**Results:** 2364 pts were enrolled and 2350 were evaluable: 674 (28.7%) were biologic naïve and 1676 (71.3%) had failed ≥1 prior biologic: 728/1676 (43.4%) failed 1 biologic, 948/1676 (56.6%) ≥2 biologics; 1605/1676 (95.8%) had failed anti-TNFs. Biologic-naïve pts had similar baseline characteristics vs biologic-failure pts, except for shorter disease duration, fewer erosions in combination with RF or anti-citrullinated protein antibody (ACPA) positivity, prior conventional DMARDs failed and ABA monotherapy, and more co-morbidities (COPD, cardiac disorders and neoplasms). Crude retention rates over 12 months were statistically higher in biologic-naïve (78.1%; 95% CI 74.7, 81.2) vs biologic-failure pts (69.9%; 95% CI 67.6, 72.1; $p<0.001$). Predictors of higher retention for biologic-naïve pts are shown (Figure). Neoplasms and psychiatric disorders were associated with lower retention and need investigation. In both treatment lines, RF/ACPA double positivity was associated with higher retention vs double negativity after stratifying for erosion status, but was significant only in pts with erosive disease at baseline. A numerically greater proportion of biologic-naïve vs biologic-failure pts had a good/moderate EULAR response (83.8 vs 73.3%) and DAS28 (CRP) <2.6 (44.5 vs 35.0%); unadjusted.

**Conclusions:** These data confirm the high levels of IV abatacept retention in the real world, particularly when used in earlier lines of treatment. Poor prognostic factors in RA, including RF/ACPA double positivity combined with erosions at baseline, positively impact retention, independently of treatment line.

**Background:** A Treat-to-Target approach (T2T), treating patients with RA towards a target, either remission or low disease activity (T2T-REM or T2T-LDA) is nowadays recommended. However it has never been assessed whether such a strategy in daily clinical practice really leads to more patients meeting that target.

**Methods:** BIODAM is a 2-year prospective cohort including patients in daily practice with RA from 10 countries, who were started or changed on DMARD and/or anti-TNF treatment and were followed-up every 3 months. Participating physicians were required to practice T2T per protocol. Per visit was decided whether a patient was treated according to T2T or not. T2T-REM was considered met: i) if a patient had already a disease activity score below the target (DAS28-CRP<2.6); or ii) if treatment was intensified (by increasing dosage or adding drugs) upon a DAS28≥2.6. T2T-LDA was computed using the benchmark for low disease activity (LDA) (DAS28<3.2) (T2T-LDA). The main outcome was the presence or absence of ACR/EULAR-boolean remission 3 months after T2T-REM or T2T-LDA. Another outcome analysed was sustained remission (present >6 months). The relationship between T2T and ACR/EULAR Boolean remission 3 months later (or sustained remission) was investigated using generalized estimating equations with auto-regression.

**Results:** In total 3084 visits of 539 patients (mean (SD) age: 56 (13) years, 76% female, disease duration 6 (8) years). In 68% of the visits, T2T-REM was applied (in 79% of the visits T2T-LDA was applied). ACR/EULAR-boolean remission was reached in 15% of the visits. Appropriate application of T2T-REM led to a 50% higher likelihood of ACR/EULAR-boolean remission 3 months later than not applying T2T-REM. Both T2T-REM and T2T-LDA strategies led to lower disease activity (with an exception of DAS28 remission or DAS28-LDA). Only 9% of the treatment intensifications followed upon a DAS28 between 2.6 and 3.2, and 79% of the intensifications were applied upon a DAS>3.2. Following T2T strategies led to higher achievement of sustained remission (table).

Table - Effect of treat-to-target approach on disease activity outcomes 3 months later

| | REMISSION ACHIEVEMENT | | | | | SUSTAINED REMISSION |
|---|---|---|---|---|---|---|
| | ACR/EULAR boolean remission (OR (95% CI)) | DAS28 remission (OR (95% CI)) | CDAI remission (OR (95% CI)) | SDAI remission (OR (95% CI)) | DAS28-LDA (OR (95% CI)) | ACR/EULAR boolean sustained remission (OR (95% CI)) |
| TT2-REM | **1.50 (1.20; 1.87)** | 0.97 (0.83; 1.13) | **1.48 (1.18; 1.84)** | **1.63 (1.32; 2.02)** | 1.08 (0.93; 1.27) | **1.64 (1.27; 2.10)** |
| TT2-LDA | **2.01 (1.50; 2.71)** | **1.35 (1.12; 1.62)** | **2.31 (1.70; 3.14)** | **2.63 (1.95; 3.53)** | **1.28 (1.07; 1.54)** | **1.66 (1.23; 2.24)** |

**Conclusions:** A treat-to-target approach, even with a modest benchmark (DAS28 = 3.2), works and leads to a higher achievement of (sustained) ACR/EULAR-remission. Our study illustrates the importance of acting upon the data that is routinely collected in a clinical encounter. Rheumatologists should be encouraged to follow a treat-to-target approach in order to improve the outcome of their patients.

## THU0068 ABSOLUTE MONOCYTE COUNTS ARE ASSOCIATED WITH ADVERSE EULAR RESPONSE AFTER 6 MONTHS OF TREATMENT WITH A BIOLOGIC AGENT FOR RHEUMATOID ARTHRITIS

S.F. Ling[1,2], K. Stylianou[3], P. Ho[3], M. Bukhari[2], D. Plant[1], A. Barton[1]. *[1]Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, University of Manchester, Manchester; [2]Department of Rheumatology, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster; [3]Kellgren Centre, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*

**Background:** Absolute monocyte counts after 3 months of treatment have been found to be predictive of clinical response to adalimumab at 6 months in rheumatoid arthritis (RA) patients[1]. It has also been shown that resistance to spontaneous apoptosis of monocytes *in vitro* predicts inadequate response to etanercept[2]. We hypothesise that absolute monocyte counts obtained from routine pre-treatment blood testing has predictive utility for treatment response to biologic agents.

**Objectives:** To assess whether monocytes and other white blood cell subtypes are associated with treatment response at 6 months in RA patients.

**Methods:** Full blood count (FBC) data was collected from patients attending 2 centres participating in the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS), Manchester Royal Infirmary and Royal Lancaster Infirmary, from 2009–2015. BRAGGSS is a UK-based multi-centre inception cohort of secondary-care RA patients. Spearman correlation was carried out to explore relationships between pre-biologic differential white cell count (WCC) and absolute DAS28 (and its components) at treatment start (baseline) and 6 months. Logistic regression was used to explore associations between differential WCC and EULAR response at 6 months. Stata v13.1 was used for all statistical analyses.

**Results:** 130 patients had WCC data available for analysis. They all satisfied American College of Rheumatology 1987 classification criteria for RA. 104 patients (80%) were female, with a mean age of 56.21 (SD 13.07). Mean baseline DAS28 score was 5.96 (SD 0.92) and mean monocyte count at baseline was $0.62*10^9$/L (SD 0.22). Patients were on a variety of biologics: etanercept (n=56), adalimumab (n=24), rituximab (n=13), abatacept (n=10), golimumab (n=5), tocilizumab (n=12) and certolizumab (n=10).

Pre-treatment monocyte count was not associated with DAS28 at baseline, but correlated with DAS28 at 6 months (rho=0.19, p=0.028). When a cut-off of $0.62*10^9$/L was used, high monocyte count was associated with DAS28>3.2 at 6 months (OR1.72 [95% CI 1.12–2.64], p=0.013), and with poor EULAR response (OR 2.82 [95% CI 1.12–7.13], p=0.028).

Neutrophil count was associated with DAS28 at both baseline (rho=0.22, p=0.013) and 6 months (rho=0.21, p=0.019). Neutrophil count was significantly associated with reduced odds of achieving a good EULAR response at 6 months (OR 0.82 [95% CI 0.69, 0.96], p=0.017). These neutrophil counts likely reflect ongoing inflammation, contributing to poor response to biologic therapy[3].

**Conclusions:** Monocyte counts were associated with increased DAS28 at 6 months, but not baseline, and with poor EULAR response at 6 months. This could provide a useful and widely available predictive biomarker, as FBC is routinely carried out in all patients commencing disease-modifying therapy in the UK. In future, monocyte count at baseline may be used to predict treatment response to biologics in RA patients at 6 months. Further studies with increased sample size are required to confirm these findings.

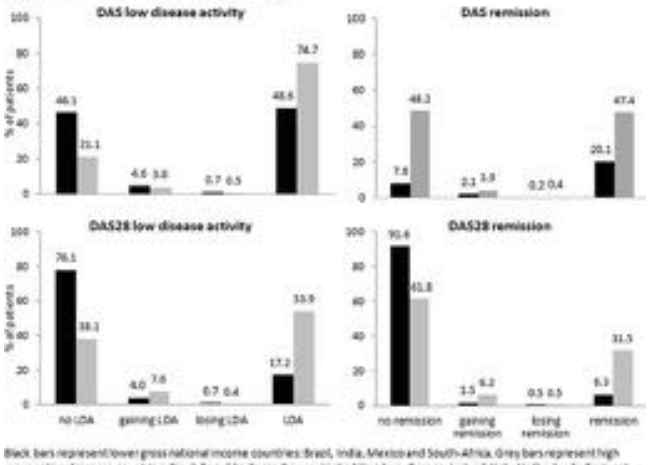
## THU0069 INFLUENCE OF THE DIFFERENCE BETWEEN PATIENT AND PHYSICIAN GLOBAL ASSESSMENT ON DISEASE ACTIVITY STATUS IN HIGH AND LOWER INCOME COUNTRIES: DATA FROM THE METEOR DATABASE

S.A. Bergstra[1], R. van den Berg[1], A. Chopra[2], J.A.P. Da Silva[3], D. Vega-Morales[4], N. Govind[5], C.F. Allaart[1], R.B.M. Landewé[6]. *[1]LUMC, Leiden, Netherlands; [2]Center for Rheumatic Diseases, Pune, India; [3]SRHUC, Coimbra, Portugal; [4]Universidad Autónoma de Nuevo Léon, Monterrey, Mexico; [5]University of the Witwatersrand, Johannesburg, South Africa; [6]AMC, Amsterdam, Netherlands*



**Background:** Patients with rheumatoid arthritis (RA) score their global disease activity (ptGD) on average higher than physicians (phGD). This difference can vary between countries with high and lower gross national income (GNI)[1]. Also, patients with RA in lower GNI countries have less access to biologic and synthetic DMARDs[2]. With targeted treatment aiming at low disease activity (LDA) or remission, this could influence treatment.

**Objectives:** To compare differences between ptGD and phGD in high and lower GNI countries and to assess how these potential differences influence disease activity measures.

**Methods:** RA patients included in the METEOR (Measurement of Efficacy of Treatment in the Era of Outcome in Rheumatology) database were selected from countries ≥30 patients with >1 visit, available phGD and DAS or DAS28. Countries were divided in high and lower GNI (World Bank definition, high income GNI per capita ≥$12746). ptGD and phGD were measured on a 100mm visual analogue scale (100 worst score); A difference ≥20 mm between ptGD and phGD (GDdif=ptGD–phGD) was considered clinically relevant. Next, ptGD was replaced by phGD in the DAS and DAS28, to assess potential changes in the number of patients in LDA or remission.

**Results:** From high GNI countries, 6928 patients were included, from lower GNI countries 5136 patients. DAS was available in 10420 patients (6179 from high GNI countries), DAS28 in 11173 patients (6839 from high GNI countries). Patients from lower GNI countries had higher disease activity [mean (SD) DAS28 4.6 (1.8) vs 3.4 (1.8); DAS 2.5 (0.9) vs 1.8 (0.9)], longer disease duration at diagnosis [55 (69) vs 27 (59) weeks] and less often reached LDA [DAS28 49% vs 75%; DAS 20% vs 48%] or remission [DAS28 7% vs 32%; DAS 20% vs 48%] than patients from high GNI countries. Compared to high GNI countries, in lower GNI countries, more patients had a GDdif ≥20 mm with ptGD>phGD (44% vs 30%) and fewer patients had a GDdif <20 mm (47% vs 67%). Also, more patients had a GDdif ≥20 mm with ptGD<phGD (9% vs 3% in lower vs high GNI countries). Replacing ptGD by phGD resulted in a mean (SD) change in DAS and DAS28 of 0.09 (0.1) and 0.4 (0.6) in high GNI countries and 0.9 (0.1) and 0.4 (0.7) in lower GNI countries. For both DAS and DAS28, the percentage of patients changing disease activity status is low in all countries [mean change in DAS LDA 4.8%, remission 3.3%; DAS28 LDA 6.4%, remission 4.4%], with most patients gaining LDA or remission (Fig. 1).

Figure 1. Percentage of patients changing DAS and DAS28 disease activity status after replacement of the patient global assessment by the physician global assessment.

Black bars represent lower gross national income countries: Brazil, India, Mexico and South-Africa. Grey bars represent high gross national income countries: Czech Republic, Spain, France, United Kingdom, Greece, Ireland, Italy, Netherlands, Portugal, Qatar and United States. Outer bars describe patients not changing disease activity status. The inner two bars describe patients changing disease activity status. LDA = low disease activity.

**Conclusions:** Compared to high GNI countries, patients from lower GNI countries had higher disease activity and less often reached LDA or remission. Clinically relevant differences between ptGD and phGD existed in more than 1/2 of the patients in lower GNI countries and 1/3 of the patients in high GNI countries, thereby influencing disease activity stronger in lower GNI countries as compared to high GNI countries. These results indicate a different access to good RA care in lower and high GNI countries.

## THU0070 RANKL, OPG AND OSCAR BUT NOT DKK-1 PREDICT RADIOGRAPHIC PROGRESSION IN AN INCEPTION COHORT OF SEROPOSITIVE RHEUMATOID ARTHRITIS (RA) TREATED-TO-TARGET WITH COMBINATION CONVENTIONAL DMARD THERAPY

M.D. Wechalekar[1,2], S. Lester[3], S. Nagpal[4], S. Cole[4], A. Das[4], P. Hissaria[5], T. Crotti[6], L. Spargo[5], J.G. Walker[1,2], M.D. Smith[2], S.M. Proudman[5,6].
*[1]Repatriation General Hospital; [2]Flinders University; [3]The Queen Elizabeth Hospital, Adelaide, Australia; [4]Janssen Research, Spring House, United States; [5]Royal Adelaide Hospital; [6]University of Adelaide, Adelaide, Australia*

**Background:** Traditional markers associated with erosive disease in RA do not reliably predict radiographic progression. There are limited data regarding the role of bone biomarkers in erosive disease in early RA treated with conventional DMARDs and no longitudinal data on osteoclast-associated receptor (OSCAR) with therapy.
**Objectives:** To determine whether bone biomarkers associated with osteoclast activation (RANKL, OSCAR and Dkk-1) or inhibition (OPG) are associated with erosion progression over 3 years, independent of disease activity in an inception cohort of RA receiving treat-to-target combination DMARD therapy without oral corticosteroids.
**Methods:** Dual RF and anti-CCP positive patients with early RA (<1 year; fulfilling ACR 1987 and/or 2010 classification criteria; n=50) received triple therapy (methotrexate, sulfasalazine and hydroxychloroquine) escalated to achieve DAS28 remission. RANKL, OPG and Dkk-1 were analysed by Luminex kits, OSCAR by ELISA at baseline, 6 and 12 months. For radiographic outcomes annual hand and feet radiographs were scored by the van der Heijde modified Sharp (SvH) method. Changes in bone biomarkers and associations with predictor variables were assessed using a linear multi-response random effects model. Relationships between bone biomarkers in the first year and DAS28 remission and radiographic erosion score outcomes over 3 years were analysed using logistic and negative binomial mixed regression respectively.
**Results:** Mean (SD) baseline DAS28ESR was 5.55 (1.14), 76% were females, 70% were current/past smokers and mean duration of symptoms prior to diagnosis was 18 (12) weeks. Median (IQR) total SvH score was 2 (7); 24% had erosive disease. With treatment, there was a reduction in DAS28 at 1 year to 3.14 (1.31), significant reduction in RANKL, slight increase in OPG and no significant change in Dkk-1 and OSCAR. DAS28 remission, assessed over 3 years, was less likely to occur both in the presence of detectable RANKL (p=0.01) and/or in the presence of higher average Dkk-1 levels (p=0.007). Baseline erosion scores were higher in the presence of RANKL (p=0.046) and lower OSCAR (p=0.021). There was a trend towards higher erosion scores in the presence of lower OPG levels (p=0.16). Unexpectedly, those with higher mean OPG over the first 12 months had a higher annual increase in erosion scores over 3 years (p=0.018), which may reflect the dynamic processes of bone inflammation.
**Conclusions:** Conventional DMARD treatment results in reduction of RANKL, but not OPG, OSCAR or Dkk-1 levels. Higher RANKL levels, lower OSCAR levels and higher mean OPG were associated with erosions. Failure of bone biomarkers to respond to treatment may warrant escalation of therapy to prevent erosion progression. Bone biomarkers may also provide an explanation for the apparent dissociation between disease activity and bone damage in RA.

## THU0071 TIME TO REMISSION IN EARLY RHEUMATOID ARTHRITIS IS SHORTER IN EARLY ARTHRITIS CLINIC COMPARED TO MIXED OUTPATIENT CLINIC

T.H. Hansen, K.M. Carlsen, P. Johansen. *Rheumatology, Copenhagen University Hospital, Holbaek, Denmark*

**Background:** Early diagnosis of rheumatoid arthritis (RA) is of paramount importance as early effective treatment reduces long-term morbidity and mortality (1,2). Evidence suggests that simple clinical criteria, facilitates earlier referral of patients with suspected RA from general practitioners (GP's) to the rheumatologist (3).
**Objectives:** Our hypothesis: Supplementary education of GP's to identify RA and refer to an Early Arthritis Clinic (EAC) shortens time to remission compared to referral to a mixed outpatient clinic.
**Methods:** In July 2011, an EAC was established in Holbæk Hospital. GP's in the hospitals catchment area were informed of the clinic, educated in the referral criteria and encouraged to refer patients suffering unspecific arthritis symptoms at early disease stages. A standardised referral form was contrived to simplify the referral process. Patients referred and diagnosed with RA were followed until remission. Patients in the trial were enrolled from July 2011 to April 2015. Controls were patients referred prior to the establishment of the EAC. The main outcome parameter was time from referral to low DAS28 <3.2 or remission at DAS28 <2.6. All patients were registered in the mandatory nationwide database DANBIO (4). Patients were evaluated and monitored by rheumatologists or rheumatology specialist nurses in the DANBIO at regular intervals and DAS28 was calculated at each visit. A Kaplan-Meier plot was calculated and compared using the log-rank test. The two groups were compared using the X2-test.
**Results:** As shown in the table, the two groups, EAC vs. controls, were similar in gender distribution. A relatively large proportion in each group already appeared to be in remission at the entry point, up to 16%, probably reflecting the proportion with only slight or minor disease activity. There was a significant proportion in the EAC that achieved both DAS28<3.2 and DAS28<2.6 compared to the control group. Likewise, a conspicuous difference was observed among the patients never achieving remission. The two Kaplan-Meier plots show the timely difference was highly significant indicating that time of remission was achieved very early.

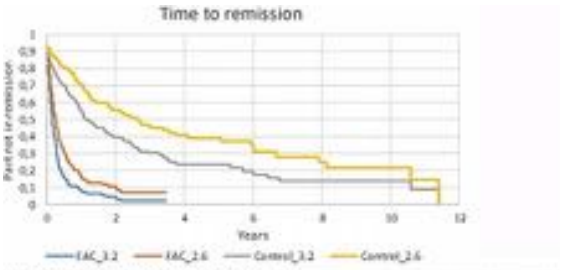

Fig. 1: Kaplan-Meier plot of EAC vs. Controls showing the remission probability DAS28<3.2 and DAS28<2.6 respectively.

| Log Rank test vs | | p |
|---|---|---|
| EAC_3.2 | EAC_2.6 | 0.41 |
| Control_3.2 | Control_2.6 | 0.003 |
| EAC_3.2 | Control_3.2 | <0.0001 |
| EAC_2.6 | Control_2.6 | <0.0001 |

| | EAC | Control | p (X2-test) |
|---|---|---|---|
| n, total | 190 | 160 | |
| Males | 59 | 48 | n.s. |
| Females | 131 | 112 | n.s. |
| DAS28<3,2 | | | |
| Already in remission, n | 29 | 16 | n.s. |
| Achieved remission, n | 153 | 92 | p<0.01 |
| Never achieved remission, n | 8 | 52 | p<0.0001 |
| Median time to remission, days | 62 | 238 | |
| DAS28<2,6 | | | |
| Already in remission | 22 | 11 | n.s. |
| Achieved remission | 116 | 73 | p=0.05 |
| Never achieved remission | 24 | 76 | p<0.0001 |
| Median time to remission, days | 70 | 341 | |

**Conclusions:** Establishing an early arthritis clinic and supplementary RA education of GP's shortens time to early disease activity or remission in patients with RA.

## THU0072 A NOVEL DOSE REDUCTION THERAPY USING BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS TO TARGET MATRIX METALLOPROTEINASE 3 NORMALIZATION TOGETHER WITH A SIMPLIFIED DISEASE ACTIVITY INDEX ≤3.3 YIELDS EFFECTS NON-INFERIOR TO STANDARD CARE IN RHEUMATOID ARTHRITIS WITH REGARDS MAINTAINING REMISSION

Y. Urata[1], S. Abe[2], B. Devers[2], Y. Nakamura[3], H. Takemoto[4], K.-I. Furukawa[5].
*[1]Department of Rheumatology, Tsugaru General Hospital, United Municipalities of Tsugaru, Gosyogawara; [2]Marketing Department, Diagnostics Division, Sekisui Medical Co., Ltd, Tokyo; [3]Department of Orthopedic Surgery, Tsugaru General Hospital, United Municipalities of Tsugaru; [4]Department of Dermatology, Tsugaru General Hospital, United Municipalities of Tsugaru, Gosyogawara; [5]Department of Pharmacology, Hirosaki University Graduate School of Medicine, Hirosaki, Japan*

**Background:** While there have been previous studies into reduction of biological disease-modifying anti-rheumatic drugs (bDMARDs) in rheumatoid arthritis (RA)

patients in clinical remission or with low disease activity, there have been no strategy studies which demonstrated non-inferiority to standard care with regard to maintaining clinical remission while reducing bDMARDs.
**Objectives:** To evaluate whether a therapy strategy using reduced doses of bDMARDs [bDMARDs: etanercept (ETN); tocilizumab (TCZ); abatacept (ABT)] achieving both a simplified disease activity index (SDAI) score of less than 3.3 and normalization of matrix metalloproteinase (MMP) 3 levels is non-inferior in maintaining disease control in patients with RA compared with standard care (rT-4 study).
**Methods:** 223 RA patients demonstrating both SDAI remission and MMP-3 normalization using bDMARDs for ≥3months were randomly allocated to one of four strategy groups: Standard care (SC group; n=56); SDAI-driven therapy (S group; n=54); MMP-3-driven therapy (M group; n=57); or both SDAI and MMP-3-driven therapy group (Twin; T group; n=56). Method of dose reduction (every 3 months): ETN - period between injections increased by one week; TCZ - dose reduced by 80mg or period between injections increased by one week; ABT - dose reduction by 250 mg or period between injections increased by one week; up to a minimum dose of: ETN - 25 mg every 5 weeks; TCZ - 80 mg every 5 weeks or 162 mg every 5 weeks; ABT - 250 mg every 5 weeks or 125 mg every 5 weeks. The dose was reversed to the previous level in the event that the target scores were exceeded, and the lower dose was eventually reattempted after the target was re-achieved. The primary outcome was the difference in the proportion of patients who maintained remission at 12 months among the four groups, compared against a non-inferiority margin of 10%. Secondary outcomes included functional and radiographic progression.
**Results:** Patient characteristic demographics are summarized in Table 1. One hundred ninety-three patients completed the observation period of 12 months and three patients dropped out. Consequently, one hundred ninety-six patients were analyzed (non responder imputation). There was no difference for the rate of reduction dose of bDMARDs at 12 months in S group, M group, and T group: 37.8, 42.3 and 42.9%, respectively (p=0.4176). The M and T groups were non-inferior to the SC group (proportion of patients who maintained remission during the 12 months: 32.7% and 40.0% v 38.2%; a variation of -1.8% and 5.5%, respectively; with 95% CIs of 3.8% to 5.3% and -1.9% to 5.3%, respectively). At month 12, functional status and radiographic progression did not differ between the SC and T groups.

Table 1 Baseline patient characteristics

| | Standard Care (n=56) | SDAI-driven therapy (n=54) | MMP-3-driven therapy (n=57) | Twin-driven therapy (n=56) | p Values |
|---|---|---|---|---|---|
| Age (years)* | 60.8 (15.9) | 65.4 (12.5) | 64.5 (11.6) | 62.8 (13.1) | 0.5108 |
| Female sex, n (%) | 35 (62.5) | 43 (79.6) | 40 (70.2) | 44 (78.6) | 0.1453 |

## Rheumatoid arthritis - comorbidity and clinical aspects

### THU0073 DAS28-CRP AND DAS28-ESR CUTOFFS FOR HIGH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS ARE NOT INTERCHANGEABLE

R.M. Fleischmann[1], D. van der Heijde[2], P.V. Gardiner[3], A. Szumski[4], L. Marshall[5], E. Bananis[5]. *[1]University of Texas, Dallas, United States; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Western Health and Social Care Trust, Londonderry, United Kingdom; [4]inVentiv Health, Princeton; [5]Pfizer, Collegeville, United States*

**Background:** Rheumatoid arthritis (RA) clinical trials have shown that mean DAS28 calculated using C-reactive protein (CRP) is lower than DAS28 calculated using erythrocyte sedimentation rate (ESR). We demonstrated that DAS28-CRP cutoffs equivalent to DAS28-ESR for remission and low disease activity (LDA) were 2.4 and 2.9, respectively, rather than 2.6 and 3.2.[1] Use of DAS28-ESR cutoffs to assess high disease activity (HDA) using DAS28-CRP likely underestimates the number of patients with HDA, although these values are often used interchangeably in clinical trials, and by payers and health organizations, probably excluding patients who should be eligible for advanced therapies.
**Objectives:** To analyze baseline (BL) data from 2 etanercept (ETN) clinical trials to determine the DAS28-CRP cutoff corresponding to the validated DAS28-ESR cutoff for HDA in RA.
**Methods:** Data were pooled from COMET and PRIZE, clinical studies in early moderate to severe RA. Descriptive statistics for DAS28-CRP and DAS28-ESR were determined for each treatment: weekly ETN 50 mg + methotrexate (MTX) or MTX only. DAS28-CRP and DAS28-ESR were compared according to the DAS28-ESR cutoff point for HDA (>5.1) using sensitivity, specificity, kappa coefficients, and proportion of discordance. Based on the DAS28-ESR cutoff, the corresponding DAS28-CRP cutoff was determined for each study and treatment group using cumulative distribution plots, receiver operator curves, and maximum concordance. These DAS28-CRP cutoffs were averaged for each study and treatment, then averaged overall. This produced the DAS28-CRP HDA cutoff corresponding best to the DAS28-ESR HDA cutoff.
**Results:** At BL, fewer patients met the value of >5.1 by DAS28-CRP than by DAS28-ESR (table). DAS28-CRP >5.1 and DAS28-ESR >5.1 had modest agreement (kappa coefficients of 0.45 and 0.53), with high sensitivity but low specificity. In the ETN+MTX group (N=571), mean (95% CI) DAS28-CRP and DAS28-ESR were 5.7 (5.6, 5.8) and 6.2 (6.2, 6.3), respectively, with a difference of 0.6 (0.5, 0.6). In the MTX group (N=262), mean (95% CI) DAS28-CRP and DAS28-ESR were 6.0 (5.9, 6.1) and 6.5 (6.4, 6.6), respectively, with a difference of 0.5 (0.5, 0.6). We determined that DAS28-CRP of 4.6 was similar to DAS28-ESR of 5.1.

Table 1. Statistical measures comparing DAS28-CRP >5.1 and DAS28-ESR >5.1 at baseline, pooled data

| | DAS28-CRP >5.1 | DAS28-ESR >5.1 | Proportion of discordance between parameters | Sensitivity | Specificity | Kappa coefficient | *P*-value |
|---|---|---|---|---|---|---|---|
| ETN+MTX | 394/571 (69.0) | 486/571 (85.1) | 98/571 (17.2) | 99.2% | 46.3% | 0.532 | <0.0001 |
| MTX | 204/262 (77.9) | 243/263 (92.4) | 38/262 (14.5) | 100.0% | 34.5% | 0.450 | <0.0001 |

Sensitivity and specificity based on standard DAS28-CRP >5.1. *P*-value from kappa test of agreement between DAS28-CRP >5.1 and DAS28-ESR >5.1. Values are n/N (%) unless otherwise noted.

**Conclusions:** More patients met the HDA cutoff according to DAS28-ESR than DAS28-CRP, and mean values for DAS28-CRP were lower, suggesting that use of the DAS28-ESR cutoff for DAS28-CRP for HDA underestimates disease activity. Use of the new HDA cutoff of >4.6 for DAS28-CRP, and the new DAS28-CRP cutoffs of ≤2.9 for LDA and <2.4 for remission will enable more accurate measurement of disease activity when DAS28-CRP is used.[1]

### THU0074 IMPACT OF THE DISCORDANCE BETWEEN C-REACTIVE PROTEIN AND ERYTHROCYTE SEDIMENTATION RATE ON CLINICAL RESPONSE TO COMBINATION ETANERCEPT-METHOTREXATE THERAPY IN RHEUMATOID ARTHRITIS

R.M. Fleischmann[1], A. Szumski[2], H. Jones[3]. *[1]University of Texas, Dallas; [2]inVentiv Health, Princeton, NJ; [3]Pfizer, Collegeville, PA, United States*

**Background:** Clinical response remains difficult to predict in patients with rheumatoid arthritis (RA). Acute phase reactants (APRs) C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are regularly measured in standard care, and abnormal CRP and ESR are frequently used as inclusion criteria for RA clinical trials. Alone or in combination with demographic, clinical, and imaging parameters, these APRs are often considered important in treatment decisions in RA. However, results of these tests for inflammation are discordant in a substantial proportion of patients,[1–3] and the clinical implications of discordant CRP:ESR findings have not been well studied.
**Objectives:** To explore the relationship between clinical response and baseline CRP:ESR discordance in RA.
**Methods:** Randomized patients with moderate-severe RA who participated in 3 etanercept (ETN) clinical trials[4–6] and had both APR measurements were included in these post hoc analyses. To allow comparison, baseline CRP and ESR were standardized to the same scale by subtracting the respective means and dividing by the respective standard deviations for each patient. Standardized CRP was subtracted from standardized ESR and differences categorized by quartile (cutoffs: Q1, –0.5; median, 0; Q3, 0.5). DAS28 (ESR) low disease activity (LDA) and remission after 16 or 52 weeks of treatment with ETN + methotrexate (MTX) were analyzed by quartile of CRP:ESR discordance.

**Results:** Across clinical trials, 693 patients received ETN+MTX and had CRP and ESR measured. After 16 or 52 weeks of ETN+MTX treatment, significantly higher proportions of patients achieved DAS28 LDA and remission in the group with higher CRP than ESR at baseline (lower ESR/higher CRP); lower proportions of responders were seen in the group with similar CRP and ESR (ESR≈CRP), and the lowest proportion in the group with lower CRP than ESR (higher ESR/lower CRP) (Table).

Table. Proportions of patients achieving DAS28 LDA and remission after 16 or 52 weeks of ETN+MTX treatment by quartile of standardized CRP:ESR* discordance at baseline in RA clinical studies.

| Study (Weeks) | Clinical Outcome | Patients, % (n/N) Discordance Quartile: ESR−CRP≤−0.5 (↓ ESR / ↑ CRP) | −0.5<ESR−CRP≤0 (ESR=CRP) | 0<ESR−CRP≤0.5 (ESR=CRP) | ESR−CRP>0.5 (↑ ESR / ↓ CRP) | P Value† |
|---|---|---|---|---|---|---|
| Klareskog et al, 2004[4] (52) | LDA | 63 (42/67) | 53 (31/58) | 48 (23/50) | 46 (26/56) | 0.048 |
| | Remission | 57 (38/67) | 31 (18/58) | 32 (16/50) | 29 (16/56) | 0.002 |
| Emery et al, 2008[5] (52) | LDA | 71 (46/65) | 70 (46/66) | 66 (48/73) | 49 (30/61) | 0.013 |
| | Remission | 55 (36/65) | 58 (38/66) | 53 (39/73) | 31 (19/61) | 0.008 |
| Kim et al, 2012[6] (16) | LDA | 48 (23/48) | 49 (26/53) | 42 (16/38) | 21 (12/58) | 0.002 |
| | Remission | 21 (10/48) | 19 (10/53) | 24 (9/38) | 5 (2/58) | 0.020 |

*Standardized CRP and ESR for each patient: (CRP−mean CRP)/SD CRP; ESR−mean ESR)/SD ESR. means and SDs used in standardized formula were obtained separately for each study.
†Cochran-Mantel-Haenszel test, non-zero correlation.

**Conclusions:** In clinical trials, elevated CRP relative to ESR at baseline was a significantly better predictor of the ability of active treatment to show clinical response after 4 months or 1 year of combination etanercept-methotrexate therapy than similar CRP and ESR or lower CRP vs higher ESR. These findings underscore the importance of incorporating this readily available biomarker (CRP) into clinical trial settings; whether this is true in clinical practice cannot be determined from this data set but should be investigated prospectively.

## THU0075 EFFICIENT SCREENING SYSTEM FOR EARLY ARTHRITIS – A PROJECT OF THE T2T INITIATIVE IN GERMANY

C. Jacobsen[1], T. Leipold[2], P. Klaus[1], V. Höhne-Zimmer[1], T. Braun[1], V. Köhler[1], B. Tenckhoff[2], R. König[3], K. Karberg[4], K. Krüger[5], J. Wendler[6], J. Wollenhaupt[7], G.R. Burmester[1], J. Detert[1]. *[1]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin; [2]Clinpath GmbH, Berlin; [3]Herz- und Rheumazentrum, Kerckhoff Klinik, Bad Nauheim; [4]Rheumapraxis Steglitz, Berlin; [5]Praxiszentrum St. Bonifatius, München; [6]Praxisgemeinschaft Rheumatologie Nephrologie, Erlangen; [7]Rheumatology and Clinical Immunology, Schön Klinik Hamburg Eilbek, Hamburg, Germany*

**Background:** Early stages of rheumatic diseases (0–12 weeks) including rheumatoid arthritis (RA) are still difficult to diagnose. For this reason, incorrect referrals to a rheumatologist result in a high use of resources in outpatient clinics.
**Objectives:** Implementation of a structured screening system for selecting and treating patients (pts) with RA or other rheumatic and musculoskeletal diseases (RMD).
**Methods:** 98 pts visited a screening appointment for early arthritis (EA) between February 2015 and September 2015 in special EA departments. Inclusion criterion was arthritis ≥ one joint for less than one year recorded by phone. Qualified health professional assistants (HPA) conducted the phone call. Upon screening, all pts filled in a tablet based questionnaire to be developed for future online use about their symptoms. Subsequently, 53 pts (group 1) were seen first by an HPA who analysed the questionnaire and performed the joint count. Based on these findings, the HPA made a suspected diagnosis. Afterwards, also a rheumatologist saw these pts and made a suspected diagnosis. In comparison, the rheumatologist directly examined 45 pts without an HPA (group 2). In both groups, typical clinical findings led to a new appointment, or in acute cases, treatment was started immediately. If an RMD was suspected or laboratory parameters were abnormal, pts received a second appointment as well. The documentation of the real-life data was carried out by the Medpath© system based on medical and flexible adaptable paths.
**Results:** Mean duration between phone call and screening was 19.6±12.8 days. Pts had an age of 18–80 years (mean 51.1±15.5 years), and 73 pts (74.5%) were female. Although all pts had reported symptoms of less than one year over the phone, only 70 pts (71.4%) fulfilled this criterion when asked in the questionnaire. In group 1, according to the HPA 22 of 53 (41.5%) pts had an RMD upon screening. The suspected diagnoses of HPA and rheumatologist corresponded in 43 of 53 (81.1%) pts in the screening. In group 2, the rheumatologist suspected 14 of 45 (31.1%) pts having an RMD in the first visit.
59 (60.2%) pts had no RMD. 23 (23.5%) pts had RA that was seropositive in 14 (14.3%) pts. All RA pts were recommended a therapy with conventional disease modifying antirheumatic drugs (cDMARDs) and glucocorticoids (GC), which 21 (21.4%) pts started 17.2±27.6 days after screening. 3 (3%) pts initially had a preclinical seropositive RA, which changed into definite RA in need for treatment with cDMARDs after 191 days in one patient. 3 (3%) pts received inpatient treatment and systemic lupus erythematosus was diagnosed in one case.

cDMARDs, conventional disease modifying antirheumatic drugs; GC, glucocorticoids; HPA, Health professional assistent; NSAIDs, Nonsteroidal anti-inflammatory drugs; RA, rheumatoid arthritis; RMD, rheumatic and musculoskeletal disease.

**Conclusions:** The structured screening system efficiently selects pts with RMDs and leads to treating RMD at an early stage in times of limited resources.

## THU0076 ASSOCIATION BETWEEN BODY MASS INDEX AND QUALITY OF LIFE AT ONE AND THREE YEARS POST DIAGNOSIS OF RHEUMATOID ARTHRITIS: RESULTS FROM AN INCEPTION COHORT

H. Helliwell[1], S. Norton[2], E. Nikiphorou[3], D. Walsh[4], P. Kiely[5], A. Young[6]. *[1]Life Sciences & Medicine; [2]Psychology Department; [3]Rheumatology, King's College London, London; [4]Faculty of Medicine & Health Sciences, University of Nottingham, Nottingham; [5]Rheumatology, St George's Hospital, London; [6]Rheumatology, West Hertfordshire Hospitals NHS Trust, St Albans, United Kingdom*

**Background:** Due to large increases in the prevalence of obesity, there is a growing need to understand the relationship between obesity and rheumatoid arthritis (RA) outcomes. RA patients with high body mass index (BMI) have a greater of risk of disease persistence and higher disease activity scores compared to RA patients with lower BMI (1,2). This leads to higher levels of pain and disability, and can reduce quality of life (QoL) for RA patients in higher BMI groups. So far, most of the research looking at obesity in RA has focused on the QoL in terms of physical outcomes, but there has been relatively little investigation on the psychological impact on QoL amongst these patients.
**Objectives:** To assess whether BMI at baseline predicts physical and mental health-related quality of life (HRQoL) for patients over three years in newly-diagnosed RA patients
**Methods:** Data were from the Early Rheumatoid Arthritis Network (ERAN), a longitudinal observational study involving 21 rheumatology centres in the UK. Between 2002 and 2011 1,236 participants (397 male) were recruited. Sociodemographic and standard clinical variables were recorded at baseline, 6 months, 12 months and and then annually until loss to follow-up or the end of study follow up in 2013. QoL was measured using the Short Form 36 Health Survey Questionnaire (SF-36), a wide-ranging measure of health related QoL. Responses are grouped to form two higher-order constructs: Physical Component (PCS) and Mental Component (MCS). Linear regression models was estimated to determine if BMI as baseline was a predictor of the PCS and MCS scores at one year and 3 years, controlling for potential confounders
**Results:** he analysis was restricted to 873 (71%) with data for both BMI and SF-36. Patients with complete data were younger (56.3 vs 58.7 years, p=.01) but did not differ in terms of gender (33% vs 30% male, p=.31), health assessment questionnaire disability (1.09 vs 1.07, p=0.68) or disease activity score (4.5 vs 4.5, p=0.88). Mean BMI at baseline was 27.6 kg/m$^2$, increasing to 28.3 kg/m$^2$ at 3 years – equivalent to a gain of 2.1 kg for an average height male (175cm), or 1.8 kg for an average height female (160cm). At baseline 66.6% of the sample

fell into a WHO BMI category of overweight or obese. BMI at baseline associated with physical but nor mental QoL ($b_{PCS}$=-0.2, p=0.003; $b_{MCS}$=-0.04, p=0.58). After controlling for age, gender, baseline disease activity and baseline PCS and MCS score, BMI at baseline was a significant predictor of both physical and mental QoL at 3 years ($b_{PCS}$=-0.5, p=0.001; $b_{MCS}$=-0.3, p=0.004). Change in BMI between baseline and one year was not related to PCS or MCS at three years ($b_{PCS}$=0.5, p=0.11; $b_{MCS}$=0.2, p=0.58).

**Conclusions:** Obesity is prevalent at the onset of disease in rheumatoid arthritis and, on average, patients gain weight over time. BMI at baseline is a predictor of poor long terms physical and mental QoL. Tailoring self-management interventions to account for obesity may help to improve long term outcomes.

## THU0077 INSUFFICIENT CARDIOVASCULAR TREATMENT IS A MAJOR RISK FACTOR FOR STROKE IN RA PATIENTS: A MATCHED CASE CONTROL STUDY FROM THE GERMAN BIOLOGICS REGISTER RABBIT

Y. Meissner[1], A. Richter[1], J. Kekow[2], H.-P. Tony[3], E. Wilden[4], A. Zink[1,5], J. Listing[1], A. Strangfeld[1]. *[1]German Rheumatism Research Center, Berlin; [2]Scientific Board, Vogelsang-Gommern; [3]Universitätsklinikum, Würzburg; [4]Rheumatologist, Köln; [5]Charité Universitätsmedizin, Berlin, Germany*

**Background:** Patients with rheumatoid arthritis (RA) are at increased risk for stroke. The particular impact of RA and its treatment in addition to known risk factors is not clear.

**Objectives:** To examine the impact of RA on the risk of stroke taking risk factors of cardiovascular disease (CVD) and age into account.

**Methods:** We performed a nested case-control study within the prospectively observed cohort of the German biologics register RABBIT. Since May 2001, RA patients are enrolled at start of a conventional synthetic (cs)DMARD or biologic (b)DMARD after ≥1 csDMARD failure. Rheumatologists report clinical characteristics, RA treatment, comorbidities and the respective therapy in a standardized manner. We considered all non-haemorrhagic strokes reported until April 2015 as cases. Two control patients, also observed in RABBIT, were matched to each case by an extensive algorithm [1] using sex, age, enrolment period, smoking status, body mass index and comorbidities at baseline (hypertension, heart failure, coronary disease or prior cerebrovascular event, diabetes). 16 cases could not be matched to a control. A multivariable Cox proportional hazard model with a random component (shared frailty model) was applied to address the matched design. Missing data were considered by multiple imputations.

**Results:** The matching algorithm generated utmost agreement of cases and controls in baseline characteristics (Table 1). Compared to the remaining cohort, cases and controls were older and had more CVD. Similarity between cases and controls was also found regarding the treatment of comorbid osteoporosis and diabetes whereas the treatment of CVD was significantly different. This significant difference was confirmed in multivariable analysis. Compared to patients without prevalent CV comorbidities, patients with treated CVD had a moderately elevated risk for stroke (hazard ratio (HR): 1.44 [95% CI: 0.72, 2.89]), whereas patients with untreated CVD had a highly increased risk (HR: 4.27 [2.04, 8.94]. Hospitalization for a serious adverse event within six months before stroke (correspondent index date in controls) and time-varying log-transformed C-reactive protein were further predictors for stroke (HR: 2.42 [1.46, 4.02] and 1.25 [1.06, 1.47]). Treatment with TNF inhibitors or other bDMARDs was not associated with the development of stroke (HR: 0.86 [0.56, 1.31] and 1.04 [0.61, 1.75], Reference: csDMARDs).

Table 1: Baseline characteristics of patients in the cohort, cases and their matched controls

| Parameter | Cohort | Cases | Controls | Matching |
|---|---|---|---|---|
| N | 11557 | 148 | 296 | 1:2 |
| Age, years (SD) | 55.9 (12.5) | 63.4 (10.9) | 63.4 (10.6) | X |

| CVD w/o treatment | 1037/4780 (21.7%) | 31/90 (34.4%) | 25/169 (14.8%) | |
| TNFi at baseline | 5857 (51%) | 77 (53.5%) | 153 (52%) | |
| Other bDMARDs at baseline | 1851 (16.1%) | 27 (18.8%) | 39 (13.3%) | |

Abbreviations: CVD, cardiovascular disease; w/o, without.

**Conclusions:** Within a strictly matched design providing the same baseline risk for stroke in cases and controls, we found that higher inflammation levels during follow-up and hospitalization were associated with a higher risk for the development of stroke. However, underlying CVD which is not medically treated was found to be the strongest risk factor for a future stroke in the RABBIT cohort. These results strengthen the need for a better CVD management in RA patients.

**Disclosure:** RABBIT is supported by a joint, unconditional grant from AbbVie, Bristol-Myers Squibb, Celltrion, Hospira, MSD Sharp&Dohme, Pfizer, Roche, and UCB.

## THU0078 MODERATE ALCOHOL CONSUMPTION IS NOT ASSOCIATED WITH SERUM LIVER ABNORMALITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS TAKING METHOTREXATE: DATA FROM THE CLINICAL PRACTICE RESEARCH DATABASE (CPRD)

J.H. Humphreys, A. Warner, S. Verstappen, M. Lunt, W. Dixon. *Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom*

**Background:** Methotrexate (MTX) is the most commonly prescribed disease modifying anti-rheumatic drug in the treatment of rheumatoid arthritis (RA). Patients taking MTX are advised to restrict their alcohol consumption because of a theoretical hepatotoxic interaction between alcohol and MTX. However data are limited to support this advice.

**Objectives:** To quantify the association between alcohol consumption and abnormal serum liver function tests (LFTs) in patients with RA taking MTX, using routinely collected clinical data.

**Methods:** Patients with RA in the Clinical Practice Research Database (CPRD) starting MTX between 1987 and 2011 were studied. Patients were included if they had alcohol consumption details recorded in CPRD and ≥6 LFTs per year, indicating adequate monitoring. Patients were grouped by reported weekly alcohol consumption. Crude rates of abnormal LFTs (defined as alanine transaminase or aspartate aminotransferase level ≥3 times the upper limit of normal) per 1000 person-years follow up were calculated. Cox proportional hazards models described the association between alcohol consumed and development of abnormal LFTs whilst taking MTX univariately, then adjusting for age and gender. Patients were censored at time of first abnormal LFT, death or the end of follow up (31/12/2011).

**Results:** 8801 patients were included in the study, 6285 (71%) female, mean age (SD) was 58 (14) years. There were 241 abnormal LFTs in 38000 person-years follow up. There was no difference in rates of abnormal LFTs between drinkers and non-drinkers, adjusted hazard ratio (HR) (95% confidence interval (CI)) 1.12 (0.82–1.51). Crude rates of abnormal LFTs appeared to increase with increasing levels alcohol consumption (table 1); similarly when treated as a continuous variable, each increased unit of alcohol consumed was associated with a higher risk of abnormal LFTs, adjusted HR (95%CI) 1.01 (1.00–1.02). In the adjusted Cox model, moderate alcohol consumption (≤14 units per week) was not associated with a statistically significant risk of developing abnormal LFTs (table 1). There was a non-significant trend to higher HR with higher levels of alcohol consumption, however power was limited in the patients consuming >14 units per week.

| Units of alcohol per week | Number of events[§†] | Crude rate (95% CI) Per 1000 person years | Hazard ratio (95% CI) Univariate | Hazard ratio (95% CI) Age & gender adjusted |
|---|---|---|---|---|
| 0 | 24 | 5.58 (3.74–8.33) | ref | ref |
| 1–7 | 83 | 5.57 (4.49–6.91) | 1.01 (064–1.58) | 1.02 (0.65–1.60) |
| 8–14 | 23 | 5.99 (3.98–9.01) | 1.07 (0.60–1.89) | 1.15 (0.65–2.06) |
| 15–21 | 11 | 7.58 (4.20–13.68) | 1.36 (0.67–2.78) | 1.59 (0.76–3.30) |
| 21–28 | 3 | 8.61 (2.78–26.70) | 1.51 (0.46–5.03) | 1.91 (0.56–6.47) |
| >28 | 6 | 9.05 (4.07–20.15) | 1.60 (0.66–3.92) | 1.92 (0.76–4.89) |

[§]Event=abnormal LFT. [†]Not all patients who were defined as drinkers/non-drinkers had alcohol consumption defined in units.

**Conclusions:** In patients with RA taking MTX, increasing alcohol consumption is associated with an increased risk of developing abnormal LFTs. The clinical importance of this increased risk may be small when drinking ≤14 units per week.

