and grey-scale synovial hypertrophy (GSSH)) have shown good sensitivity to change versus existing methods and DAS28 in RA (1). However SQS may have more variability than dichotomous scoring (DS) as SQS requires grading across multiple categories.

**Objectives:** Compare responsiveness of DS of US joint inflammation versus SQS using 2 novel and 2 existing joint selection methods.

**Methods:** Novel methods were Individualized US [IUS], which selects up to 7 or 12 most inflamed joints on US and Individualized Composite-US [ICUS], which additionally considers joint symptoms. Existing methods were a pre-defined 7-joint count and a 12-joint count derived from an US data reduction method. PD vascularity and GSSH at the joints were scored via a DS system [USDSS] as Y/N or via a SQS system [USSQS] on a 0–3 severity scale. Both systems scored tenosynovitis (PD and GS changes), tender and swollen joints as Y/N. Joint pain was scored as Y/N (with USDSS) or using a 0–3 severity scale (with USSQS). Responsiveness at 3 months was measured using the standardized response mean (SRM). Relative gains in SRM magnitude (SRM-Gains) were reported comparing novel to existing methods.

**Results:** 20 RA subjects (mean DAS28 at baseline and 3-months =4.68 and 4.19, respectively) starting/escalating on DMARDs and corticosteroid therapy were followed for 3 months. SRMs using existing methods were modest for both USDSS and USSQS (ranged from 0.30 to 0.49). SRMs ranged from 0.94 to 1.06 using novel methods with both systems. There were substantial SRM-Gains (ranged from 1.94 to 3.47) for both systems using ICUS and IUS with the 7 or 12 joint approaches.

Table 1. Results of USDSS and USSQS

| Approach | 7-joint | | 12-joint | |
|---|---|---|---|---|
| | USDSS | USSQS | USDSS | USSQS |
| ICUS[#] | | | | |
| Baseline TIS* | 2.30 (0.79) | 1.87 (0.82) | 3.16 (1.18) | 2.46 (1.11) |
| 3 month TIS | 1.62 (0.71) | 1.25 (0.68) | 2.04 (0.94) | 1.67 (0.87) |
| SRM (95% CI) | 0.94 (0.40, 1.46) | 1.05 (0.49, 1.59) | 1.06 (0.50, 1.60) | 0.96 (0.42, 1.48) |
| SRM-Gain | 3.13 | 2.92 | 3.31 | 1.96 |
| IUS[†] | | | | |
| Baseline TIS | 2.83 (1.32) | 1.81 (1.08) | 3.59 (1.88) | 2.24 (1.47) |
| 3 month TIS | 1.89 (0.95) | 1.22 (0.69) | 2.44 (1.26) | 1.49 (0.88) |
| SRM (95% CI) | 1.04 (0.48, 1.58) | 0.98 (0.43, 1.50) | 1.02 (0.47, 1.55) | 0.95 (0.41, 1.47) |
| SRM-Gain | 3.47 | 2.72 | 3.19 | 1.94 |
| Existing[†] | | | | |
| Baseline TIS | 0.62 (0.39) | 0.43 (0.29) | 1.97 (1.12) | 1.17 (0.76) |
| 3 month TIS | 0.51 (0.39) | 0.35 (0.28) | 1.78 (1.07) | 1.02 (0.67) |
| SRM (95% CI) | 0.30 (–0.15, 0.75) | 0.36 (–0.09, 0.81) | 0.32 (–0.13, 0.77) | 0.49 (0.02, 0.95) |

*TIS: Total inflammatory score reported as mean (SD). [†]TIS of IUS and existing methods = sum of individual joint scores (IJSs) derived from US subscores from relevant joints per patient. [#]TIS of ICUS = sum of IJSs derived from clinical and US subscores from relevant joints per patient.

**Conclusions:** Results of this small study suggest USDSS may be as responsive as USSQS (both had substantial SRM-Gains) using novel joint selection methods.

## AB0983 WHAT IS THE FASTEST ROUTE FOR PATIENTS WITH INFLAMMATORY ARTHRITIS TO EARLY ARTHRITIS CLINIC

A.M. Al Marzooqi, J. Al Saleh. *Dubai Health Authority, Dubai, United Arab Emirates*

**Background:** Patient self-referral to a rheumatologist, without any former visit to the general practitioner (GP), was shown to be a significant contributing factor in delivering the optimal care for patients with early arthritis [1]. The literature has limited data on the referral of patients with early arthritis by secondary care specialities to rheumatologists. This abstract compares the time required for patients with inflammatory arthritis to access the rheumatology clinic when referred by different specialities.

**Methods:** We reviewed the medical records and electronic files of all patients with synovitis who attended our rheumatology clinic between 1st June 2012 and 1st June 2015. The following data was captured; demographics, time lag between onset of symptoms and the first rheumatologist consultation, date of referral, and the speciality of the referring physician. We stratified the patients according to the source of referral into two groups; GP referral and specialist referral. Data are presented as the median values and interquartile range (IQR). Mann-Whitney test was used to compare the two groups.

**Results:** We identified 173 patients with inflammatory arthritis. 134 (77.5%) were Emirati's, 137 (79.2%) were females, and median age was 41 (IQR 34–52 years). 91 (52.6%) patients were referred by a GP. The median delay from the onset of symptoms to assessment by a rheumatologist for patients referred by GP was 214 days (IQR 59–722). Whereas, for those referred by secondary care specialities was 95 days (IQR 31–372). This difference was statistically significant (Z-Score =2.4655, p-value $<0.01$). The fastest referral was through accident and emergency department 63 days (IQR 5–185).

**Conclusions:** In our population, patients with early arthritis were referred faster to the rheumatology clinic by a secondary care specialist rather than the GP.

## AB0984 HERPES ZOSTER VACCINATION, SHOULD OUR PATIENTS WITH RHEUMATOLOGICAL DISORDERS BE PRIORITIZED?

A. Khan, T. Roopa, L. Williamson, D. Collins, E. Price, A. Ahmed, S. Carty. *Rheumatology, Great Western Hospital Swindon, UK, Swindon, United Kingdom*

**Background:** Herpes Zoster infection is a common and painful condition with potential for serious complications. The overall life time risk is one in three but the risk is much higher in immunosuppressed patients and in our patients with rheumatological diseases. For example in patients with rheumatoid arthritis alone the risk is 2 fold higher compared to the age and sex matched controls.

The risk also increases with age and more than 50% of Herpes infection occurs in those aged over 60.

The Herpes Zoster vaccination has been approved by FDA for people aged 50 years and older and CDC recommends it in those aged 60 and above.

In United Kingdom this vaccination has recently been started, last year only people who were 70 and 79 years old were being offered the vaccine and this year those aged 71 and 78 are being vaccinated. Current guidelines do not recommend vaccination on biologic treatment, high dose steroid or other significant immunosuppression.

**Objectives:** This is a small study to look into Herpes infection in our rheumatology patients and whether we need a more pro-active approach towards vaccinating our patients particularly those who are about to start biologic therapies.

**Methods:** We looked at the self-reported incidence of Herpes Zoster infection in our cohort of rheumatology patients. We sent out a questionnaire to all patients on our biologics database asking if they had ever suffered from shingles and whether they had it before or after their respective rheumatological diagnosis and if they were on a biologic or non-biologic DMARD at the time of shingles.

Of 512 sent, 160 replied. Mean Age was (65) and main rheumatological diagnoses were: Rheumatoid Arthritis 96/160 (60%), Psoriatic Arthritis 29/160 (18%), and

Ankylosing spondylitis 21/160 (13%), the rest were other conditions treated with biologics.
**Results:** 38 of 160 (23.75%) had previous shingles and 6 of these 38 patients (15.7%) had suffered more than one episode. 24 of 38 (63.1%) patients had shingles post rheumatologic diagnosis and out of these 24; 6 (25.0%) had shingles whilst on biologic treatment; 6 (25.0%) had it whilst on combination DMARDs plus biologics; 9 (37.5%) on small molecule DMARDS; 3 patients could not tell their drugs at the time of shingles.
The mean age for those who had shingles was 61.8 years.
**Conclusions:** Nearly one quarter of patients on our biologic database reported one or more episodes of shingles. Out of them 63% had it post their rheumatological diagnosis, and most patients had it whilst on Biologic or Non-Biologic DMARDs.
The mean age of those who had shingles was 61.8 years which is much less than the current cut off for vaccination in UK.
This is a small study but serves as a reminder for us to consider a more proactive approach towards shingles vaccination in our rheumatology patients, particularly before starting Biologics, in older patients who do not qualify for routine government funded Vaccination.

## AB0985 CLINICAL CHARACTERISTICS AND MORTALITY OF OUR PATIENTS ADMITTED TO ICU

A. Garcia Vadillo[1], E. Garcia-Lorenzo[1], D.A. Rodriguez-Serrano[2], I. Llorente[1], L. Merino[1], J.P. Lopez-Bote[1], M.I. Lopez-Fernandez[2], I. Gonzalez-Alvaro[1]. *[1]Rheumatology Service; [2]Intensive Care Unit, Hospital Universitario de la Princesa, Madrid, Spain*

**Objectives:** To determine the characteristics and mortality of patients with inflammatory rheumatic diseases admitted to intensive care unit (ICU).
**Methods:** We present a retrospective observational study including all patients with inflammatory rheumatic diseases admitted to the ICU of a tertiary hospital in Madrid from January 2004 to December 2014. We excluded all those with stay of less than 24 hours in this unit. Patients who were readmitted to ICU during the same hospital admission were considered as a single entry. We retrospectively collected several characteristics of the diseases, including biological activity, and also treatments received for the three months before admission to the ICU. Statistical analysis was performed using Stata 12.1.
**Results:** A total population of 56 patients required 62 income in ICU (6 of them required 2 consecutive admissions). The mean age was 58.6 ±14 years. 55% were women. 41% of patients (23) had systemic vasculitis, 7 of them ANCA positive. 28.5% (16) suffered connective tissue disease: 10 spondylitis, 3 rheumatoid arthritis and 4 other different processes. The average from diagnosis until their first ICU admission was 127± 176 months. 67% of patients had previously been treated with glucocorticoids for an average of 13 months at a dose of 7 mg (p50) prednisone/day. 14% of patients had received boluses of glucocorticoids, 20% biologic therapies and 18% cyclophosphamide. 63% showed signs of disease activity at the time of entering the ICU.
At ICU admission APACHE II severity index was p50: 20 (p25-p75: 13.5–26) and p50 SAPSII: 34.5 (p25-p75: 24–43). The most common causes were respiratory failure (58% of episodes) and septic shock (14.5%). During their stay in ICU 79% of patients required glucocorticoids, 35% received boluses of glucocorticoids, 20% cyclophosphamide and 11% plasmapheresis. 41 patients (68%) required mechanical ventilation, being invasive in 38. The mean ICU stay was 15.8 ±14 days. 28.5% (16) patients died during their stay in this unit, and 11% (7 patients) died in the hospital after leaving the ICU. Deaths was significantly associated with age (OR: 1.09 annually), elderly (OR: 7.52 for patients $>70$ compared to those $<45$) female sex (OR 3.7), APACHE II (OR: 1.15 per unit increased) and iv administration of gamma globulins in ICU (OR: 16.6) in multivariate analysis.
**Conclusions:** Vasculitis and connective tissue diseases are the main inflammatory rheumatic diseases that require our patients to ICU admission. At the time of these they have high rates of disease gravity. Mortality was associated with advanced age, elderly, female sex, severity measured by APACHE II and also with the need of gamma globulin iv administration.

## AB0986 A SYSTEMATIC SCREENING OF COMORBIDITIES BY THE RHEUMATOLOGIST IN INFLAMMATORY RHEUMATISMS IMPACTS CHRONIC DISEASE CARE

A. Tubery[1], P. Fesler[2], G. Du Cailar[2], J. Morel[1], J. Bousquet[3], B. Combe[1], C. Daien[1]. *[1]Rheumatology Department; [2]Internal Medecine Department; [3]CAMAC steering committee, CHRU Lapeyronie, Montpellier, France*

**Background:** In chronic inflammatory rheumatic diseases, comorbidities such as cardiovascular disease and infections are sub-optimally managed. EULAR recently developed points to consider to collect and report comorbidities and up-dated recommendation on cardiovascular disease evaluation.
**Objectives:** We developed a systematic screening of comorbidities in out-patient daily clinic of the Rheumatology department in Montpellier University Hospital. Our objective was to evaluate the impact of such a screening.
**Methods:** The assessment included rheumatism evaluation, cardiovascular risk factors and diseases, osteoporosis, chronic respiratory disease screenings, check-up of vaccine calendar and recommended neoplasia screenings. This was a medical and paramedics evaluation (physicians, nurses and physiotherapists) including anthropometric and blood pressure measures, blood tests, vessel ultrasound, echocardiography, self-questionnaires, spirometry and bone mineral density. Therapeutic changes for rheumatism and osteoporosis were performed during hospitalization whereas those related to cardiovascular and lung diseases were addressed to the general practitioner. Three months later, patients were called and the application of recommendation evaluated.
**Results:** 200 patients had a systematic chronic disease screening with 78.5% (n=157) of RA, 18.5% (n=37) of spondyloarthritis, and 3% (n=6) of other diseases. The mean rheumatism duration was 14±9 years, the mean age was 59±11 years. Unknown or uncontrolled hypertension was diagnosed in 20.5% (n=41); LDL above the recommended target in 63% (n=126); unknown diabetes in 3.5% (n=7) of the patients and uncontrolled diabetes in 4 of the diabetic patients (23.5%). Moreover, 7 patients had low systolic pression index (3.5%), 10 had a significant supra-aortic vessel stenosis of more than 50% (5%) and 18 had significant abnormalities in echocardiography (9%). An obstructive respiratory syndrome was found in 20 patients (10%) and sleep apnea syndrome in 78 patients (39%). An anti-osteoporosis drug was prescribed in 11% (n=22) patients. The update of the vaccinations and the neoplasia screenings were proposed for 52.5% (n=105) and 39% (n=79) patients respectively. 144 patients received physiotherapy or occupational therapy advice for the management of their rheumatologic disease (72%). At 3 months, patients declared to have followed the recommendations in 50 to 75% of the cases, the items related to rheumatology being more often applied.
**Conclusions:** A daily hospitalisation for comorbidities screening seems profitable with many abnormalities discovered in patients yet monitored regularly at hospital. The effective implementation of the proposed or prescribed measures is being assessed.
**Disclosure of Interest:** None declared

## AB0987 RECURRENCE OF NSAID - INDUCED ULCERS: HAS THE SITUATION CHANGED IN RECENT YEARS?

A. Karateev, A. Tsurgan, N. Gontarenko. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Gastric or duodenal ulcers are one of the most common side effects of NSAIDs. These lesions are important as a cause of of life-threatening complications, such as GI-bleeding. Therefore, patients who had NSAIDs-induced ulcers in history require special control for the prophylaxis of GI-complications if they need to continue to use NSAIDs.
**Objectives:** To compare the frequency of relapses of NSAIDs-induced ulcers in patients with rheumatic diseases who had long-term use of NSAIDs during the periods of 1996–2006 and 2011–2013.
**Methods:** Group 1 (1996–2006): 407 pts (85.3% females, 52.1±13.6 y.o.), with gastric or duodenal ulcers, which developed during NSAIDs treatment; and 1640 pts (83.1% females, aged 50.1±14.6 y.o.), who didn't develop ulcer during NSAIDs intake. Group 2 (2011–2013): 82 pts (80.6% females, 58.3±12.7) with NSAIDs-induced gastric or duodenal ulcers, and 206 pts (85.1% females, 51.7±15.2 y.o.), without GI lesions during NSAIDs therapy. Patients from Group 1 used selective COX-2 inhibitors (coxibs) less in comparison to pts from Group – 4.9% vs 15.7%, as well as proton pump inhibitors (PPIs) – 14.6% vs 47.6% ($p$=0.000). All pts continued to use NSAIDs at least for one year after the first upper gastrointestinal endoscopy (UGE). All patients underwent repeated UGE after 12 months.
**Results:** Relapse of NSAID-induced ulcers were documented in 40.7% pts from Group 1, and in 28.0% pts from Group 2. Another situation was observed in patients of group 1 and 2 who did not have NSAID-induced GI lesions according data of first UGE. All of them continued to use NSAIDs $\geq$12 month and only 6.5% and 2.4% had developed ulcers according data of second UGE, respectively. PPI use significantly reduced the risk of relapsing NSAIDs-induced ulcers in Group 1 and 2: odds ratio (OR) 0.51 (95% CI 0.28–0.67) and OR 0.47 (95% CI 0.11–0.74).
**Conclusions:** Relapses of NSAID-induced ulcers still remain a serious problem. Pts with NSAID-induced ulcers in history should be protected with PPIs if they require continuation of using NSAIDs. Patients, who have not observed the development of NSAID-gastropathy with short-term NSAID therapy, have a lower risk of developing these lesions by continuing to use them for a long time.

## AB0988 CONSUMER PERCEIVED NEEDS FOR NON-HEALTH CARE SERVICES RELATED TO OSTEOARTHRITIS

J. Fairley, M. Seneviwickrama, F.M. Cicuttini, A.E. Wluka. *Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

**Background:** Osteoarthritis (OA) is a common condition worldwide, resulting in significant morbidity but with limited effective disease-modifying therapies. The challenges and disability of patients living with OA may not poorly recognised.
**Objectives:** We conducted a systematic search to identify consumer perceived needs for other services (not related to the provision of health information or health services) related to OA.
**Methods:** Medline, PsychINFO, Embase and CINAHL were searched electronically from 1990–2015 using a combination of MeSH terms and key words to capture consumer perceived needs in adults related to "other services" and "osteoarthritis". Articles were identified from the comprehensive search, with reference lists of reviews also examined. From relevant manuscripts, pertinent themes were identified and evidentiary data extracted to provide a systematic review of the current literature.
**Results:** 931 papers were identified, of which 5 investigated consumer perceived needs for other services amongst people with OA using qualitative methods (semi-structured interviews and focus groups). Participants were predominantly female 49.6–65 years, recruited from the outpatient setting. Joints involved were knee or hand.
Six key areas of perceived need emerged, identified in at least 2 manuscripts, including;
1) assistance for activities of daily living: consumers' ability to perform daily activities was limited by pain, thus requiring reliance on others and support from partners, use of gadgets and assistive devices to improve function;
2) assistance to perform exercise/leisure activities: consumers identified an inability to continue activities due to pain, becoming more sedentary;
3) facilitation of social participation: consumers identified barriers that could be overcome to improve this, including limited transport options, lack of understanding from families and community and poor profile of OA in the media;
4) financial security: cost of health-seeking behaviour and impact of reduced work;
5) occupational needs: the requirement for flexibility of scheduling and the work environment;
6) transport: was noted to be limited relating to person transport, with hand OA limiting the ability to drive and also public transport due to poor mobility.

**Conclusions:** This demonstrates the breadth of impact that OA has on daily life. This work was limited as no studies focussed on the perceived need for services, but rather on problems experienced by participants. Thus perceived needs can only be extrapolated, as they have not been directly assessed. This highlights the dearth of data pertaining to knowledge of consumer perceived needs relating to other needs required to combat difficulty in performing daily tasks and social functioning, which may often be overlooked by the health care system. A better understanding of consumer perceived needs of other services is required for the health care system and support groups to better meet consumers' needs relating to OA.
**Acknowledgement:** This work was supported by arthritis and osteoporosis Victoria. AE Wluka is the recipient of an Nhmrc career development fellowship (clinical level 2).

## AB0989 A REVIEW OF PNEUMOCYSTIS PNEUMONIA IN RHEUMATOLOGY PATIENTS IN THE NORTHERN HEALTH & SOCIAL CARE TRUST

A. Mcshane, A. Millar. *Rheumatlogy Dept, Northern Health & Social Care Trust, Co. Antrim, United Kingdom*

**Background:** Formerly known as pneumocystis carinii and more recently pneumocystis jiroveci, pneumoncystis pneumonia is a potentially life threatening opportunistic infection that occurs in immunocompromised patients. In rheumatology our patients are immunocompromised both due to their underlying condition and drug treatments required. With advancements in available drug treatments we are becoming more aware of the need for prohalaxis and early recognition of opportunistic infection.
**Objectives:** To determine the Incidence of Pneumocystis in Rheumatology Patients within our Trust
**Methods:** A Retrospective analysis of all positive virology samples for pneumocystis in the Northern Health and Social Care Trust between February 2011-September 2015.
**Results:** 2498 samples were received from the Trust in total. 90 of these were positive for pneumocystis pneumonia. 38 were paediatric patients and 52 adults. 1 adult was not identifiable and therefore excluded, resulting in 51 positive adults. Of these 9 were primary rheumatology patients (17.6%). 6 patients had rheumatoid arthritis (4 seropositive, 1 seronegative, 1 unknown). The remaining patients had psoriatic arthritis, polymyalgia rheumatica and dermatomyositis. At the time of diagnosis all but one of the patients were on immunosuppressive medications. None of the patients had received biologic treatments. 7 of the patients were receiving oral Prednisolone or had received intra-muscular depomedrone within 4 weeks of diagnosis. 6 of the patients were receiving Prednisolone plus a DMARD (5 Methotrexate, 1 Salazaparin). One patient was receiving Methotrexate mono therapy (dose 15mg) and one patient had no active rheumatology treatment for 6 months prior to diagnosis due to recurrent infections (previously having received Leflunomide for several years). The minimum dose of oral prednisolone at time of diagnosis was 7mg, with the maximum dose being 25mg. The minimum dose of Methotrexate was 15mg with maximum dose being 22.5mg. Mortality rate for rheumatology patients was 44.4% compared to overall mortality rate of 43% for all positive patients.
**Conclusions:** Rheumatology patients are at risk of opportunistic infections and accounted for 17.6% of Pneumocystis pneumonia within our Trust. The mortality rate is high and was higher in our group of patients than the general population affected. There are currently no guidelines available to advise on prevention or prohalaxis of pneumocystis. Biologics had not been used in our cohort of patients however there is concern that with the increased availability and usage of biologics we may see an increase in incidence of opportunistic infections. This study highlights the need for more investigation and guidance on pneumocystis prohalaxis in rheumatology patients

## AB0990 RITUXIMAB IN CHRONIC AUTOIMMUNE RHEUMATIC DISEASES: SAFETY AND CLINICAL PROFILE AFTER 12 AND 24 MONTHS OF FOLLOW-UP

C. Mata Martínez, L. Garcia-Montoya, J.G. Ovalles-Bonilla, J.C. Nieto, F.J. López-Longo, L. Valor, B. Serrano, R.D. González, C.N. Saenz, M. Correyero, I. Janta, J. Martínez Barrio, E. Naredo, C. González, D. Hernandez, I. Monteagudo on behalf of Gregorio Marañón University Hospital. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** Rituximab (RTX) is a chimeric monoclonal anti-CD20 antibody. Several studies have proved its safety when used in different autoimmune chronic rheumatic diseases (ACRD). However, the real conditions of daily practice are not comparable to the ideal frame of a clinical trial.
**Objectives:** The aim of this study is to describe the profile of safety of RTX in patients with ACRD 12 and 24 months after the administration of the first cycle.
**Methods:** It is an observational retrospective study of patients diagnosed with ACRD who received treatment with RTX. Data were collected on demographic, clinical and biochemical profiles right before the first infusion, 12 and 24 months later. Other parameters were concomitant medication, prednisone dose, previous biologic treatment, accumulated RTX dose, infusion and anaphylactic reactions, infections, tumor relapses.Comparison was done using Wilcoxon non parametric test.
**Results:** Data were collected from 50 patients that received RTX. 24 months after treatment no major cytopenias or hypogammaglobulinemia were found. Hepatic and lipid profile did not show any alterations and complement levels did not experiment relevant changes. The average dose of prednisone was reduced significantly 1 year after the treatment. A decline in levels of acute phase reactants and antibodies was observed. This effect was maintained in every parameter with the exception of the rheumatoid factor; which continued presenting a downwards trend after 24 months. Concerning the infections, 3 patients were hospitalised (because of severe infections): two of them suffered from pneumonia and the other one required a surgical intervention in order to replace an infected prosthetic knee. 14 mild infections were registered: 8 mucocutaneous, 2 gastrointestinal, 2 respiratory and 2 genitourinary. There were no cases of primoinfection, reactivation of hepatic viruses or mycobacteria.

No tumoral relapses, new diagnosis of tumors or demyelinising diseases were observed. 5 patients experimented mild infusion reactions but none of them had an anaphylactic reaction or died.

| ITEMS | N=50 (%) | | |
|---|---|---|---|
| Total average dose of prednisone (Grs) ±SD (Range) | 4± 2,4 (1-8) | | |
| Infusion reactions | 5 (10) | | |
| Mild-moderate infections | 14 (28%) | | |
| Severe infections | 3 (6%) | | |
| | Basal Average ±SD | 12 Months Average ±SD | 24 Months Average ±SD |
| Leucocytes (10E3/µL) | 7,8± 3,7 | 7,0±1,8 | 7,2±2,2 |
| Hemoglobin (g/dL) | 13,1±1,7 | 13,5±1,4 | 13,5±1,6 |
| Platelets (10E3/µL) | 248,1±94,4 | 238,6±56,9 | 237,1±60,2 |
| ESR (mm/1ªhora) | 20,4±19,1 | 11,7±12,6 * | 12,8±16,7 * |
| CRP (mg/dL) | 1,3±1,7 | 1,1±3,6 * | 0,9±1,5 * |
| ALT (U/L) | 37,5±81 | 22,6±28,9 | 20,6±10,6 |
| Total Cholesterol (mg/dL) | 193,9±38,8 | 196,1±36,9 | 194,4±36,2 |
| Rheumatoid Factor (UI/mL) | 1203,3±455,1 | 1114±423,4 | 135,3±477,9 * |
| ACPA RA♥ (UI/mL) | 772,1±939,4 | 400,9±516,4 * | 539,5±781,5 * |
| AntiDNA♥ (UI/mL) | 96,8±130,9 | 30±26,8 | 90±173,7 |
| IgG (mg/dL) | 1203,3±455,1 | 1114,5±423,4 * | 1184,5±440,0 * |
| IgM (mg/dL) | 172,7±138,7 | 111,5±72,9 * | 110,7±83,1 * |
| IgA (mg/dL) | 283,9±154,2 | 269,2±148,6 * | 259,8±151,5 * |
| C3 (mg/dL) | 100,1±26,5 | 101,5±20,2 | 98,8±21,1 |
| C4 (mg/dL) | 17,3±6,7 | 21,9±19,6 | 20,1±8,9 |
| Prednisone (mg/día) | 6,7±7,5 | 3,6±3,3 * | 3,8±3,6 * |

**Conclusions:** RTX has reduced the average maintenance dose of prednisone and also lowered the levels of serum immunoglobulins (including antibodies) without inducing hypogammaglobulinemia. It has proved to be a relatively safe treatment that does not cause hematic, hepatic toxicity or deep immunosuppresion after 12 and 24 months of follow up in patients with ACRD. Further studies are needed in order to evaluate long term safety of RTX.

## AB0991 DO WE REALLY KNOW WHEN WE SHOULD SCREEN FOR HEPATITIS B & C BEFORE STARTING IMMUNOSUPPRESSIVE THERAPY?

C. Annem, S. Arora, J.A. Block, M. Jolly. *Rheumatology, RUSH University, Chicago, Illinois, United States*

**Background:** Established guidelines from a variety of societies are vague and do not necessarily agree about recommendations for Hepatitis B & C (Hep B/C) screening prior to initiation of immuno suppresive medications (ISM)[1].

**Objectives:** This study was designed to better understand the existing practices for Hep B/C screening among rheumatologists. There were two primary aims: a) Determination of the *actual performance measures (PM)* (i.e. screening rates prior to ISM), as well as factors significantly associated with the likelihood of screening, among rheumatology patients and b) Determination of the *self-reported PM*'s among rheumatologists for each ISM and the associated factors.

**Methods:** For actual PM's, retrospective chart review study of 200 patients seen in the rheumatology clinic was done. Data collected included demographics, total number, name and dose of ISMs currently used, and if tests (and results) for Hep B/C were ordered prior to ISM initiation. ISM use was defined as current use of any ISM including corticosteroids. We defined Significant ISM (SISM) use as a) current use of prednisone ≥7.5 mg/day with hydroxy-chloroquine (HCQ), or (b) ISM use other than only HCQ. For self-reported PM's, a survey study was designed using Survey Monkey & e-mailed to 1200 rheumatologists. Data collected included demographics, board certification, number of years out of fellowship, setting of practice, number of patients seen in a month and hours of clinical care provided per week along with Hep B/C screening prior to each ISM. Options were scaled and included the following options: routinely screened or screened only if at high risk or did not routinely screen prior to starting ISM. Chi square test was used to compare discrete variables, while t tests were used to compare continuous variables.

**Results:** *Retrospective chart study:* A total of 200 patients were included, Mean age: 40 years, 85% female; 16% were on biologics and 82% were on SISM. Actual performance measures (PM) for Hep B/C screening ranged between 28–56% prior to ISM initiation. PM's for Hep B & C prior to ISM were as follows: biologics 72% & 69%; Anti-TNF 81% & 71% and SISM 62% & 57%, respectively. Age correlated negatively whereas number of ISMs correlated positively with Hep B/C screening. *Survey study:* Survey was mailed to 1200 rheumatologists, response rate: 20% (n=251), Nearly 60% were >15 years out of fellowship, 46% practicing academics, 43% saw >80 patients/week requiring ISM, and 74% spent >20 hours/week in clinical care. Self-reported PM's were varied for routine Hep B/C screening and ranged between 8–90% prior to ISM therapy. Age & years out of fellowship correlated inversely whereas number of patients seen per month correlated positively with screening.

**Conclusions:** Actual Hep B/C screening rates are low and range from 28–56% prior to initiating any ISM. In comparison, self-reported screening rates vary from 8–90% reflecting the varied physician screening practices with regards to various ISM. There is a clear need for consistent guidelines regarding screening for hep B/C in the presence of ISM therapy, and to improve awareness among rheumatologists regarding the risks of reactivation, and the need for screening and vaccination in at-risk patients.

## AB0992 "I NEVER HAD THE VERBIAGE": ENGAGING CLINIC STAFF TO ADAPT A TOBACCO CESSATION E-REFERRAL PROTOCOL FOR RHEUMATOLOGY CLINICS

C.M. Bartels[1], A. Gilmore[2], D. Panyard[1], C. Maxcy[1], R. Adsit[3], A. Skora[3], E. Ramly[4]. *[1]Rheumatology; [2]Nursing; [3]Medicine, Center for Tobacco Research Investigation; [4]Engineering, University of Wisconsin-Madison, Madison, WI, United States*

**Background:** Smoking increases the severity and cardiopulmonary complications of many rheumatologic conditions. Yet despite tobacco assessment in many rheumatology clinics, we reported that <10% of eligible notes documented cessation counselling. New models show increased efficacy with Ask-Advise-Connect approaches using non-physician staff protocols. Under protocols, front-line clinic staff assessing pre-visit vital signs and tobacco use are cued to recommend and refer patients electronically to telephone tobacco quit line support. Such approaches increased uptake of cessation support 13-fold in primary care studies but have not been adapted for rheumatology clinics.

**Objectives:** Our objective was to engage clinic staff in participatory work system redesign to develop and plan implementing an Ask-Advise-Connect tobacco protocol in rheumatology clinics. We report the results of this redesign study under the Systems Engineering In Patient Safety (SEIPS) model's five work system domains: people, organization, technology, environment, and tasks.

**Methods:** Our multidisciplinary team facilitated participatory work system redesign with medical assistants (MA) and nurses (RN) from three US academic rheumatology clinics. Staff participated in one of two hour-long focus groups. Trained facilitators used semi-structured interview questions informed by the SEIPS domains to appraise pre-visit assessment workflows, educational needs, proposed protocols, brochures, electronic health record (EHR) tools, and implementation plans.

**Results:** Over 80% (9 MAs, 5 RNs) of clinic nursing staff participated in focus groups. SEIPS domain questions facilitated discussions on intervention design, implementation, and sustainability planning (Table 1). The work system redesign included training (people); a protocol and workflows adapted to specialty care (organization, tasks); customized EHR alerts for assessing tobacco status and an EHR order set for e-referral to quit line services (technology); and physical cues like a desktop patient brochure linking rheumatologic conditions, tobacco use, and cardiovascular risk (environment).

Focus group participants reported routinely assessing tobacco use, but most had not asked about readiness to quit. A few had asked such questions, but noted low outcome expectancy and not knowing what to do next. One nurse said, "I'd ask, 'Are you ready to quit?' and they'd say 'No' and then I'd stop." Staff groups identified that education about links between tobacco use and rheumatologic diseases and stepwise support from our Ask-Advise-Connect protocol would help them overcome barriers to tobacco cessation counselling. They requested specific best-practice language in the EHR tools and appreciated rheumatology-specific brochures with printed conversational prompts.

Table 1. Results of Participatory Work System Redesign (n=16 MA and nurse participants)

| Work System Components | Before Redesign | Protocol Redesign Components |
|---|---|---|
| People | Staff uncomfortable with tobacco conversations | 1-hour education and rehearsal session with trained tobacco cessation experts |
| Organization | No tobacco care follow-up procedure | Standard protocol supported by clinic staff and leadership |
| Technology | No use of reminders to assess readiness to quit; no easy way to refer to quit line | EHR alert & order set with talking points for quit line referral and electronic transmittal to/from quit line |
| Environment | No physical cues for tobacco cessation conversations | Patient brochure on tobacco cessation tailored to rheumatology clinics discussing links with diseases |
| Tasks | Assessment of tobacco use only | **Ask** about tobacco use and 30-day readiness to quit, **Advise** quit line support, and **Connect** via e-referral to quit line who will call the patient within 48 hours |
| Staff Quotes: | *"I never had the verbiage to continue... I never asked [about tobacco cessation] because I didn't know where to go from there." Medical Assistant* | *"It doesn't seem like this [protocol] would be hard to do." Medical Assistant* |

**Conclusions:** We engaged rheumatology clinic staff in participatory work system redesign to plan implementing a tobacco cessation protocol. The

participatory redesign process resulted in a tailored implementation plan for a quasi-experimental trial of a tobacco cessation e-referral protocol in rheumatology clinics.

## AB0993 DEPRESSIVE SYMPTOMS IN PATIENTS CONSULTING FOR THE FIRST TIME A RHEUMATOLOGY SERVICE

C.J. Troitiño, M. Adrover, G. Calizaya, J. Lares, V. Durigan, V. Sandoval, P. Marcaida, S. Scarafia, V. Duarte, A. Secco, M. Mamani. *Reumatologia, Hospital Bernardino Rivadavia, Buenos Aires, Argentina*

**Background:** Depression can easily go unnoticed in routine clinical care. The delay in the diagnosis may increase the risk of chronicity, the number of visits, health care costs and deteriorates the quality of life.[1–3]
**Objectives:** Estimate the prevalence of depressive symptoms in patients consulting for the first time and determine if patients with depression had different reasons for consultation and highest score in the visual analog scale (VAS) of pain than patients without depression.
**Methods:** A observational, prospective study was performed. We included patients who consulted for the first time in Rheumatology Service, excluding these with psychiatric treatments and rheumatic diseases. The PHQ-9 (Patient Health Questionnaire) evaluated the presence of depressive symptoms in the last two weeks. According to the score, they were classified in 4 categories: (1) major depressive syndrome, (2) other depressive disorders, (3) positive depressive symptoms and (4) negative depressive symptoms. To perform the analysis the patients were divided into those with a depressive disorder (1 and 2) and those who did not have it (3 and 4). T-test or Mann Whitney test was used as sample size distribution for continuous variables. Chi square or Fisher exact test was used as expected frequency distribution table for categorical variables. Multivariate logistic regression analysis taking depression as the dependent variable was performed.
**Results:** 121 patients were included in the study. 86% were women, mean age of 49±15 years. The most frequent reasons for consultations were polyarthralgia (35.5%) and back pain (13%). According PHQ-9, 37% of patients were classified in major depressive syndrome and 19% in other depressive disorders. No statistically significant differences between patients with and without a depressive disorder in terms of different reasons were found. However, patients with depressive disorders were more VAS pain (7, IQR 5–8) than patients without depression (5, IQR 4–6) and more days with pain in the week (7, IQR 5–7 vs 5, IQR 3–7), both with $p<0.01$. Increased frequency of self-medication (61% vs 39%) and sleep disorders (63% vs 37%) among patients with depressive disorders was observed, although these differences were not statistically significant. In the multivariate analysis, the only variable that was found associated with depression was independently VAS pain (OR 1.33, CI 1.13–1.56).
**Conclusions:** High percentage of patients had a depressive disorder with higher frequency and pain perception. So rheumatologists should be aware of this problem in order to make a proper diagnosis, optimize the application of complementary studies, and perform a multidisciplinary approach to the patient.

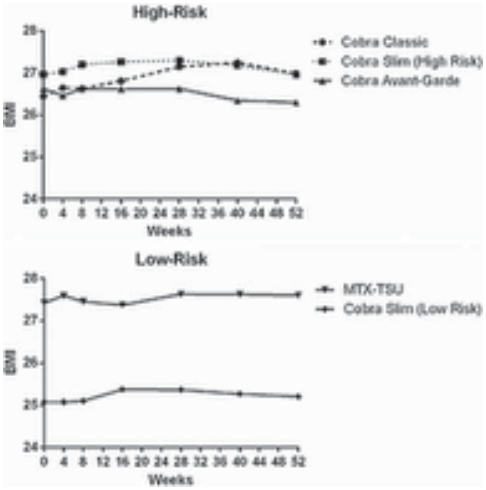
## AB0994 DETERMINANTS OF FUNCTIONAL CAPACITY IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS – A CROSS-SECTIONAL STUDY



D. Rosa-Gonçalves, M. Bernardes, L. Costa. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Impairment of functional capacity is a common problem for patients with rheumatoid arthritis (RA) with high costs for the patient and society in general. Therefore, it is important to explore its determinants.
**Objectives:** To find variables that can explain the functional capacity of patients with RA.
**Methods:** A cross-sectional study was conducted in 82 established RA patients under biological therapy from a university hospital of Portugal. The analyzed variables were: age, sex, age at disease onset, education level, disease duration, time under biological therapy, serology status, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), tender and swollen joint count, DAS28, radiographs scored by the van der Heijde modified Sharp method (sSharp score), HAQ (functional capacity), EQ-5D, physical and mental health summary measure of SF36 (SF36-PSM and SF36-MSM) and pain and patient global assessment of disease activity by visual analog scale (P-VAS and PGA-VAS). Descriptive statistics were calculated for several demographic and clinical characteristics. Pearson or Spearman correlations were used for the assessment of the correlations between the different variables and the HAQ. Subsequently, multiple linear regression analysis (backward selection) was carried out using the HAQ as the dependent variable. As independent variables, were included variables that had a significant association with HAQ in the univariate analysis.
**Results:** Most of patients (87.8%) were women; mean (SD) age was 55 (±11) years. Mean age at diagnosis was 34 (±11) years with a disease duration of 21 (±9) years. Most of the patients (n=72, 86.7%) were positive for rheumatoid factor and/or anti–citrullinated protein antibodies. Mean time under biological therapy was 7 (±3) years. Mean of HAQ was 1.19 (±0.66), DAS28 3.29 (±1.13), total sSharp score 191 (±77), EQ5D median (min,max) was 0.69 (-0.35,1.00), PSM 34.93 (14.21,65.50) and MSM 52.18 (23.07,66.23). HAQ correlation coefficients (r) above 40% were observed with, in descending order, EQ5D, PSM, PGA-VAS, P-VAS, age, total sSharp, hands and total erosion scores; $p<0.001$ for all analysis. DAS28 score and age at disease onset had a weak correlation (r=0.30 and 0.34, respectively, $p<0.05$). Time under biological therapy, serology status, disease duration, joint count, ESR and CRP showed weak or no significant correlations. Multiple regression analysis identified age, sex, total sSharp score, EQ5D and PSM as determinants of physical function (r=0.73, $r^2=0.71$; $p<0.001$). Absence of collinearity among the variables included in the regression model was observed.
**Conclusions:** This study, showed that older age, female gender, quality of life and joint damage are the main determinants of functional capacity. Furthermore, our results suggest that in established disease, HAQ score measures mainly the degree of joint damage and not the disease activity.

## AB0995 DOES BMI INCREASE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS WHEN TREATED WITH SHORT-TERM GLUCOCORTICOID REMISSION INDUCTION SCHEMES?

D. De Cock[1], R. Westhovens[1,2], V. Stouten[1], K. Van der Elst[2,3], J. Joly[2], P. Verschueren[2,3] on behalf of the CareRa Study Group. *[1]Skeletal Biology and Engineering Research Center, KU Leuven Department of Development and Regeneration, KU Leuven; [2]Rheumatology, University Hospitals Leuven; [3]Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium*

**Background:** Glucocorticoids (GCs) can rapidly reduce disease activity in many chronic inflammatory diseases. Numerous adverse events have been attributed to GCs. One of the most commonly mentioned and feared side effects is an increase in weight and BMI, especially with chronic GC use. However, data remains scarce about the impact of short term glucocorticoid remission induction schemes on BMI in patients with Early RA (ERA).
**Objectives:** To explore the BMI evolution of patients with ERA treated with short term glucocorticoid remission induction schemes in the (Care in Early RA) CareRA trial.
**Methods:** The CareRA trial is a RCT comparing remission induction regimens in a treat-to-target approach. DMARD naïve ERA patients were stratified into a high- or low-risk arm based on classical prognostic markers. High-risk patients were randomized to COBRA Classic (Methotrexate (MTX) + Sulphasalazine + prednisone step-down from 60mg), COBRA Slim (MTX + prednisone step-down from 30mg) or COBRA Avant-Garde (MTX + Leflunomide + prednisone step-down from 30mg) scheme. Low-risk patients were randomized to MTX tight step-up (MTX-TSU) without oral GCs or COBRA Slim. Prednisone was tapered down over 6 weeks to 7.5mg in Classic and 5mg in the other COBRA arms. Oral GCs were discontinued from Week 28 and stopped at week 34. Demographics including BMI and disease parameters were routinely registered. For this analysis, only patients with all BMI parameters on all study visits during the first 52 treatment weeks were included. BMI change per group was tested with a paired t-test. Differences in BMI change between groups were tested with a student's t-test, Spearman's rho was used for correlation between variables of interest and BMI change. Finally, an adjusted linear regression model further explored the effect of treatment choice on BMI change.
**Results:** 281 Of 379 patients were included. Figure 1 describes the evolution of BMI over 52 weeks for the different treatment strategies. Only patients on Cobra Classic had an increase in BMI after 52 weeks ($p=0.003$). In the High-Risk arm, change in BMI over 52 treatment weeks was larger in Classic versus Slim (High-Risk) ($p<0.039$) and in Classic versus Avant-Garde ($p<0.001$). In the Low-Risk arm, no difference between groups was found. No correlations were detected between change in BMI and cumulative GC dose, DAS28(CRP) change nor HAQ change. In the High-Risk arm, linear regression revealed a statistically significant effect of treatment strategy on BMI change, even when corrected for age, gender, GC cumulative dose, DAS28(CRP) change and HAQ change ($p=0.014$). No effect of treatment strategy on BMI change was seen in the Low-risk group in a similar linear regression model.
**Conclusions:** In general, BMI changes were small with any treatment strategy. A statistically significant increase in BMI over 52 weeks was only seen with a remission induction scheme starting at a high GC dose in patients with poor prognosis ERA. No difference in BMI change over 52 weeks was seen between

a remission induction scheme starting at a moderate GC dose and a treatment strategy without oral GCs in patients with good prognosis ERA.

## AB0996 TRANSLATION AND VALIDATION OF THE FLEMISH VERSION OF THE BRITISH DELAY QUESTIONNAIRE TO MEASURE HELP-SEEKING BEHAVIOUR IN PATIENTS WITH NEWLY ONSET RHEUMATOID ARTHRITIS

D. De Cock[1], V. Stouten[1], K. Van der Elst[2,3], J. Joly[3], S. Smulders[1], A. Engelen[1], F. Devarwaere[1], R. Westhovens[1,3], P. Verschueren[1,3]. *[1]Skeletal Biology and Engineering Research Center, KU Leuven Department of Development and Regeneration; [2]Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care; [3]Rheumatology, University Hospitals Leuven, Leuven, Belgium*

**Background:** Delays in initiating therapy in patients with Rheumatoid Arthritis (RA) adversely affect treatment outcomes such as disease activity, functional capacity and radiographic progression. Delays can be attributed to the patient, healthcare professional and the healthcare system. In Belgium and the UK, patient-related delay was shown to contribute most to overall treatment delay. A standardized instrument for measuring patients' help-seeking behaviour after symptom onset could aid in a better understanding of patient-related delay in RA.
**Objectives:** To develop a Flemish version of the original DELAY (delays in evaluating arthritis early) questionnaire following guidelines for cross-cultural adaptation and validation in Flemish speaking patients with early RA.
**Methods:** Firstly, the British questionnaire was independently forward translated by three Flemish speaking biomedical researchers (DDC, AE, SS), all fluent in the source language. A first Flemish consensus version was drafted by these three forward-translators and a rheumatologist (PV), including adaptation to intercultural differences. Secondly, a backward translation was carried out by one independent Flemish native translator (FD), naive to RA research and with advanced English language skills. This backward translated version was compared to the original questionnaire and discrepancies were discussed with the backward-translator, a forward translator (DDC) and a rheumatologist (PV) before drafting a new Flemish consensus version. This second draft was evaluated for clarity and comprehensibility by a group of five expert patients with RA and by a group of 6 healthcare professionals of our RA team, resulting in a pre-final Flemish version. Subsequently, for internal validation of the pre-final version, we randomly selected five Flemish patients with RA from the University Hospitals Leuven. After having read the questionnaire, these patients were individually inquired by DDC, and their comments were addressed in a final Flemish version of the questionnaire. External validation was performed by doing a test re-test evaluation in a consecutive sample of Flemish patients with early RA. Internal consistency and reproducibility were measured by Cronbach's alpha and the intra-class correlation coefficient (ICC), respectively.
**Results:** For the external validation, 32 patients were invited to participate. The questionnaire was completed twice within 2 weeks by 26 patients. The Flemish DELAY questionnaire showed satisfactory internal consistency (Cronbach's alpha, 0.95). Also reproducibility was satisfactory (ICC, 0.86).
**Conclusions:** The standardized translation and validation process preserved the content, construct validity and reproducibility of the original DELAY questionnaire and resulted in a valid version for mapping patient-related delay in Flemish patients with early RA.

## AB0997 DAY CARE HOSPITAL PATIENT ATTENDANCE CIRCUIT IN RHEUMATOLOGY: INTRODUCTION OF A NURSE CONSULTATION

E. Guerrero, I. Aramburu, N. Rivera, M.L. Garcia, E. Galindez, I. Torre, F. Garcia, J. Blanco, O. Fernandez, I. Calvo, E. Ruiz Lucea. *Rheumatology, Hospital Universitario de Basurto, Bilbao, Spain*

**Background:** Day care hospital (DCH) in rheumatology attends patients who need intravenous (IV) treatments, mainly biological therapy (BT), and other proceedings that cannot be made in the clinic but don't require hospitalization.The administration of BT demands a security monitoring prior to the administration that is made usually by the rheumatologist, which involves clinic overloading. The introduction of a protocolized nurse consultation (PNC)with the application of a security check-list would reduce the number of consultations without risks for the patient.
**Objectives:** To analyze the number of consultations and events registered after the introduction of a PNC in rheumatology DCH
**Methods:** Introduction of PNC in DCH with modification of the patient circuit from april 2015 in patients who receive BT as usual therapy (infliximab, abatacept, golimumab and tocilizumab). After the first consultation the patient is alternatively directed to the PNC (even consults) where the nurse applies the security check-list, provides the BT following the protocol, gives the activity questionnaires and records events, and the medical consultation (odds consults) where the rheumatologist carries out the anamnesis, physical examination, blood analysis and complementary tests review and treatment modifications. Retrospective review of patients, proceedings, consultations and events registered at DCH of Rheumatology over 2015 in a tertiary hospital after the introduction of a PNC in April 2015. Statistical analysis was made with SAS System for windows,v 9.2.
**Results:** Over 2015, 116 patients were attended in DCH: 49 rheumatoid arthritis (42,2%), 29 spondilytis (25,1%), 16 connective diseases (13,8%), 8 vasculitis (6,9%), 10 psoriastic arthritis (8,6%) and 4 juvenile arthritis (3,4%). Usual TB treatment received was: infliximab in 59, tocilizumab in 48, abatacept in 6 and golimumab in 3 patients. Over the period January- March/ April-December the following treatments were received: infliximab 72/ 214, tocilizumab 80/ 189, abatacept 8/ 36, and golimumab 3/ 21. 819 consultations were made: 610 medical (74,48%) (203 January-March and 407 April-December) and 209 nursery (25,52%) (April–December). 22 events were registered in the PNC (10,5%) that required telephone consultation with the rheumatologist: 6 common cold, 5 fever, 3 chills, 1 urinary disturbance, 2 dental removal, 2 arthritis, 1 skin eruption, 1 hypoglycemia, 1 peripheral edema), and five of them forced to the interruption of the treatment (2 urinary tract infections and 3 respiratory infections), giving the patient a new date in the medical consultation, without relevant secondary effects or complications for the patient.
**Conclusions:** The introduction of a Protocolized Nurse Consultation in Day Care Hospital in Rheumatology allows reduction in medical consultations number without relevant events in treatment administration or risks for the patient.

## AB0998 EVALUATION OF THE EFFECTIVENESS OF JOINT STATUS SELF-ASSESSMENT BY PATIENTS WITH RHEUMATOID ARTHRITIS

E. Yurova, E. Lygina, S. Yakushin, G. Bagirova, A. Vorobyev. *Ryazan State Medical University, Ryazan, Russian Federation*

**Objectives:** The cooperation in the "doctor-patient" pair is necessary to implement the TREAT TO TARGET conception in the management of rheumatoid arthritis (RA). For greater adherence to treatment, self–control of the disease activity is important for a patient. We have created an original method of training RA patients to self-assess the count of swollen and tender joints correctly. The objective of the research was to study the effectiveness of the method of training patients to self-assess the RA activity.
**Methods:** The study included 96 patients with the definite diagnosis of RA, according to the ACR/EULAR 2010 diagnostic criteria (88 females; 8 males, mean age 58,1 (51,0; 65,0), the median duration of RA was 8,3 (2,0; 11,5). During the first visit patients were trained using the original method of Disease Activity Self-Assessment (the physician demonstrated the technique of self-assessment of swollen and tender joints and provided the patient with printed guidelines and photos). During the second and third visits with one-month interval, there was an independent control of swollen and tender joint count by a physician and a patient. Statistical significance was analyzed using the McNemar's test.
**Results:** Absolute coincidence of the number of tender joints as assessed in parallel by a physician and a patient was observed in 35 cases during the second visit and in 62 (p=0,01) cases during the third visit. Absolute coincidence of the number of swollen joints as assessed in parallel by a physician and a patient was observed in 43 cases during the second visit and in 65 (p=0,01) cases during the third visit.
**Conclusions:** Our original method of Disease Activity Self-Assessment allows training most patients with RA to assess swollen and tender joints. This is

important for self-control of the diseases activity and allows a patent to visit a physician for timely therapy correction.

Pelegrin[19], R. Blanco[20], D. Diaz-Valle[4]. *[1]Rheumatology, Hospital Clínico San Carlos; [2]Research Unit, Spanish Society of Rheumatology; [3]Cancer Epidemiology Unit, National Center for Epidemiology, Instituto de Salud Carlos III; [4]Ophthalmology, Hospital Clínico San Carlos; [5]Rheumatology, Hospital Universitario Infanta Sofia, Madrid; [6]Ophthalmology, Hospital Universitario de León, León; [7]Ophthalmology; [8]Rheumatology, Hospital Universitario Dr Peset, Valencia; [9]Ophthalmology; [10]Rheumatology, Hospital de Gran Canaria Doctor Negrin, Gran Canaria; [11]Ophthalmology, Hospital Universitario Infanta Sofia, Madrid; [12]Ophthalmology, BioCruces Health Research Institute, Cruces University Hospital, Bilbao; [13]Rheumatology; [14]Ophthalmology, Hospital Universitario de Móstoles, Madrid; [15]ATLANTES Research Programme, Institute for Culture and Society, University of Navarra, Pamplona; [16]Rheumatology; [17]Ophthalmology, Hospital General Universitario de Valencia, Valencia; [18]Rheumatology; [19]Ophthalmology, Hospital Clínic of Barcelona, Barcelona; [20]Rheumatology, Hospital Universitario de Valdecilla, Santander, Spain*

**Background:** Uveitis is defined as inflammation of the uvea. As standardized and validated outcome measures are lacking in uveitis management.
**Objectives:** To develop a disease activity score for patients with uveitis and determine its discriminating ability to classify patients based on the level of activity.
**Methods:** Multicenter cross-sectional observational study. The construct "uveitis inflammation activity" was defined as intraocular inflammation. Seven dimensions and 14 items were identified and were agreed upon by experts via a two-round Delphi technique. Patients diagnosed with uveitis, who were aged five years or older and who presented inflammatory activity at the time of their visit, were selected. An ordinal logistic regression model was built in which the dependent variable was uveitis inflammatory activity (mild, moderate, or severe). Modeling accuracy for patient classification was assessed by the Area Under the Curve (AUC). Two AUC measures were calculated: one for discriminating mild versus moderate and severe activity level of uveitis, and another for mild and moderate versus severe activity.
**Results:** 195 patients were included. The regression model revealed an associations between intraocular activity level and an elevated number of anterior chamber cells ($OR_{4\ cells\ vs\ 0\ cells}$ = 27.85; 95% CI: 3.42; 226.75), a high degree of vitreous haze ($OR_{severe\ vs\ null}$ = 3.95; 95% CI: 1.40; 11.16), macular edema over 315mm ($OR_{>315\ vs\ \leq 315}$ = 3.58; 95% CI: 1.56; 8.21), inflammatory vessel sheathing (OR=4.43; 95% CI: 1.71; 11.53), higher patient evaluation scores ($OR_{1\text{-}unit\ increase}$ = 1.23; 95% CI: 1.09; 1.39), the presence of papilitis (OR=4.05; 95% CI: 1.18; 13.92) and increased numbers of choroidal or retinal lesions ($OR_{>6\ vs\ 0}$ =4.99; 95% CI =1.08; 23.01). The discriminatory capacity of UVEDAI was 87% for differentiating patients with mild uveitis from those with moderate or severe uveitis, and 88% for discriminating patients with mild or moderate uveitis versus those with severe uveitis.
**Conclusions:** UVEDAI assesses and classifies patients depending on global ocular inflammatory activity with high discriminative capacity.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2014

## AB1000 EVALUATION OF THE PRESENCE AND FREQUENCY OF NEUROPATHIC PAIN COMPONENT IN MYOFASCIAL PAIN SYNDROME

E. Tas[1], H. Genc[2], B. Nacir[2], A. Karagoz[2]. *[1]Physical Therapy and Rehabilitation, Canakkale State Hosbital, Canakkale; [2]Physical Therapy and Rehabilitation, Ankara Egitim Ve Arastirma Hastanesi, Ankara, Turkey*

**Background:** Neuropathic Pain Component in Myofascial Pain Syndrome is very imoprtant in the grups of aged between 20–50 years which is neck or upper back region. It was evalueyted by using specific diagnostic crtiteria, visual analog scale (VAS) and Neck Pain and Disability Index (NPDI)
**Objectives:** The aim of this study was to determine the presence and incidence of neuropathic pain in myofascial pain syndrome (MPS) and to detect factors that may be related to neuropathic pain
**Methods:** 112 patients with MPS in their neck or upper back region (aged between 20–50 years) and 62 age, gender and body mass index matched, healthy controls were included in the study. The existence of MPS was evaluated using specific diagnostic crtiteria. Pain assessment was made by visual analog scale (VAS). Neck Pain and Disability Index (NPDI) was used for the evaluation of the disability depends on neck and upper back pain. The existence of neuropathic pain component in both trigger point and referred pain regions was assessed with Leeds Assessment of Neuropathic Symptoms and Signs (LANSS), painDETECT and Douleur Neuropathique 4 (DN4) questionnaires.
**Results:** Mean ages of the patients with MPS was 33.4±8.0 years and controls was 33.5±8.4 years ($p>0.05$). The mean VAS score for pain and the mean NPDI values were significantly higher in the patients group (5.9±1.0 and 35.7±28.3, respectively, $p<0.001$). Neuropathic pain component was identified at both trigger points and referred pain areas in the patients group. Neuropathic component in the trigger point area was detected in 19 of 112 patients (17%) using DN4, in 4 patients (3.6%) using LANSS and in 2 patients (1.8%) using painDETECT scales. On the other hand; DN4, LANSS and painDETECT scales showed positive results for neuropathic component at 33 (% 29.5), 14 (% 12.5) and 12 (%10.7) of 112 patients in referred pain areas, respectively. Significant correlations were found between the higher values of NPDI and VAS with DN4, LANSS and painDETECT values in patiens with MPS.
**Conclusions:** In this study, the existence of neuropathic component was determined in both trigger point and referred pain regions of patients with MPS. Neuropathic component was more prominent in the referred pain area. Central pain mechanisms may be responsible for this result. Further studies with more patients are needed to confirm our results. We think that, it is important to consider neuropathic component in the treatment of MPS.

## AB1001 ONLINE CONSULTATION FOR CHINESE PATIENTS WITH RHEUMATIC DISEASES BASED ON SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILE TOOLS: A STUDY OF MEDICAL ECONOMICS

F. Xiao[1], X. Liu[2], H. Wei[3], H. Zhou[4], H. Wang[5], Y. Jiang[6], R. Mu[7], Z. Li[8], Y. Jia[1], Y. Zhao[1], Y. Liu[1], L. Zhang[1], F. Zhang[9]. *[1]Medical Department, Shanghai Gothic Internet Technology Co., Ltd., Shanghai; [2]the Third Affiliated Hospital of Peking University, Beijing; [3]Northern Jiangsu People's Hospital, Yangzhou; [4]First Affiliated Hospital of PLA General Hospital, Beijing; [5]JiaXing First Hospital, JiaXing; [6]Renji Hospital of Shanghai Jiaotong University School of Medicine, Shanghai; [7]People's Hospital, Beijing University Medical School, Beijing; [8]The First Affiliated Hospital of Bengbu Medical College, Bengbu; [9]Department of Rheumatology and Immunology, Peking Union Medical College Hospital, Beijing, China*

**Background:** China has no primary medical care and referral system. Patients can choose any hospitals or any doctors they like to seek medical care in China. As a result, most patients with rheumatic diseases rushed to a few large cities. Survey shows more than 40% of the rheumatic disease patients don't need to go to hospital and they only need advices from specialist.
Smart System of Disease Management (SSDM) is a series of applications for chronic diseases management, which develop the interaction between doctors and patients. The study shows that, after training, the RA patients can master the SSDM and perform self-management, including DAS28 and HAQ evaluations, as well as medication and lab test data entries.
**Objectives:** To evaluate the feasibility and benefit of the medical economics of online consultation based on SSDM by rheumatologist.
**Methods:** The rheumatologists implemented the education and training programs on using SSDM and assist the patients in downloading SSDM APP.
The SSDM includes doctors' application and patients' application. The patient application includes self-assessment (DAS28, HAQ), medication management, adverse events management and laboratory records. After data entry, patients can synchronize data to the authorized doctor. On the basis of understanding of the disease activities, medication and laboratory test results, the rheumatologists can accept consultation request from their patients, and practice consultation in the form of text or telephone call.
**Results:** Between February 14, 2015 and January 24, 2016, 11 rheumatologists supplied 76 patients with 58 times free and 45 paid consultations. Paid

Table 1: Detailed online consultation information with Smart System of Disease Management (SSDM).

| Doctors | Numbers of patients | Numbers of consultation | Actual payment (¥) | Projected direct cost (¥) | Projected indirect cost (¥) | Total projected cost (¥) | Saved (¥) | Saved (%) |
|---|---|---|---|---|---|---|---|---|
| Doctor FC Zhang | 18 | 29 | 9,300 | 9,300 | 46,700 | 56,000 | 46,700 | 83.39 |
| Doctor XY Liu | 23 | 24 | 800 | 4,800 | 34,100 | 38,900 | 38,100 | 97.94 |

| Doctor MZ Wang | 1 | 2 | 200 | 200 | 1,300 | 1,500 | 1,300 | 86.67 |
| Doctor YH Jiang | 1 | 2 | 150 | 150 | 2,800 | 2,950 | 2,800 | 94.92 |
| Doctor R Mu | 1 | 1 | 300 | 300 | 2,800 | 3,100 | 2,800 | 90.32 |
| Doctor Y Zhang | 1 | 1 | 200 | 200 | 1,300 | 1,500 | 1,300 | 86.70 |
| Doctor ZJ Li | 18 | 26 | 0 | 5,200 | 25,800 | 31,000 | 31,000 | 100.00 |
| Doctor YH Huang | 4 | 6 | 0 | 1,800 | 7,000 | 8,800 | 8,800 | 100.00 |
| Doctor Y Wang | 1 | 1 | 0 | 200 | 300 | 500 | 500 | 100.00 |
| Totally | 76 | 103 | 12,250 | 24,450 | 136,000 | 160,450 | 148,200 | 92.37 |

consultations included 34 times text Q&A and 11 telephone consultations. The consulting fee ranged from RMB 50 to 500 yuan (EUR: RMB =1:7.1) each in average of 272.22 ±90.40 yuan, which is approximate to the registration fee in hospital. The total amount of consultation fee was 12,250 yuan.
87% patients receiving online consultation lived in different city with the rheumatologists. If patients seek medical care in hospital, in addition to the registration fees and medical expenses, the mean cost of transportation, accommodation, meals and lost wages was 1320.39±456.10 (300 - 2,800) yuan. The total of cost for all patients would have been 160,450 yuan, which is 13.10 times compared with the cost of online. Through the SSDM system for online consultations, patients can save 92.37% of the cost. Table 1 shows detailed information. Survey shows all patients were satisfied and 64.86% of them were "very satisfied" with the consultations.
**Conclusions:** Using SSDM system to obtain online consultation, Chinese patients with rheumatic disease can enjoy reduced cost with high satisfaction. In the era lack of primary care system in China, SSDM may serve as a complimentary platform to control medical care cost, as well as relieve the tensions between health care professionals and patients.
**Disclosure of Interest:** None declared

## AB1002 DETERMINANTS OF QUALITY OF LIFE, LABOR-MARKET STATUS AND HEALTHCARE UTILIZATION IN ANKYLOSING SPONDYLITIS PATIENTS

F.M. Pimentel-Santos[1,2], I. Peyroteo[2], A.F. Mourão[1,2], E. Sousa[3], J. Costa[4], H. Santos[5], A. Barcelos[6], P. Pinto[7], J.E. Fonseca[3], J.C. Branco[1,2], P.P. Barros[8] on behalf of CORPOREA, Study Group. *[1]Rheumatology, CHLO, Hospital de Egas Moniz, EPE; [2]CEDOC, NMS-fcm, UNL; [3]Rheumatology, CHLN, Hospital de Santa Maria, EPE, Lisboa; [4]Rheumatology, Unidade Local de Saúde do Alto Minho, Hospital de Ponte Lima, EPE, Ponte de Lima; [5]Rheumatology, Instituto Português de Reumatologia, Lisboa; [6]Rheumatology, Centro Hospitalar do Baixo Vouga, Hospital de Aveiro, EPE, Aveiro; [7]Rheumatology, Centro Hospitalar de Vila Nova Gaia/Espinho, EPE, Vila Nova de Gaia; [8]NOVA School of Business & Economics, Lisboa, Portugal*

**Background:** Ankylosing Spondylitis (AS) typically affects young people, leading to progressive deterioration of physical function and quality of life (QoL) with higher use of healthcare services. Work disability and early retirement is also higher in AS patients than in the general population, with a remarkable negative impact on productivity and social costs.
**Objectives:** The objectives of this study were to assess the gradient of AS severity, measured by several well-established scores, for QoL, labour-market status and healthcare services demand, in a group of AS patients.
**Methods:** We collected cross-sectional data in patients under 65 years, concerning demographic characteristics, disease duration, time to diagnosis, BASDAI, BASFI, BASMI, SF-36, ASQoL, EQ-5D and evaluated the ASDAS. The number of appointments and emergency room visits during the year before and working status in active ages people, were also collected. To measure the gradient of AS on QoL scores, healthcare use and working status, regression models, with application of stepwise procedure for removal of statistically non-significant effects, were performed.
**Results:** A total of 369 patients were included (62.3% men and 37.1% women), with a mean age of 45.4±13.2 years (range 20–79 years). For SF-36 and ASQoL, only BASDAI and BASFI scores matter and both mean higher value associated with lower health and it seems that a one point increase in one score is roughly equal to one point increase in the other score. The same conclusion holds for EQ5D. The only difference lies with the group of patients with 7–12 years of schooling, who have higher utility score than the others. The probability of being employed is negatively related to age and to BASMI. Only the BASFI is positively associated with the number of medical appointments. Age and ASDAS are the only determinants of emergency rooms visits.
**Conclusions:** BASDAI and BASFAI, which are modifiable scores, are negatively associated with utility/ QoL scores. Age and BASMI (no modifiable scores) are negatively associated with being employed. In addition, earlier or later disease detection, have no influence on these gradients. Accuracy of therapy intervention has a pivotal role on impacts, more than a precise time in detection.

## AB1003 VALIDATION OF LAY DESCRIPTIONS OF LEVELS OF SEVERITY OF KNEE AND HIP OA IN THE KHOALA COHORT STUDY

F. Guillemin[1,2], M. Cross[3], W. Ngueyon Sime[1,2], L. March[3]. *[1]Inserm CIC-EC 1433; [2]University of Lorraine, EA 4360 APEMAC, Nancy, France; [3]Institute of Bone and Joint Research, University of Sydney, St Leonards, Australia*

**Background:** Estimating the proportion of the population with severe OA is of use in health service planning. To calculate the proportion of the population with mild, moderate or severe OA, the Global Burden of Disease 2010 Study (GBD2010) used published WOMAC scores. From this, the proportion of the population in high income countries with mild OA was estimated as 71%, moderate 27% and severe 2%.
Lay descriptions of levels of severity of OA were developed for GBD2010. If these are accurate measures of disease severity, these descriptions would be useful additions to population-based health questionnaires or brief assessments in clinical practice.
**Objectives:** To validate lay descriptions of mild, moderate and severe OA and determine the proportion of a cohort within each category.
**Methods:** Descriptions were presented to the KHOALA cohort comprising 878 OA knee and hip prevalent cases recruited as a representative sample of French patients with clinical and radiographic OA. Participants were asked to indicate which description they felt best described their condition. An additional level of "No pain or disability" was added for this cohort.
Mild OA was described as "Has pain in the leg, which causes some difficulty running, walking long distances, and getting up and down"
Moderate OA: "Has moderate pain in the leg, which makes the person limp, and causes some difficulty walking, standing, lifting and carrying heavy things, getting up and down and sleeping"
Severe OA: "Has severe pain in the leg, which makes the person limp and causes a lot of difficulty walking, standing, lifting and carrying heavy things, getting up and down, and sleeping"
Participants also completed WOMAC, EQ5D, EUROQOL VAS and walking times.
**Results:** Currently, 307 participants have completed the questionnaire with results shown below.

Table 1

| | No pain/ Difficulty Mean (sd) | Mild Mean (sd) | Moderate Mean (sd) | Severe Mean (sd) | P value |
|---|---|---|---|---|---|
| n | 49 | 135 | 80 | 43 | |
| % of total | 16.0 | 44.0 | 26.1 | 14.0 | |
| Age | 63.3 (7.1) | 60.5 (8.1) | 62.1 (8.7) | 61.3 (8.0) | |
| WOMAC Pain [0–20] | 3.0 (2.3) | 5.2 (2.6) | 7.5 (2.9) | 11.0 (2.9) | <0.0001 |
| WOMAC Function [0–68] | 11.4 (8.8) | 16.8 (9.4) | 25.1 (12.3) | 36.9 (9.3) | <0.0001 |
| EQ5D [0,1] | 0.9 (0.1) | 0.8 (0.2) | 0.7 (0.2) | 0.4 (0.3) | <0.0001 |
| EUROQOL VAS [0,100] | 76.2 (12.1) | 72.8 (15.1) | 63.8 (15.0) | 52.7 (14.9) | <0.0001 |
| Walking time | 90.9 (53.3) | 95.7 (84.9) | 55.5 (47.7) | 19.1 (12.1) | <0.0001 |

There was a significant trend for the WOMAC, EQ5D, EUROQOL and Maximal walking time to decline as self-reported level of severity moved from none through mild and moderate to severe. The lay descriptions show significant convergent and divergent validity with the standardized measures used.
**Conclusions:** These preliminary results suggest that the lay descriptions are understandable by participants in this cohort. Those who rated their condition as consistent with the severe description also scored worse on the measures of pain and function.
14% classified themselves as having severe OA, in contrast to GBD2010, where only 2% were classified as having severe OA. The burden of OA may in fact be greater than reported in GBD2010 as the proportion of the population living with more severe disease may have been underestimated.
Further assessment is being undertaken with a larger sample of the KHOALA cohort. These lay descriptions may be useful as a brief starting point for discussions in clinical care, or a contribution to the assessment of severity of OA.
**Disclosure of Interest:** None declared

## AB1004 SOURCES OF INFORMATION USED BY PATIENTS WITH RHEUMATIC DISEASES TREATED WITH SUBCUTANEOUS BIOLOGICAL THERAPY. RHEU-LIFE SURVEY

F.J. de Toro[1], E. Batlle[2], C.M. González[3], L. Cea-Calvo[4], M.A. Pérez-Calvo[4], L. Carmona[5]. *[1]Instituto de Investigación Biomédica de A Coruña, la Coruña; [2]Departamento de Salud Sant Joan, Alicante; [3]HGU Gregorio Marañón; [4]Medical Affairs, Merck Sharp & Dohme; [5]I. de Salud Musculoesquelética, InMusc, Madrid, Spain*

**Background:** Adequate information to patients on disease and therapies is important to improve lifestyle, adherence to treatments and outcomes.
**Objectives:** To describe which are the main sources of information for patients with rheumatic diseases treated with subcutaneous (SC) biological drugs, which ones they consider relevant, and their satisfaction with the information received from the clinical team.
**Methods:** RHEU-LIFE was a survey to patients >18 years with rheumatoid arthritis, axial spondyloarthritis or psoriatic arthritis treated with SC biological drugs, from 50 rheumatology outpatient clinics from Spain. The patients completed the survey anonymously at home. They selected from a list: 1) their sources of general information on disease (multiple choice), 2) the most important (one option), 3) who had informed them about the treatment alternatives (multiple choice) and 4) about the SC biological drug (multiple choice).
**Results:** The survey was given to 1000 patients, 592 responded (59.2%, mean age 51.7 years [SD 13.2], 42.4% men, 57.6% women). The main source of general information on disease was the rheumatologist (92.3%). Other sources mentioned were the primary care physician (21.7%), nurses (19.3%), medical websites (19.8%) or health related blogs (5.6%), brochures for patients (11.5%), friends or relatives (6.3%), patient associations (4.4%) or other patients (3.1%) and pharmacists (3.4%). Information about treatment options and the SC biological drug came mainly from the rheumatologist (>90%) and infrequently

from nurses or hospital pharmacists (Table). 46.1% mentioned having received only oral information, 6.0% only written and 45.2% both ways. Some 44.5% and 42.6% reported to be "very satisfied" and "satisfied" with the information received respectively, 10.6% "neither satisfied nor dissatisfied" and 2.1% and 0.2% "dissatisfied" or "very dissatisfied". 45.2% alleged to search for information about the biological treatment in sources other than the hospital clinical staff.

Sources of information mentioned by patients (multiple choice)

| | General info about treatment (%) | Specific info about the biologic drug (%) |
|---|---|---|
| Rheumatologist | 91.9 | 91.0 |
| Nurses | 10.2 | 17.9 |
| Hospital pharmacy | 3.2 | 11.5 |
| Others | 5.3 | 3.6 |
| Does not remember | 1.2 | 0.8 |
| No information received | 0.8 | 1.7 |

**Conclusions:** The rheumatologist is the main source of information for patients on SC biological drugs. Nurses and hospital pharmacists are seldom mentioned, even though being very often visited for drug dispensing. Satisfaction with the information received is high, however nearly half said to have searched for information on the biological drug in alternative sources.
**Acknowledgement:** This survey was financed by Merck Sharp & Dohme of Spain and endorsed by the patient's association ConArtritis (Arthritis National Coordinator).
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3616

## AB1005 MULTIPLE MODELING METHODS OF ADMINISTRATIVE DATA YIELD CONSISTENT RESULTS BUT LIMITED ABILITY TO PREDICT RHEUMATOID ARTHRITIS DISEASE ACTIVITY IN US VETERANS

G.W. Cannon[1], C.-C. Teng[2], N. Accortt[3], D. Collier[3], M. Trivedi[3], B.C. Sauer[2].
*[1]Rheumatology; [2]IDEAS Center, Salt Lake City VA Medical Center and University of Utah, Salt Lake City; [3]Amgen, Thousand Oaks, United States*

**Background:** Epidemiologic research would be significantly enhanced if accurate and reliable methods were available to assess rheumatoid arthritis (RA) disease activity using administrative data. The VA rheumatoid arthritis (VARA) registry is a prospective observational cohort that collects RA disease activity including the 28 joint count disease activity score (DAS28) and clinical disease activity index (CDAI). VA administrative data are available and can be employed to develop models to estimate RA disease activity measured by DAS28 and CDAI.
**Objectives:** 1. Use administrative data to develop models that predict disease activity.
2. Assess the accuracy of the model under different conditions including defining administrative variables as continuous (CON) and/or categorical (CAT) and stratifying by different disease durations.
3. Describe the accuracy of the models for predicting disease activity for both DAS28 and CDAI.
**Methods:** US Veterans with RA enrolled in the VARA registry without cancer, organ transplantation, or other autoimmune diseases were included in the model if they were enrolled in VA with one year of administrative data available before the first DAS28. We identified 1,275 administrative data elements with suspected association with disease activity for prediction modeling. The least absolute shrinkage and selection operator (LASSO) was used for variable selection and model development. A series of LASSO models were developed that varied the input variables. Variables were required to have $\geq$1% prevalence in the cohort to be included in model selection. Sub-analysis was also performed in patients with $\leq$2 years and $\leq$5 years of disease duration.
**Results:** There were 1,582 US Veterans with RA who fulfilled enrollment criteria. The average age was 62.7±11.0 years, 91% male, with a disease duration 13.7±12.1 years with 78% and 74% seropositive for rheumatoid factor and anti-CCP antibodies respectively. The adjusted r-square for the six models tested ranged from 0.20–0.24 for DAS28 and 0.17 to 0.24 for CDAI. When stratified by disease duration, the r-square associations for patients with and without $\leq$2 and $\leq$5 years of RA duration were 0.29–0.31 versus 0.22–0.27 for DAS28 and CDAI respectively.
**Conclusions:** The multiple models tested yielded very similar results with limited association of predicted disease activity with actual measured disease activity by DAS28 and CDAI in VARA. The use of CON versus CAT variables, multiple definitions for disease activity, and limitation of disease duration to early RA did drastically affect prediction accuracy. Future research should investigate additional strategies to collect components of disease activity measures directly from medical records.

## AB1006 ANTI-CITRULLINATED PEPTIDE ANTIBODIES AND RHEUMATOID FACTOR TESTING PATTERNS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN THE US

J. An[1], A. Lin[2], Z. Bider[3], E. Alemao[4], S.E. Connolly[4], T.C. Cheetham[3].
*[1]Western University of Health Sciences, Pomona; [2]Southern California Permanente Medical Group, Fontana; [3]Southern California Permanente Medical Group, Pasadena; [4]Bristol-Myers Squibb, Princeton, United States*

**Background:** Serological markers have been investigated for the identification of RA. Current diagnostic criteria recommend conducting tests for anti-citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) prior to reaching the RA diagnosis. However, there is a lack of information about how these tests are utilized in a managed care setting.
**Objectives:** To describe the frequency of ACPA/RF tests at the time of RA diagnosis and at follow-up, as well as to compare baseline characteristics between patients who received ACPA/RF tests and those who did not.
**Methods:** A cohort study was conducted using adult patients newly diagnosed with RA within a US integrated healthcare delivery system from 1 January 2007 to 31 December 2014. Individuals were followed from their first RA diagnosis (index date) until 30 June 2015. Patients were required to have two ICD-9 codes of 714.x, treatment with a DMARD, and continuous eligibility for 12 months prior to the index date (baseline period). At baseline, data were collected on co-morbid conditions, laboratory test results and dispensed medications. Descriptive statistics and multivariable logistic regression analyses were conducted to describe ACPA/RF testing patterns and to investigate baseline patient characteristics associated with ACPA/RF testing.
**Results:** A total of 7444 patients with newly diagnosed RA were identified. Mean (SD) age was 55.6 (15.0) years, 75% were female, 69% of patients received corticosteroid treatment and 22% had other autoimmune diseases at baseline. Overall, 83% had both ACPA and RF tests at baseline while 10% and 2% had only an RF or an ACPA test, respectively. Baseline ACPA and RF testing rates were increased over time ($p<0.001$) and both ACPA and RF testing rates were >90% from 2012 onwards (Table). At baseline, 34% of patients had positive ACPA and RF test results, 30% had negative ACPA and RF results, 6% had only ACPA-positive and 21% had only RF-positive results. During follow-up, 20% of patients repeated their ACPA tests; 11% had a repeat test within 1 year of baseline. Patients with a higher Elixhauser index (odds ratio [OR]=0.72, 95% CI 0.62, 0.95) were less likely to receive ACPA tests at baseline, whereas patients receiving NSAIDs (OR=1.45, 95% CI 1.25, 1.69) or corticosteroids (OR=1.23, 95% CI 1.07, 1.43) were more likely to receive baseline ACPA tests. Patients who had other autoimmune conditions were more likely to repeat their ACPA tests during follow-up.

Table 1. Baseline ACPA and RF testing rates by index year

| Index year | New RA patients, total N | Baseline ACPA test, N (%) | Baseline RF test, N (%) |
|---|---|---|---|
| 2007 | 1095 | 740 (67.6) | 919 (83.9) |
| 2008 | 926 | 703 (75.9) | 856 (92.4) |
| 2009 | 921 | 782 (84.9) | 870 (94.4) |
| 2010 | 914 | 796 (87.1) | 870 (95.2) |
| 2011 | 885 | 812 (91.8) | 856 (96.7) |
| 2012 | 921 | 847 (92.0) | 880 (95.5) |
| 2013 | 919 | 841 (91.5) | 876 (95.3) |
| 2014 | 863 | 829 (96.1) | 833 (96.5) |
| Total | 7444 | 6350 (85.3) | 6960 (93.5) |

**Conclusions:** ACPA and RF testing rates in patients with RA have increased over time, with 96% of patients with newly diagnosed RA receiving both tests at the time of RA diagnosis in 2014. However, there may be still discrepancies in testing based on co-morbidities and medications. The reasons why RF or ACPA tests were not conducted in some patients with RA remain to be identified.

**Abstract AB1005** – Table 1

| Variables included in the model | | DAS 28 (n=1,582) Numbers of variables | | | Adjusted r-square | CDAI (n=1,563) Numbers of variables | | | Adjusted r-square |
|---|---|---|---|---|---|---|---|---|---|
| | | Total | >1% prevalence | Final inclusion | | Total | >1% prevalence | Final inclusion | |
| All variables | CON + CAT | 1275 | 567 | 45 | 0.22 | 1275 | 565 | 54 | 0.21 |
| | CON only | 966 | 420 | 30 | 0.20 | 966 | 418 | 21 | 0.17 |
| | CAT only | 966 | 420 | 39 | 0.22 | 966 | 418 | 56 | 0.22 |
| Only clinical variables | CON + CAT | 253 | 175 | 32 | 0.22 | 253 | 173 | 71 | 0.24 |
| | CON only | 217 | 149 | 27 | 0.22 | 217 | 147 | 65 | 0.24 |
| | CAT only | 217 | 149 | 27 | 0.22 | 217 | 147 | 66 | 0.23 |

CON = continuous, CAT = categorical.

## AB1007 RECURRENT INFECTION AFTER BIOLOGICALS IN AUTOIMMUNE DISEASE: PRELIMINARY RESULTS WITH MUCOSAL VACCINES RECURRENT INFECTION AFTER BIOLOGICALS IN AUTOIMMUNE DISEASE: PRELIMINARY RESULTS WITH MUCOSAL VACCINES

J. Ochoa-Grullon[1], C. Morado[2], P. Macarron[2], D. Freites[2], I. Diaz[1], M. Nuñez-Beltrán[1], A. Rodriguez de la Peña[1], A. Comins-Boo[1], K. Llano Hernández[1], E. Rodriguez[1], E. Toledano[2], B. Fernandez[2], S. Sanchez-Ramón[1], G. Candelas[2]. *[1]inmunology; [2]rheumatology, Hospital Clinico, Madrid, Madrid, Spain*

**Background:** Over a decade has passed since the introduction of biologic therapies for autoimmune diseases.
The use of biologic therapies as an adjuvant to disease-modifying anti-rheumatic drugs (DMARDs) for the treatment of systemic autoimmune diseases is rapidly expanding, due the efficacy and safety profiles of these drugs, and the better understanding of the targets of altered immune regulation. However, infections complications after biologicals are major concerns in their use.
**Objectives:** The aim of this study is to evaluate the clinical benefit of new personalized polybacterial sublingual vaccines in patients with systemic autoimmune disease and recurrent infections.
**Methods:** An observational study in a cohort of patients with systemic autoimmune disease and recurrent respiratory tract infections (RRTI) (3 or more episodes of upper respiratory tract infection or at least 1 pneumonia episode per year) and recurrent urinary tract infections (RUTI) (3 or more UTIs per year) was carried out. All patients underwent immunization with sublingual polyvalent preparation (Bactek®, ImmunoteK S.L. Madrid, Spain) for RRTI (*Staphylococcus spp., S. pneumoniae, K. pneumoniae, B. catarrhalis, H. influenzae*) and RUTI (*K. pneumonia, E. coli, E. faecalis, P. vulgaris*). Immunological evaluation was performed at baseline and at 6- and 12-mo., including serum immunoglobulins, IgG subclasses, specific antibodies production and B and T cell subsets counts.
**Results:** Twenty-three patients (mean age, 55.52±15.69, 21 women and 2 men) were studied: rheumatoid arthritis (RA) (n=11, 47%), SLE (n=5, 22%), MCTD (n=3, 13%), psoriatic arthritis (n=1, 4.%), SLE/RA (n=1, 4%), DLE/Sjögren (n=1, 4%), cryoglobulinemia II (n=1, 4%) and Sjögren syndrome (n=1, 4%). All patients presented a decrease in RRTI and RUTI frequency at 6-mo of vaccine: RRTI decreased from 4.81±2.04 to 0.75±1.29 and RUTI from 4.56±1.59 to 0.22±0.44. An episode of pneumonia in two patients. Nine out of 23 patients (39%) showed alterations of the humoral immune response at baseline: hypogammaglobulinemia (n=6, 26%) and IgG2 subclass deficiency (n=3, 13%). Eleven of 23 (47%) disclosed a defect on specific antibody production to polysaccharide and protein stimuli, 7 (30%) with normal Ig serum levels and 5 (21%) with hypogammaglobulinemia. At baseline, 21 were on DMARDs (metotrexate in 12, 52%). The most used biologicals were anti-TNF-α monoclonal antibodies (n=9, 39%) followed by anti-CD20 (n=8, 34%) and tocilizumab (n=4, 17%).
**Conclusions:** Vaccination in immunosuppressed patients with systemic autoimmune disease and recurrent infections is a commonly missed opportunity. There is an urgent need to develop alternative strategies to prevent the overuse of antibiotics in what is called the post-antibiotic era. Our preliminary results seem to be promising in these patients, reducing the infections rates, avoiding chronic use of antibiotics and subsequent resistance and adverse effects.

## AB1008 PREVALENCE OF FIBROMYALGIA IN INFLAMMATORY RHEUMATIC DISEASE. SINGLE-CENTER CROSS-SECTIONAL STUDY IN 691 PATIENTS

A. Fan[1], A. Tournadre[1], B. Pereira[2], Z. Tatar[1], M. Couderc[1], S. Malochet-Guinamand[1], M. Sylvain[1], M. Soubrier[1], J.-J. Dubost[1]. *[1]Rheumatology department; [2]Biostatistics Unit, CHU Clermont-Ferrand, Clermont-Ferrand, France*

**Background:** Fibromyalgia (FM) is a prevalent syndrome in patients with inflammatory rheumatic disease.
**Objectives:** The purpose of this study was to evaluate and compare the prevalence of FM in various inflammatory rheumatic diseases.
**Methods:** This single-center cross-sectional study was conducted between September 2014 and April 2015. We screened for clinical signs of fibromyalgia in all patients presenting for rheumatoid arthritis (RA), spondyloarthritis (SpA), and connective tissue disease (Sjögren's syndrome (SS), systemic lupus erythematosus (SLE), scleroderma (Scl), myositis). Diagnosis of FM was based on ACR–90 classification criteria (to minimize interfering overlap between rheumatic disease-related pain and FM-related pain) and expert opinion.
**Results:** In total, 691 patients were included in the study: 325 RA, 298 SpA (59 psoriatic arthritis, 137 radiographic axial SpA, 64 non-radiographic axial SpA, 38 peripheral SpA), 28 SLE, 27 SS, 14 Scl, and 6 myositis. The population counted 451 women (65.3%) and 240 men (34.7%). Mean all-population age was 55.8±15.5 years. Median disease duration was 11 years [IQR 5–20]. In the total population, 55 patients (8%) met the ACR–90 criteria, and 97 patients (14%) were given a diagnosis of FM by the expert doctor. Prevalence of FM meeting ACR–90 criteria was 4.9% in RA, 11.1% in SpA, and 11.3% in connective tissue disease, and was significantly higher in the SpA group than in the RA group ($p$=0.05). The expert settled on a diagnosis of FM for 7.7% of patients with RA, 17.5% of patients with SpA, and 28.2% of patients with connective tissue disease. The expert diagnosed significantly more FM in SpA ($p$=0.003) and connective tissue disease ($p$=0.001) than in RA.
**Conclusions:** Concomitant fibromyalgia is prevalent in inflammatory rheumatic disease, especially in spondyloarthritis and connective tissue disease. The expert doctor makes the diagnosis of fibromyalgia more often than ACR–90 criteria.
**Disclosure of Interest:** None declared

## AB1009 AN EPIDEMIOLOGICAL STUDY OF THE PREVALENCE RATE OF IBP AND AXIAL SPA IN THE UNIVERSITY IN THE SOUTH OF CHINA

Z. Lin[1], F. Tong[2], Z. Hu[1], L. Fang[1], X. Chen[2], Q. Lv[1], Z. Liao[1], J. Gu[1]. *[1]Department of Rheumatology, Third Affiliated Hospital of Sun Yat-Sen Universit; [2]South China Agricultural University Hospital, Guangzhou, China*

**Background:** In China, there is little research supply the data of the prevalence rate of IBP and axial spondyloarthritis (axial SpA). However, IBP and axial spondyloarthritis were common in China, so it is important to get the data about them.
**Objectives:** Inflammatory back pain (IBP) is an important clinical features for ankylosing spondylitis and axial spondyloarthritis. We conducted an epidemiological study in a university detect prevalence rate of IBP and axial SpA.
**Methods:** 3770 students from South China Agricultural University were enrolled in our study. We investigate the patients information by questionnaires face to face. We collected patients' parameters including the parameters for diagnosis of IBP criteria (ASAS), which include onset age, insidious onset, improvement with exercise, no improvement with rest and pain at night. We also collected the parameters for diagnosis of axial spondyloarthritis criteria (ASAS). To assess prevalence rate of IBP and axial spondyloarthritis.
**Results:** (1) Data of the 3770 students enrolled were shown as follows: mean age was 19.48±2.80 years; female to male ratio was 1.45:1 (2229/1541). (1) 731 students (19.39%) had back pain. In these students, female to male ratio was 1.97:1 (485/246). (2) In patients who had the back pain, 111 (15.18%) students had IBP. In other word, in all students who involved in, 2.94% of them had Inflammatory back pain IBP. (3) After investigation, we found 333 students had received the HLA-B27 examination. 19 (5.71%) students were positive. And 13 students (3.90%) of them who had result of HLA-B27 were diagnosed as axial SpA. Based on the data, the prevalence rate of back pain and IBP was 19.39% and 2.94%, respectively. The prevalence rate of axial SpA were 3.90%. (4) Although more female students than male ones had back pain, more male than female ones were diagnosed as axial SpA (Back pain: Female/Male: 485/246, Axial SpA:Female/Male:4/9; P=0.014).

