treated with corticosteroids and DMARDs; and *group c)* those who required biologic therapy. Results were expressed as mean±standard deviation (SD) or as median and interquartile range (IQR) as appropriate. Wilcoxon test was used to compare the study parameters at baseline and at the last visit.
**Results:** The mean age±SD of the patients was 68±11 years and the mean±SD follow-up was 24.7±22.7 months. *Group a)* included 11 patients; *group b)* 12 patients treated with methotrexate (MTX) and 2 hydroxychloroquine (in one of them associated to MTX); and *group c)* 9 patients on biologic therapy: adalimumab (ADA) (n=3), tocilizumab (TCZ) (n=5) and rituximab (RTX) (n=1). In this group, 8 patients were previously treated with DMARDS: MTX (n=7) and azathioprine (n=1). The results are shown in the TABLE. Two patients receiving MTX had to withdraw it due to raised liver function test, and two patients who were on TCZ had to discontinue it because of neutropenia. Moreover, one of them had angina pectoris related to a hypertensive episode during the third TCZ infusion.

**TABLE**

| | Group a (n= 11) Only corticosteroids | Group b (n= 12) DMARDS | Group c (n= 9) Biologic therapy |

*p<0.05
# Improvement in at least one clinical manifestation.
In brackets, the number of patients with available data.

**Conclusions:** Corticosteroids are the cornerstone of treatment of noninfectious aortitis, although frequently DMARDS (usually MTX) and sometimes biologic therapy are required. The treatment seems effective and relatively safe.

## SAT0345 HISTOPATHOLOGICAL DIFFERENCES BETWEEN SINGLE-ORGAN CUTANEOUS SMALL VESSEL VASCULITIS AND OTHER CUTANEOUS VASCULITIS ASSOCIATED WITH SYSTEMIC INVOLVEMENT

C. Fernández-Díaz[1], J. Loricera[1], C. González-Vela[2], R. Blanco[1], J.L. Hernández[3], M.A. González-López[4], S. Armesto[4], W. Salcedo[2], M. Marcellán[4], M. López-Escobar[4], M. Lacalle-Calderón[4], V. Calvo-Río[1], F. Ortiz-Sanjuán[1], S. Hermana-Ramírez[2], M.Á. González-Gay[1]. *[1]Rheumatology; [2]Pathology; [3]Internal Medicine; [4]Dermatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*

**Background:** Cutaneous vasculitis (CV) encompasses a wide and heterogeneous group of disorders characterized by the presence of necrotizing inflammatory lesions in the cutaneous blood vessels. Single-organ cutaneous small vessel vasculitis (SoCSVV) is, according to 2012 Chapel-Hill criteria, a vasculitis confined to the skin.
**Objectives:** Our aim was to compare the histopathological findings of skin biopsies from patients with SoCSVV and those with systemic involvement.
**Methods:** From a series of patients with CV, we selected 3 groups: *group a)* SoCSVV; *group b)* CV with systemic involvement; *group c)* subgroup of patients of group b with involvement of 3 organs other than the skin. A comparative study between the group a) with the other two groups (b and c) was performed.
**Results:** *Group a)* was integrated by 9 patients (7 W/2 M; mean age, 64±16 years). In the *group b)* 43 patients were included (18 W/25M; mean age, 54±21 years). The underlying conditions were: severe bacterial infections (n=12), hypersensitivity vasculitis with involvement of other organs besides the skin (n=10), HSP (n=9), panarteritis nodosa (n=4), microscopic polyangiitis (n=2), cryoglobulinemia (n=2), malignancy (n=2), SLE (n=1) and Sjögren's syndrome (n=1). Finally, 7 patients (3 W/4 M; mean age, 50 ± 20 years) were included in *group c)*. The underlying conditions were: severe bacterial infections (n=3), HSP (n=3) and cryoglobulinemia (n=1). The results of histopathological comparison of *group a)* with the *groups b)* and *c)* are shown in the table. Although no parameter reached statistical significance, in our series we observed that the greater systemic involvement was more frequently associated with tissue neutrophilia, pustular dermatosis and deep involvement of arterioles. By contrast, SoCSVV tend to develop greater tissue eosinophilia and tissue lymphocytosis, whilst the intensity of the inflammatory infiltrate was lower. On the other hand, none of the samples of patients with SoCSVV showed involvement of deep arterioles.

| | SoCSVV (a) (n=9) | CV with systemic involvement (b) (n=43) | CV with involvement of 3 organs besides the skin (c) (n=7) |
|---|---|---|---|
| Hodge index#, mean±SD | 6±1 | 7±3 | 6±1 |
| Tissue eosinophilia | 3 (33.3%) | 5 (11.6%) | 0 (0%) |
| Tissue neutrophilia | 4 (44.4%) | 32 (74.4%) | 7 (100%) |
| Tissue lymphocytosis | 2 (22.2%) | 4 (9.3%) | 0 (0%) |
| Intensity of inflammatory infiltrate, mean±SD | 1±0 | 1.4±0.7 | 1.1±0.3 |
| Pustular dermatosis | 1 (11.1%) | 11 (25.6%) | 2 (28.6%) |
| Deep arterioles involvement | 0 (0%) | 5 (11.6%) | 1 (14.3%) |

#Hodge SJ, et al. J Cutan Pathol. 1987; 14: 279–84.

**Conclusions:** In this series we observed that qualitative and quantitative histological differences were correlated with the degree of systemic involvement. However, these results need to be tested in prospective studies with a larger number of patients.

## SAT0346 CUTANEOUS VASCULITIS ASSOCIATED TO CONNECTIVE TISSUE DISEASES AND OTHER AUTOIMMUNE DISORDERS. STUDY OF 35 PATIENTS FROM A SINGLE CENTRE

C. Fernández-Díaz[1], J. Loricera[1], R. Blanco[1], J.L. Hernández[2], V. Calvo-Río[1], F. Ortiz-Sanjuán[1], H. Fernández-Llaca[3], M.A. González-López[3], S. Armesto[3], C. González-Vela[4], M.Á. González-Gay[1]. *[1]Rheumatology; [2]Internal Medicine; [3]Dermatology; [4]Pathology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*

**Background:** Cutaneous vasculitis (CV) can be a clinical manifestation of a connective tissue or other autoimmune disease.
**Objectives:** Our aim was to assess the frequency and clinical features of CV associated to connective tissue diseases.
**Methods:** Study of a large series of 766 unselected patients with CV attended in the same tertiary-care hospital. CV was considered as secondary to connective tissue disease or other autoimmune disorder when occurred in the setting of any of these conditions.
**Results:** In 35 (10 men/25 women; mean age±SD, 48±15 years) of 766 patients (4.57%) CV was associated to the following connective tissue disease or autoimmune disorder: systemic lupus erythematosus (SLE) (n=15), rheumatoid arthritis (n=9), Sjögren's syndrome (n=5), ankylosing spondylitis (n=2), relapsing polychondritis (n=1), Behçet's disease (n=1), sarcoidosis (n=1) and autoimmune hepatitis (n=1). All patients developed vasculitic skin lesions: palpable purpura (n=31), maculopapular erythema (n=4) and urticarial lesions (n=2). The most common CV locations were: lower limbs (n=30), upper limbs (n=12) and trunk (n=10). The mean duration of skin lesions was 13.83±7.62 days. Other clinical features were nephropathy (n=9), joint involvement (n=6), constitutional symptoms (n=4) and gastrointestinal involvement (n=1). Regarding laboratory parameters, elevated ESR was observed in 25 patients, hematuria in 4, anemia in 7 and proteinuria in 5 patients. Immunologic findings were as follows: positive rheumatoid factor (10 of 13 patients tested), positive antinuclear antibodies (15 of 19 patients tested), and decreased serum complement levels (11 of 20 patients tested). Twenty-five patients required some drug for CV: corticosteroids (n=22), cyclophosphamide (n=6), methotrexate (n=5), NSAIDs (n=4), azathioprine (n=4), chloroquine (n=3), hidroxichloroquine (n=2), dapsone (n=1) and rituximab (n=2).
**Conclusions:** CV, although infrequent, is not exceptional in the setting of any connective tissue disease or autoimmune disorder.
**Acknowledgement:** This study was supported by a grant from "Fondo de Investigaciones Sanitarias" PI12/00193 (Spain). This work was also partially supported by RETICS Programs, RD08/0075 (RIER) and RD12/0009/0013 from "Instituto de Salud Carlos III" (ISCIII) (Spain).

## SAT0347 VALUE OF THE DOPPLER-ULTRASONOGRAPHY FOR THE DIAGNOSIS OF TEMPORAL ARTERITIS

C. Aranda-Valera[1], S. García[2], I. Monjo[2], M.J. Rodriguez[1], E. Martin-Mola[2], E. De Miguel[2]. *[1]Rheumatology, University Hospital Jerez, Jerez de la Frontera; [2]Rheumatology, Universitary Hospital La Paz, Madrid, Spain*

**Background:** Temporal Arteritis (TA) is the most common systemic vasculitis in adults. Usually, the diagnosis is based on the American College of Rheumatology (ACR) classification criteria published in 1990 based on the clinical history,

physical examination, laboratory information and histological findings in the biopsy. However, according to the literature, the biopsy can be negative in up to 68% of patients with TA and without it the predictive value diminishes considerably.
**Objectives:** Assess the value of Doppler Ultrasonography for the diagnosis of TA, compared with ACR criteria and biopsy, using the definitive clinical diagnosis of the patient as gold standard.
**Methods:** A retrospective observational, descriptive and analytical study was made, reviewing the clinical history of the patients who had an ultrasound scan of the temporal artery performed in our hospital on suspicion of TA. The standard exploration consists of the bilateral examination of the temporal superficial artery, with its common trunks and the frontal and parietal branches. In the case of diagnostic doubt, the exploration is extended to the occipital arteries and/or axilares. The ultrasound scans were realized and reported by the same person to avoid bias. The variables registered were age and sex, the presence or absence of ACR criteria, VSG value, the final diagnosis and the results of the biopsy and the ultrasound examination as well as the number of affected branches. The statistical analysis was realized by means of the software program SPSS Statistics version 20.0.
**Results:** Of the 451 patients studied, 399 were women and 52 men (88.5% vs 11.5%), with a mean age of 81. Two hundred fifty six patients (58,8%) had a definite diagnosis of TA while 195 (43,2%) presented other diagnoses. Two hundred forty patients (55.79%) fulfilled ACR criteria and 211 did not (46,78%). Of the 166 biopsies, 54 (32,53%) were positive. The validity (sensitivity and specificity) and security (positive predictive value [PPV], negative predictive value [NPV], Likelihood Ratio [LR] + and LR -) of diagnostic tests used were as follows:

| | Sensitivity | Specificity | VPP | VPN | LR+ | LR– |
|---|---|---|---|---|---|---|
| ACR criteria | 65.37% | 62.89% | 70% | 57.82 | 1.7619 | 0.5506 |
| Biopsy | 42.86% | 100% | 100% | 35.71% | | 0.5714 |
| Doppler ultrasonography | 91.60% | 95.83% | 96.62% | 89.76% | 21.81 | 0.0876 |

**Conclusions:** Doppler Ultrasonography shows great validity and safety as a diagnostic test of TA, being in addition, a cheaper and less harsh technique than the biopsy.For this reason its use in clinical practice should be considered a diagnostic option of the first line in the diagnosis of this disease.

## SAT0348 ASYMPTOMATIC DEEP VEIN THROMBOSIS IN ANCA-ASSOCIATED VASCULITIDES

E. Makarov[1], S. Moiseev[1], P. Novikov[2]. *[1]Rheumatology department, First Moscow State Medical University, Lomonosov Moscow State University, E.M. Tareev Clinic of Nephrology, Internal and Occupational Diseases; [2]Rheumatology department, First Moscow State Medical University, E.M. Tareev Clinic of Nephrology, Internal and Occupational Diseases, Moscow, Russian Federation*

**Background:** Chronic inflammatory diseases, e.g. ANCA-associated vasculitides (AAV), are associated with increased incidence of venous thromboembolism (VTE) that can be asymptomatic in a proportion of patients.
**Objectives:** To evaluate a prevalence of asymptomatic deep vein thrombosis (DVT) in a cohort of AAV patients compared with healthy controls.
**Methods:** We used compression US to study the occurrence of asymptomatic DVT in 99 patients with AAV (67 females and 32 males, average age of 54.0 years, range of 18 to 77), including granulomatosis with polyangiitis (GPA; n=72), microscopic polyangiitis (MPA; n=13) and eosinophilic granulomatosis with polyangiitis (EGPA; n=14), and 514 healthy controls (339 females and 175 males; average age of 54.7 years, range of 17 to 89 years) without signs and symptoms of DVT. Signs of activity of AAV were present in 64 patients.
**Results:** Asymptomatic DVT was detected in 8 (8.1%) of 99 patients with AAV, including 3/72 (4.2%) GPA patients, 3/13 (23.1%) MPA patients and 2/14 (14.3%) EGPA patients. All 8 patients with DVT had active vasculitis. In 6 of 8 patients AAV was diagnosed within 6 months prior to US. A prevalence of traditional VTE risk factors was comparable in patients with and without DVT, but prednisolone dose at the time of US was higher in patients with DVT (38.8 vs 10.8 mg daily, $p<0.001$). One patient with asymptomatic DVT died within 3 months after US from acute myocardial infarction, and one patient developed postthrombotic syndrome. There were no cases of pulmonary embolism. AAV was associated with significantly increased risk of asymptomatic DVT compared with healthy controls (OR =22.5, CI 4.7 to 107.7). This risk was even higher in patients with active AAV (OR =36.6, CI 7.6 to 174.5).
**Conclusions:** Patients with AAV have a high risk of asymptomatic DVT within 6 months after diagnosis. These data may justify wider screening for DVT in AAV.

## SAT0349 DURATION OF STEROID TREATMENT IN POLYMYALGIA RHEUMATICA

E. Tang, P. Shah, F. McKenna. *Rheumatology, Trafford General Hospital, Manchester, United Kingdom*

**Background:** The duration of steroid treatment in polymyalgia rheumatic (PMR) is variable. Some patients do not have raised inflammatory markers and anecdotal evidence suggests they may need a shorter duration of treatment. In order to evaluate parameters that may predict the duration of steroid treatment we have undertaken a retrospective analysis of patients on our database with a diagnosis of PMR.
**Methods:** We evaluated patients who presented with new onset PMR to the Trafford Rheumatology Unit between 2005 and 2010. Following a 14 day therapeutic trial of prednisolone 20mg od and a diagnosis of PMR confirmed by a consultant rheumatologist, all patients received a standard reducing regime of prednisolone, reducing every 2 weeks to initial maintenance of alternate day 10mg/5mg after 2 months (if possible). Doses were increased for recurrence of symptoms. After 6 months the dose was reduced to 5mg od if they had not required a dose increase and tailed off once asymptomatic on 5mg od for 6 months. All patients were followed for 10 years or until drug free remission. The electronic records were reviewed for demographic data, blood count, inflammatory markers, liver enzymes, immunology, and duration of treatment prior to drug free remission.
**Results:** 96 patients were evaluated. 15 were excluded from analysis if they had incomplete documentation or because of a positive rheumatoid factor, other immunology or revised diagnosis. The mean age was 68yrs; range 53–90yrs. Female to male ratio was 2.8:1. The median duration of symptoms prior to presentation was 4.5 months (1–36 months). At diagnosis 14% of patients were anaemic, mean CRP was 35mg/l, mean ESR was 45mm/hr and 26% had normal inflammatory markers. Only 1% of patients had raised liver enzymes. 44% were able to reduce to 5mg prednisolone after 6 months and a further 6% after 9 months. The mean duration of steroid treatment for all patients was 30 months (13–108 months). For patients with a normal ESR and CRP at diagnosis, the mean duration of steroids was 22 months compared with 32 months with raised ESR and 35 months with raised CRP. 10% relapsed after steroid withdrawal. 2 patients remained on long term steroids.
**Conclusions:** Approximately 25% of patients with PMR do not have raised inflammatory markers at diagnosis and have shorter total duration of steroids (mean 22 months). Almost half can reduce prednisolone to 5mg after 6 months. The average duration of steroids prior to drug free remission is almost 3 yrs in patients with raised inflammatory markers at diagnosis. 10% relapse after gradual steroid withdrawal.
**Disclosure of Interest:** None declared

## SAT0350 FUNCTIONAL CHARACTERISATION OF TAKAYASU ARTERITIS VASCULAR LESIONS BY MR AND FDG-PET/CT PROVIDES NON-REDUNDANT INFORMATION OVER CLINICAL ASSESSMENT

E. Tombetti[1,2], E. Tombolini[2], E. Incerti[2], A. Salerno[2], G. Benedetti[2], M. Papa[2], L. Gianolli[2], M.G. Sabbadini[1,2], F. De Cobelli[1,2], A.A. Manfredi[1,2], M. Picchio[2], E. Baldissera[2]. *[1]Vita-Salute San Raffaele University; [2]San Raffaele Scientific Institute, Milan, Italy*

**Background:** Disease activity (DA) assessment in Takayasu arteritis (TA) is an unresolved enigma as systemic inflammation and current activity measures poorly correlate with arterial progression. Morphological imaging, e.g. with morphological magnetic resonance (MR) sequencies, is the goal standard to evaluate arterial progression after its occurrence, and it is not clear whether functional characterisation of the lesions (e.g. contrast enhancement at MR or fluorodesoxyglucose [FDG] uptake at FDG-PET/CT [PET]) can predict arterial progression before its occlusion. We are prospectively following 60 TA patients with functional and morphological imaging to understand the predictors of arterial progression. Here we present the baseline assessment of the first 47 patients.
**Objectives:** to verify if activity measures, and functional lesion characterisation with PET or MR provide independent information.
**Methods:** Cross-sectional analysis of 47 TA patients according to ACR criteria followed at our Institution and undergoing closely related MR, PET and clinical evaluation. DA was evaluated with NIH criteria, indian Takayasu activity score (ITAS2010) and physician global assessment (PGA). At MR, arterial lesions were characterized by length, thickness and percentage of stenosis. Contrast to noise ratio (CNR) was calculated, when technically possible. Each vascular lesion uptake large enough to be evaluated by PET was evaluated with a quantitative ($SUV_{max}$) method. Per patients and per lesion analyses were performed.
**Results:** The median interval between MR and PET was 24 days. TA was active in 25, 17 and 35 patients according to NIH criteria, ITAS2010 and PGA (including active and grumbling disease). In total, MR identified 333 arterial lesions (median lesion N per patient 6, IQR 1–15). At the "per patient" analysis, median $CNR_{max}$ at MR was 12,43 (IQR 0,00–54,29). $CNR_{max}$ did not correlate with acute-phase markers nor activity measures, except for ITAS-CRP (rho 0.300, p=0,038). PET showed significant uptake in 18 patients. Meadian $SUV_{max}$ was 1,19 (IQR 0,00–9,00). SUVmax did not correlate with activity measures.
At the "per lesions" analysis, 56 lesions had positive uptake in PET. There was no correlation between the degree of enhancement at MR and of FDG uptake at PET (rho 0,094, p=0,529).
**Conclusions:** Current activity measures, mainly based on systemic inflammation, and functional characterisation of the arterial lesions by MR and FDG-PET provide independent information in TA. The prospective part of this study will clarify the

clinical relevance and the predictive values for progression of these different pieces of information.

## SAT0351 TOCILIZUMAB IN GIANT CELL ARTERITIS: A MULTICENTRE OPEN-LABEL STUDY OF34 PATIENTS

A. Regent[1], S. Redeker[2], A. Deroux[3], P. Kieffer[4], K. Ly[5], M. Dougados[6], L. Eric[5], C. Larroche[7], L. Guillevin[1], L. Bouillet[3], O. Espitia[8], N. Costedoat-Chalumeau[1], M. Soubrier[9], B. Brihaye[10], F. Liferman[11], G. Lefebvre[12], X. Puechal[1], L. Mouthon[1], E. Toussirot[13,14,15]. *[1]Internal Medicine, Cochin Hospital, Paris; [2]Internal Medicine, Centre Hospitalier, Abbeville; [3]Internal Medicine, University hospital, Grenoble; [4]Internal Medicine, Centre Hospitalier, Mulhouse; [5]Internal Medicine, University Hospital, Limoges; [6]Rheumatology, Cochin Hospital, Paris; [7]Internal Medicine, University Hospital, Bobigny; [8]Internal Medicine, University Hospital, Nantes; [9]Rheumatology, University Hospital, Clermont-Ferrand; [10]Internal Medicine, Centre Hospitalier, St Quentin; [11]Internal Medicine, Centre Hospitalier, Dax; [12]Internal Medicine, University hospital, Lille; [13]Rheumatology; [14]FHU INCREASE; [15]Clinical Investigation Center Biotherapy, University Hospital, Besançon, France*

**Background:** Giant cell arteritis (GCA) is a vasculitis of large and medium sized arteries affecting people older than 50 years. Glucocorticosteroids (GC) are the mainstay of therapy but relapses are common, resulting in prolonged treatment course and adverse events. IL-6 correlates with disease activity of GCA and temporal artery biopsy samples show enhanced IL-6 production. Cases series and open label studies reported the efficacy of tocilizumab (TCZ) on symptoms and inflamamtory markers in GCA.
**Objectives:** To report the French experience on the efficacy and safety of TCZ in patients with GCA and the evolution after treatment withdrawal.
**Methods:** A retrospective multicenter study on patients treated with TCZ for their GCA was conducted. Treatment efficacy was evaluated at a clinical and biological level. Side effects and evolution after treatment withdrawal were also recorded.
**Results:** Thirty-four patients (27 women and 7 males) aged 70.5±8.2 (mean±SD) were included. Diagnosis of GCA was based on the ACR criteria (30 patients) and/or on imaging abnormalities suggestive of GCA (8 patients). Giant cell disease was treated by GC and another immunosuppressant was added before TCZ introduction in 20/34 patients. Tocilizumab (8 mg/kg monthly) was introduced after a mean disease evolution of 18 months (0–107). It was efficient in all but 6 patients who still had mild symptoms while CRP was reduced from 40.4 mg/L to 1.5 mg/L ($p<0,0001$) and GC were tapered from 26.3 to 10.3 mg/day ($p<0.0001$). One patient died from a septic shock and 3 patients had to stop TCZ for adverse events. Among the 23 patients who stopped treatment (planned medical decision in 20 cases and side effects in 3 cases) eight patients experienced relapses that occurred after a mean of 3.5±1.3 months.
**Conclusions:** TCZ therapy leads to rapid and maintained improvement in patients with refractory GCA. However, side effects should be kept in mind in this population. Questions remain regarding the suspensive nature of this treatment and this should be specifically studied in future studies.
**Disclosure of Interest:** None declared

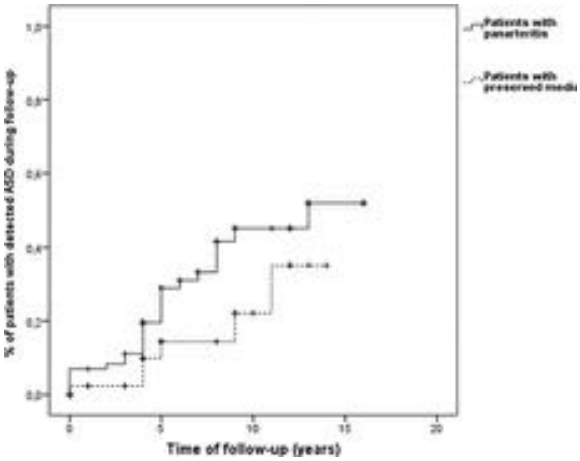
## SAT0352 ANALYSIS OF VARICELLA-ZOSTER VIRUS IN TEMPORAL ARTERY BIOPSIES POSITIVE AND NEGATIVE FOR GIANT CELL ARTERITIS



F. Muratore[1], S. Croci[2], I. Tamagnini[3], A. Zerbini[2], L. Belloni[2], S. Bellafiore[3], L. Boiardi[1], A. Bisagni[3], M. Parmeggiani[2], A. Cavazza[3], C. Salvarani[1]. *[1]Rheumatology Unit; [2]Clinical Immunology, Allergy and Advanced Biotechnologies Unit; [3]Pathology Unit, Arcispedale Santa Maria Nuova IRCCS, Reggio Emilia, Italy*

**Background:** Recent studies found an high prevalence of varicella-zoster virus (VZV) infection in temporal arteries (TAs) from both temporal artery biopsy (TAB)-positive and TAB-negative giant cell arteritis (GCA) patients compared to controls, suggesting that VZV infection may trigger the inflammatory cascade that characterizes GCA (1,2).
**Objectives:** To analyze VZV infection in TAs from patients with TAB-positive GCA (biopsy-proven GCA), TAB-negative GCA (patients with negative TAB and a final diagnosis of GCA) and controls (patients with negative TAB and a final diagnosis different from GCA).
**Methods:** A total of 75 formalin-fixed, paraffin-embedded (FFPE) TABs performed between 2009 and 2012 at a single institution from 30 TAB-positive GCA patients, 15 TAB-negative GCA patients and 30 controls were retrieved. Six 5-$\mu$m sections of all FFPE TABs were cut. The first section was analyzed by immunohistochemistry using mouse monoclonal anti-VZVgE IgG1 antibody (Santa Cruz Biotechnology) and OptiView DAB Detection Kit (Ventana, Roche). DNA was extracted from the remaining 5 sections with the QIAamp DNA FFPE tissue kit (Qiagen) and analyzed by real-time polymerase chain reaction for the presence of VZV DNA (VZV ELITe MGB kit, ELITechGroup). In addition DNA was extracted with the RNA/DNA/Protein purification kit (Norgen Biotek) from 5 positive TABs of 2 mm length obtained from GCA patients and immediately stored frozen at -80°C. Beta globin (included in the VZV ELITe MGB kit) and a short intergenic region were amplified to verify the quality of DNA.
**Results:** 60/75 (80%) patients were female. Mean (± SD) age at TAB was 72.1 (± 8.3) years. There were no significant differences in sex and age distributions between TAB-positive GCA, TAB-negative GCA and controls.
Median (Q1, Q3) time from symptoms onset to TAB was 11 (5.5, 19.3) weeks for TAB-positive GCA, 15 (9, 20) weeks for TAB-negative GCA and 12 (6, 41.6) weeks for controls, p=0.414. 22/30 (73.3%) TAB-positive GCA, 8/15 (53.3%) TAB-negative GCA and 20/30 (66.7%) controls were receiving prednisone at the time TAB was performed, p=0.407.
Immunohistochemical analysis detected VZV antigen in 1/30 TAB-positive GCA, 0/15 TAB-negative GCA and 0/30 controls, p=0.467. DNA obtained from all TABs was amplifiable. DNA obtained from frozen TABs was more concentrated than that obtained from FFPE TABs which allowed to load a higher quantity of DNA per reaction increasing assay sensitivity.VZV DNA was not found in any of the FFPE TABs as well as in frozen TABs but was clearly detected in FFPE skin lesions from patients with active infection (threshold cycle for VZV DNA =26 when 0.5 ng of DNA were amplified).
**Conclusions:** Our data do not support a role for VZV infections in the etiopathogenesis of GCA.

## SAT0353 RELATIONSHIP BETWEEN DISRUPTION OF THE MUSCULAR LAYER IN TEMPORAL ARTERY BIOPSIES OF GCA PATIENTS AND THE DEVELOPMENT OF AORTIC DILATATION/ANEURYSM DURING FOLLOW-UP

G. Murgia[1], J. Hernández-Rodríguez[1], A. García-Martínez[1], S. Prieto-González[1], M.A. Alba[1], G. Espigol-Frigole[1], I. Villar[1], E. Campo[2], M. Sánchez[3], P. Arguis[3], J.M. Grau[4], M.C. Cid[1]. *[1]Vasculitic Research Unit, Dept. Autoimmune Diseases; [2]Dept. Pathology; [3]Dept. Diagnostic Imaging; [4]Dept. Internal Medicine, Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*

**Background:** Giant cell arteritis (GCA) may be complicated by aortic dilatation/aneurysm (aortic structural damage; ASD), which may lead to life-threatening events. In GCA patients, ASD occurs 17.3 times more frequently than in the general population, affecting up to 33.3% of patients after long term follow-up[1]. ASD is in most cases a delayed complication and its pathophysiology is unclear. Necropsy/surgery specimens from patients subjected to standard treatment and control may reveal persistent inflammatory infiltrates but these are usually mild or absent and extensive disruption of elastic fibers is the most striking finding[2]. We hypothesized that extensive loss of vascular smooth muscle cells during the initial injury may prevent regeneration of elastic fibers and contribute to aortic wall weakening and subsequent dilatation.
**Objectives:** To assess whether the extent of medial layer injury in temporal artery biopsies (TABs) predicts subsequent development of aortic dilatation.
**Methods:** We performed histopathological scoring of TABs from all biopsy-proven GCA patients that underwent thoracic CT examination during follow-up for any reason. Aortic diameters in the ascending aorta, aortic arch and descending aorta were measured and ASD was defined as described [1,2]. Histopahotlogical scoring was performed as reported[3]. Fisher exact test and Kaplan-Meier estimates and long-rank test were used for statistical analysis.
**Results:** Between 1995 and 2013, 144 patients with biopsy-proven GCA were

subjected to a chest CT. In 36 (25%) patients, this was part of a prospective screening protocol for large-vessel involvement in newly diagnosed patients[4], in 94 (65.3%) CT was part of a prospective detection of a ASD[2], and in 14 (9.7%) CT was performed for a variety of medical indications. ASD was detected in 34 (23.6%) patients after a median follow up of 55.5 months (range 0–156). In 43 (29.9%) of biopsies inflammatory infiltrates preserved the medial layer and in 101 (70.1%) inflammation was panarteritic severily disrupting the structure of the media which could be hardly identified. ASD was detected at some point in 28 (27.7%) of patients with panarteritic involvement and in 6 (14%) of patients with a preserved media. However, differences did not reach statistical significance (p=0.089). In patients with panarteritic involvement, ASD was detected after a mean follow-up of 53.9 months (SD±37.7) whereas in patients with a preserved media ASD was observed after a mean follow-up of 74.1 months (SD±35.2) (p=0.094).

**Conclusions:** Patients with severe disruption of the medial layer in their temporal arteries at diagnosis had a trend to develop more frequent and earlier ASD, although differences did not reach statistical significance. Further studies are necessary to clarify this point. Supported by Marató TV3 2014/201507

## SAT0354 STUDY OF 13 AORTITIS CASES FROM A SINGLE UNIVERSITY HOSPITAL IN THE LAST 3 YEARS. DIAGNOSIS, TREATMENT AND EVOLUTION

I. Calvo Zorrilla[1], O. Fernández Berrizbeitia[1], M.L. García Vivar[1], E. Ruiz Lucea[1], J.F. García Llorente[1], I. Torre Salaberri[1], C. Gómez Arango[1], J.M. Blanco Madrigal[1], E. Guerrero Basterretxea[1], A. Santander Bilbao[2], E. Galindez Agirregoikoa[1]. *[1]Rheumatology, Basurto University Hospital, Bilbao; [2]Internal Medicine, Basurto University Hospital, Bilbao, Spain*

**Background:** Aortitis is a several and potentially lethal clinical condition. It is usually oligosymptomatic or may present with non-specific symptoms that complicate and delay the diagnosis. On the other hand, treatment of aortitis is not established.

**Objectives:** The objetive of this study is to describe clinical manifestations, laboratory studies and treatment of patients with aortitis in a single center.

**Methods:** We have reviewed the medical records of patients who had positive Positron Emission Tomography (PET) for aortitis fron January 2013 to December 2015 in the Rheumatology Department of a University Hospital. We included 13 cases and we recorded epidemiological, clinical data, laboratory results, treatment and evolution.

Quantitative variable results were expressed as mean±standard deviation (SD) or median (interquatile range-IQR). Qualitative variable results were expressed as percentage. The analysis was performed with the SAS System for Windows V 9.2.

**Results:** In the last 3 years 13 cases of aortitis were diagnosed (3 in 2013, 3 in 2014 and 7 in 2015). The male to female ratio was 3/10. Mean age±SD was 72.23±12.36 years [range, 51–83]. The underlying conditions were: giant cell arteritis (GCA) (n=7), polymyalgia rheumatica (PmR) (n=2), idiopathic (n=2), relapsing polychondritis (n=1) and Sjögren syndrome (n=1). The median interval between the diagnosis of the underline disease and the aortitis was 7 months [1–20]. The most common manifestations were constitutional syndrome (n=5), inflammatory back pain (n=4), pain irradiated to lower limbs (n=4), atypical polymyalgia (n=1) and fever (n=1).

All patients exhibited increased acute phase reactants except for the two patients

TABLE. AORTITIS. CLINICAL, LABORATORY AND TREATMENT FEATURES

| Case | Underlying disease | Months between the diagnosis of underlying disease to aortitis | Constitutional syndrome | Fever | Inflammatory back pain | Pain irradiated to lower limbs | Hb (g/dL) | CRP (mg/dL) | ESR (mm/1st hour) | Initial treatment for aortitis | Months during follow-up | CRP, last visit (mg/dL) | ESR last visit (mm/1st hour) | Last visit treatment |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | Relapsing polychondritis | 20 | no | no | no | no | 11.6 | 3.31 | 35 | Pred (30 mg)+MTX (20 mg)* | 5 | 0.10 | 1 | Pred (5 mg)+MTX (20 mg)+TCZ 800 mg IV |

*were receiving MTX previously

Abbreviations: MP: methylprednisolone / Pred.: prednisone/MTX: methotrexate / TCZ: tocilizumab / GCA: giant cell arteritis / PmR: polymyalgia rheumatica / s.c.: orally / sc: subcutaneous / iv: intravenous /NA: not available

with idiopathic aortitis. Erythrocyte sedimentation rate (ESR) mean was 62±33.84 mm/1st hour and C Reactive Protein (CRP) median level mas 3.3 [2.91–5.13] mg/dl. Five patients presented anaemia.

At the time of diagnosis, 9 patients were receiving prednisone (mean dose, 18.89±19.3 mg/day), 4 were with methotrexate (MTX) (mean dose, 15±5.77 mg/week) and the remaining 3 were not receiving any drug.

Treatment of aortitis was based on the onset or increase in prednisone dose (mean dose, 34.17±9.73 mg/day) in all cases except for one patient who needed surgery for aortic aneurysm. MTX was initiated in 5 patients and its dose was increased in 4 more (mean maximum dose, 14.72±6.43 mg/week). Three patients were treated with methilprednisolone i.v. (0.5 g/day, 3 consecutive days). Tocilizumab (TCZ) was added to therapy in 2 cases due to refractory disease.

In the first visit, two to four months later, the ESR mean was 25.92±24.88mm/1st hour and CRP median was 0.32 [0.16–1.11] mg/dl. In successive clinical controls, after a mean follow-up of 10±4.32 months, clinical and laboratory improvement was maintained.

Four patients had a new PET-TAC control 6–16 months later, 3 of them presented complete remission and another one partial remission.

**Conclusions:** According to our data, clinical and laboratory data are often nonspecific in aortitis. The increase in the diagnosis cases in the last years is probably related to a higher index of suspicion. The presence of GCA or PmR refractory to standard treatment or unexplained raised ESR or CRP, may be red flags for suspecting an aortitis. Treatment with moderate doses of corticosteroids and MTX was effective in most of our patients. In 2 refractory cases, TCZ was useful.

## SAT0355 INHIBITION OF HUMAN AORTIC ENDOTHELIAL IL-6 LEVELS BY CANDIDA ALBICANS WATER-SOLUBLE FRACTION (CAWS)

J.M. Springer[1], D. Smith[1], N. Miura[2], N. Ohno[2], M. Maz[1], K. Dileepan[1]. *[1]Allergy, Immunology and Rheumatology, Kansas University Medical Center, Kansas City, United States; [2]School of Pharmacy, Tokyo University of Parmacy and Life Science, Tokyo, Japan*

**Background:** Serum interleukin-6 (IL-6) has been shown to closely follow disease activity in large vessel vasculitis[1]. Prior research by our group has demonstrated that mast cell degranulation downregulates lipopolysaccharide (LPS) induced aortic expression of IL-6 in vivo. This is accompanied by aortic upregulation of SOCS-1[2]. This effect is lost in histamine 1 receptor knockout mice suggesting that histamine is a primary mediator of aortic IL-6 inhibition. Prior studies have also demonstrated that mice injected with *Candida albicans* water-soluble fraction (CAWS) develop coronary and aortic arteritis[3]. The mechanism through which arteritis is induced by CAWS remains poorly understood.

**Objectives:** The objective of this study is to determine the effects of histamine and CAWS on IL-6 production by human aortic endothelial cells (HAEC) in vitro.

**Methods:** HAEC were cultured with histamine (10$\mu$M), LPS (100ng/mL), CAWS (10$\mu$g/mL), CAWS (1$\mu$g/mL) or a combination of these. After 22 hours, levels of IL-6 and 6-ketoprostaglandin-F1$\alpha$, a breakdown product of prostacyclin, were measured. Microculture tetrazolium (MTT) assays were used to determine cell viability.

**Results:** IL-6 levels were significantly lower in cells treated with CAWS 10$\mu$g/mL compared to controls (175.2±11.9 vs 270.0 pg/mL, p=0.006). Similarly, IL-6 levels were significantly lower with the addition 10$\mu$g/mL CAWS to LPS compared to LPS alone (359.8±37.74 vs 2906.5±318.02, p=0.0001). No significant differences were seen between the 10$\mu$g/mL and the 1$\mu$g/mL CAWS concentrations. Histamine synergistically enhanced IL-6 levels over LPS alone (3758.0±38.18 vs 2906.5±318.0, p=0.028). CAWS had no effect on prostacyclin levels compared to controls. MTT assays demonstrated no differences in cell viability in CAWS or histamine treated cells compared to controls.

**Conclusions:** Our experiments suggest that CAWS inhibits IL-6 production in HAEC. Since IL-6 is a key cytokine in the development of large vessel vasculitis we suspect that endothelial cells do not play a role in CAWS mediated arteritis. Similarly, the inhibitory effects of histamine do not appear to be mediated through endothelial cells. Future research will focus on the in vivo effects of histamine on the development of CAWS mediated vasculitis.

## SAT0356 EXPERIENCE IN THE USE OF 18F-FDG PET/CT IN PATIENTS WITH POLYMYALGIA RHEUMATICA IN HUP LA FE

K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J.L. Loaiza Góngora[2], P. Sopena Novales[2], E. Grau Garcia[1], I. Martínez Cordellat[1], J. Valero Sanz[1], J. Ivorra Cortés[1], L. González Puig[1], I. Chalmeta Verdejo[1], C. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz Sanjuan[1], J. Fragio Gil[1], C. Alcañiz Escandell[1], G. Poveda Marín[1], C. Nájera Herranz[1], V. Fornes Ferrer[3], J. Román Ivorra[1]. *[1]Rheumatology Department; [2]Nuclear Medicine Department, HUP la Fe; [3]Biostatistics Unit, IIS la Fe, Valencia, Spain*

**Background:** Polymyalgia rheumatica (PMR) is an inflammatory disease characterized by pain and stiffness that usually affects the upper body and the pelvis. PMR is related frequently to another inflammatory disorder called giant cell arteritis (GCA), where about 50% of patients present polymyalgia. PET/CT offers functional and molecular information about inflammatory diseases that leads to the vasculitis diagnosis in an early stage, so PET/CT is a useful diagnosis tool to identify CGA associated with PMR

**Objectives:** To evaluate the incidence of GCA in patients diagnosed of PMR.

**Methods:** Prospective study from January 2011 until December 2015 including patients with PMR from the Rheumatology Department of HUP La Fe. In all cases to confirm the diagnosis of vasculitides an 18-FDG PET/CT was made. Also blood analysis that includes CRP and ERS, US and biopsy and treatment with esteroids or another DMARD was done. Statistical analysis was performed using R software 3.2.3.

**Results:** 23 patients with PMR diagnosis according to established Bird/Wood criteria were included, with a mean age at the time of PET/CT of 69.3 years (38–85). 18 were treated with steroids before PET/CT and 11 had another DMAR during follow up.

In 47.8% of patients vasculitis was detected using PET/CT. Most frequent injury locations were aorta, iliac artery, and femoral artery. In these patients there is an increase in the CRP value (P=0.03) comparing to those without vasculitides. There were no significant differences in the ESR value or in the DMAR administration.

**Conclusions:** PET/CT is a useful diagnostic tool for the early diagnosis of vasculitides associated with PMR. This allows an early and adequate treatment in order to avoid structural damages within the blood vessel (aneurysms, stenosis, oclussions), reducing morbi-mortality and fatal outcomes.

**Disclosure of Interest:** None declared

## SAT0357 COMMON AND UNCOMMON MANIFESTATIONS OF GRANULOMATOSIS WITH POLIANGIITIS (GPA) AT CHEST CT: A VASCULITIS CENTER EXPERIENCE

O. Taydas[1], L. Kilic[2], Z. Atceken[3], A. Erden[2], B. Armagan[2], A. Sari[2], A. Akdogan[2], I. Ertenli[2], O. Karadag[2], M. Ariyurek[1]. *[1]Department of Radiology, Hacettepe University Faculty of Medicine; [2]Hacettepe University Vasculitis Center (HUVAC), Ankara; [3]Department of Radiology, Koc University Faculty of Medicine, Istanbul, Turkey*

**Background:** Lung involvement is not only a presenting finding but also might have widespread pathologic findings in Granulomatosis with Poliangitis (GPA). Even though chest computed tomography (CT) has superior sensitivity and specificity for evaluation of the airways, lung parenchyma and mediastinum, there are only a few studies regarding detailed analysis of Chest CT findings in GPA.

**Objectives:** To evaluate pulmonary pathologies in GPA at the time of diagnosis with CT.

**Methods:** Hacettepe University Vasculitis center is one of the main referral centers in the country. All patients starting from October 2014 have been included and defined according to the 2012 revised Chapel Hill nomenclature criteria. Our database was screened for patients with GPA. Totally 98 patients were evaluated and 43 patients were excluded since missing data. Fifty-five patients (Female: 31 (56.4%), were included in further analysis. Demographic and clinical findings were recorded. CT scans were read by two different radiologists who were aware of the diagnosis GPA, but unaware of the phase of disease. Final CT findings were reached in consensus. The following CT findings were evaluated: Parenchymal nodules or masses, ground-glass opacification or consolidation, tracheobronchial involvement, pleural irregularities, pleural effusions, hilar and mediastinal lymphadenopathy, cardiomegaly, pericardial effusions and vascular abnormality.

**Results:** The mean age was 51.5 (16.0) years and ANCA positivity (MPOANCA/PR3ANCA: 15/29) was in 80% of patients. 76.4% of patients (n=42) have any of CT findings. In 70.9% (n=39) of patients had parenchymal involvement and most commonly observed findings were nodules/masses in 24 (43.6%) patients, ground-glass opacification or consolidation in 22 (40.0%) patients. These parenchymal findings were bilateral in 87.2% (34/39) of patients. A combination of both patterns were also available in 17.9% (7/39) of patients. Of examinations with nodules; 70.8% (17/24) demonstrated more than five nodules, and 33.3% (8/24) had cavitary lesions. Pleural effusions were seen in 13 patients (23.6%) and 46.2% (6/13) of them were bilateral. Hilar or mediastinal lymph node enlargement was discovered in 6 (10.9%) patients and all also had parenchymal involvement. In only two patients had tracheobronchial involvement; one was subglottic stenosis, the other was thickening of bronchial wall. Pericardial effusion and/or cardiomegaly was detected in 9 (16.4%) patients and all these patients also had parenchymal involvement. In subgroup analysis according to ANCA positivity and sex, pulmonary nodules/masses were more frequent in ANCA positive patients (50%vs. 18.2%, p=0.057). And ground-glass opacification or consolidation were more often in males (54.2% vs. 29.0%, p=0.059).

**Conclusions:** Even though at disease onset, most of GPA patients had any of pulmonary pathologies observed by CT. Not only nodules/masses and consolidation/ground-glass opacification were seen but also pericardial effusion and/or cardiomegaly, tracheobronchial involvement and subglottic stenosis could be found. ANCA positivity and sex might contribute pulmonary pathologies. Further studies are required.

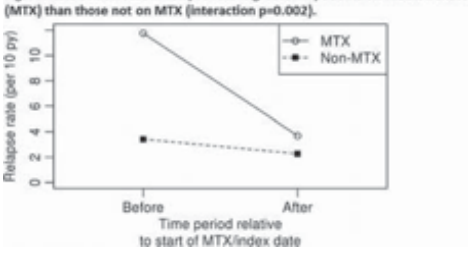
## SAT0358 EFFICACY OF METHOTREXATE IN GIANT CELL ARTERITIS

M.J. Koster[1], C. Crowson[2], C. Labarca[3], F. Muratore[4], K.J. Warrington[1]. *[1]Rheumatology; [2]Health Sciences Research, Mayo Clinic, Rochester, United States; [3]Rheumatology, Clinica Alemana de Santiago, Santiago, Chile; [4]Rheumatology, Azienda Ospedaliera Arcispedale Santa Maria NuovaIRCCS, Reggio Emilia, Italy*

**Background:** Prospective trials evaluating methotrexate (MTX) as adjunct immunosuppression in Giant cell arteritis (GCA) have provided evidence of a modest benefit for reducing risk of relapse and decreasing glucocorticoid exposure. Limited information is available regarding the use of this medication in routine clinical practice.



**Objectives:** To determine the effect of methotrexate on relapse risk and glucocorticoid use in a large single-institution cohort of patients with GCA.

**Methods:** A retrospective review of patients diagnosed with GCA from 1998–2013 was performed. Patients diagnosed with GCA were ≥50 years and had either a temporal artery biopsy (TAB) that was consistent with GCA or radiographic evidence of large vessel vasculitis. Each patient with GCA treated with adjunct MTX (case) was matched to a similar GCA patient without MTX (control). Cases and controls were matched on age, sex, disease duration at start of MTX and initial corticosteroid dose. Each control was assigned an index date to make the number of days from GCA diagnosis to index date in the control equivalent to the number of days from the GCA diagnosis to the start of MTX in cases. Baseline demographics, disease characteristics and relapse events were abstracted. Glucocorticoid requirements and relapse events before and after methotrexate initiation (or corresponding index date) were compared using rate ratios.

**Results:** A total of 84 patients with GCA receiving MTX were identified and compared to 84 patients with GCA receiving only prednisone. Mean age at diagnosis 69.5±7.0 years in cases and 70.3±6.9 in controls. No significant differences in demographics, laboratory parameters or baseline disease characteristics were observed between groups. Mean initial prednisone doses were similar (53.5±15.8 mg/day in cases, 55.0±13.5 mg/day in controls). The median (interquartile range [IQR]) time from GCA diagnosis to MTX initiation in cases was 0.7 (0.3, 1.6) years and the median (IQR) starting dose was 13.5 (10, 15) mg per week.

Prior to MTX initiation the observed relapse rate was 11.8 relapses per 10 person-years and decreased to 3.69 relapses per 10-person years following initiation. The rate ratio comparing relapse rates observed after MTX to the rate prior to initiation was significantly reduced; rate ratio (95% CI): 0.31 (0.24, 0.41). In the control group the relapse rate was 3.42 relapses per 10 person-years before the index date and 2.27 relapses per 10 person-years following the index date [rate ratio (95% CI); 0.66 (0.45, 0.99). Although both groups had a reduction in relapse rate ratios, the rate of decrease in relapse rate was significantly greater in patients on MTX than those not on MTX (p=0.002) [figure].The ratio of rates after MTX initiation/index date for achieving steroid doses <10 mg/day for >6 months or steroid discontinuation >6 months did not differ for cases and controls.

Figure: Rate of decrease in relapse rate is greater in patients on methotrexate (MTX) than those not on MTX (interaction p=0.002).

**Conclusions:** In this large single-institution cohort, the addition of methotrexate to glucocorticoid decreased the rate of subsequent relapse by 2-fold compared to patients on glucocorticoids alone. Methotrexate should be considered as adjunct therapy in patients with relapsing GCA to decrease the risk of further relapse events.

## SAT0359 EVALUATION OF MEDICATION COMPLIANCE IN BEHÇET'S DISEASE

M. Cinar[1], F.I. Cinar[2], S. Yilmaz[1], C. Acikel[3], M. Cakar[1], I. Simsek[4]. *[1]Division of Rheumatology, Gulhane Military Medical Academy, School of Medicine; [2]School of Nursing, Gulhane Military Medical Academy; [3]Department of Biostatistics, Gulhane Military Medical Academy, School of Medicine; [4]Division of Rheumatology, Guven Hospital, Ankara, Turkey*

**Background:** The management of Behcet's disease (BD) should be tailored to each patient by taking into account the existing symptoms, clinical manifestations and prognostic factors. Since there are effective treatment alternatives for each manifestation, the patient's adherence to treatment is one of the most important elements for a successful management of the disease. Adherence to treatment in patients with BD is not known well

**Objectives:** To investigate the compliance status to drug therapy in patients with BD.

**Methods:** This study was conducted at the rheumatology outpatient clinic of a tertiary hospital and 125 BD patients were included. Patient interview form, the Turkish Translation of the Compliance Questionnaire on Rheumatology (2015) (CQR-T; score 0–100), validated by Cinar et al, and Morisky Medication Adherence Scale, developed by Morisky (1986), were used to determine the sociodemographic and medical characteristics. In addition, disease activity was evaluated with Behcet's Syndrome Activity Score (BSAS, score =0–100) and Behcet's Disease Current Activity Form (BDCAF; score =0–12).

**Results:** The mean age of the patients was 31.42 ± 8.11 years and 91.2% were male. The mean disease duration, age at diagnosis, BDCAF score and BSAS score of patients were 9.34 ± 5.76 years, 25.02 ± 7.82 years, 4.79 ± 2.05 and 45.22 ± 23.56, respectively. 76.8% of the patients were using colchicine, 44.8% azathioprine, 16.0% corticosteroids, 4.8% cyclosporine, 4.0% cyclophosphamide, 4.0% infliximab, 3.2% non-steroidal anti-inflammatory drugs, 2.4% methotrexate, 1.6% sulfasalazine and 7.2% were using anticoagulants. 40 patients (32.0%) experienced drug-induced side effects. The total CQR-T score of patients was 66.48 ± 13.49 (min: 19.30-max: 94.74). According to the Morisky Medication Adherence Scale, medication compliance score of the patients was high in 25.6%, medium in 55.2%, and lower in 19.22% of patients. The total Morisky Medication Adherence Scale score was 1.43 ± 1.16 (min-max, 0–4). The demographic/medical characteristics of the patients (age, sex, marital status, education level, employment status, social support status, treatment, transportation, disease duration, symptom onset time, BSAS, BDCAF, ESR and CRP) had no association with total CQR-T scores. The total CQR-T score had a significant but weak correlation (r =0.197; p=0.027) with the age at diagnosis.

**Conclusions:** In our study, it was found that the majority of treated patients were at an intermediate level of compliance status. Adherence to treatment status of patients increases with increasing ages at diagnosis. This study emphasizes the necessity of developing new strategies for increasing the patients' adherence.

## SAT0360 HENOCH - SCHÖNLEIN PURPURA IN ADULTS: DATA FROM A REFERRAL CENTER IN SWEDEN

N. Marketos[1], M. Segelmark[2,3]. *[1]Department of Rheumatology; [2]Division of Drug Research, Department of Medical and Health Sciences; [3]Department of Nephrology, Linköping University Hospital, Linköping, Sweden*

**Background:** Henoch-Schönlein purpura or IgA vasculitis (IgAV) is a systemic vasculitis encountered both in children and adults. It may lead either to single-organ vasculitis as cutaneous IgAV or a systemic disease[1]. IgAV in adults is considered to have worse clinical features and outcome compared to that of children[2].

**Objectives:** Retrospective analysis of 43 consecutive adult IgAV patients referred to a secondary and tertiary referral centrum in a Swedish university hospital between 2008 and 2014.

**Methods:** Electronic records of patients were reviewed. EULAR/PRINTO/PRES and ACR criteria for diagnosis and EUVAS criteria for disease activity were applied[3]. MedCalc Statistical Software version 15.11.4 (MedCalc Software bvba, Ostend, Belgium) was used.

**Results:** Twenty-eight of the patients were male and 15 female. Mean age at disease onset was 43 (SD=21) years. Ten of 43 patients (23%) suffered an upper respiratory tract infection prior to disease onset. All 4 major organs were involved in 12/43 patients (28%). Skin vasculitis was present in 40 (93%), arthritis in 13 (30%), gastrointestinal involvement in 22 (51%) and renal manifestations in 29 patients (67%). Nine patients (21%) had positive findings from either endoscopy or computed tomography. Twenty of 34 patients examined (59%) had various cellular casts. Seventeen patients (40%) had albuminuria and 29 (67%) hematuria. Skin biopsy showed leucocytoclastic vasculitis in 63% of all 43 patients. IgA was shown in 9/11 renal (82%) and in 27/29 (93%) skin biopsies. Five skin biopsies had IgM deposition whereas 3 had both IgM and IgG. All 8 patients had renal involvement ($\chi^2$=4,12, p=0,04). Regarding treatment, 86% of the patients received prednisolone while 30/43 (70%) were given other immune therapy, namely mycophenolate mofetil in 6/43 (14%). Time to joint remission was shorter for women (p=0.04) but renal remission was shorter for men (p=0.001). Thirty out of 43 patients (70%) had just one incidence of IgAV while 9/43 (21%) had more than one episode, in some cases even 4 or 5 relapses.

**Conclusions:** These results confirm those from other centra[2] in an attempt to elucidate IgAV in adults. Time to remission is to our knowledge not previously studied. Unique in this study was the finding that joint response was statistically significant slower in men than women and the opposite was observed regarding renal response. IgM deposition in skin biopsy was associated to renal involvement. The outcomes may vary depending on period of follow-up and age of patients. In the lack of therapeutic consensus guidelines, treatment continues to be symptomatic and immunomodulation regimens are reserved for those with more severe disease. These results need to be confirmed in larger cohorts.

## SAT0361 KIDNEY INVOLVEMENT IN MICROSCOPIC POLIANGIITIS – RUSSIAN EXPERIENCE

N. Bulanov, E. Shchegoleva, E. Kuznetsova, P. Novikov, S. Moiseev. *Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Objectives:** Our aim was to assess frequency, clinical features and prognosis of renal involvement in microscopic poliangiitis (MPA) and used treatment modalities based on experience of Clinic of Nephrology, Internal and Occupational diseases in Moscow, Russia.

**Methods:** We performed a retrospective analysis of 61 patients with MPA, diagnosed according to Chapel-Hill Consensus Conference 2012, 23 male and 38 female, who were followed over a median of 29 (11;74) months. 58 patients (95.1% of 61) had a history of active renal vasculitis. Rapidly progressive glomerulonephritis (RPGN) was defined by the doubling of serum creatinine in $\leq$3 months. Acute kidney injury (AKI) and chronic kidney disease (CKD) stages were diagnosed according to KDIGO 2012 definition.

**Results:** In 43 patients (74.1%) renal involvement developed at the onset of the disease. Other 15 (25.9%) developed glomerulonephritis after a median of 7 (6;14) months. All patients had active urinary sediment; hematuria was present in 55 (94.8% of 58) patients; 8 patients (13.8%) developed nephrotic syndrome. Nephrogenic hypertension was present in 27 (46.5%) patients. RPGN developed in 35 patients (60.3% of 58), 6 of them (17.1%) also had nephrotic syndrome. During follow up 12 patients (20.7%) developed AKI, stage 2 was diagnosed in 5 patients, stage 3 in 7 patients. In 9 patients (15.5%) AKI developed during their first admission to the hospital. Renal involvement was confirmed by kidney biopsy in 9 cases (15.3% of 59).

By the end of the follow-up CKD stage 1 was diagnosed in 9 (15.5%), stage 2 in 13 (22.4%), stage 3A in 9 (15.5%), stage 3B in 12 (20.7%), stage 4 in 10 (17.3%) patients and only 5 (8.6%) developed end-stage renal disease (ESRD). Three more patients were likely to develop ESRD, but they died before it could be diagnosed according to KDIGO criteria. ESRD developed in 9 (8;13) months from the onset of the disease. A total of 4 patients (6.8%) died.

As the first line induction therapy all patients received corticosteroids (CS), 51 (87.9%) – cytotoxic agents, predominantly cyclophosphamide (90.3% of 51), and 4 (6.9% of 58) – rituximab (RTX). Plasmapheresis was used in 13 (22.4%) patients. Complete remission was achieved in 40 (69%) patients who received cytotoxic agents and/or CS, 14 (24.1%) developed partial remission, in 4 (6.9%) remission was not achieved. During follow up 18 patients received RTX for remission induction due to refractory disease in 12 (66.7%), severe relapses in 2 (11.1%) and/or CS and cytotoxic agents side effects or intolerance in 8 (44.4% of 18) patients. Thirteen (72.2% of 18) patients achieved complete remission on RTX, 3 (16.7% of 18) achieved partial remission, in 2 (11.1%) RTX was ineffective. 29 patients (50%) developed one or more severe relapses during follow-up; corresponding to a relapse rate of 0.186 per patient per year. Renal relapses developed in 21 (36.2%) patients, with a renal relapse rate of 0.105 per patient per year.

**Conclusions:** Our research revealed considerably lower prevalence of ESRD and fewer lethal outcomes in patients with MPA when compared with the published data. Nevertheless more than a half of patients develop RPGN during the course of the disease, and 46.6% have CKD stage 3B or worse by the end of the follow up. Despite effective induction therapy with high-dose CS, cytotoxic agents and/or RTX relapses, both renal and extrarenal, are frequent.

## SAT0362 MYCOPHENOLATE MOFETIL VERSUS METHOTREXATE IN THE MANAGEMENT OF LARGE VESSEL GIANT CELL ARTERITIS

P.I. Dospinescu[1], M. Karabayas[1], D. Kidder[2], N. Fluck[2], L. Erwig[2], J. Mason[3], N. Basu[1]. *[1]Rheumatology; [2]Renal Medicine, NHS Grampian, Aberdeen; [3]Rheumatology, Hammersmith Hospital, London, United Kingdom*

**Background:** There is an unmet clinical need to identify an effective conventional adjuvant immunosuppressive agent in the treatment of large vessel giant cell arteritis. Traditionally the therapeutic approach has employed prolonged courses of high dose glucocorticosteroids (GC) with poor long-term outcomes. Methotrexate (MTX) is currently recommended as adjuvant GC sparing immunosuppression based on modest evidence[1,2]. Evidence for the use of Mycophenolate mofetil (MMF) in this setting is lacking.
**Objectives:** We investigated the outcome of MMF and MTX usage in an extended cohort of large vessel giant cell arteritis (LVV-GCA) patients from 2 large tertiary centres in the United Kingdom.
**Methods:** We retrospectively analysed laboratory and treatment outcomes for United Kingdom patients diagnosed with LVV-GCA between January 2008 and January 2015 who attended two geographically distinct specialist Vasculitis Clinics. The two centres use different first line GC sparing agents in LVV GCA, one generally uses MMF the other MTX.
Following retrospective record review, cases were selected based on radiologic evidence of large vessel vasculitis, fulfilment of the Chapel Hill Consensus Conference 2012 GCA definition and a first line prescription of GC with adjuvant MMF or MTX. Baseline and follow up characteristics were collated. Unpaired t-test was used to compare differences between the groups.
**Results:** Twenty patients (7 male) were identified in total: 11 patients (3 male) treated with MMF and 9 patients (4 male) treated with MTX. Mean age (SD) at diagnosis was 66.15 (7.1) years with the MMF group being older (68.9 (5.9) versus 62.7 (7.2) years). Positron emission tomography–computed tomography (PET CT) confirmed evidence of active large vessel vasculitis in all patients.
At diagnosis, there was no significant difference between the mean CRP value between the two groups (56.1 (46.9) versus 47.7 (34.3) mg/l, p=0.67). Following 6 weeks of treatment, there was a dramatic reduction in the mean CRP level in both groups (8.1 (8.7) versus 3.1 (2.2), p=0.14), a response which was maintained at one year (7.6 (5.8) versus 4.5 (3.1), p=0.16). Although at diagnosis Prednisolone dose was higher in the MMF group (54.5 (9.3) versus 41.1 (17.6) mg, p=0.042), no significant difference was found between the groups at 6 weeks (24.1 (5.4) versus 29.1 (12.8) mg, p=0.26) and throughout the year (8.4 (2.8) versus 5.8 (3.7) mg, p=0.1 at one year)
**Conclusions:** To our knowledge, we describe the first case-series of MMF use in LV-GCA.
Within the limitations of this study, MMF appears to be comparable to MTX as adjunctive therapy in patients with LV-GCA, allowing a rapid taper of GC. A randomized controlled trial is required to further evaluate the role of MMF in this challenging disease subset.

## SAT0363 A SYSTEMATIC LITERATURE REVIEW ON THE TREATMENT OF SKIN, MUCOSA AND JOINT INVOLVEMENT OF BEHÇET'S SYNDROME INFORMING THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF BEHÇET'S SYNDROME

P. Leccese[1], Y. Ozguler[2], R. Christensen[3], S.N. Esatoglu[2], I. Olivieri[1], H. Yazici[2], G. Hatemi[2]. *[1]Rheumatology Department of Lucania, San Carlo Hospital, Potenza, Italy; [2]Internal Medicine, Division of Rheumatology, Cerrahpasa Medical School, Istanbul, Turkey; [3]Musculoskeletal Statistics Unit, Bispebjerg and Frederiksberg Hospital, The Capital Region of Denmark, Denmark*

**Objectives:** The aim of this systematic literature review was to inform the task force for updating the European League Against Rheumatism recommendations for the management of Behçet's Syndrome (BS), about the evidence for treatment of skin, mucosa and joint involvement of BS.
**Methods:** A systematic literature search, data extraction and statistical analyses according to pre-specified and protocolised eligibility criteria were performed using the GRADE approach. The protocol for the review was registered and is available at PROSPERO (CRD42015027033). The Cochrane Library, including the Cochrane Central Register of Controlled Trials (CENTRAL), Cochrane Database of Systematic Reviews (CDSR), Database of Abstracts of Reviews of Effects (DARE), Health Technology Assessments (HTA), MEDLINE (from 1950), EMBASE (from 1980) and International Pharmaceutical Abstracts Database (IPAD) were systematically searched. Randomised controlled trials (RCT), non-randomised controlled clinical trials and open label trials (OLT) on BS comparing an active intervention (alone or in combination) with any control or placebo were eligible. If controlled trials were not available for answering a specific research question, uncontrolled evidence from cohort studies or case series involving $\geq$5 patients were considered. The quality of evidence was assessed by using the GRADE approach. Risk ratios were calculated for the binary outcomes whereas for the continuous outcomes we calculated the standardized mean difference (SMD).
**Results:** Among the 3927 references that we have screened, 22 studies satisfied the inclusion criteria for mucocutaneous involvement and 15 studies for joint involvement. Seventeen of these studies were RCTs assessing mucocutaneous and/or joint involvement. RCTs with colchicine, azathioprine, interferon-alpha, thalidomide, etanercept and apremilast showed different levels of beneficial results on different types of skin and mucosa lesions and arthritis. Differences in the outcome measures that were used across the included studies made it difficult to compare the results. These agents were generally well tolerated with few adverse events causing withdrawal from the study in BS patients.
**Conclusions:** It was gratifying to see that randomised trials formed the majority (17/22, 77%) of the sources forming the basis for the recommendations related to skin mucosa and joint involvement in the updated EULAR recommendations for the management of BS.
**Disclosure of Interest:** None declared

## SAT0364 PENTRAXIN 3 AS BIOMARKER IN ASSESSMENT OF DISEASE ACTIVITY IN TAKAYASU ARTERITIS

P.K. Devarasetti, S.K. Appani, R.V.P. Irlapati, L. Rajasekhar. *Dept. of Rheumatology, Nizams Institute of Medical Sciences, Hyderabad, India*

**Background:** In Takayasu arteritis (TA) Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are used to monitor disease activity. Thirty percent of patients with active inflammation have normal ESR while 40% without vascular inflammation have elevated ESR.[1] Pentraxin 3 (PTX3) produced in vascular wall during inflammation, may be a better biomarker of disease activity.
**Objectives:** To compare PTX3 levels in TA patients with healthy controls and to compare the accuracy of PTX3 levels with high sensitive CRP (hs CRP) and ESR in distinguishing active from inactive disease.
**Methods:** Cross sectional prospective study conducted from 2014 to 2015.Forty consecutive TA patients fulfilling 1990 American College of Rheumatology criteria for TA and 20 healthy controls were included. Disease activity was assessed by Physician Global Assessment (PGA), Indian Takayasu Arteritis Score (ITAS)[2] and ITAS-ESR. Serum PTX3 levels (pg/ml) was measured in TA patients and controls, hsCRP (ng/ml)and ESR (mm/hr)were measured in TA patients. Based on PGA patients were divided into active, grumbling and inactive disease.Serum PTX3, hs CRP and ESR were expressed as mean (SD). ROC were constructed for serum PTX3, hs CRP and ESR in differentiating active from inactive disease. p value $<$0.05 was considered significant. SPSS Software (version 21) was used.
**Results:** Mean age of TA patients and Healthy controls was 27 (7.9), 20 (3.4) years respectively.90% patients were female.Mean disease duration was 3.4 (3.1) years (range 1–12 yrs). Weight loss, fatigue, anorexia were the presenting symptoms followed by claudication. There were 14 patients with active disease, 8 with grumbling disease and 18 with inactive disease.Mean (SD) ITAS in patients with active disease 5.9 (3.5) was significantly higher than in patients with grumbling disease 0.9 (1.2) or inactive disease 0.6 (1). Mean ITAS-ESR in active disease was higher than in grumbling and inactive disease but not different between grumbling and inactive disease.

Laboratory markers in TA patients grouped by the PGA

| | Active | Grumbling | Inactive | p |
|---|---|---|---|---|
| ESR | 52 (22.1) | 45.6 (16.2) | 34.7 (14) | $<$0.026 |
| hsCRP | 13719 (8409) | 10583 (9961) | 6165 (6658) | $<$0.03 |
| PTX3 | 1431 (1013) | 1170 (1190.5) | 357 (244) | $<$0.002 |

Mean PTX3 levels were significantly higher in cases compared to healthy controls (895 (935.6), 317 (215.5)) ($p<0.026$).

ROC parameters of Biomarkers for detecting active TA patients

| | SE % | SP% | AUC | CI |
|---|---|---|---|---|
| ESR ($>$46 mm/hr) | 50 | 89 | 0.74 | 0.563–0.921 |
| HsCRP ($>$17090 ng/ml) | 57 | 89 | 0.79 | 0.626–0.953 |
| PTX3 ($>$631 pg/ml) | 71 | 95 | 0.86 | 0.720–0.994 |

Sensitivity (SE), specificity (SP) and area under the curve (AUC) with confidence intervals (CI).

**Conclusions:** PTX3 performed better than hs CRP and ESR in differentiating active from inactive disease. Grumbling disease could not be differentiated from inactive disease using ITAS/ITAS-ESR. Inflammatory markers did not perform well in differentiating grumbling disease from active or inactive disease in TA.

## SAT0365 RISK FACTORS FOR VISUAL LOSS IN GIANT CELL ARTERITIS (GCA)

R. Solans-Laqué[1], G. Fraile[2], B. Escalante[3], E. Fonseca[4], A. Martinez-Zapico[5], M. Perez-Conesa[6], M. Abdilla[7], M. Montegaudo[8], L. Caminal[5], B. Gracia[3], M.J. Del Castillo[9], P. Fanlo[10], M. Ramentol[1] on behalf of REVAS Group from GEAS-SEMI. *[1]Internal Medicine, H Vall hebron, Barcelona; [2]Internal Medicine, H Ramon y Cajal, Madrid; [3]Internal Medicine, H Clinico, Zaragoza; [4]Internal Medicine, H Cabueñes; [5]Internal Medicine, HUCA, Asturias; [6]Internal Medicine, H Miguel Servet, Zaragoza; [7]Internal Medicine, H la Ribera, Alzira, Valencia; [8]Internal Medicine, H Parc Tauli, Sabadell; [9]Internal Medicine, H Virgen del Rocio, Sevilla; [10]Internal Medicine, Clinica Navarra, Navarra, Spain*

**Background:** visual loss is the most frequent ischemic complication and the main cause of permanent disability among patients with GCA. To identify factors related to this complication may help physicians to start an early treatment and assay new therapies

**Objectives:** To analyse clinical and histological findings related to visual loss in patients with GCA

**Methods:** demographic, clinical and histological features of patients with biopsy-proven GCA recruited at 10 Hospitals from Spain (REVAS Study) were analysed. Statistical analysis was performed using SPSS vs. 20

**Results:** 418 patients were included: 290 (69.4%) females (ratio F/M: 2.3/1). The mean age at diagnosis was 75.5 ± 7 (53–92), 55% patients being older than 75y. The median diagnosis delay was 7 weeks (IQR 4–12). Cardiovascular risk factors were present in 45% of patients (hypertension in 48.8%, hypercholesterolemia in 26.6%, diabetes mellitus in 19.4%). The most frequent symptoms at CGA diagnosis were recent onset headache (81%), constitutional symptoms (47%) and polymyalgia rheumatic (44.5%). Jaw claudication, cranial hyperesthesia and amaurosis fugax were reported by 44.5%, 31.8% and 16.5%2 of patients, respectively. A total of 84 patients suffered vision loss (in 4 cases involving both eyes), due to anterior optic ischemic neuropathy (AION) in 78 (92.8%), and to central retinal artery occlusion in 6 (7.1%). CVA was recorded in 6.5% of cases. Anemia was present in 76.3% of patients. Mean ESR was 98±23.4. Patients with visual loss presented more frequently jaw claudication (71.6% vs 39.2%), cranial hyperesthesia (52.6% vs 28.7%) and amaurosis fugax (52.6% vs 8.6%), and less frequently low-grade fever (16.7% vs 43.1%) and toxic syndrome (37.2% vs 53.4%). Regarding to histological findings: patients with visual loss presented on TAB more intimal hyperplasia (70.5% vs 57.7%) and lumen occlusion >50% (53.8 vs 19.4%). No other differences were found. Univariated analysis showed than AION was significantly related to the presence of amaurosis fugax (OR 12.8, 95% CI 7.0–23.3, $p<0.001$), jaw claudication (OR 4, 95%CI 2.3–7.1, $p<0.001$), cranial hyperesthesia (OR 2.4, 95%CI 1.5–4), and age at diagnosis ≥75 years old (OR 2.7, 95% CI 1.5–4.6, $p<0.001$). An inverse relationship between AION and the presence of low-grade fever and toxic syndrome was found. No significant relationship was found between visual loss development and cardiovascular risk factors or CVA

**Conclusions:** AION is the most frequent cause of vision loss in GCA. Jaw claudication, cranial hyperesthesia, amaurosis fugax, and age >75 older at diagnosis are significantly related to AION. A wider recognition of the disease would potentially reduce the prevalence of irreversible visual loss among GCA patients.

## SAT0366 COMPARING THE CHARACTERISTICS OF ADULT AND PEDIATRIC PATIENTS WITH POLYARTERITIS NODOSA

A. Erden, E.D. Batu, E. Bilgin, H.E. Sonmez, B. Armagan, A. Sari, Z.S. Arici, U. Kalyoncu, Y. Bilginer, S.A. Bilgen, O. Karadag, I. Ertenli, S. Ozen, S. Kiraz. *Hacettepe University Vasculitis Center (HUVAC), Ankara, Turkey*

**Background:** Polyarteritis nodosa (PAN) as a necrotizing vasculitis of medium or small arteries without glomerulonephritis or vasculitis in arterioles, venules or capillaries and not associated with antineutrophil cytoplasmic antibodies. It is more common in middle-aged adults when compared with children.

**Objectives:** The aim of this study was to examine and compare the clinical characteristics of adult and pediatric patients with PAN.

**Methods:** Nine pediatric (<18 years of age) and 28 adult patients with a clinical diagnosis of PAN who were seen at the Departments of Rheumatology and Pediatric Rheumatology, Hacettepe University, Ankara, Turkey were included in the study group. The pediatric and adult patients were classified as PAN according to the Ankara 2008 and ACR 1990 criteria, respectively. The clinical features and response to therapy were evaluated retrospectively.

**Results:** The characteristics of PAN patients were summarized in Table 1. According to the results with a statistical significance, neurologic involvement was more common and the duration of induction treatment was longer in adults ($p=0.008$ and $p<0.001$, respectively). Renal involvement was more common in adults than children, however this difference did not reach statistical significance. 4/28 (14.2%) adult and 3/9 (33.3%) pediatric patients had accompanying familial Mediterranean fever. Of adult patients, 85% (n=23) had received cyclophosphamide plus corticosteroid for induction treatment while three pediatric patients received CYC and four received mycophenolate mofetil addition to corticosteroid treatment.

**Conclusions:** Although our study population is limited, neurologic and renal involvement were more common and the duration of induction treatment was longer in adults patients with PAN. There is no previous study comparing the characteristics of pediatric and adult patients with PAN Multicenter collaboration remains essential to determine the characteristic features of PAN in patients of different age groups.

Table 1. The characteristics of adult and pediatric patients with polyarteritis nodosa (PAN)

| | Pediatric patients (n=9) | Adult patients (n=28) | P value |
|---|---|---|---|
| Gender | 5F/4M | 9F/19M | 0.25 |
| Fever, n (%) | 6 (66.7) | 17 (60.7) | 1 |
| Myalgia, n (%) | 6 (66.7) | 14 (50) | 0.70 |
| Weight loss, n (%) | 2 (22.2) | 14 (50) | 0.11 |
| Fatigue, n (%) | 8 (88.9) | 25 (89.3) | 1 |
| Arthralgia/arthritis, n (%) | 8 (88.9) | 18 (64.3) | 0.39 |
| Cutaneous involvement, n (%) | 9 (100) | 21 (75) | 0.30 |
| Hypertension, n (%) | 4 (44.4) | 14 (50) | 1 |
| Renal involvement, n (%) | 1 (11.1) | 13 (46.4) | 0.056 |
| Neurologic involvement, n (%) | 1 (11.1) | 18 (64.3) | 0.008 |
| Testicular involvement, n (%) | 0 (0) | 2 (7.1) | 1 |
| Gastrointestinal system involvement, n (%) | 5 (55.6) | 9 (32.1) | 0.26 |
| Cardiovascular involvement, n (%) | 1 (11.1) | 1 (3.6) | 0.45 |

## SAT0367 CAN WE DIFFERENTIATE TAKAYASU ARTERITIS FROM ATHEROSCLEROSIS USING CAROTID AND FEMORAL ARTERY DOPPLER USG?

S. Ugurlu[1], F. Cetinkaya[2], F.E. Keskin[3], M. Melikoglu[1], V. Hamuryudan[1], I. Fresko[1], P. Kadioglu[3], S. Yurdakul[1], E. Seyahi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul; [2]Department of Radiology, Colormed Radiology Center; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

**Background:** Clinicians can have difficulty in making differential diagnosis between Takayasu arteritis (TA) and atherosclerosis. This is especially true when laboratory evaluations and FDG PET are inconclusive. In addition to that atherosclerosis load is potentially increased in TA (1–2). About 1/3rd of the patients with TA had carotid artery plaques and almost half had diffuse aortic wall calcifications (1–2).

**Objectives:** We thought that TA might have unique vascular changes distinct from atherosclerosis when evaluated with Doppler ultrasonography (USG).

**Methods:** Consecutive patients with TA seen in the department of Rheumatology at Cerrahpasa Medical Faculty at Istanbul were studied along with healthy controls. TA patients and healthy controls were aged between 18 and 50 years. Patients with diabetes mellitus (DM) who were followed by the endocrinology outpatient clinic were also studied. For the purposes of this study, no age limit was set for patients with DM. Only females were studied. Traditional atherosclerotic risk factors were also assessed. The radiologist scanned the right and left common, internal and external carotids, carotid bulb as well as the right and left common femoral arteries using Doppler USG. Intima-media thickness (IMT) was measured and resistivity index was calculated. The presence of atherosclerotic plaques and diffuse IMT was assessed. Diffuse IMT was defined as diffuse homogenous intima-media thickening of at least 0.9 mm.

**Results:** We studied 58 patients with TA (mean age: 43 ±11), 42 patients with

Table 1. Mean age and vascular parameters observed on carotid and femoral artery USG

| | TA, n=58 | DM, n=42 | HC, n=24 |
|---|---|---|---|
| Mean age | 43±11 | 57±9* | 41±4 |
| Carotid artery | | | |
| Presence of diffuse IMT, n (%) | 45 (78)** | 1 (2) | 0 |
| Atherosclerotic plaques, n (%) | 21 (36) | 28 (67)§ | 2 (8) |
| Turbulence, n (%) | 8 (14)** | 0 | 0 |
| Intima-media thickness, mm | 0.90±0.36† | 0.96±0.25 | 0.40±0.12 |
| Resistivity index | 0.63±0.10** | 0.50±0.04 | 0.56±0.04 |
| Femoral artery | | | |
| Presence of diffuse IMT, n (%) | 5 (9)** | 0 (0) | 0 (0) |
| Atherosclerotic plaques, n (%) | 6 (10) | 15 (36)§ | 0 (0) |
| Intima-media thickness, mm | 0.71±0.26 | 1.0±0.29§ | 0.38±0.09 |

*TA vs DM. DM vs HC: $p<0.001$; **TA vs DM. TA vs HC: $p<0.05$; †TA vs HC. DM vs HC: $p<0.001$; §TA vs DM. DM vs HC. TA vs HC: $p<0.001$.

DM (mean age: 57 ± 9) and 24 healthy controls (mean age: 41 ± 4). Patients with DM were significantly older and had significantly more atherosclerotic risk factors. The mean carotid IMT was comparable between TA and DM, whereas the mean femoral IMT was significantly lower in TA. The frequency of atherosclerotic plaques in both carotid and femoral arteries was significantly higher among patients with DM (Table). Presence of diffuse wall thickenning of at least 0.9 mm and turbulence were observed almost only among patients with TA. Finally the mean resistivity index was only significantly increased in TA (Table).

**Conclusions:** Diffuse homogenous increase in IMT, presence of turbulence and higher resistivity index can be considered as suggestive of TA rather than atherosclerosis. This study showed that carotid and femoral artery USG may be helpful in differentiating TA from atherosclerosis.

## SAT0368 A SYSTEMATIC LITERATURE REVIEW ON THE TREATMENT OF MAJOR ORGAN INVOLVEMENT OF BEHÇET'S SYNDROME INFORMING THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF BEHÇET'S SYNDROME

Y. Ozguler[1], P. Leccese[2], R. Christensen[3], S.N. Esatoglu[1], I. Olivieri[2], H. Yazici[1], G. Hatemi[1] on behalf of the Task Force for Updating EULAR Recommendations for the Management of Behçet's Syndrome. *[1]Rheumatology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey; [2]Rheumatology Department of Lucania, San Carlo Hospital, Potenza, Italy; [3]Musculoskeletal Statistics Unit, Bispebjerg and Frederiksberg Hospital, The Capital Region of Denmark, Denmark*

**Background:** The first EULAR recommendation for the management of Behçet's syndrome (BS) was published in 2008 and since then new data including biologic agents have appeared.

**Objectives:** To review the evidence for efficacy and safety of management strategies in BS patients with eye, vascular, gastrointestinal (GI) and neurologic involvement.

**Methods:** We used the GRADE methodology as framework for guidelines development. For the systematic literature review, we searched The Cochrane Library, Database of Abstracts of Reviews of Effects, Health Technology Assessments, MEDLINE, EMBASE and International Pharmaceutical Abstracts Database. Randomized controlled trials (RCT), controlled clinical trials, or open label trials comparing an active drug in patients with BS with other agents or placebo were included. If controlled trials were not available for answering a specific research question, uncontrolled evidence from prospective or retrospective studies or case series about a minimum of 5 patients were also included.

**Results:** We reviewed the titles and abstracts of 3927 references, followed by the full texts of 397. A total of 166 studies related with major organ involvement met our inclusion criteria. Three RCTs with cyclosporine-A (CycA) and 1 with azathioprine (AZA) showed beneficial results in BS patients with eye involvement. There were several observational studies with interferon-$\alpha$ and TNF-$\alpha$ antagonists in patients with eye involvement, including those among patients refractory to conventional treatment modalities. Decreases in the frequency of ocular attacks, remission and improvement in visual acuity were observed in the majority of patients treated with these agents. As for vascular involvement, retrospective studies showed that immunosuppressives (IS) significantly decreased the frequency of recurrences in BS patients with deep vein thrombosis (RR 95%CI: 5.8, 2.8–11.8). A similar effect was not observed with anticoagulants+IS compared with IS alone (RR 95%CI: 1.5, 0.8–2.6). Observational studies showed that cyclophosphamide and high dose glucocorticoids (GC) decreased mortality in patients with arterial aneurysms. Treatment with IS and GC decreased postoperative complications in patients who had surgery for arterial aneurysms. Observational studies showed beneficial results with 5-ASA derivatives and AZA in the initial management of BS patients with GI involvement. Remission could be obtained with thalidomide and/or TNF- $\alpha$ antagonists in the majority of patients with refractory GI involvement. Retrospective studies also showed IS decreased postoperative recurrences in patients operated for intestinal perforations or major bleeding (RR 95%CI: 0.56, 0.33–0.95). Observational studies in BS patients with neurologic involvement showed IS and GC improved the outcome. CycA should be avoided in such patients since retrospective studies showed that CycA had increased the risk of development of neurologic involvement (RR 95%CI: 12.6, 4.7–33.7).

**Conclusions:** It is sobering to note that the majority of the studies forming the basis for the recommendations related to major organ involvement in the updated EULAR recommendations for the management of BS come from observational studies.

## SAT0369 WEIGHT GAIN IN ANCA-ASSOCIATED VASCULITIS IS INDEPENDENT OF GLUCOCORTICOID DOSING

Z. Wallace[1], E. Miloslavsky[1], S. Unizony[1], L. Lu[1], U. Specks[2], G. Hoffman[3], C. Kallenberg[4], C. Langford[5], P. Merkel[6], P. Monach[7], P. Seo[8], R. Spiera[9], B.St. Clair[10], H. Choi[11], J. Stone[11]. *[1]Rheumatology Unit, Massachusetts General Hospital, Boston; [2]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester; [3]Rheumatology, Clevelan Clinic, Cleveland, United States; [4]Immunology, University of Groningen and University Medical Center Groningen, Groningen, Netherlands; [5]Rheumatic and Immunologic Diseases, Clevelan Clinic, Cleveland; [6]Rheumatology, University of Pennsylvania, Philadelphia; [7]Rheumatology, Boston University, Boston; [8]Rheumatology, Johns Hopkins, Baltimore; [9]Rheumatology, Hospital for Special Surgery, New York; [10]Rheumatology, Duke University, Durham; [11]Rheumatology, Massachusetts General Hospital, Boston, United States*

**Background:** The treatment of ANCA-associated vasculitis (AAV) includes high doses of glucocorticoids, the use of which has been associated with increased body-mass index (BMI)[1]. A previous study suggested that this change in BMI is independent of glucocorticoid exposure[2].

**Objectives:** We sought to evaluate whether increases in BMI are related more directly to improved disease control than to glucocorticoid use.

**Methods:** We analyzed AAV patients enrolled in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial[3]. Details regarding glucocorticoid exposure before and during the trial were collected, as were regular measurements of BMI and disease activity. We used multivariate linear regression to adjust for important confounders of the relationship between glucocorticoid exposure and BMI changes. We used analysis of response profile to evaluate differences in BMI over time between subgroups and mixed effects models to determine the relationship between disease activity and change in BMI.

**Results:** Of the 197 patients enrolled in RAVE, 99 (50%) were male and the mean age was 52.8 (±15.5) years. The baseline BVAS/WG was 8.0 (±3.1). The majority (75%) had granulomatosis with polyangiitis, and PR3-ANCA+ was the most common (67%) ANCA specificity. The baseline BMI was 28.8 (±6.3) and the most significant change in BMI occurred during the first six months of the trial (+1.1 (±2.2), $P<0.0001$). In fully adjusted models, there was no association between glucocorticoid exposure and change in BMI over the course of the trial ($P>0.3$ for all analyses). Reduced disease activity (e.g., lower BVAS/WG, ESR, CRP) was independently associated with increased BMI ($P<0.0001$ for all analyses), as was randomization to rituximab ($P<0.02$ for all analyses). There was a significant association between disease status at enrollment (new diagnosis) and increasing BMI ($P\leq0.04$ for all analyses), but this association was lost in analyses adjusted for disease activity.

**Conclusions:** Following the initiation of AAV treatment, changes in BMI are related more closely to improvements in disease activity than to total glucocorticoid exposure. Additional studies are necessary to identify the respective impact of glucocorticoids and disease activity on temporal variations in BMI, including adiposity and skeletal muscle mass. The observed association between rituximab and increased BMI also deserves additional evaluation.

## SAT0370 ANTINEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA) TYPE AND BODY MASS INDEX IN ANCA-ASSOCIATED VASCULITIS

Z. Wallace[1], U. Specks[2], G. Hoffman[3], C. Kallenberg[4], C. Langford[5], P. Merkel[6], P. Monach[7], P. Seo[8], R. Spiera[9], B.St. Clair[10], H. Choi[11], J. Stone[11]. *[1]Rheumatology Unit, Massachusetts General Hospital, Boston; [2]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester; [3]Rheumatology, Clevelan Clinic, Cleveland, United States; [4]Immunology, University of Groningen and University Medical Center Groningen, Groningen, Netherlands; [5]Rheumatic and Immunologic Diseases, Clevelan Clinic, Cleveland; [6]Rheumatology, University of Pennsylvania, Philadelphia; [7]Rheumatology, Boston University, Boston; [8]Rheumatology, Johns Hopkins, Baltimore; [9]Rheumatology, Hospital for Special Surgery, New York; [10]Rheumatology, Duke University, Durham; [11]Rheumatology, Massachusetts General Hospital, Boston, United States*

**Background:** Recent studies have highlighted important phenotypic, genetic, and treatment differences between PR3- and MPO-ANCA+ ANCA-associated vasculitis (AAV) patients[1,2]. No study has evaluated differences in body mass index (BMI) between the PR3- and MPO-ANCA+ AAV subtypes.

**Objectives:** We sought to evaluate whether differences in BMI exist between patients with active PR3-ANCA+ and MPO-ANCA+ AAV using data from the Rituximab in ANCA-Associated Vasculitis (RAVE) trial[3].

**Methods:** We analyzed AAV patients who were either anti-proteinase 3 (PR3)

antibody+ or anti-myeloperoxidase (MPO) antibody+ from the Rituximab in ANCA-Associated Vasculitis (RAVE) trial. In univariate analyses, we compared the BMI/weight of PR3- and MPO-ANCA+ AAV patients at enrollment, using linear regression to adjust for age, gender, glucocorticoids prior to enrollment, relapsing disease at baseline, and baseline disease activity. We used an analysis of response profile to evaluate trends in BMI and weight by ANCA type, adjusted for the above confounders as well as cumulative steroid dosing during the trial and flares during the trial.

**Results:** Three fourths of the patients were PR3+ (147, 75%). PR3-ANCA+ patients had a higher BMI at baseline compared to MPO-ANCA+ patients (29.6±6.6 vs. 27.2 ± 5.3; P=0.01); the same was true for weight differences (89.3 ±22kg vs. 77.2 ± 16.0kg, respectively, P<0.001). A significantly greater proportion of PR3-ANCA+ patients (42%) were obese compared to MPO-ANCA+ patients (24%, P=0.04). Among those with a new diagnosis of AAV at enrollment (N=96), PR3-ANCA+ patients had a significantly higher BMI (29.2 ± 6.2) compared to MPO-ANCA+ patients (26.8 ± 4.9, P=0.04). In multivariate linear regression analyses, these differences (PR3-ANCA + BMI 2.1 kg/m$^2$ (±1.1) higher than MPO-ANCA+ patients) remained significant (P=0.047 for BMI and 0.04 for weight, respectively) after accounting for confounders. The difference in weight between PR3-ANCA+ and MPO-ANCA+ patients remained stable during the study (P=0.3).

**Conclusions:** PR3-ANCA+ patients have a significantly higher BMI than MPO-ANCA+ patients, even after adjustment for important potential confounders. Our findings may have important implications for our understanding of AAV pathogenesis, its relationship to metabolic pathways, and the management of AAV.

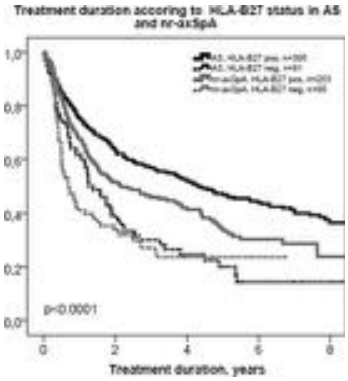
## Spondyloarthritis - treatment

### SAT0371 HLA-B27 STATUS IS ASSOCIATED WITH TNFα INHIBITOR TREATMENT OUTCOMES IN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS – OBSERVATIONAL COHORT STUDY FROM THE NATIONWIDE DANBIO REGISTRY

B. Glintborg, I. Juul Sørensen, M. Østergaard, A.A. Mahamoud, N.S. Krogh, L.S. Andersen, J.L. Raun, O. Hendricks, M.R. Kowalski, L. Danielsen, S.R. Christensen, N. al Chaer, R. Pelck, H. Nordin, J.K. Pedersen, D.G.A. Kraus, I.M. Jensen Hansen, J. Espesen, A. Schlemmer, A.G. Loft, L. Salomonsen, L. Dreyer, M.L. Hetland. *The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark*



**Background:** Little is known about tumor-necrosis-factor-alpha-inhibitor (TNFi) treatment outcomes in Ankylosing Spondylitis (AS) vs. non-radiographic axial spondyloartrhitis (nr-axSpA).

**Objectives:** To compare baseline disease activity and treatment outcomes in biologic naïve patients with AS and nr-axSpA, who initiate TNFi treatment in clinical practice taking potential confounders into consideration.

**Methods:** We performed an observational cohort study based on prospectively registered data in the nationwide Danish quality registry, DANBIO, including baseline and 3–6 months' follow-up markers of disease activity (visual analogue score (VAS) global disease, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), BAS metrology index (BASMI) and serum C-reactive protein (CRP)). Treatment response was defined as either a 50% or a 20 mm reduction in BASDAI after 3–6 mths treatment. We used Kaplan-Meier plots, Cox and logistic regression analyses to study the impact of diagnosis (AS vs. nr-axSpA) and potential confounders (gender, age, start year, HLA-B27, disease duration, TNFi type, smoking, baseline disease activity) on TNFi adherence and response. Numbers are medians (IQR) unless otherwise stated.

Table 1. Characteristics and outcomes according to axSpA sub-diagnosis

| | Nr-axSpA (N=362) | AS (N=622) | P |
|---|---|---|---|
| Baseline demographics | | | |
| Age, years | 38 (30–46) | 42 (33–52) | <0.001 |
| Male sex, n (%) | 183 (50) | 455 (73) | <0.0001 |
| HLAB27 positive, n (%) | 253 (70) | 395 (83) | 0.005 |
| Disease duration, years | 1 (0–3) | 3 (1–12) | <0.0001 |
| Baseline disease activity | | | |
| CRP, mg/l | 7 (3–17) | 11 (5–22) | <0.0001 |
| BASDAI, mm | 64 (54–77) | 59 (46–71) | <0.0001 |
| BASFI, mm | 52 (33–69) | 49 (34–67) | 0.7 |
| BASMI | 20 (10–40) | 40 (20–50) | <0.0001 |
| VAS global, mm | 76 (62–88) | 68 (50–80) | <0.0001 |
| Crude outcomes | | | |
| BASDAI50%/20mm response, % | 46 | 48 | 0.9 |
| Adherence, median (95%CI), years | 1.59 (1.15–2.02) | 3.67 (2.86–4.49) | <0.0001 |

**Results:** We identified 1,250 TNFi naïve patients in DANBIO with axSpA according to the treating physician. Of these, 50% had AS, 28% nr-axSpA and 21% lacked X-rays of sacroiliac joints. Baseline demographics and disease activity differed in nr-axSpA vs. AS (Table). Response rates were similar, but treatment adherence was poorer in nr-axSpA than in AS (univariate, Table). In confounder adjusted analyses, axSpA sub-diagnosis was not associated with response rates or treatment adherence. However, HLA-B27 positivity was associated with better treatment adherence (HLA-B27 neg/pos, nr-axSpA: HR 1.74 (1.29–2.36), AS: HR 2.04 (1.53–2.71.), both p<0.0001) (Figure) and higher response rates (nr-axSpA: 30%/55%, AS: 29%/54%, univariate, both p<0.05). Similar results for HLA-B27 were found in confounder-adjusted analyses.

**Conclusions:** In this nationwide cohort, patients with nr-axSpA had higher subjective disease activity at the start of the first TNFi treatment but had similar confounder adjusted treatment adherences and response as AS pts. HLA-B27 positive pts had better outcomes irrespective of axSpA sub-diagnosis.

### SAT0372 IMPACT OF DOSE TAPERING OF TUMOUR NECROSIS FACTOR-BLOCKERS ON RADIOGRAPHIC PROGRESSION IN THE ANKYLOSING SPONDYLITIS – A 4 YEAR PROSPECTIVE FOLLOW UP FROM SINGLE-CENTRE COHORT

J.W. Park, H.M. Kwon, J.K. Park, E.B. Lee, Y.W. Song, E.Y. Lee. *Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

**Background:** Although dose tapering of tumour necrosis factor (TNF)-blockers in ankylosing spondylitis (AS) showed a comparable clinical efficacy with favourable safety and cost in some studies, there has been no investigation comparing the radiographic progression of patients with tapering regimen versus patients with standard-dose treatment.

**Objectives:** To investigate the impact of dose reduction of TNF-blockers on radiographic progression in the AS over 4 years

**Methods:** One hundred sixty five patients treated with etanercept or adalimumab were selected from single-centre, prospective observational cohort based on the availability of cervical and lumbar radiographs at baseline and after 2 and/or 4 years of the treatment. Radiographs were scored using modified Stokes AS spinal score (mSASSS) by two independent readers. Radiographic progression of patients treated with standard-dose (standard-dose group, n=49) was compared with that of patients who tapered the dosage during the TNF-blocker treatment (tapering group, n=116) using linear mixed models.

**Results:** Demographic and clinical factors at baseline between two groups were not significantly different except for higher initial BASDAI (7.1 vs. 6.3, p=0.003) in the standard-dose group. Baseline mSASSS (SD) of the standard-dose group and the tapering group were 17.3 (17.7) and 11.0 (16.0), respectively (p=0.059). At 2 years after the treatment, mean dose quotient (SD) of the tapering group was 0.59 (0.17) and time to first dose reduction (SD) was 36.6 (28.4) weeks. During the observation period, the rate of radiographic progression in the overall patients was 0.90 mSASSS unit/year. Rate of progression was significantly higher in patients with longer disease duration (≥10 years), elderly patients (≥40 years old), smokers, or patients with a hip involvement at baseline.

Radiographic progression over 4 years between two treatment strategies was similar after the adjustment for baseline status. However, in the subgroup of

patients who have syndesmophytes at baseline, it occurred significantly faster in the tapering group (1.30 mSASSS unit/year vs. 1.82 mSASSS unit/year, p=0.008) (figure). This result was concordant when radiographic progression was assessed by the development of new syndesmophytes (0.52/year vs. 0.73/year, p=0.047).

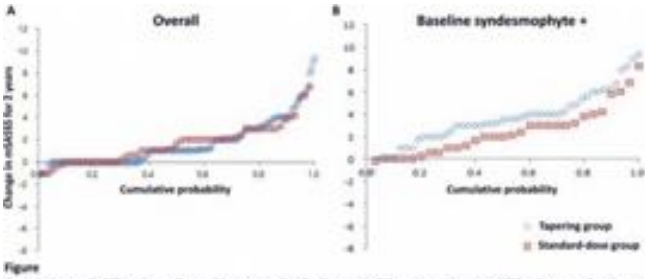

Figure
Cumulative probability plot radiographic progression for 2 years in (A) entire patients and (B) subgroup of patients who had syndesmophytes at baseline; mSASSS, modified Stoke Ankylosing Spondylitis Spine Score.

**Conclusions:** Dose tapering strategy of TNF-blockers is associated with more rapid radiographic progression in AS patients who have syndesmophytes at baseline.

## SAT0373 EFFICACY AND SAFETY OF GOLIMUMAB IN PATIENTS WITH ACTIVE, VERY EARLY PERIPHERAL SPONDYLOARTHRITIS: FIRST RESULTS FROM THE CRESPA STUDY, A MONOCENTRIC, PLACEBO-CONTROLLED RANDOMIZED TRIAL

P. Carron [1], G. Varkas [1,2], H. Cypers [1,2], L. Van Praet [1], D. Elewaut [1,2], F. Van den Bosch [1]. *[1] Rheumatology; [2] VIB inflammation Research Center, Univeristy of Ghent, Gent, Belgium*

**Objectives:** To evaluate the efficacy and safety of golimumab in patients with active peripheral Spondyloarthritis (pSpA) in a very early stage of the disease.

**Methods:** CRESPA (Clinical REmission in peripheral SPondyloArthritis) is an ongoing monocentric study of golimumab treatment in pSpA patients. Eligible patients were ≥18 years and fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for pSpA. All patients had a symptom duration of less than 3 months. Patients were randomized 2:1 to receive golimumab 50 mg every 4 weeks or matching placebo for 24 weeks. The primary endpoint was the percentage of patients achieving clinical remission at week 24. Clinical remission was defined as the absence of arthritis, enthesitis and dactylitis on clinical examination. From week 12 onwards, there was an option to start rescue medication with golimumab 50 mg SC every 4 weeks. Adverse events were recorded throughout the study.

**Results:** In total 60 patients were randomized of whom 20 to the placebo group and 40 to the golimumab group. Baseline demographics and disease characteristics were generally similar between the 2 groups. At week 24 a significant higher percentage of patients receiving golimumab achieved clinical remission compared to patients receiving placebo (75% (30/40) versus 20% (4/20); P<0.001). At week 12 similar results were observed (70% (28/40) versus 15% (3/20); P<0.001). Overall, improvement in other outcomes was significantly greater in the golimumab group compared to the placebo group (table 1). In the placebo group 10 out of 20 patients (50%) entered the rescue arm, compared to only 4 of 40 (10%) patients in the golimumab arm. The rates of adverse events were very low and similar in both treatment groups.

**Conclusions:** In patients with active, very early peripheral spondyloarthritis, treatment with golimumab led to high percentages of clinical remission and significant improvement in all secondary efficacy outcomes, compared to placebo, with a safety profile consistent with that observed in anti-TNF trials with ankylosing spondylitis and psoriatic arthritis patients.

## SAT0374 PREGNANCY OUTCOME IN COUPLES WITH MALES EXPOSED TO LONG TERM ANTI –TNF ALPHA BLOCKER THERAPIES

M.C. Micu [1], V. Bojinca [2], M. Mihai [3], C. Suta [4], A. Ramazan [4], R. Micu [5]. *[1] Rheumatology Division, Rehabilitation Clinical Hospital, Cluj- Napoca; [2] Department of Internal Medicine and Rheumatology, 'Sfanta Maria' Hospital, Bucharest; [3] ASTRA Outpatient Clinic, Sibiu; [4] 2 nd Internal Medicine Department, "Sf. Apostol Andrei" Emergency County Hospital, Constanta; [5] Assisted Reproduction Department, Gynecology I Clinic, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj- Napoca, Romania*

**Background:** Biologic disease- modifying antirheumatic drugs (b DMARDs) are used often by patients with ankylosing spondylitis (AS) around the time of conception. Pregnancy outcomes in couples where men were exposed to TNF alpha blockers needs to be carefully examined, as information regarding paternal exposure may highly influence further couple counseling. Scarce information regarding the men fertility, pregnancy outcome and risk for congenital malformations associated with chronic TNF blockers treatment prior to conception is available.

**Objectives:** To examine pregnancy outcome and decision to conception time frame in the partners of AS male patients who were exposed to TNF alpha blockers before conception compared to the outcomes in age matched men from general population.

**Methods:** Outcomes of pregnancies in fathering men exposed to continuous long term (>12 months) anti TNF alpha blockers therapies were compared with outcomes in age matched reference subjects between 2008–2015.

**Results:** Out of 127 men diagnosed with AS, mean age (37.3 ± 10.3 years), disease onset (11.7 ± 10.5 years) treated with different bDMARDs in monotherapy, 13 patients were exposed to minimum 12 months preconception therapy. One patient received Infliximab 5 mg/ kg/ 8 weeks (72 months), 9 patients received Etanercept 50 mg/ week (34.6 ± 19.4 months), 3 patients received Adalimimab 40 mg/ 2 weeks (25.25 ± 10.11 months) monotherapy. One patient fathered 2 children after 42 months and 60 months of preconception Etanercept exposure. One patient had a recent switch from Adalimumab (24 months) to Etanercept introduced 2 months prior to conception. One patient with Etanercept therapy (60 months) has a partner with an ongoing 10 weeks pregnancy. Thirteen men fathered 14 healthy, on term delivered children. All newborns had normal weight and no signs of neonatal patology. No cases of abortion, preeclampsia, eclampsia, preterm delivery or neonatal death were reported in this group. Forty-five age matched healthy men (35.1 ± 1.2 years old) fathered 37 children: 35 healthy, one with cleft lip and one with Down syndrome. Eight pregnancies ended with abortion, 3 spontaneous and five by request. The time frame between mental decisions for reproduction to conception was 14.3 ± 3.3 months vs 7.7 ±1.2 months in the patients group vs reference group.

**Conclusions:** Long term preconception paternal exposure to TNF alpha blockers is not associated with an increase in adverse pregnancy outcomes. All born children were healthy. The interval between decision for reproduction and conception is longer in patients with AS treated with b DMARDs in comparison to general population.

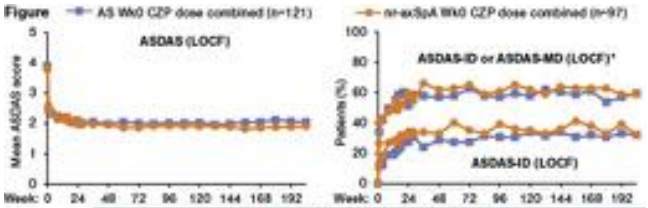
SAT0375 **CERTOLIZUMAB PEGOL FOR THE TREATMENT OF AXIAL SPONDYLOARTHRITIS: 4-YEAR OUTCOMES FROM THE RAPID-AXSPA TRIAL**

D. van der Heijde[1], M. Dougados[2], R. Landewé[3], J. Sieper[4], W.P. Maksymowych[5], M. Rudwaleit[6], F. van den Bosch[7], J. Braun[8], P.J. Mease[9], O. Davies[10], B. Hoepken[11], L. Peterson[12], A. Deodhar[13]. *[1]Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; [2]Department of Rheumatology, Cochin Hospital, Paris, France; [3]Academic Medical Center, Amsterdam and Atrium Medical Center, Heerlen, Netherlands; [4]Rheumatology Department, University Hospital Charité, Berlin, Germany; [5]Department of Medicine, University of Alberta, Edmonton, Canada; [6]Department of Internal Medicine and Rheumatology, Klinikum Bielefeld, Bielefeld, Germany; [7]Ghent University Hospital, Ghent, Belgium; [8]Rheumazentrum Ruhrgebiet, Herne, Germany; [9]Swedish Medical Center and University of Washington, Seattle, United States; [10]UCB Pharma, Slough, United Kingdom; [11]UCB Pharma, Monheim, Germany; [12]UCB Pharma, Raleigh; [13]Oregon Health & Science University, Portland, United States*

**Background:** The RAPID-axSpA trial (NCT01087762) investigated the efficacy and safety of certolizumab pegol (CZP) for the treatment of patients (pts) with axial spondyloarthritis (axSpA), including ankylosing spondylitis (AS; also termed radiographic-axSpA) and non-radiographic (nr)-axSpA pts. Previous reports have shown CZP to be safe and efficacious over 96 weeks (wks) of treatment.[1]

**Objectives:** To report 4-year efficacy and safety data from the RAPID-axSpA trial.



**Methods:** RAPID-axSpA was double-blind and placebo (PBO)-controlled to Wk24, dose-blind to Wk48 and open-label (OL) to Wk204. Pts fulfilled ASAS criteria and had active axSpA with positive sacroiliac joint MRI and/or raised CRP (>7.9mg/L). Pts originally randomized to CZP (200mg Q2W or 400mg Q4W) continued on their assigned dose in the OL period. Outcomes assessed included: ASAS responses, ASDAS, BASDAI, BASFI, BASMI-linear and enthesitis. Efficacy data are presented for pts originally randomized to CZP (combined doses) as observed case and with imputation: NRI for categorical and LOCF for continuous measures. The safety set consisted of all pts treated with ≥1 dose of CZP to Wk204.

**Results:** 325 pts were randomized, of whom 218 received CZP from Wk0. Of CZP-randomized pts, 93% completed to Wk24, 88% to Wk48 and 65% to Week 204 (AS: 67%; nr-axSpA: 63%). In the OL period, 9.2% of pts withdrew due to an adverse event (AE) and 1.4% due to lack of efficacy.

The proportion of pts achieving ASAS20/40 and partial remission (PR) responses at Wk24 was maintained over 4 years (to Wk204) in pts remaining in the study (Table). Efficacy, expressed as ASDAS ID rates (LOCF: Wk24: 30.3%; Wk204: 32.1%), mean ASDAS score (baseline: 3.84; LOCF: Wk24: 2.07; Wk204: 1.98), and all other outcomes reported, was maintained to Wk204. Similar improvements were seen in AS and nr-axSpA pts (Figure/Table) and in both CZP dose regimens (data not shown). Function (BASFI) was also improved in both subpopulations, with nr-axSpA pts having a particularly low mean score by Wk204 (Table).

Pts in the safety set (N=315) had a total CZP exposure of 981 patient-years (PY), with an AE rate (ER) per 100 PY of 292.9. No new safety signals were identified from Wk96 to Wk204, and no deaths were reported over 4 years.

SAT0376 **SERUM CRP LEVELS DEMONSTRATE PREDICTIVE VALUE FOR RADIOGRAPHIC AND MRI OUTCOMES IN PATIENTS WITH ACTIVE AS TREATED WITH THE TNF-INHIBITOR GOLIMUMAB**

J. Braun[1], X. Baraliakos[1], K.-G. Hermann[2], S. Xu[3], B. Hsu[3]. *[1]Rheumazentrum Ruhrgebiet, Herne; [2]Charité Universitätsmedizin, Berlin, Germany; [3]Janssen R & D, LLC, Spring House, United States*

**Background:** While the introduction of anti-tumor necrosis tumor (TNF) biologic agents can significantly improve signs/symptoms of ankylosing spondylitis (AS) and reduce magnetic resonance imaging (MRI)-detected spinal inflammation, the effect of such therapy on future radiographic progression is less clear. Serum C-reactive protein (CRP) associates with radiographic progression in AS patients untreated with TNF-antagonists.

**Objectives:** We assessed correlations between serum CRP after 2 years of anti-TNF therapy and radiographic progression/inflammation in the GO-RAISE trial.

**Methods:** Active AS patients receiving golimumab/placebo through week-16 (early-escape) or week-24 (crossover by design), followed by golimumab through 4 years, had sera/images obtained through week 208. Lateral spinal radiographs and spinal MRIs were scored using the modified Stoke AS spine score (mSASSS) and AS spinal MRI activity (ASspiMRI-a) score, respectively. Analyses of variance assessed differences based on CRP levels and mSASSS progression. The relationships between CRP levels and mSASSS/ASspiMRI-a score were assessed by Spearman correlation and logistic regression.

**Results:** 299/356 (84.0%) randomized GO-RAISE patients had spinal radiographs available at both timepoints. Larger proportions of patients with week-104 CRP ≥0.5mg/dL (n=47) vs. <0.5mg/dL (n=236) (40.4% vs. 22.9%; p=0.0121) had mSASSS changes ≥2 at week-104 (Figure). Across several visits, serum CRP demonstrated weak associations with mSASSS change ($r_s$ ≤0.21; p<0.05; n=262–293) and moderate associations with ASspiMRI-a change ($r_s$= -0.33–0.54; p<0.05; n=65–89). Higher baseline CRP was associated with increased risk for syndesmophytes at week-104/week-208, while large decreases in CRP from baseline to week-14/week-24 yielded decreased risk of new bone formation (Figure 1).

**Conclusions:** This is the first study to show that CRP level is not only a useful marker at baseline of the initiation of anti-TNF therapy but also at follow up examinations. Thus, elevated CRP after 2 years of anti-TNF treatment correlated with greater radiographic progression risk at 4 years. Intermittent measurements of serum CRP weakly predicted subsequent radiographic progression and

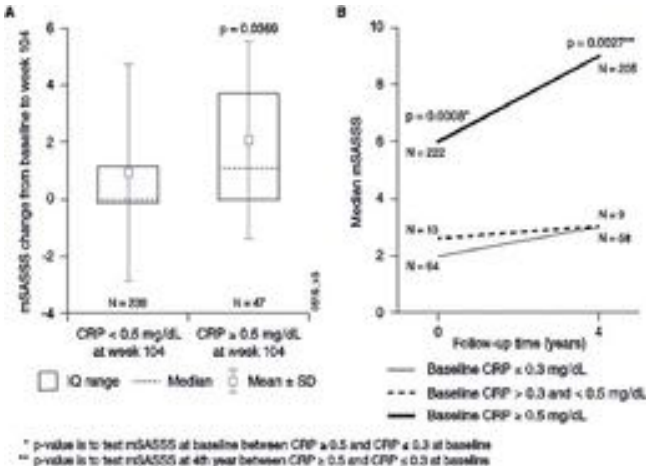

Figure 1

modestly predicted residual spinal inflammation in anti-TNF treated AS patients. Thus, incomplete suppression of inflammation in AS patients may be a relevant factor for new bone formation, and serum CRP appears to be a pertinent predictive biomarker for long-term AS progression among patients receiving TNF-antagonists. It is possible that higher doses of anti-TNF agents are necessary for patients with persistently elevated CRP values to prevent new bone formation more effectively.

## SAT0377 DRUG SURVIVAL OF TUMOR NECROSIS FACTOR-α INHIBITORS IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN KOREA

H. Jeong[1], H. Kim[1], J.-M. Oh[2], J. Kim[3], J. Lee[1], E.-M. Koh[1], H.-S. Cha[1]. *[1]Samsung Medical Center, Seoul; [2]Anyang SAM Hospital, Anyang; [3]Jeju National University Hospital, Jeju, Korea, Republic Of*

**Background:** Studies about factors for drug survival for patients with AS have not sufficient as compared with RA patients and only a few studies are available for the Asian population.

**Objectives:** To evaluate drug survival of the tumor necrosis factor-α inhibitors (TNFi) and risk factors for the drug discontinuation in patients with ankylosing spondylitis (AS).

**Methods:** We retrospectively evaluated 487 AS patients at a single tertiary hospital. Among the TNFi users, drug survival and risk factors of TNFi discontinuation were investigated.

**Results:** Among 487 patients, 128 AS patients were treated with at least one TNFi. Patients who were treated with TNFi were younger at disease onset, had more peripheral manifestations, and had higher level of acute phase reactants and BMI than those of TNFi non-users at baseline. Of 128 patients, 28 (21.9%) patients discontinued first TNFi therapy during the follow-up period of 65.1 ± 27.9 months. In the multivariable analysis, female (HR 6.08, 95% CI 2.27–16.27, p=0.003), hip involvement (HR 2.52, 95% CI 1.08–5.87, p=0.033) and a high CRP (HR 1.10, 95% CI 1.00–1.21, p=0.044) were risk factors for drug discontinuation. Etanercept showed better survival rate than infliximab. The main reason for discontinuation of TNFi was inefficacy.

**Conclusions:** About one fifth of patients with AS discontinued their first TNFi. Female sex, hip involvement, CRP, and the type of TNFi were associated with TNFi discontinuation.

**Disclosure of Interest:** None declared

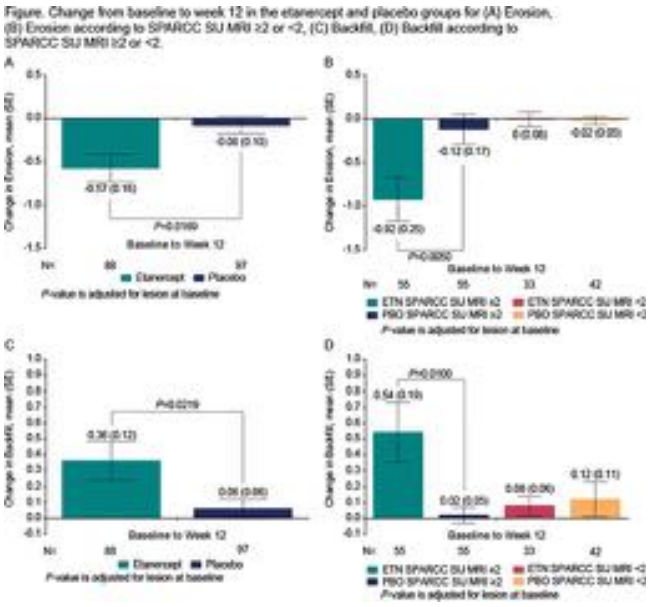
## SAT0378 MODIFICATION OF STRUCTURAL LESIONS ON MAGNETIC RESONANCE IMAGING BY ETANERCEPT: A 12-WEEK RANDOMIZED PLACEBO-CONTROLLED TRIAL

W.P. Maksymowych[1], S. Wichuk[1], M. Dougados[2], H. Jones[3], A. Szumski[4], L. Marshall[3], J.F. Bukowski[5], R.G. Lambert[1]. *[1]University of Alberta, Edmonton, Canada; [2]Paris Descartes University, Hôpital Cochin, Paris, France; [3]Pfizer, Collegeville, United States; [4]inVentiv Health, Princeton; [5]Pfizer, Collegeville, United States*

**Background:** Modification of structural lesions by anti-TNF therapy has not been demonstrated in a randomized placebo (PBO)-controlled trial. The Spondyloarthritis Research Consortium of Canada (SPARCC) sacroiliac joint (SIJ) score (SSS) assesses the degree of fat metaplasia (new tissue growth after resolution of inflammation), erosion, backfill (new tissue growth at erosion site), and ankylosis observed on MRI in the SIJ.

**Objectives:** To evaluate the impact on these lesions at 12 wks in patients with non-radiographic axial SpA receiving PBO or etanercept (ETN) in the EMBARK study (ClinicalTrials.gov: NCT01258738).



**Methods:** Patients had axial SpA per ASAS criteria without meeting modified NY radiographic criteria; BASDAI score ≥4; symptoms for >3 months and <5 yrs; and had failed ≥2 NSAIDs. Patients were randomized to double-blind ETN 50 mg/wk or PBO for 12 wks, then received open-label ETN. Structural lesions were scored using the SPARCC SSS method on T1-weighted spin echo (T1WSE) MRI. Two readers independently scored baseline (BL) and 12-wk T1WSE MRI scans, blinded to patients, time point, and inflammation scores assessed by short tau inversion recovery MRI scans. Readers' mean scores were used.

**Results:** Mean (SD) age was 32 (7.8) yrs, 60.5% were male, duration of disease symptoms was 2.4 (1.8) yrs, 71.6% were human leukocyte antigen B27+, and 80.9% had sacroiliitis on MRI (modified intent-to-treat [mITT] population, N=215). MRI scans from 185 patients (ETN, n=88; PBO, n=97) with BL and 12-wk scans were reviewed. At BL, there were no significant differences in mean SPARCC SSS scores between ETN and PBO (table). From BL to 12 wks, change in mean SPARCC SSS score was significantly greater for ETN than PBO for erosion (-0.57 vs -0.08, respectively, $p$=0.009) and backfill (0.36 vs 0.06, $p$=0.021), table. A treatment difference was also present for the subgroup of patients with MRI inflammation (figure).

Table 1. SPARCC SSS scores at baseline, week 12, and change from baseline to week 12

| | | ETN N=88 | PBO N=97 | *P*-value* ETN vs PBO ΔBL to week 12 |
|---|---|---|---|---|
| Erosion | Baseline | 2.25 (0.33) | 1.73 (0.32) | 0.009 |
| | Week 12 | 1.68 (0.25) | 1.65 (0.30) | |
| | ΔBL to week 12 | –0.57 (0.16) | –0.08 (0.10) | |
| Backfill | Baseline | 0.76 (0.22) | 0.64 (0.20) | 0.021 |
| | Week 12 | 1.13 (0.29) | 0.70 (0.23) | |
| | ΔBL to week 12 | 0.36 (0.12) | 0.06 (0.06) | |
| Fat Metaplasia | Baseline | 0.50 (0.19) | 0.27 (0.09) | ns |
| | Week 12 | 0.56 (0.22) | 0.32 (0.10) | |
| | ΔBL to week 12 | 0.06 (0.07) | 0.05 (0.05) | |
| Ankylosis | Baseline | 0.15 (0.10) | 0.13 (0.11) | ns |
| | Week 12 | 0.15 (0.11) | 0.13 (0.11) | |
| | ΔBL to week 12 | 0.01 (0.01) | 0.01 (0.01) | |

Values are mean (standard error). Observed case analysis, mITT population. *2-sample t-test. BL SPARCC SSS scores did not differ significantly between ETN and PBO. Treatment differences in ΔBL to wk 12 for erosion and backfill remained significant after adjusting for BL SPARCC SSS scores using analysis of covariance models. Δ, change; ns, non-significant.

**Conclusions:** Treatment with ETN was associated with significantly greater reduction in erosion and increase in backfill at 12 wks vs. PBO, consistent with a very early reparative response to anti-TNF therapy. The impact of this new data on disease progression in SpA should be studied further.

## SAT0379 REDUCTION IN SPINAL RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS PATIENTS RECEIVING PROLONGED TREATMENT WITH TNF INHIBITORS: RESULTS FROM THE GLAS COHORT

F. Maas[1], S. Arends[1,2], E. Brouwer[1], I. Essers[3], E. van der Veer[4], M. Efde[2], P.M. van Ooijen[5], R. Wolf[6], N.J. Veeger[7], H. Bootsma[1], F.R. Wink[2], A. Spoorenberg[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Rheumatology, Maastricht University Medical Center, Maastricht; [4]Laboratory Medicine; [5]Radiology, University Medical Center Groningen, Groningen; [6]Radiology, Medical Center Leeuwarden, Leeuwarden; [7]Epidemiology, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Previous studies showed no inhibition of spinal radiographic progression in patients with ankylosing spondylitis (AS) receiving TNF inhibitors for 2 years. There are few studies with more than 4 years of follow-up showing a possible reduction, but the results are under scientific debate.
**Objectives:** To evaluate the course of spinal radiographic progression up to 8 years of follow-up in a large cohort of AS patients treated with TNF inhibitors.
**Methods:** Consecutive patients from the Groningen Leeuwarden AS (GLAS) cohort who were treated with TNF inhibitors for 2 to 8 years were included. Baseline and biannual radiographs were randomized with radiographs of TNF naïve AS patients from a historical cohort and were scored in chronological time order by two independent readers according to the mSASSS. Longitudinal modeling of radiographic damage over time with generalized estimating equations (GEE) was used to investigate whether spinal radiographic progression followed a linear or non-linear course. The estimated progression rates per 2-year time interval were calculated based on the time model with the best fit for the data. Primary analysis was performed in patients with complete data over 4, 6, and 8 years of follow-up. Sensitivity analysis was performed after single linear imputation of radiographic data in case patients had missing data at one or more intermediate follow-up visits.
**Results:** Of 188 included GLAS patients, 70% were male, 78% HLA-B27+, mean age was 42±11 years, median symptom duration 14 (IQR: 7–23) years, mean BASDAI 6.1±1.6, mean ASDAS 3.7±0.8, and mean mSASSS 9.8±15.3. Patients were exposed to TNF inhibitors during 97% (IQR: 83–100%) of their follow-up time. All baseline characteristics including mSASSS were similar between included and excluded patient, except for age (42 vs. 46 years).
During the first 4 years of follow-up, spinal radiographic progression followed a linear course (Table 1). A deflection of a linear course was found in patients with complete and imputed data over 6 and 8 years of follow-up. The estimated progression rates based on the time model with the best fit showed a reduction in progression over time (Table 1). The non-linear time model remained statistically significant after adjustment for patient characteristics including baseline radiographic damage (mSASSS and presence of syndesmophytes), gender, HLA-B27 status, age, symptom duration, smoking duration, BMI, disease activity, and NSAID use over time in both patients with complete en imputed data.

**Table 1.** Estimated mSASSS status and progression scores of the GEE model with the best fit for the data in AS patients treated with TNF inhibitors with complete and imputed data over 4, 6, or 8 years of follow-up.

| | | 4 years (n=110) | 6 years (n=53) | 6 years with imputed data (n=80) | 8 years (n=19) | 8 years with imputed data (n=41) |

## SAT0380 NSAIDS MODIFY THE EFFECT OF TUMOR NECROSIS FACTOR INHIBITORS ON NEW BONE FORMATION IN ANKYLOSING SPONDYLITIS

L. Gensler[1], J.D. Reveille[2], M.M. Ward[3], M.A. Brown[4], M. Rahbar[5], M. Lee[6], M.H. Weisman[7]. *[1]Medicine/Rheumatology, University of California, San Francisco, San Francisco; [2]Medicine/Rheumatology, The University of Texas Health Sciences Center, Houston; [3]NIAMS, NIH, Bethesda; [4]Medicine/Rheumatology, University of Queensland, Brisbane; [5]Medicine; [6]Medicine/ Biostastics, The University of Texas School of Public Health at Houston, Houston; [7]Medicine/ Rheumatology, Cedar Sinai Medical Center, Los Angeles, United States*

**Background:** Radiographic damage in Ankylosing Spondylitis (AS) is largely defined by new bone formation. The beneficial effects of pharmacologic therapy on osteoproliferation have been difficult to prove.
**Objectives:** The objective of this study was to examine the relationship of NSAIDs and Tumor Necrosis Factor inhibitors (TNFi) on New bone formation in AS.
**Methods:** 511 AS patients meeting the modified New York criteria with at least 2 years of radiographic follow-up were included in this prospective longitudinal study. Progression was defined as an increase at any vertebral corner from 0/1 to 2 or 0/1 to 3 at any interval between radiographs to reflect syndesmophyte development. We grouped patients according to the interval between baseline and the last visit, and used progression as a dichotomized outcome in a mixed effect logistic regression model. Patients taking NSAIDs for more than 50% of the time between visits were considered high NSAID users for that visit. TNFi use was assessed at each visit and adjusted for baseline use and total duration.
**Results:** In our multivariable models after adjusting for significant covariates, we found that TNFi use was associated with less new bone formation in AS with the strongest association in patients who had 2.1–3.5 years of follow-up (OR=0.27; 95% CI 0.08–0.94; p=0.04) [Table 1]. Though not statistically significant, in patients who were followed up for 3.6 years or longer, the odds of progression for the TNFi user group was 41% (3.6–5.9 year group) and 14% (6+ year group) lower than in non-users (OR=0.59, OR=0.86). We found a significant interaction (p=0.01) between NSAID use and TNFi in relation to radiographic progression. Those patients exposed to both TNFi and with high NSAID use had an OR for progression of 0.31, 95% CI 0.13–0.75, compared to those not on high dose NSAIDs (OR=1.23, 95% CI 0.41–3.66).

| Label | Odds Ratio | p-value |

## SAT0381 SAFETY AND EFFICACY OF SWITCHING FROM INNOVATOR TO BIOSIMILAR INFLIXIMAB IN PATIENTS AFFECTED BY SPONDYLOARTHRITIS. A 6-MONTH OBSERVATIONAL STUDY

A. Batticciotto[1], S. Parisi[2], F. Li Gobbi[3], M. Antivalle[1], M. Benucci[3], E. Fusaro[2], P. Sarzi-Puttini[1]. *[1]Rheumatology Department, L. Sacco University Hospital, Milano; [2]Rheumatology Department, Città della Salute e della Scienza di Torino University Hospital, Torino; [3]Rheumatology Unit, S.Giovanni di Dio Hospital, Florence, Italy*

**Background:** Biosimilar infliximab (INX) was recently approved by the European Medicine Agency based on comparable pharmacokinetics, safety and efficacy profile to innovator INX for the treatment of Rheumatoid Arthritis, Ankylosing Spondylitis (AS), Crohn's disease, Ulcerative Colitis, Psoriatic Arthritis (PsA), and psoriasis. (1)
Switching from innovator to biosimilar INX offers cost savings but, up to now, limited evidence (from conference abstracts of open-label extension studies suggesting similar clinical efficacy) and no guidelines are available. (2)
**Objectives:** To investigate efficacy and safety of switching from innovator to biosimilar INX in patients affected by spondyloarthritis (SpA) in real life clinical practice.
**Methods:** Thirty-one patients (17 with diagnosis of AS, 4 with enteropathic arthritis, 7 with PsA and 3 with undifferentiated SpA), from three Italian Rheumatologic centers with a previous diagnosis of SpA, treated for more than 6 months with innovator infliximab (in according with the ASAS/EULAR guidelines) and clinically with an inactive or moderate disease activity (ASDAS-CRP $<$2.1), were switched to biosimilar infliximab for pharmacoeconomic reasons. All patients signed a consent form.
A six months evaluation of BASDAI, BASFI, ASDAS-CRP, DAS28-CRP (if peripheral disease), MASES, VAS pain, morning stiffness and collection of adverse events (AE) were performed.
**Results:** At switch, patients had a median age of 50,9 years (range 23–80), with a median disease duration of 124,5 months (range 14–372) and median ongoing treatment with innovator INX of 73,7 months (range 6–144). After 6 months of biosimilar INX therapy we cannot find any statistical difference in terms of median values of BASDAI (2.73 ± 1.5 Vs 2.6 ± 1.3 p=0.27), BASFI (2.34 ± 1.3 Vs 2.17 ± 1.2 p=0.051), ASDAS-CRP (1.35 ± 0.3 Vs 1.28 ± 0.2 p=0.24), DAS28-CRP (2.66 ± 0.67 Vs 2.67 ± 0.35 p=0.92), MASES (0.35 ± 0.7 Vs 0.17 ± 0.4 p=0.08), VAS pain (18 ± 14.7 Vs 16,7 ± 11.3 p=0.55). The median duration of morning stiffness was statistically lower 6 months after the switch (7.2 ± 6.9 Vs 5.8 ± 6 p=0.02). During the first six months of biosimilar INX a very low number of patients experienced an AE without a significance difference with the AE collected the six months before the switch (Fisher Test p=1.0). One patient (3%) stopped biosimilar INX therapy, after the first two administrations, for the appearance of a severe palmoplantar psoriasis.
**Conclusions:** No statistically significance differences in terms of BASDAI, BASFI, ASDAS-CRP, DAS28-CRP, MASES, VAS pain values and number of adverse events were found six months after the switch from innovator to biosimilar INX in an SpA multicentre Italian cohort.

## SAT0382 THERAPEUTIC RESPONSE IN PSORIATIC ARTHRITIS PATIENTS RECEIVING BIOLOGICAL OR CONVENTIONAL DISEASE MODIFYING ANTIRHEUMATIC DRUGS. A 5-YEAR OBSERVATIONAL STUDY

M.P. Migkos[1], T.E. Markatseli[1], E. Kaltsonoudis[1], N. Tsifetaki[2], P.V. Voulgari[1], A.A. Drosos[1]. *[1]Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina; [2]Department of Rheumatology, General Hospital "G. Hatzikosta", General Hospital "G. Hatzikosta", Ioannina, Greece*

**Background:** Introduction of biological disease modifying antirheumatic drugs (DMARDs) in the treatment of Psoriatic arthritis (PsA) have altered the therapeutic approach of these patients showing a good outcome.
**Objectives:** The main purpose of the present observational study was to estimate treatment response in PsA patients receiving conventional DMARDs, biological DMARDs or combined therapy.
**Methods:** We studied 254 patients diagnosed with PsA. Patients with axial involvement fulfilled the Assessment of SpondyloArthritis international Society (ASAS) criteria and additionally the ClASsification criteria for Psoratic ARthritis (CASPAR) for patients with peripheral joint involvement. We compared the therapeutic response in patients receiving conventional DMARDs, biological DMARDs and combined therapy. Data were collected at predefined time points, baseline, 12 weeks (wks), 24 wks, 48 and 240 wks after initiation of therapy. The treatment response was assessed by using Bath Ankylosing Spondylitis Activity Index (BASDAI), Bath Ankylosing Spondylitis Functionality Index (BASFI), Disease Activity Score in 28 joints-CRP (DAS28-CRP), Disease Activity Score in 28 joints -TKE (DAS28-TKE) and Health Assessment Questionnaire (HAQ). Patients were categorized in three groups according to their treatment: patients mainly with axial disease who were treated with biological DMARDs (anti-TNFa agents) (group A), patients with peripheral arthritis with or without axial involvement treated with conventional DMARDs: methotrexate, leflunomide, cyclosporine (group B) and combined therapy: biological and conventional DMARDs (group C) according to their therapeutic response.
**Results:** Treatment with biological DMARDs showed a statistically significant difference in all disease activity scores early in the disease course ($p<0,05$) in comparison with those receiving conventional DMARDs. More specifically 12 wks after the initiation of the treatment patients receiving biological DMARDs had significant lower values for DAS28-TKE (2,04±0,69 – 3,35±0,94 p=0,0446), DAS28-CRP (2,44±0,83 – 3,73±1,22 p=0,015), BASDAI (0,85±0,59 – 2,73±1,60 p=0,0426), BASFI (1,2±1,08 – 3,29±2,07 p=0,0366) and HAQ (0,32±0,38 – 0,80±0,48 p=0,001). The patients receiving combined therapy showed better response rates at week 12 in comparison with the patients receiving conventional DMARDs but the differences were not statistically significant ($p>0,05$ in all cases). At the time points 24, 48 and 240 wks all disease activity scores were stable with no statistically significant differences within or between the three groups ($p>0,05$).
**Conclusions:** In the current study, treatment with biological DMARDs showed better response in PsA patients than those treated with conventional DMARDs early in the disease course. After the first 12 wks there were no significant differences in treatment response with respect to treatment choice.

## SAT0383 EFFICACY OF TNF INHIBITORS IN AXIAL SPONDYLOARTHRITIS ACCORDING TO THE PRESENCE OF OBJECTIVE SIGNS OF INFLAMMATION: A MULTICENTRIC RETROSPECTIVE STUDY

C. Vidal[1], C. Lukas[2], B. Combe[2], F. Berenbaum[3], C. Jorgensen[4], J. Sellam[3], J. Morel[2]. *[1]Rheumatology; [2]Hopital Lapeyronie, Montpellier Cedex 5; [3]Rheumatology, St Antoine Hospital, Paris; [4]Rheumatology, Clinical Immunology and Therapeutic of Osteoarticular Diseases Unit, Hopital Lapeyronie, Montpellier Cedex 5, France*

**Background:** TNF inhibitors (TNFi) are effective treatment in radiographic and non-radiographic axial spondyloarthritis (r-axSpA and nr-axSpA). Nr-axSpA have lower response rate in case of absence of sacroiliitis on magnetic resonance imaging (MRI) or elevated C-reactive protein (CRP) but TNFi efficacy in the absence of clinical, biological or radiological inflammatory signs is unknown due to the low number of patients included in previous studies.
**Objectives:** To compare TNFi response rate in axSpA depending on the presence or not of objective signs of inflammation.
**Methods:** Nx-axSpA patients fulfilling ASAS 2009 criteria, without objective signs of inflammation defined as the absence at the time of TNFi initiation of radiographic and MRI sacroiliitis, elevated CRP level, dactylitis, anterior uveitis and inflammatory bowel disease, treated for at least 3 months between January 2001 and September 2015 were included in this retrospective multicentric study. They were matched 1:1, by age, sex and type of TNFi, with axSpA patients with at least one objective signs of inflammation. Efficacy was defined as an achievement of 50% improvement of the initial Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) at 3, 6 or 12 months and both groups were compared. Predictive factors of response were investigated in the two groups.
**Results:** We included 84 nx-axSpA patients without objective signs of inflammation and 84 ax-SpA patients with objective signs. Patients were mainly women (76.2%) with a mean ± standard deviation age of 42 ± 11 years. BASDAI 50 achievement rate, at 3, 6 or 12 months, was significantly higher in patients with objective signs than in patients without (61.9% versus 21.4% considering all time point for evaluation, $p<0,0001$). The BASDAI mean improvement was also significantly higher in patients with objective signs at 3 (-24.3 ± 19.8 versus -9.7 ± 15.9; $p<0.0001$), 6 (-27.7 ± 22.6 versus -8.8 ± 18.3; $p<0.0001$) and 12 months (-26.5 ± 22.5 versus -13.7 ± 24.3; p=0.01). The only significant predictive factor of non-response considering the two groups was a high mean body mass index (BMI) (26.2 ± 5.7 kg/m$^2$ in non-responders versus 24.2± 4.6 kg/m$^2$ in responders; p=0.04). This factor was especially predictive of non-response among nr-axSpA without objective signs (26.5 ± 5.6 kg/m$^2$ in non-responders versus 22.3 ± 3.0 kg/m$^2$; p=0.008).
**Conclusions:** TNFi are efficient only in 20% of axSpA patients when objective signs of inflammation are absent. A high BMI is a predictive factor of non-response in axSpA in the presence or not of objective signs of inflammation.
**Disclosure of Interest:** None declared

## SAT0384 LONG-TERM SAFETY OF ANTI-TNF AGENTS IN PATIENTS WITH SPONDYLOARTHRITIS AND POTENTIAL OCCULT HBV: AN OBSERVATIONAL MULTICENTER STUDY ON 131 PATIENTS

C. Giannitti[1], G. Lopalco[2], A. Vitale[1], M.G. Anelli[2], M. Fabbroni[1], S. Manganelli[1], B. Frediani[1], M. Barone[3], M. Galeazzi[1], G. Lapadula[2], F. Iannone[2], L. Cantarini[1]. *[1]Rheumatology Unit, Department of Medical Sciences, Surgery and Neurosciences, University of Siena, Siena, Italy, Policlinico le Scotte Siena, SIENA; [2]Interdisciplinary Dpt Medicine Rheumatology Unit, University of Bari Aldo Moro, Bari; [3]Gastroenterology Unit, Dpt Medical and Surgical Sciences, University of Foggia, Foggia, Italy*

**Background:** drugs targeting tumor necrosis factor-α (TNF) biological activity deal with an increased risk of infections. Few papers address whether TNF blockers in rheumatic patients with potential HBV occult infection are safe (1–9).
**Objectives:** to evaluate the safety of anti-TNF agents in cases of spondyloarthritis with resolved hepatitis B (HBsAg negative, HBcAb±anti-HBs positive) through a close monitoring of a possible HBV reactivation and/or rise in the aminotransferase levels.
**Methods:** the medical records for 992 outpatients with rheumatic inflammatory diseases attending two Italian Rheumatology Units between 2007–2015 were retrospectively reviewed for diagnosis of spondyloarthritis, current treatment with anti-TNF agents and seropositivity for past HBV infection. 131 patients (70 men, 61 women; mean age:60,63±9,59 years) were included in the study: 55 with ankylosing spondylitis, 65 psoriatic arthritis, 9 inflammatory bowel disease-associated arthritis, 2 non-radiographic axial spondyloarthritis. Mean disease duration was 98,64±42,60 months. 64 patients were currently in treatment with Etanercept (29 in monotherapy, 31 with MTX, 3 with SSZ, 1 with CsA); 32 with Infliximab (18 as monotherapy, 10 with MTX, 3 with SSZ, 1 with CsA); 31 with Adalimumab (16 in monotherapy, 12 with MTX, 2 with LEF, 1 with CsA); 4 with Golimumab (3 with MTX, 1 as monotherapy). 101 patients received only 1 TNF inhibitor (54 Etanercept, 27 Infliximab, 20 Adalimumab); 23 patients switched to a second and 7 patients switched to a third anti-TNF agent. 51 patients had concomitant prednisone <12,5 mg/die. All 131 patients were anti-HBc+, of which 109 were anti-HBc and anti-HBs+. No patient was positive for HBV-DNA at baseline, none received antiviral therapy prior to or during anti-TNF treatment.
**Results:** at the end of the follow-up (mean of 75,50±33,37 months of anti-TNF therapy), no case of viral reactivation was observed in anti-HBc+ patients, no matter anti-HBs positivity. HBV-DNA remained undetectable, HBsAg negative, aminotransferases normal, nor it was necessary to stop biologic therapy because of viral infection.
**Conclusions:** our retrospective analysis supports the safety of TNF inhibitors for spondyloarthritis patients with a serological pattern of previous HBV infection during a follow-up >6 years. Pre-emptive antiviral prophylaxis is not necessary routinely, but strict monitoring for AST/ALT increase, as well as for changes in HBV serology and HBV-DNA, is necessary and seems a cost-effective approach to identify early viral reactivation, whose occurrence is low, but not negligible, and consequently start antiviral therapy.

## SAT0385 IMMUNOGENICITY, TNF-INHIBITORS LEVELS AND DISEASE OUTCOMES IN ANKYLOSING SPONDYLITIS: RESULTS FROM AN OBSERVATIONAL COHORT STUDY

C. Ancuta[1,2], C. Pomirleanu[1,2], C. Belibou[1], R. Maxim[1], L. Petrariu[1], G. Strugariu[1], I. Esanu[2], R. Chirieac[3], E. Ancuta[4]. *[1]Rheumatology 2, Clinical Rehabilitation Hospital; [2]University of Medicine and Pharmacy "Gr.T.Popa"; [3]Sanocare - Medical and Research Center; [4]Research Department, "Elena Doamna" Clinical Hospital, Iasi, Romania*

**Background:** Up to one third of spondylarthritis (SpA) fail to respond to anti-TNF agents or experience drug toxicity leading to treatment withdrawal. Part of the treatment failure can be explained by the development of anti-drug antibodies (ADA).
**Objectives:** To evaluate the relation between immunogenicity, drug levels and clinical efficacy of TNF inhibitors (TNF-i) in ankylosing spondylitis (AS).
**Methods:** We performed a prospective observational study in a cohort of 47 consecutive AS patients receiving adalimumab (ADL) (13; 27.7%), infliximab (IFX) (13; 27.7%) or etanercept (ETN) (21; 44.7%). Disease
Disease activity (BASDAI, ASDAS), outcomes and adverse events were evaluated at baseline and study visit, while serum TNF-i and ADA levels collected as a single-point data in both bio-naïve (37, 78.7%) and bio-experimented patients. Serum drug levels were considered positive for IFX if >0.035 μg/mL, for ADL >0.024 μg/mL and for ETN >0.035 μg/mL, while the cut-off value for the ADA positivity to IFX was established at 5AU/ml, for ADL at 10AU/mL and ETN at 142 AU/mL (ELISA, Progenika).
Statistical analysis was performed using SSPS version 19.0, $p<0.05$
**Results:** At baseline mean BASDAI was 7.69 and mean ASDAS-CRP 3.50, with no difference in disease activity between patients who did or did not later develop ADA ($p<0.05$). 37 (78.7%) AS were BASDAI responders at study visit (BASDAI 1.16, ASDAS-CRP 1.73).
ADA were detected in 8/47 (17%) and were more frequent in patients treated with ADL (5 cases; 38.5%) *vs* IFX (3 cases; 23.1%); no with ETN. Both ADL and IFX levels were significantly higher for ADA negative than for ADA positive patients (ADL: 3.92μg/mL *vs* 0.02μg/mL, $p<0.01$; IFX: 1.82μg/mL *vs* 0.03 μg/mL, $p<0.01$).
A significant association between clinical activity (ASDAS) and immunogenicity (ADA status) was reported: patients who had developed ADA had higher disease activity (3.10 *vs* 1.73, $p<0.01$), and more patients were classified as being in a high or very high disease activity status.
Furthermore, a relation between clinical improvement (change in ASDAS) and immunogenicity was reported: ADA-positive AS achieved worse clinical response than ADA-negative cases, with a significant association between ADL respectively IFX levels and ASDAS ($p<0.05$).
**Conclusions:** ADL and IFX levels are commonly influenced by ADA-positivity, and related to clinical response in AS, suggesting that therapeutic drug monitoring should be investigated as a possible tool to optimise treatment such patients.

## SAT0386 FREE DKK-1 SERUM LEVELS ARE UNCHANGED IN SPONDYLOARTHRITIS PATIENTS TREATED BY ANTI-TNF – DATA FROM THE SPARSE STUDY

C. Miceli-Richard[1], B. Combe[2], F. Berenbaum[3], T. Schaeverbeke[4], N. Koppiker[5], I. Logeart[6], A. Dubanchet[6], M. Dougados[1]. *[1]Rheumatology, Cochin Hospital, Paris Descartes University, Paris; [2]Rheumatology, Hopital Lapeyronie, Montpellier; [3]Rheumatology, Saint-Antoine Hospital, Paris VI University, Paris; [4]Rheumatology, CHU Bordeaux, Bordeaux, France; [5]Pfizer PGRD, Sandwich, United Kingdom; [6]Pfizer, Paris, France*

**Background:** DKK-1 and SOST are two inhibitory proteins of the Wnt signaling pathway which lead to decreased bone formation by osteoblasts and osteocytes, respectively. Due to the limited data assessing free DKK-1 and SOST in SpA patients under anti-TNF treatment, a post-hoc examination of the SPARSE study was designed in order to answer these question.
**Objectives:** To assess free DKK-1 and SOST serum levels at Baseline and 24 weeks after etanercept or placebo treatment in patients from the SPARSE study.
**Methods:** In the SPARSE study, patients were randomized to receive either etanercept (N=42) or placebo (n=48) in case of active AxSpA disease (defined by mini BASDAI >40) despite optimal NSAIDs intake. The 90 patients from the SPARSE study were quantified for free DKK-1 and SOST serum levels, at Baseline and at Week 8 (w8) corresponding to the end of the placebo controlled period. DKK-1 and SOST serum levels were assessed by the use of a classic sandwich ELISA test (Biomedica, Vienna) and results were provided in pmol/L. Changes in DKK-1 and SOST serum levels were adjusted for disease activity, CRP levels, NSAIDs intake, X-ray status and treatment groups.
**Results:** LS Mean (±SE) serum DKK-1 at Baseline was not significantly different between treatment groups (ETN: 36.2 ± 1.97; PBO: 37.1 ± 1.84; p=0.72). At Baseline, DKK-1 was not associated with any of the patients' or disease characteristics: ASDAS-CRP (r=0.096; 95% CI [-0.122, 0.305]); CRP (r=0.002; 95% CI [-0.210, 0.214]); X-ray status (LS Mean (SE): negative 37.4 (±2.38) versus positive 36.3 (± 1.77); p=0.71). There were no significant differences between treatment groups in the change from Baseline to w8 in the DKK-1 serum levels (p=0.97). We also considered patients with (N=67) or w/o NSAIDs intake (n=19) within the week preceding w8 serum level assessment and found no significant difference (p=0.99). We further assessed DKK-1 serum levels at Baseline according to their Baseline CRP (<6mg/L; ≥6mg/L), X-ray status (Positive; Negative), or NSAIDs intake (Yes; No) within the week preceding w8, and found no significant differences. These analyses were repeated for SOST serum levels at Baseline and with the exception of patients with Negative X-ray status at Baseline having significantly lower values than those patients with Positive X-ray status (p=0.047), no significant differences were observed in terms of the Baseline disease characteristics; Similarly there were no differences between treatment groups in the change from Baseline to w8 SOST serum levels.
**Conclusions:** This post-hoc examination of patients randomized in the SPARSE study suggest that etanercept does not significantly change DKK-1 or SOST serum levels within the 8 first weeks of treatment. Disease activity, CRP, NSAIDs intake and X-ray status were not significantly associated with DKK-1 serum levels. These results should be considered in the context of previous studies suggesting that DKK-1 was dysfunctional in SpA patients (1). Taken together, these results suggest that DKK-1 should not be considered as a valuable bone remodeling marker in SpA, unlike in rheumatoid arthritis.

## SAT0387 ANTI TNF TREATMENT OF REACTIVE ARTHRITIS. A MONOCENTRIC EXPERIENCE

A. Brinster, X. Guillot, C. Prati, D. Wendling. *Rheumatology, CHU Jean Minjoz, Besançon, France*

**Background:** Reactive arthritis is still a matter of interest and a current problem, since its treatment is not standardized, with the possibility of a chronic evolution. Nevertheless, anti TNF agents may be of interest, as illustrated by small multicentric series.
**Objectives:** To evaluate efficacy and safety of anti TNF agents in the treatment of patients with reactive arthritis followed in a single center.
**Methods:** We analyzed retrospectively the data of patients with reactive arthritis, according to proposed criteria treated with TNF blockers, from July 2007 to December 2013 in an University Hospital in France.
**Results:** Over this period, 31 cases of Reactive arthritis were followed in our department, of whom 15 (48%) received at least one dose of anti TNF. They are in majority male (n=13), mean age 35 years, 66% HLA-B27 positive. Evidence of infection was found in 9/15 patients (4 Chlamydia). After failure of NSAIDs, steroids and conventional DMARDs, anti TNF agents were introduced with a median delay of 116 days after onset of rheumatic symptoms: etanercept (ETN) 9 cases, infliximab (IFX) and adalimumab (ADA) (3 cases each) (Table). The clinical improvement was rapid, all the patients developed a clinical response to anti TNF therapy which could be stopped in 5 cases: 3 IFX after a mean of 4.6 infusions, 2 ETN after 4 and 10 months. Eight patients developed chronic spondyloarthritis, and one psoriatic arthritis, with a mean follow-up of 4.8 years, and requiring anti TNF continuation. The last patient was lost in follow-up. The treatment was well tolerated, with a mean exposition duration of 34 months by patient, neither serious infection nor reactivation of the triggering infection was recorded. Compared to the patients with reactive arthritis not treated with anti TNF over the same period, we found no differences regarding clinical data (age, arthritis distribution, type of initial infection), biologic data (CRP, HLA-B27 positivity, evidence of infectious agent). Dactylitis were more frequent (although not significant) in patients treated with anti TNF agents (40% vs 20%). In the same way, there were no differences between the patients who could stop anti TNF after several months, due to remission, and those for whom continuation was necessary, except a shorter median delay of initiation of the TNF blocker: 44 days versus 173 days respectively.

Table 1

| Anti TNF | Delay of anti TNF introduction (days) | Duration of anti TNF if stop possible (months) | Duration of anti TNF (ongoing) (years) | Evolution | Duration of follow-up under anti TNF (months) |
|---|---|---|---|---|---|
| ADA | 3386 | | | Pso Ar | 51.6 |
| IFX | 193 | 3.5 | | remission | 1.6 |
| ETN | 70 | 4 | | remission | 3.9 |
| ETN | 59 | | 5.4 | SpA | 78.4 |
| ETN | 230 | | 5.0 | SpA | 56.6 |
| ETN | 1485 | 10 | | lost FU | 10.4 |
| ETN | 11 | | 4.8 | remission | 35.3 |
| ETN | 335 | | 3.8 | SpA | 56.3 |
| ETN | 116 | | 3.7 | SpA | 33.7 |
| ADA | 79 | | 3.4 | SpA | 46 |
| ETN | 464 | | 2.5 | SpA | 39.3 |
| IFX | 83 | 5 | | remission | 5.5 |
| IFX | 39 | 2 | | remission | 2.6 |
| ADA | 454 | | | SpA | 22.1 |
| ETN | 96 | 15 | 0.5 | SpA | 20.4 |

**Conclusions:** Anti TNF therapy for reactive arthritis seems to be associated with symptomatic efficacy and good tolerance with the possibility, in one third of the cases of short lasting treatment leading to remission, which seems associated to the precocity of anti TNF initiation, suggesting a kind of window of opportunity in this subset of spondyloarthritis. However, the impact of this treatment upon the outcome of the disease needs to be further evaluated.

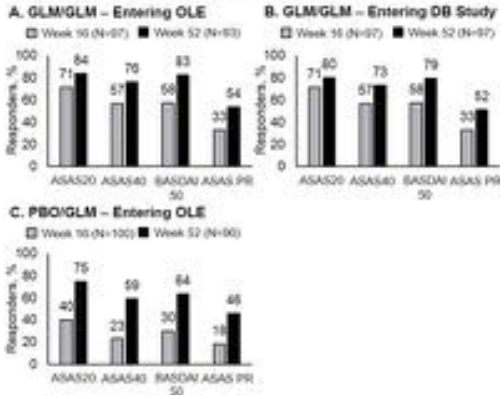
## SAT0388 LONG-TERM EFFICACY AND TOLERABILITY OF GOLIMUMAB IN ACTIVE NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: RESULTS OF THE OPEN-LABEL EXTENSION OF A RANDOMIZED, DOUBLE-BLIND STUDY

D. van der Heijde[1], M. Dougados[2], W.P. Maksymowych[3], J. Braun[4], G. Bergman[5], S.P. Curtis[5], A. Tzontcheva[5], G. Philip[5], S. Huyck[5], J. Sieper[6]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Paris-Descartes University, Paris, France; [3]University of Alberta, Edmonton, Canada; [4]Rheumazentrum Ruhrgebiet, Herne, Germany; [5]Merck & Co., Inc., Kenilworth, United States; [6]University Clinic Benjamin Franklin, Berlin, Germany*



**Background:** The efficacy and tolerability of golimumab (GLM) for nonradiographic axial spondyloarthritis (nr-axSpA) have been demonstrated in a 16-week randomized, double-blind (DB), placebo (PBO)-controlled, phase 3 study (GO-AHEAD; NCT01453725).[1]
**Objectives:** We report the long-term results from an open-label extension (OLE) of GO-AHEAD.
**Methods:** Patients (pts) completing the 16-week DB study (GLM or PBO) received open-label GLM 50 mg every 4 weeks (36-week efficacy period; 8-week safety follow-up). Prespecified responder analyses for ASAS20, ASAS40, BASDAI50, and ASAS partial remission (PR) at weeks 16, 20, 24, 32, 40, and 52 used the OLE-treated population (GLM/GLM, n=93; PBO/GLM, n=96). In a post hoc analysis, the DB-treated population was used for GLM/GLM responder analyses (GLM/GLM, n=97). Non-responder imputation was used for missing ASAS20, ASAS40, and ASAS PR values; LOCF imputation was used for missing BASDAI data. The incidence/severity of adverse events (AEs) were recorded. Data were summarized descriptively.
**Results:** In total, 176/189 (93%) pts entering the OLE completed week 60 (GLM/GLM, 85/93 [91%]; PBO/GLM, 89/96 [93%]). In the prespecified analysis, the proportions of ASAS20, ASAS40, BASDAI50, and ASAS PR responders in the OLE were similar to those in the DB phase among pts who continued GLM (GLM/GLM group); consistent results were observed in the GLM/GLM group when using the DB-treated population (Figure A,B). Among pts who switched from PBO in the DB phase to GLM in the OLE (PBO/GLM group), there were higher proportions of responders to GLM in the OLE than responders to PBO in the DB phase (Figure C). There were no notable differences in the number/types of AEs between the GLM/GLM and PBO/GLM groups (Table).

Table 1. Summary of AEs in the GO-AHEAD OLE

| AEs[a], n (%) | GLM/GLM (N=93) | PBO/GLM (N=96) | Total (N=189) |
|---|---|---|---|
| Treatment-emergent AE | 39 (41.9) | 52 (54.2) | 91 (48.1) |
| Treatment-related AE[b] | 12 (12.9) | 16 (16.7) | 28 (14.8) |
| Nasopharyngitis | 2 (2.2) | 3 (3.1) | 5 (2.6) |
| Upper respiratory tract infection | 2 (2.2) | 2 (2.1) | 4 (2.1) |
| Headache | 2 (2.2) | 2 (2.1) | 4 (2.1) |
| Discontinuation due to AE[c] | 1 (1.1) | 2 (2.1) | 3 (1.6) |
| Serious AE[d] | 2 (2.2) | 3 (3.1) | 5 (2.6) |
| Fatal AE | 0 | 0 | 0 |

[a]Includes pts who received ≥1 dose of study drug. [b]The most common AEs considered treatment-related (occurring in ≥3 pts in total) are shown. [c]GLM/GLM: acute tonsillitis and treatment-related bacterial infection (n=1); PBO/GLM: hepatitis, treatment-related rhinitis (each n=1). [d]GLM/GLM: bacterial infection, duodenitis (each n=1); PBO/GLM: treatment-related migraine, uterine polyp, staphylococcal infection (each n=1).

**Figure. Proportions of Responders in the GO-AHEAD OLE**

**Conclusions:** In the GO-AHEAD OLE, improvements in disease activity were retained in pts who received GLM and in pts who switched from PBO to GLM. Consistent with results of the GO-AHEAD DB study, treatment with GLM in the OLE was generally well tolerated in pts with nr-axSpA.

## SAT0389 LONG-TERM IMPROVEMENTS IN WORKPLACE AND HOUSEHOLD PRODUCTIVITY AND SOCIAL PARTICIPATION OVER 4 YEARS OF CERTOLIZUMAB PEGOL TREATMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS, INCLUDING ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

D. van der Heijde[1], J. Braun[2], M. Rudwaleit[3], R. Landewé[4,5], O. Purcaru[6], A. Kavanaugh[7]. *[1]Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; [2]Rheumazentrum Ruhrgebiet, Herne; [3]Endokrinologikum Berlin, Berlin, Germany; [4]Academic Medical Center, Amsterdam; [5]Atrium Medical Center, Heerlen, Netherlands; [6]UCB Pharma, Brussels, Belgium; [7]Division of Rheumatology Allergy and Immunology, UCSD, San Diego, United States*

**Background:** Axial spondyloarthritis (axSpA), including patients (pts) with ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA), is associated with a significant burden of disease and typically affects pts of working age.[1] AS has a substantial impact on pt absenteeism, as well as impeding performance at work and home;[2] limited data are available for nr-axSpA. AxSpA can also present a significant burden to caregivers.[3] Effective long-term treatments should minimize work disability, allowing pts to maintain employment and independence in household work.

**Objectives:** To report the long-term effect of certolizumab pegol (CZP) treatment on workplace and household productivity and social participation in axSpA pts over 4 years (204 weeks [wks]).

**Methods:** The RAPID-axSpA trial (NCT01087762) was double-blind and placebo-controlled to Wk24, dose-blind to Wk48 and open-label (OL) to Wk204. Pts had active disease and fulfilled ASAS criteria. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W) continued on assigned dose in the OL period. The validated arthritis-specific Work Productivity Survey (WPS)[4] assessed the impact of disease on workplace and household productivity and social participation. Data are reported for pts originally randomized to CZP (randomized set) using LOCF imputation and as observed values for pts completing each study visit.

**Table:** Workplace and household productivity over 204 wks of the RAPID-axSpA trial

| | | Wk0 CZP dose-combined | | | | | |
|---|---|---|---|---|---|---|---|

| | Wk204 | 1.7 (218) | 1.3 (141) | 1.6 (121) | 1.0 (80) | 1.7 (97) | 1.7 (61) |

[a] Based only on employed patients at the specific visit; patients employed at baseline: axSpA (157), AS (89), nr-axSpA (68); [b] Due to arthritis per month; [c] Does not include work days missed counted in the previous question; [d] 0–10 scale: 0=no interference, 10=complete interference. BL: baseline; LOCF: last observation carried forward.

**Results:** 325 pts were randomized, of whom 218 received CZP from Wk0. Of the 218 pts, 203 (93%) completed Wk24 and 142 (65%) Wk204. 157/218 (72%) pts were employed outside the home at baseline (BL). Pts reported a high BL burden of arthritis, with a mean of 7.0 days of paid work (employed pts, n=157), 12.8 days of household work, and 4.0 days of social activities (all pts, n=218) affected in the previous month.

Initial improvements in workplace and household productivity to Wk24 of CZP treatment were further sustained to Wk204 in axSpA pts, as well as in both the AS and nr-axSpA subpopulations (Table). Improvements were seen in social participation, with the number of days of family/social/leisure activities missed in the previous month reduced from 4.0 (BL) to 1.5 at Wk24 and 0.7 at Wk204 (LOCF, n=218). Caregiver burden also improved over time with 40.8% of pts at BL needing regular assistance in usual activities from a relative or friend, decreasing to 26.6% at Wk24 and 12.4% at Wk204 (LOCF, n=218, data from socio-professional module collected at each study visit).

**Conclusions:** Initial improvements seen to Wk24 with CZP treatment in workplace and household productivity, increased social participation and reduced caregiver burden further continued over long-term (4-year) treatment of axSpA, AS and nr-axSpA pts, suggesting sustained benefits to pts' lives and society.

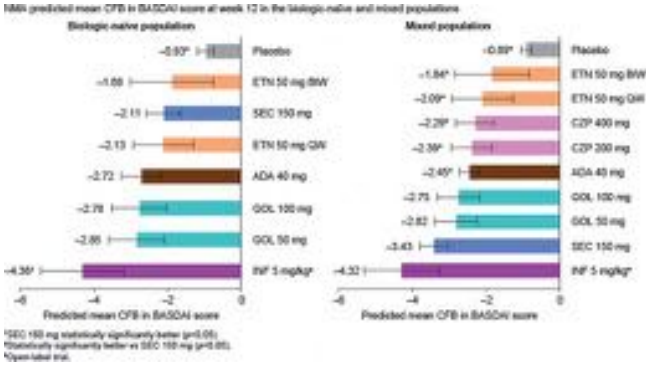
## SAT0390 SECUKINUMAB FOR THE TREATMENT OF ANKYLOSING SPONDYLITIS: COMPARATIVE EFFECTIVENESS RESULTS VERSUS CURRENTLY LICENSED BIOLOGICS FROM A NETWORK META-ANALYSIS



D. Baeten[1], P. Mease[2], V. Strand[3], I. McInnes[4], H. Thom[5], S. Kanters[6], E. Palaka[7], K. Gandhi[8], H. Richards[9], S. Jugl[9]. *[1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [2]Swedish Medical Center and University of Washington, WA; [3]Stanford University, Palo Alto, CA, United States; [4]University of Glasgow, Glasgow; [5]University of Bristol, Bristol, United Kingdom; [6]Redwood Outcomes, Vancouver BC, Canada; [7]Novartis Ireland Ltd, Dublin, Ireland; [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [9]Novartis Pharma AG, Basel, Switzerland*

**Background:** Secukinumab 150 mg (SEC) is approved for the treatment of active AS in adults who have responded inadequately to conventional therapy. The MEASURE 1 (M1) and MEASURE 2 (M2) RCTs, which included biologic-naïve and biologic-experienced patients, demonstrated superiority of SEC over placebo. In AS no direct trial comparisons of SEC with licensed biologics are currently available.

**Objectives:** To use network meta-analysis (NMA) to compare SEC vs licensed biologics in the short term.

**Methods:** A systematic literature review (January 2015) identified RCTs of licensed biologics in adults with active AS in whom conventional therapy had failed. NMAs were conducted in accordance with health technology assessment guidance using Bayesian fixed-effects models. To analyse ASAS and BASDAI50 response rates, a standard NMA model with logit link function was used. Analyses of changes from baseline (CFBs) in BASDAI and BASFI used a linear model with identity link and normal distribution. Pairwise comparisons were conducted using relative risks and mean differences. SEC results are presented as the probability of response (95% credible interval [CrI]) for ASAS and BASDAI50, and as CFB (95% CrI); CrIs can be interpreted similarly to CIs. Non-responder imputation data were used, if available; otherwise, LOCF data were used. For infliximab 5 mg/kg (INF) only data from an open label trial was available. Analyses were run at week 12 for biologic-naïve (M1, n=92; M2, n=44) and mixed (naïve or experienced; M1, n=125; M2, n=72) populations.

**Results:** In the biologic-naïve population, ASAS20 results for SEC were similar to those for adalimumab (ADA), etanercept (ETN) 50 mg BIW/QW, golimumab (GOL) 50/100 mg, and INF. The SEC response rates were 58% (46–68) for ASAS20, 42% (31–55) for ASAS40 and 39% for BASDAI50 (28–50); BASFI CFB was –1.99 (–2.39 to –1.60). For BASDAI CFB, SEC [–2.11 (–2.60 to –1.63)] was similar to all other biologics except INF, which had a statistically significantly greater CFB than SEC.
In the mixed population, SEC had similar efficacy to ADA, certolizumab pegol (CZP) 200/400 mg QW, ETN and GOL for ASAS20 [SEC response, 53% (43–63)]. SEC was also similar to ADA, CZP, ETN, GOL and INF for ASAS40 [39% (29–51)], BASDAI50 [35% (25–46)] and BASFI CFB [–1.89 (–2.24 to –1.53)]. SEC was statistically significantly superior to ADA, CZP and ETN for BASDAI CFB [–3.43 (–3.82 to –3.05)].

**Conclusions:** This NMA shows that SEC has similar efficacy to most licensed biologics at most endpoints investigated, with the exception of INF for BASDAI CFB in the biologic-naïve population and ASAS20 in the mixed population. SEC also demonstrated statistically significant superiority over ADA, ETN and CZP for BASDAI CFB in the mixed population. The short-term nature of this study is a limitation (long-term data [≥52 weeks] are available for SEC).

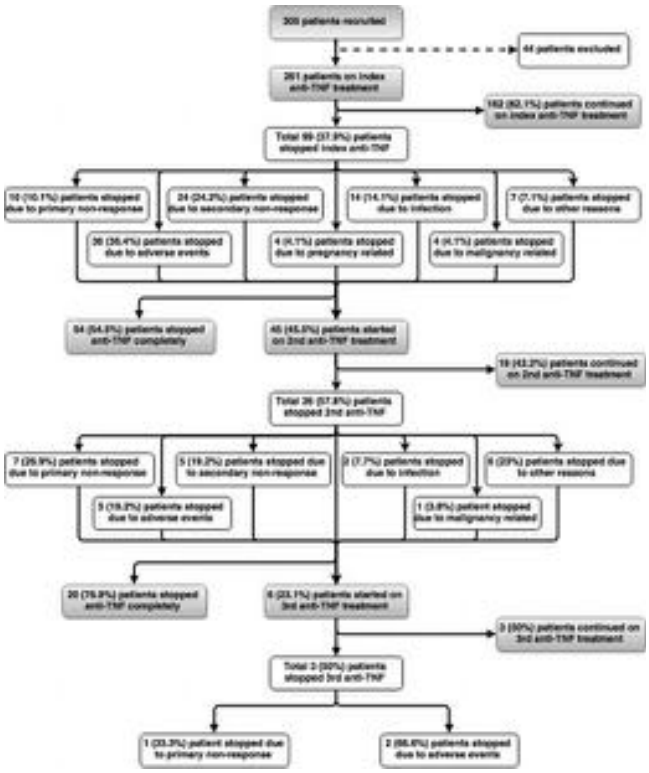
## SAT0391 THE 8-YEAR RETENTION RATE OF THE FIRST TNF-INHIBITOR IN THE TREATMENT OF SPONDYLOARTHROPATHIES: REAL-LIFE DATA FROM A MULTICENTRIC LOCAL REGISTRIES



E.G. Favalli[1], C. Selmi[2], A. Becciolini[1], M. Biggioggero[3], A. Ariani[4], D. Santilli[4], E. Fusaro[5], S. Parisi[5], M. Massarotti[6], A. Marchesoni[1], P.L. Meroni[7].
*[1]Department of Rheumatology, Gaetano Pini Institute, Milano; [2]Rheumatology, Humanitas Research Hospital, University of Milan, Rozzano; [3]Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute, Milano; [4]Medicine Department, Internal Medicine and Rheumatology Unit, University Hospital, Parma; [5]Department of Rheumatology, Città Della Salute e della Scienza, Torino; [6]Rheumatology, Humanitas Research Hospital, Rozzano; [7]Department of Clinical Sciences and Community Health, University of Milan and IRCCS Istituto Auxologico Italiano, Milano, Italy*

**Background:** Long-term data on drug survival of TNF inhibitors (TNFi) in the treatment of spondyloarthropathies are still lacking.
**Objectives:** The aim of the study is to analyze in a setting of real-life the 8-year retention rate of the first TNFi for the treatment of psoriatic arthritis (PsA) and axial spondyloarthritis (ax-SpA) and to compare the between-group discontinuation rates for each TNFi (infliximab [IFX], etanercept [ETN], and adalimumab [ADA]).
**Methods:** Data were retrospectively extracted from four local registries including all patients affected by PsA and ax-SpA treated with a biologic drug between January 2005 and May 2015. The analysis was limited to patients treated with IFX, ETN, or ADA as first-line biologic agent, with at least 1-year follow-up period. The 8-year drug survival was evaluated by Kaplan-Meier method and the risk for discontinuation among the 3 treatment groups was compared by a stratified log-rank test.
**Results:** The study population (614 patients) included 316 ax-SpA (69.9% male, mean age [±SD] 42.8 [±12.1] years, mean disease duration 7.2 [±7.9] years), treated with ADA (n=95), ETN (n=42), or IFX (n=179); and 298 PsA (51.7% male, mean age 47.8 [±12.1] years, mean disease duration 8.8 [±7.7] years), treated with ADA (n=108), ETN (n=89), or IFX (n=101). The overall median survival on treatment of the whole study population was 117.17 months (102.84 and >117.17 months for axSpA and PsA, respectively; p=NS).
The overall retention rate was 66.2% (69.5% versus 62.8% in axSpA and PsA, respectively) at 5 years and 55.5% (57.2% versus 53.4% in axSpA and PsA, respectively) at 8 years. No significant differences emerged in the comparison among ADA, ETN, and IFX in both ax-SpA group (p=0.1065) and PsA group (p=0.06). IFX and ETN showed similar survival rates in PsA and axSpA (HR 1.252, 95% CI 0.600–2.608, and HR 1.224, 95% CI 0.8441–1.774, respectively), whereas ADA showed a significantly higher survival in axSpA compared to PsA (HR 1.775, 95% CI 1.045–3.013). Overall, 265 (43.1%) patients (129 [43.2%] PsA and 133 [42.1%] axSpA), stopped the first course TNFi. Inefficacy led to discontinuation in 115 (18.7%) patients (65 [21.8%] PsA and 50 [15.8%] axSpA), without significant differences between the two disease groups (p=0.1076). Adverse events led to discontinuation in 88 (14.3%) patients, (43 [14.4%] PsA and 45 [14.2%] axSpA), without significant differences between PsA and axSpA (p=0.9049).
**Conclusions:** In a real-life setting, the 8-year retention rate of the first TNFi in the treatment of spondyloarthropathies was about 50%, with no significant difference between ax-SpA and PsA. The risk of stopping IFX and ETN treatment was similar in both ax-SpA and PsA group, whereas ADA showed a higher survival in axSpA group.

## SAT0392 THE DRUG SURVIVAL OF ANTI-TUMOUR NECROSIS FACTOR (TNF) TREATMENT IN A UK COHORT OF AXIAL SPONDYLOARTHRITIS PATIENTS

F. Yahya[1,2], C. Cavill[1], J. Berry-Jenkins[1], D. Bond[1], C. Boyle[1], R. Sengupta[1,3].
*[1]Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; [2]Department of Medicine, University Malaya, Kuala Lumpur, Malaysia; [3]University of Bath, Bath, United Kingdom*

**Background:** The use of anti-Tumour Necrosis Factor (TNF) therapy has made a huge impact in the treatment of axial spondyloarthritis (axSpA) patients which include ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA). Patients typically commence these drugs if they fulfil criteria set out by the National Institute for Health Care and Excellence (NICE) guidelines[1]. Continuation of anti-TNF therapy depends on their response, or the occurrence of adverse events (AEs). Current NICE guidelines allow switching to an alternative anti-TNF if side effects occur early in the treatment course. However, few studies have provided data regarding the patterns of drug survival and reasons for discontinuation of anti-TNF in a UK cohort of AxSpA patients[2].

**Objectives:** To analyse the long-term survival of anti-TNF in AS patients and the reasons for switching anti-TNF therapy in a UK cohort.
**Methods:** We conducted a retrospective analysis of patients who fulfilled AS or nr-axSpA ASAS Classification criteria[3], aged 18 years or above, who received at least one anti-TNF agent at the Royal National Hospital for Rheumatic Diseases (RNHRD) Bath. Data were collected from review of the patients' medical notes. Data included the types and duration of anti-TNF used, and the reasons anti-TNF therapy needed to be stopped or changed. The initial anti-TNF agent prescribed is described as the index treatment.
**Results:** 305 patients,with a mean age of 49.7 (SD12.81), were recruited from the RNHRD AxSpA Biologics database. 261 patients were included in the final data analysis with 90.8% fulfilling the modified New York criteria. Female n=63 (24.1%). The index anti-TNF treatment were Adalimumab n=123 (47.1%), Etanercept n=84 (32.2%), Golimumab n=27 (10.3%), Certolizumab pegol n=15 (5.7%), and Infliximab n=12 (4.6%). 110 (40.4%) patients had to discontinue their index treatment. The most frequent reasons for discontinuation of index anti-TNF included AEs n=36 (36.4%) and loss or lack of efficacy (LOE) n=34 (34.3%). In patients who proceeded to switch to a 2nd anti-TNF, the main reason for stopping the index anti-TNF was AEs n=18 (40%). 26 (57.8%) patients stopped their 2nd anti-TNF treatment with LOE n=12 (46.1%) as the main reason. 6 (23.1%) patients proceeded to have a 3rd anti-TNF with 3 (50%) patients had to stop this completely.
**Conclusions:** About half of the patients had to discontinue their anti-TNF treatment either as an index treatment or subsequent treatment. The most common reason for stopping anti-TNF treatment in our cohort was due to adverse events. 45.5% of patients switched to a second anti-TNF agent and 23.1% of the patients switched from a second to a third anti-TNF agent.

## SAT0393 CLINICAL AND QUALITY OF LIFE IMPROVEMENTS OBSERVED WITH GOLIMUMAB AND INFLIXIMAB IN A LARGE REAL-LIFE ANKYLOSING SPONDYLITIS POPULATION: RESULTS FROM THE QUO-VADIS STUDY

F. Van Den Bosch[1], R.-M. Flipo[2], J. Braun[3], S. Sajjan[4], S. Kachroo[4], N. Vastesaeger[5], M. Govoni[6]. *[1]University Hospital, Gent, Belgium; [2]University Hospital of Lille, Lille, France; [3]Rheumazentrum Ruhrgebiet, Herne, Germany; [4]Merck Sharp & Dohme, Kenilworth, United States; [5]Merck Sharp & Dohme, Brussels, Belgium; [6]Merck Sharp & Dohme, Rome, Italy*

**Background:** Loss of health-related quality of life (HRQoL) is documented in Ankylosing Spondylitis (AS) patients and improvement has been observed upon therapy with anti-tumor necrosis factor (TNF) agents. Parameters such as higher ASDAS, elevated CRP and younger age have been described in literature to be associated with improved clinical outcomes.
**Objectives:** The relationship between baseline (BL, pre-anti-TNF treatment) disease-specific parameters and HRQoL improvement during anti-TNF therapy with golimumab (GLM) or infliximab (IFX) was evaluated in the QUality of Life as Outcomes and its VAriation with DIsease States (QUO-VADIS) study.
**Methods:** This prospective observational study included bio-naïve AS patients (modified New York criteria) newly treated with GLM or IFX (originator). Patients were followed-up for ~6 months (data collected at BL, 3, and 6 months). Demographic and clinical characteristics, disease activity and HRQoL were summarized accordingly. The Classification and Regression Trees (CART) analysis evaluated the association of BL parameters (demographic, clinical, disease severity) with change in HRQoL at 6 months, measured by an improvement of ≥5 points of the Short-Form 36 (SF-36) Physical Component Summary (PCS) score. Clinical parameters included Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI), and AS Disease Activity Scores (ASDAS).
**Results:** 963 patients received ≥1 dose of medication; 78% received GLM and 22%received IFX. Mean age was 42.7 years, 61.4% were male, and 65.3% had ≥ one comorbidity. Mean symptom and diagnosis duration were 11.6 and 5.3 years, respectively, and 63.8%of patients were Human Leukocyte Antigen (HLA)-B27 positive. At BL, mean BASDAI, ASDAS-CRP and BASFI scores were 6.21, 3.59 and 5.34, respectively. High and very high ASDAS disease activity was observed in 41.4% and 49.3% of patients, respectively. Clinical and HRQoL improvements were shown in all collected measures following 6 months of treatment with GLM or IFX, as documented in the Table. PCS response at 6 months (improvement of ≥5 points from BL) was achieved in 52.3% (n=504) of patients. Using CART analysis, the baseline parameters, and their cutoff values, associated with HRQoL improvement as measured by SF-36 PCS response at 6 months were ASDAS (≥3.48), C-Reactive Protein (CRP) (≥8.55 mg/L), and age (≤35.5 years), and BASFI (≥1.15). This algorithm correctly identified 57.5% (sensitivity) of the patients who had improvement on PCS >5 points and 61.0% (specificity) of the patients who had improvement on PCS ≤5 points with ROC-AUC=0.61.

**Table: Improvement in Clinical and QoL Parameters Following 6 months of Treatment**

| | Overall population N=963 | Golimumab-only cohort N=751 |
|---|---|---|
| Mean (SD) BASDAI change from BL | -2.7 (2.3) | -2.6 (2.3) |
| Mean (SD) BASFI change from BL | -2.1 (2.3) | -2.2 (2.2) |
| BASDAI50 Response | 39.5% | 39.9% |
| ASAS20 Response | 50.6% | 52.6% |
| ASDAS Major Improvement | 26.6% | 26.0% |
| ASDAS Disease Activity Category | | |
| Inactive (<1.3) | 19.9% | 20.4% |
| Moderate (≥1.3 to ≤2.1) | 21.2% | 22.2% |
| High (>2.1 to ≤3.5) | 29.4% | 29.6% |
| Very High (>3.5) | 7.0% | 5.1% |
| Missing | 22.5% | 22.8% |
| SF36 PCS responders (improvement of ≥ 5 points from BL) | 52.3% | 53.3% |

**Conclusions:** This study demonstrated clinical and HRQoL improvements over 6 months in a large, real-world population of AS patients newly treated with GLM or IFX. The QUO-VADIS study also demonstrates, for the first time, the association of parameters such as higher ASDAS, elevated CRP and younger age with improvements in HRQoL and with a more robust response. The use of these predicting factors may aid clinicians in better evaluating which patients to start on antiTNF therapy with GLM or IFX.

## SAT0394 IMPACT OF DISEASE DURATION ON PATIENT REPORTED AND CLINICAL OUTCOMES IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH ANTI-TNF: AN ANALYSIS FROM A PROSPECTIVE, OBSERVATIONAL REGISTRY

M. Starr[1], M. Zummer[2], D. Choquette[3], B. Haraoui[3], D. Sholter[4], R. Arendse[5], I. Fortin[6], L. Bessette[7], P. Rahman[8], E. Rampakakis[9], E. Psaradellis[9], A.J. Lehman[10], K. Maslova[10], B. Osborne[10], F. Nantel[10], C.M. Tkaczyk[10]. *[1]McGill University; [2]Hôpital Maisonneuve-Rosemont; [3]IRM, Montreal; [4]University of Alberta, Edmonton; [5]University of Saskatchewan, Saskatoon; [6]CREQ, Rimouski; [7]Universite Laval, Quebec; [8]Memorial University, St John's; [9]JSS, Montreal; [10]Janssen, Toronto, Canada*

**Background:** Previous studies have shown that treatment outcomes are affected by disease-related aspects and patient-related factors.
**Objectives:** The aim of this analysis was to compare ankylosing spondylitis (AS) patient profiles in terms of patient characteristics and disease parameters based on disease duration and to investigate the impact of disease duration on patient reported and clinical outcomes in patients treated with anti-TNF.
**Methods:** BioTRAC is an ongoing, prospective registry of pts initiating treatment for rheumatoid arthritis, AS, or psoriatic arthritis with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included AS patients treated with IFX and enrolled since 2005 or with GLM and enrolled since 2010. Patients were classified in three subgroups (≤1 yr, 2–10 yrs, >10 yrs) based on the tertile distribution of the time elapsed since their diagnosis. The impact of disease duration on outcomes upon adjusting for potential confounders was assessed with generalized linear models and logistic regression.
**Results:** A total of 580 AS patients were included in this analysis with a mean age of 45.8 yrs and disease duration of 8.3 yrs. The majority were male and 92.6% were biologic naïve. At baseline, mean BASFI was 5.6, BASDAI was 6.2, and ASDAS was 3.6. With the exception of age which was significantly higher among pts with longer disease duration (P<0.001) no significant between-group differences were observed in baseline demographics and disease parameters.
Upon 6 mos of treatment, clinically meaningful and statistically significant improvements were observed in BASFI, BASDAI and ASDAS which were further enhanced at 12 mos. Upon adjusting for baseline age and respective parameter levels, pts diagnosed within ≤1 yr experienced significantly lower improvements in BASFI (P=0.030), BASDAI (P<0.001), and ASDAS (P=0.030) at 12 mos as compared to pts with disease duration >10 ys. For ASDAS, concomitant DMARD use was also identified as a significant predictor of improved outcome (P=0.042). Gender and prior biologic experience did not have a significant impact on outcomes. Inactive or moderate disease activity, based on ASDAS, was achieved by 47.2% of pts while clinically important and major improvements were observed for 54.9% and 32.7% of pts, respectively. Similarly to the absolute improvements, pts diagnosed within ≤1 yr were significantly less likely to achieve these endpoints.
**Conclusions:** The results of this real-world analysis have identified prior disease duration at anti-TNF initiation as a significant independent predictor of treatment outcome. Concomitant use of a DMARD was associated with significantly higher

improvement in ASDAS. These results suggest that pts with early disease may be harder to treat and highlight the need for more aggressive treat-to-target approaches in this patient subgroup.

## SAT0395 STATIN TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS

G. Wibetoe[1], E. Ikdahl[1], T.K. Kvien[2], S. Rollefstad[1], A.G. Semb[1].
*[1]Cardio-Rheuma Clinic, Dept. Rheumatology; [2]Dept. Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

**Background:** Patients with ankylosing spondylitis (AS) have increased risk of cardiovascular disease (CVD). In the general population, CVD risk reduction can be achieved by lipid lowering therapy (LLT).
**Objectives:** We aimed to evaluate the effect of statins in AS patients and factors associated with the changes (Δ) in low-density lipoprotein cholesterol (LDL-c) and total cholesterol (TC).
**Methods:** In this longitudinal, observational study, 108 patients with AS underwent CVD risk evaluation. Of these, 48 patients had an indication for LLT and received statin treatment which was adjusted until lipid targets were achieved. Variables obtaining a p-value of $<0.25$ in a univariate analyses were entered in forward, stepwise, linear regression models with ΔLDL-c and ΔTC as the dependent variables and were adjusted for age and gender, as well as baseline LDL-c levels (for ΔLDL-c) and intensity of LLT (for ΔTC).
**Results:** At first visit, median (IQR) age was 61.5 (56.0, 66.8) years, 72.9% were male, median disease duration was 27 (17.8, 32.8) years, 12.5% smoked daily, 70.8% had hypertension (HT), mean (SD) body mass index (BMI) was 26.0 (3.50) kg/m$^2$, mean LDL-c and TC, were 3.82±1.02 and 6.04±1.16mmol/L and 70.8% had carotid plaque(s). Twenty patients were treated with low or moderate intensity LLT (simvastatin 20 mg or 40 mg, rosuvastatin $<40$ mg or atorvastatin $<40$ mg), while the remaining 28 received intensive LLT (rosuvastatin 40 mg or atorvastatin $>40$ mg). LDL-c goals (50% reduction in LDL-c and /or LDL-c $<2.5$ /$<1.8$ mmol/L, for primary (n=10) or secondary prevention (n=38), respectively) were achieved in 85.4% of patients (90.0% and 84.2% for primary and secondary prevention, respectively). Reductions in LDL-c and TC were 1.60+0.41 mmol/L and 2.42+1.15 mmol/L ($p<0.001$ for both). Predictive variables explaining 86.5% ($R^2$) of the ΔLDL-c included erythrocyte sedimentation rate (ESR), established CVD and HT. Only ESR ($p=0.03$) and baseline LDL-c ($p<0.001$) contributed significantly to the final model. ESR was inversely related to ΔLDL-c. In addition, higher baseline LDL-c levels were associated with larger LDL-c reduction. The final model for ΔTC, accounting for 33.0% ($R^2$) of the variation, included ESR, waist circumference, BMI, non-steroidal anti-inflammatory drugs, and use of biologic and synthetic disease modifying anti-rheumatic drugs. Intensive LLT and high waist circumference were predictive of greater TC reductions (p=0.002 and 0.04, respectively).

Table 1

| | ΔLDL-c, $R^2$=0.865 | | | ΔTC, $R^2$=0.330 | |

| LDL-c at baseline | –0.78 (–0.89, –0.66) | <0.01 | LLT (statin dose) | –1.09 (–1.74, –0.43) | <0.01 |
| ESR | 0.01 (0.00, 0.02) | 0.03 | ESR | 0.01 (–0.02, 0.03) | 0.61 |
| CVD | 0.20 (–0.12, 0.52) | 0.21 | Waist circumference | –0.06 (–0.12, –0.00) | 0.04 |
| Hypertension | –0.16 (–0.42, 0.11) | 0.25 | BMI | 0.14 (–0.06, 0.33) | 0.16 |
| | | | NSAIDs | –0.33 (–1.08, 0.42) | 0.37 |
| | | | Biologic DMARDs | –0.34 (–1.06, 0.39) | 0.35 |
| | | | Synthetic DMARDs | 0.18 (–0.87, 1.23) | 0.73 |

**Conclusions:** Lipid lowering with statins was highly effective in AS patients. Inflammation measured by ESR was inversely related to change in LDL-c, possibly due to the suppressive effect on lipid levels. Further studies are needed to elucidate if the anti-inflammatory effect of rheumatic medication influence the lipid lowering effect of statins in patients with AS.
**Disclosure of Interest:** None declared

## SAT0396 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE ANKYLOSING SPONDYLITIS: 2-YEAR RESULTS FROM A PHASE 3 TRIAL WITH SUBCUTANEOUS LOADING AND MAINTENANCE DOSING (MEASURE 2)

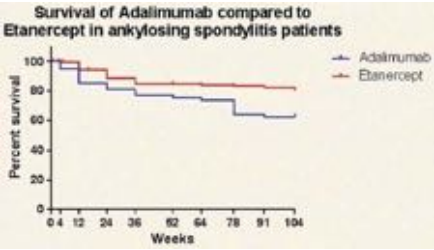
H. Marzo-Ortega[1], C.W. Legerton[2], J. Sieper[3], A. Kivitz[4], R. Blanco[5], M. Cohen[6], J. Zuazo[7], A. Readie[8], B. Porter[8], H. Richards[7] on behalf of the MEASURE 2 Study Group. *[1]Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals Trust and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [2]Low Country Rheumatology, Articularis Healthcare, Charleston, United States; [3]University Clinic Benjamin Franklin, Berlin, Germany; [4]Altoona Center for Clinical Research, Duncansville, United States; [5]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [6]Division of Rheumatology, McGill University, Montreal, Canada; [7]Novartis Pharma AG, Basel, Switzerland; [8]Novartis Pharmaceuticals Corporation, East Hanover, United States*

**Background:** Secukinumab, an anti–interleukin-17A monoclonal antibody, improved the signs and symptoms of ankylosing spondylitis (AS) over 52 weeks (wks) in the randomised, double-blind, placebo (PBO)-controlled, Phase 3 MEASURE 2 study (NCT01649375).[1]
**Objectives:** To evaluate the long-term (104 wks) efficacy and safety of secukinumab in MEASURE 2 study.
**Methods:** 219 subjects with active AS, classified by modified New York criteria, despite therapy with NSAIDs, were randomised to subcutaneous (s.c.) secukinumab 150 or 75 mg or PBO at baseline (BL), Wks 1, 2 and 3, and every 4 wks (q4w) from Wk 4. At Wk 16, PBO-treated subjects were re-randomised to secukinumab 150 or 75 mg s.c. q4w. At BL, 39% of subjects had an inadequate response/intolerance to prior anti-TNF therapy (anti–TNF-IR). Primary endpoint was ASAS20 response rates at Wk 16. Secondary endpoints included ASAS40, hsCRP, ASAS5/6, BASDAI, SF-36 PCS and ASAS partial remission. Endpoints were assessed through Wk 104, with multiple imputation for binary variables and a mixed-model repeated measures for continuous variables. Analyses stratified by anti-TNF history were pre-specified and are reported as observed.
**Results:** 60/72 (83.3%), 57/73 (78.1%) and 57/74 (77%) subjects completed 104 wks of treatment with secukinumab 150 mg, 75 mg and PBO, respectively. As reported previously, secukinumab 150 mg significantly improved all pre-specified endpoints at Wk 16 vs. PBO, except ASAS partial remission; the 75 mg dose did not reach statistical significance at Wk 16 based on hierarchical testing.[1] ASAS20/40 response rates at Wk 104 were 71.5/47.5% with both secukinumab doses. Clinical improvements with secukinumab were sustained through Wk 104 across all secondary endpoints (Table). In the subgroup of anti–TNF-naïve subjects, ASAS20/40 response rates at Wk 104 (observed data) were 76.9/56.4% and 80.0/60.0% with secukinumab 150 mg and 75 mg, respectively; corresponding rates in anti–TNF-IR subjects were 85.0/50.0% and 68.8/43.8%. Across the treatment period (mean secukinumab exposure: 735.6 days), exposure-adjusted incidence rates for serious infections/infestations, IBD, malignant/unspecified tumours and MACE with secukinumab were 1.2, 1.4, 0.5 and 0.7 per 100 subject-years, respectively. No cases of TB, opportunistic infections or suicidality-related AEs were reported.

**Table. Summary of 104 week Efficacy Results**

| | Secukinumab 150 mg s.c. N = 72 | Secukinumab 75 mg s.c. N = 73 |
|---|---|---|
| ASAS20 response, n (%) | 51 (71.5) | 52 (71.5) |
| ASAS40 response, n (%) | 34 (47.5) | 35 (47.5) |
| hsCRP, change from baseline score (Mean ± SE) | 0.50 ± 1.13 | 0.59 ± 1.13 |
| ASAS5/6, n (%) | 36 (50.2) | 30 (41.0) |
| BASDAI, mean change from baseline score (Mean ± SE) | –2.92 ± 0.27 | –2.85 ± 0.27 |
| SF-36 PCS, mean change from baseline score (Mean ± SE) | 7.29 ± 0.97 | 6.55 ± 1.01 |
| ASAS partial remission, n (%) | 14 (19.9) | 10 (13.7) |

ASAS, Assessment of Spondyloarthritis International Society; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; hsCRP, high sensitivity C-reactive protein; n, number of subjects meeting criteria; N, total number of subjects in the analysis; s.c., subcutaneous; SE, standard error; SF-36 PCS, short form-36 health survey physical component summary



**Conclusions:** Secukinumab provided sustained improvement through 2 years in the signs and symptoms of AS with improved physical function, regardless of anti-TNF status. Safety was consistent with previous reports.

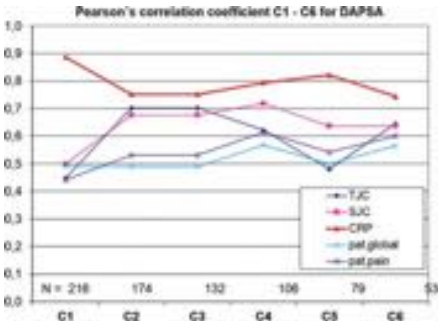
## SAT0397 COMPARISON OF LONG-TERM DRUG SURVIVAL OUTCOME WITH ETANERCEPT TREATMENT AND ADALIMUMAB TREATMENT OF ANKYLOSING SPONDYLITIS

J. Ruwaard[1], M. l'Ami[1], A. Marsman[1], E. Kneepkens[1], I.E. van der Horst-Bruinsma[2], C. van Denderen[1], M.T. Nurmohamed[1,2], G. Wolbink[1,3]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center, location Reade; [2]Rheumatology, Amsterdam Rheumatology and immunology Center, location VU medical center; [3]Department of Immunopathology, Sanquin Research and Landsteiner Laboratory Academic Medical Centre, Amsterdam, Netherlands*

**Background:** Treatment with Tumor Necrosis Factor inhibitors (TNFi) has improved the outcome of patients with ankylosing spondylitis (AS) but it is currently unknown, if response varies between different TNFi. One systemic review could not find a significant difference in clinical response and adverse events (AE) between adalimumab (ADL) and etanercept (ETN) in AS patients [1].
**Objectives:** To compare rates of drug survival and clinical response during 2-years of follow-up in patients with AS treated with ETN or ADL in routine care.
**Methods:** Two-hundred-forty-nine consecutive AS patients previously unexposed to TNFi were treated with ETN (164) or ADL (85). Treatment allocation was at the discretion of the treating rheumatologist. Clinical parameters were measured at each time point. Discontinuation was due to inefficacy on the drug, AE, lost to follow up, pregnancy wish and other reasons. Disease activity was assessed by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Response was defined as an improvement of BASDAI with 50% or as a 2 point drop compared to baseline. Data is corrected for baseline C-reactive protein, methotrexate use, BASDAI and body mass index. We imputed missing data by using last observation carried forward to assess mean BASDAI and BASDAIresponse at 2 years in patients who discontinued ETN or ADL prematurely.
**Results:** A total of 57 (22.9%) patients discontinued the drug, 28 (32.9%) patients discontinued ADL and 29 (17.7%) patients ETN. Cox-regression analysis demonstrated a significant difference in survival rate between discontinuation of the drug in the ADL patients compared to ETN patients; Hazard Ratio (HR) 2.09 (95% CI 1.25–4.50) p=0.005 (see figure) corrected for confounding; HR: 2.65 (95% CI 1.46–4.80) p=0.001. An independent t-test shows no difference at 2-years of follow-up between the ADL and the ETN patients in mean BASDAI; 3.5 (SD±2.5) respectively 4.1 (SD±2.1) p=0.336. Moreover, no difference between the ADL and the ETN patients was found in BASDAIresponse; 17 out of 30 (56.6%) reached BASDAI response at 2 year in patients treated with ADL compared to 73 out of 115 (63.5%) in patients treated with ETN; p=0.493.



**Conclusions:** No difference was found in BASDAI or BASDAIresponse at a 2-year follow up. AS patients using ETN had a higher drug survival in the first 2 years of the treatment compared to AS patients using ADL. However, this study is not designed as a head-to-head trial, which has the risk of a selection bias.

## SAT0398 APPLICATION OF DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA) IN A COHORT OF PATIENTS FOLLOWED IN THE INSTITUTE OF RHEUMATOLOGY PRAGUE

J. Stolfa[1,2], L. Sedova[1]. *[1]Rheumatology, Institute of Rheumatology; [2]Rheumatology, First Medical Faculty, Charles University, Prague, Czech Republic*

**Background:** At present new guidelines for the therapy and monitoring of psoriatic arthritis are in progress, inspired by the EULAR guidelines 2015. We propose the Minimal Disease Activity (MDA) as a target of therapy. Given the fact that the major problem of our patients is joint manifestation of psoriatic disease (PD) and only occassionally severe skin syndrome, which usually requires different therapeutic approach we have searched for an instrument which would assess the severity of joint involvement numerically, taking into account the patient's point of view. For this purpose we used the recently validated index DAPSA[1]
**Objectives:** (1) To ascertain the correlation of this index with its individual components (2) to take a look at the development of this index over time in a sample of patients from our database.
**Methods:** We picked 53 cases out of our database of 216 patients, who had at least 6 yearly controls with full set of data available. Subsequently we calculated DAPSA according to the formula: SJC+TJC+pat.pain VAS10,0cm+pat. Global VAS10,0cm+CRPmg/l[1]. Then we determined the correlation between DAPSA and individual components of the index using Pearson's correlation coefficient for each of 6 controls (C). We followed further the development of this index during the course of 6 years and calculated the percentage of patients who achieved remission (REM), low disease activity (LDA), moderate disease activity (MDA), or high disease activity (HDA) according to this index. The usual treatment algorythm was used, only the more tight control was employed.
**Results:** (1) The best correlation with DAPSA was found for CRP (0,74–0,93) and to a lesser degree for the number of swollen and tender joints (0,50–0,72 and 0,49–0,70 respectively) and for patient reported outcomes (pat. global-0,57–0,75 and pat. pain-0,44–0,61). (2) The proportion of patients in REM and LDA increased linearly during the 6-year follow up. (3) The average DAPSA score decreased during their follow-up (21,1–3,59).

**Conclusions:** The newly validated index of disease activity DAPSA seems to be a good indicator of disease activity and treatment response in patients with psoriatic arthritis. It could be a good component of local guidelines for treatment and monitoring of PsA.

## SAT0399 EFFICACY OF GOLIMUMAB FOR NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: SUBGROUP ANALYSIS BY BASELINE MRI AND C-REACTIVE PROTEIN STATUS

J. Sieper[1], D. van der Heijde[2], W.P. Maksymowych[3], J. Braun[4], G. Bergman[5], S.P. Curtis[5], A. Tzontcheva[5], G. Philip[5], S. Huyck[5], M. Dougados[6]. *[1]University Clinic Benjamin Franklin, Berlin, Germany; [2]Leiden University Medical Center, Leiden, Netherlands; [3]University of Alberta, Edmonton, Canada; [4]Rheumazentrum Ruhrgebiet, Herne, Germany; [5]Merck & Co., Inc., Kenilworth, United States; [6]Paris-Descartes University, Paris, France*

**Background:** The efficacy of golimumab (GLM) for nonradiographic axial spondyloarthritis (nr-axSpA) was demonstrated in a randomized, double-blind (DB), placebo (PBO)-controlled, phase 3 study (GO-AHEAD; NCT01453725).[1]
**Objectives:** We investigated the effect of GLM in patients (pts) with nr-axSpA based on presence or absence of objective inflammation (ASAS+ MRI sacroiliitis and/or C-reactive protein [CRP] $>$ upper limit of normal [ULN]) at baseline.
**Methods:** Pts with nr-axSpA (ASAS criteria, centrally read SI joint X-rays/MRIs, disease duration $\leq$5 years, chronic back pain $\geq$3 years, high disease activity, and inadequate response or intolerance to NSAIDs) were randomized (with

ASAS-defined MRI sacroiliitis by single central reader [yes, SI+; no, SI–] and CRP level [≤ULN or >ULN] as stratification factors) to GLM 50 mg SC or PBO Q4W for 16 wks. The primary endpoint was ASAS20 response at wk 16. Estimated between-group differences in ASAS20, ASAS40, BASDAI50, and ASAS partial remission (PR) response at wk 16 for four pt subgroups (MRI SI+ & CRP >ULN; MRI SI– & CRP >ULN; MRI SI+ & CRP ≤ULN; MRI SI– & CRP ≤ULN) were compared by Miettinen-Nurminen methods. No multiplicity control was used.

**Results:** In total, 197 pts were treated (GLM=97; PBO=100). Treatment group differences in ASAS20, ASAS40, BASDAI50, and ASAS PR response were greater in pts with baseline objective inflammation (Table). Results should be interpreted with caution, given the small subgroups and absence of multiplicity control.

Table 1. Subgroup analysis of response by MRI SI status and CRP level at baseline

| Endpoint | Subgroup | GLM n/N (%) | PBO n/N (%) | Difference vs PBO % Estimate (95% CI) | *P* value |
|---|---|---|---|---|---|
| ASAS20 | MRI SI+, CRP >ULN | 22/26 (84.6) | 10/27 (37.0) | 47.6 (21.9, 67.2) | 0.0005 |
| | MRI SI–, CRP >ULN | 12/13 (92.3) | 5/14 (35.7) | 56.6 (21.3, 79.2) | 0.0028 |
| | MRI SI+, CRP ≤ULN | 26/39 (66.7) | 15/39 (38.5) | 28.2 (5.9, 47.8) | 0.0132 |
| | MRI SI–, CRP ≤ULN | 9/19 (47.4) | 10/20 (50.0) | –2.6 (–32.7, 27.9) | 0.8711 |
| ASAS40 | MRI SI+, CRP >ULN | 18/26 (69.2) | 7/27 (25.9) | 43.3 (16.5, 64.2) | 0.0018 |
| | MRI SI –, CRP >ULN | 10/13 (76.9) | 3/14 (21.4) | 55.5 (17.6, 79.1) | 0.0047 |
| | MRI SI+, CRP ≤ULN | 19/39 (48.7) | 8/39 (20.5) | 28.2 (7.1, 47.1) | 0.0093 |
| | MRI SI–, CRP ≤ULN | 8/19 (42.1) | 5/20 (25.0) | 17.1 (–12.8, 44.6) | 0.2636 |
| BASDAI50 | MRI SI+, CRP >ULN | 18/26 (69.2) | 10/27 (37.0) | 32.2 (5.1, 54.9) | 0.0201 |
| | MRI SI –, CRP >ULN | 11/13 (84.6) | 4/14 (28.6) | 56.0 (18.7, 79.2) | 0.0041 |
| | MRI SI+, CRP ≤ULN | 17/39 (43.6) | 9/39 (23.1) | 20.5 (–0.6, 40.0) | 0.0562 |
| | MRI SI–, CRP ≤ULN | 10/19 (52.6) | 7/20 (35.0) | 17.6 (–13.6, 45.8) | 0.2733 |
| ASAS PR | MRI SI+, CRP >ULN | 8/26 (30.8) | 7/27 (25.9) | 4.8 (–19.6, 29.0) | 0.6983 |
| | MRI SI –, CRP >ULN | 9/13 (69.2) | 3/14 (21.4) | 47.8 (9.8, 73.8) | 0.0142 |
| | MRI SI+, CRP ≤ULN | 10/39 (25.6) | 5/39 (12.8) | 12.8 (–5.0, 30.6) | 0.1535 |
| | MRI SI–, CRP ≤ULN | 5/19 (26.3) | 3/20 (15.0) | 11.3 (–15.1, 37.3) | 0.3879 |

**Conclusions:** In the DB phase of GO-AHEAD, nr-axSpA pts with baseline objective inflammation (particularly with CRP >ULN) had greater responses to GLM. No GLM treatment benefit was observed in pts with MRI SI– & CRP ≤ULN.

## SAT0400 CLINICAL FACTORS IMPACTING STATIN USAGE IN A LONGITUDINAL ANKYLOSING SPONDYLITIS COHORT

J. Dau[1], M. Weisman[2], M. Lee[1], M. Ward[3], M. Brown[4], L. Diekman[1], M. Rahbar[1], L. Gensler[5], J. Reveille[1]. *[1]University of Texas Health Science Center Houston–McGovern Medical School, Houston; [2]Cedars Sinai, Los Angeles; [3]NIAMS, National Institutes of Health, Bethesda, United States; [4]Univeristy of Queensland, Brisbane, Australia; [5]University of California San Francisco, San Francisco, United States*

**Background:** Patients with ankylosing spondylitis (AS) are at higher risk for developing cardiovascular comorbidities. While aortic valve and conduction defects are most common, increased levels of LDL cholesterol are also seen. Statin usage has been reported to lower CRP and ESR though the power of these studies are limited due to small sample size and short-term follow-up (1,2).

**Objectives:** This study examines associations of statin usage with socio-demographic and clinical factors, including disease activity, functional impairment, and radiographic severity in patients with two years of follow-up or more.

**Methods:** 655 AS patients meeting modified New York criteria followed at least 2 years (and up to 12 years) were included in the analysis. Demographic and clinical parameters (disease activity and functional impairment were collected every 6 months, as well as radiographic assessments (BASRI and mSASSS) every 2 years. Univariable and multivariable mixed effect models were developed to identify independent factors associated with statin usage over time.

**Results:** Mean disease duration was 18 years (SD=13). 10% (n=66) of the cohort were using statins. Univariable longitudinal regression models are shown below:

Factors associated with statin usage based on a univariable longitudinal analysis

| Variable | OR | 95% CI | P-value |
|---|---|---|---|
| Male gender | 2.7 | (1.4,5.4) | 0.004 |
| White | 3.8 | (1.7,8.6) | 0.001 |
| Marital status: married | 3.3 | (1.9, 6.0) | <0.001 |
| Disease duration >20 years | 15.8 | (8.6, 28.7) | <0.001 |
| Age >40 years | 5.5 | (2.3,13.3) | <0.001 |
| History of hip involvement | 0.4 | (0.3, 0.8) | 0.004 |
| History of cardiovascular comorbidity | 13.7 | (7.7,24.4) | <0.001 |
| History of diabetes | 4.7 | (1.4,15.4) | 0.01 |
| History of smoking | 2.2 | (1.2,3.8) | 0.01 |
| History of hypertension | 9.9 | (5.4,17.4) | <0.001 |
| Concomitant use of NSAID's | 0.4 | (0.2,0.8) | 0.01 |
| Concomitant use of TNF-blockers | 1.0 | (0.6,1.5) | 0.96 |
| Radiographic severity (mSASSS >4) | 3.8 | (2.1,6.7) | <0.001 |
| Radiographic severity (BASRI >6) | 2.6 | (1.6,4.4) | 0.001 |
| Impaired functionality (BASFI >4) | 1.6 | (1.1,2.5) | 0.03 |
| Disease activity (BASDAI >4) | 0.6 | (0.3,0.9) | 0.04 |
| Elevated CRP | 0.7 | (0.5,0.9) | 0.03 |
| Elevated ESR | 1.1 | (0.7,1.5) | 0.76 |

Multivariable longitudinal analyses controlling for confounders showed independent associations of age >40 years (p<0.001, OR=5.5 (2.3, 13.3)), the presence of cardiovascular disease (p<0.001, OR=7.6 (3.8, 15.5)), diabetes (p=0.01, OR=4.7 (1.4, 15.4)), opiate use (p=0.03, OR=2.0 (1.1, 3.7)), and CRP (p=0.03, OR=0.4 (0.2, 0.9)).

**Conclusions:** Statin usage was, as expected, more likely in those of older age with greater disease duration and greater radiographic severity. Even though statins are known to reduce CRP, the association with markers of lower disease activity, both subjective (BASDAI on univariable analysis) and objective (CRP on both univariable and multivariable analyses), raises the possibility of a role in suppressing inflammation in patients with AS.

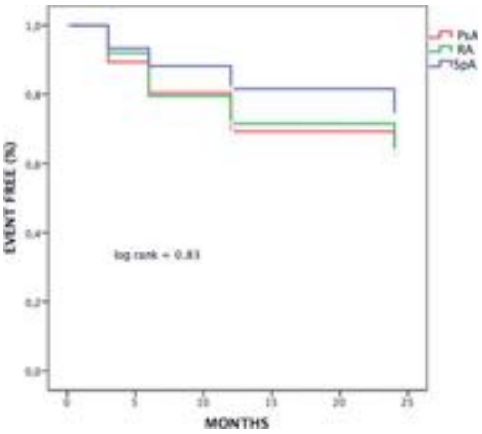
## SAT0401 TWO-YEARS SURVIVAL OF GOLIMUMAB IN 400 PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND AXIAL SPONDYLOARTHRITIS IN REAL-LIFE WORLD

L. Santo[1], A. Semeraro[2], C. Zuccaro[3], M.G. Anelli[4], R. Bucci[5], G. Carlino[6], A. Marsico[2], L. Quarta[7], F.P. Cantatore[8], A. Gaudio[8], O. Casilli[7], F. Cacciapaglia[4], P.C. Falappone[9], F. Iannone[4]. *[1]Rheumatology Service, ASL BT - DSS4 Barletta, Andria; [2]U.O. of Rheumatology, ASL TA, Taranto; [3]U.O. of Geriatrics Outpatient clinic of Rheumatology, ASL BR, Brindisi; [4]DIM – Rheumatology Unit, University of Bari, Bari; [5]Rheumatology Hospital Unit, A.O.U. "OO.RR. Foggia", Foggia; [6]Rheumatology Service, ASL LE - DSS Casarano and Gallipoli, Casarano (LE); [7]U.O. of Rheumatology, "V.Fazzi" Hospital, Lecce; [8]Rheumatology Unit, University of Foggia, Foggia; [9]Internal Medicine Unit, "S. Camillo de' Lellis Hospital", Meagsne (BR), Italy*



**Background:** It has previously been shown that the survival of anti-TNF drugs was lower in Rheumatoid arthritis (RA) than in other chronic arthritis.

**Objectives:** The objective of this study was to investigate the drug retention, as surrogate of effectiveness, of Golimumab (GOL) with axial Spondyloarthritis (AxSpA), Psoriatic arthritis (PsA) and RA. Furthermore, predictors of drug retention were evaluated.

**Methods:** This is a multicenter prospective observational study of unselected patients with AxSpA, PsA and RA starting GOL because of their active disease despite prior treatment with conventional disease modifying drugs (DMARDs) or biological DMARDs (bDMARDs) in the settings of standard care from 11 rheumatologic centres of Apulia (Southern Italy). The primary endpoint was GOL drug retention at 2 years. Time to discontinuation was defined as the time between drug initiation and last administration plus one dispensation interval. Kaplan-Meier curve analysis was used to assess drug retention, and a Cox proportional regression model, adjusting for potential confounders, including prior

bDMARD exposure, glucocorticoid or DMARD intake, patient demographics and disease characteristics, for the analysis of predictors. Clinical response was evaluated at 3,6,12 and 24 months.

**Results:** To date, 416 patients (PsA 180, RA 89, AxSpA 147) have been included in the study, 171 (41%) were biologic-naïve. Disease duration was 6.9 ±6 yrs for PsA, 8.1 ±8 for RA, and 7.4 ±7 for AxSpA, respectively. RF/ACPA were present in 72.5% of RA patients, and HLA-B27 in 43% of AxSpa. Within PsA 58 patients had also spinal involvement. At 2 years (Fig.1), the drug persistence rate was 74.5% (20.8±0.5 months) for AxSpa, 62.5% (19.5±0.8 months) for RA, and 63.9% (18.8±0.6) months for PsA, being the difference not statistically significant. For AxSpa patients, the chance of stopping GOL was associated with the female gender (hazard ratio (HR) 3.15 (95% CI 1.4–8.5), and the presence of extra-articular manifestation (HR 0.20 (95% CI 0.48–0.88). In RA the only predictor of GOL discontinuation was the achievement good EULAR response at 3 months (HR 0.36 ((95% CI 0.15–0.88), while no baseline factors correlating with drug persistence was detected for PsA. The percentage of AxSpa patients achieving BASDAI<4 was 63.4% at3 months, 69.3% at6 months, 77.5% at12 months, and 70.8% at24 months. In RA, DAS28 based remission was attained in 22.5% at3 months, 26.8% at6 months, 36.2% at12 months, and 43.9% at24 months. Finally for PsA DAS28 based remission was found in 27.5% at3 months, 33.2% at6 months, 42.1% at12 months, and 42.6% at24 months, while BASDAI<4 was 56.4% at 3 months, 73.1% at 6months, 76.2% at12 months, and 82.1% at24 months.

**Conclusions:** Unlike previous studies on TNF inhibitors, GOL seems to have similar drug survival in different chronic arthritides. Male sex and the presence of extra-articular manifestations were independently associated with GOL discontinuation in AxSpa. The achievement of good EULAR response at 3 months was the best predictor of continuing GOL in RA.

**Disclosure of Interest:** None declared

## SAT0402 SAFETY OF ETANERCEPT THERAPY IN HBSAG CARRIERS WITH ANKYLOSING SPONDYLITIS: A PROSPECTIVE STUDY

L. Fang[1], Z. Hu[2], Y. Pan[2], Z. Lin[2], Z. Liao[2], J. Gu[2]. *[1]Rheumatology division; [2]Third affiliated hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** The prevalence rate of hepatitis B virus (HBV) infection in China (13%) and many other developing countries are much higher than that in developed countries. When anti-TNF agents are more available and affordable in developing countries, the safety of anti-TNF therapy in terms of the reactivation of hepatitis B virus (HBV) infection need more concern. Rare data from a prospective study focus on the use of TNF antagonists in patients with concurrent ankylosing spondylitis (AS) and HBV infection are available by now.

**Objectives:** To evaluate the influence of Etanercept on the re-activation of HBV infection in HBsAg carriers with AS.

**Methods:** In this 48 weeks observation, HBsAg carriers with active AS (BASDAI ≥4) despite failed treatment with at least two NSAIDs and sulfasalazine (for patients with persistent peripheral arthritis) were studied. Patients must have normal liver function prior to Etanercept therapy. All patients received the treatment of Etanercept 50mg each week.

For patients who had positive HBV load (>100 copy/ml) at baseline, lamivudin were prescribed preventively. Pre-existing NSAIDs and sulfasalazine were allowed. During the study, serum aspartate aminotransferase (AST), alanine aminotransferase (ALT) and HBV load (polymerase chain reaction) were monitored every 6 weeks in the first 12 weeks and every 12 weeks after week 12. Increased AST/ALT and HBV load were managed and monitored according to expert opinion. After withdraw of Etanercept due to any reason, monitoring of ALT, AST and HBV load must be conducted until normal result was obtained in 2 consecutive tests.

**Results:** Fourteen patients (12 male, 2 female) were recruited. At baseline, ten patients (group 1, including 1 female) had normal viral load (<100 copy/ml), other 4 patients (group 2, with preventive lamivudin) had abnormal viral load (4.7e4, 5.3e7, 2.8e3, 9.8e4 copy/ml, respectively). Two patients from group 1 and one patient from group 2 discontinued Adalimumab at week 12 due to ineffectiveness. Reactivation of hepatitis B occurred in one patient from group 1, and another from group 2. The patient from group 1 had mild elevated ALT and AST (71 and 46 IU/L, respectively) and increased HBV load (7.6e3) at Week 12. After prescription of Entecavir, abnormal laboratory finding was monitored every 4 weeks, both liver enzyme and viral load decreased to normal range in 8 weeks and remained normal. The patient from group 2 (baseline viral load 4.7e4) had mild elevated ALT and AST (57 and 49 IU/L, respectively) and increased HBV load (5.2e8) at week 24. After prescription of Adefovir (combined with the pre-existing Lamivudin), both liver enzyme and viral load decreased to normal range in 8 weeks and remained normal. For the rest 12 patients, no significant elevated AST/ALT or increased viral load was seen during follow-up.

**Conclusions:** Etanercept therapy represent a safe and effective option for HBsAg carriers with AS refractory to traditional treatment. Prophylaxis strategy with more effective anti-viral drugs is recommended to reduce the risk of hepatitis B reactivation.

**Disclosure of Interest:** None declared

## SAT0403 TREATMENT WITH GOLIMUMAB OR INFLIXIMAB REDUCES HEALTH RESOURCE UTILIZATION AND INCREASES WORK PRODUCTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN THE QUO-VADIS STUDY, A LARGE, PROSPECTIVE REAL-LIFE COHORT

P. Sarzi-Puttini[1], F. Van Den Bosch[2], P. Claudepierre[3], S. Sajjan[4], N. Vastesaeger[5], M. Govoni[6], S. Kachroo[4]. *[1]UOC Reumatologia, Ospedale L. Sacco Polo Universitario, Milano, Italy; [2]Ghent University Hospital, Ghent, Belgium; [3]Université Paris Est Créteil, Créteil, France; [4]Merck Sharp & Dohme, Kenilworth, United States; [5]Merck Sharp & Dohme, Brussels, Belgium; [6]Merck Sharp & Dohme, Rome, Italy*

**Background:** The true cost of treating Ankylosing Spondylitis (AS) comprises several elements including not only medication, but also healthcare resource utilization (HCRU), reduced work productivity, and absenteeism.

**Objectives:** We report the results from the QUality of Life as Outcomes and its VAriation with DIsease States (QUO-VADIS) study on the effect of the anti-tumor necrosis factor (TNF) agents, golimumab (GLM) and infliximab (IFX), on HCRU for patients with AS as well as their ability to work.

**Methods:** This was a prospective observational study in bionaïve AS patients (modified New York criteria) newly treated with GLM or IFX (originator) in a clinical practice setting. Patients were followed-up for ~6 months of treatment with GLM or IFX and data was collected at baseline (BL), and at 3 and 6 months. The assessment of HCRU was done by evaluating data on the use of concomitant medications, hospitalizations (inpatient care or acute care) and visits in day care and outpatient settings; HCRU data reflected the prior 3 months for each timepoint. Work productivity and activity impairment (WPAI) was assessed by the number of work days missed as well as quantifying absenteeism, presenteeism, work impairment, and activity using the WPAI instrument adapted to Spondylarthritis (WPAI-SpA)(1); WPAI was based on the 7 days prior to the administration of the questionnaire.

**Results:** 963 patients received ≥1 dose of medication. The vast majority (78%, n=751) was treated with GLM, while the rest (22%, n=221) received IFX. Mean age of the patients was 42.7 years, 61.4% were male. Concomitant medication usage for AS treatment was reported by 84.3% of patients, the vast majority of whom received NSAIDs, followed by analgesics, DMARDs and corticosteroids. At BL, the percent of patients who reported hospitalizations (inpatient care) in the prior 3 months was 13.6%, which decreased to 3.1% at 6 months, while outpatient care in the 3 months prior to BL was reported by 39.4% of patients, which decreased to 19.0% at 6 months. The percent of patients receiving acute emergency care in the 3 months prior to BL reduced from 1.6%0.3% at 6 months. Further details on HCRU at BL and at 6 months are shown in the Table. The mean

**Table: Health Care Resources Utilization and WPAI-SpA Scores**

| Mean (SD) Health Care Resource Utilization Among All Patients | | |
|---|---|---|
| | Baseline | 6 months |
| Acute Care (duration of stay, hours) | 13.7 (32.5) | 3.3 (2.08) |
| Acute Care (number of admissions) | 1.1 (0.3) | 1.3 (0.6) |
| Hospitalization (duration of stay, days) | 7.3 (6.1) | 4.1 (4.5) |
| Outpatient/Day Care (number of visits) | 2.4 (1.8) | 2.1 (2.7) |
| **Mean (SD) Work Productivity and Impairment Among All Patients[a]** | | |
| | | |
| Absenteeism | 16.4 (32.3) | 6.3 (19.8) |
| Presenteeism | 51.9 (30.6) | 28.0 (26.0) |
| Work Impairment | 48.3 (34.0) | 25.1 (26.4) |
| Activity | 62.5 (24.7) | 36.1 (26.9) |

[a]Score interpretation: For all 4 outcomes, greater scores (range 0–100%) indicate greater impact of health.[15]

(SD) number of days at work, missed due to AS, was reduced from 6.3 (31.1) days at BL to 2.7 (12.3) days at 6 months. Results for WPAI-SpA assessment are presented in the Table.
**Conclusions:** In patients with AS newly treated with GLM (almost 80% of the study population) or IFX for 6 months, HCRU was reduced, as shown by the shorter mean duration of hospitalizations and the proportion of patients receiving acute, inpatient or outpatient care. Additionally, work productivity and activity increased, and patients reported fewer days of work missed due to AS after 6 months of treatment.

## SAT0404 EVALUATION OF THE CLINICAL USEFULNESS OF A STANDARDIZED DOSE REDUCTION PROTOCOL FOR MAINTENANCE OF REMISSION IN PATIENTS WITH AS UNDER ANTI-TNF TREATMENT

M. Arévalo Salaet[1], M. Aparicio[2], C. Pontes[1], F. Torres[3], T. Salman[4], F. Blanco[5], A. Sellas[6], R. Sanmarti[3], J. Gratacos[1] on behalf of REDES Group. *[1]H. Parc Taulí, Sabadell; [2]Hospital Bellvitge, Hospitalet Llobregat; [3]H.Clínic Barcelona; [4]H.Mar, Barcelona; [5]H.Juan Canalejo, A Coruña; [6]H.Vall Hebron, Barcelona, Spain*

**Objectives:** To assess if reduced dose of iTNF is not less effective than complete dose for response maintaining
**Methods:** Prospective, randomized, multicenter, real life open-label study of non-inferiority coordinated by Spanish Societies of Clinical Pharmacology and Rheumatology.
Patients included were randomized (1:1) in a complete dose arm (C) or in a reduced dose arm according to a previous standardized protocol (E).
The primary objective was the proportion of patients who after a year of following maintained the acceptable therapeutical goal (ATG) (BASDAI, physicianVAS, patientVAS, night axial pain all <4). Secondary endpoints were: proportion of patients with clinical remission) (BASDAI, physicianVAS, patientVAS, night axial pain all <2), disease activity assessed with ASAS, BASFI and quality of life.
The main analysis was made per protocol (PP), considering an ATG percentage in C group of 87% with a maximum settled difference between both treatments inferior than 17%
**Results:** 113 AS, 84% men, age of 45'6y and mean disease duration of 13'5y. 22 (40%) were treated with adalimumab, 19 (35%) with etanercept, 10 (27%) with infliximab and 4 (7%) with golimumab. Main results are shown in table1. At 12 months follow-up 48 (82.8%) in the full dose arm vs 47 (85.5%) in reduced dose arm maintained the ATG demonstrating the non inferiority hypothesis (p=ns, dif -2.5%, 95%CI -16.6 to 11.7%). We did not observe also any significant difference in any of the rest of variables analyzed including the proportion of patients in remission and safety issues. Although 30% of patients showed ≥1 flare, without differences between both treatment arms, less than 15% required treatment dropout.