**Disclosure of Interest:** None declared

## THU0079 HDL, IGG ANTI-HDL ANTIBODIES AND PON1 AXIS IN RHEUMATOID ARTHRITIS PATIENTS: A NEW TARGET FOR CV DISEASE

J. Rodríguez-Carrio[1], R. López-Mejías[2], M. Alperi-López[3], P. López[1], F.J. Ballina-García[3], M.Á. González-Gay[2,4], A. Suárez[1]. *[1]Area of Immunology, University of Oviedo, Oviedo; [2]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, Hospital Universitario Marqués de Valdecilla - IDIVAL, Santander; [3]Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo; [4]Health Research Institute of Santiago de Compostela (IDIS), Division of Rheumatology, Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, Spain*

**Background:** High Density Lipoproteins (HDL) seem to develop cardioprotective functions beyond the reverse cholesterol transport, thus pointing to their antioxidant activity as a crucial player. Paraoxonase 1 (PON1) is a HDL-associated antioxidant enzyme which has an important role in avoiding lipid oxidization. Although genetic polymorphisms are known to modulate PON1 activity, its involvement in cardiovascular disease (CVD) in Rheumatoid Arthritis (RA) is controversial, suggesting that other factors may modulate its function.
**Objectives:** since anti-HDL antibodies have been related to an impaired lipid profile and CVD in RA, we aimed to evaluate the associations between PON1 activity, anti-HDL antibodies and CVD in RA according to PON1 rs662 genetic variants.
**Methods:** serum PON1 activity, using paraoxon as substrate, and IgG anti-HDL antibodies were quantified in 212 RA patients and 110 healthy controls (HC). The PON1 rs662 genotype (Q>R) was determined with TaqMan probes. An additional group of 13 biologic-naïve RA patients was prospectively followed for three months.
**Results:** PON1 activity was decreased in RA compared to HC (p=0.005). PON1 rs662 variants influenced serum PON1 activity in both groups, QQ homozygotes exhibiting the lowest activity. Distribution of genotypes did not differ between groups (p=0.215) and Hardy-Weinberg equilibrium was observed in both populations. Interestingly, PON1 activity was not associated with disease activity, ESR or CRP. A multivariate ANOVA analysis confirmed an independent role of both rs662 ($p<0.0001$) and anti-HDL antibodies (p=0.026) on PON1 activity, but differences were noted when patients were stratified by genotypes. Anti-HDL antibodies were associated with an impaired PON1 activity (p=0.010), decreasing HDL levels (r=-0.680, $p<0.001$) and higher prevalence of CV events in univariate and multivariate models in patients carrying the QQ genotype, but not in their QR or RR counterparts. Finally, change in anti-HDL antibodies upon TNFα-blockade independently predicted improved PON1 activity (B [95% CI], p: -0.369 [-0.669, -0.069], p=0.024) after adjusting by clinical response, change in ESR and change in HDL levels.
**Conclusions:** PON1 activity is impaired in RA in association with rs662 status and anti-HDL antibodies. The presence of anti-HDL antibodies in patients with the low activity genotype was correlated with a decreased PON1 function and associated with a higher prevalence of CV events in these patients. Therefore, anti-HDL antibodies are crucial mediators to understand the link between rs662 polymorphism and CVD.

## THU0080 LIPID TESTING AND MANAGEMENT AMONG RHEUMATOID ARTHRITIS PATIENTS COMPARED TO PATIENTS WITH DIABETES AND THE GENERAL POPULATION

I. Navarro-Millan[1], S. Yang[1], L. Chen[1], M.M. Safford[2], H. Yun[3], J. Zhang[3], P. Muntner[3], K. Saag[1], J.R. Curtis[1]. *[1]Rheumatology, University of Alabama at Birmingham, Birmingham; [2]Internal Medicine, Weill Cornell Medical Center, New York; [3]Epidemiology, University of Alabama at Birmingham, Birmingham, United States*

**Background:** Patients with rheumatoid arthritis (RA) have high coronary heart disease (CHD) burden. Limited data suggest that these patients may be screened less frequently than other patients with similar CHD risk.
**Objectives:** To evaluate the rate of lipid testing and management among RA patients and compare it both to the general population and diabetes (DM) patients.
**Methods:** We used a mix of private and public health plans claims data from 2006 to 2010 with medical and pharmacy coverage. Eligible participants were required to 1) have at least 12 months of continuous medical and pharmacy coverage (baseline period), and 2) have 2+ physician diagnosis and relevant medications to categorize them as having 1) RA and DM; 2) RA only; 3) DM only; 4) Neither RA nor DM. Patients with prevalent myocardial infarction (MI)/stroke/CHD during baseline were excluded. We calculated the proportion of patients with low density lipoprotein (LDL) lab test. In a subgroup analysis, we determined the proportion of patients with lab results available with LDL ≥130 mg/dL that initiated treatment with statins. We use chi-square tests to compare differences between the 4 cohorts in the proportion tested for LDL and initiating statins.
**Results:** There were 428,109 eligible patients distributed between the 4 cohorts (Table). Overall, 60% were women. The overall age distribution was: 12% ≤40; 29%, 41–65; and 59% >65 years old. RA patients were less frequently tested for LDL compared to DM patients, with or without RA (p-value <0.001 for all comparisons). Conditional on having LDL ≥130 mg/dL, RA patients were less likely to be started on a statin compared to DM patients (p-value <0.001), and were marginally more likely to be initiated on statins compared to the general population (p-value =0.045). There was no difference in the statin prescription trend after an LDL ≥130 mg/dL between DM and RA patients compared to only RA patients (p-value =0.083)

Table 1. Frequency of lipid testing among patients with rheumatoid arthritis, diabetes, both or neither condition

| Outcome | RA Only N=20,148 | Diab Only N=100,971 | RA & Diab N=3,358 | Neither N=303,632 |
|---|---|---|---|---|
| Screening: LDL checked during 2-year period, % | 46 | 63 | 62 | 45 |
| Treatment: statin initiation (among subgroup of patients with lab results available and LDL ≥130 mg/dL not already on therapy), % | 13 | 26 | 28 | 9 |

**Conclusions:** RA patients are less frequently screened and managed for hyperlipidemia compared DM patients. Despite higher CHD risks in RA patients, hyperlipidemia screening and treatment rates in RA patients were no better than the general population. Further studies to investigate the reasons and potential interventions to ameliorate this care gap among RA patients are needed.
**Disclosure of Interest:** None declared

## THU0081 ROLE OF THE SOLUBLE FORM OF DIPEPTYDIL PEPTIDASE-4(DPP4) IN THE INSULIN RESISTANCE OF PATIENTS WITH RHEUMATOID ARTHRITIS

B. Tejera Segura[1], A. de Vera González[2], R. Lopez Mejías[3], B. Ubilla[3], F. Genre[3], J. Olmos[4], J. Hernández[4], J. Llorca[5], M. González-Gay[6], I. Ferraz-Amaro[1]. *[1]Division of Rheumatology; [2]Central Laboratory Division, Hospital Universitario de Canarias, Santa Cruz de Tenerife; [3]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division; [4]Division of Internal Medicine, Hospital Universitario Marqués de Valdecilla, IDIVAL; [5]Division of Epidemiology and Computational Biology, Facultad de Medicina, Universidad de Cantabria y CIBER Epidemiología y Salud Pública (CIBERESP); [6]Division of Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*

**Background:** Dipeptidyl peptidase 4 (DPP-4) is an enzyme which plays a fundamental role on glucose homeostasis through degradation of the incretine hormones glucagon like peptide 1 and gastric inhibitory polypeptide.
**Objectives:** To analyze if DPP-4 levels differ between Rheumatoid arthritis (RA) patients and healthy controls, as well as to investigate if they correlate with the insulin resistance (IR) that RA patients express.
**Methods:** 406 subjects, 178 patients with RA and 228 controls adjusted by age and sex, were selected. We determined in both groups glucose, insulin and C peptide levels, *Homeostatic Model Assessment* (HOMA2) index for insulin and C peptide, and blood levels of the soluble form of DPP-4. We studied with multivariant analysis adjusted for the intake of steroids and other classic factors associated with IR, the differences between patients and controls as well as the correlation of DPP-4 with the activity of the disease and with IR in both groups.
**Results:** Patients had higher levels of insulin (16±26 vs 10±7 microU/mL, p=0,001) and C peptide (1,15±1,02 vs 0,50±0,26 nmol/L, $p<0,001$) compared to controls. Equivalently, insulin resistance index HOMA-IR (1,81±1,82 vs 1,35±0,93, p=0,002) and HOMA2-IR-peptide C (2,59±2,45 vs 1,10±0,55 nmol/L, $p<0,001$) were higher in patients with RA. DPP-4 levels were lower in patients with RA than controls (beta coef. -162 [-259–65] ng/ml, p=0.001), after adjustment for age, sex, body mass index and classic factors for IR. Patients with high or moderate activity (633±270 vs 844±757 ng/ml, p=0.06) and low activity (761±340 vs 844±756 ng/ml, p=0.40) had a lower expression of DPP-4 levels compared to those patients in remission, although this difference did not reach statistical significance.
**Conclusions:** Patients with RA express lower levels of DPP-4. This decrease could be explained by the activity of the disease and could play a role in the development of insulin resistance that RA patients express.
**Disclosure of Interest:** None declared

## THU0082 MEDICATION IMPACT ON THE RISK OF INCIDENT DIABETES MELLITUS IN PATIENTS WITH RHEUMATOID ARTHRITIS: HYDROXYCHLOROQUINE AND ABATACEPT PROTECT WHILE GLUCOCORTICOIDS AND STATINS WORSEN

G. Ozen[1,2], S. Pedro[3], M. Holmqvist[4], K. Michaud[1,3]. *[1]University of Nebraska Medical Center, Omaha, United States; [2]Marmara University Faculty of Medicine, Istanbul, Turkey; [3]National Data Bank for Rheumatic Diseases, Wichita, United States; [4]Karolinska Institute, Stockholm, Sweden*

**Background:** Chronic inflammation and some anti-inflammatory medications in rheumatoid arthritis (RA) are not only responsible for accelerated atherosclerosis but also have effects on the development of traditional risk factors, among which type 2 diabetes mellitus (DM) is the most important. Although hydroxychloroquine

(HCQ) and TNF inhibitors have been reported to decrease incident DM risk in RA, there are still a number of unanswered questions regarding the impact of newer biologics, statins, and the timing, dosing, and sustainability of this effect.
**Objectives:** To investigate the impact of specific DMARDs and statins on the risk of incident DM in patients with RA.
**Methods:** Study patients were participants without baseline DM and at least 1 year in the National Data Bank for Rheumatic Diseases (NDB) from 2000 through 2015. DM was determined by patient self-report or use of DM-specific medication. Multivariable Cox proportional hazard models were adjusted for age, sex, ethnicity, socioeconomic and smoking status, comorbidities, body mass index (BMI), and RA severity while examining the time-dependent association of HCQ, other DMARDs, glucocorticoids (GC), and statins.
**Results:** During the 71,668 person-year followup of 13,669 RA patients, 1,139 developed DM. Adjusted HR (95% CI) for DM were 0.67 (0.57–0.80) for HCQ, 0.52 (0.31–0.89) for abatacept, 1.31 (1.15–1.49) for GC, and 1.56 (1.36–1.78) for statins *(Table)*. There was no evidence of risk change through MTX, other synthetic and biological DMARDs. Although the risk reduction was significantly associated with higher HCQ doses and longer (>4 years) treatment durations, HCQ dose of <400mg/day, HR 0.71 (0.52–0.96), and ≥2-year duration, HR 0.72 (0.56–0.91), were also protective. DM-free survival of the patients who discontinued HCQ were quite similar to the patients who started HCQ and kept receiving the drug. Concomitant use of GC did not adversely affect the protective effect of HCQ, HR 0.69 (0.51–0.93). However, there was significant increased risk with statins and GC, HR 2.03 (1.65–2.50). In concomitant use of HCQ and statins, the protective effect of HCQ and increased risk with statins disappeared, HR 0.92 (0.68, 1.25).

Table 1. Association of different treatments with incidence of DM in RA patients

| Time-dependent treatment | Unadjusted HR (95% CI) | *P*-value | Adjusted HR* (95% CI) | *P*-value |
|---|---|---|---|---|
| HCQ | 0.66 (0.55–0.78) | <0.001 | 0.67 (0.57–0.80) | <0.001 |
| Glucocorticoid | 1.43 (1.26–1.61) | <0.001 | 1.31 (1.15–1.49) | <0.001 |
| Statin | 1.73 (1.52–1.97) | <0.001 | 1.56 (1.36–1.78) | <0.001 |
| Concomitant synthetic or biologic DMARDs | | | | |
| MTX alone (referent) | 1.0 | | 1.0 | |
| Any abatacept | 0.82 (0.52–1.29) | 0.39 | 0.52 (0.31–0.89) | 0.02 |
| Any other combination with MTX | 0.98 (0.82–1.18) | 0.88 | 0.87 (0.72–1.05) | 0.15 |
| Other or no DMARDs | 1.36 (1.17–1.58) | <0.001 | 1.11 (1.36–1.78) | 0.19 |

*Adjusted for age, age$^2$, sex, disease duration, employment, income, ethnicity, smoking, hypertension, comorbidity index, BMI, HAQ, NSAID usage, and year of entry.

**Conclusions:** The risk of incident DM in RA was reduced with HCQ and abatacept and increased with GC and statins. HCQ not only confers a sustainable, dose and treatment duration-dependent protective effect but also abolishes the increased risk of DM as a consequence of GC or statins.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4201

## THU0083 SIMPLIFIED PATIENT-DERIVED DISEASE ACTIVITY SCORE (SPDAS2): A SIMPLIFIED VERSION WITHOUT EARLY MORNING STIFFNESS

E. Choy[1], A.M.H. Leung[2]. *[1]CREATE Centre, Section of Rheumatology, Institute of Infection and Immunity, Cardiff University, Cardiff, United Kingdom; [2]Dept. of Rheumatology, Queen Elizabeth Hosptial, Hong Kong, Hong Kong*

**Background:** Treat-to-target is the standard of care in rheumatoid arthritis (RA). Integral to this is the regular assessment of disease activity. Several tools have been developed and validated to allow patients with RA to self-assess disease activity. One of these tools is the Patient-derived Disease Activity Score (PDAS). Two versions pf PDAS are available: PDAS1 and PDAS2. PDAS-2 is a composite score that includes patient global assessment of disease activity (PGA), modified health assessment questionnaire (MHAQ), patient self-assessed 28 swollen joint count (ptSJC28) and early morning stiffness score (EMS). PDAS2 correlated with DAS28ESR and Clinical Disease Activity Index (CDAI).
**Objectives:** In order to reduce patient burden, we developed a simplified PDAS2 (sPDAS2) by removing the need to assess EMS.
**Methods:** Data from 311 patients with established RA were analysed. The original model for calculating PDAS2 was: PDAS2 = 2.667 + [(0.021 x PGA) + (0.483 x MHAQ) + (0.033 x patient 28 SJC) + (0.002 x EMS)]. Linear regression was used to develop a sPAS2 using DAS28ESR as a dependent variable and including PGA, MHAQ and ptSJC28. R-squares were used to examine the statistical model fit of sPDAS2 compared with PDAS2. sPDAS2 was further validated using data from a different cohort of 204 patients with established RA. Correlation of sPDAS-2 with DAS28 and CDAI was examined to assess criterion and construct validity.
**Results:** Based on data from 311 patients with RA. The following model for sPDAS2 was developed: sPDAS2 =2.447 + 0.028 x PGA + 0.422 x HAQ + 0.053 x patients 28SJC.
The R-square for PDAS2 (including EMS) was 0.601. R-square for sPDAS (without the EMS) was 0.594. A difference of 0.007 indicating minimal loss of statistical fit.
Using data from a different cohort of RA patients. sPDAS2 correlated well with DAS28ESR (r=0.72, p<0.001) and CDAI (r=0.74, p<0.001) demonstrating criterion and construct validity.
**Conclusions:** A sPDAS2 has been developed and validated for patients with RA to self-assess disease activity. The components of sPDAS2 included PGA, mHAQ and ptSJC28 and do not require assessment of early morning stiffness.
**Acknowledgement:** The original developed of PDAS was supported by a grant from Arthritis Research UK. The CREATE Centre is funded by Arthritis Research UK and Health and Care Research Wales.

## THU0084 TREATMENT RESPONSE IN PATIENTS WITH SIMULTANEOUS THYROID DISEASE AND RHEUMATOID ARTHRITIS IS SIGNIFICANTLY WORSE THAN PATIENTS WITH ISOLATED RHEUMATOID ARTHRITIS

A. Emamifar, I.M.J. Hansen. *Rheumatology, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory polyarthritis with a prevalence of 0.5–1% of general population.[1] Various comorbidities can complicate the course of the disease and have direct effects on the long-term prognosis and management of RA.[2] Previous studies showed that there is an increased prevalence of thyroid disease (TD) among RA patients, probably due to autoimmunity; however the association of RA disease characteristic and TD has not been evaluated before.[3]
**Objectives:** To determine the association between TD and RA and reveal the prevalence of TD among RA patients.
**Methods:** All patients diagnosed with RA since 1st of January 2010 were included in this cross sectional study. Patients' demographic data (age, sex, year of diagnosis), serology test results including rheumatoid factor (RF), anti-cyclic citrullinated peptide antibody (anti-ccp) and antinuclear antibody (ANA) as well as disease activity score in 28 joints (DAS28) at the time of diagnosis and after 4 months (±1–2 months) of treatment were extracted in December 2015. Patients' previous medical history as well as medications and laboratory tests were evaluated to find out if the patients have been diagnosed with thyroid disease as well. Patients with subclinical thyroid diseases were also considered to perform statistical analysis. Chi-square test and t-test were used to compare different variables in patients with/without TD.
**Results:** Of 439 included patients 60.14% were female. The mean of age and disease duration were 64.64±15.03 and 2.59±1.66 years respectively. Prevalence of TD was 69/439 (15.7%). The mean of ∆DAS28 in patients with simultaneous TD and RA was 1.0±1.4 and in patients with isolated RA 1.5±1.4 (P<0.05). The results of our study showed that presence of TD among RA patients is associated with female gender (P<0.001), ANA positivity (P<0.05) and anti-ccp ≥100 AU/ml (P=0.05). Furthermore, coexistence of TD and RA resulted in poor response to treatment (P<0.05). We did not find any association between TD and disease duration as well as RF positivity.
**Conclusions:** Considering the higher prevalence of TD among RA patients in comparison with general population, we recommend the routine measurement of thyroid stimulating hormone to detect TD at an earlier stage, leading to earlier treatment initiation and improve prognosis.

## THU0085 LEVEL OF CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS WITH SUBCLINICAL HYPOTHYROID DYSFUNCTION

A. Knyazeva, B. Rebrov, E. Komarova, A. Blagodarenko. *Internal Medcine, SI "Lugansk State Medical University", Lugansk, Ukraine*

**Background:** Patients with rheumatoid arthritis (RA) with subclinical hypothyroid dysfunction (SHTD) have early mortality due to cardiovascular complications. There for it is necessary to study this problem. Investigation of the SHTD effect on RA in these patients will help to define the prognosis and optimize the efficiency of integrated diagnostic and therapeutic tactics.
**Objectives:** To determine the cardiovascular risk (CVR) level in RA patients with SHTD
**Methods:** 98 patients with RA were examined. All the patients were divided into 2 groups. Group I – 59 (60,2%) patients with RA and SHTD, the second – 39 (39.8%) patients with RA without SHTD. Thyroid gland condition was determined according to international standards of SHTD diagnosis. All subjects were female. Patients in group I and II have not differed by age and RA duration. All patients

underwent clinical and functional investigation for RA diagnosis. Blood levels of total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol cholesterol (LDL-C), very low density lipoproteins (VLDL) and atherogenic index (AI) were assessed. All patients underwent ultrasound detection of vascular endothelial dysfunction. CVR is calculated by Score scale. The results were multiplied by 1,5 factor according to the latest European guidelines for CVR in RA patients. The CVR level was also evaluated by Procam scale.

**Results:** CVR factors were significantly higher in the group I, than in group II (respectively 91.7%, 69.6%). Family history of cardiovascular disease was observed in 48.1% of patients I and 35.1% II group, higher BMI – respectively at 88.8% and 27.02% ($p<0.001$), dyslipidemia – at 79.6% and 43.2% ($p<0.001$), increased blood pressure – at 62.9% and 37.8% (p=0,003), menopause – at 57.4% and 24.3% ($p<0.001$). The total risk of cardiovascular death by Score scale in group I patients was 5.7%, in II – 3.2%, and by Procam scale in I – 18.5%, in II – 13.7%, it is significantly different ($p<0.001$).

Parameters of lipid profile in group I compared with group II showed a significant increase of all investigated indices $p<0.001$, except for level of HDL cholesterol. In the study of endothelial function in both groups of patients the decrease of endothelium-dependent vasodilation (EDVD) and endothelium-independent vasodilation (EIVD) from standard indicators (EDVD brachial artery is (BA) greater or equal to 10%, and EIVD BA is more than 15%) was found. The average thickness of the complex intima-media (CIM) in patients of group I was 1.11±0.058 mm, and the II – 0.71±0.072 mm (p=0.009), which got statistical significance. Correlations between CIM and total cholesterol levels (r=0.297, p=0.021), LDL cholesterol (r=0.36, p=0.005), AI (r=0.335, p=0.008) in group I patients; and correlations between CIM and the level of LDL cholesterol (r=0.301, p=0.18) and AI (r=0.268, p=0.024) in patients of group II were defined.

**Conclusions:** The results show more significant changes of lipid profile and endothelial function indices in RA patients with concomitant SHTD, increasing CVR in these patients. This raises the need for physicians to pay more attention to thorough survey of RA patients for early diagnosis and correction of comorbid conditions, aggravating RA course

## THU0086 AN AUDIT ON RHEUMATOID ARTHRITIS PATIENTS WITH LUNG DISEASE ON METHOTREXATE AT A DISTRICT GENERAL HOSPITAL

A. Nugaliyadde, G. Kasavkar, M.A. Yusuf, A. Nandagudi. *Rheumatology, Basildon and Thurrock University Hospital, Basildon, United Kingdom*

**Background:** Interstitial lung disease (ILD) is associated with Rheumatoid arthritis (RA) in 3.7% - 7.7% of patients.[1] Methotrexate induced pneumonitis is a rare and unpredictable toxicity leading to withdrawal of treatment in 1:108 patient years.[2] British Society of Rheumatology (BSR) guidelines for pre- methotrexate treatment screening include chest x-ray and in certain cases pulmonary function tests and high resolution CT scan (HRCT). It is also recommended that methotrexate is best avoided in established cases of interstitial lung disease.[3]

**Objectives:** The aim of our audit was to check compliance with BSR guidelines.

**Methods:** We have conducted a retrospective audit on 40 RA patients treated with methotrexate with preferential selection of patients with lung disease. We looked at their records to obtain details of screening chest investigations and also any subsequent chest investigations carried out and the reasons prompting the investigations and the actions taken.

**Results:** Our cohort included patients with the median age of 63 years (Range 25 -87). There was an equal gender distribution. 80% of the patients were seropositive. Patients had pre-existing lung disease in 20% of which 50% had COPD, 25% Fibrosis, 25% benign pathology. A screening chest X-ray was performed in 97.5% of the patients with 31% being reported as abnormal. Fifty eight percent of the patients with abnormal chest x ray were symptomatic with shortness of breath (SOB) (86%) followed by cough. All these patients had subsequent HRCT revealing ILD in 57%, combination of emphysema and fibrosis in 29% and pneumonitis in 14%. All these patients were subsequently referred to a respiratory physician and methotrexate was withdrawn.

Fifty five percent of the patients with normal chest x-ray at screening subsequently developed chest symptoms (SOB (53%) and cough (34%)). Sixty seven percent of these patients had abnormal chest x rays. HRCT was requested in 80% of these patients revealing ILD in 47%. One symptomatic patient was found to have lung cancer. All of the ILD patients were subsequently referred to a respiratory physician and methotrexate was withdrawn.

The duration of methotrexate to onset of symptoms and withdrawal varied from 14 months to 12 years.

**Conclusions:** Appropriate pre-treatment screening for lung disease was performed in all patients commencing methotrexate. All patients with established ILD had methotrexate withdrawn. There is evidence for continuing methotrexate in RA patients who develop ILD with careful monitoring. However currently there are no guidelines concerning continuation or withdrawal of methotrexate in patients who develop ILD during the course of treatment.

## THU0087 SUBCLINICAL CAROTID ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS: ROLE OF SERUM CATHEPSIN S AND CYSTATIN C

B. Tejera Segura[1], A. De Vera González[2], M. González-Gay[3], I. Ferraz-Amaro[1]. *[1]Division of Rheumatology; [2]Central Laboratory Division, Hospital Universitario de Canarias, Tenerife; [3]Division of Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*

**Background:** Although Cystatin C relation with atherosclerosis has been studied before in RA patients, cathepsin S association with subclinical atherosclerosis has not been previously considered in RA patients. This could help to better stratify or predict the development of cardiovascular diseases in RA.

**Objectives:** To assess if serum cathepsin S and cystatin C, two novel markers of cardiovascular disease risk (CVDR), are associated with subclinical carotid atherosclerosis in RA patients.

**Methods:** Serum cystatin C and cathepsin S levels, carotid intima-media thickness (cIMT) and carotid plaques were assessed in a cross-sectional study involving 178 RA patients. All of them were 18 years or older and fulfilled the 2010 ACR/EULAR classification criteria.

**Results:** Patients with a mean ± SD age of 55 ± 11 years were included. Regarding cardiovascular risk factors, 35% of the patients had hypertension, 32% dyslipidemia and 15% diabetes. Disease duration was 7 (IQR 4–15) years. Patients had moderate-active disease as shown by DAS28 (3.74 ± 1.91). One third (35%) of them were taking prednisone, 86% were under disease-modifying antirheumatic drugs and 22% were taking anti-TNF-alpha or other biologic therapies. The mean cIMT was 0.670 ± 0.143 mm, and 66 patients (37%) had carotid plaques in the carotid ultrasound assessment. Both cystatin C and cathepsin S were significantly associated with hypertension, diabetes and dyslipidemia. However, neither positive rheumatoid factor nor prednisone use were associated with cystatin C or cathepsin S. A trend for lower levels of cystatin C was observed in patients undergoing anti-TNF-alpha therapy (*log* beta coef. -0.20 (-0.44–0.04), p=0.09). An association between disease activity scores with higher levels of cystatin C but not with cathepsin S was found. Cystatin C levels were also associated with cIMT in the subgroup of patients included in the higher quartile of cIMT (OR 1.31, 95%CI [1.00–1.72], p=0.04) after adjusting for traditional cardiovascular risk factors, age and sex. An association between serum cystatin C levels and carotid plaques was also found in the univariate analysis (OR 1.37, 95%CI [1.06–1.76], p=0.02). However, this significant association was lost after adjusting for traditional cardiovascular risk factors and age. Cathepsin S was not associated with cIMT or carotid plaques.

**Conclusions:** High cystatin C serum levels identify a subgroup of RA patients with high risk of subclinical atherosclerotic disease.

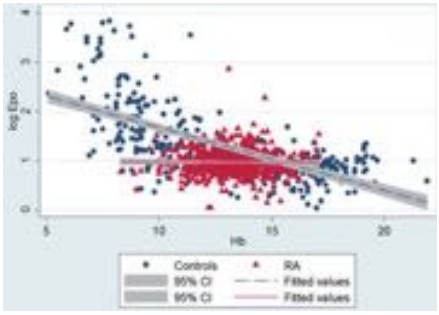
**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.1878

## THU0088 IRON DEFICIENCY AND LOW ERYTHROPOIETIN CONCENTRATIONS ARE FREQUENT ANEMIA CAUSING FACTORS IN RHEUMATOID ARTHRITIS

B. Möller[1], A.B. Leichtle[2], P. Meyer[3], M. Fiedler[2], A. Finckh[4], D. Kyburz[5], C. Gabay[4], P.M. Villiger[1]. *[1]Rheumatology, Immunology & Allergology; [2]Clinical Chemistry; [3]Rheumatology & Clinical Immunology, Inselspital - Bern University Hospital, Bern; [4]Rheumatology, University Hospitals of Geneva, Geneva; [5]Rheumatology, Basel University Hospital, Basel, Switzerland*

**Background:** Anemia was recently re-evaluated as a predicting parameter for radiographic joint damage progression in addition to standard disease activity measures in rheumatoid arthritis (RA) [1].



**Objectives:** To characterize the origin of anemia in RA.

**Methods:** All patients in the Swiss SCQM-RA cohort with available hemoglobin concentrations and a biobank sample were included. Anemia was defined according to WHO definitions (hemoglobin <12g/dl in women and <13 g/dl in men). Mean corpuscular volume (MCV) and hemoglobin (MCH) were locally acquired. Serum samples were collected and stored according to stringent pre-analytical quality requirements. Serum iron, transferrin, ferritin, soluble transferrin receptor (sTfR) and erythropoietin (EPO) concentrations were measured using standard procedures in an accredited central laboratory. Non-RA patients with normal CRP served as control for logEPO/Hb quotient interpretation. Iron deficiency anemia (IDA) was defined according to [2] in case of 1. t-sat ≤20% & ferritin ≤30 μg/l or 2. sTfR index, the quotient of sTfR divided by log-transformed ferritin concentrations ≥1mg/μg. Anemia of chronic disorders (ACD)

was diagnosed by signs of inflammation plus 1. T-sat ≤20% & ferritin ≥100 μg/ml or 2. sTfR index <1mg/μg & ferritin ≥30 μg/l. Serum hepcidin-25 was quantified using commercially available ELISA kits from Peninsula Laboratory, LLC, San Carlos, CA.

**Results:** 106 (14%) of the 779 patients included were anemic at the time of sample collection. Anemic patients were significantly older, had more comorbidities, higher DAS-28 and used more often corticosteroids, but did not differ in NSAID, conventional (75%) or biological (70%) DMARD use. They had lower MCV, lower MCH and lower transferrin levels ($p<0.04$) than non-anemic patients, but other serum parameters were not significantly different. sTfR was more sensitive than transferrin concentrations to detect possible iron deficiency (14% versus 1%).

IDA was detected in 98 (92%) of the 106 anemic patients. ACD was diagnosed in 61 (58%) of the anemic cases, when active disease was defined by CRP >10 mg/l or ESR >30 mm/h, or in 82 (77%) of subjects after including DAS-28 >3.2 as additional marker of inflammation. Only 3 respectively 6 cases could be attributed to ACD alone, while 58 (55%) respectively 76 (72%) of anemia cases had ACD and IDA in combination, dependent of the definition of inflammation. In a multivariate linear regression analysis ($r^2=0.38$, n=1075, $p<0.0001$), logEPO concentrations depended on hemoglobin concentrations (-0.1, 95%CI -0.11 to -0.09, $p<0.0001$), which increased significantly less in RA (-0.29, 95%CI -0.34 to -0.24, $p<0.001$) with decreasing hemoglobin concentrations than in controls.

**Conclusions:** Iron deficiency was the most common cause of anemia in this large RA cohort with representative prevalence of anemia for an intensively treated RA population. We further found inadequately low EPO levels in relation to observed hemoglobin concentrations among RA patients, which may further contribute to anemia in these patients. Their relation to radiographic damage progression needs to be determined.

## THU0089 RHEUMATOID ARTHRITIS AND PERIODONTAL DISEASE IN ALGERIAN PEOPLE

C. Dahou[1], F. Mechid[1], S. Salah[1], M. Meddad[2], S. Merad[3]. *[1]Rheumatology Department CHU BEO BD Said Touati, Bab El Oued; [2]Stomatology, Mustapha Bacha Hospital; [3]Bacteriology, Dely Brahim, institut Pasteur, Alger, Algeria*

**Introduction:** Rheumatoid arthritis (RA) and periodontitis (PD) are two chronic inflammatory affections that share many similarities. Many studies report the increased frequency of periodontitis during rheumatoid arthritis. The porphyromonas gingivalis, periodontopathogenic bacterium plays a main role through peptidylarginine-deiminase an enzyme capable of citrullinating endogenous proteins and generates an autoimmune reaction.

**Objectives:** The aim of this study was to determine the prevalence of periodontitis during rheumatoid arthritis and its relationship with RA severity, treatment and patient characteristics.

**Methods:** This is a multicentre,cross-sectional, prospective study. Were included adults RA. We identified sociodemographic factors, the periodontal disease status and anaerobic germs, clinical activity of RA with the Disease activity score (DAS 28-VS), the Health Assessment Questionnaire (HAQ), extraarticular manifestations, Sharp Score and periodontal anaerobic bacteria. Were determined correlations between PD and patient characteristics, treatment and RA severity.

**Results:** a total of 204 RA were included. The mean age of the patients was 50.338±12.428 years. Sex-ratio: 0.13. The mean duration disease was 10.259±8.232 years. 43% of patients had extaarticular manifestations: 43%. The DAS vs-28 =4.615±1.440. HAQ =1.140±0.821.0. The ACPA rate was 229.855±241.902. Sharp mean: 112.995±93.965. 65.7% patients were treated by methotrexate. 32.8% by biological. 77, 4% patients were under corticoids. The periodontitis frequency was 37.3% (51.1% related to the porphyromonas gingivalis (PG). The tooth loss frequency was 31, 4%.the comparison of the subjects with periodontitis and patients without it showed no significant differences. the comparison of the patients with severe periodontitis and those without showed: age p=0.0004, menopause p=0.002, DAS p 0.47, Sharp p=0.06, HAQ p=0.95.

**Conclusions:** These results suggest a high prevalence of periodontitis during RA, PG is often responsible. The tooth loss frequency is also high. There is no correlation between periodontitis and RA severity and no relationship between PD and RA treatment. On the other hand periodontitis severity is related to the age and the menopause.

**Disclosure of Interest:** None declared

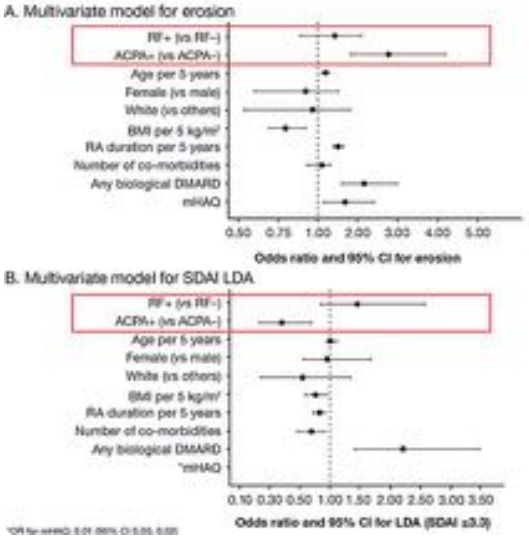
## THU0090 ASSOCIATION OF THE RHEUMATOID ARTHRITIS PROGNOSTIC FACTORS ANTI-CITRULLINATED PEPTIDE ANTIBODIES, RHEUMATOID FACTOR AND EROSIONS WITH DISEASE ACTIVITY AND WORK PRODUCTIVITY

E. Alemao[1], Z. Guo[1], C. Iannaccone[2], M. Frits[2], N. Shadick[2], M. Weinblatt[2]. *[1]Bristol-Myers Squibb, Princeton; [2]Brigham and Women's Hospital, Boston, United States*



**Background:** Autoantibody production, including RF and anti-citrullinated protein antibody (ACPA), may play a role in RA disease pathogenesis.[1] ACPA positivity(+) in patients (pts) with RA is a strong predictor of joint erosions and radiographic progression.[1,2] However, data evaluating the association of seropositive, erosive disease with disease activity and resource use (RU) are limited.

**Objectives:** To evaluate the association of ACPA+/RF+ with erosions and disease activity; to compare activity, RU and work productivity (WP) in ACPA+ pts with erosions vs all other RA pts.

**Methods:** Pts enrolled in the BRASS Registry were analysed. BRASS comprises mostly pts with established RA who were evaluated annually on clinical measures and semi-annually on clinical pt-reported outcomes and resource utilization parameters. Baseline (BL) visit was the time of enrolment into BRASS. ACPA levels at BL and annual follow-up were measured using a validated ELISA (Inova Diagnostics, San Diego, CA) until its discontinuation in 2011, and the Euro-Diagnostica assay (IBL-America, Minneapolis, MN) thereafter. RF levels at BL and follow-up were measured during the annual rheumatologist visit. RU and WP were measured at 6 months (M) via pt questionnaires. Subgroups at BL were described using Wilcoxon rank-sum test (continuous variables) and Pearson's chi-square test (categorical variables); multivariate logistic regression models (binary outcome variables) and ordinary least-square regression analysis (continuous outcome variables) were used. Covariates included in the multivariate models were age, sex, race, BMI, RA duration, number of co-morbidities and treatment.

**Results:** Among 1309 pts with ACPA data, 82% were female, mean (SD) age was 56.5 (14.1) yrs and DAS28(CRP) was 3.7 (1.6). Pts had mean (SD) TJC of 14.3 (14.0), ACPA levels of 128.3 (151.9) units/mL and RF levels of 127.7 (301.6) units/mL. After controlling for covariates, odds ratio (OR) for erosive disease was 2.72 (95% CI: 1.77, 4.18) for ACPA+ and 1.36 (0.88, 2.08) for RF+ (Fig. 1a). The OR for attaining SDAI LDA (<3.3) was 0.37 (0.21, 0.66) for ACPA+ and 1.45 (0.82, 2.56) for RF+ (Fig. 1b). ACPA titres were associated with erosive disease: 61 vs 32% of pts had erosive disease in the high vs low ACPA quartiles. ACPA+ pts with erosions (n=498) had higher mean SDAI (28.0 vs 18.1) and joint counts (19.2 vs 11.1), and greater proportions (60 vs 38%) were treated with biologic (b)DMARDs compared with all other RA pts. In multivariate analyses, the OR for SDAI remission in ACPA+ pts with erosions was 0.19 (0.10, 0.37); a significantly ($p<0.05$) greater proportion of these pts had durable equipment use (30.6 vs 22.1%) and all-cause hospitalizations (20.1 vs 13.1%) compared with all other RA

**Figure 1.** Association of ACPA+ and RF+ with erosion and disease activity.

pts at 12M. This group also had lower employment (38.7 vs 53.5%) and higher long-term disability (25.4 vs 17.3%) and retirement (32.5 vs 22.1%).
**Conclusions:** ACPA+ has a stronger association with erosions and disease activity. The presence of ACPA+ and erosions (vs absence) is associated with higher disease activity, lower odds of remission and lower WP, even when treated with standard-of-care bDMARDs.

## THU0091 TREATMENT PATTERN AND DISEASE ACTIVITY SCORES IN RHEUMATOID ARTHRITIS PATIENTS; DATA TAKEN FROM QATAR RHEUMATOID ARTHRITIS REGISTRY

F. Alam[1], M. Hammoudeh[1], P. Chandra[2], S. Al Emadi[1]. *[1]Rheumatology Internal Medicine; [2]Medical Research Center, Hamad General Hospital, Doha, Qatar*

**Background:** To date, there is no rheumatoid arthritis registry in Middle East. Rheumatoid arthritis registry in Qatar was established in 2013 with the aim of collecting data on RA patients seen in routine care at Hamad General Hospital, Qatar. It is observational study collecting data about demographic features of RA, RF and Anti CCP status, type of medication and their adverse reactions. CDAI, SDAI, DAS28, RAPID3 and HAQ questionnaire are also recorded.
**Objectives:** To describe demographic, disease activity score and treatment pattern in rheumatoid arthritis patients in Qatar.
**Methods:** All consecutive rheumatoid arthritis patients who were attending routine rheumatology outpatient clinic at Hamad General Hospital from period of June 2013 to September 2015 were included in this study.
**Results:** Data of 496 patients were analyzed: 75.8% female, 54.2% Arabs, 45.8% non Arabs, 74.9% were positive for rheumatoid factor, 79.8% were positive for anti CCP and 31.3% have erosion at the time of data collection. One hundred thirty one patients (26.4%) were receiving biologic drugs: (9.3% etanercept, 6% rituximab, 5.6% tocilizumab, 4.4% adalimumab, 0.4% abatacept, 0.4% certolizumab, and 0.2% infliximab). Among patients who are receiving biologic therapy, 42 patients (32%) are on biologic monotherapy. (9.9% on rituximab monotherapy, 9.9% on tocilizumab, 6.9% on etanercept and 5.3% on adalimumab monotherapy). Similarly, 49.23% of those patients receiving biologic, are also using concurrent methotrexate.
Methotrexate (MTX) was the most commonly prescribed synthetic DMARD (65.3%); 27% MTX monotherapy, 9.9% combined MTX and hydroxychloroquine, 6% combined MTX and sulfasalazine, 4.8% combined MTX and leflunomide and 3.6% triple therapy. Hydroxychloroquine was used by 29.4% of patients (4.6% patients were only on hydroxycholoquine monotherapy). Sulfasalazine was used by 21.2% patients (3.2% were only on sulfasalazine monotherapy). Leflunomide was used by 13.7% of patients (3.4% were only on leflunomide monotherapy). Good number of patients (39.7%) was receiving corticosteroid in our cohort. Mean dose of methotrexate, sulfasalazine and prednisolone was 15.88 ± 4.98 mg per week, 1.64 ± 0.57 gram daily and 5.45 ± 1.81 mg per day respectively.
Different disease activity scores in our cohort were as follows: DAS28 (4) 3.2 ± 1.2, CDAI 8.5 ± 7.9 and SDAI 9.7 ± 9.1. Mean HAQ score was 0.9 ± 0.7. Disease activity categorized by these indices differs considerably; 18% and 17.5% patients were in remission according to CDAI and SDAI scores respectively while 30.3% patients were in DAS 28 remission. Similarly, 23.1% patients were in low disease activity according to DAS28 (4) score while 51.6% patients were in low disease activity according to CDAI and SDAI scores.
**Conclusions:** This observational study describes a cohort of RA patients seen at Hamad General Hospital, Doha Qatar. Treatment pattern is somewhat similar to what is reported worldwide. One fourth of patients are receiving biological DMARD. Approximately two third of patients are categorized as having low disease activity or in remission. Disease activity categorized by various scores differs considerably.

**DOI:** 10.1136/annrheumdis-2016-eular.1203

## THU0092 EFFECT OF DISEASE MODIFYING ANTI RHEUMATIC DRUG METHOTREXATE ON THE LIPID PROFILE OF PATIENTS WITH RHEUMATOID ARTHRITIS

G.S. Sidhu. *rheumatology, Sir ganga ram hospial, New Delhi, delhi, India*

**Background:** Cardiovascular morbidity and mortality appear to be increased in rheumatoid arthritis (RA), which might be due to increased prevalence of risk factors for cardiovascular disease, such as an accelerated progression of atherosclerosis. Patients with active RA frequently show an atherogenic lipid profile, which has been linked with the inflammatory reaction.
**Objectives:** The AIM of this study is to determine the effect of treatment with methotrexate on the lipid profile of patients with rheumatoid arthritis.
**Methods:** We studied 25 patients with newly diagnosed rheumatoid arthritis who had not been treated with corticosteroids or disease-modifying antirheumatic drugs. We measured serum lipid profile of patients, who achieve remission according to DAS28 scores, at baseline and 3, 6 and 12 months post methotrexate to study the effect of the drug on the lipid levels.
**Results:** Twenty five patients were included in this prospective study 22 females (88%) and 3 males (12%). The mean age of patients was (46.40 ± 13.00). In these patients, mean high density lipoprotein (HDL) increased by 18.8 ± 11.3% ($p<0.001$), 21.9 ± 12.5% ($p<0.001$) and 26.8 ± 12.3% ($p<0.001$) and total cholesterol (TC) increased by 16.39 ± 22.12% ($p<0.001$), 14.38 ± 18.18% ($p<0.001$) and 12.94 ± 16.81% ($p<0.001$) at 3, 6, and moths respectively. Increase in Light density lipoprotein (LDL) was statistically significant at 3 months {9.89 ± 18.84% ($p<0.042$)} where as significant decrease in the level of triglycerides was noted at 6 months 2.69 ± 3.94% ($p<0.003$) and at 12 months2.62 ± 4.52% ($p<0.010$). Despite the increase in HDL, LDL and TC the atherogenic ratios (TC/HDL and LDL/HDL ratios) showed improvement at 3, 6 and 12 months post MTX treatment. There was negative association between changes in DAS28(ESR) after 3 months therapy and changes in HDL, LDL and TC levels.
**Conclusions:** Lipid profile and atherogenic ratios (TC/HDL and LDL/HDL ratios) improves substantially following effective treatment with methotrexate of rheumatoid arthritis. This improvement may reduce the risk of cardiovascular disease. With a decline in disease activity, a rising trend was observed for all lipids. However, changes in disease activity (DAS28) were only significantly related to changes in HDL cholesterol and LDL cholesterol levels.

## THU0093 EFFICIENCY OF NON-BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (DMARDS) IN RHEUMATOID ARTHRITIS (RA) PATIENTS WITH COMORBIDITY

G. Mykytenko, O. Iaremenko. *Internal Diseases at Stomatological Faculty, O.O.Bogomolets National Medical University, Kyiv, Ukraine*

**Background:** The impact of comorbidity on the course and results of RA treatment isn't investigated enough.
**Methods:** 402 RA patients (pts) (50.0% with early RA, including 12.4% pts with very early RA) were studied. Mean age at inclusion was 49.6±0.58 yrs, disease duration – 52.3±3.15 month. 84.1% of the pts were women; 63.2% were positive for rheumatoid factor and 75.2% - for antibodies against cyclic citrullinated peptides. 175 pts had extra-articular manifestations (EAM): mostly rheumatoid nodules (22.1%), lymphadenopathy (13.3%) and weight loss or fever (10.1%), less frequently - Sjögren's syndrome, vasculitis, eye disease, serositis. Pts were treated with methotrexate (mean dose – 11.6±0.29 mg/w, n=157), leflunomide (19.2±0.28 mg/d, n=95), sulfasalazine (2 g/d, n=76) or combined basic therapy (n=74). Effectiveness outcomes were evaluated after 2 yrs of treatment by ΔDAS28 and modified Sharp-van der Heijde score (ΔSHS).
**Results:** Comorbidity was observed in 58.7% RA pts, 25.0% of them had several comorbid conditions. The following most common comorbidities were recorded in pts with RA: arterial hypertension (AH) (22.5% of comorbidities), thyroid disease (11.9%), osteoarthritis (9.17%), chronic pyelonephritis (5.96%), diabetes mellitus (5.50%), peptic ulcer disease (5.05%), liver pathology (5.05%).
After 2 years clinical response to the treatment was significantly less in pts with comorbidity versus pts without comorbidity (ΔDAS28 2.12±0.13 vs 2.63±0.17, $p<0.05$), while a degree of radiological progression was only slightly higher (ΔSHS 11.7±1.20 vs 10.0±1.39, $p>0.05$).
The impact of the most common comorbidities in RA (AH and thyroid disease) on clinical and radiological response to treatment was assessed. Our results suggests that DMARDs efficiency doesn't depend on AH presence (ΔDAS28/ΔSHS – 2.0±0.19/9.05±1.55 vs 2.38±0.17/10.0±1.39 in pts with and without comorbidity respectively). However, in pts with thyroid disorders clinical response to treatment was significantly lower (ΔDAS28 – 1.57 ± 0.29) versus pts without comorbid diseases (2.38 ± 0.17, $p<0.05$), radiological progression in the compared groups did not differ significantly (ΔSHS – 11.5±2.77 vs 10.0±1.39).
To study the possible mutual aggravating influence of comorbidity and EAM of RA the effectiveness of DMARDs in the relevant subgroups was analyzed: in pts with comorbidity and EAM (n=94) or without EAM (n=142), pts without comorbidity, but with EAM (n=68) or without EAM (n=98). The clinical response in pts without comorbidity and EAM of RA was better (ΔDAS28 2.52±0.20) then in pts with comorbidity and with or without EAM (2.01±0.21 and 1.87±0.17 respectively, $p<0.05$). The lowest rate of radiographic progression (ΔSHS 8.85±1.13) in pts without comorbidity and EAM was observed (comparing 12.1±1.12 in pts with comorbidity and EAM, $p<0.05$).
**Conclusions:** 1. Comorbidity in more than half of Ukrainian pts with RA is observed, mostly arterial hypertension and thyroid disease.

2. The presence of comorbidity in pts with RA is associated with a worse clinical efficacy of DMARDs and the trend to greater radiological progression of RA.
3. Pts without comorbidity and EAM of RA have the best clinical response to non-biological DMARDs treatment (significantly better then pts with comorbidity, without EAM) and the lowest degree of radiological progression (vs pts with comorbidity and EAM).