Table 1. The number of students with back pain, IBP and axial SpA in this study

| | Back pain | IBP | axial SpA |
|---|---|---|---|
| Female n (%) | 485 (66.35) | 61 (54.95) | 4 (30.77) |
| Male n (%) | 246 (33.65) | 50 (45.05) | 9 (69.23) |
| Totle | 731 | 111 | 13 |

**Conclusions:** In the south of China, the prevalence rate of back pain and IBP was 19.39% and 2.94% in university respectively, and the prevalence rate of axial SpA were 3.90%. Although more female students than male ones had back pain, male ones were more likely to suffer from axial SpA.

## AB1010 ACHIEVEMENT OF NICE QUALITY STANDARDS FOR PATIENTS WITH NEW PRESENTATION OF INFLAMMATORY ARTHRITIS: RESULTS FROM THE UK NATIONAL CLINICAL AUDIT FOR RHEUMATOID AND EARLY INFLAMMATORY ARTHRITIS

J. Ledingham[1], N. Snowden[2], J. Galloway[3], A. Rivett[4], J. Firth[2], E. Macphie[5], N. Kandala[6], I. Rowe[4], Z. Ide[4], E. Dennison[7] on behalf of BSR National Audit Project Working Group. *[1]Portsmouth Hospitals NHS Trust, Portsmouth; [2]Pennine MSK Partnership, Oldham; [3]King's College London; [4]British Society for Rheumatology, London; [5]Lancashire Care NHS Foundation Trust, Preston; [6]University of Portsmouth, Portsmouth; [7]Southampton University, Southampton, United Kingdom*

**Background:** The national audit office reported variation in the quality of services for patients with Inflammatory Arthritis (IA) in the UK in 2009. The Health Quality Improvement Partnership funded a national audit to explore this further.
**Objectives:** We set out to assesses whether trusts in England & Wales are achieving the 7 quality standards (QS) published by the National Institute for Health & Care Excellence (NICE).
**Methods:** All individuals >16 years presenting to specialist rheumatology services in England & Wales with suspected new onset IA were recruited. Clinician & patient derived data were collected against all NICE QS over the 1st 3 months of specialist care.
**Results:** 6,354 patients were recruited nationally from 1 February 2014 to 31 January 2015. 94% of trusts/health submitted data. Patients were predominantly female (66%); white British (79%); and of working age (70%). At recruitment 46% had a diagnosis of Rheumatoid Arthritis (RA); 16% undifferentiated inflammatory arthritis (EIA).
Only 17% of patients were referred by their general practitioner (GP) within 3 days of first presentation (QS1); median time interval 34 days. Over 25% waited >3 months. 12% of referrals had no indication that EIA was suspected.
Specialist assessment occurred <3 weeks of referral for 38% (QS2). The median time interval was 4 weeks, >25% of patients waited >7 weeks. Higher staffing levels (>1 consultant/100,000 population) & the presence of EIA clinics were associated with shorter waiting times (odds ratio (95%CI) 1.3 (1.1–1.4) & 1.6 (1.4–1.7) respectively).
Disease modifying anti-rheumatic drug (DMARD) initiation within 6 weeks of referral (QS3) was achieved in 53% of RA patients; 36% were treated with combination DMARDs & 82% with steroids.
Clinicians reported that 59% of patients received structured education (QS4). Treat to target plans were set for 91% of patients. These targets were achieved in only 27% (QS5). Almost all trusts reported access to urgent advice (QS6) & incorporated annual review services (QS7).
**Conclusions:** This audit has enabled English & Welsh rheumatology services to measure their performance against NICE QS for the early management of IA & RA, benchmarked to regional & national comparators for the first time. The findings clearly demonstrate where improvement is needed. Delays in referral from primary care as well as delays in offering a first appointment in secondary care have been identified as key barriers to effective early arthritis care.

## AB1011 VITAMIN D STATUS – A TRANSVERSAL EVALUATION IN RHEUMATIC PATIENTS

J.L. Borges[1], S. Fernandes[1], V. Vieira[2], A. Cardoso[3], H. Madeira[1], M.J. Mediavilla[1], R. Leitão[1], C. Silva[1], A. Faustino[1]. *[1]Rheumatology, Instituto Português de Reumatologia, Lisbon; [2]Centro Hospitalar de Leiria, Leiria; [3]Nutrition, Instituto Português de Reumatologia, Lisbon, Portugal*

**Background:** Vitamin D deficiency is a condition reported both in young adults and in elderly and institutionalized patients. It has been increasingly recognized and, although conflicting data subsists, hypovitaminosis D has been related to a variety of rheumatic conditions from osteoporosis (OP) to inflammatory diseases and generalized pain syndromes.
**Objectives:** To assess vitamin D status in a rheumatic outpatient setting.
**Methods:** Observational, transversal, retrospective study encompassing rheumatic outpatients with at least one 25-hidroxyvitamin D determination since 2014. Data ascertained included gender, age, parathyroid hormone (PTH) and vitamin D levels, rheumatic conditions (<3/patient), co morbidities and therapeutics. Bone mineral density was assessed by densitometry (DXA) and results classified as normal (Tscore >-1), osteopenia (-2.5<Tscore<-1) and osteoporosis (Tscore<-2.5). Statistics: Mann-Whitney, Kruskal-Wallis, ANOVA and Chi-Squared tests and Pearson's correlation; $p<0.05$. Software: SPSS 17.
**Results:** 370 patients included, 87.3% female, mean age 64.9±13.9 years (y), 151 patients <65y. Most prevalent rheumatic conditions: osteoarthritis (OA; 47.8%), OP (43.5% - 33.5% of which with reported fractures), fibromyalgia (FM; 14.6%) and rheumatoid arthritis (RA; 13.2%); 43.9% patients had inflammatory diseases. Most common co morbidities: arterial hypertension (38.6%), dyslipidemia (32.4%) and depression (22.9%). 38.4% were on synthetic Disease Modifying Anti-Rheumatic Drugs (DMARD); 34.1% on corticosteroids (CTC), 49.2% on bisphosphonates (BF) and 69.5% on calcium/vitamin D (Ca/D) supplements. As for patients with available DXA, 41.4% were classified as having osteopenia and 43.6% as having osteoporosis. Mean vitamin D was 29.7±24.5μg/L; 65.4% patients had vitamin D levels <30μg/L. Mean PTH was 56.6±31.3ng/L and alkaline phosphatase (ALP) was 73.8±31.8U/L. In the group >65y, mean PTH was higher than in the <65y group (61.3±33.6 vs 49.7±26.1, p=0.015); 70.9% of the patients <65y and 61.6% of the patients >65y had vitamin D<30 – not significant. We compared vitamin D in OP vs OP with fractures vs OA vs associated OP/OA and found lower vitamin D levels in patients with isolated OA (38.7±32.5 vs 38.1±33.9 vs 25.9±23.3 vs 30.6±20.7, p=0.012); 76.6% with isolated OA had vitamin D<30. 55.7% of the patients on BF >5y, 61.2% on BF <5y and 72.3% without BF had vitamin D<30 (p=0.013). 68.7% in the group with inflammatory conditions and 62.9% in the group with non-inflammatory conditions had vitamin D <30 – not significant. We further compared vitamin D levels in OA vs AR, AR vs FM and OA vs FM, DMARD and CTC use and Ca/D supplementation and found no difference. There was a positive correlation between age and vitamin D (r=0.111, p=0.033), age and PTH (r=0.208, p=0.010) and vitamin D and ALP levels (r=0.311, p<0.0001).
**Conclusions:** In this study, vitamin D levels <30μg/L were found in nearly 2/3 of patients, across disease groups. There was a tendency for higher vitamin D levels in elderly patients, in the group with OP comparing with OA and in the group on BF, which may be related to previous supplementation. A potential bias is the fact rheumatologists request vitamin D dosing in patients with risk factors/clinical features of hypovitaminosis.

## AB1012 KNOWLEDGE AND USE OF DERIVATION PATHWAYS FROM PRIMARY HEALTH CARE TO ONSET ARTHRITIS OUTPATIENT CLINICS. IMPROVEMENT STRATEGIES

J.J. Perez Venegas, Y. Cabello Fernandez, M.J. Rodriguez Valls, C. Aranda-Valera, M.D. Toledo Coello. *Rheumatology, Hospital de Jerez, Jerez de la Frontera, Spain*

**Background:** Among the factors that allow early diagnosis of recent-onset arthritis, there is the implementation of preferential derivation pathways from Primary Health Care (PHC). For 18 months, the Rheumatology unit from Health Area North of Cadiz (HANC) provides these routes (WEB/FAX) with criteria agreed with PHC. We analyze the opinion of primary care physicians on the need for early diagnosis of arthritis, degree of knowledge and use of these tools by PHC and collect proposals for improving the accessibility of these patients to our unit.
**Objectives:** To analyze the level of knowledge and use of the preferential derivation pathways from primary care physicians to onset arthritis outpatient clinics; assess the satisfaction of the response received from the doctor and the importance of early diagnosis of rheumatoid arthritis for primary care physicians and collect proposals for improvement.
**Methods:** Sharing a survey to primary care physicians from HANC serving 411,000 habitants. Demographics of respondents, uptime in the public health system, number of patients seen per day, % estimated of musculoeskeletal pathology patients treated per day, importance of early diagnosis of rheumatoid arthritis and motives, level of knowledge of preferential derivation pathways collected by FAX/WEB, degree of utilization of these pathways, assessment and utility response received and proposals for improvement. A descriptive analysis of the sample is performed.
**Results:** A total of 77 surveys from 13 Health Centers from HANC were analyzed. The 62.34% were men and 66.1% older than 50 years; 62% of respondents has worked in the public health system over 20 years. 88.3% (68) professionals attend over 40 patients/day and 40.2% (31) of respondents reported that 20–30% of consultations were musculoskeletal cause. 96.1% (74) of respondents gave importance to the early detection of arthritis, the main reason to avoid joint damage and improvement in quality of life (84.4%) and the establishment of an early treatment (79.2%). 87.01% (67) was unaware of the preferential derivation pathways through the web and 38.9% (30) knew via FAX. Only 19 doctors (24.6%) respondents acknowledged having used the pathway in the past 6 months; 17 of them (22.08%) considered appropriate response received. 97.4% of respondents considered helpful the existence of these preferential derivation pathways. Between strategies for improvement, 81.2% (63) propose conducting training and outreach campaigns, 88.31% (68) raises the need for training sessions and 79.2% (61) considered necessary conducting face consultations in health centers.
**Conclusions:** A high percentage of primary care physicians surveyed recognize the importance of early diagnosis of recent-onset arthritis. Despite having preferential derivation pathways, there is a high degree of ignorance and low utilization of them. However, professionals who use them regard the response perceived as adequate. Most respondents believe that conducting training, outreach and onsite consulting and improvement strategies for early diagnosis of arthritis onset are necessary.

## AB1013 SYSTEMATIC REVIEW OF PATIENT PERCEIVED HEALTH SERVICE NEEDS IN INFLAMMATORY ARTHRITIS

J.D. Segan, K. Connelly, F.M. Cicuttini, A.E. Wluka. *Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

**Background:** The inflammatory arthritides (IA) are a heterogeneous group of diseases which cause significant morbidity and mortality. Optimising patient engagement to provide patient-centred care are important in improving outcomes in IA. Although individual aspects of patient preferences and satisfaction relating to health services have been previously examined, few studies have directly investigated people with IAs perceived needs of health service needs.
**Objectives:** The aim of this review was to systematically identify the existing literature relating to patient perceived health service needs related to IA, including use of allied health (AH) and complementary and alternative medicines (CAM).
**Methods:** A systematic literature review of MEDLINE, EMBASE, CINAHL and PsycINFO was conducted (1990 – May 2015). Using a comprehensive search strategy, studies examining patient perceived needs relating to health service needs relating to inflammatory arthritis was performed. Data regarding study design and methodology were extracted. Needs were identified and collated to show the current knowledge of this issue.
**Results:** The search strategy returned 1778 papers of which 24 articles were identified as relevant (figure 1): 14 used qualitative methods, 9 used quantitative methods and 1 used mixed methods. 16 studies included only patients with rheumatoid arthritis (RA). The quality of the included literature was variable.
The main areas of need, identified in at least 2 studies, related to
1) Communication needs: consumers wanted clear, empathic communication and to be involved with decision making. Positive relationships with health care providers with an holistic approach were prized.
2) Characteristics of ongoing care: adequate consultation length with continuity and timely care were valued.
3) Factors influencing care seeking behaviour: an individual's attitude towards health care, and disease activity and severity affected care seeking behaviour. Financial factors and family expectations, influence and beliefs were also seen to impact on the perception of need.
4) AH and CAM were perceived as useful by many. CAM was seen as an adjunct to conventional therapy, especially where pain control was inadequate. The reporting of CAM use to their doctors was variable, with several factors related for under-reporting.

**Conclusions:** Within the existing literature that has infrequently targeted patient perceived health services needs, this review identified factors that patients with IA perceive to be important in their management. It also identified gaps in this area of knowledge, such as patient preferences for alternative methods of health care delivery, information from non-European and North American countries and information about patients with IA other than RA. Increasing knowledge regarding patient perceived needs in this area has the potential to inform novel methods of health care provision which could improve patient satisfaction whilst optimising outcomes for both the patient and health care system.

## AB1014 COMPARISON BETWEEN ARASHI SCORE AND MODIFIED TOTAL SHARP SCORE IN THE EVALUATION OF LARGE JOINTS DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS UNDER DISEASE CONTROL OF BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS

K. Hashizume[1], K. Nishida[2,3], Y. Nasu[3], R. Nakahara[3], T. Machida[3], M. Horita[3], A. Takeshita[3], D. Kaneda[3], M. Natsumeda[4], K. Ezawa[4], T. Ozaki[3]. *[1]Department of Orthpaedic Surgery, Okayama Rosai Hospital; [2]Department of Human Morphology, Science of Functional Recovery and Reconstruction; [3]Department of Orthopaedic surgery, Science of Functional Recovery and Reconstruction, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama; [4]Department of Internal Medicine, Kurashiki Sweet Hospital, Kurashiki, Japan*

**Background:** Treatment of rheumatoid arthritis (RA) has improved over the past decade with the modification of treatment strategy and recent application of biologic agents (Bio). It has been revealed that the treatment by Bio achieved not only improvement of clinical symptom, but also inhibition of the progression of joint destruction in small joints of hand and foot. However, there are little evidences of inhibition of the progression of the large joint destruction with the treatment by Bio.
ARASHI score, is composed of ARASHI Status Score (ASS) and ARASHI Change Score (ACS), and have been newly developed to evaluate the progression of the large joint destruction as well as remodeling[1)]
**Objectives:** We aimed to investigate the correlation among the ARASHI score, modified total sharp score (mTSS), and other clinical parameters, and to clarify the patients' parameters leading to large joint destructions in patients with RA under disease control by Bio.
**Methods:** 75 patients with RA under disease control by Bio were available for the current study. Average patients' age, disease duration, and follow-up periods were 62.6 (years old), 11.7 (year), and 21.8 (month), respectively. They were examined for serum level of C-reactive protein (CRP), mHAQ, DAS28-CRP, SDAI, CDAI, mTSS, and ASS at the beginning of the study. The amount of change of CRP, mHAQ, DAS28-CRP, SDAI, CDAI, and mTSS at the final follow-up were defined as ΔCRP, ΔmHAQ, ΔDAS28-CRP, ΔSDAI, ΔCDAI, and ΔmTSS, respectively. Statistical analysis was performed by Spearman's correlation co-efficient.
**Results:** Average ΔCRP, ΔmHAQ, ΔDAS28-CRP, ΔSDAI, ΔCDAI, ΔmTSS, and ACS were 0.01, -0.02, -0.28, -2.62, -2.64, and 0.03, respectively. There was no significant correlation between the ACS and ΔmTSS. There were no significant correlations between ΔmTSS and other clinical parameters, whereas ACS was significantly correlated with ΔCRP (r=0.39), ΔmHAQ (r=0.28), ΔDAS28-CRP (r=0.39), ΔSDAI (r=0.35), and ΔCDAI (r=0.32).
**Conclusions:** The correlation between the destruction of small joints of hands and feet and the disease activity was not seen among the current patients group with long-standing disease. In contrast, our results suggested that sufficient suppression of the disease activity is important to prevent the progression of large joint destruction among long-standing RA patients under control by Bio.

## AB1015 MORTALITY RATE ACCORDING TO CAUSE IN PATIENTS WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A META-ANALYSIS

K. Sheth[1], C.-L. Kuo[2], D. Modi[3], S. Nanavaty[4], C. Scola[5]. *[1]Internal Medicine; [2]Biostatistics, University of Connecticut, Farmington; [3]Internal Medicine, Jamaica Hospital Medical Center, Jamaica; [4]Internal Medicine, WCGME, Scranton; [5]Rheumatology, Hartford Hospital, Hartford, United States*

**Background:** Hemophagocytic lymphohistiocytosis (HLH) is a rare syndrome of excessive immune activation associated with high mortality. Early diagnosis and treatment can reduce mortality among these patients.
**Objectives:** To determine the rate of mortality independently and according to the cause in patients with HLH.
**Methods:** Pubmed database with the MeSH terms ("lymphohistiocytosis, hemophagocytic" [MeSH Terms] OR ("lymphohistiocytosis" [All Fields] AND "hemophagocytic" [All Fields]) OR "hemophagocytic lymphohistiocytosis" [All Fields] OR ("hemophagocytic" [All Fields] AND "lymphohistiocytosis" [All Fields])) AND cases [All Fields] were queried which yielded 466 results. Case series referenced from these studies were also studied. 74 studies were identified out of which the studies with a sample size smaller than 10 were excluded. 48 studies were kept with a total of 1983 patients. Meta analysis was performed to combine the mortality rates of all studies and studies of patients with the same cause. The results were presented in a Forest plot. Prior to the meta analysis, the heterogeneity test on mortalities was conducted to choose a fixed or random effects model. $I^2$, a common heterogeneity measure, was reported with 25%, 50%, 75% suggesting low, moderate, and high heterogeneity.
**Results:** The combined mortality rate for all studies was 41.99% [95% confidence interval (CI) 36%>49%]. In studies of patients with EBV infection (n=4), the combined mortality rate was 44% (95% CI 18%>74%) whereas the mortality rate in studies with other infections (n=4) was 46% (95% CI 13–83%). The

mortality rate in patients with hematological malignancy (n=8) was higher at 60% (95% CI 44%>74%]. For studies of patients with autoimmune diseases (n=2) and in transplant (n=4) patients, the combined mortality rate was 11% (95% CI 5%>21%) in patients with autoimmune disease and 38% (95% CI 27%>51%) in transplant patients. $I^2$ for the mortalities of all studies and each cause was presented as follows: $I^2$=0% (p=0.764) for autoimmune disease, $I^2$=94.8% [89.6%; 97.4%] (p<0.0001) for EBV infection, $I^2$=75.2% [50%; 87.7%] (p=0.0002) for hematological malignancy, $I^2$=75.2% [50%; 87.7%] (p=0.0002) for infection malignancy, $I^2$=89.2% [75.1%; 95.3%] (p<0.0001) for other infection, and $I^2$=0% [0%; 52.1%] (p=0.811) for transplant. The heterogeneity test result remained significant but for the causes of autoimmune disease and transplant.
**Conclusions:** Based on our results, mortality is higher in patients with hematological malignancy compared to patients with other causes, whereas it is lower in patients with autoimmune disease.
**Disclosure of Interest:** None declared

## AB1016 THE CHANGE OF PREVALENCE OF RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS IN KOREA BETWEEN 2011 AND 2014

K.W. Moon. *Department of Internal Medicine, Kangwon National University Hospital, Chun-cheon, Korea, Republic Of*

**Background:** Rheumatoid arthritis (RA) and Osteoarthritis (OA) are common arthritis in adults, and leading causes of disability. Estimating the prevalence of RA and OA is important for planning health care and public health systems. In South Korea, the Korean National Health Insurance (NHI) database has the medial and prescription claims data for most of Korean people. We evaluated the change of prevalence of RA and OA using NHI database between 2011 and 2014.
**Objectives:** The purpose of this study is to evaluate the prevalence and annual direct medical costs of rheumatoid arthritis and osteoarthritis in Korea.
**Methods:** We used data provided by Korean Health Insurance Research and Assessment agency. Identification of patients with RA and OA was based by main diagnostic code in database. The prevalence of RA and OA was evaluated in adults aged 20 years or older from 2011 to 2014. Annual direct medical costs per patient were also calculated.
**Results:** The prevalence of RA was decreased from 0.74% at 2011 to 0.68% at 2014. On the other hand, that of OA was increased from 7.96% at 2011 to 8.75% at 2014. Annual direct medical costs per patient tended to increase in both RA and OA, but rate of increase was greater in RA. In OA, annual direct medical costs were $226.86 at 2011, and increased up to $239.95 (105.8%). In RA, those were $209.95 at 2011, and increased up to $319.19 (152.0%).

Table 1. The change of prevalence and annual direct medical cost per patient of rheumatoid arthritis and osteoarthritis

| | | 2011 | 2012 | 2013 | 2014 |
|---|---|---|---|---|---|
| Prevalence (%) | RA | 0.74 | 0.72 | 0.69 | 0.68 |
| | OA | 7.96 | 8.31 | 8.33 | 8.75 |
| Annual direct medical cost per patient (USD) | RA | 209.95 | 238.69 | 277.26 | 319.19 |
| | OA | 226.86 | 232.92 | 235.35 | 239.95 |

**Conclusions:** The prevalence of RA was decreased, but that of OA was increased in Korea between 2011 and 2014. Annual direct medical costs per patient increased in both RA and OA, but rate of increase was greater in RA.

## AB1017 RHEUMATOID ARTHRITIS IN GREECE: PATIENT JOURNEY, ACCESS TO TREATMENT BARRIERS AND THEIR IMPACT TO ADHERENCE

V. Stathakopoulos, A. Evaggelatos, G. Painesis, K. Kottikas. *Marketing and Communication, Athens University of Economics and Business, Athens, Greece*

**Background:** Early active treatment of rheumatoid arthritis (RA) by a rheumatologist and adherence to the prescribed drugs are crucial factors for inducing remission and preventing irreversible joint damage[1,2]. However, Greece's fiscal situation has inevitably impacted the healthcare sector by raising barriers to patient access to treatment and medication and limits to patient and doctor education[3]. Hence, identifying obstacles/adherence issues and attempting to overcome them is essential to improving RA care.
**Objectives:** The objectives of this national patient study were to record: a) the patient journey from the 1st symptom until official diagnosis and the physician specialties that were visited, b) the potential barriers in access to treatment and medicines and c) the possible adherence issues for patients suffering from RA in Greece.
**Methods:** An innovative research method was followed, using a structured questionnaire. Using a stratified sampling methodology, 1,030,000 randomly selected households were contacted over the telephone, via an Interactive Voice Response (IVR) system asking them to participate in the survey concerning auto-immune diseases. Eventually, 1,422 households agreed to do so and were subsequently interviewed by a telephone researcher. The achieved response rate is well above previous studies and scientifically accepted standrads[4].
**Results:** 557 RA patients were identified (90% women, median age 56–65 years), making RA the most prevalent rheumatic autoimmune disease (44% of sample). The average time needed from the 1st symptom until an official diagnosis is 23.3 months. Only 31% of RA patients visited a rheumatologist first and 10% have to make 3 or more visits until they are officially diagnosed. 43% of them did not receive any medicine and of those receiving, 34% were non-adherent during the last six months (at least 1 day late to take the medicine or skipping at least 1 dose). 28% of biological treatment patients were non-adherent. The physician's visit cost was the main barrier to treatment access (31%), followed by the need to use someone else to pick the medicine due to patients' inability (18%) and by the difficulty of booking an appointment with a specialist (15%). For SSF pharmacies the distance from the patient's home (31%) plus a long waiting time (17%) were additional barriers. $\chi^2$ tests revealed that most barriers exerted a statistically significant influence on adherence (p<0.05).
**Conclusions:** Appropriately educating the public and the doctors about RA's symptoms and to visit the appropriate physician, and removing the barriers to treatment and medication access will massively benefit RA patients and consequently society.

## AB1018 DOES FATIGUE IMPROVE IN A SIMILAR MANNER TO PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH A BIOLOGIC? A REANALYSIS OF RANDOMIZED CONTROLLED TRIALS OF ABATACEPT IN 1536 PATIENTS WITH ACTIVE RA

L. Gossec[1], S. Ahdjoudj[2], E. Alemao[3], V. Strand[4]. *[1]Paris 06 University & Pitié Salpêtrière Hospital, Paris; [2]Bristol-Myers Squibb, Rueil-Malmaison, France; [3]Bristol-Myers Squibb, Princeton; [4]Stanford University School of Medicine, Palo Alto, United States*

**Background:** Fatigue is a major issue for patients (pts) with RA. Biologic DMARDs including abatacept (ABA) have shown efficacy in improving fatigue in randomized controlled trials (RCTs),[1–3] but questions remain.
**Objectives:** We explored the effects of ABA on fatigue versus on pain in RA.
**Methods:** This was a *post hoc* analysis of 3 RCTs of ABA in RA: AIM[1] and ATTAIN[2] in established RA, and AGREE3 in early RA. Pts were randomized to ABA versus placebo (pbo), with concomitant MTX in both treatment arms in most cases. Fatigue and pain were assessed by visual analogue scales (VAS, 0–10 cm) at baseline (BL), Days 29, 85 and 169; mean changes from BL were analysed using an ANCOVA model with treatment as a factor and BL value as a covariate. Associations between fatigue VAS score and pain score were evaluated using Pearson correlation coefficients at BL and Days 29, 85 and 169. Agreement of reporting minimum clinically important differences (MCID; improvement of ≥10 mm from BL to 169 day) for fatigue and pain was evaluated using Kappa coefficients, MCID was cross-tabulated for fatigue and pain. Data from each trial were analysed separately.

**Results:** Data were available for 1536 pts (women: 78–79%, mean age: 50–53 years across RCTs). Mean disease duration was 8.5–12.2 years (AIM and ATTAIN) and 6.2–6.7 months (AGREE). ABA was efficacious relieving fatigue, with mean relative decreases from BL to day 169 of 30–44%. Benefit on fatigue was reported early, decreasing by 18–24% at Day 29, indicating that ~50% of the mean decrease in fatigue was already achieved by this time point. Results were consistent across RCTs, although the effect of ABA on fatigue was greater in pts with shorter versus longer disease duration. ABA also significantly reduced pain: mean decreases were 29–49% across trials. There was an association between treatment effects on fatigue and pain: Pearson correlation coefficients were 0.69–0.72 at Day 169. Agreement between MCID improvements in pain and fatigue were, however, moderate: kappas ranged from 0.30–0.51 across RCTs and time points. Cross-tabulation indicated most pts who reported improvements ≥MCID in fatigue also did so in pain (795/903 pts; 88.0%), and vice versa (795/1004 pts; 79.2%) at Day 169.

**Conclusions:** ABA led to a rapid improvement in both fatigue and pain in pts with active RA. However, agreement between clinically meaningful improvements in these outcomes was only moderate, suggesting that the pathways of fatigue and pain in RA represent different domains of response. Fatigue should be further studied in RA.

## AB1019 IS THE SELF-ASSESSMENT OF DISEASE ACTIVITY (AUTO-DAS28) BY PATIENTS A FEASIBLE AND ACCEPTABLE MEASURE OVER THE LONG TERM IN RHEUMATOID ARTHRITIS (RA)? THREE-YEAR FOLLOW-UP OF A NURSE-LED PROGRAM IN 771 PATIENTS WITH ESTABLISHED RA

L. Gossec, A. Molto, F. Foissac, M. Soubrier, F. Fayet, P. Gaudin, M. Dougados.
*COMEDRA Working Group, Paris, France*

**Background:** Patients with RA can be trained in self-assessment of disease activity by a self-assessment of their joints and calculation of the Disease activity Score 28 (DAS28) [1].

**Objectives:** To assess if such an auto-DAS assessment is a feasible measure over the long-term (i.e., do patients adhere to such an assessment) and to determine the characteristics of patients related to adherence to auto-DAS.

**Methods:** This was an open long term (2–4 years) extension of the 6 month randomized controlled COMEDRA trial of patients with definite, stable RA. Patients were trained to perform auto-DAS by a nurse, using a video and teaching of self-assessment of joints (the training took approximately 30 minutes) and nurses provided the advice to perform the auto-DAS regularly in a dedicated booklet. 2–4 years after the end of the trial, patients were seen in a face-to-face interview with a nurse and the frequency of auto-DAS was assessed through the auto-DAS booklet and if unavailable, from patient questioning. Adherence to auto-DAS was defined as the performance of at least one auto-DAS more than 6 months after the end of the trial. Characteristics of adherent versus non adherent patients were compared by univariate and multivariate logistic regression analyses and included demographic and disease activity variables as well as the centre (high versus low inclusion rate, based on the median).

**Results:** Of the 970 recruited patients, 771 (79.5%) were followed up at 3 years and had available data regarding auto-DAS: mean (±standard deviation) age 61 (±11) years, median [IQR] disease duration 15 [9 - 23] years; 615 (80%) were women and 82% had received a biologic. The mean (±sd) baseline and 3-year DAS28 scores were respectively 3.1±1.3 and 2.8±1.4.

After 3 years, 354 (46%) patients were adherent to auto-DAS (i.e., had at least one auto-DAS completed more than 6 months after the end of the trial). For adherent patients the median [IQR] number of auto-DAS performed was 5.4 [1.7 – 12.8] overall, i.e. 2.3 [0.8 – 5.9] per year. However among the adherent population, the number of patients who completed their autoDAS booklet at least once per year decreased over time, with 351 (99%), 162 (46%) and 118 (33%) patients respectively for 2012, 2013 and 2014 ($p<0.0001$).

In the multivariate analysis, only larger inclusion centres were significantly associated to an adherent behaviour (OR [95% CI] 2.9 [2.0 – 4.1], $p<0.0001$).

**Conclusions:** After a short training, many of these long-standing, moderately active RA patients continued to perform an auto-DAS, though the performance of auto-DAS decreased over time in this cohort where patients did not receive any ongoing positive feedback on their auto-DAS. In the larger inclusions centres, autoDAS adherence was higher, perhaps related to more patient/physician interaction around autoDAS results.

Self-assessment of disease activity is feasible in RA but positive reinforcement appears necessary. Further studies should analyse if outcomes are better for patients who self-assess.

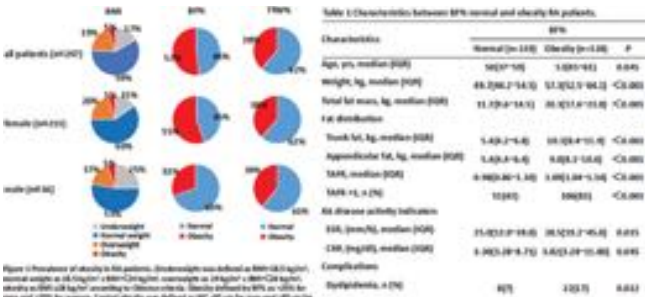
## AB1020 HIGH PREVALENCE OF BF% OBESITY IN CHINESE PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY



J.-Z. Lin[1], Y.-B. Chen[2], X.-T. Lin[2], J.-D. Ma[1], Y.-Q. Mo[1], X.-Y. Wang[1], L. Dai[1].
*[1]Department of Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University; [2]Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China*

**Background:** There is about 14%–19% lipid of weight in normal people and most of the lipid stores in fat cells that can secrete adipokines to promote inflammation, which may exacerbate rheumatoid arthritis (RA) synovial inflammation, rise severity of clinical feature, disable functional capacity and reduce quality of life. A worldwide study in 15 countries (mainly in Europe and the United States) identified 18% of RA patients as obese defined by body mass index (BMI ≥30 kg/m$^2$), while higher prevalence of 25% in a USA-based study and 31% in a UK–based study were reported. However, little is known about the prevalence of obesity in Chinese RA patients.

**Objectives:** To investigate the prevalence and character of obesity in Chinese RA patients.

**Methods:** Two hundred and forty–seven consecutive RA patients were assessed BMI, waist circumference (WC), waist–to–hip ratio (WHR) and waist–to–height ratio (WHtR). Clinical data including RA disease activity, physical function and complications were collected. Body fat percentage (BF%) was assessed by bioelectric impedance and obesity by BF% was defined as >25% for men and >30% for women.

**Results:** (1) According to Chinese criteria of BMI, there were 19% patients with overweight and 5% with obesity. According to BF%, there was 52% patients with obesity and female RA patients had significantly higher prevalence of obesity than male patients (55% vs 31%, P=0.006, Figure 1). (2) Weight, total fat mass and trunk–to–appendicular fat ratio (TAFR) were significantly higher in BF% obesity patients than normal ones (all $P<0.05$). The percentages of patients whose fat distributed mainly in trunk rather than appendicular extremities (TAFR >1) was also higher in BF% obesity patients than normal ones (83% vs 43%, $P<0.001$, Table 1). (3) According to WC, WHR and WHtR, there were 33%, 41% and 42% patients with central obesity respectively. The trunk-fat-to-weight percentage (TfW%) was significantly higher in central obesity patients (according to WC in Chinese criteria) than that in normal WC patients (female: 18.7% (16.6%–19.8%) vs 13.6% (11.0%–15.7%); male: 15.0% (12.4%–18.3%) vs 7.4% (3.8%–10.6%), both $P<0.001$). ROC curve analysis showed that the cut–off value of the TfW% for diagnosing central obesity was 11.8% in men with sensitivity 91.7% and specificity 87.5% and 16.3% in women with sensitivity 81.2% and specificity 83.1% (male: AUC=0.941, 95%CI: 0.868–1.0; female: AUC=0.865, 95%CI: 0.811–0.919, both $P<0.001$). There were 95 (38%) patients with central obesity according to the cut–off value of the TfW% (female 38% and male 39%, Figure 1). (4) Comparing with normal BF% patients, BF% obesity patients were older with higher disease activity indicators (ESR and CRP) and had more complications such as dyslipidemia and fat liver (all $P<0.05$, Table 1).

**Conclusions:** This cross–sectional study suggests that high prevalence of BF% obesity in Chinese RA patients especially in female patients which might be associated with disease activity.

## AB1021 SYSTEMATIC REVIEW OF LOW BACK PAIN CONSUMERS' PERCEIVED NEEDS OF ALLIED HEALTH AND COMPLEMENTARY AND ALTERNATIVE THERAPIES

L. Chou, F.M. Cicuttini, D.M. Urquhart, A.E. Wluka. *Department of Epidemiology and Preventative Medicine, Monash University, Melbourne, Australia*

**Background:** Low back pain (LBP), a major public health problem, is the leading cause of disability worldwide (1). Current management recommendations include medical, psychological and physical treatments, complementary and alternative medicines (2,3). Initiatives to improve the management of LBP have been largely based on outcomes determined by health professionals. The relative success and requirement for health care interventions may differ from the patient's perspective.
**Objectives:** To systematically review the literature about consumer perceived needs of allied health and complementary and alternative therapies (CAM) relating to LBP.
**Methods:** A comprehensive systematic review of MEDLINE, EMBASE, CINAHL and PsycINFO was conducted to identify studies examining consumer perceived needs relating to allied health and CAM services in managing LBP (1990 - May 2015). Data regarding study design and methods were extracted. Emergent themes were identified and aggregated to provide a systematic review of the current literature.
**Results:** 1779 manuscripts were identified, of which 39 were found to be relevant (figure 1). Of these, 25 used qualitative, 14 used quantitative and 1 used mixed methods. The quality of the literature was variable. Few studies directly addressed the review question. Many results were consistent, with the following main themes emerging from at least 2 studies:
1) CAM elicited conflicting views from consumers, with some willing to try CAM, believing it to be beneficial and CAM practitioners perceived to be more empathetic and understanding. Other consumers questioned the legitimacy of CAM and believed it offered only transitory benefits.
2) Chiropractic therapy was perceived to be effective by some consumers, but not others, who had concerns about side effects and were disappointed with the temporary effects.
3) Physiotherapy and exercise therapy were often preferred by patients for LBP. Consumers believed these to help with pain relief, prevent worsening of back pain and to improve mobility and function. Consumers strongly preferred physiotherapy to be individually tailored to their health needs and abilities.
This review identified a paucity of data examining LBP consumers' perceived needs of allied health and CAM in males, geriatric populations and patients from developing countries or non-English speaking backgrounds.

**Conclusions:** Consumers with LBP perceive a role for physiotherapy but have inconsistent beliefs regarding CAM and chiropractic therapy. This review has highlighted significant gaps in the literature relating to consumers' needs of allied health and CAM for LBP. Health care practitioners need to understand consumers' beliefs regarding the multiple modes of therapy used by consumers to manage their LBP, to better align care provision. Incorporating this into care has the potential to improve outcomes for both consumers and the health system.

## AB1022 ASSOCIATION BETWEEN PSORIASIS AND INCIDENT DIABETES MELLITUS: A POPULATION-BASED STUDY IN TAIWAN

L.-H. Huang, C.-F. Kuo, S.-F. Luo, K.-H. Yu, Y.-F. Fang. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

**Background:** Psoriasis is a known risk factor of cardiovascular disorders in addition to traditional risk factors such as diabetes mellitus (DM). However, the association between psoriasis and DM is unclear.
**Objectives:** To quantify the risk by comparing the incidence of DM between patients with psoriasis and the general population in Taiwan.
**Methods:** The study cohort consisted of two populations. The first population is the whole patients first diagnosed with psoriasis in 2000 in Taiwan, and the second population is a nationally representative cohort of 1,000,000 individuals from the Longitudinal Health Research Database in 2000. Those who younger than age of 10 or had DM before 2000 were excluded from analysis. They were followed from 2000 until the occurrence of DM, death or 31 December 2012. Incidence rates of DM were calculated. Poisson regression was used to estimate incidence rate ratios (IRRs) and 95% confidence intervals (CIs) for DM, adjusted for age, gender and pre-existing comorbidity.
**Results:** The study cohort comprised 756,333 subjects with a mean follow-up of 11.27 years; among them 15,099 patients with incident psoriasis were identified. Patients with psoriasis had a higher comorbidity of renal disease (1.48%), congestive heart failure (0.91%), cardiac dysrhythmia (1.82%), cerebrovascular disease (2.74%) and peripheral vascular disease (0.94%) than the general population. The incidence rate for DM was 2.04 (95% CI, 2.01–2.08) per 100 person-years for psoriasis patients comparing to 1.10 (95% CI 1.03–1.16) per 100 person-year in the general population. The adjusted IRR of incident DM was 1.34 (95% CI 1.29–1.38) for patients with psoriasis.
**Conclusions:** Patients with psoriasis has an increased risk for DM. A vigilant monitoring for DM in patients with incident psoriasis is warranted to reduce long-term cardiovascular risks.
**Disclosure of Interest:** None declared

## AB1023 RHEUMA SPACE: STANDARD PRACTICE AIMING CLINICAL EXCELLENCE IN RHEUMATOLOGY

C. Macieira[1], L. Cunha-Miranda[2], A. Lourenço[3], A. Santos[4], J. Sousa[5], M. Bogas[6], P. Lucas[5], P. Laires[7], S. Farinha[8], J. Eurico da Fonseca[1], J. Canas da Silva[9]. *[1]Rheumatology, Centro Hospitalar de Lisboa Norte; [2]Rheumatology, INSTITUTO PORTUGUÊS DE REUMATOLOGIA; [3]Hospital Administrators, Associação Portuguesa de Administradores Hospitalares, Lisboa; [4]Medical Department, Pfizer; [5]Healthcare, IMS Healthcare, Oeiras; [6]Medical Department, Roche, Amadora; [7]Outcomes Research, MSD, Oeiras; [8]Market Access, Abbvie, Amadora; [9]Rheumatology, Hospital Garcia de Horta, Almada, Portugal*

**Background:** The evaluation of the quality of medical practice and the implementation of corresponding measures to improve it are crucial steps for the development of Rheumatology in Europe. Herein we describe the implementation of a national program, Rheuma Space, aiming at quality improvement in the field of Rheumatology.
**Objectives:** To develop standards for the quality of care accepted by most of the rheumatology services in Portugal.
**Methods:** Quality indicators were obtained through a four-step RAND-modified Delphi methodology. The first step involved a literature search for international benchmarking of quality of care initiatives and indicators, followed by a pre-selection of a initial set of criteria by a task force. The final steps, aiming at defining a smaller set of criteria that could best analyze rheumatology quality of care, encompassed an online Delphi round with all Portuguese rheumatologists and a consensus meeting with a panel of invited experts representing all the Portuguese Rheumatology Departments of the National Health Service.
**Results:** A total of 412 different indicators were collected throughout the first project phase and the final set of 26 quality indicators was defined, within the three Donabedian dimensions of healthcare quality: nine "*structure*", eleven "*processes*" and seven "*outcome*" indicators. These criteria cover eleven domains of quality of care: personnel and organizational structure, training and research, facilities, equipment and IT, budgeting and financial resources, access to care, clinical records, patient communication, multidisciplinary management, clinical outcomes, and patient and personnel satisfaction.
**Conclusions:** The 26 quality indicators set constitutes the basis for a quality management tool, which is now being implemented in all the Portuguese Rheumatology Departments of the National Health Service. Direct surveys derived from the 26 quality indicators are being applied to health professionals and patients allowing to benchmark departments and to identify strengths and weakness for future improvement. This initiative is deemed to improve the process of care for Portuguese rheumatic patients, thereby ensuring quality standards of structure and process criteria, for a patient-oriented clinical practice, favouring desirable continuous quality improvement on health outcomes.
**Acknowledgement:** Portuguese Rheumatology participating in the online Delphi and all the participants in the expert consensus meeting

## AB1024 HEALTH-RELATED QUALITY OF LIFE IN DIFFERENT MUSCULOSKELETAL DISORDERS: A COMPARISON AMONG THE CONDITIONS AND WITH A SELECTED SAMPLE OF HEALTHY INDIVIDUALS USING SF-36 QUESTIONNAIRE, EQ-5D AND SF-6D UTILITY VALUES

M. Di Carlo[1], F. Salaffi[1], M. Carotti[2], A. Ciapetti[3], M. Gutierrez[4].
*[1]Rheumatology Departement, Polytecnic University of the Marche, Jesi; [2]Radiology Department, Polytechnic University of Marche, Ancona, Italy; [3]Rheumatology Department, Betsi Cadwaladr University Health Board, Glan Clwyd Hospital, Bodelwyddan, United Kingdom; [4]Musculoskeletal Departement, National Rehabilitation Institute, Mexico City, Mexico*

**Background:** Given the high prevalence of musculoskeletal (MSK) disorders, there is a need to determine which conditions have the greatest impact on health-related quality of life (HRQoL).
**Objectives:** To compare the HRQoL scores of the Medical Outcomes Study Short-Form 36 Health Survey (SF-36) and of the two widely used indirect utility instruments, the EuroQol Five Dimensions questionnaire (EQ-5D) and the Short-Form Six Dimensions questionnaire (SF-6D) among 14 different MSK disorders and to compare them with the results of a selecting sample of healthy controls.
**Methods:** 2,633 patients participated to this study. MSK disorders were classified into five diagnostic groups: inflammatory rheumatic diseases (IRD), connective tissue disorders (CTD), symptomatic peripheral osteoarthritis (SPOA), soft tissue disorders (STD) and osteoporosis (OP). IRD were further classified into 3 subgroups: rheumatoid arthritis (RA) (n=572), peripheral psoriatic arthritis (PsA) (n=150) and ankylosing spondylitis (AS) (n=251). CTD were classified into sistemic sclerosis (SSc) (n=75), sistemic lupus erythematosus (SLE) (n=83) and Sjogren sindrome (SS) (n=50). SPOA included symptomatic knee (n=176), hip (n=136 patients), and hand OA (n=87). The STD group included fibromyalgia (FM) (n=226 patients), low back pain (n=141) and shoulder tendinitis/adhesive capsulitis (n=112 patients). The OP group included 172 women who had vertebral fractures due to osteoporosis, and a group of 402 asymptomatic osteoporotic women without vertebral fractures. For comparison were used 649 healthy controls. The HRQoL was evaluated with the SF-36, using physical (PCS) and mental (MCS) component scales and EQ-5D. The SF-6D utility values were calculated from SF-36 by using a definite scoring function.
**Results:** The five major rheumatic disease groups, compared to healthy people, significantly impaired all eight health concepts of the SF-36 ($p<0.0001$). Similar results were found for EQ-5D, EQ-VAS and SF-6D. The patients with IRD have poorer self-reported health status than those without arthritis in all domains of living, but particularly with respect to scales measuring aspects of physical functioning or mobility, role limitation due to physical health problems and usual activities, and bodily pain. RA had the largest negative impact on HRQoL at the individual level, followed by FM, vertebral fractures due to OP, OA of the hip, and SSc.
**Conclusions:** Our results indicates that MSK conditions have a clearly detrimental effect on the HRQoL, and physical domain is more impaired than mental and social ones. These findings may help clinical decision making and priority setting for management of individuals with MSK diseases.
**Disclosure of Interest:** None declared

## AB1025 GLYCEMIA AND SYSTEMIC BLOOD PRESSURE IN PATIENTS WHO RECEIVE CORTICOSTEROID PULSE THERAPY

M.U. Martinez Martinez[1], C. Abud-Mendoza[1], J. Martínez-Lozano[2], E.S. Acevedo-Castañeda[2], D.A. Herrera-van Oostdam[1]. *[1]Unidad de Investigaciones Reumatológicas; [2]Hospital Central "Dr. Ignacio Morones Prieto", Universidad Autónoma de San Luis Potosí, San Luis Potosi, Mexico*

**Background:** Supra-pharmacological doses of corticosteroids (pulse therapy) are used in various autoimmune disorders. Methylprednisolone and dexamethasone pulse therapy have demonstrated similar efficacy for some diseases;[1] therefore, differences in their adverse effects can help the selection of any of them.
**Objectives:** To evaluate changes in glycemia and blood pressure in patients who received pulse therapy with dexamethasone or methylprednisolone.
**Methods:** We evaluated the charts of patients who received corticosteroid pulse therapy with dexamethasone (200 mg/day) or methylprednisolone (1000 mg/day). We included patients who received at least three days of pulse therapy and who had records of glycemia and blood pressure four times at day. We evaluated the blood pressure and glycemia measurements before the first pulse therapy and the next three-day measurements each six hours. We evaluated through linear mixed models the factors associated with an increase in glycemia or blood pressure (systolic or diastolic) in the program R 3.0.2. For the glycemia analysis we excluded patients with diabetes history and patients having glycemia $>180$ before the pulse therapy.
**Results:** We included 117 patients, 83 received pulse therapy with methylprednisolone and 34 with dexamethasone. Multivariate mixed models showed a statistically significant increase in glycemia and blood pressure (systolic and diastolic) from the first measurement after the initial dose of pulse therapy (Figure 1);

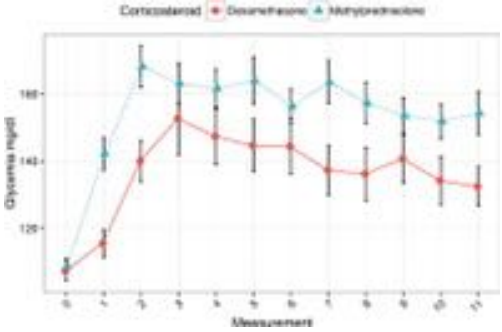

Figure 1. Mean and standard error of glycemia according each measurement.

factors associated with hyperglycemia (adjusted for creatinine levels, sex and units of insulin received) were higher glycemia before the pulse therapy ($p=0.0016$) and the use of methylprednisolone ($p=0.0098$). Factors associated with an increase of systolic or diastolic blood pressure were: higher blood pressure before the first pulse therapy ($p<0.0001$) and higher creatinine levels ($p=0.0099$ and $0.0031$) but not the type of corticosteroid (dexamethasone or methylprednisolone).
**Conclusions:** Pulse therapy with methylprednisolone showed a higher increase in glycemia than dexamethasone. Susceptible patients to an increase of glycemia are who have initial hyperglycemia; patients susceptible to an increase in blood pressure are who have elevated serum creatinine levels and who have initial hypertension.

## AB1026 ACHIEVING MINIMAL DISEASE ACTIVITY AND REMISSION IN PSORIATIC ARTHRITIS PATIENTS TREATED CONTINUOUSLY WITH TNF INHIBITORS FOR 2 YEARS IN THE REAL LIFE

M.S. Chimenti, P. Triggianese, M. Tonelli, P. Conigliaro, G. Gigliucci, L. Novelli, F. Sunzini, R. Perricone. *"Medicina dei Sistemi", Rheumatology, Allergology and Clinical Immunology, University of Rome "Tor Vergata", Rome, Italy*

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory arthropathy commonly associated with psoriasis. Minimal disease activity (MDA) and remission represent treatment targets. However, their assessment is to date an unmet need in PsA patients.
**Objectives:** Aim of the study was to prospectively evaluate MDA and remission in PsA patients who were treated with subcutaneous TNF inhibitors (iTNF), every 3/6 months for 2 years.
**Methods:** Clinical and laboratory data from 221 PsA patients were analyzed (F:M=1.3, age 55±13 years, disease duration 12.3±6.1 years) at baseline (T0), after 22 (T22), 54 (T54) and 104 (T104) weeks from the beginning of TNFi (adalimumab n=94; etanercept n=84; golimumab n=43). Values of DAS28-CRP, CPDAI, and DAPSA were calculated, and MDA/remission were assessed at the all the time points. MDA was defined as the occurrence of 5/7 criteria, while remission was assessed as DAS28-CRP$<2.6$, DAPSA$\leq3.3$, and CPDAI$<2$. Occurrences of comorbidities such as cardio-vascular, renal, respiratory, infectious, metabolic, neuropsychiatric and thyroid diseases were registered. Concomitant therapies (steroids and csDMARDs) and predictive factors of remission were analyzed in accordance with the above-mentioned scores. The Chi-square test was used to compare the remission rate at the follow-up and to analyze the predictive factors. Cohen's kappa analysis was performed to measure the concordance between clinimetric scores: kappa $\geq0.6$ was considered as a good agreement and kappa $\geq0.8$ was considered as an excellent agreement.
**Results:** Prevalence of patients on DAS28 and DAPSA remission was significantly higher at T104 comparing to T0, T22 and T54 while patients on MDA and CPDAI remission were more frequent at T104 compared with T0 and T22 (Figure1A). At all the time points, a good concordance between MDA and DAS28$<2.6$ occurred (k=0.63) and an excellent concordance was obtained between MDA, CPDAI$<2$ and DAPSA$\leq3.3$ (k=0.81). At T22, patients with thyreopathies achieved the CPDAI remission in a lower percentage compared to patients without thyreopathies (P=0.02, OR=3.3) (Figure 1B). At T104, the female sex was

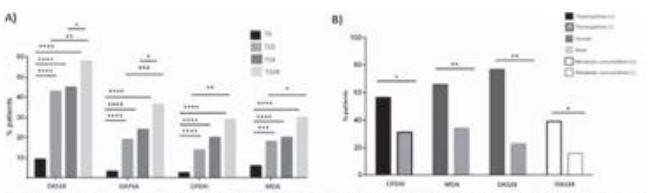

**Figure 1. Panel A:** Patients (as a percentage) on DAS28, DAPSA, CPDAI remission and MDA at T0, T22, T54, T104. **Panel B:** Patients (as a percentage) who were not on CPDAI remission at T22 in accordance with the presence of thyreopathies, and MDA/DAS remission at T104 according to female sex and metabolic comorbidities. *P<0.05; **P<0.01; ***P<0.001; ****P<0.0001.

associated with a lower prevalence of patients on DAS28 remission (P=0.005, OR=2.3) and MDA (P=0.01, OR=2.7) while a lower percentage of patients with metabolic comorbidities was on DAS28 remission with the respect to patients without them (P=0.02, OR=3.3) (Figure1B). Patients on concomitant steroid therapy were fewer at T22/54/104 with the respect to T0 ($P<0.0001$ for all the comparisons) while the rate of patients on csDMARDs was lower at T104 compared with T0 ($P<0.01$).

**Conclusions:** In clinical practice, MDA and remission were achieved in a high prevalence of PsA patients during TNFi treatment with a rate that increased from 22 to 104 weeks. Tapering of the concomitant treatment was thus allowed. Predictors as thyreopathies, female sex, and metabolic comorbidities were associated with a lower probability to achieve clinical remission.

## AB1027 USE OF BIOLOGIC DMARDS IN RUSSIAN PATIENTS WITH RHEUMATIC DISEASES: ANALYSIS OF THE 6 YEAR-EXPERIENCE OF THE MOSCOW REGIONAL RESEARCH AND CLINICAL INSTITUTE

M.V. Sokolova[1], L.V. Ivanitskiy[2], A.V. Elonakov[2]. *[1]Faculty of Fundamental Medicine, Lomonosov Moscow State University; [2]Rheumatology, Moscow Regional Research and Clinical Institute ("MONIKI"), Moscow, Russian Federation*

**Background:** Biologic disease-modifying antirheumatic drugs (bDMARDs) are increasingly used for treating patients with different rheumatic diseases. The safety and effectiveness of using biologics therefore become important issues of the rheumatologists' practice.

**Objectives:** To analyze the data, gathered over the 6 year-experience of using bDMARDs in Moscow Regional Research and Clinical Institute ("MONIKI"), including safety issues, reasons for biologic switch and its frequency.

**Methods:** A retrospective open cohort study was conducted. 159 patients (female – 89; 56%; men – 70; 44%), that were followed up at the rheumatology department of "MONIKI" for more than 0,5 year during the period from the 01 Sept 2009 until the 01 Nov 2015, and taking bDMARDs, were randomly included, regardless of the diagnosis or the biologic agent. To the undesirable events during the treatment with bDMARDs applied: cases of infections (latent or active tuberculosis, active herpes zoster infection, candidiasis, urinary infection, unusually frequent acute respiratory infections, pneumonia) and elevated liver enzymes.

**Results:** The median age of patients was 46 years. The median duration of the disease – 12 years. The diagnoses were ankylosing spondylitis (n=83; 52,2%), rheumatoid arthritis (n=58; 36,48%), psoriatic arthritis (n=15; 9,4%), systemic lupus erythematosus (n=2; 1,3%), Takayasu arteritis (n=1; 0,6%). The used bDMARDS were infliximab (n=63; 39,62%), adalimumab (n=42; 26,42%), etanercept (n=18; 11,32%), rituximab (n=16; 10,1%), abatacept (n=7; 4,4%), golimumab (n=6; 3,77%), tocilizumab (n=3; 1,89%), belimumab (n=2; 1,26%), certolizumab pegol (n=2; 1,26%). In 45 patients (28,3%) the biologic was switched, in 13 – two or more times. In 17 patients (37,8% of all switches) the underlying cause was an ineffectiveness of the bDMARD; in 14 (31,1%) the reason for the switch were adverse events or infusion reactions. Most frequently were switched for the reason of ineffectiveness etanercept (14,8%) and infliximab (14%). The incidence of the undesirable events among all the agents was 8,344 per 100 patient years. 8,18 per 100 patient years in rituximab; 5,34 in etanercept; 10,11 in infliximab and 6,14 in adalimumab patients. One adverse event was registered on abatacept patient. The median period of adverse events appearance was 12 months. Infusion reactions were most common in patients taking rituximab (n=7; 43,8%; $p<0,01$) and none were present in patients on etanercept. Ten cases of tuberculosis were registered during the treatment with infliximab, including 1 lethal case, therefore one or none cases were registered in patients taking other bDMARDs.

**Conclusions:** In our department, ankylosing spondylitis was the most frequent reason for treatment with biologics. For the reason of ineffectiveness almost one third of patients have required a biologic switch and a large part even more than once. Another one third of switches was made due to undesirable events or infusion reactions. Infliximab is widely used for the treatment of patients with rheumatic diseases, although we registered an increased frequency of undesirable events during the treatment with infliximab, including tuberculosis, and a high frequency of the switch for the reason of ineffectiveness.

## AB1028 DEVELOPMENT AND VALIDATION OF A PATIENT QUESTIONNAIRE ON RHEUMATOID ARTHRITIS DISEASE RELATED KNOWLEDGE IN THE TREAT TO TARGET ERA: PRELIMINARY RESULTS

M.J. de Jonge[1], M.A.H. Oude Voshaar[2], A.M.P. Huis[1], M.A.F.J. van de Laar[2], M.E.J.L. Hulscher[1], P.L.C.M. van Riel[1,3]. *[1]IQ healthcare, Radboud Institute for Health Sciences, Radboud university medical center, Nijmegen; [2]Department of Psychology, Health and Technology, University of Twente, Enschede; [3]Rheumatology, Bernhoven, Uden, Netherlands*

**Background:** Patient involvement and personalisation of healthcare has become increasingly important in managing chronic diseases. Knowledge about their disease and its treatment is an important precondition for patients to be able to be involved in their own care.[1] Hence, EULAR recommends education to be an integral and continuous element of Rheumatoid Arthritis (RA) management, so that patient can be involved in their RA care.

An instrument to assess patients' knowledge about their disease and its treatment can provide insight into the effectiveness of healthcare professionals' education efforts. Moreover, it can be used as an instrument to personalize education based on individual patients' knowledge gaps. Currently available patient knowledge questionnaires were developed before the introduction of biologicals as well as treat to target strategies in rheumatoid arthritis (RA). Therefore we started the development and validation of an RA knowledge questionnaire for patients.

**Objectives:** To propose an instrument to measure factual disease related knowledge in RA patients with additional focus on knowledge related to modern treatment methods.

**Methods:** Content to be covered by the instrument was adopted from existing questionnaires. Consensus was reached on relevant content by a RAND modified Delphi scoring procedure by six rheumatology nurses and six rheumatologists, and a subsequent consensus meeting among six rheumatology nurses and four rheumatologists. Six rheumatology nurses and five rheumatologists provided written feedback on a preliminary pool of items written to assess the identified content domains. Subsequently, a focus group among nine patients was organised to identify additional content areas that might have been omitted from the item pool. Readability, feasibility and comprehensiveness of the resulting pool of 63 items were rated by eight patients from the focus group.

**Results:** Cross-sectional data of 340 patients recruited from Bernhoven rheumatology department were used to evaluate psychometric properties. Preliminary analysis suggests that 21 (27%) items should be discarded based on an item total point biserial correlation $<0.30$. Confirmatory factor analysis with weighted least squares estimation on the polychoric correlation matrix suggested acceptable fit for a unidimensional measurement model for the remaining 45 items (CFI =0.95, TLI=0.95, RMSEA=0.02, WRMR=0.95). Internal consistency was also high for 45 items, with Cronbach's $\alpha$=0.92.

**Conclusions:** These preliminary results suggest that the questionnaire is a valid and reliable measure for assessing factual disease related knowledge in RA patients. Further validation efforts based on modern item response theory based approaches are ongoing as well as work directed at developing a calibrated item bank, tailored short-forms and a computerized adaptive testing algorithm.

## AB1029 COSTS OF BIOLOGICAL AGENTS AND PATTERNS OF BIOLOGICAL THERAPY IN ROUTINE TREATMENT FOR RHEUMATOID ARTHRITIS

M. Kamiya[1], S. Soen[1], H. Kikuchi[2], N. Okada[3]. *[1]Department of Orthopaedic Surgery and Rheumatology, Nara Hospital, Kinki University Faculty of Medicine, Ikoma-City; [2]Department of Orthopaedic Surgery and Rheumatology, Sakai Hospital, Kinki University Faculty of Medicine, Sakai-city; [3]Orthopaedic Surgery, Itsuki Hospital, Sumoto-city, Japan*

**Background:** Biological agents, introduced in the late 1990s, had significant impact on treatment for rheumatoid arthritis and patient outcomes. However, this treatment is costly, and increases in healthcare payment are of concern.

**Objectives:** This study examined the costs and patterns of biological therapy in routine treatment provided at our hospital.

**Methods:** Subjects were 206 rheumatoid arthritis patients who received etanercept, infliximab, adalimumab, tocilizumab, or abatacept between January 2005 and December 2014. Cumulative costs of each agent administered to a patient over a period of 1, 2, and 3 years were calculated using the current prices of biological agents listed by the National Health Insurance program. Therapy continuation rates and relative dose intensities (RDI) were calculated, and reasons for treatment withdrawal were investigated to ascertain patterns of biological therapy.

**Results:** There were a total of 360 cases of biological agent treatment (174 etanercept cases, 44 infliximab cases, 27 adalimumab cases, 49 tocilizumab cases, and 66 abatacept cases) in 206 rheumatoid arthritis patients, among which 60 etanercept, 9 infliximab, 9 adalimumab, 9 tocilizumab, and 12 abatacept cases were continued for at least 3 years without disruption. When exchanging 1 euro with 127 yen, cumulative costs of one-year and three-year treatment with 25 mg/week etanercept (53 cases) were approximately 6,160 euro and 17,490 euro per patient, respectively, while costs with 50 mg/week etanercept (7 cases) were approximately 11,450 euro and 32,240 euro per patient, respectively. Costs of 1- and 3-year treatment with infliximab were approximately 11,910 euro and 32,430

euro per patient, respectively; those with adalimumab were approximately 13,450 euro and 38,590 euro per patient, respectively; those with tocilizumab were approximately 8,690 euro and 24,730 euro per patient, respectively; and those with abatacept were approximately 13,460 euro and 34,140 euro per patient, respectively. Withdrawal from therapy with any biological agent was due mainly to insufficient therapeutic effect (50% of withdrawals), adverse effects (35.5%), patients' circumstances (9.2%), and remission (5.3%). Therapy continuation rates for etanercept, infliximab, adalimumab, tocilizumab, and abatacept at the end of 3 years were 57.7%, 24.7%, 42%, 25%, and 39.3%, respectively (Kaplan-Meier method). The continuation rate of etanercept therapy was significantly higher than the rates of therapy with any of the other 4 biological agents (log-rank test, $P<0.05$). Mean RDI values (95% CI) for 3 years were calculated for etanercept 25 mg/week (0.93; 0.81–1.04), etanercept 50 mg/week (0.86; 0.64–1.07), infliximab (1.10; 1.002–1.19), adalimumab (0.95; 0.89–1.01), tocilizumab (0.84; 0.78–0.89), and abatacept (0.85; 0.75–0.94). Decreases in tocilizumab and abatacept dosage were confirmed, and longer dosing intervals were speculated. Furthermore, the dose intensity of infliximab was increased by 10%, indicating increases in dosage and shortened dosing intervals. Significant changes in dosage were not confirmed for etanercept and adalimumab therapy.

**Conclusions:** Etanercept therapy had a high continuation rate. In particular, a 25 mg/week regimen was rarely changed to a 50 mg/week regimen, suggesting that the use of 25 mg/week etanercept therapy may be able to reduce medical costs.

**Disclosure of Interest:** None declared

## AB1030 EFFECTS OF CONDUCTING DIRECTLY OBSERVED TREATMENT, SHORT-COURSE (DOTS) STRATEGY AND CONFERENCES ON LATENT TUBERCULOSIS INFECTION IN RHEUMATOID ARTHRITIS PATIENTS UNDERGOING IMMUNOSUPPRESSIVE THERAPY

M. Tsujimura[1], T. Fujita[2], S. Endo[3], S. Nagai[4], E. Watanabe[5]. *[1]Medical liaison office, Fuji Orthopedic Hospital; [2]Medical and Health Division, Fuji Public Health Center; [3]Endo Naika-lin; [4]Fuji Public Health Center; [5]Department of Orthopedic Surgery, Fuji Orthopedic Hospital, Fuji-city, Shizuoka-pref, Japan*

**Background:** As our hospital lacks a pulmonologist, screening for respiratory infections in the treatment of rheumatoid arthritis (RA) is carried out through collaboration with a pulmonary medicine specialist outside of our facility. Patients in whom latent tuberculosis infection (LTBI) is detected by screening are prescribed isoniazid (INH). At the Fuji Public Health Center, which has jurisdiction over our hospital, directly observed treatment, short-course (DOTS) is implemented for all tuberculosis patients, including the LTBI cases registered. In our practice, we have held DOTS conferences (DOTS-C) with the health center regularly since 2013 to ensure proper patient education and thorough patient management.

**Objectives:** We investigated the status of the respiratory infection screening conducted in our hospital and studied the impact of DOTS-C on treatment outcomes in LTBI and the treatment of RA.

**Methods:** For 250 patients who underwent screening for respiratory infections between 2010 and 2014, we retrospectively examined data in regard to the items associated with LTBI and RA treatment.

**Results:** There were 58 patients diagnosed with LTBI and prescribed INH. As of October 31, 2015, immunosuppressive drugs used in the 58 patients were methotrexate in 37 patients at doses of 7.57±2.28 mg/week (mean ± standard deviation), prednisolone in 6 patients at doses of 2.17±0.85 mg/day, and biological preparations in 45 patients. In all cases, the scheduled duration of INH therapy was 270 days. DOTS-C was conducted in 23 patients. The number of patients who completed the entire treatment course was 19 (82.6%) in the DOTS-C group and 11 (31.4%) in the non-DOTS-C group. The number of patients hospitalized and treated for infections and other complications developing during RA treatment was 1 (4.3%) in the DOTS-C group and 8 (22.9%) in the non-DOTS-C group.

**Conclusions:** In our medical institution, despite not having a pulmonologist, it was possible to complete the entire course of LTBI treatment through collaboration with an associated public health center. Our findings indicate that DOTS-C is useful for achieving both the completion of LTBI treatment and patient education to prevent complications.

## AB1031 RHEUMATOID ARTHRITIS, A SINGLE-CENTER EGYPTIAN EXPERIENCE

M.M. Elfishawi[1], B.R. Sakr[1], M.H. El-Arousy[2], A.K. Hatw[2], A.N. Abdulkarim[2], A.B. Tammam[2], A.N. Kotp[2], M.E. Hamed[2], I.E. Genedy[2], E.D. El Desouky[3], Z.O. Nawito[1]. *[1]Rheumatology, Kasr AlAiny Hospital, Cairo University; [2]Rheumatology, Kasr AlAiny Medical School; [3]Epidemiology and Biostatistics, National Cancer Institute, Cairo University, Giza, Egypt*

**Background:** The Epidemiology of Rheumatoid Arthritis (RA) is changing over time provided by several studies showing an increase in frequency and change in joint presentation.(1) Moreover, the characteristics of the disease may differ among different ethnicities and populations that necessitate studying each population to define its own pattern of RA.

**Objectives:** Our aim was to define disease characteristics in a cohort of Egyptian RA patients by retrospective analysis of their medical records through a period of 20 years.

**Methods:** Medical records of all cases who fulfilled the ACR 1987 criteria for diagnosis of RA starting from January 1995 till July 2015 were reviewed (n=3219). All patients were receiving medical follow–up at the Rheumatology outpatient clinic, Kasr AlAiny Hospital. Demographic data and disease characteristics were documented and statistically analyzed.

**Results:**

A total of 3219 patients fulfilling the ACR 1987 criteria of RA were identified in the duration (1995–2015), 84% were females with mean age 48.8±13.8 that was not significantly lower than that of males 49.1±15.7 (p-value=0.62).The mean age of onset was 36.1±13.4 years and the mean disease duration was 12.9±7.9 years.

Rheumatoid factor (RF) was detected in 49.9% of cases; erosions were found at diagnosis in 19.6% of patients.77.1% of RA cases presented with polyarticular and 22.9% with oligoarticular patterns.

There was a significant increase by 0.12% in newly diagnosed cases annually (P-value=0.01) throughout the period studied (20y) (Fig. 1), however there was a significant decrement by 0.4% annually in females (p-value=0.02). On the other hand there was a significant steady increase in the mean age of onset by 0.2 year annually (P-value<0.001). While, there was a steady decline in erosions by 0.5% annually (p-value=0.01)

Females were more prone to have erosions although this was not found to be statistically significant; on the other hand RF was significantly higher in the erosive group (32.6%). Similarly the mean age at disease onset and age at diagnosis were statistically significantly higher in the erosive group (p-value=0.002 and p-value<0.001 respectively).

Regarding Extra-articular manifestations at the time of diagnosis, there was a significant decline in the presence of subcutaneous nodules and Sicca symptoms by0.4% & 0.5% annually respectively (P-value=0.03).

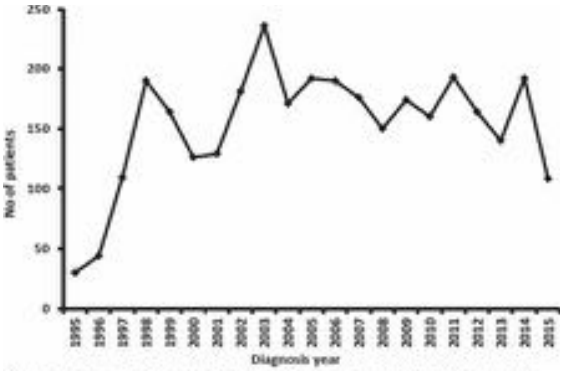

Figure one showing increase in newly diagnosed cases by 0.12% annually

**Conclusions:** The present study describes the demographic and disease characteristics of RA in the largest retrospective study as regards Egyptian RA patients.

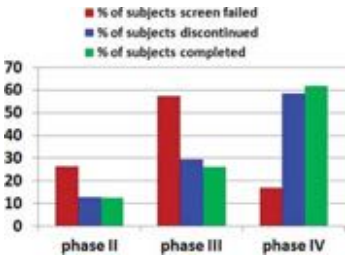
## AB1032 PROFILES OF PATIENTS AGED OVER 80 YEARS WITH RHEUMATOID ARTHRITIS IN AORA REGISTRY

M. Kobayashi[1], S. Miyamoto[2], T. Kashiwagura[3], Y. Sugimura[2], N. Konishi[4], M. Urayama[5], H. Ito[6], T. Sakuraba[7], T. Aizawa[8], H. Abe[9], K. Kamo[10], H. Aonuma[11], N. Miyakoshi[12], Y. Shimada[12]. *[1]Dept. of Orthop. Surg, Hiraka General Hospital, Yokote; [2]Dept. of Orthop. Surg., Nakadori General Hospital; [3]Dept. of Orthop. Surg., Akita City Hospital; [4]Dept. of Rehab. Med., Akita Kousei Medical Center, Akita; [5]Dept. of Orthop. Surg., Ogachi Central Hospital, Yuzawa; [6]Dept. of Orthop. Surg., Yamamoto Kousei Medical Center, Noshiro; [7]Dept. of Orthop. Surg., Hiraka General Hospital, Yokote; [8]Dept. of Orthop. Surg., Kita Akita Municipal Hospital, Kita-Akita; [9]Dept. of Orthop. Surg., Ugo Municipal Hospital, Akita; [10]Dept. of Orthop. Surg., Akita Rosai Hospital, Odate; [11]Dept. of Orthop. Surg., Kakunodate Municipal Hospital, Senboku; [12]Dept. of Orthop. Surg., Akita University Graduate School, Akita, Japan*

**Background:** The proportion of the aging population is increasing worldwide. Currently, the population of aging individuals is the highest in Japan; the percentage of 65-year-old people is 26.7%, indicating an aged society. Furthermore, the proportion of elderly people over 65 years of age is the highest (33.6%) in Akita prefecture, Japan.



**Objectives:** We investigated the data of patients with rheumatoid arthritis (RA) in various medical centers where in the orthopedic surgeons belonged to Akita

Orthopedic Group on RA (AORA) in Akita. We think that Akita registry is the future vision for RA treatment.
**Methods:** In this cohort study, we examined 324 of 2021 cases of patients aged ≥80 years (16.0%) from AORA registry in 2015 (average age, 66 years).
**Results:** The average age of our cohort was 84 years (range, 80–99 years); of the 324 patients, 59 were men and 265 were women, and the average disease period was 14 years (range, 2 months–66 years). Two-hundred sixty eight (83.0%) cases were of elderly-onset RA (EORA). According to the Steinbrocker classification criteria, 82 cases were stage I; 69, stage II; 80 stage III; and 87, stage IV. Further, 77cases were cass 1; 128 class 2; 89 class 3; and 22, class 4. The past medical history of the patients was as follows: 176 cases of hypertension, 59 cases of respiratory diseases, 56 cases of heart diseases, and 38 cases of diabetes. MTX (average, 5.5 mg per week; range, 1–14 mg per week) was administered to 101 patients. Prednisolone (average, 3.8 mg/d; range, 1–12.5 mg/d) was administered to 170 patients. A combination of conventional systemic disease-modifying antirheumatic drugs was administered as follows: bucillamine to 97, salazosulfapyridine to 84, tacrolimus to 21, mizoribine to 8, gold sodium isothiomalate to 7, actarit to 5, iguratimod to3, and auranofin to 1 patient. Biologics were administered to 33 patients (10.2%); etanercept was administered to 15, abatacept to 6, adalimumab to 4, tocilizumab to 4, infliximab to 3, golimumab to 1, and certolizumab pegol 1 patient. DAS28CRP remission was observed in 149 patients. The disease activity was low, moderate, and high in 53, 74, and 4 patients, respectively. In our study, a few patients showed high disease activity and an increase in the extent of functional disorder. These results may be attributed to the limited number of patients visiting the orthopedic department and the quality of the patients.
**Conclusions:** The study showed the low using ratio of MTX and high using ratio of PSL as much as previous reports. Sixty two percent of RA patients over 80 years of age showed rather low disease activity. Conventional therapy, without the use of bDMARDs, was used to treat 89.8% of the elderly patients with RA.

## AB1033 CHALLENGES IN RECRUITMENT AND RETENTION OF SUBJECTS IN CONDUCTING CLINICAL DRUG TRIALS IN A DEVELOPING COUNTRY

N. Bhanushali, R.R. Uppuluri, S. Arava, M. Younis, F. Fatima, A. Rani, D. Kumar, S. Jonnada, S. Deepti, S. Challa, S. Challa. *Rheumatology, Sri Deepti Rheumatology Centre, Hyderabad, India*

**Background:** Increasing enrollment and retention rates is important for clinical trials and healthcare advancements. Barriers in conducting clinical trials are physician-related, protocol-related or patient-related. Some of the factors that may hinder successful completion of a clinical drug trial are screen failures, adverse events leading to withdrawals and dropout of subjects. Inability to achieve adequate sample size for the trial may make the data insufficient to conclude objectives of a clinical drug trial and also increase overall cost and duration.
**Objectives:** To study the factors such as subject recruitment and retention that may impede the successful conduct of clinical drug trials in India.
**Methods:** Sixteen clinical drug trials conducted at a tertiary care for rheumatological disorders in Hyderabad, India were analyzed. The study period was during 2006–2015. Thirteen trials were pertained to rheumatoid arthritis (RA) and 3 to osteoarthritis (OA). Three trials were of phase II, 8 in phase III and 5 in phase IV. Ethics committee approval was obtained for each trial. After obtaining the informed consent, subjects were screened to evaluate study specific inclusion/exclusion criteria; those not fulfilling the criteria were not included into the trials. While conducting the trials the number of subjects withdrawn or dropped out was duly noted. Factors relating to subjects recruitment and retention were analyzed.
**Results:** Among 228 screened subjects (mean age 47.3±11 years) women were 201 (88%). A total of 42 (18.4%) subjects were screen failed; 19 (45.3%) due to infection (latent tuberculosis) and 23 (54.7%) due to other reasons. One hundred and eighty six (81.6%) subjects were enrolled into the trials after fulfilling study specific inclusion and exclusion criteria. Screen failures were more in phase II (26.2%) and phase III (57.1%) trials; nearly half of them were due to latent tuberculosis.

Among 186 subjects enrolled, 162 (87%) completed the trials and 24 (13%) discontinued. Half of the subjects discontinued (n=12) were withdrawn in view of adverse events. Two (8.3%) withdrew consent from the trials and 10 (41.7%) were lost to follow up. Maximum number of subjects discontinued was in phase IV (figure).
**Conclusions:** Screen failures have an impact on recruitment of the subjects. Number of screen failure was more in phase III. Number of screen failure was least and number of discontinuation was most in phase IV. In the present study nearly half of the subjects screen failed due to latent tuberculosis peculiar to endemic countries like India. Subject retention is also important in conducting successful clinical trials. In this study 40% of subjects dropped out due to unknown reasons. Further studies are required to analyze the factors related to subject recruitment and retention from the clinical trials conducted at other centers in developing countries like India.

## AB1034 THE EPIDEMIOLOGY OF THE RHEUMATIC MANIFESTATIONS ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE: THE PRELIMINARY DATA FROM A HOSPITAL-BASED COHORT STUDY IN ISTANBUL

N. Cakir[1], N. Imeryuz[2], O. Atug[2], H. Akin[2]. *[1]Department of Rheumatology, FSM Training and Research Hospital; [2]Department of Gastroenterology, Medical School of Marmara University, Istanbul, Turkey*

**Background:** Rheumatic manifestations are the most common frequent extra-intestinal manifestations (EIM) of inflammatory bowel disease (IBD), which includes Crohn's disease (CD) and ulcerative colitis (UC), and affected 6–46% of patients[1].
Despite the common manifestations, data on the various ethnic populations are limited so far. Therefore, the cohort study seems a more useful tool to learn more about epidemiology and possible risk factors in the different geographical and racial groups[2].
**Objectives:** We conducted this survey to estimate the prevalences of some rheumatic manifestations associated with IBD and to study epidemiological factors of IBD in Istanbul, Turkey.
**Methods:** The patients were enrolled from the Gastroenterological Out-patient Clinics at two Hospitals. The diagnosis was made by gastroenterologists using endoscopy and histological studies. All patients with established diagnosis of CD and UC were evaluated byr heumatolgogists for EIM. Inflammatory back pain (IBP) was defined according to Calin's criteria. The modified New York criteria were used to define ankylosing spondylitis (AS) and the European Spondyloarthropathy Study Group criteria for spondyloarthropathy (SpA).
**Results:** A total of 223 patients diagnosed as IBD.115 ulcerative colltis (UC) and 108 Crohn'sdisease (CD).We estmated the prevalence of IBP as 21%; AS: 2.7%; sacroiliitis (SA): 5.4%; psoriasis: 1.3%; psoriatic arthritis (PsA): 0.9%; pustulosis: 0.9%; uveitis: 1.8%; polyarticular arthritis: 6%; oligoarticular arthritis: 9%; arthralgia: 27%; erythema nodosum (EN): 2.2%; recurrent oral aphthous (ROU): 18.4% (Table 1).

Table 1. Demographic and clinical features of patients with IBD

| | Total, n (%) | UC | CD |
|---|---|---|---|
| IBD no. | 223 | 115 | 108 |
| Age | 41.8±12.6 | 43.5±12.6 | 39.8±11.9 |
| Arthralgia | 60 (27%) | 27 | 33 |
| Polyarticular arthritis | 14 (6%) | 6 | 8 |
| Oligoarticular arthritis | 20 (9%) | 10 | 10 |

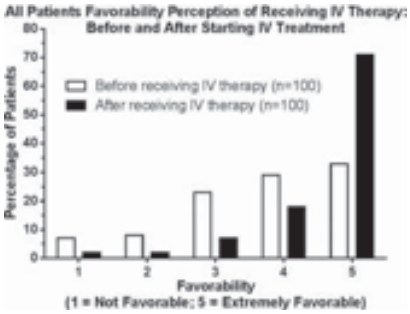
## AB1035 RHEUMATOID ARTHRITIS AND JUVENILE IDIOPATHIC ARTHRITIS REGISTRIES: A QUALITATIVE ANALYSIS OF DATA IN CLINICALTRIALS.GOV



N. Goel[1,2], F. Eisenberg[3], M. Barboza[4], D. Campion[4], K. Bibeau[1]. *[1]Quintiles Inc; [2]Duke University School of Medicine, Durham, NC; [3]iParsimony, Washington, DC; [4]Quintiles Inc., Rockville, MD, United States*

**Background:** Efforts to standardize and catalog outcome measures for registries are important to improve our understanding of conclusions drawn both intra- and inter-registry(ies). A generic framework, the Outcome Measures Framework Model (OMFM),[1] has been developed to use across all registries with the aim to identify the major categories of outcome measures. A condition specific framework exists for rheumatology clinical trials defined by the Outcome Measures in Rheumatology group (OMERACT),[2] and may be applied to observational studies.
**Objectives:** We undertook a qualitative evaluation of various rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA) registries to evaluate the types and details of the outcome measures reported as a mechanism to refine the existing frameworks to guide registry data collection.
**Methods:** Active RA and JIA registries within ClinicalTrials.gov (CT.gov) were identified using a cutoff date of 23 June 2015. The 10 largest registries based on anticipated enrollment were selected for evaluation and supplemented by additional registries, not necessarily in CT.gov but considered important for inclusion by the project team and external stakeholders. Two reviewers, an epidemiologist and rheumatologist, evaluated the registry reported outcome measure details, terminology, and variations qualitatively.
**Results:** Twenty-one registries were evaluated, 11 in common by both reviewers. Registries included populations from the US, the EU, Asia and Latin America and were run by various government, industry, or non-profit organizations. Key findings were that the outcome measures utilized and the time points of their assessment were often not clearly defined in CT.gov. Both the OMERACT framework and OMFM were missing various outcome measures and their definitions to properly categorize all the identified outcomes. Registries varied with respect to detailing how results would be analyzed, e.g., prospective or post hoc analyses. Diagnostic criteria used for inclusion were frequently vague, e.g., investigator judgement vs available classification criteria vs not specified. Published data from earlier investigations were typically not cited, results to date not reported, and links to registry websites not provided. Data not available in CT.gov were often available in publications or websites regarding analytical methods, but these external resources were not always easily located.
**Conclusions:** Current CT.gov registry postings often are missing key details to ensure a clear understanding regarding the populations enrolled, outcomes data to be collected and analyzed, and opportunities to combine data amongst registries. This preliminary work also identified instances to improve the OMERACT framework and OMFM as well as expand the OMERACT outcome measures to address the needs of observational studies beyond clinical trials.

## AB1036 UPDATED RESULTS FROM THE PRO ASSESSMENT OF INFLAMMATORY ARTHRITIS PATIENTS' EXPERIENCE WITH IV ADMINISTERED BIOLOGIC THERAPY

N. Gaylis[1], J. Sagliani[1], S. Black[2], K. Tang[3], R. Dehoratius[2,4], D. Parenti[2]. *[1]AARDS Research, Aventura; [2]Janssen Scientific Affairs, LLC, Horsham; [3]Janssen R & D, Spring House; [4]Kimmel School of Medicine, Thomas Jefferson U, Philadelphia, United States*

**Background:** Pt-reported outcomes (PRO) are used to assess pt-related benefit in clinical trials. Inflammatory arthritis (IA) pts are equally receptive to intravenous (IV) or subcutaneous (SC) biologic treatment[1].
**Objectives:** We obtained PRO data to understand characteristics of pts who receive IV biologic agents for IA.
**Methods:** This was a questionnaire-based study conducted at a rheumatology practice with extensive clinical trial experience. A total of 100 pts enrolled & are included in this final analysis. Inclusion criteria: a diagnosis of IA with IV biologic use for ≥3 mo; ≥18 yrs age; able to read, write & speak English, willing to complete the questionnaire & a signed informed consent form. IV biologic treatment was per clinical practice; there were no treatment assignments & study drug was not supplied. The questionnaire had 30 questions which pts completed prior to receiving a regularly scheduled dose of IV biologic.
**Results:** Mean (±SD) age of pts was 58.35 (±14.64) yrs with mean disease duration of 10.1 (±8.13) yrs (range 0.7–45 years). Pts were Caucasian (38%), African American (28%), Latino/Hispanic (22%), Asian/Pacific Islander (1%) & 11% not identified. IV biologics used were infliximab [IFX](71%), rituximab [RTX](12%), tocilizumab [TCZ](10%), abatacept [ABT](6%) & golimumab [GLM](1%). The mean duration of current IV therapy was 4.07 (±3.27) yrs (range 0.1 to 16.0 yrs). Pts' favorability perception of IV therapy BEFORE & AFTER starting IV therapy is shown in the Figure. Amongst all pts, "Extremely favorable" increased ($p<0.05$) from 33% to 71% after receiving IV therapy; the increase in "Extremely favorable" was evident in pts with or without previous SC biologic therapy. Of the 33% of pts reporting an "Extremely favorable" rating BEFORE starting IV therapy, 6% changed their opinion to a lesser rating AFTER starting therapy, whereas 44% of patients reporting "Extremely favorable" AFTER starting IV therapy had indicated a lesser rating BEFORE starting IV therapy.

**Conclusions:** These results suggest that among IA pts receiving IV biologic therapy for treatment of IA, there is a high degree of pt satisfaction, including a similar favorability perception of IV therapy among pts who switched from a SC to an IV biologic. Our results support the concept that when there is a shared decision making discussion with pts regarding biologic treatments, the option of IV therapy should be an essential part of that discussion & that the IA pts' perspective should be given meaningful consideration.

## AB1037 EFFECTIVENESS OF CONVENTIONAL DMARD THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SUCCEEDING COST-SAVINGS FOR A HEALTH SYSTEM BY DIMINISHING USE OF BIOLOGICAL THERAPY

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Rheumatology; [2]Psychology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Biological therapy is useful to prevent clinical and radiological progression in patients with rheumatoid arthritis (RA) but is associated with high costs and has impacted budget in Colombian health system. Consequently, it is important to develop strategies to achieve positive outcomes in RA patients and at the same time to obtain cost-savings for health system.
**Objectives:** We describe effectiveness of conventional DMARD therapy in RA patients with moderate-severe disease activity, usefulness of Treat to Target (T2T) strategy with a multidisciplinary care team (MCT) model and subsequently cost-savings obtained.
**Methods:** We conducted a real-world, retrospective, cross-sectional study. We included patients who had moderate-severe disease activity; these patients were potential candidates for biologic therapy because were using conventional treatment; they were followed-up and treated according to T2T and MCT model. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1); therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. The aim of the study was to evaluate patients who were in moderate-severe disease activity and reached low disease activity or remission impacting on health costs. Descriptive epidemiology was done, the medians were analyzed using t-Student by performing a normality test for DAS28 distribution; the disease activity was analyzed using Pearson's statistics.

**Results:** 526 patients were included, mean age 63.5±11.8, 424 (80%) female and 102 (20%) male. These patients had a DAS28 on average 4.5±1 at beginning and after 24 months 410 patients (78%) got remission/low disease activity status with a mean DAS28 2.57±1. The costs of biological therapy in Colombia finishing 2015 on average were $7,725 US dollars/year/patient, and taking into account that 410 patients in moderate-severe disease activity who were candidates to biologic treatment and reached at least low disease activity, the amount in costs-savings projected for health system by preventing early use of biologics was approximately $3,167,551million dollars/year, ranging between the cheapest biological and the most expensive ($4,878 and $12,774 US dollars/year respectively).
**Conclusions:** This study showed that it is possible to decrease disease activity and obtain a significant cost-reduction in treatment of RA by using conventional DMARDs in a model with therapeutic goals like T2T and optimizing a multidisciplinary approach.