Table 1

| | Control (n) | Experimental (n) | Difference |
|---|---|---|---|
| Per protocol efficacy analysis | 55 | 58 | |
| ATG 12 months (% [95%CI]) | 83.8% [64.8% to 102.7%] | 81.3% [62.8% to 99.8%] | –2.5% [–16.6% to 11.7%] |
| ITG 12 months (% [95%CI]) | 83.7% [64.7% to 102.7%] | 78.2% [59.7% to 96.8%] | –5.5% [–20.6% to 9.7%] |
| Intention to treat efficacy analysis | 60 | 60 | |
| ATG 12 months (% [95%CI]) | 84.8% [66.2% to 103.3%] | 80.1% [61.7% to 98.5%] | –4.7% –4.7% |
| ITG 12 months (% [95%CI]) | 84.7% [66.1% to 103.2%] | 77.3% [59.0% to 95.7%] | –7.33% [–22.2% to 7.5%] |
| Other variables of efficacy | | | |
| BASDAI (median (P25, P75)) | 1 (0.6, 1.7) | 1 (0.2, 1.4) | ns |
| VAS nocturnal axial pain (mean (SD)) | 0.84 (1.01) | 1.02 (1.15) | ns |
| Physician GA (median (P25, P75)) | 1 (0.0, 2.0) | 1 (0.0, 1.0) | ns |
| Patient GA (median (P25, P75)) | 1 (0.0, 2.0) | 1 (0.0, 1.0) | ns |
| ASDAS-CRP (median (P25, P75)) | 1.1 (0.8, 3.5) | 1.0 (0.7, 1.9) | ns |
| Withdrawal for inefficacy (physician crit.) | 3 (5%) | 9 (14%) | ns |
| Safety | | | |
| Adverse events | 40% | 30% | ns |
| Infections | 25% | 17% | ns |
| Severe adverse events | 7% | 3% | ns |

**Conclusions:** In patients with persistent clinical remission, dose reduction is not inferior to the standard dose. The presence of clinical flare is not uncommon, although less than half of cases lead to a change in the treatment.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4049

## SAT0405 NO RADIOLOGICAL SACROILIAC JOINT PROGRESSION AFTER 2 YEARS OF ETANERCEPT TREATMENT IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: DATA FROM THE EMBARK STUDY

M. Dougados[1], W.P. Maksymowych[2], D. van der Heijde[3], R. Pedersen[4], R. Bonin[4], I. Logeart[5], J. Bukowski[4], H. Jones[4]. *[1]Paris Descartes University, Hôpital Cochin, Paris, France; [2]University of Alberta, Edmonton, Canada; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Pfizer, Collegeville, PA, United States; [5]Pfizer, Paris, France*

**Background:** Radiological structural changes in the sacroiliac joint (SIJ) over time in non-radiographic axial spondyloarthrits (nr-axSpA) can be evaluated by measuring the progression from non-radiographic to radiographic damage status according to modified New York (mNY) criteria but also with other more sensitive methods.[1,2] However, the question remains whether anti-tumor necrosis factor therapy can prevent this structural progression, particularly in patients with nr-axSpA.
**Objectives:** To evaluate radiographic progression in SIJ after 2 years of etanercept (ETN) treatment in nr-axSpA according to different outcome measures.
**Methods:** *Study design:* 104-week follow-up of patients enrolled in the EMBARK trial who received ETN either from baseline (active treatment arm) or week 12 (placebo [PBO] arm). *Patients:* Active nr-axSpA refractory to ≥2 NSAIDs. *Study drug:* ETN 50 mg once a week. *Outcome measures:* Pelvic X-rays were performed at both baseline and week 104. After anonymization, 3 trained readers evaluated the films blinded to chronology using the 0–4 grade scale of the mNY radiographic criteria for each (left and right) SIJ. *Statistical analysis:* X-rays from patients who completed the 104-week study were assessed. For continuous variables (e.g., total score from 0 to 8 for the left and right SIJ according to mNY grading), the mean score from the 3 readers was evaluated (bias was possible because readers knew that all patients were previously considered to have nr-axSpA); for binary variables (e.g., change from non-radiographic to radiographic axSpA, worsening of ≥1 grade in ≥1 SIJ and an absolute final value of ≥2 in the worsened joint), the score agreed upon by ≥2 readers was used for analysis.
**Results:** Of 215 randomized patients, 169 completed the open-label period at 104 weeks; 161 patients had X-rays available at both baseline and week 104. Only 1 patient was found to have satisfied mNY criteria for radiographic SIJ damage (ie, at least bilateral grade II or unilateral grade III) at baseline. Of 160 patients with mNY negative scores at baseline, none became mNY positive at week 104. The mean score (SD) for the total (left and right) SIJ (scale, 0–8) was 0.87 (0.83) at baseline and 0.88 (0.85) at week 104 (change, 0.01 [0.15]; *P*=0.386). No patients had *both* worsening of ≥1 grade in ≥1 SIJ *and* an absolute final value of ≥2 in the worsened joint.
**Conclusions:** This study suggests that, whatever the outcome measure, no structural radiological progression in the SIJ occurred after 2 years of etanercept treatment in patients with nr-axSpA. Given this study's limitations, eg, lack of controls and inclusion of completers only, it is unclear whether this is an effect of etanercept. Additional studies using X-rays and MRI of the SIJ should be conducted to further address this question.

## SAT0406 EFFICACY AND SAFETY OF LOXOPROFEN HYDROGEL PATCH VERSUS LOXOPROFEN TABLET IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A RANDOMIZED CONTROLLED TRIAL

M. Fan, S. Cao, L. Tu, Q. Wei, R. Yuan, J. Gu. *the third affiliated hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Non-steroidal anti-inflammatory drugs (NSAIDs) are the cornerstone of medication for patients with ankylosing spondylitis (AS). However, oral NSAIDs are associated with adverse events such as gastrointestinal, cardiovascular and renal events.
**Objectives:** To assess the efficacy and safety of loxoprofen sodium hydrogel patch (LX-P) versus loxoprofen sodium tablet (LX-T) in the treatment of active AS.
**Methods:** The study population consisted of patients who met the modified New York radiographic criteria for AS and had to be active disease, defined by the Bath AS Disease Activity Index (BASDAI) ≥4 or the Ankylosing Spondylitis Disease Activity Score using the C-reactive protein level (ASDAS-CRP) ≥1.3. Patients were randomly assigned to either the LX-P group or the LX-T group

for 4 weeks. The primary efficacy endpoint was the proportions of patients reaching Assessment in Ankylosing Spondylitis 20% response (ASAS20) at week 4. Secondary efficacy outcomes included mean changes from baseline to week 4 for ASDAS-CRP, BASDAI and patient's global assessment of disease activity (PTGA). Adverse events were monitored throughout the study.
**Results:** Of 70 randomized patients, 35 patients were allocated to the LX-P group and 35 to the LX-T group. In the intent-to-treat population, no significant differences were found between the two groups in the proportion of patients achieving ASAS20 response at week 4 (19 of 35 [54.3%] for LX-P group versus 26 of 35 [74.3%] for LX-T group; P=0.081). And there were no significant differences for the mean change of ASDAS-CRP, BASDAI and PTGA from baseline to week 4 between LX-P and LX-T group. Post hoc analyses suggested that patients without peripheral arthritis in the LX-P group were more likely to achieve ASAS20 response than those with peripheral arthritis. A lower incidence of gastrointestinal disorders was observed in LX-P group. No serious adverse events were reported in the two groups.
**Conclusions:** LX-P is noninferior to LX-T for improvement of disease activity in patients with active AS, and has few gastrointestinal adverse events.

## SAT0407 DERMOSCOPIC CHANGES IN MELANOCYTIC NEVI IN PATIENTS WITH ANKYLOSING SPONDYLITIS USING TUMOR NECROSIS FACTOR-ALPHA INHIBITORS: A PROSPECTIVE COHORT STUDY

M. Cinar[1], E. Caliskan[2], S. Yilmaz[1], A. Boru[2], I. Simsek[3], E. Arca[2], M. Cakar[1], S. Pay[4], H. Erdem[5]. *[1]Division of Rheumatology; [2]Department of Dermatology, Gulhane Military Medical Academy, School of Medicine; [3]Division of Rheumatology, Guven Hospital; [4]Division of Rheumatology, Yüksek Ihtisas University, Special Koru Hospital; [5]Division of Rheumatology, Medicana International Ankara Hospital, Ankara, Turkey*

**Background:** Tumor necrosis factor-alpha (TNF-α) inhibitors have been proposed to increase the risk of malignancy. Skin tumors have been reported among the most common malignancies seen in the use of these drugs and melanoma has a much higher importance compared to other skin tumors.
**Objectives:** To investigate the dermoscopic changes in melanocytic nevi in ankylosing spondylitis (AS) patients, under TNF-α inhibitors or conventional therapy (CT-sulfasalazine, non-steroidal anti-inflammatory drugs).
**Methods:** The study included 94 consecutive ankylosing spondylitis patients with at least one melanocytic nevus. 56 patients (F/M=5/51) in the cohort were patients initiated TNF-α inhibitor treatment and 38 (F/M=1/37) were patients receiving CT. Treatment-related changes that occur in nevi were prospectively followed dermoscopically. All changes detected in the follow-up period were recorded, and evaluated in two groups as substantial and non-substantial changes in terms of melanoma development risk. Substantial changes included expansion of nevi, shape change, regression, discoloration and melanoma-specific structural changes; and non-substantial changes included opening/darkening of the global color of nevi, change in the number of brown globules, reduction/loss of blackheads, diffuse-brown pigmentation at the pigment network and the presence of inflammation.
**Results:** Mean age of the TNF-α inhibitor group was 39.7±7.7 years and disease duration was 11.3±6.0 years. The mean age of CT patients was 37.5±7.2 years and disease duration was 8.4±4.5 years. Among age groups, there was no difference in terms of gender and disease duration ($p>0.05$). In TNF-α inhibitor group 220 (3.9±4.6) nevi, and in CT group 129 (3.4±1.8) nevi were followed (p=0.823). The median follow-up periods of the TNF-α inhibitor and CT groups were 20.4±4.8 and 16.5±4.2 months, respectively (p=0.052). 5 nevi in TNF-α inhibitor group (5 shape changes) and 4 nevi in CT group (3 shape changes, 1 expansion) had substantial changes in terms of the risk of melanoma (p=0.468). 15 nevi in TNF-α inhibitor group (7 opening in color, 3 darkening in color, 1 change in the number of brown globules, 3 reduction/loss of blackheads, 1 inflammation) and 6 nevi in the CT group (2 opening in color, darkening in 2 colors, 1 change in the number of brown globules, 1 reduction/loss of blackheads) had non-substantial changes in terms of melanoma risk (p=0.590). 3 of 5 nevi having major changes in terms of the risk of melanoma were excised.Pathological examination did not reveal malignancy.
**Conclusions:** In the literature, an association between rheumatoid arthritis and risk of developing melanoma has been reported, but there is no similar data pointing to an increased risk in patients with AS. This study has shown that the TNF-α inhibitors did not cause the development of melanocytic nevi in about 2 years of follow-up in patients with AS. While a limitation of the study is the small number of patients, close monitoring of patients under the risk of melanoma development is an important long-term benefit of the study.

## SAT0408 ANTI TNF-α THERAPY PROVIDES BENEFICIAL EFFECTS ON CHOROIDAL THICKNESS INCREASE IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: A POSSIBLE MECHANISM OF INFLIXIMAB EFFECTIVENESS IN SUPPRESSING UVEITIS ATTACKS

M. Karkucak[1], A. Kalkısım[2], M. Kola[2], E. Capkın[1], A. Türk[2], A. Ayar[3]. *[1]Department of Physical and Rehabilitation Medicine; [2]Department of Ophthalmology; [3]Department of Physiology, Karadeniz Technical University, Medical school, Trabzon, Turkey*

**Background:** Patients with ankylosing spondylitis (AS) have higher choroidal thickness values (CT) compared to controls.
**Objectives:** To quantitatively asses the profile of CT in patients with AS using optical coherence tomography (OCT), and to examine whether the posterior eye segment abnormalities in active AS patients were reversible by infliximab therapy
**Methods:** Thirty-one patients with AS receiving infliximab therapy and 24 healthy controls were enrolled. Patient's clinical and demographic characteristics were recorded. Using OCT, we performed retinal imaging and choroidal *thickness measurements* in AS patients before and after 6 months of infliximab therapy, and in healthy controls who returned 6 months after the first visit. We compared patients before versus 6 months after infliximab therapy, as well as controls.
**Results:** Patients with AS had higher CT (mean± SD; 347.5±114.4 μm) compared to healthy controls (322.1±62.8 μm) (p=0.283), although this did not reach statistical significance. At 6 months after the first measurement, the mean CT was significantly decreased (after treatment with infliximab: 326.5±99.7μm vs. before: 347.5±114.4 μm, n=31, p=0.018) in AS group, but not in the control group ($p$=0.102). Retinal nerve fiber layer was significantly decreased at 6 months after treatment with infliximab in AS group (106.4±13.5 μm vs 105.0±13.0μm *p=0.008*).
**Conclusions:** This is the first study to evaluate the posterior eye segment in patients with AS using OCT. Our data indicate that CT abnormalities in active AS is reversible by therapy, and this CT decreasing effect of infliximab may be involved in its effective suppressing action of uveitis attacks in AS.

## SAT0409 IMPROVED CLINICAL OUTCOMES AND WORKABILITY IN SPONDYLOARTHRITIDES DURING REAL-LIFE ADMINISTRATION OF ADALIMUMAB IN CENTRAL AND EASTERN EUROPE

P. Géher[1], S. Szántó[2], D. Opriş[3], O. Iaremenko[4], O. Nagy[5], V. Chernyshov[6]. *[1]Hosp. Br. Hospital, Budapest; [2]DEKK, Debrecen, Hungary; [3]Sf. Maria Hospital, Bucharest, Romania; [4]NMU, Kyiv, Ukraine; [5]AbbVie, Budapest, Hungary; [6]AbbVie, Minsk, Belarus*

**Background:** There is a dearth of data on effectiveness and patient reported outcomes in patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA) treated with adalimumab (ADA) in Central and Eastern Europe
**Objectives:** P12–768 study aimed at establishing the impact of ADA on disease activity, extra-articular manifestations (EAMs), functional capacity, work productivity and collecting ADA's safety data in patients with AS and PsA
**Methods:** A prospective, 12-month follow up, single-arm, multi-country observational study enrolling AS and PsA patients eligible for ADA therapy with 3-monthly follow up visits. Upon the presence of axial (ax) or peripheral (per) symptoms, disease activity was assessed by BASDAI and ASDAS or DAS28, whereas functional capacity was assessed by BASFI or HAQ-DI, respectively. Primary endpoint was the percentage of patients with BASDAI 50% decrease (ax) or DAS28 decrease by at least 1.2 (per). WPAI-questionnaire was used to assess productivity impairment. Frequencies of EAMs and serious adverse events (SAEs) were reported. Descriptive statistics and LOCF-analysis were used
**Results:** 566 subjects were enrolled, 555 had sufficient data for statistical analysis (72.6% AS; 27.2% PsA); 449 completed last visit. 64.9% were male; mean age was 45.6 (range 18–80) years, mean disease duration 12.2 ± 10.0 years. At baseline 76.1% and 26.1% of patients had axial and peripheral symptoms, respectively. 54.8% of patients previously received NSAIDs and

34.6% were biologic experienced. Primary endpoint was achieved in 76.1% with axial symptoms and in 83.5% with peripheral symptoms. BASFI decreased from 6.8±2.0 to 2.8±2.3 and HAQ-DI from 1.3±0.6 to 0.6±0.5. At baseline, enthesitis was the most frequent EAM in patients with AS (23.1%) followed by uveitis (12.7%). Most frequent EAM in patients with PsA were psoriasis (90.1%) and enthesitis (17.2%). Percentage of patients with EAMs decreased from 40.4% to 9.7% (AS) and from 90.1% to 46.4% (PsA), whereas proportion of patients free of EAMs increased from 46.1% to 79.5% by study end. Total activity impairment decreased from 64.3% to 28.0%. Among all employed patients (n=255; 45.9% at baseline) presenteeism decreased from 56.7% to 20.1%, absenteeism from 15.6% to 6.4% and total work productivity impairment from 59.9% to 22.1%. 52 episodes of SAEs occurred in 26 patients (4.7%)

**Conclusions:** Adalimumab was effective in improving clinical, functional and working status and reduced frequency of EAMs in patients with AS and PsA in routine clinical use. No new safety signals were observed.

## SAT0410 SECUKINUMAB IMPROVES PHYSICAL FUNCTION AND QUALITY OF LIFE IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: 2-YEAR DATA FROM MEASURE 1, A PHASE 3 RANDOMISED TRIAL

P. Emery[1], D. Baeten[2], A. Deodhar[3], A. Wei[4], P. Geusens[5,6], Z. Talloczy[7], Y. Gong[8], B. Porter[9] on behalf of the MEASURE 1 Study Group. *[1]University of Leeds, Leeds, United Kingdom; [2]Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands; [3]Oregon Health & Science University, Portland, United States; [4]Chung Shan Medical University Hospital, Taichung, Taiwan, Province of China; [5]Maastricht University Hospital, Maastricht, Netherlands; [6]University of Hasselt, Hasselt, Belgium; [7]Novartis Pharmaceuticals Corporation, East Hanover, United States; [8]Beijing Novartis Pharma Co. Ltd., Beijing, China; [9]Novartis Pharma AG, Basel, Switzerland*

**Background:** Ankylosing spondylitis (AS) has significant adverse effects on an individual's health status.[1] Secukinumab, an interleukin (IL)-17A inhibitor, improved signs and symptoms and patient-reported outcomes (PROs) over 52 weeks (wks) in the randomised, double-blind, placebo (PBO)-controlled, Phase 3 MEASURE 1 study (NCT01358175).[2,3]

**Objectives:** To evaluate the effect of secukinumab on disease activity, pain, physical function, fatigue, and general and AS-specific quality of life (QoL) measures over 104 wks.

**Methods:** 371 adults with active AS were randomised to receive secukinumab 10 mg/kg i.v. at baseline (BL), Wks 2 and 4, and then s.c. 150 mg (IV→150 mg) or 75 mg (IV→75 mg) every 4 wks from Wk 8, or PBO. At Wk 16, PBO-treated patients (pts) were re-randomised to receive secukinumab 150 mg or 75 mg s.c. from Wk 16 (non-responders) or Wk 24 (responders). PROs assessed included: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI); Short Form-36 physical and mental component summaries (SF-36 PCS and SF-36 MCS, respectively); AS Quality of Life (ASQoL); patient's global assessment of disease activity; patient's assessment of total spinal pain; patient's assessment of nocturnal pain; Bath Ankylosing Spondylitis Functional Index (BASFI); Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue); and EuroQoL-5-dimension health status questionnaire (EQ-5D). BASDAI, SF-36 PCS and ASQoL were predefined secondary endpoints and are reported using a mixed-effect model repeated measures (MMRM) analysis. Other PROs and analyses by prior anti-tumor necrosis factor (anti-TNF) therapy use were exploratory endpoints and are reported as observed data (Wk 104).

**Results:** 97/125 (77.6%) and 103/124 (83.1%) pts randomised to IV→150 mg and IV→75 mg, respectively, completed 104 wks of treatment. The improvements in BASDAI, SF-36 PCS and MCS, ASQoL, BASFI, and FACIT-Fatigue achieved with secukinumab at Wk 52 were sustained at Wk 104, with mean changes from BL being greater than minimum clinically important differences (Table). Improvements were also observed in patient's global assessment of disease activity, total spinal pain, nocturnal pain, and EQ-5D. Sustained improvements were observed regardless of prior anti-TNF use. In anti–TNF-naïve pts, mean changes from baseline at Wk 104 with secukinumab IV→150 mg and IV→75 mg were: –3.5 and –3.1, respectively, for BASDAI; 8.4 and 7.4 for SF-36 PCS; and –5.0 and –4.4 for ASQoL. Corresponding changes in anti-TNF-IR pts, were: –3.2 and –2.9 (BASDAI); 6.9 and 7.6 (SF-36 PCS); and –4.1 and –5.1 (ASQoL).

**Conclusions:** In pts with active AS, secukinumab provided sustained improvements through 2 years in PROs including disease activity, pain, physical function, fatigue, as well as general and AS-specific measures of QoL.

**Table. Mean Change from Baseline in Patient-Reported Outcomes (PROs) for Patients Originally Randomised to Secukinumab**

| | Wks | Secukinumab IV→150 mg N = 125 | Secukinumab IV→75 mg N = 124 |
|---|---|---|---|
| BASDAI | 52[a] | −2.8 ± 0.2 | −2.7 ± 0.2 |

[a]Values are Least Squares Mean ± Standard Error from mixed-effect model repeated measures (MMRM)

[b]Values are Mean ± Standard Deviation from observed data

BASFI: n = 87 for secukinumab IV→150 mg; n = 86 for IV→75 mg; SF-36 MCS and FACIT-Fatigue: n = 87 for secukinumab IV→150 mg; n = 85 for IV→75 mg

MCID, Minimum Clinically Important Differences

**Results:** Of the 251 PsA patients meeting the inclusion criteria, 26% (n=65) discontinued/switched the index biologic and 74% (n=186) stayed on the index biologic by the 2nd follow-up visit. A significantly greater percent of females discontinued/switched the index biologic (56% vs 41%, $p<0.05$). However both cohorts were similar in age (mean: 55 yrs vs 53 yrs), and disease duration (12 vs 12 yrs.). Group 1 patients reported significantly higher scores for pain (mean: 42 vs 27) and fatigue (mean: 48 vs 33) compared to Group 2 ($p<.0001$). Almost one-third of patients in Group 1 reported greater overall work impairment (mean: 30% vs 15%, $p<0.01$) compared to Group 2. Patients in Group 1 were most likely to have higher disease activity (mean CDAI: 13 vs 9, $p<0.0001$) and enthesitis (26% vs 15%, $p<0.05$) vs. group 2. Overall a majority of patients had a history of prior biologic use (97%), with about 55% on current monotherapy. The major reason for discontinuing the index biologic was lack of efficacy (60%), followed by other reasons (16%) and side effects (12%).

## SAT0411 BIOLOGIC DISCONTINUATIONS AMONG PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS REGISTRY

P.J. Mease[1,2], C. Karki[3], M. Liu[3], A. Kavanugh[4], C.T. Ritchlin[5], D.H. Huynh[6], R. Pandurengan[3], V. Herrera[7], J.B. Palmer[7], J.D. Greenberg[3,8]. *[1]Swedish Medical Center; [2]University of Washington School of Medicine, Seattle, WA; [3]Corrona, LLC, Southborough, MA; [4]University of California, San Diego, LaJolla, CA; [5]University of Rochester Medical Center, Rochester, NY; [6]Scripps La Jolla and Mercy Hospital, San Diego, California; [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [8]NYU School of Medicine, New York, NY, United States*

**Background:** Over the past years, introduction of biologics for treatment of psoriatic arthritis (PsA) has improved the treatment responses in all clinical domains. However, little is known regarding the characteristics of patients who discontinue/switch biologics in non-clinical trial setting.

**Objectives:** To characterize PsA patients who discontinue/switch the index biologic and evaluate the reasons for discontinuation in the Corrona PsA/Spondyloarthritis (SpA) registry, a large US national cohort of patients with PsA/SpA.

**Methods:** PsA patients enrolled in the registry between 3/2013 and 7/2015, with a biologic at baseline (registry enrollment) and at least 2 follow-up visits were included. Two cohorts were identified: patients who discontinued/switched the index biologic (group 1) and those who stayed on the index biologic by the 2nd follow-up visit approximately 15 months after the enrollment (group 2). Descriptive analyses on patient demographics, clinical outcomes (eg. clinical disease activity index (CDAI), dactylitis, enthesitis), patient reported outcomes (eg. pain, fatigue, work productivity and activity impairment (WPAI)) and treatment at time of enrollment were examined. Chi-square tests and t-tests were used for continuous and categorical variables respectively to evaluate differences.

**Conclusions:** About a quarter of patients discontinued their index biologic over an average of 15 months follow up period. Those patients were more likely to have higher disease activity (CDAI) and poorer patient reported outcomes (pain, fatigue, WPAI) at enrollment. The most common reason for switching was lack of efficacy.

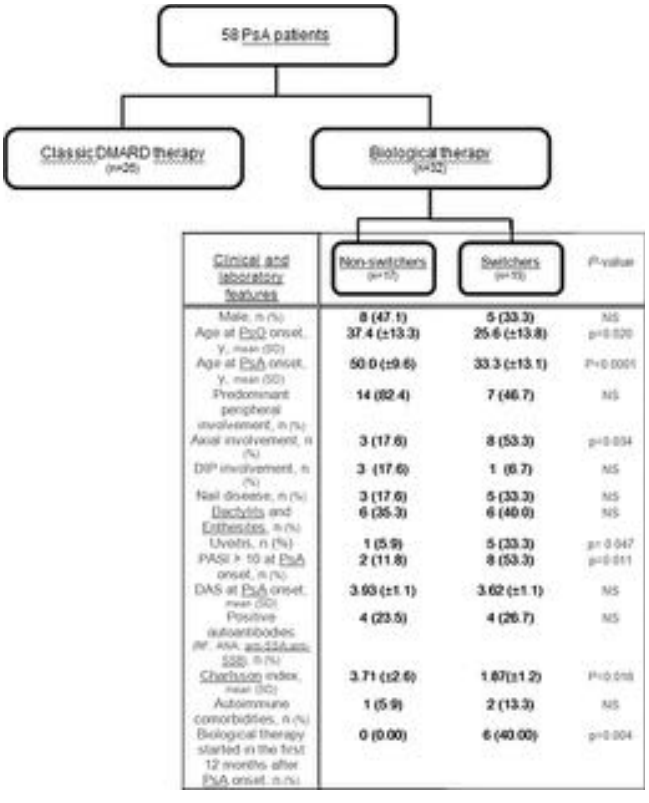
## SAT0412 BIOLOGICAL THERAPY IN PSORIATIC ARTHRITIS (PSA): DIFFERENCES BETWEEN SWITCHERS AND NON-SWITCHERS



R. Ramos Pinheiro[1], A. Brasileiro[1], A. Brito[2], P. Barreto[2], S. Pinheiro[2]. [1]*Dermatology;* [2]*Internal Medicine, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

**Background:** Switching biological therapies is becoming increasingly common in routine management of PsA patients. However, evidence in this topic is still scarce. Predictive markers for an optimal approach to the sequential prescription of biologics are lacking.

**Objectives:** In a population of PsA patients, we aimed to determine differences in baseline clinical and laboratory features between switchers and non-switchers.

**Methods:** We conducted a retrospective analysis of the PsA patients followed at our outpatient clinic in the last 24 months. Demographic, clinical and laboratory data were collected. Severity of skin manifestations and peripheral arthritis at PsA onset were recorded using PASI and DAS28 score. Patients who changed biological therapies due to therapeutic failure (primary or secondary) or toxicity were defined as switchers.

For comparison of clinical and laboratory features we used chi-square test for categorical variables and Mann-Whitney or T-Student test for continuous variables.

| Clinical and laboratory features | Non-switchers | Switchers | *P*-value |
|---|---|---|---|
| Male, n (%) | 8 (47.1) | 5 (33.3) | NS |
| Age at PsO onset, y, mean (SD) | 37.4 (±13.3) | 25.6 (±13.8) | |
| Age at PsA onset, y, mean (SD) | 50.0 (±9.6) | 33.3 (±13.1) | |
| Predominant peripheral involvement, n (%) | 14 (82.4) | 7 (46.7) | NS |
| Axial involvement, n (%) | 3 (17.6) | 8 (53.3) | |
| DIP involvement, n (%) | 3 (17.6) | 1 (6.7) | NS |
| Nail disease, n (%) | 3 (17.6) | 5 (33.3) | NS |
| Dactylitis and Enthesitis, n (%) | 6 (35.3) | 6 (40.0) | NS |
| Uveitis, n (%) | 1 (5.9) | 5 (33.3) | |
| PASI > 10 at PsA onset, n (%) | 2 (11.8) | 8 (53.3) | |
| DAS at PsA onset, mean (SD) | 3.93 (±1.1) | 3.62 (±1.1) | NS |
| Positive autoantibodies (RF, ANA, anti-CCP, anti-SSB), n (%) | 4 (23.5) | 4 (26.7) | NS |
| Charlsson index, mean (SD) | 3.71 (±2.6) | 1.67(±1.2) | |
| Autoimmune comorbidities, n (%) | 1 (5.9) | 2 (13.3) | NS |
| Biological therapy started in the first 12 months after PsA onset, n (%) | 0 (0.00) | 6 (40.00) | |

**Results:** 58 PsA patients were included, 60.3% were women; the mean age at PsA and psoriasis (PsO) onset was 46.4 (±15) and 34.8 (±15) years, respectively. At PsA onset, 24.1% of patients had a PASI score>10 and a mean DAS of 3.76 (±1.0). Laboratory features, arthritis and extra-articular manifestations were assessed (Image). 94.8% of patients were prescribed with non-biologic DMARD therapy and 55.2% with biological therapy, after failing to respond to a classic DMARD treatment alone. Median time from diagnosis until biological therapy prescription was 25.9 (±56,5) months.

Out of 32 patients prescribed with biologics, 15 (46.9%) switched to another biologic agent, mainly due to secondary failure (63.6%), primary failure (18.2%) and adverse events (13.6%). 15.65% and 3.1% of patients required 2 or 3 switches. Etarnacept was the first line agent prescribed in the majority (78.8%) of patients. Adalimumab (73.3%) and ustekinumab (50.0%) were the most used agents as second and third line biological therapies, respectively.

Switchers were significantly younger at psoriasis onset (25.6 (±13.8) vs 37.4 (±13.3) years, p=0.020) and also at PsA onset (33.3 (±9.6) vs 50.0 (±13.1) years, p<0.0001). They had higher PASI (p=0.011) levels comparing to non-switchers. Uveitis and axial involvement were significantly more common in switchers (p=0.047 and p=0.034, respectively). All patients starting biological therapy on the first 12 months after disease onset switched to another biological agent.

**Conclusions:** Age at PsO and PsA onset is a well-established clinical factor with significant impact in disease severity and in skin and arthritis manifestations. Our work suggests that it might also play a role in first biological treatment failure determining a need to switch. Higher PASI score at PsA onset, axial involvement and uveitis also seem to be associated with more likelihood of switching.

Our results should be considered exploratory. Larger studies are required to determine the role of these clinical features in predicting biological treatment switching.

**Disclosure of Interest:** None declared

## SAT0413 GENETIC ASPECT OF INTER-INDIVIDUAL VARIABILITY IN THE RESPONSE TO NON-STEROIDAL ANTI-INFLAMMATORY DRUGS IN AXIAL SPONDYLOARTHRITIS

G. Kilic[1], C. Sakalar[2], B. Kurt[2], M. Cakir[2], E. Kilic[1], S. Ozgocmen[1]. [1]*Erciyes Univ. Sch. Med. Div. Rheum. Kayseri;* [2]*Medical Biology, Genome and Stem Cell Center (GEN-KOK), Erciyes Univ. Sch. Med., Kayseri, Turkey*

**Background:** Non-steroidal anti-inflammatory drugs (NSAIDs) are first line therapies in patients with axial spondyloarthritis (axSpA). Patients with axSpA frequently response to NSAIDs and good response to NSAIDs is an important clinical feature. However, nearly 20–50% of patients with ankylosing spondylitis may have active disease despite NSAID treatment. NSAIDs acts through cyclooxygenase (COX) inhibition and inter-individual variability in response to NSAIDs may be related to genetic factors that regulate COX enzymes.

**Objectives:** We hypothesized that incomplete inhibition of COX enzymes as a consequence of genetic variability in the regulatory region of the COX genes may influence the response to NSAIDs. To examine this hypothesis, we investigated the association between selected polymorphism in COX-1 and COX-2 genes and NSAIDs response in axSpA.

**Methods:** Patients with axSpA who were followed by our outpatient clinic and met ASAS classification criteria for axSpA were enrolled. Healthy controls were recruited from hospital staff and visitors. Patients and controls were assessed for clinical and laboratory data. Inadequate response (IR) to NSAID therapy was defined either as persistence of symptoms despite maximal dosage of NSAIDs therapy or as persistent disease activity with a BASDAI>4 or an ASDAS >2 during NSAID therapy. Promoter variant of COX-2 -765G>C that is located in a putative binding site for the Sp1 transcription factors plays significant role as a positive activator of COX2 transcription. The Pro17Leu variant of COX-1–50C/T is associated with changed prostaglandin production and coxib selectivity. The DNA was isolated from blood samples the frequency of both COX-2- 765G/C (rs20417) and COX-1–50C/T (rs3842787) polymorphisms were analyzed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) methods using the Faul restriction enzyme and appropriate primers.

**Results:** A total of 177 patients with axSpA (108M, 69F; mean age, 37.5±9.6 yrs) and 103 healthy controls (60M, 43F; mean age, 33.0±7.6 yrs) were included. Genotype distribution is given in the table. We did not found any significant differences in genotype of COX polymorphism regarding good/inadequate response to NSAIDs in patients with axSpA. Also there was no significant difference in the allele frequency distributions of COX-2–765G/C and COX-1–50C/T between patients and healthy controls.

| axSpA | NSAID responders (n=95) | NSAID IR (n=81) | *p* |
|---|---|---|---|
| Male, n (%) | 50 (52.6) | 58 (71.6) | **0.010** |
| nr-axSpA | 46 (48.4) | 21 (25.9) | **0.002** |
| COX-1–50C/T | | | |
| Heterozygote, n (%) | 6 (6.3) | 5 (6.2) | 0.969 |
| COX-2–765G/C | | | |
| Heterozygote, n (%) | 26 (27.4) | 33 (40.7) | 0.061 |
| Homozygote, n (%) | 6 (6.3) | 4 (4.9) | 0.755 |
| Current smoker | 33 (34.7) | 40 (49.4) | **0.049** |
| HLA-B27 +ve n=154 | 45 (50.0) | 44 (68.8) | 0.356 |

**Conclusions:** The current study is the first to investigate the possible role of genetic variation of COX genes in the NSAID response in axSpA. Our results suggest that genetic polymorphism of COX-1–50C/T and COX-2 -765 do not play a significant role in NSAID response in axSpA. Further studies are needed to confirm these finding in patients with axSpA from different ethnic population.

## SAT0414 IN SPONDYLOARTHRITIS; DOES IMMUNOGENICITY INFLUENCE ON DRUG SURVIVAL OF ANTI-TNF?

S. García-Carazo[1], C. Plasencia[1], D. Pascual-Salcedo[2], D. Peiteado[1], G. Bonilla[1], L. Nuño[1], A. Villalba[1], M. Díaz[3], F. Arribas[2], A. Balsa[1].
*[1]Rheumatology; [2]Immunology; [3]Biostatistics, La Paz Universitary Hospital., Madrid, Spain*

**Background:** The anti-TNF therapy has been demonstrated effective in patients with Spondylarthritis (SpA). The lack of efficacy and adverse events (1) have been reported as the most common reasons for the discontinuation of these drugs. In Rheumatoid Arthritis, the immunogenicity has been proved to be an influential factor in the survival of treatment, but this has not been proved in SpA.
**Objectives:** To assess the survival of 3 anti-TNF agents in a cohort of patients with SpA, and to determine if there are differences in the survival of the 3 anti-TNF between patients who develop anti-TNF antibodies and those who do not.
**Methods:** Patients with SpA who started Adalimumab (ADA), Infliximab (IFX) or Etanercept (ETN) as first anti-TNF treatment between 2001–2015 were included. Diagnoses were: Ankylosing Spondylitis (55.5%), Non Radiographic Axial SpA (20%), SpA associated with inflammatory bowel disease (5.9%) and Psoriatic SpA (18.6%). Patients with only peripheral involvement were excluded. Clinical and demographic data were collected, and in the case of ADA and IFX, the presence or absence of anti-drug antibodies were identified. No anti-ETN antibodies were identified. The reasons for drug discontinuation were classified as adverse event, administration reaction, primary inefficacy, secondary inefficacy, recovery and other (this included pregnancy, malignancies, etc). The event was defined as drug discontinuation due to only the first 4 reasons. Cumulative incidence through competitive risk was performed to compare drug survival.
**Results:** Of the 220 patiens studied, 58.6% were men, with a mean age of 43.5±12.4 years. Out of them, 38.6% (85) started treatment with IFX, 30% (66) with ADA, and 31.4% (69) with ETN. No statistically significant difference (p=0.3) was found in the survival of the 3 anti-TNF: IFX had a probability of drug discontinuation of 32.9% at 5 years, compared to 35.5% of ADA and versus 31.8% of ETN. The most common reasons for discontinuing treatment were: Primary inefficacy for IFX (22.4%), primary and secondary inefficacy for ADA (13.6% each), and others (pregnancy, etc) for ETN (26.1%).
30.6% of patients treated with IFX developed anti-IFX antibodies (AIA). Anti-ADA antibodies (AAA) were observed in 22.7% of 66 patients who received ADA. In both drugs, the drug survival was lower in patients who developed anti-TNF antibodies, but this difference was statistically significant only in the group of IFX:

Cumulative incidence through competitive risk (probability of drug discontinuation)

| | 1 year | 5 years | 10 years | p value |
|---|---|---|---|---|
| Infliximab | | | | |
| NO AIA | 13.5% | 25.4% | 34.3% | 0.003 |
| WITH AIA | 11.5% | 50.0% | 69.2% | |
| Adalimumab | | | | |
| NO AAA | 14.7% | 33.4% | | 0.5% |
| WITH AAA | 21.0% | 43.5% | | |

When survival was analyzed by subgroups of patients treated with IFX and ADA who had not developed antibodies compared with ETN, no statistically significant difference was found (p=0.5).
**Conclusions:** In our cohort, the three anti-TNF showed a similar survival. However, and particularly in the case of IFX, the development of anti-drug antibodies proved to be an influential factor in the survival of treatment.

## SAT0415 DIASTOLIC LEFT VENTRICULAR DYSFUNCTION IN ANKYLOSING SPONDYLITIS IMPROVES DURING TUMOR NECROSIS FACTOR ALPHA BLOCKING THERAPY

S.C. Heslinga[1], T.C. Konings[2], I.E. Van der Horst-Bruinsma[1], O. Kamp[2], H.A. De Bruin-Bon[3], V.P. Van Halm[2,3], M.J. Peters[4], M.T. Nurmohamed[1].
*[1]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade and VU University Medical Center; [2]Cardiology, VU University Medical Center; [3]Cardiology, Academic Medical Center; [4]Internal Medicine, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Ankylosing spondylitis (AS) is associated with concomitant cardiac pathology, such as diastolic left ventricular (LV) dysfunction (1), valvular dysfunction, and aortic disease (2), all presumably caused by inflammation. The precise prevalence of diastolic left ventricular (LV) dysfunction and the effects of anti-inflammatory treatment thereon are currently unknown.
**Objectives:** To investigate the prevalence of diastolic LV dysfunction compared to controls and the effects of tumor necrosis factor (TNF) -α blocking therapy on ventricular function in AS patients.
**Methods:** Forty consecutive AS patients were included and treated for one year with TNF-α blocking therapy. Transthoracic echocardiography was performed at baseline and at one year. Forty age and gender matched asymptomatic random controls were included from an established echocardiographic cohort. Diastolic LV function (normal, dysfunction grade I, II, or III) and systolic LV function (ejection fraction, EF) were assessed. Valvular and aortic pathology was documented. Disease activity was measured with C-reactive protein (CRP), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score–CRP (ASDAS).
**Results:** At baseline, diastolic LV dysfunction (all grades) was present in nine patients (23%) vs one (3%) control (p=0.011). Systolic LV dysfunction was present in 0 (0%) patients vs one (3%) control (p=0.625). In total, 13 (33%) AS patients and six (15%) controls (p=0.066) had some form of cardiac pathology (i.e. one or more of the following: diastolic and/or systolic LV dysfunction, aortic valve dysfunction, aortic dilatation; one AS patient and one control had two disorders). Treatment with TNF-α blocking therapy had no effect on systolic LV function, but diastolic LV dysfunction (n=3 grade I, n=1 grade II) improved to normal in four patients (p=0.125), and neither worsened nor developed in the other patients. After the start of TNF-α blocking therapy CRP decreased from 4.0 (1.3–12.0) mg/l to 2.0 (1.9–3.2) mg/l ($p<0.001$), BASDAI decreased from 5.2±1.6 to 3.7±2.0 (p=0.001) and ASDAS decreased from 3.1±1.2 to 2.0±1.0 ($p<0.001$).
**Conclusions:** AS patients had a significantly increased prevalence of diastolic LV dysfunction compared to controls which improved during treatment with TNF-α blocking therapy. This appears to be related to the anti-inflammatory effects of TNF-blocking therapy.

## SAT0416 SIGNIFICANTLY REDUCED RECURRENCE RATE OF ACUTE ANTERIOR UVEITIS IN ANKYLOSING SPONDYLITIS DURING TREATMENT WITH GOLIMUMAB

S.C. Heslinga[1], M.T. Nurmohamed[1], A.H. Gerards[2], E.N. Griep[3], C. Koehorst[4], M.R. Kok[5], A.M. Schilder[6], M. Verhoef[7], I.E. Van der Horst-Bruinsma[1].
*[1]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade and VU University Medical Center, Amsterdam; [2]Rheumatology, Vlietland Hospital, Schiedam; [3]Rheumatology, Antonius Ziekenhuis, Sneek; [4]Rheumatology, Gelre Hospital, Apeldoorn; [5]Rheumatology, Maasstad Hospital, Rotterdam; [6]Rheumatology, Medical Centre Leeuwarden, Leeuwarden; [7]Immunology, Merck Sharp & Dohme, Haarlem, Netherlands*

**Background:** Acute anterior uveitis (AAU) is common in ankylosing spondylitis (AS) (1). Golimumab, a tumor necrosis factor alpha (TNF-α) blocker, has proven to be effective in the treatment of AS (2). We have shown earlier that treatment with adalimumab, another TNF-α blocker, leads to a significant decrease in the recurrence rate of AAU (3) in AS. At present, the effect of golimumab on the recurrence rate of AAU in AS is unknown.
**Objectives:** To investigate the effect of golimumab treatment on the recurrence rate of AAU attacks in AS patients.
**Methods:** Consecutive AS patients were enrolled who all fulfilled the 1984 Modified New York criteria, and fulfilled the criteria for initiating treatment with a TNF-α blocker in the Netherlands. All patients were treated with golimumab 50mg once a month for 12 months. During treatment, all occurring AAU attacks were assessed. The historic presence of AAU attacks was assessed from the year before baseline for non-biological treated patients, or the year before the first

treatment with a TNF-α blocker in case of a switch from another TNF-α blocker to golimumab. Disease activity was measured with the Ankylosing Spondylitis Disease Activity Score – C-reactive protein (ASDAS). Response to treatment was assessed with the ASAS-20.

**Results:** In total, 93 patients (65% male) were evaluable as per protocol, with a mean age of 44±13 years and a median disease duration of 7 (0–53) years. Fifty-one patients (55%) were TNF-α blocker naive. Median ASDAS score at baseline was 3.1 (0.7–5.5), which decreased to 1.9 (0.1–5.1) at 12 months. ASAS-20 response was achieved by 36% of patients at month three ($p<0.001$), and by 49% of patients at month twelve ($p<0.001$).

Six patients (7%) had a prior history of AAU with a total of nine attacks in the year prior to the first TNF-α blocker use (9.8/100 patient years). During golimumab treatment, the rate of recurring AAU attacks was reduced to two new attacks (2.2/100 patient years), a significant reduction of 78% ($p<0.001$). These two AAU attacks occurred in two separate patients, of whom one had no history of AAU.

**Conclusions:** Treatment of AS patients with golimumab leads to a significant decrease in disease activity. Simultaneously, the rate of recurring AAU attacks decreased significantly during golimumab treatment.

## SAT0417 EVOLUTION OF MRI INFLAMMATION AND STRUCTURAL LESIONS ON SERIAL SCANS OVER 5 YEARS IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TUMOR-NECROSIS-FACTOR-ALPHA INHIBITORS

S.J. Pedersen[1], U. Weber[2], R. Said-Nahal[3], I.J. Sørensen[1], A.G. Loft[4], N. Tvede[1], G. Kollerup[1], L. Juul[1], G. Thamsborg[1], O.R. Madsen[1], M. Østergaard[1]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen; [2]Dep. of Rheumatology, King Christian X Hospital and University of Southern Denmark, Graasten, Denmark; [3]Dep. of rheumatology, Université Versailles – Saint-Quentin, Ambroise-Paré Hospital, Boulogne-Billancourt, France; [4]Deps. of Rheumatology, Sygehus Lillebælt and Århus University Hospital, Vejle and Århus, Denmark*

**Background:** Only few studies have investigated evolution of MRI inflammation (infl.) and structural lesions by serial MRI and radiography (CX) in patients with ankylosing spondylitis (AS).

**Objectives:** To investigate evolution of infl. and structural lesions over 5 years on MRI and CX during treatment with TNFα inhibitors (TNFα-I) with multiple serial examinations.

**Methods:** The study population comprised 34 patients with AS followed for 5 years after initiation of TNFα-I. MRIs of the sacroiliac joints (SIJs) and lower spine (Th9-S1) and spinal CXs were performed 7 and 4 times, respectively. UW and RSN evaluated the MRIs and CXs, respectively, in known time sequence. MRIs were evaluated according to the SPARCC sacroiliac (SIJ) and Spine Infl. Index and Structural Scores (SSS) (1). The Canada-Denmark MRI definitions of infl., fat (2), erosion and new bone formation (3,4) were transformed into scores. The CXs were scored according to the modified Stoke AS Spine Score (mSASSS).

**Results:** MRI infl., compared to baseline, decreased significantly in SIJ and spine from week 22 and onwards, while SIJ erosion decreased significantly from week 46 (see table). Conversely, the SIJ and spinal MRI fat and SIJ ankylosis scores increased significantly from week 22. Only minor changes for SIJ backfill and spine erosion score were observed. These findings indicate that reduction of infl. during TNF-I is followed by structural progression. During the 5 years of TNF-I, mSASSS and the structural MRI spine score SASSS had, compared to baseline, increased significantly from year 1 and 2, respectively, and onwards.

**Conclusions:** Shortly after initiation of TNF-I spine and SIJ MRI infl. decreased and structural scores changed indicating new bone formation. Thereafter the MRI scores remained unchanged. In constrast, mSASSS continuously increased.

## SAT0418 THE EFFECT OF BISPHOSPHONATES ON BONE MINERAL DENSITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN DAILY CLINICAL PRACTICE

S. Arends[1,2], J.G. Veneberg[1,2], F.R. Wink[2], R. Bos[2], E. Brouwer[1], E. van der Veer[3], H. Bootsma[1], E.N. van Roon[4], F. Maas[1], A. Spoorenberg[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Laboratory Medicine, University Medical Center Groningen, Groningen; [4]Clinical Pharmacy and Pharmacology, Medical Center Leeuwarden, Leeuwarden, Netherlands*

**Background:** Ankylosing spondylitis (AS) is not only characterized by excessive bone formation, but also by excessive bone loss which may lead to low bone mineral density (BMD). So far, little is known about the effect of treatment with bisphosphonates on BMD in patients with AS.

**Objectives:** To evaluate the effect of bisphosphonates in combination with calcium/vitamin D supplements on BMD over 2 years in patients with AS stratified for the use of TNF-α inhibitors.

**Methods:** Patients from the Groningen Leeuwarden AS (GLAS) cohort, fulfilling the modified New York criteria for AS, who were treated with bisphosphonates and had 2-year follow-up BMD measurements available were included. All patients were treated with bisphosphonates in combination with calcium and/or vitamin D supplements. Alendronate (70 mg/week) and risedronate (35 mg/week) were used most frequently.

BMD of the lumbar spine (anterior-posterior projection at L1-L4) and hip (total proximal femur) were measured using DXA. Wilcoxon-signed rank test was used to compare BMD scores at first visit and after 2 years. Analyses were stratified for the use of TNF-α inhibitors.

**Results:** In total, 28 patients were included; 68% were male, 82% HLA-B27+, mean age was 53 ± 14 years, median symptom duration 20 years (range 1–60), and mean BASDAI 5.1±2.5. Fifteen patients (54%) started treatment with bisphosphonates before inclusion in the GLAS cohort (median 3.1 years). Most patients (86%) used bisphosphonates during the entire 2-year follow-up within GLAS.

Overall, lumbar spine BMD increased significantly from median Z-score of -0.8 at first visit to -0.3 after 2 years of treatment with bisphosphonates within the GLAS cohort. Hip BMD increased significantly from -1.1 at first visit to -0.9 after 2 years. In the 10 patients not using TNF-α inhibitors, only lumbar spine BMD increased significantly after 2 years of treatment. In the 14 patients starting TNF-α inhibitors,

Mean (SD). Wilcoxon Signed-Rank Test. Follow-up visit compared with week 0. *$p<0.05$; #$<0.01$; †$p<0.001$.

lumbar spine and hip BMD increased significantly after 2 years. The remaining 4 patients already used TNF-α inhibitors (Table 1). Comparable results were found for BMD T-scores.

Table 1. Lumbar spine and hip BMD Z-scores at first visit and after 2 years of follow-up in AS patients treated with bisphosphonates, stratified for the use of TNF-α inhibitors.

| | First visit | 2-year follow-up | P-value |
|---|---|---|---|
| *Total group (n=28)* | | | |
| BMD LS Z-score | -0.8 (-2.1 – 0.4) | -0.3 (-1.5 – 1.0) | <0.001 |
| BMD hip Z-score | -1.1 (-1.6 – -0.6) | -0.9 (-1.5 – 0.0) | 0.006 |
| *Patients not using TNF-α inhibitors (n=10)* | | | |
| BMD LS Z-score | -1.2 (-2.5 – -0.3) | -0.8 (-2.0 – 0.8) | 0.007 |
| BMD hip Z-score | -1.2 (-1.6 – -0.2) | -0.9 (-1.4 – -0.3) | 0.433 |
| *Patients starting TNF-α inhibitors (n=14)* | | | |
| BMD LS Z-score | -1.5 (-2.2 – 0.3) | 0.2 (-1.5 – 4.9) | 0.004 |
| BMD hip Z-score | -1.2 (-1.8 – -0.8) | -0.8 (-1.6 – 0.0) | 0.007 |
| *Patients using TNF-α inhibitors (n=4)* | | | |
| BMD LS Z-score | 0.2 (-0.8 – 2.6) | 0.6 (-0.7 – 3.1) | 0.066 |
| BMD hip Z-score | -0.8 (-1.4 – 2.3) | -0.7 (-1.6 – 2.8) | 0.593 |

Values are presented as median (interquartile range).

**Conclusions:** In our observational cohort study, lumbar spine BMD improved significantly after 2 years of follow-up in all AS patients treated with bisphosphonates. This improvement was most pronounced in patients starting TNF-α inhibitors. Hip BMD only improved significantly in patients also starting TNF-α inhibitors.

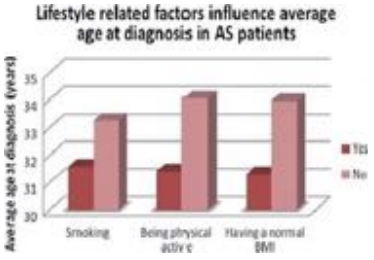
## SAT0419 GENDER DIFFERENCES IN DISEASE ACTIVITY, PHYSICAL FUNCTION AND QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TNF-α INHIBITORS

B.P. van der Slik[1], S. Arends[1,2], E. Brouwer[1], F.R. Wink[2], M. Efde[2], H. Bootsma[1], F. Maas[1], A. Spoorenberg[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden, Netherlands*

**Background:** The clinical presentation of ankylosing spondylitis (AS) can be different between genders.
**Objectives:** To investigate differences in clinical assessments of disease activity, physical function and quality of life between male and female AS patients before the start of TNF-α inhibitors and after 2 years of follow-up.
**Methods:** Patients from the Groningen Leeuwarden AS (GLAS) cohort who started TNF-α inhibitors because of active disease with baseline and 2-year follow-up visits were included. Disease activity was assessed using the BASDAI, ASDAS, CRP, and patient GDA. Physical function and quality of life were assessed using the BASFI and ASQoL, respectively.
**Results:** Of the 220 included AS patients with active disease, 69% were male, 78% HLA-B27 positive, mean age was 43±12 years, and median duration of symptoms 16 years (IQR 8–25). Patient characteristics were comparable between men and women.
At baseline, female patients with AS experienced significantly higher disease activity according to BASDAI, ASDAS, and patient GDA compared to male patients. Baseline CRP levels were comparable between genders. Furthermore, physical function (BASFI) and quality of life (ASQoL) were significantly worse in female patients (Table 1).
After staring TNF-α inhibitors, all clinical assessments improved significantly during 2 years of follow-up. The change over 2 years was comparable between male and female patients for all measures of disease activity, physical function, and quality of life (Table 1). After 2 years, significantly less women were still using their first TNF-α inhibitor (53% vs. 81%) and significantly more women had switched to a second TNF-α inhibitor (31% vs. 15%).

Table 1. Clinical assessments at baseline and change over 2 years in male and female AS patients who started treatment with TNF-α inhibitors

| | All (n=220) | Men (n=152) | Women (n=68) |
|---|---|---|---|
| *Baseline* | | | |
| BASDAI (0–10) | 6.0 ± 1.7 | 5.8 ± 1.7 | 6.6 ± 1.6* |
| $ASDAS_{CRP}$ | 3.75 ± 0.82 | 3.67 ± 0.85 | 3.92 ± 0.72* |
| CRP (mg/l) | 13 (5-24) | 13 (4-22) | 13 (6-27) |
| Patient GDA (0–10) | 6.6 ± 1.9 | 6.4 ± 1.9 | 7.0 ± 1.9* |
| BASFI (0–10) | 5.8 ± 2.1 | 5.5 ± 2.1 | 6.3 ± 2.1* |
| ASQoL (0–18) | 9.9 ± 4.1 | 9.3 ± 4.0 | 11.4 ± 4.0* |
| *2-year change* | | | |
| BASDAI (0–10) | -2.7 ± 2.1 | -2.7 ± 2.0 | -2.6 ± 2.2 |
| $ASDAS_{CRP}$ | -1.59 ± 1.10 | -1.67 ± 1.11 | -1.42 ± 1.07 |
| CRP (mg/l) | -8 (-17-0) | -8 (-16-0) | -8 (-20-0) |
| Patient GDA (0–10) | -3.1 ± 2.8 | -3.2 ± 2.6 | -2.8 ± 3.1 |
| BASFI (0–10) | -2.1 ± 2.2 | -2.1 ± 2.1 | -2.2 ± 2.4 |
| ASQoL (0–18) | -4.7 ± 4.1 | -4.5 ± 3.8 | -5.3 ± 4.8 |



Values are presented as mean ± SD or median (interquartile range).
* P-value<0.05 compared to men.

**Conclusions:** In this large cohort of AS patients with active disease, cross-sectional analysis showed that women experience higher disease activity and worse physical function and quality of life on self-reported assessments than men. Longitudinal analysis after starting TNF-α inhibitors showed that the changes in clinical assessments over 2 years were comparable between genders.

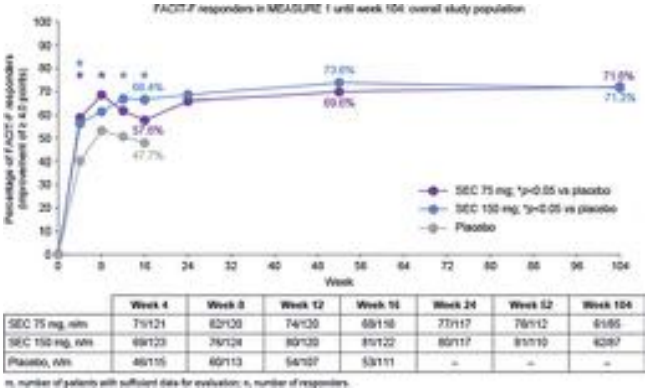
## SAT0420 SMOKING RELATED WITH DISEASE RESPONSE AND AGE AT DIAGNOSIS IN ANKYLOSING SPONDYLITIS

T. Rusman[1], M. Nurmohamed[2], I. Visman[3], I. van der Horst-Bruinsma[4]. *[1]Rheumatology, VUMC University Amsterdam; [2]Amsterdam Rheumatology immunology Center, Reade and VU University medical center; [3]Amsterdam Rheumatology immunology Center, Reade; [4]Amsterdam Rheumatology immunology Center, VUMC University Amsterdam, Amsterdam, Netherlands*

**Background:** Lifestyle related factors, such as smoking and Body Mass Index (BMI) are known to increase the disease activity and progression in rheumatoid arthritis (1,2). In ankylosing spondylitis (AS), only a few studies are available regarding this topic (3–5). Smoking was associated with an earlier diagnosis of AS, higher disease activity (OR=2.5) and a doubled increased radiographic progression compared to non smokers. In addition, alcohol consumption and having a physical demanding occupation were associated with more axial radiographic lesions. A higher BMI was associated with a lower response rate to Tumor Necrosis Factor inhibitors (TNFi) compared to AS patients with a normal BMI (49% vs 78%, respectively). Most studies included only one lifestyle related factor in association with disease activity and early diagnosis in AS, while our study aimed to test for multiple related lifestyle factors on disease activity and early diagnosis.
**Objectives:** To determine whether factors related to lifestyle (smoking, alcohol consumption, BMI, physical activity and occupation) are associated with age at diagnosis of AS and response rate to TNFi.
**Methods:** Consecutive AS patients (fulfilling the modified New York criteria) who started or switched treatment with TNF inhibitors were included in a prospective, observational cohort. Data on disease activity (Ankylosing Spondylitis Disease Activity Score (ASDAS) and lifestyle factors (smoking, alcohol consumption, BMI, occupation and physical activity) were collected at baseline and 6, 12 and 24 months after the start of treatment. Lifestyle factors, with $p<0.05$ in relation to age at diagnosis and ASDAS were subsequently entered in the overall regression model.
**Results:** In total 312 AS patients were included with a mean follow-up of 18.9 months (6–24). The majority 172 (55%) improved on TNFi whereof, 86 patients (27.7%) showed a clinical important improvement (decrease in ASDAS >1.1) and 86 (27.7%) a major clinical improvement (decrease in ASDAS >2.2). In multivariate analysis, age at diagnosis was negatively influenced by a positive smoking status ((regression coefficient in years) B= -2.78, p=0.041, 95% CI= -5.60 – -0.01), being physical active (B=-2.98, p=0.026, 95% CI=-5.59 – -0.37) and having a normal BMI (B= -3.1, p=0.019, 95% CI=-5.73 – -0.52) (Figure 1). No risk factors were related with the change in ASDAS during treatment. No relation between alcohol consumption and disease onset or treatment response was found.



**Conclusions:** Smoking, moderate physical activity and normal BMI were associated with an earlier age at diagnosis. A significant improvement of the ASDAS at both 1 and 2 year follow-up under TNF treatment was found, confirming the efficacy of TNF inhibitors in a real life cohort. However, contrary to the expectations no relations were found between lifestyle factors and disease activity.

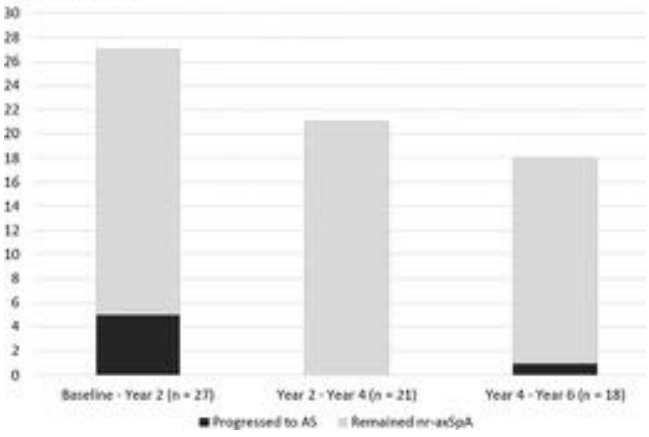
## SAT0421 REDUCTION IN FATIGUE IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: RESULTS OF TWO PHASE 3 STUDIES OF SECUKINUMAB

T.K. Kvien[1], P.G. Conaghan[2], A. Deodhar[3], L. Gossec[4], M. Østergaard[5], J. Cañete[6], K. Gandhi[7], H. Richards[8], N. Williams[9], S. Jugl[8]. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]University of Leeds, Leeds, United Kingdom; [3]Oregon Health & Science University, Portland, OR, United States; [4]Paris 06 University, Paris, France; [5]Copenhagen Center for Arthritis Research (COPECARE), Rigshospitalet, Denmark; [6]Hospital Clinic de Barcelona e IDIBAPS, Barcelona, Spain; [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [8]Novartis Pharma AG, Basel, Switzerland; [9]RTI Health Solutions, Durham, NC, United States*

**Background:** Patients with active ankylosing spondylitis (AS) experience fatigue which frequently leads to reduced health-related quality of life (HRQoL). Secukinumab (SEC) treatment results in rapid improvements in signs and symptoms, physical functioning and HRQoL in patients with active AS versus placebo (PBO) in the phase 3 studies MEASURE 1 (M1) and MEASURE 2 (M2).
**Objectives:** To assess the impact of SEC on fatigue in patients with AS, including biologic-naïve patients and those with an inadequate response to TNF therapy (TNF-IR) and to investigate correlations between fatigue and baseline characteristics or clinical endpoints.
**Methods:** The two phase 3 studies involved patients with active AS (M1, N=371; M2, N=219). Patients were randomized to receive subcutaneous SEC 150 mg or 75 mg or PBO administered every 4 weeks after initiating therapy. Patients randomized to PBO who did not meet predefined response criteria at week 16 were re-randomized at week 24 to SEC 150 mg or 75 mg. Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale. The FACIT-F response analyses were based on observed data with no imputation. A change in FACIT-F score of $\geq$4 from baseline was used to define fatigue response. Possible correlations between baseline characteristics or clinical response criteria and improvements in fatigue at weeks 16 and 52 were investigated using a logistical regression model.
**Results:** From week 4 onwards, greater improvements in fatigue response were observed for both SEC groups compared with PBO. At week 16, 66.4% (M1) and 77.6% (M2) of patients receiving SEC 150 mg achieved a fatigue response, compared with 47.7% (M1) and 50.0% (M2) for PBO ($p$ <0.05 for both comparisons; see figure). Response rates for SEC 150 mg at week 16 were numerically higher in biologic-naïve patients (M1, n=271; M2, n=134) than in TNF-IR patients (M1: 68.9% vs 59.4%; M2: 86.0% vs 62.5%, respectively). Responses were sustained at week 52 in both studies (M1, 73.6%; M2, 80.6%) and at week 104 in M1 (71.3%; see figure for M1 data) in the overall population, and in the two subgroups according to prior biologic therapy status. Correlation analyses based on pooled data from both studies did not identify any baseline factors that consistently predicted an improvement or worsening of FACIT-F score at week 16 or 52. Achieving a fatigue response was strongly positively correlated at weeks 16 and 52 with clinical response (ASAS20, 40, 5/6 responses, ASAS partial remission, ASDAS-CRP major improvement and BASDAI 50 response).

| | Week 4 | Week 8 | Week 12 | Week 16 | Week 24 | Week 52 | Week 104 |
|---|---|---|---|---|---|---|---|
| SEC 75 mg, n/m | 71/121 | 82/120 | 74/120 | 69/116 | 77/117 | 78/112 | 61/85 |
| SEC 150 mg, n/m | 69/123 | 76/124 | 80/120 | 81/122 | 80/117 | 81/110 | 62/87 |
| Placebo, n/m | 46/116 | 60/113 | 54/107 | 53/111 | – | – | – |

n, number of patients with sufficient data for evaluation; n, number of responders.



**Conclusions:** SEC 150 mg provided rapid improvement in fatigue, regardless of prior biologic therapy, and response was sustained up to 104 weeks. Fatigue response showed a strong correlation with improvement in clinical response criteria, indicating a relationship between fatigue and disease activity in AS and is an important treatment goal for patients with AS.

## SAT0422 LONG-TERM ANTI-TNF TREATMENT IS ASSOCIATED WITH REDUCTION OF PROGRESSION OF RADIOGRAPHIC CHANGES IN THE SACROILIAC JOINTS IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPA: SIX-YEAR RESULTS OF THE ESTHER TRIAL

V. Rios Rodriguez[1], J. Sieper[1], K.-G. Hermann[1], H. Haibel[1], C. Althoff[1], B. Buß[1], O. Behmer[2], D. Poddubnyy[1]. *[1]Charité Universitätsmedizin Berlin; [2]Pfizer Pharma, Berlin, Germany*

**Background:** Data from observational studies suggests a 10–12% biannual rate of progression from non-radiographic axial SpA (nr-axSpA) to ankylosing spondylitis (AS) [1] in patients not treated with tumor necrosis factor $\alpha$ (TNF) blockers. It is not known, whether anti-TNF treatment might be able to prevent such a progression in patients with nr-axSpA.
**Objectives:** To assess the radiographic progression in the sacroiliac joints (SIJ) during long-term (up to 6 years) treatment with the TNF-blocker etanercept in patients with early axSpA.
**Methods:** In the ESTHER trial [2] a total of 76 patients with early ($\leq$5 years symptom duration) and active axSpA were randomized to be treated with either etanercept or sulfasalazine for one year. At year 1, all patients who were not in remission continued with etanercept directly; patients in remission discontinued their therapy and were followed-up until year 2, in case of disease flare the etanercept therapy was (re)-introduced and continued until the end of year 6. X-rays of SIJ were collected at baseline and every 2 years thereafter. Two trained readers (VRR and DP), who were blinded for all clinical data, scored independently the SIJ x-rays in a concealed and randomly selected order, according to the grading system of the modified New York (mNY) criteria for AS. Patients were classified as having AS if both readers recorded the presence of definite radiographic sacroiliitis according to the mNY criteria. Active inflammatory and fatty lesions on magnetic resonance imaging (MRI) of SIJ were assessed according to the Berlin MRI scoring system (KGH and CA).
**Results:** A total of 55 patients from the 76 patients of ESTHER trial were included in the current analysis due to the availability of X-rays of SIJ. 19 patients (34.5%) were classified at baseline as AS and 36 (65.5%) as nr-axSpA based on the independent reading results with a fair agreement between both readers (k =0.33, p=0.01). Radiographic progression from nr-axSpA to AS was observed mainly between baseline and year 2 – in 18.5% (5/27) of the patients classified as nr-axSpA at baseline with available SIJ X-rays at year 2. There were no patients who progressed to AS between year 2 and year 4 and only one patient (5.6%, 1/18) progressed to AS between year 4 and year 6 – figure.

**Figure.** Progression from nr-axSpA to AS in patients treated with etanercept for up to 6 years in the ESTHER trial.

Treatment arm in the first year (entanercept or sulfasalazine) had no significant impact on progression from nr-axSpA to AS. Elevated C-reactive protein – CRP (≥5 mg/l) at baseline was associated with a higher odds for progression: odds ratio =7.0 (95%CI 0.7–73.9). There was no difference in the baseline osteitis score on MRI of SIJ between progressors and non-progressors (since MRI inflammation was an entry criterion), however, progressors had higher fatty lesions score at baseline as compared to non-progressors: 10.3±7.1 vs. 4.9±5.8, respectively, p=0.064.

**Conclusions:** In the ESTHER trial, there was a substantial reduction of radiographic sacroiliitis progression between year 2 and year 6 of anti-TNF treatment. Higher baseline CRP and higher MRI fatty lesions score demonstrated a positive association with progression from nr-axSpA to AS.

### SAT0423 PATIENT-REPORTED QUALITY OF LIFE IN PATIENTS WITH BASELINE OBJECTIVE SIGNS OF INFLAMMATION AND ACTIVE NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS TREATED WITH GOLIMUMAB: RESULTS OF THE OPEN-LABEL EXTENSION OF A RANDOMIZED, DOUBLE-BLIND STUDY

W.P. Maksymowych[1], M. Dougados[2], J. Sieper[3], J. Braun[4], G. Bergman[5], S.P. Curtis[5], A. Tzontcheva[5], G. Philip[5], S. Huyck[5], D. van der Heijde[6]. *[1]University of Alberta, Edmonton, Canada; [2]Paris-Descartes University, Paris, France; [3]University Clinic Benjamin Franklin, Berlin; [4]Rheumazentrum Ruhrgebiet, Herne, Germany; [5]Merck & Co., Inc., Kenilworth, United States; [6]Leiden University Medical Center, Leiden, Netherlands*

**Background:** In a randomized, double-blind (DB), placebo (PBO)-controlled, phase 3 study (GO-AHEAD; NCT01453725), patients (pts) with nonradiographic axial spondyloarthritis (nr-axSpA) had significantly greater improvement in quality of life (QoL) after 16 weeks of treatment with golimumab (GLM) compared with PBO.[1]

**Objectives:** To assess QoL during the open-label extension (OLE) of GO-AHEAD in pts who had objective signs of inflammation (MRI sacroiliitis+ and/or C-reactive protein >upper limit of normal) at baseline of the DB phase.

**Methods:** Pts completing the 16-week DB study (GLM or PBO) received GLM 50mg Q4W during the 44-week OLE (36-week efficacy period; 8-week safety follow-up). QoL evaluations in pts with objective inflammation included Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL), 36-item Short Form Health Survey (SF-36), and EuroQol Group 5 Dimensions Health Questionnaire (EQ-5D) Index and Health State (0–10cm VAS), and Work Productivity and Activity Impairment (WPAI) at weeks 16 and 52 and the Patient's Global Disease Assessment (PGDA; 0–10cm VAS) at weeks 16, 20, 24, 32, 40, and 52. Data were summarized descriptively.

**Results:** In total, 153 pts with objective inflammation at baseline of the DB study were treated in the OLE (GLM=76; PBO=77). Pts who received GLM during the DB phase and continued GLM in the OLE (the GLM/GLM group) had continued improvement in QoL at week 52 as measured by the EQ-5D, SF-36, ASQoL, and PGDA VAS scales (Figure). Pts who received PBO during the DB phase and switched to GLM during the OLE (the PBO/GLM group) had notable improvements in these QoL scales at week 52 (Figure). Likewise, pts in the GLM/GLM group had continued benefits in work productivity and impairment, and those in the PBO/GLM[1] group had notably improved benefits in work productivity and impairment (Table).

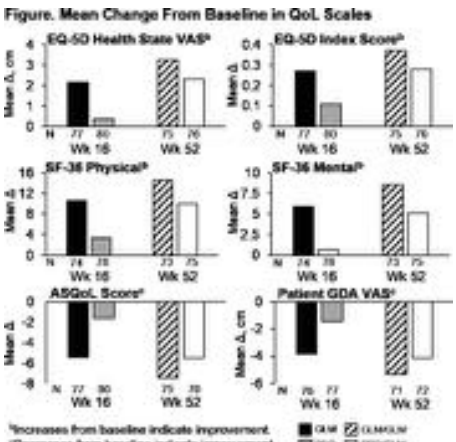

Table 1. Mean (SD) change from baseline in WPAI scores

| | n | GLM Week 16 | n | GLM/GLM Week 52 | n | PBO Week 16 | n | PBO/GLM Week 52 |
|---|---|---|---|---|---|---|---|---|
| Percent impairment while working* | 51 | –23.3 (26.5) | 47 | –30.4 (25.3) | 46 | –11.7 (29.8) | 46 | –26.7 (30.0) |
| Percent work time missed* | 47 | –6.0 (17.6) | 47 | –7.1 (24.0) | 46 | 2.1 (30.9) | 45 | –8.7 (19.7) |
| Percent overall work impairment* | 46 | –21.2 (24.7) | 45 | –31.1 (25.3) | 45 | –8.4 (28.5) | 45 | –26.5 (27.2) |
| Percent activity impairment | 76 | –25.5 (28.7) | 74 | –36.4 (26.2) | 80 | –7.0 (78.3) | 75 | –22.7 (32.1) |

*Questions completed only by patients who were working.

**Conclusions:** Among pts with objective inflammation before treatment in the DB phase of GO-AHEAD, those who continued GLM in the OLE had continued benefits in QoL and work productivity, and those who switched to GLM in the OLE from PBO in the DB phase had notable improvement in QoL and work productivity.

## Osteoarthritis

### SAT0424 TRENDS IN OSTEOARTHRITIS INCIDENCE IN BRITISH COLUMBIA, CANADA, 2001-2012

J.A. Kopec[1], E.C. Sayre[2], J. Cibere[1], L.C. Li[1], N. Bansback[1], H. Wong[1], M.M. Rahman[3], J.M. Esdaile[1]. *[1]University of British Columbia, Vancouver; [2]Arthritis Research Canada, Richmond, Canada; [3]East West University, Dhaka, Bangladesh*

**Background:** Osteoarthritis is the most common joint disease and a massive public health problem worldwide. Incidence rates of OA reported in the literature vary widely. Several studies predicted that OA burden would increase due to population aging and increasing prevalence of obesity. However, population data on trends in OA incidence are extremely limited.

**Objectives:** The purpose of the study was to describe trends in crude, age-specific and age-adjusted incidence of physician-diagnosed OA for men and women in British Columbia, Canada, between 2001 and 2012.

**Methods:** A random sample of 742,070 records was obtained from Population Data BC, an administrative database which covers virtually all hospitalizations and visits to health professionals in the province of British Columbia, Canada since 1986. Similar to prior studies [1,2], we defined incident OA as a hospital discharge or two visits to a health professional (within 2 years and not on the same day) with a diagnostic code for OA (715 in ICD-9 or M15-M19 in ICD-10) in a person without OA within the previous 10 years. Person-years were obtained from individual data on registration with the provincial health plan. The 2006 BC population was used for standardization of rates. Confidence intervals were estimated as exact Poisson intervals and p-values for trend were obtained using a Poisson regression model with a linear year effect.

**Results:** Crude OA incidence rate in the population (men and women combined) rose from 7.1 (95% CI 6.9–7.4) per 1000 person-years in 2001 to 10.2 (9.9–10.4) per 1000 p-y in 2012. The rates were higher in women and increased in both men (5.9 to 8.7 per 1000 p-y) and women (8.4 to 11.5 per 1000 p-y). Age-specific

rates increased significantly ($p<0.05$) among those aged 40–49 and 50–59 in both sexes. Age-standardized rates for selected years are shown in Table 1. A significant upward linear trend between 2001 and 2012 was observed for men ($p<0.001$) and women ($p=0.008$).

Table 1. Age-standardized OA incidence rates per 1000 p-y in BC, Canada

| Year | Men | Women | Overall |
|---|---|---|---|
| 2001 | 6.7 | 9.5 | 8.1 |
| 2006 | 7.0 | 9.9 | 8.4 |
| 2012 | 7.4 | 9.7 | 8.5 |

**Conclusions:** The study confirms an upward trend in crude OA incidence rates in BC observed in prior studies [1,2]. Unlike prior studies, which covered a shorter period, current data show a significant trend in age-standardized incidence in both men and women. This could be due to an increase in obesity prevalence in BC [3]. Our data also show an increase in OA incidence in relatively young persons (40–59), which has not been previously reported. A limitation of the study is the definition of OA based on administrative data.

## SAT0425 DOES WEIGHT IN THE OFFSPRING OF PEOPLE WITH A TOTAL KNEE REPLACEMENT FOR SEVERE PRIMARY KNEE OSTEOARTHRITIS HAVE A MORE DETRIMENTAL EFFECT ON KNEE CARTILAGE AND PAIN? A 10-YEAR PROSPECTIVE STUDY

F. Pan[1], L. Blizzard[2], J. Tian[3], F. Cicuttini[4], T. Winzenberg[1], C. Ding[1], G. Jones[1]. *[1]Musculoskeletal Unit; [2]Statistics Unit; [3]Public Health, Menzies Institute for Medical Research, University of Tasmania, Hobart; [4]Department of Epidemiology and Preventive Medicine, Monash University Medical School, Melbourne, Australia*

**Background:** Although being overweight or obese is an important risk factor for the development of knee osteoarthritis (OA), the complex interplay between weight and genetic factors on the early-onset knee OA is still unclear.

**Objectives:** To determine the effects of weight on knee cartilage volume, defects and knee pain over 10 years in offspring having at least one parent with a total knee replacement for severe primary knee OA and in controls with no family history of knee OA.

**Methods:** 372 participants (186 offspring and 186 controls) aged from 26–61 years were recruited at baseline, and followed at 2.3 (Phase 2) and 10.2 (Phase 3) years later. T1-weighted magnetic resonance imaging (MRI) of the right knee was used to measure cartilage volume and defects at each time-point. Knee pain was only assessed at Phase 2 and Phase 3 using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Data were analysed using mixed-effects model with adjustment for potential confounders.

**Results:** Study participants were middle-age adults (mean age 45 years and mean weight of 77.5 kg) at baseline. In multivariable analysis, increasing body weight was negatively associated with medial tibiofemoral cartilage volume ($\beta$=-0.28 ml, per 1 SD increase, 95% CI -0.49 to -0.07) and the presence of medial tibiofemoral cartilage defects (OR=1.70, per 1 SD increase, 95% CI 1.20 to 2.33) in offspring over 10.2 years. Similar associations were observed for lateral tibiofemoral cartilage volume ($\beta$=-0.19 ml, P=0.059), and defects (OR=1.56, P=0.050). Over 7.9 years, body weight was positively associated with total knee pain ($\beta$=1.78, per 1 SD increase, 95% CI 0.49 to 3.06) and all pain subscales ($\beta$=0.36 to 0.58, all $P<0.05$) apart from sitting and standing in offspring while adjusting for potential confounders and knee structural factors. There were no statistically significant associations between weight, and cartilage volume or defects or pain in controls (all $P>0.05$).

**Conclusions:** Body weight is associated with knee cartilage volume, defects and pain in offspring of parent with primary knee OA but not in controls, suggesting an interplay between genetic factors and overweight/obesity in the pathogenesis of early knee OA.

**Disclosure of Interest:** None declared

## SAT0426 FUNCTIONAL CONNECTIVITY ALTERATIONS IN KNEE OA PATIENTS: AN FMRI STUDY

D. Marques-Gil[1], J. Pujol[2], M. Lopez-Ruiz[1], J. Llorente-Onaindia[1], L. Orpinell Palacio[1], F. Montañes[1], M.A. Campillo[1], P. Benito[1], G. Martinez-Vilavella[2], D. Macia[2], J. Monfort[1]. *[1]Rheumatology; [2]Unit of MRI, Hospital del Mar, Barcelona, Spain*

**Background:** Central sensitization (CS) is a common phenomenon among patients with knee osteoarthritis. In a previous study, our team showed that CS occurs gradually, and no dummy, and has an important role in the development of chronic pain. Neuroimaging is a procedure that allows us to objectify the pain assessment. The study of the resting state help us to detect alterations in brain function at rest.

**Objectives:** The aim of this study is to identify the subgroup of patients sensitized and to characterize their changes in functional connectivity with functional Magnetic Resonance Imaging (fMRI).

**Methods:** This is a cross-sectional, single blind (investigator) study of 60 patients with knee osteoarthritis. Presence of CS was assessed using extended version of the Arendt-Nielsen peripatellar map, following the evidence of regional spread of pain and, also, temporal summation which is increased pain response to repeated stimulation. FMRI included two resting sequences in which the subject had to remain lying down and stay as relaxed as possible and let flow the mind. These sequences were interspersed with another sequence in which painful stimulation of the medial interline was applied in order to observe changes in functional connectivity before and after a similar pain caused by the disease itself.

**Results:** A total of 33 patients showed some degree of CS of which 19 of them met all the established criteria. In the analysis of the resting state sequence before painful stimulation, no significant differences between sensitized and non sensitized patients were found. However, the results of resting state sequence after pain stimulation showed a significant heightened functional connectivity, especially in the posterior insula. When the somatosensory cortex (SII) was selected as a region of interest, we found enhanced functional connectivity, in resting state sequence before pain, with the anterior insula and also, a reduction of functional connectivity with the anterior cingulate cortex was identified. In the resting state sequence after pain stimulation, a similar pattern was revealed with increased intensity.

**Conclusions:** It is widely known that SII is associated to the information processing coming from the leg and insula, which is related to information integration and visceral sensation or interoception. The increased connectivity found between both SII and insula, after painful stimulation stopped, could show that sensitized patients experience pain even when the initial stimulation has disappeared, such a fingerprint.

These results, together with those previously obtained in the sequences of painful stimulation, help to get an overall picture of these patients. This study is a starting point to investigate new therapeutic approaches to expand the current management of these patients and improve their quality of life.

## SAT0427 THE ABSENCE OF SYMPTOM IN SUBJECTS WITH ADVANCED KNEE OA

K.M. Son[1], H.S. Lee[1], D.H. Kim[2], M.C. Paik[3], D.G. Jang[3], S.Y. Lee[4], H.A. Kim[4]. *[1]Department of rheumatology., Hallym University CHUncheon Sacred Heart Hospital; [2]Deparmtent of Social and Preventive Medicine, Hallym University College of Medicine, Gangwon-do; [3]Deparment of Statistics, Seoul National University, Seoul; [4]Department of rheumatology., Hallym University Sacred Heart Hospital, Anyang, Korea, Republic Of*

**Background:** Although osteoarthritis (OA) is predominantly considered as a disease of cartilage, articular cartilage is an aneural tissue, and there is a consensus that the association between knee radiographic OA and knee pain is modest.

**Objectives:** To investigate the prevalence of asymptomatic subjects with advanced knee OA, we examined databases obtained from 2 Korean community residents.

**Methods:** Subjects included were from Hallym Aging Study (HAS) or from the Korean National Health and Nutrition Examination Survey (KNHANES, year 2010–2012). Participants in each study were asked knee-specific questions regarding the presence of knee pain. Radiographic evaluations consisted of weight-bearing anteroposterior, weight-bearing semi-flexed knee radiographs. For HAS cohort, MRI of the knee was available. Each knee was evaluated for the presence of osteophytes, joint space narrowing, subchondral sclerosis, and cysts, and was graded for overall evidence of radiographic OA using the K-L grade. Advanced knee OA was defined as K-L grade 4 (large osteophytes, severe joint space narrowing, and/or bony sclerosis). Clinical factors associated with the presence of knee pain were evaluated with multivariate logistic regression analysis.

**Results:** Included were 504 subjects from HAS and 8679 from KNHANES. Advanced knee OA was identified in 47 (9.3%) and 685 (7.8%) in HAS and KNHANES, respectively. The mean age of the study subjects were 72.5 years and 16.5% were male. Two hundred twenty five subjects (44.3%) did not report any pain despite having K-L grade 4 OA. Female, non-smoker, the presence of osteoporosis, and lower education were significantly associated with knee pain. After multivariate association, female and osteoporosis was significantly

associated with the presence of knee pain. Advanced OA subjects without knee pain did not differ from non-OA subjects in the general physical health measured with the short-form (SF-12), except for the physical functioning. Regardless of the presence of pain, MRI finding such as summary cartilage score, bone marrow lesion score, the presence of synovitis and effusion was similar in advanced OA subjects.

**Conclusions:** Our community study showed that a significant number of subjects with K-L grade 4 OA was asymptomatic. The guidance of therapeutic decision merely based on imaging study as well as treatment option focusing solely on cartilage engineering should be viewed with caution.

**Disclosure of Interest:** None declared

## SAT0428 SAFETY, CLINICAL AND IMAGING OUTCOMES OF A NOVEL, INTRA-ARTICULAR, INJECTABLE, WNT INHIBITOR (SM04690) IN THE TREATMENT OF OSTEOARTHRITIS OF THE KNEE: EXPLORATORY ANALYSIS OF RESULTS FROM A 24 WEEK, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 1 STUDY

Y. Yazici[1], T.E. McAlindon[2], R.M. Fleischmann[3], A. Gibofsky[4], N.E. Lane[5], A.J. Kivitz[6], S. Majumdar[7], V. Strand[8], C.J. Swearingen[1], A. DiFrancesco[1], J. Tambiah[1], J. Hood[1], M.C. Hochberg[9]. *[1]Samumed, LLC, San Diego; [2]Tufts Medical Center, Boston MA; [3]Metroplex Clinical Research Center, Dallas TX; [4]Hospital for Special Surgery, New York NY; [5]University of California Davis, Davis CA; [6]Altoona Arthritis and Osteoporosis Center, Altoona PA; [7]University of California San Francisco, San Francisco CA; [8]Stanford University, Palo Alto CA; [9]University of Maryland Medical Center, Baltimore MD, United States*

**Background:** Wnt signaling pathway plays a central role in joint tissue formation and altered Wnt signaling has been associated with cartilage loss in preclinical/clinical studies.[1] SM04690 is an IA small molecule inhibitor of the Wnt pathway.

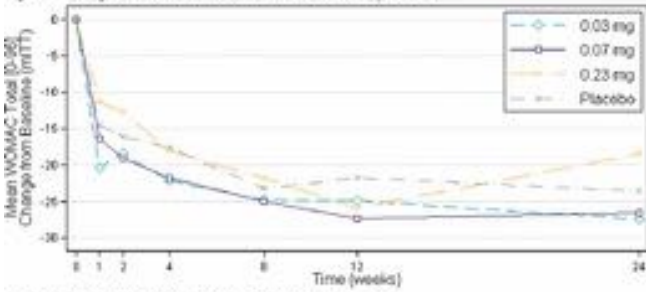
**Objectives:** To report safety, clinical and imaging efficacy results from a 24 week phase 1 randomized, double-blind, placebo-controlled, dose-escalation clinical trial of a small molecule Wnt pathway inhibitor, SM04690, in knee OA.

**Methods:** Subjects with symptomatic, radiographic knee OA were randomized to receive a single IA injection in the target knee with either 0.03, 0.07, 0.23 mg SM04690 or vehicle (volume 2mLs) in a 4:1 SM04690 (N=16): vehicle (N=4) ratio. Safety, pharmacokinetics, WOMAC Total, Function, Pain subscales and strict OARSI responses[2], and radiographs were collected at baseline and during the 24 week trial. Analyses of efficacy outcomes were conducted using a modified Intention-To-Treat (mITT) baseline-adjusted analysis of covariance (ANCOVA) and logistic regression.

**Results:** A total of 61 subjects (female N=41, mean age 62.6 yrs, BMI 30.4 kg/m$^2$) were enrolled. Serum levels of SM04690 in all subjects were below limits of detection at all time points. Two dose limiting toxicities (DLTs), paroxysmal tachycardia, (also an SAE), and increased pain were reported in 0.07 mg cohort. A total of 72 AEs were reported in 28 (46%) subjects; 16 AEs in 8 subjects were considered possibly or probably related to study drug.

At Week 24, improved WOMAC Total Score was seen for both 0.03 mg and 0.07 mg cohorts (change from baseline, -27.4 and -26.6 respectively) compared to placebo (-21.7) (Figure 1). Odds of having an OMERACT-OARSI strict response in 0.07 mg cohort were higher than in the placebo cohort at week 12 (odds ratio=5.7, 95% CI: 1.1, 30.0, P=0.04); odds of an OMERACT-OARSI strict response in 0.03 mg cohort were higher than in the placebo cohort at week 24 (odds ratio=4.8, 95% CI: 0.9, 25.8, P=0.07) (Figure 2). Joint space width by radiographs showed no change from baseline to Week 24 in the 0.03 mg cohort (0.00 mm), an increase in the 0.07 mg cohort (0.49 mm), and a decrease in the 0.23 mg cohort (-0.15 mm), with the placebo cohort exhibiting a larger decrease (-0.33 mm). Compared to placebo, the change in joint space width seen in 0.07 mg cohort was statistically significant (P=0.02).

Figure 1. Change from Baseline in WOMAC Total over time by Cohort



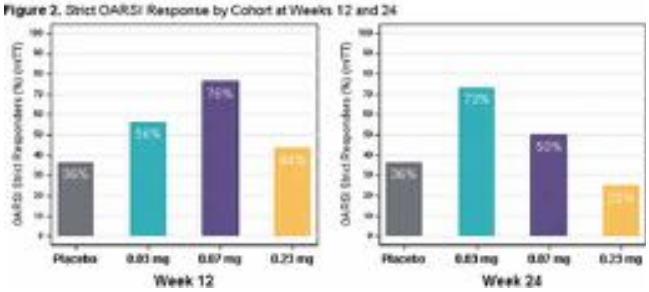


Figure 2. Strict OARSI Response by Cohort at Weeks 12 and 24

**Conclusions:** These phase 1 data suggested that an intra-articular injection with a novel Wnt inhibitor SM04690 into the knee of OA patients was safe and well-tolerated. SM04690 appeared to potentially improve function, pain and knee joint space width. Additional studies are underway to further evaluate safety, tolerability, efficacy and potential DMOAD properties.

## SAT0429 EFFECT OF VITAMIN D SUPPLEMENTATION ON EFFUSION-SYNOVITIS IN KNEE OSTEOARTHRITIS: A RANDOMIZED CONTROLLED TRIAL

X. Wang[1], F. Cicuttini[2], X. Jin[1], A.E. Wluka[2], W. Han[1], Z. Zhu[1], L. Blizzard[1], B. Eathakkattu Antony[1], T. Winzenberg[1], G. Jones[1], C. Ding[1]. *[1]Menzies Institute for Medical Research, University of Tasmania, Hobart; [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

**Background:** Synovial inflammation is commonly observed in osteoarthritis (OA). Vitamin D has showed anti-inflammatory properties in joint disorders which have not been reported in OA.

**Objectives:** To examine the effect of vitamin D supplementation on synovial inflammation in patients with symptomatic knee osteoarthritis (OA) and low vitamin D levels over 24 months.

**Methods:** In a multi-center, randomized, placebo-controlled and double-blind trial, symptomatic knee OA patients with a low 25-(OH)D level (12.5–60 nmol/l) were recruited. 413 patients (age 63.2±7.0 years, 208 females) were allocated to either a 50,000IU monthly vitamin $D_3$ capsule (n=209) or placebo (n=204) for 24 months. In this post-hoc analysis, changes in knee effusion-synovitis volume and score (0–3) were assessed using MRI (fig 1). A least significant criterion (LSC) was used to define an increase of effusion-synovitis volume by correcting measurement errors.

**Results:** At baseline, total effusion-synovitis volume was 8.0 ml with a prevalence of 47.7% (score ≥2). Over 24 months, the total effusion-synovitis volume remained stable in vitamin D group (mean: 0.26 ml, 95% CI: -0.82, 1.34) but increased significantly in placebo group (mean: 2.20 ml, 95% CI: 1.01, 3.38) (difference between groups: -1.94 ml, 95% CI: -3.54, -0.33). This effect was evident in those with baseline effusion-synovitis (difference: -2.04 ml, 95%CI: -3.83, -0.25) and in suprapatellar pouch (difference: -2.49 ml, 95%CI: -4.74, -0.25). Increases in total (relative risk: 0.66, 95%CI: 0.49, 0.90) and suprapatellar (relative risk: 0.64, 95%CI: 0.44, 0.93) effusion-synovitis volume were less in vitamin D than placebo group.

**Conclusions:** Vitamin D supplementation over 24 months significantly reduced progression of effusion-synovitis in patients with knee OA and low 25-(OH)D level.

**Acknowledgement:** We specially thank the participants who made this study possible, and we gratefully acknowledge the role of Vitamin D Effect on Osteoarthritis Study staff and volunteers in collecting the data. We thank the research assistants Jodi Barling, Kay Nguo, Judy Hankin and Alice Noone who were involved in the coordination of this study. Special thank to Yuelong Cao who wrote the study protocol. We also thank Rob Warren measured knee cartilage volume.

**Disclosure of Interest:** None declared

## SAT0430 NEITHER OBESITY, SMOKING AND ALCOHOL ARE ASSOCIATED WITH HAND OSTEOARTHRITIS (OA) - LONGITUDINAL DATA FROM OSTEOARTHRITIS INITIATIVE (OAI)

I.K. Haugen[1], K. Magnusson[1], A. Turkiewicz[2], M. Englund[2]. [1]*Rheumatology, Diakonhjemmet Hospital, Oslo, Norway;* [2]*Clinical Sciences Lund, Lund University, Lund, Sweden*

**Background:** Obesity is a strong risk factor for knee OA. Despite few longitudinal studies, it is often stated that obesity also increases the risk of hand OA. Smoking has been suggested to decrease the risk of OA, but results have been inconsistent. Alcohol may also induce a pro-inflammatory state with negative impact on joints.
**Objectives:** To examine whether baseline obesity, smoking and alcohol intake are associated with more severe hand OA, and whether they are associated with hand OA development 4 years later.
**Methods:** We included 1232 persons (1598 hands) from OAI without *knee* OA. Longitudinal *hand* x-rays were available for 994 persons. We focused on the distal (DIP) and proximal interphalangeal (PIP) joints. 406 (41%) persons (502 hands) had no radiographic DIP/PIP OA at baseline and were included in analyses on incident radiographic hand OA.
In cross-sectional analyses, we explored whether obesity, smoking and alcohol use were associated with more severe hand OA (KL sum score in DIP/PIP joints) at baseline. In longitudinal analyses, we studied whether baseline obesity, smoking and alcohol were associated with incident DIP/PIP OA in persons who had *no* OA in these joints at baseline. We used linear and logistic regression, respectively, using Generalized Estimating Equations to account for two hands per person. Each risk factor was evaluated in a separate model adjusted for age, sex and education.
**Results:** Mean (SD) age was 58.4 (8.9) years, and 58% were women. Mean (SD) BMI was 26.8 (4.5) and 22.5 (2.9) kg/m$^2$ at baseline and age 25, respectively. Alcohol use was reported by 83%, and the majority had <1 drink/week (37%). Current and former smoking was reported by 9% and 41%, respectively, and mean (SD) pack-years in cigarette smokers were 20.0 (18.6).
In cross-sectional analyses, a statistically significant association was found between 1–3 alcoholic drinks/week and KL sum score (B=1.55, 95% CI 0.42–2.67), but no dose-response relationship was found. No associations were found for obesity (Table) or smoking (data not shown).
Incident hand OA was found in 82/502 (16%) hands. We found *higher* odds of incident hand OA in current smokers (OR=2.20, 95% CI 1.02–4.77), but no dose-response relationship was found for smoking pack-years. Obesity (Table) and alcohol use (data not shown) did not increase the odds of developing hand OA.

Table 1. Associations between overweight/obesity and hand OA

| | KL sum score (DIP/PIP) at baseline B (95% CI) | Incident DIP/PIP OA after 4 years OR (95% CI) |
|---|---|---|
| Current BMI | | |
| <25 | 0.00 (Ref.) | 1.00 (Ref.) |
| 25–30 | 0.56 (–0.19, 1.31) | 1.34 (0.76, 2.35) |
| 30+ | 0.58 (–0.30, 1.46) | 1.05 (0.53, 2.08) |
| BMI at age 25 | | |
| <25 | 0.00 (Ref.) | 0.00 (Ref.) |
| 25+ | 0.62 (–0.27, 1.52) | 1.29 (0.67, 2.47) |
| Waist circumference | 0.15 (–0.12, 0.43) | 0.97 (0.79, 1.18) |

**Conclusions:** In contrast to a common belief that obesity is associated with increased risk of hand OA, we did not find any statistically significant associations with hand OA for neither measures of overweight/obesity. Furthermore, alcohol use was not associated with increased risk of hand OA. An unexpected association was found between current smoking and the development of hand OA, but the lack of a dose-response relationship between smoking pack-years and incident hand OA and no associations in cross-sectional analyses suggest that this may be a chance finding.

## SAT0431 THRESHOLD OF JOINT SPACE WIDTH FOR KNEE PAIN: THE ROAD STUDY

S. Muraki[1], T. Akune[2], H. Oka[1], S. Tanaka[3], H. Kawaguchi[4], K. Nakamura[2], N. Yoshimura[1]. [1]*22nd Century Medical and Research Center, University of Tokyo, Tokyo;* [2]*National Rehabilitation Center for Persons with Disabilities, Saitama;* [3]*Orthopaedic Surgery, University of Tokyo;* [4]*Orthopaedic Surgery, Japan Community Health Care Organization, Tokyo Shinjuku Medical Center, Tokyo, Japan*

**Background:** Knee pain is the principal clinical symptom of knee osteoarthritis (OA). Although much effort has been devoted toward defining knee pain, the correlation between knee pain and radiographic severity of knee OA by categorical methods, such as the Kellgren Lawrence grade, was not as strong as expected. In this categorical system, joint space narrowing and osteophytosis are not assessed separately, while accumulating lines of evidence indicate that joint space narrowing and osteophytosis may have distinct etiologic mechanisms, and their progression may be neither constant nor proportional. Although osteophytosis also has some effect on activities of daily living and quality of life, joint space narrowing is the primary outcome in studies of OA. Therefore, to examine the association between knee OA and pain, joint space narrowing should be assessed separately. Thus, an automatic system that can quantify the joint space width of the knee in OA on standard radiographs and allow for objective, accurate, and simple assessment of the structural severity of knee OA was developed.
**Objectives:** The objective of the present study was to clarify the association of joint space narrowing with knee pain in Japanese men and women using a large-scale, population-based cohort of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study.
**Methods:** This study examined the association between minimum joint space width (mJSW) in the medial compartment and pain in the knee. mJSW was measured in the medial and lateral compartments of the knee using a knee OA computer-aided diagnosis system.
**Results:** From the 3,040 participants in the ROAD study, the present study analyzed the data from 2,733 participants who completed the radiographic examinations and questionnaires regarding knee pain (975 men and 1,758 women; mean age, 69.9 years). Subjects with lateral knee OA were excluded. mJSW in subjects with and without knee pain were 2.4 ± 1.2 mm and 3.3 ± 0.9 mm, respectively, in men ($p<0.05$) and 2.0 ± 1.1 mm and 2.8 ± 0.8 mm, respectively, in women ($p<0.05$). medial mJSW/lateral mJSW in subjects with and without knee pain were 57.2 ± 27.6% and 72.8 ± 20.8%, respectively, in men ($p<0.05$) and 52.2 ± 31.5% and 71.4 ± 33.0%, respectively, in women ($p<0.05$). After adjustment for age and BMI, medial mJSW and medial mJSW/lateral mJSW, were significantly associated with knee pain ($p<0.05$). The threshold of medial mJSW by ROC curve analysis was 2.87 mm (sensitivity 0.67, specificity 0.65, AUC 0.70) in men and 2.01 mm (sensitivity 0.43, specificity 0.689, AUC 0.69) in women, while that of medial mJSW/lateral mJSW was 55.2% (sensitivity 0.45, specificity 0.68, AUC 0.66) in men and 57.9% (sensitivity 0.57, specificity 0.75, AUC 0.69) in women.
**Conclusions:** The present cross-sectional study, using a large-scale population from the ROAD study, showed that joint space narrowing was significantly associated with knee pain. The thresholds of joint space width for knee pain were approximately 3 mm in men and 2 mm in women.

## SAT0432 BLENDED PHYSICAL ACTIVITY INTERVENTION WITH REDUCED FACE-TO-FACE CONTACT AND USUAL PHYSICAL THERAPY SHOW SIMILAR EFFECTIVENESS IN PATIENTS WITH KNEE AND HIP OSTEOARTHRITIS: A RANDOMIZED CONTROLLED TRIAL

C.J. Kloek[1], D. Bossen[2], D.H. de Bakker[3], J. Dekker[4], C. Veenhof[5]. [1]*TRANZO, Tilburg University, Tilburg;* [2]*ACHIEVE Centre of Expertise, Faculty of Health, Amsterdam University of Applied Sciences, Amsterdam;* [3]*Netherlands Institute for Health Services Research, Utrecht;* [4]*Department of Rehabilitation Medicine & Department of Psychiatry, EMGO Institute, VU University Medical Center Amsterdam, Amsterdam;* [5]*Department of Rehabilitation, Nursing Science & Sports, Brain Center Rudolf Magnus, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** Exercise therapy is an effective treatment in patients with knee and hip osteoarthritis. However, face-to-face therapy is an expensive regimen. Blended exercise therapy, in which face-to-face contact is combined with a web-based program, might be a cost-effective alternative. Moreover, a blended intervention supports home-exercises and self-management through technology which is available at any time and place. We developed the blended intervention e-Exercise, a 12-week program in which up to five usual physical therapy sessions are integrated with a web-based program.
**Objectives:** The objective of this study was to evaluate the short-term effectiveness of e-Exercise compared to usual physical therapy for patients with knee and/or knee osteoarthritis.
**Methods:** A multicentre cluster randomized controlled trial was conducted. A number of 247 physical therapists were randomly allocated to e-Exercise (intervention group) or usual physical therapy (control group). The web-based part of e-Exercise is based on graded activity principles. Individual assignments for a central activity, such as walking or cycling, are gradually increased and supported with strength/stability exercises and information modules. Program progress can be evaluated during the face-to-face sessions. Content of these sessions were in both groups based on the Dutch physiotherapy guideline Osteoarthritis Hip-Knee which recommend education, self-management promotion, exercise therapy and if necessary manual therapy. Primary patient-outcomes, measured at baseline and after 12 weeks, were physical functioning and physical activity. Secondary outcome measures were pain, tiredness, quality of life, self-efficacy and the number of physical therapy sessions. Data were analysed using a mixed linear model.
**Results:** Totally, 208 patients were included. There were no significant differences in baseline demographics between the intervention (N=108) and control group (N=100). 176 (85%) participants completed the follow-up questionnaire. After 12 weeks, none of the primary outcome measures were significant different between groups. Within group analyses, however, showed for both groups a significant

improvement in physical functioning (IG: +4.1 points/100, p<0.01; CG: +5.3 points/100, p<0.01). Participants in the intervention group reported an increase of 23.7 minutes (p=0.03) physical activity per day, the control group an increase of 13.1 minutes (p=0.21). However, no significant differences were found for physical activity measured with ActiGraph accelerometers. With respect to the other outcomes, tiredness reduced significant (p<0.02) more in the intervention group (-1.3 points/10) compared to the control group (-0.5 points/10). Within both groups there were significant improvements for pain, tiredness, quality of life and self-efficacy. The intervention group received 5 face-to face sessions (range 2–16), the control group 12 (range 2–29).

**Conclusions:** In this study we found that e-Exercise is an effective treatment option in patients with knee and hip osteoarthritis. Subgroup-analysis, long-term effectiveness and cost-effectiveness of e-Exercise compared to usual physical therapy are forthcoming.

**Disclosure of Interest:** None declared

## SAT0433 ZOLEDRONIC ACID DOES NOT SLOW SPINAL RADIOGRAPHIC PROGRESSION IN THOSE WITH RADIOGRAPHIC OSTEOARTHRITIS

H.I. Keen[1], L.V. Host[2], L.L. Laslett[3], D.M. Black[4], G. Jones[5]. *[1]School of Medicine and Pharmacology, UWA, Perth; [2]Rheumatology, FSH, Murdoch; [3]Menzies Insititute for Medical Research, Hobart, Australia; [4]Division of Clinical Trials & Multicenter Studies, San Fransisco, United States; [5]Menzies Institute for Medical Research, Hobart, Australia*

**Background:** Post-hoc analyses of pivotal studies for osteoporosis therapies such as alendronate[1] and strontium ranelate[2] have demonstrated a reduction in the progression of spinal structural osteoarthritis (OA) measures. There is strong data demonstrating that subchondral bone alterations in osteoarthritis are involved in cartilage degradation. In knee osteoarthritis, zoledronic acid (ZA) improved pain and decreased bone marrow lesion size over 6 months[3]. ZA helps back pain and this benefit is independent of changes in bone mass and fracture[4] suggesting a possible effect on OA. However, there is no data at present on whether ZA influences radiographic OA. We analyzed data from the HORIZON PFT study, in which osteoporotic post-menopausal women were randomised to 36 months of yearly ZA or placebo for fracture reduction. Our aim in this post-hoc analysis was to explore the effect of ZA on spinal osteophytes and disc space narrowing.

**Objectives:** To assess whether administration of ZA delays the structural progression of spinal osteophytes or disc space narrowing in those with pre-exiting spinal radiographic osteoarthritis.

**Methods:** A post-hoc blinded analysis of the spinal radiographs HORIZON PFT study was undertaken on a subset of paired spinal radiographs. Post menopausal women that received at least one dose of study medication, and who had both baseline and 36 month spinal radiographs, with a non zero score for spinal osteophytes at baseline were included. Xray scoring of paired images was performed, using the current gold standard method for osteoarthritis[5]; separately for osteophytes and disc narrowing at all evaluable levels from T4–12 and L1–5.

**Results:** 505 sets of paired radiographs were included in the analysis; 245 in the ZA group and 260 in the placebo group. Overall, rates of change were low but were not different between groups (see table).

Table 1

| | Treatment arm | Baseline | 36 Months | Change, whole spine | Change, L spine |
|---|---|---|---|---|---|
| Osteophytes, mean score (SD) | Placebo | 19.2 (8.0) | 20.0 (8.1) | 0.8 (1.3) | 0.3 (0.7) |
| | ZA | 20.0 (8.8) | 20.9 (9.0) | 1.0 (1.6) | 0.3 (0.8) |
| | p value | | | 0.1 | 0.4 |
| Disc space narrowing, mean score (SD) | Placebo | 3.6 (4.2) | 3.9 (4.4) | 0.3 (0.7) | 0.3 (0.8) |
| | ZA | 3.8 (4.6) | 4.1 (4.8) | 0.3 (0.8) | 0.3 (1.) |
| | p value | | | 0.7 | 0.7 |

**Conclusions:** ZA was not associated with a slowing of progression of osteophytes or disc space narrowing in the thoraco-lumbar spine in this cohort.

## SAT0434 OSTEOARTHRITIS RELATED EFFUSION: FOLLOW UP OF PAIN AND FLUID THICKNESS AFTER TREATMENT WITH SPIRONOLACTONE. A PROSPECTIVE STUDY

A.R. Radwan[1], A. Elsaman[1], S. Ohrndorf[2]. *[1]Rheumatology, Sohag university faculty of medicine, Sohag, Egypt; [2]Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany*

**Background:** Osteoarthritis (OA) is a group of mechanical disorders leading to joint components degradation, including articular cartilage and subchondral bone. Incidence and prevalence of knee OA is rising by increasing average age of general population and increasing obesity (1). Treatment of knee effusion includes: rest, cold compresses, elevation, NSAIDS and aspiration (2). Spironolactone is a specific pharmacologic antagonist of aldosterone, acting primarily through competitive binding of receptors at the aldosterone-dependent sodium-potassium exchange site in the distal convoluted renal tubule. (3).

**Objectives:** Evaulation of low dose Spironolactone as a treatment for osteoarthritis related effusion using ultrasound and pain VAS.

**Methods:** This study was carried out on 200 patients who aged 40 years or above with unilateral knee effusion related to osteoarthritis based on clinical examination, musculoskeletal ultrasonography (US) and synovial fluid analysis. Group 1 consisted of 50 patients received spironolactone 25 mg daily for 2 weeks, in group 2; 50 Patients took Ibuprofen 1200 mg daily for two weeks, in group 3; 50 patients used cold compresses two times daily for two weeks, and in group 4; 50 patients received placebo for the same time duration. Visual analog scale (VAS) for pain was done to the study participant at time 0 (baseline), after 2 weeks and after 4 weeks.

**Results:** The mean age of the participants was 51.2±8.1 years. The mean duration of effusion was 16.5±3.6 days. In group 1, 66% had complete improvement, 20% partial improvement and 14% no response. In group 2, 24% had complete improvement, 12% partial improvement and 64% no response. In group 3, 28% had complete improvement, 14% partial improvement and 58% no response. In group 4, 6% had complete improvement, 10% partial improvement and 84% no response. VAS had a strong relation to fluid thickness as it decreased with the improvement of effusion and increased again among those patients who developed recurrence after 4 weeks.

**Conclusions:** Low dose spironolactone is a safe and effective medical treatment for OA related knee effusion, especially in mild and moderate knee effusion.

## SAT0435 TIBIAL SPINE MORPHOLOGY AND ASSOCIATION WITH ANTERIOR CRUCIATE LIGAMENT DEGENERATION – A COMBINED MRI, X-RAYS AND HISTOLOGY STUDY OF EARLY KNEE OSTEOARTHRITIS

A.L. Tan[1,2], T. Baboolal[1], M. Benjamin[3], T. Yonenaga[4], D. Binks[1,2], D. McGonagle[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds; [3]School of Biosciences, Cardiff University, Cardiff, United Kingdom; [4]Department of Radiology, The Jikei University School of Medicine, Tokyo, Japan*

**Background:** Knee osteoarthritis (OA) may supervene on traumatic anterior cruciate ligament (ACL) injury/rupture. However, knee OA with advanced disease on MRI may have ACL deficiency without a history of injury. We hypothesised that the complex enthesis organ structure of the ACL with the adjacent tibial tuberosities might be predisposed to ACL degeneration, and hence the elaborate ACL enthesis organ might contribute to joint degeneration.

**Objectives:** To describe the histology of the ACL enthesis organ structure including the relationship with the adjacent tibial spines and to determine whether tibial spine morphology and height (as determined by X-ray) may be linked to knee damage in early OA (as determined by MRI).

**Methods:** 333 datasets from the progression cohort of the Osteoarthritis Initiative (OAI) with Kellgren and Lawrence (KL) scores ≤1 were analysed. The lateral and medial tibial spine heights (LH, MH) were measured perpendicular to the tibial plateau width (W) (figure). 252 datasets with available corresponding MRI at 48 months were analysed for ACL injury and degeneration. Microanatomy of tibial spine was described from histology of tibial plateaus obtained from total knee replacement surgery.

**Results:** 170 ACLs assessed at 48 months were scored as normal (67.5%). 73

(29%) had tibial side ACL degeneration; 1 (0.4%) had femoral side degeneration; 3 (1.2%) were completely degenerate, and 5 (2%) had a chronic ACL tear. A significant association was seen between the increasing mediolateral width of the tibial plateau and ACL degeneration ($p<0.001$). Significant associations were also observed between the medial tibial spine height and ACL degeneration (p=0.007); and between lateral tibial spine height and ACL degeneration; (p=0.009). No significant associations were observed when medial and lateral tibial spine heights were normalised to the tibial plateau width (i.e. MH/W, LH/W). Histology shows the ACL curves reciprocally around the spine and the adjacent surface is modified as a sesamoid fibrocartilage. The ligament shows evidence of degenerative changes (numerous small cysts and loss of normal fibrillar density). The cartilage covering the spine including the intercondylar notch area showed typical early OA changes (cell clustering, fissuring, fibrillation and loss of surface staining). Proliferation of the synovium on the surface of the ACL and areas of inflammatory cell infiltration was observed within the ACL.

**Conclusions:** We describe the complex enthesis organ of the region posterior to the ACL and show that the intercondylar notch and tibial spines are part of an enthesis organ lined by cartilage. ACL degeneration was observed with increasing tibial plateau width or bigger bones, and increasing height of tibial spines relative to the tibial plateau. Age-related degenerative changes at the ACL have been noted in the absence of cartilage loss, suggesting that microdamage at the ACL could predate cartilage loss in anatomically susceptible individuals.

## SAT0436 PLATELET-RICH PLASMA VERSUS HYALURONIC ACID IN TREATMENT OF KNEE OSTEOARTHRITIS

A.E. El Deeb, H. Khallaf, N. El Gazzar, S. El morsy, H. Hashem. *Physical Medicine, Rheumatology and Rehabilitation Department, Faculty of Medicine, Tanta University, Tanta, Egypt*

**Background:** Platelet rich plasma (PRP) therapy is a simple, low-cost and minimally invasive method that provides a natural concentrate of autologous blood growth factors (GFs) that can be used to enhance tissue regeneration (1). Recent evidences have shown that PRP can be helpful as an osteoarthritis (OA) therapeutic tool by intra-articular injection (2). Hyaluronic acid (HA)is widely used therapy for relief of OA pain and stiffness by intraarticular injection. In addition, there is a sufficient evidence for being significant disease-modifying effects (3,4).
**Objectives:** our aim was to compare the clinical efficacy of platelet-rich plasma with that of hyaluronic acid viscosupplementation.
**Methods:** This study included forty patients with knee osteoarthritis. These patients were selected from the outpatient clinic of Physical Medicine, Rheumatology and Rehabilitation Department, Faculty of Medicine, Tanta University. Patients were randomly divided into two groups. The first group consisted of 20 patients treated by using intraarticular injection of 2 ml autologous PRP (PRP group).The second group consisted of 20 patients they were treated by using intraarticular injections of low molecular weight (hyaluronic acid [HA]) (32mg/2mL) of HA (HA group). All patients received 3 injections with one week interval (3) *For Follow up:* The subjective clinical outcome were measured at baseline, 1, 3, 6 and 12 months after the last treatment dose using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and the 11-point pain intensity Numeric Rating Scale (NRS) (5).
**Results:** At 1,3 months' follow-up, the PRP and LW HA groups showed an improvement, with non-significant difference between the two groups. However after 6 months follow up there was significant improvement in PRP group than HA group ($P<0.005$). The follow up after 12 months reveled subsided improvement than that was at 6 months. Nevertheless, this subsidence was less in PRP group.
**Conclusions:** Autologous PRP injections showed more and longer efficacy than HA injections in reducing pain and symptoms and recovering articular function. Further studies are needed to confirm these results and to investigate the persistence of the beneficial effects observed.

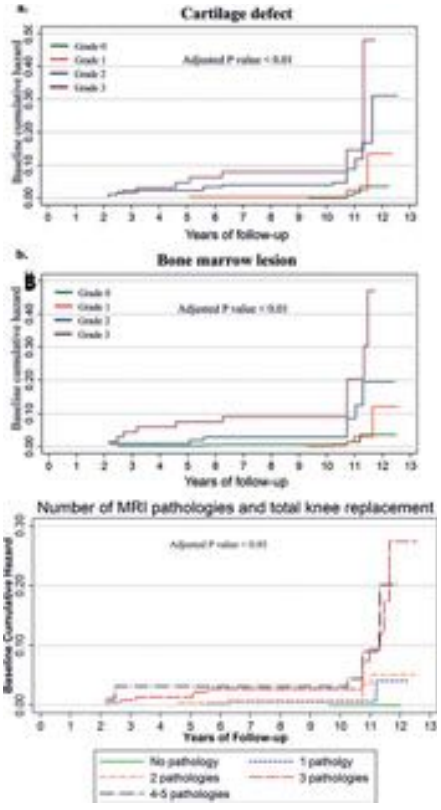
## SAT0437 OSTEOARTHRITIS PAIN IS DIFFERENTIALLY ASSOCIATED WITH TISSUE DEGRADATION AND JOINT INFLAMMATION



A.-C. Bay-Jensen[1], S.B. Abramson[2], J. Samuals[2], I. Byrjalsen[1], S. Krasnokutsky[2], T. Manon-Jensen[1], M.A. Karsdal[1], M. Attur[2]. *[1]Biomarkers and Research, Nordic Bioscience, Herlev, Denmark; [2]Division of Rheumatology, Department of Medicine, New York University School of Medicine, New York, United States*

**Background:** Osteoarthritis (OA) is heterogeneous disease characterized by pain and tissue destruction which is in some case concomitant with inflammation. However, the link between pain and tissue destruction is yet unknown, and there is a lack objective quantifiable parameters. Collagens are the main structural proteins of the joint extracellular matrix. The degradation type I (connective tissue), II (cartilage), III (synovium) and IV (basement membrane) collagens have been shown to be elevated in joint degenerative diseases.
**Objectives:** To investigate whether biomarkers reflecting collagen degradation were associated with symptomatic knee OA representing with different pain and inflammatory phenotypes.
**Methods:** 111 knee OA patients, 62% women, from NYUHJD progression cohort study with varying degree of OA were included: mean (SD) age, 32 (10); mean (SD) BMI, 27 (4); NSAID users, 23%; radiographic OA ($KL\geq2$) 68%; and bilateral knee OA; 87%. Pain was assessed by $VAS_{pain}$ and WOMAC at baseline (BL) at a 2-year follow-up (FU) visit. Median (IQR) were 39 (13–69) and 37 (13–52) for BL $VAS_{pain}$ and $WOMAC_{pain}$. 4 BL serum biomarkers of type I, II, III and IV collagen degradation (C1M, C2M, C3M, C4M), and the 2 inflammatory biomarkers CRPM and hsCRP, were assessed. Data were log2 transformed. Associations between BL biomarkers, BL pain and change (CHG) pain scores were assessed by multivariate linear model including gender, age, BMI, $KL_{signal\ knee}$, bilateral knee OA and NSAID use. Patients with cont. mild/moderate pain had a BL VASpain<54 and FU VASpain<30, cont. moderate/severe pain had VASpain>30 at baseline and FU, and transitional severe pain had either VASpain_BL<30 and VASpain_FU>54 or VASpain_BL>54 and VASpain_FU<30 (ref). Patients with; low biochemical disease activity index (bDAI) low in CRPM (<12nM) moderate bDAI were high in CRPM but low in hsCRP (<5), and high bDAI (flare) were high in CRPM and hsCRP.
**Results:** *BL association between pain and biomarkers.* C2M ($\beta$ -17.9, $p<0.0001$) and $KL_{signal\ knee}$ ($\beta$ -5.4, p=0.0031) were significantly associated with WOMAC pain. C2M ($\beta$ -12.4, p=0.0033), C3M ($\beta$ -19.9, p=0.059), age ($\beta$ -0.84, $p<0.0018$), $KL_{signal\ knee}$ ($\beta$ 8.9, p=0.0021) and bilateral knee OA ($\beta$ -12.2, p=0.087) were associated with $VAS_{pain}$. *Association between BL biomarkers and CHG pain.* C2M ($\beta$ 13.3, p=0.0016), age ($\beta$ 0.5, p=0.029) and bilateral OA ($\beta$ -12.0, p=0.043) were significantly associated with delta $WOMAC_{pain}$. Only age, BMI and NSAID use was associated with CHG $VAS_{pain}$. *Association between pain phenotypes and BL biomarkers.* Patients with cont. mild/moderate pain had significantly higher C2M compared patients with transitional severe pain (p=0.0014) and cont. moderate/severe pain (p=0.04). *Biomarker, BL pain and CHG pain in patients w. inflammatory OA.* Patient with low bDAI had lower $WOMAC_{pain}$ ($p<0.05$) and $VAS_{pain}$ ($p<0.1$). C1M was higher ($p<0.05$) in the flare group compared to the low and moderate bDAI groups. C3M was higher ($p<0.05$) in the moderate bDAI group than the low DAI group.
**Conclusions:** Different collagen degradation products are linked differentially to different phenotypes. Cartilage degradation (C2M) was consistently linked to pain CHG and phenotypes, whereas it was not associated with an inflammatory phenotype. In contrast, C1M and C3M were linked to inflammatory OA and flared OA.

## SAT0438 MAGNETIC RESONANCE IMAGING MARKERS AS PREDICTORS FOR TOTAL KNEE REPLACEMENT OVER 10.7 YEARS IN OLDER ADULTS

B.S. Eathakkattu Antony[1], X. Jin[1], F. Cicuttini[2], J. Martel-Pelletier[3], J.-P. Pelletier[3], C. Ding[1], G. Jones[1]. *[1]Menzies Institute for Medical Research, University of Tasmania, Hobart; [2]Epidemiology, Monash University, Melbourne, Australia; [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre, Montreal, Canada*

**Background:** Quantitative and semi-quantitative assessments of structural changes on magnetic resonance images (MRI) have been widely adopted in knee osteoarthritis (KOA) research. However, there are no long-term studies that describe the independent association of these structural factors and total knee replacement (TKR) in older adults.
**Objectives:** This study aimed to describe the predictability of MRI-based measures (cartilage defects, bone marrow lesions (BMLs), meniscal tears, meniscal extrusions, bone area increase and cartilage volume loss) for TKR over 10.7 years.
**Methods:** 983 participants (mean age 62.8 years, 50% female) were randomly recruited from the local community of southern Tasmania and followed up at 2.6 years (range 0.9–4.8) and 10.7 years (range 9.2–12.5) later. A 1.5T MRI scan of the right knee was acquired at baseline (n=930) and 2.6 years (n=399). Tibiofemoral and patellar cartilage volume and tibial bone area at baseline and 2.6 years were measured using a manual segmentation method on the T1-weighted fat saturated 3D GRE images. Cartilage defects were assessed on T1-weighted MRI using a modified Outerbridge scoring system (grade 0–4). BMLs were measured on T2-weigthed fat saturated FSE images using a modified Whole-Organ MRI scoring system (grade 0–3). Meniscal extrusion (grade 0–2) and meniscal tears (grade 0–3) were measured using the T1- and T2-weighted MRI. TKR data were recorded at baseline, 2.6 years, 5.1 years and 10.7 years later. Analyses were performed using cox proportional hazards models after adjustment for age, sex, body mass index (BMI), baseline WOMAC knee pain and radiographic KOA status. Other MRI structural pathologies were added to the model in order to explore the independent association of each of these predictors.
**Results:** 863 subjects (88%) responded for 2.6 years follow-up, 758 subjects (77%) for 5.1 years follow-up and 560 subjects (57%) for 10.7 years follow-up. After adjustment for age, sex, BMI, baseline WOMAC knee pain and radiographic KOA status, baseline MR imaging markers such as cartilage defects per grade (HR=2.28, $p<0.01$), BMLs per grade (HR=2.10, $p<0.01$), tibial bone area per $cm^2$ (HR=1.17, $p<0.01$), and percentage annual cartilage volume loss at medial tibiofemoral compartment (HR=1.19, $p<0.05$) were significantly associated with TKR over 10.7 years. These associations were independent of each other and there was a dose-response relationship between cartilage defects and BMLs at baseline and increased risk of TKR (Fig. a,b). Those who had TKR all had grade 3 meniscal tears at baseline, but meniscal extrusion was not associated with TKR. The risk of TKR increased significantly when more MRI pathologies were simultaneously present at baseline (HR=1.84/unit, $p<0.01$). There was also a number-response relationship between the number of MRI pathologies at baseline and the risk of TKR (Fig. c).

**Conclusions:** Baseline MRI structural pathologies such as cartilage defects, BMLs, meniscal tears, bone area increase and cartilage volume loss are independent predictors of TKR over 10.7 years. Presence of multiple pathologies increased the risk of TKR, suggesting that MRI structural markers are good predictors of rapid knee OA progression in the general population.

## SAT0439 COMPREHENSIVE TRANSCRIPTOME ANALYSIS OF SYNOVIAL FIBROBLASTS FROM HEALTHY, RA AND OA KNEES

C. Ospelt[1], G. Russo[2], A. Bratus[2], C. Kolling[3], A. Filer[4], G.A. Renate[1], B.A. Michel[1], C.D. Buckley[4], S. Gay[1], M. Frank-Bertoncelj[1]. *[1]Center of Experimental Rheumatology, University Hospital of Zurich; [2]Functional Genomics Center, ETH and University of Zurich; [3]Schulthess Clinic, Zurich, Switzerland; [4]Center for Translational Inflammation Research, University of Birmingham, Birmingham, United Kingdom*

**Background:** Synovial fibroblasts (SF) are recognized to play a vital role in the pathogenesis of rheumatoid arthritis (RA). However, their pathogenic role in osteoarthritis (OA), remains unclear despite the fact that OA SF are activated and affected during the course of the disease. To characterize the dysregulated pathways in both RA and OA several gene expression studies have been conducted mainly using microarrays and by comparing RASF to OASF. However these studies rarely include a healthy control group and do not take into account joint anatomical location.
**Objectives:** To measure changes in the expression of microRNA (miR) as well as mRNA and long non-coding RNA (lncRNA) in SF isolated from knees of RA and OA patients compared to healthy individuals.
**Methods:** SF were cultured from RA (n=3) and OA (n=3) patients undergoing total knee replacement. Healthy knee SF (n=3) were cultured from biopsies of individuals with arthralgia but no clinical or histological signs of synovitis. Total RNA was extracted after SF were grown for 5–7 passages and RNA sequencing was performed with the Illumina HiSeq 2000 sequencing system. Changes with a false discovery rate adjusted p-value below 0.05 were considered significantly changed. Functional annotation clustering of mRNAs was done using Database for Annotation, Visualization, and Integrated Discovery (DAVID).
**Results:** We found 31 mRNAs, 6 lncRNA and 3 miR (miR-7–5p; miR-181a-3p; miR-378a-3p) upregulated in OASF, but not RASF compared to healthy, and 14 mRNA, 3 lncRNA and 5 miR (miR-3118; miR-514a-3p; miR-585–5p; miR-615–3p; miR-615–5p) were downregulated in knee OASF specifically.15 mRNA, 11 lncRNA and 3 miR (miR-143–3p; miR-145–3p; miR-493–3p) were upregulated in knee RASF, but not OASF compared to healthy. In this RA group 7 mRNA, 4 lncRNA and 4 miR (miR-124–5p; miR-204–5p; miR-3065–5p; miR-4657) were specifically downregulated. 29 mRNA, 6 lncRNA and 8 miR were upregulated in RA as well as OASF and 9 mRNA, 2 lncRNA and 7 miR were downregulated. Pathway analysis in mRNAs that were upregulated specifically in OA included cell adhesion pathways mainly based on the regulation of protocadherins (PCDH1; PCDHAC2). Pathways that were restricted to RA were extracellular matrix related genes such as Fraser Extracellular Matrix Complex Subunit 1 (FRAS1). The Wnt signaling pathway was regulated in both diseases, e.g. by upregulation of R-Sponding 3 (RSPO3) which has previously found to be upregulated in RASF compared to healthy SF.
**Conclusions:** Using a next generation sequencing approach we have identified pathways and non-coding transcripts that are specifically dysregulated in OASF or RASF in the knees. These data corroborate and further elucidate the role of synovial fibroblasts in RA pathogenesis. Furthermore this study clearly demonstrates the involvement of SF in the pathogenesis of OA and identifies differences in the pathways activated in knee OA and knee RA, respectively.

## SAT0440 RADIOLOGIC PROGRESSION OF DISTAL INTERPHALANGEAL JOINT OSTEOARTHRITIS IN RHEUMATOID ARTHRITIS

C. Lechtenboehmer, V.K. Jaeger, D. Kyburz, U.A. Walker, T. Hügle. *Rheumatology, University Hospital Basel, Basel, Switzerland*

**Background:** Distal interphalangeal (DIP) joint osteoarthritis (OA) is a disorder associated with female sex and age and is considered as unrelated to rheumatoid arthritis (RA). The long term radiologic course of DIP OA in patients with RA is unknown.
**Objectives:** To investigate the prevalence and demographic characteristics of DIP OA progression in RA patients.
**Methods:** RA patients of the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) cohort, who had at least two subsequent hand radiographies

taken between November 1983 and October 2014 were analysed. DIP joints (II-V) were scored for the radiologic presence and severity of osteophytes, subchondral sclerosis, joint space narrowing and erosions according to the modified Kellgren Lawrence Score (KLS).
**Results:** 2890 (35%) patients out of 8280 of the SCQM RA cohort fulfilled the inclusion criteria. Their mean age was 57.5 years (standard deviation (SD) 10.5), 76% were female, 78% were rheumatoid factor positive and 69% were ACPA positive. At baseline, the mean disease duration was 9.7 years (SD 8.5). The mean follow-up between the first and last radiography was 5.4 years (SD 3.2). Baseline radiographies showed osteophytes in 21% of 21,333 DIP joints, joint space narrowing in 13%, osteosclerosis in 9% and erosions in 1%. The KLS was 1 in 13% of DIP joints, 2 in 22%, 3 in 4% and 4 in 2% at baseline radiographies. The KLS increased in 12% of DIP joints during the radiologic follow-up, decreased in 2% and remained stable in 86% of DIP joints. Female sex ($p<0.001$), age>55 years (p=0.005) and a negative rheumatoid factor (p=0.049) were associated with OA progression.
**Conclusions:** Known risk factors for DIP OA were also associated with its radiologic progression in RA patients. Radiologic progression and erosions in DIP OA are low in this cohort, potentially due to RA treatment.

## SAT0441 PREVALENCE OF SELF-REPORTED KNEE JOINT INSTABILITY AND ITS ASSOCIATION WITH RADIOGRAPHIC FEATURES IN SEVERE KNEE OSTEOARTHRITIS

C. Leichtenberg[1], J. Meesters[1], S. Verdegaal[2], B. Kaptein[1], L. Koster[1], H. Kroon[3], R. Nelissen[1], T. Vliet Vlieland[1], M. van der Esch[4]. *[1]Orthopedics, Leiden University Medical Center, Leiden; [2]Orthopedics, Alrijne Hospital, Leiderdorp; [3]Radiology, Leiden University Medical Center, Leiden; [4]Revalidation and Rheumatology, Amsterdam Rehabilitation Research Center/Reade, Amsterdam, Netherlands*

**Background:** Self-reported knee instability has been reported in 60–80% of all patients suffering from mild to moderate knee osteoarthritis (OA) [1], but the prevalence of self-reported knee joint instability in patients with end-stage OA is unknown. So far, a clear cause for this sense of instability has not been elucidated. Two opposing hypotheses have been described: (i) low knee joint instability is associated with osteophyte formation and (ii) high knee joint instability is associated with joint space narrowing.
**Objectives:** To describe the prevalence of self-reported knee joint instability in patients with end-stage OA and to explore the associations between self-reported knee joint instability and JSN and osteophyte formation.
**Methods:** In this cross-sectional study patients on the waiting list for primary Total Knee Arthroplasty (TKA) in one Dutch hospital were included. The primary outcome measures were preoperative self-reported knee joint instability and radiographic severity (assessed by conventional radiography (CR)). Self-reported knee instability was examined by means of a knee joint instability questionnaire. The item on the presence of knee joint instability was formulated as follows: "the sensation of buckling, shifting or giving way of the knee in the previous 3 months" with the following answering options: 1 never (0 episodes); 2 seldom (1–2 episodes); 3 regular (3–5 episodes); 4 very often (more than 5 episodes). These options were later dichotomized into no episodes of knee joint instability (option 1) or 1 or more episodes of knee instability (option 2–4). Radiographic severity consisted of the presence of osteophyte formation and joint space narrowing (JSN), which were both independently scored for the index knee on a 0–3 scale ranging from 0 no JSN/osteophytes, 1 minute JSN/osteophytes, 2 definite JSN/osteophytes and 3 ankylosis JSN/large osteophytes. These scores were dichotomized into present JSN/osteophyte formation (if JSN/osteophyte score >2) or absent JSN/osteophyte formation (if JSN/osteophyte score <2). Potential confounders included in the logistic regression analyses were patient characteristics (gender, age, body mass index) and joint characteristics (pain, physical function).
**Results:** 227 patients (mean age 68 years; SD 9.0 and 145 females (63%)) were included. Self-reported knee instability was present in 163 patients (72%). The distribution of JSN and osteophyte formation in the total group, the patients with knee joint instability and the patients without knee joint instability is shown in Table 1.

Table 1. Distribution of radiographic features in the total group, the patients reporting knee joint instability and the patients not reporting knee joint instability in the previous 3 months

| | Total group (n=227) | Knee joint instability, yes (n=163) | Knee joint instability, no (n=64) |
|---|---|---|---|
| JSN | | | |
| 0 | 26 (11%) | 19 (12%) | 6 (9%) |
| 1 | 45 (20%) | 31 (19%) | 13 (20%) |
| 2 | 108 (47%) | 80 (49%) | 28 (44%) |
| 3 | 50 (22%) | 33 (20%) | 17 (27%) |
| Osteophyte formation | 57 (25%) | 42 (26%) | 14 (22%) |
| 0 | 81 (35%) | 57 (35%) | 24 (38%) |
| 1 | 84 (37%) | 59 (36%) | 24 (38%) |
| 2 | 7 (3%) | 5 (3%) | 2 (3%) |
| 3 | | | |

In univariate regression analyses no associations were found between self-reported knee instability and JSN or osteophyte formation (p-values 0.537 and 0.829).
**Conclusions:** In conclusion, the majority (72%) of patients with severe OA reported knee joint instability. Knee joint instability was not associated with either JSN or osteophyte formation.

## SAT0442 WAIST CIRCUMFERENCE IS THE ANTHROPOMETRIC VARIABLE MORE RELATED TO CLINICAL SEVERITY IN WOMEN WITH KNEE OSTEOARTHRITIS WITH SYNOVIAL EFFUSSION

C. Orellana[1], J. Calvet[1], A. Caixàs[2], N. Navarro[1], M. Arévalo[1], J. Gratacós[1], M. Larrosa[1]. *[1]Rheumatology; [2]Endocrinology, Parc Taulí Sabadell Hospital Universitari, Sabadell, Spain*

**Background:** Different anthropometric variables such as obesity with its different ways of measure (body fat index, waist circumference, waist/hip ratio) as well as the metabolic syndrome and his individual components have been related to knee osteoarthritis (OA). However, no specific studies analyzing the influence of these factors on clinical severity have been carried out in patients with synovial effusion.
**Objectives:** To assess the relationship between different anthropometric measures, the metabolic syndrome and its individual components with clinical severity as measured by the Lequesne algofunctional questionnaire in women with knee OA and significant synovial effusion.
**Methods:** Transversal study including consecutively women aged 50 to 80 years with symptomatic knee OA, Kellgren-Lawrence I-IV with significant synovial effusion (>4mm at mid-patellar line on US examination). Demographic data and history of hypertension (HT), dyslipidemia, obesity or diabetes mellitus (DM) were collected. Blood samples were taken to determine basal glycemia, total, HDL- and LDL-cholesterol, insulinemia and glycated hemoglobin. Anthropometric variables assessed included weight, height, body mass index (BMI), waist circumference, hip circumference and percentage of body fat as measured by bioelectrical impedance analysis). Patients were evaluated for the presence of metabolic syndrome by strict NCEP-ATP-III criteria. All patients underwent joint aspiration to confirm non-inflammatory synovial fluid without microcrystals. To evaluate knee OA clinical severity patients completed the Lequesne algofunctional index. Univariant and multivariant analyses were performed to evaluate which variables had a greater influence on the Lequesne index.
**Results:** One hundred and fifteen women were analysed, average age 68.8 ±11.1 years, average knee OA symptoms duration 50 ±23 months. Percentage of HT was 54.58%, DM 10.4%, obesity 57.4% and dyslipidemia 47.8%, all above the expected by age and gender (40%, 10%, 40% and 30%, respectively). Metabolic syndrome was present in 40.9% of patients, also above 30% expected. In the univariant analysis all the anthropometric variables showed a significant association with the Lequesne index with weak to moderate correlation (body fat index p=0.008/r =0.243, BMI p=0.002/r =0.277, weight p=0.007/r =0.249, waist circumference $p<0.001$/r =0.404, waist circumference, p=0.006/r =0.252 and hip circumference and waist/hip ratio p=0.01/r =0.221). Neither the metabolic syndrome nor any of its individual components achieved statistical significance. After performing a forward stepwise multivariate analysis including OA symptom duration, age and Kellgren-Lawrence, waist circumference emerged as the only significant variable ($p<0.001$/r =0.338), observing a magnitude effect of a 0.9 increase in the Lequesne index for every increase of waist circumference of 5 cm (beta coefficient 0.180, 0.083–0.276). The relationship between BMI and Lequesne index was confirmed but when the waist circumference was included in the model only the waist circumference remained significant.
**Conclusions:** In this study waist circumference was the anthropometric variable more related to clinical severity measured by the Lequesne index in women with knee OA and synovial effusion.

## SAT0443 COMPARISON OF THERAPEUTIC RESPONSE RATES, USING VARIOUS RESPONSE DEFINITIONS IN A PROSPECTIVE RANDOMIZED NON-INFERIORITY TRIAL COMPARING TWO INTRA-ARTICULAR HYALURONIC ACID PRÉPARATIONS (1-SHOT IAHA) IN SYMPTOMATIC KNEE OSTEOARTHRITIS (OA), AND PREDICTIVE FACTORS OF A BETTER RESPONSE

E. Maheu[1], L.R. Dreiser[2], B. Avouac[3], T. Bardin[4]. *[1]Rheumatology, St-Antoine Hospital - APHP; [2]Rheumatology, Hôpital Bichat - APHP, Paris; [3]Rheumatology, CHU Henri Mondor, Créteil; [4]Rheumatology, Hôpital Lariboisière - APHP, Paris, France*

**Background:** Selecting an appropriate primary efficacy criterion is of key importance in the design of a randomized controlled trial (RCT) evaluating

therapeutic interventions in knee OA. One may choose among various possible primary efficacy criteria which can be classified as 1/ continuous variables such as pain (on a visual analog scale (VAS)) or function by one of the OA-specific available instruments (providing a numeric variation on a scale indicating the amount of therapeutic effect, which clinical relevance has to be established), or 2/ binary global response criteria, such as the OMERACT-OARSI (1), or response criteria based on the Patient Acceptable Symptom State (PASS) or the Minimum Clinical Important Improvement (MCII) applied to pain, function, or patient global assessment (PGA) (2), which results are expressed in % of responders (yes/no). The sensitivity of these global response instruments has not been compared yet.
**Objectives:** The aim of this study was to compare responder's rates using various definitions of response in a knee OA trial of IAHA, and to identify factors associated with a better response.
**Methods:** Data obtained from a RCT comparing one single IA injection of 40 mg/2.0ml non-chemically modified HA with 48 mg/6.0ml hylan G-F20 were used for this post hoc analysis (3). As non-inferiority of the non-crosslinked HA was demonstrated over 6 months, data of both treatment groups were pooled (280 patients in the full analysis set, 266 completers). Uni- and multivariate stepwise regression analyses were performed to compare response criteria and identify potential factors associated with the best clinical response. OMERACT-OARSI responder criteria were compared to the PASS ($\leq$40 mm) and MCII ($\geq$15 mm improvement) responder criteria calculated for the following outcomes: pain using WOMAC A1 0–100mmVAS format, physical function using WOMAC C (VAS format) and the 0–100 normalized Lequesne index, and PGA on a 0–100 mmVAS.
**Results:** The three most sensitive response instruments were the MCII (relative) for pain, followed by the OMERACT-OARSI responder criteria and the MCII (absolute) for pain with around 80% responders (Fig1). Factors associated with a better response were: a higher pain at baseline (OR [95%CI]: 1.05 [1.02; 1.08]), a shorter delay since diagnosis of knee OA (0.93 [0.88; 0.99]), bilateral knee OA (2.51 [1.11; 5.68], and a better PGA (i.e. a lower score; 0.95 [0.92; 0.98]).

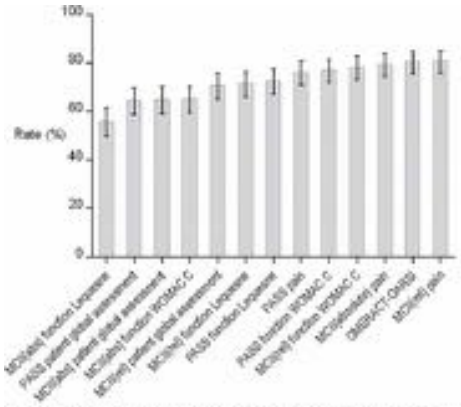

Fig. 1 Responder rates at 6 months using various response criteria (full analysis set, 280 patients)

**Conclusions:** In this post-hoc analysis, comparing for the first time several definitions of therapeutic response in a clinical trial of IAHA in knee OA, MCII for pain and OMERACT-OARSI criteria seemed to be the most responsive outcome criteria. Response rates were higher in patients presenting with more pain at baseline, a shorter duration since diagnosis, bilateral knee OA and a better PGA.

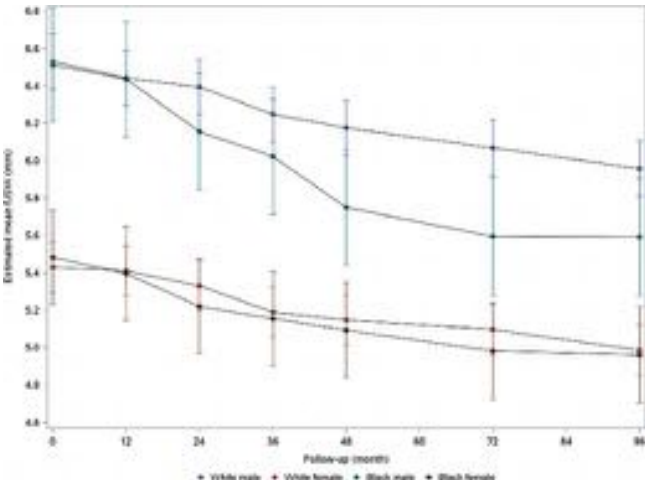
## SAT0444 COMPARASION OF EFFICACY OF INTRAARTICULER STEROID INJECTIONS IN THE PATIENTS WITH KNEE OSTEOARTHRITIS WITH OR WITHOUT SYNOVITIS

E. Capkin[1], O. Yerligök[2], M. Karkucak[2]. [1]*PM&R and Rheumatology;* [2]*Karadeniz Technical University, Faculty of Medicine, Trabzon, Turkey*



**Background:** Osteoarthritis is a common joint disorder. In the knee, injections of corticosteroids into the joint may relieve inflammation, and reduce pain and disability
**Objectives:** The present study aims to compare efficiency of intraarticular steroid injection administered on knee osteoarthritis (OA) patients between conditions whether synovitis exists, or not.
**Methods:** The study included totally 90 patients (76 women and 14 men) who applied to the knee pain symptom and were diagnosed with knee OA. Based on the existence of synovitis determined clinically, patients were subclassified in 3 groups each consisted of 30 patients. Whereas the 1st group was including the patients with clinicaly synovitis; the 2nd group was including without synovitis. The 3rd group was considered as the control group with no synovitis. Each group was administered quadriceps strengthening exercises in addition to the prescription including 5% ibuprofen topical twice a day, and 75 mg diclofenac sodium taken orally twice a day. Group 1 and 2 patients were administered intraarticular steroid injection (20 mg Triamcinolone hexasetonit). Before the treatment, patients were evaluated in terms of Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) pain score, joint involvement score, physical function score and visual analog scale. In the post-injection period, patients invited for control at the 2nd and 8th weeks were evaluated based on the same parameters.
**Results:** In all three treatment groups, a statistically significant recovery was observed in terms of pain, physical activity, and morning stiffness values at the end of both the 2nd and the 8th weeks compared to the initial period ($p<0.05$). The recovery in the injection groups was statistically more significant compared to the control group ($p<0.001$). There was no statistically significant all parameters difference between the synovitis OA and non-synovitis OA groups based on the controls at the 2nd and the 8th weeks ($p>0.05$)
**Conclusions:** It was observed that intraarticular steroid injection reduced pain and stiffness related scores whether patients diagnosed with knee OA have synovitis, or not; and developed the functionality. However, these effects were observed only for limited period. Thus, concerning the patients who do not respond to medical treatment, intraarticular steroid injection can be considered as an effective treatment only for a short term.

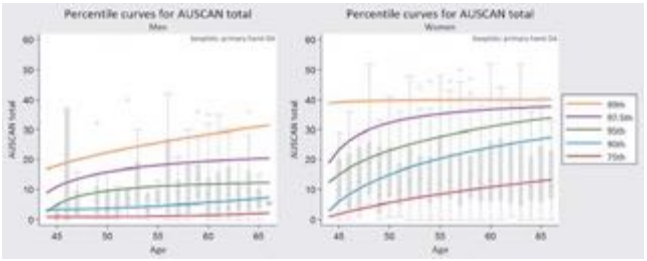
## SAT0445 RACE AND SEX DIFFERENCES IN RADIOGRAPHIC PROGRESSION OF KNEE OSTEOARTHRITIS

E.R. Vina[1], D. Ran[2], E. Ashbeck[1], C.K. Kwoh[1]. [1]*Rheumatology;* [2]*Biostatistics, University of Arizona, Tucson, United States*

**Background:** Knee osteoarthritis (KOA) is more common in African-Americans (AAs) than Whites (WHs) in the United States. The prevalence and severity of osteophytes, bone sclerosis and joint space narrowing (JSN) are also greater among AAs than among WHs. Radiographic KOA features between the two races may also vary according to sex.
**Objectives:** To determine if the pattern of radiographic progression in KOA varies by race and sex
**Methods:** Knees of AAs and WHs with minimal or no radiographic KOA (Kellgren-Lawrence [K-L] grades 0 or 1) at baseline in the Osteoarthritis Initiative (OAI) were selected for analysis. Serial fixed-flexion knee x-rays through the 96 month visit were scored for K-L grade and tibiofemoral JSN based on Osteoarthritis Research Society International grade. A subset, enriched for those that developed radiographic KOA, were assessed for joint space width (JSW) using digital imaging software. Mixed models for repeated measures were used to estimate race- and sex-specific mean JSW and 95% confidence interval at fixed locations in the medial (x=0.250mm) and lateral (x=0.725mm) compartments, as well as average annual loss in fixed JSW (fJSW). Generalized estimating equation logistic regression models were used to estimate the effect of race and sex on: summary radiographic grade progression (defined by any increase in K-L grade $\geq$1), and JSN progression (defined by any increase in OARSI grade $\geq$1) in the medial and lateral compartments. Models were adjusted for time to progression, baseline age, body mass index (BMI), family history of joint replacement, bony enlargements in the distal interphalangeal joints, frequent knee-bending, and history of knee injury or surgery.
**Results:** 3,776 knees were studied from 695 WH men, 932 WH women, 93 AA men, and 168 AA women, with mean age of 59 years and BMI of 28 kg/m$^2$. Mean baseline medial fJSW was as follows: 6.53 in WH men, 5.43 in WH women, 6.51 in AA men, and 5.48 in AA women. Figure 1 displays the race and sex-specific mean medial fJSW during the study period, after adjustment, with 95% CIs. Annual medial fJSW loss (mm/year) over 8 years was significantly greater in AA men (-0.13) than in all other subgroups (-0.07 WH men, -0.06 WH women, -0.07 AA women, $p<0.0001$). There was no evidence of difference in annual loss of JSW in the lateral compartment.
In the adjusted models, odds of radiographic K-L grade progression were significantly higher in AA men (adjusted odds ratio [aOR] 2.18, 95%CI [1.22–

3.91], p=0.009) and in WH men (aOR 1.53, 95% CI [1.18–1.98], p=0.002), in comparison to WH women. The odds did not significantly differ between AA and WH women (p=0.476). In fully adjusted models, the odds of having OARSI grade progression in medial JSN was slightly higher in AA women in comparison to WH women (aOR 1.38, 95% CI [0.91–3.46]), p=0.090), though this was not significant. Compared to WH women, WH men had greater odds of lateral JSN progression (aOR 2.25, 95% CI [1.29–3.92], p=0.004). There was no significant difference in lateral JSN progression among AA women (p=0.542) and AA men (p=0.509), in comparison to WH women.



**Conclusions:** Compared to WHs and AA women, AA men were more likely to have radiographic knee OA progression over time. Loss of JSW and progression of JSN in specific compartments may vary based on race and sex. Further research to characterize and identify causes of differential KOA progression by race and sex is warranted.

## SAT0446 REFERENCE CURVES FOR THE AUSTRALIAN/CANADIAN HAND OSTEOARTHRITIS INDEX (AUSCAN) IN THE GENERAL POPULATION

F. Kroon[1], S. Ramiro[1], P. Royston[2], S. Le Cessie[3,4], F.R. Rosendaal[3], M. Kloppenburg[1,3]. *[1]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [2]MRC Clinical Trials Unit, University College London, London, United Kingdom; [3]Clinical Epidemiology; [4]Medical Statistics and Bio-informatics, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Patient-reported outcomes are important to evaluate treatment, but their interpretation depends on the availability of benchmarks. The AUSCAN is a widely used questionnaire evaluating hand pain, stiffness and function.
**Objectives:** To establish population-based reference curves for the AUSCAN, and to investigate factors associated with AUSCAN scores in the general population.
**Methods:** Analyses were performed in a population-based sample, the Netherlands Epidemiology of Obesity study (n=6671, aged 45–65 years). Participants completed questionnaires on demographic and clinical information, including the AUSCAN (range 0–60, higher is worse). Standardised physical examination of the hands was performed. Primary hand osteoarthritis (OA) was defined as fulfilment of the American College of Rheumatology criteria for hand OA without an inflammatory rheumatic disease. “Pre-hand OA” was defined as having hand pain and at least two bony swellings or deformities of distal interphalangeal joints (IPJs), proximal IPJs or first carpometacarpal joints and not having primary hand OA or an inflammatory rheumatic disease. Age- and sex-specific reference curves were developed using quantile regression in conjunction with fractional polynomials. Factors associated with AUSCAN scores were analysed with ordered logistic regression, since AUSCAN data were non-normally distributed and heavily zero-inflated, dividing AUSCAN into three categories (0 vs. 1–5 vs. >5). Analyses are reported as odds ratios (ORs) with 95% confidence intervals (CIs), representing the OR of being in the highest compared to the middle or lowest category for a unit change in the determinant. The final percentile curves were compared to observed AUSCAN scores of individuals with primary hand OA. All analyses were stratified by sex.
**Results:** Median age was 56 years (interquartile range (IQR) 50–61), 56% were women. Primary hand OA was present in 12% of participants. AUSCAN scores were low (median 1, IQR 0–4). Reference curves were higher for women, and moderately increased with age (figure). Other associated factors (adjusted for age) were not only primary hand OA (OR 13.8 (95% CI 9.3 to 20.5) and 8.4 (6.2 to 11.4) in men and women), but also self-reported inflammatory rheumatic diseases (OR 2.3 (1.4 to 3.6) and 4.5 (2.7 to 7.5)), fibromyalgia (OR 265 (32 to 2203) and 20.2 (9.6 to 42.5)), “pre-hand OA” (OR 9.8 (6.1 to 15.8) and 5.7 (3.8 to 8.5)), education (as proxy for socio-economic status, OR 0.8 (0.6 to 0.9) and 0.8 (0.7 to 1.0)), and BMI (OR 1.03 (1.00 to 1.06) and 1.03 (1.02 to 1.05)). Median AUSCAN scores of individuals with primary hand OA spread constantly between the 75th and 95th centiles of the general population (figure).

**Conclusions:** AUSCAN scores in a population-based sample were overall low, and higher in women than in men. These reference curves could serve as benchmark in both research and clinical practice settings in hand OA, although it should be kept in mind that the AUSCAN does not seem to measure hand complaints specific for hand OA.

## SAT0447 IDENTIFICATION OF PREDICTIVE BIOMARKERS OF THERAPEUTIC RESPONSE IN KNEE OA: THE MOVES STUDY

V. Calamia[1], J. Mateo[1], P. Fernández-Puente[1], L. Lourido[1], M. Camacho[1], N. Oreiro[2], A. Raga[2], M. Acasuso[2], M. Herrero[3], H. Martinez[3], J. Verges[3], C. Ruiz-Romero[1], F.J. Blanco[1,2]. *[1]Grupo de Proteomica-PBR2-ProteoRed/ISCIII-Servicio de Reumatología; [2]Unidad de Investigacion Clinica-Servicio de Reumatología, Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña, A Coruña; [3]Clinical R&D Area, Bioiberica S.A., Barcelona, Spain*

**Background:** The high costs incurred when drugs fail during clinical trials has prompted interest in biomarkers as biological indicators for progress of disease, effect of therapeutic interventions, and/or drug-induced toxicity[1].
**Objectives:** The aim of this study is to identify predictive protein biomarkers useful to stratify osteoarthritis (OA) patients into responders and non-responders, either to Droglican® (Bioiberica S.A.,Barcelona,Spain) or Celecoxib, in order to optimize therapeutic outcomes in OA.
**Methods:** A shotgun proteomic analysis was performed on sera from patients enrolled in the Multicentre Osteoarthritis interVEntion trial with Sysadoa (MOVES)[2]. Sixteen serum pools from a representative group of the whole cohort (n=80) were analyzed to find a panel of proteins quantitatively different between responders and non-responders at baseline. The samples were classified between responders and non-responders, either to Droglican (glucosamine hydrochloride+chondroitin sulfate) or Celecoxib, according to the WOMAC pain score (<20 and <70) and the OMERACT-OARSI criteria recorded at the end of the trial (after 6 months of treatment). Two independent set of experiments were carried out. The pools from each condition to be compared were subjected to immunodepletion, protein digestion and labeled with the different 8-plex iTRAQ reagents as previously described[3]. The labeled peptide mixtures were mixed and resolved by reversed phase chromatography. The eluted fractions were collected onto a MALDI plate for the subsequent mass spectrometric analysis. The identification of proteins was performed with ProteinPilot v4.0 software (ABSciex). Furthermore, the results obtained were verified by ELISA assay.
**Results:** The proteomic screening led to the identification of 176 different proteins in the serum samples at baseline. The Protein Pilot software also provided data relative to the quantification between each of the samples (iTRAQ ratios). All ratios were obtained comparing the abundance of each protein identified in the responders to the abundance in the non-responders. Several proteins showed at baseline a statistically significant increase in the responder groups, such as beta-2-glycoprotein 1 (APOH) in the droglican responders and thrombospondin 1 (TSP1) in the celecoxib responders, among others. The putative biomarker usefulness of TSP1 was validated by ELISA assay on individual sera from the same cohort. The results for TSP1 (n=80) confirmed that the levels of this protein at baseline are lower in the group of non-responders to celecoxib in comparison to the responders one according to WOMAC criteria.
**Conclusions:** Protein biomarkers, such as APOH or TSP1, can predict patient response to a specific compound (droglican or celecoxib) by identifying certain OA patient populations that are more likely to respond to a specific drug therapy. This shift toward personalized medicine can help the clinicians to choose the best treatment option for each OA patient, thus enhancing the probability of success of the pharmacotherapy while reducing specific adverse events.

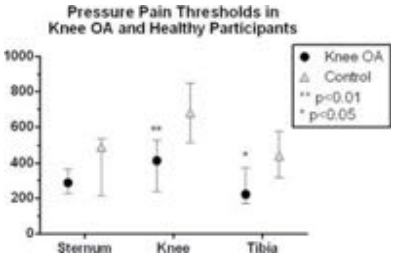
## SAT0448 A COMPARISON OF THE DIFFERENT QUANTITATIVE SENSORY TESTING MEASUREMENTS ADDRESSING PAIN MECHANISMS IN PEOPLE WITH OSTEOARTHRITIS



H. Hassan[1,2,3], D.F. McWilliams[1,2], D. Wilson[3], N. Frowd[1,2], D.A. Walsh[1,2,3]. *[1]Arthritis Research UK Pain Centre; [2]Division of Rheumatology, Orthopaedics and Dermatology, University of Nottingham, Nottingham; [3]Department of Rheumatology, Sherwood Forest Hospitals NHS Foundation Trust, Sutton in Ashfield, United Kingdom*

**Background:** People with osteoarthritis (OA) can experience both nociceptive pain, as a result of local joint damage, and pain that is indicative of abnormal central pain processing. Quantitative sensory testing (QST) is psychophysical testing of somatosensory function and can been used to investigate somatosensory abnormalities in people with OA.
**Objectives:** The aim of this study was to assess the reliability discriminant ability of two different mechanical stimuli for QST measurements, pressure and punctate, in people with knee OA and healthy participants.
**Methods:** Twenty six knee OA participants and 25 healthy participants were recruited. QST was performed in all participants at three sites on the body (sternum, index knee and anterior tibia). Two mechanical QST modalities (pressure and punctate) were performed. Pressure pain threshold (PPT) was assessed using digital algometry. Punctate QST measurements, {mechanical pain threshold (MPT), mechanical pain sensitivity (MPS) and wind-up ratio (WUR)}, were assessed using pinprick stimulators. The procedures were repeated during a second assessment four weeks later by the same examiner to determine repeatability. All participants completed the Intermittent and Constant Osteoarthritis Pain (ICOAP) questionnaire (Rasch transformed).
**Results:** The mean age for OA participants was 66 years (standard deviation (SD) (9), (50% female) and for the healthy participants was 58 years (SD 11), (48% female). People with knee OA demonstrated significantly higher values on ICOAP Rasch transformed; Intermittent {mean 7.13 (4.47) and Constant mean 4.40 (4.47)} than healthy participants; Intermittent {mean 1.12 (2.31) and Constant {mean 0.29 (1.03)} ($P<0.001$). The test-retest reliability of the QST measurements before and after 4 weeks interval expressed as intraclass correlation coefficients (ICCs) are given in Table 1.

Table 1. Test retest reliability of QST measurements

| QST | Site | ICC | 95% CI | P |
|---|---|---|---|---|

People with knee OA had significantly lower PPT at knee and tibia than normal controls (Graph). Differences between OA and control groups remained significant after adjustment for age and sex. Whereas there were no significant differences found in any punctate QST measurements between knee OA and healthy participants.

**Conclusions:** This study demonstrated that PPT is a reliable QST measurement with less variability compared to other mechanical QST measurements assessed. PPT at the tibia, a site distal to the affected joint, is believed to reflect augmented central pain processing. PPT may be a preferred QST modality to investigate altered central pain processing in people with OA.

## SAT0449 THE RELATIONSHIP BETWEEN THE ARTICULAR SURFACE PROJECTION AND RADIOLOGIC LAXITY OF THE TRAPEZIOMETACARPAL JOINT

H.S. Gong. *Department of Orthopaedic Surgery, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

**Background:** The etiology of trapeziometacarpal joint (TMCJ) osteoarthritis is not yet clearly confirmed. Laxity of the TMCJ is considered as one of the causes of osteoarthritis. Previous studies evaluated the relationship between the bony morphology and TMCJ laxity mainly in osteoarthritic TMCJs. It is unclear, however, whether there is such relationship in non-arthritic TMCJ.
**Objectives:** We aimed to determine whether the articular surface projection was associated with laxity of the TMCJ.
**Methods:** We measured the trapezial tilt and the first metacarpal base articular slope in radiographs of 108 women without thumb TMCJ osteoarthritis. The mean age was 57 years (range, 32 to 79 years). The trapezial tilt (TT) was defined as the angle formed by the intersection of a tangent to the middle third of the distal trapezial articular surface and a line parallel to the longitudinal axis of the index metacarpal in the posteroanterior radiograph of the trapezium ($\alpha$ in Fig 1A). The metacarpal articular slope (MS) was defined as the angle between the dorsal cortex and the articular surface of the first metacarpal base in a true lateral view of the thumb metacarpal ($\beta$ in Fig 1B). We evaluated the radiologic laxity of the TMCJ using subluxation ratio (SR) in the TMCJ stress view radiograph (RS (radial subluxation)/AW (articular width) in Fig 1C). We divided the subjects into four subsets according to the TT and MS, and compared the mean SR between the upper and lower quartile groups.
**Results:** There was a statistically significant difference in the mean SR between those in the upper and lower quartiles of the MS (0.24 vs 0.32, P=0.013). However, there was no difference in the SR with regard to the TT (P=0.189).

**Conclusions:** This study suggests that a steeper articular slope of the first metacarpal base could be associated with radiologic laxity of the TMCJ. Further longitudinal studies are necessary to determine whether this anatomic difference represent a risk factor for later development of TMCJ osteoarthritis.

## SAT0450 IMPACT OF MYOFASCIAL PAIN SYNDROME ON PAIN AND FUNCTIONAL STATUS IN PATIENTS WITH HAND OSTEOARTHRITIS

H.-O. Kim[1], Y.S. Suh[1], Y.-H. Cheon[2], K.S. Park[3], S.-H. Kim[4], R.B. Kim[3], S.-I. Lee[2]. *[1]Internal Medicine, Changwon Gyeongsang National University School of Medicine, Changwon; [2]Internal Medicine; [3]Preventive Medicine, Gyeongsang National University School of Medicine, Jinju; [4]Internal Medicine, Dongsan Medical Center, Keimyung University, Daegu, Korea, Republic Of*

**Background:** Various upper extremity musculoskeletal diseases (MSDs) can affect pain and disability in patients with hand osteoarthritis (HOA). However, there was no previous study investigating the relationship between upper extremity MSDs and HOA.
**Objectives:** To explore the influence of major upper extremity MSDs on pain severity and functional status of patients with HOA.
**Methods:** In this study, we enrolled 1150 farmers who lived in Gyeongnam province in Korea from June 2013 to December 2015. Physical examinations were performed by rheumatologists, orthopedists, and rehabilitation specialists. Grip powers of both hands also were evaluated. Plain radiography, a nerve conduction velocity (NCV) examination, and magnetic resonance imaging (MRI) of shoulders were performed. The Australian/Canadian Osteoarthritis Hand Index (AUSCAN) was used to assess pain severity and functional status of hand joints. The diagnosis of HOA was made by the 1990 American College of Rheumatology classification criteria. Carpal tunnel syndrome (CTS) was confirmed by NCV findings, and rotator cuff tear (RCT) was diagnosed by MRI findings. Myofascial pain syndrome (MPS) was diagnosed by palpations of myofascial trigger points.
**Results:** Of 1150 participants, 307 were diagnosed with HOA. Among HOA patients, 151 (49.7%), 192 (62.5%), and 249 (80.1%) patients had CTS, RCTs, and MPS, respectively. HOA patients with MPS showed significantly higher AUSCAN scores (350.4±285.0 vs 200.4±201.8, $p<0.001$) and decreased grip power of a dominant hand (22.5±9.8 vs. 26.2±9.8, p=0.011) compared with HOA without MPS. Linear regression analysis also showed that MPS was associated with AUSCAN scores after adjustment for age and gender ($\beta$=0.21, p=0.001). The

existence of CTS or RCT did not influence on AUSCAN scores and grip power. Compared to participants with none of major upper extremity MSDs, participants with MPS only were also higher AUSCAN scores.
**Conclusions:** MPS has a significant impact on pain and functional status in patients with HOA. Therefore, management of coexisting MPS is the better way to improve pain and function of hand joints in patients with HOA.

## SAT0451 THE ASSOCIATION OF PATELLA ALTA WITH THE SEVERITY OF RADIOLOGICAL TIBIOFEMORAL KNEE OSTEOARTHRITIS

I. Coskun Benlidayi[1], N. Cuzdan Coskun[2], T. Sarpel[1]. [1]*Department of Physical Medicine and Rehabilitation;* [2]*Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Cukurova University Faculty of Medicine, Adana, Turkey*

**Background:** Patella alta is the malalignment of the patella in the vertical plane. There are a number of studies that confirmed the relation of patella alta and patellofemoral knee osteoarthritis (OA). Nevertheless, to our knowledge, none has studied the possible relationship between patella alta and tibiofemoral knee OA.
**Objectives:** The objectives of the current study were i) to determine the prevalence of patella alta among patients with radiographic tibiofemoral knee OA and ii) to evaluate whether the frequency of patella alta differs by the severity of knee OA.
**Methods:** Patients who had undergone X-ray examination of the knee with a diagnosis of knee OA between January 2013-February 2016 were included in the study. Following the application of the exclusion criteria, remaining patients' radiographs were graded according to the Kellgren Lawrence grading system. Knees were divided into mild OA (KL grade 1–2) and severe OA (KL grade 3–4) groups. Computerized measurement of the craniocaudal patellar distance (CPD) and the patellar tendon length (PTL) was performed on lateral knee radiographs. According to the Insall-Salvati method, the PTL/CPD ratio $>1.2$ was regarded as "patella alta". The overall prevalence of patella alta was determined. The rate of patella alta was compared between mild and severe OA groups.
**Results:** A total of 712 radiographs were assessed for eligibility. Measurements were performed on 416 lateral knee radiographs belonging to 253 patients with a mean age of 62.7±11.3 years. The prevalence of patella alta in the whole group was 9.1%. The frequency of patella alta was significantly higher in the severe OA group when compared with the mild OA group ($p<0.001$).
**Conclusions:** According to the results of the present study, patella alta appears to be associated with increased severity of radiographic tibiofemoral knee OA. "High riding" patella should be kept in mind as a determinant of disease severity in patients with knee OA.
**Disclosure of Interest:** None declared

## SAT0452 DO TRADITIONAL RISK FACTORS FOR KNEE OSTEOARTHRITIS PREDICT PAIN FLARES IN KNEE OSTEOARTHRITIS?

I. Atukorala[1], A. Pathmeswaran[2], T. Chang[3], Y. Zhang[4], D.J. Hunter[5]. [1]*Clinical Medicine, Faculty of Medicine, University of Colombo;* [2]*Public Health, University of Kelaniya;* [3]*Department of Clinical Medicine, Colombo, Sri Lanka;* [4]*Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, United States;* [5]*Institute of Bone and Joint Research, University of Sydney, Sydney, Australia*

**Background:** Knee pain is the main cause of disability and reduced function in knee osteoarthritis (KOA). Though knee pain in osteoarthritis was previously perceived as a chronic condition it is now established that KOA pain fluctuates.There is emerging evidence that time variant risk factors-such as knee injury, buckling and mood- are associated with knee pain flares. But, it is not known whether conventional risk factors associated with KOA – age, gender, body mass index-are associated with pain flares in KOA.
**Objectives:** This study examines whether conventional time invariant risk factors for KOA and baseline pain felt by the patient are associated with KOA pain flares.
**Methods:** Study participants were selected from a 3-month web-based longitudinal follow up study developed to identify risk factors for KOA pain flares. Participants were requested to complete online questionnaire at days 0, 30, 60 and 90 (control period assessment points) and at time points whenever they experienced knee pain flare (case period assessment points) during the follow up period. A KOA pain flare was defined as current pain with a greater than 2 point increase (on a 0–10 point numeric rating scale) from the mildest KOA pain intensity reported at day 0.
The association of pain flares with traditional risk factors for knee osteoarthritis -gender, weight, height, body mass index- was assessed by negative binomial regression. The duration of knee osteoarthritis, baseline pain intensity (lowest pain and highest pain scores at baseline) were similarly evaluated. The best explanatory variable was decided by forward selection.
**Results:** 345 persons (61.2% females) with multiple KOA pain flares were selected. Their mean age was 62.1years (SD ±8.2). The mean body mass index was 29.8kg/m$^2$ (SD ±6.5). The participants rated their baseline pain (on a numeric rating scale) as being 4.41 (SD± 2.02) and their worst pain as being 7.91 (SD ±1.74).
An average of 1.92 (SD 2.59) flares were documented during the 3-month period. The levels of baseline pain – usual and worst pain felt at baseline- were the only parameters significantly associated with KOA pain flares (Table 1).

Table 1. Association between time invariant risk factors of KOA and KOA pain flares

| | Incidence rate ratio (95% CI) | P value |
|---|---|---|
| Age | 0.99 (0.98–1.01) | 0.99 |
| Female gender | 0.87 (0.65–1.16) | 0.35 |
| Height | 0.99 (0.98–1.01) | 0.76 |
| Weight | 1.00 (0.99–1.01) | 0.16 |
| Body mass index | 1.02 (0.99–1.04) | 0.08 |
| Duration of knee osteoarthritis | 0.99 (0.98–1.00) | 0.49 |
| Baseline pain score – lowest level of pain intensity | 1.25 (1.17–1.34) | <0.001 |
| Baseline pain intensity – highest pain intensity felt at baseline | 1.29 (1.18–1.40) | <0.001 |

CI: Confidence Interval.

**Conclusions:** The baseline pain scores were the strongest predictors of pain flares of knee osteoarthritis. The traditional risk factors associated with knee osteoarthritis did not usefully predict pain flares. The traditional time invariant risk factors may not be associated with short term variability in pain though they are associated with long term outcomes of knee osteoarthritis. It is postulated that as knee pain is already present, time invariant risk factors that contributed to the original symptom causation are not associated with pain flare.

## SAT0453 DOES RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM BLOCKADE INFLUENCE PAIN, FUNCTION AND RADIOGRAPHIC PROGRESSION IN KNEE OSTEOARTHRITIS? AN ANALYSIS OF OSTEOARTHRITIS INITIATIVE DATA

I. Shirinsky, V. Shirinsky. *Institute of Clinical Immunology RAMS, Novosibirsk, Russian Federation*

**Background:** Renin-angiotensin-aldosterone system (RAAS) has been proposed as a potential target for the treatment of osteoarthritis (OA). In experimental studies, RAAS blockade led to the reduction of inflammation and modulated cartilage metabolism. Recently, a study showed chondroprotective effects of captopril in an animal model of OA [1]. The effects of RAAS blockade on knee OA have never been studied in humans.
**Objectives:** To investigate longitudinal effects of RAAS blockade on knee pain, function, and radiographic progression of knee OA.
**Methods:** For the current analysis we used data from the publically available Osteoarthritis Initiative (OAI) database. We assessed longitudinal data from OAI participants who did not use angiotensin converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) on baseline (new user design) and who had radiographically suspected or confirmed knee OA. The evaluated clinical outcomes were WOMAC pain and WOMAC function subcategories. Radiographic progression was assessed using minimal joint space width (mJSW). The outcomes were measured annually from the baseline to year 4 of follow up. We used structural equation modeling to assess the correlations between the trajectories of ACEI/ARB use and WOMAC knee pain, WOMAC knee function, and mJSW. The models were adjusted for potential baseline confounders.
**Results:** A sample of 1796 OAI participants was analyzed. The proportion of ACEI/ARB users rose from 4.7% on year 1 to 15.14% on year 4 of follow up. No associations between ACEI/ARB use and knee pain, function, and knee OA radiographic progression trajectories were found in the analyses both adjusted or non-adjusted for baseline covariates.
**Conclusions:** RAAS system blockade has no influence on knee OA.

## SAT0454 IN A TWO-YEAR DOUBLE-BLIND RANDOMIZED CONTROLLED MULTICENTER STUDY, CHONDROITIN SULFATE WAS SIGNIFICANTLY SUPERIOR TO CELECOXIB AT REDUCING CARTILAGE LOSS WITH SIMILAR EFFICACY AT REDUCING DISEASE SYMPTOMS IN KNEE OSTEOARTHRITIS PATIENTS

J.P. Pelletier[1], J.P. Raynauld[2], A. Beaulieu[3], L. Bessette[4], F. Morin[5], A.J. Brum-Fernandes[6], F. Abram[7], M. Dorais[8], J. Martel-Pelletier[2].
*[1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM); [2]Osteoarthritis Research Unit, CRCHUM, Montreal; [3]Centre de rhumatologie St-Louis, Montreal; [4]Groupe de Recherche en Rhumatologie et Maladies Osseuses, Quebec, Quebec; [5]Centre de Recherche Musculo-squelettique, Trois-Rivières, Trois- Rivieres; [6]Rheumatology Division, University Hospital, Sherbrooke, Sherbrooke; [7]Medical Imaging Research & Development, ArthroLab Inc; [8]StatSciences Inc., Montreal, Montreal, Canada*

**Background:** In osteoarthritis (OA) treatment, although chondroitin sulfate (CS) was found in a number of studies using radiography to have a structure modifying effect, to date the question is still under debate. A clinical study using quantitative magnetic resonance imaging (qMRI) is therefore of the utmost importance.
**Objectives:** The present study has the objective to explore, as the first aim, in a two-year randomized, controlled double-blind clinical study using qMRI, the disease modifying effect of CS treatment versus celecoxib (CE) on cartilage volume loss (CVL) in knee OA. The second aim was to investigate and compare the effect of CS and CE on symptoms.
**Methods:** Symptomatic primary knee OA patients according to ACR criteria with Kellgren-Lawrence grades 2–3 and synovitis were included and treated with CS (1200 mg a day) or CE (200 mg once daily) for 24 months. Patients at high risk for cardiovascular and/or gastrointestinal disease were not included. MRI was performed at baseline, 12 and 24 months. CVL, bone marrow lesion (BML) size, and synovial membrane thickness were evaluated using qMRI, and presence of joint swelling and effusion clinically evaluated. Clinical symptoms were also assessed by validated questionnaires.
**Results:** In the intention-to-treat analysis (n=194), patients treated with CS had reduced CVL at 24 months in the medial compartment (p=0.026) and condyle (p=0.008) compared to celecoxib. In the completer analysis, CS reduced CVL in the medial compartment at 12 months (p=0.026) and medial compartment and condyle at 24 months (p=0.030, p=0.010). A trend toward a reduced (p=0.070) synovial thickness in the medial suprapatellar bursa was observed in CS patients. Both treatment groups experienced a marked reduction in incidence of patients with joint swelling/effusion and in symptoms (WOMAC total, pain, and function, and VAS pain) over time. Data showed similar good safety profiles for both drug treatments.
**Conclusions:** This trial demonstrated, for the first time, the superiority of CS over CE at reducing the long term progression of knee OA structural changes. Moreover, both drugs were found equally effective at reducing the symptoms of OA. These findings have important implications regarding the usefulness of CS for long term management of knee OA and its impact on disease outcome.

## SAT0455 BASELINE AND PERSISTENT KNEE SYMPTOMS ARE INDEPENDENT PREDICTORS OF STRUCTURAL PROGRESSION OF KNEE OSTEOARTHRITIS

J. Martel-Pelletier[1], A.J. Teichtahl[2], F.M. Cicuttini[3], Y. Wang[3], F. Abram[4], J.-P. Pelletier[1]. *[1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada; [2]Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Alfred Hospital; Baker IDI Heart and Diabetes Institute; [3]Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Alfred Hospital, Melbourne, Australia; [4]Medical Imaging Research & Development, ArthroLab Inc., Montreal, Canada*

**Background:** Although studies have predominantly focused on whether disease progression predicts symptoms in knee osteoarthritis (OA), there is very little data examining whether the presence of knee symptoms may be an independent predictor of the structural progression of knee OA.
**Objectives:** To complement and extend previous studies, we examined whether baseline and persistent knee symptoms predicted accelerated cartilage volume loss, incident and progressive radiographic OA (ROA) and total knee replacement (TKR).
**Methods:** Participants from the Osteoarthritis Initiative were grouped according to the absence (Kellgren-Lawrence [KL] grade $\leq$1, n=2120) or presence (KL $\geq$2, n=2249) of baseline ROA. Clinical symptoms (pain, stiffness and function) were assessed at baseline using Western Ontario and McMaster University Osteoarthritis Index (WOMAC). Cartilage volume in the medial and lateral compartments was assessed by magnetic resonance imaging (MRI) at baseline and 48 months. Associations with incident and progressive ROA were assessed at 48 months and TKR at 72 months.
**Results:** Higher levels of baseline and persistent knee symptoms predicted greater annual percentage of cartilage loss in the medial (all $p<0.05$) and lateral (all $p\leq0.03$) compartment in people both with and without ROA. Greater baseline and persistent knee symptoms were associated with incidence (OR range 1.02 to 1.29, all $p\leq0.005$) and progression (OR range 1.01 to 1.22, all $p\leq0.01$) of ROA, as well as TKR (OR range 1.03 to 1.35; all $p<0.001$).
**Conclusions:** Greater baseline and persistent knee symptoms predicted accelerated cartilage loss, incident and progressive ROA and TKR. Although a major focus in OA research has been the link between structural disease and symptom progression, data from this study demonstrate that symptoms are important independent predictors of disease progression. This suggests that targeting symptoms may be important for preserving joint structure.

## SAT0456 LONG-TERM EFFECTS OF TREATMENT ON THE PROGRESSION OF STRUCTURAL CHANGES IN KNEE OSTEOARTHRITIS: 6-YEAR FOLLOW-UP

J. Marte-Pelletier[1], J.P. Raynauld[1], F. Abram[2], P. Delorme[3], J.P. Pelletier[1].
*[1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM); [2]2Medical Imaging Research & Development, ArthroLab Inc., Montreal, Quebec; [3]Medical Imaging Research & Development, ArthroLab Inc., Montreal, Quebec, Montreal, Canada*

**Background:** The Osteoarthritis Initiative (OAI) is the largest knee osteoarthritis observational cohort. It provides the possibility to study the evolution of OA structural changes over time and the associated risk factors. It also allows the potential disease-modifying OA drug effects to be explored in patients over time.
**Objectives:** This study aimed to examine, for the first time, the long-term (6-year) protective effect of combined glucosamine (Glu) and chondroitin sulfate (CS) treatment on OA knee cartilage volume using the OAI cohort.
**Methods:** Participants from the OAI Progression and Incidence sub-cohorts who had MRI data on the target knee at baseline and at 6 years and with a JSW greater than 1 mm, and information on the Glu/CS consumption were included (n=1593). The participants were stratified into two main groups based on whether or not they had medial meniscal extrusion at baseline, and the former group (n=429) were further stratified into subgroups based on their exposure time: not exposed, 1 year, 2 to 3 years, and 4 to 6 years. MRI assessments were done using fully automated quantitative technologies[1,2]. Statistical analysis included the Jonckheere-Terpstra trend test as well as multivariate analysis test.
**Results:** Findings indicate that in participants with knee OA, treatment with the combined Glu/CS significantly reduced the loss of cartilage in the global knee associated with the lateral compartment. Moreover, the extent of the treatment's positive effect was also found to be related to the exposure time to treatment, the protective effect at 6 years being significant in participants who were exposed to 2 or more years of treatment.
**Conclusions:** The findings of this study are in line with previous data showing chondroprotective effects of glucosamine and chondroitin sulfate treatment with preferential effects, and provide future support for the long-term structure-modifying effects of such treatment in knee osteoarthritis subjects.

## SAT0457 A MARKEDLY HIGHER PROPORTION OF THE VARIANCE IN HIP ARTHROPLASTY THAN IN KNEE ARTHROPLASTY CAN BE EXPLAINED BY HERITABILITY

K. Magnusson[1], E. Ystrøm[2], R. Ørstavik[2], T. Nilsen[2], C. Nielsen[2], Ó.A. Steingrímsdóttir[2], P. Ferreira[3], K. Scurrah[3], A.M. Fenstad[4], O. Furnes[4], K.B. Hagen[1]. *[1]Rheumatology, Diakonhjemmet Hospital; [2]Norwegian Institute of Public Health, Oslo, Norway; [3]Australian Centre of Excellence in Twin Research, University of Melbourne, Melbourne, Australia; [4]Orthopaedic Surgery, Haukeland University Hospital, Bergen, Norway*

**Background:** Osteoarthritis (OA) may lead to costly total joint replacements (TJR) of the knee and hip joints. To what extent TJR due to OA at the different joint sites is caused by hereditary or environmental factors is unknown. This information may aid in determining whether hip or knee arthroplasties are possible to prevent.

**Objectives:** To explore the genetic contribution to TJR due to hip and knee OA for women, men, young and elderly using a twin registry design.
**Methods:** The study is a prospective cohort study based on a linkage of the Norwegian Twin Registry and the Norwegian Arthroplasty Registry using the National ID number in 2014. The presence of a TJR due to hip and knee OA has been registered for >95% of the population from 1987 (hip) and 1994 (knee). We first calculated prevalence estimates across twin groups (same sex twin pairs born 1915–1960), and subsequently examined the relative contribution of genetic factors (heritability), shared and non-shared environmental factors, applying the classical twin model.
**Results:** The sample comprised 9029 complete pairs of which 3803 monozygotic (MZ) and 5226 dizygotic (DZ) pairs (54% females and mean (SD) age 71.5 (12.7) for both zygosity groups). The prevalence for having a TJR was similar across zygosity with 3.6% (n=614) for the hip and 1.8% (n=317) for the knee joint. In total 50 MZ/30 DZ and 10 MZ/5 DZ twin pairs were concordant for hip and knee arthroplasty, respectively. Concordances and polychoric correlations were higher for MZ twins than DZ twins both for hip and knee artrhoplasty in all age and sex strata (Table). A model including only genetic and environmental factors unique to each twin in a pair provided the best fit. The heritability for TJR largely depended on OA site. A markedly higher proportion of the variance in hip arthroplasty than in knee arthroplasty could be explained by heritable factors (Table). The variance in TJR due to knee OA was to a greater extent explained by environmental factors unique to each twin (Table). A significant gene-age interaction could be observed for the knee joint with a high observed heritability for twins below median age (68 years) changing to a low heritability after median age. Heritability estimates for TJR due to hip OA remained high and stable across age and sex groups, although a slightly higher heritability could be observed for men (Table).

Table. Heritability for hip and knee arthroplasty due to osteoarthritis.

Concordance: the probability that an affected twin has a co-twin who is also affected. MZ: Monozygotic twins, DZ: Dizygotic twins. Common environmental factors omitted from the classical twin model for each strata due to poor model fit.

**Conclusions:** The heritability of TJR due to OA depends on joint site. Preventive interventions may have a greater potential for knee arthroplasty than hip arthroplasty, particularly for knee arthroplasty at old age. The difference in heritability across age and sex groups for TJR due to knee OA should be further studied due to a low number of concordant pairs.

## SAT0458 RISK FACTORS FOR LENGTH OF HOSPITAL STAY AFTER TOTAL KNEE ARTHROPLASTY: A FIVE-YEAR CONSECUTIVE CASE SERIES

K. Kawakami. *Kamagaya General Hospital, Chiba, Japan*

**Background:** The length of hospital stay (LOS) has become a valuable outcome measure of any operation, and it also directly impacts hospital cost.
**Objectives:** To identify risk factors for LOS after total knee arthroplasty (TKA) in rheumatoid arthritis (RA) and osteoarthritis (OA) patients.
**Methods:** A retrospective study involving 507 consecutive patients undergoing TKA was conducted during a five-year period from January 2010 to December 2014 (mean age 72 years, 433 females, 82 RA patients, and 58 bilateral TKA). The diagnosis of deep vein thrombosis (DVT) was based on ultrasonography.
Multiple linear regression analysis was performed to identify the variables predictive of prolonged LOS and operative time. Multiple logistic regression analysis was performed to analyze the risk factors for postoperative DVT (dependent variables: gender, age, BMI, RA, operative time, antiplatelet agents, cementless TKA, and bilateral TKA).
**Results:** Of the patients undergoing TKA, the mean LOS was 26 days, and the mean operative time was 73 minutes. The results of the multiple linear regression analysis indicated that female gender (P=0.006), age (P<0.001), higher BMI (P=0.03), operative time (P=0.001), and bilateral TKA (P=0.009) were risk factors for prolonged LOS. A subanalysis of operative time revealed that male gender (P=0.01) and BMI (P=0.03) were associated with longer operative time.
A total of 195 (38.5%) cases were DVT positive. Multivariate logistic regression analysis revealed that osteoarthritis (P=0.03) and cementless TKA (P=0.01) were risk factors for DVT after TKA.
**Conclusions:** Female gender, age, higher BMI, operative time, and bilateral TKA were risk factors for longer LOS. Male gender and higher BMI were risk factors for longer operative time. Osteoarthritis and cementless TKA were risk factors for DVT. Further research investigating the risk factors for longer LOS is needed to reduce total hospital costs.

## SAT0459 ASSOCIATIONS BETWEEN BODY COMPOSITION MEASURES OF OBESITY AND RADIOGRAPHIC OSTEOARTHRITIS IN OLDER ADULTS: DATA FROM THE DONG-GU STUDY

K.-E. Lee, L. Wen, Y.-R. Yim, J.-E. Kim, J.-W. Lee, D.-J. Park, S.-S. Lee.
*Rheumatology, Chonnam National University Medical School, Gwangju, Korea, Republic Of*

**Objectives:** We examined the effects of fat deposition on radiographic osteoarthritis (OA) to determine the role of obesity in the pathogenesis of radiographic OA.
**Methods:** Data were taken from the Dong-gu cohort, a cross-sectional study of 2,367 subjects. Baseline characteristics, waist circumference (WC), waist-to-hip ratio (WHR), fat mass, and fat percentage were collected, along with X-rays of the knees and hands. Total knee and hand radiographic OA scores were summed using a semi-quantitative grading system, and then stratified by gender using a multiple linear regression model.
**Results:** After adjusting for confounders, weight was the only factor significantly associated with knee radiographic OA, regardless of gender (all p<0.01). Regarding the hand, fat percentage had the largest effect on radiographic OA in males (p=0.008), while WHR was the most significant factor in females (p=0.001). For the knee, fat mass was the most important factor for radiographic OA in males (p=0.001), while in females, body mass index was the most important factor (p<0.001). Among the variables, only fat percentage was significantly related to both hand and knee radiographic OA in both genders (all p<0.01).
**Conclusions:** Regardless of gender, mechanical stress was significantly associated with knee radiographic OA. Otherwise, fat deposition correlated with hand and knee radiographic OA in both genders, while the distribution of fat tissue was significantly associated with hand and knee radiographic OA only in females, with the largest effect on hand and knee radiographic OA.

## SAT0460 THE EFFECT OF THERAPEUTIC ULTRASOUND ON PAIN AND PHYSICAL FUNCTION IN THE PATIENTS WITH KNEE OSTEOARTRITIS

T. Yeğin[1], L. Altan[2], M. Kasapoğlu Aksoy[1].

[1]Bursa High Speciality Training and Research Hospital; [2]Uludag University, Physical Therapy and Rehabilitation, Bursa, Turkey

**Background:** Osteoartritis (OA) is one of the most frequent causes of pain, loss of function and disability in adults (1,2). The prevalence of OA is expected to increase substantially in the future (1). Knee osteoarthritis is the most common subset of OA (2). Therapeutic ultrasound (US) is one of several physical therapy modalities suggested for the management of pain and loss of function due to OA (3).
**Objectives:** The purpose of our study was to investigate the efficacy of US therapy in reducing pain and functional loss and improving the quality of life in patients with knee osteoarthritis in comparison to sham ultrasound therapy.
**Methods:** The study involved 62 patients. The patients were randomly divided into two groups. The patients in Group 1 (n=30) were administered 1 Watt/cm$^2$, 1 MHz continuous US, and the patients in Group 2 (n=32) were administered sham US. The ultrasound treatment was applied for 8 min to each knee, 16 min in total, 5 days a week, for a total of 10 sessions during two weeks. The patients were evaluated immediately after treatment and 1 month after therapy according to VAS, night pain, EHA, morning stiffness, WOMAC, Lequesne and SF-36 scales, and 6 min walking distance.
**Results:** Improvement in pain and joint functions was observed in both groups according to the evaluation immediately after treatment and at 1 month after the therapy. According to the evaluation results immediately after treatment; there was significant improvement in all pain scales (VAS, WOMAC, Lequesne, SF-36), morning stiffness and 6 min walking distance in patients receiving real US treatment (p<0.05) but only in some pain scales (VAS, WOMAC) and functions in the group receiving sham US (p<0.05). Significantly better improvement was observed in some pain scales (SF-36), functions (WOMAC, SF-36) and 6 min walking distance in the real US group. At 1 month after therapy, no significant difference was observed between groups except for improvement in night pain in real US group.

**Conclusions:** This study comfirms that US therapy is effective to improve physical function, in reducing pain and also it is a reliable method. Short term efficacy of US is superior to plasebo, on the other hand long term effect is not different from placebo. The results can provide guidance regarding the organization of the treatment of the patient with knee OA. Further systematic investigation is needed with larger group of patients.

## SAT0461 EFFICACY OF HYALURONIC ACID IN SMALL JOINTS OSTEOARTHRITIS (OA) – THE RESULTS OF MULTICENTER RANDOMIZED PLACEBO-CONTROLLED 48 WEEKS STUDY

E. Tsvetkova, L. Denisov, E. Nasonov, E. Panasyuk, E. Sharapova, N. Kashevarova, S. Anikin, L. Menshikova, E. Smidt, D. Goryachev. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Objectives:** Assessment of the efficacy, tolerability and aftereffect period on the single administration into Ist carpometacarpal and Ist metatarsophalangeal OA joints of 1.0ml (20mg) of hyaluronic acid (Durolane SJ) as compared with placebo.
**Methods:** The study included 120 pts with OA of small hand joints or feet, pain intensity >40mm by VAS and consisted of two phases: "blind" phase up to 24 weeks, period of open assessment of long term efficacy results – 48 weeks. The efficacy was assessed by 40% pain subsiding, index AUSCAN (for the hand), daily dose of NSAID, total effect assessment by VAS.
**Results:** Both groups were comparable by basic clinical criteria. 40% pain subsiding by VAS (mm) was noted in experimental group to 24th week in 79.7%, in the placebo group – 30% (chi-square: $p<10^{-5)}$ relation of chances (OR) equal to 9.1 (3.9–21.1). Dispersion analyses of pain, stiffness and function by AUSCAN index revealed reliable differences between Durolane SJ and placebo. Adverse effects related to the therapy were not found. Effect, achieved to 24th week of observation included pain, stiffness, functional status, general assessment of condition by the therapist and patient, was preserved without changes to 48th week.
**Conclusions:** High efficacy and 48 weeks considerable duration of aftereffect of single administration of Durolane SJ (small joints) as compared to placebo was demonstrated.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3414

## SAT0462 AUTOLOGOUS PLATELET-RICH PLASMA (PRP) IN OSTEOARTHRITIS TREATMENT

L. Smolina, L. Khimion. *Department of Family Medicine, National Medical Academy of Postgraduate Education, Kiyv, Ukraine*

**Background:** The results of the PRP use in knee OA treatment are discussed ib the article.
**Objectives:** To study the efficacy and safety of the PRP use in early stages of the knee OA.
**Methods:** The study was conducted at the Department of Family Medicine of the NMA of Postgraduate Education (Kyiv, Ukraine) and included 68 patients with diagnosed knee OA (I-II radiological stages).The patients with severe co-morbidities,trauma or after knee surgery were not included at the study.68 patients (27 men (39.7%) and 41 women (60.3%), mean age 41,3±1,2 years) were divided into 2 groups.Gr.1 included 34 patients who consented to receive standard OA treatment and 3 intra-articular injections of PRP (total volume 24–30ml,mean platelets number 869,24±32,$1x10^9/\mu l$)weekly;gr.2 consisted of 34 patients of comparable age with the same diagnosis who received only standard OA treatment.The CRP-level,WOMAC scale and Lequesne index was analyzed before treatment and in 1,3,6,12 months after course of treatment in both groups.
**Results:** CRP level was modestly abnormal in the 43,5% patients of group 1 and 38,7% patients of group 2; during the treatment period CRP got to normal in all patients, but during the follow-up period-after 6 and 12 months of treatment in the study group it was significantly lower (6,44±0,52) and (4,34±0,22) mg/L, than in the control group (7,96±0,60) and (6,72±0,51)mg/L ($p<0,005$). In addition in 5 patients of group 2 CRP level had increased again after 6 months which was the sign of OA exacerbation.WOMAC and Lequesne index had positive dynamic during treatment in both groups.At month 12 functional status of the patients in gr.1 improved by 33% in stiffness,pain during movement and after passing the distance decreased after treatment by 38.5% in gr.1,pain and discomfort when climbing and descending the stairs decreased by 38.9%. At the end of follow up period patients functional activity increased by 47.4% in gr.1 which was better then positive changes in gr.2 and was accompanied by a significant reduction of restrictions in daily activities.There were no adverse events due to use of PRP injections in gr.1.
**Conclusions:** The course of 3 intra-artricular injections added to the standard treatment of knee OA improves functional activity,reduces pain and probably can prolong remission in patients with the early stages of disease.The further long-term studies are needed with ultrasound/MRI monitoring of the articular cartilage to obtain more accurate information and determine the most effective methods of PRP use in OA treatment.

## SAT0463 THE PREVALENCE OF KNEE OSTEOARTHRITIS ESTIMATED BY VALIDATED SCREENING QUESTIONNAIRE IN THE GENERAL POPULATION OF SINGAPORE

M. Noviani[1,2], J. Thumboo[1,2], C.M. Lee[3], I. Soh[3], S. Ma[3], Y.Y. Leung[1,2]. *[1]Rheumatology and Immunology, Singapore General Hospital; [2]Duke-National University of Singapore Graduate Medical School; [3]Ministry of Health, Singapore, Singapore*

**Background:** Knee osteoarthritis (OA) is one of the leading causes of disability worldwide. The prevalence of knee OA is higher in Chinese than Caucasian subjects, despite the lower body mass index in Chinese populations.[1,2] Among other Asian ethnicities, the prevalence of knee OA may also be high, and the prevalence of knee OA in the multi-ethnic Singapore population is still unknown.
**Objectives:** Our study aimed to estimate the prevalence of knee OA in the general population of Singapore, using a validated questionnaire consisting of 3 knee OA symptoms or 1 symptom and a physician diagnosis (sensitivity of 54%, specificity of 87%).[3]
**Methods:** We recruited a subset of subjects from the National Health Surveillance Survey (NHSS) 2013 who provided telephone numbers. Consenting subjects were invited to complete a validated screening questionnaire by mail.[3] If no response was received after 4 weeks, the subjects were interviewed by telephone to complete the screening questionnaire. The national prevalence of knee OA was estimated by accounting for the proportion of subjects who provided telephone numbers; it was weighted to the gender, age, and ethnic distribution profiles of the final respondents.
**Results:** From the NHSS cohort of respondents (n=9,631 subjects), 4,633 (48.1%) subjects provided telephone numbers. A total of 3,364 sets of screening questionnaires were completed, out of 4,557 sent (response rate=73.8%). The demographic profile of the responders were not significantly different from the original NHSS cohort profile. The estimated national prevalence of knee OA was 11%. Women (13.1%) had a higher prevalence of knee OA than men (8.8%). The prevalence of knee OA increased with age and was 19.7% for age ≥60 years old, compared to 8.6% for age 18–59 years old. Across the different ethnic groups, knee OA was more prevalent among Indian (20.5%), followed by Malay (17.7%), and Chinese (9.3%).
**Conclusions:** Using a validated screening questionnaire, we estimated the national prevalence of knee OA in the multi-ethnic Singapore population. Indian and Malay had higher prevalence of knee OA, which could be attributed to the higher prevalence of obesity among these ethnic groups as compared to Chinese.[4]

## SAT0464 RISK FACTORS FOR PROGRESSION OF KNEE JOINT OSTEOARTHROSIS IN PATIENTS WITH EARLY GONARTHROSIS IN THE 5-YEAR PROSPECTIVE STUDY

N. Kashevarova, E. Zaitseva, O. Pushkova, A. Smirnov, N. Dyomin, L. Alekseeva, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** -
**Objectives:** To identify risk factors for progression of knee joint osteoarthrosis (OA) in the first 5 years of disease.
**Methods:** Prospective 5-year study included 110 female-patients with primary knee OA (CCR criteria), in 52 of them disease duration did not exceed 5 years, (mean age – 59,11±8,95 years). All relevant patients' data, including anthropometric parameters, case history, evaluation of pain intensity by VAS, knee joint status and therapeutic modalities used during the follow up period were recorded in individual patient's file. Instrumental diagnostic methods used in each patient included plain radiography of knee joints (gonarthrosis stage was classified by Kellgren J.- Lawrence J. scale), dual energy X-ray absorptiometry (DEXA) of the lumbar spine, femoral neck and of subchondral bone of the hip and tibia, ultrasound (US) and MRI examination of knee joints. First OA stage was documented in 22 (42,3%) out of 52 patients, 2-nd - in 24 (46,2%) patients, 3d stage - in 6 (11,5%) patients.
**Results:** During 5 year follow up radiographic progression of knee OA was documented in 14 patients (Group with progression), while in 38 patients radiographic stage remained unchanged. Patients from both groups were similar in terms of age (58,29 ± 7,68 vs 56,05 ± 8,74 years), and disease duration (3,43 ± 1,34 vs 3,47 ± 1,33 years). Although, patients with OA progression had more intense knee pain when walking: 60,36 ± 18,33 vs 48,71 ± 17,81, $p$=0,043 (mm); higher BMI: 34,45 ± 4,60 vs 28,92 ± 4,92, $p$=0,001 (kg/m$^2$); higher incidence of synovitis: 57,1% vs 18,4%, $p$=0,006 based on US findings, bone marrow edema in medial tibia aspect 64,3% vs 13,2%, $p$=0,001, based on MRI findings, and higher rate of serious medial condyle damage: 50,0% vs 7,8%, $p$=0,001 distinct from patients without OA progression. DEXA identified significantly higher absolute bone mineral density (BMD) values in the lumbar spine 0,91 ± 0,08 vs 0,82 ± 0,11, $p$=0,015 (g/cm$^2$) and femoral neck 0,85 ± 0,09 vs 0,76 ± 0,08, $p$=0,007 (g/cm$^2$), as well as higher BMD in the medial condyle of the tibia 0,95 (0,85–1,24) vs 0,75 (0,65–0,82), $p$=0,001 (g/cm$^2$) as compared to patients without OA progression. Patients' re-examination in 5 years revealed similar statistically significant differences between the groups. Multifactorial analysis identified the following major risk factors, responsible for gonarthrosis progression: synovitis, bone marrow edema, and high BMD values in the medial condyle of the tibia, while intake of chondroitin sulfate (ChS) and glucosamine (GA) combination for more than 6 months a year during 5 years was identified as risk reduction factor. Based on identified factors and their coefficients a predictive model was suggested (with area under the ROC curve equal to 0,93), allowing to prognosticate the future course of the disease in an individual patient with high accuracy, i.e. 85,7%, sensitivity and 84,2% specificity.

| Factors | Discriminant function coefficients |
|---|---|
| US: synovitis | 2,17 |
| MRI: bone marrow edema | 3,19 |
| Tibial medial condyle BMD | 5,19 |
| Intake of ChS and GA | −1,03 |
| Constant | 11,83 |

ROC-curve

**Conclusions:** synovitis, bone marrow edema, and high subchondral BMD in the medial condyle of the tibia are the major risk factors responsible for progression of knee OA in patients with disease duration up to 5 years. While intake of ChS and GA had a positive impact on radiological OA progression.

## SAT0465 SENSORIMOTOR PERFORMANCE AND FUNCTION IN PEOPLE WITH OSTEOARTHRITIS OF THE HAND: A CASE-CONTROL COMPARISON

N. Magni[1], P. McNair[1], D. Rice[1,2]. *[1]Health and Rehabilitation Research Institute, Auckland University of Technology; [2]Waitemata Pain Service, North Shore Hospital, Auckland, New Zealand*

**Background:** Hand osteoarthritis (OA) is a common cause of pain and disability, affecting 20% of adults over age 70 [1]. Classically this pathology has been attributed solely to impairments of peripheral structures (e.g. joint and surrounding tissues). However, recent evidence has shown that changes in the central nervous system may contribute to the maintenance of pain and disability [2]. To date no evidence has focused on brain related sensorimotor impairments in hand OA, highlighting the need for further studies on this topic. We hypothesised that patients with hand OA would present with evidence of sensorimotor impairments and that these changes would be correlated to hand function.
**Objectives:** To determine whether motor imagery (MI), tactile acuity, and body perception, are disrupted in people with hand OA. To verify if a correlation exists between these measures and hand function in people with hand OA.
**Methods:** Twenty patients with symptomatic hand OA and 19 healthy pain-free controls undertook MI (hand left/right judgments), a brain speed processing task (controls left/right judgments), two-point discrimination (TPD) threshold testing, a neglect-like symptoms questionnaire (assessing body perception) and hand performance tests.
**Results:** People with hand OA were slower and less accurate in the MI task ($P$ <0.05) when compared to healthy controls, with no brain processing differences between groups. No difference was found between groups for two-point discrimination measures. Patients with hand OA presented with higher ($P$ <0.05) scores on the neglect-like questionnaire. Interestingly, people with left hand pain demonstrated enhanced neglect-like symptoms ($P$ <0.05) compared to those with right-sided hand pain. A correlation between TPD thresholds and measures of hand performance was identified, however no relation was found between MI and hand function.
**Conclusions:** Patients with hand OA demonstrate brain related sensorimotor deficits. Additionally, the side of the pain appears to influence body perception, probably due to differences in right and left hemispheric functions. Sensorimotor measures partially correlate to function, specifically tactile acuity is moderately related to hand function.

## SAT0466 PROGRESSION OF PAIN AND ULTRASOUND DETECTED SYNOVITIS IN PATIENTS WITH EROSIVE HAND OSTEOARTHRITIS OVER ONE YEAR

O. Sleglova, O. Ruzickova, K. Pavelka, L. Senolt. *Institute of Rheumatology, Prague, Czech Republic*

**Background:** Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive disease and erosive, sometimes referred to as inflammatory, HOA. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconclusive.
**Objectives:** The aim was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a one-year longitudinal study.
**Methods:** Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and one-year follow-up.
**Results:** Altogether, 129 patients (12 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2015. Out of these patients, 72 had erosive disease. The disease duration ($p$<0.01) was significantly higher in patients with erosive compared with non-erosive disease at the study entry.
Patients took symptomatic slow-acting drugs (SYSADOA) twice a year, non-steroidal anti-inflammatory drugs (NSAIDs) and analgesics on demand. Duration of morning stiffness ($p$<0.01) and number of clinically swollen joints ($p$<0.05) were significantly higher in patients with erosive compared with non-erosive disease at study entry. Duration of morning stiffness ($p$<0.05) become shorter in patients with erosive, but not in those with non-erosive disease, however the number of clinically swollen joints were not significantly changed at one year follow-up in both groups.
According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain ($p$<0.05) and stiffness ($p$<0.01) at study entry. Pain, but not stiffness, got worse ($p$<0.05) in patients with erosive compared with non-erosive disease. US-detected pathologies such as gray-scale synovitis total score ($p$<0.001), intensity of PDS ($p$<0.01) and number of osteophytes ($p$<0.01) were significantly higher in patients with erosive compared with non-erosive disease at study entry and got worse in gray-scale synovitis total score ($p$<0.01), intensity of PDS ($p$<0.01) and numerically also in number of osteophytes ($p$<0.1) at one-year follow-up. There were no significant differences in consumption of NSAIDs and SYSADOA for OA between both groups during the study.
**Conclusions:** This study shows that pain associated with US-detected synovial hypertrophy, inflammatory signs and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease and is more likely to progress over one year.

## SAT0467 NEUROPATHIC PAIN IN KNEE OSTEOARTHRITIS: IS ITS PREVALENCE RELATED TO A GREATER IMPACT?

O. Akkar, L. Lehlou, L. Ichchou. *Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*

**Background:** Knee osteoarthritis (OA) is a common and progressive joint disease with an estimated incidence rate of 240 per 100000 person-years. Pain from Knee OA is generally classified as nociceptive; however, a neuropathic component is possible.
**Objectives:** The objective of this study was to determine the prevalence of neuropathic pain (NP) in patients with painful knee OA using the DN4 questionnaire and to evaluate the relationship between NP, pain intensity, WOMAC function and stage of OA.
**Methods:** We included in this study patients with knee osteoarthritis according to ACR criteria. Pain score using Visual Analogue Scales (VAS), Western Ontario and McMaster Universities Osteo-arthritis Index (WOMAC), DN4 score, duration of symptoms, severity of OA using the Kellgren-Lawrence (KL) system, were evaluated using a Pearson's correlation coefficient. $p<0.05$ was considered statistically significant.
**Results:** One hundred patients (96 females, 4 males) with a mean±SD age of 59.4±10.4 years were included in the study. Mean±SD duration of symptoms was 72±54 months. The mean ± SD VAS was 5.2±2 and the total WOMAC 50±19. The prevalence of neuropathic pain was 26%. DN4 score was significantly correlated with the VAS (r=0.6, p=0.0001) and the WOMAC (r=0.53, p=0.0001). However, there was no significant correlation between DN4 score and KL grade.
**Conclusions:** DN4 score classified 26% of pain from knee OA as NP. Patients with severe pain and disability may have a NP component in their knee OA pain. It is important to be aware of considering the existence of NP in the treatment of knee OA pain.

## SAT0468 DIFFERENTIAL PROFILE OF ENDOGENOUS PEPTIDES DETECTED BY TARGETED PROTEOMICS IN CARTILAGE SECRETOME, SYNOVIAL FLUID AND SERUM FROM OSTEOARTHRITIS PATIENTS AND CONTROLS

P. Fernandez Puente[1], V. Calamia[2], L. Lourido[2], L. Gonzalez[2], M. Camacho[2], C. Ruiz-Romero[2], F. Blanco[2]. *[1]Grupo de Proteomica-PBR2-ProteoRed/ISCIII-Servicio de Reumatología, Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas, Universidade da Coruña (UDC); [2]Grupo de Proteomica-PBR2-ProteoRed/ISCIII-Servicio de Reumatología, Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas, Universidade da Coruña (UDC), A Coruña, Spain*

**Background:** Peptidomics is an emerging field branching from proteomics that targets endogenously produced protein fragments. A peptidomic analysis that we recently performed enabled the identification of endogenous peptides that were differentially released from wounded (WZ) and unwounded (UZ) zones of human articular osteoarthritic cartilage, compared to healthy tissue.
**Objectives:** In the present work, we aimed to develop a targeted method for the quantitative monitoring of this panel of peptides in synovial fluids and sera from osteoarthritis (OA) patients, in order to unravel the putative biomarker value of these molecules.
**Methods:** Synovial fluid and serum samples were obtained from OA patients at different stages of the disease. Proteins secreted from human articular cartilage (secretomes) were obtained by culture of tissue explants, according to optimized procedures [1]. The enrichment of endogenous peptides in these three types of samples was standardized, using ultrafiltration procedures and solid phase extraction (SPE) with reversed phase (C18) resins. A method for the targeted identification of endogenous peptides by Multiple Reaction Monitoring (MRM)-mass spectrometry was developed employing cartilage secretome samples, and then applied on synovial fluid and serum. The peptides were separated by nano-LC coupled to a 5500 QTRAP mass spectrometer. Data analysis was performed using the Skyline software. Peptide identifications were searched against a human database (human_fasta) using the ProteinPilot program.
**Results:** The peptidomic study led to the identification of a panel of 262 peptides corresponding to 36 different proteins that were differentially released from the WZ and UZ in OA cartilage. From these, we first performed independent data analyses (IDA) by mass spectrometry using cartilage secretomes and synovial fluids to detect those peptides that are better identified in these types of samples, which led to a list of 27 different peptides. Then, a final MRM method was designed for the detection of these peptides, belonging to unique proteins that were characteristic of human articular cartilage.
**Conclusions:** A multiplexed targeted method for the simultaneous identification of a panel of 17 endogenous peptide released from 7 proteins characteristic of articular cartilage has been developed. The proteins detected are Cartilage oligomeric matrix, Cartilage intermediate layer protein 1, Fibronectin, Prolargin, Dermcidin, Matrix gla protein, Clusterin and Glia-derived nexin. This method is based on liquid chromatography-multiple reaction monitoring (LC-MRM) mass spectrometry. By these means, endogenous peptides were simultaneously detected and relatively quantified in synovial fluids and sera from OA patients and controls. Further qualification studies will be necessary to establish their usefulness for OA diagnosis and progression studies.

## SAT0469 OSTEOARTHRITIS IS THE MOST FREQUENT CAUSE OF RHEUMATHOID ARTHRITIS MISDIAGNOSIS IN A COLOMBIAN SPECIALIZED CENTER

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], D. Buitrago-Garcia[6], C. Castro[6]. *[1]Rheumatology; [2]Psychology; [3]Health Services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** There is a lack of expertise in rheumatoid arthritis (RA) diagnosis in primary level of Colombian medical centers, leading to misdiagnosis; many times osteoarthritis (OA) and another rheumatic diseases are misdiagnosed as RA which derives in wrong treatment for patients with clinical and health economics implications.
**Objectives:** The objective of this study was to describe demographic and clinical characteristics of a cohort of patients derived to a specialized RA center with presumptive RA diagnosis and finally diagnosed as osteoarthritis.
**Methods:** A descriptive cross sectional study was done. Patients referred to a specialized RA center in a 48 month period with presumptive diagnosis of rheumatoid arthritis were assessed. Each patient was evaluated to confirm or rule-out diagnosis of RA as follows: a rheumatologist fulfilled a complete medical record, including all previous clinical, laboratories and imaging data; it was assessed rheumatoid factor, anti-citrullinated antibodies and other laboratories depending on each case. Also were made x-rays of hands and feet, and in some cases of persistent doubt about the diagnosis was requested comparative MRI of hands or/and feet. Frequencies and percentages were calculated for the demographic and clinical characteristics of the cohort of patients in which the diagnosis of RA was ruled-out.
**Results:** A total of 5176 patients derived during the last four years to specialized in RA center with presumptive RA diagnosis, after medical, laboratory evaluation and imaging had a wrong RA diagnosis; of them patients 2930 (57%) had finally osteoarthritis diagnosis and of these patients 2594 (88%) were women and 336 (12%) men, with an average age of 59 ± 13 years old. Majority of these patients were followed by general physicians or internists and treated with non-biologic and some few cases with biologic disease modifying anti-rheumatic drugs (DMARDs) in the past years, for an average time of 4.5 years.
**Conclusions:** In this cohort of patients the most frequent diagnosis of patients misdiagnosed with RA was osteoarthritis, being more than two thirds of them, predominantly women. This shows the need for the implementation of specialized clinics in RA and educational strategies for primary care physicians in order to avoid the impact of this wrong diagnosis.

## SAT0470 VALIDITY AND RELIABILITY OF THE CHINESE VERSION OF THE PAINDETECT QUESTIONNAIRE IN SUBJECTS WITH KNEE OSTEOARTHRITIS

R.F. Zhang[1,2], Y.Y. Leung[1,3]. *[1]Department of Rheumatology & Immunology; [2]Department of Speciality Nursing, Singapore General Hospital; [3]Duke NUS Medical School, Duke NUS, Singapore, Singapore*

**Background:** Patients with knee osteoarthritis (KOA) may have pain sensitization which is a potential risk factor for chronic pain after total knee replacement surgery (TKR). A neuropathic pain questionnaire may facilitate the identification of patients with KOA who has central sensitization.
**Objectives:** We aim to evaluate the validity and reliability of the Singapore Chinese version of the painDETECT questionnaire (PDQ-Chi).
**Methods:** The PDQ-Chi was cross-culturally adapted from the source English version with forward and backward translation according to standard guidelines, followed by cognitive debriefing in ten patients with KOA. The PDQ-Chi was administered to consecutive KOA patients enlisted for TKR in two weeks' time. The construct validities of the 7-items and 9-items PDQ-Chi were evaluated in comparison with the pressure pain threshold measured at medial knee joint line (the side that is going for TKR), and the volar area of right forearm. Test retest reliability was assessed by intraclass correlation coefficient (ICC) and classification consistency (proportion with no change in pain phenotype), in a subset of patients on day of TKR.

**Results:** 165 patients (82.4% women, mean age 67.5 ± 7.8 years) were recruited to the study. The patients generally had low scores for PDQ-Chi (mean 4.9 ± 3.9). Only one patient had neuropathic pain as classified by PDQ-Chi (score ≥19). The Cronbach's alpha of the 7-items and 9-items PDQ-Chi were 0.60 and 0.58 respectively. Factor analysis of the 7-items PDQ-Chi revealed a 2-factor structure that explained 48% of total variance. The 9-items total PDQ-Chi scores correlated with pain scores, but not pressure pain threshold of knee or forearm. The PDQ-Chi did not correlate with the hypothesized trait of measurement. 17 patients administered the PDQ-Chi a second time on the day of TKR. The ICC of the 7-items and 9-items PDQ-Chi was 0.59 and 0.50, respectively; while the classification consistency of the 9-items PDQ-Chi was 94%.
**Conclusions:** In this group of patients with KOA enlisted for TKR, both the 7-items and 9-items of PDQ-Chi were suboptimal in internal consistency and hypothesis testing. Using the 9-items PDQ-Chi with cut-offs as screening instrument for neuropathic pain, it had good classification consistency. Further studies with larger sample size are required for criterion validity.

## SAT0471 OSTEOARTHRITIS IS RELATED TO CARDIOVASCULAR DISEASE AND INCREASED ARTERIAL STIFFNESS. A CASE-CONTROL STUDY

S.A. Provan[1], S. Rollefstad[2], I.J. Berg[1], I.B. Wilkinson[3], C.M. McEniery[3], A.G. Semb[2], T.K. Kvien[1], N. Østerås[4], I.K. Haugen[1]. *[1]Rheumatology; [2]Preventive Cardio-Rheuma clinic, Diakonhjemmet Hospital, Oslo, Norway; [3]Division of Experimental Medicine and Immunotherapeutics, Addenbrooke's Hospital, University of Cambridge, United Kingdom; [4]National Resource Centre for rehabilitation in Rheumatology. Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

**Background:** Osteoarthritis (OA) is associated with an increased risk of CVD[1], but confounder bias has not been sufficiently explored in observational studies. Pulse wave velocity (PWV) and augmentation index (AIx) are predictors of future CVD events.
**Objectives:** To investigate the relationship between OA and CVD, PWV and AIx, accounting for confounders.
**Methods:** All residents of Ullensaker municipality, aged between 40 and 79 years were mailed a questionnaire concerning general health and musculoskeletal pain (Musculoskeletal pain in Ullensaker Study (MUST)). Respondents who reported having OA were invited to an extended clinical examination at Diakonhjemmet Hospital, Oslo, Norway. OA was diagnosed according to the ACR clinical classification criteria. Demographics and co-morbidities were recorded on questionnaires. AIx and PWV were measured (Sphygmocor apparatus, Atcor®). Participants in the Oslo control cohort were recruited by Statistics Norway, and underwent a similar data-collection (response rate 41%). Data from the Anglo-Cardiff Collaborative Trial (ACCT), a community based population study (response rate 85%) from the United Kingdom, formed a secondary control population. In separate logistical regression models, adjusted for age, sex, we compared the odds ratio (OR) for CVD and elevated AIx and PWV (dichotomized at median) between participants in MUST, ACCT controls and Oslo controls. Patients with hand OA were compared against patients with lower limb OA (hip and/or knee OA). AIx was adjusted for heart rate and height, whereas PWV was adjusted for heart rate. A confounder was defined as a variable which changed the estimate of the exposure effect by ≥20% when entered into the model.
**Results:** Out of 583 patients in MUST with self-reported OA, 153 (26.2%) had isolated hand OA according to the ACR criteria and 153 (26.2%) had lower limb OA. 134 persons consented to participate in the Oslo control cohort. 1111 patients without inflammatory joint disorders from the ACCT were randomly selected as controls. The age and sex adjusted logistical regression models are presented in the table. Analyses with additional adjustment for smoking, BMI, CRP, anti-hypertensive and statin treatment, respectively, gave similar results.

Table 1

| | MUST vs ACCT | MUST vs Oslo controls | Hand OA vs Lower limb OA | ACCT vs Oslo controls |
|---|---|---|---|---|
| CVD dependent variable, OR (95% CI) | 4.2 (2.7, 6.3)** | 2.0 (0.7, 5.4) | 0.5 (0.2, 1.0)* | 0.5 (0.2, 1.4) |
| AIx dependent variable, OR (95% CI) | 2.4 (1.8, 3.3)** | 1.6 (0.9, 2.8) | 1.0 (0.6, 1.7) | 0.9 (0.5, 1.5) |
| PWV dependent variable, OR (95% CI) | 1.4 (1.1, 1.8)* | 1.0 (0.6, 1.7) | 0.8 (0.4, 1.4) | 0.9 (0.6, 1.6) |

*p<0.05, **p<0.001.

**Conclusions:** Patients with OA have an increased frequency of CVD, and higher levels of AIx and PWV, compared to ACCT controls. Lower limb OA seems to be associated with CVD to a greater extent than hand OA. No confounder variables were identified in these analyses.

## SAT0472 IS ELECTROTHERAPY EFFECTIVE IN THE MANAGEMENT OF PAIN, RANGE OF MOTION, QUALITY OF LIFE, EDEMA FOLLOWING TOTAL KNEE ARTHROPLASTY SURGERY? RANDOMIZED CONTROLLED TRIAL

M.R. Kadi[1], S. Hepguler[1], E. Dede[1], C. Ozturk[1], S. Aydogdu[2], K. Aktuglu[2], N. Ozkayin[2], F.C. Atamaz[1]. *[1]Physical Medicine and Rehabilitation; [2]Orthopaedic Surgery, Ege University School of Medicine, Izmir, Turkey*

**Background:** Knee osteoarthritis is a current problem that causes limitations in patients' activities of Daily living (1). There are many therapeutic options. Total knee arthroplasty is one of these treatment methods.Postoperative pain is one of the most commonly seen problems after this operation.The target of postoperative pain management is pain alleviation with minimum morbidity that is caused by analgesic modalities (2). Interferential current (IFC) therapy is a physical modality whose effects on postoperative pain, range of motion, edema and analgesic use has previously been shown (3).
**Objectives:** In this double-blind randomized controlled study, we aimed to investigate the effectiveness of interferential current (IFC) following total knee arthroplasty (TKA) surgery
**Methods:** 98 patients who had TKA surgery were included into the study. Patients were randomized into two groups: Group 1: IFC (n=49) and group 2: sham IFC group (n=49). After all patients received the same rehabilitation programme and cold pack, the patients in group 1 administered IFC 30 minutes 2 times a day for 5 days. Same treatment instructions were given in sham group blindly. Patients were assessed at days 0, 5 and 30th after surgery with following parameters: VAS pain (cm), edema (cm), range of motion (ROM), Short Form 36 (SF 36) and paracetamol intake (gr)
**Results:** All patients had significant improvements in all evaluation parameters ($p<0,05$) except the subscales of the physical role and mental health in the SF 36. In comparison of the groups, paracetamol intake was significantly lower in the IFC group at 5th day ($p<0.05$). There was no difference between groups for other evaluation parameters in all visits.
**Conclusions:** Although all patients showed significant improvement in all parameters during the study, paracetamol intake was significantly lower in the IFC group. This finding supports that IFC can decrease pain -even postoperative pain-. However, it is still uncertain which frequency is most suitable, how many times and how much minutes we need to use IFC in these patients in order to improve pain significantly.