## THU0094 SYSTEMIC EFFECT OF WRIST SURGERY ON QUALITY OF LIFE AND MENTAL WELLNESS FOR THE PATIENTS WITH RHEUMATOID ARTHRITIS

H. Ishikawa[1], A. Abe[1], A. Murasawa[1], T. Kojima[2], M. Kojima[3], N. Ishiguro[2], S. Ito[1], K. Nakazono[1], T. Nemoto[1], H. Lee[1], D. Kobayashi[1], C. Takai[1].
*[1]Rheumatology, Niigata Rheumatic Center, Shibata; [2]Orthopedic Surgery, Nagoya University Hospital; [3]Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

**Background:** By a remarkable advance in the medical treatment of rheumatoid arthritis (RA), uncontrollable synovitis in the past has been well comtrolled. However, some patients still have a problem in their wrist due to structural damage and smoldering synovitis. Surgical reconstruction for the wrist is required, if the conservative treatment failed. Recently, patients desired to achieve functional remission aiming at the higher level of quality of life (QOL) and the mental wellness.
**Objectives:** The objective of this study was to clarify the systemic effect of wrist surgery on the disabled patients with RA using the assessment of patient-reported outcome (PRO) and disease activity.
**Methods:** Surgical reconstruction was scheduled on 74 wrists in 74 patients (male:10, female:64) with RA between October 2012 and September 2014. The average age was 62 (19–88) years old and the average duration of the disease was 14 (1–60) years. Correction of the thumb and the finger deformities were combined in 18 wrist surgeries. The procedure included Darrach procedure (ulnar head resection) in 55 wrists, radiolunate arthrodesis in 31, Sauvé-Kapandji operation in 11, extensor tendon reconstruction in 11 etc. Steinbrocker stage I, II, III, IV was 2, 22, 29, 21 patients, and Steinbrocker class I,II, III, IV was 7, 47, 20, 0 patient(s), respectively. MTX was used in 48 patients (65%) with the average dose of 8.7mg/w, and PSL was used in 45 patients (61%) with the average dose of 4.1mg/d. Biologics was used in 12 patients (16%) including ETN:2, TCZ:3, IFX:3, ADA:3 patients. PRO was assessed by Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), and patient's general health using visual analogue scale of 100mm (Pt-GH). Upper extremity function was assessed by Disabilities of the Arm, Shoulder and Hand (DASH). Disease activity was assessed by 28-joint Disease Activity Score using C reactive protein (DAS28-CRP). They were measured just before surgery (baseline), at 6 and 12 months after surgery.
**Results:** As a whole, physical function (HAQ-DI, DASH), QOL (HAQ-DI, EQ-5D, Pt-GH) and mental wellness (BDI-II, Pt-GH), disease activity (DAS28-CRP) significantly improved at 6 and 12 months after surgery compared to those at baseline ($p<0.01$) (Table1,Figure1). The rate of clinical remission in DAS28-CRP ($<2.3$) at baseline, 6 and 12 months after surgery was 14%, 60% and 57%, respectively. The rate of functional remission in HAQ-DI ($<0.5$) was 28%, 35% and 41%, respectively. The rate of minimal depression in BDI-II ($\leq 13$) was 54%, 70% and 68%, respectively.

Table 1. Change in patient-reported outcome and disease activity (n=74)

| | HAQ-DI | DASH | EQ-5D | BDI-II | Pt-GH | DAS28-CRP |
|---|---|---|---|---|---|---|
| Baseline | 1.0 (0.9) | 40 (21) | 0.72 (0.12) | 13.5 (9.4) | 58 (21) | 3.2 (0.9) |
| 6mos.after surgery | 0.8* (0.7) | 34* (18) | 0.77* (0.14) | 11.6* (8.5) | 23* (22) | 2.2* (0.8) |
| 12mos.after surgery | 0.7* (0.6) | 30* (19) | 0.77* (0.14) | 11.3* (8.8) | 24* (20) | 2.3* (0.8) |

mean(SD), *p<0.001 compared to baseline

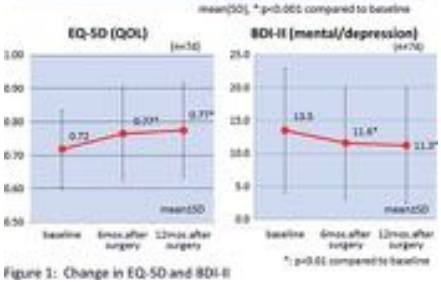

Figure 1: Change in EQ-5D and BDI-II

**Conclusions:** Favorable effects of wrist surgery on QOL and mental wellness as well as physical function were confirmed in the disabled patients with RA. To improve QOL and mental wellness, surgical treatment for the damaged wrist should be considered in combination with tight medical control. It also had an ameliorating effect on disease activity.

## THU0095 CLINICAL CHARACTERISTICS OF ELDERLY ONSET RHEUMATOID ARTHRITIS (EORA) COMPARED TO YOUNG ONSET RHEUMATOID ARTHRITIS (YORA) IN YOUNG AND OLD

I. Yoshii[1], T. Chijiwa[2]. *[1]Orthopaedics, Yoshii Hospital, Shimanto City; [2]Rheumatology, Kochi Memorial Hospital, Kochi, Japan*

**Background:** As aging society and treatment of rheumatoid arthritis (RA) progress, problem of elderly onset RA (EORA) raised up in developed countries recent decade. Number of patient who suffers RA in elderly days has increasing. Grasping characteristics of EORA compared to young onset RA (YORA) is beneficial information for daily clinical practice for RA.
**Objectives:** RA patient's clinical courses were investigated from our small cohort study, and clinical characteristics of EORA were evaluated.
**Methods:** 549 RA patients visited as RA as diagnosed with 2010 ACR/EULAR classification criteria since August 2010, when treat to target strategy (T2T) have been accepted in our clinic, and have continued to be treated consecutively. Our clinic is the only medical institute in where rheumatologists that is certified Japan College of Rheumatology work in the area that consists of hundred thousand of population.
In these, patients who had been thrown of methotrexate before first visit, and dead patients before November 2015 were eliminated, then 436 patients have been investigated in this study. Patients were classified according to age at onset. We defined EORA as their onset age is sixty-five or more. The other patients (YORA) were also classified according to age at last visit. Patient who is younger than 65-year-old was classified as yYORA, and another group was defined as oYORA. Average values of disease activity score with 28 joints with C-reactive protein (DAS28-CRP), CRP, patient's pain score with visual analogue scale (PS-VAS), and health assessment questionnaire (HAQ-DI), for first visit (@BL), six months later (@6M), and average value throughout follow up (@AV), concomitant methotrexate (MTX) and glucocorticoid (GCS) thrown ratio, and average dosage of these drugs for first 24 weeks were calculated and compared with Mann-Whitney's U-test, unpaired T-test and chi-square test among groups and two of the three groups.
**Results:** 176 EORA, 123 oYORA, and 137 yYORA were picked up. Average DAS28-CRP were 3.83, 3.59, 3.71 @BL, 1.82, 1.85, 1.73 @6M, 1.99, 2.03, 2.22 @AV, while CRP were 1.61, 0.88, 0.83 @BL, 0.58, 0.46, 0.54 @6M, 0.73, 0.62, 0.57 @AV, and PS-VAS were 37.87, 30.73 33.74 @BL, 20.78, 17.32, 22.57 @6M, 25.79, 24.74, 26.19 @AV, and HAQ-DI were 0.53, 0.50, 0.26 @BL, 0.27, 0.20, 0.15 @6M, 0.46, 0.40, 0.26 @AV, for EORA, oYORA, and yYORA, respectively.
MTX and GCS thrown ratio were 47.7%, 38.9%, 45.3%, and 27.8%, 15.9%, 10.8% for EORA, oYORA, yYORA, respectively. Thrown dosage of MTX were 7.99, 8.25, 8.87mg, while GCS were 3.24, 3.07, 3.44mg, for EORA, oYORA, yYORA, respectively.
In Table 1, their statistical significances have been described.

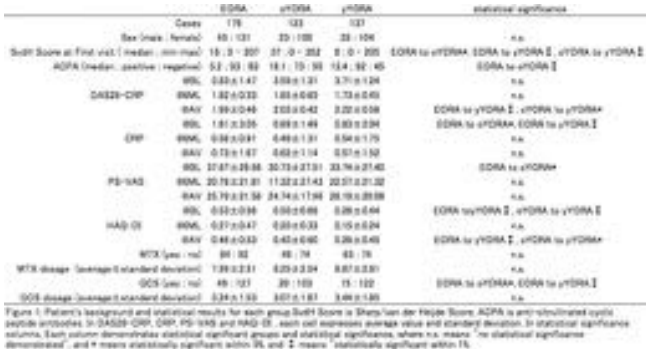

Figure 1. Patient's background and statistical results for each group Sharp/van der Heijde Score, ACPA is anti-citrullinated cyclic peptide antibodies, in DAS28-CRP, CRP, PS-VAS and HAQ-DI , each cell expresses average value and standard deviation. In statistical significance columns, Each column demonstrates statistical significant groups and statistical significance, where n.s. means "no statistical significance demonstrated", and * means statistically significant within 5% and ‡ means " statistically significant within 1%.

**Conclusions:** EORA patient has tendency to demonstrate higher CRP and PS-VAS at baseline than YORA, As well as CRP, DAS28-CRP is likely to demonstrate relatively higher, however, also demonstrates sensitive response for treatment including for GCS, then reduces PS-VAS as well as DAS28-CRP. However, elderly RA patient tends to remain in higher level of HAQ-DI than yYORA.

## THU0096 SERUM INFLAMMATION IDENTIFIES INCREASED RISK OF FRAILTY IN RHEUMATOID ARTHRITIS

J. Andrews[1], E. Wahl[2], G. Schmajuk[2], E. Yelin[2], P. Katz[2]. *[1]Rheumatology, University of Washington, Seattle; [2]Rheumatology, University of California San Francisco, San Francisco, United States*

**Background:** Frailty is defined as "excess vulnerability to stressors, with reduced ability to maintain or regain homeostasis after a destabilizing event"[1]. Frailty is closely related to body composition and physical functioning, and is associated with increased risk of poor health outcomes including death. Serum inflammation is associated with differences in body composition and physical functioning in the general population and individuals with chronic disease. The ability of serum markers of inflammation to identify increased frailty among individuals with rheumatoid arthritis (RA) is unknown.
**Objectives:** We tested whether serum erythrocyte sedimentation rate (ESR) and C-Reactive Protein (CRP) are associated with increased risk of frailty among men and women with RA.
**Methods:** Participants were individuals in a longitudinal RA cohort. ESR and high sensitivity CRP were assessed from blood samples using standard clinical assays. Individuals with 3 or more of the following physical deficits were classified as frail[1]: 1) body mass index $\leq$18.5, 2) low grip strength (adjusted for sex and BMI, measured by handheld dynamometer), 3) severe fatigue (measured by the Fatigue Severity Inventory), 4) slow 4-meter walking speed (adjusted for sex and height), 5) low physical activity (measured by the International Physical Activity Questionnaire). Individuals with 1 or 2 deficits were classified as pre-frail, and those with no deficits as robust.[1] Multinomial logistic regression analyses controlling for age, sex, smoking status, RA disease duration, prednisone use, tumor necrosis factor inhibitor use, appendicular lean mass, and pain modeled the effects of ESR and CRP on severity of frailty.
**Results:** Of the 141 participants, 60% were female; mean age was 58 (±11) years, duration of RA was 19 (±11) years, ESR was 19 (±19) mm/h, and hsCRP was 5 (± 8) mg/L. Sixteen participants (11%) were frail, 86 (61%) pre-frail, 22 (16%) robust, and 17 (12%) were missing grip strength data. In adjusted models, higher ESR was associated with significantly increased risk of frailty (Table 1). Similar trends were observed between CRP and risk of frailty, but did not reach statistical significance in adjusted models.

Table 1. Multinomial logistic regression relative risk ratios (95% CIs) for the effect of serum sedimentation rate and C-reactive protein on risk of frailty category among individuals with RA

| | ESR | | CRP | |
|---|---|---|---|---|
| | Unadjusted | Adjusted[#] | Unadjusted | Adjusted[#] |
| Frail | 1.69 (0.94, 3.07) | 2.56* (1.16, 5.65) | 1.49 (0.88, 2.52) | 1.96$^{+}$ (0.96, 4.03) |
| Pre-Frail | 1.43 (0.95, 2.15) | 1.92* (1.05, 3.48) | 1.26 (0.85, 1.86) | 1.66$^{+}$ (0.94, 2.94) |
| Robust | Ref. | Ref. | Ref. | Ref. |

[#]Adjusted for age, sex, smoking status, disease duration, prednisone use, TNF inhibitor use, appendicular lean mass, and pain due to rheumatoid arthritis. *$p<0.05$, $^{+}p<0.1$.

**Conclusions:** Frailty and pre-frailty were common in our cohort of individuals with RA, with a greater prevalence than that of geriatric populations. ESR levels were associated with approximately twice the risk of being frail or pre-frail compared to being robust. CRP demonstrated similar effects on risk of frailty, though trends did not reach statistical significance. These findings underscore the burden of frailty among individuals with RA, and they may suggest a clinical role for serum ESR and CRP to identify individuals with RA at greatest risk of frailty.

## THU0097 DESCRIPTIVE ANALYSIS OF LARGE SINGLE CENTER EXPERIENCE OF PATIENTS WITH INTERSTITIAL LUNG DISEASE AND RHEUMATOID ARTHRITIS

J.A. Zamora-Legoff[1], C.S. Crowson[2], M.L. Krause[1], E.L. Matteson[1]. *[1]Rheumatology; [2]Biomedical Statistics and Informatics, Mayo Clinic, Rochester, United States*

**Background:** ILD may present as a rare but serious extraarticular manifestation in patients with RA and can have dramatic effect on morbidity and mortality.
**Objectives:** To evaluate the course of pulmonary disease in a large prevalence cohort of patients with RA who have ILD.
**Methods:** Prevalent cases of RA with ILD from 01/01/1998 to 01/01/2014 were identified in a single center's electronic medical record using advanced software to identify cases using ICD-9 diagnosis codes. All cases were manually reviewed and screened for inclusion. RA characteristics and pulmonary findings including high-resolution computed tomography (HRCT) and pulmonary function testing (PFT) were evaluated. Descriptive statistics were used to summarize the data.
**Results:** Two-hundred and one patients with ILD and RA were identified. Patients were predominately Caucasian (97%); 54% were males; mean age was 66.6 years (±10.9) at ILD diagnosis. Mean follow-up from ILD diagnosis was 4.1 years (±4.0) and median time from RA to ILD diagnosis was 4.9 (range -15.7 to 45.6) years. Seventy-three (37%) were never smokers. Eighty-seven (43%) had usual interstitial pneumonia (UIP) and/or idiopathic pulmonary fibrosis (IPF) and sixty-seven (33%) had non-specific interstitial pneumonia (NSIP) by HRCT. Anti-citrullinated protein antibody (ACPA) was present in 110 (77%) of 142 tested patients, and rheumatoid factor (RF) was present in 161 (84%). Erosive disease was present in 52 (28%) of patients and 103 (51%) had other extraarticular manifestations of RA prior to or at time of ILD diagnosis. The baseline predicted PFTs at time of ILD diagnosis included a forced vital capacity (FVC) of 72% (± 21), a forced expiratory volume in 1 second (FEV1) of 71% (±21), and a diffusing capacity for carbon monoxide (DLCO) of 55% (±19). Ninety-four (49%) patients required supplemental oxygen with a mean requirement at last followup of 2.9 liters (±1.6). At last follow-up 79 had died, with pulmonary disease accounting for 23 (29%) of deaths.

Table 1. Interstitial lung disease (ILD) with rheumatoid arthritis (RA) cohort summary

| Characteristic | Value* |
|---|---|
| Age at ILD diagnosis (years) | 66.6 (±10.9) |
| Age at RA diagnosis (years) | 57.9 (±13.4) |
| Sex, male | 108 (54%) |
| Smoking status | |
| never | 73 (37%) |
| former | 120 (60%) |
| current | 7 (4%) |
| Years from ILD to last follow-up | 4.1 (±4.0) |
| RA disease duration at ILD diagnosis | |
| median | 4.9 |
| range | –15.7 to 45.6 |
| RF positive | 161 (84%) |
| ACPA positive, % of patients tested | 110 (77%) |
| Erosive disease | 52 (28%) |
| Extra-articular RA other than pulmonary disease | 98 (49%) |
| Type of lung disease | |
| UIP/IPF | 87 (43%) |
| NSIP | 67 (33%) |
| Other | 47 (23%) |
| Pulmonary function tests (baseline) | |
| FEV1 percent predicted | 70.5 (±21.0) |
| FVC percent predicted | 71.5 (±20.5) |
| DLCO percent predicted | 55.4 (±19.4) |
| Required supplemental oxygen | 94 (49%) |
| Oxygen requirement at last visit (liters) | 2.9 (±1.6) |

**Conclusions:** In this largest single-center reported cohort of patients with RA-ILD, most patients were seropositive, male, and had a prior history of tobacco use. UIP was more common than NSIP. Almost half of patients required supplement oxygen, and nearly one third died from pulmonary disease which was the most common known cause of death.

## THU0098 NO RELATIONSHIP BETWEEN LOW SERUM 25-HYDROXYVITAMIN D LEVEL AND DECREASED BONE MASS OR BONE QUALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS – TOMORROW STUDY

K. Inui[1], T. Koike[2], Y. Sugioka[2], T. Okano[1], K. Mamoto[1], M. Tada[3], H. Nakamura[1]. *[1]Orthopaedic Surgery; [2]Center for Senile Degenerative Disorders, Osaka City University Graduate School of Medicine; [3]Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

**Background:** Vitamin D deficiency in patients with rheumatoid arthritis (RA) is commonly observed. Previous studies have investigated the relationship between vitamin D deficiency and RA and increased risk of cardiovascular events and the role of immunomodulation. While RA is recognized as a risk factor for osteoporosis, there are few reports examining the relationship between vitamin D level and bone mass or metabolism markers in RA patients compared with healthy controls.
**Objectives:** To examine the relationship between serum 25-hydroxyvitamin D (25(OH)D) level, bone mineral density, and bone metabolic markers of RA patients compared with age-and sex-matched healthy volunteers (Vo group) using a cross-sectional method.
**Methods:** In 2010, we began a prospective cohort study called the TOMORROW Study (UMIN000003876) which compares data from RA patients with age- and sex-matched controls (Vo) recruited through mass media. Laboratory data were collected for all participants, including 25(OH)D level, insulin resistance, bone metabolic markers (urinary pentosidine, homocysteine, collagen type 1 cross-linked N-telopeptide (NTX), and osteocalcin), and anthropometric parameters. Bone mineral density of the lower extremities and body composition were determined using whole-body dual-energy X-ray absorptiometry (DXA). The parameters were compared with healthy controls, and multiple regression analysis was carried out in the RA population only. In RA patients, disease activity score 28 was measured by clinical assessment.
**Results:** There were 413 participants (208 RA patients, 205 Vo group; 349 females; mean age of 58 years) enrolled in the study. In RA patients (mean disease duration of 13 years), bone density was significantly lower ($p<0.01$; Student's

*t*-test), and urinary NTX ($p<0.01$), pentosidine ($p<0.01$), and homocysteine ($p<0.05$) were higher compared with the Vo group. The serum 25(OH)D level was lower in RA patients compared with the Vo group ($p<0.01$) (Table). Multiple linear regression analysis in the RA population revealed no significant relationship between DXA and vitamin D level (p=0.18) or pentosidine (p=0.61).

Table 1. Differences between RA patients and healthy controls (Vo) (Student's *t*-test)

| Variables | Vo (n=205) | RA (n=208) | P-value |
|---|---|---|---|
| HbA1c | 5.1 | 5.2 | 0.37 |
| HOMA-R | 1.06 | 1.25← | 0.03 |
| Serum 25(OH)D (ng/dL) | 21.6 | 18.5↓ | <0.001 |
| DXA (g/cm$^2$) | 1.03 | 0.97↓ | <0.001 |
| Urinary NTX (nM/mM Cr) | 44.3 | 59.0← | <0.001 |
| Osteocalcin (ng/mL) | 7.3 | 7.2 | 0.81 |
| Urinary pentosidine (pmol/mg Cr) | 54.1 | 72.6← | <0.001 |
| Homocysteine (nmol/mL) | 9.1 | 10.9← | <0.001 |

**Conclusions:** No relationship was found between low vitamin D level and decreased bone mass or bone quality in RA patients.

## THU0099 CARDIOVASCULAR MR (CMR) EVIDENCE FOR REDUCED LV MASS IN RHEUMATOID ARTHRITIS (RA), SUGGESTING PATHOLOGY OTHER THAN ATHEROSCLEROSIS FOR HEART FAILURE

L.-A. Bissell[1,2], B. Erhayiem[3], E.M. Hensor[1,2], G. Fent[3], A. Burska[1,2], H. Donica[4], S. Plein[3], M.H. Buch[1,2], J.P. Greenwood[3], J. Andrews[1,2]. *[1]LIRMM, University of Leeds; [2]Nihr Lmbru; [3]LIGHT, University of Leeds, Leeds, United Kingdom; [4]Medical University of Lublin, Lublin, Poland*

**Background:** An increased risk of heart failure in RA exists[1]. Aetiology is unclear with some evidence that cardiomyopathy may occur early in RA, from pathology distinct to atherosclerosis[3]. Large well characterised CMR-RA studies to investigate pathogenesis are few[2].
**Objectives:** To evaluate sub-clinical CVD in an asymptomatic-CVD established RA cohort compared to healthy controls (HC), using reference standard CMR-measured outcomes & novel CMR-measures of carotid artery.
**Methods:** 76 ACR1987 RA patients (pts) with dis.>5yrs, no CVD/diabetes, assessed for CV traditional risk factor (TRFs)/RA profile, pulse wave velocity (PWV), non-contrast 3T CMR (heart & carotids) reported by CMR-cardiologists, compared to 26 HC. Carotid measures inc. mean (MWT) & maximum (MxWT) wall thickness, wall (WVol) & luminal (LVol) volume & WVol-index (WVol-I, WVol/(WVol+LVol)). UVA variables (var.)=TRFs, BMI, waist/hip ratio (WHR), HOMA-IR, NTproBNP, dis. duration (ddur), 3vDAS28, ACPA, HAQ-DI, joint surgery hx, biologic use & PWV. MVA var.=age/sex/known associated (ass.) var./UVA r>0.3.
**Results:** Mean (SD) age (yrs) of RA pts; 60 (9.2), 74% female; HC 52 (11.4), 54% female. Median (IQR) ddur 16.5 (10.7, 25.7)yrs, 81% ACPA+ve, DAS28CRP 2.59 (1.30, 3.33), 67% on biologic. There were no significant differences in lipids/glucose/HOMA-IR between RA/HC. Trend for higher NT-proBNP in RA seen. In MVA (inc. age/sex), increasing ddur ass. with NTproBNP (0.5% rise in NTproBNP per 1% increase in ddur, p0.034). RA pts (after adj. for age/sex/TRFs) had reduced LVmass/BSA, LVEF, native T1 values & increased strain (Mid-S') vs HC; no difference seen for LVEDV, LVESV, SV, LVmass/EDV, torsion or arterial stiffness (PWV/distensibility). No significant differences in carotid measures between RA/HC seen. In RA pts, 10yr JBS2 CV risk score correlated with WVol (r0.377 p=0.004) & LVol (r0.441 p=0.001). TRFs ass. with cardiac & carotid measures in RA.

Table 1. CMR results

| CMR measure | Mean difference (95% CI) RA vs HC, p value adj. for age/sex/TRFs | RA group ass. var.: UVA (p) & MVA B (95% CI, p) |

–ve = negative correlation.

MVA (inc. age/sex), increasing ddur ass. with NTproBNP (0.5% rise in NTproBNP per 1% increase in ddur, p0.034). RA pts (after adj. for age/sex/TRFs) had reduced LVmass/BSA, LVEF, native T1 values & increased strain (Mid-S') vs HC; no difference seen for LVEDV, LVESV, SV, LVmass/EDV, torsion or arterial stiffness (PWV/distensibility). No significant differences in carotid measures between RA/HC seen. In RA pts, 10yr JBS2 CV risk score correlated with WVol (r0.377 p=0.004) & LVol (r0.441 p=0.001). TRFs ass. with cardiac & carotid measures in RA.
**Conclusions:** CMR evidence for reduced LV mass in RA, suggesting pathology other than atherosclerosis as the cause of heart failure; perhaps microvascular dysfunction. TRFs, not RA features, are important determinants of CMR measures of subclinical CVD in RA.

## THU0100 SERUM LEPTIN AS A BIOMARKER OF FAT MASS EXCESS IN RHEUMATOID ARTHRITIS BRAZILIAN PATIENTS

M.F. Guimaraes[1], C.J. Machado[2], E.L.M. Vieira[2], M.R.C. Pinto[1], M.V. Andrade[2], A.L. Junior[2], A. Kakehasi[2]. *[1]HC UFMG; [2]Faculdade Medicina UFMG, Belo Horizonte, Brazil*

**Background:** although obesity is a risk factor for developing coronary artery disease[1] and cardiovascular diseases account for approximately half of the deaths among rheumatoid arthritis (RA) patients[2], anthropometric measures are not accurate for fat mass quantification in this population.[3]
**Objectives:** to identify a serum biomarker of fat excess in patients with RA.
**Methods:** cross-sectional study in adults with established RA. Disease activity was assessed by DAS28 and CDAI. Anthropometric measures included waist circumference (WC), weight and height for body mass index (BMI) calculation. Body composition by DXA (Hologic Discovery W, software 3.3.01) was used to fat mass excess quantification.[4] Circulating levels of IL-6, TNF alpha, IL- 1β and leptin were measured in a single sample of peripheral blood using the technique of Bead-Based Multiplex Immunoassays- Luminex; while adiponectin was measured by Enzyme-Linked Immunosorbent Assay-ELISA.
**Results:** 99 patients were included, 89.9% women, with mean age of 54.5 (±11) years and mean disease duration of 16.5 (±9.3) years. The frequency of obesity was 31.3% by BMI, 85.9% by WC and 57.6% by DXA. Mean serum leptin concentration was 24.5 (± 22.5) ng/ml. Leptin correlated with obesity by the three methods: BMI, WC and DXA. This correlation was stronger with DXA. The correlation between leptin and DXA was not influenced by DAS28, C-reactive protein, erythrocyte sedimentation rate, nor by inflammatory cytokines levels (IL -6, TNF-alpha, IL- 1β). Analysis by ROC curve determined the cut-off point of 6.52 ng/ml of leptin as obesity marker, with a sensitivity of 96.43% and a specificity of 23.81%.
**Conclusions:** serum concentration of leptin presents as a fat mass excess biomarker, being useful since more accurate diagnostic methods for measuring fat mass are not available in clinical practice.

## THU0101 THE PREDICTORS OF FRAGILITY FRACTURE IN PATIENTS WITH RHEUMATOID ARTHRITIS: AN OBSERVATIONAL STUDY

R. Sinha, M. Bukhari. *Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom*

**Background:** Rheumatoid arthritis (RA)is a well known risk factor for osteoporosis (OO) and is an independent risk factor in the FRAX ™ tool, additionally the femoral neck Bone mineral density (BMD) is included in the tool as a risk factor for fracture, but not the lumbar spine.
**Objectives:** To determine the predictors of fragility fractures in an observational cohort of patients with RA referred for BMD estimation, and whether using lumbar spine BMD would predit risk.
**Methods:** Patients referred for BMD estimation in a scanner in the North west of England between 2004 and 2014 with a history of RA were identified from a dual X-ray absorptiometry (DEXA) database. Demographics and other risk factors

were also recorded. Fragility fractures were also recorded. Initially those who had sustained a fracture were compared to those who had not sustained a fracture using chi squared test for categorical variables and Student's T test for continous variables. Subsequently univariate and multivariate logistic regression models were fitted. Variables included age at scan, gender, weight, height and body mass index (BMI),family history of fracture, alcohol, smoking, current steroid exposure, causes of secondary OP as per the FRAX™ definition, in addition to BMD in the lumbar spine (L1-L4) and the non-dominant femoral neck.

**Results:** 1527 patients were scanned in the referral period. Mean age at scan was 64.3 year (SD 11.6), 1207 (79.0%) were female, 406 (26.6%) had sustained a fracture. Patients who had sustained a fracture were more likely to be female 347/860 (28.8%) vs 59/320 (18.4%) ($p<0.001$) and older 65.6 years (SD11.6) vs 63.9 years (SD11.5) (p=0.01). They also had lower BMD in the lumbar spine and the femoral neck. Results of the univariate analysis unadjusted and adjusted for age and gender are shown in table 1 with significant predictors marked with an asterisk (*).

| Predictor | Unadjusted Odds ratio (95% CI) | Adjusted OR (95% CI) |
|---|---|---|
| Age at scan in decades | 1.14 (1.03,1.26*) | – |
| Female gender | 1.78 (1.31,2.43*) | – |
| Lumbar spine BMD | 0.14 (0.08,0.25*) | 0.17 (0.09,0.32)* |
| Femoral neck BMD | 0.10 (0.05,0.22*) | 0.14 (0.06,0.33)* |
| Height | 0.97 (0.96,0.98*) | 0.98 (0.97,1.00)* |
| Weight | 0.98 (0.98,1.00*) | 0.99 (0.98,1.00) |
| Smoking | 0.96 (0.76.1.21) | 1.03 (0.82,1.31) |
| Excess alcohol | 1.40 (0.81,2.42) | 1.81 (1.03,3.19)* |
| Secondary osteoporosis | 1.68 (1.21,2.33*) | 1.52 (1.09,2.12)* |
| Family history of fracture | 1.30 (0.92,1.84) | 1.31 (0.92,1.86) |
| Current Steroid exposure | 0.86 (0.68,1.08) | 0.92 (0.73,1.15) |
| Body mass index kg/m$^2$ | 0.99 (0.97,1.01) | 0.99 (0.97.1.01) |

In the multivariate model, the variables that predicted fractures in this cohort the BMD in the lumbar spine (OR 0.33 95%CI 0.14,0.80), BMD in the femoral neck (OR 0.29 95%CI 0.09,0.94)and alcohol excess (OR 2.01 95%CI 1.12,3.61)family history (OR 1.49 95%CI 1.01,2.19)and secondary osteoporosis (OR 1.50 95%CI 1.03,2.18). Using the lumbar spine only gave an area under the curve (AUC) of the model of 0.640 whilst using the lumbar spine only gave an AUC of 0.633, using both gave an AUC of 0.646.

**Conclusions:** In univariate analysis, many risk factors are associated with fracture in this cohort with RA. Using the lumbar spine BMD improved the prediction of fractures, this is not included in the FRAX™ tool and would underestimate the fracture risk in this cohort. Further models including the L1l4 BMD should be developed to more accurately predict fractures in patients with RA.

## THU0102 PLATELET ASSOCIATED IGG IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Nishikawa, S. Kaneshiro, H. Owaki, T. Fuji. *Orthopaedic Surgery, Japan Community Health Care Organization Osaka Hospital, Osaka City, Osaka, Japan*

**Background:** Thrombocytopenia was sometimes shown in clinical medical treatment in patients with rheumatoid arthritis (RA). The causes of thrombocytopenia in patients with RA are various. Drug induced thrombocytopenia and idiopathic thrombocytopenia are ones of these causes. The diagnosis of thrombocytopenia is important because the method of treatment depends on it.

**Objectives:** Increased levels of platelet associated IgG (PAIgG) found in patients with idiopathic thrombocytopenia. We investigated in the relationship between platelet and PAIgG to evaluate the clinical significance in patients with RA.

**Methods:** Total 266 patients (60 males: 206 females) with RA were enrolled in this study. The serum level of PAIgG were examined. We evaluated age at onset of RA, age of PAIgG test, disease duration of RA, platelet number, platelet bindable IgG (PBIgG), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), rheumatoid factor (RF), anti-cyclic citrullinated peptide antibody (ACPA), matrix metalloproteinase-3 (MMP-3), Disease activity score including a 28-joint count (DAS28)-CRP, DAS28-ESR, simplified disease activity index (SDAI), clinical disease activity index (CDAI), and methotrexate (MTX) dose between PAIgG(+) and (–) groups.

**Results:** PAIgG were positive in 60.9% (162/266). There were no significant differences in age at onset of RA, age of PAIgG test, disease duration of RA, PBIgG, CRP, ESR, ACPA, MMP-3, DAS28-CRP, DAS28-ESR, SDAI, CDAI, and MTX dose between PAIgG(+) and (–) groups. There were significant differences only in RF and platelet number between PAIgG(+) and (–) groups. RF were higher in PAIgG(+) than those in (–) significantly (126.4 IU/mL vs. 84.4 IU/mL, p=0.03). RF(+) rate were also higher in PAIgG(+) than those in (–) significantly (75.3%: 122/162 vs. 61.5% 64/104, p=0.02). Platelet number were lower in PAIgG(+) than those in (–) significantly (207,000/μL vs. 218,000/μL, p=0.03). However, the PAIgG(+) patients whose platelet number were under normal limit were only 11.1% (18/162). There was no significant difference compared with PAIgG(–) patients whose platelet number were under normal limit (8.7%: 9/104).

**Conclusions:** PAIgG shows high value in immune thrombocytopenia, systemic lupus erythematosus, etc. However, we found high PAIgG(+) rate in RA which usually shows thrombocytosis. Although platelet number in PAIgG(+) were lower significantly, the mean value was within normal limit. The rates under normal limit between 2 groups were not different significantly. Although PAIgG had small effect on platelet number in RA, RF were higher in PAIgG(+) significantly. Further investigation is needed to evaluate the clinical significance of PAIgG in patients with RA.

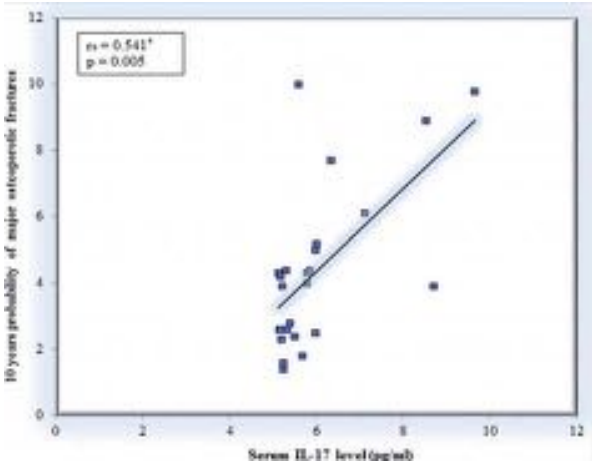
## THU0103 IS INTERLEUKIN 17 IMPLICATED IN OSTEOPOROSIS PATHOGENESIS IN RHEUMATOID ARTHRITIS? RELATION BETWEEN IL-17 SERUM LEVEL AND FRAX INDEX IN PREMENOPAUSAL RHEUMATOID ARTHRITIS PATIENTS

N.A. Aboeladl[1], H.K. Koryem[1], M.A. Rezk[2], M.M. Hassan[1], S.S. Eltawab[1]. *[1]Physical Medicine, Rheumatology and Rehabilitation; [2]Clinical and Chemical Pathology, Faculty of Medicine Alexandria University, Alexandria, Egypt*

**Background:** Rheumatoid arthritis (RA) is one of the most common form of inflammatory arthritis. It is characterized by being chronic, progressive with systemic inflammation. Patients with RA are at an increased risk of osteoporosis (OP) and consequentaly osteoporotic fractures (OFs). Interleukin-17 (IL-17) is a cytokine expressed in inflammatory and autoimmune diseases. It plays an important role in the pathogenesis of RA and OP. Fracture Risk Assessment Tool (FRAX)is a computer-based algorithm used to measure the 10-year probability of a major osteoporotic fractures and the 10-year probability of hip fracture. Current studies focus on better assessment of risk factors of OFs in RA patients aiming to prevent them and their subsequent complications.



**Objectives:** To study the correlation between serum IL-17 level and FRAX index scores in pre-menopausal RA patients.

**Methods:** This study included 25 premenopausal RA patients and 20 healthy controls. Serum IL-17 level was measured by using ELISA technique, bone mineral density (BMD) measured using DEXA scan and FRAX index was calculated by using online FRAX calculator (Femoral neck BMD was used to enhance fracture risk prediction).

**Results:** Serum IL-17 level among RA patients was significantly higher than healthy controls, (5.99 ± 1.22pg/ml), (3.73 ± 2.15pg/ml) respectively with a $p<0.001$. Serum IL-17 levels showed a positive significant correlation with the FRAX index scores in RA patients.

| | Serum IL-17 | |
|---|---|---|
| | $r_s$ | *p* |
| Major osteoporotic fracture | 0.541 | 0.005* |
| Hip fracture | 0.492 | 0.013* |

$r_s$: Spearman coefficient. *Statistically significant at $p \leq 0.05$.

**Conclusions:** IL-17 is highly suspected to be implicated in the pathogenesis of OP in RA patients which may spotlight that the emergence of IL 17 blockade as a future therapy in RA is to be highlighted.

## THU0104 LIMITED SAFETY SIGNALS, BUT NO ADVANTAGE OF COBRA-LIGHT OVER COBRA COMBINATION THERAPY 4 YEARS AFTER INITIATION OF THE COBRA-LIGHT TRIAL IN EARLY RHEUMATOID ARTHRITIS

N. Konijn[1], L. van Tuyl[1], M. Boers[1,2], D. den Uijl[1], M. ter Wee[1,2], L. van der Wijden[1], P. Kerstens[3,4], A. Voskuyl[1], D. van Schaardenburg[3,5], M. Nurmohamed[1,3], W. Lems[1,3]. [1]*Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center;* [2]*Epidemiology & Biostatistics, VU Medical Center;* [3]*Rheumatology, Amsterdam Rheumatology and immunology Center, Reade, Amsterdam;* [4]*Rheumatology, Westfriesgasthuis, Hoorn;* [5]*Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center, Amsterdam, Netherlands*

**Background:** COBRA and COBRA-light combination therapy are equally effective and safe treatments for early rheumatoid arthritis (RA) after 26 and 52 weeks [1,2], but long-term safety of COBRA-light therapy is unknown.
**Objectives:** To investigate survival and comorbidities of initial COBRA and COBRA-light combination therapy after a 4 year follow-up period. A detailed analysis of long-term efficacy will be presented separately.
**Methods:** In the COBRA-light trial, 164 patients with recent-onset RA were randomized to either COBRA (prednisolone 60 mg/day, tapered to 7.5 mg/day in 6 weeks; MTX 7.5 mg/wk and sulfasalazine 2 g/day; n=81) or COBRA-light therapy (prednisolone 30 mg/day, tapered to 7.5 mg/day in 8 weeks and MTX escalated to 25 mg/wk in 8 weeks; n=83). Between 26 and 52 weeks; treatment intensification of MTX and addition of etanercept was protocollized (treat-to-target). After 52 weeks, treatment was continued without protocol. Four year after trial initiation, all patients who had initiated therapy (n=162) were invited to participate in the COBRA-light extension study. All patients were interviewed and clinical records were protocollized examined for new comorbidities developed during the follow-up period.
**Results:** A total of 149 out of 162 original trial patients participated in the extension study (77 COBRA and 72 COBRA-light). During the follow-up period, 5 five patients had died: 2 COBRA (both cancer) and 3 COBRA-light (1x dementia; 2x unknown); 6 were not able or willing to participate, and 2 were in drug-free remission and out of care. After the 52 weeks trial period, 43% COBRA vs. 42% COBRA-light patients used prednisolone for ≥90 days, 34% vs. 44% switched to other DMARDs, and 39% vs. 28% used biologicals during the follow-up period. After mean 4 years follow-up, 118 patients (79% in each treatment group) had developed new comorbidities. Cardiovascular events, hypertension, hypercholesterolemia and diabetes mellitus were equally prevalent in both treatment groups (Table 1), notably angina pectoris and heart failure were not seen. Bone quality tended lower in the COBRA-light group, as evidenced by prevalence of osteoporosis on DXA (1% COBRA vs. 6% COBRA-light, p=0.20); clinical fractures (8% vs. 18%, p=0.06), and especially vertebral and rib fractures (0% vs. 6%, p=0.05). Seven patients developed cancer during follow-up: 2 COBRA (both lung cancer, both deceased during follow-up), and 5 COBRA-light (3x lung cancer, 1x basal cell carcinoma and 1x meningioma).

**Table 1.** New comorbidities developed during the 4 year follow up period of the COBRA light extension trial (n=149)

| | COBRA (n=77) | COBRA-light (n=72) |
|---|---|---|
| Any cardiovascular event | 5 (7) | 7 (10) |
| – Myocardial infarction | 1 (1) | 1 (1) |
| – Stroke [1] | 2 (3) | 5 (7) |
| – Arrhythmia | 3 (4) | 1 (1) |
| – Peripheral vascular disease | 1 (1) | 1 (1) |
| Hypertension | 7 (9) | 5 (7) |
| Hypercholesterolemia | 5 (7) | 7 (10) |
| Diabetes mellitus | 1 (1) | 3 (4) |
| Any clinical fracture | 6 (8) | 13 (18)* |
| – Hip and pelvis | 1 (1) | 2 (3) |
| – Vertebra and rib | 0 (0) | 4 (6)* |
| – Leg and ankle | 2 (3) | 1 (1) |
| – Arm and wrist | 1 (1) | 3 (4) |
| – Hand and feet | 3 (4) | 5 (7) |
| Osteoporosis at 4 year DXA (T score < -2.5 at spine and/or hip) [2] | 1 (1) | 4 (6) |
| Vertebral fracture at 4 year spine X-ray [3] | 7 (10) | 8 (13) |
| Bone necrosis | 0 (0) | 1 (1) |
| Any infection with antibiotic or antiviral drugs | 39 (51) | 38 (53) |
| Any gastrointestinal event | 3 (4) | 4 (6) |
| Glaucoma | 0 (0) | 1 (1) |
| Cataract | 5 (7) | 3 (4) |
| Cancer [1,4] | 0 (0) | 5 (7) |

*Results are reported as frequencies (%); [1]No CVA, 5x TIA, 1x eye infarct and 1x venous occlusion left eye; [2]Based on DXA's of 135 patients; [3]Based on spine X-rays of 134 patients; [4]No significant difference between treatment groups when taking into account the 2 deceased COBRA cancer patients; *In each treatment group, 1 patient had a basal cell carcinoma relapse during the follow-up period; *Trend for significant difference between treatment groups (p=0.10)*

**Conclusions:** Over a 4 year follow-up period, early RA patients initially treated with COBRA and COBRA-light therapy showed limited and similar safety signals in terms of survival and major comorbidities, except for the higher incidence of clinical fractures in the COBRA-light group, which could not be explained by a significant higher prevalence of osteoporosis. Overall, attenuating the original COBRA regimen did not further improve its favorable safety profile.

## THU0105 FRAX 10-YEAR FRACTURE RISK IN RHEUMATOID ARTHRITIS - ASSESSMENTS WITH AND WITHOUT BONE MINERAL DENSITY MAY LEAD TO VERY DIFFERENT RESULTS IN THE INDIVIDUAL PATIENT

K.D. Elde[1], O. Rintek Madsen[1,2]. [1]*Department of Rheumatology, Copenhagen University Hospital Gentofte, Hellerup;* [2]*DANBIO, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

**Background:** Osteoporosis is a well-known complication in patients with rheumatoid arthritis (RA). The FRAX tool is an online computer-based algorithm developed by WHO to evaluate the 10-year risk of an osteoporotic hip fracture and major fracture (hip, clinical spine, proximal humerus or forearm fracture) (ref). Clinical risk factors include age, height and weight and dichotomized risk factors comprising prior fragility fracture, parental history of hip fracture, current tobacco smoking, ever use of long-term oral glucocorticoids, RA, other causes of secondary osteoporosis and alcohol consumption. Bone mineral density (BMD, g/cm$^2$) of the femoral neck can be optionally included as a risk factor but FRAX does not provide recommendations on which side to measure BMD. The usability of fracture risk assessment without BMD has been evaluated on group level, but the agreement between fracture risks assessed with and without BMD in individual patients has not met much attention.
**Objectives:** To investigate the intra-individual agreement between 10-year fracture risk calculated with and without BMD in patients with RA.
**Methods:** Data from 50 RA patients registered in the Danish rheumatology registry (DANBIO) were used for analysis. BMD of the left and right femoral neck was measured using a Lunar iDXA-scanner (GE, Lunar) by experienced laboratory technicians. The intra-individual agreement between fracture risk assessed with and without BMDs was examined using the Bland-Altman method. 95% lower and upper limits of agreement (LLoA and ULoA) were estimated as the mean difference (bias) in percent point (pp) between paired measurements ± 1.96SD (2.5% - 97.5% range for side comparison due to screwed distribution). Student's t-test was used for comparison on the group level.
**Results:** Mean age was 63.6 ± 11.7 (range 40–50) years, mean disease activity score (DAS28-CRP) 3.3 ± 3.5 and the mean femoral neck T-score -1.4 ± 1.2. 64% of the patients were on oral steroids, 50% on DMARDs and 46% on biological treatment (±DMARD). The mean 10-year risk of a major fracture and a hip fracture calculated with BMD was 22.9 ± 15.8% and 8.5 ± 10.8%, respectively. There was an overall trend of a greater bias, the higher the FRAX fracture risk but the bias was lower and LoA more narrow in osteopenic and osteoporotic patients compared to patients with normal BMD. The LLoA and ULoA [bias] for major fracture risk calculated with and without BMD (side with lowest value) were -14.5 pp and 20.4 pp [2.93 pp, $p<0.05$]. For hip fracture risk, LLoA and ULoA were -14 pp and 23.2 pp [4.6 pp, ($p<0.001$)]. When calculating fracture risk based on the side with lowest versus highest BMD, the LLoA and ULoA for hip fracture were 0 pp and 6.8 pp [0.8 pp, $p<0.001$] and for major fracture 0 pp and 7.3 pp [1.0 pp, $p<0.001$].
**Conclusions:** The FRAX 10-year fracture risk estimated with and without BMD may disagree to a substantial degree in individual RA patients and should therefore not be considered inter-changeable in the daily clinic. Choice of measurement side may also impact the fracture risk assessment, especially in the individual patient.

Crestani[1], P. Dieude[1]. *[1]CHU Bichat, Paris; [2]CHU de Lille, Lille; [3]CHU de Tours, Tours; [4]CHU Avicennes, Bobigny; [5]CHU de Bordeaux; [6]CHU Avicennes, Bordeaux; [7]CH Aix en Provence, Aix-en-Provence; [8]CHU Cochin; [9]CHU Lariboisière, Paris; [10]CHU de Lyon, Lyon; [11]CHU Strasbourg, Strasbourg; [12]CHU Tenon, Paris; [13]CHU de Clermont Ferrand, Clermond Ferrand, France*

**Background:** Rheumatoid arthritis (RA) is a systemic autoimmune disease, the most severe manifestation being interstitial lung disease (ILD). Therapeutic options are undefined and ILD is one of the leading causes of mortality for RA patients. A better characterization of RA-ILD–associated factors may improve the risk stratification of RA patients.
**Objectives:** To identify variables associated with ILD occurrence in RA.
**Methods:** RA-ILD patients (RA-ILD+) in a French multicentric cohort were compared to monocentric RA cases without ILD (RA-ILD-). All patients fulfilled 2010 ACR/EULAR criteria for RA and had a HRCT chest scan for suspected ILD or during a pre-biologic assessment. ILD was defined by HRCT results. Because ILD occurrence increases with RA duration, RA-ILD+ and RA-ILD- patients were matched by disease duration (1:1). Demographic data, clinical features of RA and treatment modalities before the ILD diagnosis were collected. Results significant on univariate analysis ($P<0.15$) were selected for multivariate analysis to identify variables independently associated with RA-ILD. Duration of methotrexate (MTX) and anti-TNF agent use was adjusted to mean MTX or anti-TNF duration before ILD diagnosis.
**Results:** Among 253 consecutive RA patients, 81 were male (32.02%), 112 (48.07%) were smokers, mean age at RA onset was 48.11 ± 16.33 years, and mean RA duration 11.69 ± 10.10 years; 199 patients (85.78%) were ACPA-positive and 171 (71.85%) had erosive status; 134 (60.63%) received MTX and 63 (28.25%) a TNF inhibitor. Among the 253 patients, 138 (54.55%) had ILD. Among the RA-ILD+ patients, 72 (74.23%) had UIP and 25 (25.77%) NSIP. On univariate analysis, ILD was associated with older age at RA onset (52.69 ± 15.00 *vs* 42.86 ± 16.26 years, P=0.0001), male sex (40.68% *vs* 21.74%, P=0.001), ACPA rate ≥60 N (20.63% *vs* 6.41%, P=0.012), less use of anti-TNF agents and MTX (14.55% *vs* 41.59%, P=0.001, and 50.94% *vs* 69.57, P=0.005, respectively) and lower MTX dosage (15.26 ± 4.44 *vs* 16.83 ± 4.31 mg/week, P=0.046). There was no difference for erosive status. On multivariate analysis, ILD was independently associated with older age at RA onset ($P<0.0001$), male sex ($P=0.0006$), less use of MTX ($P=0.015$) with lower dosage ($P=0.005$) and less use of anti-TNF agents ($P=0.004$).
**Conclusions:** As previously reported, ILD was independently associated with male sex as well as older age at RA onset and, of interest, less use of MTX and anti-TNF biologics before ILD diagnosis, even though patients did not differ in erosive status. Larger prospective studies are required to further elucidate the role of DMARDs and anti-TNF biologics in ILD occurrence and progression in RA patients.