## AB1038 HIGH COSTS FOR HEALTH SYSTEM OF MISDIAGNOSING OSTEOARTHRITIS AS RHEUMATOID ARTHRITIS

D. Buitrago-Garcia[1], C. Castro[1], P. Santos-Moreno[2], L. Villarreal[3], G. Ballesteros[2], J. Bello[2], E. Castillo[2], R. Giraldo[2], D. Gomez[2], A. Aza[4], A. Lopez[5], A. Cardozo[4], N. Palacio[6]. *[1]Epidemiology; [2]Rheumatology; [3]Psychology; [4]Health services; [5]Pharmaceutical chemist; [6]Nursing, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** There are an important number of patients with osteoarthritis (OA) that are misdiagnosed as rheumatoid arthritis (RA) in general practice in Colombia. They are treated as such with disease modifying anti-rheumatic drugs (DMARDs), leading to higher economic costs for health system.
**Objectives:** The aim of this study was to calculate the possible direct economic costs of the care of OA patients misdiagnosed as RA in a 48 month period in a cohort of patients derived to a specialized RA center in Colombia.
**Methods:** A descriptive cross sectional study was performed. Patients derived during a 48 month period to a RA specialized center with presumptive diagnosis of this disease and found finally diagnosed with OA were included in analysis. Each patient was evaluated to confirm or rule-out diagnosis of RA as follows: a rheumatologist fulfilled a complete medical record, including joint counts; it was assessed rheumatoid factor and anti-citrullinated antibodies, and other laboratories depending on each case. Also were made x-rays of hands and feet, and in some cases of persistent doubt about the diagnosis was requested comparative MRI of hands or/and feet. Then we described the direct costs of care in Colombian pesos (COP) of these false-positive RA patients assuming an average of 4 visits/year to general practitioner (8.400 COP/medical appointment), 2 visits/year for physiatrist and orthopedics (33.995 COP/ medical appointment) and 4 set/year of conventional laboratories (92.161 COP/set). Cost of medication doses were calculated for an average use of methotrexate, sulfasalazine, chloroquine and prednisolone (200.840 COP/monthly). Indirect costs were not calculated.
**Results:** We found 2930 OA patients misdiagnosed as RA in a period of 48 months. For each patient we calculated 33.600 COP/year for general practitioner visits, 135.980 COP/year for specialized medicine visits, 368.644 COP/year for laboratory sets and 2.431.248 COP/year for medications. This leads to a total cost of 2.969.472 COP/year per patient. Given a total of 2930 misdiagnosed patients cost rise to 8.700.552 million COP/year ($2,900,184 US dollars/year).
**Conclusions:** There is an important economic implication of the misdiagnosis of OA as RA, being this the most frequent mistake in the diagnosis of this disease. The implementation of educational programs for health care primary physicians and specialized RA centers where a process of screening diagnosis is made could save this amount of money for the health system in Colombia.

## AB1039 BETTER OUTCOMES OF DISEASE ACTIVITY IN A LARGE COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Rheumatology; [2]Psychology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA). This strategy is being used last years in Colombia. On the other hand a multidisciplinary care team (MCT) model was generated in order to improve outcomes.
**Objectives:** The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 24-month period in a large cohort of patients from a Colombian specialized in RA center with a MCT model.
**Methods:** A descriptive retrospective study was performed. Records of patients from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 $>$5.1), every 7–9 weeks (DAS28 $\geq$3.1 and $\leq$5.1), and every 11–13 weeks (DAS28 $<$3.1). Therapy had to be adjusted with DAS28 $>$3.2 unless patient's conditions don't permit it. A MCT model means that a patient should be seen by other specialties such as physiatrist, physical and occupational therapy, nutritionist and psychologist at least 3 times a year. We divided patients in three groups: low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission (REM). Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
**Results:** 1147 patients were included in this study, 934 (81%) women and 213 (19%) men. Mean was 62±10 years. In regard to treatment it was found that 370 (33%) patients were treated with biologics, and 767 (67%) patients with conventional therapy. It was found a global increase in the percentage of patients in LDA/REM and decrease in moderate and severe disease activity groups. The mean of DAS28 was 4.1±1.1 at the beginning and 24 months after was 2.8±0.61. At 24 months was observed an increase in percentage of patients in remission or LDA (up to 80%) and a decrease in percentage of patients in MDA/SDA disease activity statistically significant. The difference of medians for each variable showed improvement with statistical significance ($p<0.00$). Although there was a slight decrease in HAQ, this was not statistically significant.

| ACTIVITY LEVEL | TIME 0 n (%) | 6 MONTHS n (%) | 12 MONTHS n (%) | 24 MONTHS n (%) |
|---|---|---|---|---|
| REM | - | 305 (26) | 541 (47) | 562 (49) |
| LDA | 269 (23) | 350(30) | 278 (24) | 362 (31) |
| MDA | 635 (55) | 436 (38) | 305 (26) | 217 (19) |
| SDA | 243 (21) | 56 (5) | 24 (3) | 6(1) |

1147 PATIENTS IN CONVENTIONAL AND BIOLOGICAL TREATMENT

**Conclusions:** This study shows improvement of DAS28 and level of disease activity in a cohort of RA patients from a specialized center in Colombia treated under recommendations of T2T strategy and based on a MCT model. This revision shows the importance of T2T follow-up and treatment for this disease.

## AB1040 COMPARISON OF ADHERENCE AND DOSING INTERVAL OF SUBCUTANEOUS ANTI-TNF BIOLOGICS IN INFLAMMATORY ARTHRITIS FROM A CANADIAN ADMINISTRATIVE DATABASE

P. Bhoi[1], L. Bessette[2], M. Bell[3], C. Tkaczyk[1], F. Nantel[1], K. Maslova[1]. *[1]Janssen Inc., Toronto; [2]Université Laval, Quebec; [3]Sunnybrook Health Sciences Centre/University of Toronto, Toronto, Canada*

**Objectives:** Subcutaneous (SC) anti-TNF agents such as Golimumab (GLM) Adalimumab (ADA), Etanercept (ETA) and Certolizumab pegol (CZP) have been used for many years for the treatment of inflammatory arthritis. It is known that across diseases, and especially with chronic diseases, adherence to therapy is an important modifiable factor that may compromise treatment outcomes. The aim of this analysis was to compare adherence and dosing interval of SC anti-TNF in the treatment of inflammatory arthritis.
**Methods:** We used the IMS Brogan database which combined both private (PDP) and public drug plan databases of the provinces of Ontario (OPDP) and Quebec (RAMQ). Target drugs included SC anti-TNF biologics for indication of rheumatoid arthritis, ankylosing spondylitis, and psoriatic arthritis combined. The Index period was from January 1, 2010 - June 30, 2012 and patients were followed for 24 months through June 30, 2014. Patient selection criteria were adult patients newly prescribed a target biologic drug with at least three prescriptions and retained on therapy at 24 months.
Recommended dose regimens as per the Canadian product monographs were used to compare actual vs. expected drug utilization. The compliance rate (MPR) was calculated as the estimated days' supply in the defined period divided by the number of days in the defined period. Patients who scored $>$80% were considered adherent. For dose-interval analysis, the average days between units was estimated by taking the total days on therapy and dividing by the number of units the patient received. A unit is a syringe or vial; the total amount of drugs dispensed (in mg) were standardized at units as per the following: GLM: 50 mg; ADA: 40 mg; ETA: 50 mg; CZP: 200 mg. P-value obtained from Chi-square and Pair-wise comparison tests for statistical differences on the proportion of adherent patients; p-value $<0.05$ is considered to be statistically significantly different.
**Results:** There were 4,035 new patients on target biologic drugs with at least three prescriptions and retained on therapy at 24 months. The number of patients for each biologic drug used was 683, 1400, 1765 and 187 for GLM, ADA, ETA and CZP, respectively. The data source was as follow: PDP national (N=2509), RAMQ (N=634) and OPDP (N=892). In 24 months-retained patients, there was a greater proportion of GLM-treated adherent patients (n=595/683, 87%, $p<0.0001$) compared to ADA- (n=1044/1400, 75%), ETA- (n=1285/1765, 73%) or CZP-treated patients (132/187, 71%). We also investigated the number of patients receiving biologic drug at a shorter dosing interval. That proportion was

similar between groups and was 5%, 6%, 12% and 4% in GLM- (≤26 days), ADA- (≤12 days), ETA- (≤6 days) and CZP-treated patients (≤12 days), respectively.
**Conclusions:** In this real life Canadian administrative database, GLM has better adherence compared to other SC biologics. The reason for this difference and impact on long-term outcomes are currently under investigation.

## AB1041 HOUSEHOLD ERGONOMICS: DEVELOPMENT AND VALIDATION OF A NOVEL TOOL TO ASSESS PHYSICAL EXPOSURES CONTRIBUTING TO HOUSEHOLD WORK RELATED LOW BACK PAIN

P.D. Ranasinghe[1], I. Atukorala[2], A. Samaranayake[3], N.S. Gunawardana[4]. *[1]Ministry of Health, Health Education Bureau; [2]University of Colombo, Department of Clinical Medicine, Colombo 8; [3]Department of Health-Western Province, PDHS office, Colombo 10; [4]University of Colombo, Department of Community Medicine, Colombo 8, Sri Lanka*

**Background:** Household ergonomic risks-especially physical exposures straining the low back during manual household work can contribute to low back pain in housewives. To date, there are no screening tools to identify physical exposures that cause household work related low back pain.
**Objectives:** To develop and validate "Physical Exposure Check-Household work related low back pain (PEC-HLBP)", a tool to assess physical exposures contributing to household work related low back pain.
**Methods:** Items for PEC-HLBP were generated based on a theoretical framework developed through review of literature, qualitative observations and expert opinion. Item reduction was by a panel of 10 experts based on a scoring system. The draft PEC-HLBP was developed into an interviewer-administered questionnaire with responses in a Likert scale to facilitate responses on the gradient of the physical exposure and the scoring system adopted reflected the gradient of exposure. PEC-HLBP was designed to be answered based on household work activities routinely being performed by the respondent.
Exploratory factor analysis using principal component analysis was performed on a sample of 250, 20–50 year old eligible housewives to further reduce items and to assess construct validity. Internal consistency and test retest assessed the reliability.
**Results:** The initial PEC-HLBP contained 36 items. Ten items which scored an average score less than 2 by the panel of experts (score based on the importance as a physical exposure on a 1–5 scale) were eliminated. Exploratory factor analysis of draft PEC-HLBP with 26 items showed 9 factors (Eigen values 1.008–5.163) explaining 64.18% of total variance. All 26 items in draft tool showed factor loadings above 0.4 not requiring further reduction of items. Two factors with items of similar loadings were amalgamated based on the theoretical framework. Finalized PEC-HLBP contained 26 items in eight domains which were assigned names to depict the items they contained (figure 1). Experiencing the physical exposures or not were determined based on a predetermined cut off score for each domain.
The mean duration to complete the questionnaire was 16 (±4) minutes. Cronbach's Alpha was 0.789 (95% CI 0.725–0.825).The test-retest reliability was good (Spearman's coefficient above 0.77) for all domains. Response rate among housewives was 83.3% and the response rate for each question was 100% with no missing data.
**Conclusions:** PEC-HLBP is a valid, reliable and acceptable tool to assess physical exposures contributing to household work related low back pain among housewives
**Acknowledgement:** Medical Research Institute, Sri Lanka
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2850

## AB1042 PATIENT BELIEFS REGARDING ASSOCIATIONS BETWEEN WEATHER AND PAIN; AN ANALYSIS OF ENROLMENT QUESTIONNAIRES WITHIN "CLOUDY WITH A CHANCE OF PAIN"

R. Patel[1], J. Sergeant[1], J. McBeth[1], D. Schultz[2], C. Sanders[3], L. Cook[1], J. Ainsworth[3], W. Dixon[1]. *[1]Arthritis Research UK Centre for Epidemiology; [2]Centre of Atmospheric Science; [3]Centre for Primary Care, University of Manchester, Manchester, United Kingdom*

**Background:** The association between the weather and chronic pain is complex and largely undetermined. More than 80% of patients believe in an association between weather and pain. However, beliefs vary about which weather variable (e.g. temperature, atmospheric pressure) influences pain, with possible differences across pain disorders.
**Objectives:** To describe participants' beliefs about an association between weather and pain at the time of enrolment to a national smartphone study entitled "Cloudy with a Chance of Pain", stratified by self-reported diagnosis.
**Methods:** Participants in the UK aged 17 years or older, with access to a smartphone and who had arthritis or other chronic pain for at least 3 months were recruited to "Cloudy with a Chance of Pain". Participants completed an 8 point enrolment questionnaire which included two questions about their beliefs: 1) Belief strength: On a scale of 0–10, how likely do you think weather is associated with pain? 2) Belief type: If you think there is a possible association, which weather condition(s) affect your pain the most? Both questions offered categorical response options. In question 2, participants were permitted to select multiple categories and a "free text" option was also offered. We present a descriptive analysis of the categorical data and sub-analyses of differential beliefs by age (above/below 50yrs), gender and self-reported diagnosis. Results are reported as median (IQR) or number (%). Mann-Whitney U-Test and Fisher's exact test were used for statistical analysis. Within Table 1, significant associations ($p<0.05$) are denoted by bold text.
**Results:** 5,282 enrolment questionnaires were included in analysis. Median belief strength was 7 (5–9). 8% reported a belief strength of 4 or less. Participants most commonly believed that "damp/rain" affected their symptoms (72%). When compared to the total study population, those with fibromyalgia, chronic headache and neuropathic pain more frequently believed that changes in temperature and pressure correlated with pain. Indeed, participants with fibromyalgia and neuropathic pain more commonly reported belief in an association between all aspects of weather and pain when compared to the total study population. Table 1 summarises belief strength and belief type by gender, age and underlying diagnosis.

| | | Belief strength | Belief type | | | | |
|---|---|---|---|---|---|---|---|
| | | (0–10) | Temp change | Damp/ rain | Pressure change | Hot | Cold |
| | All (n=5282) | 7 (5–9) | 28% | 72% | 30% | 15% | 67% |
| Sex | Male (n=1667) | 7 (5–8) | 27% | **70%** | 31% | **11%** | **67%** |
| | Female (n=4115) | 7 (6–9) | 28% | **73%** | 29% | **16%** | **63%** |
| Age | <50 (n=2538) | 7 (6–9) | **34%** | **71%** | 29% | **17%** | **72%** |
| | ≥50 (n=2466) | 7 (5–8) | **22%** | **75%** | 31% | **12%** | **61%** |
| Diagnosis | Arthritis (other) (n=2425) | 7 (6–9) | 26% | **78%** | 30% | **13%** | 68% |
| | Fibromyalgia (n=1102) | 8 (6–9) | **44%** | **78%** | **40%** | **24%** | **77%** |
| | RA (n=1052) | 7 (5–9) | 27% | 70% | 29% | 17% | 62% |
| | Neuropathic pain (n=626) | 8 (6–9) | **38%** | **77%** | **40%** | **21%** | **73%** |
| | Spondyloarthropathy (n=493) | 7 (6–9) | 30% | 73% | 33% | 16% | 65% |
| | Chronic headache (n=337) | 8 (6–10) | **43%** | 70% | **49%** | **22%** | 67% |
| | Crystal arthritis (n=215) | 7 (5–9) | **34%** | **64%** | 33% | 20% | **56%** |

**Conclusions:** Most participants strongly believed in an association between weather and pain. Participants most commonly believed that damp/rain affected their pain. Specific beliefs vary between participants and between diagnostic groups, perhaps reflecting different causal pathways in these conditions.

## AB1043 THE RELATIONSHIP AMONG PAIN SLEEP DISORDERS AND SMOKE IN PATIENTS WHO ACCESS FOR THE FIRST TIME IN A RHEUMATOLOGY UNIT

R. Tirri, R. Ferrara. *Reumatologia, Seconda Università degli Studi di Napoli, Napoli, Italy*

**Background:** Pain is the most frequent manifestation of musculoskeletal conditions. Sleep disorders are common in a variety of rheumatologic diseases (1). The cigarette smoking is associated with exacerbated pain intensity and related symptoms (2,3).
**Objectives:** This study aimed to investigate the relationship between pain,sleep disorders and current smoker status in an Italian population sample who suffered by muscoloskeletal conditions.
**Methods:** A total of 978 patients were consecutively included from december 2014 to december 2015.Partecipants were assessed by Visual Analogic Scale (VAS) for pain intensity and by questions about sleep duration for sleep disorders (<6 h short sleeper;6–9 h normal sleeper, >9 h long sleeper) Smoker o non smoker current status was determinate by using one question. We considered patients without pain as controls.
**Results:** The mean age of partecipants was 52,7 years in wich most of them (86%) was female. Strong correlation (p=0.0058) was found between high pain, current smoker and short sleeper status. A correlation (p=0,085) was found between high pain, no current smoker and short sleeper status.High pain was strongly associated with short sleeper satus.(p=0,0078)
**Conclusions:** Short sleeper status is very prevalent in patients suffered by a musculoskeletal condition with high pain.Current smoker status is an independent variable.

## AB1044 PAIN AND PSYCHOLOGICAL HEALTH MAY BE ASSOCIATED TO RISK FACTORS FOR CARDIOVASCULAR DISEASE IN PATIENTS WITH RHEUMATIC JOINT DISEASE

S.A. Provan[1], I.J. Berg[1], H. Dagfinrud[2], N. Østerås[2], T.K. Kvien[1], T. Uhlig[1]. *[1]Rheumatology, Diakonhjemmet Hospital; [2]National Advisory Unit on Rehabilitation in Rheumatology, Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

**Background:** Patients with rheumatological joint diseases (RJD) have an increased risk of cardiovascular disease (CVD). There is a lack of knowledge concerning the impact of health status on CVD risk. Augmentation index (AIx) and reactive hyperemia index (RHI) are two markers of CVD risk. High values of AIx, and low values of RHI signify an increased risk of CVD.
**Objectives:** To investigate whether pain and self-reported health status are associated with CVD risk in patients with RJD.
**Methods:** 895 patients with RJD were included. 425 patients with self-reported osteoarthritis (OA), 159 patients with ankylosing spondylitis (AS) and 148 patients with rheumatoid arthritis (RA).
Variables of demography, co-morbidities, self-reported pain, health related quality of life (EuroQOL (EQ-5D) (AS and OA)) and health status (Short form 36 (SF-36)) were collected on questionnaires. Clinical examinations were performed by a study nurse and the 28-tender joint count recorded (28-TJC) (RA and OA). AIx (Sphygmocor apparatua (Atcor®)) and RHI (Itamar®) were measured. Cross-sectional linear regression analyses were performed with AIx and RHI as dependent variables in separate models. The associations between pain, health status and CVD risk (AIx and RHI as dependent variables) were examined in cross-sectional models adjusted for type of RJD, age and sex. (AIx was also adjusted for height). Possible confounders were identified from previous literature and plotted in directed acyclic graphs[1]. Relevant variables were entered into multivariate models.
**Results:** 895 patients with RJD were included, mean age was 61.3 (range 28–85), (64.7%) females. AIx was available in 143 patients with RA, 130 with AS, and 424 with OA. RHI was available in 143 patients with RA and 42 with AS. The results from the linear regression models are presented in the table. The multivariate models were adjusted for body mass index and disease activity (DAS ≥2.6 or ASDAS ≥1.3 = active disease).
**Conclusions:** Pain and psychological health are related to markers of CVD risk in RJD, after adjustments for disease activity. These novel findings require confirmation in longitudinal studies.

## AB1045 EFFICACY OF ETANERCEPT ON RADIOGRAPHIC PROGRESSION IN ADULT PATIENTS WITH RHEUMATOID ARTHRITIS OR PSORIATIC ARTHRITIS: RESULTS FROM THE SECOND INTERIM ANALYSIS OF A GERMAN NON-INTERVENTIONAL, PROSPECTIVE, MULTI-CENTER STUDY

S. Wassenberg[1], R. Rau[2], T. Klopsch[3], M. Buecheler[4], P.-A. Loeschmann[4]. *[1]Fachklinik 360°, Ratingen; [2]Expert Rheumatology, Düsseldorf; [3]Private Practice, Neubrandenburg; [4]Pfizer Pharma GmbH, Berlin, Germany*

**Background:** Several clinical trials have shown that etanercept (ETN) is highly effective in reducing clinical disease activity and reaching remission while it may also decrease and even reverse radiographic progression in rheumatoid arthritis (RA) and in psoriatic arthritis (PsA). However, the proportion of patients with RA or PsA achieving remission and radiographic non-progression in routine everyday practice is not known.
**Objectives:** To assess radiographic change and clinical disease activity in RA and PsA patients during long-term routine use of ETN under real-world conditions in a non-interventional trial. This is an interim analysis of the data after 52–78 weeks of observation per patient.
**Methods:** 1,600 adult RA and 400 PsA patients will be included into the study. Radiographs of hands and feet taken at baseline (±3 months start of ETN treatment), after 12 to 18 and 36 months follow up and 12 to 36 months before baseline ("historic"), if available, are scored by 2 blinded readers with random time order by the "van der Heijde modified Sharp score"[1] ($mTSS^{RA}$) for RA patients and the "van der Heijde modified Sharp score adapted"[2] ($mTSS^{PsA}$) for PsA patients. Additional parameters such as disease activity score (DAS28) and (serious) adverse events are recorded regularly.
**Results:** 282 RA and 87 PsA patients (77% vs. 51% females) were evaluated for this interim analysis. The median disease duration at baseline was 5.3 (range: 0;46) years (RA) and 4.3 (0;37) years (PsA). At baseline, mean $mTSS^{RA}$ was 22.1±33.2 (n=136), mean $mTSS^{PsA}$ was 21.6±30.6 (n=34). X-rays after 52–78 weeks were available for 131 RA (32 PsA) patients with a mean annualized radiographic progression of 1.4±6.4 (-0.9±4.2) under ETN therapy. During ETN treatment, 29.8% RA (28.1% PsA) patients experienced no change (-0.5 to 0.5) and 30.5% RA (43.8% PsA) an improvement (<-0.5) in mTSS. In total, numerically more PsA than RA patients were considered to be in radiographic non-progression (60.3% RA vs. 71.9% PsA, change in $mTSS^{RA/PsA}$ ≤0.5 from baseline). 65 RA (16 PsA) patients had a historic (i.e. 12–48 months prior to baseline) and a baseline x-ray with a mean annualized radiographic progression of 3.7±21.3 (2.1±3.5). Comparison between the annualized radiographic progression under ETN therapy with prior disease progression (before baseline x-ray) revealed less annual radiographic progression under therapy with ETN in both treated groups (RA: n=61; -3.6±22.1; p=0.205, PsA: n=14; -3.5±6.1; p=0.049). In RA (PsA) patients, the DAS28 decreased from a mean baseline value of 4.6±1.3 (4.2±1.0) to 2.9±1.2 (2.4±1.0) at week 78 indicating an important decrease of disease activity under ETN treatment. At week 78 fewer RA than PsA patients reached remission (DAS28<2.6) (44.6% RA vs. 60.7% PsA). Treatment with ETN was well tolerated and no new safety signals were observed.
**Conclusions:** The results of this interim analysis suggest that treatment with ETN slows radiographic progression and reduces disease activity in RA and PsA patients in routine clinical care.

## AB1046 THE IMPACT OF BIOLOGIC THERAPY ON WORKING CAPACITY IN SERBIAN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Zivojinovic[1], S. Stojanovic[2], M. Lazarevic[3], S. Mamula Masic[4], N. Damjanov[1]. *[1]Institute for Rheumatology, Belgrade, Belgrade; [2]Institute Niska Banja, Niska Banja; [3]Specialized Hospital for Rheumatic Diseases Novi Sad, Novi Sad; [4]Roche d.o.o., Belgrade, Serbia*

**Background:** Rheumatoid arthritis (RA) is a chronic progressive disease that can have profound influence on working capacity of affected people. It has been highlighted that reduced productivity is one of the major issue in RA and represents a significant economic burden on the patients, their families, and society.
**Objectives:** The objective of this study was to estimate the impact of biologic therapy on self-reported working capacity in Serbian patients with RA.
**Methods:** During the period from November 1 to December 15, 2015, 315 consecutive RA patients who were treated in one of three randomly chosen Serbian clinics were enrolled in a cross-sectional study. The inclusion criteria were: age $\geq$18 years, diagnosis of RA of at least 6 months, current MTX use for at least 1 month (with or without concomitant usage of biologic therapy), and written informed consent. The severity of pain is estimated by visual analogue scale (VAS). The differences between groups were assessed using the Mann-Whitney U-test. The relationships between the biologic therapy-related changes in productivity and the indicated parameters were evaluated using the Spearman rank correlation.
**Results:** Distribution of study sample regarding the employment status showed that 26.3% of the responders were employed, 23.5% were unemployed, while 50.2% were retired. The analysis of self-reported working ability demonstrated that 25.4% of the RA patients stated full work capacity, 38.1% partial work capacity, while 36.5% of the participants reported inability to work. Work incapacity was statistically significantly correlated with following variables: duration of RA ($\rho$=0,136; p=0,016), duration of MTX treatment ($\rho$=0,179; p=0,001) and the use of biologic therapy ($\rho$=-0,134; p=0,017). More than half (51.7%) of RA patients used biologic therapy. The average value of VAS score in the group currently receiving biologic therapy was 48.6±28.8 mm, while in the group that was not receiving a biological therapy was 61.3±25.1 mm, with statistically significant difference between these two groups (Z =-3.948; p$<$0.001). The majority of the participants (82.2%) who used biologic drug reported an improvement of working capacity following the introduction of this therapy. Also, more than half of these patients (53.4%) stated that the increase of working capacity occurred after 4 weeks of biologic therapy initiation.
**Conclusions:** The results of our study suggested that biologic therapy deeply and rapidly improved working capacity in patients with RA. Keeping in mind the fact that the loss of working ability is a significant outcome of RA, the effectiveness of treatment strategies should be evaluated not only using traditional clinical, functional, and radiographic measures, but also by establishing the possible influence of these treatments on working ability in this group of patients.

## AB1048 THE TRANSFORMATION OF INPATIENT RHEUMATOLOGY SERVICES IN A POST-BIOLOGICS ERA

S.C. Mcdonald, G. Wright. *Belfast Health and Social Care Trust, Belfast, United Kingdom*

**Background:** Over the last 15 years the rapid development of an armoury of biological drugs has revolutionised the management of inflammatory arthritis and other rheumatological conditions[1]. In the past Rheumatology inpatient wards were largely occupied with patients with difficult rheumatoid arthritis and associated extra-articular disease, with little option bar synthetic DMARDS, corticosteroid, respite and physiotherapy.
**Objectives:** In 1996 we audited inpatient services for the month of February within the Belfast Rheumatology Unit and a report was issued as a result of this to help plan service development. Twenty years later we repeated the audit.
**Methods:** We audited the inpatient admissions between 5th October 2015 and 5th November 2015. Data was collected contemporaneously by reviewing the medical notes whilst the patients remained on the ward and any omissions filled in retrospectively using our local database NIECR. Information collected included age, gender, method of admission, diagnosis on discharge, duration of admission, procedures carried out, allied health professionals inputting, radiology services required and onward referral as inpatient to other specialities. We compared this to the audit report from 1995.
**Results:** The audit discovered that there was some similarities between the two eras including:
1) Inpatients remain predominantly female – 77% in February 1996 compared with 88% in October 2015.
2) Emergency admissions remain in the minority – 17% in February 1996 compared with 25% in October 2015.
3) 59 patients were admitted to the ward in February 1996 compared with 44 in October 2015.
4) The mean age of our inpatients was 56 years. The commonest age interval in 1996 in both males and females was 45–64.
Conversely there are a few notable differences including;
1) In 1996 there were 44 beds in the department compared with 16 beds currently.
2) In 2015 21/44 patients were elective admissions to the ward for administration of Iloprost or Flolan. Other common reasons for admission included multiple joint injections (5/44) and flares of inflammatory arthritis (4/44). In 1996, 23/49 patients were admitted for the management of flares of inflammatory arthritis. This represents a 38% reduction in admissions for disease flares.
3) Less patients required access to the multidisciplinary team (MDT). In 1996 85% of patients were reported to access inpatient physiotherapy, compared with 52% in 2015. 80% of patients in 1996 were said to access OT, but it was 18% in 2015.
4) The mean length of stay in 1996 was 11.8 days, compared with 7.1 days in 2015.
**Conclusions:** Our ward serves a comparable number of patients nowadays, as it did in 1996. However the inpatient population has certainly evolved. Better treatments for inflammatory arthritis have reduced the number of admissions to manage flares. Those patients that are admitted, stay for a shorter time and require less MDT input, perhaps due to less acquired disability.

## AB1049 MUSCULOSKELETAL MANIFESTATIONS IN RENAL HEMODIALYSIS PATIENTS

T.A. Gheita[1], S. Sayed[1], A. Al-ghitany[2], H. Ezzat[2]. *[1]Rheumatology and Clinical Immunology, Faculty of Medicine, Cairo University; [2]Nephrology, Faculty of Medicine, Ain Shams University, Cairo, Egypt*

**Background:** Pain is a significant problem in more than 50% of hemodialysis patients and is not being effectively managed[1]. In patients on regular dialysis, musculoskeletal pain was identified as the most disturbing pain and the majority reported that pain limited their daily life activities[2]
**Objectives:** The aim of the study is to detect and describe the incidence of musculoskeletal manifestations, comorbidities and gender differences in renal failure patients on regular hemodialysis
**Methods:** Forty-nine patients with renal failure and on regular dialysis were included in the present study. The patients were subjected to full history taking and clinical examination. Blood samples were collected before the mid-week session for laboratory investigations. The bone mineral density (BMD) was assessed by dual energy X-ray absorptiometry (DXA) in all patients. Kt/V was used as a marker of dialysis adequacy
**Results:** The 49 patients mean age was 54.41±15.9 years. They were 28 males and 21 females. The dialysis duration was 3±2.31 years. Comorbidities were present as diabetes (45%), hypertension (96%), cardiovascular (33%), cerebrovascular stroke (6%), hyperuricemia (37%), hepatitis C (16%) and amyloidosis (8%). The following musculoskeletal findings were present in descending frequency: fibromyalgia syndrome (51%), myalgias (37%), arthralgia (37%), flexor tenosynovitis (29%), cramps (29%), ectopic calcifications (25%), flexion deformity of the elbow (16%), carpal tunnel syndrome (14%), and destructive spondyloarthritis (8%). Vasculitis was present in 2. Positive anti-CCP was present in 1 female and rheumatoid factor in 4 females and 1 male. Otherwise, there was a tendency to a higher frequency of musculoskeletal findings in males. Vitamin D insufficiency (25.1±14.6ng/ml) and reduced bone mineral density were present. The DXA t-score at lumbosacral spine was -1.51±1.77, hip (-1.65±1.59) and forearm (-1.89±1.9).
**Conclusions:** Musculoskeletal manifestations and comorbidities are frequent and overlooked in hemodialysis patients especially males and the associated chronic pain may affect their quality of life.

## AB1050 FACTORS OF WORK DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Janković, J. Zvekic-Svorcan. *Special Hospital for Rheumatology Diseases, Novi Sad, Serbia*

**Background:** Rheumatoid arthritis (RA) is a progressive disease which leads to early work disability.
**Objectives:** To determine the factors of work disability in patients with RA.
**Methods:** The study included 283 patients with RA in the Special Hospital for Rheumatic Diseases Novi Sad in the period of one year. Patients average age was 51.5 years (range 30–68), mean disease duration 11 years (range 2–37 years). All patients were treated with conventional DMARD's and 38% got prednisolone,too. They were determined with disease activity-DAS28, HAQ-DI Health Assessment Questionnaire for Rheumatoid Arthritis and made a X-ray of hands and feet. All patients filled out a questionnaire that included questions related to education, qualifications, type of work, conditions of the workplace, motivisanos to work, distance and way of coming to work, the existence of some of the categories of disability and time of its creation, and the existence of other diseases.
**Results:** After 2 years of the disease, 99% of patients were able to work. After 5 years in 30% was required retraining, 10% had part-time work, while 9% of patients were permanently disabled for work. After 10 years of the disease in 50% of patients was required retraining, 10% had part-time work, while 40% was permanently work disabled. After 15 years, 61% of patients were permanently unable to work. After 23 years there was no working abled patients. The most common cause of work disability 32% was the weight of work that has been associated with a low level of education ($p<0.001$) -without a professional education 50%, 42% high school education, 28% had high disease activity that is correlated with high values of HAQ-DI ($p<0.001$). Poor working conditions as risk factors were present in 17%, the presence of concomitant diseases in 10% (57% cardio vascular diseases), lack of motivation to work in 8%, distance from work in 5%.
**Conclusions:** The lower level of education, heavier physical labor and poor working conditions in patients with high disease activity and low functional ability led to early work disability. Early and aggressive treatment of RA with conventional DMAR and biological medications, also as raising the level of education and the improvement of working conditions can affect the reduction of work disability after years of disease duration.

## AB1051 EPIDEMIOLOGY OF EARLY RHEUMATOID ARTHRITIS: RESULTS FROM AN EARLY ARTHRITIS RESEARCH CENTER FROM ROMANIA

T. Serban[1,2], I. Satulu[1], O. Vutcanu[1], A. Circiumaru[1], M. Milicescu[1,2], C. Mihai[1,2], M. Bojinca[1,2]. *[1]"Dr. I Cantacuzino" Hospital; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*

**Background:** The early phase of rheumatoid arthritis (RA), known as "window of opportunity" was considered to be represented by the first years of evolution, but nowadays this period is considered to be very short and therapeutic intervention at this point is very important for better long-term outcomes (1).
**Objectives:** The aim of this study is to describe the epidemiology of early RA (ERA) in a population of Romanian patients from an Early Arthritis Research Center (EARC).
**Methods:** We have evaluated the data obtained from patients diagnosed with ERA in the EARC of "Dr. I. Cantacuzino" Hospital. Only data form patients who fulfilled EULAR/ACR 2010 criteria for RA (2) and had symptom duration less than 12 months were analyzed.
**Results:** 217 patients were referred to the EARC between 2010 and 2015, among whom only 47 patients fulfilled the EULAR/ACR criteria for RA and had a duration of symptoms for less than 12 months. There was a clear predominance of women (61.7%). The mean age was 55.17±14.62 years and the difference wasn't statistically significant between sexes (p=0.311). 17 patients (36.2%) were smokers and they presented higher values of ACPA but the difference wasn't significant between smokers and non-smokers (p=0.466). The mean duration of symptoms was 3.48±3.32 months and 36 patients (76.59%) had a duration of symptoms less or equal to 3 months which classifies them as very ERA (VERA). Patient positives for RF and ACPA were 87.2% and 82.1%, respectively. The vast majority of patients (74.5%) presented with polyarticular involvement. 68.1% of patients administered treatment with NSAIDs, while 23.4% didn't receive any treatment and no patient was treated with DMARDs previously. Patients with no previous treatment had higher values of disease activity indices than those who had administered NSAIDs, but the difference assessed by Wilcoxon test wasn't significant ($p>0.05$ for all disease activity indices). The median value and interquartile range for lab tests and for disease activity indices are shown in Table 1.

Table 1. Lab tests and disease activity indices results

| Lab test | Median (Interquartile range) |
|---|---|
| CRP (mg/l) | 8.63 (2.63–18.44) |
| ESR (mm/h) | 27 (11–44) |
| RF (IU/ml) | 34.00 (10.08–79.30) |
| ACPA (IU/ml) | 34.50 (5.00–134.77) |
| DAS28 | 4.75 (3.63–5.35) |
| CDAI | 22.80 (14.70–29.55) |
| SDAI | 26.12 (14.94–32.13) |

The level of acute phase reactants didn't correlate with the level of RF or ACPA ($p>0.05$ for each Spearman correlation). CDAI and SDAI identified more patients with high disease activity than DAS28.
**Conclusions:** There are large variations in epidemiologic parameters of different populations with early RA and knowing the particularities of the population treated is important to improve clinical practice. Although the majority of patients presented very early in the course of the disease, they had polyarticular involvement and very active disease. NSAIDs were administered by the majority of patients before the first presentation and this can lead to a decrease in disease activity parameters. This is an ongoing study and we have to see if this results are maintained on larger numbers of patients.

## AB1052 JOINT DAMAGE IN RHEUMATOID ARTHRITIS APPEARS AS SEVERE AS INFLAMMATION IN CONTEMPARY CARE AT ONE SITE, WHICH MAY EXPLAIN IN PART LIMITATIONS TO TREAT-TO-TARGET

T. Pincus[1], I. Castrejon[2], J. Chua[2], J. Block[2]. *[1]Rush University Medical Center, Chicago, United States; [2]Rheumatology, Rush University Medical Center, Chicago, United States*

**Background:** "Treat-to-target" should guide treatment of patients with rheumatoid arthritis (RA), with intensification of therapy if an index indicates moderate/high disease activity. However, low activity or remission are unusual in even 50% of patients. One study suggests a partial explanation, as about 20% of patients with high index scores whose therapy is not intensified had clinically important joint damage[1]. However, a quantitative estimate of the extent of joint damage is not included in quantitaive assessments of patients with RA.
**Objectives:** To analyze quantitative physician estimates on visual analog scales (VAS) for inflammation and damage in routine care of patients with RA for the proportions of clinical management decisions which are attributable to either inflammation and/or damage.
**Methods:** All patients seen at a one academic site complete an MDHAQ/RAPID3 at each visit, and rheumatologists complete a RheuMetric physician checklist, which includes four 0–10 VAS, for overall global estimate, inflammation or reversible disease, damage or irreversible disease, and distress or fibromyalgia, etc., explained by neither inflammation nor damage. Physicians also estimate the proportion of decisions concerning management that is attributable to inflammation, damage, or distress, totaling 100%. Cross-tabulations here were performed to analyze the proportion of clinical decisions attributable to inflammation and/or damage (not including distress), classified as low (<20%), moderate (20–60%), and severe (>60%), using chi square tests for statistical significance.
**Results:** 110 RA patients were studied. Mean age was 56.2 (SD=17.5); 84.4% were female. Mean estimate of the physician VAS for inflammation was 2.3 (SD=2.2) and for damage was 3.1 (SD=2.2). Among the 110 patients, 29 (26%) were estimated to have clinical decisions based on high inflammation, while 39 (35%) were estimated to have high damage (Table). A high level of inflammation and low level of damage was estimated in 19 patients (22% of all patients), while a high level of damage and low level of inflammation was estimated in 27 patients (35% of all patients).

Proportion of clinical decision in 110 RA patients based on inflammation vs damage*

| % Based on damage (total=100%) | % Based on inflammation (total=100%) | | | |
|---|---|---|---|---|
| | Low (<20%) | Moderate (20–60%) | High (>60%) | Total |
| Low (<20%) | 3 (3%) | 0 (0)% | 19 (17%) | 22 (20%) |
| Moderate (20–60%) | 9 (8%) | 37 (34%) | 10 (9%) | 56 (51%) |
| High (>60%) | 27 (25%) | 5 (5%) | 0 (0%) | 32 (29%) |
| Total | 39 (35%) | 42 (38%) | 24 (26%) | 110 |

*All percentages (%) shown are of total of 110 RA patients, $p<0.001$.

**Conclusions:** Damage appears to impact clinical decisions in current treatment of patients with RA as much as inflammation. Structural damage is unlikely to be ameliorated by aggressive medical therapy, and these data may explain in part why clinical trials of established patients indicate only 60% ACR20 responses with all 10 approved biological agents for RA. Moreover, the data may explain in part why fewer patients are in remission than might be expected using a "treat-to-target" strategy. Estimates of inflammation, damage and distress are feasibly completed by rheumatologists in busy clinical settings, and may help clarify and document decisions concerning therapies and outcomes.

## AB1053 THE NATIONWIDE DANISH RHEUMATOLOGIC BIOBANK – PAVING THE ROAD TO PERSONALIZED TREATMENT OF PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

T. Kringelbach, B. Glintborg, J. Johansen, E. Høgdall, M.L. Hetland. *Danish Rheumatologic Biobank and DANBIO registry, Capital Region, Denmark*

**Background:** The medical treatment of inflammatory rheumatic diseases has improved during the last decades. However, many patients experience treatment failure due to lack of effectiveness or serious adverse events. Biomarkers are promising future tools to predict treatment outcome on the patient level (personalized treatment), but these biomarkers still remain to be identified. The newly started nationwide Danish Rheumatologic Biobank (DRB) provides the infrastructure needed to promote research within this field. The protocol "Identification of biomarkers that improve diagnostics, predict treatment responses, adverse events or prognosis among patients with inflammatory rheumatic disease followed in the Danish nationwide DANBIO registry" (approvals: H-2–2014–086 and GLO-2015–6) is the first national study within DRB. DRB is built on the infrastructure of the Danish CancerBiobank [1] and is funded by The Danish Rheumatism Association and the hospital owners (Danish Regions).
**Objectives:** The aim of DRB is to promote the identification of new biomarkers for personalised treatment of patients with inflammatory rheumatic diseases. We here present the first protocol in DRB.
**Methods:** DRB is established through the collaboration between Depts. of Rheumatology and Depts. Clinical Biochemistry at hospitals in all regions of Denmark. Currently, 9 hospitals participate. Patients are included after having signed an informed consent. Blood samples are collected 1) cross-sectionally (i.e. patients provide one blood sample); 2) longitudinally (i.e. patients are enrolled when they start a new disease-modifying anti-rheumatic drug (DMARD, biologic or conventional synthetic) and provide blood samples at 0, 3, 6, 12, 24, 36, 48 and 60 months and at time of treatment withdrawal. Synovial fluid, tissue and urine may also be collected. Samples are collected, handled and stored (at minus $80^0$C) according to nationally approved Standard Operating Procedures (SOPs) and all data regarding the samples are registered in the nationwide database, the Biobank of Danish Regions. Sample-associated high-quality clinical data are registered prospectively in the nationwide quality and research registry, DANBIO, e.g. patient demographics and patient-reported outcomes, previous and current treatment (DMARDs) including reasons for withdrawal, and physician-reported outcomes (clinical characteristics, treatment response, imaging) [2].
**Results:** From May 2015 to January 2016, 840 patients with rheumatoid arthritis (67%), axial spondyloarthritis (22%), psoriatic arthritis (9%) and other diagnoses (2%) had been included in the study, and had contributed 1,239 blood sample packages stored at minus $80^0$C, each including whole blood (1x1.5 ml), buffy coat (1x1.5 ml), EDTA plasma (2x2 ml), serum (4x2 ml) and whole blood in PAXgene RNA tubes (2x2.5 ml).
**Conclusions:** The establishing of DRB has been successful with >1,200 samples collected. Sampling from patients included in the first biomarker protocol continues and the first scientific results are expected in 2016. DRB is unique due to the nationwide and parallel collection of clinical data and biological material from patients with inflammatory rheumatic diseases.

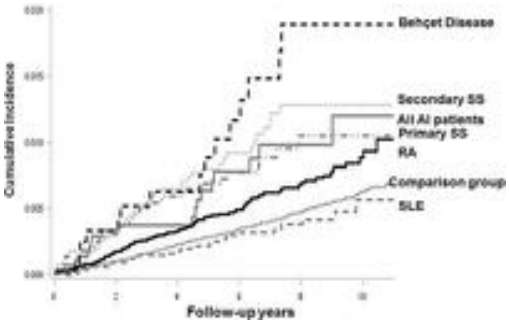
## AB1054 THE BURDEN OF SYSTEMIC LUPUS ERYTHEMATOSUS ON PATIENT'S OCCUPATIONAL ACTIVITIES



V. Sadovici-Bobeica[1], V. Salaru[2], L. Mazur-Nicorici[1], M. Cebanu[1], M. Pasali[1], M. Mazur[1]. *[1]Rheumatology; [2]Family Medicine, State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

**Objectives:** To determine the burden on systemic lupus erythematosus (SLE) on patient's occupational activities
**Methods:** We conducted a cross-sectional study of SLE patients, fulfilling SLICC/ACR 2012 classification criteria. All patients were assessed for disease activity by SLEDAI, damage index by SLICC/ACR DI, general assessments by PGA and MGDA. We collected data on work activity using the Work Productivity Activity Impairment (WPAI) questionnaire for lupus patients. All patients completed the SF-8 questionnaire, estimating physical and mental component summaries (PCS and MCS) of the quality of life (QoL).
**Results:** The study included 102 SLE patients, 94,1% females, mean age ±SD 42,4±13,3 (range 20–73) years, mean disease duration±SD 93,9±77,1 (range 0,1–228) months. A proportion of 34,3% of the patients had high university education. The employment history in our cohort included: 23,5% of subjects were working full time and 3,9% part time. Meantime, 58,8% of patients had disability for SLE and 6,9% - disability for other disease than SLE; 3,9% of the subjects were studying and 2% were not employed at the moment of the questionning. The results of WPAI questionnaire confirmed a dicrease of all work domains, by absenteism (10%) and presenteism (63.4%). To be noticed that 20 from 28 working subjects were missing from their work during last 12 months during 15,3 days (range 5–40 days) for SLE problems. The analysis of the QoL showed a dicrease of both components, PCS and MCS were 43,2±9,6 and 46,9±13,4 points, respectively. According to the results, the level of the QoL and the disease activity were predictors for impaired work productivity ($R^2$=0.21 and $R^2$=0.5, $p<0.05$).
**Conclusions:** Systemic lupus erythematosus had a substantial burden on patient's occupational activities, high disease activity and low indices of the quality of life were predictors for impaired work productivity.

## AB1055 THE RISK OF OBSTRUCTIVE SLEEP APNEA IN 52994 PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES IN TAIWAN: A NATIONWIDE POPULATION-BASED STUDY

W.-S. Chen. *Rheumatology, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China*

**Background:** Several pathological mechanisiums may underlies an association between sleep apnea and autoimmune diseases. There are few evidances of increasing risk of OSA in patients with rheumatoid arthritis, ankylosing spondylitis. The risk of OSA in RA or Sjogren syndrome (SS)was thought to be attributed to upper airway dryness with a resulting in a colappsibility or temporomandibular joint involvement (1,2). The association between asystemic autoimmune disease nd obstructive sleep apnea were not clear in Asian. We hypothesized that autoimmune diseases would predispose patients to the occurance of OSA.
**Objectives:** To explore the association between the obstructive sleep apnea (OSA) and autoimmune diseases
**Methods:** 52994 adult patients with systemic autoimmune diseases diagnoses recorded in the Taiwan National Health Insurance Research Database between 2002 and 2011, after excluding those with antecedent obstructive sleep apnea. A comparison cohort of 211976 participants was formed by age-, gender-matched controls. Multivariable Cox regression was performed on the two cohorts to compute the risk of OSA during follow-up period.
**Results:** In patients with systemic autoimmune diseases, the overall risk for incident OSA was significantly higher than in controls (adjusted hazard ratio [HR] =1.58, 95% confidence interval [CI] =1.38–1.82). Risk of OSA in individual autoimmune diseases, including rheumatoid arthritis (RA), Sjögren's syndrome (SS) and Behçet disease, was also significantly higher than in controls (HR [95% CI] for RA, primary SS, secondary SS and Behçet disease were 1.36 [1.12–1.63], 2.28 [1.68–3.10], 2.88 [2.14–3.87] and 2.39 [1.43–4.01], respectively). Increased risk for systemic lupus erythematosus did not reach statistical significance (HR: 0.79 [0.49–1.28]).

**Conclusions:** Patients with systemic autoimmune diseases including of RA, primary or secondary SS and Behçet disease were associated with a higher risk for developing OSA.

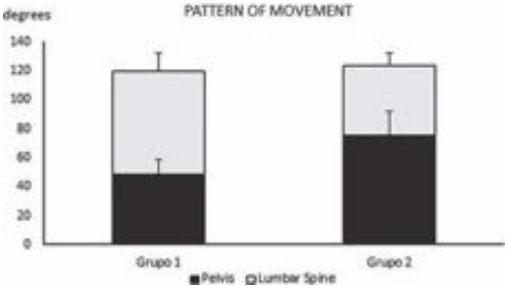
AB1056 **PSYCHOMETRIC TESTING OF THE DUTCH EVALUATION OF DAILY ACTIVITIES QUESTIONNAIRE IN RHEUMATOID ARTHRITIS**

A. Hammond[1], J. Meesters[2], T. Vliet Vlieland[3], A. Peeters[4], A. Tennant[5], S. Tyson[6], U. Nordenskiold[7], Y. Prior[1]. *[1]Centre for Health Sciences Research, University of Salford, Salford, United Kingdom; [2]Physical Therapy; [3]Rheumatology, Leiden University Medical Centre, Leiden; [4]Rheumatology, Reinier de Graaf Hospital, Delft, Netherlands; [5]Swiss Paraplegic Research, Notwil, Switzerland; [6]School of Nursing, Midwifery & Social Work, University of Manchester, Manchester, United Kingdom; [7]Department of Clinical Neuroscience and Rehabilitation, University of Gothenburg, Gothenburg, Sweden*



**Background:** The Evaluation of Daily Activity Questionnaire (EDAQ) is a patient reported measure of activity limitations in Rheumatoid Arthritis (RA) and other musculoskeletal conditions, for which there is a Swedish (1) and an updated English version (2–4). The English version was translated into Dutch, and linguistically validated, with phrasing changes made following cognitive debriefing interviews with six Dutch people with RA. The Dutch EDAQ includes 138 items in 14 "domains" (Eating/ Drinking; Personal Care; Dressing; Bathing; Cooking; Moving Indoors; House Cleaning; Laundry; Moving and Transfers; Moving Outdoors; Gardening/Household Maintenance; Caring; and Leisure/ Social Activities). Each domain is split into two sections: one (A) scores whether activities can be performed without aids, alternate methods or help; and another (B) which scores whether the activities can be performed with aids or alternate methods. All items are scored on a 0–3 scale (no difficulty to unable to do).
**Objectives:** To test the reliability and validity of the Dutch version of the EDAQ in people with RA in the Netherlands.
**Methods:** Participants from an out-patient Rheumatology clinic (Reinier de Graaf Hospital, Delft) completed postal questionnaires of demographic questions, the EDAQ, HAQ, SF36v2, RAQOL, a hand pain numeric rating scale (NRS) and a current condition severity scale. Three weeks later, the EDAQ was mailed again. Test-retest reliability of domain scores was evaluated using nonparametric correlations. Internal consistency was tested using Cronbach's alpha. Validity of the 14 domains of the EDAQ against the other measures was assessed with non-parametric correlations.
**Results:** 252 people participated: 155 women and 93 men; age =65.16 (SD 13.45) years; RA duration =11.75 years (SD 9.93). 68 (27%) were employed; 20 had children <18y at home. Average pain score =3 (IQR 1–6) and fatigue =4 (IQR 2–7).
155 (62%) completed Test 2 and test-retest reliability of total domain scores was excellent for nine domains ($r_s$=0.81 -0.88) and moderate-substantial for five ($r_s$=0.56–0.78). Internal consistency was high in all domains: Cronbach's alpha=0.79–0.92 for Section A.
All domains of the EDAQ correlated significantly ($p<0.001$) with: HAQ $r_s$=0.51-0.88; SF36v2 (Physical Function) $r_s$= -0.55 to -0.87; SF36v2 Bodily Pain $r_s$=0.44–0.67; SF36v2 (Vitality) $r_s$= -0.35 to -0.62; RAQOL $r_s$=0.50–0.83; and hand pain $r_s$=0.46–0.64. An exception was the "Caring" domain as many did not have childcare responsibilities, and thus validity was lower compared to the above variables, although still significant ($p<0.01$; $r_s$=0.16 to 0.31).
**Conclusions:** The Dutch version of the EDAQ is a valid and reliable measure of daily activity in people with RA. It can be used in both clinical practice and research.

## Rehabilitation

AB1057 **RISK FACTORS ASSOCIATED WITH DIFFERENT LUMBOPELVIC PATTERNS OF MOVEMENT**

M. Sarti[1], D. Ybáñez-García[2], M.Á. Fuster-Ortí[3], L.J. Villaplana-Sarti[1], R. Expositor-Rodríguez[4], C. Barrios[5]. *[1]Human Anatomy and Embryology; [2]Rheumatology; [3]Statistics and Operational Research, Universidad de Valencia (UVEG); [4]Institute of Research of Musculoskeletal Disorders; [5]Institute of Research of Musculoskeletal Disorders, Universidad Católica de Valencia (UCV), Valencia, Spain*

**Background:** Rapid flexion movement increases the loading on the spine and it increases the risk of injuries[1]. In asymptomatic subjects lumbar-dominant and pelvis-dominant patterns of movement during trunk flexion have been observed[2,3]. However, little information about lumbar spine kinematics has been provided.
**Objectives:** To find out whether exhibiting different lumbopelvic patterns of movement during trunk flexion affects the kinematics of the lumbar spine in terms of velocity of motion.
**Methods:** Differential lumbar spine and pelvis angular displacement during the time course of a standardised sagittal trunk flexion from an upright position was recorded with an electromagnetic tracking device in 32 asymptomatic females (22.65±3.5 years). Range of motion (ROM) (degrees) for the lumbar spine, pelvis and average angular velocity (degrees/sec) for the entire movement were calculated. Subjects were divided into groups according to moving more in the lumbar spine than in pelvis, group1 (n=17) and vice-versa moving more in the pelvis (at the hip joint) than in lumbar spine, group2 (n=15). The one-way MANOVA followed by F test showed significant differences in lumbar spine velocity between groups.
**Results:** The lumbopelvic pattern of movement is shown for both groups in the figure. Average angular velocity (degrees/sec) for the spine was significantly ($p<0.01$) greater in group 1 (18.7±3.8) than in 2 (13.1±2.4).

**Conclusions:** Changes in the lumbopelvic pattern of movement bring about differences in lumbar spine velocity of motion. Consequently, the risk of injury for the spine may be different for both groups and clinical implications may be different as well.

AB1058 **THE NEW JOINT WEIGHTED SCORING SYSTEM WHICH PREDICTS THE MODIFIED HEALTH ASSESSMENT QUESTIONNAIRES SCORES IN RHEUMATOID ARTHRITIS PATIENTS: A VALIDATION STUDY USING THE NATIONAL DATABASE OF RHEUMATIC DISEASES BY IR-NET IN JAPAN**

K. Ono[1], S. Ohashi[2], H. Oka[3], Y. Kadono[1], Y. Omata[1], T. Matsumoto[1], N. Izawa[1], J. Nishino[1], S. Tanaka[1], S. Tohma[4]. *[1]Orthopaedic Surgery, the University of Tokyo Hospital, Tokyo; [2]Orthopaedic Surgery, Sagamihara Hospital, National Hospital Organization, Kanagawa; [3]Department of medical research and management for musculoskeltal pain, 22nd Century medical & research center, faculty of medicine, university of Tokyo, Tokyo; [4]Clinical research center for allergy and rhematology, Sagamihara Hospital, National Hospital Organization, Kanagawa, Japan*

**Background:** We reported the impact of each joint disease on the MHAQ (Modified Health Questionnaire) by using 2011 NinJa (the National Database of Rheumatic Diseases by iR-net in Japan) data in the past study. The odds ratio of physical impairment according to the MHAQ using multivariable logistic regression models for bilateral and unilateral joints, respectively, were: shoulder, 4.0 and 1.8; elbow, 2.6 and 1.8; wrist, 1.9 and 1.5; hip, 1.7 and 3.0; knee, 2.6 and 1.9; ankle, 2.3 and 2.0; finger, 1.4 and 1.2; and toe, 1.0 and 1.1. The MHAQ score was significantly affected by shoulder, elbow, wrist, knee, and ankle joint disease, and bilateral disease tended to have a greater effect on physical impairment than unilateral disease. We also developed a joint weighted scoring system from the results of the odds ratio. An integer score was assigned to each identified bilateral and unilateral joint disease, respectively, as follows: shoulder, 4 and 2; elbow, 3 and 2; wrist, 2 and 2; hip, 0 and 3; knee, 3 and 2; ankle, 2 and 2; finger, 1 and 1. We acquired 3 points as the cut-off value of this scoring system through statistical analysis (Modern Rheumatology, 2015, Epub ahead of print).
**Objectives:** To validate this scoring system by applying to NinJa in 2014.
**Methods:** A total of 13,459 subjects (2,586 men, 10,873 female) from NinJa in 2014 were analyzed. The presence or absence of disease in each joint (swelling and/or tenderness were considered as disease) and whether the disease was unilateral or bilateral were investigated. ROC curve analysis was performed to each patient with total score calculated according to the scoring system.
**Results:** The patients' mean age and disease duration was 64.1 and 13.0 years, respectively. The Disease Activity Score-28CRP was 2.4. ROC analysis'

results were as follows: cut-off value, 3 points; AUC, 0.68; sensitivity, 53.4%; and specificity, 75.0%.
**Conclusions:** This joint weighted scoring system was validated and suggested to be useful to predict of functional disability of RA patients in a daily practice.
**Disclosure of Interest:** None declared

## AB1059 CLINICAL AND ELECTROPHYSIOLOGICAL EVALUATION OF THE EFFECTIVENESS OF LOCAL INSULIN INJECTION IN MANAGEMENT OF IDIOPATHIC CARPAL TUNNEL SYNDROME (PROSPECTIVE STUDY)

M.H. Abu-Zaid[1], S. Eid[1], N. Elgazzar[1], H. Murad[2], S. Khodeir[3]. *[1]Rheumatology & Rehabilitation; [2]Clinical Pathology; [3]Internal Medicine, Faculty of Medicine Tanta University, Tanta, Egypt*

**Background:** Carpal tunnel syndrome (CTS) is the most common type of peripheral nerves entrapment; It has a great socioeconomic impact. CTS may be idiopathic or secondary to many causes, especially diabetes mellitus. Insulin has anti-inflammatory effects[1] and the effectiveness of local insulin Injection in diabetic patients with CTS has been previously evaluated [2]. Local insulin Injection in idiopathic CTS has not been studied.
**Objectives:** To evaluate the effectiveness of local insulin injection as a therapeutic tool in management of idiopathic CTS.
**Methods:** Twenty eight consecutive hands of mild & moderate idiopathic CTS (diagnosed clinically & electrophysiologically and classified according to American association of neuromuscular diagnostic medicine monograph) received two local injections of 10 IU NPH insulin into the affected carpal tunnel 2 weeks intervals after informed consent. Patients with severe or secondary type of CTS were excluded from this study. Evaluation of the patients at baseline, then at 1 & 3 months after 2nd insulin injection was done clinically [by measuring visual analogue scale (VAS), paraesthesia, Phallen and compression tests] and electrophysiologically (by measuring motor and sensory nerve conduction studies of the median and ulnar nerves using a standardized technique).
**Results:** Clinically; there was statistically significant improvement in VAS, paraesthesis, Phallen and compression tests at 1 & 3 months after 2nd insulin injection ($p<0.01$). Electrophysiologically; there was statistically significant improvement in distal motor latency (DML) and distal sensory velocity of median nerve 1 and 3 months after treatment ($p<0.01$), but the improvement was not statistically significant as regards median distal motor and sensory amplitudes ($p>0.05$).

| | Before injection | 1 month after injection | 3 months after injection |
|---|---|---|---|
| VAS | 7.57±0.95 | 4.678±1.41 | 3.285± 2.07 |
| Paraesthesia | 100% | 39.2%, | 25% |
| Positive Phallen test | 100% | 53.5% | 28.6% |
| Positive Compression test | 92.8% | 60.7% | 32.1% |
| DML | 4.52±0.83 msec | 4.25±0.38 msec | 4.15±0.47 msec |
| Distal median sensory velocity | 34.41±4.89m/s | 36.76±4.96m/s | 39.01±3.41m/s |
| Median distal motor amplitude | 3.756±0.96 mv | 3.603±1.046 mv | 3.626±0.91 mv |
| Median distal sensory amplitude | 12.56+7.19 μv | 14.62+7.185 μv | 15.93+7.21 μv |

**Conclusions:** Local insulin injection is a promising effective treatment for idiopathic CTS. This is the first study to detect the effect of local insulin injection in idiopathic CTS.

## AB1060 QUADRICEPS MUSCLE ENDURANCE IN KNEE OSTEOARTHRITIS

P. McNair, J. Molloy. *Health and Rehabilitation Research Institute, Auckland University of Technology, Auckland, New Zealand*

**Background:** Current rehabilitation programs place a significant emphasis on strength training, with minimal attention paid to specifically developing muscle endurance. Yet resistance to fatigue may be of importance, as the successful performance of many functional activities requires individuals to sustain muscle activity over long periods. To date, there has been limited research into the fatigue characteristics of the quadriceps in those with OA and findings are contrasting.
**Objectives:** The objective of this study was to investigate differences in the fatigue resistance of the vastus medialis quadriceps muscle of subjects with and without knee joint osteoarthritis. Endurance characteristics were investigated during a sub-maximal (50%) isometric contraction with a high-spatial resolution surface electromyography technique.
**Methods:** Twenty-six subjects with unilateral knee osteoarthritis, and seventeen subjects with no known knee pathology were evaluated. All subjects performed initial tests to evaluate maximum voluntary contraction (MVC), voluntary activation levels, and true maximum force (TMF). Endurance time was assessed during an isometric quadriceps contraction at 50% of the true maximum force with the knee at 90 degrees flexion while sitting. Surface electromyography (sEMG) data was collected from the vastus medialis muscle of the quadriceps group during the endurance test with a Laplacian high spatial resolution electrode. The variables of interest were median frequency (MDF); mean power frequency (MPF); root mean square (RMS); muscle fibre conduction velocity (CV); the relative slopes of each sEMG parameter calculated over the initial thirty seconds ($T_{30}$), and the percentage change in each parameter over the entire endurance test.
**Results:** MVC tests showed that the affected leg of the group with osteoarthritis was significantly weaker ($p<0.05$) than the unaffected leg. Voluntary activation data showed that subjects with osteoarthritis presented with significant bilateral deficits ($p<0.05$). TMF data showed a significantly lower ($p<0.05$) true potential for force generation in the affected compared to the unaffected leg of the osteoarthritis group.
No significant differences were observed between the endurance times of the groups: affected legs mean: 83 sec, SD: 31; unaffected legs mean: 79 sec, SD: 33; control legs 67s, SD: 23. Irrespective of group, all parameters were significantly different at the beginning of the contraction compared to the end of the test. MDF, MPF and CV decreased with time, while RMS increased with time. In comparison to the unaffected leg, the affected leg showed significantly lower ($p<0.05$) initial values for MDF, MPF and CV. No significant differences were seen between the initial values of the unaffected legs and controls. From initial to end values, across groups, a significant difference ($p<0.05$) was detected in the conduction velocity between the affected (-14.3%) and un-affected (-28.3%) legs of the group with osteoarthritis.
**Conclusions:** The endurance times and the behaviour of the EMG signals indicate an improvement in the relative fatigue resistance of the affected leg in relation to the unaffected leg of the group with knee osteoarthritis. Such findings are consistent with other literature showing increased resistance to fatigue during isometric contractions in muscles with low proportions of type-2 muscle fibres, as well as studies indicating improved relative fatigue resistance following knee injury.

## AB1061 IS CERAMIC ART USEFUL IN TREATMENT OF RHEUMATOID ARTHRITIS?

R. Tanaka, T. Tsuchida. *Tsuchida Clinic, Chiba Institute of Rheumatic Disease, Chiba, Japan*

**Background:** A published study demonstrating that listening to Rakugo (a comic story) alleviated the pain experienced by patients with rheumatoid arthritis (RA), accompanied by reduction in serum IL-6 and cortisol levels [1]. Overall physical condition improvement and pain alleviation with music therapy have also been reported [2]. However, only few studies have assessed the efficacy of occupational therapy (particularly handcraft work) in outpatients with RA.
**Objectives:** The present study evaluated the usefulness of handcraft work (particularly ceramic art) for both physical and mental rehabilitation for outpatients with RA.
**Methods:** The study involved 10 outpatients with RA managed at our hospital (all females, all right-handed persons, mean age 63.1 years, the average duration of disease was 10.7 years). For physical and mental evaluation, grip, pinching power, VAS score for systemic pain, 20-level FACE scale score, self-rating depression scale (SDS) score were measured before and after participation in ceramic art craft and compared. In addition, a questionnaire survey was administered to assess patient perception of ceramic art.
**Results:** The range of annual changes among the participants was 0.4±0.3 for Modified Health Assessment Questionnaire (m-HAQ) and 0.9±1.6 for C-reactive protein (CRP).
Right hand grip was 14.3±7.2 kgw before participation and 14.8 ±7.1 after participation in ceramic art craft. Left hand grip was 12.1±7.1 and 13.4±7.1 before and after participation, respectively.
Right pinching power was 8.2±4.1 and 10.8±4.0 and left pinching power was 8.7±4.0 and 10.8±3.8 before and after participation, respectively.
VAS score for systemic pain was 38.0±29.2 and 22.4±21.5, and FACE scale scores was 4.7±3.6 and 2.9±3.3 before and after participation, respectively.
SDS score was 41.2±11.8 and 37.1±9.4 before and after participation, respectively.
Thus, all parameters except right hand grip and left pinching power differed significantly between the pre-participation and post-participation periods.
In the questionnaire survey, many patients answered “having pleasure/joy in creation and use of ceramic products.” This indicates that ceramic art can serve as a continued activity for patients with RA, useful not only during treatment but also during daily living. In addition, ceramic art was shown to be useful in

functional training, e.g., in “maintaining and reinforcing grip and finger function” and “maintaining and checking skilled movements.” These results suggest that ceramic art is an activity effective as a means of rehabilitation, with both physical and mental effects perceptible to the patients.

**Figure:** Change in before and after the implementatrion of ceramic art therapy

**Conclusions:** Ceramic art is an activity capable of improving the physical condition and mental state (alleviation of depression, etc.) of patients with RA and improving physical functions such as grip of opposite hand and dominant pinching power. It is useful in the treatment of RA, similar to listening to Rakugo and music therapy.

## AB1062 INVESTIGATION OF INTERACTION BETWEEN HAND DEXTERITY AND PARENTAL ATTITUDE IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

U. Berberoğlu[1], E. Ünal[1], P. Dizmek[1], G. Arın[1], Y. Bilginer[2], E.D. Batu[2], Z.S. Arıcı[2], H.E. Sönmez[2], S. Özen[2]. *[1]Physical Therapy and Rehabilitation; [2]Hacettepe University, Ankara, Turkey*

**Background:** There was a gap in the literature about the reason of high prevalence of hand- and wrist-related symptoms in children with juvenile idiopathic arthritis (1).

**Objectives:** This study was planned for investigate hand dexterity and the relationship between children’s hand dexterity and parental attitude in children with Juvenil Idiopathic Arthritis (JIA).

**Methods:** 34 children with JIA (according to International League Aganist Rheumatism (ILAR) Classification) and 38 healthy children that matched according to age, sex and hand dominance. 9 Hole Peg Test (9PHT) and Functional Dexterity Test (FDT) were used to evaluate hand dexterity for both groups (2,3). Childhood Health Assessment Questionnaire (CHAQ) was applied for assessing daily living activities (4). Beck Depression Inventory (BDI), Beck Anxiety Inventory (BAI) and State and Trait Anxiety Inventory (STAI) were applied to investigate parental attitude.

**Results:** There was no difference between hand dexterity values of two groups ($p>0.05$). There was no relationship between Hand Dexterity Scores and CHAQ, BDI, BAI, STAI.

**Conclusions:** Consequently, the result of the tests we used have shown that hand dexterity was not affected by parental attitude.

## AB1063 A SURVEY OF MUSCULOSKELETAL ULTRASOUND (MSUS) TRAINING AMONGST RHEUMATOLOGISTS AND TRAINEES ACROSS WALES

F. Sheikh[1], E. Humphreys[2], V. Lim[3], E. Choy[1], S. Chitale[4]. *[1]Rheumatology Department, University Hospital of Wales, Cardiff; [2]Rheumatology Department, Prince Charles Hospital, Merthyr Tydfil; [3]Rheumatology Department, Wrexham Maelor Hospital, Wrexham; [4]Peter Maddison Rheumatology Centre, Llandudno General Hospital, Llandudno, United Kingdom*

**Background:** Although MSUS is routinely used in rheumatology practice, expertise in performing MSUS and training opportunities vary considerably across UK and Europe. [1, 2, 3] There is a growing consensus to include MSUS in the UK Rheumatology curriculum. The All Wales Rheumatology Ultrasound group (AWRUG) conducted a preliminary survey of rheumatologists across Wales in 2013 and based on this survey, developed a modular MSUS training programme to improve training facilities and access to mentorship.[4] In August 2015, AWRUG re-surveyed rheumatologists across Wales, seeking their feedback and views on MSUS training. This 2 year follow on survey depicts the current state of Rheumatology MSUS training and expertise in Wales.

**Objectives:** 1. To ascertain the level of MSUS expertise and interest following the modular MSUS training programme.

2. To ascertain the opinion of rheumatology consultants and trainees as to whether MSUS training should be part of the Rheumatology curriculum in the UK.

**Methods:** An online survey link was sent to all rheumatologists in Wales by email in August 2015, asking for their feedback on the AWRUG delivered MSUS training and about their expertise in MSUS.

**Results:** Out of 32 respondents including 9 trainees and 21 consultants, 14 (44%) had access to US mentorship and training facilities. 11 (34%) respondents had no MSUS training and 2 (6%) were expert/ trainers. 13 (41%) could identify synovitis/ erosions on MSUS. 18 (56%) attended an AWRUG MSUS masterclass (with 11 finding it useful and 7 very useful). 17 (53%) were using MSUS routinely in their clinical practice, mostly requesting scans for synovitis or shoulder pathology.

27 (85%) felt that MSUS should be included in the rheumatology curriculum; however 3 (33%) trainees and 2 (9%) consultants felt that it should not be included. 13 (41%) felt that theoretical knowledge of MSUS plus scanning for synovitis should be mandatory. Regarding service provision, 20 (62%) felt that Routine MSUS should be provided by radiology department whereas 11 (34%) felt that rheumatologists should also offer this. Most respondents felt that MSUS for synovitis should be provided by rheumatologists wholly 9 (28%) or in collaboration with radiology 15 (47%).

**Conclusions:** 1. All respondents who attended the AWRUG Masterclasses, found them useful, confirming the need for an ongoing regional training programme.

2. Most rheumatology consultants and two thirds of rheumatology trainees in Wales feel that MSUS training should be included in the rheumatology curriculum.

## AB1064 EVALUATION OF SAFETY SKILLS OF BIOTHERAPIES IN TUNISIA

I. Henchiri, K. Ben Abdelghani, A. Fazaa, S. Kassab, A. Laatar, L. Zakraoui. *rhumatology, mongi slim hospital, Tunis, Tunisia*

**Background:** Biotherapies have become common practice in Tunisia, however, they present specific risks that patients must know and learn to manage. So far, patients’ security skills have not been studied in our country.

**Objectives:** The present work aims to assess the skills level of patients using biotherapies, in order to improve them.

**Methods:** Patients with chronic arthritis were recuited. we have established a questionnaire with practical situations in which the patient is confronted, based on the biosecure questionnaire. the main items were the leading symptoms to consult, vaccination, contraception, and situations excluding biotherapy.

**Results:** Thirty nine patients were recuited for the study, 77% with SA and 23% with RA. The mean age was 52, and 54% were female. 48% of patients have high education level. Etanercep was used in 15 cases, adalimumab in 12 cases, infleximab in 9 cases and one patient used tocilizumab. The mean duration of biotherapy was four years. 38% were in clinical remission. 69% had already

received therapeutic education session about security of biotherapy use, by a doctor in 77% of cases. The median score of the questionnaire was 71,4% (58,8–100%). skills on symptoms must lead to consult and contraception are the least mastered.

**Conclusions:** This work showed that all patients didn't master all situations concerning biotherpy. However, it is important for patients to have a basic control, to minimize the incidence of severe and avoidable side effects such as severe infections.

**Disclosure of Interest:** None declared

## AB1065 DEVELOPMENT OF THE FIRST SKILL FRAMEWORK IN JUVENILE IDIOPATHIC ARTHRITIS

J.-D. Cohen[1], A. Belot[2], W. Fahy[3], P. Quartier[4], C. Sordet[5], S. Trope[6]. *[1]Rheumatology, Lapeyronie Hospital, Montpellier; [2]Herriot Hospital, Lyon; [3]KOURIR; [4]Necker Hospital, Paris; [5]HautePierre Hospital, Strasbourg; [6]ANDAR, Paris, France*

**Background:** In the " list of healthcare treatments and interventions-JIA " of 2009, HAS recalls that " therapeutic education must ensure involvement of the patient and his parents: understandability of the disease, mastering of the technical skills, and adaptation of the lifestyle. The main aim of the ETP of the child, the adolescent, and his relatives is to take care of and prevent complications and to learn the skills involved in care. "

**Objectives:** In this context, we have decided to develop a framework of the necessary skills needed for children suffering from JIA (REAJI) in order to improve their quality of life (knowledge, know-how, know-how-to-be).

**Methods:** The steering committee is composed of health professionals involved in paediatric rheumatology and patients' associations.

Different stages are scheduled:

1. Literature review
2. Setup of four focus groups (FG) with different facilitation methods: 2 patient FGs (8–12 year olds and adolescents), 1 parent FG, 1 health professional (HP)
3. Analysis by the steering committee et production of a first skills list.
4. Submission of the list to a panel of patients and to the national JIA competence centres for further information.
5. Submission of the completed list to the same participants for ranking (primary and secondary objectives).
6. Validation of the final list by the committee.

**Results:** The steering committee is made up of two rheumatologists, two paediatricians, and two patients associations, ANDAR (association of patients suffering from RA) and KOURIR (association of parents whose children suffer from JIA).

The press review highlights a number of works, mainly on adolescents and outside the French territory.

The HP FG is composed of 1 rehabilitation doctor, 1 rheumatologist, 1 paediatrician, 1 psychologist, 1 occupational therapist, 1 nurse and 1 pain nurse. The parent FG is composed of 10 people (6 mothers, 1 aunt, 3 fathers).

The 8–12 year olds FG had 3 children and the adolescents FG 4 teenagers.

The committee gathers to establish the initial skills list and then proposes to complete it via an online questionnaire to a selection of HPs from the 38 French centres listed by the Francophone Society of Rheumatology And Internal Paediatric Medicine (SOFREMIP) and an equal number of patients/ parents.

This expanded list is sent back to participants using the same method in order to rank it and lastly to be validated in its final version by the committee.

**Conclusions:** The collectively-developed REAJI framework is a consensus-based support tool that anyone will be able to call upon: not only individual families but in particular teams working on educational projects. This mutidisciplinary participative, national effort is an example of health democracy, the results of which will be made available to all.

## AB1066 ASSESSING AWARENESS OF THE EFFECTS OF SMOKING IN A RHEUMATOLOGICAL OUTPATIENT SETTING

J. Maundrell, S. Dubey. *Rheumatology, University Hospital Coventry and Warwickshire, Coventry, United Kingdom*

**Background:** Tobacco smoking is an important modifiable environmental risk factor in the development and disease activity of autoimmune rheumatic disease including rheumatoid arthritis (RA), systemic lupus erythematous, systemic sclerosis and antiphospholipid syndrome. In RA the risk is two-fold in ever vs never smokers[1], appears to be dose related[2] and correlated to severe extra-articular disease[3]. Response to disease-modifying antirheumatic drugs and tumour necrosis factor inhibitors is also decreased in smokers[4].

**Objectives:** This pilot study is to assess awareness of the negative impact of smoking on rheumatic disease and establish the methods by which previous smokers achieved long-term abstinence.

**Methods:** 100 patients (median age 55 years) in a rheumatology outpatient setting were asked to complete a questionnaire relating to smoking history. Surveys were distributed over a two month period. Rheumatological diagnosis, comprehensive smoking history and awareness of the negative impact of smoking on rheumatic disease was established. Ever-smokers (those having smoked >100 cigarettes or equivalent over their lifetime) were specifically questioned whether they had received information regarding smoking and rheumatological disease burden, or cessation advice directly from healthcare professionals. Methods to achieve smoking abstinence was also established.

**Results:** 34/49 individuals completing the questionnaire met inclusion criteria. 17/34 (50%) identified themselves as current or former smokers and of this population only 8/17 (47%) were aware of the negative association of smoking and rheumatological disease. All current smokers said they would like to stop, with the majority 4/7 (57%) stating health reasons as the impetus to do this. Of ever-smokers 7/17 (41%) had received cessation advice from a healthcare professional, 3/17 (18%) stated this was from a rheumatologist. The majority of former smokers 8/10 (80%) abstained without pharmaco- or behavioural therapies and 9/10 (90%) felt they would be unlikely or very unlikely to restart. Of current smokers 3/7 (43%) had previously tried to stop, 2/7 (29%) had attempted on 10 or more occasions using 3 or more therapies. Only e-cigarettes were deemed a beneficial adjuvant in smoking cessation.

**Conclusions:** This survey highlights the need for enhanced patient education regarding the risks of smoking in rheumatalogical disease.

## AB1067 QUANTITY AND QUALITY OF FEEDBACK ON CLERKING OBTAINED BY 4TH YEAR MANCHESTER MEDICAL STUDENTS DURING RHEUMATOLOGY AND ORTHOPAEDICS

K. Lazarewicz, J. Oldbury, P. Watson. *Department of Rheumatology, University Hospital of South Manchester, Manchester, M23 9LT, United Kingdom*

**Background:** Feedback is the cornerstone of effective clinical teaching [1] allowing students to improve by reinforcing good practice and improving poor practice. The ability to take a clinical history is a key skill required to practise effectively as a doctor. The four week Rheumatology and Orthopaedic placement for the University of Manchester medical students requires them to take a minimum of 12 case histories, at least four of which must be presented to clinicians to obtain feedback.

**Objectives:** To review quantity and quality of feedback on clerking obtained by 4th year Manchester Medical students as a part of Rheumatology and Orthopaedic placement.

**Methods:** A questionnaire survey of 4th year medical students studying Rheumatology and Orthopaedics at the University Hospital of South Manchester was performed to review clinical history taking and feedback during this module. It consisted of 13 questions designed around the four levels of training evaluation described by Kirkpatrick's evaluation framework [2]. It was given to three cohorts of students on the day that they completed their Rheumatology and Orthopaedics block.

**Results:** 43/64 (67.2%) of students responded to the questionnaire, of which 21 students (48.8%) either agreed or strongly agreed that it was easy to find patients from whom to take clinical histories during the placement. However, 18.6% of students reported not achieving the minimum of 12 case histories required. 32.6% of students agreed that it was easy to identify staff from which feedback could be sought, and 44.2% received feedback for at least four clinical histories. The majority of the students (81.4%) agreed that feedback was useful. The content of the feedback that was evaluated in the first two cohorts of students varied greatly, with very few students received feedback covering positive and negative comments as well as ways to improve (Orthopaedics 19.2%; Rheumatology 31.7%). Feedback varied in length of time with 58.1%taking less than five minutes, 25.6% lasting 5–10 minutes and 11.6% lasting 11–15 minutes.

**Conclusions:** Our survey demonstrates that there are some issues with the current system for facilitating student history taking, and obtaining feedback on this. The vast majority of feedback received is perceived as useful. Over half of students are not achieving the amount of feedback that they should receive, hence students are potentially missing out on an important opportunity to improve their clinical performance. Considering the results of this survey the authors plan to develop an intervention to try to increase the quality and quantity of feedback given, similar to the feedback postcard project being piloted in Edinburgh [3],

which seems on track to improve both the quality and quantity of feedback during clinical placements.

## AB1068 SPECIFIC DIET FOR GOUT - CAN GENERAL PRACTICIONER EDUCATE THEIR PATIENTS?

M.S. Panchovska[1], N.G. Nikolov[2], L.R. Despotova-Toleva[3]. *[1]Departement of Internal Medicine, Medical University-Plovdiv, Plovdiv; [2]Departement of Internal Medicine, Medical University-Pleven, Pleven; [3]Departement of Health Management, Medical University-Plovdiv, Plovdiv, Bulgaria*

**Background:** Gout is a chronic disease that occurs with joint crises. Almost 50% of patients with gout are treated by general practitioners (GPs). Nonpharmacological treatment - proper diet and lifestyle, are held parallel with medication throughout life (1).
**Objectives:** The aim of the study was to analyze the training of GPs on gout diet and the opportunities for educating patients with gout in general practice.
**Methods:** A direct anonymous questionnaire among 37 GPs was performed. Seven (7) close questions with possible answers "yes" or "no" were included. Collected data were processed by alternative analysis.
**Results and discussion:** Unfavorable relationship between alcohol (beer, spirits, wine) noted 37 of all 37 respondents (100%). Regarding the increased intake of coffee and the worsening of gout information had 19 of the 37 GPs (51.35%). Nine of 37 respondents (2.43%) believe that black tea has unfavorable effect on gout. Traditionally recommended milk and yoghurt in gout noted as useful 33 of 37 (85.19%) of GPs. About the relationship between low-fat yogurt and worsening the in serum levels of uric acid 7 of 37 respondents (18.92%) are informed. Eleven (11) of 37 GPs (29,73%) are aware on the positive effect of vit.C supplementation on the relative frequency of joint crisis, as well as 5 of 35 (13,51%) noted the beneficial effects of vitamin D supplementation in gout.
Regularly updated recommendations and guidelines for patients with gout are very helpful in their everyday life (2). New data about this disease known since the time of Hippocrates, are accumulated in recent years especially on gout diet (3,4).
**Conclusions:** Good medical practice requires constant upgrading of knowledge. The survey data has shown need to extend education programs for GPs about gout, focusing on diet as an essential part of the treatment.

## AB1069 THE EDUCATIONAL NEEDS OF PEOPLE WITH SPONDYLOARTHROPATHIES (AS AND PSA): A CROSS-SECTIONAL STUDY

M.L. Marques[1], R. Ferreira[1], M. Santiago[1], A. Marques[1], P.M. Machado[2], J.A.P. da Silva[1], M. Ndosi[3]. *[1]Rheumatology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Centre for Rheumatology Research & MRC Centre for Neuromuscular Diseases, University College London; [3]School of Healthcare, University of Leeds, Leeds, United Kingdom*

**Background:** Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA) have significant impact on patients' lives and patient education is integral to the management of the diseases.
**Objectives:** To assess the self-reported educational needs of patients with AS and PsA, and test differences across gender, age, disease duration and educational background.
**Methods:** In this cross-sectional study, patients completed the Portuguese version of the Educational Needs Assessment Tool (PortENAT). Data was then Rasch-transformed to obtain interval-level measures of their educational needs which were summarized descriptively. Univariable analyses were used to determine differences between patient subgroups.
**Results:** The study included 121 AS and 132 PsA patients (mean age =47.3 and 53.8 years; disease duration =15.6 and 14.4 years, respectively). Overall, patients with AS had higher educational needs than those with PsA (Table 1). On the domains' scores, age, gender and educational background had different effects in the disease groups; gender affected all domains, except treatments and support systems, with women expressing higher educational needs. Educational background had the strongest effect on overall score – higher education being related to higher educational needs.
**Conclusions:** The educational needs vary by disease and demographic characteristics. Assessing individual patient education needs with tools such as the PortENAT may help target individual patient education.

**Disclosure of Interest:** None declared

## AB1070 COULD ENHANCED PATIENT EDUCATION IMPROVE THE OUTCOME OF CLINICAL TRIALS IN RHEUMATOID ARTHRITIS?

R.M. Cseuz[1], M. Megyaszai[1], B. Shenker[1], A. Mirzahosseini[2]. *[1]Revita Clinic; [2]Dept. of Pharmaceutical Chemistry, Semmelweis University, Budapest, Hungary*

**Background:** Patient education is considered to be a highly cost-effective way to limit disability in rheumatic diseases as well as to achieve an improvement in quality of life. Since 1997 our team has carried out a variety of educational programs for RA patients [1]. Since the year 2000 several clinical trials have been carried out on RA patients at Revita Clinic.
**Objectives:** Internationally, medical teams involved in clinical trials work according to the "gold standard" (ICH-GCP) based on regular training and international guidelines. It is suggested that apart from the known and obvious prerequisites for clinical trials, individual sites could add to the process of developing a new molecular entity by enhancing the education of recruited patients thereby improving compliance and reducing the failure rate of investigational products used in such trials.
**Methods:** Data and statistical analyses from 16 RA studies on biologics & JAK inhibitors from the last 5 years involving 185 patients are presented of which 144 were involved in customized educational programs utilizing an educational DVD, and 6-week courses involving meetings with other patients, doctors, and physiotherapists. Compliance measured using standard and site-specific questionnaires were compared with meta-analyses of international studies. Efficacy measures a) withdrawal risk [2]; b) HAQ; c) DAS28; d) GAD VAS; e) Physician Assessment, were analyzed and compared with meta-analyses of international studies.
**Results:** The mean withdrawal risk of Revita Clinic patients was found to be

**Abstract AB1069** – Table 1. Educational needs by age, gender, disease duration, educational background and disease[§]

| Domain (score range) | Patients | Disease | Age | | Gender | | Disease duration | | Educational background | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | Older | Younger | Male | Female | Longer | Shorter | Lower | Higher |
| Managing pain (0–24) | AS | 14.3±5.3 | 14.3±4.5 | 14.6±5.9 | 13.3±4.8* | 15.6±5.5* | 14.3±5.6 | 13.9±4.1 | 13.6±3.9 | 14.5±5.9 |

[§]Values are mean ± standard desviation; age subgroups based on median split; disease duration categories based on split at 25th percentile. *Significant p-value (<0.05) for that parameter within disease, [#]Significant p-value (<0.05) for difference between diseases groups.

| | Withdrawal (%) | DAS28 | HAQ | GAD | Physician Assessment |
|---|---|---|---|---|---|
| Revita | 4.2 ±1.8 | -2.23 ±1.68 | -0.39 ±0.54 | -26 | -30 |
| Global mean | 9.3 ±0.6 | -1.17 ±0.67 | -0.28 ±0.12 | | |
| | p=0.05 | p<0.0001 | p<0.0001 | | |

significantly lower compared to global data [2] ($p<0.05$). The mean DAS28 value change is -2.23±1.68, significantly higher than the global average of -1.17±0.67 [3] ($p<0.0001$). The mean HAQ value change is -0.39±0.54, significantly higher than the global average: -0.28±0.12 [3] ($p<0.0001$). The mean GAD VAS and Physician Assessment, changes are -26 and -30, respectively.

**Conclusions:** The overall goal is to increase participation, reduce costs, and accelerate the time factor in clinical trials. The high failure rate of investigational products in such trials, especially in the later stages of development, is a significant contributor to the costs and time associated with bringing new molecular entities to market. Enhanced patient education might well help to overcome the present shortcomings thereby increasing the cost-effectiveness of clinical trials.