## SAT0473 POOR DIETARY CARBOHYDRATE QUALITY IS ASSOCIATED WITH SYMPTOMATIC KNEE OSTEOARTHRITIS IN WOMEN: A CROSS-SECTIONAL STUDY

S. Lee[1], M.W. So[2], J.S. Oh[3]. *[1]Department of Internal Medicine, Inje University College of Medicine, Haeundae Paik Hospital, Busan; [2]Department of Internal Medicine, Pusan National University Yangsan Hospital, Gyeongnam; [3]Department of Internal Medicine, University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, Korea, Republic Of*

**Background:** Knee osteoarthritis (KOA) related to metabolic stress and its risk factors, so called metabolic KOA, is a well-known subtype. Recent epidemiologic studies showed that poor dietary carbohydrate quality, such as a high proportion of carbohydrate energy intake as sugar, is associated with a higher risk for metabolic complications and cardiovascular mortality.
**Objectives:** The purpose of this study was to analyze dietary nutritional factors

associated with KOA, focusing on the dietary glycemic index (DGI), a higher score of which means poor dietary carbohydrate quality.
**Methods:** This was a cross-sectional study including 9,203 participants aged ≥50 years from The Fifth Korean National Health and Nutrition Examination Survey, who were selected using two-step stratified clustered equal-probability systematic sampling. Radiographic KOA (RKOA) was defined as a Kellgren-Lawrence grade of ≥2. Dietary information was obtained using the 24-hour dietary recall method. The quality of dietary carbohydrate was calculated using glycemic index (GI) based on glucose (GI of glucose being 100). The amount of carbohydrate (g) from each food item participants recalled having had in the previous 24 hours was multiplied by the GI of each item, and the products were summed. The summation was divided by total carbohydrate intake (g) in the 24 hours, and the resulting average GI, the DGI was used as the measure of dietary carbohydrate quality. Sensitivity analysis was performed in a sub-population not undergoing diet modification for weight loss, and excluding participants having extremely high or low dietary energy intake (beyond 2 standard deviation of the distribution). All analyses were stratified by sex and weighted for the sampling design.
**Results:** The prevalence of each knee-state group was as follows: normal (NO) 72.0% (95% CI 70.2%–73.8%), radiographic KOA (RKOA) 16.8% (15.3%–18.3%), chronic knee pain without RKOA (CP) 6.8% (5.9%–7.8%) and symptomatic RKOA (SRKOA) 4.4% (3.8%–5.2%) in men, and NO 47.3% (45.4%–49.2%), RKOA 23.9% (22.4%–25.4%), CP 9.6% (8.7%–10.6%) and SRKOA 19.2% (17.8%–20.6%) in women. In women, DGI was significantly higher in CP (61.2 [SE 0.4]) and SRKOA group (63.1 [0.3]) than in NO group (59.3 [0.2]), and the estimates for age-adjusted mean difference were 1.3 (SE 0.4, P-value 0.007) for CP group and 1.2 (0.3, 0.001) for SRKOA group. In analysis adjusted for age, obesity and the day of week of the dietary recall, the association with SRKOA across quintiles of DGI was Q1 1.00 (reference), Q2 OR 1.20 (95% CI 0.81–1.76), Q3 1.54 (1.09–2.18), Q4 1.63 (1.14–2.32) and Q5 1.73 (1.22–2.44; P value 0.025). CP did not show a linear relationship across the quintiles of DGI. RKOA was not significantly associated with DGI. The association was consistent in the sub-population of no dietary modification and no extreme energy intake. In men, there was no significant association between DGI and any knee state.
**Conclusions:** There was a significant association between poor dietary carbohydrate quality and symptomatic KOA in women. This study provides the foundation for clinical research that addresses the causality of the relationship and the effect of dietary modification on KOA and its co-morbidities.
**Disclosure of Interest:** None declared

## SAT0474 A PROTEOMIC PANEL PREDICTS DRUG RESPONSE TO THE COMBINATION OF GLUCOSAMINE AND CHONDROITIN SULFATE

V. Kraus[1], H. Martinez[2], M. Herrero[2], J. Verges[2]. *[1]Duke Molecular Physiology Institute, Durham, United States; [2]Clinical R&D Area, Bioiberica S.A., Barcelona, Spain*

**Background:** Biomarkers can help identify patients that are more likely to respond favorably to a given therapy (a Predictive or patient stratification biomarker). Biomarkers can also be used to provide objective proof of a biological response to a drug (Efficacy of Intervention biomarker).
**Objectives:** The overall goal of this project was to identify protein biomarkers that predict likelihood of response to glucosamine hydrochloride and chondroitin sulfate (GH+CS), both predictive and efficacy of intervention biomarkers. We hypothesized that a subset of peptides in a mass spectrometry panel, developed to predict Osteoarthritis (OA) progression, would identify responders to GH+CS, knowing that CS is an NFkB activity and inflammation inhibitor.
**Methods:** This study analyzed a subset of 80 baseline serum samples from the MOVES (Multicentric Osteoarthritis Intervention Study with SYSADOA) trial[1]. The MOVES trial was an international multicentric, phase IV, double-blind, non-inferiority, randomized trial to compare the efficacy and safety of the combination of glucosamine hydrochloride (GH 1.500mg/day) and chondroitin sulfate (CS 1.200mg/day) known as Droglican® (Bioiberica), versus celecoxib Celebrex (200mg/day) in patients with Kellgren Lawrence grades 2–3 knee OA with severe pain. The sample selected for this study consisted of half drug responders and half non-responders by OARSI-OMERACT criteria. A total of 25 peptides from 23 proteins were analyzed by mass spectrometry. This panel was based on results of discovery proteomic studies in synovial fluid (n=23), urine (n=45) and serum (n=40) from knee OA subjects to identify biomarkers indicative of an OA diagnosis and OA progression.
Quantitative LC/MRM was performed on a 1 μg of protein digest spiked with 10 fmol of 25 stable isotope labeled peptides using a nanoAcquity UPLC system (Waters Corp) coupled to a Waters Xevo TQ-S triple quadrupole mass spectrometer via a nanoelectrospray ionization source. Technical variability (based on spiked in yeast alcohol dehydrogenase was 10.4%). Logistic regression was used to evaluate the association of demographics (age, gender and BMI) and the biomarkers with drug response (yes/no) after 180 days of treatment. P values <0.05 were considered significant.
**Results:** The sample was 90% female, mean age 64 (SD 7) years, 55% with BMI >30 kg/m$^2$. Higher age (p=0.004) but neither gender, nor KL grade were associated with likelihood of drug response. Age plus the marker panel significantly predicted drug response (overall model p=0.0007). In the multivariable logistic regression, adjusted for age, a total of 12 peptides, corresponding to 11 proteins, were significantly independently associated with drug response (p<0.0001 by Effect likelihood Ratio tests).
**Conclusions:** These biomarkers in theory could be used to stratify different patient groups in terms of likelihood of clinical response to GH+CS in efforts to develop personalized treatment algorithms for OA patients.

## SAT0475 HEALTH SYSTEM FRUSTRATION EXPRESSED BY PATIENTS WITH KNEE OSTEOARTHRITIS

V. Salaru[1], V. Sadovici-Bobeica[2], L. Mazur-Nicorici[2], A. Stirbul[2], T. Rotaru[2], M. Mazur[2]. *[1]Family Medicine; [2]Internal Medicine, State Univeristy of Medicine and Pharmacy, Nicolae Testemitanu,Chisinau, Moldova, Republic of*

**Objectives:** To explore the challenges experienced by patients with knee osteoarthritis.
**Methods:** A structured interview was conducted with patients that fulfilled the ACR classification criteria for knee osteoarthritis (OA) (1991). We collected data on demographic and socioeconomic characteristics, use of health and social services, and effect on occupation and living arrangements over the previous 12 months. The patients completed Knee Osteoarthritis Outcomes Score (KOOS) and Patient Satisfaction Questionnaire. This study was conducted according to the principles of the Declaration of Helsinki (1996) and Good Clinical Practice.
**Results:** There were 51 patients enrolled in the study including 39 females (76,5%), mean age 64,45 ±8,07 (range 50–82) and the disease duration was 9,9±6,97 (range 2–24) years. Knee pain was present in 49 (96%) of patients. The radiographic characteristics: KL I – 1 (1,9%), II – 29 (56,9%) patients, KLIII – 17 (33,3%) and the most severe form KLIV – 4 (7,9%) cases. The KOOS results showed that Pain was 59,6±20,6%, Symptoms 63,74±17,38%, Activity Daily Living – 45,35±21,1%, the possibility to practice sport was the worse score 25,69±25,2%, and the QoL-37,66±28,88% qualified as low. Patients notice health system frustration: poor communication (70,6%), uncoordinated health services (86,2%), lack of efficient and timely information (41,2%), that determine the difficulties in making decisions about their care. The patients in 50 (98,0%) cases manifested a high level of dissatisfaction with financial aspects (the out-pocket expenders representing 29,7% from incomes) and low level of social support.
**Conclusions:** Patients with knee osteoarthritis experience social-economic and organizational difficulties, their pointing could lead to the improvement of the quality of medical care and increased patient's satisfaction.

## SAT0476 EFFICACY OF 14% PLAI VS. PLACEBO CREAMS FOR SYMPTOMATIC CONTROL OF PATIENTS WITH KNEE OSTEOARTHRITIS

W. Kosuwon, W. Sirichativapee, T. Wisanuyotin, P. Paholpak, P. Laupattarakasem. *Orthopedics, Faculty of Medicine, Khon Kaen University, Khon Kaen, Khon Kaen, Thailand*

**Background:** Non-operative treatments for mild to moderate knee osteoarthritic (OA) is recommended. Plai (Zingibercassumunar Roxb.) belongs to the ginger family. It is a Thai herb used in Thai traditional medicine for relieving muscle and joint pain (1–2). Plai has anti-inflammatory activities due to compounds found in its extracts (1–4). These findings suggest that topical plai cream is a potentially useful drug for the treatment of painful OA of the joints. Since there have not been any studies on the efficacy of plai cream alone for relieving symptoms of OA knee joint, we aimed to test its value.
**Objectives:** To assess the efficacy of topical plai cream for the treatment of primary osteoarthritis (OA) knee.
**Methods:** This was a 9-week (4 weeks treatment + 1 week wash-out + 4 weeks placebo) phase III randomized, double-blind, controlled, cross-over, community trial of Plai vs. placebo, in adults with OA of the knee. This study aimed to determine whether Plai cream was more effective at reducing pain than a placebo cream, as measured using a visual analog scale (VAS) plus the Western Ontario McMaster (WOMAC) score.
**Results:** A total of 120 pairs of subjects were enrolled. The mean different VAS favoring Plai varied between 0.46 and 1.4 (p<0.05). The respective percentage of patients in the Plai group who reached MCII of VAS, WOMAC pain, stiffness and function was 37.9%, 40.10%, 26.45% and 54.58%. The respective percentage of patients in the Plai group who experienced 50% improvement of VAS, WOMAC pain, stiffness and function was 33.33%, 31.77%, 41.66% and 24.68%. The respective number of cases needed to treat to reduce pain of Plai based on MCII and 50% improvement of VAS was 2.63 (95% CI; 2.44, 2.84) and 3 (95% CI; 2.75, 3.29). Four cases in the Plai group had a mild skin reaction.
**Conclusions:** This cross-over, randomized, controlled, communit, trial demonstrated that Plai cream is an effective topical agent for relieving the symptoms of mild to moderate OA knee.

## SAT0477 LYSOPHOSPHATIDYLCHOLINES TO PHOSPHATIDYLCHOLINES RATIO PREDICTS ADVANCED KNEE OSTEOARTHRITIS

W. Zhang[1], G. Sun[1], D. Aitken[2], S. Likhodii[1], M. Liu[1], G. Martin[1], A. Furey[1], E. Randell[1], P. Rahman[1], G. Jones[2], G. Zhai[1]. *[1]Memorial university of newfoundland, St. John's, Canada; [2]University of Tasmania, Hobart, Australia*

**Background:** Knee Osteoarthritis (OA) is a heterogeneous disease with variable clinical outcomes. Some patients do not have any symptoms or significant functional loss for many years after the onset of the disease whereas others can progress rapidly to advanced stage [1], making it highly clinical relevant to identify those who are at high risk of progressing rapidly so that targeted interventions at early stage of the disease can be implemented [2–4].
**Objectives:** To identify novel biomarker(s) for predicting advanced knee OA.
**Methods:** Study participants were derived from the NFOAS and the TASOAC studies. All knee OA cases were patients who underwent total knee replacement (TKR) due to primary OA. Metabolic profiling was performed on fasting plasma using a targeted metabolomics approach. 4,018 plasma metabolite ratios that were highly correlated with that in synovial fluid in our previous study [5] were generated as surrogates for joint metabolism.
**Results:** The discovery cohort included 64 TKR cases and 45 controls and the replication cohorts included a cross-sectional cohort of 72 TKR cases and 76 controls and a longitudinal cohort of 158 subjects, of whom 36 underwent TKR during the 10-year follow-up period. We confirmed the previous reported association of the branched chain amino acids to histidine ratio with advanced knee OA ($p=9.3\times10^{-7}$) and identified a novel metabolic marker - lysoPCs to PCs ratio - that was associated with advanced knee OA ($p=1.5\times10^{-7}$) after adjustment for age, sex, and BMI. When the subjects of the longitudinal cohort were categorized into two groups based on the optimal cutoff of 0.09 of the ratio, we found the subjects with the ratio $\geq$0.09 were 2.3 times more likely to undergo TKR than those with the ratio $<$0.09 during the 10-year follow-up (95% CI: 1.2–4.3, p=0.02).
**Conclusions:** We identified the ratio of lysoPCs to PCs as a novel metabolic marker for predicting advanced knee OA. Further studies are required to examine whether this ratio can predict early OA change.

## SAT0478 COMORBIDITY IN HAND OSTEOARTHRITIS: ITS IMPACT ON HAND PAIN AND FUNCTION

W. Damman[1], R. Liu[1], F. Rosendaal[2], M. Kloppenburg[1]. *[1]Rheumatology; [2]Epidemiology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Although hand pain and function are important complaints in patients with hand osteoarthritis (OA), their determinants are unclear. Comorbidity is shown to be associated with complaints in knee and hip OA.
**Objectives:** Therefore, we studied the association of comorbidities with hand pain and function in hand OA patients.
**Methods:** Cross-sectional data were used of the HOSTAS (Hand OSTeoArthritis in Secondary care) study, which included consecutive patients diagnosed by their treating rheumatologist with primary hand OA from 2009 to 2015. Self-reported comorbidity was assessed by a 17-item list (modified Charlson index). Additionally, presence of knee and/or hip OA (poly OA) was determined by fulfilling the ACR criteria and presence of obesity by body mass index (BMI) $\geq$30 kg/m$^2$. Number of comorbidities (max 19) and groups of comorbidities (figure) were studied. Self-reported hand pain (0–20) and hand function (0–36) were assessed by Australian/Canadian Hand OA Index (AUSCAN, Likert scale), where higher scores mean worse health. Multivariable linear regression analysis was used to associate comorbidities with hand pain and function, adjusting for age, sex and education (3 categories, as proxy for socioeconomic status). To assess clinical relevance, we compared mean differences between absence and presence of specific comorbidities, with the minimal clinically important improvement (MCII, published by Bellamy et al.), which was 1.6 (95%CI 1.0 to 2.0) for pain and 1.4 (0.1 to 2.2) for function.
**Results:** 538 patients were included with a mean (SD) age of 61 (9) years, mean BMI of 27 (5) kg/m$^2$, 86% women and 91% fulfilling the ACR hand OA criteria. 27% had a low education level. 38% of patients reported $\geq$1 comorbidity (of 17), 24% had poly OA (mainly knee) and 23% had obesity. Mean (SD) pain and function were 9.3 (4.3) and 15.6 (8.5), where women had worse scores than men. Presence of any comorbidity was associated with worse pain and function; mean difference (95%CI) pain 1.1 (0.3 to 1.9) and function 1.8 (0.2 to 3.3). Also the number of comorbidities resulted in worse complaints (regression coefficient (95%CI) pain 0.8 (0.4 to 1.1) and function 1.4 (0.8 to 2.1)). Presence of poly OA or lung disease was associated with both pain and function, while presence of cardiovascular disease was associated with pain only and osteoporosis with function only. Other comorbidities, like obesity, were not associated (figure). For pain, only the presence of cardiovascular disease was similar to the MCII, while all associations (i.e. presence of any comorbidity, poly OA, osteoporosis and lung disease) were clinically relevant for function. For example, presence of lung disease resulted in 3.4 points higher (worse) score for function (figure), while MCII was 1.4, so this difference could be considered clinically relevant.

**Figure:** Association between specific comorbidities and hand pain or function. Mean differences with 95% confidence intervals, adjusted for age, sex and education.

| Comorbidity | Present/absent, n of patients | Self-reported pain | Self-reported function |
|---|---|---|---|
| Poly OA (ACR knee/hip) | 161/366 | **0.8 (0.01 to 1.7)** | **1.9 (0.3 to 3.5)** |
| Osteoporosis | 42/477 | 1.2 (-0.3 to 2.6) | **3.7 (0.9 to 6.5)** |
| Obesity | 121/402 | 0.6 (-0.3 to 1.5) | 1.1 (-0.7 to 2.8) |
| Diabetes mellitus* | 40/479 | 1.1 (-0.4 to 2.5) | 1.5 (-1.3 to 4.3) |
| Lung disease (COPD) | 58/461 | **1.3 (0.1 to 2.5)** | **3.4 (1.0 to 5.7)** |
| Malignant disease* | 34/485 | 1.2 (-0.4 to 2.8) | -0.2 (-3.2 to 2.9) |
| Gastrointestinal disease* | 24/495 | 1.0 (-0.8 to 2.8) | 2.4 (-1.1 to 5.8) |
| Cardiovascular disease* | 59/460 | **1.6 (0.3 to 2.9)** | 2.0 (-0.5 to 4.4) |

*Diabetes mellitus: combination of diabetes with and without end organ damage. Malignant disease: combination of malignancy and metastatic solid tumor. Gastrointestinal disease: combination of ulcer disease and mild and moderate/severe liver disease. Cardiovascular disease: combination of myocardial infarction, cardiac failure, peripheral vascular disease and stroke.

**Conclusions:** Presence as well as number of comorbidities showed a clinically relevant association with self-reported hand pain and function in patients with hand OA. Remarkably, as in knee OA, not only musculoskeletal comorbidity was associated with hand symptoms, but also non-musculoskeletal comorbidities (lung and cardiovascular disease). Further studies should investigate the role of comorbidities in clinical burden in hand OA and how these can be modified.

## SAT0479 ASSOCIATIONS BETWEEN ENDOGENOUS SEX HORMONES AND MRI STRUCTURAL CHANGES IN PATIENTS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS

X. Jin[1], B.H. Wang[2], X. Wang[1], B.E. Antony[1], Z. Zhu[1], W. Han[1], F. Cicuttini[3], A. Wluka[3], T. Winzenberg[1], L. Blizzard[1], G. Jones[1], C. Ding[1]. *[1]Menzies Institute for Medical Research, Hobart; [2]Centre of Cardiovascular Research and Education in Therapeutics; [3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

**Background:** Increased prevalence of knee osteoarthritis (OA) among post-menopausal women suggests involvement of endogenous hormones in pathogenesis. However, the effects of endogenous sex hormones on knee OA structures remain uncertain.
**Objectives:** To describe the longitudinal associations between serum levels of estrogen, progesterone and testosterone and knee structural changes using magnetic resonance imaging (MRI) in both males and females with symptomatic knee OA.
**Methods:** We examined 200 participants (mean age 63.0 ± 7.3 years) from a

clinical trial of vitamin D supplement for symptomatic knee OA. Serum levels of estradiol, progesterone, testosterone and sex hormone binding globulin (SHBG) were analyzed at baseline and 24 months later. Magnetic resonance imaging (MRI) scans of the knees were obtained at both baseline and follow-up for the measurement of cartilage volume, cartilage defects, bone marrow lesions (BMLs) and effusion-synovitis volume. Knee pain was assessed using a 100mm visual analogue scale (VAS). Longitudinal data were analyzed using linear mixed-effects model.

**Results:** 107 males and 93 females were included in this study. For females, after adjustment for age, body mass index, and treatment allocation, progesterone was associated with cartilage volume (β =0.12 per quartile, p=0.01). Estradiol levels were associated with lower grades of BMLs (β = -0.45 per quartile, p=0.03), while estradiol (β = -1.26 per quartile, p=0.05), progesterone (β = -1.60 per quartile, p<0.01) and testosterone (β = -1.49 per quartile, p=0.02) were inversely associated with effusion-synovitis volume for females. No consistent associations were observed for males.

**Conclusions:** Endogenous estradiol, progesterone and testosterone may be protective for joint structural changes in women but not men. This may contribute to observed sex differences in knee OA.

**Acknowledgement:** Jodi Barling, Kay Nguo, Judy Hankin and Alice Noone have been involved in the coordination of this study. Rob Warren measured knee cartilage volume.

**Disclosure of Interest:** None declared

### SAT0480 BONE MARROW LESION IN ADVANCED OSTEOARTHRITIS OF THE KNEES. CORRELATION STUDY BETWEEN HISTO-PATHOLOGICAL FINDINGS AND STRUCTURAL DAMAGE

Y. Hussein, H. Bassiouni, A. Aly. *Alazhar University Hospital, Cairo, Egypt*

**Background:** Osteoarthritis, the most common form of arthritis, is the leading cause of mobility-related disability in elderly persons. With the aging of the population, the prevalence of osteoarthritis is increasing. Loss of hyaline articular cartilage is a central pathologic event in osteoarthritis, but the pathogenesis of cartilage loss is poorly understood. Specifically, there is a paucity of information about what factors identify joints at high risk for progression. Identification of such factors might permit better understanding of the disease process.

**Objectives:** To correlate histopathology of a bone marrow lesion (BML) pattern with severity and structural damage in osteoarthritic knees.

**Methods:** Twenty consecutive patients (age range, 59–66 years; mean, 65 years) referred for total knee replacements were examined with sagittal short inversion time inversion-recovery (STIR) and T1- and T2-weighted MRI one week prior to surgery before surgery. Different structural abnormalities on MRI were compared with those on histologic maps.

**Results:** The histopathology of BML in cases of OA revealed that 6 biopsies of cases showing bone marrow fibrosis (30%), 4 of them grade 1 (20%) and 2 of them grade 2 (10%). 18 biopsies showing cyst (90%), 9 biopsies showing abnormal trabeculae (45%), 2 of them with grade 1 (10%), 4 of them grade 2 (20%) and 3 of them grade 3 (15%). 5 biopsies showing lymphocyte (25%), 40% of them had ++CD3, while 60% of them had ++CD20. 5 biopsies showing fatty marrow (25%), 9 biopsies showing haemosidrotic marrow (45%), 6 biopsies showing blood vessels (30%), 5 of them with grade 2 (25%) and 1 with grade 3 (5%).

The MRI findings of OA patients had been revealed that there were 6 patients with BML of grade 1 (30%), 10 patients of grade 2 (50%) and 4 patients of grade 3 (20%).

**Conclusions:**

– BML has a strong correlation with radiographic everity measurements of osteoarthritis of the knee and pain.
– In patients with knee osteoarthritis, BML in bone underneath cartilage markedly increase risk for structural progression in the knee.
– Hyperemia and hematopoietic marrow were possible reasons for appearance of BML as high signal- intensity on STIR images.
– BMLs are a cornerstone in progression of osteoarthritis.

## Infection-related rheumatic diseases

### SAT0481 CLINICAL FEATURES ASSOCIATED WITH HIGHER MORTALITY IN ADULTS WITH SEPTIC ARTHRITIS - A 10-YEAR RETROSPECTIVE STUDY

A. Premkumar[1], C. Pawa[1], M. Lahiri[2], A. Santosa[2]. *[1]Yong Loo Lin School of Medicine (National University of Singapore); [2]National University Health System, Singapore, Singapore*

**Background:** Septic Arthritis (SA) is associated with considerable morbidity and mortality.

**Objectives:** We describe the clinical features and outcomes of SA in patients admitted to a tertiary hospital in Singapore over 10 years.

**Methods:** Adult patients admitted between 2005 and 2015 with diagnosis codes for SA were identified from electronic medical records. Detailed medical record review was performed to confirm the diagnosis of SA based on positive gram stain or cultures from the joint, or alternatively a clinical diagnosis of SA with positive cultures from blood or genital swabs. Patients with negative cultures, purely extra-articular infections and insufficient documentation were excluded. Data were collected by 2 independent researchers with standardization performed on 30 randomly selected patients.

**Results:** 1067 patients were identified from diagnosis codes, of which 249 (23.3%) were confirmed to have culture positive SA. The median (IQR) age at diagnosis was 58 (46, 71) years and 64% were male. Sixty percent were Chinese, 22% Malay and 11% were Indian.

*Clinical features:* The most commonly affected joints were the knee (56.2%), shoulder (12.8%) and ankle (11.6%); 13.6% of patients had involvement of more than one joint. Fever was present in 43% patients and elevated white count (WC) and C-reactive protein (CRP) were observed in 62.6% and 96.8% respectively. Only 2.7% had both a normal CRP and WC. The most common organism was *Staphylococcus aureus* (53%), 29.6% of which (15.6% of all patients) were methicillin resistant *Staphylococcus aureus* (MRSA). Gram negative bacteria and Group B streptococcus (19.7% and 18.1%, respectively) accounted for most of the remaining cases.

*Predisposing conditions:* Pre-existing joint disease was identified in 59 (23.9%) patients (30 gout, 25 osteoarthritis, 5 rheumatoid arthritis and 1 systemic lupus erythematosus). Prosthetic joint infections accounted for 18.9% of cases. 3.6% patients were current intra-venous drug abusers and 27.7% had diabetes. Ten patients had potential preceding joint inoculation, including two with recent intra-articular corticosteroid injection and three with recent acupuncture to the index joint. Data on use of complementary medications and alcohol were not readily available in this retrospective study.

*Treatment and prognosis:* Eighty-three percent patients underwent surgical joint washout. Of those with prosthetic joint infection, 49% required removal of the prosthesis. The median (IQR) duration of intravenous antibiotics was 33 (18, 42) days and median (IQR) length of hospital stay was 21 (11, 35) days. 7.6% patients

Table: Clinical factors and their association with mortality in patients with culture positive septic arthritis

| Variable | Odds ratio (95% Confidence Interval) | P value |
|---|---|---|
| **Age, years (≥ 70 vs. < 70)** | **3.55 (1.09, 11.58)** | **0.04** |
| Female gender (vs. male) | 1.27 (0.39, 4.12) | 0.69 |
| Diabetes mellitus (vs. no diabetes) | 1.9 (0.58, 6.19) | 0.29 |
| Pre-existing joint disease (vs. none) | 1.06 (0.28, 4.07) | 0.93 |
| **White count ($10^9$/L) (for every 1 x $10^9$ increase)** | **1.11 (1.04, 1.18)** | **0.002** |
| CRP, mg/L (top vs. bottom tertile) (top tertile median = 319mg/L, bottom tertile median = 58mg/L) | 4.11 (0.45, 37.7) | 0.21 |
| **Fever (vs. those without fever)** | **0.10 (0.01, 0.82)** | **0.03** |
| Surgical washout (vs. no surgical washout) | 2.04 (0.25, 16.39) | 0.5 |
| Infection with *Staphylococcus aureus* (vs. other organisms) | 1.82 (0.53, 6.22) | 0.34 |
| Infection with Methicillin sensitive *Staphylococcus aureus* (MSSA) (vs. other organisms) | 0.53 (0.14, 2.03) | 0.36 |
| **Infection with Methicillin resistant *Staphylococcus aureus* MRSA (vs. other organisms)** | **4.26 (1.28, 14.21)** | **0.02** |

experienced a recurrence of infection in the same joint within a year. There were inpatient 12 deaths. Using univariate logistic regression, age ≥70 years, high WC, absence of fever and infection with MRSA were associated with higher mortality (Table).

**Conclusions:** *Staphylococcus aureus* remains the most common cause of SA. Most patients in our dataset had at least one predisposing factor. There were more deaths in patients who were afebrile at presentation, possibly because the absence of fever led to a delay in diagnosing SA. Early aggressive treatment may be warranted in older patients, especially in those with higher WC or infection with MRSA.

## SAT0482 RISK FACTORS FOR SEVERE INFECTION AND OUTCOME OF SECONDARY HYPOGAMMAGLOBULINAEMIA IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES TREATED WITH RITUXIMAB: PRELIMINARY RESULTS FROM 400 PATIENTS AT A SINGLE CENTRE

M.Y. Md Yusof[1,2], E.M. Hensor[1,2], S. Das[1,2], E.M. Vital[1,2], P. Emery[1], S. Savic[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds;* [2]*NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Rituximab (RTX) is used in various autoimmune rheumatic diseases (AIRDs) that are refractory to standard therapies. Attrition of long-lived plasma cells and hypogammaglobulinaemia may occur with repeat cycles of therapy leading to serious infection.

**Objectives:** To evaluate risk factors for severe infection and assess outcome of secondary hypogammaglobulinaemia during RTX treatment in AIRDs.

**Methods:** We conducted a retrospective observational study of all patients with AIRDs treated with RTX at a single centre.Each cycle of RTX consisted of 2x1000mg infusions repeated on clinical relapse. IgM, IgA and IgG levels were measured at baseline and 6 months after each cycle. Baseline factors for association with serious infection within 12 months of a RTX cycle were tested using univariate (UVA) and multivariate (MVA) logistic regression analyses.

**Results:** The first 400 consecutive patients from a total cohort of 800 were analysed. 254 (63%) had RA, 88 (22%) SLE, 47 (12%) AAV, 6 (1.5%) DM, 3 APS (1%) and 2 (0.5%) SSc. Total follow-up: 1650.3 patient-years. There were 166 serious infections recorded in 101 patients; 135 in 88 within 12 months of a cycle (8.1/100 patient years). Rates were lower in connective tissue disease (6.5) than RA (9.4). In MVA, previous severe infection, corticosteroids and low IgG were significantly associated with increased risk of serious infection.

Ig data were available in 375 (94%) patients. At RTX initiation, 23 (6%) patients had low IgG (normal range 6–16 g/L). Following RTX treatment, 18 remained low, 3 returned to normal and 15 had developed new low IgG. 6 patients required Ig replacement due to recurrent serious infections related to low IgG.

**Conclusions:** We have identified risk factors for serious infection at RTX initiation including previous serious infection, concomitant corticosteroids and low IgG. Most hypogammaglobulinaemia persisted with subsequent treatment thus highlighting the need for Ig monitoring. Further analysis of changes in Ig levels and infection in repeat cycles is in progress and can be used to develop guidelines for safety monitoring of rituximab.

## SAT0483 ULTRASONOGRAPHY CHANGES DURING THE COURSE OF SEPTIC ARTHRITIS ARE ASSOCIATED WITH FUNCTIONAL OUTCOME

E. Gaigneux[1], G. Cormier[2], O. Merot[3], Y. Maugars[1], B. Le Goff[1]. [1]*Nantes University Hospital, Nantes;* [2]*Hospital, la Roche sur Yon;* [3]*Hospital, Saint Nazaire, France*

**Background:** Ultrasonography (US) is useful to study the joints and the synovial tissue. It allows the evaluation of the synovial membrane thickness and inflammation. It can depict effusions and help to assess the surrounding soft tissues. Therefore, US could be of interest in the monitoring of septic arthritis.

**Objectives:** The main goal of this study was to describe the US changes observed during the course of septic arthritis and their association with clinical and functional outcomes.

**Methods:** We included all patients seen for a native joint infection in 3 different hospitals between January 2014 and July 2015. We collected baseline demographic, clinical, biological and microbiological characteristics. Patients were followed up prospectively with clinical and US evaluation at Day 0, 4, 15 and at 3 months (M3). US exam included the study of synovial membrane thickness, Power Doppler and involvement of the periarticular tissue. Evolution of the synovial thickness was compared to baseline (% of change). X-Ray of the joint was made at baseline and M3. Functional outcome was assessed at M3 (range of motion; SF-36 score).

**Results:** Thirty four patients were included, mean age 63.7 (range 22–90) with 24 men (70.6%). Most of the time, septic arthritis occurred in patients with pre-existing joint disease (n=24; 70.6%) and the knee was mostly affected (n=19; 55.9%). Predominant causative organism was Staphylococcus Aureus (n=15; 44.1%). Twelve patients (35.3%) underwent joint lavage mean time 4.2 days (range 0–13) after the diagnosis with synovectomy in 2 cases (5.9%). US synovitis was present in 96.4% of the cases at D0, 100% at D15 but was less frequent at M3 (77.8%; p=0.051). The synovial thickness increased at D4 and D15 compared to baseline (respectively median +17.3%, +20%, p=0.015) and significantly decreased at M3 (median -31.5%; p=0.015). Doppler signal was frequent (64.3% (D0); 66.7% (D4); 61.3% (D15)) and decreased significantly at M3 (25.9%; p=0.04). The effusion was present at D0 (92.8%), D4 (88.9%), D15 (80.6%) and significantly less frequent at M3 (55.6%, p=0.001). Periarticular abscess or cellulitis was rare (10.7% and 3.7% at D0 respectively). At M3, one patient died (2.9%) and 5 (14.7%) patients were lost to follow-up. Twenty (58.8%) patients had a decreased joint range of motion. A high total Sharp score and a high joint space narrowing score at M3 was associated with a late start antibiotic treatment (respectively p=0.048, p=0.03). We found no correlation between US characteristics and any of the baseline clinical or biological parameters. In contrast, joint limitation at M3 was associated with an increase of the synovial thickness between D0 and M3 (p=0.024) and with the persistence of Doppler at D15 and at M3 ((p=0.033; p=0.002).

**Conclusions:** Septic arthritis have a poor functional outcome in more than half of the cases. US synovitis remains present at 3 months in most patients but with a significant decrease in synovial thickness compared to baseline. Doppler signal persists in a quarter of the cases at M3. Persistence of Doppler signal and a thickened synovial tissue at 3 months are associated with a poor clinical outcome.

## SAT0484 LONG-TERM SAFETY OF NON-TNF INHIBITOR BIOLOGICS IN RHEUMATOID ARTHRITIS PATIENTS WITH CHRONIC OR PAST HEPATITIS B VIRUS INFECTION

C. Koutsianas, K. Thomas, E. Hadziyannis, A. Makris, A. Lazarini, D. Vassilopoulos. *Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National University of Athens Medical School, Athens, Greece*

**Background:** Rheumatoid arthritis (RA) patients with chronic hepatitis B virus infection (HBV) are at risk for HBV reactivation during TNF inhibitor (TNFi) therapy.

Recent data in patients with hematologic diseases have shown an increased risk for HBV reactivation after rituximab (RTX)-based therapies, even in past HBV infection. Similar data are sparse in RA patients especially with the newer non-TNFi biologics (abatacept-ABA, tocilizumab-TCZ).

**Objectives:** To evaluate the long term safety of non-TNFi biologics in RA patients with chronic or past HBV infection and in HBV vaccinated patients.

**Methods:** A retrospective systematic chart review of the 346 RA patients treated with biologics in our Rheumatology Unit from 1/1/2003 to 31/12/2015 was performed. All patients were followed regularly with appropriate clinical and laboratory monitoring (ALT, HBV DNA levels). We identified 44 patients; 8 with chronic HBV infection (HBsAg+), 25 with past infection (anti-HBc+/anti-HBs+ n=12, anti-HBc+ only n=10, anti-HBs+ only n=3) and 11 HBV vaccinated patients (anti-HBs+) who were treated with IV non-TNFi biologics (ABA, RTX, TCZ). Patient's files were reviewed for biochemical or virological reactivation and anti-HBs titers (before and during therapy) were measured in stored patients' sera.

**Results:** 38/44 (86%) of patients were women with a mean age of 64 ± 16.8 years and a mean disease duration of 14.4 ± 11.3 years. 28/44 (65%) were seropositive (RF and/or anti-CCP) and 80% had been previously treated with TNFi (median: 14 months). Eight patients with chronic HBV infection (all HBV DNA negative at baseline) received 9 courses of non-TNFi (RTX: n=4, ABA: n=4, TCZ n=1) under appropriate antiviral prophylaxis (tenofovir: n=5, lamivudine: n=2, entecavir: n=2, median treatment period: 19 months). During follow-up, no evidence of biochemical or virological reactivation was observed. Similarly, there were no cases of HBV reactivation among 25 patients with past HBV infection treated with 33 courses of non-TNFi (RTX: n=21, TCZ n=7, ABA: n=5, median treatment period: 18 months). Anti-HBs titers were measured during non-TNFi treatment in 26 anti-HBs+ patients (past infection: n=15, vaccinated: n=11, median interval between testing: 28 months) who had received 32 treatment courses (RTX: n=15, TCZ: n=12, ABA: n=5). Although anti-HBs titers decreased with all non-TNFi, this was statistically significant only for TCZ (from 436 ± 388 iu/L to 323 ± 368 IU/L, p=0.021) and not for RTX (from 394 ± 396 iu/L to 381 ± 417 IU/L, p=0.213) or ABA (from 362 ± 413 IU/L to 279 ± 410 iu/L, p=0.144). Anti-HBs titers dropped $<$10 IU/L in only 3 patients (10%, 2 with past infection on RTX, 1 vaccinated on TCZ); all had low anti-HBs titers before treatment (26 ± 9 IU/L) and none exhibited HBV reactivation.

**Conclusions:** In this long term study, non-TNFi biologics proved to be safe for patients with chronic HBV infection on oral antivirals as well as in patients with resolved HBV infection. Despite a small decrease in anti-HBs titers during treatment, only 10% of anti-HBs+ patients exhibited levels below the protective cut-off and this was not associated with HBV reactivation.

## SAT0485 PREVALENCE OF AUTOIMMUNE DISEASES IN HIV-INFECTED PATIENTS IN MEXICO

E. Martín Nares[1], J.F. Andrade Villanueva[2], L.A. González Hernández[2], J.J. Torres Ruiz[3], D. Gómez Martín[3], O. Morado Aramburo[4]. *[1]Internal Medicine; [2]HIV Unit, Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara; [3]Immunology and Rheumatology; [4]Internal Medicine, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

**Background:** Autoimmune diseases (AD) in patients with HIV have been observed since the beginning of the HIV/AIDS pandemic. Epidemiologic studies have reported a prevalence of rheumatic and autoimmune manifestations ranging from 1–72%, including only systemic (SAD) and articular AD (AAD), and not organ-specific AD (OSAD)[1]. Prevalence of AD in patients with HIV infection in Mexico has not been fully addressed.

**Objectives:** The aim of this study was to assess the prevalence of AD in HIV-infected patients.

**Methods:** We performed a retrospective study in two tertiary referral centers in Mexico. All subjects seen from june 15th 2003 to june 15th 2014 with a confirmed diagnosis of HIV infection and a diagnosis of an AD were included. We extracted demographic data, HIV infection history, and AD history from the clinical record

**Results:** A total of 5876 HIV-infected patients were seen during the study period. Eighty one AD were found in 77 patients (prevalence: 1.31%). Eight (9.9%) were SAD, 12 (14.8%) AAD and 61 (75.3%) OSAD (Table 1). Four patients (5.2%) had 2 AD. Fifty eight were male (75.3%). Mean age at diagnosis of AD was 34.8 years. In twenty two (27.2%) AD preceded HIV infection, in 23 (28.4%) HIV infection was diagnosed simultaneously with the AD, in 36 (44.4%) AD developed after HIV infection. Mean CD4 T lymphocyte count in patients with a simultaneous diagnosis of HIV infection and AD was 287 cel/μl, only one with undetectable viral load; mean CD4 T lymphocyte count in patients who developed AD after HIV infection was 353 cel/μl, half with undetectable viral load. Sixteen patients were classified with AIDS at AD diagnosis. Five (6.2%) AD were a consequence of immune reconstitution inflammatory syndrome (IRIS); prevalence of autoimmune IRIS was 0.08%. Prevalence of HBV and HCV coinfection was 5.2% and 2.6% respectively. Immunosuppressive treatment was used in 87% of patients.

Table 1

| Autoimmune diseases | No. | Prevalence |
|---|---|---|
| Systemic: SLE (5), AFS (1), Sjögren syndrome (1), DILS (1) | 8 | 0.13% |
| Articular: rheumatoid arthritis (5), spondyloarthritis (7) | 12 | 0.20% |
| Neurological: Guillain-Barré syndrome (3), CIDP (2), ADEM (1) | 6 | 0.10% |
| Dermatologic: psoriasis (10), vitiligo (1), alopecia areata (1), cutaneous vasculitis (3) | 15 | 0.25% |
| Endocrinological: DM1 (5), autoimmune adrenal insufficiency (2), Graves' disease (3), Hashimoto's thyroiditis (1) | 11 | 0.18% |
| Gastroenterological/hepatic: ulcerative colitis (6), Crohn's disease (2), autoimmune hepatitis (2) | 10 | 0.17% |
| Hematologic: immune thrombocytopenia (18), autoimmune hemolytic anemia (1) | 19 | 0.32% |

**Conclusions:** This is the first study to address solely AD without combining non-autoimmune musculoskeletal entities and the largest cohort to date. Prevalence of AD in HIV-infected patients in Mexico was low (1.31%) and OSAD was the most frequent. AD were diagnosed in all stages of HIV infection. Prevalence of HBV and HCV coinfection and autoimmune IRIS was very low. Prospective studies are needed to identify risk factors for the development of autoimmune IRIS.

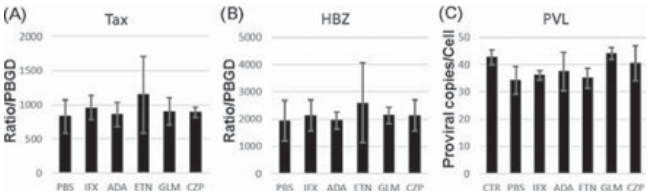
## SAT0486 TNF INHIBITORS HAVE NO EFFECTS TO HUMAN T-LYMPHOTROPIC VIRUS TYPE-I (HTLV-I)-INFECTED CELL LINE



S. Fukui[1], H. Nakamura[1], Y. Takahashi[1], H. Hasegawa[2], K. Yanagihara[2], T. Nakamura[3], A. Kawakami[1]. *[1]Immunology and Rheumatology; [2]Laboratory Medicine, Nagasaki University Graduate School of Biomedical Sciences; [3]Human Community, Nagasaki International University, Nagasaki, Japan*

**Background:** Biologics are very effective to autoimmune diseases including rheumatoid arthritis and ankylosing spondylitis, but could cause infectious diseases as adverse effects. Human T-lymphotropic virus type-I (HTLV-I) is a retrovirus that infects 10 to 20 million people worldwide (1). The virus is associated with severe diseases, such as adult T-cell leukemia/lymphoma and HTLV-I-associated myelopathy (HAM). It is unknown if HTLV-I proliferates when biologics including TNF inhibitors (TNFi) are used.

**Objectives:** We evaluated effects of TNFi to HTLV-I infected cells regarding cytokine profiles, TNF receptor (TNFR), mRNA of associated proteins, proviral load (PVL) and apoptosis.

**Methods:** We used an HTLV-I infected cell line named HCT-5, which is derived from cells in spinal fluid of a patient with HAM. Multiplex cytokine/chemokine bead assays, cytokine levels assessed by enzyme-linked immunosorbent assays (ELISA), fluorescence activated cell sorting (FACS) analysis of TNFR, immunofluorescence staining of GAG, which is a HTLV-1 structural protein, quantitative reverse transcription PCR for Tax (2) and HTLV-I bZIP factor (HBZ) (3), which are needed for immortalization and proliferation of HTLV-I infected cells respectively, HTLV-I PVL (4), and apoptotic ladder detection were performed. We also used Jurkat as a control cell line.

**Results:** Multiplex cytokine/chemokine bead assays showed supernatants of HCT-5 without any stimuli had time-dependent elevation of IL-6, TNF-alpha, RANTES and ICAM-1. Supernatants of HCT-5 treated with infliximab (IFX), adalimumab (ADA), etanercept (ETN), golimumab (GLM) and certolizumab pegol (CZP) assessed by ELISA showed no differences in levels of these molecules compared to that of HCT-5 with phosphate buffered saline (PBS). In FACS analysis, except for TNFR 2 with ETN, expressions of TNFR 1 and TNFR 2 with each TNFi did not differ from PBS. TNFR 2 declined and internalization of TNFR 2 was detected in HCT-5 with ETN. There was no differences in levels of mRNA of Tax (Figure A, PBGD: house keeping gene) and HBZ (Figure B) with TNFi compared to that with PBS. PVL were also not changed (Figure C, CTR: without any reagents). Immunofluorescence staining of GAG showed no differences between each TNFi and PBS. DNA ladder was not detected in any TNFi and PBS.

**Conclusions:** *In vitro*, TNFi did not affect the cytokine profiles, TNFR 1, mRNA of associated proteins, proviral load and apoptosis of HCT-5. Only ETN caused internalization of TNFR 2.

## SAT0487 SCREENING FOR PAST INFECTION WITH HEPATITIS B IN PATIENTS RECEIVING RITUXIMAB: AN AUDIT

M. Cates, C. Gut. *Department of Rheumatology, Derriford Hospital, Plymouth, United Kingdom*

**Background:** Hepatitis B virus (HBV) causes an acute, often subclinical infection which can progresses to chronic disease with active viral replication. The risk of chronic infection is determined largely by the age at which the virus is contracted. Even in patients who clear the initial infection, the virus may lie dormant; one study found evidence of HBV DNA in 13 of 14 healthy liver donors with serological evidence of past but not current infection (HBV surface antigen (HBsAg) negative, core antibody (HBcAb) positive) [1]. There are case reports of viral reactivation in patients receiving immunosuppressive therapy including rituximab and as such Roche recommend screening all patients to include HBsAg and HBcAb prior to treatment [2]. In our experience not all rheumatology clinical staff are familiar with this guidance.
**Objectives:** Our primary objective was to establish what proportion of patients receiving rituximab through a rheumatology department were fully screened for HBV before and after an education programme. Our secondary objective was to establish what proportion of newly screened patients had evidence of past HBV infection.
**Methods:** We undertook an audit of patients receiving rituximab for all rheumatological indications between January and August 2015 in a unit with a catchment area of 450,000 patients. We recorded the proportion of patients who were tested for HBsAg and HBcAb prior to treatment and then undertook an education programme to clinical staff and updated an electronic blood requesting system before re-auditing patients between September 2015 and January 2016.
**Results:** 89 rheumatology patients received Rituximab between Jan 2015 and August 2015. 43 (48%) had a complete screen (HBsAg and HBcAb) prior to treatment; 37 (42%) had been tested for sAg only; 7 (8%) for HBcAb only and 2 (2%) had neither test. Following an education programme 60 of 68 patients (90%) were fully screened. 38 patients were newly tested for HBcAb and 1 patient was found to be HBcAb positive suggestive of past infection (HBsAg negative). Subsequent analysis for HBV DNA was negative. Following discussion with a hepatologist this patient was treated with lamivudine whilst continuing Rituximab therapy.
**Conclusions:** There is a risk of reactivation of HBV in patients who have evidence of past infection and are treated with rituximab. We found there was some uncertainty regarding the required serological screening blood tests amongst rheumatology staff, highlighted by incomplete testing in 52% of patients receiving Rituximab. Following an education programme, the proportion of patients completely screened rose to 90%. One patient with evidence of past infection was identified.

## SAT0488 TUBERCULOSIS IN A REGISTRY OF RHEUMATIC PATIENTS TREATED WITH BIOLOGICAL DRUGS

N. Benzaquén, M. Haye Salinas, J. Pirola, S. Retamozo, F. Caeiro, A. Alvarellos, M. De la Vega, G. Casado, G. Gomez, G. Citera, M. Gallardo, A. Quinteros, I. Exeni, M. Medina, P. Astesana, C. Sanchez Andia, J. Sarano, A. Granel, A. Peluzzon, A. Cappucciona, A. Eimon, R. Quintana, B. Pons Estel, E. Mussano, S. Scarafia, F. Tamaño, C. Costi, M. De la Sota, K. Kirmayr, E. Velozo, A. Ortiz, M. Larroudé, A. Bertoli, S. Aguero, C. Battagliotti, S. Soares de Souza, E. Cavillon, A. Perez Dávila, J. Barreira, J. Roberti, V. Saurit. *SAR, Córdoba, Argentina*

**Background:** Biologic therapies (bDMARDs) have improved the treatment of rheumatic diseases; however, the risk of tuberculosis (TB) infection or reactivation in patients treated with this drug class remains a concern.
**Objectives:** We investigated the clinical characteristics and prognostic factors of TB in an Argentine registry of rheumatic diseases patients treated with bDMARDS.
**Methods:** Database included demographics of patients, type and duration of treatments and clinical information of adverse events. A control group was included for comparison consisting of patients not treated with bDMARDs but similar demographics. Values are expressed as mean±standard deviation, median (ranges), and frequencies (percentages), as appropriate. Multivariate logistic regression analysis was used to identify variables associated with the occurrence of TB; OR and 95% CI were calculated by exponentiation of regression coefficients.
**Results:** As of January 2016, 3483 patients, 4762 treatments and 2580 adverse events were studied. Mean age 56.1±15,7 years; 2748 (78.9%) patients were women. Initial treatments were 1472 (42.3) bDMARD *vs.* 2011 (57.7) non-bDMARD. Main diagnosis: Rheumatoid arthritis (RA) 2706 (77.7), Psoriatic arthritis (PsA) 293 (8.4), juvenile idiopathic arthritis (JIA) and lupus with 117 (3.36) each. Of 4762 treatments, most frequent biological drugs were etanercept 119 (25,1), adalimumab 626 (13,2), and abatacept with 282 (5.9). Of 3483 patients, 18 (0.5) presented TB as an adverse event, their mean age was 52.9±2.8; 16 (88.9) had AR and 2 (11.1) had PsA; 16 (88.9) had initially received bDMARD vs. 2 (11.1) who had received non- bDMARD treatments. PPD test was performed in 2002/2883 (69.4) bDMARD treatments vs. 372/1879 (19.8%) non-bDMARD treatments, with 126 (6.3) vs 35 (9.4) positive tests, respectively. Median time from treatment commencement to TB was 15.1 (range 1.6–137.5) months. Treatments during which, TB was diagnosed were etanercept 5 (27.8), adalimumab 4 (22.2), non-bDMARD 3 (16.7), abatacept and infliximab with 2 (11.1) each and tocilizumab 1 (5.6), the distribution was not significantly different (Table 1). The risk of developing TB was higher in patients whose first treatment was bDMARDs (OR 5.6 95%CI 1.3–24.3).

**Conclusions:** A higher frequency of TB was seen in patients treated with bDMARDs; however, results should be interpreted cautiously because of registries inherent limitations.
**Disclosure of Interest:** None declared

## SAT0489 BIOLOGIC THERAPIES AND INFECTIONS IN THE DAILY PRACTICE: A STUDY ON HISTORICAL COHORT FROM 3 ITALIAN RHEUMATOLOGIC UNITS

P. Cipriani[1], O. Berardicurti[1], F. Masedu[2], F. D'Onofrio[3], L. Navarini[4], P. Ruscitti[1], N. Maruotti[3], D.P.E. Margiotta[4], V. Liakouli[1], P. Di Benedetto[1], F. Carubbi[1], M. Valenti[2], F.P. Cantatore[3], A. Afeltra[4], R. Giacomelli[1]. *[1]Division of Rheumatology; [2]Division of Medical Statistic Unit, University of L'Aquila, L'Aquila; [3]Rheumatologic Clinic, University of Foggia, Foggia; [4]Unit of Allergology, Immunology, Rheumatology, Campus Bio-Medico University, Rome, Italy*

**Background:** Since the introduction of biologics many concerns about the increased risk of infections, have been reported [1]Available data from randomized controlled trials, national registries and open label studies do not fully clarify the magnitude of this risk [2]. To date, the real impact of infections in the daily practice in the rheumatologic centers is still largely unknown.
**Objectives:** To evaluate the infection rates associated with the use of biologics in a large cohort of patients enrolled in 3 tertiary referral rheumatologic units in Italy. In addition, the risk of infections, including serious infections, was correlated with different clinical features.
**Methods:** A retrospective study, between January 2010 and December 2013, enrolled 731 rheumatic patients: 332 with rheumatoid arthritis (RA), 308 with psoriatic arthritis (PsA), 85 with ankylosing spondylitis (AS), 16 with primary Sjogren syndrome (pSS). Demographic and disease characteristics, therapies, comorbidities and infectious events were recorded and statistically analysed by multivariate analysis.
**Results:** All patients received at least 1 biologic, 82 patients 2 biologics, 30 patients 3 biologics, 6 patients 4 biologics and 4 patients 5 biologics. Two-hundred-thirty-five infectious episodes were observed in 208 (28.4%) patients. About total infections, bacteria were identified in 70.6% out of total cases, and viruses in 18.3%. The most common site of infection was the urinary tract (39.1%). Duration of disease (p=0.02), longer follow-up (p=0.0001), concomitant steroid therapy (p=0.001), comorbidities (p=0.015), treatment with infliximab (p=0.001), etanercept (p=0.029), golimumab, (p=0.004), abatacept (p=0.0001) and tocilizumab (p=0.0001) were significantly associated with any infection. In our cohort, 17 episodes fulfilled the criteria of serious infection, and occurred in 17

different patients (2.3%), the majority involving the lower respiratory tract (41.2%). Serious infections were associated with the beginning of biologics in older age (p=0.002), the use of i.v. therapy with infliximab (p=0.02), rituximab (p=0.05) and tocilizumab (p=0.01).

**Conclusions:** Surprisingly, our study shows that, in daily practice, a lower rate of infections was observed in our patients, when compared with previous reports. Duration of disease, concomitant steroid therapy and comorbidities may be considered risk factors for the occurrence of infections in treated patients. Of note, serious infections seem to be associated with older age of patients and i.v. treatments.

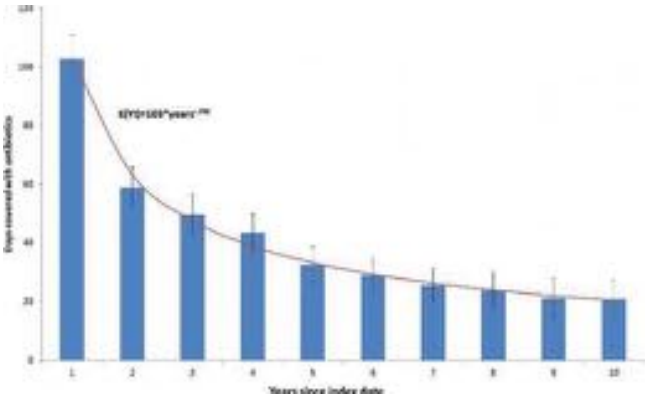
## SAT0490 POOR LONG-TERM ADHERENCE TO SECONDARY PENICILLIN PROPHYLAXIS AMONG PEDIATRIC PATIENTS WITH RHEUMATIC FEVER



G. Amarilyo[1,2], G. Chodick[3], I. Somekh[2,4], J. Zalcman[2], L. Harel[2,5]. *[1]Pediatric Rheumatology Unit, Schneider Children's Medical Center of Isarel, Petah-Tikva; [2]Sackler School of Medicine, Tel Aviv University; [3]2Department of Medical Informatics, Maccabi Healthcare Services, Tel Aviv; [4]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [5]Pediatric Rheumatology Unit, Schneider Children's Medical Center of Israel, Petah Tikva, Israel*

**Background:** Recurrent episodes of acute rheumatic fever (RF) may contribute to the development or worsening of rheumatic heart disease (RHD) and was estimated to occur in 50–70% of RF patients prior to the introduction of penicillin. Meta-analyses from the United States showed that secondary penicillin prophylaxis (SPP) may reduce the incidence of RHD. Moreover, SPP using monthly Intra muscular (IM) Benzathine Penicillin was more effective in prevention of RF recurrences than daily oral SPP.

**Objectives:** We aimed to evaluate the long-term adherence to SPP in RF patients using real-life data.

**Methods:** The study population included children up to 18 years old in Maccabi Healthcare Services (MHS), a 2-million member health organization in Israel, who were diagnosed with acute RF between 1/1996 to 5/2015 and were dispensed at least one monthly pack of penicillin (either in oral or IM form). Treatment persistence was defined as continuation of drug use for the entire duration of therapy or until age 18, whichever occurred first. Adherence to treatment refers to the extent of drug use during the period of persistence, expressed as mean proportion of days covered (PDC). This was calculated by dividing the quantity of penicillin dispensed by the total time span between index date and age 18, leaving MHS, or 31 April 2015, whichever occurred first.

**Results:** A total of 842 RF patients were identified. Mean (SD) ages at diagnosis among patients on oral (n=734) and IM (n=108) initial therapy were 8.6y (3.7y) and 10.9y (3.2y), respectively. The median PDC for the treatment regimens were oral: 8% [interquartile range (IQR) 2–33%] and IM: 10% (IQR 3–28%). Overall, days covered with SPP (figure 1) decreased exponentially from 103 days in the first year of therapy to 20 days in the 10th year.

**Conclusions:** Adherence and persistence to secondary penicillin prophylaxis among Israeli children diagnosed with RF is poor. Although less effective, oral SPP was the preferred regimen. Intervention plans to increase adherence and persistence to SPP must be implemented in countries where RF still exists.

**Disclosure of Interest:** None declared

## SAT0491 HIGHER LEVELS OF ANTI-BORRELIA IGG ASSOCIATE WITH ARTHRITIS IN LYME DISEASE AT PRESENTATION: A NORTHERN ITALY REFERRAL CENTER COHORT

A. Berti[1], M. Felicetti[2], A. Volpe[3], R. Bortolotti[3], F. Cavatorta[3], G. Barausse[3], S. Peccatori[3], L. Leveghi[3], C. Pedrotti[4], G. Paolazzi[3]. *[1]Internal Medicine and Clinical Immunology, San Raffaele Scientific Institute, Milan; [2]Department of Rheumatology, University of Padua, Padua; [3]Department of Rheumatology; [4]Unit of Microbiology and Virology, Santa Chiara Hospital, Trento, Italy*

**Background:** Lyme disease (LD) is a multisystemic infection caused by Borrelia burgdorferi (*Bb*) *sensu lato* complex, involving skin, joints, nervous system and heart.

**Objectives:** To assess clinical and serological data of patients with LD at presentation in an endemic area of Northeast Italy (Trentino), with a special focus on rheumatic manifestation.

**Methods:** We retrospectively collected clinical data of *Bb* seropositive patients from 2014 to 2015, tested with ELISA (Enzyme-Linked Immunosorbent Assay) IgM/IgG and Western blot (WB; IgM/IgG immunoblots). Only patients with a LD' diagnosis confirmed by a trained physician of our center were selected. Other laboratory and instrumental tests (*Bb*-PCR on synovial fluid, anti-*Bb* antibodies research on cerebrospinal fluid, etc.) were performed if deemed necessary by clinical judgment.

**Results:** Seventynine patients resulted seropositive for *Bb*, but only 54 met the inclusion criteria. Among patients with confirmed LD, 27 (50%) were female, mean age at presentation was 48±21years; children were 12.9%. The main presenting symptom was erythema migrans in 72% of cases (39/54), arthritis in 17% (9/54), flu-like symptoms in 7% (4/54), chronic atrophic acrodermatitis and cognitive dysfunction in 2% of cases (1 patient each). Among arthritis, 89% (8/9) presented with acute knee monoarthritis and one patient with hand PIP arthritis. Other concomitant or further developed manifestations were CNS involvement (2/54), cranial neuropathy (1/54), pleuropericarditis (1/54), I°grade atrioventricular block (1/54), transitory leucopenia (2/54), flu-like symptoms (12/54). All patients received antibiotic treatment: 58% doxycycline, 25% amoxicillin, 5% ceftriaxone (12% not reported). Twentysix (48%) patients remember tickborne bite, with a mean latency of 10.4±16.9 weeks.

When compared to the rest of the cohort, patients presenting with arthritis were younger (48y±12 vs 56y±12; p=.04), remember tickborne bite in 22% of cases (2/9; p=ns), and had increased ESR (mm/h, 51.1±36.6 vs 24.3±20.3; p=.03) and CRP levels (mm/L, 19.6±23.3 vs 5.6±10.2; p=.01).

Arthritis-presenting LD-patients had higher serum IgG antibody levels if compared to overall non-arthritis presenting LD-patients (124.0 vs 25.5; $p<.0004$) and to the subset tested for anti-*Bb* antibodies presence after the 4th week from bite (124.0 vs 29.0, $p<.0003$; mean latency 7.8±5.9 weeks).

**Conclusions:** Arthritis is the second most frequent presenting symptoms of LD (17%). Knee monoarthritis is typical, patients affected are younger and only 20% recall a tick bite.

We first demonstrated higher levels of serum anti-*Bb* IgG antibodies in patients presenting with arthritis. This seems not directly related to a longer time from bite to disease development, since anti-*Bb* IgG levels of patients with arthritis remain significantly higher if selectively compared to patients without arthritis tested for antibodies after the decline of the primary immune response, after 4th week.

## SAT0492 WHIPPLE'S DISEASE MIMICKING RHEUMATOID ARTHRITIS LEADS TO MISDIAGNOSIS, TREATMENT FAILURE, AND PROLONGED DISEASE COURSE: A SINGLE-CENTER CASE SERIES OF SEVEN PATIENTS

C. Glaser[1], S. Rieg[2], C. Scholz[3], T. Wiech[4], R.E. Voll[1], J. Thiel[1], N. Venhoff[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Center for Infectious Diseases, University Medical Center; [3]Rheumatology, Private Practice, Freiburg; [4]Institute of Pathology, University Hospital Eppendorf, Hamburg, Germany*

**Background:** Whipple's disease (WD) is a rare disease caused by a chronic infection with *Tropheryma whipplei* (TW). Joint involvement is common. The rarity, the broad spectrum of symptoms, and the similarity to rheumatoid arthritis (RA) may result in misdiagnosis. Without antibiotic treatment WD may be fatal, misleadingly induced immunosuppressive treatment may even accelerate disease progression.

**Objectives:** To describe the clinical presentation, the disease course with respect to immunosuppressive treatment and the response to antibiotic treatment in patients with WD presenting with inflammatory arthritis.

**Methods:** Retrospective single center observational study of seven patients. Medical charts were screened for articular and extra-articular symptoms. Diagnosis of WD was made by histological analysis using periodic acid-Schiff stain (PAS) and/or polymerase chain reaction (PCR).

**Results:** Median age at disease onset was 57 years (range 34- 64), six patients were male. The median time until diagnosis of WD was 5 years. All patients presented with polyarthritis with a predominantly symmetric pattern in

five and a chronic, intermittent disease course in six patients. Affected joints were: wrists (5/7), MCP (5/7), knees (5/7), PIP (3/7), hips (2/7), elbow (2/7), shoulder (2/7). All patients had increased C-reactive protein and/or ESR and were negative for RF and anti-CCP-antibodies. Three had erosive arthritis. Thus, initially all patients were classified as a seronegative RA following EULAR/ACR criteria with a median DAS28 of 4.34 (range 2.8–6.28). All but one patient received antirheumatic treatment consisting of prednisone (n=6), combined with methotrexate (n=5) or leflunomide (n=4). Three patients were treated with at least one biologic agent (anti-TNFα, abatacept, rituximab, tocilizumab). All patients showed insufficient treatment response, in one disease course was even worsened by the use of biologicals. Finally diagnosis of WD was made by a combination of positive PAS staining and a positive TW-PCR test in three patients. In five patients PCR was positive in at least two different sites. In all patients TW was detected in synovial fluid. Extra-articular manifestations of WD were frequent, but mainly mild and unspecific for WD, GI-symptoms were mild or absent even in patients with TW detected in small bowel biopsy. Five patients received long-term trimethoprin/sulfamethoxazole, two started with doxycycline plus hydroxychloroquine. Five patients had to change antibiotic regimen due to side effects or microbial resistance. All had a good treatment response with improvement of arthritis and extra-articular manifestations. Two are still on antibiotics while five patients could already stop treatment.

**Conclusions:** WD is rare and can mimic RA. Patients are therefore at risk of not only a delay of diagnosis but also of receiving insufficient or even worsening treatment. Hence, seronegative RA with a prolonged disease course and insufficient treatment response should be reevaluated for WD.

**Disclosure of Interest:** None declared

## SAT0493 TUBERCULOSIS OF THE HAND: CLINICAL PRESENTATION AND TREATMENT

M.A. Sbai[1], H. Sahli[2], W. Khoffi[1], A. Ben Tekaya[3], R. Tekaya[3]. *[1]Traum Department; [2]Rhumatology Department, Mohamed Taher Maamouri University Hospital, Nabeul; [3]Rhumatology Department, Charles Nicolle Hospital, Tunis, Tunisia*

**Background:** The tuberculosis remains one of the most world wide spread infectious diseases. The ostéoarticular localization is rare, affecting the hand remains exceptional. The incidious presentation, the poor symptomatic character of the tubercular dactylitis may explain the constant delay in the diagnosis. It is often delayed and confused essentially with bone tumors which imply histological confirmation.

**Objectives:** To study the epidemio-clinical features, stages, therapeutics and course of tuberculosis of the hand.

**Methods:** We made a retrospective study of 14 medical records of cases of tuberculosis involving the hands in an orthopedic department over the last ten years. We collected and analyzed the clinical, bacteriological, radiological and therapeutic data.

**Results:** The mean age was 45 years. There were 9 men and 5 women. A manual work was noted in 10 cases. Two patients had a diabetes mellitus and one breast cancer. The dominant side was achieved in 60% of cases. Mean symptoms duration was 3.6 months. Lesions are divided into 6 cases of pseudotumoral tuberculosis of soft tissue of the hand, arthritis and osteoarthritis in 5 cases and tenosynovitis in 3 cases. The ring and little fingers are the most affected fingers. Biopsy was done in all cases. Anti-tubercular chemotherapy was indicated for all patients: isoniazid, rifampicin, pyrazinamide and ethambutol for 2 months followed by isoniazid and rifampicin during 10 months. These antibiotics were combined with immobilization in all cases. Good outcome was seen in the 14 cases.

**Conclusions:** Tuberculosis should be suspected in cases of longstanding pain and swelling of a finger especially in an endemic area. Efficiency of anti-tubercular treatment remains undisputed. The surgical indications are limited to the biopsy, usually essential to the diagnosis.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3688

## SAT0494 BACTERIOLOGIC PROFILE OF SEPTIC ARTHRITIS: A RETROSPECTIVE STUDY OF 59 CASES

A. Bachali[1], H. Sahli Ep Hedi[2,3], R. Tekaya[4], I. Mahmoud[4], R. Khalfallah[2], O. Saidane[4], L. Abdelmoula[4]. *[1]Laboratory Department, Mohamed Taher Maamouri University Hospital; [2]Rhumatology Department, Mohamed Taher Maamouri University Hospital, Nabeul; [3]Rhumatology Department, Hôpital Universitaire Mohamed Taher Maamouri de Nabeul, Dar Chaabane El Fehri; [4]Rhumatology Department, Charles Nicolle Hospital, Tunis, Tunisia*

**Background:** Septic arthritis (SA) is an infection of synovial tissue that can affect one or more joints in patients of any age. It is considered as a medical and therapeutic emergency. Diagnosis is based on the presence of a microorganism in joint aspiration or in withdrawal of a possible gateway or a secondary location.

**Objectives:** To describe the bacteriologic profile of SA among adult subjects in a rheumatologic department.

**Methods:** This is a descriptive retrospective study including records of cases of SA collected in a rheumatology department, over a period of 17 years [1998–2014]. The epidemio-clinical features and evolution were noted. Bacteriologic exams were collected and analyzed.

**Results:** Fifty nine records of 59 patients with SA were selected. The mean age was 54.6 ± 19 years [range 15 to 95]. There were 28 men and 31 women with a sex ratio M/F =0.9. Fifty 50 cases (84.7%) had a single joint involvement, 6 cases (10.2%) had oligoarticular arthritis and 3 cases had polyarticular arthritis (5.1%). The joint aspiration was performed in 53 patients (89.8%). The appearance of the liquid was clear in 6 cases (11.5%), hematic in 5 cases (9.6%), purulent in 18 cases (34, 6%) and trouble in 23 cases (44.2%). White blood cells varied between 4000 and 100,000/mm$^3$ with an average of 27.520 elements. Direct bacteriologic exam was positive in 16 cases (30.8%). Twenty seven subjects (46%) had a positive culture. The study of the synovial fluid identified staphylococcus as the most frequently isolated microorganism (5 cases), followed by Streptococcus (3 cases), Koch bacillus (2 cases) and E.Coli (2 cases). One patient had septic arthritis due to Neisseria gonorrhoeae.

**Conclusions:** The bacteriologic profile is this series is not different than known in literature but showed that less than a half of patients had an identified microorganism as defined the SA.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3257

## SAT0495 CHIKUNGUNYA VIRAL ARTHRITIS IN MEXICO: INFLAMMATORY BIOMARKERS, DISABILITY AND DISEASE ACTIVITY INDEX MAY BE PREDICTORS OF CHRONIC ARTHRITIS

J. Sepúlveda-Delgado[1,2], O.L. Vera-Lastra[3], L.J. Jara[4], K.D.C. Trujillo Murillo[5], R.A. Sanchez Gonzalez[5], A. Lugo Trampe[6], A. Contreras Contreras[7], A. Mendoza Torres[7], J.C. Ramirez Valdespino[8], M. Ocaña Sibilla[8]. *[1]Head of Internal Medicine Department, Hospital Regional de Alta Especialidad Ciudad Salud; [2]Internal Medicine Department, Instituto Mexicano del Seguro Social, Tapachula; [3]Head of Internal Medicine Department, Instituto Mexicano del Seguro Social, UMAE Centro Médico la Raza; [4]Education and Research Unit, Instituto Mexicano del Seguro Social, Mexco City; [5]Research Unit, Hospital Regional de Alta Especialidad Ciudad Salud; [6]Molecular Biology Department, Centro Mesoamericano de Salud Pública y Desastres, Tapachula; [7]Internal Medicine Department, Hospital Juarez de México, Mexco City; [8]Internal Medicine Department, Hospital Regional de Alta Especialidad Ciudad Salud, Tapachula, Mexico*

**Background:** Between 2013 to 2014 autochthonous cases ChikV virus were confirmed in the Americas and Mexico. The clinical and inflammatory profile and the prevalence of chronic disease were analyzed in Mexican patients.

**Objectives:** To describe clinical profile, self reported-disability, inflammatory biomarkers and chronic articular (CA) disease during 10 month follow-up in ChikV Mexican patients.

**Methods:** Ten patients with ChikV confirmed by real-time PCR were included. Clinical manifestations, Disease Activity Index (DAS-28), self-reported disability by 32 item WHODAS-2 score and inflammatory biomarkers (C-reactive protein (CRP), eritrosedimentation rate (ESR), Rheumatoid Factor (RF), high sensivity Interleukin-6 (hsIL-6) were measured at onset and every month until 10 months of follow-up.

**Results:** Ten patients (6 women and 4 men) with mean age 48.0 15.04 years-old were followed. Acute symptoms were: fever (100%), arthralgias (100%), myalgias (80%), rash (80%), synovitis (60%), nausea (50%), vomiting (20%) and back pain (20%); number of tender joints was 13.8 (SD 5.09) and number of articulations with synovitis was 7.1 (SD 3.78). At diagnosis biomarkers were: CRP 5.09 (SD 7.23) mg/dl, ESR: 32.6 (SD 17.5) mm/h, rF: 64 (SD 21.7) IU/ml and hsIL-6: 17 (SD 10.3) pg/ml. At diagnosis WHODAS-2 score was 74.5 (SD 7.59) % and DAS-28 was 4.37 (SD 0.78). Four cases resolved in acute phase, 5 developed subacute and CAand 1 patient died (with Systemic Lupus Erythematosus). During follow-up ESR, hsIL-6, DAS-28 index and WHODAS2 score were higher in patients with subacute or CA compared to solved cases ($p<0.05$). High levels of ESR and hs-IL6 at onset of ChikV infection were related with the development of CA ($p<0.05$). High DAS 28 index and WHODAS-II score were related to development of subacute or CA ($p<0.05$).

**Conclusions:** Fever, polyarthralgias, myalgias and rash were the main acute symptoms of ChikV fever and 50% of patients developed CA and a high disability. High levels of hsIL-6 and ESR could be used as a biomarkers to predict CA since acute phase. Inflammatory biomarkers, disability and DAS-28 remained high in subacute an CA compared to solved cases.

## SAT0496 BRUCELLOSIS SPONDYLODISCITIS: RETROSPECTIVE EVALUATION OF THE CLINICAL, LABORATORY AND EPIDEMIOLOGICAL FEATURES OF 21 CASES

K. Baccouche, N. Elamri, S. Belghali, Z. Alaya, H. Zeglaoui, E. Bouajina.
*rheumatology, farhat hached hospital, sousse, Tunisia*

**Background:** Brucellosis is a common zoonosis which still remains a major health problem in our country. Osteoarticular involvement is the most frequent complication.
**Objectives:** The aim of this study was to retrospectively evaluate the clinical, radiological aspects, laboratory characteristics, complications and treatment oucomes of brucellar spondylodiscitis (BS) cases who were followed between 1997 and 2015.
**Methods:** this is a retrospective study of 21 cases of brucella spondylitis collected in our rheumatology department
**Results:** Among 118 cases of infectious spondylodiscitis diagnosed and treated, 21 (17, 8%) were due to brucellosis. It was 16 men and five women with a mean age of 48.9 years. Among our patients, 38% had a profession exposed and 76, 2% were consumers of unpasteurized milk and dairy product. The delay from onset to diagnosis was 4 months and a half. The clinical presentation was fever in 81% cases, sweating in 81% and spinal pain in 100% cases. Neurological signs were observed in 42, 8% cases. A muscular deficit was objectified in 14, 3% cases. Vésicosphinctériens disorders were observed in 9, 5% cases. A single case of spinal cord compression was noted. The localisation of the infection was thoracic, thoraco-lumbar, lumbar and lombo-sacral respectively in 14, 3%, 9, 5%, 62% and 14, 3%. One vertebrae level was affected in 71, 4%. In view of laboratory findings, increased erytrocyte sedimentation rate was detected in 76, 2%, C-reactive protein positivity in 62%, lymphomonocytosis in 19% and anemia in 28, 5% of them. All of the patients had > or =1/160 titers of brucella agglutination test and negative blood culture. MRI findings are as follows: Predilection for the lumbar spine (62%), moderate paraspinal abnormal soft tissue with abscess formation only in 14,3% cases, and diffuse but exclusively anterior involvement, intact vertebral architecture despite evidence of diffuse vertebral osteomyelitis, and disc space involvement. Additionally, epidural extension was detected in 28, 5% cases, and root compression in 9, 5% cases. Clinical and radiological improvements were observed with a combined antimicrobial therapy of doxycycline and rifampicin during 12 weeks.
**Conclusions:** In endemic areas and in our country, BS is still a public health problem and should be considered in the differential diagnosis of patients with spondylodiscitis. It is difficult to diagnose because its symptoms and signs are non-specific. Therefore, MRI, blood cultures, tissue biopsy and cultures are recommended in suspected cases.
**Disclosure of Interest:** None declared

## SAT0497 EPIDEMIOLOGICAL STUDY OF INFECTIOUS SPONDYLITIS IN A TUNISIAN CENTER: ABOUT 118 CASES

K. Baccouche, N. Elamri, S. Belghali, M. Bouzaoueche, H. Zeglaoui, E. Bouajina.
*rheumatology, farhat hached hospital, sousse, Tunisia*

**Background:** Infectious spondylitis remains frequent in Tunisia and is a common reason for hospitalization in rheumatology. We report the experience of our rheumatology department in the diagnosis and management of infectious spondylitis.
**Methods:** This is a retrospective study of 118 cases of infectious spondylitis observed between 1997 and 2015. The diagnosis was based on clinical, biological, radiological and bacteriological data.
**Results:** Our population consisted of 76 men (64.4%) and 42 women (35.6%) with a mean age of 59.2 years [18–84]. A supporting ground was found in 27% of patients. This was diabetes in 17.8% of cases, extra-articular history of tuberculosis in 7.6% of cases, hemodialysis for renal failure in 2.5% of cases, recent spinal surgery in 3.4% of cases, visceral surgery in 2.5% of cases and a long-term corticosteroid in 1.2% of cases. Spinal pain was present in all cases and had an inflammatory rhythm in 89.8% of cases. Fever was observed in 48.3% of cases, night sweats in 27.1% of cases and impaired general condition in 50% of cases. Neurological signs, present in 55.9% of cases were: radiculalgia in 55.1% of cases, motor deficit in 20.3% of cases and spinal cord compression in 9.3% of cases. The inflammatory syndrome was absent in 10.2% of cases. Spinal MRI and CT performed respectively in 77% and 47.4% of cases showed an epidural in 52.5%, a soft tissue abscess in 34.7%, soft tissue infiltration in 27.9% and a root canal abscess in 14.4% of cases. The spondylitis was multifocal in 7.7% and multi-stage in 11% of cases. Affected levels were: lumbar spine in 66.6%, the thoracic level in 26.9% and the cervical level in 8.5% of cases. The germ was isolated in 53.5% of cases. The disco-vertebral biopsy (performed in 42.3% of cases) was contributory in 27.2% of cases. A puncture of a soft tissue abscess (formed in 14.1% of cases) was contributory in 85.9% of cases. Blood cultures were positive in 7.7% of cases. The urine culture had found the germ in 6.4% of cases and a skin sample in 1.2% of cases. Wright serology was positive in 20.5% of cases. These germs were: tuberculosis in 44.9% of cases, brucellosis in 20.5% and pyogenic germs in 29.5% of cases.
**Conclusions:** The clinical presentation of infectious spondylitis is polymorphic and determination of the causative organism can be difficult. In our series, in most cases it was a spondylodiscitis -specific germ. Support by appropriate antibiotic therapy leads overall to a good clinical outcome. Neurological complications can regress, more rarely from is fatal.

## SAT0498 IMPORTANCE OF ANTI- CYCLIC CITRULLINATED PEPTIDE AS A MARKER DIFFERENTIATING HEPATITIS C RELATED ARTHROPATHY FROM RHEUMATOID ARTHRITIS

R.A. Abdel Noor[1], M. Gabr[1], M. Alnaggar[1], M. Enaba[1], S. Hammad[2]. *[1]Internal Medicine; [2]Clinical Pathology, Tanta University, Faculy of Medicine, Tanta, Egypt*

**Background:** Hepatitis C arthropathy is one of the most important extra-hepatic manifestations of HCV. Its clinical presentation is rheumatoid like in about 30% of the cases and the differentiation between both is very important and difficult at the same time as the treatment is completely different. Anti-cyclic citrullinated peptide (Anti- CCP) antibodies can be used as serological markers in differentiation between them but many studies have variable and non-conclusive results concerning its importance.
**Objectives:** The aim of this study is to determine whether anti- CCP antibody is helpful alone in discriminating patients with HCV-associated arthropathy from patients with rheumatoid arthritis.
**Methods:** In this cross sectional comparative study we included 70 subjects, from Tanta University Hospital, Egypt and divided them into four groups: 30 Rheumatoid arthritis patients not infected with HCV,15 HCV patients with typical polyarthritis like RA without erosions or rheumatoid nodules, 15 HCV patients without arthropathy and 10 Normal subjects as a control group. We measured the level of Anti-CCP and RF in all groups.
**Results:** By the end of the study we found that anti-CCP was positive in 83.3% of RA group, 66.7% of HCV with arthropathy group, 40% of HCV without arthropathy group and in 30% of normal control group and there was a significant difference between RA group and HCV without arthropathy and control group, but there was no significant difference between RA and HCV arthropathy However during the comparison between the four groups as regard the degree of positivity of anti-CCP level there was a big difference in the degree of positivity in RA group and HCV arthropathy where 19 (63.3%) were strong positive in RA groups while only (20%)were strong positive in HCV related arthropathy.

Table 1. Comparison between anti-CCP among the studied groups

| | Group I | Group II | Group III | Group IV | $\chi^2$ | P value |
|---|---|---|---|---|---|---|
| Negative | 5 (16.7%) | 5 (33.3%) | 9 (60%) | 7 (70%) | | |
| Weak positive | 4 (13.3%) | 5 (33.3%) | 5 (33.3%) | 3 (30%) | | |
| Moderate positive | 2 (6.7%) | 2 (13.3%) | 0 (0%) | 0 (0%) | 29.7 | 0.000* |
| Strong positive | 19 (63.3%) | 3 (20%) | 1 (6.7%) | 0 (0%) | | |

**Conclusions:** Anti CCP can be a used as an early step in differentiating RA from HCV related arthropathy. If its level is strong positive this can highly suggest early rheumatoid arthritis but if the level is moderately positive or weak positive or even negative it is not enough alone as a marker differentiating RA from HCV related arthropathy.

SAT0499 **SEPTIC ARTHRITIS IN RHEUMATOLOGY: MANAGEMENT AND EVOLUTION OVER THE PAST 50 YEARS. ABOUT 374 CASES**

R. Leroy[1], N. Segaud[1], H. Migaud[2], E. Senneville[3], B. Cortet[1], R.-M. Flipo[1]. *[1]Rheumatology; [2]Orthopedic, CHRU lille France, lille; [3]Infectious Disease, CH Tourcoing, Tourcoing, France*

**Background:** Septic arthritis is a multidisciplinary emergency which poses diagnostic problems due to the lack of biological and clinical specificity, and variable treatment modalities in the absence of formal consensus.
**Objectives:** The objective of this study was to describe epidemiology, management and evolution of rheumatologic septic arthritis over the past 50 years.
**Methods:** This epidemiological, retrospective, observational, single-center study, included patients hospitalized between 1997 and 2014 in one Rheumatology Department of a University Hospital, for septic peripheral arthritis of native joint. The diagnosis was determined according to Newman's criteria. After a first descriptive part, we tried to determine associated factors for joint morbidity (define by the use of a non-sparing surgery or functional sequelae) and mortality after a follow-up of 1 year. Finally, we compared the results with a previous study, conducted in the same Department between 1966 and 1993 over 176 cases.
**Results:** On the 1997–2014 period, 198 patients were included corresponding to an annual incidence of 11 cases. The average age of patients was 56 years, with 57% men. Main comorbidities were arthropathy (37%), neoplasia (18%) and diabetes (17%). The most common presentation was monoarthritis (88%), of the knee (32%), caused by Staphylococcus aureus (56%). Nine percent of patients had received prior intra articular intervention. We noted 15% of arthritis with no identified pathogen. Endocarditis was found in 6% of patients. The support was multidisciplinary particularly between 2006 and 2014, with an increase of cooperation with bacteriologist (15% of cases between 1997–2005 versus 67% between 2006 and 2014, $p<0.0001$), and a decrease in antibiotic duration (97.1 days versus 75.5 days, p=0.002). The surgical treatment was required in 33% of cases. The death rate at 1 year was 6% and the joint morbidity rate was 20%. Mortality risk factors have been identified (endocarditis OR =12.6 [2.0 to 81.4], p=0.008); MRSA OR =13.8 [1.9 to 100.6], p=0.009). Patients receiving corticosteroids had an excess risk of joint morbidity (OR =3.0 [1.0 to 8.7], p=0.04). In comparison with the previous study, there were more comorbidities ($p<0.01$ for diabetes, neoplasia, rheumatoid arthritis), more bacterial identification and surgical care ($p<0.01$). Iatrogenic origin and mortality remain stable.
**Conclusions:** In the absence of formal recommendations, multidisciplinary cooperation could impact directly on the diagnostic and therapeutic management of septic arthritis. The management seems better than in the 60–90's period, with no change in mortality. Infective endocarditis appears to be an important risk factor for mortality and its research should be systematic.

SAT0500 **A COMPARATIVE ANALYSIS OF RADIOLOGICAL FINDINGS BETWEEN TUBERCULOUS AND BRUCELLAR SPONDYLODISCITIS**

S. Bouden, O. Saidane, I. Mahmoud, M. Sahli, R. Tekaya, L. Abdelmoula. *hopital charles nicolle, tunis, Tunisia*

**Background:** Tuberculous and brucella spondylodiscitis are endemic in tunisia. Both present in various pathological patterns, but there are significant radiological differences that permit a presumptive aetiological diagnosis and orient the initial empirical treatment.
**Objectives:** The aim of this study was to compare radiological features between these two diseases.
**Methods:** A retrospective monocentric study was performed. Patients diagnosed with tuberculous spondylodiscitis (TSD) or brucellar spondylodiscitis (BSD) between 2008 and 2016 were included. Clinical status and radiological results were assessed.
**Results:** A total of 33 patients were enrolled in the study including 17 men and 16 women. The mean age was 59 years (29–96 years). Twenty four had TSD (72,8%) and 9 BSD (27,2%). CT scan was performed in 9 cases and magnetic resonance imaging (MRI) in 24 cases. For both TSD ans BSD the most common region affected wad lumbar spine (respectively 58% and 77%). Preverebral, paravertebral, epidural and psoas abscess formations were significantly more frequent in TSD compared with BSD [p=0,01]. When considering neurological complications such as epiduritis and cord compression, TSD was not significantly different from BSD [p=0,17].
**Conclusions:** The results of this study show that TSD is a more suppurative disease with abscess formation.
**Disclosure of Interest:** None declared

SAT0501 **HLA SYSTEM IN CHLAMYIDIA TRACHOMATIS-INDUCED REACTIVE ARTHRITIS**

V. Dostanko[1], N. Dostanko[2], V. Yagur[2], K. Chizh[2]. *[1]Infomed; [2]2-d Department of Internal Medicine, BSMU, Minsk, Belarus*

**Background:** It should be noted considerable incidence rate of reactive arthritis (ReA) in the last decades and the fact that the majority of them are due to Chlamydia trachomatis infection (CTI) [1,2]. In some patients with CTI ReA and chronic ReA will develop [3,4], therefore search for risk factors of possible ReA development in CTI patients is an essential problem.
**Objectives:** To perform the typing of ReA patients induced by CTI for HLA antigens in order to reveal possible genetic markers of susceptibility and resistance to ReA development.
**Methods:** 30 ReA patients observed in Byelorussian Republican Rheumatologic Center (17 women and 13 men from 19 to 56 years old, mean age 36.4±10.5 years) with urogenital CTI confirmed by culture and immunofluorescence serology were studied for frequency of I and II class HLA antigens (A, B, C, DR, DQ locus, total number of studied specificities - 71) by means of microdroplet lymphocyte cytotoxicity test. Data on frequency of I and II class HLA antigens in 308 and 106 unrelated Minsk (Belarus) inhabitants were used as a control.
**Results:** We revealed significant increase of antigen frequency in B locus for B27 ($\chi^2$=26.5; $p_{corr}$=0.00025; RR=5.7) and B60 ($\chi^2$=4.3; $p<0.05$; RR=2.7) antigens, in DR locus for DR1 (43.3% in ReA vs 16.6% in controls, $\chi^2$=10.1; RR=4.0) and DR13 (40.0% in ReA vs 21.7% in controls, $\chi^2$=4.1; RR=2.4) antigens as well as for phenotype DR1,DR13 frequency ($\chi^2$=5.3; $p<0.05$, RR=5.3) in ReA patients. In addition significant decrease of DR7 (10.0% vs 32.1% in controls, $\chi^2$=5.8; RR=-4.2), DR11 (13.3% vs 31.1%, $\chi^2$=3.7; RR=-2.9) and DR53 (23.3% vs 47.2% $\chi^2$=5.4; RR=-2.9) antigen frequency was revealed in ReA patients. We registered significant increase of antigen DQ5 frequency (56.7% vs 28.3%, $\chi^2$=8.3; RR=3.3) as well as phenotype DQ5,6 frequency ($\chi^2$=10.1; RR=16.2) and significant decrease of antigen DQ2 frequency (20.0% vs 37.7%, $\chi^2$=3.4; RR=-2.4) in ReA patients in comparison with controls.
**Conclusions:** The revealed genetic markers of susceptibility to ReA development in patients with urogenital CTI are: HLA B27, B60, DR1, DR13, DQ5 antigens, as well as DR1, DR13 and DQ5, DQ6 phenotypes. We consider DR7, DR11, DR53, DQ2 antigens as factors of resistance to ReA development.

## Back pain, mechanical musculoskeletal problems, local soft tissue disorders

SAT0502 **TOLERANCE AND ACCEPTABILITY OF US GUIDED EPIDURAL INJECTIONS VIA THE SACRAL HIATUS**

A. Colombey, T. Garraud, G. Bart, C. Darrieutort-Lafitte, B. Le Goff. *Hopital Hotel Dieu et HME, Nantes, France*

**Background:** Epidural injection with corticosteroids is a common treatment option for patients with lower back pain or sciatica. It can be performed via the interlaminar/interspinous routes or via the sacral hiatus. US has shown its interest to guide steroid injection via the sacral hiatus with a high rate of injection success. However, it is thought that this route might be less well tolerated and more painful for the patient than the interspinous one. It has also been demonstrated that the shape of the sacral hiatus could lead to more difficult injections.
**Objectives:** The goal of our study was to evaluate the pain during the injection, the acceptability of the procedure and to find clinical or anatomical factors associated with a painful procedure. We compared the pain during sacral hiatus epidural and interspinous injections.
**Methods:** We performed a cross-sectional study. Patients undergoing an epidural steroid injection for the treatment of radicular pain due to a disc herniation were included. Epidural injection was performed under US guidance via the sacral hiatus. After a local anesthesia with 5 mL lidocaine, 1.5 mL of cortivazol followed by 18.5 mL sterile serum were slowly injected. Pain during the procedure was evaluated using VAS pain scale. US characteristics of the sacral hiatus was recorded. Acceptability was assessed by the question "If needed, would you accept to have the procedure again". Association between pain and any clinical or anatomical characteristics of the hiatus were assessed by linear regression analysis. Pain during the procedure was compared to the pain during interspinous injection evaluated in one of our previous study (1).
**Results:** There were 52 patients, 28 male (53%), with a mean age 52.5 years

(±15). Mean BMI was 26.5 (±5). Radicular VAS pain before the procedure was 5.2 (±2.1). On US, sacral hiatus mean depth was 7.4 mm (±5.4). Intercornual distance was a mean 12.3 mm (±4) and the mean length of the sacrococcygien ligament was 22.8 mm (±7). Mean VAS pain during the procedure was 3 (±2.4) with no significant difference when compared to the interspinous route (mean VAS = 2.8±2.1; p=NS). No immediate complication was recorded. Forty-height patients (92%) would either be very likely or somewhat likely to a repeat procedure. Only one patient would be somewhat unlikely to have a new injection. Thirty-six (69%) patients would surely recommend this procedure to one of their friends. We found no significant association between the pain during the procedure and any of the clinical or anatomical parameters. Importantly, no association was found between the pain and the US shape of the sacral hiatus.

**Conclusions:** US guided epidural injections through the sacral hiatus is a simple and well tolerated procedure. We found no difference of pain between the interspinous or the sacral hiatus routes. Most of the patients would accept to have this procedure again. We did not find any clinical or anatomical characteristic associated with a painful procedure.

## SAT0503 RELATIONSHIPS BETWEEN WEIGHT, PHYSICAL ACTIVITY AND BACK PAIN IN YOUNG ADULT WOMEN

S.R.E. Brady[1], S.M. Hussain[1], W.J. Brown[2], S. Heritier[1], B. Billah[1], Y. Wang[1], H. Teede[1], D.M. Urquhart[1], F.M. Cicuttini[1]. *[1]School of Public Health and Preventive Medicine, Monash University, Melbourne; [2]School of Human Movement Studies, University of Queensland, St. Lucia, Australia*

**Background:** Back pain is a major global health problem, causing greater disability worldwide than any other condition. It is associated with a significant economic burden and major disability, as therapeutic options have limited efficacy. Given limited treatment options, clarifying predictors of back pain is important in order to optimize preventive strategies. Furthermore, as previous episodes of back pain are predictive of future recurrence, understanding risk factors associated with back pain in early adulthood is particularly important.

**Objectives:** The study aims were to identify whether modifiable risk factors, weight and physical activity, are predictive of back pain in young adult women.

**Methods:** Community dwelling women born between 1973 and 1978 were randomly selected from the Australian national health insurance scheme database to participate in the Australian Longitudinal Study of Women's Health. Women were recruited nationally with intentional oversampling from rural and remote areas. Self-reported data on back pain in the last 12 months, age, weight, physical activity, depression and other socio-demographic factors were collected in 2000, 2003, 2006, 2009 and 2012. In 2000, 9,688 women completed the questionnaire and 83% completed follow up 12 years later.

**Results:** At baseline, median age was 24.6 years and 41% had self-reported back pain. For every 5kg higher weight at baseline, there was a 5% (95% CI 4% - 6%) increased risk of back pain over the next 12 years, after adjusting for age, height, education status, physical activity and depression. Higher weight also predicted back pain risk over each 3 year survey interval ($p<0.001$). The effects of weight on back pain were most significant in those with body mass index $\geq$25 kg/m$^2$ and were observed at all levels of physical activity. Inadequate physical activity and depression were independent predictors of back pain over the following 12 years (both $p<0.001$), after adjusting for above confounders.

**Conclusions:** Back pain is common in community-based young adult women. Higher weight, inadequate levels of physical activity and depression were all independent predictors of back pain over the following decade. Furthermore, the adverse effects of weight on back pain were not mitigated by physical activity. Our findings highlight the role of both higher weight and physical inactivity in back pain among young adult women and suggest potential opportunities for future prevention.

## SAT0504 PREVALENCE AND CORRELATES OF HOUSEHOLD WORK RELATED MUSCULOSKELETAL DISORDERS IN LOW BACK REGION AMONG SRI LANKAN HOUSEWIVES

P.D. Ranasinghe[1], I. Atukorala[2], A. Samaranayake[3], N.S. Gunawardana[4]. *[1]Ministry of Health, Health Education Bureau; [2]University of Colombo, Department of Clinical Medicine, Colombo 8; [3]Department of Health-Western Province, PDHS office, Colombo 10; [4]University of Colombo, Department of Community Medicine, Colombo 8, Sri Lanka*

**Background:** Household work is a significant cause of low back disorders particularly in the South Asian settings where work is manually performed and labour intensive. However, the prevalence household work related back pain in south Asian settings is unknown.

**Objectives:** To determine the prevalence of household work related musculoskeletal disorders (HWMSD) in low back region and its correlates among 20–50 year old housewives in an urban setting in Sri Lanka

**Methods:** A community based cross-sectional study was conducted on a sample of eligible housewives (n=1102) in an urban Sri Lankan setting using the multi-stage cluster sampling technique. Participants were women whose sole occupation was unpaid household work in their own homes for a minimum of 4 hours (continuously or intermittently) daily for at least 5 days a week, for a minimum of 2 years. Those with menopause, inflammatory arthritis, pregnant or in postpartum period, previous disability unrelated to household work were excluded. A novel validated tool- household work related musculoskeletal disorder questionnaire (HWMQ) with a sensitivity of 94.5% (91.7–97.3) and specificity of 99.3% (98.3–100) was used to identify HWMSD in low back. Correlates of HWMSD in low back region were conceptualized as physical exposures related to the housework, psychosocial factors and individual level factors. An analytical cross-sectional study using multivariate analyses comparing those with HWMSD of the low back region (n=397) and without HWMSD in any region of the body (n=405) determined the correlates of HWMSD in the low back region among housewives.

**Results:** The majority of housewives were performing multiple of household chores [cooking related activities (n=1031, 93.6%), hand washing clothes (n=811, 73.6%), ironing (n=972, 88.2%), sweeping indoor and outdoor (n=374, 33.9%), cleaning bathrooms/toilets (n=912, 82.8%), shopping (n=725, 65.8%) and carrying children (n=374, 33.9%)]. The prevalence of HWMSD in low back region among 20–50 year old housewives was 36% (95%CI: 33.1%>39%).

Correlates of HWMSD in low back region among 20–50 year old housewives identified as significant are shown in Table 1.

Table 1. Correlates of HWMSD in low back among 20–50 year old housewives

| Correlates of HWMSD in low back | Adjusted OR (95% CI) |
|---|---|
| Physical exposures | |
| Handling weight | 1.5 (1.1–2.2) |
| Working in awkward posture | 2.2 (1.5–3.1) |
| Working ≥8 hours per day | 2.3 (1.6–3.3) |
| Psychosocial factors | |
| Psychological distress | 1.8 (1.3–2.6) |
| Not having rest breaks | 1.8 (1.1–3.3) |
| Individual level factors | |
| Not being satisfied with family income | 1.8 (1.2–2.5) |
| Being employed more than two years prior to the study | 1.9 (1.3–2.7) |
| Having a child aged <5 years | 1.7 (1.1–2.6) |
| Married for ≥10 years | 2.0 (1.3–3.0) |
| Poor self-rated general health status | 3.7 (2.5–5.4) |
| Having long term illness | 1.8 (1.1–2.8) |
| Usual residence not being an owned house | 0.7 (0.5–0.9) |

**Conclusions:** Prevalence of HWMSD in low back was high among housewives in Sri Lanka. The study identified several modifiable and a few non-modifiable physical exposures, psychosocial factors and individual level factors as significant correlates of HWMSD in low back region.

## SAT0505 SEVERELY-DISABLING CHRONIC LOW BACK PAIN: COMBINATION TREATMENT WITH GLUCOSAMINE–CHONDROITIN SULFATE REDUCES DISABILITY, PAIN AND NSAID CONSUMPTION – RESULTS FROM A LARGE, COMMUNITY-BASED, PILOT, OPEN PROSPECTIVE INTERVENTIONAL STUDY

G. Singh[1], L. Alekseeva[2], V. Alekseev[2], D. Goriachev[3], A. Barinov[3], E. Nasonov[2], A. Mithal[4], S. Pyanykh[5]. *[1]Stanford University, Woodside, United States; [2]State NII of Rheumatology of Russian Academy of Sciences; [3]First Moscow State University, Moscow, Russian Federation; [4]ICORE, Woodside, United States; [5]Unipharm Inc, Moscow, Russian Federation*

**Background:** Low back pain (LBP) is the leading cause of Years Lived with Disability worldwide (1). The number of people suffering from LBP grew more than 50% from 1990 to 2013, to 651 million (1). Glucosamine-chondroitin sulfate (GCS) combination is widely used in the treatment of OA; however there are few prospective scientific investigations of its therapeutic merits in severe LBP.

**Objectives:** To study the efficacy of GCS in the decreasing disability in patients with severe disability due to chronic low back pain in a large open pilot prospective observational study.

**Methods:** We studied patients 40–65 years of age who had severe disability (Oswestry Score >40) due to LBP. The Oswestry scale contains ten sections on pain intensity, lifting, ability to care for oneself, walking, sitting, standing, sexual function, social life, sleep quality, and ability to travel. Each question is scored on a scale of 0–5 with the scores for all questions summed, then multiplied by two to obtain the index (range 0 to 100). Scores above 40 indicate severe disability. Major exclusion criteria were the presence of fibromyalgia, degenerative spondylolisthesis, and alcohol and/or drug abuse. All patients were treated with ARTRA (combination of glucosamine hydrochloride 500 mg and chondroitin

sulfate 500 mg in tablet form; Unipharm Inc.) at a dose of 1 tab bid for the first month and then 1 tab daily for the next two months. Oswestry index was measured at enrollment into the study and then after 1 month, 2 months and 3 months of starting therapy.

**Results:** The study population included a total of 4,588 patients with Oswestry index of 40 or more (mean age 52.9±7.4 years, 66% women, mean BMI 27.7±5.4, median of duration of LBP 6 months, LQ-4.0; UQ-20.0). Intent-to-Treat (ITT) analysis with worst observation carried forward (WOCF) showed an improvement in disability Oswestry Scale mean (95%CI) from 58.4 (57.9 -58.7) to 13.9 (13.5–14.3) ($p<0.0001$, ANOVA for repeated measures). Significant improvement was also observed in pain scores: pain at rest improved from mean (95%CI) of 5.93 (5.87–5.98) at study entry to 1.49 (1.45–1.55) at 3 months ($p<0.0001$). Pain at movement decreased from 7.53 (7.49–7.57) to 2.36 (2.31–2.42) ($p<0.0001$). NSAIDs were used by 74.9% of patients at study entry; at 3 months of treatment, only 9.9% of patients required NSAIDs for pain control ($p<0.0001$, McNemar's test).

An adverse event (AE) was reported by 311 (6.8%) patients (mostly GI in origin, such as nausea, abdominal pain and dry mouth) but only 134 (2.9%) patients deemed the AE to be severe enough to discontinue therapy.

**Conclusions:** Although open and uncontrolled, this pilot, community-based efficacy and safety study shows dramatic reductions in pain and disability in patients with severe disability as measured with Oswestry index. With its benign safety profile, GCS therapy deserves serious evaluation in the management of severe LBP in a prospective randomized double-blinded clinical trial.

## SAT0506 TELEVISION VIEWING TIME, PHYSICAL ACTIVITY AND LOW BACK PAIN IN COMMUNITY-BASED ADULTS: RESULTS FROM A PROSPECTIVE COHORT STUDY

S.M. Hussain[1], D.M. Urquhart[2], Y. Wang[1], D. Dunstan[3], J.E. Shaw[3], D.J. Magliano[3], A.E. Wluka[1], F.M. Cicuttini[1]. *[1]Monash University, Melbourne, Australia; [2]Monash University, Monash University; [3]Baker IDI Heart and Diabetes Institute, Melbourne, Australia*

**Background:** Low back pain (LBP) has an enormous negative economic impact on individuals, families, communities, industries and governments. As such, understanding the aetiology and risk factors for LBP is important in reducing the significant burden of this condition. In an effort to achieve this, epidemiological studies have examined a number of factors, including demographic (age and gender), obesity, and lifestyle factors (physical activity and sedentary lifestyle). The role of lifestyle factors on LBP has become a particular area of importance as they can be modified. Two systematic reviews concluded that there was limited evidence to support an association between physical activity and sedentary behaviour and developing (LBP).

**Objectives:** To examine the associations of physical activity and television viewing time with LBP intensity and disability in community-based adults.

**Methods:** 5,058 participants (44% men) of the Australian Diabetes, Obesity and Lifestyle Study had physical activity and television viewing time measured in 1999–2000, 2004–2005 and 2011–2012, and LBP intensity and disability assessed in 2013–2014 using the Chronic Pain Grade Questionnaire. Logistic regressions were used to estimate the odds ratio for LBP intensity and disability associated with physical activity and television viewing time. Analyses were adjusted for age, education, smoking, dietary guideline index score, body mass index, Mental component summary score. To test whether associations of physical activity or television viewing time with LBP intensity and disability were modified by sex, obesity, or age, interactions were tested using the likelihood ratio test.

**Results:** 81.7% men and 82.1% women suffered from LBP. Most of the men (63.6%) and women (60.2%) had low intensity LBP with a lower proportion having high intensity LBP (18.1% men, 21.5% women). Most of the participants had no LBP disability (74.5% men, 71.8% women) with the remainder reporting low (15.8% men, 15.3% women) or high (9.7% men, 12.9% women) disability due to LBP. Insufficient physical activity (<2.5 hours/week) was not associated with LBP intensity or disability in either men or women. High television viewing time (≥2 hours/day) was associated with greater prevalence of disability due to LBP in women (low disability OR 1.35, 95% CI 1.04–1.73; high disability OR 1.29, 95% CI 1.01–1.72). Women with insufficient physical activity and high television viewing had an increased risk of disability due to LBP (OR 1.42 95% CI 1.07–1.88) compared with women with sufficient physical activity and low television viewing.

**Conclusions:** Our findings indicate that high levels of television viewing, a marker of sedentary behaviour, is associated with an increased risk of LBP disability in women but not in men. Insufficient physical activity was not associated with LBP intensity or disability in either men or women. These findings suggest that targeting time spent watching television and possibly other prolonged sedentary behaviours such as occupational sitting may have the potential to reduce disability due to LBP in community-based adults, particularly in women.

## SAT0507 COMPARISON OF ORAL SPLINTING AND KINESIOTAPING IN TEMPOROMANDIBULAR JOINT PAIN

K. Baklaci. *Physical Medicine and Rehabilitation, TAF Health Command, Ankara, Turkey*

**Background:** Kinesiotaping is widely used in pain due to various musculoskeletal conditions. Especially sports injuries are the main area for kinesiotaping.

**Objectives:** In our study we aimed to use in different topic, temporomandibular joint (TMJ) pain and to show the efficacy on joint function and quality of life.

**Methods:** We assessed 86 patients aged 18 to 38 years who attended outpatient clinic with acute or chronic TMJ pain and discomfort while chewing. A board of one physiatrist and a dentist (oral and maxillofacial surgeon) evaluated the patients. Previous dental surgery/ jaw injury and other dental pathologies excluded and 69 patients with myofascial pain and the history of sleep disorders like clenching or grinding teeth while sleeping were randomly divided into the oral splint (bite guard) and the kinesiotaping group. Kinesio taping was applied to the skin over TMJ in reverse "V" shape extended to inferior border of jaw muscle and to the anterolateral aspect of neck. Taping was applied two times per week for two weeks. In splint group, bite guard were used all day long for two weeks except sleeping period. Presence of locking of the the joint, clicking or crepitation sound were noted and limitation of ROM in TMJ were measured by distance between upper and lower incisives, Speech, eating and sleeping behaviors were assessed for daily living activities. Pain intensity was measured by the visual analog scale (VAS). All the parameters were evaluated before and after intervention.

**Results:** Thirty four subjects were assigned to the kinesiotaping group, and thirty five subjects were assigned to the oral splint group. Both in the kinesiotaping and splint group, the level of pain intensity was decreased and the ROM was increased significantly ($p<0.01$), ($p<0.05$). Comparison between the groups did not reveal significant differences in VAS and ROM. Daily eating activity and sleeping quality were improved in both groups but not in other oral activities.

**Conclusions:** Although many etiological causes of TMJ pain, for the patients with myofascial pain and fibromyalgia, kinesiotaping is as effective as oral splints like bite guards. During daily practice, the myofascial pain syndrome and fibromyalgia background should be assessed for the ideal treatment. In contrast to splinting, kinesiotaping is non-invasive, easy-to-apply intervention method and do not interrupt daily oral activities.

## SAT0508 MANUAL THERAPY AND EXERCISE FOR ROTATOR CUFF DISEASE: A COCHRANE REVIEW

M. Page[1], S. Green[1], B. McBain[2], S. Surace[3], J. Deitch[3], N. Lyttle[4], M. Mrocki[4], R. Buchbinder[4,5]. *[1]School of Public Health and Preventive Medicine, Monash University; [2]Melbourne Hand Rehab; [3]Monash University; [4]Monash Dept Clinical Epidemiology, Cabrini Institute; [5]Dept Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

**Background:** Initial management of rotator cuff disease often includes manual therapy and exercise, usually delivered together as components of a physical therapy intervention. To best inform current practice, an up-to-date review which incorporates the most recently available evidence is needed.

**Objectives:** To systematically identify and synthesise the available evidence regarding the benefits and harms of manual therapy and exercise, alone or in combination, for the treatment of rotator cuff disease.

**Methods:** We included randomised controlled trials, including adults with rotator cuff disease, and comparing any manual therapy or exercise intervention with placebo, no intervention, a different type of manual therapy or exercise or any other intervention. Interventions included mobilisation, manipulation and supervised or home exercises, delivered alone or in combination. Trials investigating the primary or add-on effect of manual therapy plus exercise were the main comparisons of interest. Main outcomes of interest were overall pain, function, pain on motion, patient-reported global assessment of treatment success, quality of life and the number of participants experiencing adverse events.

We searched CENTRAL, MEDLINE, EMBASE, CINAHL Plus, ClinicalTrials.gov and the WHO ICTRP clinical trials registries up to March 2015, unrestricted by language. Two review authors independently selected trials for inclusion, extracted data, performed risk of bias assessment and assessed the quality of the body of evidence for the main outcomes using the GRADE approach.

**Results:** We included 60 trials (3620 participants). Only one trial compared manual therapy plus exercise with placebo (inactive ultrasound therapy) (120 participants; high quality evidence). At 22 weeks, there were no between-group differences in mean change in overall pain (placebo: 17.3 points on a 100-point scale; manual therapy plus exercise: 24.1 points; adjusted mean difference (MD) 6.8 points, 95% CI -0.7 to 14.3 points) and similar findings for function, pain on motion, treatment success and quality of life. More participants reported adverse events with manual therapy plus exercise (17/55, 31%) versus placebo (5/61, 8%):

RR 3.77 (95% CI 1.49 to 9.54)) but these were mild and short-lived (short-term pain following treatment).
Five trials (low quality evidence) found no important differences between manual therapy plus exercise compared with glucocorticoid injection and one trial (low quality evidence) showed no important differences between manual therapy plus exercise and arthroscopic subacromial decompression.
**Conclusions:** Despite identifying 60 eligible trials, only one trial has compared a combination of manual therapy and exercise reflective of common current practice to placebo. It was judged of high quality and found no clinically important differences between groups in any outcome. Effects of manual therapy plus exercise may be similar to those of other active interventions (e.g. glucocorticoid injecton, surgery), but this is based on low quality evidence.

## SAT0509 FEASIBILITY OF ULTRASOUND-GUIDED FACET JOINT INJECTIONS THROUGH A LONGITUDINAL APPROACH

C. Darrieutort-Laffite, A. Colombey, J. Glemarec, Y. Maugars, B. Le Goff. *Rheumatology, Nantes University Hospital, Nantes, France*

**Background:** Facet joint-mediated pain has been identified as a common cause of lumbar pain. Steroid injections are currently made to treat them, they are usually performed under fluoroscopy or computed tomography guidance. Ultrasound (US) is also appropriate to study facet joints and some studies showed feasibility and efficacy of facet joint injections performed under US-guidance through a transversal approach. On a longitudinal view, facet joints are easy-to-identify as a series of lumps with the joint capsule appearing as a thin hypoechoic line that envelops the joint.
**Objectives:** Considering the good visibility of these joints and their capsule on the longitudinal view, we studied the feasibility of US-guided facet joint injections using a longitudinal inline approach.
**Methods:** Patients referred to our rheumatology department to receive facet joint injections under fluoroscopy were included. To realize the injection, we first located the accurate lumbar level on a longitudinal median view going through the spinous processes. Facet joints were identified as previously described placing the probe 2–3 cm away from the median line. Then, the needle was inserted to reach the hypoechoic line corresponding to the capsule or, if not visible, the top of the lump formed by the inferior articular process of the superior vertebra overlying the superior articular process of the vertebra below it. When we obtained the bone contact, we injected iodinated contrast medium followed by cortivazol. Finally, we made a lumbar X-ray to analyze the needle position and the quality of the arthrography.
The first objective was to assess the number of injections realized in front of the joint. For secondary objectives, we assessed the number of accurate arthrography, the duration of the procedure and the occurrence of adverse events. During US examination, the visibility of the capsule and the presence of osteophytes were collected.
**Results:** Thirty-eight patients have been included by two operators. We excluded four patients because of a poor visibility of the spinal structures. Mean age was 58,4 years (range, 30–82) and mean BMI was 25,2 kg/m$^2$ (range, 18–34). US showed osteophytes in 42% and the joint capsule was inconstantly visible (25%). One-hundred and forty-four injections were performed (72 at the L4-L5 level and 72 at the L5-S1 level) and 141 X-ray were analyzed. One-hundred and twenty-three injections (87%) were accurately realized in front of the joint, i.e. in front of the inferior articular process of the superior vertebra. However, a proper arthrogram was obtained in only 35 cases (25%). Mean procedure duration was 8.5 minutes for four injections. Six patients (18%) reported transient pain exacerbation and no severe complication occurred during the first month after the procedure.
**Conclusions:** With a longitudinal inline approach, US-guided facet joint injections were feasible and 87% injections were realized right in front of the joint. However, we obtained a correct arthrogram in only 25%. The depth of the target-point, the inconstant visualization of the capsule and the obliquity of the needle probably explain this result. Additional studies will be necessary to improve the accuracy of the technique.
**Disclosure of Interest:** None declared

## SAT0510 PAINFUL SHOULDER: RELEVANCE OF CLINICAL AND SONOGRAPHIC DATA ON CORTICOSTEROID INJECTION OUTCOME

M. Cerqueira, J. Sousa Neves, D. Santos Faria, F. Teixeira, M.C. Afonso, J.A. Costa. *Rheumatology, Hospital Conde de Bertiandos, ULSAM, Ponte de Lima, Portugal*

**Background:** Painful shoulder (PS) is a common condition and a frequent cause of referral to a Rheumatology department, particularly in refractory patients.
**Objectives:** To study the association between clinical and sonographic data and corticosteroid injection (CI) outcome in PS patients.
**Methods:** Adult patients with PS, consecutively observed in a Rheumatology outpatient clinic were included. Demographic and clinical data (age, gender, time of symptoms, pain in contralateral shoulder, past CI of any shoulder, active abduction limitation and dominant side) were registered. The portuguese version of QuickDASH questionnaire (QD) and pain Visual Analogic Scale (VAS) were answered by the patient. If the patient fulfilled clinical criteria for CI (inflammatory or mixed pattern of pain, refractory to at least a 2 week NSAID treatment on full dose, or contra-indication to NSAID, and absence of contraindication to CI), a shoulder ultrasound (US) was performed before CI, and the sonographic findings were registered (presence of subacromial bursitis (SAB), long bicipital head tenosynovitis (LBHT), tendon calcification or supraspinatus (SS) tear). After 9 ± 2 weeks, patients were reassessed, repeating the QD and VAS questionnaires. Absolute and relative variation of QD score (a$\Delta$QD and r$\Delta$QD, respectively) and absolute and relative variation of pain VAS (a$\Delta$VAS and r$\Delta$VAS, respectively) were calculated. Patients with generalized pain syndromes, with suspected or confirmed chronic rheumatic inflammatory disease or secondary cause of the shoulder pain, with sonographic complete supraspinatus tear or glenoumeral effusion and those refusing CI treatment or proposed for calcification lavage, or those in whom reassessment was out of the defined interval were excluded. Statistical analysis was performed using SPSS 21.0 software.
**Results:** Sixty-eight patients were included, of whom 36 were excluded because of presenting at least one of the exclusion criteria. Thirty-two patients, 23 women, with a mean age of 58.9 ± 10.2 years, concluded the study. The mean time of symptoms was 8 ± 7.4 months; 11 (34.4%) patients had also pain in the contralateral shoulder, 8 (25%) had active abduction limitation, 5 (15.6%) had history of shoulder CI, and 24 (75%) had pain on the dominant side. Regarding US findings, 18 (56.3%) had SAB, 12 (37.5%) had LBHT, 16 (50%) had intratendinosis or transtendinosis SS tear and 11 (34.4%) had any tendon calcification.
Age or time of symptoms did not correlate with any of the improvement scores. Higher baseline QD score correlated with higher a$\Delta$QD ($r$=0.55, $p$<0.01) and r$\Delta$QD ($r$=0.37, $p$<0.05); higher baseline VAS score correlated with higher a$\Delta$VAS ($r$=0.38, $p$<0.05). SS tear was present in older patients ($p$<0.05), but it was not associated to improvement scores. Active abduction limitation was associated with greater a$\Delta$QD or r$\Delta$QD ($p$<0.01), and a$\Delta$VAS or r$\Delta$VAS ($p$<0.05). Patients with sonographic inflammatory signs (SAB or LBHT) had greater a$\Delta$VAS and r$\Delta$VAS scores ($p$<0.05); there was also a trend towards greater improvement on QD scores, although not statistically significant.
**Conclusions:** Patients with more severe symptoms or active abduction limitation have greater benefit from CI; having any of the inflammatory US findings described is also associated with greater pain relief after CI.

## SAT0511 MANAGEMENT OF ADHESIVE CAPSULITIS WITH LANDMARK GUIDED HIGH VOLUME STEROID INJECTIONS IN THE COMMUNITY BASED MUSCULOSKELETAL CLINIC

S. Baltsezak[1,2]. [1]*Musculoskeletal and Pain Service, Anglian Community Enterprise, Colchester;* [2]*Musculoskeletal Service, BUPA, London, United Kingdom*

**Background:** Pathology of frozen shoulder (FS) includes inflammatory response with fibroblastic proliferation [1]. It results in global loss of motion due to rotator cuff interval and coraco-humeral ligament contracture as well as capsular thickening. Recently, image guided hydro-dilatation combined with steroid inj became popular FS management. Sometimes three injections with 2 week intervals are given [2]. This procedure is usually performed in outpatient radiology department and requires referral to secondary care. I present an audit of community based treatment of the frozen shoulder. All patients were treated during their 1st appointment at musculoskeletal clinic. I observed that patients respond well to landmark guided high volume steroid injection. It is quick to administer, does not require assistance or additional imaging.
**Objectives:** To assess whether landmark guided high volume steroid injections combined with home based unsupervised stretching exercises are effective in the treatment of frozen shoulder.
**Methods:** All patients diagnosed with Frozen shoulder during 1st appointment between September 2013 and August 2015 were included in the audit. They were followed up at 2–3 months. They were treated with high volume steroid injection: 1 ml 40 mg triamcinolone, 9 ml of 0.5% marcaine +/– normal saline. Standard posterior approach was used for glenohumeral joint injection. Four shoulder stretches were advised to patients for regular home unsupervised exercise. All patients had opportunity to access MSK service within 6 months from the 1st appointment. Their electronic record was reviewed again in January 2016 to establish whether they represented to our MSK service with the same problem. The primary end point of the study was the need for further secondary care orthopaedics referral.
**Results:** 90 patients were treated within the study period. 35.6% (32) of patients were male and 64.4% (58) were female. The mean age of the patients was 56.6 years. 54.4% of patient had duration of symptoms from 1–6 months, 37.8% of patient had duration of symptoms from 7–12 months, 6.7% had duration of symptoms from 13–18 months and 1.1% - 1 patient had symptoms for 24 months. 29 patients (32.2%) had ≥30ml of fluid injected in the glenohumeral joint (GHJ). 48 patients (53.3%) had 10 ml injected the GHJ. 10 patients (11.1%) had ≥20 ml injected in the GHJ. 3 patients (3.3%) had 15ml volume injection. 35 (38.8%) patients required more than 1 injection.

Overall, during study period 3 (3.3%) patients required further orthopaedic management. 96.7% of patients were satisfied with the management and declined further orthopaedic referral during follow up appointment.
**Conclusions:** Landmark guided high volume steroid injections combined with stretching exercises are effective at relieving symptoms of frozen shoulder. This treatment can be recommended before considering further secondary care orthopaedics interventions.

## SAT0512 DOES SWITCHING FROM ONE NON-STEROIDAL ANTI-INFLAMMATORY DRUG (NSAID) TO ANOTHER IMPROVE PAIN CONTROL?

A. Karateev, N. Gontarenko, A. Tsurgan. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** NSAIDs - the main medications for control of musculoskeletal pain in rheumatic diseases (RD). However, their use does not always lead to a significant reduction of pain and may be accompanied by side effects. There is a need to replace the first NSAID with another in many patients.
**Objectives:** To evaluate the results of the use of the selective COX-2 inhibitor etoricoxib in patients with acute/subacute pain related to background RD despite using other NSAIDs.
**Methods:** A group of patients of 1566 patients (63.5% women and 31.1% men, age 48.8 ± 13.9 years) with acute/subacute pain associated with RD (mainly osteoarthritis and back pain) was included in an open-label study. The criterion for selection of patients was dissatisfaction with the treatment (10 cm VAS pain >3 cm) by background NSAIDs. The patients mainly used diclofenac (24.5%), nimesulide (27.2%) and meloxicam (25.6%). After inclusion in the study all patients started etoricoxib instead of other NSAIDs. The dose and duration of treatment were determined by a physician: the majority of patients (59.6%) took etoricoxib 90 mg/day. The results of treatment were assessed after 2 weeks.
**Results:** After start of treatment with etoricoxib a significant improvement was observed in the majority of patients. Pain decreased from 6.21 ± 1.4 to 1.93 ± 1.3 cm VAS. The complete pain relief was achieved in 12.5% of patients, 58.3% achieved low intensity of pain (VAS <2 cm). Additional therapy for symptom control (muscle relaxants, other analgesics, local injections of glucocorticoids, and others) needed in 31.2% of patients. The best effect was observed when using a higher dose of etoricoxib: decrease of pain intensity on 120 mg, 90 mg and 60 mg per day was 4.77 ± 1.88, 4.69 ± 2.01 and 3.50 ± 1.48 cm VAS respectively (the difference between 120 and 60 mg/day, 90 and 60 mg/day was significant, $p<0.001$). Treatment tolerability was assessed as “good” in 62.7%, "satisfactory" in 36.7% and "bad" in 0.6% of patients. Adverse events were reported in 55 patients (3.5%), mainly dyspepsia – in 21 (1.3%) and arterial hypertension - in 27 patients (1.7%).
**Conclusions:** Switching from previous therapy with NSAIDs to etoricoxib provides an effective reduction of acute/subacute pain. High doses etoricoxib are more effective. Short-term use of etoricoxib rarely causes adverse events.

## SAT0513 OSTEOID OSTEOMA OF THE ODONTOID PROCESS OF THE AXIS: A RARE CAUSE OF NECK PAIN

A. Bilgici[1], G. Alayli[1], S. Aslan[2], C. Aslan[1], D. Durmus[1], O. Kuru[1]. *[1]Physical Medicine and Rehabilitation; [2]Radiology, Ondokuz Mayis University Medical Faculty, Samsun, Turkey*

**Background:** Osteoid osteoma is painful benign tumor that comprises approximately 3% of all bone tumors and approximately 10% of all benign bone tumors. Most of the cases occur in the first three decades and two to three times more frequently in men than in women. The tumor is very uncommon after the age of 40 years or during infancy. More than 50% of osteoid osteomas involve long tubular bones especially those of the lower extremities. Osteoid osteoma of the spine is relatively uncommon. Pain is the primary symptom of initial and recurrent disease, although reports of osteoid osteoma without the presence of pain exist. It is often difficult to diagnose, especially when the patient does not complain of pain.
**Objectives:** Here we report our patient who had an osteoid osteoma at the odontoid process of the second cervical vertebra (axis).
**Case presentation:** A 48-year-old woman was admitted to the of physical medicine and rehabilitation department with an 8-month history of neck pain. There was no history of previous injury. For the first 4 months, she had intermittent neck pain, but there after severe neck pain developed during the nighttime that sometimes kept her awake. Her neck pain was relieved transiently by non-steroidal anti-inflammatory drugs (NSAIDs). The pain was worsened 4 months prior to presentation and was associated with frequent occipital headaches. External immobilization with a soft neck collar could not control her symptoms.

Figure 1. CT of cervical spine: A.Axial B.Coronal C.Sagittal images showing the nidus and perifocal sclerosis.

Physical examination revealed limitation of rotation and extension with neck pain. Neurologic examination was normal. There was no spinal tenderness. Her laboratory data was within the normal ranges. Computed tomography showed an oval nidus and marked sclerosis around the lesion at the odontoid process of the axis (Figure 1A-C). Since the patient refused surgery and considering the benign nature of osteoid osteoma, we prescribed NSAID to the patient. With the treatment, the patient’s symptoms improved and the range of motion of the cervical spine was also recovered. At one-year follow-up, the patient is free of symptoms with the conservative treatment.
**Conclusions:** Osteoid osteoma most frequently involves the posterior vertebral elements. An osteoid osteoma of the odontoid process of C2 is rare. Previously, only three cases between the ages 14–18 were reported to have osteoid osteoma involving the odontoid process of the axis. To the best of our knowledge this is the first case of osteoid osteoma involving the odontoid process in an adult female patient. Our patient demonstrated the typical radiological appearance of osteoid osteoma on imaging modalities. Since surgery is risky regarding the damage of the spinal cord, and/or vertebral artery, conservative approach should be considered for the treatment of osteoid osteoma of the cervical spine, especially the odontoid process. Surgery may be suggested to the patients who do not respond to palliative treatment.

## SAT0514 EFFECTIVENESS OF ABDOMINAL CORE STABILIZATION EXERCISES IN PATIENTS WITH LOW BACK PAIN. OVERVIEW OF SYSTEMATIC REVIEWS (PRELIMINARY RESULTS)

M.B. Nishishinya[1], C.A. Pereda[2], A.C. Cis[3], M. Guerra Balic[4], G. Urrutia[5], M. Solana-Tramunt[6]. *[1]Rheumatology, 1. Instituto Traumatológico Quiron, Barcelona; [2]Rheumatology, Hospital Mediterraneo; [3]Sport Medicine, Centro Médico de Hospital Mediterráneo, Almeria; [4]FPCEE-Blanquerna, University Ramon Llul; [5]Servei d'Epidemiologia Clínica i Salut Pública, Hospital de la Sant Creu i Sant Pau; [6]FPCEE-Blanquerna, University Ramon Llull, Barcelona, Spain*

**Background:** Low back pain is a large and frequent disorder, with a lifetime prevalence that ranges from 60 to 80%. It is also the main cause of work absence and permanent disability. Exercise therapies appear to be an effective treatment to reduce pain and improve axial performance in patients with chronic low back pain. Yet, abdominal CORE exercises have been incorporated for several years in different rehabilitation programmes. Core muscles, can be divided into two groups: 1- deep muscles or stabilizing muscles (connected to lumbar vertebral segment) and 2- shallow muscles, (not connected to lumbar spine (LS)) but enables additional spinal control. Physical activity focused on these groups of muscles could contribute to pain alleviation and spinal functional improvement.
**Objectives:** To perform a global review (overview) of systematic reviews (SR) to evaluate the beneficial effect of abdominal core stabilization exercises on: 1- pain, 2- LS performance, 3-evaluate adverse effects.
**Methods:** We conducted a global review of systematic reviews (SR), based on 3 online databases: CENTRAL, MEDLINE/Pubmed y PEDro, in English and Spanish. Critical appraisal of included studies was performed by 3 authors independently. AMSTAR system was used to rate the quality of SR.
**Results:** From 17 potential studies found, 9 were included and analysed. Quality of SR was good (AMSTAR 6–11). Metanalysis was performed in 55, 5% of references, Quality of references included in SR were rated on different scales: PeDro (3), Cochrane collaboration (5) and Jadad (1). Globally there were 59 articles included but two were not RCT. Interventions and comparisons assessed were deeply heterogeneous. In addition the study population was small. In general, pain and LS function experimented improvement with CORE stabilization exercises in the short and medium term follow-up, but not in the long term. The types of exercises performed on CORE muscles were drastically heterogeneous. The five papers were metanalysis was performed, showed a significant improvement of pain and LS function with Motor Control exercises (MCE) when compared to general exercises or minimal interventions or control. This was observed in the short and medium term, but not in the long term. No studies mentioned adverse effects.
**Conclusions:** 1. The reviews analysed showed methodological limitations 2. CORE stabilization exercises improve pain and LS function in the short and medium term, but not in the long term. 3. MCE appear to be better than general exercises, minimal interventions or control for pain and LS function. 4. There is no information about adverse effects. 5. Due to the different exercises programmes performed on CORE muscles, and different comparisons evaluated, the clinical efficacy remain uncertain.

## SAT0515 LUMBAR CT-GUIDED STEROID INFILTRATION ON THE REFRACTORY LOW BACK PAIN. STUDY OF 258 PROCEDURES IN THE SAME CENTER

E. Galindez Agirregoikoa[1], M.L. Garcia-Vivar[1], E. Ruíz Lucea[1], J.F. García Llorente[1], I. Torre Salaberri[1], O. Fernández Berrizbeitia[1], C. Gómez Arango[1], J.M. Blanco Madrigal[1], E. Guerrero Barrenetxea[1], I. Calvo Zorrilla[1], N. Rivera Garcia[1], M.J. Allande Lopez-Linares[1], C. Morandeira Arrizabalaga[2], F. Díez Renovales[2]. *[1]Rheumatology; [2]Radiology, H. Universitario Basurto, Vizcaya, Spain*

**Background:** Low back pain of mechanical origin is a major cause of disability and surgical intervention. The lumbar computed tomography (CT)-guided steroid infiltration can accelerate the recovery process and sometimes avoid the surgery.
**Objectives:** Our aim was to review the indications, efficacy and complications of this technique in a wide series of unselected patients. In addition a comparative study of efficacy was performed according to the lumbar underlying pathology, type of steroid and approach of injection.
**Methods:** Study of lumbar CT-guided steroid injections performed in a University Hospital between January 2012 and June 2015. The minimum follow-up was 3 months.
The procedure was performed in patients with low back pain refractory to standard medical therapy and Lumbar Spine Rehabilitation.
Efficacy was assessed at 1 and 3 months according to a semiquantitative scale as the pain response as a) total response, b) partially c) no or d) worsening pain.
A comparative study of the efficacy and safety was performed, regarding: a) underlying pathology, b) approach of injection and c) the different types of steroids used.
Fisher's test and $\chi^2$ and the SAS System for Windows V program 9.2.were used for statistical analysis.
**Results:** During the study period 258 procedures were performed in 171 patients (132 men/126 women) with a mean age ± SD of 58.24±13.45 years (range, 18–88).
The indications for the injection were: a) disc herniation (44.57%), b) lumbar stenosis (34.11%), c) postoperative fibrosis and spondylolisthesis (20.15%) and d) facet joint synovial cysts syndrome (1.17%).
Approaches used were: a) posterior epidural (24.42%), b) lateral recess (58.91%), and c) foraminal (16.67%).
The chosen steroid was triamcinolone (74.81%), dexamethasone (23.64%) and methylprednisolone (1.55%).
In a significant proportion of the procedures improvement in the patient's sintomatology was reported at the first month, regardless of the indication, route of corticosteroid injection and steroid used (TABLE).
Regarding the overall outcome, at 3 months 72.48% of the patients experienced clinical improvement. And only 21.71% of patients required a subsequent surgery.
The clinical efficacy showed no statistically significant differences according to the indication of the procedure or the route used for the injection. However, the improvement of pain was significantly greater in patients treated with triamcinolone than those treated with dexamethasone (p=0.01).
Regarding safety there were 6 (2.3%) local complications (puncture of the thecal sac) and 3 (1.16%) systemic complications (allergic reaction). None of these complicationes were of clinical relevance and they were not associated with the corticosteroid used.

Table: Efficacy at 1 month according to Indication, Approach and Steroid

| | Total response n(%) | Parcial response n (%) | No response n (%) | Worsening n (%) | TOTAL n (%) |
|---|---|---|---|---|---|
| Indication | | | | | |
| -disc herniation | 7 (6.9%) | 83 (72.2%) | 23 (20.0%) | 2 (1.7%) | 115(44.6%) |
| -spinal stenosis | 4 (4.6%) | 60 (68.2%) | 22 (25.0%) | 2 (2.3%) | 88(34.1%) |
| -postsurgical pain syndrome | 1 (2.1%) | 36 (75.0%) | 11 (28.6%) | 0 (0.0%) | 48(18.6%) |
| -others | 0 (0.0%) | 5 (71.4%) | 2 (28.6%) | 0 (0.0%) | 7(2.7%) |
| Approach | | | | | |
| -posterior epidural | 2 (3.2%) | 43 (68.3%) | 18 (28.6%) | 0 (0.0%) | 63(24.4%) |
| -lateral recess | 9 (5.9%) | 107 (70.4%) | 33 (21.7%) | 3 (2.0%) | 152(58.9%) |
| -foraminal | 1 (2.3%) | 34 (79.07%) | 7 (16.3%) | 1 (2.3%) | 43(16.7%) |
| Steroid | | | | | |
| -Triamcinolone Acetonide | 12(6.2%) | 142 673.6%) | 36 (18.7%) | 3 (1.6%) | 193(74.8%) |
| -Dexamethasone | 0 (0.0%) | 39 (63.93 %) | 21(34.4%) | 1 (1.6%) | 61(23.6%) |
| -Methylprednisolone | 0 (0.0%) | 4 (100.0%) | 0 (0.0%) | 0 (0.0%) | 4(1.6%) |
| TOTAL n= 258 | 12 (4.7%) | 184 (71.3%) | 57 (22.5%) | 4 (1.6%) | 256(100%) |

**Conclusions:** CT-guided corticosteroid injection is an effective and safe treatment in low back pain refractory to standard medical therapy in patients with spinal stenosis, disc herniation and postoperative fibrosis.
Triamcinolone infiltration seems to be more effective than dexamethasone.
**Disclosure of Interest:** None declared

## SAT0516 EPIDURAL ABSCESS PREDICTS THE PROGNOSIS OF PATIENTS WITH CONSERVATIVELY TREATED PYOGENIC SPONDYLITIS

F. Kugimiya[1], S. Muraki[2], H. Umekoji[1], D. Nagakura[1], H. Oda[1], K. Takahashi[1]. *[1]Saitama Medical University, Moroyama town, Iruma, Saitama; [2]22nd Century Medical and Research Center, the University of Tokyo, Hongo 7–3-1 Bunkyo Tokyo, Japan*

**Background:** Although initial treatments for pyogenic spondylitis include conservative approaches such as rest and antibiotics, some cases are refractory to conservative therapy.
**Objectives:** The objective of this study was to clarify the predictors for achievement of C-reactive protein (CRP) normalization in pyogenic spondylitis.
**Methods:** In the present study, we enrolled 83 patients (51 men and 32 women) with conservatively treated pyogenic spondylitis at Saitama Medical University from 2006 to 2015. We defined CRP normalization as a CRP level decrease to $<$0.25 mg/dl. A multiple logistic regression analysis was used to examine the association of achievement of CRP normalization with the number of infected vertebrae, bacterial strain, blood data, and the expansion of abscess to the epidural space by using functional magnetic resonance imaging. The blood data analysis included the following measurements: WBC, Hb, ALB, GOT, GPT, gamma GTP, BUN, Cr, UA, ALP, LDH, eGFR, TG, LDL, HDL, IP, and HbA1c levels.
**Results:** Among 83 patients, 39 patients (47.0%) achieved the normalization of CRP levels. The average period from the onset to admission was 56.3 days. The average number of infected vertebrae was 2.19. Of the 83 patients, 81% had the following complications: diabetes (25 patients), high blood pressure (22 patients), heart disease (16 patients), urinary tract disease (9 patients), collagen disease (7 patients), dialysis (5 patients), malignant tumor (5 patients), hepatic dysfunction (4 patients), high uric acid (hyperuricemia, 3 patients). The pathogenic bacteria were MSSA (14 patients), MRSA (23 patients), others (5 patients), and unknown (41 patients). We found significant differences in the subjects with and without achievement of CRP normalization with respect to age (68.6 vs. 62.5 years), the number of affected vertebrae (1.9 vs. 2.6), ratio of resistant pathogenic bacteria (10% vs. 43%), ratio of expansion of abscess to the epidural space (27% vs.71%), and blood data such as Hb (12.0 vs. 10.6), ALB (3.1 vs. 2.8), eGFR (91.2 vs.71.8), Cr (0.9 vs. 1.9), and ALP (369 vs. 290) levels. After adjustment for age and sex, the number of infected vertebral bodies ($\geq$3 vs. 2, odds ratio 1.03, 95% confidence interval: 1.00–1.07), resistant bacteria (7.7, 1.97–42.4), expansion of abscess to the epidural space (4.20, 1.63–11.5), and Hb level (1.31,1.04–1.69) showed significant associations with the normalization of CRP. In addition, to examine the variables independently associated with the normalization of CRP level, we used multiple logistic regression analysis with age, sex, number of infected vertebral bodies, resistant bacteria, expansion of abscess to the epidural space, and serum Hb level as explanatory variables, and found that expansion of the abscess to the epidural spaces was significantly associated with the normalization of CRP level (3.40, 1.11–10.7).
**Conclusions:** The number of infected vertebral bodies, resistant strains of pathogenic bacteria, expansion of abscess to the epidural space, and serum Hb level predicts the prognosis of patients with pyogenic spondylitis. Particularly, expansion of abscess to the epidural spaces was strongly associated with the achievement of CRP normalization.

## SAT0517 MIZORIBINE IS AS EFFECTIVE STEROID-SPARING AGENT AS METHOTREXATE FOR POLYMYALGIA RHEUMATICA: A RETROSPECTIVE CASE SERIES ANALYSIS

K. Shiraishi, M. Suda, R. Rokutanda, M. Okada. *Immuno-Rheumatology Center, St Luke's International Hospital, Tokyo, Japan*

**Background:** Patients with polymyalgia rheumatica (PMR) often need long-term steroid treatment, which raises concern for chronic side effects of steroid. In the 2015 ACR/EULAR recommendations for the management of PMR, methotrexate (MTX) was recommended as a 1st line agent for steroid sparing. However, elderly patients often cannot tolerate MTX. Mizoribine (MZR), an inosine monophosphate dehydrogenase inhibitor, has been widely used in the field of organ transplantations in Japan. We have reported the efficacy and the excellent safety of MZR in the rheumatology field (1), and its steroid sparing effect as well (2). The role of MZR on PMR treatment has not been clarified.
**Objectives:** To evaluate efficacy and safety of MZR compared to MTX in terms of steroid-sparing effect in PMR.
**Methods:** The study design was a retrospective single-institution case series analysis. We searched for all PMR patients who were diagnosed as PMR at St. Luke's International Hospital from 1998 to 2014. The inclusion criteria were

fulfillment of the 1979 classification criteria of PMR, and receiving treatment with prednisone in combination with either MTX or MZR. The exclusion criteria were the diagnosis of giant cell arteritis or other connective tissue diseases, use of both MTX and MZR, and use of other immunosuppressants. The following data were collected; total prednisone dose that participants had received within 48 weeks after stating MTX or MZR, the dose of the steroid on 48 weeks after starting MTX or MZR, and side effects profile.

**Results:** A total of 24 participants (14 for MZR group; 10 for MTX group) were included. The cumulative prednisone dose in 0–48 weeks was 2154 (1181 to 3127) mg in MTX group and 1940 (1379 to 2502) mg in MZR group, and the difference between the arms was -214 mg (a one-sided 90% CI: -1019 to 591.7). The dose of the steroid on 48 weeks after starting steroid sparing agent was 4.17 mg (95%CI: 1.64 to 3.90) in MTX arm and 2.71 mg (95% CI: 1.78 to 6.55) in MZR arm, seeming in favor of MZR although statistically not significant (P=0.20). Side effect profile was as follows; in MTX group, 3 out of 10 patients experienced a transient elevation in liver enzymes and 1 patient developed gastrointestinal symptom which lead to MTX withdrawal. In MZR group, one patient experienced a transient elevation in liver enzymes, 1 patient developed gastrointestinal symptom which were tolerable, and one patient was hospitalized due to pneumonia requiring 1 week of iv antibiotics, which lead to MZR withdrawal.

**Conclusions:** MZR may be non-inferior or may be even superior to methotrexate in terms of steroid sparing effects on PMR patients, although statistically not significant due to small sample size. MZR generally has fewer side effects than MTX. Further investigation with a larger number of patients in RCT is needed for confirmation.

## SAT0518 LOW BACK PAIN PREVALENCE IN ITALIAN ADOLESCENTS AND ITS ASSOCIATION WITH QUALITY OF LIFE

L. Bakdounes[1], P. Galozzi[2], I. Maghini[1], F. Oliviero[2], E. Caputo[3], M. Chia[4], M. Ermani[5], S. Masiero[1], L. Punzi[2]. *[1]Dept. of Medicine DIMED, Physical Medicine and Rehabilitation, University of Padua; [2]Dept. of Medicine DIMED, Rheumatology Unit, University of Padua, Padua; [3]IIS Marco Polo - Liceo Artistico High School; [4]Health and Motion Venice Association (HEMOVE), Venice; [5]Dept. of Neuroscience, University of Padua, Padua, Italy*

**Background:** Low Back Pain (LBP) is a very common health problem that affects people of all ages. It has profound effects on well-being and is often the cause of significant physical and psychological disability. Until now, very few studies have investigated these aspects in adolescents[1].

**Objectives:** To define the prevalence and the characteristics of LBP in high school adolescents from the city of Venice (Veneto region, Italy) and to investigate its impact on disability, lifestyle and quality of life (QoL).

**Methods:** The cross-sectional study included 145 students (89 females and 56 males) with a mean age of 15.9 ± 0.72 years that completed the Short Form 36 Questionnaire (SF-36) for QoL assessment and a structured questionnaire concerning anthropometric data and participants' characteristics as well as the symptoms prevalence, duration and treatment, health provider consultation, and referral for diagnostic tests. For normally distributed variables the Student T test was used while, for categorical variables, the Pearson's Chi Square was performed.

**Results:** Among the 145 subjects included in the study, 82 (56.5%) referred having experienced LBP: 8.2% at the moment of survey, 27.6% in the past with complete resolution of the symptoms, and 20.7% in the past without symptoms resolution. Females experienced LBP significantly more frequently than males (52.2% versus 47.8%, $p<0.05$). There was no association between LBP and age or physical activity. 59.0% of the adolescents with LBP had sought medical evaluation and the 47.3% of this group had been referred for diagnostic tests.

Concerning pain resolution, 78.9% of positive resolved respondents did not take any actions while, out of the total number of subjects involved, 58.3% used drugs, 60.0% recurred to rehabilitation and 20.0% combined drugs and rehabilitation. This latter category was also more sceptical than the others (p=0.016) about the future possibility of solving LBP, confirmed by lower QoL scores, although it was the most interested in participating to a prevention program (p=0.04).

Furthermore, there was a strong correspondence between the QoL of the students that experimented LBP only in the past and the QoL of those who had never suffered of LBP in their lives.

**Conclusions:** Our study confirmed that LBP is frequent in Italian adolescents and that a large number of subjects consult a healthcare service[1]. The results highlighted the strong impact of LBP on QoL, leading to significant physical and psychological health issues. According to our data, SF 36 may be a reliable tool to describe the QoL modifications related to the presence of pain. Further investigations are necessary to understand the inverse association observed between therapy and pain resolution.

## SAT0519 THE ASSOCIATION BETWEEN OBESITY AND LOW BACK PAIN AND DISABILITY IS AFFECTED BY MOOD DISORDERS – A POPULATION-BASED, CROSS-SECTIONAL STUDY OF MEN

L. Chou[1], S. Brady[1], D. Urquhart[1], A. Teichtahl[1,2], F. Cicuttini[1], J. Pasco[1,3,4], S. Brennan-Olsen[3,4,5], A. Wluka[1]. *[1]Department of Epidemiology and Preventative Medicine, Monash University; [2]Baker IDI, Melbourne; [3]School of Medicine, Deakin University, Geelong; [4]Northwest Academic Centre, The University of Melbourne; [5]Australian Institute of Musculoskeletal Sciences, Melbourne, Australia*

**Background:** Low back pain (LBP) and obesity are both major public health problems. Obesity has been linked with LBP, with recent studies reporting that increased fat but not lean tissue mass is associated with LBP, however previous studies predominantly examined women. The relationship between body composition and LBP in men is unknown.

**Objectives:** The aim of this study was to examine the relationship between body composition and LBP and disability in a population-based sample of men.

**Methods:** 978 male participants from the Geelong Osteoporosis Study (GOS), a population-based Australian study designed to investigate the epidemiology of osteoporosis among adults, were invited to participate in a follow up study in 2006. Participants completed questionnaires on sociodemographics and health status. LBP was determined using the validated Chronic Back Pain Grade Questionnaire and the presence of mood disorders was assessed using the Hospital Anxiety Depression Scale. Body composition was measured using dual energy x-ray absorptiometry. Independent samples t-tests and chi-square tests were used to compare the baseline characteristics of men with and without LBP and/or disability. Estimated marginal means were used to examine the relationships between obesity measures and body composition in participants with high intensity pain and disability compared to those with no or low pain and disability. Multivariate analyses included adjustments for age, mood disorder, education, mobility and body mass index (BMI). To examine the multivariate associations between body composition and back pain, adjustment was also made for the alternate body composition measure. Interactions between risk factors for LBP and measures of obesity, including measures of body composition were examined.

**Results:** Of the 820 respondents (84% response rate), 124 (15%) had high intensity LBP and/or disability. Participants with high intensity pain and/or disability were older, more likely to have a mood disorder, less likely to have completed secondary school and more likely to have poor mobility than those with no or LBP and disability ($p<0.002$ for all). LBP was associated with higher BMI (28.7±0.4 vs 27.3±0.2 kg/m$^2$, p=0.02) and waist-hip ratio (0.97±0.006 vs 0.96±0.006, p=0.04), with increased tendency towards having a higher fat mass index (8.0 vs 7.6 kg/m$^2$, p=0.08), but not fat-free mass index (p=0.68). The associations between LBP and measures of obesity were stronger in those with a mood disorder, particularly for waist-hip ratio (p=0.05 for interaction) and fat mass index (p=0.06 for interaction).

**Conclusions:** In a population-based sample of men, high intensity LBP and/or disability were associated with increased levels of obesity, particularly in those with mood disorders. This provides evidence to support a biopsychosocial interaction between mood disorders and obesity with LBP.

## SAT0520 INDICATIONS AND CLINICAL IMPACTS OF MAGNETIC RESONANCE IMAGING OF THE KNEE IN OLDER PATIENTS: ARE WE CHOOSING WISELY?

M.-E. Parent[1], F. Vézina[2], N. Carrier[3], C. Giguère[4], A. Masetto[3]. *[1]Department of Internal Medicine; [2]Department of Orthopaedic Surgery; [3]Department of Rheumatology; [4]Department of Radiology, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, Canada*

**Background:** The use of magnetic resonance imaging (MRI) seems to be increasing in patients with gonalgia. Findings such as osteoarthritis and meniscal damages are very prevalent in older patients, often simultaneously [1–3]. These findings are of undetermined significance, as invasive therapeutic procedures provide no additional benefit [4].

**Objectives:** The aim of this study is to analyze MRI indications and clinical impact in this population in our center.

**Methods:** We retrospectively analyzed 215 medical records of patients older than 50 yo having undergone a knee MRI in 2009. Medical charts were reviewed up

to 2014 for: patient characteristics, MRI indication, ordering physician specialty, radiography prior to MRI, MRI findings and clinical impacts of the MRI.
**Results:** Patient's average age was 60.6±7.5. Main MRI indications were meniscopathy: 148 (68.8%) and chronic pain: 92 (42.8%). Most MRIs were ordered by general practitioners (GP): 148 (68.8%) and orthopedic surgeons (OS): 55 (25.6%). Chronic pain investigation was significantly higher in GPs than in OS (48.0% vs 27.3%, p=0.008). Findings show that 185 (86%) patients had osteoarthritis (OA) and 170 (79.1%) had meniscal lesions. Overall, 87 (40.5%) patients were seen by an OS and 27 (31%) of them underwent an invasive intervention. Among the 81 patients with moderate-to-severe OA on MRI, 36 (46%) had evidence of moderate-to-severe OA on a previous plain radiography, 28 (34.6%) were seen by an OS, and 3 (3,7%) underwent a meniscectomy.
**Conclusions:** Our study reproduces the known association between OA and degenerative meniscal changes in older patients. About half of our cohort could have been appropriately diagnosed and treated based on available radiographic information, thus avoiding the MRI and subsequent OS evaluation. Meniscectomy - an MRI dependent procedure - was rare, particularly in patients with advanced OA. Educational and pragmatic measures must be emphasized to limit the inappropriate use of this costly imaging modality.

## SAT0521 DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS: CAN WE IDENTIFY DIFFERENT CLINICORADIOLOGICAL PATTERNS?

M.T. Clavaguera[1], R. Valls[2], M.C. Rodríguez Gimeno[2], M.T. Maneiro[3], N. Arañó[3]. *[1]Rheumatology, Hospital de Palamos, Sant Feliu de Guíxols; [2]Rheumatology; [3]Rehabilitation, Hospital de Palamos, Palamós, Spain*

**Background:** Diffuse Idiopathic Skeletal Hyperostosis (DISH) was described based on vertebral radiological signs (Resnick-Niwayama 1976). Subsequently, Utsinger presented other criteria that add extraspinal involvement that allowed DISH diagnosis even without vertebral signs [2]. Mader et al have tried to develop a new set of criteria without a final consensus about the inclusion of multiple peripheral enthesopathies [3].
**Objectives:** To identify in our patients affected from DISH the existence of different clinicoradiological patterns based on the spinal and/or extraspinal involvement.
**Methods:** We conducted a descriptive analysis of our cohort of patients who met Resnick and/or Utsinger classification criteria for DISH. Demographic, clinical, radiographic and comorbidity data were collected. Radiographic scans and medical records were reviewed since 2004. Patients were divided into 3 clinicoradiological patterns: 1) Axial pattern 2) Peripheral pattern 3) Mixed pattern. We excluded patients with positivity of HLA27 and/or past o present psoriasis and/or inflammatory bowel disease although radiographic features met the criteria described.
**Results:** We included 93 patients, 57% were male. The average age at diagnosis was 65.5 y (47–84) but the age of onset of symptoms was 58.5 y (36–80). In women the age at onset and diagnosis was earlier, 62.8 and 55.7 y, respectively. The delay in diagnosis was 6.36 years (0–25). All patients met Utsinger criteria: 72% definite; 20.5% probable and 7.5% possible, 28% did not meet Resnick's definition. The symptoms that led to the diagnosis were: 46.2% pain and/or limitation of thoracic-lumbar spine, 15.4% pain and/or limitation cervical spine, 22% a peripheral enthesopathy, 5.4% hip pain and 11% was a radiological finding. We identified: a) predominantly axial pattern (69.5%); b) predominantly peripheral pattern (19.6%); and a mixed pattern (10.9%). We also observed that women predominated in peripheral pattern (66%) and men in axial (65%). We didn't find any sex differences in the mixed pattern. Moreover, patients with peripheral pattern were diagnosed at earlier ages. We found hyperostotic signs in: 63.4% cervical spine, 93% thoracic spine and 55.4% lumbar spine, 51.9% had bony excrescencies of acetabulum, 80% enthesopathies of pelvic girdle and/or trochanter, 65% in knees, 68.4% elbows, 82% in Achilles tendon and 62% in fascia plantaris. Although the value of retrospective data is limited, the clinical history of enthesopathy was collected in a 46.2%.
**Conclusions:** We propose three patterns in DISH based on clinical symptoms and characteristic radiological signs. We need prospective studies to elucidate if they correspond to different stages of the disease or if they are different patterns related to sex or age.Because our evidence we consider the importance to investigate the extraspinal involvement when we establish the diagnosis of DISH.

## SAT0522 EFFICACY AND SAFETY OF ULTRASONOGRAPHIC GUIDED PERCUTANEOUS NEEDLE PLANTER FASCIOTOMY AS A TREATMENT FOR CHRONIC PLANTER FASCIITIS

M. Mortada, D.M. Sharaf, M.A.H. Hammad, N. Ezzeldin. *Rheumatology & Rehabilitation, Faculty of Medicine Zagazig University, Zagazig, Egypt*

**Background:** Plantar fasciitis (PF) is the most common cause of heel pain. Approximately 10% of the cases develop recalcitrant symptoms and are offered various forms of surgical intervention. Ultrasound guided needle planter fasciotomy is a minimal invasive method that may help this group of patients (1).
**Objectives:** To assess the efficacy and safety of ultrasonographic guided percutaneous needle planter fasciotomy as a treatment for chronic planter fasciitis.
**Methods:** ultrasound guided planter fasciotomy (1) was carried out in one hundred and seven patients who had chronic planter fasciitis that did not respond to conservative treatment including medical treatment, physiotherapy and local corticosteroid injection. Following induction of local anesthesia, a 14-gauge needle was guided toward and into the plantar fascia by real-time sonography.Visual analogue scale (VAS) for heel pain and ultrasonographic character of planter fascia (thickness and echogenicity) were assessed on the initial (W0), 2 weeks later (W2) and 6 months after treatment (W24).
**Results:** A highly significant difference was found between VAS and sonographic findings before and after fasciotomy. Patients improved significantly at 2 weeks compared to baseline and also at 6 months compared to baseline and 2 weeks (table 1). Nighty seven (90.7%) of patients stated that "the procedure had been worthwhile". There were no complications during or following needle fasciotomy.

Table 1. Comparison between VAS and sonographic findings at Baseline, 2 weeks and 6 months post-injection

| | Baseline | Two weeks | Six months | P |
|---|---|---|---|---|
| VAS | 80 (60–100) | 20 (10–60) | 10 (0–80) | 0.000** |
| Sonography | | | | |
| Fascia thickness | 6.9 (4.8–8.3) | 6.1 (5.1–7.9) | 5.3 (4.6–7.3) | 0.000** |
| Echogenecity | 2.5 (1–3) | 2 (1–3) | 1 (0–3) | 0.000** |

VAS visual analogue scale. **Highly significant difference $p<0.001$. Analysis was done by Kruskal Wallis tests. Post-Hoc tests were done also and revealed highly significant difference between baseline & 2 weeks (P=0.000), between baseline & 6 months (P=0.000), and between 2 weeks & 6 months (P=0.000) regarding VAS and sonographic findings.

**Conclusions:** Ultrasonographic guided percutaneous needle planter fasciotomy is a safe and an effective method in patients with chronic planter fasciitis who did not respond to conservative treatments including local corticosteroid injections.

## SAT0523 EFFICACY OF LOCAL AUTOLOGOUS PLATELET RICH PLASMA INJECTION COMPARED TO LOCAL CORTICOSTEROID IN TREATMENT OF PLANTAR FASCIITIS; AN ULTRASONOGRAPHIC EVALUATION

N.A. Sherpy[1], M.A.H. Hammad[1], E.H. Hagrass[2], H. Samir[2], S. Abu Elmaaty[3], M. Mortada[1]. *[1]Rheumatology & Rehabilitation; [2]Clinical Pathology, Faculty of Medicine Zagazig University, Zagazig; [3]Rheumatology & Rehabilitation, Dekernes Hospital, Mansora, Egypt*

**Background:** Plantar fasciitis (PF) is the most common cause of heel pain. Corticosteroid injections are used for cases of PF refractory to conservative treatment. Platelet-rich plasma (PRP) has been gaining popularity as a treatment for PF pain.
**Objectives:** The aim of this study was to compare between local autologous PRP injections and local steroid injections both clinically and sonographically within 3-months regarding its effect on pain, function, thickness, and echogenecity of the plantar fascia and also regarding its safety.
**Methods:** This study was carried out on 50 patients with chronic PF, attending the Rheumatology and Rehabilitation outpatient clinic in Zagazig University Hospitals. Patients were divided into two groups: Steroid group (n=25) and PRP group (n=25). Pre-injection all patients of our study were subjected to full history taking, thorough physical examination, visual analogue scale (VAS: 0–100), Foot Health Status Questionnaire (FHSQ) which included Short Form 36 (SF36), complete blood count (CBC) to exclude anemia and thrombocytopenia, plain x- ray to

detect calcaneal spur, and ultrasonography. Patients were reassessed by VAS, FHSQ, and ultrasonography at 1.5 months & 3 months postinjection. The clinical evaluator and sonographer were blinded to the type of injection.
**Results:** We found that at 1.5 months post injection, there was more improvement in the PRP group than the steroid group both clinically and ultrasonographically ($p=0.008$, $p<0.01$). Also, although at 3 months no great difference was found between the two groups ($p>0.05$), PRP patients continued to improve from 1.5 months to 3 months ($p=0.000$, $p<0.01$). None of our patients of either groups experienced any complications from injection at the end of the follow-up period. No post-injection foot deformities nor infection were noted ($P>0.05$).
**Conclusions:** We suggest that the PRP injection is a new, readily available and safe choice of therapy for PF and is not inferior to steroid injection in short term follow up. To our best knowledge this is the first study to compare steroids and PRP by ultrasonography.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4429

## SAT0524 COMPARISON OF ULTRASONOGRAPHY-GUIDED INJECTION WITH BLIND INJECTION IN FACET SYNDROME; A 6-WEEK RANDOMIZED CONTROLLED TRIAL

M. Karkucak[1], I. Batmaz[2], S. Kerimoglu[3], A. Ayar[4]. *[1]Department of Physical and Rehabilitation Medicine, Karadeniz Technical University, Medical school, Trabzon; [2]Department of Physical and Rehabilitation Medicine, Dicle University, Medical School, Diyarbakır; [3]Department of Orthopedics and Traumatology; [4]Department of Physiology, Medical School, Karadeniz Technical University, Medical school, Trabzon, Turkey*

**Background:** Local injection is a good alternative medical treatment in soft tissue disorders. Ultrasonography (US) is a good guide for local applications which increases the efficacy of the treatment.
**Objectives:** To compare the local injection performed by US-guided with blind injection in facet syndrome
**Methods:** Forty seven patients with the diagnosis of facet syndrome were included in the study.Patients were randomized into two groups. The patient's history, physical examination and routine laboratory parameters were used to diagnosis of facet syndrome.
Inclusion criteria for the study were as follows: pain for at least 6 weeks, pain extending to gluteal region and thigh, presence of pain with lumbar hyperextension and lateral flexion, paravertebral tenderness at the facet joint localization, negative straight leg raising test and normal neurological examination findings.
Approximately 5 cc of injection solution which was a mixture of 1–2% lidocaine hydrochloride and triamcinolone was applied twice within 15 days to maximum 2 points most tender with palpation (bilateral; L4–5 or L5-S1, unilateral; L4–5 and L5-S1). Assessment was made within 0, 2 and 6 weeks with Visual analog scale (VAS), Modified Oswestry scale and State-Trait Anxiety Inventory.
**Results:** The patients' initial VAS and Oswestry scale scores were similar. When the two groups were compared at the 6th week in terms of VAS scores, improvement was more pronounced in US-guided injection group (US-guided group before 7.6±2.2, after 3.0±1.7, $p=0.000$ vs blind group before 7.2±1.3, after 5.2±2.0, $p=0.000$). According to Oswestry scale scores at the 6th week there was no statistically significant difference between the two groups. The improvement in initial and 6th week Oswestry scale scores was statistically significant in the US-guided injection group ($p=0.006$). The improvement in trait anxiety scale scores was significant in both groups.
**Conclusions:** The US-guided local injections used in the treatment of facet syndrome have positive impact on both pain and functions.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2644

## SAT0525 THE USE OF ANALGESIC AND OTHER PAIN RELIEF DRUGS TO MANAGE CHRONIC LOW BACK PAIN – RESULTS FROM A NATIONAL SURVEY

N. Gouveia[1], A. Rodrigues[2], S. Ramiro[3], M. Eusébio[4], P.M. Machado[5], H. Canhão[2], J.C. Branco[1]. *[1]CEDOC - NOVA Medical School UNL; [2]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Portuguese Society of Rheumatology, Lisbon, Portugal; [5]University College London, Centre for Rheumatology Research & MRC Centre for Neuromuscular Diseases, London, United Kingdom*

**Background:** Managing chronic pain is challenging due to the long-term safety profile of most drugs. The treatment of chronic Low Back Pain (CLBP) represents a significant medical and financial burden and aims at relieving pain, improving functional ability, and preventing recurrence and chronicity. It is therefore important to gain insight into how CLBP is managed in the population.
**Objectives:** To characterize the intake profile of analgesic and other pain relief drugs in the Portuguese adult population with CLBP, taking the World Health Organization (WHO) analgesic ladder and pain intensity into account. To assess the relationship between having CLBP and the intake of analgesic and other pain relief drugs.
**Methods:** EpiReumaPt was a cross-sectional Portuguese population-based study (10,661 subjects). Self-reported active CLBP (ACLBP) was considered: LBP on the day of enrollment and for ≥90 days. Prevalence and profile of analgesic intake was characterized among those self-reporting ACLBP, taking into account the intensity of pain and the WHO analgesic ladder. To understand whether the presence of ACLBP was a factor associated with drug intake, multivariable logistic regressions were conducted for each of the analgesic/pain relief therapeutic groups (in separate models), adjusted for confounders.
**Results:** Among 1,487 subjects with ACLBP, 18.7% were using analgesic/pain relief drugs. Estimated prevalences were: anxiolytics, 14.1%; NSAIDs, 12.3%; antidepressants, 10.1%; analgesic antipyretic, 6.6%; anticonvulsants, 3,4%; central muscle relaxants, 2.6%; opioids, 1.6%. Most subjects with severe pain were in the 1st step of the WHO analgesic ladder: NSAIDs plus anxiolytics, sedatives & hypnotics (4.6%); NSAIDs plus antidepressants (3.2%); NSAIDs plus central muscle relaxants (2.5%). The presence of ACLBP was significantly associated with the intake of all therapeutic groups (table):

Table 1. Association of the presence of ACLBP with the intake of each class of analgesic/pain relief drugs (separate multivariable models)

| Dependent variables* | Active CLBP (yes/no) | |
|---|---|---|
| | OR (95% CI) | p-value |
| Anxiolytics, sedatives & hypnotics§ | 8.86 (6.08–12.90) | <0.001† |
| NSAIDs± | 8.56 (5.84–12.53) | <0.001† |
| Antidepressants§ | 12.56 (7.96–19.81) | <0.001† |
| Analgesics, Antipyretics¶ | 7.68 (3.38–17.48) | <0.001† |
| Anticonvulsants | 9.27 (4.16–20.69) | <0.001† |
| Analgesic Opioids | 8.13 (2.78–23.77) | <0.001† |
| Central Muscle Relaxants | 12.01 (5.88–24.51) | <0.001† |

*All the analyses were adjusted for: age, gender, geographic area, education level, number of self-reported comorbidities, and self-report of rheumatic and musculoskeletal diseases. §Additionally adjusted for: anxiety and depressive symptoms; ¶Additionally adjusted for: heart disease and gastrointestinal diseases.

**Conclusions:** ACLPB was associated with the intake of drugs belonging to all analgesic drug classes. Nevertheless, this drug intake was very low, even for those with severe pain. The WHO analgesic ladder was carefully followed with an extremely conservative use of analgesic opioids even for those with severe pain. There is clearly an unmet need in what concerns pain management in patients with ACLBP, particularly taking into account the well-know burden of LBP.

## SAT0526 SELF-MANAGEMENT IN CHRONIC NECK PAIN CAUSED BY CONGENITAL CERVICAL VERTEBRA BLOCK: A RANDOMIZED CLINICAL TRIAL

R. Traistaru, A.M. Bumbea, D. Kamal, R. Marcu, O. Rogoveanu. *Rehabilitation Department, University of Medicine and Pharmacy of Craiova, Craiova, Romania*

**Background:** Single congenital fusions are common anomalies, found most often at the C2–3 and C5–6 levels had moderate or severe degenerative changes in their cervical spines, or displayed signs of cervical instability. There is no motion at the level of congenital block vertebrae, as noted in flexion and extension radiographic analysis, resulting in excessive mobility and early degenerative changes at the adjacent unfused motion segments.
**Objectives:** The aim of our single blind, randomized controlled study was to assess the efficacy of comprehensive home exercise program on neck pain and physical performance in patients with block vertebrae in lower cervical segments (C5-C6 and C6-C7).
**Methods:** 36 patients with chronic neck pain and cervical block vertebrae were randomly assigned into exercise home group (G1, 19 patients) and second group (G2, 17 patients - noncompliant to exercise program). All patients were complete assessed (clinical, imagistic, functional). Kinetic program (first light positive exercise, next gradually strengthening exercises for the all cervical muscle exercise, one set of 10 repetitions each direction, twice a day and neck school exercises) was initiated in rehabilitation clinic. Duration of follow-up was 16 weeks after start of the intervention. At 4 and 16 weeks an independent physiotherapist unaware of the treatment allocation performed outcome assessments - pain (VAS) and Neck Disability Index (NDI) for functional status.
**Results:** Comparing week 16 with baseline, pain improved significantly ($p<0.05$). Significant improvement in NDI scores for pain and functional status were found at week 4 and week 16 in the G1 compared to baseline. At 16 weeks, 16 (84.2%) patients mentioned their functional status as improved and only 3 (15.8%) as similar at baseline.
**Conclusions:** The exercise program performed daily led to improvements in pain and physical measures. Optimal neck care in congenital cervical vertebra block includes pain-relieving exercises that also help restore neck posture, limitation of the neck movement and the muscular weakness. These techniques can help recover and provide good control against future symptoms (atrophy and neurological sensory loss, myelopathy).

SAT0527 **PREDICTORS OF BACK PAIN IN MIDDLE AGED WOMEN: DATA FROM THE AUSTRALIAN LONGITUDINAL STUDY ON WOMEN'S HEALTH**

S.R.E. Brady[1], S.M. Hussain[1], W.J. Brown[2], S. Heritier[1], Y. Wang[1], H. Teede[1], D.M. Urquhart[1], F.M. Cicuttini[1]. [1]*School of Public Health and Preventive Medicine, Monash University, Melbourne;* [2]*School of Human Movement Studies, University of Queensland, St. Lucia, Australia*

**Background:** Back pain is a major public health issue, causing greater disability worldwide than any other condition. Given the limited treatment options available, an understanding of the predictors of back pain is vital to optimize preventive strategies. Women are not only more likely to suffer from back pain, they are also more likely to utilise health care services to a greater extent than men. However, few studies to date have examined modifiable predictors of back pain in middle-aged women, with exposure and outcome measures assessed at multiple time points and major inconsistency and knowledge gaps persist in this area.
**Objectives:** Our aim was to identify modifiable risk factors for back pain in middle-aged women.
**Methods:** Women born between 1946 and 1951 were randomly selected from the Australian national health insurance scheme database to participate in The Australian Longitudinal Study of Women's Health. Self-reported data on back pain in the last 12 months, weight, height, age, physical activity, depression, menopause status and other socio-demographic factors were collected in 1998, 2001, 2004, 2007, 2010 and 2013. In 1998, 12,338 women completed the survey and 10,011 (74%) completed the 2013 survey 15 years later.
**Results:** At baseline, median (range) age was 49.5 (44.6 – 53.5) years and 54% reported back pain. In longitudinal multivariate analysis, baseline weight (per 5kg increments) and depression were independent predictors of back pain over each 3 year survey interval and over the following 15 year period, whereas participation in vigorous physical activity was protective. Mean weight gain over the first three years of 1.4kg was associated with an increased risk of back pain over the following 12 years (multivariate OR 1.01, 95% CI 1.01–1.02). The effects of weight on back pain were not affected by participation in vigorous physical activity, being menopausal, or depression status, but the association between weight and back pain tended to be more consistent in those who were overweight or obese.
**Conclusions:** Back pain is common in middle-aged women. Increased weight, weight gain and depression were independent predictors of back pain over 15 years, whereas participation in vigorous physical activity was protective. Targeting these lifestyle factors is an important area for future research on reducing the burden of back pain in middle-aged women.

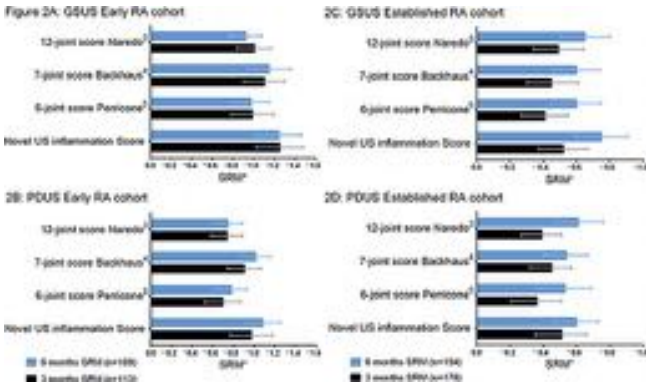
## Diagnostics and imaging procedures



SAT0528 **DEVELOPMENT AND VALIDATION OF A RESPONSIVE ULTRASOUND JOINT INFLAMMATION SCORE FOR RHEUMATOID ARTHRITIS THROUGH A DATA-DRIVEN APPROACH**

A.-B. Aga[1], E. Lie[1], I.C. Olsen[1], H.B. Hammer[1], T. Uhlig[1], S. Lillegraven[1], D. van der Heijde[2], T.K. Kvien[1], E.A. Haavardsholm[1] on behalf of the ARCTIC Working Group. [1]*Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway;* [2]*Leiden University Medical Center, Leiden, Netherlands*

**Background:** No consensus exists on which joints and tendons should be systematically examined by ultrasound (US) to assess inflammation in rheumatoid arthritis (RA). Validity and responsiveness must be balanced against feasibility. Our group has previously developed and validated an US joint inflammation score[1].
**Objectives:** To optimize the US joint inflammation score in terms of sensitivity to change and feasibility, and to validate the score in a separate cohort.
**Methods:** Between Jan 2010 and June 2013 patients (pts) were included in two cohorts: Early RA (DMARD-naïve pts with RA of <2 yrs symptom duration fulfilling 2010 ACR/EULAR classification criteria), and established RA (pts starting or switching biologic DMARDs). An extensive US examination was performed by experienced sonographers using a validated grey-scale (GSUS) and power Doppler (PDUS) semi-quantitative scoring system with scores 0–3 for GSUS and PDUS in each of the following 36 joints and 4 tendons bilaterally: MCP 1–5, PIP 2–3, radiocarpal, distal radioulnar (DRUJ), intercarpal, elbow, knee, talocrural, MTP 1–5, extensor carpi ulnaris (ECU) and tibialis posterior (TP) tendons. An US atlas was used as reference[2]. We performed principal component factor analyses (PCA) of GSUS and PDUS changes from baseline to 3 months (ΔGSUS and ΔPDUS) to identify joint groups with high internal correlation, and selected a candidate joint/tendon set based on these analyses. 3- and 6-month standardised response means (SRMs) with 95% CIs (bootstrapping) were estimated for the candidate set and 3 formerly developed scores in both the early RA cohort and the validation cohort of established RA. Finally, as part of the validation, we assessed the loss of information in the novel score compared to the full score by $R^2$ from linear regression analyses in both cohorts.
**Results:** A total of 330 pts were included, 118 with early and 212 with established RA; 71% vs. 81% anti-CCP pos, mean (SD) age 51 (13) vs. 52 (13) yrs, DAS28 4.7 (1.2) vs. 4.7 (1.4), median (25–75 perc) 28-SJC 6 (3–11) vs. 5 (2–10), disease duration 0.5 (0.2–0.8) vs. 8 (3–15) yrs. We identified 12 joint/tendon groups based on PCA in the early RA data, and 8 joints* and 1 tendon* were included in the final score based on these results (Table). SRMs at 3 and 6 months were higher for the novel score than formerly developed scores in the early RA cohort, with similar results in the validation cohort of established RA (Fig). Based on baseline data from the early RA cohort, the final score retained 87% (GSUS) and 90% (PDUS) of the information in the full score. The corresponding numbers in the validation cohort were 90% (GSUS) and 92% (PDUS).

Table 1

| Group 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Radiocarpal* | MCP3* | MTP2* | Elbow | MCP2* | MCP1* | MTP3* | TP-t | ECU-t* | PIP2* | PIP3* | MTP1 |
| Intercarpal | MCP4 | | | | | MTP4 | | | | | |
| DRUJ | MCP5 | | | | | MTP5 | | | | | |

**Conclusions:** We used a data-driven approach to further develop an ultrasound inflammation score in RA. We propose a score of 8 joints and 1 tendon assessed bilaterally, with improved sensitivity to change compared to formerly developed scores. Our results show that assessment of inflammation by US is feasible and may be a valuable addition to RA disease assessment.

SAT0529 **HYDROXYCHLOROQUINE RETINOPATHY: UPDATE ON APPLICATION OF THE 2011 SCREENING GUIDELINES IN AN ACADEMIC PRACTICE**

S.M.A. Shah[1], E.M. Schönbach[1], H.P. Scholl[1], M. Petri[2]. [1]*Ophthalmology;* [2]*Rheumatology, Johns Hopkins University, Baltimore, United States*

**Background:** The risk of end-stage retinopathy (bull's eye maculopathy) from hydroxychloroquine is reported as 0.65%. With recent advances in retinal structure and function testing, American Academy of Ophthalmology (AAO) issued revised guidelines to detect early signs of hydroxychloroquine retinopathy with the use of ancillary testing including Optical Coherence Tomography (OCT), Fundus Autoflourescence (FAF) and multifocal Electroretinography (mfERG) in addition to clinical exam and visual fields. Risk of retinopathy as defined by combination of these tests ranges from 7.5–12% in those on HCQ for at least 5 years or longer. This is an expanded cohort of patients previously presented at the 2015 American College of Rheumatology (ACR) meeting in San Francisco, CA.
**Objectives:** To determine the application of AAO guidelines in an academic practice and the prevalence of HCQ retinopathy based on advanced ancillary tests recommended by AAO.
**Methods:** Microperimetry (MP) was used as a substitute for Humphrey Visual Fields (HVF). Ophthalmic exam, MP, OCT, FAF, mfERG were performed on SLE patients meeting SLICC criteria on hydroxychloroquine. Ophthalmic examinations and testing were interpreted by experienced retina specialists.
**Results:** The mean duration of treatment with HCQ was 11.8 years in 125 (246 eyes) consecutive patients with SLE on whom all 4 tests done. Overall, HCQ-related abnormalities were noted in 12 (5%) eyes on OCT, 14 (6%) on FAF, 26 (11%) on mfERG and 24 (10%) on MP. A total of 45 eyes (18%) had abnormal findings on OCT and 12 (27%) of these were related to HCQ. A total of 36 eyes (15%) had abnormal findings on FAF and 14 (39%) of these were related to HCQ. For mfERG, we found a total of 99 (40%) abnormal tests with 26 (26%) eyes with

changes consistent with HCQ retinopathy. A total of 72 (29%) of all MP tests were abnormal and 24 (33%) of these were related to HCQ. Only 3 patients (2.4%) showed changes in all 4 tests suggestive of HCQ retinopathy.
**Conclusions:** Our updated series reaffirms our previous findings presented at the ACR conference and demonstrates that in absence of pre-HCQ data for the AAO recommended ancillary tests it may be difficult to interpret changes seen on these tests since most of the screenings are done by regular ophthalmologists who lack the equipment and experience with specialized testing such as mfERG, FAF and OCT. Nonspecific abnormalities are common with these tests, which need careful interpretation by retina specialists. We recommend repeat testing in those with abnormal tests and additional testing in patients in which all four modalities were not used to determine early toxicity. In our expanded cohort, we found substantial number of cases with abnormalities unrelated to HCQ. A discussion needs to take place between the patient care team including the ophthalmologist and rheumatologist to decide about the continuation or stopping HCQ based on these nonspecific abnormalities in individual tests that are not supported by the respective other modalities.

## SAT0530 DEEP CLINICAL REMISSION - AN OPTIMIZED TARGET IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS? EXPERIENCE FROM AN ULTRASONOGRAPHY STUDY

Y. Geng, Z. Zhang. *Rheumatology and Clinical Immunology Department, Peking University First Hospital, Beijing, China*

**Background:** Treat-to-target strategy, aiming at clinical remission, has greatly improved the prognosis of RA. However, the ultrasonographic subclinical synovitis was correlated with bone erosion and disease flare.
**Objectives:** The aim of this study was to evaluate whether deeper clinical remission (DAS28(ESR) $\leq$1.98) reflects the better control of subclinical synovitis.
**Methods:** 126 RA patients in clinical remission were enrolled in the study. Disease activity and ultrasongraphy were evaluated at baseline, and every 3 months during a 12-month follow-up. The relationship between the extent of clinical remission, flare and ultrasonographic features was analyzed.
**Results:** In 126 RA patients, 76 achieved deep clinical remission and 50 achieved mild clinical remission. In all, 54 (42.9%) patients relapsed at average of 6.8±3.3 months during follow-up. Patients in deep remission possessed not only lower risk to relapse (30.3% vs. 62.0%, $P<0.01$), but also longer duration of remission before relapse (8.1±3.3 vs. 5.9±3.1 months, $P<0.05$). Besides, applying DAS28(ESR) $<$1.895 to predict ultrasonographic remission defined as negativity of both PD and SH was highly accurate ($P<0.001$). Subclinical PD synovitis at baseline was an independent risk factor for predicting relapse in RA patients achieved clinical remission (OR 8.8 [95% CI 2.7–28.4]).
**Conclusions:** Subclinical synovitis was common in RA patients even in deep clinical remission. The deeper the clinical remission, the milder the subclinical synovitis, and the lower risk to relapse. Therefore, achieving deeper clinical remission, which reflected better control of subclinical synovitis and less tendency to flare, could be an optimized treatment target of RA.

## SAT0531 CAN HISTOLOGICALLY DEFINED PERI-ARTICULAR VASCULAR CHANNELS BE IDENTIFIED ON HIGH-RESOLUTION COMPUTED TOMOGRAPHY? A STUDY IN CADAVERIC FINGER JOINTS

A. Scharmga[1,2,3], K.K. Keller[4], M. Peters[1,2,3], A. van Tubergen[1,2], J. van den Bergh[1,3,5,6], B. van Rietbergen[7], R. Weijers[8], D. Loeffen[8], E.M. Hauge[4,9], P. Geusens[1,2,6]. *[1]Rheumatology, MUMC; [2]CAPHRI; [3]NUTRIM, Maastricht, Netherlands; [4]Rheumatology, Aarhus University Hospital, Aarhus, Denmark; [5]Internal Medicine, Viecuri Medical Center, Venlo, Netherlands; [6]Faculty of Medicine and Life Sciences, Hasselt University, Hasselt, Belgium; [7]Biomedical Engineering, TUE, Eindhoven; [8]Radiology, MUMC, Maastricht, Netherlands; [9]Clinical Medicine, Aarhus University, Aarhus, Denmark*

**Background:** Several studies have indicated that High Resolution peripheral CT (HR-pQCT) scanning is more sensitive than radiography in detecting cortical breaks in destructive joint diseases like rheumatoid arthritis (RA)[1–3]. Cortical breaks are also seen in healthy controls, but the exact nature of these breaks is not known, and might represent vascular channels (VCs). No previous study has compared histology to HR-pQCT images in finger joints. We hypothesized that VCs seen on histology can also be detected by HR-pQCT imaging.
**Objectives:** To identify histologically defined VCs in cadaveric hand joints on HR-pQCT imaging.
**Methods:** Based on HR-pQCT, three regions in metacarpophalangeal joints from female cadavers with an unknown medical history (mean age 84.7, SD 5.5 years) were selected. These regions were extracted, embedded undecalcified in methylmetacrylate and histologically sectioned (thickness 15$\mu$m) parallel to the axial plane. Every second section (n=450) was stained with Goldner Trichrome. VCs were identified as a cortical break in one histological section which contained one or more vessels. HR-pQCT images (thickness 82$\mu$m) were independently scored by two trained readers for the presence of cortical breaks and if applicable categorized as VC. A break on HR-pQCT was defined as an interruption of the cortex seen on 2 consecutive slices in at least 2 orthogonal planes. A VC was defined as a break that is linear in shape with parallel lining. Finally, the histological sections were matched visually to corresponding axial HR-pQCT images.
**Results:** A total of 56 VCs were identified on histology. On HR-pQCT 20 breaks were identified, of which 7 were categorized as VC. Only 3 VCs matched with VCs on histology. Of the remaining 53 histologically identified VCs, 34 could be detected on HR-pQCT, but the interruption of the cortex was not seen on 2 consecutive slices therefore they were not classified as a break. Eight histologically VCs fulfilled the definition of a break on HR-pQCT, but were not categorized as a VC. Eleven histologically VCs could not be identified on HR-pQCT. Figure 1 demonstrates histology and HR-pQCT images.

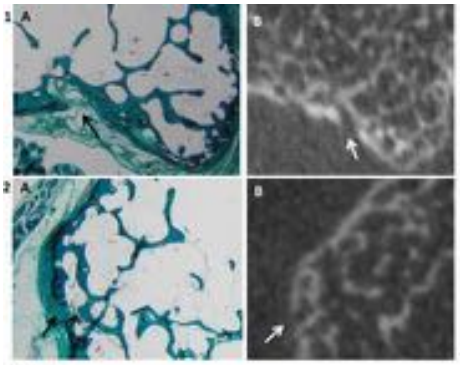

Figure 1.
Panel 1: A vascular channel on histology (A) (arrow) and HR pQCT imaging (B) (arrow)
Panel 2: A vascular channel on histology (A) (arrow) and a cortical break not defined as vascular channel on HR pQCT (B) (arrow)

**Conclusions:** VCs were frequently seen on histology. Only a minority of histologically defined VCs is interpreted as VC using a pre-specified definition on HR-pQCT images. Small histological VCs were often identified as an interruption but rarely considered a break according to the current definition of a VC on HR-pQCT. Therefore, additional criteria in order to diagnose the presence of VCs on HR-pQCT are warranted.

## SAT0532 TIBIAL CORTICAL THICKNESS MEASURED BY HIGH–RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY DISCRIMINATES VERTEBRAL FRACTURES IN PATIENTS ON LONG-TERM GLUCOCORTICOIDS INDEPENDENT OF AREAL BONE MINERAL DENSITY

J. Shen, L.-S. Tam on behalf of Hong Kong GIOP Study Group. *Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

**Background:** Glucocorticoid-induced osteoporosis is the commonest cause of secondary osteoporosis and related fracture. The current gold-standard for the diagnosis of osteoporosis is dual x-ray absorptiometry (DXA) that measures areal bone mineral density (aBMD). However, aBMD has a low predictive value for vertebral fracture. High–resolution peripheral quantitative computed tomography (HR-pQCT) allows assessment of volumetric BMD (vBMD) and bone macro/microstructure. Whether HR-pQCT can better predict vertebral fractures in patients on long-term glucocorticoids (GC) compared to DXA remained uncertain.
**Objectives:** To determine if peripheral bone parameters evaluated by HR-pQCT can discriminate patients on long-term GC with and without vertebral fracture independent of aBMD.
**Methods:** This is an ongoing, cross-sectional study of 1100 rheumatic disease patients on long-term GC to access prevalent vertebral fracture radiographically (Genant semi-quantitative assessment). 110 patients with fracture (fracture group) and 110 patients without fracture (control group) underwent assessment with 1) aBMD using DXA; and 2) vBMD/structural assessment of the non-dominant distal radius and tibia using HR-pQCT. We hereby report the interim results of the first 78 and 77 patients in the fracture and control groups respectively.
**Results:** Both groups were matched in gender [female: 63 (81%) vs 59 (77%); $p$=0.528], disease type [SLE/RA/others: 28 (36%)/27 (35%)/23 (29%) vs 36 (47%)/16 (21%)/25 (32%); $p$=0.143], and cumulative GC dose (17.3±13.6 vs 20.2±18.1g, $p$=0.447). Patients in the fracture group were older (62±14 vs 57±11 years, p=0.009), more postmenopausal [50 (79%) vs 37 (63%), $p$=0.048], of lower body mass index (BMI) (22.7±3.5 vs 24.2±3.4 kg/m$^2$, $p$=0.010), and more likely to be on vitamin D [53 (68%) vs 35 (45%), $p$=0.005] and bisphosphonates [19 (24%) vs 6 (8%), $p$=0.005]. Only 26 (35%) of the vertebral fracture patients were classified as osteoporotic (femoral neck T-score$\leq$2.5). Fracture patients had a lower vBMD and impaired bone architecture compared with controls (Table). In multivariate logistic regression analysis, after adjusting for age, gender, BMI, vitamin D and bisphosphonate use, and aBMD, lower cortical thickness in the distal tibia (odds ratio: 1.38 for per 0.1mm decrease, 95%CI 1.13–1.67; $p$=0.001) and current use of vitamin D (3.78, 1.47–9.71; $p$=0.006) were independently associated with vertebral fracture.

Table 1. HR-pQCT parameters in patients with and without vertebral fracture

| | Fracture | Control | Difference (%) | $p$ |
|---|---|---|---|---|
| Radius | | | | |
| Total vBMD, mg/cm$^3$ | 268±77 | 339±72 | –21.0 | <0.001 |
| Ct. vBMD, mg/cm$^3$ | 843±90 | 899±61 | –6.2 | <0.001 |
| Ct. thickness, mm | 0.69±0.23 | 0.87±0.20 | –20.8 | <0.001 |
| Tb. vBMD, mg/cm$^3$ | 101±43 | 132±43 | –23.5 | <0.001 |
| Tb. number, mm$^{-1}$ | 1.27±0.42 | 1.47±0.30 | –13.6 | 0.002 |
| Tibia | | | | |
| Total vBMD, mg/cm$^3$ | 218±64 | 273±62 | –20.1 | <0.001 |
| Ct. vBMD, mg/cm$^3$ | 798±78 | 856±62 | –6.7 | <0.001 |
| Ct. thickness, mm | 0.82±0.27 | 1.09±0.28 | –24.9 | <0.001 |
| Tb. vBMD, mg/cm$^3$ | 116±38 | 140±36 | –17.1 | <0.001 |
| Tb. number, mm$^{-1}$ | 1.36±0.32 | 1.52±0.27 | –10.5 | 0.002 |

Ct, Cortical; Tb, Trabecular.

**Conclusions:** Our results suggest that skeletal abnormalities in patients with vertebral fracture are much more pronounced than those indicated by DXA. In particular, reduction in cortical thickness may be an important mechanism of vertebral fracture in rheumatic patients on long-term GC.
**Disclosure of Interest:** None declared

## SAT0533 KNEE SYNOVITIS: ULTRASONOGRAPHIC FINDINGS STRONGLY CORRELATE WITH SYNOVIAL MEMBRANE HISTOLOGY

A. Najm [1,2], C. Orr [2], U. Fearon [3], D. Veale [2,3]. *[1]Rheumatology, Nantes University Hospital, Nantes, France; [2]Rheumatology, Saint Vincents University Hospital; [3]Dublin Academic Medical Centre, University College Dublin and Saint Vincents University Hospital, Dublin, Ireland*

**Background:** Arthroscopy, by allowing direct visualization of the synovial membrane, is the gold standard for the assessment of knee synovitis. Given the fact that it is an invasive procedure, other reliable ways to assess synovitis has developed over the past few years. Ultrasonography (US) is a fast, available and low cost imaging tool and has been validated for detecting knee synovitis (1). Ultrasonographic and arthroscopic findings have been shown to correlate (2). However, few studies have yet assessed the correlation between ultrasonographic and histological findings.
**Objectives:** The aim of this study was to assess the correlation between ultrasonographic scores, arthroscopic scores and histological scores for inflammation and vascularity in knee joint synovitis.
**Methods:** Patients with knee pain and/or effusion were prospectively included. Knee was divided in three compartments (medial, lateral and superior). 1 operator (AN) performed a knee ultrasonography (B mode and Doppler mode) prior to the arthroscopy with a semi-quantitative assessment for degree of synovitis. 1 operator then performed a knee arthroscopy (CO, DJV) and scored macroscopic aspects with a 100-mm visual analogic scale (VAS) blindly from US findings and retrieved biopsies from each compartment. Biopsies were analyzed by 1 operator (UF) blindly from both US and arthroscopic findings and scored for: lining layer hyperplasia, inflammation and vascularity. Statistical analysis was made with non parametric Spearman correlation test.
**Results:** 23 patients were included. 16 had rheumatoid arthritis (RA) (ACR/EULAR 2010 criteria). 3 patients had psoriatic arthritis (PsA) (CASPAR criteria), 3 had osteoarthritis (OA) and 1 had gout. Mean ultrasonographic, arthroscopic and histological scores for both synovitis and vascularity were calculated for each patient. A strong correlation was observed between: US synovitis grade and histological inflammation score (r=0.71; p=0.001), US Doppler grade and histological score for vascularity (r=0.6; p=0,0003); US measured synovial thickness and lining layer hyperplasia (r=0.61; p=0,002). Moreover, high positive correlations were observed for both histological lining layer hyperplasia and inflammation between lateral and medial compartments (r=0,90; p=0,00005 and r=0,66; p=0,014 respectively), lateral and superior compartments (r=0,75; p=0,001 and r=0,51; p=0,048, respectively) and medial et superior compartments (r=0,61; p=0,012 and r=0,62; p=0,010, respectively).
**Conclusions:** B mode and Power Doppler US findings strongly correlate with histological inflammation and vascularity scores in actively inflamed knee joints. Ultrasound is therefore a reliable tool for knee joint assessment of the four most common rheumatological diagnoses - RA, PsA, OA and gout -. Moreover, the histological inflammation and hyperplasia scores highly correlate between the superior, medial and lateral compartments of the knee, highlighting the homogeneity of synovial membrane features within the same joint.

## SAT0534 HOW TO DEFINE SONOGRAPHIC SIGNS OF AXILLARY VASCULITIS IN GIANT CELL ARTERITIS?

M. Milchert, M. Brzosko. *Department of Rheumatology Internal Medicine and Geriatrics, Pomeranian Medical University, Szczecin, Poland*

**Background:** Extracranial large vessel vasculitis (LVV) diagnosis is delayed compared to classical temporal arteritis. There is a need for simple and reliable tests for the diagnosis of extracranial large vessel giant cell arteritis (GCA). Identifying extracranial giant cell arteritis increases diagnostic specificity and adds prognostic value, as extensive vascular involvement may be associated with a poorer treatment response. Color duplex sonography (CDS) is most promising tool for the assessment of not only temporal but also large vessel arteritis. However, the proper interpretation of the vasculitis findings remain an important concern, as for an inexperienced ultrasonographer it remains elusive. There is still a need to define ultrasound findings, unify the diagnostic cut-offs and implement such standards by educating ultrasonographists.[1,2]
**Objectives:** We present a novel idea to define a simple, sonographic sign of axillary arteritis.
**Methods:** 214 consecutive patients suspected for GCA were included in the study between 2011 and 2015 and followed up for at least 0,5 year. Axillary arteries were scanned from axillary approach by continuing distally in a longitudinal plane down to brachial arteries. All examinations, together with categorization into arteritis and non-arteritis findings, were performed by a single physician with at least 5 years long experience in LVV ultrasound, that was blinded to diagnosis but aware of clinical presentation. Esaote MyLab25Gold Machine with 10 and 18 MHz linear probes was used.
Slide sign was considered positive (Figure 1) if there was an increased axillary artery wall thickening, (hypoechoic, homogenous, with distorted wall structure resulting in no clear intima-media structure, usually circumferential, over long distance but not limited only to the place of arterial bifurcation), that was followed by a brachial artery without wall thickening and with normal IM structure (clear double line).
The diagnosis was based on ACR criteria (for cranial GCA), or presence of typical manifestations together with large vessel arteritis confirmed by whole aorta CT or ultrasound (for extracranial GCA). Non-GCA patients served as controls.
**Results:** GCA was diagnosed in 81 patients. Extracranial LVV was diagnosed in 28 patients. Axillary vasculitis was diagnosed in 23 patients and was not found in controls. Positive slide sign was found in 23 patients. They've matched the patients with ultrasnographic signs of axillary vasculitis, so congruency between both methods was 100%.

Figure 1

**Conclusions:** Slide sign compared with large vessel halo sign serves at least non inferior diagnostic performance. Although qualitatively accessed slide sign does not bring additional diagnostic value over signs of axillary vasculitis it is easier to define and to observe.
This proposed definition of slide sign contains description of pathological findings in axillary artery, normal findings in brachial artery - which is typically not involved in vasculitis or involved only per continuum in a proximal part, and some features to help to exclude arteriosclerosis.

## SAT0535 CAROTID ULTRASOUND IN THE CARDIOVASCULAR RISK STRATIFICATION OF PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULTS OF A POPULATION-BASED STUDY

J. Rueda-Gotor[1], C. Fernández Díaz[1], J. Llorca[2], A. Corrales[1], R. Blanco[1], P. Fuentevilla[1], V. Portillo[1], R. Expósito[3], C. Mata[3], T. Pina[1], C. González-Juanatey[4], M.A. Gonzalez-Gay[1]. *[1]Rheumatology, Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, IDIVAL, University of Cantabria; [2]Division of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, Santander; [3]Rheumatology, Hospital Comarcal de Laredo, Laredo; [4]Cardiology, Hospital Lucus Augusti, Lugo, Spain*

**Objectives:** To determine if the use of carotid ultrasonography (US) may improve the cardiovascular (CV) risk stratification in patients with ankylosing spondylitis (AS).
**Methods:** A set of 127 consecutive patients without history of CV events, diabetes mellitus or chronic kidney disease that fulfilled definitions for AS according to the 1984 modified New York criteria were recruited to assess carotid intima-media thickness and presence of plaques. CV risk was calculated according to the systematic coronary risk evaluation (SCORE), the Framingham Risk Score (FRS) and the Reynolds Risk Score (RRS).
**Results:** Men outnumbered women (61.4%). The mean±SD age at the time of the study was 44.5±11.6 years. The median (interquartile range) delay to the diagnosis was 5 (1–12) years. HLA-B-27 was positive in 77.2%, and syndesmophytes were present in 38.9%. Carotid plaques were found in 43 (33.9%). Regardless of the algorithm used for CV risk stratification, more than 50% of the patients classified as having moderate CV risk had carotid plaques. Moreover, 20.8%, 24.6% and 53.3% of AS that fulfilled the category of low CV risk according to the total cholesterol (TC)-SCORE, FRS and RRS, respectively had carotid plaques. A model that included patients with a chart TC-SCORE $\geq$5% or SCORE-TC $\geq$1% $<$5% plus carotid plaques or TC-SCORE $<$1% and CRP $>$3 mg/L at diagnosis plus syndesmophites and carotid plaques or TC-SCORE $<$1% and CRP $>$3 mg/L at diagnosis plus extraarticular manifestations plus carotid plaques yielded the highest sensitivity (93.0%) for high/very high CV risk in these patients. The presence of syndesmophytes was associated with increased risk of carotid plaques in AS that fulfilled definitions for low CV risk according to the TC-SCORE (OR 8.75 [95% CI 2.11 - 36.40]; p=0.002).
**Conclusions:** Our results support the use of carotid US in the assessment of CV risk in patients with AS.

## SAT0536 UTILITY OF 18F-FLUORO-DEXOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY FOR THE DIAGNOSIS OF POLYMYALGIA RHEUMATICA: A CONTROLLED STUDY

M. Sondag[1], X. Guillot[1], F. Verhoeven[1], O. Blagosklonov[2], C. Prati[1], H. Boulahdour[2], D. Wendling[1]. *[1]Rheumatology; [2]Nuclear Medicine, CHU Jean Minjoz, Besançon, France*

**Objectives:** To compare[18]f-Fluoro-Dexoxyglucose Positron Emission Tomography (FDG-PET/CT) findings in patients with polymyalgia rheumatica (PMR) and controls without rheumatologic disease.
**Methods:** We have retrospectively included 50 patients with a diagnosis of PMR (EULAR/ACR criteria), who have had a FDG-PET/CT. For comparison, 53 patients who have had a FDG-PET/CT for initial staging or follow-up of neoplasm have been included as controls. 17 sites have been analyzed (2 shoulders, 2 acromio-clavicular and 2 sterno-clavicular joints, 2 greater trochanters, 2 hips, 2 ischial tuberosities, 2 iliopectinal bursitis, 2 pubic symphysis enthesis and only the interspinous space with the most FDG uptake). An FDG uptake score has been used (semi-quantitative scoring system, by Goerres and al. to evaluate visually FDG uptake (0 to 3 compared to liver uptake) into these sites. We calculated the FDG uptake score corresponding to the mean of intensity over all sites, and the number of sites with significant uptake (FDG uptake 2 or 3) for each patient. The cut offs for number of sites with high activity and for FDG uptake score were assessed using ROC curves and Odds Ratios.
**Results:** The two groups were comparable for the median patient age (69.3 years for PMR vs. 68.1 for controls). Significant differences between the two groups were found for FDG uptake score (1.12 vs 0.34, p$<$0.00001) and for number of sites with significant uptake: 6.36 sites vs 1.49 sites, p$<$0.00001.
The presence of 3 or more sites with significant uptake was correlated with the diagnosis of PMR with 74% sensitivity, 79% specificity [OR =10.8]. For the FDG uptake score the cut off is 0.53 [Se 80%, Sp 77%; OR 13.6].
We found significant differences in all sites for FDG uptake score, and number of sites with significant uptake, particularly marked for shoulders, ischial tuberosities and interspinous bursitis (p$<$0.00001 for FDG uptake score).

| | FDG uptake score (0–3) | Number of sites with significant uptake (0–17) |
|---|---|---|
| PMR group (N=50) | 1.12 [%CI 0.90–1.33] | 6.13 [%CI 4.99–7.26] |
| Control group (N=53) | 0.34 [%CI 0.26–0.41] | 1.49 [%CI 1.38–1.59] |
| p | p$<$0.00001 | p$<$0.00001 |

**Conclusions:** We found significant uptake in all sites studied in PMR compared to controls. We propose the number of 3 sites with significant uptake and a FDG uptake score superior at 0.53 for the diagnosis of PMR.

## SAT0537 SENSITIVITY AND SPECIFICITY OF ULTRASOUND SCORE FOR THE DIAGNOSIS OF GOUT

M.M. Basaric, G. Radunovic, N. Damjanov, M. Perovic-Radak. *Institut of rheumatology, Belgrade, Serbia*

**Objectives:** To determine sensitivity and specificity of ultrasound score (US-score) for the diagnosis of gout, by ultrasound (US) examination, of the first metatarsophalangeal (MTP1) joint.
**Methods:** A groups of 60 patients (pts) with primary gout of the MTP1 joints were examined. Diagnosis was established by EULAR criteria for diagnosis of gout. In the group of gouty patients, only symptomatic MTP1 joints (n=83 joints) were examined by US. US findings of 60 pts (83 joints) were compared with US findings of 35 healthy controls (n=70 joints). Both groups were comparable according to age, sex and BMI. US examination was done by 18 MHz probe. The existence of: “double contour”, tophi, “starry sky” and/or “snowstorm” signs, hyperechoic cloudy areas (HCA), joint effusion, bone erosions, power Doppler signal and synovial hypertrophy were assessed. After determining the sensitivity and specificity of all these US signs individually, they were qualitative scored as 0 (absent) or 1 (present) and scored as follows: US8-US0-score “0–8”, whereby “0” means that none of the characteristics are present, and “8” means that all listed US findigns are present.
**Results:** The area under the ROC curve for total US8-score was 0.901 ± 0.025. The diagnostic sensitivity and specificity of US8-score in the MTP1 joint was 79,5% and 85,7% respectively, if value 1,50 was determined as cut-off (table 1). The synovial hypertrophy was excluded from the equation and US7- score was calculated. According to our findings US7-score in the MTP1 joint had the best sensitivity and high specificity for diagnosis gout, because the area under the ROC curve was 0.924 ± 0.021. The sensitivity of the US7-score was 82.9% and specificity 91.7%, if value 1.50 was determined as cut-off (table 1).

Table 1. The area under the ROC curve, sensitivity and specificity of US8-score and US7-score

| Test result variable(s) | The area under the ROC curve | Positive if greater than or equal to[a] | Sensitivity | Specificity |
|---|---|---|---|---|
| US8-score | 0.902 | 1.50 | 0.795 | 0.857 |
| US7-score | 0.924 | 1.50 | 0.829 | 0.917 |

**Conclusions:** US7 score (“double contour”, tophi, “starry sky” and/or “snowstorm”

signs, HCA, joint effusion, bone erosions and power Doppler signal) had highest area under the ROC curve (0,924), and highest sensitivity (82,9%) and specificity (91,7%) for the diagnosis of gout.

## SAT0538 KNEE ULTRASOUND EXAMINATION – DO WE KNOW ENOUGH? A SYSTEMATIC LITERATURE REVIEW OF ADULT KNEE ULTRASOUND ASSESSMENT FEASIBILITY STUDIES

A. Peltea, F. Berghea, T. Gudu, R. Ionescu. *Rheumatology, "Sf. Maria" Hospital, RCRD; "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** Musculoskeletal ultrasound (MSUS) has an increasingly important role in the evaluation and monitoring of knee arthritis, mainly because it is definitely more sensitive than clinical examination for detecting synovitis [1]. Although the method has been dramatically improved and refined in the last two decades, it can't occupy the right place in patient's medical management without a feasibility assessment.
**Objectives:** To identify and analyse existing data regarding the feasibility of knee ultrasound (US) exam in clinical practice.
**Methods:** A systematic literature search of PubMed and Web of Knowledge (Thomson Reuters), along with hand search of any available work or references not yet indexed, was performed using the terms: ("knee") AND ("ultrasound" OR "ultrasonography") AND ("feasibility" OR "pilot" OR "proof of concept"). The inclusion criteria consisted of feasibility studies regarding knee US or MSUS aided maneuver involving knee joint (unless including a surgical intervention) published during 2005–2015; non-adult based studies and those focused only on accuracy, reliability or validity, without considering the entire feasibility aspects, have been excluded. The selected papers were evaluated against a complex framework constructed around key areas mandatory for feasibility studies: acceptability, demand, implementation, practicality, adaptation, integration and expansion [2]. Aspects that might influence feasibility, such as machine characteristics, assessor's level of training and use of standardized scoring systems, were also considered.
**Results:** One hundred fifty-two papers have been identified, of which 11 were finally selected for the review; 8 papers evaluated novel US scores, while the rest (3 articles) focused on evaluating US measurement of articular cartilage thickness by comparison with magnetic resonance imaging, US-guided intra-articular injections and incorporating MSUS in clinical practice, respectively. The total number of patients involved was 1172 – most of them (81.5%) suffering from rheumatoid arthritis (RA). Nine out of eleven studies quantified feasibility by the amount of time spent for the evaluation, without assessing any other aspects related to it; two discussed few more aspects: acceptability, implementation and practicality, but none of them practiced a systematic assessment of all feasibility areas.
**Conclusions:** Although the knee is one of the most accessible joints with MSUS, the feasibility of this technique is poorly addressed. Almost all of the identified papers focus on a very limited aspect of feasibility (namely the amount of time needed to perform US) and on a very narrow pathology (patients with RA have been studied ten times more than those with osteoarthritis, despite the prevalence of these two diseases). This information gap should be properly addressed in next future works, in order to ensure the right place for MSUS technique.

## SAT0539 A NEW METHOD FOR THE QUANTITATIVE ANALYSIS OF HAND MUSCLE VOLUME FOR PATIENTS WITH RHEUMATOID ARTHRITIS

A. Friedberger[1], O. Museyko[1], C. Figueiredo[2], T. Bäuerle[3], O. Chaudry[1], A. Grimm[1], G. Schett[2], K. Engelke[1]. *[1]Institute of Medical Physics; [2]Department of Medicine 3, Rheumatology and Immunology, University Erlangen-Nuremberg; [3]Radiological Institute, University Hospital of Erlangen-Nuremberg, Erlangen, Germany*

**Background:** Rheumatoid arthritis (RA) is characterized by bone, cartilage and muscle loss in context of chronic inflammation. While bone and cartilage damage have been extensively studied in the past, the effects of RA on the muscles of the hand have not been studied. This situation is surprising, since visible hand muscle atrophy is a hallmark of RA and hand muscle composition determines the functional state of the patients function.
**Objectives:** Development of a method to quantitatively assess hand muscles in patients with RA, using magnetic resonance imaging (MRI) and 3D segmentation of the hand muscles.
**Methods:** T1 weighted MRI scans of healthy subjects and RA patients were used to develop a new segmentation method for hand muscles. Three groups (20 subjects each) were studied: (1) healthy subjects, (2) untreated RA patients and (3) DMARD-treated RA patients. The new approach uses a graph cuts based segmentation, which is initialized by fuzzy clustering. In a second step the segmented muscle volume of interest (VOI) is further refined and limited to the interosseal muscles and the *thenar* and *hypothenar* eminence. This segmentation procedure is fully automated. Nevertheless an extensive set of 3D editing tools such as hole filling, morphological operators and 3D surface manipulation is available to the operator, should the automatic approach not be satisfactory. Typically this happens in elderly diseased subjects with pathologic muscle and bone changes.
The results of the automatic hand muscle segmentation were checked and confirmed by two experienced MRI readers.
**Results:** The automatic segmentation procedure took about 3 min per patient. In about 70% of the cases the automatic procedure resulted in an accurate muscle segmentation, as judged by the experts. In 30% of the cases additional operator interaction was necessary, primarily to correct for over segmentation. On average, the user interaction could be completed within 2 min. Final segmentation results were confirmed again by the experts. The figure shows a slice of a T1 weighted fat suppressed MRI image in the metacarpal region. Top without and bottom with overlaid muscle VOI (red). The quantitative analysis of muscle volume and the determination of among group differences is currently being performed.

**Conclusions:** We successfully developed a new accurate 3D-segmentation for hand muscles, which allows quantitative analysis of hand muscles in RA patients.

**Disclosure of Interest:** None declared

## SAT0540 POWER DOPPLER ULTRASOUND IMAGING OF THE JOINT-DRAINING LYMPH NODE COMPLEX IN RHEUMATOID ARTHRITIS

A. Manzo, F. Benaglio, B. Vitolo, S. Bugatti, R. Caporali, C. Montecucco. *Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, IRCCS Policlinico San Matteo Foundation/University of Pavia, Pavia, Italy*

**Background:** The afferent lymphatic network and the draining lymph node (LN) are fixed environments acting as remote complementary check-points through progressive phases of the inflammatory response. LN Power Doppler ultrasonography (PDUS) is a non-invasive and sensitive imaging technique commonly adopted in the preoperative diagnostic work-up of cancers. Whether the draining LN undergoes PDUS-sensitive dynamic modifications during chronic inflammation in humans and whether these modifications can be tracked to improve disease assessment is currently unclear.
**Objectives:** To investigate axillary LN sono-morphology and Doppler activity in established RA, defining the existence of alterations compared to healthy individuals and dissecting their relationship with synovitis in peripheral joints.
**Methods:** 40 RA patients refractory to conventional synthetic DMARDs (DAS28$\geq$3.2) were evaluated through complete clinical and PDUS examination in hands/wrists and axillary LN. 20 healthy individuals served as controls. 31 patients starting anti-TNF treatment were followed-up prospectively with further assessments at weeks 4 and 24. Axillary LN PDUS characteristics were assessed according to 0–3 semi-quantitative scores for global LN volume, structure of the lymphocyte-rich cortex and local perfusion. Patient-related indices for each parameter were constructed for comparative, correlative, response-to-treatment and outcome analyses. Synovitis degree (PD and gray scale) was quantified according to 0–3 semi-quantitative scales and 12-joint cumulative indices.
**Results:** Baseline assessment of perfusion and sono-morphologic characteristics showed the existence of quantitative changes in a subset of RA axillary LN, collectively leading to a distinct sonotype differentiating patients and controls. Combining data derived from morpho-structural and vascularity indices, evidence for parameters exceeding the threshold of controls was restricted to 17 out of 40

patients (42.5%), indicating variable levels of LN response despite established active disease. No relationships were observed between LN parameters and ACPA-RF status, DAS28, acute phase reactants, tender-swollen joint counts. Significant correlations (at systemic and ipsilateral level) were instead consistently detected when sensitive PDUS imaging of the synovium was applied (LN-joint PD index correlation: r=0.35, p=0.03). Plasticity of the observed LN alterations was confirmed by responsiveness analyses showing clear-cut reduction at week 24 of both structural and perfusion scores in patients with LN alterations at baseline (LN PD index: $p<0.002$, LN cortical index: $p<0.02$, LN volume index: $p<0.03$). Patient stratification according to EULAR response at 6 months demonstrated the existence of specific differences in baseline LN scores (but not in clinical features and joint US parameters) with significant decrease in the moderate/non responder group (LN PD index median [IQR] 0 [0–1] vs 2 [1–4.25], p=0.01). At its lowest detectable threshold, the LN perfusion index was the only negative predictor of achievement of good response (OR=0.08, p=0.005).

**Conclusions:** PDUS assessment of axillary LN allows detection of inflammatory-related changes in a subset of patients with active established RA. Lack of signs of LN challenge appears a negative predictor of clinical response.

**Disclosure of Interest:** None declared

## SAT0541 MORE THAN HALF OF DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS PATIENTS MAY FULFILL THE ASAS DEFINITION OF A POSITIVE MRI OF THE SPINE: A RETROSPECTIVE ANALYSIS OF 53 CASES

A. Latourte[1,2], S. Charlon[3], A. Etcheto[1], A. Feydy[3], Y. Allanore[2], M. Dougados[1], A. Molto[1]. *[1]Rheumatology B Department, Cochin Hospital; [2]Rheumatology A Department, Cochin Hospital; [3]Radiology B Department, Cochin Hospital, AP-HP, Paris, France*

**Background:** Clinical and radiological presentation of diffuse idiopathic skeletal hyperostosis (DISH) and axial radiographic spondyloarthritis (axSpA) may overlap in the elderly. To date, it is not known whether MRI may help to discriminate between those two diseases.

**Objectives:** 1) To describe the MRI findings in DISH patients and 2) to assess the proportion of DISH patients whose MRI findings would fulfill the Assessment of SpondyloArthritis international Society (ASAS) criteria for a positive MRI of axSpA [1] and the factors associated with such fulfillment.

**Methods:** This retrospective study involved all DISH patients (diagnosed with DISH according to the rheumatologist) who had a spine or sacroiliac joints (SIJ) MRI performed between January 2009 and December 2014. Demographics, and disease characteristics were collected by review of the medical files. Available X-rays and MRI were analyzed and blindly scored by an experimented reader (modified Stoke AS Spine Score (mSASSS) and modified New York (mNY) grades for spine and SIJ Xrays and the Spondyloarthritis Research Consortium of Canada (SPARCC) score for both spine and SIJ MRI).

**Results:** Fifty-three DISH patients (mean age ± SD 65.6 ± 13.0 years, 71.7% male patients) were included in the analysis, with 31 SIJ MRI, 52 spine MRI and 37 spine or SIJ Xrays. On SIJ Xrays, 8 (19.5%) patients presented with sacroiliitis according to the mNY criteria. On spine Xrays, mean mSASSS score was 6.48 (± 8.86) and 40 (97.6%) patients had osteophytes with an angle of $\geq$45°, and up to 14 (34.15%) with an angle <45°. Mean SPARCC score of the spine was 18.3 ± 23.5. Thirty five (67.3%) patients had at least one fatty corner, and 41 (78.9%) patients had osteophytes $\geq$45° while only 2 (3.88%) with <45°. Thirty (57.7%) patients met the ASAS definition of a spine MRI suggestive of axSpA, but only 6 (19.4%) patients with an available SIJ MRI had a sacroiliitis according to ASAS criteria, and none of them had $\geq$3 erosions on the SIJ. Severe intervertebral disc lesions (Pfirmann score $\geq$4/5) were found in 38 (73.1%) patients. No factor was found to be significantly associated with fulfilment of ASAS criteria for a positive MRI of the Spine for axSpA.

**Conclusions:** Inflammatory lesions of the spine are also present on the MRI of patients with DISH and more than a half of DISH patients presented with inflammatory lesions of the spine that would meet the ASAS criteria for a spine MRI suggestive of axSpA. However only few patients would meet the ASAS definition of a positive MRI for SIJ, suggesting that MRI of the SIJ but not of the spine might allow the differential diagnosis of DISH vs. axSpA in the eldery.

## SAT0542 THE PREVALENCE OF CALCIUM PYROPHOSPHATE DEPOSITS AT ULTRASOUND EXAMINATION: RETROSPECTIVE ANALYSIS IN A COHORT OF PATIENTS

C. Toscano, A. Adinolfi, I. Bertoldi, V. Di Sabatino, V. Picerno, M. Galeazzi, B. Frediani, G. Filippou. *University of Siena, Siena, Italy*

**Background:** The Calcium Pyrophosphate Deposition Disease (CPPD) is a disease frequently observed in the clinical practice but currently its exact prevalence is unknown. In fact, the data available in the literature vary depending on method used, generally x-ray or synovial fluid analysis, while no studies evaluated the ultrasound (US) prevalence of Calcium Pyrophosphate (CPP)deposits.

**Objectives:** The evaluation of the prevalence of CPP deposits in a cohort of patients (pt) that undergo US examination of wrists and knees.

**Methods:** We extracted from our database all reports of pt undergoing US exam of wrists and knees, referred to our outpatient clinic from October 2005 to January 2015. All US exams were performed by rheumatologists expert in muscoloskeletal ultrasound (MSUS) using an Esaote MyLab70 equipped with a 4–13 MHz linear probe. We recorded the presence of CPP deposits at the medial meniscus (MM), the lateral meniscus (LM) and the hyaline cartilage (HC) in the knees and at the triangular fibrocartilage (TF) of the wrists. Statistical analysis was performed with SPSS.

**Results:** US reports of 984 pt (81,9% female, mean age 50,28 SD±17,22) were included in this study. The overall prevalence of CPP deposits was 6,6% (65/984pt). In this group, the CPP deposits were observed in the 32,3% (21/65pt) of the wrists (bilaterally 61,9%) and in the 93,8% (61/65pt)of the knees (bilaterally 67,21%). The involvement of both joints were observed in the 26,15% (17/65pt).
Analysing the prevalence by ages, it was 2,1% (14/664pt) in pt under 60 years old (yo), while it increased to 16,7% (51/306pt) in pt over 60. The prevalence was 8,7% (16/184pt) between 60 and 70 yo, 26,7% (24/90pt) between 70 and 80 yo, and increased to 34,4% (11/32pt) in pt over 80.
Regarding the different joint structures, the prevalence was 89,2% (58/65pt) in menisci, (83,1% MM, 78,5% LM) and 32,3% (21/65pt) in the HC. The TF was involved in 32,3% of cases (21/65pt). Thus, according to previous studies[1], our results showed that menisci, particularly MM, are the most involved by CPPD, appearing as the favorite site for US identification of CPP deposits. Moreover, this study confirmed the correlation between the aging and the increased prevalence of CPP deposits. However, our analysis showed a higher prevalence respect to the values obtained in previous studies that considered the x-ray as the reference method[2]. However, this trend should be further confirmed with a prospective assessment conducted in a larger sample of patients.

**Conclusions:** To our knowledge this is the first attempt to define the CPPD prevalence with US, that recently entered in EULAR recommendations as a promising diagnostic tool for CPPD[3]. Considering its accuracy, non-invasiveness and low cost, the US could be widely used for CPPD diagnosis also for large scale evaluation, planned in order to define the prevalence of this disease.

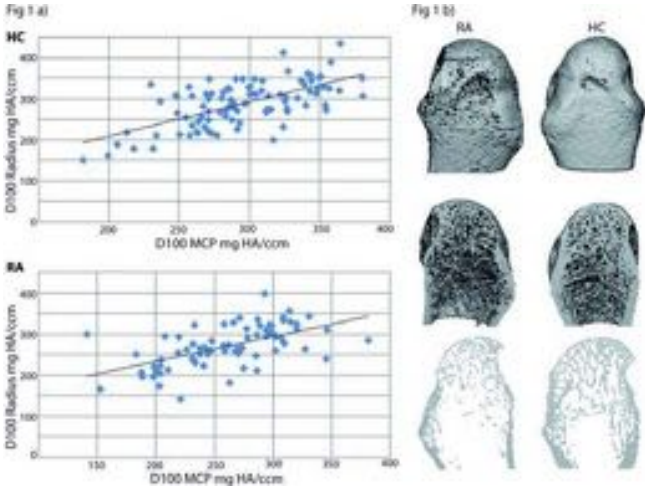
## SAT0543 ACCURATE DETERMINATION OF PERIARTICULAR BONE COMPOSITION IN HEALTHY INDIVIDUALS AND COMPARISON TO ACPA-POSITIVE RHEUMATOID ARTHRITIS PATIENTS



D. Simon[1], A. Kleyer[1], F. Stemmler[1], C. Simon[1], A.J. Hueber[1], E. Kampylafka[1], M. Englbrecht[1], C. Figueiredo[1,2], K. Engelke[3], A. Berlin[1], J. Haschka[1,4], J. Rech[1], G. Schett[1]. *[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [2]Bone Metabolism Laboratory, Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [3]Institute of Medical Physics (IMP), Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [4]Medical Department II, The VINFORCE Study Group, St. Vincent Hospital, Vienna, Austria*

**Background:** Periarticular bone loss is a typical finding in rheumatoid arthritis (RA) patients. However, this structural bone change is yet insufficiently characterized. Larger studies assessing periarticular bone composition in healthy controls (HC) and RA patients by high-resolution imaging have not been undertaken and have not been validated against standard measurement at the distal radius.

**Objectives:** To assess periarticular bone by high-resolution peripheral quantitative computed tomography (HR-pQCT) in the metacarpal heads and compare it with standard measurement in the distal radius in HC and anti-citrullinated peptide antibodies-positive (ACPA+) RA patients.

**Methods:** HR-pQCT (XtremeCT, Scanco, Switzerland) scans of the distal radius and of the metacarpal head 2 joints of HC and RA patients were performed. In contrast to previous studies the entire metacarpal head was assessed. After motion grading of the images by two independent readers, images with a motion grade more than 3 were excluded. A graphical objet (GOBJ) was generated and evaluated using the standard evaluation protocol for the radius provided by the manufacturer for both, the metacarpal head and the distal radius. In the last step, bone density values such as average bone density (D100 [mg HA/cm$^3$]), bone volume/total volume (BV/TV), number of trabeculae (Tb N [1/mm])) were

determined and compared between (i) the metacarpal head and the radius and (ii) between HC and RA patients.
**Results:** 222 subjects (110 HC and 112 RA) were analyzed. Sex and age distribution were balanced between HC (f/m: 58/52; 50.1±16.1 years) and RA patients (f/m: 53/59; 53.2±12.4 years; disease duration 9.2±8.7 years). Bone density in HC was 288.3±54.7 mg HA/cm$^3$ in the distal radius and 294.4±43.3 mg HA/cm$^3$ in the metacarpal head with significant correlation ($\rho$=0.583 ($p<0.001$)) (Fig1a, top row). Respective bone densities in RA patients were 269.8±49.6 mg HA/cm$^3$ and 263.3±46.0 mg HA/cm$^3$ with significant correlation ($\rho$=0.632 ($p<0.001$)) (Fig. 1a, bottom row). Similar correlations were found for BV/TV (HC: $\rho$=0.590, $p<0.001$, RA: $\rho$=0.687, $p<0.001$) and Tb N (HC: $\rho$=0.576, $p<0.001$, RA: $\rho$=0.705, $p<0.001$). Comparing bone densities between HC and RA patients we found significant bone loss in both the metacarpal head ($p<0.001$, U=3834.5, Z=-4.860) and the distal radius (p=0.018, U=2700.5, Z=-2.357) in RA patients. Examples of measurements in the metacarpal heads of HC and RA patients are shown in Figure 1b.

**Conclusions:** In this large study, we show that the assessment of periarticular bone structure in metacarpal heads is feasible and correlates well with standard measurement in the distal radius. Furthermore, we show significant bone loss in RA patients as compared to HC in both anatomical sites.