## THU0107 PREVALENCE OF POSITIVE QUANTIFERON-GOLD TEST IN ADULT PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND ITS SIGNIFICANCE IN DEVELOPING COUNTRIES

R. Cama[1], C. Manaktala[2]. *[1]Medical Services; [2]Strategic Drug Development, Quintiles Research P Ltd, New Delhi, India*

**Background:** The detection of latent TB infection (LTBI) and institution of appropriate prophylactic therapy is an essential requirement before prescribing biologic disease modifying anti-rheumatic drugs (DMARDs) to patients with rheumatoid arthritis. With several biologics going off-patent and a mushrooming of biosimilars, biologics which were hitherto unaffordable and unavailable in the developing world are soon likely to be widely available. In view of the high prevalence of active tuberculosis (TB) and LTBI in these regions, the increased prescribing of biologics will raise some pertinent questions in the context of LTBI testing, test result interpretation and management.
**Objectives:** The objective of this study was to identify the prevalence of latent TB infection in a geographically diverse population of patients with Rheumatoid Arthritis eligible for treatment with biologic DMARDs.
**Methods:** A retrospective analysis of QuantiFERON-TB Gold (QFT-G) test results of samples received at Quintiles Central Laboratories from Jan 2010 to Dec 2013 was conducted. All samples were from adult subjects who were consented and screened for clinical trials. All subjects had active Rheumatoid arthritis of at least 6-month duration as per ACR 1987 criteria and had inadequate response to conventional DMARDs including MTX therapy.
**Results:** The QFT-G test results of 4471 samples were analyzed. Samples were received from 40 countries with 66% from Europe, 18% from USA and Canada, 18% from APAC region and 5% from Latin America.
The total incidence of positive QFT-G in this sample size was 12.3% with range of positivity extending from 2.4% in Canada to 37.8% in China. Romania, Korea, Bosnia and Mexico also had significant QFTG positivity of 31.5%, 30.2%, 28.7% and 20.3% respectively. The total incidence of indeterminate results to QFT-G test was 5.2%.
The Asian countries predictably showed a higher prevalence of LTBI, with 25.2% of test results being positive. Eastern Europe and Latin America followed with 13.1% and 11.5%, while Western Europe had 8.2% and USA & Canada had only 4.5% positive QFT-G test results
**Conclusions:** With increasing availability of biologics in regions with high tuberculosis disease burden there appears to be a requirement to develop country-specific guidelines for prophylaxis of latent TB tailored to the needs of the populace. In terms of duration of prophylaxis, will the recommended 6-month INH prophylactic regimen be adequate to effectively prevent re-activation of TB in the developing countries? As patients with Rheumatoid Arthritis continue to take biologic DMARDs for longer durations of time, will a life-long preventive strategy be necessary? There is also concern for presence of INH resistance in these regions, effectively bringing into play more toxic prophylactic regimens for prevention of tuberculosis. National guidelines for patient pathways and selection of biologic may be the required solution to enable patients of rheumatoid arthritis to avail of better therapies while avoiding potential risks.

## THU0108 CLOSING THE AUDIT CYCLE: HAVE CARDIOVASCULAR RISK ASSESSMENT AND MANAGEMENT IN RHEUMATOID ARTHRITIS PATIENTS IMPROVED?

R. Magro[1], K. Bartolo[2], R. Corso[2], M. Buhagiar[3], N. Taliana[4], A. Borg[1]. *[1]Department of Rheumatology; [2]Department of Medicine, Mater Dei Hospital; [3]Department of Oncology, Sir Anthony Mamo Oncology Hospital; [4]Department of Paediatrics, Mater Dei Hospital, Msida, Malta*

**Background:** Patients who suffer from rheumatoid arthritis have an increased risk of morbidity and mortality from cardiovascular disease. This is due to the high prevalence of traditional risk factors and the effect of systemic inflammation.
**Objectives:** The aim of the audit was to determine whether the cardiovascular risk assessment and management in rheumatoid arthritis patients at Mater Dei Hospital is in concordance with the recommendations by the European League Against Rheumatism (EULAR).
**Methods:** An audit was carried out retrospectively on 91 patients who suffer from rheumatoid arthritis by using the medical notes to collect data on demographics, co-morbidities, drug history and cardiovascular risk assessment and management over a two year period (August 2010 to July 2012). The results of the first audit were then disseminated through the rheumatology department and a form for cardiovascular risk assessment and management in rheumatoid arthritis patients was implemented. The audit was repeated on 107 patients and data was collected retrospectively over the two year period starting from January 2013 to December 2014.
**Results:** Documentation of cardiovascular risk factors over the two year period audited improved as follows from the first to the second audit: weight in 27.5% to 52.3%, height in 0% to 27.1%, BMI in 0% to 10.3%, smoking status in 72.5% to 93.5%, blood pressure in 72.5% to 92.5%, blood glucose in 72.5% to 97.1% and lipid profile in 54.9% to 96.3%. Documentation of smoking cessation advice improved from 15.8% to 41.1% and advice on other lifestyle changes improved from 14.3% to 18.7%. Moreover calculation of DAS28 over a one year period improved from 20.9% to 51.4%.
In the first audit, 13.8% of patients who had complete data and in whom the ten year cardiovascular risk could be calculated (29 patients), would benefit from the use of a statin according to the guidelines (and were not currently receiving one). In the re-audit, this decreased to 8.6% of such patients (93 patients).
In the second audit it was noted that the form that had been introduced for cardiovascular risk assessment was used in 15% (16 patients). The documentation of lifestyle advice was significantly higher ($p<0.001$) in the group of patients in whom the form was used. The same applies for documentation of weight ($p<0.001$), height ($p<0.001$), BMI ($p<0.001$) and calculation of DAS28 over a one year period ($p<0.001$).
The prevalence of diagnosed hypertension in our cohort of rheumatoid arthritis patients was 49.0%; diabetes was 19.7%; hyperlipidaemia was 21.8%; and ischaemic heart disease was 8.8%.
**Conclusions:** Cardiovascular risk factors are highly prevalent in rheumatoid arthritis patients. This audit showed that cardiovascular risk assessment and management improved through raising awareness of its importance in the rheumatology department as well as the implementation of the cardiovascular risk assessment form.

## THU0109 VACCINATION RATES IN ADULTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES AND THE PATIENTS' PERSPECTIVE ON THEIR INFECTION RISK

R. Magro, M. Rogers, F. Camilleri. *Rheumatology, Mater Dei Hospital, Msida, Malta*

**Background:** Patients suffering from autoimmune rheumatic diseases are at increased risk of developing infections, especially if they are on immunomodulatory treatment.
**Objectives:** The aim of the study was to determine whether vaccination in adult patients with autoimmune inflammatory rheumatic diseases (AIIRD) attending the Rheumatology Clinic at Mater Dei Hospital, is in concordance with the European League Against Rheumatism (EULAR) guidelines.
**Methods:** 60 patients with AIIRD attending the Rheumatology Clinic were recruited for the audit. Demographic data and vaccination status were completed using the medical notes. Further information on their vaccination history and their perceived importance of vaccination was obtained by interviewing the patients. Approval to carry out this study was obtained from the University Research Ethics Committee.
**Results:** The study included patients with a variety of AIIRD including rheumatoid arthrtitis, systemic lupus erythematosus, ankylosing spondylitis and psoriatic arthritis. 58% were females and the mean age was 62.4 years (range 24 to 81 years). Out of the 60 patients audited, 43 were on a synthetic disease modifying anti-rheumatic drug (sDMARD) alone, 6 were on a biologic drug alone, and 3 were on a combination of both a biologic drug and sDMARD. 13 patients were on glucocorticoids; of which 12 were also receiving a sDMARD. Information on vaccination history was found in the medical notes in only 2 cases.
The influenza vaccine was taken in 44 patients (73.3%) of which it was taken yearly in 30 patients. Out of those who had taken the influenza vaccine, most of them claimed they had been advised to do so either by their general practitioner (43.2%) or through public health campaigns (27.3%). 32 patients (53.3%) claimed that they had the intention to take it the following year. The proportion of patients who took the influenza vaccine yearly was significantly higher in those above 65 years ($p<0.001$) and in those who had co-morbidities (including lung disease, diabetes and ischaemic heart disease) ($p=0.024$). 5 patients (8.3%) claimed they had taken the pneumococcal vaccine. All of these claimed they had been advised to do so by a hospital doctor. 38.3% claimed that they knew that they were at increased risk of infections because of their condition or treatment. Only 6.7% stated that they had been advised to take vaccination because of this.
**Conclusions:** Even though this study may have under-estimated vaccination rates and advice given to patients because of recall bias, it has clearly shown that improved patient education on their infection risk and need for vaccination is required. This can be encouraged by having structured documentation of patients' vaccination status in the medical notes and by raising awareness of its importance within the Rheumatology Department.

## THU0110 EFFECTIVENESS OF BIOLOGIC AND NONBIOLOGIC ANTIRHEUMATIC DRUGS ON ANEMIA IN ADULT PATIENTS (PTS) WITH RHEUMATOID ARTHRITIS (RA): NEW EVIDENCE FROM REAL-WORLD DATA

S.K. Paul[1], K. Klein[1], J.H. Best[2], S. Gale[2], A. Pethö-Schramm[3], K. Sarsour[2]. *[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia; [2]Genentech, South San Francisco, United States; [3]F. Hoffmann-La Roche, Basel, Switzerland*

**Background:** Anemia, a common complication of RA, has a negative impact on RA symptoms and QOL and is associated with a more severe form of RA. Roles of biologic DMARDs (BDMARDs), including the IL-6 pathway–inhibiting biologic tocilizumab (TCZ), in the pathophysiology of anemia have not been well explored at the population level.
**Objectives:** Evaluate the impact of treatment (Tx) with nonbiologic (NB) and BDMARDs on hemoglobin (Hb) and hematocrit (Hct) in a real-world setting.
**Methods:** Using the GE EMR database, a longitudinal cohort study was conducted on 153,672 adult RA pts in the US who had ≥6-mo follow-up. 4 mutually exclusive DMARDTx groups (TxGs) were identified: TCZ, tofacitinib (TOFA), other BDMARDs (OBDMARD), and other NBDMARDs (ONBDMARD). To evaluate changes in Hb and Hct at 6 and 12 mo from index date (ID) in different TxGs, unadjusted and adjusted mean (95% CI) changes were obtained, adjusting for age, sex, smoking status, RA duration, concomitant medications, CRP, and other covariates. Separate analyses were conducted for pts with Hb <12/13.5 g/dL for women/men (anemic).
**Results:** Demographics of the cohort were: 55 y mean age, 76% female, 59% white, 57% current or ex-smokers, 44% obese (mean BMI 30 kg/m$^2$). 2% of pts had ischemic heart disease, 2% renal disease, and 7% diabetes. Mean Hb and Hct levels at ID across TxGs were 13.3 g/dL and 40%. Average CRP (1.6 mg/dL) and ESR (23 mm/h) were clinically similar across TxGs at ID. Adjusting for covariates, increases in Hb and Hct levels at 6 and 12 mo were significantly higher in the TCZ group vs the other TxGs (Table). Among anemic pts at ID, increases in Hb and Hct at 6 mo were significantly higher in the TCZ group vs the other TxGs. Significantly greater reductions in ESR and CRP levels over all follow-up periods were observed in the TCZ group vs the other TxGs.
**Conclusions:** This study suggests significant increases in Hb and Hct levels after TCZ therapy vs other nonbiologic and biologic therapies in RA pts with anemia, in line with the potential role of IL-6 in RA pts with anemia. Further study is needed to better evaluate the role of IL-6–based OBDMARDs as a Tx option for RA pts with anemia.

## THU0111 BIOLOGICS DISCONTINUATION AND BMI PREDICT RA FLARE RISK AFTER HIP AND KNEE ARTHROPLASTY

S.M. Goodman[1], S.J. Bartlett[2,3], R.W. Cummings[1], K.M. Andersen[1], L.T. Donlin[1], D.E. Orange[1,4,5], A. Hoang[1], M.P. Figgie[1], V.P. Bykerk[1]. *[1]Hospital for Special Surgery, New York; [2]Johns Hopkins School of Medicine, Baltimore, United States; [3]McGill University, Montreal, Canada; [4]New York Genome Center; [5]The Rockefeller University, New York, United States*

**Background:** Immunosuppressive medications are often stopped prior to arthroplasty to mitigate infection risk, but this may increase the risk of disease flares post surgery in patients with rheumatoid arthritis (RA).
**Objectives:** To describe rates, characteristics, and risk factors for flare after total hip (THA) and total knee (TKA) arthroplasty surgery.
**Methods:** Pre- and post-operative characteristics were examined in 58 RA patients undergoing TKA/THA. Perioperative medication use was standard of care: biologics were stopped before surgery, while steroids and methotrexate (MTX) continued. Clinicians evaluated RA clinical characteristics, on average, 0–2 weeks before and 6 weeks post-surgery. Post-surgery, patients completed weekly questions about RA symptoms, impact, and flare status using the OMERACT Flare Questionnaire. Baseline characteristics were compared using t-tests and chi-square, and multivariate logistic regression was used to identify baseline characteristics associated with post-surgical RA flares.
**Results:** Of 68 patients, 10 (15%) were flaring prior to surgery and were excluded. 88% met 2010/1987 RA criteria; those who did not meet criteria were included by rheumatologist diagnosis. Patients had a mean [SD] age of 61 [12], BMI of 30.6 [7.2], and RA duration of 16 [12] yrs. 59 (87%) were female, 53 (78%) were white, 33 (49%) were having THA, and 35 (52%) were on biologics. 35 (60%) had flared by 6 weeks post surgery. At baseline, flarers had significantly ($p<.05$) higher BMI, higher disease activity indicators (DAS28, RAPID3), inflammatory markers (ESR, CRP), and pain, and more were undergoing THA and used biologics (Table 1). After controlling for age, surgical joint, and baseline DAS28, the odds of flaring by 6 weeks post-surgery were significantly higher in patients who had

## THU0112 PREVALENCE AND RISK FACTORS FOR NEW VERTEBRAL FRACTURES IN PATIENTS WITH RA: FIVE-YEAR FOLLOW-UP OF THE TOMORROW STUDY

T. Okano[1], K. Inui[1], M. Tada[2], Y. Sugioka[3], K. Mamoto[1], T. Koike[3], H. Nakamura[1]. *[1]Departmento of Orhopedic surgery, Osaka City University Graduate School of Medicine; [2]Departmento of Orhopedic surgery, Osaka City General Hospital; [3]Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka, Japan*

**Background:** Rheumatoid arthritis (RA) is one cause of secondary osteoporosis [1]. Multifactorial osteoporosis can be due to the disease itself, a decrease in physical activity, treatment with glucocorticoids, and being postmenopausal. Accelerated generalized bone loss often leads to increased risk of vertebral fractures [2]. We started a prospective cohort study (TOtal Management Of Risk factors in Rheumatoid arthritis patients to lOWer morbidity and mortality: TOMORROW study, UMIN000003876) to compare risk factors for osteoporosis between patients with RA and controls.
**Objectives:** We previously reported that the prevalence of vertebral fractures is significantly higher in patients with RA than controls. We compared the prevalence of new vertebral fractures and associated risk factors between patients with RA and controls based on the 5-year follow-up findings of the TOMORROW study.
**Methods:** This study included 208 patients with RA (among whom 112 were medicated with biological agents and 96 received conventional therapy) and 205 age- and sex-matched healthy volunteers (n=413). Vertebral fractures evaluated using thoracolumbar spine X-rays, whole body bone mineral density (BMD) assessed using a QDR-4500 (Hologic, Marlborough, MA, USA) and bone metabolic markers were compared in 2010, 2011, and 2015. The prevalence of new vertebral fractures and associated risk factors were evaluated.
**Results:** Thoracolumbar spine radiographs and clinical data were analyzed from 182 patients with RA and 190 controls. More new vertebral fractures were found in the patients than in the controls (26 [14.3%] vs. 14 [7.4%]; *P*=0.03) and they were likely to be more severe in the patients. The SQ grade was $\geq$2 in 53.8% and 42.9%, respectively, and more than one new vertebral fracture was found in 26.9% and 21.4%, respectively of the patients and controls. Logistic regression analysis of patients with RA selected previous vertebral fracture (adjusted OR, 7.88; 95% CI, 2.00–31.0), persistent low BMD (adjusted OR, 5.11; 95% CI, 1.13–23.1), glucocorticoid use (adjusted OR, 3.71; 95% CI, 1.14–12.0), and age (adjusted OR, 1.07; 95% CI, 1.01–1.14) as risk factors for new vertebral fractures.

Table 1. Logistic regression anlysis

| | New vertebral fractures (n=25) | No new fractures (n=157) | OR (95% CI) | *P* value |
|---|---|---|---|---|
| Age | 71.8 (8.0) | 62.0 (12.6) | 1.07 (1.01–1.14) | 0.034 |
| Female | 23 (92.0) | 130 (82.8) | 0.22 (0.03–1.44) | 0.114 |
| Weight | 51.7 (9.3) | 55.1 (10.5) | 0.99 (0.93–1.04) | 0.615 |
| Bisphosphonate medication | 12 (48.0) | 54 (34.4) | 0.33 (0.10–1.04) | 0.058 |
| Previous vertebral fracture | 22 (88.0) | 60 (38.2) | 7.88 (2.00–31.0) | 0.003 |
| Glucocorticoid use | 8 (32.0) | 27 (17.2) | 3.71 (1.14–12.0) | 0.029 |
| Persistent low BMD | 5 (20.0) | 6 (3.8) | 5.11 (1.13–23.1) | 0.034 |

**Conclusions:** New vertebral fractures were significantly more frequent in patients with RA during follow-up for five years. Pre-existing vertebral fracture and persistent low BMD were risk factors for new vertebral fractures.

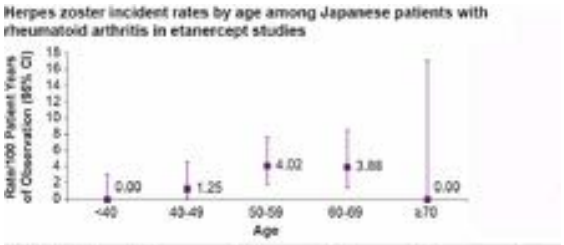
## THU0113 GENETIC VARIATIONS IN THE ALANINE-GLYOXYLATE AMINOTRANSFERASE-2 (AGXT-2) GENE ARE NOT RELATED TO LEVELS OF DIMETHYLARGININES IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Dimitroulas[1,2], J. Hodson[3], A. Sandoo[4], J. Smith[2], G. Kitas[5]. *[1]Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Department of Rheumatology, Dudley Group NHS FT, Dudley; [3]Wolfson Computer Laboratory, University Hospital Birmingham NHS Foundation Trust, Queen Elizabeth Hospital Birmingham, Birmingham; [4]School of Sport, Health and Exercise Sciences, Bangor University, Gwynedd; [5]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom*



**Background:** Rheumatoid arthritis (RA) is associated with high rates of cardiovascular (CV) events and increased CV morbidity and mortality mainly due to coronary and cerebrovascular atherosclerotic disease. Asymmetric (ADMA) and symmetric (SDMA) dimethylarginines are endogenous inhibitors of nitric oxide synthase and have been repeatedly linked with adverse CV outcomes in the general population and various disease settings. ADMA and SDMA levels differ in RA individuals compared to non-RA subjects but whether such abnormalities are driven by genetic variations remains under investigation.
**Objectives:** The aim of the current study was to investigate the effect of alanine-glyoxylate aminotransferase-2 (AGXT-2) gene polymorphisms on circulating levels of ADMA and SDMA in RA patients.
**Methods:** Serum ADMA and SDMA levels were measured in 201 individuals with RA [155 females median age 67 (59–73)]. Two tag SNPs in AGXT-2 gene – rs37369 and rs28305 – were genotyped. Distributions of SDMA and ADMA were skewed, hence comparisons across the gene polymorphisms were performed using Mann-Whitney tests, and summarised using medians and interquartile ranges. Multivariate analysis examined each of the genes after adjustment for parameters of systemic inflammation, insulin resistance and renal function namely [erythrocyte sedimentation rate (ESR), quantitative insulin sensitivity check index (QUICKI) and estimated glomerular filtration rate (EGFR)] which we have previously shown affect ADMA and SDMA levels in RA.
**Results:** Univariable analysis found no evidence to suggest that either SDMA or ADMA differed significantly between the categories of rs37369AGXT2 (p=0.911, 0.507) or rs28305AGXT2 (p=0.233, 0.501). A multivariable analysis was then performed, which accounted for potential confounding factors. This showed ESR ($p<0.001$) and EGFR (p=0.007) to be significantly associated with ADMA, whilst QUICKI (p=0.029) and EGFR ($p<0.001$) were significantly associated with SDMA.
**Conclusions:** Our study in a well-characterized RA population did not show any associations between serum concentrations of dimethylarginines and gene variants of AGXT2, as reported to occur in the general population and patients with diabetic mellitus.

## THU0114 INCIDENCE OF HERPES ZOSTER AND MALIGNANCY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ETANERCEPT

T. Takeuchi[1], N. Sugiyama[2], N. Miyasaka[3], Y. Morishima[2], H. Yuasa[4], N. Sugiyama[5]. *[1]Keio University, Tokyo, Japan; [2]Medical Affairs, Pfizer Japan, Tokyo, Japan; [3]Tokyo Medical and Dental University, Tokyo, Japan; [4]Clinical Research, Development Japan, Pfizer Japan, Tokyo, Japan; [5]Clinical Statistics, Development Japan, Pfizer Japan, Tokyo, Japan*

**Background:** Both herpes zoster (HZ) and malignancies have been reported

in patients treated with TNF blockers such as etanercept (ETN). In Japanese patients with RA, information regarding the incidence of HZ and malignancy following long-term treatment with TNF blockers is limited.
**Objectives:** The objective of this study was to analyse the incidence rates (IR) of HZ and malignancy in Japanese patients with RA treated with ETN in order to expand the safety data set available for this patient population.
**Methods:** Data were pooled from 4 clinical trials of ETN in Japanese patients with RA. Two studies were double-blind trials of 10 and 25 mg ETN vs placebo (study 202) or methotrexate (study 315-JA), and were of 12 and 52 weeks duration, respectively. The other 2 studies were open-label, long-term trials of ETN (studies 310-JA and 313-JA) and were of 183 and 134 weeks duration, respectively. Crude IR for HZ and malignancy per 100 patient-years, with 95% confidence intervals (95% CI), were calculated and the rates were stratified by age and time of symptom development.
**Results:** A total of 521 patients with RA were included in this analysis. Mean age was 51.9 years and 81.6% of patients were female. Mean and standard deviation (SD) duration of RA was 5.2 ± 6.5 years, and the mean (SD) disease activity score 28-erythrocyte sedimentation rate was 6.15 ± 1.20. Following ETN treatment, 18 incidences of HZ in 17 patients were reported. The IR/100 years [95% CI] for the entire population was 2.5 [1.45, 4.00]. IR of HZ was highest in the 50–59 age bracket, followed by the 60–69 age bracket (Figure). IR [95% CI] was highest during the first 6 months of treatment with ETN (3.81/100 patient years [1.74, 7.23]) and subsequently declined with a stable cumulative IR seen up to 48 months of treatment (2.50/100 patient years [1.45, 4.00] across the entire treatment period). In addition, 4 incidences of malignancy in 4 patients were reported following treatment with ETN. There was 1 incidence of hypopharyngeal cancer which occurred in the first 6 months of treatment, 2 incidences of breast cancer, each occurring between Months 6–12 of treatment, and 1 incidence of liposarcoma, which occurred between Months 30–36 of treatment with ETN. IR/100 patient years [95% CI] for malignancy was 0.57 [0.15, 1.46].

**Conclusions:** In Japanese patients with RA treated with ETN, increased IR of HZ in patients aged over 50 was observed. This trend is consistent with previous observations in the Japanese general population. IR of HZ was similar to that seen in a study of Japanese patients with RA treated with the IL-6 blocker tocilizumab (2.29/100 patient years),[1] and might be higher compared with a large cohort study of Japanese patients with RA (2005–2010) where only 3% of patients used a biological treatment for RA (0.91/100 patient years).[2] Malignancies occurred in a small number of patients with limited exposure, and there was no increase in the cumulative IR of malignancy during the treatment period.
Tsutomu Takeuchi and Naonobu Sugiyama are equally credited first authors.

## THU0115 DEPENDENCE OF ARTERIAL PRESSURE IN PATIENTS WITH RHEUMATOID ARTHRITIS ON THE GENOTYPE OF BCL1 POLYMORPHISM IN GLUCOCORTICOID RECEPTOR GENE

V. Kmyta, O. Savchenko. *internal medicine department, Sumy State University, Sumy, Ukraine*

**Objectives:** The objective is to study the incidence of arterial hypertension in patients with rheumatoid arthritis in regard to the genotype of BCL1 polymorphism in the glucocorticoid receptor gene.
**Methods:** 161 subjects with rheumatoid arthritis aged 40 years and older were investigated by means of instrumental, clinical and laboratory examinations. Rheumatoid arthritis was diagnosed according to ACR/EULAR Classification Criteria (2010). Arterial hypertension was diagnosed, when systolic arterial pressure was at or above 140 mmHg and diastolic arterial pressure – at or above 90 mmHg. Bcl1 polymorphism in exon 2 was defined by means of polymerase chain reaction with subsequent analysis of restriction fragment length polymorphism by I. Fleury et al. (venous blood was taken for the study). Statistical analysis was performed using SPSS–17 program.
**Results:** The patients with rheumatoid arthritis revealed the following: 10 patients had hypotension (6.2%); 60 subjects had normal arterial pressure (43.5%); 91 patients had arterial hypertension (56.5%). Of those having hypotension, 4 patients had C/C genotype (8.9%), 4 individuals presented with C/G genotype (5.1%) and 2 – with G/G genotype. Among the patients with normal pressure, 22 subjects were homozygous for the C allele (48.9%), 32 were heterozygous (40.5%) and 6 were homozygous for the G allele (16.2%). In the hypertensive group 19 individuals were homozygous for the C allele (42.2%), 43 were heterozygous (C/G allele) (54.4%) and 29 were homozygous for the pathologic G allele (78.4%). A significant difference was determined by Pearson's chi-squared test (p=0.02) as for the genotype distribution in patients with rheumatoid arthritis and different levels of arterial pressure. Analysis of frequency of arterial pressure levels in these patients demonstrated an association between arterial hypertension and G/G genotype.
**Conclusions:** An association was found between the Bcl1 polymorphism in glucocorticoid receptor gene and arterial pressure level in patients with rheumatoid arthritis. A strong association between arterial hypertension and G/G genotype was proved.
**Disclosure of Interest:** None declared

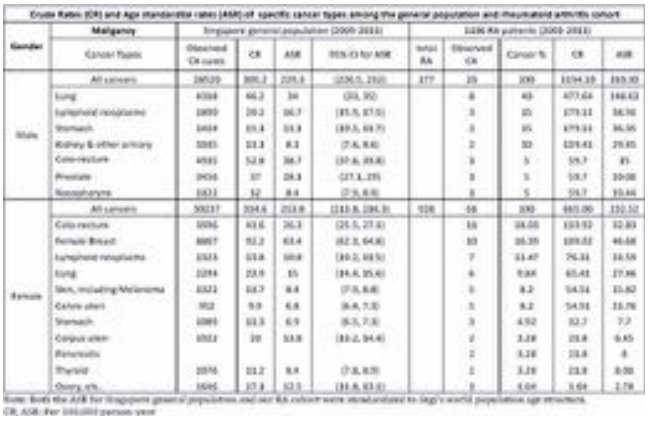
## THU0116 SINGAPORE PATIENTS WITH RHEUMATOID ARTHRITIS HAVE A HIGHER INCIDENCE OF SOLID-ORGAN MALIGNANCIES THAN THE GENERAL POPULATION: FINDINGS FROM THE TTSH RA REGISTRY

X.R. Lim[1], X. Gao[2], W.L.J. Tan[1], L.W. Koh[1], T.Y. Lian[1], W.Q. See[2], K.P. Leong[1], E.T. Koh[1] on behalf of Tan Tock Seng Hospital Rheumatoid arthritis Study Group. *[1]Rheumatology, Allergy and Immunology; [2]Tan Tock Seng Hospital, Singapore, Singapore*

**Objectives:** Patients with rheumatoid arthritis (RA) have been shown to have an increased risk of developing malignancies. This study was undertaken to determine the incidence and patterns of malignancy in RA patients and identify risk factors of malignancy among patients with RA.
**Methods:** Patients from the TTSH RA Registry were followed up longitudinally and those who developed malignancies from 2001 to 2013 after the onset of

**Abstract THU0116** – Table 1. Demographics, disease characteristics and treatment history of patients without malignancy and those who develop malignancy



| | | Total No. of patients n=1106 (%) | No. of patients without maligancy n=1025 (%) | No. of patients with maligancy after 1st study entry n=81 (%) | Univariate test p-value (t-test or chi2) |
|---|---|---|---|---|---|
| Demographics | | | | | |
| Age at RA onset (yrs) | mean (SD) | 45.03 (13.40) | 44.58 (13.20) | 50.77 (14.59) | 0.0001 |
| Age at RA diagnosis (yrs) | mean (SD) | 47.31 (13.69) | 46.74 (13.55) | 54.43 (13.52) | <0.0001 |
| Duration of RA onset to RA diagnosis (mths) | mean (SD) | 27.34 (66.63) | 26.02 (64.86) | 43.96 (84.61) | 0.0196 |

| No. of swollen joints at 1st study visit | mean (SD) | 2.34 (3.59) | 2.26 (3.45) | 3.37 (4.90) | 0.0072 |
| DAS28 at 1st study visit | mean (SD) | 3.35 (1.41) | 3.33 (1.39) | 3.61 (1.57) | 0.0894 |

RA were identified. Age-standardised rates (ASRs) of various cancers were analyzed and compared with the Singapore Cancer Registry data. Risk factors for developing malignancy, including demographics and disease characteristics at baseline, were analyzed using Chi-squared test and student's t test.

**Results:** Of the 1,134 patients in the registry, 28 patients were excluded as they developed malignancy prior to study enrollment. 1,106 patients were included in the final analysis. Of the 1,106 patients, 81 patients developed malignancies at a mean interval of 15.1 (SD 9.7) years after the onset of RA. The mean age of the 81 patients was 65.9 (SD 10.8) years, of which 61 (75.31%) were females and 69 (85.19%) were Chinese. There were 70 (86.4%) with solid-organ tumours and 11 (13.6%) haematological malignancies.

The ASR of cancer in RA patients was 310.3 for males and 232.5 for females per 100,000 person-years, compared with 229.3 (95%CI 226.5–232) for males and 218.3 (95%CI 213.8–216.3) for females in the general population. By cancer type, there is an increased risk of lung cancer, lymphoid neoplasms and stomach cancer in RA compared with the general population.

The risks factors for developing malignancy ($p<0.05$) include male gender, non-Indian ethnicity, onset of RA at an older age, untreated RA and higher disease activity.

**Conclusions:** The incidence of solid-organ malignancies was higher than hematological malignancies, unlike that in the literature. The overall risk of malignancy is higher in RA patients. Chronic inflammation from RA is associated with increased risk of malignancy.

## THU0117 DIAGNOSTIC VALUES OF ANTI-SA AND ANTI-RA33 ANTIBODIES IN RHEUMATOID ARTHRITIS: A META-ANALYSIS

Y.H. Lee, Y.H. Seo, S.J. Choi, G.G. Song. *Rheumatology, Korea University Medicial Center, Seoul, Korea, Republic Of*

**Background:** Anti-Sa antibody was identified in 1994 and belongs to a class of antibodies that target citrullinated antigens. Anti-Sa antibody is highly specific for diagnosing rheumatoid arthritis (RA, but it is associated with low prevalence and sensitivity. Anti-RA33 antibody was identified in 1989 and targets RA33 complex or heterogeneous nuclear ribonucleic protein. In contrast to anti-Sa antibody, anti-RA33 antibody does not target citrullinated antigens. Both anti-Sa and anti-RA33 antibodies are considered as specific serological markers for RA. However, studies assessing the diagnostic value of these antibodies in RA have provided inconsistent results.

**Objectives:** The aim of this study is to evaluate the diagnostic performance of anti-Sa and anti-RA33 antibodies in RA.

**Methods:** PubMed, Embase, and Cochrane library databases were searched for relevant studies and 2 meta-analyses were performed to determine the diagnostic accuracy of anti-Sa and anti-RA33 antibodies in patients with RA.

**Results:** The meta-analysis included 17 studies. Of these, 9 studies, which included 1,095 patients and 1,667 controls, were on anti-Sa antibody and 8 studies, which included 905 patients and 835 controls, were on anti-RA33 antibody. Pooled sensitivity and specificity of anti-Sa antibody were 39.5% (95% confidence interval [CI], 36.5–42.4) and 96.8% (95% CI, 95.9–97.4), respectively, and those of anti-RA33 antibody were 31.8% (95% CI, 28.7–35.0) and 90.1% (95% CI, 87.8–92.1), respectively. PLR, NLR, and DOR of anti-Sa antibody were 14.11 (95% CI, 7.076–28.13), 0.607 (95% CI, 0.558–0.703, and 22.76 (95% CI, 11.10–46.69), respectively, and those of anti-RA33 antibody were 3.429 (95% CI, 2.039–5.765), 0.761 (95% CI, 0.681–0.851), and 4.597 (95% CI, 2.602–8.121), respectively. AUC and $Q^*$ index for anti-Sa antibody were 0.558 and 0.543, respectively, while those for anti-RA33 antibody were 0.501 and 0.500, respectively.

**Conclusions:** Our meta-analysis indicated that both anti-Sa and anti-RA33 antibodies were highly specific and the PLR of anti-Sa antibody was very useful for diagnosing RA, although they were not sensitive for diagnosing RA.

**Disclosure of Interest:** None declared

## THU0118 TREND OF ATYPICAL FEMORAL FRACTURES IN RHEUMATIC PATIENTS IN THE HIGHLY SUPER AGING AREA OF NORTH JAPAN

Y. Takakubo, D. Ota, Y. Naganuma, H. Oki, A. Narita, J. Ito, K. Sasaki, M. Takagi. *Department of Orthopaedic Surgery, Yamagata University Faculty of Medicine, Yamagata, Japan*

**Background:** A number of recent case reports and series have identified atypical fractures of the femoral shaft. Atypical femoral fractures (AFFs) with lack of trauma or less-energy have been reported to relate using of the bisphosphonates (BPs) and glucocorticoids (GCs) for a long time, affecting collagen diseases[1,2].

**Objectives:** We have analyzed the AFFs in rheumatic patients in the highly super aging area of North Japan, in which the rate more than 65 year-old people in the population was 28%.

**Methods:** We investigated retrospectively all cases of AFF summarized by the American Society for Bone and Mineral Research (ASBMR) Task Force 2013[1] including affected rheumatic disease patients in all hospitals of our prefectural area from 2009 to 2014. Two independent orthpaedic surgeons have diagnosed blindly AFF and estimated proximal femoral geometry by using radiographic analyses. Observation end of this study was settled on Feb 2016.

**Results:** We have 86 cases 99 AFFs in our prefectural area from 2009 to 2014 (1.43 cases/100,000 person/year). The rheumatic patients with AFFs were eleven femurs in eight women in that periods and increased year by year (Fig. 1). Three cases have bilateral AFFs (six femurs, 55%). The mean age of them was 54.9 year-old (33–80). As comorbid conditions, five patients have systematic lupus erythematosus, two dermatomyositis and rheumatoid arthritis, one polyarteritis nodosa and systemic sclerosis. Fracture types were seven subtrochanteric and four diaphyseal femoral fractures. Mean femoral neck angle was 133 degrees (120–141) and femoral shaft angle was 6.1 degree (3–10). Six patients with AFF had prodromal pain (55%). All patients received BPs and all but one prednisolone (PSL). Mean duration of receiving those drugs was 52 months (24–120) and 109 months (36–120), respectively. Mean dosage of PSL was 14 mg/day (0–30). In addition, bilateral AFF group has more PSL dose and duration of PSL, more varus deformity of their femur compared to unilateral AFF group ($p<0.05$). After affecting the fractures, BPs were quitted in seven femurs except four. The surgery using intramedullary nail fixation were performed in all cases excluding one femur using a locking plate. Teriparatide and therapy of low-intensity pulsed ultrasound was induced for five cases after healing their operated wounds. Mean duration of post-operative observation was 28 months (12–70). At the latest follow-up, ten femurs were observed the sign of union at fracture site on X-ray or computed tomography of their femurs, but not one femur. Mean duration of union of the fracture site was 12.6 months (6–24) in ten femurs.

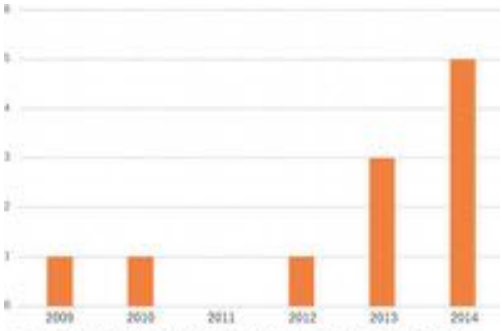

Fig. 1 The trend of atypical femoral fractures in rheumatic patients in the highly super aging area of North Japan

**Conclusions:** Eleven AFFs were observed in 2009–14 in rheumatic patients and the numbers were increased year by year in the highly super aging area of North Japan. The careful management and treatment for the AFFs in rheumatic patients are required even after the surgery, because our all cases have been observed the delayed union or non-union of fracture site at their latest follow-up[3]. In addition, AFF patients who show varus deformity of their femurs and receive much dose of PSL have highly risk of contralateral AFF.

### THU0119 RHEUMATOID ARTHRITIS AND PERIODONTAL DISEASE: ASSOCIATION BETWEEN SALIVARY CITRULLINE, ACPA LEVELS AND CLINICAL PRESENTATION

I. Tar[1], É. Csösz[2], É. Veiszenbacher[3], E. Végh[4], K. Bágyi[5], K. Lundberg[6], N. Kharlamova[6], I. Márton[1], Z. Szekanecz[4]. *[1]Department of Periodontology, University of Debrecen, Faculty of Dentistry; [2]Center for Molecular Medicine, University of Debrecen, Faculty of Medicine, Debrecen, Hungary; [3]Faculty of Dentistry, Medical and Pharmacological University of Tirgu Mures, Tirgu Mures, Romania; [4]Department of Rheumatology, University of Debrecen, Faculty of Medicine; [5]Department of Restorative Dentistry, University of Debrecen, Faculty of Dentistry, Debrecen, Hungary; [6]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden*

**Background:** Periodontitis and other dental conditions have been associated with the pathogenesis of rheumatoid arthritis (RA). In addition, these dental pathologies are also important comorbidities for RA.
**Objectives:** We wished to evaluate the periodontal involvement of rheumatoid arthritis (RA) patients, and we correlated with various laboratory biomarkers including lipids, autoantibodies, serum vitamin D levels, markers of bone metabolism in relation with the periodontal condition and cariological indices; and also correlated them with salivary citrulline and anti citrullinated protein autoantibody levels with the above mentioned clinical and blood test findings.
**Methods:** Twenty-three RA patients were recruited for the study. Saliva samples were taken following whole scale periodontal and cariological examination. Protein concentration, peptidyl-citrulline and anti-cyclic citrullinated protein (anti-CCP) levels were measured from saliva samples. Blood test results were provided by rheumatologists. Citrullinated enolase protein-1 (CEP-1) level from serum was also measured.
**Results:** Periodontal diagnoses (scores) seem to have a positive dependency on LDL (R=0.722, p=0.008), PTH1 (R=0.586, p=0.022), $D_3$ vitamin level (R=0.586, 0.022), the sum of D3/D2 (R=0.634, p=0.011) respectively, in these patients. Anti-CEP-1 positive patients had significantly higher periodontal scores (2.71±0.11 vs 2.50±0.09, $p<0.05$) compared to anti-CEP-1 negative subjects. Interestingly, anti-CEP-1 positive patients had significantly higher triglyceride levels compared to seronegative ones (1.81±0.17 vs 1.42±0.05 mmol/l; $p<0.05$). Salivary citrulline and salivary anti-CCP, (p=0.007, R: 0.583) level has a correlation with the maximum of clinical probing depth.
**Conclusions:** Our results may add further pieces to the mosaic of RA-periodontitis connection. The possible role of antimicrobial immunity, as well as the possible role of lipids and bone metabolism have also been delineated. Future therapies should aim the disruption of this framework.
**Disclosure of Interest:** None declared

## Rheumatoid arthritis - anti-TNF therapy

### THU0120 LONG TERM SAFETY AND EFFICACY OF BIOSIMILAR INFLIXIMAB AMONG PATIENTS WITH INFLAMMATORY ARTHRITIS SWITCHED FROM REFERENCE PRODUCT

A. Abdalla[1], N.E. Byrne[2], R. Conway[2], T. Walsh[2], G. Mannion[2], M. Hanly[2], M. O'Sullivan[2], A. Curran[2], J.J. Carey[1]. *[1]Rheumatology Department; [2]Merlin Park University Hospital, Galway, Ireland*

**Background:** Biologic medications are effective treatments for inflammatory arthritis, however they are expensive, costing around €15,000 per patient per year, or 5% of the annual healthcare budget in Ireland. Measures to reduce this cost without sacrificing efficacy or safety are important. Studies switching patients to cheaper approved biosimilar products are few.
**Objectives:** To evaluate the efficacy and safety of biosimilar Infliximab in adult patients with inflammatory arthritis switched from reference product in our centre.
**Methods:** In April 2014 all patients attending our rheumatology service for Infliximab infusions were switched from reference product to a biosimilar infliximab following verbal consent and hospital approval. Our local I.R.B. approved a retrospective review of these patients following requests from other centres for information on our experience.
**Results:** 34 patients with inflammatory arthritis were switched from reference product Infliximab in 2014: 50% female, mean (SD) age 55 years (12.9), mean disease duration 14.8 years (9.7), mean duration on infliximab 70 months (59.6) and two thirds were taking oral DMARDs. There was no difference in efficacy or safety in the first 6 months of therapy. By the end of 2015, the mean follow-up on biosimilar infliximab was 15.8 months (6.3). Our results show no significant difference in HAQ score, patient global assessment of disease activity, number of disease flares or medication dose between the originator and the biosimilar Infliximab. However reported pain and CRP values were significantly higher during the longer follow-up period (*p* value 0.028, 0.001 respectively). There was no significant difference in the number of adverse events or infusion reactions during similar follow-up periods, or the number of patients who discontinued therapy (3 Vs 5). 1 frail patient with multiple co-morbidities died during follow-up. Substantial savings were obtained by using the biosimilar product.
**Conclusions:** Our patients experienced similar efficacy and safety for managing their arthritis with biosimilar infliximab as reference product Infliximab, but at a much lower cost.

### THU0121 LOW DISEASE ACTIVITY AND ACR70-RESPONSE IS ASSOCIATED WITH THE INHIBITION OF PERIARTICULAR BONE LOSS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH CERTOLIZUMAB PEGOL PLUS METHOTREXATE

A. Pfeil[1], A. Nussbaum[1], C. Jung[2], L. Reinhardt[3], P. Oelzner[1], A. Malich[4], J. Böttcher[5], G. Wolf[1]. *[1]Department of Internal Medicine III, Friedrich-Schiller-Univerisity Jena, Jena; [2]Department of Medicine, Division of Cardiology, Pulmonology and Vascular Medicine, University Hospital Duesseldorf, Duesseldorf; [3]Department of Internal Medicine III, Friedrich -Schiller-University Jena, Jena; [4]Institute of Diagnostic Radiology, Suedharz-Hospital Nordhausen, Nordhausen; [5]Institute of Diagnostic and Interventional Radiology, SRH Wald-Klinikum Gera, Gera, Germany*

**Background:** Anti-TNF treatment with certolizumab pegol is an effective therapy in patients with rheumatoid arthritis (RA).
**Objectives:** The aim of this study, based on a post-hoc analysis of the data set used in the RAPID 1 trial (1), focuses on the associations between metacarpal bone mineral density as estimated by Digital X-ray Radiogrammetry and disease activity as well as ACR70-Response in RA patients treated with certolizumab pegol plus methotrexate (CZP+MTX).
**Methods:** The post-hoc analysis of the RAPID 1 trial evaluates a total of 345 patients: 34 patients who received placebo plus methotrexate (PBO+MTX), 155 patients who received CZP 200 mg (every two weeks) plus MTX and 156 patients who received CZP 400 mg (every two weeks) plus MTX. All patients underwent x-rays of the hand at baseline and week 52 as well as computerized calculations of bone mineral density (BMD) by DXR (2). ACR70-response was evaluated.
**Results:** The highest CRP reduction was observed for patients treated with CZP 400 mg + MTX (-63.6%, $p<0.05$) and CZP 200 mg + MTX (-55.9%, $p<0.05$) compared to the PBO+MTX (-24.7%, $p<0.05$). An equal constellation was revealed regarding the DAS28-CRP (CZP 400 mg + MTX: -50.5%, $p<0.05$; CZP 200 mg + MTX: -49.3%, $p<0.05$ and PBO + MTX: -31.3%, $p<0.05$). In accordance with these results, DXR-BMD showed a minor significant bone loss for the treatment groups undergoing therapy with CZP 400 mg + MTX and CZP 200 mg + MTX with -1.1% ($p<0.05$) versus -1.3% ($p<0.05$), and an advanced periarticular metacarpal bone loss of -5.5% ($p<0.05$) in the PBO+MTX. The patients treated in the small PBO+MTX group revealed no significant ACR70-Response. Both CZP+MTX groups revealed a significant ACR70-Response. In the case of ACR70-Response no significant change of the DXR-BMD was observed.
**Conclusions:** The study highlights that patients treated with CZP+MTX showed a high reduction of CRP and DAS28-CRP in association to a less accentuated periarticular bone loss as estimated by DXR in comparison to patients treated with PBO+MTX. Additionally, patients with ACR70-Response revealed no periarticular demineralisation. The reduced periarticular demineralization functions as a surrogate marker for the bone protective effects of certolizumab pegol.

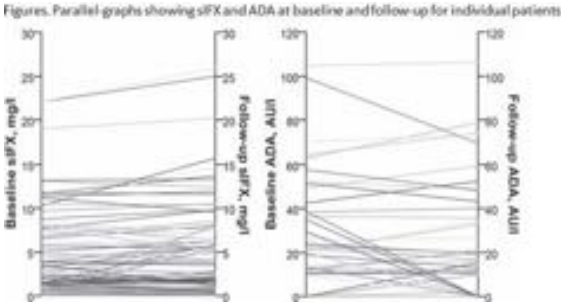
## THU0122 ETANERCEPT TREATMENT DOES NOT ADVERSELY AFFECT TRADITIONAL CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Deodhar[1], B. Bitman[2], Y. Yang[2], D. Collier[2]. [1]*Oregon Health and Science University, Portland;* [2]*Amgen Inc., Thousand Oaks, United States*



**Background:** Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular (CV) disease.
**Objectives:** To evaluate changes in metabolic and lipid CV risk factors in patients with RA treated with etanercept (ETN)
**Methods:** This was an exploratory analysis in a randomized, double-blind, placebo-controlled study to evaluate the efficacy and safety of ETN in patients with moderate RA despite disease-modifying antirheumatic drug therapy. Adults with active, moderate RA (3.2 < DAS28-CRP ≤ 5.1) for ≥6 months and receiving a stable dose of methotrexate for ≥8 weeks were randomized 1:1 to receive ETN 50 mg or placebo (PBO) weekly for 12 weeks; after week 12, all patients received ETN 50 mg weekly for 12 weeks. Laboratory tests evaluated baseline, week-12, and week-24 levels of metabolic and lipid analytes, and shifts in grade (low, normal, or high).
**Results:** In total, 210 patients enrolled: 104 PBO and 106 ETN; 77% female, 86% white, and mean (SD) age 56 (12) years. There were 14% with a medical history of type 2 diabetes and 30% a medical history of hyperlipidemia or hypercholesterolemia; 22% were receiving statins, 10% oral antidiabetic medications, 3% insulin, and 52% prednisone. Baseline, week-12, and week-24 values for each analyte are listed below. Over 24 weeks, there were no significant changes in metabolic or lipid analytes. Patients with diabetes and hyperlipidemia resembled the overall study population, except for decreases in fasting glucose and insulin through week 12 and slight decreases in hemoglobin A1C through week 24 in diabetics receiving ETN (n=17). For the majority of patients, all analytes were in the normal range at baseline and remained normal at week 24.There were no gross abnormalities in liver function tests. Safety results are consistent with the current safety profile.
**Conclusions:** Treatment with ETN did not adversely affect the levels of traditional metabolic and lipid CV risk factors in patients with RA. Results in patients with diabetes are hypothesis generating and might be clinically relevant if demonstrated in a larger study.