## AB1071 HOW MUCH IS THE AWARENESS ABOUT RHEUMATOLOGY? SURVEY AMONG MEDICAL STUDENTS (YR 3) IN VELAMMAL MEDICAL COLLEGE, MADURAI, TAMILNADU, INDIA

S. Nallasivan. *Assistant Professor and Consultant, Dept of Rheumatology, Velammal Medical College Hospital and Research Institute, Madurai, India*

**Background:** Rheumatology is a fascinating medical subspeciality. Over 200 syndromes and diagnosis have been described in rheumatology and recently lot of thrust has been given to improve the Rheumatology both in government and private sectors in health care in India. Rheumatology as super specialty in India is slowly gaining prominence, however public awareness still needs to improve.
**Objectives:** 1. To assess the awareness of rheumatology and musculoskeletal health among the medical students (year 3). 2. To gain insight in to their knowledge about this medical subspecialty, in order to improve their educational tools and sessions, which inturn will shape up the changes in their curriculum.(MBBS)
**Methods:** This survey was conducted as anonymised questionnaire. All 3rd yr medical students were requested to express their opinion while answering on a scale of 1 to 10.
**Results:** 118 students participated in this survey and answered 10 questions:

| All ratings were scored from 1 to 10, 1 being low and 10 being high | Mean score |
|---|---|
| 1. How much are you aware about Rheumatology as medical sub speciality? | 5.59 |
| 2. How complex are rheumatological diseases? | 6.44 |
| 3. Are you aware that most rheumatological diseases are multi system disease? | 6.9 |
| 4. Do you think the musculoskeletal problems will top the list of chronic diseases | 5.49 |
| 5. Do you think rheumatological diseases in India are comparable to Europe? | 4.49 |
| 6. How likely you would be interested to take up Rheumatology as career option? | 4.58 |
| 7. How much you are aware that Research and Rheumatology are interlinked? | 4.85 |
| 8. How much do you know about EULAR or BSR as Europe's Rheumatology leagues? | 3.09 |
| 9. Can you rate your current rheumatology knowledge against your curriculum? | 4.26 |
| 10. Do you feel that non governmental agencies and charities need more support? | 6.48 |

**Conclusions:** Although this is the first of its kind, young medical students have insights in to the rheumatology around the world. They are aware about the multisystem nature of the diseases, research benefits and support to the charities. We are aware about their interests.
We need to improve the access to rheumatology education and help our patients. There has been increasing awareness about the EULAR/BSR/ACR/APLAR-the four big leagues around the world, which guide the patients and medical professionals in Rheumatology

**Acknowledgement:** Special acknowledgement to all the year 3 medical students.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5692

## AB1072 GENERAL PRACTITIONER PERCEPTIONS OF METHOTREXATE AND ANTI-TNF TREATMENTS: A QUALITATIVE STUDY

E. Berthet[1], M. De Rosa[2], J. Lopez[1], P. Vorilhon[2], M. Soubrier[1], S. Mathieu[1]. *[1]Rheumatology; [2]General Medicine, Hopital Gabriel Montpied, Clermont Ferrand, France*

**Background:** The objective of rheumatic disease management is to achieve remission. Methotrexate (MTX) is the first-line treatment choice and tumor necrosis factor alpha antagonists (anti-TNFs) are used in case of MTX failure or intolerance. While these treatments are initially prescribed then renewed by rheumatologists, general practitioners (GPs) are often confronted with them during routine patient follow-up.
**Objectives:** We sought to study the perceptions of GPs from Auvergne (a region of France) regarding MTX and anti-TNFs treatments in common daily practice.
**Methods:** A qualitative study was carried out among 14 GPs following up patients receiving methotrexate and anti-TNFs. The semi-structured interviews were conducted between May and October, 2014. Thematic transversal analyses of the data were conducted by both the interviewer and an independent researcher. Each difference detected between them was discussed, then resolved by consensus.
**Results:** Of the 285 physicians who completed a preliminary questionnaire, 31 consented to participate in the qualitative. A total of 14 interviews, sufficient to obtain data saturation, *i.e.,* until no new data emerged, were conducted, lasting between 8 minutes and 1 hour, with a mean duration of 23 minutes 30 seconds. In total, 57% of the physicians interviewed were female and 42% of all practiced within 15km of a rheumatologist. The participating physicians were either young doctors (14%) or had over 20 years of experience (78%).
Four principal themes were recognized in the analysis: the GP's role with regard to the patients, their experience and difficulties concerning these treatments, their opinions of therapeutic education programs, as well as the need for improvements in clinical practices. The physician's role consisted in renewing methotrexate prescription (10/14) and managing comorbidities *via* vaccination, for example (7/14). The GPs reported good tolerance (10/14) and efficacy (8/14) with the treatments. However, there was still concern over the immunosuppression and increased infection risk associated with these treatments, causing them to hesitate in using them. The difficulties especially concerned drug interactions and managing anti-TNF discontinuation in the event of infection (5/14), especially for rural-based practices with less easy access to specialists. All the physicians expressed a desire for a practical tool to be implemented aiding them to manage these treatments (10/14).
**Conclusions:** All the physicians reported difficulties in their daily management of these treatments. Close collaboration between GPs and specialists thus appears essential for this management. GP training is also to be encouraged.

**Disclosure of Interest:** None declared

## AB1073 EXPLORATION OF THE DIFFICULTIES ENCOUNTERED BY GENERAL PRACTITIONERS WITH METHOTREXATE AND TNF-INHIBITOR TREATMENT IN COMMON PRACTICE

E. Berthet[1], M. De Rosa[2], P. Vorilhon[2], M. Soubrier[1], S. Mathieu[1]. *[1]Rheumatology; [2]General Medicine, Hopital Gabriel Montpied, Clermont Ferrand, France*

**Background:** Rheumatic diseases are frequently occurring pathologies (approximately 1% of the population exhibits rheumatoid arthritis), causing pain, articular destruction, and functional handicaps. Early diagnosis and regular disease monitoring are required in order to avoid such complications. The therapy's objective is to attain remission, which entails optimal use of long-term treatments, such as methotrexate (MTX) or TNF-alpha inhibitors (anti-TNF alpha). These treatments are then increasingly prescribed. General practitioners (GPs) therefore must be able to manage such treatments, along with their potential side-effects.
**Objectives:** Our study's aim was to explore the potential difficulties of GPs from the Auvergne region of France with regard to using anti-TNF alpha and MTX in their common practice.
**Methods:** A questionnaire collecting the GPs' characteristics, difficulties in daily clinical practice, and expectations designed to ease the management of MTX and anti-TNF alpha treatments was mailed to 1,190 GPs in our region.
**Results:** The response rate was 24.9%, equating to 296 responses. The analysis covered 285 responses, since 11 doctors did not wish to participate. The majority of doctor respondents was men (57%) and was in group practice settings (55%). No respondents had practices situated at more than 100 km from a rheumatologist. Of the 230 GPs treating patients on MTX (81%: 230/285), 113 reported difficulties in managing therapy, such as infectious problems (30%) and the occurrence of side-effects (23%). Overall, 31% were troubled by potential drug interactions. GPs practicing for less than 10 years had more difficulties than the others ($p=0.002$). No significant differences were observed based on practice location, type of practice, or distance from the rheumatologist. In total, 22% of doctors surveyed (n=41) were prepared to initiate MTX therapy.
Of the 189 respondents (66%) managing patients on TNF inhibitors, 127 encountered similar difficulties, yet with a higher frequency (infectious problems: 53%; side-effects: 29%, and drug interactions: 39%). No differences were observed based on GPs characteristics. Overall, 57.2% of the GPs (163/285) felt that TNF-inhibitor therapies displayed a favorable benefit/risk ratio. Amongst the respondents, 80% (228/285) desired further training.
**Conclusions:** In our study, more than half of the GPs managing patients on MTX- or TNF-inhibitor therapy reported difficulties with the treatment.

### THU0639-HPR A NEW ELECTROMECHANICAL PLATFORM FOR SUBCUTANEOUS DRUG DELIVERY: RESULTS FROM AN EU USABILITY STUDY

B. Domanska, S. Poon, C. Pichon, O. Stumpp. *UCB Pharma, Brussels, Belgium*

**Background:** UCB Pharma have designed and developed an innovative electromechanical, universal injection platform for subcutaneous drug delivery (eDevice), providing full electronic management of the injection process via an interactive graphical user interface (GUI). Here, the eDevice was tested for use with certolizumab pegol (CZP).
**Objectives:** To validate that patients (pts) can self-inject safely and effectively using the eDevice, and that healthcare professionals (HCPs) are able to configure the eDevice and demonstrate its operation by performing a simulated injection, in the expected scenarios and environments, using the instructions for use (IFU), eDevice GUI and training cassette.
**Methods:** The study took place in Stockport and London, UK, with 15 pts with moderate to severe rheumatoid arthritis (RA), and 15 HCPs. An injection test scenario was performed in a room simulating a home (pts) or office (HCPs). Pts/HCPs were supplied with the eDevice, IFU, training cassette and a CZP cassette containing sorbitol, mimicking CZP viscosity. Using an artificial skin pad attached to the intended injection site (abdomen/thigh), pts were asked to perform 2 simulated self-injections of CZP loading dose (LD; 2 x 200mg) and determine the next scheduled injection date. HCPs were asked to configure CZP LD (2 x 200mg Q2W at Wks 0, 2, 4) and 2 maintenance regimens (200mg Q2W, 2 x 200mg Q4W), and perform 2 simulated pt injections. No training was provided; pts/HCPs could use only the IFU, GUI and training cassette for guidance.
An independent human factors researcher scored pts and HCPs against 18 and 22 predefined critical tasks, respectively. Pts/HCPs had 3 attempts for each task. Critical tasks were those required to safely and effectively use the eDevice, scored on the final attempt as pass, pass with difficulty, or fail. Pts/HCPs were then interviewed for 120 mins to identify root causes (RC) of difficulties/failures. RC analyses were reported as perception failure (misreading GUI/IFU), cognition failure (misinterpreting GUI/IFU), action failure (participant understood task but performed incorrectly), prior experience (assumed eDevice was same as other injection devices), test artefact (if pt said "I did not do X as it is not a real situation") or medical condition (symptoms caused use error).
**Results:** All 15 pts and 15 HCPs were able to inject the full simulated CZP LD. 330 critical tasks were assessed for HCPs, and 270 for pts. 4 task failures were recorded for HCPs and 8 for pts (Table). The 1 HCP failure to correctly configure the eDevice was due to poor English understanding, not device design (post-study interview RC analysis). 14 pt and 26 HCP critical tasks were passed with difficulty (Table); the most common reason being an inability to find information within IFU (RC analysis). There were no needle stick injuries or unexpected user errors.

**Table:** Scores for critical tasks completed with difficulty/failed during the injection simulation

| | RA patients | | | HCPs | | | RCA of failed tasks |
|---|---|---|---|---|---|---|---|
| | n | Difficulty | Fail | n | Difficulty | Fail | |
| Configure eDevice for Q2W | N/A | N/A | N/A | 15 | 6 | 1 | Cognition failure |
| Configure eDevice for Q4W | N/A | N/A | N/A | 14 | 5 | 0 | |
| Configure eDevice to maintenance dose 1 | N/A | N/A | N/A | 14 | 2 | 0 | |
| Configure eDevice to maintenance dose 2 | N/A | N/A | N/A | 14 | 2 | 0 | |
| Prepare 1 or 2 cassettes | 15 | 1 | 0 | 15 | 0 | 0 | |
| Inspect cassette window for visible defects | 15 | 0 | 1 | 15 | 0 | 1 | Perception failure (patient and HCP) |
| Insert cassette into eDevice | 15 | 1 | 0 | 15 | 0 | 0 | |
| Remove needle cap | 15 | 2 | 0 | 15 | 1 | 0 | |
| Position eDevice | 15 | 2 | 0 | 15 | 1 | 0 | |
| Re-cap cassette | 15 | 0 | 0 | 15 | 3 | 0 | |
| Dispose of used cassette correctly | 15 | 0 | 5 | 15 | 0 | 2 | Test artefact (patients and HCPs) |
| Clean eDevice | 15 | 3 | 2 | N/A | 0 | 0 | Perception failure |
| Respond to high and medium priority alarms correctly | 15 | 5 | 0 | 15 | 6 | 0 | |

n: number of study subjects. HCPs: healthcare professional; N/A: not applicable; RCA: root cause analysis.

**Conclusions:** All study participants could perform a simulated injection and administer a full CZP LD safely and effectively. There were no incidences of potential over or under dosing, either by self-injection or incorrectly reading the next treatment date on the GUI. All HCPs able to read the instructions could configure the eDevice.
Most difficulties encountered by pts/HCPs could be rectified by improving the IFU design.

### THU0640-HPR PROVISION OF CARE SERVICES FOR RHEUMATIC AND MUSCULOSKELETAL DISEASES-RELATED FOOT AND ANKLE PROBLEMS: A SURVEY FROM SIXTEEN EUROPEAN COUNTRIES

B.A.-P. Alcacer-Pitarch[1], M. Backhouse[1], G. Gijon-Nogeron[2], D. Biscontini[3], S. Bonafede[4], A. Ferreira[5], A. Gatt[6], Y. Lescure[7], T.N. Nava[8], A. Redmond[1] on behalf of EULAR Foot & Ankle Study Group. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine and Leeds NIHR Biomedical Research Unit, University of Leeds, Leeds, United Kingdom; [2]Department of Nursing and Podiatry Facultad de Ciencias de la Salud, Universidad de Malaga, Malaga, Spain; [3]Unit Department of Rheumatology, Hospital University of Perugia Santa Maria della Misericordia, Perugia; [4]Department of Physiotherapy, S. Raffaele University Hospital, Milan, Italy; [5]St George's Healthcare NHS Trust, London, United Kingdom; [6]Faculty of Health Sciences, University of Malta, Msida, Malta; [7]Intitut Nationla de Podologie, Paris, France; [8]Department of translational medicine and surgery, University of Milan Bicocca, Milan, Italy*

**Background:** The increased prevalence of foot and ankle pathologies in Rheumatic and Musculoskeletal diseases (RMDs) is well documented[1], however the provision of foot & ankle (F&A) healthcare services for people with RMDs in Europe has not been evaluated.
**Objectives:** To assess the current healthcare systems for providing foot & ankle healthcare services for people with RMDs in Europe.
**Methods:** A survey was undertaken to evaluate current provision of F&A health care services for people with RMDs across Europe. A questionnaire was distributed to all 22 country presidents representing HP associations within EULAR. The questionnaire used was developed and piloted (in 7 countries) by the EULAR F&A Study Group, and structured to capture the provision and type of F&A services for people with RMDs. When the HP presidents felt unable to answer specific questions they were encouraged to consult a colleague who may be better placed to provide the answers.
**Results:** Sixteen questionnaires were completed (Norway, Ireland, Sweden, Hungary, Netherlands, UK, Denmark, Portugal, Italy, Switzerland, Austria, France, Czech Republic, Spain, Belgium, Malta). Of the 16, 13 respondents indicated provision of F&A health care services in their country, but only three countries had services specialising in RMD-related F&A problems (Netherlands, UK, Malta). The professions providing the care for patients with RMD-related F&A problems were different depending on the pathology and the country (Table1). Podiatrists provided care for F&A pain and deformity problems in 11 countries, but provided F&A ulcer care in only 8 countries.

Table 1. Number of countries reporting which professions are involved in providing the health services specialising in RMD-related F&A problems. Only professions that were present in ≥10 countries were included

| Professions | Foot problems | | |
|---|---|---|---|
| | F&A pain No. Countries (N=16) | F&A deformity No. Countries (N=16) | F&A ulcers No. Countries (N=16) |
| General Practitioner | 14 | 7 | 10 |
| Rheumatologist | 15 | 11 | 10 |
| Rehabilitation Medical Dr | 11 | 10 | 5 |
| Nurses | 9 | 5 | 14 |
| Podiatrist | 11 | 11 | 8 |
| Physiotherapist | 14 | 11 | 3 |
| Orthotist/prosthetist | 14 | 14 | 8 |
| Orthopaedic surgeon | 12 | 14 | 7 |

**Conclusions:** Only 3 countries have F&A health care services specialised to the needs of people with RMDs. The professions providing the care varied between countries, and also depended on the F&A pathology. Interestingly, F&A healthcare services were provided by professions that do not solely specialised in F&A care. Further research is needed to assess the variation of F&A healthcare services

between and within European countries and the impact on healthcare of various F&A healthcare service designs.

## THU0641-HPR THE CHALLENGE OF PET THERAPY IN RHEUMATOLOGY: EVIDENCE FOR THE IMPROVEMENT OF PATIENTS COMPLIANCE IN SYSTEMIC SCLEROSIS

G. Fiori[1], F. Bartoli[1], T. Marzi[2], C. Bruni[1], G. Lepri[1], S. Bellando-Randone[1], S. Guiducci[1], V. Denaro[1], G. Tesei[1], M. Matucci-Cerinic[1]. *[1]Department of Experimental and Clinical Medicine, Division of Rheumatology; [2]Department of Neurosciences, Psychology, Drug Research and Child Health, University of Firenze, Firenze, Italy*

**Background:** "Pet Therapy", better defined as Animal-assisted Intervention (AAI), is based on the interaction between animal and human being and is a tool which may complement and support traditional therapies. It can be used on patients affected by different diseases, improving their quality of life from behavioral, physical and psychosocial point of view.

**Objectives:** The aim of our study was to evaluate the effect of AAI in improving quality of life and compliance to standard pharmacological treatment in a cohort of Systemic Sclerosis (SSc) patients.

**Methods:** 42 SSc patients attending at Scleroderma Unit and undergoing iloprost intravenous infusion were divided in three groups: 1) 14 SSc patients (mean age 60.4±8.6 yrs) submitted to 20 AAI sessions with a professional team (doctor, nurse, couple of animal-handler); 2)control (C1) 14 SSc patients (mean age 63.4±5.3 yrs) engaged in alternative social activity as create a cookbook; 3)control (C0) 14 SSc patients (mean age 62.3±6.8 yrs) without any alternative activity. All patients underwent psychological evaluation at baseline (t0) and at the end of project of AAI (t1); moreover the following test (italian standardized version) was performed at the beginning (s0) and at the end (s1) of each single session: General Anxiety State-Trait Anxiety Inventory (STAI-T), Beck Depression Inventory (BDI), Social Interaction Anxiety Scale (SIAS), Eysenck Personality Questionnaire-Revised (EPQ-R), the Social Phobia Scale (SPS), the Toronto Alexythymia Scale (TAS-20), the Thought Control Questionnaire (TCQ), the Visual Analog Scale (VAS), the State-anxiety (STAI-S).

**Results:** At the end of each session, AAI group showed a decrease of the anxiety state level while it was higher in the two control groups ($p_s<0.001$). VAS scale resulted lower both in AAI group ($p<0.001$) and in C1 group ($p<0.01$). Moreover, STAI-T and TAS scores were significantly reduced in AAI group at t1 compared to t0 and to both control groups ($p_s<0.001$). No significant differences were found for depression in the BDI scores at the end of all sessions. TCQ scale showed that patients treated with AAI, compared to control group C0, had greater capacity to avoid unpleasant and unwanted thoughts by using positive distraction strategies ($p<0.05$).The EPQ-R test (used for analyze personality traits, such as extraversion/introversion) revealed in AAI group an enhancement of extroversion trait compared to both C1 and C0 ($p<0.05$).

**Conclusions:** In agreement with literature [1], our work showed that AAI might be a crucial tool to support the traditional therapies thanks to the creation of a different relationship between patient and doctor. This may allow a better compliance to the therapy in a chronic disease like SSc, where patient's compliance is usually low.

## THU0642-HPR BETTER ARTHRITIS CARE: WHAT TRAINING DO COMMUNITY BASED HEALTH PROFESSIONALS NEED TO BETTER CARE FOR PEOPLE WITH ARTHRITIS?

J. Erwin[1], A. Woolf[1], K. Mattick[2], S. Hewlett[3], S. Whitcombe[4], S. Kilty[5]. *[1]Bone & Joint Research Group, Royal Cornwall Hospitals NHS Trust, Truro; [2]Centre for Research in Medical Learning, University of Exeter Medical School, Exeter; [3]HAS, University West of England, Bristol; [4]School Healthcare Studies, Cardiff University, Cardiff; [5]Arthritis Care, Truro, United Kingdom*

**Background:** It has been shown that arthritis management in primary care does not always meet guidelines (Goodwin 2010) and that insufficient knowledge of Rheumatoid Arthritis (RA) and Osteoarthritis (OA) can lead to a lack of ability to educate and inform patients. To ensure people with arthritis receive the care they need and consistent self-management and life style messages it is important that all health professionals (HPs) they may have contact with are familiar with arthritis, its impact, diagnosis and management. There is very little evidence on the education community based HPs need in order to fulfil these requirements (Fletcher 2012, Lillie 2012, Mann 2012).

**Objectives:** To identify what education community based nurses and allied health professionals (AHPs) need to enable them to appropriately assess, care for and manage arthritis.

**Methods:** The study used a Delphi survey technique with an Expert Panel of 43 rheumatology specialists and expert patients was established to identify the competencies needed by community based nurses and AHPs (occupational therapists, physiotherapists, podiatrists and community pharmacists) to enable them to care for people with arthritis. Focus groups were held with a total of 25 women and men with inflammatory arthritis (IA) and OA and with 26 community based nurses and AHPs to elicit their views on what nurses and AHPs need to know to enable them to appropriately and effectively care for people with arthritis.

**Results:** Frameworks for the core competencies in arthritis care for community based HPs and for profession specific training were developed. The key goals identified were to increase HPs understanding of arthritis, and its impact on patients' lives and to increase their ability to help patients self-manage their condition and access all the means of support available to them. Competencies include a basic understanding of the pathology underlying inflammatory and non-inflammatory arthritis, the ability to distinguish between the two and to recognise early warning signs with emphasis on OA, RA, gout and septic arthritis. Essential competencies included the ability to engage in shared decision making, goal setting, signposting, to provide patients with education and information and to make appropriate referrals.

**Conclusions:** Health professionals (HPs) working in the community commonly encounter arthritis as a presenting problem or as co-morbidity. Care quality to people with IA and OA is currently highly variable and sub-optimal and could be significantly improved (Goodwin et al 2010). This study identifies the core competencies that all community based nurses and AHPs should have in relation to OA and IA.

## THU0643-HPR PREVALENCE OF FOOT PROBLEMS IN PEOPLE WITH INFLAMMATORY ARTHRITIS IN SINGAPORE

K. Carter[1], M. Lahiri[2], P. Cheung[2], A. Santosa[2], K. Rome[3]. *[1]Podiatry; [2]Department of Medicine, National University Hospital Singapore, Singapore, Singapore; [3]Faculty of Health and Environmental Science, AUT University, Auckland, New Zealand*

**Background:** Foot problems are highly prevalent in people with inflammatory arthritis [1]. Podiatry intervention can significantly reduce foot pain and disability [2]. Most knowledge of the epidemiology of foot involvement is based on studies from the UK, Europe and New Zealand [1,3,4] with limited evidence relating to the podiatric need of people with inflammatory arthritis in Singapore.

**Objectives:** To evaluate the prevalence of foot problems in people with inflammatory arthritis in Singapore.

**Methods:** People with inflammatory arthritis were recruited from the rheumatology outpatient clinic of a large public hospital in Singapore. Disease and clinical characteristics included age, sex, disease duration, BMI, current disease modifying anti-rheumatic drug (DMARD) medications, ESR and CRP. Foot pain was measured using a 10cm visual analogue scale. The Leeds Foot Impact Scale (LFIS) [5] was used to evaluate foot impairment and disability and the Modified Health Assessment Questionnaire (MHAQ) was used to assess global function [6]. Foot assessments were conducted and prevalence of foot deformity was ascertained.

**Results:** We recruited 101 people with inflammatory arthritis, of which 50% were female. The mean of age was 52±15 years, and the mean disease duration was 9.3±0.3 years. The most commonly reported inflammatory arthritis conditions were rheumatoid arthritis (46%), spondyloarthritis (18%) and gout (15%). Most (61%) were overweight with a mean BMI of 27.2±5.4 kg/m$^2$. 42% of all participants were on a current prescription of methotrexate and 52% were receiving a combination DMARD therapy. Only 4% were receiving biologic therapy. The mean ESR was 31.6±21.2mg/hr and mean CRP was 27.4±32.2mm/L. The mean of the total LFIS was 17±13 indicating moderate to severe levels of foot impairment and activity limitation. The mean MHAQ score was 0.25±0.36. Over 80% of participants experienced foot problems during the course of their condition, and 48% reported current foot pain. The mean pain score was 5.0±2.3. Despite the high prevalence of foot problems (81%), only 21 participants (21%) had been referred to a podiatrist.

**Conclusions:** This is the first study to investigate the prevalence of foot problems in people with inflammatory arthritis in Singapore. The majority of the participants reported foot problems, but had not been referred to a podiatry service. Findings

from this study will be used to improve referral rates, service provision and quality of patient care.

## THU0644-HPR E-LEARNING: AN EFFECTIVE METHOD TO IMPROVE DISEASE KNOWLEDGE AND SELF-EFFICACY FOR PATIENTS WITH AXIAL SPONDYLOARTHRITIS

L.A. Passalent[1,2], R. Kang[1], D. Lawson[1], C. Hawke[1], A. Omar[1], N. Haroon[1], R.D. Inman[1]. *[1]Toronto Western Hospital; [2]University of Toronto, Toronto, Canada*

**Background:** There is a growing body of evidence to support the effectiveness of education programs for patients with arthritis. However, there has been little investigation into education strategies for patients with axial spondyloarthritis (axSpA). A number of studies examining education strategies for patients with arthritis have involved an interdisciplinary approach and found positive impact on disease activity, function and overall health (1). Furthermore, the use of electronic formats for education are preferred over other formats for patients with axSpA (2). As such, the Toronto Western Hospital Spondylitis Program developed a novel e-Learning education module for patients with axSpA with input from patients and an interdisciplinary team of health care professionals. The module consists of an interactive web-based platform covering evidence-based topics including diagnosis, treatment and self-management for axSpA.
**Objectives:** To measure the effect of the axSpA e-Learning patient education module with respect to: 1) chronic disease self-efficacy; 2) knowledge of axSpA, and 3) exercise behaviour.
**Methods:** Fifty-four adult patients with axSpA attending a tertiary academic spondylitis clinic were randomly assigned to one of two groups: 1) e-Learning intervention, where patients were emailed a link to the web-based patient education module and were asked to complete the module at their leisure; or, 2) usual care. All patients completed baseline and follow-up questionnaires that included: the Ankylosing Spondylitis (AS): "what do you know" knowledge questionnaire; Stanford Chronic Disease Self-Efficacy Scale (CDSE), and, the Stanford questionnaire for Exercise Behaviours.
**Results:** Twenty-one patients with axSpA completed the e-Learning module and 33 patients continued with usual care. Overall, mean (SD) age was 42.6 (13.2) years, 70% were male, mean (SD) disease duration was 19.3 (10.1) years and 85% had a post-secondary education. There were no statistically significant differences in the above outcome measures between the two groups at baseline or follow-up. However there was significant improvement from baseline to follow-up in patients that completed the e-Learning module with respect to their AS knowledge mean score (SD) 19.0 (4.1) vs 19.9 (5.0) (p=0.0002) and CDSE sub-scale "manage disease in general" mean score (SD) regarding when to visit a doctor and ability to manage health condition 7.5 (1.8) vs. 7.9 (1.9) (p=0.02) and 7.3 (1.8) vs. 7.9 (2.1) (p=0.02) respectively.
**Conclusions:** The above demonstrates an increase in overall disease knowledge and improved self-efficacy through the implementation of a novel e-Learning patient education module. This e-Learning module has the potential to provide benefit to patients with axSpA who have limited access to specialized care, ultimately optimizing outcomes in this patient population.

## THU0645-HPR PERCEIVED BARRIERS AND FACILITATORS FOR BDMARD DOSE OPTIMIZATION: A QUALITATIVE STUDY INTO RA PATIENTS' PERSPECTIVES

L.M. Verhoef[1], E.M. Selten[1], F. van den Hoogen[1,2], A.A. den Broeder[1,2], M.E. Hulscher[3]. *[1]Department of Rheumatology, Sint Maartenskliniek; [2]Department of Rheumatology; [3]Scientific Institute for Quality of Healthcare, Radboud university medical center, Nijmegen, Netherlands*

**Background:** Although bDMARDs are effective in treating RA, they are associated with high costs and (rare) dose-dependent side effects. It is therefore desirable to find and use the lowest effective dose in individual patients. Several studies have shown that dose reduction or interval lengthening of bDMARDs using the tight control principle can be successful in RA patients while preserving stable low disease activity.[1] Unfortunately, bDMARD dose optimization is still limited in clinical practice.[2] The successful implementation of bDMARD dose optimization could, among other factors, be influenced by patient's attitudes and beliefs. Insight into RA patients' barriers and facilitators to bDMARD dose optimization might help to improve implementation.
**Objectives:** To investigate the self-reported barriers and facilitators for bDMARD dose optimization in RA patients.
**Methods:** We performed semi-structured interviews with RA patients who used or had used a bDMARD. Patients were recruited at the Sint Maartenskliniek through purposive sampling. Patients with varying characteristics were included, looking at type of bDMARD, treating rheumatologist and experience with tapering/stopping. The interviews were performed by one researcher (18 by telephone, 4 face-to-face), audio-recorded and transcribed verbatim. Two researchers analyzed the transcriptions by inductive thematic analysis using the qualitative data analysis software MAXQDA.
**Results:** 22 RA patients were interviewed (68.2% female; age: 61.8±7.6 years; disease duration: 13.2±9.4 years; 90.9% current bDMARD user). RA patients' overall attitude towards bDMARD optimization was positive. Nine main themes emerged from the interviews: disease activity, functioning/pain, adverse effects, practical use of bDMARDs, attitude towards medication, previous experiences with tapering/stopping, social aspects, organizational aspects and costs. Within these themes, a total of 43 barriers and facilitators were identified. These include affective factors (e.g. fear), cognitive factors (e.g. beliefs) and practical factors (e.g. organization of care, costs).
**Conclusions:** RA patients perceive several barriers and facilitators that influence their willingness to attempt tapering or stopping their bDMARD treatment. The results of this study could be used to target strategies aiming at implementation of bDMARD optimization in clinical practice.

## THU0646-HPR EXPERIENCES OF LIFE WITH BIOLOGIC DRUG THERAPY: "I'M DOING MORE THAN I THOUGHT POSSIBLE 3-4 YEARS AGO!"

L. Sanders. *Rheumatology, Dorset HealthCare University NHS Foundation Trust, Wimborne, United Kingdom*

**Background:** With significant advancements in new treatment modalities for rheumatoid arthritis with biological therapies, the literature has largely focused on quantifying improvements. However from an extensive review of the literature very little evidence is available relative to experiences of mobility in this group after commencing biologic drug therapy. A challenge exists in informing services of what patients truely experience with changes to their pharmacological management. Furthermore if they notice changes, how do they value them. Three key qualitative publications were identified. Marshall et al (2004) reported improvements in physical function, pain and well-being. Arkell et al (2013) found that participants were very positive about being on anti-TNFα as it was described to make dramatic changes in their physical symptoms. Linden and Bjorklund (2010) concluded that with successful anti-TNFα treatment most participants experienced dramatic changesincluding a return to leisure interests. However Linden & Bjorklund (2011) also suggested that such dramatic changes may risk overuse and consequent strain. The aim of this study was to use a qualitative method to explore the understanding and experiences of People with Rheumatoid Arthritis (PwRA) who are receiving biological therapy treatment, relative to their physical function and lower limb mobility levels.
**Methods:** An interpretative phenomenological analysis (IPA) approach was used to explore the understanding and experience of PwRA when receiving biologics. A purposive selection of a small sample of PwRA was adopted and in-depth semi structured interviews were used. Interviews were conducted in the homes of participants and then later transcribed verbatim. Thematic analysis was employed for identifying meanings, analysing and reporting patterns within data.
**Results:** Five PwRA participated in the study. The mean duration of their RA disease was 20.2 years (range 6 -32 years) and all were being treated with biologic therapies. Four key themes emerged from the interviews: 1) Life before biologic treatment. 2) Life with biologic treatment. 3) Sense of self. 4) Podiatric implications.
**Conclusions:** The findings from this study reinforce those known such as improved physical function. The dramatic, postive change experienced by participants and a sense of appreciation was linked with physical improvements and a return to activity. However there are consequences to these improvements. Regardless of improvements in physical ability and reduced pain, it emerges that lower limb complications are an ongoing experience for people receiving biologics. Importantly an ongoing need for foot health advice and management involving the multidisciplinary team in this patient group is warranted.

## THU0647-HPR IMPROVING ACCESS TO A BETTER MODEL OF CARE FOR PEOPLE WITH KNEE AND HIP PAIN IN PRIMARY CARE - THE OSTEOARTHRITIS ADVISOR

M. Hurley[1,2], A. Walker[1,2], F. Sibley[2], A. Carter[2], D. Stamp[3], S. Thakar[3], M. Creasey[3], R. Williams[3]. *[1]St George's University of London, London; [2]Health Innovation Network, South London; [3]Lewisham and Greenwich NHS Trust, London, United Kingdom*

**Background:** Primary care management of osteoarthritis (OA)is often sub-optimal[1] because physicians feel overwhelmed by patient numbers and don't have time or skills to deliver lifestyle advice effectively – information, self-management, physical activity, weight control[2]. Allied healthcare professionals (AHPs) are better skilled in delivering lifestyle coaching. Although AHP-led care is common in many chronic conditions, it is still uncommon in primary care management of OA.
**Objectives:** We placed an AHP in the primary care pathway to improve access of more people, and to assess if AHP-led primary care was feasible, safe, effective and valued.
**Methods:** In February 2015 a physiotherapist began running clinics for people with knee/hip OA in a primary care surgery.
At an initial assessment (~30 minutes) the *Advisor;*
– assessed their pain and function, physical activity level, waist circumference, body mass
– taught the effective self-management strategies - weight control, exercise, pain management
– used behavioural change techniques - motivational interviewing, set SMART goals, action/coping plans, monitoring, feedback
– help construct personalised care plans
– identified people's physical activity preferences (swimming, walking) and identified local availability
– referred to relevant agencies (dietician) if necessary
Patients were invited to return for review (30 mins) 6 weeks later when the *Advisor*;
– repeated the outcome measures
– feedback progress and success
– reinforced health messages
– offered on-going support, reassurance and encouragement
Qualitative interviews assessed people's opinions of the effectiveness and value.
**Results:** 117 patients were recruited.
Initially people were not receiving recommended advice and support. Between the initial assessment and the 6-week follow-up improvements were seen across *all* outcomes:
- Knee/Hip Osteoarthritis Outcome Score improved - pain 16%; function 17%; quality of life 15%
– waist circumference decreased by 1.8cm
– weight decreased by 0.8kg
– physical activity increased by 2.1 days walking 20min per week
– patients were able to do on average 5.6 more "sit-to-stands" in 30 seconds
Patient satisfaction was very high. they valued advice tailored to their individual needs, appreciated easier access to care, the convenience and familiarity of the service being in their local GP surgery. This translated into self-reported improvements;
*"...it worked...I got a big improvement..."*
*"...from February to April I wasn't walking, now I can..."*
*"...I was 10 stone and went down to 9 stone..."*
Staff satisfaction was also very positive and interest from neighbouring practices meant the role was adopted by 4 other surgeries.
**Conclusions:** AHP-led care of people with knee/hip OA is feasible, safe, quickly accepted and implements evidence-based guidelines care management recommendations that improves important clinical outcomes. Patients, GPs and other practice staff liked and wanted the service.

## THU0648-HPR INCREASING ACCESS TO COMMUNITY-BASED REHABILITATION FOR OSTEOARTHRITIS

M. Hurley[1,2], A. Carter[1], A. Rosam[3], A. Jordan[3], N. Wilson[3]. *[1]Health Innovation Network, South London; [2]St George's University of London; [3]Kings College Hospital NHS Trust, London, United Kingdom*

**Background:** *Enabling Self-management and Coping with Arthritic Pain using Exercise, ESCAPE-pain,* is a rehabilitation programme for people with knee and/or hip osteoarthritis (OA). It delivers guideline core recommendations (information, self-management advice, exercise) that reduce pain, improve function, is cheaper and more cost-effective than usual care[1,2] and participants value its benefits[3].
The programme is usually delivered in physiotherapy departments. However, financial and logistical constraints limit the number of people able to access the programme. Delivering *ESCAPE-pain* in community centres would increase accessibility, "reach" and provide better on-going support, and many more people would benefit.
**Objectives:** This study wanted to establish if delivering *ESCAPE-pain* in community leisure centres was feasible, effective, acceptable and sustainable.
**Methods:** The programme (described in detail at http://www.escape-pain.org/) was supervised by 2 physiotherapists in 3 Inner London leisure centres. Briefly, participants attended 12 sessions (2 sessions/week for 6 weeks) each comprised of a 25-minute education component and 45-minute exercise component. The education is a supervisor-guided theme discussions giving information, self-management and coping advice and incorporates behavioural change techniques. The exercise is an individualised, progressive regimen circuit that helps participants come to appreciate exercise is a safe, effective self-management strategy that reduces the impact of OA.
Pain, function and quality of life (Knee Osteoarthritis Outcome Score), anxiety and depression (Hospital Anxiety and Depression Scale) were measured before and after the programme. Participant experiences were evaluated using semi-structured interviews.
**Results:** 136 people with knee OA were recruited, mean age 63 years old.
Before (n-136) After (n=117)
KOOS-pain 46 (±20) 54 (±18; $p<0.0001$)
KOOS-ADL 48 (±22) 56 (±20; $p<0.0001$)
KOOS-QoL 31 (±23) 39 (±21; $p<0.0001$)
HADS-depression 7.5 (±4.1) 6.2 (±4.3; $p<0.016$)
HADS-anxiety 8.3 (±4.5) 7.0 (±4.5; $p<0.016$)
Attendance was good 64% of people attended ≥9 sessions. Participant were very satisfied with the programme and its outcomes, not only describing improvements in knowledge and symptoms, but also their confidence and attitude to exercise and understanding of the role of exercise in the management of OA. A large majority (80%) planned to continue exercising at leisure centres after completing the programme. The leisure centres decided to run the programme permanently.
*"...I now have more movement and less pain..."*
*"...it has helped me get back into regular exercise..."*
*"...I have gained more confidence and knowledge about my arthritis..."*
**Conclusions:** Delivering *ESCAPE-pain* in community settings is feasible, safe, improves clinical outcomes, acceptable, sustainable and nurtures an exercise habit. It is a community-based programme capable of caring for the large and rapidly increasing number of people with chronic joint pain.

## THU0649-HPR VARIATION IN THE PROVISION AND COMPOSITION OF MULTIDISCIPLINARY TEAMS IN RHEUMATOLOGY SERVICES ACROSS THE UK: A CROSS-SECTIONAL STUDY

M. Ndosi[1], R. Ferguson[2], M.R. Backhouse[1], L. Bearne[3], P. Ainsworth[4], A. Roach[4], E. Dennison[5], L. Cherry[2]. *[1]University of Leeds, Leeds; [2]University of Southampton, Southampton; [3]King's College; [4]British Society for Rheumatology, London; [5]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom*

**Background:** Care by the multidisciplinary team (MDT) is recommended by the current treatment guidelines in the UK and elsewhere in Europe. In rheumatology the evidence to support the effectiveness of multidisciplinary working is limited.[1,2] Furthermore, the availability of all members of the MDT in rheumatology teams across the UK is unclear.
**Objectives:** To describe the national provision of MDT care within Rheumatology services across the UK.
**Methods:** This was a "service" survey conducted in all rheumatology departments within the UK. In England, the survey was a part of a broader national audit for rheumatoid and early inflammatory arthritis commissioned by Healthcare Quality Improvement Partnership (HQIP). The approval to undertake this sub-analysis was gained from HQIP and supported by the British Society for Rheumatology research committee and British Health Professionals in Rheumatology. Scotland

and Northern Ireland were not included in the national audit therefore a separate, but identical, survey was conducted.
The design of the service survey content was agreed in consultation with the BHPR committee, which is formed of health professionals with clinical and research experience in rheumatology. The survey collected organisation data regarding the specific inclusion of, or direct access to, medical, nursing, physiotherapy, podiatry and occupational therapy practitioners as part of the MDT. Detail regarding the whole time equivalent (WTE) availability of each named speciality was recorded and summarised by region.
**Results:** The survey response rate was 98% (164/167). Table 1 shows the overall rheumatology staffing levels measured in WTE between professional groups. All departments reported having medical staff present and almost all had a nurse but the inclusion of physiotherapists, occupational therapists and podiatrists in the MDT was variable. Only 48% of the teams surveyed had access to a podiatrist.
There was a high degree of regional variation in the provision of health professionals and only 28 (17%) of the surveyed teams had all the named professional groups represented in their multidisciplinary teams.

Table 1. Overall rheumatology MDT staffing levels between professional groups

| Profession | Adjusted mean* WTE | SD | Range | Represented within MDT Y/N (%) |
|---|---|---|---|---|
| Medical | 1.05 | 0.62 | 0.70–3.09 | 164 (100) |
| Medical trainee | 0.32 | 0.08 | 0.22–0.54 | 132 (80) |
| Nursing | 0.99 | 0.34 | 0.51–1.55 | 162 (99) |
| Physiotherapy | 0.30 | 0.14 | 0.00- 0.60 | 120 (73) |
| Occupational therapy | 0.28 | 0.11 | 0.15–0.52 | 123 (75) |
| Podiatry | 0.11 | 0.06 | 0.00–0.20 | 79 (48) |

*Adjusted to per 100,000 population.

**Conclusions:** There is a high degree of regional variation in the composition and staffing levels of the Rheumatology MDT across the UK. Further research is required determine the most efficient configuration of the MDT in rheumatology services.

## THU0650-HPR PHYSICAL ACTIVITY AND AEROBIC CAPACITY ASSESSMENT - A SURVEY AMONG HEALTH PROFESSIONALS IN SWEDEN, IRELAND AND DENMARK

S.G. McKenna[1], N. Brodin[2], B. Nordgren[2], B.A. Esbensen[3], T. Swinnen[4], N.M. Hammer[5], S. Willemijns[4], N. Kennedy[1]. *[1]Department of Clinical Therapies, University of Limerick, Limerick, Ireland; [2]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Karolinska, Sweden; [3]Center for Rheumatology and Spine Diseases VRR, University of Copenhagen, Copenhagen, Denmark; [4]Division of Rheumatology, University of Leuven, Louvain, Belgium; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark*

**Background:** Regular physical activity (PA) is associated with improvements in health outcomes, such as quality of life, aerobic fitness, and disease-related characteristics, including pain, stiffness and inflammation, in people with inflammatory arthritis. Current practice in the management of patients with inflammatory arthritis emphasises the importance of Health Professionals (HP's) in assessing PA and aerobic capacity. To ensure baseline knowledge on PA and aerobic capacity assessment among HP's, it is important to identify if knowledge and training gaps exist.
**Objectives:** Investigate the awareness and use of objective and subjective measures of PA and aerobic capacity and to identify barriers for implementation of such methods in Health Professionals (Physiotherapist; Occupational Therapist; Nurse) working in the field of rheumatology in Sweden, Ireland and Denmark.
**Methods:** Health Professional's in Rheumatology were invited to participate in a cross-sectional, descriptive, observational study using an online survey methodology. Separate ethics approval was received in each country. Descriptive statistics and chi-square tests were used to analyse the data using SPSS v22.
**Results:** One hundred and forty four (144) HP's responded (50 Denmark, 28 Ireland and 66 Sweden), with 93% being female. Results found the mean number of years qualified to be 20.08 (SD 9.37) and years working in Rheumatology to be 12.29 (SD 8.27), with 61% reporting half of their workload coming from people who have inflammatory arthritis. The majority of respondents (96%) believe it is important to measure PA. Moderate levels of confidence were reported in using a simple body-worn sensor (mean 6.15/10; SD 3.63) and paper questionnaire (6.85/10; SD 3.62) as ways in monitoring PA, with lower levels of confidence in using a complex body-worn sensor (3.80/10; SD 3.55) and digital diary (4.22/10; SD 3.67). There was no statistically significant association between longer years qualified, more years working with people with inflammatory arthritis, age or gender in relation to the importance in measuring PA. When assessing aerobic capacity 58% were very familiar/somewhat familiar using a bicycle ergometer, 44% a treadmill and 56% other aerobic capacity tests. Low levels of confidence were reported in instructing their patients in performing aerobic capacity tests (4.54/10; SD 3.74) and in interpreting the results (4.79/10; SD 3.58). A large majority would be interested in further education around measuring PA (83%) and aerobic capacity measurement (74%), with an online module favoured for both.
**Conclusions:** The majority of Health Professionals surveyed believe it is important to measure PA however, levels of confidence are moderate to low when using various devices/ways. Regarding aerobic capacity tests low levels of familiarity were reported for both performing and interpreting results. There is strong interest in further education around measuring PA and aerobic capacity measurement highlighting a need to develop education and training for HP's in this area.

## THU0651-HPR STRUCTURE, PROCESS AND OUTCOME OF PRIMARY CARE RHEUMATOLOGY NETWORKS FOR PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES IN THE NETHERLANDS

W.F. Peter[1], F.J. van der Giesen[1], S. de Jong[2], Y. Kat[2], E.H. van den Ende[3], J. Dekker[4], T.P. Vliet Vlieland[1] on behalf of Rheumatology Network Project Group. *[1]Dep of Orthopedics, Leiden University Medical Center, Leiden; [2]Dutch Arthritis Foundation, Amsterdam; [3]Dep of Rheumatology, St.Maartenskliniek, Nijmegen; [4]Dep of Rehabilitation Medicine, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Primary care networks of health professionals (HPs) are instituted to improve the quality of care for patients with rheumatic and musculoskeletal diseases (RMDs). So far, research into their organization and outcomes is limited.
**Objectives:** To describe the characteristics of primary care rheumatology networks in the Netherlands, and satisfaction of patients with RMDs treated by network members.
**Methods:** Through the Internet and personal communication, existing primary care rheumatology networks were identified. Data on network characteristics were collected by interviewing network coordinators, and an online questionnaire for all network members (organizational aspects, education, patient load, and satisfaction). Members were asked to invite max. 4 patients to complete an online satisfaction questionnaire (Consumer Quality Index (CQ) subscales: Information, Attitude of HPs, Cooperation and Self-management (range 1–4)), and grading satisfaction (range 1–10). Satisfaction scores of patients treated within the networks were compared with aggregated data from a national dataset of 1648 patients treated in 45 physiotherapy (PT) practices using unpaired Students' T-tests.
**Results:** 19 rheumatology networks were identified, with 5 having an organizational structure, 17 networks set membership criteria, in 7 a fee was imposed. In 10 networks patients were involved, and 17 collaborated with a hospital rheumatology department. There were 479 network members (median 18 per network, range 7–106), with 15 including only PTs, 18 organized network meetings for professionals and 11 for patients. Communication within the network and with referring rheumatologists was scored as insufficient by 7 and 6 network coordinators, respectively, whereas all expressed the need for central support regarding network organization and activities. 214 network members returned the online survey, 38% had taken part in accredited postgraduate education on RMDs, 21% had seen no patients with Rheumatoid Arthritis, Osteoarthritis or Spondylarthropathy in the past year. Standardization of postgraduate education and organizational requirements for networks was desired by 70–80% of the members. 149 patients returned the survey. Compared to the reference set the patients treated in the rheumatology networks were significantly more satisfied

concerning CQ information (3.6 (SD 0.4) vs 3.8 (SD 0.3); CQ attitude of health professionals (3.8 (SD 0.3) vs 3.9 (SD 0.3); CQ cooperation and self-management (3.3 (SD 0.6) vs 3.5 (SD 0.5); and overall satisfaction (8.7 (SD 0.8) vs 8.4 (SD 1.1) (all $p<0.001$).

**Conclusions:** There is a large variety concerning the structure and process of primary care networks focusing on the management of patients with RMDs in the Netherlands. Although their added value with respect to patient satisfaction is plausible, there is a need for standardization of postgraduate education and the organization of such networks on the national level.

**Acknowledgement:** This study was financially supported by the Dutch Arthritis Association.

We are indebted to all HPs, patient representatives, rheumatologists, and other stakeholders for their valuable contribution to the project (interviews, surveys, group meetings and individual advices).

## Physiotherapy & miscellaneous forms of clinical care

### FRI0610-HPR COMPARATIVE STUDY OF THE FUNCTIONAL MEASUREMENTS OF THE RHEUMATIC FOOT

Á. Kőszegvári[1,2], B. Monek[1,2], A. Mikula[1], G. Poór[1]. [1]*National Institute of Rheumatology and Physiotherapy;* [2]*Department of Physiotherapy, Semmelweis University, Institute for Applied Health Sciences, Budapest, Hungary*

**Background:** During rheumatoid arthritis the structure of the foot as well as the plantar pressure surfaces are changing due to the disease. The examinations carried out with the help of machines serve as an overview of the objective state of the foot during function, whereas the functional surveys cumulate the subjective opinion of the patients during the everyday usage of the foot.

**Objectives:** In the study research methods were used which help the work of the physiotherapists, have lack of tool demand and make the diagnosis more accurate.

**Methods:** The study was carried out from 2015 September onwards among the patients of the National Institute of Rheumatology and Physiotherapy with rheumatoid arthritis (RA) and osteoarthritis (OA). The survey was based on the Foot Functional Index (FFI), the Leed's Foot Impact Scale (LFIS) and Health Assessment Questionnaire (HAQ). The function of the foot during walking was examined by the Zebris-FDM Treadmill system (7 zones e.x. Forefoot Medial, Lateral, Heel Medial, Lateral). To examine the structural deviations and deformities the Foot Posture Index (FPI) was used. The percentage values of time maximum force measured by the Zebris FDM-T system compared with FPI values. The examination consisted of two groups, patients with RA (n=23, age mean=61,47±11,13 years) and OA (n=22, age mean=59,54±13,73 years) as control group. For statistical analysis Statsoft Statistica v. 7.0 61.0 EN program was used and the Pearson correlation was calculated. The results were defined with $p<0,05$ statistical margin.

**Results:** In the values of the questionnaire based examination, there were significant correlations between FFI and $LFIS_{IF}$ (r=0,606; p=0,002), FFI and LFIS (r=0,511; p=0,013), $LFIS_{AP}$ and HAQ (r=0,537; p=0,008) in RA. In the control group there were significant correlations between FFI and $LFIS_{IF}$ (r=0,430; p=0,046), FFI and $LFIS_{AP}$ (r=0,727; p=0,000), FFI and LFIS (r=0,680; p=0,000), FFI and HAQ (r=0,794; p=0,000), HAQ and $LFIS_{AP}$ (r=0,635; p=0,001), HAQ and LFIS (r=0,575; p=0,005).

In the results of the dynamic and static measurement methods, there was a significant tendency between FPI and Forefoot Lateral (p=0,085) and there was a negative correlation between FPI and Heel Medial (r=-0,922; p=0,026) in RA group (FPI>5). In the OA group there were significant tendencies between FFI and Forefoot Medial (r= -376; p=0,084) and between FFI and Heel Medial (r=-0,395; p=0,068).

**Conclusions:** Our study is the first comparison of the physical examination, gait analysis and questionnaires in case of rheumatic foot.

In the light of the results it is recommended in the clinical practice that both static and dynamic examinations should be executed.

### FRI0612-HPR THE DEVELOPMENT OF PHYSIOTHERAPY-LED MUSCULOSKELETAL TRIAGE SERVICES IN IRELAND

A. Brennan[1], R. Breen[2], J. Ashton[2], C. Edel[3], C. Farrell[4], D. Moore[1], P. Kenny[5], O. FitzGerald[6]. [1]*Tallaght Hospital, Tallaght, Dublin 24;* [2]*Beaumont Hospital, Dublin;* [3]*Merlin Park, Galway;* [4]*RSCI;* [5]*Connolly Hospital, Blanchardstown;* [6]*St Vincents University Hospital, Dublin, Ireland*

**Background:** In 2012, funding was approved for twenty-four Advanced Practice Physiotherapy (APP) posts in Ireland through the Clinical Strategy and Programmes Directorate of the HSE. These posts were to provide orthopaedic and rheumatology triage clinics across 16 hospitals throughout the country.

**Objectives:** The aims of these clinics were to reduce the waiting time for outpatient consultation for orthopaedic and rheumatology patients; to establish a diagnosis and triage patients along the most appropriate care pathway according to their diagnosis.

**Methods:** Initially 18 APPs were recruited in 2012 and currently there are 22.5 in post nationally. Guidelines regarding inclusion for attendance at these clinics were disseminated to APPs recruited to posts. Clinical governance for APP clinics is provided by either a consultant orthopaedic surgeon or a consultant rheumatologist who provide support with clinical diagnosis; with the ordering of investigations and with management of patients as appropriate.

**Results:** From January 2012 to May 2015 48,279 patients have been removed from orthopaedic and rheumatology waiting lists nationally. In orthopaedic clinics APPs reviewed 33,092 new patients and discharged 25,917 (78%); in rheumatology clinics APP's reviewed 7,550 new patients and of this 5,417 (72%) were discharged following their review.

**Conclusions:** Advanced Practice Physiotherapist's can assist in the management of orthopaedic and rheumatology waiting lists. These services provide patients with early access for a specialist opinion and management and therefore prevent chronicity of symptoms. It can be hypothesized that prevention of chronicity would result in a reduction in the use of health care resources by this subgroup of patients.

### FRI0613-HPR DO PHYSIOTHERAPISTS DOCUMENT WEIGHT AND DISCUSS THE INFLUENCE OF WEIGHT ON PATHOLOGY IN PATIENTS WITH OSTEOARTHRITIS?

A. Brennan[1], M. Maria[1], P. Robinson[1], M. Fitzgerald[1], H. Nolan[1], E. Sheehy[1], A. Curley[1], E. Lee Moloney[2], R. McCullom[1], C. Kelleher[1], C. Ni She[1]. [1]*Tallaght Hospital, Tallaght, Dublin 24, Dublin, Ireland;* [2]*Physiotherapy, Tallaght Hospital, Tallaght, Dublin 24, Dublin, Ireland*

**Background:** There is a strong association between increased body weight and osteoarthritis (OA). The NICE (2014) and ACR (2012) guidelines strongly recommend that patients with OA consider weight loss if overweight.

**Objectives:** The aim of this audit was to investigate if physiotherapists treating patients with knee and lumbar-spine OA: i) Documented patients weight; ii) Discussed the role of increased weight on OA

**Methods:** An audit of seventy physiotherapy charts of patients attending physiotherapy in 2013 found that 15percent (knee) and 11percent (lumbar-spine) had their weight documented. The role of increased weight was discussed with 15percent (knee) and 11percent (lumbar-spine). A "BMI station" was set up to use with patients. A lifestyle education class was established. In 2015 a re-audit was carried out on patients who attended for physiotherapy in 2014.

**Results:** Seventy physiotherapy charts were randomly selected and included. The median age was 64years (knee) and 53years (lumbar-spine). Of these 7 were male and 23 female (knee), 17 were male and 19 female (lumbar-spine). Of these, 38percent (knee) and 31percent (lumbar-spine) had their weight documented. The role of increased weight was discussed with 19percent (n=7) (knee) and 22percent (n=8) (lumbar-spine).

**Conclusions:** Physiotherapists have improved in relation to documenting weight and discussing the role of increased weight on OA since the previous audit. However, it is evident that they do not regularly document weight in patients with knee and lumbar-spine OA or document if they advised patients regarding the role of weight management for the treatment of OA. Further strategies to address this are necessary.

### FRI0614-HPR DELAYED DIAGNOSIS, PAIN AND LOSS OF FUNCTION ARE SOME OF THE CONSEQUENCES OF SPONTANEOUS FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS – A QUALITATIVE ANALYSIS OF PATIENTS' EXPERIENCE

A. Havelund Rasmussen[1], D. Melgaard[1], A. Yurtsever[2], P. Simonsen Lentz[1]. [1]*Physio- and Occupational Therapy;* [2]*Medicine Department, Vendsyssel Hospital, Hjørring, Denmark*

**Background:** Spontaneous fractures in patients with rheumatoid arthritis (RA) have only occasionally been reported in the literature[1,2]. However, rheumatologists

at Vendsyssel Hospital have noticed several cases where new onset knee or ankle pain was misdiagnosed as arthritis activity but was later shown to be spontaneous fractures. An x-ray examination did not reveal the fracture, but it was identified on an MRI examination. The fractures are at risk of being overlooked, and this fact may lead to a delay in diagnosis and a risk of ineffective treatment with e.g. steroid injections.

**Objectives:** The study was carried out in the Physio- and Occupational Therapist unit in Vendsyssel Hospital. The included patients were diagnosed with RA and spontaneous fractures. Fifteen patients, all women, were identified. Ten patients in the age of 57–88 years participated in the study. They had an average disease duration of 14.2 years and a MRI was performed at a median of eight months.

**Methods:** The patients were divided into two age specific groups: 57–69 and 70–88 years. The focus groups data were subjected to thematic analysis to provide a sense of the important themes. Categorizing, coding and analysing the data from the focus groups identified the themes.

**Results:** All patients identified the missing diagnosis as a significant burden. The patients were experiencing pain, but did not receive a diagnosis or an explanation for their symptoms. "I've never been as happy as when I was told my leg was broken ..." Most of the patients experienced more pain than usual for their RA: *"You suddenly have a lot more pain, but you just don't know where it comes from".* All patients noticed a significant loss of function before the diagnosis was made and during immobilisation: *"I was so unhappy about not being able to do anything ... even just getting up at night to go to the toilet ...".* When the patients were immobilised they were offered crutches, but they were not able to use standard crutches due to their RA: *"I can't use crutches because I don't have enough strength to lift myself..."*

**Conclusions:** Patients with RA with spontaneous fractures experience the delayed diagnosis as a burden, and it is stressful for them to wait for an explanation for their pain. Due to the patients missing ability to use crutches or use a wheelchair, it is important to find other aids that patients with RA and spontaneous fractures can use. When the patients were immobilised they experienced loss of function. This calls for the need to focus on the diagnosis and guidance of these patients in relation to daily activities and aids.

## FRI0615-HPR BLUNTED CARDIAC AUTONOMIC RESPONSE TO THE ACTIVE STANDING IS RELATED TO THE IMPACT OF FIBROMYALGIA ON QUALITY OF LIFE

A.R. Zamuner, C.P. Andrade, M. Forti, E. Silva. *Department of Physical Therapy, Federal University of Sao Carlos, Sao Carlos, SP, Brazil*

**Background:** Several studies have shown that autonomic dysfunction plays an important role in the fibromyalgia syndrome (FMS).[1–3] Recent studies have used the active standing test to assess the cardiovascular autonomic control responses to the orthostatic stimulus in several disorders, including FMS.[4] However, there are few studies correlating symptoms and clinical factors with cardiovascular autonomic dysfunction.

**Objectives:** To assess the relationship between the impact of fibromyalgia on quality of life and cardiac autonomic control response to the active standing test.

**Methods:** Ten women (47.9±7.3 years old) with clinical diagnosis of FMS took part in the study. Diagnosis followed the criteria established by the American College of Rheumatology.[5] All participants answered the fibromyalgia impact questionnaire (FIQ)[6] and underwent the recording of RR intervals (RRi) using a transmitter belt. The RRi were recorded for 15 min in resting supine position and during 15 min in an orthostatic position reached by active standing. The cardiac autonomic control was assessed by indices computed via spectral analysis of RRi in low frequency (LF, 0.04–0.15 Hz) and high frequency bands (HF, 0.15–0.4 Hz). To quantify the magnitude of cardiac autonomic response to the orthostatic stimulus, the delta between values obtained in supine and standing positions was calculated for all variables. Changes induced by the orthostatic stimulus were evaluated by Wilcoxon test. Spearman's coefficient was used to assess the association between the delta of the HRV indices and the FIQ scores. $\alpha$ =5%.

**Results:** There were no significant differences between the supine and standing positions in any of the spectral indices. Positive correlation was found between FIQ scores and HF (n.u.) (r =0.67; p=0.03). Negative correlations were observed between the FIQ scores and LF (n.u.) index (r = -0.67; p=0.03, Figure 1B) and LF/HF ratio (r = -0.73; p=0.016, Figure 1C).

**Conclusions:** The results showed that the larger the magnitude of the cardiac autonomic adjustments to the gravitational stimulus, the smaller the impact of FMS on quality of life.

## FRI0616-HPR CARDIAC AUTONOMIC RESPONSE TO OSTHOSTATIC CHANGES IN FIBROMYALGIA SINDROME

C.P. Andrade, A.R. Zamunér, M. Forti, E. Silva. *Department of Physical Therapy, Federal University of Sao Carlos, São Carlos, Brazil*

**Background:** Patients with fibromyalgia syndrome (FMS) have autonomic nervous system (ANS) related disorder[1]. The orthostatic stimulus is an important method for the assessment of neurocardiac integrity[2]. However, little is known about the cardiac autonomic response to the active standing test in women with FMS.

**Objectives:** To evaluate the cardiac autonomic control response to the active standing test in women with FMS.

**Methods:** Ten women with FMS (FMSG n=10) and ten healthy women (HG n=10) took part in the study. The volunteers were submitted to the recording of RR intervals (RRi) during 15 min in supine and 15 min in orthostatic (active standing) positions. RRi were recorded by a heart rate monitor. The parameters of the frequency domain were determined by the heart rate variability (HRV) spectral analysis, obtained in low frequency (LF, 0.04–0.15 Hz) and high frequency bands (HF, 0.15–0.4 Hz) in normalized units (n.u.) and LF/HF ratio[3].

**Results:** The results are shown in table 1. There were significant group x posture interaction for LF (n.u.) and HF (n.u.). Post hoc analysis revealed that the HG increased LF (n.u.) and decreased the HF (n.u.) during active standing, compared to the supine position. On the other hand, the FMSG presented no significant differences between supine and orthostatic position. Regarding between group comparisons, FMSG presented higher LF (n.u.) and lower HF (n.u.) at supine position.

Table 1. Power Spectral Analysis in the HRV of FMSG and HG from supine position to orthostatic (active standing)

| | HG (n=10) | | FMSG (n=10) | | P-value | | |
|---|---|---|---|---|---|---|---|
| | Supine | Orthostatic | Supine | Orthostatic | Posture | Groups | Interaction |
| LF (n.u.) | 50.11±10.28*† | 71.03±8.54 | 72.13±11.00 | 71.62±14.58 | 0.006 | 0.009 | 0.004 |
| HF (n.u.) | 49.89±10.28*† | 28.97±8.54 | 27.87±11.00 | 28.37±14.58 | 0.006 | 0.009 | 0.004 |
| LF/HF | 1.09±0.46*† | 2.82±1.45 | 3.26±2.13 | 4.82±2.20 | 0.03 | 0.04 | 0.08 |

Data are expressed as mean± SD. LF = low frequency component of RR intervals; HF = high frequency component of RR intervals; n.u. = normalized units. Two-way mixed ANOVA with Bonferroni's post hoc test. *p<0,05 GS supine posture vs FMSG supine posture. †p<0,05 GS supine posture vs GS orthostatic posture.

**Conclusions:** FMSG showed cardiac autonomic dysfunction at supine position, characterized by higher sympathetic and lower parasympathetic cardiac autonomic

modulation. In addition, FMSG present a blunted cardiac autonomic control response to the active standing, characterized by a lack of cardiac sympathetic modulation increase and parasympathetic decrease. Therefore, the neurocardiac integrity seems to be compromised in the FMSG.

## FRI0617-HPR AN AUDIT OF THE ROLE OF A CLINICAL SPECIALIST PHYSIOTHERAPIST IN RHEUMATOLOGY TRIAGE

C.M. Cullen[1], M. Phelan[2], S. Harney[3], J. Ryan[3]. *[1]Physiotherapy; [2]Rheumatology, South Infirmary Victoria University Hospital; [3]Rheumatology, Cork University Hospital, Cork, Ireland*

**Background:** Clinical Specialist Physiotherapy roles were developed in Ireland in 2012 as part of the National clinical care programs. A Rheumatology triage post was assigned to the South /South West group. The Musculoskeletal Assessment Clinic (MAC) runs across two sites the South Infirmary Victoria University Hospital (SIVUH) and Cork University Hospital (CUH). Triage by physiotherapists has been running in other parts of the world for a number of years with favourable outcomes in terms of patient experiences, GP satisfaction and diagnostic accuracy (1). Patients are triaged to the MAC by the Rheumatology consultant based on information supplied in the GP referral letter indicating non inflammatory conditions. These include mechanical neck and back pain, OA and soft tissue rheumatism suitable for injection therapy.
**Objectives:** The objective of this of this audit was to establish (1) the number of patients seen at MAC (b) number of referrals onwards to the Rheumatology consultant led clinics from MAC, (c) to assess the appropriateness of these onward referrals (d) the rate of re-referral to the rheumatology service of patients assessed at the MAC Rheum and discharged.
**Methods:** A retrospective audit of GP referrals to the Rheumatology service triaged to MAC between July 2012 and October 2015 was undertaken.
**Results:** 1,297 new patients were assessed at the MAC between July 2012 and October 2015. 92% were managed by the triage physiotherapist without seeing the Rheumatology team although in some cases the physiotherapist did consult with the Rheumatology consultant at initial assessment. 8% (98 Patients) were referred to a Rheumatology consultant led clinic for assessment. Of these 49% (48) were confirmed as having an inflammatory arthritis, 39% (38 patients had a variety of other diagnoses requiring medical review including SLE,CREST, Paget's, new vertebral fracture and CPPD. The remaining 12% (12 patients) were diagnosed as OA on review and discharged. At the time of audit 4% (55 patients) had been re-referred to the service. 2% (1 patient) was assessed by the Rheumatology consultant and diagnosed as having an inflammatory arthritis. 25% (14 patients) were reviewed at MAC and discharged, 22% (12 patients) were reviewed by consultant and discharged. 4% (2 patients) DNA follow up appointment. 47% (26) were still awaiting routine review with consultant.
**Conclusions:** 92% of patients triaged to the MAC were assessed and managed by the triage physiotherapist without the need for review by the Rheumatology team. The low rate of onward referral (8%) from MAC to Rheumatology and of re-referral (4%) to the Rheumatology service would appear to indicate the patients triaged to the MAC are appropriate for that pathway. Of the patients referred on to the consultant clinic 88% required input by the Rheumatology team. This initiative helps reduce OPD waiting times for specialist services by reducing the time spent by the Rheumatology team on non inflammatory mechanical disorders. GP satisfaction and patient experience surveys are currently being undertaken and the results will be included in the presentation.

## FRI0618-HPR THE SHORT-TIME EFFECTS OF KINESIOTAPING ON HALLUX VALGUS DEGREE, PAIN INTENSITY AND PLANTAR PRESSURE DISTRIBUTION IN RHEUMATOID FOOT: A PILOT STUDY

E. Tonga[1], B. Özgül[1], E. Timurtaş[1], I. Demirbüken[1], N. Şen[2], M.E. Tezcan[2], M.G. Polat[1]. *[1]Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Marmara University; [2]Department of Rheumatology, Dr. Lüffü Kırdar Kartal Education and Research Hospital, Istanbul, Turkey*

**Background:** Hallux valgus is one of the most common deformities of rheumatoid arthritis.[1] The foot deformities as hallux valgus that causes consequent antalgic gait often result in unusual forces on bones and soft tissues of the plantar surface.[2] Accordingly, elevated plantar pressures while walking are thought to cause mechanical damage to the rheumatoid foot.[3] A recent study showed that 10-day kinesiotape implementation improved the pain and joint alignment in patients with hallux valgus.[4] There is no study that investigates the implementation effects of kinesiotaping in rheumatoid foot.
**Objectives:** The aim of this study is to investigate the effects of kinesiotaping on hallux valgus angle, pain intensity and plantar pressure distribution in individuals with rheumatoid arthritis.
**Methods:** A total of 6 rheumatoid arthritis patients (age:50.00±10.71 years, HAQ: 18.66±3.82) diagnosed with hallux valgus in total of 12 feet were recruited in our study.A toe goniometer was used to determine the angle of hallux valgus, Visual Analog Scale (VAS) was used for pain assessment, Foot Posture Index (FPI) was used to determine foot posture and Emed-50/D pedobarographic system was used to analyze peak pressure under 10 foot regions. Kinesiotaping was implemented after the first assessment and renewed in days 3 and 7 by a qualified physiotherapist with 5-year experience. After the big toe was aligned to its estimated correct with a moderate to high tension, first Y-shaped kinesiotape was implemented through the first ray. The second Y-shaped tape was placed over metatarsophalangeal joints with a mechanical correction technique on hallux.[4] The evaluations were renewed in days 3, 7, and 10. Friedman test was used to compare to differences among repeated assessments.
**Results:** All of the feet were determined as normal foot posture according to FPI. There was a significant reduction in hallux valgus angle ($\chi^2$=27.94, $p<0.001$). There was significant reductions for the assessment of days of 3, 7, and 10 compared to initial assessment of VAS scores ($p<0,05$). There was no significant differences at peak pressure data under 10 foot regions among all repeated assessments ($p>0,05$).

**Conclusions:** Pain and hallux valgus angle were decreased after a 10-day kinesiotape implementation in patients with RA. Our results of plantar pressure distribution couldn't show statistically change which might arise by low number of patients. Further studies should be carried out by increasing the number of cases in the future. Also radiographic changes of foot should be investigated in long term.

## FRI0619-HPR INVESTIGATING THE EFFECTS OF A MULTIDIMENSIONAL EXERCISE PROGRAM ON SYMPTOMS AND ANTIINFLAMMATORY STATUS IN OA PATIENTS OF THE KNEE

E. Unal[1], P. Kısacık[1], S. Oksuz[2], G. Arın[1], O. Dogan[3], E. Karabulut[4]. *[1]Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Science, Ankara, Turkey; [2]Physiotherapy and Rehabilitation, Eastern Mediterrenean University Faculty of Health Science, Famagusta, Cyprus; [3]Child Development, Hacettepe University Faculty of Health Science; [4]Biostatistics, Hacettepe University Faculty of Medicine, Ankara, Turkey*

**Background:** Effects of exercise on pain, physical function, daily living activities

and cytokines have been investigated in osteoarthritis (OA) patients (1). However there is no reported multidimensional approach including all these parameters at once in OA patients. On the other hand, the cognitive exercise therapy approach (BETY: Bilişsel Egzersiz Terapi Yaklaşımı) was used as a multidimensional exercise model including effects of improvements on symptoms and anti-inflammatory status in ankylosing spondylitis patients (2).

**Objectives:** The purpose of this study is to investigate the effects of a multidimensional (BETY) exercise program on symptoms and anti-inflammatory status in OA patients of the knee.

**Methods:** Forty patients with knee osteoarthritis defined as Kellgren-Lawrence (K-L) grade1 and 2, were included in this study, and divided randomly into two groups (BETY group and control). Health Assessment Questionnaire (HAQ), The Western Ontario and McMaster Universities Arthritis Index (WOMAC) was used for functional evaluation and IL-6 were analyzed for anti-inflammatory status in both groups. Control group did not get any exercise intervention. However, BETY group were participated to exercise sessions 3 times a week for 10 weeks. All measurements were repeated after 10 weeks in both groups.

**Results:** WOMAC pain, physical function and WOMAC total score values were decreased significantly ($p<0.05$) in exercise group. However HAQ, WOMAC stiffness score were remained stable according to pretreatment values in this group ($p>0.05$). Although any significant change in IL-6 in both groups were not observed, IL-6 decreased in BETY group. Moreover, TNF-a showed significant increase in control group ($p<0.05$). No change was observed for other values between pre- and post-treatment in control group ($p>0.05$). There was no difference between two groups after 10 weeks ($p>0.05$).

Table.1. Comparison of the all scores

| | BETY group (n=19) | | | Control group (n=21) | | | P intergroups |
|---|---|---|---|---|---|---|---|
| | X ± SD | | p | X ± SD | | p | |
| | Before | After | | Before | After | | |
| WOMAC $_{pain}$ | 3.94±2.20 | 3.44±2.00 | 0.019 | 3.09±1.49 | 2.87±1.78 | 0.531 | 0.373 |
| WOMAC $_{function}$ | 4.30±1.91 | 3.24±1.81 | 0.013 | 3.40±1.56 | 3.01±2.37 | 0.045 | 0.610 |
| WOMAC $_{stiffness}$ | 0.46±0.22 | 0.41±0.23 | 0.223 | 0.35±0.24 | 0.34±0.23 | 0.832 | 0.419 |
| WOMAC $_{total}$ | 8.71±4.16 | 7.09±3.72 | 0.015 | 7.00±3.14 | 6.23±4.14 | 0.099 | 0.452 |
| HAQ | 11.88±8.50 | 9.29±9.06 | 0.224 | 8.38±6.29 | 6.42±5.45 | 0.171 | 0.490 |
| IL-6 | 5.21±6.12 | 2.96±1.77 | 0.053 | 2.68±0.76 | 2.45±1.14 | 0.195 | 0.524 |
| TNF-a | 4.45±2.00 | 4.65±2.47 | 0.753 | 3.44±2.10 | 4.27±2.09 | 0.047 | 0.641 |

**Conclusions:** This study is an original study in terms of analyzing exercise-induced TNF-a and IL-6 relationship in OA patients of the knee. We concluded that BETY program did not cause negative effects in OA patients. BETY should be taken into consideration as a multidimensional exercise program for OA patients.

## FRI0620-HPR EFFICACY OF LOCAL INFILTRATION ANALGESIA IN TOTAL KNEE ARTHROPLASTY: A RANDOMISED, PLACEBO-CONTROLLED, DOUBLE-BLIND TRIAL

B. Unver[1], E. Yuksel[2], S. Kalkan[2], F. Maltepe[1], V. Karatosun[1]. *[1]Dokuz Eylul University, izmir, Turkey; [2]Physical Therapy and Rehabilitation, Dokuz Eylul University, izmir, Turkey*

**Background:** Total knee arthroplasty (TKA) is a common surgical procedure in patients with end-stage osteoarthritis to reduce pain and improve locomotor function. However, TKA may result in severe postoperative pain, usually requiring hospitalization from 5 to 10 days to provide effective analgesia (1). Local infiltration analgesia (LIA) is a simple technique for the treatment of postoperative pain after TKA. However, the specific efficacy of LIA has been confounded by frequent limitations in study design (2).

**Objectives:** To investigate the efficacy of LIA in patients with TKA.

**Methods:** The study was designed as a *randomized double blind placebo control* trial. A total of 63 patients with primary total knee arthroplasty were randomized either to receive a periarticular local infiltration analgesia or to receive placebo injection (63 patients: 57 knee in LIA group, 44 knee in placebo group). Pain intensity, active range of motion, knee function score [Hospital for Special Surgery (HSS) score] and length of hospital stay (LOS) were evaluated. Functional activities were evaluated using the Iowa Level of Assistance Scale, and walking speed was evaluated using the Iowa Ambulation Velocity Scale. The dates of ability to perform straight leg raise actively and to reach 70° of knee flexion were recorded. Patients and investigator were blinded the groups.

**Results:** There were no significant differences between the groups for demographic characteristic. Lower pain scores were recorded on postoperative day 1 and postoperative day 2 after the operation in Group LIA ($p<.0001$ and $p=0.022$, respectively). Higher range of motion of knee flexion and extension postoperative day 1 and postoperative day 2 in Group LIA (Flexion:$p=0.004$ and $p=0.020$, respectively; extension: $p=0.028$ and $p=0.022$ respectively). There were also a significant differences in terms of the date of 70° knee flexion reach ($p=0.034$) and ability to perform straight leg raise actively in favour of Group LIA ($p=0.034$). There was no significant difference between the groups in the HSS score, Iowa Level of Assistance Scale, Iowa Ambulation Velocity Scale and LOS.

**Conclusions:** Andersen and Kehlet reported that LIA significantly reduced pain intensity, specifically during standing and walking up to 48 h after operation. Our results suggest that LIA significantly reduced pain intensity in early postoperative day. This results are corroborate with Andersen and Kehlet's study (2). We also have found a better recovery of knee flexion immediately after operation. Possible mechanisms of better recovery of knee flexion could be lower pain scores. Patients with lower pain scores can also perform earlier straight leg raise. However, LIA technique did not provide additional impact on LOS because LOS depends on many other factors. In conclusion, LIA significantly reduced pain intensity, improve recovery of active range of motion but did not provide additional impact on LOS compared with placebo injection in patients with TKA.

## FRI0621-HPR REFERENCE VALUES FOR THE MODIFIED FUNCTIONAL REACH TEST IN YOUNGER AND MIDDLE-AGED TURKISH POPULATION

E. Yuksel[1], D. Ilgin[2], H. Kul Karaali[2], O. Ozcan[2], B. Unver[1]. *[1]Physical Therapy and Rehabilitation, Dokuz Eylul University, izmir; [2]Physical Therapy and Rehabilitation, Celal Bayar University, Manisa, Turkey*

**Background:** Modified Functional Reach Test (MFRT) is reliable, precise, and less time-consuming for detecting dynamic sitting balance (1). Normative data for this measurement tool have been reported in Indian and American population (1,2). Reference values for MFRT are not available in Turkish population.

**Objectives:** Our aim was to establish reference values for the MFRT to examine the effect of gender and various anthropometric measurements on MFRT in healthy younger and middle-aged Turkish population

**Methods:** Ethics approval for this study was obtained from the Ethics Committee of Celal Bayar University. Informed consent was obtained from all participants in accordance with the Declaration of Helsinki before participation.

Participants (employee and academic staff) were recruited from Celal Bayar University campus. Permission was obtained from authorities of the University to carry out the study. Therefore, 462 participants within the age range of 20 to 59 years successfully included to the study and completed all necessary process. Based on the literature, these participants were stratified into 2 age groups; younger age group (ages 20–39 years) and middle age group (ages 40–59 years). There were 278 people in the younger age group and 184 people in the middle-aged group.

Prior to testing, the participants were screened based on inclusion criteria: both gender without balance problems, healthy subjects and 120 of shoulder flexion and abduction range of motion to perform the reach tests. Participants were excluded based on following criteria: any neurological disorder, balance disorder and any treatment for an ear infection within the past 6 weeks.

**Results:** For younger age group, the reference value of forward reach was 41.8±11.9 cm and reference values for lateral right and left reach were 30.9 ± 9.5 cm and 30.5 ± 9.5 cm, respectively. For middle-aged group, the reference values of forward, lateral right and left reach were 46.3± 12.4 cm, 33.1±10.5 cm and 32.9±10.8 cm, respectively. There is no significant differences between male and female in terms of all scores in each group. Anthropometric characteristics were similar in both age groups.

**Conclusions:** Although these reference values are similar with American populations, the mean MFRT scores for younger and middle aged Turkish population are higher than same age Indian population, especially reference values of lateral reaches. These normative data will be also useful to researchers and clinicians in the sitting balance assessment in the Turkish population.

FRI0622-HPR **A NEW PATIENT REPORTED TOOL IN THE ASSESSMENT OF PHYSIOTHERAPY FOR PATIENTS WITH KNEE OSTEOARTHRITIS**

H. Nutland, A. Dean, M. Nisar, R. Laxminarayan, H. Smith, S. Arthanari. *Dept of Rheumatology, Burton Hospitals NHS Foundation Trust, Burton on Trent, United Kingdom*

**Background:** Symptoms in patients with knee osteoarthritis (KOA) reflect many factors including lifestyle, fitness, weight, extent of damage and altered biomechanics etc. Our patients with KOA attend an education session followed by 4 weekly exercise sessions. The aim of the program is to improve knowledge and understanding and self-management techniques. Activity modification and exercises help symptoms in the short term and provide motivation in the long term. A new user-friendly patient reported outcome measure has been developed to easily and reliably assess patient perspectives of well-being and symptoms in musculoskeletal conditions. The application of this tool in KOA is explored
**Objectives:** To use a new patient reported outcome tool to assess the value of the components of a specific package of physiotherapy for KOA
**Methods:** 49 consecutive patients referred from rheumatology clinics with a diagnosis of KOA completed the assessment tool at their first physiotherapy session.
The tool consists of 12 statements each defining a separate domain - communication, relationships, knowledge, anxiety, fatigue, pain, movement, strength, independence, mobility, work and social aspects. These are domains assessed independently or in three clusters broadly addressing emotional, physical and functional status of the patient at a time point.
The patients score each of the 12 statements on a visual analogue scale (0–10) reflecting their perceived status in that domain at the time of assessment. The measure is repeated with the patient blinded to original scores after their final exercise session in the KOA program.
The change in domain scores is documented on a database allowing multi-variate analysis within individual domains and the three composite clusters
**Results:** Overall improvement with the treatment program was reported by 41 (84%) of patients with improvement ranging from 30% in 9 (18%) to 10% in 27 (55%) of patients. Thus only 8 patients reported a decline after the treatment program. In patients with decline in average scores, this is domain specific and not global. Overall cohort analysis shows on average all 12 domains improved but to varying degrees with the largest VAS change ($\geq$2.0) in two domains, ability to communicate and knowledge of their condition. In three domains (relationships, independence and social activities) change was marginal with average VAS improvement score less than 1.0. In the other 7 domains improvement was moderate ranging between 1.0 and 2.0 on the VAS.
**Conclusions:** The new tool is effective and efficient in a time limited, busy clinical setting. It is easily understood and quickly completed by patients allowing for accurate reflection of their domain specific perspective at a specific time.
Through the successful application of this assessment tool the value of this specific physiotherapy package of care has been demonstrated. This validation of practice is of value to patients, the clinical team involved and managers. The tool allows the assessment of positive and negative response to the treatment package to be analysed within domains. KOA patients improve in physical and functional clusters but show only marginal change in the emotional cluster of domains. Our new patient assessment tool will allow for appropriate and informed modifications of the treatment package to further improve patient outcome.

**DOI:** 10.1136/annrheumdis-2016-eular.5926

FRI0623-HPR **KINESIOPHOBIA AFFECTS RANGE OF KNEE FLEXION AT EARLY STAGE FOLLOWING ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION**

I. Demirbüken, B. Özgül, E. Arıkan, E. Tonga, M.G. Polat. *Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Marmara University, Istanbul, Turkey*

**Background:** One of the most common complications following anterior cruciate ligament (ACL) reconstruction in sport rehabilitation is loss of knee motion (1). A fear of re-injury of ACL may contribute limitations of knee functions in terms of range of motions during rehabilitation process (2). Some athletes are not able to return to their pre-injury level due to loss of knee function and fear of motion in other words kinesiophobia.
**Objectives:** To investigate the relationship between range of motion (ROM) of the knee which is an important target in rehabilitation and kinesiophobia degree following ACL reconstruction in professional athletes.
**Methods:** The study was carried out with 14 certified athletes (8 male and 6 female, mean age: 21.5±5.86 years; mean body weight: 68.7±15.2 kg; mean height: 177.5±10.3 cm) who had unilateral ACL reconstruction and started post-op physiotherapy treatment participated in the study. All assessments were performed at 15th day following reconstruction. Kinesiophobia degrees of the athletes were assessed with Tampa Kinesiophobia Scale. A high score obtained from the scale indicates a high degree of kinesiophobia. Active and passive flexion degrees of knee joint were measured by using goniometer in accordance with Kendall-McCreary's criteria. All ROM measurements were performed 3 times and mean values of 3 measurements were saved for data analysis. The relationships between kinesiophobia degrees and active & passive flexion of the knee joint were analyzed by using Spearman's Correlation test.
**Results:** There was a strong negative relationship between the kinesiophobia degrees and active ($r=-0.881$, $p<0.001$) & passive ($r=-0.887$, $p<0.001$) ROM degrees of knee flexion.
**Conclusions:** One of the important aims of the treatment following ACL reconstruction is regaining functional level before injury and providing an early return to sports without any movement limitation. The results of this study revealed that presence of kinesiophobia at early stage influenced active and passive range of motion of knee joint negatively. Assessment of the kinesiophobia at early stage in ACL reconstructions could make a significant contribution to rehabilitation process in terms of achieving projected ranges of motions sooner in clinical settings.

FRI0624-HPR **THE RELATION BETWEEN FOOT POSTURE AND CHRONIC LOW BACK PAIN INTENSITY**

I. Demirbüken, B. Özgül, A. Alioğlu, E. Timurtaş, S.U. Yurdalan, M.G. Polat. *Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Marmara University, Istanbul, Turkey*

**Background:** The link between foot structure and low back pain (LBP) has been investigated recently because of biomechanical abnormalities are widely believed to be the likely causes of LBP (1, 2). Back and spine impairments were more common in women (3) and women slightly more often reported some kind of consequences due to spinal pain (4). Despite of detected gender differences arising from spinal pain, there has been no study that investigates the effect of foot posture on LBP among men and women separately.
**Objectives:** The aim of this study to investigate the gender differences in foot posture and back pain intensity and to explore relation between foot posture and level of pain in men and women suffering from chronic LBP.
**Methods:** 50 subjects of age 51.02±12.41years who admitted with chronic LBP to Physiotherapy Clinics between December 2014-March 2015 participated in this study. Foot posture of dominant side was determined by using Foot Posture Index (FPI). Higher positive FPI scores indicates a pronated foot posture, negative scores indicates a supinated foot posture (5). Visual Analog Scale (VAS) and Oswestry back pain scale was used for pain assessment. Mann Whitney U test was used to compare FPI scores and pain intensity according to VAS and Oswestry back pain scale. Spearman correlation test was used to determine the relationship between foot posture scores and level of LBP for men and women separately.
**Results:** There was no statistically difference between men and women for FPI scores ($p=0.552$) and LBP pain intensity according to VAS ($p=0.579$) and Oswestry back pain scale ($p=0.890$). While there was no statistically correlation between FPI scores and LBP pain intensity among men ($p>0.05$), a positively moderate correlation was detected between FPI scores and LBP pain intensity according to VAS among women ($r=-0.393$, $p=0.019$).
**Conclusions:** In the literature, excessive pronation of foot was detected more frequently in individuals with LBP (6). Similarly in this study, women with pronated foot posture have higher level of LBP, not men. Therefore, clinicians should be interpreted the link between foot posture and LBP by considering gender.

FRI0625-HPR **LEARNING TO GUIDE PEOPLE WITH RHEUMATOID ARTHRITIS TO HEALTH-ENHANCING PHYSICAL ACTIVITY BEHAVIOR: PHYSIOTHERAPISTS' KNOWLEDGE, BELIEFS AND BEHAVIOR**

T. Nessen, C.H. Opava, I. Demmelmaier. *Dept of Neurobiology, Care Sciences and Society, Karolinska Institutet, Huddinge, Sweden*

**Background:** Physiotherapists (PTs) are raised in a biomedical tradition. They promote health-enhancing physical activity (HEPA) in persons with RA mainly by providing information, instructions and follow-up of prescribed exercises. To facilitate maintained HEPA behavior, PTs in rheumatology need to integrate their knowledge on RA and exercise physiology with use of evidence-based behavior change techniques (BCTs). Detailed, theory-based studies of how PTs can integrate these competencies are scarce. To gain more knowledge on PTs learning in this aspect, we performed the present study as a substudy in a HEPA intervention in the Physical Activity in RA (PARA 2010) program.
**Objectives:** To describe changes in PTs' knowledge, beliefs and behaviours assessed before, during and after a theory-based skills training course preparing them to guide persons with RA to HEPA within a one-year intervention trial.
**Methods:** This was a longitudinal case study performed within a one-year HEPA intervention for persons with RA, including circuit training at public gyms twice a week and 30 minutes daily free-living physical activity of moderate intensity, framed by 20 bi-weekly support group sessions led by a PT. Our participants were ten registered PTs leading 10 support groups with 5–10 persons each. To prepare the PTs for their task we gave a course based on Social Cognitive Theory (SCT) principles and structured use of BCTs, see Figure 1. Data were collected by questionnaire at five occasions; at baseline, three times during the course and once after the course, assessing knowledge on physical activity in RA (score 0–6), knowledge on BCTs (score 0–18), fear-avoidance beliefs about physical activity in RA (score 8–48), and self-efficacy to guide in behaviour change (score 9–54). The questionnaire had good face validity and good test-retest reliability with ICC 0.88–0.98 for the four variables. Data were also collected by a log book for self-reported use of BCTs during group sessions, dichotomised as adherence to the support group session protocol or not.
**Results:** PTs' knowledge on BCTs and their self-efficacy to guide in behaviour change increased significantly (Friedman's test, $p<0.05$) from baseline to post-course from median 9 to 13 and from median 38 to 46.5, respectively. Their knowledge on physical activity in RA and their fear-avoidance beliefs were adequate at baseline and did not change. Two out of ten PTs fulfilled the pre-established criteria for adherence to the group session protocol for use of BCTs throughout the HEPA intervention.

Figure 1. Format, learning activities and targets of PT course in the PARA 2010 program.

| | Before the HEPA intervention | During the HEPA intervention |
|---|---|---|
| Format | 2 times 2 course days | 2 times 1 course day |
| Learning activities | • Lectures, workshops with role-play<br>• Home assignments between course days | • On-site visits with video recordings and feedback on performance during support group sessions<br>• Viewing video sequences from sessions to provide model examples |
| Targets | • Knowledge on HEPA in RA<br>• Knowledge on BCTs<br>• Fear-avoidance beliefs<br>• Self-efficacy in guiding to behaviour change<br>• Skills to use the following BCTs: goal-setting, action planning, self-monitoring, positive reinforcement, modeling, problem solving, review of goals and relapse prevention | |

**Conclusions:** A course for PTs based on SCT principles emphasizing skills training and feedback on performance seems useful to affect knowledge on BCTs and self-efficacy to guide in behaviour change. To improve adherence in PTs applying evidence-based BCTs to guide persons with RA to HEPA, closer monitoring and more frequent feedback on performance are suggested.