## SAT0544 ENTHESEAL INVOLVEMENT IN ASYMPTOMATIC HIV PATIENTS: AN ULTRASONOGRAPHIC STUDY

G. Ciancio[1], L. Sghinolfi[2], F. Furini[1], D. Segala[2], I. Farina[1], E. Galuppi[1], S. Bonazzi[1], E. De Stefani[1], M. Libanore[2], M. Govoni[1]. *[1]Rheumatology Unit, Department of Medical Sciences, University of Ferrara and Azienda Ospedaliera-Universitaria Sant'Anna - Ferrara (Italy); [2]Infectious Diseases Unit of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna, Ferrara, Italy*

**Background:** A complex variety of musculoskeletal manifestations have been described in HIV patients, including conditions belonging to the wide spectrum of spondyloarthropathies (SpA). Enthesitis is a distinctive feature of SpA. Peripheral enthesitis is usually revealed by clinical findings but it may also be asymptomatic and detected only by imaging, such as conventional radiography, magnetic resonance or ultrasonography (US).
**Objectives:** The aim of the present study was to evaluate by US examination the prevalence of enthesitis in patients with HIV infection without rheumatic clinical symptoms in comparison with control healthy subjects.
**Methods:** 28 patients with aymptomatic HIV infection (22 M and 6 F; mean age:43 ± 8.6) were consecutively examined with US (Toshiba- Aplio XG- 12–18 MHz linear array transducer). All patients were recently diagnosed as HIV infected, didn't take any HIV treatment and had no clinical signs or symptoms of joint or enthesis involvement. 25 healthy subjects, matched for sex, age and BMI were studied as controls. The following sites were examined bilaterally by US: common extensor tendon insertion on the lateral epicondyle of the humerus; quadriceps tendon insertion on the superior pole of the patella; patellar tendon insertion (patellar ligament origin and the patellar ligament insertion at the tibial tuberosity); Achilles tendon insertions on the calcaneus. The following abnormal findings were recorded: thickness, bony erosions, enthesophytes and bursitis. Local blood flow was examined using Power Doppler (PD) mode. US and PDUS were performed by an experienced operator and blinded to the clinical examination.
**Results:** 20/28 HIV patients (71.4%) presented almost one enthesis abnormality in comparison with 3/25 (12%) healthy controls ($p<0.05$). In 17/28 (60.7%) HIV patents was evidenced thickness; in 15/28 (53.5%) bursitis; in 13/28 (46.4%) enthesophytes and in 4/28 (14.2%) erosions. PD was positive in 11/28 (39.2%) HIV patients. In healthy controls, US showed thickness in 2/25 (8%), enthesophytes in 1/25 (4%) and altered PD in 1/25 (4%). The intra and inter-reader agreements were high (>0.8 intra-class correlation variability).
**Conclusions:** US revealed a high frequency of subclinical enthesis abnormalities in asymptomatic HIV patients without rheumatic clinical signs and symptoms, highlighting the important role of US investigation and the strong association of HIV infection with rheumatic manifestations typical of SpA.

## SAT0545 THE EFFECT OF ANTI-TNF ALPHA TREATMENT ON EROSION PROGRESSION IN RHEUMATOID ARTHRITIS BY HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY: THREE-MONTH DATA

H. Choi[1,2], U. Heilmeier[2], M. Tanaka[2], A.J. Burghardt[2], N. Chanchek[2], T.M. Link[2], J. Graft[3], J.B. Imboden[3], X. Li[2]. *[1]Department of Internal medicine, Division of Rheumatology, Gachon University Gil Hospital, Incheon, Korea, Republic Of; [2]Department of Radiology & Biomedical Imaging, Musculoskeletal Quantitative Imaging Research; [3]Department of Internal medicine, Division of Rheumatology, UCSF, San Francisco, United States*

**Objectives:** High-resolution peripheral quantitative computed tomography (HR-pQCT) is an emerging imaging technology for early detection of erosion in rheumatoid arthritis (RA). In this study, we use HR-pQCT to investigate the effects of anti-tumor necrosis factor alpha (anti-TNFa) treatment on erosion progression for three months follow-up period.
**Methods:** Fourteen patients with clinically diagnosed RA (Group I, n=4, on methotrexate (MTX) treatment only, and Group II, n=10, on combined anti-TNFa and MTX treatment) underwent clinical evaluation using disease activity score (DAS) score and HR-pQCT scan. Scans were performed on metacarpophalangeal (MCP) joint at baseline (prior to anti-TNF initiation for Group II) in all patients and in twelve patients (4 in group I, 8 in group II) after three months. The maximum width and depth of erosions at the second, third MCP and proximal phalangeal bases (PB) were measured manually in accordance with SPECTRA definition. Erosion volume was calculated as width depth. Mann-Whitney U, Chi-square and paired T-test were done to compare measurements between and within groups from baseline to 3-month.
**Results:** The mean of ages was 71.8±3.8 in group I vs. 49.4±13.6 years in groups II (p=0.019), and of disease duration was 9.0±6.3 vs. 4.0± 4.5 years (p=0.076). The mean of total erosion volume at baseline was 8.0±10.4 mm$^3$ in group I vs. 24.5±42.1 mm$^3$ in group II (p=0.733). In group I, erosions were on PB2 (n=1), MCP2 (n=2), PB3 (n=0), and MCP3 (n=2); in group II, it was 2, 6, 2, and 5 respectively. There was a significant decrease of disease activity in group II (DAS28-CRP, p=0.001 and DAS28–ESR, p=0.002) from baseline to 3-month. Although there was no statistically significance between or within the groups, the mean changes of erosion volume by HR-pQCT tended to increase in group II (0.0±2.5 in group I vs. 4.0±6.8 in group II).
**Conclusions:** At 3 months follow-up, we observed a dissociation between clinical response and erosion volume measured by HR-pQCT in patients on anti-TNFa treatment. The significant decrease in DAS28-CRP, DAS28-ESR and tendency of increase in erosion volumes suggest that although anti-TNFa treatment suppresses inflammation within a 3-month treatment period, the structural joint damage may require more time to be hold. HR-pQCT is a sensitive tool for evaluating erosion volume changes even within a time window of 3-month. Now we are waiting one-year data of our cohort.

## SAT0546 ULTRASOUND-DETECTED SYNOVITIS AND TENOSYNOVITIS PREDICT RA IN EARLY DISEASE

I. Sahbudin[1,2], L. Pickup[1,2], P. Nightingale[3], G. Allen[4], Z. Cader[1], P. de Pablo[1,2], C.D. Buckley[1,5], K. Raza[1,5], A. Filer[1,2]. *[1]Rheumatology Research Group, Institute of Inflammation and Ageing; [2]Rheumatology Department; [3]Wolfson Computer Laboratory, University Hospitals Birmingham NHS Foundation Trust, Birmingham; [4]Green Templeton College, University of Oxford, Oxford; [5]Rheumatology Department, Sandwell and West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom*

**Background:** Ultrasound-detected synovitis improves the prediction of RA in early disease. Although ultrasound-detected tenosynovitis in common in early RA, its relative utility in the prediction of RA alongside ultrasound-detected synovitis and conventional serological and clinical variables is unclear.
**Objectives:** To identify a minimal core set of ultrasound, clinical and serological variables predicting RA in a cohort of patients with early arthritis using a data-driven approach.

**Methods:** 107 patients [female n=60, median age 51] with ≥1 joint with clinically apparent synovitis and a symptom duration ≤3 months underwent clinical, laboratory and ultrasound assessments. Final diagnoses were determined at 18 month follow-up. Ultrasound assessment determined the presence of synovitis at 28 joints (bilateral MCPs 1–5, PIPs 1–5, wrists, and MTPs 2–5) and tenosynovitis at four tendon sites (bilateral finger flexor and extensor carpi ulnaris tendon). First, principal component analysis (PCA) was performed on 1) clinical and serological variables (age, gender, symptom duration, ESR, CRP, RF, ACPA, duration of early morning stiffness, tender joint and swollen joint count), and 2) joint and tendon ultrasound variables. Then the variable with the highest loading factor from each component was extracted and made available in a forward step-wise multivariate logistic regression analysis.
**Results:** 46 patients developed RA, 17 developed non-RA persistent inflammatory arthritis and 44 patients had resolving disease. Seven components were identified on clinical and serological PCA and four components were identified within ultrasound synovitis and tenosynovitis variables (Table 1). The final multivariate logistic regression model included ACPA positivity (OR=12.61, CI: 3.50–45.52, p<0.001), digit flexor ultrasound tenosynovitis (OR=4.58, CI: 1.67–12.56, p=0.003) and MCP 1 ultrasound synovitis positivity (OR=4.75, CI: 1.78–12.64, p=0.002).

Table 1. PCA analysis of clinical, serological, joint and tendon ultrasound variables

| Component | Clinical and serological variables |
|---|---|
| 1 | Swollen joints >6* , tender joints >6 |
| 2 | Age ≥60* |
| 3 | Early morning stiffness ≥60 min* |
| 4 | Swollen joint = 1*, Tender joint = 1 |
| 5 | ACPA positivity* |
| 6 | Abnormal CRP*, abnormal ESR |
| 7 | Gender* |
| **Component** | **Joint and tendon ultrasound variables** |
| 1 | MCP 1*, MCP 4, MCP 5, PIP 1, PIP 4 |
| 2 | Digit flexor tendon*, MCP 2, MCP 3, extensor carpi ulnaris tendon, wrist joint |
| 3 | PIP 2*, PIP 3, PIP 5 |
| 4 | MTP 2*, MTP 3, MTP 4 |

*Variables with the highest loading factor within each component.

**Conclusions:** Both ultrasound-detected synovitis and tenosynovitis provide independent data in addition to clinical and serological variables in the prediction of RA in early disease. MCP 1 and digit flexor scanning provide the optimal predictive data in this cohort.
**Disclosure of Interest:** None declared

## SAT0547 ULTRASOUND ASSESSMENT OF CARTILAGE DAMAGE AT METACARPAL HEAD LEVEL IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

J. Hurnakova[1,2], A. Di Matteo[2], F. Salaffi[2], M. Carotti[3], E. Cipolletta[2], A. Draghessi[2], E. Di Donato[2], M. Di Carlo[2], V. Lato[2], K. Pavelka[1], E. Filippucci[2], W. Grassi[2]. *[1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Rheumatology Department, Università Politecnica delle Marche, "C. Urbani" Hospital, Jesi, Ancona; [3]Radiology Department, Università Politecnica delle Marche, Ancona, Italy*

**Background:** Ultrasound (US) with very high frequency probe (up to 22 MHz) has a resolution power of 0.1 mm and allows for the direct visualization of the hyaline cartilage of the metacarpal head.
**Objectives:** To determine the prevalence and distribution of US-detected cartilage damage at metacarpal heads of patients with rheumatoid arthritis (RA) and osteoarthritis (OA) and to investigate if cartilage damage evaluated by US method is associated with radiographic scores (Sharp van der Heijde score and Simple Erosion Narrowing Score (SENS) in RA and Kallman score in OA).
**Methods:** 50 patients with RA and 19 patients with OA were enrolled in this study. The US examination of the metacarpal head cartilage from II to V finger of both hands was performed. 400 metacarpophalangeal (MCP) joints in RA and 152 MCP joints in OA were scanned with a very high-frequency linear probe (i.e. 10–22 MHz), using a previously described scoring system for cartilage damage[1]. In a subgroup of 27 patients with RA and 7 with OA the radiographic scores were calculated. Pearson's correlation coefficient and Cohen κ were used to investigate associations between US and radiographic scores.
**Results:** The US examination of the metacarpal head cartilage from II to V finger of both hands lasted a mean of 6 minutes. The metacarpal head cartilage was found positive for cartilage damage by US in 139 out of 400 (34.8%) MCP joints in RA and in 65 out of 152 (42.8%) MCP joints in OA. In RA, the hyaline cartilage of the II right metacarpal head was the most frequently affected followed by the II left and the III right metacarpal head. The less affected was the V metacarpal head bilaterally. In OA, cartilage damage was homogeneously distributed in all MCP joints. Symmetric damage of cartilage was observed in 97/400 (24.3%) RA joints and in 44/152 (28.9%) OA joints. Conversely, asymmetric damage of the cartilage was observed in 42/400 (10.5%) RA joints (only in patients with disease duration more than 2 years) and in 21/152 (13.8%) joints in OA. A significant positive correlation was found between US total score and either Sharp van der Heijde score or SENS score (r=0.584, p<0.001; r=0.510, p<0.001, respectively) in RA and between US total score and Kallman score (r=0.687, p<0.001) in OA. Agreement between two imaging methods was high, 78% in RA (κ=0.570, p<0.001) and in 91% in OA (κ=0.750, p<0.001).
**Conclusions:** The present study provides evidence supporting the feasibility of the US assessment of the metacarpal head cartilage. A positive significant correlation was found between the US findings, obtained with a very high frequency probe by an experienced sonographer and the radiographic scores assigned by an expert radiologist.

## SAT0548 POSITRON EMISSION TOMOGRAPHY WITH 18F-FLORBETAPIR (FBP) AS A MARKER OF BURDEN OF DISEASE IN AMYLOIDOSIS

J. Mestre Torres[1], C. Lorenzo-Busquet[2], R. Solans-Laque[1], E. Garcia-Vives[1], A. Fernandez-Codina[1], S. Bujan-Rivas[1], J. Castell-Conesa[2], F. Martinez-Valle[1]. *[1]Internal Medicine; [2]Nuclear Medicine, Hospital Vall d'Hebron, Barcelona, Spain*

**Background:** Amyloidosis comprises a group of diseases characterized by a deposition of amyloid fibrils which have an antiparallel B-sheet secondary structure. Active research in seeking evolution of deposits must be done regularly with several tests. FBP is a radiotracer with tropism to proteins with β-sheet conformation that is used in Alzheimer's disease[1].
**Objectives:** The purpose of this study was to evaluate the utility of FBP in studying the extension of the amyloidosis.
**Methods:** We performed an observational descriptive study with 14 subjects controlled at our Amyloidosis Unit: twelve patients with a biopsy-proven disease, one patient with senile amyloidosis and one woman with a familiar TTR mutation without evidence of diposits. Study was conducted from February 2015 until August 2015. A PET/CT was performed with injection of 370MBq FBP. Images were acquired after 40–50 minutes of injection and a qualitative description was done. Evaluation also included traditional techniques like echocardiogram, cardiac MRI, blood and urine tests, and electromyography. If other organs were involved, they were registered. The correlation between traditional techniques and PET/CT was studied.
**Results:** The median age at diagnosis was 69 years (IQR: 60 – 75) and the median follow up 22.2 months (IQR 2 – 32). Two patients had hereditary amyloidosis by transthyrretin (TTR), 1 patient a senile amyloidosis, 8 patients a primary amyloidosis and 2 a secondary amyloidosis. Traditional evaluation detected heart involvement in 9 patients (69.23%), kidney involvement in 6 (46.15%) and soft tissue was involved in 4 patients (30.76%): 2 of them had macroglossia, 1 patient had thyroid gland amyloidosis and the remaining one had amyloid deposits in the stomach.
PET/CT showed cardiac involvement in 8 patients (61.53%), kidney in 3 patients (23.07%) and soft tissue in 6 (46.15%) patients: tongue in 2 patients, thyroid gland in 2, spleen in 1, lungs in 2. Multiple organs were involved in 4 patients (30.76%).
Correlation between traditional techniques and PET/CT showed that 6 patients had both positive tests for heart involvement. Two patients identified as having cardiac amyloidosis by echocardiogram and cardiac MRI had a negative PET. Two patients with a positive PET had a negative cardiac MRI but echocardiogram showed left ventricular hypertrofia. Kidney involvement was present in 3 patients with a previously known renal disease (50% of patients). Soft tissue involvement showed an increased uptake in the tongue in the two patients with macroglossia, thyroid involvement in the patient with goiter but didn't show gastric involvement in the remaining patient. Two subjects had bilateral lung involvement which was not previously suspected and another patient had thyroid and spleen involvement. The healthy subject (affected by the familial TTR mutation) had a normal PET/CT.
**Conclusions:** FBP PET/CT is a promising technique to evaluate the number of organs affected in patients with amyloidosis. Prospective studies with bigger cohorts are required to validate its use during our clinical practice.

## SAT0549 VALIDATION OF 3 NOVEL AUTOANTIGENS FOR SYSTEMIC SCLEROSIS

J. Schulte-Pelkum[1], P. Budde[1], H.D. Zucht[1], D. Wirtz[1], P. Schulz-Knappe[1], O. Distler[2], S. Jordan[3], N. Hunzelmann[4], M. Schneider[5], B. Maurer[2]. *[1]Protagen AG, Dortmund, Germany; [2]Division of Rheumatology; [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [4]Department of Dermatology, University of Cologne, Cologne; [5]Rheumatology, Heinrich-Heine-University, Dusseldorf, Germany*

**Background:** Systemic sclerosis (SSc) is a systemic autoimmune disease that manifests as progressive fibrosis of the skin and internal organs. SSc is associated with the presence of several autoantibodies (aab) to intracellular targets, with the three most important SSc-specific being anti-centromere antibodies, anti-Scl70 antibodies and anti-RNA polymerase III antibodies, which occur in over 50% of SSc patients. Autoantibody specificities are strongly associated with pattern of organ involvement and disease outcome, making autoantibodies an essential tool in the clinical management of SSc. This highlights the need for additional specific and sensitive diagnostic and prognostic biomarkers in SSc. We have recently conducted high-content autoantibody profiling studies of SSc, systemic autoimmune diseases (AID), and healthy controls and found novel SSc associated autoantibodies.
**Objectives:** These novel SSc-associated autoantibody biomarker candidates and their diagnostic value were evaluated by testing samples derived from different SSc cohorts from the University Hospital Düsseldorf and the University Hospital Zurich.
**Methods:** Three novel identified biomarker candidates, namely Lysine (K)-specific demethylase 6B (*KDM6B*), Protein Phosphatase Inhibitor 2 (PPP1R2) and Bicaudal Drosophila Homolog 2 (BICD2) were developed into ELISA Kits using highly purified recombinant antigen and evaluated. Autoantibody specificities were analyzed using an independent and well characterized cohort consisting with sera of patients suffering from SSc (n=198), myositis (n=20), RA (n=20), SLE (n=40) and healthy blood donors (n=132). Assay threshold levels were calculated using a receiver operation characteristic analysis and set for specificities of >95%.
**Results:** Using the respective cut-off for the ELISA tests we were able to find autoantibody reactivity against BICD2 in 29.2% of SSc patients and 4.8% of control samples, against PPP1R2 in 15% SSc and 3.2% of controls and against KDM6B in 20% of SSc patients and 2.6% of control samples, respectively. Positive results of anti-BICD2 and anti-PPP1R2 aab co-migrated with anti-Centromere aab, but were also found in anti-Centromere and anti-Scl-70 negative samples. Interestingly, both anti- BICD2 and anti-PPP1R2 aab were found in SSc samples tested negative for anti-RNA Polymerase III auto-reactivity.
**Conclusions:** In this study we were able to confirm the diagnostic value and high specificity of the newly discovered autoantigens using ELISA. Anti-BICD2 aab showed significant inverse correlation with pulmonary fibrosis. Thus, anti-BICD2 aab may be associated with a decreased incidence of severe lung disease.

## SAT0550 PREDICTIVE VALUE OF POWER DOPPLER ULTRASONOGRAPHY (PDUS) FOR THE DIAGNOSIS OF RHEUMATOID ARTHRITIS IN PATIENTS WITH BASAL NEGATIVE ACUTE PHASE REACTANTS

L. Mayordomo[1], M.L. Velloso[1], C. Almeida[2], A. Gutierrez-Leonard[3], P. Gonzalez-Moreno[4], J.L. Marenco[1]. *[1]Rheumatology Department; [2]Research and Statistics Department, Hospital Universitario Valme; [3]Hospital Virgen Rocio; [4]Rheumatology Department, Hospital Virgen Macarena, Sevilla, Spain*

**Background:** The presence of acute phase reactants high can assist in the diagnosis and classification of patients with rheumatoid arthritis, although on occasions in early arthritis may be within the range of normality.
**Objectives:** The objective was to establish whether the presence of basal Doppler signal in patients with negative reactants may be helpful in order to establish the risk of final diagnosis of rheumatoid arthritis a year, following ACR criteria 1987
**Methods:** We studied the presence of Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, knees) and 44 joints (28 joints and in addition hips, Tarsus, ankles and MTPs), with a mid-range equipment GE L5, in patients with suspected early arthritis in which the ESR was normal according to two different criteria or the CRP was negative. The patients had at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes (*Criteria SERAP Study), with <12 months of evolution of the symptoms. None of the patients had a previous diagnosis of rheumatoid arthritis or other inflammatory joint disease nor had received prior treatment with steroids or DMARDs. It was considered normal CRP ≤5mg/L (normal range 0–5). It was considered normal ESR (mm/h) according to two criteria: a) ESR +1: ≤20 in all patients or (b) ESR +2 (criterion depending on the age and sex): Age ≥50 years is normal ≤20 in males and ≤30 in women; minors of 50 years is normal ≤15 mm/h in males and ≤20 in women (1). At one year follow-up was established whether patients met criteria for RA 1987 ACR.
**Results:** In 35 patients with normal basal ESR, by criteria 2 (criterion by ESR age and sex), the presence of basal power doppler signal in ≥1 joints of 44 (PD44) in baseline visit shows statistically significant association with the RA diagnosis at 12 months by ACR 1987 classification criteria, with p=0.032, OR=6 (1,33–27,05). In 32 patients with normal basal ESR by criteria ESR 1 (<20 mm/h), the presence of basal power doppler signal in at least one joint of 44 (PD44 basal) shows statistically significant association with the diagnosis at year of AR, with p=0.030, OR=6 (1,25–28,84), not so PD28 (p=0.150). In 25 patients with basal negative CRP, the presence of at least one joint with power doppler signal (PD28 and PD44) are not associated in a statistically significant way with final diagnosis of RA at 12 months following ACR 1987 criteria (p=0.428 and p=0.226, respectively).

| | | | RA YES | Chi-square Fisher exact test (p) | OR | 95 % CI |
|---|---|---|---|---|---|---|
| CRP | PD44 | YES | 9/15 (60%) | 0.226 | - | - |
| NEGATIVE | | NO | 3/10 (30%) | | | |
| ESR+1 | PD44 | YES | 15/20 (75%) | 0.030 | 6 | (1,25-28,84) |
| NEGATIVE | | NO | 4/12 (33,3%) | | | |
| ESR+2 | PD44 | YES | 16/22 (72,7%) | 0.032 | 6 | (1,33-27,05) |
| NEGATIVE | | NO | 4/13 (30,8%) | | | |

**Conclusions:** The presence of at least one joint with power doppler signal of 44 joints (PD44) on baseline visit may help to predict the RA diagnosis at 12 months of follow up according to criteria ACR 1987, in patients with normal basal ESR. In patients with normal basal CRP, PD44 could not establish statistically significant differences for the diagnosis of AR a year according to criteria ACR 1987. In our study PD28 could not predict the RA diagnosis at 12 months by ACR 1987 criteria.

## SAT0551 PREDICTIVE VALUE OF ULTRASONOGRAPHY FOR RADIOGRAPHIC PROGRESION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

L. Mayordomo[1], C. Jurado[2], C. Almeida[3], M.L. Velloso[1], L.M. Jimenez-Liñan[1], J.L. Marenco[1]. *[1]Rheumatology Department; [2]Radiology DEPARTMENT; [3]Research and Statistics Unit, Hospital Universitario Valme, Sevilla, Spain*

**Background:** There is a short window of opportunity for early diagnosis and treatment of rheumatoid arthritis, that may be crucial for reaching remission and a low rate of radiographic progression. High resolution power doppler ultrasonography (PDUS) is helpful in early detection of synovitis and may help to select patients at higher risk of developing structural radiographic progression of joint damage.
**Objectives:** To establish whether the presence of basal power doppler signal in patients with early arthritis may be helpful in order to establish the risk of radiographic progression at 12 months of follow-up.
**Methods:** We studied the presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, knees) and 44 joints (28 joints and in addition hips, Tarsus, ankles and MTPs), with a mid-range equipment GE L5, in 70 patients with suspected early arthritis. The patients were included with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with <12 months duration of the symptoms. Presence or not of basal high acute phase reactants (CPR>5 mg/dl; ESR >20 mmHg) and DAS28>5.1 for each patient were registered. In 62 patients completed hands and feet radiology were available both in basal and 12 months visits. Scores according Sharp/van der Heijde method (Sharp modified method) (1) were recorded for each patient. Clinical relevant Radiographic progression was defined for each patient as a stadistical significant difference between Sharp/van der Heijde method scores in basal and 12 months visits that exceeded the SDD (smallest detectable difference) obtained from the intraobserver variability study for radiographic assessment (SDD: Erosions 2,5; narrowing 2,71; Total 2,25). Statistical study: Chi-square, Fisher exact test, p univariant and Odds Ratio calculation, SDD.
**Results:** The presence of basal power doppler signal in ≥1 joints of 44 (PD44) at baseline shows statistically significant association with radiographic progression of erosions and total progression (erosions plus narrowing) at 12 months p<0.005, OR 5,57 (1,56–19,79) and p=0.048, OR=3,42 (1,02–11,49) respectively, whereas the presence of at least one joint with power doppler signal of 28 joints (PD28) was only associated to total progression p=0.017, OR 4,23 (1,23–14.49). High acute phase basal reactants (CRP and ESR) were as well associated to progression of erosions, p=0.005 OR 4,80 (1,53–15,16) and p=0.025, OR 3,25 (1.14–9,28)

respectively. A DAS28>5,1 at baseline was associated to radiographic progression of erosions (p=0.021), narrowing (p=0.005) and both (p=0.001).

| | | PROG EROSIONES | PROG PINZAMIENTO | PROG TOTAL (E+P) |
|---|---|---|---|---|
| PD28 | SI<br>NO | NS | NS | 37/44(84,1%)<br>10/18 (55,5%)<br>p=0.017<br>OR=4,23(1,21-14,69) |
| PD44 | SI<br>NO | 28/46 (60,8%)<br>5/16 (31,2%)<br>p=0.048<br>OR=3,42 (1,02-11,49) | NS | 39/46 (84,8%)<br>8/16 (50%)<br>p=0.005<br>OR=5,37 (1,56-19,79 |
| DAS>5,1 | SI<br>NO | 22/32 (68,7%)<br>11/30 (36,6%)<br>p=0,021<br>OR=3,80(1,32-10,89) | 23/32 (71,8%)<br>11/30 (36,6%)<br>p=0.005<br>OR=4,41 (1,51-12,87) | 30/32(93,7%)<br>17/30 (56,6%)<br>p=0.001<br>OR=11,47 (2,30-56,99) |
| VSG1 | SI<br>NO | 23/35 (65,7%)<br>10/27 (37%)<br>p=0.025<br>OR=3,25(1,14-9,28) | NS | NS |
| PCR | SI<br>NO | 27/43(63,8%)<br>6/21(28,5%)<br>p=0.005<br>OR=4,8(1,53-15,16) | NS | NS |

**Conclusions:** The presence of at least one joint with power doppler signal of 44 joints (PD44) at baseline may help to predict the progression of erosions at 12 months of follow up in patients with early RA. The presence of positive acute phase reactants (CRP,ESR) and DAS28 high activity (>5,1) in our study increased the risk of radiographic progression of erosions as well.

## SAT0552 MUSCULOSKELETAL ULTRASOUND (MSUS) SHOWING ENTHESEAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): SOMETHING UNEXPECTED

A. Di Matteo [1], I. Satulu [2], M. Di Carlo [1], V. Lato [1], A. Draghessi [1], E. Di Donato [1], J. Hurnakova [3], E. Filippucci [1], W. Grassi [1]. *[1]Clinica Reumatologica-Jesi-Università Politecnica delle Marche, Jesi, Italy; [2]2 Internal Medicine and Rheumatology Department, Dr. I. Cantacuzino" Clinical Hospital, Bucharest, Romania; [3]Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic*

**Background:** Musculoskeletal involvement is one of the most common manifestations of SLE and, recently, different studies have demonstrated the role of MSUS in the evaluation of tendons and joints involvement in SLE patients (1). The enthesis is traditionally not included as a potential target of the inflammatory process of the disease, remaining a yet unexplored anatomical area in this cohort of patients.

**Objectives:** To investigate the prevalence and distribution of entheseal abnormalities in SLE patients using MSUS.

**Methods:** 30 consecutive SLE patients were enrolled in the present study. The scanned entheses were those included in the Glasgow Ultrasound Enthesitis Scoring System: the patellar insertion of the quadriceps tendon (QT), the patellar and distal insertion of the patellar tendon (PT), the calcaneal insertion of the Achilles tendon (AT) and the calcaneal insertion of the plantar fascia (PF). All patients underwent both clinical and ultrasound examination aimed at assessing the entheseal involvement. MSUS entheseal pathology was evaluated by detecting the presence of grey scale changes and power Doppler (PD) signal, as defined by the OMERACT Ultrasound Task Force (2). All the factors that may affect the MSUS findings at entheseal level (lipid profile, body mass index, history of trauma, sport activity and corticosteroid therapy) were carefully evaluated.

**Results:** MSUS entheseal abnormalities were found in 20 out of the 30 patients (66.6%) and in 59 of the 300 entheses examined (19.6%). Patients were clinically asymptomatic in 71.4% of the cases. Among the entheses affected, the distal insertion of the PT was the most commonly involved area (37.2%), followed by the calcaneal insertion of the AT (22%) and the proximal insertion of the PT (16.9%). The patellar insertion of the QT and the calcaneal insertion of the PF were involved in the 13.5% and 10.4% of the cases respectively. With regard to the pathological changes PD signal, hypoechoic areas and entheseal thickening were the most frequently detected abnormalities (29.3%, 26.7% and 24.1%, respectively). Calcifications and bone erosions were found in 11.3% and 8.6% of the cases respectively.

**Conclusions:** Although the inflammatory process in SLE patients is traditionally considered to be localized at synovial tissue level, this study shows that entheseal changes are not uncommon in SLE, especially at PT insertions, occurring frequently in asymptomatic patients. These preliminary results should lead to further investigations aimed at identifying the factors associated with entheseal involvement in SLE patients.

## SAT0553 DIAGNOSTIC VALUE OF QUANTITATIVE SIALOSCINTIGRAPHY COMPARED TO LABIAL SALIVARY GLAND BIOPSY IN PATIENTS WITH SUSPECTED SJÖGREN' SYNDROME

M. Garcia Gonzalez, H. Sanchez Perez, I. Ferraz Amaro, V. Hernandez Hernandez, B. Rodriguez Lozano, S. Bustabad Reyes. *Servicio de Reumatología, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain*

**Background:** Salivary gland dysfunction is one of the most common features of Sjögren' syndrome (SS). Sialoscintigraphy (sSC) is the only technique nowadays available to objectify salivary gland dysfunction that provides simultaneous information about type of functional defect, distribution and severity. In recent years its interpretation based mainly on qualitative indices and the appearance of the American College of Rheumatology (ACR) criteria have shifted in favor of the biopsy (Bp). Some studies have analyzed the role of quantitative scintigraphic indices, mainly excretion fraction (EF%), in the diagnosis of SS, with mixed results.

**Objectives:** 1) To describe glandular involvement patterns and EF% values useful in SS diagnosis. 2) To compare diagnostic accuracy of scintigraphic indices and Bp.

**Methods:** Patients with suspected SS and with sSC and Bp performed between 2006–2012 were included. sSC were performed in a 30 minutes protocol with 99mTc sodium pertechnetate and lemon juice stimulation. Patients already diagnosed of SS and/or with sSC or Bp requested by specialists other than rheumatologists were excluded. Correlations between glandular involvement patterns and EF% and diagnosis of SS were analyzed with Fisher exact test and Kruskal Wallis respectively. Sensitivity, specificity and receiver operating characteristic curve analysis of scintigraphic indices and Bp were performed.

**Results:** Among 272 patients with sSC performed in that period, 71 fulfilled inclusion criteria. 68 (96%) were women with a mean age of 52 ± 14 in the timing of sSC. 57 (80%) reported xerostomia, the majority (39%) with onset in recent months. Qualitative sSC were reported as abnormal in 51 cases (71%); data on age, xerostomia duration, xerostomia related drugs and presence of thyroid disease showed similar frequencies among normal and abnormal sSC groups. Sufficient data to apply American-European Consensus Group and ACR criteria were available in 69 and 48 patients respectively, with diagnosis of SS in 38 (54%). Uptake dysfunction (96 vs 77% p 0.134) and submandibular involvement (59 vs 30% p 0.236) were observed most frecuently in SS patients. All glands showed lower EF% medians in this group, with significant differences for submandibulary ones: right gland 29 (7–37) vs 49 (41–57) p 0.004; left gland 30 (10–45) vs 52 (29–64) p 0.007. Submandibular EF% (right gland AUC 0.793 ± 0.091 p 0.004 IC 95% [0.61–0.97]; left gland AUC 0.764 ± 0.083 p 0.007 IC 95% [0.60–0.93]) showed better diagnostic accuracy than qualitative sSC (AUC 0.601 ± 0.070 p 0.149 IC 95% [0.47–0.74]) and similar to Bp (AUC 0.789 ± 0.055 p 0.000 IC 95% [0.68–0.90]). Submandibulary EF% cuttoff values of 39.5 (right gland) and 47.5 (left gland) showed a sensitivity of 95–82% and specificity of 71–67%, compared to 82% and 39% for qualitative sSC, and 58% and 100% for Bp.

**Conclusions:** 1) Patients fulfilling SS criteria show lower submandibular EF% compared to those who do not. 2) Diagnostic accuracy of submandibular EF% is better than qualitative sSC and similar to Bp. 3) Cutoff values of submandibular EF% of 39.5 (right gland) and 47.5 (left gland) show a sensitivity comparable to qualitative sSC but a significantly higher specificity.

## SAT0554 TIME-INTENSITY CURVES OF CONTRAST-ENHANCED ULTRASONOGRAPHY: PARAMETERS VARIATION AND JOINT DIFFERENCES IN EARLY ARTHRITIS PATIENTS WITH WRIST INVOLVEMENT

M.M. Tamas [1], N. Rednic [2], C. Bondor [3], L.J. Ghib [1], A. Petcu [1], S. Rednic [1]. *[1]Rheumatology, "Iuliu Haţieganu" University of Medicine and Pharmacy; [2]Medical Department IV, Railway Hospital; [3]Department of Informatics and Biostatistic, "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania*

**Background:** Contrast enhanced ultrasonography (CEUS) may be superior to power Doppler US in detecting synovial inflammation by visualizing and quantifying low velocity blood flow at the microvascular level, thus making possible the differentiation of active synovitis from inactive intra-articular thickening. Time-intensity curve (TIC) parameters are descriptive and offer an objective quantification of vascularization in a specific anatomical area. Currently, the role of CEUS in daily rheumatological clinical practice is not well defined. [1,2] It is still not clear which CEUS abnormalities are of special interest for rheumatologists.

**Objectives:** The main objective of our study was to compare TIC parameters of CEUS at four joint levels in early arthritis (EA) patients having wrist involvement, with the purpose of characterizing CEUS parameters uniformity. As a secondary objective, we aimed to identify which TIC parameters vary most in the examined joints.

**Methods:** Patients diagnosed with active early rheumatoid or undifferentiated arthritis on the basis of the 2010 ACR/EULAR classification criteria, having bilateral wrist arthritis and both radiocarpal (RC) and intercarpal (IC) synovial hypertrophy identified by grey scale US, were consecutively enrolled. CEUS was performed using a second-generation contrast agent and quantified using dedicated software. The examinations started with the dominant hand. After 30 minutes, the other hand was examined, using the same protocol. The region of interest (ROI) was selected as the area corresponding to the synovial hypertrophy of the RC and IC joints. TIC parameters were calculated for the first minute of contrast enhancement and were analyzed in each of the four examined joints.
**Results:** Nineteen patients were included in the study. Right hand dominance was present in 94.7% of patients. Dominant hand expressed higher peak, AUC and slope values, compared to the other hand. The percentage difference of the parameters measured at right IC and the other joints varied between 12–32% for Peak (p=0.007), 22–38% for AUC (p=0.015) and 9–30% for slope (p=0.514). No differences for any of the TIC parameters between the other assessed joints were found.
**Conclusions:** CEUS behaviour was not uniform in the wrists joints of EA patients, TIC parameters revealing the highest degree of inflammation at IC joint of the dominant hand. Peak and AUC in CEUS, measured at this joint level, demonstrated the highest variation when compared to the other examined joints, suggesting their potential value for quantification of synovial inflammation.

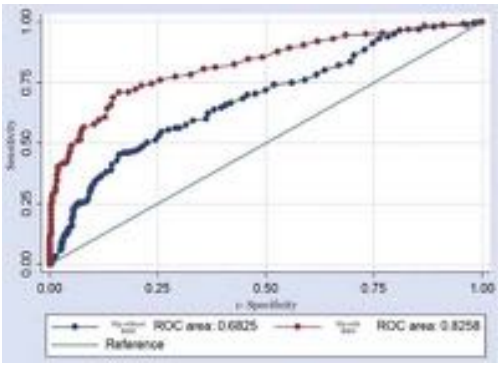
## SAT0555 PROOF OF CONCEPT – STUDY FOR THE EVALUATION OF HEALTHY JOINTS AND PERIARTICULAR STRUCTURES IN CHILDREN

M. Naumann[1], N. Tzaribachev[2], G. Elmardenly[3], M. Eichner[4], G.-R. Burmester[1], M. Backhaus[1], S. Ohrndorf[1]. *[1]Department of Rheumatology and Clinical Immunology, Charite University Hospital, Berlin; [2]Pediatric Rheumatology Research Institute, Bad Bramstedt, Germany; [3]Faculty of Medicine Cairo University, Cairo, Egypt; [4]Epimos GmbH, Dusslingen, Germany*



**Background:** Musculoskeletal ultrasonography (US) has become an important diagnostic tool for the diagnosis and follow-up of inflammatory joint diseases in pediatric rheumatology. However, there is lack of clinical studies in pediatric joint ultrasonography concerning normal findings of healthy joints and periarticular structures in children.
**Objectives:** The aim of the study was to evaluate normal values for the thickness of healthy joint cartilage, capsule and tendons of the hand (finger/wrist), elbow, hip, knee, ankle and forefoot in children by musculoskeletal ultrasound (US). Furthermore, power Doppler activity was measured.
**Methods:** The joints were assessed by four physicians experienced in musculoskeletal US with equally preset Esaote Mylab Twice with high frequency (13 to 18 MHz) probes. N=75 healthy children (41 boys, 34 girls) between 4.9–11.1 years (girls) and 4.3–13.1 years (boys) were included in the study.
**Results:** If there was no significant difference between girls and boys, common reference intervals were calculated (see attached Table 1). Otherwise, 95% separate reference intervals were defined for boys and girls each (not presented in abstract). Power Doppler US (PDUS) signals were measured in all joints. PDUS signals were found regularly, notably in the wrist and finger joints.
**Conclusions:** The reference intervals for healthy children are helpful for the interpretation of pathological findings in juvenile idiopathic arthritis (JIA). The intervals show a wide range; therefore pathology should be examined carefully. Especially in younger children, joint measurements might have different values due to the growing structures, which need further evaluation. Furthermore, PDUS signals in children can be quite common, depending on the joint region and the selected standard scan.

Table 1:

| Examined joint and periarticular structure | gm (mm) | 95% RI (mm) | N |
|---|---|---|---|
| **Elbow:** Capsule in the humero-radial joint (anterior longitudinal view) | 1.19 | 0.43-3.28 | 21 |
| **Wrist:** Capsule above the radio-scaphoid joint (dorsoradial longitudinal view) | 0.95 | 0.41-2.21 | 26 |
| **Wrist:** Cartilage above the radio-scaphoid joint (dorsoradial longitudinal view) | 0.80 | 0.36-1.80 | 26 |
| **Finger joints:** Cartilage of the MCP II (dorsal longitudinal view) | 0.61 | 0.26-1.43 | 25 |
| **Finger joints:** Capsule of the MCP III (dorsal longitudinal view) | 0.67 | 0.33-1.40 | 25 |
| **Finger joints:** Capsule of the MCP V (dorsal longitudinal view) | 0.67 | 0.31-1.46 | 25 |
| **Finger joints:** Cartilage of the MCP V (dorsal longitudinal view) | 0.64 | 0.23-1.31 | 25 |
| **Finger joints:** Capsule of the MCP V (volar longitudinal view) | 1.18 | 0.54-2.56 | 23 |
| **Finger joints:** Cartilage of the MCP V (volar longitudinal view) | 1.13 | 0.47-2.71 | 22 |
| **Hip:** Capsule in the middle of femoral head perpendicular to the head (anterior transverse view) | 3,40 | 1.94-5.96 | 36 |
| **Knee:** diameter of the quadriceps tendon (anterior longitudinal subpatellar view) | 4.59 | 2.94-7.15 | 42 |
| **Forefoot:** Cartilage of the MTP III (dorsal longitudinal view) | 1.17 | 0.64-2.54 | 32 |
| **Forefoot:** capsule of the MTP IV (dorsal longitudinal view) | 1.28 | 0.76-2.05 | 29 |

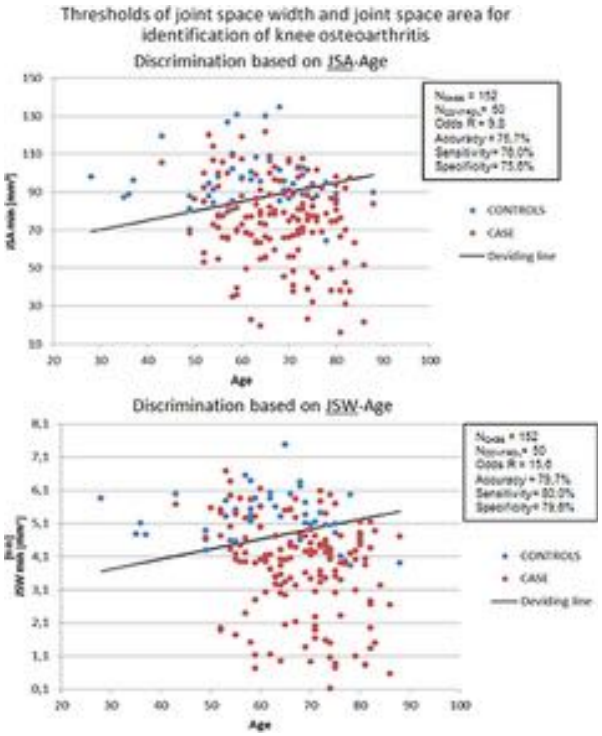
**gm:** geometrical mean; **95% RI:** 95% reference interval based on T-distribution; **N:** Number of subjects

**Objectives:** To compare the indication for pharmacological treatment in a Brazilian elderly population considering the results of FRAX® with bone mineral density (FRAX®/BMD), FRAX® without BMD (FRAX®) and of BMD classification according to the WHO.
**Methods:** The study population consisted of patients over 60 years of age from primary care units who had clinical indication for BMD assessment. BMD was undertaken at lumbar spine and femur by dual-energy X-ray absorptiometry (DXA) Hologic Discovery W system (Madison USA, software version 3.3.01) and BMD results were classified according to the WHO criteria. Clinical data was obtained from patient records (secondary osteoporosis, smoking, alcohol consumption, use of glucocorticoids, rheumatoid arthritis, family history (father or mother) with hip fracture, and previous history of fracture) and the 10-year probability of hip and major fractures was calculated using FRAX® tool. Receiving operator curve (ROC) analysis, model calibration and decision curve analysis were used to compare fracture prediction in FRAX® and FRAX®/BMD groups.
**Results:** 1,000 subjects were included, mean age 76.4 years, 755 (75.5%) women. Osteoporosis, osteopenia and normal BMD were found in 439 (43.9%), 426 (42.6%) e 135 (13.5%) patients, respectively. One hundred and nine (10.9%) patients have already suffered a fragility fracture and 40 of those individuals presented with normal BMD or osteopenia. In 366 (36.6%) patients it was not possible to calculate FRAX® score due to inability of recollection. The application of FRAX® tool would lead to the indication of treatment for 40% of the osteopenic patients and for 62.4% of the osteoporotic patients. Correlations between FRAX and FRAX/BMD were positive and statistically significant for both the 10-year probability of hip fracture and major fracture (0.704 and 0.594, respectively, $p<0.001$). ROC curve analysis showed that the FRAX/BMD was superior in identifying patients at risk of hip (Figure 1) and major fractures.

**Conclusions:** Despite the easy access and simplicity of FRAX® it is not possible to disregard the DXA, especially for patients with risk factor for fragility fractures.

## SAT0556 UTILITY AND PITFALLS OF THE FRAX® TOOL RESULTS IN BRAZILIAN ELDERLY POPULATION

O.B. Malheiro, M.A.M. Maia, C.J. Machado, E.N. de Moraes, A.M. Kakehasi. *Federal University of Minas Gerais, Belo Horizonte, Brazil*



**Background:** The Fracture Risk Assessment Tool (FRAX®) was introduced by the World Health Organization (WHO) to estimate the 10-year probability of osteoporotic fractures in untreated patients with osteopenia[1]. This tool is validated for Brazilian population since 2013 but the applicability in this developing country has not been confirmed.

## SAT0557 A CLINICAL STUDY TO EXAMINE THRESHOLDS OF JOINT SPACE WIDTH AND JOINT SPACE AREA FOR IDENTIFICATION OF KNEE OSTEOARTHRITIS

R. Ljuhar[1], S. Nehrer[2], B. Norman[1], D. Ljuhar[1], T. Haftner[1], J. Hladuvka[3], M. Bui Thi Mai[3], H. Canhão[4], J. Branco[4], A.-M. Rodrigues[4], N. Gouveia[4], A. Fahrleitner-Pammer[5], H.-P. Dimai[5]. *[1]Braincon Technologies, Vienna; [2]Center for Regenerative Medicine & Orthopedics, Danube University, Krems; [3]VRVis Research Competence Center, Vienna, Austria; [4]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [5]Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria*

**Background:** Osteoarthritis (OA) is a degenerative, slowly developing joint disease and characterized by pain and functional disability. Although clinical indications of OA can vary among different definitions there is a general agreement that the disease is associated with cartilage narrowing and the development of osteophytes and sclerosis within the subchondral bone. However, there is no general consensus about the threshold below which the joint space width (JSW) and the respective joint space area (JSA) can be certain indicators for the state of OA.
**Objectives:** Therefore this study evaluates these limits to reveal quantitative information about indicators of OA.
**Methods:** The study included 226 standardized knee radiographs from 101 female patients with OA, and 125 controls. All images were acquired in PA direction and standardized positions. The minimum JSW and JSA were calculated by using the i3a software. 3 physicians assessed the 2D radiographs by using the Kellgren & Lawrence Score and assigned the images to either a Case or Control group. A knee was assigned to the Case group, if at least two physicians assessed it as being affected by OA. The JSW was defined as the vertical distance from the inferior femur condyle to the superior tibia condyle on both the medial and lateral compartment, obtained from 4 distinct points from each side. By building a spline curve between the points of each condyle, the upper and lower boundaries of the JSA are defined for each side, whereas the outer points define the horizontal boundaries. For the JSW and JSA, only the minimum value of each variable was taken into account.
**Results:** Considering the minimum JSW, an odds ratio of 5.63 (CI: 3.17–9.99) with an accuracy of 70.35% and a sensitivity of 70.30% can be obtained. Every subject that has a minimum JSW below 3.4mm belongs to the Case group. With respect to the minimum JSA, the odds ratio is 3.60 with an accuracy of 65.49% and a sensitivity of 65.35%. Results also show that every subject with a minimum JSA below 50mm$^2$ is being considered to have OA.

**Conclusions:** Based on this study it can be concluded that a JSW below 3.4mm and a JSA below 50mm$^2$ at the knee joint are strong indicators for OA. Thus, for clinical assessments it is suggested to consider these threshold values for diagnostic purposes. In further studies, symptomatic knee OA should be incorporated to verify whether minimum JSWs and JSAs can also be linked to symptomatic knee pain.

## SAT0558 NEW GENERATION TRANSLOCATOR PROTEIN PET TRACERS TO IMAGE ARTHRITIS BY MACROPHAGE TARGETING IN RHEUMATOID ARTHRITIS PATIENTS: A PROOF OF CONCEPT STUDY

S. Bruijnen[1], Y. Gent[1], M. Huisman[2], A. Windhorst[2], M. Kassiou[3], A. Lammertsma[2], O. Hoekstra[2], A. Voskuyl[1], C. Van der Laken[1]. *[1]VU University Medical Center, Amsterdam Rheumatology and immunology Center; [2]Department of Radiology & Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands; [3]Medicinal Chemistry, The University of Sydney, Sydney, Australia*

**Background:** Previously, PET and macrophage targeting by translocator protein (TSPO) tracer [$^{11}$C]-(R)-PK11195 has shown promising value to predict development of RA in the very early arthralgia phase, and flares in clinical remission. Nevertheless, the tracer [$^{11}$C]-(R)-PK11195 showed rather high peri-articular background uptake which may limit detection of more subtle arthritis activity. In preclinical setting, our group recently showed more favorable imaging characteristics of two new candidate high affinity translocator protein (TSPO) tracers, [$^{11}$C]DPA-713 and [$^{18}$F]DPA-714, to visualize arthritis.
**Objectives:** To investigate the imaging potential of [$^{11}$C]DPA-713 and [$^{18}$F]DPA-714 as compared to [$^{11}$C]-(R)-PK11195 for visualization of inflamed joints of RA patients using PET-CT.
**Methods:** RA patients with at least two clinically inflamed hand joints were included. PET-CT scans of their hands were obtained after intravenous injection of [$^{18}$F]DPA-714, [$^{11}$C]DPA-713 or [$^{11}$C]PK11195. Two different tracers were compared per patient, respectively [$^{11}$C]PK11195 vs. [$^{18}$F]DPA-714 or [$^{18}$F]DPA-714 vs. [$^{11}$C]DPA-713. Quantitative analysis was done by drawing volumes of interest (VOI) over joints with visually elevated tracer uptake and background VOIs were drawn on metacarpal bone. Standardized Uptake Values (SUVs) and target-to-background (T/B) ratios were determined. Data of the tracer [$^{18}$F]DPA-714 were pooled for analysis. Furthermore, blood was drawn to investigate TSPO receptor polymorphism because a TSPO rs6971 polymorphism is believed to show lower binding affinity (1).
**Results:** Nine RA patients (female3/9; age 54±18; RF+ 7/9; aCCP+ 6/9) were included with a DAS28 of 4.7±1.4 at inclusion. Clear visualization of arthritic joints was obtained with all three tracers. The absolute uptake (SUV) in arthritic joints was comparable for all 3 tracers with a trend of slightly higher uptake of [$^{11}$C]DPA-713 (Table). However, T/B ratios of both [$^{18}$F]DPA-714 and [$^{11}$C]DPA-713 were higher than of [$^{11}$C]PK11195 respectively almost 2-fold higher of [$^{18}$F]DPA-714 and 2,5-fold of [$^{11}$C]DPA713 (Table). Although the “low binding” TSPO polymorphism rs6971 was present in 3/9 patients, PET outcome was not different from patients without the polymorphism.

| | [$^{11}$C]PK11195 | [$^{18}$F]DPA714 | [$^{11}$C]DPA713 |
|---|---|---|---|
| SUV (mean ± SD) | 1.5±0.1 | 1.5±0.2 | 1.7±0.1 |
| T/B ratios (mean ± SD) | 2.4±0.2 | 4.2±0.7 | 5.6±3.4 |

**Conclusions:** This is the first study that shows excellent arthritis imaging with both new generation TSPO tracers, [11C]DPA-713 and [18F]DPA-714, in active RA patients. Although imaging outcome was slightly more favorable of [11C]DPA-713, both tracers performed well with higher target-to-background as compared to the previously investigated macrophage tracer [$^{11}$C]PK11195. The tracers provide opportunities for potential clinical applications of both early diagnosis and therapy monitoring of RA disease activity.

## SAT0559 THE ANATOMICAL DISTRIBUTION OF INFLAMMATION, FAT, EROSION AND NEW BONE FORMATION IN THE SPINE ASSESSED ACCORDING TO THE CANADA-DENMARK MRI DEFINITIONS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

S. Krabbe[1], M. Østergaard[1], I.J. Sørensen[1], B. Jensen[1], O.R. Madsen[1], G.P. Eng[2], K.H. Asmussen[1], J. Møller[3], L. Balding[3], S.J. Pedersen[1]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Frederiksberg, Gentofte and Hillerød; [2]Department of Rheumatology, Køge Sygehus; [3]Department of Radiology, Herlev and Gentofte Hospitals, Denmark*

**Background:** On MRI, patients with axial spondyloarthritis (axSpA) demonstrate lesions at several anatomical locations. These locations include the vertebral bodies, e.g. anterior and posterior corners and lesions without relation to the corners, and also the posterior segments of the vertebrae, e.g. the costo-transversal joints, costo-vertebral joints, facet joints, spinous/transverse processes, and surrounding soft tissue. The Canada-Denmark (CanDen) definitions of MRI lesions in the spine allows a detailed evaluation of all these anatomical locations for inflammation, fat, erosions and new bone formation.(1–3)
**Objectives:** To assess the anatomical location of positive scores by the CanDen MRI scoring system of the spine.
**Methods:** 49 patients with axial SpA (ASAS criteria) and clinical indication for tumor necrosis factor alpha (TNF$\alpha$) inhibitor, including BASDAI $>$40 mm, had MRI of the spine performed at baseline. 51% were male. Median symptom duration (range) was 12 (0–45) years. Images were scored using the CANDEN MRI scoring system by a reader blinded to clinical data.
**Results:**

Table 1. Percentage of patients with a score $\geq$1 according to the CANDEN MRI scoring system by anatomical location and category (inflammation, fat, erosion, bone spurs/ankylosis). No soft tissue inflammation was found

| | | Cervical spine (C2/C3 to (C7/T1) | Thoracic spine (T1/T2 to (T12/L1) | Lumbar spine (L1/L2 to (L5/S1) |
|---|---|---|---|---|
| Anterior corner lesions | Inflammation | 16% | 41% | 51% |
| | Fat/Erosion | 16%/0% | 45%/2% | 33%/0% |
| | Bone spurs/Ankylosis | 6%/2% | 0%/2% | 4%/6% |
| Posterior corner lesions | Inflammation | 4% | 29% | 18% |
| | Fat/Erosion | 8%/0% | 16%/2% | 22%/0% |
| | Bone spurs/Ankylosis | 2%/0% | 0%/6% | 0%/2% |
| Non-corner lesions | Inflammation | 4% | 14% | 10% |
| | Fat/Erosion | 2%/2% | 4%/8% | 12%/4% |
| | Bone spurs/Ankylosis | 0%/0% | 0%/6% | 0%/2% |
| Antero-lateral corner lesions | Inflammation | NA | 22% | 29% |
| | Fat/Erosion | NA | 16%/0% | 18%/0% |
| Postero-lateral corner lesions | Inflammation | NA | 33% | 8% |
| | Fat/Erosion | NA | 18%/0% | 6%/0% |
| Costo-transversal joint transverse process | Inflammation | NA | 4% | 2% |
| Facet joint | Inflammation | 6% | 8% | 6% |
| | Fat/Erosion | 0%/0% | 2%/0% | 2%/0% |
| | Bone spurs/Ankylosis | 10%/0% | 8%/0% | 8%/0% |
| Spinous process | Inflammation | 0% | 2% | 0% |

In total, 10 of 49 patients (20%) had involvement of the costo-transversal joints, facet joints, spinous/transverse processes or soft tissue.
**Conclusions:** The most frequent lesion in patients with axSpA were inflammation and fat lesions in the rim of the vertebral bodies (the anterior, posterior, antero-lateral and postero-lateral corner lesions) in the thoracic and lumbar spine. 1/5 of the patients had involvement of the posterior segments.

## SAT0560 AUTOMATED IFA METHODS COMPARE WELL WITH ESTABLISHED MANUAL IFA SCREENING AND TITRATION FOR ANA HEP-2

J. Blecken[1], T. Matthias[2], A. Frey[1], M. Daves[3], A. Joos[3], S. Platzgummer[3]. *[1]R&D; [2]CEO, AESKU. Diagnostics GmbH&Co KG, Wendelsheim, Germany; [3]R&D, Labor f. Clin.Chem. Analysis and Microbiology, Meran, Italy*

**Background:** Often, only basic nuclear patterns, like homogenous, speckled, nucleolar, centromere or cytoplasmic, are reported by laboratories. The detection of other patterns requires well trained readers. As a result, different systems have been developed which automate part of or the complete IFA method and reading process.
**Objectives:** This study compares 2 commercially available HEp-2 antinuclear antibody (ANA) indirect fluorescent antibody (IFA) assays using a sensitivity panel (120 clinically determined patients) and a specificity panel consisting of 80 clinically confirmed negative patients.
**Methods:** We compared two different automated systems (A and B) to assess their capability for screening and titration of these samples. The automated method was directly compared to manual reading of the same processed slides on respective microscopes and also compared with the known clinical information.
**Results:** The results of the two automated methods were in good agreement. System A detected 188 samples correctly from negative and positive samples, versus 187 samples detected by the system B. The falsely detected positive samples were all of low titer (1:80). System A found 157 and System B 156 patterns in agreement to the target pattern. From 80 negative samples system A detected 73 and system B 71 samples correctly.
**Conclusions:** Both systems resulted in an overall sensitivity $>$95% and a specificity of 91.25% and 88.75%. The pattern recognition also showed only minor aberrant findings resulting in a slightly better detection of cytoplasmic and nuclear membrane patterns by system A while system B detected slightly better the centromeric pattern.

## SAT0561 FINGER JOINT CARTILAGE EVALUATED BY ULTRASOUND AND X-RAY IN RHEUMATOID ARTHRITIS AND CONTROL JOINTS

T. Ogura, A. Hirata, N. Hayashi, H. Ito, S. Takenaka, K. Mizushina, Y. Fujisawa, M. Imamura, R. Kujime, S. Nakahashi, N. Yamashita, H. Kameda. *Division of Rheumatology, Toho University Ohashi Medical Center, Tokyo, Japan*

**Background:** Joint destruction in RA includes both bone and cartilage lesions. By X-ray examination, cartilage destruction is evaluated as a joint space narrowing (JSN). However, joint space narrowing is not a direct evaluation of cartilage.
**Objectives:** The aim of the study was to examine the finger joint cartilage by ultrasound (US) imaging and to compare it with JSN score in relation to clinical relevance.
**Methods:** We enrolled 27 RA patients in low disease activity or clinical remission (DAS28-CRP $<$2.7) and 21 healthy controls in this study. The cartilage thickness (CT) of metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints of 2nd to 5th fingers was bilaterally visualized and measured from a dorsal view, with approximately 90 degrees flexion. In addition, JSN of finger were scored by van der Heijde- modified Sharp method.
**Results:** In patients with RA, CT in MCP joints ranged from 0.0 to 0.8 mm (median 0.4 mm), and CT in PIP ranged from 0.0 to 0.4mm (median 0.2mm), respectively. The sum of total CT from 8 fingers ranged from 2.7 to 6.8 mm (median 4.7 mm), and there was a significant difference in CT, but not in JSN score, between male and female patients (5.6 versus 4.6, respectively, p=0.005). Healthy controls had the sum of total CT significantly thicker as compared with RA ($p \leq 0.001$). Importantly, CT was well correlated with JSN ($r=-0.696$, $p<0.001$). Although CT was not correlated with age, disease duration, DAS28-CRP, functional disability score, positivity of rheumatoid factor and anti-CCP-antibody, CT was reduced in RA patients with elevated serum matrix metalloproteinase-3 (MMP-3) values compared with those with normal MMP-3 (3.9 versus 5.0, p=0.015).
**Conclusions:** The US method of direct visualization and quantification of cartilage in MCP and PIP joints can be valid and useful in RA, and our results may support the importance of MMP-3 in the pathophysiology of cartilage destruction.
**Disclosure of Interest:** None declared

## SAT0562 COMPARISON OF MRI AND RADIOGRAPHY IN DETECTING STRUCTURAL DAMAGE OF THE SACROILIAC JOINTS IN PATIENTS WITH CHRONIC LOW BACK PAIN USING LOW-DOSE CT AS STANDARD OF REFERENCE – RESULTS FROM THE SIMACT STUDY

T. Diekhoff[1], J. Greese[1], J. Sieper[2], K.-G.A. Hermann[1]. *[1]Department of Radiology, Charité Berlin; [2]Clinic of Rheumatology, Medical Department I, CBF, Charité Universitätsmedizin Berlin, Berlin, Germany*

**Background:** The ability of magnetic resonance imaging (MRI) to detect structural changes of the sacroiliac joint (SIJ) is subject to discussion, whereas radiography as established method provides poor reliability.
**Objectives:** The aim of this study was to compare the ability of MRI and radiography in detecting erosions, sclerosis, pseudowidening and ankylosis of the SIJ using low dose computed tomography (ldCT) as standard of reference.
**Methods:** We prospectively included 110 patients in the study. All patients underwent a ldCT (Somatom Definition Flash, Siemens, Germany) and an MRI (3.0T Magnetom Skyra, Siemens, Germany) including a paracoronal T1 sequence of the SI-joints. Imaging data were compared with X-ray of the pelvis. Two readers independently scored the datasets for the presence of erosions, sclerosis and changes of the joint space in a blinded fashion using a comprehensive scoring system. Contingency table analysis was performed using ldCT as standard of reference. Inter-rater reliability was calculated using Cohen's kappa. The agreement of all modalities with the expert rheumatologists diagnosis was calculated for three diagnostic categories (axSpA, mechanical back pain, normal).
**Results:** We found following sensitivity and specificity for the detection of structural lesions on patient's level: erosions (0.42/0.86 for radiography, 0.79/0.93

for MRI), sclerosis (0.7/0.9 radiography, 0.3/0.96 MRI) and joint space alterations (0.41/0.95 radiography, 0.76/0.99 MRI), respectively. Inter-rater reliability was fair for radiography (0.32 to 0.4) and substantial for MRI (0.35 to 0.62) and ldCT (0.5 to 0.7) with the poorest reliability for sclerosis each. Diagnostic accuracy ranged from 0.41 to 0.52 for radiography, 0.62 to 0.72 for MRI and 0.63 to 0.75 for ldCT.
**Conclusions:** MRI is superior to radiography in detecting erosions and alterations of the joint space, however, inferior in detecting sclerosis. Most reliable diagnostic parameters amongst all imaging modalities were erosions and joint space alterations. Cross-sectional imaging modalities, including MRI, provide a superior diagnostic accuracy compared to conventional radiography.
**Acknowledgement:** The authors thank the Assessment of Spondyloarthritis international Society (ASAS) for supporting the study with a research grant.
**Disclosure of Interest:** None declared

## SAT0563 OPTIMIZED DOPPLER SETTING INCREASE SCORES OF SYNOVITIS AND COLOUR FRACTION IN RHEUMATOID ARTHRITIS WRIST JOINTS - EXPERIENCE FROM A TARGETED ULTRASOUND INITIATIVE WORKSHOP

U. Møller Døhn[1], S. Torp-Pedersen[2], H.B. Hammer[3], J. Koski[4], R.L. Luosujarvi[5], L. Terslev[1]. *[1]Center for Rheumatology and Spine Diseases; [2]Department of Diagnostics, Rigshospitalet, Glostrup, Denmark; [3]Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Department of Internal Medicine, Mikkeli Central Hospital, Mikkeli; [5]Line of Rheumatology, Center of Inflammatory Diseases, Helsinki University Hospital, Helsinki, Finland*

**Background:** Blood flow in small vessels of synovial membrane in inflamed joints is characterized by slow-flow. The ability to detect this flow with Doppler ultrasound (US) is influenced by the quality of the US unit, Doppler modality and the Doppler settings. The standard Doppler settings provided by manufacturers of US units have previously been shown not to be optimal for the detection of this slow flow. However, significant improvement of Doppler sensitivity is possible.[1]
**Objectives:** The purpose of the study was to investigate how factory Doppler settings (FS) on a high-end US unit could be improved with respect to Doppler sensitivity by ultrasonographers who had just received lectures on optimizing Doppler settings. Secondly, how scoring and quantification of Doppler activity were affected by more sensitive Doppler settings.
**Methods:** During an US course arranged as part of targeted ultrasound initiative (TUI) in Helsinki, participants were taught on Doppler settings and how to optimize these. The Doppler settings were adjusted by participants for increased Doppler sensitivity as suggested by Torp-Pedersen et al.[2] A General Electric LOGIQ-E9 ultrasound unit with a 6–15 MHz linear array transducer was used. Four rheumatoid arthritis (RA) patients with a clinically active wrist joint were examined with US by four groups of course participants. US was done using both the FS for superficial musculoskeletal US and the optimized setting (OS). Findings of each joint was scored semi-quantitatively (0–3) and for the maximum colour fraction (CF) using four seconds video clip. CF was calculated using the US unit's software for quantitative analysis based on a drawn region of interest (ROI).
**Results:** All groups were capable of adjusting FS to a more sensitive Doppler setting as suggested in the preceding lectures. The median Doppler score for the four wrist joints were 1 (range: 0–2) on FS and 2 (1–2) on OS. In 12/16 evaluations the Doppler score increased by at least one point on OS compared to FS, and were unchanged in the remaining. In 5/16 evaluations (three patients) the score changed from 0 (normal) to a score of 1 or 2 using OS. The mean CF was 0.021 (range: 0–0.093) on FS and 0.082 (0.008–0.20) on OS (p=0.001; Wilcoxon signed rank test). No significant difference was observed in the area of the ROI (mean: 45 and 44 $mm^2$ on FS and OS, respectively).
**Conclusions:** Optimization of Doppler settings for increased sensitivity for slow flow in synovial tissue of RA wrist joints is possible after proper instruction. An optimized Doppler setting led to significantly higher scores and CF in the examined wrist joints and in some patients synovial Doppler activity was observed only with an optimized setting. Consequently, using FS could result in active joint inflammation being missed or underestimated by the examiner. This small study demonstrates that knowledge on optimizing Doppler settings can be learned in workshops and highlights the importance of knowledge on how to improve Doppler sensitivity wherever US is used in clinical practice.

## SAT0564 ARTICULAR INVOLVEMENT IN BEHÇET DISEASE: AN ULTRASONOGRAPHIC STUDY

V. Picerno, G. Filippou, L. Cantarini, A. Adinolfi, V. Di Sabatino, I. Bertoldi, C. Toscano, M. Galeazzi, B. Frediani. *Rheumatology Unit, University of Siena, Departement of Clinical Sciences, Surgery and Neurosciences, Rheumatology Unit, Siena, Italy*

**Background:** An articular involvement is reported in Behçet disease up to 70% of patients, varying from referred arthralgia to arthrtitis, generally non-erosive, poly- or oligoarticular. Some authors compared this joint involvement to Seronegative Spondyloarthritis, reporting prevalent involvement of entheses and sacroiliitis. Few US studies has been conducted in Behçet, focusing on tendon and enthesal evaluation
**Objectives:** To evaluate the presence of US pathological findings of joints, tendons and entheses of patients affected by Behçet disease
**Methods:** We enrolled consecutive patients with Behçet disease reaching the Rheumatologic Unit of our hospital between Feb 2014 and Jan 2016, irrespective of disease activity status and therapy. US exams was performed by a single operator with 8–18 MHz linear transducers (Esaote MyLab70). 42 joints (shoulders, elbows, wrists, MCPs, PIPs, hips, knees, ankles, MTPs), 12 entheses (triceps tendons,common extensor tendons, knee entheses, Achilles tendons) and 20 tendon sheats (flexor digitorum tendons, wrist's flexor and extensor tendons, anterior and posterior tibialis and peroneal tendons) were evaluated for each patient, using a stardardized technique. Grey scale (GS) and power Doppler (PD) US exam was performed to detect joint effusion, synovial hypertrophy and PD, classified with dicotomic and semiquantitative score (grade 0–3); effusion and synovial hypertrophy were combined in a single score and defined as synovitis. The presence/absence of tenosynovitis was evaluated for each site. At the entheseal level, we evaluated the presence of GS abnormalities of tendon structure (hypoechogenicity/thickness), enthesophytes and Doppler signal within the tendon or at the entheseal site, all classified as present/absent
**Results:** We evaluated a total amount of 1596 joints, 760 tendons and 456 entheses from 38 patients (20 women). A grade 1 synovitis was observed in 158 joints (9,9%): 87 MTPs, 21 knees, 19 MCPs, 14 wrists, 11 ankles, 4 PIPs and 2 elbows; in 72 patients the finding was monolateral while in 43 patients it was observed bilaterally, notably at I and II MTPs and knees joints. A grade 2 synovitis was observed in 18 joints (1,12%): 16 MTPs, 1 knee and 1 MCP; no grade 3 synovitis was observed. A grade 1 PD was detected in 2 wrists, 2 MCPs and 7 MTPs joints and a grade 3 PD was observed in a single MCP joint. We observed the presence of tenosynovitis in 36 cases, all involving hand or wrist tendon structures. 12 entheses presented altered fibrillar pattern with hypoecogenicity (8 common extensor tendons and 4 knee entheses), while the presence of enthesophytes was observed at the common extensor in 4 cases, at triceps in 8, at quadriceps in 6, at proximal patellar insertion in 2, at Achilles tendon in 21; the presence of at least 1 grey scale abnormality was observed in 63 entheseal sites (13,81%). An intratendineous PD signal was observed in 27 cases (5,9%): 16 common extensor tendons, 4 quadriceps, 3 proximal patellar insertion, 4 Achilles tendons
**Conclusions:** In a population of patients with Behçet disease we observed the presence of joint effusion in 11% and PD signal in 0,7% of examined joints, notably involving hands and feet joints. GS alteration of tendon structure was detected in 13,81% and an intratendineous PD signal in 5,9% of entheseal sites.A mild tenosynovitis was observed in 4,7% of examined tendons
**Disclosure of Interest:** None declared

## SAT0565 RELIABILITY OF THE QUANTITATIVE ASSESSMENT OF PERIPHERAL BLOOD PERFUSION BY LASER SPECKLE CONTRAST ANALYSIS IN A SYSTEMIC SCLEROSIS COHORT

V. Lambrecht[1], M. Cutolo[2], F. De Keyser[1,3], S. Decuman[4], B. Ruaro[2], A. Sulli[2], E. Deschepper[5], V. Smith[1,3] on behalf of EULAR Study Group on Microcirculation in Rheumatic Diseases. *[1]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; [3]Department of Internal Medicine, Ghent University Hospital; [4]Department of Internal Medicine; [5]Biostatistics Unit, Department of Public Health, Ghent University, Ghent, Belgium*

**Background:** In systemic sclerosis (SSc) there is increasing interest to evaluate blood perfusion in a dynamic way, to evaluate evolution of disease and response to therapy. Laser speckle contrast analysis (LASCA) is an emerging technique that measures peripheral blood perfusion (PBP) in real time over a large area and is convenient in use (1,2). In order to be used as an outcome measure, first reliability of LASCA needs to be attested.
**Objectives:** To investigate the reliability of the quantitative assessment of PBP by LASCA between two raters in a SSc cohort.
**Methods:** Two independent raters evaluated PBP in 40 consecutive patients with SSc (according to the 2013 ACR/EULAR classification criteria) using LASCA. After acclimatization for 20 minutes in a temperature controlled room, PBP was measured at the level of the fingertips, dorsal and volar bilaterally, for 30 sec each. Measurements were performed under standardized environmental, patient and instrumental conditions. PBP values were reported as perfusion units (PU) by creating regions of interest with fixed 1 cm diameter at central area of the fingertips. Mean PU per finger, left and right, dorsal and volar, per rater was calculated. Inter rater reliability was assessed by calculation of intraclass correlation coefficients (ICC). Patients with flexion contractures (n=6) were excluded because they could not meet the standardization requirements.
**Results:** ICC (95% confidence interval) values for PBP measurements varied from 0.82 (0.67 to 0.91) to 0.91 (0.83 to 0.96) for the dorsal fingertips, and from 0.74 (0.55 to 0.86) to 0.86 (0.74 to 0.93) for the volar fingertips (Table 1).

Table 1. ICC (95% CI) for PBP measured by LASCA by two independent raters

| | ICC | 95% CI |
|---|---|---|
| Dorsal left | | |
| F2 | 0.85 | 0.71; 0.92 |
| F3 | 0.89 | 0.79; 0.94 |
| F4 | 0.89 | 0.80; 0.95 |
| F5 | 0.83 | 0.68; 0.91 |
| Dorsal right | | |
| F2 | 0.91 | 0.83; 0.96 |
| F3 | 0.90 | 0.81; 0.95 |
| F4 | 0.88 | 0.77; 0.94 |
| F5 | 0.82 | 0.67; 0.91 |
| Volar left | | |
| F2 | 0.86 | 0.74; 0.93 |
| F3 | 0.85 | 0.72; 0.92 |
| F4 | 0.84 | 0.70; 0.92 |
| F5 | 0.80 | 0.63; 0.89 |
| Volar right | | |
| F2 | 0.84 | 0.70; 0.91 |
| F3 | 0.76 | 0.58; 0.87 |
| F4 | 0.74 | 0.55; 0.86 |
| F5 | 0.81 | 0.66; 0.90 |

ICC, intraclass correlation coefficient; CI, confidence interval; PBP, peripheral blood perfusion; LASCA, laser speckle contrast analysis; F, fingertip.

**Conclusions:** This is the first study to demonstrate reliability of the quantitative assessment of peripheral blood flow by LASCA in a SSc cohort between two raters, performed under standardized patient, instrumental and environmental conditions. With this study, we took the first step in the validation of LASCA, though further studies are needed to confirm these results.

## SAT0566 SALIVARY GLAND ULTRASONOGRAPHY AND ITS APPLICATIONS IN PATIENTS WITH SJÖGREN'S SYNDROME AND SICCA SYMPTOMS

Y.P. Tsao[1,2], W.S. Chen[1,2], C.Y. Tsai[1,2]. *[1]Medicine, Taipei Veterans General Hospital; [2]National Yang Ming University, Taipei, Taiwan, Province of China*

**Background:** Sjögren's syndrome is an autoimmune disease that involves the exocrine glands. In the criteria declared in 2002 and 2012, salivary gland biopsy remains crucial in diagnosing the disease, and the aggregation of lymphocytes correlates with the disease activity. However, salivary gland biopsy is invasive and is not recommended for monitoring the disease activity. Ultrasonography provides easy access, low cost and real-time image. Recent systemic review indicated ultrasonography revealing abnormalities of salivary glands, which may be helpful for rheumatologist in diagnosing Sjögren's syndrome, but the reliabilities need to be confirmed among different scoring systems.

**Objectives:** To investigate the usefulness of salivary gland ultrasonography in Sjögren's syndrome and its correlations with EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) questionnaires (Seror R, 2011).

**Methods:** 50 patients, including primary and secondary Sjögren's syndrome, as well as some patients with sicca symptoms were enrolled. Ultrasonography by a 13MHz linear probe was performed at parotid and submandibular glands. Each gland was scored from 0 to 4 according to the criteria proposed by previous study (Takagi Y, 2010), with a total maximum score with 16. ESSPRI questionnaires and blood samplings were also performed within 1 week after ultrasonography.

**Results:** Total 31 primary Sjögren's Syndrome, 8 secondary Sjögren's Syndrome, and 13 patients with sicca symptoms were enrolled. The average score of salivary gland ultrasonography was 8, 8, 5 respectively in each group. A significant correlations between salivary gland ultrasonography summation score with serum anti-La (SSB) ($p=0.006$) and ESSPRI score ($p<0.001$) were noted. The score also correlated with the fatigue score ($p<0.001$) and dry score ($p=0.001$) in the ESSPRI questionnaire, but not with the pain score ($p=0.135$). The correlations with serum anti-Ro antibody was not significant ($p=0.902$).

**Conclusions:** Summation score of salivary gland ultrasonography correlated well with serum anti-La titers and ESSPRI score. Ultrasonography provided real-time, easily accessible information on patients' salivary gland conditions, as well as good correlations with patients' subjective discomfort. The relationship between the ultrasonography images and disease activity deserves further investigations.

## SAT0567 DEMOGRAPHIC, CLINIC AND LABORATORY FEATURES OF 755 PATIENTS WITH NEONATAL LUPUS ERYTHEMATOSUS: SYSTEMATIC REVIEW

A. Erden[1], L. Kilic[1], E. Bilgin[2], S. Ceylan[2], B. Hymabaccus[2], Y.Z. Sener[2], F. Gürler[2], A. Sari[1], B. Armagan[1], O. Karadag[1], S. Kiraz[1], U. Kalyoncu[1]. *[1]Department of Rheumatology; [2]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey*

**Background:** Neonatal lupus erythematosus (NLE) which is caused by trans placental transmission of maternal anti SS-A/Ro and anti SS-B/La antibodies. Cutaneous, cardiac, hepatic and hematologic manifestations can be seen.

**Objectives:** The objective of this systematic review was to analyze demographic data, clinical manifestations, autoantibodies, treatment modalities and mortality status of NLE patients.

**Methods:** Systematic review has been done at August 2015 on Pubmed Medline. Publications are determined by using MeSH term: ("neonatal lupus, congenital hearth block" (MeSH)) and restricted to "in humans" and "in English". Out of study design, abstracts of all publications has been assessed. 1377 article has been assessed in abstract format, after that; 277 original article/case report has been evaluated in full-text format. Finally, 199 article/ case report has been included to study after full-text evaluation. Totally, 755 patients enrolled. Demographic, clinical, laboratory features were assessed both maternal and infant level.

**Results:** *Maternal features:* Mean maternal age was 29.7 (4.8) years. Median gestational week was 23 (21–40) weeks. Accompanying diseases were known in 547 patients (SLE 176 (32.2%), Sjogren syndrome 99 (18.1%), undifferentiated connective tissue disease 31 (5.7%), rheumatoid arthritis 7, other autoimmune disease 53 (9.6%), no disease 179 (32.7%)). ANA results were known in 349 mothers with 287 (82.2%) positivity. ENA were known in 601 mothers (SS-A 506 (84.2%), SS-B 313 (52.1%), anti-RNP 31 (5.2%), negative 57 (9.1%)). In 327 mothers, diagnosis time of collagen tissue disease was known (212 (64.8%) mothers before pregnancy, 18 (5.5%) during pregnancy and 97 (29.7%) postpartum period). Maternal treatments before pregnancy were known in 137 of mothers (glucocorticoid 38 (27.7%), hydroxychloroquine 13 (9.5%), azathioprine 4 (2.9%), IVIG 2 (1.4%), and no treatment 94 (68.6%)).
*Infants' features:* Totally, 272/477 (57.0%) was female. Mean birth weight was 2680 (364–4370) gram, median delivery week was 37 (19–42) and 126 of 295 (42.7%) NLE was premature. Autoantibodies were known in 272 infants (225 (82.7%) SS-A, 126 SS-B (46.3%), 25 (9.2%) anti-RNP, all negative 20 (7.4%)). Mortality data were available for 485 infants with 412 (84.9%) were alive (85 with pacemaker), 37 (7.6%) were intrauterine exitus, and 36 (7.4%) were post-partum exitus.
*NLE features:* Most common manifestations of NLE was; cardiac 467 (61.8%), cutaneous 249 (33.1%), hematologic 117 (15.5%), and hepatic 78 (10.5%). Cardiac involvement types were known in 284 infants (AV complete block 219 (77.1%), 2. block 27 (9.5%), 1. block 19 (6.7%), and sinus bradycardia 19 (6.7%). Totally, 62 of 195 (31.2%) AV complete block detected post-partum period.

**Conclusions:** NLE was cause of premature (almost 43%) delivery and had high mortality ratio (almost 15% of infants). SLE and Sjogren's syndrome were leading maternal diagnosis. Although ANA and SS-A are main maternal autoantibodies, SS-B may also be found half of the cases. Congenital heart block, particularly AV block, is life-treating involvement, and unfortunately one of three infants have diagnosed at post-partum period.

**Disclosure of Interest:** None declared

## SAT0568 INITIATION OF BIOLOGIC TREATMENT OVER THE PAST 15 YEARS REFLECTS CHANGES IN TREATMENT STRATEGIES: RESULTS FROM THE PROSPECTIVE COHORT OF THE GERMAN BIOLOGICS REGISTER RABBIT

A. Richter[1], D. Pattloch[1], B. Manger[2], R. Dockhorn[3], L. Meier[4], A. Zink[1], A. Strangfeld[1]. *[1]Epidemiology, German Rheumatism Research Center, Berlin; [2]Scientific Board, Erlangen; [3]Rheumatologist, Weener; [4]Rheumatologist, Hofheim, Germany*

**Background:** Since approval of the first biologic (b) DMARDs for the treatment of rheumatoid arthritis (RA) in 2001, bDMARDs have been utilized to treat patients with severe disease. However, characteristics of patients treated with bDMARDs in the first years after approval differ substantially from those receiving bDMARDs nowadays.

**Objectives:** To investigate which clinical parameters influence the decision of rheumatologists to start the 1st bDMARD treatment in patients with RA over the past 15 years.

**Methods:** We used data of a prospectively observed cohort of RA patients from the German biologics register RABBIT. Since 2001, patients have been enrolled at start of a conventional synthetic (cs)DMARD or bDMARD after $\geq$1 csDMARD failure. 13,568 RA patients were included until April 2015. After exclusion of patients with prior biologic treatment (n=2558), insufficient information on prior treatment (n=579) or inclusion in 2007/2008 (n=918), where no patients with

csDMARD start were recruited, 9.513 patients remained for the analyses. They were stratified according to their year of inclusion in RABBIT (2001–2003, 2004–2006, and 2009–2015). We applied a machine learning method of model-based boosting to select clinical parameters which have a relevant impact on treatment decisions in each of the three episodes and compared the results with multiple logistic regression models.

**Results:** N=1781 biologic-naive patients were included during 2001–3, n=2781 in 2004–6 and n=4951 after 2008. The proportion of patients included with the start of a bDMARD was consistently between 60–62%. Patient characteristics at start of the first bDMARD changed over time. Mean disease duration decreased from 11.9 to 9.1 years, mean number of DMARD failures declined from 3.6 to 2.2 and mean disease activity (DAS28) fell from 6.0 to 5.0. The proportion of patients with osteoporosis declined from 24.5% to 11.9%.

High disease activity (DAS28), prior DMARD failures and high doses of glucocorticoids (GC) were associated with starting a biologic treatment independent from the enrollment year. Over time, more patients with only moderate disease activity, lower doses of GC and positive rheumatoid factor as well as those with more severe comorbidities like heart failure and chronic renal disease were included in the bDMARD cohort. Male sex was associated with the start of bDMARD in 2001–2003 but the effect receded in recent years of enrollment.

| | Enrollment period | | | |
|---|---|---|---|---|
| | 2001-2003 | | 2009-2015 | |
| | OR LogReg (95%CI) | Boosting approach | OR LogReg (95%CI) | Boosting approach |
| Intercept | 0.70 (0.19-2.60) | * | 0.19 (0.10-0.37) | * |
| Sex (males vs. females) | 2.04 (1.52-2.74) | * | 1.17 (1.00-1.37) | |
| Age (by 10 years increase) | 0.66 (0.59-0.74) | * | 0.78 (0.73-0.82) | * |
| Rheumatoid factor (neg. vs. pos.) | 1.15 (0.86-1.54) | | 1.55 (1.34-1.78) | * |
| # previous csDMARDs | 2.61 (2.34-2.90) | * | 4.20 (3.79-4.66) | * |
| Renal disease (yes vs. no) | 2.78 (1.26-6.17) | | 2.14 (1.43-3.19) | * |
| Heart failure (yes vs. no) | 1.68 (0.75-3.77) | | 4.56 (2.16-9.59) | * |
| Glucocorticoids (<5mg/d Reference) | | | | |
| GC 5-7.5 mg/d | 1.13 (0.83-1.53) | * | 1.42 (1.21-1.65) | * |
| GC >7.5 mg/d | 2.08 (1.55-2.78) | * | 2.60 (2.16-3.12) | * |
| DAS28 (<3.2 Reference) | | | | |
| DAS28 3.2-5.1 | 1.35 (0.57-3.15) | | 1.95 (1.55-2.46) | * |
| DAS28 >5.1 | 2.32 (0.99-5.44) | * | 3.22 (2.51-4.13) | * |
| Fatigue | 1.03 (0.98-1.09) | * | 0.99 (0.96-1.03) | |
| Pain | 0.97 (0.90-1.04) | * | 0.98 (0.95-1.02) | |
| Improved physical function (by 10%) | 0.87 (0.81-0.93) | * | 0.96 (0.92-1.00) | * |

* Covariates marked with an asterisk were selected in the boosting approach with comparable ORs, the remaining covariates were excluded from the model.

**Conclusions:** The increasing use of biologics in patients with moderate disease activity and GC treatment shows that new treatment guidelines recommending earlier use during disease course to prevent further damage are realized in daily care practice. Growing knowledge and experience with biologics increasingly allows rheumatologists to treat also patients with serious comorbidities like heart failure.

**Disclosure:** RABBIT is supported by a joint, unconditional grant from AbbVie, Bristol-Myers Squibb, Celltrion, Hospira, MSD Sharp & Dohme, Pfizer, Roche, and UCB.

**Disclosure of Interest:** None declared

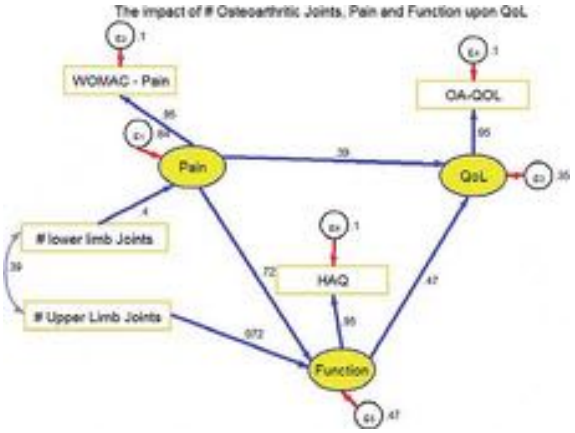
## SAT0569 THE IMPACT OF PAIN AND PHYSICAL FUNCTION UPON QUALITY OF LIFE IN OSTEOARTHRITIS



A.A. Tennant[1], S. Kutlay[2], S.P. McKenna[3], T. Bender[4], J. Braun[5], C. Castillo-Gallego[6], M. Favero[7], P. Geher[8], U. Kiltz[5], E. Martin-Mola[9], R. Ramonda[7], J. Twiss[3], J. Wilburn[3], A.A. Küçükdeveci[2]. *[1]Swiss Paraplegic Research, Nottwil, Switzerland; [2]Ankara University, Ankara, Turkey; [3]Galen Research, Manchester, United Kingdom; [4]4Hospitaller Brothers of St John of God, Budapest, Hungary; [5]Rheumazentrum Ruhrgebiet, Herne, Germany; [6]Hospital Universitario La Paz, Madrid, Spain; [7]University of Padova, Padova, Italy; [8]Hospitaller Brothers of St John of God, Budapest, Hungary; [9]6Hospital Universitario La Paz, Madrid, Spain*

**Background:** Pain, physical function (PF) and quality of life (QoL) are important aspects of the lived experience of those with chronic disease[1].

**Objectives:** A EULAR funded study to adapt the Osteoarthritis Quality of Life Scale (OAQoL) into five languages (German, Hungarian, Italian, Spanish, Turkish) gave the opportunity to explore the relationships between these key attributes in osteoarthritis (OA).

**Methods:** A Path Model was employed, within a Structural Equation Framework, utilising Rasch-transformed latent estimates as single indicator latent variables. Measures included lower & upper limb joint count (Manikin), pain on function (WOMAC), PF (HAQ) and QoL (OAQoL). The hypothesis was that the impact of pain upon QoL would be partially mediated by PF and this relationship will be invariant by age, gender and country.

**Results:** 677 patients with OA were recruited across 5 countries, approximately 20% from each. 76% were female, 33% aged 60 and under. 65% were married, 22% in work. Duration differed significantly across countries, with 10.1% of those in Turkey with duration of 15 years or more, compared with 32.5% of those in Spain. Joint count also varied significantly, e.g. 33.8% of those recruited in Spain reported no lower limb involvement compared with just 1.5% in Hungary. Path model fit was acceptable ($\chi^2$ 7.52 (df 4) p=0.111; RMSEA 0.036; TLI 0.992, CFI 0.997) (Figure). All path weights were consistent with the basic hypothesis and 43% of the impact of pain upon QoL was mediated through PF (Sobel-Goodman Z 10.93; $p<0.001$). The number of upper & lower joints influenced PF and pain respectively. Thus an increase in pain, and greater limitation in PF gave a worse QoL. The total effect of pain (direct & indirect) was the strongest influence upon QoL. The Wald Test for group invariance showed no significant difference of regression weights ($p>0.01$) by age, gender, duration and, to a large extent, by country. In the latter there were slight variations in the magnitude of paths weights between pain and PF. The effect appeared much stronger in Italy and Turkey than elsewhere. Overall, the model appeared robust across countries (Model fit $\chi^2$ 26.85 (df 20) p=0.14; RMSEA 0.05; TLI 0.985, CFI 0.993). Country-specific adjusted $R^2$ for explained variance in QoL ranged between 0.59–0.71.

**Conclusions:** Pain, PF and the consequent reduction in perceived QoL are at the centre of the lived experience of those with OA. The relationship between these three variables, including the mediating role of PF, was found to be consistent across age, gender and, with slight variations, country. This "standard model" for OA opens up the opportunity to further explore potential psychological mediating factors which may improve QoL as well as moderating factors such as different types of intervention.

## SAT0570 BIOLOGICS AND BIOSIMILARS: DO PHYSICIANS UNDERSTAND THE DIFFERENCES?

A. Molinari[1], H. Gewanter[2], M. Reilly[2], B. Kennedy[1], D. Charles[1]. *[1]Global Alliance for Patient Access, Washington, DC; [2]Alliance for Safe Biologic Medicines, Arlington, VA, United States*

**Background:** Physicians across many medical specialties, including Rheumatology, Dermatology, and Neurology, commonly prescribe biologic therapies, such as TNF inhibitors, botulinum toxins, growth factors, and vaccines. A biosimilar is not identical to the innovator biologic. Because biosimilars are structurally distinct from innovator biologics, biosimilars may produce significantly different side effects and safety profiles compared to innovator biologics. Therefore, it is critically important that physicians are aware of the differences between biologic therapies. It is unknown whether physicians' understanding of biologic and biosimilar medicines differs across geographic regions.

**Objectives:** To determine whether differences exist in physicians' understanding of biologic and biosimilar medicines in the U.S., Latin America, and Europe.

**Methods:** An internet-based survey was completed by physicians in the U.S., Latin America (Colombia, Argentina, Brazil, and Mexico), and Western Europe (Spain, UK, France, Italy, and Germany). Survey respondents practiced in multiple settings and represented the following medical specialties: Rheumatology, Neurology, Dermatology, Nephrology, Endocrinology, and Oncology.

**Results:** The survey was completed by 376 U.S. physicians, 399 Latin American physicians, and 470 European physicians. The majority of survey respondents in the U.S., Latin America, and Europe (91%, 88%, 92%, respectively) indicated that they prescribed biologic medicines to patients. U.S. physicians were 41% more likely than Latin American physicians and 43% more likely than European physicians to believe that biologic medicines with the same non-proprietary name have identical chemical structures. In addition, U.S. physicians were 34% more likely than Latin American physicians and 43% more likely than European physicians to believe that biologics sharing the same non-proprietary name produce the same therapeutic results. Eighty-two percent of U.S. physicians, 85% of Latin American physicians, and 74% of European physicians indicated that the

authority to write "dispense as written" when prescribing a biologic is critical or very important.
**Conclusions:** Across all geographic areas, physicians consistently believe that it is critically important that physicians retain the authority to choose which biologics their patients will receive. However, significant differences exist in the proportion of physicians who believe that biologics sharing the same non-proprietary name have the same chemical structure and produce identical results. These differences suggest that European physicians have a more accurate and complete understanding of the differences between biologics and biosimilar medicines compared to U.S. and Latin American physicians. Additional research is needed to determine the reasons for these differences.
**Acknowledgement:** Data for this study was obtained with permission from surveys conducted by the Alliance for Safe Biologic Medicines.

## SAT0571 TRENDS IN STRONG OPIOID ANALGESIC PRESCRIPTIONS BY FRENCH RHEUMATOLOGISTS: A NATIONWIDE SURVEY

A.-P. Trouvin[1], E. Curis[2], I. Nicolis[2], E. Dahan[3], R.-M. Javier[4], P. Vergne-Salle[5], S. Perrot[6], S. Pouplin[1]. *[1]Rheumatology, Rouen Universitary Hospital, Rouen; [2]Biomathematics, Paris Descartes University, School of pharmacy, Paris; [3]Rheumatology, CH Selestat, Selestat; [4]Rheumatology, Strasbourg Universitary Hospital, Strasbourg; [5]Rheumatology, Limoges Universitary Hospital, Limoges; [6]Pain Evaluation and Treatment Department, Paris Centre Universitary Hospital, Cochin, Paris, France*

**Background:** Opioid analgesic prescription represents a growing problem in many countries with increased opioid-related overdoses and deaths being reported. In rheumatology setting, strong opioids are considered poorly effective and not recommended as first line treatment in pain management.
**Objectives:** The aim of this study was to investigate rheumatologists' opioid prescribing patterns, demographic and practice characteristics, in relation with beliefs about prescription appropriateness and risks of opioids use.
**Methods:** We conducted a nationwide survey with a 47-item questionnaire. The questions were developed by the French Study Group on Rheumatic Pain (CEDR), focusing on opioid prescription and pain training Questionnaires were mailed and e-mailed to every registered rheumatologist in France, with the help of French Rheumatology Society. Answers were anonymous.
**Results:** 2490 questionnaires were sent, response rate was 33.7% (n=839), mean age 50,4 years, 49,2% were men, 33,6% had exclusive hospital practice, 65,4% reported having no special education on pain. Of these 58 (6.9%) self-reported never prescribing opioids in non-cancer pain.
Specific pain assessment was performed by 66,1% of rheumatologists to initiate, modify or maintain opioid prescription. It was significantly more frequent in young rheumatologists (<40 years), in women, in hospital practice and after special education on pain.
Main indications for opioids were: acute radicular pain (93,1%), vertebral fracture (91,4%) and acute back pain (67,1%). Only 1% would consider prescribing opioid in fibromyalgia.
Morphine and/or oxycodone were first line treatments for 613 prescribers (78,5%), fentanyl, hydromorphone and buprenorphine only for 168 prescribers (21,5%). The average starting daily dose was 45mg morphine equivalent, 80% (n=625) described a mean of 1.2 months testing period for opioid efficacy. 42% (n=328) reported a ceiling daily dose of 100mg/day morphine equivalent above which they stop increasing prescription. 70,3% reported screening for opioid misuse risk before initiating treatment.
Specific training on pain was significantly associated with opioid testing period (p=0,006); screening for risk of misuse at initiation (p<0,0001) and at continuation (p<0,0001).
Opioid side effects were prevented in 69,8% with a laxative and in 62,1% with anti-vomiting treatment. Prescribers with pain training prescribed more frequently laxative (p=0,015) and anti-vomiting treatment (p=0,0003).
**Conclusions:** To our knowledge, this is the first national survey on trends in strong opioid prescriptions concerning rheumatologists. French rheumatologists are more likely to prescribe opioids in acute pain conditions at low dose, without exceeding the recommended 200mg daily dose for non-cancer pain, together with side effects prevention. Morphine sulfate is the first drug choice. Impact of pain education in rheumatologists' opioid uses is important, and emphasizes the need to include systematically pain training in rheumatology core curricula.
French rheumatologists have mostly a safe and careful prescribing pattern of opioid in non-cancer pain. Mostly they abide by national and international recommendations.

## SAT0572 LIVER FAT INDICES RELATE WITH INFLAMMATORY PROFILE IN INFLAMMATORY ARTHRITIS PATIENTS

C. Bruno, C. Tripolino, F. Ursini, K. Nicolosi, S. Naty, R.D. Grembiale. *Magna Graecia University, Catanzaro, Italy*

**Background:** Rheumatic diseases associate with metabolic and cardiovascular disorders [1]. These complications might be a side effect of drugs exposure (i.e. corticosteroids) but also a direct consequence of the widespread systemic inflammation. While the association between inflammatory markers and metabolic disturbance has been extensively explored, few data are available about liver involvement in inflammatory arthritis [2].
**Objectives:** To explore possible association between inflammatory markers and serum indicators of non-alcoholic fatty liver disease (NAFLD) in a sample of unselected inflammatory arthritis subjects. The liver fat score (LFS) and the hepatic steatosis index (HSI) were employed as serum NAFLD markers [3].
**Methods:** Subjects who met ACR/EULAR criteria for rheumatoid arthiritis (RA), CASPAR criteria for psoriatic arthritis (PsA) and ESSG criteria for undifferentiated spondiloarthritis (uSPA) were consecutively recruited for the present investigation. After overnight fasting, the following serum analytes were determined: blood glucose, lipids, insulin, complete blood count, erythrocyte sedimentation rate (ESR), high sensitivity C-Reactive Protein (hsCRP). *LFS* was calculated with the formula: -2.79 + 1.18 * Metabolic Syndrome (yes=1/no=0) + 0.45 * Type 2 Diabetes (yes=2/no=0) + 0.15 * Insulin + 0.04 * AST - 0.94 * AST/ALT. *HIS* was calculated with the formula: 8 * ALT/AST + BMI +2, if DM2; +2, if females. Metabolic syndrome was defined according to the criteria of the International Diabetes Federation. Pearson's or Spearman's correlation analyses were used as appropriate to test the associations between continuous variables. Not normally distributed variables were log-transformed before analysis.
**Results:** Overall, a total of 55 subjects (27 AR, 18 PsA and 10 uSPA) were recruited. The prevalence of female gender was 60%. The mean age was 53.5±9.8. Twenty-four patients were under stable treatment with methotrexate (MTX). In simple correlation analyses, LFS significantly correlated with ESR (r=0.37, p<0.01), LnCRP (r=0.46, p<0.001), complement C3 (r=0.46, p<0.001), BMI (r=0.55, p<0.001), Waist (r=0.52, p<0.001); HSI significantly correlated with ESR (r=0.40, p<0.01), LnCRP (r=0.28, p=0.05), complement C3 (r=0.38, p<0.01). After correction for MTX therapy, waist and BMI only ESR and complement C3 correlated with LFS and HSI.
**Conclusions:** The results of the present study, although conducted in a limited sample, demonstrated an interesting association between liver fat indices and inflammatory markers. Our data, if confirmed in other population, might add important information about the relationship linking metabolic complications and rheumatic diseases.

## SAT0573 VALIDITY OF THE SHORT FORM 6D UTILITY MEASURE IN EARLY AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE DESIR COHORT

C. Gaujoux-Viala[1,2], L. Gossec[3], M. Dougados[4], J.-P. Daurès[2]. *[1]Rheumatology, Nîmes University Hospital; [2]EA2415, Montpellier University, Nîmes; [3]Rheumatology, Pitié-Salpêtrière Hospital;GRC-UPMC 08 – EEMOIS; [4]Rheumatology B, Cochin Hospital, Paris, France*

**Background:** The quantification of health improvements is essential, notably in the current context of increasingly expensive therapies and more and more limited resources. Preference-based measures of health have become important for estimating health states in calculating quality-adjusted life years (QALYs), an essential component of cost-utility analysis. The SF-6D is an indirect preference-based health-related quality of life instruments increasingly being used for economic evaluation of clinical interventions and health programs. Data on economic as well as QoL outcomes among early axial Spondyloarthtritis (axSpA) patients remain scarce.
**Objectives:** To evaluate the validity of an utility measure, the SF-6D, in early axSpA especially concerning the ability of this measure to reflect the change in patients' condition over time.
**Methods:** DESIR (Devenir des Spondyloarthropathies Indifférenciées Récentes) is a French, multicentre, longitudinal cohort of 708 patients with early inflammatory back pain suggestive of axSpA.
SF-6D utility measures were assessed in 607 patients over 1 year. To investigate whether the change in SF-6D is a valid measure of change in axSpA health status, we used Spearman's product-moment correlation to compare change scores for SF6D with those for external measures of health, the HAQ, SF36 physical component, SF36 mental component and AS-QOL from baseline to 6

and 12 months. Responsiveness was tested by the effect size (ES) at 6 and 12 months for the entire sample and subgroups by disease evolution (increase or decrease-stabilization in BASDAI). Bootstrap methods were used to estimate 95% confidence intervals [95% CI]. Sensitivity to change of the HAQ was calculated as a benchmark.

**Results:** At baseline, mean value of SF-6D was 0.69±0.12 (range 0.30 to 0.95). The distribution was near normal. Few missing values were observed: 2.4%. No floor or ceiling effects were evidenced. Correlations of the SF6D change with change in HAQ and physical component of SF-36 scores were moderate at 6 months (r=-0.42 and 0.44, respectively). Correlations with change in mental component of SF-36 and AS-QOL scores were good (r=0.60 and -0.60, respectively). Correlations were stable over 1 year.

For the entire sample at 6 months, the SF-6D was more sensitive to change than the HAQ: ES 0.36 [95% CI 0.28;0.44] versus -0.22 [-0.28;-0.17]. The SF-6D was more responsive than the HAQ for improved condition: ES 0.45 [0.37;0.54] vs -0.32 [-0.38;-0.26] without difference for patients with deteriorated condition: ES SF-6D -0.23 [-0.41;-0.04] vs 0.33 [0.18;0.50] for HAQ. Results were similar at 12 months.

**Conclusions:** The SF-6D is valid and able to reflect the change in patients' condition over time, especially improvement, in patients with early inflammatory back pain suggestive of axSpA.

**Disclosure of Interest:** None declared

## SAT0574 IMPROVING TIMELY FOLLOW-UP AFTER HIGH BLOOD PRESSURES IN RHEUMATOLOGY CLINICS USING STAFF PROTOCOLS

C.M. Bartels[1], E. Ramly[2], H. Johnson[3], P. McBride[3], Z. Li[4], Y. Zhao[5], K. Lewicki[6], D. Lauver[7]. *[1]Medicine, Rheumatology; [2]Engineering; [3]Medicine, Preventive Cardiology; [4]Biostatistics, University of Wisconsin-Madison, Madison, WI; [5]Biostatitstics, Fred Hutchinson Research Center, Seattle, WA; [6]Medicine; [7]Nursing, University of Wisconsin-Madison, Madison, WI, United States*

**Background:** Hypertension (HTN) is the most prevalent cardiovascular disease (CVD) risk factor among adults with rheumatic conditions. However, we found that blood pressures were addressed in <1/3 of rheumatology visits, even when severely elevated (≥160/100 mmHg). At this range, only 11 patients need to be treated for HTN to prevent one CVD event. In primary care, HTN protocols executed by nurses (RNs) or medical assistants (MAs) during vital sign assessment have improved control of high blood pressure (BP). Yet, such protocols have not been tested in rheumatology clinics.

**Objectives:** Our objective was to study the feasibility and impact of an intervention using a staff HTN protocol to facilitate timely (<4 wks per Medicare quality measure) primary care follow-up for patients with high blood pressures at rheumatology visits.

**Methods:** We conducted a pre-post study in three academic rheumatology clinics. All eligible adult (≥18 years-old) rheumatology visits with BP ≥140/90 mmHg (12/2014–5/2015) were compared to pre-intervention visits (2012–9/2014). Our multi-dimensional intervention included: (1) educating staff on HTN, rheumatologic diseases, and CVD risk, (2) electronic health record (EHR) alerts for staff to re-measure BPs if ≥140/90 and 3) cuing brief patient education and scheduling primary care follow-up if 2nd BP ≥140/90, and (4) monthly audit and feedback with staff about performance. We assessed timely primary care follow-up of high BPs among patients who received primary care in our system using EHR data.

We performed multivariable logistic regression and compared the odds (OR, 95%CI) of timely primary care follow-up before and during intervention, while controlling for baseline socio-demographics, comorbidities, utilization, and clinic.

**Results:** We compared 689 intervention period visits to 4,683 pre-intervention visits with BPs ≥140/90. Patient groups were comparable before and during intervention. Staff initiated BP re-measurement in 80% of eligible visits during intervention months 4–6, compared to <1% pre-intervention; overall improvement 60%, p<0.001. More patients received timely primary care follow-up for HTN during the intervention, (44%, vs 29% before, p=0.0003). Multivariable analysis showed that eligible visits during the intervention had two-fold higher odds of timely follow-up compared to pre-intervention, OR 2.1, 1.4–3.0 (p<0.0001). We observed positive associations between timely follow-up and race (black vs. white OR 1.7, 1.1–2.5) and diabetes (vs. no diabetes OR 1.3, 1.01–1.6) post intervention.

**Conclusions:** Our intervention was feasible for usual rheumatology clinic staff and it doubled rates of timely BP follow-up. Future studies should examine this intervention in other rheumatology clinics, and its impact on HTN control to reduce CVD risk in rheumatology patients.

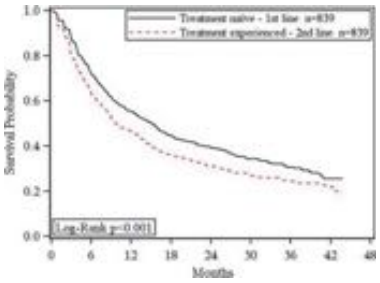
## SAT0575 FIRST AND SECOND LINE TREATMENT PERSISTENCE AMONG PATIENTS WITH IMMUNE-MEDIATED RHEUMATOID DISEASE TREATED WITH SUBCUTANEOUS TNF-ALPHA INHIBITORS



J. Dalen[1], A. Svedbom[2], C.M. Black[3], S. Kachroo[3]. *[1]Mapi; [2]Department of Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Merck & Co., Inc., Kenilworth, United States*

**Background:** The treatment of ankylosing spondylitis (AS), psoriatic arthritis (PsA), and rheumatoid arthritis (RA), collectively referred to as Immune-Mediated Rheumatoid Disease (IMRD), has evolved in recent years with the introduction of subcutaneous TNF-alpha inhibitors (SC-TNFi).

**Objectives:** The aims of this study were: i) To assess real-world persistence in SC-TNFi naïve and experienced patients treated with SC-TNFi for IMRD in Sweden; and ii) to estimate and compare health care resource utilization (HCRU) costs in these two patients populations.

**Methods:** This study was a retrospective, observational register analysis of treatment patterns and costs based on anonymized patient-level data extracted from Swedish national health data registers. Patients (≥18 years old) were identified through filled prescriptions for adalimumab, etanercept, certolizumab pegol, and golimumab between 5/6/2010 and 12/31/2012 from the Swedish Prescribed Drug Register. Information on prescriber specialty and department was used to exclude patients initiating treatment with SC-TNFi for diseases other than IMRD. Patients were excluded if they filled at least one prescription from a department other than rheumatology, orthopedics or rehabilitation and if the prescription was issued by a non-rheumatologist. The included patients were classified by diagnosis as AS, PsA, RA, "other arthritis", or "unknown". To enhance comparability, propensity score matching (PSM) was implemented. Patients were matched based on age, gender, index year, diagnosis, therapy, Charlson Comorbidity Index, and non-biologic DMARD use. Persistence was estimated using non-parametric survival analysis. Health care resource utilization (HCRU) was captured 12 months after treatment initiation and comprised specialized outpatient care, inpatient care, and non-DMARD medication.

**Results:** A total of 5,748 patients were identified (treatment naïve – 1st line: 4,903, treatment experienced – 2nd line: 845). A successfully balanced PSM cohort was generated with 839 matched pairs. Comparisons over the study period showed that patients initiating their first line of treatment had significantly higher persistence than patients initiating their second line of treatment with SC-TNFis (p<0.001). HCRU was evaluated for a subset of 393 matched pairs, where both patients were persistent for at least six months. In the twelve months post treatment initiation, patients on first line therapy incurred lower mean total costs than patients on second line therapy (USD 3,206 vs. 4,540, p<0.001).

**Conclusions:** SC-TNFi-naïve IMRD patients initiating treatment had significantly higher persistence rates than patients initiating a second line of treatment with SC-TNFis in Sweden. In addition these patients also incurred significantly lower mean total HCRU costs twelve months post treatment initiation. These results indicate that it may be advisable to prescribe the SC-TNFi which has demonstrated best long-term persistence as first line SC-TNFi. It appears especially important for indications which have fewer choices of approved biologics.

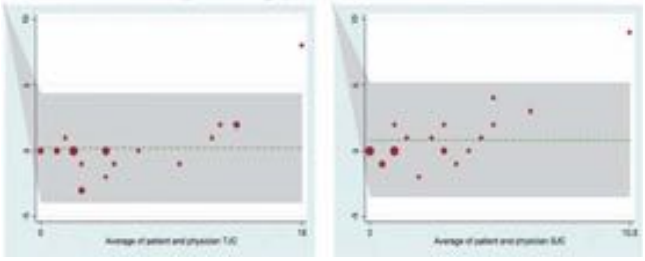
## SAT0576 ASSOCIATIONS BETWEEN FIVE IMPORTANT DOMAINS OF HEALTH AND THE PATIENT ACCEPTABLE SYMPTOM STATE IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS: A CROSS SECTIONAL STUDY OF 977 PATIENTS

D. Puyraimond-Zemmour[1], A. Etcheto[2], B. Fautrel[1], A. Balanescu[3,4], M. de Wit[3,4], T. Heiberg[3,4], K. Otsa[3,4], T.K. Kvien[3,4], M. Dougados[3,5], L. Gossec[1,3,4]. *[1]Rheumatology, Paris 06 University; [2]Rheumatology, Paris Descartes University, Paris, France; [3]RAID EULAR Working Group; [4]PsAID EULAR Working Group, Zurich, Switzerland; [5]Paris Descartes University, Paris, France*

**Background:** The objectives of treatments in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) include acceptable quality of life from the patient's perspective. One simple question can be used to evaluate the level of acceptability of the disease status by a patient: the patient acceptable symptom state (PASS) which corresponds to the concept of "feeling well".



**Objectives:** The objective was to explore the link between a patient acceptable symptom state (PASS) and patient-perceived impact in rheumatoid arthritis (RA) and psoriatic arthritis (PsA).
**Methods:** Cross-sectional study of unselected patients with definite RA or PsA. Five domains of health were analysed: Pain, functional capacity, fatigue, coping and sleep disturbance. They were assessed by a numeric rating scale (0–10) and were compared between patients in PASS or not (Cohen's effect sizes). The domains of health associated with PASS status were assessed by multivariate logistic regression, and PASS thresholds were determined using the 75th percentile method and ROC analyses.
**Results:** Among 977 patients (531 RA, 446 PsA) mean age was 53.4±13.2 yrs; mean disease duration was 11.2±10.0 yrs; 637 (65.8%) were females. In all, 595 patients (60.9%) were in PASS: they had lower symptom levels, and all domains of health except sleep disturbance discriminated clearly between patients in PASS or not (effect sizes, 0.73 to 1.45 in RA and 0.82 to 1.41 in PsA). In multivariate analyses, pain and coping were predictive of not being in PASS: odds ratio [95% confidence interval] 0.81 [0.67–0.96] and 0.63 [0.52–0.75] for pain and 0.84 [0.74–0.96] and 0.83 [0.71–0.97] for coping, in RA and PsA respectively. The cut-offs of symptom intensity (range 0–10) corresponding to PASS for the five domains of health and the two diseases with a score were similar, i.e. around 4–5.
**Conclusions:** Two thirds of 977 unselected tertiary care patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA) were in PASS. In RA and PsA, PASS was associated with the five domains of health analysed, and in particular with less pain and better coping. PASS levels in the two diseases for the five domains of health, as well as the RAID and PsAID scores were similar with cut-offs around 4–5 points (0–10 scale).

## SAT0577 PATIENT-REPORTED DAS28 IN RHEUMATOID ARTHRITIS: ITS RELIABILITY IN A LONGITUDINAL STUDY

E.Y. Tang[1], C. Chattopadhyay[2], K.L. Hyrich[3]. *[1]Faculty of Medical and Human Sciences, The University of Manchester, Manchester; [2]Rheumatology, Wrightington, Wigan and Leigh NHS Foundation Trust, Lancashire; [3]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom*

**Background:** There have been increasing studies focusing on patient derived joint counts in RA. Patient self-reported DAS28 with training has not been observed longitudinally in the UK.
**Objectives:** The aims of the study were to (1) evaluate the reliability of patient self-assessment of DAS28 compared to physician DAS28; (2) determine whether the agreement between patient-reported and physician-reported DAS28 improves over time with training.
**Methods:** This was a longitudinal study with a total of 3 study visits 6 weeks apart carried out at two hospitals sites in the United Kingdom. All 42 patients had training on joint count self-assessment. A single physician performed joints assessment on patients independently blinded to the patients' data. Correlations between patient and physician measurements were analysed using Spearman correlation coefficient whereas agreement between patient and physician was analysed with Bland-Altman plots.

**Figure 1.** Bland Altman plot of the difference between patient TJC, SJC and physician TJC, SJC versus mean of patient and physician TJC, SJC

**Results:** There was very strong correlation between patient and physician DAS28-CRP, DAS28-ESR, TJC and SJC ($r > 0.80$). The limits of agreement of DAS28 were consistent (range -0.65 to 0.69) but exceeded the set difference of 0.6, although with very small mean difference.
**Conclusions:** Overall, it is reasonable to conclude that there were good agreement of tender and swollen joint assessments between patient and physician. Patient training has positive effects in increasing the reliability of patient self-assessment of joint counts. Our study showed patient-reported DAS28 was not exactly same as physician-reported DAS28, although DAS28, TJC and SJC from both patient and physician were all very strongly correlated. Patient-reported joint counts were shown to have a strong predictive value and therefore could be incorporated in clinical practice. Patient DAS28 and physician DAS28 could act synergistically to reach a consensus evaluation of RA in order to achieve treatment optimisation.

Table 1. Agreement between patient and physician of disease activity, tender joint count and swollen joint count over three study visits

| | First visit | Second visit | Third visit |
|---|---|---|---|
| Number of patients | 42 | 34 | 24 |
| DAS28-CRP | | | |
| Range | 1.56–6.09 | 1.35–6.51 | 2.48–5.69 |
| Mean difference | 0.0007 | –0.023 | 0.022 |
| Limits of agreement | –0.66–0.66 | –0.69–0.64 | –0.65–0.69 |
| DAS28-ESR | | | |
| Range | 1.46–6.33 | 1.33–6.96 | 1.41– 6.15 |
| Mean difference | –0.0002 | –0.023 | 0.022 |
| Limits of agreement | –0.66–0.66 | –0.74–0.69 | –0.65–0.69 |
| TJC | | | |
| Range | 0–18 | 0–24 | 0–16 |

## SAT0578 THE ASSOCIATION OF ARTHRITIS AND LUNG DISEASE: A POPULATION-BASED STUDY

E.M. Badley[1,2], M. Maguire[2], A.V. Perruccio[1]. *[1]Division of Health Care and Outcomes Research, Krembil Research Institute; [2]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada*

**Background:** Rheumatoid arthritis (RA) is known from clinical studies to be associated with a number of different lung conditions, but the relationship with arthritis in the population, where overwhelmingly the most frequent type of arthritis is osteoarthritis, has been less well studied.
**Objectives:** To examine whether arthritis is associated with an increased likelihood of reporting asthma and/or COPD.
**Methods:** Data from the 2011- 2012 Canadian Community Health Survey, a representative survey of the household population were used, restricting analyses to the population age ≥35 years (n=88,734). Participants were asked whether they had specific long term health conditions diagnosed by a health professional: conditions asked about included arthritis (excluding fibromyalgia), asthma, and COPD (specifically chronic bronchitis, emphysema or chronic obstructive pulmonary disease). Multinominal logistic regression was used to examine associations between lung conditions (none, asthma only, COPD only, both asthma and COPD) and arthritis, controlling for covariates: age, sex, education, household income, smoking status (never, former, current), body mass index (BMI: underweight, normal, overweight, obese), and mean number of other chronic conditions (out of 9). As metabolic and inflammatory pathways have been postulated given the strong association of obesity and arthritis, sensitivity analyses were undertaken stratified by BMI category.
**Results:** People with arthritis (23% of the population) more frequently reported lung conditions than those without, respectively asthma 8.2% vs 5.5%, COPD 5.4% vs 2.0%, and asthma+COPD 3.4% vs 0.8%. There was no difference in the proportion of current smokers between those with and without arthritis (20.5%), although those with arthritis were more likely to be former smokers (49.8% vs 36.5%). They were also more likely to be obese (26.8% vs 16.7%) and have more other chronic conditions (mean 1.5 vs 0.5). In regression analyses controlling for covariates, arthritis was significantly associated with reporting of all lung conditions: OR (95%CI): asthma only 1.48 (1.26, 1.73); COPD only 1.60 (1.34, 1.91); asthma+COPD 1.98 (1.65, 2.37). In addition, the odds of all lung conditions were significantly higher for females. Obesity was also a significant risk factor for reporting all lung conditions, as was the number of other chronic conditions. The sensitivity analyses showed the associations between arthritis and the lung conditions were significant and similar for normal, overweight and obese BMI categories. Being a current or former smoking was significantly associated with COPD, but not with asthma only.
**Conclusions:** This study confirms a relationship between arthritis and lung disease, and the multivariate analyses adds to the scant previous population-based literature which was mainly descriptive. That those with arthritis had increased odds of reporting lung disease, asthma, COPD, and asthma+COPD compared to those without arthritis, controlling for a range of other factors, including smoking, raises questions as to the mechanism. The consistency of the association over levels of BMI suggests other pathways in addition to those mediated by obesity/metabolic factors. The findings also suggest that recommendations for the management of arthritis should consider the potential implications of having lung disease, for example, for physical activity.

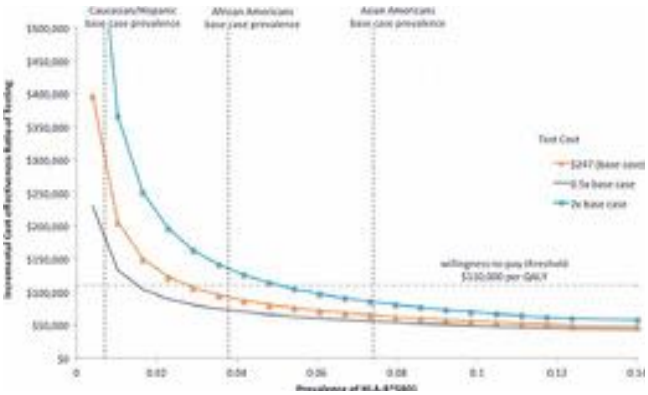
## SAT0579 TRENDS IN USE OF PHYSIOTHERAPISTS, CHIROPRACTORS AND COMPLEMENTARY AND ALTERNATIVE MEDICINE PRACTITIONERS FOR ARTHRITIS OVER TIME AND ACROSS GENERATIONS



E.M. Badley[1,2], M. Canizares[3]. *[1]Division of Health Care and Outcomes Research, Krembil Research Institute; [2]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada; [3]Institute of Medical Sciences, University of Toronto, Toronto, Cape Verde*

**Background:** Non-pharmacologic strategies contribute to the management of arthritis in the community, but little is known about the use of these therapies and how this varies by age and over time. Rehabilitation therapies, such as physiotherapy (PT), and chiropractic, have been shown to improve the management of arthritis, and there is also evidence for the benefit of acupuncture and massage therapy.
**Objectives:** a) to compare the age-trajectories of use, by people with arthritis, of physiotherapy, chiropractic, and complementary and alternative medicine (CAM) over 18 years by birth cohort and b) to determine how these trajectories are affected by socio-economic status (SES), lifestyle factors, and reported pain.
**Methods:** We used data from the Canadian Longitudinal National Population Health Survey (1994–2010). We examined 10,330 participants in five birth cohorts: pre-World War II (born 1935–1934), World War II (born 1935–1944), Older Baby Boomer (born 1945–1954), Younger Baby Boomer (born 1955–1964), and Generation X (born 1965–1974). Data on visits to physiotherapists, chiropractors, and CAM practitioners, arthritis, SES (education, income), and lifestyle factors (BMI, physical activity, sedentary behavior, and smoking), and pain that prevents activities were collected biannually. For each type of practitioner our outcome was whether participants reported 1+ visits in the past year. We used multilevel logistic growth models to examine cohort effects and predictors of each outcome, among arthritis patients.
**Results:** At baseline (in 1994), 14.5% reported visiting physiotherapists, 14.2% chiropractors, and 6.0% CAM practitioners (most frequently for massage therapy or acupuncture). We found an increase in use of all types of practitioner with age in all cohorts. Comparing the age-trajectories of PT, chiropractic, and CAM use over time, we found significant cohort differences ($p<0.0001$) such that when compared at the same age, each succeeding younger cohort had higher odds of consulting with these practitioners than their older counterparts. Cohort differences were largest for CAM, where recent cohorts were more likely to use these services. Women had higher odds of using all types of practitioner than men in all cohorts. Pain and high SES were the main predictors of PT and chiropractic use. The predictors of CAM were similar with the addition of having a normal BMI as a significant predictor.
**Conclusions:** The use of PT, chiropractic, and CAM is significantly higher in younger cohorts of people with arthritis. While pain was a major predictor, notably use of these practitioners was greater in those with higher SES, implying potential educational and income access barriers to this type of care. Healthcare providers for people with arthritis need to be aware that younger generations may have different patterns of use of other services such PT, chiropractic, and CAM.

## SAT0580 THE COST-EFFECTIVENESS OF HLA-B*5801 GENETIC SCREENING TO GUIDE INITIAL URATE-LOWERING THERAPY FOR GOUT

E. Jutkowitz[1], M. Dubreuil[2], N. Lu[3], K.M. Kuntz[4], H. Choi[5]. *[1]Division of Health Policy and Management, University of Minnesota, Minneapolis; [2]Section of Rheumatology, Department of Medicine, Boston University; [3]Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston; [4]Divison of Health Policy and Management, University of Minnesota, Minneapolis; [5]Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, United States*

**Background:** Allopurinol is the most commonly used first-line urate-lowering therapy for the management of gout. Although allopurinol is generally safe, it is associated with severe allopurinol-hypersensitivity syndrome (AHS) (i.e., Steven Johnson Syndrome and Toxic Epidermal Necrolysis). AHS is fatal in up to 30% of cases. Patients with the human leukocyte antigen *HLA-B*5801* are at higher risk of developing AHS. The prevalence of *HLA-B*5801* and risk of AHS varies by race and is highest in Asians. The 2012 ACR gout guideline recommends testing for *HLA-B*5801* in Asians prior to the allopurinol initiation, but the guideline did not take into account its cost-effectiveness.
**Objectives:** We evaluate the cost-effectiveness of testing for *HLA-B*5801* prior to initiation of allopurinol according to race.
**Methods:** We modified a previously developed Markov decision model to evaluate the cost-effectiveness of testing for *HLA-B*5801* prior to the initiation of allopurinol (300mg) – febuxostat (80mg) sequential therapy compared to treating with allopurinol (300mg) –febuxostat (80mg) sequential therapy without testing. Hypothetical patients in the testing strategy received a polymerase chain reaction test for *HLA-B*5801* prior to the initiation of therapy. Patients that tested positive for *HLA-B*5801* were assumed to be treated with febuxostat. Patients that tested negative for *HLA-B*5801* and those in the no testing strategy were assumed to initially receive allopurinol. We took account of the variation in risk of hypersensitivity by race (Caucasians 0.0003; African Americans 0.0015; Asian Americans 0.0034) and prevalence of *HLA-B*5801* by race (Caucasians 0.007; African Americans 0.038; Asian Americans 0.074). Patients on allopurinol could experience a minor (e.g., erythema multiforme minor) or major (e.g., Stevens-Johnson Syndrome) AHS event. Cost and quality-adjusted life years (QALYs) were evaluated over the lifetime of a hypothetical gout cohort. Finally, we conducted a sensitivity analysis to evaluate the effect variation in cost of testing, the prevalence of *HLA-B*5801,* and background AHS risk on the cost-effectiveness of testing.
**Results:** Given a willingness-to-pay threshold of $110,000 per QALY, *HLA-B*5801* testing is not cost-effective for Caucasians (incremental cost-effectiveness ratio $268,020), but it is cost-effective for African Americans (incremental cost-effectiveness ratio $91,870) and Asian Americans (incremental cost-effectiveness ratio $64,140). As the prevalence of HLA-B*5801 increases the incremental cost-effectiveness ratio of testing decreases (Figure 1). When the prevalence of *HLA-B*5801* is greater than 0.029 testing is cost-effective.

**Conclusions:** Testing for the presence of *HLA-B*5801* is cost effective in African American and Asian Americans compared with accepted willingness-to-pay thresholds.

## SAT0581 COST SAVINGS WITH BIOSIMILARS IN RHEUMATOLOGY: A SYSTEMATIC LITERATURE SEARCH OF BUDGET IMPACT ANALYSIS

F. Araújo[1,2], J. Gonçalves[3], J. Eurico Fonseca[4,5]. *[1]Rheumatology Unit, Hospital Ortopédico de Sant'Ana, SCML, Cascais; [2]Institute of Microbiology, Faculdade de Medicina da Universidade de Lisboa; [3]iMed- Research Institute for Medicines, Faculdade de Farmácia da Universidade de Lisboa, Portugal; [4]Instituto de Medicina Molecular da Faculdade de Medicina da Universidade de Lisboa; [5]Rheumatology Department, Hospital de Santa Maria, Lisbon, Portugal*

**Background:** The growing use of biological therapies in immune-mediated rheumatic diseases represents a significant burden to healthcare systems struggling with tighter budgets.
**Objectives:** Our aim was to assess potential cost savings associated with the use of biosimilar anti-rheumatic therapies.
**Methods:** We performed a systematic literature search in the Medline database as well as EULAR, ACR and ISPOR meeting abstracts to identify budget impact analysis on biosimilars of infliximab (IFX), etanercept (ETA) and adalimumab (ADA) used in the treatment of rheumatic diseases. We included articles and abstracts published from 2013 onwards.
**Results:** We screened 195 articles by title and abstract and 2 publications fulfilled our inclusion criteria, both concerning IFX. Five abstracts were also included (2 on ETA, 2 on IFX and 1 on IFX+ETA+ADA). Five studies performed the analysis on rheumatoid arthritis and the other 2 also in spondyloarthritis, psoriasis and inflammatory bowel disease. The heterogeneity of budget impact models didn't allow for direct comparisons but all studies pointed out significant cost savings, from dozens to thousands of millions of euros, depending on the countries analysed, time horizon, discount scenarios and biosimilar uptake shares. The reinvestment of biosimilar-related savings would also allow for the treatment of thousands of additional rheumatic patients. The authors of these models stress, however, that some of the assumptions made may not reflect real-world scenarios. Table 1 summarizes the main findings in the included studies.
**Conclusions:** The use of biosimilar anti-rheumatic therapies may represent a strategy to reduce drug-related expenditure and contribute to financial sustainability of healthcare systems worldwide.

**Abstract SAT0581** – Table 1

| | Biosimilar; Population | Time horizon (years) | Projected cost savings (millions) | Additional treated patients |
|---|---|---|---|---|
| Ruff L, et al (2015) | ETA; RA | 5 | UK €62–162; France €19–46; Germany €42–105; Italy €26–62; Spain €16–37 | 1530 UK, 8430 Germany |

F. Bartoli[1], C. Bruni[1], G. Tesei[1], V. Denaro[1], F. Nacci[1], L. Antonuzzo[2], F. Di Costanzo[2], M. Matucci-Cerinic[1], G. Fiori[1]. *[1]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Firenze; [2]Division of Oncology, Azienda Ospedaliera Universitaria Careggi, Firenze, Italy*

**Background:** Over the past decade, it has been frequently suggested that the risk of cancer may be increased in patients with inflammatory rheumatic diseases treated with biologics. These drug have been considered as reducing immune surveillance. However, data from registries from different continents reported that treatment with TNF inhibitors did not increase the risk of malignancies, except for skin cancer (1).
**Objectives:** To evaluate the incidence of malignancies in a cohort of our patients with inflammatory rheumatic diseases treated with biological drugs.
**Methods:** The charts of 1468 patients with Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis treated with Adalimumab, Etanercept, Infliximab, Certolizumab, Golimumab, Tocilizumab and Abatacept followed up from 2005 to 2015 at the Department of Rheumatology, University of Florence, were reviewed. Patients who developed a cancer (excluding basal cell skin cancer) during biological therapy were identified. The incidence of malignancies in our patients was compared to the incidence of cancer in the general population in the same period, same geographic area and with same age.
**Results:** Out of 1468 patients, 828 (56,4%) were affected by Rheumatoid Arthritis, 290 (19.7%) by Ankylosing Spondylitis and 350 (23.9%) by Psoriatic Arthritis. Twenty-five out of 1468 patients (1.7%) (mean age 65±9 years), developed cancer: in details, we found 5 (20%) lung cancer, 5 (20%) melanoma, 2 (8%) breast cancer, 1 (4%) liposarcoma, 1 (4%) tongue cancer, 1 (4%) colo-rectal cancer, 1 (4%) liver cancer, 1 (4%) squamous cell skin cancer, 1 (4%) intestinal lymphoma, 1 (4%) myeloid leukemia, 1 (4%) endometrial cancer, 1 (4%) cervical intraepithelial neoplasia (CIN III), 1 (4%) gastric cancer, 1 (4%) bladder cancer, 1 (4%) laryngeal carcinoma and 1 (4%) follicular NHL of parotid gland. Incidence among patients resulted as follows: 2,05% Rheumatoid Arthritis, 1,37% Ankylosing Spondylitis and 1,14% Psoriatic Arthritis. The percentage of cancer in patients was respectively: Etanercept 2,31%, Adalimumab 1,46%, Infliximab 1,18%, Golimumab 1%, Abatacept 1%, Tocilizumab 3,92% and Certolizumab 2,43%. From 2005 to 2010, the incidence of malignancies (excluding basal cell skin cancer), in general population between the age of 60 and 70 years in the Florence area was 0.39%.
**Conclusions:** Our data suggest that in patients with inflammatory rheumatic diseases treated with biological drugs, cancer is increased of 289% compared to the general population. In these patients, the risk of malignancy still remains to be verified in larger cohorts in our area with a long-term controlled registry.

clinical setting. Patient-reported outcomes (PROs) are being increasingly used to measure various domains of disease status relevant to patients and physicians. The EULAR Outcome Measures Library (OML) is a freely available website with structured access to a growing database of validated PROs [1], but currently there are no PROs available on SSc at the EULAR OML.
**Objectives:** To provide a comprehensive review of validated SSc-specific PROs and to critically appraise their validity.
**Methods:** A sensitive search was developed in Medline and Embase (08/2015) to identify all validation studies, cohort studies, reviews or metaanalyses in which the objective were the development or validation of PROs evaluating organ involvement, disease activity or damage in SSc. A reviewer screened title and abstracts, selected the studies, and collected data concerning validation using ad hoc forms based on the COSMIN checklist.
**Results:** From 13,140 articles captured, 74 met the predefined criteria. After excluding an instrument for the unavailability of an English version, the selected studies provided information on 6 SSc-specific PROs: the Scleroderma Assessment Questionnaire (SAQ), the scleroderma functional score (FS), the Raynaud's condition score (RCS), the Mouth Handicap in SSc (MHISS), the University of California Los Angeles-Scleroderma Clinical Trial Consortium Gastro-Intestinal tract (UCLA-SCTC-GIT 2.0), and the Skin Self-Assessment. The table summarizes the instruments and their measurement properties:
**Conclusions:** Six SSc-specific PROs have a minimum validation and will be included in the EULAR OML. In general, the level of validation attained could be improved. Further development in the area of disease-specific PROs in SSc is warranted.

## SAT0584 THE INCIDENCE AND PREVALENCE OF THROMBOANGIITIS OBLITERANS IN TAIWAN: A NATIONWIDE, POPULATION-BASED ANALYSIS OF DATA DURING 2002–2011

H.-H. Chen[1], Y.-M. Chen[1], K.-L. Lai[2], C.-H. Lin[1], D.-Y. Chen[3]. *[1]Department of Medical Research; [2]Division of Allergy, Immunology and Rheumatology; [3]Department of Medical Education, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

**Background:** Thromboangiitis obliterans (TAO) is a nonatherosclerotic segmental inflammatory disease that most commonly affects the small and medium-sized arteries, veins, and nerves of the arms and legs. Most epidemiologic studies were conducted using hospital-based data, and only few population-based epidemiologic studies of TAO have been published.
**Objectives:** To estimate the incidence and prevalence of thromboangiitis obliterans (TAO) in Taiwan during 2002 to 2011.
**Methods:** We identified all patients with a diagnosis of TAO (International Classification of Diseases, Ninth Revision code 443.1) in Taiwan's National Health Insurance Research Database from January 2002 to December 2011. We calculated the age- and sex-specific incidence and prevalence rates of TAO during the study period.
**Results:** During 2002–2011, 158 patients were diagnosed with TAO; of these, 76% were men. Most (63%) patients were <50 years of age when they were first diagnosed. After attaining 20 years of age, the incidence rate increased with age and peaked among those aged ≥60 years. The average incidence rate of TAO during 2002–2011 was 0.068 per $10^5$ years. The incidence of TAO decreased with time: from 0.10 per $10^5$ years in 2002 to 0.04 per $10^5$ years in 2011. The prevalence increased from $0.26\times10^{-5}$ in 2002 to $0.65\times10^{-5}$ in 2011.

| Age group | Case number | | | Person-years | | | Incidence rate† | | |
|---|---|---|---|---|---|---|---|---|---|
| | F | M | T | F | M | T | F | M | T |
| 0–9 | 1 | 2 | 3 | 19050837 | 20763899 | 39814736 | 0.01 | 0.01 | 0.01 |
| 10–19 | 1 | 0 | 1 | 16112069 | 17223717 | 33335786 | 0.01 | 0.00 | 0.00 |
| 20–29 | 7 | 20 | 27 | 20335969 | 19005493 | 39341462 | 0.03 | 0.11 | 0.07 |
| 30–39 | 1 | 30 | 31 | 19137215 | 19243068 | 38380283 | 0.01 | 0.16 | 0.08 |
| 40–49 | 8 | 29 | 37 | 17444626 | 17434089 | 34878714 | 0.05 | 0.17 | 0.11 |
| 50–59 | 5 | 17 | 22 | 10321223 | 10007057 | 20328281 | 0.05 | 0.17 | 0.11 |
| ≥60 | 15 | 22 | 37 | 12027557 | 11781867 | 23809424 | 0.12 | 0.19 | 0.16 |

†per $10^5$ years.

**Conclusions:** This is the first epidemiologic study of TAO in Taiwan using a nationwide, population-based analysis of data from 2002 to 2011. This study showed a trend of decreasing incidence of TAO with time. It is warranted to conduct future clinical studies to further investigate whether or not such findings are associated with a decreasing smoking rate or periodontal disease prevalence in Taiwan.

## SAT0585 BARRIERS TO T2T IMPLEMENTATION: RA PATIENT'S PERSPECTIVES ABOUT COMORBIDITIES AND STRUCTURAL DAMAGE IN THERAPEUTIC DECISIONS

I. Laurindo[1], L. Mota[2], L. Romeiro[3], R. Ranza[4], M. Freitas[5], I. Pereira[6], J. Vasconcelos[7], C. Brenol[8], L. Rezende[9], M. Bertolo[10], D. Torigoe[11]. *[1]FMUSP, São Paulo; [2]UNB, Brasília; [3]UNESA, Rio de Janeiro; [4]UFU, uberlandia; [5]UFC, Fortaleza; [6]UFSC, Florianópolis; [7]UFP, Teresina; [8]HCPA, Porto Alegre; [9]UFP, Curitiba; [10]UNICAMP, Campinas; [11]Santa Casa de Misericordia, São Paulo, Brazil*

**Background:** T2T strategies have been largely recognized and incorporated in national guidelines. Structural changes, functional impairment and comorbidities should be considered along with RA disease activity state when making therapeutic decisions.
**Objectives:** To evaluate patient's perspectives on the interference of comorbidities and structural changes/functional impairment in treatment decisions.
**Methods:** RA patients (1987 criteria) in regular follow-up were recruited from community (private practice) and academic public medical centers by 11 investigators in different urban and rural areas of the country. Structured questionnaires were applied and socio-demographics, disease activity and treatment data were collected. The focus of this study was two main questions: a) In your opinion, other diseases that you have can change the arthritis treatment? b) Do you think that having deformities modify your treatment? Affirmative answers would be followed by more specific questions. Statistical analysis: ANOVA or Kruskal-Wallis; Fisher or Fisher-Freeman-Halton (FFH) as needed; $p<0.05$. Data expressed as % [95%CI} or mean (SD).
**Results:** 485 RA patients were included, 89.7% females, mean age 52.3 (13.8) years, 8.0 (5.2) years of education; 32.4% in use of biologics and 28.3% in private practice. Less than 40% of the patients considered that any of these conditions influenced the treatment.
Deformities, surrogate for structural damage, were considered to imply in more severe disease or more pain and medications by respectively 54.8% and 34% of the positive responders (n=177); these patients were more frequently living in the northwest area (60.2vs 31.7%; =0.0001; [16.2–40]), were from higher socio-economic level (43.2vs30.2%; p=0.0001; [4,1–21.7]), younger (49.4 (12.3) vs 54.3 (12,7); p<0,001) and with shorter disease duration (median 8.0 (range4.0–15) vs 12 (6.0–19); $p<0.001$).
Regarding comorbidities, there were 39.4% (n=191) positive answers, predominantly from younger patients [51.3 (13.1) vs 54.5 (11.6); $p<0.003$]. The patients from private system (80.3 vs 56.3%;p=0.0004; [9.3–36.7]) and higher socio-economic level (71.8 vs55%; p=0.01;[2.9–30.1]), as well as patients with more schooling years ($p<0.001$) and shorter disease duration ($p<0.041$) worried that comorbidities could hinder the choice of arthritis medication, while some patients from public service (25.5vs9.8%;p=0,01;[3.2–25.8]) and low socio-economic levels (14 vs 1.99%;p=0,001;[4.1–20.6]) had concerns about too many pills.
**Conclusions:** patient's skepticism about comorbidities or structural changes interfering with their therapeutic decisions is prevalent and needs to be addressed.

## SAT0586 HERPES ZOSTER IN THE BRAZILIAN REGISTER -BIOBADABRASIL

H. Carvalho[1], I.M.M. Laurindo[1], R. Ranza[1], D. Titton[1], M. Bertolo[1], W. Bianchi[1], C. Brenol[1], G. Castelar[1], G. Castro[1], I. Costa[1], A. Duarte[1], V. Fernandes[1], M. Freire[1], P. Louzada[1], J. Macieira[1], J. MIranda[1], J. Moraes[1], I. Pereira[1], M. Sauma[1], B. Stadler[1], R. Toledo[1], V. Valim[1], C. Baaklini[2]. *[1]BiobadaBrasil; [2]Presidente da SBR, São Paulo, Brazil*

**Background:** Herpes Zoster has been reported with increased frequency in association with rheumatic diseases and biologic therapy.
**Objectives:** To study herpes zoster (HZ) in patients with rheumatic diseases included in the Brazilian Register for monitoring of biologic therapies in rheumatic diseases - BiobadaBrasil,
**Methods:** BiobadaBrasi is a prospective observational cohort study, part of an international initiative (biobadaAmerica) in collaboration with BiobadaSer. Patients with rheumatic diseases are enrolled at the moment of introduction of their first biologic therapy; a comparison cohort of patients with active RA receiving traditional disease-modifying antirheumatic drugs (DMARDs) was recruited in parallel in each center. This register was established in 2009 and is an ongoing study ran by the Brazilian Society of Rheumatology comprising 32 centers (30 public, located at academic centres, 2 private) in almost all states of the country. Data quality is under constant monitoring (online, by phone and "in situ"). In this report all biologic administered to more than a hundred patients were included: abatacept, adalimumab, etanercept, infliximab, rituximab and tocilizumab. Data

was expressed as mean (SD); crude incidence rates (IR) were calculated as number of HZ episodes per 1000 patient-years- IR (1000 patient-years).
**Results:** Up to January 2016, 2715 patients were included in the register, 70% female, mean age 51 (14.3) yrs, submitted to 3770 treatments; 1721 patients with diagnosis of RA; \$54 with AS and APs=181.
61 HZ episodes were related including only one relapse reported in a 44years-old female patient with AR and in use of rituximab. The crude IR (95% CI) of HZ in the study population (biologic agentes) was 8.3 (1000 patient-years) vs 4.45 (1000 patient-years) in the control population (traditional DMARds), (p=0,7 95%CI-3,7–4,7). Only 6 cases were considered severe by the investigators, two of them were HZ ophthalmicus, one periorbital and all lead to some impairment. These patients were taking different biologic agents (etanercept, adalimumab, infliximab – 2 patients) and one was using traditional DMARDS.
Treatment with steroids (HR 1.99; 95%CI 1.092–3.6) was the only factor associated with zoster development. There was no difference in age, sex, specific disease or biologic agent associated with HZ episodes.
**Conclusions:** In our database, the risk of HZ was significantly increased in association with corticosteroid treatment but neither with biologic agents nor with inflammatory rheumatic diseases.

## SAT0587 RHEUMATOLOGISTS' ESTIMATES OF PROGNOSIS WITHOUT AND WITH TREATMENT IN ROUTINE CARE OF PATIENTS WITH RA, SLE, OA, FM

I. Castrejon, J. Chua, J.A. Block, T. Pincus. *Rheumatology, Rush University Medical Center, Chicago, United States*

**Background:** Physician estimates of prognosis affect management of patients with chronic rheumatic diseases. Different rheumatic diseases may be associated with varying estimates of the value of therapy in affecting prognosis in individual patients. Therefore, two simple quantitative scales for prognosis without and with therapy, may be useful as a form of "triage," to support and document the basis for clinical decisions in patient care.
**Objectives:** To analyze physician estimates of prognosis without and with treatment in 4 rheumatic diseases: rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), osteoarthritis (OA), and fibromyalgia (FM), seen in routine care at an academic rheumatology center.
**Methods:** All patients complete a multi-dimensional health assessment questionnaire (MDHAQ) at each visit, and doctors complete a RheuMetric, which includes prognosis estimated without and with therapy as excellent=1, very good=2, good=3, fair=4, and poor=5. Patients seen over a six-month period in 2015 were classified according to diagnosis into four categories: RA, SLE, OA, and FM. Mean levels of prognosis without and with therapies, and the differences between estimates with and without therapies, were compared for each diagnosis according to ANOVA.
**Results:** The study included 791 patients, 231 with RA, 146 with SLE, 263 with OA, and 151 with FM. Mean estimate for prognosis without therapy in all patients was 2.67 (between "fair" and "good" - closer to "fair"); estimates were in a relatively narrow range from 2.55 in OA to 2.60 in SLE, 2.75 in RA, and 2.81 in FM (Table). Estimates of prognosis with therapy in all patients was 1.76 (between "good" and "very good" – closer to good), a difference of 0.91 units from the prognosis without therapy (34%, $p<0.001$). These estimates differed over a wider range, from 1.44 in SLE, to 1.49 in RA, 1.91 in OA, and 2.21 in FM. The rheumatic disease rated most likely to improve with therapy was RA (1.26 units), followed by SLE (1.16 units), OA (0.65 units) and FM (0.60 units) ($p<0.001$). The proportion of patients rated to have a poor or fair prognosis without therapy ranged from 57% for OA, to 63% for SLE, 64% for RA and 74% for FM, versus very good or excellent in 10% or fewer. The proportions rated as likely to have a good to excellent prognosis with therapy were 12% for FM, 21% for OA, 34% for SLE, and 49% in RA with therapy ($p<0.001$), with an increase of 43% in RA, 24% in SLE, 18% in OA, and 8% in FM (Table).

| | RA (N=231) | SLE (N=146) | OA (N=263) | FM (N=151) |
|---|---|---|---|---|
| Prognosis scales, mean value | | | | |
| Prognosis without | 2.75 | 2.60 | 2.55 | 2.81 |
| Prognosis with | 1.49 | 1.44 | 1.91 | 2.21 |
| Difference | 1.26 | 1.16 | 0.65 | 0.60 |
| Prognosis without treatment | | | | |
| Excellent or very good | 14 (6%) | 22 (10%) | 8 (3%) | 6 (4%) |
| Good | 69 (30%) | 42 (18%) | 104 (40%) | 33 (22%) |
| Poor or fair | 148 (64%) | 82 (63%) | 151 (57%) | 112 (74%) |
| Prognosis with treatment | | | | |
| Excellent or very good | 113 (49%) | 79 (34%) | 55 (21%) | 18 (12%) |
| Good | 106 (46%) | 59 (26%) | 175 (67%) | 82 (54%) |
| Poor or fair | 12 (5%) | 8 (3%) | 33 (13%) | 51 (34%) |

**Conclusions:** Rheumatologists estimated improvement with therapy to be greatest for patients with RA, followed by SLE, OA, and FM. While these findings have face validity, they demonstrate the practicality of assigning quantitative estimates of prognosis in routine care. Quantitative estimates of prognosis rather than narrative descriptions may influence clinical decisions and help document a rationale for treatment choices.

## SAT0588 MDHAQ AS A USEFUL SCREENING TOOL FOR FIBROMYALGIA IN BUSY CLINICAL SETTINGS

K. Gibson[1], J. Chua[2], I. Castrejon[2], T. Pincus[3]. *[1]Rheumatology, Liverpool Hospital, Sydney, Australia; [2]Rheumatology; [3]Rush University Medical Center, Chicago, United States*

**Background:** Fibromyalgia (FM) is more prevalent than most rheumatic diseases in the general population, and is seen as a secondary phenomenon in 20–40% of people who have inflammatory rheumatic diseases. Formal ACR criteria to identify FM using self-report questionnaire data have been established (1), but generally not applied in busy clinical settings, in which it is not feasible to use multiple different patient questionnaires. A multidimensional health assessment questionnaire (MDHAQ) is feasible for completion by patients in the waiting area, and informative in rheumatoid arthritis (RA) as well as many other rheumatic diseases, and may be useful in FM. (2)
**Objectives:** To develop a cumulative index based on specific cutpoints of individual MDHAQ measures to screen for patients with primary or secondary fibromyalgia in busy clinical settings.
**Methods:** In two rheumatology settings, patients complete an MDHAQ at each visit. Nine MDHAQ scales were analyzed: 0–10 scores for physical function, pain, patient global estimate, and fatigue; 0–3 sores for sleep quality, anxiety, and depression; a RA disease activity index (RADAI) 0–48 self-report painful joint count and symptom checklist of 60 items. Scores on all MDHAQ scales were compared in Setting A in patients with a clinical diagnosis of primary FM vs RA with no secondary FM, and in Setting B in patients who had secondary FM according to ACR FM criteria vs other patients who did not meet ACR FM criteria. Only patients with complete data for all 9 MDHAQ scales and the ACR FM scales in Setting B were included in the study. Comparisons included frequencies, t tests, cross-tabulations with various cut-points, and receiver-operator curves, as well as a kappa statistic comparing clinician diagnosis of secondary FM vs FM by ACR criteria in setting B. A possible cumulative index based on specific cutpoints of individual measures, analogous to RA classification criteria (3), was explored with several cutpoints of different numbers of MDHAQ measures.
**Results:** In Setting A, 286 patients with RA were compared to 195 with FM. In setting B, 22 patients who had other diagnoses but secondary FM by ACR criteria were compared to 68 patients who had no FM by ACR criteria. All 9 MDHAQ scales were significantly higher in patients with FM compared to patients with RA or other diagnoses in both settings according to t tests and receiver-operator curves (data not shown). In Setting B, the kappa statistic was 0.68, indicating >80% agreement between the clinician diagnosis and ACR FM criteria. The highest levels of significance were seen for symptom checklist, RADAI self-report joint count scores, and pain scores. For example, an index provided a clue to primary or secondary FM at either site, with 2 of the following 3 measures: Pain ≥5, RADAI ≥16, symptom checklist ≥16.

Table 1

| Setting A | | | Setting B | | |
|---|---|---|---|---|---|
| 1° Fibro – Clin (n=195) | RA Clin (n=286) | p | 2° Fibro ACR (n=22) | No 2° Fibro (n=68) | p |
| 156 (80%) | 94 (33%) | p<0.0001 | 18 (81%) | 12 (18%) | p<0.0001 |

**Conclusions:** MDHAQ scales can provide clues to identify primary and secondary FM. Of course, a diagnosis requires a physician history and physical examination, but a screening tool may save time and increase recognition of FM in busy clinical settings.
**Disclosure of Interest:** None declared

## SAT0589 MEDICATION ADHERENCE IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: A REGISTER STUDY

J.T. Joensuu[1], K.J. Aaltonen[1], H. Valleala[2], K. Puolakka[3], T. Yli-Kerttula[4], T. Varjolahti-Lehtinen[5], T. Sokka[6], M. Blom[1], D. Nordström[2]. *[1]University of Helsinki; [2]Helsinki University Central Hospital, Helsinki; [3]South Karelia Central Hospital, Lappeenranta; [4]Satakunta Central Hospital, Rauma; [5]Hatanpää Hospital, Tampere; [6]Jyväskylä Central Hospital, Jyväskylä, Finland*

**Background:** Previous studies have reported medication adherence ranging from 49.5% to 98.5% in patients with rheumatoid arthritis (RA) [1]. Adherence to TNFi has been estimated to be 59%[2]. Non-adherence has been associated with poorer health outcomes, such as physical disability and increased need for health services.
**Objectives:** The aim of the study was to analyse adherence to self-injectable biologic disease-modifying antirheumatic drugs (bDMARDs), conventional syn-

thetic disease-modifying antirheumatic drugs (csDMARDs) and glucocorticoids in Finnish RA patients using their first bDMARDs.
**Methods:** RA patients starting their first bDMARD in 2007–2011 were identified from the National Register for Biologic Treatment in Finland (ROB-FIN). Restriction to the patients with available baseline data and at least 360 days follow-up with their first bDMARD was made. Data on prescribed medication was recorded in ROB-FIN while medication claims were retrieved from the register of the Social Insurance Institution of Finland. The proportion of days covered (PDC) during a 360-day period was calculated to define adherence. Patient was considered adherent if PDC was ≥80%.
**Results:** Fifty-two percent (n=424) of the 823 patients remained on the first bDMARD and were followed for at least 360 days. Forty-three percent of them (205) were adherent to all prescribed anti-rheumatic medication. CsDMARDs were prescribed to 372 patients of which 53% (196) were adherent while 5% (20) claimed no cdDMARD at all. Methotrexate was the most common csDMARD and was prescribed to 281 patients. The proportions of patients adherent to methotrexate and patients who claimed no methotrexate at all were 60% (170) and 9% (26), respectively. Self-injectable bDMARDs were prescribed to 319 of which 59% (187) were adherent and 8% (25) did not claim any of the prescribed bDMARD. Mean PDC for csDMARDs, methotrexate and self-injectable bDMARDs were 73%, 74% and 74%, respectively.
**Conclusions:** Less than half of the RA patients using bDMARDs were adherent to their antirheumatic medication. However, the current data measures only the medication claims instead of actual use. Moreover, the high proportion of patients lost to follow-up may cause bias to the results.

## SAT0590 PNEUMOCOCCAL VACCINATION IN PATIENTS WITH RHEUMATOID ARTHRITIS – RESULTS OF A CLAIMS DATA ANALYSIS

J. Callhoff[1], A. Luque Ramos[2], F. Hoffmann[2], A. Zink[1], K. Albrecht[1].
*[1]Department of Epidemiology, German Rheumatism Research Centre, Berlin; [2]Department of Health Services Research, Carl von Ossietzky University, Oldenburg, Germany*

**Background:** Due to autoinflammation and immunosuppressive therapy, patients with rheumatoid arthritis (RA) are at increased risk of developing pneumonia. The German Standing Vaccination Committee recommends standard vaccination against pneumococcal infections from age 60 onwards and for all persons with an increased health risk [1]. In patients with immunosuppression, booster vaccination is recommended every 5 years.
**Objectives:** To assess the vaccination status for pneumonia and the prevalence of hospitalised pneumonia in patients with RA and unaffected population controls in Germany using claims data.
**Methods:** This cross sectional study based on data of a large German statutory health insurance fund (Barmer GEK). The members had to be continuously insured between 2009 and 2013 and had to be between 18 and 99 years old. Insurants who had a diagnosis of RA (ICD-10 codes M05 or M06) in at least two quarters of the year 2013 were matched by age and sex in a ratio of 1: 5 to members without RA. Pneumococcal vaccination (once between 2009 and 2013) was evaluated with regard to age, sex, comorbidities, biologic treatment, primary or rheumatologic care and region of residence. Prevalences of inpatient pneumonia were compared to regional vaccination rates.
**Results:** The data of 111,482 RA patients and 557,410 matched controls were available for analysis. The mean age was 66.2 years and 79.7% were female. Compared to controls, RA patients were vaccinated more frequently (15.0% vs. 10.0%). Vaccination rates were comparable between male and female insurants and increased with older age. In proportion, RA patients <60 years were vaccinated 4–11 times and patients >60 years 1.2–1.5 times more frequently than controls. In East Germany, pneumonia vaccination rates were highest, the lowest rates were found in Southern Germany. Inpatient pneumonia prevalence was 2–3 times higher in RA patients compared to controls and tended to be higher in regions with low vaccination rates.
**Conclusions:** The increased pneumonia prevalence in RA patients confirms their status as a risk group. In consequence, they are vaccinated more frequently than controls, especially if they do not meet the generally recommended age criterion or if other additional risk factors are present. Overall, vaccination rates are still low. Historically, vaccination was performed more frequently in East Germany due to stricter regulations, and the lower pneumonia prevalences in these areas indicate that consequent vaccination may help to reduce pneumonia in RA.

**Background:** Nowadays there is a great variability in evaluation and management of patients with autoimmune and inflammatory diseases during fertility, pregnancy, post-partum and breastfeeding, in part due to lack of knowledge.
**Objectives:** To develop recommendations on the evaluation and management of patients with autoimmune and inflammatory diseases during fertility, pregnancy, post-partum and breastfeeding based on the best evidence and experience.
**Methods:** Recommendations were generated following nominal group methodology and Delphi technique. A panel of experts was established (12 rheumatologists). A systematic literature review and a narrative review (websites, clinical guidelines and other relevant documentation) were performed and presented to the panel in the 1st panel meeting to be discussed and to help define recommendations. A first draft of recommendations was generated and circulated for comments and wording refinements. A national survey analyzing different aspects of this topic was undertaken separately. Then, a Delphi process (2 rounds) was carried out. Recommendations were voted from 1 (total disagreement) to 10 (total agreement). We defined agreement if at least 70% voted ≥7. The level of evidence and grade or recommendation was assessed using the Oxford Centre for Evidence-based Medicine Levels of Evidence.
**Results:** A total of 14 recommendations (see figure) were generated on the preconception period (oral and hormonal anticonception, reproductive techniques), pregnancy (planning, treatment and follow-up), and breastfeeding (treatment and follow-up). High risk situations were included as lupus or antiphospholipid syndrome. A consensus >90% was reached in all but one recommendation.

**Conclusions:** These recommendations are intended to provide rheumatologists, patients, families and other stakeholders a consensus on the evaluation and management of patients with autoimmune and inflammatory diseases during fertility, pregnancy, post-partum and breastfeeding.

**Disclosure of Interest:** None declared

## SAT0592 PEAK-INCIDENCE AGE IN RHEUMATOID ARTHRITIS HAS NOT SHIFTED IN FINLAND SINCE THE TURN OF MILLENNIUM

K. Puolakka[1], V. Rantalaiho[2,3], H. Kautiainen[4,5]. *[1]Department of Medicine, South Karelia Central Hospital, Lappeenranta; [2]Centre for Rheumatic Diseases, Tampere University Hospital; [3]School of Medicine, University of Tampere, Tampere; [4]Department of General Practice and Primary Care, University of Helsinki and Helsinki University Hospital, Helsinki; [5]Unit of Primary Health Care, Turku University Hospital, Turku, Finland*

**Background:** Over the recent decades several studies have observed a shift towards higher age at disease onset in the incidence of rheumatoid arthritis (RA). The cause of this phenomenon is unknown.
**Objectives:** To find out whether the peak-incidence age has still been increasing during this millennium.
**Methods:** From the nationwide drug reimbursement register maintained by the Finnish Social Insurance Institution we collected data on all patients with incident inflammatory rheumatic diseases from January 1st 2000 to December 31st 2014. Patients with incident RA were identified by the ICD-10 codes of M05 and M06. The peak-incidence age of this cohort was modelled using the Poisson regression with restricted cubic splines (5 knots).
**Results:** During the observation time altogether 27 764 patients (mean age 61.3 at disease onset, 67.5% female) with a new diagnosis of RA were identified. Table shows the peak-incidence ages as well as mean ages at disease onset during the whole observation time and by 3-year periods. The peak-incidence age remained stable over the 15 years since the turn of millennium. The mean age at disease onset increased slightly in male.

| Period | All | Female | | Male | |
|---|---|---|---|---|---|
| | Peak-incidence age | Peak-incidence age | Mean age at RA onset (SD)* | Peak-incidence age | Mean age at RA onset (SD)** |
| 2000–14 | 69 | 67 | | 70 | |
| 2000–02 | 69 | 68 | 56.6 (15.3) | 70 | 57.7 (13.2) |
| 2003–05 | 68 | 66 | 56.8 (14.9) | 70 | 58.5 (12.7) |
| 2006–08 | 68 | 67 | 56.5 (15.8) | 68 | 59.1 (12.7) |
| 2009–11 | 68 | 66 | 56.8 (15.2) | 70 | 58.8 (13.4.) |
| 2012–14 | 70 | 69 | 57.1 (15.8) | 71 | 59.9 (13.5) |

*p=0.71; **p=0.001 for linearity of the trend in mean age at RA onset.

**Conclusions:** These results suggest that the unknown factors in the population and environment behind the earlier observed shift towards higher age in the incidence of RA have no longer been gaining power during the 21th century.
**Disclosure of Interest:** None declared

## SAT0593 DISCREPANCY BETWEEN PATIENTS AND PHYSICIANS ON GLOBAL DISEASE ASSESSMENT OF RA AND ITS DETERMINANTS: AN ANALYSIS FROM THE TRAV COHORT

K. Tascilar[1], G. Hatemi[2], N. Inanc[3], I. Simsek[4], C. Swearingen[5], M. Cinar[4], S. Ugurlu[2], S. Yilmaz[4], G. Ozen[3], S. Pay[4], H. Direskeneli[3], Y. Yazici[5]. *[1]Internal Medicine III, Okmeydani Teaching and Research Hospital; [2]Department of Rheumatology, Istanbul University Cerrahpasa Faculty of Medicine; [3]Department of Rheumatology, Marmara University, Istanbul; [4]Department of Rheumatology, Gulhane Military Medical Academy, Ankara, Turkey; [5]Hospital for Joint Disease, New York University, New York, United States*

**Background:** Patient-reported assessments have a considerable weight both in disease activity assessment in practice and response criteria in clinical trials of rheumatoid arthritis (RA). Discrepancies and disagreement on global disease activity between patients and physicians may result in disagreement in treatment decisions in routine care and impact assessment of treatment response in clinical trials as well.
**Objectives:** We aimed to illustrate the amount of discrepancy between patient and doctor global assessments (PGA and DGA) in routine care and asses the determinants thereof.
**Methods:** We used data from RA patients registered in the Turkish Rheumatoid Arthritis Registry (TRAV), a prospective registry established in 2010 in order to record clinical data at each visit of all RA patients seen at three academic rheumatology centers in a routine care setting. Currently 1923 RA patients are registered in TRAV. We used the initial visits of these patients to define a global assessment discrepancy (GAD) variable, GAD=PGA-DGA. We calculated the average GAD, overall correlation of PGA with DGA and constructed linear regression models to determine the predictors of PGA, DGA and GAD. Age, gender, physical function (MD-HAQ score), pain score (numeric rating scale; NRS), fatigue score (NRS), patient's joint assessment (PJA), physician reported tender (TJC) and swollen joint counts (SJC), erythrocyte sedimentation rate (ESR) and center of follow-up were included in these models as potential predictors.
**Results:** The mean age (standard deviation) of the registered patients was 52.0 (12.8) and 1561 (81%) were females. The average PGA was 3.59 (2.99) and the average DGA was 2.85 (2.63) Overall correlation of PGA and DGA was low (0.18) and average GAD was 0.70 (95% CI: 0.53–0.87). Confidence intervals around GAD indicated that on average patients rated their current disease activity as significantly worse than that of physicians. In the regression analyses; MD-HAQ, pain scores and center were common predictors of both PGA and DGA. Additional predictors of PGA were age, fatigue scores and PJA whereas additional predictors of DGA were ESR, PJA, TJC and SJC. Predictors of GAD were pain, fatigue, TJC, SJC, ESR and treatment center (see table).

NRS, numeric rating scale; TJC, tender joint count; SJC, swollen joint count; PJA, patient's joint assessment; MD-HAQ, multidimensional health assessment questionnaire; ESR, erythrocyte sedimentation rate
*Compared to Site-1

**Conclusions:** We found a weak correlation between patient and doctor global assessments of overall disease activity in RA patients under routine care. Higher pain and fatigue scores and different treatment centers were associated with a PGA higher than DGA whereas increasing TJC, SJC and ESR were associated with a DGA higher than PGA suggesting that patients and physicians prioritized different aspects of RA in their global assessments. Variation of the discrepancy by centers warrants further research with respect to a possible impact in multi-center treatment trials.

## SAT0594 CHOICE OF BIOLOGICAL AGENTS IN THE PUBLIC HEALTH SECTOR OF TUCUMAN, ARGENTINA

V. Bellomio[1], M. Espindola[1], M. Guardia[1], G. Lavado[2], H. Jovanovics[3], M. Montero[3] on behalf of Programa de Atención Integral del Paciente con Enfermedades Reumatológicas. *[1]Programas Integrados de Salud; [2]Direccion de PRIS; [3]PRIS, SIPROSA, Tucuman, Argentina*

**Background:** The province of Tucuman is located northwest of Argentina and has a population of 1,448,716 inhabitants, according to the last census. Within the public health sector, access to high-cost medication in patients with rheumatic diseases depends on the provincial government. Since 2012 it carries a registration and monitoring of patients with autoimmune diseases treated with biological drugs in this province
**Objectives:** To determine the preference of biological agents prescribing for patients with Rheumatoid Arthritis (RA), Spondyloarthritis (SpA), Juvenile Idiopathic Arthritis (JIA), Systemic Lupus Erythematosus (SLE) and other connective tissue diseases and describe the reason for change of therapy
**Methods:** A descriptive cross-sectional study was conducted. Registration of children and adult patients, assisted in public hospitals, with drug treatment with high-cost was done in PRIS (Integrated Health Programs) belonging to the Provincial Health System TUCUMAN, from January 2012 to June 2015. In Tucuman, biological drugs are indicated only by rheumatologists, monthly record and approval is based on local recommendations of the Argentine Society of Rheumatology. Demographics data, pathology, drug start, drug switch (2nd, 3rd or 4th choice), kind of switch, continuation or discontinuation of treatment were analyzed.
**Results:** Of 445 registered patients with high-cost drugs, we excluded those with no rheumatic disease (example Vogt-Koyanagi-Harada), primary osteoporosis, and 1 patient with Graft vs Host Disease (sclerodermiform syndrome treated with etanercept). Treatments were then analyzed in 393 patients, 84% women, mean age 47.7 ± 13.7 years, whose diagnoses were: 321 RA (81.7%), 38 SpA (9.6%), 13 JIA (3.3%), 12 SLE (3.1%) and the rest consisting of other connective tissue diseases (vasculitis, MTDC, ITCD).
In RA the first biological drug applied was: etanercept (36%), adalimumab (25%) and tocilizumab (10%). The average treatment time with the first biological agent was 18 ± 14.6 months; 63% received treatment continuously. Required switch to another drug 68 patients (21.2%) being the most frequent cause secondary failure and the most frequently prescribed drug rituximab or tocilizumab. The same trend is maintained then the 2nd switch. Only one patient received in 3 years 5 biological agents (4 switch).
In patients with SLE, rituximab and belimumab were treatments in equal

proportion (50%). In patients with SpA, etanercept was the first drug prescribed and adalimumab in 2nd place.
**Conclusions:** In this register of patients treated with biological drugs in Tucuman, the drug of start choice was etanercept; 21.2% needed to change therapy and the most frequent cause was secondary failure.
**Disclosure of Interest:** None declared

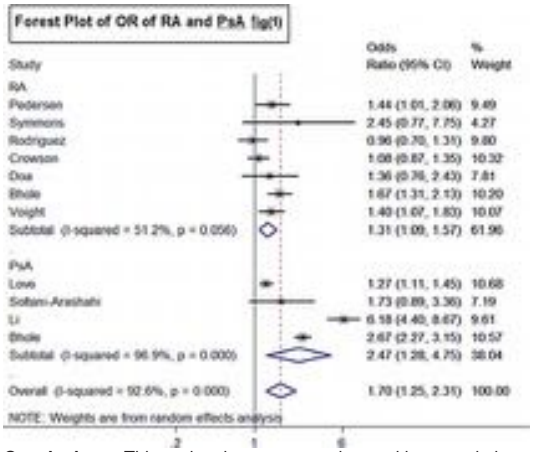
## SAT0595 SPONDYLOARTHRITIS PREVALENCE IN EUROPE, A EULAR-ENDORSED SURVEY

M.I. Zlatkovic-Svenda[1], A. Saraux[2], T. Tuncer[3], J. Dadoniene[4], D. Miltiniene[4], E. Gilgil[3], R. Stojanovic[1], F. Guillemin[5]. *[1]Institute of Rheumatology, University of Belgrade School of Medicine, Belgrade, Serbia; [2]Rheumatology, University Hospital, Brest, France; [3]Department of Physical Medicine, Rehabilitation and Rheumatology, Akdeniz University Faculty of Medicine, Antalya, Turkey; [4]Institute of experimental and Clinical Medicine, Vilnius University, Vilnius, Lithuania; [5]Inserm CIC-EC 1433, Nancy University Hospital, and Université de Lorraine, EA 4360 APEMAC, Nancy, France*

**Background:** The spondyloarthritis (SpA) prevalence has shown a trend to increase in the last two decades, in line with better recognition of the disease as well as the use of new classification criteria (1). The need to estimate and compare the SpA prevalence accross Europe was recognized.
**Objectives:** to estimate the SpA prevalence in several European countries: France, Turkey, Lithuania and Serbia using identical methodology and sampling; to standardize the results with reference to the European Standard Population by using direct method.
**Methods:** A two-step approach was taken. First, a unique detection Questionnaire, covering self-reported diagnosis, SpA classification criteria (ESSG 1991), personal and family history for SpA (2), previously translated and validated for each of the participating countries, was administered to a population sample. A two-stage sampling was carried out on seven areas covering 20 counties in France, seven geographical regions covering 25 administrative provinces in Turkey, two largest cities- Vilnius and Kaunas in Lithuania and two geographical regions covering four counties in Serbia. Second, diagnoses were confirmed by rheumatologists. Results were standardized by age and sex using the European Standard Population, defined as EU-27+EFTA, 2010 estimates.
**Results:** Detection Questionnaire was administered by telephone on 15219 persons in France (3), 6558 in Lithuania (4) and 6213 in Serbia (1), with 64.7%, 64.7% and 63.3% response rate, respectively. In Turkey, Questionnaire was administered face-to face on 4012 persons. Diagnoses were confirmed for 29 cases in France (37.9% male), 18 in Turkey (16.7% male), 27 in Lithuania (55.6% male) and 16 in Serbia (37.5% male). Estimates of the SpA prevalence standardized for age and sex are given in Table 1.

Table 1. Age- and sex- standardized SpA prevalence, % (95% CI) for France, Lithuania, Turkey and Serbia, ≥18 years



| | Men | Women | Total |
|---|---|---|---|
| France | 0.29 (0.12–0.47) | 0.31 (0.16–0.45) | 0.30 (0.19–0.41) |
| Lithuania | 1.38 (0.68–2.09) | 0.39 (0.16–0.63) | 0.89 (0.78–1.00) |
| Turkey | 0.17 (0.00–0.36) | 0.57 (0.28–0.87) | 0.37 (0.18–0.56) |
| Serbia | 0.38 (0.06–0.71) | 0.32 (0.10–0.54) | 0.35 (0.17–0.54) |

**Conclusions:** Age- and sex-standardized SpA prevalence estimates in France, Turkey and Serbia were in line, but were as twice as high in Lithuania, confirming a north-south decreasing gradient using homogenous sampling and case ascertainment method. Standardized SpA prevalence estimates in men and women were similar in France and Serbia, but not in Turkey and Lithuania. This study adds to previous observation on similarity of RA and SpA prevalence estimates.

## SAT0596 OBESITY AND INFLAMMATORY ARTHRITIS (RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS)

M. Sharif, J. Galloway. *Rheumatology, King's college Hospital, London, United Kingdom*

**Background:** RA is the commonest autoimmune joint disease & the incidence is 0.5 – 2%. PsA is another common inflammatory condition, which affects women and men equally, with an incidence of 6 per 100,000 per year and a prevalence of about 1–2 per 1000. Metabolic syndrome increases the risk of inflammatory arthrides. This is also known as syndrome X and insulin resistance syndrome. Patients with chronic inflammatory arthritis such as RA and PsA are prone to accelerated atherosclerosis and its complications. We took this systematic review to establish the relationship between obesity & inflammatory arthritis
**Objectives:** The primary aim of the study was to establish whether the obesity has any relationship with the development of inflammatory arthritis. We also looked for the relationship between obesity & serology of RA as well. Smoking & ACPA status also plays role in development of RA
**Methods:** We searched Medline/EMBASE (1946 to July 2013) using the terms Arthritis, Psoriatic, Psoriatic arthritis, Rheumatoid, Rheumatoid Arthritis, seronegative arthritis.mp OR ankylosing spondylitis/ OR ankylosing spondylitis.mp OR spondyloarthritis.mp OR spondyloarthritis/ OR inflammatory arthritis.mp &Obesity/ OR Obesity.mp OR Body Mass Index/ OR Body Mass Index.mp OR BMI.mp. Observational studies were included in the review, which included case control, cohort & cross sectional for both RA and PsA, and the risk of inflammatory arthritis was reported. The data were used for the calculation of effect size ORs/RR with 95% CIs] in obese vs non obese. A Forest plot was created using the OR/RR for both RA & PsA.
**Results:** Ten studies (from 113793 articles) met our inclusion criteria, comprising three case control (954 RA cases; 3273 individuals) & two cohort studies (1372 RA cases; 6419 individuals) & one Cross sectional studies (105 RA cases; 210 individuals) for RA and two cohort (1122 PsA cases and 164103 individuals), ultivariate logistic regression analysis (116137 individual and 350 RA and 644 PsA patients)Hierarchical Cox Regression mode design (250 PsA cases and 1193 individuals) for PSA were found. A significant correlation was found between obesity & the development of inflammatory arthritis.The summary OR for RA was 1.31 (1.09, 1.57) and for PsA was 1.70 (1.28, 4.75) in obese vs non obese patients. The data to establish any relationship between serology and obesity was not completely given in all studies included so it was not possible to conclude on that relationship. On sub group analysis the positive correlation between obesity& inflammatory arthritis was seen in case control studies of RA but for PsA, the relationship has been noted in all the studies included except one with somewhat less effect.

**Conclusions:** This review has suggested a positive correlation with the development of inflammatory arthritis and obesity. These results are demonstrated in case control studies for RA and all studies for PsA. There were mixed results associated with presence and absence of ACPA and development of inflammatory arthritis in patients with high BMI. Further research is indicated using more cohort studies to show the correlation and also the more studies using ACPA/RF to determine the correlation with obesity.

## SAT0597 FACTORS ASSOCIATED WITH NON-ADHERENCE TO METHOTREXATE AMONG SERBIAN PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

N. Damjanov[1], J. Nedovic[2], M. Lazarevic[3], S. Mamula Masic[4]. *[1]Institute for Rheumatology, Belgrade, Belgrade; [2]Institute Niska Banja, Niska Banja; [3]Specialized Hospital for Rheumatic Diseases Novi Sad, Novi Sad; [4]Roche d.o.o., Belgrade, Serbia*

**Background:** Methotrexate (MTX) is a cornerstone therapy and common first-line drug for patients with rheumatoid arthritis (RA), worldwide. However, there is significant variability in patients' response to MTX, both in efficacy and toxicity. It has been hypothesized that this finding may be partially explained by non-adherence to MTX.
**Objectives:** The aims of this study were to assess patients' self-reported adherence to MTX and to identify factors associated with non-adherence.
**Methods:** In the period between November 1 and December 15, 2015, 315 consecutive RA patients who were treated in one of three randomly chosen Serbian clinics were enrolled in cross-sectional study. The inclusion criteria were: age $\geq$18 years, diagnosis of RA of at least 6 months, current MTX use for at least 1 month (with or without concomitant usage of another RA drugs), and written informed consent. The associations between investigated demographic and clinical characteristics of the patients and non-adherence to MTX were assessed applying univariate logistic regression analysis. Furthermore, baseline variables with a significant association with non-adherence in univariate logistic regression analysis (defined as $p<0.05$) were entered into a multivariate logistic regression equation to identify independent predictors of non-adherence to MTX.
**Results:** Study population was predominantly female (74.0%), and the average current age was 56.0±12.5 years. The median duration of RA was 8 years, while the median duration of MTX treatment was 5 years. The majority of the patients (82.2%) reported using the oral formulation of MTX. The median maximum dose of MTX which responders received was 15 mg per week. Most of the participants in our survey stated that MTX was well tolerated, while 20% of RA patients reported poor tolerance. The overall prevalence of non-adherence to MTX was 24.8%. Forgetting to take medication (43.7%) was the most commonly-reported reason for MTX non-adherence. According to the results of univariate regression analysis the following factors are significantly associated with non-adherence to MTX: younger age (OR=0.963; $p<0.001$), employment (OR=1.859; p=0.029), poor self-reported MTX tolerance (OR=1.289; p=0.041), laboratory blood analyses performed less than once in three months (OR=2.170; p=0.043) and concomitant use of biological therapy (OR=2.312; p=0.002). Finally, in the multivariate regression model the following variables remained statistically significant and were identified as independent predictors of non-adherence to MTX: younger age (OR=0.969; p=0.006), laboratory blood analyses performed less than once in three months (OR=2.735; p=0.015) and concomitant use of biological therapy (OR=2.067; p=0.017).
**Conclusions:** The results of our study have shown that about one forth of RA patients met the criteria for non-adherence to MTX. Identification of vulnerable groups who are likely to be non-adherent to MTX has practical implications in identifying the patients who would benefit from alternative RA treatments and, would present an opportunity for timely intervention and optimization of treatment response.

## SAT0598 OUTCOMES, RATES, AND RISK FACTORS OF TRANSITION OF RAYNAUD'S PHENOMENON TO A CONNECTIVE TISSUE DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS

N. Ughi[1], F. Ingegnoli[2], C. Crotti[1], M. Mosca[3], C. Tani[3]. *[1]Division of Rheumatology, Gaetano Pini Institute, Department of Clinical Sciences & Community Health, University of Milan; [2]Division of Rheumatology, Istituto Gaetano Pini, University of Milan, Milan; [3]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

**Background:** A number of observational studies were carried out in patients with isolated Raynaud's phenomenon (RP) to investigate the predictors of transition to RP secondary to connective tissue diseases (CTDs). Data from a meta-analysis, including studies until June 1996, highlighted the potential role of nailfold capillaroscopy and/or antinuclear antibodies (ANAs) in predicting such transition [1].
**Objectives:** To provide an updated comprehensive review and meta-analysis on the rates and the role of predictors of transition to CTDs and systemic sclerosis (SSc) in patients with RP.
**Methods:** A systematic search of observational studies was undertaken using Medline and Embase (07/1996 to 08/2014). From the list of records retrieved, studies were screened by titles/abstracts and the full papers were sought where abstracts were felt to be relevant. Cohort studies reporting incidence and risk factors of transition from primary RP (pRP) or suspected secondary RP (ssRP) to CTDs were selected and data collected in ad hoc forms. pRP was defined according to Leroy and Medsger criteria (no history or physical findings suggestive of a secondary cause, normal capillaroscopy, negative serologic findings); ssRP was defined in presence of positive ANAs and/or abnormal capillaroscopy (even in association with symptoms or physical findings suggestive of a secondary cause without fulfilling criteria for a definite CTD). Relative risk (RR) and 95% confidence interval (CI) were extracted or calculated to present the association between risk factors and transition to CTDs. Random effects model was used to pool the results.
**Results:** From 2.221 articles captured, 36 met the predefined criteria, 29 were excluded on full text, and 7 selected studies provided information on transition from pRP and/or ssRP to secondary RP: 5 prospective and 2 retrospective cohort studies. Six studies included a total of 4051 patients with pRP with a cumulative mean follow-up of 20241 person-years (mean follow-up 4.9±2 years); a total of 1220 transitions to overt CTDs were recorded (pooled incidence rate 2.5/100 person-years of observation, range 0–7.7); among these, 321 transitions were to SSc (pooled incidence rate 1.58/100 person-years, range 0–2.8). Five studies included 657 patients with ssRP with a cumulative mean follow-up of 2377 person-years (mean follow-up 3.6±1.1 years); a total of 188 transitions to CTDs were recorded (pooled incidence rate 7.9/100 person-years, range 3.3–26) and 135 to SSc (pooled incidence rate 5.7/100 person-years, range 2.1–13). With respect to the patients with pRP, having ANA without capillary abnormalities provided a modest risk to develop SSc (pooled RR 2.8, CI 2.1–3.8), even weaker resulted the association between capillary abnormalities without ANA and the risk of SSc transition (RR 1.3, CI 0.7–2.4). On the other hand, the coexistence of ANA and abnormal capillaroscopy significantly increased the risk of transition to SSc (RR 8.1, CI 6.9–9.7).
**Conclusions:** A low incidence rate of transition from pRP to overt CTDs was confirmed. In patients with ssRP, whilst accepting the influence of selection bias of different studies, there appears to be a strong risk of transition toward a CTD regarding the concomitant presence of ANAs and abnormal capillaroscopy.

## SAT0599 AUTOIMMNUNE DISEASE IN ACUTE CORONARY SYNDROMES. CLINICAL IMPLICATIONS

N. Lozano-Rivas[1], C. Marras-Fernández Cid[1], P. Flores-Blanco[2], F.J. Pastor-Perez[2], L.F. Linares[1], F.A. Martinez-Angosto[1], J. Martínez-Ferrin[1], S. Manzano-Fernández[2]. *[1]Rheumatology Department. University Hospital Virgen Arrixaca; [2]Cardiology Department. University Hospital Virgen Arrixaca, murcia, Spain*

**Background:** Patients with autoimmune diseases (AID) have a high burden of cardiovascular disease leading to premature morbidity and mortality[1]. But it is unclear if it is due to a higher prevalence of cardiovascular disease, to a worse case fatality or to a different management after an index event.
**Objectives:** The aim of the study is to assess the prevalence of AID in patients with acute coronary syndrome (ACS), the management and prognostic implications.
**Methods:** The study included consecutive patients admitted after ACS from January 2011 to May 2014. For AID patients, in-hospital management and ACS presentation was compared to non-AID patients. We also compared in-hospital and 1-year major adverse events (MACE): death, recurrent myocardial infarction, stroke and major bleeding, between groups. The percentage lost to follow-up was $<$1%.
**Results:** Of 964 patients, 53 had AID (5.5%): 11 rheumatoid arthritis, 9 inflammatory bowel disease, 7 ankylosing spondylitis, 7 psoriatic arthritis, 5 polymyalgia rheumatica, 4 systemic lupuserythematosus and 10 miscellanea. Mean evolution of the disease was 14±3 years. No significant differences were found in clinical and demographics characteristics between groups except for a higher percentage of previous stable coronary heart disease in non-AID patients. Compared to non-AID patients, AID patients had similar clinical ACS presentation and no differences were found with respect to revascularization strategies or medical treatment at discharge. Overall there were 207 MACE (69% during hospitalization): 108 deaths, 52 recurrent myocardial infarctions, 19 ischemic strokes and 28 major bleedings. The two groups had comparable rates of MACE both during hospitalization (9.6% vs 12.2%, p=0.58) and at 1 year (26.4% vs 19.1%, p=0.19), AID vs non-AID respectively. The presence of AID was not associated with increased in-hospital mortality (OR 1.1, 95% CI 0.4 to 3.3) but it was a risk factor for higher 1-year crude mortality (OR 2.2, 95% CI 1.1 to 4.4), with a trend to higher 1-year mortality after multivariable adjusting (OR 1.7, 95%CI 0.8 to 3.9).
**Conclusions:** The presence of AID did not change ACS presentation and clinical management. Moreover it is not independently associated with worse outcomes during hospitalization although there is a trend to higher 1-year mortality.

## SAT0600 THE APPROACH OF RHEUMATIC AND MUSCULOSKELETAL DISEASES COMBINING VIRTUAL AND FACE-TO-FACE CONSULTATIONS IS A RESOURCE-SAVING STRATEGY

P. Vela[1,2], B. Zapata[3], E. Santonja[3], A. Ortiz[3], L. Roig[3], F. Martinez[3], A.I. Marti[3], M.C. Marin[3], A.M. Lechuga[3], M.J. Jorda[3], C. Egea[3], J.C. Deltell[3], E. Camblor[3], B. Calvo[3], M. Arana[3], A. Aracil[3], V. Almela[3]. *[1]Medicine, Miguel Hernandez University, Elche (Alicante); [2]Rheumatology, Hospital General Universitario Alicante; [3]Centro de Salud "Lo Morant", Departamento19, Servicio Valenciano de Salud, Alicante, Spain*

**Background:** The high prevalence of rheumatic and musculoskeletal diseases (Ref 1) along with the limited resources allocated to the specialty of rheumatology, has made us think about new models of care. A mixed virtual and face-to-face rheumatology consultation, working together Lo Morant's Health Center (HC) and the Rheumatology Section of Alicante Hospital, began to work in May-2014. (Ref 2).
**Objectives:** To analyse the causes of consultation from primary care to rheumatology, the distribution of the pathologies and the way they were resolved.
**Methods:** The primary care physician (PCP) made a virtual consultation (VC) to the rheumatologist within the electronic record system "Abucasis". Once a month, the rheumatologist and one of the PCP attended a face-to-face consultation (F2F) in the HC. The same day, a formative-informative session took place in the HC with rheumatologist and PCPs attendance. Variables recorded: Number of patients, VC, F2F, technics performed, diagnosis and attitude. STATISTICAL ANALYSIS: Descriptive variables.
**Results:** The period between May-2014 to December-2015 was analysed. 806 consultations (607 VC, 199 F2F, 537 patients), were performed. After VC, 75 patients (13,9%) were referred to specialised rheumatology consultation (SRC), but 280 were resolved (52,1%, 132 mechanical problems (47,1%), 51 osteoporosis (18,2%), 40 tendinitis (14,2%), 12 fibromyalgia (4,3%), 8 microcrystal diseases (2,8%), 5 inflammatory/autoimmune (1,7%), 5 no disease (1,7%), 21 were referred to other speciality (7,5%)). In F2F, 181 patients were attended (33,7%), 21 joint aspiration with microscopic synovial fluid exam, and 104 local injections were performed, 13 patients were referred to other speciality, and 31 were referred to SRC. The final diagnostics of the 106 patients referred to SRC were: 24 mechanical and tendinosus problems (22,8%), 22 chronic arthritis (20,9%), 21 microcrystal diseases (20%), 12 autoimmune diseases (11,4%), 9 severe osteoporosis (8,5%), 2 cancers, 2 no disease, 1 Sudeck atrophy, 1 neuropathy.
Comments:VC avoided displacement of 301 patients (280 resolved, 21 referred to appropriate speciality), reducing the lost of working days and displacement costs, and diminishing SRC load. Minor problems (soft tissue and mechanic problems) were usually resolved in F2F of HC, while severe and inflammatory pathologies were mainly referred to SRC, where chronic patients are managed.
**Conclusions:** Mixed rheumatology consultation is very effective, avoids unnecessary patients displacements, and makes easier the appropriate level of attendance of pathology. Continuing education in primary care and tight relationship with rheumatologist allowed a better referral of patients, reserving SRC for more severe and complicated situations that required it.

## SAT0601 INCIDENCE OF SERIOUS INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS EXPOSED TO A-TNF THERAPY. RESULTS FROM BIOBADABRASIL REGISTRY

R. Ranza[1], I. Laurindo[1], D. Titton[1], M. Bertolo[1], W. Bianchi[1], C. Brenol[1], H. Carvalho[1], G. Castro[1], M. Cecconi[1], I. Costa[1], A. Duarte[1], V. Fernandes[1], M. Freire[1], P. Louzada-Jr[1], J. Maciera[1], J. Miranda[1], J. Moraes[1], I. Pereira[1], G. Pinheiro[1], M. Sauma[1], B. Stadler[1], R. Toledo[1], V. Valim[1], C. Baaklini[2], M. Descalzo[3]. *[1]BiobadaBrasil; [2]President, Brazilian Society of Rheumatology, São Paulo, Brazil; [3]Research Unit, Academia Española de Dermatología y Venereología, Madrid, Spain*

**Background:** The safety profile of biologic drugs might have substantial regional differences. Since 2009, the Brazilian Society of Rheumatology runs BiobadaBrasil, a registry for monitoring of biologic therapies in rheumatic diseases, in collaboration with other Latin America countries (BiobadaAmerica) and with Biobadaser
**Objectives:** To report the incidence of serious infectious adverse events (SIAE) in Rheumatoid Arthritis (RA) and Spondyloarthritis (SpA) patients exposed to biologic a-TNF drugs in Brazil
**Methods:** BiobadaBrasil counts on thirty two centers, from almost all Brazilian states, that prospectively include patients with active rheumatic diseases who started a biologic drug or a synthetic DMARD as a parallel control group. A constant three level monitory of data quality is maintained (online, by phone and "in situ"). This study focuses on SIAE (for definition: Protocolo 1.1 at https://biobadaser.ser.es/biobadamerica/Brasil/cgi-_bin/upload/documentacion.aspx) in RA and SpA (Ankylosing Spondylitis+Psoriatic Arthritis) patients exposed to a-TNFs from January 2009 to June 2015. Time of exposure was set from start of the drug to the date of last administration or censorship. Continuous variables were expressed as mean with standard deviation (SD). SAE incidence rate was calculated per 1000 patient/years with 95%CI
**Results:** 1601 subjects with RA (1024) and SpA (577) exposed to a-TNF drugs were included in BiobadaBrasil, 6298 p/y, follow-up 2.9 (2.3) yrs, 65% females, at baseline: age 52 (12.5) yrs, disease duration 8.6 (8) yrs. Controls were 572 (RA 528, SpA 44), 2093 p/y, follow-up 3.6 (2.2) yrs, 90% females, at baseline: age 55 (13) yrs, disease duration 5.3 (7.3) yrs. The incidence rates of SIAE were: a-TNF RA & SpA 35 [30,40] vs controls 15 [10,21], ratio 2.34 [1.6,3.5] $p<0.001$, a-TNF RA 43 [37,50] vs a-TNF SpA 21 [16,28], ratio 0.5 [0.36,0.69] $p<0.001$. Subsequent a-TNF was associated with a higher incidence of SIAE when compared with first (ratio 1.6 [1.17,2.17], p=0.0013). When only RA patients were considered, incidence ratio between a-TNFs and controls raised to 3.11 [2.06,4.86] $p<0.001$ and Adalimumab comes out as the a-TNF with a lower incidence of SIAE, 29 [22,39] vs Infliximab 55 [43,70], ratio 0.53 [0.35,0.79] p=0.0006, with no statistical difference between Etanercept 48 [37,62] and Infliximab, ratio 0.87 [0.6,1.26] p=0.22. In both groups, a-TNF and controls, respiratory and urinary tracts serious infections accounted for 2/3 of all events, followed by skin/soft tissues and osteo articular and SIAE were not statistically associated with age, disease duration or corticosteroid use
**Conclusions:** In BiobadaBrasil registry, patients exposed to a-TNF drugs had an incidence rate of serious infections 2-fold that of the control group, significantly lower in SpA than in RA.

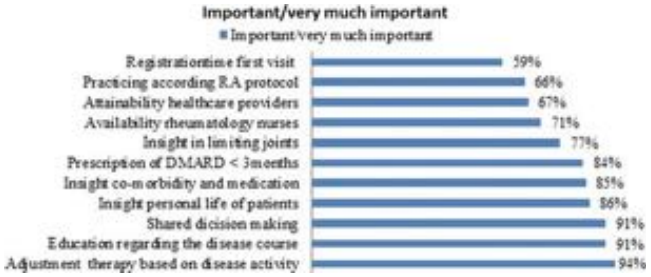
## SAT0602 IS A BRIEF EDUCATION INTERVENTION EFFECTIVE TO MOTIVATE PATIENTS TO STOP SMOKING?



R. Tekkatte, L. Williamson, E. Price, S. Carty. *Rheumatology, Great Western Hospital, Swindon, United Kingdom*

**Background:** Smoking has been associated with an increased risk of developing rheumatoid arthritis (RA), more severe disease and poor response to disease modifying drugs (DMARD). Motivation is the most important aspect of giving up smoking and also awareness of its ill-effects, self-confidence and support.
**Objectives:** We have looked at the immediate effect on patient motivation to stop smoking by creating awareness of its ill-effects.
**Methods:** We surveyed Rheumatology outpatients with an anonymous questionnaire including demographics, smoking status, education status, employment status and awareness of the ill-effects of smoking. Motivation to stop smoking was assessed by 10cm Visual analogue scale (VAS) before and after receiving information on adverse effects of smoking on RA. The information provided was about increased risk of RA, severe disease and poor response to DMARD.
**Results:** 100 unselected patients completed the questionnaire: 74% female; 46% RA; 22% current smokers; 37% never smokers; 41% ex-smokers. 68% of patients in all categories had attended secondary school. A higher proportion of never smokers had attended University compared with current smokers [20% (8/37) vs. 5% (1/22)]. A higher proportion of current smokers were unemployed as compared with never smokers [32% (7/22) vs. 8% (3/37)]. 50% of patients stated that they had never asked about smoking during consultations. When asked how important smoking is in arthritis, 55% of all patients scored >8/10 on a VAS (0=not bad /10=very bad). There was no significant difference in understanding the importance of smoking on arthritis between current smokers (VAS mean; SD 7.06; 2.35) and never smokers (VAS mean; SD 7.37; 2.15) (p=0.115) and between current smokers and ex-smokers (Mean; SD 7.74; 1.87) (p=0.23).
73% (16/22) of current smokers motivation to give up smoking score increased after they were given information on adverse effects of smoking on RA (mean VAS 4.43 before; 5.79 after) (p=0.03). 27% (6/22) did not change, none decreased.
50% (11/22) of patients felt lack of support and help prevented them stopping smoking. Preferred methods for smoking cessation help were: leaflets 41%; verbal advice 9%; GP review 18%. 54% (22/41) of ex-smokers were happy to speak to the current smokers to provide tips on stopping smoking.
**Conclusions:** This small study suggests that brief educational intervention may help motivate patients to give up smoking. Lack of support is a common difficulty patients perceive when they try to give up smoking. As RA outcomes are worsened by smoking, clinicians need to be more proactive about promoting smoking cessation. Outpatient appointments provide a good opportunity for this.

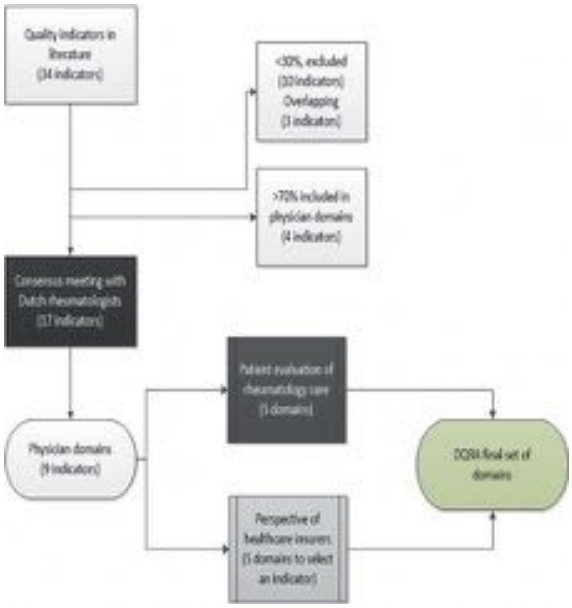
## SAT0603 EVALUATING QUALITY OF CARE IN RHEUMATOID ARTHRITIS: PATIENTS PERSPECTIVE

S. Mahmood[1], M. van Oosterhout[2], S. de Jong[2], R. Landewé[1], P. van Riel[3], L. van Tuyl[1]. *[1]Amsterdam Rheumatology and immunology Center; [2]Reumafonds, Amsterdam; [3]Radboud UMC, Nijmegen, Netherlands*

**Background:** Standardized measurement of outcomes allows for quality improvement of health care delivery. While a total of seven sets of RA quality indicators are available in the international literature, none of them reports extensively on the patients' representation (1).
**Objectives:** As patients and healthcare providers have a different perspective regarding health care outcomes, we studied the patients' perspective on quality of care and incorporated this in the Dutch national Quality Registry for Rheumatoid Arthritis (DQRA).
**Methods:** A group of patients (n=6) connected through the Dutch Arthritis Foundation, was consulted by focus group methodology and inquired about their positive and negative experiences and thoughts with rheumatology-care. During the meeting, all patients were required to form a "top-three" of most important domains; resulting domains were ranked in order of importance by the group. A set of nine domains (physician domains), defined by Dutch rheumatologists in a separate process were then introduced. These domains were compared with the domains as formed by the patients, resulting in the preliminary set of domains. The preliminary set of domains was sent to all RA members of the Dutch Arthritis Foundation panel (n=1132) through an online survey. Patients were asked to score all items on a seven-point Likert scale from "not important" to "extremely important", and to rank the items into a top five of important domains for the evaluation of quality of care.
**Results:** The focus group discussion resulted in 7 domains: 1) education regarding the disease course; 2) attainability of healthcare providers; 3)availability of rheumatology nurses; 4) shared decision making; 5) insight in personal life of patient 6) insight in co-morbidities and co-medication 7) insight in limiting joints (for example after arthrodesis). The physician domains that were added to this set were; 8) adjustment of therapy based on disease activity; 9) prescription of a DMARD <3 months of diagnosis; 10) practicing according to a RA protocol and 11) registration time to first visit to rheumatologist.
A total of 640 RA patients completed the online survey. Domains considered as "important or extremely important" for rheumatology care are displayed in figure 1. The 5 domains that were ranked highest through the online survey included: 1) adjusting therapy based on the disease activity; 2) insight in personal life of patient; 3) shared decision making; 4) education regarding the disease course; 5) insight in co-morbidity and co-medication.



**Conclusions:** This is the first study that has incorporated the patients' perspective on quality of RA care in the development of a national quality indicator set. Five domains were identified by patients, reflecting their perspective on quality of RA care.

## SAT0604 DUTCH QUALITY REGISTRY RHEUMATOID ARTHRITIS: DEVELOPMENT OF QUALITY INDICATORS

S. Mahmood[1], L. van Tuyl[1], J. Braspenning[2], P. van Riel[3], R. Landewé[1]. *[1]Amsterdam Rheumatology and immunology Center, Amsterdam; [2]NFU, Leiden; [3]Radboud UMC, Nijmegen, Netherlands*

**Background:** While innovation and research has provided high quality care, we are largely unable to quantify this increase in quality in clinical practice, while costs are rising to unacceptable levels. As health care facilities are unable to measure their performance (use of different measures), no information is available about quality of care between facilities.
**Objectives:** In order to standardize care processes and to give more insight in the provided care in The Netherlands, the Dutch Quality registry Rheumatoid Arthritis (DQRA) is developed. The rise of the DQRA and selection of quality indicators is described in this abstract.
**Methods:** Stakeholders involved in the development of the DQRA were; rheumatologists, patients and healthcare insurers. All were approached in separate ways:
Rheumatologists: Expert group meetings were held to evaluate the current practice in the represented hospitals and regions. Available quality indicators for rheumatoid arthritis (RA) from the literature were presented and merged into an online survey. Indicators were selected based on their validity, feasibility and importance regarding the quality of rheumatology care. Indicators selected by <30% of rheumatologist were excluded; indicators selected by >70% of rheumatologists were directly included in the set of physician domains (domains are needed to form the actual indicator, e.g. disease activity). Remaining indicators were discussed further during a consensus meeting and were included to the physicians domains.
Patients perspective was assessed by means of a focus group discussion (n=6), combined with an online survey (n=1132). This approach resulted in the patients' perspective regarding quality of rheumatology care.
Healthcare insurers were also approached by means of a focus group discussion (n=6). The physicians' domains and the domains as formed by the patients were presented to representatives of healthcare insurers. This discussion resulted in domains that can be used to select an indicator.
During a final expert group meeting in which all three stakeholders were represented, the final set of domains was discussed and established after final adjustments.
**Results:** The physician domains consist of; tender and swollen joint count (28); acute phase reactant; patient and physician VAS (together forming the disease activity) and drug-treatment. Patient-evaluation of rheumatology care is measured by the following domains; 1) adjusting therapy based on disease activity; 2) insight in the patient's personal life; 3) shared decision making; 4) education about the disease (course); 5) insight into co-morbidities and co-medication).
These domains form the foundations for the development of quality indicators. Indicators will be selected based on the characteristics formed by healthcare insurers; 1) ability to detect quality differences; 2) ability to detect the expediency; 3) clearness; 4) can be standardized and 5) ability to detect the added value of a certain therapy.

**Conclusions:** The DQRA is the first Dutch quality registry with the ambition to comprise all RA patients in the Netherlands. A minimal set of quality domains is formed from the perspectives of three stakeholders. Prospective data from the registry will be used to develop valid and reliable quality indicators ("norms") that help clinicians to continuously improve their practices.

## SAT0605 TOWARDS A TAXONOMY THAT IS SCIENCE-BASED AND CLINICALLY USEFUL: THE NEW WHO - ICD11 CLASSIFICATION OF MUSCULOSKELETAL PAIN DISORDERS

S. Perrot[1], M. Cohen[2]. *[1]Pain Clinic, Cochin Hospital, Assistance Publique Hopitaux de Paris, Universite Paris Descartes, INSERM U 987, Paris, France; [2]Pain Medicine & Rheumatology, St Vincent's Clinical School, Sydney, Australia*

**Background:** The current ICD 10 classification of musculoskeletal pain disorders is not relevant, combining anatomical, pathophysiological and clinical approaches. In 2015, the WHO started a new program for ICD11 classification, to be delivered in 2017. In this new program, physicians and researchers from rheumatology and pain clinics have been involved for the musculoskeletal pain chapter that will be developed in collaboration with the IASP/ International Association for the Study of Pain.

**Objectives:** To develop a taxonomy for musculoskeletal (MSK) pain conditions that merge insights from both pain pathophysiology and rheumatological clinical classification for both clinical and scientific uses.
**Methods:** As members of the IASP-WHO Task Force for the Classification of Chronic Pain in ICD-11, the authors have reviewed the taxonomy of musculoskeletal conditions in ICD-10 and earlier iterations and conventional taxonomy in rheumatology, all of which are disease-based and commonly do not reflect the problems encountered in the practice of pain medicine. The authors have pragmatically integrated recent advances in musculoskeletal pain pathophysiology into diagnostic labelling in this diverse field as a prelude to a multiaxial approach.
**Results:** Two sets of taxonomic reforms will be presented. The first conforms to the format required by ICD which remains anatomically or disease based. This comprises four main categories: chronic musculoskeletal pain from persistent inflammation; chronic musculoskeletal pain associated with structural changes; chronic musculoskeletal pain due to disease of the nervous system; and chronic primary musculoskeletal pain (to include spinal pain and widespread pain).
The second prefers classification by pain mechanisms and identifies conditions characterized by nociceptive pain and primary hyperalgesia and those characterized by nociplastic* pain and secondary hyperalgesia.
**Conclusions:** The authors contend that the somatic dimension of musculoskeletal pain conditions is better conceptualized by incorporating underlying pain pathophysiology in conventional disease labels rather than by describing MSK pain as different disease entities or as "pain syndromes". These proposed new taxonomic sets are not mutually exclusive and can probably be integrated for clinical purposes, not only in pain clinics but also in rheumatology settings. Although they refer to the somatic or biomedical dimension of the complex experience of musculoskeletal pain, they can be readily integrated with the psychological and social axes of evolving taxonomy.

## SAT0606 THE COMORBIDITY BETWEEN SYSTEMIC LUPUS ERYTHEMATOSUS AND MALIGNANCIES: A CROSS-SECTIONAL POPULATION BASED STUDY

S. Azrielant[1,2], S. Tiosano[1,2], N. Mahroum[1,2], D. Comaneshter[3], A.D. Cohen[3,4], H. Amital[1,2]. [1]*Department of Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer;* [2]*Sackler Faculty of Medicine, Tel-Aviv University;* [3]*Chief Physician's Office, Clalit Health Services, Tel-Aviv;* [4]*Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

**Background:** Autoimmune conditions often reflect dysregulation of the immune system, which appears to be of great significance in the development of malignancies [1]. Previous studies support an association between systemic lupus erythematosus (SLE) and malignancies; however, their findings on specific malignancies are inconsistent, and their design might not represent the population of SLE patients, due to selection bias [2–4].
**Objectives:** Our goal was to investigate the association between the presence of SLE and various malignancies, in a large-scale population-based study.
**Methods:** Data for this study was collected from the database of "Clalit Health services", the largest state-mandated health service organization in Israel. All adult members diagnosed with SLE were included (n=5,018) and their age and sex-matched controls (n=25,090), creating a cross-sectional population-based study. Medical records of all subjects were analyzed for documentation of malignancies. Logistic regression was preformed to control for age, gender, BMI, smoking and socioeconomic status.
**Results:** Diagnosis of malignancy (of any type) was more prevalent in the SLE population in comparison to controls (odds ratio [OR] 3.35, 95% confidence interval [CI] 3.02–3.72). Also, SLE diagnosis was found to be independently associated with higher proportions of non-Hodgkin lymphoma (OR 3.02, 95% CI 2.72–3.33), Hodgkin lymphoma (OR 2.43 95% CI 1.88–2.99), multiple myeloma (OR 2.57, 95% CI 1.85–3.28), cervix uteri malignancies (OR 1.65, 95% CI 1.10–2.20) and genital organ malignancies (OR 2.32 95% CI 1.42–3.22), after adjustment for confounding variables.

| | Non-Hodgkin lymphoma (OR, 95% CI) | Hodgkin lymphoma (OR, 95% CI) | Multiple myeloma (OR, 95% CI) | Cervix uteri malignancies (OR, 95% CI) | Genital organ malignancies (OR, 95% CI) |
|---|---|---|---|---|---|
| Age | 1.04 (1.03-1.05) | 1.01 (0.99-1.03) | 1.06 (1.04-1.09) | 1.02 (1.01-1.04) | 1.06 (1.03-1.09) |
| Sex - male | 1.28 (0.91-1.66) | 1.49 (0.84-2.15) | 2.52 (1.78-3.27) | - | 0.53 (-0.96-2.02) |
| Smoking | 1.06 (0.74-1.39) | 0.75 (0.14-1.36) | 1.78 (1.04-2.52) | 1.26 (0.73-1.78) | 0.81 (-0.23-1.84) |
| BMI | 1.0 (0.98-1.03) | 0.97 (0.92-1.03) | 0.92 (0.84-0.99) | 0.99 (0.95-1.04) | 0.95 (0.86-1.03) |
| SLE | **3.02 (2.72-3.33)** | **2.43 (1.88-2.99)** | **2.57 (1.85-3.28)** | **1.65 (1.10-2.20)** | **2.32 (1.42-3.22)** |

**Conclusions:** SLE diagnosis was found to be independently associated with higher proportions of malignancies, specifically hematologic malignancies. These findings should be considered when treating SLE patients, and possibly influence their screening routine.

## SAT0607 PATTERNS OF ADOPTION OF TREAT-TO-TARGET APPROACHES IN RHEUMATOID ARTHRITIS AND THEIR IMPACT ON PATIENT BURDEN IN EUROPE

S. Narayanan[1], Y. Lu[2], R. Hutchings[2], S. Mentzer[2]. [1]*Global Evidence Generation, Value and Access COE, Ipsos Healthcare, Potomac, United States;* [2]*Ipsos Healthcare, London, United Kingdom*

**Background:** Heterogeneity in treatment strategies exist to varying degrees in the management of rheumatoid arthritis (RA). Assessment of impact of treat-to-target (T2T) approaches implemented in clinical practices may help identify best practices and to alleviate patient (pt) burden.
**Objectives:** To assess the patterns of adoption of T2T approaches in RA and their impact on patient burden in Europe (EU5: UK/France/Germany/Italy/Spain).
**Methods:** A multi-center medical chart-review study of RA pts was conducted among physicians (rheumatologists) in hospitals/private practices in EU5 to collect de-identified data on pts who were currently on (or recently discontinued $\leq$3mo) a biologic. Physicians were screened for practice-duration and patient-volume and recruited from a large panel to be geographically representative of respective countries. Patient charts of ~5 successive pts visiting each center/practice during study period were selected. Physicians abstracted patient diagnosis, treatment patterns/dynamics and patient symptomatology/disease status (incl. assessment of "disease remission" per physician clinical judgment (both objective & subjective)). The adoption of the following T2T approaches was investigated: T2T-1: disease remission, with normalization of function; T2T-2: alleviate symptoms of disease or improve patient reported outcomes; T2T-3: Normalization of function or lower severity scores or inhibits disease progression; T2T-4: use validated composite measures of disease severity involving DAS28, tender joint count (TJC) or swollen JC (SJC) frequently; T2T-5: consider comorbidities (e.g., diabetes, obesity, heart disease), patient factors and drug-related risks; T2T-6: measure disease severity every month for moderate/severe disease pts and within 1–6 month frequency for mild/remission pts; T2T-7: Consider structural changes, functional impairment and comorbidity in addition to T2T-4; T2T-8: adjust drug therapy every 3mo until treatment target is reached; T2T-9: maintain desired treatment target for remaining course of disease; T2T-10: involve patient in treatment decisions. Pts for whom $\geq$7 T2T approaches applied (High-T2T) were compared to the rest (Low-T2T).
**Results:** In 2Q2015, 1331 RA patient charts were abstracted across EU5; adoption of T2T approaches were:T2T-1:36%, T2T-2:38%, T2T-3:70%, T2T-4:87%, T2T-5:31%, T2T-6: 63%, T2T-7: 60%, T2T-8: 86%, T2T-9: 52%, T2T-10: 64%; High-T2T: 39% (range: 29% (Italy)-44% (UK/Spain)), Low-T2T: 61% (range: 56% (UK/Spain)- 71% (Italy)). Age, gender, time since RA diagnosis, duration of current/recent biologic and frequency of physician visits were similar between High-T2T & Low-T2T, whereas, time from diagnosis to first biologic initiation (40.7/46.6mo), % positive rheumatoid factor (89%/83%; $p<.01$), % positive anti-CCP (76% /71%; $p<.05$), mean TJC (3.5/4.3; $p<.01$), mean SJC (2.4/2.9; $p<.05$), school/work lost because of disease in last 3mo (3.0/4.6 days), % in remission (78%/47%; $p<.01$) differed between High-T2T/Low-T2T respectively.
**Conclusions:** A significantly higher proportion of pts in High-T2T group were in remission and exhibited relatively lower disease burden. These observed patterns warrant further scrutiny to determine the best practices and profile pts still in need for improvement to alleviate burden.

## SAT0608 PERCEPTION OF ANTI-TNF BIOSIMILARS AMONG PAYERS IN EUROPE

S. Narayanan[1], Y. Lu[2], R. Hutchings[2], S. Mentzer[2]. [1]*Global Evidence Generation, Value and Access COE, Ipsos Healthcare, Potomac, United States;* [2]*Ipsos Healthcare, London, United Kingdom*

**Background:** Tumour necrosis factor inhibitor class (anti-TNFs) represent the most widely prescribed biologic medications globally to manage chronic immunologic conditions. Biosimilars in this arena may provide an effective alternative

to curtail looming economic burden associated with managing these conditions while alleviating patient burden. A survey of rheumatologists revealed moderate barriers to uptake of biosimilars, with 60% in key European countries (EU5: UK/France (FR)/German (DE)/Italy (IT)/Spain (ES)) reporting definitely or highly likely to prescribe a biosimilar when available. (Narayanan & Nag, 2015) Regional and national payer perceptions concerning biosimilar adoption is evolving.

**Objectives:** To assess the perception of anti-TNF biosimilars among national, regional and hospital payers in the EU5.

**Methods:** A cross-sectional survey was conducted in the EU5 among individuals meeting the following inclusion criteria: have a clinical background in immunology and play a role in influencing the approval of new drugs in that area, must have participated in a review of autoimmune diseases for reimbursement, funding, and/or formulary placement decisions within the last 24 months at national or regional level, and must be in a role that influences hospital formulary decisions for autoimmune diseases (within hospital payer category). A forty-minute online survey assessed the overall perception of anti-TNF biosimilars, specific barriers to prescribing them and factors (besides price) influencing the endorsement of biosimilars.

**Results:** Eighty four payer stakeholders across EU5 (UK:15, FR:20, DE:15, IT:15, ES:19) participated; 61% (range: 20% (FR)–100% (UK)) reported highly or very favorable perception/opinion of biosimilars. Factors influencing their overall perception were: cost-benefit opportunities (23%), comfortability with biosimilar efficacy (23%), healthy market competition (13%) and saving opportunity and long-term sustainability (12%); 12% reported efficacy and safety concerns. On a scale of 1–7 (1: not at all important; 7: very important), rating of importance of place of manufacturing of anti-TNF biosimilars to be the same as the originator drug was 4.3 (range: 3.0 (DE)–5.6 (IT)); rating of level of comfort with extrapolation of clinical data permitting approval of a biosimilar for a therapeutic indication in which it has not been clinically evaluated, but for which an originator is approved was 4.8 (range: 4.3 (FR)–5.4 (ES)). 29% (range: 20% (UK/FR)–42% (ES)) reported the quality of clinical and economic data they have access to or would require to evaluate biosimilars to be very or extremely high. Top-5 factors influencing endorsement of biosimilar were availability of robust safety and efficacy data, comparable long-term clinical response, product quality and reliability of product supply. Majority (94%) expected biologically naïve patients to benefit the most from biosimilars.

**Conclusions:** Payer stakeholders reported positive perceptions towards biosimilars, while expressing some concerns towards product attributes. Evidence generation and communication efforts addressing these payer perceptions may facilitate optimal access to biosimilars.

## SAT0609 VITAMIN D BENEFICIAL EFFECT ON ARTERIAL HYPERTENSION

F. Salma[1], A. Omezzine[2], M. Turki[1], H. Fourati[3], M. Ezzedine[3], M. Chaabane[3], N. Salem[3], S. Baklouti[3], F. Ayadi[1]. *[1]Biochemistry, CHU Habib Bourguiba, Sfax; [2]Biochemistry, CHU Sahloul, Sousse; [3]Reumatology, CHU Hedi Chaker, Sfax, Tunisia*

**Background:** Both vitamin D deficiency and hypertension are increasingly prevalent public health concerns in developing countries.

**Objectives:** This study aims to assess 25-hydroxyvitamin D (25(OH)D) status in postmenopausal women and to analyze its relationships with arterial hypertension.

**Methods:** A total of 200 tunisian postmenopausal women aged from 50 to 89 years were recruited from the rheumatology departement in CHU Hedi Chaker, Sfax, Tunisia.

Clinical characteristics and patient medical history were collected using a validated questionnaire. Blood samples were taken for measurements of vitamin D, intact parathyroid hormone (PTH), and routine chemical analysis.

Serum 25(OH)D and PTH were measured by electrochemiluminescence.

SPSS 20 was used for the statistical analysis.

**Results:** The mean age was 63,74 ± 7,8 years. Mean PTH was 61,80 ± 25,6 ng/L.

Serum 25(OH)D levels were below 10, 20, and 30 ng/ml in 55, 30.5 and 14.5% of participants, respectively. Systolic blood pressure (SBP) was above 140mmHg in 60,5% of the patients while 26.5% had a diastolic blood pressure (DBP) higher than 90mmHg. PTH was highly correlated to 25(OH)D (r=-0,305, p<0,001) but not to the blood pressure levels. Serum 25(OH)D levels were negatively correlated to SBP (r=-0,121, p=0,045) and to HBP(r=-0,163, p=0,021).

After multivariate adjustment for a range of potential covariates (Age, Body mass index, waist size and glomerular filtration rate) in a binary logistic regression model, a significant inverse association was found between serum 25(OH)D concentration and systolic hypertension risk: In fact Risk of systolic hypertension seems to be lowered in the group with high 25(OH)D levels (≥15 ng/mL) compared with those with low levels (<15 ng/mL) (adjusted OR=0,512, CI 0.270–0.972), p=0,03). However, we have not noted a significant association between vitamin D levels and the risk of systolic hypertension (adjusted OR=1.01, 95% CI=0.495–2.064, p=0,97).

**Conclusions:** This study is timely, because a discrepancy exists between findings from observational studies and results of randomized intervention trials.

Reverse causation, inherent weakness of observational studies, is a possible explanation as individuals with hypertension might have more chronic diseases and therefore spend less time outdoors with sun exposure, important for endogenous vitamin D production.

In fact, randomized intervention trials will be needed to determine whether vitamin D supplementation can be used to prevent or treat hypertension.

## SAT0610 THE PROSPECTIVE RISK FOR LONG TERM SICKNESS ABSENCE, UNEMPLOYMENT, AND DISABILITY PENSION, AND THE PROBABILITY FOR RETURN TO WORK IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.M. Hansen[1], M.L. Hetland[2], J. Pedersen[1], M. Østergaard[2], T.S. Rubak[1], J.B. Bjorner[1]. *[1]Epidemiology, The National Research Centre for the Working Environment, Copenhagen; [2]The DANBIO Database, Centre for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark*

**Background:** Long term sickness absence (LTSA), unemployment and early retirement are some of the most important outcomes of rheumatoid arthritis (RA), both for patient and society. Historically, RA patients have increased risk of LTSA and early disability pension. Modern treatment strategies have improved disease control in the last decades, and a decreased risk of LTSA and disability pension during later years have been reported. It is not known whether this represents a disease-specific decline or if the reduction of disability pension merely reflects a reduction in disability pension in general, due to political, demographic, and socioeconomic changes.

**Objectives:** To study in a multi-state model 1) the risks of LTSA, unemployment, and disability pension, and the chance of return to work in RA compared to a matched control population and 2) the changes in risks between1994–2011.

**Methods:** A cohort study of 6,677 RA patients at working age identified in the nationwide DANBIO registry, a register on adult patients with inflammatory joint diseases, and 56,955 matched (age, gender, area of residence) controls from the general population. By linkage with the DREAM registry (a national registry on employment status and sick-leave) and other registries, we analyzed in a multi-state model all shifts between the work-related states simultaneously and calculated hazard rates (HR), stratified by disease duration (early RA (<1yr) and established RA (≥1yr)), controlled for socio-demographic factors, physical job exposure, somatic and psychiatric comorbidities.

**Results:** The RA patients had increased risk of LTSA (e.g. early RA: HR=4.00) and disability pension (e.g. established RA: HR=2.75) relative to controls, see table. The relative risks of LTSA and disability pension decreased from 1994–99 to 2006–11 (e.g. in established RA: from work to LTSA HR 2.25 to 1.63, and from LTSA to disability pension HR 3.49 to 2.40). Compared to controls, RA patients had a lower chance of returning to work from LTSA (early RA: HR=0.60) or unemployment (early RA: HR=0.77), and this did not change over time.

RA patients compared to matched general population controls during follow up

| Shifts | | Dis. duration <1 yr | | Dis. duration ≥1 yr | |
|---|---|---|---|---|---|
| From | To | HR | 95% CI | HR | 95% CI |
| Work | LTSA | **4.00** | 3.64–4.30 | **1.84** | 1.75–1.94 |
| Unemployment | LTSA | **2.46** | 1.99–3.04 | **1.62** | 1.45–1.81 |
| Work | Unemployment | 0.92 | 0.83–1.03 | **0.82** | 0.77–0.87 |
| LTSA | Unemployment | **0.42** | 0.35–0.51 | **0.62** | 0.56–0.69 |
| LTSA | Work | **0.60** | 0.55–0.66 | **0.78** | 0.75–0.82 |
| Unemployment | Work | **0.77** | 0.70–0.85 | **0.80** | 0.76–0.83 |
| Work | Disability pension | **8.60** | 6.34–11.67 | **12.20** | 10.96–13.58 |
| LTSA | Disability pension | **1.52** | 1.26–1.84 | **2.75** | 2.54–2.98 |
| Unemployment | Disability pension | **2.36** | 1.57–3.54 | **3.41** | 2.92–3.98 |

Values in bold: P<0.001.

**Conclusions:** RA patients remain at high risk for LTSA and disability pension, but a positive trend is seen from 1996–1999 to 2006–2011. Returning to work from unemployment or LTSA remains a challenge for RA patients.