## THU0123 NON-MEDICAL SWITCH FROM ORIGINATOR TO BIOSIMILAR INFLIXIMAB AMONG PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE – IMPACT ON S-INFLIXIMAB AND ANTIDRUG-ANTIBODIES. RESULTS FROM THE NATIONAL DANISH RHEUMATOLOGIC BIOBANK AND THE DANBIO REGISTRY

B. Glintborg[1], T. Kringelbach[1], E. Høgdall[1], I.J. Sørensen[2], D.V. Jensen[2], A.G. Loft[2], O. Hendricks[2], I.M. Jensen Hansen[2], N. Bolstad[3], K. Grøn[2], G. Eng[2], C. Enevold[2], C.H. Nielsen[2], D. Warren[3], G. Goll[3], J. Gehin[3], J.S. Johansen[1], M.L. Hetland[1]. [1]*Danish Rheumatologic Biobank and DANBIO registry, Rigshospitalet and Herlev University Hospital;* [2]*On behalf of all Danish Departments of Rheumatology, Copenhagen, Denmark;* [3]*Department of Medical Biochemistry, OUS-Radiumhospitalet and Diakonhjemmet Sykehus, Oslo, Norway*

**Background:** According to national guidelines issued in 2015, a non-medical switch from originator infliximab (IFX) to biosimilar IFX was conducted in all Danish patients with inflammatory rheumatic diseases treated in routine care.
**Objectives:** To investigate effects of the switch on serum (s) IFX and anti-drug antibodies (ADA) in patients with rheumatoid arthritis (RA), axial spondyloarthrits (SpA) and psoriatic arthritis (PsA).
**Methods:** We included originator infliximab treated patients, who switched to and were treated with biosimiilar infliximab for >2 months with 2 available trough level serum samples (baseline immediately before switching/follow-up 2–4 months after switching time of 2nd–4th infusion). Patients stopping treatment earlier were not included. Trough sIFX <3mg/l was considered low and ≤1mg/l very low. If sIFX <5mg/l, ADA was measured. ADA ≤30AU/l was considered low and ADA >30AU/l median-high. sIFX and ADA were analyzed using automated in-house assays at OUS-Radiumhospitalet. Characteristics and outcomes were registered in the DANBIO registry. Remission was defined by disease activity indices (DAS28 <2.6 (RA, PsA) and ASDAS <1.3 (SpA)). Comparisons were by Mann Whitney U test (unpaired) and Wilcoxon signed rank test (paired). Outcomes are shown as medians (interquartile ranges).
**Results:** 96 pts (192 samples) from 4 departments (49 RA, 27 SpA, 10 PsA, 10 other) were included (age 52 (43–62) years, 47% women). Previous IFX treatment duration was 7.5 (5.1–10.3) years. Follow-up was after 81 (71–90) days. 58 patients (60%) received concomitant methotrexate (15 (10–20) mg/wk). Baseline IFX dose was 3.1 (3.0–4.8) mg/kg every 7 (6–9) weeks. At baseline, 60% of pts had low sIFX and 29% very low and at follow-up it was 57% and 29%, respectively. At baseline, 14 pts (15%) had medium-high ADA, at follow up 16%. Median sIFX was lower at baseline vs. follow-up (1.8 (0.8–5.8) vs 2.4 (0.8–6.2) mg/l, p=0.006) whereas ADA were similar (p=0.7). Six of 58 pts with low baseline sIFX had high sIFX at follow-up, and 3 of 38 pts with high baseline sIFX had low sIFX at follow-up. Similar numbers for low vs. medium–high ADA at baseline and follow-up were 2/81 and 3/15. For the rest, sIFX and ADA remained stable between baseline and follow-up in 87/96 (91%) and 91/96 (95%), respectively (Figure). MTX use was not associated with sIFX or ADA (both p>0.05). Patients with low sIFX received lower IFX doses than pts with sIFX ≥3mg/l (255 (200–320) mg vs. 300 (250–400) mg, p=0.02) and with longer intervals (8 (6–10) weeks vs. 6 (6–6)weeks, p<0.01). Remission rates at baseline (56%/11%/75%) or follow-up (52%/21%/100%) for RA/SpA/PsA were not associated with sIFX (all p>0.05).

Figures. Parallel graphs showing sIFX and ADA at baseline and follow-up for individual patients

**Conclusions:** In this highly selected group of patients treated with originator infliximab for >5 years, non-medical switch to biosimilar IFX had no negative impact on sIFX or ADA 2–4 months following switch. At baseline, 60% of patients had low sIFX but few patients had ADA, perhaps indicating low immunogenicity in these patients.

| Total cholesterol, mg/dl | 195.2 (44.2) | 186.6 (37.1) | 190.9 (40.7) | 184.8 (37.4) | 197.0 (41.7) | 191.1 (39.6) |
| HDL, mg/dl | 62.0 (18.1) | 62.1 (21.7) | 60.5 (17.1) | 61.6 (18.3) | 62.1 (18.5) | 62.2 (22.9) |
| LDL, mg/dl | 105.6 (36.3) | 97.8 (30.0) | 103.2 (35.4) | 96.9 (33.2) | 105.5 (35.4) | 101.7 (31.0) |
| Triglycerides, mg/dl | 135.2 (91.6) | 133.1 (80.1) | 139.2 (85.5) | 131.8 (69.4) | 149.6 (104.0) | 136.6 (76.2) |
| Apolipoprotein A1, mg/dL | 159.6 (27.8) | 160.5 (35.4) | 159.2 (28.1) | 162.0 (32.8) | 163.7 (32.1) | 161.6 (38.0) |
| Apolipoprotein B, mg/dL | 91.6 (25.5) | 86.2 (22.2) | 89.5 (24.7) | 84.9 (23.8) | 91.8 (24.2) | 88.7 (25.0) |
| Adiponectin, mg/L | 11.6 (6.8) | 11.5 (8.7) | 11.7 (7.4) | 11.6 (8.8) | 12.3 (7.2) | 11.6 (9.1) |
| Leptin, μg/L | 29.3 (20.9) | 33.5 (28.5) | 30.1 (22.7) | 35.6 (30.9) | 30.8 (22.7) | 34.5 (28.9) |
| Plasma NT-ProBNP, ng/L | 242.0 (554.1) | 170.1 (334.6) | 232.2 (630.8) | 168.2 (297.8) | 244.2 (687.5) | 164.2 (315.7) |

safety and efficacy. In some countries, the WHO SBP guidelines are not being consistently adopted or implemented and ICs of etanercept (ETN), originally developed by Pfizer (Wyeth), are being marketed as biosimilar versions, although rigorous regulatory criteria for analytical testing and clinical demonstration of biosimilarity may not have been fully assessed.

**Objectives:** Pfizer conducted an analytical assessment of multiple lots of 4 ICs, and a single lot of 1 IC of ETN that have received marketing approval in various global markets. The results for critical quality attributes are compared with the licensed specifications of ETN.

**Methods:** ICs of ETN manufactured by Shanghai CP Guojian (China), Lafrancol (Colombia), Cipla (India), Probiomed (Mexico) and AryoGen (Iran) were assessed. Analyses included a subset of the release tests for ETN, together with evaluation by additional characterization methods to provide appropriate comparative detail on biochemical composition. Results for each product were evaluated against licensed specifications and historical ranges for ETN and ETN reference standard for the additional characterization test results.

**Results:** None of the ICs met all of the individual product quality criteria that Pfizer apply for analytical comparability, although each product met some of the requirements. Principal differences were observed during assessments of *identity* (as measured by tryptic peptide map high-performance liquid chromatography [HPLC]), *purity* (as measured by hydrophobic interaction chromatography [HIC]), degree of *aggregation* (size exclusion [SE] HPLC), distribution of *charged species* (isoelectric focusing [IEF]/anion exchange [AEX] chromatography) and *carbohydrate profile* (N-linked oligosaccharide map). These are shown in the table.

| Key structural differences* | IC Manufacturer | | | | |
|---|---|---|---|---|---|
| | Shanghai CP Guojian | Lafrancol | Cipla | Probiomed | AryoGen |
| Identity (tryptic peptide map HPLC): Atypical | | | | | Y |
| Aggregation (SE HPLC): above specification limit | Y | Y | Y | | |
| Charged species (IEF/AEX chromatography): Differences in distribution vs ETN | Y | Y | Y | | Y |
| Purity (HIC): Atypical profile | Y | Y | Y | | |
| Carbohydrate profile (N-linked oligosaccharide map): Atypical (additional species not in ETN profile) | | | | Y | Y |

*Relative to ETN release specifications and additional characterization historical data. Y, yes.

**Conclusions:** While a degree of structural similarity with ETN was observed for each of the ICs analyzed, a number of significant structural and biochemical differences were noted. None of the products analyzed meet the combination of release specification and additional characterization criteria Pfizer typically apply to support a comparability assessment with ETN.

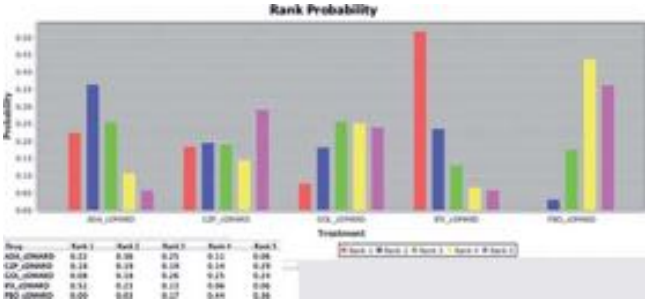
## THU0125 DRUG RETENTION AND REASONS FOR DRUG DISCONTINUATION OF ANTI-TNF THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS. A NETWORK META-ANALYSIS

C.P. Lee Ching[1], E. Donath[1], Y. Sergeyenko[2], D. Mai[2], T. Desai[1], A. Shah[1], C. Patel[2], S.M. Kothadia[2], R.L. Morrison[2], C.-C.J. Lee[2], E. Tappy[2], S. Kumar[3].
*[1]University of Miami/JFK Med Ctr Palm Beach Regional GME Consortium; [2]University of Miami, Atlantis; [3]Rheumatology, West Palm Beach Veterans Affairs Medical Center, West Palm Beach, United States*



**Background:** Drug retention is considered an indicator of the overall effectiveness, safety and tolerability of a treatment. It is a useful guide to decide the best anti-TNF therapy in patients with R.A.

**Objectives:** To determine which of the TNF inhibitors has the highest retention rate in patients with R.A and to analyze the different reasons for drug discontinuation.

**Methods:** A search of MEDLINE, CENTRAL and EMBASE identified 201 randomized controlled trials (RCTs). We included those comparing a TNF inhibitor (standard dose) with a placebo group, plus concomitant use of conventional DMARDs. We excluded those allowing rescue therapy or not reporting the outcomes of interest. These outcomes were: drug discontinuation and reasons, adverse events, serious adverse events, infections, serious infections and acute infusion events or injection site reactions. A mixed-treatment comparisons analysis was constructed to indirectly compare each study group to one another. Calculation of the probability that each treatment is best was implemented using the Bayesian Markov chain Monte Carlo method.

**Results:** 18 RCTs, including 6948 patients, were extracted. The mean length of study was 6.6 months. On average, patients were 52 years old with active R.A of 5.5 years duration, with 24 TJC, 15 SJC and CRP of 2.3 mg/dl at baseline.

All TNF inhibitors were associated with relatively high rates of drug survival and no statistically significant differences were noted. By rank probability, Infliximab had the highest probability (52%) of retaining patients, and Golimumab (26%) and Certolizumab (29%) had the highest probabilities of being least likely to retain patients (see graphic). Regarding discontinuation due to lack/loss of efficacy, Certolizumab was the most likely and Infliximab the least likely drug to be discontinued. With respect to discontinuation due to adverse events, Infliximab had a 77% probability of being the most likely drug to be discontinued and Certolizumab (30%) was the least likely drug to be discontinued. Additionally, regarding adverse event-related outcomes, several observations were notable. Both Adalimumab and Golimumab were statistically significantly less likely than Infliximab to cause infections and, by rank probability, Infliximab had a 96% chance of being the drug most likely to cause infections. Regarding infusion/injection reactions, both Certolizumab and Infliximab were associated with very high probabilities (51% and 47%, respectively) relative to the other agents of being most likely to cause infusion reactions.

**Conclusions:** Infliximab had the highest retention rate and was the least likely drug to be discontinued due to lack or loss of efficacy, but had the highest discontinuation rate due to adverse events. More data is needed with longer study periods to further reinforce these findings.

## THU0126 DOSE TITRATION OF BIOLOGICS FOR THE TREATMENT OF RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS: A SYSTEMATIC LITERATURE REVIEW

C.S. Lau[1], A. Gibofsky[2], N. Damjanov[3], S. Lula[4], L. Marshall[5], H. Jones[5], P. Emery[6]. *[1]University of Hong Kong, Hong Kong, Hong Kong; [2]Weill Cornell Medical College, New York, United States; [3]Belgrade University School of Medicine, Belgrade, Serbia; [4]Envision Pharma Group, London, United Kingdom; [5]Pfizer, Collegeville, United States; [6]University of Leeds, Leeds, United Kingdom*

**Background:** Increasingly, clinicians treating rheumatoid arthritis (RA) or ankylosing spondylitis (AS) are trying to dose-titrate biologics, due to cost, patient preference, and safety. Recent clinical guidelines recommend down titration for RA. However, evidence of safety and efficacy is limited.

**Objectives:** Conduct a systematic literature review to assess breadth and quality of published data and evaluate whether sufficient evidence exists to support dose titration of biologics in RA or AS.

**Methods:** Medline, Embase, and the Cochrane library were electronically searched on February 2, 2015, and conference abstracts from 2010 to November 2015 were hand searched. Eligible studies included: randomized controlled trials (RCTs), non-RCTs, observational, and pharmacoeconomics. Biologics included: abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. Outcomes were (1) efficacy and sustained remission, (2) flares and retreatment, (3) economic impact.

**Results:** The search yielded 21,585 records; after screening, 73 studies in 90 publications/abstracts were retained, including 15 full-text RCTs, 15 full-text non-RCTs and 43 conference abstracts. Efficacy and economic data were limited. Heterogeneity in disease duration, dosing strategies, and definition of treatment success/failure complicated the interpretation and comparison of regimens. Dose titration rationale varied greatly, and few studies used established definitions of flare (table). Level of evidence was low, with most studies presented as conference abstracts.

**Abstract THU0126** – Table 1. Decisions driving downward dose-titration in RA and definitions of flare, according to study/publication type and biologic

| | # RCTs | # Observational studies | # Congress abstracts |
|---|---|---|---|
| Decisions driving dose-titration | | | |
| Sustained DAS28 remission or LDA | 2 ETN | 1 ADA, 2 ETN, 3 INF | 2 ETN, 4 TCZ |
| Clinical remission or LDA (no additional information) | | | 1 ADA, 2 ETN |
| EULAR response (moderate or good) | 1 RTX | | 2 RTX |
| Good sustained response or clinical judgment | | | 1 ADA, 1 ETN, 1 RTX, 1 TCZ |

ACR, American College of Rheumatology; ADA, adalimumab; DAS28, disease activity score-28 joints; DMARD, disease modifying anti-rheumatic drug; ETN, etanercept, EULAR, European League Against Rheumatism; HAQ, health assessment questionnaire; INF, infliximab; LDA, low disease activity; RTX, rituximab; SDAI, simplified disease activity index; TCZ, tocilizumab.

**Conclusions:** Studies evaluating dose titration of biologics are heterogeneous in design and lack standardized definitions. Little evidence of safety and efficacy exists to support dose titration of biologics in RA or AS; RCTs with defined indicators of treatment success and failure are needed.

## THU0127 INTRAVENOUS GOLIMUMAB THERAPY IMPROVES HEMOGLOBIN, RESULTING IN REDUCED ANEMIA, IMPROVED PHYSICAL FUNCTION AND FATIGUE IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS: RESULTS FROM GO-FURTHER PHASE III CLINICAL TRIAL

C. Han[1], M.E. Weinblatt[2], R. Westhovens[3], L. Kim[4], E.C. Hsia[4], D. Parenti[5], S. Kafka[5], C.O. Bingham III[6] on behalf of the GO-FURTHER Investigators.
*[1]Johnson & Johnson Pharmaceutical Services, Malvern; [2]Brigham & Women's Hospital, Boston, United States; [3]Rheumatology, UZ KU Leuven, Leuven, Belgium; [4]Janssen Research & Development, Spring House; [5]Janssen Scientific Affairs, Horsham; [6]Johns Hopkins University, Baltimore, United States*

**Background:** Clinical studies demonstrated that patients with rheumatoid arthritis (RA) experience lower hemoglobin level and higher prevalence of anemia than general population.

**Objectives:** This study was to examine the treatment effect of intravenously administered golimumab on improving hemoglobin (Hgb) level, and relieving anemia and anemia-related outcomes among patients with RA using data from the phase III clinical trial GO-FURTHER.

**Methods:** In the GO-FURTHER trial, adult patients with active RA were randomized to placebo + MTX (PBO group) or GLM (2mg/kg) plus MTX at week 0, 2, and every 8 weeks thereafter (GLM group). Patients in placebo group with <10% improvement in tender and swollen joint count from baseline at week 16 entered early escape (EE) and received a 2 mg/kg golimumab infusion at Weeks 16 and 20. In this post hoc analysis, Hgb was assessed at baseline, week 4, 12, 20, 28, 44. Anemia was defined based on World Health Organization (WHO) criteria as Hgb <12 g/dl in women and <13 g/dl in men. Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT fatigue) Scale, SF-36 vitality scale, and Health Assessment Questionnaire (HAQ) were collected. Pearson's correlation and linear regression model were used to test correlation. Comparisons between groups at Week 12 before EE were performed using t-test for numeric variables or Mantel-Haenszel Chi-square test for dichotomous variable.

**Results:** At baseline, mean (SD) of Hgb was 12.1 (1.39) g/dl in female and 13.8 (1.29) g/dl in male, and 40.8% female patients and 23.4% male patients had anemia. Significantly greater improvement in hemoglobin in the GLM-treated patients than patients in the placebo group was observed as early as Week 4. At Week 12, mean improvement in Hgb was 0.34g/dl in male and 0.69g/dl in female in the GLM group, compared to an improvement of 0.01g/dl in male ($p<0.001$) and 0.07g/dl in female ($p<0.001$) in the PBO group; and greater proportion of patients in the GLM group achieved an increase of ≥1g/dl in Hgb than PBO group. Among patients who had anemia at baseline, prevalence of anemia at Week 12 was 66.4% in female, and 26.3% in male in the GLM-treated patients, compared to 75% in female and 33.3% in male in placebo-treated patients. After adjusting for baseline anemia and gender difference, GLM-treated patients were more likely to have an improvement of ≥1g/dl in Hgb with a Relative Risk (RR) of 1.87 ($p<0.001$), and less likely to have anemia (RR =0.73, $p<0.001$) at Week 12. Improvement in Hgb at Week 12 was correlated with improvement in HAQ-DI (r=0.16, $p<0.001$), FACIT-fatigue (r=0.10, $p<0.001$) and SF-36 vitality score (r=0.12, $p<0.01$). Treatment effect of intravenous golimumab on Hgb was maintained through Week 112.

**Conclusions:** Intravenously administered golimumab therapy improves Hgb, resulting in reduced anemia, improved physical function and fatigue in patients with moderate to severe active RA despite MTX.

## THU0128 MAINTENANCE OF IMPROVEMENTS IN WORKPLACE AND HOUSEHOLD PRODUCTIVITY AND PHYSICAL FUNCTION AT 2 YEARS IN EARLY RA PATIENTS WITH SEVERE PROGRESSIVE DISEASE WHO ACHIEVED SUSTAINED LOW DISEASE ACTIVITY FOLLOWING 1 YEAR OF INITIAL THERAPY, WITH TWO DOSING FREQUENCIES OF CERTOLIZUMAB PEGOL

C. Bingham[1], P. Emery[2], M. Weinblatt[3], G.-R. Burmester[4], D.E. Furst[5], X. Mariette[6], R. van Vollenhoven[7], B. VanLunen[8], O. Purcaru[9], V.P. Bykerk[10].
*[1]John Hopkins University, Baltimore, United States; [2]University of Leeds, Leeds, United Kingdom; [3]Brigham and Women's Hospital, Boston, United States; [4]Charité - University Medicine, Berlin, Germany; [5]University of California, Los Angeles, United States; [6]Université Paris-Sud, Paris, France; [7]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [8]UCB Pharma, Raleigh, United States; [9]UCB Pharma, Brussels, Belgium; [10]Weill Cornell College, New York, United States*

**Background:** RA leads to high burden on patient (pt) work, functioning and quality of life. Certolizumab pegol (CZP)+MTX improves physical function,[1] and workplace and household productivity,[2,3] in established and early active RA. Here we report impact of maintaining, reducing frequency or stopping CZP from Week (Wk) 52 to 104 in pts who achieved sustained low disease activity (sLDA) following 1 year (yr) of CZP+optimized MTX.

**Objectives:** To assess effect of 2 dosing frequencies of CZP+MTX vs stopping CZP on physical function and workplace/household productivity in Period 2 of C-EARLY, a phase 3 study in early RA pts with severe progressive disease.

**Methods:** CZP+MTX-treated pts achieving sLDA (DAS28[ESR]≤3.2 at Wks40 and 52) in C-EARLY Period 1 (NCT01519791)[4] entered Period 2 (NCT01521923), a randomized, double-blind study. Pts were randomized 2:3:2 to CZP standard dose (200mg Q2W+MTX), CZP reduced-frequency dose (200mg Q4W+MTX) or CZP stopped (PBO+MTX). Physical function (HAQ-DI) and %pts achieving normative physical function (HAQ-DI≤0.5) from Wk52 to 104 are reported (ANCOVA model with factors treatment, region, time since diagnosis at BL [≤4 vs >4 months], and BL/Wk52 values as covariate and logistic regression models [treatment, region and time since diagnosis at BL as factors] respectively; CZP stopped as comparator; LOCF). Workplace/household productivity (Work Productivity Survey, WPS)[5] at Wk52 and 104 are reported (LOCF); non-parametric bootstrap-t method (CZP stopped as comparator).

**Results:** In Period 2, 289 pts were included in the full analysis set: CZP Q2W+MTX (n=84), CZP Q4W+MTX (n=126) or PBO+MTX (n=79). Improvements in physical function were maintained from Wk52 to 104 in CZP Q2W+MTX (HAQ-DI mean [SD] 0.32 [0.42] to 0.37 [0.48], respectively) and CZP Q4W+MTX (0.33 [0.49] to 0.41 [0.57]), whereas deterioration was seen in PBO+MTX (0.33 [0.47] to 0.57 [0.65]). %pts with normative function was generally maintained between Wk52 to 104 in CZP Q2W+MTX (80.7% to 71.4%) and CZP Q4W+MTX (80.2% to 70.6%), but decreased in PBO+MTX pts (75.9% to 57.0%). At Wk104, employed CZP Q2W+MTX and CZP Q4W+MTX pts maintained on average the improvements in workplace productivity, whereas worsening was seen in pts stopping CZP (Table). Similar trends were observed in household productivity and need for regular assistance (Table).

**Conclusions:** Pts continuing CZP treatment (both dose frequencies) after 1yr further maintained improvements at 2yrs in physical function and workplace/household productivity, compared with pts who stopped CZP.

**Table:** C-EARLY Period 2: Improvements in workplace and household productivity, and need for assistance with daily activities at Wk52 and Wk104

## THU0129 CLINICAL OUTCOMES OF IMMUNOGENICITY IN RHEUMATOID ARTHRITIS PATIENTS UNDER ANTI-TNF BIOLOGICS: RESULTS FROM AN OBSERVATIONAL STUDY

C. Ancuta[1,2], C. Pomirleanu[1,2], C. Belibou[1], R. Maxim[1], L. Petrariu[1], G. Strugariu[1], R. Chirieac[3]. *[1]Rheumatology 2, Clinical Rehabilitation Hospital; [2]University of Medicine and Pharmacy "Gr.T.Popa"; [3]Sanocare - Medical and Research Center, Iasi, Romania*

**Background:** Anti-drug antibodies (ADA) develop in up to one third of patients treated with biologic agents, immunogenicity being one of the main reasons for loss of efficacy and tolerance of the biodrug.
**Objectives:** To investigate the clinical relevance of anti-drug antibodies, drug levels and their relationship with disease outcomes in rheumatoid arthritis (RA) patients receiving TNF-inhibitors (TNF-i).
**Methods:** We performed a prospective observational study in a cohort of forty-eight consecutive RA treated with adalimumab (ADL; 24), infliximab (IFX; 15) or etanercept (ETN; 9). Disease activity, clinical outcomes and adverse events were evaluated at baseline and during study visit, while serum TNF-i and ADA levels collected as a single-point data in both bio-naïve and bio-experimented patients.
Lab assays (IgG-ADA, TNF-i) were measured following the manufacturer's instructions using ELISA Progenika kits, with detection limit set at 10AU/mL for anti-ADL, 142AU/mL for anti-ETN and 5AU/mL for anti-IFX, 0.024μg/mL ADA, 0.035μg/mL ETN, 0.035μg/mL IFX.
Statistical analysis was conducted in SPSS-19 ($p<0.05$).
**Results:** ADA were detected in 8/48 (16.7%) patients (5/24 ADL, 20.8%; 3/9 IFX, 33.3%; while no anti-ETN) and associated with lower functional serum drug (2.17 vs 5.53μg/mL ADL; 2.10 vs 3.82μg/mL IFX; $p<0.01$), higher disease activity (DAS28: 3.5 vs 3.3 in ADL-group $p<0.05$; 3.6 vs 3.0 in IFX-group), less remission ($p<0.01$) compared to ADA negative. Moreover, high ADA levels predict therapy discontinuation ($p<0.01$).
Treatment failure was demonstrated in 12/48 (25%) cases, strongly associated with ADA status ($p<0.01$) and drug levels ($p<0.01$), with a specific profile for secondary non-responders meaning ADA positivity at higher titers (62.51 vs 101.54AU/mL anti-ADL; 5.41 vs 39.80AU/mL anti-IFX; $p<0.01$), lower free serum TNF-i (6.14 vs 1.64μg/mL ADL; 3.01 vs 4.08μg/mL IFX; $p<0.01$), lower biologic exposure (32.2 vs 38.58 months for ADL, 40.17 vs 73.33 months for IFX; $p<0.01$), lower DAS28 at baseline (6.14 vs 6.7 for ADL, $p<0.05$; 6.88 vs 7.04 for IFX; $p<0.05$).
No difference in immunogenicity for ETN-treated cases ($p>0.05$), although lower levels of drug in non-responders (1.92 vs 2.89μg/mL, $p<0.05$). In addition, adverse events happened more often in ADA positive then ADA negative status ($p<0.01$)
**Conclusions:** Immunogenicity to ADL and IFX but not to ETN have large impact on clinical practice (disease activity, treatment failure) and may represent key findings towards optimizing biological therapeutics in RA during long-term follow-up.

## THU0130 COMORBIDITIES AND EFFICACY OF ANTI-TNF THERAPIES: HISTORY OF DEPRESSION AS A POSSIBLE INDICATOR OF LOWER RESPONSE

D. Parenti[1], G. Reed[2], S. Kafka[1], L. Ellis[1], J.D. Greenberg[3], R.J. DeHoratius[4]. *[1]Janssen Scientific Affairs, LLC, Horsham; [2]Corrona, LLC/U of Mass Sch of Med, Southborough/Worcester; [3]Corrona, LLC/NYU Sch of Med, Southborough/NY; [4]Janssen Scientific Affairs, LLC/Kimmel Sch of Med, Horsham/Phila, United States*

**Background:** Little is known about the influence of specific comorbidities on response to biologic therapy.
**Objectives:** To examine the impact of comorbidities on anti-TNF therapy efficacy in rheumatoid arthritis (RA) patients (pts) within the US CORRONA RA registry.
**Methods:** A retrospective cohort of adult RA pts with moderate-to-severe RA (CDAI>10) who initiated anti-TNF biologics after June 1, 2009 and had a 6 month follow up (in a window of 3–9 months) were included. Comorbidity assessments included a modified Charlson comorbidity index (CCI) [HIV status was not assessed]) and diagnoses of diabetes, cardiovascular disease (CV) and history of depression. Propensity score (PS) method was employed to match pts with and without select comorbidities. Variables used for PS matching were selected if standardized differences were ≥0.1 between groups. PS were stratified by line of therapy. The primary outcome was achievement of low disease activity (LDA) at 6 months (CDAI ≤10). Secondary outcomes included DAS28(ESR) LDA (DAS<3.2), modified ACR 20/50/70. Post hoc analysis was performed on the CDAI components to estimate pt and MD reported outcomes.
**Results:** A total of 4064 anti-TNF initiations were included. For CCI, diabetes and CV, there were no significant differences in response in the matched populations. For patients with a history of reported depression (hxdep), LDA rates were significantly lower (29% for hxdep vs 39% for no hxdep, $p<0.001$ OR=0.65 [0.56, 0.75]). In the matched population (n=1810) LDA rates remained significantly different: 31% vs 36% (hxdep vs no hxdep), p=0.027, OR=0.80 [0.66, 0.98]. Matched patients differed in mean (SD) patient fatigue (VAS 0–100): hxdep: 61.4 (26.2) and no hxdep: 54.7 (27.9) $p<0.001$. In pts matched on factors including patient fatigue (n=1252) there was no significant difference in response rates: 31.8% vs 31.8% OR=1.0 [0.79, 1.27]. Similar results were found in the secondary outcomes. Estimates of the CDAI components [Table 1] showed the Pt Global and Tender Jts were the largest contributors to CDAI change.

| Outcome Difference in mean Δ | Unadjusted N=4064 | Matched patients N=1810 | Matched including Pt fatigue N=1452 |
|---|---|---|---|
| ΔMD Global* | 0.48 [0.32, 0.64] | 0.20 [–0.02, 0.42] | 0.025 [–0.22, 0.27] |
| ΔPt Global* | 0.37 [0.18, 0.56] | 0.56 [0.30, 0.82] | 0.057 [–0.23, 0.34] |
| ΔTender Jts | 1.12 [0.61, 1.63] | 0.64 [–0.08, 1.35] | 0.13 [–0.66, 0.92] |
| ΔSwollen Jts | 0.90 [0.51, 1.28] | 0.09 [–0.44, 0.61] | 0.06 [–0.52, 0.64] |

*VAS 0–10.

**Conclusions:** Of the comorbidities examined, a history of reported depression in RA patients is an indicator of lower response rates to TNFi. CDAI was primarily influenced by patient responses. Patient fatigue may be a manifestation of depression and explained response rate differences. Further analyses are needed to explore this relationship.

## THU0131 MIRNA PROFILING USING HTG-EDGESEQ PLATFORM PREDICTS RESPONSE TO ANTI-TNF ALPHA THERAPY IN RHEUMATOID ARTHRITIS

E. Schordan, G. Bilger, M. Coq, S. Danilin, M. Mehdi, M. Schumacher, H. Firat.
*TcLand Expression SA, Huningue, France*

**Background:** Millions of patients suffering Rheumatoid Arthritis (RA) are treated with TNF-α inhibiting agents, however, response rate is low (30 to 40%) and no tool exists to predict the treatment response.
**Objectives:** Using the HTG-Edgeseq platform, an innovative combination of nuclease protection assay and next generation sequencing, we identified sets of miRNAs that discriminate responders from non-responders to anti TNF-α therapy.
**Methods:** Sixty-seven patients diagnosed with RA, eligible for treatment with 1st line anti-TNFα and for whom DMARD therapy had failed were enrolled in the study. Twelve to 14 weeks after anti-TNFα therapy, patients were categorized as responders or non-responders based on DAS28 index. Patients' miRNA profile was established from 15μl of plasma using HTG-Edgeseq Whole Transcriptome Assay (WTA) miRNA panel (2256 miRNA). Results were normalized based on the median of the sample and Random forest was used as the classification model. For 8 patients, miRNA were also analyzed with the qPCR Exiqon miRNA panel V4 to determine HTG-Edgeseq accuracy. Method reproductibility was assessed by analyzing 4 times an independent sample on different sites, with different instruments/days/operators.
**Results:** Results obtained from both HTG-Edgeseq and qPCR methods showed an overall correlation of 0.63 for the 341 miRNA common between those 2 kits, and correlations factors between the 4 independent experiments ranged from 0.993 to 0.999. Statistical analysis of patients' miRNA profile identified 2 panels of 6 and 52 miRNAs with significant predictive power to discriminate responders from non-responders (sensitivity was 0.898 and 0.918, and AUC 0.773 and 0.824 respectively).
**Conclusions:** In conclusion, miRNA profiling in RA patients using HTG-EdgeSeq allowed us to build 2 predictive models for response to anti-TNF-α drugs. Moreover, we showed that HTG-Edgeseq platform offers accurate and sensitive miRNA expression measurement. Its low sample input requirement and compatibility with all biological material makes it an invaluable tool for biomarkers discovery.
**Disclosure of Interest:** None declared

## THU0132 COMPARATIVE EFFECTIVENESS OF TNFI AND TOFACITINIB MONOTHERAPY IN CLINICAL PRACTICE: RESULTS FROM CORRONA REGISTRY

G.W. Reed[1], R.A. Gerber[2], Y. Shan[1], L. Takiya[3], K.J. Dandreo[1], D. Gruben[2], J.M. Kremer[4], G. Wallenstein[5]. *[1]Corrona, LLC, Southborough; [2]Pfizer, Inc., Groton; [3]Pfizer, Inc., Collegeville; [4]Albany Medical College, Albany; [5]Pfizer, Inc., New York, United States*

**Background:** TNF inhibitors (TNFi) can be used as monotherapy (mono) or in combination (combo) with conventional DMARDS (cDMARDS). Clinical trial data and European registry data have shown evidence of better effectiveness of TNFi combo therapy than mono. Effectiveness of mono vs combo in US clinical practice, in particular among biologic naïve and experienced patients, has not been assessed.
**Objectives:** This study was carried out to quantify the prevalence and effectiveness of TNFi monotherapy use in US clinical practice. A secondary objective was to contrast this with tofacitinib (tofa) monotherapy use and effectiveness.
**Methods:** RA patients initiating a TNFi (adalimumab, etanercept, infliximab, golimumab, certolizumab pegol) or tofa with a six month follow-up in Corrona US were identified. A subcohort of TNFi initiations after 11/6/2012 (market approval of tofa) were used for comparisons with tofa initiators. We defined combo therapy as TNFi or tofa used with MTX alone and mono as no use of any cDMARD. The primary outcome was achieving low disease activity (LDA) or remission based on CDAI ($\leq$10) at 6 months. Patients switching to another biologic prior to 6 months were defined as non-responders. Secondary outcomes included modified ACR20/50/70 and mean change in CDAI. Combo and mono initiators were matched within line of therapy using a propensity score. Covariates for the model were selected if the standardized mean difference between the groups $>$0.1.
**Results:** There were 7076 TNFi initiations in Corrona, with 2091 (30%) mono initiations. Mono by line of therapy was 21%, 35% and 41% for 2nd, 3rd and 4th line therapy, respectively. There were 325 tofa initiations with 201 (61%) mono and mono rates of 50%, 65% and 63% for 2nd, 3rd and 4th line therapy, respectively. In the matched populations, across outcome measures (Table 1), TNFi combo was more effective than TNFi mono in 2nd line therapy (55.6% LDA vs 47.1% LDA) and similar in 3rd and 4th line therapy. Tofa combo therapy was similar to mono in the matched populations (35.4% LDA vs 32.3% LDA). Tofa mono was similar to TNFi combo therapy in the matched populations (33.3% LDA vs 33.3% LDA).
**Conclusions:** TNFi monotherapy is common in U.S. clinical practice. TNFi monotherapy is less effective than combination therapy especially in biologic naïve patients. There is no evidence that tofa monotherapy is less effective than tofa combination therapy or TNFi combination therapy.

## THU0133 STATISTICAL ASSESSMENT ACROSS MULTIPLE EARLY TIME POINTS VALIDATES BIOSIMILARITY OF BOW015 TO REFERENCE INFLIXIMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS ON STABLE METHOTREXATE DOSES

G. Castañeda-Hernández[1], M. Wyand[2], C. Lassen[3], L. Shneyer[4], J. Kay[5]. *[1]Nacional Centro de Investigación y de Estudios Avanzados del Instituto Politécnico, Ciudad de México, Mexico; [2]Epirus Biopharmaceuticals, Inc., Boston, United States; [3]Epirus Biopharmaceuticals (Switzerland) GmbH, Zug, Switzerland; [4]Shneyer Statistics LLC, New Jersey; [5]University of Massachusetts Medical School and UMass Memorial Medical Center, Worcester, United States*

**Background:** No formal guidelines exist to inform the selection of appropriate equivalence margins or the timing of efficacy assessment for comparative effectiveness trials of biosimilars in rheumatoid arthritis (RA). Studies to date have specified a single time-point for assessment of the primary outcome and an equivalence margin based on experience in placebo-controlled trials of the reference product. Neither of these adequately describes the dynamic early responses to TNF inhibition nor provides an optimally sensitive measure to assess bioequivalence. However, by applying multiple statistical analyses across frequent early time points, a "totality-of-the-evidence" might be generated that could sufficiently demonstrate clinical similarity.
**Methods:** To compare the statistical evaluation of bioequivalence using aggregate information from early time-points to that using data from the primary endpoint at week 16, 189 subjects with active RA on stable doses of oral methotrexate were randomized 2:1 to receive double-blinded treatment with BOW015 or reference infliximab (rIFX) and assessed for efficacy at weeks 0, 2, 6, 14, and 16. The pre-specified primary endpoint was the proportion of subjects achieving an ACR20 response at week 16, as previously reported. In this novel post-hoc analysis,

**Abstract THU0132** – Table 1. Matched patients

| | TNFi Combo vs TNFi Mono | | | Tofa Combo vs Tofa Mono | TNFi Combo vs Tofa Mono |
|---|---|---|---|---|---|
| | 2nd line* (n=1130) | 3rd line (n=1044) | 4th line (n=680) | 3rd & 4th line (n=130) | 3rd and 4th line (n=186) |
| LDA OR [95% CI] | 1.4 [1.1–1.8] | 1.1 [0.9–1.5] | 0.7 [0.5–1.0] | 1.2 [0.5–2.5] | 1.0 [0.4–1.8] |
| mACR20 OR [95% CI] | 1.6 [1.2–2.1] | 1.2 [0.9–1.5] | 1.2 [0.8–1.8] | 0.6 [0.3–1.6] | 0.9 [0.5–1.8] |
| ΔCDAI mean△ [95% CI] | –2.0 [–3.4–0.6] | –0.9 [–2.5–0.6] | –2.1 [–4.1–0.1] | 0.2 [–4.8–5.2] | –1.6 [–4.8–1.7] |

*2nd line was defined as prior use of at least one cDMARD and no prior use of any biologic.

a generalized estimating equation, logistic regression, and an exponential time response model were applied to aggregate data from the early time-points in this trial. Aggregated and integrated analysis were compared to the assessment of bioequivalence using data only from the primary endpoint.

**Results:** At the week 16 primary endpoint, comparable proportions of BOW015- and rIFX treated-patients achieved an ACR20 response, yielding a 95% confidence interval (CI) for the treatment difference of -12.6% to 19.3% by the protocol-specified 2-sided Fisher's Exact test methodology. Analyses to assess the average proportion of ACR20 responders over multiple time-points during the first 16 weeks provide a more stringent assessment of equivalence, with 95% CIs for the treatment difference that fall within a narrower range than that achieved using the Exact test at week 16 (Table 1). Non-linear modeling further confirmed this comparable time-response profile across 16 weeks in agreement with averaged findings.

Table 1

| Method of Analysis | Reference Infliximab %ACR20 responders | BOW015 %ACR20 responders | Difference | Exact 95% CI |
|---|---|---|---|---|
| Exact test, week 16 | 86.44% | 89.83% | –3.39% | (–19.27, 12.60) |
| GEE, week 0–16 | 67.49% | 67.47% | 0.02% | (–15.95, 15.95) |
| Logistic regression, week 0–16 | 66.65% | 67.97% | –1.70% | (–17.61, 14.28) |
| Logistic regression, week 2, 6 | 49.1% | 46.37% | 2.73% | (–13.44, 18.44) |
| Logistic regression, week 2, 6, 14 | 57.58% | 56.88% | 0.70% | (–15.11, 16.78) |

CI, Confidence interval.

**Conclusions:** Assessment of therapeutic equivalence by aggregating multiple time-points during the steep phase of the time response curve, using appropriate statistical methods to validate attainment of bioequivalence margins, can provide a more comprehensive assessment of biosimilarity than a measure taken at a single timepoint.

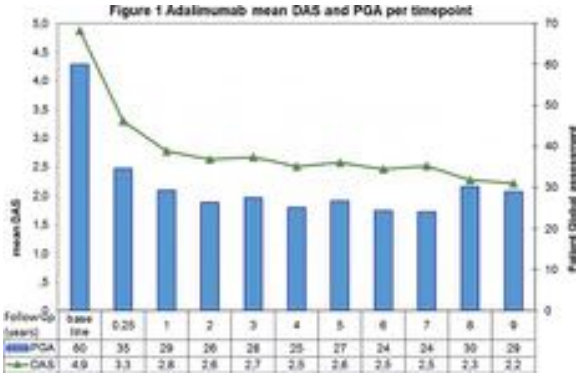
## THU0134 GOOD RESPONSE ON ADALIMUMAB TREATMENT FOR PATIENTS WITH RHEUMATOID ARTHRITIS PERSISTS FOR UP TO 9 YEARS

I.M. Visman[1], G.-J. Wolbink[1], M. Nurmohamed[2] on behalf of Amsterdam Rheumatology and immunology Center (ARC). *[1]Amsterdam Rheumatology and immunology Center, Reade; [2]Amsterdam Rheumatology and immunology Center, Reade and VU University medical center, Amsterdam, Netherlands*

**Background:** With the advent of biological therapy a range of new drugs have become available for patients with rheumatoid arthritis (RA). Adalimumab was one of the first biologicals to become widely available, and as many patients use biologicals indefinitely, data on very long-term efficacy and safety in daily clinical practice is important as results obtained in short-term clinical registration trials might differ from those observed in long-term daily clinical practice, especially after many years of continuous use.



**Objectives:** To ascertain the efficacy and safety of very long- term adalimumab treatment for RA.

**Methods:** From December 2004 to October 2013, 587 consecutive patients have been included in the adalimumab for RA (AdRA) cohort at the Jan van Breemen research center at Reade in Amsterdam, the Netherlands.

**Results:** The mean age was 54 years (SD:13), and 469 (80%) were female. At baseline, the median disease duration was 7 (3–15) years, and 399 (70%) were Rheumatoid factor positive. At baseline, 373 (64%) used methotrexate, 183 (31%) used prednisolone, and 144 (25%) a DMARD other than MTX and 176 (39%) had used at least one other biological prior to start. On average patients had used 3.2 (SD:2.1) DMARDs. A total of 237 (40%) patients are currently on drug, and 350 (60%) patients have dropped out. The median follow-up duration was 4.0 (IQR:1.0–7.2) years for patients currently still on adalimumab treatment, and 0.7 (0.3–2.2) years for drop-outs. The maximum follow-up duration was 9.2 years, the total was 1507 patients years. The main reason for discontinuing adalimumab treatment were failure (121, 35%), followed by adverse events (69, 20%). Eight (2%) patients discontinued because of remission and 3 (1%) patients died while on drug (one of sepsis, one of lung cancer, and one at age 84 of unknown causes). In total 1892 adverse events were reported by patients, who deemed 137 to be severe, 51 times patients required hospitalization, and 317 times antibiotics were given.

The mean DAS-28 drops significantly from 4.9 (SD: 1.3) at baseline to 3.3 (1.4) at 16 weeks. This improvement was sustained, and steadily improved further over the whole 9 years with a DAS-28 of 2.8 (1.3), 2.6 (1.2), 2.6 (1.2) and 2.2 (0.6) at 1, 2, 5 and 9 years, respectively (see Figure 1). The patient reported outcome of patient global assessment (PGA) was also good, the mean PGA drops from 60 (23) to 35 (25) at 16 weeks of treatment, and remains stable after that with a mean PGA of 29 (23), 26 (22), 27 (22) and 29 (28) at 1, 2, 5 and 9 years, respectively (see Figure 1).

Figure 1 Adalimumab mean DAS and PGA per timepoint

**Conclusions:** The initial good response on adalimumab persists for the 9 years of follow-up, with the decrease in DAS28 continuing for the entire 9 years. Over time, a satisfactory response in DAS28 and PGA is sustained during further follow-up for 9 years.

## THU0135 THE IMPACT OF EARLY TREATMENT WITH ADALIMUMAB ON RHEUMATOID FACTOR AND ANTI-CITRULLINATED PEPTIDE ANTIBODY LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN THE OPTIMA TRIAL

J.S. Smolen[1], A. Kavanaugh[2], D. Aletaha[1], S. Florentinus[3], Y. Li[3], I. Lagunes[3]. *[1]Medical Univ. of Vienna, Vienna, Austria; [2]Univ. of California San Diego, San Diego; [3]AbbVie, N. Chicago, IL, United States*

**Background:** In patients (pts) with rheumatoid arthritis (RA), rheumatoid factor (RF) and anti-citrillunated peptide antibody (ACPA) are associated with higher disease activity and damage progression.

**Objectives:** To explore whether early initiation of combination therapy with the TNF-inhibitor, adalimumab (ADA) + methotrexate (MTX) is associated with conversion in RF or ACPA status.

**Methods:** Data were from the OPTIMA trial[1], where pts with early RA were initially treated for 26 weeks (wks, period 1) with ADA+MTX, or placebo (PBO) +MTX. In total, 708/900 (78.7%) were RF+, 728/884 (82.4%) were ACPA+ at wk 26. If pts on ADA+MTX attained 28-joint disease activity score based on C - reactive protein (DAS28-CRP) $<$3.2 at wks 22 and 26 (responders), they were randomized to withdraw ADA, continue PBO+MTX, or continue ADA+MTX until wk 78 (period 2). Pts on PBO+MTX, who were responders at wks 22 and 26, received PBO+MTX until wk 78. Pts who did not reach DAS28-CRP $<$3.2 either on ADA+MTX or MTX alone (non-responders, NR), received Open Label (OL) ADA+MTX until wk 78. Levels of RF and ACPA were measured at baseline (BL), wks 26, 52 and 78. Results obtained in OPTIMA were validated with data from PREMIER (early RA; RF levels at BL, wks 26 and 52)[2] and DE019 trials (established RA; RF at screening, wks 24 and 52).[3]

**Results:** In OPTIMA, pts on ADA in period 1 tended to have lower RF levels than pts in the PBO+MTX arm at wks 26 and 78, irrespective of the treatment after wk 26. In pts who switched to or continued ADA in period 2 [ADA+MTX/ADA+MTX, ADA+MTX/OL ADA+MTX and PBO+MTX/ADA+MTX arms], RF levels decreased from wk 26 to 78 (table); pts in the PBO+MTX/ADA+MTX arm had the largest decrease from wk 26, in line with a decrease of clinical disease activity. In pts who switched to or continued on PBO+MTX in period 2 (ADA+MTX/PBO+MTX and the PBO+MTX/PBO+MTX arms), the RF levels increased from wk 26 to 78, despite overall maintenance of a low disease activity. A similar pattern was observed for ACPA levels. In PREMIER, combination ADA+MTX therapy was also more effective in reducing RF levels vs ADA or MTX monotherapy (table). More pts on ADA+MTX (19.4%) vs ADA (10.2%) or MTX (8.8%) monotherapy, who were RF+ at BL became RF- after 26 wks. In DE019, ADA+MTX therapy was effective in reducing RF levels compared to PBO (on background MTX), and more pts in the ADA arms vs PBO, who were RF+ at screening became RF- after 24 wks (ADA 20 mg: 7.5%; ADA 40 mg: 7.1%; PBO: 2.3%).

Table 1. Change (Δ) in RF and ACPA levels with treatment, in OPTIMA, PREMIER and DE019, Least Square Means (SE) adjusting for BL RF and BL DAS28

| Treatment arm | ΔRF | ΔACPA |
|---|---|---|
| OPTIMA PERIOD 1: Δ BL to wk 26 | | |
| ADA+MTX | -125.5 [5.47]* | -20.6 [2.54] |
| PBO+MTX | -101.1 [5.48] | -17.4 [2.53] |
| OPTIMA PERIOD 2: Δ wk 26 to wk 78 | | |
| ADA+MTX / PBO+MTX | 20.9 [16.67]† | 5.1 [5.1]§,* |
| ADA+MTX / ADA+MTX | -16.6 [15.43] | -8.9 [4.79] |
| ADA+MTX / OL ADA+MTX | -10.6 [10.56] | -9.0 [3.21] |
| PBO+MTX / PBO+MTX | 22.8 [16.21]† | 4.1 [4.88]§,* |
| PBO+MTX / OL ADA+MTX | -24.7 [8.9] | -15.5 [2.73] |
| PREMIER | | |
| | ΔRF BL to wk 26 | ΔRF BL to wk 52 |
| MTX | -159.9 [18.95] | -205.9 [29.38] |
| ADA 40mg | -77.9 [18.56] | -59.0 [29.95] |
| ADA 40mg +MTX | -245.0 [17.97]# | -267.3 [27.60]# |
| DE019† | | |
| | ΔRF BL to wk 24 | ΔRF BL to wk 52 |
| PBO+MTX | 37.9 [30.32] | 24.0 [29.84] |
| ADA 20mg +MTX | -96.5 [27.90]‡ | -129.3 [26.76]‡ |
| ADA 40mg +MTX | -94.5 [28.04]‡ | -128.2 [27.18]‡ |

*P<.05 vs PBO+MTX; §P<.05 vs PBO+MTX/OLADA+MTX; †P<.05 vs ADA+MTX/OLADA+MTX; ‡P<.001 vs PBO+MTX/OLADA+MTX; #P≤.05 vs ADA or MTX monotherapy; *P<.001 vs ADA; §P≤.001 vs PBO. †In DE019, screening visit was considered as BL.