FRI0626-HPR **PHYSIOTHERAPISTS' MANAGEMENT OF CHALLENGING SITUATIONS IN GUIDING PERSONS WITH RHEUMATOID ARTHRITIS TO HEALTH-ENHANCING PHYSICAL ACTIVITY**

T. Nessen [1], C.H. Opava [1], C. Martin [2], I. Demmelmaier [1]. *[1]Dept of Neurobiology, Care Sciences and Society, Karolinska Institutet, Huddinge; [2]Dept of Neuroscience, Uppsala University, Uppsala, Sweden*

**Background:** Physical activity is crucial for the management of rheumatoid arthritis (RA). In the Physical Activity in RA 2010 (PARA 2010) program we evaluated a one-year health-enhancing physical activity (HEPA) intervention. It included circuit training at public gyms twice a week and daily free-living physical activity of moderate intensity, framed by 20 bi-weekly support group sessions led by a physiotherapist. The PTs were trained to facilitate HEPA behavior not only by instructing exercises and check exercise intensity, but by inviting participants to share their experiences and give social support as they strived to reach HEPA. Integrating these communication competencies may be challenging to PTs, traditionally providing expert advice on exercise and physiology.
**Objectives:** The aim was to explore strategies that PTs use to manage challenges when guiding persons with RA to HEPA behavior within a one-year intervention.
**Methods:** The study was exploratory and descriptive. Eleven PTs, all women, were included. To prepare the PTs for their group leader task, they participated in a six-day skills training course and received a written manual for the support group sessions. In addition, they received individual feedback on performance during group sessions twice during the HEPA intervention. Data were collected by video recordings during altogether 22 support group sessions ranging from 46 to 78 minutes in length (mean 57 minutes, 1433 minutes in total). The analysis procedure was performed by three researchers in three stages; a preliminary review, a substantive review and an analytic search according to Heath et al (2010).
**Results:** Analysis revealed three categories of challenging situations deemed to be of clinical relevance for PTs and other health professionals promoting HEPA in patients. The challenges occurred while the support group participants perceived barriers to performing physical activity, when they neglected using the diary for planning physical activity as intended in the program, and when they experienced a mix of negative and positive outcomes of physical activity. The analysis yielded eight strategies PTs used to manage these three challenges (Figure 1). The strategies either focused on provision of information or on involvement of group participants in discussions. The PTs switched back and forth between strategies, demonstrating that they adapted to different situations.

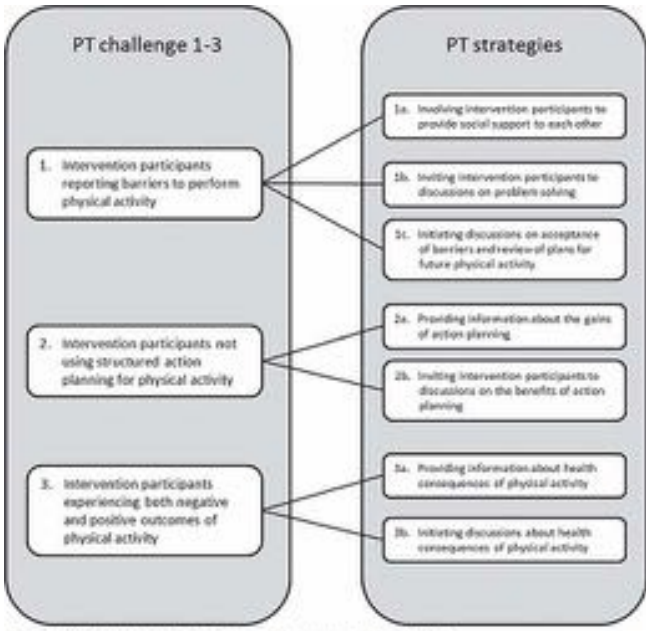

Figure 1. PT challenges and strategies in guiding persons with RA to HEPA.

**Conclusions:** Our results are promising for future initiatives to integrate PTs' traditional information-provision strategies with strategies facilitating participation by inviting group participants to interaction and discussion, potentially enhancing the uptake of HEPA interventions in group formats.

FRI0627-HPR **IN PATIENTS WITH INFLAMMATORY MYOPATHY QUANTITATIVE MUSCLE TESTING HAS A HIGHER RELIABILITY THAN MANUAL MUSCLE TESTING**

I. Sterkele[1], P. Baschung Pfister[2,3,4], E.D. de Bruin[4,5,6], B. Maurer[7], R.H. Knols[2]. *[1]Physiotherapy and Occupational Therapy; [2]Directory of Research and Education, University Hospital Zurich, Zürich; [3]Department of Health, Zurich University of Applied Sciences, Winterthur, Switzerland; [4]CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands; [5]Institute of Human Movement Sciences and Sport, ETH Zurich, Zürich, Switzerland; [6]Centre for Evidence Based Physiotherapy, Maastricht University, Maastricht, Netherlands; [7]Division of Rheumatology, University Hospital Zurich, Zürich, Switzerland*

**Background:** Inflammatory myopathies (IMs) are systemic autoimmune diseases, characterized by reduced muscle strength and endurance. Although IMs are relatively rare, patients' disabilities in daily life are substantial. Thus, there is a need for appropriate and reliable assessments to quantify muscle weakness. Although the manual muscle test (MMT) and the quantitative muscle test (QMT), which employs a dynamometer, are commonly used tests to evaluate muscle strength, their psychometric properties (e.g. reliability) have not yet been sufficiently studied[1].
**Objectives:** To determine the reliability of the MMT8 and the QMT in patients with IM.
**Methods:** Twenty-four adult, German speaking patients with established diagnosis of IM were included. The majority of patients was female (83%), 57±12 years old with a mean disease duration of 28±29 months. The maximum isometric strength of eight muscle groups, which are most often affected, was evaluated with the MMT8 using the 10 point Kendall scale and the QMT indicating strength in Newton (N). For intra-rater reliability, one tester performed the MMT8 and the QMT twice and for inter-rater reliability, they were tested by a second independent tester. The Intraclass Correlation Coefficient (ICC) and the Standard Error of Measurement (SEM) were evaluated.
**Results:** The intra-rater reliability of the MMT8 yielded moderate to good ICCs (0.63–0.89) for all muscle groups and an excellent ICC (0.92) for the total score. Inter-rater reliability yielded moderate to good ICCs (0.54–0.84) for shoulder abductors, wrist and hip extensors, hip abductors, neck flexors and the total score, and low ICCs (0.08–0.34) for the remaining muscle groups (elbow flexors, knee and foot extensors). The SEM was smaller for the intra-rater (SEM 0.5/10 point of Kendall scale for muscle groups and 2/10 points for the total score) than for inter-rater reliability (SEM 0.5–1/10 point for muscle groups and 3/10 points for the total score). QMT presented moderate to excellent intra- and inter-rater reliability (ICCs 0.52–0.92) for all muscle groups. The intra-rater comparison for shoulder abductors was 10N, inter-rater comparison 13N and the intra-rater and inter-rater comparisons for the knee extensors were 28N and 35N, respectively. In contrast to the QMT, the MMT8 showed high ceiling effects between 18% and 77% for all but one muscle group (hip extensors).
**Conclusions:** In this study, the QMT showed a better reliability than the MMT8 because of missing ceiling effects and due to the good to excellent intra- and inter-rater reliability. Notably, the QMT seems to be more accurate to measure single muscle groups especially in patients with mild weakness as for example in early disease. If no hand-held dynamometer is available, the total score of MMT8 represents an appropriate alternative.

FRI0628-HPR **ADVANCED PRACTICE MUSCULOSKELETAL PHYSIOTHERAPISTS IN RHEUMATOLOGY- A NATIONAL REPORT OF THE 2014 DATA**

J. Ashton[1], R. Breen[1], A. Brennan[2], E. Callanan[3], C. Farrell[4], D. Moore[5], P. Kenny[6], D. Carey[7], O. Fitzgerald[8] on behalf of Rheumatology and Orthopaedic Clinical Care Programmes. *[1]Physiotherapy, Beaumont Hospital; [2]Physiotherapy, AMNCH, Dublin; [3]Physiotherapy, Merlin Park Hospital, Galway; [4]Orthopaedic Clinical care programme, RCSI; [5]Orthopaedics, AMNCH; [6]Orthopaedics, Cappagh Hospital; [7]Clinical Strategy & Programmes Directorate and, Dr Steevens' Hospital; [8]Rheumatology, St. Vincents University Hospital, Dublin, Ireland*

**Background:** Research studies have supported the role of Advanced Practice Physiotherapists (APP's) acting as first contact practitioners in the management of musculoskeletal (MSK) patients[1]. In 2012, funding was approved for 24 APP posts in Ireland through the Clinical Strategy and Care Programmes Directorate of the Health Service Executive (HSE) in Ireland. These posts were to provide orthopaedic and rheumatology triage clinics across 16 hospitals throughout the country as a waiting list initative for patients with MSK complaints.
**Objectives:** i)To present the data reported on the throughput of Rheumatology patients seen by the APPs nationally in 2014.
**Methods:** 13 sites provided MSK triage through rheumatology clinics nationally in 2014. While each post has a target of seeing 1,000 patients per year it has been reported that APP's see a ratio of 5:1 orthopaedic to rheumatology patients. Data was collected monthly from all sites and reported directly to the rheumatology clinical care programme. Descriptive data was analysed using a Microsoft® Excel package.
**Results:** 2,177 new and 530 return rheumatology patients were seen nationally in 2014. Regarding new patients the most common areas were shoulder (n=329, 15.1%) and lumbar spine (n=288, 13.2%), 35.2% (n=766) had multiple pain sites. Regarding waiting times 58.6% (n=1275) were seen within 6months of referral and 21% (n=457) had imaging ordered. 40.1% (n=873) were referred for physiotherapy within the hospital or primary care. 63.3% (n=1378) were discharged directly from the APP clinic and 15% (n=327) were referred on to another medical speciality.
**Conclusions:** APPs have been effective in triaging MSK referrals within a rheumatology setting. A large proportion of patients were discharged back to the referring source.

FRI0629-HPR **BACK TO ACTION: A GUIDE TO EXERCISING SAFELY IN THE GYM WITH ANKYLOSING SPONDYLITIS - BOOK AND APP USER PERSPECTIVES**

J. Hamilton[1], C. Garces Bovett[1], C. Harris[2], C. Jeffries[3], T. Jones[4]. *[1]National Ankylosing Spondylitis Society; [2]London North West Healthcare NHS Trust, London; [3]Solent NHS Trust, Portsmouth; [4]Defence Medical Rehabilitation Centre, Epsom, United Kingdom*

**Background:** *Back to Action* (*B2A*) is a guide designed to help people with ankylosing spondylitis and axial spondyloarthritis (AS) exercise safely in the gym, produced by NASS in association with the Defence Medical Rehabilitation Centre at Headley Court. It was first published in print in 2010, and was published as a free iOS app in 2011 and in Android format in 2012. Two surveys were conducted from 1 November 2014 to 30 April 2015 to gather information on user satisfaction with the *B2A* book and app, and their impact on users. Key findings included; the structure and content of *B2A* was highly regarded, 67% now exercise more at home than previously, and 95% of respondents would recommend the guide to others with AS.
**Objectives:** The information and comments collected will help to shape the next phase of *B2A*'s development as well as help to review the current versions of the book and app to ensure that the needs of the user are met fully.
**Methods:** One survey dealt with the printed version of *B2A*, the other with the app. Apart from questions relating to format-specific topics, both surveys contained the same 17 questions designed to elicit both numerical ratings and qualitative comments, and were advertised via the NASS website, Facebook and Twitter. Additionally, the apps survey was sent to all users via a push notification update. The answers to both surveys were analysed together.
**Results:** Two hundred and five people completed the surveys. Sixty-five percent were in the 25–44 age range. Each section of *B2A* received an average rating of 4.10 or above out of a possible 5 for excellence, with the guide overall receiving an average rating of 4.23 out of 5. Ninety-five percent of those surveyed would recommend *B2A* to someone with AS. In terms of measuring *B2A*'s impact, 67% said that they exercise more at home since buying or downloading the guide. When asked to rate how significantly the guide has improved their general fitness (where 5 is very significantly), the average rating was 3.50. The average rating was 3.20 when respondents were asked to rate how significantly *B2A* had improved their AS. Suggestions for future development of *B2A* showed a strong desire for sections on the use of free weights (53%) and gym balls (33%). Other respondents asked for walking and cycling tips, and stretches for the swimming pool.
**Conclusions:** Although the structure and content of *B2A* were rated high, the impact of the guide on respondents' general fitness and AS symptoms did not rate as correspondingly high. However, the material never formally addressed how to measure general fitness and therefore the potential variability in interrupting this may explain the low score. More successfully, *B2A* seems to have had an effect on the numbers of users now exercising more at home, as well as encouraging others to join gyms, crucial to the management of AS. Compliance in exercising at home is low amongst people with AS despite awareness of the benefits of exercise [i] and so the book and app were successful in this area. Various areas for future development were also identified, which should increase the scope and impact of subsequent editions.

## FRI0630-HPR THE IMPACT OF STRETCHING ON AXIAL SPONDYLOARTHRITIS (AXSPA): A LITERATURE REVIEW

K.E. Arnold[1], R. Marshall[2]. [1]*Physiotherapy Department;* [2]*Rheumatology Department, University Hospitals Bristol NHS Trust, Bristol, United Kingdom*

**Background:** AxSpA encompasses the conditions Axial Spondyloarthritis (AS) and non-radiographic axial spondyloarthritis. [1] AxSpA patients often present with symptoms such as inflammatory back pain, stiffness, fatigue and joint swelling. [2] To date, optimal management of axSpA has included a combination of medical and therapy interventions. [3] Regular exercise and stretching are fundamental parts of AS rehabilitation that has been used for many years.
The protein Tumour Necrosis Factor- alpha (TNF) is often overproduced in axSpA leading to inflammation which can damage connective tissue structures. In the last decade, anti-TNF agents (biologics) have been used more regularly in the treatment of AS. [4]
**Objectives:** To establish an evidence-base for a physiotherapy-led programme by:
– Clarifying the effect of stretching exercise therapy for patients with axSpA
– Determining whether exercise therapy is indicated in the management of axSpA patients receiving biologic therapy
**Methods:** The search databases used were AMED, EMBASE, HMIC, BNI, Medline, PsycInfo, CINAHL, and HEALTH BUSINESS ELITE. The "PICO" approach to literature searching was used.
"'P' Patient/ population: Ankylosing Spondylitis, Axial Spondyloarthritis
"I" Interaction: Stretch*, Active, Passive, Dynamic, Resistant, Yoga, Pilates, Proprioceptive neuromuscular facilitation
"C" Comparison: Not applicable
"O" Outcomes: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Functional Index (BASFI)
**Results:**
– Stretching with other modes of exercise improves BASDAI, BASMI, and BASFI measurement
– Individual specific stretching programs have better results than segmental stretching
– Stretching with strengthening is a favourable approach with a focus on movement control
– Possible decrease in inflammatory processes during stretching
– Possible decreased occurrence of tendinopathy/ enthesopathy which may lower risk of ossification and associated stiffness
**Conclusions:** There is evidence to support that exercise is beneficial for the axSpA patient, and research is beginning to study the components of such programs. Patients with axSpA on biologics should complete regular multi-modal exercise. Exercise works synergistically with Biologics to aid decrease of systemic inflammation. This review has shown that stretch is used as an integral part of patients' exercise programs. Only a few articles have looked specifically into the effects of stretching on axSpA, therefore it is difficult to give definitive recommendations regarding intensity and frequency. High quality studies are needed on axSpA patients completing specific postural stretches in a group setting, with further investigation into the impact on BASDAI, joint ROM and systemic inflammation. Different frequencies and intensities of stretching could then be studied.

## FRI0631-HPR A NEW IMPULSE RESPONSE METHOD TO ASSESS EARLY KNEE OSTEOARTHRITIS DIFFERENCES BETWEEN YOUNG AND ELDERLY WOMEN

K. Aimoto[1], K. Hase[2], T. Sakai[3], Y. Itoh[4], I. Kondo[1], S. Ota[5]. [1]*Department of Rehabilitation Medicine, National Center for Geriatrics and Gerontology, Obu;* [2]*Department of Mechanical Engineering, Tokyo Metropolitan University, Hachioji;* [3]*Graduate School of Science and Engineering, Saitama University, Saitama;* [4]*Institute for Developmental Research, Aichi Human Service Center, kasugai;* [5]*Department of Rehabilitation and Care, Seijoh University, Tokai, Japan*

**Background:** Decreased shock absorbing of the cartilage between the femur-tibia is assumed in patients with knee osteoarthritis (OA), and the impulse response method was considered to apply the evaluation of initial degeneration for cartilage.
**Objectives:** The purposes of the present study were 1) to establish the impulse response method deciding the appropriate location for input and output impulse to assess cartilage degeneration in the knee joint, and 2) to determine the differences between young and elderly women using this method.
**Methods:** 1) Ten young women (age: 20 ± 0 years) participated. Input value was measured by an input device attached to the distal end of the load cell. Output value was measured by a one-axis accelerometer. Input locations were the medial epicondyle and the medial condyle. Output points were distal 5 cm, 10 cm and 15 cm from the knee joint space. The input-output ratio of ten times was calculated to six combinations of input points and output points. The intraclass correlation coefficient (ICC) was calculated by re-measurement several days before.
2) Two groups of 26 elderly (age: 69 ± 6 years) and young (age: 21 ± 1 years) women each were recruited. The elderly group included those who matched the knee osteoarthritis classification criteria by clinical findings. The outcome measures were the input-output ratio (unit: $\times 9.8$ m/s$^2$/N) and the attenuation rate that was the ratio of a second amplitude for the first amplitude, the frequency, and the power spectrum. The power spectrum was obtained by Fast Fourier Transform and each 10 Hz ranging from 1 to 100 Hz was used as the final analysis [1,2].
**Results:** 1) ICCs of output location at 15 cm point with two input locations were greater than 0.9. The medial condyle (22.7±3.1 [N]) was significantly greater than compared to the medial epicondyle (18.4±2.8 [N], $p<0.001$).
2) The input-output ratio was 0.11 ± 0.03 in the young group and 0.11 ± 0.04 in the elderly group; there were no significant differences in the input-output ratio. The attenuation rates of the young and elderly groups were 0.38 ± 0.14, and 0.36 ± 0.19, respectively, and there were no significant differences in the attenuation rate of the two groups. The frequencies (unit: Hz) were 68.7 ± 13.1, and 77.2 ± 25.2, respectively, and there were no significant differences in the frequency of the two groups. The power spectrum (unit: $(\times 9.8$ m/s$^2)^2$) of the young group ($1.21\times10^{-4}\pm1.06\times10^{-8}$) was significantly greater than the value of the elderly group ($2.97\times10^{-4}\pm1.61\times10^{-7}$) at 21–30 Hz (p=0.036). Additionally, the power spectrum of 21–30 Hz was correlated to knee pain (r=0.39, p=0.049).
**Conclusions:** The location of the medial condyle was appropriate in the input point, and 15 cm point distal from the knee joint space was a suitable location as the output point based on the present findings.
In 21–30 Hz, the impulse absorbing by the cartilage in elderly women was less than compared to the values in young women. The impulse response method of the present study could be applied to assess early knee osteoarthritis.

## FRI0632-HPR PATIENT EDUCATION EVENT: "WHY DOES MY BACK HURT?"

L. Van Rossen. *Rheumatology Physiotherapy, NHS, East Kent Hospitals, United Kingdom*

**Background:** Back pain is common; 84% of people suffer with back pain at some point in their life.(1) 1.3%>5.3% of back pain sufferers have Axial Spondyloarthritis (AxSpA), a chronic inflammatory condition predominantly involving the spine and sacroiliac joints (SIJ).(1,2) With recent developments for the treatments of AxSpA, this condition can be treated much more effectively, reducing pain and improving quality of life. Differentiating between mechanical and inflammatory back pain remains a challenge. The mean delay in diagnosis is still 8.54 years in the UK.(3) A lot of work has been done to raising awareness with medics and Allied Health Professionals. Improving the understanding of back pain sufferers also has a role in reducing the time to diagnosis.
**Objectives:** To raise awareness of AxSpA, and ensure patients (pts) get referred correctly to receive appropriate investigations, diagnosis and treatment.
**Methods:** An event was organised with the objective of raising awareness of AxSpA and identifying those suffering with the condition. The event was advertised through local press, social media and East Kent Hospital University Trust (GP Practices, physiotherapists, osteopaths and chiropractors).
Attendees completed a back pain questionnaire before, immediately after and at 6 months after the event. The event consisted of 3 lectures: differentiating inflammatory and mechanical back pain, management on inflammatory back pain and 10 top tips for back pain. The National Ankylosing Spondylitis Society was also represented. An "Ask The Expert" session followed this, where pts had the opportunity to ask a panel consisting of therapists, rheumatologists and NASS representative questions.
**Results:** 104 people with undiagnosed back pain, attended the event. 87 questionnaires were completed the on the day; 54 described themselves as back pain sufferers and 33 were supporters of back pain sufferers. The response rate at 6 months was 28 (52%) As a result of the survey, 5 pts were diagnosed with AxSpA, with a further 9 undergoing further investigations in secondary care (Table).

| Outcome | No. of attendees | % |
|---|---|---|
| AxSpA | 5 | 2.7 |
| Red flag (prostate cancer, myeloma) | 2 | 1.08 |
| Undergoing investigations in secondary care | 9 | 4.86 |
| Referred to physiotherapy | 5 | 2.7 |
| Private physiotherapy/osteopathy | 3 | 1.62 |
| Offered spinal surgery after orthopaedic review | 1 | 0.54 |
| GP took no action | 3 | 1.62 |

These results not only highlight that, as a result of this event, 5 people were diagnosed with AxSpA, but also demonstrate that there is a substantial amount of "undiagnosed" back pain, needing different treatment pathways.
**Conclusions:** Educational events such as this can facilitate early diagnosis and treatment of pts with AxSpA. The high response rate at 6 months illustrates the event was well received and useful to the audience. Further education events would be useful both for pts and professionals to facilitate diagnosis and early treatment.

## FRI0633-HPR "IT MIGHT HURT, BUT STILL IT'S GOOD": PEOPLE WITH RHEUMATOID ARTHRITIS BELIEFS AND EXPECTATIONS ABOUT PHYSICAL ACTIVITY INTERVENTIONS

L. Larkin[1], N. Kennedy[1], A. Fraser[2], S. Gallagher[3]. *[1]Department of Clinical Therapies, University of Limerick; [2]Department of Rheumatology, University Hospitals Limerick; [3]Department of Psychology, University of Limerick, Limerick, Ireland*

**Background:** People who have Rheumatoid Arthritis (RA) report low levels of physical activity despite the many health benefits of being physically active [1,2]. Involving key stakeholders is important when designing interventions which target behaviour change as it allows consideration of particular issues that may influence the delivery of complex interventions [3,4].
**Objectives:** This study aimed to explore the views of people who have RA on being physically active and the design of a future physical activity intervention.
**Methods:** A qualitative methodology using a constructivist approach was employed. Recruitment was through an outpatient rheumatology clinic in an urban hospital. Interviews were conducted by telephone, with an interview question guide being used by the interviewer. Interviews were transcribed and analysed using thematic analysis. Transcripts were read, notes made and ideas formulated to facilitate coding. The research team searched for patterns, analysed and coded the data, and generated sub-themes and themes. Themes were reviewed by the research team to check if the themes worked in relation to the coded extracts and the entire data set.
**Results:** Twelve females and five males participated in the study. Their mean age was 59.8 years (range 35–83, SD 12.5) and mean disease duration was 13.7 years (range 1–47, SD 15.3). Four main themes were generated: "*Being active*", "*Barriers and facilitators*", "*Information and advice*", and "*Supporting physical activity*". "*Being active*" encapsulated the participants' understanding of physical activity, their perceptions' that they could be active and their physical activity limits due to having RA. Beliefs and emotions were highlighted as both key barriers and facilitators to being active, e.g. fear about increasing disease activity by "overdoing it" whilst locating an intervention in a hospital setting was discussed as being negative. The need for accurate information about being physically active from a credible source was highlighted in "*Information and advice*", whilst goal setting, monitoring and social support were thought to be important to support physical activity.
**Conclusions:** There is a lack of information and knowledge about being physically active amongst people who have RA, which contributes to uncertainty about being active. Future interventions should consider delivery in a group, community setting and should incorporate methods which support and monitor behaviour. This study highlights the importance of involving key stakeholders when designing future physical activity interventions as such contributions can help to ensure that such interventions are successful.

## FRI0634-HPR COMPLEX TREATEMENT OF PATIENTS WITH GOUTY ARTHRITIS

N.G. Nikolov[1], M.S. Krastanova[2], M.S. Panchovka[3]. *[1]Clinic of Rheumatology; [2]Physical and Rehabilitation Medical Clinic, UMHAT "Dr. Georgi Stranski", Pleven, Pleven; [3]Departement of Internal Medicine, Medical University Plovdiv, Plovdiv, Bulgaria*

**Background:** Gout is a type of arthritis caused by the formation of uric acid crystals within or around the joints. It is the most common type of inflammation arthritis for people over 40.
For some of the patients, the leading symptoms are pain and stiffness in the joints, while others develop heavy joint deformations and permanent disabilities. Applying a complex rehabilitation approach with rheumatologic aid and a physio-rehabilitation program significantly improves the condition of the patients with gouty arthritis, the strength of their symptoms diminishes, and becoming handicapped is avoided or significantly delayed.
**Objectives:** The aim of this study is to measure the effect of conducting a complex drug treatment combined with a physio-rehabilitation program in patients with gouty arthritis in an acute or chronic stage that heavily affects the musculoskeletal system.
**Methods:** Between 2013 and 2015, 39 patients with gouty arthritis were hospitalized and treated at the Rheumatology Ward at UMHAT "Dr. Georgi Stranski" – Pleven. 26 of them were male and 13 female, aged between 43 and 62 years old, in subacute or chronic stage (SUE $<$25 mm, fibrinogen and CRP at relevant values, AST and RF (–).
In addition to the drug therapy with analgesics, NSAIDs and chondoprotectors, uricoinhibitors and urikoeliminators during the non-paroxysmal period, the patients also undergo a complex physical and rehabilitation program consisting of: electrotherapy (magnetic field, mid-frequency currents and ultrasound therapy with NSAIDs, therapeutic massages, cryotherapy, active methods of kinesitherapy and occupational therapy.
Functional tests and measurements – VAS for the pain, a daily activities life test (DAL) and complex functional assessment test (CFA) – were made for the purpose of the study at the beginning and at the end of the observed period.
**Results:** An individual file was created for every patient where the results from the tests and measurements are stored in order to track the patient's condition over the course of treatment. The treatment consists of 3 stages: a period in the Rheumatology ward, treatment in the Medical Rehabilitation ward and ambulatory physio-rehabilitation courses.
Conducting physiotherapeutic treatment for patients with gouty arthritis in an acute or chronic stage complements the drug treatment and leads to faster relief of the symptoms during an acute stage, decreases the timeframe of the temporary inability to work, prevents any permanent damage to the affected joints and prevents the occurrence of permanent disabilities.
**Conclusions:** For patients with gouty arthritis in an acute or chronic stage that heavily affects the musculoskeletal system, the complex physio-rehabilitational and rheumathological treatment is effective and leads to a significant improvement in the quality of life of the patients.
**Disclosure of Interest:** None declared

## FRI0635-HPR THE MYOSITIS ACTIVITY PROFILE – FIRST RESULTS OF CONTENT AND CONSTRUCT VALIDITY OF THE GERMAN VERSION

P. Baschung Pfister[1,2,3], N. Wechsler[4], E.D. de Bruin[4,5,6], B. Maurer[7], R.H. Knols[1]. *[1]Directorate of Research and Education, University Hospital Zurich, Zurich; [2]Department of Health, Zurich University of Applied Sciences, Winterthur, Switzerland; [3]CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands; [4]Institute of Human Movement Sciences and Sport, ETH Zurich, Zurich; [5]CAPHRI School for Public Health and Primary Care; [6]Centre for Evidence Based Physiotherapy, Maastricht University, Maastricht; [7]Division of Rheumatology, University Hospital Zurich, Zurich, Switzerland*

**Background:** The Myositis Activity Profile (MAP), a questionnaire to assess limitations of activities of daily life in patients with inflammatory myopathy (IM), was developed and tested on psychometric properties in Sweden and later on translated and validated in English[1,2]. To the best of our knowledge, there is no validated version available for German speaking patients.
**Objectives:** To translate and cross-culturally adapt the MAP into German language and to determine content and construct validity.
**Methods:** A cross-cultural adaptation of the English version of the MAP into German was performed following international guidelines. To assess content validity of the new German version, patients rated difficulty and importance of items of the MAP using a visual analog scale (VAS range 0–10). For construct validity the correlation between the MAP and five functional tests (Short Physical Performance Battery, one leg stand, Grip Ability Test, upper and lower Progressive Isoinertial Lifting, and the 6 minute walk) were analyzed with the Spearman correlation coefficient. Additionally, for discriminative validity differences between patients and age and gender matched healthy controls were analyzed using the Mann-Whitney- U Test. Item fit within subscales was calculated by Cronbach's alpha.
**Results:** Twenty German speaking patients with a diagnosis of acute (20%),

subacute (25%) or chronic (55%) myositis were included. Participants were 56.5 ±10.13 years old and 75% of them were female. The median combined difficulty and importance of the 32 items of the MAP was 5.67 (range 5.3–6.5). Correlations between the total score of the MAP and the Short Physical Performance Battery (-0.52), Grip Ability Test (0.52), Progressive Isoinertial Lifting Evaluation (lumbal part: -0.62, cervical part -0.60) and the 6 minute walk test (-0.69) were moderate and the correlation with the one leg stand test was low (-0.26). Healthy participants had significant lower scores (single items, subscales and total score) than patients ($p \leq 0.05$). Cronbach's alpha coefficients for the four subscales varied between 0.85 and 0.92.

**Conclusions:** This initial validation of the German version of the MAP showed that the 32 items from the English version were also suitable for Swiss conditions. Cronbach's alpha coefficients were similar to those from the English version. As expected the MAP correlated moderately with functional tests, except with the one leg stand. Although balance may be important in patients with IM, the MAP does not cover balance ability. In summary, the MAP seems to be a valid and easy applicable methodology for assessing limitations of activity in daily life. However, further research is required to confirm these preliminary results and to test reliability.

## FRI0636-HPR EFFECTS OF CLINICAL PILATES EXERCISES COMBINED WITH DANCETHERAPY ON MOOD IN PATIENTS WITH RHEUMATIC DISEASES

P. Kisacik [1,1], G. Arin [1], S. Oksuz [2], U. Berberoglu [1], G. Arın [1], A. Akdogan [3], A. Akdogan [4], O. Dogan [5], O. Dogan [5], E. Karabulut [6], E. Karabulut [7], E. Unal [1], E. Unal [1]. *[1]Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Science, Ankara, Turkey; [2]Physiotherapy and Rehabilitation, Eastern Meditterrenean University Faculty of Health Science, Famagusta, Cyprus; [3]Rheumatology-Internal Medicine, Hacettepe University Faculty of Medicine; [4]Internal Medicine-Rheumatology, Hacettepe University Faculty of Medicine; [5]Child Development, Hacettepe University Faculty of Health Science; [6]Biostatistics, Hacettepe University Faculty of Medicine; [7]Biostatistics, Hacettepe University Faculty of Health Science, Ankara, Turkey*

**Background:** Clinical pilates exercises are described as mind-body exercise models which are also recommended on treatment of rheumatic diseases (1, 2). Since dancetherapy has positive effects on mood, it has been preferred in the rehabilitation of the chronic diseases in recent years (3,4). However, clinical pilates exercises combined with dancetherapy in rheumatic patients is not found in the literature.

**Objectives:** To investigate the effects of clinical pilates exercise combined with dancetherapy on mood in rheumatic patients.

**Methods:** 20 rheumatic patients aged 42.00±12.00 years were participated in this study. Mood status of the patients were assessed by Beck Depression Inventory (BDI), Hospital Anxiety and Depression Scale (HADS) and The Multidimensional Scale of Perceived Social Support (MSPSS). Patients performed supervised clinical pilates exercises in a period of one hour, 3 times a week for 10 weeks. Dancetherapy was added to only 12 of patients' program once a week, one hour, for 10 weeks.

**Results:** All scores improved in all patients' for the post-exercise assessments relevant to the pre-exercise assessments. However, statistically significant improvement were observed only in MSPSS scores for the patients participated to the dancetherapy sessions ($p<0.05$) (Table.1).

Table 1. Comparison of the all scores

| | Pilates and dencetherapy group (n=12) | | | Only pilates group (n=8) | | | P intergroups |
|---|---|---|---|---|---|---|---|
| | X ± SD | | p | X ± SD | | p | |
| | Before | After | | Before | After | | |
| MSPSS | 59.83±10.24 | 69.00±11.24 | 0.003 | 64.38±5.85 | 66.13±7.49 | 0.307 | 0.282 |
| HADS | 13.08±4.05 | 15.32±3.45 | 0.260 | 13.5±3.62 | 11.88±3.68 | 0.463 | 0.664 |
| BDI | 10.58±5.61 | 7.08±5.36 | 0.760 | 12.25±6.20 | 9.75±6.60 | 0.089 | 0.496 |

**Conclusions:** Clinical pilates exercises may provide improvement in mood characteristics in rheumatic patients. We concluded that these exercises enhance patients social support perceptions when combined with dancetherapy.

## FRI0637-HPR THE EFFECTS OF CLINICAL PILATES EXERCISES ON KINESTESIA AND POSITION SENSE IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE

P. Kisacik [1,1], S. Oksuz [2], S. Oksuz [2], G. Arın [1], G. Arın [1], A. Akdogan [3], A. Akdogan [3], O. Dogan [4], O. Dogan [4], E. Karabulut [5], E. Karabulut [5], E. Unal [1], E. Unal [1]. *[1]Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Science, Ankara, Turkey; [2]Physiotherapy and Rehabilitation, Eastern Meditterrenean University Faculty of Health Science, Famagusta, Cyprus; [3]Rheumatology-Internal Medicine, Hacettepe University Faculty of Medicine; [4]Child Development, Hacettepe University Faculty of Health Science; [5]Biostatistics, Hacettepe University Faculty of Medicine, Ankara, Turkey*

**Background:** Proprioception is a deep perception which constitutes kinesthesia and position sense. In particular, it is extremely affected due to cartilage degeneration in patients with osteoarthritis (OA) of the knee (1–3). Although exercise treatment is suggested as an effective method in OA, there is no study that investigates the effects of clinical pilates exercises on proprioception in patients with OA of the knee.

**Objectives:** The aim of this study is to investigate the effects of clinical pilates exercises on kinesthesia and position sense in patients with knee OA.

**Methods:** 39 patients with knee osteoarthritis defined as Kellgren-Lawrence (K-L) grade1 and 2 at mean age 55.95± 5.54 years and disease duration 6.59± 3.15 years were participated in this study (Control group; 20 patients, Exercise group; 19 patients). Exercise group attended in clinical pilates exercises sessions for three times a week (one hour session) during ten weeks. Kinesthesia and position sense were assessed with PMS-1000 Proprioception Test, Sport Expert Proprioceptional Sports Tech. Instrument. All measurements were repeated after ten weeks.

**Results:** Although the kinesthesia perception of patients improved ($p<0.05$), position sense did not improve in exercise group ($p>0.05$). There were no improvements in control group according to pre- and post-treatment values.

Table 1

| | BETY group (n=19) | | | Control group (n=20) | | | P intergroups |
|---|---|---|---|---|---|---|---|
| | X ± SD | | p | X ± SD | | p | |
| | Before | After | | Before | After | | |
| Kinestesia | 3.04±2.84 | 2.33±1.74 | 0.050 | 1.87±1.47 | 2.18±2.23 | 0.938 | 0.672 |
| Position sense | 1.75±1.44 | 1.08±0.70 | 0.480 | 2.27±2.73 | 1.20±0.96 | 0.121 | 0.865 |

**Conclusions:** As a conclusion, clinical pilates exercises should be kept in mind in terms of kinesthesia in patients with OA of the knee. We recommended that in further OA-related-studies using clinical pilates exercises, position sense should be examined in more detail.

## FRI0638-HPR INVESTIGATING PLANTAR PRESSURE DURING WALKING IN PLANTAR FASCIITIS

R.H. Baris [1], S. Narin [1], A. Elvan [1], M. Erduran [2]. *[1]School of Physical Therapy and Rehabilitation; [2]Department of Orthopedics, Faculty of Medicine, Dokuz Eylül University, Izmir, Turkey*

**Background:** Plantar fasciitis (PF) is an inflammation of the plantar fascia on the bottom of the foot, characterized by stiffness of medial arch and pain especially during the first steps. It can effect on daily living activities such as walking and a difference in the plantar pressures during walking can be expected (1). But, no studies were found in the literature related to this situation.

**Objectives:** The aim of this study was to investigate the dynamic plantar pressure during walking and compare the pedography measurements of the affected and unaffected feet of patients with plantar fasciitis during walking.

**Methods:** Forty patients (28 female, 12 male) with unilateral plantar fasciitis

were included in the study. Pain status and functionality was assessed with a visual analog scale (VAS) and Foot Function Index (FFI), respectively. EMED-m pedography platform (Novel GmbH, Germany) was used for dynamic foot plantar pressure measurements. Maximum force, contact area and contact time were measured for total object and hind foot in both affected and unaffected feet. These measures were recorded three times and average values were used in the analysis.The data were not distributed normally and as a result, non-parametric tests were used for interpreting the data.

**Results:** Average age, height and weight were 51.1 (min-max: 74–33), 165.7 (min-max: 150–190), 82.4 (min-max: 60–110), respectively. VAS was 7.5 (min-max: 6–8) FFI was 55.9 (min-max: 40–63). The results related to pedography measurements were given in Table 1. While, it was observed that hind foot maximum force and contact area were diminished in the affected foot, no differences were found in measures related to total object nor contact time of hind foot. Although a moderate relationship was found between pain status and functionality (rho: 0.57, $p<0.001$), none of these variables were correlated with pedoghraphy measures ($p>0.05$).

**Table 1. Pedography measurements**

| | Affected Foot Median (IQR 25/75) | Unaffected Foot Median (IQR 25/75) | p |
|---|---|---|---|
| Total Object Maximum Force (N) | 998.7 (886.0/1115.7) | 1011.1(897.5/1106.6) | 0.536 |
| Total Object Contact Area ($cm^2$) | 128.1 (118.3/142.2) | 131.2 (121.8/144.1) | 0.074 |
| Total Object Contact Time (ms) | 840.0 (780.0/899.2) | 853.3 (800.0/927.1) | 0.492 |
| Hindfoot maxium Force (N) | 500.6 (442.0/557.9) | 536.5 (460.5/619.5) | **0.044** |
| Hindfoot Contact Area ($cm^2$) | 31.6 (29.1/35.1) | 32.5 (30.1/36.3) | **0.010** |
| Hindfoot Contact Time (ms) | 550.0 (432.5/615.7) | 530.0 (485.4/598.7) | 0.812 |

N: Newton; ms: microseconds; IQR: Interquartile Range; $p<0.05$.

**Conclusions:** According to the results of this study, there was a difference in plantar pressures between affected and unaffected feet in plantar fasciitis patients. It seems that the difference is not related to pain status nor functionality. Treatment strategies aiming to resolve this difference might be beneficial to improve outcomes of the treatment. More studies are needed to understand the importance of the dynamic foot pressures during walking in this patient population.

## FRI0639-HPR GENDER DIFFERENCES IN ACUTE INFLUENCE OF RESTRICTED ANKLE DORSIFLEXION ANGLE ON KNEE ADDUCTION MOMENT DURING GAIT

R. Fujita[1], S. Ota[1], M. Ueda[2], K. Aimoto[3], A. Nakanishi[2]. *[1]Department of Care and Rehabilitation, Seijoh University, Tokai; [2]Division of Rehabilitation, Syutaikai Hospital, Yokkaichi; [3]Department of Rehabilitation Medicine, National Center for Geriatrics and Gerontology, Obu, Japan*

**Background:** Ankle dorsiflexion (DF) is necessary during terminal stance of gait, and its restricted range leads to increased knee adduction moment (KAM) in a previous report. Females are found to have a greater decrease in DF than males across age groups (every 5 years from 55 to 85 years old). Female gender is one of the critical risk factors of advanced and symptomatic medial knee osteoarthritis (knee OA). From this point of view, restricting the ankle range of motion is thought to be more related to increase the risk of knee OA in female compared to the risk in male. However, it is not clear whether there are gender differences in the influence of restricted ankle dorsiflexion angle on KAM during gait.

**Objectives:** The purpose of the present study was to investigate gender differences in KAM during the terminal stance of gait between unrestricted and restricted ankle range of motion.

**Methods:** Forty-nine healthy volunteers (24 males, 25 females) walked with a custom-designed ankle brace that restricted ankle DF. Kinematics and kinetics were collected using a 7-camera motion analysis system and two force plates. Ankle DF was unrestricted and restricted to 0 degree. Ankle DF angle, knee extension angle and KAM were measured during terminal stance. The significant difference was set for both conditions of $p<0.05$ and above 0.50 effect size (ES) in the present study.

**Results:** Peak ankle DF angles for unrestricted and restricted by the brace were 13.9 ± 4.1° and 7.0 ± 5.4° in males, and 10.1 ± 5.6° and 2.8 ± 4.1° in females, and peak knee extension angles were –9.0 ± 4.8° and –4.0 ± 6.4° in males, and –3.2 ± 5.2° and 2.0 ± 5.7° in female, respectively. The peak KAMs were 0.38 ± 0.15 Nm/kg and 0.42 ± 0.15 Nm/kg in males ($p=0.018$, ES =0.27), and 0.37 ± 0.12 Nm/kg and 0.47 ± 0.12 Nm/kg in females ($p<0.001$, ES =0.83). KAM was significantly different between unrestricted and restricted ankle range of motion in females.

In both genders, significant correlations were observed between the changes with both conditions in KAM and changes in peak knee extension angle. A stronger relationship was observed between them in females than in males ($r=0.52$, $p=0.012$ in males, $r=0.64$, $p=0.001$ in females). Significant correlations were observed between changes in peak knee extension angle and changes in peak ankle DF angle in males ($r=-0.65$, $p=0.001$), but no relationship was observed in females.

**Conclusions:** KAM in females was more affected by restricted ankle DF during terminal stance of gait than KAM in males. Increased KAM was related to greater knee extension angle, which may be caused by restricted ankle DF. However, knee extension angle in female is assumed to be affected by the genu recurvatum observed during the restricted ankle range of motion condition and the ceiling effect shown in the relationship with changes in peak ankle DF angle.

## FRI0640-HPR EFFECTS OF POSTURAL TAPING ON PAIN AND FUNCTION FOLLOWING OSTEOPOROTIC VERTEBRAL FRACTURES – A PILOT STUDY

S. Palmer[1], R. Lewis[2], S. Barnett[1], M. Cramp[1], A. Berry[1], A. Thomas[1], E. Clark[3]. *[1]Department of Allied Health Professions, University of the West of England; [2]Department of Physiotherapy, North Bristol NHS Trust; [3]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom*

**Background:** Osteoporotic Vertebral Fractures (OVFs) are common and present a significant burden to patients and healthcare services. It is known that poor posture (such as forward flexion) can increase the pressure on vertebrae, increasing pain and the risk of further fracture. Postural taping may therefore act to reduce spinal loading and pain.

**Objectives:** To assess the effects of postural taping on pain and function when used for a 4-week period in addition to usual care. To decide if a fully-powered study is feasible.

**Methods:** *Recruitment:* Men and women with OVFs recruited from two local healthcare organisations. *Inclusion criteria:* At least one painful OVF; Fracture not immobilised; Independently mobile (with or without an aid); Able to apply taping device independently or with assistance. *Exclusion criteria:* Osteoporosis secondary to metabolic bone disorders or other disease (steroid-induced osteoporosis was *not* an exclusion); Fragile or broken skin; Known allergy to adhesive plasters; Vertebroplasty or kyphoplasty. Diagnosis was confirmed by a consultant rheumatologist. A mutually convenient appointment was agreed when participants gave formal consent and completed baseline questionnaires.

*Outcome measures:* Outcomes were assessed at baseline and at 4 weeks. *Pain:* Visual Analogue Scale (VAS) for pain on movement and at rest. *Function and Quality of Life:* Quality of Life Questionnaire of the European Foundation for Osteoporosis (QUALEFFO).

*Intervention:* Following baseline assessment, participants were randomly allocated to receive the taping device ("PosturePlast") for home use and received full instruction (including skin care) and a supply of devices. The taping device is like a large sticking plaster with a built-in flexible plastic "X". The manufacturer claims it controls back movement, reduces pain and improves posture. Those randomised to the control condition continued with usual care.

**Results:** 25 participants took part (taping n=13, control n=11). The groups were comparable in terms of age and time between assessments, although the control group contained more men (n=3 versus n=0) and scored slightly lower on most clinical scores.

Descriptive analysis showed fairly consistent improvements in outcomes in both groups. The mean difference favoured the taping group for most outcomes. Generally the observed standardised effect sizes were small to medium (see Table). The largest effects were evident for pain and physical function. As might be expected in a small study, the observed mean group differences were associated with large confidence intervals.

| | | Standardised effect size (Cohen's *d*) |
|---|---|---|
| VAS pain at rest | | 0.37 |
| VAS pain on movement | | 0.45 |
| QUALEFFO total score | | 0.66 |
| QUALEFFO subscales | Pain | 0.54 |
| | Physical function | 0.78 |
| | Social function | 0.06 |
| | General health perception | –0.29 |
| | Mental function | 0.35 |

**Conclusions:** The taping device has the potential to improve pain and function, which is notable for such a simple device. However the findings need to be replicated in an appropriately powered study. The study procedures were acceptable to most participants and it seems that a definitive trial is feasible.

**Acknowledgement:** Supported by the North Bristol NHS Trust Springboard Fund and the National Osteoporosis Society. Research Ethics Committee reference 13/WM/0357.
**Disclosure of Interest:** None declared

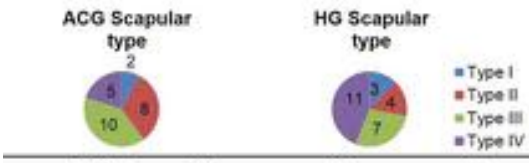
## FRI0641-HPR BENEFICAL EFFECT OF A GAIT MODIFICATION, "NANBA STYLE WALK," FOR DECREASED KNEE ADDUCTION MOMENT

S. Ota, Y. Ogawa, H. Ota, T. Fujiwara, T. Sugiyama. *Department of Rehabilitation and Care, Seijoh University, Tokai, Japan*



**Background:** The knee adduction moment (KAM) during gait was reported to affect knee osteoarthritis (OA) [1], and therefore a gait style with decreased KAM

is thought to be one way to prevent knee OA [2]. The Nanba style walk (N-walk) is a walking style with the step of the leg and swing of the arm at the same time as small trunk rotation [3], and the body's center of gravity is directly moved close to the center of the pressure. This gait modification is assumed to decrease the lever arm of the KAM, so that the KAM would be decreased due to the N-walk.
**Objectives:** The purpose of the study was to investigate the effect of the Nanba walk on KAM during gait in healthy adults as a preliminary study.
**Methods:** 28 healthy adults consisting of 16 men and 12 women (21.7 ± 0.4 years old) participated. All participants including those in the pilot study were informed as to the nature of the study, and their informed consent was obtained as approved by the Ethics Committee of Seijoh University. A three-dimensional analysis system (Venus 3D; Nobby Tech, Tokyo, Japan) with a 10-camera and a force plate (AccuGait; AMTI, MA, USA) were used to obtain the kinematics and kinetic data by inverse dynamic methods and global optimization. KAMs were normalized to body mass and leg length (no unit). The 1st and 2nd peak KAMs during stance phase and the lever arm length of the KAM (frontal plane) at both peak KAMs were measured to compare with free gait and N-walk. N-walk gait speed was controlled within ± 5% of a free gait. Subjects were asked to walk along a 6-m walkway, and three successful trials were recorded. Average data were used in final analysis. The EMG of the gluteus medius muscle, which was reported to relate to KAM [4], was measured, and Integral EMGs (iEMG) of the first and second half of the stance phase after full-wave EMG rectification were used to compare the two gait styles.
**Results:** The peak 1st and 2nd KAM of N-walk (4.9 ± 1.2 $\times 10^{-2}$ and 4.7 ± 1.5 $\times 10^{-2}$) were significantly decreased compared to the KAMs of free gait (5.6 ± 1.1 $\times 10^{-2}$ and 5.6 ± 1.6 $\times 10^{-2}$). The lever arm length at the peak 1st and 2nd KAM of N-walk (3.7 ± 1.1 and 3.3 ± 1.0 cm) were also significantly decreased compared to the lever arm length of free gait (3.9 ± 1.0 and 4.1 ± 1.0 cm). The iEMGs of gluteus medius muscle of the first and second half of the N-walk (2.8 ± 1.3 and 3.0 ± 1.4 Vs) were significantly increased compared to the iEMGs of the free gait (1.9 ± 0.9 and 2.1 ± 1.0 Vs, $p<0.05$).
**Conclusions:** The 1st and 2nd peak of KAM with N-walk were significantly decreased compared to the KAMs of free gait due to the lever arm length of KAMs with increased gluteus medius muscle activity. N-walk is one of the traditional Japanese walking styles when wearing a *kimono*. This gait modification is assumed to one of the indications of a walking style to help prevent medial knee osteoarthritis.

## FRI0642-HPR SCAPULAR BIOMECHANICS IN PATIENTS WITH ADHESIVE CAPSULITIS

T. Zoroglu[1], S. Basar[2]. [1]*Vocational School of Health Services, Karabuk University, Karabuk;* [2]*Physiotherapy and Rehabilitation, Gazi University, Ankara, Turkey*

**Background:** It is necessary that coordinated, synchronous motion of humerus, scapula and clavicula for full shoulder mobility and function. This motion may be impaired by adhesive capsulitis (AC) which is characterized by fibrosis and contracture of the glenohumeral joint capsule and ligaments.
**Objectives:** In this study we aimed to assess scapular biomechanics in patients with adhesive capsulitis and determine changes.

*Differences for HG derived by subtracting the measured side from the other side. Differences for subjects with AC derived by subtracting the injured side from the uninjured side. All measurements are expressed in centimeters. $p<0.05$

**Methods:** Twenty five patients with AC (21 female, 4 male; mean age 53±6 years; age range 44–67) and twenty five healthy people (21 female, 4 male; mean age 51±7; age range 39–65) were included in this study. Mean Body Mass Index (BMI) was 29.02±4.89 in AC group (ACG) and 28.40±4.67 in healthy group (HG). 11 dominant and 14 non-dominant shoulders in ACG and 12 dominant and 13 non-dominant shoulders in HG were measured. Kibler's observational classification system and lateral scapular slide test (LSST) were used for evaluating scapular position and mobility.
**Results:** There were 2 type I, 8 type II,10 type III and 5 symetric scapula in ACG and 3 type I, 4 type II,7 type III and 11 symetric scapula in HG. 80% of ACG and 56% of HG had scapular dyskinesia but it was not significant ($p>0.05$). There was significant difference between groups in LSST the distance between inferior angle of scapula and T7 at 90° abduction ($p<0.05$) (Table 1).
**Conclusions:** In this study, our results showed that scapular biomechanics were impaired in patients with AC. Especially the majority of type III scapula and the distance between inferior angle of scapula and T7 at 90° abduction demonstrate increase in scapular upward rotation in upper degrees of elevation.

## FRI0643-HPR A MULTICENTRE FOCUS GROUP STUDY ON IMPORTANT OUTCOMES FOR PATIENTS WITH PSORIATIC ARTHRITIS

E. Dures[1], W. Tillett[2], J. Lord[3], C. Bowen[4], N. McHugh[5], S. Hewlett[1] on behalf of the PROMPT Study. [1]*University of the West of England, Bristol;* [2]*Royal National Hospital for Rheumatic Diseases, Bath;* [3]*Patient Partner, University Hospitals Bristol, Bristol;* [4]*Patient Partner, the Psoriatic Arthritis Support Group (PsAZZ);* [5]*University of Bath, Bath, United Kingdom*

**Background:** Psoriatic arthritis (PsA) is a variable and complex inflammatory arthritis. Symptoms can arise from psoriasis, enthesitis, dactylitis, and arthritis, which can compromise physical function, cause disability, and accrue significant health costs. The PROMPT research programme includes a randomised controlled trial (RCT) to investigate the benefit of earlier diagnosis of PsA on long term outcomes. Before the RCT can begin, it is important to include patient reported outcomes (PROMs) that are meaningful to patients. The measures currently used in PsA trials cover some of these domains and occasionally include a combined instrument such as the Composite Psoriatic Disease Activity Index questionnaire (CPDAI). However, they have been developed largely by professionals, consequently it is not known whether they capture what is most important to patients.
**Objectives:** To identify the disease activity and impact outcomes that are important to patients with PsA.
**Methods:** Eight focus groups at 5 hospital sites. Focus groups were audio-recorded, transcribed, anonymised, and analysed using Inductive Thematic Analysis. The full data set was analysed by the lead researcher, and a subset by 3 other team members (including patient partners).
**Results:** Forty-one patients sampled for a range of phenotypes and domains of disease activity took part: men=20; mean age=58 years (range 28–75; SD 11.4); mean disease duration=9 years (range 0.5–39; SD 8.3); mean HAQ=1 (range 0.0–2.5; SD 0.7). Over 60 outcomes were identified and grouped into 5 main categories:
1. Symptoms: including pain (e.g. back, arms, hips); swelling (e.g. sausage digits; puffy hands); stiffness (e.g. feet, hands); fatigue (e.g. physically tired, mentally foggy); skin (e.g. red, itchy, flaky), and poor sleep.
2. Personal impact: including physical (e.g. loss of fitness, restricted mobility); emotional (e.g. low mood, anxiety, anger); and social (e.g. embarrassment; isolation; loss of work).
3. Negative outcomes from treatment: including experiences (e.g. side effects, nausea); fears (e.g. concerns about toxicity); and practical challenges (e.g. mode of administration; requirement of regular blood tests).
4. Effective outcomes of treatment: including alleviation of symptoms (e.g. pain, stiffness); better skin; life-changing/miraculous drugs; and able to lead a normal life.
5. Expectations of treatment: including able to do more; improve quality of life/wellbeing; halt long term joint damage and symptoms of PsA; maintain independence; gain greater disease control (e.g. fewer flares); and understand reasons for prescribed treatment.

**Conclusions:** Qualitative data captured varied outcomes important to patients, from specific physical symptoms to the psychological, social and emotional impact on wellbeing and daily life. As it is not feasible or acceptable to include measures for all the outcomes generated, patients will now prioritise them in nominal groups. These priorities will be compared to the existing core set and the CPDAI. If patients identify important outcomes not currently measured, validated PROMs to

capture these will be identified. This will lead to a set of measures capturing all relevant domains of PsA from the patient perspective.

## FRI0644-HPR PERCEIVED PHYSICAL ACTIVITY BENEFITS AND BARRIERS IN RHEUMATOID ARTHRITIS PATIENTS

L. Sammut[1], P. Clayton[1], J. Arnold[2], B. Davidson[1]. [1]*Rheumatology, University Hospital Southampton NHS Foundation Trust;* [2]*Sports Science, Southampton Solent University, Southampton, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is associated with an increased risk of osteoporosis and cardiovascular disease, a reduction in physical fitness, and consequently a reduction in quality of life. Scientific evidence now supports various forms of exercise as both safe and even beneficial for RA patients. In RA, physical activity appears to play a central role in the management of the disease, maintenance of muscular function, joint range of motion and the ability to perform activities of daily life.
**Objectives:** The present study aimed to examine the perceived exercise benefits and barriers in a cross-section of patients diagnosed with RA, with the hope to tailor physical activity interventions to this group of patients.
**Methods:** Utilising a cross sectional study design thirty-seven participants (age, 58 ± 13 yrs) completed a self-administered survey. Participants were convenience-sampled from patients diagnosed with RA, attending the day-case unit for regular biologic intravenous infusions. Exercise barriers and perceived benefits of exercise were assessed using the exercise benefits/barriers scale (EBBS), with added questions in a rheumatology specific subscale. Physical activity guidelines (PAG's) were assessed using the single question physical activity questionnaire. Data are presented as means ± SD. Statistically significant differences reported by those meeting, and those not meeting PAG's was assessed using independent samples *t*-tests.
**Results:** The greatest perceived benefit of exercise was the physical performance subscale (score, 3.0 ± 0.4), and the greatest perceived barrier was the physical exertion subscale (score, 3.0 ± 0.6).Within the rheumatology specific subscale, "Exercise keeps my joints moving" was the highest perceived benefit, whereas "Exercise causes pain" was the highest perceived barrier. Despite attending regular intravenous biologic drug infusion sessions, patients disagreed that they do not have enough time to exercise (score, 2.1 ± 0.6) as presented by the time expenditure subscale. Of 37 participants, 43.2% ($n$=16) do not meet current PAG's. Such patients reported significantly lower overall perceived benefits of exercise than those meeting PAG's (respective scores, 2.6 ± 0.3 vs. 3.0 ± 0.4, $P<0.05$), and significantly higher overall barriers (respective scores, 2.5 ± 0.4 vs. 2.1 ± 0.4, $P<0.05$). Of the various specific EBBS subscales, statistically significant ($P<0.05$) differences were reported across life enhancement, physical performance, psychological outlook and physical exertion subscales, between those meeting, and those not meeting PAG's. Furthermore, those not meeting PAG's reported significantly greater perceived barriers in the rheumatoid specific subscale (score,3.1± 0.5 vs. 2.4± 0.4, $P<0.001$).
**Conclusions:** Less than half of the sample currently meet PAG's, with significant differences in perceived benefits/barriers between who meet and those who do not meet guidelines. Fatigue related to exercise was the greatest perceived barrier overall, which is also regarded as an extra-articular symptom of the disease. Contrary to the traditional advice, exercise is an intervention targeted against fatigue and has a critical bearing on wellbeing and quality of life in RA patients. Patients attending for biologic drug infusions represent a key opportunity to promote physical activity in this population.

## FRI0645-HPR FREQUENTLY ASKED QUESTIONS OF PATIENTS WITH OSTEOARTHRITIS: A CONSENSUS EXERCISE

A. Claassen[1], S. Koëter[2], J. Botman[3], H. Schers[4], C. van den Ende[1] on behalf of Project Group "Towards a Regional Approach of Osteoarthritis".
[1]*Rheumatology, Sint Maartenskliniek;* [2]*Orthopaedic Surgery, Canisius Wilhelmina Hospital;* [3]*Stichting Gezondheidscentrum de Kroonsteen-de Vuursteen;* [4]*Primary and Community Care, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Providing unambiguous information about osteoarthritis (OA) and describing options for self-management help patients to become actively involved in their own care. The lack of consensus among clinicians and the heterogeneous terminology between involved disciplines may complicate effective communication. Therefore, we decided to develop an educational course based on a structured inventory of informational needs and on consensus-based information addressing those needs.
**Objectives:** 1) to make an inventory of the most frequently asked questions (FAQs) on OA, expressed by patients to their different health care providers, 2) to formulate answers based on consensus among health care providers in the area of Nijmegen.
**Methods:** To identify and formulate answers to FAQS the following steps were taken: 1) Orthopaedic surgeons, rheumatologists, nurse practitioners from 3 different hospitals, and general practitioners and physiotherapists participating in a local network, were invited to provide 5–10 FAQs, not covered by a website providing information on OA (ran by The Dutch College of General Practitioners). Additionally the Dutch Arthritis Foundation was asked to provide FAQs from their arthritis helpline. 2) After deleting overlapping FAQs, the remaining FAQs were categorized by two researchers. 3) Care providers who provided FAQs and patients (responding to a call on various websites of local patient organisations) were asked to indicate a top 5 of most important FAQs per category and divide 100 points among their top 5 per category. 4) Twenty most important FAQs were selected for answer formulation. Then, for each FAQ 3 care providers from 3 different disciplines were asked to formulate an answer. 5) Finally, in consensus meetings draft answers were combined into one final answer per FAQ.
**Results:** A total of 28 responders provided 192 FAQs. From these FAQs, 93 overlapping FAQs were deleted and remaining 99 FAQs were categorized into 9 categories of 7–14 FAQs each, namely: "OA; cause, symptoms and disease course", "diagnostics", "medication", "care providers", "lifestyle", "surgery", "work", "self-management", "other". Seventeen professionals and 29 patients responded to the subsequent round of prioritising. The overall top 5 FAQs were: 1."What are the newest treatment options?" 2. "What is the natural course of OA?" 3. "If medication does not work, what other treatment options do I have?" 4. "'What sports are suitable? At what frequency and intensity?" 5. "When am I eligible for a joint replacement?". In 3 meetings the project group reached consensus on answers of the Top-20 FAQs.
**Conclusions:** Our study shows that it is feasible to achieve consensus among disciplines on information on topics not covered by guidelines, which can help to overcome communication hazards between patient and professionals from different disciplines. Formulated answers have been used in the development of an OA educational self-management course for OA-patients. Future research is necessary to examine to what extent consistency of information can contribute to self-management.

## FRI0646-HPR DOES PAINFUL HAND ARTHRITIS INFLUENCE MOTOR CORTEX EXCITABILITY AND MOTOR SKILL LEARNING?

R. Parker[1,2], G. Lewis[1], D. Rice[1,3], P. McNair[1]. [1]*Auckland University of Technology;* [2]*Physiotherapy;* [3]*Pain Service, Waitemata District Health Board, Auckland, New Zealand*

**Background:** Painful hand arthritis frequently leads to reduced quality of life [1] and impaired hand function [2]. This may be partially mediated by impaired motor control [3] and changes in primary motor cortex excitability [4]. Previous studies have shown that other chronic pain conditions are associated with reduced motor cortex inhibition [5], which is also associated with motor learning [6]. Therefore, impaired motor control and learning in arthritic pain populations is potentially due to changes in motor cortex excitability. Supporting this, previous studies have shown that motor learning may be influenced by acute experimental pain. However, no previous study has sought to establish whether chronic arthritic pain may influence motor learning and if this relates to changes in motor cortex excitability.
**Objectives:** To provide a thorough analysis of corticomotor and intracortical excitability in people with painful hand arthritis, and to examine the relationship between these measures and performance on a motor skill learning task.
**Methods:** Twenty three people with arthritic hand pain and 20 pain-free controls participated in a cross-sectional study. Hand pain and function were assessed using the AUSCAN osteoarthritis hand index. Transcranial magnetic stimulation was used to measure corticomotor and intracortical excitability of a finger muscle. Motor skill learning was assessed using a 30 minute training task involving the index finger of the same hand.
**Results:** Compared with controls, participants with hand arthritis showed evidence of reduced intracortical inhibition and enhanced facilitation ($p<0.05$). However, overall corticomotor excitability was normal. Participants with arthritis were initially poorer at the motor skill task, but over the total training time performance was equivalent between groups. There were no associations found between measures of intracortical or corticomotor excitability and motor skill learning or hand function.
**Conclusions:** This study provides novel evidence that hand arthritis is associated with reduced intracortical inhibition similar to other chronic pain populations. However, no relationship was observed between these cortical alterations and impaired function or skill learning.

FRI0647-HPR **PHYSICAL ACTIVITY AND AEROBIC CAPACITY ASSESSMENT - A SURVEY AMONG PATIENTS WITH RHEUMATIC DISEASE IN SWEDEN, IRELAND, AND DENMARK**

N. Brodin[1,2], N. Kennedy[3], T. Swinnen[4,5], B. Appel Esbensen[6,7], S. McKenna[3], S. Willemijns[5], N.M. Hammer[7], B. Nordgren[2]. *[1]Division of Physiotherapy, Orthopaedic clinic, Danderyd Hospital, Stockholm; [2]Division of Physiotherapy, Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Huddinge, Sweden; [3]Department of Clinical Therapies, University of Limerick, Limerick, Ireland; [4]Division of Rheumatology, UZ Leuven; [5]Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven, Leuven, Belgium; [6]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen; [7]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases VRR, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark*

**Background:** Despite its positive effects on health outcomes, insufficient levels of physical activity (PA) have been found in the arthritis population. In addition, lower aerobic capacity adds to the patient's risk for cardiovascular disease. Increasing PA is thus important for this group and the use of objective and self-reported measures of PA should be encouraged as self-monitoring and evaluation of PA support promotion of healthy PA behaviours.
**Objectives:** To investigate the familiarity with objective and self-reported PA and aerobic capacity assessments and to identify barriers for their implementation in patients with rheumatic disease in Sweden, Ireland and Denmark.
**Methods:** Patients with rheumatic disease were invited through each country's patient organisations to participate in a cross-sectional, observational study using online survey methodology.
**Results:** A total of 791 patients (87% female) responded (579 Danish, 90 Irish and 122 Swedish) with Rheumatoid Arthritis (42%), Ankylosing Spondylitis (14%), Psoriatic Arthritis (25%) as main diagnoses. 99% of the patients reported pain during the past week in hand (62%), leg (60%), arm (58%), foot (51%), back (49%) and/or neck (36%). A total of 25% reported large limitations in moderate daily activities and 24% in climbing stairs. Use of biological disease modifying anti rheumatic drugs (Bio-DMARDS) was reported by 28% and non-biological DMARDS by 47%. Two thirds found it important to measure PA and approximately half stated they do not receive information regarding the same. Moderate levels of familiarity with simple body-worn sensor (mean 5.47/10; SD 4.04) to measure PA was found. Familiarity was lower with paper questionnaires (4.09/10; SD 3.69), complex body-worn sensors (3.70/10; SD 3.87), digital diaries (3.07/10; SD 3.53), paper diaries (3.45/10; SD 3.64) and digital questionnaires (3.46/10; SD 3.67) to measure PA. There was no statistically significant association between diagnosis, physical limitation or localisation of pain in relation to the familiarity of the above measures of PA ($p>0.05$), however, patients on Bio-DMARDS were more familiar with simple ($p=0.016$) and complex sensors ($p=0.003$), digital questionnaires ($p=0.009$) and diaries ($p=0.006$). 34% reported that their aerobic capacity had been tested whilst 57% reported no testing. Barriers for patients with rheumatic disease for measuring PA were reported by 43% and access to device (25%), uncertainty of handling the results (14–17%) and cost of device (10%) were most common.
**Conclusions:** Although most patients with rheumatic diseases in our sample perceived measures of PA as important, familiarity and information of their use was largely lacking. Also, aerobic capacity assessment occurred infrequently. To motivate behavioural change towards a more physically active lifestyle and to support individuals' independence of health care, health professionals should facilitate awareness and knowledge of PA measures, encourage their patients to regularly self-monitor PA and more often offer PA and aerobic capacity testing to their patients.

FRI0648-HPR **GOAL SETTING IN REHABILITATION; A SYSTEMATIC SYNTHESIS OF CLINICAL PRACTICE DESCRIBED IN RANDOMIZED CONTROLLED TRIALS**

A.-L. Sand-Svartrud[1], G. Smedslund[1], H. Lundgaard Søberg[2,3], G. Engen[4], I. Kjeken[1]. *[1]Dept of Rheumatology, Diakonhjemmet Hospital; [2]Oslo and Akershus University of Applied Sciences; [3]Dept of Physical Medicine and Rehabilitation, Oslo University Hospital; [4]Research Centre of Habilitation and Rehabilitation Models & Services (CHARM), University of Oslo, Oslo, Norway*

**Background:** Person-centred goal setting and shared decision-making are emphasised as essential parts of effective team work and good clinical practice in rehabilitation.
**Objectives:** To explore the practice of collaborative goal setting in rehabilitation for adults with rheumatic and musculoskeletal diseases (RMDs), as described in published randomized controlled trials (RCTs).
**Methods:** A comprehensive, systematic literature search was undertaken to identify RCTs evaluating the effect of rehabilitation involving health professionals from at least two disciplines. We included trials from the period 1997–2012. Participants in the trials had a RMD with duration of more than three months.
Following a deductive approach, four categories and nine keywords were developed from existing theory (1) and prior research about goal setting. The categories were i) goal negotiation, ii) specific goal setting, iii) goal-directed planning, iv) goal evaluation. Keywords were goal, aim, expect, need, tailor, objective, target, plan and outcome. The categories and keywords were used to identify text units in the articles, which were analyzed using a directive and summative content analysis.
**Results:** 21 RCTs were included, of which 12 included participants with chronic low back pain and 9 included participants with inflammatory arthropathies, connective tissue diseases or fibromyalgia. The intervention was inpatient or outpatient rehabilitation, and involved group and/or individual sessions. The multidisciplinary teams consisted of 3 to 7 professions. A total of 430 text units were identified, of which 18 (4%) contained descriptions of patients as active participants in the goal setting process. These units came from 8 papers. Goal negotiation was described in 7 of these 8 papers, and specific goal setting in all 8 papers. Goal-directed planning was described in 6 papers, and patient-centred goal evaluation in 3 papers. No papers described a specific instrument or a formal method of goal setting. The remaining text units (96%) did not describe any collaboration in the goal setting process between patients and health professionals. However, content related to predefined treatment goals was identified in 19 papers. These treatment goals were set by health professionals without patient involvement.
**Conclusions:** In articles reporting results from RCTs examining the effect of rehabilitation, the occurrence of patients as active participants in collaborative goal setting in general was low, and lower than the occurrence of predefined treatment goals set by health professionals alone. The results indicate that there is a gap between the emphasis on goal setting in rehabilitation theory and its implementation in clinical practice and research.

FRI0649-HPR **INNOVATION IN HEALTH CARE – LABORATORY VALIDITY AND RELIABILITY OF A NEW SENSOR DEVELOPED TO MEASURE CERVICAL ROTATION**

C. Fongen[1], N. Østerås[1], F.R. Andersen[2], V. Berre[2], A.T. Tveter[3], K.B. Hagen[1]. *[1]Diakonhjemmet Hospital, Oslo; [2]Apertus, Asker; [3]University of Oslo, Oslo, Norway*

**Background:** For patients with axial spondyloarthritis (axSpA) it is recommended to monitor spinal mobility regularly. Cervical rotation (CR) is usually measured with goniometer or myrinometer, but might give imprecise results. Technological innovation provides opportunities to develop and improve measurement methods for use in clinical practice.
**Objectives:** To evaluate validity and reliability of a sensor developed to measure rotation around the vertical axis in a laboratory setting.
**Methods:** A sensor was developed by engineers in close collaboration with health professionals and patients with axSpA. It was tested in a laboratory setting and the data collected was compared with Cybex 6000 simulation data as gold standard. The sensor was mounted to the cybex with a bracket in six different positions, 1) straight up 2) straight down 3) up, tilted 30°around the frontal axis 4) down, tilted 30°around the frontal axis 5) up, tilted 30°around the frontal axis, 20° around the sagittal axis 6) down, tilted 30°around the frontal axis, 20° around the sagittal axis. Reference angles were set at approximately 10, 30, 60, 90 and 120 degrees. From a centre position the sensor was moved from left to right (one cycle) by manual force at the speed allowed (60°/second) until stop brackets were reached.
Criterion validity and reliability for single measures and for the mean of three trials (left, right or cycle) was evaluated with two ways mixed interclass correlation coefficient$_{agreement}$ (ICC). Limits of agreement (LoA) (Bland and Altman method), and smallest detectable change$_{agreement}$ (SDC$_{95\%}$) with 95%CI were calculated to evaluate the measurement error of the sensor.
**Results:** A total number of 261 cycles were performed. The ICC values were excellent for all measurement (ICC: 1.0; 95% CI 1.0, 1.0). One cycle of movement showed lower measure error (LoA) compared to single measures (left or right) (table 1). The measurement error was further improved by using the mean of 3 cycles (figure 1). The SDC$_{95}$ was 0.87 for one cycle and 0.80 for the mean of three cycles.

Table 1. Results from the reliability evaluation of a new sensor

| | | Mean diff (SD) | LoA | SDC$_{95\%}$ |
|---|---|---|---|---|
| Single | Left, ° | –0.06 (0.93) | –1.88–1.76 | 1.82 |
| | Right, ° | 0.28 (1.35) | –2.36–2.93 | 2.65 |
| | Cycle, ° | 0.11 (0.44) | –0.78–0.98 | 0.87 |
| Mean of three | Left, ° | –0.02 (0.82) | –1.59–1.61 | 1.61 |
| | Right, ° | 0.30 (1.25) | –2.15–2.75 | 2.44 |
| | Cycle, ° | 0.14 (0.40) | –0.65–0.93 | 0.80 |

**Conclusions:** The sensor showed excellent criterion validity and reliability for rotation around the vertical axis in the range of motion from 10 to 120 degrees, especially for cycles and mean of 3 cycles. When assessing a single cycle or the average of three cycles, a change of 1 degree is needed for real change beyond

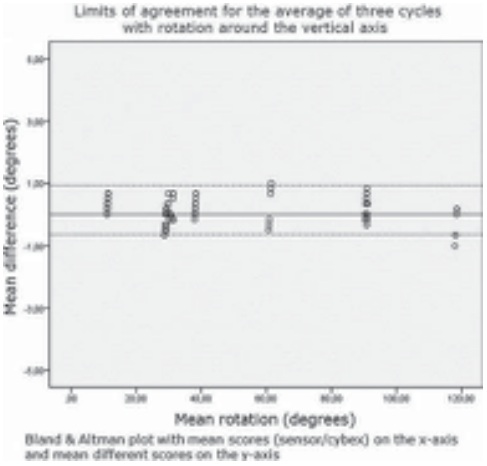

Figure 1

measurement error. Our findings justify proceeding with further evaluations of the sensor in patients with axSpA.
**Disclosure of Interest:** None declared

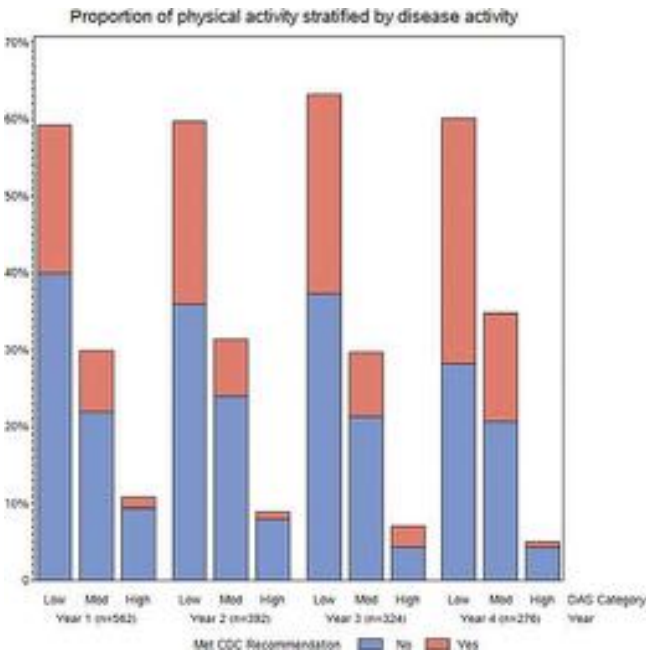
## FRI0650-HPR COMPARISON OF THE EFFECTIVENESS OF FUNCTIONAL AND NIGHT SPLINT FOR RHIZARTHROSIS: A CONTROLLED, RANDOMIZED, BLINDED CLINICAL TRIAL

F.C. Silva, S.M.M. Adolph, R.V. Timoteo da Silva, J. Natour. *Medicina- Disciplina de Reumatologia, Unifesp - Universidade federal de São Paulo, São Paulo, Brazil*

**Background:** Rhizarthrosis is an inflammatory degenerative joint disease affecting the trapeziometacarpal joint of the thumb that impairs lateral pinching and movements of opposition and retroposition. The main symptom is pain, leading to difficulty with hand functions and reduced quality of life. Immobilization of the trapeziometacarpal joint of the thumb by splint has proved effective in reducing pain and improving hand function in patients suffering from the condition. Two randomized controlled trials found in the literature reported similar findings in terms of pain reduction and improved hand function with the use of a short orthosis for rhizarthrosis; one of the trials showed the benefits when the device was used for daytime function while the other showed the benefits when the orthosis was used during nighttime rest.
**Objectives:** To compare the effectiveness of functional (daytime) and night splint (Figure 1) in reducing pain and improving functionality in patients with rhizarthrosis.



**Methods:** A controlled, randomized, blinded clinical trial with sixty patients diagnosed with rhizarthrosis. The patients were assessed by a blinded assessor at the beginning of the treatment and after 45, 90 and 180 days the following variables were evaluated: pain at the base of the thumb using a a numerical pain scale; thumb range of motion measured using a goniometer; grip strength evaluated by a hydraulic hand dynamometer; pinch strength using the pinch gage; hand dexterity evaluated with the pick-up test; function evaluated by the Brazilian version of the AUSCAN LK 3.01 Hand Osteoarthritis Index, the Cochin Hand Function Scale, the Michigan Hand Outcomes Questionnaire and a Likert-type scale. The Hand Outcomes Questionnaire, Cochin Scale and Michigan Questionnaire were used to assess hand function and patient satisfaction using a Likert scale.
**Results:** Most of the variables analyzed, including patient characteristics such as age, gender, disease duration and hand dominance, were homogeneous at the beginning of the study. In both groups there was a reduction in hand pain with time (intragroup analysis). Pain in the functional group, expressed as mean ± standard deviation, was 6.82±1.72 and 4.77±2.45 at the beginning and end of the treatment, respectively, and the corresponding figures for the nighttime group were 7.20±1.63 and 4.83±2.68. The p values for both groups were $p<0.001$. There were no statistically significant differences in the majority of the parameters assessed between the groups. The only domains with a statistically significant difference ($p<0.001$) between the two groups were: *activities of daily living* in the AUSCAN questionnaire and *satisfaction* in the Michigan questionnaire, for both of which the functional group had better scores
**Conclusions:** There was no statistically significant difference between functional and night splint in terms of pain, function or any of the other parameters assessed in rhizarthrosis patients.

## FRI0651-HPR THREE YEAR TRENDS IN PHYSICAL ACTIVITY IN ADULTS WITH RHEUMATOID ARTHRITIS

M. Iversen[1,2], M. Frits[3], J. vonHeideken[4], J. Cui[5], C. Iannaccone[3], N. Shadick[2]. *[1]Physical Therapy, Movement & Rehabilitation Sciences, Northeastern University; [2]Section of Clinical Sciences, Brigham & Women's Hospital, Harvard Medical School; [3]Section of Clinical Sciences, Brigham & Women's Hospital, Boston, United States; [4]Women's and Children's Health, Karolinska Institute, Stockholm, Sweden; [5]Section of Clinical Sciences, Brigham & Women's Hospital, Boston, United States*

**Background:** Adults with Rheumatoid Arthritis (RA) demonstrate low physical activity (PA) levels and excess cardiovascular risk. Most PA studies in RA are cross-sectional and PA interventions are often part of self-management programs of short-term duration ($\leq$1 year). Longitudinal examination of PA in RA may inform PA intervention design.
**Objectives:** To identify trends in PA in adults with RA over 3 years and to longitudinally characterize correlates of PA.
**Methods:** This 3-yr study included 573 RA registry patients with $\geq$1 annual visit and complete PA data. Baseline and annual measures were: demographics, medical history/meds, alcohol use, psychosocial support, self-efficacy, disease activity, quality of life, patient/physician global assessment, function, and PA defined as either meeting or not meeting the US Dept Health & Human Services (DHHS) recommendations of 150 min of moderate activity/wk or 90 min vigorous PA/week, at each interval. McNemar $\chi^2$ tests assessed the relationship between disease activity (DAS-CRP3 categories) and PA. A mixed model repeated measures analysis identified factors associated with PA, adjusting for disease activity over time.
**Results:** 94% of adults were Caucasian, 83% female with a mean age of 61 yrs (SD=12). Average RA duration was 19.5 yrs (SD=11.8). At baseline, 59.2% had low disease activity, 29.9% moderate and 10.9% highly active disease. 36% of subjects were sedentary and 29% met the PA recommendations. Over 3 years, PA was significantly negatively associated with disease activity ($\chi^2$, $p<0.001$). Factors associated with meeting PA recommendations, after adjusting for disease activity, were being Caucasian (OR=2.86; 95%CI 1.26–6.48), married/living with partner (OR=1.43; 95% CI 1.03,1.98), and alcohol use (OR=1.33; 95%CI 1.04,1.71). Older age (>53–62 OR=0.62; 95%CI 0.40,0.94; age >62–69 OR=0.64; 95%CI

0.42,0.96; age >69 OR=0.53; 95%CI 0.33,0.83) poor mental health (OR =0.58; 95%CI 0.38,0.87) and higher patient global assessment scores [10–20] OR=0.59; 95%CI 0.41,0.85; [>20–50] OR=0.61; 95%CI 0.39,0.96; [>50] OR=0.51; 95%CI 0.29,0.89) were associated with not meeting the PA threshold.

**Conclusions:** A small proportion of adults with RA met PA recommendations, despite well-controlled disease, and the proportion decreased over time. After controlling for disease activity, modifiable correlates of PA were linked to lifestyle, mental health and patient perceptions of disease, suggesting PA interventions target patient perspectives and lifestyles.

## FRI0652-HPR SPINAL MOBILITY IN LONG STANDING ANKYLOSING SPONDYLITIS. APPLICATION OF NEWLY DEVELOPED REFERENCE INTERVALS ON CLINICAL DATA

B. Sundström, L. Ljung, S. Wållberg-Jonsson. *Public health & clinical medicine, rheumatology, Umeå University, Umeå, Sweden*

**Background:** A hallmark of ankylosing spondylitis (AS) is the progressive decline of spinal mobility. Recently published reference intervals (RI) for spinal mobility measurements in healthy individuals offer new possibilities to assess impairment during the course of the AS disease (1).

**Objectives:** To evaluate the development of subnormal spinal mobility among patients with AS with regards to disease duration.

**Methods:** The cohort comprised all patients born 1937 or later with a validated (modified NY criteria) AS diagnosis 1980–2015 at the Rheumatology department in Västerbotten, whom had one or more registered spinal mobility measurement (n=232). The first subnormal value (lower than the 2.5th percentile of healthy individuals) regarding 10 cm Schober test, lateral spinal flexion, chest expansion, and cervical rotation, respectively, using the age-, sex- and length specific reference intervals, was defined as outcome. The follow-up started at the first measurement and ended at the date of the outcome, the study end (June 30, 2015), death or the time point for the last visit + 2 years. The results were presented by Kaplan-Meier curves.

**Results:** The median (range) of the total disease duration during follow-up was 31 (5–61) years. 3706 examinations were evaluated, with a median of 24 examinations/patient, or median (range) 1.0 (0.1–2.8) examinations/year of follow-up. The proportion of patients with subnormal mobility increased by disease duration for all measurements. Lumbar mobility was most impaired, but after 15–20 years half of the patients still had mobility measurements within the normal range (Figure 1).

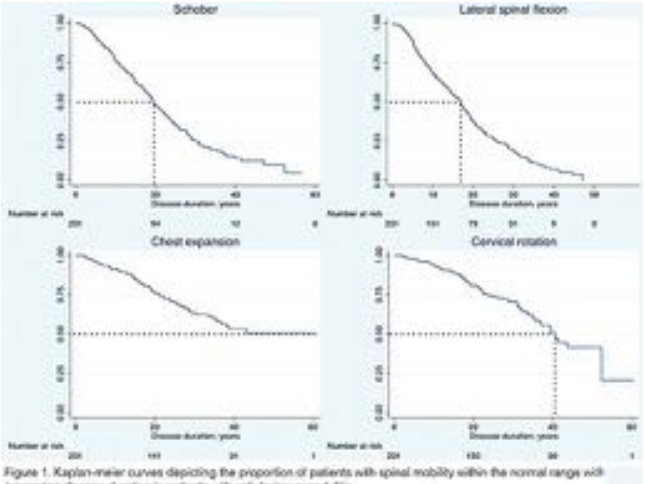

Figure 1. Kaplan-Meier curves depicting the proportion of patients with spinal mobility within the normal range with increasing disease duration in patients with ankylosing spondylitis.

**Conclusions:** Preserved spinal mobility is common in long-standing AS. However, the results indicated a continuous progression of spinal stiffness also after 20 years of AS disease.

# Nursing

## SAT0627-HPR EDUCATIONAL NEEDS OF FRENCH RHEUMATOLOGY NURSES ARE NOT LIMITED TO INFLAMMATORY ARTHRITIS MANAGEMENT. RESULTS OF THE MULTICENTRIC "CAIRE" SURVEY

C. Beauvais[1], S. Pouplin[2], A. Mulliez[3], F. Fayet[4], R.M. Poilverd[1], L. Gossec[5], S. Perrot[6], C. L'Amour[5], M. Mezières[7], M.P. Aubert[8], N. Jaccaz Vallée[9], C. Savel[4]. *[1]Rheumatology Department, Hopital Saint Antoine, Assistance Publique Hôpitauc de Paris, Paris; [2]Rheumatology Department, University Hospital, Rouen; [3]Biostatistics; [4]Rheumatology Department, University Hospital Gabriel Montpied, Clermont Ferrand; [5]Rheumatology Department, University Hospital Pitié Salpétrière; [6]Pain Center; [7]Rheumatology Department, University Hospital Cochin, Paris; [8]Rheumatology Department, University Hospital, Nantes; [9]Rheumatology Department, University Hospital, Tours, France*

**Background:** EULAR recommendations aim to promote the role of the nurse in the management of inflammatory arthritis (IA) (1). A survey among French nurses in 2014–2015 showed a gap between educational needs and reported competences of French nurses regarding IA management (2).

**Objectives:** The objective was to investigate competencies in other rheumatic and musculoskeletal conditions (RMD), patient education and research compared with those found in IA.

**Methods:** The list of potentially useful competencies for RN was validated by a multidisciplinary group (2). The survey was conducted through 3 on-line quesitionnaires in Dec 2014-Jan 2015 (2) then in Jan-May 2015, including 78, 72, 70 items. For each item, the RN were asked on a 4 point likert scale if they believed they had acquired the competency and considered it of importance.

**Results:** All RMD were adressed: rheumatoid arthritis RA, spondyloarthritis SpA, connective tissue diseases (CTD), other RMD e.g osteoarthritis, osteoporosis, low back pain. The cross-functional skills were pain management, patient-nurse communication, patient education, research. Respectively 104, 71 et 64 RN responded the 3 on-line investigations, 92% female, 70% worked full time, 70% in a university hospital; 30–29% declared qualifications in patient education, 9–20% in pain management, 6–17% in research. Reported competencies were very good in DMARDS, analgesics and NSAIDs, good in patient-nurse communication and patient education. In other fields, educational needs are high, particularly for non-pharmacological treatments, CTD, osteoarthritis, low back pain and research (table). Practical skills were less than cognitive skills.

| Competencies | "Very much or rather acquired" competencies % | | Competencies rated "rather important or essential"(%) | |
|---|---|---|---|---|
| | Cognitive | Know how | Cognitive | Know how |
| RA-SpA | 56 [8–94]* | 44 [6–94] | 96 [57–100]* | 91 [48–100] |
| – DMARDS | 79 [57–83] | 72 [50–76] | 100 [93–100] | 100 [86–100] |
| – Symptomatic treatments | 90 [87–94] | 87 [85–94] | 100 [100 – 100] | 100 [100–100] |
| – Non pharmacological treatments | 53 [28–64] | 41 [31–45] | 97 [9–98] | 95 [89–100] |
| – Co morbidités | 43 [36–50] | 37 [31–43] | 98 [98 – 98] | 91 [90–93] |
| CTD | 28 [21–40] | | 90 [86–98] | |
| Osteoporosis | 54 [19–83] | 27 [6–68] | 97 [67–99] | 90 [68–99] |
| Low back pain | 30 [3–72] | 19 [3–54] | 87 [65–96] | 84 [62–95] |
| Osteoarthritis | 31 [5–47] | 18 [3–47] | 87 [62–97] | 86 [58–99] |
| Pain management | 63 [25–81] | 39 [17–87] | 98 [75–100] | 98 [72–100] |
| Patient-nurse communication | 64 [29–84] | 54 [7–80] | 98 [90–100] | 98 [77–100] |
| Patient education | 63 [25–78] | 55 [32–68] | 96 [85–99] | 95 [85–99] |
| Research | 28 [10–35] | 26 [9–35] | 69 [52–82] | 66 [35–82] |

*Median, extreme values.

**Conclusions:** This multicentric survey provides accurate information on French RN educational needs. They are greater in the management of RMD other than RA and SpA. These results should be considered in elaborating a curriculum to improve RN competencies.