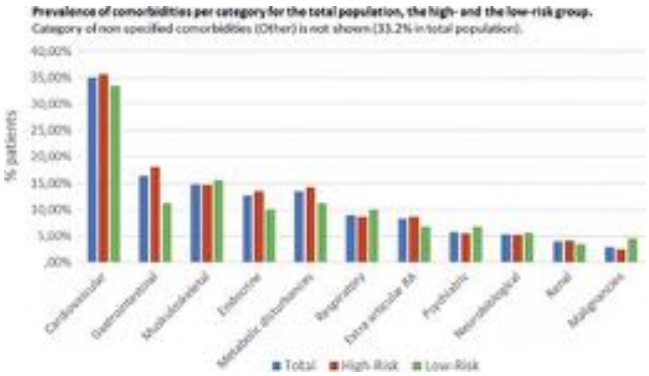
## SAT0611 THE IMPACT OF ADHERENCE TO BIOLOGIC AGENTS ON HEALTH CARE RESOURCE UTILIZATION FOR PATIENTS WITH RHEUMATOID ARTHRITIS



U. Lathia, F. Nantel, E. Ewara. *Janssen Inc., Toronto, Canada*

**Background:** Poor adherence to therapy increases the burden and complexity of chronic diseases such as rheumatoid arthritis (RA). In the past 15 years, biologics have revolutionized the treatment of RA. However, little data is available on impact of adherence to biologics on health-care resources.
**Methods:** As part of a pilot project at the Institute for Clinical Evaluative Sciences (ICES), analyses were performed by ICES scientists on ICES administrative data to study the research question provided by Janssen Inc. Note, the approach and methodological details were determined by Janssen researchers. Patients were identified from the Ontario RA Database which contains all Ontario RA patients identified since 1991. Study population included RA patients, age 65+, with a prescription for a biologic drug between January 1, 2003 and December 31, 2013. Exclusion criteria are diagnosis of inflammatory bowel disease, psoriatic arthritis or psoriasis in the 5 years prior to the index event and discontinuation of biologic drug during the 12 months after the index event. Adherence was defined as a Medication Possession Ratio (MPR) of $\geq$0.8 measured as the proportion of days for which a patient had biologic treatment(s) over a defined follow-up period. Adherent were matched to non-adherent patients on a propensity score calculated using seventeen variables capturing patient demographics and heathcare resource use in the year prior to index event.
**Results:** A total of 4,667 RA patients were identified. Patients had a mean age (SD) of 69.9 (5.46) years and 75% were female. Of the total study cohort 1,877 matched pairs were identified (adherent to non-adherent patients). Relative rates for resource use (GP and cardiologist visits, ED visits, hospitalization, home care and rehabilitation) for the matched cohort were significantly lower ($p<0.0001$) in adherent patients. Additionaly the median (IQR) length of stay of hospitilizations was shorter for adherent patients - 10 days (4–23) vs. 14 days (5–38). 67% of non-adherent patients used oral prednisone which is significantly higher ($p<0.001$) than 54% in the adherent cohort.
**Conclusions:** The results of this large population based study have shown that RA patients who are adherent to biologic therapy have lower heathcare resource use and lower steroid use compared to non-adherent patients. Despite the inherent limitations of administrative database studies, the findings of the study have implications for physicians, patients and healthcare payers demonstarting the importance of adherence in the management of RA.
**Disclosure of Interest:** None declared

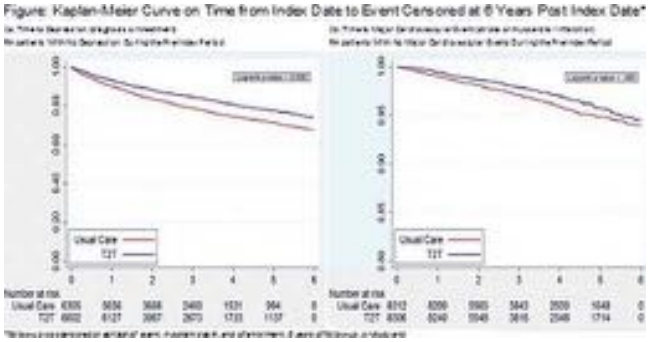
## SAT0612 PREVALENCE OF COMORBIDITIES IN CARERA PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AT DISEASE ONSET

V. Stouten[1], D. De Cock[1], R. Westhovens[1,2], J. Joly[2], K. Van der Elst[2,3], P. Verschueren[1,2]. *[1]Skeletal Biology and Engineering Research Center, KU Leuven Department of Development and Regeneration; [2]Rheumatology, University Hospitals Leuven; [3]Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care, Leuven, Belgium*

**Background:** Comorbidities are highly prevalent in patients with Rheumatoid Arthritis (RA) and have been demonstrated to influence disease outcome. A better awareness of the number and type of comorbidities at disease onset and their influence on the disease course, could allow more timely intervention to prevent long term morbidity and mortality.
**Objectives:** To investigate the presence of comorbidities in patients with recently diagnosed RA, its association with clinical features and impact on disease outcome.
**Methods:** The presence of comorbidities was recorded on screening, before initiation of DMARDS or glucocorticoids in 379 patients with recently diagnosed RA (<1 year) participating in the Care in early RA (CareRA) trial, an RCT comparing different intensive remission induction strategies in a treat to target setting after stratification in a high- or low-risk arm based on classical prognostic markers (RF/ACPA, DAS28, erosion). Patients were grouped as having no comorbidities or having a comorbidity in at least one predefined category (cardiovascular, respiratory, endocrine, musculoskeletal, renal, neurobiological, psychiatric conditions, malignancies, metabolic disturbances, extra-articular RA manifestations and other). Disease activity (DAS28-ESR/CRP) was measured at baseline and after 1 year. Demographics including gender, age, smoking status, BMI and vital signs were registered on screening.
**Results:** Out of 379 patients (289 high- and 90 low-risk), 262 (69.1%) had a comorbidity in at least one of the predefined categories. In the group with comorbidities, the mean age was significantly higher (54.7 vs 45.7, $p<0.001$), as was the systolic blood pressure (134.9 vs 129.3 mmHg, $p=0.008$), compared to the group without comorbidities. Moreover, DAS28-ESR (5.3 vs 4.8 $p<0.001$) and DAS28-CRP (4.9 vs 4.5 $p=0.001$) were significantly higher in patients with compared to without comorbidities. DAS28 scores also tended to increase depending on the number of comorbidities per individual. After 1 year of intensive treatment to target, no more statistically significant difference was seen between the group with or without baseline comorbidities in terms of DAS28-CRP scores, but DAS28-ESR remained higher in patients with comorbidities ($p=0.031$). Overall, the most frequently reported comorbidities were cardiovascular (35.1%), gastrointestinal (16.4%) and musculoskeletal (14.8%). No significant differences in prevalence were found between risk groups.



**Conclusions:** At the onset of RA, nearly three-quarters of patients had a comorbidity in at least one category. Patients with comorbidities were significantly older and had a significantly higher disease activity at baseline, disappearing after one year of treatment. No significant difference in the number or type of comorbidities was found between so-called High- and Low-Risk patients.

## SAT0613 DEPRESSION AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) USING A TREAT-TO-TARGET (T2T) APPROACH TO THERAPY VERSUS USUAL CARE

N. Princic[1], D. Fugh[1], B.C. Chu[1], V. Garg[2]. *[1]Truven Health Analytics, Reading; [2]AbbVie, Chicago, United States*

**Background:** RA is an inflammatory autoimmune disease associated with increased prevalence of depression and cardiovascular comorbidities[1,2]. A T2T approach to therapy has been shown to significantly improve RA patient outcomes over usual care.
**Objectives:** To compare incidence rates of depression and major cardiovascular events in RA patients with a T2T approach to therapy to a matched group of RA patients with usual care.
**Methods:** This retrospective cohort study used MarketScan administrative claims databases to select adults with at least 1 inpatient or 2 outpatient diagnoses of RA (ICD-9-CM 714.0x) at least 30 days apart and within a year during 1/1/2005 to 1/31/2014. The index event was the first biologic or non-biologic disease-modifying antirheumatic drug at least 6 months following diagnosis. Patients had 6 months of pre-index continuous enrollment and follow-up was variable in length with a 1 year minimum imposed (baseline year). Patients were categorized as having T2T approach if they had at 3 or more visits to a rheumatologist where the initial visit was within the first 90 days of follow-up and were determined to have low disease activity through implementation of a validated claims-based algorithm[3] during the baseline year. Patients that did not meet both criteria were identified as having usual care. Incidence rates of depression (diagnosis or treatment) and major cardiovascular events (stroke or myocardial infarction) were calculated for the T2T cohort and the matched usual care cohort. Kaplan Meier (KM) method was used to examine the probability of time to event between groups.
**Results:** Of the 80,509 RA patients, 10.4% (N=8,333) were identified as having

T2T based management strategy and matched 1:1 to 8,333 of the 72,174 (89.6%) patients with usual care. After matching both cohorts had similar demographic characteristics (e.g., mean age 57.5 years, 73% female).Compared to the usual care cohort, a significantly ($p<0.001$) lower proportion of patients in the T2T cohort were newly diagnosed with a major cardiovascular event (2.5% vs. 3.2%) or newly treated for or diagnosed with depression (12.9% vs. 16.3%). Patients in the T2T cohort had a lower depression rate (1.56 vs. 2.14) per 10,000 person-years (PY) and major cardiovascular event rate (0.22 vs. 0.28) compared to patients with usual care. KM analysis also suggested that patients in the T2T cohort (versus usual care) had a significantly higher probability of not experiencing depression or a major cardiovascular event during follow-up (log rank tests all $p<0.001$) (Figure).

**Conclusions:** A T2T approach to RA management was associated with lower incidence of major cardiovascular events and depression and should be considered when prescribing care. Future studies in different populations are needed to confirm these findings.

## SAT0614 JOINT HYPERMOBILITY AND ANKLE OSTEOARTHRITIS IN A COMMUNITY-BASED COHORT

Y.M. Golightly[1], A.E. Nelson[1], M.T. Hannan[2], H.J. Hillstrom[3], V.B. Kraus[4], R.J. Cleveland[1], A.P. Goode[4], T.A. Schwartz[1], J.B. Renner[1], J.M. Jordan[1]. *[1]University of North Carolina, Thurston Arthritis Research Center, Chapel Hill, NC; [2]Hebrew SeniorLife, Boston, MA; [3]Hospital for Special Surgery, New York, NY; [4]Duke University, Durham, NC, United States*

**Background:** Clinical impressions suggest that joint hypermobility, a condition in which range of motion is greater than normal at most joints, is associated with osteoarthritis (OA), but results vary across the few published cohort studies on this subject. To our knowledge, no prior cohort study has examined the association of hypermobility and ankle radiographic features and symptoms of OA.

**Objectives:** This cross-sectional analysis examined the association of joint hypermobility and ankle OA outcomes in a large community-based cohort in the United States.

**Methods:** Of the 863 participants with complete tibiotalar radiograph data collected during 2012–2015, 848 had Beighton (joint hypermobility) data available for analyses. The Beighton criteria determined the ability to complete nine maneuvers: passive dorsiflexion right/left fifth finger $\geq$90 degrees, passive apposition right/left thumbs to forearm, right/left elbow hyperextension $\geq$10 degrees, right/left knee hyperextension $\geq$10 degrees, and palms on floor during forward trunk flexion with knees extended. One point was assigned for each completed maneuver (total score: 0 [unable to perform any maneuver] to 9 [performed all maneuvers]). Joint hypermobility was defined as a Beighton score $\geq$4; we also focused on the knee maneuver since the knee and ankle are closely linked along the kinetic chain. Radiographs were read for tibiotalar osteophytes (OST) and joint space narrowing (JSN). Presence of ankle symptoms consistent with OA was based on an affirmative response to the question: "On most days of any one month in the last 12 months did you have pain, aching or stiffness in your left/right ankle?" Separate logistic regression models were used to estimate associations of ankle OST, JSN, and symptoms with hypermobility, adjusting for covariates of gender, race, age, body mass index (BMI), and history of ankle injury. Statistical interactions between hypermobility and covariates were examined at the 0.10 significance level.

**Results:** The sample was 68% women and 33% African American with a mean age of 71 years and mean BMI of 31 kg/m$^2$. Hypermobiltiy was present in 59 participants (7.0%), which was most common among those <55 years (12.1%); 643 (75.5%) participants had OST, 65 (7.5%) had JSN, and 146 (17.2%) had ankle symptoms. Although not statistically significant, the adjusted odds of OST and ankle symptoms were 87% and 55% higher, respectively, among participants with vs. without hypermobility (Table). The adjusted odds of ankle symptoms was over 4 times as high among participants able vs. unable to perform the knee maneuver. There were no statistically significant interactions of hypermobility by covariates, but the estimates of the hypermobility-OST association generally increased with age (<55 years: adjusted odds ratio [aOR] = 1.02; 55–<65 years: aOR = 2.20, 65+years: aOR=2.88), while the hypermobility-ankle symptoms estimates declined (<55 years: aOR = 2.02; 55–<65 years: aOR = 1.68, 65+ years: aOR = 0.82).

Table. Unadjusted and adjusted* odds ratios (OR) and 95% confidence intervals (CI) for association of ankle outcomes and Beighton Criteria.

| | Beighton Score | | OR (95% CI) | |
|---|---|---|---|---|
| Ankle Outcome | ≥4 (n=59) | <4 (n=789) | Unadjusted | Adjusted* |
| Radiographic OST‖≥1 | 46 (81.4%) | 584 (74.0%) | 1.53 (0.78, 3.00) | 1.87 (0.92, 3.80) |
| Radiographic JSN‖≥1 | 2 (3.4%) | 63 (8.0%) | 0.40 (0.10, 1.70) | 0.47 (0.11, 2.03) |
| Ankle symptoms | 14 (23.7%) | 132 (16.7%) | 1.55 (0.83, 2.90) | 1.55 (0.80, 3.01) |
| | Knee Maneuver | | OR (95% CI) | |
| Ankle Outcome | Able (n=34) | Unable (n=811) | Unadjusted | Adjusted* |
| Radiographic OST‖≥1 | 27 (79.4%) | 602 (74.2%) | 1.34 (0.58, 3.12) | 1.50 (0.62 3.66) |
| Radiographic JSN‖≥1 | 3 (8.8%) | 61 (7.5%) | 1.19 (0.35, 4.00) | 1.32 (0.38, 4.56) |
| Ankle symptoms | 15 (44.1%) | 131 (16.2%) | 4.10 (2.03, 8.27) | 4.41 (2.06, 9.44) |

*Adjusted for age, gender, race, ankle injury and body mass index
‖ OST=osteophytes; JSN=joint space narrowing

**Conclusions:** Joint hypermobility may be associated with OST and symptoms of the ankle. Longitudinal studies are needed to determine the contribution of hypermobility to the incidence and progression of ankle OA outcomes.

## SAT0615 INFLUENCE OF FUNCTIONAL CAPACITY ON SELF-REPORTED PHYSICAL FUNCTION, AND ASSOCIATIONS WITH MECHANICAL MUSCLE FUNCTION IN SPORADIC INCLUSION BODY MYOSITIS PATIENTS

A.N. Jørgensen[1,2], P. Aagaard[2], J.L. Nielsen[2], M. Christiansen[2], L.G. Hvid[2], U. Frandsen[2], L.P. Diederichsen[1,3]. *[1]Department of Clinical Research; [2]Department of Sports Science and Clinical Biomechanics, University of Southern Denmark; [3]Department of Rheumatology, Odense University Hospital, Odense M, Denmark*

**Background:** Sporadic inclusion body myositis (sIBM) represents a progressive inflammatory muscle disorder associated with severe loss of skeletal muscle tissue and impaired muscle function, which eventually results in drastically lowered physical function, reduced quality of life, and loss of independency[1–4]. No previous study has investigated the potential linkage between functional capacity and health-related quality of life and the relations to mechanical muscle function in sIBM patients.

**Objectives:** To investigate the associations between self-reported physical function, functional capacity and mechanical muscle function in patients with sIBM.

**Methods:** Twenty-two patients with sIBM volunteered to participate in the study. All participants filled out the short form (36) health survey, and performed a 2-min walk test (2MWT), a Timed up & go test (TUG) and a 30-sec chair stand test (CS), followed by evaluations of unilateral leg extension maximal muscle power (POW; Nottingham Power Rig) and maximal isometric knee extension muscle strength (MVC; KinCom dynamometer). Multiple linear regression analyses were applied to analyze associations between the investigated variables.

**Results:** All functional capacity tests revealed positive relationships with self-reported physical function (SF-36, physical function domain). TUG performance was the strongest predictor of self-reported physical function among the functional capacity tests (TUG: $r^2$=0.56; CS: $r^2$=0.43; 2MWT: $r^2$=0.42; $p<0.05$). MVC and MVC asymmetry (%inter-limb deficit) combined were the strongest indicators of TUG performance ($r^2$=0.50; $p<0.05$), with MVC exerting a positive effect and asymmetry a negative effect on TUG score. MVC asymmetry alone showed the strongest association (negative) with 2MWT performance ($r^2$=0.49; $p<0.05$). CS performance, was not correlated to MVC, but was predicted by POW and POW asymmetry combined ($r^2$=0.33, $p<0.05$) with a positive coherence for POW and a negative coherence for POW asymmetry.

**Conclusions:** The Timed up & go test appears to be the functional capacity test that best predicts self-perceived physical function in sIBM patients. Notably, it was found that between-limb asymmetry in maximal knee extensor strength had a clear negative impact on motor tasks involving gait function. This finding underlines that increasing attention should be directed to evaluate inter-limb strength asymmetry in sIBM patients in order to prevent function loss and achieve more effective rehabilitation in this patient group.

## SAT0616 KNEE ISOMETRIC AND ISOKINETIC STRENGTH IN FALLERS AND NON-FALLERS WITH RHEUMATOID ARTHRITIS

C. Clarke[1], J. Smith[1], M. Yates[1], L. Watts[1], K. Graham[1], V. Pomeroy[1], T. O'Neill[2], A. Macgregor[1]. *[1]UEA, Norwich; [2]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom*

**Background:** Muscular weakness is a cause of instability that has been reported to contribute to falling. Isokinetic and isometric dynamometry is a method of muscle assessment useful to measure the muscular strength and gives a quantification of the weakness and a comparison of strength across limbs and in reciprocal muscles.
**Objectives:** To compare isokinetic and isometric knee flexion and extension strength between fallers and non-fallers with Rheumatoid Arthritis (RA).
**Methods:** Sixty people with RA who gave informed consent were divided into two groups based on having a fall or not in the period of one year before evaluation, fallers (n=30, age 72.4years 15 males) and non-fallers (n=30, age 72.5 years, 16 males). Knee flexor and extensor strength was assessed using isokinetic and isometric dynamometry. Participants both limbs were tested at three fixed angular velocities isokinetically: 120°/s, 90°/s, and 60°/s and at three fixed positions isometrically, 90°, 60° and 30°. Bilateral comparison was determined by the percent deficit between left and right limbs for each participant. The ipsilateral comparison was determined between reciprocal muscles by the flexion/extension ratio. Independent t-test was used to identify significant differences between the fallers and non-fallers. The significance level was set at $p<0.05$
**Results:** 25 fallers and 30 non-fallers completed the isometric tests and 23 fallers and 28 non-fallers completed the isokinetic tests. In the bilateral comparison of the weaker and stronger limb in the fallers and non-fallers groups showed a large percentage deficit (range 22–43%) of isokinetic muscle strength between limbs in flexion and extension. Fallers had a significantly larger percentage deficit than non-fallers of isometric muscle strength between limbs in extension at 90° ($p=0.02$) and 60° ($p=0.01$).
The ipsilateral comparison shows that the fallers had a significantly ($p<0.05$) smaller flexion/extension ratio indicating a reduced hamstring strength at all isokinetic speeds (120°/sec F:0.73, NF:0.97, 90°/sec F:0.75, NF:0.94, 60°/sec F:0.74, NF:0.90). The fallers also had a significantly ($p<0.05$) smaller flexion/extension ratio isometrically at 60° and 30°.
**Conclusions:** These results demonstrate both RA fallers and RA non-fallers showed a large deficit in muscle strength between limbs. RA fallers had a significantly larger limb deficit in isometric extensor strength at 90° and 60°. The RA fallers had a significantly reduced flexion/extension ratio compared to the RA non-fallers indicating an imbalance between quadriceps and hamstring strength. Addressing the weakness in one limb and the imbalance between quadriceps and hamstrings may reduce the number of falls in this population.
**Disclosure of Interest:** None declared

## SAT0617 12-MONTH COMPLEX REHABILITATION PROGRAM FOR RHEUMATOID ARTHRITIS PATIENTS RECEIVING BIOLOGIC DMARDS

E. Orlova[1], D. Karateev[2], L. Denisov[1], A. Kochetkov[3], E. Nasonov[4]. *[1]Laboratory of Clinical Trials; [2]Early Arthritis department, V.A. Nasonova Research Institute of Rheumatology; [3]Central Rehabilitation Hospital, Federal Medical Biological Agency; [4]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Rehabilitation techniques, including physical exercises, physiotherapy, occupational therapy, patient education, give the patients with rheumatoid arthritis (RA) the strategies necessary to manage their disease in addition to drug treatment [1–4].
**Objectives:** To evaluate the efficacy of 12-month complex rehabilitation program in patients with RA receiving biologic DMARDs.
**Methods:** 64 patients with RA (87,5% females, age of 19 to 62 years, disease duration of 9 months to 10 years) were included and randomized into 2 groups. All patients received biologic DMARDs (adalimumab subcutaneously 40 mg once every 2 weeks or etanercept subcutaneously 50 mg per week or abatacept intravenously 750 mg once every 4 weeks) with methotrexate 20–25 mg per week. 34 study group patients underwent 12-month complex rehabilitation program: 15-min local air cryotherapy (–60°C, Criojet Air C600) for joints, 2 courses for 10 sessions with a mean interval of 6,4 months; 45-min therapeutic exercises 3 times a week, at first under the supervision of a trainer, further own at home; 45-min occupational therapy (joint protection strategies, use of assistive devices and adaptive equipment), 10 sessions; wrist and knee orthoses, orthopedic insoles; education program (4 daily 90-min studies). 30 patients received only drug therapy (control). Tender and swollen joint count, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), joint pain on 100-mm VAS, DAS28, HAQ, RAPID3, hand grip strength, the average powers of knee extension and ankle flexion by EN-TreeM movement analysis were evaluated at baseline and at 12 months.
**Results:** 27 patients finished 12-month rehabilitation program. 7 patients did not complete the study, because they had a low compliance to home-based exercises. After 12 months in the study group tender joint count decreased by 83,7% ($p<0,01$), swollen joint count – by 81,6% ($p<0,01$), ESR – by 72,3% ($p<0,01$), CRP – by 68,3% ($p<0,01$), pain on VAS – by 80,4% ($p<0,01$), DAS28 – by 44,7% ($\Delta$DAS28=2,25±0,79, $p<0,05$), HAQ – by 73,8% ($\Delta$HAQ=1,39±0,56, $p<0,01$), RAPID3 – by 65,1% ($\Delta$RAPID3=6,23±1,73, $p<0,01$). The grip strength of a more affected hand enhanced by 48,6% ($p<0,01$), of a less affected – by 36,5% ($p<0,05$). The average extension power of a weaker knee increased by 87,3% ($p<0,01$), of a stronger – by 70,5% ($p<0,01$). The average flexion power of a more affected ankle joint elevated by 79,3% ($p<0,01$), of a less affected – by 74,7% ($p<0,01$). In the study group there were statistically significant differences from the control group in the most parameters ($p<0,05$), excluding CRP and DAS28 ($p>0,05$). After 12 months in the study group there was significantly more frequently a good response to treatment according to the EULAR criteria (DAS28) (92,6% vs 70,0% in the control group, $p<0,05$).
**Conclusions:** 12-month complex rehabilitation improves functional ability, motion activity and quality of life, relieves pain and helps to control disease activity in biologic DMARD-treated RA patients.

## SAT0618 EFFICACY OF TWO LONG-TERM EXERCISE PROGRAMS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: RESULTS OF 12-MONTH RANDOMIZED CONTROLLED TRIAL

E. Orlova[1], D. Karateev[2], L. Denisov[1], A. Kochetkov[3], E. Nasonov[4]. *[1]Laboratory of Clinical Trials; [2]Early Arthritis department, V.A. Nasonova Research Institute of Rheumatology; [3]Central Rehabilitation Hospital, Federal Medical Biological Agency; [4]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** International recommendations and results of randomized controlled trials consider physical exercises, aiming to improve range of motion, aerobic capacity and muscle strength, as an important part of treating rheumatoid arthritis (RA) [1–3].
**Objectives:** To compare the efficacy of two 12-month exercise programs in patients with early RA.
**Methods:** 51 patients with early RA (92,2% females, age of 18 to 53 years, disease duration of 2 to 17 months) were randomized into 3 groups. All patients received methotrexate or leflunomide. At hospital stage 15 patients underwent 10 high-intensity dynamic exercises using gym apparatus Enraf-Nonius with biofeedback for 45–60 min, including aerobic part (En-Cardio) and 18–20 muscle-strengthening exercises (En-Dynamic Track), 18 patients – 10 therapeutic exercises for joints for 45 min under the supervision of a trainer. At outpatient stage the exercises lasted for 12 months 3 times a week. 18 patients received only drug therapy (control). Tender and swollen joint count, pain on 100-mm VAS, erythrocyte sedimentation rate (ESR), DAS28, HAQ, RAPID3, the average powers of knee extension and ankle flexion by EN-TreeM movement analysis were evaluated at baseline and at 12 months.
**Results:** After 12 months in the both exercise groups there were statistically significant differences from the control group in most parameters ($p<0,05$), excluding ESR and DAS28 ($p>0,05$). Efficacy of the gym exercises was higher

**Abstract SAT0618** – Table 1

| Parameters | Baseline | | | 12 months | | |
|---|---|---|---|---|---|---|
| | Gym | Therapeutic exercises | Control | Gym | Therapeutic exercises | Control |
| Tender joint count | 7.9±3.1 | 7.6±2.5 | 7.8±2.4 | 1.3±0.6*#§ | 2.1±1.2*# | 3.3±1.5* |
| Swollen joint count | 4.8±2.8 | 4.5±1.9 | 4.9±2.5 | 0.9±0.3*# | 1.3±0.7*# | 2.4±1.5* |
| ESR, mm/h | 21.9±14.2 | 23.4±17.6 | 22.3±14.9 | 8.4±2.6* | 7.7±2.1* | 9.1±4.7* |
| Pain on VAS, mm | 60.5±21.3 | 62.4±18.3 | 59.7±14.6 | 10.5±8.3*#§ | 18.1±11.5*# | 27.2±16.1* |
| DAS28 | 4.13±1.28 | 4.32±1.53 | 4.49±1.42 | 2.64±1.16* | 2.79±1.62* | 3.18±1.31* |
| HAQ | 1.35±0.63 | 1.38±0.34 | 1.30±0.83 | 0.37±0.15*# | 0.45±0.21*# | 0.98±0.54* |

| Extension power of a weaker knee joint, W | 4.54±2.58 | 3.99±3.11 | 4.27±1.13 | 9.97±4.34*#§ | 7.74±3.56*# | 5.72±2.17* |
| Flexion power of a weaker ankle joint, W | 0.39±0.15 | 0.44±0.21 | 0.41±0.22 | 0.79±0.26*# | 0.70±0.35*# | 0.56±0.24* |

*significance of differences from baseline, #significance of differences from control, §significance of differences between two exercise groups, $p<0.05$.

than the therapeutic exercises by tender joint count, pain on VAS, RAPID3 and extension power of a weaker knee joint ($p<0,05$).
Adherence to the regular therapeutic exercises for 12 months was better (72,2%) then to the gym exercises (53,3%). Predictors of the regular gym exercises were the young age (under 40 years) and the very early stage of RA at the onset of the study. Patients of the both exercise groups, who regularly did exercises during 12 months, had DAS28 low disease activity or remission.
**Conclusions:** The both long-term exercise programs reduce pain, increase functional status, quality of life and power of motion in early RA patients without negative effect on disease activity.

## SAT0619 RELATIONSHIP BETWEEN HAQ DISABILITY SCORES AND MEASURES OF OBSERVED FUNCTIONAL ABILITY IN PATENTS WITH RHEUMATOID ARTHRITIS, OSTEARTHRITIS AND FIBROMYALGIA AND THE ASSOCIATION TO PAIN AND FATIGUE

K. Amris, L.E. Kristensen, E.E. Wæhrens. *The Parker Institute, Copenhagen University Hospital Bispebjerg and Frederiksberg, Frederiksberg, Denmark*

**Background:** Functional ability, which includes the ability to perform activities of daily living (ADL), is considered a core outcome domain in rheumatology. Recommendations for assessing ADL ability include the use of generic and diseases-specific questionnaires based on self-report and one of the most frequently used instruments is the Health Assessment Questionnaire Disability Index (HAQ-DI). Self-report reflects the person's perception of extent of disability, which may be influenced by pain and other psychosocial factors. A poor agreement between self-reported and observed ADL ability has previously been demonstrated in rheumatic populations based on other self-report instruments.
**Objectives:** to evaluate relationships between HAQ-DI scores and measures of observed ADL ability in patients with inflammatory and non-inflammatory rheumatic diseases and the association between pain and fatigue and these disability measures.
**Methods:** patients with rheumatoid arthritis (RA), knee osteoarthritis (OA) and fibromyalgia (FM) were assessed with the HAQ-DI. The Assessment of Motor and Process Skills (AMPS) was used to obtain measures of observed ADL ability. Two domains of observed ADL ability were evaluated: ADL motor skills (moving self and objects) and ADL process skills (organizing and adapting actions). Pain and fatigue were assessed by 100mm visual analogue scales (VAS). The project was approved by the local ethical committee (H-B-2007–084).
**Results:** 143 women (50 with RA, 27 with knee OA, 66 with FM), mean age 51.2 (11.8) participated. Baseline characteristics and correlations are presented in table 1. Patients with FM had the highest pain, fatigue, and HAQ disability scores and the poorest performance on the AMPS. The relationships between self-reported and observed ADL motor ability were weak to moderate across all diagnostic groups; strongest in patients with knee OA. Relationships with the AMPS ADL process ability measure were weak to insignificant. Level of pain, and not fatigue, showed the strongest relationship with self-reported functional ability across all diagnostic groups. A weak to moderate relationship between pain and AMPS ADL motor ability measures were also present in patients with RA and OA, but insignificant in patients with FM (r= -0.16, p=0.195).

Table 1

| Demographics | All (n = 143) | RA (n=50) | OA (n= 27) | FM (n=66) |
|---|---|---|---|---|
| Age (y) | 51.2 (11.8) | 54.1 (12.3) | 58.6 (7.5) | 48.2 (10.6) |
| HAQ-DI | 1.08 (0.60) | 1.02 (0.62) | 0.86 (0.61) | 1.22 (0.55) |
| VAS Pain (mm) | 52.6 (27.57) | 56.65 (25.55) | 45.00 (22.76) | 67.45 (22.74) |
| VAS Fatigue (mm) | 63.74 (29.26) | 51.45 (28.10) | 49.58 (25.51) | 78.45 (18.94) |
| AMPS ADL motor | 1.26 (0.46) | 1.40 (0.40) | 1.43 (0.49) | 1.08 (0.48) |
| AMPS ADL process | 1.11 (0.26) | 1.20 (0.17) | 1.05 (0.24) | 1.08 (0.24) |

| Correlations | | AMPS ADL Motor | | AMPS ADL Process | | HAQ-DI | |
|---|---|---|---|---|---|---|---|
| | Groups | r | p | r | p | r | P |
| HAQ-DI | All (n = 143) | -0.49 | 0.000 | -0.20 | 0.020 | | |
| | RA (n = 50) | -0.47 | 0.001 | -0.22 | 0.133 | | |
| | OA (n = 27) | -0.54 | 0.004 | -0.35 | 0.076 | | |
| | FM (n = 66) | -0.44 | 0.000 | -0.25 | 0.232 | | |
| VAS Pain | All (n = 143) | -0.42 | 0.000 | -0.24 | 0.004 | 0.55 | 0.000 |
| | RA (n = 49) | -0.31 | 0.033 | -0.24 | 0.091 | 0.60 | 0.000 |
| | OA (n = 27) | -0.53 | 0.006 | -0.31 | 0.119 | 0.62 | 0.001 |
| | FM (n = 66) | -0.16 | 0.195 | -0.20 | 0.103 | 0.40 | 0.001 |
| VAS Fatigue | All (n = 143) | -0.28 | 0.001 | -0.20 | 0.016 | 0.38 | 0.000 |
| | RA (n = 48) | -0.11 | 0.459 | -0.21 | 0.148 | 0.26 | 0.076 |
| | OA (n = 27) | -0.37 | 0.065 | -0.37 | 0.100 | 0.48 | 0.014 |
| | FM (n = 66) | -0.04 | 0.760 | -0.25 | 0.046 | 0.31 | 0.013 |

**Conclusions:** the relation between self-reported and observed functional ability is low across a spectrum of musculoskeletal diagnoses, even when using instruments recommended for these populations including the HAQ-DI. This has major implications on how to interpret and measure functional ability in the future as both methods should probably accompany each other. Interestingly pain was not associated with observed motor ADL ability in FM as opposed to RA and OA.

## SAT0620 VALIDATION OF THE DUTCH-FLEMISH PROMIS FATIGUE ITEM BANK IN PATIENTS WITH RHEUMATOID ARTHRITIS

M.H. Crins[1], C.B. Terwee[2], R. Westhovens[3,4], D. van Schaardenburg[5], N. Smits[6], J. Joly[3,4], P. Verschueren[3,4], K. van der Elst[3,4], D. Cella[7], K.F. Cook[7], J. Dekker[8,9], M. Boers[2,10], L.D. Roorda[1]. *[1]Amsterdam Rehabilitation Research Center, Reade; [2]Department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands; [3]Department of Development and Regeneration, KU Leuven; [4]Rheumatology, University Hospitals Leuven, Leuven, Belgium; [5]Amsterdam Rheumatology and immunology Center, locations Reade and Academic Medical Center; [6]Research Institute of Child Development and Education, University of Amsterdam, Amsterdam, Netherlands; [7]Department of Medical Social Sciences, Northwestern University Feinberg School of Medicine, Chicago, United States; [8]Department of Rehabilitation Medicine; [9]Department of Psychiatry, VU University Medical Center; [10]Amsterdam Rheumatology & Immunology Center, locations Reade and VU University Medical Center, Amsterdam, Netherlands*

**Background:** In the assessment of patients with rheumatoid arthritis (RA) it is important to measure fatigue. The National Institutes of Health's Patient-Reported Outcomes Measurement Information System (PROMIS) initiative developed an item bank for measuring fatigue. This item bank was translated into Dutch-Flemish language according to the FACIT methodology.
**Objectives:** The aim of current study was to validate the Dutch-Flemish translation of the PROMIS Fatigue item bank (DF-PROMIS-Fatigue) in Dutch and Flemish RA patients. This is the first validation study of the PROMIS Fatigue item bank in RA patients.
**Methods:** 2030 RA patients (1370 Dutch and 660 Flemish RA patients) completed a paper-and-pencil or web-based survey, including the full DF-PROMIS-Fatigue (95 items, 5-point Likert scale). One-factor confirmatory factor analysis assessed unidimensionality. Item response theory (IRT) models evaluated the item characteristics of the item bank, to facilitate future development of a computer adaptive test (CAT). A graded item response model (GRM) was fitted and construct validity was studied. Ordinal regression models evaluated Differential Item Functioning (DIF) for e.g. language (Dutch-Flemish vs. English and Dutch vs. Flemish), to analyse cross-cultural validity.
**Results:** The analyses support unidimensionality of the DF-PROMIS-Fatigue (CFI=0.996 and TLI=0.996). Only 45 out of 4465 (1%) item pairs were marked as possibly locally dependent. The data of the item bank fit the GRM, and showed good coverage across the fatigue continuum (threshold-parameters ranged from -3.8 to 5.8). The item bank showed good cross-cultural validity: none of the DF-PROMIS-Fatigue items showed DIF between Dutch and Flemish language. Furthermore, the item bank showed good reliability (Cronbach's alpha=0.993). Analyses of construct validity are in progress and will be presented at the conference.
**Conclusions:** The results indicate that the items of the DF-PROMIS-Fatigue fit a GRM. The DF-PROMIS-Fatigue can be used to develop a CAT for measuring fatigue in Dutch and Flemish RA patients.

## SAT0621 EFFECT OF AN EXERCISE THERAPY ON SYSTEMIC BIOMARKERS FOR CARTILAGE METABOLISM

M. Azukizawa[1], H. Ito[1], T. Yasuda[1,2], M. Furu[1,3], Y. Hamamoto[1], T. Fujii[1], Y. Morita[1], A. Okahata[1], K. Masamoto[1], S. Matsuda[1]. *[1]Department of Orthopaedic Surgery, Graduate school of Medicine, Kyoto University, Kyoto; [2]Department of Orthopaedic Surgery, Kobe City Medical Center General Hospital, Hyogo; [3]Department of the Control for Rheumatic Diseases, Graduate school of Medicine, Kyoto University, Kyoto, Japan*

**Background:** The number of osteoarthritis (OA) patients is increasing year by year because of the aging society. Especially, knee OA is reported to reduce the health life expectancy. The majority of patients are at the early stage of knee OA and are adapted to conservative treatments such as exercise therapy. A lot of biomarkers for cartilage metabolism were previously reported. However, there are few reports that exercise therapy has an effect on the biomarkers related for cartilage metabolism.
**Objectives:** To investigate the effect of an exercise therapy on cartilage metabolism using biomarkers.
**Methods:** Thirty-eight females (mean age: 59 years) participated in this study. All participants started a weekly exercise and continued it for twelve weeks. Before and after the exercise program, we measured their physical activities; Timed Up and Go test (TUG) and Three Minutes Walking test (3MW). Since the program started, we have collected serum and urine samples from the participants at the start of the program (0 week), at the end of it (12 weeks) and 12 weeks after it (24 weeks). For the collected samples, we measured the following two anabolic and

one catabolic biomarkers; serum cartilage type II procollagen carboxy propeptide (sPIICP), serum cartilage oligomeric matrix protein (sCOMP), urine C-terminal telopeptide of collagen type II (uCTX-II). These biomarkers were measured with the enzyme-linked immunosorbent assay method.
**Results:** After the twelve weeks exercise program, both TUG and 3MW were significantly improved ($P < 0.01$ each, respectively) (Fig. A, B). sCOMP concentrations at 12 weeks were relatively greater than those at 0 week. However, sCOMP concentrations at 24 weeks were significantly greater than those at 12 weeks ($P < 0.01$) (Fig. C). In contrast, uCTX-II concentrations at 24 weeks were significantly less than those at 0 week ($P < 0.01$) (Fig. D). There was no significant difference between pre- and post-excise sPIICP concentrations.

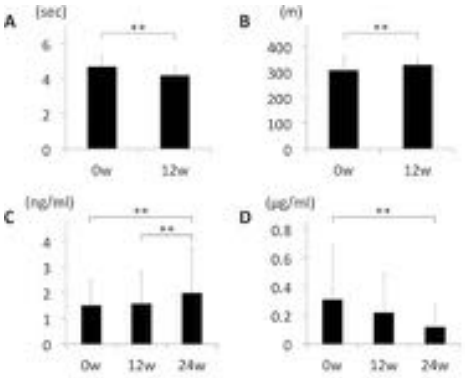

**Fig. A.** Timed Up and Go test. **B.** Three Minutes Walking test. **C.** Changes of serum cartilage oligomeric matrix protein concentrations. **D.** Changes of urine C-terminal telopeptide of collagen type II concentrations.
**: $P < 0.01$

**Conclusions:** These results suggest that an exercise therapy will improve physical activities and that this therapy could influence both cartilage anabolic and catabolic biomarkers.

## SAT0622 CO-CREATING AN ONLINE REHABILITATION PROGRAMME FOR PEOPLE WITH CHRONIC KNEE/HIP PAIN

M. Hurley[1,2], J. Pearson[3], N. Walsh[3], D. Carter[2]. *[1]St George's University of London, London; [2]Health Innovation Network, South London; [3]UWE, Bristol, United Kingdom*

**Background:** Chronic knee and hip pain is very prevalent, causes disability and reduces mobility. Evidence-based guidelines recommend exercise and self-management. *Enabling Self-management and Coping of Arthritic Pain through Exercise, ESCAPE-pain* (www.escape-pain.org), is a rehabilitation programme that integrates self-management advice with exercise that reduces pain, improves physical and psychosocial function and well-being[1]. It is usually delivered as face-to-face programmes in clinical departments. Unfortunately this limits its "reach" so few people benefit. An online version could reach many more people. However, online programmes developed without input from potential users often produce unwanted, unusable, "high tech, low impact" and ineffective programmes with poor uptake.
**Objectives:** We asked potential users what they considered were the important features of the content and design of an online *ESCAPE-pain* programme to maximise its uptake and effectiveness.
**Methods:** The opinions and preferences 24 people with chronic knee/hip pain as potential users of an online *ESCAPE-pain* programme were gathered to co-design a prototype website. From those 24 participants a further of 8 people were purposively selected to participate in semi-structured "think aloud" evaluations of the prototype website, commenting on its content, aesthetics, quality, verbalising their thoughts, difficulties, (dis)likes and suggestions.
Their opinions and preferences were thematically analysed, then aligned to the behavioural change techniques taxonomy (BCTT)[2] to see how the *ESCAPE-pain* online programme supported people to change their behaviour.
**Results:** PParticipants had many different opinions and preferences, often mutually exclusive, about the content and format of the online programme. They wanted a simple, easy to navigate, engaging online resource, which was succinct, unambiguous, jargon free, and tailored to each person's needs (BCTT 4.Shaping knowledge; 5.Natural consequences). Descriptive videos of older people exercising were enthusiastically welcomed (BCTT 4.Shaping knowledge; 5.Natural consequences; 7.1Associations – cues and prompts). Entering pertinent information about exercise (number of repetitions, time) to enable people to chart and monitor progress was important (BCTT 2.Feedback/monitoring). Some people wanted to share this information with others and receive feedback to get a comparative overview of their situation and progression (BCTT 2.Feedback/monitoring; 3.Social support; 6.Comparison of behaviour). Support from peers and healthcare professionals (BCTT 3. Social support) via blogs/forums was popular with some, but not all participants. Endorsement by trusted, non-commercial organisations or healthcare professionals was strongly advocated (BCTT 9.Comparisons of outcomes - credible sources). Commercially-backed websites were treated with suspicion.
**Conclusions:** People with chronic knee and hip pain helped us co-create an online version of the *ESCAPE-pain* programme which incorporates well recognised behavioural change techniques. It will be available as a mobile website and smartphone app from March 2016, enabling many more people to access and benefit from the *ESCAPE-pain* programme.

## SAT0623 THE ROLE OF REHABILITATION IN AVASCULAR NECROSIS OF THE HUMERAL HEAD – RANDOMIZED STUDY

R. Traistaru[1], A.M. Bumbea[1], D. Kamal[1], C. Kamal[2], O. Rogoveanu[1]. *[1]Rehabilitation Department; [2]University of Medicine and Pharmacy of Craiova, Craiova, Romania*

**Background:** Avascular necrosis of the humeral head (AVNHH), a pathologic process with multifactorial etiology that results from interruption of blood supply to the bone, leading to the collapse of humeral head that requires shoulder hemiarthroplasty, is the second most common site of this disorder behind the femoral head. Trauma is a common cause, but atraumatic necrosis has developed for patient with risk factors. The successful treatment is related directly to the stage of disease at diagnosis. Early detection and conservative treatment with physical therapy, modification of activity, kinetic program and analgesics is the key to best management.
**Objectives:** The objectives of our study (a single blind, randomized controlled trial) were: to establish the risk factors associated with disease and to evaluate the effect of rehabilitation program on clinical and functional parameters and to assess the short-term effects of this program on quality of life of patients with AVNHH.
**Methods:** 12 patients aged between 35 - 45 years with AVNHH stage I and II (precollapse stages), were randomized into two groups: Group 1 – 7 patients (G1) was treated by complex therapy (medication, stretching and strengthening exercises, ultrasound and interferential current), and group 2 – 5 patients (G2) control receiving only medication. The duration of rehabilitation program was 4 weeks. All patients were evaluated initial and finally. The outcome assessments at the beginning and at the end of the rehabilitation were pain intensity (with dolorimeter), active range of shoulder movements and HAQ score.
**Results:** The AVNHH is associated with shoulder traumatic conditions (5 patients) and the mentioned risk factors were corticosteroid administration (10 patients), heavy alcohol intake (4 patients), rheumatoid arthritis (3 patients).
In both groups, improvements were found in pain intensity (65% in G1 and 35% in G 2, respectively) and this reduction was significantly higher in G1. The mean value of range of shoulder movements (flexion, abduction, rotations) and HAQ score showed significant improvements in G1 group.
**Conclusions:** Our study confirms the literature data that rehabilitation program can be very effective in treating AVNHH if it is detected early. Maintaining range of motion and muscle strength are crucial to avoid further humeral head collapse and improvement in pain scores and upper limb function.
**Disclosure of Interest:** None declared

## SAT0624 EFFICACY OF A 4-WEEK TEAM-REHABILITATION PROGRAM IN WARM CLIMATE ON DISABILITY, HEALTH AND BODY FUNCTION FOR UP TO ONE YEAR: A PROSPECTIVE STUDY IN SWEDISH PATIENTS WITH INFLAMMATORY JOINT DISEASES

S. Ajeganova, M. Wörnert, I. Hafström. *Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden*

**Background:** The need of team-rehabilitation for patients with chronic arthritis in the era of biologics has been questioned.
**Objectives:** We evaluated the short and long-term patient-oriented effects of rehabilitation program in warm climate in patients with inflammatory joint diseases who had inadequate response to physiotherapy in Sweden. We further questioned if patient-reported responses were influenced by demographic, disease factors and level of physical activity.
**Methods:** In all, 161 patients with peripheral arthritis and spondyloarthritis, mean age 53 years (range 21 to 77), 73% women, 51% with comorbid condition, 49% treated with synthetic DMARDs and 63% with biologics, who experienced activity limitations and reduced quality of life despite physiotherapy in Sweden, received structured team-rehabilitation during 4 weeks in warm climate. The change in outcomes (variables of the International Classification of Functioning, Disability and Health) pre- and post-rehabilitation and after 3 and 12 months was assessed: HAQ (in patients with peripheral arthritis), BASFI (in patients with spondyloarthritis), EQ-5D, VAS of patient reported general health (VAS-GH) and

pain (VAS-pain). The International Physical Activity Questionnaire (IPAQ) was used to assess the level of physical activity.
**Results:** At inclusion patients reported activity limitations, HAQ mean (SD) 1.13 (0.55), and reduced quality of life, EQ-5D median (IQR) 0.66 (0.52–0.73). HAQ, VAS-GH and VAS-pain improved significantly from pre-rehabilitation to all follow-up time-points, and BASFI and EQ-5D from pre-rehabilitation up to 3 months. At the 3 and 12 months the proportion of patients reporting improvement from baseline above minimal clinically important difference (MCID) was for HAQ 62% and 35%, BASFI 73% and 61%, EQ-5D 47% and 39%, VAS-GH 68% and 52%, for VAS-pain 68% and 51%, respectively. The improvement in HAQ and VAS scores was not dependent on demographic or disease-related variables, while improvement in BASFI was hampered in older patients and improvement EQ-5D was lower in patients with comorbidity. The gained effect was not affected by changes in treatments as confirmatory analyses on patients without changed medication or unexpected clinical events yielded stable results across all outcomes.
Physical activity increased significantly from pre-rehabilitation to 12 months, $p<0.001$. Increased IPAQ correlated with improvement in EQ-5D ($r=0.20$, $p=0.040$) and trendwise with reduction in VAS-pain and HAQ ($r=0.18$, $p=0.059$; $r=0.19$, $p=0.086$).
**Conclusions:** Comprehensive team-rehabilitation in warm climate is still important for the patients treated up-to-date, benefits functional ability and quality of life. The benefit of the intervention was evident post-rehabilitation and in many patients sustained for up to one year. The improvements in HAQ, VAS general health and VAS pain 3-month post-rehabilitation were comparable with improvements reported in recent randomized clinical trials of biologicals in RA. The health advantages of the rehabilitation program were combined with increased health-enhancing physical activity.

## SAT0625 CHALLENGES OF DISEASE-RELATED COMMUNICATION IN THE DAILY LIVES OF PERSONS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES. RESULTS OF A PARTICIPATORY RESEARCH PROJECT

W. Mau[1], J. Lamprecht[1], A.C. Schöpf[2], M. Schlöffel[2], E. Farin-Glattacker[2], A. Thyrolf[1]. *[1]Institute for Rehabilitation Medicine, Martin-Luther-University Halle-Wittenberg, Germany, Halle; [2]Institute for Quality Management and Social Medicine, Medical Center – University of Freiburg, Freiburg, Germany*

**Background:** At least every ninth person with rheumatic and musculoskeletal diseases (RMDs) reports severe limitations of social participation due to multiple health problems and reduced resources [1]. Reduced participation is frequently associated with social interactions and communication around the subject of disease-related problems [2]. These conversations may be necessary for the patients in order to follow their interests or reach certain goals. If the patients experience difficulties in these situations, low communication skills may be significant barriers to social participation.
**Objectives:** To identify significant factors of disease-related everyday communication of persons with RMDs in a nationwide project funded by the Deutsche Rheumaliga Bundesverband e.V. (DRL). Based on the results, a training to enhance the communication skills of persons with RMDs in various situations significant for social participation will be developed.
**Methods:** An online questionnaire addressing context, content, difficulties, and burden of the disease-related everyday communication was answered by 1.015 persons with RMDs (87% females, mean age 55 (SD 12) years, mean disease duration 16 (SD 12) years). Communication skills were recorded by the short version of the Insecurity Questionnaire [3]. In this participatory research project four persons with RMDs are involved throughout the project.
**Results:** More than half of the participants report difficulties in disease-related conversations across various situations. The majority of these persons suffer from this experience as a burden particularly in conversations at the work place or in civil services. Compared to men, women report difficulties more frequently in the private environment and with representatives of public authorities and they feel a higher burden due to difficult conversations in all situations. In comparison with population samples the communication skills of persons with RMDs are lower with higher scores of the scales “fear-of-failure/criticism”, “fear-of-contact”, and “inability-to-say no” of the Insecurity Questionnaire.
**Conclusions:** The project offers new insight into the disease-related communication of persons with RMDs. The subsequent training (“KOKOS-Rheuma”) will include difficult and strenuous conversations especially at the work place or in civil services. Persons with RMDs will be given exercises for typical situations that require saying no, adequate arguing, and giving feedback in order to reduce fear of failure and criticism.

## SAT0626 LOCAL CRYOTHERAPY (PULSED CO2 OR ICE) DECREASES IL-6, IL-1β AND VEGF SYNOVIAL LEVELS IN KNEE ARTHRITIS

X. Guillot[1,2], N. Tordi[2], C. Laheurte[3], L. Pazart[4], C. Prati[2], P. Saas[3], D. Wendling[1]. *[1]Rheumatology department, Besançon University Hospital, Besançon; [2]FDE EA4267, FHU INCREASE, Bourgogne Franche-Comté University, Besançon; [3]INSERM U1098, Biomonitoring Platform, EFS Bourgogne-Franche-Comté; [4]INSERM-CIC 1431, Besançon University Hospital, Besançon, France*

**Background:** Cryotherapy is widely and empirically used in an adjuvant and symptomatic setting in inflammatory rheumatic diseases, with a low level of evidence.
**Objectives:** The aim of this work was to evaluate the effects of two local cryotherapy (LC) techniques (ice or hyperbaric cold CO2) applied twice on pain and pro-inflammatory cytokine levels in arthritic knees.
**Methods:** Thirty-five patients suffering from non-septic knee arthritis were included (16 gouts, 8 calcium pyrophosphate dehydrate crystal deposition diseases, 5 spondyloarthritides, 6 rheumatoid arthritides). Patients didn’t receive any concurrent anti-inflammatory drug (corticosteroids, NSAIDs, colchicine, DMARDs, biologics) throughout the study period (24 hours). They were randomized to receive local ice (for 30 minutes) or cold pulsed CO2 (for 2 minutes - Cryo+® Cryonic) at 9 A.M and 5 P.M. Synovial fluid was collected just before the first cold application then 24 hours later (also at 9 A.M). Synovial fluid cell count and cytokine levels (IL-6, IL-1β, TNF-α, IL-17A, VEGF by Multiplex flow cytometry – CBA® BD biosciences) were measured and compared before and after the two LC applications. Paired Wilcoxon tests were performed. The factors associated with cytokine level evolution were assessed (uni- then multivariate analysis by logistic regression).
**Results:** Pain VAS significantly decreased after 24 hours in both treatment groups (Ice: 5.3±1.3 versus 2.7±1; n=20;p=0.0003 – CO2: 5.6±1.4 versus 3.1±1.2; n=15;p=0.002). Synovial fluid leukocyte count non-significantly decreased (23580±10015 versus 19120±8981; p=0.49). IL-6 levels significantly decreased after 2 LC applications 456100±163570pg/mL versus 281500±142006pg/mL; n=35; p=0.0001). This decrease was also significant in ice-treated subgroup (n=20; p=0.0002) but not in CO2-treated patients (n=15; p=0.07). In multivariate analysis, IL-6 decrease was associated with a higher CRP rate at baseline (r=0.35; p=0.004) and a greater skin temperature drop during LC (r=0.33; p=0.03). IL-1β levels also decreased after treatment (26.75±8.95pg/mL versus 23.10±10.11pg/mL; n=35; p=0.02) but the difference didn’t reach significance in treatment subgroups (Ice: n=19; p=0.07 – CO2: n=15; p=0.15). In multivariate analysis, IL-1β decrease was associated with “ice” modality (r=3.25; p=0.03) and negatively associated with BMI (r=-4.02; p=0.04). VEGF levels also decreased globally (1391±295pg/mL versus 1263±281pg/mL; n=34; p=0.03) but not significantly in subgroups (Ice: n=19; p=0.2 – CO2: n=15; p=0.07). IL-17A rates also tended to decrease (16.3±15.75pg/mL versus 14.95±15.2pg/mL; n=35; p=0.065). TNF-α levels tended to decrease in CO2 group (n=15; p=0.08).
**Conclusions:** LC (ice or pulsed CO2) applied twice during one day showed anti-inflammatory effects by reducing synovial IL-6, IL-1β and VEGF levels in arthritic knees. Both techniques equally reduced pain but sample sizes were still insufficient to show any difference in terms of local cytokine level reduction.

### AB0001 GENETIC VARIANTS IN IL-12B AND IL-27 IN THE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Paradowska-Gorycka[1], A. Sowinska[2], B. Stypinska[1], M. Grobelna[3], M. Walczyk[4], M. Olesinska[4], P. Piotrowski[5], P.P. Jagodzinski[3]. *[1]Department of Biochemistry and Molecular Biology, National Institute of Geriatrics, Rheumatology and rehabilitation, Warsaw; [2]Department of Computer Science and Statistics; [3]Department of Biochemistry and Molecular Biology, Poznan University of Medical Sciences, Poznan; [4]Department of Connective Tissue Diseases, National Institute of Geriatrics, Rheumatology and rehabilitation; [5]Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland*

**Background:** Type-1 immunity plays a fundamental pathogenic role in various diseases including systemic lupus erythematosus (SLE), which is a multisystem autoimmune disorder with heterogeneity in clinical manifestations and disease course. Although the etiology and pathogenic mechanisms of SLE remains elusive, the actual state of knowledge allow diagnose that genetic information is important for understanding the mechanisms of the disorder. In this respect several studies support that gene encoding cytokines, which regulate CD4+T cells differentiation, are attractive genetic factors that may predispose to susceptibility and severity of SLE
**Objectives:** To investigate the potential association between *IL-12B* and *IL-27* gene polymorphisms and SLE, we performed a case-control study based on Polish population.
**Methods:** SLE patients and healthy individuals, were examined for -6415 CTCTAA/GC (rs17860508) and +1188A/C (rs3212227) in *IL-12B* and -924A/G (rs153109) and 4730T/C (rs181206) in *IL-27* gene polymorphisms using the HRM method, PCR–RFLP method and TaqMan SNP genotyping assay, respectively.
**Results:** An increased frequency of GC/GC genotype as well as GC allele of the IL-12B rs17860508 was found in patients with SLE, as compared with healthy subjects ($p<0.001$). We did not find differences in genotype and allele frequencies of the *IL-12B* rs3212227 and IL-27 rs153109 and rs181206 variants between SLE patients and controls. *IL-27* haplotype CG indicated higher risk for SLE (P=0.002), whereas haplotype TG indicated reduced risk for SLE (p=0.005). The *IL-12B* rs3212227 A/C polymorphism was associated with the mean value of the platelets, urea and complement C3 level. Furthermore *IL-12B* rs17860508 genetic variant showed correlation with platelets, prothrombin time, international normalized ratio and alkaline phosphatase.
**Conclusions:** Our results revealed that *IL-12B* rs17860508 as well as *IL-27* haplotype CG are genetic risk factors for SLE and that both *IL-12B* rs17860508 and rs3212227 predict disease phenotype.

### AB0002 GENETIC VARIANTS IN IL-17F, IL-23 AND IL-23R IN THE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Paradowska-Gorycka[1], A. Sowinska[2], B. Stypinska[1], M. Grobelna[3], M. Walczyk[4], M. Olesinska[4], P. Piotrowski[5], P.P. Jagodzinski[3]. *[1]Department of Biochemistry and Molecular Biology, National Institute of Geriatrics, Rheumatology and rehabilitation, Warsaw; [2]Department of Computer Science and Statistics; [3]Department of Biochemistry and Molecular Biology, Poznan University of Medical Sciences, Poznan; [4]Department of Connective Tissue Diseases, National Institute of Geriatrics, Rheumatology and rehabilitation; [5]Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland*

**Background:** Systemic lupus erythematosus (SLE) is a severe multi-system autoimmune disease characterized by uncontrolled autoantibody formation, excessive proinflammatory cytokine production, tissue inflammation and damage to multiple organ systems. The IL-23-IL-17 axis, rather than the loop of IL-12 and IFN-c, have a central role in the autoimmune inflammation, and interaction between IL-23 and IL-17 is not only essential for the onset phase, but also for the destruction phase of SLE characterized by the T cell-mediated activation of osteoclastogenesis.
**Objectives:** To investigate the potential association between IL-17F, IL-23 and IL-23R gene polymorphisms and SLE, we performed a case-control study based on Polish population.
**Methods:** SLE patients and healthy individuals, were examined for *IL-23A* 703 G/A (rs11171806) and *IL-23R* (rs1884444 G/T, rs10489629 G/A) by TaqMan SNP genotyping assay, and for *IL-17F* 7488A/ G (rs763780) and 7383A /G (rs2397084) gene polymorphisms using the PCR– RFLP method.
**Results:** An increased frequency of AG genotype as well as G allele of the IL-17F 7488 A/G (rs763780) was found in patients with SLE, as compared with healthy subjects (p=0.0007 and p=0.0012, respectively). Frequencies of the rs1884444 TT genotype and the rs1884444 T allele were also higher in SLE patients (both $p<0.0001$). Overall, very weak LD was observed between the *IL-17F* 7488A/ G (rs763780) and 7383A /G (rs2397084) polymorphisms (D'-0.003, r2 – 0.000). From four possible haplotypes, frequencies of one (AG) showed significant differences between both examined groups ($p<0.0001$). Moreover, we also observed a weak LD between the *IL-23R* rs10489629G/A and rs1884444 G/T (D'-0.199, r2 – 0.026). The genotype-phenotype analysis showed significant association between the IL-17F 7383 A/G (rs2397084) and mean value of the hemoglobin (p=0.01), between the IL-17F 7488 A/G (rs763780) and age (p=0.008) and lupus anticoagulant (p=0.09), between the IL-23 703 G/A (rs11171806) and urea (p=0.08) and C3 complement (p=0.03), and between the IL-23R rs1884444 G/T and activated partial thromboplastin time (p=0.06).
**Conclusions:** Present findings indicated that IL-17F 7488 A/G (rs763780) and IL-23R rs1884444 G/T polymorphisms may be involved in susceptibility to SLE in the Polish population.

### AB0003 IL-23R AND IL-17A POLYMORPHISMS CORRELATE WITH SUSCEPTIBILITY OF ANKYLOSING SPONDYLITIS IN CHINESE HAN POPULATION

B. Yang, J. Chen, L. Wang. *Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China*

**Background:** The association between the IL-23R and IL-17A polymorphisms and ankylosing spondylitis (AS) in a Chinese Han population is still unclear.
**Objectives:** The purpose of this study is to detect the association between IL-23R and IL-17A polymorphisms and AS.
**Methods:** A case–control study consisting of 486 AS patients and 480 healthy controls was performed. We used the high-resolution melting methods (HRM) to

genotype the selected five single nucleotide polymorphisms (SNPs), four of them (rs6693831, rs7517847, rs1884444, rs10889677) on the IL-23R gene and one (rs2275913) on the IL-17A gene. Meanwhile the laboratory indexes (RBC, WBC, PLT, MONO%, LYMPH%, NEUT%, ALB, ALP, ALT, AST, BUN, CHOL, CK, CREA, Cys-C, DBIL, GGT, GLB, GLU, HBDH, HDL-C, IBIL, LDH, LDL-C, TBIL, CRP, C3 and C4) were recorded.

**Results:** In this study, patients with genotype CC (p=8.574E-8) and allele C (p=3.206E-31) on SNP rs6693831 (IL-23R) showed decreased risk of AS. The genotype TT (p=4.551E-6) and allele T (p=0.02) on SNP rs1884444 (IL-23R) showed significant lower risk of AS. Individuals carrying the allele A on SNP rs2275913 (IL-17A) showed higher risk of AS [p=0.04, OR (95%CI) = 0.825 (0.690–0.987)]. Significant higher level of CRP was found among AS patients with genotype CT on rs6693831 ($\chi^2$=7.633, P=0.030).

**Conclusions:** We first demonstrated that rs6693831 and rs1884444 on IL-23R gene and rs2275913 on IL-17A gene are genetic susceptibility factor for AS. We also noticed that patients with CT genotype on rs6693831 have higher CRP level.

## AB0004 POLYMORPHISMS IN GENES IN THE IL-17 PATHWAY AND B CELL MEDIATED IMMUNE RESPONSE MODULATE THE DEVELOPMENT OF SPECIFIC AUTOIMMUNE MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

C. Perricone[1], C. Ciccacci[2], F. Ceccarelli[1], E. Cipriano[1], C. Alessandri[1], F.R. Spinelli[1], S. Rufini[2], C. Politi[2], A. Latini[2], G. Novelli[2], G. Valesini[1], P. Borgiani[2], F. Conti[1]. *[1]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma; [2]Department of Biomedicine and Prevention, Section of Genetics, University of Rome "Tor Vergata", Rome, Italy*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease in which a complex interaction between genetic, environmental and immunological factors determines the susceptibility and the phenotype. Dysregulations in IL-17 pathway as well as in B-cell mediated immune response have been observed in SLE. We have recently demonstrated that polymorphisms in TRAF3IP2 gene are associated with susceptibility for SLE and can predispose for the development of pericarditis (1). TRAF3IP2 encodes for Act1, a molecule that acts as a negative regulator of B cell by inhibiting CD40-mediated signaling and as a positive signaling adapter in IL-17-mediated cellular responses. TRAF6 is essential for the IL-17/Act1-mediated activation of NF-kB, while CD40 is the target for the Act1 mediated inhibition of B cell response.

**Objectives:** The primary goal of our study was to evaluate the association of polymorphisms in CD40, TRAF6 and TNFSF4 (OX40) genes with susceptibility to SLE. Secondary objectives were to assess the possible association of these polymorphisms with the clinical and laboratory features.

**Methods:** We recruited 315 Italian SLE patients and 278 healthy controls. Genotyping of rs4810485 in CD40, rs4755453 and rs5030437 in TRAF6, and rs2205960 and rs10489265 in TNFSF4 (OX40) SNPs was performed by allelic discrimination assay. A case/control association study and a genotype/phenotype correlation analysis were performed.

**Results:** Deviations from Hardy–Weinberg equilibrium for the three SNPs were not observed. None of the studies polymorphisms was associated with susceptibility for SLE. Only CD40 rs4810485 was associated at genotypic (P=0.034) but not at the allelic level. Nonetheless, these polymorphisms seem to contribute to define disease phenotype. TRAF6 was associated with the presence of anemia (P=0.019, OR=1.96), rs2205960 of TNFSF4 was associated with the pericarditis (P=0.013, OR=2.14), and rs4810485 of CD40 with the presence of anti-SSB/La (P=0.014, OR=2.26) and lupus nephritis (P=0.024, OR=1.8).

**Conclusions:** We were not able to confirm previous association of TRAF6 and CD40 polymorphisms with susceptibility for SLE. However, such SNPs seem to influence the disease phenotype. In particular, it is of interest the association of rs4810485 in CD40 with lupus nephritis and the presence of anti-SSB/La. Indeed, the modulation of CD40-mediated T cell-dependent antibody response has already been associated with the development of anti-SSB/La in association with SLE-like nephritis in a mouse model (2), probably due to an uncontrolled B cell activation signal.

## AB0005 WEIGHTED GENE CO-EXPRESSION NETWORK ANALYSIS REVEALS LINK BETWEEN PROTEIN KINASE SIGNALLING AND RESPONSE TO METHOTREXATE IN NEW-ONSET RHEUMATOID ARTHRITIS

D. Plant[1], S. Smith[2], N. Nair[2], J. Massey[2], K. Hyrich[2], A. Barton[3], S. Verstappen[2]. *[1]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust; [2]Arthritis Research UK Centre for Genetics and Genomics and Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre; [3]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust. Arthritis Research UK Centre for Genetics and Genomics and Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester, Manchester, United Kingdom*

**Background:** Methotrexate (MTX) is recommended as the first-line therapy in rheumatoid arthritis (RA). However, only 55% of patients remain on this inexpensive drug beyond 2 years after initiation of treatment. A stratified medicine approach therefore necessitates identification of reliable biomarkers of MTX response which are currently lacking.

**Objectives:** To identify gene co-expression networks in pre-treatment blood of new-onset RA patients that correlate with response to MTX at 6-months.

**Methods:** Patients with RA participating in the Rheumatoid Arthritis Medication Study (RAMS), a multi-centre one-year longitudinal observational study investigating predictors of response to MTX in the UK, who were EULAR good or poor responders at 6-months were included in this analysis. Total RNA was extracted from Tempus™ tubes using the Tempus Spin RNA isolation kit according to the manufacturer's protocol. Following extraction, quantification and assessment of RNA integrity, RNA samples were labelled with biotin and amplified (Illumina TotalPrep RNA Amplification Kit) prior to being loaded onto an Illumina HumanHT-12 v4 BeadChip, which targets over 47,000 probes. Highly correlated genes were identified from the expression data and summarised with a modular eigengene using the weighted gene co-expression network analysis (WGCNA) bioconductor package. Pearson's correlation was used to assess the significance of the correlation between eigengene and improvement in disease activity, defined using EULAR response and change in CRP.

**Results:** Thirty-two good and 43 poor responders were included in this study [76% female; mean age 60 (SD 14) years, median symptom duration 6-months (IQR 3.7, 19) at MTX start]. Seventeen co-expression modules were identified. None of the modules were correlated with EULAR response at 6 months. However, one module including 1,840 genes was correlated with change in CRP between baseline and 6-months (corr 0.37, p=0.001). Furthermore, the genes most central to the module were also the most correlated with CRP difference (cor 0.5, p=5.6e-117). The most significant gene ontology (GO) molecular function term for this module was protein kinase (61 genes, 1.50 fold enrichment, p=4.2e-04, Benjamini p=0.04). Within this GO the expression of TYK2 was found to be correlated with CRP change (p=0.005). Patients with higher TYK2 expression at baseline experienced more improvement in CRP following MTX treatment.

**Conclusions:** These results suggest gene co-expression network analysis has the potential to reveal important insight into the biological effects of MTX therapy in RA. The assumption behind this analysis is that networks of genes are co-regulated e.g. by an environmental exposure, transcription factor of genetic variants. The next step will be to incorporate genome-wide single nucleotide polymorphism data to identify eigengene and gene expression quantitative trait loci.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.2890

## AB0006 ASSESSMENT OF RHEUMATOID AND PSORIATIC ARTHRITIS SUSCEPTIBILITY LOCI IN A GENETIC HOMOGENEOUS POPULATION OF GREECE

E. Myrthianou[1], M.I. Zervou[1], A. Budu-Aggrey[2,3], E. Eliopoulos[4], N. Kougkas[1], D. Kardassis[1], D.T. Boumpas[5,6], A. Barton[2,3,7], P. Sidiropoulos[1], G.N. Goulielmos[1]. *[1]Medical School, University of Crete, Heraklion, Crete, Greece; [2]Institute for Inflammation and Repair, The University of Manchester; [3]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kindom; [4]Depatrment of Biotechnology, Agricultural University of Athens; [5]Faculty of Medicine, University of Athens, Athens; [6]IMBB, FORTH, Heraklion, Greece; [7]The Kellgren Centre for Rheumatology, NIHR Manchester Biomedical Research Centre, Manchester, United Kindom*

**Background:** Genome wide association studies (GWAS) have detected a considerable number of rheumatoid arthritis (RA) susceptibility loci [1]. Some RA loci have also been found to be associated with psoriatic arthritis (PsA) [2], demonstrating that there is a degree of genetic overlap between various autoimmune diseases.
**Objectives:** We sought to investigate whether single nucleotide polymorphisms (SNPs) mapping to previously reported RA and/or PsA susceptibility loci, including *PLCL2* (rs4535211), *CCL21* (rs2812378), *REL* (rs13017599), *STAT4* (rs10181656), *CD226* (rs763361), *PTPN22* (rs2476601) and *TYK2* (rs34536443), are associated with risk for the two diseases in a genetically homogeneous Greek population.
**Methods:** A total of 392 RA patients, 126 PsA patients and 521 healthy age and sex matched controls from Greece were included. Genotyping of the SNPs was performed with Taqman primer-probe sets, using a Real-Time PCR platform (Applied Biosystems, ViiA™ 7 Real-Time PCR System). Odds ratios (OR) and 95% confidence intervals (CI) were calculated and the statistical difference in allele distribution was assessed by means of $x^2$ test or Fisher's exact test. Bioinformatic analysis was performed using BlastP, Pymol and Maestro and Desmond (Schrodinger Inc.).
**Results:** A significant association was detected between the GC genotype of rs34536443 (*TYK2*) in both the PsA (p=0.019, OR=0.099, 95% CI 0.005–1.65) and RA cohorts (p=0.033, OR=0.33, 95% CI 0.123–0.90). The C allele of this SNP was associated with PsA only (p=0.02, OR=0.10, 95% CI 0.006–1.681). This polymorphism, located on exon 3, causes a Pro1104Ala mutation which is located at the beginning of an alpha-helical structure. Significant evidence for association with PsA was also found for the GG genotype and G allele of the rs10181656 SNP of *STAT4* (p=0.04, OR=4.3, 95% CI 1.01–18.39 and p=0.03, OR=1.46, 95% CI 1.03–2.08, respectively). Bioinformatics analysis revealed that the C but not G allele of this SNP is located within a putative binding site for transcription factors Pax-4, PPAR/RXR and ZNF99. The TC genotype of the rs763361 SNP of *CD226* was associated with PsA (OR=0.61, p=0.04) but no association was found with RA. This SNP, results in a Gly307Ser substitution, and is thought to be associated with the generation of a protein phosphorylation site. No association was found with the remaining four loci examined.
**Conclusions:** Genetic overlap between PsA and RA was detected for the rs34536443 SNP of *TYK2* gene within a Greek population. The Pro1104Gly mutation of TYK2 may influence its functionality by affecting structural and dynamical elements of the molecule. An association of *STAT4* (rs10181656) with PsA was confirmed while *CD226* (rs763361) was associated with PsA but not RA, in contrast to previous reports. The different findings of this study compared to previous ones highlights the importance of comparative studies that include various ethnic or racial populations.

**Background:** Genome-wide association studies (GWAS) in Psoriatic Arthritis (PsA)patients and controls have allowed the identification of multiple variants associated with disease risk. To date, however, no GWAS for PsA phenotypes has been reported.
**Objectives:** The main objective of this study was to identify new genetic variation associated with clinical phenotypes in PsA.
**Methods:** A total of n=835 patients diagnosed with PsA using CASPAR criteria were recruited in the discovery stage and genotyped for >600,000 single nucleotide polymorphisms. GWAS were performed for clinical and biological phenotypes associated with joint and skin disease. After allelic association analysis, those SNPs with highest level of significance were analyzed in an independent cohort of n=414 PsA patients.
**Results:** In the GWAS stage, several genomic regions showing high evidence of association with different PsA phenotypes (P<5e-6) were identified, including axial disease, peripheral disease, bone proliferation, degree of radiological sacroileitis and the presence of syndesmophytes. Also, GWAS on cutaneous phenotypes identified two regions associated with nail disease and skin disease severity. Using the replication cohort, the association between one locus and peripheral pattern, and two loci with axial pattern were validated.
**Conclusions:** Usign a GWAS approach, new loci associated with axial and peripheral disease in PsA have been identified.
**Disclosure of Interest:** None declared

## AB0008 LACK OF ASSOCIATION BETWEEN POLYMORPHISMS IN INTERLUKIN (IL)-12, IL-12R, IL-23, IL-23R GENES AND TAKAYASU ARTERITIS IN A CHINESE POPULATION

K.-Q. Yang[1], Y.-K. Yang[1], D. Wen[2], X. Meng[1], Y. Zhang[1], X.-J. Jiang[1], H.-Y. Wu[1], H.-M. Zhang[1], L. Song[1], J. Bian[1], X.-L. Zhou[1]. *[1]Fuwai Hospital, National Center for Cardiovascular Disease, Chinese Academy of Medical Sciences and Peking Union Medical College; [2]Beijing Anzhen Hospital, Capital Medical University, Beijing, China*

**Background:** Takayasu arteritis (TA) is a chronic inflammatory arteritis with unknown cause. Genetic components may play an important role in the pathogenesis of TA. It is indicated that HLA-B*52 allele contributes to TA development worldwide. *IL12B* is identified as a susceptibility gene for TA in two recent genome-wide association studies. To date, several loci in the genes coding for members of the IL-12/IL-23 pathway have been found to be involved in the pathogenesis of various immune-mediated diseases.
**Objectives:** The goal of this study was to investigate the relationship between polymorphisms in interleukin (IL)-12, IL-12R, IL-23, and IL-23R genes and TA in a Chinese population.
**Methods:** A case-control study was performed to investigate the associations of nineteen single nucleotide polymorphisms (SNPs) mapping to *IL12A*, *IL12B*, *IL12RB1*, *IL12RB2* and *IL23R* with susceptibility to TA in 145 Chinese TA patients and 300 healthy controls. Genotype identification was performed with the MassARRAY system from Sequenom. In addition, HLA-B*52 genotypes were detected by the polymerase chain reaction using the sequence-specific primers (PCR-SSP).The statistical analysis was conducted by chi-square test and unconditional Logistic regression with plink.
**Results:** No significant differences were found for the distribution of allele and genotype frequencies of these SNPs between TA patients and healthy controls. However, a trend for *IL12A* rs582054 and *IL23R* rs1004819 in association with the TA phenotype was detected. TA patients carrying the rs582054/ rs568408 haplotype ($P_c$=0.019) appeared less likely to progress to a more severe form of disease. And the C allele ($P_c$=0.082) of *IL23R* rs1004819 appeared to be a protective factor to refractory disease. The association of TA with HLA-B*52 was confirmed in this cohort of Chinese patients. Whereas, there was no interaction between HLA-B*52 and polymorphisms in IL-12/IL-23 axis genes.
**Conclusions:** These findings suggest that the polymorphisms of *IL12A*, *IL12B*, *IL12RB1*, *IL12RB2* and *IL23R* might make no contribution to the susceptibility of TA in the Chinese population.

## AB0009 PADI4 GENE POLYMORPHISM AS A PREDICTOR OF RESPONSE TO METHOTREXATE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

L.S. Nazarova[1], K.V. Danilko[1], V.A. Malievsky[1], T.V. Viktorova[1,2]. *[1]Bashkir State Medical University; [2]Institute of Biochemistry and Genetics, Ufa, Russian Federation*

**Background:** Methotrexate (MTX) is the most widely used disease-modifying anti-rheumatic drug in the treatment of juvenile idiopathic arthritis (JIA); however, there is a variation in the clinical response to MTX among the patients [1]. Previous studies have shown conflicting results regarding predictors of the response to MTX. No unequivocal predictive SNP has been found yet, because many were assessed in only one study, or were predictive in one study and showed no effect in others [2].
**Objectives:** The aim of the study was to assess whether the *PADI4* rs2240336 gene polymorphism is a predictor of the disease severity and the response to MTX in patients with JIA from Bashkortostan, Russia.
**Methods:** 283 patients with JIA were genotyped for the *PADI4* rs2240336 gene polymorphism using real-time PCR. The statistical analysis was performed using two-tailed Fisher's exact test, odds ratio, 95% confidence interval and logistic regression in Microsoft Excel, WinPepi v.11.44, R v.3.2.0, SNPStats programs. The disease course was assessed as more severe if the MTX therapy was required. The response to MTX was considered as good if clinical remission on medication (Wallace) was achieved, otherwise – as insufficient. An addition of a biological agent to the MTX therapy was also assessed as a marker of an insufficient response.
**Results:** The requirement of the MTX treatment and its absence was noted at 261 (92.3%) and 22 (7.8%) children with JIA respectively, and the distribution of the genotypes and alleles of the *PADI4* rs2240336 gene polymorphism were similar in both groups (p=0.982). At the same time the frequency of the genotype AG was significantly higher (59.8% vs. 35.5%, p=0.0029, OR=2.71, 95% CI 1.41–4.94), and the frequency of the genotype GG was significantly lower (23.8% vs. 45.2%, p=0.0041, OR=0.38, 95% CI 0.20–0.73) in patients, who received MTX and not achieved clinical remission on medication (n=122) than in those who achieved (n=62). The best model of inheritance was overdominant, where the genotype AG marked an insufficient response to MTX (AG vs. GG + AA, p=0.0017, OR=2.71, 95% CI 1.44–5.11). The association with an insufficient response to MTX was also observed under the dominant (AG + AA vs. GG, p=0.0034, OR=2.64, 95% CI 1.38–5.06) and codominant (AG vs. GG, p=0.0041, OR=3.20, 95% CI 1.58–6.48) models of inheritance. Moreover, the genotype AG frequency was significantly elevated in patients who required an addition of a biological agent to the MTX therapy (n=73) (p=0.012, OR=2.097, 95% CI 1.20–3.66) and the overdominant model of inheritance also proved the best (p=0.0088, OR=2.10, 95% CI 1.20–3.68).
**Conclusions:** Thus, in this study we revealed that the genotype AG of the *PADI4* rs2240336 gene polymorphism was a marker of increased risk of an insufficient response to MTX in children with JIA from Bashkortostan, Russia. If this finding will be confirmed in other studies, it can be potentially used for the early prediction of the response to MTX in patients with JIA.

## AB0010 ASSOCIATION OF GENE POLYMORPHISMS IN ETS-1 WITH RANKL IN RHEUMATOID ARTHRITIS

L. Chen, Z. Huang, B. Yang, B. Cai, Z. Su, L. Wang. *West China Hospital, Sichuan University, Chengdu, China*

**Background:** Rheumatoid arthritis (RA) is a complicated autoimmune disease characterized by progressive destruction of cartilage and bone. Recently, receptor activator of nuclear factor κB ligand (RANKL) have been found to be involved in the differentiation of osteoclasts [1]. Also, the association between the RANKL expression and the pathogenesis of bone-destructive rheumatoid arthritis (RA) has been described in several joints [2]. It indicated that RANKL play a crucial rule in RA. Meanwhile, E26 transformation specific sequence 1 (ETS-1), belonging to the ETS family of transcription factors that regulate the expression of various immune-related genes, was reported to confer susceptibility and development to RA [3]. Moreover, ETS-1 was found to be overexpressed in RA synovial membrane and to be involved in the destructive pathway of RA [4], but it was not clearly defined.
**Objectives:** We aimed to identify how RANKL changes in RA and whether polymorphisms in ETS-1 play a role in that changes by describing in Chinese Han population.
**Methods:** 170 RA patients and 136 healthy controls were included for this analysis. Clinical information was gathered and disease activity was determined according to the disease activity score for 28 painful/swollen joints (DAS28). The serum level of RANKL were detected by magnetic luminex assays. Four single nucleotide polymorphisms (SNPs) in ETS-1 were genotyped by high resolution melting (HRM) curve method.
**Results:** Compared with healthy controls, Level of RANKL in serum of patients was elevated (28.69 (17.24–44.90) versus 14.24 (17.00–20.00), $P<0.01$). The RA patients with rs73013527 TT genotype had higher RANKL levels (P=0.019 in a dominant model). Furthermore, we found that T allele of rs73013527 was overrepresented in RA group as well (25.7% versus 42.6%, $P<0.001$). Besides, an association was found between rs73013527 TT genotype and DAS28 (P=0.001). No statistically significant difference was observed in the distribution of other three SNPs (rs10893872, rs4937333 and rs11221332) alleles or genotypes in this study (all $P>0.05$).
**Conclusions:** This study suggests that RANKL increased in RA and the polymorphisms in the ETS-1 region may be associated with the changes of RANKL in RA. The patients with rs73013527 TT genotype may be not prone to RA but have higher RANKL which could lead a sever condiction. However, larger studies, most likely through multicenter collaboration will be needed to fully validate the significance of these findings.

## AB0011 HLA-DP POLYMORPHISMS PLAY PROTECTIVE ROLE IN SYSTEMIC LUPUS ERYTHEMATOSUS IN CHINESE HAN POPULATION

Z. Junlong, Z. Wenli, T. Anning, C. Lin, Y. Bin, W. Lanlan. *Department of Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China*

**Background:** With the application of Genome-Wide Association studies (GWAS), the SLE risk gene loci in HLA-DR and HLA-DQ are gradually revealed [1]. However, the association of HLA-DP polymorphisms with SLE is pretty few reported. Considering the variants in rs3077 and rs9277535 in HLA-DP region were estimated influenced the immune response by affecting antigen presentation of HLA class II molecules to CD4+ T cells [2], it is worthy to explore the role of HLA-DP polymorphisms in SLE.
**Objectives:** Exploring the effects of presently hot HLA-DP SNPs, rs3077 and rs9277525 on SLE.
**Methods:** 335 SLE patients and 635 healthy controls were recruited in present study. Genotyping was performed with polymerase chain reaction-high resolution melting (PCR-HRM) assay and the data was analyzed using SPSS19.0.
**Results:** A significantly positive correlation was observed between the SNP rs3077 and rs9277535 of HLA-DP and SLE susceptibility (rs3077, OR=0.74, 95%CI=0.60–0.91, P=0.004; rs9277535, OR=0.72, 95%CI=0.60–0.91, P=0.001). Moreover, in cytokines, there was significant positive association between rs3077 and IL-17 and INF-γ(P=0.037 and P=0.020 respectively; recessive model, P=0.011 and P=0.008, respectively) and the AA genotype predisposed to lower IL-17 and INF-γcompared with other two genotypes. However, none positive connection was found between rs3077 and IL-1 alpha, IL-4, IL-6, IL-10, and IL-23 (P=0.739, 0.624, 0.685, 0.887, and 0.937 correspondingly). None significant positive correlation could be observed between rs9277535 and any cytokines.
**Conclusions:** HLA-DP polymorphisms (rs3077 and rs9277535) play a protective role in SLE susceptibility. And rs3077 play the role by affecting antigen presentation of HLA class II molecules for CD4+T cells and down-regulating the Th17 signal pathway.

AB0012 **GENETIC SIGNATURES IN RHEUMATOID ARTHRITIS: CHANGES UPON ANTI-TNF THERAPY AND ASSOCIATION WITH RESPONSE TO BIOLOGICAL TREATMENT**

S. Poliska[1], E. Végh[2], A. Váncsa[2], S. Szamosi[2], M. Csumita[1], G. Zahuczky[3], G. Szücs[2], S. Szántó[2], L. Nagy[4], Z. Szekanecz[2]. *[1]Department of Biochemistry and Molecular Biology; [2]Department of Rheumatology, University of Debrecen, Faculty of Medicine; [3]x, UD-Genomed Ltd, Debrecen, Hungary; [4]x, Sanford Burnham Medical Discovery Institute, Lake Nona, FL, United States*

**Background:** Genetic signatures may be involved in the pathogenesis of rheumatoid arthritis (RA) and ankylosing spondylitis (AS). In addition, such genetic patterns may change overtime upon treatment with anti-TNF biologics. With respect to pharmacogenomics, pre-treatment genomics may predict response or non-response to biological therapy.
**Objectives:** In the present study, we wished to determine gene expression changes due to anti-TNF therapy. Furthermore, we wished to study associations between baseline genetic signature and response to TNF blockade.
**Methods:** Altogether 23 RA and 17 AS patients were recruited for the study. Among RA patients, 10 received certolizumab pegol (CZP), and 13 etanercept (ETN). All AS patients were treated with ETN. Gene expression analysis using Affymetrix microarray and PrimeView array was performed at baseline and after 2 weeks of treatment. EULAR response criteria were used to differentiate responders (R) from non-responders (NR) after 12 weeks of treatment using GeneSpring software. Principal Component Analysis (PCA) was also performed. Changes in gene expression patterns were also determined between baseline and 2 weeks.
**Results:** In the CZP-treated RA group, 4 patients were R and 6 were NR. Altogether 453 genes showed significantly differential expression between N and NR. In the RA-ETN group, 10 patients were R, and 3 were NR. Here, 836 genes exerted differential expression. When a CZP- and ETN-treated patients, were pooled, 165 genes separated R from NR. In the AS population, 14 patients were R and 3 were NR. 177 genes differentiated between R and NR. When changes in gene expression patterns from baseline to week 2 were determined, in the RA-CZP, RA-ETN, RA-all and AS groups 370, 79, 24 and 76 genes showed significant changes in expression.
**Conclusions:** Using microarray, genetic signatures may differentiate RA patients responding or not responding to anti-TNF therapy. Furthermore, a large set of genes show differential expression before versus 2 weeks after biologic treatment.
**Disclosure of Interest:** None declared

## Adaptive immunity (T cells and B cells) in rheumatic diseases

AB0013 **GLOMERULAR IL-4 SIGNALING MEDIATES FOOT PROCESS EFFACEMENT AND PROTEINURIA IN NEPHROTIC SYNDROMES**

A.H. Kim[1], S. Akilesh[2], A. Koziell[3], B. Saunders[4], S. Jain[5], J. Hodgin[6], B. Zinselmeyer[4], T. Stappenback[4], J. Miner[5], A. Shaw[7]. *[1]Rheumatology, Washington University School of Medicine, Saint Louis, MO; [2]Pathology, University of Washington, Seattle, WA, United States; [3]Experimental Immunobiology, King's College, London, United Kingdom; [4]Pathology and Immunology; [5]Renal, Washington University School of Medicine, Saint Louis, MO; [6]Pathology, University of Michigan, Ann Arbor, MI; [7]Genentech, Inc., South San Francisco, CA, United States*

**Background:** Podocyte foot process effacement is a feature of proteinuria, thought to be a stereotyped response of the podocyte to injury. The stimulus for podocyte injury and foot process effacement is unknown, although changes in the actin cytoskeleton has been implicated. B cell depletion therapies have demonstrated efficacy in some patients with proteinuria including those with minimal change disease. Since pathogenic antibodies are not causative, we hypothesized that a B cell derived cytokine might be capable of directly inducing podocyte injury and foot process effacement.
**Objectives:** Develop a B cell model of proteinuria in mice, and identify glomerulopathic cytokines derived from B cells.
**Methods:** B cell model antigen model hen egg lysozyme (HEL) was biotinylated, complexed to avidin and injected into mice. HEL-specific B cells were adoptively transferred and proteinuria assessed. Two-photon microscopy was performed in vibrotomed kidneys following transfer of CFSE-labeled HEL-specific B cells with or without HEL antigen injection. Cultured podocyte membrane ruffling was assessed with DIC videomicroscopy. IL-4 expression in mice was achieved by hydrodynamically injecting murine IL-4 in the piggyBac vector system. Human kidney biopsies were assessed for phospho-STAT6 by immunohistochemistry.
**Results:** We identified IL-4 as a B cell derived cytokine capable of stimulating podocyte actin rearrangement. Using a novel model of B cell induced proteinuria, B cells polarized to secrete IL-4 upon activation with HEL induced proteinuria without antibody or complement deposition. Using two-photon microscopy, we observed an accumulation of HEL-specific B cells within glomeruli containing HEL antigen.
To confirm the glomerulopathic properties of IL-4, we overexpressed IL-4 in mice and found this was sufficient to induce foot process effacement and proteinuria. Inhibition of IL-4 signaling with a JAK1/3 inhibitor markedly reduced proteinuria in these IL-4 overexpressing mice. Finally, a subset of patients (31%) with steroid-sensitive nephrotic syndrome possessed glomerular STAT6 activation.
**Conclusions:** These findings suggest a potential explanation for the utility of immunosuppression and more targeted anti-B cell therapy with rituximab in the treatment of steroid-sensitive nephrotic syndromes. These results support the role of IL-4 in human nephrotic syndromes and represents a novel therapeutic target.

AB0014 **NANOPARTICLES AS MRI CONTRAST AGENT FOR EARLY DIAGNOSIS OF RA: EFFECTS OF AMINO-PVA-COATED SPIONS ON CD4+ T CELL ACTIVITY**

C. Strehl[1,2], L. Maurizi[3], S. Hermann[1], T. Häupl[1], H. Hofmann[3], F. Buttgereit[1], T. Gaber[1,2]. *[1]Department of Rheumatology and Clinical Immunology, Charité University Medicine; [2]German Rheumatism Research Centre (DRFZ), Berlin, Germany; [3]Institute of Materials Powder Technology Laboratory, École polytechnique fédérale de Lausanne EPFL, Lausanne, Switzerland*

**Background:** In medical applications nanotechnology provides new opportunities for diagnostic and therapeutic interventions in a variety of human diseases. Superparamagnetic iron oxide nanoparticles (SPION) are used as high-sensitive enhancer for magnetic resonance imaging, where they represent a promising tool for early diagnosis of destructive diseases such as rheumatoid arthritis (RA) and osteoarthritis (OA).
However, safety aspects still represent crucial problems for the further development of nanotechnology based products. Therefore, the focus of our work here was to identify more in detail putative unwanted effects of amino-polyvinyl alcohol-coated (a-PVA) SPION on human immune cell functions.
**Objectives:** Since we could demonstrate in former studies that professional phagocytes are activated by a-PVA-SPION, we here focused on the influence of these nanoparticles on human T helper cell activity.
**Methods:** PBMCs were isolated from blood samples obtained from healthy donors (HD, $n \geq 9$) or patients suffering from RA ($n \geq 11$). Primary human CD4 positive T cells were separated via MACS-Sort and incubated with the mitogen PHA-L (5$\mu$g/ml) and/or varying doses of a-PVA-SPION (1 $\mu$g/ml, 10 $\mu$g/ml, and 100 $\mu$g/ml) or left untreated for 20 h (analysis of caspase-3/7-activity, intracellular ATP content and CD25 expression) or 72 h (analysis of proliferation and CD25 expression). Cells were incubated under either normoxia (app. 18%O2) or hypoxia (1%O2) in order to mimic conditions found in the circulation and in the inflamed joint, respectively.
**Results:** We observed for PHA-L/a-PVA-SPION co-stimulated T cells from HD a decrease in cell count (all $p<0.05$) whereas the caspase-3/7-activity is increased (all $p<0.05$) in these samples, as expected. Although, we observed that T cells from RA patients are more susceptible to low-dose a-PVA-SPION-induced apoptosis than T cells from HD ($p<0.05$), in both groups a-PVA-SPION do not activate CD4+ T cells *per se* and do not influence mitogen-mediated T cells activation with regard to CD25 expression and cell proliferation. Nevertheless, we were able to demonstrate that CD4+ T cells obtained from RA patients and healthy subjects differ in their response to mitogen stimulation and oxygen availability.
**Conclusions:** PVA-SPION at concentrations up to 100$\mu$g/ml do neither activate nor significantly influence mitogen-stimulated CD4+ T cells activation and have negligible influence on T cells apoptosis.
**Disclosure of Interest:** None declared

AB0015 **EVALUATING THE EFFECT OF ANTI-TNF, ANTI-IL6R AND ANTI-CTLA4 ON ACPA ISOTYPES IN PATIENTS WITH RHEUMATOID ARTHRITIS**

D. Hernandez-Flórez, T. del Río, J. Nieto, J. Ovalles, J. Martínez, B. Serrano, C. Mata, C. Gonzalez, I. Monteagudo, J. Lopez-Longo, E. Naredo, L. Valor. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** B-cell depletion therapy decreases autoantibodies formation as rheumatoid factor and anti–citrullinated protein antibodies (ACPA). Other therapeutic targets (TT) such as anti-TNF (tumor necrosis factor), anti-IL-6R (interleukin-6 receptor) and anti-CTL4A (cytotoxic T-lymphocyte antigen-4) modulate the B-cells proliferation/maturation and indirectly the production of autoantibodies. ACPA titers provide us information about disease activity and may be critical for inducing clinical remission in rheumatoid arthritis (RA) patients.
**Objectives:** To evaluate the impact of the therapeutic targets: anti-TNF; anti-IL6R and anti-CTLA4 on ACPA titers in RA patients.
**Methods:** In this longitudinal study we selected ACPA positive patients naïve to

BT (N=27). All patients were assessed at baseline and after 4, 8, 12, 24 and 36 months (m) of treatment initiation. Disease activity was assessed by the 28 joint count-disease activity score (DAS28) according to C-Reactive Protein (CRP). ACPA isotypes (IgG, IgA and IgM) were determined by ELISA (CCP2-plates, Eurodiagnostica,SE). Anti-human antibodies isotype specific were used (Binding Site, UK). Statistical analysis was performed according to TT (anti-TNF, anti-IL6R and anti-CTLA4) and anti-TNF therapies (IFX, ADA, ETN).

**Results:** We found a significant DAS28-CRP decrease in: anti-IL6R (p=0.017, p=0.018, p=0.018, p=0.028, p=0.028) and anti-TNF (p=0.002, p=0.002, p=0.003, p=0.004, p=0.007) groups at 4, 8, 12, 24 and 36m. Evaluating the anti-TNF treatments, we found a significant decrease on DAS28 in ADL at 4 (p=0.046) and ETN groups at 4, 8, 12 and 24m of treatment (p=0.043, p=0.043, p=0.043, p=0.043). Comparing TT, the most outstanding reduction of DAS28 was found in anti-IL6R group compared to anti-CTLA4 group (p=0.017) at 8m, probably due to a greater reduction of CRP in anti-IL6R group (p=0.018). Regarding ACPA isotypes, we only found a significant decrease in IgA-ACPA titers in anti-IL6R group at 4, 8 and 12m of treatment (p=0.012, p=0.036, p=0.046). No changes were found neither in other TT nor in anti-TNF therapies. Comparing TT, we found lower IgG-ACPA titers in anti-CTLA4 group compared to anti-IL6-R group (50.25,98.2U/ml) at 4m. The highest IgG-ACPA titers were found in anti-IL6R (228.7 U/ml) than anti-TNF (53.7U/ml) and anti-CTLA4 groups (71.7U/ml) (p=0.048, p=0.024) at 24m. For IgM-ACPA, the lowest titers were found in anti-IL6R than anti-CTLA4 at 4 and 12m (4m: 2.988 y 3.093OD;12m: 3.004 y 3.116OD) (p=0.012, p=0.017, p=0.017).

**Conclusions:** Patients treated with anti-IL6R and anti-TNF had the most outstanding reduction of DAS28 at the first 8m of treatment. Regarding ACPA isotypes, IgM-ACPA levels were higher in anti-CTLA4 than anti-IL6R probably due to inhibition of B cells class-switching by anti-IL6R therapy. Those patients treated with anti-IL6R presented a progressive decrease of IgA-ACPA and total IgA, as well as, a higher IgG-ACPA titer at 24m. These results showed that both therapies modulate the B cell maturation/differentiation and ACPA production by different immune-regulation pathways, as well as, the cell-cell interaction process. Our data suggests that B-cells and ACPA isotypes monitoring may be useful to further understand their role in the RA pathogenesis and its association with clinical response to BT.

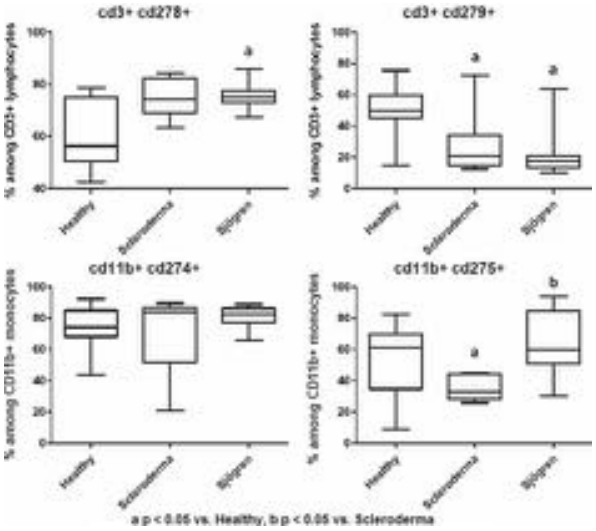
## AB0016 B7 COSTIMULATION AND INTRACELLULAR INDOLEAMINE 2,3-DIOXYGENASE (IDO) EXPRESSION IN SYSTEMIC SCLEROSIS AND PRIMARY SJÖGREN'S SYNDROME



G. Toldi[1], L. Berta[1], N. Legány[2], A. Balog[2]. *[1]First Dept of Obstetrics, Semmelweis University, Budapest; [2]Dept of Rheumatology, University of Szeged, Szeged, Hungary*

**Background:** Antigen presentation and costimulation are the initial steps of adequate T cell function and play an important role in the coordination of pro- and anti-inflammatory events. B7 costimulatory molecules are expressed on antigen presenting cells (APCs) and influence intracellular expression of indoleamine 2,3-dioxygenase (IDO), another molecule with important immune regulatory functions. Alterations in the expression of B7 costimulatory molecules and receptors may play a role in the autoimmune response in two clinically and pathogenetically distinct disorders, systemic sclerosis (SSc) and primary Sjögren's syndrome (pSS).

**Objectives:** In this study, we aimed to describe the expression of B7 costimulatory molecules on monocytes and their corresponding receptors on T lymphocytes in SSc and pSS peripheral blood samples compared to healthy controls, as well as the intracellular expression of IDO.

**Methods:** We determined the frequency of activated (CD11b+) monocytes expressing B7-1 (CD80), B7-2 (CD86), B7-H1 (CD274), and B7-H2 (CD275) molecules, and that of CD3+ T cells and CD4+ T helper cells expressing the corresponding CD28, CTLA-4 (CD152), PD-1 (CD279), and ICOS (CD278) receptors in peripheral blood samples of 20 healthy adults, 9 SSc and 15 pSS patients using flow cytometry. We also examined the intracellular expression of IDO by staining with fluorescent antibodies.

**Results:** The expression of B7-1 and B7-2 costimulatory molecules was comparable in all three study groups. The expression of CD28 was lower in both SSc and pSS patients. Furthermore, the frequency of CTLA-4 was increased in pSS. The level of negative feedback in this pathway is more pronounced in pSS compared to SSc. The expression of ICOS, a stimulator of T cell activation was elevated in pSS, but not in SSc, while that of its corresponding costimulatory molecule, B7-H2 was strongly decreased in SSc compared to controls (Figure). Therefore, this pathway appears to play a more dominant role in pSS. The frequency of PD-1 expressing T lymphocytes was decreased both in pSS and SSc. At the same time, there was no difference in the expression of the corresponding CD274 molecule on APCs between the investigated study groups (Figure). The T cell inhibitory effect of this receptor appears to be diminished both in pSS and in SSc, which may be related to a common autoimmune pathogenesis. While no difference was observed in IDO expression between controls and SSc patients, the frequency of IDO expressing APCs, as well as intracellular IDO content (mean fluorescence intensity) in T cells was higher in pSS than in controls.

**Conclusions:** Our investigation identified a number off differences in B7 costimulation between SSc and pSS patients which may play a role in the distinct pathogenesis and clinical features of these autoimmune disorders. B7 costimulatory molecules and their receptors may be potential therapeutic targets in the future.

## AB0017 PILOT STUDY ON THE PATTERNS OF B LYMPHOCYTS INFILTRATION IN KIDNEY FROM PATIENTS WITH LUPUS NEPHRITIS

G.-F. Dong[1], K.X. Long[2]. *[1]rheumatology, Guangdong General Hospital, Guangdong Academy of Medical Sciences; [2]rheumatology, Pan Yu People's Hospital, Guang zhou, China*

**Background:** B lymphocytes infiltration associated ectopic lymphoid tissue (ELT) formation in situ kidney tissue had been showed to play an important role in the pathogenesis of *MRL/lpr* lupus nephritis mice model, until now there are few studies to identify the significance of them in the pathogenesis, diagnosis and treatment of human lupus nephritis (LN).

**Objectives:** To know the significance of B lymphocytes infiltration and associated ectopic lymphoid tissue (ELT) formation in the pathogenesis, diagnosis and treatment of human LN

**Methods:** The renal specimen were analyzed by light microscopy examination of routine pathology and immunohistochemistry detection of CD3+,CD20+ and CD21+ cells expression. The enrolled patients were grouped based on the WHO classification of pathology or ELT patterns. Clinical datawere collected and evaluated.

**Results:** 89 LN patients were experienced with GC and IS combination therapy and WHO III 21, WHO IV 53 and WHO V 15. 69 cases of CD20+ cells group and 20 of CD20-cells group could be divided. comparing to CD20-group, no difference could be founded in age, sex, blood leucocytes, urine protein, C3 level, C4 level, ESR, CRP, antiDNA, acute injury index and chronic injury index of renal tissue and total remission rate (all $P>0.05$), but significant difference can be found in mean disease duration (CD20+group: 21.8±9.9 months VS CD20-group: 9.8±6.2 months) (P=0.045) and complete disease remission rate (CD20+group: 63.8% VS CD20-group: 90%) (P=0.047) at 6 month of treatment. With respect to B lymphocytes infiltration associated ELT formation, there was focal distribution of CD3+ T cells and CD20+B cells (type 2) in 51 cases (57.3%), scattering distribution of CD3+ T cells and CD20+B cells (type 1) in 18 cases (20.2%) and no CD20+B cells infiltration in 20 cases (22.5%) but no expression of CD21+ dendritic cells expression in all. There was longer disease duration in type 2 patients than in type 1 or type 0 patients. compared to WHO V-LN patients, there was different ELT distribution patterns in WHO III and WHO IV-LN patients, but there were no difference in ELT distribution patterns between WHO III and WHO IV-LN patients.

**Conclusions:** Focal distribution of CD3+ T cells and CD20+B cells (type 2 ELT)was main pattern in the renal interstitial tissue of LN patients. B cells infiltration-associated ELT formation is a predictor of longer disease duration and poor response to conventional combination therapy of high-dose GC and IS.

## AB0018 DISEASE SPECIFIC EFFECTS OF LIPID ANTIGENS ON VDELTA1+ AND VGAMMA9+ T CELLS IN SYSTEMIC SCLEROSIS

I. Bank, H. Migalovich Sheikhet. *Medicine, Sheba Medical Center, Tel Hashomer, Israel*

**Background:** T cells (TC) expressing Vδ1+ TC receptors recognize lipids presented by CD1d (1). Oligoclonal Vδ1+ TC infiltrate skin and internal organs and are activated in the peripheral blood (PB) in systemic sclerosis (SSc) suggesting lipids as pathogenic immunogens (2,3).
**Objectives:** To determine effects and molecular pathways of the auto antigenic lipid – cardiolipin- in SSc and healthy controls (HC).
**Methods:** Mononuclear cells (MC) were isolated from PB of 12 SSc patients and 8 HC by density centrifugation and cultured in IL2C (RPMI-1640 with 10% fetal bovine serum + 100 international units of interleukin-2), CARDC or OCHC [IL2C+cardiolipin 2.5μg/ml or OCH 50ng/ml (analogue of α-galactosyl ceramide) respectively]. Zoledronate (zol, 2μM), a Vγ9+ γδTC stimulant that induces their CD1d expression, was added to parallel cultures (labeled ILCzol etc.) (4,5). Flow-cytometry (FC) of 4–5 day cultures after staining with monoclonal antibodies (mAb) or CD1d tetramers to detect %CD25+ cells (%CD25+) or tetramer+ cells, was performed.Means were compared by two tailed student t-test; $p<0.05$ was considered significant.
**Results:** Vδ1+ and Vγ9+TC consisted 11.85±2.0% and 14.7±3.5% vs 10.42±2.4% and 7.08±1.2% of the CD3+ TC in SSc and HC IL-2C respectively (values not significantly different). In HC cultures, %CD25+ was non significantly different in IL2C, OCHC and CARDC for all TC subsets.Furthermore, IL2Czol increased %CD25+ on all TC subsets relative to IL2C, which was further amplified on Vδ1+ TC in CARDCzol (33.16±7.0% to 56.93±6.3% $p<0.007$). In SSc, in contrast OCHC and CARDC enhanced %CD25+Vδ1+TC whereas CARDC %CD25+Vγ9+TC was suppressed (76.06±8.7% vs 66.9±10.9%, $p<0.036$) relative to IL2C. In IL2Czol, however, %CD25+Vγ9+TC increased to 73.93±8.12%. In contrast, IL2Czol decreased SSc %CD25+Vδ1+TC (69.58±8.29% to 55.02±10.54%, $p<0.028$), but this decrease was partially abrogated in CARDCzol. Both SSc and HC IL2C Vδ1+TC were highly reactive with native and OCH-bound CD1d tetramers (25–70%, n=5 and 50–54% n=2 respectively), but binding was suppressed in SSc samples by zol. In addition, blocking mAb against CD1d abolished the increased expression of CD25 in SSc CARDCzol Vδ1+ TC (from +27±3% to -8.9±2.3%, n=5 $p<0.0251$) but not in HC (n=2).
**Conclusions:** Cardiolipin induced suppression of CD25 expression on Vγ9+ TC in SSc, which could be reversed by zol. On the other hand cardiolipin reversed SSc- specific zol induced suppression of CD25 expression on Vδ1+TC in a CD1d dependent-manner. These results suggest that cardiolipin may suppress Vγ9+ TC while augmenting Vδ1+TC activation in SSc, at least in part via CD1d mediated interactions.

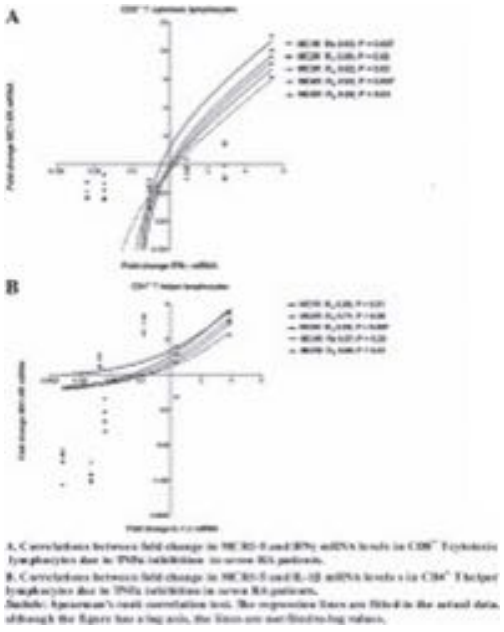
## AB0019 IL-10-PRODUCING BREGS ARE DECREASED IN PSORIATIC ARTHRITIS AND INVERSELY CORRELATE WITH TH17 CELLS



A. Mavropoulos[1], A. Varna[1], I. Alexiou[1], C. Liaskos[1], E. Zafiriou[2], M. Vlychou[3], D.P. Bogdanos[1], L.I. Sakkas[1]. *[1]Rheumatology; [2]Dermatology; [3]Radiology, Medical School, University of Thessaly, Larissa, Greece*

**Background:** B cells may form ectopic lymphoid-like structures in the synovium of patients with psoriatic arthritis (PsA) but the significance of this finding is not clear. A recent study found high frequency of autoantibodies in PsA[1]. Whether regulatory B cells (Bregs) are decreased or not in PsA is not clear.
**Objectives:** To assess the phenotypic and functional characteristics of Breg subsets, CD19(pos)CD27(pos)CD24(high) memory and CD19(pos)CD24(high) CD38(high) transitional Bregs in patients with PsA.
**Methods:** Peripheral blood mononuclear cells, isolated from 61 PsA patients, 21 patients with psoriasis (Ps) and 15 normal controls (NCs), were assessed. The expression of surface CD19, CD24, CD27 and CD38 and cytoplasmic IL-10 by Bregs was examined by flow cytometry following 24 hour bacterial CpG (ODN2006) stimulation using fluorochrome-conjugated monoclonal antibodies. We also measured IL-17 expression from T cells (Th17 cells) stimulated with PMA plus Ionomycin for 5 hours followed by intracellular staining (BD Biosciences).
**Results:** Transitional Bregs were significantly decreased in PsA patients compared to NCs (0.72±0.54 *vs*1.56±0.58, $p$=0.000) and in Ps compared to NCs (1.08±0.38 *vs* 1.56±0.58, $p$=0.016, as well as in PsA compared to Ps patients ($p$=0.002). Memory Bregs were significantly decreased in PsA patients compared to NCs (2.93±2.31*vs* 6.94±2.03, $p$=0.000) and in Ps patients (2.97±1.83) compared to NCs ($p$=0.000) but did not differ between PsA and Ps patients. The impairment of Bregs in PsA was not associated with number of swollen or tender joints, CRP, ESR, or treatment with biologics. IL-10-producing Bregs inversely correlated with Th17 cells in PsA and in Ps.
**Conclusions:** PsA exhibits numerical decrease and functional impairment of Bregs, especially of transitional Bregs. IL-10-producing Bregs inversely correlate with Th17 cells. The impairment of IL-10-producing Bregs may contribute to the pathogenesis of psoriatic disease.

## AB0020 THE MELANOCORTIN SYSTEM IS RESPONSIVE IN DISEASE DRIVING IMMUNE CELLS IN RHEUMATOID ARTHRITIS AND MAY OFFER A PATHWAY TO CURATIVE TREATMENT

M. Andersen[1], M.K. Meyer[1], I. Nagaev[2], O. Nagaeva[2], J.E.S. WIkberg[3], L. Mincheva-Nilsson[2], G.N. Andersen[4]. *[1]Health science and technology, Aalborg University, Aalborg, Denmark; [2]Clinical Microbiology, Clinical Immunology, Umeå; [3]Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden; [4]Clinical Medicine, Aalborg University, Aalborg, Denmark*

**Background:** Although biological agents may manage rheumatoid arthritis (RA), curative treatment is still the "holy grail". Induction of auto-antigen specific immune tolerance might offer a solution and obviate the need for life-long immunosuppression. Melanocortins are small peptides with considerable immune tolerance inducing, inflammation resolving and tissue preserving qualities (1). In animal experimental, autoimmune conditions, melanocortins have been demonstrated to bind differentially to melanocortin receptor (MCR) 1–5 on immune cells and to transform auto-reactive $CD4^+$ T helper (Th) lymphocytes (ly) as well as sensitized $CD8^+$ T cytotoxic (Tc) ly into regulatory T (Treg) ly and thus clear cell-mediated auto-immunity and delayed type hypersensitivity. In contrast to the situation in organ transplantation, clinical application of Treg therapy in human autoimmune disease is still non-existing, primarily because of a lack of in depth understanding.
**Objectives:** To explore if the pro-resolving melanocortin system may offer a pathway to immune tolerance induction, we examined whether the melanocortin system is present and responsive in pathogenic immune cell subsets in RA. To this end, we related changes due to TNFα inhibition (I) in MCR1–5 mRNA levels to changes in Th1 signature-, inflammatory and regulatory cytokine mRNA levels.
**Methods:** $CD4^+$ Th, $CD8^+$ Tc ly, $CD19^+$ B-ly and $CD14^+$ monocytes from seven patients with definite RA were isolated by Dynabeads before and three months after the start of TNFαI. Total RNA was extracted and mRNAs for MCR1–5 and a panel of disease driving Th1, inflammatory and regulatory cytokines were measured by real-time qRT-PCR. Fold changes in MCR1–5 gene levels were correlated to changes in cytokine gene levels.
**Results:** MCR1–5 gene expressions were reduced in al examined cell types, significantly so in $CD8^+$ Tc ly and $CD19^+$ B ly in RA patients responding to TNFαI. In addition, Th1 and inflammatory cytokine mRNA levels were reduced in all cell types in responders. In a non-responding patient MCR1–5 gene expressions as well as Th1 and inflammatory cytokine gene levels increased substantially. The changes in MCR1–5 gene expressions in $CD8^+$ Tc cells correlated significantly to changes in the Th1 cytokine IFNγ gene level in this cell type. Furthermore, we

found significant correlations between changes in MCR 1, 3, 5- and change in IL-1β gene levels in CD4+ Th ly.

**Conclusions:** Our results point at a responsive melanocortin system in immune cells in RA. Moreover, its regulation seems intimately connected to the disease driving Th1 response, that is IFNγ production by CD8+ Tc ly. Our results are underlined by the recently reported importance of IFNγ producing CD8+ Tc ly in early RA. Thus our findings indicate that the melanocortin pathway lies open to treatment of auto-reactive effector T ly from RA patients with MCR type specific synthetic ligands in vivo or in vitro to induce Treg transformation. Future curative induction of auto-antigen specific immune tolerance in RA may therefore involve the melanocortin system.

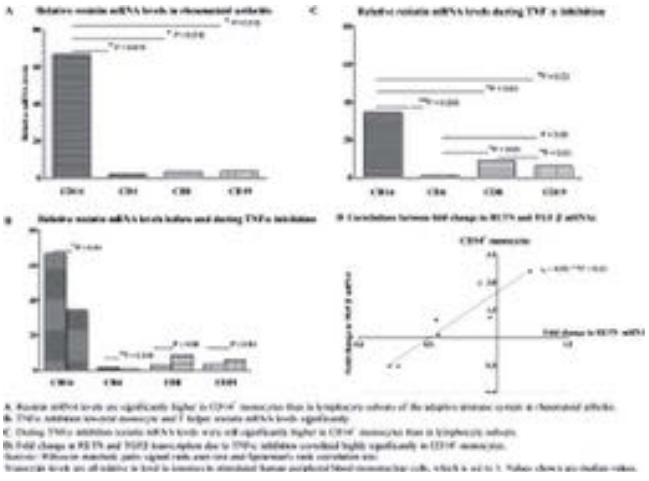
## AB0021 RESISTIN GENE TRANSCRIPTION IS REGULATED IN ADAPTIVE AND INNATE IMMUNITY IN RHEUMATOID ARTHRITIS



M. Andersen[1], M.K. Meyer[1], I. Nagaev[2], O. Nagaeva[2], J.E.S. Wlkberg[3], L. Mincheva-Nilsson[2], G.N. Andersen[4]. *[1]Health science and technology, Aalborg University, Aalborg, Denmark; [2]Clinical Microbiology, Clinical Immunology, Umeå; [3]Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden; [4]Clinical Medicine, Aalborg University, Aalborg, Denmark*

**Background:** Resistin (RETN) was described in 2001 as an adipokine secreted by murine adipocytes resulting in insulin resistance. However, in man, adipocyte synthesis of RETN is controversial, while monocyte RETN production is well established (1). Curiously, RETN synthesis and its regulation in pathogenic immune cell subsets have not been examined in rheumatoid arthritis (RA), although blood RETN levels correlate to disease activity. In RA, -a risk factor for coronary artery disease (CAD), RETN might contribute to atherosclerosis. E.g. macrophage secreted RETN in atheromas, facilitates cholesterol uptake and plaque instability. Considering this, an in depth understanding of the regulation and effects of RETN synthesis in pathogenic immune cell subsets may provide clues to the aetiology of CAD, known to be associated with factors (high CRP, RF and ACPA), characterizing active RA.

**Objectives:** The aim of our investigation was to explore whether RETN gene transcription in pathogenic cell subsets of innate and adaptive immunity is detectable and if present, amenable to TNFα inhibition (I) and correlated to important cytokines in RA.

**Methods:** We examined the reaction of RETN gene transcription to TNFαI in CD14+ monocytes, CD4+ T helper (Th) lymphocytes (ly), CD8+ T cytotoxic (Tc) ly, and CD19+ B ly in RA patients, responding to adalimumab. Leukocyte subsets from 7 RA patients were isolated by Dynabeads before and 3 months after start of TNFαI. Total RNA was extracted and mRNAs for RETN and a panel of disease driving Th1, inflammatory and regulatory cytokines were measured by real-time qRT-PCR.

**Results:** RETN gene transcription was present in al cell subsets and in CD14+ monocytes and CD4+ Th ly responded to TNFαI with a significant decrease. In CD14+ monocytes the RETN gene was transcribed to a significantly higher degree than in lymphocyte subsets of the adaptive immune system both before and during TNFαI. In active RA, prior to TNFαI, RETN and TGFβ mRNA levels correlated significantly in CD4+ Th ly (P=0.03), while in CD14+ monocytes fold change in TGFβ and RETN mRNAs due to TNFαI correlated highly significantly (P=0.01). Furthermore, RETN and IL-8 mRNA levels tended to correlate (P=0.06) in CD14+ monocytes prior to TNFαI.

**Conclusions:** We here report regulated RETN gene transcription in human CD4+ Th ly as well as in CD14+ monocytes. Our results point at wider functions for RETN. Thus we found TNFαI regulated RETN gene transcription in CD4+Th ly in RA, indicating a possible immune response directing role. In this aspect, our results are in concert with increased RETN mRNA correlating to CD4+Th17 ly number in human cecum. The idea of RETN pleiotropic actions is further supported by the correlation to TGFβ transcription. RETN and TGFβ share a pathway for their synthesis and fibrogenic ability (2), on top TGFβ also has a prominent role in immune tolerance. The relation to IL-8 indicates influence on neutrophil trafficking (1).

## AB0022 MODULATION OF TREG STABILITY AND FUNCTION BY INHIBITION OF IL-1BETA

G. Almanzar[1], M. Greupner[2], P. Morris[2], K. Hoefner[1], N. El Hajj[3], T. Haaf[3], M. Schmalzing[4], J.P. Haas[5], H.P. Tony[4], M. Prelog[1]. *[1]Department of Pediatrics; [2]University of Wuerzburg, Wuerzburg, Germany; [3]Human Genetics; [4]Internal Medicine II, Rheumatology and Immunology, University of Wuerzburg, Wuerzburg; [5]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany*

**Background:** High plasticity was described for Th1 and Th17 cells depending on the local cytokine milieu and regulation by Tregs. Pathogen-induced human Th17 cells and Tregs are strongly regulated by IL-1beta. So far, the influence of IL-1beta on FoxP3 methylation and stability of the Treg lineage has not been investigated. Further, whether inhibition of IL-1beta and its receptor is able to promote FoxP3 demethylation and to conserve Treg functions, such as suppression of Th17 and Th1 functions, has not been assessed in healthy humans, as well as in patients with autoimmune arthritis.

**Objectives:** Thus, the present study aimed to investigate *in vitro* nTreg and iTreg functions in lymphocytes obtained from stored routine blood samples of patients with juvenile idiopathic arthritis (JIA) or rheumatoid arthritis (RA) in different disease activity states.

**Methods:** Proportions of peripheral nTregs and cultured iTregs from stored routine blood samples taken from JIA, RA patients and healthy, age-matched controls (HC) and intracellular cytokine production were analyzed by flow cytometry. Suppressive function of iTregs under *in vitro* inhibition of IL-1beta was studied by suppression assays. *FOXP3* expression and methylation were analyzed by quantitative PCR and bisulfite pyrosequencing.

**Results:** Lower proportions of nTregs were found in samples of JIA patients with acute disease flare (mean 2.3% of CD4+ T cells) compared to HC (4.1%) ($p<0.001$). Using IL-1beta and other Th17-stimulating cytokines, proportions of induced iTregs were similar between JIA samples with acute disease flare (mean 34.6% of CD4+ T cells) and healthy children (38.1%), but lower in remission (13.2%) ($p<0.001$). Proportions of iTregs were markedly induced by blockade of IL-1beta in both JIA (mean 78.1% of CD4+ T cells) and HC (84.0%) compared to cells without blockade ($p<0.01$). IL-1beta blockade reduced proliferation of effector T cells by induction of suppressive function of iTregs in both JIA (suppression from 55.1% to 34.2% proliferating effectors) and HC (from 48.2% to 31.8%) ($p<0.001$). Intracellular IL-10 production was not influenced by blockade of IL-1beta.

**Conclusions:** Induction of Tregs seems to be different depending on disease activity status in autoimmune arthritis. DNA methylation at the *FOXP3* promoter and enhancer regions may influence expression of FoxP3 in Tregs and, thus, modify their phenotype. Although IL-10 was not markedly influenced by IL-1beta-dependent mechanisms, our findings indicate that suppressive iTreg functions may be restored by selective blockade of IL-1beta.

## AB0023 THE REGULATION OF HUMAN IN VITRO TH17 CELL DIFFERENTIATION BY CYTOKINES

E. Baricza, E. Lajkó, L. Kőhidai, B. Molnár-Érsek, N. Marton, E.I. Buzás, G. Nagy. *Department of Geneticts-, Cell- and Immunolbiology, Semmelweis University, Budapest, Hungary*

**Background:** Th17 cells have a central role in inflammation via their pro-inflammatory cytokine production, such as interleukin (IL)-17A, -17F, -21, -22, tumor necrosis factor-α and the expression of master regulator transcription factor RORc. The Th17 cells have essential role in many autoimmune diseases via induction of the development of inflammation.

**Objectives:** We studied the *in vitro* Th17 cell differentiation of healthy donors and patients with rheumatoid arthritis (RA).

**Methods:** CD45RO- and CD45RO+ cells were isolated from peripheral blood mononuclear cells with a two-step negative magnetic separation. The cells were activated with anti-CD3 and anti-CD28 antibodies and treated with TGFβ (2.5

ng/ml), IL-6 (25 ng/ml), IL-1β (10 ng/ml) and IL-23 (10 ng/ml) cytokines and with an anti-IL-4 (10 μg/ml) blocking antibody. After 5 and 10 days IL-17 and IL-22 productions were measured by ELISPOT and ELISA; the RORc and Tbet expression were measured by quantitative real-time PCR methods. Cell viability was monitored by impendance-based cell analyzer (CASY-TT).
**Results:** Although anti-CD3/CD28 activation increased the IL-17 and IL-22 productions, it did not alter the RORc expression of the CD45RO- cells of healthy donors. The IL-22 production and the Tbet expression of the RORc producing cells were inhibited by TGFβ and stimulated by IL-23 treatment. The CD45RO+ cells of healthy donors expressed higher level of RORc, T-bet and IL17 without stimulation or cytokine treatment compared to the CD45RO- cells. However, there was no difference between the RORc and Tbet expression of the freshly separated CD45RO+ and CD45RO- cells of RA patients. IL-23 treatment increased both of IL-17 and IL-22 cytokine production of the differentiated CD45RO- cells.
**Conclusions:** IL-17 and IL-22 production are differently regulated during human Th17 differentiation. Our data suggest that the increased baseline RORc expression of CD45RO- cells may contribute to the accelerated Th17 differentiation in RA.

## AB0024 B-CELL MARKERS EXPRESSION IS AFFECTED BY TNF-INHIBITORS AND TOCILIZUMAB TREATMENT IN RHEUMATOID ARTHRITIS

R.A. Moura[1], C. Quaresma[1], A.R. Vieira[1], M.J. Gonçalves[1,2], J. Polido-Pereira[1,2], V. Romão[1,2], N. Martins[2], H. Canhão[1,2], J.E. Fonseca[1,2]. *[1]Rheumatology Research Unit, Instituto de Medicina Molecular; [2]Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisbon, Portugal*

**Background:** The use of TNF-inhibitors and/or the IL-6 receptor antagonist, tocilizumab, in rheumatoid arthritis (RA) have pleiotropic effects that also involve circulating B-cells.
**Objectives:** The main goal of this study was to assess the effect of TNF-inhibitors and tocilizumab on B-cell phenotype and gene expression in RA.
**Methods:** Blood samples were collected from untreated early RA (ERA) patients, established RA patients under methotrexate (MTX) treatment, established RA patients before and after treatment with TNF-inhibitors and tocilizumab, and healthy donors. B-cell subpopulations were characterized by flow cytometry and B-cell gene expression was analyzed by real-time PCR on isolated B-cells. Serum levels of BAFF, CXCL13 and sCD23 were determined by ELISA.
**Results:** The frequency of total CD19+ B cells in circulation was similar between controls and all RA groups, irrespective of treatment. However, established RA patients under MTX treatment had significantly increased frequencies of double negative (IgD-CD27-) B cells in comparison with controls. Treatment with TNF-inhibitors and tocilizumab did not affect the circulating levels of B-cell subpopulations. CD86 and CD95 had, respectively, a significantly lower and higher expression on B-cells after anti-TNF treatment. HLA-DR MFI values were also significantly increased in RA patients after treatment with TNF antagonists and tocilizumab. BAFF-R, TACI, BCMA, CD69, CXCR5, TLR9, IgM and CD5 expression on B cells were not significantly affected by TNF-inhibitors and tocilizumab. In addition, alterations in B cell gene expression of BAFF-R, TACI, TLR9, FcγRIIB, BCL-2, BLIMP-1 and β2M were found in ERA and established RA patients under MTX treatment when compared to controls, but no significant differences were observed after anti-TNF and tocilizumab treatments when comparing baseline and follow-ups. Moreover, CXCL13 and sCD23, but not BAFF serum levels were significantly increased since early RA, but no effect of TNF-inhibitors and tocilizumab treatment was observed.
**Conclusions:** In RA patients, the use of TNF-inhibitors and/or tocilizumab treatment affects B-cell phenotype in circulation, but not B-cell frequencies or B-cell gene expression. Our results suggest that TNF-inhibitors and tocilizumab help to reduce B-cell infiltration in inflammatory sites, allowing these activated B-cells to recirculate through blood and lymphatic systems.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5045

## AB0025 EVOLUTION OF REGULATORY B CELLS UNDER TREATMENT BY BIOLOGICS IN RHEUMATOID ARTHRITIS

S. Salomon[1], C. Guignant[2], C. Brault[2], G. Flahaut[2], B. Gubler[2], P. Fardellone[1], J. Marolleau[3], V. Goeb[1]. *[1]Rheumatology; [2]immunology; [3]Haematology, Amiens University Hospital, Amiens, France*

**Background:** In clinical daily practice, the response to biologics is unpredictable in patients with rheumatoid arthritis (RA) and there is a crucial need for biomarkers of response.
**Objectives:** The main objective of our study is to describe the evolution of regulatory B cells (Bregs) in patients with RA treated with biologics and to investigate whether there is a correlation between the rate of Bregs and the clinical response.
**Methods:** This was a propective single-center pilot study, descriptive and not randomized. Patients were included with RA fulfilling the ACR/EULAR 2010 criteria, with an active disease according to the DAS28 score despite treatment, and in whom initiation or switch of a biologic except rituximab was required. Acontrol group of patients without any autoimmune disease or immune dysfunction was also assessed. B and T lymphocytes whole blood phenotyping, as well as an analysis of the production of IL-10 were performed by multicolor flow cytometry (FCM) in both patients and controls at baseline (M0) and in patients after 1 (M1), 3 (M3) and 6 (M6) months of treatment. CD24hiCD38hi CD24hiCD27+ subpopulations were selected for the phenotypic study of Bregs (24–38 and 24–27 Breg). The primary endpoint was the rate and absolute value of Bregs as a percentage and absolute value measured at each time of the study and compared with disease activity.
**Results:** Thirty patients and 15 controls were included in this study. Nowadays, phenotypic analysis was performed at baseline in all patients, but only in 15 patients at M1 and 13 patients at M3. The complete data will be available for the EULAR congress. There was an increase in circulating 24–38 Bregs between M1 and M3 (p=0.06) whatever the biologic prescribed. At baseline, the 24–38 Bregs were significantly lowered in patients compared to controls in percentage and absolute value (p=0.001 and p=0.013 respectively). The DAS28 remission and EULAR response at M3 were associated with a quantitative increase of 24–38 and 24–27 Breg at baseline compared to the values of the non-responders patients. Thus, a high initial rate of 24–27 and 24–38 Breg seemed associated with a good clinical response and an EULAR remission at 3 months. The rate of CD19 + B producing IL-10 obtained by PBMC culturing seemed lower in controls as compared to the patients.
**Conclusions:** We observed an increase of Bregs under treatment by biologics and a quantitative decrease in Bregs in patients with active RA compared to healthy subjects and patients with inactive disease. Thus, Bregs could be a marker of activity of the disease and their level may represent a potential predictor of the therapeutic response. Full data are required to confirmed these preliminary results.

## AB0026 A SIMPLE METHOD OF REMOVING LOW DENSITY GRANULOCYTES FROM PERIPHERAL BLOOD MONONUCLEAR CELLS IN AUTOIMMUNE DISEASES

S. Zhang, H. Shen. *Department of Rheumatology, Lanzhou University Second Hospital, Lanzhou, China*

**Background:** Low density granulocytes (LDGs) can form neutrophil extracellular traps (NETs) spontaneously and excessively. When peripheral blood mononuclear cells (PBMCs) were used for studying T lymphocytes, PBMCs-contained LDGs may decrease the threshold of activating T lymphocytes by forming NETs.
**Objectives:** This study focused on profiles of LDGs in common autoimmune diseases and method of removing LDGs from PBMCs.
**Methods:** LDGs percentages in PBMCs from 55 dermatomyositis (DM) patients, fifteen polymyositis (PM) patients, forty-two rheumatoid arthritis (RA) patients, twenty-five SLE patients and 19 healthy controls were tested by flow cytometer. Increasing relative centrifugal force (RCF) method, PBMCs adherence method and whole blood sedimentation method were used to remove LDGs from PBMCs. PBMCs from six patients with positive T-SPOT.*TB* were adhered one hour and then tested for T-SPOT.*TB* again.
**Results:** Compared with controls (1.28±0.73%), patients with DM (8.41±10.87%, $P<0.0001$), PM (8.41±10.39%, $P<0.0001$), RA (4.05±6.97%, $P=0.0249$) and SLE (7.53±11.52%, $P=0.0006$) showed significantly higher LDGs percentage in PBMCs. Increasing RCF in a limited range can decrease LDGs percentage for cases with high LDGs percentages, but not remarkably increase LDGs clearance rate. PBMCs adherence method can significantly remove LDGs and scarcely influence the T lymphocyte percentage in PBMCs compared to whole blood sediment method. T-SPOT.*TB* value significantly decreased after LDGs were removed from PBMCs by using the PBMCs adherence method.
**Conclusions:** Similar to SLE, LDG percentages in PBMCs were significantly increased in patients with DM, PM and RA. LDGs' influences on T lymphocytes cannot be ignored in PBMCs culture. PBMCs adherence method was a simple and easy-to-use method of removing LDGs from PBMCs.

## Innate immunity in rheumatic diseases

### AB0027 A NOVEL TRANSCRIPTION FACTOR NFAT5 PLAYS AN IMPORTANT ROLE AS CRITICAL REGULATOR IN THE INFLAMMATORY RESPONSE OF RHEUMATOID ARTHRITIS FIBROBLASTS MEDIATED VIA TOLL-LIKE RECEPTOR 4 SIGNALING PATHWAYS

K. Umekita[1], S. Miyauchi[1], M. Matsuda[1], K. Kubo[1], M. Komura[1], H. Nomura[1], A. Kawano[1], K. Umeki[1], I. Takajo[1], Y. Nagatomo[1], M. Frank-Bertoncelj[2], R.E. Gay[2], S. Gay[2], A. Okayama[1]. *[1]Division of Rheumatology, Infectious Diseases and Laboratory Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland*

**Background:** Damage-associated molecular patterns (DAMPs) are proposed to drive aberrant stimulation of Toll-like receptors (TLRs) in the rheumatoid arthritis (RA) joints resulting in increased expression of proinflammatory cytokines and chemokines. In the recent study we demonstrated that the neutrophil-derived lactoferrin (LTF) induces inflammatory response in RA synovial fibroblasts (RASF) via TLR-4 (Ref.). However, the molecular mechanisms of TLR-4 signaling in activated RASF are still unclear.
**Objectives:** To clarify the molecular mechanisms of TLR-4 signaling pathways in activated RASF.
**Methods:** Recombinant human neutrophil-derived LTF was used as one of the TLR-4 ligands. RASF were treated with LTF and/or TNF-α, and the expression of proinflammatory cytokines and chemokines, such as IL-6, IL-8 and CCL20 in RASF was measured by RT-qPCR and ELISA. To repress the TLR-4 signaling pathways, a small molecular inhibitor of TLR-4 (TAK-242), TAK1 inhibitor (5Z-7-Oxozeaenol), nuclear factor kappa B (NF-kB) inhibitor (BMS345541), and p38 mitogen activated protein kinase (MAPK) inhibitor (SB202190) were used. The role of nuclear factor of activated T cells 5 (NFAT5) in the TLR-4 signaling in RASF was investigated using a small interfering RNA targeting NFAT5.
**Results:** Stimulation of RASF with LTF significantly increased the expression of IL-6, IL-8 and CCL20 mRNA and proteins (p=0.01). LTF enhanced the expression of these cytokine and chemokine mRNA in RASF stimulated by TNFα. TAK-242 completely repressed the expression of these cytokines and chemokines in RASF stimulated by LTF, while the TAK-1 inhibitor did not suppress the expression of these cytokines and chemokines in RASF. The NF-kB inhibitor, but not the p38MAPK inhibitor, partially repressed the expression of IL-6 and IL-8 mRNA induced by LTF. However, neither the NF-kB inhibitor nor p38MAPK inhibitor repressed the expression of CCL20 mRNA. Interestingly, silencing of NFAT5 significantly decreased the basal expression of IL-6, IL-8 and CCL20 mRNA in RASF. Additionally, silencing of NFAT5 significantly repressed the expression of not only IL-6, IL-8, but also of CCL20 mRNA in RASF treated by LTF.
**Conclusions:** These findings suggest that NFAT5 plays an important role as a critical regulator in the proinflammatory response of RASF mediated by the TLR-4 signaling pathway.

### AB0028 INNATE LYMPHOID CELLS ARE PRESENT AT NORMAL HUMAN ENTHESIS PROVIDING A POTENTIAL MECHANISM FOR SPONDYLOARTHROPATHY PATHOGENESIS

R.J. Cuthbert[1], E. Fragkakis[1], R. Dunsmuir[2], P. Millner[2], Y. El-Sherbiny[1], D. McGonagle[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]Department of Spinal Surgery, National Health Service, Leeds, United Kingdom*

**Background:** The pathogenesis of murine spondyloarthropathy (SpA) has been intimately linked to the presence of IL-23 responsive, innate like lymphocytes at peripheral and spinal enthesis (1). Human SpAs are associated with SNPs in genes related to the IL-23 pathway and drugs that block IL-12/23 have shown efficacy (2).
**Objectives:** We hypothesised that the normal human enthesis has a population of resident innate lymphoid cells (ILCs) that could be key in governing entheseal immune homeostasis partly via interaction with resident mesenchymal stromal cells (MSCs). Therefore we examined the lymphocytic content of human entheseal tissue with particular emphasis on ILCs.
**Methods:** Normal spinal enthesis were harvested from patients undergoing spinal decompression surgery and enzymatically digested prior to sorting or flow cytometry. Immunophenotyping and cell sorting was performed on enthesis samples harvested from 6 patients and unmatched peripheral blood. The expression of RORγt and key immunomodulatory transcripts was tested in sorted populations by RTqPCR. Anterior cruciate ligament and Achilles enthesis were obtained from patients with knee OA and Achilles tendon rupture and analysed by immunohistochemistry (IHC). Adherent cells from entheseal digest were cultured under standard MSC culture conditions and expression of known MSC markers was assessed by flow cytometry.
**Results:** All sorted samples contained ILC3s, median proportion 0.09% (range 0.015–0.63). Transcript analysis confirmed elevated expression of RORγt transcript in sorted ILC3 compared to all other ILCs and 51-fold greater relative expression in comparison to unsorted mononuclear cells (p=0.043). 5 of 6 sorted samples contained ILC2s, median proportion 0.20% (range 0–0.49). RORγt expression was detected in knee OA and there was widespread expression of RORγt in inflammatory infiltrates in injured enthesis as shown by IHC. Culture expanded adherent cells grew in characteristic fibroblastoid colonies and expressed phenotypic markers consistent with bone marrow derived MSCs.
**Conclusions:** Our findings show that both ILCs and MSCs are present in the normal human spinal enthesis. ILCs may also be greatly increased in frequency following injury. The co-localisation of ILC and MSC populations at the enthesis suggests a potential link between cellular dysregulation of the IL-23/17 axis and human SpA pathology.

## Cytokines and inflammatory mediators

### AB0029 RELATIONSHIP SCD36 LEVELS AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A.A. Saldaña Millan, J.D.J.E. Gómez Bañuelos, P.M. Madrigal Ruíz, E. Chavarría Ávila, B.T. Martín Márquez, R.E. Navarro Hernández, M. Vázquez-Del Mercado. *Instituto de Investigacion en Reumatologia y del Sistema Musculo-Esqueletico, Universidad de Guadalajara, Guadalajara, Mexico*

**Background:** The main cause of death in RA patients is cardiovascular disease [1]. CD36 is a scavenger receptor has been postulated as a molecule involved in the atherogenic process [2,3]. A soluble fraction, sCD36 has been reported and has been proposed as a marker of atherosclerosis and other metabolic diseases [4,5], however, little is known of the pathways involved in these processes in RA.
**Objectives:** The objective of this study was to evaluate the levels of sCD36 and examine the association between clinical characteristics, disease activity and inflammatory markers in patients with RA.
**Methods:** The study groups were composed of 59 patients with RA (ACR/EULAR 2010) vs. 79 controls. sCD36, PCR, FR, Anti-CCP, insulin, TC, TG, HDL-C, VLDL-C, LDL-c were measured by ELISA. Index Disease Activity 28 (DAS-28) C-reactive protein (CRP) was calculated. VSG by Wintrobe method. cIMT using a Class B ultrasonography. Data were analyzed using descriptive statistics, Student t test, chi-square and ANOVA, as appropriate, with SPSS V.23 software.
**Results:** We found high levels of sCD36 in the control group (1861.10 ±6491.42±29.87 vs. 76.71, $P<0.01$) as well as ESR (21.26±12.79 vs. 13.29±8.85, $P<0.01$), CRP (8.97±7.32 vs. 7.27±4.11, $P<0.01$), and VLDL-c (33.36±17.26 vs. 52.21±21.70, $P<0.01$). sCD36 was positively correlated with the levels of DAS28pCr, PCR, FR, TG, insulin and IMT; negatively with HDL-c. Finally, we note a proportional direct relationship between sCD36 levels and Index Disease Activity 28 by pCr (Fig. 1).

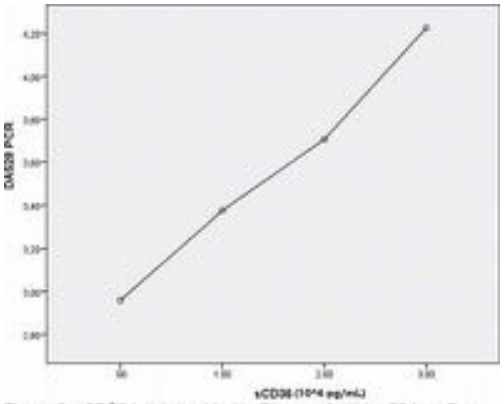

Figure 1. sCD36 levels and Index Disease Activity 28 by pCr

**Conclusions:** High levels of sCD36 were observed in serum from RA patients compared to a control group, as well as a relationship between sCD36 levels and Index Disease Activity 28 by pCr. It could be proposed to sCD36 as a marker of clinical activity of RA, however, more studies are needed to validate our findings and clarify the regulation and the role of sCD36 in RA.

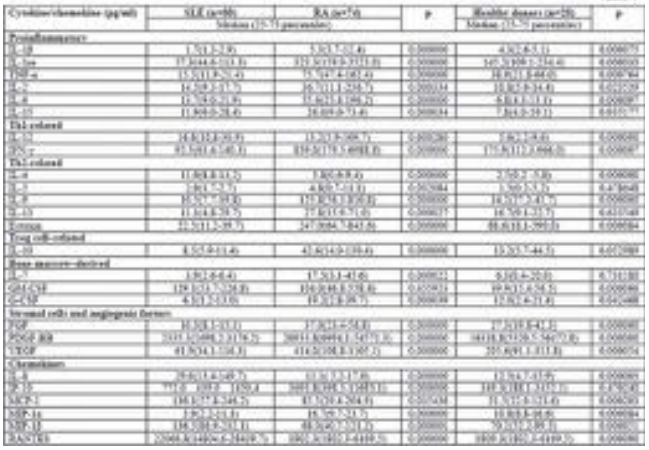
## AB0030 CYTOKINE PROFILES IN SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

A. Novikov, E. Aleksandrova, Z. Verizhnikova, T. Panafidina, T. Popkova, D. Karateev, E. Luchihina, E. Nasonov. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*



**Background:** Our aim was to compare serum levels of cytokines in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).

**Objectives:** Comparative data on cytokine profile in SLE and rheumatoid arthritis RA patients are scarce.

**Methods:** We examined serum samples from 80 pts with SLE, median and interquartile range (25th–75th percentile) of disease duration 48 (2–432) months; age 31,5 (16–65) years; 72 female; 74 pts with RA, disease duration 90,0 (30,00–192,0) months; age 54,0 (44,0–62,0) years; 59 female, and 28 healthy donors. Cytokine analyses were performed with Bio-Plex® technology (Human Grp I Cytokine 27-plex panel).

**Results:** Pts with SLE had significantly lower levels of IL-1β, -1ra, -2, -9, eotaxin, G-CSF, IFN-γ, MIP-1β, TNF-α, VEGF and higher levels of IL-4, -6, -8, -12, GM-CSF, MCP-1, PDGF-BB, RANTES than healthy donors. Compared to RA, cytokine/chemokine levels from SLE were significantly different. The concentrations of IL-1β, -1ra, -2, -5, -6, -7, -9, -10, -13, 15, eotaxin, FGF, G-CSF, IFN-γ, IP-10, MIP-1α, TNF-α, VEGF in SLE were significantly lower than RA. The concentrations of IL-4, -8, MCP-1, MIP-1β, PDGF-BB, RANTES was higher in the SLE cohort (Table 1).

Table 1

**Conclusions:** Serum concentration of most proinflammatory, Th-2 related, bone marrow–derived cytokines, stromal cells and angiogenic factors in SLE pts is substantially lower than in healthy donors and pts witch RA. These data demonstrate significantly higher chemokine levels in SLE versus RA.

## AB0031 EVALUATION OF SERUM FETUIN-A AND APELIN LEVELS IN FAMILIAL MEDITERRANEAN FEVER (FMF) PATIENTS AND HEALTHY SUBJECTS

A. Şahin[1], Ö. Demirpençe[2], M. Şahin[2], D. Seven[3], H.O. Doğan[2], A. Camcı[1]. *[1]Rheumatology - Internal Medicine; [2]Biochemistry; [3]Internal Medicine, Cumhuriyet University Medical Faculty, Sivas, Turkey*

**Background:** Apelin is an adipokine that its level is increased by some proinflammatory cytokine such as TNF-alpha in metabolic, autoimmune and inflammatory conditions (1). Fetuin-A is protein secreted by liver, kidney, bone, brain, lungs and cardiovascular system (2). The levels of fetuin-a are decreased in some rheumatic diseases (ie. Rheumatoid arthritis, osteoarthritis). It has been suggested that fetuin-a can be a novel inflammatory biomarker in familial Mediterranean fever (FMF) (3).

**Objectives:** To evaluate of the serum Apelin, Fetuin-A levels in patients with FMF during attack-free period (AFP) and to compare with healthy subjects.

**Methods:** Thirty-FMF patients with AFP and thirty healthy subjects were included this study. The erythrocyte sedimentation rate (ESR), CRP, fibrinogen, hemogram, Mediterranean fever (MEFV) gene profiles, BMI, insulin, HOMA-IR, lipid profiles, serum apelin, fetuin-a levels were investigated.

**Results:** Of the FMF patients and control, 20 (66.7%) was female and 10 (33.3%) was male. The distribution of MEFV gene mutation frequencies in the FMF patients was no mutation in 4 (13.3%) patients, M694V heterozygous in 7 (23.3%), M694V homozygous in 3 (10%), E148Q heterozygous in 5 (16.7%), M680I heterozygous in 2 (6.7%), M680I homozygous in 1 (3.3%), V726A in 2 (6.7%) and compound heterozygous mutation in 6 (20%). The median levels of apelin were 307.82±52.76 ng/mL in healthy subjects and 113,07±15,9 ng/mL in FMF (p=0.002) (Figure 1). The median levels of fetuin-a were 843,82±137.66 ng/mL in control group and 1352.2±127.61 ng/mL in FMF group (p=0.009) (Figure 1).

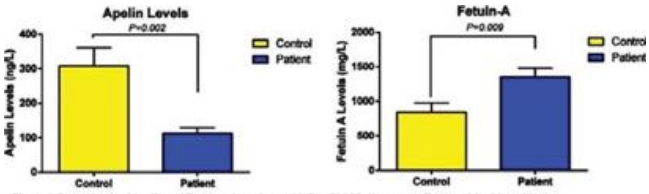

**Figure 1. Serum levels of Apelin and Fetuin-A in patients with Familial Mediterranean Fever and healthy subjects.**

**Conclusions:** The lower serum apelin and higher fetuin-a levels in FMF patients with AFP than in healthy subjects were observed. It may be suggested that subclinical vascular inflammation is continued during attack-free period in patients with FMF.

## AB0032 THE ADENOSINE DEAMINASE ISOFORMS ACTIVITY IN SYNOVIAL FLUID IN PATIENTS WITH DIFFERENT ARTHRITIS

A. Antonyan[1], R. Harutyunyan[2], S. Sharoyan[1], L. Karapetyan[1], S. Mardanyan[1]. *[1]H.Ch. Buniatian Institute of Biochemistry of Armenian NAS; [2]"Yerevan" Medical Center, Yerevan, Armenia*

**Background:** Arthritis is one of the most common causes of people's disability in the world. Recent years investigations were done to find biomarkers which can help in differentiating the type of arthritis, to evaluate the correlation between marker and disease severity. A purine nucleoside adenosine possesses anti-inflammatory activity via decreasing the level of pro-inflammatory cytokines, increasing the level of anti-inflammatory cytokines and represents one of the potent regulators of the inflammatory response. Adenosine deaminase (ADA) metabolizes adenosine

to inosine, decreasing its anti-inflammatory activity. The significant elevation of ADA activity in rheumatoid arthritis (RA) and other inflammatory joint disorders has been observed. In our earlier study we have shown that the ADA activity can be used as a biomarker suitable for RA and osteoarthritis differentiation (1). The cutoff value of the enzyme activity in synovial fluid (SF) for differentiating these diseases in Armenian population has been evaluated. We observed the increasing of small-molecular (SADA, catalytic unit) to large-molecular (LADA, a complex of the catalytic unit with ADA-binding protein) isoforms ratio in RA SFs at increasing of the total activity of enzyme. The linear correlation between the initial activity and the SM/LM ratio of ADA isoforms has been shown (correlation coefficient r =0.97, P=0.0017).

**Objectives:** The aim of the present investigation was to analyze the levels of ADA activity in SFs of patients with different arthritis and their probable correlation with the SADA/LADA ratios in various cases.

**Methods:** The SFs of RA, reactive arthritis, ankylosing spondylitis and gout patients were studied. The activity of ADA was assayed, evaluating the amount of ammonia, liberated in the reaction of adenosine deamination. To compare the levels of SADA and LADA isoforms, the SFs were subjected to gel-filtration on the column with G-200 Sephadex. The elution diagrams regarding the ADA activity in the obtained fractions were constructed.

**Results:** The values of ADA activity in SFs of different arthritis mainly scatter in the higher region of the enzyme activities in SFs of RA. The elution diagrams after G-200 Sephadex gel-filtration of SFs of various arthritis manifested the absence or very low levels of SADA isoform even at high total initial activity of the enzyme. That excluded any correlation between the total activities of the enzyme and the ratios of its isoforms.

**Conclusions:** The earlier observed and proved in this study significant correlation between total activity of ADA and its isoforms ratio at RA might be in account of the SADA release from the damaged synoviocytes. This phenomenon appeared specific for RA and was not observed in the other arthritis types. We can conclude that the mechanism of joint inflammation at RA has some peculiarities, which may be a subject of special future study.

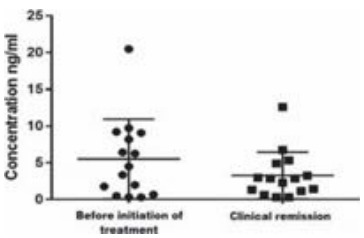
## AB0033 HIGH MOBILITY GROUP BOX 1 PROTEIN IS NOT ELEVATED IN ACTIVE PHASES OF GIANT CELL ARTERITIS



A. Diamantopoulos[1,2], G. Myklebust[1], I. Kvivik[3], R. Omdal[3]. *[1]Rheumatology, Hospital of Southern Norway Trust, Kristiansand; [2]Rheumatology, Hospital for Rheumatic Diseases in Haugesund, Haugesund; [3]Clinical Immunology Unit, Stavanger University Hospital, Stavanger, Norway*

**Background:** High mobility group box 1 (HMGB1) is a non-histone DNA-binding protein. It exists in all types of cells and has complex functions. When secreted extracellularly HMGB1 acts as an alarmin and induces and potentiates *NF-κB* activity. HMGB1 is raised in patients with active granulomatous vasculitis (1). However, a recent study did not find any association of HMGB1 protein concentration and disease activity in Giant cell arteritis (GCA) (2). Our aim was to investigate whether HMGB1 protein rises during the active phase of giant cell arteritis (GCA) and falls after initiation of treatment.

**Objectives:** Our aim was to investigate whether HMGB1 protein rises during the active phase of giant cell arteritis (GCA) and falls after initiation of treatment.

**Methods:** GCA patients were recruited at the Department of Rheumatology at the Hospital of Southern Norway in Kristiansand between January 2012 and January 2014. The diagnosis was based on positive ultrasonography of temporal arteries and /or large vessels and typical clinical manifestations. All patients fulfilled the ACR classification criteria. Blood samples were drawn at time of diagnosis and before treatment and after clinical remission. HMGB1 levels in serum were measured by ELISA (IBL International GMBH, Hamburg, Germany), using a high sensitive protocol (range 0,313–10 ng/ml).

**Results:** Fifteen GCA patients (mean age 68 years (SD 9.2), 3 males and 12 females), were included during the study period. The median time until remission was 6 months (range 1–6). Eight patients had isolated cranial arteritis while seven patients had in addition large vessel vasculitis (LVV). Mean HMGB1 concentration at diagnosis and in clinical remission were 5.5 ng/ml (SD 5.4) and 3.3 ng/ml (SD 3.0) respectively. The difference was not significant (mean difference 2.2 ng/ml (CI 95% -1.2–5.7, p=0.182), Figure 1. No differences were observed for HMGB1 concentrations at diagnosis nor at remission for cranial (p=0.2) or LVV (p=0.7).

**Conclusions:** In GCA patients, no differences in HMGB1 protein levels were observed at diagnosis compared with remission. In addition, no differences were seen between pure cranial and LVV. Thus, HMGB1 protein seems not to be a useful biomarker for disease activity in GCA.

## AB0034 PHARMACOKINETICS AND SAFETY OF BCD-057, ADALIMUMAB BIOSIMILAR CANDIDATE, COMPARED TO HUMIRA IN HEALTHY VOLUNTEERS (RESULTS OF PHASE I CLINICAL STUDY)

A. Eremeeva, S. Fogt, E. Chernyaeva, A. Kushakova, T. Ostroukhova, R. Ivanov. *BIOCAD, Saint-Petersburg, Russian Federation*

**Background:** BCD-057 is an adalimumab biosimilar candidate manufactured by BIOCAD, Russia. Full spectrum of physicochemical and preclinical studies showed equivalence of BCD-057 to innovator drug Humira (reference adalimumab, rADA).

**Objectives:** To establish the equivalence of pharmacokinetics and absence of differences in safety of BCD-057 and rADA after the single subcutaneous injection in healthy volunteers.

**Methods:** 94 healthy volunteers were enrolled into the study. 10 of them withdrew consent before drug administration and were not included in analysis. All patients were randomly assigned into 2 groups in a ratio of 1:1 to receive a single subcutaneous injection of BCD-057 or rADA at a dose of 40 mg. The primary endpoints were $C_{max}$ and $AUC_{0-\infty}$ after the single adalimumab injection. The secondary PK endpoints included $AUC_{0-1680\,h}$, $T_{max}$, $T_{1/2}$, $V_d$, $K_{el}$, CL. Adalimumab serum concentrations were evaluated immediately before the injection and after 6, 24, 48, 72, 96, 120, 144, 168, 192, 336, 672, 1008, 1440 and 1680 hours after it. Safety and immunogenicity were also assessed during the study.

**Results:** Pharmacokinetic (PK) analysis demonstrated that 90% CI for the ratio of geometric means of $C_{max}$ of adalimumab after single injection of BCD-057 or rADA was 87.48–111.84%. 90% CI for the ratio of geometric means of $AUC_{0-\infty}$ lied within 87.90–117.22%. Both of these facts confirm the bioequivalence of BCD-057 and rADA. There were no statistically significant differences between the groups for all other secondary PK parameters. BCD-057 and rADA were well tolerated. No SAEs were observed during the study. AEs were observed in 9 (22.5%) healthy volunteers in BCD-057 group and in 14 (31.8%) volunteers in rADA group (p=0.463, Fisher's exact test [two-tailed]). They were presented by laboratory abnormalities including leucopenia, neutropenia, monocytosis, monocytopenia, increase in total bilirubin, ALT and AST. All AEs were mild (Grade 1 [CTCAE 4.03]), transient and were not associated with any clinical symptoms. 27 (67.5%) subjects in BCD-057 group and 33 (75.0%) subjects in rADA group (p=0.478, Fisher's exact test [two-tailed]) developed anti-adalimumab antibodies. Neutralizing antibodies to adalimumab were found in 2 (5.0%) volunteers in BCD-057 group and in 5 (11.4%) volunteers in rADA group (p=0.437, Fisher's exact test [two-tailed]).

**Conclusions:** PK, safety and immunogenicity of BCD-057 and rADA after a single subcutaneous administration in healthy volunteers are considered to be equivalent. These data allow to proceed to the subsequent BCD-057 study aimed to assess efficacy and safety in patients with moderate-to-severe plaque psoriasis.

## AB0035 BACTERICIDAL/PERMEABILITY-INCREASING PROTEIN LEVELS IN HUMAN SYNOVIAL FLUID AND ITS EFFECTS IN EXPERIMENTAL CRYSTAL-INDUCED INFLAMMATION

A. Scanu[1], R. Luisetto[2], F. Oliviero[1], P. Galozzi[1], R. Ramonda[1], L. Punzi[1]. *[1]Rheumatology Unit, Department of Medicine - DIMED; [2]Department of Surgical Oncological and Gastroenterological Sciences - DISCOG, University of Padova, Padova, Italy*

**Background:** Bactericidal/Permeability-Increasing Protein (BPI) is an antibacterial and antiinflammatory protein stored in polymorphonuclear cells (PMN). BPI has been detected in synovial fluid (SF) of patients with reactive arthritis, rheumatoid arthritis (RA), psoriatic arthritis (PsA) and osteoarthritis (OA).

**Objectives:** The aims of this study were to evaluate the presence of BPI in SF of patients with crystal-induced arthritis and to compare its levels with those of

other arthropathies. Furthermore, we tested whether BPI exerts antiinflammatory effects in *in vitro* models of sterile inflammation.
**Methods:** SF was collected from the knees of 50 untreated patients: 9 with gout, 9 with calcium pyrophosphate (CPP) crystal-induced arthritis (CPP-IA), 8 with OA, 8 with OA and CPP crystals in SF (OA+CPP), 8 with RA and 8 with PsA. SF was examined under optical light microscopy. White cell count (WBC) and the PMN percentage were determined in SF according to standard procedures. SF BPI levels were assayed by ELISA.
As regard the study in vitro, the THP-1 cell line was primed for 3h with phorbole myristate acetate (300 ng/ml), reincubated overnight, and treated with sterile synthetic monosodium urate (MSU) (0.5 mg/ml) or CPP (0.1 mg/ml) crystals for 24h in presence or absence of BPI (1 or 5 μg/ml). Cell supernatants were tested by ELISA for IL-1β and IL-8 production.
**Results:** The results of SF analysis and BPI levels are reported in the table.

| | No. cases | WBC, $\times 10^3/mm^3$ | PMN, % | BPI, ng/ml |
|---|---|---|---|---|
| Total group | 50 | 12.40±12.68 | 59.03±36.62 | 43.78±53.17 |
| Gout | 9 | 25.32±10.13 | 87.75±15.28 | 31.07±7.31 |
| CPP-IA | 9 | 25.32±10.13 | 87.75±15.28 | 23.53±9.47 |
| OA | 8 | 0.3±0.54 | 0.33±0.52 | 12.21±8.40 |
| OA+CPP | 8 | 0.82±0.70 | 28.80±25.16 | 15.87±14.73 |
| RA | 8 | 21.35±8.98 | 68.00±22.63 | 146.02±32.10 |
| PsA | 8 | 9.16±3.56 | 63.00±24.17 | 63.79±31.87 |

BPI levels were similar and the lowest in SFs from OA and OA+CPP. Although the BPI concentrations in gout and CPP-IA SFs were higher than in OA and OA+CPP, the differences did not reach statistical significance. RA SF showed the highest BPI levels ($p<0.001$ vs gout, CPP-IA, OA, OA+CPP, PsA). In the total group of patients, we found a correlation between BPI and WBC count ($r=0.474$; $p=0.004$) and PMN ($r=0.354$; $p=0.037$).
Exposure of THP-1 cells to MSU or CPP crystals increased the production of IL-1β (MSU: 655.5±28.28 pg/ml; CPP: 496.5±9.19 pg/ml) and IL-8 (MSU: 4538.5±37.48 pg/ml; CPP: 4424.7±9.55 pg/ml). The treatment with BPI decreased the release of both cytokines induced by crystals in a dose dependent manner. Indeed, in the presence of BPI 1 or 5 μg/ml, the IL-1β secretion was reduced by 19% and 40%, respectively. IL-8 crystal-induced production was inhibited in the presence of BPI 1 μg/ml (MSU: 20%; CPP: 27%), and abolished when THP-1 cells were treated with BPI 5 μg/ml.
**Conclusions:** This study is the first to define the presence of BPI in SF of crystal-induced arthritis. Our results demonstrate that although SFs from gout and CPP-IA contained the WBC and PMN highest levels, BPI was present at significantly lower concentrations than in RA and PsA. This could be explained by the lack of PMN activators able to induce the release of BPI in crystal-induced arthritis.
The use of BPI in our *in vitro* models of crystal-induced inflammation leads to a significant inhibition of the proinflammatory cytokine release, suggesting an antiinflammatory activity of this protein also in sterile inflammation.

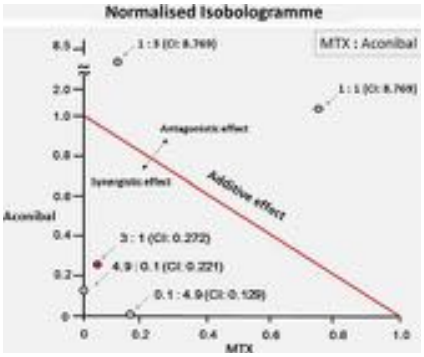
## AB0036 SOLUBLE CD83 PLASMA LEVELS ARE ASSOCIATED WITH DISEASE ACTIVITY AND COURSE OF DISEASE IN EARLY RHEUMATOID ARTHRITIS



A.-M. Kristensen[1], M.L. Hetland[2], K. Hørslev-Petersen[3], P. Junker[4,5,6], M. Østergaard[2], K. Stengaard-Pedersen[7,8], P. Höllsberg[1], M. Hvid[1,8], B. Deleuran[1,7,8]. *[1]Department of Biomedicine, Aarhus University, Aarhus; [2]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup; [3]King Christian 10th Hospital for Rheumatic Diseases, University of Southern Denmark; [4]Department of Rheumatology; [5]Department of Clinical Biochemistry and Pharmacology, Odense University Hospital; [6]Institute of Molecular Medicine, University of Southern Denmark, Odense; [7]Department of Rheumatology, Aarhus University Hospital; [8]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark*

**Background:** The immune modulatory dendritic cell (DC) marker CD83 has previously been associated with autoimmune diseases.[1,2] Levels of soluble CD83 (sCD83) are elevated in RA synovial fluid[3], however the relation to clinical outcome of RA remains unknown. We hypothesize that CD83 plays a central role in the inflammatory process and disease development in RA.
**Objectives:** To investigate the potential association of sCD83 with disease activity measures, treatment response and auto-antibody status in patients with early RA (eRA).
**Methods:** Plasma samples from eRA (n=88) randomized to conventional DMARD treatment with or without 12 months of additional adalimumab therapy (MTX+ADA and MTX+PLA, respectively) were randomly selected from the OPERA cohort.[4] A commercial sandwich ELISA was used to quantify plasma levels of sCD83 in patients and in age- and gender-matched healthy volunteers (HV, n=43). Spearman's rank correlation coefficient between soluble CD83 plasma levels and measures of disease activity (tender joint count (TJC28,40), swollen joint count (SJC28,40), DAS28 and CRP), treatment response (ACR20,50,70,90) and auto-antibody status (IgM-RF and ACPA) was calculated. All results are expressed as median with interquartile range and compared by non-parametric statistics.
**Results:** At baseline, sCD83 in eRA was significantly higher than in HV plasma (168.5pg/ml (136.1pg/ml-203.5pg/ml) and 136.1pg/ml (116.9pg/ml-149.4pg/ml), respectively), $p<0.0001$. At 12 months follow-up sCD83 had decreased by approximately 10% (167.2 vs 151.2pg/ml, p=0006) in the MTX+PLA group while it remained unchanged in the MTX+ADA arm, (p=0.3).
In MTX+ADA (n=43) group baseline sCD83 levels correlated with ACR50 at 6 and 24 months ($\rho$= -0.33, p=0.04 and $\rho$= -0.34, p=0.03, respectively) and ACR90 at 24 months ($\rho$= -0.37, p=0.02). In the MTX+PLA (n=45) group baseline sCD83 levels were found to correlate with TJC28 at 12 and 24 months ($\rho$= -0.30, p=0.05 and $\rho$= -0.43, p=0.003, respectively) and TJC40 at 24 months ($\rho$= -0.32, p=0.04). sCD83 showed no association with IgM-RF and ACPA positivity.
**Conclusions:** This study demonstrated that sCD83 levels were significantly elevated in eRA compared with HV. With additional adalimumab treatment, high sCD83 levels at baseline were sustained over time. A high sCD83 level at baseline was associated with changes in prospective disease activity parameters in both treatment groups, which points to a possible predictive value of sCD83 in eRA.

## AB0037 CHARACTERISING MULTIPLE MOLECULE-MODULATING RESPONSE OF TNF-ALPHA AND INTERLEUKIN-6 BY COMBINATION OF METHOTREXATE AND ACONITE IN INTERFERON GAMMA-INDUCED TOXICITY SETTING

D.-S. Oh, G. Park, S. Choi. *The K-herb Research Centre, Korea Institute of Oriental Medicine, Daejeon, Korea, Republic Of*

**Background:** TNF-alpha (TNF-α) and interleukin-6 (IL-6) are one of the molecules which have been the targets of interest in rheumatoid arthritis (RA). Among the therapeutic strategies, simultaneous modulation of the two is regarded as providing the stability on the networks of the relevant molecules and sufficient profile for multi-therapeutic targets.
**Objectives:** To characterise multiple molecule-modulating profile of TNF-α and IL-6, we experimented the anti-inflammatory phenotypes of the two by adopting well-known therapeutic, methotrexate (MTX) and newly recognised herbal, aconite (*Aconitum carmichaelii*) in the setting of interferon-gamma-induced inflammatory toxicity in macrophage.
**Methods:** Mouse macrophage Raw264.7 cells were treated with MTX (0.01–1 mM) and processed aconite (Aconibal®, 0.01–1 mg/mL). The levels of TNF-α and IL-6 were measured by spectrophotometre (VersaMax ELISA, Molecular devices, USA), then, as a parametric approach, median and dose effect were analysed to calculate the combination index (CI) and standard isobologramme were presented using CalcuSyn software (CalcuSyn 2.0, Biosoft, UK).
**Results:** Anti-inflammatory phenotypes of TNF-α and IL-6 level were shown in aconite dose-dependent manner. The doses of 0.75 mg/mL of aconite and 0.25 mM of MTX indicated the lowest CI as 0.272 for TNF-α and 7916 for IL-6, which was sparing effect compared with single treat by 3.9 mM and 0.6 mM of MTX, respectively. Reflecting the response, TNF-α was modulated with the synergistic profiles in normalised isobologramme.

**Conclusions:** Stable modulation of TNF-α and IL-6 and synergistic response on TNF-α were characterised. Further approaches on network stability of the relevant molecules are needed.

## AB0038 SERUM AND SYNOVIAL GRANULOCYTE COLONY STIMULATING FACTOR (G-CSF) LEVELS AS MARKERS OF DISEASE ACTIVITY AND SEVERITY IN RHEUMATOID ARTHRITIS

E. Baraka[1], N. Fouad[2]. *[1]Rheumatology, Rehabilitation and Physical Medicine, Benha Faculty of Medicine, Benha University, Cairo; [2]Microbiology and Medical Immunology, Benha Faculty of Medicine, Benha University, Benha, Egypt*

**Background:** Rheumatoid arthritis (RA) is a chronic polyarticular disease manifesting as painful inflammation of the synovial tissue with progressive joints destruction. The colony-stimulating factors (CSFs) are a family of four cytokine growth factors originally identified by their ability to support the proliferation and differentiation of hemopoietic progenitor stem cells into mature monocytes/macrophages and granulocytes. The CSF family comprises the lineage-specific members, macrophage CSF (M-CSF or CSF-1) and granulocyte CSF (G-CSF), and the nonlineage-specific members, granulocyte-macrophage CSF (GM-CSF) and multi-CSF [also called interleukin (IL)-3
**Objectives:** to determine serum and synovial levels of the granulocyte colony stimulating factor (G-CSF) in order to evaluate their utility as biomarkers of disease activity and/or severity in rheumatoid arthritis (RA) patients.
**Methods:** Thirty patients with established RA as well as a control group of 20 apparently healthy individuals matched for age and sex to our patients were included and thoroughly examined. RA disease activity was assessed using the modified disease activity score of 28 joint count (DAS28)while, disease severity was evaluated using the clinical spread severity Index (SSI).Plain radiography was done for both knees as well as affected joints with evaluation according to Laresn scores. *Serum and synovial* levels of (G-CSF) were measured by the ELISA technique
**Results:** Both serum and synovial G-CSF levels of RA patients were higher than their levels in the controls (mean±SD 1.36± 0.69pg), (0.875±0.531pg)versus (mean±SD 0.47±0.07 pg), (0.47±0.04 pg) with a significant difference between both groups ($p<0.05$). The serum and synovial G-CSF levels were also higher in patients with a positive rheumatoid factor ($p<0.05$) and those with subcutaneous nodules ($p<0.01$) compared to other RA patients and the difference were statistically significant. Investigating the correlations of serum and synovial G-CSF levels with different clinical and laboratory parameters of RA showed that both levels of G-CSF significantly correlated positivey with morning stiffness durations ($p<0.01$),VAS values ($p<0.05$), spread severity index scores ($p<0.01$), DAS scores ($p<0.01$), ESR values ($p<0.01$), inversely with HB concentrations ($p<0.01$) but they were not correlated with either disease durations or radiographic larsen scores
**Conclusions:** Our results reveal that G-CSF has a potential role in driving joint inflammation and also underscore that G-CSF would likely be a therapeutic target in RA.

## AB0039 INTERLEUKIN-17 IN SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS PATIENTS: CORRELATION WITH CLINICAL PRESENTATION, LABORATORY PARAMETERS AND ACTIVITY INDICES

R.F. Moftah[1], E.H.E.-S. Hassan[2]. *[1]Clinical pathology; [2]Internal Medicine, Rheumatology, Faculty of Medicine, Alexandria University, Alexandria, Egypt*

**Background:** Serum interleukin (IL)-17 concentrations have been reported to be increased in systemic lupus erythematosus (SLE), but associations with clinical characteristics are not well understood. Autoimmune diseases such as RA, classically believed to be Th1-mediated, are predominantly driven by a Th17 immune response.
**Objectives:** this study aimed to compare the serum levels of IL-17 in patients with SLE and RA, it is correlation with clinical presentations, laboratory findings and disease activity in both diseases.
**Methods:** The study was carried out on 3 groups. Group I: 20 patients with SLE. Group II: 20 patients with RA. Group III: 10 of age and sex matched healthy subjects as control group.
**Results:** In this study, the mean of age were 43.1±8.98, 46.8±8.17 and 41.98±8.25 for group I (SLE), II (RA) and III (control) respectively, with no statistical significant differences between the studied groups. Also, there were no statistical significant differences between the three studied groups regarding sex, disease duration, disease activity, laboratory investigations (except HB, WBC and platelet count). The mean of IL-17 were 173.2±52.11, 82.6±48.17 and 73.07±41.05 for group I (SLE), II (RA) and III (Control) respectively, group I have values statistically higher than other groups, and group II have values statistically higher than group III. Serum IL-17 levels were significantly higher in SLE patients compared to healthy group.
**Conclusions:** Serum IL-17 concentration correlates with SLE and RA diseases activity but is significantly elevated in patients with SLE disease. The association of other cytokines with serum IL-17 suggests that IL-17 may drive activation of diverse immune pathways in SLE and RA.
**Disclosure of Interest:** None declared

## AB0040 ANTIOXIDANT POTENTIAL AND FREE RADICAL POTENTIAL OF SYNOVIAL FLUID (SF) IN RHEUMATOID ARTHRITIS (RA) AND OSTEOARTHRITIS (OA)

G. Kudriavtseva, Y.A. Malencov, V.V. Shishkin, V.I. Shishkin. *Sait Petesburg State University, Saint Petersburg, Russian Federation*

**Background:** Intra-articular dynamics of free radical processes in RA and OA reflects the degree of cellular destruction and the depth of the membrane pathological changes. Multi-component antioxidant system hinders the development of these negative phenomena.
**Objectives:** We studied the dynamics of free radical processes (the rate of lipid peroxidation (LPO - the level of malondialdehyde - MDA), activity of phospholipase (PHL-A2) and phospholipids - PHL) and the antioxidant defense system (activity superoxiddismutase (SOD), catalase (CAT), glutathione-S-transferase (G-S-T), tocopherols (TF) and ceruloplasmin (CP) in SF of patients with RA and OA. The data were compared with the levels of inflammation cytokines.
**Methods:** Investigated the SG of the knee in 15 patients with RA and 15 patients with OA, female, age 50±12 years. Besides the well-known methods of biochemistry and enzymology, for determining the activity of PHL-A2 used immunoassay method and reagent kits of company "Cayman chemical", analysis of cytokines was performed enzymelinked immunosorbent method.
**Results:** In OA, and especially in RA in SF, with the intensification of free radical processes (intensified the breakdown of phospholipids, increases the level MDA – secondary product of LPO and marker of degradation of membrane structures). Against this background, the observed inhibition of the antioxidant defense system (decreased activity of SOD, CAT, G-ST – enzyme conjugates with glutathione toxic products LPO and promotes their excretion; reduced level TF, designed to stabilize the lipid composition of membranes and protect them from degradation caused PHL-A2, and also block the damaging effect of singlet oxygen; also dramatically reduced the level of CP, which neutralizes free radicals). These changes are consistent with activation in SF with RA and OA proinflammatory cytokines and TNF-$\alpha$. Table 1.Free radicals, antioxidant defense system and cytokine status of SF with RA and OA

| The analyzed parameters | Normal level | RA | OA |
|---|---|---|---|
| PHL (mg/l) | 215.9±24 | 97.8±9.2* | 110.5±7.4* |
| PHL-A2 (ng/ml) | 0.64±0.10 | 1.47±0.04* | 0.98±0.09* |
| MDA (mmol/l) | 1.54±0.27 | 4.47±0.31* | 3.74±0.25* |
| SOD (unit/ml) | 1370.2±30. | 4 670.±25.9* | 820.7±45.9* |
| CAT (mmol/ml/min) | 10.4±0.7 | 5.9±0.9* | 8.9±0.8** |
| G-S-T (mmol/ ml/min) | 44.6±6.4 | 18.2±0.5* | 27.3±0.9* |
| TF ($\mu$/ml) | 41.5±7.2 | 22.4±8.3* | 38.2±2.7** |
| CP (mg/ml) | 259.7±37.5 | 137.9±12.7* | 154.8±13.9* |
| TNF-$\alpha$ (pg/ml) | 6.4±0.2 | 69.7±8.4* | 29.8±1.3* |
| IL-1$\beta$ (pg/ml) | 5.9±0.2 | 65.4±2.1* | 20.2±2.1* |
| IL-6 (pg/ml) | 5.1±0.2 | 120.3±9.7* | 29.4±1.3* |

The difference with a normal level *$p<0.05$. **$p>0.05$.

**Conclusions:** Intensification of free radical processes, generation of reactive oxygen species as a result of suppression of antioxidant protection is a cause of metabolic disorders of proteins and lipids in LF with RA and OA, the cause of the inflammatory process that causes apoptosis and cell destruction. The current strategy for the treatment of RA and OA is focused on reducing pain and preventing progressive degeneration of articular cartilage and subchondral bone, based on identified pathogenetic mechanisms, such as the development of inflammation and tissue destruction caused by the activation of free radical processes, suppression of antioxidant protection, dynamics of proinflammatory cytokines and TNF-$\alpha$.

## AB0041 SERUM AMYLOID A STIMULATES THE INDUCTION OF INFLAMMATORY MEDIATORS IN MONOCYTES FROM BEHÇET'S DISEASE PATIENTS: A PROOF OF CONCEPT STUDY

G. Lopalco[1], O.M. Lucherini[2], L. Cantarini[2], A. Lopalco[3], A. Vitale[2], V. Venerito[1], A. Chialà[1], M. Fornaro[1], M.G. Anelli[1], C. Scioscia[1], F. Cacciapaglia[1], D. Natuzzi[1], G. Lapadula[1], F. Iannone[1]. *[1]Interdisciplinary Department of Medicine, Bari; [2]Research Center of Systemic Autoinflammatory Diseases and Behcet's Disease Clinic, Siena, Italy; [3]Department of Pharmaceutical Chemistry, Lawrence, United States*

**Background:** Behcet's disease (BD) is a complex inflammatory disorder characterised by an abnormal innate and adaptive immune response leading to hyper-activation of pro-inflammatory mediators. Recurrent oral aphthous, genital ulcers and chronic relapsing bilateral uveitis are the hallmarks of the disease. Serum amyloid-A (SAA) is a biomarker of inflammation recently associated to BD, and pro-inflammatory stimuli including IL-6, IL-1 and TNF are known to be involved in the SAA production. Moreover, several innate immune cells such as neutrophils, monocytes and macrophages have been reported to produce pro-inflammatory cytokines also through inflammasome activation after SAA stimulation.
**Objectives:** The purpose of this study was to investigate the involvement of SAA in the pathogenesis of Behçet's disease
**Methods:** Monocytes obtained from heparinised venous blood of Behçet's disease patients (BD, n=14) and healthy controls (HC, n=7) were stimulated or not with SAA, and serum cytokine levels of IL-1β, IL-18, IL-6 and TNF-α were analysed in the medium using a multiplex bead analysis. Statistical approaches included two-tailed Mann-Whitney test (for two non-parametric groups) and Student's t-test (for two parametric groups) were used for statistical comparisons between groups. Correlations were calculated using Spearman's correlation (two-tailed p-value) analysis.
**Results:** BD monocytes showed an increased IL-1β (p=0.0017), TNF-α (p=0.0003) and IL-6 (p=0.0003) secretion after SAA stimulation. No differences were observed in the amounts of pro-inflammatory cytokines production between HC and BD. We also found that IL-1β levels positively correlated with IL-6 (r=0.842, p<0.001), and TNF-α (r=0.889, p<0.001), whilst TNF-α levels positively correlated with IL-6 (r=0.894, p<0.001) levels. Moreover, also IL-18 showed a positive trend with no significant differences between the two groups

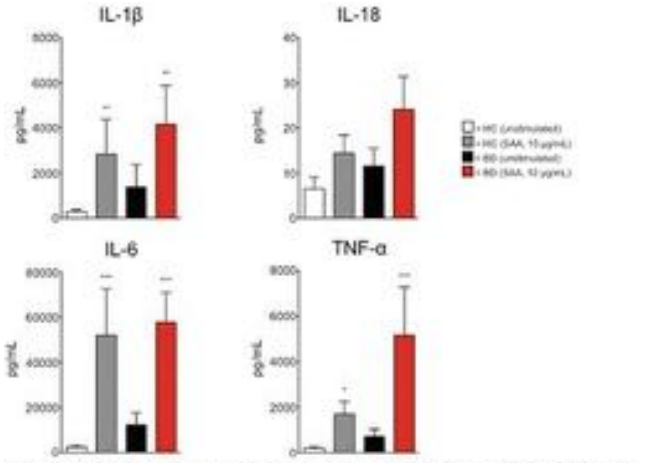

**Fig.1. SAA induction of cytokines in monocytes from Healthy Controls (HC) and Behçet's Disease (BD) patients.** Monocytes from BD patients (n=14) and HC (n=7) were stimulated or not with SAA (10 μg/mL) in serum-free RPMI for 24 h and cytokines concentrations in supernatants were measured by multiplex bead analysis. Data are expressed as mean + SEM. Mann-Whitney U-test and Student's t-test were carried out to check for statistical significance between groups (*p<0.05, **p<0.01, ***p<0.01).

**Conclusions:** These findings suggest that SAA can promote inflammatory mediators production thereby contributing to the inflammatory manifestations typically observed in BD.

## AB0042 IDENTIFICATION OF SULFIDO-CONJUGATED MEDIATORS THAT PROMOTE RESOLUTION OF INFECTION AND ORGAN PROTECTION

J. Dalli[1], N. Chiang[2], C. Serhan[2]. *[1]Biochemical Pharmacology, William Harvey Research Institute, London, United Kingdom; [2]Anesthesiology, Perioperative and Pain Medicine, Harvard Medical School, Boston, United States*

**Background:** When inflammation is self-limited it is host protective and leads to the repair and regeneration of damaged tissues. Chronic conditions, such as inflammatory arthritis, are though to arise from a failure of the host response to engage resolution mechanisms. The pro-resolving mechanisms engaged by the host response to promote tissue regeneration remain of interest.
**Objectives:** In the present stud we aim to identify mediators produced during the resolution phase of acute inflammation, that promote the termination of the inflammatory response, tissue repair and regeneration.
**Methods:** We employed LC-MS-MS and RP-UV-HPLC based lipid mediator metabololipodomics to investigate novel bioactive molecules in isolates from mouse and human tissues and cells. Bioactions for identification and characterization of the novel molecules were determined using planaria, mice and human primary leukocytes.
**Results:** Here we identified potent molecules present in infectious murine exudates, regenerating planaria, human milk as well as macrophages that stimulated tissue regeneration in planaria and are pro-resolving. Characterization of their physical properties and isotope tracking indicated that the bioactive structures contained sulfido-conjugated (SC) triene double bonds that proved to be 13-glutathionyl,14-hydroxy-docosahexaenoic acid (SCI) and 13-cysteinylglycinyl, 14-hydroxy-docosahexaenoic acid (SCII). These molecules rescued *E. coli* infection-mediated delay in tissue regeneration in planaria, improving regeneration intervals from ~4.2 to ~3.7 days. Administration of SC protected mice from second organ injury and promoted repair via limiting neutrophil infiltration, upregulating Ki67 and Roof plate-specific spondin 3 in lung tissues. At nanomolar potencies these conjugates also resolved *E. coli* infections by limiting neutrophil infiltration, stimulating bacteria phagocytosis and clearance as well as efferocytosis of apoptotic cells.
**Conclusions:** Together, these findings identify previously undescribed, conserved chemical signals and pathways in planaria, mice and human tissues that stimulate resolution of inflammation and promote the restoration of function.

## AB0043 SERUM CYTOKINE CONCENTRATIONS IN INFLAMMATORY BOWEL DISEASE (IBD) AND IBD-RELATED SPONDYLOARTHRITIS (SPA)

J. Dmowska-Chalaba[1], E. Kontny[2]. *[1]Early Arthritis Clinic; [2]Department of Pathophysiology and Immunology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*

**Background:** Inflammatory bowel disease (IBD) is a group of recurrent gastrointestinal disorders, involving Crohn disease (CD) and ulcerative colitis (UC), that is characterized by chronic mucosal inflammation and extraintestinal symptoms. Rheumatic abnormalities of a broad spectrum of symptoms, from arthralgia to spondyloarthritis (SpA), are the most common extraintestinal manifestations of IBD. The pathogenesis of IBD-related arthritis is unclear.
**Objectives:** In this study, we analyzed the serum cytokine concentrations (interleukins: IL-10, IL-18, IL-21, IL-23, interferon γ) in patients with IBD-associated spondyloarthritis and patients with IBD not complicated with SpA symptoms.
**Methods:** The study group consisted of 75 patients (44 female/29 male, age 43,7±12,3 year) suffering from IBD alone (n=35) or with IBD accompanied by arthritis (n=39), i.e. spondyloarthritis (IBD-SpA, n=16) or ankylosing spondylitis (IBD-AS, n=23). The control group included age and sex matched healthy volunteers (n=42). Serum cytokine concentrations were measured using commercially available kits from eBioscience, San Diego, CA, USA (Platinum ELISA for IL-18, ReadySetGo ELISAs for IL-10, IL-21, IL-23, interferon γ).
**Results:** The concentrations of IL-23 (the mean ± SEM =156 ±14 vs 115±49 pg/ml) and IL-21 (232±79 vs 20.6 ±8 pg/ml) were significantly higher (p<0.0001) in the total group of patients than control sera. Similar significant elevation of IL-21 and IL-23 was found in IBD (146±35 and 133±40 pg/ml, respectively), IBD-SpA (124±48 and 151±37 pg/ml, respectively) and IBD-AS (194±62 and 417±228 pg/ml, respectively) groups comparing with control sera (p≤0.001). There was no significant difference between control and patients groups in the serum concentrations of other tested cytokines, except IL-18. The levels of IL-18 were significantly lower in the sera of IBD-AS group than in healthy volunteers (59±19 vs 180±36 pg/ml, p=0.02). Although we failed to show significant difference in serum cytokine concentrations between IBD and IBD-SpA or IBD-AS patients, in the IBD-AS group there was again tendency to downregulation of serum IL-18

in comparison with patients suffering from IBD alone (59±19 vs 121 ±27 pg/ml, p=0.08).
**Conclusions:** Significant elevation of serum IL-21 and IL-23 found in IBD patients irrespectively of complication with SpA suggests implication of these cytokines in the underlying disease pathology. On the other hand, diminution of serum IL-18 in IBD-AS may point to protective action of this cytokine in AS development.

## AB0044 NICOTINAMIDE PHOSPHORIBOSYLTRANSFERASE IN THE PATHOGENESIS OF INFLAMMATION IN OSTEOARTHRITIS

J. Polyakova, L. Seewordova, B. Zavodovsky, Y. Akhverdyan, A. Zborovsky.
*Federal State Budgetary Institution "Research Institute of Clinical end Experimental Rheumatology", Volgograd, Russian Federation*

**Background:** Nicotinamide phosphoribosyltransferase (Nampt) is involved in various biological processes such as metabolism, stress response and the aging process.There are some data that TNF-α and other proinflammatory molecules may influence on exchange of NAD.
Currently, there is no common understanding of the Nampt's role in the pathogenesis of joint diseases. The recent recearches of its participation in the processes of metabolism and inflammation support the hypothesis of involvement of this protein in the induction and maintenance of inflammation in osteoarthritis (OA). The presence of pseudogenes complicates Nampt investigation and enhance research bias.
**Objectives:** To clarify the OA pathogenesis by examining serum concentrations of Nampt.
**Methods:** We observed 87 patients with various forms of OA aged 36 to 78 years, comparable with the group of healthy subjects ($t = 1,87$ $p > 0.05$).We used Althman R. D. criteria to diagnose OA (199). X-ray stages were evaluated using the Kellgren-Lawrence scale. Serum Nampt level was determined by ELISA with commercial test kits (RaiBiotech, cat No. EIA-VIS-1).
**Results:** We assessed the level of Nampt in the serum of healthy individuals. The Median of Nampt normal values was 2,29 [Confidence interval (CI) =2,02 - 2,8] ng/ml. The Median Nampt level OA patients was 3,98 [CI =2,00 - 9,04] ng/ml, which was significantly higher than in normal subjects ($p < 0.001$).
Elevated levels of Nampt were revealed more often in patients with constant pain than in ones who had pain only on movement.
The correlation coefficient between Nampt level and Lequesne functional index was equal to 0,4917 (p=0,041), with total index WOMAC - 0,589 (p=0,049).
We notedsignificant statistical link between the Nampt's serum level and laboratory markers of inflammation in OA. Higher C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)concentrations were detected in patients with elevated Nampt level. Those facts indirectly confirm the anti-inflammatory properties of Nampt. These studies may support the hypotheses of Nampt's properties to influence on cytokines production, which are responsible for the maintenance of the inflammatory process in the synovium and the destruction of the cartilage.
There are some data that Nampt inhibitors lead to downstream NF-kBinhibition, resulting in decreasing of intracellular level of nicotinamide adenine dinucleotide (NAD). So Nampt inhibitors may be used to suppress inflammation, for the treatment of diseases in which angiogenesis is involved, for the prevention and treatment of ischemia and other pathological states.
Significant advances in molecular biology allow us to hope for the development of highly effective drugs that can delay the progression of OA and change his clinical course.
**Conclusions:** Thus, in our study the increased Nampt level was detected in 29% of OA patients. It's increasing is associated with secondary synovitis, elevated of ESR, CRP, with most severity of articular syndrome.
The findings suggest the likely role Nampt in the pathogenesis of OA.

## AB0045 LOW MOLECULAR WEIGHT-BAFF RECEPTOR ANTAGONISTS SUPPRESS IGG PRODUCTION BY B CELLS CO-CULTURED WITH MONOCYTES

K. Yoshimoto[1], K. Suzuki[1], E. Ishioka[1], A. Nishikawa[1], K. Sugahara[2], T. Takeuchi[1]. *[1]Keio University School of Medicine, Tokyo; [2]Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan*

**Background:** We have previously reported that soluble BAFF (sBAFF) robustly increases IL-6 production in vitro by peripheral monocytes of patients with primary Sjogren's syndrome (pSS) and that the expression level of a BAFF receptor (BR3) is abnormally enhanced in pSS monocytes. Additionally, the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the sBAFF-induced IL-6 production by peripheral monocytes and the serum IgG level of pSS patients. These data collectively suggest that the elevated expression of BR3 in monocytes is involved in the pathogenesis of pSS which is often accompanied with hypergammaglobulinemia (HgG). Our findings also suggest that BR3 is a therapeutic target to treat pSS. However, no therapeutics has been available except antibodies against BAFF signaling so far. In this study, we show some of our latest data on low molecular weight compounds that inhibit a BAFF signaling pathway.
**Objectives:** The purpose of our study is to discover low molecular weight BAFF receptor antagonists as drug candidates for pSS.
**Methods:** High-throughput screening (HTS) of a chemical library was carried out to search for compounds that block binding of sBAFF to BR3. In brief, human BR3-expressing CHO-K1 cells were cultured in the presence of FMAT Blue-labeled sBAFF and each compound in 384-well plates, and the binding of sBAFF to BR3 was monitored by an Applied Biosystems 8200 Cellular Detection System. Hit compounds were further screened to eliminate false positives as follows: First, IFN-γ-stimulated THP-1, a human acute monocytic leukemia cell line, was cultured in vitro with sBAFF and primary hits, and the cumulative production of IL-6 was measured by ELISA. Second, sBAFF-stimulated pSS monocytes were cultured in vitro with or without pSS B cells in the presence of hit compounds, and IL-6 production by monocytes and IgG production by B cells were measured by ELISA.
**Results:** A total of 18,562 compounds were examined for inhibitory activities of sBAFF binding to BR3. Finally, two hit compounds, both of which were pyrrolopyrimidine derivatives (BIK12 and BIK13), were discovered and further investigated for biological activities. IL-6 production by sBAFF-stimulated peripheral pSS monocytes was significantly suppressed by BIK12 and BIK13 in a dose dependent manner. Similarly, IgG production by B cells cultured with sBAFF-stimulated peripheral pSS monocytes was also significantly suppressed by these compounds. Because sBAFF itself had no effects on IgG production by B cells, these data suggest that inhibition of BAFF binding to BR3 on monocytes caused suppression of IgG production by B cells in the co-culture probably through suppression of IL-6 production by monocytes.
**Conclusions:** We have successfully discovered low molecular weight BR3 antagonists, pyrrolopyrimidine derivatives, by HTS and found that these compounds suppressed IgG production by B cells in a co-culture with monocytes. These compounds may provide not only lead compounds in drug development for pSS which often accompany HgG, but also novel tools to explore pathological mechanisms of pSS.

## AB0046 ENDOCANNABINOID SYSTEM AND SYSTEMIC LUPUS ERYTHEMATOSUS

L. Navarini[1], P. Mozetic[2], D.P.E. Margiotta[1], F. Basta[1], S. Saracini[2], A. Afeltra[1], M. Maccarrone[2], T. Bisogno[2,3]. *[1]Unit of Allergology, Immunology, Rheumatology, Department of Medicine; [2]Unit of Biochemistry and Molecular Biology, Department of Medicine, Università Campus Bio-Medico, Rome; [3]Endocannabinoid Research Group, Institute of Biomolecular Chemistry, National Research Council, Pozzuoli, Italy*

**Background:** Endocannabinoid (eCB) system comprises endogenous lipid mediators (eCBs) like *N*-arachidonoylethanolamine (anandamide, AEA) and 2-arachidonoylglycerol (2-AG), along with their specific G protein-coupled type-1 ($CB_1$) and type-2 ($CB_2$) cannabinoid receptors, and the proteins responsible for eCB biosynthesis, inactivation, transport, and accumulation. In recent years, many studies have evaluated the role of eCBs in the homeostasis of the immune system. Notably, AEA and the eCB-like molecule *N*-palmitoylethanolamine (PEA) seem to be anti-inflammatory mediators, while 2-AG is implicated in both pro-inflammatory and anti-inflammatory functions. Moreover, the effects of eCBs on immune system seem to be mostly mediated by $CB_2$, more expressed in immune cells than by $CB_1$. The latter receptor, instead, is more implicated in neurotransmission. Several studies have already investigated the role of eCB system in different immune-mediated diseases, such as multiple sclerosis and type-1 diabetes.
**Objectives:** To investigate the role of eCB system in patients with systemic lupus erythematosus (SLE) and age and sex matched healthy subjects.
**Methods:** 10 female patients with SLE and 10 healthy subjects were enrolled from outpatient clinic of Campus Bio-Medico University of Rome. Every SLE patient was positive for anti-dsDNA antibodies and/or exhibited hypocomplementemia with or without hypergammaglobulinemia, ENA or aPL positivity. None of them was treated with biological therapy at the time of enrolment, nor with steroid bolus in the previous six months, while treatment with conventional immunosuppressants was allowed. SELENA-SLEDAI and BILAG were used to assess disease activity and SDI as damage index. AEA, 2-AG and PEA levels were quantified in plasma of SLE patients and healthy controls by using liquid chromatography-tandem mass spectrometry (LC-MS).

**Results:** No significant difference among ages was found in the two groups (SLE patients 37.9±5.9 years, healthy subjects 37.8±6.2, p=ns). In SLE patients, 80% of the subjects exhibited low C3, 50% low C4, 90% anti-dsDNA positivity; 30% of them were not taking glucocorticoids, 20% $\leq$5 mg of daily prednisone and 50% $>$5 mg of daily prednisone; 70% were taking conventional immunosuppressive treatment and 80% were taking hydroxychloroquine. Value of the disease activity score evaluated by SELENA-SLEDAI was assessed as 6±4.7; 10% of the patients exhibited at least 1 BILAG A and 60% at least 1 BILAG B; value of the damage index evaluated by SDI was assessed as 0.6±0.8. eCBs was significantly altered in SLE patients. In particular, plasma levels of 2-AG were significantly increased in SLE patients compared to healthy controls (p=0.005), while no differences were found in AEA and PEA concentrations between the two groups.
**Conclusions:** Our results demonstrate, for the first time, an alteration of eCB system in SLE patients; these data may help to better understand the role of lipid mediators in SLE pathogenesis.

## AB0047 HIGH SOLUBLE IL-7 RECEPTOR EXPRESSION IN SJÖGREN'S SYNDROME IDENTIFIES PATIENTS WITH INCREASED IMMUNOPATHOLOGY AND DRYNESS

M.R. Hillen[1], S.L. Blokland[1], A.P. Risselada[1], A. Bikker[1], B.R. Lauwerys[2], A.A. Kruize[1], T.R. Radstake[1], J.A. van Roon[1]. *[1]Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands; [2]Department of Rheumatology, Catholic University Louvain, Louvain, Belgium*

**Background:** Increased expression of interleukin (IL)-7 and its receptor plays a critical role in immunopathology of primary Sjögren's syndrome (pSS). The IL-7/IL-7R axis is involved in formation of (ectopic) lymphoid structures, which is a predictor for lymphoma development in pSS. IL-7 activity is potentiated by the soluble form of its receptor (sIL-7R), which is produced in inflamed tissues by activated stromal cells. Thus, sIL-7R may serve as a biomarker for IL-7-driven activation and lymphoid neogenesis.
**Objectives:** We studied the expression of sIL-7R in pSS in relation to markers of inflammation and saliva production.
**Methods:** 95 pSS patients were diagnosed according to the 2002 criteria. sIL-7R concentration was measured in serum of 68 pSS patients using ELISA and compared to 51 healthy individuals (HC). Labial salivary gland (LSG) biopsy tissues were taken from 27 patients and were incubated in sterile saline for 1 hour at room temperature. sIL-7R was measured using multi-cytokine analysis by Luminex and compared to 24 non-Sjögren's sicca (nSS) patients.
**Results:** Serum levels of sIL-7R were significantly higher in pSS patients compared to healthy controls (median [range]: 610 [52–2201] vs. 294 [58–821] pMol/mL, p=0.0001). pSS patients with sIL-7R levels above those of HC, defined as sIL-7Rhigh, showed markedly increased ESR, serum IgG and lymphocytic focus scores compared to the other pSS patients. Furthermore, sIL-7Rhigh patients had significantly decreased salivary output, as measured by stimulated whole saliva and unstimulated whole saliva (median [range]: 0.2 [0.0–0.9] vs. 1.2 [0.0–4.6] mL/min, p=0.01). In addition, we observed increased sIL-7R production in LSG supernatants from pSS patients compared to nSS. Similar to serum, a sIL-7Rhigh group could be discerned, with higher levels of serum IgG and increased prevalence of ANA, anti-SSA, and anti-SSB autoantibodies (all at least $p<0.05$).
**Conclusions:** Thus, sIL-7R is increased in serum and LSG supernatant of pSS patients, in which high sIL-7R levels identifies patients with increased markers of inflammation and decreased salivary output. The sIL-7R increase in pSS LSG supernatants indicates that the increased systemic sIL-7R levels are at least partially mediated by local production. High local production of sIL-7R was related to increased B-cell activity and autoimmunity, in line with the described role of IL-7 in lymphoid neogenesis.
**Disclosure of Interest:** None declared

## AB0048 DEVELOPMENT OF THE NEW RHEUMATOID ARTHRITIS DISEASE ACTIVITY MARKER USING GLYCOSYLATION CHANGE OF MMP-3

M. Takeshita, K. Suzuki, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** It is known that almost all secreted proteins are glycosylated, that glycosylation patterns are influenced by cellular differentiation, and that serum glycoproteins exhibiting disease-associated glycosylation changes have potential to be biomarkers [1]. In rheumatoid arthritis (RA), C-reactive protein (CRP) and matrix metalloproteinase-3 (MMP-3) are widely used as serologic disease activity markers, but they lack sufficient specificity or precision. Thus, development of a RA-specific fine disease activity marker is needed.
**Objectives:** We focused on an existing marker, MMP-3, and examined the association between its glycosylation pattern and RA disease activity.
**Methods:** Serum was taken from RA patients (n=24) whose disease activity was scored using composite measures, and MMP-3 immunoprecipitated and subjected to recently developed antibody-overlay lectin microarray analysis. A disease activity index was developed based on lectin signal, and validated using another cohort, which included 60 serum samples from 30 RA patients, before and after treatment. Synovial fluid MMP-3 in RA and osteoarthritis (OA) patients was also analysed.
**Results:** Intense signals were observed on the O-glycan binding lectins (ABA, ACA, and Jacalin) and a sialic acid binding lectin (ACG) by applying sub-nanogram levels of serum MMP-3. Jacalin and ABA, ACA, and ACG revealed differences in MMP-3 quality and quantity, respectively. The resultant index, ACG/Jacalin, correlated with disease activity. This correlation was validated using second cohort ($r^2$=0.341, $p<0.0001$), and the correlation was greater than those of MMP-3 and CRP. In addition, the change in ACG/Jacalin and disease activity before and after treatment also correlated. Furthermore, we confirmed that MMP-3, which generated a high ACG/Jacalin score, accumulated in RA but not OA patient synovial fluid.
**Conclusions:** We succeeded in development a new RA specific and sensitive disease activity marker using glycosylation change of MMP-3. The difference in quality but not quantity of MMP-3 may be a useful index for estimating RA disease activity.

## AB0049 OXIDATED LIPIDS IN EARLY ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

N.A. Bashlakova[1], T.D. Tyabut[2], A.E. Buglova[2]. *[1]Ultrasound Diagnostic; [2]Cardiology and rheumatology, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus*

**Background:** There is increasing evidence that oxidatively modified form of low-density lipoprotein cholesterol (LDL) is more important than native LDL in atherogenesis and vascular damage. The accelerated development of atherosclerosis has been recognized in patients with autoimmune rheumatic diseases, such as rheumatoid arthritis and systemic lupus erythematosus. Recent studies reported about the oxidation ratio of LDL that can be more significant in the premature development of coronary artery disease.
**Objectives:** To estimate the oxidated forms of LDL and their involvement in atherosclerotic lesions of the vessel wall in female-patients with autoimmune rheumatic diseases (ARD).
**Methods:** The study included 77 female-patients with ARD (RA (n=37), mean age 45,0 (33,0; 51,0) years old, disease duration 9,0 (3,0; 14,0) years, disease activity (DAS28=5,37 (4,69; 5,86) points) and SLE (n=40), mean age 33,5 (27,5; 44,5) years old, disease duration 8,0 (5,0; 14,5) years, disease activity SLEDAI-2K 7,0 (4,0; 11,5) points). Twenty-two women with the history of myocardial infarction (MI) (i.e. clinical manifestation of atherosclerosis) formed the control group.
The levels of OxLDL, high sensitive C-reactive protein (hs-CRP), interleukin-6 (IL-6), tumor necrosis factor - $\alpha$ (TNF-$\alpha$) were determined with ELISA according to the instruction of manufacturer. The oxidation ratio of LDL (Ox-LDL/TC, Ox-LDL/HDL-C, Ox-LDL/LDL-C) was calculated. The presence of carotid atherosclerotic alterations (intima-media thickness and the presence of atherosclerotic plaques) was revealed ultrasonographically according to the described ESH/ESC Guidelines for the management of arterial hypertension.
**Results:** The levels of OxLDL, hs-CRP, IL-6, TNF-$\alpha$, Ox-LDL/HDL-C were significantly higher in ARD patients than in the control group, what may indicate the disease activity. The presence of subclinical atherosclerosis was observed in 54,55% patients with ARD. When we compared the values of investigated parameters in patients with subclinical and clinical atherosclerosis, we revealed that only inflammatory markers (hs-CRP, IL-6, TNF-$\alpha$) were significantly higher in ARD patients with atherosclerosis. However those without atherosclerosis had significantly higher values of OxLDL, hs-CRP, IL-6, Ox-LDL/TC, Ox-LDL/HDL-C,

Ox-LDL/LDL-C than the control group. The positive association between hs-CRP, IL-6 and oxidation ratio Ox-LDL/TC was found in patients with subclinical atherosclerosis (p=0,0003 and p=0,007, respectively), between TNF-α and Ox-LDL/LDL-C in patients without atherosclerosis (p=0,002). The negative association between TNF-α and Ox-LDL/TC was found in patients with MI that can explain because of the lower levels of OxLDL in this group of patient considering that statins can inhibit oxidative stress.

**Conclusions:** More than half of patients with ARD had subclinical atherosclerosis. We demonstrated the elevated levels of OxLDL and inflammatory markers (hs-CRP, IL-6, TNF-α) in patients with ARD. The presence of OxLDL, especially when used in combination with TC, is better than only OxLDL for estimation of association with inflammation in patients with clinical and subclinical atherosclerosis. Thus we suggest that inflammation can influence to oxidative modification of LDL in patients with RA and SLE and during this process induce endothelial dysfunction and early development of atherosclerosis as its result.

**Disclosure of Interest:** None declared

## AB0050 DETECTION OF INTERLEUKIN-22 AND TUMOR NECROSIS FACTOR RECEPTOR ASSOCIATED FACTOR 1 (TRAF1) IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS: CORRELATION WITH DISEASE ACTIVITY

N. Mohannad[1], E. Rashwan[2], M. Moaaz[2], E. Medhat[2]. *[1]1Alexandria University hospitals, Internal Medicine Department, Rheumatology Unit, Faculty of Medicine, Aexandria University; [2]Department of immunology and allergy, Medical research institute, Alexandria, Egypt*

**Background:** In autoimmune diseases including rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), cytokines play a central role in initiating and maintaining diverse immune and inflammatory responses.In addition to IL-17A and F, Th17 cells also secrete IL-21, IL-22, and granulocyte macrophage colony-stimulating factor (GM-CSF). IL-22, member of IL-10 cytokine family, has been believed as an important player in regulating inflammatory responses associated with many inflammatory diseases. There is apparently a strong functional synergism of TNF-α and IL-22; the interaction of IL-22 & TNF-α is mediated through TNFR I and IL-22R heterodimer and intracellularly by MAP kinases. The combination of IL-22 & TNF-α strongly induced the phosphorylation and translocation of MAP kinases to the nucleus whereas the single cytokine only weakly contributed to MAP kinase activation. The discovery of the IL-22/TNF-α axis gives a first insight that could lead to new therapeutic approaches of RA.

**Objectives:** to evaluate the role of IL-22 and TRAF1 in patients (pts) with RA & SLE, and their association to the disease activity.

**Methods:** 70 RA pts, 64 SLE pts aged & 45 healthy matched controls were enrolled. DAS28 & SLEDAI were used to assess activity.

**Results:** IL-22 was significantly higher in RA&SLE pts than healthy controls. significant positive correlation was found between IL-22 levels and tender joints count, CRP and ESR. However, In SLE pts CRP only showed a positive correlation with IL-22 levels

*Statistical significance at p<0.05.RF +ve>20 IU/ml. Anti-CCP +ve >30 IU/ml.

Analysis of TRAF1 polymorphism: in RA pts; the magnitude of association was increased in those patients who were autoantibody positive either RF+ or anti-CCP+. TRAF1 A allele was significantly associated with RF+ and anti-CCP+ RA patients when compared withcontrol. (OR =3.344 CI: 1.79–6.24, P<0.001, OR =1.881 CI: 1.03–3.41 P<0.034)respectively,in SLE pts, TRAF1 rs10818488 was not significantly different in pts and control

**Conclusions:** Theses results indicate that IL-22 is associated with inflammatory process and it has a role in RA and SLE pathogenesis and prognosis.Although there are inconsistent findings which need to be resolved, there are a synergism between TNF-α, IL 17 & IL-22,mso,targeting IL-22 cytokine may be an effective therapeutic approach for chronic inflammation in the future.Also TRAF1 was significantly associated with RF positive, anti-CCP positive pts, ESR and tender joints count and this confirm importance of TRAF1 in progression of RA

## AB0051 ANGIOGENIC AND ANTI-ANGIOGENIC FACTORS: BIOMARKERS FOR LARGE VESSEL VASCULITIS?

O. Addimanda[1,2], L. Pulsatelli[3], L. Boiardi[4], E. Assirelli[3], G. Pazzola[4], F. Muratore[4], P. Dolzani[3], A. Versari[5], M. Casali[5], L. Magnani[4], B. Bottazzi[6], A. Mantovani[7], C. Salvarani[4,8], R. Meliconi[1,2]. *[1]Medicine and Rheumatology Unit, Rizzoli Ortopaedic Institute; [2]DIBINEM, University of Bologna; [3]Lab. of Immunorheumatology and tissue regeneration, Rizzoli Ortopaedic Institute, Bologna; [4]Rheumatology Unit; [5]Nuclear Medicine Unit, Santa Maria Nuova Hospital, IRCCS, Reggio Emilia; [6]Immunopharmacology Lab; [7]Humanitas Clinical and Research Center, Rozzano (MI); [8]University of Modena and Reggio Emilia, Modena, Italy*

**Background:** Large vessel vasculitides (LVV) – Takayasu Arteritis (TA) and Giant Cell Arteritis (GCA) are inflammatory diseases of the aorta and its main branches. A cytokine cluster involving the IL-6 – IL-17 axis as well as another one centring on the IL-12-IFN-γ axis are involved in LVV pathogenesis. (1) Disease activity could be evaluated by measuring ESR and CRP as well as by using imaging techniques (Doppler Ultrasound, Computed Tomography scan, Magnetic Resonance Imaging or Positron Emission Tomography scan – CT/PET) and specific scoring systems (Indian*Takayasu's* Arteritis Activity *Score* - ITAS and Kerr/National Institutes of Health index - *Kerr*/*NIH)*. To date, angiogenic factors have been evaluated but specific biomarkers for disease activity are still lacking (2)

**Objectives:** The aim of our study was to evaluate angiogenic and anti-angiogenic factor expression in LVV, in order to evaluate their role as biomarkers.

**Methods:** We enrolled 67 patients with LVV [TA (40, 59.7%) or GCA (27, 40.3%)] and 50 Normal Controls (NC). Angiogenic (angiopoietin-1, angiopoietin-2, Fibroblast Growth Factor2 – FGF-2, Vascular Cell Adesion Molecule1 – VCAM-1, Vascular Endothelial Growth Factor – VEGF) and anti-angiogenic (angiostatin, Endostatin-1, Pentraxin 3 – PTX3) factors were analysed using enzyme-linked immuno-sorbent assay (ELISA). Disease activity was evaluated according to Kerr (≥2) and ITAS (≥1) scores, only 47 (70.1%) patients underwent CT/PET. Serum levels of angiogenic and anti-angiogenic factors were compared among active LVV, inactive LVV and NCs. When evaluating disease activity according to CT/PET, it was considered active if SUV >2. Statistical analysis was performed utilizing Mann Whitney, Kruskal Wallis for multiple comparison and Dunn's post hoc test, using Graph Pad Prism software.

**Results:** No significant differences were found between LVV and NCs in angiogenic factors. Conversely, anti-angiogenic factors were all significantly increased in LVV (both GCA and TA) in comparison with NCs (angiostatin: TA vs NC, p<0.0001; GCA vs NC, p=0.0008; endostatin: TA vs NC, p=0.0002; GCA vs NC, p=0.001; PTX-3: TA vs NC, p<0.0002; GCA vs NC, p=0.001). Stratifying patients according to disease activity (with Kerr and Itas scoring systems, as well as taking into account CT/PET), no significant differences were found in angiogenic factors. Anti-angiogenic factors were significantly higher both in active LVV and inactive LVV compared with NCs (p<0.05).

**Conclusions:** Our data show an imbalance between angiogenic and anti-angiogenic factor levels in serum. No disease activity related changes were observed for these factors.

## AB0052 INVESTIGATING THE NEUTROPHIL-MACROPHAGE INTERPLAY IN JUVENILE LUPUS NEPHRITIS PATHOGENESIS

P. Dimou, A. Midgley, M. Peak, R.D. Wright, M.W. Beresford. *Translational Medicine, University of Liverpool, Liverpool, United Kingdom*

**Background:** Juvenile systemic lupus erythematosus (JSLE) is a multifactorial systemic autoimmune disease that can cause severe kidney damage and lead to end-stage renal failure. In JSLE increased neutrophil apoptosis and NETosis combined with impaired phagocytosis[1,2] result in prolonged autoantigen exposure and enhanced autoimmunity. We hypothesized that in lupus nephritis (LN) apoptotic and/or NETotic neutrophils infiltrate the kidneys in response to pro-inflammatory stimuli. Monocytes are then recruited to the kidney where they induce native kidney cell damage leading to proteinuria and potentiated inflammation. Studies have shown that monocytes isolated from SLE patients produce high levels of IL-1Ra, and IL-1β has been detected in the glomerular biopsies from LN patients[3]. Macrophages may significantly contribute to LN development by regulating the local IL-1β/IL-1Ra balance in the kidney.

**Objectives:** To investigate the mechanisms and outcomes of macrophage activation by viable and apoptotic neutrophils and determine how this affects the secretion of pro-inflammatory IL-1β and anti-inflammatory IL-1Ra.

**Methods:** Paired monocytes and neutrophils were isolated from healthy adult donors (n=7), neutrophil culture medium was collected at 2h and 24h after incubation at 37℃. Monocytes were cultured for 6 days in RPMI (+10% FCS +50ng/mL M-CSF) and their differentiation into macrophages was determined by light microscopy. Macrophages were then treated for 6h with culture media

from the 2h viable (mean apoptosis - 9.5%) and 24h apoptotic neutrophils (mean apoptosis - 70%), with LPS as a positive control. Following 6h the macrophage culture media were collected and IL-1β/IL-1Ra levels were assessed via ELISA.
**Results:** IL-1β levels did not significantly differ within treatment groups with levels being below the lower limit of detection for most samples. IL-1Ra expression however was significantly increased in LPS-treated macrophages (4374pg/ml ±910.3, P=0.0012) compared to control (845.6pg/ml ±240) while no significant difference was seen with 2h (1379pg/ml ±344.4) or 24h (1696pg/ml ±371.1) neutrophil culture medium.
**Conclusions:** Macrophages treated with culture medium from both apoptotic and viable neutrophils produce high levels of IL-1Ra, however this does not differ from levels seen in control macrophages. IL-1β levels are below the level of detection under all conditions. This suggests that secreted factors from apoptotic neutrophils do not induce an IL-1 response in macrophages but does not exclude a role for direct cell-cell contact. Other immune cells may also be playing a role in promoting renal cell damage through IL-1β secretion.

## AB0053 A USEFUL MARKER IN ASSESSMENT OF REMISSION AND ACTIVATION OF DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS: SERUM HUMAN NEUTROPHIL PEPTIDES 1-3

M. Okcu[1], P. Oktayoglu[1], N. Mete[2], M. Bozkurt[1], M. Caglayan[1], K. Nas[3]. *[1]Department of Physical Medicine and Rehabilitation; [2]Biochemistry, Dicle University Faculty of Medicine, Diyarbakir; [3]Department of Physical Medicine and Rehabilitation, Division of Rheumatology and Immunology, Sakarya University Faculty of Medicine, Sakarya, Turkey*

**Background:** Rheumatoid arthritis (RA) is a chronic disease of unknown etiology that is characterized by articular inflammation and deformities and may also present with extra-articular findings. Various cellular and molecular immunological factors are involved in the pathophysiology of RA. Recent studies suggest that neutrophils and alpha-defensins released from the neutrophils assume significant roles in the pathogenesis of RA.
**Objectives:** The purpose of this study was to investigate the potential association between serum alpha-defensin levels especially human neutrophil peptides (HNP) 1–3 and disease activity, functional status and radiologic damage as well as some other laboratory parameters such as erythrocyte sedimentation rate (ESH) and C-reactive protein (CRP) in patients with RA.
**Methods:** A total of 42 patients with established RA who presented to the Outpatient Clinic of Physical Medicine and Rehabilitation of Dicle University Hospital and 38 healthy control subjects were included in this study. All the subjects underwent a through physical examination. Swollen and tender joints were noted for each patient. Disease activity was assessed by Disease Activity Scale 28 (DAS28). Quality of life was assessed by Rheumatoid Arthritis Quality of Life (RAQoL) Questionnaire and Nottingham Health Profile (NHP). Functional status was assessed by Stanford Health Assessment Questionnaire (HAQ). Laboratory examinations included complete blood count, ESH, CRP, and human neutrophil peptides (HNP) 1–3 tests.
**Results:** The patients with an active disease exhibited higher HNP 1–3 levels compared to the patients in remission. At cut off 708 pg/ml, the sensitivity and the specificity of the test for HNP 1–3 were 72% and 70.6%, respectively. Moreover, HNP 1–3 levels correlated significantly with WBC counts as well as with HAQ, NHP total, NHP pain, NHP physical activity and NHP sleep scores. There were no significant differences between the patients and the control subjects in serum HNP 1–3 levels.
**Conclusions:** In the present study, serum HNP 1–3 levels correlated significantly with WBC counts as well as with HAQ, NHP total, NHP pain, NHP physical activity, and NHP sleep scores. In addition, the patients with an active disease had significantly higher serum HNP 1–3 levels compared to the patients in remission. In this respect, serum HNP 1–3 can be a useful marker in assessment of disease activity and remission in patients with RA.

## AB0054 FORMULATION OF IBUPROFEN IN LIPID-CRYSTAL NANO-PARTICLES ENHANCES EFFICACY AND REDUCES GASTRIC MUCOSAL EROSIONS IN A RAT CARRAGEENAN-INDUCED PAW INFLAMMATION MODEL

R. Lu[1], R.J. Mannino[2]. *[1]Matinas BioPharma, Inc; [2]Matinas BioPharma, Inc., Bedminster, United States*

**Background:** Non-steroidal anti-inflammatory drugs (NSAIDs) are some of the most commonly prescribed drugs in the world for their analgesic and anti-inflammatory properties. However, NSAID use is limited by gastrointestinal (GI) toxicity. NSAIDs injure the gut by causing topical injury to the mucosa and by systemic effects associated with mucosal prostaglandin depletion derived from COX inhibition. New formulations that prevent exposure of the NSAID to the GI mucosa may help reduce the GI toxicity associated with NSAIDs and maintain their anti-inflammatory effects.
**Objectives:** To demonstrate that ibuprofen formulated in two types of cochleates (lipid-crystal, nano-particles) provide enhanced anti-inflammatory effects while reducing the associated mucosal GI toxicity.
**Methods:** Male Sprague Dawley rats treated orally (one hour prior to right hind footpad injection of carrageenan) with vehicle or 50, 10, 2, 0.4, or 0.1 mg/kg of Ibuprofen, Ibuprofen Geodates or Ibuprofen Lipid-Crystal Cochleates (LCC) were evaluated for effects of treatment on inflammatory edema. Animals were terminated five hours after dosing with test articles (four hours after carrageenan injection). Efficacy evaluation was based on weight difference due to inflammation-induced swelling in injected (right) vs. uninjected (left) paws. In addition, gastric mucosa were evaluated for differences in incidence and severity of mucosal congestion and erosions.
**Results:** Treatment of rats with 50 mg/kg of all test articles or with 10 or 2 mg/kg Ibuprofen Geodates or 10 mg/kg Ibuprofen LCCs resulted in significant inhibition of paw weight difference when compared to the vehicle control group. The Ibuprofen LCC formulation was most effective ($ED_{50}$=6 mg/kg) followed by Ibuprofen Geodates ($ED_{50}$=7 mg/kg) and Ibuprofen ($ED_{50}$=30 mg/kg). Rats treated with 50 mg/kg Ibuprofen had significantly increased numbers of gastric lesions and increased total stomach lesion length. Some rats treated with 10 mg/kg Ibuprofen also had gastric lesions. Rats given 50 mg/kg Ibuprofen LCC had increased length and number of stomach lesions as compared to vehicle treated rats, but both parameters were significantly smaller when compared to Ibuprofen treatment alone. Rats treated with 50, 10 or 2 mg/kg Ibuprofen Geodates ($ED_{50}$=7 mg/kg) had significant inhibition of carrageenan-induced paw edema without evidence of gastric irritation. Treatment with LCCs at 10 mg/kg resulted in the greatest inhibition of paw edema for any formulation at this dose and there was no evidence of gastric irritation. There were no gastric lesions in rats given 2, 0.4 or 0.1 mg/kg of any formulation.
**Conclusions:** Results of this study demonstrated that Ibuprofen LCC ($ED_{50}$=6 mg/kg) had greater beneficial effects on carrageenan paw edema than did either Ibuprofen ($ED_{50}$=30 mg/kg) or Ibuprofen Geodates ($ED_{50}$=7 mg/kg). Gastric lesions occurred in some rats treated with single-dose 50 mg/kg (9 of 10) or 10 mg/kg (1 of 10) Ibuprofen whereas none were observed in rats given Geodates. Only 6 of 10 rats given 50 mg/kg LCC and none treated with 10 mg/kg had gastric lesions. Therefore both efficacy as well as incidence and severity of gastric irritation were significantly improved by cochleate formulations of Ibuprofen.

## AB0055 CYTOKINE PROFILES OF KOREAN PATIENTS WITH ADULT ONSET STILL'S DISEASE TREATED WITH TUMOR NECROSIS FACTOR INHIBITORS

S.T. Song, S. Lee, S.W. Lee, I.W. Sohn, H.-J. Jeong, D.-H. Yoo. *Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of*

**Background:** Adult onset Still's disease (AOSD) is a rare inflammatory disorder of unknown etiology. Several studies have reported that pro-inflammatory cytokines including interleukin (IL)-1, IL-6, IL-18, tumor necrosis factor (TNF)-α, and interferon (INF)-γ, are involved in the pathogenesis of AOSD. Refractory AOSD patients have been treated successfully with anti-cytokine biologics.
**Objectives:** Herein, to investigate predictors for therapeutic response of biologic drugs in refractory AOSD, we analyzed cytokines profiles in Korean patients with AOSD who were treated with anti-TNFα inhibitors.
**Methods:** Twenty two AOSD patients treated with anti-TNFα agents were recruited from a university hospital for rheumatic diseases in Korea. The dosages

of anti-TNFα (infliximab in 18 patients, etanercept in 4, and adalimumab in 3) were same as rheumatoid arthritis. White blood cells, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) levels, ferritin levels, liver enzymes, and serum cytokines (TNFα, IL-1β, IL-6, IL-8, IL-17α, and INF-γ) and IL-2 receptor α in sera were analyzed by multiplex flowcytometry. A good response to anti-TNFα inhibitors was defined as decreased modified Pouchot score more than 2 score compared to initial treatment of anti-TNFα inhibitors. A no response to anti-TNFα inhibitors was defined as no decrease of modified Pouchot score. We used the Mann-Whitney test or Wilcoxon signed rank test for continuous variable and Fisher's exact test for categorical variables.