**Conclusions:** Early combination treatment with ADA+MTX resulted in lower levels of RF and ACPA. The withdrawal of ADA led to increases in levels of RF and ACPA. These data suggest that effective therapy reduces autoantibody levels. Further studies are needed to elucidate the consequences of these changes.

## THU0136 USE OF A GLOBAL RISK SCORE TO IDENTIFY PATIENTS WITH RHEUMATOID ARTHRITIS AT RISK OF SERIOUS INFECTIOUS EVENTS DURING CERTOLIZUMAB PEGOL TREATMENT

J.R. Curtis[1], K. Winthrop[2], M. de Longueville[3], C. O'Brien[3], M.N. Ndlovu[3], B. Haraoui[4]. *[1]University of Alabama at Birmingham, Birmingham; [2]Oregon Health and Science University, Portland, United States; [3]UCB Pharma, Brussels, Belgium; [4]Department of Medicine, Centre Hospitalier de l'Université de Montréal, Montréal, Canada*

**Background:** Anti-TNF drugs are an effective therapy for patients (pts) with rheumatoid arthritis (RA) but are associated with an increased incidence of serious infectious events (SIEs). We have previously identified baseline (BL) age and comorbidity as risk factors for SIEs in certolizumab pegol (CZP)-treated RA pts.[1]

**Objectives:** To identify RA pts at high/low risk of developing SIEs during long-term CZP treatment, using a BL age-adjusted comorbidity index (AACI).

**Methods:** CZP safety data from anti-TNF naïve patients were pooled from the RAPID1 and RAPID2 randomized controlled trials (NCT00152386/NCT00160602) and their open-label extensions (NCT00175877/NCT00160641). Post-hoc analyses of SIEs with onset after the first CZP dose and ≤84 days after the last CZP dose or withdrawal are presented. Pts' AACI was based on the Charlson index: it included medically-treated comorbidities (diabetes mellitus, chronic obstructive pulmonary disease/asthma, cardiac disorder, hypertension, lipidemia, transient ischemic attack or cerebrovascular disorder; each with score=1) and the resulting score was increased by 1 for each decade over the age of 40 years (yrs) at BL.[2] Incidence rates (IRs) of SIEs were calculated per 100 pt-yrs (PY), with 95% confidence intervals (CIs); time at risk = time from first CZP dose to the first SIE, or the total CZP time at risk for pts without SIEs. A multivariate Cox proportional hazards model (selection criteria: p≤0.25) was used to estimate the relative risk (hazard ratio [HR]) of BL pt covariates to the first SIE. BL covariates analyzed were AACI (≤1; 2; 3; ≥4), BMI (<20; 20–30; >30 kg/m$^2$), DAS28(CRP), disease duration (<2; ≥2 yrs), HAQ-DI, joint erosion score, MTX dose (≤15; >15 mg/week) and systemic steroid use (Yes; No). High/low risk pt groups were defined based on co-occurrence of the highest/lowest risk categories in the Cox model, respectively.

**Results:** 201/1506 anti-TNF naïve CZP pts reported ≥1 SIE over ~6 yrs of CZP treatment (IR 3.66/100 PY, 95% CI 3.17–4.21; total exposure 5778.6 PY). Overall, the observed IR of SIEs increased with AACI (Figure 1A). According to the Cox model, AACI ≥3 was a risk factor for SIEs; AACI=2, BL systemic steroid use, disease duration <2 yrs and DAS28(CRP) also contributed to SIE risk (Figure 1B). 195 pts (12.9%) were identified as "low risk" at BL (AACI≤1, no systemic steroid use) and 141 pts (9.4%) as "high risk" (AACI≥4, systemic steroids used). Over time, high risk pts reported more SIEs than low risk pts; across all pt groups, the observed IR was highest in the first yr of CZP treatment (Figure 1C). Results should be interpreted with caution, as it was not possible to compare the absolute risk of SIEs between CZP and placebo pts with similar AACI, due to limited placebo exposure.

**Figure 1:** Impact of baseline age-adjusted comorbidity score (AACI) on the risk of SIEs in CZP-treated patients with RA

A) Overall incidence of SIEs in CZP patients categorized by baseline AACI (n=1506)

| | Baseline AACI | | | |
|---|---|---|---|---|
| | ≤1 (n=530) | 2 (n=408) | 3 (n=312) | ≥4 (n=256) |
| Events (n [a]), % | 57 (52, 9.8) | 69 (58, 14.2) | 58 (50, 16.0) | 52 (41, 16.0) |
| IR/100 PY (95% CI) | 2.53 (1.89, 3.32) | 3.61 (2.74, 4.66) | 4.71 (3.49, 6.20) | 5.37 (3.85, 7.28) |

B) Multivariate analysis of baseline predictors of SIEs [b]

| | HR | (95% CI) | p value |
|---|---|---|---|
| Disease duration (years), ≥2 vs <2 | 0.75 | (0.53, 1.06) | 0.103 |
| Systemic steroid use, Yes vs No | 1.27 | (0.95, 1.69) | 0.109 |
| AACI, 2 vs ≤1 | 1.42 | (0.97, 2.07) | 0.070 |
| AACI, 3 vs ≤1 | 1.81 | (1.23, 2.68) | 0.003 |
| AACI, ≥4 vs ≤1 | 2.07 | (1.37, 3.12) | <0.001 |
| DAS28(CRP) imputed | 1.12 | (0.95, 1.32) | 0.182 |

C) Observed incidence of SIEs in high risk and low risk patient groups over time

| | IR/100 PY (95% CI) [c] | | |
|---|---|---|---|
| | Low risk patients (n=195) | High risk patients (n=141) | Remaining patients (n=1170) |
| Overall | 1.98 (1.11, 3.26) | 5.00 (3.05, 7.72) | 3.83 (3.27, 4.46) |
| Time since first CZP dose | | | |
| 6 months | 3.21 (0.66, 9.39) | 10.74 (4.32, 22.12) | 5.59 (3.80, 7.93) |
| 1 year | 4.47 (1.93, 8.80) | 11.85 (6.48, 19.89) | 5.38 (4.08, 6.97) |
| 2 years | 2.99 (1.43, 5.50) | 6.85 (3.75, 11.50) | 5.10 (4.15, 6.20) |
| 3 years | 2.76 (1.47, 4.72) | 5.81 (3.32, 9.43) | 4.55 (3.79, 5.42) |
| 4 years | 2.53 (1.41, 4.16) | 5.05 (2.94, 8.09) | 4.27 (3.61, 5.02) |
| 5 years | 2.13 (1.19, 3.51) | 4.95 (2.98, 7.72) | 4.03 (3.44, 4.69) |

[a] Number of patients with SIEs; [b] A covariate was defined as a risk factor for SIEs if p≤0.05 (highlighted in red), or as a contributing factor if p≤0.25; missing BL values were imputed by linear regression using non-missing components; [c] IR of SIEs observed up to the indicated time since the first CZP dose.

**Conclusions:** In RA pts treated with CZP, higher age-adjusted comorbidity index was associated with a greater relative risk of SIEs. The stratification of RA pts at BL using a global risk score may help clinicians to better assess the risks and benefits of long-term CZP treatment.

## THU0137 NON-ADHERENCE TO SUBCUTANEOUS BIOLOGICAL THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS. ARCO STUDY

J. Calvo-Alén[1], C. Marras Fernandez-Cid[2], I. Monteagudo[3], G. Salvador Alarcón[4], T.R. Vázquez-Rodríguez[5], J.V. Tovar Beltrán[6], P. Vela[7], F. Maceiras[8], M.S. Bustabad Reyes[9], J.A. Román Iborra[10], E. Peiró Callizo[11], L. Cea-Calvo[12], M.J. Arteaga[12], S. Fernández[12], J. Rosas[13], E. Raya Alvarez[14]. *[1]H. Txagorritxu, Araba, Vitoria; [2]HUVA, Murcia; [3]HGU Gregorio Marañón, Madrid; [4]HU Mutua Terrassa, Barcelona; [5]HU Lucus Agusti, Lugo; [6]GHU Elche, Elche; [7]HGU de Alicante, Alicante; [8]Complexo Universitario de Vigo-XXVI, Vigo; [9]HU de Canarias, Canarias; [10]HU la Fe, Valencia; [11]HU Marqués de Valdecilla, Santander; [12]Medical Affairs, Merk Sharp & Dohme, Madrid; [13]H Marina Baixa, Villajoyosa, Alicante; [14]HU San Cecilio, Granada, Spain*

**Background:** Lack of adherence to medication in rheumatoid arthritis (RA) can

worsen disease activity, but data on adherence to biological drugs is scarce.
**Objectives:** To evaluate RA patients adherence to the subcutaneous (SC) biological treatment prescribed by the physician during the first year of treatment.
**Methods:** Retrospective study in RA patients ≥18 years-old from 42 Spanish hospitals, which had been prescribed a SC biological drug 12 to 18 months prior to the study visit. Data were collected from patients' clinical records and hospital pharmacy drug-dispensing logs. Adherence was evaluated through the Medication Possession Ratio (MPR) (actual number of days covered by the taken medication/theoretical number of days covered by the prescribed medication). The number of days theoretically covered was calculated considering the interval of administration of the prescribed biological drug, if induction dose was prescribed, and if there were suspension periods or changes in the dose. The actual number of days covered was calculated with the number of vials that the patient had taken from the hospital pharmacy during the study period. Non-adherence was diagnosed if MPR was ≤80%.
**Results:** 364 patients were included (age 54.9 years [12.5]; 77.5% women, median RA duration 7.8 years). The initial interval of administration of the biological drug was weekly (44.2%), biweekly (39.1%) and monthly (17.3%); the median duration of the period studied was 14.8 months. For the primary analysis, 363 patients were valid, of which 52 patients were non-adherent (MPR ≤80%) to the prescribed schedule (14.3%; 95% CI: 11.1–18.3). There were no differences in adherence by age ranges, gender or other socio-demographic factors, such as level of education, smoking habit or alcohol intake, employment status, comorbidities or polypharmacy (all, p= NS). Non-adherence was less frequent in patients with a monthly administration schedule (6.4%) than in patients with a weekly (17.4%, p=0.034) or biweekly administration (14.4%, p=0.102), and slightly more frequent in those receiving induction (21.6% vs 12.5% without induction, p=0.068). No differences were observed between patients who used syringes or pen devices, or in patients who had periods of treatment interruption.
**Conclusions:** In RA patients, 14.3% were non-adherent to the prescribed SC biological medication during the first year of treatment, with no differences related to socio-demographic variables. Adherence was higher in those patients with monthly subcutaneous administration.

## THU0138 SECONDARY EFFICACY RESULTS UP TO WEEK 24 FROM A PHASE III STUDY COMPARING SB5 (AN ADALIMUMAB BIOSIMIAR) WITH ADALIMUMAB REFERENCE PRODUCT IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS DESPITE METHOTREXATE THERAPY

J. Kay[1], M. Weinblatt[2], E. Keystone[3], M.C. Genovese[4], A. Baranauskaite[5], S.Y. Cheong[6], J. Ghil[7]. *[1]UMass Memorial Medical Center, Worcester; [2]Brigham and Women's Hospital, Boston, United States; [3]Mount Sinai Hospital, University of Toronto, Toronto, Canada; [4]Stanford University, Palo Alto, United States; [5]Lithuanian University of Health Sciences, Kaunas, Lithuania; [6]Samsung Bioepis Co., Ltd., Suwon; [7]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

**Background:** SB5 is a biologic agent developed as a biosimilar of the adalimumab reference product (ADL). Pharmacokinetic equivalence was demonstrated in a phase I study in healthy subjects[1]. Primary efficacy and safety results from a phase III study in rheumatoid arthritis (RA) patients showed equivalent efficacy and comparable safety and were reported previously[2].
**Objectives:** To compare secondary efficacy endpoints up to Week 24 in the phase III study of SB5 vs. ADL in patients with moderate-to-severe RA despite methotrexate (MTX) treatment.
**Methods:** Patients with moderate to severe RA despite MTX treatment were randomly assigned to receive 40 mg of either SB5 or ADL administered subcutaneously every other week for 24 weeks. At Week 24, patients on ADL were randomised again to receive 40 mg of either SB5 or ADL subcutaneously every other week for an additional 28 weeks. Patients on SB5 continued to receive SB5. The primary endpoint was the ACR20 response rate at Week 24. Secondary efficacy endpoints up to Week 24, including ACR20, ACR50, ACR70, disease activity score based on 28 joints (DAS28), simplified disease activity index (SDAI), clinical disease activity index (CDAI), and health assessment questionnaire-disability index (HAQ-DI), were compared for patients receiving SB5 and ADL.
**Results:** 544 patients were randomised and 542 patients were included in the full analysis set (SB5 [N=269] or ADL [N=273]) for assessment of secondary efficacy endpoints. ACR response rates (ACR20/50/70) were comparable between the two treatment groups at every visit up to Week 24. DAS28, SDAI, and CDAI were also comparable up to Week 24. The mean change in DAS28 from baseline to Week 24 was –2.74 for SB5 and –2.68 for ADL; the 95% confidence interval of the difference in the least square means between each treatment group was –0.26 to 0.17, which was within the pre-defined equivalence margin of –0.6 to 0.6. Comparable proportions of patients on SB5 and ADL achieved low disease activity and remission at Week 24, as assessed by DAS28, SDAI, and CDAI. Patient reported outcomes, assessed by HAQ-DI, were also comparable between SB5 and ADL up to Week 24. Other efficacy endpoints (ACR-N, EULAR response) were comparable up to Week 24.

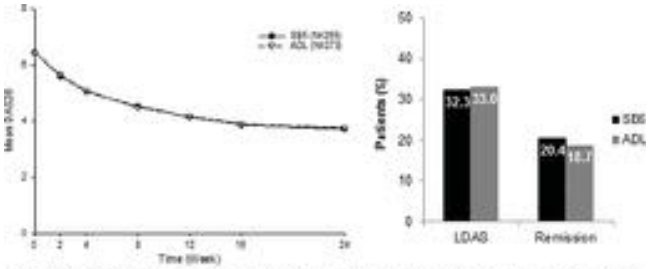

Figure 1. Mean DAS28 up to Week 24 and Proportion of Patients with Low Disease activity and Remission Based on DAS28 at Week 24

DAS28: disease activity score measured by 28 joints based on erythrocyte sedimentation rate.
Remission is defined as DAS28 < 2.6 and low disease activity is defined as DAS28 < 3.2 at Week 24.

**Conclusions:** Efficacy of SB5 and of ADL was comparable up to Week 24 for all secondary efficacy endpoints, as well as for the primary efficacy endpoint.

## THU0139 COMPARISON OF THE EFFICACY AND TOLERANCE OF THE "TRIPLE ORAL THERAPY" VERSUS "ANTI-TNF PLUS METHOTREXATE" IN RHEUMATOID ARTHRITIS WITH INADEQUATE RESPONSE TO METHOTREXATE: A SYSTEMATIC LITERATURE REVIEW

J. Mary[1], M. Debandt[1], C. Lukas[2], J. Morel[2], B. Combe[2]. *[1]Rhumatologie, CHU Pierre Zobda-Quitman, Fort-De-France; [2]Rhumatologie, CHU Lapeyronie, Montpellier, France*

**Background:** For patients with rheumatoid arthritis (RA) who have an inadequate response to methotrexate (MTX), there is some uncertainty about the relative effectiveness of combination of conventional DMARDs compared with combination of TNF inhibitors and MTX, as second line therapy.
**Objectives:** To compare efficacy and tolerance of triple oral DMARD therapy versus anti-TNF associated with MTX in patients with RA after MTX failure.
**Methods:** A systematic search of literature up to Mars 2014 was performed, in Medline, Embase, the Cochrane library and abstracts from the ACR and EULAR congresses from 2006 to 2013. Studies were included if they were randomised and controlled trial in patients receiving a triple oral combination therapy (MTX + sulfasalasine + hydroxychloroquine) compared with biologic agents plus methotrexate. Treatment effects on disease activity (DAS 28), American College of Rheumatology and the European League Against Rheumatism response criteria and structural damage using Sharp score were studied.
**Results:** Our search identified 263 articles, among them only 5 responded to the selection criteria. At six months and two years, there is a significantly larger number of participants achieving an ACR 70 response in the anti-TNF group. At one year, a significantly higher percentage of patients in the anti-TNF group reached a good EULAR response. Patients treated with TT have a significantly greater increase in modified Sharp than patients treated with MTX-infliximab at two years.
Analysis based on ACR-EULAR response criteria, the DAS 28 score and Sharp score were in favor of anti-TNF combined with MTX. There was no difference between treatments on functional disability (HAQ) and rates of adverse events.
**Conclusions:** In patients with RA in whom MTX has failed, addition of tumour necrosis factor antagonist to MTX is a valid option with better clinical outcomes and better radiographical results. Addition treatment with DMARDs is an appropriate treatment option in the absence of poor prognostic factors and/or in case of TNF inhibitors contraindications in a health-economic restreint context.

## THU0140 EFFICACY AND SAFETY ANALYSIS BY OVERALL ANTI-DRUG ANTIBODY RESULTS UP TO WEEK 30 IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SB2 (AN INFLIXIMAB BIOSIMILAR) OR INFLIXIMAB REFERENCE PRODUCT IN PHASE III STUDY

J.-Y. Choe[1], J.S. Smolen[2], E. Keystone[3], M.C. Genovese[4], J. Choi[5], Y.H. Rho[5]. *[1]Daegu Catholic University Medical Center, Daegu, Korea, Republic Of; [2]Medical University of Vienna, Vienna, Austria; [3]Mount Sinai Hospital, University of Toronto, Toronto, Canada; [4]Stanford University, Palo Alto, United States; [5]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

**Background:** SB2 is developed as a biosimilar of the infliximab reference product (INF). The clinical results of this Phase III study have been reported[1,2].
**Objectives:** To compare efficacy results (ACR responses, ACR-N, DAS28, and proportion of patients with remission/low disease activity based on DAS28, SDAI or CDAI) and safety results including infusion related reaction by anti-drug antibody (ADA) status up to Week 30 in patients with rheumatoid arthritis (RA) treated with SB2 or INF.
**Methods:** This study is a randomised, double-blind phase III study. A total of 583 patients with RA were treated with 3 mg/kg of SB2 or INF with background methotrexate (MTX). Efficacy, safety and immunogenicity were measured.
**Results:** Patients who developed ADA up to Week 30 were 55.1% in SB2 and 49.7% in INF. In both ADA positive and ADA negative subgroups, the ACR responses and other efficacy endpoints were comparable between SB2 and INF up to Week 30. There was a trend towards decreased efficacy in ADA positive subgroups compared with ADA negative subgroups for all efficacy parameters evaluated in both treatment arms. Safety profiles were also comparable between SB2 and INF in both ADA positive and negative subgroups. Within each treatment group, safety profiles were comparable between ADA positive and negative subgroups. Two patients (1.6%) treated with SB2 and 4 patients (2.7%) treated with INF in the ADA negative subgroups, and 8 patients (5.1%) treated with SB2 and 9 patients (6.2%) treated with INF in the ADA positive subgroups reported an infusion related reaction.

**Table 1. Efficacy Results at Week 30 by 30-week Overall ADA Results**

| | (-) ADA, SB2 (N=129) | (-) ADA, INF (N=147) | (+) ADA, SB2 (N=158) | (+) ADA, INF (N=145) |
|---|---|---|---|---|
| ACR20 | 80/110 (72.7%) | 94/132 (71.2%) | 81/143 (56.6%) | 79/133 (59.4%) |
| ACR50 | 49/110 (44.5%) | 57/132 (43.2%) | 40/143 (28.0%) | 42/133 (31.6%) |
| ACR70 | 29/110 (26.4%) | 27/132 (20.5%) | 16/143 (11.2%) | 23/133 (17.3%) |
| Change in DAS28 from Week 0 | −2.7 (1.44) | −2.4 (1.39) | −2.0 (1.31) | −2.3 (1.57) |
| Change in SDAI from Week 0 | −26.0 (13.12) | −24.0 (12.84) | −22.0 (14.57) | −23.0 (15.94) |
| Change in CDAI from Week 0 | −25.0 (13.08) | −23.0 (12.79) | −22.0 (13.96) | −23.0 (15.45) |
| LDA (DAS28) | 39/110 (35.5%) | 37/132 (28.0%) | 26/143 (18.2%) | 31/133 (23.3%) |
| Remission (DAS28) | 27/110 (24.5%) | 25/132 (18.9%) | 10/143 (7.0%) | 17/133 (12.8%) |

Data are presented in n/n' (%) or mean (SD)
Remission is defined as DAS28 < 2.6 and low disease activity is defined as DAS28 ≤ 3.2

**Conclusions:** Regardless of the overall 30-week ADA status, efficacy results were comparable between SB2 and INF. Efficacy tends to be lower in ADA positive subgroups compared with ADA negative subgroups of patients treated with either SB2 or INF. Safety profiles including infusion related reactions were also comparable between SB2 and INF regardless of ADA status, but a higher proportion of patients reported infusion related reactions in ADA positive subgroups compared to ADA negative subgroups in both treatment groups.

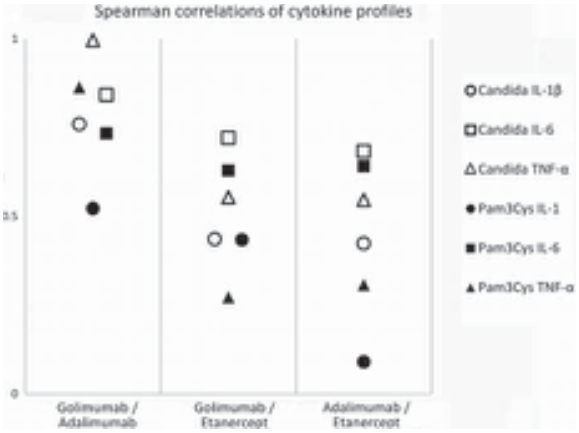
## THU0141 A NON-INTERVENTIONAL CLINICAL STUDY EVALUATING THE USE OF GOLIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA), PSORIATIC ARTHRITIS (PSA), AND ANKYLOSING SPONDYLITIS (AS) IN A REAL-LIFE SETTING IN GERMANY

K. Krüger[1], G.R. Burmester[2], S. Wassenberg[3], M. Bohl-Bühler[4], M.H. Thomas[5]. *[1]Rheumatologisches Praxiszentrum, München; [2]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin; [3]Rheumazentrum and Fachklinik 360°, Ratingen; [4]Rheumahaus Potsdam GbR, Potsdam; [5]Medical Affairs, MSD SHARP & DOHME GmbH, Haar, Germany*



**Background:** Golimumab (GOL) has shown its efficacy and safety in various randomized clinical trials with patients eligible for clinical studies. Data from daily clinical practice in Germany are still lacking.
**Objectives:** To gather data in daily clinical practice from German patients with RA, PsA, AS starting a treatment with GOL sc once monthly. The aim was to monitor safety, effectiveness, socio- and health economic parameters, as well as patient reported quality of life in a real-life setting.
**Methods:** Patients were enrolled in the non-interventional study GO-NICE at 168 German sites to explore days of sick leave, ability to work, data of quality of life and clinical effectiveness by DAS28, PsARC and BASDAI as well as safety.
**Results:** 1,613 patients were documented. A total of 1,458 (90.4%) patients were eligible for final analysis, and had a baseline assessment as weel as at least one additional visit. 664 (41.2%) completed the 24-month observational period.
*RA-patients* (n=474): Mean age was 54.9 years, 72.8% were female, 45.7% were employed and 64.7% were biologic-naïve at baseline (BL). DAS28 was initially 5.0 and dropped to 2.9 within 24 months ($p<0.0001$). After 3 months of therapy, 33.7% of patients were in remission (DAS28 <2.6), and after 24 months 44.6%.
*PsA-patients* (n=501): Mean age was 50.5 years, 54.1% were female, 55.7% were employed, 56.5% were biologic-naïve at BL. 197 patients had a nail involvement (39.3%), 106 dactylitis (21.2%) and 70 enthesitis (14.0%) at BL. 54.1% showed a good response (mod. PsARC) after 3 months with a further increase to 67.9% after 24 months.
*AS-patients* (n=483): Mean age was 43.6 years, 66.5% were male, 69.6% were employed, 61.0% were biologic-naïve at BL. The most common extra-articular manifestations were iritis (15.1%), enthesitis (12.4%), IBD (5.8%) and dactylitis (3.5%). The mean BASDAI score (1–10) decreased from 5.1 (month 0) to 2.4 (month 24) ($p=0.0001$).
*Days of absenteeism* from work due to the underlying disease in the last 6 months were evaluated at BL and after 2 years of treatment. These dropped from 16.2 to 4.1 (RA), from 10.6 to 2.0 (PsA) and from 14.7 to 3.9 days (AS). The disease impact on *quality of work* within the last 6 months, determined by 0 (no impact) to 10 (very severe impact) decreased within 24 months of treatment from 4.8 to 2.4 (RA-), from 4.8 to 2.2 (PsA-) and from 4.8 to 2.0 (AS-patients).
An improvement of *quality of life* (EQ-5D-3L) and *functional ability* (FFbH) was seen in all three patient groups after 6 months and was maintained over 24 months.
After 24 months the treating rheumatologists rated more than 80% of the treatment courses as "successful", 10–15% as "partially successful", and less than 4% as "unsuccessful".
The *safety profile* of GOL was consistent with that observed in other studies of GOL. 4 deaths occurred: 1 patient unlikely related, and 3 patients not drug-related to treatment of GOL.
**Conclusions:** GOL sc once monthly was an effective treatment in patients with RA, PsA and AS in a real-life setting in Germany. It showed remarkable improvements in clinical effectiveness, health economic and patient-reported quality of life parameters. No new safety signals were detected.

## THU0142 HIGH SIMILARITY BETWEEN EX-VIVO INHIBITED CYTOKINE PROFILING BY GOLIMUMAB AND ADALIMUMAB AS A PUTATIVE EXPLANATION FOR INFERIOR TREATMENT RESPONSE TO GOLIMUMAB AFTER ADALIMUMAB FAILURE IN RHEUMATOID ARTHRITIS

L. Tweehuysen[1], K. Schraa[2], M. Netea[2], F. van den Hoogen[1], L. Joosten[2], A. den Broeder[1]. *[1]Rheumatology, Sint Maartenskliniek; [2]Experimental Internal Medicine, Radboud University Medical Centre, Nijmegen, Netherlands*

**Background:** Better prediction of treatment response to biologics in rheumatoid arthritis (RA) would contribute to optimal individualised treatment. Clinical data suggest that the response of RA patients to treatment with golimumab is much lower among those who switched from adalimumab compared with those who had previously received etanercept or infliximab.[1] In order to elucidate the mechanism behind this difference in response to sequential biologic treatment, we have performed ex-vivo inhibited cytokine profiling.
**Objectives:** To compare the ex-vivo effect of six different biologics on multi-cytokine profiles of RA patients.
**Methods:** In a prospective longitudinal prediction cohort study (BIO-TOP [Biologic Individual Optimised Treatment Outcome Prediction]), blood samples were obtained from patients at baseline (before start biologic). Within 24 hours peripheral blood mononuclear cells (PBMCs) were isolated, washed and pre-incubated for one hour with the therapeutic concentration of six different biologics (adalimumab and golimumab (anti-TNF-$\alpha$), etanercept (TNFR-Fc) abatacept (CTLA4-Ig), rituximab (anti-CD20) and tocilizumab (anti-IL-6R)). Subsequently, the cells were stimulated with Candida albicans or Pam3Cys. Supernatants were harvested after 24 hours and stored at -20C. The cytokine concentrations of IL-1$\beta$, IL-6 and TNF-$\alpha$ were determined by ELISA. The correlation of absolute changes of cytokine levels after inhibition by each biologic were calculated and analysed by means of Spearman rank correlations ($r_s$).
**Results:** Ex-vivo cytokine profiling was performed in 71 patients. The absolute change of cytokine level after inhibition by golimumab was significantly ($p<0.001$)

correlated with the absolute change of cytokine level after inhibition by adalimumab for both IL-1β, IL-6 and TNF-α (Figure). In other words, the cytokine profile after inhibition by golimumab or adalimumab was moderately to highly correlated with each other, while the correlation with the cytokine profile after inhibition by etanercept was much lower for both. Correlations between the cytokine profiles after inhibition by any of the three TNF inhibitors and cytokine profiles after inhibition by any non-TNFi were all weak (data not shown; all $r_s < 0.6$).

**Conclusions:** The high similarity between ex-vivo inhibited cytokine profiling by golimumab and adalimumab provides a putative explanation for the previously found inferior treatment response to golimumab after adalimumab failure in RA. This interesting finding is relevant for clinical practice, because it seems that RA patients who are non-responsive to adalimumab should not switch to golimumab and vice-versa. Furthermore, the similarity in both cytokine profile and clinical outcome for golimumab and adalimumab suggests that ex-vivo inhibited cytokine profiling could be a predictor of individual treatment response to biologics. This is currently being investigated in the BIO-TOP study.

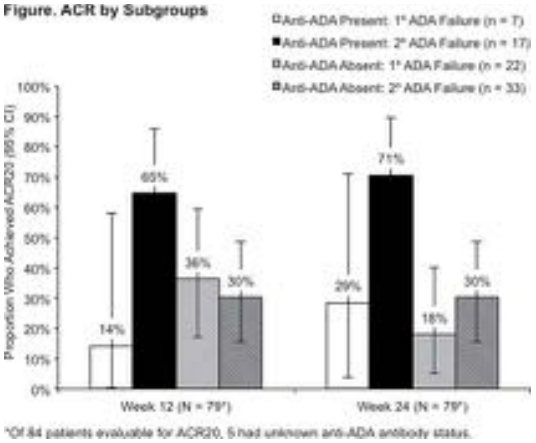
## THU0143 SINGLE-ARM STUDY OF ETANERCEPT (ETN) IN ADULT PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS (RA) WHO FAILED ADALIMUMAB (ADA) TREATMENT

L. Bessette[1], M. Khraishi[2], A.J. Kivitz[3], A. Kaliyaperumal[4], R. Grantab[5], M. Poulin-Costello[5], D. Collier[4]. *[1]Centre de recherche du CHU de Québec, Québec ON; [2]Memorial University of Newfoundland, St John's NL, Canada; [3]Altoona Arthritis and Osteoporosis Center, Altoona PA; [4]Amgen Inc., Thousand Oaks CA, United States; [5]Amgen Canada Inc., Mississauga ON, Canada*



**Background:** EULAR guidelines for RA[1] recommend adding a biologic disease-modifying antirheumatic drug (bDMARD) to a conventional synthetic DMARD (csDMARD) like methotrexate (MTX) if poor prognostic factors are present or response to csDMARD treatment alone is insufficient. If a first bDMARD fails, another bDMARD should be used, such as switching from one tumor necrosis factor inhibitor (TNFi) to another TNFi. It is not known whether antibodies to one TNFi influence the effectiveness of a different TNFi.

**Objectives:** This phase 4, single-arm study evaluated the efficacy and safety of ETN in adult RA patients who had failed ADA.

**Methods:** Adults (age ≥18 years) with moderate to severe RA (disease activity score using 28-joint count and C-reactive protein [DAS 28-CRP] ≥3.2) who failed to respond to ADA+MTX (1º ADA failure) or lost a satisfactory response to ADA+MTX (2º ADA failure) were enrolled. After ≥2 weeks without ADA, ETN 50 mg once weekly for 24 weeks was added to ongoing MTX treatment. Visits occurred at weeks 0, 4, 8, 12, 18, and 24. Assessments included American College of Rheumatology 20% (ACR20), 50% (ACR50), and 70% (ACR70) improvement criteria, and DAS28-CRP. The primary efficacy endpoint was ACR20 at week 12.

**Results:** Of 85 patients who received ETN, 80% were women; mean age was 56.6 years. Overall, 28% had anti-ADA antibodies (42% were neutralizing and 58% non-neutralizing), including 21% (7/33) with 1º ADA failure and 33% (17/52) with 2º ADA failure. Median duration of prior ADA therapy was 46 weeks (range, 12–466 weeks). Of 84 evaluable patients, 30 (36%) achieved ACR20 at week 12 (95% confidence interval [CI]: 26%, 47%) and 29 (35%) achieved ACR20 at week 24. The rates for ACR50 and ACR70 with ETN were 11% and 2%, respectively, at week 12, and 16% and 4%, respectively, at week 24. ACR20 rates by visit are shown by subgroup in the figure. Of the subgroups, patients with 2º ADA failure and anti-ADA antibodies were most likely to have an ACR20 response with ETN at week 12 (65%; odds ratio vs no anti-ADA antibodies 5.2; 95% CI: 2.0, 13.5; $P < 0.001$). DAS28-CRP improved by a mean of 0.8–2.0 in each subgroup at week 12 of ETN, with the greatest improvement in patients with anti-ADA antibodies and 2º ADA failure. Most patients (82%) in this subgroup had DAS28-CRP improvement ≥1.2 at week 12 of treatment with ETN. ACR20 responses at week 12 occurred in patients with anti-ADA binding antibodies that were either neutralizing (4/10; 40%) or non-neutralizing (8/14; 57%). Safety results (≥1 adverse event in 73% of patients and no fatal adverse events) were consistent with the known safety profile of ETN.

**Figure. ACR by Subgroups**

*Of 84 patients evaluable for ACR20, 5 had unknown anti-ADA antibody status.

**Conclusions:** In patients who fail ADA, ETN could be considered as a therapeutic option. The presence of anti-ADA antibodies in patients with 2º ADA failure may guide treatment decisions.

## THU0144 PHARMACOKINETICS AND SAFETY OF GP2015, A PROPOSED ETANERCEPT BIOSIMILAR, ADMINISTERED SUBCUTANEOUSLY BY AN AUTOINJECTOR OR PREFILLED SYRINGE IN HEALTHY MALE SUBJECTS

M. Afonso, D. Kollins, L. Macke, H. Woehling, G. Wuerth. *Global clinical development, Biopharmaceuticals, Hexal AG, Holzkirchen, Germany*

**Background:** Rheumatoid arthritis (RA) being a joint-destructive disease, patients with advanced stages of the disease face difficulties in operating conventional or pre-filled syringes (PFS) for subcutaneous (sc) administration. Therefore, GP2015, a proposed etanercept biosimilar, is planned to be presented in a ready to use, fixed dose, disposable autoinjector (AI), identical to secukinumab autoinjector, allowing one-hand injection without requiring fine finger manipulations.

**Objectives:** To compare the pharmacokinetics (PK) and safety of GP2015 administered via AI or PFS in healthy male subjects.

**Methods:** In this open-label, randomised, 2-way cross over study, male healthy subjects (N=51), ≥18–≤55 years of age, were randomised to receive a single 50 mg sc dose of GP2015 via AI or PFS followed by a wash-out period of at least 35 days and a second 50 mg sc injection of GP2015 via PFS or AI vice versa. Subsequent follow up was 28 days. Randomisation was stratified by body weight (50–79.9 kg, 80–99.9 kg, 100–140 kg), allocating 17 subjects per each weight category.

**Results:** Out of 51 subjects enrolled into the study, 48 were evaluable for PK analysis. Subjects exhibited a mean body weight of 91.5 kg (range: 54.4–133.7 kg) and a mean body mass index (BMI) of 27.7 kg/m$^2$ (range: 19.3–39.0 kg/m$^2$). The 90% confidence intervals (CIs) for the ratios of geometric means of maximum observed serum concentration ($C_{max}$), area under the serum concentration-time curve measured from the time of dosing to the last measurable concentration ($AUC_{0\text{-last}}$), and AUC measured from the time of dosing and extrapolated to infinity ($AUC_{0\text{-inf}}$) were contained within the limits of 80–125% confirming bioequivalence between GP2015 applied via AI or PFS (Table). Within each body weight category, the serum concentration profiles of GP2015 were similar for both treatment administrations. The 90% CI for the ratios of geometric means of all PK parameters were within 80–125% in low and medium weight groups. In

the high weight group, due to a single subject with low exposure after dosing by PFS, the upper limit of the 90% CI was above 125%, while without this outlier the upper limit of CI was below 125%. The most common adverse events (AEs) regardless of relationship to the study drug were headache [GP2015-AI, n=8 (16%); GP2015-PFS, n=5 (10%)] and neutropenia [GP2015-AI, n=5 (10%); GP2015-PFS, n=5 (10%)]. All treatment related AEs were of mild severity and resolved during the study. None of the neutropenias (range: 1.1–1.7 x $10^9$/L; reference range: 1.8–7.9 x $10^9$/L) were considered clinically significant. No serious AEs or deaths occurred during the study. Three subjects had a mild injection site reaction [GP2015-AI, n=1 (2%); GP2015-PFS, n=2 (2%)]. No anti-drug antibodies were detected in any of the subjects.

**Table. Geometric LS means and 90% Confidence intervals for PK parameters**

| PK parameters | LS means | | Ratio GP2015-AI/GP2015-PFS | |
|---|---|---|---|---|
| | GP2015-AI | GP2015-PFS | Estimate | 90% Confidence Interval |
| $C_{max}$ (µg/mL) | 3.7 | 3.6 | 1.01 | (0.94, 1.08) |
| $AUC_{0\text{-}tlast}$ (h*µg/mL) | 684.1 | 678.4 | 1.01 | (0.95, 1.07) |
| $AUC_{0\text{-}inf}$ (h*µg/mL) | 745.2 | 737.4 | 1.01 | (0.96, 1.07) |

Using an analysis of variance (ANCOVA) model with treatment, period and sequence as fixed effects, body weight as covariate, and subject within sequence as random effect.
AI, autoinjector; $AUC_{0\text{-}tlast}$ area under the serum concentration-time curve measured from the time of dosing to the last measurable concentration; $AUC_{0\text{-}inf}$ area under the serum concentration-time curve measured from the time of dosing and extrapolated to infinity; $C_{max}$ maximum observed serum concentration; LS, least squares; PFS, pre-filled syringe; PK, pharmacokinetic

**Conclusions:** This study demonstrated PK bioequivalence of GP2015 administered by AI or PFS. Both administrations were bioequivalent, including when analysis was stratified by body weight. A single dose of 50 mg GP2015 administered by AI or PFS was well tolerated, with a safety profile consistent with previous reports for etanercept. These results suggest that the AI is an effective application form of GP2015 with a similar safety profile compared to the PFS.

## THU0145 PHARMACOKINETICS AND SAFETY OF GP2015, A PROPOSED ETANERCEPT BIOSIMILAR, AND ETANERCEPT ORIGINATOR PRODUCT IN HEALTHY MALE SUBJECTS: A RANDOMISED TWO-WAY CROSSOVER STUDY

M. Afonso, S. Sanguino Heinrich, J. Poetzl, H. Woehling. *Global clinical development, Biopharmaceuticals, Hexal AG, Holzkirchen, Germany*

**Background:** GP2015 is a proposed etanercept (tumor necrosis factor inhibitor) biosimilar.
**Objectives:** To compare the pharmacokinetics (PK) and safety of GP2015 and etanercept originator product (EU-authorised) in healthy subjects.
**Methods:** Healthy subjects (N=54) were randomised to receive a single 50 mg subcutaneous (sc) injection of GP2015 or etanercept originator product, followed by a wash-out period of at least 35 days, and a single 50 mg sc injection of originator product or GP2015, respectively. Subsequent follow up was 28 days. The primary PK parameters were normalised by the protein content of the administered dose before fitting in the analysis of variance model (dose normalised PK analysis). Bioequivalence between GP2015/etanercept originator product for primary PK parameters [maximum observed serum concentration ($C_{max}$), area under the serum concentration-time curve measured from the time of dosing to the last measurable concentration ($AUC_{0\text{-}tlast}$) and AUC measured from the time of dosing and extrapolated to infinity ($AUC_{0\text{-}inf}$)] was demonstrated if the 90% confidence intervals (CIs) for the ratio of geometric means were completely contained within the predefined bioequivalence limits of 0.80–1.25.
**Results:** The 90% CIs for the ratios of geometric means of dose normalised primary PK parameters ($C_{max}$, $AUC_{0\text{-}tlast}$ and $AUC_{0\text{-}inf}$) were within the interval of 0.80–1.25 (Table). For the respective nominal dose (not dose normalised) primary PK parameters, the 90% CIs of the ratios of geometric means were also within the interval of 0.80–1.25 (Table). The most common AEs regardless of relationship to study drug were neutropenia [GP2015, n=7 (13%); originator product, n=8 (14.8%)], headache [GP2015, n=5 (9.3%); originator product, n=5 (9.3%)] and nasopharyngitis [GP2015, n=4 (7.4%); originator product, n=4 (7.4%)]. All treatment-related AEs were of mild or moderate intensity. No serious AEs and deaths occurred during the study. Three subjects had low titer and non-neutralising anti-drug antibodies (ADAs) at the 28-day follow-up visit (treatment sequence GP2015/etanercept originator product).

**Table. Mean ratio and 90% confidence intervals for PK parameters**

| PK parameters (dose normalised) | GP2015/the etanercept originator product | |
|---|---|---|
| | Mean ratio (%) | 90% confidence interval |
| $C_{max}$ (ng/mL) | 1.03 | (0.98 – 1.09) |
| $AUC_{0\text{-}tlast}$ (h*ng/mL) | 0.92 | (0.88 – 0.95) |
| $AUC_{0\text{-}inf}$ (h*ng/mL) | 0.90 | (0.87 – 0.94) |
| **PK parameters (nominal dose)** | | |
| $C_{max}$ (ng/mL) | 1.11 | (1.05 – 1.17) |
| $AUC_{0\text{-}tlast}$ (h*ng/mL) | 0.98 | (0.94 – 1.02) |
| $AUC_{0\text{-}inf}$ (h*ng/mL) | 0.96 | (0.93 – 1.00) |

Using an analysis of variance (ANOVA) model with treatment, period and sequence as fixed effects, and subject within sequence as random effect.
$AUC_{0\text{-}tlast}$ area under the serum concentration-time curve measured from the time of dosing to the last measurable concentration; $AUC_{0\text{-}inf}$ area under the serum concentration-time curve measured from the time of dosing and extrapolated to infinity; $C_{max}$ maximum observed serum concentration; PK, pharmacokinetic

**Conclusions:** This study demonstrated PK bioequivalence between GP2015, a proposed etanercept biosimilar and the etanercept originator product with no relevant differences in safety. The safety and immunogenicity profiles observed in this study are consistent with previous reports on etanercept originator product.

## THU0146 IMPACT OF ANTI-DRUG ANTIBODIES ON EFFICACY AND SAFETY UP TO WEEK 24 FROM A PHASE III STUDY COMPARING SB5 (AN ADALIMUMAB BIOSIMILAR) WITH ADALIMUMAB REFERENCE PRODUCT IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS DESPITE METHOTREXATE THERAPY

M.C. Genovese[1], M. Weinblatt[2], E. Keystone[3], A. Baranauskaite[4], S.Y. Cheong[5], J. Ghil[6]. *[1]Stanford University, Palo Alto; [2]Brigham and Women's Hospital, Boston, United States; [3]Mount Sinai Hospital, University of Toronto, Toronto, Canada; [4]Lithuanian University of Health Science, Kaunas, Lithuania; [5]Samsung Bioepis Co., Ltd., Suwon; [6]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

**Background:** SB5 is a biologic agent developed as a biosimilar of the adalimumab reference product (ADL). The primary efficacy and safety results from a phase III study in rheumatoid arthritis (RA) patients have been reported previously[1]. Immunogenicity to monoclonal antibodies may affect patients' safety and efficacy.
**Objectives:** To compare efficacy and safety results by anti-drug antibody (ADA) status in patients with RA treated with SB5 or ADL (with background Methotrexate, MTX) up to Week 24.
**Methods:** Patients with moderate to severe RA despite MTX treatment were randomly assigned to receive 40 mg of either SB5 or ADL administered subcutaneously every other week. Efficacy, safety, and immunogenicity were measured.
**Results:** The ADA incidence up to Week 24 was 32.8% in SB5 and 31.5% in ADL. In both ADA positive and ADA negative subgroups, ACR responses and other efficacy endpoints were comparable between SB5 and ADL up to Week 24. Within SB5, there was a trend towards decreased efficacy (ACR20, ACR50, ACR-N, change in DAS28 from baseline, and in patients with remission based on DAS28, SDAI or CDAI) in the ADA positive subgroup compared to the ADA negative subgroup. Within ADL, there was a trend towards decreased efficacy for patients in remission based on DAS28, SDAI or CDAI in the ADA positive subgroup compared with the ADA negative subgroup, but other efficacy endpoints were comparable. The safety profiles of SB5 and ADL were generally comparable in both ADA positive and ADA negative subgroups. Within each treatment group, the safety profiles were comparable between ADA positive and ADA negative subgroups. Among ADA negative subgroup, 2.2% in SB5 and 3.8% in ADL experienced ISR and among ADA positive subgroup, 4.5% in SB5 and 1.2% in ADL experienced ISRs.

**Table 1. Efficacy Results at Week 24 by 24-week Overall ADA Results**

| | (–) ADA, SB5 (N=178) | (–) ADA, ADL (N=183) | (+) ADA, SB5 (N=88) | (+) ADA, ADL (N=86) |
|---|---|---|---|---|
| ACR20 | 134/171 (78.4%) | 125/174 (71.8%) | 49/85 (57.6%) | 59/84 (70.2%) |
| ACR50 | 73/171 (42.7%) | 68/174 (39.1%) | 25/85 (29.4%) | 32/84 (38.1%) |
| ACR70 | 31/171 (18.1%) | 36/174 (20.7%) | 16/85 (18.8%) | 14/84 (16.7%) |
| Change in DAS28 from Week 0 | −2.9 (1.24) | −2.7 (1.30) | −2.5 (1.39) | −2.7 (1.24) |
| Change in SDAI from Week 0 | −26.9 (12.85) | −24.7 (12.36) | −24.1 (14.08) | −25.6 (11.35) |
| Change in CDAI from Week 0 | −26.4 (12.47) | −24.1 (12.13) | −23.4 (13.55) | −24.8 (11.85) |
| LDA (DAS28) | 59/170 (34.7%) | 63/173 (36.4%) | 28/85 (32.9%) | 27/84 (32.1%) |
| Remission (DAS28) | 41/170 (24.1%) | 39/173 (22.5%) | 14/85 (16.5%) | 12/84 (14.3%) |

Data are presented in n/n' (%) or mean (SD)
Remission is defined as DAS28 < 2.6 and low disease activity is defined as DAS28 ≤ 3.2

**Conclusions:** The efficacy was comparable between SB5 and ADL regardless of 24-week overall ADA status. Patients with positive ADA status were more likely to have reduced efficacy in SB5, but there was a weaker correlation between the presence of ADA and clinical efficacy in ADL. The safety was generally comparable between SB5 and ADL regardless of the 24-week overall ADA status. Safety was generally comparable between ADA negative and ADA positive subgroups in both treatment groups

## THU0147 DRUG SURVIVAL OF GOLIMUMAB IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS IS INDEPENDENT OF METHOTREXATE AND PREDNISOLONE CONCOMITANCE: RESULTS FROM THE MULTICENTER BIOLOGICS REGISTRY

M. Hayashi[1], T. Kanamono[1], H. Matsubara[1], K. Kishimoto[1], N. Takahashi[2], T. Kojima[2], N. Ishiguro[2]. *[1]Departments of Orthopedics Surgery and Rheumatology, Nagano Red Cross Hospital, Nagano; [2]Departments of Orthopedics Surgery, Nagoya University, Nagoya, Japan*

**Background:** When using biological agents, particularly tumor necrosis factor (TNF) inhibitors, in patients with rheumatoid arthritis (RA), the use of methotrexate (MTX) or prednisolone (PSL) can cause considerable problems for patients because they cause adverse events. Therefore, safety would be increased if MTX and PSL could be tapered or stopped. The objective of this report was to determine the drug retention rate of golimumab (GLM) in Japanese patients with RA and identify potential predictors associated with treatment discontinuation.
**Methods:** A prospective analysis was performed on 152 patients with RA who were treated with GLM in our multicenter biologics registry. We assessed the age, body weight, disease duration, use of pre-biological agents, Disease Activity Score 28-Erythrocyte Sedimentation Rate, and use and dose of MTX and PSL as baseline characteristics of the patients, and we compared cumulative survival among these factors.
**Results:** The overall 52 weeks drug survival rate of GLM was 71.6%. The patients with a body weight of <50 kg had a better drug survival rate than those with a body weight of >50kg (see Table). The use and dose of MTX and use of PSL did not show statistical differences in drug survival rate (see Table).