SAT0628-HPR **CARDIOVASCULAR RISK ASSESSMENT IN INFLAMMATORY ARTHRITIS PATIENTS IN A NURSE-LED CLINIC AND SUPPORTED BY ULTRASONOGRAPHY**

J. de la Torre-Aboki, C. García-González, M. Andrés, P. Vela. *Alicante General and University Hospital, Alicante, Spain*

**Background:** There is a wide range of evidence of increased risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) and other forms of inflammatory arthritis. Although people wiht RA have an increased number of the traditional risk factors for the development of CVD, it seems the presentation of a chronic inflammatory state is pivotal because of the accelerate atherogenesis as a result of endotelial dysfunction, leading to increased thickness and plaque formation in carotid arteries. EULAR recommendations for CV risk advised to assess CV risk in all patients with RA, and the patient's risk should be scored according to the SCORE system. Nurse-led care is a model of care, where nurses manage their own patient caseload, monitor patients' sign and symptoms, provide education and refer appropriately.
**Objectives:** The aim of this study was to assess CVD risk in patients with RA and other inflammatory arthritis, in a nurse-led clinic and, supported by a carotid ultrasonography (US).
**Methods:** Patients with inflammatory arthritis (RA, PsA, SpA, SLE) attends a nurse-led clinic for diseases activity measurement and based in a self-efficacy framework, lifestyle change support and, CV risk assessment. Those patients with smoking habits, blood pressure above the recommended level and total colesterol above 250 mg/dl were follow up closer with the nurse based in a motivational interview, treatment were prescribed by the rheumatologist and written leaflets concerning smoking cessation, low-lipid diet were offered. The CV assessment included: age, gender, blood pressure, glucose, triglycerides, total cholesterol, HDL, LDL cholesterol, smoking habits, height, weight and BMI were measured. Presence and type of diabetes were asked. Patient's risk SCORE was calculated. The risk SCORE was multiplied by 1.5 if the patient met certain criteria associated with higher CV risk. No multiplication was proposed for other arthritides. In those patients with intermediate risk SCORE (1–4%) a carotid ultrasonography was performed by a rheumatologist.
**Results:** 68 patients with inflammatory arthritis had an intermediate risk SCORE. 51 were RA, 13 SpA, 1 PsA, 3 SLE. Mean age: 60 years. 59% were women. Mean modified risk SCORE: 2,6%. Prior to performing US, 68 patients had intermediate risk SCORE. Media right IMT:0,77 mm, plaque was found in 19 patients (28%); media left IMT:0,82 and plaque was found in 27 patients (40%) Only 41% of our patients remained with intermediate riks SCORE after US. 43% patients had a very high risk SCORE after US and, 13% a high risk SCORE. Overall, a total of 48 patients (59%) had their CV risk upgraded after nurse and US assessment
**Conclusions:** Adding carotid US to nurse assessment in CVD risk stratification in patient wiht inflammatory arthritis and intermediate risk SCORE increases performance, being thus, a helpful technique for a CV tight control.

SAT0629-HPR **RAPID ACCESS TRIAGE CLINIC: A NURSING SERVICE THAT SHORTENS RHEUMATOLOGY CLINIC WAITING TIME AND FACILITATES EARLY TREATMENT**

S.K.G. Kwok, L.M.M. Tang, H.Y.J. Chung, K.Y.C. Yuen, T.K.C. Ho, C.S. Lau. *Medicine, Queen Mary Hospital, Hong Kong, Hong Kong*

**Background:** The waiting time for newly referred patients to the rheumatology clinic is approximately 24 months. The Rheumatology Nurse Rapid Access Triage Clinic aims to shorten the waiting time of patients suspected to have rheumatoid arthritis (RA). It is hoped that patients with active RA can be fast-tracked to commence earlier treatment for better disease control.
**Objectives:** To validate if Rheumatology Nurses (RhN) can screen out patients with active RA for earlier treatment and to evaluate the level of agreement in RA diagnosis between RhN and rheumatologists.
**Methods:** Newly referred patients suspected to have RA were assessed by RhN from March 2012 to September 2015. Based on a protocol modelled upon the 2010 European League Against Rheumatism (EULAR)/American College of Rheumatologists (ACR) criteria for the classification of RA, RhN performed history taking, physical examination of joints, and ordered relevant blood and X-ray investigations. RhN then reviewed all results to discriminate between RA and non-RA. Paired t-tests and logistic regression were used to compare variables between RA and non-RA patients diagnosed by RhN. Correlation coefficient (CC) was used to compare the level of agreement between RhN's and rheumatologists' assessment.
**Results:** RhN assessed 102 patients (mean age =53.46 ± 12.59 years, 84.3% women). The group diagnosed to have RA by RhN had shortened waiting time for the rheumatology clinic when compared to the non-RA group. (11.5 vs 3.6 months; $p<0.001$) Agreement between RhN diagnosed RA and rheumatologist diagnosed RA was excellent (CC 90%; $P<0.001$). Comparing with the non-RA group, RhN diagnosed RA group also had greater chance of receiving disease modifying anti-rheumatic drugs (DMARDs) early (OR 43.08, $p<0.001$). The mean duration between onset of joint symptom and DMARDs commencement was 8.26 ± 11.52 months ranging from 3 to 52 months.
**Conclusions:** The Rheumatology Nurse Rapid Access Triage Clinic provides accurate diagnosis and shortens RA patient's waiting time. It also helps to screen out active patients to receive earlier treatment.

SAT0630-HPR **VARIABLES PREDICTIVE OF THE SLEEP DISORDERS IN PATIENTS WITH PSORIATIC ARTHRITIS AND SPONDYLARTHRITIS**

L. Cano-Garcia, S. Manrique-Arija, N. Mena-Vázquez, M.C. Ordóñez-Cañizares, C.M. Romero-Barco, C. Domic-Bueno, M. Rojas-Giménez, C. Fuego-Valera, F.G. Jiménez-Núñez, I. Ureña-Garnica, M.V. Irigoyen-Oyarzábal, V. Coret-Cagigal, Á. Belmonte-López, A. Fernández-Nebro. *Reumatología, Hospital Regional Universitario de Málaga, Málaga, Spain*

**Background:** Since insomnia is a chronic problem in patients with chronic diseases, factors that are associated with it are varied.
**Objectives:** To study the variables associated with the severity of insomnia according to the questionnaire of Oviedo's dream (QOD) in patients with spondylarthritis (AE) and psoriatic arthritis (PsA), including the activity of the disease as measured by restriction, BASDAI and DAS28.
**Methods:** Design. Descriptive cross-sectional study. Patients: Were selected by sampling consecutive patients with AE or PsA in follow-up by our unit of biologic therapy. Inclusion criteria: adults ($\geq$16 years old) with AE (ASAS criteria) or PsA (CASPAR criteria) capable of understanding and willing to make the questionnaires. Exclusion criteria: other rheumatic diseases, age $<$16 years old. Protocol: arriving at the inquiry, he was offered participate in study, explained to him and gave the patient the battery of questionnaires; your doctor performed the evaluation of activity of disease and registration of comorbidities and current medication. Main outcomes: the 3 dimensions of QOD: subjective (1) satisfaction with sleep, insomnia (2) and (3) Hypersomnia. The QOD is a semi-structured interview help diagnose insomnia and Hypersomnia according to the diagnostic criteria of CIE-10 and DSM-IV. Other variables: current medication for the AE or PsA, comorbidities, medication use for sleep and/or CPAP according to QOD, disease activity questionnaire: AE (BASDAI) and PsA (DAS28), quality of life related to health (HRQOL) by means of EQ-5 d and SF-36, perception of pain (questionnaire Brief Pain Inventory BPI), AE (BASFI, BASDAI) and PsA (DAS28, HAQ) and fatigue by FACIT. Statistical analysis: descriptive and analysis of normality. Bivariate Chi-square, T-Student, Mann-Whitney or correlations, as appropriate. Multiple="Multiple" linear regression to 3 dependent variables (subjective satisfaction with sleep, insomnia and hypersomnia).
**Results:** 120 patients participated: 60 patients with ad (36.7% women, 45, 1±10, 6 years) and 60 patients with APs (58.6% women, 49, 9±9, 2 years). The most common comorbidities were: anxiety, depression, and disc disease. Women had more multimorbidity (p=0, 047) and osteoporosis ($p<0$, 001) than men. We found no correlation between disease activity and results in QOS. Also found correlation of variables COS with an HRQOL in SF-36 with EQ-5D, or physical function. There were no differences in treatment with biological and/or DMARs. Multiple linear regression analysis showed an inverse association between subjective satisfaction with sleep and the results of the FACIT and the middle pain. Insomnia showed an association with FACIT and interference of pain with daily life. And finally, hypersomnia partnered with FACIT and middle pain.
**Conclusions:** The insomnia and hypersomnia are 2 health problems strongly linked to pain and fatigue in patients with AE ans PsA but not with the activity of the disease. It would be necessary to work in nursing consultation the improvement in the management of sleep in these patients in a structured way to decrease the impact of insomnia and hypersomnia.

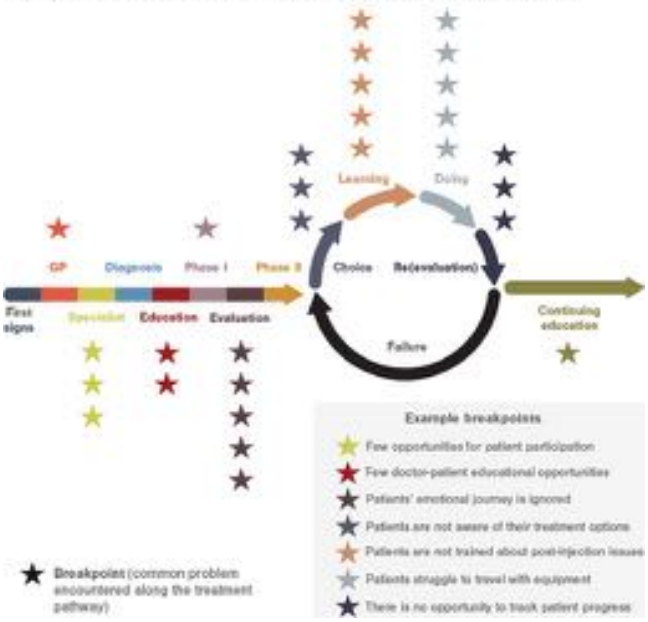
SAT0631-HPR **CHRONIC DISEASE AND SELF-INJECTION: ETHNOGRAPHIC INVESTIGATIONS INTO THE PATIENT EXPERIENCE DURING TREATMENT**

M.H. Schiff[1], M. Aris[2], S. Saunderson[3], I. Mountian[4], P. Hartley[3]. *[1]University of Colorado School of Medicine, Denver, United States; [2]CMFT, Manchester, United Kingdom; [3]Idea Couture, Toronto, Canada; [4]UCB Pharma, Brussels, Belgium*

**Background:** Drug administration by self-injection is often an option to treat



chronic diseases. This treatment option can be emotionally and physically demanding for patients (pts).[1]

**Objectives:** To use a holistic approach to identify common themes both along the treatment pathway (ie. from diagnosis and throughout treatment), and at the moment of self-injection that, if changed, have potential to improve pt experience and treatment outcomes.

**Methods:** Two ethnographic research projects were designed and conducted: Field Insights CODE (FI[CODE]) provided an overview of the treatment pathway and Injection Mission 2020 (IM2020) focused on the moment of self-injection. FI(CODE) consisted of individual and group interviews investigating the treatment process from a pt and healthcare professional (HCP) perspective. It used an open ethnographic approach (no set questions/discussion guides) to avoid restricting the feedback obtained. Interviews were conducted in San Francisco, Chicago, London and Manchester, with 10 HCPs and 58 pts (8 pts in-home and 50 pts over 12 focus groups). IM2020 consisted of a review of over 50 UCB Pharma injection device design internal information sources, and expert interviews aiming to understand how injection devices affect individuals. Interviews were conducted in San Francisco, London, Boston, Atlanta, New York, Toronto and Tokyo with 10 pts, 7 HCPs and 5 medical device design experts.

**Results:** FI(CODE) interviews identified common problems encountered along the treatment pathway that could increase treatment failure rates (Figure). Pts with more treatment options and greater disease understanding through education were less likely to struggle with the treatment process. Pt treatment choice was limited by the healthcare system (ie. institutional guidelines, reimbursement restrictions) and the method of device selection; specifically, pre-selection by doctors and nurses reduced the number of device options for the pt. By focusing closely on the moment of self-injection, IM2020 demonstrated that pts who developed an effective, personalized injection process had greater levels of success with self-injection. Five tightly linked components that influence the injection experience were identified: delivery process, emotional state, social perception, educational level and ritualized development. Pts who successfully mastered all 5 of these were more likely to succeed at self-injection.

**Figure:** Number of breakpoints identified at each step in the treatment pathway

**Conclusions:** By examining the pt treatment journey in a novel way, FI(CODE) and IM2020 identified common problems along the treatment pathway, advancing our understanding to help improve pt treatment experience. Small changes that improve pt education and increase choice at the start of the treatment process were identified as key to improving treatment success rates. Pt education should aim to help pts understand their disease and develop an optimum personalized self-injection process.

## SAT0632-HPR THE EFFICACY OF BIOLOGICS ON HEALTH STATUS INCLUDING PSYCHOLOGICAL STATUS, SELF-EFFICACY AND PATIENT SATISFACTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Fusama[1], K. Yukioka[2], T. Kuroiwa[2], C. Yukioka[2], M. Inoue[2], K. Higashi[1], A. Ogata[3], N. Murata[2], T. Kuritani[3], K. Maeda[3], H. Sano[4], M. Yukioka[2], H. Nakahara[3]. *[1]Division of Nursing, NTT West Osaka Hospital; [2]Yukioka Hospital; [3]NTT West Osaka Hospital, Osaka; [4]Hyogo collage of medicine, Nishinomiya, Japan*

**Background:** Biologics are effective for improving disease activity in patients with rheumatoid arthritis (RA). We also reported the efficacy of biologicals on health status [1]. However, efficacy of biologics on psychological status, self-efficacy and patient satisfaction in RA patients is not well evaluated.

**Objectives:** We evaluated improvement of health status, psychological status, self-efficacy and patient satisfaction in patients with RA treated with biologics.

**Methods:** The patients with RA who were planning to be treated with the biologics (adalimumab (ADA), tocilizumab (TCZ) and abatacept (ABT)) were enrolled. Disease activity was evaluated using SJC, TJC, PGA and CDAI. Psychological status was examined using the Hospital Anxiety and Depression Scale-Depression (HADS-D) and Anxiety (HADS-A). Self-efficacy and health status including patient satisfaction were assessed using the General Self-Efficacy Scale (GSES) and the Arthritis Impact Measurement Scale 2 (AIMS-2), respectively. Comparison analysis was performed between the baseline and 24 weeks after biological therapy. To further investigate the items related to satisfaction, correlation analysis was performed between patient satisfaction and disease activity and health status including psychological status. Data analyses were performed utilizing Wilcoxon rank-sum test and Spearman correlation analysis.

**Results:** Twenty-six patients (male/female: 7/19) (ADA: 8, TCZ: 9, ABT: 9) were evaluated. Patients' characteristics were as follows: median (interquartile range) age of 57 (49.2 - 75.0) years and duration of 2.9 (0.8 - 5.5) years. SJC, TJC, PGA and CDAI showed statistically significant improvement at week 24 compared to the baseline ($p<0.0001$, for each of all items). In the components of AIMS-2, "physical", "symptom", "affect" and "role" improved significantly at week 24 compared to the baseline, while "social interaction" did not improve. Patient satisfaction and GSES also improved significantly at week 24 ($p<0.0001$, $p=0.0124$, respectively). As for psychological status, HADS-A and HADS-D improved significantly at week 24 compared to the baseline ($p=0.018$, $p=0.0143$, respectively).

Patient satisfaction showed statistically significant correlation with SJC ($r=0.686$, $p<0.0001$), TJC ($r=0.758$, $p<0.0001$), PGA ($r=0.586$, $p<0.0001$), HADS-A ($r=0.561$, $p<0.0001$) and HADS-D ($r=0.512$, $p=0.0001$). PGA and TJC were also correlated with HADS-A ($r=0.374$, $p=0.0062$, $r=0.325$, $p=0.018$, respectively) and HADS-D ($r=0.412$, $p=0.0024$, $r=0.392$, $p=0.0040$, respectively). Moreover, patient satisfaction was also statistically significantly correlated with "physical" ($r=0.804$, $p<0.0001$), "symptom" ($r=0.751$, $p<0.0001$), "affect" ($r=0.746$, $p<0.0001$) and "role" ($r=0.717$, $p<0.0001$), "social interaction" ($r=0.279$, $p=0.0476$) of AIMS-2.

**Conclusions:** Biologics were effective in improving psychological status, patient satisfaction and self-efficacy as well as disease activity and health status. For further improving patient satisfaction, psychological support and social assistance by health professionals' team in addition to appropriate treatment may be required.

## SAT0633-HPR SOCIAL SUPPORT MAY BE IMPORTANT FOR IMPROVING PATIENT SATISFACTION AND HEALTH STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS

M. Fusama[1], K. Yukioka[2], T. Kuroiwa[2], C. Yukioka[2], M. Inoue[2], K. Higashi[1], A. Ogata[3], N. Murata[2], T. Kuritani[3], K. Maeda[3], H. Sano[4], M. Yukioka[2], H. Nakahara[3]. *[1]Division of Nursing, NTT West Osaka Hospital; [2]Yukioka Hospital; [3]NTT West Osaka Hospital, Osaka; [4]Hyogo collage of medicine, Nishinomiya, Japan*

**Background:** The clinical benefits of biologics to patients with rheumatoid arthritis (RA) have been demonstrated in various clinical trials. However, patient satisfaction in patients treated with biologics is not well evaluated.

**Objectives:** We evaluated patient satisfaction and health status in patients with RA treated with biologics.

**Methods:** The patients with RA who were planning to be treated with IL-6 inhibitor (tocilizumab; TCZ) (IL-6 group) and TNF inhibitor (adalimumab: ADA, infliximab; IFX, etanercept; ETN) (TNF group) were enrolled. Disease activity was evaluated using swollen joint counts (SJC), tender joint counts (TJC) and patient global assessment (PGA), and Clinical Disease Activity Index (CDAI). Patient satisfaction was evaluated utilizing patient satisfaction scores of the Arthritis Impact Measurement Scale 2 (AIMS-2). Satisfaction was measured before and after 6-months of treatment with each of the biologics, and the results were compared. Statistical analysis was performed utilizing Wilcoxon rank-sum test and t-test.

**Results:** Patients with RA (n=85) were evaluated in this study. 48 patients were

treated with TCZ, and 47 patients were treated with anti-TNF agents (ADA: 17, IFX:17, ETN:13).Patients characteristics were as follows as follows: mean±SD of age (55.6±11.9 years old) and duration (7.29±8.83 years), male/female (16/79). Both at baseline and at 6 months after treatment, there was no statistically significant differences in SJC, TJC, PGA, EGA and CDAI between TCZ group and TNF group. All these evaluations showed statistically significant improvement after 6 months of treatment in each group.As for health status, all 5 components of AIMS-2 showed statistically significant improvement at 6 months compared to the baseline in TNF groups. In IL-6 group, "physical", "symptom", "affect" and "role" improved significantly at 6 months ($p<0.001$, for all items), while "social interaction" did not statistically improve compared to the baseline (p=0.114). Out of 12 satisfaction scores, all scores except "understanding and support for patients' problems by families or friends" (p=0.133) showed statistically significant improvement with 6 months of treatment in TNF group, while all 12 scores improved significantly at 6 months in IL-6 groups.

**Conclusions:** Patient satisfaction and health status except social interaction were improved by TNF inhibitor or IL-6 inhibitor. To solve the problems related to social function, understandings and social support for patients by health professionals may be required.

**Disclosure of Interest:** None declared

## SAT0634-HPR TREAT TO TARGET ACCESS, CARE AND OUTCOME: A NURSE LED CARE INITIATIVE

P. Minnock on behalf of Irish Rheumatology Nursing Forum. *Rheumatic Musculoskeletal Disease Unit, Our Lady's Hospice & Care Services, Dublin, Ireland*

**Background:** Contributing factors to the acknowledged inefficient clinical pathway for patients with inflammatory arthritis (IA) in Ireland include the inadequate number of practicing rheumatologists and specialist nurses (0.7 per 100,000 and 0.5 per 135, 000 inhabitants, respectively). There is evidence that nurse led care (NLC) delivers quality care, improves access and delivers cost savings.

**Objectives:** To address lengthy waiting lists, inefficient use of physician time, reduced patient outcome, and deliver as standard care patient centred Treat to Target (T2T) in a cost neutral/cost effective manner through NLC.

**Methods:** The IRNF presented a business case to the Health Service Executive detailing how patient centred T2T could be realised nationally, through the implementation of 12 advanced nurse practitioner (ANP), and 29 clinical nurse specialist (CNS) posts, under the direction of consultant rheumatologists. Evidence to support this proposal as a cost neutral investment was compiled based on the secondary benefits of T2T, firstly as a NLC initiative and secondly, through improved medication optimisation/management.

**Results:** The non–inferiority of NLC versus rheumatologist led care, and superiority with respect to satisfaction and costs is proven. In Ireland an estimated 4,500 patients are diagnosed with IA annually, T2T requires each patient to have up to 6 reviews creating the demand for 27,000 out-patient reviews during year 1. NLC could provide the required access for 300–600 out-patient reviews per 100,000 head of population (≈13,500–27,000 per annum). Optimisation of methotrexate (MTX) dosing has demonstrated both efficacy and reduced requirements for more expensive treatments in specific patients. Through nurse led MTX optimisation 12 patients in 17 rheumatology departments saved from initiation of a biologic therapy (12 x 17 x €12,300) could provide €2.5 million savings annually. A potential national saving of €15 million through reduced biologic dosing in stable disease has already been demonstrated. Therefore, a 50% dose reduction of a biologic treatment in 10 patients could yield annual savings of €67,500 which exceeds the maximum ANP/CNS salary scale. This evidence demonstrates that the estimated required funds (€2.9 million) could be generated and a potential saving of €13m realised from the secondary benefits of T2T, namely a NLC initiative, and improved medication optimisation. A specially commissioned electronic patient record will ensure capture of agreed health care performance statistics to demonstrate the impact on improvements in service access and costs to the implementation, as well as on patient outcome, of these additional nursing posts.

**Conclusions:** This proposal demonstrates how this physician directed nurse led initiative to implement T2T can be realised in a cost neutral/cost effective manner. Estimated conservative and speculative benefits to the health service profit and loss account range from zero loss to circa €15 million savings, respectively. These savings will more than adequately fund the additional posts. Moreover, tighter disease management and control in early IA will lessen the requirement for more expensive treatments in the long term, and enhance patient outcome.

**Disclosure of Interest:** P. Minnock Grant/research support from: The development of the business case was supported by an unrestricted educational grant from MSD, who partnered with the IRNF in an advisory capacity during the project

**DOI:** 10.1136/annrheumdis-2016-eular.4041

## SAT0635-HPR EFFECTS AND COSTS OF A COMMUNITY-BASED SELF-MANAGEMENT SUPPORT PROGRAM FOR KOREAN MEDICAL AID BENEFICIARIES WITH OSTEOARTHRITIS: 12-MONTH FOLLOW-UP

Y.-H. Ahn. *Nursing, Wonju College of Medicine Yonsei University, Wonju, Korea, Republic Of*

**Background:** Osteoarthritis (OA) is increasing in frequency and becoming a growing burden in terms of both illness and cost. Support for self-management may have a part to play in the effective disease management. However, the evidence for arthritis self-management support program is inconclusive, and economic evaluations in this field are relatively rare.

**Objectives:** The purpose of this study was to identify changes in over time and costs of a newly developed self-management support program for Korean medical aid beneficiaries with osteoarthritis

**Methods:** The research design was an open-label, randomized and controlled evaluation of a community-based self-management intervention. Medical aid beneficiaries with osteoarthritis were allocated to the intervention group (n=30) or the control group (n=30). The 8 week-intervention program which focused on patient-centered, tailored intervention was developed to support disease self-management. A trained case manager with cognitive-emotional-behavioral approaches and coaching strategy led the participants. Outcome measures included patient activation, joint flexibility, and health related quality of life. Data were collected at baseline, 8 weeks (post-intervention), 6 and 12-month follow-up using structured questionnaire, goniometer and tape. Data were analyzed using mixed-effects regression model. For economic evaluation, a cost-benefit analysis was done using the net benefit and benefit/cost ratio.

**Results:** As compared with the control group, the experimental group showed significantly greater improvement across the follow-ups on patient activation (Time x Group, $F=13.395$, $p<.0001$), joint flexibility, (Time x Group, Right Shoulder $F=7.550$, $p<.0001$; Left Shoulder $F=5.692$, $p=.001$; Right Knee $F=5.998$, $p=.0007$; Left Knee $F=3.395$, $p=.0195$) and health-related quality of life (Time x Group, $F=6.381$, $p=.0004$). The experimental group had large initial improvements in patient activation, joint flexibility, and health–related quality of life. These improvements declined over time, but still were better than at baseline except for joint flexibility. The result of cost-benefit analysis was found that the total cost was 72,096 Korean won per person and the net benefit was 167,904 Korean won per person, so the ratio of benefit versus cost was 2.33.

**Conclusions:** Findings indicate that this 8-week community-based self-management support program is effective for patient activation, joint flexibility and health-related quality and an efficient model of nursing care reducing healthcare costs for medical aid beneficiaries with osteoarthritis. This study has the potential to be a sustainable model for practice in the community.

## SAT0636-HPR STARTING CARE AT THE PEEP OF RHEUMATOID ARTHRITIS- A PATIENT EDUCATION AND EMPOWERMENT PROGRAM

Y.S. Cheung, P.F. Lee, S.K. Tang. *Medicine and Geriatrics, United Christian Hospital, Hong Kong Special Administrative Region, China*

**Background:** Rheumatoid arthritis (RA) is a chronic, systemic, autoimmune disease which impacting on physical, psychosocial and economic aspects. Poor disease control will cause flare up and remission periodically and increase the risk of deformity. Various studies indicating that patient education on disease knowledge, treatment plan and self-management skill are all contributing factors for disease control and successful coping with long-term condition. However, barriers such as knowledge deficit on disease and related treatments are common in general public, a patient education and empowerment program (PEEP) was then designed and conducted for newly diagnosed RA patients in a regional hospital of Hong Kong.

**Objectives:** To evaluate the effectiveness of PEEP on improving disease control; patient's functional ability and self-management knowledge for newly diagnosed RA patients.

**Methods:** This was a retrospective and observational study, the data retrieved from January 2014 to December 2015. Patients with newly diagnosed RA were recruited into a health education and patient empowerment program (PEEP)

conducted by specialist nurse in rheumatology. The program included one-to-one interview in nurse-led clinic and telephone advice line (TAL) support. A health education checklist was designed to standardize the health education content and ensure essential information was delivered to participants. A disease knowledge assessment form to assess disease knowledge, medication management and self-management skill was designed to measure patient's understanding; and health assessment questionnaire (HAQ) was used to assess patient's functional ability and health outcome. Patient's knowledge score accompanied with disease activity score (DAS 28) and HAQ score were collected before and after the PEEP.
**Results:** Until the end of year 2015, totally 73 patients have been recruited into the program. 51 patients attended the program once and 22 patients attended twice. Age of participants between 17 and 79, majority (82.2%) was female. Mean knowledge assessment score was increased from 22.6% to 72% after PEEP, reflecting an average increase of 49.4% in the knowledge of disease, treatment and self-management skill. Mean DAS 28 score before PEEP was 4.44 (2.05 to 7.27) while post PEEP was 3.61 (1.55 to 7.0) which indicated improvement on arthritis control (mean difference -0.83; $P<0.0001$). Mean HAQ score of pre and post PEEP were 0.84 and 0.59 respectively indicated an improved functional and health outcome. During the study period, TAL support was sought for 41 times, in which 19 episodes were related to drug problems and 10 episodes were related to disease flare up.
**Conclusions:** Health education is an effective way to increase patient's disease knowledge, improve medication management and enhance self-management skill; which also contribute to better disease control and better functional ability. A structured and comprehensive patient education and self-management program should be promoted for all newly diagnosed RA patients.
**Disclosure of Interest:** None declared

## Miscellaneous forms of clinical care

### SAT0637-HPR BIOSIMILARS: THE PERCEPTION AMONGST MALTESE CLINICIANS

K. Cassar[1,2], D. Zammit Dimech[3], L. Grech[1,2], D. Balzan[2], A. Cutajar[2], P.J. Cassar[3]. *[1]Department of Pharmacy, University of Malta; [2]Department of Pharmacy; [3]Department of Medicine, Mater Dei Hospital, Msida, Malta*

**Background:** The concept of biosimilar presents a myriad of issues such as patient safety, efficacy and financial aspects to clinicians, pharmacists and policy makers. The introduction of biosimilar infliximab, the first biosimilar on the local national health system in Malta, put clinicians at the forefront of these challenges.
**Objectives:** The objective of the study was to assess the perception and awareness of Maltese clinicians working within the National Health System on the concept of biosimilars.
**Methods:** The questionnaire developed by the Alliance for Safe Biologics Medicines and which was previously run in 5 European countries was shortlisted to be used in the study[1]. Permission from the Alliance for Safe Biologics Medicines was sought to use the questionnaire. The questionnaire was sent online to prescribing clinicians working within the Maltese National Health System. The clinicians were given one month to answer the questionnaire during which time three reminders were forwarded.
**Results:** A total of 132 prescribers participated in the study giving a 14% response rate. Approximately 34% prescribed biologics within their practice whereas 40% treated patients prescribed biologics by another specialist. Out of the total respondents 6% consider themselves very familiar with the concept of biosimilars, 35% had a basic understanding of biosimilars whereas 59% could not define biosimilars or had never heard of them. Less than half of the respondents (36%) believe that patients can safely receive either originator or biosimilar and expect the same result. Only 27% agree that patients can safely be switched between products during the course of treatment and 46% state that is is very important or critical for them to have the sole authority to decide whether to prescribed the biosimilar or originator. Around 27% answered that they prescribe by generic name irrespective of whether the drug is a biologic or not.
**Conclusions:** The awareness (6%) on biosimilars in Malta is much less than that achieved in 5 European countries where an average of 22% of prescribers considered themselves very familiar with the concept of biosimilars[1]. Although prescribing of biologic medicines is regulated by Subsidiary Legislation 458.59 "Prescribing and Dispensing requirement rules", Maltese prescribers are unaware that biosimilars should be prescribed by brand name. Switchability is an aspect where Maltese clinicians are not comfortable since only 27% believe that patients can be safely switched between products during treatment. This however correlates to results of the ASBM European survey where only 39% agree with switchability. Increased awareness on biosimilars together with more robust data on switchability will help Maltese clinicians adopt biosimilars in their practice without having concerns on patient safety and efficacy.

## Psychology/Social sciences

### SAT0638-HPR DELAYS IN DIAGNOSING OF PATIENTS WITH RHEUMATIC DISEASES IN POLAND

J. Grygielska, P. Samel-Kowalik, A. Kłak, M. Mańczak, F. Raciborski. *Department of Gerontology and Public Health, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*

**Background:** According to the recommendations of EULAR 2007, every patient with persistent swelling of at least one joint should be referred to a rheumatologist and examined within 6 weeks from the onset of the first symptoms. Time from first symptoms to start of treatment on rheumatoid arthritis (RA) is only 12 weeks. Results of unique research conducted in Poland showed that diagnostic delay in RA is 35 weeks and it is one of the biggest in Europe. Early diagnosis has positive impact for effectiveness of treatment, cost economization and patient well-being.
**Objectives:** The aim of the study was to determine the time passed since the onset of the first symptoms of rheumatic disease to the first visit the doctor. Additional objective of the study was to identify factors of the delay and of speeding up the diagnostic process.
**Methods:** An anonymous questionnaire survey was carried out in the period from June 2014 to June of 2015 among patients treated in 6 rheumatological centers in different regions of Poland. The questionnaire consisted of 18 closed questions concerning: first symptoms of disease and actions taken by patient, absence in workplace/school, factors influencing patient's decision, path of patient from first contact with general practitioner (GP) to rheumatologist, diagnosed diseases and taking care of him/her own health. During the study 239 completed questionnaires were collected.
**Results:** The first symptoms connected with rheumatic disease before contact with physician declared by respondents were: pain of the joints (86%), morning stiffness (71%), swelling of the joints (70%) and tiredness (69%). The greatest impact on searching help with the doctor were: worsening of symptoms (86%), difficulties in everyday activities (83%), talks with relatives (65%) and a fear that there are symptoms of severe disease (64%). The most important causes of delay of contact with physician were: limited access to physician (68%), belief that symptoms will pass spontaneously (56%) and lack of time to visit a doctor (45%). Only 17% of patients visit a doctor up to 7 days from first onset of rheumatic diseases (from 7 to 30 days - 32%; during 2–3 months - 23%; later than 3 month from first symptoms 28%). Before first visit to rheumatologist 97% of patients were treated by general practitioner (GP), 56% by orthopaedist, 41% - by neurologist.
**Conclusions:** Patient's behaviour and the functioning of the health care system has an impact on delay of diagnosis of rheumatic diseases in Poland. One of the main problem identified by the study is GPs and other specialists low awareness of proper handling of a patient with early arthritis. As a result, the patient is treated in an inefficient way and referral to a rheumatologist as the disease is in the advanced stage.

## Nursing

### SAT0639-HPR THE MOST FREQUENT INQUIRIES OF PATIENTS ON SUBCUTANEOUS ANTI -TNF ALPHA THERAPIES

M. Pavic Nikolic, A. Hocevar. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** Subcutaneous TNFα blockers enable patients with inflammatory arthritis to better control their disease and subsequently improve the quality of their daily functioning. At our Department of Rheumatology trained nurses provide education about proper subcutaneous (s.c.) administration techniques and telephone counseling about different issues asked by patients concerning their treatment. One of the key components of patient education and counseling is to explain when to postpone the biologic therapy in case of infection or planned surgical procedure.
**Objectives:** The aim of our study was to look at the most frequent questions raised by patients about their treatment. In addition we looked at a potential association between particular patient problem and specific subcutaneous TNFα blocker.
**Methods:** Data was collected between January 2013 and May 2014 and included

demographic data, prescribed anti-TNF drug, and description of the patient reported query regarding their s.c. anti-TNF treatment. Patient queries were grouped into six topics: skin reactions, infections, vaccinations, drug interactions, planned surgical procedures and other (Table 1). Appropriate statistical methods were used to analyze data.
**Results:** During the observation period 98 patients (23% males, mean (SD) age 56.1 (13.9) years) treated with subcutaneous TNFα blocker asked for help using a telephone call. Patients were treated with the following s.c. anti-TNF drugs: certolizumab (9%), etanercept (27%), adalimumab (41%), and golimumab (23%). The most common patient problems on subcutaneous TNFα inhibitors are presented in Table 1.

Table 1. The patient's inquiries grouped by topics

| Patients queries | % | Patients queries | % |
|---|---|---|---|
| Skin reactions | 20% | Drug interactions | 10% |
| Infection | 36% | Planned surgical procedures | 10% |
| Vaccinations | 2% | Other | 22% |

In 22% of cases patients seeked telephone advice for other different health problems (swollen joints, drug ineffectiveness, potential adverse effects).We did not find any significant difference concerning particular TNFα blocker and the pertinent patient problem.
**Conclusions:** Telephone assistance is valuable for patients. Patients request more information about their treatment and continuous patient education could improve outcomes in the management of inflammatory rheumatic diseases.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2170

## Miscellaneous forms of clinical care

### SAT0640-HPR UNDERSTANDING THE IMPORTANCE OF A PATIENT'S ROLE IN THE MANAGEMENT OF RA: PHYSICIAN- AND PATIENT-BASED SURVEY RESULTS DEVELOPED BY THE RA NARRATIVE ADVISORY PANEL

A. Dikranian[1], J. Galloway[2], J. Kekow[3], C.A.F. Zerbini[4], M. de la Vega[5], G. Lee[6], A. Maniccia[7], E. Bananis[8], D. Ponce de Leon[9], A. Gibofsky[10]. *[1]San Diego Arthritis Medical Clinic, San Diego, United States; [2]King's College, and King's College Hospital, London, United Kingdom; [3]University of Magdeburg, Magdeburg, Germany; [4]Centro Paulista de Investigação Clinica, São Paulo, Brazil; [5]CEIM Investigaciones Médicas, Buenos Aires, Argentina; [6]Hong Kong Sanatorium & Hospital, Hong Kong SAR, China; [7]Pfizer Inc, New York; [8]Pfizer Inc, Collegeville, United States; [9]Pfizer Inc, Lima, Peru; [10]Weill Cornell Medical College and Hospital for Special Surgery, New York, United States*

**Background:** RA is a chronic, debilitating condition for which there is no cure.
**Objectives:** To identify and better understand the perspectives of both healthcare providers (HCPs) and patients (pts) regarding RA treatment and management, using data from an HCP- and a pt-based survey, developed by the RA NarRAtive global advisory panel.
**Methods:** The RA NarRAtive initiative comprises an advisory panel of 39 RA experts from 17 countries. An HCP-based (16 countries) and a pt-based survey (15 countries), designed by the working group, were fielded online between Aug-Oct 2015, and Sept 2014-Jan 2016, respectively. Results are presented from pts treated by a rheumatologist. All respondents are from the same 15 countries.
**Results:** 3987 pts responded (1653 were currently managed by a rheumatologist): mean age 51.5 years (yrs), 64% female, median time since diagnosis 7 yrs; respondents represented a wide spectrum of disease activity: moderate to severe (30%; 501) and severe (11%; 176). In the HCP survey, 90% of respondents were satisfied with their communications with pts but 68% acknowledged, "I wish my pts and I talked more about goals and treatment". In the pt survey, 53% of pts acknowledged that dialogue with the HCP would optimise the management of their RA. 61% of all respondents felt uncomfortable raising concerns or fears to their HCP. 93% of HCP respondents discuss quality of life (QoL) issues with their pts including impact of RA on ability to work, participation in activities and lifestyle goals. 86% discuss treatment-related issues including adherence to therapy, medication preferences and whether pts seek treatment from other HCPs. The most common topics that pts report worrying about (and HCPs believe their pts worry about) are similar but these factors were ranked differently between pts and HCPs: the number one factor for pts is the impact on QoL; the number one factor for HCPs is prescription side effects. HCPs and pts have similar views on what they would most like to change about currently available RA medications, ie severity and number of side effects, cost and efficacy. HCPs highlighted disease remission as a treatment goal; while pts more frequently referred to symptom reduction. Overall, 88% of HCPs agreed that pts involved in making treatment decisions tend to be more satisfied with their treatment experience; 74% felt that pts who are not involved are less likely to adhere to treatment. Setting treatment goals with pts and agreement on the treatment plan are considered important by 78% and 79% of HCPs, respectively, as is being able to have an open dialogue (86%).
**Conclusions:** Differences between treatment goals set by pts and HCPs were reported, highlighting the importance of an open pt-HCP dialogue in the successful management of RA. These findings could help improve adherence and pt satisfaction with their disease management.
**Acknowledgement:** These surveys were funded by Pfizer Inc. Editorial support was provided by S Johnson of CMC and funded by Pfizer Inc.

### SAT0641-HPR REASONS TO STOP DRINKING ALCOHOL AMONG PATIENTS WITH RHEUMATOID ARTHRITIS – A MIXED METHOD STUDY

M. Andersson[1,2], I. Larsson[2,3] on behalf of BARFOT Study Group. *[1]Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund; [2]Spenshult Research and Development Center; [3]School of Health and Welfare, Halmstad University, Halmstad, Sweden*

**Background:** Studies of alcohol use in patients with rheumatoid arthritis are sparse and studies of why patients choose to stop drinking alcohol in particular
**Objectives:** The aim of the current study was twofold: first to identify patients with RA who stopped drinking alcohol and compare those to patients drinking alcohol, and second, to explore reasons to stop drinking alcohol.
**Methods:** In 2010 a self-completion postal questionnaire was sent to all 2,102 prevalent patients in the Better anti-rheumatic farmacotherapy (BARFOT) study enquiring about disease severity, physical function (HAQ) and health related quality of life (EQ5D), pain, fatigue, patient global assessment (PatGA) and lifestyle factors e.g. alcohol. The questions assessing alcohol included the question "Have you stopped drinking alcohol?" and an open question "Why have you stopped drinking alcohol?" A mixed method design was used and 1512 patients had answered the alcohol questions and was included in the study of those 86 had stopped drinking alcohol. Seventy-one patients answered the open question and their answers were analyzed with qualitative content analysis (1).
**Results:** Comparing patient with RA using alcohol or not, the patients who stopped drinking alcohol was older median age (min-max) 69 (36–90) vs. 66 (23–95), p=0.011, more men 42% vs. 29%, p=0.015, had worse physical function, median HAQ (min-max) 0.50 (0–3.00) vs. 1.00 (0–2.75), p<0.001, worse health related quality of life, median EQ5D (min-max), 0.69 (-0.59–1.00) vs. 0.76 (-0.02–1.00), p<0.001, worse self-perceived health, median PatGA (min-max) 5 (0–10) vs. 3 (0–10), <0.001, more pain, median (min-max) 5 (0–10) vs. 3 (0–10), p<0.001, and more fatigue median (min-max) 6 (0–10) vs 4 (0–10), p<0.001. There were no differences between the groups regarding disease duration, swollen and tender joints. The qualitative content analysis resulted in five categories describing the reasons for patient with RA to stop drinking alcohol: disease and treatment, health and wellbeing, work and family, faith and belief and dependences and abuse
**Conclusions:** Patients with RA who stopped drinking alcohol have a lower physical function, health related quality of life, self-perceived health and more pain and fatigue comparing to patients with RA drinking alcohol. The reasons to stop drinking alcohol were of different nature such as medical, physical, mental, social and spiritual

### SAT0642-HPR COLLABORATION OF PATIENTS AND HEALTH PROFESSIONALS IN DEVELOPMENT AND RESEARCH OF CARE-INTERVENTION: CASE EXAMPLE PRESENTED BY A PATIENT RESEARCH PARTNER

N.C. De Boer-Nijhof[1], B. Maat[1], S. de Jong[2], A.A. Kruize[3], R. Geenen[4], J.W. Ammerlaan[3]. *[1]Expert patients; [2]Dutch Artritis Foundation, Amsterdam; [3]Rheumatology & Clinical Immunology, University Medical Center Utrecht; [4]Psychology, Utrecht University, Utrecht, Netherlands*

**Background:** Patient participation in research and in development of interventions

has become a hot topic. Research on health beliefs of stakeholders shows that patients do have other views on health and well-being than health professionals without any experience of a chronic condition themselves (Ubel 2003, Huber 2014). Additionally, including the patients' perspective in research is a necessary condition for reaching patient-related-outcomes (De Wit 2014). Moreover, active involvement of patients is a critical factor for the actual use of an intervention in healthcare (Van Gemert-Pijnen 2011). Thus, including the patients' perspective has significant value. EULAR recommendations aim to stimulate the collaboration with patient (research) partners. Sharing examples may help both patients as health professionals to undertake these valued steps.
**Objectives:** To share experiences of the collaboration between patient research partners and health professionals in building an online self-management training, and in developing the framework and outcome measures of research on the efficacy of the intervention.
**Methods:** Patient partners and health professionals formed a research team who collaborated in all stages of development and research. The team conducted online focus groups among adult patients, a card sorting task and cluster analyses, all focusing on patients' needs and preferences. Results of this study were used to develop the content and structure of the online intervention.
**Results:** Throughout the process experiences and perspectives of patients were used to guide the development and research. Consequently, the results yielded in an online expert-patient guided intervention, tailored to the needs, life, disease stage, and goals of the patient. Hence, the framework of research is customized to these results. In sustaining constructive collaboration in development and research, we found it important to be clear about expectations and roles of all involved in the research team.
**Conclusions:** The involvement of patients had major influences on input, the details of the intervention, the framework of research including outcome measures customized to individual needs. To secure collaboration agreement about the roles and (load-taking) capacities of each research partner is essential. Concurrently, it is important to be clear about expectations, responsibilities, and ways of communication between all involved. Including patients in the development of interventions and research benefits all stakeholders and the product that results from the collaboration.

## Miscellaneous forms of clinical care

### SAT0643-HPR POINTS TO CONSIDER FOR HEALTH PROFESSIONALS UNDERTAKING MUSCULOSKELETAL ULTRASOUND FOR RHEUMATIC AND MUSCULOSKELETAL DISEASES: PROGRESS OF A EULAR TASK FORCE

H.J. Siddle[1], P. Mandl[2], D. Aletaha[2], T.P. Vliet Vlieland[3], M. Backhaus[4], P. Cornell[5], M.A. D'Agostino[1,6], K. Ellegaard[7], A. Iagnocco[8], B. Jakobson[9], T. Jasinski[10], N.H. Kildal[11], M. Lehner[2], I. Möller[12], G.M. Supp[2], P. O'Connor[13], A.C. Redmond[1], E. Naredo[14], R.J. Wakefield[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [2]Division of Rheumatology, Medical University of Vienna, Vienna, Austria; [3]Department of Orthopaedics, Rehabilitation amd Physical Therapy, Leiden University Medical Centre, Leiden, Netherlands; [4]Department of Internal Medicine, Rheumatology and Clinical Immunology, Academic Hospital of the Charité Berlin, Berlin, Germany; [5]Rheumatology, Poole Hospital NHS Foundation Trust, Poole, United Kingdom; [6]Laboratoire d'Excellence INFLAMEX, Versailles-Saint-Quentin University, Saint-Quentin en Yvelines, France; [7]The Parker Institute, Copenhagen University Hospital Bispebjerg-Frederiksberg, Copenhagen, Denmark; [8]Rheumatology Unit - Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy; [9]Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, St. Olavs Hospital, Trondheim, Norway; [10]Patient Research Partner, Estonian Rheumatism Association, Tallinn, Estonia; [11]Faculty of Health and Social Science, Norwegian University of Science and Technology, Trondheim, Norway; [12]Instituto Poal de Reumatologia, Barcelona, Spain; [13]Department of Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [14]Department of Rheumatology, Hospital GU Gregorio Marañón, Madrid, Spain*

**Background:** Musculoskeletal ultrasound (MSUS) has evolved into an important method for identifying musculoskeletal abnormalities, confirming the diagnosis in patients with suspected inflammatory arthritis, monitoring therapeutic response, influencing clinical decision making and guiding interventions. The role of the non-medical health professional has advanced with many health professionals undertaking training and using MSUS to extend their scope of practice. Guidelines to support training for rheumatologists have been identified but currently there are not any recommendations to support the education and training needs of non-medical health professionals using MSUS.
**Objectives:** The EULAR Task Force was established to reach a consensus on the role and education and training needs of non-medical health professionals undertaking MSUS for the management of patients with rheumatic and musculoskeletal diseases (RMDs).
**Methods:** The EULAR Task Force comprised an expert group from 11 European countries. The Task Force met twice and included rheumatologists, nurses, physiotherapists, a radiologist, radiographer and podiatrist with patient representation. In the first meeting the aims of the Task Force were defined and fourteen research questions were developed. This was followed by a comprehensive systematic search of the literature to identify publications on the role of health professionals using MSUS, their competency requirements and training undertaken. During the second meeting the Task Force were presented with the results of the literature review which supported the formulation and consensus of "points to consider". The level of agreement between task force members for each "point to consider" was determined after the second meeting.
**Results:** In total, seven "points to consider" were formulated. Two points covered the role and scope of health professionals using musculoskeletal ultrasound and one point addressed the application and feasibility in daily practice. Three "points to consider" focused on the training and competency required by health professionals and the final point addressed the added value in daily practice. The strength of the "points to consider" was D based on the category of evidence (3–4). A high level of agreement (range 9.0–9.7) was achieved between Task Force members. Additionally, the Task Force agreed upon eight topics for the future research agenda.
**Conclusions:** Seven "points to consider" for health professionals using MSUS for the management of patients with RMDs were developed using a combination of research-based evidence and expert consensus approach.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4411

## Nursing

### SAT0644-HPR BELIEFS, KNOWLEDGES AND REPRESENTATIONS OF PATIENTS WITH GOUT DISEASE FOLLOWED BY GENERAL HEALTHCARE AND HOSPITAL RHEUMATOLOGY: FROM DIONYSUS TO THE SWORD OF DAMOCLES

C. Sarran[1], C. Bougeois Sarran[1], C. Deprouw[2], M. Guignot[3], A. Frazier[3], L. Baumann Coblentz[4], E. Hang Korng[1]. *[1]rheumatology, Lariboisière Hospital, Paris; [2]Lariboisière Hospital; [3]Lariboisière Hospital, Paris; [4]General Practice Department, Bichat hospital, paris, France*

**Background:** Gout disease is common and potentially serious due to its joint, renal and cardiovascular complications. It is well treated with multiple efficient treatments; however, we notice a lack in the medical care of this disease, especially due to a bad compliance with the treatment. This compliance depends of numerous factors as personal history of the patient, relation to the healthcare system, social and familial environment.
**Objectives:** To explore knowledge, beliefs and representations of gout with gout patients followed in general practice and hospital rheumatology
**Methods:** Qualitative study by semi directive interviews of gout patients followed by general practice. Population: 26 patients, with 14 patients followed in general practice (22 men) from 44 to 85 yo sampled for their familial situation, ethnical origin and comorbidities. The areas explored concerned the disease itself, the medical care, the family and professional environment, and the health care system. The interviews were recorded and then analyzed through the grounded theory model: encoding of the interviews as we go along until data saturation. The codes are combined into sets and then analyzed in order to deduct concepts with the Nvivo 10 software.
**Results:** Emerging concepts: shameful disease, traumatic disease on a physical level (painful and disabling), and on a psychic level (self-image damaged). Nevertheless, even if the disease is considered as trivial, it is for most of the patients like the sword of Damocles: permanent fear for the next attack. Each patient had its own physiopathological conception, a wrong one most of the time. For example, they believe the disease was directly link to a personal responsibility (bad food hygiene...) or linked to an external cause (professional diner, heredity...). Gout attack triggered by overeating was often reported, due to a trust relationship between patient and medical doctors. Most of the patients were counting on their wife or husband to manage treatment, diet and familial organization. The role of the diet was predominant for the medical care, much more than the hypo-uricemiant treatment. But it appeared that the diet was binding with questioning of the lifestyle, and was managed day by day. There was not much difference between the patients of general medicine and those of rheumatology.
Model of a relation between medical care – disease – patient: each patient develops its own gout under different influences: his life, returned image, information

received. All this creates a unique entity, with a particular physiopathology... And a proper medical care modeled by experience, family, doctor and information. Then there is a balance between benefits and barriers to observance.
**Conclusions:** The very personal and intimate vision of gout disease and its treatment by the patients should be taken into account in therapeutic education.
**Disclosure of Interest:** None declared

## Psychology/Social sciences

### SAT0645-HPR RESULTS OF A GOAL MANAGEMENT INTERVENTION FOR PATIENTS WITH POLYARTHRITIS WITH MILD DEPRESSIVE SYMPTOMS

R. Arends[1], C. Bode[1], E. Taal[1], M. van de Laar[2]. [1]*University of Twente;* [2]*Medisch Spectrum Twente, Enschede, Netherlands*

**Background:** Persisting disease symptoms can threaten attainment of personal important goals for patients with polyarthritis, resulting in elevated levels of depression and anxiety[1]. Interventions that provide patients with the skills and techniques to live with and manage their disease in daily life are essential, as people have to manage a chronic disease most of the time outside of the health-care system. For this purpose participants practice four goal management competencies (goal maintenance, goal adjustment, goal disengagement and goal re-engagement) and the flexible use of these strategies during the self-management intervention "Right on Target".
**Objectives:** The purpose of this study was to establish whether an intervention aimed at increasing goal management capacities is effective in decreasing symptoms of depression and increasing adaptation in patients with polyarthritis with elevated levels of depressive symptoms.
**Methods:** In total, 85 persons with a diagnosis of polyarthritis and elevated levels of depression received the group-based goal management intervention *Right on Target* with measurements at baseline, post-intervention (after 2 months) and follow-up (6 months). A quasi-experimental design was applied in which the reference group consisted of 151 participants of a previously conducted observational study selected according to the inclusion criteria for the intervention group. Primary outcome was depression, secondary outcomes anxiety, purpose in life, positive affect and satisfaction with participation. Mediating variables were goal management strategies and arthritis self-efficacy. Linear mixed model procedure was applied to evaluate changes in outcomes. Proportions showing clinically relevant changes and possible mediators were analyzed.
**Results:** No improvement was found for depressive symptoms. Positive affect significantly improved in the intervention group mediated by an increase in goal adjustment. No changes were found for the other secondary outcomes, while goal maintenance decreased and self-efficacy for other symptoms than pain increased in the intervention group.
**Conclusions:** This study indicates the value of improving the management of personal threatened goals of people with polyarthritis and showed that especially facilitating goal adjustment and downgrading goal tenacity are potentially helpful. While more research is needed, the present study provides a small but promising direction towards greater wellbeing for patients with polyarthritis.

### SAT0646-HPR WOMEN WITH PSORIATIC ARTHRITIS WHO ARE HOMEMAKERS OR OFFICE WORKERS DECLARE SIMILAR DIFFICULTIES DURING WORKING

E. Kilic[1], G. Kilic[2], K. Nas[3], R. Cevik[4], E. Capkin[5], A.Z. Dagli[4], M. Karkucak[5], S. Ozgocmen[6]. [1]*Rheumatology, Afyonkarahisar State Hospital;* [2]*Physical Medicine and Rehabilitation, Afyon Kocatepe University, Medical Faculty, Afyon;* [3]*Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya University, Faculty of Medicine, Sakarya;* [4]*Division of Rheumatology, Department of Physical Medicine and Rehabilitation, Dicle University, Faculty of Medicine, Diyarbakır;* [5]*Physical Medicine and Rehabilitation, Karadeniz Technical University, Faculty of Medicine, Trabzon;* [6]*Division of Rheumatology, Department of Physical Medicine and Rehabilitation, Erciyes University, Faculty of Medicine, Kayseri, Turkey*

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis. The differences between homemaker (HM) and working at paid work (PW) in women were not assessed.
**Objectives:** The aim of this study was to assess differences between being HM and working in PW in female patients with PsA related to clinical findings, quality of life and difficulties at working.
**Methods:** Female patients with PsA over the age of 18-year-old who met the CASPAR classification criteria were underwent clinical and laboratory evaluation by using standardized protocol and case report form, from three different universities outpatient's clinics. Female patients with PsA were divided into age matched two group as a HM or working in PW. Patients who were HM or PW were asked to mark their level of difficulty during household works or office works respectively, on a 0–10 Likert scale. 0, indicated no difficulty during household/office works; 10, unable to do household/office works because of PsA and high scores indicated more difficulty.
**Results:** A total of 115 female patients with PsA (mean age 41.9±11.9 year) were included. Mean symptom duration was 10.7±9.3 year. Out of 86 (74.8%) patients with PsA were HM and 29 (25.2%) were working at a regular PW. Homemaker had higher body mass index than PW (25.1±7.4 vs 29.7±6.6 p=0.012). Dactylitis (current or having history) were higher in PW (58.6 vs 31.4% p=0.014) whereas enthesitis (current or having history) were higher in HM (27.6 vs 52.3% p=0.021). Disease activity measures (acute phase reactants, BASDAI, DAS28, VAS-pain, physician's and patient's global assessment, tender and swollen joint count), functional status and health related quality of life assessments (BASFI, BASMI, Duruoz hand index, SF-36, Nottingham health profile, psoriatic arthritis quality of life, hospital anxiety and depression scale, fatigue severity scale) were similar between HM and PW patients with PsA ($p>0.05$). Level of difficulties in working at household works were 5.2±2.6 in HM and level of difficulties in office works were 5.3±2.3 (p=0.804) in PW. Depression risk (HAD-depression $\geq$7) was relatively higher in PW (59.3 vs 43.7%), but anxiety risk (HAD-anxiety $\geq$10) was relatively higher in HW (26.8 vs 22.2%) ($p>0.05$). Fatigue severity scale score$\geq$36 was associated with depression risk in all women with PsA by using univariate logistic regression analysis (OR: 5.1, 95% CI: 2.0–12.8 $p<0.0001$).

Table 1

| | Working at PW (n=29) | HM (n=86) | p |
|---|---|---|---|
| Age | 40.4±12.7 | 42.3±11.2 | 0.481 |
| Number of pregnancies | 3.6±3.6 | 4.4±2.6 | 0.354 |
| Difficulties in household/office work (0–10) | 5.3±2.3 | 5.2±2.6 | 0.804 |
| Dactilitis (current or having positive history) | 17 (58.6) | 27 (31.4) | 0.014 |
| Tenosynovitis (current or having positive history) | 8 (27.6) | 25 (29.1) | 0.887 |
| Enthesitis (current of having positive history) | 8 (27.6) | 45 (52.3) | 0.021 |
| BASDAI | 4.4±2.3 | 4.0±2.5 | 0.506 |
| DAS 28 | 4.0±1.4 | 4.0±1.7 | 0.992 |
| PsAQoL | 7.4±6.5 | 6.2±5.7 | 0.530 |
| HADS - - Depression | 6.8±3.7 | 6.8±4.0 | 0.945 |
| HADS – Anxiety | 5.9±4.9 | 6.6±4.3 | 0.529 |
| Fatigue severity scale | 3.9±1.5 | 3.9±1.0 | 0.561 |

**Conclusions:** Women with PsA who were homemakers or working in paid work do not differ from each other in terms of disease burden, health related quality of life, difficulties at homework or at office work.Furthermore, increased fatigue may be associated with depression risk in female patients with PsA.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4878

### SAT0647-HPR PATIENT PERSONALITY INFLUENCES THE PRESCRIPTION OF TREATMENT FOR RHEUMATOID ARTHRITIS

L. Leon[1,2], M. Redondo[2], A. Garcia-Vadillo[3], I. Gonzalez-Alvaro[3], M.A. Perez-Nieto[2], J.A. Jover[1], L. Abasolo[1]. [1]*Rheumatology, Hospital Clinico San Carlos;* [2]*Health Faculty, Universidad Camilo Jose Cela;* [3]*Rheumatology, Hospital Universitario la Princesa, Madrid, Spain*

**Background:** Individualized treatment of rheumatoid arthritis (RA) based on genetic and serologic factors is increasingly accepted. In addition, patients are more actively involved in the management of their disease. However, personality has received little attention with respect to perception of the need and adherence to treatment.
**Objectives:** Our objective was to evaluate the influence of personality on the intensity of RA treatment.
**Methods:** We performed a cross-sectional study in two hospitals with early arthritis clinics where sociodemographic, clinical, and therapeutic variables are systematically recorded. Patients completed Eysenck Personality Questionnaire, Multidimensional Health Locus of Control, Pain-Related Self-Statement Scale and Pain-Related Control Scale. Aggressive treatment was considered if patients received more than two DMARDs or biological agents during the first year of follow-up. Multivariate logistic regression analysis was performed to determine predictors of aggressive treatment.
**Results:** 176 RA patients were included (80% women, disease begin median age 55 years). Treatment was considered aggressive in 57.9% of the sample. Scores were high in extraversion in 50.8% of patients, neuroticism in 29.5%, and psychoticism in 14.7%.Neuroticism was the only factor associated with aggressive treatment, which was less probable (p=0.04, OR =0.40). Neuroticism also decreased the possibility of receiving a combination of biologics and DMARDs (p=0.04, OR =0.28).
**Conclusions:** Patients with high scores on neuroticism are more worried, obsessive and hypochondriac, leading them to reject more aggressive therapy. It is important educate patients about their disease so that they will accept more aggressive approaches in clear cases of poor outcome.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4025

SAT0648-HPR **EXPLORING PHYSICIANS' PERCEPTIONS OF ILLNESS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS: A VIGNETTE-BASED STUDY**

S. Arat[1], P. Moons[2,3], J. Vandenberghe[4,5], J. Lenaerts[6,7,8], K. de Vlam[6], R. Westhovens[1,6]. *[1]Development and Regeneration, KU Leuven, Leuven, Belgium; [2]Health and Care Sciences, University of Gothenburg, Gothenburg, Sweden; [3]Public Health and Primary Care, KU Leuven; [4]Psychiatry, UZ Leuven; [5]Neurosciences, KU Leuven; [6]Rheumatology, UZ Leuven, Leuven; [7]Rheumatology, Jessa Hospital; [8]Rheumatology, Rheuma Institute, Hasselt, Belgium*

**Background:** Systemic Lupus Erythematosus (SLE) and Systemic Sclerosis (SSc) are complex chronic auto-immune diseases with a wide presentation of multi organ involvement, comorbidities and complications. This complexity implies that the management and treatment of SLE and SSc needs a multidisciplinary care team that exists of healthcare professionals from different professions, and physicians of different disciplines. Within this multidisciplinary approach, each physician might have certain ideas and beliefs about the disease of a particular patient with SLE and SSc. Differences in opinions and views can cause inconsistent advice, confusions and misinterpretations.
**Objectives:** The aim of this study was to cluster physicians based on their illness perceptions of patients with SLE and SSc.
**Methods:** A sample of 287 physicians from nine disciplines, working at three hospitals in Belgium was approached. The inclusion criteria were that physicians had to be certified in their specialism, and had experience with SLE or SSc patients. Participating physicians were asked to complete the Revised Illness Perception Questionnaire for Healthcare Professionals (IPQ-R HP) on the basis of four patient vignettes, i.e. 2 vignettes per disease (SLE-SSc). These vignettes were based on real-life patients followed at our outpatient clinic. The IPQ-R HP (38-items scored on a 5-point scale rated from 1 = strongly disagree to 5 = strongly agree) measures beliefs of the healthcare professional in relation to duration and cyclical nature of the patients' illness; perceived consequences; emotional impact; personal/treatment control; and understanding of the illness by the patient. Statistical analysis was performed using k-means cluster analysis for each disease separately.
**Results:** Fifty physicians (62% men, mean age 43 y (SD=11), mean working experience 13 y (SD=12)) were included. For each disease, three clusters of physicians with different illness perceptions were identified. For SLE, cluster 1 (42%) reported less severe consequences, less emotional impact and a clear picture of SLE by the patient. Cluster 2 (36%) perceived severe consequences for the patient and a chronic and cyclical time course. Cluster 3 (22%) reported less personal control and understanding of SLE by the patient. Three of the 5 rheumatologists were detected in cluster 2. For SSc, cluster 1 (22%) perceived less consequences and less emotional representations by the patient. Cluster 2 (42%) reported the cyclicity of SSc, emotional impact and severe consequences due to SSc. Cluster 3 (36%) perceived a non-cyclical time course and less personal/treatment control by the patient. Three of the 5 rheumatologists were present in cluster 2.
**Conclusions:** There is a lot of variability in illness perceptions between physicians of different disciplines and within physicians of the same discipline regarding SLE and SSc patients. Further studies should focus on the factors that determine these differences in perceptions and eventual consequences for patient care.
**Disclosure of Interest:** None declared

## Occupational therapy

SAT0649-HPR **WOMEN WITH EARLY RA PREFER TO USE INTERACTION AND ADJUSTMENT STRATEGIES TO DEAL WITH THEIR EVERYDAY LIFE DILEMMAS: THE TIRA PROJECT)**

A. Sverker[1,2], M. Björk[3], I. Thyberg[4], G. Östlund[5]. *[1]Department of Activity and Health, Department of Medical and Health Sciences; [2]Department of Social and Welfare studies; [3]Department of Rheumatology and Department of Social and Welfare Studies; [4]Department of Rheumatology and Department of Clinical and experimental medicine, Linköping University, Linköping; [5]Division of Social Work, School of Health, Care and Socail Welfare, Mälardalen University, Eskilstuna, Sweden*

**Background:** Due to advancements in medications and treatment, many patients with rheumatoid arthritis (RA) have high expectations of maintaining health, even though they still report participation restrictions in daily life. More women than men RA are affected and women have higher disease activity and more disability than men. Thereby there is a need for further exploration of women's perspective in order to provide tailored multi professional interventions.
**Objectives:** The aim of this study was to explore RA women's strategies for dealing with the dilemmas in everyday life.
**Methods:** The data collection was conducted with semi-structured interviews based on the Critical Incident Technique (CIT) [1]. The sample consists of women with early RA (n=35). The strategies for dealing with RA dilemmas of everyday life were analyzed and categorized using content analysis [2] and linked to the International classification of functioning, disability and health (ICF) domains [3]. This study is part of a longitudinal RA project approved by the Research Ethics Committee at Linkoping University (M168–05 T84–09).
**Results:** The women with early RA described four types of health strategies; interaction, adjustment, avoidance and acceptance. The interaction strategy was most frequently used, however often in combination with adjustment or avoidance strategies. The *interaction strategy* included to verbally express needs and wants and to interact with others. More easily said, to talk about the problem. In the *adjustment strategy* new behaviors and habits were developed to deal with the experienced participation restriction or the everyday life dilemma. The *avoidance strategy* included to deliberate avoid possible participation restrictions, and the *acceptance strategy* was identified by utterances that included descriptions of accepting the experienced situation or restriction. The everyday dilemmas experienced where related to several of ICF domains such as dressing, eating, drinking, driving, preparing meals, formal and informal relationships, interpersonal interactions and family relationships, employed work, and in leisure activities.
**Conclusions:** Women with early RA used combined health strategies to deal with everyday life dilemmas and participation restrictions. Especially the interaction strategy was preferred which could be argued to be an important facilitator for communication within health promotion initiatives and in rehabilitation. This highlights the importance of that health professionals, colleagues, family members and other persons in the social environment listen to women's articulations in order to support and decrease women's participation restrictions in early RA.

### AB1074-HPR INTERRUPTION OF BIOLOGICAL THERAPY: REASONS AND IMPACT ON DISEASE ACTIVITY

A. Lopez Esteban, J.C. Nieto Gonzalez, I. Janta, F. Garcia Calle, C. Garaballu, T. del Rio, A. Beltran, M.D.C. Ramos, C.M. Gonzalez, F.J. Lopez-Longo, E. Naredo, I. Monteagudo. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** The development of biological therapies (BT) represented an important advancement in the treatment of patients with inflammatory arthritis. These treatments have proven to be effective in controlling disease activity, leading to clinical remission and avoiding disease progression, allowing a better prognosis of these patients.
**Objectives:** To describe the reasons of intra-venous BT interruption in a Rheumatology Day-Care Hospital. To evaluate whether this interruption of BT leads to an increased disease activity.
**Methods:** This is an observational, retrospective study performed in the Rheumatologic Day-Care Hospital of a UniversityHospital between June 2014 and December 2015. We included all patients treated with intra-venous BT [i.e. infliximab (IFX), tocilizumab (TCZ) and abatacept (ABA)] with a treatment interruption longer than 15 days. Demographics (i.e. gender, age), RA features (i.e. treatment, disease duration), clinical evaluation (i.e. tender joint count, swollen joint count, patient global pain intensity VAS) and laboratory tests (i.e. ESR, CRP) were recorded. Composite scores and indices (i.e. DAS28, CDAI, SDAI, ASAS, HAQ, BASDAI and BASFI) were calculated before and at BT re-starting.
**Results:** Out of 272 patients treated with BT, 55 (20.2%) had a temporary interruption of the treatment $\geq$15 days. Out of these patients, 56% were females, the mean (SD) age was 50 (32) years with a mean (SD) disease duration of 18.5 (18) years and a mean (SD) treatment duration of 8.1 (7.8) years. The diagnoses of these patients were as follows; 25 (45.4%) had rheumatoid arthritis (RA), 17 (30.9%) had spondyloarthritis (Sp), 8 (14.5%) had psoriatic arthritis (PsA), and 5 (9%) had other autoimmune disease. The BT received was as follows; 43 (78.1%) IFX, 8 (14.5%) TCZ and 4 (7.3%) ABA. Twenty two (40%) patients received also treatment with synthetic disease modifying drugs (sDMARDs) and 21 (38.1%) received also corticoid therapy with a mean dosage of 6.2 mg/day. The most frequent reasons for BT interruption were infections in 27 (49%) patients of which 11 required hospitalization (i.e. 8 pneumonias, 1 cholelithiasis, 1 lower urinary tract infection and 1 herpes zoster infection) and 16 didn't required hospitalization (i.e. 6 respiratory tract infections, 3 lower urinary tract infections, 1 herpes zoster infection, 1 cellulitis and 5 oral infections). The second reason for BT interruption was the performance of surgical procedures in 16 (29%) patients and the third reason was related to other situations such as the performance of diagnostic procedures for ruling out other diseases, work reasons or forgetfulness 12 (21.8%). In 3 patients the BT was interrupted because of a neoplasia (colon, lung and bladder adenocarcinoma) and 3 patients were pending to restart the treatment after ruling out cancer or infection. The mean (range) interruption duration was 72 (16–365) days. The disease activity before and after BT interruption is displayed in table 1.

| Clinical evaluation | | | |
|---|---|---|---|
| Variable | Basal | Restart | p-value |
| Patient global assessment by VAS | 4,12 | 6,14 | <0,001 |
| [redacted] | | | |
| Swollen joints | 2,17 | 1,89 | 0,029 |
| [redacted] | | | |
| DAS 28 ESR | 3,27 | 4,39 | 0,003 |
| [redacted] | | | |
| CDAI | 14,96 | 21,70 | 0,030 |
| [redacted] | | | |
| Back pain | 1,89 | 3,42 | 0,133 |
| [redacted] | | | |
| BASDAI | 2,58 | 3,82 | 0,076 |
| [redacted] | | | |
| ABDAS ESR | 1,52 | 2,11 | 0,059 |
| [redacted] | | | |
| ESR mm/h | 15,19 | 19,24 | 0,239 |

**Conclusions:** The most frequent reasons for BT interruption were infections, in particular respiratory tract infections and surgical procedures. BT interruption occurred in a wide age range. After BT reintroduction, we detected an increase in pain and disease activity as well as a decrease in the functional status.

### AB1075-HPR A SURVEY OF IRISH RHEUMATOLOGY NURSES EXAMINING CLINICAL PRACTICE, PROFESSIONAL BEHAVIOUR AND EDUCATION NEEDS

E. Shinners. *Education & Research Centre, Our Lady's Hospice & Care Services, Dublin, Ireland*

**Background:** Rheumatology nurses, as integral members of rheumatology teams, are instrumental in increasing treatment in response to clinical need to improve patient outcomes. Yet their specialist knowledge and skills are not always recognised or acknowledged with specialist or advanced practice titles (IRNF, 2014).
**Objectives:** The objectives of this online survey were to characterise rheumatology nursing role activities, assess confidence with these roles, and assess educational requirements to gain understanding about current rheumatology nursing practice in Ireland.
**Methods:** Approval was granted by Our Lady's Hospice & Care Services and the UK authors to use the tool. Following conversion from paper to online, it was emailed to all Irish Rheumatology Nursing Forum (IRNF) members (approx. 75 members at time of survey), with 2 further reminders. The UK survey was originally 38 questions with a mix of multiple choice and likert type questions analysing demographic information, patient-based and non-patient based clinical and professional activities, and self-assessment of competence in practice related clinical activities. Minor language changes were required within the tool to make it suitable to an Irish population. An additional component was added asking about postgraduate education to date, intention to study further and courses of interest. It took approx. 15–20 mins to complete.
**Results:** Response rate was approximately 45%, from rheumatology nurses. Respondents were working as specialist (51%), advanced (6%) or registered nurses (25%) or others (including management and research roles) (18%). Patient based clinical activities include high levels of confidence counselling patients on Methotrexate (73%), calculating a DAS score (68%) and to a lesser extent performing a joint count (54%) and least of all 19% supporting patients with chronic pain. Clinical activities included monitoring patients on DMARDs (62.5%) and Biologics (68%) as a major role although the majority were not qualified to prescribe medications (72%) or give joint/ soft tissue injections (68%). Providing psychological support was a major or significant role for all respondents. Non-patient based activities included majority of those surveyed taking part in activities such as clinical research (63%), teaching nursing students (58%), conducting audits (55%) with less writing business cases (26%) or giving talks outside their department (42%). 72% had undertaken rheumatology specific education while a third were considering further post graduate study.
**Conclusions:** The rheumatology nurses who completed the survey demonstrated advanced clinical knowledge and skills that are not reflected by their occupation title with many nurses not employed as specialist or advanced practitioners. Characterising the clinical practice of rheumatology nurses will inform the debate on nurses being acknowledged for the clinical skills they are delivering

### AB1076-HPR PROMOTING LOCAL RESEARCH THROUGH A POSTER CAMPAIGN: THE IMPORTANCE OF KNOWING YOUR AUDIENCE

H. Hanson[1], D.W. Lendrem[2], J.D. Isaacs[2], B. Lendrem[2], T. Rapley[3]. *[1]Rheumatology, Newcastle upon Tyne Hospitals NHS Foundation Trust; [2]Institute of Cellular Medicine; [3]Institute of Health and Society, Newcastle Universtiy, Newcastle upon Tyne, United Kingdom*

**Background:** Recruiting sufficient patients into studies is a perennial challenge for researchers. Increasing patient and carer awareness of local research

activity promotes recruitment through normalising the experience of research participation.
**Objectives:** To evaluate a programme promoting local research through a poster campaign in musculoskeletal clinic waiting areas. To measure differences in awareness of local research before and after the poster campaign.
**Methods:** 8 posters were developed collaboratively by clinical staff, research staff and patient representatives for display in musculoskeletal clinic waiting areas in a large UK teaching hospital. Each poster briefly describes the findings and potential impact of a study carried out locally. A questionnaire measuring awareness of local research was given to consecutive patients and relatives/friends/carers (aged 16+) entering the clinics on 6 dates and times before and 6 months after introduction of the posters. Responses were analysed adjusting for age and gender using ordinal logistic regression, with the SAS JMP Statistical Visualization System.
**Results:** The response rate was 92% (n=156/170). A majority of respondents were aged 50–69y (43%, n=56), with all other age groups (16–29, 30–49 and 70+) represented. 56% (n=88) of respondents were female and 74% (n=116) were patients. There were no significant differences in awareness of local research before and after the poster campaign ($p>0.20$ in all cases). 6 months after introduction of the posters, only 24% of people reported seeing the posters. There were, however, some differences in awareness of local research for those respondents who had seen the posters. This group were significantly more likely to agree with the statement 'Research is going on at this hospital to understand arthritis and develop new treatments' ($p<0.001$).
**Conclusions:** The poster campaign failed to increase awareness of local research amongst people using musculoskeletal clinic waiting areas. This was despite significant input to design and content by patient research partners and high approval of final drafts by this group. Few people reported seeing the posters, which may be due to the high volume of competing posters on display. This concurs with existing data that people fail to see and be influenced by posters in clinic waiting areas (1). Those people who had seen the posters were significantly more aware of local research, which may be due to the impact of the poster. Another explanation is that people already aware of local research disproportionately noticed and remembered the posters. To increase the success of a research awareness campaign, tools should be developed and tested with their target audience (i.e. patients not aware of or involved in research) in addition to patients already actively involved.

## AB1077-HPR FIBROMYALGIA SYNDROME: NURSE CASE MANAGEMENT FOR A STRUCTURED PATIENT PATHWAY

K. El Aoufy, G. Piemonte, S. Mikhaylova, L. Rasero, S. Maddali Bongi.
*Experimental and Clinical Medicine, Florence, university, Florence, Italy*

**Background:** Fibromyalgia Syndrome (FMS) is a common, potentially disabling, chronic disorder that is defined by widespread pain, often accompanied by fatigue and sleep disturbance, cognitive and somatic symptoms. Fibromyalgia continues to present a challenge for healthcare professionals (HCPs) because of the lack of a clear patient pathway. Nurses' role need to be better defined.
**Objectives:** Our aim is to investigate the presence of correlations between clinical and clinimetric parameters and Fibromyalgia Scale (FS) assessed by 2011 ACR criteria, in order to define which parameters should have priority in the construction of a care plan for FMS patients, as well as outline a role for nurses specifically designed for FMS patients.
**Methods:** 168 patients (155 women and 13 men; age MEAN±DS 54.50 ± 12.32) were evaluated for clinical and demographic parameters: age, sex, disease duration, year of diagnosis and latency of the disease. They were assessed by FS, which is divided into Wide Pain Index and Symptoms Score, and gives a total score of severity (FS with range 0–31 and cut off $\geq$13). They were also assessed for pain and sleep (Numeric Rating Scale Pain and NRS Sleep), Regional Pain Scale (RPS), disability (Fibromyalgia Impact Questionnaire and Health Assessment Questionnaire), mood disorders (Hospital Anxiety and Depression Scale), sleep quality (Numeric Rating Scale Sleep), fatigue (Functional Assessment of Chronic Illness Therapy- Fatigue) and quality of life (Short Form-36).
**Results:** FS is significantly and positively correlated with HADS-D for depression, HADS-A anxiety, NRS for pain, FIQ, HAQ and FACIT-F ($p<0.01$) and Tender-Points ($p<0.05$), it is also significantly and negatively correlated with the NRS for sleep quality, SF 36 all subscales, and ISF (p: $<0.05$) and ISM (p: $<0.01$). At linear regression model, FS is significantly and independently associated with RPS, FACIT-F and with SF_36_RE, that together explain the variability of FS in 96% (88.7%; 5.4%;1.9% respectively).
**Conclusions:** It would be desirable, therefore, the use of FS scale in everyday clinical practice, thus allowing nurses to assess FMS patients and plan their clinical and therapeutic pathway, together with the rheumatologist. Our results confirm that important aspects to be treated in FMS patients are quality of life, pain and fatigue, they are considered as independent predictors for FS. Thus, they explain 96% of FS score variability. In this context nurses' role is crucial since FMS most common symptoms seem to be adequately treated with a multimodal and holistic approach and with interventions tailored to the individual. Thus, we propose a Case Manager Nurse (CMN) that should set up and coordinate a multidisciplinary approach aiming at improving FMS patients' QoL and self-perceived health status.

## AB1078-HPR TELEPHONE FOLLOW-UP, STANDARDIZED TO THE INITIATION OF BIOLOGIC THERAPY OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IN A SPECIFIC UNIT OF BIOLOGIC THERAPY. PILOT STUDY

L. Cano-Garcia[1], S. Manrique-Arija[1], I. Ureña[1], N. Mena-Vazquez[1], M.C. Ordoñez-Cañizares[1], C.M. Romero-Barco[2], C. Domic-Bueno[1], M. Rojas-Gimenez[1], C. Fuego-Varela[1], F.G. Jimenez-Nuñez[1], M.V. Irigoyen[1], V. Coret[1], A. Belmonte[1], A. Fernandez-Nebro[1]. *[1]Reumatología, Hospital Regional Universitario de Málaga; [2]Reumatología, Hospital Universitario Virgen de la Victoria, Málaga, Spain*

**Objectives:** To know the usefulness of follow-up call legalized at the beginning of biologic therapy and patient contact with consultation of nursing after the start of treatment.
**Methods:** Observational study cross.Patients: We collected 120 patients who began treatment with biologic therapy, intravenous or subcutaneous from December 2013 to November 2015. Protocol: Protocol is education for self-management of subcutaneous biological therapy at the beginning of the treatment. This Protocol includes a follow-up call from the consultation of nursing that matches the first administration of the treatment at home or within 3–5 days after the first infusion. This call is made in the case of the biological subcutaneous as per guideline: etanercept (7 days), adalimumab (14 days), golimumab (28 days), tocilizumab (7days), certolizumab (14 days), abatacept (7days) either guideline prescribed in case of dose reduction. Offers the possibility of contact (telephone and e-mail) with the consultation of nurses in case of doubt or incidence during treatment and is analytical control to the month of the beginning of nurse telephone consultation. Statistical analysis: a descriptive analysis of the main variables.
**Results:** 120 patients with RA initiated treatments were: etanercept 33,3% (n40), adalimumab 8,3% (10), tocilizumab sc 20% (24), abatacept sc 12,5% (15), golimumab 13,3% (16), rituximab 6,7% (8), certolizumab pegol 3,3% (4), biosimilar 2,5% (3). In terms of the associated FAME: none 38,3% (46), methotrexate 49,2% (59), Leflunomide 8.3% (10), sulfasalazine 1,7% (2), hydroxychloroquine 2,5% (3).They were detected in the Protocol call patients with incidences 14,16% (17): local reaction3.3% (4), pruritus 5.8% (7), upset general 0.8% (1), diarrhea 0.8% (1), constipation 0.8% (1), headache 1.7% (2). The patients called the nursing consultation to communicate incidences 10.83% (13): anemia 0.8% (1), hypertransaminasemia 1,7% (2), implant dental 0.8% (1), bruising 0,8% (1), inefficiency 6.7% (8). Also communicated to the consultation of nursing infections during 16.6% (20): urinary tract infection 5,8% (7), upper respiratory tract infection 1,7% (2), upper respiratory tract infection+herpes simplex 0,8% (1), lower respiratory tract infection 3,3% (4), surgical wound infection 0.8% (1), dental infection 0,8% (1), herpes simplex 0,8% (1), gastroenteritis 0,8% (1), not frightening infection 1,7% (2).Patients who started biologic therapy in the period studied only 8.3% (10) changed treatment.The emergence of new comorbidities were detected during treatment with biologic therapy 4,16% (5): hypertension 0,8% (1), hypertension + diabetes mellitus II 1,7% (2), nonspecific Interstitial pneumonia 0,8% (1), psoriasis 0,8% (1).
**Conclusions:** The follow-up call is a useful tool for the control of security of the new beginnings of biological agents. It could foster adherence to treatment monitoring at home and offering the possibility to communicate with the nursing.

## AB1079-HPR ADAPTATION AND VALIDATION OF THE SYSTEMIC SCLEROSIS QUALITY OF LIFE QUESTIONNAIRE INTO POLISH: ITEM ANALYSIS USING RASCH MODELS

M. Sierakowska[1], S. Sierakowski[2], J. Sierakowska[3], E. Krajewska-Kułak[1], A. Redmond[4], M. Ndosi[5]. *[1]Department of Integrated Medical Care; [2]Department of Rheumatology and Internal Diseases; [3]Department of Foreign Languages, Medical University of Bialystok, Bialystok, Poland; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine; [5]School of Healthcare, University of Leeds, Leeds, United Kingdom*

**Background:** Systemic Sclerosis SSc is a multisystem autoimmune disease with serious effects on patients' Quality of Life (QoL). SScQoL questionnaire was developed in the in the UK to measure needs-based patient-reported quality of life in SSc.[1]
**Objectives:** The aim of this study was to adapt and validate the SScQoL for use in Poland.
**Methods:** This cross-sectional study involved the (i) adaptation phase and (ii) validation phase. In the adaptation phase, the SScQoL was translated into Polish using a standard process for adaptation of self-report quality of life measures.[2] In the validation phase, patients with SSc were recruited from 8 rheumatology centres in Poland and they were asked to complete the Polish version of the SScQoL. The data was then analysed using Rasch models to determine fit to the model, local dependency, internal consistency, unidimensionality and psychometric equivalence with other European versions of the SScQoL.
**Results:** The SScQoL translated well into Polish. The sample included 231 patients, 198 (86%) of whom were women. Their median age was 58 (IQR: 48 to 64) years, median disease duration, 6 (IQR: 3 to 12) years and the majority left school at age 19. The analysis of the 29 items revealed lack of fit to the Rasch model and suggested some multidimensionality (Table 1). Items were grouped into 5 subscales derived from components of the International Classification of Functioning, Disability and Health. Re-analysis of the 5-subscale SScQoL resulted into a valid, reliable and unidimensional scale (only 4.3% of independent t-tests were significant).[3] The scale was found to have measurement equivalence with five other European countries as described elsewhere.

Table 1. Summary statistics for the overall fit to Rasch model and unidimensionality

| Analyses | Item Fit Residual | | Person Residual | | Chi square Interaction | | PSI | N | Independent T-tests (95% CI)** |
|---|---|---|---|---|---|---|---|---|---|
| | Mean | SD | Mean | SD | Value (df) | p-value* | | | |
| 29-item SScQoL | −0.52 | 1.38 | −0.34 | 0.95 | 187.49 (116) | <0.001 | 0.90 | 224 | 0.10 (0.06 to 0.14) |
| 5-subscale SScQoL | −0.35 | 2.14 | −0.31 | 0.97 | 22.45 (15) | **0.097** | 0.84 | 221 | **0.04** (0.02 to 0.07) |

SD, Standard deviation; df, degrees of freedom; *P-value >0.05 suggest adequate fit to the model; PSI, Person separation index reliability (value >0.7 acceptable reliability); **Less than 5% significant independent t-tests suggests unidimensionality[3].

**Conclusions:** The Polish version of the SScQoL is a valid measure of needs-based quality of life in SSc. Transformed scores can be compared across five European countries.