**Results:** Six (27.3%) patients showed good response to anti-TNFα inhibitors and 3 (13.6%) patients showed partial response. Thirteen (59.1%) patients did not respond to anti-TNFα inhibitors. At starting time point of anti-TNFα inhibitors, levels of ferritin, TNFα, IL-1β, IL-6, and IFNγ in no responders (mean±SD 4,142.0±7,128.6 ng/mL (range 27–18,331), 6.9±10.5 pg/mL (0.0–27.9), 2.6±2.9 pg/mL (0.0–7.4), 16.9±18.7 pg/mL (1.2–221.6), and 13.2±9.1 pg/mL (4.9–30.9), respectively) seemed to be higher compared to those with good response (566.4±633.0 ng/mL (18–1,901), 13.8±24.3 pg/mL (0.0–67.0), 8.7±16.9 pg/mL (0.0–50.8), 77.1±157.8 (2.0–485.4), and 69.3±146 pg/mL (0.0–453.3), respectively), but without statistically significant differences between the 2 groups. We didn't raise the dosage of infliximab in no responders, in whom tocilizumab was used as second biologic therapy. Of those, seven (63.6%) patients showed improvement in clinical and laboratory findings.

**Conclusions:** This study showed that AOSD patients who were refractory to anti-TNFα inhibitors might have distinct cytokine profiles. Therefore, dosage of anti-TNF agents in AOSD patients might be individualized according to pre-treatment cytokine profiles.

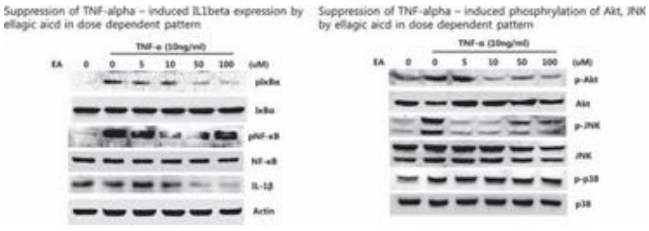
## AB0056 DOWNREGULATION OF TUMOR NECROSIS FACTOR AND INTERLEUKIN-1 BY ELLAGIC ACID



S.-H. Park, H. Lee, J.-Y. Choe, S.-K. Kim, C.W. Lee, J.-W. Kim, J. Kim. *Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of*

**Background:** Ellagic acid (EA) is a phenolic constituent in fruits and nuts, such as raspberries, strawberries, walnuts, mango kernel and pomegranate. It was documented that EA shows anti-fibrotic, anti-inflammatory activity in vivo model of bowel inflammation and lung fibrosis, however the precise mechanism of signal inhibition was not extensively investigated.

**Objectives:** The objectives of this study are first, to elucidate the anti-inflammatory effect of EA in RAW 264.7 murine macrophage cell line by NF-kB pathway in vitro, and second, to compare it with effect of other immuno-modulating agent, tacrolimus and colchicine.

**Methods:** We determined the cytotoxic effect of EA using MTT assay. The effects of EA on tumor necrosis facor (TNF)-alpha induced mRNA and protein expression were investigated using quantitative real-time PCR and western blot. In addition, we examined the effects of pharmaceutical drugs with anti-inflammatory properties on expression of TNF-alpha.

**Results:** EA significantly suppressed the expression of interleukin-1 beta and TNF-alpha in a dose dependent manner. EA suppressed TNF-alpha induced inflammatory genes expression by inhibiting the phosphorylation of JNK and Akt, whereas had no significant effect on p38 activation. In addition, the inhibitory effect of EA on TNF-alpha induced inflammatory genes expression was regulated by suppression of IkB-alpha phosphorylation and NF-kB translocation. The expression of TNF-alpha mRNA level was reduced comparably treated with EA and other anti-inflammatory agents (ascorbic acid, dexamethasone and colchicine).

**Conclusions:** These findings suggest that EA suppresses inflammatory genes expression through phosphorylation of JNK/Akt and regulation of NF-kB signal pathway in TNF-alpha induced inflammation. Further investigation regarding effects of EA on autoimmune, inflammatory is scheduled.

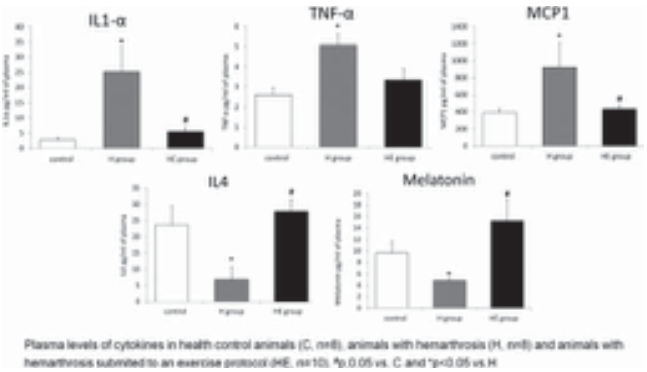
## AB0057 SWIMMING EXERCISE CAN ALTER THE PATTERN OF PLASMA CYTOKINES IN HEMARTHROSIS: AN EXPERIMENTAL STUDY



F. Souza[1], F. Roque[2], E. Oliveira[2], G. Picollo[3], Y. Cury[3], C. Tanaka[4], S.B. Mello[5]. *[1]Internal Medicine, Rheumatology Division, School of Medicine, University of São Paulo; [2]School of Physical Education and Sports, University of Sao Paul; [3]Pain & Signalling Laboratory, Butantan Institute, Brazil; [4]Department of Physical Therapy, Communication Sciences & Disorders, and Occupational Therapy, University of Sao Paulo, Brazil); [5]Internal Medicine/Rheumatology Division, School of Medicine, University of São Paulo, São Paulo, Brazil*

**Background:** Arthropathy is one of the major complications in hemophilia, leading to functional limitations and poor quality of life. Exercise is recommended as being beneficial for people with hemophilia to counteract the consequences of repetitive hemarthrosis, yet a lack of exercise-related evidence using exercise and control groups exists in this population.

**Objectives:** To evaluate in an experimental model of blood-induced joint damage the effects of swimming exercise on systemic inflammatory parameters and pain behavior.

**Methods:** The arthropathy was induced in Wistar rats by eight weekly intra-articular injections of 0.1 mL of autologous blood in their right knees, contra lateral knees were injected with the same amount of saline. Animals were divided into Control Group (C; n=8), Hemarthrosis (H; n=8), Hemarthrosis + Exercise (HE; n=10). HE group performed during 8 weeks a swimming protocol during 60 min/day (5 x week) with 5% body weight attached on their tails. Joint diameters were measured with a digital microcaliper and the difference (Δ) between both side were calculated post-study. Pain status was also assessed with a static weight-bearing incapacitance test (SWIT). Blood samples were collected before sacrifice and the serum levels of interleukins (IL-10, IL-1α, IL-6, IL-4, IL-17), tumor necrosis factor (TNF)-α, vascular endothelial grown factor (VEGF) and monocyte chemoattractant protein-1 (MCP-1) were analyzed by Multiplex assay. Plasmatic Corticosteroid, ACTH and Melatonin hormones were also assessed.

**Results:** When compared with H group, HE group presented reduced joint swelling (Δ=2.39cm vs. 0.66cm; p=0.0001) and pain (39.54 vs. 8.58% decrease weight-bearing in hemarthrosis side; p=0.002). As show in the figure below, hemarthrosis promoted an increase in the plasmatic level of IL1-α (H=10.9 pg/ml ±0.13 vs. HE=5.51 pg/ml ±0.46; p=0.039), TNF-α (H=5.08 pg/ml ±2 vs. HE=3.35 pg/ml ±1.78; p=0.031) and MCP-1 (H=639.86 pg/ml ±45.9 vs. HE 433.1 pg/ml ±10.7; p=0.033) and were reduced by swimming exercise protocol. The level of these plasmatic pro-inflammatory cytokines were also positively correlated with pain (IL1-α: p=0.039; TNF-α: p=0.013; MCP-1: p=0.014). A contrary effect was observed in the anti-inflammatory cytokine IL-4 (p=0,001) where it was reduced in hemarthrosis group (H=6,81pg/ml ±0.81) and was increased by the exercise protocol (HE=27.77 pg/ml ±4.8). Interestingly the pattern of Melatonin levels (H: 4.75 pg/ml ±1.4 vs. HE: 15.26 pg/ml ±5.4; p=0,049) was similar to IL-4.

Plasma levels of cytokines in health control animals (C, n=8), animals with hemarthrosis (H, n=8) and animals with hemarthrosis submitted to an exercise protocol (HE, n=10). *p 0.05 vs. C and *p<0.05 vs. H

**Conclusions:** This is the first study showing the beneficial effects of swimming exercise inflammatory parameters of the blood-induced hemarthrosis in rats. Our data also showed the effectiveness of the exercise in controlling at the same time systemic cytokines and pain in the arthropathy. The most surprising finding of this study was swimming promoting melatonin liberation, which possibly act as an anti-inflammatory agent.

### AB0058 EOSINOPHIL CATION PROTEIN (ECP) – THE TOPPING ATTRACTOR OF THE DISEASE ACTIVITY IN RHEUMATIC ARTRITIS (RA)

V.I. Shishkin, G.V. Kudriavtseva, V.V. Shishkin, Y.A. Malenkov. *Saint Petersburg State University, Saint Petersburg, Russian Federation*

**Background:** RA is systemic autoimmune disease characterized by the production of auto-reactive antibodies, formation of immune complexes causing tissue and organ damage, that reflects the degree of cellular destruction and the depth of the membrane pathological changes. ECP hinder the development of these negative phenomena.
**Objectives:** To assess serum levels of ECP, interleukins (IL-5, IL-10, IL-18) levels and immunoglobulins (IGA, IGE) levels in a population of patients with RA.
**Methods:** 15 patients with RA and 20 healthy controls were investigated in this study. Their ages changed from 35 to 60 years (female/male=3:1). The serum ECP, IL-5, IL-10, IL-18 and IGA, IGE levels were determined using (ELISA), and their correlations with the disease activity were measured using the DAS 28 and laboratory parameters including RF, antiCCP, erythrocyte sedimentation rate, complement (C3, C4), anti-double stranded – DNA antibody levels were analyzed. The clinically relevant correlation reported in the study parameter.
**Results:** The serum ECP, IG and IL levels were significantly higher (mean values ECP: 2500±134,7 ng/ml; IGA: 6970,5±357,9 mg/ml; IGE: 4350,9±210,7 ng/ml; IL-5: 632,5±19,9 pg/ml; IL-10: 956,4±14,7 pg/ml; IL-18: 2307,8±325,4 pg/ml) in RA patients compared to the control (mean values ECP: 21,7±0,9 ng/ml; IGA: 516,7±39,4 mg/ml; IGE: 37,0±9,4 ng/ml; IL-5: 53,7±12,6 pg/ml;IL-10: 93,4±17,8 pg/ml; IL-18: 187,3±25,4 pg/ml), ($p<0,001$). Furthermore, such in increase in the levels of these analyzed parameters showed a highly significant positive correlation with the disease activity and laboratory parameters.
**Conclusions:** The production of pro-and anti-inflammation mediators and ECP in blood from patients with active RA shows a high degree of correlation with clinical disease activity measures. The level of ECP reflects the intensity of RA-inflammatory processes. It is proved expediency of application of the ECP-test in dynamics, status and forecast of the RA.

## Cartilage, synovium and osteoimmunology

### AB0059 TNF PRODUCED BY INFLAMMATORY BLOOD MONONUCLEAR CELLS DIRECTLY CONTRIBUTES TO ARTICULAR CARTILAGE DAMAGE

A. Yarilina[1], T. Melim[2], Z. Kaymakcalan[1]. *[1]Global Biologics; [2]Pharmacology, AbbVie Bioresearch Center, Worcester, United States*

**Background:** TNF is one of the major cytokines involved in the pathogenesis of rheumatoid arthritis (RA) and anti-TNF therapies are effective at preventing inflammation and structural damage in this disease. However, it is not clear whether TNF destroys cartilage directly or via induction of other cytokines including IL-1β. Furthermore, the cellular sources for TNF within the inflamed joints remain controversial.
**Objectives:** Here, we studied effects of TNF on cartilage and compared TNF production by different cell types to gain deeper insights into the mechanism of action for anti-TNF biologics in RA.
**Methods:** *In vitro* studies were performed using primary human synovial fibroblasts (SF), chondrocytes or cartilage explants, and human peripheral blood mononuclear cells (PBMC) from individuals without history of joint disease. Cells and tissues were stimulated with recombinant human TNF, IL-1β, LPS, or members of alarmin family (S100A8 and S100A9). Adalimumab, etanercept, or certolizumab pegol were used to block TNF. Levels of cytokines and matrix metalloproteinases (MMPs) were detected using mesoscale discovery (MSD) assay, and gene expression was measured by real-time PCR. For *in vitro* cartilage destruction studies, bovine explants were co-cultured with activated human PBMC followed with proteoglycan quantification. *In vivo* effects of adalimumab on cartilage were evaluated in human TNF transgenic (hTNF-Tg) mouse model of arthritis.
**Results:** We first examined whether TNF blockade provide cartilage protection *in vivo* and found that adalimumab treatment significantly decreased proteoglycan depletion from the articular cartilage of hTNF-Tg mice. *In vitro*, TNF induced strong up-regulation of IL-6, MMP1, and MMP3 in isolated human chondrocytes and cartilage explants. Additionally, TNF treatment resulted in significant proteoglycan depletion from bovine cartilage explants confirming previous findings; showing that bovine cartilage can respond to human cytokines. In an effort to identify cellular sources of TNF, we challenged chondrocytes, PBMC and SF with inflammatory stimuli, including alarmins, known to be involved in joint pathology and found that PBMC produced significantly higher levels of TNF. In sharp contrast with SF and chondrocytes, TNF failed to induce high amounts of IL-6, MMP1, and MMP3 in PBMC; suggesting that different cell populations play a distinct role in triggering and propagating joint inflammation. Furthermore, blocking both endogenous and exogenous TNF with anti- TNF biologics protected cartilage from proteoglycan depletion *in vitro*.
**Conclusions:** This work demonstrates that TNF directly triggers the catabolic program in human chondrocytes leading to cartilage damage. Our findings also suggest that neutralization of TNF, produced by PBMC infiltrating inflamed joint, decreases catabolic activity of chondrocytes and fibroblasts, which contributes to cartilage protective effects of anti-TNF biologics in RA.

### AB0060 HISTOPATHOLOGICAL CHANGE CAUSED BY BIOLOGICAL TREATMENT IN RHEUMATOID ARTHRITIS SYNOVIAL TISSUE

A. Kubota, T. Suguro, M. Sekiguchi, S. Ikata, S. Takeuchi, K. Tsuchiya. *Toho Univeisity School of Medicine, Department of Orthopaedic Surgery, Tokyo, Japan*

**Background:** Multiple studies addressing the effects of biologics on the synovial tissue in rheumatoid arthritis (RA) patients have been reported. There are, however, few studies comparing histopathological changes in the synovial tissue in the same RA patients between before and after biologics treatment.
**Objectives:** We examined biologics impacts on RA synovial tissues based on pathological findings in them collected during surgeries for the same patient before and after biological drug usage.
**Methods:** Synovial tissues were collected from 22 RA joints before and after biologics. The average age and disease duration of the study subjects were 63.3 and 21.8, respectively. Histopathological changes in the synovial tissues were compared based on Rooney's score, and presence or absence of fibrinoid degeneration and plasma cell infiltration in the subsynovial tissue. We examined correlation between pathological findings in RA synovium and disease activity under biologics. Disease activity was assessed by CDAI. Etanercept, Infliximab, Tocilizumab, Adalimumab and Abatacept was used as biological drug for 11, 5, 2, 2 and 2 joints respectively.
**Results:** Rooney score between before and after biological drug usage improved from 30.6 to 12.6 showing significant difference. Significant improvement in Rooney score was observed in all items. Fibrinoid degeneration was observed in 18 cases (81.8%) and 4 cases (18.2%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. After biologics treatment, Rooney's scores in the remission and low disease activity, and moderate disease activity were 7.1 and 15.9, respectively, showing a statistically significant difference. In addition, the moderate disease activity had significantly higher scores in perivascular lymphocytic infiltration, lymphoid follicle and lymphocyte infiltration compared to the remission and low disease activity. Plasma cells after biologics treatment were observed at 0%, 22.2% and 63.3% in the remission, low disease activity and moderate disease activity respectively, indicating the greater disease activities were associated with the more plasma cells in the subsynovial tissue.
**Conclusions:** The study results demonstrated that biologics treatment significantly ameliorated inflammatory changes in the synovial lining cells and subsynovial tissue. In addition, the results suggested that histopathological findings in the subsynovial tissue reflected disease activity.
**Disclosure of Interest:** None declared

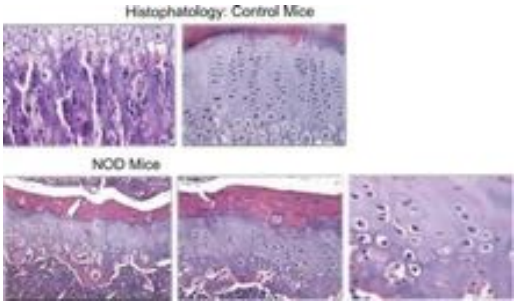
### AB0061 EFFECTS OF LONG TERM ADMINISTRATION OF RANITIDINE, AN ANTAGONIST OF H2 - RECEPTOR, ON BONE METABOLISM IN MALE GROWING RATS

B. Nowak, A. Matuszewska, D. Jedrzejuk, E. Sadanowicz, M. Landwojtowicz, J. Kwiatkowska, M. Piesniewska, M. Bolanowski, A. Szelag. *Wroclaw Medical University, Wroclaw, Poland*



**Background:** $H_2$ - antagonists belong to wildly used drugs. Results of epidemiological studies assessing the influence of long-term therapy with $H_2$-antagonists on bone mineral density (BMD) and fractures risk are ambiguous [1,2].
**Objectives:** The aim of the study was top evaluate influence of ranitidine, a $H_2$ antagonist, on bone turnover and bone mineral density (BMD) in growing rats.
**Methods:** The experiment was carried out on 24 young (8-week-old) male Wistar rats. Rats were randomly assigned to one of two groups (12 animals in each group): group R – rats receiving ranitidine (10 mg /kg) in saline solution (4ml/kg), and group C (control group) – rats receiving saline solution (4ml/kg). Saline solution and ranitidine were given intraperitoneally once daily for 84 days. On day 85 blood samples for serum isolation were collected. After animal scarification right femurs were obtained from each animal and femur index defined as ratio of femur weight and body weight (15 femur mass [g] body mass [g] x 100%'>) was calculated. Serum calcium and phosphate levels were assessed in certified laboratory. Markers of bone turnover were assessed with commercial ELISA kits according to producers' instruction. Bone mineral density (BMD) of right femur was measured by dual-energy X-ray absorptiometry (DXA) with Hologic

DXA equipment (Hologic Dicovery W 81507) using a small animal software. The experiment was performed with the approval of the First Local Ethics Committee for Experiments on Animals in Wroclaw.
**Results:** Femur index and BMD were significantly decreased in rats receiving ranitidine comparing co control group (0.36% ±0.03% vs. 0.03% ±0.02%, p=0.02 and 0.263±0.008 g/cm$^2$ vs. 0.272±0.007 g/cm$^2$, p=0.01, respectively). Serum phosphate level was significantly increased in rats receiving ranitidine comparing to control group (5.06±1.21 mg/dl vs. 4.14±0.39 mg/dl, p=0.02). No significant difference in serum calcium levels between analyzed groups was detected (10.15±0.38 mg/dl in group R vs. 10.34± 0.21 mg/dl in group C, p>0.05). C-terminated telopeptide of type I collagen (CTX) level was increased in group R comparing to group C (140.5± 35.1vs. 102.2±50.0 pg/mL, p=0.04). No significant differences between analyzed groups in serum osteocalcin (OC), osteoprotegerin (OPG) and receptor activator of nuclear factor kappa B ligand (RANKL) levels were detected (342.5±123.3 pg/ml vs. 269.3±76.6 pg/ml, p>0.05; 0.42±0.25 ng/ml vs. 0.30±0.18 ng/ml, p>0.05 and 227.4±57.3 pg/ml vs. 214.7±50.5 pg/ml, p>0.05, respectively).
**Conclusions:** In young growing rats receiving ranitidine we observed decreased BMD and femur index. It seems to be the consequence of increased bone resorption in rats receiving ranitidine.

## AB0062 ALTERATION OF TIBIAL METAPHYSIS AREA IN NOD MICE WHIT SJÖGREN'S SYNDROME

C.A. Gobbi[1], B. Busamia[2], M.B. Guglielmotti[2], S. Fontana[2], M.C. Mariani[2], K. Rhys[2], E. Albiero[1], M.A. Yorio[1]. [1]*Internal Medicine and Rheumatology;* [2]*Dentistry, Universidad Nacional de Córdoba, Córdoba, Argentina*

**Background:** Previously our group described in X-ray studies bone alterations in NOD mice affected with Sjögren's syndrome (SS), characterized by the radiopacity decrease of the tibia cortical layers, compared to controls. These results would suggested that NOD mice with SS could developed disorders in tibial histological architecture. In the current literature, have not been described accurately bone disorders related to the SS.
**Objectives:** To assess histologically the tibial metaphysis area of non-obese diabetic mice with SS, compared to controls NOD without SS.
**Methods:** We used 10 NOD female mice with SS (group SS) and 10 controls NOD without SS (group C, control). They were cared in the animal facilities of the Faculty of chemistry of the UNC. At 4 months of age (weight 80 g ± 10) mice were anesthetized with ketamine-xylazine, both tibias were extracted, and then they were taken to euthanasia. The bones were fixed in formalin buffer, decalcified with EDTA and processed for its inclusion in paraffin; cuts were oriented to the longitudinal axis of the tibia. The samples obtained were stained with hematoxilin and eosin and was assessed qualitatively the tibial metaphysis area histology of both groups.
**Results:** In the SS group an histological architecture alteration was demonstrated in the cartilage and bone trabeculae, which less trabeculae, with less length, as well as sealing trabeculae, when they were compared to the C group.

**Conclusions:** The radiographic findings of the previous study in which it was observed a decrease in the tibial cortical bone density and the alterations in the histological architecture detected in the tibial metaphysis area in this qualitative preliminary study, we would suggest that NOD with SS mice generate changes in bone tissue. It's necessary to carry out histomorphometric studies in 2D and immunostaining techniques of quality and activity of bone tissue, with the purpose of objectify the response in NOD mice with SS.

## AB0063 COMPLEX OF ADALIMUMAB AND TNF INDUCES A DIVERGENT PROTEOMIC PROFILE IN TNF-STIMULATED HUMAN OSTEOCLAST PRECURSORS TO THAT RESEMBLING A MONOCYTIC CELL

B.P. Harvey[1], C. Hu[2], D. Wang[2], Y. Tian[2], Z. Kaymakcalan[1]. [1]*Biologics;* [2]*DMPK, Abbvie Bioresearch Center, Worcester, United States*

**Background:** TNF has been shown to contribute to osteoclastogenesis independently and in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast (OC) development. We have previously demonstrated that TNF enhances the kinetics of RANKL-induced human osteoclastogenesis and that its effects are mitigated more effectively by the anti-TNF biologic adalimumab (ADA) as compared to etanercept (ETN).
**Objectives:** To determine the mechanism responsible for the difference in effectiveness between the two biologics, a label-free quantitative proteomics study was conducted on TNF-activated human OC upon biologic treatment using an EASY Nano LC1000/ QExactive Plus LC/MS system.
**Methods:** Human OC precursors (OCP) were exposed for 5 days to M-CSF, M-CSF+RANKL (RANKL) alone or in combination with 100 ng/mL TNF +/– 5 ug/mL ADA, ETN or human IgG1 (IGG) as a pre-formed complex. OC differentiation was confirmed by measuring tartrate-resistant acid phosphatase 5b (TRAP 5b) activity. Peptides from cell lysates were generated using modified Filter Aid Sample Preparation (FASP). Quality control sample pooling (sham) strategy was used to minimize false discovery by applying a cut off value (ratio >150% or <66.7%) based on reproducibility between sham samples. Data was analyzed with a 3 database search algorithm through Proteome Discoverer (PD) 2.0 and a 4th algorithm using MaxQuant. Protein IDs were aggregated in Scaffold software using the Local FDR data (LFDR) scoring system. Relative quantification was achieved using precursor ion area extraction function within PD and summarized as top 3 precursor ion intensity in Scaffold. Data is expressed as percentage based on ratio of ion counts of each condition to that of RANKL with differences considered significant if ≥150% only for proteins whose percentage between TNF and IGG conditions are similar.
**Results:** Ten OC-related proteins were identified (CA2, ITGAV, ITGB3, OSTF1, NFATC1, *ACP5*, *CTSK*, *MMP9*, *TCIRG1*, *ATP6V0D2*), 5 of which (underlined) were induced by TNF (≥161%), decreased by ADA (≤77%), but unaffected by ETN. Overall, TNF upregulated the levels of 110 proteins as compared to that of RANKL. A greater proportion of these proteins had levels reduced following ADA treatment as compared to ETN (69% and 20%, respectively) concordant with a greater reduction in OC maturation in the presence of ADA as to that of ETN (similar to IGG) (TRAP 5b levels of 11, 40, and 38 U/L, respectively). In addition to lowering the levels of TNF-induced proteins concordant with neutralization by adalimumab, we observed indications for OCP development toward an alternative myeloid lineage based on its ≥1.5-fold induction of 25 proteins that are typically expressed at high levels in monocytic cells (e.g., PSMB9, DPP7, IFI30 & BAG3) including 2 proteins reportedly shown to negatively regulate OC development (LGMN & ZFAND5).
**Conclusions:** Our findings demonstrate that ADA treatment, unlike exposure to ETN, dramatically reduces the TNF-induced protein levels in human OC and moreover, that the TNF:ADA complex may potentially alter their proteome to a profile resembling that of a monocytic cell through an increase in negative regulators of OC development.

## AB0064 ADALIMUMAB IS MORE EFFECTIVE THAN ETANERCEPT IN REDUCING CHEMOTAXIS OF HUMAN MONOCYTES IN RESPONSE TO TNF-INDUCED CHEMOKINE SECRETION FROM HUMAN OSTEOCLAST PRECURSORS

B.P. Harvey, Z. Kaymakcalan. *Biologics, Abbvie Bioresearch Center, Worcester, United States*

**Background:** Tumor necrosis factor-alpha (TNF) contributes to the pathological osteolysis observed in rheumatoid arthritis either directly by stimulating the development of osteoclasts, or indirectly through the induction of the pro-osteoclastogenic cytokine RANKL. However, the role of TNF in promoting human

osteoclast differentiation and/or recruitment of osteoclast precursors (OCP) through the secretion of chemokines in the presence of RANKL is poorly understood.
**Objectives:** To determine the impact of TNF on RANKL-induced human osteoclast development and then assess the contribution of TNF-induced chemokines to promote the chemotaxis of monocytes, potential precursors of osteolasts, to inflammatory sites, both in the absence or presence of various anti-TNF biologics.
**Methods:** Human OCP were cultured for up to 6 days with M-CSF and RANKL +/– 100 ng/mL TNF pre-treated for 30 min with increasing concentrations of hIgG, adalimumab (Ada) or etanercept (Etn). Osteoclast maturation was determined by measuring tartrate-resistant acid phosphatase (TRAP5b) activity. Collagen degradation was assessed by measuring release of plate-bound Europium-labeled collagen (Eu-col). Chemokines were identified by 9-plex MSD. Chemotaxis was assessed in 5 mm pore size plate with human monocytic THP-1 cells in upper chamber, and culture supernatant harvested on day 5 from OCP in lower chamber +/– pre-treatment for 30 min with anti-chemokine antibodies. Cell migration was detected with CellTiter Fluor.
**Results:** TNF promoted greater maturation (3-fold increased TRAP5b) and enhanced collagen degradation (3-fold increased Eu-col levels) of osteoclasts as compared to RANKL alone. Ada restored osteoclast differentiation (at a 10-fold lower concentration than Etn, 0.74 μg/mL and 20 μg/mL, respectively) as well as collagen degradation to levels comparable to RANKL alone. Chemokines including MDC, IL-8, MCP-1 and MIP-1b were detected at higher levels in TNF-exposed OCP cultures as compared to RANKL alone, with a 2-fold reduction in each only in the presence of Ada except for MDC, which was equally inhibited by both Ada and Etn. Culture supernatants from OCP treated only with combination of TNF and RANKL significantly induced chemotaxis of THP-1 ($p<0.0001$) in an MCP-1 dependent manner as demonstrated by a 3-fold reduction in presence of anti-MCP-1 neutralizing antibody. Addition of Ada, but not Etn, to TNF-exposed OCP cultures led to a significant reduction ($p<0.001$) in THP-1 chemotaxis in response to TNF-induced chemokines secreted from the OCP.
**Conclusions:** Overall, the results of our investigation demonstrate that TNF can enhance RANKL-induced osteoclast development and promote secretion of chemokines such as IL-8, MIP-1b and MCP-1. In addition, TNF stimulation of OCP led to the chemotaxis of human monocytic cells, suggesting that additional precursors, such as monocytes, may be recruited to the erosion site through the increased chemokine expression. Interestingly, Ada was more effective than Etn to inhibit all three TNF-mediated events, suggesting that Ada may be more effective in preventing TNF-induced OCP population development and expansion in areas of osteolysis.
**Acknowledgement:** Authors thank Drs. Jochen Salfeld, Anna Yarilina and Jing Min for their critical review.
**Disclosure of Interest:** B. Harvey Shareholder of: AbbVie Inc., Employee of: AbbVie Inc., Z. Kaymakcalan Shareholder of: AbbVie Inc., Employee of: AbbVie Inc.

## AB0065 GALECTIN-3 IS A MAJOR DETERMINANT OF FEMORAL NECK BONE MINERAL DENSITY IN A PARTIAL REGRESSION MODEL: A PRELIMINARY STUDY

C. Ko, Y.-J. Su. *Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

**Background:** Low bone mass is an essential extra-articular feature of rheumatoid arthritis (RA). Patients with RA might present an increased risk of low bone mass as a result of systemic inflammation by alteration of the RANK/RANKL/osteoprotegerin and Wnt/ catenin pathways. In RA, serum galectin-3 correlated with C-reactive protein levels and was considered as biomarker of inflammation. However, recent studies showed abundant galectin-3 observed in the area of severe bone destruction may act as a negative regulator for the upregulated osteoclastogenesis. The role of Galectin-3 is unclear in the regulation of bone resorption in RA.
**Objectives:** The objectives of our study were to evaluate bone mineral density (BMD) and the levels of Galactin-3 and Dkk-1 in RA patients and to study the relation between these parameters.
**Methods:** Patients with active RA were checked with galactin-3, Dkk-1 and followed up with BMD assessment and inflammatory evaluation by ultrasonography (US). Serum galectin-3, Dkk-1 concentrations were assayed with ELISA assay. BMD was measured at hip neck by a Dual-energy X-ray absorptiometry (DXA) (Explorer; Hologic Inc., USA). Grey scale and Power doppler US were graded using a 4-grade semiquantitative scoring system, on a scale of 0–3 at wrist. Each wrist was scanned from lateral to medial aspects in longitudinal planes Radius-Lunate-capitate (volar and dorsal), dorsal Radius-scaphoid-trapezoid, and dorsal Ulna-triquetral. Demographic and clinical data, DAS-28, and erythrocyte sedimentation rate (ESR) were recorded for each patient. Correlations between variables and multilinear regression analysis were performed to check serum galectin-3 expression levels and BMD parameters.
**Results:** (1) Six RA patients 50% were female, age was 57.3±4.4 years, disease duration was 6.9±3.8 years and disease activity DAS 28 was 6.33±0.31. (2) The galectin-3, Sonography inflammatory score and serum iPTH levels showed a significant negative association with BMD at the hip.(Table.1) (3) The multilinear regression analysis showed iPTH, Galactin3 and US score were found to explain 99% of the variance in BMD in hip neck.(4) However, the galectin-3 in multilinear regression analysis showed a positive association with BMD at the hip. (correlation coefficient=0.126, *p* value=0.014) (Table.2)

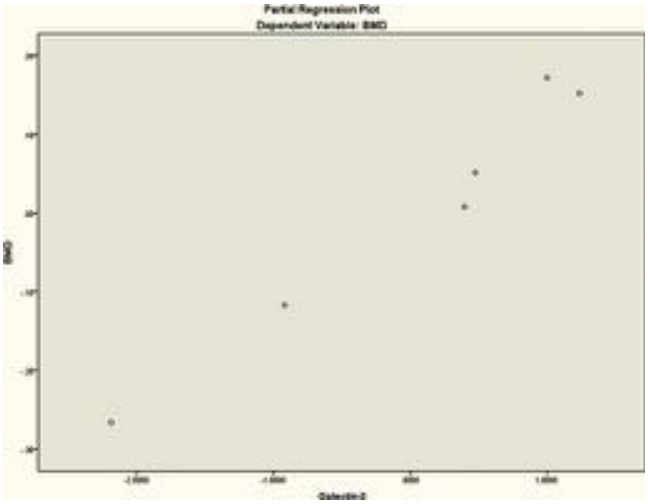

Table 1. Characteristics of patient and Variables that correlated with hip neck bone mineral density (BMD)

| | Mean ± standard deviation (N=6) | Correlation (BMD) |
|---|---|---|
| Age | 57.3±4.4 | –0.164 |
| Rheumatoid factor | 282±178.1 | –0.337 |
| Erythrocyte sediment rate (1hour) | 24.3±10.2 | –0.317 |
| Sonography inflammatory score | 12±5.4 | –0.865* |
| Dkk-1 | 2450.4±712.7 | –0.657 |
| Galactin-3 | 6.02±3.18 | –0.828* |
| iPTH | 40.1±12.5 | –0.921** |
| Alkyine phosphatase | 87.8±18.3 | –0.460 |

*Correlation is significant at the 0.05 level. **Correlation is significant at the 0.01 level.

Table 2. Final step in multilinear regression analysis with backward elimination

| | Unstandardised coefficients | | 95% CI for B | |
|---|---|---|---|---|
| (Constant) | B | P Value | Lower bound | Upper bound |
| Galactin3 | 0.126 | 0.014 | 0.060 | 0.192 |
| iPTH | –0.116 | 0.002 | –0.139 | –0.093 |
| Sonography | –0.081 | 0.002 | –0.096 | –0.065 |

**Conclusions:** Galectin-3 is a major determinant of femoral neck BMD in this partial regression model, after controlling iPTH and sonography inflammatory score, in our preliminary study.

## AB0066 MRI-DETECTED OSTEITIS IS NOT ASSOCIATED WITH THE PRESENCE OR LEVEL OF ACPA ALONE, BUT WITH THE COMBINED PRESENCE OF ACPA AND RF

D.M. Boeters, W.P. Nieuwenhuis, M.K. Verheul, E.C. Newsum, R.E.M. Toes, L.A. Trouw, A.H.M. van der Helm-van Mil. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** In patients with rheumatoid arthritis (RA) bone marrow edema (BME) as observed by magnetic resonance imaging (MRI) represents osteitis with infiltration of leucocytes and an increased number of osteoclasts. Both BME and anti-citrullinated protein antibodies (ACPAs) are predictors of radiographic progression in RA and recent data indicate that ACPA can directly activate osteoclasts. These findings together lead to the hypothesis that ACPA is associated with BME; indeed, two small studies observed an association between BME and ACPA. Thus far the association of ACPA with other forms of MRI-detected inflammation (synovitis and tenosynovitis) has not been thoroughly explored. Furthermore, it is unknown if the association with MRI-detected inflammation is only present for ACPA or also for other RA-related auto-antibodies.
**Objectives:** This study aimed to investigate the associations of ACPA, RF and antiCarP with BME, synovitis and tenosynovitis.
**Methods:** A total of 589 early arthritis patients, included in the Leiden Early Arthritis Clinic cohort, underwent contrast-enhanced 1.5T MRI of the unilateral wrist, metacarpophalangeal and metatarsophalangeal joints at baseline. BME, synovitis and tenosynovitis were scored according to the RAMRIS-method. ACPA, rheumatoid factor (RF) and anti-carbamylated protein (antiCarP) antibodies were determined at baseline.

**Results:** BME, synovitis and tenosynovitis were concomitantly present on MRI. In univariable analyses, ACPA-positive patients had higher BME-scores than ACPA-negative patients (median scores 4.5 vs. 2.0, $p<0.001$), but not more synovitis and tenosynovitis. Besides ACPA, also RF (median scores 3.75 vs 2.0, $p<0.001$) and antiCarP antibodies (median scores 3.5 vs 2.5, $p=0.012$) were associated with higher BME-scores in univariable analyses. To explore the association of the different antibodies with BME the BME-scores of patients with different auto-antibody combinations were compared. ACPA+RF-antiCarP- patients did not have higher BME-scores than ACPA-RF-antiCarP- patients, however ACPA+RF+antiCarP- and ACPA+RF+antiCarP+ patients had higher BME-scores (median 5.0 and 4.5 versus 2.0 respectively, $p<0.001$ and $p<0.001$). ACPA and RF levels were not associated with BME-scores.
**Conclusions:** The presence and the level of ACPA alone were not associated with BME-scores. However, the combined presence of ACPA and RF did associate with more BME. This suggests an additive role of RF to ACPA in mediating osteitis.

## AB0067 AUTOTAXIN INVOLVEMENT IN OSTEOCLAST DIFFERENTIATION AND FUNCTION

S. Flammier, T. Gicquel, F. Duboeuf, O. Peyruchaud, I. Machuca-Gayet, F. Coury. *INSERM UMR 1033, Lyon, France*

**Background:** Autotaxin (ATX) is a secreted protein produced by various tissues in the body including the liver, adipose tissue and bone. Autotaxin (ATX) is an enzyme with a phospholipase D activity responsible for cleavage of lysophosphatidylcholine (LPC) in lysophosphatidic acid (LPA). LPA is a bio phospholipid, which acts as a growth factor, affecting proliferation, differentiation, and migration. It has been shown that the biological effect of LPA could be the direct consequence of local production of Autotaxin (ATX) in a given tissue or cell type (1). Recently, we have shown that LPA controls two steps of osteoclastogenesis: the fusion and bone resorption capacity of osteoclasts (2).
**Objectives:** The aim of this study is to test if ATX produced by osteoclasts could play a direct role in osteoclastogenesis and in bone mass control.
**Results:** First we observed that Enpp2 (ATX gene) was a target gene of RANK-L and as a consequence was up regulated during the course of osteoclastogenesis from bone marrow (BM) wild type (WT) cells. Next we generated Ctsk-Cre+;ATXfl/fl mice and use of these animals as a source of osteoclasts-ATX deficient progenitors. In vitro experiments showed a major impact of ATX on osteoclastogenesis and osteoclast mediated bone resorption. Because LPA is massively present in sera, to explore either LPA or ATX putative effect in culture, the use of delipidated serum was mandatory. Using such conditions, we observed a drastic reduction in the number of mature osteoclasts after 5 days of differentiation from BM-WT progenitors, but osteoclasts number were restored by the use of LPA, recombinant ATX plus LPC, or LPC. These results were confirmed by the use of LPA and ATX specific inhibitors (KI16425 and PF8380). Osteocorning bone resorption assays showed that ATX is required for osteoclasts activity, that decreased of 50% when delipidated sera is used in the assays and that was fully restored by the addition of either LPC or recombinant ATX plus LPC.
**Conclusions:** All together, and more specifically the results obtained in presence of LPC alone suggest that (i) ATX is secreted by osteoclasts and (ii) is functionally involved in osteoclast differentiation and function in vitro. Current studies are conducted on Ctsk-Cre+;ATXfl/fl mice to fully characterize the role of ATX in the bone mass control in physiological and pathological conditions due to ageing (osteoporosis) and inflammation (rheumatoid arthritis).

## AB0068 STRUCTURAL CHARACTERISTICS OF POLYSACCHARIDES INFLUENCE VISCOSUPPLEMENTATION EFFICACY IN OSTEOARTHRITIS

R.R. Castro[1], R.M. Nunes[2], C.M. Silva[3], P.L. Cunha[4], R.C. Paula[4], J.P. Feitosa[4], V.C. Girão[5], M.L. Pompeu[6], J.A.D. Leite[3], F. Rocha[2]. *[1]Chemistry, Superior Institute of Biomedical Sciences, State University of Ceará, Limoeiro do Norte; [2]Internal Medicine; [3]Surgery, Faculdade de Medicina - Universidade Federal do Ceará; [4]Organic and Inorganic Chemi, Universidade Federal Do Ceara; [5]Morphology, Faculdade de Medicina - Universidade Federal do Ceará; [6]Pathology, Universidade Federal Do Ceara, Fortaleza, Brazil*

**Background:** Intra-articular (i.a) injection of a purified Guar gum (GG) solution or hydrogel provided analgesia similar to that of Hylan G-F20 in experimental osteoarthritis (eOA) suggesting that rheology is not crucial to viscosupplements.
**Objectives:** Evaluate the effect of purified GG (DGG), sulfated (DGGSU) of oxidized (DGGOX) GG on pain and cartilage damage in eOA
**Methods:** GG was oxidated with a n-oxil-2, 2, 6, 6-tetra metilpiperidina (TEMPO) reagent or subjected to sulfation to produce carboxylated and sulphate groups. Rats subjected to anterior cruciate ligament transection (ACLT) of the knee received 100 μg GG, sulfated or oxidized GG or vehicle (NT) i.a. at day 4 to 7 after ACLT. Joint pain was recorded using the articular incapacitation test. A group received GG weekly or vehicle from day 7 to 70 and joint damage assessed by histology and biochemically, measuring hondroitin-sulfate (CS) cartilage content (μg/mg) and Mw of CS through PAGE.
**Results:** FT-InfraRed spectra of DDGSU and DDGOX were different from protein free DGG. DGGSU has a new intense band at 1262 $cm^{-1}$, due to S=O. Spectral difference occurs in DGGOX but not DGG and a C=O stretching is present in DGGOX spectrum (COOH group). $^{13}C$ NMR spectrum of DGGOX and DGG revealed absence of the signal at 63.7 ppm present in DGG and two new signals at 177.5 and 177.8 ppm. Absence of the signal from C-6 of free mannose indicates it was substituted in the oxidation. The new signals are from C=O group from COOH. $^{1}H$-$^{13}C$ HSQC spectra exhibited a shift to a lower d value of the proton H-1 from mannose residue in DGGOX, indicating substitution at C-6 from mannose. New signals at 70.3, 75.6, and 100.5 ppm were observed in $^{13}C$ NMR spectrum of sulfated gum due to the insertion of sulfate group in the primary carbon (C-6). All derivatives show lower molar mass than the original guar gum. DGG $M_w$ =3.9 x $10^6$ g/mol, DGGOX and DGGSU, 2.6 x $10^6$ and 2.8 x $10^6$ g/mol, respectively. DGGOX has the lowest intrinsic (2.2 dL/g) and apparent viscosity (9.0 mPa s).DGG exhibits the highest values ([h] =6.2 dL/g and $h_{app}$ =58 mPa s). Intermediate values are obtained for DGGSU ([h] =4.9 dL/g and $h_{app}$ =39 mPa s). GG significantly reduced joint pain, as compared to vehicle whereas oxidat ion or sulfation of GG abrogated GG analgesia. GG also prevented the increase in both CS content (43.8±4.7 μg/mg) and Mw (mobility: 1.18 ±0.03), as compared to NT ($p<0.001$). GG also significantly prevented joint damage at histopathology (median =7; range 2.5 - 18), as compared to NT ($p<0.05$).
**Conclusions:** The structural integrity of GG is crucial to its analgesia. Intra-articular polysaccharides can be analgesic and chondroprotective regardless of being water-soluble.

## AB0069 FOLLISTATIN-LIKE 1 PROMOTES OSTEOCLAST DIFFERENTIATION VIA RANKL-MEDIATED ACTIVATION OF NF-κB AND MAPK SIGNALING PATHWAYS

H.-J. Kim, H.-J. Yoon, W.Y. Kang, S.J. Seong, Y.-R. Yoon. *Cell and Matrix Research Institute, BK21 Plus KNU Biomedical Convergence Program, Clinical Trial Center, Kyungpook National University, Daegu, Korea, Republic Of*

**Background:** Follistatin-like 1 (FSTL1) functions as a pivotal modulator of inflammation and is implicated in many inflammatory diseases such as rheumatoid arthritis, yet its role in osteoclast development is currently unknown.
**Objectives:** The aim of this study was to investigate the role of FSTL1 in osteoclast development mediated by M-CSF and RANKL.
**Methods:** Osteoclastogenesis was assessed using mouse primary bone marrow-derived macrophages. The mRNA expression was analyzed by real-time or RT-PCR. RANKL or M-CSF signaling was assessed by immunoblotting and NF-κB transcriptional activity by luciferase reporter assay. Apoptosis assay was performed by cell death ELISA and cell proliferation using BrdU ELISA system.
**Results:** We show that FSTL1 expression is strongly upregulated during osteoclast differentiation of bone marrow-derived macrophages (BMMs) and FSTL1 positively regulates receptor activator of NF-κB ligand (RANKL)-induced osteoclastogenesis. The overexpression of FSTL1 or the treatment of recombinant FSTL1 (rFSTL1) in BMMs enhances the formation of multinuclear osteoclasts and the induction of c-Fos and nuclear factor of activated T cells c1 (NFATc1), transcription factors important for osteoclastogenesis. Conversely, knockdown of FSTL1 using a small hairpin RNA suppresses RANKL-mediated osteoclast formation and the expression of these transcription factors. While FSTL1 does not affect the RANKL-stimulated activation of p38 MAPK, the phosphorylation of IκBa, JNK, and ERK was increased by overexpression or addition of rFSTL1. Furthermore, rFSTL1 accelerated RANKL-induced NF-κB transcriptional activity in a dose-dependent manner.
**Conclusions:** Our study demonstrates that FSTL1 promotes osteoclast differentiation by stimulating NF-κB and MAPK activation in response to RANKL. Thus, we identify FSTL1 as a pro-osteoclastogenic factor that plays an important role in RANKL-induced osteoclast differentiation.

## AB0070 A ROLE OF SYNOVIAL EXOSOMES IN OSTEOCLAST DIFFERENTIATION OF INFLAMMATORY ARTHRITIS

J.E. Song[1], J.H. Shin[1], K.W. Moon[2], S.H. Shon[1], J.S. Park[3], E.B. Lee[3], Y.W. Song[1,3], E.Y. Lee[3]. *[1]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Institute, Seoul National University, Seoul; [2]Department of Internal Medicine, Kangwon National University Hospital, Chuncheon; [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of*

**Background:** Exosomes are small membrane vesicles (40–150 nm) of endocytic origin secreted by many types of cells and engage in cell-to-cell communication by transferring proteins, microRNAs, mRNA, and lipid to recipient cells. Exosomes are also identified in various biological fluids including blood, urine, amniotic fluid, saliva, malignant ascites, and synovial fluid. Until now, the role of exosomes from synovial fluid (SF) on human osteoclastogenesis is unknown.
**Objectives:** We aimed to identify the characteristics of synovial exosomes and evaluate the effects on human osteoclastogenesis.
**Methods:** Synovial exosomes were isolated from SF of rheumatoid arthritis (RA), osteoarthritis (OA), ankylosing spondylitis (AS), and gout patients using ExoQuick (System Biosciences, USA). Monocytes were isolated from human peripheral blood mononuclear cell and were differentiated into macrophages by treatment of 20 ng/ml recombinant human macrophage colony-stimulating factor (M-CSF) for 3–4 days. Then, macrophages were incubated with synovial exosomes in alpha-MEM supplemented with 10% FBS and 1% penicillin/streptomycin for 9–10 days. Osteoclast differentiation was evaluated by tartrate resistant acid phosphatase stain. Exosomes from RA (n=11), OA (n=5), AS (n=6), and gout (n=6) patients were quantified by measuring acetylcholinesterase activity in colorimetric assay.
**Results:** The number of synovial exosomes isolated from same volume of SF from RA, OA, AS, and gout patients was assessed. We found that exosomes are abundant in SF of RA, AS, and gout patients compared to OA patients. (mean ± SEM $7.36\times10^7\pm1.35\times10^7$, $9.91\times10^7\pm2.50\times10^7$, $7.50\times10^7\pm2.17\times10^7$ vs. $2.66\times10^7\pm0.42\times10^7$). Interestingly, the number of exosomes from AS SF was significantly higher (by 3.72 fold, p=0.0476) than exosomes from OA SF. Exosomes from RA, OA, AS, and gout patients induced proliferation and osteoclast formation without M-CSF and receptor activator of nuclear factor kappa-B ligand (RANKL) (Figure 1), which is essential to proliferation and differentiation of osteoclast. Noticeably, exosomes from RA SF had higher potential on osteoclast differentiation than other three diseases. (20.28±14.28 fold vs. 2.38±0.42 fold).

Figure 1.

**Conclusions:** Our results suggest that exosomes from SF of various inflammatory diseases might have differential functional roles in osteoclast differentiation and the number of exosomes may be associated with inflammatory conditions.

## AB0071 ALPHA-ENOLASE EXPRESSION ON THE CELL SURFACE OF OSTEOCLAST PRECURSORS PLAYS A POSITIVE ROLE IN OSTEOCLASTOGENESIS OF MONOCYTE/MACROPHAGE IN RHEUMATOID ARTHRITIS

J.H. Shin[1], J.E. Song[1], J.S. Park[1], S.H. Shon[1], E.Y. Lee[2], E.B. Lee[2], Y.W. Song[1,2]. *[1]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University; [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of*

**Background:** The local bone loss around the inflamed joints is found from the early stage of rheumatoid arthritis. We previously reported that cell-surface expression of alpha-enolase (ENO1), multifunctional glycolytic protein, is increased in monocytes and macrophages isolated from RA patients and related to production of proinflammatory cytokines (1).
**Objectives:** This study was performed to examine the role of surface ENO1 on osteoclastogenesis in rheumatoid arthritis.
**Methods:** Monocytes isolated from RA patients and healthy control were used to examine the surface level of ENO1 by flow cytometry and confocal microscopy. U937, human monocytic cell line, was treated with ENO1-targeting siRNA (siENO1) to down-regulate ENO1 expression, then osteoclast differentiation were induced by RANKL and the level of ENO1 and NFATc1 was measured. Also, monocytes from RA patients were differentiated into macrophages and transfected with siENO1 to assess the effect on osteoclast differentiation.
**Results:** We found the surface expression level of ENO1 was higher in monocytes isolated from RA patients than healthy control and gradually decreased during osteoclastogenesis in both cells, while the total level of ENO1 remained unchanged. ENO1-specific siRNA significantly decreased the surface ENO1 level in U937, but did not affect the viability and proliferation of the cells. When osteoclast formation was induced by RANKL, osteoclast-specific transcription factor, nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1) expression was markedly inhibited in ENO1 down-regulated cells compared to control cells. We also examined the effect of down regulation of ENO1 in osteoclast precursor cells isolated from RA patients (N=10). The surface ENO1 level was significantly decreased and RANKL-induced osteoclast differentiation was markedly inhibited in ENO1 down-regulated cells compared to control cells.
**Conclusions:** These results suggest that increased expression level of ENO1 on the surface of monocytes/macrophages have positive effect on osteoclast formation in RA.

## AB0072 RECRUITMENT OF RNA TARGETS BY CONNEXIN 43 RNA-BINDING MOTIFS: NOVEL MECHANISMS OF CELLULAR COMMUNICATION

M.D. Mayan[1], M. Varela-Eirin[1], A. Varela-Vázquez[1], M. Rodríguez-Candela Mateos[1], A. Vila-Sanjurjo[2], B. Acea[1], E. Fonseca-Capdevila[1]. *[1]CellCOM Research Group, INIBIC A Coruña; [2]GIBE Research Group, Universidade de A Coruña, A Coruña, Spain*

**Background:** Connexins (Cxs) are integral membrane proteins that form plasma membrane channels, allowing cell-matrix and cell to cell communication. Initially described in joining excitable cells (nerve and muscle), gap junctions (GJs) are found joining virtually all cells in solid tissues and are essential for the functional co-ordination of organs by enabling direct transfer of small signalling molecules, metabolites, ions, and electrical signals. Several studies have revealed diverse channel-independent functions of Cxs, including control of cell growth and tumorigenicity. Chondrocytes from osteoarthritic cartilage have increased expression of connexin 43 (Cx43). The myriad roles of Cx43 and its implication in the development of diseases such as cancer, osteoarthritis or alzheimer have rise to many novel questions.
**Objectives:** The aim of this study was to investigate possible RNA binding domains in the Cx43 and Cx26 sequences in order to study if cells are able to exchange molecules of RNA anchored to Cx43/Cx26 sequences present in exosomes or vesicles.
**Methods:** Amino acids sequences from Cx43 and Connexin 26 (Cx26) were obtained from the Protein Database (NCBI) and the Cx26 structure from the Protein Data Bank (RCSB) [1]. Protein sequences from both Cxs were aligned and compared with Protein Blast and Lalign servers. Analysis of RNA-binding propensity of Cx43 and Cx26 sequences was evaluated with three computational methods with the high predicting accuracy [2] aaRNA, Bind+ and Pprint.
**Results:** Protein sequences were highly conserved between Cx43 and Cx26 with the exception of the the C-terminal end (CTD). The combination of the scores obtained from the three predictors showed four domains that potentially interact with RNA sequences. Two of these domains include the intracellular loop (ICL) and the CTD.
**Conclusions:** Our results suggest that Cx43 and Cx26 are able to interact with RNA targets including siRNA and mRNA. These interactions would have a range of potential implications for cellular communication and control of signalling pathways.

## AB0073 A VALUE OF PULSE THERAPY IN THE TREATMENT OF RELAPSING POLYCHONDRITIS

M.M. Tashpulatova, E.R. Djuraeva, N.A. Ganiyeva, K.E. Azadayeva. *Internal disease, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** Relapsing polychondritis (RP) - is a rare systemic disease with undulating course, presumably autoimmune origin characterized by recurring exacerbations of inflammation in the cartilage tissue, leading to their destruction. Clinical manifestations of RP are divided according to location, severity and duration. In the pathological process may involve all types of cartilage and other

structures, rich proteoglycans: eyes, internal ear and vessels. So far, a unified approach to the treatment of RP in terms of evidence-based medicine does not exist. Due to the rarity of the disease clinical studies for comparative evaluation of different drugs have been conducted. For relief of attacks polychondritis most commonly used nonsteroidal antiinflammatory drugs (NSAIDs) and glucocorticoid therapy (corticosteroids), but there is no evidence of their impact on the progression of the process and to prevent relapse.
**Objectives:** to study the efficiency of pulse therapy in patients with RP.
**Methods:** 4 patients with RP were hospitalized in the clinic of I cardiorheumatological department of Tashkent Medical Academy (TMA). The diagnosis was made on the basis of diagnostic criteria developed by Macadam. All patients underwent clinical, immunological, biochemical studies, chest X-ray, ECG.
**Results:** Patients were performed following treatment, Prednisolone 30 mg/day per os, NSAIDs and combination pulse therapy course (1st and 3rd - days solumedrol 1.0 g intravenously, the second day solumedrol 1.0 g in combination with cyclophosphamide 800 mg). The therapy was showed improvement of general condition of patients, decreased pain in the cartilage of nose and swelling of ears, back pain, general weakness. Patients were discharged under the supervision of district therapeutist and rheumatologist with recommendations to continue receiving NSAIDs, corticosteroids and program of the pulse therapy for 6 months.
**Conclusions:** Thus, the use in the treatment of RP pulse therapy had a positive effect on the clinical condition of patients and prevent progression of disease.
**Disclosure of Interest:** None declared

## AB0074 THE EFFECT OF EXTRACELLULAR VESICLES ON HUMAN IN VITRO OSTEOCLASTOGENESIS IN HEALTH AND IN ARTHRITIS

N. Marton[1], O.T. Kovacs[1], E. Baricza[1], D. Gyori[2], A. Mocsai[3], F. Meier[4], C.S. Goodyear[4], I.B. McInnes[4], E.I. Buzas[1], G.S. Nagy[1]. *[1]Department of Genetics, Cell, - and Immunobiology Semmelweis Univ, Semmelweis University, Budapest, Hungary; [2]The Babraham Institute, Cambridge, United Kingdom; [3]Department of Physiology, Semmelweis University, Budapest, Hungary; [4]Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom*

**Background:** Extracellular vesicles (EVs) like microvesicles (MVs) and exosomes (EXOs) are released in an evolutionary conserved manner by cells. EVs mediate intercellular communication with the transmission of molecules from their parent cell to their targets.
**Objectives:** Our objective was to investigate the effect of EVs on human *in vitro* osteoclastogenesis in healthy donors, rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients.
**Methods:** Blood samples of healthy volunteers, RA patients and PsA patients with peripheral arthritis were collected. EVs were isolated by filtration and differential centrifugation. CD14+ cells were isolated from PBMCs by using positive selection, and the cells were stimulated with 50 ng/ml recombinant human M-CSF for 24 hrs. Then the samples were treated with 50 ng/ml recombinant human RANKL and blood-derived microvesicles or exosomes. After 7 days, the cells were fixed and stained for tartarate resistant acid phosphatase (TRAP). TRAP-positive cells with at least 3 nuclei were considered as osteoclasts and counted by using the ImageJ software.
**Results:** Healthy and RA-derived exosomes significantly ($p<0.01$) inhibited osteoclast differentiation of the CD14+ cells from the same donors, while PsA-derived exosomes had a stimulatory effect ($p<0.05$) on osteoclastogenesis. In cross-induction experiments where EXOs and cells were interchanged between the 3 groups healthy (n=5) and RA (n=5) derived EXOs inhibited ($p<0.01$) the generation of osteoclasts in both groups but PsA (n=7) derived EXOs did not have an inhibitory effect. Microvesicles did not alter the number of mature osteoclasts in any groups.
**Conclusions:** Our data suggest that EXOs profoundly regulate human osteoclastogenesis. PsA-derived EXOs stimulate, while healthy and RA-derived EXOs inhibit the osteoclast differentiation.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3952

## AB0075 AICAR INDUCED MITOCHONDRIAL APOPTOSIS AND INHIBITED CELL PROLIFERATION AND MMP-3/RANKL SECRETION VIA ENHANCEMENT OF MITOCHONDRIAL BIOGENESIS IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIAL CELLS

T. Ueha[1], Y. Sakai[1], T. Maeda[2], M. Morishita[2], K. Fukuda[2], S. Hayashi[2], H. Nishimoto[2], Y. Miura[2,3], R. Kuroda[2], A. Hashiramoto[4], M. Kurosaka[1,2]. *[1]Division of Rehabilitaion Medicine; [2]Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine; [3]Department of Rehabilitation Science; [4]Clinical Immunology, Kobe University Graduate School of Health Sciences, Kobe, Japan*

**Background:** Joint destruction in rheumatoid arthritis (RA) progresses via the hyperproliferation of the synovium and secretion of MMP-3/RANKL from fibroblast-like synoviocytes (FLS). [1] In tumors, we previously reported that the expression of mitochondrial biogenesis-related genes is low and increased numbers of mitochondria enhance cell apoptosis. [2] However, the relationship between mitochondrial biogenesis and cell apoptosis in RA-FLS remains unclear.
**Objectives:** This research was investigated the relationship between mitochondrial biogenesis and cell apoptosis in RA-FLS.
**Methods:** RA and Osteoarthritis (OA)-FLS were obtained during total knee replacement surgery from patients with RA. All experiments were conducted using cells from passages 3–7. Quantitative PCR was used to assess the expression of mitochondria-related mRNA (PGC-1α, NRF-1, and TFAM) and number of mitochondrial DNA (mtDNA) in RA- and OA-FLS with/without 5-aminoimidazole-4-carboxamide riboside (AICAR) (2 mM). Apoptosis was evaluated immunoblot analysis for cleaved caspase-3, -8, -9, and PARP 48 hours after an AICAR treatment in RA-FLS. Cell viability was assessed using WST-8 assay, and MMP-3/RANKL secretion was measured using an immunoassay (immunoblot and ELISA) with/without IL-1β or TNFα stimulation in RA-FLS. Inhibitory experiments were used AMPK inhibitor (20 μM Compound C) and mitochondrial biogenesis-inhibitor (10 μM TFAM-siRNA) by Lipofectamine® RNAiMAX Reagent in RA-FLS.
**Results:** The expression of NRF-1 and TFAM and the levels of mtDNA were lower in RA-FLS than in OA-FLS. In RA-FLS, the levels of mtDNA and mRNA expression of mitochondria-related genes were enhanced by AICAR. Additionally, AICAR enhanced mitochondrial apoptosis (Increased the protein of cleaved caspase-3, -9, and PARP), and Treatment with an AMPK inhibitor (compound C) and a mitochondrial biogenesis- inhibitor (TFAM-siRNA) suppressed the inhibitory effect of AICAR on apoptosis. Moreover, AICAR inhibited cell viability and IL-1β- or TNFα-induced MMP-3/RANKL secretion in inflammation-induced RA-FLS.
**Conclusions:** Mitochondrial biogenesis in RA-FLS was down-regulation. Enhancement of mitochondrial biogenesis resulted in the suppression of disease activities of RA, such as increasing mitochondrial apoptosis and reducing RA-FLS viability and secretion of MMP-3/RANKL from RA-FLS. A novel therapeutic approach by changing mitochondrial biogenesis is proposed.

## AB0076 ANALYSIS FOR THE GENE EXPRESSION PROFILES IN RHEUMATOID SYNOVIAL FIBROBLASTS REGULATED BY LIGHT

T. Maeda[1], Y. Miura[1], K. Fukuda[2], S. Hayashi[1], M. Kurosaka[1]. *[1]Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe; [2]Department of Orthopaedic Surgery, Kakogawa City Hospital, Kakogawa, Japan*

**Background:** Rheumatoid Arthritis (RA) is an autoimmune disease characterized by over-proliferation of synovial tissues and subsequent joint destruction [1]. Lymphotoxin-like, exhibits inducible expression, and competes with herpes simplex virus glycoprotein D for herpes virus entry mediator, a receptor expressed on T lymphocytes (LIGHT) is a member of tumor necrosis factor (TNF) receptor superfamily and is expressed on antigen-presenting cells through the activation of T cells. LIGHT modulates T-cell activation and promotes inflammation through the activation of nuclear factor (NF)κB by binding to its specific receptors herpes virus entry mediator (HVEM) and lymphotoxin (LT)-βR [2]. Furthermore, decoy receptor 3 (DcR3) competitively binds soluble LIGHT and inhibits LIGHT signaling via HVEM [3,4]. Studies have suggested that LIGHT is overexpressed in RA fibroblast-like synoviocytes (RA-FLS) and production of TNFα is induced by stimulation with LIGHT, and that LIGHT may be related to autoimmune diseases such as inflammatory bowel disease or multiple sclerosis [5].
**Objectives:** In this study, we investigated the genes regulated by LIGHT in RA-FLS by comprehensive genetic analysis using microarrays to elucidate the involvement of LIGHT in RA pathogenesis.
**Methods:** *Microarray assay.* Four individual lines of primary cultured RA-FLS were incubated with either 1.0 μg/ml recombinant human LIGHT protein or phosphate buffered saline (PBS) diluted with serum-free Opti-MEM medium as non-stimulated control for 12 hours at 37℃ with 5% CO2. Gene expression was detected using cDNA microarray assay (Human Genome U133 Plus 2.0, GeneChip® 3' Expression Array, Affymetrix), and the gene expression profiles of LIGHT-stimulated cells and controls were compared.
*Real-time polymerase chain reaction (real-time PCR).* The four most highly up- and down-regulated genes were discovered by comprehensive genetic analysis using the microarray. The relative mRNA expression levels of those genes were compared using TaqMan® real-time PCR on a StepOne™ real-time PCR system.
**Results:** *Microarray assay.* The microarray analysis revealed that 1042 genes were up-regulated and 801 genes were down-regulated more than twofold by stimulation with LIGHT in RA-FLS.
*Expression of LIGHT-related genes in RA-FLS.* The real-time PCR analysis

confirmed that mRNA expression of the top-four genes up-regulated and those down-regulated was actually regulated by LIGHT.
**Conclusions:** To our knowledge, this is the first report on the expression profiles of genes regulated by LIGHT in RA-FLS, which suggested the involvement of LIGHT-HVEM/DcR3 signaling in the pathogenesis of RA.

## AB0077 TARGETING SYNOVIAL FIBROBLASTS WITH MELANOCORTIN DRUGS

T. Montero-Melendez[1], C.D. Buckley[2], A. Filer[2], J.D. Turner[2], M. Perretti[1]. *[1]William Harvey Research Institute, School of Medicine and Dentistry, Queen Mary University of London, London; [2]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom*

**Background:** The adrenocorticotropin hormone (ACTH) is a melanocortin (MC) peptide approved for the treatment of inflammatory conditions including gout and rheumatoid arthritis (RA) but undesired effects associated with continued elevated glucocorticoid production limit its clinical use[1]. Research in the last few years has focused on new strategies to develop melanocortin drugs without those side effects. The anti-inflammatory and protective effects of melanocortins on immune and joint cells - such as chondrocytes and osteoclasts – are well characterized. However melanocortin role and therapeutic potential on synovial fibroblasts (SF) are unknown. SF are key effector cells in RA, involved in leukocyte recruitment, cartilage destruction and RA progression and hence proposed as therapeutic targets for RA.
**Objectives:** To characterize expression and function of the MC system in SF and explore its potential therapeutic application in synovial inflammation.
**Methods:** Expression of the MC system in SF from RA patients was studied by PCR (receptors expression $MC_1$-$MC_5$) and ELISA (endogenous peptides $\alpha$-,$\gamma$-MSH and ACTH). MC-induced signalling was assessed by measuring cAMP production, $Ca^{2+}$ flux and ERK1/2 phosphorylation. Cytokine release was measured in supernatants by ELISA. The MC compounds studied include $\alpha$-MSH (endogenous peptide, non-selective), DTrp (synthetic peptide, non-selective) and BMS-470539 (synthetic small molecule, $MC_1$ selective).
**Results:** SF expressed the receptors $MC_{1,3,4,5}$ and produced endogenous ACTH. MC targeting in these cells did not induce $G\alpha_s$ mediated cAMP production – of interest, as cAMP is the canonical MC pathway- but evoked increases in intracellular $Ca^{2+}$ and ERK1/2 phosphorylation suggesting a cell-specific differential signalling, not previously observed in other cell type. The consequences and molecular mechanism of this unusual signalling bias are not known. Treatment of SF with these drugs reduced cytokine release (IL-6, CXCL-5, CCL-2) as well as cell proliferation. Interestingly, the BMS-470539 compound induced cell senescence associated with $p16^{INK4a}$ expression, measured by SA-$\beta$-galactosidase staining and immunofluorescence. This effect was only observed with BMS-470539 – and not by the peptide agonists – suggesting a prominent role of $MC_1$ in MC-induced senescence in SF. On-going studies include the characterization of the BMS-470539-induced senescence associated secretory phenotype.
**Conclusions:** We show herein that the MC system is functional in SF from RA patients and may be targeted pharmacologically for innovative anti-inflammatory approaches. SF are aberrantly activated in the inflamed synovium and MC treatment can reduce activation state (reduced cytokines) and proliferation. Detailed analyses of senescence-associated secretory phenotype induced by the BMS-470539 drug will help to understand the benefits of this approach on SF-associated synovial inflammation.

## AB0078 ROLE OF IL-8 AND ITS RECEPTOR IN ANTI-CITRULLINATED PROTEIN ANTIBODY MEDIATED OSTEOCLASTOGENESIS IN RA

Y. Liu[1,2], A. Krishnamurthy[2], A.H. Hensvold[2], V. Joshua[2], M. Sun[2], M. Engstrom[2], H. Wähämaa[2], V. Malmström[2], L.A. Jopling[3], B. Rethi[2], A. Catrina[2]. *[1]Rheumatology and Immunology, Peking University People's Hospital, Beijing, China; [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Director Immunology Scientific Innovation, Johnson & Johnson, One Chapel Place, London W1G 0BG UK, United Kingdom*

**Background:** Circulating levels of IL-8 is related to the bone loss associated with breast cancer metastasis. Recently, we have shown that anti-citrullinated protein antibodies (ACPA) can induce osteoclastogenesis.
**Objectives:** We aimed to investigate the role of IL-8 and its receptors in mediating osteoclastogenesis in presence or absence of ACPAs
**Methods:** IL-8 levels was measured by ELISA in serum of risk RA patients and synovial fluid samples of RA patients. CD14 positive monocytes were used to generate osteoclasts with M-CSF and RANKL. Inhibition of IL-8 and its receptor were tested with IL-8 neutralizing antibody or small molecule CXCR1/2 anta-agonist (Reparixin and SCH-527123) on osteoclasts (OC) in the presence or absence of ACPA. The number of the OC's were counted in light microscope after TRAP staining. Cell counting kit 8 (CCK8) assay was performed to detect cytotoxicity. CXCR1 and CXCR2 expression was analyzed using flow cytometry and immunohistochemistry during different days of osteoclasts maturation.
**Results:** Increased IL-8 levels were observed in the serum of ACPA positive at risk RA healthy individuals and in synovial fluid of established ACPA positive RA patients. Exogenous IL-8 dose dependently increased OC numbers in presence of RANKL. IL-8 neutralizing antibody inhibited the OC numbers even in the presence of ACPA. Reparixin and SCH-527123 significantly inhibited RANKL mediated osteoclastogenesis at 100 $\mu$M concentration. No cytotoxicity of the drugs were detected with CCK8 assay. Immunohistochemistry staining confirmed the CXCR1/2 expression on OC precursors. We found high expression of IL-8 using immunohistochemistry on the inflammed RA synovium.We observed CXCR1 and CXCR2 expression with flow cytometry in the OC precursors at day 0 and in presence of RANKL the expression was completely lost at day 1 and it reappeared at day 4.
**Conclusions:** Our data provides insights in to the importance of IL-8 autocrine loop in RANKL and ACPA mediated OC development. IL-8 receptor blockade might be a novel way of targeting bone loss in RA.

# Rheumatoid arthritis - etiology, pathogenesis and animal models

## AB0079 DEMONSTRATION OF PARVOVIRUS B19 INFECTION IN RHEUMATOID ARTHRITIS

A. Kadisa[1], S. Kozireva[2], O. Bratslavska[1], V. Groma[3], P. Studers[4], A. Lejnieks[5], M. Murovska[2]. *[1]A.Kirchenstein Institute of Microbiology and Virology; [2]A.Kirchenstein Institute of Microbiology and Virology, Riga Stradins University; [3]Institute of Anatomy and Anthropology, Riga Stradins University; [4]Traumatology and Orthopaedics Hospital; [5]Department of Internal Diseases, Riga Stradins University, Riga, Latvia*

**Background:** The exact cause of the rheumatoid arthritis (RA) is not known. Parvovirus B19 (B19) is one of the most perspective candidates in capacity of etiological agent of RA. Evidence implicating B19 in RA causation is conflicting, but several reports have clearly confirmed its role in the pathogenesis of RA.
**Objectives:** In this study we detect the presence of B19 infection markers and the spectra of synovial and supporting tissue damage in RA patients.
**Methods:** 52 RA patients and 25 age and gender matched healthy individuals were enrolled in this study and peripheral blood samples collected. RecomLine test was used to detect of B19-specific antibodies, nPCR – to detect virus-specific sequences and proliferation test – to detect PBMC response to B19 antigens. Patients' synovial, cartilaginous and osseous samples from 7 RA patients were obtained and conventionally processed for histopathology. B19 capsid proteins VP1/VP2 expression was assessed by immunohistochemistry.
**Results:** The markers of active B19 infection were found in 26.9% (14/52) RA patients in comparison with 8.0% (2/25) control group's individuals. Anti-B19 IgG class antibodies were detected in 76% of healthy persons and in 92.3% of RA patients. In control subjects the antibodies to no more than four B19 antigens were found. 38.5% (20/52) RA patients had also antibodies to B19 non-structural protein NS1 (p=0.001 in comparison with control group's individuals). The presence of viral genomic sequence in DNA from cell-free blood plasma was detected in 25% (13/52) of RA patients and 4% (1/25) of healthy individuals. On the 3rd day of cultivation in the presence of B19 antigens PBMC proliferation was observed in 48.0% (25/52) of RA patients and only in 8.0% (2/25) of healthy persons (p=0.00068). On the 6th day of cultivation PBMC of 63.5% (33/52) of RA patients and 32.0% (8/25) of control individuals responded to B19 antigens (p=0.01436). The PBMC of both control group persons with active B19 infection and 74.1% (10/14) of RA patients with the active virus infection had reacted to B19 antigens by proliferation on the 3rd day. Proliferative response to B19 antigens on the 3rd day was detected also in 44.8% (13/29) remotely infected RA patients while in control group no response was found in remotely infected persons (p=0.00071), but on the 6th day PBMC proliferative response to B19 antigens among remotely infected persons was detected in 68.9% (20/29) RA patients and 41.1% (6/17) control group's patients, respectively (p=0.0347). B19 capsid proteins' VP1/VP2 expression was confirmed as nuclear staining demonstrated in the sublining infiltrating cells and fibroblast-like synoviocytes in the intimal lining.
**Conclusions:** The high frequency of active B19 infection markers, increased PBMC proliferative response to B19 antigens and B19 antigen expression detected in RA patients' synovial, cartilaginous and osseous tissues suggest that B19 infection is involved in the RA development and course. Affection of

fibroblast-like synoviocytes may promote further behaviour changes contribute to disease mechanisms.

AB0080

WITHDRAWN

## AB0081 OCCUPATION AND RISK OF DEVELOPING RHEUMATOID ARTHRITIS

A. Ilar[1], L. Alfredsson[1,2], P. Wiebert[1,2], L. Klareskog[2,3], C. Bengtsson[1].
*[1]The Institute of Environmental Medicine, Karolinska Institutet; [2]Centre for Occupational and Environmental Medicine, Stockholm County Council; [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden*

**Background:** Due to the proposed etiologic involvement of the lung in the development of rheumatoid arthritis (RA), there is reason to study whether other airborne exposures than smoking and silica dust increase the risk of RA. By finding occupations that are related to RA, we can get a hint of which hazardous agents that may be involved in the disease development.
**Objectives:** The aim of this study was to estimate the association between occupation and the risk of anti-citrullinated protein antibody positive (ACPA+) or ACPA- RA in men and women.
**Methods:** The study was based on the Swedish population-based case-control study Epidemiological Investigation of Rheumatoid Arthritis (EIRA), including men and women aged 18–70 years. Controls were matched to cases on sex, age group and residential area. Participants were enrolled between 1996 and 2014. Self-reported data on occupational history, environmental- and lifestyle factors were collected by a questionnaire. Blood samples were taken at clinics to assess the ACPA status of the cases.
We used unconditional logistic regression to assess the odds ratios (ORs) and 95% confidence intervals (CIs) of RA due to last occupation before study inclusion among 3,557 cases and 5,665 controls. Occupations were divided into 70 occupational groups and occupations within the professional, technical, administrative, managerial and administrative fields served as the reference group. Crude ORs were adjusted for age group and geographical area, and for the adjusted model we added pack-years of smoking, alcohol use, university degree and BMI.
**Results:** After adjusting for confounding from pack-years of smoking, alcohol use, university degree and BMI, only assistant nurses and attendants in psychiatric care were associated with a significantly increased risk of ACPA+ RA (OR: 1.3, 95% CI: 1.1–1.5). No occupations among women were significantly related to ACPA- RA after adjustment for the confounders. Among men, electrical and electronics workers (OR: 2.1, 95% CI: 1.1–3.7), bricklayers and concrete workers (OR: 2.9, 95% CI: 1.4–5.7) and material handling operators (OR: 2.1, 95% CI: 1.2–3.9) had an increased risk of ACPA+ RA. Electrical and electronics workers (OR: 2.6, 95% CI: 1.3–5.0) as well as bricklayers and concrete workers (OR: 2.6, 95% CI: 1.1–5.9) also had an increased risk of ACPA- RA.
**Conclusions:** Several occupations were related to ACPA+ or ACPA- RA. Mainly occupations within the manufacturing field were related to RA, and fewer women than men were working in this field. Adjustment for pack-years of smoking, alcohol use, university degree and BMI could not explain why certain occupations were related to an increased risk of ACPA+ or ACPA- RA, supporting the theory that there is an involvement from other harmful, occupational agents.

## AB0082 ANTI-INFLAMMATORY ACTIVITY OF A HUMAN ENDOGENOUS RETROVIRAL GENETIC ELEMENT IN EXPERIMENTAL ARTHRITIS

M.J. Laska[1,2], A. Troldborg[3,4], E.M. Hauge[5], S. Bahrami[2], K. Stengaard-Pedersen[3]. *[1]Biomedicin; [2]Clinical Medicin, Aarhus University; [3]Rheumatology; [4]Clinical Medicin, AARHUS University Hospital; [5]Rheumatology, Aarhus University, Aarhus, Denmark*

**Background:** Human Endogenous Retroviruses (HERVs) are ancient retroviral integrations fixed in the genome of humans. As for all retroviruses, HERVs contain three protein coding genes: *gag*, *pol* and *env*. The retroviral envelope proteins can influence human biology through their inherent immune suppressive activity (1) localized to a secondary protein structure (the ISU domain) in the envelope protein.
Our previous research has shown that the env-59-protein of HERV-H is negatively correlated to the inflammatory marker IL-6 in SLE patients, and has an inhibitory effect on stimulated PBMC's from both RA and SLE patients. We aimed to investigate, if this effect could be translated from *in vitro* to *in vivo* experiments.
**Objectives:** To examine the anti-inflammatory potential of a peptide based on the ISU domain of HERV-H ENV-59 in the SKG mouse model (2).
**Methods:** At 7–11 weeks of age, female SKG mice were randomized to treatment groups. Arthritis was induced with mannan. After disease induction, the animals were treated daily with subcutaneous injections of a synthetically developed peptide (Env59-ISU), a scrambled peptide or saline. Two 4-week studies were performed. In study one, we wished to demonstrate an anti-inflammatory effect of Env59 ISU. Three groups of 5 mice were tested (group #1: 4 μg peptide/day, group #2:40 μg peptide/day, group #3: saline).
Study two aimed to confirm the results of study one. Forty mice were randomized to 5 treatment groups (group 1: saline, group 2: 1μg/peptide/day, group 3: 4μg/peptide/day, group 4: 20 μg/peptide/day and group 5: 4 μg/scrambled-peptide/day). SKG arthritis was assessed and scoring was performed independently by two persons and blinded to treatment group.
Hind paws from two mice were fixated in 70% ethanol, and subsequently embedded undecalcified in methylmethacrylate. Tissue sections were stained with Masson-Golden trichrome.
**Results:** In study one, we found significantly lower arthritis score in Env59-treated mice compared to those treated with saline. Group #3 receiving 4μg peptide had the lowest average arthritis score throughout the trial (Fig.1), which was confirmed by study two showing, that the 4μg peptide- treated group (group 3) had significantly lower arthritis score compared to saline and the scrambled peptide. The pattern observed in the arthritis score was confirmed using serum amyloid A3 (SAA3) as a biomarker for inflammation and using histology in mice treated with saline compared to peptide-treated mice.

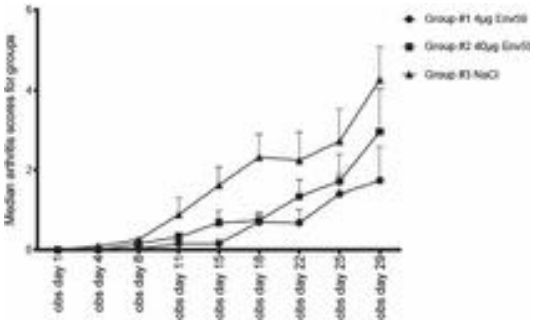

Figure 1

**Conclusions:** We demonstrate that a synthetic peptide corresponding to the sequence of Env59-ISU has anti-inflammatory effect in a chronic inflammatory mouse model of RA and propose the peptide as a potential new treatment for inflammatory diseases.

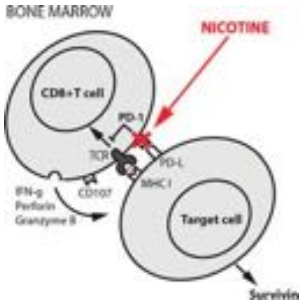
## AB0083 ARTHRITIS INDUCES EARLY BONE STRUCTURAL DEGRADATION AND MECHANICAL WEAKNESS



B. Vidal[1], R. Cascão[1], I. Lopes[1], M. Finnila[2,3], S. Saarakkala[2,4,5], H. Canhão[1,6], J.E. Fonseca[1,6]. *[1]Rheumatology Research Unit, Instituto de Medicina Molecular, Lisboa, Portugal; [2]Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu; [3]Department of Applied Physics, University of Eastern Finland, Kuopio; [4]Medical Research Center, University of Oulu; [5]Oulu University Hospital, Oulu, Finland; [6]Rheumatology Department, Lisbon Academic Medical Centre, Lisboa, Portugal*

**Background:** We have previously found in the chronic SKG mouse model of arthritis that long standing (5 and 8 months) inflammation directly leads to high collagen bone turnover, disorganization of the collagen network, disturbed bone microstructure and ultimately declining of bone biomechanical properties [1].
**Objectives:** Our main goal was to study the effects of the inflammatory process on the microarchitecture and mechanical properties of bone in the early stages of arthritis development.
**Methods:** Fifty Wistar adjuvant-induced arthritis (AIA) rats were monitored throughout arthritis development and sacrificed after 4, 11 and 22 days of disease induction. Thirty healthy non-arthritic rats, age and sex-matched, were sacrificed at the end of the experiment and used as controls for comparison. The inflammatory score, ankle perimeter and body weight were measured over the experimental period. At the time of sacrifice, bone and serum samples were collected for micro-CT and 3-point bending analysis as well as bone turnover markers (CTX-I and P1NP), respectively. All experiments were approved by the Animal User and Ethical Committees at the Instituto de Medicina Molecular (Lisbon University), according to the Portuguese law and the European recommendations.
**Results:** We have observed that bone turnover markers, CTX-I and P1NP, increased soon after arthritis onset ($p<0.0001$ and $p=0.0034$, respectively, when compared to healthy controls). Moreover, micro-CT analyses showed both in trabecular and cortical parameters, that the effects of inflammation on bone microstructure were evident since the 4th day of arthritis development. Of particular interest, trabecular bone volume fraction decreased and cortical porosity increased at day 22 post disease induction when comparing to healthy controls ($p=0.0001$ and $p<0.0001$, respectively). Biomechanical tests revealed that arthritic bone have altered biomechanical properties, such as maximal bending force (arthritic group lower than healthy control, $p<0.0001$).
**Conclusions:** The inflammatory process induced bone loss, and reduces bone strength since the very early phase of arthritis.

## AB0084 NICOTINE CAUSES ENRICHMENT OF SURVIVIN IN SERUM BY ACTIVATING CYTOTOXIC CD8+ T CELLS IN EXPERIMENTAL ARTHRITIS AND PATIENTS WITH RHEUMATOID ARTHRITIS

C.C. Wasén, K.M. Andersson, M.C. Erlandsson, M. Brisslert, M.I. Bokarewa. *Department of Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg, Sweden*

**Background:** Smoking is the most extensively studied environmental risk factor of rheumatoid arthritis (RA). We have recently shown that smoking is associated with high serum levels of survivin (Svensson, Hafström et al. 2014). Survivin is a novel biomarker for RA that can predict severe joint destruction as well as treatment outcome for RA patients (Levitski et al, 2015). We hypothesized cytotoxic activity to be the reason for the increased serum levels of survivin observed in RA patients and we wished to further investigate possible molecular mechanisms behind cytotoxicity in RA.
**Objectives:** We have studied the effect of nicotine on cytotoxic activity of T lymphocytes during RA paying special attention to the expression of PD-1, a receptor that inhibits activation of T cells.
**Methods:** We used female Balb/c mice that received 0.03% nicotine in drinking water or regular tap water as controls, after 18 days mice were immunized with collagen and subsequently developed arthritis (CIA). At the end of experiment bone marrow, lymph nodes and serum were collected and analyzed using flow cytometry (FACS), qPCR and ELISA. To confirm nicotine-dependent nature of experimental findings, we analyzed blood samples of female RA patients and healthy women with known smoking status.
**Results:** The proportion of CD8+ cells was 1.9 times larger in nicotine treated mice compared to control ($p=0.00020$). Meanwhile, the nicotine treated mice had a 2.3 times less PD-1 expressing CD8+ cells in the bone marrow ($p=0.032$), but PD-1 expression in the lymph nodes was not affected by nicotine. This resulted in an accumulation of the CD8+PD-1- population in the bone marrow of the nicotine treated mice ($p=0.0074$). The nicotine treated mice had higher levels of serum survivin (0.0 vs 0.29 ng/ml, $p=0.017$) which also correlated to the size of CD8+PD-1- population in the bone marrow ($r=0.52$, $p=0.024$). The decrease in PD-1 expression of CD8+ T cells caused by nicotine was confirmed in smoking women. Smokers had a 1.7 times less PD-1 positive CD8+ T cells compared to non-smokers ($p=0.041$). In patients, the serum levels of survivin correlated to the expression of the cytotoxic marker CD107 on CD8+ T cells ($r=0.52$, $p=0.047$).

**Conclusions:** Nicotine exposure supports cytotoxic phenotype of CD8+ T cells characterized by high CD107 and low PD-1 expression in experimental arthritis and RA patients. Increased cytotoxic activity of CD8+ T cells is a plausible mechanism for the enrichment of survivin in serum in RA patients. See graphical abstract.

## AB0085 OSTEOCLAST PROGENITORS ARE ATTRACTED BY CCL2/CCR2 AND CCL5/CCR5 CHEMOTACTIC SIGNALS TO THE SITES OF OSTEITIS ASSOCIATED WITH COLLAGEN INDUCED ARTHRITIS

D. Flegar, A. Sucur, A. Markotic, N. Kovacic, T. Kelava, V. Katavic, S. Ivcevic, K. Zrinski Petrovic, D. Grcevic. *Croatian Institute for Brain Research, University of Zagreb School of Medicine, Zagreb, Croatia*

**Background:** Osteitis, replacement of bone marrow adipocytes with inflammatory cells, is an early sign of inflammation in rheumatoid arthritis (RA), seen as bone marrow edema by magnetic resonance imaging. Osteoclast progenitors (OCPs), normally present within circulating monocytes, are presumed to be increasingly attracted to inflamed joints in RA, where their enhanced activation and differentiation leads to excessive osteoresorption.
**Objectives:** Our goal was to identify attraction signals important for homing of OCPs to the sites of osteitis. Therefore, we analyzed changes in immune cell populations as well as OCP chemokine receptor profile and migration potential in circulation, affected joints and periarticular bone in collagen induced arthritis (CIA) as a mouse model of RA.
**Methods:** After obtaining Ethical approval, C57BL/6 mice were immunized with chicken type II collagen in complete Freund's adjuvant and evaluated for CIA development by clinical and histological scoring and anti-collagen antibody detection. Subchondral bone loss and osteitis were assessed by histology and histomorphometry. Distal tibial bone marrow, peripheral blood (PBL) and collagenase-digested tarsometatarseal joints were analyzed by flow-cytometry for the expression of hematopoietic markers and chemokine receptors (CD3, B220, NK1.1, CD11b, CD115, Gr1, CCR2, CCR5, CCR9). Transwell system was used to assess migration potential of M-CSF/RANKL stimulated PBL cells toward CCL2 or CCL5 gradient *in vitro*. For migration tracking, labeled PBL cells were transferred to recipient CIA mice and assessed by *in vivo* fluorescence imaging.
**Results:** Immunized mice developed CIA with the maximum incidence of 60%. Arthritic areas showed histological presence of osteitis and significant subchondral bone loss (BV/TV 46.8±13.4% in control vs 32.1±8.6% in CIA) with increased number of mature osteoclasts (1.4±1.1 in control vs 5.4±4.7 in CIA). Flow-cytometry analysis revealed significant expansion of several populations in CIA, including lymphoid-negative CD11b+/Gr-1+ OCP subset within affected joints (24±4.1% in control vs 49±12.7% in CIA); lymphoid-negative CD11b+CD115+ OCP subset in PBL (4.6±0.7% in control vs 8.8±3.3% in CIA) and periarticular bone marrow (9.6±1.1% in control vs 21.9±3.4% in CIA). PBL OCP populations expressing chemokine receptors were reduced in arthritis (CCR2+ 32.1±4.3% in control vs 24.7±5.1% in CIA; CCR5+ 23.3±4.5% in control vs 18.1±3.7% in CIA; CCR9+ 5.9±3.7% in control vs 0.4±0.1% in CIA). *In vitro* migration of PBL

cells toward chemotactic gradients was significantly enhanced in CIA (11.5 (IQR 11–13.25) in control vs 20.5 (IQR 20–25) in CIA for CCL2; 12.5 (IQR 9–18.5) in control vs 33.5 (IQR 23–35.75) in CIA for CCL5). Fluorescently-labeled PBL cells were efficiently attracted to tarsometatarseal joints 48 hours after *in vivo* transfer in mice with CIA.

**Conclusions:** In fully developed CIA OCP populations are highly induced, with the reduction of circulating OCP subpopulations expressing chemokine receptors, possibly indicating their increased migration and homing to bone surfaces of the inflamed joints. Therapeutic blocking of chemokine signals may therefore be a promising approach to reduce osteoresorption in RA.

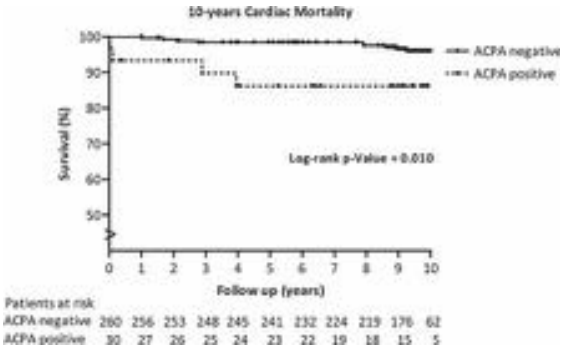
## AB0086 ANTI-CITRULLINATED PROTEIN ANTIBODIES IN PATIENTS WITH CARDIOVASCULAR DISEASE WITHOUT RA



D. Van Der Woude[1], M.P. Hermans[2], D. van der Velden[1], L.A. Trouw[1], T.W. Huizinga[1], J. Kuiper[3], M.J. Schalij[2], W.J. Jukema[2], R.E. Toes[1]. *[1]Rheumatology; [2]Cardiology, Leiden University Medical Center; [3]Leiden Academic Center for Drug Research, Leiden, Netherlands*

**Background:** Anti-citrullinated protein antibodies (ACPA) are thought to be highly specific for RA. ACPA are associated with risk factors for RA and with joint destruction, and are therefore presumed to be involved in RA pathogenesis. ACPA-positive RA patients also have increased cardiovascular mortality (1). In cardiovascular disease, inflammatory changes occur in vessel walls, raising the question whether ACPA (presumed to be pro-inflammatory) may contribute to this process.

**Objectives:** To investigate the prevalence and prognostic implications of ACPA in patients with cardiovascular disease without RA.

**Methods:** ACPA were determined by anti-CCP3 commercial assay in baseline sera from 290 patients with ST-elevation myocardial infarction participating in the MISSION intervention study (2). Patients with RA were excluded. The association between ACPA and long-term mortality was investigated.

**Results:** 30/290 (10.3%) of the non-RA patients with cardiovascular disease were ACPA-positive. ACPA-positive non-RA patients had a significantly increased long-term cardiac mortality compared to ACPA-negative non-RA patients (Figure). Corrected for age, ACPA positivity was independently associated with long-term mortality [HR 2.4 (CI 1.1–5.4) p-Value=0.026].

**Conclusions:** ACPA can be detected in a considerable proportion of non-RA patients with cardiovascular disease. This challenges the presumed specificity of ACPA for RA. In both RA and cardiovascular disease, ACPA are associated with a worse disease outcome possibly by an ACPA-specific enhancement of inflammation. Future studies into ACPA in patients with cardiovascular disease offer the opportunity to dissect which risk factors are associated with ACPA in RA versus non-RA patients. This may supply crucial insights into the development of this autoimmune reaction.

## AB0087 CYTOTOXICITY AND GENOTOXICITY IN RHEUMATOID ARTHRITIS: A DUAL EFFECT OF DISEASE AND DRUGS

E. Soliman[1], M. Tayel[1], H. Mahrous[2], S. Shawky[3]. *[1]internal medicine, rheumatology and immunology, Alexandria Faculty of Medicine; [2]Human Genetics1, Medical Research Institute; [3]internal medicine, ministry of health hospitals, alexandria, Egypt*

**Background:** Studies about cytotoxicity and genotoxicity in rheumatoid arthritis (RA) are limited and the toxicity of Disease Modifying Anti-Rheumatic Drugs (DMARDs) commonly used in treatment is still a concern.

**Objectives:** to assess cytotoxicity and genotoxicity in RA and the possible cyto and genotoxic effects of some DMARDs used in treatment.

**Methods:** The study included 30 female RA patients divided according to treatment into three groups and ten healthy controls. Two groups received DMARDs for at least 3 months period: methotrexate (MTX) only group (n=12 patients), MTX with SSZ (sulphasalazine) group (n=8) and ten DMARDs naieve RA who received only Non Steroidal Anti-Inflammatory Drugs (NSAIDs). The MTX dose was 15–20 mg/wk, SSZ dose was 1.5–2 gm daily. All RA on DMARDs received concomitant daily folic acid dose of 0.5 mg.Peripheral blood samples were taken to assess the cytotoxicity by chromosomal analysis (karyotyping) using solid Giemsa stain and GTG-banding according to the International System for Human Chromosome Nomenclature. Genotoxicity and DNA damage was assessed by the miconucleustest usin g cytochalasin –B.

**Results:** Compared to controls, RA patients had significantly higher chromosomal aberrations (CAs) in the form of breaks, satellite association, endoreduplication, aneuploidy, double minute, and other aberrations. There was also a statistically significant increase in the markers of genotoxicity in RA patients compared to controls: micronuclei (MN), nucleoplasmic bridges (NPB) and necrotic and/or apoptotic cells (Table1). CAs were found in all RA groups, those receiving DMARDs as well as the DMARD naieve group. CAs were significantly higher in MTX and in MTX-SSZ group when compared to RA on NSAIDs only. Meanwhile, there was no significant difference between the CAs in the MTX and the MTX-SSZ groups. In addition, the number of binucleated (BN) cells with MN, NPB, and the necrotic and/or apoptotic cells was statistically higher in MTX-RA and MTX-SSZ-RA compared to the NSAIDs group. Whereas, no statistical difference was found between the two DMARDs groups.RA patients who were on DMARDs for a longer duration (>5 years) showed a statistically significant increase in all cytotoxicity and genotoxicity markers than those for shorter duration (<5 years).

| Markers of cyto/genotoxicity | Control (n=10) Mean ± SD | Total RA (n=30) Mean ± SD | P |
|---|---|---|---|
| Breaks | 0.6±1.07 | 14.77±11.58 | <0.001* |
| Satellite association | 6.2±6.49 | 38.16 ±14.77 | <0.05* |
| Double minute | 0.0±0.0 | 2.03±4.77 | <0.05* |
| Endo- reduplication | 0.0±0.0 | 9.7±8.31 | <0.05* |
| Aneuploidy | 0.0±0.0 | 5.3±4.5 | <0.05* |
| Other aberrations | 0.0±0.0 | 0.70±0.51 | <0.05* |
| BN cells with MN | 1.5±1.2 | 21.73±12.38 | <0.01* |
| BN cells with NPB | 0.8±1.0 | 13.27±9.96 | <0.01* |
| Necrotic and/or apoptotic cells | 2.3±1.8 | 29.93±12.10 | <0.001* |

*P is significant at values ≤0.05.

**Conclusions:** RA patients show significantly increased markers of cytotoxicity and genotoxicity, regardless the type of medications received, sugggesting them to represent underestimated disease features which could provide new insights into its pathogenesis. MTX further aggrevates the cyto- and genotoxicity, whereas SSZ combination does not seem to play additional role and concomitant folic acid supplementation does not provide the sufficient protection.

## AB0088 TRANSGENIC ZAP-70+ B CELLS MICE SHOW A MORE SEVERE COLLAGEN ANTIBODY INDUCED ARTHRITIS (CAIA) THAN WILD TYPE

F. Biscetti[1], F. Angelini[2], S. Gobessi[3], E. Gremese[1], B. Tolusso[1], D. Efremov[3], G. Ferraccioli[1]. *[1]Rheumatology; [2]Internal Medicine, Catholic University School of Medicine; [3]International Centre for Genetic Engineering and Biotechnology, Rome, Italy*

**Background:** Zeta-chain-associated protein kinase 70 (ZAP-70), a tyrosine kinase constitutively expressed in T cells, can be found in B cells and is used as a prognostic marker in identifying different forms of chronic lymphocytic leukemia. We previously provided evidence that a subset of B cells in patients with rheumatoid arthritis (RA) expresses ZAP-70, that marks the memory B cell subsets (IgD+CD27+ and IgD-CD27+), thus suggesting that the ZAP-70+ B cells represent a memory activated subset likely involved in the maintenance of an activated B cell pool [1–3].

**Objectives:** The aim of the present study was to clarify whether B cells, especially ZAP-70 expressing B cells, represent indeed a risk for a severe expression of arthritis in a transgenic ZAP-70+B murine model.

**Methods:** Male transgenic ZAP-70+B mice, that has already been shown to present an high ZAP-70 expression in the B cell lineage [4], aged 8–12 weeks old were used for experiments. All the animals were injected with a cocktail of 5 monoclonal antibodies recognizing the conserved epitopes on various species of type II collagen. Three days later the mice were injected with LPS from *E. coli* 0111:B4 to trigger arthritis development. Animals were evaluated every 3 days after the infusion of the antibody cocktail for arthritis incidence and each paw was evaluated and scored individually on a scale of 0–4. An arthritis index (AI) that expressed a cumulative score for all paws was calculated for each animal.

**Results:** We found that the transgenic ZAP-70+B cells mice presented a more severe form of arthritis, compared to wild type age-matched mice ($p<0.001$) (Figure). Histological and immunohistochemical analyses confirmed the presence

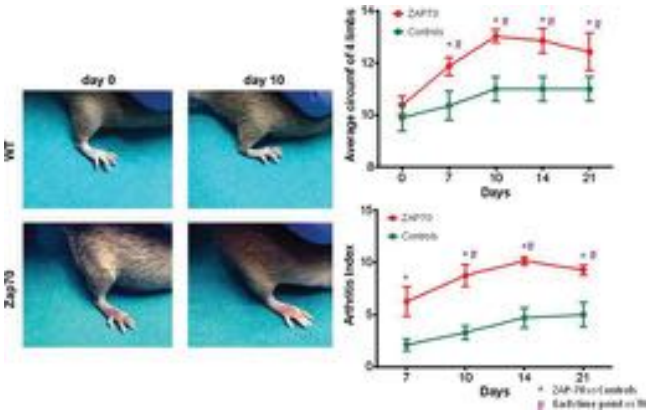

Figure 1

of joint erosions and inflammatory infiltrate at the level of the synovium of ZAP-70+B cells mice.
**Conclusions:** These data suggest that B cells amplify the degree of CAIA, that ZAP-70 is involved in the pathogenesis of arthritis in an RA-like model, and that this tyrosine kinase likely represents a possible target of therapy.

## AB0089 NON-STEROIDAL ANTI-INFLAMMATORY DRUGS AND ENDOTHELIAL FUNCTION IN RA: HARMFUL OR BENEFICIAL? A STUDY IN RAT ADJUVANT-INDUCED ARTHRITIS

F. Verhoeven[1,2], C. Prati[1,2], K. Maguin-Gate[1], P. Totoson[1], D. Wendling[2,3], C. Demougeot[1]. *[1]EA 4267 "fonctions et dysfonctions épithéliales", UFR SMP, université de Franche Comté; [2]Rhumatologie, CHRU de Besançon; [3]EA 4266 "Agents pathogenes et inflammation", UFR SMP, université de Franche Comté, Besançon, France*

**Background:** Rheumatoid Arthritis (RA) is associated with increased cardiovascular risk (CVR) explained in part by accelerated atherosclerosis as a consequence of endothelial dysfunction. Non-steroidal anti-inflammatory drugs (NSAIDs) are widely prescribed in RA patients in case of acute pain. Surprisingly, despite the commonly-held belief that NSAIDs worsen CVR, data regarding their effect on endothelial function in RA are lacking.
**Objectives:** The present study investigated the effect of naproxen (a non-selective COX inhibitor), diclofenac (a preferential COX-2 inhibitor) and celecoxib (a selective COX-2 inhibitor) on vascular function in arthritic rats and identified the underlying mechanisms.
**Methods:** Adjuvant-induced arthritis (AIA) was induced in 6 weeks-old male Lewis rats by injection of *Mycobacterium butyricum* in adjuvant at the basis of the tail. At the onset of arthritis, rats were daily treated (i.p.) with naproxen (10 mg/kg/d), diclofenac (5mg/kg twice a day), celecoxib (3 mg/kg/d) or saline (Vehicle) for 21 days. Arthritis scores were daily monitored. At the end of treatment, thoracic aortas were harvested to measure the relaxation to acetylcholine (Ach) on pre-constricted aortic rings in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), arginase (nor-NOHA), EDHF (Apamin/Charybdotoxin), or a superoxide dismutase analog (Tempol). The effects of a NO donor (sodium nitroprussiate, SNP) and norepinephrine (NE) were studied on endothelium-denuded aortic rings.
**Results:** All NSAIDs significantly reduced to the same extent arthritis score in AIA ($p<0.05$). By contrast, differences exist between NSAIDs regarding endothelial function. Both naproxen and diclofenac significantly ($p<0.05$) improved Ach-induced relaxation whereas celecoxib did not change the response to Ach. These differences on endothelial function were not explained by differences in the response of vascular smooth muscle to NE or SNP which remained unchanged after the 3 treatments. Of interest, the positive effects of naproxen and diclofenac likely relied on different mechanisms. Whilst naproxen tends to improve NOS activity and decrease superoxide anion production, diclofenac decreased arginase activity, superoxide anion production and improved EDHF production.
**Conclusions:** Our study demonstrates for the first time that naproxen and diclofenac have positive effects on endothelial function in case of arthritis whereas celecoxib had no effect, despite a similar reduction of inflammatory symptoms. From a clinical perspective, these data highlight the heterogeneity of effects of NSAIDs as regards CVR in RA and encourage designing clinical trials to confirm our experimental data and help guiding the better choice of NSAIDs for the global management of RA patients.

## AB0090 REACTIVITY TO CITRULLINATED PEPTIDE OF 14-3-3ETA PROTEIN IS ASSOCIATED WITH WORSE RADIOGRAPHIC OUTCOMES IN PATIENTS WITH RECENT-ONSET INFLAMMATORY ARTHRITIS

N. Carrier[1], A. Marotta[2], W.P. Maksymowych[3], G. Boire[4]. *[1]Centre hospitalier universitaire de Sherbrooke, Sherbrooke; [2]Augurex Life Sciences Corp., Vancouver; [3]Medicine, University of Alberta, Edmonton; [4]Department of Medicine/Division of Rheumatology, Universite de Sherbrooke, Sherbrooke, Canada*

**Background:** 14–3-3η protein is citrullinated in the serum of Rheumatoid Arthritis (RA) patients. RA-associated HLA-DRB1 alleles preferentially bind citrullinated (cit) peptides but may bind both cit and arginylated (arg) peptides[1]. Autoreactivity to both cit and arg peptides may thus coexist in patients.
**Objectives:** To examine serum reactivity to 8 peptides representing the arg and cit versions of 4 putative citrullination sites on the 14–3-3η protein and their association with RA serology and radiographic outcomes.
**Methods:** Baseline serum reactivity to 4 pairs of cit and arg peptides was evaluated in a cohort of 331 patients (median age 60 years; 62% women) with recent onset polyarthritis (EPA). Receiver Operating Characteristic (ROC) curves were used to establish the optimal threshold of the ratios of reactivity to the 4 pairs of cit to arg peptides (Cit/Arg) for prediction of definite radiographic progression according to the Sharp/van der Heijde (SvH) score ($\Delta$SvH $\geq$5) from baseline to 3 to 5 years. Spearman correlations were used to determine the relationships between the Cit/Arg ratios with anti-CCP2 and 14–3-3η. Generalized estimating equations (GEE) with repeated measures were used to predict risk of developing $\Delta$SvH $\geq$5 over 5 years expressed as relative risk (RR) and 95% confidence intervals (95% CI).
**Results:** At baseline, comparable reactivity was found against all 4 sets of cit peptides (2 linear: CIT4 and CIT7; 2 cyclic: CYC-CIT1 and CYC-CIT2) and their corresponding arg peptides (ARG4; ARG7; CYC-ARG1; CYC-ARG2). Linear peptides appeared better recognized in their arg form, and the reverse was true for the cyclic ones (Table).
Only the anti-CYC-CIT2/CYC-ARG2 ratio was significantly associated with $\Delta$SvH $\geq$5 at 5 years (mean AUC=0.588, p=0.008); the best ROC cut-off for this ratio was 1.64. The anti-CYC-CIT2/CYC-ARG2 ratio was weakly correlated with anti-CCP2 (r=0.32, $p<0.001$) and with 14–3-3η (r=0.33, $p<0.001$), while anti-CCP2 and 14–3-3η protein were moderately correlated (r=0.53, $p<0.001$).
Anti-CCP2 positivity, 14–3-3η $\geq$0.50 ng/ml, and anti-CYC-CIT2/CYC-ARG2 $\geq$1.64 were respectively present in 133 (40.2%), 119 (36%) and 80 (24.2%) patients and were associated with higher risk for $\Delta$SvH $\geq$5 over time (RR 1.44 (1.14–1.80), p=0.002; 1.60 (1.28–2.00), $p<0.001$; RR 1.68 (1.35–2.09), $p<0.001$).
Patients with both 14–3-3η $\geq$0.50 and anti-CYC-CIT2/CYC-ARG2 $\geq$1.64 had an increased risk for $\Delta$SvH $\geq$5 compared to patients without either of the two (RR: 2.18 (1.68–2.83), $p<0.001$). The presence of only one marker also increased the risk (RR: 1.55 (1.20–2.01), $p<0.001$).
In a multivariate GEE model with 14–3-3η $\geq$0.50, positive anti-CCP2, positive Rheumatoid Factor, positive anti-Sa/citrullinated vimentin, CRP >8.0 mg/L and anti-CYC-CIT2/CYC-ARG2 $\geq$1.64, only CRP and anti-CYC-CIT2/CYC-ARG2 were significant to predict $\Delta$SvH $\geq$5 over 5 years (RR: 1.43 (1.11–1.84), p=0.006 and 1.45 (1.14–1.83), p=0.002; respectively).

| | Serum reactivity (Units/ml) Median (25th-75th percentile) | Ratio of serum reactivity cit/arg Median (25th-75th percentile) |
|---|---|---|
| CIT 4 | 274 (208-353) | |
| ARG 4 | 307 (230-409) | |
| CIT 7 | 316 (235-481) | |
| ARG 7 | 446 (333-584) | |
| CYC CIT 1 | 373 (279-502) | |
| CYC ARG 1 | 278 (215-372) | |
| CYC CIT 2 | 411 (299-565) | |
| CYC ARG 2 | 299 (233-403) | |
| Ratio CIT-4/ARG 4 | | 0.90 (0.76-1.10) |
| Ratio CIT-7/ARG 7 | | 0.73 (0.60-0.92) |
| Ratio CYC CIT-1/CYC-ARG 1 | | 1.28 (1.05-1.58) |
| Ratio CYC CIT-2/CYC-ARG 2 | | 1.32 (1.13-1.63) |

**Conclusions:** Many patients react against 14–3-3η arg peptides as well as against cit peptides. Citrullination at only one of 4 sites appeared linked to outcomes. An anti-CYC-CIT2/CYC-ARG2 $\geq$1.64 and elevated CRP protein both contributed independently to predict worse radiographic outcomes in patients with EPA.

## AB0091 HYPOXIA INDUCE SLUG EXPRESSION VIA JAK/STAT3 PATHWAY IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

H. Kim [1], H. Jeong [1], J. Lee [1], H.-S. Cha [1], E.-M. Koh [1], J.K. Ahn [2]. *[1]Department of Medicine, Samsung Medical Centre, Sungkyunkwan University School of Medicine; [2]Department of Internal Medicine, Gangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of*

**Background:** Accumulating evidence implicates hypoxia in the pathogenesis of rheumatoid arthritis (RA). The effect of hypoxia on the expression of Slug, a transcriptional repressor that impairs apoptosis of RA fibroblast-like synoviocytes (FLS), remains unknown.
**Objectives:** The aim of this study is to investigate the role of hypoxia in the expression of Slug in RA FLS and to delineate the signaling pathway involved in the process.
**Methods:** After RA FLS were exposed to hypoxia, expression of HIF1-a and phosphorylation of ERK, JNK, and STAT3 were analyzed by Western blot. The experiment was repeated with RA FLS pretreated with WP1066, an inhibitor of the JAK/STAT pathway. RT-PCR was performed to measure HIF-1a mRNA and Slug mRNA expressions in RA FLS under hypoxia. RA FLS was transfected with HIF-1a cDNA to investigate the effect of overexpression of HIF-a on Slug expression. Immunohistochemistry was used to assess the presence HIF-1a and Slug in RA synovial tissue. Microarray analysis was performed to investigate the change in Slug gene expression when FLS were exposed to hypoxia. Finally, the effect of TNF-$\alpha$ on Slug and HIF-1$\alpha$ expressions under normoxic conditions was assessed in RA FLS by Western blot.
**Results:** Hypoxia induced the expression of HIF-1a and phosphorylation of STAT3, but not JNK and ERK was increased in RA FLS. Pre-treatment of RA FLS with WP1066 before exposure to hypoxia inhibited the expression of p-STAT and HIF-1a. Hypoxic conditions induced Slug mRNA expression from RA FLS, and similarly, overexpression of HIF-1a in RA FLS reproduced enhanced Slug expression. Microarray analysis revealed a significantly up-regulated Slug expression. Immunohistochemical staining showed that HIF-1a and Slug were co-localized in the lining area of RA synovium. Stimulation of FLS with TNF-$\alpha$ alone without hypoxia resulted in increased expression of Slug HIF-1a and Slug.
**Conclusions:** Our study demonstrates that HIF-1a expression from RA FLS induced by hypoxia or TNF-a alone is mediated through JAK/STAT3 signaling pathway, which ultimately leads to the expression of Slug. Hypoxia-driven pathway of Slug expression may become a novel treatment target in RA.
**Disclosure of Interest:** None declared

## AB0092 ABLATION OF FC GAMMA RECEPTORS LEADS TO A DECREASED BONE EROSION IN EXPERIMENTAL ARTHRITIS BY INHIBITING SYNOVIAL INFLAMMATION AND OSTEOCLAST ACTIVATION

I. Di Ceglie [1], S. Verbeek [2], P. van der Kraan [1], W. van den Berg [1], P. van Lent [1]. *[1]Experimental Rheumatology, Radboud University Medical Center, Nijmegen; [2]Human genetics, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Rheumatoid Arthritis (RA) is characterized by bone destruction in joints caused by enhanced activity of osteoclasts. Ig-G containing immune complexes (ICs) correlate with disease severity and bone erosion and are recognized by Fc gamma receptors (Fc$\gamma$Rs) on myeloid cells. In this study we investigated the role of Fc$\gamma$Rs in osteoclast-mediated bone erosion comparing development of immune complex mediated antigen induced arthritis (AIA) between mice lacking all Fc$\gamma$Rs (Fc$\gamma$RI, II, III, IV$^{-/-}$) and their wild type controls.
**Objectives:** To investigate the role of Fc$\gamma$Rs in bone erosion in experimental arthritis
**Methods:** AIA was induced by injection of 60 $\mu$g mBSA into the knee joint of Fc$\gamma$RI, II, III, IV$^{-/-}$ and wild type (WT) control mice previously immunized with mBSA/CFA. Joint inflammation and bone destruction was determined in total knee joints sections. mBSA antibody titers were measured using ELISA and T cell response monitored with a lymphocyte stimulation test. The percentage of osteoclast precursors in the bone marrow was defined through FACS analysis. Gene expression was measured using RT-PCR. Number of mature osteoclasts within the inflamed joints was defined through TRAP staining. Protein expression was measured with bead-based multiplex immunoassay luminex in the synovial wash-out or through immunohistochemistry on knee joint section.
**Results:** In Fc$\gamma$RI, II, III, IV$^{-/-}$ mice the development of bone erosion in knee joints was significantly reduced both at days 7 and 21 after induction of AIA (30% and 25% lower) when compared to WT controls. The immune response against mBSA (serum level of specific anti mBSA (total IgG, IgG1, IgG2a, IgG2b) and mBSA specific T-cell response) was comparable between the two strains. The percentage of osteoclast precursors within the bone marrow (CD11b $^{low\text{-}neg}$/ Ly6C $^{high}$, described to be upregulated during arthritis) was comparable between Fc$\gamma$RI, II, III, IV$^{-/-}$ and WT controls. At day 7 after AIA induction, the decrease in bone erosion in Fc$\gamma$RI, II, III, IV$^{-/-}$ was associated with a significantly decrease in the number of inflammatory cells present within the joint (infiltrate and exudate 29% and 27% lower respectively compared to WT control). Although less macrophages were detected within the synovium, no differences were found in the number of mature osteoclasts present at locations of bone erosion (32±13 osteoclasts/section in Fc$\gamma$RI, II, II, IV$^{-/-}$ versus 28±9 osteoclasts/section in WT), suggesting that mainly the activity of osteoclasts was affected in the KO animals. In line with this observation levels of macrophage derived factors like IL-1$\beta$ and S100A8, known to strongly induce osteoclast activity, were reduced both at gene expression level and protein level in the synovium of Fc$\gamma$RI, II, III, IV$^{-/-}$ mice.
**Conclusions:** Fc$\gamma$Rs promote bone erosion in AIA by enhancing influx of macrophages within the synovium and release of factors such as IL-1$\beta$ and S100A8 able to stimulate osteoclast activity.

## AB0093 REGULATION OF AUTOPHAGIC FLUX ALTERS INTERLEUKIN-17A-INDUCED MIGRATION AND PROLIFERATION OF FIBROBLAST-LIKE SYNOVIOCYTES FROM THE PATIENTS WITH RHEUMATOID ARTHRITIS

J.-M. Kim [1], J. Bang [2], Y.S. Kim [3], H.-S. Kim [4], S.-J. Hong [5], S.-S. Kim [6], H.-J. Jeong [1], C.-N. Son [1], S.-H. Kim [1]. *[1]Division of Rheumatology, Department of Internal Medicine, Dongsan Medical Center, Keimyung University School of Medicine; [2]Keimyung University Graduate School of Medicine, Daegu; [3]Division of Rheumatology, Department of Internal Medicine, Chosun University Hospital, Gwangju; [4]Division of Rheumatology, Department of Internal Medicine, Soonchunhyang University Seoul Hospital; [5]Division of Rheumatology, Department of Internal Medicine, Kyung Hee University School of Medicine, Seoul; [6]Division of Rheumatology, Department of Internal Medicine, Ulsan University School of Medicine, GangNeung Asan Hospital, Gangwon-do, Korea, Republic Of*

**Background:** Interleukin-17A (IL-17A) plays a critical role in the pathogenesis of rheumatoid arthritis (RA), which is characterized by exaggerated synovial proliferation. Autophagy is required to prevent accumulation of cellular damage and to ensure cellular homeostasis. Dysregulated autophagy has been reported to be involved in the pathogenesis of several diseases such as cancer and infections. Here, we hypothesized that IL-17A, a key cytokine in the development of RA, might have an impact on autophagic flux and that aberrant autophagy might be involved in expansion of synovial fibroblasts in the patients with RA, which is stimulated by pro-inflammatory cytokines.
**Objectives:** The aims of this study were (1) to evaluate whether IL-17A influences on autophagic flux in the synovium of the patients with RA and (2) to investigate whether the modulation of autophagy can regulate migration and proliferation of fibroblast-like synoviocytes (FLS) from the patients with RA (RA-FLS) under inflammatory milieu.
**Methods:** Synovial tissue was obtained from the patients with RA or osteoarthritis (OA) during total knee replacement surgery. FLS was cultured with IL-17A, autophagy inducer or inhibitor. The expression of marker proteins for autophagic flux (LC3B, Beclin1, Atg5, p62) and the formation of autophagolysosome (LAMP1) were analyzed by western blot. A migration scratch assay was used to assess FLS migration in response to stimulation with IL-17A. Proliferation of FLS was determined by the viable cell count using trypan blue. Bafilomycin was used for inhibiting autophagic flux.
**Results:** The expression of autophagy markers (LC3B, Beclin1, Atg5) was increased in the synovium of the patients with RA than in that of the patients with OA. Autophagy was also enhanced in RA-FLS compared with OA-FLS. IL-17A upregulated the expression of LC3B, Atg5, Beclin1, LAMP1 in RA-FLS. In particular, IL-17A-induced accumulation of p62 was prominent in RA-FLS. Migration and proliferation of FLS stimulated by IL-17A was suppressed by the inhibition of autophagy.
**Conclusions:** This study reveals that IL-17A stimulates autophagic flux and that intervention of autophagy can control IL-17A-induced migration and proliferation of FLS. Our results also provide additional evidence for a significant role of

autophagy in the pathogenesis of RA. Thus, we suggest that autophagy might be a potential therapeutic target for the management of RA.

## AB0094 A DUAL PATHOMECHNISM OF LOCAL TNF PRODUCEING IGA B CELLS IN RA SYNOVIAL TISSUE

Z. Konthur[1], U. Nonhoff[1], M.M. Wiemkes[2], J. Detert[2], T. Braun[2], J.M. Hollidt[1], G.R. Burmester[2], K. Skriner[2]. *[1]Hennigsdorf, Germany, DRDx; [2]Department of Rheumatology and Clinical Immunology, Humboldt University and Free University, Berlin, Germany*

**Background:** So far no mechanism for non response to biologicals targeting TNFα has been described despite one third of rheumatoid arthritis patients treated are non-responders.
**Objectives:** We investigated the differences in seroreactivity of patients responding and not responding to TNF therapies prior and after therapy and identified diagnostically applicable IgA autoantigenicity set to identify non response.
**Methods:** Screening with patient sera were conducted with 5 different roteins candidates which were identified by protein maroarray screening (Anal Biochem. 1999 May 15;270(1):103–11.9) expressed recombinantly in *E. coli*, purified and further stratified with a large well defined patient cohort by ELISA. Baseline sera form PREDICT trial treated with Enbrel) and patients treated with Humira in the HIT HARD (Ann Rheum Dis. 2013 Jun;72(6):844–509 trial and 66 baseline sera from Charite in addition treated with (Cimzia, Infiximab) were ivestigated by Pre. mark TNF ELISA from DRDx GmbH.
**Results:** Pretreatment sera from patients with diagnosis of RA based on the ACR classification criteria who were initiated on therapy with TNFalpha inhibitors were analyzed with five markers from the biomarker set of highest priority (RAB11B, PPP2R1A, KPNB1,Cog 4, FTFT1) using an ELISAs assay. In total, analyses of 203 patients were carried out, of which 162 were clearly defined as Responder and 41 were clearly defined as non-Responder after 6 month treatment. 81% of Non-responder could be clearly identified with the pre.markTNF Test. The assay has currently a specificity 94%. Moreover, 80 baseline serum samples from the PREDICT study with Enbrel and 57 baseline sera from an early intervention trial Hit Hard (Ann Rheum Dis. 2013 Jun;72(6):844–509) with Humira were analysed. In early subset, all 3 non-responder were identified and the specificity of the assay was 98%. In the PREDICT study Enbrel non responders were identified with 68.8% sensitivity and a specificity of 92.5%. Moreover 60 patients treated with TNFalpha inhibitors TNF from Stockholm and Vienna have been tested with >90% specificity to predict non response. The amount of IgA produceing B cell in the synovia differs significantly between the patients which is not seen with IgG produceing B cells. Moreover the potent IgA autoantibodies induce high amount of TNF alpha in marophage assay were IgG do not. A dual pathomechnism of local TNF produceing IgA B cells in RA synovial tissue and TNF produceing macrophages is proposed.
**Conclusions:** These data suggest that non-response to anti-TNFα biologicals might be predicted based on frequency and magnitude of autoantibodies to specific IgA autoantigens. SFB can stimulate multiple intestinal homeostatic IgA and TNF induceing B cells might be important for disease persistence in TNFα non responders.

## AB0095 INVESTIGATING THE ROLE OF TRANSIENT RECEPTOR POTENTIAL CANONICAL 5 (TRPC5) IN COMPLETE FREUND'S ADJUVANT (CFA)-INDUCED ARTHRITIS

K. Alawi[1], F.A. Russell[1], A.A. Aubdool[1], Y. Riffo-Vasquez[2], L. Baldissera-Jr[1], P. Thakore[1], E.S. Fernandes[1,3], S.D. Brain[1]. *[1]BHF Cardiovascular Centre of Excellence; [2]Sackler Institute of Pulmonary Pharmacology, Institute of Pharmaceutical Science, King's College London, London, United Kingdom; [3]3Programa de Pós-Graduação, Universidade Ceuma, São LuísSão Luís, Brazil*

**Background:** Rheumatoid arthritis (RA) is a chronic autoimmune disease characterised by inflammation of diarthrodial joints. Sensory neurons expressing transient receptor potential (TRP) channels, a wide family of non-selective cation channels, have been shown to play a role in the pathogenesis of RA[1]. Transient receptor potential 5 (TRPC5) is a member of the canonical family of TRPC channels and is abundantly expressed in the central nervous system and periphery[2], including $CD55^+$ fibroblast-like synoviocytes[3], but the role of TRPC5 in arthritis is unknown.
**Objectives:** To evaluate the for the first time, the contribution of TRPC5 in an *in vivo* model of arthritis and investigate the role of TRPC5 in the modulation of hyperalgesia and joint inflammation.
**Methods:** All experiments were conducted under the guidelines of the United Kingdom Home Office Animals (Scientific Procedures) Act 1986. Age-matched, male 129S1/SvImJ wildtype (WT) and TRPC5 knockout (KO) mice littermates bred from heterozygotic mice provided by Prof. D.E. Clapham, USA[2]. Induction of arthritis using CFA was performed as previously described[1]; inflammation was allowed to progress to 14 days. Nociceptive tests were carried out weekly. Synovial blood flow was assessed in anaesthetised WT and TRPC5 KO mice using a full-field laser perfusion imager (FLPI)[4] on day 14. *Ex vivo* analysis included assessment of cellular infiltration in the knee joint, and determination of cytokine concentrations. In separate studies, WT and TRPC5 KO mice received the TRPC4/5 antagonist, ML204[5](2mg/kg, *i.p.*, n=6) or vehicle (2% DMSO in saline, n=4) daily following *i.art.* injection of CFA. Results are presented as mean ± s.e.m. and analysed by 2-way ANOVA and Bonferonni *post hoc* test.
**Results:** WT mice developed primary hyperalgesia with a significant reduction in withdrawal threshold compared to baseline responses (334.7±25.7 vs 452.2±8.2 gram force (gf); $p<0.01$]). Primary hyperalgesia was exacerbated in TRPC5 KO mice compared to WT mice on day 14 (267.4±34.2 vs 334.7±25.4gf; $p<0.05$]). This was associated with similar deficits in weight-bearing on the ipsilateral hind-limb which was significantly reduced compared to WT mice. Ipsilateral synovial blood flow was significantly increased in TRPC5 KO mice compared to the contralateral synovium (291.3±50.2 vs 198.2±21.4 flux units (AU); $p<0.01$), and WT ipsilateral synovium ($p<0.001$). Pharmacological antagonism of TRPC5 in WT mice corroborated the results observed in TRPC5 KO mice, where hyperalgesia and joint inflammation was significantly exacerbated compared to vehicle treated WT mice.
**Conclusions:** Our results reveal a protective ability of TRPC5 in inflammatory joint conditions *in vivo*. Genetic deletion or pharmacological antagonism of TRPC5 resulted in an exacerbated inflammatory response highlighted by heightened nociceptive responses, increased cellular infiltration and cytokine concentrations in the knee joint.

## AB0096 PRESENCE OF ACPA AND RF AUTOANTIBODIES IN ULCERATIVE COLITIS AND CROHN'S DISEASE

K.M.J. Janssen[1], H. Hop[2], A. Vissink[1], G. Dijkstra[3], E. Brouwer[4], J. Westra[4]. *[1]Department of Oral and Maxillofacial Surgery; [2]Department of Internal Medicine; [3]Department of Gastrenterology and; [4]Department of Rheumatology and Clinical Immunology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands*

**Background:** Presence of arthritis autoantibodies is specific for rheumatoid arthritis (RA). Anti-citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) can be detected several years before the onset of arthritis and are thought to have a pathogenic role. However, where and when autoantibody production starts is unclear. A potential trigger could be chronic mucosal inflammation as in inflammatory bowel disease (IBD) since the gut microbiome is thought to be involved in induction of (auto) immunity. This assumption is supported by the demonstration of citrullinated proteins in intestinal tissue of IBD patients.
**Objectives:** To assess the prevalence of ACPA and RF in IBD patients as well as to assess the prevalence of joint complaints in autoantibody positive versus autoantibody negative IBD patients.
**Methods:** Serum was collected from 227 patients with ulcerative colitis (UC) and 164 with Crohn's disease (CD) participating in the Dutch IBD pearl chain institute biobank initiative. Baseline disease characteristics including enthesitis, arthralgia, arthritis and comorbid conditions like spondylarthropathy were obtained from medical electronic records. IgG and IgA ACPA levels were measured by anti-CCP2 ELISA from EuroDiagnostica (ED) and IgM and IgA-RF levels were measured by in-house ELISA. The cut-off value for IgG ACPA positivity was 2 U/mL and for IgA ACPA 1.04 aU/ml based on the mean +2SD of a group of healthy reference samples. Seropositivity for IgM and IgA-RF was defined at ≥10 IU/ml and ≥25 IU/ml, respectively.
**Results:** Thirty-two (14.1%) UC and 33 (20.1%) CD patients had an IgG ACPA level >2 U/ml. However, all IgG ACPA levels were below the diagnostic cut off level for RA which is set at ≥25 U/ml. IgA ACPA levels were increased in 83 (36.5%) UC and 48 (29.3%) CD patients. IgM-RF seropositivity was observed in 11 (4.8%) UC and 6 (3.7%) CD patients. IgA-RF seropositivity was observed in 6 (2.6%) UC and 8 (4.9%) CD patients. A total of 101 (44.5%) UC and 76 (46.3%) CD were seropositive for at least 1 arthritis autoantibody. Arthralgias were reported in 19.1% of UC and 33.3% of CD, respectively. Among patients with arthralgias, the percentage of individuals being seropositive for 1 or more autoantibodies was comparable to patients without arthralgias.
**Conclusions:** The results of our study support the hypothesis that inflammation of intestinal mucosa induces low systemic levels of ACPA, which eventually may play a role in induction of RA. However, the development of arthralgias in IBD patients is independent on the presence of low systemic presence of arthritis autoantibodies.

## AB0097 THE PRESENCE OF STAPHYLOCOCCAL TOXINS IN THE URINE OF PATIENTS WITH RHEUMATOID ARTHRITIS

L.E. Grace[1], M. Bukhari[2], R.M. Lauder[3], L.A. Bishop[3,4], A.M. Taylor[1].
*[1]Lancaster Medical School, Lancaster University; [2]Rheumatology Department, UHMB NHS Trust; [3]Biomedical and Life Sciences, Lancaster University; [4]UHMB NHS Trust, Lancaster, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is a disease of unknown etiology; with a pathogenesis that is due to a mixture of genetic, immunological and environmental factors. A T-cell immune response to the presence of pyrogenic toxin superantigens (PTSAgs) in the joints of RA patients has previously been described.
A link has been proposed between pathogenic micro-organisms and the development of chronic, autoimmune conditions. Potential pathogenic mechanisms include the hygiene hypothesis and molecular mimicry. Due to the widespread prevalence of RA, it has been hypothesised that the pathogenesis could involve a common bacterium. Previously, *Porphyromonas gingivalis*, a periodontal pathogen, has been suggested due to its ability to citrullinate proteins. In RA one potential bacterial candidate that has been suggested is *Staphylococcus aureus*. Current published data averages the presence of *S.aureus* at 30% in the general population from nasopharyngeal swabs[1]. Furthermore, our unpublished data suggests immune complexes containing *S.aureus* antigens are detectable in urine.
**Objectives:** To investigate the presence of staphylococcal enterotoxins B and C (SEB/SEC), toxic shock syndrome toxin 1 (TSST-1) and alpha haemolysin (AH) in the urine of patients with RA to support the hypothesis that they may play a role in RA.
**Methods:** Following ethical approval, mid-stream urine samples were obtained from patients with RA and a control group (patients with closed fractures). Both populations had no active infection(s) and were recruited from British Rheumatology and Orthopaedic departments in the same hospital. Samples were collected and processed aseptically, then analysed by western blot using commercially available primary (sheep) antibodies to SEB, SEC, TSST-1 and AH; and a rabbit anti-sheep HRP conjugated secondary antibody.
**Results:** The RA population comprises 110 females and 38 males aged 25–90 (median =65–74). The control population comprises 18 females and 9 males (median age =55–64) to date.
Western blot analysis demonstrated the presence of AH/SEB/SEC in 81 of 148 (54.7%) RA patient urine samples and 9 of 27 (33.3%) control samples.
**Conclusions:** Our work demonstrates the presence of bacterial toxins in urine from RA patients, with 54.7% demonstrating the presence of at least one staphylococcal toxin. This study is the first to demonstrate the presence of common staphylococcal enterotoxins in RA patient urine, raising the question of what role they may have in the disease pathogenesis, given that these patients have no active infections.
We also show that *S.aureus* toxins are present in urine of nearly 2 times more of the RA population than the general population. This raises questions of whether the bacteria and their toxins are involved in an individual's likelihood of getting RA; are those people with RA more likely to have *S.aureus* infections due to their immunological state? The presence of *S.aureus* in RA patient tissues warrants further investigation to determine if it is causative of, or a result of RA diagnosis.

## AB0098 SHIFT WORK MAY BE ASSOCIATED WITH AN INCREASED RISK OF RHEUMATOID ARTHRITIS IN WOMEN, BUT NOT IN MEN

L. Arvidsson[1], U. Bergström[1,2], M. Pikwer[1,3], J.-Å. Nilsson[1,2], L. Jacobsson[1,4], C. Turesson[1,2]. *[1]Rheumatology, Department of Clincal Sciences, Malmö, Lund University; [2]Department of Rheumatology, Skåne University Hospital, Malmö; [3]Department of Rheumatology, Eskilstuna Hospital, Eskilstuna; [4]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

**Background:** Rheumatoid Arthritis (RA) is a chronic inflammatory disease, with symptoms varying with the circadian rhythm (i.e. stiffness and pain are increased in the mornings, and associated with increased inflammatory cytokine production). Shift work, defined here as working outside regular day shifts, can cause circadian dysfunction, and is considered to be a potential contributory factor to a range of clinical and pathological conditions, including inflammation. There is limited data on the relation between shift work and RA, but one previous cohort study (1) reported an association between shift work and RA development in women.
**Objectives:** To further investigate the relation between shift work and the risk of subsequent development of RA in women and men separately.
**Methods:** Among participants in a population-based health survey (N=30447), incident cases of RA were identified by linking the cohort to local and national RA registers, followed by a structured review of the medical records. For each validated case, four controls, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected. Life style related factors and other exposures had been assessed in the survey using a questionnaire. Individuals who responded yes to the question "Does your work mean inconvenient working hours or shift work?" were classified as shift workers. The impact of shift work on the risk of RA was examined in conditional logistic regression models, stratified by sex.
**Results:** A total of 172 patients (136 women/36 men, mean age at RA diagnosis 63 years) were diagnosed with RA after inclusion in the health survey. The median time from inclusion to RA diagnosis was 5 years (range 1–13). Among pre-RA cases, 55 individuals, 47 women (38%) and 8 men (27%), were classified as shift workers. The corresponding figures for the controls were 28% among women and 25% among men. Shift work was associated with an increased risk of subsequent development of RA in women (odds ratio (OR) 1.60; 95% confidence interval (CI) 1.01–2.57). There was no significant association between shift work and RA in men (OR 1.04; 95% CI 0.35–3.05). The estimated impact of shift work on the risk of RA in women was similar in separate models adjusted for level of formal education (OR 1.56; 95% CI 0.97–2.50) and smoking (OR 1.53; 95% CI 0.95–2.45).
**Conclusions:** In this nested case-control study, women with inconvenient working hours or shift work had an increased risk of a future diagnosis of RA compared to those with regular working hours. This association did not appear to be explained by potential confounders, i.e. level of formal education or smoking. This suggests that exposures associated with shift work in women, possibly including circadian dysfunction, may contribute to the development of RA.

## AB0099 OVEREXPRESSION OF UPAR IN FIBROBLAST-LIKE SYNOVIOCYTES PROMOTES ANGIOGENESIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Yan, P.Y. Feng, W.Y. Ting, L. Meng. *Division of Rheumatology, Department of Internal Medicine, The 3rd Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** Urokinase-type plasminogen activator receptor (uPAR), is a multifunctional receptor on cell surface, widely present in endothelial cells, fibroblasts, and a variety of malignant cells. Our previous studies have suggested that expression of uPAR is higher in patients with rheumatoid arthritis (RA) compared to osteoarthritis (OA) and the traumatic patients.
**Objectives:** Our objective was to investigate the promoting-angiogenesis effects of uPAR in fibroblast-like synoviocytes from patients with rheumatoid arthritis (RA-FLSs).
**Methods:** Chemically synthesized small interference RNA (siRNA) specifically targeting the uPAR gene was transfected into RA-FLSs by cationic liposome and the cell supernatants from uPAR gene-silenced RA-FLSs were extracted to cultivate the EA.hy926 (a human endothelial cell line). Transwell and tubule formation assays were used to explore the influence of RA-FLSs uPAR on EA.hy926 angiogenesis.
**Results:** EA.hy926 cells treated with conditioned medium of uPAR-siRNA RA-FLSs had a worse migrating ability and tubule formation effects, for they had only about 38% transmembrane cells and the average number of complete tubular structures decreased to 38.2%,relative to the transfection reagent control group (*P<0.05).

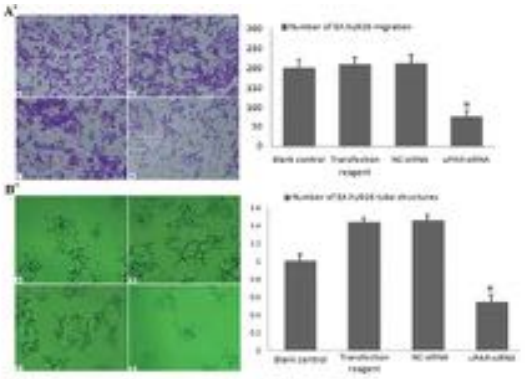

Figure • Interference of uPAR in RA-FLSs could suppress endothelicyte angiogenesis by reducing cell migration and tubule formation. A*. The EA.hy926 cell migration ability in different conditioned medium described below were evaluted by a transwell chamber assay. B*. The EA.hy926 cells with different conditioned medium described below were added into Matrigel coated 96-well for 24h to form tubule. A, Blank control group, serum-free DMEM; B, Transfection reagent group, conditioned medium of RA-FLSs transfected only with transfection reagent; C, NC-siRNA group,conditioned medium of RA-FLSs transfected with a negative control (NC, 40 nM) ; D, uPAR-siRNA group, conditioned medium of RA-FLSs transfected with uPAR-siRNA (40 nM). In both A* and B*, left panel showed representative images; right panel presented quantification (means ± SEM) of 4 independent experiments.*P < 0.05, compared with blank control.

**Conclusions:** uPAR in RA-FLSs affects neoangiogenesis of synovial tissues in patients with RA, which imply that targeting uPAR and its downstream signal pathway may provide beneficial therapeutic effects on RA.

## AB0100 IL-22-MEDIATED BCL-2 EXPRESSION IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES THROUGH STAT3 ACTIVATION

M. Liu, Y. Pan, Y. Liu, Y. Wu, M. Yang, B. Mo. *Rheumatology, The Third Affiliated Hospital to Sun-Yet San University, Guangzhou, GuangDong Province, China*

**Background:** Interleukin-22 (IL-22) is a novel cytokine that is mostly produced by T cells and innate lymphoid cells but selectively stimulates non- immune cells, which immediately caught the attention of many fields such as tumor, chronic inflammatory disease and infectious disease. Considering the persistent biological abnormalities in rheumatoid arthritis fibroblast-like synoviocytes (RA-FLSs) and transient effects of current best treatment such as anti-TNF biologics, other cytokines might be involved and we focus here on the role of IL-22.
**Objectives:** To test the effect of IL-22 on the survival of RA-FLSs and to investigate whether signal transducer and activator of transcription 3 (STAT3) is implicated in this process.
**Methods:** Bcl-2 mRNA and Bcl-xL mRNA expression in the RA-FLSs, osteoarthritis-FLSs and trauma-FLSs were determined using the Real-time quantitative polymerase chain reaction (RT-qPCR), Bcl-2 protein expression in FLSs were detected by the Western Blotting analysis. The effects of recombinant human interleukin-22 (rhIL-22) at concentrations of 0, 1, 10, 100 ng/mL and STA-21 (a STAT3 inhibitor at concentrations of 0, 25μM, 50μM) on the protein levels of Bcl-2 and p-STAT3 in the RA-FLSs were determined by Western blotting analysis. RA-FLSs were co-cultured with rhIL-22 in the presence or absence of STA21 for 24 h, and the protein levels of Bcl-2 and p-STST3 were evaluated by Western blotting analysis.
**Results:** The anti-apoptotic Bcl-2 ($P<0.05$) and Bcl-xL ($P<0.01$) are increased in RA-FLSs compared with osteoarthritis-FLSs and trauma-FLSs, and so is Bcl-2 protein ($P<0.01$). IL-22 increased, and STA-21 decreased the protein levels of Bcl-2 and p-STAT3 (IL-22: $F_{Bcl\text{-}2}=48.63$, $P_{Bcl\text{-}2}<0.01$; $F_{P\text{-}STAT3}=25.7$, $P_{P\text{-}STAT3}<0.01$ STA-21: $F_{Bcl\text{-}2}=49.74$, $P_{Bcl\text{-}2}<0.01$l; $F_{P\text{-}STAT3}=109.97$, $P_{P\text{-}STAT3}<0.01$) in the RA-FLSs obviously. Additionally, treatment with STAT3 inhibitor STA-21 reversed the effect of IL-22-induced Bcl-2 upregulation in the RA-FLSs ($F_{Bcl\text{-}2}=84.67$, $P_{Bcl\text{-}2}<0.01$; $F_{P\text{-}STAT3}=82.46$, $P_{P\text{-}STAT3}<0.01$).
**Conclusions:** STAT3 is critical in the process which IL-22-induced Bcl-2 upregulation in the RA-FLSs. The effects of IL-22/STAT3 confer on them the potential to be used for therapeutic applications in RA.
**Disclosure of Interest:** None declared

## AB0101 IMPACT ON BONE DESTRUCTION BY LILRA3: A HIGH RISK SUSCEPTIBLE GENE IN RHEUMATOID ARTHRITIS

M. Liu[1], Y. Du[1], Y. Zou[1], H. Liu[1], J. Guo[1], Z. Li[2]. *[1]Rheumatology and Immunology; [2]Rheumatology and Immunology, Peking University People's Hospital, Beijing, China*

**Background:** Leukocyte immunoglobulin-like receptor A3 (LILRA3) is a putatively secreted protein belongs to the leukocyte immunoglobulin-like receptor (LILR) family. Our previous study provided the first evidence that the functional LILRA3 was a novel genetic risk for rheumatoid arthritis (RA) in Chinese Han population.
**Objectives:** we undertake this study to investigate the role of LILRA3 on bone destruction in RA patients.
**Methods:** i) The expression of LILRA3 in serum and synovial fluid from patients with RA, OA, and health controls were measured by using ELISA. Bone destruction was scored using modified Sharp-vander Heijde score (SHS) on hands. ii) RAW264.7 cells and peripheral blood mononuclear cells (PBMCs) from RA,OA patients and health controls were cultured in the medium containing different concentration of recombinant LILRA3 protein in the presence or absence of Receptor Activator for Nuclear Factor-κ B Ligand (RANKL) and macrophage colony-stimulating factor (M-CSF). Osteoclasts were identified by tartrate-resistant acid phosphatase (TRAP) staining. Bone resorption activity of osteoclasts was determined by bone slices stained with toluidine blue, iii) PBMCs from patients with RA, OA and health controls were transfected with LILRA3 plasmid or control vector. The expression of osteoclasts related genes, including TRAP, CTSK, MMP-9 was measured by q-PCR array and Western Blotting method. MAPK and NF–κB signaling pathway activation levels were detected by Western Blotting method. One-way analysis of variance was used to detect the differences between the group means.
**Results:** Compared with health controls, the expression of LILRA3 in RA and OA serum was high and LILRA3 was specifically express in synovial fluid with RA patients. The serum level of LILRA3 in RA patients was positively correlated with bone damage. We demonstrated that LILRA3 can promote bone damage independently or synergy with RANKL in RAW264.7 cells through MAPK and NF–κB signaling pathway. Furthermore, we proved that LILRA3 can induce the differentiation of osteoclasts in the presence of RANKL and M-CSF both in vitro and in a transfect system in PBMCs with RA,OA patients and health controls.
**Conclusions:** Our data indicate that LILRA3 can promote done destruction through MAPK and NF–κB signaling pathway. These findings may give us some clues for the study on the pathogenesis of RA.

## AB0102 IGURATIMOD (T-614) SUPPRESSES RANKL-INDUCED OSTEOCLAST DIFFERENTIATION AND MIGRATION IN RAW264.7 CELLS VIA NF-κB AND MAPK PATHWAYS

K. Gan, L. Yang, W. Tan, M. Zhang. *Rheumatology Department, The First Affiliated Hospital of Nanjing Medical University Jiangsu Province hospital, Nanjing, Jiangsu province, China*

**Background:** Iguratimod (T-614) has been confirmed as a highly efficacious and safe novel disease-modifying anti-rheumatic drug (DMARDs) for rheumatoid arthritis therapy in China and Japan due to its potent anti-inflammation effect.
**Objectives:** Here, we investigate the effects of Iguratimod on osteoclast differentiation, migration and function.
**Methods:** The effect of Iguratimod on osteoclastogenesis, migration and bone resorption were assessed by TRAP staining, transwell migration assay and osteologic discs, respectively. Relative expressions of osteoclastic related genes, chemokines and transcription factors were assessed by reverse transcription polymerase chain reaction (RT-PCR) and signaling pathways were analyzed by western blotting.
**Results:** Iguratimod significantly inhibits osteoclast differentiation, migration and bone resorption in RANKL-induced RAW264.7 cell in a dose-dependent manner. The expressions of osteoclastic related genes including TRAP, CTSK and CTR were increased in RAW264.7 cell upon RANKL stimulation but were obviously suppressed in the presence of Iguratimod. RANKL induced the expression of chemokines including CCL7, CCL4 and CCL12 and osteoclastic related transcription factors of c-Fos, c-JUN and NFATc1 could be significantly inhibited by Iguratimod in a dose dependent manner. Western blotting indicated Iguratimod could suppress the activation of MAPKs and NF-κB pathway in RANKL induced osteoclastogenesis in RAW264.7.
**Conclusions:** These findings revealed a directly inhibitory role of Iguratimod on osteoclast formation and function, which is distinct from previous report, suggesting Iguratimod provide a unique therapeutic strategy for RA and especially in light of preventing bone destruction.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5679

## AB0103 HUMORAL IMMUNITY TO FOOD ANTIGENS IN PATIENTS WITH EARLY STEROID AND DMARD NAÏVE RHEUMATOID ARTHRITIS

M. Grujic[1], M. Zlatanovic[1], S. Prodanovic[1], I. Matic[2], M. Djordjic Crnogorac[2], A. Damjanovic Velickovic[2], B. Kolundzija[2], I. Besu[2], Z. Juranic[2], D. Babic[3,4], N. Damjanov[1,4]. *[1]Institute of Rheumatology; [2]Institute of Oncology and Radiology of Serbia; [3]Institute of Medical Statistics and Informatics; [4]School of Medicine, University of Belgrade, Belgrade, Serbia*

**Background:** The presence of different antibodies in the serum of patients with rheumatoid arthritis (RA) before detectable joint inflammation points to a source of RA autoimmunity different then synovium. Recent data [1] support that RA-related autoimmunity may originate at a mucosal site: oral, lung and gastrointestinal mucosa. Special emphasis is on the antibodies of IgG class and their effector function of binding to Fc gamma receptors (FcRγ) on many different immune cells.
**Objectives:** The aim of this study was to investigate the presence and possible association between humoral immunity to food antigens and disease activity in patients with early treatment naive RA (eRA). Also, we examined the expression of FcRγ (CD16) on lymphocytes, NK cells and granulocytes in peripheral blood of these patients and its possible relation with humoral food immunity.
**Methods:** Study included 50 patients newly diagnosed with RA, who had not received any corticosteroid or DMARD therapy and whose conventional radiographs of hands and feet showed no structural damage. Control group consisted of 106 healthy volunteers. The presence and intensity of serum IgG, IgA and IgM antibodies to cow's milk proteins (CMP) and gliadin were determined by ELISA assays. The expression of CD16 and CD56 on immunocompetent cells of peripheral blood was performed by flow cytometry.
**Results:** Significantly enhanced levels of IgG antibodies to gliadin were detected in patients with eRA in comparison with healthy controls (p=0.028). Levels of IgA and IgM antibodies to CMP were significantly higher in sera of eRA patients compared to healthy controls (p=0.0009, p<0.0001, respectively). The percentage of CD16+ lymphocytes and CD16+CD56+ cells in peripheral blood were significantly decreased in patients with eRA compared to healthy controls

($p<0.0001$, $p<0.0001$, respectively). No significant difference in the percentage of CD16+ granulocytes in peripheral blood between the examined groups was detected, however significantly higher mean fluorescence intensity (MFI) of CD16 on granulocytes was detected in patients with eRA ($p<0.0001$). MFI of CD16 expression on lymphocytes was significantly increased in patients with eRA in comparison with healthy individuals ($p=0.004$). The significant decrease in the percentage of lymphocytes in patients with eRA ($p=0.002$) was detected. Positive correlation was found between IgG anti-gliadin antibodies and CD16 expression on lymphocytes ($r=0.360$, $p=0.025$). Furthermore, these antibodies inversely correlated with the percentage of CD16+ granulocytes ($r=-0.326$, $p=0.045$).

**Conclusions:** Significantly higher levels of antibodies to food antigens like gliadin and CMP are present in sera of patients with eRA and could have possible role in the early stages of this disease through activating IgG receptors on immunocompetent cells.

## AB0104 ROLE OF CD14+ AND CD16+ MONOCYTE SUBTYPES IN THE ATHEROTHROMBOSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS: EPIGENETIC MECHANISMS INVOLVED

N. Barbarroja[1], P. Ruiz-Limon[1], C. Perez-Sanchez[1], Y. Jimenez-Gomez[1], M.C. Abalos-Aguilera[1], I. Arias de la Rosa[1], P. Segui[2], P. Font[1], M.A. Aguirre[1], J. Calvo[1], R. Ortega[1], M.C. Castro[1], E. Collantes-Estevez[1], A. Escudero[1], C. Lopez-Pedrera[1]. *[1]Rheumatology Service; [2]Radiology service, IMIBIC/University of Cordoba/Reina Sofia Hospital, Cordoba, Spain*

**Background:** Monocytes play a key role in the pathogenesis of the cardiovascular disease (CVD). Three monocyte subsets have been described based on their CD14 and CD16 profile, with different actions in the vascular pathology. The distribution of these monocytes subsets and their epigenetic profile associated with CVD in rheumatoid arthritis (RA) remain unravelled

**Objectives:** To functionally characterize the monocytes subsets in RA patients and analyze their role in the endothelial dysfunction, altered oxidative status and proinflammatory/prothrombotic profile associated to RA.

**Methods:** Fifty RA patients and 30 healthy donors were included. Endothelial function was measured through post occlusive hyperaemia using Laser-Doppler. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. The monocyte subsets were characterized by flow cytometry and isolated by immunomagnetic selection. Proinflammatory cytokines, peroxides levels and cellular activation markers were analyzed. NanoString nCounter miRNA Expression Array was used to profile 800 microRNAs in isolated CD14+ and CD16+ monocytes. PCR array gene expression was used to analyze the expression of 84 genes related to atherosclerosis. Target genes of the differentially expressed miRNAs were identified by using the Ingenuity Pathway Analysis Software (IPA). The predicted microRNA-mRNA interactions were characterized by the microRNA Target Filter tool of IPA. The resulting identified interactions were revalidated by RT-PCR on the whole cohort of RA patients

**Results:** CD16+ monocytes were significantly extended in RA patients. These subsets had increased protein and gene expression of proinflammatory cytokines, markers of atherosclerosis and peroxide levels. miRNA expression profiling showed that 38 miRNAs were significantly altered ($\geq$2 fold) in CD14+ RA monocytes compared to CD16+ RA monocytes. Functional classification of those miRNAs showed a preponderance of targets mRNAs involved in the pathological process of RA such as inflammatory state, immune response and CVD. RA patients had impaired endothelial function, with a reduced perfusion value after ischemia. Increased CD16+ monocytes and reduced CD14+ cells percentage were associated with a pathologic CIMT. Clinical parameters strongly correlated with endothelial dysfunction, decreased percentage of CD14+ monocytes and increased number of CD16+ subsets.

**Conclusions:** 1) RA patients exhibit an increased number of CD16+ monocytes, which display a specific atherogenic and inflammatory pattern directly associated to the autoimmune profile, the progression of the disease and the altered microvascular function. This atherogenic profile might be associated with an altered epigenetic pattern. That data suggest that CD16+ subpopulation might play a key role in the CVD pathogenesis associated with RA.

## AB0105 INHIBITION OF A STREPTOCOCCAL CELL WALL MODEL OF ARTHRITIS FLARE BY REPOSITORY CORTICOTROPIN INJECTION

P. Higgins, D. Decker, P. Becker. *Mallinckrodt Pharmaceuticals, Ellicott City, MD, United States*

**Background:** Repository corticotropin injection (RCI), a melanocortin peptide preparation, is FDA approved as adjunctive therapy for short term administration to tide patients over acute episodes or exacerbations of rheumatoid arthritis (RA), but has not been studied in an animal model of arthritis flare.

**Objectives:** To test the efficacy of RCI in a *Streptococcal* cell wall-induced model of arthritis flare in rats [1].

**Methods:** Dark Agouti rats were primed on day 0 by an intra-articular injection of a proteoglycan/polysaccharide (PGPS) preparation from *Streptococcal* cell wall into the right ankle and vehicle (phosphate buffered saline) into the left. On days 14 and 28, transient arthritic flares were induced in the ankle by intravenous injection of PGPS. Caliper measurements of the right and left paw diameters were made daily beginning on the day of induction of the first flare. RCI was administered subcutaneously at doses of 40, 160, and 400 U/kg beginning day 1 after induction of the first flare and dosed every other day until animals were sacrificed on day 35, after recovery from the second flare. Arthritis was assessed by measuring the diameter difference between the right (PGPS injected) and left ankles. Histologic analysis was performed on the paws obtained at sacrifice (day 35).

**Results:** RCI dose-dependently inhibited paw swelling in rats after induction of both the first and second arthritic flares. Doses of 160 U/kg and 400 U/kg inhibited physical signs of the first flare by 69% ($p<0.01$) and 86% ($p<0.001$) and inhibited the second flare by 87% ($p<0.0001$) and 90% ($p<0.0001$), respectively. Histologic analysis showed that inflammatory cell infiltration into joints was significantly decreased by 53% ($p<0.01$) and 77% ($p<0.0001$) at the 160 and 400 U/kg doses of RCI, respectively, and that total histopathologic damage scores, which included measures of pannus, cartilage damage, bone resorption and periosteal bone formation were significantly reduced by 78% and 91% at 160 and 400 U/kg, respectively.

**Conclusions:** These preclinical results demonstrate the efficacy of RCI in an animal model of RA flare and support the potential clinical benefit of the drug for the treatment of inflammatory arthritis exacerbations.

## AB0106 CELECOXIB INDUCES BOTH APOPTOTIC AND AUTOPHAGIC CELL DEATH IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

S.-H. Kim[1], J. Bang[2], Y.S. Kim[3], H.-S. Kim[4], S.-J. Hong[5], S.-S. Kim[6], H.-J. Jeong[1], C.-N. Son[1], J.-M. Kim[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keimyung University School of Medicine, Dongsan Medical Center; [2]Keimyung University Graduate School of Medicine, Daegu; [3]Division of Rheumatology, Department of Internal Medicine, Chosun University Hospital, Gwangju; [4]Division of Rheumatology, Department of Internal Medicine, Soonchunhyang University Seoul Hospital; [5]Division of Rheumatology, Department of Internal Medicine, Kyung Hee University School of Medicine, Seoul; [6]Division of Rheumatology, Department of Internal Medicine, Ulsan University School of Medicine, GangNeung Asan Hospital, Gangwon-do, Korea, Republic Of*

**Background:** An aggressive proliferation of synovium is the hallmark of rheumatoid arthritis (RA). Previous studies suggested that resistance of fibroblast-like synoviocytes (FLS) to apoptosis is involved in synovial hyperplasia in the patients with RA. Recently, the possibilities that autophagy regulates apoptosis resistance and hyperplasia of FLS were also presented. Selective cyclooxygenase-2 (COX-2) inhibitor, celecoxib, has been reported to affect apoptosis or autophagy in various cancer cells.

**Objectives:** The aim of this study is to investigate the influence of celecoxib on viability of RAFLS and to reveal how celecoxib affects the viability of RAFLS.

**Methods:** RA synovial tissue was obtained from patients during total knee replacement surgery or arthroscopy. FLS was cultured with celecoxib, caspase inhibitor (z-VAD-fmk) or autophagy inhibitor (3-methyladenine; 3-MA, bafilomycin A1; bafi A1, chloquine; CQ). Cell viability was measured by MTS assay and by cell count using trypan blue staining. The expression of autophagy flux (LC3, p62) and apoptosis related protein (caspase3 and poly (ADP-ribose) polymerases (PARP)) was analyzed by western blot.

**Results:** Celecoxib dose-dependently decreased cell viability (mean IC50 of 120 $\mu$M) of RAFLS. Activation of Caspase 3 and PARP cleavage were observed in RAFLS after the treatment with celecoxib. Combination treatment with caspase inhibitor and celecoxib increased cell viability than a single treatment with celecoxib. Celecoxib also increased the expression of LC3II and p62 in RAFLS. Treatment with autophagy inhibitor (3-MA, bafi A1, CQ) restored viability of RAFLS which was decreased by celecoxib.

**Conclusions:** This study demonstrates that both apoptosis and autophagy contribute to celecoxib-induced cell death in RAFLS. Further studies to identify the effects of celecoxib on chronological sequence of autophagy and apoptosis in RAFLS are need.

## AB0107 ASSOCIATION HETEROGENEITY MAPPING IDENTIFIES AN ASIAN-SPECIFIC ASSOCIATION OF THE GTF2I LOCUS WITH RHEUMATOID ARTHRITIS

K. Kim[1], S.-Y. Bang[1], K. Ikari[2], D.H. Yoo[1], S.-K. Cho[1], C.-B. Choi[1], Y.-K. Sung[1], T.-H. Kim[1], J.-B. Jun[1], Y.M. Kang[3], C.-H. Suh[4], S.-C. Shim[5], S.-S. Lee[6], J. Lee[7], W.T. Chung[8], S.-K. Kim[9], S. Momohara[2], A. Taniguchi[2], H. Yamanaka[2], S.K. Nath[10], H.-S. Lee[1], S.-C. Bae[1]. *[1]Rheumatology, Hanyang University Hospital, Seoul, Korea, Republic Of; [2]Rheumatology, Tokyo Women's Medical University, Tokyo, Japan; [3]Rheumatology, Kyungpook National University, Daegu; [4]Rheumatology, Ajou University School, Suwon; [5]Rheumatology, Chungnam National University Hospital, Daejeon; [6]Rheumatology, Chonnam National University, Chonnam National University; [7]Rheumatology, Ewha Womans University, Seoul; [8]Rheumatology, Dong-A University, Busan; [9]Rheumatology, Catholic University of Daegu School, Daegu, Korea, Republic Of; [10]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma, United States*

**Background:** Genetic association studies using multiple ancestral cohorts have revealed a large overlap of rheumatoid arthritis (RA)-risk alleles among different ancestries, but there are some exceptional loci showing heterogenic association among populations.
**Objectives:** Here we investigated genetic variants with distinct effects on the development of RA in Asian and European populations.
**Methods:** Ancestry-related association heterogeneity was examined using the association data from large Korean (n=9,299) and European (n=45,790) rheumatoid arthritis cohorts with Immunochip and genome-wide SNP array data. Novel disease associations detected in Koreans were validated using two independent Asian cohorts (n=5,166) and a meta-analysis.
**Results:** We identified significant heterogeneity between the two ancestries for the common variants in the *GTF2I* locus and showed that this heterogeneity is due to an Asian-specific association effect ($P_{Heterogeneity}$ =9.6×10$^{-9}$ at rs73366469 [$OR_{Meta}$ =1.37 and $P_{Meta}$ =4.2×10$^{-13}$ in Asians; $OR_{Meta}$ =1.00 and $P_{Meta}$ =1.00 in Europeans]) in RA. Trans-ancestral comparison and bioinfomatics analysis revealed a plausibly causal SNP (rs117026326; linked to rs73366469), whose minor allele is common in Asians but rare in Europeans.
**Conclusions:** We identified the largest effect on Asian RA across human non-HLA regions at *GTF2I* by heterogeneity mapping followed by replication studies, and pinpointed a possible causal variant.

## AB0108 RESVERATROL INHIBITS CANONICAL WNT SIGNALING AND AMELIORATES EXPERIMENTAL ARTHRITIS

S.S. Koca[1], S. Yolbas[1], A. Yildirim[1], Z.B. Celik[2], E.E. Onalan[2], M. Akin[3]. *[1]Department of Rheumatology, Faculty of Medicine, Firat University; [2]Department of of Medical Biology, Faculty of Medicine, Firat University; [3]Department of Pathology, Faculty of Medicine, Firat University, Elazig, Turkey*

**Background:** Rheumatoid arthritis (RA) is an inflammatory joint disorder, the progression of which leads to the destruction of cartilage and bone. Wnt signaling pathway act several important biological functions, such as cell differentiation, embryonic development, limb development and joint formation. Accumulated evidence has suggested that this signaling pathway plays a key role in the FLS activation, bone resorption and joint destruction in RA.
**Objectives:** The purpose of this study was to investigate the activity of Wnt/β-catenin pathway in collagen-induced arthritis (CIA) in rats, and to research the therapeutic effect of resveratrol in this arthritis model.
**Methods:** Thirty Wistar albino female rats were randomized to 3 groups (n=10 in each group): Group-I as the control group, Group-II as the arthritis (sham) group, and Group-III as the Resveratrol group. Arthritis was induced by intradermal injection of chicken type II collagen combined with incomplete Freund's adjuvant. One day after the onset of arthritis, resveratrol (20 mg/kg/day) was given via oral gavage, until they were killed on day 29. Animals were sacrificed at the 15th day after the onset of arthritis. The paws of the rats were obtained for further analysis. Perisynovial inflammation and cartilage-bone destruction were determined histopathologically in the paws. Tissue Wnt-5a, axin-2, DKK1, mitogen-activated protein kinase (MAPK), Src tyrosine kinase and signal transducer and activator of transcription-3 (STAT3) mRNA expressions were determined by real-time polymerase chain reaction (RT-PCR).
**Results:** Arthritis was clinically developed at 12 to 13 days after the injection of collagen (Fig. 1a). The 29th day scores were decreased in the paricalcitol and pyrvinium groups compared to the own 13th day score ($p<0.05$ for both), while it was increased in the sham group ($p<0.05$). Histopathological analysis demonstrated the extensive perisynovial inflammation and marked cartilage-bone destruction in sham group rats. Resveratrol treatment decreased the perisynovial inflammation and cartilage-bone destruction in the paws. Moreover, the tissue mRNA expressions of Wnt5a (11 folds), axin-2 (22 folds) and DKK1 (3 folds) were increased in the sham group compared to the control group (Fig. 1b-d). However, resveratrol treatment decreased their expressions.

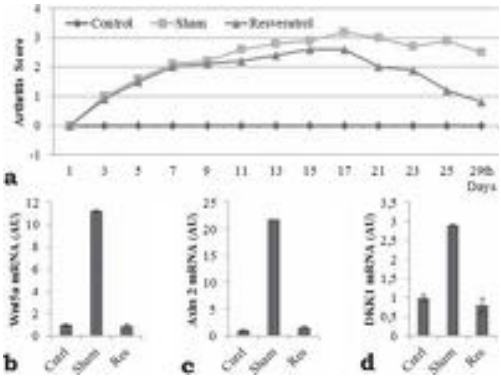

Figure 1. Assessments of daily arthritis score (a) and the tissue mRNA expressions of Wnt5 (b), axin 2 (c) and DKK1 (d) in the all study groups.

**Conclusions:** The present study shows that Wnt signaling pathway is active in CIA model. Resveratrol inhibits Wnt pathway and ameliorates CIA.

## AB0109 THE LUNG MICROBIOME IN RHEUMATOID ARTHRITIS AND ASSOCIATED LOCAL/SYSTEMIC AUTOIMMUNITY

J.U. Scher[1], V. Joshua[2], C. Ubeda[3], A. Artacho[3], J. Grunewald[4], L. Segal[5], A.I. Catrina[2]. *[1]Division of Rheumatology, NYU School of Medicine, New York, United States; [2]Rheumatology Unit, Department of Medicine, Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [3]Institute for Research in Public Health, Valencia, Spain; [4]Division of Respiratory Medicine, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden; [5]Division of Pulmonary and Critical Care Medicine, NYU School of Medicine, New York, United States*

**Background:** Airway abnormalities and increased lung tissue citrullination is found in both RA patients and individuals at at-risk for the development of disease. Recent data suggest that the gut (*Prevotella copri*) and oral (*Porphyromonas gingivalis*) microbiome might potentially contribute to the priming of an aberrant systemic immune response characteristic of RA.
**Objectives:** Our objective was to study whether RA lung microbiome contains distinct taxonomic features associated with local and/or systemic autoimmunity.
**Methods:** Bronchoalveolar lavage (BAL) samples from 20 subjects with RA, 10 with sarcoidosis and 28 healthy controls were obtained by research bronchoscopy. 16S rRNA sequencing was performed to define microbiota composition. Autoantibodies, including anti-CCP, RF and ACPAs were also measured in sera of RA subjects.
**Results:** The 16s sequencing data showed similar alpha/beta diversity between RA and sarcoid groups, but significantly different from healthy (ANOSIM test; p=0.002 and 0.021 for healthy vs RA and healthy vs sarcoid, respectively). Taxonomic comparison between groups was performed using LEfSe, which revealed several significant differences. RA BALF samples had a decrease in the families *Actinomycetaceae (*$P<0.0001$*) and Spirochaetaceae (*$P=0.0009$*)* compared to healthy. *Burkholderia* was significantly decreased in both RA and sarcoidosis compared to controls. The genus *Treponema* (also highly associated

with periodontitis) was exclusively found in healthy subjects' BALF ($P<0.01$ vs RA). RA disease activity was positively correlated with *Micrococcus* and *Renibaterium* at the genus level, and with various OTUs belonging to *Pseudonocardia* and *Xanthomonadaceae* whereas, the genus *Veillonella* and unclassified *Oxalobacteraceae* had a negative correlation. Levels of local autoantibodies i.e., anti-CCP2 correlated positively with the genus *Corynebacterium*, *Megasphera* and *unclassified Comamonadaceae*. Circulating anti-CCP (IgA isotype), had a positive significant correlation with relative abundance of BALF *Enhydrobacter* and unclassified *Bradyrhizobiaceae* (P=0.015 and 0.004, respectively). A modest association with erosive disease was observed with the presence and abundance of *Pseudonocardia* in the RA BALF (85% of erosive RA patients vs. 23% of non-erosive RA; P=0.019).
**Conclusions:** Despite the relatively small number of samples analyzed, several taxonomic differences were noted between groups. Correlations between relative abundance of specific taxa in RA BAL with serum autoantibodies (i.e., anti-CCP) support an association between the lung microbiome and the host immune phenotype in RA. Further evaluation of the functional aspects of this microbiome may provide insights into its possible contribution to RA.

## AB0110 THE PROTEASOME IS RELATED TO MUSCLE WASTING IN EXPERIMENTAL ARTHRITIS AND IS ALTERED BY ETANERCEPT TREATMENT

V.D.O.N. Teixeira[1,2], P.V.G. Alabarse[1], K. Ghannan[3], J.M.S. Silva[1], L. Martinez-Gamboa[3], L.I. Filippin[4], E. Feist[3], R.M. Xavier[1,2]. *[1]Faculdade de Medicina, Universidade Federal do Rio Grande do Sul; [2]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [3]Department of Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany; [4]Mestrado em Saúde e Desenvolvimento Humano, Centro Uiversitário la Salle, Canoas, Brazil*

**Background:** Rheumatoid arthritis is an autoimmune inflammatory disease associated with systemic complications like fatigue and muscle wasting. Muscle wasting could be related to the activation of the ubiquitin-proteasome system.
**Objectives:** To evaluate muscle loss and involvement of the proteasome in collagen-induced arthritis (CIA), with or without treatment with methotrexate or a TNF inhibitor (etanercept).
**Methods:** Male DBA1/J mice were divided into 4 groups (n=8 each): CIA (saline); ETN (etanercept, 5.5 mg/kg) and MTX (methotrexate, 35 mg/kg), treated twice a week for 6 weeks, and a healthy control group (CO). Treatments started one week after booster injection. Clinical score, hind paw oedema, and body weight were analysed during the experimental period. Gastrocnemius muscles (GA) were weighted after death and used to quantify proteasome activity, protein levels and mRNA expression of its subunits by Western blot and rtPCR. Significance was considered when $p\leq0.05$.
**Results:** Treatments slowed disease development, observed through smaller clinical score and hindpaw edema in ETN and MTX. ETN presented higher body weight (21±1.0g) compared to MTX (19±1.3) at weeks 5 and 7. GA weight was heavier in ETN (105±12g) than CIA and MTX (80±10 and 79±10g, respectively), a result also observed after normalization of muscle with body weight. Of note, the catalytic properties of 26S proteasome showed an increase of caspase-like activity in CIA and MTX groups (150 and 200% of activity, respectively). Furthermore, muscles of MTX treated animals showed higher protein levels for proteasomal subunits PSMB8 and PSMB9 and increased gene expression for Psmb5, Psmb8 and Psmb9. In contrast, expression of Psmb6 was decreased and of Psmb9 was enhanced in CIA.
**Conclusions:** Although both drugs improved the disease score, ETN presented a stronger anti-arthritic effect and was the only treatment able to partially prevent muscle wasting. In contrast to ETN, MTX treatment did not prevent muscle loss due to CIA accompanied by persistent up-regulation of proteasome expression and activity.

## AB0111 THE UNDERLYING PATHOGENIC EFFECT OF IMPARED DNASE I ACTIVITY ON RHEUMATOID ARTHRITIS

X. Xu[1], H. Shen[2]. *[1]The Second Clinical Medical College of Lanzhou University; [2]The Second Hospital of Lanzhou University, Lanzhou, China*

**Background:** Aberrant formation of neutrophil extracellular traps (NETs) play important role in the pathogenesis of rheumatoid arthritis (RA) and Deoxyribonuclease I (DNase I) can remove NETs in vivo.
**Objectives:** We aimed to investigate the underlying pathogenic effect of DNase I on RA.
**Methods:** Serum DNase I activity was measured by radial enzyme diffusion method in 83 RA patients and 60 healthy volunteers, synovial fluid (SF) from 27 RA patients and 38 other inflammatory arthritis patients was measured by the same way. The SF cfDNA level was measured by Pico Green Kit. Correlation analysis were performed between DNase I activity, cfDNA level and clinical parameters of RA patients.
**Results:** Serum DNase I activity was significantly lower in RA group than in healthy control group [0.2913 (0.2029, 0.4064)U/ml vs 0.3980 (0.2864, 0.5484)U/ml, $P<0.001$] and negatively correlated with ESR (r=-0.2862, P=0.0122), CRP (r=-0.2790, P=0.0184) and neutrophil cell counts (r=-0.287, P=0.011). SF DNase I activity in RA group, ankylosing spondylitis (AS) group and gouty arthritis (GA) group were almost negative. SF cfDNA level in RA group was significantly higher than that in OA group [40.00 (12.47, 163.22) ug/ml vs 9.27 (4.62, 17.58) ug/ml, P=0.002], but there were no significant difference when compared to AS group [36.80 (4.84, 84.82) ug/ml, P=0.428] and GA group [156.72 (89.81, 257.11) ug/ml,P=0.132]. In inflammatory arthritis patients, SF cfDNA level was positively correlated to ESR (r=0.4106, P=0.0116)and CRP (r=0.5747, P=0.0002).
**Conclusions:** Impairment of DNase I activity may be responsible for the enhanced NETs generation and involve in the pathogenesis of RA.

## AB0112 CSD-125, A SOFT CORAL-DERIVED ANTI-INFLAMMATORY COMPOUND, ATTENUATES JOINT DESTRUCTION VIA OSTEOCLASTOGENESIS IN A TYPE II COLLAGEN-INDUCED ARTHRITIS RAT MODEL

Y.-Y. Lin[1], S.-C. Lin[2], H.-P. Li[2], Y.-H. Jean[2], Z.-H. Wen[1]. *[1]Marine Biomedical Laboratory and Center for Translational Biopharmaceuticals, Department of Marine Biotechnology and Resources, National Sun Yat-Sen University, Kaohsiung; [2]Department of Orthopaedic Surgery, Ping-Tung Christian Hospital, Ping-Tung, Taiwan, Province of China*

**Background:** Rheumatoid arthritis (RA) is a common rheumatic disease that is characterized by synovial inflammation of the synovial tissue that lines the joints [1]. Osteoclasts become active and mature by stimulation of inflammatory cytokines such as macrophage colony-stimulating factor (M-CSF), interleukin-1b (IL-1b), interleukin-17A (IL-17A), and tumor necrosis factor-a (TNF-a), and also play a critical role in the bone destruction in RA [2]. Soft corals have been considered an important resource of anti-inflammatory agents that may be beneficial for treating inflammatory diseases [3–5].
**Objectives:** In this present study, we investigated the therapeutic effects of CSD-125, a soft coral-derived compound in type II collagen-induced arthritis (CIA), via its role in the anti-osteoclastic pathway.
**Methods:** A rat model of CIA was established, and knee joint tissue destruction was evaluated in rats treated with and without CSD-125 by the RA index, histopathology, immunohistochemistry, and western blotting. We also analyzed the level of pro-inflammatory cytokines such as M-CSF and IL-17A in the blood serum.
**Results:** The results demonstrated that CSD-125 significantly attenuated CIA-induced RA progression in rats. CSD-125 also decreased the expression of osteoclast-related proteins, including cathepsin K, matrix metalloproteinases-9, matrix metalloproteinases-2, cluster of differentiation molecule 11B, nuclear factor of activated T cells, cytoplasmic 1 (NFATC 1), and triggering receptor on myeloid cells 2 (TREM 2), in multinucleated cells. Moreover, CSD-125 reduced the number of cells showing positive expression of IL-17A, IL-1b, and TNF-a, phospho-extracellular signal-regulated kinases (p-ERK), phospho-c-Jun N-terminal kinase (p-JNK), and phospho-p38 (p-P38) in the synovial tissue of CIA-rats. The levels of M-CSF and IL-17A also decreased following administration of CSD-125 to CIA-rats.
**Conclusions:** These results provide strong support that CSD-125 could attenuate the joint destruction in type II CIA, likely through inhibition of osteoclast activation.

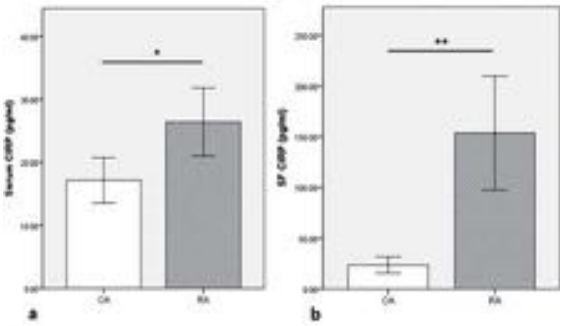
## AB0113 THE SERUM AND SYNOVIAL FLUID LEVELS OF COLD-INDUCIBLE RNA-BINDING PROTEIN (CIRP) IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Kim, J. Kim, S.W. Kang, S.-C. Shim, I.S. Yoo, S.-J. Yoo. *Chungnam National University Hospital, Daejeon, Korea, Republic Of*

**Background:** The cold-inducible RNA-binding protein (CIRP) is 18 kDa protein of the glycine-rich RNA binding protein (GRP) family, and these proteins function as RNA chaperones to facilitate translation. Extracellular CIRP is a recently identified endogenous proinflammatory mediator and damage-associated molecular pattern molecules (DAMP) that triggers inflammatory responses in sepsis and inflammatory bowel disease.
**Objectives:** This study was planned to investigate the relationship between CIRP and rheumatoid arthritis.
**Methods:** Peripheral blood and synovial fluid were collected from 15 patients with rheumatoid arthritis (RA) and 16 patients with osteoarthritis (OA). The concentration of CIRP was measured by sandwich Enzyme-Linked Immunosorbent Assay (ELISA).
**Results:** The concentration of serum CIRP was significantly elevated in RA patients group (RA patients=26.39±10.48 pg/ml, OA patients=17.14±7.24 pg/ml, p=0.009). Furthermore, the RA patients group showed significantly higher CIRP concentration than the OA patients group in synovial fluid (153.56±108.93 pg/ml vs. 23.63±16.18 pg/ml, p<0.001) (Fig.1).
The mean concentration of synovial fluid CIRP was significantly higher than that of serum in RA patients group (Serum concentration=26.39±10.48 pg/ml, Synovial fluid=153.56±108.93 pg/ml, p<0.001). Also, we found the tendency that the CIRP concentration of synovial fluid was significantly higher than that of serum in same patient (P=0.025) (Fig.2).
DAS28-ESR and DAS28-CRP were positively correlated with synovial fluid concentration of CIRP (DAS28-ESR: r=0.582, p=0.023, DAS28-CRP: r=0.541, p=0.037, by correlation analysis).

**Fig.1. The concentration of CIRP was increased in RA patients. a: The serum concentration of CIRP was higher in RA patients than in OA patients. b: The synovial fluid concentration of CIRP was significantly higher in RA patients than in OA patients. (Mean ± Standard Error of the Mean; SEM) * p<0.05, ** p<0.001**



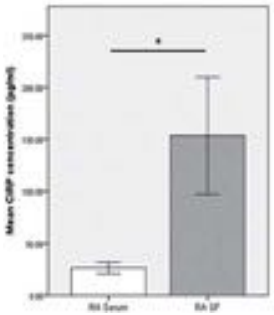


**Fig.2. The synovial fluid concentration of CIRP was elevated in RA patients. The concentration of CIRP was significantly increased in the synovial fluid of RA patients (RA SF). Data are shown as the Mean ± SEM. * p<0.05**

**Conclusions:** The serum and synovial concentration of CIRP in RA patients was increased compared to OA patients. Also synovial concentration of CIRP in RA patients correlated well with the disease activity, i.e. the DAS28-ESR/CRP. Based on these results, the CIRP mediates the inflammation and is potential marker for synovial inflammation.

## AB0114 PTEN EXPRESSION IN FIBROBLAST-LIKE SYNOVIOCYTES OF RHEUMATOID ARTHRITIS

Y. Wu, Y. Liu, M. Liu, M. Yang, B. Mo, Y. Pan. *Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** Fibroblast-like synoviocytes (FLS), with some tumor-like characters, play a key role in the pathogenesis of rheumatoid arthritis (RA) [1]. Phosphatase and tensin homolog (*PTEN*) is a tumor suppressor gene, and its mRNA expression has been reported to be absent in the lining layer of RA synovium, which is supposed to contribute to the invasive behavior of RA-FLSs [2,3]. It has been demonstrated in various kinds of tumor cells that the PTEN protein is a negative regulator of the PI3K/Akt signal pathway [4]. However, data of the PTEN protein level in RA-FLSs and its effect on the phosphorylation status of Akt (Thr308) is limited.
**Objectives:** To investigate the expression of *PTEN* gene in cultured human RA-FLSs and its effect on Akt (Thr308) phosphorylation status.
**Methods:** FLSs were isolated from synovial tissues obtained from patients with RA, osteoarthritis (OA) or joint trauma during joint replacement surgery or arthroscopy, and each group contains 3 patients. The mRNA expression of *PTEN* was detected by RT-qPCR. The protein levels of PTEN, pAkt (Thr308) and total Akt, were measured by western blotting. The phosphorylation status of Akt was determined by protein expression ratio of pAkt (Thr308)/total Akt.
**Results:** The expression of PTEN mRNA was significantly lower in RA-FLSs compared with OA-FLSs and joint trauma-FLSs ($P<0.01$), while no statistically significant difference was observed between those of OA-FLSs and joint trauma-FLSs ($P>0.05$). Similarly, the PTEN protein level in RA-FLS was much lower than OA-FLSs and joint trauma-FLSs ($P<0.05$), and there was no difference between the latter two ($P>0.05$). Moreover, the phosphorylation level of Akt (Thr308) in RA-FLSs was significantly higher than those in the other two control groups ($P<0.01$), and that in OA-FLSs was much lower than joint trauma-FLSs ($P<0.01$).
**Conclusions:** The mRNA and protein expression of *PTEN* are both decreased in cultured RA-FLSs, suggesting that low expression level of *PTEN* is conserved in RA-FLSs out of the inflammatory environment *in vitro* throughout passages. And it may contribute to the increased phosphorylation level of Akt (Thr308).

## Spondyloarthritis - etiology, pathogenesis and animal models

### AB0115 DIFFERENTLY ASSOCIATED FREQUENCY OF B LYMPHOCYTE SUBPOPULATIONS WITH DISEASE ACTIVITY IN ANKYLOSING SPONDYLITIS COMPARED TO RHEUMATOID ARTHRITIS

Z. Jajic[1], A. Sucur[2], F. Grubisic[1], M. Ikic Matijasevic[3], A. Stipic Markovic[4], N. Kovacic[2], D. Grcevic[2]. *[1]Department of Rheumatology, Physical Medicine and Rehabilitation, Clinical Hospital Center "Sisters of Mercy", University of Zagreb Medical School; [2]Croatian Institute for Brain Research; [3]Department of Clinical Immunology and Allergology, Clinical Hospital "Holy Spirit"; [4]Department of Clinical Immunology and Allergology, University Hospital "Sveti Duh", Zagreb, Croatia*

**Background:** Both rheumatoid arthritis (RA) and ankylosing spondylitis (AS) belong to the group of chronic rheumatic diseases with the important role of autoimmune pathogenic mechanisms. However, these forms differ in the major target tissues as well as the intensity of bone and cartilage destruction, with RA being the prototype of "destructive" arthritis affecting peripheral joints and AS being the prototype of "remodeling" arthritis predominantly of the axial skeleton.
**Objectives:** Both forms of arthritis are associated with abnormal immune cell functions, including B lymphocytes. Although several recent studies stressed the role of B lymphocyte subpopulations and autoantibodies in AS, these mechanisms in the AS pathogenesis are significantly less understood compared to RA and other rheumatic autoimmune diseases.The aim of our study was to compare the frequency of B lymphocyte subpopulations between RA and AS patients, and to correlate them with the disease activity.
**Methods:** Mononuclear cells were isolated from peripheral blood of healthy controls (n=30), RA (n=33) and AS (n=18) patients, after obtaining Ethical approval and informed consent from patients. The B lymphocyte phenotype of peripheral-blood mononuclear cells was determined using flow cytometry for the following surface markers: CD19, CD27, IgD, CD32 and CD38. In addition, statistical correlation was assessed to test the association between the frequency of selected B lymphocyte subpopulations and the disease-activity score, DAS28 (Disease Activity Score 28) for RA and BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) for AS.
**Results:** Gating strategy applied for flow-cytometry data was set to discriminate between naïve B lymphocytes (CD19+ IgD+ CD27-), unswitched memory B lymphocytes (CD19+ IgD+ CD27+), class-switched memory B lymphocytes (CD19+ IgD- CD27-) and plasmablasts (CD19+ IgD+ CD27hi CD38+). In addition, expression of CD32 (FcgRII receptor) and CD86 (B7-2 co-stimulator), associated with the maturation and activation of B lymphocytes, within these B lymphocyte subsets were assessed. Data analysis showed expanded CD32+ subset among naïve and memory B lymphocytes in RA (16.4±11.6% and 9.8±8.2%) compared to control (4.3±2.7% and 7.6±3.5%) and AS (5.6±2.6% and 5.8±1.9%). Similarly, there were more CD86+ cells among naïve and unswitched memory B lymphocytes in RA (9.0±8.2% and 18.2±8.0%) compared to control (2.8±1.3% and 11.7±5.5%) and AS (4.9±5.9% and 11.6±6.2%). Class-switched memory B lymphocytes were negatively associated with disease activity score in RA ($\rho$=-0.45) but positively in AS ($\rho$=+0.39), whereas the associations were reversed for the population of naïve B lymphocytes ($\rho$=+0.32 for RA and $\rho$=-0.38 for AS).
**Conclusions:** Our results indicate that B lymphocyte-mediated immune response may be important for both RA and AS, but with distinct effector mechanisms. Therefore it is reasonable to suggest that B lymphocyte subpopulations may represent promising cellular targets for the therapeutic interventions in different forms of arthritis.

### AB0116 INDUCTION OF NETOSIS-MEDIATED CELL DEATH IN ANKYLOSING SPONDYLITIS PATIENTS

A. Escudero-Contreras, P. Font, C. López-Pedrera, P. Ruiz-Limón, C. Pérez-Sanchez, N. Barbarroja, M.C. Ábalos-Aguilera, M.C. Castro-Villegas, R. Ortega-Castro, J. Calvo, E. Collantes-Estévez, Y. Jimenez-Gomez. *Rheumatology Service, IMIBIC/Reina Sofia University Hospital/Cordoba University, Cordoba, Spain*

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease, of unknown aetiology, that mainly affects sacroiliac joints and spine, and is associated with the development of several comorbidities such as atherosclerosis. Recently, a cellular death mechanism, NETosis, has been described in neutrophils that involves the extracellular release of a meshwork of DNA nuclear and granule proteins upon activation by microorganisms and other activating molecules. Excessive generation of these meshworks, as a result of non-infectious inflammatory processes, is associated with the pathogenesis of inflammatory and autoimmune diseases, as well as with the development of atherosclerosis, thrombosis and other cardiovascular complications. Nevertheless, this process has not been described yet in AS patients.
**Objectives:** 1) To analyze the induction of NETosis in AS patients. 2) To evaluate the relationship among NETosis markers and their correlation with disease activity, oxidative stress and endothelial function.
**Methods:** Thirty four patients with AS and 34 healthy donors were included in the study. Disease activity was determined by BASDAI index and, CRP and ERS levels. To evaluate NETosis, purified neutrophils were stained with Sytox and visualized by fluorescence microscopy. In parallel, markers of oxidative stress, inflammation and NETosis were determined in neutrophils by flow cytometry and RT-PCR. Plasma DNA was quantified by fluorimetry. Antioxidant enzyme activities in neutrophils, as well as nitric oxide (NO) and total antioxidant capacity (TAC) of plasma were measured by specific kits. Endothelial function was determined by the post occlusive hyperaemia test using Laser-Doppler.
**Results:** Neutrophils from AS patients displayed a significant increase in NETosis percentage compared to healthy donors that was associated with an increase in plasma DNA in these patients. In parallel, AS patients showed endothelial dysfunction, along with an increase of inflammatory markers (STAT3, TNF-$\alpha$ and IL-1$\beta$ mRNA) in neutrophils. It was also observed an alteration of oxidative status, with an increase of catalase and glutathione peroxidase (GPx) activities, and a reduction of mitochondrial superoxide dismutase (mSOD) activity in neutrophils, as well as an increase in TAC and NO at plasma level.
Correlation and association studies showed that plasma DNA levels positively correlated with CRP, oxidative damage (catalase activity and TAC) and endothelial dysfunction in AS patients.
**Conclusions:** 1) NETosis is a cellular death mechanism occurring in AS patients. 2) NETosis induction is associated with an inflammatory and oxidative profile in neutrophils from AS patients. Thus, NETosis may act as a key mediator in disease progression and endothelial dysfunction in AS patients.

### AB0117 NEW IDENTIFIED IL-23 RECEPTOR GENE MUTATIONS IN ANKYLOSING SPONDYLITIS

M. Akyol[1], A.B. Avci[2], S. Ureyen[3], E. Terzioglu[2]. *[1]Medical Biology and Genetics; [2]Rheumatology, Internal Medicine, Akdeniz University Faculty of Medicine, Antalya; [3]Rheumatology, Internal Medicine, Sakarya University Education and Research Hospital, Sakarya, Turkey*

**Background:** The pathogenesis of ankylosing spondylitis (AS) has strongly been associated with the gene *HLA-B27*; however, AS occur only in 1%–5% of HLA-B27-positive individuals and increasing evidence suggests involvement of also non-HLA genes. Previous work has confirmed association with single nucleotide polymorphisms in interleukin-23 receptor (IL-23R).
**Objectives:** The aim of the study is to confirm the association of IL-23R gene polymorphisms with ankylosing spondylitis in Turkish population and to find out possible mutations responsible from this association.
**Methods:** We included 48 AS patients and 48 healthy unrelated individuals. Extracted DNA from patient specimens was amplified with polymerase chain reaction and sequenced.
**Results:** We identified 6 new point mutations at IL-23R gene in patients with AS (Table). 2824DelC mutation (1/41 - 2,4%) was found to be in the intronic region that probably does not have an effect on the protein. 34521GT mutation (1/36 - 3,8%) was located at the exon-intron boundary and changes the exon recognition site. This should be the reason for exon skipping. The mutation probably changes the protein structure and function of IL-23R protein. Ala228Ala (2/42 - 4,8% - p.0,0306) was a silent mutation that does not change the protein structure of the IL23R protein. Ala364Gly mutation (6/43–17% - p.0,074) missense mutation was found at 6 patients as a heterozygote. Ala364Gly mutation looks associated with AS. Leu371Phe mutation (1/43 - 2,3%) was also missense mutation and caused change on the aminoacid. As the last point, Tyr436Stop is a silent mutation that is an early stop truncating the protein 194 aminoacid earlier than the usual process.

**Abstract AB0117** – Table 1. Characteristics of IL-23R mutations determined in patients with ankylosing spondylitis

| Mutation | Function | Position | Homozygote major genotype | No. of homozygote major genotype | Heterozygote genotype | No. of heterozygote major genotype | Homozygote minor minor genotype | No. of homozygote minor genotype | p (genotype) | p (allelic) |
|---|---|---|---|---|---|---|---|---|---|---|
| 2824DelC | Intronic | – | –/– | 40 (97.6%) | –/DelC | 1 (2.4%) | DelC/DelC | 0 | 0.276 | 0.277 |
| 34251 GT | Exon skipping | – | GG | 35 (97.2%) | GT | 1 (2.8%) | TT | 0 | 0.245 | 0.246 |
| ALA(GCA)228ALA (GCC) | Aminoacid change ALA-ALA | 228 aa | GG | 40 (95.2%) | GC | 0 | CC | 2 (4.8%) | 0.126 | 0.0306 |
| ALA(GCT)364 GLY(GGT) | Aminoacid change ALA-GLY | 364 aa | CC | 37 (86%) | CG | 6 (14%) | GG | 0 | 0.074 | 0.085 |
| LEU(TTG)371PHE (TTC) | Aminoacid change LEU-PHE | 371 aa | GG | 42 (97.7%) | GC | 1 (2.3%) | CC | 0 | 0.288 | 0.284 |
| Tyr (TAT) 436 STOP (TAA) | Tyr-Stop | 436 aa | Tyr/Tyr | 43 (97.7%) | Tyr/STOP | 1 (2.3%) | STOP/STOP | 0 | 0.293 | 0.295 |

None of the mutation exist in control group.

**Conclusions:** We have determined 6 new point mutations in 11 patients included. Although two of the mutations probably do not have an effect on the protein, other four mutations cause changes in the protein structure of IL-23R protein. We consider that these mutations probably contribute to the pathogenesis of AS by effecting the functions of the protein.

## AB0118 MIR-29A AND MESSENGER RNA EXPRESSION OF BONE TURNOVER MARKERS IN CANONICAL WNT PATHWAY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

J. Huang[1], G. Song[2], Z. Yin[3], Z. Fu[3], Z. Ye[3]. *[1]Rheumatology, The University of Hong Kong-Shenzhen Hospital; [2]The Third People's Hospital of Shenzhen; [3]Rheumatology, The Fourth People's Hospital of Shenzhen, Shenzhen, China*

**Background:** Recent studies showed that canonical Wnt pathway and miR-29a play important roles in the pathogenesis of bone formation.
**Objectives:** We studied the levels of miR-29a and bone turnover markers in canonical Wnt pathway in ankylosing spondylitis (AS).
**Methods:** The levels of miR-29a and mRNA of bone turnover markers in canonical Wnt pathway from peripheral blood mononuclear cells were determined by real-time quantitative polymerase chain reaction in 43 patients with AS and 42 healthy controls. Correlation analysis was conducted between the levels of miR-29a and mRNA and clinical measurements using Spearman's correlation test. Serum levels of components of canonical Wnt pathway including Dickkopf-1 (DKK-1), GSK-3β, β-catenin, alkaline phosphatase (ALP) and osteocalcin (OC) were detected using ELISA method.
**Results:** Compared to healthy controls, the levels of miR-29a, Dickkopf (DKK)-1, β-catenin and Runx2 mRNA were significantly higher in AS patients ($p<0.05$). In contrast, the levels of Gsk-3βmRNA was significantly lower in AS patients than that in healthy controls ($p<0.05$). Gsk-3βmRNA was positively correlated withβ-catenin mRNA expression ($p<0.05$). Only DKK-1 mRNA expression was negatively correlated with disease course ($p<0.05$). No significant difference was observed between AS patients and healthy controls for the levels of GSK-3β, β-catenin, ALP and OC, respectively ($p>0.05$).The levels of DKK-1 was significantly higher in AS patients (1914.46±407.82 pg/ml) than that in healthy controls (1729.07±352.86 pg/ml) ($p<0.05$). There was no correlation between high DKK-1 level and any of the clinical parameters contributing to inflammation or bone formation. However, the correlation between OC and disease duration was significant in AS patients ($r=0.323$, $p=0.034$).
**Conclusions:** The osteoblastic marker miR-29a and downstream mRNA of canonical Wnt signaling was upregulated in AS, suggesting their possible role in the new bone formation in AS. Alteration of bone turnover markers in canonical Wnt pathway was observed in AS. This might partially explain the complicated mechanism of bone formation in the disease.

## AB0119 DEREGULATED EXPRESSION OF MIRNAS IN PURIFIED DISEASE RELEVANT BLOOD CELL POPULATIONS IN PATIENTS WITH SPONDYLOARTHRITIS

J. Tost[1], A. Bugge Tinggaard[1], S.-F. Wang-Renault[1], F. Busato[1], M. Dougados[2,3], C. Miceli-Richard[2,4]. *[1]Laboratory for Epigenetics & Environment, Centre National de Génotypage, CEA - Institut de Génomique, Evry; [2]Rheumatology Department, Paris Descartes University, Cochin Hospital, AP-HP; [3]Inserm (U1153), Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité; [4]Immunoregulation Unit, Pasteur Institute, Paris, France*

**Background:** MiRNAs have been shown to play a critical role in the regulation of both the innate and the adaptive components of the immune system. Deregulated miRNA expression has been found in different inflammatory and autoimmune diseases and may have anti- or pro-inflammatory activities based on their specific target mRNAs. Altered miRNA expression has been detected in several inflammatory diseases such as inflammatory bowel disease (IBD) and psoriasis. Although a few studies concerning correlation between Spondyloarthritis (SpA) and miRNA have been published, no systematic studies in specific cell populations have been reported so far. Moreover, a recently published computational analysis (1) showed a large overlap of active gene regulatory regions with genetic variation associated with SpA for CD4 T cells and CD14 monocytes.
**Objectives:** This study aimed to analyze the miRNA expression pattern in these two disease relevant cell populations of purified CD4 T cells and CD14 monocytes from SpA patients and controls.
**Methods:** SpA patients were monocentrically recruited between October 2014 and May 2015 in the department of rheumatology (Cochin hospital). These patients had an active disease despite NSAIDs intake and were eligible for a TNF-blocker treatment. The mean BASDAI (± SD) was 53.2±23.7; ASDAS 3.2±1.1 and CRP 13±16.6 mg/L. Among these patients, 23 fulfilled the ASAS classification criteria (imaging arm) with sacro-iliitis on X-rays (n=16) or objective signs of inflammation on MRI (n=21). Only one patient fulfilled the clinical arm. We first analyzed the expression of 360 MiRNAs in cell-sorted (MACS) monocytes and CD4 T-lymphocyte populations from these SpA patients and 16 age and sex-matched controls by qPCR using the Exiqon MicroRNA Ready-to-Use Human Panel I on the miRNA-enriched fraction from both CD4+ and CD14+ cell populations.
**Results:** In CD4 cells 6 miRNAs were found to be differentially expressed including miR-491-3p, recently reported to be downregulated in ulcerative colitis, and miRNA-26a, a well know inflammation associated miRNA implicated in both allergic inflammation and autoimmune diseases. In monocytes, 25 miRNAs were found to be differentially expressed including the paradigmatic anti-inflammatory miRNA miR-146a and as the most significantly expressed miRNA, a miRNA involved in the degradation of TNFα.
**Conclusions:** The study is the first to analyze miRNA expression in purified disease-relevant blood cell populations in SpA bringing into evidence a number of interesting miRNAs whose deregulation might contribute to the pathogenesis of the disease. Integration with RNA expression data will allow the functional impact of the miRNA expression changes patterns in the blood cell populations allowing to better understand the molecular changes in SpA and potentially identify novel targets for therapeutic intervention. The validation of 10 differentially expressed miRNAs by qPCR-based assays in additional samples of monocytes and CD4 lymphocytes from independent 12 patients and 12 controls is ongoing.

## AB0120 CYTOKINE GENE EXPRESSION MRNA PROFILE OF PERIPHERAL BLOOD CELLS IN ANKYLOSING SPONDYLITIS

M. Ivanova Goycheva[1], I. Manolova[2], L. Miteva[3], R. Stoilov[1], S. Stanilova[3]. *[1]Clinic of Rheumatology, University Hospital "Sv. Iv. Rilski", Medical Faculty, Medical University, Sofia; [2]Department of Health Care; [3]Department of Molecular Biology, Immunology and Medical Genetics, Medical Faculty, Trakia University, Stara Zagora, Bulgaria*

**Objectives:** The aim of the present study was to investigate cytokine gene-expression profile into peripheral blood cells from Bulgarian patients with ankylosing spondylitis (AS).
**Methods:** Total RNA from peripheral blood was isolated from 12 healthy controls and 20 patients with AS with a mean disease duration of 13.2 years (range 2.9 - 26). Nine of the patients were only on first-line therapy, a non-steroidal anti-inflammatory drug (NSAID) and 11 were being treated with TNF-blocking agents. cDNAs were used for TaqMan gene expression assays of IL10, TGFB1, IL23A, IL12B, TNFA, IL18, Foxp3 and GAPDH. Relative quantitative evaluation of mRNAs was performed by the comparative ΔΔCt method and results are presented as relative quantity (RQ).
**Results:** From all examined cytokine genes in AS, we found up-regulated most

of them in the following order according to RQ values: IL12B>IL23A>TGFB>IL10>IL18. The gene expression of IL23A and IL12B was significantly higher (p=0.016; RQ=2.04; RQ=2.64, respectively) into peripheral blood cells from AS patients compared to controls, whereas TGFB, IL10 and IL18 were slightly but not significant overexpressed (RQ vary from 1.2 to 1.4.) In contrast, a significant down regulation of TNFA (RQ=0.716; p=0.02) was observed among investigated patients compared to controls. In addition, mRNA expression of FoxP3, a transcription factor driving regulatory FoxP3+ T cells was also down regulated in AS patients (RQ=0.455; p=0.0014). In terms of drug usage, the cytokine gene expression profile between AS patients treated with TNF inhibitors and those without TNF-blocking agents was comparable. A positive correlation was found between gene expression of IL23A with TNFA and IL18 in AS (r=0.67, p=0.001; r=0.456, p=0.038, respectively) and negative correlation between IL23A and TGFB1 (r=-0.58, p=0.006).

**Conclusions:** Our results demonstrated differences in the expression of mRNA encoded regulatory and effector cytokines in peripheral blood cells of AS patients pointed on IL-23 and cytokine related transcription factor FoxP3.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3262

## AB0121 DIFFERENTIALLY EXPRESSED MICRORNAS AS CANDIDATE BIOMARKERS FOR DISEASE ACTIVITY IN ANKYLOSING SPONDYLITIS

M.N. Magrey[1], A. Haseeb[2], T. Haqqi[2]. *[1]Rheumatology, Case Western Reserve University Medical School at Metrohealth Medical Center, cleveland; [2]Anatomy/Neurobiology, Northeast Ohio Medical University, Rootstown, United States*

**Background:** Research on miRNAs as regulators of immune system has fast emerged. miRNA expression profile is believed to be reflective of specific physiologic and pathologic processes and can serve as potential biomarkers of disease activity.

**Objectives:** In the present study, we proposed to test the hypothesis that, "patients with ankylosing spondylitis (AS) have an altered miRNA expression profile compared to control subjects." We also proposed to test whether the expression profile of selected miRNAs identified in the study correlates with disease activity as measured by BASDAI and ASDAS and markers of inflammation:ESR and CRP.

**Methods:** Fifty-one patients ≥18 years of age with AS based on modified New York classification criteria and 23 healthy controls were prospectively recruited. Subjects with malignancy in last 5 years, RA, SLE, evidence of HIV or chronic hepatitis B or C infection were excluded. Patients and controls were screened, consented and peripheral blood samples (5 ml) were obtained. ESR and CRP were measured using routine laboratory methods. Validated Questionnaires to assess disease, and functional activity in AS were administered to patients. Sixty-eight circulating miRNAs in the plasma of all the study subjects were profiled by Firefly Multiplex Circulating miRNA Assay (Abcam, Cambridge, MA) using the Immunology Panel. Forty microliters of plasma samples were first digested using supplied enzyme mix and then the assay was performed following the instructions provided by manufacturer. The assay beads were scanned on BD Accuri C6 flow cytometer. Data were analyzed using Firefly Analyis Workbench (Abcam). Descriptive analyses included continuous variables (the mean ± SD) and the categorical variables percentage. Linear regression analysis was performed to assess the association between BASDAI, BASMI, ASDAS, Rapid 3, ESR, CRP and differentially dysregulated miRNAs in AS patients.

**Results:** There were 34 males/51 with mean age of 49.8± 12.2; 30.6% African-Americans, 47.0% were HLA-B27 positive, 29.4% were negative and 23% indeterminate, and 45% on anti-TNF alpha inhibitors. Mean (±SD) values were: BASDAI score 5.23 (±2.5); BASFI score 4.7 (±2.8); PGA, 5.1 (±2.4); ASDAS-CRP score 3.4 (±1.13); RAPID 3 score 13.76 (±7.21); ESR, 22.4 mm/hr (±22.0) and CRP levels, 1.3 mg/dl (±1.9). Six microRNAs (miR-181b-5p, miR-181a-5p, let-7i-5p, miR-34a-5p, miR-30b-5p and miR-146a-5p) were found to be differentially expressed in AS patients compared to healthy controls ($p<0.05$). miR-181b-5p also showed a significant linear relationship with BASDAI score (p=0.0083) and ASDAS (p=0.0547). Some of the predicted targets of miR-181b-5p according to miRTarBase have been shown to inhibit TIMP-3 which is a tissue inhibitor of matrix metalloproteinase and TMED 7 which is involved in TLR-4 signaling. MicroRNA-181b has also been shown to serve as a potent regulator of downstream NF-κB signaling

**Conclusions:** Patients with AS as compared to controls, have dysregulated expression of selected miRNAs in the plasma; and levels of miR-181b-5p were significantly higher in patients with active disease and showed significant correlation with BASDAI and ASDAS scores. miR-181b-5p is predicted to target genes regulating inflammatory processes and may be proposed as a potential biomarker for disease activity in AS.

## AB0122 CORRELATION STUDIES BETWEEN ANOCTAMIN 6 GENE POLYMORPHISM AND EXPRESSION AND ANKYLOSING SPONDYLITIS

M. Yang, Z. Hu, Y. Zhang, Q. Li, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Objectives:** To explore the gene polymorphism of a new susceptibility gene Anoctamin 6 (ANO6) related to disease risk of Ankylosing Spondylitis (AS), and the abnormal expression of ANO6 in AS patients. And provide theoretical basis for ANO6 involved in the pathogenesis of AS.

**Methods:** Direct sequencing was performed to explore disease-related SNP in exon and transcription regulatory region of ANO6 between 417AS patients and 541 healthy controls (HCs), and linkage disequilibrium and haplotype analysis was used with candidate SNP. RT-PCR was performed to test the difference of the expression of mRNA in peripheral blood mononuclear cells (PBMCs) between 40 AS patients and 32 HCs. Immunohistochemistry was employed to discover the difference of protein expression in tendon tissues between 9 AS patients and 5 control subjects.

**Results:** Age and sex were not significantly different between AS cases and controls. Our study found that risk alleles of 5 SNP loci (rs79662606, rs76186361, rs17095830, rs80224086 and rs75712006)had a significant correlation with the susceptibility of AS, and strong linkage disequilibrium among each two of SNP loci. Haplotype analysis dicovered a higher proportion of GTGCG, CATGTA and ACGTA in cases ($p<0.001$). The expression of mRNA of peripheral blood mononuclear cells is 0.49±0.21 in AS cases and 0.86±0.38 in HCs, and the difference is significant ($p<0.001$). The expression of ANO6 protein went up in tendon tissues (p=0.001), and average Histoscore of IHC in 9 AS patients (182.22±30.732) was significantly higher than in 5 controls (62.00±35.637)(P=0.001).

**Conclusions:** ANO6 is the new susceptibility gene of AS and risky haplotype is GTGCG, ATGTA and ACGTA. The risky haplotype have no relationship with phenotype of AS. The expression of mRNA of PBMCs decreased while the expression of ANO6 protein went up in tendon tissues, which suggested that ANO6 might participant in the generation and development of AS.

## AB0123 IMMUNOPHENOTYPING OF LYMPHOCYTE POPULATIONS BY HYPERSPECTRAL CYTROMETRY ON PATIENTS WITH SPONDYLOARTHRITIS

N. Rosine[1], S. Menegatti[1], C. Leloup[1], E. Latis[1], E. Bianchi[1], M. Dougados[2], L. Rogge[1]. *[1]Paris, Département d'immunologie Unité " immunorégulation ", CNRS URA 1961 Institut Pasteur Paris; [2]Paris, Université Paris Descartes, Service de Rhumatologie B, Hôpital Cochin - Assistance Publique- Hôpitaux de Paris, INSERM (U1153): Clinical epidemiology and biostatistics, PRES Sorbonne Paris-Cité., Paris, France*

**Background:** The etiology of spondyloarthritis (SpA) is unknown but seems to indicate a link between genetic and environmental factors. Many GWAS studies demonstrated a strong association between IL23R gene and the disease. Moreover, several IL-17 producing lymphocyte populations characterized by the expression of CCR6 (TD4+, TCD8, Tγδ and ILC) are involved in pathophysiolgy of SpA.

**Objectives:** The aim of the study was to identify cells population involved in the disease development:

- By comparing simultaneously cells population TCD4+, TCD8+, Tγδ et ILC (and sub-population ILC3) in patients and healthy controls.

By analysing simultaneously the expression of IL23R and CCR6 by TCD4+, TCD8+, Tγδ and ILC in patients

**Methods:** *Patients:* 10 patients aged from 18 to 50, fulfilling the ASAS criteria and presenting a BASDAI>40 were recruited from diagnosis (between February to may 2015), and compared to 7 healthy subjects paired according to their age.

Methods: The cell analysis was realized by hyperspectrale cytrometry (Sony SP6800®) after cell staining of the mononuclear cells. This emerging technology combines optical spectroscopy and flow cytrometry. The panel used included 13 colours (BV421 conjugated to anti-CD127, V450 conjugated to anti-CD3, V500 conjugated to anti-CD4, BV570 conjugated to anti-CD8, BV605 conjugated to anti-CD62L, BV650 conjugated to anti-CD117, BV711 conjugated to anti-CCR6, BV786 conjugated to anti-NKp46, Percp Cy5.5 conjugated to anti-CD161, PE conjugated to anti IL23R, PE-CF594 conjugated to anti-CRTH2, PE-Cy7 conjugated to anti-TCRgd).

**Results:** The quantitative analysis of cell populations did not show any significant difference between patients and controls: TCD4+ (p=0.2), TCD8+ (p=0.93), Tγδ (p=0.52), ILC (p=0.46) et ILC3 (p=0.71). These results suggested that the functional properties of immune cells (rather than their frequencies) were involved in the disease process. We have demonstrated TCD4+, TCD8+, Tγδ and ILC, all expressed IL23R as well as CCR6. However, we did not notice any difference in expression of these two markers between patients and controls. Then, we showed that in SpA, the level of CCR6 expression was higher in TCD4+ lymphocyte populations (p=0.0031). Similarly, the level of expression of IL23R was higher in TCD8+ lymphocyte ($p<0.0001$).

**Conclusions:** These preliminary results suggest SpA development does not result from the increase of specific cell populations but rather from the modification of

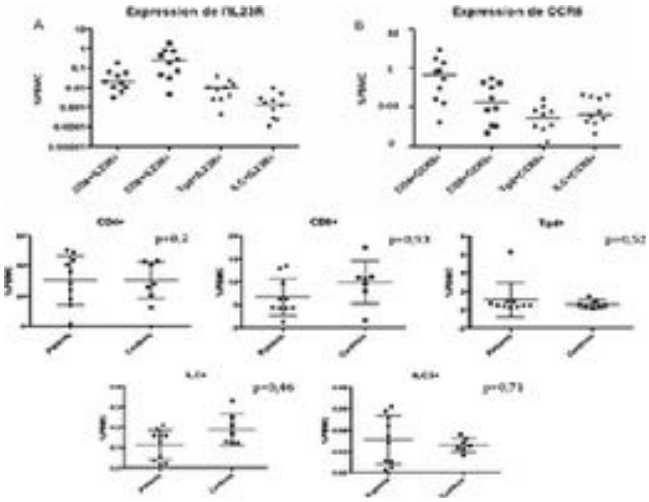

Figure 1. A: IL23R level of expression by TCD4+, TCD8+, Tγδ and ILC on patients. B: CCR6 level of expression by TCD4+, TCD8+, Tγδ and ILC on patients. Fig C: Comparison of TCD4+, TCD8+, Tγδ et ILC and ILC3+ cell populations between patients and controls.

the functional properties of immune cells. The increase of CCR6 expression in TCD4+ and IL23R in TCD8+ shows that these two cell populations take a major part in the disease. In spite of recent datas concerning Tγδ and ILC3, our results did not highlight a major participation of these cells. These prelimanry data need to be confirmed in a larger cohort of patient.

### AB0124 PERIPHERAL BLOOD MONONUCLEAR CELLS FROM ANKYLOSING SPONDYLITIS PATIENTS DISPLAY AN ATHEROGENIC PROFILE ASSOCIATED WITH DISEASE ACTIVITY AND ENDOTHELIAL DYSFUNCTION

Y. Jimenez-Gomez, P. Font, C. Pérez-Sánchez, P. Ruiz-Limón, N. Barbarroja, M.C. Ábalos-Aguilera, M.C. Castro-Villegas, R. Ortega-Castro, J. Calvo, C. López-Pedrera, A. Escudero-Contreras, E. Collantes-Estévez. *Rheumatology Service, IMIBIC/Reina Sofia University Hospital/Cordoba University, Cordoba, Spain*

**Background:** Several studies have demonstrated that Ankylosing Spondylitis (AS), a chronic inflammatory disease of unknown aetiology, is associated with several comorbidities such as cardiac pathology, accelerated atherosclerosis and cardiovascular disease. Yet, the relevance of peripheral blood mononuclear cells (PBMCs) in the development of atherosclerosis in AS patients is not fully known.
**Objectives:** 1) To analyze the gene expression profile associated with the development of atherosclerosis in PBMCs from AS patients. 2) To evaluate the role of PBMCs in the endothelial dysfunction present in AS patients.
**Methods:** Twenty five patients with AS and 25 healthy donors were included in the study. Disease function and activity status were analyzed using the BASFI and BASDAI indexes, respectively. The expression of 84 genes related to atherosclerosis was analyzed in purified PBMCs by PCR array, using total ARN pools of patients and healthy donors. Next, validation of several differentially expressed genes in PBMCs, selected on the basis of their expression levels and relevance in AS pathology, was carried out in our patient and healthy donor cohort. Endothelial function was determined by the post occlusive hyperaemia test using Laser-Doppler. To analyze the role of PBMCs in endothelial function, *in vitro* co-cultures of endothelial cells (HUVEC) and PBMCS from AS patients with different inflammatory status were performed.
**Results:** The endothelial function analysis demonstrated a significant reduction of post occlusive hyperaemia area in AS patients in relation to healthy donors, thus pointing at the presence of a prominent endothelial dysfunction in these patients.
The analysis of the genetic profile in PBMCs showed a significant alteration in the expression of genes related to inflammatory (CCL2, CCL5, CCR1, CCR2, IL1R2, IL1A, IL2, IL5, NOS3, SPP1), and oxidative stress response (APOE, SOD1). An altered expression of genes linked to cellular adhesion (CDH5, ICAM-1, SELL, SPP1, CTGF, FN1, THBS4, TNC), lipid metabolism and transport (ABCA1, APOA1, APOE, FABP3, LPL, LPA, MSR1), cell growth and proliferation (CSF2, SSP1, BCL2, FABP3, FGF2, LIF, CRGF), as well as transcription and apoptosis regulators (PPARA, PPARD, EGR1, BCL2, BCL2A1, BCL2L1) was further demonstrated.
*In vitro* treatment of HUVECs with PBMCs from AS patients with a high pro-inflammatory profile promoted a significant activation of the endothelial cells, which displayed increased expression of adhesion molecules, oxidative stress markers, cytokines and chemokines, all of them associated to the pro-atherogenic profile of these patients.
**Conclusions:** 1) Peripheral blood mononuclear cells from AS patients display an altered expression profile of key genes involved in the development of atherosclerosis. 2) That highly inflammatory PBMCs are responsible, at least partially, for the endothelial dysfunction displayed by AS patients.

## SLE, Sjögren's and APS - etiology, pathogenesis and animal models

### AB0125 DENDRITIC CELLS DISPLAY ABERRANT TOLL-LIKE RECEPTOR RESPONSES DURING THE ONSET OF SYSTEMIC LUPUS ERYTHEMATOSUS

A.L.Y. Yim, S. Yan, C.C.P. Lee, C.S. Lau, V.S.F. Chan. *Division of Rheumatology and Clinical Immunology, Department of Medicine, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong*

**Background:** Systemic lupus erythematosus (SLE) is a chronic, multifactorial autoimmune disease causing multi-organ damages (eg. kidney, heart and skin) and predominantly affects young female. The dysregulation of multiple immune cell populations leads to the development of SLE and the role of dendritic cells (DCs) in the disease pathogenesis has drawn great attention. Plasmacytoid DCs (pDCs) are potent type I interferon (IFN) producers and myeloid DCs (mDCs) are professional antigen-presenting cells. Clinically, the level of serum interferon alpha (IFNa) correlates with the severity of disease with pDC infiltration in nephritic kidney suggested that pDCs may contribute to SLE pathogenesis [1, 2]. Moreover, monocyte-derived mDCs from SLE patients also display activated phenotypes [3]. These findings suggested that different DC subtypes may contribute to the disease development but the exact mechanism is not fully understood.
**Objectives:** This study aimed to investigate whether different DCs subtypes display any abnormalities during the onset of SLE and thus, contribute to SLE pathogenesis.
**Methods:** Using the New Zealand Black /White F1 (BWF1) murine lupus model, the phenotypic and functional properties of different DCs subsets were compared before and after disease onset using flow cytometry, ELISA and qPCR.
**Results:** Symptomatic mice had a lower frequency but similar number of splenic pDCs when compared with its pre-symptomatic counterparts. In terms of activation markers and co-stimulatory molecules, splenic pDCs from symptomatic and pre-symptomatic mice expressed similar levels of CD40, CD80 and MHC II upon Toll-like receptor (TLR) 7 or TLR9 stimulation. The levels of IFNa produced upon TLR9 stimulation were also comparable. For splenic mDCs, both the frequency and number were higher in symptomatic mice. Surprisingly, *ex-vivo* mDCs from symptomatic mice expressed lower levels of CD80 and MHC II but their ability in inducing allogenic T cell proliferation was comparable to mDCs from pre-symptomatic mice. On the other hand, the basal mRNA expressions of TLR7 and TLR9 on mDCs from symptomatic mice were higher. Upon TLR7 or TLR9 stimulation, the induction of IL-10 and CXCL13 mRNA in mDCs from symptomatic mice were also greater than its pre-symptomatic counterparts
**Conclusions:** Results showed that mDCs displayed abnormality upon SLE onset and may contribute to SLE pathogenesis via aberrant TLR signalling. More work should be done to further investigate the exact role of mDCs in SLE pathogenesis.

### AB0126 COMPARISON OF SERUM APELIN, FETUIN-A LEVELS AND CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH SJÖGREN'S SYNDROME AND HEALTHY SUBJECTS

A. Şahin[1], D. Seven[2], Ö. Demirpençe[3], D. Seven[4], A. Camcı[1]. [1]*Rheumatology - Internal Medicine;* [2]*Internal Medicine;* [3]*Biochemistry;* [4]*Radiology, Cumhuriyet University Medical Faculty, Sivas, Turkey*

**Background:** Apelin is a glycoprotein, adipocytokine that plays an important role in decreasing the vascular inflammation on cardiovascular and metabolic disorders (1). Fetuin-A is also another glycoprotein that can be an acute phase

protein negatively correlates with inflammation (2). Carotid intima-media thickness (C-IMT) may indicate vascular inflammation in primary Sjögren's syndrome (3). However, we do not know the relationship between serum apelin, fetuin-a levels and C-IMT in patients with Sjögren's syndrome.

**Objectives:** To compare of the serum Apelin, Fetuin-A levels and C-IMT in patients with Sjögren's syndrome (SjS) and healthy controls.

**Methods:** Sixty-SjS patients and sixty healthy subjects were enrolled to this study. Serum apelin, fetuin-a levels were measured by ELISA. Concomitant C-IMT evaluations of the participants were performed. The BMI, insulin, HOMA-IR, lipid profiles were studied. Other laboratory parameters, autoantibody profiles, minor salivary gland biopsy scores (Chisholm) were obtained from patient's record files. The study was approved by the local ethics committee.

**Results:** The median levels of apelin were 178.02±55.23 ng/mL in healthy subjects and 98.66±37.25 ng/mL in SjS ($p<0.05$) (Figure 1). The median levels of fetuin-a were 1370.3±81.74 ng/mL in control group and 1613±64.49 ng/mL in SjS group (p=0.021) (Figure 1). The C-IMT was negatively correlated with apelin levels in SjS patients (r= - 0.209, p=0.02). There was no significant correlation between fetuin-a levels and C-IMT in SjS (p=0.08). However, there were significant correletions between C-IMT and hemoglobin-A1c (r=0.353, p=0.005), C3 (r=0.36, p=0.004), C4 (r=0.351, p=0.005).

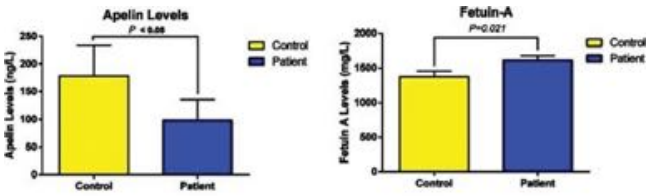

Figure 1. Comparison of serum Apelin and Fetuin-A levels of the patients with Sjögren's syndrome and healthy controls.

**Conclusions:** We found lower serum apelin and higher fetuin-a levels in SjS patients than in healthy subjects. Apelin and fetuin-a may be a new possible surrogate biomarker of inflammation in Sjögren's syndrome.