Table 1. Characteristics of patients with RA receiving GLM at baseline

| Characteristic (unit) | Group range (number) | *P* value† |
|---|---|---|
| Body weight (kg) | <50 (41) | |
| | 50–60 (54) | 0.040* |
| | >60 (26) | 0.010* |
| Number of biologics used before GLM | 0 (80) | 0.363 |
| | 1 (48) | |
| | >1 (24) | 0.015* |
| DAS28-ESR | <3.2 (14) | |
| | 3.2–5.1 (48) | 0.722 |
| | >5.1 (67) | 0.589 |
| MTX use | negative (45) | |
| | positive (103) | 0.829 |
| MTX dose (mg/w) | <8 (30) | 0.177 |
| | 8 (32) | 0.185 |
| | >8 (41) | |
| PSL use | negative (74) | |
| | positive (75) | 0.520 |

†*P* value was calculated using log-rank test in each variable against its controls. **P* value of <0.05 was considered to indicate statistical significance.

**Conclusions:** In daily practice, patients with RA taper or stop their MTX or PSL use while undergoing treatment with biological agents if their RA disease activities are low. On the other hand, MTX with biological agents, particularly TNF inhibitors, would produce better efficacy than higher dose. Our result indicates that Japanese patients with RA receiving GLM may be able to taper or stop MTX and PSL use, which could increase safety and raise the drug retention rate in these patients. These data would be of value in selecting biological agents for MTX-intolerant RA patients.
**Disclosure of Interest:** None declared

## THU0148 ECONOMIC CONSIDERATIONS AND PATIENTS' PREFERENCES AFFECT TREATMENT SELECTION FOR RHEUMATOID ARTHRITIS PATIENTS: A DISCRETE CHOICE EXPERIMENT AMONG EUROPEAN RHEUMATOLOGISTS

M. Hifinger[1,2], M. Hiligsmann[2], S. Ramiro[3], V. Watson[4], H. Severens[5], B. Fautrel[6], T. Uhlig[7], R. van Vollenhoven[8], P. Jacques[9], J. Detert[10], J. Canas da Silva[11], C. Scirè[12], F. Berghae[13], L. Carmona[14], M. Péntek[15,16], A. Keat[17], A. Boonen[1,2]. *[1]Maastricht University Hospital; [2]Maastricht University, Maastricht; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Health Economics Research Unit, University of Aberdeen, Aberdeen, United Kingdom; [5]Erasmus Rotterdam University, Rotterdam, Netherlands; [6]Pierre Louis Institute of Epidemiology and Public Health - AP-HP, Pitie Salpetriere University Hospital, Paris, France; [7]Diakonhjemmet Hospital University of Oslo, Oslo, Norway; [8]Unit for Clinical Therapy Research Inflammatory Diseases, Karolinska Institute, Stockholm, Sweden; [9]Department of Rheumatology, University Hospital Ghent, Ghent, Belgium; [10]Charité - Universitätsmedizin Berlin, Berlin, Germany; [11]Hospital Garcia de Orta, Almada, Portugal; [12]Epidemiology Unit, Italian Society for Rheumatology, Milan, Italy; [13]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [14]Instituto de Salud Musculoesqueletica, Madrid, Spain; [15]Flór Ferenc Hospital, Kistarcsa; [16]Corvinus University of Budapest, Budapest, Hungary; [17]Arthritis Center, Northwick Park Hospital, Harrow, United Kingdom*

**Background:** Economic considerations and patient preferences are increasingly important when choosing treatments. It is not known to what extent rheumatologists across Europe account for these factors when changing drug therapies in patients with active rheumatoid arthritis (RA).
**Objectives:** To compare the value that rheumatologists across Europe attach to patients' preferences and economic aspects when choosing treatments for rheumatoid arthritis (RA) patients.
**Methods:** In a discrete choice experiment European rheumatologists chose between two hypothetical drug treatments for a patient with moderate disease activity. Treatments differed in five attributes: efficacy (improvement and achieved state on disease activity), safety (probability of serious adverse events), patient's preference (level of agreement), medication costs and cost-effectiveness (incremental cost-effectiveness ratio (ICER)). A Bayesian efficient design defined the fourteen choice sets and a random parameter logit model was used to estimate relative treatment preferences for rheumatologists across countries.
β Coefficients presented in table 1 indicate whether the attribute has a negative or positive effect on the rheumatologists' preference
Cluster analyses and latent class models were applied to understand preference patterns across countries and among individual rheumatologists.
**Results:** Responses of 559 rheumatologists from 12 European countries were included in the analysis (49% females, mean age 48 years). In all countries, efficacy dominated the treatment decision followed by economic considerations and patient's preferences. Across countries, patient's agreement with the treatment was associated with an increased treatment preference of rheumatologists and a stronger, negative impact on rheumatologists treatment preference was seen when patents dislike treatments. The economic aspect also played an important role. Higher economic burden was consistently associated with decreased treatment preference. Interestingly, medication costs contributed significantly in all countries, whereas cost-effectiveness was only significant in 9 of 12 countries (table).Latent class models revealed four respondent profiles: one of which traded off all attributes, and the remaining three classes that disregarded ICER. Among individual rheumatologists, 57% disregard ICER in treatment choices, and these were more likely to be located in Italy, Romania, Portugal or France (cluster 2, table)

**Conclusions:** Overall, European rheumatologists are willing to trade between treatment efficacy, patients' treatment preferences and economic considerations. However, the degree of trade-off differs between countries and among individuals.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1671

## THU0149 THE 54-WEEK RESULTS OF INTERFERON-γ RELEASE ASSAY IN A PHASE III STUDY COMPARING SB2, AN INFLIXIMAB BIOSIMILAR, TO INFLIXIMAB REFERENCE PRODUCT IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Durez[1], E. Mysler[2], J.S. Smolen[3], J.-Y. Choe[4], J. Choi[5], Y.H. Rho[5]. *[1]Cliniques Universitaires Saint-Luc, Brussels, Belgium; [2]Medical Research Organization, Buenos Aires, Argentina; [3]Medical University of Vienna, Vienna, Austria; [4]Daegu Catholic University Medical Center, Daegu; [5]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

**Background:** Patients who are being treated with anti-TNF therapy are at increased risk of developing active tuberculosis (TB) by reactivation of latent TB infection (LTBI) or de novo infection. SB2 is developed as a biosimilar of the infliximab reference product (INF). The primary results (30-week) and 54-week results of Phase III study have been reported[1,2].
**Objectives:** To evaluate the prevalence of positive interferon-γ release assay (IGRA) at Screening, the incidence of positive seroconversion in IGRA, and the incidence of active TB in the patients receiving SB2 or INF for 54 weeks.
**Methods:** This study is a randomised, double-blind phase III study. IGRA (QuantiFERON® Gold in-tube test) was performed at Screening, Week 22 and Week 54. Patients who have been diagnosed as active TB were excluded from the study. Patients with a positive IGRA test without any evidence of active TB could be enrolled after receiving TB prophylaxis treatment. Patients who newly seroconverted during the study also were recommended to receive TB prophylaxis.

**Results:** Of 804 patients with IGRA results at Screening, 143 patients (17.8% of 804) had positive results. Among them, 46 patients (19 patients in SB2 and 27 patients in INF) were randomised after the 30-days of TB prophylaxis treatment and the others were excluded from the study. At Week 22 and 54 or early termination visit, respectively, 19 (6.6%) and 7 (2.4%) patients in SB2 and 20 (6.8%) and 7 (2.4%) patients in INF had newly positive IGRA results. Among the patients with positive IGRA results at Week 22, 73.7% (14/19) in SB2 and 50.0% (10/20) in INF were treated with anti-TB treatment. During the study period, there was 1 active TB case in each treatment group (tuberculous pleurisy in SB2 [Korea] and pulmonary tuberculosis in INF [Lithuania]) and there was no case of active TB reported in patients with positive IGRA results at Screening or Week 22.

Table 1. Positive interferon-γ release assay[a] rate during the study

| IGRA test time | SB2 (N=290) | | INF (N=293) | |
|---|---|---|---|---|
| | Positive IGRA n (%) | Seroconversion[b] n (%) | Positive IGRA n (%) | Seroconversion[b] n (%) |
| Screening[c] | 19 (6.6%) | | 27 (9.2%) | |
| Week 22 | 28 (9.7%) | 19 (6.6%) | 36 (12.3%) | 20 (6.8%) |
| Week 54 or early termination | 26 (9.0%) | 7 (2.4%) | 24 (8.2%) | 7 (2.4%) |

[a]Patients, whose first and second interferon-γ release assay results were indeterminate, were considered to have the positive IGRA (at Screening 1 patient in each SB2 and INF; at Week 22, 4 patients in SB2 and 5 patients in INF for both positive IGRA and seronconversion; at Week 54, no patient in each SB2 and INF). [b]Seroconversion defined as negative to positive test change at each test time. [c]Randomised patients only.

**Conclusions:** The incidence of positive seroconversion in IGRA was comparable between the two treatment groups. Among patients with positive IGRA results at Screening or Week 22, there were no cases of active TB and only 2 cases of active TB were reported in this study. IGRA is therefore an useful method to prevent active TB in anti-TNF treated RA patients.

## THU0150 LONG-TERM SAFETY AND EFFICACY OF SB4 (ETANERCEPT BIOSIMILAR) IN PATIENTS WITH RHEUMATOID ARTHRITIS: COMPARISON BETWEEN CONTINUING SB4 AND SWITCHING FROM ETANERCEPT REFERENCE PRODUCT TO SB4

P. Emery[1], J. Vencovský[2], A. Sylwestrzak[3], P. Leszczyński[4], W. Porawska[5], B. Stasiuk[6], J. Hilt[7], Z. Mosterova[8], S.Y. Cheong[9], J. Ghil[10]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [2]Institute of Rheumatology, Prague, Czech Republic; [3]NZOZ Medica Pro Familia Sp. Z O.O., Warsaw; [4]Poznan University of Medical Sciences, Poznan; [5]Poznanski Osrodek Medyczny NOVAMED, Pultusk; [6]Medicome Sp. Z O.O., Oswiecim; [7]Centrum Terapii Wspolczesnej J.M. Jasnorzewska Sp. Komandytowo-Akcyjna, Bialystok, Poland; [8]Revmacentrum MU Dr. Mostera Sro, Brno, Czech Republic; [9]Samsung Bioepis Co., Ltd., Suwon; [10]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

**Background:** SB4 is approved by the European Medicines Agency as a biosimilar of the etanercept reference product (ETN). The phase I clinical study results and 52-week results of phase III clinical study have been reported previously.[1–3]

**Objectives:** To evaluate the long term safety, immunogenicity, and efficacy of continuing SB4 vs. switching (as will occur in clinical practice) from ETN to SB4 in patients with moderate to severe RA.

**Methods:** The phase III randomised, double-blind study period consisted of 52 weeks of treatment with either weekly dose of subcutaneous 50 mg SB4 or ETN with background methotrexate (MTX) in patients with moderate to severe RA. After 52 weeks of treatment, patients in Czech Republic and Poland were enrolled into the open-label, extension period and received SB4 for additional 48 weeks. Efficacy, safety, and immunogenicity were assessed up to Week 100.

**Results:** At Week 52, 245 patients from the randomised, double-blind study period enrolled into the extension study: 126 patients continued to receive SB4 (SB4/SB4) and 119 patients switched from ETN to SB4 (ETN/SB4). Among them, 119 (94.4%) patients of SB4/SB4 and 113 (95.0%) patients of ETN/SB4 completed 100 weeks of treatment. SB4 was well tolerated and the safety profile was comparable between SB4/SB4 and ETN/SB4 during the open-label, extension period (Table 1). Adverse events were those newly occurring after Week 52 in 47.6% of SB4/SB4 and 48.7% of ETN/SB4. There were no cases of injection site reactions reported after Week 52. The overall incidence of anti-drug antibodies after Week 52 was 0.8% in SB4/SB4 and 0.9% in ETN/SB4. Efficacy was sustained and comparable between SB4/SB4 and ETN/SB4 up to Week 100 (Table 2).

**Conclusions:** SB4 was well tolerated and effective over 2 years in patients with RA. Efficacy, safety, and immunogenicity were comparable between the SB4/SB4 and ETN/SB4, demonstrating that switching produced no treatment emergent issues such as loss of efficacy, increase in adverse events, or increase in immunogenicity.

Table 1. Safety and Immunogenicity Outcome During the Open-label, Extension Period (From Week 52 to Week 100)

| Number of patients with | SB4/SB4 (N=126) | | ETN/SB4 (N=119) | |
|---|---|---|---|---|
| | n | (%) | n | (%) |
| At least 1 TEAE | 60 | (47.6) | 58 | (48.7) |
| At least 1 SAE | 6 | (4.8) | 2 | (1.7) |
| Serious infections | 1 | (0.8) | 1 | (0.8) |
| Active tuberculosis | 0 | (0.0) | 0 | (0.0) |
| Injection site reactions[a] | 0 | (0.0) | 0 | (0.0) |
| Malignancy[b] | 1 | (0.8) | 0 | (0.0) |
| Death[b] | 1 | (0.8) | 0 | (0.0) |
| ADA positive[c] | 1 | (0.8) | 1 | (0.9)[d] |

ADA: anti-drug antibody; SAE: serious adverse event; TEAE: treatment-emergent adverse event
[a] Defined as high level group terms of administration site reactions
[b] Hepatic cancer was reported in SB4/SB4
[c] Defined as at least one ADA positive up to Week 100 after Week 52
[d] Percentage is based on the number of patients with ADA results (117 patients)

Table 2. ACR Response Rates During the Open-label, Extension Period (From Week 52 to Week 100)

| ACR response | Timepoint | SB4/SB4 (N=126) | | ETN/SB4 (N=119) | |
|---|---|---|---|---|---|
| | | n/n' | (%) | n/n' | (%) |
| ACR20 | Week 52 | 99/125 | (79.2) | 98/119 | (82.4) |
| | Week 76 | 102/125 | (81.6) | 90/117 | (76.9) |
| | Week 100 | 95/122 | (77.9) | 91/115 | (79.1) |
| ACR50 | Week 52 | 65/125 | (52.0) | 64/119 | (53.8) |
| | Week 76 | 74/125 | (59.2) | 62/117 | (53.0) |
| | Week 100 | 73/122 | (59.8) | 70/115 | (60.9) |
| ACR70 | Week 52 | 48/125 | (38.4) | 39/119 | (32.8) |
| | Week 76 | 49/125 | (39.2) | 44/117 | (37.6) |
| | Week 100 | 52/122 | (42.6) | 48/115 | (41.7) |

## THU0151 MULTICENTER, OPEN-LABEL STUDY TO EVALUATE THE PREDICTABILITY OF DISEASE CONTROL AT WEEK 52 BASED ON EARLY RESPONSE TO CERTOLIZUMAB PEGOL (IN COMBINATION WITH METHOTREXATE) IN ITALIAN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS: THE CZP-SPEED STUDY

P. Sarzi-Puttini[1], E. Filippucci[2], S. Adami[3], P.L. Meroni[4], P. Talavera[5], T. Kumke[6], W. Grassi[2]. *[1]Azienda Ospedaliera Luigi Sacco Polo Universitario, Milan; [2]Università Politecnica delle Marche, Ancona; [3]Università degli Studi di Verona, Azienda Ospedaliera di Verona, Verona; [4]Istituto Ortopedico Gaetano Pini, Milan, Italy; [5]UCB Pharma, Madrid, Spain; [6]UCB Pharma, Monheim, Germany*

**Background:** Early identification of patients (pts) unlikely to achieve good long-term disease control with anti-TNF therapy in rheumatoid arthritis (RA) is important for physicians following treat-to-target recommendations. Predictability of response has previously been demonstrated in RA pts treated with certolizumab pegol (CZP), with previous work focusing on the predictability of long-term (1-year) response based on response at Week (Wk) 12.[1] In addition to clinical and patient-reported outcomes, musculoskeletal ultrasonography (US) is an increasingly important tool for assessing pt disease activity.

**Objectives:** To assess the impact of CZP treatment on clinical, patient-reported and US outcomes, and to assess the ability of early treatment response to predict long-term outcomes in Italian pts with RA.

**Methods:** CZP-SPEED (NCT01443364) was a 52-wk, open-label, prospective, interventional, multicenter study. Pts were biologic-naïve, had active RA ($\geq$6 swollen and $\geq$6 tender joints), and had failed treatment with $\geq$1 DMARD. All pts received CZP (400mg at Wks 0, 2 and 4, followed by 200mg every 2 wks). Positive predictive value was defined as the percentage of pts with clinical response (reduction from baseline in DAS28(ESR)$\geq$1.2) at an early time point who also had clinical response at Wk52. Early time points were Wks 1, 2, 4, 6, 8 and 12. Clinical and patient-reported outcomes were DAS28(ESR), ACR20/50/70, HAQ-DI, Pain (VAS) and PtGADA. US was assessed using the composite power Doppler/US (PDUS) score, defined as the sum of synovial fluid

and proliferation, Doppler signal/blood flow, cartilage damage and bone erosion scores. US operation parameters were harmonized across all study sites. Data are reported descriptively with NRI imputation for dichotomous data and LOCF for continuous data.

**Results:** 132 pts were enrolled and received CZP (safety set; SS), of whom 131 (99%) provided ≥1 baseline and ≥1 post-baseline DAS28(ESR) assessment (full analysis set; FAS), and 91 (69%) completed to Wk52. Pts had a mean age of 54.8, 82% were female, and disease duration was relatively short (median 1.8 years). Between 64–70% of pts who responded at Wk 2, 4, 6, 8, or 12 maintained response at Wk52 (Figure). Rapid improvements in clinical and US outcomes were observed at Wk8 and were maintained to Wk52 (Table). There were 301 adverse events (AEs) in 94 pts (71.2%) and 25 serious AEs in 16 pts (12.1%). No deaths or cases of tuberculosis were observed. No new safety signals were observed for CZP.

**Figure:** Positive predictive value (PPV) for clinical response at Week 52 based on clinical response at Weeks 1, 2, 4, 6, 8, and 12 (FAS, N=131)

Clinical response at Weeks 1–12 and Week 52 was defined as reduction in DAS28(ESR)≥1.2 from baseline.

**Table:** Clinical and ultrasound outcomes over 52 weeks of CZP treatment (FAS, N=131)

| | Baseline | Change from baseline to Week 8 | Change from baseline to Week 52 |
|---|---|---|---|
| DAS28(ESR), mean (SD) | 5.9 (1.1) | -2.2 (1.1) | -2.3 (1.5) |
| ACR20, n (%) | - | 86 (65.6) | 81 (61.8) |
| ACR50, n (%) | - | 57 (43.5) | 62 (47.3) |
| ACR70, n (%) | - | 27 (20.6) | 39 (29.8) |
| HAQ-DI, mean (SD) | 1.3 (0.7) | -0.5 (0.6) | -0.6 (0.7) |
| Pain, mean (SD) | 56.5 (23.4) | -25.2 (25.6) | -26.2 (29.9) |
| PtGADA, mean (SD) | 57.3 (23.2) | -25.8 (26.6) | -26.5 (30.9) |
| PDUS, mean (SD) [a] | 20.5 (11.7) | -4.5 (5.5) | -4.8 (7.5) |

[a] Measured in the PDUS subgroup (n=66). PDUS: power Doppler/ultrasonography; PtGADA: patient's global assessment of disease activity.

**Conclusions:** In Italian RA pts treated with CZP, clinical response up to Wk12 was predictive of long-term response at Wk52. In addition to the rapid and sustained clinical improvements observed in this cohort, this is the first report of the maintenance of US improvements over 52 wks in CZP-treated pts. Coupled with the clinical predictability data, US evaluation may allow rheumatologists to make decisions earlier in the treatment journey.

## THU0152 OPTIMIZATION STRATEGIES OF BIOLOGICAL THERAPY IN RHEUMATOID ARTHRITIS. CREATE REGISTRY RESULTS AFTER TWO YEARS OF FOLLOW-UP

R. Ortega Castro[1], J. Calvo Gutiérrez[1], M.C. Castro Villegas[1], D. Ruiz Vilchez[1], M. Romero Gómez[1], M. Cárdenas Aranzana[2], S. De la Fuente Ruíz[2], P. Carreto Font[3], A. Escudero Contreras[1], E. Collantes Estévez[1], P. Font Ugalde[1].
*[1]Rheumatology Department, Reina Sofia Universitary Hospital/IMIBIC/University of Cordoba; [2]Pharmacy Department, Reina Sofia Universitary Hospital/IMIBIC/University of Cordoba, Córdoba; [3]FCM Management of Valladolid. East Area, Valladolid, Spain*

**Background:** Treat to Target (T2T)is an international initiative to define Rheumatoid Arthritis (RA) treatment targets and recommendations to measure disease severity and encourage earlier diagnosis and optimize treatment. The primary target for treatment of RA should be a state of clinical remission.After reaching remission there are different therapeutic approaches to consider. In recent years, optimization of Biological Therapy (BT)is a strategy employed in patients with RA in remission, consists in a dose reduction or an extended dose interval, searching a minimum effective dose for each patient, which limits the occurrence of adverse effects and promotes economic saving

**Methods:** RA patients (ACR criteria 1987)of CREATE registry that November 1, 2013 had clinical remission (DAS28 value <2.6)of at least 6 months constituted the cohort of patients who were optimized. According to the consensus of the Spanish Society of Rheumatology and Hospital Pharmacy, dose optimization involved the reduction of between 20 and 50% of it.Decisions about treatment and dose reduction was performed by a multidisciplinary team of clinical rheumatologists and pharmacists in a tertiary hospital,which involved the application of protocols and patients revision at least every 2 months

**Results:** We performed a prospective observational cohort study in 70 RA optimized patients. (81.4% were women with a mean age at onset optimization of 56.9 ± 13.7 years. 68.8% were RF positive and 66.7% ACPA positive). Optimization occurred in 41.4% of patients in the first year and 58.8% in the second year (p=0.001).64 patients completed 24 month of follow-up, suffering 36 of these patients (56.3%) clinical relapse (mean DAS28 2.81 (0.88) at 1 year, reason why it was decided to return to the usual dose again reaching clinical remission in all patients after 2 years (DAS 28 2.59 (0.58).43.8% patients maintained optimization after 2 years of follow-up without suffering relapse (mean DAS28 2.19 (0.84)). Statistically significant differences were found when comparing the mean baseline DAS 28 between both groups, being lower in the subgroup of patients who maintains remission compared to the relapsing group (1.97 (0.85) vs 2.44 (0.66) (p=0.012)

**Conclusions:** -The use of an extended dose interval maintained remission status in patients with established RA who are in sustained clinical remission it is possible in 41.2% patients after 2 years of follow-up in clinical practice (CREATE registry)-This strategy is possible in patients with controlled disease persistently and in view of our results, we might consider that those patients who have a lower level of activity at onset optimization, are less likely to relapse and therefore maintain this strategy-After 2 years of follow up all patients maintained clinical remission (DAS28 <2.6),even the patients who relapsed at 12 months and returned to their usual dose

## THU0153 HEMOGLOBIN IS A BETTER PREDICTOR FOR RADIOGRAPHIC PROGRESSION THAN DAS28 IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS-ANALYSIS FROM INTRAVENOUSLY ADMINISTERED GOLIMUMAB GO-FURTHER STUDY

R. Westhovens[1], C. Han[2], M.E. Weinblatt[3], L. Kim[4], E.C. Hsia[4], D. Parenti[5], S. Kafka[5], C.O. Bingham III[6] on behalf of GO-FURTHER Investigators.
*[1]Rheumatology, UZ KU Leuven, Leuven, Belgium; [2]2. Johnson & Johnson Pharmaceutical Services, Malvern; [3]Brigham & Women's Hospital, Boston; [4]Janssen Research & Development, Spring House; [5]Janssen Scientific Affairs, Horsham; [6]Johns Hopkins University, Baltimore, United States*

**Background:** Clinical studies demonstrated that baseline disease activity including C-reactive protein (CRP) level was a predictor variable for radiographic joint damage in patients with rheumatoid arthritis (RA).

**Objectives:** To identify variables associated with radiographic joint damage in patients with RA treated with intravenously administered golimumab (GLM) + Methotrexate (MTX) or MTX + placebo (PBO).

**Methods:** GO-FURTHER was a multicenter, randomized, placebo-controlled study. Adult patients with active RA despite MTX therapy (≥6 tender and swollen joints, CRP ≥1.0 mg/dL, and RF and/or anti-CCP positive) were randomized to placebo (PBO) + MTX or GLM (2mg/kg) plus MTX at week 0, 2, and every 8 week thereafter (GLM group). Patients in PBO group with <10% improvement in tender and swollen joint count from baseline at week 16 entered early escape (EE) and received a 2 mg/kg GLM infusion at weeks 16 and 20 and every 8 weeks subsequent. Radiographic progression was measured using Total *Sharp score* (TSS). The correlations of TSS with hemoglobin, disease activity score (DAS28-CRP)and physical function evaluated with Health Assessment Questionnaire (HAQ) were assessed using Spearman's correlation or multivariable liner regression model. Anemia was defined based on World Health Organization (WHO) criteria as Hgb <12 g/dl in women and <13 g/dl in men.

**Results:** Moderate to severe RA was demonstrated by a mean DAS28 score of 5.9 with TSS of 48.5 in all patients group at baseline. In linear regression models, baseline DAS28, HAQ score, and Hgb level was correlated with baseline TSS with Spearman's correlation coefficient (r) of 0.148 (p<0.01), 0.0.193 (p<0.001) and -0.129 (p<.001), respectively. Similar correlation relationships of TSS score with DAS28, HAQ and Hgb were observed at Week 24. In multiple linear regression models, after adjusting for effect of other factors, Hgb level demonstrated significant correlation with TSS at the baseline or Week 24. The change in Hgb at Week 20 also was correlated with change in TSS at Week 24 after adjusting for change in DAS28 and HAQ. GLM IV + MTX-treated patients demonstrated less radiographic damage than MTX+PBO-treated patients regardless of their anemia status at baseline or week 20.

**Conclusions:** Hemoglobin level is an independent variable predicting radiographic progression in MTX refractory RA patients.

## THU0154 EFFECTS OF ETANERCEPT BIOMIMICS ON LIPID PROFILES IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Zhu, H. Shen. *The Second Hospital of Lanzhou University, Lanzhou, China*

**Objectives:** To compare the modifications in lipid profiles among patients with RA receiving anti-TNF-α agents – one Etanercept biomimics plus disease modifying anti-rheumatic drugs (DMARDs) versus DMARDs, explore the relationship between dyslipidemia, inflammation in RA patients.
**Methods:** 100 newly diagnosed RA patients were randomly divided into biological agent treatment group and non-biological agent treatment group, each group included 50 patients. At baseline and at 12 and 24 weeks, levels of lipids, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), as well as the atherogenic index of plasma (AIP) was calculated, antibodies against cyclic citrullinated peptide (ACCP), carotid intima-media thickness (CIMT)were studied at baseline and 24 weeks. Statistical analyses are performed with SPSS software version 19.0.
**Results:** Baseline values for lipid levels were similar in both groups. Pearson correlation test was carried out and found that CIMT and ESR, CRP, AIP were positively correlated, and HDL, Apo-AI were negatively correlated at baseline. At 12 weeks and 24 weeks in the biological agent treatment group, the levels of HDL, Apo-AI were increased and levels of Lpa, AIP were decreased when compared to the baseline, and at 24 weeks, CIMT was decreased compared to the baseline. At 24 weeks in the non-biological agents treatment group, the level of HDL was increased, levels of LDL, Lpa, CIMT, AIP were all decreased compared to the baseline. At 12 weeks in the biological agent treatment group, the levels of AIP, Lpa were lower than non-biological agent group, levels of TC, HDL, Apo-AI were higher than non-biological agent group, and at 24 weeks in the biological agent treatment group, the levels of Apo-B, Lpa were lower than non-biological agent group, level of LDL, Apo-AI were higher than non-biological agent group (all $P<0.05$).
**Conclusions:** (1) Inflammatory status may affect the lipid profiles and the endothelial function and is associated with the atherosclerosis. (2) The Etanercept biomimics and DMARDs both can improve lipid profiles, and the protective effect of the Etanercept biomimics on cardiovascular complications is superior to traditional DMARDs, but the medication's effect lasts shorter lengths of time, therefore further studies and large samples are needed in the future.

## THU0155 ANALYSIS OF BIO-FREE CONDITION OF ADALIMUMAB (ADA) AND EARLY INTRODUCTION OF ADA IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Ito[1], D. Kobayashi[1], C. Takai[1], T. Nemoto[1], H. Lee[1], A. Abe[1], H. Otani[1], H. Ishikawa[1], A. Murasawa[1], I. Narita[2], K. Nakazono[1]. *[1]Department of Rheumatology, Niigata Rheumatic Center, Shibata City; [2]Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata City, Japan*

**Background:** HOPEFUL-1 trial and HIT HARD trial showed the effect of combination therapy of methotrexate (MTX) plus adalimumab (ADA) for MTX naïve patients with active early rheumatoid arthritis (RA). Although the biologic disease modified anti rheumatic drugs (bDMARDs) are the most effective treatment of RA, the costs are much higher than that of conventional synthetic DMARDs (csDMARDs). Considering the total medical cost, strategies such as tapering and withdrawal of bDMARDs without disease flare can be an important option. However, the condition for discontinuation of bDMARDs in a real clinical setting has not been fully investigated.
**Objectives:** To analyze the bio-free condition of ADA and the effect of early introduction of ADA in RA patients in a real world.
**Methods:** We used ADA in 132 RA patients. Study 1: Twenty three patients discontinued ADA. We analyzed 14 patients who were followed up for more than 24 weeks after discontinuation. Study 2: Twenty four patients started ADA within 3 months from the introduction of MTX. Two patients stopped ADA due to inefficacy. We analyzed 14 patients who were followed up for more than 52 weeks.
**Results:** Study 1. Patients were 54.6 ± 10.5 years old, disease duration 3.2 ± 2.7 years, Bio-naïve: 13 patients, switch: 1 patient, Prednisolone was increased in 1 patient. csDMARDs were added in 8 patients (4 patients before and 4 patients after discontinuation of ADA). DAS28-CRP did not change until 24 weeks and no patient re-started bDMARDs. Study 2. Patients were 45.0 ± 14.9 years old, disease duration 1.5 ± 2.7 years, 6 patients used MTX alone as csDMARD and 5 patients among them started other csDMARDs additionally. DAS28-CRP decreased from 4.9 ± 1.1 to 1.8 ± 0.6 ($p<0.0001$), 9 patients achieved clinical remission (64.3%), and 3 patients (21.4%) achieved bio-free condition without relapse.
**Conclusions:** In Study 1, ADA made bio-free condition in 17.5% of RA patients without relapse until 24 weeks, which indicates the possibility of sustainable bio-free in the real clinical setting. In Study 2, patients with early RA who started ADA within 3 months from the introduction of MTX achieved clinical remission (64.3%) and bio-free condition (21.4%). This result shows early introduction of ADA for bio-free condition might be a good choice in terms of reducing a total medical cost in the long term. In these studies, additional use of csDMARDs after bDMARDs discontinuation is thought to be important for maintaining bio-free condition without disease flare.

## THU0156 ACHIEVEMENT OF LOW DISEASE ACTIVITY IN PATIENTS INITIATING INFLIXIMAB WITH AND WITHOUT DOSE ESCALATION

S. Cohen[1], G. Reed[2], R. Magner[3], S. Kafka[4], L. Ellis[4], R.J. DeHoratius[5], J.D. Greenberg[6]. *[1]Metroplex Clinical Research Center, Dallas; [2]Corrona, LLC/U Mass Med School, Southborough/Worcester; [3]U of Mass Med School, Worcester; [4]Janssen Scientific Affairs, LLC, Horsham; [5]Janssen Scientific Affairs, LLC/Kimmel Sch of Med, Horsham/Phila; [6]Corrona, LLC/NYU Sch of Med, Southborough/NY, United States*

**Background:** Dose escalation is a common strategy for patients (pts) having an inadequate response to a medication.
**Objectives:** To examine low disease activity (LDA) among pts receiving infliximab (IFX) who did and did not escalate therapy above 3mg/kg in CORRONA, a US national registry of rheumatoid arthritis (RA) pts.
**Methods:** We identified all RA pts who initiated IFX on or after 6/2009 at a dose ≤3mg/kg and with moderate or high disease activity (CDAI>10). Eligible pts required at least 6 mos of follow-up after initiation or after dose escalation. Dose escalation was defined as an increase of >1mg/kg or reduction in infusion intervals by ≥1 wk. We divided pts into 3 groups: pts achieving LDA (CDAI ≤10) without dose escalation; pts not achieving LDA and not dose escalating; pts dose escalating. The last group was further divided into pts achieving LDA after dose escalation and pts not achieving LDA after dose escalation. We compared the populations at time of initiation by demographics, BMI in categories of normal (BMI<25), overweight (25≥BMI<30), obese (BMI ≥30), disease characteristics and activity, comorbidities (including diabetes), and medications (prior and current conventional disease modifying anti-rheumatic agents or biologics). For dose escalators, we determined the last dose at time of LDA or in those not achieving LDA, the last dose. The dose is normalized to mg/kg/8wk for comparative purposes.
**Results:** There were 286 pts who met inclusion criteria. 124 (43.4%) reached LDA without escalation; 50 (17.5%) either switched without escalation or had not reached LDA by at least 9 mos; 112 (39.2%) escalated. Of the escalators, 64 (57.1%) reached LDA and 48 (42.9%) switched or did not reach LDA by at least 9 mos. Pts who reached LDA without escalation were more likely to be biologic naïve (67.7%) than those who escalated but did not reach LDA (45.8%, p=0.008). Pts reaching LDA without escalation had lower disease activity measures at initiation (tender joints, physician global assessment, pt global assessment, pt pain) than pts not reaching LDA with or without escalation ($p<0.05$ for all measures). However, swollen joint counts were not significantly different. Pts escalating had higher rates of obesity (57%) and diabetes (13.4%) than pts reaching LDA without escalating (obesity: 41% [p=0.02] and diabetes: 5.7% [p=0.046]). Pts not reaching LDA after escalation had the highest rate of obesity (62.5%). Pts reached LDA at a median dose of 6.0mg/kg/8wks, Interquartile Range (IQR): [5, 8]; pts not reaching LDA had a final median dose of 6.7mg/kg/8wks, IQR: [5, 8.5]. There was no significant difference in last dose by BMI group.
**Conclusions:** Pts more likely to reach LDA without dose escalation are biologic naïve and have lower disease activity measures at initiation. Both high BMI (obese) and diabetes are associated with requiring dose escalation to achieve LDA. In this analysis, ≤25% of patients received dose escalation beyond 8mg/kg/8wks, which may have clinical relevance.

## THU0157 CLINICAL OUTCOMES AT WEEK 104 AND ANALYSIS OF ASSOCIATED BASELINE FACTORS AFTER AN INITIAL 1 YEAR OF CERTOLIZUMAB PEGOL AND MTX TREATMENT IN MTX-NAÏVE PATIENTS WITH EARLY RA: RESULTS FROM THE SECOND YEAR OF THE C-OPERA STUDY

T. Atsumi[1], K. Yamamoto[2], T. Takeuchi[3], H. Yamanaka[4], N. Ishiguro[5], Y. Tanaka[6], K. Eguchi[7], A. Watanabe[8], H. Origasa[9], T. Shoji[10], O. Togo[10], T. Okada[11], D. van der Heijde[12], N. Miyasaka[13], T. Koike[1,14]. *[1]Hokkaido University Graduate School of Medicine, Sapporo; [2]The University of Tokyo; [3]Keio University School of Medicine; [4]Tokyo Women's Medical University, Tokyo; [5]Nagoya University, Nagoya; [6]University of Occupational and Environmental Health, Kitakyushu; [7]Sasebo Chuo Hospital, Sasebo; [8]Tohoku University, Sendai; [9]University of Toyama School of Medicine, Toyama; [10]UCB Pharma; [11]Astellas Pharma Inc, Tokyo, Japan; [12]Leiden University Medical Center, Leiden, Netherlands; [13]Tokyo Medical and Dental University, Tokyo; [14]Sapporo Medical Center NTT EC, Sapporo, Japan*

**Background:** The efficacy and safety of certolizumab pegol (CZP) treatment in combination with optimized-dose MTX in Japanese MTX-naïve early rheumatoid arthritis (RA) patients (pts) with poor prognostic factors have previously been reported (1-year [yr] results from the C-OPERA study).[1]
**Objectives:** 1. Investigate whether the clinical impact of initial 1-yr treatment with CZP+MTX was maintained to Week (Wk) 104 with MTX therapy alone; 2. Identify factors associated with the final outcomes of the 2-yr therapy by post-hoc logistic regression analysis.
**Methods:** MTX-naïve early RA pts were eligible to enter C-OPERA (NCT01451203). Pts were randomized to CZP+MTX (n=159) or placebo (PBO)+MTX (n=157); oral MTX was escalated to 16mg by Wk8, or maximum tolerated dose (optimized-dose). After pts completed the 52-wk double-blind (DB) period, CZP or PBO was discontinued and MTX monotherapy continued up to Wk104. Full analysis set population was analyzed using LOCF for SDAI remission, and linear extrapolation for mTSS in patients who withdrew before Wk104. Post-hoc univariate logistic regression analysis was used to investigate factors associated with radiographic non-progression (change from baseline [BL] in mTSS$\leq$0.5 at Wk104) or SDAI remission at Wk104, and factors with p$<$0.1 were included in a multivariate analysis.
**Results:** After stopping CZP at Wk52, the radiographic non-progression rate was higher at Wk104 in the Yr 1 CZP+MTX treatment group vs Yr 1 PBO+MTX treatment group (84.2% vs 67.5%, p$<$0.001). Although SDAI remission rates of the Yr 1 CZP+MTX treatment group decreased after CZP discontinuation, higher rates were maintained up to Wk104 vs PBO+MTX (41.5% vs 29.3%, p=0.026). Initial treatment with CZP, lower BL HAQ-DI and mTSS were considered to be associated with radiographic non-progression, whereas SDAI remission at Wk104 associated with male gender, lower BL DAS28(ESR) and initial treatment with CZP (Table). Incidence of overall adverse events was similar between groups, with no new safety signals.

**Table:** Logistic regression analyses to identify factors associated with Week 104 outcomes

[a] mTSS change from baseline ≤0.5; [b] SDAI ≤3.3.

**Conclusions:** Primary analyses showed the clinical benefit of initial 1-yr CZP+MTX therapy in MTX-naïve early RA pts with poor prognostic factors was maintained to 2yrs with MTX alone. Different BL factors were identified as associated with clinical remission and radiographic non-progression. Effectiveness of initial 1-yr CZP treatment on both clinical and radiographic 2-yr outcomes was confirmed by multivariate logistic regression adjusting for BL factors.

## THU0158 WHICH PATIENT CHARACTERISTICS INFLUENCE THE CHOICE OF BIOLOGICAL THERAPY AFTER FIRST TNF INHIBITOR THERAPY IN RA? A NATIONWIDE STUDY OF CHANNELING IN SWEDEN 2010-2012

T. Frisell[1], D. Di Giuseppe[1], S. Ernestam[1], H. Forsblad-d'Elia[2], L. Jacobsson[3], C. Turesson[4], R. van Vollenhoven[1], J. Askling[1] on behalf of ARTIS study group. *[1]Karolinska Institutet, Stockholm; [2]Umeå University, Umeå; [3]Gothenburg University, Gothenburg; [4]Lund University, Malmö, Sweden*

**Background:** The past decade has seen the introduction of many biological DMARDs (bDMARDs) for treating RA, but there is only limited evidence from comparative studies to guide the choice of therapy for specific patients. Whilst a TNF inhibitor (TNFi) is typically used as the first bDMARD, many patients will switch from this initial therapy. The choice of the next bDMARD is, however, largely a matter of patient and physician preference. Perceived or established differences between available bDMARDs may lead to non-random allocation of treatment, a quantification of which is essential for a correct assessment of comparative effectiveness and safety in observational studies.
**Objectives:** To describe baseline patient characteristics at initiation of different bDMARDs after a switch from a TNFi as first bDMARD
**Methods:** Patients with RA who initiated a second bDMARD in 2010–2012 within one year of discontinuing initial TNFi treatment were identified using the

Swedish Rheumatology register (SRQ). Data on disease history, defined as ever diagnosed with relevant co-morbidities, were retrieved by linking to the nationwide and virtually complete Swedish Patient Register.

**Results:** The most common bDMARDs after initial TNFi therapy were rituximab and etancercept; the least common was infliximab. Across drugs, there were only modest differences in demographics and RA characteristics, and moderate differences in disease history. Those initiating a second TNFi were slightly younger, less often RF+, and had slightly lower DAS28 than those initiating a non-TNFi bDMARD. Initiators of rituximab had longest disease duration, highest proportion RF+ and with history of malignancy or COPD, while etanercept-initiators had the lowest proportion with history of malignancy. Those initiating a second TNFi had more often switched due to adverse events, though lack of effect was the most common reason for all drugs.

Numbers are median (IQR) or %.

**Conclusions:** We observed some evidence for channeling regarding disease history, both by class and by drug within class. These differences were small compared to previously reported channeling to non-TNFi as first bDMARD, but should still be taken into account in observational studies of comparative effectiveness and safety of different biological therapies.

**Disclosure of Interest:** None declared

## THU0159 A LARGE-SCALE PROSPECTIVE SINGLE COHORT OBSERVATIONAL STUDY OF WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ADALIMUMAB: THE FINAL ANALYSIS OF 48-WEEK DATA FROM THE ANOUVEAU STUDY

T. Takeuchi[1], R. Nakajima[2], N. Agata[2], Y. Tanaka[3]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]AbbVie GK, Tokyo; [3]The First Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan*

**Background:** Rheumatoid arthritis (RA) significantly impairs work productivity and daily activities, for which therapeutic approaches have still to be investigated.

**Objectives:** To examine the effectiveness of adalimumab (ADA) with respect to RA-related work productivity and activity impairment, as well as associations between changes in work outcomes and changes in disease activity, in Japanese patients with different employment statuses. The first 24-week interim results from the 48-week, multicenter, prospective, single-cohort observational study of self-reported work productivity and activity impairment (ANOUVAEU study) were presented at EULAR in 2013, and here we report the final 48-week results from the study.

**Methods:** Data were obtained from 1973 Japanese RA patients enrolled in the ANOUVAEU study. Work-related outcomes were measured using the Work Productivity and Activity Impairment questionnaire for RA (WPAI/RA), including employment status [paid-worker (employed for ≥35 hr/week), home-worker (employed for <35 hr/week) or non-employed], absenteeism (work time missed), presenteeism (impairment while working), overall work impairment (OWI) and activity impairment (AI) due to RA. The Health Assessment Questionnaire Disability Index (HAQ-DI), EQ-5D, disease activity score based on 28 joint count (DAS28), Clinical Disease Activity Index, and Simplified Disease Activity Index were used to assess clinical response. Factors associated with improvement of WPAI/RA domain scores were analyzed by multivariate analysis, and correlations between changes in WPAI/RA domain scores and clinical responses were estimated.

**Results:** Overall, absenteeism, presenteeism, OWI and AI scores were significantly improved by treatment with ADA, and the observed improvements at week 24 were sustained until week 48 (Table). HAQ-DI and EQ-5D were also consistently improved from week 12 until week 48 ($p<0.0001$). In parallel with these improvements, the clinical remission rate as determined by DAS28-CRP significantly increased from 9.0% at baseline to 32.5% at week 12 and 41.1% at week 48 ($p<0.0001$). Additional results including factors associated with improvement of WPAI/RA domain scores and correlations between changes in WPAI/RA domain scores and clinical responses will be discussed.

Table 1. Effects of treatment with ADA on WPAI/RA

| | Week 0 | Week 24 | Week 48 |
|---|---|---|---|
| Absenteeism, % | 8.17±20.64 (825) | 3.01±12.65 (617) p<0.0001 | 1.25±8.13 (426) p<0.0001 |
| Presenteeism, % | 40.09±28.83 (888) | 19.51±21.94 (655) p<0.0001 | 12.71±16.44 (454) p<0.0001 |
| OWI, % | 41.85±30.00 (812) | 20.65±23.75 (611) p<0.0001 | 13.37±17.15 (420) p<0.0001 |
| AI, % | 48.43±28.09 (1538) | 24.67±23.87 (1128) p<0.0001 | 19.08±20.68 (774) p<0.0001 |

Values are mean ± SD (n). P-values were calculated by paired t-test.

**Conclusions:** ADA demonstrated significant sustained improvements in RA-related work productivity and activity impairment in Japanese RA patients. Treatment with ADA for RA patients may reduce their potential risks of becoming unemployed and financially impaired.

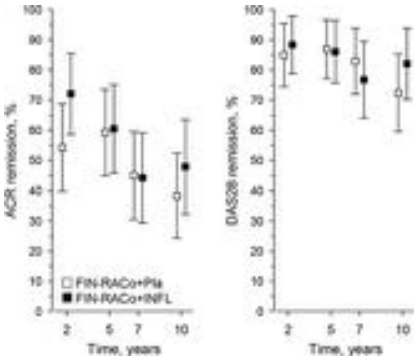
## THU0160 EXCELLENT OUTCOMES SUSTAINED EVEN IN LONG-TERM WHEN TARGETED TREATMENT WITH A COMBINATION OF TRADITIONAL DMARDS IS USED IN EARLY RHEUMATOID ARTHRITIS. THE 10-YEAR FOLLOW-UP RESULTS OF A RANDOMIZED CLINICAL TRIAL, THE NEO-RACO TRIAL



V. Rantalaiho[1,2], T. Sandström[3], J. Koski[4], H. Kautiainen[5], M. Leirisalo-Repo[6,7]. *[1]Centre for Rheumatic Diseases, Tampere University Hospital; [2]School of Medicine, University of Tampere, Tampere; [3]Dept. of Rheumatoloy, Helsinki University Hospital, Helsinki; [4]Dept. of Internal Medicine, Mikkeli Central Hospita, Mikkeli; [5]Dept. of General Practice, University of Helsinki; [6]Dept. of Rheumatology, Helsinki University Hospital; [7]University of Helsinki, Helsinki, Finland*

**Background:** The short term outcomes of remission-targeted treatments of rheumatoid arthritis (RA) are well established, but the long-term success of such strategies is less clear, as is the role of initial add on biologics.

**Objectives:** To assess the evolution of clinical and radiograpich outcomes over 10 years in patients with early RA treated with initial remission-targeted combination-DMARD therapy and additional infliximab or placebo infusions for the first six months

**Methods:** Ninety-nine patients with early, DMARD-naïve RA were treated with a triple combination of DMARDs, starting with methotrexate (max 25mg/week), sulfasalazine (max 2g/day), hydroxychloroquine (35mg/kg/week), and with prednisolone (7.5mg/day), and randomized to double-blindly receive either infliximab (3mg/kg; FIN-RACo+INFL) or placebo (FIN-RACo+PLA) infusions during the first 6 months. After 2 years the treatment strategies became unrestricted, but the treatment goal was strict ACR remission. At 10 years the clinical and radiographic outcomes were assessed using the intention-to-treat principal.

**Results:** Ninety patients (91%) were followed after 2 years, 43 in the FIN-RACo+INFL and 47 in the FIN-RACo+PLA group. At 10 years, the respective proportions of patients in strict ACR and in DAS28 remissions in the FIN-RACo+INFL and FIN-RACo+PLA groups were 48% and 38% [p=0.37 (NNT=10)], and 82% and 72% [p=0.30 (NNT=11)] (Figure 1). The radiographic progression remained slow in most of the patients up till 10 years, the mean (SD) total Sharp van der Hejde score (TSS) was 9.8 (14.8) in the FIN-RACo+INFL and 7.3 (8.1) in the FIN-RACo+PLA group (p=0.34). Only 15% of the patients had TSS>20, and 22% had TSS 0. By ten years, 26% of the FIN-RACo+INFL group patients and 30% of the FIN-RACo+PLA group patients were using biologics (p=0.74). After 5 years, 56% of the patients were at least sporadically using prednisolone, the mean (SD) daily dose was 1.8 (1.6) mg in the FIN-RACo+INFL group and PLA 1.6 (1.4) mg in the FIN-RACo+PLA group.

**Conclusions:** In early RA, excellent results can be maintained up till 10 years in most patients treated with initial combination DMARDs and targeted treatment strategy. Adding initial infliximab for 6 months does not improve these outcomes.