## AB1080-HPR THE ORGANIZATIONAL AND ENVIRONMENTAL FACTORS THAT AFFECT PATIENT SATISFACTION IN DAY CARE UNITS

M. Pavic Nikolic, B. Huzjan, S. Kosir Jost, K. Perdan Pirkmajer. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** Patients with inflammatory rheumatic disease, who are treated with biologics, often need a lifelong therapy and frequent examinations. Some of them receive biologics intravenously (i.v.) in a day care unit.Their satisfaction is an important indicator of quality in health care and is influenced by many yet undetermined nonclinical factors.
**Objectives:** The aim of our study was to determine the circumstances that have important influence on satisfaction of patients in our day care unit.
**Methods:** Patients treated in the day care unit of the Department of Rheumatology, University Medical Centre Ljubljana, Slovenia were enrolled from November 2014 to the end of January 2015. 130 questionnaires focusing on environmental adequacy of day care units, privacy during the treatments, organization of day care units, satisfaction with health care and access to phone advice were distributed. Data were analyzed using independent samples t-test when appropriate.
**Results:** One hundred and nineteen patients treated in our day care unit were included. Their average age was 57 ± 12, 6 years old, 73, 9% of them were women. The most frequently represented rheumatic disease was rheumatoid arthritis (77, 3%), the average disease duration was 14, 7 years. Most patients (41%) were being treated with biological therapy for 3–5 years. Most patients in our day care unit organised their own transport to the hospital (73, 9%), 49, 6% of patients commuted from places which are more than 25 km away. According to our questionnaire suitability of treatment rooms, have only marginal, t statistically unimportant, impact on patient satisfaction (p=0,050). The organization of work in daily hospital, the way of providing information about health condition, future treatment options, privacy during the treatment and possibility of obtaining information by phone all had important influence ob patient satisfaction (all $p<0.005$). Overcrowded rooms, high environmental temperatures in the summer, long waiting times for the treatment and the absence of the rheumatologist during the treatment in day-care unit all negatively affected patient satisfaction.
**Conclusions:** Our study shows important connections between the level of patient satisfaction and environmental as well as organizational aspects of day care unit treatment. This data provide new opportunities for our day care unit environmental improvements and organizational changes.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2683

## AB1081-HPR PHARMACOLOGICAL ADHERENCE TO CONVENTIONAL OR BIOLOGICAL THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A COLOMBIAN SPECIALIZED RHEUMATOLOGY CENTER

N. Palacio[1], P. Santos-Moreno[2], L. Villarreal[3], G. Ballesteros[2], J. Bello[2], E. Castillo[2], R. Giraldo[2], D. Gomez[2], A. Aza[4], A. Lopez[5], A. Cardozo[4], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Nursing; [2]Rheumatology; [3]Psychology; [4]Health services; [5]Pharmaceutical chemist; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** The lack of pharmacological adherence and consecutive therapeutic failure is a prevalent and relevant problem in clinical practice, especially in the treatment of chronic diseases such as rheumatoid arthritis (RA). In the context of chronic diseases, World Health Organization considers lack of adherence like a public health priority because represents negative consequences like: therapy failures, higher rates of hospitalization and increased costs of health care.
**Objectives:** The aim of this observational study was determine adherence to treatment in patients with RA, their demographic characteristics and clinical variables.
**Methods:** An observational, descriptive cross sectional study conducted in a non-probability sample of convenience in patients with RA who consult to rheumatology institution specialized in RA patients. Descriptive epidemiology was applied for continuous variables, measures of central tendency and dispersion for categorical and qualitative variables (averages/percentages); we used Pearson's chi-squared test ($\chi^2$) and T student test to evaluate bivariate correlation.
**Results:** 356 patients were included, 186 (52%) received DMARDs therapy and 170 (48%) biological therapy. 309 (86%) were female and 47 (43%) were male meanDAS28 was 2.5 ± 1 HAQ was 0.87 ± 1.3. The most frequent comorbidity was osteoporosis 145 (40%) and hypertension 135 (37%). 103 (28%) participants suspended the medication when they felt polimedicated. In the group using DMARDs 71 (38%) suspended the medication due to an adverse event and in the biological therapy group 55 (32%). 71 (38%) patients in the group with DMARDs referred administrative difficulties while in the group with biological therapy 56 (32%) referred the same issue. When we explored the adherence, regarding age the group where we found fewer adherence in the group between 40 and 60 years this correlation was not statistically significative. When patients suspended the medication when they felt medicated with many drugs mean DAS28–2.6 higher than who did not suspend medication mean DAS28–2.4. When the medication due to an adverse event was suspended mean DAS28–2.57 higher than those who did not suspend the medication (DAS28–2.46) and was statistically significative.
**Conclusions:** This study shows that most of patients (two thirds) are adherent to conventional or biological treatment; however a important number remains non-adherent with a higher DAS28 score with clinical and economical implications.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5732

## AB1082-HPR PROVIDING DRUG COUNSELLING ON METHOTREXATE IS ONE OCCASION ENOUGH?

S.J. Ryan, C. Thwaites, S. Kamath. *Rheumatology, Haywood Hospital, Stoke on Trent, United Kingdom*

**Background:** Methotrexate is used in the treatment of patients with an active inflammatory arthritis. Patients routinely receive drug information on the commencement of treatment, often from the rheumatology nurse specialist, and can remain on Methotrexate for many years if it remains safe and effective. Despite the long duration of use of Methotrexate there is often no mechanism to reinforce information about continuing to take the medication safely.
**Objectives:** The aim of this survey was to establish what safety information patients recalled receiving about Methotrexate and whether patients would like to be updated with information about taking this medication.
**Methods:** A questionnaire was developed and distributed to patients attending

for their Methotrexate drug monitoring appointment in a rheumatology community hospital. The content of the questionnaire focused on:
a) The side effects patients had been asked to report.
b) When methotrexate could be safely taken (including pregnancy, alcohol intake, influenza vaccination and contraceptive precautions).
c) What action would be taken if a problem related to their Methotrexate occurred.
4) Whether patients would like to be updated with information about Methotrexate and if so how they would like to be updated and what information they would want to be included.
**Results:** The survey was completed by 100 patients on Methotrexate. The majority of the respondents (58%) were over 61 years and had been taking Methotrexate for longer than a year. Ony 35% of respondents recalled being asked to report shortness of breath and only 42% would report the presence of infection. Forty one per cent of respondents felt a small amount of alcohol was safe. Although all respondents stated that Methotrexate should not be taken in pregnancy, sixty seven percent of respondents did not know whether contraceptive precautions should be taken. Eighty eight percent of respondents would contact the rheumatology adviceline with a problem and 27% of respondents did not know whether it was safe to have the influenza vaccination. Eighty six per cent of respondents would like to be updated with information about Methotrexate with 83% requesting written information on any aspect that would enhance the safe taking of Methotrexate.
**Conclusions:** The majority of patients taking Methotrexate would not report shortness of breath or the presence of infection, both serious events that would require the Methotrexate to be stopped. It would appear that there is a need to update patients with safely information when they remain on Methotrexate for many years. Patients would welcome being updated with written information to enhance the safe taking of this medication. Further research would be required to identify if providing information at regualr intervals did improve the reporting of side effects and the safe administration of Methotrexate.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1186

## AB1083-HPR COMPUTERIZED NEUROPSYCHOLOGICAL PERFORMANCE IN PERSONS WITH RHEUMATOID ARTHRITIS

S.Y. Shin[1], J.H. Lee[2], B.Y. Yoon[2]. *[1]Department of Nursing, College of Medicine, Inje University; [2]Division of Rheumatology, College of Medicine, Inje University, Ilsan Paik Hospital, Busan, Korea, Republic Of*

**Background:** For persons with chronic diseases such as rheumatoid arthritis (RA), intact cognitive function is crucial for performing main daily activities and adhering to self-management regimens. Persons with impaired cognitive function have decreased functional independence, reduced quality of life, and increased risk of mortality. Although several mechanisms may influence cognitive function in RA, it has not been well-studied in this population.
**Objectives:** This study explored the prevalence of cognitive impairment in persons with RA using a set of computerized neurocognitive tests and the factors that were significantly correlated with cognitive impairment.
**Methods:** Individuals with RA were recruited by their rheumatologists during follow-up visits at one university hospital in Korea. After getting signed consents, a trained research nurse assessed participants with a range of physical, psychosocial, and biological metrics. Cognitive function was assessed using a set of 6 computerized neurocognitive tests yielding 18 indices covering a range of cognitive domains. Subjects were classified as "impaired" if they performed 1 *SD* below age-based population norms on each test [1]. The total cognitive impairment score was calculated by summing the transformed scores, ranging from 0 (no impairment) to 18 (worst impairment). Pearson correlation coefficient analyses were conducted to identify the variables that might be significantly associated with cognitive impairment.
**Results:** Twenty three subjects with a mean (±*SD*) age of 64.9 (±12.4) years were included in preliminary analyses. 87% were female, 87% were married, and mean educational level was 9.7 (±5.2) years. Mean DAS-28 level was 2.6 (±1.2) and mean disease duration was 116.5 (±85.4) months. Mean HAQ score was 0.6 (±0.8) and mean cardiovascular disease (CVD) risk factors were 3.1 (±1.5). 35% had depression and 70% had sleep problems. The proportion of persons who were classified as cognitively impaired on each test were 34% in Card Sorting Test (executive function), 68% in Trail Making Test (visuo-motor coordination), 78% in Visual Span Test (language memory), 83% in Verbal Learning Test (visuo-spatial memory), 83% in Visual Continuous Performance Test (continuous attention), and 91% in Word-Color Test (selective attention). Mean total cognitive impairment score was 11.0 (±4.2), and ranged from 2–17. 95% were classified as cognitively impaired on five or more test indices. Education (r=-514, $p<.05$), income (r=-.638, $p<.05$), and CVD risk factors (r=.434, $p<.05$) were significantly correlated with total cognitive impairment score.
**Conclusions:** A significant number of RA patients were cognitively impaired. Low educational levels, low income, and increased CVD risk factors may be potential risks of cognitive impairment in this population. These findings suggest that the burden of cognitive impairment in RA is significant, and future studies identifying specific etiological contributors to cognitive impairment are warranted.

## AB1084-HPR LIGHT-MINDED FOLLOW UP OF OSTEOPOROSIS PROPHYLAXIS AT NURSE CONSULTATIONS IN GLUCOCORTICOID TREATED POLYMYALGIA RHEUMATICA LEADS TO HIGHER COMPLIANCE

S.H. Jakobsen, A. Emamifar, I.M.J. Hansen. *rheumatology, Outpatient Clinic, Reumatologi, Svendborg, Denmark*

**Background:** Compliance to osteoporosis prophylaxis in postmenopausal women is described to be very poor [1]. The compliance to prophylactic osteoporosis medication in patients with inflammatory diseases treated with Glucocorticoids (GC) is higher [2], probably due to the risk of osteoporotic fractures as a side effect of GC treatment [3].
**Objectives:** To evaluate the adherence to osteoporosis prophylaxis in a group of patients suffering from polymyalgia rheumatica (PMR) treated with GC.
**Methods:** At our department patients with milder disease are seen at every second consultations by a nurse specialized in rheumatology. At all nurse consultations the patients are asked, in a friendly and understanding manner, if they remember to take the prescribed calcium and vitamin D, as well as the name of the medication and where they buy it. If Bisphosphonate is prescribed they will be questioned about this as well. The nurses also check the date of dual-energy x-ray absorptiometry (DEXA) scans. In this cross sectional study, all patients (138) diagnosed with PMR within 2013 were interviewed about their compliance toward osteoporosis prophylaxis using a standardized questionnaire.
**Results:** 138 patients were identified, 20 patients were excluded (diagnoses were changes (12), did not want to participate (2), unreachable (3), found dementia (3)). A total of 118 patients were included. Of these 117 were prescribed calcium and vitamin D. 88.9% of these took the medication as prescribed. The reasons for the non-compliance were given as: "Forgetfulness, did not want to eat so many pills and side-effects". Bisphosphonate was prescribed in patients (61) when the results of DEXA scan gave a T-score of less than -1. Of these patients 96.6% took the medication on a regular basis. Noncompliance to Bisphosphonate was in all cases due to gastrointestinal side effects.
**Conclusions:** Our results illustrate that it is possible to increase compliance considerably if the nurses at every consultation ask about the prophylactic medications, at least in this group of patients with a very painful disease. Furthermore we think that the friendly atmosphere, in which questions are given and the dialogue about the importance of the medication to avoid side effects of GC such as fractures, is very important. Our results should be confirmed in a randomized clinical trial, to rule out information bias.

## AB1085-HPR AUDIT OF NURSE-LED DGH RHEUMATOLOGY ADVICE LINE

T. Bellerby, D. Stevens, T. Arnold, L. Kerton, G. Ortiz, E. Price, D. Collins, A. Ahmed, S. Carty, L. Williamson. *Rheumatology, Great Western Hospital, Swindon, United Kingdom*

**Background:** We introduced a nurse led Rheumatology Advice Line in 2004 to offer telephone advice to patients with inflammatory arthritis (1). Since then there has been a year-on-year increase in the number and complexity of calls, putting unsustainable demand on service and staff. A service review in April 2014 demonstrated one third of calls were inappropriate, including calls about the Home delivery service, appointment times and general practice related problems. We therefore changed the recorded message with the expectation that the helpline be used for telephone consultations concerning: medication side effects and effectiveness; flares of arthritis; possible complications of biologics and DMARDs; results of blood and X-Ray tests to avoid outpatient appointments. We audited the use of the Advice Line.
**Methods:** We documented the number of calls to the Advice Line from 2004–2014. The recorded message for the Advice Line was altered in May 2014. We

audited the calls in April 2014 and compared with data from calls between May and December 2015. All calls were documented and categorised as: Patient calls leading to clinic appointment; Patient calls with advice give related to medication or inflammatory arthritis; GP or district nurse calls with advice given; Home delivery related; Inappropriate calls (including non rheumatological conditions, appointment time related, in-house calls). We also documented whether letters were generated and made a judgement about whether Consultant or GP consultation had been avoided

**Results:** The total annual number of calls increased from 438 in 2004; 2752 in 2006; 3074 in 2008; 2817 in 2010; 3857 in 2012; 3210 in 2014.

After the recorded message was changed, the number of inappropriate calls fell from 97/311 (31.2%) in April 2014 to 8/258 (3.1%) from April to December 2015. However the number of appropriate calls rose from 131/311 (42.1%) in April 2014 to 194/258 (75.2%). The complexity and time needed to deal with calls has also increased.

| Reason for call | April 2014 | April–December 2015 monthly mean (range) |
|---|---|---|
| Patient call – Appointments generated | 71 | 53 (37–55) |
| Patient call – Advice given | 131 | 182 (125–209) |
| GP/district nurse call – Advice given | 3 | 8 (3–11) |
| Home delivery related | 9 | 7 (2–12) |
| Inappropriate calls | 97 | 8 (4–12) |
| Total number of calls | 311 | 258 (224–282) |
| Number of letters generated | 60 | 59 (41–77) |
| Consultant/GP appointment saved | – | 117 (74–116) |

**Conclusions:** The Rheumatology Nurse Practitioner led Advice Line provides a valuable clinical service as an adjunct to face to face consultation. This audit suggests a saving over 100 face-to-face consultations per month. Changing the Advice Line message led to a fall in the number of inappropriate calls but the number and complexity of calls continues to increase. This will need to be reflected in future service evaluation.

### AB1086-HPR CULTURAL AND QUALITY OF LIFE CONSIDERATIONS WHEN ADMINISTERING CORTICOSTEROIDS AS A THERAPEUTIC STRATEGY FOR AFRICAN AMERICAN WOMEN LIVING WITH SYSTEMIC LUPUS ERYTHEMATOSUS

D. Applyrs[1], E. Williams[2]. [1]*School of Health Sciences, Excelsior College, Albany;* [2]*Public Health Sciences, Medical University of South Carolina, Charleston, United States*

**Background:** African American women with Systemic Lupus Erythematosus (SLE) disproportionately experience poor emotional and physical health, loss of self-esteem and earning potential compared to other women with the disease (Baker K, 2009) (Guillermo P, 2010) (Yuen H K, 2012) (Utset T, 2006). Despite ethic variations among African Americans, differences are rarely considered for SLE quality of life factors and therapeutic strategies such as corticosteroids.

**Objectives:** This study investigated the association among corticosteroids, emotional health, physical health, and work and regular daily activities among a racially- and ethnically-diverse sample of women with SLE (n=224) and controls (n=60).

**Methods:** A secondary analysis of data from the Medical University of South Carolina Lupus Database was conducted. Included in the sample were 57 Caucasian Americans, 141 Gullah African Americans, a subpopulation of African Americans from the Sea Islands of South Carolina and 86 non-Gullah African Americans. Linear regression analyses were performed to assess associations among corticosteroid use, emotional health, physical health and work and regular daily activities. Statistical models were also constructed to assess any moderating effects of ethnicity on emotional health and work and regular daily activities among women with SLE.

**Results:** Emotional health outcomes were better for women with SLE compared with controls. High emotional health scores may be influenced by cultural factors such as masking emotion, disease-coping mechanisms, religion and strong familial and social support. While a significant association was not detected for emotional health and work and regular daily activities, after adjusting for corticosteroid use, a significant association was detected. These findings suggest corticosteroid use does influence the strength of the association between emotional health and work and regular daily activities

**Conclusions:** These study findings highlight the importance of considering the impact of corticosteroids on emotional health among women with SLE. In particular, among African American women who disproportionately experience poor emotional health outcomes. Although this therapeutic strategy improves physical health, the emotional health implications should not be overlooked. Compounded poor emotional health can negatively influence health outcomes for women with SLE. Since SLE is such a debilitating chronic condition, researchers and practitioners must put equal emphasis on improving quality of life and decreasing mortality. However, these improvements in SLE outcomes can only be accomplished if racial and ethnic-sociocultural factors are examined in research and accounted for in the administering of corticosteroids and the development and implementation of interventions

### AB1087-HPR NON-PHARMACOLOGICAL, NON-SURGICAL CARE IN HIP AND KNEE OSTEOARTHRITIS: THE VIEW OF HEALTHCARE PROVIDERS

E.M. Selten[1], J.E. Vriezekolk[1], W.H. van der Laan[2], R.G. van der Meulen-Dilling[3], M.W. Nijhof[4], H.J. Schers[5], R. Geenen[6], C.H. van den Ende[1]. [1]*Department of Rheumatology, Sint Maartenskliniek, Nijmegen;* [2]*Department of Rheumatology, Sint Maartenskliniek, Woerden;* [3]*Physical Therapy and Manual Therapy Velperweg Partnership, Arnhem;* [4]*Department of Orthopedics, Sint Maartenskliniek;* [5]*Department of Primary and Community Care, Radboud University Medical Centre, Nijmegen;* [6]*Department of Psychology, Utrecht University, Utrecht, Netherlands*

**Background:** Non-pharmacological, non-surgical treatment modalities are underused in the management of knee and hip osteoarthritis (OA)[1]. One possible explanation of this suboptimal use could be health care providers' lack of knowledge about non-pharmacological, non-surgical treatment modalities which might act as a barrier for referring patients to these treatment modalities[2].

**Objectives:** The objective of this qualitative study was to identify healthcare providers' view on non-pharmacological, non-surgical care of knee and hip OA.

**Methods:** Semi-structured in-depth interviews with 24 healthcare providers working in the field of OA were held (rheumatologists, orthopaedic surgeons, physiotherapists and GPs). Interviews were transcribed verbatim and analysed using a three-step thematic approach consisting of open, axial and selective coding. Two independent researchers continuously reflected upon, compared, discussed and adjusted the coding.

**Results:** Eight themes were identified: 1) patients' difficulties with weight reduction; 2) dieticians' capabilities in weight reduction management; 3) healthcare providers' responsibilities in weight reduction; 4) the importance of lifestyle advices; 5) (mis)trust in physiotherapy modalities; 6) the endorsement of non-pharmacological, non-surgical treatment to delay surgery; 7) dialogue between disciplines; 8) perceptions of healthcare providers' roles.

**Conclusions:** This study identified multiple factors affecting the suboptimal use of non-pharmacological, non-surgical treatment modalities in knee and hip OA from the perspective of the healthcare provider. The results of this study may be used to improve healthcare providers' knowledge and communication skills regarding weight reduction strategies. To enhance the cooperation between health care providers, opportunities should be created for easy referral to effective weight reduction programmes and to evidence-based physiotherapeutic interventions.

### AB1088-HPR INTENSE EMOTIONS AND MOOD STATES INFLUENCE THE DISEASE ACTIVITY AND QUALITY OF LIFE IN RHEUMATOID ARTHRITIS

G. Udrea[1,2], G. Niculescu[3], C. Stefan[4]. [1]*Internal Medicine and Rheumatology, Dr I Cantacuzino Clinical Hospital;* [2]*University of Medicine and Pharmacy "Carol Davila" Bucharest;* [3]*Romanian Association of Person-Centered Psychotherapy, Bucharest, Romania;* [4]*Psychology, University of New York in Prague, Prague, Czech Republic*

**Background:** Researchers began to unravel the complex interactions between mental and physical health. Some particular feelings (intense emotions) triggered

by a chronic disease as rheumatoid arthritis (RA) can induce different types of mood, such as generalized anxiety or stress with possible implications on disease activity and the quality of life HRQoL.

**Objectives:** The aims of the study were to investigate the associations of the intense positive and negative feelings, level of negative affect with aspects of HRQoL and disease activity in RA patients.

**Methods:** 50 patients with RA who met the 2010 ACR/EULAR classification criteria for RA but without an emotional disorder or mental health diagnosis were enrolled in this study. Disease activity was assessed with DAS 28-CRP, and visual analog scale (VAS) for pain. The study used: the Short Form-36 (SF-36), general questionnaire for assessment HRQoL, Depression, Anxiety and Stress Scale (DASS-21R) to measure the three related negative emotional states of depression, anxiety and stress. Both of them were Romanian validated versions of the original questionnaires[1,2]. Information about positive and negative feelings was collected by open- questions. Pearson correlations were used to verify associations between normally distributed variables, One Way Anova to compare means for different intense feelings and linear regression to identify the predictors for DAS 28-CRP, and components of HRQoL.

**Results:** The response rate was 74%. The study included 89% females, mean age 53.4 ± 13.3 years, mean duration of the disease 10.5 ± 7.1 years, DAS 28-CRP score 4.2 ± 1.1, mean pain score 4.9±2 cm. We found a moderate negative correlation between total DASS-21 scale and mental component score (MCS) of HRQoL (R=-0.428;p=0.007*). Intense feelings in the last month: positive, negative, positive and negative, without feelings are correlate with DAS28 CRP – F (3,35)=5.931, p=0.00. We identified that predictors for DAS 28 CRP are MCS with F(1,37)=13.176, p=0.00 with $R^2$=0.263, and PCS with F(1,37)=16.371, p=0.00 with $R^2$=0.306. The significant predictors for MCS were total DASS-21R score F(1,36)=8.062, p=0.00 with $R^2$=0,183, depression score F(1,37)=4.139, p=0.04 with $R^2$=0,317, anxiety score F(1,36)=6.961, p=0.01 with $R^2$=0,162 and stress score F(1,37)=4.928, p=0.03 with $R^2$=0,118. For PCS the only significant predictor we found was DAS-CRP F(1,37)=16,279, p=0.00 with $R^2$=0,306.

**Conclusions:** The negative affect doesn't impact the disease activity or pain in RA but it influences the mental health component of HRQoL. The experienced intense emotions (feelings) are very important for mental health and also for disease activity in RA and could represent a starting point for further research in orther to avoid bias in clinical trials.

## AB1089-HPR PERCEPTIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS ABOUT PREDICTIVE TESTING FOR TREATMENTS: A QUALITATIVE STUDY

K. Kumar, L. Cordingley, D. Maskell, N. Nair, A. Barton. *Institute of Inflammation and Repair, University of Manchester, Manchester, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is a long term condition that requires early treatment to control symptoms and improve long-term outcomes.[1,2]. Identifying biomarkers predictive of treatment response offers an opportunity to improve clinical decisions about which treatment to recommend in patients[3]. For this, we should take into account patients' perspective of these tests and that requires an understanding of the range of effects that predictive testing can have on RA patients. This study explored the factors that might influence a patients' decision to agree to tests using a qualitative approach.

**Objectives:** To explore the factors that might influence a patients' decision to agree to tests.

**Methods:** A qualitative study was undertaken in which explorative focus groups were conducted with RA patients from Manchester, Birmingham and London, UK. Semi-structured interviews about their perceptions of the use of tests to predict response to treatments were performed. Interviews were audio-recorded, transcribed verbatim and analysed using thematic analysis.[4]

**Results:** Interviews were conducted with 16 patients. [13 female, age ranges: 26–80 years old, disease duration: 3–34 years]. Five interlinking themes influenced how RA patients would make decisions about predictive tests: [1] Perceptions surrounding the use of synovial biopsy and/or blood tests: [2] Perceptions surrounding the use of synovial biopsy vs blood test: [3] Utility of the test to manage expectations: [4] The stages of illness on decision making for predictive testing: [5] Understanding the predictive tests in clinic.

**Conclusions:** Besides supporting clinical decision making, the development of predictive testing in RA is supported by patients. Patients recommended that additional support should be offered to help them cope with results that might not accurately predict response. Developing strategies which communicate risk information about predictive testing effectively while reducing the psychological burden associated with this information is essential.

## AB1090-HPR USE OF THEORY IN SELF-MANAGEMENT INTERVENTIONS FOR EXERCISE AND PHYSICAL ACTIVITY IN ADULTS WITH RHEUMATOID ARTHRITIS

M. Iversen[1], I. Demmelmaier[2]. *[1]Physical Therapy, Movement & Rehabilitation Sciences, Northeastern University, Boston, United States; [2]Dept of Neurobiology, Care Sciences and Society, Karolinska instituet, Huddinge, Sweden*

**Background:** The incorporation of behavioral theories into trials to promote self-management yields positive outcomes. Behavioral theories can inform study design, outcome measure selection and development and influence statistical analyses. However, the persuasiveness of behavioral theory application of exercise/physical activity (PA) trials in rheumatoid arthritis (RA) is limited.

**Objectives:** To identify the use of behavioral theories involving interventions that target exercise and physical activity, determine the most prevalent theories used, and describe how theory was used.

**Methods:** A literature review, searching articles published in English, between 01–01–1980 and 08–12–2015. MEDLINE, Cochrane Central Register of Controlled Trials and CINAHL were searched using the following terms "arthritis, rheumatoid" OR "rheumatoid arthritis" AND exercise [MESH] OR (exercise OR physical activity OR strengthening OR aerobic OR dynamic exercise OR isotonic OR static OR aquatic) AND (theory OR theories OR model OR models) in the title, abstract, or keywords. Inclusion criteria were: (1) published in international academic peer-reviewed journals; (2) evaluated an intervention designed to promote PA behavior; (3) had at least one PA behavior variable as the outcome (4) included adults (≥18 yrs) with RA. Study references and relevant review articles were also checked. Two investigators (ID, MDI) independently selected articles and extracted data using the Theory Coding Scheme (TCS), a standardized 19-item coding tool with good reliability that describes if and how theory informs intervention studies (Michie, 2010). Additional extracted data included: author, publication year, behavioral outcomes (PA and/or exercise), type and duration of intervention, and control group

**Results:** Of 245 articles identified, 45 were duplicates. 200 articles were screened as well as article references. A total of 29 full text articles met inclusion criteria and were reviewed. Of these, 17 were excluded (10 no theory mentioned, 5 were PA studies but were not intervention studies, 1 non-PA intervention and 1 health education evaluation, leaving 12 articles. These 12 studies included 1585 participants, of which 1209 (76%) women. Eleven studies (92%) were randomized controlled trials and 1 was a cohort study. Nine studies (82%) assessed self-management plus exercise and 2 (18%) exercise interventions. Program durations ranged from 5 wks–1 yr. Ten studies (83%) used a single theory. Social Cognitive /Social Learning Theory was the most prevalent theory; 7 studies (58%) linked at least 1 intervention technique to theory, 3 studies (25%) analyzed mediating effects of theoretical constructs, and in 6 studies (50%) results were discussed in relation to the theoretical model.

**Conclusions:** Most theory-based interventions to promote exercise were self-management programs. Social Cognitive/Social Learning Theory was most commonly used in interventions, focusing on self-efficacy, PA/exercise and self-regulation skills. However, only 50% of studies used theory to inform the intervention content and discuss results. We suggest expanding the use of theory throughout the design, evaluation and interpretation of results in intervention studies targeting physical activity in RA.

AB1091-HPR **SEXUAL DISTURBANCES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND IT'S RELATION WITH DISEASE ACTIVITY**

L. Villarreal[1], P. Santos-Moreno[2], G. Ballesteros[2], J. Bello[2], E. Castillo[2], R. Giraldo[2], D. Gomez[2], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Psychology; [2]Rheumatology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Sexuality is an important dimension of personality and human body, therefore any involvement in this area should be considered as important. Sexual disturbances in rheumatoid arthritis (RA) patients are poorly described in literature.
**Objectives:** The aim of this study was to describe sexual disturbances using CIE-10 in population with RA and a possible correlation with disease activity.
**Methods:** A descriptive cross-sectional study was performed in a specialized clinic dedicated to care patients with RA. 1298 patients were included in the study, which were seen by the area of psychology, which information was collected through semi-structured interviews and non-probability sampling. Descriptive epidemiology was applied for continuous variables, using measures of central tendency and dispersion for categorical and qualitative variables by averages and percentages. We used chi2 test to stablish a relationship between disease activity severity and sexual disturbances.
**Results:** Total sample of patients was 1298, 1048 (80%) were women and 250 (19%) were men. Patients had a DAS28 2.6 in average ± 1.1; mean age was 55.1 ± 8.8 years; According to CIE-10 739 patients (57%) had psychological disorders, 279 patients (21%) had sexual and 373 (28%) had sleep disorders. Regarding entire cohort, 338 (26%) of the total of participants reported any sexual disturbances. *Regarding women*, 421 (40%) reported no sexual activity, while 627 (67%) reported sexual activity; from reporters of sexual activity 377 (60%) reported satisfactory sexual activity, while 101 (16%) reported no-satisfactory sexual activity, 49 (7%) reported lack or loss of sexual desire, 86 (13%) reported dyspareunia, and 14 (2.9%) orgasmic dysfunction. *Regarding men*, 77 (30%) of men reported no sexual activity, while 173 (69%) reported sexual activity; of these, 21 (12%) premature ejaculation, 85 (49%) reported satisfactory sexual activity, 23 (13%) reported no-satisfactory sexual activity, 10 (5%) reported lack or loss of sexual desire, 28 (16%) orgasmic dysfunction, 6 (3%) reported dyspareunia. When we analized these results with any factor that could precipitate any sexual disturbance (infidelity, wrong information about sexuality, insecurity in the sexual role, and biological or physical causes) we found that 117 of 338 patients with any sexual disturbance had insecurity in the sexual rol and this relationship was statistically significant ($p<0.00$). The relationship between having a sexual disturbance and disease activity severity was not statistically significant.
**Conclusions:** We found that patients with AR a high percentage reported not having any sexual activity and between patients with sexual activity there are many (one fourth) reporting any sexual disturbances. The level of disease activity has no relationship with having a sexual disturbance, but having any sexual disturbance had relationship with insecurity in the sexual role.

AB1092-HPR **DEVELOPING AN ONLINE SELF-MANAGEMENT PROGRAM FOR RHEUMATOID ARTHRITIS PATIENTS, USING BEHAVIORAL CHANGE TECHNIQUES AND PATIENTS' INPUT**

R. Zuidema[1,2], H. Repping[1,3], R. Nijhuis[1,2], S. van Dulmen[1,4], B. van Gaal[2]. *[1]Radboudumc, Nijmegen, Netherlands; [2]IQ healthcare; [3]Rheumatology; [4]Primary and community care, Radboudumc, Nijmegen, Netherlands*

**Background:** To support individual behavioral change by self-management interventions, behavioral change techniques (BCT) may be helpful to induce behavior change [1]. Conditions for effectivity of BCT's are that they fit to experienced problems in self-management and that the conditions under which they work (parameters) are taken into account. So important steps in the development of self-management programs are 1) identifying the self-management behavioral problems and factors (determinants) affecting these problems in patients, 2) link BCT techniques to these behavioral problems and determinants, 3) identifying parameters of the BCT's and 4) implement BCT techniques into the intervention [2].
**Objectives:** Development of an online self-management program for Rheumatoid Arthritis (RA) patients.
**Methods:** A panel of 5 RA patients and 5 health professionals identified self-management behavioral problems and prioritized them. Determinants of these behavioral problems were identified in literature and confirmed by patients. Two independent researchers coded techniques from a list of BCT's linked to the determinants of the identified problems with the panel and discussed, which led to consensus [3]. Afterwards, parameters of BCT's where identified from literature. Lastly, RA patients' input during a meeting was used to implement the techniques into the intervention.
**Results:** In total 9 behavioral problems related to self-management were mentioned, namely: balancing rest and activity, setting boundaries in daily life, asking for help and supportuse of medicines, communication with health professionals, use of assistive devices, performing physical exercises, coping with worries, and coping with RA. Determinants of these problems were: knowledge, awareness, risk perception, social influence, attitude, self-efficacy, and habits. To change patients' self-management behavior, 15 BCT's were identified, for example persuasive communication, guided practice and self-monitoring. After identifying, the BCT's were linked to the determinants of behavioral problems and parameters where identified.An example of the BCT modeling, linked to a low self-efficacy an parameters, is presented in table 1.

**Table 1. Example of elaboration of a BCT, suited to the target group.**

| Behavioral problem | Behavioral goal | Identified BCT to change behavior | Parameters for the BCT modeling | Patients input to translate the BCT modeling into the program |
|---|---|---|---|---|
| Patients are not able to set their boundaries in daily life, for example in: - work situations - household chores - taking care of (grand)children | Setting boundaries in daily life | Modeling | There need to be similarities between the model and observer | RA patients mentioned the following similarities as important: age, gender, disease duration, and having problems in the same situations (at work, household chores, taking care of (grandchildren) |
| | | | The model must serve as a coping model | Model need to show that he/she has overcome the problems and demonstrate this with the specific techniques that he/she has used. |
| | | | The model must demonstrate successful skills | Model must demonstrate successful skills to learn to set boundaries in work situations, household chores, taking care of (grand)children |

**Conclusions:** Although the BCT taxonomy was helpful as a starting point to induce behavioral change in self-management, firstly the problems related to self-management and their determinants must be clear. Afterwards, the parameters of the BCTs and patients' preferences need to be taken into account when translating these techniques into the self-management program.

## Physiotherapy

AB1093-HPR **INVESTIGATION OF HAND FUNCTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

S. Baglan Yentur[1], Z. Tuna[1], A. Gokkurt[1], O. Mete[1], G. Tore[1], A. Tufan[2], D. Oskay[1]. *[1]Physiotherapy and Rehabilitation; [2]Internal Medicine, Division of Rheumatology, Gazi University, Ankara, Turkey*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune, chronic disease that may start with the involvements of small joints like hand and fingers in many patients. Hand problems can vary considerably from mild arthralgia to severe deformed hands. The most common problems are pain, stiffness, weakness, numbness and difficulty in daily living activities clinically. Inhibition in hand functions effects daily living activities and increases disability level.
**Objectives:** To investigate hand functions and disability level in women with SLE.
**Methods:** 27 women with SLE, 27 women with Rheumatoid Arthritis (RA) and 26 healthy controls were included in this study. Grip and pinch strength was assessed with dynamometer, dexterity was assessed with nine hole peg test (NHPT) and disability level was assessed with Turkish version of Disability Arm Shoulder and Hand Questionnaire (DASH). Differences between these measurements were analyzed.
**Results:** There were significant differences between patients with SLE and healthy controls ($p<0,05$) and also between patients with RA and healthy controls for all measurements. However, there were significant differences only in gross strength for both hands between patients with SLE and RA ($p<0,05$).
**Conclusions:** Hand functions and disability level were significantly different between patients with SLE and healthy controls although these measurements were generally similar between patients with SLE and RA. Hand involvement, disability and disfunction are known for patients with RA in literature. According to our results, hand disfunctions of patients with SLE are as prominent as patients with RA. So, in the treatment of SLE, hand functions should not be ignored and should be included in rehabilitation programme.

## AB1094-HPR DEVELOPMENT OF A PATIENT REPORTED SELF-ASSESSMENT TOOL FOR RHEUMATOLOGY PATIENTS

M. Nisar, A. Dean, R. Laxminarayan, S. Arthanari, H. Nutland, H. Smith. *Dept of Rheumatology, Burton Hospitals NHS Foundation Trust, Burton on Trent, United Kingdom*

**Background:** Clinical outcome measures are required to define patient status and demonstrate the efficacy, quality and safety of clinical care to patients, clinicians and managers. Current assessments of the patient's perspective lack detail and clinical relevance and fail to reflect modern MDT care
**Objectives:** To develop a patient self-assessment tool that is clinically relevant, easy to administer, reproducible, practical and sensitive to change
**Methods:** Through a reiterative process at informal focus groups, patients described the facets of their lives affected by rheumatic illness. The transcripts were themed into 12 domains- communication, relationships, knowledge, anxiety, fatigue, pain, movement, strength, independence, mobility, work and social. These domains were clustered into 3 categories, emotional, physical and functional, each with 4 component statements defining that domain. The patients scored each of the 12 statements on a visual analogue scale (0–10) reflecting the patients' status in that domain at a time point.
Use of the assessment tool was repeated with the patient blinded to original scores, whenever required eg at a time when clinician and/or patient reported a change in disease status or to assess the result of some intervention, physical, therapeutic or both
**Results:** 212 patients have completed the paper based assessment tool each taking a maximum of five minutes on a minimum of two occasions at either physiotherapy clinic or day case attendance.

| Patient Cohort | 212 |
|---|---|
| Inflammatory Arthritis on DMARD | 70 |
| Inflammatory Arthritis on biologics | 31 |
| Osteoarthritis | 86 |
| Osteoporosis | 2 |
| CTD | 17 |
| Soft tissue | 6 |

Patient feedback on clarity of the tool and value was scored and documented on an EXCEL database as were diagnosis, disease status, medication group and work status for analysis and grouping purposes.
"Vertical" aggregated score of whole or part of patient cohort were analysed to:
- Define change in the 12 separate domains and 3 domain clusters.
- Indicate cumulative or disease/medication specific changes in domains with treatment or time.

"Horizontal" scores allowed 360 deg assessments of individual patients at a time point
- Showed changes for individual patients over time, indicative of patient outcome.

**Conclusions:** This self-reported assessment tool is easily understood and completed by patients. It accurately reflects their perception of their rheumatic health status and priorities at that time. When used with detailed history taking and examination, it conveys the impact of arthritis on their life and exposes particular problems to be addressed. It allows the clinician to confirm the findings of their assessment against the patient's perceptions. Joint goals can be established and expectations from planned interventions agreed thus enhancing the patient/clinician partnership.
The assessment can be repeated at any appropriate or agreed time point to gauge progress and response to treatment within the 12 domains individually or as a composite score. This tool provides a valuable and detailed patient perspective to compliment clinical examination and investigation, and inform decision making before treatment change is planned

## AB1095-HPR EVALUATION OF THE STATIC FOOT FUNCTION IN PATIENTS WITH REDUCED MOBILITY IN THE COURSE OF RHEUMATIC DISEASES

A. Kuryliszyn-Moskal[1], K. Kaniewska[2], Z. Dzięcioł-Anikiej[1], P.A. Klimiuk[3]. *[1]Department of Rehabilitation, Medical University Bialystok; [2]Department of Rehabilitation; [3]Department of Rheumatology and Internal Disease, Medical University of Bialystok, Bialystok, Poland*

**Background:** Rheumatic diseases such as osteoarthritis (OA) and rheumatoid arthritis (RA), constitute the most frequent pathological states leading to the development of foot deformities, which reduce the quality of life and cause disability.
**Objectives:** The aim of the present study was to compare the results of plantoconturographic examination, obtained by means of a computer podoscope, in OA and RA patients. Special attention was paid to the differences in the values of each parameter determining the level of foot function.
**Methods:** The study was conducted on 94 female patients divided into two groups according to the type of disease. There were 54 patients with RA and 40 with OA. The control group consisted of 34 healthy women. The plantographic assessment of static foot structure was carried out by means of a device for computer-aided foot examination.
**Results:** A fallen transverse arch of the right foot was statistically much more frequent in the RA patients than in OA patients or the control group. Significant differences in the values of the Wejsflog index were observed between RA patients and the control group. Similarly, there were statistically significant differences in the values of the hallux valgus angle ($\alpha$) for the right foot between RA and OA patients vs. the control group, as well as between OA patients and the control group.
**Conclusions:** Rheumatic diseases predispose patients to the disturbances of static foot function. The obtained results highlight the importance of diagnosing foot statics disorders in the prevention of destructive changes affecting the functioning of OA and RA patients.
**Acknowledgement:** foot function, mobility, plantoconturography, RA patients, OA patients
**Disclosure of Interest:** None declared

## AB1096-HPR USE OF PHYSIOTHERAPY AND EXERCISE PREFERENCES IN PEOPLE WITH ANKYLOSING SPONDYLITIS IN THE NETHERLANDS AND SWITZERLAND

A.-K. Rausch[1], F. van der Giesen[2], K. Niedermann[1], R. Braem[3], T. Vliet Vlieland[2]. *[1]School of Health Professions, Zurich Universtiy of Applied Sciences, Winterthur, Switzerland; [2]Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden University Medical Center, Leiden, Netherlands; [3]Swiss Ankylosing Spondylitis Association, Zurich, Switzerland*

**Background:** Physiotherapy is a cornerstone in the management of ankylosing spondylitis (AS) [1]. Exercise interventions should be based on the available evidence as well as the patients' experiences and expectations.
**Objectives:** To survey the use of individual and group physiotherapy and exercise preferences in people with AS from the Netherlands (NL) and Switzerland (CH).
**Methods:** In NL, the questionnaires were sent by post-mail to 458 patients registered in hospitals in the Leiden area. In CH, an online survey was conducted. The link to the questionnaire was sent to 1742 German speaking members of the Swiss Ankylosing Spondylitis Association.
**Results:** Response rate was 45% (n=206) in NL and 29% in CH (n=507). Dutch and Swiss participants had a similar mean age (56 (SD±15) vs 53 (SD±13) years, but the Dutch sample consisted of less women (31% vs 48%), had a longer mean disease duration (23 [range 1–58] vs 14 [1–66]) and was less healthy according to ASAS health index (6 [1–16] vs 4 [1–16]).
44% and 84% of the Dutch and 28% and 54% of the Swiss have currently or had at least once in the past respectively, individual physiotherapy treatment. The major reason for stopping was "I could do the exercises at home myself" in both countries. 9% and 31% of the Dutch and 30% and 27% of the Swiss are currently, or were in the past respectively, participating in group physiotherapy. The major reasons to stop were "It was too heavy for me" in NL (28%) and "It consumed too much of my time" in CH (7%).
8% and 18% of the Dutch and 20% and 23% of the Swiss have currently or had at least once in the past respectively, participated in hydro-group physiotherapy. Reasons to stop were "I did not experience any positive effects" in NL (28%) and again "It consumed too much of my time" in CH (7%). When asked about preferences regarding exercising without supervision, 40% of the participants in NL and CH wanted "individually designed exercise programmes" and approximately 50% in NL and CH to exercise self-responsible regarding mode, intensity, and frequency.
When asked about their preferred type of supervised exercises, around a quarter of the answers in both countries supported each: "AS specific exercise groups", "fitness centers" and "individual physiotherapy", however the Swiss clearly preferred AS specific exercise groups (47%).
With respect to the supervision and physiotherapists specialized in AS as supervisors (38% NL vs 60% CH).
Their willingness to pay for a supervised group session was 8€ in NL and 25€ in CHF.
**Conclusions:** There are differences in the use of physiotherapy in both countries. But there are also similarities between the Dutch and Swiss AS patients regarding their preferences for exercises, except the financial valuation of group exercise classes. Findings may help to further develop patient-centred services in both countries. Especially, enabling people with AS to perform exercises independently would meet their needs and might enhance their daily physical activity.

## AB1097-HPR A PAIN SCHOOL REHABILITATION PROGRAM FOR PATIENTS WITH CHRONIC WIDESPREAD PAIN – A QUALITATIVE INTERVIEW STUDY

C. Goksör, A. Ericsson, K. Mannerkorpi. *Institute of Neuroscience and Physiology/Physiotherapy, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

**Background:** The prevalence of chronic widespread pain is approximately 10–15% and it is a common problem in primary health care. Being female and older is associated with higher prevalence. Chronic pain is generally associated with low activity level, low work capability, and negative health consequences. Studies of education and exercise have shown effective results for patients with chronic pain. This pain school rehabilitation program "Knowledge for life" has been developed by professionals together with the Swedish Rheumatoid Association for use in primary health care, but is not previously evaluated.
**Objectives:** To evaluate the experience of participation in the pain school rehabilitation program Knowledge for life in patients with chronic widespread pain
**Methods:** 12 women (age 25–72 years) with chronic widespread pain were included in this qualitative interview study set in primary health care. Semi-structured interviews were held 10 weeks after participating in four weekly group sessions. Interviews were performed by two authors and transcribed verbatim. Data was analyzed through content analysis according to Graneheim and Lundman (1). Analyzes were performed by the first author, but was controlled by co-authors for agreement. Results are presented through themes and categories. Informed consent were signed by all participants.
**Results:** The preliminary results are based on four interviews. The analysis resulted in five themes, which are *the meaning of the group, positive experience of movement, change of relationship to self, change of relationship to pain, and external circumstances of change. The meaning of the group* reflects upon the shared experiences and a sense of belonging deriving from the group discussions. *Positive experience of movement* describes the participants' experiences of physical activity and exercise related to their body, group activities and change of habit and attitude towards movement in general. The participants described a *change of relationship to self* and *change of relationship to pain* related to increased knowledge, acceptance, and active strategies. *External circumstances to change* was also identified describing the leader and setting to be important factors in stimulating change.
**Conclusions:** Participation in a pain school rehabilitation program contributed to increased knowledge and awareness about pain and about the self for the patients with chronic widespread pain in the present study. They also reported positive experiences of group sessions and of physical activity and exercise. The program provides a structure of rehabilitation for patients with chronic widespread pain.

## AB1098-HPR COMPARISON BETWEEN KINESIOTAPING AND COLD THERAPY ON MUSCLE STRENGTH FUNCTIONAL PERFORMANCE OUTCOMES AFTER TOTAL KNEE ARTHROPLASTY: PRELIMINARY RESULTS OF A RANDOMIZED CONTROLLED TRIAL

E. Yuksel[1], B. Unver[1], V. Karatosun[2]. *[1]Physical Therapy and Rehabilitation; [2]Dokuz Eylul University, izmir, Turkey*

**Background:** Total knee arthroplasty (TKA) are increasing steadily each year. Ninety percent of patients reported reduced pain, improved functional ability, and greater health related quality of life after TKA. Kinesiotaping (KT), a type of elastic tape that is being increasingly used for the management of pain and oedema after surgery (1). Cold therapy (CT) can also help relieve pain and swelling during early postoperative period (2). These two application may have impact on functional performance outcomes in patients with TKA. The number of studies that include KT in the rehabilitation process is increasing, but there isn't any study that compare KT application and CT after TKA.
**Objectives:** To compare the effectiveness of kinesiotaping and cold therapy on muscle strength and functional performance outcomes in patients with TKA during early postoperative period.
**Methods:** Fifteen patents with TKA randomly assigned to control, KT and CT groups (nC=nKT=nCT=5). KT group received KT for lymphatic correction and rectus femoris facilitation technique. CT group received CT immediately after operation and following postoperative days. After surgery, all patients received standard post-operative treatment. After operation, pain intensity, active range of motion and knee function score [Hospital for Special Surgery (HSS) score] and walking speed was evaluated using the Iowa Ambulation Velocity Scale. Isometric muscle strength measure of quadriceps femoris and hamstring muscles assessed by Hand-Held Dynamometer. All measurements evaluated at the discharge. One way *ANOVA* was used in statistical analysis.
**Results:** There was a significant group interaction in pain scores and active range of motion of knee (p=0.005). Following up this interaction, the KT group and CT group have lower pain score at discharge in comparison with control group (p=0.019). The KT group and CT group have higher range of motion of knee flexion at discharge (p=0.017). However, there was no significant differences between KT group and CT group ($p>0.05$). There was also significant group interaction in functional performance outcomes (p=0.033). KT group and CT group have better HSS score (p=0.010) and walking speed (p=0.013), but KT group and CT group *have no superiority* over each other in terms of functional performance outcomes ($p>0.05$). There was no significant in quadriceps femoris (QF) and hamstring muscles in groups.
**Conclusions:** Our preliminary results suggest that KT and CT reduce postoperative pain in patients with TKA in inpatient period. KT group and CT group have better knee functional score. Possible mechanisms of better functional performance in KT and CT group could be due to lower pain score. Functional activities may have limited by high level of pain after surgery. Both KT and CT are cost-effective to achieve sufficient pain relief following TKA. Sufficient pain relief may influence functional performance. However, both KT and CT have no impact on muscles strength. In conclusion, KT and CT can be used with standard post-operative treatment in patients with TKA, and they have no *s*uperiority over each other. However, future study on a larger sample of subjects is needed to attain more clear results.

## AB1099-HPR COMPARISON OF THE EFFECT OF DAILY LIVING ACTIVITIES AND DEPRESSION ON QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS

G. Arin[1], P. Kisacik[1], A. Akdogan[2], L. Kilic[3], U. Berberoglu[1], E. Karabulut[4], O. Dogan[1], E. Unal[1]. *[1]Hacettepe University Faculty of Health Science; [2]Hacettepe University Faculty of Medicine; [3]3Yenimahalle Research Hospital; [4]Hacettepe University Biostatistics Department, Ankara, Turkey*

**Background:** Increasing activity and improving function are valuable parameters to prevent disability (1,2). The relationship between the functional impairment in depression and the activities of daily living was well known in terms of the quality of life in chronic diseases (3). However, studies comparing these effects on various rheumatic diseases were not sufficient.
**Objectives:** This study was conducted to compare the effects of depression and activities of daily living on quality of life for the patients with two different rheumatic diseases (Ankylosing Spondylitis (AS) and Rheumatoid Arthritis (RA)).
**Methods:** 265 patients with AS and 111 patients with RA were included in the study. The demographic data were collected for two groups. Mean age of the study group was 39.88±13.33. All patients were evaluated with disease-specific questionnaires according to their diseases. The patients with AS were asked to fill the Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) for quality of life, and the Rheumatoid Arthritis Quality of Life Questionnaire (RAQoL) were used for RA patients. Beck Depression Index (BDI) was used to assess depression levels of the subjects, and Health Assessment Questionnaire (HAQ) to assess activities of daily living in both groups.
**Results:** A mild and positive correlation was found between HAQ ($p<0.001$, r=0,564), BDI ($p<0.001$, r=0.477) and RAQoL scores. Similarly, a mild and positive correlation was found between HAQ ($p<0.001$, r=0.513), BDI ($p<0.001$, r=0.443) and ASQoL scores. In all patients, there was a fair-mild positive correlation between HAQ and BDI scores ($p<0.001$, r=0.350) (Table 1).

Table 1. Correlation between all variables

| | BDI | ASQoL | RAQoL |
|---|---|---|---|
| HAQ | r=0,350 | r=0,513 | r=0,564 |
| | $p<0.001$ | $p<0.001$ | $p<0.001$ |
| BDI | | r=0,443 | r=0,477 |
| | | $p<0.001$ | $p<0.001$ |

**Conclusions:** It is concluded that the depression level and the activities of daily living has similar effects on the quality of life for RA and AS patients. Also depression should be taken into consideration in both rheumatic diseases.

## AB1100-HPR EFFECT OF RESISTANCE TRAINING IN WOMEN WITH JOINT HYPERMOBILITY – PRELIMINARY RESULTS OF A RANDOMISED CONTROLLED TRIAL

G. Luder[1,2], C. Mueller Mebes[1], M.L. Verra[1], D. Aeberli[3], J.-P. Baeyens[2]. *[1]Department of Physiotherapy, Inselspital, Bern University Hospital, Bern, Switzerland; [2]Physical education and physiotherapy, Vrije Universiteit Brussel, Brussel, Belgium; [3]Department of Rheumatology, Clinical Immunology and Allergology, Inselspital, Bern University Hospital, Bern, Switzerland*

**Background:** Little is known about the clinical management of persons with generalized joint hypermobility (GJH). Affected persons are often restricted in performing sports or leisure activities, as well as during work, due to pain and disability (1). Adequate muscle strength for movement control might be an important issue to overcome these restrictions. Resistance training has the possibility to improve muscle strength (2), but so far no study investigated how resistance training influences strength and muscle size in women with GJH.
**Objectives:** To evaluate the effects of a 12-week resistance training program on muscle properties of women with GJH.
**Methods:** This pragmatic randomised controlled trial included 51 hypermobile women (mean age 26.5, sd 4.5 years) with a Beighton-score of six or more (3). 27 women performed for 12 weeks a guided resistance training twice weekly and 24 women did not exercise. Before and after the 12 weeks maximum isometric strength of knee extensors and flexors was measured, which was the primary outcome. Additionally muscle cross-sectional-area (mCSA) of the thigh was measured at 33% above the knee, using peripheral quantitative computer tomography (pQCT). Data were analysed on an intention-to-treat basis. Differences between groups were tested with independent t-test at a significance level of p=0.05.
**Results:** The groups were comparable at baseline. Change of maximum strength of knee extensors in the training group was 6.3 N (sd 57.7, CI -16.5 to 29) and in the control group 8.3 N (sd 42.1, CI -9.4 to 26.1), with no significant difference between groups. Similar results were seen for knee flexors: change in training group was 8.0 N (sd 59.8, CI -15.6 to 31.7) and in control group 16.1 N (sd 42.8, CI -2.0 to 34.2). Muscle CSA of the thigh in the training group showed a significant increase (194 $mm^2$, CI 78 to 310 $mm^2$), compared to the control group (46 $mm^2$, CI -25 to 118 $mm^2$; p=0.031). Muscle mass at the thigh significantly increased 19.1 mg (sd 27.3, CI 8.3 to 29.9) in the training group, compared to the control group with 4.3 mg (sd 14.4, CI -1.8 to 10.33) mean change. Muscle density, however, showed no change in both groups.
**Conclusions:** The 12-week resistance training did not change isometric knee muscle strength, but led to a significant increase of mCSA of the thigh in women with GJH. However, this difference was only 2.4% and thus may not be clinically significant. In strength testing possibly no change was seen because the dynamic training could not be transformed to the isometric test condition and the intensity of the training might not have been high enough. The detailed analysis of the training protocols will provide further details concerning this issue. However, the small increase in muscle area may indicate that strength training is a possible option for these hypermobile women. Further analysis of the additional measurements in this trial, may give more insight into changes in pain or disability. Further research should investigate if the muscle increase could be optimized by a more intense or better supervised training.

## AB1101-HPR QUALITY OF LIFE IN PATIENT WITH ESTABLISHED RHEUMATOID ARTHRITIS: A QUALITATIVE STUDY

K. Malm[1,2,3], A. Bremander[1,3,4], M.L.E. Andersson[1,3], S. Bergman[1,3,5,6], I. Larsson[1,5]. *[1]Spenshult Research and Development Center; [2]Rheumatology, Capio Movement, Halmstad; [3]Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund; [4]School of Business, Engineering and Science; [5]School of Health and Welfare, Halmstad University, Halmstad; [6]Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, Gothenburg, Sweden*

**Background:** Fatigue, pain, stiffness and impaired physical function are some of the most pronounced symptoms in rheumatoid arthritis (RA) that may affect quality of life. Quality of life is an individual experience composed of a wide range of factors, including physical health, psychological state, level of independence, social relationships, and the patients' relationship to salient features of their environment. There is a need to describe and assess quality of life in chronic diseases like established RA. Previous research has mainly focused on disease-specific instruments for assessing quality of life. A deeper understanding of patients' experience of quality of life in established RA is important in both clinical research and daily clinical practice.
**Objectives:** To describe variations in patients' experiences of quality of life in established RA
**Methods:** The study had a qualitative design with a phenomenographic approach, including 22 interviews with patients from the Swedish BARFOT (Better Anti-Rheumatic FarmacoTherapy) cohort, BARFOT, a long time follow up study of early RA. Patients were strategically selected by gender (14 women and 8 men), age (30 to 84 years old), disease duration (8–23 years), function as measured by HAQ (0–1.38), and quality of life as measured by EQ5D (0.52–1.00). The interviews were recorded, transcribed verbatim and coded into categories.
**Results:** Four categories emerged from the patients' experiences of quality of life in established RA: well-being, freedom, empowerment, and participation. Quality of life as well-being meant pleasure and being physical active. Quality of life as freedom meant dependence or independence in the ability to manage daily life activities. Quality of life as empowerment meant different coping strategies, such as positive thinking and resources to manage fatigue, pain and physical function. Quality of life as participation meant togetherness in different contexts with other people.
**Conclusions:** Quality of life in established RA could be understood by the patients in different ways. The patients experienced quality of life as well-being, freedom, empowerment, and participation. This is important knowledge when evaluating the concept of quality of life in RA research, and for health professionals when promoting quality of life in patients with RA.

## AB1102-HPR "IF A JOINT IS HOT IT'S NOT THE TIME": HEALTH PROFESSIONALS' VIEWS ON DEVELOPING PHYSICAL ACTIVITY INTERVENTIONS FOR PEOPLE WHO HAVE RHEUMATOID ARTHRITIS

L. Larkin[1], S. Gallagher[2], A. Fraser[3], N. Kennedy[1]. *[1]Department of Clinical Therapies; [2]Department of Psychology, University of Limerick; [3]Department of Rheumatology, University Hospitals Limerick, Limerick, Ireland*

**Background:** Although numerous physical activity interventions exist for people who have RA sustaining physical activity levels after an intervention is completed has been challenging. Involving key stakeholders is important when designing complex interventions which target behaviour change [1]. Health professionals (HPs) working in rheumatology can provide unique views on the design of interventions and can highlight potential challenges/facilitators to a proposed intervention for people who have RA [2–3].
**Objectives:** This study aimed to explore the views of HPs on physical activity in people who have RA, and the design of a behaviour change intervention to promote physical activity participation amongst people who have RA.
**Methods:** We used a qualitative methodology and constructivist approach. Interviews were conducted by phone, with the use of an interview guide. Interviews were transcribed and analysed using thematic analysis. The interview transcripts were read, notes made and ideas formulated to facilitate coding. The research team searched for patterns, analysed and coded the data, and generated sub-themes and themes. Themes were reviewed by the research team to check if the themes worked in relation to the coded extracts and the entire data set.
**Results:** 14 interviews were conducted (rheumatologists n=7, physiotherapists n=4 and clinical nurse specialists n=3). Mean clinical practice experience was 15 years (range 3–34 years, SD ±8.76 years). Three key themes were generated: "*Personal opinions", "Supporting physical activity*" and *'An ideal world'*. Although HPs viewed physical activity as important, recommending it was largely based on a persons' disease status rather than empirical evidence. There was also a strong feeling that physical activity should reduce during a disease flare-up. Supporting physical activity in clinical practice was discussed as being through the provision of information, goal setting and behaviour monitoring. Having contact with a HP was also thought to support physical activity. The "ideal world" was discussed with resources being highlighted as a key challenge to interventions in clinical practice, e.g. lack of time, staff numbers. Some participants felt that a group setting was most feasible in clinical practice whilst others preferred a 1:1.
**Conclusions:** HPs believe physical activity is important for people who have RA, although there is uncertainty regarding physical activity recommendations for this population. Thus there is scope to increase HPs' knowledge of recent evidence. Views varied on how an intervention to promote physical activity should be delivered but consideration of barriers to delivery in clinical practice is important.

AB1103-HPR **RELATIONSHIP BETWEEN PHYSICAL AND MENTAL STATUS AND KINESIOPHOBIA IN PATIENTS WITH ARTHROPLASTY DURING INPATIENTS PERIOD**

S. Cekmece[1], R.H. Baris[1], B. Unver[1], V. Karatosun[2]. *[1]School of Physical Therapy and Rehabilitation; [2]Department of Orthopedics, Faculty of Medicine, Dokuz Eylül University, Izmir, Turkey*

**Background:** Kinesiophobia is simply defined as a fear of movement and physical activity.It can be seen in patients as a result of any injury, which results in pain or a fear of injury recurrence. It leads to decreased motion and disuse that may result in a chronic pain syndrome and decreased physical function. Especially arthroplasty patients who suffer from osteoarthritis before the operation, physical and mental state of the patients affected due to pain and bigger incision areas (1). This situation can cause kinesiophobia, mental problems and a lower quality of life.
**Objectives:** The purpose of this study was to investigate the relationship between kinesiophobia, mental condition and quality of life in patients undergoing arthroplasty.
**Methods:** One hundred ninety one arthroplasty patients [76 total knee arthroplasty (TKA) and 115 total hip arthroplasty (THA)] were included in the study. Quality of life was evaluated with the *12-Item Short Form Health Survey* (SF-12) and European Quality of Life-5 Dimensions (EQ-5D), kinesiophobia was evaluated with the TAMPA Scale and anxiety-depression were evaluated with the Hospital Anxiety and Depression Scale (HADS) preoperatively and at discharge. The patients' daily health condition were evaluated with EQ-5D Visual Analogue Scale (EQ-5DVAS). All five components of EQ-5D (mobility, self-care, usual activities, pain and anxiety/depression), EQ-5DVAS and two components of SF-12 [physical component (PCS-12) and mental component (MCS-12], HADS, TAMPA Scale were used in the statistical analysis. Bivariate correlation and coefficient pearson were used in the analysis ($p<0.05$).
**Results:** Both gender and age parameters showed similarity between patients with THA and patients with TKA. There was a correlation between TAMPA and both pre-operative scores [TAMPA/SF-12 Total (r=0.204), TAMPA/EQ5D Total (r=0.226), TAMPA/HADS Anxiety (r=0.243), TAMPA/ HADS Depression (r=0.320)] and discharge scores [TAMPA/SF-12 Mental component (r=0.227), TAMPA/SF-12 Physical component (r=0.150), TAMPA/SF-12 Total (r=0.256), TAMPA/EQ5D Mobility (r=0.221), TAMPA/EQ5D Self-Care (r=0.129), TAMPA/EQ5D Usual Activities (r=0.143), TAMPA/EQ5D Pain/Discomfort (r=0.247), TAMPA/EQ5D Anxiety/Depression (r=0.268), TAMPA/HADS Anxiety (r=0.341), TAMPA/ HADS Depression (r=0.313)].
**Conclusions:** According to the results of this study, SF-12, EQ5-D and HADS have been found to correlate with TAMPA. This situation shows that the deterioration in quality of life is related to anxiety-depression and kinesiophobia. The reason of having a low score on TAMPA scale could be associated with high pain level. This high pain level limits the daily living activities such as walking. Daily living activity limitation in patients with THA and TKA due to pain, kinesiophobia could lead to more depression. Researchers considering this relationship might be beneficial to improve outcomes of the treatment.

AB1104-HPR **ENGAGEMENT WITH PEOPLE WHO HAVE INFLAMMATORY ARTHRITIS, ON THEIR SLEEP QUALITY, SLEEP DISTURBANCES AND PHYSICAL ACTIVITY: A SURVEY OF IRISH HEALTH PROFESSIONALS IN RHEUMATOLOGY**

S.G. McKenna, N. Kennedy. *Clinical Therapies, University of Limerick, Limerick, Ireland*

**Background:** Sleep disturbance is common in people who have inflammatory arthritis and can contribute to disability, symptomatology, and increased healthcare use. Poor sleep quality and disturbances may exacerbate pain in this disease, which may further lead to reduced levels of physical activity. Little is known regarding the current practice of Health Professionals in Rheumatology on their engagement with patients in discussing their sleep quality and disturbances therefore, it is important to investigate if there are any educational needs in this important area of practice.
**Objectives:** To investigate the awareness of Irish Health Professionals in Rheumatology on their patients' engagement when discussing sleep quality, sleep disturbances and physical activity, among Irish people who have Inflammatory Arthritis.
**Methods:** Members from the Irish Rheumatology Health Professionals Society (IRHPS) (n=43) were invited to participate in a cross-sectional survey hosted on SurveyMonkey$^{(R)TM}$. Ethics approval was received through the University of Limerick. Descriptive statistics, Chi-square tests/Fisher's exact tests were used to analyse the data using SPSS v22.
**Results:** Twenty eight (65%) Health Professional's responded. Results found the mean number of years qualified to be 16.93 (SD 6.82), mean number of years working in Rheumatology to be 10.07 (SD 4.04) and 40% of respondents reporting half of their patient workload coming from people who have inflammatory arthritis. Just 52% discuss sleep with their patients with 46% mentioning fatigue as their main reason when enquiring. Of those who do discuss sleep, 100% of their patients mentioned "pain" and "waking up in the middle of the night or early morning" as disturbances when discussing their sleep, while 67% reported "taken prescribed or over the counter medication" to help with their sleep. There was no statistically significant association between longer years qualified, more years working with people with inflammatory arthritis or health profession, when discussing sleep. When using the SQUASH questionnaire, Health Professional's physical activity levels were 2,248 minutes per week, which exceeds the American College of Sports Medicine (ACSM) physical activity guidelines however, is low compared to other physical activity Health Professional surveys from European countries.
**Conclusions:** Only half of Irish Health Professional's discuss sleep with their patients, with fatigue as the main reason when enquiring. Health Professional's meet the physical activity guidelines however, are less active than their European peers. There is a need to develop education and training for physiotherapists in the importance of enquiring about their patients sleep quality and disturbances and the potential impact it has on their physical activity levels. In addition, the effects of physical activity interventions on poor sleep quality and disturbances needs to be examined so that Health Professional's are in a better position to promote health and well-being in people with Inflammatory Arthritis, in this important area of practice.

AB1105-HPR **EVALUATING OF RHEUMATOLOGIC PATIENTS' VIEWS ON PHYSIOTHERAPY AND REHABILITATION PROGRAMS: A PILOT STUDY**

S. Karaca, Ö. Ipek, B. Bayar, K. Bayar. *Physiotherapy and Rehabilitation, Mugla Sıtkı Kocman University, Health Sciences Faculty, Muğla, Turkey*

**Background:** Rheumatologic diseases are one the state that causes loss of function, despite the use of very effective conservative and surgical approaches in treatment in recent years (1). In physiotherapy and rehabilitation of rheumatologic diseases, protecting the patients' functional status for the prevention of disability improves the quality of life of patients (2). Therefore, it is very important that practice of physiotherapy and rehabilitation starts and implements with medical treatment as early as possible (1,2).
**Objectives:** The aim of this study was to assess rheumatologic patients' knowledge, expectation and satisfaction about physiotherapy and rehabilitation programs.
**Methods:** In this study, 36 rheumatologic patients participated voluntarily who attended physiotherapy and rehabilitation programs in various health centers. The data on age, gender, economic status, diagnosis, habits of the participating individuals were recorded by researchers. For assessing the patients' views on physiotherapy and rehabilitation program, a questionarre was prepared by researchers which investigated patients' level of knowledge about their diseases, physiotherapists' duties, the aims of the applied treatment modalities. Also, the questionarre included the questions which examined patients' expectations, complaints and level of satisfaction for physiotherapy and rehabilitation program, changes in health quality and daily life after rehabilitation. The questionnaire was administered face to face to the volunteers.
**Results:** Of the 36 patients included, 20 (55.5%) were female and 16 (44.5%) were men. The mean age of individuals was 47.58 ± 11:23. 60% of rheumatologic patients expressed that physiotherapists did not define the therapists' duties and rehabilitation programme. 72% of rheumatologic patients expressed that physiotherapists did not explain the purpose of the treatment modalities. 46% of rheumatologic patients expressed that they did not know the importance of rehabilitation. A significant positive correlation was found between increasing of physiotherapists' explanations which were related to rehabilitation program and patients' satisfaction ($p<0.05$). It was determined that patients who graduated from university were more conscious about their diseases and attended therapy sessions more regularly. 78% of patients who began to work with physiotherapist in acute period stated that rehabilitation programme facilitated their daily life. 23% of patients who began to work with physiotherapist in chronic period stated that rehabilitation programme facilitated their daily life. A significant positive correlation was found between starting home exercise programme in acute period and reduction of patients' complaints ($p<0.05$). The common proposal of rheumatologic patients to physical therapists was that introducing and explaining of rehabilitation programme in all respects.
**Conclusions:** This study indicates that when rheumatologic patients start to work with physiotherapists in acute period and physiotherapists inform their patients about therapy in every respects, improvements of patients increase in daily life.

## AB1106-HPR ALTERATION IN BODY POSTURE IS RELATED TO DECREASED FLEXIBILITY IN ADOLESCENTS WITH A HISTORY OF LOW BACK PAIN: A PILOT STUDY

S. Özyürek[1], A. Genç[1], H.K. Karaali[2], C. Algun[3]. *[1]School of Physical Therapy and Rehabilitation, Dokuz Eylül University, Izmir; [2]School of Health, Department of Physiotherapy and Rehabilitation, Celal Bayar University, Manisa; [3]Faculty of Health Sciences, Department of Physical Therapy and Rehabilitation, Medipol University, Istanbul, Turkey*

**Background:** Low back pain (LBP) is a significant public health problem among adolescent population. Postural alterations and decreased flexibility have been considered as possible risk factors for adolescent LBP. Thus, examination of posture and muscle flexibility is essential for determining any potential contributing factors (1–3). However, studies addressing the relationship between posture and flexibility in the adolescents with a history of LBP are limited.
**Objectives:** To examine whether the alteration in three-dimensional (3D) body posture is related to flexibility in adolescents with a history of LBP.
**Methods:** Fourteen adolescent students (9 female, 5 male, median age 14 years) participated in this study. For 3D evaluation of posture, internet-based postural assessment system was used. Thirteen reflective markers were placed on anatomical landmarks of subjects. Three digital photographs were obtained in upright stance (antero-posterior, left-right lateral) and were analyzed through the system. Postural displacements of head, rib cage, and pelvis were calculated as rotations in degrees and translations in millimeters. Alteration in body posture (head, rib cage, and pelvis) was evaluated using posture index which is total postural displacements score. In this system, total score is 96 points. The higher posture index score indicates more severely displaced posture. Flexibility was measured by a sit-and-reach test. Spearman's rank correlation coefficient (rho) was used to evaluate the association between the measured parameters. The significance level was set at $p<0.05$.
**Results:** As a result, 14.3% (n=2) of the adolescents had slight, 71.4% (n=10) had significant and 14.3% (n=2) had a moderate displacement in their posture according to posture index score. Participants had a median sit-and-reach score of 21 cm and a median posture index score of 17 points. Strong negative correlation was observed between posture index score and sit-and-reach test (rho=-0.610, p=0.020).

Table of Grades for Posture Index™

| Region | | | | | | Total Per Region |
|---|---|---|---|---|---|---|
| Head | 0 | 0 | 0 | 0 | 6 | 6 |
| Ribcage | 0 | 0 | 1 | 0 | 2 | 3 |
| Pelvis | 4 | 0 | N/A | 0 | 2 | 6 |
| Totals | 4 | 0 | 1 | 0 | 10 | 15 |
| Total Posture Index™ | P.I. = 15 , SIGNIFICANTLY DISPLACED | | | | | |

**Conclusions:** In conclusion, this pilot study suggests that alteration in body posture may be related to decreased flexibility in adolescents with a history of low back pain. Future studies should attempt to determine postural changes, flexibility evaluations and associations between these parameters more extensively.

## AB1107-HPR LONG TERM EXERCISE TRAINING IMPROVES THE TOTAL HIP ARTHROPLASTYPATIENTS' ABILITY TO FORGET THEIR ARTIFICIAL JOINT

S. Onal[1], H. Guney[1], G.I. Kinikli[1], C. Sarial[1], B. Atilla[2], I. Yuksel[3]. *[1]Physiotherapy and Rehabilitation Department, Hacettepe University, Faculty of Health Sciences; [2]Department of Orthopedics and Traumatology; [3]Physiotherapy and Rehabilitation Department, Hacettepe University, Faculty of Medicine, Ankara, Turkey*

**Background:** Total Hip Arthroplasty (THA) is among the most widely performed procedures in orthopedic practice and outcome studies consistently showed an overall satisfaction by both patients and physicians.The purpose of this study was to determine effect of exercise duration on the ability to forget the artificial joint, in hip osteoarthritis patients who underwent THA.
**Objectives:** Forty-two patients (female=26, male=16) who underwent unilateral THA were included in the study. Patients were divided into two groups either to do exercise for less than 6 months (Group I; short term exercise, n=24) or over 6 months (Group II; long term exercise, n=18). Mean age was 53.9± 15.1 years, mean Body Mass Index (BMI) was 27.2 ± 5.2 kg/m$^2$ in Group I and mean age was 57.5 ± 13.3 years, mean BMI was 27.2 ± 5.2 kg/m$^2$in Group II, respectively.
**Methods:** Forgotten Joint Score (FJS) was applied to detect the patients' ability to forget the artificial hip joint after THA surgery. Western Ontario and McMaster Osteoarthritis Index (WOMAC) pain, stiffness and activity of daily living (ADL) questionnaire were used to determine the functional status. Intensity of pain was measured with visual analog scale (VAS). Statistical analysis of the data was performed with Mann Whitney-U test.
**Results:** There were no differences in WOMAC stiffness scores (p=0.146) between groups. WOMAC pain scores (p=0.003), WOMAC ADL scores (p=0.019), VAS scores (p=0.000) were better in Group II. FJS scores (p=0.005) were in favor with Group II which the patients who were exercising more than 6 months.

| Variables | Group I (short term exe) Mean ±SD | Group II (long term exer) Mean± SD | p |
|---|---|---|---|
| Pain | 1 ± 1 | 3.2 ± 1.8 | p=0.000 |
| FJS | 53.2 ± 12.1 | 69.6 ± 22.2 | p= 0.005 |
| WOMAC pain | 3 ± 3.3 | 6.6 ± 3.9 | p=0.003 |
| WOMAC stiff | 1.3 ± 1.8 | 2.1 ± 1.8 | p=0.146 |
| WOMAC adl | 11.6 ± 8 | 19.7 ± 12 | p= 0.019 |

**Conclusions:** Exercise training over 6 months improves the THA patients' ability to forget their artificial joint.

## AB1108-HPR AQUATIC EXERCISE FOR WOMEN WITH PERSISTENT KNEE PAIN. A PILOT RANDOMISED CONTROLLED TRIAL

S. Mcilroy[1,2], L. Bearne[3], P. Browning[2]. *[1]Physiotherapy, King's College Hospital, London; [2]University of Hertfordshire, Hertfordshire; [3]Academic Department of Physiotherapy, Kings College London, London, United Kingdom*

**Background:** Persistent Knee Pain (PKP) is a common cause of disability in Europe[1]. Therapeutic exercise, education and weight loss are central to the management of PKP[2]. Aquatic therapy (AT), (therapeutic exercise in water) is recommended but the optimal effective dosage is unknown.
**Objectives:** To investigate the acceptability and efficacy of six sessions of AT and self-management advice compared to self-management advice only on self-reported pain, function and general health in adults with PKP.
**Methods:** This two arm, single blinded, pilot, randomised controlled trial received ethical approval from the Joint UCL/UCLH Research Ethics Committee (08/H0715). A convenience sample of adults ≥50 years old with self reported knee pain of >12 weeks were recruited from an inner city physiotherapy department. They were randomly assigned to receive either 6 weekly sessions of group AT consisting of 30–40 minutes strengthening, stretching and balance exercises facilitated by a physiotherapist or a comparison group. All participants attended a single session of self-management advice and prescribed home exercises by a physiotherapist. Process outcomes: number of people willing to enter the study and adverse events were recorded by the researcher, attendance at AT sessions was recorded by treating physiotherapists. Clinical outcomes: Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Pain visual analogue scale (0 -10cm VAS), SF12 and six minute walk distance (6MWD) were assessed at baseline and 6 weeks by a researcher blind to participant group allocation.
Process outcomes were evaluated using descriptive statistics. Clinical data were

analysed on an intention to treat basis and between group differences in mean change were investigated using Analysis of Covariance adjusted for baseline differences. Significance was accepted at $P<0.05$ level.
**Results:** 34 eligible patients were invited to participate in the study. 14 (41%) women (mean age 63 (7.46) years) were enrolled into the trial and 13 (93%) people completed the 6 week assessment. Compliance was 98% in the AT group. No adverse effects were reported. All clinical outcomes improved in the AT group in pre-post scores (mean change (95% CI)): WOMAC -17.7 (3.9, 31.6), VAS -3.4 (-.2, 7.0) SF12-Physical 4.3 (-16.2, 7.5), SF12-Mental 8.2 (-16.7, 0.4), 6WMD 48.6m (-102.3, 5.2) but not the comparison group: WOMAC 2.6 (-11.4, 6.3), VAS 0.5 (-1.5, 0.5), SF12-Physical 0.009 (-3.8, 3.7) and SF12-Mental 1.2 (-6.0, 3.7), 6MWD 22.9m (-62.6, 16.6). There were between group differences in change in WOMAC over 6 weeks (20.3 (-33.9, -1.0) p=0.039), the WOMAC pain subscale (5.4 (-8.6, -0.8) p=0.022) and SF12 mental subscale (6.982 (0.4, 13.2) p=0.04), but not other outcomes, favouring the AT group.
**Conclusions:** Whilst our study had a good recruitment rate, only women agreed to participate. Attendance at AT was high and no adverse events were reported. This study suggests that 6 sessions of AT improves PKP and function but not walking distance compared to self management only in women. Understanding the reasons why men did not wish to participate in the study warrants further investigation.

### AB1109-HPR COMPARISON OF JOINT POSITION SENSE AT END RANGE AND MID RANGE IN FROZEN SHOULDER

T. Zoroglu[1], S. Basar[2]. [1]*Vocational School of Health Services, Karabuk University, Karabuk;* [2]*Physiotherapy and Rehabilitation, Gazi University, Ankara, Turkey*

**Background:** Frozen shoulder (FS) is characterized by a painful, gradual loss of both active and passive glenohumeral motion resulting from progressive fibrosis and contracture of the glenohumeral joint capsule. Deformation of capsuloligamentous tissue is believed to stimulate mechanoreceptors in the tissue and provide the central nervous system with proprioceptive information. It was shown by studies that joint position sense acquity is good near the end of motion in healthy shoulders. There is not enough study about JPS in FS.
**Objectives:** The aim of this study is to compare the effect of mid or end range of motion on joint position sense (JPS) in patients with FS.
**Methods:** Twenty five patients with FS (21 female, 4 male; mean age 53±6 years; age range 44–67) were included in this study. Mean Body Mass Index (BMI) was 29.02±4.89. 11 dominant and 14 nondominant shoulders were measured. JPS was assessed with active repositioning process by inclinometer in flexion, elevation and rotations at mid range (MR) and end range (ER).
**Results:** Error scores at ER were lower than at MR in flexion (p=0.44), elevation (p=0.01) and internal (p=0.00) and external (p=0.19) rotations. There were significant difference in elevation and internal rotation ($p<0.05$) (Table 1).

Table 1. Joint position sense at mid range and end range

| | MR (X ± SD) | ER (X ± SD | p |
|---|---|---|---|
| Flexion | 4.90±2.99 | 4.37±2.73 | 0.44 |
| Elevation | 6.97±4.49 | 4.60±3.62 | 0.01 |
| Internal rotation | 6.70±3.96 | 3.70±2.15 | 0.00 |
| External rotation | 4.64±3.36 | 3.52±2.36 | 0.19 |

Measurements are expressed in degrees. X: mean, SD: standard deviation. $p<0.05$

**Conclusions:** Our study showed that JPS at ER is better than MR. Especially elevation and internal rotation that more affected motions in FS were more sensitive to JPS. It was thought that at end ranges capsuloligamentous structure is stimulated more than mid ranges.

### AB1110-HPR INVESTIGATION OF FEAR AVOIDANCE BELIEFS IN ANKYLOSING SPONDYLITIS PATIENTS

T. Özen[1], S. Dönmez[2], Ö.N. Pamuk[2], M.A. Balcı[2], S. Özdinç[1]. [1]*Physiotherapy and Rehabilitation;* [2]*Department of Rheumatology, Trakya University, Edirne, Turkey*

**Background:** Ankylosing Spondylitis is an chronic, inflamatory, systemic illness which effect on sacroiliac joints and spine. Chronic pain is an important problem in ankylosing Spondylitis patients (1). Catastrophic beliefs, which is developed by patients who experienced pain for along time, cause avoidance of use, defect and depression (2). As far as some studies there is a correlation between pain and psychological state (3). There is no study which investigate factors related with fear avoidance beliefs.
**Objectives:** The aim of this study was to investigate factors that association with fear avoidance beliefs in ankylosing spondylitis.
**Methods:** 51 patients with ankylosing spondylitis, who applied to Rheumatology Department of Trakya University Faculty of Medicine Hospital, were included in this study. Spinal mobility evaluated by Bath Ankylosing Spondylitis Metrology Index (BASMI), function evaluated by Bath Ankylosing Spondylitis Functional Index (BASFI); disease activity defined by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). To evaluate quality of life, Ankylosing Spondylitis Quality of Life (ASQoL) is used. The Fear Avoidance Beliefs Questionnaire (FABQ) is used to evaluate the fears, beliefs, and avoidance behaviors of patients with AS in relation to physical and work-related activities. Short Physical Performance Battery (SPPB) is used for evaluate the functions of mobility. C-reactive protein (CRP) and Erythrocytes sedimentation rate (ESR) were saved.
**Results:** Of the 51 patients included, 12 (23,52%) were female and 39 (76,47%) were male. There was no meaningful statistical difference in FABQ scores between active and inactive disease groups.Physical activity subscale score of FABQ was associated with age (r=0,355, p=0.014), ESR (r=-0.361 p=0.042), quality of life (r=0.428, p=0.0002), BASFI scores (r=0,287, p=0,041), intermalleolar distance,which is BASMI's subscale and assess hip mobility (r=-0,452, p=0,002) and SPPB (r=-0.303, p=0,041). Work subscale of FABQ was associated with age (r=0,353, p=0,015), ASQoL (r=0.461, p=0,001), intermalleolar distance (r=-0,457, p=0,002).
**Conclusions:** There is an association between fears, beliefs, and avoidance behaviors of patients with AS in relation to physical and work-related activities and mobility function, quality of life, hip mobility. So we think preserving and developing techniques of mobility function will play a role AS treatment plan. And also we think new researches which investigate factors about fear avoidance beliefs in AS should be done.

## Occupational therapy

### AB1111-HPR VALIDITY OF CANADIAN OCCUPATIONAL PERFORMANCE MEASUREMENT IN PATIENTS WITH UPPER LIMB DISORDERS IN TURKEY

E. Tonga. *Faculty of Health Sciences, Department of Physiotherapy, Marmara University, Istanbul, Turkey*

**Background:** The Canadian Occupational Performance Measure (COPM)[1] was developed to identify and prioritize *patient-specific* occupational problems and evaluate changes in these problems. In literature on the COPM, consensus exists about the feasibility of the COPM as an instrument to identify a wide range of problems in daily activities.[2,3] There is only one research that investigate the validity of COPM with Disabilities of Shoulder arm Hand Questionnaire (DASH) in upper limb disorders.[4] This study did not showed the correlations between COPM and DASH, only reported the percentages.
**Objectives:** The aim of our study was to determine the construct validity of COPM by investigating the correlations with two different upper limb functional questionnaires in Turkish patients with upper limb problems. Second aim of our study was to determine the occupational performance problems specific to upper limb in Turkish culture.
**Methods:** Physical therapy outpatients (n=l02, 70% female, age 49.1±16.6) with upper limb disorders were consecutively recruited. All participants completed the the Upper Limb Functional Index Turkish (ULFI-Tk) and the DASH Turkish-version

(DASH-Tk) criterion. COPM was conducted by qualified therapist who has 5 year experience of using COPM. Pearson correlation analyses were done between COPM and DASH-Tk, ULFI-Tk.
**Results:** The COPM performance demonstrated statistically significant relationship with DASH-Tk disability scores (r=-0.217;p=0.02) and with ULFI-Tk (r=-0.290; p=0.003). There were also significant relationship between COPM satisfaction scores and DASH-Tk disability (r=-0.220;p=0.02), ULFI-Tk (r=-0.309; p=0.002). Totally 216 activity performance problems (self-care: 80, productivity:71, leisure: 65) determined with COPM.
**Conclusions:** The results of our study demonstrated that COPM is valid assessment in upper limb disorders. Our study was showed performance problems of patients with upper limb disorders that related with Turkish culture.

## AB1112-HPR SYSTEMIC SCLEROSIS TREATMENT: AN OCCUPATIONAL THERAPISTS' VIEW

J. Stöcker[1,2], C. van den Ende[1], K. Gevers[2], P. van Keeken[2], A. Wilting[2]. *[1]Sint Maartenskliniek; [2]Department of Occupational Therapy, HAN University of Applied Sciences, Nijmegen, Netherlands*

**Background:** SSc has a great impact on daily functioning [1]. People with SSc make regular use of allied health care, mainly physiotherapy and occupational therapy (OT), for guidance in coping with the many consequences of the disease. Little is known about the current practice of occupational therapy for people with SSc [2].
**Objectives:** The purpose of this qualitative pilot study was to map the experience of Dutch occupational therapists about their daily practice and vision on optimal SSc care through OTs.
**Methods:** Five female OTs, median age 38.6 years (range 25–46 years) from different work settings and regions with an average work experience of 8.6 years in SSc care, were recruited through the Dutch organisation of Health Professionals in rheumatology. A semi-structured interview was conducted with each participant and transcribed verbatim. Data were analysed by the three-step method of Boeije [3].
**Results:** OTs describe that in CURRENT PRACTICE patients report problems on a functional, activity and participation level, while the treatment is mostly aiming at functional level (including aids and compensations). They experience that their work is experience-based due to the lack of available evidence. The nature of interventions is significantly dependent on the phase of disease in which patients are. They experience a low number of referrals in a late state of the disease and suggest that this might be due to the lack of knowledge about occupational therapy.
In an OPTIMAL SITUATION OTs are involved earlier in the disease process and focus on training and patient needs. They would want to focus on prevention and education including the social environment of the patient. In order to offer optimal treatment they would want to work guideline-based and establish sustained treatment relationships. Earlier referral in the disease process would enable meaningful treatment. They express their need for a clear OT profile to be known by rheumatologists, to facilitate timely and appropriate referrals to OTs.
**Conclusions:** We found a distinct difference between current and ideal OT practice. The newly gained knowledge of this study can be used by OTs for a transition from treatment addressing compensation to a treatment targeting activity and participation. More attention should be paid to timely referrals with a transparent indication.

## AB1113-HPR DESCRIPTION OF THE SPARE TIME UTILIZATION AND RELATIONSHIP BETWEEN FUNCTIONALITY AND DISEASE ACTIVITY IN A COLOMBIAN RHEUMATOID ARTHRITIS COHORT

E. Rangel[1], L. Villarreal[2], P. Santos-Moreno[3,3], N. Palacio[4], C. Castro[5], D. Buitrago-Garcia[5]. *[1]Occupational therapy; [2]Psychology; [3]Rheumatology; [4]Nursing; [5]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Spare time utilization is defined as delectable and non-remunerated activities that a person realizes through its vital cycle. In rheumatoid arthritis (RA) patients this activities might be altered by multiple causes as functional deterioration, psychological problems and social exclusion.
**Objectives:** The aim of this study is to describe the spare time activities and possible relationship with disease activity and functionality of a RA patient's cohort.
**Methods:** A descriptive cross sectional study was realized. A revision of medical records of a cohort of RA patients was performed, including occupational therapy records. For all patients DAS28, HAQ, clinical evaluation and interests check list were made. Percentages, averages and Pearson's statistics were used for clinical and occupational variables.
**Results:** Total sample of patients was 1298, 1048 (80%) were women and 250 (19%) were men. Patients had a DAS28 2.6 in average ± 1.1; mean age was 55.1 ± 8.8 years; 846 (65%) were in remission, 205 (16%) were in low disease activity, 208 (16%) in moderate disease activity and 42 in severe disease activity (3%). Regarding education, 6% were illiterate, 44% had elementary school, 33% high school, 8% had a technical degree and only 7% had college level. In the spare time activities the most frequent were: mixed activities 26% housekeeping 24%, and intellectual activities 15% and handcrafting activities 12%. It was not established correlation between spare time use and disease activity or functionality.

| Occupations | n | % | HAQ (Mean) | | DAS 28 (Mean) | |
|---|---|---|---|---|---|---|
| | | | F | M | F | M |
| Sport and enjoying activities | 62 | 4.78 | 0.86 | 0.16 | 2.58 | 1.6 |
| Handcrafting activities | 158 | 12.17 | 1.06 | 0.36 | 2.66 | 2.55 |
| House keeping activities | 320 | 24.65 | 0.91 | 0.61 | 2.60 | 2.01 |
| Academic activities | 200 | 15.41 | 0.31 | 0.51 | 2.60 | 2.60 |
| Mixed activities | 341 | 26.27 | 0.49 | 0.48 | 2.70 | 2.4 |
| Not reported | 217 | 16.72 | 0.41 | 0.44 | 2.85 | 2.60 |

SPARE TIME USE. FUNCTIONALITY AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

**Conclusions:** Even we did not find a statically correlation between practicing spare activities or not practice and the disease activity, we found that practicing sports improves in men DAS score. Most patients in this cohort prefer mixed activities as their main spare time activity, and other main frequent activities were handcrafting or home activities; perhaps it's important to maintain in this cohort low activity disease and make more studies about this topic because study suggests that male who did only academic activities had more active disease.

# Miscellaneous forms of clinical care

## AB1114-HPR BIOLOGIC DOSE TAPERING IMPROVES PATIENT CARE AND ADVANCES THE RHEUMATOLOGY SERVICE

C. Holloway, H. Robinson, D. Rees, J. McDowell, S. Andrews, A. Joshi, V. Jolliffe, J. Trickey, A. Peall. *Rheumatology Department, Wye Valley NHS Trust, Hereford, United Kingdom*

**Background:** Wye Valley NHS Trust has approximately 500 rheumatology patients on biologic therapy, with an annual growth rate of over 15%, increasing the clinical, administrative and financial burden to both the trust and commissioners. Evidence regarding the success of biologic dose tapering in rheumatoid arthritis (RA) patients in remission is emerging[1]. Savings generated by dose tapering can be shared between the provider and commissioner. We discuss the development of a dose tapering gain share which benefits the patient, provider and commissioner.
**Objectives:** The aim was to develop an evidence based protocol for tapering of biologic drugs and to embed the protocol in clinical practice, benefitting patients by reducing their biologic therapy without adversely affecting their arthritis. The savings generated would fund the project including a biologics pharmacist, co-ordinator, consultant time, IT support and ultrasound equipment. To achieve this, the Clinical Commissioning Group (CCG) was to be approached to establish a gain share agreement.
**Methods:** A gain share was agreed with the CCG. The initial savings would fund the cost of the project whilst the remainder would be split 50:50 in the first year, 60:40 in the second year and 70:30 in the subsequent three years, between the CCG and Trust respectively. A literature review was undertaken to devise an evidence-based dose tapering protocol for RA patients. The protocol also specified that ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients'

biologics could be tapered at the discretion of the clinician, as there is currently a lack of evidence in these diseases. Eligible patients were identified and their doses tapered according to the protocol. Outcomes were recorded on a database, from which we extracted clinical and financial information.
**Results:** After the first 8 months of dose tapering, 25 RA, 4 PsA and 3 AS patients' doses have been tapered. Only 2 RA patients (8%) so far have resumed their original doses due to disease flares. This indicates that we are likely to generate the savings required to fund the project. Importantly we have been able to reduce the medication burden of patients, hence reducing adverse effects whilst retaining disease control. There have also been fewer day case infusions, increasing the availability for day case treatments for other patients and reducing trust expenditure. In addition the project has enhanced the department's relationship with the CCG.
**Conclusions:** This innovative project in a district general hospital demonstrates that savings from a dose tapering gain share can enhance and support an expanding biologics service. Initial results suggest that biologic doses can be successfully tapered in the majority of patients, whilst maintaining remission, with original doses reinstated for small numbers thus far. Further studies are required to assess long term outcomes. The team working exhibited by the rheumatology department and the CCG was essential for the success of the project.