## AB0127 THE FREQUENCY OF NUEROLOGICAL INVOLVEMENT IN SJÖGREN'S SYNDROME: A SINGLE CENTER EXPERIENCE

A. Şahin[1], M. Şahin[2], A. Camcı[1], D. Seven[3], D. Seven[4]. *[1]Rheumatology - Internal Medicine; [2]Biochemistry; [3]Internal Medicine; [4]Radiology, Cumhuriyet University Medical Faculty, Sivas, Turkey*

**Background:** Sjögren's syndrome is an autoimmune rheumatic disease that affects many glandular and extra-glandular tissues (1). Autoantibodies (mainly anti-Ro-SS-A and anti-La-SS-B) contribute to playing roles in its clinical pictures (2). Central and peripheral nervous system involvement may be seen as different sign, symptoms and varying its frequencies (2).

**Objectives:** The aim of this study is to investigate the frequency of neurological and other involvement patterns of the Sjögren's syndrome (SjS).

**Methods:** Between June 2015 and December 2015, fifty-eight-SjS patients that following-up at Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department were evaluated in the study. The clinical complaints, glandular and extra-glandular findings, age, sex, other epidemiological data, ANA, RF, anti-Ro/La, C3, C4, IgG, IgA, IgM levels were recorded.

**Results:** The mean age of the patients was 47.8±1.3 years, and the mean age at diagnosis was 46.8±1.2 years. Of the SjS patients, fifty-four (93.1%) were female and four (6.9%) were male. The frequencies of the clinical symptoms were as follows arthralgia in 81%, arthritis in 48.3%, skin dryness in 50%, rashes (including palpable purpuric lesions) in 17.2%, biopsy proven vasculitic lesions in 5.2%. The frequencies of the neurological symptoms were as follows headaches in 32.8%, localized numbness in 5.2%, seizure in 1.7%, paresthesia in 3.4%, diffuse nonfocal symptoms in 1.7% (Figure 1). The total frequency of neurological involvement was 24.1% in SjS patients. Peripheral nervous system involvement in 8.6%. The findings of the magnetic resonans imaging of the patient with neurological involvement were as non-spesific gliotic lesions in 21.4%, periventricular lesions in 28.6%, paranchymal vasculitic lesions in 35.7%, multiple sclerosis-like plaques in 14.3%. There was found that anti-Ro positivity in 58.6%, anti-La in 19.2%, RF in 51.7%, ANA in 48.3%, low complement levels in 15.5%. However, anti-Ro positivity was lower in patient with neurological involvement than in patient without neurological involvement (p=0.025).

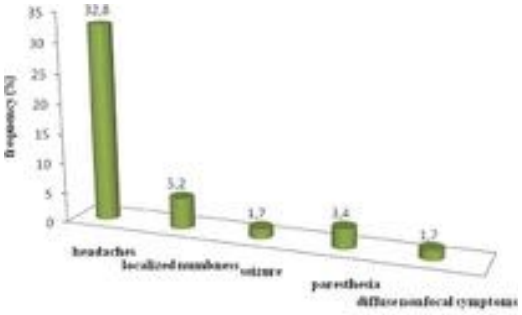

Figure 1. The frequency of clinical symptoms of the patients with Sjögren's syndrome.

**Conclusions:** The neurological involvement should be kept in mind when the patient has been diagnosed as SjS. It can be seen than it is expected. In addition, further studies need to be done to evaluate the role of anti-Ro autoantibody in SjS patients with neurological involvement.

## AB0128 P-SELECTIN ABSENCE TRIGGERS A LUPUS-LIKE SYNDROME IN MICE

R. González-Tajuelo[1], A. Pérez-Frías[1], J. Silván[1], M. de la Fuente-Fernández[1], E. Vicente[2], S. Castañeda[2], C. Gamallo[3], A. Urzainqui[1]. *[1]Immunology; [2]Rheumatology; [3]Histopathology, Hospital Universitario de la Princesa, IIS-IP, Madrid, Spain*

**Background:** Selectins regulate the tethering and rolling of leukocytes before their extravasation. P-Selectin/PSGL-1 interaction is involved in the generation of regulatory T cells[1] and *Psgl-1*$^{-/-}$ mice have altered the colonic lamina propria tolerance/immunity balance[2] and spontaneously develop an autoimmune syndrome similar to human scleroderma[3]. Systemic lupus erythematosus is an autoimmune disease characterized by the production of autoantibodies, immune complexes deposition, complement activation and polyclonal expansion of autorreactive lymphocytes[4,5].

**Objectives:** To characterize the development and progression of a lupus-like syndrome in P-Selectin KO (*P-sel*$^{-/-}$) mice and to analyze P-Selectin expression in skin biopsies of lupus patients.

**Methods:** Mice skin and internal organs were analyzed histologically. Deposition of Immune complexes was determined by immunohistochemistry (IHQ). Levels of serum autoantibodies were quantified by ELISA. Peripheral blood leukocytes and splenocytes were analyzed by flow cytometry. UVB radiation (0.306 J/cm$^2$) was performed to 3 month-old WT and *P-Sel*$^{-/-}$ mice every other day for a week. The expression of P-Selectin in skin biopsies from healthy controls and lupus patients was assessed by IHQ.

**Results:** *P-Sel*$^{-/-}$ mice showed skin alterations characteristic of lupus prone mice. Lupus-like pathogenesis was characterized by deposition of immune complexes in the dermoepidermal junction and renal glomeruli and the presence of anti-dsDNA and anti-Sm autoantibodies in the serum. The histological analysis revealed immune infiltration of the skin, kidney and lung, and tissue structural alterations such as renal infarcts and nonspecific interstitial pneumonia. We found a reduction in the IL-10 producing PBLs, and splenic T cells showed a more effector phenotype. More important, skin biopsies of lupus patients did not show increased expression of P-Selectin, as described for other inflammatory diseases, and the number of vessels expressing P-Selectin was reduced.

**Conclusions:** P-Selectin deficiency leads to a lupus-like syndrome similar to established lupus mouse models. Additionally, we found imbalanced regulatory/proinflammatory leukocytes ratio in peripheral blood and spleen. These results reaffirm the notion that the PSGL-1/P-Selectin axis is crucial for maintaining immune system homeostasis and preventing autoimmunity.

## AB0129 INVESTIGATING THE PHAGOCYTIC POTENTIAL OF NEUTROPHILS FROM JUVENILE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS (JSLE) PATIENTS

A.E.A. Glaser[1], H.L. Wright[2], A. Midgley[1], M. Peak[3], M.W. Beresford[3].
*[1]Department of Women's and Children's Health; [2]Department of Biochemistry; [3]University of Liverpool, Liverpool, United Kingdom*

**Background:** Reduced phagocytic clearance of apoptotic cells in Juvenile-onset Systemic Lupus Erythematosus (JSLE) may lead to prolonged exposure of nuclear autoantigen to the immune system. The generation of autoantibodies against nuclear antigens can cause damage in various organs and a diversity of symptoms.
Impaired phagocytosis is also thought to increase the formation of neutrophil extracellular traps (NETs) in a process called NETosis, which may be a potential source of nuclear autoantigens in SLE.
Understanding the phagocytic potential of JSLE neutrophils is therefore important. However only very limited data is published on this subject for neutrophils, especially in juvenile-onset disease.
Transcriptomic analysis of JSLE and control neutrophils by our group found genes for phagocytosis to be differentially expressed between the two groups. These genes included receptors for pathogen recognition (TLR-2), apoptotic material (AnxA3), for microbial size (Dectin-1), for opsonized material (CR3, FcγRIIIb), and adherence to and digesting of the target (CamK1D) as well as genes thought to promote phagocytosis (S100A9).
By investigating the expression of these genes as well as the phagocytic function of JSLE neutrophils, this study aims to provide important insight into the phagocytic potential of JSLE neutrophils.
**Objectives:** To compare the mRNA expression of phagocytosis genes in neutrophils from JSLE and paediatric healthy control patients and the ability of JSLE and control neutrophils to phagocytose different pathogens in the presence of JSLE and control serum.
**Methods:** Neutrophil RNA was extracted from children (diagnosed <17 years) with JSLE (n=9) and paediatric healthy controls (n=8). The mRNA expression of TLR-2, Dectin-1, AnxA3, CamK1D, FcγRIIIb, CR3 and S100A9 were measured using qPCR. The expression of b-actin was analysed as an internal standard. For functional assays the neutrophils were incubated in JSLE or control serum with *E.coli*, *S.aureus* and zymosan fluorescent particles and analysed using flow cytometry and confocal microscopy.
**Results:** Expression (fold change relative to housekeeping gene ± SEM) of TLR-2 (Control 0.013±0.001, JSLE=0.029±0.003, p=0.001) and S100A9 (Control 1.59±0.22, JSLE=2.73±0.33, p=0.02) were both significantly higher in JSLE patients compared to paediatric healthy controls. No difference was observed in CamK1D expression (p=0.94). Increased expression was also observed in the JSLE group of Dectin-1 (p=0.28), AnxA3 (p=0.18), FcγRIIIb (p=0.11) and CR3 (p=0.23), although was not statistically significant.
Early preliminary data of the functional assay indicate a general reduction of phagocytosis in JSLE compared to control neutrophils and decreased phagocytosis of each pathogen in the presence of JSLE serum.
**Conclusions:** Here, we show increased expression of key genes involved in phagocytosis in JSLE neutrophils compared to controls. This may be reflective of the response of the cells to the apoptotic burden observed in these patients. Further assays are currently being carried out to confirm the preliminary observations noted in this study.

## AB0130 EXPRESSION OF REGULATORY B CELLS IN PERIPHERAL BLOOD OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Xiaoyan. *Department of Rheumatology, The First Municipal People's Hospital, Guangzhou 510180, China, Guangzhou, China*

**Background:** It is generally considered that B cells regulate immune response mainly through producing specific antibodies or a variety of cytokines., but recent studies have found that the lack of B cells and CDl9 –/– mice in experimental autoimmune encephalomyelitis (EAE) mouse model is more serious, and in T cell mediated inflammation experiment, CDl9–/– mice show a more serious contact hypersensitivity (CHS). Therefore, it indicated that B cells also play an important role in the negative immune regulation.
**Objectives:** To investigate the expression of regulatory B cells (Bregs) in peripheral blood of patients with systemic lupus erythematosus (SLE) and the function of Bregs in the pathogenesis of SLE.
**Methods:** Thirty-eight active SLE patients, twenty-two inactive SLE patients and twenty healthy controls were enrolled in this study. The expression of IL-10$^+$CD19$^+$Breg and CD19$^+$CD24$^{hi}$CD38$^{hi}$Breg in peripheral blood mononuclear cells (PBMC) was evaluated by flow cytometric analysis. IL-10 was measured in the culture supermatants by ELISA.
**Results:** The expression of IL-10$^+$CD19$^+$Breg in PBMCs of active SLE patients was 1.54±0.64%, lower than those in inactive SLE patients (2.42±0.75)% ($P$<0.001) and healthy controls (4.35±1.00)% ($P$<0.001). And the expression of CD19$^+$CD24$^{hi}$CD38$^{hi}$Breg was 1.26±0.45%, also lower than those in inactive SLE patients (2.01±0.61)% ($P$<0.001) and healthy controls (3.14±0.87)% ($P$<0.001). The level of IL-10 in the culture supermatants of active SLE patients significantly decreased, which was lower than those in inactive SLE patients ($P$<0.05) and healthy controls ($P$<0.001). The percentage of IL-10$^+$CD19$^+$Breg and CD19$^+$CD24$^{hi}$CD38$^{hi}$Breg in peripheral blood of SLE patients was positively correlated with the level of IL-10 in the culture supermatants (r=0.652, $P$<0.001 and r=0.574,$P$<0.001).
**Conclusions:** Expression of IL-10 related Bregs was significantly decreased in peripheral blood of active SLE patients. Bregs may play a critical role in the pathogenesis of SLE.

## AB0131 TISSUE BETA 2 GLYCOPROTEIN I IN BRAIN ISCHEMIC INJURY

C. Artusi[1], S. Fumagalli[2], M. Oggioni[2], M.O. Borghi[1,3], C. Grossi[3], P.L. Meroni[1,3], F. Tedesco[3], M.G. De Simoni[2]. *[1]Department of Clinical Sciences and Community Health, University of Milan; [2]Department of Neuroscience, IRCCS Istituto di Ricerche Farmacologiche Mario Negri; [3]Laboratory of Immuno-Rheumatology, Istituto Auxologico Italiano, Milan, Italy*

**Background:** Thrombosis of arteries in the central nervous system (CNS) represents the most frequent CNS manifestation and the most frequent arterial event in antiphospholipid syndrome (APS). Previous in vivo studies demonstrated that beta2 glycoprotein I (β2GPI) - the main antigenic target for anti-phospholipid antibodies (aPL) - does not localize in brain in resting conditions. However, β2GPI is detectable on the brain vascular endothelium in association with IgG and complement elements in immunized mice treated with lipopolysaccharide. These data suggest that after an appropriate second hit, β2GPI can play a critical role of in APS CNS damage, likely interacting with the complement system. To date, the pathophysiological functions of β2GPI in brain ischemic injury have not been investigated.
**Objectives:** To investigate the presence and the distribution of the activated form of β2GPI in the ischemic brain at different time points.
**Methods:** Eleven-week old male mice underwent focal cerebral ischemia induced by 60' transient middlecerebral artery occlusion (tMCAo), or sham-operation. Mice were sacrified at 90', 6h, 24h, 48h, 4d or 7d after tMCAo to obtain brains and plasma. The presence and time course of β2GPI deposition within the ischemic territory and its spatial distribution relative to blood vessels and brain cells were defined the by *post mortem* immunofluorescence and confocal microscopy. The activated β2GPI was detected by anti-beta2 glycoprotein I minibody (MBB2) – a human monoclonal IgG antibody targeting β2GPI domain I.
**Results:** β2GPI was present in the ischemic brain tissue starting from 90' after ischemic onset and was still detectable at 7d. β2GPI localized within blood vessels and in brain parenchyma at all times. Notably, at 24h β2GPI was mainly extravascular and colocalized with neurons (NeuN positive cells). Sham-operated mice showed only a faint signal for β2GPI.
**Conclusions:** β2GPI is present in its activated conformation in the brain vessels and tissue after experimental cerebral ischemia. It localizes on neurons in brain ischemic areas. These data suggest that an ischemic/inflammatory hit may up-regulate β2GPI tissue presence and may expose the N-terminal domain I of the molecule which is thougth to be the main target for pathogenic aPL.

## AB0132 INCREASED CD4+CD69+ T CELLS AND REDUCED CD4+CD25+ TREG CELLS IN MURINE LUPUS-LIKE MODEL

T.V. Peixoto, N. Ugriumov, S. Carrasco, D.A.C. Botte, T.M. Lima, S.B.V. Mello, F.G. Soriano, C. Goldenstein-Schainberg. *Faculdade de Medicina da Universidade de São Paulo e Hospital Das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil*

**Background:** Proliferation of auto reactive T cells and loss of immunological tolerance are features of SLE. In human lupus, enhanced expression of CD69 in peripheral CD4 T cells indicates incremented activation and lower numbers of CD4$^+$CD25$^+$FoxP3$^+$Treg cells contributes to autoimmunity. Pristane-induced lupus murine model has clinical similarities to human disease, nonetheless whether cellular characteristics of this model resemble those of lupus patients remains unknown.

**Objectives:** To analyse the expressions of CD69 activation receptor on CD4 Tcells and of $CD4^+CD25^+FoxP3^+$Treg cells in peripheral blood and spleen of pristane-induced SLE balb/c mice.
**Methods:** Tweenty one female Balb/c mice were analyzed: 13 received a single intraperitoneal 0,5 ml dose of pristane and 8 the same dose of saline. Euthanized mice samples of blood and spleen were collected 120 (T120) days after inoculation of pristane or saline. Mononuclear cells from peripheral blood (PBMC) and splenocytes were obtained by lysis of erythrocytes followed by washings with RPMI medium 1640 and centrifugation, subsequently criopreserved until evaluation by flow cytometry using the appliance GuavaEasyCyteTM HT (Millipore). For this step, cells were unfrozen, washed with RPMI medium 1640 and incubated with monoclonal antibodies against CD3, CD4, CD25, CD28, CD69 and FoxP3 (BD PharmingenTM). The results are expressed as mean ± SD and Mann-Whitney test was used for statistical analysis, being considered significant $p<0,05$.
**Results:** Compared to control, SLE pristane-induced animals presented increase of CD4+CD69+ T cells in blood and in spleen ($p=0.008$ and $p=0.049$, respectively), while the porcentage of Treg CD4+CD25+FoxP3+ was lower in blood and in spleen ($p=0.012$ and $p=0.018$, respectively).
**Conclusions:** Increase of CD4+CD69+ T cell and reduction of CD4+CD25+ FoxP3+ Treg expression suggests activated T CD4 cells and loss of peripheral autotolerance in pristane-induced SLE mice. These alterations are similar to observations in human lupus, in indicating that this model may be useful in evaluating mechanisms of cellular activation, peripheral tolerance and homeostatic immune imbalance involved in LES.

## AB0133 INCREASED EXPRESSION OF ACTIVATED LY6G+CD11B+CD62L- NEUTROPHILS IN BALB/C MICE WITH PRISTANE INDUCED LUPUS-LIKE DISEASE

N. Ugriumov, C. Goldenstein-Schainberg, S. Carrasco, I. Begalli Mendes, T.M. Lima, T. Vasconcelos Peixoto, S.B. Veríssimo de Mello, F.G. Soriano.
*Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil*

**Background:** Neutrophils are important cells of innate immunity's first line of defense and IL-8 cytokine contributes to its activation. In patients with lupus there is an increase of activated neutrophils in plasma, however data about the contribution of IL-8 on disease development are conflicting.
**Objectives:** To analyze and quantify activated Ly6G+CD11b+CD62L- neutrophils in peripheral blood (PB) and spleen as well to evaluate the production of IL-8 in Balb/c mice with pristane induced lupus-like disease.
**Methods:** We studied 37 mice (13 healthy controls; 24 pristane-induced mice). Pristane-induced mice (PIM) received a single intraperitoneal 0.5ml dose of pristane, while healthy controls received the same dose of saline. Samples of blood and spleen were collected after euthanasia 90 and 120 days after injections; red blood cells were lysed and remaining cells stained with monoclonal antibodies: anti-Ly6G (total neutrophils), anti-CD11b (activated neutrophils) and anti-CD62L (anergic neutrophils) (BDPharmingen™). All cell samples were evaluated by flow cytometry (Guava EasyCyte™ HT, Millipore). Plasmatic IL-8 levels were assessed by ELISA (MyBioSource™). Mann-Whitney's non-parametric test was used for statistical analysis, and $P<0.05$ considered significant.
**Results:** Compared to control, PIM had higher percentage of total neutrophils 90 and 120 days after injection in PB (26.9±2.46 vs. 46.75±5.41%, P=0.002 and 26.9±2.46 vs. 38.52±4.03%, P=0.004) and spleen (15.94±1.86 vs. 33.7±6.48%, P=0.01 and 15.94±1.86 vs. 35.98±3%, $P<0.0001$) respectively. In PB, the percentage of activated neutrophils was similar in PIM compared to controls ($P>0.05$), while in the spleen, PIM had increased activated neutrophils 120 days after induction (41.83±3.63 vs. 58.73±3.94%, P=0.004). PIM and controls expressed similar percentages of anergic neutrophils in both PB and spleen ($P>0.05$). Controls and PIM produced similar plasmatic IL-8 levels 90 and 120 days after injection (0.65±0.18 vs. 0.2±0.05pg/ml, $P\geq0.05$ and 0.65±0.18 vs. 1.2±0.51pg/ml, $P>0.05$), respectively though PIM had higher plasmatic IL8 levels

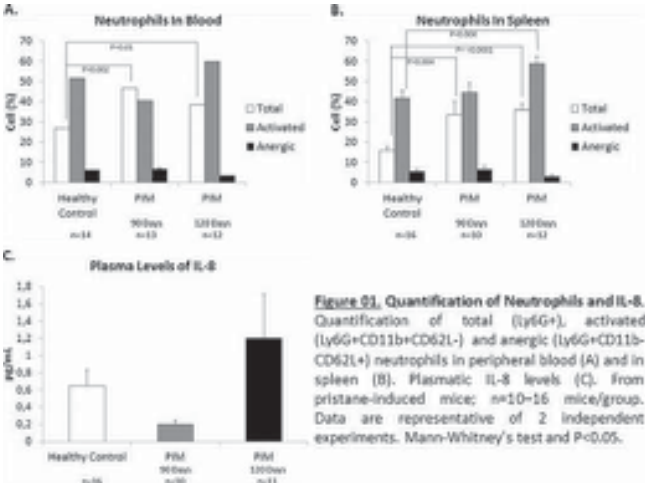

Figure 01. Quantification of Neutrophils and IL-8. Quantification of total (Ly6G+), activated (Ly6G+CD11b+CD62L-) and anergic (Ly6G+CD11b-CD62L+) neutrophils in peripheral blood (A) and in spleen (B). Plasmatic IL-8 levels (C). From pristane-induced mice; n=10-16 mice/group. Data are representative of 2 independent experiments. Mann-Whitney's test and P<0.05.

120 days compared to 90 days after induction (1.2±0.51 vs 0.2±0.05pg/ml, P=0.01).
**Conclusions:** Increased percentage of activated neutrophils in PIM indicates innate immunity involvement. Delayed IL8 levels increments over time might suggests that this cytokine may be involved in neutrophil activation in this animal model. Therefore, additional studies are needed in order to clarify IL8 role and further pathways involved in neutrophil activation and disease development in PIM.

## AB0134 OXIDATIVE STRESS LEVELS ARE INCREASED IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH A HIGHER ACCUMULATIVE DAMAGE SCORE

E. Grau Garcia[1,2], M. Fernández Matilla[2], G. Poveda Marín[1], C. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz Sanjuan[1], N. Fernández-Llanio[3], D. Hervás Marín[4], V. Fornes Ferrer[4], R. Rodrigo Nicolás[5], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortés[1], J. Fragio Gil[1], I. Martínez Cordellat[1], J. Valero Sanz[1], I. Chalmeta Verdejo[1], L. González Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], J. Castellano Cuesta[3], J. Román Ivorra[1]. *[1]Rheumatology Department, HUP la Fe; [2]Rheumatology Research Group, IIS la Fe; [3]Rheumatology Department, Hospital Arnau de Vilanova; [4]Biostatistics Unit; [5]CIBERER, IIS la Fe, Valencia, Spain*

**Background:** Oxidative stress is increased in Systemic Lupus Erythematosus (SLE) patients, and contributes to the immune system imbalance, abnormal activation of apoptotic processes, autoantibodies production and the development of serious complications, such as cardiovascular comorbidities.
**Objectives:** To evaluate the influence of oxidative stress as an additional factor to the classical cardiovascular risk ones, in SLE patients.
**Methods:** Cross-sectional prospective study of SLE patients according to the SLICC-2012 criteria, coming from the Rheumatology Service of Arnau de Vilanova Hospital and La Fe Hospital. In all patients we analyzed the serum concentration of GS-Nem (GSH) and GSSG by UPLC-MS/MS (Acquity UPLC System). We have also taken healthy individuals as negative controls, who had the same blood-test. In patients was also made a complete blood-test, and clinical, treatment and biometric data were collected by personal interview. Biostatistical analysis was performed by the *R* software version 3.2.3., using a simple, binominal and logistic lineal regression.
**Results:** A total of 140 patients were evaluated; (95% women) with 33.39±13.63 year-old average at the diagnosis time with a 10.05± 11.42 year-evolution of SLE. We used GSH/GSSG ratio to assess the oxidative stress rate, being this value higher in patients than in healthy controls (P=0.005).
We observed a statistically significant relationship between the presence of oxidative stress and accumulated damage assessed by SLICC-ACR ($P<0.0001$). No differences according to the disease activity, specific autoimmune profile or by organ or systems affected. However, we found a slight difference in the GSH/GSSG ratio among patients who have had a CVD (1±0.39) and those who have not suffered CVD (1.19±0.55). No differences in the levels of oxidative stress are observed according to treatment with folic acid or the administration of biological therapies.
**Conclusions:** We observed increased levels of oxidative stress in our SLE patients compared to healthy controls. Data suggest a rise of oxidative stress in

patients with a greater cumulative damage, which is consistent with the presence of severe comorbidities in these patients. It seems to be a slight tendency to increased oxidative stress levels measured with GSH/GSSG ratio in patients with SLE and cardiovascular involvement, but more independent studies are needed to confirm it.

## AB0135 DECREASED LUPUS MANIFESTATIONS IN PRISTANE-INDUCED MICRORNA 155-DEFICIENT MICE

H. Leiss[1], W. Salzberger[1], B. Jacobs[2], I. Gessl[1], N. Kozakowski[3], S. Blüml[1], A. Puchner[1], B. Niederreiter[1], T. Shvets[1], C.W. Steiner[1], J. Smolen[1], G. Stummvoll[1]. *[1]Rheumatology, Medical University Vienna, Vienna, Austria; [2]Rheumatology, Medical University Vienna, Vienna, -; [3]Pathology, Medical University Vienna, Vienna, Austria*

**Background:** Deregulation of endogenous miR155 was observed in many autoimmune conditions, including systemic lupus erythematosus (SLE).
**Objectives:** We herein examined the role of miR155 in the development of systemic manifestations in mice with pristane-induced lupus (PIL).
**Methods:** MiR155-deficient and C57/Bl6 mice were injected with pristane or PBS as control and analyzed after 8 months. Glomerulonephritis and pneumonitis were quantified by using the composite kidney biopsy score (KBS) and by analyzing the numbers of affected lung-vessels and the area of the inflammatory lung-infiltrate, respectively. Specimens were stained with B220 (B), CD3 (T), Neu7/4 (neutrophils) and F4/80 (macrophages) and analyzed by cell-identification algorithms for nuclear segmentation (HistoQuest). Serum levels of anti-dsDNA, anti-histone and anti-chromatin antibodies were measured by ELISA. Frequencies of B cells, activated and regulatory CD4+ T cells as well as Th1, Th2, Th17 cells were measured by flow cytometry. Quantitative real-time polymerase chain reaction was used to measure expression levels of interferon-signature and T-cell subset related as well as miR155-associated genes.
**Results:** All pristane-injected mice showed signs of pneumonitis, while controls did not. Compared to wild types treated with pristane, similarly treated knockouts showed significantly decreased perivascular inflammatory area with B cells being the most prominent inflammatory cell. Wildtypes had a more severe renal involvement in the KBS than knockouts. Corresponding with reduced organ involvement, miR155 deficient mice had significantly lower serum levels of anti-dsDNA antibodies, anti-chromatin and anti-histone antibodies and decreased frequencies of activated $CD4^+CD25^+(Foxp3^-)$ cells. Interestingly, also frequencies of $CD4^+CD25^+Foxp3^+$ regulatory T cells were lower in these mice. Upon restimulation, $CD4^+$ cells showed a more pronounced Th2 response in wild types, but no significant differences in Th1 and Th17 phenotype. Regarding INF-signature and T-cell subset activation, pristane-treated wild types showed significantly up-regulated gene-expression patterns whereas equivalently treated mutants showed the same levels as PBS-treated controls.
**Conclusions:** MiR155 deficiency in PIL mice did not prevent disease, but was associated with less severe organ involvement, lower serum auto-abs levels, lower frequencies of Th2 cells, whereas lower expressions of genes jointly responsible for disease development may be one key mechanism. Thus, antagonisation of miR155 might be a future approach in treating SLE.

## AB0136 IN VITRO INDUCED REGULATORY T-CELLS CAN REDUCE SEVERITY OF LUPUS ARTHRITIS

H. Leiss[1], B. Jacobs[2], I. Gessl[1], A. Puchner[1], B. Niederreiter[1], C.W. Steiner[1], J. Smolen[1], G. Stummvoll[1]. *[1]Rheumatology, Medical University Vienna, Vienna, Austria; [2]Rheumatology, Medical University Vienna, Vienna, -*

**Background:** Even though joint involvement is a major burden in patients suffering from systemic lupus erythematosus (SLE), it is not focus of scientific research and treatment strategies continue to be limited. Studying lupus arthritis and possible treatment options can be done with the murine model of Pristane-induced lupus (PIL).
**Objectives:** We herein investigate if *in vitro* induced regulatory T-cells (*i*Treg) are capable of ameliorating PIL arthritis and help us evaluate possible new treatment options.
**Methods:** BALB/c mice were injected i.p. with either 0.5ml of pristane (PIL-group) or PBS (controls). Naive $CD4^+$ thymocytes were sorted and cultured and cell suspensions with >80% of $CD4^+FoxP3^+$ cells (*i*Treg) were injected intravenously (i) once when PIL was induced ($5x10^6$ *i*Treg, *i*Treg-boost), or (ii) every 4 weeks ($1x10^6$ *i*Treg, *i*Treg-rep). Animals were monitored for paw swelling and grip strength. After 8 months histological analysis evaluated for cartilage degradation, number of osteoclasts and the extent of inflammation and bone erosion. In addition, the cellular composition of the inflammatory tissue was determined by a cell-identification algorithm for nuclear segmentation (HistoQuest). Serum levels of anti-dsDNA, anti-histone and anti-chromatin antibodies were measured by ELISA.
**Results:** Monthly injections of $1x10^6$ *i*Treg reduced the clinical as well as the histological severity of PIL-arthritis, seen by a higher mean grip strength (2.964±0.024 vs. 2.732± 0.063, $p<0.01$), less mean paw swelling (0.044±0.020 vs. 0.360 ±0.069) and retardation of the symptom onset. 62% of PIL-mice and 33% of *i*Treg-rep mice had erosive arthritis. There was a significant reduction of arthritis severity in all histological parameters (inflammatory area 0.188±0.0574 vs. 0.688±0.113; erosive area 0.011 ±0.009 vs. 0.069±0.017; number of osteoclasts 2.000± 1.125 vs. 9.143±1.999; cartilage degradation 0.059±0.004 vs. 0.187±0.033). The single boost of $5x10^6$ *i*Treg could not prevent joint manifestation. However, a slight retardation in "loss of grip strength" and a significantly less erosive area was seen. In regards to the cellular composition of the inflammatory tissue, a significantly increased relative amount of Foxp3 cells was seen in the *i*Treg-rep group compared to the PIL group (5.2±2.3 vs. 0.6±0.2). Corresponding to the reduced severity in joint involvement, the *i*Treg-group had significantly lower serum levels of antibodies.
**Conclusions:** Repeated injections of *i*Treg ameliorate the clinical and histological severity of PIL- arthritis. A single boost of *i*Treg at the time of disease induction does not prevent joint manifestation, but retards the onset of symptoms and progression of erosive bone degradation. Thus, *i*Treg have significant positive effects on PIL arthritis, which may have consequence for future therapeutic considerations.

## AB0137 CD40-PATHWAY ACTIVATION IN ECTOPIC LYMPHOID STRUCTURE (ELS)-RESIDENT B CELLS CONTRIBUTES TO DISEASE PATHOLOGY IN PRIMARY SJÖGREN'S SYNDROME

G. Wieczorek, M. Bigaud, S. Pfister, S. Hoersch, K. McMichael, C. Afatsawo, M. Hamburger, C. Texier, C. Cojean, M. Henry, J. Rush. *Novartis Institutes for Biomedical Research, Basel, Switzerland*

**Background:** T cell-dependent activation of B lymphocytes is a key effector arm of the adaptive immune system, resulting in protective antibody responses and long-lived humoral immunity. Such B cell responses often occur in germinal centres (GCs); specialized anatomical locations within secondary lymphoid organs. Similar GC-like structures can also be found in involved tissue in various autoimmune diseases, including the salivary glands of primary Sjögren's syndrome (pSS) patients.
**Objectives:** Previous work has implicated CD40-CD154 pathway-dependent processes in regulating B cell survival and function in GCs, and we were wanted to investigate whether this costimulatory pathway might be linked to ELS formation and function in pSS.
**Methods:** Histological analysis of minor salivary gland biopsies from pSS patients revealed evidence of CD40 and CD154 expression on ELS-resident B and T cells respectively, co-locating receptor and ligand positive cells in affected tissue. These results suggested that there might be ongoing T-B cell collaboration in these ELS and we therefore wanted to examine whether there was evidence of CD40 pathway activation *in situ*. To do this we first generated a CD40-pathway gene signature in primary human B cells following recombinant CD154 stimulation *in vitro*.
**Results:** Using a published microarray dataset generated using parotid gland biopsies we could demonstrate upregulation of a portion of the B cell CD40 gene signature in biopsies from pSS patients but not from healthy donors or individuals with Sicca symptoms, suggesting that CD40 pathway activation was occurring within disease-relevant tissue in lymphocytes implicated in disease pathology. To better understand the role of CD40-CD154 interactions in ELS, we examined salivary glands in CD40 knockout NOD mice. Wild-type NOD mice develop sialadenitis, anti-SSA/SSB autoantibodies, and display evidence of ELS in salivary glands. In contrast, there was no evidence of ELS, sialadenitis or autoantibodies in CD40 deficient NOD mice up to one year of age. Further, anti-CD154 treatment resulted in disaggregation in splenic GCs as well as established ELS in NOD mice and resulted in decreased levels of IgG secreting cells in salivary glands.
**Conclusions:** Collectively our data indicate that CD40 pathway signalling is essential for formation and maintenance of salivary gland ELS and suggest that CD40 pathway signalling is active in established ELS from pSS patients, supporting the notion that blockade of CD40-CD154 interactions may provide therapeutic benefit in patients suffering from this autoimmune exocrinopathy.

AB0138

WITHDRAWN

AB0139 **INTERLEUKIN-21 IS OVEREXPRESSED IN KIDNEY TISSUE FROM LUPUS NEPHRITIS PATIENTS AND ITS SERUM LEVELS ARE CORRELATED WITH SYSTEMIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY**

J.-M. Kim[1], H.-J. Jeong[1], S.-H. Kim[1], S.-H. Park[2]. [1]*Division of Rheumatology, Department of Internal Medicine, Dongsan Medical Center, Keimyung University School of Medicine, Daegu;* [2]*Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of*

**Background:** Interleukin-21 (IL-21) has various effects on a number of immune cells including B cells, T cells, natural killer (NK) and NKT cells. One of the essential roles of IL-21 is to contribute to autoantibody production as a result of promoting hyperactivity of B cells. Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease characterized by pathogenic autoantibody production and systemic organ damage. A few studies have been conducted for investigating the contribution of IL-21 to the pathogenesis of murine SLE. However, only limited studies have been performed concerning the role of IL-21 in human SLE and the results are still controversial.
**Objectives:** The aim of this study was to evaluate whether IL-21 participates in the pathogenesis of human SLE.
**Methods:** Serum IL-21 levels were measured in SLE, osteoarthritis (OA) patients and healthy controls (HC). Serum IL-21 levels were analyzed for revealing the correlation with laboratory data or a disease activity index for SLE. Kidney tissues from patients with lupus nephritis and controls were used for evaluating the expression of IL-21 and IL-21R. Normal portions of human kidneys removed for renal carcinoma were used as normal controls.
**Results:** Serum levels of IL-21 were increased in the patients with SLE as compared to the patients with OA or HC. Serum IL-21 levels of the patients with SLE were positively correlated with serum levels of IgG, the titers of anti–double-stranded DNA antibodies and the scores of SLE Disease Activity Index. SLE patients with low C4 concentrations had higher serum IL-21 levels than those with normal C4 concentrations. The expression of IL-21 was higher in renal tubular epithelial cells of the patients with lupus nephritis than in those of controls.
**Conclusions:** This study reveals the association between IL-21 and disease activity in the patients with SLE. We also first demonstrate IL-21 expression in renal tissue of the patients with lupus nephritis. These findings suggest that IL-21 is critically implicated in the pathogenesis of SLE.

AB0140 **ALTERED LIPOPROTEINS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS INDUCE AUGMENTED OXIDATIVE STRESS IN VITRO AND IN VIVO**

J.K. Park[1], J.Y. Moon[1], E.Y. Ahn[1], E.Y. Lee[1], E.B. Lee[1], K.H. Cho[2], Y.W. Song[1]. [1]*Internal Medicine, Seoul National University Hospital, Seoul;* [2]*Research Institute of Protein Sensor, Yeungnam University, Gyeongsan, Korea, Republic Of*

**Background:** Patients with systemic lupus erythematosus (SLE) are at an increased risk of developing a cardiovascular disease which are not solely explained by the traditional cardiovascular (CV) risk factors. This higher CV risk might be associated with chemical and functional alteration of lipoproteins in SLE patients.
**Objectives:** This study aimed to investigate the lipoprotein modification from SLE patients and its effects on oxidative stress *in vivo* and *in vitro*.
**Methods:** A total of 35 SLE patients and 15 age and sex matched heathy controls (HC) were compared in regard to lipid profile including low density lipoprotein (LDL). Oxidation and susceptibility to oxidation as well as structure of LDL were measured by quantifying malondialdehyde (MDA), *de novo* formation of conjugated dienes in the presence of 5 uM CuSO4 and gel electrophoresis, respectively. The uptake of LDL by THP-1 cells was examined. In *vivo* radial oxygen species (ROS) formation and toxicity of LDL were examined in zebra fish embryos.
**Results:** LDL levels did not differ between SLE and HC (134.7±54.5 mg/dL vs. 118.3±29.9 mg/dL, P=0.277). LDL from SLE showed an increased fragmentation pattern during mobility through electrophoresis gel. As compared to HC-LDL, SLE-LDL were more oxidized (MDA level: 56.1±10 vs. 25.4±2.3 nM/mg, $p<0.001$) and were also more susceptible to cupric-ion-mediated oxidation *in vitro* (3.5±0.5% vs. 1.9±1.9%, $p<0.001$). In addition, more SLE-LDL were engulfed by THP-1 cells than HC-LDL (2501±401.2 AU vs. 524.1±59.8 AU, $p<0.001$). Finally, the zebra fish embryos that were injected with SLE-LDL generated higher levels of ROS (1592±58.7 vs. 459.6±66.4, $p<0.001$) and survived less (survival 49.1±2.8% vs. 87.8±1.2%, $p<0.001$) as compared to those treated with HC-LDL.

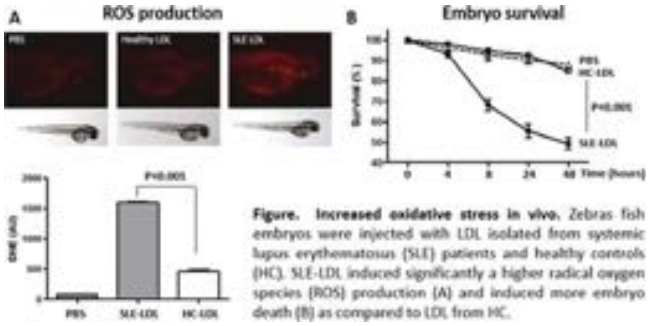

**Figure. Increased oxidative stress in vivo.** Zebras fish embryos were injected with LDL isolated from systemic lupus erythematosus (SLE) patients and healthy controls (HC). SLE-LDL induced significantly a higher radical oxygen species (ROS) production (A) and induced more embryo death (B) as compared to LDL from HC.

**Conclusions:** LDL from SLE patients is altered with increased oxidation, structural instability and an augmented oxidative potential. Treatment with anti-oxidants might normalize the altered LDL property and so decrease the CV risk in SLE patients.

## AB0141 DEPLETION OF LYMPHOID-LIKE STROMAL CELLS IMPAIRS TERTIARY LYMPHOID ORGAN FORMATION IN AN ANIMAL MODEL OF SJÖGREN'S SYNDROME

J. Campos[1], S. Nayar[1], A.P. Croft[1], A.E. Denton[2], D.T. Fearon[2], C.D. Buckley[1], F. Barone[1]. *[1]Centre for Translational Inflammation Research, Institute of Inflammation and Ageing, College of Medical and Dental Sciences, University of Birmingham, Birmingham; [2]Department of Medicine and Cancer Research UK Cambridge Institute, University of Cambridge, Cambridge, United Kingdom*

**Background:** Tertiary lymphoid organs (TLO) characterised by germinal centre formation and B cell proliferation represent the histological hallmark of primary Sjögren's syndrome (pSS). TLO persistence in the salivary glands is associated with systemic disease manifestations and lymphoma development in pSS patients (1).
We previously demonstrated that gp38+ stromal cells are instrumental for TLO development and provide chemokines, such as CXCL13, CCL19 and CCL21 necessary for lymphocyte recruitment and organization (2). Similarly, in the lymph node, FAP+gp38+ lymphoid stromal cells regulate lymphocyte homing and homeostasis. Accordingly, deletion of FAP+gp38+ cells results in aberrant expression of lymphoid survival factors, disrupted lymph node organization and decreased ability to mount efficient immune responses (3, 4).
**Objectives:** To dissect the effects of FAP+gp38+ cell deletion in TLO dynamic and function in an animal model of pSS.
**Methods:** We used a model of conditional depletion of FAP-expressing cells, in which FAP-DTR mice were treated prophylactically with Diphtheria Toxin (DTx). Following depletion, submandibular salivary glands of FAP-DTR mice and littermate controls were intra-ductally cannulated with luciferase-encoding replication-deficient adenovirus to induce TLO formation and pSS-like disease as previously described (5). A combination of immunofluorescence, quantitative RT-PCR and flow cytometry on digested salivary glands was used to address the consequences of stromal cell deletion in the TLOs.
**Results:** We confirmed that in cannulated, inflamed wild-type salivary glands, FAP is upregulated on a population of activated stromal cells that expresses gp38 and produces lymphoid chemokines. As anticipated, analysis of DTx-treated FAP-DTR salivary glands reveals significantly decreased numbers of gp38+ stromal cells and deletion of FAP+ stromal cells leads to a significant defect in lymphoid chemokine production, decreased number of infiltrating lymphocytes and severely compromises TLO formation.
**Conclusions:** These data demonstrate that salivary glands gp38+ activated stromal cells express FAP and are required for TLO organization and maintenance in the tissue. Deletion of activated lymphoid stroma affects lymphocyte recruitment and organization, thus providing the rational for stromal cell targeting in TLO associated autoimmune diseases.

## AB0142 SJÖGREN'S SYNDROME-ASSOCIATED TRANSCRIPTS SHOW CORRELATION WITH OBJECTIVE MEASURES OF DRYNESS

J.A. Ice[1], I. Adrianto[1], A. Rasmussen[1], D.U. Stone[2,3], B.M. Segal[4], N.L. Rhodus[5], L. Radfar[6], C.G. Montgomery[1], R.H. Scofield[1,6,7], K.L. Sivils[1], C.J. Lessard[1]. *[1]Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City; [2]Johns Hopkins University, Baltimore, United States; [3]King Khaled Eye Specialist Hospital, Riyadh, Saudi Arabia; [4]Hennepin County Medical Center; [5]University of Minnesota, Minneapolis; [6]University of Oklahoma Health Sciences Center; [7]US Department of Veterans Affairs, Oklahoma City, United States*

**Background:** Sjögren's syndrome (SS) is a chronic autoimmune disorder in which exocrine dysfunction can lead to chronic, debilitating dryness. Expression studies in SS have identified the dysregulated expression of coding and non-coding transcripts enriched in innate and adaptive immune response pathways.
**Objectives:** In our recent SS RNA-seq study, we identified 3748 transcripts showing differential expression (DE; FC>2 or <0.5, q<0.05) in SS patients compared to healthy controls. Of these SS-associated transcripts,[CL1] we sought to identify transcripts whose expression is significantly correlated with objective measures of dryness employed by the 2002 American-European Consensus Group (AECG) classification criteria of SS, including whole unstimulated salivary flow (WUSF), lissamine green (LG) staining, and Schirmer's (Sch) tear migration.
**Methods:** Normalized expression data from a whole blood SS RNA-seq study was obtained for 57 cases and 11 healthy controls who underwent multidisciplinary clinical evaluation for the 2002 AECG classification criteria. Objective dryness measures (WUSF, LG, & Sch) were normalized by $\log_2$ transformation and correlation analysis (Spearman for WUSF and LG; Pearson for Sch) was performed for each clinical measure against all of 3748 DE transcripts. Both $r$ or $\sigma$ and a FDR-corrected $p$-value, or $q$-value, were calculated. Significantly correlated transcripts were defined by $q<0.05$.
**Results:** For WUSF, the significant positive correlation between WUSF rate and the expression of 2 non-coding transcripts was observed: the small Cajal body-specific RNA 5 (*SCARNA5*; $\sigma$=0.50, $q$=0.018) and the uncharacterized antisense lncRNA RP11–137H2.4 ($\sigma$=0.50, $q$=0.018). For LG, positive correlation was observed for 31 transcripts ($0.42<\sigma<0.51$, $0.017<q<0.05$) mostly represented by interferon-inducible (IFI) protein-coding genes (e.g. *IFIT3*, *OAS3*, and *IRF7)*, although for the pseudogene, *ZDHHC4P1*, and its neighboring IFI gene *EPSTI1* both showed significant positive correlation. For LG, the only negatively correlated transcript was the sodium bicarbonate transporter *SCL4A10* ($\sigma$= -0.43, $q$=0.045). For Sch, 3 transcripts (*CARD16*, *HMGB2*, and *BLC2A1*) were negatively correlated ($-0.51<\sigma<-0.49$, $0.018<q<0.019$), while the transcript *IQCH* was positively correlated ($\sigma$=0.49, $q$=0.019).
**Conclusions:** We identified SS-associated transcripts whose expression correlates with clinical measures of dryness. For WUSF, the ncRNA *SCARNA5* is situated within an intron of the Crohn's disease-associated gene autophagy-related 16-like 1 (*ATG16L1*). Although IFI genes have previously shown correlation with WUSF, the ZDHHC4P1 pseudogene could regulate neighboring SS-associated IFI gene *EPSTI1*. For Sch, *CARD16* is a caspase inhibitor that influences apoptotic responses that induces NF-kB activation in inflammation, while *BLC2A1* has been shown to slow apoptoic responses. Further transcript characterization will allow us to assess their potentialas biomarkers or surrogates of objective clinical measures for SS.

## AB0143 UMBILICAL CORD MESENCHYMAL STEM CELLS INCREASE TREG CELLS VIA SHLA-G IN SLE PATIENTS

C. Chen, J. Liang, W. Chen, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Human leukocyte antigen-G (HLA-G) is a non-classical HLA class I molecule, exhibiting strong immunosuppressive properties by inducing the differentiation of regulatory T cells (Treg). Previous studies showed that umbilical cord mesenchymal stem cells (UCMSCs) transplantation could alleviate disease progression in SLE patients. However, the underlying mechanisms are largely unknown.
**Objectives:** To explore whether sHLA-G was involved in upregulation effects of MSCs on Treg, which contribute to the immune torlerance during SLE.
**Methods:** The level of sHLA-G was detected by ELISA in SLE patients and healthy controls. The correlations between the levels of sHLA-G and clinical features, percentages of HLA-G receptor ILT2 and Treg cells were analyzed by Sparman's correlation test respectively. The percentage of ILT2 on T and B lymphocytes was examined by flow cytometry. PBMC were isolated from SLE patients and co-cultured with UC-MSCs for 3 days at different ratios (50:1, 10:1, 2:1) with or without HLA-G antibodies, and then the frequencies of CD4+CD25+Foxp3+T cells were determined by flow cytometry.
**Results:** The concentration of sHLA-G was increased in SLE patients compared with healthy control subjects (21.76 ng/mL ±1.206 VS 16.84 ng/mL ±1.656, $p<0.05$). However, there was a negative correlation between sHLA-G levels and SLEDAI scores in active SLE patients (SLEDAI >4). We found that sHLA-G levels were negative correlated with urea nitrogen, serum creatinine and 24-hour urine protein but positively correlated with platelet in SLE patients. What's more, the sHLA-G levels were significantly lower in SLE patients with renal involvement compared with those without renal involvement. The expression of ILT2 in CD4+ T cells from SLE patients decreased significantly compared to controls. A positive relationship between the frequency of Treg cells and $CD4^+ILT2^+$ T cells in SLE patients was found. The levels of sHLA-G increased 24 hours post MSCs transplantation. *In vitro* studies showed MSCs increased the frequency of Treg cells in SLE patients in a dose-dependent manner, which was partly abrogated by anti-HLA-G antibody.
**Conclusions:** Our results suggested that UCMSCs could alleviate SLE through upregulating Treg cells partly dependent on sHLA-G.

## AB0144 INTERLEUKIN-17 IMPAIRS SALIVARY TIGHT JUNCTIONS IN NON-OBESE DIABETIC MICE

L.-W. Zhang[1], X. Cong[2], G.-Y. Yu[3], L.-L. Wu[2], H. Hua[1]. *[1]Department of Oral Medicine, Peking University School and Hospital of Stomatology; [2]Department of Physiology and Pathophysiology, Peking University Health Science Center; [3]Department of Oral and Maxillofacial Surgery, Peking University School and Hospital of Stomatology, Beijing, China*

**Background:** Sjögren's syndrome (SS) is an inflammatory autoimmune disease that causes secretory dysfunction of the salivary glands. It has been reported that pro-inflammatory cytokine interleukin-17 (IL-17) was elevated and tight junction (TJ) integrity was disrupted in minor salivary gland from SS patients. The aim of the research was to observe the alteration of TJs in salivary glands of non-obese diabetic (NOD) mice and explore the impact of IL-17 on TJs.
**Objectives:** The aim of the research was to observe the alteration of TJs in

salivary glands of non-obese diabetic (NOD) mice and explore the effect of IL-17 on TJs.

**Methods:** 12-week-old female NOD mice and BALB/c mice were used. Stimulated salivary flow rate and histopathological changes were evaluated. The expression of TJ molecules and IL-17 in SMG and PG were detected by real-time PCR and western blot analysis. Immunohistochemistry was used to observe the distribution of TJ molecules and IL-17 in SMGs and PGs. In addition, the alternation of TJs under the stimulation of IL-17 (50 ng/ml) were evaluated in cultured SMG and PG tissues.

**Results:** Lymphocyte infiltration was mainly observed in submandibular glands (SMGs), but not in parotid glands (PGs) of NOD mice (Fig. A). Likewise, IL-17 was significantly increased and mainly located in lymphocytic infiltrating regions in SMGs, but not detectable in PGs of NOD mice (Fig. B-D). Claudin-1 and -3 were elevated whereas claudin-4, occludin and zonula occludens-1 (ZO-1) were reduced in SMGs of NOD mice. However, no change in the expression of TJ proteins was found in PGs. *In vitro*, IL-17 significantly decreased the protein levels of claudin-4 and ZO-1 in the cultured SMG tissues, as well as claudin-1, occludin and ZO-1 in PG tissues.

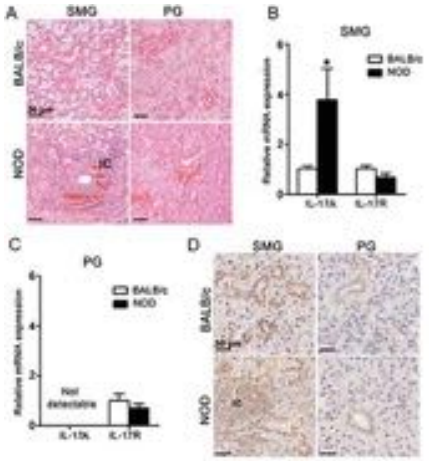

Figure (A) Histological evaluation of SMGs and PGs in BALB/c and NOD mice (B, C) The mRNA expression of IL-17A and IL-17R in SMGs and PGs of BALB/c and NOD mice (D) Immunohistochemical staining of IL-17A in SMGs and PGs of BALB/c and NOD mice.

**Conclusions:** IL-17 derived from infiltrating lymphocyte impairs the integrity of TJ, and thus might contribute to salivary gland dysfunction in SS.

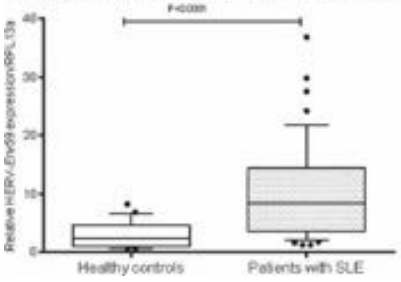
## AB0145 PUTATIVE ROLE OF A GENE ENCODING AN ENDOGENOUS RETROVIRAL ENVELOPE PROTEIN IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

M.J. Laska[1,2,3], A. Troldborg[2,3], E.M. Hauge[1,3], S. Bahrami[1], K. Stengaard-Pedersen[1,3]. *[1]Department of Clinical Medicine; [2]Department of Biomedicine, Aarhus University; [3]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark*

**Background:** Human Endogenous Retroviruses (HERVs) are remnants of past retroviral infections in the human genome. Most of HERV elements have accumulated mutations and deletions and thus have become inactivated with time. At the same time the presence of open reading frames (ORFs) in only a few HERV genes, suggest an evolutionary selective pressure to maintain the protein coding capacity of some HERV envelope ORFs (1).



HERVs have been implicated both in diseases such as cancers and autoimmune disorders but interesting also shown to have been adapted to play a role in important aspects of human biology such as development of the placenta.

**Objectives:** We aimed to identify HERVs which affect development of Systemic Lupus Erythematosus (SLE) and to describe what role such putative HERV elements might play in autoimmunity.

**Methods:** The study subjects compromised 45 female patients with SLE and 50 geographically and age matched healthy female controls, recruited consecutively from Aarhus University Hospital, Denmark. Using real-time RT-PCR strategy we analyzed transcriptome of 11 genes with coding capacity for complete envelope protein in Peripheral Blood Mononuclear Cells (PBMCs) isolated from SLE patients or healthy controls. The Mann-Whitney *U* test analyzes showed that the expression of HERV-H *Env59* gene in SLE patients was significantly higher than in healthy controls. Subsequently we cloned the *Env59* envelope gene and using psuedotyped lentiviral particles, examined whether it retains its activity as a retroviral fusion protein. A sequence analysis of the protein identified an immune suppressive domain (ISD). A peptide corresponding to this ISD was synthesized and examined *in vitro* for immune suppressive activity on stimulated human PBMCs and the monocytic THP-1 cells line.

**Results:** We found that a specific HERV-H derived *Env* gene (Env59) is overexpressed in SLE patients ($P<0.0001$). Interestingly, we found that the expression of this gene is negatively correlated with etiological factors of autoimmune rheumatic diseases such as IL-6 ($P=0.0065$) and TLR-7 ($P=0.02$) in patients. This gene is capable of encoding a fully functional envelope glycoprotein and contains a domain which shows strong anti-inflammatory activity including the ability to lower IL-6 levels *in vitro*.

Figure 1 Expression of HERV-Env59 mRNA in patients with SLE and healthy controls

**Conclusions:** We interpret these results to show that the *Env59* gene has been adapted by the immune system as a control mechanism in autoimmunity. More precisely the activity of the immune suppressive domain of this retroviral envelope protein seems to be directly responsible for lower IL-6 levels in some SLE-patients. The ISD peptide derived from this retroviral gene shows anti-inflammatory activity *in vitro* and represents a potentially new strategy for treatment of autoimmune diseases.

## AB0146 SELF-REACTIVE IGE EXACERBATES INTERFERON RESPONSES ASSOCIATED WITH AUTOIMMUNITY

M.A. Sanjuan[1], J. Henault[2], J. Riggs[2], J.L. Karnell[1], V. Liarski[3], L. Shirinian[4], L. Xu[4], K. Casey[5], M.A. Smith[5], D. Khatry[4], L. Clarke[4], R. Herbst[4], R. Ettinger[4], M. Petri[6], M.R. Clark[3], T. Mustelin[4], R. Kolbeck[4]. *[1]RIA, Medimmune, Gaithersburg, MD; [2]RIA, Medimmune, Gaithersburg; [3]University of Chicago, Chicago; [4]Medimmune, Gaithersburg, MD; [5]Medimmune, Gaithersburg; [6]Johns Hopkins University School of Medicine, Baltimore, MD, United States*

**Background:** The discovery of Immunoglobulin E (IgE) nearly 40 years ago was a breakthrough in the field of allergy research. IgE directed against parasitic worms and allergens binds mast cells and basophils, triggering an inflammatory response that is characterized by the release of histamine and Th2 cytokines.

Here we report that double-stranded DNA (dsDNA)-specific IgE autoantibodies complexed to DNA activate plasmacytoid dendritic cells (pDC), an immune cell type linked to viral defense, leading to the secretion of substantial amounts of IFN-a. Although typical IgE mediated responses are not a hallmark of systemic lupus erythematosus (SLE), IFN-a producing pDCs are a key driver for loss of immune tolerance to host DNA in SLE. We, therefore, investigated this apparent paradox and found that even the small concentrations of circulating dsDNA-specific IgE found in SLE patients greatly potentiated pDC secretion of IFN-a by triggering phagocytosis via the Fc-epsilon receptor I (FceRI) and TLR9-mediated DNA sensing in the phagolysosome. Consequently, this potent pDC signaling mechanism reduces the threshold of pDC activation, which has the potential to expand anti-DNA responses and greatly exacerbate self-inflicted damage. These findings expand the known pathogenic mechanisms of IgE mediated inflammation beyond those found in allergies and demonstrate that, in addition to recognizing exogenous allergens, IgE can also bind to autoantigens and drive an aberrant and self-destructive anti-viral response. This previously unrecognized link between IgE and the interferon pathway provides additional insights into the pathological mechanisms underlying autoimmunity and may be useful in the rational design of therapies for the treatment of diseases such as SLE.

## AB0147 STUDY THE SYNCHRONOUS EFFECT OF INTENSIVE CARE TO CONDITION OF CARDIOVASCULAR SYSTEM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

E.R. Djurayeva, F.K. Ziyayeva, N.A. Ganiyeva, M.B. Kasymova, D.U. Berdiyeva. *Internal disease, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** To date, little is known about the pathogenesis, course and efficacy of cardiac complications of systemic lupus erythematosus (SLE), which requires the development of new therapies that allow to increase the life expectancy of patients.

**Objectives:** To study the effect of simultaneous intensive therapy on cardiovascular system in SLE.

**Methods:** The study involved 92 patients with SLE at the age of 18–55 years, with disease duration from 2 to 23 years. We analyzed the traditional cardiovascular risk factors, disease activity (SLEDAIK2, EKLAM).

**Results:** The vast majority of patients - 72 (78.6%) - revealed a subacute variant of the disease, and the average level of activity (80.2%). The classic cardiovascular risk factors were observed in 85 (92.3%) patients. Depending on the treatment options for the patients were divided into the following groups: I group - 32 patients received the classic three-day pulse therapy - metipred or Solu-Medrol 1000 mg/day and the second day of cyclophosphamide 1000 mg/day, against the background of glucocorticosteroids (GCS) according to the degree activity. Group II - 24 patients underwent synchronous intensive therapy: 2–3 sessions of plasmapheresis followed by 1000mg metipred (solumedrol), against GCS disease activity, respectively, III group - 36 patients received conventional therapy with oral administration in dose of Valium 20–40mg/day.

Patients of group II marked a complete stabilization of clinical symptoms, decrease in activity, the positive dynamics of cardiovascular manifestations.

**Conclusions:** Thus, the ineffectiveness of the standard basic therapy in SLE patients should include the feasibility of timely implementation of synchronous pulse therapy, which helps to reduce cardiovascular complications and improves the quality of life of patients.

**Disclosure of Interest:** None declared

## AB0148 DIFFERENTIAL PERIPHERAL B-CELL PHENOTYPE IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME (PSS) COMPARED TO SECONDARY SJÖGREN'S SYNDROME ASSOCIATED WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE/SS)

N.L. Thompson, D.A. Isenberg, E. Jury, C. Ciurtin. *Rheumatology, University College London, London, United Kingdom*

**Background:** Peripheral B-cell abnormalities are a feature of both lupus (SLE) and primary Sjogren's syndrome (pSS). However, whereas patients with pSS have increased frequencies of Bm1/Bm2 (naïve), Bm2' (germinal centre founders) and Bm3–4 (centroblasts/centrocytes), but decreased Bm5 (memory) compared with healthy controls (HC), patients with SLE have increased Bm5 levels, which correlated with disease activity. No previous studies investigating the peripheral B-cell phenotype in patients with SLE and secondary SS (SLE/SS) are available.

**Objectives:** We questioned whether the defective B-cell phenotype in pSS patients was also present in patients with SS/SLE, and whether differences in B-cell phenotype could be related to changes in B-cell lipid-raft expression and BAFF-receptor function in pSS and SLE/SS patients.

**Methods:** Blood samples and clinical and laboratory parameters from 32 patients with pSS and SS/SLE and 13 age/sex matched HC were obtained. We used flow-cytometry to perform B-cell immunophenotyping and analysis of lipid-raft expression (marker of B-cell activation). *In vitro* cultures assessed lipid-raft expression in response to BAFF.

**Results:** Patients with SLE/SS had a district B-cell phenotype, characterised by decreased Bm1 and Bm5 and increased Bm2 populations compared to HC ($p=0.031$, $p=0.035$ and $p=0.01$, respectively), and increased Bm2 compared to pSS ($p=0.027$). Bm1-cells were decreased in both pSS and SLE/SS patients compared to HC ($p=0.028$ and $p=0.031$, respectively). Both age and disease duration correlated strongly with Bm2' cells in SLE/SS patients ($r=0.9572$, $p=0.0428$), and the immunosuppressive treatment correlated negatively with the number of circulating Bm2 and Bm2' cell in pSS ($r = -0.54$, $p=0.01$ and $r = -0.56$, $p=0.008$, respectively). B-cells from patients with pSS had a significant increase in lipid-raft expression compared to HC ($p=0.01$) and patients with SS/SLE ($p<0.05$). Furthermore, lipid-raft levels correlated with BAFF-receptor expression in HC and SLE/SS B-cells ($p=0.17$, $r=0.694$) but not in pSS patients. Both disease activity score (ESSDAI) and IgG level correlated positively with lipid rafts expression in B cells from patients with pSS ($r =0.79$, $p=0.004$ and $r =0.53$, $p=0.04$, respectively).

**Conclusions:** We showed that patients with SLE/SS had more significant B-cell abnormalities compared to HC and pSS, detectable even in a small number of patients. Also the relationship between lipid-raft and BAFF-receptor expression was altered between pSS and SLE/SS patients, and correlated with the disease activity and Ig G levels in pSS group. Further studies will validate our findings and investigate whether B-cell lipid-rafts mediate differential BAFF-receptor signalling.

## AB0149 ASSOCIATIONS OF ANTI NUCLEOSOME ANTIBODY IN SYSTEMIC LUPUS ERYTHEMATOSUS IN INDIA

N. Gupta[1], J.K. Doss[1], H. Mohan[1], A. Nair[1], T. Sebastian[2], D. Danda[1]. *[1]Clinical Immunology & Rheumatology; [2]Biostatistics, CHRistian Medical College, Vellore, India*

**Background:** Nucleosomes are basic elements of chromatin and are considered to be the major antigens in the pathophysiology of systemic lupus erythematosus (SLE).

**Objectives:** This study aimed to look for associations between anti nucleosome antibodies and clinical and laboratory parameters in SLE

**Methods:** This retrospective study was done in department of Clinical immunology & Rheumatology in Christian Medical College, Vellore, India. Patients with SLE by SLICC 2012 criteria between March 2013 and September 2015 subjected to anti nucleosome antibody test formed the study cohort. A cut off of $\geq$20 U/ml by ELISA was defined as per manufacturer's (Euroimmune, Germany) instructions. Associations of anti nucleosome antibody with clinical and laboratory parameters in SLE was studied.

**Results:** Anti nucleosome antibody was available for 238 patients with SLE. Mean age of the patients was 28.98±9.01 years with male to female ratio of 17: 221. Median disease duration was 8 (5–12) months prior to doing this test. Positive titers of anti nucleosome antibody ($\geq$20 U/ml) were noted in 107 patients (46.5%). Renal involvement was seen in 134 (56.3%) patients. Univariate analysis reflected raised anti-c1q antibody, ESR, urinary protein creatinine ratio (UPC), anti dsDNA antibody, SLE disease activity index (SLEDAI), renal SLEDAI, low C3 and C4 as significant association of elevated anti nucleosome antibody levels. No significant association with arthritis, serositis, major infections, serositis, anti-phospholipid antibodies, autoimmune hematological cutaneous, neuropsychiatric, cardiovascular, respiratory, vasculitic and gastrointestinal manifestation was present.

Multivariate regression analysis showed that raised anti-c1q antibodies and DsDna were associated with raised anti nucleosome antibody with odds ratio of 17.46 (95 CI: 1.46–213.86, $p=0.02$) and 82.94 (95 CI: 3.62–189.93, $p=0.006$) respectively.

**Conclusions:** As per literature search, this is the largest single centre study of anti nucleosome antibody in SLE. In this study, raised anti-c1q antibodies and DsDna were independently associated with raised anti nucleosome antibody in SLE.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4237

## AB0150 UNDERSTANDING THE ROLE OF THE IL12/IL35 BALANCE IN SJÖGREN SYNDROME

O. Fogel[1,2], E. Rivière[2], R. Seror[3], G. Nocturne[3], B. Ly[2], S. Boudaoud[2], J.-E. Gottenberg[4], J.-J. Dubost[5], V. Le Guern[6], P. Dieudé[7], P. Chanson[3], J. Nititham[8], K. Taylor[8], L. Criswell[8], X. Mariette[3], C. Miceli-Richard[6]. *[1]CHU Purpan, Toulouse; [2]Inserm UMR1184; [3]CHU Bicetre, Paris; [4]CHU Hautepierre, Strasbourg; [5]CHU Gabriel Montpied, Clermont-Ferrand; [6]Chu Cochin; [7]CHU Bichat, Paris, France; [8]UCSF, San Francisco, United States*

**Background:** Primary Sjögren Syndrome (pSS) is an autoimmune disease mediated by B-cells as evidenced by the occurrence of non-Hodgkin lymphoma mainly involving salivary glands and increased B-cell activation markers in the serum of pSS patients. A type I interferon response is also observed among some patients. However, some mice models and large genetic studies suggest an alternative/coexisting involvement of the Th1 pathway in the pathophysiology of the disease. In fact, polymorphisms of *IL-12A*, which encodes for IL-12p35, have been associated with pSS[1]. IL-12p35 subunit is shared by 2 heterodimers, IL-12 and IL-35.
**Objectives:** To confirm the genetic association of *IL-12A* polymorphism with pSS and to elucidate the involvement of the IL-12/IL-35 balance in pSS through functional studies.
**Methods:** The genetic studies were performed on French pSS from 2 cohorts. Functional studies were performed on sorted monocytes and stimulated *ex vivo* under inflammatory conditions. Interleukin-12A mRNA, IL-12 and IL-35 proteins were quantified by qRT-PCR for mRNA and by ELISA and multiplex kit respectively for IL-35 and IL-12.
**Results:** We confirmed the association between rs485497 and pSS and found an increased level of IL-12 in sera of pSS patients carrying the risk allele (p=0.016). IL-12 was increased in pSS compared to healthy controls (p=0.0001), especially in patients with a more active disease contrary to IL-35 which was decreased in pSS (p=0.0001). We observed that 99% of patients with high serum levels of IL-35 did not developed lymphoma *versus* 93% in the group with low IL-35 (p=0.03).
**Conclusions:** Our findings emphasize the involvement of the balance IL-12/IL-35 in the pathogenesis of pSS. Further studies especially on regulatory B-cells and plasma cells as well as in animal models of autoimmune diseases assessing the effect of recombinant IL-35, would help to decipher whether this regulatory cytokine could be of interest for future therapeutic approaches.

## AB0151 ANTI-MAJOR VAULT PROTEIN: A NEW AUTOANTIBODY PREVALENT IN SYSTEMIC LUPUS ERYTHEMATOSUS

P. Budde[1], S. Vordenbäumen[2], H.-D. Zucht[1], P. Schulz-Knappe[1], M. Schneider[2]. *[1]Protagen AG, Dortmund; [2]Dept. Rheumatology & Hiller Research Unit Rheumatology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany*

**Background:** Systemic lupus erythematosus (SLE) is a complex, multifactorial autoimmune disease that affects multiple organ systems, including the kidney, skin, heart, lung, and hematopoietic and nervous systems. A hallmark of SLE is the production of high titers of autoantibodies against a broad spectrum of antigens. Given the broad spectrum of immune defects in SLE, it may be possible that autoantigens are generated by different pathogenic processes.
**Objectives:** Broad autoantibody profiling in SLE may yield novel autoantibody targets for and may shed light on pathogenic pathways leading to the generation of autoantigens.
**Methods:** In the discovery phase the autoantibody reactivity of serum samples from 130 SLE patients, 794 AID patients (systemic sclerosis, rheumatoid arthritis/RA, early RA, ankylosing spondylitis) and 343 healthy controls was tested against 6,912 recombinant human proteins. Following validation in independent SLE samples (n=101), consistent autoantibody reactivity against 46 antigens was found (p-value $<0.05$ and Cohen's d effect size $<0.3$).
**Results:** A data base search of 46 known and novel SLE-associated antigens revealed that the expression of ten proteins is upregulated by type I interferon (INF) (http://www.interferome.org). Beyond known antigens (TRIM21/Ro52, SSB), we identified a novel autoantibody target MVP with a frequency of 20 -38% in SLE. Interestingly, MVP is the major constituent of the vault particle, the largest known ribonuclear protein complex. Literature data suggest that vaults are involved in a diversity of cellular processes, including multidrug resistance, transport mechanisms, signal transmission, autophagy, immune and radiation response [1].
**Conclusions:** MVP is a virus- and INF$\gamma$-induced and host factor, which up-regulates type I INF production [2]. Although more studies are needed, our findings suggest a previously undescribed linkage of INF pathways and the generation of autoantigens.

## AB0152 CLUSTERED AUTOANTIBODY REACTIVITY PROFILES AND DEFINITION OF HOMOGENEOUS SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENT GROUPS

P. Schulz-Knappe[1], P. Budde[1], H. Goehler[1], H.-D. Zucht[1], M. Schneider[2], S. Vordenbäumen[2]. *[1]Protagen AG, Dortmund; [2]Policlinic of Rheumatology, Heinrich-Heine-University, Düsseldorf, Germany*

**Background:** In SLE, early diagnosis, differentiation to other autoimmune diseases and prognostic stratification are still great challenges. Hence, SLE represents an enormous challenge for the clinical development of effective therapies. Detecting a broad set of SLE-associated autoantibodies might help to utilize overall reactivities, co-prevalence and similarities of autoantibody reactivities in SLE patients. Such measures are expected to generate homogeneous SLE-subgroups which may represent common underlying pathophysiologies with different response to medicines and hence orffer improved medical care options.
**Objectives:** Here, we describe the development of a multiplexed autoantibody assay incorporating over 40 known SLE-antigens plus novel human protein antigens derived from large scale autoantibody screening in SLE and other autoimmune diseases such as rheumatoid arthritis, systemic sclerosis and healthy controls, The resulting assay is intendedto comprehensively analyse 87 autoantibodies in SLE patients for disease subgroupd formation.
**Methods:** A Luminex bead-based autoantibody assay was designed by combining traditional with novel biomarkers. Antigens were selected to be used for a) the diagnosis and b) differential diagnosis of SLE, have previously been linked to c) disease activity, and d) specific organ involvement, are encoded by e) interferon type I response genes, and f) may have utility for patient subgrouping. Autoantibody reactivity against these antigens was tested in over 700 SLE, healthy controls (n=1000), and autoimmune disease samples (n=500).
**Results:** Based on the individual marker pattern, we defined an autoantibody reactivity score and four SLE patient clusters (C1-C4) including patients: C1: with a higher disease activity score, broad and homogeneous autoantibody reactivity; C2: with broad, but heterogeneous autoantibody reactivity; C3) who have few autoantibodies and C4) with unusual autoantibody pattern.
**Conclusions:** High content autoantibody profiling of SLE patients reveals relevant differences in autoantibody reactivities both in amount of total reactivity as well as towards autoantibody clusters indicating specific pathophysiologies. Although more studies are needed, our findings suggest that SLE patients can be stratified into distinct, homogenous subgroups. This might be useful in clinical studies to increase the probability of successful drug development.

## AB0153 REDUCED REGENERATIVE POTENTIAL OF SALIVARY GLAND STEM CELLS IN PRIMARY SJÖGREN'S SYNDROME

S. Pringle, H. Bootsma, G.M. Verstappen, A. Vissink, F.K.L. Spijkervet, R.P. Coppes, F.G.M. Kroese. *Rheumatology and Clinical Immunology, University Medical Centrum Groningen, Groningen, Netherlands*

**Background:** The involvement of the epithelium in the pathology of primary Sjögren's syndrome (pSS) has long been proposed. Epithelial cells have potential to transmit immune initiation signals and to serve as autoimmune targets, in addition to their function as saliva channeling/modulating agents in the salivary gland. Recently, we have demonstrated isolation of stem cells from the human salivary gland [1–2]. Salivary gland stem cells (SGSCs) are cultured as clusters of cells, termed salispheres. SGSCs, like all stem cells, possess the ability to self-renew (reproduce themselves) and to differentiate into all salivary gland lineages. Our ability to isolate and characterize the epithelium-derived SGSCs provides a tool to study the involvement of epithelial cells in pSS pathology.
**Objectives:** We aim to isolate SGSCs from biopsies of pSS parotid salivary glands, and characterize their regenerative potential in comparison to healthy controls. This will be a first step towards to assessment of complicity of SGSC/epithelial malfunction in pSS, and in identifying any innate properties specific to pSS-SGSCs.
**Methods:** Salivary gland stem cells were isolated using enzymatic and mechanical digestion, in a protocol adapted from Pringle et al, 2016. The self-renewal capability of pSS-SGSCs was assessed using our published self-renewal assay. The potential immunomodulatory nature of pSS-SGSCs was assessed using

qPCR for expression of matrix metalloprotease (MMP) enzymes, and mass spectrometry for identification of immune-related proteins in the medium.
**Results:** Yield of SGSCs from pSS biopsies was markedly lower than from healthy control tissues (Figure 1 A-C). When exposed to a self-renewal assay, SGSCs from pSS biopsies generated significantly fewer SGSCs (Figure 1 D-F). Expression of MMP2 and MMP9 was notably higher in SGSCs isolated from pSS biopsies. In addition, proteins involved in both pro-inflammatory (polymeric immunoglobulin receptor, immunoglobulin kappa constant) and anti-inflammatory (annexin A1) immunereactions and in rheumatoid arthritis (rheumatoid arthritis antigen A-47) were detected in conditioned medium from pSS SGSCs at greater levels than controls. These data suggest the transcriptome and secretome of SGSCs from pSS biopsies differs significantly from that of healthy controls.

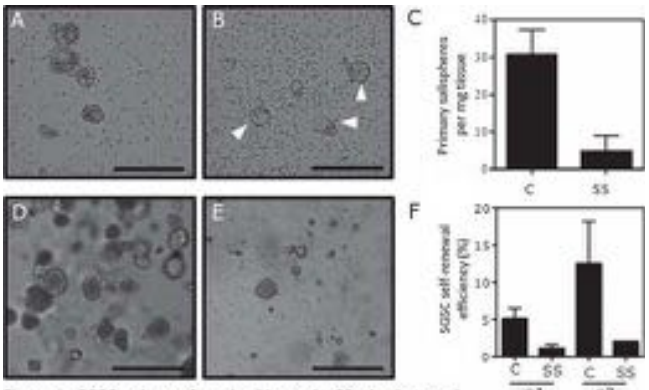

Figure 1. SGSC cultures from healthy and pSS glands reveal regenerative disadvantage in pSS samples. Bar = 50 µM. Arrowheads = salispheres with fewer cells.

**Conclusions:** Our preliminary data demonstrates that the established SGSC isolation technique can be applied to the study of primary Sjögren's Syndrome. Furthermore our data suggest there is an an innate difference in the regenerative potential and immune-reactive nature of SGSCs from pSS biopsies, compared to healthy controls. We anticipate that full characterization of SGSC from pSS biopsies will at least shed light on the mechanisms underpinning epithelial cell involvement in pSS, and permit development of new therapeutic and/or biological agents for the treatment of primary Sjögren's' Syndrome.

## AB0154 ROLE OF PRO-INFLAMMATORY CYTOKINES IN THE ENDOPLASMIC RETICULUM ASSOCIATED-PROTEIN DEGRADATION IN SJÖGREN'S SYNDROME PATIENTS

M.-J. Barrera[1], S. Aguilera[2], I. Castro[1], J. Cortés[1], V. Bahamondes[1], U. Urzúa[1], S. González[3], C. Molina[3], C. Leyton[1], M.-J. González[4]. *[1]ICBM, Facultad de Medicina, Universidad de Chile; [2]Reumatología, Clínica INDISA; [3]Patología Oral, Universidad Mayor; [4]Programa de Biología Celular y Molecular, ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile*

**Background:** Due to its high secretory activity and the complexity of synthesized secretory products, salivary gland (SG) acinar cells are susceptible to endoplasmic reticulum (ER) stress under physiological conditions. ER stress triggers a mechanism known as the "Unfolded Protein Response" (UPR) aiming to restore ER homeostasis. Various ER stress-related disorders have been described in SG of Sjögren's syndrome (SS) patients, including intracellular accumulation of mucins (1) and dilated ER cisternae (2). Also, high levels of pro-inflammatory cytokines present in SG of SS-patients may act as local ER stressors and may play an important role in ER stress induction and perpetuation (chronicity). Previous results from our laboratory indicate a decreased activation of the IRE1α/XBP-1s pathway of the UPR (unpublished data) indicating a chronic ER stress condition. Despite this, the SG acinar cells from SS-patients have low levels of apoptosis (3), suggesting that alternative UPR pathways such as ATF6α could be activated. ATF6α pathway promotes survival mechanisms such as ER-associated protein degradation (ERAD), which has been found hyper-activated in arthritis rheumatoid (4).
**Objectives:** To determine the expression and localization of ATF6α pathway components and molecules participating in ERAD in labial SG (LSG) of SS-patients. The effect of pro-inflammatory cytokines on both ERAD and cell survival was also studied using LSG extracts of SS patients and a three-dimensional (3D) acini model.
**Methods:** Expression of ATF6α, ERAD-components, pro-inflammatory cytokines, cIAP2 and cleaved-caspase-3 were determined in SG of SS-patients and controls by Western-blot and qPCR. Localization of selected molecules was evaluated by immunofluorescence. Correlation between cytokines and ERAD-components was analyzed with the Pearson's test. ATF6α and ERAD activation, pro- and anti-apoptotic markers and cell viability were determined in a 3D HSG cell culture system treated with cytokines.
**Results:** LSG of SS-patients showed high cytokines levels and high activities of ATF6α and ERAD pathways. No significant differences in cleaved-caspase-3 and cIAP2 levels between both groups were observed. Significant positive correlations were observed between pro-inflammatory cytokines and ERAD-components expression levels. These correlations were demonstrated in *in vitro* 3D cell cultures treated with TNF-α and/or IFN-γ for prolonged times, without increased apoptosis.
**Conclusions:** In SS-patients, the permanent action of pro-inflammatory cytokines establishes a chronic ER stress condition with ATF6α pathway activation and increased ERAD mechanism. Higher ATF6α pathway levels would increase ERAD activity, which may help to control chronic ER stress and prevent death by apoptosis.

## AB0155 MICRORNA-155 MEDIATES AUGMENTED CD40 EXPRESSION IN LUPUS PLASMACYTOID DENDRITIC CELLS

Y. Sheng[1], A.L.Y. Yim[1], R.C.Y. Tam[1], A. Chan[1], L. Lu[2], C.S. Lau[1], V.S.F. Chan[1]. *[1]Division of Rheumatology and Clinical Immunology, Department of Medicine; [2]Department of Pathology, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong*

**Background:** Systemic lupus erythematosus (SLE) is a chronic multi-organ autoimmune disease characterized by hyperactivated immune responses to self and persistent systemic inflammation. In addition to autoreactive T and B cells, dendritic cells also play an important role in inducing inflammation. Previously, we have reported abnormalities in circulating and bone marrow (BM)-derived plasmacytoid dendritic cells (pDCs) from SLE patients which suggested that pDCs may play a role in mediating SLE pathogenesis[1–3].
**Objectives:** In this investigation, we aim to seek for potential regulators that mediate functional aberrations of pDCs in SLE.
**Methods:** Bone marrow-derived pDCs from NZB/W F1 mice before and after the disease onset were compared for costimulatory molecule expressions and toll-like receptor (TLR) 7 stimulated responses. TLR7-induced microRNA (miRNA) profile changes in pDCs were examined to identify specific miRNA regulator. Functional validation of specific miRNA was further studied by transfection of miRNA mimics.
**Results:** *In vitro* derivation of pDCs from BM of pre-symptomatic and symptomatic NZB/W F1 mice showed similar basal expression of co-stimulatory molecules and TLRs -7 and -9. Functionally, symptomatic pDCs exhibited hypersensitivity to TLR7 but not TLR9 stimulation, as represented by the elevated upregulation of CD40, CD86 and MHC class II molecules upon R837 stimulation. In miRNA profiling, a significantly higher induction of miR-155 in symptomatic pDCs following TLR7 stimulation was observed. The transfection of miR-155 mimics in pre-symptomatic pDCs induced an augmented expression of *Cd40* which is consistent with the increased CD40 expression in symptomatic pDCs. *Cd40* expression was also found to negatively correlate with the miR-155 target *Ship1* in pDCs.
**Conclusions:** Overall, results from the current study provide evidence for miR-155-mediated regulation in pDC functional abnormalities in SLE. Findings from this study contribute to a better understanding of SLE pathogenesis and ignite future interests in evaluating the molecular regulation in autoimmunity.

## AB0156 QUANTITATIVE PROTEOMIC APPROACHES FOR IDENTIFYING URINARY BIOMARKERS IN LUPUS NEPHRITIS

V.G. Anania[1], M. Cascino[2], L.L. Dragone[2], C. Looney[1], J. Rae[1], P. Liu[3], W. Sandoval[3], T.R. Katsumoto[2], M. Neighbors[1], A. Morimoto[1], A.E. Herman[1], W.R. Mathews[1]. *[1]Biomarker Development; [2]Clinical Science; [3]Research, Genentech, South San Francisco, United States*

**Background:** Lupus nephritis (LN) is a severe clinical manifestation of systemic lupus erythematosus (SLE) associated with significant morbidity and mortality. Assessment of severity and activity of renal involvement in SLE requires a kidney biopsy, an invasive procedure with limited prognostic value. Despite years of research, a need remains for proximal, non-invasive biomarkers to help inform treatment decisions and to monitor disease activity and progression. Recent retrospective studies have revealed that baseline urine protein-creatinine ratio (UPCR) and reduction in UPCR during induction therapy are significantly associated with renal outcome[1]. Although proteinuria is highly correlated with disease progression in LN, the composition of the urinary proteome of LN patients remains poorly characterized.
**Objectives:** To better characterize the urinary LN proteome, we performed a preliminary proteomics study comprised of three complimentary discovery proteomic methods to identify urinary biomarkers of LN.
**Methods:** Urine samples from three female patients with biopsy confirmed LN, high proteinuria (>3 mg/mmol, and low serum complement C3 (<80 mg/dL) were compared to age- and gender- matched healthy controls. These samples were profiled using three mass spectrometry-based methods: 2D SDS-PAGE fractionation, a chemical labeling approach using tandem mass tags, and a label free data-independent acquisition (DIA) method.
**Results:** Using these combined approaches >2600 proteins were identified, 290 of which are up-regulated >2-fold in LN samples compared to healthy controls. While the chemical labeling approach enabled identification of more total proteins (2,598 with chemical labeling vs. 919 with DIA, 1% False Discovery Rate), the DIA approach outperformed the chemical labeling approach in identification of proteins significantly up-regulated in LN samples (52 with chemical labeling vs. 173 with DIA).
**Conclusions:** These results suggest that DIA-based approaches are less biased towards high abundance analytes and therefore potentially more suitable for proteomic profiling of biological matrices with a broad dynamic range like urine. Furthermore, candidate biomarkers identified using the DIA method are easily adapted into a targeted, multiplexed mass spectrometry assay suitable for absolute quantitation of candidate biomarkers in a clinical trial. Results from this study will be used to inform longitudinal and interventional studies focused on understanding the biological implications of these candidate biomarkers and to direct development of novel tools to evaluate disease progression and treatment efficacy of current and future LN therapeutics.

## AB0157 FC GAMMA RECEPTOR EXPRESSION PROFILE IN PEDIATRIC-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

V. Williams, A. Rawat, A. Gupta, S. Singh. *Pediatrics, Advanced Pediatrics Centre, PGIMER, Chandigarh, India*

**Background:** Polymorphisms in the Fcγ receptor (FcγRI, FcγRIIa, and FcγRIIb and FcγRIIIa genes) have been associated with an increased susceptibility to autoimmune diseases including SLE and up-regulation of these may vary with disease activity and infection. There is a paucity of data on FcγR expression pattern in pediatric subjects with SLE.
**Objectives:** To assess the expression of CD 64 (FcγRI), CD32b (FcγRIIb) and CD16 (FcγRIII) on B lymphocytes, neutrophils and monocytes in children with pediatric-onset SLE (pSLE) and their correlation with disease activity as estimated by the SLEDAI score.
**Methods:** A cross - sectional descriptive study was conducted at PGIMER, Chandigarh, India. Children aged between 0 and 15 years fulfilling American College of Rheumatology classification criteria (1997) for SLE were enrolled. The study population was divided into active and inactive group using SLEDAI score. Controls were age and sex matched.
Blood samples of cases and controls were assessed for CD 64, CD32b, and CD16 expression on B lymphocytes, neutrophils and monocytes by flow cytometry using standard techniques. Median fluorescence intensity (MFI) and percentage of cells expression were calculated using the FACS DIVA software and Kaluza software.
**Results:** Thirty one children with SLE (14 in active group) and 13 controls were analyzed. The median values of percentage expression of CD 64 on lymphocyte and monocytes and MFI of CD16 on neutrophils in cases and control are tabulated.
Statistically significant difference ($p<0.05$) in expression of CD64 on lymphocytes, MFI of CD16 on neutrophils was noted in cases as compared to controls, while there was no difference between active and inactive cases. No difference was noted in expression of CD64 on monocytes between cases and controls.CD20 was reduced in cases probably secondary to therapy.
**Conclusions:** The percentage expression of CD 64 expression in lymphocytes and MFI of CD 16 expression in neutrophils were increased in patients of pSLE but no significant association was obtained with disease activity. There is paucity of data in pSLE and thus further studies are warranted to substantiate our finding. No correlation of CD16 and CD32b expression with disease activity was noted in our cohort, probably due to the small sample size.

## AB0158 THE EXPRESSION OF BLIMP-1 IN B CELLS IN PERIPHERAL BLOOD FROM PATIENTS WITH SLE AND ITS CLINICAL SIGNIFICANCE

M. Wang, Y. Zhou, L. Jin, X. Fang, X. Li, G. Wang, X. Li. *Rheumatology and immunology, Anhui Provincial Hospital, Hefei, Anhui, PR China, Hefei, Anhui, China*

**Objectives:** To detect the mRNA expression of B lymphocyte induced maturation protein-1 (Blimp-1) in $CD19^+$ B cells in peripheral blood of patients with systemic lupus erythromatosus (SLE) and healthy controls, and explore its clinical significance.
**Methods:** Expression level of Blimp-1 mRNA in $CD19^+$B cells in peripheral blood was determined by real-time PCR in 40 SLE patients and 20 healthy controls. The ratio of $CD19^-CD138^+$ plasma cells to $CD19^+$ B cells and the ratio of $CD19^+CD27^+$ memory B cells to $CD19^+$ B cells were studied by flow cytometry in peripheral blood of two groups.
**Results:** 1. The expression level of Blimp-1 mRNA in $CD19^+$ B cells in peripheral blood od SLE patients was higher than that in healthy controls ($P<0.05$), and the expression level of Blimp-1 in active SLE patients was higher than that in inactive SLE patients ($P<0.05$). 2. The $CD19^-CD138^+$ plasma cells/$CD19^+$ B cells ratio was increased in SLE patients compared to healthy controls ($P<0.01$), and the $CD19^-CD138^+$ plasma cells/$CD19^+$ B cells ratio in active SLE patients group was higher than that in inactive SLE patients ($P<0.05$). However, the $CD19^+CD27^+$ memory B cells/$CD19^+$ B cells ratio showed no significantly different between SLE patients and healthy controls ($P>0.05$). 3. The expression level of Blimp-1 was positive correlated with the $CD19^-CD138^+$ plasma cells/$CD19^+$ B cells ratio ($r_s=0.336$, $P=0.034$), positive correlated with anti-dsDNA antibody and immunoglobulin G ($r_s=0.493$, $P=0.006$; $r_s=0.527$, $P=0.004$), positive correlated with anti-nucleosome antibody and anti-C1q antibody ($r_s=0.452$, $P=0.040$; $r_s=0.522$, $P=0.015$), negative related with white blood cell count and platelet count ($r_s= -0.367$, $P=0.046$; $r_s= -0.386$, $P=0.035$).
**Conclusions:** The expression of Blimp-1 was up-regulated in SLE patients and significantly correlated with plasma cells, which suggests that Blimp-1 may be involved in the pathogenesis of SLE by promoting plasma cells differentiation.

## AB0159 PROLACTIN INDUCES INTERFERON REGULATORY FACTOR 1 ACTIVATION AND HISTONE H4 HYPERACETYLATION IN PRIMARY MONOCYTES COMPARABLE TO CHANGES SEEN IN MONOCYTES FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Y.T. Leung[1], K. Sullivan[2], L. Shi[3], K. Maurer[3], L. Song[3], M. Petri[4]. *[1]Temple University; [2]Children's Hospital of Philadelphi; [3]Children's Hospital of Philadelphia, Philadelphia; [4]Johns Hopkins University, Baltimore, United States*

**Background:** Epigenetic changes in systemic lupus erythematosus (SLE) offer a potential explanation for the chronicity of disease. We previously found a global increase in histone H4 acetylation (H4ac) in SLE monocytes and 63% of genes with increased H4ac had potential interferon regulatory factor (IRF) 1 binding sites within the 5kb upstream region. We identified specific H4 lysine acetyl groups with significant hyperacetylation in SLE monocytes, as well as an imbalance in specific histone acetyltransferases (HATs) and histone deacetylases (HDACs) in favor of hyperacetylation. IRF1-overexpression drove H4 hyperacetylation and

**Abstract AB0157** – Table 1

| Parameter | Total cases Median (IQR)* | Active cases Median (IQR) | Inactive cases Median (IQR) | Controls Median (IQR) |
|---|---|---|---|---|
| Percentage of CD 64 on lymphocyte | 1.57 (0.86, 3.13) | 1.60 (1.14, 3.39) | 1.50 (0.66, 2.91) | 0.74 (0.44, 1.67) |
| Percentage of CD 64 on monocytes | 55.00 (30.31,73.50) | 55.75 (40.81, 77.85) | 40.92 (27.82, 69.78) | 44.08 (37.52,72.90) |
| MFI of CD16 on neutrophils | 3.47 (1.4, 21.40) | 2.70 (1.37, 6.65) | 6.25 (1.41, 47.85) | 11.40 (5.36, 37.91) |

*IQR- interquartile range.

IRF1 recruitment of HAT p300 to target genes increased IRF1 binding to genes with pathological expression in SLE monocytes.
IRF1 is highly inducible by prolactin, a hormone implicated in the pathogenesis of SLE: hyperprolactinemia has been reported in 15–33% of SLE patients as compared to 0.4–3% of controls. Prolactin upregulation of IRF1 can lead to H4ac in Nb2 T cells, representing a potential pathological pathway in SLE.
**Objectives:** Prolactin-induced IRF1 activation in primary monocytes and THP1 cells was examined, with the aim to identify IRF1 interactions with histone acetyltransferases (HATs) and histone deacetylases (HDAC) leading to pathological H4ac in SLE.
**Methods:** Flow cytometry for acetylated H4 lysines: K5, K8, K12, K16 were run on the Accuri C6 with isotype controls. H4ac was defined in primary monocytes from 12 normal males under both unstimulated and prolactin-stimulated conditions. Real-time quantitative reverse transcription polymerase chain reaction (qRT-PCR) evaluated HAT/HDAC expression in monocytes. IRF1 activation by prolactin in primary monocytes was studied by immunofluorescence microscopy. Interactions of IRF1 and HATs/HDACs were studied in THP1 cells by ChIP analysis.
**Results:** Flow cytometry found significantly increased total H4ac, H4K5, H4K8, H4K12, and H4K16 acetylation ($p$=0.01, 0.01, 0.01, 0.002, 0.04) in monocytes stimulated at prolactinoma levels (2000 ng/mL); acetylation at total H4ac, H4K5, H4K8, H4K12, and H4K16 was also increased at pregnancy levels (200 ng/mL).These results were similar to the increase in H4ac seen in SLE monocytes. Immunofluorescence showed translocation of IRF1 from the cytoplasm to the nucleus in prolactin-stimulated primary monocytes at both 200 ng/mL and 2000 ng/mL cells by 1 hr, demonstrating IRF1 activation.
qRT-PCR studies of HAT/HDAC expression patterns found increases in PCAF, P300, CBP, GCN5 and ATF2 expression monocytes stimulated by prolactin that was time dependent. Additionally, ChIP assays in THP1 cells suggested that prolactin-stimulation can recruit IRF1 and acetylated H4 to prolactin target genes.
**Conclusions:** These data demonstrate that prolactin stimulation of monocytes induces IRF1 activation and a pattern of acetylated H4 that corresponds to the changes seen in SLE. This helps to explain the known association of prolactinomas with SLE. The identification of candidate HATs that associate with IRF1 in the context of prolactin stimulation may provide for potential therapeutic targets in SLE.

### AB0160 MIR-155 FACILITATE THE DIFFERENTIATION OF TH17 CELL BY INHIBITING THE GENE EXPRESSION OF ETS-1 IN VITRO/IN VIVO EXPERIMENTS

Z. Ye, Z. Yin, X. Luo, X. Chen, W. He. *Rheumatology Institute of Guangdong Medical College, Shenzhen, China*

**Background:** MicroRNA (miR) as a class of regulatory elements are plays important role in various autoimmune diseases, including rheumatoid arthritis.MiR-155 has been demonstrated as a central regulator of the autoimmune system, but its function during autoimmune arthritis is still poorly understood.
**Objectives:** To clarify the function of miR-155 in CD4$^+$regulatory Th17 cell differentiation, as well as the mechanism involved in autoimmune arthritiTo clarify the function of miR-155 in CD4$^+$regulatory Th17 cell differentiation, as well as the mechanism involved in autoimmune arthritis.
**Methods:** In vitro, CD4$^+$ cell was isolated from DAB1 mice' spleen. We performed gain-and-loss-of-function analysis by transfection miR-155 mimics and miR-155 inhibitors into purified CD4+T cells. Also, we used RNA interference to silence Ets-1 gene expression. In addition, in vivo, up regulation of miR-155 expression by lent virus miR-155 (LV-miR-155) infection and silencing of miR-155 expression by lent virus-anti-miR-155 (LV-anti-miR-155) was researched in the experimental mice with type II collagen (CII)-induced arthritis (CIA). The ratio of IL-17 was analyzed using flow cyctometry (FCM).The related gene expression such as Foxp3, RORgt, IFN-g, Ets-1and stat3 was detected by Quantitative Real-time PCR (qPCR) and western blotting.
**Results:** The result showed that miR-155 promoted Th17 cell differentiation. It also induced related gene expression, such as Foxp3, RORgt, IFN-g and stat3; it inhibited Ets-1 gene expression. This may because miR-155 modulates Th-17 cell differentiation by targeting Ets-1.Here we identify miR-155 was highly correlated with disease in mice with experimental CIA. In vivo over expression of miR-155 led to more Th-17cells and severe CIA, and the related genes were higher express, but Ets-1 was lower expression. In contrast, the down regulation of miR-155 expression resulted in fewer Th17 cells and Normal mice. The related genes were lower express, but Ets-1 was higher expression.
**Conclusions:** Our data show a critical role for miR-155 in Th17 differentiation and the pathogenesis of autoimmune arthritis, and it might be involved in the occurrence and development of autoimmune diseases in rheumatoid arthritis.

## Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models

### AB0161 INVESTIGATION OF OXIDATIVE STRESS, OXYGENATION AND ERYTHEMA IN PATIENTS WITH SYSTEMIC SCLEROSIS, PRIMARY RAYNAUD'S PHENOMENON AND UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE AND IN HEALTHY CONTROLS

I. Poxon[1], T.L. Moore[2], J.B. Manning[2], S. Leggett[2], M. Dickinson[1], A.L. Herrick[2], A.K. Murray[1,2]. *[1]Photon Science Institute, University of Manchester, Manchester; [2]Centre for Musculoskeletal Research, University of Manchester, Salford, United Kingdom*

**Background:** Systemic sclerosis (SSc) is a rare connective tissue disease characterised by skin fibrosis and microvascular dysfunction. Oxidative stress, hypoxia and ischaemia have previously been implicated in SSc pathogenesis.
**Objectives:** The aim of this study was to further elucidate the pathophysiology of different subtypes of Raynaud's phenomenon (RP) by measuring oxidative stress, oxygenation and perfusion in patients with primary RP (PRP), undifferentiated connective tissue disease (UCTD), and SSc, comparing between groups and with healthy controls. Patients with UCTD were included to understand more about their early structural and functional changes as they are potentially an interim group between PRP and SSc. Our hypothesis was that oxidative stress would be increased in the UCTD and SSc groups and the oxygenation and perfusion would be decreased.
**Methods:** Measurements of oxidative stress, oxygenation and erythema (skin redness, an approximate, indirect measure of perfusion) were taken at a single point, at 9 sites, over the body using spectroscopy. Oxidative stress was measured as an increase in fluorescence induced by UV light. Oxygenation and erythema were calculated from white light reflection spectra.
**Results:** Measurements were taken from 53 healthy controls (HC), 36 female (f), median age 45, IQR [38–54] years; 20 patients with PRP, 17 f, 46 [39–52] years, duration of RP 8 [3–25] years; 37 patients with UCTD, 26 f, 43 [31–54] years, duration of RP 7 [5–16] years; 100 patients with SSc, 83 f, 59 [52–66] years, duration of RP 16 [8–24] years, duration of SSc 11 [4–18] years. A subset of data over the 9 sites is shown in Table 1. Oxidative stress was increased at all sites (statistically significant differences between groups [$p<0.05$] at 7/9 sites) in patients with SSc as compared to HC. Oxygenation showed no trend. Erythema showed a trend of lower values at all sites for patients with SSc vs. HC (statistically significant at 7/9 sites).
**Conclusions:** Patients with SSc showed a trend towards increased oxidative stress and decreased erythema compared to HC as hypothesised, providing further evidence that both oxidative stress and ischaemia are associated with SSc. Oxygenation showed no trend, suggesting that oxygenation measurements may not be sensitive enough to detect differences or that oxygenation is not affected at baseline (i.e. it is functional rather than structural). Further studies may clarify whether incorporating a dynamic challenge (e.g. temperature change) would aid differentiation between groups.
**Acknowledgement:** Arthritis Research UK and EPSRC funded this study.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3934

### AB0162 ABNORMAL B-CELL DISTRIBUTIONS IMPROVED BY TOCILIZUMAB MONOTHERAPY IN PATIENTS WITH POLYMYALGIA RHEUMATICA

G. Carvajal Alegria[1], V. Devauchelle-Pensec[1], Y. Renaudineau[2], A. Saraux[1], J.-O. Pers[2], D. Cornec[1]. *[1]Rheumatology, CHRU Cavale Blanche; [2]Immunology, CHRU Morvan, Brest, France*

**Background:** Abnormalities in B-cell population distribution were recently reported in polymyalgia rheumatica (PMR), which improved with glucocorticoïds. Data about cytokine involvement in PMR pathophysiology are scarce and contradictory.
**Objectives:** Our objective was to analyze the subsets of lymphocytes and level

of cytokines in patients with PMR and to follow their evolution after tocilizumab treatment.
**Methods:** The TENOR study [Clinicaltrials.gov (NCT01713842)] was an open labeled prospective trial including patients with recent PMR fulfilling the Chuang criteria. Patients had active disease and were glucocorticoïds (GCs) free. Patients with suspected giant cell arteritis were excluded. Patients were treated with tocilizumab infusions (week 0, 4 and 8) without GCs (period 1) and then by low-dose GCs from week 12 to week 24 (period 2). Peripheral blood lymphocyte profiling was performed by multicolor flow cytometry in 18 patients at week (W) 0 (before first tocilizumab infusion), W2, W12 and W24. Cytokine levels were estimated using membrane cytokine array enabling detection of 34 different cytokines. Interleukine (IL) 6 and 10 levels were evaluated by ELISA at W0 and W12. They were compared to 16 sex and age-matched healthy controls (HC).
**Results:** At baseline, total lymphocyte (p=0.31), T cell (p=0.46), B cell (p=0.08) and NK cell (p=0.905) levels were similar between PMR patients and HC. Transitional B cells ($CD24^{high}$, $CD38^{high}$) and mature-naïve B cells ($CD24^{low}$, $CD38^{low}$) were lower in patients with PMR than in HC, 3±6 vs 6±6 per $mm^3$ (p=0.01) and 46±41 vs 92±53 per $mm^3$ (p=0.01), respectively. After tocilizumab, total lymphocyte count slightly increased (1739±539/$mm^3$ at W0, 2030±591/$mm^3$ at W2, 2068±775/$mm^3$ at W12, and 2031±584/$mm^3$ at W24, $p<0.01$). The absolute number and proportion of $CD4^+$ T cells and NK cells were unaffected by the treatment. In contrast, both absolute number and proportion of B cells increased between W0 and W12, respectively from 176±105/$mm^3$ to 260±192/$mm^3$ (p=0.004) and from 10.1% to 13.0% ($p<0.001$). Among B-cell subsets, these modifications were mainly attributable to the variations of the memory compartment. Unswitched (IgD+CD27+) and switched (IgD-CD27+) memory B-cell absolute number and proportions significantly increased after tocilizumab ($p<0.001$). After cytokines detection using membrane cytokine array only IL-6 level was significantly different between patients and HC. IL-6 and IL-10 levels were measured in ELISA. IL-6 level was higher in patients (112±78 pg/ml) than in HC (13±13) ($p<0.0001$) and was found associated with disease activity measured by PMR-AS (r=0.628; p=0.006). IL-6 decrease in patients treated with tocilizumab infusion was not significant.
**Conclusions:** The drastic clinical improvement following tocilizumab monotherapy in PMR patients is paralleled by an increase in peripheral blood memory B cells. These observations suggest that B cells are involved in disease pathophysiology, and that IL-6 blockade could restore B-cell homeostasis.
**Disclosure of Interest:** None declared

### AB0163 NO ASSOCIATION BETWEEN THE PERCENTAGE OF MEMORY OR TRANSITIONAL B REGS AND DISEASE-RELATED AUTOANTIBODIES IN SYSTEMIC SCLEROSIS

A. Mavropoulos, C. Liaskos, T. Simopoulou, A. Varna, C.G. Katsiari, D.P. Bogdanos, L.I. Sakkas. *Rheumatology, Medical School, University of thessaly, Larissa, Greece*

**Background:** Recently, we found that Breg cells are numerically decreased and functionally impaired in patients with systemic sclerosis (SSc)[1] A subsequent study confirmed these data and reported a negative correlation between Breg levels and the titres of anti-topo I and anti-centromere antibodies (ab) in patients with SSc[2].
**Objectives:** To assess the relation between memory or transitional Bregs with SSc-specific anti-topo I, anti-centromere (CEN) and anti-RNA pol I abs in our cohort of SSc patients.
**Methods:** Fifty patients with Ssc were tested for disease-specific abs (Topo I, CENP, RNA pol I) using line blot analysis (EUROIMMUN), and for memory [CD19(pos)CD27(pos)CD24(high)] and transitional [CD19(pos)CD24(high) CD38(high)] Bregs using flow cytometry.
**Results:** Anti-CEN, anti-Scl-70 and RNA pol I abs were present in 12 (24%), 23 (46%) and 7 (14%) patients with SSc, respectively. The % of memory and transitional B regs was comparable between anti-CEN ab-positive and -negative patients (1.56±1.40 vs 1.74±1.01 and 0.78 ±0.73 vs 0.65±0.68 respectively, $p>0.05$), and also beween anti-RNA ab-positive and -negative patients with SSc (1.96±1.26 vs 1.65±1.09 and 0.54±0.53 vs 0.7±0.72 respectively). While the % of memory Bregs did not differ between anti-topo I-positive and -negative patients (1.96±1.26 vs 1.65±1.09 and 0.54 ±0.53 vs 0.7±0.72 respectively), the % of transitional Bregs tended to be decreased in patients with anti-topo I-positive compared to anti-topo I ab-negative patients (0.49±0.46 vs 0.84±0.61 p=0.066). Levels of B regs (memory or transitional) did not negatively correlate with autoantibody titres by line blot analysis.
**Conclusions:** We failed to find an association between percentages of memory and transitional B regs with SSc-specific autoantibodies.

Hunzelmann[1] on behalf of all participating DNSS centers. *[1]Dermatology, University Hospital Cologne, Cologne; [2]Rheumatology, Heidelberg University Hospital, Heidelberg; [3]Rheumatology, Charité University Medicine Berlin, Berlin; [4]Rheumatology, University Hospital Tuebingen, Tuebingen; [5]Dermatology, University hospital of the Ruhr University of Bochum, Bochum; [6]Rheumatology, University Hospital Erlangen, Erlangen; [7]Rheumatology, Immanuel Hospital Berlin-Buch; [8]Dermatology, Charité University Medicine Berlin, Berlin; [9]Rheumatology, Hospital St. Josef, Wuppertal; [10]Rheumatology, Johanniter Hospital, Treuenbrietzen; [11]Dermatology, HELIOS University Hospital Wuppertal, Wuppertal; [12]Dermatology, University Hospital of Cologne, Cologne; [13]Dermatology, University Hospital Muenster, Muenster; [14]Dermatology, HELIOS St. Elisabeth Hospital Oberhausen, Oberhausen; [15]Dermatology, Ludwig Maximilian University, Munich; [16]Rheumatology, Schleswig-Holstein University Hospital, Luebeck; [17]Rheumatology, Kerckhoff Hospital, Bad Nauheim; [18]IMSIE, University Hospital Cologne, Cologne, Germany*

**Background:** Systemic sclerosis (SSc) is a heterogeneous multisystem connective tissue disease, usually subdivided into the main SSc subsets, e.g. limited (lcSSc), diffuse SSc (dcSSc) and SSc overlap syndromes. However, some patients present with symptoms suggestive of, but not conclusive for a diagnosis of definite SSc. This subset has been referred to as undifferentiated or very early SSc. It was defined as positive RP together with at least one further feature of SSc and/or detectable SSc-specific autoantibodies.
**Objectives:**
**Methods:** Up to date, more than 3400 patients have been registered within the German network for systemic scleroderma. Disease progress after initial patient registration and further follow-up visits was analysed to determine, whether clinical features in patients with undifferentiated SSc change over time into definite SSc.
**Results:** Among 3473 registered patients, 8.1% (282/3473) were diagnosed with undifferentiated SSc. Of these, 87.5% were female with a mean age at onset of 59.9±1.5years. A significant difference was detectable comparing patients with undifferentiated SSc and lcSSc (54.8±0.5years; $p<0.001$) as well as dcSSc (49.8±0.6years; $p<0.001$). Positive antinuclear antibodies (ANA) were detectable in 219 (77.7%) patients; of these 40.2% were anti-centromer (ACA) positive and 12.8% anti-topoisomerase antibody (ATA) positive. No substantial difference regarding organ manifestations between patients with or without existing ANAs was found.
34.0% of undifferentiated SSc patients suffered from sicca symptoms, followed by 31.2% with gastrointestinal (GI) involvement, 30.5% with musculoskeletal involvement, 14.5% with lung fibrosis, 6.0% with heart involvement, 5.0% with pulmonary arterial hypertension (PAH) and 0.4% with renal crisis. Musculoskeletal involvement, sicca symptoms and heart involvement were found in a similar percentage in patients with undifferentiated and lcSSc. Lung fibrosis, PAH and GI involvement occurred significantly less in patients with undifferentiated SSc compared to lcSSc. Within a mean follow-up time of 3.6years, the majority of the patients classified initially as undifferentiated SSc, remained within this subset (76.6%), while only 16.3% converted into lcSSc. 4.6% were classified as dcSSc and 3.2% as SSc overlap syndromes.
**Conclusions:** Patients classified as undifferentiated SSc, develop clinical features suggestive of SSc at a significantly older age than other subsets (i.e. 5–10 years). During follow up progression into a limited, diffuse or SSc overlap syndrome subset was observed, however, the majority of undifferentiated SSc patients remained stable and did not develop definite SSc.

### AB0165 IN DEPTH IMMUNOPHENOTYPIC ANALYSIS IN JUVENILE IDIOPATHIC ARTHRITIS (JIA): A CROSSECTIONAL STUDY

E. Quesada-Masachs[1], D. Álvarez de la Sierra[2], M. Garcia Prat[2], V. Bittermann[1], R. Pujol Borrell[2], A.M. Marín Sánchez[2], C. Modesto Caballero[1], M. Martínez Gallo[2]. *[1]Rheumatology; [2]Immunology, Hospital Universitario Vall d'Hebron, Barcelona, Spain*

**Background:** The potential of expanded flow cytometric analysis of PBLs has not been yet been fully exploited to study JIA heterogeneity neither to monitor JIA patients' on biological treatments
**Objectives:** To analyze in depth lymphocyte subpopulations in treated JIA patients stratified by age and gender.
**Methods:** One hundred one patients, 69 children and 32 adult fulfilling JIA (ILAR) criteria attending HUVH rheumatology clinic were included. All patients were treated with either MTX, anti-TNFα, or a combination of both. Controls were sex/age matched volunteers either healthy or attending the clinics of HUVH for

non inflammatory conditions (59 controls, 29 paediatric and 30 adult). Extended immunophenotype following FITMaN protocol that discerns 57 peripheral blood lymphocyte (PBL) subpopulations was applied. Bonferrroni's correction indicated that the cut off for significance was $p<0.00041667$.

**Results:** Changes common to each group of patients irrespective of treatment are as follows: paediatric patients showed lower percentage of CD8 effector cells (CD45RA+CCR7-) when compared to controls (10.53±5.71 *vs* 16.92±5.71). Percentage of total CD4 cells was higher on JIA children than in controls (42.21±7.40 *vs* 36.04±5.22). No differences were found on percentages nor in absolute number of Th1 (CXCR3+CCR6-), Th2 (CXCR3-CCR6-), or Th17 (CXCR3-CCR6-) CD4 cells. Interestingly all Th subpopulations showed decreased expression of HLA-DR in JIA children when compared with controls (6.06±3.08 *vs* 10.49±5.02; 0.81±0.51 *vs* 1.48±0.64; 8.57±3.81 *vs* 12.6±4.95; respectively). JIA adults presented no significant differences in T cells subpopulations compared to adult controls, but showed higher percentage of CD21- switch-memory B cells (IgD-IgM-CD27-) than controls (10.82±5.33 *vs* 4.29±4.33).

In a second analysis of the JIA patients few differences were observed according to the administered therapy. Paediatric patients treated with MTX (n=27) showed a lower proportion of the effector memory (CD45RA-CCR7-) cells both CD4+ and CD8+, when compared to controls, anti-TNF, and anti-TNF plus MTX groups (20.01±7.76 *vs* 27.64±9.27; 20.01±7.76 *vs* 27.84±4.27; 20.01±7.76 *vs* 27.07±10.05; for CD4s and 26.42±7.23 *vs* 37.10±12.38; 26.42±7.23 *vs* 42.08±11.59; 26.42±7.23 *vs* 37.27±12.54 for CD8s, respectively). Percentage of CD25+ lymphocytes was higher in the anti-TNF plus MTX group. The Th1–17 (CCR6+CXCR3+) CD4 cell subpopulation was significantly increased in anti-TNF and anti-TNFα plus MTX groups compared with controls and MTX (10.45±3.14 *vs* 6.38±3.89; 10.45±3.14 *vs* 4.78±2.56 and 9.43±4.63 *vs* 6.38±3.89; 9.43±4.63 *vs* 4.78±2.56, respectively). Adult patients treated with anti-TNFα+MTX and MTX presented higher levels of CD21- naïve B cells compared to HC and to anti-TNF groups (4.86±3.24 *vs* 2.32±1.69; 4.86±3.24 *vs* 2.95±1.94 and 5.38±1.54 *vs* 2.32±1.69; 5.38±1.54 *vs* 2.95±1.94).

**Conclusions:** In depth phenotypic analysis of PBL in JIA showed alterations in cell subpopulations that seem dependent on age group. Our data also suggests that detailed in depth phenotypic analysis can be a valuable tool for monitoring and comparing JIA treatments.

### AB0166 SEX-SPECIFIC GENE EXPRESSION DIFFERENCES IN OLIGOARTICULAR JUVENILE IDIOPATHIC ARTHRITIS

R.C. Chiaroni-Clarke[1,2], R.A. Chavez[1,2], J.E. Munro[1,3], R.C. Allen[1,3], J.D. Akikusa[1,3], A. Oshlack[1], J. Maksimovic[1], A.-L. Ponsonby[1,2], R. Saffery[1,2], J.A. Ellis[1,2]. *[1]Murdoch Childrens Research Institute; [2]Department of Paediatrics, University of Melbourne; [3]Paediatric Rheumatology Unit, Royal Children's Hospital, Parkville, Australia*

**Background:** Juvenile idiopathic arthritis (JIA) is a paediatric autoimmune disease (AD) with a female preponderance, though this differs by subtype. Whether this sex bias is reflective of differing disease pathogenesis between the sexes is unknown. Gene expression signatures can be biologically and clinically informative, but few expression studies have been performed in JIA. Though gene expression is recognised as sexually dimorphic in many states, its role in JIA sex bias has not been considered. In response to infection females produce more antibodies than males, which could increase natural autoantibody production and the risk of developing AD. Gene expression differences between the sexes may reflect this. The reduced heterogeneity afforded by sex-stratified transcriptome-wide analysis may provide insight into how sex influences disease pathogenesis in JIA.

**Objectives:** We aimed to identify sex-specific differences in patients with oligoarticular JIA versus healthy controls through RNA-seq analysis on CD4+ T cells.

**Methods:** Six male and six female oligoarticular JIA cases, with no prior exposure to disease-modifying anti-rheumatic drugs, were age and sex-matched to healthy controls. CD4+ T cells were selected as existing data links T cell gene networks to JIA. RNA was extracted from CD4+ T cells using the Qiagen miRNeasy extraction kit. Sequencing library preparation was performed using the Illumina TruSeq Stranded Total RNA LT kit. One female sample did not pass quality control and was not sequenced. Sequencing was performed using 75bp paired-end reads to a depth of ~20 million reads on the Illumina NextSeq. Quality trimmed reads were mapped to the genome using the STAR aligner. Read counts across exons and genes were summarised using featureCounts. Normalised read counts were used for differential gene expression analysis with edgeR. GOseq was used for gene ontology analysis. Males and females were analysed separately.

**Results:** No sex-specific differentially expressed (DE) genes reached FDR adjusted $p<0.05$. At unadjusted $p<0.05$ there were far more male (1480) than female (118) specific DE genes, with 24 overlapping. Pathway analysis of male-specific DE genes highlighted antigen processing and presentation, immune response, and IFNϒ production, among other disease-relevant gene networks. Corresponding female-specific analysis did not reveal obvious disease-relevant networks. For many genes DE between male cases and controls, male case gene expression appeared more similar to all females (Figure 1).

**Conclusions:** We have identified sex-specific differences in CD4+ T cell gene expression between healthy controls and oligoarticular JIA cases predominantly in males, despite the female preponderance. Our data may reflect that some of the pathogenesis for JIA differs between the sexes, and that gene expression differences play a particularly important role in male JIA, perhaps by a more "female" immune response occurring in male cases. Given the small sample size, replication is necessary and is underway.

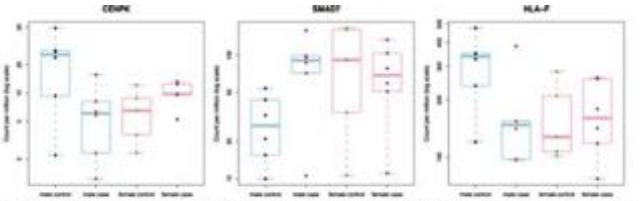

**Figure 1:** Distribution of normalised gene transcript counts by RNA-seq in male and female JIA cases and age-matched controls at top-ranked male-specific differentially expressed genes. *CENPK*, 2nd ranked gene, $p=1.1x10^{-5}$; *SMAD7* 4th ranked gene, $p=1.7x10^{-5}$; HLA-F, 5th ranked gene, $p=2.3x10^{-5}$. Note the similarity of the male cases to the female cases and female controls (columns 2,3,4).

## Rheumatoid arthritis - prognosis, predictors and outcome

### AB0167 ACR/EULAR REMISSION IN EARLY RHEUMATOID ARTHRITIS ASSOCIATES WITH A SHORTER TIME TO FULFILMENT THE CLASSIFICATION CRITERIA AND A LOWER BMI

A. Zabotti, L. Quartuccio, S. Salvin, L. Picco, S. Sacco, S. De Vita. *Clinica Reumatologica, Udine, Italy*

**Background:** A prolonged disease duration is associated to a lower chance to achieve disease remission in rheumatoid arthritis. Onset of the disease can be defined in a number of ways and, when possible, the following data should be recorded: 1) first musculoskeletal (MSK) symptoms relevant to the current compliant 2) first persistent patient-reported joint swelling 3) initial fulfilment of criteria for RA based on data obtained retrospectively[1].

**Objectives:** The aim of this study was to identify the variables associated with ACR/EULAR remission[2] in a cohort of early rheumatoid arthritis (ERA). In particular, the different types of disease onset, as defined[1], were investigated.

**Methods:** All the patients, referred to the Early Arthritis Clinic of the University Rheumatology Clinic of Udine between October 2013 and October 2015, with a diagnosis of RA and fulfilling ACR/EULAR 2010 criteria, were included. The EULAR recommendations for treat to target were followed. At the first visit, 13 clinical and laboratory variables associated with RA, including the different type of onset[1], were recorded. The variables associated with remission at the 12th month (+12) of therapy by univariate analyses were included in a multivariate logistic regression model. Receiver operator characteristic (ROC) curves were used to evaluate the discriminative capability of the different types of onset.

**Results:** Ninety-two patients with ERA were assessed and 65 completed 12-month evaluation. 15/65 (23,1%) reached ACR/EULAR remission at +12. Two variables were selected in the logistic regression analysis (i.e. BMI and time to fulfilment of ACR/EULAR classification criteria). A low BMI (OR 0,54; CI 95% 0,33 to 0,86; p=0,01) predicted remission and 23,5 being the optimal BMI cut-off value. Time to fulfilment of ACR/EULAR classification criteria for RA was also significantly associated with remission at +12 (OR 0,21; CI 95% 0,05–0,92; p=0,039) and 2,5 months was the cut-off value showing the best discriminative power for remission achievement. By contrast, a shorter time from the onset of MSK symptoms (5.5 months showing the best discriminative power) was selected only by univariate analysis.

**Conclusions:** From a clinical perspective the present preliminary data may be reassuring if confirmed by larger analyses: a shorter time from the fulfilment of ACR/EULAR classification criteria of RA, when treatment has been frequently started (thus, not necessarily the time from the onset of MSK symptoms) is associated with disease remission at +12 in ERA. From a biologic point of view, starting the treatment as soon as disease begins (i.e. onset of MSK symptoms) may be more effective, but the currently available prognostic, diagnostic and treatment tools do not allow this recommendation yet. Furthermore remission is related to BMI, since patients with BMI >24 showed a lower chance to achieve remission

## AB0168 DYNAMICS OF LIPID PROFILE IN PATIENTS WITH A HIGH ACTIVITY OF RHEUMATOID ARTHRITIS

A. Hon[1], M. Sultanova[2]. [1]*Cardio-rheumatology Department;* [2]*Rheumatology Department, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** The main cause of high mortality of RA patients is early formation and progression of atherosclerotic lesion in vessels, leading to an increased risk of myocardial infarction, congestive heart failure, stroke, and sudden death. A similar profile of the immune response is the activation of T-cells and mast cells, the production of proinflammatory cytokines, increased levels of α-metalloproteinase; the identity of cellular composition of an atherosclerotic plaque and the inflammatory infiltrate in synovium with RA; correlation between the level of C-reactive protein (CRP), ESR, cytokines (especially Interleukin-6 (IL-6)), cell adhesion molecules and blood lipid spectrum (HDL-C, apoA1) – all these indexes help to explain the high frequency of atherosclerosis manifestations in RA patients.
**Objectives:** Identify blood lipid profile disturbances in patients with a high activity of rheumatoid arthritis.
**Methods:** The study is based on the follow-up results of 48 RA patients under treatment at the Republican Centre of Rheumatology attached to Tashkent Medical Academy. Criteria for inclusion of patients in the study were – RA diagnosis, verified in accordance with the ACR/EULAR (2010) criteria, active RA, the informed consent to participate in the study. All patients had a high disease activity defined by DAS28. Activity indexes ranged from 5.11 to 8.29 and averaged 6.44. Analysis of the blood lipid profile was based on optimum values: total cholesterol (TC) – less than 5 mmol/l (193.4 mg/dl), low-density cholesterol (LDL) – less than 3 mmol/l (116.0 mg/dl), high-density cholesterol (HDL) – greater than 1.2 mmol/l (46.4 mg/dl) for women and more than 1 mmol/l (38.7 mg/dl) for men, triglycerides (TG) – less than 1.77 mmol/l (68.4 mg/dl).
**Results:** The average age of RA patients was 49.7 years (ranged from 36 to 72), the average RA duration was 8.2 years (ranged from 1 to 22 years). The dyslipidemia was revealed in 37 patients of the study group, amounting to 77.1%. TC level increase have been reported in 31 out of 48 (64.6%) cases and was associated with an imbalance of other components of the lipid profile. The average TC value was 5.8 mmol/l (224.28 mg/dl). Increased TG levels have been reported in 11 of 48 cases (22.9%), reduced HDL - in 27 out of 48 (56%) cases. The average TG level – 1.8 mmol/l (69.6 mg/dl), HDL – 1.1 mmol/l (42.5 mg/dl). The most significant was increase in LDL – revealed in 35 patients (72.9%). Mean LDL – 3.9 mmol/l (150.8 mg/dl). Most of the patients had type II hyperlipidemia (highly atherogenic): IIa – 23 (47.9%), IIb - 7 (14.6%).

**Conclusions:** Results of our investigation showed the presence of a coarse lipid imbalance in patients with highly active RA. The most expressed imbalance was the increase in TC and LDL. Similar violations observed in the majority of patients are associated with a highly atherogenicity in RA and a high risk of cardiovascular events.

## AB0169 NEUTROPHIL TO LYMPHOCYTE RATIO AND CORRELATION TO RHEUMATOID ARTHRITIS ACTIVITY

A. Papazoglou[1], G.C. Lygouris[1], R. Patel[2], L. Brent[2]. [1]*Internal Medicine;* [2]*Rheumatology, Einstein Medical Center, Philadelphia, Philadelphia, United States*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by joint pain and swelling, as well as destruction of synovial joints leading to significant morbidity and mortality[1]. Patients are classified as having RA with a combination of a history of prolonged symptom duration, a swelling of joints on physical examination, serological markers including rheumatoid factor (RF), anti-cyclic citrullinated peptide (CCP) antibodies, and acute-phase response measures including the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)[2]. The blood neutrophil-to-lymphocyte ratio (NLR) has been identified as a potentially useful marker of disease activity in disease states with an inflammatory component such as malignancies, cardiovascular disease, and rheumatologic diseases[3–5].
**Objectives:** To investigate whether NLR can be used as a marker of inflammation and disease activity in RA patients with varying disease activity levels as assessed by the RAPID 3 (routine assessment of patient index data 3) at their most recent visit in the rheumatology clinic.
**Methods:** We conducted a retrospective chart review of 229 consecutive patients with a diagnosis of RA as determined using the 2010 ACR criteria for diagnosis of RA seen at the outpatient Rheumatology clinic of Einstein Medical Center in Philadelphia, PA, a tertiary urban hospital. At the time of each visit, each patient completes the RAPID3 questionnaire and the data are recorded in the electronic medical record. NLR was calculated using data from the complete blood count drawn at the time of the visit. Pearson's correlation coefficient (r) between NLR and well accepted disease activity markers (RAPID 3, ESR, CRP) was calculated. Multivariate linear regression was also performed to assess the association of the above variables.
**Results:** Two hundred seven patients (85% women) with a mean age of 59.6 years were included in the analysis. At the time of the random visit, mean NLR was 2.97, RAPID 3 score 13.8, ESR 36.5 mm/hr and CRP 2.3 mg/L. The NLR significantly correlated with RAPID 3 score ($r=0.24$, $p<0.01$), but not ESR ($r=0.1$, $p=0.13$) or CRP ($r=0.12$, $p=0.07$). Multivariate linear regression analysis showed that NLR was independently associated with RAPID 3 score ($b=0.75$, $p<0.01$).
**Conclusions:** NLR is an inexpensive and readily available inflammatory marker which may be useful as an indicator of disease activity in patients with RA.

## AB0170 VITAMIN D DEFICIENCY IS ASSOCIATED WITH HIGHER DISEASE ACTIVITY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A. Raczkiewicz, A. Juszkiewicz, A. Bachta, O. Bujakowska, J. Kur-Zalewska, B. Kisiel, M. Tłustochowicz, W. Tłustochowicz. *Department of internal medicine and rheumatology, Military Institute of Medicine, Warsaw, Poland*

**Background:**
Vitamin D deficiency is common in rheumatoid arthritis (RA) and may be related to disease activity.
**Objectives:** 1. To study the relationship between vitamin D deficiency and disease activity at RA onset. 2. To investigate possible influence of vitamin D supplementation on disease activity in early RA patients.
**Methods:** We studied 81 consecutive patients with new RA onset (71,6% women, mean age 60±14 years) admitted to the Department of Internal Medicine and Rheumatology, Military Institute of Medicine in Warsaw. Demographic, clinical, laboratory, and treatment variables were collected. The patients were treated with methotrexate, low dose of glucocorticoids and supplemented with vitamin D. Disease activity was assessed every month during the first year of therapy using DAS28-ESR, DAS28-CRP, CDAI, SDAI indices. Serum 25-hydroxy- vitamin D (25(OH)D3) was measured at baseline, after 6 and 12 months. Ultrasound assessment of hand joints was performed by the same assesssor at baseline and after 12 months. We defined vitamin D serum concentration <20ng/mL as vitamin D insufficiency and serum concentration <10ng/mL as vitamin D deficiency. New erosions found at ultrasound examination after 12 months were considered disease progression.
**Results:** At baseline mean 25(OH)D3 serum concentration was 14,6±7,7ng/mL. Sufficient vitamin D serum concentration was found in 22% patients, 49% of patients had vitamin D insufficiency and 29% were vitamin D deficient. The patients with vitamin D deficiency at baseline had significantly higher number of tender and swollen joints, higher physician global assessment and higher number of joint effusion detected by ultrasound examination than other patients. There were no significant differences in ESR and CRP values according to vitamin D concentration. After 12 months (the data available for 65 patients) 20,3% of the patients had still insufficient vitamin D concentration and 4,7% were vitamin D deficient. Taking into account the mean vitamin D concentration during

observation period only 52,4% of patients were vitamin D sufficient. New erosions in ultrasound examination were found in 14 (21,5%) patients. We have found no significant difference between vitamin D sufficient and insufficient patients according to the average indices of disease activity, disease activity improvement, time to achieve remission, duration of the remission and disease progression during the first year of therapy.

**Conclusions:** Higher disease activity at RA onset is associated with lower serum vitamin D concentration. Vitamin D supplementation does not improve disease outcome during the first year of therapy.

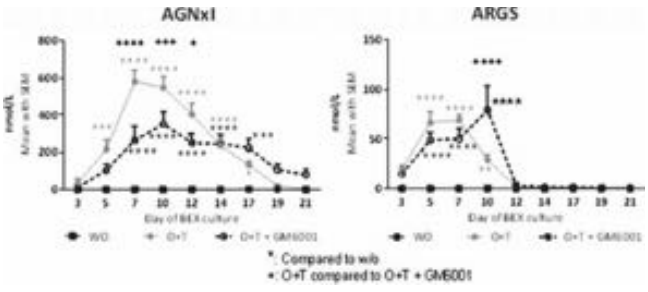
## AB0171 AGGRECAN DEGRADATION IS NOT JUST AGGRECAN DEGRADATION – A STUDY OF NEO-EPITOPES (NITEGE AND ARGS) OF AGGRECANASE DEGRADATION



A.S. Siebuhr, Y. He, S. Hoielt, Y.R. Luo, M.A. Karsdal, A.-C. Bay-Jensen.
*Biomarkers and Research, Nordic Bioscience, Herlev, Denmark*

**Background:** Cartilage degradation is a hallmark of arthritic disease. The main constituents of cartilage is aggrecan and type II collagen. Previous studies have shown that aggrecan degradation is prior to type II collagen degradation and that only aggrecanase degradation but not matrix metalloproteinases (MMP) degradation of aggrecan was reversible[1]. It is therefore essential to have biomarkers that can detect reversible and irreversible aggrecan degradation to identify the condition of the cartilage. Of the well-known aggrecanase degradation site at NITEGE$^{373_374}$ARGS, ARGS is released by only aggrecanse, but NITEGE is retained in the aggrecan molecule and in theory needs additional aggrecan degradation to be released. The numbers indicate the aggrecanase cleavage site.

**Objectives:** Investigate the profile of two neo-epitope biomarkers of aggrecanase degraded aggrecan at NITEGE373–374ARGS in a bovine cartilage explants model.

**Methods:** Catabolic stimulated (oncostatin M and TNF-a; O+T) bovine cartilage explants were treated with or without the generic MMP inhibitor, GM6001. Explants without catabolic stimulation was used as negative control. In the culture supernatant two biomarkers investigating aggrecanase degraded aggrecan was measured. The AGNxI competitive ELISA detects the NITEGE$^{373}$ neo-epitope and the ARGS sandwich ELISA detects the $^{374}$ARGSVI neo-epitope. Statistical differences between groups were tested by two-way ANOVA.

**Results:** The AGNxI level was significantly increased compared to w/o from day 5 to day 17. GM6001 significantly lowered the release of AGNxI compared to O+T alone at day 7 ($p<0.0001$), day 10 ($p=0.0007$) and 12 ($p=0.01$). In addition, GM6001 shifted the release to 2days later in the culture period, as the AGNxI level was first significantly increased compared to w/o at day 7 to day 17, where the level was higher than O+T, but non-significant. The ARGS level was significantly increased at day 5, 10 and 12 for both O+T and O+T + GM6001 compared to w/o. At day 10 the ARGS level was higher in O+T + GM6001 than O+T ($p<0.0001$).

**Conclusions:** The prolonged release of AGNxI and the significantly lowered level of AGNxI with the MMP-inhibitor, suggest that the AGNxI release is somewhat dependent of MMP activity. In contrast, the ARGS release seems not to be MMP-dependent as there was a significant increase in O+T with the MMP-inhibitor compared to w/o and the peak was pronounced. In summary, aggrecan degradation is not just aggrecan degradation and different neo-epitopes have different importance in cartilage degradation.

## AB0172 USEFULNESS OF THE JAPANESE VERSION OF THE PATIENT-RATED ELBOW EVALUATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Takeshita[1], D. Kaneda[1], M. Horita[1], T. Machida[1], R. Nakahara[1], Y. Nasu[2], K. Hashizume[3], K. Nishida[4], T. Ozaki[1]. *[1]Orthopaedic Surgery; [2]Medical Materials for Musculoskeletal Reconstruction, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences; [3]Rehabilitation, Japan Labour Health and Welfare Organization Okayama Rosai Hospital; [4]Human Morphology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City, Japan*

**Background:** Patient self-administered questionnaires remove the possibility of observer bias, and are important instruments for the assessment of clinical outcome. The patient-rated elbow evaluation (PREE) is a joint-specific, self-administered questionnaires.

**Objectives:** We aimed to investigate the correlation between the Japanese version of PREE (PREE-J) and other clinical parameters in rheumatoid arthritis (RA) patients before and after total elbow arthroplasty (TEA).

**Methods:** Thirty-five elbows in 32 RA patients (M/F: 3/29) were replaced by TEA. The mean age was 62.1 (range 41–79) years at the time of surgery, the mean follow-up period was 21.5 (range 12–36) months. All patients were assessed pre- and post-operatively by PREE-J, elbow and forearm range of motion (ROM), Disease Activity Score with 28 joint using CRP (DAS28-CRP), Mayo Elbow Performance Score (MEPS), Japanese version of the Disabilities of the Arm, Shoulder and HAND (DASH-JSSH) and Health Assessment Questionnaire Disability Index (HAQ-DI). The changes of parameters after surgery were examined by Wilcoxon signed-rank test, and the correlation between PREE-J and other parameters was examined using Spearman's correlation coefficients.

**Results:** Both pre- and post-operative PREE-J significantly correlated with DAS28-CRP, DASH-JSSH, and HAQ-DI. Significant improvement was observed after surgery in all parameters except for HAQ-DI. The mean postoperative MEPS improved from 50.3±16.4 points to 98.1±3.2 points, the average postoperative PREE-J improved from 54.7±19.3 points to 27.1±24.4 points. The correlation between PREE-J and MEPS was significant preoperatively ($p<0.01$), but the correlation disappeared postoperatively. The correlation between PREE-J and ROM was not significant pre- and post-operatively.

**Conclusions:** The current study indicated that elbow evaluation by patients who underwent TEA showed significant correlation with disease activity, upper limb function and disability in daily life. It was revealed preoperative PREE-J also well correlated with MEPS, which is widely accepted evaluation system by elbow surgeons. Interestingly, PREE-J did not correlate with MEPS and ROM postoperatively. As PREE-J contains many questions about complex motions required the multiple joint function of upper extremity, it is possible PREE-J might be influenced by other joints affected by RA. MEPS (up to 100 points) evaluates pain (45), ROM (20), function (25) and instability (10) of the elbow, and reached almost perfect score by TEA. PREE-J evaluates pain and function with more detailed questionnaires than MEPS, some of them cannot be solved by a single joint surgery. Our results suggested PREE-J might be useful and wide range evaluation instrument for functional improvement of upper extremity after TEA.

## AB0173 ROLE OF ANTI CITRULLINATED PROTEIN ANTIBODIES IN FOLLOW-UP AND RADIOGRAPHIC DAMAGE IN A GROUP OF PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

C. Carrasco Cubero[1], E. Vergara Prieto[2], I. Alcalá Peña[2], J.L. Álvarez Vega[1], J.M. Salazar Vallinas[1], M. Mota Medina[3], C. Rodríguez Godoy[4], D. Sánchez Paré[4], M.L. Vargas Pérez[2]. *[1]Rheumatology; [2]Immunology, Hospital Infanta Cristina; [3]Mathematics, University of Extremadura; [4]Radiology, Hospital Infanta Cristina, Badajoz, Spain*

**Background:** Autoantibodies in early rheumatoid arthritis (RA) have important diagnostic value. Anti citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) are believed to be associated with more severe clinical outcomes, but the utility of both autoantibodies in the clinical follow-up of disease is controversial. It has recently been described that bone damage in early and even recent-onset RA is attributed to ACPAs, which form years before clinical symptoms start to emerge[1].

**Objectives:** To investigate the longitudinal course of immunological markers, ACPA and RF, during the first year after diagnosis of RA, to see their utility for the clinical follow-up. In addition, to assess if the baseline values of ACPA are associated with the severity of initial radiographic involvement.

**Methods:** The study population was 52 patients diagnosed with early RA according to ACR-EULAR 2010 classification criteria, with ACPA positive. Serum samples at baseline, 3, 6 and 12 months were analyzed, and levels of ACPA, RF, C reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were determined. Values of DAS 28, SDAI and HAQ were employed as clinical activity markers.To analyse the variations of the measured parameters, we expressed the values of each analytic and clinical parameter as "Variation Index" on the baseline value for each patient (VI (x month)=Value (x month)/Value (baseline)). The statistical study was made through canonical correlation analysis and linear regression. Radiographic damage was evaluated using Sharp scores modified

by Van der Heijde. Comparisons between this score and ACPA levels and other serological markers were evaluated by Spearman correlation coefficient.
**Results:** A high correlation between clinical markers and analytical variables is observed with a first canonical correlation of 0,96 ($p<0,001$) at 3 months and 0,89 ($p<0,001$) at 12 months. The correlation is mainly determined by the relation between DAS 28 and HAQ with CRP and ESR. A correlation between autoantibodies and clinical markers is not found. We show no significant radiological damage in our patients, despite all being ACPA positive. The Sharp score modified by Van der Heijde was measured in 47 patients, with values between 0 and 101 (mean: 24,76±24,54). We find no correlation between Sharp score and ACPA, RF, ESR and clinical activity markers, and a weak correlation between Sharp Score and CRP (Spearman Rho: 0,459; p=0,005)
**Conclusions:** In our group of patients with early RA, repeated measurement of ACPA or RF during the first year after onset of RA does not offer major additional information. Their quantification would not be indicated for follow-up disease, which means a cost reduction in the Autoimmunity Laboratory. We find no correlation between radiographic damage and ACPA titers at diagnosis. So, although ACPA are associated with bone wound, this is independent of the levels of antibodies.

## AB0174 CHANGES IN TYPE VI COLLAGEN DEGRADATION REFLECT RESPONSE TO TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

C.S. Thudium[1], N.S. Gudmann[1], K. Musa[2], M.A. Karsdal[1], A.-C. Bay-Jensen[1]. *[1]Biomarkers and Research, Nordic Bioscience A/S, Herlev; [2]Laboratories, Nordic Bioscience, Herleve, Denmark*

**Background:** Rheumatoid arthritis is a chronic autoimmune disease characterized by progressive inflammation and joint deterioration. Inflammation is driven largely by up-regulation of proteolytic enzymes such as MMPs and results in a greatly increased tissue turnover. Treatment with the αIL-6 receptor agent Tocilizumab (TCZ) results in decreased extracellular matrix (ECM) remodeling. Type VI collagen (Col VI) is found at the interface between the interstitial- and the basement membrane where it binds with both matrix proteins and support cell-cell interactions. The MMP mediated degradation of Col VI can be measured in serum by the protein fingerprint biomarker C6M.
**Objectives:** The aim of the study was to investigate the predictive value of C6M in response to tocilizumab (TCZ) treatment on a methotrexate (MTX) background for 52 weeks in patients with rheumatoid arthritis in the LITHE study.
**Methods:** C6M was measured in the LITHE study (n=740), a one year double blind, placebo controlled phase III parallel group study in patients receiving placebo, 4mg/kg or 8 mg/kg TCZ in combination with MTX. Col VI degradation was measured by the protein fingerprint biomarker C6M in serum at baseline, week 4, 16, 24 and 52. C6M's capacity to predict response to treatment was analyzed by calculating the odds ratio (OR) of ACR20, 50 and 70 criteria at 16 or 52 weeks, given a 20 or 50% reduction in C6M at 4 weeks, independent of treatment type and dose. Results were adjusted for age, sex, BMI, duration of disease and CRP.
**Results:** Treatment with TCZ resulted in an early dose dependent reduction of C6M serum levels in both 4 and 8 mg/kg doses compared to placebo and the reduction persisted throughout the study. In patients responding to treatment after 52 weeks, C6M was significantly decreased in patients with ACR70 ($p<0.01$) response, throughout the treatment period, while C6M reduction in ACR20 and 50 responders was only significant at week 52 ($p<0.05$ and $p<0.01$, respectively). C6M was also significantly reduced in patient with DAS remission (score $<2.6$ at week 52) and DAS score reduction ($>1.2$).
To assess the short term predictive value of C6M we calculated the OR for a 20% or 50% reduction in C6M resulting in an ACR response already after 16 weeks. The OR of an ACR response given a 20% reduction in C6M was ACR20) 1.56 (CI 1.14 to 2.13), ACR50) 2.20 (CI 1.49 to 3.24) and ACR70) 2.69 (1.48 to 4.90) respectively, while a 50% reduction gave the OR 1.88 (1.30 to 2.71), 2.49 (1.66 to 3.72) and 1.37 (0.75 to 2.50). Similar findings were seen for week 52 responders.
**Conclusions:** C6M was dose dependently and significantly decreased from week and throughout study in patients receiving either 4 or 8 mg/kg TCZ compared to placebo. Furthermore, C6M was significantly decreased in patients having ACR20, 50 and 70 response as well as DAS28-ESR reduction and remission compared to non-responders. Importantly, changes in C6M after 4 weeks were able to predict response to treatment by ACR score independent of treatment group. The data suggest that and early decrease in ECM turnover following TCZ treatment, measured by the protein fingerprint marker C6M, increases the odds of a positive patient outcome.

## AB0175 PREVALENCE AND SIGNIFICANCE OF RHEUMATOID FACTOR AND ANTI-CCP IN PATIENTS WITH INTERSTITIAL LUNG DISEASE AND RHEUMATOID ARTHRITIS

C. Aguilera Cros[1], A. Ruíz Román[1], M. Lisbona Muñoz[1], M. Luque León[1], P. León Rubio[1], J.P. Sanchez Serrano[2], J. Povedano Gómez[1], J.A. Rodrigez Portal[3]. *[1]Rheumatology, University Hospital Virgen del Rocío, Seville; [2]Animal Breeding and Genetics, IRTA Caldes de Montbui, Barcelona; [3]Pneumology, University Hospital Virgen del Rocío, Seville, Spain*

**Background:** Rheumatoid Arthritis (RA) is an autoimmune disease that can cause systemic manifestations such as interstitial lung disease (ILD). In these patients serum autoantibodies may appear, such as Rheumatoid Factor (RF) and Anti-Citrullinated Peptide antibody (anti-CCP), important for its relationship with structural damage and extra-articular manifestations.
**Objectives:** To determine the presence of anti-CCP and RF, clinical-radiological characteristics and evaluate the degree of association between the titles of anti-CCP and RF and the time course of disease in patients with RA and diagnosis of ILD.
**Methods:** We performed a descriptive study, including 45 patients, treated at a specialized consultation Interstitial lung diseases, during the first half of 2015. Patients were subdivided into groups based on RF level: $<24$ U/ml Negative, 24–72 U/ml Low Titer and $>72$ U/ml High Titer. Anti-CCP level: 0–10 U/ml Negative, 10–150 U/ml Low Titer, 151–299 U/ml Moderate Titer and$>300$ U/ml High Titer.
Furthermore, ILD has been divided into different subtypes (the diagnostic includes a clinical exam, pulmonary function tests and high resolution CT): Usual Interstitial Pneumonia (UIP), nonspecific Interstitial Pneumonia (NSIP), Lymphocytic Interstitial Pneumonia (LIN), bronchiolitis obliterans (BO).
Evolution time (ET) of the disease was defined as the difference in months between the date of diagnosis of RA and the date of diagnosis of pulmonary involvement. The association between ET and Anti-CCP level and RF level was studied by two analyzes of variance of a ranking factor.
The association between the categories of titer and subtype ILD was studied by two tests Chi-square.
**Results:** Baseline characteristics were: 32 women and 13 men with a mean age of 66±9.6 years (mean ± SD), 36 RA and 9 with secondary Sjogren's syndrome. The most common extraarticular manifestation was ocular 37%. Erosive disease was present in 80% patients.
82% were RF positive (High Titer 78% and Low Titer 22%) and 8% seronegative. Anti-CCP were tested in 32 (71%) and present in 29 (27% High Titer, 42% Moderate Titer and 31% Low Titer).
The mean time from RA diagnosis to ILD diagnosis was 6.87 years, with a standard deviation of 6.90 years.
The time course of the disease is not significantly ($p<0.05$) affected by the titer of anti-CCP or the RF. On the one hand, the enormous variability in the time course of the disease and on the other the lack of information about the time of the determination of autoantibody titers, could explain the lack of statistical association found.
Among the different subtypes nor have we found: NSIP 42%, 35% UIP, LIN 7%, 15% BO. No significant association ($p<0.05$) between the titer of RF and anti-CCP with radiological clinical pattern in our series did not appreciate.
**Conclusions:** In our study, the high titers of RF and anti-CCP were not associated with prematurity on lung involvement in patients with RA, considering the enormous variability in the time evolution has been observed in the sample. Moreover RF levels and anti-CCP also not associated with subtype ILD.
Further prospective studies are needed to fully assess the implications of a positive RF and anti-CCP in patients with RA and ILD.

## AB0176 PULMONARY ASSESSMENT IN ACPA POSITIVE SUBJECTS WITHOUT INFLAMMATORY ARTHRITIS AND IN PATIENTS WITH EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS: THE ROLE OF FUNCTIONAL AND INFLAMMATORY BIOMARKERS

C. Iannuccelli[1], M.C. Gerardi[2], M. Di Paolo[3], M. Bonini[3], M. Vomero[1], B. Lucchino[1], P. Palange[3], M. Di Franco[1], G. Valesini[1]. *[1]Department of Internal Medicine and Medical Specialities, Sapienza university of Rome, Roma; [2]L. Sacco University Hospital, Milano; [3]Department of Public Health and Infectious Diseases, Sapienza university of Rome, Roma, Italy*

**Background:** It is known that citrullinated proteins (ACPA) may be present years before the onset of clinical manifestations of Rheumatoid Arthritis (RA). Recent findings suggest that the lung may represent an early site of autoimmune-related injury in ACPA-positive patients without signs of arthritis (1, 2).
**Objectives:** The purpose of the present study was to evaluate the presence of subclinical pulmonary abnormalities in ACPA-positive subjects without arthritis and in RA-patients through functional and inflammatory biomarkers.
**Methods:** Thirty consecutive patients: 11 ACPA-positive without arthritis, 10 naïve to therapy with early ACPA-positive RA ($<24$ weeks) and 9 with established

ACPA-positive RA (<36 months duration) were enrolled. After obtaining informed consent, all subjects underwent baseline pulmonary function tests (PFTs), DLCO measurement and cardiopulmonary exercise testing (CPET). A blood sample for the ELISA evaluation of Surfactant protein D (SP-D) serum levels was collected. Serum levels of SP-D were also measured in 9 healthy control age and sex-matched. Exclusion criteria were: cardiovascular disease, lung disease already known, diabetes, other autoimmune diseases

**Results:** The cohort consisted of 7 men and 23 women, mean age 48,93 (DS ±12.1). PFTs resulted abnormal only in 2 patients. A DLCO reduction was observed in 54.5% of ACPA-positive subjects without RA, in 60% and in 55.6% of patients with early and established RA, respectively. In RA patients, an inverse correlation between disease duration and ratio of the diffusing capacity to the alveolar volume (DLCO/Va) (r=-0.50; p=0.03) was observed. The exercise tolerance (V'O2 peak) at CPET was reduced in 54.5% of ACPA-positive subjects without RA, in 20% of patients with early RA and in 55.6% of those with established RA. Serum levels SP-D were higher in established RA (p=0.079) and in ACPA-positive subjects and early RA than in healthy control. Interestingly enough, ACPA levels positively correlated (r=0.45; p=0.01) with CPET parameters of ventilatory inefficiency (ratio of the increase in ventilation (V'E) to the increase in CO2 output (V'CO2) at lactic threshold (LT)-V'E/V'CO2@LT), suggesting a ventilation/perfusion mismatch. A negative correlation between ACPA and SP-D levels and CPET metabolic parameters (oxygen uptake (V'O2)) was also observed (SP-D-V'O2@LT/kg r=-0.38 p=0.03 – V'O2@LT/kg-ACPA r=-0.36 p=0.05).

**Conclusions:** The lung involvement in RA, particularly in the early phases of disease, is often subclinical and baseline PFTs are scarcely informative. Although preliminary, these findings suggest that DLCO, CPET parameters and SP-D can represent early markers of the subclinical lung injury. Additional studies are however needed to clarify lung abnormalities in RA.

## AB0177 PATIENT-REPORTED OUTCOME OF UPPER EXTREMITY SURGERY FOR RHEUMATOID ARTHRITIS

D. Kaneda[1], H. Ohashi[1], A. Takeshita[1], M. Horita[1], T. Machida[1], R. Nakahara[1], Y. Nasu[2], K. Hashizume[3], K. Nishida[1,4], T. Ozaki[1]. *[1]Department of Orthopaedic Surgery; [2]Department of Medical Materials for Musculoskeletal Reconstruction, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [3]Department of Orthopaedic Surgery, Okayama Rosai Hospital; [4]Department of Human Morphology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, Okayama, Japan*

**Background:** The goal of treat to target (T2T) is the clinical remission in patients with early disease, but it is difficult to achieve the functional remission. Although patient's subjective evaluation is important for the assessment of postoperative functions of rheumatoid arthritis (RA) patients, there are few reports examined the patients-reported functions after upper extremity surgery for RA.

**Objectives:** Between 2011 and 2014, 158 RA patients underwent the surgical treatment on upper extremities, and all patients were available for detailed clinical review over a 1-year follow-up period. There were 144 females and 14 males with a mean age at surgery of 59.7 (range, 18–85) years. The average disease duration at the surgery was 19.6 (range, 1–59) years.

**Methods:** The clinical outcome of the surgery was assessed by the disease activity (DAS28-CRP), Health Assessment Questionnaire Disability Index (HAQ-DI), Disability of Arm Shoulder and Hand (DASH), Hand20 questionnaire (Hand20). The patients were divided by surgical site into 3 groups (elbow, wrist and finger groups) and by the use of biological disease-modifying anti-rheumatic drugs (bDMARDs) into 2 groups (bDMARDs and non-bDMARDs groups) to compare and evaluate the outcomes.

**Results:** The mean of preoperative/postoperative DAS28-CRP, HAQ-DI, DASH and Hand20 were 2.9/2.3, 0.88/0.94, 46.4/39.1 and 59.1/47.6, respectively. All outcomes except for HAQ-DI significantly improved after the surgery. All outcomes improved significantly in the elbow group, but could not reach significant improvement in the finger group. We further examined the postoperative change in each items of DASH and Hand20, and found the significant improvements in items about pain and weakness in elbow group, pain and rotation of forearm in wrist group, and delicate movement and cosmetic factor in finger group. Postoperative DASH and Hand20 scores were tend to improve in the both bDMARDs and non-bDMARDs group.

**Conclusions:** Our results confirmed the surgery on upper extremity of RA improved the patient's reported function, as well as the disease activity. There were surgical site-specific pattern of improvement of DASH and Hand20, such as that gross movement and pain significantly improved in larger joints, and dexterity movement and cosmetic factor in smaller joints. Postoperative upper extremity function was tend to improve, but more significantly in non-bDMARDs group, probably because the patients might had relatively better baseline function in the bDMARDs group. Understanding of site-specific patterns of improvement after surgery might be useful to achieve the functional remission, and may contribute to decision making of surgical indication, priority of surgical site on upper extremity, and prospection of surgical outcome.

## AB0178 MENOPAUSE IS A PREDICTOR FOR THE DEVELOPMENT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES IN WOMEN AT RISK FOR RHEUMATOID ARTHRITIS

D. Alpizar-Rodriguez[1], R. Müller[2], B. Möller[3], J. Dudler[4], A. Ciurea[5], I. Von Mühlenen[6], D. Kyburz[6], P. Zufferey[7], S. Bas[1], D. Gascon[1], C. Lamacchia[1], P. Roux-Lombard[1], K. Lauper[1], D. Courvoisier[1], C. Gabay[1], A. Finckh[1]. *[1]HUG, Geneve; [2]KSSG, St Gallen; [3]Inselspital, Bern; [4]HFR, Fribourg; [5]USZ, Zurich; [6]USB, Basel; [7]CHUV, Lausanne, Switzerland*

**Background:** Many controversies exist about the role of sex hormones and reproductive factors in the development of rheumatoid arthritis (RA). Post-menopause is a period of important hormonal and immunologic changes and has been associated with increased risk of seronegative-RA (1). Earlier age at menopause has been associated with increased risk of RA (2), therefore factors related to menopause may be relevant for the development of preclinical phases of RA.

**Objectives:** To study the association between reproductive and menopausal factors and the risk of development systemic autoimmunity associated with RA, in particular of anti-citrullinated protein antibodies (ACPA), in women at increased risk for RA.

**Methods:** This is a nested cohort study within an ongoing prospective study of individuals genetically at risk of developing RA, namely first degree relatives of patients with RA (FDRs). Individuals without clinical evidence of RA were enrolled, and followed-up yearly with clinical and laboratory assessments. We included all women with available ACPA status (anti-CCP 2, 3.1 or 3.0). Reproductive and menopausal factors were self-reported. We operationally defined perimenopausal women as those with recent menopause (<3 years) or aged between 47 to 53 years with menopause-related symptoms. Total ovulatory years were estimated by substracting the age at menarche from the age at menopause minus one year for every childbirth and the total years of oral contraceptive use as previously

(a) Univariable logistic regression analysis (c) P<0.05
(b) Multivariable logistic regression analysis

described (3). We used logistic regression to analyze univariable and multivariable associations between ACPA-positivity and menopause factors.
**Results:** Of the 809 FDR women analyzed, 50 (6%) were ACPA-positive and had a median age of 46 (interquartile range (IQR): 34–56) years. Characteristics of FDR women are shown in Table 1. In univariable analysis, older age, ≥1 tender joint on examination, post-menopausal status and total ovulatory years were significantly associated with ACPA positivity. Perimenopausal status tended to be associated with ACPA status (OR:1.8, 95%CI:0.9–3.4), but did not reach significance. Other menopausal factors, such as age at menopause, earlier menopause or surgical menopause were not associated with ACPA positivity. Due to high correlation between age and menopausal status (r=0.73), we included tobacco smoking, post-menopausal status and having ≥1 tender joint on examination in the multivariable adjusted analyses, post-menopausal status and ≥1 tender joint on examination remained independently associated with ACPA positivity.
**Conclusions:** Post-menopausal FDR women have an increased risk of ACPA positivity, suggesting menopausal hormonal changes are associated with the development of ACPAs, which may be linked to previously described increase of pro-inflammatory cytokines during menopause (4).

## AB0179 REVISION OF EUROPEAN MEDICINE AGENCY'S (EMA) GUIDELINE ON CLINICAL INVESTIGATION OF MEDICINAL PRODUCTS OTHER THAN NSAIDS FOR TREATMENT OF RHEUMATOID ARTHRITIS, 2016

E. Rook on behalf of Rheumatology/Immunology Working Party (RIWP), European Medicine Agency (EMA). *Medicine Evaluation Board, Utrecht, Netherlands*

**Background:** The EMA's Committee for Medicinal Products for Human Use (CHMP) prepares scientific guidelines in consultation with regulatory authorities in the EU Member States, to help applicants prepare marketing-authorisation applications for human medicines, including rheumatology. These guidelines are developed by the RIWP, which is composed of European experts selected from or associated with national agencies.
**Objectives:** The current EMA Guideline on rheumatoid arthritis (RA) dates from 2003. Ever since, there has been a major change in treatment paradigm of RA, with treatment to target in an earlier disease phase. These advancements require modified recommendations regarding the development of RA therapies.
**Methods:** Development and release for consultation of the concept paper by RIWP.
All external comments received are currently reviewed and the draft guideline will be amended as required before release of the final guideline by the CHMP.
**Results:** New primary endpoints were defined, reflecting treatment targets of low-disease activity (LDA) or even remission, in place of the previous primary endpoint of ACR20 scores. Furthermore, a distinction is made in the design and endpoints for DMARD naïve patients, where a DAS28-ESR score <2.6 is considered as a realistic target, or patients irresponsive to MTX or a biological DMARD, where a DAS28 score <3.2 is considered as an acceptable endpoint. For patients with long-standing disease irresponsive to multiple DMARDs, ACR20 is still considered a suitable primary endpoint. For the main study, a three-arm trial including placebo and an active comparator is required. For ethical reasons, placebo may be as short as 6–12 weeks, using rescue medication. Alternatively, superiority of the new product may be shown to an active comparator in a two-arm study.
The ultimate goal of RA treatment is the prevention of structural joint damage. However, showing an effect on structural damage has become increasingly challenging, since the placebo control should be kept short, and milder or more controlled patients may be eligible for studies of new DMARDs. According to this updated guideline, maintenance of remission and LDA could serve indirectly as an indicator for the prevention of structural damage, provided that routine monitoring by X-ray do not indicate a deviating trend as compared to an established comparator treatment. Considering the challenges of demonstrating structural damage regarding power, non-inferiority does not need to be demonstrated formally.
**Conclusions:** The EMA guideline on the development of products in the treatment of RA, has undergone some major revisions regarding endpoints and study design, in accordance to current European clinical practice.

## AB0180 SMOKING AND PERSISTENT DISEASE ACTIVITY ARE ASSOCIATED WITH AN INCREASED RISK OF RAPID JOINT DESTRUCTION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

E. Rydell [1,2], C. Book [1,2], K. Forslind [3,4], J.-Å. Nilsson [1,2], L. Jacobsson [1,5], C. Turesson [1,2]. *[1]Rheumatology, Department of Clinical Sciences, Malmö, Lund University; [2]Department of Rheumatology, Skåne University Hospital, Malmö; [3]Section of Rheumatology, Department of Clinical Sciences, Helsingborg, Lund University; [4]Section of Rheumatology, Department of Medicine, Helsingborg Hospital, Helsingborg; [5]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden*

**Background:** Joint destruction is a major cause of disability in patients with rheumatoid arthritis (RA). Early predictors of rapid joint destruction would be helpful in clinical decision-making, with the potential to yield better patient outcomes. There are conflicting data on the impact of smoking on radiographic progression, and limited information on the importance of disease activity over time in this context.
**Objectives:** To study the relation between patient characteristics at RA diagnosis (baseline) and after 1 year and subsequent rapid radiographic progression (RRP) of joint damage over 5 years.
**Methods:** An inception cohort of patients with early RA (symptom duration <12 months), recruited in 1995–2005 from a defined area, was investigated. Patients were followed according to a structured program, with follow-up visits at 12 and 60 months after inclusion. The same rheumatologist performed the clinical examinations. Those included in the study were managed according to usual care, with no pre-specified protocol for anti-rheumatic treatment. Radiographs of hands and feet were scored in chronological order by a trained reader according to the modified Sharp-van der Heijde score (SHS). RRP was defined as an increase of ≥5 points in SHS per year. Logistic regression models were used to assess potential predictors of RRP.
**Results:** Two hundred and thirty three patients with early RA (70% women, mean age 62 years, 62% RF- and 58% anti-CCP positive) were included. Radiographs were available from 232 patients at baseline, 211 at 1 year and 164 at 5 years. Thirty-six patients were classified as RRP from baseline to 5 years, and the same number from year 1 to 5 years. As expected, RF (odds ratio (OR) 5.70; 95% confidence interval (CI) 1.90–17.10) and anti-CCP (OR 6.04; 95% CI 1.98–18.47) were predictive of RRP over 5 years. A history of ever smoking was associated with a significantly increased risk of RRP up to 5 years (OR 2.69; 95% CI 1.01–7.18, adjusted for RF and baseline presence of erosions). High CRP and ESR at inclusion were predictive of RRP, whereas there were no significant associations for baseline DAS28, swollen joint count, tender joint count or patient's global assessment (Table 1). At the 1-year follow-up, in addition DAS28 and swollen joint count were also significantly associated with RRP up to 5 years (Table 1). Elevated CRP (>9 mg/l) at 1 year was a robust predictor of subsequent RRP (adjusted OR 6.98; 95% CI 2.85–17.14).

**Table 1. Impact of disease activity at inclusion and at the 1-year follow up on rapid radiographic progression up to 5-years**

| | 0-5 years | | | | 1-5 years | | | |
|---|---|---|---|---|---|---|---|---|
| | Crude | | Adjusted[1] | | Crude | | Adjusted[1] | |
| Variables | OR | 95% CI | OR | 95% CI | OR | 95% CI | OR | 95% CI |
| DAS28[2] | 1.47 | (0.99-2.18) | 1.41 | (0.94-2.11) | 2.89 | (1.81-4.61) | 2.54 | (1.54-4.19) |
| Swollen[2] joint count | 1.26 | (0.87-1.84) | 1.26 | (0.86-1.86) | 1.97 | (1.35-2.87) | 1.79 | (1.18-2.70) |
| Tender[2] joint count | 0.85 | (0.55-1.32) | 0.94 | (0.60-1.48) | 1.49 | (1.01-2.19) | 1.46 | (0.94-2.29) |
| Patient's[2] global assessment | 1.36 | (0.92-2.00) | 1.29 | (0.85-1.94) | 1.59 | (1.08-2.34) | 1.71 | (1.10-2.66) |
| ESR[2] | 1.89 | (1.33-2.69) | 1.70 | (1.17-2.46) | 2.82 | (1.77-4.50) | 2.10 | (1.30-3.37) |
| CRP > 9 mg/l | 2.89 | (1.31-6.39) | 2.36 | (1.04-5.38) | 10.32 | (4.44-24.00) | 6.98 | (2.85-17.14) |

OR=Odds ratio; CI=Confidence interval.
[1]Adjusted for RF and baseline erosions.
[2]Per standard deviation.

**Conclusions:** Early RA patients with a history of smoking were more likely to have rapidly progressive joint damage. High disease activity measures at 1 year were strongly associated with rapid radiographic progression. These results underline the importance of early successful anti-rheumatic treatment and suppression of disease activity, to lower the risk of rapid joint destruction in early RA.

## AB0181 SONOGRAPHIC PERSISTENCE OF SUBCLINICAL JOINT AND TENDON INFLAMMATION IN RHEUMATOID ARTHRITIS PATIENTS ACHIEVING SUSTAINED CLINICAL REMISSION ON SYNTHETIC OR BIOLOGIC DRUG THERAPY: PRELIMINARY DATA OF A CROSS-SECTIONAL STUDY

A. Becciolini[1], E.G. Favalli[1], M. Di Carlo[2], M. Biggioggero[3], C. Crotti[3], F. Salaffi[2], P.L. Meroni[4]. *[1]Department of Rheumatology, Gaetano Pini Institute, Milano; [2]Rheumatology Department, Polytechnic University of the Marche, Jesi, Ancona; [3]Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute; [4]Department of Clinical Sciences and Community Health, University of Milan and IRCCS Istituto Auxologico Italiano, Milano, Italy*

**Background:** Based on more recent recommendations, remission or low-disease activity are pivotal targets to be achieved in the treatment of rheumatoid arthritis (RA). However, despite a clinical remission, subclinical joint and tendon inflammation potentially leading to structural and functional worsening can be detected in a large number of patients.
**Objectives:** To determine the prevalence of joint and tendon inflammation by ultrasound (US) gray scale (GS) and power Doppler (PD) in RA patients treated with biological (bDMARDs) or synthetic disease modified anti-rheumatic drugs (sDMARDs) achieving a sustained clinical remission.
**Methods:** RA patients treated with sDMARDs or bDMARDs achieving a sustained clinical remission (defined as DAS28$<$2.6 since at least 6 months and no swollen joints) were prospectively selected from two Rheumatology Departments. All subjects underwent US examination of hands and wrists bilaterally. The US evaluation was performed on 22 joints (bilateral proximal interphalangeal, metacarpophalangeal and wrists) and 26 tendons/tendon compartments with synovial sheath (first through sixth wrist extensor compartments, first through fifth finger flexor digitorum superficialis and profundus tendons, flexor radialis carpi, and flexors digitorum at the carpal tunnel). The presence of synovial/tenosynovial effusion or hypertrophy in GS and pathological hypervascularization at PD were reported and graded based on a semi-quantitative scoring system: none, mild, moderate and severe (0 to 3). The two treatment groups were compared by Fisher exact test.
**Results:** Forty-eight RA patients were enrolled (20 on bDMARDs and 28 on sDMARDs). A total of 1056 joints and 1248 tendons/tendon compartments with synovial sheath were examined. Twenty-seven (56.2%) patients presented at least one joint with GS synovial effusion or hypertrophy (9/20 in bDMARD and 16/28 in sDMARD group, respectively; p=0.559). In 15 (31.2%) patients we found at least one joint with active PD signal (7/20 in bDMARD and 8/28 in sDMARDs group, p=0.755). In 8 (16.7%) patients at least one tendon sheath with GS synovial effusion or hypertrophy (2/20 treated with bDMARDs and 6/28 with sDMARDs, respectively; p=0.440) was reported. No patients presented at least one tendon sheath with active PD signal in bDMARD group and 3/28 in sDMARD group (p=0.255). Finally, GS alterations were significantly more frequent in the dominant hand compared to the contralateral (22 [45.8%] vs 10 [20.8%], p=0.017).
**Conclusions:** Our data confirmed the high prevalence of US-detected subclinical active synovitis/tenosynovitis in RA patients achieving a sustained DAS28 remission. Joints resulted more frequently involved than tendons in subclinical detected inflammatory process. No differences were found according with bDMARD or sDMARD treatment. GS synovitis was more frequently demonstrated in the dominant hand.

## AB0182 BASELINE FINDINGS FROM A PATIENT-CENTERED, TREAT-TO-TARGET APPROACH IN RHEUMATOID ARTHRITIS

E. Ruderman[1], G. Greene[2], J. Beaumont[2], A. Muftic[2], E. Bacalao[1], A. Mandelin[1], A. Eisenstein[3], D. Cella[2]. *[1]Northwestern University Feinberg School of Medicine; [2]Northwestern University; [3]CJE SeniorLife, Chicago, United States*

**Background:** The Patient Reported Outcomes Measurement Information System (PROMIS) is an NIH initiative to develop patient-reported outcome measures for use across chronic conditions. PROMIS instruments assess outcomes relevant in Rheumatoid Arthritis (RA) including pain interference, physical function social function, fatigue, and depression. We aimed to learn whether the use of PROMIS instruments could inform the treat-to-target (T2T) approach to RA management, and to understand whether patient reports of disease impact correlate with objective clinical measures.
**Objectives:** For this study, patients are treated for 1 year using a T2T approach. Using PROMIS item banks, we developed patient-centered targets in five domains: pain, fatigue, depression, physical function, and social function. We report on the baseline status of the full sample of patients enrolled in the study (n=119) stratified by disease activity (remission or low disease activity, CDAI $\leq$10 vs. moderate or high disease activity, CDAI $>$10). We also report on patient satisfaction with the individualized T2T approach, in addition to clinician feedback on the feasibility and usefulness of this approach.
**Methods:** Patients with RA diagnosed by 2010 ACR/EULAR criteria were recruited from our academic clinical practice. At baseline data collection, standard RA assessments included joint counts, RAPID3, and CDAI scores. The research assessment battery included clinical questionnaires, PROMIS CAT's (computer adaptive tests), prioritization of PROMIS domains, and selection of five items that patients felt were most important within their most highly prioritized domain.
**Results:** The baseline sample consists of 119 RA patients with a median age of 57 years (range: 21–77). The sample was 91% female, 71% White, and 12% Hispanic. Approximately 54% (n=57) exhibited moderate or high disease activity (CDAI m=13.4; SD=11.0). When selecting prioritization areas for treatment targets, 39% of patients selected physical function, followed by 37% of participants selecting pain, 16% fatigue, 5% depression, and 3% social function. Those with high active disease were more likely to select pain (44% vs. 22%). Compared to the U.S. general population reference values for PROMIS (m=50; SD=10), patients reported worse fatigue (m=56.4), pain interference (m=57.6), and physical function (m=42.3). Baseline scores on depression and social functioning were closer to average in the general U.S. population. Patient feedback about the study has been positive. An overwhelming majority of patients reported that they would be "somewhat" (33%) to "very likely" (56%) to participate in similar treatment programs. Response from health care providers has been positive as well, with limited reports of negative impacts of data collection on clinic flow.
**Conclusions:** Most patients selected physical function, pain, and fatigue as the most important domains for their personal treatment goal setting. Consistent with these selections, patients' health ratings in these domains were worse compared to the general population. We will continue to explore correlations between PROMIS scores and standard disease activity measures, as well as clinician impressions of the impact of these data on their treatment decisions.

## AB0183 LONG TERM OUTCOME OF EARLY ARTHRITIS: FROM REMISSION THROUGH RHEUMATOID ARTHRITIS

T. Cukadar[1], S.Z. Aydın[2], H. Keskin[1], E. Kasapoglu-Gunal[3]. *[1]Internal Medicine, Istanbul Medeniyet University Goztepe Training aneResearch Hospital, Istanbul, Turkey; [2]Rheumatology, University of Ottawa Faculty of Medicine, Ottawa, Canada; [3]Rheumatology, Istanbul Medeniyet University Goztepe Training aneResearch Hospital, Istanbul, Turkey*

**Background:** Real life experience of early arthritis; remission or evolving to rheumatoid arthritis
**Objectives:** To assess long term outcome, drug free remission rates of patients with early arthritis and classification based on 1987 ACR[1] or 2010 ACR/EULAR[2] rheumatoid arthritis (RA) criteria.
**Methods:** Patients with arthritis with symptom duration within the first 3 months at first visit were assessed after disease age of at least 6 months. Patients with unclassified arthritis (UA) and classified as RA were included. Patients using drugs other than non-steroidal anti-inflammatory drugs (NSAID) at first visit were excluded. Glucocorticoids were given if NSAIDs failed to induce remission. Patients were interviewed with telephone and those accepted were admitted to the outpatient clinic. Patients were telephoned for 3 times if first 2 call were missed. There were 135 patients. Among 92 patients interviewed only one refused to participate. 37 (27%) were admitted to outpatient clinics, 54 (40%) were interviewed with telephone. Patients were classified as RA according to either 1987 ACR or 2010 ACR/EULAR criteria.
**Results:** Demographic features were as follows: 66 (73%) were woman, mean age was 50 (19–85) (first admission). Mean swollen and tender joint count was 5 (1–22) and 8 (1–36) respectively. Most frequently affected joints were MCP (50%), wrist (48%), and PIP (32%). Morning stiffness was longer than 30 minutes in 67%. RF and anti-CCP were positive 20%, 17%, respectively. Mean age of disease at the last assessment was 4 years (6 months- 8 years). Patients were classified as RA according to 1987 ACR (8%) and 2010 ACR/EULAR (20%) criteria. Glucocorticoids were given 75%. Mean glucocorticoid dosage was 10 mg (5–50) and 8% patients were given 50 mg equivalent of prednisolon for 3 days in order to induce remission. Drug free remission was induced with NSAIDs and glucocorticoids in 18% and 20% patients respectively. DMARDS were given in 44 (48%) patients (HQ, 45%; MTX, 44%; SSZ 17%; LEF 11%; only 1 patient TNF inhibitors). 13 patients (14%) voiced that although they were given DMARD, they stopped to take DMARDs and they were symptom free for approximately 3 years.
**Conclusions:** Early arthritis patients with the diagnosis of unclassified arthritis or RA were assessed. Drug free remission was achieved in approximately 40% of the patients. These patients were still symptom free after about four years. Nearly half of the patients were given DMARD although only 20% of the patients fulfilled either 1987 or 2010 criteria. About 10% of the patients stopped taking DMARDs although given and they were symptom free. There are contradictory results about efficacy of MTX in probable RA and UA in disease progression. Along with these results, we are still in the need of criteria that would indicate the early arthritis patients to start with DMARDs so that we would neither be late nor avoid any unnecessary prescription.

## AB0184 DISEASE-DRUG INTERACTION OF SARILUMAB AND SIMVASTATIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

E.B. Lee[1], N. Daskalakis[2], C. Xu[2], A. Paccaly[3], B. Miller[2], R. Fleischmann[4], I. Bodrug[5], A. Kivitz[6]. *[1]Seoul National University College of Medicine, Seoul, Korea, Republic Of; [2]Sanofi, Bridgewater; [3]Regeneron Pharmaceuticals, Inc, Tarrytown; [4]Metroplex Clinical Research Center, Dallas, United States; [5]Arensia Exploratory Medicine GmbH, Düsseldorf, Germany; [6]Altoona Center for Clinical Research, Duncansville, United States*

**Background:** Elevated IL-6 levels occur in rheumatoid arthritis (RA) and can lead to modulation of cytochrome P450 (CYP) enzyme activity and changes in drug levels (CYP substrates) compared with individuals without RA. Conversely, blockade of IL-6 signaling by IL-6 receptor (IL-6R) antagonists may reverse this effect of IL-6 and restore CYP activity. Hence, IL-6 is expected to inhibit CYP3A4 activity, while IL-6 inhibitors, such as sarilumab, are expected to restore elevated simvastatin (a CYP3A4 substrate) concentrations in patients with RA back to those observed in healthy individuals.
**Objectives:** This study (NCT02017639) evaluated the pharmacokinetic profile of simvastatin, a CYP3A4 substrate, before and after a single dose of sarilumab, an investigational anti–IL-6R monoclonal antibody, in patients with active RA to assess disease-drug interaction of sarilumab on simvastatin.
**Methods:** Nineteen adult patients with moderate-to-severe RA with CRP >6.0 mg/L at baseline received simvastatin 40 mg 1 day before and 7 days after subcutaneous injection of sarilumab 200 mg. A series of plasma samples were collected over 24 hours and analyzed for concentrations of simvastatin and its major metabolite, β-hydroxy-simvastatin acid, using a validated LC-MS/MS method. Pharmacokinetic parameters of plasma simvastatin and β-hydroxy-simvastatin acid were calculated using noncompartmental analysis. The geometric mean ratios (with vs without sarilumab) and 90% CIs for peak plasma concentration ($C_{max}$) and area under the plasma concentration-time curve extrapolated to infinity ($AUC_{0-\infty}$) were calculated. C-reactive protein was also analyzed.
**Results:** The majority of patients were female (78.9%) and Caucasian (63.2%). All patients had moderate-to-severe disease activity per study inclusion criteria with a mean CRP (± SD) of 22.1±24.4 mg/L. Administration of a single dose of sarilumab along with simvastatin to patients with RA resulted in reduced exposure to simvastatin by 45% and to β-hydroxy-simvastatin acid by 36% compared with simvastatin alone. Mean effect ratios (90% CI) for simvastatin $C_{max}$ and $AUC_{0-\infty}$ were 54.1% (42.2%>69.4%) and 54.7% (47.2%>63.3%), respectively (Table). There were no changes in time to $C_{max}$ ($t_{max}$) or half-life ($t_{1/2}$) for either simvastatin or β-hydroxy-simvastatin acid following sarilumab exposure (Table). Levels of CRP decreased from 22.1±24.4 mg/L at baseline to reach a nadir of 1.9±0.9 mg/L at 1 wk after sarilumab administration and remained low thereafter. Consistent with the anticipated effects of IL-6 inhibition and the known safety profile of sarilumab, the most frequently reported TEAE across all study treatments was neutropenia, followed by increased alanine aminotransferase level.

**Table.** Geometric Mean (± SD) Pharmacokinetic Parameters for Simvastatin and β-Hydroxy-Simvastatin Acid With Treatment Ratio Estimates and Associated 90% CIs

| | Simvastatin | | | β-Hydroxy-simvastatin acid | | |
|---|---|---|---|---|---|---|
| Parameter | Simvastatin (n=17[a]) | Simvastatin after sarilumab (n=17[a]) | Point estimate ratio (90% CI) | Simvastatin (n=17[a]) | Simvastatin after sarilumab (n=17[a]) | Point estimate ratio (90% CI) |
| $C_{max}$, ng/mL | 21.3 (12.8) | 11.0 (5.8) | 0.541 (0.422-0.694) | 4.2 (3.4) | 3.0 (2.8) | 0.641 (0.555-0.741) |
| $t_{max}$, h[b] | 2.0 (1.0-4.0) | 2.0 (0.5-4.0) | | 4.0 (2.0-6.0) | 4.0 (4.0-6.0) | |
| $AUC_{last}$, ng*h/mL | 82.7 (52.8) | 46.6 (32.7) | 0.540 (0.465-0.628) | 29.6 (22.9) | 20.5 (18.3) | 0.628 (0.536-0.737) |
| $AUC_{0-\infty}$, ng*h/mL | 84.3 (53.6) | 47.9 (33.4) | 0.547 (0.472-0.633) | 31.5 (23.3) | 22.2 (19.0) | 0.641 (0.541-0.758) |
| $t_{1/2}$, h | 3.7 (1.2) | 3.8 (1.4) | | 3.8 (1.2) | 3.5 (1.3) | |

$AUC_{0-\infty}$, area under the plasma concentration-time curve extrapolated to infinity; $AUC_{last}$, AUC from time zero to last quantifiable concentration; CI, confidence interval; $C_{max}$, peak plasma concentration; SD, standard deviation; $t_{1/2}$, terminal half-life associated with the terminal slope; $t_{max}$, time to simvastatin $C_{max}$.
[a]Pharmacokinetic parameters could not be calculated for 2 patients because of sample stability issues during bioanalysis.
[b]Median (min – max).

**Conclusions:** Sarilumab reverses IL-6–mediated suppression of CYP3A4 activity in patients with active RA. The observed reduction of simvastatin exposure is consistent with similar studies conducted with tocilizumab and sirukumab, in agreement with IL-6–mediated disease-drug interaction effect.

## AB0185 UNDERCARBOXYLATED OSTEOCALCIN AS A MARKER FOR METABOLIC DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

E.-J. Lee[1], B. Ghang[2], D.-H. Lim[2], S. Hong[2], C.-K. Lee[2], B. Yoo[2], Y.-G. Kim[2]. *[1]Asan Institute for Life Science; [2]Department of Rheumatology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of*

**Background:** Osteocalcin (OC) has been known as one of bone-forming markers and the serum level in rheumatoid arthritis (RA) patients was usually lower than that in healthy control. Serum OC, secreted from osteoblasts, exists in either carboxylated OC (cOC, major form) or undercarboxylated OC (ucOC, minor form). Different to the osteogenic role of cOC, ucOC has been suggested to be involved in energy metabolism. Recent studies have shown that significantly lower concentration of ucOC in the blood was associated with metabolic derangement including insulin resistance. Therefore, we would like to investigate whether level of ucOC in RA patients decreased and it was accompanied by metabolic dysregulation, which has never been studied before.
**Objectives:** To determine the association between ucOC and metabolic alteration including insulin resistance in patients with RA
**Methods:** Clinical information of patients and healthy volunteers was collected from electronic data base of single center registry. The concentrations of cOC and ucOC were measured in the sera from established RA patients (n=30) and healthy subjects (n=13) by enzyme-linked immunosorbent assay (ELISA). Various metabolic parameters, including insulin concentration, homeostasis model assessment of insulin resistance (HOMA-IR) and body mass index (BMI), were measured and analyzed.
**Results:** The concentration of cOC in blood was not significantly different between RA patients (13.49±2.97 ng/mL) and healthy controls (14.45±2.48 ng/mL). However, the concentration of ucOC was significantly lower in the sera of patients with RA (3.29±2.36 ng/mL) than in those of healthy individuals (5.94±2.75 ng/mL, $p$=0.003). Intriguingly, ucOC levels have been found to be positively associated with parameters of metabolic derangement including insulin levels, HOMA-IR and BMI (Figure 1). These associations were not found in healthy controls.

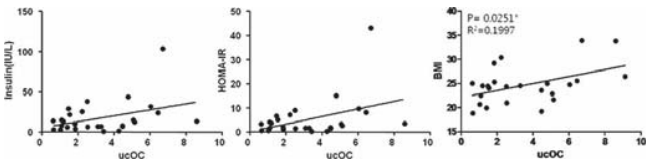

Figure 1. Positive correlation between the levels of ucOC and the values of insulin (left), HOMA-IR (middle), and BMI (right) in the sera of RA patients.

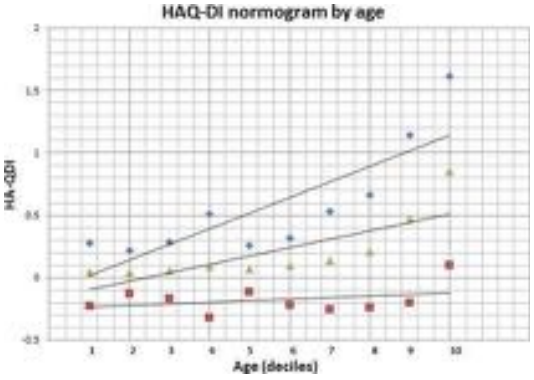

**Conclusions:** The present study show that the concentration of ucOC, but not cOC was significantly lower in patients with RA, and its value was positively correlated with insulin resistance. Therefore, ucOC can be supposed to have a unique role in metabolic dysregulation in RA.
**Disclosure of Interest:** None declared

## AB0186 BENCHMARKING DISABILITY WITH THE HAQ-DI. A NEW NORMOGRAM IN A LATIN AMERICAN NON-RHEUMATIC POPULATION

F. Espinosa-Ortega[1], O. Enriquez-Antonio[2], C.A. Arce-Salinas[2], E. Ruiz-Medrano[2] on behalf of PRECIS Group. *[1]Rheumatology; [2]Medicina Interna, Hospital Central Sur de Alta Especialidad, Mexico City, Mexico*

**Background:** The HAQ-Di is broadly used to measure functional disability in RA, and other rheumatic diseases. It can not differentiate disability caused by arthritis or that caused by other illnesses. Whether non-modifiable constitutional factors (e.g. age), personal behaviors, or common comorbidities exert influence over disability measurement, has only been assessed in quite few trials.
**Objectives:** We aimed to determine disability values in a population without previous musculoskeletal conditions, and recognize its main determinants.
**Methods:** Our Hospital ambulatory area offer primary care attention over thirty thousand people. HAQ-Di was ask to be filled by 1,000 patients of a an annual check-up program, and other primary care areas. Were evaluated those older than 18 years and younger than 95 who signed informed consent; participants with any previous rheumatic disease, and chronic pain condition were excluded. Demographic variables, as well as formal education, health behaviors (smoking and exercise), and comorbidities (Charlson index) were recorded. Bivariate correlations by Spearman, and Kruskall Wallis or t-tests were performed as appropriate. We considered $p<0.05$ as statistically significant value.
**Results:** Nine hundred and seventy eight patients were enrolled (22 rejected), their mean age was 56.5±14.6 years, 38% were female, mean BMI was 27.5±4.7

kg/m$^2$, and a Charlson's score of 1.15±1.9. HAQ-Di population mean was 0.21±0.51 with 29% of the respondents had some kind of disability (HAQ-Di value >0.0). Accordingly to the normogram, disability increased with age (figure 1) (r =0.4; p<0.000). Higher HAQ-Di scores were also related with female gender (women 0.307±0.596 vs. men 0.137±0.385; p<0.001); higher Charlson score (r=0.435; p<0.001); lower formal education (rs=0.41, p<0.001; from 0.723±0.847 in group with only 6 years of instruction to 0.078±0.230 in postgraduate group); and no or mild physical activities (rs=-0.320, p<0.001; from HAQ-Di of 0.489±0.724 in the lowest fitness group to 0.118±0.370 in higher exercise group). We could not find influence in disability by smoking status or BMI. Moreover, those with diabetes mellitus (DM) or high blood pressure (HBP) disclosed higher disability (with DM 0.434±0.7 vs. without DM 0.113±0.329, p=0.005, and with HBP 0.445±0.703 vs. without HBP 0.092±0.278; p=0.001)

**Conclusions:** Almost one third of our non-rheumatic population has some kind of functional disability. Although It seems to appear as an aging phenomenon in the general population, might be influenced by comorbidities, healthy behaviours, and sociocultural factors. Thus, these variations must be taken into account when HAQ-Di is used in patients with rheumatic conditions, particularly RA, where HAQ-Di is frequently used in the making decision process.

## AB0187 INFLUENCE OF EDUCATIONAL LEVEL ON THE OUTCOMES OF RHEUMATOID ARTHRITIS

F. Essafi[1], A. Fazaa[1], S. Kchaou[2], K. Ben Abdelghani[1], S. Kassab[1], S. Chkili[1], A. Laatar[1], L. Zakraoui[1]. *[1]rheumatology, monji slim hospital, sidi daoud; [2]Polyclinic of the National Guard, Aouina, Tunisia*

**Background:** Formal educational background has been associated with a worse health outcome and greater disease activity among patients with Rheumatoid Arthritis (RA).

**Objectives:** The aim of this study was to evaluate the influence of educational level on the outcomes of RA, in terms of disease activity and functional impairment.

**Methods:** This is a cross-sectional study, including patients with RA (1987 ACR criteria). Disease activity was evaluated by erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and Disease Activity Score (DAS28) ESR. Functional disability was assessed by Health Assessment Questionnaire (HAQ). Patients were classified according to their educational level into 4 categories: illiterate, primary, secondary or university levels. Statistical analysis was done using one-way analysis of variance (ANOVA) and linear regression models. The significance level was set at p<0.05.

**Results:** A total of 67 patients with RA were evaluated, 5 men and 62 women. The mean age was 53 years [28–75] and the mean disease duration was 9.19 years [1–30]. Eighty eight percent of patients were treated with synthetic DMARDs (Disease modifying antirheumatic drugs) and 20% were treated with biologic DMARDs.

With regard to the educational level, 34.3% were illiterate, 20.89% had primary level, 34.3% secondary level and 10.44% had university level

There were no statistically significant differences for ESR, CRP, DAS28 and HAQ when comparing the four educational levels (p=0.176, p=0.252, p=0.528, p=0.410, respectively). However, in the multivariate analysis, after adjusting for age and biologic DMARDs, DAS28 and HAQ were significantly associated to the educational level (p=0.024, p=0.014, respectively).

**Conclusions:** This study shows that educational levels may have an influence on the disease activity and functional impairment in patients with RA.

## AB0188 EFFECT OF SMOKING ON JOINT DAMAGE AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

F. Sivas[1], F.G. Yurdakul[1], A. Kılıcaslan[1], S. Duran[2], B. Baskan[1], H. Bodur[3]. *[1]Physical Medicine and Rehabilitation; [2]Radiology, Ankara Numune Training and Research Hospital; [3]Physical Medicine and Rehabilitation, Yıldırım Beyazıt University, Ankara, Turkey*

**Background:** It is known that smoking is a poor prognostic factor for the development of rheumatoid arthritis (RA) and other inflammatory rheumatic diseases. According to our knowledge in Turkish population there are no studies about effects of smoking on joint damage and disease activity of RA patients.

**Objectives:** In this study, we investigated the relationship between smoking with disease activity and radiological damage in Turkish patients with RA.

**Methods:** The study included 165 patients with RA. Patients' demographics, disease duration, age at onset, drugs, rheumatoid factor (RF) levels, anti- Cyclic Citrullinated Peptide (a- CCP) levels and smoking habits recorded. Morning stiffness duration, tender and swollen joint count (TJC, SCJ), pain with using visual analog scale (VAS pain), patient and physician global assessment (PGA, PhGA), Health assessment questionnaire (HAQ) evaluated. Disease activity score 28 (DAS 28) calculated. All patients in the study examined for lung involvement and 127 patients standard hand radiographs evaluated using modified Sharp method.

**Results:** Mean disease duration was 139.4±96.4 months. Patients were divided into 3 groups according to smoking habits. Ninety nine (60%) patients were never smoker, 45 (27.3%) patients were long-term smoker (more than 2 years), and 21 (12.7%) patients were new smoker (2 or less years). While the groups were similar in terms of age and disease duration, male gender was more in long-term smokers. Three groups compared for disease activity. DAS 28 scores were 3.2±1.2; 3.2±1.3; 3.2±1.4 respectively (p>0.05). The erosion score (2.6±5.8; 7.1±10.9; 11.1±19.2 respectively) and joint space narrowing score (9.9±7.3; 18.6±14.9; 17.3±12.3 respectively) according to modified Sharp method were significantly lower in never smokers group than other groups (p<0.05). RF titrations were 55.2±58.9; 84.9±71.5; 60.5±63.1; and long- term smokers group was significantly higher than the other groups (p<0.05). Likewise RF titration was higher in ≥20 pack-years smokers than the other patients (never smokers and <20 pack-years smokers). There was no relationship between a-CPP levels with smoking and joint damage (p>0.05).

**Conclusions:** Although smoking known as a poor prognostic factor in RA, there was no correlation between disease activity and smoking in our population. On the other hand, less radiographic damage has been found in never smoker group. Although cigarette smoking does not appear to correlate with disease activity may be effective in the long-term joint damage.

## AB0189 ANTI-MODIFIED PROTEIN ANTIBODY RESPONSE PATTERN INFLUENCES THE RISK FOR DISEASE RELAPSE IN RHEUMATOID ARTHRITIS PATIENTS TAPERING DISEASE MODIFYING ANTI-RHEUMATIC DRUGS

C. Figueiredo[1], H. Bang[2], J.F. Cobra[3], M. Englbrecht[4], A.J. Hueber[4], J. Haschka[5], B. Manger[4], A. Kleyer[4], M. Reiser[4], S. Finzel[6], H.-P. Tony[7], S. Kleinert[8], J. Wendler[8], F. Krueger[17], J. Rech[4], G. Schett[4]. *[1]Universiy of Erlangen-Nuremberg, Erlangen; [2]Orgentec Diagnostica, Mainz, Germany; [3]Instituto de Reumatologia de Sao Paulo, Sao Paulo, Brazil; [4]University of Erlangen-Nuremberg, Erlangen, Germany; [5]Medical Department II, St. Vincent Hospital, the VINFORCE Study Group, Academic Teaching Hospital of Medical University of Vienna, Vienna, Austria; [6]University Medical Center Freiburg, Rheumatology and Clinical Immunology, Freiburg; [7]Department of Internal Medicine 2, University of Wuerzburg, Würzburg; [8]Rheumatology Practice, Erlangen; [9]Clinic Burghausen, Rheumatology Practice and Department of Internal Medicine 2, Burghausen; [10]Department of Rheumatology and Clinical Immunology, Asklepios Medical Center, Regensburg; [11]Rheumatology Practice, Bamberg; [12]Rheumatology Practice, Bayreuth; [13]Medicine V, University of Heidelberg, Heidelberg; [14]Rheumatology Practice, Nuernberg; [15]Schlosspark-Klinik, Teaching Hospital Charite, Internal Medicine, Rheumatology, Berlin; [16]University Hospital Tuebingen, Centre for Interdisciplinary Clinical Immunology, Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II, Tübingen; [17]Praxiszentrum St.Bonifatius Muenchen, Muenchen, Germany*

**Background:** Autoimmunity is still present in rheumatoid arthritis patients in sustained disease remission. In the absence of inflammation the pattern of autoimmunity against post-translationally modified proteins could potentially impact the course of disease of rheumatoid arthritis patients, espepcially their risk to experience relapse of disease when disease modifying anti-rheumatic drugs (DMARDs) are tapered or stopped

**Objectives:** To perform a detailed analysis of the autoantibody response against post-translationally modified proteins in rheumatoid arthritis (RA) patients in sustained remission and to test whether its composition influences the risk for disease relapse when tapering DMARD therapy.

**Methods:** Immune responses against 10 citrullinated, homocitrullinated/carbamylated and acetylated peptides, as well as unmodified vimentin (control) and cyclic citrullinated peptide 2 (CCP2) were tested in baseline serum samples from 94 patients of the RETRO study. Patients were classified according to the number of autoantibody reactivities (0–1/10, 2–5/10 and >5/10) or specificity groups (citrullination, carbamylation and acetylation; 0 to 3) and tested for their risk to develop relapses after DMARD tapering. Demographic and disease-specific parameters were included in multivariate logistic regression analysis for defining the role of autoantibodies in predicting relapse.
**Results:** Patient varied in their anti-modified protein antibody response with the extremes from recognition of no (0/10) to all antigens (10/10). Antibodies against citrullinated vimentin (51%), acetylated ornithine (46%) and acetylated lysine (37%) were the most frequently observed sub-specificities. Relapse risk significantly (p=0.011) increased from 18% (0–1/10 reactivities) to 34% (2–5/10) and 55% (>5/10). With respect to specificity groups (0 to 3), relapse risk significantly (p=0.021) increased from 18% (no reactivity) to 28%, 36% and finally to 52% with one, two or three antibody specificity groups, respectively.
**Conclusions:** The data suggest that the pattern of anti-modified protein antibody response determines the risk of disease relapse in RA patients tapering DMARD therapy.

## AB0190 TREAT TO TARGET STRATEGY VERSUS ROUTINE CARE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

G.H. Brinkmann[1,2], E.S. Norli[2,3], T.K. Kvien[2], A.J. Haugen[1], L. Grøvle[1], H. Nygaard[4], D.M. Soldal[5], A. Wierød[6], H.C. Gulseth[7], M.D. Mjaavatten[2], E. Lie[2]. *[1]Østfold Hospital Trust, Moss; [2]Diakonhjemmet Hospital, Oslo; [3]Martina Hansen Hospital, Bærum; [4]Lillehammer Hospital for Rheumatic Diseases, Lillehammer; [5]Hospital of Southern Norway Trust, Kristiansand; [6]Veste Viken Hospital Trust, Drammen; [7]Betanien Hospital, Skien, Norway*

**Background:** The treat to target (T2T) strategy has provided good results in clinical trials and is part of current management recommendations, but real life data are still needed to support the implementation of T2T in clinical practice.
**Objectives:** To investigate 2-year outcomes (DAS28 and EQ-5D) in early RA before and after implementation of the T2T monitoring and treatment strategy.
**Methods:** Pts in the Norwegian Very Early Arthritis Cohort (NOR-VEAC) were included from 2010 through 2015 and treated according to T2T with visits at baseline, 3, 6, 9, 12 months and then every 6 months *plus* monthly visits until DAS28<2.6. We compared this group of pts to pts included in the NOR-DMARD register during 2006–2009 who were treated according to routine care at the time and followed up at 3,6,12 months and then yearly after start of each new DMARD regime. Both groups had a clinical diagnosis of RA (<1 year), were DMARD naive and started DMARD treatment at baseline. We studied DMARD use, DAS28 and EQ-5D during 2-yr follow-up.
**Results:** The current analyses included 252 pts from NOR-VEAC (mean (SD) age 54 (14) yrs, 65% females, 73% seropos, duration of joint swelling median (25,75 perc) 97 (57,168) days) and 586 pts from NOR-DMARD (mean (SD) age 55 (13) yrs, 67% females, 74% seropos, median (25,75 perc) 4 (0,67) days since diagnosis). 2-yr follow-up data were available in 56%/67% of pts in NOR-VEAC/NOR-DMARD. Methotrexate monotherapy was the dominant initial DMARD treatment in both groups (93% in NOR-VEAC vs 87% in NOR-DMARD). Proportions of pts achieving remission (DAS28<2.6) at 1 and 2 yrs were higher in NOR-VEAC than in NOR-DMARD (64% vs 42% and 69% vs 50%, respectively, both p<0.001).Table 1 shows DAS28 and EQ-5D values at BL, 1 and 2 yrs in the NOR-VEAC-and NOR-DMARD cohorts as well as DMARD use during follow-up. 25% vs. 17% of those with 2-yr follow-up data used biologic DMARDs over 2 yrs, p=0.06.
**Conclusions:** Pts treated according to the T2T strategy achieved lower DAS28 scores and higher (better) EQ-5D scores during follow-up despite similar baseline values. The differences in DMARD use between cohorts were relatively small, however there is a trend towards more use of biologic DMARD in the T2T cohort.

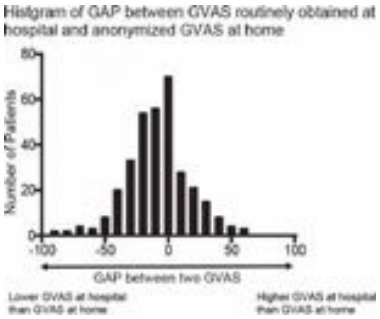
## AB0191 DURABILITY OF FIRST BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG IS NOT INFLUENCED BY INITIAL/EARLY DAS28

G. Rohekar[1], M. Movahedi[2], J.E. Pope[1], C. Bombardier[3] on behalf of Ontario Best Practices Research Initiative (OBRI). *[1]University of Western Ontario, London; [2]Ontario Best Practices Research Initiative; [3]University of Toronto, Toronto, Canada*

**Background:** The Ontario Best Practices Research Initiative (OBRI) collects data on RA treatment in a real-world setting. Patients are enrolled and prospectively followed to assess among other things, response to biologic Disease-Modifyng Antirheumatic Drugs (bDMARDs) and conventional synthetic Disease-Modifying Antirheumatic Drug (csDMARD) therapy.
**Objectives:** The objective of this study was to look at a real-world population and determine if initial disease activity influences the durability of the first used biologic in RA treatment.
**Methods:** bDMARD-naïve RA patients were included if they started a biologic at baseline or at any time after entry into OBRI. For initial DAS, we used the DAS28 value between 6 months before and 3 months after the start of the first biologic, whichever was closer to the date of biologic use. Patients were censored at date of first biologic, or at date of last follow-up after initiation, whichever occurred first. Analysis was performed for all years of follow up, and also censored at 1.5 years (for investigating initial DAS impact). Persistence was defined as the length of time the patients continued to receive the drug, irrespective of change in dose, route, or addition of any other csDMARD or steroids. If the drug was stopped for <60 days after which the patient restarted the same medication, it was considered a continuation and the duration was calculated accordingly. Patients were divided into three groups for analysis based on initial DAS28 score: remission (≤2.60), medium to high DAS28 (2.61–5.10) and severe (>5.10). Survival was compared using KM curves.
**Results:** 563 patients were included. At 1 year, the survival probability was 0.78. The median survival of biologic was 57.8 (95% Confidence Interval: 42.2) months and with a mean survival of 44.5 (SE: 1.5) months. Patients who were on biologic monotherapy, with no concomitant csDMARD use, has worse persistence of their initial biologic. Figure 1 shows the KM Plot of survival on biologic stratified by



DAS28. Despite the initial trend towards better survival associated with lower initial DAS, this was not statistically significant. Similarly, type of insurance (public/private) did not impact biologic survival. As seen in other studies, the only factor to impact longer persistence on initial biologic was use of a csDMARD with the bDMARD.
**Conclusions:** Early/initial DAS28 score did not impact patients' persistence on their initial bDMARD, nor did insurance type. This suggests that initial DAS28 score does not influence the durability of the first bDMARD in active RA. Combination of csDMARD and bDMArD was more durable than bDMARD monotherapy.
**Disclosure of Interest:** None declared

## AB0192 SOME OF THE PAINFUL RA PATIENTS UNDERRATE GLOBAL HEALTH VAS AT HOSPITALS

G. Kageyama[1,2], A. Onishi[2], Y. Ueda[2], Y. Kamei[2], H. Yamada[2], Y. Ichise[2], D. Waki[2], I. Naka[2], K. Tsuda[2], T. Okano[2], S. Takahashi[2], M. Nishida[2], K. Akashi[2], K. Nishimura[2], S. Sendo[2], Y. Kogata[2], J. Saegusa[2], A. Morinobu[2]. *[1]Department of Rheumatology, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki; [2]Department of Rheumatology, Kobe University Hospital, Kobe, Japan*

**Background:** Evaluating patient global VAS is one of the most essential process in RA practice. Despite reliability of patient global VAS being highly important in clinical practice, there has been no study comparing global VAS scores obtained at hospitals and those obtained at home where patients answer anonymously.
**Objectives:** To compare the patient global VAS obtained before clinical examination in hospital with those answered anonymously at home.
**Methods:** We asked RA patients to answer and mail the EQ5D data set anonymously. EQ5D consisted of 5 component questions (mobility, self-care, usual activities, pain/discomfort, anxiety/depression) and patient assessment global health VAS. EQ5D global VAS is anonymized patient global VAS evaluated at home. We compared the patient global VAS which is routinely surveyed at hospital before clinical examination with those surveyed anonymously at home.
**Results:** The anonymized VAS score was higher than those routinely evaluated at hospital ($p<0.0001$). Global VAS scores obtained at hospital poorly correlated with those obtained anonymously at home ($r=0.426$). We compared patients who had higher patient global VAS at hospital than anonymized VAS at home with patients who had lower patient global VAS at hospital than anonymized VAS at home. Pain VAS scores remained to be risk factor to be higher anonymized VAS at home than those routinely evaluated at hospital after multivariate analysis.

**Conclusions:** Discrepancy exists between patient global VAS evaluated in the hospital before clinical examination and those evaluated anonymously at home. There is a possibility that patients rating high pain VAS are underrating their global VAS scores at hospital.
**Disclosure of Interest:** None declared

## AB0193 THE UTILITY OF USING ADMINISTRATIVE DATA TO STRATIFY US VETERANS WITH RHEUMATOID ARTHRITIS ON THE BASIS OF DISEASE ACTIVITY

G.W. Cannon[1], C.-C. Teng[2], N. Accortt[3], D. Collier[3], M. Trivedi[3], B.C. Sauer[2]. *[1]Rheumatology; [2]IDEAS Center, Salt Lake City VA Medical Center and University of Utah, Salt Lake City; [3]Amgen, Thousand Oaks, United States*

**Background:** The ability to assess rheumatoid arthritis (RA) disease activity using administrative data could provide a potential mechanism to identify patients with high disease activity who may be candidates for enhanced RA treatment. The Veterans Affairs rheumatoid arthritis (VARA) registry is a prospective observational cohort that collects RA disease activity measurements including the 28 joint count disease activity score (DAS28) at twelve US Veterans Affairs (VA) Medical Centers.
**Objectives:** This study used VA administrative data to develop a model to predict DAS28 in US Veterans.
**Results:** We identified 1,582 US Veterans with RA who fulfilled enrollment criteria. The average age was 62.7±11.0 years, 91% male, with a disease duration 13.7±12.1 years with 78% and 74% seropositive for rheumatoid factor and anti-CCP antibodies respectively. Of the 1,275 variables evaluated, 175 had prevalence of 1% or more for consideration in the model. Of these 175 candidate variables, 32 remained in the final model. The key variables associated with disease activity were related to number of clinic visits (rheumatology, primary care, and ancillary services), numbers of laboratory tests, medication changes, imaging episodes, and surgery. The association of the predicted and observed DAS28 was relatively limited with unadjusted and adjusted R-square as 0.24 and 0.22 respectively. The model was very sensitive for detection of high/moderate disease (sensitivity =91.3%) but the specificity was only 25.3%.US Veterans with RA enrolled in the VARA registry with administrative data available for the year prior to DAS28 measurement and were evaluated. Patients were excluded if they had cancer, organ transplantation, or other autoimmune diseases. We identified 1,275 administrative data elements with suspected association with disease activity to investigate for association with DAS28 score. Least absolute shrinkage and selection operator (LASSO) was used to develop a model for the prediction of DAS28 as a continuous variable. The sensitivity, specificity, positive and negative predictive values were calculated. For these calculations, we defined high/moderate disease as DAS28>3.2 and low disease as DAS28≤3.2 in a categorical manner.

| | | Measured DAS28 | | |
|---|---|---|---|---|
| | | High/Moderate | Low | Total |
| Predicted DAS28 | High/Moderate | 874 | 467 | 1341 |
| | Low | 83 | 158 | 241 |
| | Total | 957 | 625 | 1582 |
| | | Sensitivity | | 91.3% |
| | | Specificity | | 25.3% |
| | | Positive predictive value | | 65.2% |
| | | Negative predictive value | | 65.6% |

**Conclusions:** While there were multiple administrative elements that correlated with disease activity measured by DAS28, it was not possible to develop a strong predictive model using available administrative data. These observations suggest that the continued direct observation of disease activity remains the most effective measure to identify RA patients with high disease activity. However the transient nature of RA disease activity may predicate the need to refine our model to account for disease duration. Additionally a single point-in-time measurement may not be indicative of patient disease activity over a long period of time. The development of other methods that can extract information from provider assessment of disease from electronic medical records has the potential to meet this critical need.

## AB0194 ANTI-CYCLIC CITRULLINATED PEPTIDES ANTIBODIES (ANTI-CCP) IN CUTANEO-ARTHRITIC BUT NON-PULMONIC CASE OF SARCOIDOSIS

H. Al Attia, K. Al Kateeb, I.A. Khan. *Universal Hospital, Abu Dhabi, United Arab Emirates*

**Background:** Anti-CCP antibodies have a high predictive value in RA patients and associated with disease severity. They have also been detected in few conditions such as Palindromic rheumatism, Psoriatic arthritis, Sjogren's syndrome and other rheumatic disorders. Sarcoidosis on the other hand is a chronic inflammatory and potentially multi-systemic disease which is classically forming non-caseating granuloma, is not characteristically associated with positive anti-CCP Abs. There is only one report in the previous English literature that has described 2 patients with pulmonic sarcoidosis who were tested positive for anti-CCP Abs.
**Case report:** For more than a year, this 52 year old smoker lady has been noticing the development of a rather painless papular rash into a nodular one over the extensor surface of the hands, mainly in the knuckles (figure 1). No specific diagnosis was offered to here in due course however, in the last few months she begun to experience polyarthralgia in the joints of the hands and mild stiffness. The initial impression by the dermatologist colleague was that of erythema elevatum diutinum Routine blood and biochemistry workups was runemarkable apart from an ESR of 29mm/HR and hypovitaminosis D but with normal serum total calcium of 10.1mg/dL (N 8.4–10.5). Tests for RF, ANF, ds DNA, ENAs, CPK and LDH were negative yet the ELISA test for anti- CCP was positive repeatedly but in rather low titre of 36.73 and 37.62 U/mL (N<17).The CXR showed no enlarged hilar lymphadenopathy or interstitial lung changes (Figure 2), the hands X-ray showed osteopenia and narrowing of the PIP Joint of the left ring finger (figure3).The MRI of the left hand showed erosion in the head of the 5th metacarpal bone and minimal effusion in the first MPJ (Figure 4, a and b). The biopsy of one skin nodule revealed many loose well circumscribed islands of granulomas but without caseous necrosis consistent with cutaneous sarcoidosis. Both tuberculin skin test and Quantiferon TB Gold test were negative. Serum angiotensin converting enzyme was within normal

values of 49 U/L (N 16–72).She was managed with hydroxychloroquine and pentoxifylline.
**Conclusions:** Sarcoidosis is capable of mimicking several rheumatic diseases. However, this case is unusual in the sense of being presented with cutaneo-arthritic sarcoidosis without any pulmonic disease. The presence of positive anti-CCP makes it the third reported case in the literature of such association and may also be reflecting an overlap syndrome of sarcoidosis-RA.

## AB0195 BONE EROSION AND BONE LOSS PROFILE IN RHEUMATOID ARTHRITIS: ABOUT 93 MOROCCAN PATIENTS

H. Azzouzi, O. Akkar, M. Lehraiki, L. Lehlou, L. Boutouala, L. Ichchou.
*Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*

**Background:** Rheumatoid arthritis (RA) is a known cause of joint destruction and systemic bone loss. It is now clear that the management of inflammation in RA is the key to a better control of articular damage and osteoporosis. However, systemic inflammation is not the only determinant of bone damage.
**Objectives:** The aim of the present work is to evaluate the bone erosion and bone loss profile in RA patients.
**Methods:** Ninety-three patients have been identified meeting the ACR EULAR criteria of RA. We have collected data about age, smoking, alcoholism, steroid prescription, body mass index (BMI), disease duration and activity (DAS28), functional disability (HAQ) and bone mineral density (BMD) measured with DXA. Bone erosion was calculated by the Sharp Van Der Heijde score. Data analysis was carried out using the SPSS 20 Software. $p<0.05$ was considered statistically significant.
**Results:** The mean±SD age was 51.59±12.38 years and the mean±SD disease duration 12.07±9.19 years. The mean±SD sharp score was 70.33±48.93 and 36.6% of patients had osteoporosis. The median RA diagnosis lag time was 24 months [12–72] after onset of symptoms. Bone mineral density in the femoral neck was significantly associated with Sharp score (p=0.000) and age (p=0.004), HAQ (p=0.003), disease duration (p=0.000), steroid intake (p=0.035), spine BMD (p=0.000) and BMI (p=0.044). Adjusted to age, spine BMD and BMI, femoral neck BMD (p=0.04) was an associated factor of bone damage (OR: - 0.442, 95% CI -240.24 to -19.51).
**Conclusions:** Delayed diagnosis has led to greater bone damage in our RA population. Consequently, more efforts should be done to shorten this period in order to improve the disease control and the patients' quality of life.

## AB0196 THE RELATION BETWEEN BASELINE ACR/EULAR 2010 CLASSIFICATION CRITERIA AND STRUCTURAL JOINT DAMAGE MEASURED WITH RAAD SCORE IN RHEUMATOID ARTHRITIS

M. Vermeer, A. ter Avest, H. Bernelot Moens. *Ziekenhuisgroep Twente, Almelo, Netherlands*

**Background:** In 2010 the ACR/EULAR classification criteria for rheumatoid arthritis (RA) were proposed. They focus on features at earlier stages of disease that are associated with persistent and/or erosive disease, which may help to adapt treatment regimens on the basis of individual prognosis. The criteria have been applied in a large number of studies, but information on the relation with long-term outcome is scarce (1). Early intervention with DMARDs aims to reduce current disease activity and prevent structural damage. Based on clinical assessment, the Rheumatoid Arthritis Articular Damage (RAAD) scores 1 or 2 points for structural damage in 35 joints, resulting in a range from 0 to 70 (2). The RAAD score correlates strongly with radiographic damage in hands and feet, but is more comprehensive, including all joints that may be damaged by RA. It has been applied in various small studies.
**Objectives:** To evaluate structural joint damage according to the RAAD score in RA patients with a disease duration of 5 years or longer and its relation to the ACR/EULAR 2010 classification criteria at baseline.
**Methods:** In a large regional teaching hospital, the RAAD score is recorded annually by rheumatologists and nurses since 2014 as part of routine clinical assessment of disease activity in order to evaluate disease progression and quality of care. ACR/EULAR 2010 classification criteria and the presence of radiological erosion were obtained retrospectively from the patients' medical records. Statistical analyses were performed on the total group of patients, and stratified by disease duration (5–9 years versus 10 years or longer). Data were analysed using Spearman correlation and Mann-Whitney U tests.
**Results:** The database consists of 1966 patients with a clinical diagnosis of RA. All patients were treated with s- and/or b-DMARDs. In January 2016, the RAAD-score had been performed at least once in 425 patients with a disease duration of at least 5 years. 68.5% of patients were female. At baseline, mean (SD) age was 64.1 (13.1) years, 78.4% were RF and/or anti-CCP positive and 73.2% scored 6 or higher on the ACR/EULAR 2010 classification criteria for RA. The median (IQR) disease duration at the time of assessing the RAAD score was 12.3 (7.8–19.6) years. The highest RAAD score was 55 and the median (IQR) in the total group was 2.0 (0.0–7.0). The correlation of the sum of the ACR/EULAR 2010 classification criteria at baseline and the RAAD score at follow-up was very weak (r=0.11, p=0.033). Table 1 presents the RAAD scores for individual ACR/EULAR 2010 classification criteria. Acute-phase reactants, higher number of affected joints and erosions at baseline resulted in higher RAAD scores.

*Table Median (IQR) RAAD scores presented for the total group, disease duration 5-9 years and disease duration 10+ years, stratified by clinical characteristics at baseline.*

| | Total | | | Disease duration 5-9 years | | | Disease duration 10+ years | | |
|---|---|---|---|---|---|---|---|---|---|
| *RAAD score* | Median (IQR) | n | p | Median (IQR) | n | p | Median (IQR) | n | p |
| All patients | 2.0 (0.0-7.0) | 425 | | 0.0 (0.0-2.0) | 167 | | 4.0 (1.0-11.0) | 258 | |
| ACR/EULAR 2010 score ≤5 | 1.0 (0.0-5.3) | 110 | 0.056 | 0.0 (0.0-2.0) | 49 | 0.25 | 4.0 (0.0-10.0) | 61 | 0.24 |
| ACR/EULAR 2010 score >5 | 2.0 (0.0-7.0) | 301 | | 0.0 (0.0-2.0) | 116 | | 5.0 (1.0-12.0) | 185 | |
| RF and anti-CCP negative | 2.0 (0.0-7.0) | 90 | 0.384 | 0.0 (0.0-2.0) | 39 | 0.721 | 4.0 (0.0-11.0) | 51 | 0.658 |
| RF and/or anti-CCP positive | 2.0 (0.0-7.0) | 327 | | 0.0 (0.0-2.0) | 126 | | 4.0 (1.0-11.0) | 201 | |
| CRP and ESR normal | 1.0 (0.0-5.0) | 140 | 0.032 | 0.0 (0.0-1.8) | 60 | 0.028 | 3.5 (1.0-12.0) | 80 | 0.866 |
| CRP and ESR not normal | 2.0 (0.0-7.0) | 271 | | 1.0 (0.0-2.0) | 106 | | 4.0 (1.0-11.0) | 165 | |
| ACR/EULAR 2010 affected joints subscore ≤3 | 1.0 (0.0-4.0) | 145 | <0.001 | 0.0 (0.0-2.0) | 68 | 0.33 | 3.0 (0.0-7.5) | 77 | 0.015 |
| ACR/EULAR 2010 affected joints subscore >3 | 2.0 (0.0-8.8) | 272 | | 0.0 (0.0-2.0) | 98 | | 5.0 (1.0-13.0) | 174 | |
| No erosions | 1.0 (0.0-5.0) | 290 | <0.001 | 0.0 (0.0-2.0) | 137 | 0.005 | 3.0 (0.0-9.0) | 153 | 0.01 |
| Erosions | 4.0 (1.0-9.0) | 108 | | 2.0 (0.0-3.0) | 28 | | 5.5 (2.0-13.0) | 80 | |

**Conclusions:** In a cohort of RA patients, the sum score of the ACR/EULAR 2010 classification criteria at baseline correlated weakly with long-term structural joint damage. The presence of erosions at baseline, not included in the criteria set, was the best predictor of a higher RAAD score.

## AB0197 EVALUATION OF SERUM IL-10 AND IP-10 LEVELS IS USEFUL AS PROGNOSTIC BIOMARKERS FOR SELECTION OF IL-6R ANTIBODY (TCZ) PRIOR TO TUMOR NECROSIS FACTOR (TNF) INHIBITOR IN RHEUMATOID ARTHRITIS TREATMENT

T. Kameda[1], H. Dobashi[1], M. Inoo[2], I. Onishi[2], N. Kurata[2], M. Izumikawa[1], Y. Takeuchi[1], S. Nakashima[1], H. Shimada[1], H. Ozaki[1], R. Wakiya[1], N. Kadowaki[1]. *[1]Department of internal medicine division of hematology, rheumatology and respiratory medicine, Kagawa University; [2]Internal medicine, Utazu Hospital, Kagawa, Japan*

**Background:** Biomarkers of response to treatment in rheumatoid arthritis (RA) are sorely needed given the large inter-individual variability in efficacy of the available drugs. However, there is few reported to distinguish between responses to the different biologics (Bio) [1)]. Some authors think it will be difficult to obtain good predictive biomarkers for the efficacy of Bio before administration. Consequently, it is important that we identify the novel biomarker to predict the efficacy of these agents before the administration of Bio.
**Objectives:** To identify a serum biomarker for prediction of the response to Bio in patients with RA, we investigated whether serum cytokine level before treatment with Bio may represent useful prognostic biomarkers for TNF inhibitor (GLM) or IL-6R antibody (TCZ) treatment in bio-naïve RA.
**Methods:** To identify a serum biomarker for prediction of the response to Bio in patients with RA, we performed serum cytokines analysis in RA patients before and after Bio treatment with TCZ and GLM. At the first, we enrolled 10 responder and 10 poor-responder RA patients treated with Bio. 29 cytokines levels before treatment were measured using MILLIPLEX MAP Human Cytokine/Chemokine®. According to analysis of these 29 cytokines, IL-17, IL-6, IL-10 and IP-10 were eliminated as candidates for novel biomarker to predict the effectiveness of RA treatment. Then we enrolled 41 bio-naïve RA patients before administration of TCZ (n=27) or GLM (n=14). We measured these four serum cytokines before

and after treatment with each Bio using ELISA. At baseline and 24 weeks after Bio-therapy with TCZ or GLM, we assessed DAS28 and measured serum levels of IL-17, IL-6, IL-10 and IP-10 using commercial ELISA kits. Responders and non-responders were defined as patients who had clinical remission (CR; DAS28 $<2.6$) and non-CR (DAS28 $>2.6$) at 24 week after administration of Bio. Wilcoxon two samples test was performed to compare cytokine levels.

**Results:** Mean age was 57.6±15.9, 70.6±14.7 years old and mean disease duration was 77.1±86.2, 114.0±142.6 months in TCZ and GLM patients, respectively. Disease activity of RA was 4.78±0.98 and 4.23±0.76 with DAS28 in TCZ and GLM patients, respectively. In CR group of TCZ (n=19), the serum IP-10 and IL-10 levels decreased compared with non-CR group by ELISA, significantly ($P<0.05$). As for RA patients treated with TCZ, IP-10 levels were significantly higher in responders. As for RA patients treated with GLM, responders showed a trend toward higher levels of baseline IL-10 compared to non- responders, while IP-10, IL-17 and IL-6 differences did not reach statistical significance.

**Conclusions:** In our study, the serum levels of IP-10 and IL-10 before Bio administration appeared to be associated with favorable responses to TCZ. Furthermore, these cytokines including IP-10 were not associated to response of GLM treatment. It is suggested that bio-naïve RA with low serum IP-10 levels might be treated with TCZ better than TNFi (GLM).