## AB1115-HPR DOSE REDUCTION OF BIOLOGICAL THERAPIES IN RHEUMATOID ARTHRITIS - THE PATIENT'S PERSPECTIVE

D. Wallis[1], C. Holroyd[1], K. Sonpal[2], J. Zarroug[2], J. Adams[3], C.J. Edwards[1,2]. *[1]University Hospital Southampton NHS Foundation Trust; [2]NIHR Wellcome Trust Clinical Research Facility; [3]Centre for Innovation and Leadership in Health Sciences, University of Southampton, Southampton, United Kingdom*

**Background:** Although it is not possible to stop biological therapies for RA patients with established disease, it appears that dose reduction can be successful for some patients in remission or low disease activity. Dose reduction may reduce the risk of adverse events and produce economic benefits that allow greater numbers of patients to receive therapy. Negative consequences might include flares of disease, joint damage and immunogenicity. A vital component of developing dose reduction strategies is to include the patient perspectives. However, these have not been formally reported. Engagement of patients in shared decision-making about their management is vital to improving outcomes and a stated aim of many treatment guidelines.
**Objectives:** To develop a questionnaire, informed by patients and experts, that explores the views of patients with RA about biological therapies and dose reduction.
**Methods:** As a first step in developing a questionnaire we held a patient public involvement (PPI) qualitative focus group (9 patients, 8 female, mean age 49y, mean disease duration 17y) with RA. Eight were on a biological therapy with 2 on a reduced dose. Discussion was facilitated using an interview schedule by two PPI experts and a consultant rheumatologist and recorded. Participants (1) discussed biological therapy in general, (2) listed the top 10 concerns about biological therapy and (3) explored attitudes towards dose reduction. Statements describing the perceived benefits and concerns about dose reduction were separated into two lists and world clouds were generated for each list of statements. Respondent validation of the main themes identified and confirmed the findings.
**Results:** Common themes arising during discussion about biologics in general were: delays in accessing treatment, adverse effects, impact of disease on health, need for education about biologics, inefficacy of previous treatments, impact of disease on family and work and patient autonomy. When exploring attitudes towards dose reduction, the most common concerns were loss of disease control, delay in access to the previous dose and potential loss of efficacy of a previously successful treatment. Perceived benefits were a lower risk of adverse effects and reduced frequency of injection. The positive and negative aspects of dose reduction as cited by patients are shown in word clouds where the size of the word is proportional to the frequency of the word in the patients' statements (Fig 1). This work has led to the development of a questionnaire that will be given to a large population of patients receiving biological therapies to assess their views.

Figure 1. Word clouds demonstrating positive and negative aspects of biologic dose reduction according to patients

**Conclusions:** Patients were prepared to consider dose reduction but need reassurance about rapid access to higher doses should their disease flare. The data provide insight into patients' beliefs and attitudes towards biological therapies and dose reduction and have been used to generate a questionnaire to be distributed to a larger group of patients. The development of a questionnaire that is informed by patient experience and involvement, to explore the views of a wider population of patients, will be an important next step and will assist in the development of patient focussed strategies for dose reduction.

## AB1116-HPR SHARED UNDERSTANDING AND HIGH INTENSITY – THE PATIENTS' PERSPECTIVES OF ATTENDING A REHABILITATION PROGRAM IN WARM CLIMATE SPECIALLY DESIGNED FOR YOUNG ADULTS

H.S. Koksvik, B. Jakobsen, I.R. Nilssen, H. Bjørngaard. *National Advisory Unit on Pregnancy and Rheumatic diseases, University Hospital of Trondheim, Trondheim, Norway*

**Background:** It has been a tradition in Norway to admit patients with rheumatic diseases (RMDs) to rehabilitation in a warm climate for periods of 3- 4 weeks. Young adults with RMDs have to deal with life challenges such as; relating to friends, family and partners, education, establish a family, adjusting to working life, and handling physical and emotional changes, in addition to coping with their RMD. Since young adults may have different challenges and needs than older adults, we developed a 17 day intensive rehabilitation programme aimed at this age group. Two pilot groups with a total of 15 young adults with RMDs age 18–35 participated. The main interventions were intensive exercise (2–3/day), individual physiotherapy (daily), individual treatment plans, group interventions (daily) and patient education (daily). Climatotherapy was also a part of the intervention.
**Objectives:** The aim of this study was to describe the perceptions and experiences of young patients with participating in a 17 day intensive warm climate rehabilitation program that was targeted, organized and adjusted to their age group.
**Methods:** In order to capture the patients' own experiences and perceptions of the rehabilitation program, a focus group interview was conducted six months after the end of the intervention (3 females, 2 men, age 27 - 35 years, disease duration 2 - 13 years, diagnosis: Juvenile Arthritis (1), Rheumatoid Arthritis (1) and Spondyloarthropathy (3)). The interview focused on topics related to the rehabilitation program, such as content and organization, confidence in the staffs' competence, possible effects on health and everyday life, significance of meeting other young adults, satisfaction/dissatisfaction with the programme and feasible negative aspects related to the intervention. Qualitative content analyses were used to make abstractions and categories.
**Results:** The identified themes were "shared understanding", "length of program", "changes in daily life routine", "high intensity" and "competence of healthcare providers'. Shared understanding of their life situation with the other group members was seen as an important component in the program. Sharing knowledge and personal experience with others who are in similar phases in life enhances learning was seen as a useful and positive way of providing self-management. Due to their phases of life, all the participants said that the length of the program was perfect. They could not have attended a traditionally four week program. The intensity of the exercise was higher than traditionally programs and suited the group. After the program they had made changes to their daily life routine both in exercise and diet, but they would like a form of organized follow up from a health care provider. All agreed that the physiotherapists provided an individual program with high intensity and adjusted programme suitable for the young group.
**Conclusions:** This qualitative study suggests that patients experience that their needs were met in this targeted rehabilitation program. The patients reported that the length and intensity of the program and being with others in the same phase of life seemed to enhance motivation and have positive effect on self-management. Further research is needed to document the long term effect of the program.

## AB1117-HPR EVALUATION OF PATIENT REPORTED OUTCOME DATA FOLLOWING PERSISTENT MUSCULOSKELETAL PAIN SERVICE REDESIGN

H. Light, J. Firth, K. Kinsey. *Pennine MSK Partnership ltd, Oldham, United Kingdom*

**Background:** Persistent musculoskeletal pain (lasting >3 months) is common

in the UK and Europe. Following an independent review of service provision, a person-centred, integrated pathway of bio-psychosocial care was commissioned in Oldham, UK. A stepped care model was introduced comprising a single point of access to multidisciplinary care including psychological medicine, prescribing advice and exercise classes.
**Objectives:** To evaluate improvements in pain reported by patient and clinicians discharged from the service and compliance with data capture in the first 6 months.
**Methods:** Outcome data was collected on all patients opting in between 1st June-30th November 2015 including Pain Self-Efficacy Questionnaire (PSEQ) and DoloTest scores on entry and discharge and Clinical Global Impression-Improvement scale (CGI-I) on discharge. PSEQ scores range from 0–60; lower scores reflect little/ no confidence in performing daily activities. DoloTest scores range from 0–800 with lower scores reflecting a lower impact on quality of life. CGI-I is a clinician assessment of patient improvement, scores range from 1–7, with low scores reflecting an improvement and high scores reflecting deterioration.
**Results:** 369 patients opted in throughout the 6 month period, of which 170 (46%) have been discharged. Mean PSEQ score on entry was 17.3 (n=163), which improved to 30.7 (n=50) on discharge. 86% had an improvement in their PSEQ scores with 60% benefiting from a clinically significant improvement. The mean improvement was a score of 17, the mean improvement of significantly improved patients was 22.2 points. Mean DoloTest score on entry was 546.5 and 431.3 on discharge. 70% had an improvement in their DoloTest results; mean improvement was 154 points. There is no available benchmark for a clinically significant improvement for DoloTest. 72% of patients assessed using CGI-I were scored as having very much or much improved.

Table 1

| | On entry | On discharge |
|---|---|---|
| PSEQ scores – mean; median (range) | | |
| All patients with complete data, n=50 | 17.4; 15 (0–60) | 30.7; 29 (4–58) |
| Improved patients, n=43 (86%) | 14.7; 12 (0–50) | 31.8; 29 (4–58) |
| No improvement, n=7 (14%) | 33.9; 30 (9–60) | 23.6; 17 (9–57) |
| Improvement ≥10 points | 12.8; 8 (0–35) | 35; 34 (18–58) |
| DoloTest scores – mean; median (range) | | |
| All patients with complete data, n=37 | 522.5: 526 (191–751) | 445.2; 427 (56–772) |
| Improved patients, n=26 (70%) | 538; 520 (191–751) | 384.1; 378 (56–725) |
| No improvement, n=11 (30%) | 485.7; 366 (242–538) | 589.5; 465 (266–772) |

59 patients (35%) had missing discharge data. Reasons included patients failing to attend follow ups or opting out (46%), stepping up care up to secondary care provision for patients with complex needs (25%), and missing data, unknown (29%). 13 (8%) patients were discharged at first appointment therefore no follow up assessments were completed.
**Conclusions:** In all assessments, the majority of patients improved throughout their treatment. A change in PSEQ score around 10 is considered clinically significant. Of 7 patients with no improvement in PSEQ score, 2 scored <20 indicating their focus on pain could influence their willingness to engage in activity. Of the remaining 5 patients, 3 had high initial scores (>40) thought to be incongruent with requiring a pain management programme. Missing data affected the evaluation and qualitative work is being undertaken to understand the reasons for this and to inform strategies to increase data capture.
**Disclosure of Interest:** None declared

## AB1118-HPR HEALTH PROFESSIONALS' (HPS) PERSPECTIVES WHEN WORKING WITH PEOPLE WITH RHEUMATOLOGICAL & MUSCULOSKELETAL DISORDERS (RMDS) AND LOWER LEVELS OF HEALTH LITERACY: A QUALITATIVE FOCUS GROUP STUDY

J. Adams[1], W. Lowe[1], R. Armstrong[2], C. Russell[1], J. Lueddeke[3], J. Protheroe[4], K. McCaffery[5], D. Nutbeam[1], C. Ballinger[1]. *[1]University of Southampton; [2]University Hospital, Southampton; [3]Brockenhurst College, Brockenhurst; [4]University of Keele, Keele, United Kingdom; [5]University of Sydney, Sydney, Australia*

**Background:** The high prevalence of RMDs and the high proportion of time HPs spend on advising patients with RMDs means that implementing effective self-management strategies is important. Health literacy includes the cognitive and social skills which determine the motivation and ability of individuals to access, understand and use information to promote good health. People with lower health literacy levels have lower levels of activation for self-care and worse functional health outcomes than people with higher levels of health literacy.
**Objectives:** To explore HPs' patient education practice and perspectives when working with patients with RMDs and lower levels of health literacy.
**Methods:** Key contacts from clinics, community GP surgeries and groups identified interested HPs. They were eligible if they had supported patients in developing self-management skills. Participants completed a health literacy questionnaire prior to taking part in a focus group guided by an interview schedule. These were audio-recorded, transcribed and analysed thematically.
**Results:** Five focus group and 2 individual interviews (n=33) were conducted including a consultant rheumatologist; GPs, advance nurse practitioners, nurses, care assistants, occupational therapists, physiotherapists, a podiatrist, a patient advocate, health researchers, a project manager. Key themes included: *Experiencing low health literacy as a RMD service provider:* whilst HPs generally had not previously considered health literacy as an issue for their patients, most could identify indicators of low health literacy such as difficulty recalling information, adhering to exercises or medication and recurrent healthcare-seeking behaviour. *Working with lower health literacy and RMD patients:* HPs experienced that patients with lower health literacy had unrealistic expectations of a cure for their RMD pain. This could impact on patient perceptions about the need for ongoing self-management. *Delivering patient education:* HPs identified that person-centred advice, tailored to the needs of the individual constituted core practice. Time limitations, especially for GPs were the biggest challenge for delivering education. Several practical, educational strategies were in use and identified as relevant for patients with lower health literacy. *Strategies to support self-management:* different communication modes that did not rely on written material were in use alongside effective interpersonal techniques such as using analogies and metaphors to explain detail. The use of positive and encouraging language was recognised as important.
**Conclusions:** HPs did not have a clear way of identifying patients with low health literacy but used behaviour e.g. poor adherence and repeat appointments as indicators. Patients' perceived unrealistic expectations about a cure for their RMD and pain impacted negatively on their perceptions about self-management. There was evidence for health professionals utilising effective educational and inter-personal strategies as a means of supporting patients with lower health literacy.

## AB1119-HPR EVALUATION OF THE PODIATRIC NEED OF PEOPLE WITH INFLAMMATORY ARTHRITIS IN SINGAPORE

K. Carter[1], M. Lahiri[2], P. Cheung[2], A. Santosa[2], K. Rome[3]. *[1]Podiatry; [2]Department of Medicine, National University Hospital Singapore, Singapore, Singapore; [3]Faculty of Health and Environmental Sciences, AUT University, Auckland, New Zealand*

**Background:** Foot problems are common in people with inflammatory arthritis [1]. International guidelines recommend referral to podiatry of all people with rheumatic disease and foot problems [2–4]. Areas covered in the guidelines include access to foot care, assessment and review, foot orthoses and footwear. It is known that access to podiatry services varies between, and even within, countries [5,6]. Such information relating to access and uptake to podiatry services in Singapore for people with inflammatory arthritis is not available.
**Objectives:** To assess the referral rate from a hospital rheumatology department to podiatry services, and the level of satisfaction of referred patients with their podiatry assessment and interventions.
**Methods:** People with inflammatory arthritis were recruited from the rheumatology outpatient clinic of a large public hospital in Singapore. Disease and clinical characteristics were recorded. Participants were asked questions relating to foot problems, access to podiatry services and their perceived usefulness of foot assessment and/or interventions in alleviating their foot symptoms. A footwear assessment was also conducted.
**Results:** 101 patients with inflammatory arthritis were recruited, of which 50% were female. The mean age was 52±15 years, and the mean disease duration was 9.3±0.3 years. The majority (86%, n=78) of participants with foot problems had discussed their foot symptoms with their rheumatologist, though only 21% of participants (n=21) were referred to a podiatrist. Of these, most (n=17, 81%) reported the foot assessments and the podiatric interventions as having been useful (n=15, 71%); 13 (62%) had been prescribed foot orthoses, of which only 9 reported finding them to be beneficial in reducing foot pain. Over 50% of all the study participants (n=51) reported problems with footwear. Only 32 people had correctly fitting footwear. No participants had been issued with therapeutic footwear.
**Conclusions:** Though the majority of people with inflammatory arthritis reported foot problems few received a referral to podiatry. This study is the first to identify an unmet need in Singapore in the podiatric treatment of foot problems in people with inflammatory arthritis, and the under utilization of podiatry service. The results provide a foundation for further study to identify and provide solutions to overcome barriers preventing the utilization of podiatry services.

## AB1120-HPR APPLICATION OF THE INNOVATIVE RHEUMATOID ARTHRITIS MEDICATION ASSEMENT TOOL WITHIN A PHARMACEUTICAL CARE MODEL

L. Grech[1,2], V. Ferrito[1], L. Camilleri[3], A. Serracino Inglott[1], L.M. Azzopardi[1].
[1]*Department of Pharmacy, University of Malta;* [2]*Department of Pharmacy, Mater Dei Hospital;* [3]*Department of Statistics and Operations Research, University of Malta, Msida, Malta*

**Background:** Pharmacists must adapt and evolve in order to face challenges and sustain the profession to continuously provide optimum personalised patient care to rheumatoid arthritis patients. Rheumatoid arthritis medication assessment tool, RhMAT is an innovative evidence-based instrument developed specifically to assess pharmacetherapy adherence to rheumatoid arthritis evidence-based guidelines and recommendations.
**Objectives:** The objective of the study was to use the RhMAT within an outpatient rheumatology clinic to identify pharmaceutical care issues and assess therapeutic management of rheumatoid arthritis patients.
**Methods:** Rheumatoid arthritis patients regularly attending the rheumatology clinic at Mater Dei Hospital eligible to participate in the study were offered a pharmaceutical care session. The pharmacist screened each patients' pharmacetherapy using the RhMAT at two time points, Phase 1 (time =0 months) and Phase 2 (time = approximately 12 months).The RhMAT adherence rate for each patient was calculated at both time points. A score of 50% of less was determined as low adherence, a score between 51% and 74% showed intermediate adherence and a score of 75% or more was determined as high adherence to the RhMAT.Gaps in non-adherence to the RhMAT which led to pharmaceutical care issues were documented and discussed with the clinician. Data analysis of the mean score at both phases was analysed using Wilcoxon signed rank test, SPSS verion 22.
**Results:** A total of 78 patients (52 females) participated in the study. The mean age was 64 years (SD 12).The majority of the patients (55%) were prescribed at least one traditional disease modifying anti-rheumatic drug (tDMARD) whereas 45% were on biologic disease modifying anti-rheumatic drug (bDMARD). The most common tDMARD prescribed was methotrexate (n=52 patients). The mean RhMAT adherence rate at phase 1 was 81.7%. Following the pharmacist's contribution whereby the identified gaps leading to non-adherence such as lack of appropriate monitoring or lack of drug therapy counselling, were discussed as necessary with the respective clinician and the patient, the mean RhMAT adherence rate at the follow up session at Phase 2 statistically significantly increased to 85.2% (Wilcoxon signed rank test p value $<0.05$).
**Conclusions:** The RhMAT is an innovative tool which aids pharmacists to identify adherence of prescribed pharmacotherapy in accordance to established guidelines. At the same time, the RhMAT allows pharmacists to identify gaps in individual patients care which lead to pharmaceutical care issues. Through the RhMAT, pharmacists further improve the quality of care offered to rheumatoid arthritis patients.

## AB1121-HPR QUALITY OF LIFE AS A CRITERION OF EFFICIENCY IN TREATMENT OF PATIENTS WITH OSTEOARTHRITIS

M. Ramkhelawon[1], M. Myakishev[2], G. Suleymanova[1], R. Grekhoff[1].
[1]*Rheumatology, Research Institute for Clinical and Experimental Rheumatology;* [2]*Hospital therapy, VOLGMU, Volgograd, Russian Federation*

**Objectives:** To study the quality of life (QoL) of patients with osteoarthritis (OA), and how it changes depending on the clinical features of the disease and the psychological characteristics of the patients.
**Methods:** We examined 30 patients with OA prior and after treatment. For better comparisons, a control group was set up, which comprised of 30 residents of Volgograd city, in the same age range and sex and who did not suffer from serious somatic diseases. QoL was studied using the questionnaire "SF-36" (Ware JE, 1993).
**Results:** The QoL scores on all scales of the SF-36 questionnaire, in patients with OA were significantly lower than in the control group ($p<0.05$). This showed the lowest scores in QoL osteoarthritis patients ever had before treatment. The physical activity in patients with OA was considerably affected due to the physical ($p<0.001$) and role functioning (RF, RP) ($p<0.001$), as well as indicators of somatic pain (BP) ($p<0.01$). Factors that significantly impaired the physical component of QoL in patients with OA were: age of patients, stage of disease, the severity of joint pain on a visual analogue scale (VAS), and presence of clinically manifested anxiety ($p<0.05$). Factors that significantly impaired social and psychological component of quality of life in OA patients were: stage and duration of the disease and increased functional insufficiency of the joints ($p<0.05$). By improving the physical components of health (physical and role functioning, somatic pain) and psychological components (role emotional functioning, mental health) ($p<0.05$), therapeutic measures significantly had a positive impact on the basic parameters of QoL in patients with OA. Role physical (RP) and role emotional (RE) functioning significantly changed by more than 42% ($p<0.001$). The regularities were significantly associated with decreasing functional failure of the joints, decrease in the intensity of joint pain in VAS and decrease in ESR ($p<0.05$).
**Conclusions:** Thus, after treatment, patients with OA had a significant improvement in physical health, noted by a reduction in pain and physical limitations, and, as a consequence, improved performance. The effectiveness of therapy in the hospital environment contributed in the formation of a positive subjective assessment of the health status in patients with OA.

## AB1122-HPR LOCUS OF CONTROL AND THE PHENOMENON OF ALEXITHYMIA IN ANKYLOSING SPONDYLITIS PATIENTS

M. Ramkhelawon[1], G. Suleymanova[1], R. Grekhoff[1], E.G. Cherkesova[2].
[1]*Rheumatology, Research Institute for Clinical and Experimental Rheumatology;* [2]*Hospital therapy, VOLGMU, Volgograd, Russian Federation*

**Objectives:** To examine the role of locus of control and the phenomenon of alexithymia in the formation of psychosomatic personality traits in ankylosing spondylitis (AS) patients.
**Methods:** The group studied, comprised of 27 patients suffering from AS. The selection of patients for the study was conducted in accordance with the recommendations of the group of experts working on AS (ASAS, 2003). The patients were of an average age - 44, 94±13, 8 years and had an average duration of the disease - 3, 02 ± 3, 69 years. The main contingent of patients with AS was represented by males (89%). A study of locus of control was conducted by the method of "level of subjective control" (Bazhin E. F., et al. 1987). The study of alexithymia was conducted using the Toronto Alexithymia Scale (TAS) (G. J. Taylor et al., 1985).
**Results:** The study of locus of control in patients with AS showed a significant trend towards external locus of control in common sphere (3,81+1,387), as well as on the scale of failures (3,51+0,64), family relations (4,18+0,55), professional relations (2,74+0.98) and in relation to health (4,66+1,94). Trends towards internal locus of control were observed in the sphere of interpersonal interaction and achievements (5, 14+0, 71 and 5.0+1, 24 respectively). Correlation between the levels of locus of control with other clinical and psychological characteristics, such as age, activity, duration of disease and the level of neurotic disorders in patients has not been established.
A high level of alexithymia (77, 35±1.8 points) was also recorded in patients with AS. The level of alexithymia as such, did not depend on sex, age, character of duration and activity of the pathological process, but was inversely correlated with the level of education of the patients (r=-0.37 with p=0,028) and internality in relation to the disease (r=-0,64, p=0.031).
**Conclusions:** Thus, a certain correlation is formed between the development of the alexithymia phenomenon and some clinical and psychological characteristics in AS patients. This correlation is usually causal in nature, the understanding of which has implications for the organization of preventive measures, aimed at correction of alexithymia traits. Characteristics of locus of control in patients with AS can largely be predetermined by the peculiarities in the formation of personal relationships and the choice of certain strategies. These changes may hinder the effectiveness of therapeutic interventions and need for psychological adjustment in time.

## AB1123-HPR THE ROLE OF PSYCHOLOGICAL DEFENSE MECHANISMS AND THE LEVEL OF SUBJECTIVE CONTROL IN THE DEVELOPMENT OF AFFECTIVE DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Ramkhelawon, G. Suleymanova, R. Grekhoff, S. Kharchenko. *Rheumatology, Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation*

**Objectives:** To examine the role of psychological defense mechanisms (PDM) and level of subjective control (LSC) in the development of affective disorders in patients with rheumatoid arthritis (RA).
**Methods:** We observed 28 patients with RA. The average age was 55, 59±8, 76 years and the average duration was – 7, 2±4,3years. The questionnaire "level of subjective control" (LSC) (Bazhin E. F., et al. 1993) was used in the study. Psychological defense mechanisms were studied according to the "index of lifestyle" inventory (IL) (E. B. Klubov et al., 1995). The study of affective disorders was conducted by the "neuroticism and psychopatization" psychological test (L. L. Dmitrieva, 1990).
**Results:** In women, a high intensity of PDM in the type of "Reactive formation" was seen. And in men, a higher tension in PDM in the type of "Displacement" and "Intellectualization" ($p<0.01$) was noted. RA patients with the third stage of activity had lowest indices related directly to defense "Denial" ($p<0.05$). Asthenia, depression, anxiety and hypochondria are directly correlated with the parameters of PDM "Reactive formations" (H). The level of asthenia and anxiety were directly correlated with intensity of "Regression" defense mechanism (r=0,316 and r=0,365; p=0.010 and p=0.003). The level of asthenia and depression were directly correlated with the defense "Projection" (r=0,399 and r=0,343; p=0.001 and p=0.005).
Patients with RA were mostly characterized by external locus of control in common

sphere (3,81+1,387), failures (3,51+0,64), family relations (4,18+0,55), industrial relations (2,74+0,98), health (4,66+1,94). The general internal locus of control in RA patients was significantly decreased (p=0.006) along with increasing stage of the disease. Significant negative correlations were established between the levels of asthenia, anxiety and hypochondria and internal locus of control (p=-0, 45; p=-0, 52; p=-0, 40, respectively, when r=0,005); and between level of anxiety and internality of failures (p=-0, 42, p=0.05).

**Conclusions:** The obtained data indicate the passiveness of RA patients fighting with the disease, and failure to appreciate the connection between their actions and important events of their lives; hence in this background, a choice more towards non-adaptive psychological defense mechanisms is made which in turn exacerbates the neurotic reactions in RA patients.

## AB1124-HPR KEY ASPECTS OF HEALTH PROFESSIONALS REQUIRED TO BE EXPERTS IN RHEUMATIC DISEASES (REUMAPPA)

M. Gobbo[1], L. Carmona[2]. [1]*Positivamente Centro de Psicología;* [2]*Instituto de Salud Musculoesquelética, Madrid, Spain*

**Background:** Spanish Rheumatology League (Liga Reumatológica Española, LIRE) is developing an application for mobile devices and web browsers that incorporates a map of resources for rheumatic patients and professionals who treat them (Reumappa). This app helps locate with ease professionals and specialized services in rheumatic pathologies in Spain. A focus group with rheumatic patients was conducted in a previous phase in order to identify which fields of health professionals are required to manage their disease. It was then considered interesting to know whether there are relevant aspects of these specialties that distinguish professionals who can provide better care for rheumatic patients.

**Objectives:** To identify key issues that health professionals should have to bring added value in the management of rheumatic patients.

**Methods:** Focus Group with health professionals selected by patients as useful for the management of their disease (occupational therapist, physiotherapist, podiatrist, nurse, nutritionist, dentist, psychologist, and 2 social workers), sex (4 male, 5 female), age (3 <45, 6>45), years of professional experience (3 <10, 6>10), sector (5 private, 4 public). Key question: "*What aspects do you think add value to the care your specialty provides to rheumatic patients?*".

**Results:** Table 1 shows the results of the focus group. N = nurse, SW = social worker, OT = occupational therapist, Nu = nutritionist, Po = podiatrist, Psi = psychologist, Phy = physiotherapist, D = dentist.

Table 1. Health professionals skills for optimal management of rheumatic diseases.

| | N | SW | OT | Nu | Po | Psi | Phy | D |
|---|---|---|---|---|---|---|---|---|
| General knowledge of rheumatic diseases (RD) | x | x | x | x | x* | x | x | x** |
| Knowledge of treatments | | | | | | | | |
| Pharmacological | x | | | x | | x | x | x |
| Specific exercises for RD | x | x | x | x | x | x | x | |
| Orthotics and prosthetics | x | x | x | | x | | x | x |
| Cognitive behavioral techniques | x | | x | | | x | x | |
| Dietary supplements | | | | x | | | | |
| Pain management (evaluation and treatment) | x | x | x | | x | x | x | |
| Specific exercises for RD | x | x | x | x | | x | x | |
| Knowledge of immunology | x | | | x | | x | x | |
| Occupational health | x | x | x | | | | | |
| Knowledge of local resources | x | x | | | | x | x | |

*Podiatrists only RA and osteoarthritis; **Dentists only Sjögren and osteoarthritis.

Imperative Required Advisable

**Conclusions:** All health professionals who treat rheumatic patients should have at least a general knowledge of rheumatic diseases. Most health professionals should have a knowledge of drug treatments and recommended exercises. Nurses, psychologists, and physiotherapists require greater specialization to treat these patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.5922

## AB1125-HPR HEALTH- RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHROPATHIES AND BIOLOGIC THERAPY

M. Álvarez-Payero[1], F. Maceiras[1,2], R. Melero[1], C. Mouriño[1,2], A. Martin[1], M. Rodríguez-Rodríguez[1], M. Ucha[1,2], N. Martínez[1,2], I. Hernandez[1], C. Barbazán[1], M. Rodríguez[2], V. Balboa[3], J. Uña[3], G. Piñeiro[1], J. Pego[1,2]. [1]*H;* [2]*IBI- IRIDIS Group;* [3]*U, Vigo, -*

**Background:** Chronic inflammatory arthropaties-CIA (RA-rheumatoid arthritis, PA-psoriatic arthritis, and AS-ankylosing spondylitis) cause functional disability and reduces health-related quality of life (HRQoL) of patients[1]

**Objectives:** To evaluate HRQoL in patients with CIA and biologic therapy (BT), as a measure of patient reported outcome.

**Methods:** Descriptive cross-sectional study (August 2014) in a tertiary hospital. Inclusion criteria:a)adult patients with RA, PA, SA and other CIA (O) attended at the Rheumatology Service and b)≥2 months of treatment with BT (sc/iv adalimumab-ADA, sc/iv etanercept-ETA, iv infliximab, sc golimumab, sc certolizumab, sc/iv abatacept, sc/iv tocilizumab or iv rituximab). Sociodemographic and clinical variables were obtained by structured interview and review of medical record.Degree of disease activity measures: DAS28 index (≤3.2:low activity; >3.2-≤5.1:moderate; >5.1:high) for RA and PA peripheral; BASDAI (<4:low activity ≥4:high activity) for AS and PA with predominant axial involvement. HRQoL was mesured by a self-administered questionnaire:EQ5D-5L[2]. It evaluates 5 dimensions:mobility (M), self-care, usual activities (UA)pain/discomfort (PD) and anxiety/depression. Each dimension has 5 levels of severity. A HRQoL score is obtained (EQ-index) from 0 (death) to 1 (full health). It also has a visual scale (EQ-VAS) of global health from 0 (the worst health) to 100 (the best health). Descriptive and multiple linear regression analysis (LRA) were performed to determine which variables contributed on HRQoL.

**Results:** A total of 382 patients were eligible for the study.314 patients agreed to answer the questionnaire (women:55.7%, average age (±SD): 55.2±13.9 years, average disease duration (±SD):13.05±8.1 years). Pathologies distribution: 44.3% RA, PA 26.1%, 21.3% AS, 8.3% O. BT: 51.9% ADA, 28.7% ETA and 19.4% others. 65.9% of patients had a first line of TB. 50% of patients had concomitant drug (corticosteroid/methotrexate/leflunomide). 71.7% of patients had low activity, with standard drug regimen (61.8%) and optimized regimen (37.6%). The EQ-index perceived was:0.73±0.22 and a global health EQ-VAS: 64.2±21.0 points. The worst rated questionnaire dimensions (severities 3–4-5) were P (33.7%), UA (29.9%) and M (26.7%).

LRA showed significance differences (p<0.001) for disease activity, disease duration and education. 0.4 and 9.05 EQ-VAS points were reduced for each year of evolution and each DAS28 point increase, respectively. Differences were not significant for age, sex, pathology, drug or line number.

**Conclusions:** Generally, patients evaluated have a good control of disease activity and an acceptable HRQoL perceived. Chronic P and loss of autonomy to perform UA are the worst rated dimensions

## AB1126-HPR HOW PHYSICALLY ACTIVE ARE NORDIC PATIENTS WITH MODERATE TO SEVERE OSTEOARTHRITIS?

R.H. Moe[1], T. Uhlig[2]. [1]*Rheumatology, NKRR, Diakonhjemmet Hospital, Oslo, Norway;* [2]*Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

**Background:** Osteoarthritis (OA) is one of the most frequent chronic rheumatic and musculoskeletal diseases (RMD), and one of the leading causes of pain and disability worldwide. Physical activity is a key lifestyle advice along with weight reduction if overweight. However, data on the amount of physical activity in patients with OA are limited.

**Objectives:** To examine physical activity in people referred to specialist care for their OA.

**Methods:** Patients with known OA with moderate to severe OA referred to a specialist clinic in Oslo, Norway were after informed consent mailed questionnaires on demographic data and physical activity before visiting the clinic. Of 391 people, 86% (n=338) were females with mean age (SD) 61.2 (7.8) years). Patients rated their weekly physical activity that included shortness of breath, based on experiences from the last two weeks. Other patient reported outcomes included pain, fatigue and stiffness on numeric rating scales, and body mass index (BMI). Through descriptive statistics and explorative analyses the group was described. Patients who fulfilled 3 hours of physical activity per week or more were slightly

Table 1. Patient characteristics (N=391)

| Variable | Value |
|---|---|
| Age (years), mean (SD) | 61.2 (7.8) |
| Gender women, n (%) | 338 (86%) |
| BMI (SD) | 25.6 (4.9) |
| Pain (NRS), mean (SD) | 5.3 (2.0) |
| Fatigue (NRS), mean (SD) | 4.1 (2.9) |
| Stiffness (NRS), mean (SD) | 5.2 (2.4) |

BMI = body mass index, NRS = numeric rating scales (11-point, range 0–10).

Table 2. Self-reported physical activity

| Weekly physical activity* | N (%) |
|---|---|
| 0 hours PA | 53 (13.6) |
| >1 hours PA | 56 (14.3) |
| 1–2 hours PA | 78 (19.9) |
| 2–3 hours PA | 81 (20.7) |
| 3–4 hours PA | 52 (13.3) |
| 4–5 hours PA | 28 (7.2) |
| 5< hours PA | 37 (9.5) |

*Self-reported physical activity.

leaner and had a numerically lower BMI than those who were less physically active (non-significant differences, data not shown) than those who were less physically active.
**Results:** See tables.
**Conclusions:** 29.9% (N=117/391) of OA patients fulfilled the recommended minimum of 3 hours of physical activity per week, while almost 14% reported not being physically active at all. To enhance recommended physical activity, emphasis on physical activity in OA is required during clinical care as well as easy access to programmes for health-enhancing physical activity. These interventions may decrease the burden of OA in the future.

## AB1127-HPR CONSTRUCT VALIDITY TESTING OF RAST, A NEW RA STIFFNESS PATIENT REPORTED OUTCOME MEASURE (PROM)

S. Halls[1], E. Dures[1], J. Kirwan[2], J. Pollock[1], G. Baker[3], A. Edmunds[3], S. Hewlett[1]. *[1]Faculty of Health and Applied Sciences, The University of the West of England; [2]School of Clinical Sciences, University of Bristol; [3]Rheumatology Department, Bristol Royal Infirmary, Bristol, United Kingdom*

**Background:** Morning stiffness is a frequently used clinical and research outcome measure and is important to patients[1], but was omitted from the RA core set because of poor measurement properties[2]. Current stiffness assessment is inconsistent with patient's perspectives of the symptom[3,4] and has not been developed according to PROM development guidelines[5]. A new 21 item, 3-component Rheumatoid Arthritis Stiffness questionnaire (RAST) has been developed based on qualitative work[3] with RA patients and statistical assessment to enhance content validity and now requires testing for appropriate relationships with other measures of disease (construct validity).
**Objectives:** To perform construct validity testing of RAST.
**Methods:** The 21 item RAST was developed from 45 items assessing stiffness included in a questionnaire pack which was posted to patients with RA based in the South-West of England. The questionnaire pack also contained individual items capturing pain (VAS), fatigue (NRS), patient global assessment (PtG VAS), questionnaires capturing disability (MHAQ), and patient-reported disease activity (PDAS2[6], scores generated from an algorithm including PtG, swollen joint count (SJC), and MHAQ), and basic demographic information. The RAST was subjected to construct validity testing using a correlation matrix of Spearman's correlation coefficients (reported as explained variance ($R^2$).
**Results:** 277 patients (91 male) aged 23–97 years with disease durations 1–45 years participated in the study (42.9% response rate). The individual components and sum score of RAST demonstrated appropriate relationships with other measures of disease (pain $R^2$=45–72%; fatigue $R^2$=43–55%; PtG $R^2$=48–68%; MHAQ $R^2$=55–78%; PDAS2[6] $R^2$=56–78%). The shared variance indicated that while RAST (individual components and sum score) is related to other measures of disease, it is not measuring the same thing. Importantly, as identified by patients in earlier qualitative work[3], the variance explained by the RAST (individual components and sum score) and the (patient-reported) SJC included within the PDAS2[6] was between 31–41% indicating that RAST may capture something not currently included within disease activity assessment. The pattern of relationships between individual components and measures of disease also provided support for the 3-component structure. As expected, the "physical component" shared the most variance with disability ($R^2$=78%), the "severity component" shared the most variance with pain ($R^2$=72%) and PtG ($R^2$=68%), and the "psychosocial component" shared less variance with the above disease related measures.
**Conclusions:** During preliminary validity testing RAST, the new RA stiffness PROM, demonstrated promising construct validity. Further testing of RAST is now required in a fresh population to generate measurement property evidence of reliability and sensitivity to change to support its use.

## AB1128-HPR DEVELOPING A NEW RHEUMATOID ARTHRITIS (RA) STIFFNESS PATIENT REPORTED OUTCOME MEASURE (PROM)

S. Halls[1], E. Dures[1], J. Kirwan[2], J. Pollock[1], G. Baker[3], A. Edmunds[3], S. Hewlett[1]. *[1]Faculty of Health and Applied Sciences, The University of the West of England; [2]School of Clinical Sciences, University of Bristol; [3]Rheumatology Department, Bristol Royal Infirmary, Bristol, United Kingdom*

**Background:** Morning stiffness is a frequently used clinical and research outcome measure and is important to patients[1], but was omitted from the RA core set because of poor measurement properties[2]. Current stiffness assessment is inconsistent with patient's perspectives of the symptom[3,4] and has not been developed according to PROM development guidelines[5]. The appropriate content of a new RA stiffness PROM was previously explored and developed through qualitative interview[3] and focus group studies. Draft items were subsequently tested and refined with patients during cognitive interviews, resulting in 39 draft items for inclusion in a PROM. Here we report a quantitative assessment to create the smallest and most internally consistent set of items for a developmentally valid stiffness PROM.
**Objectives:** To develop the content and structure of a new RA stiffness PROM.
**Methods:** A postal questionnaire pack was sent to patients with RA based in the South-West of England. It contained 45 items assessing stiffness (39 draft items and 6 items currently used in stiffness assessment), individual items capturing pain (VAS), fatigue (NRS), patient global assessment (VAS), questionnaires capturing disability (MHAQ), and patient-reported disease activity (PDAS2[6]), and basic demographic information. Initial investigation identified items with poor response rates, distributions or correlations for removal. A series of principal component analyses were undertaken with the remaining items, balancing Cronbach's alpha for internal consistency, stability of the component structure (assessed by multiple analyses using random 50% samples of the respondents (bootstrapping)) and parsimony. Based on the statistical results and aided by expert judgement, the smallest number of informative items were retained.
**Results:** 277 patients (91 male) aged 23–97 years with disease durations 1–45 years participated in the study (42.9% response rate). Seven of the 45 items were removed during initial item investigation. The remaining 38 items demonstrated high Cronbach's alpha (>0.9). During successive rounds of analytical refinement, 17 items were removed. After round 5, a 3-component structure emerged which remained consistent for a further 13 rounds of testing item removal, demonstrating stability. These components captured "stiffness severity", "physical impact" and "psychosocial impact". The overall Cronbach's alpha of the final 21 items was 0.95 indicating a homogenous set of items and bootstrapping further demonstrated the stability of the structure.
**Conclusions:** A new 21 item, 3-component RA stiffness PROM has been developed based on qualitative work[3] with RA patients to enhance content validity. Further testing is now required to assess the validity, reliability and sensitivity to change of the new RA stiffness PROM.

## AB1129-HPR CROSS-CULTURAL ADAPTATION AND VALIDATION OF THE PATIENT REPORTED OUTCOME MEASURES QUESTIONNAIRE FOR INFLAMMATORY ARTHRITIS FOR BULGARIAN-SPEAKING INDIVIDUALS

Y. El Miedany[1], R. Nestorova[2], T. Petranova[3], M. El Gaafary[4]. *[1]Darent Valley Hospital, Dartford, Kent, United Kingdom; [2]Centre of Rheumatology "St. Irina"; [3]Clinic of Rheumatology, Medical University, Sofia, Bulgaria; [4]Community and Public Health Department, Ain Shams University, Cairo, Egypt*

**Background:** The PROMs-Arthritis questionnaire [1] was developed to evaluate the patient reported outcomes in individuals with inflammatory arthritis. Translation of the questionnaire to other languages will provide a standard outcome measure across populations.
**Objectives:** To translate the English version of the Patient Reported Outcome Measures for inflammatory arthritis (PROMs-Arthritis) to Bulgarian; and evaluate the psychometric properties of the Bulgarian version.
**Methods:** The PROMs-Arthritis questionnaire was cross-culturally adapted to Bulgarian, according to established guidelines. The validity and reliability of the Bulgarian version were assessed in 110 patients with rheumatoid arthritis (RA) as well as 44 healthy control. The questionnaire includes assessment for functional disability, quality of life, VAS for joint pain, patient global status, fatigue, duration of morning stiffness, assessment of co-morbidities, patient activation as well as self-reported joint pain.
**Results:** The expert committee and the participants considered the questionnaire to have good face and content validity. Dimensionality analysis revealed a 1-factor solution, explaining 97% of the total variance. Known group validity

was demonstrated by significant differences between patients compared with the asymptomatic group ($P<0.001$). An item analysis showed a high degree of internal consistency (Cronbach $\alpha$=0.805).The Bulgarian version exhibited excellent test-retest reliability (intraclass correlation coefficient =0.805 for the arthritis group). The questionnaire items correlated significantly ($p<0.01$) with clinical parameters of disease activity (DAS-28), physician global assessment, ESR and CRP levels. RA patient self-reported tender joints correlated significantly with the physicians' scores (0.893). Changes in functional disability, quality of life as well as Patient Activation scores showed significant ($p<0.01$) variation, with diseases activity status (DAS-28). The questionnaire showed also a high degree of comprehensibility (9.4).

**Conclusions:** Integrating patient reported outcome measures into standard clinical practice is feasible and applicable. The Bulgarian version, adapted from the original English PROMs-Arthritis questionnaire, shows a considerable validity and reliability, and its psychometric properties are comparable with the original version.

## AB1130-HPR COGNITIVE THERAPY FOR REDUCING THE IMPACT OF RHEUMATOID ARTHRITIS FATIGUE: SUCESSFUL STRATEGIES FOR MEETING TARGETS IN A COMPLEX HEALTH CARE INTERVENTION

Z. Plummer[1], C. Almeida[1], N. Ambler[2], P. Blair[3], E. Choy[4], E. Dures[1], A. Hammond[5], W. Hollingworth[3], J. Kirwan[3], J. Pollock[1], C. Rooke[6], J. Thorn[3], K. Tomkinson[3], S. Hewlett[1]. *[1]University of the West of England; [2]North Bristol NHS Trust; [3]University of Bristol, Bristol; [4]Cardiff University, Cardiff; [5]University of Salford, Salford; [6]University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom*

**Background:** Complex interventions are widely used in modern health care practice and are defined as those having potentially interacting components. Evaluation can be challenging due to difficulties in logistics, standardisation, delivery, recruiting to time and target (particularly in multi-centre studies) and minimising attrition and data loss.

We report how the RAFT study (a 7-centre randomised controlled trial comparing a complex, group cognitive-behavioural intervention with standard care, for the reduction of fatigue impact in patients with rheumatoid arthritis) is implementing successful strategies to meet targets. The study requires patients to make a substantial commitment over a two year period and for the intervention to be delivered by routine clinical staff trained for this purpose.

**Objectives:** To recruit to time and target, ensure intervention delivery, minimise attrition and maximise retention.

**Methods:** Maximising recruitment: Funded research nurse time at all 7 sites, mailshot approach option, recruitment posters, flexible/pragmatic approach to session attendance, telephone, email and postal contact, newsletter and regular knowledge exchange between the central management team and sites, weekly recruitment review. Ensuring intervention delivery: Flexible course dates and times, regular discussions around foreseeable issues and preventative actions, provision of real-time clinical supervision and full-time telephone/email support. Minimising attrition and data loss: Primary outcome collected by telephone ensuring regular personal contact. Secondary data collected by postal questionnaire reducing the number of hospital visits. Telephone reminders, partial withdrawal options, personalised letters and thank you cards. Patient involvement: Acceptability and feasibility consultations with our 2 patient partners. Both have experience of attending the intervention, were co-applicants on the grant proposal and continue to provide the patient perspective as members of the trial management group.

**Results:** Recruitment: Target of 300 participants with no recent medication changes and a fatigue level of $\geq$6 (on a 1–10 scale where 10 is totally exhausted). During the 2 year recruitment phase 333 participants were randomised (11% over target). Intervention delivery: 28/28 programmes successfully delivered with 7/7 sites and 14/15 tutors remaining fully engaged with the study. Attrition and data loss: Retention at 6 months is currently 92.5% (sample size allows for 20% attrition). Data returned by those reaching the 6 month time point is 100% for the primary outcome and 97% for secondary outcomes.

**Conclusions:** Advanced planning and consistent application of these strategies has ensured success so far. A flexible and pragmatic approach, regular communication between local and central teams, personal contact with participants and extensive patient partner input are key components.

## Patient information and education

### PARE0001 THE "SWEDISH YOUNG RHEUMATICS" PARTNERED UP WITH ANOTHER YOUNG IMID ASSOCIATION AND ABBVIE TO PRODUCE AN INFORMATIVE AND HOPE GIVING BOOK ON "STARTING A FAMILY". THE COLLABORATION RESULTED A HIGHLY INFORMATIVE BOOK THAT PROVIDES A WEALTH OF INFORMATION ON FAMILY PLANNING

M. Beermann. *Unga Reumatiker, Bandhagen, Sweden*

**Background:** For patients with an immune-mediated inflammatory disease (IMID), starting a family can seem like a daunting decision due to the lack of information and guidance around how IMID affects pregnancy. In addition to the normal concerns about pregnancy, living with a chronic illness raises complicated questions about the ability to conceive, caring for a young child or even whether patients should become parents given the potential for children to inherit the disease. As patients seek answers – and often find none – they can begin to lose hope, and some may forgo the decision to have a family altogether. The "Swedish Young Rheumatics" partnered up with another young IMID association, "Young with Psoriasis" and AbbVie to produce an informative and hope giving book. The collaboration resulted an informative book that provides a wealth of information on family planning for IMID patients

**Objectives:** We recognized that this was an issue that no one wanted to take on, but something very important in most young patient's life.

The purpose was to create a book that filled the void, something to start a discussion round and something to find comfort and support in for everybody involved.

The book also addresses questions regarding medication, adoption and IVF

**Methods:** In order to show the broadest and truest spectra of the topic, both "Swedish Young Rheumatics" and "Young with Psoriasis" searched through their channels, to find members who wanted to share their stories on the topic. The search was carried out through social media and their member magazines. Singles and couples were interviewed by an external party, finally 7 couples and 4 singles stories reached the book. The stories contain hope, longing, happiness, strength and a lot of questions is raised and answered. Everybody were interviewed in depth and their stories accompanied by beautiful pictures taken in their natural environment. All medical parts of the book were approved and checked by Prof of Dermatology Mona Ståhle and Prof of Rheumatology Lennart Jacobsson.

**Results:** The result is a highly informative photo-filled book that provides a wealth of information on family planning for IMID patients. "Starting a Family" captured a range of positive stories from young couples with IMID conditions who had been successful in starting a family, weaving a narrative of hope and providing definitive answers around family planning. The book has also led to initiated discussions with new target groups such as midwives, and the Associations have reached out with their messages in new channels, which have resulted in new valuable contacts and relationships. The book has been distributed for free to everybody who has got in contact with one of the associations and also to health care, both through the associations and the project partner AbbVie.

**Conclusions:** The Swedish Rheumatism Association believes in the importance of empowering the patients. By offering tools for self-help combined with personal advice from a professional health care worker we can support a general movement towards a healthier lifestyle.

**Disclosure of Interest:** None declared

### PARE0002 A PHOTO-PROJECT ABOUT YOUNG PEOPLE SUFFERING FROM JUVENILE ARTHRITIS

B. Ziegler. *Photographer/Freelancer, Dortmund, Germany*

**Background:** "It is a vicious cycle. Early morning, you wake up. First thought: how much pain will I have today? Can I stand up? Can I move my joints? Can I go to school? Or can I go out later to play with my friends?"

These questions are normal for me, a twenty-five years old photojournalist; and all the other children in the world who suffer from juvenile idiopathic arthritis. Arthritis is a disease commonly considered by the general public to be an "old person's disease". The reality is that many young people live with this disease. The chronic progressive inflammation – primarily of the joints – appears for reasons unknown. It is one of the most common chronic diseases beginning in childhood.

So what does it mean for a child to suffer from this painful chronic disease so early?

**Objectives:** I am a photographer, or a "storyteller", but I am also affected by this disease; making the subject matter deeply personal. My goal is to share the voices of other young rheumatics and show how other young people deal with their arthritis individually. Through the means of photography and personal observations it is possible to create deeper insights into children's perspectives.

**Methods:** Driven by my personal ambitions of starting a professional career as a freelance photographer and living at the same time with a chronic disease, I started to follow young children and teenagers suffering from juvenile arthritis.

In 2014 the project began: for a couple of weeks I moved in with a family who had two arthritic children, in order to photograph their daily life. In 2015, I continued photographing more protagonist all over Germany. From there, the project became part of my final bachelor exam for my current University-level photographic studies. I spent weeks in hospitals in order to capture the realities that these young people are living within. I took part in support group events and weekends. In addition, I followed these subjects in their daily life and free time. My goal was to gain the closest possible relationship that I could with my protagonists.

**Results:** By spending such a considerable amount of time with these young people, I was not just a silent observer, I was part of their life. This helped me develop a deep understanding of their point of view and enabled me to tell their stories. The resulting photo-essay brings together all the different aspects of lives of children with rheumatism.

Juvenile arthritis is a disease which is often not visible. The pain can feel so different on a daily basis and is highly individual. My photographic series tries to approach this fact in an atmospheric way.

Young rheumatics have their ups and downs. One day they may wake up with a lot of pain and be unable to move, if their joints have stiffened. The next day they may feel fine; able to go out and live their lives as regular people. This creates the so called vicious cycle. These young people are obligated to accept these circumstances as continuously present hurdles and factors in their life.

**Conclusions:** The project is intended to be a sensitive example of how young people cope with such a disease. On one hand it is intended give courage to viewers who also have arthritis by showing them that they are not alone. On the other hand, the message is intended to introduce juvenile arthritis to a wider audience; the general public, whom are likely unaware of the realities of this disease.

### PARE0003 WHAT DO I WANT TO TALK ABOUT?

T. Bellerby, D. Stevens, L. Williamson. *Rheumatology, Great Western Hospital, Swindon, United Kingdom*

**Background:** Face to face appointment time between patient and clinician is precious. Patients can wait months between appointments, and usually allow clinicians to take the lead in their consultations. These may concentrate on disease related outcome measures and treatment targets. Patients may not feel able to raise other issues, or may forget to ask about them. Waiting time for appointments is almost inevitable, so to help patients make best use of their waiting time we decided to add a "What Do I Want to Talk About" area.

**Objectives:** To assess patient response to "What do I Want to Talk About".

**Methods:** In the centre of patient waiting area we put up an "What Do I Want To Talk About" A4 poster, encouraging patients to write down the questions important for them to discuss within their consultation. We provided A6 paper sheets and pens for patients to take into their consultations. We asked patients to provide feedback by anonymous questionnaire asking these questions:

Do you think this is a good idea? Yes/No; Have you used it? Yes/No.

Would you use it in future? Yes/No; Other comments?

**Results:** 26 patients completed the questionnaire. Of these, 25 patients (96%) thought it was a good idea. 3 (12%) said they had used these slips previously. 18 (69%) said they would use them on their next visit.

Comments: 'Good Idea thanks. I usually forget what I want to ask when I get in there and then remember on my way home'; "Why hasn't this been done before?"; "I always do notes before my appointments as it helps both doctor and patient"; "This is a really good idea, and thanks for the pen"
Clinician's comments: "Really helpful for consultations, patients seem better prepared "; "I used the same paper to respond to questions and as an aide-memoire for patients"
**Conclusions:** 'What do I Want to Talk About' is a very simple, universally applicable idea which uses minimal resources. It may help some patients better prepare for consultations, and ensure key issues important to patients are addressed during consultations.
**Disclosure of Interest:** None declared

### PARE0004 TOOLS FOR A CUSTOMIZED HEALTHCARE PLAN FOR DUTCH PEOPLE WITH RHEUMATIC DISEASES

R. van den Brink, E. Schouws. *Reumafonds, Amsterdam, Netherlands*

**Background:** It is vital for people with rheumatic diseases to have a suitable healthcare plan in order to cover essential healthcare that is critical to maintain health and quality of life, to treat rheumatic diseases and to prevent high medical costs. Despite the urgency, finding a suitable healthcare plan is complicated: there are many options to choose and healthcare plans differ in coverage of rheumatic disease-specific healthcare (such as physical therapy, foot care and spa therapy), price, medical selection and provider network. Also the time to decide whether to change their healthcare insurer or plan is limited. Consequently, people may decide not to change their healthcare plan at all, at the risk of having an unsuitable healthcare plan in relation to the care they need and paying unnecessarily high medical costs. By developing tools and information, we tried to help people with rheumatic diseases finding a suitable healthcare plan in that short time limit.
**Objectives:** The purpose of this project was to make it less complicated for Dutch people with rheumatic diseases to find a personal healthcare plan which covers their personal needs for healthcare.
**Methods:** Through patient consultation (a survey) we got more insight in the needs, experiences and wishes among rheumatic disease-specific healthcare and healthcare plans. We analyzed the composition, price and conditions of individual healthcare plans concerning rheumatic disease-specific care. We analyzed the reimbursements of healthcare that is essential for patients with a rheumatic disease. In line with this we developed tools.
**Results:** The survey (n=1420) showed that people with rheumatic diseases want: 1. more information about reimbursement of rheumatic disease-specific healthcare, in particular physical therapy, medication and foot care. 2. more insight in personal health needs 3. an aid to compare healthcare plans and find a healthcare plan that fits personal health and budget *needs*.
Responding to these outcomes we developed three tools:
1. A "*checklist*" to make an overview of personal health and budget needs. People can fill in the checklist on their own or together with their care provider(s).
2. A "*healthcare plan comparison tool*" for comparing healthcare plans on rheumatic disease-specific care and finding a healthcare plan that matches with personal health and budget needs.
3. The *checklist* and the *healthcare plan comparison tool* are integrated in the "*Roadmap healthcare plans*". This roadmap guides people through the process of finding a suitable healthcare plan in 5 steps. In addition to these tools, we updated our online information about rheumatic disease-specific healthcare.

**Conclusions:** In response to the tools, we received positive reactions from people with rheumatic diseases. Local patient organizations paid attention to the tools as well. We think we made a step forward by launching interactive tools. With individual needs as a starting point, people can compare healthcare plans. Nevertheless, the Dutch system of healthcare plans is still complex and our information is still extensive. For the Dutch Arthritis Foundation it's important to keep paying attention to useful information and tools for people with rheumatic diseases.

## Building patient led organisations

### PARE0005 BRIEF OVERVIEW OF ENCA (EUROPEAN NETWORK FOR CHILDREN WITH ARTHRITIS)

Y. Egert[1], W. Costello[2], M. Kepic[3]. [1]*Inbar, Tel Aviv, Israel;* [2]*ICAN, Dublin, Ireland;* [3]*Društvo za pomoč otrokom z imunskimi boleznimi, Ljubljana, Slovenia*

**Background:** ENCA, the European Network for Children with Arthritis was founded in 2002 by parents representing national JIA (Juvenile Idiopathic Arthritis) associations from several European countries. ENCA is a broad based association that covers JIA and other orphan joint associated conditions. It is run on a voluntary basis by parents who wish to advance the quality of treatment their children receive through networking, communications and research. ENCA is associated with the Paediatric Rheumatology European Society (PReS) the European scientific society for healthcare professionals in the field of paediatric rheumatology.
ENCA is structured as an informal network between national JIA associations, and is open to all JIA associations.
**Objectives:** As an international networking group, ENCA's role is to gather and circulate information, knowledge, and expertise gathered by individual associations in order to promote knowledge and positive practices among all the associations. This knowledge, in turn, filters down through the national associations to medical systems, parents and sick children, thus upgrading the quality of care offered in each country.
ENCA has three strategic themes:
- Exchange information about the activities of each association
- Promote common projects at European level
- Set up information networks and regular exchanges between associations

**Methods:** Member associations are asked to send representatives to the yearly ENCA conference which takes place in conjunction with the PReS (every 4th year also as part of Eular). A website, closed Facebook group and a yahoo group allow members to have constant communication. International networking helps solve problems faced by all organizations on a national level and parents on an individual level. Pooling resources can help weaker countries acquire better treatment and social services by belonging to an International organization.
In addition ENCA collaborates with Doctor Organizations and research establishments to promote, initiate and facilitate research aimed to advance sick children's needs.
**Results:** Since its inception, ENCA has made advances in both fields: communication between the associations, and research with the medical establishment. Establishing communications between the associations has proven itself as an effective method for solving common problems faced by children in all countries, as well as an opportunity to bring information to the fore. In addition, ENCAs' cooperation with PReS and PRINTO have facilitated two important projects: The SHARE parents' survey initiated by PReS to collect information about the quality of care of JIA patients. The study was conducted through ENCA, allowing for a wider resource base and more accurate results. In addition, ENCA facilitated the translation of the new upgraded PRINTO (The European Union site for information on paediatric rheumatic diseases) site into national languages, thereby enabling access of up to date information to parents.
**Conclusions:** As parents of children with JIA, ENCA has greatly increased our knowledge within all areas of health and social care. It has given us a diverse network allowing us access to a broad source of expertise, knowledge and resources. Through pooled resources it has helped weaker organizations.
**Acknowledgement:** PReS, Share, Printo
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1162

### PARE0006 IDENTIFICATION AND PRIORITIZATION OF RESOURCES FOR RHEUMATIC PATIENTS (REUMAPPA)

M. Gobbo[1], L. Carmona[2]. [1]*Positivamente Centro de Psicología;* [2]*Instituto de Salud Musculoesquelética, Madrid, Spain*

**Background:** Spanish Rheumatology League (Liga Reumatológica Española, LIRE) is developing an application for mobile devices and web browsers that incorporates a map of resources for rheumatic patients and professionals who treat them (Reumappa). This app helps locate with ease professionals and specialized services in rheumatic pathologies in Spain.
**Objectives:** Identify and prioritize resources to be included in Reumappa.
**Methods:** Focus group with characteristic rheumatic diseases patients (Rheumatoid arthritis, Osteoporosis, Sjögren, Scleroderma, Spondylarthritis, Psoriatic Arthritis, Fibromyalgia, Behcet's disease, Lupus, and Osteoarthritis), sex (4 male, 6 female), age (3<45, 5 between 45 and 65, 2>65) and years of disease progression (4<10, 6>10). Key question for identification: "*If you could use an app to obtain information about professionals, services or useful things to cope better with your condition what would you expect to find in it?*" Prioritization was established by scoring from 0 = no relevance to 10 = maximum relevance.
**Results:** Resources that patients identified as important to help them with their disease and their appraisals according to their relevance (mean, SD) are in table 1 (see p. 1322).
**Conclusions:** There are a number of resources that can be helpful for rheumatic patients. Among professional resources most popular medical specialists are rheumatologists, ophthalmologists, pediatricians, gastroenterologists and dermatologists; nonmedical professionals that are considered most necessary are physiotherapists and psychologists. Services identified as most important are patient associations, units specialized in specific pathologies, orthopedics stores and gyms.

## Best practice campaigning

PARE0007 **A SUCCESFULL CAPS RECYCLING PROGECT "NOT SATIATE CAPS"**

A. Phoka Charalambous. *Cyprus League Against Rheumatism, Nicosia, Cyprus*

**Background:** The organization in the effort to implement the goal of social integration of people with RMDs and improve their self-service in order to feel independent and to have self-esteem, presented a need for providing free self-help tools to the members of the association. The need was created because of the economic crisis that exists in the country with all its consequences and, therefore, the high cost of living and reduced resources of people with Rheumatism.
**Objectives:** The main objective is to gain funds for the provision of self-help tools for everyday life and assessment and configuration of house and workplace, of people with Rheumatism. At the same time, the organization aims in The Raise Awareness of Rheumatism and The Raise of Volunteerism.
**Methods:** Use of recycling of caps in order to gain funds. As a result of the public interest, the organization decided to expand the campaign in the Junior and Kindergarten Schools because, children of this age are the best means to transfer the messages we want to convey to society. A collaboration with a Big Insurance Company started for this project, who sponsored the amount of 90000€. The Ministry of Education and Culture became an important supporter and the Media were involved too. Eventually, the recycling company agreed to enlarge their collecting program.
Through this program, we invite children to collect plastic caps from water containers, milk, and any other plastic caps, and place them in yellow plastic bins bought specifically for this purpose by the sponsor and placed in schools.
**Results:** More than 210 schools have declared their participation from the 2 bigger cities in the country. Leaflets have been prepared to share to all students in the schools for informing them and their families about the project, RMD's and organization.
A presentation has been also prepared to be shown to students by volunteers in the schools.
TV and radio advertisements have been prepared with the slogan "Not satiate caps".
A special website has been developed which a simple and understandable educational tool for children on recycling issues and rheumatic diseases as well as for the actions of the program.
A Press Conference has been made for the Campaign by the Organization together with the Ministry of Education and Culture, and the big Sponsor. A competition was launched between the schools participating in the program, with the first three schools from each district being awarded at a special ceremony to be held in May 2016, the total amount of 10,000€.
**Conclusions:** This campaign has successfully managed to: fund raise a big amount for help-self tools to be able to give them free to organization's members to Raise Awareness primarily for the RMD's and the Organization, and last but not least the Protection of the Environment and recycling and to Raise Volunteerism by building the next generation of volunteers.
**Disclosure of Interest:** None declared

## Building patient led organisations

PARE0008 **SETTING UP A YOUTH GROUP: A CHALLENGE WORTH TACKLING – ANMAR'S STEP ZERO PROJECT**

U.G. Viora, S. Ostuzzi, S. Rosi, S. Severoni. *ANMAR Italia, Rome, Italy*

**Background:** EULAR PARE recommendations state that, by 2020, every European country member of the EULAR PARE network should have a youth group within its national association. Through EULAR's Knowledge Transfer Program, ANMAR – Italian national association for people with RMDs –, has made a start in this crucial direction. Before the Step Zero project, dedicated to the creation of Italy's first youth group, ANMAR hadn't promoted any activity specifically targeting young patients yet, counting very of them among its members. Thus, ANMAR was strongly willing to involve this rather invisible portion of RMDs patients and make space for their specific needs.
**Objectives:** ANMAR's Step Zero Project main aim was to identify, get in touch with and involve a first team of young Italian patients willing to be part of the first Italian Group for Young People with RMDs. By applying to EULAR's knowledge Transfer Program ANMAR aimed to share knowledge and learn best practices in creating a youth group by partnering with a country much more advanced than Italy in this field. The project had also an inspirational nature: by getting in direct touch with the young experts from our partner association, Youth-R-Well.com from the Netherlands, our young participants would begin to learn how an Italian youth group could be settled and nourished, this being a mid-term objective within the Step Zero Project.
**Methods:** starting from a real zero step, ANMAR – fruitfully synergic with other Italian associations working in the field of rheumatology (especially the parents' of children with RMDs' associations) – has in the first place collected and shared the existing contacts of young patients. Over three months, 15 young patients willing to be a part of this project have been reached. The Step Zero meeting has taken place in Milan on November 20th, 21st, 22nd 2015, registering the presence of 12 young patients, aged from 18 to 35, reaching Milan from 8 different Italian regions, and two guest speakers from the Netherlands. The meeting has focused firstly on mapping the unmet needs of Italian youth with RMDs, and secondly on thinking about solutions to effectively target those need
**Results:** This first group of participants is currently working on the development of a communication strategy aiming to reach and involve individuals under 35 suffering from RMDs across Italy. ANMAR's Youth Group is now transitioning from Step Zero to Step One, gradually engaging in advocating for better care and quality of life for Italian young rheumatic patients, as well as raising consciousness about the impact of rheumatic diseases on individuals under the age of 35.
**Conclusions:** Setting up a youth group is a very complex and challenging experience, and yet it is a challenge undoubtedly worth tackling. It is fundamental to be able to keep sharing those experiences within the European network EULAR YOUNG PARE, since empowering youth groups across Europe is crucial in order to improve health care for young rheumatic patients, involve them in the life of patients' associations and support their specific – and often still unmet – needs.
**Disclosure of Interest:** None declared

## Best practice campaigning

PARE0009 **ESTONIAN YOUTH AWARENESS OF INVISIBLE CHRONIC DISEASES**

L. Kullamaa. *Hugo Treffner Gymnasium, Tartu, Estonia*

**Background:** Chronic conditions affect people all over the world; over 100 million citizens or 40% of the population in Europe above the age of 15 is reported to have a chronic disease [1]. One of the main tasks of patient organisations is to raise awareness of them. So far, there have not been any studies conducted in Estonia that would show how successful they have been in raising awareness in the general population and among the youth in Estonia.
**Objectives:** The objective of the study was to find out how aware are 15–35 years

old Estonians of chronic diseases, and furthermore, through which channels they first learned about the diseases.
**Methods:** The study focused on the five most prevalent disease groups, out of which were selected specific diagnoses: juvenile idiopathic arthritis, diabetes mellitus, asthma, depression and chronic hypertension. The criteria for choosing the diagnoses were the following: diagnoses that have the most effect on young people are most prevalent or have the highest incidence rate. The data was collected via an online survey, which was spread on different social networks and among the pupils of two secondary schools.
**Results:** In total there were 191 responses from which 172 answers could be used. The average age of the respondents is 20 years. Most of them have heard about asthma (89.5%), diabetes mellitus (89.0%), chronic hypertension (78.0%) and depression (90.1%), but only 29.3% has heard about juvenile idiopathic arthritis. Most of the people, who answered, say that they first heard about the diseases from their family, friends or their acquaintances, 14.5% from television or radio and 13.4% from social media.
**Conclusions:** Although rheumatic and musculoskeletal diseases (RMDs) are one of the most common chronic conditions in Europe, from the results of the study it can be concluded that very few people in Estonia are aware of them. Since RMDs are not directly life-threatening like asthma or diabetes, it could be suggested that patients do not want to disclose their diagnosis to their acquaintances in fear of social stigma and discrimination. However, since this was a quantitative study, it is not possible to point out direct reasons and further qualitative research is needed. Additionally, from the results it can be concluded that the organisations for patients with RMDs should contribute more into raising awareness using the mediums of television, radio, and the internet.

## Patient information and education

### PARE0010 INFLUENCE OF RMDS ON SEXUALITY AND COUPLE'S RELATIONSHIP: AN HARD PROBLEM FOR PATIENTS WHICH REMAINS UNSPOKEN

U.G. Viora, M.G. Pisu, S. Tonolo, G. Voltan. *ANMAR Italia, Rome, Italy*

**Background:** Over 50% of patients consider RMDs as a disabling illness which has a strong impact on sense of self, self-esteem and on the couple's wellbeing.
Many patients tend to deal with these issues independently, passively accepting them in the belief they are unsolvable.
As it is the task of an association to understand, to analyze and to find solutions to the problems of the people represented, ANMAR carried a survey into this problem on Italian patients.
**Objectives:** to evaluate frequency and importance of interferences on the relationship; to identify the main causes and the most useful tools to overcome the problem
**Methods:** inside a larger surveying program set by ONDA (National Observatory on Women's Health) we elaborate a 24 questions questionnaire about RMDs. For this analysis we mostly considered the answers to 10 questions, regarding how patients perceive their health, sense of self, self-esteem and the disease impact on sexuality.
**Results:** we evaluate answers from 719 patients - 2/3 with RA, 3/4 female – 56 years old in average, still working despite illness and pain and with a RA diagnosis over 10 years old in 50% of cases.
The disease is considered as disabling, has a strong impact on physical and mental wellbeing (50% defines their health "not good" or "fair" and refers many sacrifices in daily life due to illness) and on sense of self ad self-esteem: 50% of patients think that illness made him/her different and it has deeply undermined confidence in himself/herself and his own self-image.
Women will suffer more intensely the effects, appearing most suffering psychologically (they are angrier, they feel changed, they are liking less) and physically (they refer stronger pain, they have a more difficult relationship with the therapy and they are forced to more waivers, in home, children and partner care).
50% of those who have a love life says that their sexuality has suffered from the disease for loss of mobility (66%) or decreased sexual desire (50%); 74% did not share the problem with anyone and of these 66% would not want to do it, because they think it is unnecessary.
Males and females similarly perceive the impact of the disease on the intimacy of couples and equally share the problem with someone (25% for both genders), but choose to approach different figures: women their gynecologist (64%), men their partners (50%).
Men are more closed and resigned: only 16% of those who did not mention it, would like to do it, while the percentage rises up to 28% among women.
**Conclusions:** simple information, support and reassurance regarding the perception of self and the intimacy, but also practical tips and tricks to relieve pain or to facilitate mobility during sex, or simply offering communicative cues that lead us to reflect on the problem without aside it with resignation may be enough not to give up living with serenity the intimacy, in keeping with our body and with the limitations the disease imposes.

### PARE0011 LIGAFLASH, BEYOND AN IMAGE. A PHOTOGRAPHIC EXHIBITION

V. Romero Pazos[1], F.J. Carreira Roca[2], A.I. Vázquez Lojo[3], C. Van Riel[3] on behalf of Liga Reumatolóxica Galega. *[1]International Dept., Liga Reumatológica Española; [2]Accesibility Dept., Grupo de Accesibilidad de A Coruña; [3]Board of Directors, Liga Reumatolóxia Galega, A Coruña, Spain*

**Background:** The impact in the Spanish society of the rheumatic disease (RDs) is of 1 out of 5.
The rheumatic diseases are around 250 which affect all ages and can become chronic and be very invasive.
To raise awarness among or society about the social and emotional impact we decided to organize a exhibition of photography.
**Objectives:** Get rid off myths about rheumatic disease from a positive perspective.
**Methods:** The themes that were selected to be represented in the exhibition are the following:
1. Pregnancy and Maternity: On one hand some RDs increase the risk of miscarriage. On the other hand the need of medical treatment to control the disease makes more difficult to get pregnant.
2. Sexuality:Almost a third part of people with arthritis have difficulties in their sexual life because of the disease.
Pain, functional and articular impotence and the selfperception difficult secual relationships.
3. Work Life: RDs are the first cause of physical disability in the western world, according to the Health World Organization, and cause a big economic problem in our country, not because of the sick leaves or the disability pension but because it consumes a lot of sociosanitary resources.
This could be solved by making work policies more flexible with patient autocare.
**Childhood affected by rheumatic diseases:** In Spain, between 8,000 and 10,000 children are affected by RDs, so an specialized attention is needed, according to the President of the Spanish Rheumatic Society (SERPE), because generally this pathologies are associated with old age.
**Results:** Our organization elaborates this project with the intention of showing a new image of the person affected by the rheumatic disease, we leave morbidity behind and search beauty, symbology, sexuality, happiness and demonstrate that beyond illness there is another world, much richer and with variation in the life of a person with any type of disease.
For Galicia Rheumatic League, art is a therapeutical way of enriching the spirit that brings us happiness Therefore we give great importance to the performing arts, dance, painting, photography, cinema, theatre, etc. always with a double purpose: 1. raising awarness; 2. from a normalizing point of view.
All the people involved in this project overcame a personal challenge, the models where patients who where showing a very personal and sensitive part of their life in an image, the photographer trying to capture that important message with his camera, etc.
This exhibition was able to involve the patients family and their social environment as well as to catch the attention of politians and health professionals and is set to travel along the peninsula and abroad.

**Conclusions:** Raising awarness presenting the rheumatic diseases normalized and integrated in our society.
This exhibition has been in diferent cities within the Galician region breaking prejudices and building a different image of the rheumatic disease seeing in the images of the exhibition people who transcend happiness above pain, overcoming the limitation, etc.

## Best practice campaigning

### PARE0012 REVMA CHALLENGE 2015 – GIVE A HELPING GLOVE AND SUPPORT A PATIENT WITH RHEUMATOID ARTHRITIS

H. Smucrova. *Institute of Rheumatology and Czech Rheumatological Society, Prague 2, Czech Republic*

**Background:** Czech League Against Rheumatism plays an important role in promoting rheumatic patients in the Czech Republic. Its activity is aimed at raising awareness about rheumatic diseases, the struggle for full and equal life for people with rheumatic diseases and the establishment of regional clubs of Czech League Against Rheumatism.
**Objectives:** Create a campaign aimed to raise awareness about rheumatoid arthritis - a serious disease that destroys lives insidious way over 100,000 inhabitants of the Czech Republic. When most people understand the nature of rheumatoid arthritis, they can better help the patients manage their daily struggle with the disease.
**Methods:** Creating a campaign... "Give a helping glove and support a patient with rheumatoid arthritis" with the participation of experts from rheumatology and also the participation of personalities from the cultural and scientific life. Rheumatoid arthritis is most often manifested impairment of the joints of the hands. The symbol of the campaign thus became a special glove, developed by scientists from the Institute of Technology in the US, Georgia. These gloves can restrict the movement of the fingers and hand grip strength using metal plates - and faithfully simulate the symptoms of the disease. It can show a healthy people feeling in the shoes of people with rheumatoid arthritis. Creating a video with personalities who use gloves to perform daily activities and leisure activities.
**Results:** The main outcome of the campaign was the debate with an expert on the generation of positioning whitepaper document for timely treatment for patients with rheumatic disease. In response to the campaign has increased the number of members in Czech League Against Rheumatism, an increased number of visitors and fans of the Facebook page Czech League Against Rheumatism. It managed to raise awareness of rheumatic diseases among the general public.
**Conclusions:** This campaign seems to be very useful in influencing the professional and lay public. It is one of the ways how they can be involved in the functioning of the organization.

## Patient information and education

### PARE0013 JUVENILE IDIOPATHIC ARTHRITIS: IT'S NOT JUST AN OLD PERSON'S DISEASE

S.R. Stones on behalf of MyJIA Virtual Expert Advisory Group. *Faculty of Life Sciences, The University of Manchester, Manchester, United Kingdom*

**Background:** Juvenile Idiopathic Arthritis (JIA) is a common form of chronic arthritis in children and young people (CYP), diagnosed under the age of 16 [1,2]. It is a long-term condition (LTC) that is poorly understood by the general public, and can severely impact patient quality of life [3,4]. Therefore, it is important to support CYP in self-managing their condition, particularly as they transition into adult health services. The need for interactive health communication applications (IHCAs) to improve knowledge and health behaviours of CYP with LTCs, supplementary to clinical advice, is well reported in the literature [5]; however, many existing resources are static and do not actively engage CYP in learning about their condition.
**Objectives:** Our research aims to improve the understanding of JIA amongst the general public, musculoskeletal researchers, and CYP living with JIA, using a variety of resources.
**Methods:** Four resources were developed to raise the understanding of JIA: two magazine articles, a presentation to musculoskeletal researchers, and the IHCA, translated from existing static resources produced by charities in the United Kingdom (UK). An expert advisory group (EAG) helped to design, distribute and evaluate the research. Distribution of the resource to CYP with JIA, aged 11 to 18, was achieved via JIA charities across the UK.
**Results:** The Biological Sciences Review article, aimed at young Biologists, focuses on the role of the immune system in JIA, highlighting the impact of the disease on quality of life. The New Scientist article discusses the pathophysiology of the disease, and novel therapies currently used. A presentation at The University of Manchester's Centre for Musculoskeletal Research's seminar adressed a diverse team of researchers, exposing them to JIA and the importance of patient involvement. The IHCA resource takes CYP on an interactive journey about JIA, the medicines that they take, and how they can be proactive in leading a healthy lifestyle.
**Conclusions:** The project helps to raise awareness of JIA. In addition, it is hoped that it will strengthen national and international relationships with regards to user involvement in research. Finally, this research will add to the wealth of literature on eHealth interventions, representing a "smart way of thinking", to improve efficiency in a modern healthcare delivery system, by optimising input from costly professional organisations, in a way that CYP find more accessible.

### PARE0014 PATIENT ADVOCACY FOR BETTER INFORMATION ON BIOSIMILARS AND SWITCHING

G. Korevaar. *Patient advocacy, Dutch Arthritis Foundation (Reumafonds), Amsterdam, Netherlands*

**Background:** During the past ten years, treatments with biologics have proven added value for several inflammatory illnesses, such as rheumatoid arthritis, spondyloarthritis and juvenile arthritis. In 2015, the first biosimilars for infliximab were introduced in the Netherlands. They were welcomed for their financial benefits, but also some questions arose. The Dutch Arthritis Foundation was frequently asked to comment or advise on biosimilars. Yet, we found that clear and unbiased patient information was scarcely available, that opinions differed regarding switching existing patients, and lastly, that there were no recommendations available on switching practices, studies and monitoring.
**Objectives:** As several patents for widely-used biologics will expire the coming years, it was important to approach this development carefully and realistically. We wished to develop patient information and a view on biosimilars that would fit both new patients and existing arthritis patients. And it was clear to us that patients who worried about switching to biosimilars, wished for unbiased and reliable answers. Therefore, we contacted the Dutch Society for Rheumatology (NVR), who were updating their recommendations on biological treatments, and started working closely together with patient organisations, dealing with the same information challenges. And lastly, considering all the strong (financial) opinions around biosimilars, we wanted to raise awareness for the more practical issues and questions, arthritis patients had shared with us.
**Methods:** The Dutch Medicine Evaluation Board (MEB) published its stance in April 2015, permitting the exchange between biological medicines. However, the conditions for switching patients were interpreted differently, as we experienced in panel discussions and workshops with prescribing doctors, pharmacists, pharmaceutical companies and health insurers. Therefore, as patient organisations, we jointly asked MEB for guidance regarding patient information. In July 2015, MEB organised a meeting on biosimilars in the fields of IBD and arthritis, in which we expressed our concerns and asked for careful monitoring of patients and traceability of treatments. After this meeting, MEB started developing a patient information leaflet, involving several patient organisations. We analysed and collected all questions from arthritis patients on biosimilars and switching, and sent those to MEB.
**Results:** While biosimilars were being prescribed and administered, there was hardly any practical information available to patients in 2015, or patient organisations. Most information focused on the biochemistry and interchangeability of biosimilars, but did not answer practical questions on switching conditions, long-term (side) effects or health insurance issues. The MEB patient information leaflet will be ready in January 2016. And we will update our information for arthritis patients afterwards, closely cooperating with NVR.
**Conclusions:** It is interesting and important to learn from the introduction of infliximab biosimilars and the current switching studies. Also to prepare for the near future when biosimilars will be introduced for biological treatments that patients administer themselves. Patients ask for practical information instead of lessons in biochemistry. With suitable patient information, we can try to avoid concerns or prevent that adherence issues arise if medicines look slightly differently, or if the administration and packaging work slightly differently.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4843

## Innovations in arthritis health care

PARE0015 **PATIENT INVOLVEMENT IN THE DESIGN OF TECHNOLOGICALLY-ENHANCED CLOTHING TO HELP MANAGE MUSCULOSKELETAL CONDITIONS**

S. de Souza[1,2], A. Chan[3], C. Simpson[1,2], D. Atkinson[3], D. Williams[3], H. Lempp[1]. *[1]Academic Rheumatology, King's College London; [2]Rheumatology, King's College Hospital NHS Foundation Trust; [3]London College of Fashion, London, United Kingdom*

**Background:** Patients with musculoskeletal conditions manage their symptoms on a daily basis. The physicality of dress demands movement and dexterity that this population often find difficult to perform due to pain and restricted joint mobility. Mainstream garments do not accommodate such concerns; as a result, patients have limited clothing choice and subsequently devise alternate methods of dress. Emerging technologies such as the 'Internet of Things'[1], wearables and biotechnology create the future potential for clothing to be used as a vehicle in the management of musculoskeletal conditions, by which to deliver topical medication and/or provide real time biofeedback to the patient's healthcare team (so their condition can be continuously monitored).
**Objectives:** 1) To design fashionable everyday garments which cater to the needs of patients with musculoskeletal conditions, and 2) to assess the acceptability of incorporating potential technological enhancements.
**Methods:** Four adult participants who met the inclusion criteria (diagnosis of a musculoskeletal condition and ability to communicate in English) were recruited from the Independent Patient Group, part of a London hospital rheumatology outpatient department, by the group's patient co-chairs (SdS and CS). Two males and two females (aged 37–68 years, 3 rheumatoid arthritis: 1 ankylosing spondylitis, disease duration 6–50 years and of diverse ethnic background) agreed to take part in four co-design workshops over a 4 month period in 2015. Workshops were conducted by a student fashion designer (AC). Garment prototypes were presented to patients and continually modified between workshops based on group feedback.
**Results:** Patients wanted a mode of dress to enable independence and provide comfort; whilst maintaining dignity and a sense of self-expression. It was important that the garments were easy to wear, versatile, made of a lightweight breathable fabric and looked like regular clothing (rather than a garment designed for those with additional physical needs). Patients requested minimum fuss with fastenings. The 5 resultant garments had three basic accommodative dress methods: entry from the bottom-up, side and a flip-over mechanism. Once the basic template designs were established, garments could be personalised to suit individual tastes. Patients were receptive to the potential future use of the clothing to deliver topical pain relief medication and would be happy for biofeedback data to be shared with their healthcare team, provided this data could be transmitted securely.
**Conclusions:** Garments can be instrumental in an individual's continued perception of normalcy, control and confidence over their lives. Technologically-enhanced clothing proposes a more personalised and empowering approach to healthcare delivery by way of connecting the interdisciplinary threads of fashion, medicine, new emerging technologies and user-focused design. Clothing is a big part of everyday life; its enhancement can play a welcome, unobtrusive role in the management of patients with musculoskeletal conditions.

## Arthritis research

PARE0016 **FAMILY PLANNING IN WOMEN WITH INFLAMMATORY ARTHRITIS: THE PATIENT'S PERSPECTIVE**

C. Sobrino Grande[1], W.A. Sifuentes Giraldo[1], A. Alía Jiménez[1], C. Medina Quiñones[1], J.F. Borja Serrati[1], C. Redondo Romero[1], L.V. Maldonado Romero[1], M. Grandal Platero[1], C. Velázquez Arce[1], L. León Mateos[2], J. Bachiller Corral[1], M. Vázquez Díaz[1]. *[1]Rheumatology, University Hospital Ramon y Cajal; [2]Rheumatology, University Hospital San Carlos, Madrid, Spain*

**Background:** The inflammatory arthritis (IA) - rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and juvenile idiopathic arthritis (JIA) - affect a significant number of women of childbearing age. Epidemiological studies have shown that the number of births is lower in these patients compared with healthy controls, but the fertility rate is not always decreased. Personal choice of family planning in these patients is influenced by several factors, such as disease activity, use of potentially teratogenic drugs, functional impairment and information received.
**Objectives:** To assess the aspects related to the disease that have greater impact on family planning in women with IA and identify areas for improvement from the point of view of the patient.
**Methods:** We performed a cross-sectional study in women with IA (RA, AS, PsA and JIA) of childbearing age (17–47 years) during the period from June 2014 to July 2015. Two anonymous questionnaires were used for data collection, a questionnaire included clinical data and was completed by the physician and another questionnaire with demographic data, reproductive history and family planning was completed by the patient. Family planning assessment included 16 closed-ended questions about influence of disease activity, secondary concerns and fears, knowledge on diagnosis, treatment and its effects on pregnancy, and information provided by her rheumatologist. All patients signed an informed consent.
**Results:** A total number of 108 women were included. The mean age was 37.4±7.5 years and their diagnoses were: RA 43, AS 31, PsA 19 and JIA 16. The mean age at diagnosis was 27.7±10.2 years and 54% had children (0.82 children/woman). 33% of patients had been a mother before diagnosis and only 20% later (0.24 children/woman), although 40% had considered pregnancy during the disease. IA was considered a conditioning factor for family planning in 70% of cases, and the disease activity was chosen as the most influential factor followed by the treatment. Concerns about disease worsening was found in 64%, transmission of IA to their children in 48% and limitation for care them adequately due to functional impairment in 45%. Half of the patients reported having little knowledge about side effects of drugs on the mother or fetus and have received none or scarce information about pregnancy and breastfeeding from their rheumatologists in 52% and 68%, respectively. More than a third of the patients had considered a new pregnancy if they had received more information. There was no relationship with socio-demographic variables and no significant differences were found in the subgroup analysis (IA type, age, treatment).
**Conclusions:** Women with IA have a low birth rate. The factors with a greater impact in family planning were disease activity and treatment, but were also important the fear of worsening, disease transmission and not be able to care for children properly. Lack of knowledge and information needs to be detected in these patients and should be resolved since the diagnosis. A better understanding of their disease could help these patients to diminish their fears and facilitate family planning in those who wish it.

## Patient information and education

PARE0017 **EULAR YOUNG PARE: THE VOICE OF YOUNG PEOPLE WITH RHEUMATIC DISEASES ACROSS EUROPE**

J. Andersen[1,2,3], S. Stones[1,4,5], P. Balazova[1,6], L. Van Nieuwkoop[1,7], T. Papastavrou[1,8], N. Caeyers[9], F. Klett[10]. *[1]Young PARE, EULAR, Zurich, Switzerland; [2]SLE/LUPUS UNG DK, Figtforeningen, Gentofte, Denmark; [3]Lupus Europe, Essex; [4]Paediatric Rheumatology CSG, NIHR CRN: Children/Arthritis Research, Liverpool; [5]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom; [6]Slovak League Against Rheumatism, Piestany, Slovakia; [7]Youth-R-Well.com, Rotterdam, Netherlands; [8]ELEANA Hellenic League Against Rheumatism, Athens, Greece; [9]ReumaNet Jong & Reuma, Bresserdijk, Belgium; [10]EULAR, Zurich, Switzerland*

**Background:** The group of Young Patients with Arthritis/Rheumatism in Europe (PARE) in EULAR, the European League Against Rheumatism, is a network of young people, from across Europe, living with a rheumatic or musculoskeletal disease (RMD) and working with a patient organisation in their country. They volunteer their time to represent young people with RMDs within EULAR PARE, advocating for better care, communication and quality of life for individuals, under 35, across Europe.
**Objectives:** When the group was established, objectives were designed to:
(1) establish and strengthen national RMD youth groups across Europe; (2) create and support the European network of RMD youth groups to exchange best practices; (3) empower youth leaders; and (4) ensure that the voice of young people with RMDs is heard on all levels in society.
**Methods:** EULAR Young PARE are actively involved in local, national and international activities to support young people with RMDs. Members of EULAR Young PARE developed an action plan to communicate and promote their work, embedding the youth perspective into and supporting all EULAR PARE activities.
**Results:** A strong voice of young people, especially at the Annual European Conference of PARE, has been established, with topics delivered and dedicated to the needs of young people. All PARE activities and projects now entail a young person living with an RMD, feeding back into the Young PARE working group. Furthermore, strengthening collaboration with the EMEUNET network is a leading example of how we learn together.
**Conclusions:** Young PARE have moved forward considerably over the last twelve months, gathering and sharing information about the ways that young people with RMDs are supported in European countries. Now, EULAR Young PARE is continuing to unite patient organisations across Europe, helping to raise awareness and make a difference to young people living with RMDs while challenges remain. It is important to keep the network sustainable, and EULAR Young PARE committed to working on this over the coming years.