## AB0198 CLINICAL ANALYSIS OF PREOPERATIVE DEEP VEIN THROMBOSIS RISK FACTORS IN PATIENTS UNDERGOING PRIMARY TOTAL KNEE ARTHROPLASTY

H. Wakabayashi, M. Hasegawa, S. Kato, G. Miyamura, T. Yamaguchi, A. Sudo.
*Orthopaedic Surgery, Mie University Graduate School of Medicine, Tsu, Japan*

**Background:** Venous thromboembolism (VTE) [i.e., pulmonary embolism (PE) and deep vein thrombosis (DVT)] is a common complication during and after a hospital admission. Further, VTE is a leading cause of major complications and death after major orthopedic surgery. To avoid the development of VTE after orthopedic surgery, it is essential to reduce the onset of deep vein thrombosis (DVT) and to diagnose DVT early. It leads to early diagnosis to find a risk factor of DVT from medical history of the patient. Total knee arthroplasty (TKA) reliably relieves pain and improves function in patients with end-stage arthropathy of the knee such as osteoarthritis (OA) and rheumatoid arthritis (RA). The most common complication after knee arthroplasty is DVT. However, the risk for preoperative DVT in patients for knee joint orthopedic surgery remains unclear. Therefore, we investigated the patient's background and medical history in patients admitted to hospital for primary TKA, and identified the risk factors for DVT development before TKA.

**Objectives:** The objectives are investigated the risk factors of DVT in patients admitted for primary TKA.

**Methods:** *Patients.* From 2003 to 2013, 303 patients admitted for primary TKA at Mie University Hospital were eligible for the present retrospective study. The patients' sex, weight, body mass index (BMI, weight in kilograms divided by the square of the height in meters), and data from the medical history and medical condition were recorded.

*Diagnosis of DVT.* B-mode ultrasonography with compression and color Doppler imaging were performed for bilateral common femoral veins, the superficial veins, the popliteal veins, and the calf veins.

*Statistical analysis.* The patients' preoperative characteristics were compared between the DVT-positive and DVT-negative patients using the Mann-Whitney U test and Fisher's exact test. Multiple linear regression analysis was performed to identify independent risk factors for preoperative DVT. P values $<0.05$ were considered statistically significant.

**Results:** The preoperative diagnosis was OA in 261 patients (86.1%) and RA in 42 patients. The most frequent preoperative medical history or medical condition was hypertension (52.1%). The second most frequent preoperative medical history or medical condition was major surgery (47.5%).

Preoperative DVT was diagnosed in 48 of 303 (15.8%) patients overall. Significantly elevated risks of DVT were found in patients who had RA ($p<0.05$) using Fisher's exact test. Multiple linear regression analysis was performed to test the association of DVT with putative risk factors. The analysis showed that admission for RA ($p<0.05$) were significant independent risk factors for preoperative DVT.

**Conclusions:** A high prevalence (15.8%) of preoperative asymptomatic DVT was found in patients admitted for primary TKA. In this study, RA was risk factors for preoperative DVT among those admitted to the hospital for primary TKA.

**Disclosure of Interest:** None declared

## AB0199 ULTRASOUND EXAMINATION IN RA PATIENTS ACHIEVING COMPREHENSIVE DISEASE CONTROL (CDC) OR CLINICAL REMISSION AFTER 1 YEAR FOLLOW-UP AND T2T STRATEGY: REAL LIFE EXPERIENCE FROM A SINGLE CENTER, EARLY ARTHRITIS CLINIC

I. Farina, E. Galuppi, S. Sergi, F. Bergossi, C. De Giorgio, G. Ciancio, M. Govoni.
*Department of Medical Sciences, UOL Rheumatology, Section of Haematology and Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna, Ferrara, Italy*

**Background:** According to international task force recommendations, primary goal of rheumatoid arthritis (RA) treatment is to achieve control of symptoms, prevent structural damage and normalize functional status.Simultaneous achievement of DAS28 PCR remission $<2.6$, HAQ DI $<0.5$ and change from baseline in modified Total Sharp Score (SHS)$<0.5$, has recently defined as comprehensive disease control (CDC). Residual sub-clinical synovitis on ultrasonography/power doppler (US-PD) examination is one of the major driver of radiographic progression, but US-PD evaluation has not been yet included in definition of CDC.

**Objectives:** To analyze the achievement of CDC in an Early Rheumatoid Arthritis (ERA) Cohort after 1 year from diagnosis and to evaluate if this status was also associated to absence of US subclinical active synovitis. Compared US status in patients who achieved CDC with those achieving DAS 28 PCR-REM but not CDC.

**Methods:** ERA patients fulfilling 2010 ACR/EULAR who consecutively attended our Early Arthritis Clinic between 2009–2014 were retrospectively analyzed. Patients with available follow-up of 1 year were included. Standardized therapeutic approach has been performed according to EULAR T2T guidelines. Disease activity and functional disability has been evaluated using DAS28 PCR and HAQ DI every 3 months and after 12 months (T12) from diagnosis. Being more easily applicable in daily practice activity, radiographic progression has been assessed using Simple Erosion Narrowing Score (SENS). Therefore we considered as radiographic non progressors those patients who showed no change in SENS score at 12 months, from baseline (assimilated to $<0.5$ point change in mHSS). Patients were stratified in CDC-achievers and CDC non-achievers. Among those patients who reached DAS28-REM alone were identified. All patients were evaluated by US-PD of both wrists and II and III metacarpophalangeal. US-PD assessment was drawn at T12, considering as active subclinical synovitis a PD signal $\geq 1$ in more than 1 Joint.

**Results:** 125 patients out of 323 met the inclusion criteria. After 12 month from diagnosis, 30% were CDC-achievers (n=38) and 70% CDC non-achievers (n=87); of this last group, 38,4% (n=48) achieved REM. 81,2% (39/48) of patients in REM didn't achieved CDC because of radiographic progression. When comparing US-PD findings in both CDC-achievers and REM 6/38 (15.7%) and 12/48 (25%) respectively showed residual US-PD synovitis. In REM 10/12 (83%) of those with residual synovitis didn't achieve CDC because of radiographic progression.

**Conclusions:** In our Cohort a significant proportion of patients achieved CDC one year after diagnosis and a T2T therapeutic strategy. As already known our findings confirm that clinical remission is not fully protective against radiographic progression in ERA since 83% of those with residual US-PD synovitis did radiographically progress.However, the meaning of residual synovitis observed also in our CDC-achievers patients, although to a lesser amount (15.7%), is still unknown and has to be ascertained in a properly designed prospective study with longer follow-up.

## AB0200 CYP2C9 ACTIVITY IN TURKISH PATIENTS WITH RHEUMATOID ARTHRITIS

E.K. Ozer[1], I. Albayrak[2], M.T. Goktas[3]. *[1]Department of Pharmacology; [2]Department of Physical Medicine and Rehabilitation, Selçuk University, Faculty of Medicine, konya; [3]Department of Pharmacology, Yıldırım Beyazıt University, Faculty of Medicine, Ankara, Turkey*

**Background:** *Rheumatoid arthritis* (RA) is a chronic, autoimmune, multisystemic, inflammatory and common disease with unknown etiology. *Cytochrome* P450 2C9 (CYP2C9) is responsible for up to 40 drugs metabolism in the liver such as oral anticoagulants (warfarin), oral antidiabetics (tolbutamide, glyburide), angiotensin II receptor antagonists (losartan, irbesartan), phenytoin (1). Most of the drugs convert to active or inactive metabolites by CYP2C9. In a recent study Goktas MT *et al.* showed that CYP2C9 activity reduced in Behçet's disease that an autoimmune disease (2).

**Objectives:** This study aimed to investigate activity of CYP2C9 in patients with RA.

**Methods:** Losartan and its metabolite (E-3174) concentrations were analysed in healthy subjects (n=38) and RA patients (n=32) urine by high-performance liquid chromatography (HPLC). A acetonitrile and 66/34 mixture of phosphate tamponate (NaH2PO4, 15 mM, pH=2.8) were used as mobile phase. Urine samples in mobile phase and isopropanol (2/1/1 in volume, respectively) were injected into Agilent Eclipse XDB-C18 (5 μm, 4.6x150 mm) column via Agilent Technologies 1200 HPLC system (Agilent Technologies, Waldbron, Germany).

Losartan and its metabolite E-3174 were detected via a UV detector at 245 nm. The inter- and intra-day coefficient of variation (CV) was less than %4 for losartan and its metabolite. The ratio of losartan to its metabolite (E-3174) was calculated (metabolic ratio, MR) and used as a marker of the activity of the CYP2C9 enzyme.
**Results:** MR (losartan/its metabolite ratio) was increased in RA patients from 1.34±0.22 to 1.75±0.31. This result shows that CYP2C9 activity decreased in RA patients compared with healthy subjects.
**Conclusions:** CYP2C9 activity decreased in RA patients so we must be carefully when using the drugs that metabolized with CYP2C9. The efficacy of some treatments would be compromised in RA patients because they were given drugs in dosages that might be ineffective or cause adverse drug reaction and toxicity. This study is continued at other centers.

## AB0201 A NEW PERSPECTIVE OF IMMUNOLOGICAL DETECTION OF NEUROLOGICAL INJURIES IN RHEUMATOID ARTHRITIS

I.P. Gontar, E.V. Baranov, L.A. Maslakova, A.S. Trofimenko, O.I. Emelyanova, O.V. Paramonova. *Clinical Immunology Lab, FSBSU Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation*

**Background:** The neurological injury in rheumatoid arthritis (RA) is one of the most common organ lesions, but its clinical statement is quite complicated because of absence of reliable signs, as well as frequent coexistence with other neurological conditions. Therefore, the new improved approaches for diagnosing of nervous system involvement are rather necessary, and immunological methods of detection are appeared more promising and more specific for RA than imaging. The most obvious candidate antigens for this purpose are the constituents of nervous tissue, such as myelin and its principal component, myelin basic protein (MBP).
**Objectives:** Improvement of immunological detection of neurological involvement in RA by means of polyacrylamide magnetic beads with immobilized MBP.
**Methods:** The research was carried out in agreement with the principles of the World Medical Association Declaration of Helsinki. The informed consent had been signed by all involved persons, another obligate requirement was age 18 years or more. The patients were from the rheumatologic wards in Volgograd Municipal Hospital No. 25 and Volzhsky Municipal Hospital No. 1. Diagnosis of RA was established by ACR-EULAR criteria (2010), RA activity was evaluated using DAS28. Serum anti-MBP antibodies were measured by ELISA, with MBP immobilized on polyacrylamide magnetic beads as an antigen. The antibody concentrations were expressed as optical density units (ODU) and were considered positive if the cutoff value (M+2$\sigma$ of the reference group, 0.050 ODU) was exceeded. The results were expressed as mean±$\sigma$, differences were considered significant when $p<0.05$. Pearson correlation coefficient (r) was also used.
**Results:** 40 healthy persons (29 mans and 11 women), and 95 female patients with RA and the neurological signs, appeared during active phase of the disease, were recruited for this study. Mean age of the healthy controls was 36±7 years, and for the RA group it was equal to 55±11 years. Mean RA duration was 4.2±2.9 years. 13 patients had low, 52 – moderate, and 8 – high disease activity. The most common types of neurological involvement were mononeuropathy (n=29), polyneuropathy (n=65), radiculopathy (n=80); cervicocranialgias (n=51), and trigeminal neuralgias (n=14). The symptoms of central nervous system damage (TIA, seizures, cerebellar ataxia, dysarthria) were found in 21 patients. In RA group, anti-MBP antibodies were detected in 37 (38.9%) cases, with mean concentration 0.141±0.027 ODU. The patients with different neurological signs had mean anti-MBP antibody concentration 0.198±0.050 ODU, the subgroup without any neurological signs had 0.120±0.024 ODU (p=0.022). There was positive correlation between anti-MBP concentration and DAS28 score (r=0.67, p=0.039).
**Conclusions:** We found an association between neurological involvement in RA and elevation of anti-MBP antibody concentrations, as well as correlation between the latters and DAS28 score. These findings give us an opportunity to improve the diagnosis of minor neurological damage in RA and thus to make more precise adjustment of the treatment.

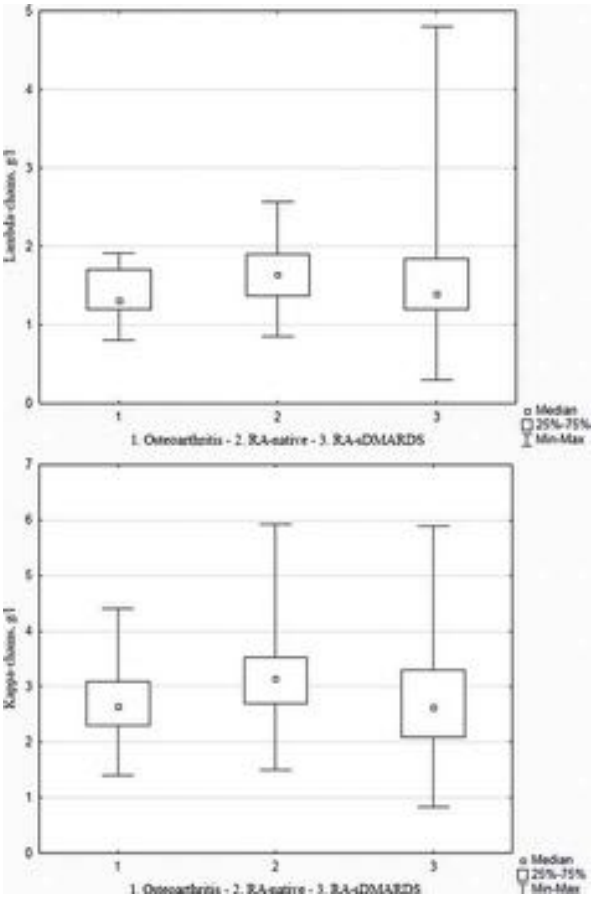
## AB0202 HANDS MAGNETIC RESONANCE IMAGING (MRI) IN PATIENTS WITH SERONEGATIVE ARTHRITIS



I. Nayshtetik[1,2], L. Khimion[2], O. Piura[3], O.B. Yaschenko[2], Y. Kovalenko[4]. *[1]Rheumatology, Kyiv Clinical Regional Hospital; [2]P.L. Shupyk National Medical Academy of Postgraduate Education; [3]Rheumatology, Kyiv Regoinal Clinical Hospital; [4]Radiology, Kyiv Regional Clinical Hospital, Kyiv, Ukraine*

**Background:** It is proved that early treatment can modify the further course of rheumatoid arthritis (RA), so early diagnosis is very important for better results of treatment. at present the most sensitive method for the detection of significant changes in the joints in the early stages of RA is magnetic resonance imaging (MRI).
**Objectives:** We have used this method to detect early RA in patients with seronegative (anticitrullinated peptide antibody (ACPA)/RF –negative) arthritis.[2]
**Methods:** 52 ACPA/RF-negative patients aged between 18 to 65 years with undifferentiated arthritis lasted for no more than 6 months and no clinical signs of hands and wrists joints involvement underwent MRI of hands and wrists; level of CRP and ESR was determined as well. Synovitis and bone marrow oedema (BME) were scored according to the OMERACT rheumatoid arthritis magnetic resonance imaging scoring system.
**Results:** In 22 of 52 patients (42.31%) MRI had detected significant signs of inflammation and BME in small hands joint and/or wrists which was used to establish diagnosis of early RA. The hither synovitis scores were correlated with CRP levels (P=0.007) and ESR (P=0.022).
**Conclusions:** MRI signs of synovitis in the small joints of the hands and wrists are observed in a significant amount of patients (42.31%) with seronegative arthritis without clinical signs of hands joints or wrists involvement, which can be used for early RA detection in patients without enough RA diagnostic criteria.[1]

## AB0203 POLYCLONAL IMMUNOGLOBULIN LIGHT CHAINS LEVELS IN ELDERLY PEOPLE WITH RHEUMATOID ARTHRITIS: REAL CLINICAL PRACTICE – THE INFLUENCE OF SDMARDS

I.V. Pozharov[1], Z.U. Mutovina[1], A.D. Astakhova[1], E.V. Ryazantseva[1], A.V. Gordeev[2]. *[1]Rheumatology, The Central Clinical Hospital of the Department for Presidential Affairs; [2]Rheumatology, Nasonova Research Institute of Rheumatology, Russian Academy of Medical Sciences, Moscow, Russian Federation*

**Background:** Polyclonal immunoglobulin light chains (PLC) represent biomarkers of B cell activity in rheumatoid arthritis (RA) and are associated with increased mortality in general population. PLC levels appear to be elevated during preclinical and active periods of RA. Serum k and l light chains are important inflammatory indexes and may be used as indicators of disease activity in RA.
**Objectives:** To explore association between serum PLC in cohorts of patients with RA depending on treatment and to determine whether PLC can be used as markers of treatment effectiveness.
**Methods:** 150 patients with RA untreated and treated with sDMARDs were included in the study (n=52, n=98, respectively), and 31 patient with osteoarthritis. Approximately 75% of patients in all groups were elderly people. Serum levels of PLC were measured by immune nephelometry.
**Results:** Median [lower and upper quartiles] polyclonal k and $\lambda$ light chains serum concentrations in cohort of untreated RA patients were significantly higher in comparison with osteoarthritis and treated RA patients ($\kappa$: 3.1 [2.7; 3.6] vs 2.6 [2.1; 3.3] and 2.6 [2.3; 3.1] g/l, H=12.1, $p<0,01$; $\lambda$: 1.7 [1.3; 1.9] vs 1.4 [1.2; 1.8] and 1.3 [1.2; 1.7] g/l, p=0.014). Comparing groups treated with methotrexate, sulfasalazine and leflunomide (n=48, 15 and 16, respectively) showed no statistically significant difference of PLC levels. It appeared that treatment with methotrexate during at least 6 months reduced serum concentrations of PLC in patients with RA ($\kappa$ untreated 3.0 [2.6; 3.4] vs $\kappa$ methotrexate 2.6 [2.0; 2.8], $p<0.01$; $\lambda$ untreated 1.8 [1.6; 2,05] vs $\lambda$ methotrexate 1,4 [1.0; 1,7], $p<0.01$).
**Conclusions:** PLC can be used as markers of treatment with sDMARDs effectiveness among elderly patients with multimorbidity.

## AB0204 GLUCOCORTICOID-SPARING EFFECTS OF ABATACEPT IN RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH BOTH ABATACEPT EFFECTIVENESS AND SEROPOSITIVITY

J.-E. Gottenberg[1], D. Courvoisier[2], M. Hetland[3], C. Turesson[4], H. Canhão[5], M.V. Hernandez[6], F. Iannone[7], E. Lie[8], K. Pavelka[9], D. Choquette[10], X. Mariette[11], A. Finckh[2] on behalf of PANABA Collaboration. *[1]University Hospital, Strasbourg, France; [2]University Hospital, Geneva, Switzerland; [3]University Hospital, Copenhagen, Denmark; [4]Skåne University Hospital, Malmö, Sweden; [5]University hospital, Lisbon, Portugal; [6]Hospital Clinic, Barcelona, Spain; [7]University Hospital, Bari, Italy; [8]Diakonhjemmet Hospital, Oslo, Norway; [9]University Hospital, Prague, Czech Republic; [10]CHUM, Montreal, Canada; [11]Paris-Sud University Hospital, Paris, France*

**Background:** We recently reported a glucocorticoid (GC)-sparing effect of Abatacept (ABA) in patients with RA in real life practice (reference 1).
**Objectives:** To analyze the association between ABA GC-sparing effect and both disease characteristics, such as seropositivity, and abatacept effectiveness in RA patients.
**Methods:** This is a pooled analysis of nine European RA registries (ARTIS, ATTRA, BIOBADASER, DANBIO, GISEA, NOR-DMARD, ORA, SCQM, Reuma.pt) and one North-American (RHEUMDATA). Inclusion criteria were a diagnosis of RA, initiation of ABA treatment, and at least one subsequent follow-up visit with data on GC use. The basal dosage of GC was categorized as none (dose =0 mg/d), low (>0 and ≤5 mg/d), moderate (>5 and ≤10.0 mg/d) or high dose (>10.0 mg/d). We assessed the predictors of reaching both a EULAR good/moderate responder status and stopping/tapering GC in a multivariable model including age, sex, disease duration, number of previous biologics, DAS28 at baseline (BL), RF/ACPA positivity, and concomitant treatment with methotrexate.
**Results:** Of the 1719 patients with information on GC dose, 634 (36.9%) patients were on a low, 745 (43.3%) were on moderate, and 340 (19.8%) patients were on high dose GCs at BL. Patients with moderate/high dose of GCs had significantly higher BL disease activity (mean DAS28 5.3 vs 4.9, $p<0.001$) and were more frequently RF or ACPA-positive (73.6% vs 65.4%, p=0.02). Among the 373 patients who stopped or reduced GC, 276 (74.0%) were EULAR good/moderate responders at 12 months, compared to only 63.4% of those who did not reduce GC ($p<0.001$). 78.4% of the patients who could stop or reduce GC within 12 months were RF positive, compared to 70.8% among those who did not reduce GC. Similarly, 74.3% of patients stopping or reducing GC were ACPA-positive, compared to 62.2% ACPA-positive patients among those who did not reduce GC. In the multivariable model, shorter disease duration (OR 0.95, 95%CI: [0.91; 0.99], p=0.01), lower number of previous biologics (OR 0.76, 95%CI: [0.59; 0.99], p=0.04), lower initial DAS28 (OR 0.56, 95%CI: [0.41; 0.77], p=0.0003), and seropositivity (OR 1.86, 95%CI: [1.09; 3.29], p=0.03) were significantly associated with stopping and reducing GC and being a EULAR good or moderate responder.
**Conclusions:** These results add further evidence to the association between seropositivity and ABA effectiveness by demonstrating that a higher proportion of patients with seropositive RA on ABA therapy are able to reduce or stop concomitant GC compared to seronegative patients, despite having higher doses of GC at baseline.

## AB0205 IL-22 SERUM LEVELS AS A BIOMARKER FOR EROSIVE DISEASE IN RHEUMATOID ARTHRITIS

J. Leipe, H. Schulze-Koops, A. Skapenko. *Division of Rheumatology and Clinical Immunology, University of Munich, Munich, Germany*

**Background:** Consistent with models of experimental arthritis implicating IL-22 in the development of joint destruction we could previously demonstrate that elevated IL-22 serum levels were associated with the development of erosive disease in patients with early RA.
**Objectives:** To study value of IL-22 as a marker for erosive disease in established RA, to assess whether IL-22 is increased in other joint destructive rheumatic diseases, and to evaluate the influence of comorbidities on IL-22 serum levels.
**Methods:** We measured serum IL-22 levels by Enzyme-Linked Immunosorbant Assay (ELISA) and analyzed their correlation to erosive disease (assessed by radiographs of hand and feet) and clinical parameters in patients with established RA (n=142), psoriatic arthritis (n=15), gout (n=15), age-matched patients with hypertension (n=10), diabetes (n=10), coronary heart disease (n=10), and healthy individuals as controls.
**Results:** 81 of 142 patients with established RA demonstrated elevated IL-22 levels compared with the range of healthy controls. A significant greater percentage of these "IL-22 high" patients (59%) demonstrated erosive disease compared the "IL-22 normal" patients (37%, $p<0.05$). In the "IL-22 high" compared to "IL-22 normal" group the fractions of patients positive for RF (70% vs 83%) and ACPA (74% vs 64%) were slightly higher, however not statistically significant different. Similar, measures of disease activity including DAS28 (2.3 vs 2.8) and CRP (0.5 vs 0.3 mg/dl) only tended to be higher in the "IL-22 high" than the "IL-22 low" group. Irrespective of erosive joint disease, patients with psoriatic arthritis and gout demonstrated lower IL-22 levels compared to established RA and only slightly higher than healthy individuals. Patients with hypertension, diabetes and coronary heart disease had IL-22 serum levels comparable to healthy controls.
**Conclusions:** High IL-22 levels are associated with erosive disease also in established RA, potentially in parts independent of serology, and might serve as a marker for joint destruction also in this cohort.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5902

## AB0206 TREATMENT PATTERNS IN RHEUMATOID ARTHRITIS AFTER METHOTREXATE: DATA FROM THE ONTARIO BEST PRACTICE RESEARCH INITIATIVES COHORT

J. Pope[1], M. Movahedi[2], A. Cesta[2], X. Li[2], S. Couto[2], J. Sampalis[3], E. Rampakakis[4], C. Bombardier[5]. *[1]University of Western Ontario, St. Joseph's Healthcare Centre, London; [2]Ontario Best Practices Research Initiative, Toronto; [3]JSS Medical Rsearch; [4]JSS Medical Research, Quebec; [5]University Health Network, Toronto, Canada*

**Background:** Guidelines support the use of combination conventional synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs), switching csDMARDs and/or use of biologic DMARDs (bDMARDs) treatment in active rheumatoid arthritis (RA) after use of methotrexate (MTX).
**Objectives:** The purpose of this study was to determine treatment practices after use of MTX in patients with RA who were on either monotherapy or combination csDMARDs in a large observational cohort (OBRI) in order to determine contemporary practice where use of bDMARDs from government coverage is restricted to active RA (+RF and/or +ACPA) or erosions, SJC≥5 with MTX failure, combination failure (triple csDMARDs: MTX + hydroxychloroquine + sulfasalazine) or use of leflunomide.

**Methods:** Patients enrolled in OBRI with documented MTX failure defined as discontinuation due to side effect, primary/secondary failure, or patient/physician decision. Demographics and disease parameters at MTX failure were compared between monotherapy failures, double therapy (Rx) failures, and triple Rx failures.
**Results:** A total of 313 patients with MTX failure were included with a mean (SD) age of 58.8 (13.2) years and disease duration of 6.7 (8.2) years. Of these, 102 (32.6%) were on MTX monotherapy, 156 (49.8%) were double (MTX +1 csDMARD) Rx, and 55 (17.6%) were on triple or more (MTX + multiple csDMARDs)Rx, respectively, at the time of MTX failure. At the time of MTX failure disease duration was numerically higher in patients failing monotherapy and double Rx as compared to triple Rx (7.5 vs. 6.8 vs. 4.5 years, respectively; P=0.276) while patients failing triple Rx were more likely to have an erosion (43.1% vs. 37.2% vs. 61.8%; P=0.009) and had significantly higher patient global (3.5 vs. 3.9 vs. 4.8; P=0.046). When looking at patient transition to csDMARDs monotherapy, csDMARDs combination Rx or bDMARDs treatment, patients receiving monotherapy were more apt to have switches to other monotherapy (87% of patients), whereas those on combination Rx received more combination csDMARDs (78% and 74% of patients on MTX + 1 csDMARDs or MTX + multiple csDMARDs, respectively) and bDMARDs combination Rx (21% and 26%, respectively)(Figure 1).

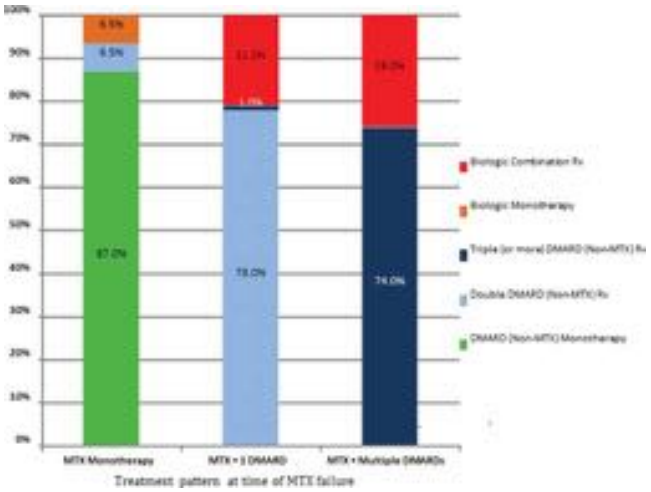

Figure 1. Treatment profile after MTX failure by type of MTX failure

**Conclusions:** There are inherent differences in the selection of subsequent treatment regimen between patients failing MTX monotherapy vs. MTX combination therapy. Overall, the results of the current analysis suggest the use of a sequential treatment intensification strategy in routine clinical practice in Ontario.
**Disclosure of Interest:** None declared

## AB0207 DIAGNOSTIC EVALUATION OF A COHORT OF PATIENTS WITH UNDIFFERENTIATED ARTHRITIS

J. Calvo Gutierrez, R. Ortega Castro, M. Castro Villegas, P. Font Agalde, A. Escudero Contreras, E. Collantes Estevez. *Dpt of Rheumatology, Univ Cordoba, Maimonides Inst Biomed Res Cordoba (IMIBIC), Reina Sofia Hospital, Córdoba, Córdoba, Spain*

**Background:** One of the most important knowledge of rheumatoid arthritis (RA) landmarks has been evidence that an early and vigorous treatment interferes with the progression and its physical consequences. That is why the early diagnosis has become essential. Today it is considered that the diagnosis must be made within the first 3 months of the onset of the disease, the period in which aggressive treatment should be started before the anatomical damage appears ("The Window oportunity"). The term of "indefinite arthritis" includes patients with different clinical ways of expression, shaped self-limiten arthralgia or arthritis of such low activity forms that when evaluated by the rheumatologis no notes about, so it is raeallity difficult the early manegement of this patients. There are a second group of patients with arthritis observable when assessed do not meet the classification criteria for RA, terming these forms as "undifferentiated arthritis" (UA). A third group of patients to be evaluated who meet the diagnostic criteria for RA are defined as "recent onset rheumatoid arthritis" RRA". Finally, there are a group of patient who are referred with positive laboratory tests without clinical disease criteria.
**Objectives:** 1) To evaluate UA prognostics factors in patients with UA that allow us to predict evolve to defined RA. 2) Analysis of other clinical characteristics predictive of progression to RA.
**Methods:** Descriptive observational study of a cohort of patients who, after a first clinical evaluation are diagnosed with UA, from 2005 to 2015, presenting arthritis in one or more joints lasting less than one year of evolution and not meet 87 ACR diagnostic criteria for RA. Of the patients evaluated at that time, 200 were diagnosed with UA and subsequently followed for more than 3 years. Were analyzed baseline and diagnosis characteristics for each patient
**Results:** Of the 200 patients diagnosed with (UA), 72 were women (52.2%) with a mean age of 48.44 (17–87) years. During the 12-month follow-up, 40 (20%) evolved AR, 52 (26%) a palindromic rheumatism, 53 (26.5%) and 52 to other rheumatic disease (26%) remained as undifferentiated. Of the group of patients who evolved RRA, 53.6% were women, with an average age of 51.7 (18–82) years. Introducing a form of polyarticular onset in 27 (67.5%), small and medium joints affected 22 (55%), symmetrical involvement 36 (90%) and morning stiffness>1 hour 20 (50%). 75% were FR+, OR =2.49 (95% CI =2.11 to 8.13) and 78,5% were ACPCC +, while it was negative in patients with UA remained as an OR =9.77 (95% CI 4.18 to 22.8). At 3 years of follow-up only 5.1% remained as undifferenciated forms, 24.8% as palindromic forms.
**Conclusions:** For early diagnosis, it is essential to identify patients with UA to develop an AR. A quarter of the patients analyzed in our study diagnosed with UA, evolved AR. Patients evolved AR debuted in more than half of the cases with a predominance of polyarticular involvement and medium and small joints affected. The presence of RF and ACPA are predictors of evolution AR, being the latter the most relevant.

## AB0208 PREDICTION OF FLARE IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS WITH LOW DISEASE ACTIVITY RECEIVING TNF INHIBITORS: ROLE OF CALPROTECTIN AND DRUG TROUGH SERUM LEVELS. A ONE-YEAR PROSPECTIVE COHORT STUDY

J. Inciarte-Mundo [1], M. Hernández [1], V. Ruiz-Esquide [1], J. Ramírez [1], A. Cuervo [1], S. Cabrera-Villalba [1], M. Pascal [2], J. Yagüe [2], J. Cañete [1], R. Sanmarti [1]. *[1]Rheumatology Department; [2]Immunology Department, Hospital Clinic, Barcelona, Spain*

**Background:** Calprotectin and TNF antagonist (TNFa) trough serum levels are associated with disease activity.
**Objectives:** To determine if calprotectin serum levels or drug trough serum levels predict relapse in RA and PsA patients with low levels of disease activity during TNFa therapy.
**Methods:** Prospective 1-year follow-up, single center study (INMUNOREMAR cohort). RA (ACR 1987) and PsA (CASPAR) patients in clinical remission (CR) (DAS28-ESR <2.6) or low disease activity (LDA) (DAS28-ESR <3.2) in ≥2 consecutive visits treated with adalimumab (ADA), etanercept (ETN) or infliximab (IFX) for ≥3 months were included. Demographic data, disease duration, time to initiate csDMARD and bDMARD, time to achieve remission, remission duration, autoantibody status, radiological data, concomitant csDMARD therapy, dose and duration of biological therapy were collected. Clinical and laboratory assessment was made every 4 months and at the time of flare. Calprotectin serum levels (ELISA Kit Calpro AS®) and TNFa trough serum levels (ELISA Kit Promonitor®, Progenika) were determined. Disease flare was defined as DAS28-ESR>3.2 and increase in ΔDAS28-ESR >0.6. Univariate and multivariate regression models were used to identify predictors of disease flare.
**Results:** 103 patients (47RA, 56PsA) were included. Mean Age 57 (30–81) years. 78 (75.8%) had CR and 25 (24.2%) LDA. Mean CR/LDA duration was 58 (4–163) months. 36 patients had received treatment with ADA, 50ETN, and 17IFX. Mean biologic treatment duration 61 (7–166) months. 47.4% patients were on monotherapy, 47% on reduced dose, and 17.9% received steroids. 84 patients (91%) remained in CR/LDA for 12 months, and 12 patients (13%; 8 RA, 4 PsA) experienced flares. Patients with flares had a longer time to achieve CR/LDA [CR/LDA (n=81) 3.1 (1–6) months vs. Flare (n=12) 20 (5–31) months, p<0.001], a shorter CR/LDA duration [CR/LDA (n=81) 59 (5–163) months vs. Flare (n=12) 25 (3–134) months, p=0.031], higher calprotectin levels [CR/LDA (n=81) 1.4 (0.6–3.7) μg/mL vs. Flare (n=12) 6 (4.5–7.9) μg/mL, p<0.001], and lower drug trough serum levels [CR/LDA (n=83) 2.6 (0.6–12) μg/mL vs. Flare (n=12) 0.6 (1–1.2) μg/mL; p<0.001], even when analyzed by biologic [ADA CR/LDA (n=30) 7 (0.2–12) μg/mL vs. Flare (n=4) 0.5 (0.4–1) μg/mL; p=0.003; ETN CR/LDA (n=44) 1.5 (0.7–4.7) μg/mL vs. Flare (n=5) 0.8 (0.9–1.2)μg/mL; p=0.039; IFX CR/LDA (n=14) 3.1 (0.5–7.7) μg/mL vs. Flare (n=3) 0.1 (0–1) μg/mL; p=0.021] at baseline. According to the cut-off developed by our group [1], patients with flares had sub-therapeutic baseline drug serum trough levels [CR/LDA (n=22) 26% vs. Flare (n=12) 100%, p<0.001]. Baseline TNFi trough serum levels [hazard ratio (HR) = 0.47], steroid treatment (HR=3.21), time to CR/LDA (HR=1.17), and baseline calprotectin levels (HR=2.38) significantly predicted flare in the univariate analysis but only baseline calprotectin levels significantly predicted flare in the multivariate analysis [HR=2.74 (1.74–4.31); p<0.0001].
**Conclusions:** Calprotectin and TNF trough serum levels are promising biomarkers to predict flare in RA and PsA patients with low disease activity during anti-TNF treatment.

## AB0209 FEMALE SEX INCREASES THE RISK OF FOREFOOT DEFORMITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Inui[1], K. Orita[1], T. Okano[1], K. Mamoto[1], Y. Sugioka[2], M. Tada[3], T. Koike[2], H. Nakamura[1]. *[1]Orthopaedic Surgery; [2]Center for Senile Degenerative Disorders, Osaka City University Graduate School of Medicine; [3]Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

**Background:** Forefoot involvement in patients with rheumatoid arthritis (RA) is common, and reported to be present in 50–90% of patients without any clear gender predisposition. However, patients with RA that undergo surgical treatment for their forefoot deformities are mostly female, which seems much higher rate than the prevalence of forefoot involvement by arthritis condition.
**Objectives:** In this study we evaluate the factors that contribute to forefoot deformity in RA, and investigate the significance of gender differences in forefoot deformity.
**Methods:** In this cross sectional study, 265 patients (530 feet) with RA (165 females) were enrolled. On AP and lateral standing radiographs of the foot, the angle formed by the first and second (M1/M2) and first and fifth metatarsal bones (M1/M5), the angle formed by the first metatarsal bone and the first proximal phalanx (HV), and the calcaneal pitch angle (CPA) were measured. Patient characteristics and laboratory tests were also analyzed for their potential association with forefoot deformity. As the indications for the surgical treatment of rheumatoid forefoot deformities are strongly influenced by the severity of the hallux valgus deformity, we therefore analyzed patient factors in relation to the measured HV angle.
**Results:** The HV angle was statistically greater in female RA patients than males. Patient age, sex, body mass index, disease duration, Steinbrocker staging, M1/M2 angle, M1/M5 angle, CPA, erythrocyte sedimentation rate, c-reactive protein, matrix metalloproteinase-3, and anti-citrullinated protein antibody measurements were correlated with the HV angle using a single regression analysis. Patient age, BMI, Steinbrocker stage, M1/M2 angle, M1/M5 angle, and the female gender were correlated independently with the HV angle.

| | Regression coefficient (β) | Standard error | P value | Variance inflation factor |
|---|---|---|---|---|
| Gender | –3.175 | 1.295 | <0.0001 | 1.12 |
| M1/M2 | 1.538 | 0.171 | <0.0001 | 1.48 |
| M1/M5 | 0.458 | 0.118 | 0.0001 | 1.53 |
| Stage | 2.942 | 0.437 | <0.0001 | 1.56 |

**Conclusions:** The hallux valgus deformity observed in patients with RA was more severe in females, which was independent of other patient factors. This finding emphasizes that the female gender is a risk factor for the progression of the rheumatoid forefoot deformity.
**Disclosure of Interest:** None declared

## AB0210 QUALITY OF LIFE INDEXES IN PATIENTS WITH VERY EARLY RHEUMATOID ARTHRITIS (VERA): A TWO CENTER SUBGROUP ANALYSIS FROM THE ADAPTHERA COHORT

K. Triantafyllias[1], R. Leiß[2], A. Lauter[2], M. De Blasi[1], M. Hesse[3], A. Schwarting[1,2]. *[1]Rheumatology, Acura Clinics Rhineland-Palatinate, Bad Kreuznach; [2]Rheumatology, Johannes Gutenberg University, First Department of Medicine, Mainz; [3]Rheumatology, Private Practice, Bad Kreuznach, Germany*

**Background:** The significance of early diagnosis and early therapy initiation in patients with RA is tremendous. ADAPTHERA is a state wide rheumatology network based in Rhineland-Palatinate, Germany. ADAPTHERA aims to improve RA prognosis and quality of patients' life by reducing the time-to-RA-diagnosis. While there have been a lot of studies regarding quality of life in patients with established RA[1,2], adequate data concerning very early rheumatoid arthritis (VERA) (disease duration <3 months) are lacking.
**Objectives:** To study quality of life in VERA patients and to investigate its associations with various RA associated clinical and laboratory parameters.
**Methods:** In a two center subgroup analysis from the ADAPTHERA cohort, we studied quality of life indexes such as Hannover Functional Ability Questionnaire (HFAQ), Health Assessment Questionnaire (HAQ), EuroQol-5D-3L (EQ-5D-3L), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue) and World Health Organisation-5 Well Being Index (WHO-5) in patients with VERA. Moreover, we examined the statistical relationship of these indexes with various clinical and laboratory RA associated parameters such as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), rheumatoid factor (RF)-/ cyclic citrullinated peptide antibodies (anti-CCP)-status and Disease Activity Score 28 (DAS28) as well as its components [counts of tender and swollen joints, Visual Analogue Scale (VAS)].
**Results:** 74 Patients (50 females, 24 males) with a median age of 62 years (IQR 49, 71) were identified as VERA patients. 36 of them were anti-CCP positive and 34 RF positive. Median scores for HFAQ, HAQ, EQ-5D-3L, FACIT-Fatigue, and WHO-5 were 75.5 (IQR 61, 92.5), 0.75 (IQR 0.26, 1.25), 0.89 (IQR 0.79, 0.89), 40 (IQR 32, 46) and 60 (IQR 32, 76) accordingly. The results of the statistical associations between these scores and RA associated parameters are seen in Table 1.

Table 1. Associations between quality of life indexes and RA associated clinical and laboratory parameters

| Significance (P) | HFAQ | HAQ | EQ-5D-3L | WHO-5 | FACIT |
|---|---|---|---|---|---|
| ESR¶ | 0.001** | 0.006** | 0.379 | 0.046* | 0,243 |
| CRP¶ | 0.001** | 0.008** | 0.392 | 0.020* | 0,424 |
| RF§ | 0.020** | 0.095 | 0.831 | 0.722 | 0.580 |
| anti-CCP§ | 0.003** | 0.003** | 0.597 | 0.460 | 0.922 |
| Tender joint count¶ | 0.001** | 0.003** | 0.021* | 0.066 | 0,342 |
| Swollen joint count¶ | 0.008** | 0.042* | 0.562 | 0.686 | 0,177 |
| DAS28 (ESR)¶ | 0.001** | 0.001** | 0.041* | 0.046* | 0.393 |
| DAS28 (CRP)¶ | 0.001** | 0.001** | 0.039* | 0.094 | 0.558 |
| Morning stiffness¶ | 0.017* | 0.002** | 0.130 | 0.143 | 0.584 |
| Disease Activity patient (VAS)¶ | 0.200 | 0.010** | 0.039* | 0.254 | 0.493 |
| Current pain¶ | 0.085 | 0.001** | 0.001** | 0.003** | 0.001** |

¶Spearman test was used; §Mann Witney test was used; * P<0.05; **P<0.005.

**Conclusions:** The quality of life indexes HFAQ, HAQ, EQ-5D-3L and WHO-5 are associated with two or more markers of disease activity in patients with VERA. Therefore, improvement of patients' quality of life is linked to the achievement of disease remission. In contrast, the FACIT-fatigue index seems to be solely associated with arthritis pain intensity. Thus, improvement of fatigue requires an effective pain management strategy.

## AB0211 WHICH DISEASE ACTIVITY SCORE 28 (DAS28) BASED FLARE CRITERIA IMPACT ON FUNCTIONAL DISABILITY IN PATIENTS WITH RA IN DAS28 REMISSION STATE USING THE IORRA COHORT

K. Shidara, E. Tanaka, E. Inoue, R. Yamaguchi, Y. Shimizu, D. Hoshi, N. Sugimoto, A. Nakajima, S. Momohara, A. Taniguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** The therapeutic goal for patients with rheumatoid arthritis (RA) is achieving remission state or at least low disease activity state. We demonstrated that sustaining remission leads to good functional disability at[1)]. However, not a few patients flared after achieving remission state in daily practice. Several published Disease Activity Score 28 (DAS28) based flare criteria are reported[2–5)]. It is useful to investigate which DAS28 based flare criteria lead to functional disability.
**Objectives:** To investigate associations between DAS28 based flare criteria and functional disability in RA patients after achieving DAS28 remission in daily practice using the large, observational, Institute Of Rheumatology, Rheumatoid Arthritis (IORRA) cohort.
**Methods:** The IORRA survey has been conducted biannually. RA patients with DAS28 remission in April 2012 (baseline) and participated in both subsequent surveys in October 2012 and October 2013 were extracted from the IORRA cohort. Flare in each patient was evaluated according to four previously published DAS28 based flare criteria [(1) increase in DAS28 >1.2 (2) increase in DAS28 >0.6 or if a DAS28 ≧3.2 (3) reaching DAS28>3.2 (4) reaching DAS28>2.6][2–5)] in October 2012. Functional disability was assessed by validated Japanese version of the Health Assessment Questionnaire (J-HAQ)[6)] in April 2012 and October 2013. Change in J-HAQ (ΔJ-HAQ) score was defined as follows: ΔJ-HAQ = J-HAQ score in April 2012 - J-HAQ score in April 2012. Average ΔJ-HAQ score in patients achieving each flare criteria was calculated. The association between ΔJ-HAQ as outcome and achieving each flare criteria as explanatory variable was analyzed using multiple regression analysis adjusting for gender, age, disease duration, pain (Visual Analogue Scale) VAS, general VAS and J-HAQ score at baseline.
**Results:** A total of 1,874 patients were analyzed. Females comprised 80.6% of the study population. The mean (SD) age and disease duration were 58.2 (12.7) years and 11.9 (8.9) years, respectively. The mean (SD) DAS28 and J-HAQ score were 2.0 (0.5) and 0.3 (0.5), respectively. Proportions of the patients met each flare criteria in October 2012 were (1) 9.7% (2) 24.4% (3) 11.3% and (4) 28.1%, respectively. Average ΔJ-HAQ score in patients met each flare criteria was (1) 0.13, (2) 0.06, (3) 0.10, and (4) 0.05, respectively. Multiple regression analysis demonstrated that achieving each flare criteria significantly associated with increase in J-HAQ score; (1) 0.11 (p<0.001), (2) 0.05 (p=0.0003), (3) 0.10 ((p≤0.001), and (4) 0.04 (p=0.0012), respectively.

**Conclusions:** Regardless of flare criteria, flares resulted in progressed functional disability in patients with RA. Aachieving flare criteria using (1) increase in DAS28 >1.2 and (3) reaching DAS28>3.2 led to worse physical functional outcome, suggesting that usage of these flare criteria might predict functional disability.

## AB0212 CONTRIBUTION OF THE SUBJECTIVE COMPONENTS OF THE DISEASE ACTIVITY SCORE TO THE RESPONSE TO TREATMENT IN RHEUMATOID ARTHRITIS

K.M. Son [1], S.Y. Lee [2], H.S. Lee [1], Y.I. Seo [2], H.A. Kim [2,3]. *[1]Department of rheumatology., Hallym University CHUncheon Sacred Heart Hospital, Gangwon-do; [2]Department of rheumatology., Hallym University Sacred Heart Hospital, Anyang; [3]Institute of Skeletal Aging, Hallym University College of Medicine, Gangwon-do, Korea, Republic Of*

**Background:** In recently, with development of biologic agents, RA patients increased the change of reaching remission. But some patients with normalization of inflammatory sign didn't reach to clinical remission state after optimization of treatment.

**Objectives:** This study was performed to investigate the contribution of the more subjective versus the objective component of the DAS28 to response to treatment in RA patient. The secondary aim was to examine the factors associated with 6 month change in pain and EULAR response.

**Methods:** The DAS28-P was calculated (Subjective components of DAS28 relative to the total DAS28: DAS28-P=0.56*sqrt(TJC28) + 0.014*(VAS-GH)/0.56*sqrt(TJC28) + 0.28*sqrt(SJC28) + 0.78 ln(ESR) + 0.014*(VAS-GH)). From September 2011 to 2013, 462 new patients were included in this study. EULAR response was assessed after 6month of treatment.

**Results:** The mean age of the included patient was 54 years, and 79% were female. The mean DAS28 at baseline was 4.91±1.07 (range 3.21–8.56) and that at after 6 months of treatment was 3.29±1.28 (range 0.49–8.47). Good responders according to the EULAR criteria were 180 (38.9%), moderate responders 150 (32.4%) and none responders 96 (22.5%). The change of DAS28-P score at baseline and 6 month was significant only for good responders (0.43±0.11 versus 0.3±0.25, p<0.001) and for moderate responders (0.45±0.09 versus 0.41±0.15, p=0.003) but not significant for none responders (0.44±0.13 versus 0.44±0.12, p=0.727). Among those were failed have good response, those who had objective measures (ESR, CRP, and swollen joint) normalized were defined as failure due to subjective measure. Subjects with failure due to subjective measure were less likely to be RF positive and had lower DAS28 after 6month but higher DAS28-P after 6 month.Higher baseline DAS28 score was associated with better pain response while DAS28, DAS28-P and baseline characteristics of patients (sex, age, RF) were not related to EULAR response

**Conclusions:** Our study showed that there are distinct RA patients with high DAS28-P, an index derived from subjective measures, who fails to respond adequately to treatment despite normalization of objective measures.

**Disclosure of Interest:** None declared

## AB0213 IS DISEASE DURATION AN INDEPENDENT PREDICTOR OF LOW DISEASE ACTIVITY/REMISSION AMONG BIOLOGIC-NAÏVE PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT?

L.R. Harrold [1], H.J. Litman [2], S.E. Connolly [3], S. Kelly [3], W. Hua [2], E. Alemao [3], L. Rosenblatt [3], S. Rebello [2], J.M. Kremer [4]. *[1]University of Massachusetts Medical School, Worcester; [2]Corrona, LLC, Southborough; [3]Bristol-Myers Squibb, Princeton; [4]Albany Medical College and The Center for Rheumatology, Albany, United States*

**Background:** Patients with long-standing RA may have more treatment-resistant disease than those with shorter disease duration.

**Objectives:** To examine whether disease duration is an independent predictor of treatment response among biologic-naïve patients with RA initiating abatacept in a US national, observational cohort.

**Methods:** Using the Corrona RA registry, we identified new initiators of abatacept between Feb 2006 and Jan 2014 who were biologic naïve with a follow-up visit at 1 year (±3 months) and assessment of disease activity (CDAI) at initiation and 1-year follow-up. The primary outcome was mean change from baseline in CDAI; the secondary outcomes were: 1) achievement of low disease activity (LDA; CDAI ≤10) among those who initiated abatacept in moderate or high disease activity, and 2) achievement of remission (CDAI ≤2.8) in those who initiated abatacept in low, moderate or high disease activity. Patients were stratified by disease duration (0–2, 3–5, 6–10, >10 years). For patients who switched agents before 1 year, the last observation before the switch was used to calculate mean change in CDAI. Switchers were imputed as non-responders for calculation of LDA and remission. Linear and logistic regression models were fit, as appropriate.

**Results:** In total, 281 biologic-naïve patients with RA initiating abatacept met inclusion criteria (disease duration 0–2 years: n=107; 3–5 years: n=45; 6–10 years: n=50; >10 years: n=79). Baseline characteristics were similar across disease duration groups for sex (76–89% female) and disease activity (mean CDAI: 15.3–19.1). Increasing disease duration was associated with older patient age (p=0.047) and a higher number of prior conventional (c)DMARDs (p<0.001). Mean change in CDAI ranged from –10.22 to –4.63 in patients with 0–2 and >10 years disease duration (Table). In analyses adjusted for age, sex, baseline CDAI and prior number of cDMARDs (Table), increasing disease duration was significantly associated with smaller mean change in CDAI (p=0.015) and lower likelihood of achieving LDA (p=0.048); association with decreasing likelihood of remission reached borderline significance (p=0.055).

Table 1

| | 0–2 years (n=107) | 3–5 years (n=45) | 6–10 years (n=50) | >10 years (n=79) | p |
|---|---|---|---|---|---|
| Unadjusted outcomes | | | | | |
| Mean (SE) Δ in CDAI | –10.22 (1.19) | –7.82 (1.83) | –6.16 (1.74) | –4.63 (1.38) | 0.017 |
| LDA, n (%)* | 53/91 (58.2) | 17/32 (53.1) | 15/33 (45.5) | 23/56 (41.1) | 0.21 |
| Remission, n (%)† | 29/103 (28.2) | 11/40 (27.5) | 12/48 (25.0) | 11/72 (15.3) | 0.23 |
| Adjusted outcomes‡ | | | | | |
| Mean (SE) Δ in CDAI | –9.65 (1.02) | –8.60 (1.53) | –6.77 (1.45) | –4.58 (1.19) | 0.015 |
| LDA, OR (95% CI)* | Reference | 0.89 (0.37, 2.10) | 0.49 (0.21, 1.18) | 0.36 (0.17, 0.78) | 0.048 |
| Remission, OR (95% CI)† | Reference | 0.85 (0.35, 2.05) | 0.57 (0.24, 1.35) | 0.32 (0.13, 0.77) | 0.055 |

*CDAI ≤10 among those with moderate or high disease activity. †CDAI ≤2.8 among those with low, moderate or high disease activity. ‡Adjusted by age, sex, baseline CDAI and prior number of cDMARDs. OR = odds ratio.

**Conclusions:** In biologic-naïve patients initiating abatacept, change in CDAI was significantly greater for shorter versus longer disease duration (unadjusted and adjusted models). After adjusting for covariates, shorter disease duration was associated with a greater likelihood of patients achieving LDA.

## AB0214 ADIPONECTIN DETERMINATION IN RHEUMATOID ARTHRITIS PATIENTS COMPLICATED BY OSTEOPOROSIS

L. Seewordova [1], J. Polyakova [1], B. Zavodovsky [1], Y. Akhverdyan [1], M. Kuznetsova [1], I. Zborovsky [2]. *[1]Treatment and Prevention of Joint Disease Laboratory; [2]Research Institute of Clinical end Experimental Rheumatology, Volgograd, Volgograd, Russian Federation*

**Background:** Bone mineral density and proteins/peptides determination in blood and urine as markers of bone resorption and formation are currently used to diagnose osteoporosis (OP) and metabolic bone diseases. However, these methods have some disadvantages for bone turnover evaluation. Recent evidence suggests that in RA changes in the secretion of hormones of white adipose tissue can be revealed [1,2]. One of them is Adiponectin possessing anti-inflammatory, anti-diabetic and anti-atherogenic properties. Changes in Adiponectin levels may reflect influence of immune inflammation on bone turnover.

**Objectives:** To study the clinical and diagnostic value of serum Adiponectin determination in RA patients complicated by OP.

**Methods:** We examined 88 women with documented diagnosis of RA and mean disease duration of 6.56±0.88 years. We used EULAR/ARA 2010 criteria to diagnose the patients. Female patients with II degree of disease activity (DAS28), Steinbrocker stage II (erosive), rheumatoid factor- and anti-cyclic-citrullinated peptide antibody-positive were prevalent. We excluded patients who had surgery or developed an infection within the last 8 weeks, pregnant and breast-feeding

women, those with severe heart, liver or kidney disease, immune deficiency, leukopenia or chronic infection.
A control group of 45 healthy females aged of 25 and 59 years were included in the study. There were no reported findings of joint pain and RA symptoms in the group. The groups were adjusted for age ($p>0.05$) and showed no statistically significant differences.
We measured serum Adiponectin levels (μg/ml) using Human Adiponectin ELISA commercial test systems (BioVendor, Czech Republic, cat No. RD195023100). We used spectrophotometer with wavelength of 450 nm to detect the test results ("Multiskan" immunoenzyme analyzer, Finland). We plotted a curve using computer software. We diagnosed OP using dual-energy X-ray absorptiometry with LUNAR DPX PRO (GE, USA).
**Results:** Serum adiponectin levels in the control group were 12.5±0.9 μg/ml (M±m). Adiponectin levels in healthy subjects measured as M ±2d, ranged between 0.44 and 24.56 μg/ml. Patients with OP and RA had significantly higher levels of serum Adiponectin ($p<0.001$). Mean serum Adiponectin levels in RA patients who had normal bone density and had no OP were 35.21±0.6 μg/ml. Mean serum Adiponectin levels in RA/OP patients with low bone mineral density were 52.42±0.69 μg/ml. Adiponectin levels of 44 μg/ml and higher were associated with osteoporosis. Adiponectin levels of 43.9 μg/ml and lower were associated with normal bone density.
**Conclusions:** Thus, we revealed that Adiponectin levels depend on osteoporosis presence in RA patients. We suppose that Adiponectin determination may be useful laboratory marker for OP diagnosis. The test may be used to reduce the risk of low-energy fractures and to improve the quality of life in RA.

## AB0215 THE COMBINATION OF METHOTREXATE WITH HYDROXYCHLOROQUINE IS MORE EFFECTIVE THAN MONOTHERAPY IN EARLY RHEUMATOID ARTHRITIS: A QUASI-EXPERIMENT

L.A.H.A. Gevers, W.M.T. van den Hombergh, L.G. Schipper, I.L. Meek, J. Fransen. *Department of Rheumatology, Radboud university medical centre, Nijmegen, Netherlands*

**Background:** A tight-control strategy starting with a combination of methotrexate (MTX) and hydroxy-chloroquine (HCQ) was implemented between 2010–2015 in our clinic; without evidence from RCTs for the combination of MTX with HCQ in early RA (1). Some physicians chose not to adhere to this combination, which post-hoc gave the opportunity for a quasi-experiment.
**Objectives:** To investigate the effect of starting with MTX + HCQ combination therapy, versus MTX or HCQ mono therapy, on the DAS28 at 6 and 12 months in patients with early RA, while treating to the target of remission (DAS28 $<2.6$).
**Methods:** All patients with early RA (ACR-EULAR criteria) between April 2010 and October 2015 were eligible. Two sub cohorts were formed according to whether the treatment was started with MTX+HCQ as intended, or with MTX or HCQ. There were n=50 patients in the adherent-group and n=38 patients in the non-adherent group who were initially treated with MTX or HCQ mono therapy (sometimes with addition of the other drug after more than four weeks). The primary outcome was the ΔDAS28 at 6 months.
**Results:** In the study period 176 RA patients were treated and 88 could not be included due to lack of follow-up data. At baseline, there were no large or significant ($p<0.05$) differences between MTX+HCQ and mono therapy groups regarding age (mean 57 years), gender (73% female), disease duration (median 21 weeks). Also, rheumatoid factor positivity (48% and 34%), mean baseline DAS28 (4.3 (1.3) and 4.2 (1.1)) were not different ($p>0.05$) between MTX+HCQ and mono therapy groups. In the mono therapy group, 30 patients started with MTX and 8 started with HCQ. After 6 months, the DAS28 decreased – 1.4 in the MTX+HCQ group and – 0.8 in the non-adherent group (p=0.044). After 12 months, the DAS28 decreased – 1.7 in the MTX+HCQ group and – 0.8 in the non-adherent group (p=0.007). After 12 months, 48% of adherent patients were in DAS28 remission compared to 26% of non-adherent patients (p=0.039). There were no baseline confounders operational.

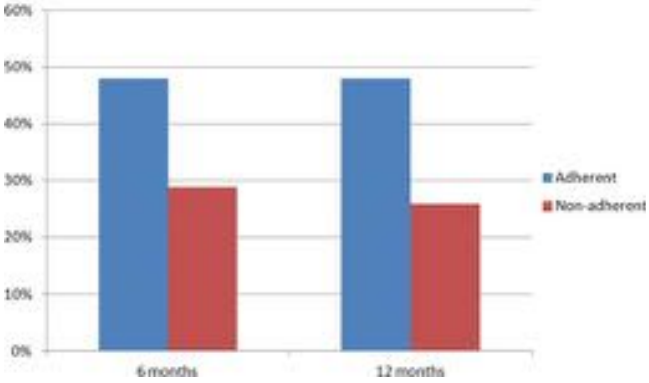

Table 1. (Decrease in) disease activity at 0, 6 and 12 months

| | Adherent (n=50) | Non-adherent (n=38) | p value* |
|---|---|---|---|
| DAS28 0 months (mean (SD)) | 4.3 (1.3) | 4.2 (1.1) | 0.755 |
| ΔDAS28 0–6 months (mean (SD)) | –1.4 (1.5) | –0.8 (1.3) | 0.044 |
| ΔDAS28 0–12 months (mean (SD)) | –1.7 (1.9) | –0.8 (1.3) | 0.007 |

*p value for between group comparisons.

**Conclusions:** In early RA starting with MTX and HCQ combination therapy leads to a larger decrease in DAS28 after 6 and 12 months and higher percentages of remission after 12 months in comparison with mono therapy with MTX or HCQ.

**Figure 1** Percentages of patients in remission (DAS28 < 2.6) at 6 and 12 months

## AB0216 OVEREXPRESSION OF SYNOVIAL LINING PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-GAMMA COACTIVATOR-1β INVOLVED IN JOINT DESTRUCTION THROUGH UPREGULATING MMP-3 IN RHEUMATOID ARTHRITIS

J. Jing, J.-D. Ma, Y.-Q. Mo, L.-F. Chen, L. Dai. *Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

**Background:** Our previous study showed that suppression of peroxisome proliferator-activated receptor-gamma coactivator-1β (PGC-1β) alleviated the secretion of matrix metalloproteinase (MMP)-3 from fibroblast-like synoviocytes and inhibited osteoclastogenesis in vitro. However, little was known about PGC-1β with joint destruction in RA patients.
**Objectives:** To investigate the expression and correlation of synovial PGC-1β with joint destruction in RA patients.
**Methods:** Eighty-one patients with active RA were recruited and followed up for one year. Serum MMP3 was detected by ELISA. Synovial tissue was obtained by closed-needle biopsy for H&E and immunohistochemistry staining for PGC-1β, MMP-3, CD3, CD20, CD38, CD68 and CD15. X-ray assessment of hand/wrist was repeated at baseline and one year and radiographic progression was defined as TSS≥0.5 unit.

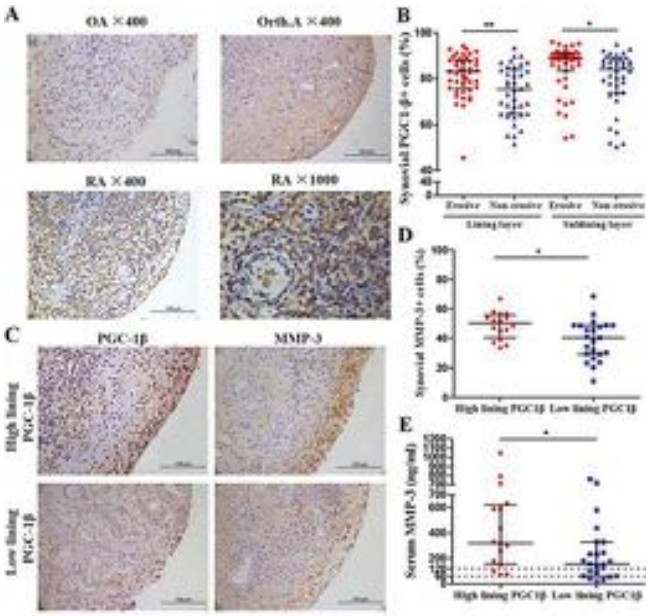

Fig. 1 A: Immunohistochemical staining of PGC-1β in OA, Orth.A and RA synovium; B: Percentage of synovial PGC-1β+ cells in patients with or without erosive disease (*$P<0.05$, **$P<0.01$); C: Immunohistochemical staining of PGC-1β and MMP-3 in patients with high or low synovial lining PGC-1β; D: Percentage of synovial MMP-3+ cells in patients with high or low synovial lining PGC-1β (*$P<0.05$); E: Serum MMP-3 in patients with high or low synovial lining PGC-1β (*$P<0.05$).

**Results:** (1) PGC-1β expression in RA was observed with intense nuclear staining in lining cells and sublining inflammatory cells (including macrophages, lymphocytes and plasma cells) which were significantly higher than osteoarthritis (OA) or orthopedic arthropathies (Orth.A, Fig. 1A).
(2) The percentage of lining PGC-1β+ cells significantly correlated with serum and synovial MMP-3 ($r$=0.394 and 0.376, both $P$<0.01), as well as CRP, ESR, CD15+ neutrophils and CD68+ macrophages in sublining area of RA synovium ($r$=0.266–0.356, all $P$<0.05), and the percentage of sublining PGC-1β+ cells significantly correlated with CRP, ESR, total synovitis score, CD3+ T cells, CD20+ B cells and CD38+ plasma cells, CD68+ macrophages in sublining area of RA synovium ($r$=0.225-0.428, all $P$<0.05).
(3) Forty-three (53%) RA patients had erosive disease (2013 EULAR definition) at baseline and their percentage of lining and sublining PGC-1β+ cells was significantly higher than non-erosive patients (both $P$<0.05, Fig. 1B). Both percentages of lining and sublining PGC-1β+ cells were significantly correlated with mTSS, joint space narrowing and erosion subscore ($r$=0.228-0.261, all $P$<0.05).
(4) Thirty-nine patients had finished one year follow-up and 23% of them had radiographic progression. The percentage of lining PGC-1β+ cells was significantly higher in progressive patients than non-progressive patients [83% (79%–91%) vs 75% (65%–82%), $P$=0.002]. ROC curve analysis showed that the tradeoff value of lining PGC-1β+ cells for predicting 1-year radiographic progression was 78% with sensitivity 89% and specificity 70% (AUC=0.833, 95% CI: 0.689–0.978, $P$=0.003).
(5) Serum and synovial MMP-3 were significantly higher in patients with high synovial lining PGC-1β than that in patients with low synovial lining PGC-1β (both $P$<0.05, Fig. 1C–E). Multivariate logistic regression analysis showed that high lining PGC-1β+ cells was a significant predictor of 1-year radiographic progression after adjustment for synovial and serum MMP-3 (OR: 15.002, 95% CI: 1.43–156.698, $P$=0.024, Fig. 1C).
**Conclusions:** Overexpression of synovial lining PGC-1β might play important roles in aggravating joint destruction through upregulating MMP-3 in RA.

## AB0217 VALIDITY OF TREAT TO TARGET STRATEGY FOR COMPREHENSIVE DISEASE CONTROL IN CHINESE PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-WORLD, PROSPECTIVE COHORT STUDY

J. Ma, X. Wang, Y. Mo, L. Chen, L. Dai. *Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** The ultimate goal for rheumatoid arthritis (RA) management is comprehensive disease control (CDC) including clinical remission, normal physical function and non-radiographic progression. However, current recommendations suggest that decision and adjustment of RA therapy mainly bases on disease activity and adheres to the treat-to-target (T2T) strategy which target is remission or low disease activity (LDA). Little was known about the validity of T2T strategy in achieving CDC in real world practice.
**Objectives:** To evaluate the validity and impact factors of T2T strategy in achieving CDC in Chinese RA patients.
**Methods:** Patients with moderately to severely active RA (DAS28-ESR≥3.2) were recruited and treated according to T2T strategy and followed up at the 1st, 3rd, 6th, and 12th months. Clinical data was collected simultaneously at baseline and each visit. X-ray assessment of hand/wrist was repeated and scored according to modified total Sharp score (mTSS). Therapeutic target was remission (DAS28-ESR<2.6) or LDA (2.6≤DAS28-ESR<3.2). One-year CDC was defined as DAS28-ESR<2.6, HAQ score<0.5 and mTSS≤0.5.
**Results:** (1) One hundred and three patients fulfilled 1-year follow-up. There were 33%, 48%, 57% and 56% patients achieved therapeutic target at the 1st, 3rd, 6th, 12th months respectively and 32% patients achieved CDC at the 12th month (Table 1). (2) Comparing with CDC-achieving group, the disease duration, baseline bony erosion and mTSS were significantly greater in CDC non-achieving group, while bDMARDs therapy was significantly less (all $P$<0.05). Further multivariate logistic regression analysis showed that bDMARDs therapy was a significant predictor of CDC-achieving (OR: 3.089, 95% CI: 1.255–7.600, $P$=0.008), while bony erosion at baseline was a significant predictor of CDC-non-achieving (OR: 4.392, 95%CI: 1.484–12.998, $P$=0.008). (3) The percentages of patients achieved clinical remission and normal physical function in CDC-achieving group were significantly higher than those in CDC-non-achieving group at the 1st, 3rd, 6th, 12th months respectively (all $P$<0.05). Univariate logistic regression analysis showed that remission and normal physical function at the 1st, 3rd, 6th were significant predictors of 1-year CDC (all $P$<0.05). Adjusted for bony erosion at baseline and bDMARDs therapy, multivariate logistic regression analysis showed that remission at the 3rd month (OR: 4.159, 95% CI: 1.647–10.506, $P$=0.003) and normal physical function at the 1st month (OR: 8.199, 95% CI: 2.078–32.340, $P$=0.003) predicted 1-year CDC.
**Conclusions:** Our results implies only 32% patients achieved 1-year CDC under DAS28-based T2T strategy and the patients with baseline bony non-erosion, bDMARDs therapy and having rapid clinical and functional improvement within 3 months might be more likely to achieve 1-year CDC.

**Table 1. Baseline demographic, clinical features and outcome of RA patients**

| Characteristics | All patients (n=103) | CDC-achieving group (n=33) | CDC-non-achieving group (n=70) | *P* |
|---|---|---|---|---|
| **Baseline demographic** | | | | |
| Age, years, median (IQR) | 49 (38–58) | 48 (37–58) | 49 (38–58) | 0.904 |

## AB0218 RHEUMATOID FACTOR IS ASSOCIATED WITH MORE PARAMETERS OF THE DISEASE ACTIVITY THAN ANTI-CITRULLINATED PEPTIDE ANTIBODIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

L.K. Damjanovska. *Rheumatology Clinic, University "Sts Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic Of*

**Background:** Rheumatoid arthritis (RA) is an evolving disease. In order to have a tight control and treat it to target, different markers for the measurement of disease activity have been investigated. A new hope emerged with the appearance of the new diagnostic anti-citrullinated protein antibodies (ACPA), such as anti-CCP and antibodies against mutated citrullinated vimentin (anti-MCV).
**Objectives:** The aim of this study was to evaluate the association of ACPA and RF with the parameters of the disease activity and composite disease activity indices.
**Methods:** We performed a cross-sectional study with 220 participants: 95 RA patients, 95 Non-RA patients with systemic inflammatory diseases and 55 healthy controls (HC). Demographic data, laboratory data and physical examination were performed and radiographies taken. ACPA antibody were measured with ELISA method and RF was measured with conventional Latex test.
**Results:** The mean age of the patients was 50, mean disease duration 4,8 years and average disease activity DAS 28 4,83. The sensitivity and specificity of the Anti-MCV, anti-CCP and RF regarding Non-RA patients were as follows: sensitivity 0.72, 0.71 and 0.69 and specificity 0.82, 0.88 and 0.86, respectfully with the area under the curve 0.77, 0,80 and 0,77. Anti-MCV and Anti-CCP antibody positivity was associated with 8 parameters of the disease activity. The common parameters for all the 3 antibodies were ESR, CRP, DAS28 and SDAI. Anti-MCV positivity was associated with Anti-CCP ($p$<0,001) but not with RF positivity, with higher platelet number, morning stiffness and swollen joint count with $p$<0,05. Anti-CCP positivity was associated with anti-MCV and RF positivity and titer ($p$<0,001) and it was exclusively associated with the higher Sharp van der Heijde radiography scores. RF positivity was associated with anti-CCP and anti-MCV positivity and titer, ($p$<0,05 and 0,04), patient assessment of pain, SJC, TJC, DAS28, CDAI, SDAI and HAQ DI ($p$<0,05).
**Conclusions:** ACPA antibodies should be further evaluated in association with parameters of RA disease activity but RF should not be neglected as well.

## AB0219 PREVALENCE AND RISK FACTORS FOR LUNG DISEASE IN RHEUMATOID ARTHRITIS

L. Lehlou, L. Ichchou. *Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*

**Background:** Lung disease is the most common extra-articular location of Rheumatoid Arthritis (RA).
**Objectives:** This study aims to evaluate the prevalence and risk factors for lung disease in Rheumatoid Arthritis.
**Methods:** A cross-sectional study of 72 patients fulfilling RA ACR/EULAR criteria was conducted over one year. Epidemiological data and RA parameters were collected. Pulmonary function tests, chest X-ray and high resolution computed tomography (HRCT) were performed. Data analysis was carried out using the SPSS 20 Software. $p<0.05$ was considered statistically significant.
**Results:** Means of age and disease duration were 51.39± 12.40 and 11.76±8.17 years respectively. Smoking was active and passive in 8.3% and 9.7% of cases respectively. RA was seropositive in 70% of cases. Means of DAS28, HAQ, Scharp were 4.59±1.80, 1.19 ±0.96 and 71, 05±43.62 respectively. 58.82% of patients were under Methotrexate, 18.1% under Salazopyrine and 81.9% under prednisone. Only 29.2% were symptomatic on the respiratory level. 12.5% had abnormal physical examination. Chest radiography showed abnormalities in 46% and pulmonary function tests were abnormal in 47% of cases. 55.3% of patients had a lung disease confirmed by HRCT and dominated by interstitial disease (19.4%). RA respiratory functional signs were statistically related to the duration time and positive ACPA. Abnormal HRCT was significantly related to age (p=0.01), activity by DAS 28 (p=0.02) and VS (0.04), severity by RF rate (p=0.04) and HAQ (p=0.01). On multivariate analysis, interstitial disease, rheumatoid nodules, emphysema and pleurisy were respectively associated with smoking, sex, respiratory functional signs and age greater than 40 years.
**Conclusions:** Respiratory disease affects one in two patients in our RA population. It would be related to age and female gender, but also smoking, activity and severity that we should control.
**Disclosure of Interest:** None declared

## AB0220 WHAT PROPORTION OF PATIENTS FAIL TO ACHIEVE CDAI AND AND SDAI REMISSION BASED ON PHYSICIAN GLOBAL ASSESSMENT? AN ANALYSIS FROM A PROSPECTIVE, OBSERVATIONAL REGISTRY

M. Starr[1], B. Haraoui[2], D. Choquette[2], L. Bessette[3], A. Chow[4], P. Baer[5], S. Kapur[6], J.T. Kelsall[7], M. Teo[8], E. Rampakakis[9], E. Psaradellis[9], F. Nantel[10], A.J. Lehman[10], B. Osborne[10], K. Maslova[10], C.M. Tkaczyk[10]. *[1]McGill University; [2]Institut de Rhumatologie de Montreal, Montreal; [3]Université Laval, Quebec; [4]McMaster University, Mississauga; [5]Private practice, Scarborough; [6]Ottawa Hospital, Nepean; [7]St Paul's Hospital, Vancouver; [8]Penticton Regional Hospital, Penticton; [9]JSS Medical Research, Montreal; [10]Janssen, Toronto, Canada*

**Background:** Physician's Global Assessment of Disease Activity (MDGA) is a measure that is frequently incorporated in disease activity indices which reflects the physician's perception of disease activity in rheumatoid arthritis (RA).
**Objectives:** The aim of this analysis was to assess the proportion of patients failing to achieve CDAI and SDAI remission based on MDGA in a real-world, routine clinical care setting in Canada.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible patients for this analysis included RA patients treated with IFX or GLM between 2005 and 2015. Modified versions of CDAI (mCDAI) and SDAI (mSDAI) were calculated by omitting MDGA from the formulas. Correlation of the standard and modified versions of each index was assessed with the Pearson's correlation coefficient. ROC curve analysis was used to identify new thresholds for the modified versions of low disease activity (LDA) and remission. Cross-tabulations with the Chi-square test were used to assess the agreement between the standard and modified definitions of remission and LDA.
**Results:** A total of 1206 patients were included in the analysis with a mean (SD) age of 56.1 (13.4) years and a disease duration of 8.4 (8.9) years.
A strong positive correlation was observed between the standard and modified versions of CDAI ($r=0.99$; $P<0.001$) and SDAI ($r=0.99$; $P<0.001$). Based on ROC analysis the new thresholds for remission and LDA were: CDAI (remission=2.65, LDA=10.05) and SDAI (remission=3.31, LDA=10.73). The proportion of patients achieving remission by both indices was 17.8% and 19.5%, patients not achieving remission by both indices was 75.3% and 74.4%, and patients achieving remission by the new thresholds only was 6.9% and 6.1%, for CDAI and SDAI, respectively. Cross-tabulation of the standard and modified thresholds showed that an additional 8.4% and 7.6% of non-remission cases for CDAI and SDAI, respectively, would be classified as remission with the modified definitions. Similarly, an additional 17.6% and 15.1% of non-LDA cases for CDAI and SDAI, respectively, would be classified as LDA.
**Conclusions:** The results of this analysis showed that MDGA could account for up to 8% of non-remission cases and up to 18% of non-LDA cases as measured by CDAI and SDAI. Omission of MDGA from these disease activity indices could have a significant impact on patient management in preventing overtreatment with DMARDs and biologics and avoiding unnecessary switching of DMARDs and biologics.

## AB0221 PREDICTIVE VALUE OF POWER DOPPLER ULTRASONOGRAPHY (PDUS) IN THE DIAGNOSIS OF VERY EARLY RHEUMATOID ARTHRITIS

L. Mayordomo[1], M.L. Velloso[1], C. Almeida[2], L.M. Jimenez-Liñan[1], C. Gomez-Cano[1], J.L. Marenco[1]. *[1]Rheumatology Department; [2]Research and Statistics Unit, Hospital Universitario Valme, Sevilla, Spain*

**Background:** There is a short window of opportunity for early diagnosis and treatment of rheumatoid arthritis, that may be crucial for reaching remission and a low rate of radiographic progression. High resolution power doppler ultrasonography (PDUS) is helpful in early detection of synovitis and allows an accurate classification of patients with joint inflammation.
**Objectives:** To establish wether the presence of basal power doppler signal in patients with very early arthritis may be helpful in order to establish the risk of final diagnosis of rheumatoid arthritis according ACR criteria 1987 at a year of follow up.
**Methods:** We studied the presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, knees) and 44 joints (28 joints and in addition hips, Tarsus, ankles and MTPs), with a mid-range equipment GE L5, in 40 patients with suspected early arthritis The patients were included with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with $<12$ weeks of duration of the symptoms. Presence or not of basal high acute phase reactants and basal erosions (score $\geq 2$ in at least one joint by modified Sharp method) for each patient were registered (37 patients with completed hands and feet radiology available). Presence of RF and/or ACPA positive were recorded as well. At one year follow-up was established whether patients met criteria for RA according1987 ACR or not. Statistical study: Chi-square, Fisher exact test, p univariant and Odds Ratio calculation.
**Results:** The presence of basal power doppler signal in $\geq 1$ joints of 44 (PD44) in baseline visit shows statistically significant association to RA diagnosis at 12 months by ACR 1987 classification criteria, p=0.008, OR=10,72 (1,76–65,24) but the presence of at least one joint with power doppler signal of 28 joints (PD28) did not (p=0.246). FR/ACPA were positive in only 20% and 15% of patients respectively, and were not associated to RA final diagnosis (p=0.236, p=0.152). Presence of basal radiographic erosions were associated to RA, $p<0.0005$ and OR 28,28 (3,05–261,87), as well as high CRP p=0.045 OR 4,63 (1,62–13,25) and ESR p=0.046, OR 4.5 (1.08–18,69). 17/17 (100%) of patientes with PD44 basal and radiographic erosions had final diagnosis of RA at 12 months.

| BASAL VARIABLES n=40 | | AR (ACR 1987) YES | p univariate | OR | IC 95 % |
|---|---|---|---|---|---|
| PD 28 | YES | 22/30 (73,3%) | NS | - | - |
| | NO | 5/10 (50%) | 0.246 | | |
| PD 44 | YES | 25/32 (78,1%) | 0.008 | 10,72 | (1,76-65,24) |
| | NO | 2/8 (25%) | | | |
| PD 44+ERORX (n=37) | YES | 17/17 (100%) | <0.0005 | NC (=) | - |
| | NO | 8/20 (40%) | | | |
| EROSION RX (n=37) | YES | 18/19 (94,7%) | < 0.0005 | 28,28 | (3,05- 261,87) |
| | NO | 7/18 (38,9%) | | | |

**Conclusions:** The presence of at least one joint with power doppler signal of 44 joints (PD44) on baseline visit may help to predict the RA diagnosis at 12 months of follow up according to criteria ACR 1987, in patients with very early RA. Presence of positive acute phase reactants and radiographic basal erosions increased the risk of RA as well. Moreover 100% of patients with PD44 in addition to radiographic basal erosions developed RA at 12 months.

## AB0222 BODY MASS INDEX, SMOKING STATUS AND RESPONSE TO RITUXIMAB IN RHEUMATOID ARTHRITIS: A REAL LIFE STUDY

M.C. Gerardi, A. Batticciotto, M. Antivalle, S. Bongiovanni, R. Talotta, F. Rigamonti, V. Varisco, F. Atzeni, P. Sarzi Puttini. *Rheumatology Unit, L. Sacco University Hospital, Milan, Italy*

**Background:** Several studies have demonstrated that obesity and smoking could have a negative influence on the response to anti-TNFα in Rheumatoid Arthritis (RA). Very few data are available about the impact of body mass index (BMI) and smoking status on other biologic agents.
**Objectives:** To evaluate the influence of BMI and smoking status on response to Rituximab (RTX) in RA.
**Methods:** A total of 68 RA patients treated with RTX were included in this monocentric retrospective study. BMI was calculated at the initiation of treatment. After six months of treatment, C-reactive protein level, tender and swollen joints, change of DAS28 from baseline, rates of EULAR good response and rates of remission were evaluated.
**Results:** At baseline, the median [interquartile range] BMI was 25.04 [21.4–28.8] kg/m$^2$. The number of patients with normal weight, overweight and obesity was 34, 22 and 12, respectively. The number of patients smokers, past smokers and never smoked was 12, 17 and 38, respectively. Baseline characteristics did not differ between the three subgroups of BMI and smoking status. After six months, the number of RA patients with DAS28 decrease $\geq$1.2, EULAR good response and remission was 20 (29.41%), 13 (19,11%) and 12 (17.64%), respectively.
The median BMI did not differ between responders and non-responders for DAS28 decrease $\geq$1.2 (25.7 [22.28–28.63] vs. 24.7 [21.09–29.3], p=0.49), EULAR good response (24.22 [20.91–39.75] vs. 25.1 [21.23–28.99], p=0.96) and remission (24.08 [21.84–28.24] vs. 25.1 [21.22–29.3], p=0.81). The percentages of smokers, past smokers and never smoked did not differ between responders and non-responders for DAS28 decrease $\geq$1.2 (smokers 15%, past smokers 25%, never smoked 60% vs. smokers 19,15%, past smokers 25.53%, never smoked 55.32%, p=0.9), EULAR good response (smokers 15,38%, past smokers 30,77%, never smoked 53,85% vs. smokers 18,52%, past smokers 24,07%, never smoked 57,41%, p=0.87) and remission (smokers 25%, past smokers 41,67%, never smoked 33,33% vs. smokers 16.36%, past smokers 21.82%, never smoked 61.82%, p=0.18).
Multivariate analysis performed on data corrected for age, sex, disease duration, concomitant treatments, and previous anti-TNFs, confirmed that BMI, body weight, and smoking status did not influence the clinical response to RTX ($p>0.05$ for all outcome variables considered).
**Conclusions:** This monocentric evaluation of RA patients demonstrated that there is no influence of BMI and smoking status on response to RTX in RA. However, larger and prospective studies are needed to confirm these results that could be useful for the selection of biologics in obese and smokers RA patients.

## AB0223 NEOPTERIN IN EARLY ARTHRITIS: DISEASE ACTIVITY AND SERUM MARKERS OF INFLAMMATION, CORRELATION INTO THREE TIME PERIODS, AN EXPERIENCE IN ARGENTINA

M.Y. Aguirre, D. Pereira, C. Pena, M. Garcia. *Buenos Aires, HIGA San Martin, la Plata, Argentina*

**Background:** Neopterin is a molecule produced by monocytes by stimulation of Interferon Gamma. It is elevated in infections, autoimmune diseases, malignancies, transplant rejection, neurodegenerative, and cardiovascular conditions such as pregnancy [1,2].
**Objectives:** To investigate the serum levels of neopterin in patients with early arthritis (EA) and establish its relationship with activity disease.
**Methods:** Non-experimental, prospective and longitudinal study was conducted in patients with EA (<2 years of evolution) and >18 years of age. On days 0, 6 and 12 months physical examination and analysis of parameters of activity within 7 days of the blood sample (DAS28, HAQ, EVA and ESR, CRP, FR, anti-CCP and ANA) were performed. Neopterin determination was made by ELISA reagent kit Gen Way Biotech Inc and calculated with Logit-log. Normal value below 10 nmol/l was considered.
Radiographs of hands and feet at the initial visit and 12 months through SENS method (score of grips and erosions) were evaluated.
Neopterin values were compared to a control population of 47 healthy individuals. Stata 9.0 for data analysis. Fisher 2 to chi-2.
**Results:** Twenty-seven patients (36±13 years), 19 (70%) women and 8 (30%) males were evaluated. At first the mean value of neopterin in EA Group was 7.51 (5.5–11.4) vs 5.32 (3.5–6.44) in the control grou p (p=0.0004). It was correlated with scores of activity, and the activity measured by DAS28 was observed that in the initial period: Neopterin >10 nmol/L (n=8): 3.37 [2.53–4.36] vs Neopterin standard value (n=19): 3.86 [3.24 -4.54] (p=0.34).At 6 months: Neopterin>10 (n=5): 3.33 [2.14–4.33] vs Neopterin standard (n=22): 2.96 [2.66–3.73] (p=0.6); and at 12 months: Neopterin >10 (n=9): 3.08 [2.49–3.79] vs Neopterin standard (n=18): 2.90 [2.34–3.27] p=0.53. No correlation was found between neopterin and DAS 28.
**Conclusions:** In this study the results showed no correlation between disease activity (DAS28) and high concentrations of serological marker (neopterin) compared in the three periods or with other international assessment rates. Correlation was observed between DAS 28 and acute phase reactants (ERS and CRP) in the three periods. It would require studies with more patients to confirm these data.

## AB0224 ROLE OF ANTI-RA33 AS A BIOMARKER FOR DIAGNOSIS IN COLOMBIAN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Peña, F. Rondón. *Rheumatology, Universidad Nacional de Colombia, Bogotá, Colombia*

**Background:** Accurate and early diagnosis of rheumatoid arthritis (RA) is vital for the timely implementation of a comprehensive treatment aimed at halting or slowing its progression (1). The sensitivity of existing biomarkers, rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP) is low (2). It requires a new diagnostic biomarker with better performance in RA.
**Objectives:** To evaluate the diagnostic value of anti-RA33 (3) test in a simple of RA patientes and controls of Bogotá, Colombia, by measuring its sensitivity, specificity, positive and negative likehood ratio compared to RF and anti-CCP. Additionally, to asses the association between clinical and serological variables with the functional impairment degree in patients with RA.
**Methods:** A cross-sectional study in a sample of 80 RA patients and 20 controls without RA who attended to outpatient service in two hospitals of Bogotá from 2014 until 2015 was conducted by measuring their sociodemographic characteristics, arthritis activity degree by DAS-28 index, functional ability by HAQ-DI score and serological status for anti-RA33, RF and anti-CCP. A statistic analysis with proportions, summary and dispersion measures, contingency tables for measure of sensitivity, specificity, likehood ratios, ROC curves and multiple linear regression analysis was performed.
**Results:** Sensitivity score for anti-RA33, RF and anti-CCP was 15%, 85% and 93% respectively; while specificity was 100%, 90% and 85% respectively. The positive likelihood ratio was 8.5 for RF and 6.2 for anti-CCP. Finally, negative likelihood ratio was 0.87 for anti-RA33, 0.16 for RF and 0.08 for anti-CCP. The anti-RA33 seropositive patients were greater arthritis activity and functional disability as well as higher titers of RF and anti-CCP although these differences were not statistically significant. Finally, a moderately strong positive correlation was found between DAS-28 and HAQ-DI scores ($R^2$ =0.51). In the multiple linear regression model, DAS-28 index was the only predictor variable that explained the changes in the HAQ-DI functional ability score.
**Conclusions:** Findings suggest that anti-RA33 test does not seem to have any clinical utility for the diagnosis of RA in Colombian population. The importance of DAS-28 activity index as a score of association with functional disability in patients with RA was confirmed.

## AB0225 ASSOCIATION OF SPECTRAL DOPPLER RESISTIVE INDEX WITH POWER DOPPLER AND DAS28 IN ESTABLISHED RHEUMATOID ARTHRITIS

M.C. Bisi[1], A.D. Do Prado[2], D.M. Piovesan[1], M. Bredemeier[3], I.G. Silveira[4], J.A. Mendonça[5], H.L. Staub[1]. *[1]Rheumatology; [2]Pontificia Universidade Catolica do Rio Grande do Sul; [3]Rheumatology, Grupo Hospitalar Conceição; [4]Rheumatology, PUCRS, Porto Alegre; [5]Rheumatology, Pontificia Universidade Catolica de Campinas, Campinas, Brazil*

**Background:** Angiogenesis and vasodilatation play a crucial role in the development and perpetuationof synovitis in rheumatoid arthritis (RA). Ultrasonography (US) is an useful tool for evaluation of pannus vascularization in active RA. Differently from US power Doppler (pD), the resistive index (RI) of spectral Doppler provides a quantitative analysis of vascular inflammation. As the musculoskeletal structures are characterized by high-resistance flows, the RI has a value of 1 in normal conditions; a decrease in the RI is registered in case of inflammation.
**Objectives:** To investigate a possible association of the RI spectral Doppler with other US parameters of synovitis and clinical measures of disease activity in established RA.

**Methods:** 95 pD-positive RA patients (1987 ACR criteria) were consecutively evaluated and scanned in this prospective cross-sectional study. Disease acitivity and disability were measured using Disease Activity Score in 28 joints (DAS28) and Health Assessment Questionnaire (HAQ), respectively. US examination was performed by ultrasound-trained rheumatologists in 10 hand joints (the wrists, 2nd and 3rd metacarpophalangeal and 2nd and 3rd proximal interphalangeal joints) using high-resolution equipment (MyLab 60, Esaote). Clinical and US evaluations were performed in a blinded fashion. Gray-scale (GS) and pD were searched using a semi-quantitative scale (0–3). For each patient, the most inflammed joint on US examination was identified and, then, RI was measured at least on three different sites of the sinovial area. The sum of the individual joint scores for GS and pD (10-joint score GS or pD) and the mean RI of the most US-affected joint were calculated. Kappa statistics was used to evaluate interobserver reability. Mann-Whitney test and Spearman correlation coefficient (rS) were used for statistical analysis.
**Results:** Patients' features were mean age, 55.6±11.8 years; female gender 79%, positive rheumatoid factor, 58%; median disease duration, 7 (range, 1–36) years; mean DAS28, 4.33±1.66; mean HAQ, 1.04±0.88. Real-time US interobserver kappa was 0.77 for GS, 0.87 for pD, and 0.68 for RI. RI was not significantly associated with 10-joint pD-score (rS=-0.15, 95% CI -0.33 to 0.05, p=0.15; figure 1), 10-joint GS-score (rS=-0.14, 95% CI -0.31 to 0.04, p=0.17), DAS28 (rS=0.05, 95% CI -0.17 to 0.26, p=0.61) or HAQ (rS=-0.01, 95% CI -0.22 to 0.20, p=0.95). There was also no association of RI with the presence of bone erosions (p=0.72).

Figure 1: Correlation of the 10-joint PD score with Resistive Index

MediaRI - mean value of resistive index, Score10PD - sum of all joint value in power Doppler semi-quantitative score, rs = Spearman correlation coefficient

**Conclusions:** RI was not either clinically or statistically correlated with clinical measures of disease acitivity, US inflammatory parameters, and structural damage in our study. Adding the RI to musculoskeletal US evaluation does not seem to improve US performance in PD-positive patients with established, long standing RA.

## AB0226 ONE YEAR EXPERIENCE OF A BDMARD SPACING PROTOCOL IN REAL LIFE RHEUMATOID ARTHRITIS PATIENTS

M. Todoerti, S. Monti, V. Grosso, F. De Nard, S. Breda, I. Chiapparoli, R. Caporali, C. Montecucco. *Rheumatology, Policlinico S. Matteo IRCCS Foundation, Pavia, Pavia, Italy*

**Background:** Current guidelines about rheumatoid arthritis (RA) management might admit tapering schedules of biologic disease modifiying drugs (bDMARDs) when disease activity control has been achieved and maintained, in line with growing scientific evidences [1]. Great heterogeneity in target populations, end-points, study designs, therapeutic protocols, criteria for bDMARD discontinuation and resumption globally prevents from univocal interpretation of study results [2]. Real life data might provide additional information on the topic, which could be better extended to routine care.
**Objectives:** To analyze the impact of a bDMARD down-titration strategy (spacing) on clinical and sub-clinical disease activity control over time (12 months) in real life RA patients attending a single Italian Rheumatologic Unit.
**Methods:** RA patients with at least 1 year of bDMARDs treatment and a well-controlled disease (at least low disease activity/LDA according to DAS28 criteria for at least 6 months) were offered to undergo a spacing (doubling the inter-administration period) of their ongoing bDMARD (anti-TNF, Abatacept/ABA, Tocilizumab/TCZ) medication. When present, concomitant conventional synthetic DMARDs (csDMARDs) and/or low dosage (less than 7,5 mg/d prednisone-equivalent) oral corticosteroid (CS) were admitted and maintained: Group A= CS-on patients; Group B= CS-off patients. Disease activity was monitored every 2 months through DAS28 in order to detect any clinical relapse (>LDA): relapsing Group A patients immediately resumed original bDMARD schedule, relapsing Group B patients started firstly low dose CS (5 mg/d) while keeping on bDMARD spacing. At the same time-points, ultrasonographic (US) assessment (Gray Scale/GS and power Doppler/PD scores) was performed on dorsal view of bilateral hands and wrists. Clinical and US results were analyzed either globally and by CS-co-medication, as to detect any bDMARD sparing effect.
**Results:** Thirty-seven RA patients consented to the bDMARD spacing. Most patients were on anti-TNF agents (4 TCZ, 1 ABA) in association with csDMARDs (7/37 csDMARD free), and without CS co-medication (30/37 CS free). At time of spacing overall clinical (mean DAS28±sd 1,92±0,59), lab (median ESR [IQR] 10,50 [7–16] mm/h, median CRP [IQR] 0,14 [0,10–0,49] mg/dL) and US parameters (median GS score [IQR] 9 [6–13,5], median PD score [IQR] 0 [0–0]) were consistent with disease control; more than half patients had negative prognostic factors. Globally, trends over time of either clinical and US parameters did not significantly differ between groups, regardless of CS co-administration. Nevertheless, over the first year of observation more CS-off than CS-on patients experienced disease relapse (12 versus 4 patients, respectively, p=0,99); this occurred sooner in CS-off patients, too (mainly in the first 6 months of follow up).
**Conclusions:** The feasibility of bDMARDs step-down schedules in RA patients should be clarified in real life setting, as well as in clinical trials. bDMARD spacing might be a possible choice, especially when low dosage CS are co-administered: their eventual bDMARD sparing effect should be confirmed with larger and longer observations, together with complete evaluations about cost-effectiveness and risk-to-benefit profiles.

## AB0227 VALIDATION OF PATIENT-DERIVED DISEASE ACTIVITY SCORE IN CHINESE RHEUMATOID ARTHRITIS PATIENTS

M.-H.A. Leung [1], E. Choy [2], C.S. Lau [3]. *[1]Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong; [2]Arthritis Research UK and Health and Care Research Wales CREATE Centre, Institute of Infection and Immunity, Cardiff University, Cardiff, United Kingdom; [3]Department of Medicine, LKS Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong*

**Background:** The current standard of care for rheumatoid arthritis (RA) is treat to remission or low activity state. This underlines the need of regular assessment of disease activity. Patient-derived Disease Activity Score (PDAS) is one of the tools that have been developed and validated to allow patients with RA to self-assess disease activity.[1] Two versions of PDAS are available: PDAS1 (with ESR) and PDAS2 (without ESR). The corresponding cut-off points of RA activity statuses had been reported.[2] PDAS was developed in English speaking patients.
**Objectives:** To explore the validity of PDAS in Chinese speaking RA patients.
**Methods:** 100 RA patients were recruited from rheumatology specialist clinic in Hong Kong. They were asked to complete in Chinese version of questionnaires before clinic which included functional status (Health Assessment Questionnaire)[3], self assessed swollen and tender joint count, morning stiffness and global assessment. Standard disease activity score DAS28ESR and CDAI were assessed by Rheumatologists at these visits. Correlation with PDAS1 and 2 was done with Spearman rank test and categorical agreement by kappa statistics. The study was approved by local ethics committee.
**Results:** Patient characteristics are as follows: mean age 60 years (standard deviation SD 12), mean RA disease duration 14 years (SD 9), 90% female, 71% seropositive, 48% patients in remission or low disease activity while 52% in moderate or high disease activity. PDAS in Chinese patients showed equally high correlation with DAS28ESR and CDAI. Spearman rank correlation coefficients were similar to those in original PDAS derivation (in brackets) (all P<0.0001):

| | DAS28ESR | CDAI |
|---|---|---|
| PDAS1 | 0.86 (0.85) | 0.67 (0.69) |
| PDAS2 | 0.70 (0.70) | 0.77 (0.73) |

When comparing RA activity statuses ([remission or low] versus [moderate or high activity]) using kappa statistics, PDAS showed considerable agreement with DAS28ESR, noting that within this patient group, the agreement of DAS28ESR with CDAI itself was only 0.60:

| | DAS28ESR | CDAI |
|---|---|---|
| PDAS1 | 0.52 | 0.58 |
| PDAS2 | 0.28 | 0.53 |

In particular for PDAS2, a formula without the need of blood test, has good sensitivity (96%) of picking up DAS28 remission or low activity, and good negative predictive value (89%) to signal moderate or high activity.
**Conclusions:** PDAS can be adapated to Chinese language speaking RA patients

in routine clinical setting. PDAS2 is useful in two aspects: informing patients that they are well treated-to-target; and concuring with patients having moderate or high disease actiivity.

## AB0228 ARTHRITIS WITH CHILDHOOD ONSET IN ADULT PATIENTS: LONG-TERM OUTCOMES AND SOCIAL ADAPTATION

N. Muravieva, Y. Muraviev. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** Follow-up care and social adaptation issues in adult patients with childhood onset arthritis are highly relevant, as the prognosis and long-term outcomes of the disease are not sufficiently studied.
**Objectives:** To assess long-term outcomes and social status of adults with childhood onset arthritis.
**Methods:** Establishment of the adult patients with childhood onset arthritis database, covering the period from 2003 year to 2015 year, allowed to analyze the disease activity, the radiographic stage and functional class (using *Steinbrocker method*), complications, used pharmacotherapies, as well as social status (education, professional activity, marital status).
**Results:** The database includes 235 patients: 176 females, 59 males, mean age 27.7±8.0 years, disease duration 18.1±8.5 years. Persisting arthritis was found in 72% patients. Radiographic stage II was established in 139 patients, stage III – in 49, stage IV – in 47 patients. Functional class II predominates in the majority of patients. The most common disease-modifying anti-rheumatic drug (DMARD) used was methotrexate – in 73% of patients, each 3rd patient was taking sulfasalazine, each 4th - leflunomide, 15% of patients had never used whatever DMARDs. 53 patients were administered biologic drugs: 30 patients received 1, 16 patients – 2, 6 patients – 3, 1 patient received 4 of biologic drugs. Glucocorticoids (GCs) were administered in 55% of patients, more than 60% continue on GCs, including 42 patients using GCs for >10 years. Aseptic bone necrosis (predominantly of femoral head) was reported in 25% of patients. Bone fractures were documented in 8 patients. Joint prosthetics were required in 23 patients: single joint – in 9, 2 joints – in 11, 3 joints – in 2, 4 joints - in one patient. Arterial hypertension, requiring medication, was found in 12 patients. Nanism was diagnosed in 27 patients, primary amenorrhea – in 11, secondary amenorrhea – in 2, steroid diabetes – in 2 patients. Light perception visual acuity was documented in 2 patients, poor vision was reported in 3 patients. Amyloidosis was found in 2 cases. At present higher education was finished or in the process of continuation by 49 patients (including 2 patients – in medical institute), special education was finished or in the process of continuation by 169 patients. Only school education has 17 patients. Out of those with full education (127 patients) 85 are working (including 2 rheumatologists and 1 pediatrician), while 42 patients are in dependence. 52 patients have family (93% - women), 36 patients (91% - women) have children: one – 27, two – 7, three – 1, six – 1.
**Conclusions:** Only 1/3 of adult patients with childhood onset arthritis have satisfactory long-term clinical outcomes; at the same time the majority of patients are well adapted socially.

**Disclosure of Interest:** None declared

## AB0229 DOES SERUM LEVEL OF IL-17 AFFECT DISEASE ACTIVITY AND FUNCTIONAL DISABILITY IN RHEUMATOID ARTHRITIS PATIENTS? RELATION BETWEEN SERUM IL-17 LEVEL, DAS-28 AND HAQ-DI

N.A. Aboeladl[1], H.K. Koryem[1], M.A. Rezk[2], M.M. Hassan[1], S.S. Eltawab[1]. *[1]physical medicine, rheumatology and rehabilitation; [2]clinical and chemical pathology, faculty of medicine alexandria university, alexandria, Egypt*

**Background:** Rheumatoid arthritis (RA) is a chronic, progressive, systemic inflammatory disease. Interleukin-17 (IL-17) is a cytokine that is expressed in inflammatory and autoimmune diseases and expected to play an important role in the pathogenesis of RA. Many years, the measurement of disease activity in RA has been held by Disease Activity Score-28 (DAS-28). Regarding the correlation between serum level of IL-17 and disease activity, some authors found a good significant correlation between these parameters,while others stated that DAS-28 values for expressing disease activity in RA patients may be flawed by coexisting fibromyalgia lead to higher total scores. Health Assessment Questionnaire – Disability Index (HAQ-DI) has been usually used for disability assessment in RA patients. It is one of the most widely used comprehensive, validated and patient-oriented outcome assessment instruments.
**Objectives:** To study the relation between serum IL-17 level, DAS-28 CRP and HAQ-DI in RA patients.
**Methods:** The study included 25 RA patients and 20 healthy controls. Serum IL-17 was measured by ELISA, disease activity by DAS-28 CRP and functional disability by HAQ-DI.
**Results:** Serum IL-17 level among RA patients was significantly higher than healthy control ($p$ <0.001). Serum IL-17 levels showed insignificant correlation with DAS-28 CRP and HAQ-DI of RA patients.

Table 1

| | Serum IL-17 | |
|---|---|---|
| | r | p |
| DAS-28 CRP | 0.070 | 0.741 |
| HAQ-DI | 0.222 | 0.286 |

**Conclusions:** IL-17 doesnot correlate with disease activity and functional disability in RA patients.

## AB0230 CENTROMERE PATTERN EXHIBITS A SPECIFIC DISTRIBUTION OF TITERS AMONG ANTI-NUCLEAR ANTIBODIES (ANAS) AND CHARACTERIZES A DISTINCT SUBSET IN RHEUMATOID ARTHRITIS

N. Kuramoto[1], C. Terao[2], K. Ohmura[1], K. Ikari[3], M. Furu[4], N. Yamakawa[1], K. Yano[3], M. Hashimoto[4], H. Ito[4], T. Fujii[1], K. Murakami[1], R. Sasai[1], Y. Imura[1], H. Yoshihuji[1], N. Yukawa[1], A. Taniguchi[3], S. Momohara[3], H. Yamanaka[3], F. Matsuda[2], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Center for Genemic Medicine, Kyoto University Graduate School of Medicine, Kyoto; [3]Tokyo Woman's Medical University, Tokyo; [4]Department of the Control for Rheumatic Disease, Kyoto University Graduate School of Medicine, Kyoto, Japan*

**Objectives:** Centromere pattern is a staining pattern of anti-nuclear antibodies (ANAs). Here, we characterize the titer distribution of centromere pattern and analyze clinical and genetic features of centromere pattern-positive rheumatoid arthritis (RA).
**Methods:** We examined ANA by indirect immunofluorescence for 9,575 healthy volunteers and 1,211 RA patients without systemic sclerosis in Kyoto University Hospital. HLA-DRB1 was genotyped for 285 RA patients. We compared distributions of titers among ANA and analyzed associations between centromere pattern

and clinical or genetic features in the subjects. For validation, we recruited another cohort of 2,424 RA patients in Tokyo Woman's Medical University Hospital to confirm the associations between centromere pattern and clinical features.
**Results:** Eighty seven healthy volunteers (0.91%) and 25 RA patients (2.76%) were positive for centromere pattern of ANA. Centromere pattern was the only ANA staining pattern that demonstrated a definite bimodal distribution of levels in both healthy volunteers and patients with RA. Centromere pattern showed significantly higher levels than the other ANA patterns in the subjects positive for each ANA ($p<0.0001$). Centromere pattern-positivity was associated with old age and females in both healthy population and patients with RA.
Centromere pattern-positive patients with RA showed lower positivity of rheumatoid factor (RF) ($p=0.0011$) that is one of risk factors for bone destruction. Centromere pattern was associated with Raynaud's phenomenon and complication of Sjögren's syndrome and primary biliary cirrhosis ($p\leq0.0052$). No HLA-DRB1 alleles were significantly associated with centromere pattern.
In validation study, 82 RA patients (2.41%) were positive for centromere pattern. Centromere pattern-positivity was again associated with old age, females and negativity of RF ($p\leq0.0044$). Information of complications and symptoms was not available in the replication cohort. Centromere pattern-positive patients tended to show higher Total Sharp Score in spite of lower frequencies of RF in both cohorts.
**Conclusions:** Centromere pattern showed a specific distribution of levels among ANA. Centromere pattern-positive RA is a distinct subset with specific clinical features and complications. Centromere pattern is a possibly new risk factor of bone destruction in RA.

**DOI:** 10.1136/annrheumdis-2016-eular.3857

## AB0231 HIGHER PEAK DISEASE ACTIVITY WAS IMPLICATED AS A RISK FACTOR IN THE DEVELOPMENT OF VERTICAL SUBLUXATION IN RA PATIENTS

O. Ishida, K. Ikari, A. Taniguchi, H. Yamanaka, S. Momohara. *Inst Rheumatology, Tokyo Women's Med Univ, Tokyo, Japan*

**Background:** Instability of the upper cervical spine is common in patients with rheumatoid arthritis (RA) and can lead to sudden death in worst case scenarios.
**Objectives:** The aim of this study was to evaluate the relationship between upper cervical spine instability and clinical factors, especially focusing on disease activity of RA.
**Methods:** The study included patients who had been enrolled in the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort study within two years from the onset of RA symptoms and who had cervical spine radiographs taken as part of the preoperative testing for elective joint surgery (e.g. joint replacement surgery) at the institute between April 2010 and March 2013. The anterior atlantodental interval (ADI) and Redlund-Johnell (R-J) values were measured to diagnose atlantoaxial subluxation (AAS) and vertical subluxation (VS), respectively. We obtained clinical data from the IORRA cohort study collecting various clinical data biannually, starting in October 2000.
**Results:** Finally, the current study included 56 patients. Nearly half of the patients had AAS (27 patients, 48.2%) and 12 patients (21.4%) had VS. In total, 59.6% of the patients had upper cervical instability. There was no significant correlation between the ADI and R-J values ($\rho$= -0.025; P=0.8). Multiple linear regression analysis revealed the maximum Disease Activity Score in 28 joints (DAS28) during the study period and height were significantly related to R-J values. No variable was significantly associated with the ADI. Univariate logistic regression analyses indicated only the maximum DAS28 during the study period was significantly associated with developing VS, and no variables were shown to be significant in relation to the development of AAS. Median (IQR) values for the maximum DAS28 during the study period in patients with and without VS were 6.1 (5.0 to 6.6) and 5.1 (4.6 to 5.5), respectively. The area under the ROC curve (AUC) showed the predictions using the maximum DAS28 (cutoff = 5.56, specificity = 79.1%, sensitivity = 69.2%, and AUC =0.714) were moderately accurate (Figure 1).

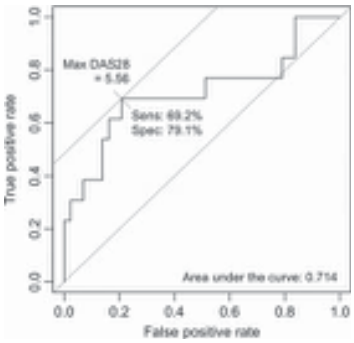

Figure 1

**Conclusions:** Higher peak disease activity was implicated as a risk factor in the development of VS in RA patients. We suggest that tight control of disease activity is desirable to reduce the risk of VS.

## AB0232 NEUROPATHIC PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

O. Akkar, M. Lehraiki, H. Azzouzi, L. Boutouala, L. Ichchou. *Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*

**Background:** Rheumatoid arthritis (RA) pain is traditionally attributed to peripheral inflammation of the joints. However, pain control is often inadequate, even when inflammation appears to be well controlled. This suggests that neuropathic pain (NP) may also be present in patients with RA.
**Objectives:** The objective of this study was to examine NP symptoms and associated factors in patients with RA.
**Methods:** Patients with RA according to ACR 1987 or ACR/EULAR 2010 classification criteria were included in this cross-sectional study. Demographic data and RA characteristics were collected. Pain was measured using a visual analogue scale (VAS). Disease activity was assessed by the Disease Activity Score (DAS 28). Functional disability was evaluated by the Health Assessment Questionnaire (HAQ). Joint destruction was assessed by the Van der Heijde-modified Sharp Score. NP symptoms were assessed using the DN4 questionnaire. Data analysis was carried out using the SPSS 20 Software. $p<0.05$ was considered statistically significant.
**Results:** Eighty-four patients with a mean±SD age of 50.6 ±12.29 years were enrolled. Eighty-nine per cent were female. Mean±SD duration of symptoms was 11.24±8.91 years. Thirty one per cent had NP and 96.2% of them were taking steroids. In the NP group, means±SD of VAS pain, DAS28, HAQ, sharp score were 3.85±2.73, 3.21±2.21, 1.00±0.95 and 63.27±43.52 respectively. NP patients did not significantly differ from those with no NP symptoms in terms of age, disease duration, disease activity, VAS pain, functional disability and joint destruction. The regression analysis showed that there was no significant correlation between NP and the RA parameters.
**Conclusions:** The prevalence of NP was 31% in our RA population. It is important to consider the existence of NP in the assessment and treatment of RA pain. However, larger studies are needed to investigate factors associated with NP in RA patients.

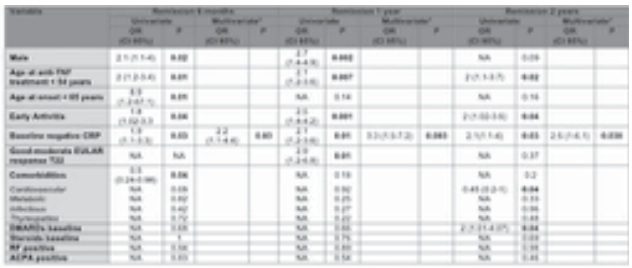
## AB0233 ANTERIOR ATLANTOAXIAL SUBLUXATION IN RHEUMATOID ARTHRITIS: PREVALENCE AND PREDICTIVE FACTORS

O. Akkar, J. Eddarami, L. Ichchou. *Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*



**Background:** Cervical spine involvement is common and potentially severe in patients with Rheumatoid Arthritis (RA). The most common abnormality is anterior Atlanto Axial Subluxation (aAAS), which has been reported in 19–70% of patients.
**Objectives:** The aim of this study was to determinate the prevalence of aAAS by plain radiographs and to assess its predictive factors.
**Methods:** A cross-sectional study was carried out with RA patients diagnosed according to ACR 1987 or ACR/EULAR 2010 classification criteria. Demographic characteristics and features of disease were collected. Pain was measured using a visual analogue scale (VAS). RA activity was assessed by the Disease Activity Score (DAS 28). Functional disability was evaluated by the Health Assessment Questionnaire (HAQ). Joint destruction was assessed by the van der Heijde-modified Sharp Score. aAAS was assessed on lateral radiographs taken in flexion. The diagnosis was based on an anterior atlantodental interval (AADI) greater than 4 mm. Data analysis was carried out using the SPSS 20 Software. $p<0.05$ was considered statistically significant.
**Results:** One hundred and sixteen patients with a mean±SD age of 49.07±13.23 years were recruited. Eighty-five per cent were female. Mean±SD duration of symptoms was 11.3±9.30 years. The diagnosis of aAAS was made in 11 (9.5%) of cases. RA patients with aAAS had longer disease duration, higher Sharp scores, and higher functional disability. On regression analysis, significant predictors of aAAS were disease duration ($p=0.008$), joint destruction ($p=0.002$), functional disability ($p=0.028$) and presence of coxitis ($p=0.038$). The multivariate analysis showed that structural damage was a predictive factor of aAAS ($p=0.007$ OR: 1.02, 95% CI 1.006–1.035) adjusted to functional disability and presence of coxitis.
**Conclusions:** The prevalence of aAAS was 9.5% in our RA population. Larger studies are required to identify the profile of RA patients at high risk of cervical spine involvement.
**Disclosure of Interest:** None declared

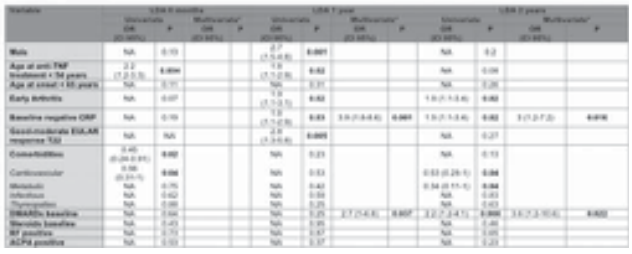
## AB0234 PREDICTIVE RISK FACTORS OF REMISSION AND LOW-DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ANTI-TNF DRUGS IN REAL PRACTICE: RESULTS FROM A SINGLE CENTRE



P. Conigliaro, M. Tonelli, P. Triggianese, M.S. Chimenti, F. Sunzino, R. Perricone.
*Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy*

**Background:** The goals of treatment in Rheumatoid Arthritis (RA) are remission and low disease activity (LDA); therefore, it is important to identify reliable predictive factors of these targets so that treatment can be tailored.
**Objectives:** We aimed at identifying positive and negative predictive factors of remission and LDA in RA patients treated in real practice with first line anti-TNF drugs.
**Methods:** Retrospective analysis of DAS28 remission/LDA in 308 RA patients treated for two years with first line anti-TNF drugs from January 2008 to December 2014: [female n=251 (81.5%), age 55±13 years, disease duration 7.6±8.4 years, rheumatoid factor (RF, n=220 (71.4%)), anti-citrullinated antibodies (ACPA, n=214 (69.5%)), baseline C-reactive protein (CRP, 11.4±16.5 (mg/L)), baseline DMARDs (n=225 (73.1%)), baseline steroid (n=160 (51.9%)), Adalimumab (n=109 (35.4%)), Etanercept (n=177 (57.5%)), other anti-TNF (n=22 (7.1%))]. Predictive factors considered for achievement of remission and LDA were: gender, age at the time of anti-TNF treatment (cut-off >54 yrs old, n=139 (45.1%)), age at onset >65 yrs old (n=27 (8.8%)), early arthritis (n=99 (32.1%)), baseline negative CRP (n=150 (48.7%), RF/ACPA positivity, good/moderate EULAR response at 6 months (n=169 (54.9%)), presence of any comorbidity (n=210 (68.2%)), cardiovascular comorbidity (n=83 (26.9%)), metabolic syndrome (n=26 (8.4%)), infectious (n=49 (15.9%)), thyreopathies (n=64 (20.8%)), concomitant DMARDs/steroid treatment. Intention to treat, ROC-curve, univariate and multivariate analysis by logistic regression were performed. Selection of the variables to be included in the multivariate analysis was performed on the basis of their statistical significance in the univariate analysis.
**Results:** In the univariate analysis positive predictors of remission and LDA at 6 months, 1 year and 2 years of anti-TNF treatments were identified as follows (Figure 1A): male gender, age at the time of anti-TNF treatment <54 yrs old, age at onset <65 yrs old, early arthritis, baseline negative CRP levels, good/moderate EULAR response at 6 months and concomitant DMARDs treatment. Negative predictors were presence of any comorbidity, cardiovascular comorbidity and metabolic syndrome. In the multivariate analysis the only significant positive predictor of remission and LDA at 6 months, 1 and 2 years of treatment was the negative CRP levels at baseline (Figure 1B).

A

B

**Conclusions:** Negative CRP levels prior to commence anti-TNF treatments in RA patients appeared to be a reliable predictor of remission and LDA in clinical practice.
**Disclosure of Interest:** None declared

## AB0235 EFFECT OF TOCILIZUMAB COMBINED WITH METHOTREXATE ON BLOOD-BASED NEOEPITOPE BIOMARKERS IN THE RADIATE STUDY

P. Juhl, A.S. Siebuhr, C. Thudium, N.S. Gudmann, M. Karsdal, A.-C. Bay-Jensen.
*Nordic Bioscience, Herlev, Denmark*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease with elevated extracellular matrix (ECM) turnover. It is important to determine the efficacy of a therapy quickly to ensure that patients are given the right treatment. Biomarkers of ECM turnover could be such possible biomarkers. Matrix metalloproteinase degraded fragments of type III and IV collagen and C-reactive protein (C3M, C4M and CRPM) have previously found to be dose-dependently inhibited to tocilizumab (TCZ) and could identify ACR50 responders.
**Objectives:** 1) Confirm that TCZ have a dose dependent effect on the circulating biomarkers C3M, C4M, and CRPM and 2) investigate if these biomarkers are associated with disease activity and pain in RA patients undergoing TCZ treatment.
**Methods:** RA patients (n=217) fulfilling the American College of Rheumatology (ACR) criteria were included from a phase III randomized controlled trial (RADIATE). Patients received either TCZ+MTX (4mg/kg; TCZ4 or 8mg/kg; TCZ8) or placebo+MTX (PBO) every 4 weeks. C3M, C4M and CRPM were assessed in serum at baseline (BL) and week 16. Difference of a biomarker level over time was tested by paired t-test. Difference between the treatment groups was examined by one-way ANOVA. Correlation between biomarkers and clinical observations was investigated with Spearman's correlation. Bonferroni correction was used to find the critical p-value<0.0071 for correlations.
**Results:** C3M significantly decreased (p=0.027) at week 16 compared to BL for TCZ8. TCZ8 and TCZ4 was decreased in both C4M (p=0.0001) and CRPM (p<0.0001) at week 16 compared to BL. A dose dependent decrease was observed for C4M and CRP as the difference between TCZ8 and TCZ4 (p=0.031 and p=0.02), TCZ8 and PBO (p<0.0001 and p<0.0001), and TCZ4 and PBO (p=0.002 and p=0.004)Changes to week 16 in the biomarker levels of all patients were found to correlate with the changes in HAQ-QI (C3M: ρ=0.26, C4M: ρ=0.33, CRPM: ρ=0.33), DAS28 (C3M: ρ=0.36, C4M: ρ=0.38, CRPM: ρ=0.39), VAS pain (C3M: ρ=0.32, C4M: ρ=0.35, CRPM: ρ=0.32), CRP (C3M: ρ=0.5, C4M: ρ=0.55, CRPM: ρ=0.55) and ESR (C3M: ρ=0.51, C4M: ρ=0.54, CRPM: ρ=0.58). The CRPM BL level correlated negatively with the changes in HAQ-QI (ρ=-0.21). C3M, C4M and CRPM BL levels correlated negatively with changes to week 16 in VAS pain (C3M: ρ=-0.23, C4M: ρ=-0.28, CRPM: ρ=-0.26), CRP (C3M: ρ=-0.29, C4M: ρ=-0.36, CRPM: ρ=-0.34) and ESR (C3M: ρ=-0.17, C4M: ρ=-0.23, CRPM: ρ=-0.27).
The changes in C4M and CRPM levels were significantly higher in ACR20 and ACR50 responders (C4M: p=0.011 and p=0.009, respectively and CRPM: p=0.004 and p=0.025, respectively) compared to non-responders.

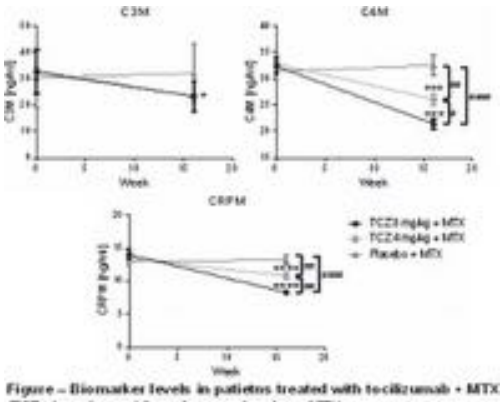

**Figure – Biomarker levels in patients treated with tocilizumab + MTX (TCZ: 4 mg/kg and 8 mg/kg, or placebo + MTX.**

**Conclusions:** C4M and CRPM decreased in a dose dependent manner in response to TCZ, while C3M was significantly reduced by TCZ8. Changes to week 16 in C3M, C4M and CRPM levels correlated with changes in disease activity and VAS pain. These findings support that ECM biomarkers are predictive biomarkers of treatment benefit. This was furthermore supported by the finding that there were difference between ACR20 and ACR50 responders in C4M and CRPM levels. Overall, these data confirm that ECM biomarkers are applicable as predictive tools in RA.

## AB0236 THE ROLE OF VITAMIN D RECEPTOR IN RHEUMATOID ARTHRITIS

P. Nemec[1], M. Sefcik[2], J. Sevcikova[2], L. Prochazkova[1], M. Pavkova-Godbergova[2]. *[1]2nd. Dept. of Internal Medicine, St. Anne's Faculty Hospital Brno and Faculty of Medicine, Masaryk University; [2]Department of Pathological Physiology, Masaryk University, Brno, Brno, Czech Republic*

**Background:** Rheumatoid arthritis (RA) is a disease characterized by chronic inflammation of synovial tissue, and progressive destruction of the joints. In RA patients a high prevalence of serum vitamin D deficiency/insufficiency was described. Vitamin D has a central role in the immune system and also correlates with increased levels of estrogen receptor α.
**Objectives:** The study analyzed the relationships between polymorphisms in the gene for vitamin D receptor (VDR) and the development and/or progression of the disease.

**Methods:** A total of 156 patients were enrolled with a diagnosis of RA (median age 55.6 years; 78% of them women; control group of 50 subjects). Development of the disease was scored by positive antibodies against cyclic citrullinated peptide (anti-CCP), rheumatoid factor (RF), CRP. Disease progression was assessed by the modified Sharp-van der Heijdeovou method Total Sharp Score (TSS). Polymorphisms were detected by PCR and subsequent restriction analysis (rs4516035 EcoRV; rs7975232: ApaI; rs731236: TaqI).
**Results:** The results show the relation of polymorphism VDR rs4516035 to seropositivity for anti-CCP in the distribution of genotypes (P=0.03), with a higher prevalence of the TT genotype when compared to the CC + CT variants (p=0.007, OR =3.2). The relationship was found also in the frequency of alleles (p=0.04). Further, a borderline relationship of this polymorphism to RF IgA levels (P=0.06) was detected. A relationship of polymorphism VDR rs731236 with the disease progression evaluated by TSS (p=0.02) was demonstrated, with the highest TSS in the patients carrying the GG variant.
**Conclusions:** The results show that the GG variant of VDR rs731236 polymorphism was associated with a worse prognosis of RA. Moreover, the VDR rs4516035 polymorphism was related to the seropositivity for anti-CCP, with a significant prevalence of TT genotype in positive RA patients.

## AB0237 GRADATION OF CHANGES IN AXIAL AND PERIPHERAL SKELETON WITH RESPECT TO THE AGE AT RHEUMATOID ARTHRITIS (RA) ONSET

I. Dydykina, E. Petrova, A. Smirnov, P. Marina, P. Kovalenko, E. Nasonov, E. Vetkova. *V.A. Nasonova Research INSTITUTE OF RHEUMATOLOGY, Moscow, Russian Federation*

**Background:** Patient's age at RA onset predefines the course of the disease, rate of progression and severity of erosive-destructive changes in hand and feet joints, mineral bone density (BMD) and deformities of the spine vertebrae.
**Objectives:** To compare the changes in axial and peripheral skeleton in pts in relation to the age of RA onset.
**Methods:** 164 females with RA aged 20 -65 y. were included. Mean age was 47,9±12,9 y., RA duration - 12,1±9,3 y. Genant semiqiantitative radiographic morphometry of lumbar and thoracic spine was obtained for all patients, erosive and destructive changes assessed using Sharp/van der Heijde scoring system. BMD was measured at lumbar spine level (L1–4), femoral neck (FM) and distal forearm (DF) of a non-dominant arm using Hologic "Discovery A" system. Data analysis was made with Statistica 6.0 software.
**Results:** All pts were grouped into 3 arms depending on the age at RA onset: Group 1 – 63 (38,4%) pts, whose age at RA onset was $\geq$18 $\leq$30 y., Group 2 – 78 (47,6%) pts, $\geq$31 $\leq$50 y. age at RA onset, Group 3 – 23 (14,0%) pts, $\geq$51 y. age at RA onset. Mean age of pts from Group 1 was 37,8±12,7 y, Group 2 – 51,9±7,8 y., Group 3 – 62,1 ±2,6 y ($p<0.05$), disease duration - 15,1±12,3 y., 11,0±6,6 y., and 7,1±3,1 y., respectively ($p<0.05$). Menopause was established in 30% of pts in Group 1, in 60% - in Group 2, in 100% - in Group 3; peripheral fractures in past medical history were documented in 19 (30%), 28 (36%), and 11 (49%) pts from Groups 1, 2, and 3, respectively ($p>0.05$), 50% of fractures occurred before RA onset. The groups were comparable in terms of the number of RF-positive pts, receiving DMARDs, the duration and cumulative dose of GCs. DAS28 RA activity score, the number of pts with extra-articular RA manifestations and the number of pts taking GCs by the moment of examination were less in Group 1vs Group 2 ($p<0.05$). Lumbar vertebral deformity scores (VDS), BMD values of L1–4, FN, DF, narrowed joint spaces and total Sharp score were comparable in all groups (p>0,05). Number of erosions in Group 1 was 46,3±59,7 scores, in Group 2 - 30,8±38,5 scores, in Group 3 - 19,3±27,4 scores (Groups 1 and 3 $p<0,05$). Vertebral deformities were found in 19% pts from Groups 1 and 2, and in 39% pts from Group 3 (Groups 2–3 $p<0,05$). Thoracic VDS was 0,78±0,08, 0,78±0,07 and 0,73±0,13, respectively (Groups 3 and 1; 3 and 2 $p<0,05$).
**Conclusions:** RA onset during attainment of peak bone mass and long lasting disease produced negative effect on axial and peripheral skeleton. Despite young age and absence of menopause the majority of pts presented with OP, peripheral fractures, BMD in all skeletal sites, and lumbar VDS values that were comparable to those in pts with later onset of the disease. Pts with RA onset after menopause and shorter duration of the disease present with equal to pts with early onset degree of joint space narrowing and total Sharp score, but not with similar number of erosions. Early onset of RA and therefore longer duration of disease is associated with more amount of erosions.
**Disclosure of Interest:** None declared

## AB0238 THE PERFORMANCE OF A SINGLE CENTRE INTERVENTIONAL CLINIC IN EARLY RHEUMATOID ARTHRITIS

R. Ješe, A. Ambrožič, N. Gašperšič, A. Hočevar, B. Lestan, M. Plešivčnik Novljan, S. Praprotnik, Ž. Rotar, A. Šipek, D. Šuput Skvarča, M. Pavic Nikolic, M. Tomsic. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** In early rheumatoid arthritis (RA), first assessment by a rheumatologist and/or initiation of disease-modifying anti-rheumatic drugs (DMARD) within 12 weeks of symptom onset are associated with a significant benefit in long-term disease outcome.[1,2]
**Objectives:** To determine the proportion of patients with newly diagnosed RA in whom first rheumatology assessment and/or initiation of DMARD therapy was within the desired time frame.
**Methods:** A retrospective chart review of adult patients diagnosed with RA during year 2014 and the first half of year 2015 was performed at our rheumatology department, which is a part of an integrated secondary/tertiary teaching hospital that provides rheumatology services for a population of more than 500.000 residents. Potential cases were identified by searching the electronic medical records for ICD-10 codes M05.* and M06.* Electronic and paper records of patients were then thoroughly reviewed. Dates were recorded for onset of inflammatory joint symptoms, referral to rheumatologist, initial assessment by a rheumatologist and initiation of DMARD therapy. The percentage of patients assessed by a rheumatologist and/or treated with a DMARD within 12 weeks of symptom onset and the median times for delay were then calculated.
**Results:** Between 01.01.2014 and 30.06.2015, 188 new cases of RA were identified at our Department of Rheumatology. Of those, 153 (81.4%) were referred to our early interventional clinic. Within 12 weeks of symptom onset, 89 (47.3%) new RA patients were examined by a rheumatologist and 68 (36.2%) were started on DMARD therapy; the median time from symptom onset to consultation was 12.8 (IQR 4.9–27.7) weeks, median time from referral to consultation was 1 (IQR 1–3) day and median DMARD treatment delay was 16.1 (IQR 8.6–32.8) weeks.

Table 1. Demographic data, clinical history, and delays

| | |
|---|---|
| Gender (female/male) (%) | 143/45 (76/24) |
| Age, years (mean ± SD) | 62.4±15.4 |
| DAS28 3v (mean ± SD) | 5.3±1.3 |
| Patients fulfilling 2010 ACR/EULAR classification criteria for RA, # (%) | 177 (94.1) |
| Time from symptom onset to first rheumatologist assessment, weeks (median) | 12.8 (IQR, 4.9–27.7) |
| Time from referral to first rheumatologist assessment, weeks (median) | 0.14 (IQR, 0.14–0.43) |
| Time from symptom onset to glucocorticoid initiation, weeks (median) | 13.0 (IQR, 5.8–27.2) |
| Time from symptom onset to DMARD initiation, weeks (median) | 16.1 (IQR, 8.6–32.8) |

Legend: SD: standard deviation, IQR: interquartile range.

**Conclusions:** 47% of new RA patients were assessed by a rheumatologist and 36% were treated with a DMARD within the recommended time frame of 12 weeks. Most of the treatment delay was due to the time elapsed between symptom onset and referral to a rheumatologist. These results substantiate the efficacy of our early interventional clinic in diagnosing and treating patients with early RA: despite the heavily protracted nationwide waiting times for first rheumatologist assessment and significantly (40%) lower number of rheumatologists per capita compared to European Union average, the percentage of timely treated patients was comparable to recent reports.

## AB0239 ASSOCIATION OF A TRAF1 GENE POLYMORPHISM WITH JOINT DESTRUCTION IN ANTI-CITRULLINATED PEPTIDE ANTIBODY-NEGATIVE PATIENTS WITH RHEUMATOID ARTHRITIS

S. Yoshida [1,2], K. Ikari [1], K. Yano [1], M. Matsumoto [2], M. Nakamura [2], A. Taniguchi [1], H. Yamanaka [1], S. Momohara [1]. *[1]Institute of Rheumatology, Tokyo Women's Medical University; [2]Department of Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan*

**Background:** Many studies show that heritability plays a part in joint destruction in rheumatoid arthritis (RA); however, the details are poorly understood. In the recent report by van Steenbergen et al., 43 polymorphism in a 66 Kb region spanning tumor necrosis factor receptor-associated factor 1 (*TRAF1*) were associated with radiographic progression in anti-citrullinated peptide antibody (ACPA)-negative patients with RA in a multicohort study from Europe and North America. Specially, the polymorphisms were located in the area downstream of the complement component 5 (*C5*)-*TRAF1* region and upstream to the *TRAF1*-PHD finger protein 19 (*PHF19*) region. We were intrigued by these findings and curious to know the relevance in Asian populations. Thus, we investigated the association of the 66 Kb region within *C5-TRAF1-PHF19* with progression of joint destruction in Japanese patients with RA.
**Objectives:** The purpose of this study was to identify genetic variants associated with progression of joint destruction in Japanese ACPA-negative patients with RA.
**Methods:** We studied 120 ACPA-negative patients with RA for whom Sharp/van der Heijde scores (SHS) of the hands were available at 5-year disease duration. DNA samples of the subjects were obtained from the Institute of Rheumatology Rheumatoid Arthritis cohort study (IORRA) DNA collection. All of the patients consented to participate in this study in accordance with the process approved by the Tokyo Women's Medical University Genome Ethics Committee. Identification of tag single nucleotide polymorphisms (SNPs) in the *C5-TRAF1-PHF19* region

was performed using Haploview (version 4.2; minor allele frequency >0.05, pairwise $r^2$>0.8). A total of 12 tag SNPs were selected and genotyped. We used rs2900180 as a proxy for rs7021880 ($r^2$=1.0), which was the polymorphism with the lowest *P*-value found by van Steenbergen et al. Linear regression analyses were performed to examine the association between each SNP and log-transformed SHS.

**Results:** The A allele of rs3761847 in *TRAF1* was significantly associated with SHS in the recessive model (*P*=0.00099, Table 1). The other SNPs had no association with SHS.

Table 1. Association of each SNP with Sharp/van der Heijde scores of hands in the first 5 years after onset of ACPA-negative RA.

*MAF in CEU was based on HapMap-CEU phase 3.
MAF, minor allele frequency; CEU, Utah residents with ancestry from Northern and Western Europe; SE, standard error; NA, not applicable.

**Conclusions:** Our study demonstrated that the A allele of rs3761847 in the *TRAF1* gene was associated with joint destruction. We previously reported that the same allele was associated with an increased risk for development of RA in the Japanese population. Although the association between rs2900180 and joint destruction in RA patients was not validated in our study, we show that an association between *TRAF1* locus and joint destruction might exist in Japanese ACPA-negative patients. Our results contribute to the understanding of the pathogenesis of RA, especially in ACPA-negative patients.

## AB0240 MMP-3 AS A BIOMARKER OF DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS

S. Kumagai[1,2], Y. Uemura[2], T. Saito[2], R. Umeda[1], A. Muta[1], M. Izumi[1], K. Abe[1], S. Sendo[3], G. Tsuji[1]. *[1]Center for Rheumatic DIseases, Shinko Hospital; [2]Center for Rheumatic DIseases, Shinko Institute for Medical Research; [3]Graduate School of Medicine, Kobe University, Kobe, Japan*

**Background:** Measurement of serum MMP-3 levels has been considered useful to estimate the disease activity of rheumatoid arthritis (RA). We have shown that serum MMP-3 was significantly correlated with DAS28 (CRP) and could be a useful marker in predicting joint destruction[1,2]. CXCL13 attracts CXCR5-expressing B and helper T cells to the follicle and probably has central roles of ongoing immune activation in RA development[3]. Serum MMP-3 and CXCL13 have been reported as biomarkers for detecting the disease activity and predicting the therapeutic outcomes of RA[4].

**Objectives:** The aim of this study is to confirm the clinical significance of serum MMP-3 and CXCL13 measurement in the evaluation of disease activity and prediction of therapeutic outcome in RA patients treated with biologics.

**Methods:** Serum MMP-3 was serially measured by MMP-3 Latex kit (Sekisui Medical Co.) for 146 RA patients before and after treatment with biologics. Number of patients treated with each biologic were 39, 28, 19, 17, 26, and 17 patients treated with abatacept, adalimumab (ADA), etanercept, golimumab, infliximab (IFX), and tocilizumab, respectively. CXCL13 was measured by ELISA kit (Quantikine human CXCL13, R&D systems) for patients treated with ADA and IFX before and 24 weeks after treatment. The patients were classified into 61 responders (good) and 85 non-responders (moderate and none) by ACR/EULAR definition of remission criteria weeks after treatment.

**Results:** Serum MMP-3 before the treatment was significantly increased in 146 RA patients as compared with 196 healthy subjects (196.0± 197.4 vs 58.6±27.4 ng/ml, p<0.001), and showed significant positive correlation with DAS28 (Rs=0.3842, p<0.001), but no significant difference was found between 61 responders (210.6±213 ng/ml) and 85 non-responders (185.6±186.3 ng/ml). As shown in Figure 1 (left), the MMP-3 levels gradually decreased 4, 12, and 24 weeks after successful treatment with biologics (p=0.04, p<0.001, and p<0.0001, respectively), and extent of the decrease were significantly bigger in responders than non-responders 12 and 24 weeks after treatment. Serum CXCL13 level before the treatment significantly correlated with MMP-3 levels (Rs =0.4648, p<0.001) as well as DAS28 (Rs =0.5182, p<0.001). After treatment with ADA, serum CXCL13 was significantly decreased after 24 weeks in responders as compared with non-responders (Figure 1 right, p<0.05). However, such difference was not found in patients treated with IFX. Patients with lower serum CXCL13 levels (<82.7 pg/ml) before the treatment were shown to become non-responders (p<0.07), especially their serum MMP-3 levels were low (<69.1 ng/ml).

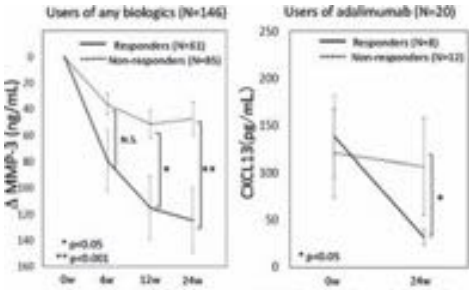

Figure 1. Time course of serum MMP-3 levels and CXCL13

**Conclusions:** Serum MMP-3 and CXCL13 was shown to be useful as disease activity markers, and serial measurement were helpful to evaluate the effect of treatments with biologics. CXCL13 may be useful in evaluating and predicting the therapeutic outcome of some kinds of biologics.

## AB0241 PLASMA MICRO-RNAS POTENTIALLY ASSOCIATED WITH THE INCREASE RISK FOR CARDIOVASCULAR DISEASE IN RHEUMATOID ARTHRITIS PATIENTS

S. Paredes[1], D. Taverner[1], J.C. Vallve[2], R. Ferre[3], A. Castro[3], L. Masana[3]. *[1]Rheumatology, Hospital Sant Joan; [2]Departamento de Medicina, Universitat Rovira i Virgili; [3]Medicina Interna, Hospital Sant Joan, Reus, Spain*

**Background:** Rheumatoid arthritis (RA) patients are at increased risk for cardiovascular diseases and an accelerated atherogenesis is considered the cause of this increase. MicroRNAs (miRs) are small, non-coding RNA molecules which negatively regulate gene expression. Plasmatic miRs have been identified as biomarkers in a wide range of cardiovascular diseases (CVD).

**Objectives:** To identify plasmatic miRs in RA patients that can facilitate earlier diagnosis of CVD and provide insight regarding the increase risk for CVD in these patients.

**Methods:** We compared plasmatic profiles of 754 miRs in 7 RA patients without CVD, in 7 patients with acute myocardial infarction (AMI) but without RA, and in 7 healthy controls with the objective to find miRs commonly expressed in the two groups of patients but at different levels from the controls. All participants were male and were matched for age and for classical cardiovascular risk factors. Plasma profile of miRs were analyzed by real time PCR using validated TaqMan® OpenArray® MicroRNA panels which enables the quantification of 754 human miRNAs. Differential expression was analyzed with Expression Suite software. Selected miRs were further analyzed with $2^{-DDct}$ method. Kruskal-Wallis test and Dunns post- test were used for the statistical analyses.

**Results:** We were able to measure in the three groups, 50% (379) of the

miRs represented in the array. Plasma profile of circulating miRs in RA and AMI patients were different from the controls. Plasma miRs that were commonly expressed in AR and AMI and expressed significantly different versus controls were: mir-Let-7a, miR-96, miR-381, miR-451, miR-518d, miR-425–5p, miR-572, miR-190b, miR-708, and miR1180. Interestingly, all 10 miRs were down-regulated compared with controls. Furthermore, 9 miRs were differentially expressed in AMI patients versus controls and 16 miRs in RA patients versus controls.
**Conclusions:** In the present study we have identified a group of 10 miRs that potentially can be involved in the increase risk for CVD seen in RA patients. Among all these miRs, miR-451 and Let-7a have been previously associated with CVD and it might be the best candidates for future validation studies.
**Disclosure of Interest:** None declared

## AB0242 IL6 GENETIC VARIANTS AND IGA-RF AS MARKERS OF EROSIVENESS AT ONSET IN EARLY RHEUMATOID ARTHRITIS

S. Canestri, A.L. Fedele, B. Tolusso, L. Petricca, S. Alivernini, M.R. Gigante, E. Gremese, G. Ferraccioli. *Institute of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy*

**Objectives:** To determine whether genetic variants in the loci of interleukin-6 (IL-6) are associated with clinical and biologic phenotypes of Rheumatoid Arthritis (RA).
**Methods:** Three hundred and forty five early RA (ERA) patients were enrolled in this study (76.2% female; mean age: 54.4±14.1 years; 33.6% VERA). 239 patients (69.3%) were seropositive for at least one antibody: 62.9% ACPA, 48.7% RF -IgM and 33.0% RF-IgA positive, respectively. At diagnosis, 101 subjects (29.3%) had detectable erosions in hands and feet radiographs. All patients were treated according to a tight control strategy (Methotrexate for 3 months, and if an incomplete response was reached after 3 months a combination with Tumor Necrosis Factor (TNF) blockers was started) and at each visit, clinical remission was evaluated according to ACR/EULAR criteria (Felson DT et al. Arthritis Rheum 2011). ERA patients were genotyped for IL6–174G/C polymorphism by PCR and compared with a cohort of healthy subjects (n=293).
**Results:** The frequency of C allele of the IL-6–174G/C SNP was higher in ERA patients (30.7%) compared to healthy controls [23.7%; OR (95%CIs): 1.43 (1.11–1.83)], while the GG genotype was present in 49.6% of ERA and in 59.4% of control subjects [OR (95%CIs): 0.67 (0.49–0.92)] respectively. At baseline, ERA patients carriers of the GG genotype were more likely seropositive compared to patients carrying the C allele [74.9% vs 63.8%, p=0.03], mainly for the IgA-RF positivity [38.6% vs 27.7%; OR (95%CIs): 1.64 (1.04–2.57)]. At diagnosis, IgA-RF positive ERA patients were more likely erosive than IgA-RF negative ones [33.1% vs 25.2%; OR (95%CIs):1.80 (1.11–2.95)]. Conversely, radiographic damage was not associated with gender, symptoms duration, smoking habit, positivity for ACPA or IgM-RF antibodies and disease activity. The percentage of erosive disease increased to 39.6% in ERA patients IgA-RF + carrying the GG genotype compared to the others (24.7%; OR (95%CIs): 2.002 (1.23–3.26)], with a lower presence of radiographic damage in carriers of C allele and IgA-RF negative (12.5%). Finally, patients carrying C allele of IL6–174G/C SNP and IgA- RF negative at diagnosis, were less prone to develop erosions over time than subjects with at least one risk factor (8.0% vs 19.1%, respectively, p=0.02).
**Conclusions:** In our cohort of ERA patients, the presence of C allele of IL6–174G/C SNP associates with RA susceptibility whereas the GG genotype associates with seropositivity for IgA-RF and erosions. These data add new information about the biology underlying the development of radiographic damage in the early phases of RA.

## AB0243 THE IMPORTANCE OF BIOMARKERS (RF, ACPA AND MMP-3) SERUM LEVELS OF RHEUMATOID ARTHRITIS (RA) IN PREDICTION BONE EROSIONS IN PATIENTS WITH EARLY RA AND NO VISIBLE RADIOGRAPHIC STRUCTURAL DAMAGES-AN ECHOSONOGRAPHIC STUDY

S.Z. Prodanovic[1], G. Radunovic[2], M. Sefic-Bukilica[2], S. Seric[3], N. Damjanov[4]. *[1]clinical IVb, Institute of Rheumatology; [2]clinical IVa, Institute of Rheumatology, School of medicine, Belgrade University; [3]radiology, Institute of Rheumatology; [4]Director of Institute, Institute of Rheumatology, School of Medicine, Belgrade University, Belgrade, Serbia*

**Background:** Rheumatoid factor (RF) and autoantibodies against citrullinated peptides/proteins (ACPA) has been recognized as an important predictor of more severe structural joint damage. Baseline matrix metalloproteinases 3 (MMP-3) serum levels were described as a predictor for the development of joint erosions.Ultrasonography is more sensitive than X-ray in detecting erosions in RA.
**Objectives:** to assess the importance of the RF, ACPA and MMP-3 serum levels in prediction of hands and feet bone erosions, detected by ultrasound (US) examination, in patients with early rheumatoid arthritis, without structural damage visible on X-ray.
**Methods:** A group of 65 patients (56 female, mean age 53.8±14.6 yrs.) with early RA (Eular/ACR 2010 classification criteria) and ≤1 year duration, (mean duration 3.8 month), were enrolled in the cross sectional clinical study. All patients had been disease-modifying anti-rheumatic drug (DMARDs) and glicocorticoid therapy naïve and had no visible structural damage on hands and feet X-ray. The serological markers of RA were measured: RF (normal concentration<16 U/ml), ACPA (normal concentration<20 IU/ml) and total MMP-3 (normal cut-off range for females: 18–60 ng/ml and males: 24–120 ng/ml). The levels above normal were reted as positive. Ultrasound examination of both hand (wrist, MCP2, MCP5 joints) and MTP5 joints was performed by Esaote My Lab 70 machine using 18 MHz linear probe. Findings of bone erosion were determined according to OMERACT US group definition. Collected data were analyzed in SPSS 16 system.
**Results:** Joint bone erosions were found in 59 (90.8%) pts. by US examination. Forty-two (64.6%) pts. were RF positive (mean concentration 88.8±108.2). The mean 2.1 vs.1.6 US bone erosions were detected in RF positive in comparison to RF negative pts. respectively. Forty-six (70.7%) pts. were ACPA positive (mean concentration 467.0±454.4) with mean bone erosions 1.9 vs.1.8 bone erosions in ACPA negative pts. Forty-six out of 63 (73.0%) pts were MMP-3 positive (mean concentration 185.1±241.0) with mean bone erosions 2.1 vs.1.5 bone erosions in MMP-3 negative pts. The 0.500 value of the area under the ROC curve is found for RF, 0.443 for ACPA and 0.627 value for MMP-3. The 75.4% sensitivity, 67% specificity (cut of 99.2 ng/ml) of MMP-3, 71.9% sensitivity, 50% specificity (cut of 232 IU/ml) of ACPA and 66.7% sensitivity, 67% specificity (cut of 79.5 U/ml) of RF were established in predicting US bone erosion.
**Conclusions:** Early RA patients with no visible structural damages on X-ray, and increased RF, ACPA and MMP-3 serum levels had higher number of bone erosions assessed by US. Baseline MMP-3 serum levels had the highest sensitivity in predicting joint bone erosions assessed by ultrasound examination.
**Disclosure of Interest:** None declared

## AB0244 MIR-155 EXPRESSION IN B CELLS OF RHEUMATOID ARTHRITIS PATIENTS IS RELATED TO FOLLICULAR SYNOVITIS AND MIRRORS B CELL SUBPOPULATIONS CHANGES AFTER IL-6R INHIBITOR TREATMENT

S. Alivernini[1], B. Tolusso[1], L. Petricca[1], M. Kurowska-Stolarska[2], A.L. Fedele[1], E. Gremese[1], G. Di Sante[3], I.B. McInnes[2], G. Ferraccioli[1]. *[1]Institute of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy; [2]Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom; [3]Institute of General Pathology, Catholic University of the Sacred Heart, Rome, Italy*

**Background:** MicroRNA-155 (miR-155) was shown to be a key regulator of B cell biology. The fine-tuning of the transcription factor PU.1 by miR-155 is required for high-affinity IgG1 production and B cell maturation. However, the role of miR-155 in the activation of B cells in Rheumatoid Arthritis (RA) has not been explored.
**Objectives:** To investigate miR-155 expression in RA B cells and its association with B cell subpopulations distribution, synovial histological pattern and anti-IL6R treatment response.
**Methods:** 42 RA patients naive to treatment who underwent synovial tissue (ST) biopsy were enrolled and 30 RA no responder to MTX (MTX-IR) and 15 Osteoarthritis (OA) patients were used as comparison. Based on immunostaining for CD68, CD21, CD3 and CD20 cells, ST samples were categorized as diffuse or follicular pattern. CD19+ cells were isolated from peripheral blood (PB) and B cells subpopulations were assessed by FACS using IgD/CD27 classification. In 14 MTX-IR ERA patients starting TCZ (8 mg/kg), PB-derived CD19+ cells were tested for B cells subpopulations at baseline and after 3–6 and 12 months in association with miR-155 and PU.1 expression by qPCR. IL-6 receptor (IL6-R) was experimentally confirmed as miR-155 target by Luciferase assay. PB-derived CD19+ cells of HC were stimulated with IL-6 (20 pg/mL) and miR-155 expression was checked after 24–48 and 72h respectively.
**Results:** At study entry, naive RA and MTX-IR patients showed higher incidence of follicular synovitis than OA patients (p=0.001 and p=0.002 respectively). Moreover, RA patients with follicular synovitis were more likely ACPA positive (p=0.001) compared to patients with diffuse pattern. At baseline, PB derived B cells of RA patients were characterized by higher $IgD^{-}CD27^{-}$ cells (p=0.05) percentages compared to HC. Moreover, PB-derived CD19+ cells of RA patients with follicular synovitis showed an activated memory phenotype compared to patients with diffuse pattern (p=0.01). Finally, PB-derived CD19+ cells of naive and MTX-IR RA patients with follicular synovitis showed significantly higher expression of miR-155 compared to HC (p=0.001 and p=0.002 respectively) mainly in ACPA positive patients (p=0.001). During IL-6R inhibitor treatment, we found that $IgD^{-}CD27^{-}$ cells percentage significantly decreases after 12 months ($p<0.05$) follow-up compared to baseline. miR-155 expression in PB-derived CD19+ cells was significantly down-regulated after 3 (p=0.01), 6 (p=0.002) and 12 (p=0.001) months of TCZ treatment respectively. Conversely, PU.1 expression in PB-derived CD19+ cells was significantly up-regulated after 12 months (p=0.04) of TCZ treatment. Finally, miR-155 was found to be an inducible miR after IL-6 stimulation ($p<0.05$).
**Conclusions:** B-cells of naïve and MTX-IR RA patients with follicular synovitis show a memory phenotype and a high expression of miR-155 which is related with ACPA positivity. Moreover, miR-155 expression in PB-derived B cells of RA patients significantly decreases during IL-6R inhibitor treatment mirroring the

changes of B cell subpopulations distribution. Thus, miR-155 may represent a key regulator of B-cells in RA through IL-6 pathway.

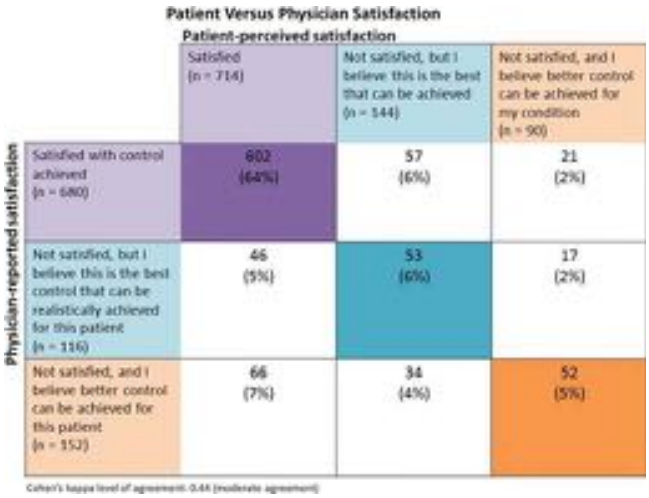
## AB0245 UNMET NEEDS AND BURDEN OF ILLNESS IN PATIENTS CURRENTLY RECEIVING BIOLOGIC TREATMENTS FOR RHEUMATOID ARTHRITIS: A COMPARISON OF PHYSICIAN PERCEPTION OF REMISSION AND DAS28-MEASURED REMISSION IN A REAL WORLD STUDY

S. Peterson[1,2], E. Sullivan[3], D. Kielar[2], N. Li[1,2]. [1]*Janssen Immunology Global Commercial Strategy Organization, Horsham, PA;* [2]*Janssen Research & Development, LLC, Spring House, PA, United States;* [3]*Adelphi Real World, Bollington, United Kingdom*

**Background:** Biologics have greatly improved the management of rheumatoid arthritis (RA), demonstrating efficacy and safety in alleviating symptoms, inhibiting bone erosion, and preventing loss of function.[1] The current study hypothesis was that despite significant improvement in patient (pt) outcomes since the introduction of biologics, significant unmet need and burden of illness remains.
**Objectives:** The main objective was to test our primary hypothesis. Secondary objectives were to explore patterns of physician use of disease activity measures and compare degree of reported unmet need as ascertained by subjective physician assessment and objective disease activity measures.
**Methods:** Descriptive analyses of the following outcomes were performed using ADELPHI RA Disease Specific Program (DSP) data for US and EU5 pts who had been receiving biologic therapy ≥3 months: remission based on DAS28 ESR (<2.6), physician-reported remission, disease severity, satisfaction with current control of pt's RA, and rating (100-point VAS) of pt's overall condition. Data were evaluated for the overall population receiving biologics and separately for pts receiving 1st- and 2nd-line biologics.
**Results:** After ≥3 months on biologics (n=1299), 56% of pts were in remission based on physician judgement, while 31% were in remission based on DAS28 ESR (<2.6; Table). Objective measures of disease activity were not calculated for 30% (389/1299) of pts overall (higher in the US, 63% [274/437] vs EU5, 13% [115/862]; $P<0.0001$). Physicians reported that 29% of pts had moderate to severe disease; 16% of pts had no improvement in disease severity or worsened with treatment; and 41% of pts taking biologics were in worse overall condition than the average (64.8 [100-pt VAS]) for all RA pts enrolled in the DSP (n=3379). 23% (304/1299) of physicians were dissatisfied with current control of the pt's RA on biologic treatment. Levels of unmet need were similar for 1st-line biologic pts relative to the overall group of biologic-treated pts and higher for 2nd-line biologic pts.

Table 1. Clinical outcomes for pts taking biologics

| Outcome, n (%) | Any biologic (n=1299) | 1st-line biologics (n=876) | 2nd-line biologics (n=403) |
|---|---|---|---|
| Remission | | | |
| Based on physician's assessment | 727 (56) | 539 (62) | 182 (45) |
| Based on DAS28[a,b] | 259 (31) | 181 (46) | 78 (37) |
| Additional physician's assessments | | | |
| Moderate to severe disease | 378 (29) | 218 (25) | 149 (37) |
| No improvement in RA severity with treatment | 204 (16) | 131 (15) | 66 (16) |
| Worse overall condition than DSP average | 530 (41) | 327 (37) | 191 (47) |



[a]Remission defined as DAS28 <2.6. [b]Any biologic, n=839; 1st-line, n=392; 2nd-line, n=210.

**Conclusions:** There are significant unmet needs among RA pts on biologic treatment, regardless of line of therapy, suggesting the need for biologics with novel mechanisms of action. Remission based on physician judgement appeared to be over-reported as compared to remission indicated by disease activity measure DAS28. Clinical disease activity measures were not used consistently by physicians. Future study is warranted to explore whether under-utilization of disease activity measures is associated with the discrepancy between physician subjective judgement and clinical measurement.

## AB0246 DISCREPANCY BETWEEN PHYSICIANS' AND PATIENTS' SATISFACTION WITH RHEUMATOID ARTHRITIS DISEASE CONTROL

S. Peterson[1,2], E. Sullivan[3], D. Kielar[2], N. Li[1,2]. [1]*Janssen Immunology Global Commercial Strategy Organization, Horsham, PA;* [2]*Janssen Research & Development, LLC, Spring House, PA, United States;* [3]*Adelphi Real World, Bollington, United Kingdom*

**Background:** An important element of the management of rheumatoid arthritis (RA) is the discussion of the degree to which patients are currently satisfied with their disease control. However, satisfaction with treatment disease control is not always aligned between patients and physicians.
**Objectives:** To explore the degree of discrepancy between physicians' and patients' satisfaction regarding RA disease control and to understand factors that may contribute to this discrepancy.
**Methods:** A multivariate logistic regression analysis was performed using ADELPHI RA Disease Specific Program (DSP) data in the US and EU5. Age and gender were forced in the model, and other covariates were included if the univariate $P$ value was <0.20. The missing indicator method was used to handle missingness.
**Results:** A total of 948 patients were included in this analysis. Overall, there was a discrepancy between physicians' and patients' perspectives on RA disease control in 26% of physician/patient pairs (Figure). Of 90 patients who rated their satisfaction as "*not satisfied, and I believe better control can be achieved for my condition*," 23.3% (n=21) had physicians who reported being satisfied with the RA disease control achieved. In contrast, of 714 patients who reported being satisfied with the RA disease control achieved, 9.2% (n=66) had physicians who rated their satisfaction as "*not satisfied, and I believe better control can be achieved for my condition*". After controlling for other covariates, some patients were more likely to disagree with their physicians' assessment of RA disease control, including those with the following disease characteristics: (1) longer disease duration (adjusted odds ratio [95% CI], 1.01 [1.00, 1.02]; $P=0.03$); (2) compared to DAS28 (CRP) ≤2.6 as reference level, higher disease activity (based on DAS28): DAS28 >2.6 to ≤3.2 (1.84 [0.96, 3.53]); DAS28 >3.2 to ≤5.1 (2.65 [1.45, 4.84]); DAS28 >5.1 (2.42 [1.02, 5.78]; all $P\leq0.05$); (3) greater activity impairment (based on the WPAI questionnaire; 1.10 [1.03, 1.17]; $P=0.003$). In contrast, patients who were in remission were more likely to agree with their physicians' assessment of disease control (0.43 [0.32, 0.60]; $P<0.0001$). In the multivariate analysis, a significant predictor of worse assessments of disease control by patients versus their physicians was greater activity impairment, based on the WPAI (1.31 [1.18, 1.44]; $P<0.0001$). In contrast, a significant predictor of better assessment of disease control by patients versus their physicians was a lower EuroQol-5 Dimension health status index score (indicating worse health status; 0.40 [0.17, 0.94]; $P=0.04$).

**Conclusions:** Results of this analysis showed a discrepancy between physicians' and patients' perspectives on RA disease control. Patients whose condition (objectively measured by longer disease duration, higher disease activity, and greater activity impairment) was worse were more likely to disagree with their physicians regarding their disease control. More impaired utility and health economic measurements were strongly associated with patients having a worse assessment of disease control than physicians. These results highlight need for further research to identify causes of this discrepancy in stated satisfaction.

## AB0247 A NEW DISEASE ACTIVITY BIOMARKER ALTERNATIVE TO CRP UNDER TOCILIZUMAB THERAPY FOR RHEUMATOID ARTHRITIS VIA PEPTIDOMIC ANALYSIS

T. Seno[1], D. Nonaka[2], M. Kohno[1], H. Sofue[1], A. Kasahara[1], R. Sagawa[1], T. Kida[1], Y. Kukida[1], K. Fujioka[1], W. Fujii[1], K. Murakami[1], L.-J. Lee[2], K. Tanaka[2], Y. Kawahito[1]. [1]*Inflammation and Immunology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto;* [2]*Membrane Protein and Ligand Analysis Center, Protosera Inc., Amagasaki, Japan*

**Background:** Tocilizumab, anti-IL-6 receptor monoclonal antibody, is widely used for patients with rheumatoid arthritis. IL-6 is essential for production of C-reactive

protein (CRP). Tocilizumab fully inhibit the production of CRP. Therefore, we have difficulty in objective assessment of infection and disease activity because the level of CRP is suppressed under tocilizumab therapy. The development of new biomarker alternative to CRP is needed for daily practice.

**Objectives:** To discover new biomarkers alternative to CRP under tocilizumab therapy for rheumatoid arthritis.

**Methods:** We registered patients with rheumatoid arthritis treated with tocilizumab. We collected serum samples from those patients at baseline, 4 weeks after the first tocilizumab administration when patient's CRP level is almost normal, and 1 year later. And we measured CRP, ESR and clinical disease activity index (CDAI) score.Serum peptidomic analysis was conducted by newly-established one-step direct transfer technology (BLOTCHIP-MS analysis), a rapid quantitative technology for peptidomic analysis. All sample measurements were repeated four times. Statistical analyses of MS spectral data were conducted using ClinProTools version 2.2 (Bruker Daltonics).

**Results:** We registered 14 patients and their background is shown in Table 1. The levels of CRP were 1.16±0.99 mg/dl at baseline, 0.02±0.01 mg/dl at 4 weeks and 0.01±0.01mg/dl at 1 year, respectively. Their CDAI score were 22±9.2 at baseline, 15±8.9 at 4 weeks and 3±2.6 at 1 year, respectively. CRP titer decreased to almost normal level at 4 weeks regardless whether CDAI score did not fully decrease.

We detect 6 biomarkers, named as PRSJ01 to PRSJ06, by the peptidomic analysis (Table 2). The AUC of diagnostic value of these markers is from 0.742 to 0.858. For example, the level of PRSJ06 significantly decreased 4 weeks (Wilcoxon singed-rank test, $p$=0.02) and 1 year (Wilcoxon singed-rank test, $p$=0.003) after first tocilizumab administration (Figure 1). and it was inversely-correlated with CDAI score.

Table 1. Patient background at baseline

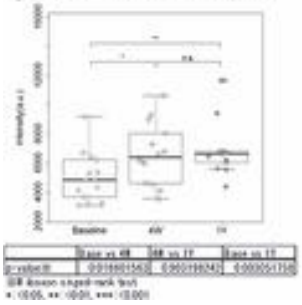
| | |
|---|---|
| Sex (n) | Female 10, Male 4 |
| Age (years) | 55.7±14.2 |
| CRP (mg/dl) | 1.16±0.99 |
| ESR (mm/h) | 33.4±24.1 |
| CDAI | 22±9.2 |
| MTX use (n) | 9/14 |
| MTX dose (mg/week) | 9.33±1.41 |

All values indicate mean ± SD.

Table 2. Diagnosis performance of biomarkers

| marker | Baseline vs 4W | | | Baseline vs 1Y | | |
|---|---|---|---|---|---|---|
| | AUC | SN | SP | AUC | SN | SP |
| PRSJ01 | 0.858 | 80 | 87 | 0.871 | 73 | 87 |
| PRSJ02 | 0.84 | 80 | 80 | 0.756 | 100 | 40 |
| PRSJ03 | 0.836 | 80 | 80 | 0.853 | 80 | 80 |
| PRSJ04 | 0.822 | 67 | 93 | 0.858 | 87 | 73 |
| PRSJ05 | 0.742 | 87 | 60 | 0.707 | 80 | 60 |
| PRSJ06 | 0.742 | 73 | 73 | 0.849 | 93 | 73 |

Figure 1. Level of PRSJ06 at each period.



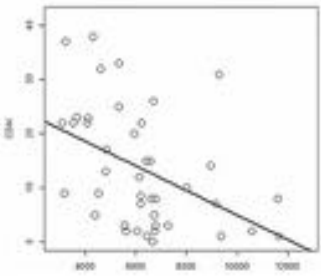


Figure 2. Correlation of PRSJ-6 and CDAI score

**Conclusions:** We detect new disease activity biomarkers alternative to CRP under tocilizumab therapy for rheumatoid arthritis. It is useful for exact evaluation of disease activity and infection during tocilizumab therapy.

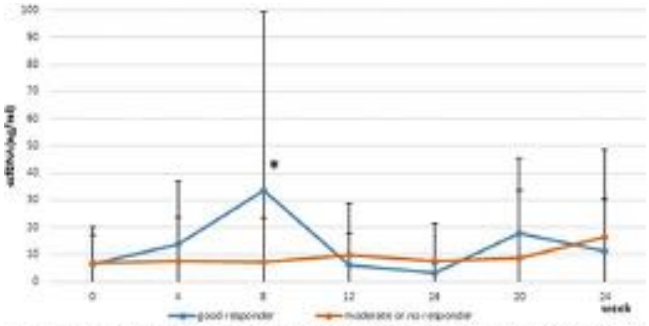
## AB0248 CIRCULATING CELL FREE DNA; A MARKER TO PREDICT THE THERAPEUTIC RESPONSE FOR BIOLOGICAL DMARDS IN RHEUMATOID ARTHRITIS



T. Hasimoto[1,2], K. Yoshida[3], N. Hashimoto[3], K. Kaneshiro[3], A. Nakai[3], Y. Kawasaki[1], A. Hashiramoto[3]. *[1]Rheumatology, Kobe Kaisei Hospital; [2]Internal Medicine, Kobe University Graduate School of Medicine; [3]Biophysics, Kobe University Graduate School of Health Sciences, kobe, Japan*

**Background:** DNA is fragmented and released into blood circulation as results of damage or death of cells from peripheral bloods as well as organ tissues, and circulating cell-free DNA (ccfDNA) has been recognized as biomarkers of several medical conditions [1]. In patients with rheumatoid arthritis (RA), serum concentration of ccfDNA has been reported to be elevated [2], however, the relation between ccfDNA and the pathogenesis of RA remains unclear.

**Objectives:** To evaluate the correlation between ccfDNA in plasma and clinical disease activities in patients with RA.

**Methods:** The study group included 29 patients with RA who started biological DMARDs therapy. The concentration of ccfDNA in plasma was measured by quantitative real-time PCR at baseline to 24 weeks in every 4 weeks-period from 29 patients, and 21 healthy individuals. We also evaluated the correlation between ccfDNA and the clinical activities or the response for biological DMARDs, using disease activity score of 28 joints erythrocyte sedimentation rate (DAS28ESR) and the european league against rheumatism (EULAR) response criteria. In addition, synovial fluid samples of knee joint were collected from 14 patients with RA and12 with osteoarthritis (OA) to measure ccfDNA

**Results:** The concentration of ccfDNA in RA patients at baseline was higher than healthy controls (p=0.016).When evaluated the concentration of ccfDNA, it was increased until 8 weeks-period from the baseline, and then decreased after 12weeks-period. The average of DAS28ESR was improved in all patients enrolled. At 12weeks-period after treatment, 15 patients were good responders of the EULAR response criteria, 9 showed the moderate response and 5 showed no response. The concentration of ccfDNA in good responder was increased until 8weeks while those of moderate or no responder were not (P=0.042) (figure), and there was no significant difference between ccfDNA at baseline and other parameters in all patients. In joint fluid of RA patients, the concentration of ccfDNA was remarkably increased as compared to those from OA (P=0.00011).

The concentration of ccfDNA in good responder and moderate or no responder from baseline to 24 weeks-period.
*P<0.05

**Conclusions:** Increase of ccfDNA at 8 weeks-period was associated with improvement of disease activity. Compared with the biomarkers reported before, ccfDNA is possible to predict the early therapeutic effects of biological DMARDs in RA patients.

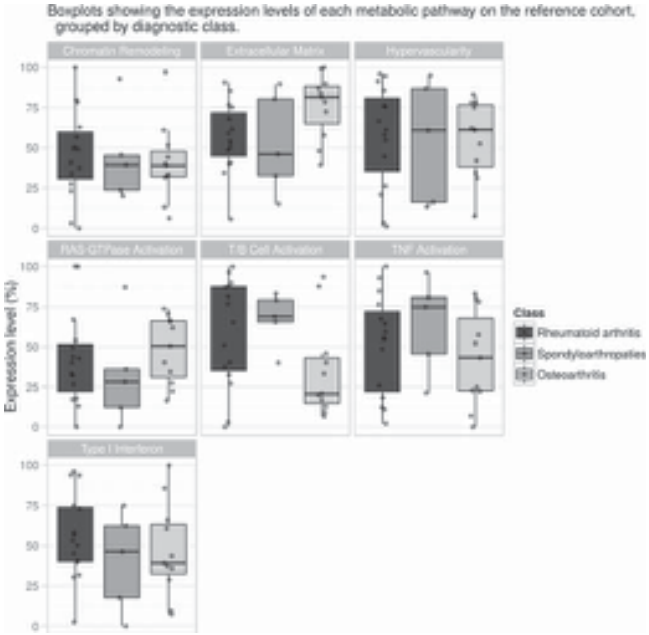
## AB0249 ROUTINE USE OF SYNOVIAL BIOPSIES FOR DIAGNOSIS AND TREATMENT GUIDANCE

T. Helleputte, P. Gramme. *DNAlytics, Louvain-la-Neuve, Belgium*



**Background:** Previous work [1] reports a differential diagnostic solution for patients with undifferentiated arthritis (UA) based on synovial gene expression. This diagnostic model uses a previously established signature of 96 genes [2] and 3 clinical variables (skin psoriasis, rheumatoid factors, hand arthritis), achieving 93.5% sensitivity and 86.8% specificity for the diagnosis of rheumatoid arthritis among UA patients. The signature covers 7 metabolic pathways involved in the pathogenesis of rheumatic conditions.

**Objectives:** To show the feasibility and relevance of a routine diagnostic test based on clinical and transcriptomic data from synovial biopsies, relying on a mathematical model, a central laboratory and an online software.

**Methods:** Kits for sample transportation, containing vials of RNA-preserving solution (RNAlater, Thermo Fisher Scientific) were sent to clinicians who harvested synovial tissue ($\leq$0.3cm$^3$) via needle-arthroscopy or an ultrasound-guided approach from the patient's joint (mostly knees, a few MCPs). Samples were shipped on an individual basis to a central laboratory (BE) using next day transportation at ambient temperature. No data about the patient or the doctor were provided to the laboratory aside from a sample ID.

RNA was extracted with RNEasy mini kit (Qiagen). Purity and concentration were checked with NanoDrop (Thermo Fisher Scientific). Retro-transcription was performed, followed by a qPCR (TLDA, 7900HT, Applied Biosystem). Four samples were analysed on each 384-well plate. The lab operator uploaded the PCR data on a dedicated secure web platform. In parallel, clinicians filled the 3 clinical values on that web platform. Based on both sources of information the software computed the differential diagnosis and the expression level of the 7 metabolic pathways, to feed doctor's therapeutic choices. PDF reports were then automatically sent via email to the doctor in charge of each patient. The software also managed all administrative aspects in order to get a fully functional portal.

**Results:** Synovial biopsies of 21 patients underwent the whole process. 19 (90.5%) showed satisfactory RNA quality. For the remaining 2, back up samples (harvested at the same time as the initial ones) could be analysed. One other sample (4.8%) could not be analysed due to insufficient RNA concentration. Gene expression values, diagnostic and pathways outputs were thus obtained for 20 samples (95.2%). The correlation between diagnosis and pathways expression levels was consistent with descriptions found in the literature [3,4] (Figure)

**Conclusions:** The routine implementation of a multi-gene RT-qPCR diagnostic test based on synovial biopsies in a real-life setting is successful. The operations put in place allowed a hassle-free management for the clinicians, thereby increasing the availability and reproducibility of the test. Early results with ultrasound-guided biopsy seem promising but require additional confirmation.

## AB0250 ASSESSMENT OF BALANCE AND ITS RELATION WITH CLINICAL PARAMETERS IN RHEUMATOID ARTHRITIS PATIENTS

C. Sanal Top[1], T. Duruoz[2], H. Gunduz[1]. *[1]PM&R Department; [2]PM&R Department, Rheumatology Division, Marmara University, School of Medicine, Istanbul, Turkey*

**Background:** Rheumatoid Arthritis (RA) one of the deformitive disease for feet. Patients generally need the special care, shoes and assistive devices because of their feet deformities.

**Objectives:** To evaluate the static and dynamic balances of the RA patients and to assess its relationship with clinical, functional and radiological parameters.

**Methods:** Patients diagnosed with RA according to ACR 2010 criteria were recruited into the study. A*ge and gender matched* healthy subjects were into the control group. The demographic (age, sex) and clinical properties (BMI, DAS28 etc) of patients were recorded. The state of balance of the patients was evaluated by means of "Berg Balance Scale" (BBS) and also 3 static and 4 dynamic balance tests with 25 parameters were assessed via the "*Neurocom Balance Master*" device. Radiographic assessments of feet were done to consider the deformities. "Foot and Ankle Outcome Score" (FAOS) was applied for foot function assessment. The level of fatigue (MAF: Multidimensional Assessment of Fatigue), depression (Beck Depression Inventory) and sleep disorders (Pitsbourg Sleep Quality Index) of all patients were evaluated and corelated with balance parameters.

**Results:** This study included 165 cases that consist of 81 RA group (66 female, 15 male) and 84 healthy control group (70 female, 14 male). The mean age of patients and controls were 48.90±10.36 and 45.89±12.07 years, respectively. Age, sex and BMI data of both groups were similar ($p>0.05$). There was a significant difference between the static and dynamic balance test results of the patient and the control groups ($p<0.05$). It was deduced that 66.7% of patients have depression, 64.2% sleep disorders and 93.8% fatigue according to surveys; however there was no correlation between these symptoms and presence of balance disorders. Although 92.4% of patients were established with foot deformities, these deformities were not correlated with FAOS and balance disorders. The presence of the swollen joint was determined as the most relevant factor about the balance disorders of RA patients.

**Conclusions:** Although RA patients have balance disturbances when we compared them with healthy controls, this disturbances has not significant relation with clinical, functional and radiological parameters. Balance problems are an important finding independently from other parameters during the course of the disease

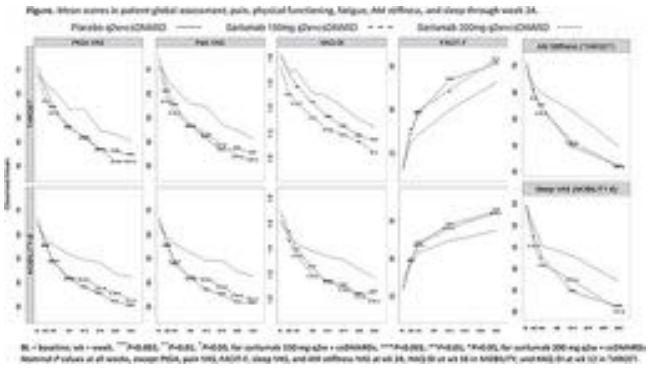
## AB0251 EARLY ONSET OF BENEFIT BY PATIENT-REPORTED OUTCOMES (PROS) WITH SARILUMAB TREATMENT IN RA



V. Strand[1], C. Chen[2], P. Mahajan[3], M. Kosinski[4], E.K. Mangan[2], H. van Hoogstraten[3], N. Graham[2], Y. Lin[3], E. Keystone[5], J. Braun[6]. *[1]Stanford University, Palo Alto; [2]Regeneron Pharmaceuticals, Inc, Tarrytown; [3]Sanofi, Bridgewater; [4]Optum, Lincoln, United States; [5]Immunology and Rheumatology University of Toronto and Mount Sinai Hospital, Toronto, Canada; [6]Rheumazentrum Ruhrgebiet, Herne, Germany*

**Background:** Efficacy, including improvements in patient-reported outcomes (PROs), was demonstrated in 2 phase 3 trials, MOBILITY[1] (NCT01061736) and TARGET[2] (NCT01709578), of sarilumab, an investigational human anti–interleukin 6 receptor monoclonal antibody. The most common treatment-emergent adverse events in both studies were infections, neutropenia, injection site reactions, and increased transaminases.

**Objectives:** To evaluate the early onset of benefit of sarilumab treatment measured by PROs.

**Methods:** In both studies, adults with moderate-to-severe, active rheumatoid arthritis (RA) were randomized to 1 of 3 groups receiving placebo, sarilumab 150 mg, or sarilumab 200 mg subcutaneously (SC) every 2 weeks (q2w) plus methotrexate (MTX; MOBILITY) or conventional synthetic disease-modifying antirheumatic drugs (csDMARDs; TARGET). PROs assessed as early as week 2 included patient global assessment of disease activity (PtGA), pain assessed by visual analog scale (VAS), Health Assessment Questionnaire–Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F), sleep by VAS (MOBILITY), and AM stiffness by VAS (TARGET). Changes from baseline were analyzed using mixed-model repeated measures with region, number of prior tumor necrosis factor inhibitors (TNFis) (TARGET) or prior biologic use (MOBILITY), visit, treatment, treatment-by-visit interaction, and baseline PRO scores as covariates.

**Results:** Greater improvements were reported by patients treated with sarilumab 150 and 200 mg SC q2w vs placebo as early as week 2 in PtGA, pain VAS, HAQ-DI, FACIT-F, sleep VAS, and AM stiffness VAS (nominal $P<0.05$) (Figure) and sustained through week 24. Between-group differences were statistically significant for FACIT-F and sleep VAS at week 24 in MOBILITY and for HAQ-DI at week 12 (TARGET) and week 16 (MOBILITY).

**Conclusions:** Sarilumab treatment rapidly improved a broad range of PROs in patients with RA with inadequate response to MTX (MOBILITY) or TNFis (TARGET); these improvements were observed as early week 2 and maintained through week 24. The results demonstrate the early benefit of sarilumab treatment based on patients' own assessments of their disease.

## AB0252 BENEFIT OF SARILUMAB WITH CSDMARDS ON PATIENT PRODUCTIVITY IN WORK, HOUSEHOLD WORK AND FAMILY, SOCIAL, LEISURE ACTIVITIES IN TNF-IR RA PATIENTS

V. Strand[1], P. Mahajan[2], C. Chen[3], H. van Hoogstraten[2], E.K. Mangan[3], O. Hagino[2], N. Graham[3], G.da R.C. Pinheiro[4], A. Kivitz[5]. *[1]Stanford University, Palo Alto; [2]Sanofi, Bridgewater; [3]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [4]Discipline of Rheumatology, Rio de Janeiro State University, Rio de Janeiro, Brazil; [5]Altoona Center for Clinical Research, Duncansville, United States*

**Background:** The effect of active rheumatoid arthritis (RA) on participation, active and meaningful engagement by patients in activities important to them, has significant individual and societal costs. Sarilumab is an investigational human anti–interleukin 6 (IL-6) receptor monoclonal antibody. In the phase 3 TARGET study (NCT01709578), sarilumab + conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) demonstrated efficacy in adults with moderate-to-severe, active RA and inadequate response to TNF inhibitors. The most common treatment-emergent adverse events were infections, neutropenia, and increased transaminases; laboratory changes were consistent with IL-6 signaling blockade.

**Objectives:** To evaluate the effect of sarilumab treatment on patient productivity within and outside of the home; requirement for outside help; and family, social, or leisure activities in the past month as assessed by the RA-specific Work Productivity Survey (WPS-RA).[1]

**Methods:** The intent-to-treat population included 546 patients randomized 1:1:1 to placebo, sarilumab 150 mg, or sarilumab 200 mg every 2 wks (q2w) subcutaneously (SC) + background csDMARDs. The WPS-RA was assessed for patients employed outside of (completed all 8 items) and within the home (completed only the 5 items related to productivity within the home and participation in family, social, and leisure activities) at baseline and wks 4 (not reported), 12, and 24. Mixed-model repeated measures analyses were used to evaluate differences in individual WPS-RA items at a significance level of 0.05 if O'Brien's global test[2] showed significance ($P<0.025$).

**Results:** At baseline, 544 patients were administered the WPS-RA, 33.1%, 33.7%, and 35.7% (placebo, sarilumab 150, and sarilumab 200 mg q2w SC, respectively) of whom were currently employed outside of the home. Global testing indicated significantly greater overall improvement in patients treated with sarilumab 150 mg q2w SC (wk 12, $P$=0.0010; wk 24, $P$=0.0004) and sarilumab 200 mg q2w SC (wk 12, $P$=0.0036; wk 24, $P$=0.0003) vs placebo. At wk 24, patients currently employed outside of the home receiving sarilumab 200 mg q2w SC reported significantly greater reductions in number of work days missed due to RA and less interference with work productivity. Patients receiving both doses reported significantly greater reductions in number of days missed engaging in household work, days requiring hired help, and rate of arthritis interference in household work and less time missed engaging in family, social, and leisure activities.

**Conclusions:** Sarilumab treatment was associated with significant improvements in participation in work; household work; and family, social, and leisure activities. Improvements in productivity outside of the home were also significant among patients in the sarilumab 200 mg q2w SC group vs placebo, although only a proportion of patients worked outside of the home. These data indicate important improvements in overall participation following sarilumab treatment.

## AB0253 FACTORS ASSOCIATED TO POOR HAND FUNCTION PERFORMANCE IN A COHORT OF RA PATIENTS: THE IMPACT OF DISEASE ACTIVITY

A.K. Romero-Guzmán, V.M. Menchaca-Tapia, I. Contreras-Yáñez, V. Pascual-Ramos. *Departamento de Inmunología y Reumatología, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México Distrito Federal, Mexico*

**Background:** Small joints of the hands and wrists are universally affected in rheumatoid arthritis (RA) and hand function (HF) may be impaired; few indices include HF assessment, beyond swollen and tender joint counts.

**Objectives:** To evaluate HF in RA patients from an early arthritis clinic initiated in 2004, to compare it with HF from paired controls and to identify factors associated to impaired function.

**Methods:** From February 2014 to June 2015, 139 patients currently attending the clinic (97.2% of the cohort) had disease activity scored (DAS28) and tip-, key- and palmar-pinch and grip strength measured as recommended (1); in addition, patients completed the Michigan Hand Outcome Questionnaire (MHQ) (2) and the Disabilities of the Arm, Shoulder and Hand Outcome Measure (DASH) (3). Sixty-nine paired (according to age ±5 years and gender) controls had same evaluations (but DAS28). Cut-offs for normal tests were obtained from normative data and controls values (median + 1 SD). Descriptive statistics and regression analysis were used. Patients and controls signed informed consent.

**Results:** Patients were more frequently middle-aged (44.1± 13.1 years) female (89.2%) with median disease duration of 7 years (IQR: 3–9 years) at HF assessment; of them, 91 patients had DAS28-remission, 16 low disease activity, 23 moderate and 9 patients had high disease activity. Controls (age: 43.8±11.5 years, 89.9% female) scored better HF tests and questionnaires than patients with (any) disease activity; nonetheless, remission patients had similar DASH and key pinch than controls but worse MHQ (92.5 vs. 98.9), grip strength (18.7 vs. 22.3), tip pinch (3.8 vs. 4.5) and palmar pinch (5 vs. 6), (p=0.000 for all comparisons). DAS28 was consistently associated to HF impairment (β coefficient from 2.2 to 2.7, $p\leq0.05$); additional predictors were age and gender. Cut-off for DAS28 to predict normal HF varied (according to HF assessment, i.e, MHQ, DASH, grip strength or pinches) from 1.8 to 2.9. MHQ and DASH were highly correlated; pinches had moderate correlations with questionnaires and grip strength had the best correlation (rho=0.6 for either MHQ or DASH).

**Conclusions:** Disease activity consistently predicted HF in a cohort of RA patients with variable follow-up. Additional predictors were age and gender.

Remission's patients showed similar HF performance to controls, when evaluated by DASH and key pinch although the MHQ and grip strength measurement identified impairment of their HF. Routine assessment of RA patients should include a comprehensive evaluation of HF; according to our results, we propose grip strength and MHQ to assess it.

## AB0254 SEVERITY AND IMPROVEMENT OF MORNING STIFFNESS INDEPENDENTLY ASSOCIATE WITH TENOSYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Kobayashi[1,2,3], K. Ikeda[1], M. Yamagata[1,4], T. Nakamura[1,5], T. Nakazawa[1,6], S. Tanaka[1], S. Furuta[1], T. Umibe[2], H. Nakajima[1]. *[1]Department of Allergy and Clinical Immunology, Chiba University Hospital, Chiba; [2]Rheumatology Center, Matsudo City Hospital, Matsudo; [3]Department of Internal Medicine, Chiba Aoba Municipal Hospital, Chiba; [4]Department of Rheumatology, National Hospital Organization Shimoshizu Hospital, Yotsukaido; [5]Research Center for Allergy and Clinical Immunology, Asahi General Hospital, Asahi; [6]Department of Rheumatology, Allergy, and Clinical Immunology, National Hospital Organization Chiba-East Hospital, Chiba, Japan*

**Background:** Morning stiffness has long been recognized by both patients and rheumatologists as a characteristic feature of rheumatoid arthritis (RA). However, morning stiffness is no more included in 2010 ACR/EULAR Classification Criteria for RA [1] or in major instruments for evaluating disease activity of RA such as Disease Activity Score (DAS) [2] and 2011 ACR/EULAR Provisional Definition of Remission [3] for the lack of solid evidence for its independent value.

**Objectives:** We aimed to clarify the associations between morning stiffness and synovial inflammation and determine the independent value and the optimal measurement of morning stiffness in patients with RA.

**Methods:** We enrolled 76 consecutive RA patients who underwent musculoskeletal ultrasound and agreed to participate in the study. In addition to asking the duration of morning stiffness, we asked patients to complete a diagram which represents the time course of their morning stiffness in the dominant hand. We also determined the activity of synovitis in 11 joints and tenosynovitis in 8 tendons/tendon compartments in the same hand by using power Doppler (PD) ultrasound with a semiquantitative score (0–3).

**Results:** Study patients were predominated by women (78.9%) with a mean age of 58.4 (SD 14.6) years and a median disease duration of 24 (IQR 8–63.75) months. Rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA) had been positive in 84.2% and 77.6%, respectively. For synovitis, swollen/tender joint counts more strongly correlated with total PD scores ($\rho$=0.379–0.561, $p \leq 0.001$) than did any parameters of morning stiffness ($\rho$=0.217–0.314, p=0.006–0.021) (Table 1). For tenosynovitis, however, the severity on awakening and the improvement of morning stiffness more strongly correlated with total PD scores ($\rho$=0.503–0.561, $p<0.001$) than did swollen/tender joint counts ($\rho$=0.276–0.388, p=0.001–0.016) (Table 1). Multivariate analyses identified the severity on awakening and the improvement but not the duration of morning stiffness as factors that independently associate with the total tenosynovial PD score.

**Table 1. Correlations between clinical manifestations and ultrasound scores in dominant hand**

| | Joint count | | Morning stiffness | | | | |
|---|---|---|---|---|---|---|---|
| | Swollen joint | Tender joint | Duration | Severity VAS on awakening | Improvement of VAS at 1/4 | Improvement of VAS at 1/2 | Improvement of VAS at bedtime |
| Intra-articular synovial power Doppler score | | | | | | | |
| $\rho$* | 0.561 | 0.379 | 0.265 | 0.314 | 0.217 | 0.266 | 0.306 |
| p value* | < 0.001 | 0.001 | 0.021 | 0.006 | 0.060 | 0.020 | 0.007 |
| Tenosynovial power Doppler score | | | | | | | |
| $\rho$* | 0.388 | 0.276 | 0.280 | 0.503 | 0.505 | 0.561 | 0.538 |
| p value* | 0.001 | 0.016 | 0.014 | < 0.001 | < 0.001 | < 0.001 | < 0.001 |

*Spearman's correlation coefficient
VAS, visual analogue scale

**Conclusions:** Our data demonstrate a pathophysiological link between morning stiffness and tenosynovitis and also give an insight into the optimal measurement of morning stiffness. Our data support an independent value of evaluating morning stiffness in the management of RA.

## AB0255 THE ASSOCIATION BETWEEN RHEUMATOID FACTOR POSITIVITY AND EFFECTS OF TREATMENT WITH A FIRST BIOLOGIC AGENT IN RHEUMATOID ARTHRITIS

Y. Ogawa, T. Kojima, N. Takahashi, K. Funahashi, N. Ishiguro. *Department of Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** The presence of rheumatoid factor (RF) plays an important role in diagnosis for patients suspected with rheumatoid arthritis (RA) [1]. However, it remains unclear whether RF positivity is related to the effects of treatment with biologic disease-modifying antirheumatic drugs (DMARDS).

**Objectives:** The objective of the current study was to determine whether RF positivity was associated with the effects of treatment with biologic DMARDS among bio-naïve RA patients.

**Methods:** We used demographic and clinical data from the Tsurumai Biologics Communication Registry, which comprises Nagoya University and 20 affiliated hospitals in Japan. Patients aged 20–80 years who fulfilled the ACR 1987 revised classification criteria or the 2010 ACR/EULAR classification criteria for RA were selected; those with prior exposure to biologic DMARDS were excluded. The RF status was divided into negative (0–15 IU/ml) or positive (>15 IU/ml). Multivariate logistic regression analysis was used to assess the association between RF positivity and the possibility of sufficient response to biologic DMARDS treatment, as defined by good response at week 16 in the EULAR response criteria, based on DAS28. Crude and adjusted odds ratios (ORs) and corresponding 95% confidence intervals (95% CIs) were calculated. Adjustment variables included sex, age, whether or not tumor necrosis factor inhibitor had been used, baseline use of methotrexate (MTX) and glucocorticoids, and baseline stage and class as defined by the Steinbrocker classification.

**Results:** The demographic and disease characteristics of the patients at baseline were comparable between RF-negative (n=120) and RF-positive (n=557) groups. The mean age was 57 years; 81% were women. Patients had longstanding RA (mean 9.3 years), and the baseline DAS28 was 5.1. Among the patients, 80% and 61% received MTX and glucocorticoids, respectively. A good response as per EULAR response criteria was identified in 73 (60.8%) RF-negative patients and 268 (48.1%) RF-positive patients. The crude OR for the association between RF positivity and the possibility of good response as per EULAR response criteria was 0.60 (95% CI 0.40–0.89) compared with RF negativity. After adjustment for the aforementioned covariates, RF-positivity was associated with a decreased possibility of good response to biologic DMARDS compared with RF-negativity (OR 0.64, 95% CI 0.41–0.98).

**Table 1. Association between RF status and the possibility of good response as per EULAR response criteria, as determined by binary logistic regression analysis***

| | Crude OR (95% CI) | Adjusted OR (95% CI)† |
|---|---|---|
| RF status | | |
| negative | 1.00 (referent) | 1.00 (referent) |
| positive | 0.60 (0.40–0.89) | 0.64 (0.41–0.98) |

* OR = Odds ratio; 95% CI = 95% confidence interval. RF = rheumatoid factor
† Adjusted for sex, age, whether or not tumor necrosis factor inhibitor had been used, baseline use of methotrexate and glucocorticoids, and baseline stage and class as defined by the Steinbrocker classification.

**Conclusions:** This study demonstrated that RF-positivity was independently associated with a decreased possibility of good response to biologic DMARDS in bio-naïve RA patients.

## AB0256 VERY EARLY RESPONSE TO ABATACEPT COULD BE A PREDICTIVE FACTOR FOR REPAIR OF BONE EROSION IN PATIENTS WITH RHEUMATOID ARTHRITIS ASSESSED BY MRI

Y. Kukida[1], A. Kasahara[1], T. Seno[1], T. Inoue[1], N. Kamio[1], R. Sagawa[1], T. Kida[1], A. Nakabayashi[1], H. Nagahara[1], A. Yamamoto[1], S. Morita[2], H. Ito[3], M. Kohno[1], Y. Kawahito[1]. *[1]Inflammation and Immunology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine; [2]Department of Biomedical Statistics and Bioinformatics, Kyoto University Graduate School of Medicine; [3]Department of Radiology, Kajiicho Medical Imaging Center, Kyoto, Japan*

**Background:** There is no report investigating predictive factors for MRI erosion change in treatment of rheumatoid arthritis (RA) with abatacept (ABT), because very little data are available on the efficacy of ABT assessed by MRI.
**Objectives:** The aim of this study is to examine the efficacy of ABT in patients with RA assessed by MRI and identify factors associated with change of bone erosion score.
**Methods:** Thirty-five RA patients were included in this prospective study. MRI of bilateral hands and conventional radiographs (CR) of bilateral hands and feet were performed at baseline and month 12 of treatment with intravenous ABT. MRI images were scored for synovitis, osteitis and bone erosion according to the Rheumatoid Arthritis MRI Scoring System. CR images were assessed according to the van der Heijde modified total Sharp score.
**Results:** Thirty-one patients completed this study. Mean Simplified Disease Activity Index (SDAI) and Health Assessment Questionnaire Disability Index (HAQ-DI) at baseline were 23.4±12.0 and 1.1±0.6 respectively. At the group level, mean MRI synovitis and osteitis scores showed statistically significant reductions through 12 months of treatment with ABT (from 17.1±7.0 to 11.4±6.2 ($p<0.0001$) and from 5.1±8.2 to 1.9±2.5 ($p=0.003$), respectively). On the other hand, mean MRI erosion scores showed no change throughout the study period (from 28.2±38.6 to 28.7±39.2). Mean CR erosion scores also showed no change (from 17.3±42.5 to 17.6±42.6). However, at the patient level, reductions of MRI erosion score were observed in 13% of patients, whereas no patient showed reduction of CR erosion score. The functional remission rates, which is defined as HAQ-DI$\leq$0.5, of patients with regressive, unchanged and progressive MRI erosion score were 100%, 71% and 33%, respectively. On multiple regression analysis, SDAI response rate at month 1 and CRP at baseline were identified as the predicting factors for changes of erosion score (regression coefficient; -0.70 ($p<0.001$)/0.42 ($p=0.02$), respectively). Optimal cutoff value of SDAI response rate at month 1 was 0.524 ($p=0.019$). It is interesting that patients with regression of MRI erosion had high titer of rheumatoid factor (median: 591IU/ml) and anti-CCP antibody (median: 254U/ml) at baseline.
**Conclusions:** This study demonstrated ABT has a strong inhibitory effect on joint damage reducing synovitis and osteitis and not progressing bone erosion in RA patients. Over 10% patients showed repair of bone erosion assessed by MRI, which resulted in functional remission. SDAI response rate at month 1 could be a predictive factor for repair of bone erosion.

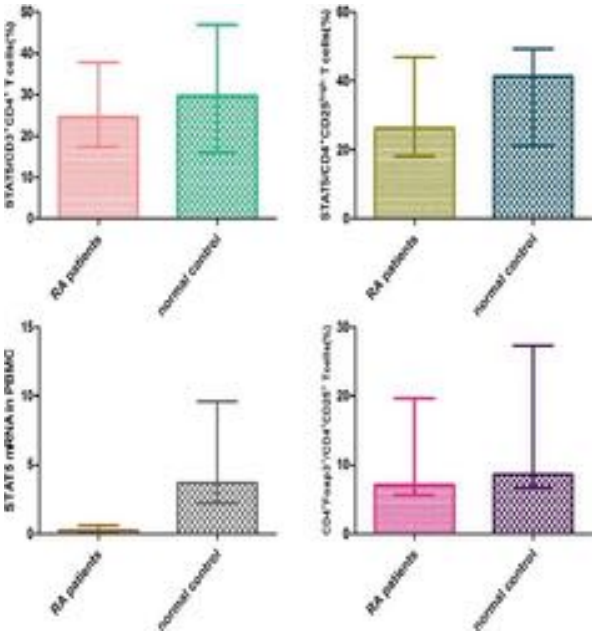
## AB0257 CLINICAL OUTCOME OF 2 YEARS TREATMENT OF THE EARLY PHASE RHEUMATOID ARTHRITIS



Y. Sugimura[1], S. Miyamoto[2], T. Kashiwagura[3], M. Kobayashi[4], N. Miyakoshi[1], Y. Shimada[1]. *[1]Orthopedic Surgery, Akita University Graduate School of Medicine; [2]Orthopedic Surgery, Nakadori General Hospital; [3]Rehabilitation Medicine, Akita City Hospital; [4]Orthopedic Surgery, Hiraka General Hospital, Akita, Japan*

**Background:** Few studies have reported long term clinical outcome of patients with early phase rheumatoid arthritis (RA).
**Objectives:** The objectives of this study were to investigate outcome of 2 years treatment for RA which was started less than 12 months after RA symptoms first appeared and to evaluate prediction factors of poorly controlled patients at 2 years.
**Methods:** From a total of 1663 RA patients registered in the Akita Orthopedic Group on Rheumatoid Arthritis (AORA) in 2012, 66 patients were treated within the first year of RA appearance, and enrolled in this study. Sex, age, RA disease duration, Steinbroker's stage, Steinbroker's class, medications and DAS28-CRP at the baseline and 2 years post-treatment were evaluated. Furthermore, we compared the group of remission (REM) or low disease activity (LDA) with the group of medium disease activity (MDA) or high disease activity (HDA) at 2 years.
**Results:** At the baseline, the patients included 13 males and 53 females. Mean age and RA disease duration were 59 (21–85) years and 7 (1–11) months, respectively. Fifty-four, 8, 4 and 0 patients were classified into Steinbroker's stage I, II, III, and IV, respectively. Thirty-nine, 25, 2 and 0 patients were classified into Steinbroker's class I, II, III, and IV, respectively. Thirty-seven (56%), 24 (36%), and 16 (24%) patients were treated with MTX, DMARDs, and PSL, respectively. In DAS28-CRP, 19 (29%), 13 (20%), 32 (48%), and 2 (3%) patients showed REM, LDA, MDA, and HDA, respectively. Forty-four patients were followed-up for 2 years. At 2 years, 30, 7, 5, and 2 patients were classified into Steinbroker's stage I, II, III, and IV, respectively. Thirty-one, 12, 1, and 0 patients are classified into Steinbroker's class I, II, III, and IV, respectively. In DAS28-CRP, 33 (75%), 4 (9%), 7 (16%), and 0 (0%) patients showed REM, LDA, MDA, and HDA, respectively. Compared with the group of REM or LDA, the group of MDA or HDA had significantly older age (P=0.018), higher Steinbroker's stage (P=0.012) and higher DAS28-CRP (P=0.049) at the baseline.
**Conclusions:** At 2 years, 75% of patients with early phase RA achieved REM. Older age, higher Steinbroker's stage and higher DAS28-CRP at the baseline could be prediction factors of poorly controlled patients at 2 years.
**Acknowledgement:** We wish to thank the members of AORA.
**Disclosure of Interest:** None declared

## AB0258 DECREASED PHOSPHOSTAT5 CONTRIBUTED TO IMPAIRMENT OF CD4+CD25+FOXP3+ TREGS IN RA PATIENTS

Z. Huang, L. Chen, B. Yang, J. Chen, L. Wang. *West China hospital of Sichuan University, Chengdu, China*

**Background:** Our previous research has demonstrated decreased expression of $CD4^+CD25^+Foxp3^+$ regulatory T cells (Tregs) enrolled in the pathogenesis of rheumatoid arthritis (RA). Anti-TNF-$\alpha$ mAb therapy could improve Tregs expansion in RA and associate with clinical amelioration of RA patients. STAT5 is reported to have effects on many aspects of immune function, particularly in regulatory T cell development.
**Objectives:** In this study, we aim to monitor phosphoSTAT5 expression in Tregs and investigate its role in RA disease.
**Methods:** Flowcytometry was employed to detect the phosphorylation level of STAT5 in $CD3^+CD4^+$ T cells, $CD4^+CD25^{high}$ regulatory T cells and the expression of $CD4^+CD25^+Foxp3^+$Tregs in peripheral blood of 20 patients with RA disease and 20 age and gender-matched normal controls. STAT5 mRNA expression in peripheral blood mononuclear cells (PBMC) were also monitored of these RA patients and normal controls.
**Results:** Phosphorylation level of STAT5 deceased in RA patients both in $CD3^+CD4^+$ T cells and in $CD4^+CD25^{high}$ regulatory T cells, along with reduction of expression of $CD4^+CD25^+Foxp3^+$ Tregs. Detection of mRNA also confirmed STAT5 down regulation in Tregs in RA patients.

**Conclusions:** Compared with normal controls, the expression of $CD4^+CD25^+Foxp3^+$Tregs decreased in RA patients. PhosphoSTAT5 reduction in $CD3^+CD4^+$ T cells, mainly in $CD4^+CD25^{high}$ regulatory T cells contributed to impairment of $CD4^+CD25^+Foxp3^+$ regulatory T cells in RA.

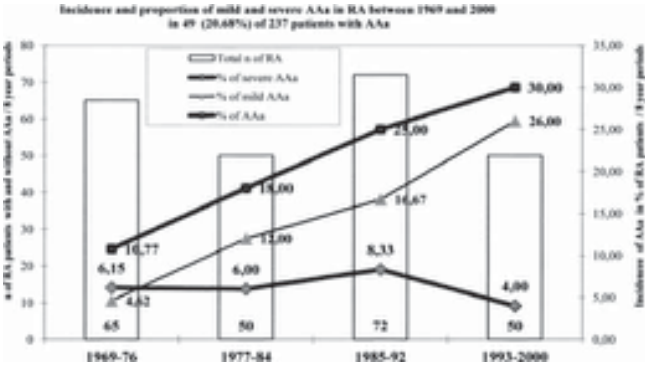
## Rheumatoid arthritis - comorbidity and clinical aspects



### AB0259 THE CHANGING FACE OF RHEUMATOID ARTHRITIS AND AA AMYLOIDOSIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 237 RHEUMATOID ARTHRITIS PATIENTS

Á. Apáthy[1], M. Bély[2]. [1]*Department of Rheumatology, St. Margaret Clinic;* [2]*Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, Budapest, Hungary*

**Background:** According to some clinicians the course of rheumatoid arthritis (RA) has been changing in the last decades. However, AA amyloidosis (AAa) remains one of the most important complications of RA [1].
**Objectives:** The aim of this study was to verify this clinical impression, the "changing face of RA", characterized by AAa.
**Methods:** At the National Institute of Rheumatology 12138 patients died between 1969 and 2000; among them 237 with RA, and all of them were autopsied.
This non-selected autopsy population of 237 was the subject of present study. In 49 (20.68%) of 237 patients, RA was complicated by AAa.
**RA** was confirmed clinically according to the criteria of the American College of Rheumatology (ACR). The existence of AAa was determined histologically. The extent of amyloid A deposition/patient was evaluated by semi-quantitative visual estimation on a 0 to 3 plus scale. The average incidence of AAa was calculated in percentage of the number of RA patients, who died during four periods of time (8–8–8-8 years) covering 32 years (between 1969 and 2000).
**Results:** Demographics, duration and onset of disease (in years) of RA patients with AAa is summarized in Table 1, as well as the average incidence of AAa in RA between 1969 and 2000 in Figure 1.

| Years of death | 1969–1976 | 1977–1984 | 1985–1992 | 1993–2000 |
|---|---|---|---|---|
| Average age of RA pts. in years | 56.71 | 59.56 | 66.06 | 64.08 |
| Average onset of disease in years | 46.50 | 45.44 | 48.94 | 42.43 |
| Average disease duration in years | 12.00 | 14.11 | 17.11 | 20.71 |

During these four periods of time (1969 to 2000) the average age of the RA patients with AAa continuously increased somewhat (from 56.71 to 64.08 years). In the four periods RA was diagnosed increasingly earlier in life (42.43 years versus 46.5) and the course of the disease became longer (20.71 years versus 12.00).
The average incidence of AAa continuously increased (from 10.77% to 30.0%) between 1969 and 2000. This was due to the raised prevalence of mild AAa (the proportion of cases with severe AAa decreased (from 6.15% to 4.0%).

**Conclusions:** The earlier onset of RA and the longer life span may explain the changing face of RA and/or the more effective therapy. The increased incidence of AAa may be related to the longer duration of the inflammation.
The changing proportion of severe and mild amyloid deposition, i.e. the decrease of severe cases has likely been related to the introduction of more effective immunosuppressive therapy.
Our data from the end of the last century allow comparison with the changes following the introduction of the much more effective biological therapy of the present.

### AB0260 MULTIMORBIDITY IN RHEUMATOID ARTHRITIS PATIENTS: IMPORTANCE OF RENAL FUNCTIONAL CONDITION

A.Y. Zakharova, A.V. Gordeev, E.A. Galushko, E.L. Nasonov. *Nasonova Reserch Institute of Rheumatology, Moscow, Russian Federation*

**Background:** RA pts commonly present with multiple concurrent chronic disease, compromising pts quality of life, limiting the use of potential therapies, contributing into disability, rate and costs of hospitalization [1–3].
**Objectives:** To identify the prevalence and extent of multi-morbid background in RA pts (ACR 1987 y) and relate pts multimorbidity status with RA activity and duration.
**Methods:** 209 RA pts (F-70,6%, mean age 67,0±11,3y), admitted to rheumatology division, were included into analysis. RA duration was 20 [6;109] mo, average disease activity (DAS28) - 5,2±1,7, radiographic stage 1–2 was identified in 54,5% (n=114) pts using the Steinbrocker scoring system. The severity of multimorbid environment was rated using Charlson Comorbidity Index (CCI) and Cumulative Illness Rating Score (CIRS). CCI was calculated using the rating scale with 19 nosological entities, ICD-10 (0–36); CIRS was calculated using the 5 score scale (0–4) to assess 14 major organ systems of the body (0–56). Values of CCI>5 and CIRS>4 were considered as important clinical and prognostic factors in RA pts.
**Results:** Mean CIRS value in RA pts was 15 [10;19] scores, and CCI value - 7 [4;10] scores. There was an obvious correlation between the two indices (r=0,86, $p$=0,005). CIRS and CCI values were independent of the RA duration (r=-0,43, $p$=0,53; r=-0,12, $p$=0,82, respectively) and RA activity (r=-0,12, $p$=0,08; r=0,02, $p$=0,7). The strongest correlation of the two indices was found with eGFR (using CKD-EPI formula), (CIRS r= -0,61, CCI r= -0,49; $p$<0,01), and with age (r=0,57, r=0,49; $p$<0,05). CIRS and CCI values also correlated ($p$<0,05) with MAP (mean arterial pressure) (r=0,48; r=0,37), excess body weight (r=0,28; r=0,35), creatinine levels (r=0,44, r=0,39), uric acid levels (r=0,32, r=0,31), as well as with hemoglobin level (r=-0,28, r=-0,25) and HAQ scores (r=0,31; r=0,32). No correlation was found between CIRS and gender, VAS score, and ESR, CRP, cholesterol and liver transaminases levels ($p$>0,05).
**Conclusions:** High multimorbid burden was established in the absolute majority of RA pts. RA duration and activity had no impact on the level of multimorbid burden, measured with CCI and CIRS indices (objective measure of cumulative physical illness burden). Compromised renal function, apart from the age, is of dominant importance in pts management issues, limiting the range of available effective therapies, thus, aggravating RA natural course on one side, and inducing and catalyzing the severity of dysmetabolic syndrome, AH and anemia – on the other.

### AB0261 DOES THE PRESENCE OF RHEUMATOID FACTOR AND/OR ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY POSITIVITY AFFECT THE MANIFESTATIONS OF RHEUMATOID ARTHRITIS?

A. Chan, X. Gao, W. See, K. Leong, E. Koh on behalf of Tan Tock Seng Rheumatoid Arthritis Study Group. *Tan Tock Seng Hospital, Singapore, Singapore*

**Background:** Since the 2010 revision of the American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) Classification Criteria and the availability of anti-cyclic citrullinated peptide antibody (ACCP) testing, patients newly diagnosed with rheumatoid arthritis (RA) are commonly tested for both rheumatoid factor (RF) and ACCP. Patients with ACCP or RF positivity are reported to have worse clinical and radiographic outcomes; however, the presence of ACCP may confound the effects of RF and vice versa.
**Objectives:** To determine if there were any differences at study baseline in RA patients who were ACCP-positive, RF-positive, doubly positive and doubly negative in terms of demographics, clinical, functional, laboratory features and radiographic erosions in a multi-ethnic cohort of RA patients in a tertiary rheumatology centre in Singapore.
**Methods:** This cross-sectional study was conducted at Tan Tock Seng Hospital in Singapore. 1206 patients fulfilled the ACR 1987 criteria for RA, of whom 475 were excluded due to a lack of both ACCP and RF status. Serum levels of ACCP and RF were analysed for differences in demographics (gender, ethnicity, age, smoking status, disease duration before study entry), clinical activity (Disease Activity Score-28 (DAS-28)), functional status (Health Assessment Questionnaire (HAQ) score), quality of life (Short-Form 36 (SF-36) physical and mental components), haemoglobin levels (Hb), erythrocyte sedimentation rate (ESR), hand radiographic erosions, and the use of prednisolone and disease modifying anti-rheumatic drugs (DMARDs) at study entry.
**Results:** 731 patients were studied of whom 491 were ACCP+RF+, 54 were ACCP+, 82 were RF+ and 104 were doubly negative. Mean disease duration of RA

prior to study entry was similar among the groups at 97.8–105.1 months (p=0.971) and mean disease duration before first DMARD was 38.8–42.7 months (p=0.966). 24.4% of the ACCP+RF+ patients were in remission (DAS-28 <2.6) compared to 36.6–39.4% in the other groups (p<0.05). ESR was higher (40.4mm/hour) in the ACCP+RF+ group compared to 30.6–30.9 mm/hour in the others (p<0.05). The use of prednisolone and number of DMARDs was higher in the ACCP+RF+ group (1.40±0.71) compared to the doubly negative group (1.13±0.59) (p<0.05). There were no differences in demographics, radiographic erosions, functional status and quality of life scores.

**Conclusions:** Patients who had dual positivity for ACCP and RF had lower remission rates and required more corticosteroid and DMARD treatment at baseline. However, this did not seem to have an impact on their functional status, quality of life and radiographic erosions. Future prospective studies would be useful to determine if the prognosis of patients with RA are affected by ACCP and RF positivity.

## AB0262 VERIFICATION OF ANTIBACTERIAL EFFECT OF SULFASALAZINE IN RHEUMATOID ARTHRITIS PATIENTS

A. Kitada, C. Min, Y. Kataoka, S. Kaneshita, M. Suda, K. Takasugi, Y. Ohara, R. Rokutanda, H. Shimizu, T. Tsuda, M. Kishimoto, K. Yamaguchi, M. Okada.
*Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan*

**Background:** Sulfasalazine (SSZ) might have antibacterial effect, because it contains sulfa residue. However, its clinical usefulness in patients of rheumatoid arthritis (RA) has been unclear.

**Objectives:** Our aim was to evaluate whether SSZ could prevent bacterial infections especially in newly diagnosed RA patients.

**Methods:** The adult patients who were newly diagnosed with RA at St. Luke's International Hospital, Tokyo, Japan from January 2006 to December 2013 were included in this retrospective open cohort study. The patients were divided into two groups, either SSZ group in which the treatment was started with SSZ or non-SSZ group in which the treatment was started with DMARDs except for SSZ. The diagnosis of infections was defined by the prescription of antibiotics. We investigated whether SSZ group showed lower incidence rate of infections compared to non-SSZ group by multivariate logistic regression analysis for well-known risk factors for infections, such as age and other immunosuppressive DMARDs use.

**Results:** There were 179 eligible patients in SSZ group and 157 patients in non-SSZ group. Mean ages were 57.3±15.8 and 55.1±15.1 years old, and male percentages were 23.0 and 17.8% in SSZ group and non-SSZ group, respectively. Percentages who had received additional immunosuppressive agents including csDMARDs and bDMARDs were 68.2 and 86.0% for each groups. Incidence rate of bacterial infection was prone to be lower in SSZ group than in non-SSZ group in univariate analysis (17.7 per 100 person-years vs. 26.3 per 100 person-years, p=0.07). However, prevalence of infections in SSZ group did not differ from that of non-SSZ group both in univariate and multivariate analysis (0.30 vs. 0.30, p=0.49, 95% CI 0.51–1.37).

**Conclusions:** SSZ did not prevent bacterial infections in newly diagnosed RA patients.

## AB0263 AGREEMENT BETWEEN DAS28, ACR/EULAR, SDAI, CDAI AND ULTRASOUND REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BIOLOGICAL TREATMENT IN ROUTINE CARE

C.H. Brahe[1], L. Terslev[1], S. Krabbe[1], M. Østergaard[1], H. Røgind[1], H.S. Jensen[1], A. Hansen[1], J. Nørregaard[1], S. Jacobsen[2], K. Ellegaard[2], V. Fana[1], L. Juul[1], T. Huynh[1], D. Jensen[1], N. Manilo[1], K. Asmussen[1], P.B. Frandsen[1], S.T. Pedersen[1], N.S. Krogh[3], M.L. Hetland[1]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet; [2]The Parker Institute, Copenhagen University Hospital at Frederiksberg; [3]ZiteLab ApS, Copenhagen, Denmark*

**Background:** Different remission criteria are available for patients with rheumatoid arthritis (RA). None of the criteria includes imaging remission, even though studies have shown that many RA patients in sustained clinical remission have synovitis detectable by ultrasound (US), i.e. grey scale synovial hypertrophy and/or Doppler signal in the synovium.

**Objectives:** We aimed to investigate the agreement between different clinical remission criteria and remission defined by US in patients with RA receiving biological therapy in routine care.

**Methods:** A total of 117 RA patients in sustained remission (i.e. DAS28 ≤2.6 for ≥1 year and no radiographic progression the last year) on biological therapy were recruited. All patients underwent US of 24 joints for grading of grey scale (GS) synovial hypertrophy (0–3) and synovial Colour Doppler activity (CD) (0–3). Imaging remission was defined in two ways: either GS=0 and CD=0 in all 24 joints, or GS≤1 and CD=0 in all 24 joints.

**Results:** Baseline characteristics are shown in table 1. At baseline patients received the following disease-modifying antirheumatic drugs (DMARDs): methotrexate (MTX; 72%), sulphasalazine (3%), azathioprine (2%), leflunomide (2%), no DMARDs (21%) and the following treatment with biological therapy: abatacept (2%), adalimumab (28%), certolizumab (3%), etanercept (28%), golimumab(3%), infliximab (27%), tocilizumab (9%).

For patients fulfilling DAS28 remission criteria, US defined remission was present in 9% (GS=0 and CD=0 in all 24 joints, termed "very strict" US remission) or 29% (GS ≤1 per joint and CD=0 in all 24 joints, termed "strict" US remission) and 24% had CD>1 in at least 1 joint (table 1). For patients fulfilling other criteria for clinical remission (CDAI, SDAI and ACR/EULAR remission), patients were in very strict US remission in 12%, 12% and 10%, respectively and in strict US remission in 28%, 29% and 20%, respectively. CD activity >1 in at least 1 joint was present in 22%, 25% and 22% of patients, respectively. The anatomical distribution of the GS synovial hypertrophy was 31% in metacarpophalangeal joints, 27% in metatarsophalangeal joints, 19% in wrists, 10% in knees, 7% in elbows and 6% in ankles. Thus, 33% of the total GS synovial hypertrophy was observed in the feet, which are not included in the DAS28 remission criteria.

There were no significant differences in US findings (GS or CD) between patients

Tabel 1: Baseline characteristics and agreement between clinical remission and ultrasound remission

| Characteristics | DAS28 remission | CDAI remission | | | SDAI remission | | | ACR/EULAR remission | | |

| SJC28 | 0 (0-0) | 0 (0-0) | 0.2 | 0 (0-0) | 0 (0-0) | 0.9 |
| TJC28 | 0 (0-0) | 0 (0-0) | 0.4 | 0 (0-0) | 0 (0-0) | 0.9 |
| CRP (mg/dL) | 5 (2-6) | 5 (3-5) | 0.4 | 5 (3-8) | 5 (3-5) | 0.8 |
| Pt. VAS global | 13 (4-26) | 10 (6-18) | 0.5 | 11 (4-25) | 16 (7-28) | 0.3 |
| Total GS score | 8 (4-14) | 3 (0-9) | NA | 9 (5-15) | 2 (0-3) | NA |
| Total CD score | 1 (0-2) | 0 (0-0) | NA | 1 (0-2) | 0 (0-0) | NA |
| CD = 0 | 50% | 100% | NA | 37% | 100% | NA |
| CD ≤1 | 79% | 100% | NA | 68% | 100% | NA |
| GS =0 | 1% | 100% | NA | 1% | 32% | NA |
| GS ≤1 | 33% | 100% | NA | 15% | 100% | NA |

Values are median (IQR) unless otherwise indicated. Mann-Whitney U test for continuous data. Pearson-Chi square test for binomial data. US included bilateral scan of the following 24 joints: elbows, wrists, metacarpophalangeal joints 2-5, knees, ankles, metatarsophalangeal joints 2-5. NA: Non applicable

in remission vs patients not in remission, no matter which clinical remission criteria were used.
**Conclusions:** Subclinical synovitis was frequently detected by US in RA patients treated with biological drugs in routine care showing poor agreement between the clinical remission criteria and US remission. Further studies are needed to evaluate the benefit of US remission as a goal for treat to target strategies on patient-reported outcomes and radiographic progression.

## AB0264 FATTY LIVER INDEX PREDICTS GLUCOSE METABOLISM DISTURBANCE IN INFLAMMATORY ARTHRITIS PATIENTS

C. Tripolino, F. Ursini, C. Bruno, K. Nicolosi, S. Naty, R.D. Grembiale. *Magna Graecia University, Catanzaro, Italy*

**Background:** Several studies reported an increased prevalence of nonalcoholic fatty liver disease (NAFLD) in subjects with rheumatic diseases [1]. NAFLD can be evaluated non-invasively and reliably by magnetic resonance spectroscopy, computed tomography and ultrasound. However, these methods are time consuming or associate with high costs. Thus, alternative estimates of NAFLD based on routine risk factors and serum biomarkers have been proposed [2]. Interestingly, these surrogate indices associate with insulin resistance and risk of type 2 diabetes in the general population [3]. To date, no data are available about a possible association between surrogate indices of NAFLD and glucose metabolism disturbance in the setting of inflammatory arthritis.
**Objectives:** To analyze the relationship between sierological markers of liver fat accumulation and 2-hours plasma glucose concentration (2hPG) in a population of rheumatic disease subjects undergoing an oral glucose tolerance test (OGTT).
**Methods:** For our aim, we recruited 45 subjects diagnosed with inflammatory arthritis (rheumatoid arthritis, RA; psoriatic arthritis, PsA; undifferentiated spondiloarthritis, uSpa). Exclusion criteria were: current diabetes, severe renal and hepatic disease. After overnight fasting, OGTT was performed by oral administration of a standard dose of 75 g anhydrous glucose dissolved in water. Plasma glucose levels were measured in a fasting state and again two hours after its administration. Other laboratory analyses included: lipids, complete blood count, erythrocyte sedimentation rate (ESR), high sensitivity C-Reactive Protein (hsCRP), serum alanine transaminase (ALT), aspartate transaminase (AST) and and gamma-glutamyltransferase (GGT). The liver fat score (LFS), the hepatic steatosis index (HSI) and fatty liver index (FLI) were employed as serum NAFLD indices as previously described [2]. Pearson's or Spearman's correlation analyses were used as appropriate to test the associations between continuous variables. Not normally distributed variables were log-transformed before analysis.
**Results:** 20 AR, 15 PsA and 10 uSpa composed our sample. Of these 16 were males and 29 were females. The mean age was 54±9.1. According to the OGTT results: 31 subjects were classified as NGT, 9 had IGT and 5 had diabetes. In simple correlation analyses, Ln2hPG significantly correlated with Age ($r=0.48$, $p=0.001$), BMI ($r=0.44$, $p<0.01$), HSI ($r=0.43$, $p<0.01$), LFS ($r=0.37$, $p=0.01$) and FLI ($r=0.54$, $p<0.001$). After controlling for BMI and age only FLI associated with 2hPG.
**Conclusions:** Our data demonstrate an association between 2hPG and NAFLD surrogate indices in a population of inflammatory arthritis patients. Among these FLI seems better associate with glucose metabolism disturbance.