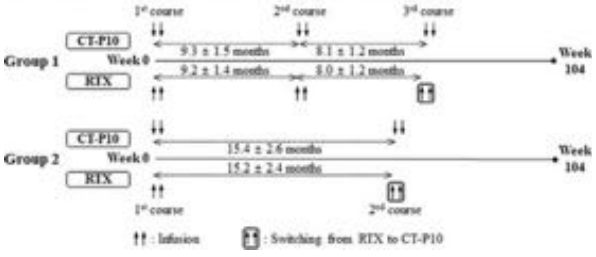
## THU0161 PREDICTION OF FLARING IN RHEUMATOID ARTHRITIS PATIENTS UPON BIOLOGICS DOSE TAPERING: A CHART REVIEW STUDY IN TAIWAN

C. Chang[1], K. Chen[2], Y. Chen[3], T. Cheng[4], P. Hsu[5], N. Lai[6], J. Lan[7], C. Lee[8], S. Lee[9], H. Lin[10], G. Tsay[11], J. Yen[12], C. Tsai[13], V. Garg[14], Y. Bao[14], M. Yang[15], E.Q. Wu[15]. *[1]Taipei Medical University Hospital; [2]Cathay General Hospital; [3]National Yang-Ming University; [4]Chang Gung Memorial Hospital; [5]National Taiwan University, Taipei; [6]Tzu-Chi University, Hualien; [7]China Medical University Hospital, Taichung; [8]Mackay Memorial Hospital; [9]Cheng Hsin General Hospital; [10]Taipei Veterans General Hospital & National Yang-Ming University School of Medicine, Taipei; [11]Chung Shan Medical University, Taichung; [12]Kaohsiung Medical University Hospital, Kaohsiung; [13]AbbVie, Taipei, Taiwan, Province of China; [14]AbbVie, North Chicago; [15]Analysis Group, Boston, United States*

**Background:** The OuTcomes Associated with taPering biologics among patiEnts with Rheumatoid arthritis (TAPER) is a retrospective chart review study to assess real-world implication of Taiwan policy on tapering/withdrawing biologics in stable rheumatoid arthritis (RA) patients.[1]
**Objectives:** To assess RA flare rates before and after anti-TNF dose tapering and to identify predictors of flaring upon tapering.
**Methods:** Medical chart data were collected from RA patients tapering adalimumab (ADA) or etanercept (ETN) (methods described elsewhere).[1] RA flares were assessed for 6-month pre-tapering, and for short-term (6 months) and longer-term (12 to 18 months) post-tapering. Three alternative flare definitions were used: 1) TAPER: defined *a priori* the Institutional Review Board submission as a) increase in DAS28≥1.2, b) increase in number of swollen/tender joints, or c) use of injectable steroids during outpatient/ER visits; 2) OMERACT: a) increase in DAS28>1.2, or b) increase in DAS28>0.6 if prior DAS28≥3.2; and 3) Taiwan National Health Insurance Administration: a) increase in DAS28≥1.2 and b) erythrocyte sedimentation rate (ESR) >25mm/h and c) increase in ESR>25%. Logistic regression models were developed to identify factors significantly associated with post-tapering flare.
**Results:** Data came from medical charts of 261 patients (ADA=40.6%; ETN=59.4%). More than half patients had a 12- to 18-month follow-up (58.6%: ADA=40.5%; ETN=59.5%). All three flare criteria showed that a greater proportion of patients had flare post-tapering (see table). During the short-term post-tapering, the risk factors of flaring included a longer disease duration (odds ratio=1.05, p=0.049) and having prior concomitant therapy on Cox-2 inhibitors (OR=2.61, p=0.003); being in remission (DAS28<2.6) prior to tapering was associated with a reduced risk (OR=0.41, p=0.037). Over a longer-term, a longer disease duration (OR=1.13, p=0.028) and having a flare within 6-month post-tapering were associated with an increased risk of flaring (OR=9.99, p<0.001).

| | Pre-Tapering | Post-Tapering short-term | Post-Tapering longer-term |
|---|---|---|---|
| **TAPER Criteria** | | | |
| Flare rate (per patient per year) (SD) | 0.47 (0.98) | 1.18 (1.43) | 1.60 (1.30) |
| Patients with at least one flare, n (%) | 54 (20.7) | 115 (44.1) | 113 (73.9) |
| **OMERACT Criteria** | | | |
| Flare rate (per patient per year) (SD) | 0.05 (0.30) | 0.52 (1.08) | 0.62 (0.96) |
| Patients with at least one flare, n (%) | 6 (2.3) | 53 (20.3) | 65 (42.5) |
| **Taiwan National Health Insurance Administration Criteria** | | | |
| Flare rate (per patient per year) (SD) | 0.01 (0.12) | 0.12 (0.47) | 0.16 (0.40) |
| Patients met dose returning criteria, n (%) | 1 (0.4) | 14 (5.4) | 28 (18.3) |



**Conclusions:** Careful considerations are needed when tapering a biologic in stable RA patients in order to avoid potentially increased risk of disease flaring. This could include assessing disease duration and remission status prior to tapering, and whether there is a flare within 6-month of tapering when considering for in long-term.

## THU0162 COMPARABLE TIME TO RETREATMENT WITH CT-P10 AND INNOVATOR RITUXIMAB UP TO 2 YEARS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

W. Park[1], D.H. Yoo[2], C.H. Suh[3], S.C. Shim[4], S.J. Lee[5], S.Y. Lee[5], T.S. Kwon[5], S.M. Kim[5]. *[1]Inha University Hospital, Incheon; [2]Hanyang University Hospital for Rheumatic Diseases, Seoul; [3]Ajou University Hospital, Suwon; [4]Chungnam National University Hospital, Daejeon; [5]Celltrion, Inc., Incheon, Korea, Republic Of*

**Background:** A randomised controlled trial (RCT) and its open label extension trial (OLE) demonstrated comparable pharmacokinetics (PK), efficacy and safety between CT-P10 and innovator rituximab (RTX) (including switched from RTX to CT-P10) up to 2 years in rheumatoid arthritis (RA) patients (NCT01534884 and NCT01873443).[1,2]
**Objectives:** To compare time to retreatment and confirm clinical similarity in efficacy and safety by the number of treatment courses in the RCT between CT-P10 and RTX in RA patients up to 2 years.
**Methods:** One hundred fifty three patients were randomised in 2:1 ratio and received up to 2 treatment courses of either CT-P10 or RTX in RCT, and they had a chance to receive up to 2 additional courses of CT-P10 in OLE. Retreatments were given based on disease activity. Post-hoc analyses using combined data obtained from the RCT and OLE studies were performed in 2 different groups according to the number of treatment courses in RCT as following; Group 1: patients who received 2 courses in RCT; Group 2: patients who received 1 course in RCT.
**Results:** A total of 82 patients (59 received CT-P10 and 23 received RTX) were in Group 1 and 20 (13 received CT-P10 and 7 received RTX) were in Group 2. Time to retreatment was similar between CT-P10 and RTX (including switched to CT-P10) in each group (Figure 1).

**Figure 1. Overall Schema of Retreatment Interval up to 2 Years**

DAS28 improvement at Week 24 of each course was similar between CT-P10 and RTX (including switched to CT-P10) in both groups (Table 1).

Table 1. DAS28 Improvement at week 24 in each course

| Mean ± SD (n) | Group 1 (2 courses in RCT) | | Group 2 (1 course in RCT) | |
|---|---|---|---|---|
| | CT-P10 | RTX | CT-P10 | RTX |
| DAS28-CRP | | | | |
| Baseline | 6.2±0.8 (59) | 6.0±0.7 (23) | 5.4±1.0 (13) | 5.4±0.6 (7) |
| Changes after 1st course | –2.0±1.1 (59)* | –1.9±1.1 (23)* | –1.9±1.1 (13)* | –1.6±1.2 (7)* |
| Changes after 2nd course | –2.3±1.2 (57)* | –2.0±1.3 (19)* | –1.8±1.3 (10) | –1.7±0.9 (6)§ |
| Changes after 3rd course | –2.4±1.1 (23) | –2.5±1.3 (10)§ | N/A | N/A |
| DAS28-ESR | | | | |
| Baseline | 7.0±0.8 (59) | 6.8±0.8 (23) | 6.5±1.0 (13) | 6.2±0.6 (7) |
| Changes after 1st course | –2.1±1.2 (59)* | –2.1±1.2 (23)* | –2.3±1.1 (13)* | –1.5±1.3 (7)* |
| Changes after 2nd course | –2.5±1.2 (57)* | –2.0±1.2 (19)* | –2.5±1.2 (11) | –2.1±0.8 (6)§ |
| Changes after 3rd course | –2.7±1.2 (23) | –2.7±1.6 (10)§ | N/A | N/A |

RTX, innovator rituximab; DAS28, disease activity score in 28 joints; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; SD, standard deviation. *Course(s) treated during RCT up to 72 weeks. §DAS28 improvement after switching to CT-P10 from RTX.

Infusion related reactions by treatment course up to 2 years was similar between

the CT-P10 and RTX groups and tended to decrease over time in line with RTX historical data.[3] Incidence rate of adverse event, serious adverse event and infection was comparable between CT-P10 and RTX groups.

**Conclusions:** The results of the post-hoc analyses demonstrated comparable duration of disease control between CT-P10 and RTX (including switched to CT-P10) with clinical similarity in efficacy for 2 years. The safety profile of CT-P10 was similar to that of RTX and in line with RTX historical data.

## THU0163 EARLY RESPONSE AS A PREDICTOR OF LONG-TERM CLINICAL RESPONSE IN DMARD-NAÏVE PATIENTS WITH SEVERE, ACTIVE AND PROGRESSIVE RA TREATED WITH CERTOLIZUMAB PEGOL PLUS OPTIMIZED MTX VERSUS OPTIMIZED MTX ALONE

X. Mariette[1], C. Bingham[2], G.-R. Burmester[3], V.P. Bykerk[4], P. Emery[5], D. Furst[6], D. van der Heijde[7], R. van Vollenhoven[8], B. VanLunen[9], C. Arendt[10], M. Weinblatt[11]. *[1]Université Paris-Sud, Paris, France; [2]John Hopkins University, Baltimore, United States; [3]Charité - University Medicine, Berlin, Germany; [4]Weill Cornell College, New York, United States; [5]University of Leeds, Leeds, United Kingdom; [6]University of California, Los Angeles, United States; [7]Leiden University Medical Center, Leiden; [8]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [9]UCB Pharma, Raleigh, United States; [10]UCB Pharma, Brussels, Belgium; [11]Brigham and Women's Hospital, Boston, United States*

**Background:** C-EARLY (NCT01519791) assessed the efficacy and safety of certolizumab pegol (CZP)+optimized MTX vs placebo (PBO)+optimized MTX in inducing and maintaining a sustained clinical response, and inhibiting radiographic damage, in DMARD-naïve patients (pts) with active, severe, progressive RA.[1] Here, we examine the association between an inadequate response to PBO+MTX or CZP+MTX treatments at Week (Wk) 12 (lack of improvement from baseline [BL] in DAS28[ESR], DAS28[CRP] or CDAI) and corresponding response at Wk 52.

**Objectives:** To examine the association between Wk12 response and Wk52 clinical response (remission [REM]/low disease activity [LDA]) in recently diagnosed DMARD-naïve pts with active, severe, progressive RA, treated with CZP+optimized MTX vs PBO+optimized MTX.

**Methods:** This multicenter, double-blind, randomized controlled trial enrolled pts who were DMARD-naïve with active, severe, progressive RA (<1yr since diagnosis, fulfilling 2010 ACR/EULAR criteria). 879 pts were randomized 3:1 to CZP (200mg Q2W+MTX; n=660) or PBO Q2W+MTX (n=219). MTX was initiated at 10mg/wk and increased to 25mg/wk by Wk8; maximum tolerated dose per pt (mean optimized dose, CZP: 21mg/wk, PBO: 22mg/wk) was maintained to Wk52. Negative predictive values (NPV) were defined as probability of failing to achieve Wk52 REM (DAS28[ESR]/[CRP]<2.6 or CDAI≤2.8) or LDA (DAS28[ESR]/[CRP]≤3.2 or CDAI≤10) after failing to achieve a corresponding defined response at Wk12; change from BL in DAS28(ESR)/(CRP)≥0.6 or ≥1.2/CDAI≥6 and ≥12. DAS28(CRP) LDA/REM definitions are not validated. Observed data were utilized for Wk12 responses; missing Wk52 values were imputed using non-responder imputation.

**Table:** Probability of failing to achieve Week 52 clinical response after failing to respond at Week 12

| | PBO+MTX patients (n=213) | | | | | |
|---|---|---|---|---|---|---|
| | DAS28(CRP) | | DAS28(ESR) | | CDAI | |
| Week 12 reduction from baseline (observed case) | <0.6 (n=23) | <1.2 (n=49) | <0.6 (n=18) | <1.2 (n=42) | <6 (n=13) | <12 (n=28) |
| Week 52 LDA (NRI) | 87% (n=20) | 76% (n=37) | 94% (n=17) | 81% (n=34) | 69% (n=9) | 68% (n=19) |
| Week 52 remission (NRI) | 87% (n=20) | 84% (n=41) | 94% (n=17) | 83% (n=35) | 77% (n=10) | 79% (n=22) |
| | CZP+MTX patients (n=655) | | | | | |
| | DAS28(CRP) | | DAS28(ESR) | | CDAI | |
| Week 12 reduction from baseline (observed case) | <0.6 (n=45) | <1.2 (n=87) | <0.6 (n=36) | <1.2 (n=86) | <6 (n=23) | <12 (n=48) |
| Week 52 LDA (NRI) | 80% (n=36) | 72% (n=63) | 89% (n=32) | 86% (n=74) | 91% (n=21) | 73% (n=35) |
| Week 52 remission (NRI) | 82% (n=37) | 79% (n=69) | 92% (n=33) | 93% (n=80) | 91% (n=21) | 90% (n=43) |

Week 52 LDA: DAS28(ESR)/(CRP)<3.2, CDAI ≤10; Week 52 remission: DAS28(ESR)/(CRP)<2.6, CDAI ≤2.8.

**Results:** The NPV of Wk12 responses were high (Table): PBO+MTX pts who did not achieve DAS28(ESR) improvements from BL ≥0.6 had 94% probability of not being in REM or LDA at Wk52. CZP+MTX pts who did not achieve DAS28(ESR) improvements from BL ≥1.2 had 93% probability of not being in REM at Wk52. NPV of changes in DAS28(CRP) and CDAI at Wk12 were less informative for predicting remission at 1yr (Table).

**Conclusions:** In early RA pts treated with optimized-dose MTX, failure to achieve a ≥0.6 DAS28(ESR) reduction from BL at Wk12 was associated with a low probability (6%) of DAS28(ESR) REM/LDA at Wk52, supporting treatment step-up at 3 months. For pts with active, severe RA with poor prognostic factors where CZP has been initiated as first-line treatment, failure to achieve a rapid decrease of 1.2 points was associated with a reduced likelihood of achieving REM (7%). These findings in DMARD-naïve pts are consistent with the negative predictability outcomes for CZP in established RA.[2]

## THU0164 EFFICACY OF INFLIXIMAB FOR SUPPRESSING RADIOGRAPHIC PROGRESSION OF CERVICAL LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH METHOTREXATE; TWO YEARS OF FOLLOW-UP – A MULTICENTER REGISTRY STUDY

Y. Kanayama[1], T. Kojima[2], Y. Hirano[3], N. Takahashi[2], Y. Yabe[4], N. Ishiguro[2] on behalf of TBCR Study Group. *[1]Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [2]Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya; [3]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [4]Rheumatology, JCHO Tokyo Shinjuku medical Center, Tokyo, Japan*

**Background:** Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously, in particular, with their efficacy in suppressing joint destruction having been emphasized. We reported the efficacy of infliximab (IFX), anti-tumor necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13 and 14. However there is still few studies of efficacy of against RA cervical lesions of IFX comparison with methotrexate (MTX).

**Objectives:** To evaluate the efficacy of IFX for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 2 years.

**Methods:** We used MTX or MTX+IFX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 40 and 88 patients received continuous MTX and IFX treatment for at least 2 years. MTX was used in all patients receiving IFX. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation and Year 1,2.

**Results:** In the patients receiving MTX (n=40) and IFX (n=88), the number of female were each 33 (83%) and 75 (85%) cases (p=0.794). The mean age was 62.5 ± 10.7 and 53.9 ± 12.9 years old (p<0.001); disease duration was 9.3 ± 10.0 and 10.7 ± 9.2 years (p=0.127) and the mean dose of MTX was 7.3 ± 2.4 and 7.8 ± 2.1 mg/w (p=0.414). Clinical findings related to RA were as follows; CRP 1.3± 2.0 and 3.1± 2.8 mg/dl (p<0.001); ESR 28.1 ± 21.1 and 49.9 ± 29.1mm/h (p<0.001); MMP3 170 ± 303 and 337 ± 309ng/ml (p<0.001); DAS28 4.07 ± 1.42

and 5.47 ± 1.25 (p<0.001); ADI 2.6 ± 1.6 and 3.6 ± 1.9mm (p=0.001); SAC 20.2 ± 2.7 and 18.1 ± 2.7mm (p<0.001) and Ranawat value 16.0 ± 1.5 and 14.5 ± 2.2mm (p<0.001). The respective changes in cervical lesion parameters after 1 year were as follows: ADI: 0.25 ± 0.44 and 0.22 ± 0.44 mm (p=0.591); SAC: –0.18 ± 0.39 and –0.16 ± 0.40 mm (p=0.716); and Ranawat value: –0.13 ± 0.34 and –0.15 ± 0.36 mm (p=0.733). The respective changes in cervical lesion parameters after 2 years were as follows: ADI: 0.53 ± 0.72 and 0.35 ± 0.59 mm (p=0.193); SAC: –0.48 ± 0.64 and –0.27 ± 0.60 mm (p=0.038); and Ranawat value: –0.35 ± 0.58 and –0.26 ± 0.47 mm (p=0.486) (Fig. 1). The numbers of patients who did not showed progression in ADI, SAC and Ranawat value were each 24 (60%) and 62 (70%) cases (p=0.310); 24 (60%) and 67 (76%) cases (p=0.058) and 28 (70%) and 66 (75%) cases (p=0.666) after 2 years. Also the number who was able to suppress progression in all three parameters were each 24 cases (60%) receiving MTX and 58 cases (66%) receiving IFX (p=0.555) after 2 years (Fig. 2).

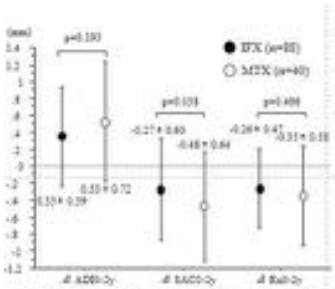

Figure 1 : Respective changes in ADI, SAC and Rana value from Year 0 to Year 2 between MTX and IFX patients

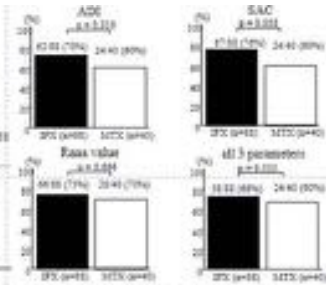

Figure 2 : The rate of patients who did not showed progression in ADI, SAC, Rana value and all three parameters after 2 years

**Conclusions:** This study suggested that IFX treatment can be used to suppress the progression of RA cervical lesions more than MTX treatment.

## Rheumatoid arthritis - non-biologic treatment and small molecules

### THU0165 LONG-TERM RADIOGRAPHIC AND PATIENT-REPORTED OUTCOMES BASED ON CLINICAL DISEASE ACTIVITY INDEX RESPONSES WITH TOFACITINIB AT 6 MONTHS

V. Strand[1], A. Kavanaugh[2], A. Kivitz[3], D. van der Heijde[4], K. Kwok[5], E. Akylbekova[6], A. Soonasra[7], M. Snyder[7], C. Connell[8], E. Bananis[7], J. Smolen[9]. *[1]Biopharmaceutical Consultant, Portola Valley; [2]University of California, San Diego; [3]Altoona Center for Clinical Research, Duncansville, United States; [4]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [5]Pfizer Inc, New York; [6]Quintiles, Durham; [7]Pfizer Inc, Collegeville; [8]Pfizer Inc, Groton, United States; [9]Medical University of Vienna, Vienna, Austria*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of RA.
**Objectives:** This analysis assessed if patients achieving Clinical Disease Activity Index (CDAI) remission (REM) or low disease activity (LDA) at Month 6 had less radiographic progression and improved patient-reported outcomes (PROs) at Month 24 and compared results between tofacitinib and MTX.
**Methods:** ORAL Start (NCT01039688) and ORAL Scan (NCT00847613) were Phase 3 randomised controlled trials (RCTs) in MTX therapeutically naïve and MTX inadequate response (IR) patients with RA, respectively. In ORAL Start and Scan, patients received tofacitinib 5 or 10 mg twice daily (BID) monotherapy vs MTX monotherapy or tofacitinib 5 or 10 mg BID + MTX vs placebo + MTX, respectively. This was an observed analysis of patients with radiographs at Months 6, 12 and 24, excluding placebo-treated patients in ORAL Scan. Patients were classified according to CDAI responses at Month 6: REM (CDAI ≤2.8); LDA (CDAI >2.8 to ≤10); or incomplete-responders (CDAI >10). Outcomes included the proportion of patients with no radiographic progression (change in modified Total Sharp Score [mTSS] ≤0) and/or HAQ-DI ≤0.5 (defined as normative) at Month 24, and mean changes from baseline in mTSS and HAQ-DI.
**Results:** In ORAL Start, 250, 269 and 98 patients received tofacitinib 5 mg BID, tofacitinib 10 mg BID and MTX, respectively. In ORAL Scan, 193 and 201 patients received tofacitinib 5 and 10 mg BID, respectively. Baseline demographics were generally similar between subpopulations within each RCT; however, incomplete responders generally had higher baseline disease activity. In both ORAL Start and Scan, patients in REM or LDA with tofacitinib at Month 6 were more likely to be radiographic non-progressors and achieve normative HAQ-DI scores at Month 24 (Table). Tofacitinib-treated patients in REM at Month 6 generally had better HAQ-DI scores at Month 24 than LDA patients. In ORAL Start at Month 6, a higher proportion of tofacitinib- than MTX-treated patients were in REM or LDA (Table). CDAI incomplete responders receiving tofacitinib had improved HAQ-DI scores and less radiographic progression compared with MTX-treated counterparts. Overall, more tofacitinib-treated patients who achieved REM or LDA were non-progressors or achieved HAQ-DI scores ≤0.5 compared to those treated with MTX.

**Conclusions:** More MTX-naïve or MTX-IR tofacitinib-treated patients achieving CDAI REM or LDA at Month 6 were radiographic non-progressors or achieved normative HAQ DI scores at Month 24, compared with CDAI incomplete responders. In ORAL Start, more tofacitinib-treated than MTX-treated MTX-naïve patients achieved CDAI REM or LDA at Month 6 with better PROs and radiographic outcomes at Month 24.

### THU0166 SAFETY PROFILE OF BARICITINIB IN PATIENTS WITH ACTIVE RA: AN INTEGRATED ANALYSIS

J. Smolen[1], M. Genovese[2], T. Takeuchi[3], D. Hyslop[4], W.L. Macias[4], T.P. Rooney[4], L. Chen[4], C. Dickson[4], J. Riddle[4], T. Cardillo[4], K. Winthrop[5]. *[1]Medical Univ of Vienna, Vienna, Austria; [2]Stanford Univ School of Medicine, Palo Alto, United States; [3]Keio University, Tokyo, Japan; [4]Eli Lilly & Co., Indianapolis; [5]Oregon Health Sciences University, Portland, United States*

**Background:** Baricitinib (bari; an oral JAK 1/JAK 2 inhibitor) is in development for patients (pts) with active RA.
**Objectives:** To assess the safety of bari in pts with active RA across 8 completed studies (4 Ph3, 3 Ph2, 1 Ph1b) and 1 ongoing long-term extension (LTE) study.
**Methods:** Primary safety analysis was based on 6 studies with bari 4 mg QD and placebo (PBO) arms and dose response assessments on 4 studies with bari 2 and 4 mg QD and PBO arms. In addition, the all-bari RA set included all patients exposed to any bari dose. 2 studies contained active comparators.
**Results:** 3464 pts were exposed to bari (4214 pt-yrs (PY); 2166 pts (62.5%) >1 yr; 467 (13.5%) >2 yrs). In controlled periods of the program, no increases in deaths, AEs leading to study drug discontinuation, malignancies, MACE, or serious infections were seen for bari vs PBO/active treatment. Herpes zoster was reported more frequently for bari vs PBO. In randomized, controlled periods

of the program, TB was reported in 2 pts: 1 bari 4 mg, 1 adalimumab; in uncontrolled periods, 6 TB events were reported (bari 4 mg: 2 with incomplete TB screening, 3 without organism confirmed). All TB occurred in endemic areas. Two GI perforations were reported (0.05/100 PY). No confirmed opportunistic infections were reported. Bari treatment has been associated with changes in selected hematology/clinical chemistry analytes; few patients (<1%) discontinued due to abnormal lab results. There was no observed increased risk over time for the above outcome measures with longer exposure.

Table 1. Safety outcomes - Data are reported as "n" and "(IR)"

| | Death | AE leading to perm DC | Malignancy ex. NMSC | MACE | Serious infection | Herpes Zoster |

## THU0167 THE EFFECT OF FILGOTINIB (GLPG0634), AN ORAL JAK1 SELECTIVE INHIBITOR ON PATIENT-REPORTED OUTCOMES: RESULTS FROM TWO 24-WEEK PHASE 2B DOSE RANGING STUDIES

M. Genovese[1], R. Westhovens[2], A. Kavanaugh[3], L. Meuleners[4], A. Van der Aa[4], P. Harrison[4], C. Tasset[4]. *[1]Division of Immunology & Rheumatology, Stanford University School of Medicine, Palo Alto, United States; [2]Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven, Leuven, Belgium; [3]University of California San Diego, La Jolla, United States; [4]Galapagos NV, Mechelen, Belgium*

**Background:** Filgotinib (GLPG0634) is a novel oral, potent and selective JAK1 inhibitor that showed rapid and sustained improvements of signs and symptoms of active rheumatoid arthritis (RA) in patients with inadequate response to methotrexate (MTX) in two 24-week Phase 2B studies, with an acceptable safety profile.

**Objectives:** To investigate the effect of filgotinib add-on to MTX or monotherapy on patient-reported outcomes (PROs).

**Methods:** In DARWIN 1 (add-on to MTX) and DARWIN 2 (monotherapy), patients with active RA were randomized in a double blinded manner to placebo (PBO) or one of the three daily doses of filgotinib (50mg, 100mg or 200mg) for 24 weeks. In DARWIN 1, once (qd) and twice daily (bid) regimens were assessed. At week 12, patients on PBO (in DARWIN 1) and 50mg daily dose (in DARWIN 1 and DARWIN 2) whose tender and swollen joint counts did not improve by at least 20% were reassigned to 100mg daily dose. In DARWIN 2, all patients on PBO were reassigned to 100mg daily dose. Assessed PROS were patient evaluation of disease activity & pain, physical function, fatigue and HRQoL-SF36.

**Results:** In total 594 and 283 patients were randomized and treated in DARWIN 1 and DARWIN 2, respectively. Mean HAQ-DI baseline value was 1.74 and 1.81, respectively, indicating severe impairment. Filgotinib demonstrated rapid and significant improvement in PROs (patient assessment of disease activity and pain, physical function, fatigue and HRQoL-SF36) in both studies, with the 200mg daily dose showing statistically significant effects as early as week 1–2 on HAQ-DI and the patient VAS global disease and pain and from week 4 on the FACIT and SF-36-PCS. After week 12, these responses were maintained or continued to improve through 24 weeks. At week 24 with identical daily doses, the filgotinib effect was comparable between qd and bid regimens (in DARWIN 1) and between add-on and monotherapy (between study comparison)"

Table 1. PRO responses for the 200mg daily dose

| | | Mean change from baseline (LOCF) | | | | | |
|---|---|---|---|---|---|---|---|
| | | Patient's VAS disease activity | Patient's VAS pain | HAQ-DI | FACIT | SF-36 PCS | SF-36 MCS |
| DARWIN 1 | | | | | | | |
| PBO (N=86) | Wk12 | –16.7 | –16.9 | –0.38 | 5.6 | 3.2 | 4.3 |
| | Wk24 | –17.9 | –17 | –0.37 | 6.0 | 2.8 | 4.7 |
| 200mg qd (N=86) | Wk12 | –34.2*** | –31.4** | –0.75*** | 11.4*** | 8.9*** | 8.1 |
| | Wk24 | –34.9** | –34.6*** | –0.82*** | 11.6** | 9.7*** | 7.2 |
| 100mg bid (N=84) | Wk12 | –35.6*** | –37.9*** | –0.84*** | 11.3*** | 10.5*** | 6.2 |
| | Wk24 | –39.1*** | –37.9*** | –0.90*** | 12.8*** | 11.6*** | 7.1 |
| DARWIN 2 | | | | | | | |
| PBO (N=72) | Wk12 | –11.5 | –13.3 | –0.23 | 3.9 | 3.0 | 2.7 |
| | Wk24 | – | – | – | – | – | – |
| 200mg qd (N=69) | Wk12 | –28.2*** | –31.3*** | –0.74*** | 11.2*** | 8.6*** | 6.8** |
| | Wk24 | –35.1 | –37.7 | –0.85 | 13.7 | 9.7 | 8.5 |

*p<0.05; **p<0.01; ***p<0.001 vs. PBO. Subjects who switched at wk 12 were handled as if they discontinued at wk 12. In DARWIN 2 statistical comparison vs. PBO is not possible after wk 12.

**Conclusions:** In the DARWIN 1 and DARWIN 2 studies, filgotinib led to a rapid decrease in disease burden as demonstrated by the significant improvement in all assessed PROs. After 24 weeks of treatment, filgotinib in combination with MTX as qd or bid or as monotherapy demonstrated comparable benefit in improving PROs in RA patients with high disease activity.

## THU0168 BARICITINIB INHIBITS RADIOGRAPHIC PROGRESSION OF STRUCTURAL JOINT DAMAGE AT 1 YEAR IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) AND AN INADEQUATE RESPONSE TO CSDMARDS

D. van der Heijde[1], M. Dougados[2], Y.-C. Chen[3], M. Greenwald[4], E. Drescher[5], R. Klar[6], L. Xie[7], I. de la Torre[7], T.P. Rooney[7], S. Witt[7], D. Schlichting[7], S. DeBono[7], P. Emery[8]. *[1]Leiden University Medical Centre, Leiden, Netherlands; [2]Cochin Hospital, Paris, France; [3]Chang Gung Memorial Hospital-Kaohsiung, Taiwan, China; [4]Desert Medical Advances, Palm Desert, United States; [5]Veszprem Csolnoky Ferenc County Hospital, Veszprem, Hungary; [6]Quintiles Transnational INC, Durham; [7]Eli Lilly & Co., Indianapolis, United States; [8]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Univ of Leeds, Leeds, United Kingdom*

**Background:** Baricitinib (bari), a JAK1 and JAK2 inhibitor, was efficacious in a 24-week (wk) Ph 3 study in patients (pts) with active RA and an inadequate response (IR) to conventional synthetic DMARDs (csDMARDs) (RA-BUILD)[1].

**Objectives:** To evaluate radiographic progression of structural joint damage in RA-BUILD pts with IR or intolerance to ≥1 csDMARD over 48 wks of bari treatment in the long-term extension study, RA-BEYOND.

**Methods:** In the 24-wk RA-BUILD study, pts were randomized to placebo (PBO; N=228), bari 2mg (N=229) or bari 4mg (N=227) once daily (QD), with rescue possible from Wk16. Pts completing RA-BUILD and entering RA-BEYOND continued to receive the bari dose received at the end of RA-BUILD. Pts receiving PBO at the end of RA-BUILD were switched to bari 4mg in RA-BEYOND. Pt and investigator blinding was maintained in RA-BEYOND. Joint damage was measured using the van der Heijde modified total Sharp score (mTSS). To account for missing scores and scores obtained after rescue or discontinuation of study drug, data were analyzed using 1) linear extrapolation (LE), and 2) last observation carried forward (LOCF). The observed/LOCF method used all

available observed data, including after rescue or switch, with pts analyzed according to original treatment assignment.

**Results:** Using LE, progression of mTSS, bone erosion, and joint space narrowing (JSN) at 24 and 48 wks was statistically significantly lower for both bari 2 or 4mg compared to PBO (Table). Only bari 4mg demonstrated statistically significant inhibition of progressive radiographic joint damage compared to PBO using observed/LOCF at Wk 48 or based on categorical measures.

| | Wk 24 | | | Wk 48 | | |
|---|---|---|---|---|---|---|
| | PBO† | 2 mg QD | 4 mg QD | PBO/ 4 mg QD† | 2 mg QD | 4 mg QD |
| Linear extrapolation | | | | | | |
| Change in (D) mTSS | 0.72 | 0.27* | 0.25* | 1.36 | 0.43** | 0.45** |
| D Erosion | 0.43 | 0.20* | 0.17* | 0.82 | 0.31** | 0.32** |
| D JSN | 0.29 | 0.08* | 0.08* | 0.55 | 0.12* | 0.13* |
| D mTSS ≤0, n (%) | 150 (78) | 169 (81) | 167 (84) | 150 (78) | 175 (80) | 169 (83) |
| D mTSS ≤0.5, n (%) | 157 (82) | 179 (86) | 175 (88) | 150 (78) | 183 (84) | 174 (85) |
| D mTSS ≤SDC, n (%) | 165 (86) | 188 (90) | 186 (94)* | 162 (84) | 195 (89) | 186 (91)* |
| Observed/LOCF | | | | | | |
| D mTSS | 0.57 | 0.26* | 0.25* | 0.69 | 0.41 | 0.32* |
| D Erosion | 0.36 | 0.18* | 0.17* | 0.43 | 0.24 | 0.23* |
| D JSN | 0.21 | 0.08* | 0.08* | 0.26 | 0.17 | 0.10 |
| D mTSS ≤0, n (%) | 152 (78) | 169 (81) | 169 (85) | 151 (74) | 172 (79) | 169 (82) |
| D mTSS ≤0.5, n (%) | 163 (83) | 183 (87) | 178 (89) | 166 (81) | 188 (86) | 179 (87) |
| D mTSS ≤SDC, n (%) | 171 (87) | 192 (91) | 188 (94)* | 182 (89) | 205 (94) | 193 (94) |

Data are least squares mean change from baseline, unless otherwise stated; †Pts were switched to treatment with bari at rescue or at Wk 24. SDC: smallest detectable change. Wk 24 SDC=1.1; Wk 48 SDC=1.7; Comparisons analyzed using ANCOVA; *p≤0.05, **p≤0.01 vs. PBO.

**Conclusions:** Once daily oral bari inhibited radiographic progression of structural joint damage in pts with an IR or intolerance to csDMARDs over 48 wks of treatment. The most robust benefit across measures of radiographic progression was seen for the 4mg dose.

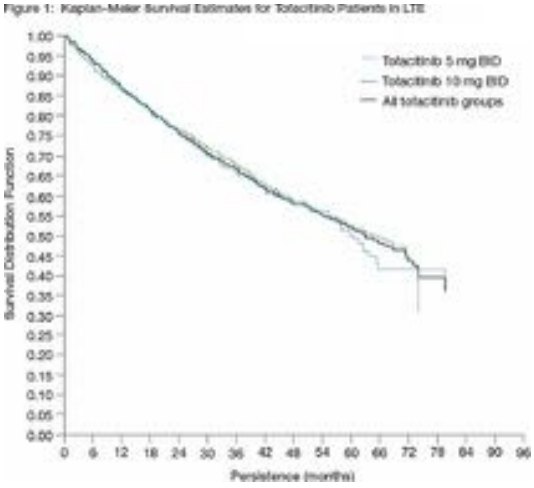
## THU0169 PERSISTENCE OF TOFACITINIB IN THE TREATMENT OF RHEUMATOID ARTHRITIS IN OPEN-LABEL, LONG-TERM EXTENSION STUDIES UP TO 7 YEARS



J. Pope[1], E. Keystone[2], S. Jamal[3], L. Wang[4], L. Fallon[5], J. Woolcott[5], I. Lazariciu[6], B. Haraoui[7]. *[1]Western University, London; [2]Mount Sinai Hospital, Toronto; [3]University of British Columbia, Vancouver, Canada; [4]Pfizer Inc, Groton, United States; [5]Pfizer Canada; [6]Quintiles Canada; [7]Institut de Rheumatologie de Montreal, Montreal, Canada*

**Background:** Tofacitinib is an oral JAK inhibitor for treatment of rheumatoid arthritis (RA). Open-label, long-term extension (LTE) studies have enrolled tofacitinib-treated patients (pts) to evaluate safety and efficacy over time. Time on treatment is considered a composite measure of efficacy and safety; discontinuation (D/C) is often due to lack of efficacy (LOE) and/or adverse events (AEs) for disease-modifying antirheumatic drugs (DMARDs).[1]

**Objectives:** To estimate drug survival of tofacitinib up to 84 months (mo) in LTE studies and describe reasons for D/C.

**Methods:** Data were pooled from two LTE studies (NCT00413699 [up to April 2014; study ongoing, database unlocked] and NCT00661661 [completed]). Of 6553 pts from Phase (P) 1, 2 and 3 studies, 4858 pts (74.1%) received treatment in LTE studies. Tofacitinib 5 or 10 mg BID were initiated as monotherapy or with background DMARDs; pooled data and data for each dose ± background DMARDs were analysed. Pts were assigned tofacitinib 5 or 10 mg BID based on average daily dose in LTE. Kaplan-Meier (K-M) analyses estimated drug survival in tofacitinib-treated pts who withdrew for any reason, due to LOE or due to AE in the LTE, including pts who had previously responded to and tolerated treatment in P1P2P3 studies. Ongoing pts were censored as of April 2014, while pts completing the trial(s) were censored at their completion date. Safety data were included over 84 mo and efficacy data up to 72 mo due to limited pt numbers after 72 mo for efficacy. Retention data were divided into dose and mono vs combination therapy.

**Results:** 4858 pts were treated for a mean (maximum) duration of 2.5 (6.9) years (yrs) (results previously reported).[2] Overall, median survival for all tofacitinib treated pts was 5.2 yrs [95% CI 5.0, 5.6] (Figure 1). Median survival for pts receiving tofacitinib with background DMARDs or as monotherapy was 5.3 [4.9, 5.7] and 5.4 [4.8, not evaluable] yrs, respectively. K-M estimates appear similar between 5 and 10 mg BID, median survival was 5.4 [4.9, 5.9] and 5.0 [4.7, 5.5] yrs, respectively (Figure 1). The D/C rate due to LOE was considerably lower than due to AEs (AEs: 17.8%, 22.9%, 15.6%; LOE: 2.7%, 3.3%, 2.5% for all tofacitinib, 5 or 10 mg BID, respectively). The most commonly reported reasons for D/C due to AEs by class were infections/infestations (7.2%, 7.8%, 7.0%), investigations (3.1%, 4.6%, 2.5%) and neoplasms (benign, malignant, unspecified) (2.7%, 3.9%, 2.1%) for all tofacitinib, 5 or 10 mg BID, respectively.

**Conclusions:** Drug survival in LTE studies provides early information on the long-term safety, efficacy and tolerability of a therapy. In this analysis, median survival of tofacitinib was approximately 5 yrs, with D/C more commonly associated with AEs than LOE. Similar survival medians were observed for the 5 and 10 mg BID dose groups and monotherapy vs background DMARD therapy. These data support the use of tofacitinib for long-term management of RA.

## THU0170 ADHERENCE TO PARENTERAL METHOTREXATE IN RHEUMATOID ARTHRITIS IS NOT A MAJOR ISSUE AND DOES NOT INFLUENCE THE OCCURRENCE OF MAJOR CARDIOVASCULAR EVENTS

M. Todoerti[1], G. Carrara[2], I.B. Olivieri[3], C.A. Scirè[2] on behalf of RECORD of the Italian Society for Rheumatology. *[1]IRCCS San Matteo Foundation, Pavia; [2]Epidemiology Unit, Italian Society for Rheumatology, Milan; [3]Rheumatology Department, San Carlo Hospital, Potenza, Italy*

**Background:** Cardiovascular (CCV) burden in rheumatoid arthritis (RA) is well defined. Several studies showed benefits from methotrexate (MTX) in reducing overall CCV morbidity and mortality [1]. Thus, MTX adherence could be crucial not only to achieve its disease modifying properties on articular signs and symptoms, but also to maximize long-term disease-related outcomes, including major CVV events.

**Objectives:** To explore the impact of MTX adherence on the occurrence of hospitalized major CCV events in real life RA patients while persisting in MTX medication.

**Methods:** Data including demographics, drug delivery, out-patient services and hospital admissions were extracted from health care administrative databases of the Lombardy Region (Italy) for the period between 1/1/2004 and 31/12/2013. Patients with RA were identified by a validated algorithm [2]. RA patients with a new course of treatment with parenteral MTX (new users) and at least 12

months of persistence were included. Hospitalizations/deaths for CCV events (acute myocardial infarction, stroke, heart failure) were evaluated through the Hospital Discharge Forms based on relevant ICD-9CM codes. The association between adherence to MTX - calculated as Proportion Days Covered (PDC) ≥80% - and risk of hospitalization for CCV event was assessed by survival models for competing risks. The results are presented as hazard ratios (HR) and 95% CI, crude and adjusted for sex, age, disease duration, Charlson comorbidity index, concomitant use of corticosteroids, NSAIDs, biologic disease modifying anti-rheumatic drugs/bDMARDs and combination of conventional synthetic DMARDs/csDMARDs.

**Results:** A total of 5337 RA patients [F 3629, 68%; mean age (SD) 62.78 (12.7) years] were included in the analysis. Patients were mainly early onset RA [4015 (75%) <1 year disease duration], generally taking MTX as monotherapy [29 (1%) and 1218 (23%) patients on concomitant bDMARDs and non-MTX csDMARDs, respectively] in association with corticosteroids [3055 (57%)] and NSAIDs [2037 (38%)]. Mean (SD) Charlson comorbidity index was 1.34 (0.83). Most patients [4284 (80%)] resulted adherent to MTX. During 17.104 patient-years of observation, 440 hospital admissions due to major CVV events were registered (344 in adherent versus 96 in non adherent patients). Adherent vs non adherent patients did not significantly differ in the occurrence of CVV events (HR 0.82 CI95% [0.66–1.04]) causing hospital admission, even after adjusting for confounders (Table).

Table 1

| Variable | Adjusted Hazard ratio (95% CI) |
|---|---|
| Adherence to MTX | 0.85 (0.67–1.07) |
| Age (year) | 1.08 (1.06–1.09) |
| Sex (F) | 0.56 (0.46–0.68) |
| Disease duration (>1 year) | 1.11 (0.89–1.38) |
| Charlson index | 1.25 (1.14–1.36) |
| Concomitant Corticosteroids | 0.98 (0.81–1.20) |
| Concomitant csDMARDs | 1.06 (0.84–1.34) |
| Concomitant bDMARDs | 0.84 (0.12–6.02) |

**Conclusions:** In a cohort of real life RA patients from Italy, adherence to parenteral MTX is very high and does not significantly affect the occurrence of major CVV events, even after taking into account potential confounders. These results suggests persistent use of MTX, beside the adherence to it, still carries benefits in preventing from CCV events and that the parenteral administration route of MTX fosters adherence to treatment in RA.

## THU0171 EFFECT OF FAST ESCALATION OF THE DOSE OF SUBCUTANEOUS METHOTREXATE ON THE NEED FOR BIOLOGICAL DMARDS IN PATIENTS WITH VERY EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS

E. Luchikhina, D. Karateev, N. Demidova, G. Loukina, M. Kanonirova, Y. Mouraviev, G. Gridneva, E. Aleksandrova, A. Novikov, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The ongoing REMARCA study (Russian acronym: Russian InvEstigation of MethotrexAte and biologics in eaRly aCtive inflammatory Arthritis) included patients with early and established active RA, who did not use subcutaneous methotrexate (SC MTX) and/or biologics. The main goal of the study is an adaptation of "Treat to target" (T2T) recommendations for clinical practice.

**Objectives:** The purpose of this part of REMARCA trial is to compare two regimens of escalation of the dose of SC MTX in pts with very early (duration of symptoms ≤6 months) and established RA.

**Methods:** 191 patients (pts) with active severe RA (34 males, 157 females, 51,8% with very early RA, 80,1% RF(+), 81,2% anti-CCP(+), DAS28 5,52±1,12, SDAI 30,8±14,7, CDAI 27,3±12,5) were followed up for at least 12 months, among them 115 pts (18 males, 97 females, 60% with very early RA) were followed for 24 months. All patients received SC MTX as a fist-line therapy. We used two regimens of SC MTX dose escalation: 1) fast escalation – starting dose 15 mg/week increasing with increments of 5 mg every 1–2 week to achieve 20–30 mg/week in 4–6 weeks; 2) "slow" escalation (usual recommendations) - starting dose 10 mg/week increasing with increments of 2,5–5 mg every 2–4 week to achieve maximal dose in 8–12 weeks. Fast and "Slow" regimens were prescribed in random manner (with exception of pts who had signs of probable safety problems, such as liver, kidney disease etc., when "slow" regimen used). Use of oral steroids was limited to continuation of previously administered low doses (in 14,7% pts) and intra-articular injections (2 doses per 3 months). Therapy revision and initiation of biological DMARDs in combination with SC MTX (adalimumab, certolizumab, or abatacept), was made every 3 months (or more often if indicated) in order to reach T2T targets.

**Results:** After 12 months, 73 (38,2%) pts achieved SDAI low disease activity (LDA) and 65 (34%) achieved SDAI remission. In the group followed up to 24 months, 45 (39%) and 49 (42,6%) achieved stable SDAI LDA or remission respectively. At 12 month 36,1% pts responded well to monotherapy with SC MTX, and 63,9% required a switch to a combination therapy with biologics. In the group followed up to 24 months the proportion of pts left on MTX monotherapy and switched to biologics was 32,2% and 67,8% resp. Fast escalation regimen used in 87 (45,5%) pts was associated with less need for biologic therapy (see table). When fast escalation used in pts with very early RA (n=47, 24,5%), monotherapy with SC MTX was sufficient in 68,1–66,7% of pts.

**Conclusions:** Early administration of SC MTX with fast escalation of the dose leads to the achievement of T2T goals without need for combination with biological DMARDs in 2/3 of patients with severe active RA.

## THU0172 RISK FOR SERIOUS ADVERSE EVENTS ASSOCIATED WITH ORAL CORTICOSTEROID THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A UK POPULATION-BASED STUDY

J.C. Wilson[1], K. Sarsour[2], S. Gale[2], A. Pethö-Schramm[3], S.S. Jick[4], C.R. Meier[1,5]. *[1]University of Basel, Basel, Switzerland; [2]Genentech, South San Francisco, United States; [3]F. Hoffmann-La Roche AG, Basel, Switzerland; [4]Boston University School of Public Health, Boston, United States; [5]University Hospital Basel, Basel, Switzerland*

**Background:** Rheumatoid arthritis (RA) is a chronic, erosive form of inflammatory arthritis characterized by a distinctive pattern of bone and joint destruction. Along with disease-modifying antirheumatic drugs and newer biologic therapy, treatment can include oral corticosteroids (oCS), predominantly prednisolone or prednisone. CS are associated with a variety of adverse effects.[1]

**Objectives:** Using data from the UK's Clinical Practice Research Datalink, we estimated the incidence rates (IRs) and incidence rate ratios (IRRs) of known oCS-related serious adverse events (SAEs) of interest in an RA cohort and in a non-RA general population (GP) comparison group matched on age, sex, and time. We also explored the role of oCS use on the risk for SAEs of interest by comparing RA patients of varying exposure levels of oCS.

**Methods:** Patients with a first-time diagnosis of RA who were ≥18 years of age were identified and matched to patients in a non-RA GP comparison group of equal size. Group IRs and IRRs were estimated for diabetes, osteoporosis, fractures, glaucoma, hypertension, thrombotic stroke or myocardial infarction (MI), gastrointestinal (GI) perforation or bleeding, and death for the RA group and the GP group. We then performed a series of nested case-control analyses examining the effect of oCS use on the risk for SAEs of interest. We used conditional logistic regression to calculate the unadjusted and multivariate adjusted odds ratios (ORs) with 95% confidence intervals (CIs) for the association between oCS use and the risk for each separate outcome of interest. We stratified the analyses according to increasing cumulative and average daily oCS use.

**Results:** The cohort consisted of 34,047 RA patients and 34,047 matched non-RA GP patients. Mean follow-up time was ~8 years. The incidence for most SAEs was greater in the RA group than in the GP group. IRRs (95% CIs) for SAEs of interest were diabetes (1.21; 1.13–1.31), osteoporosis (2.11; 1.96–2.27), fractures (1.16; 1.08–1.24), glaucoma (1.08; 0.94–1.22), hypertension (1.13; 1.09–1.18), thrombotic stroke or MI (1.22; 1.11–1.34), GI perforation or bleeding (1.3; 1.15–1.47), and death (1.17; 1.11–1.22). In multivariate analyses, increasing risks for diabetes, osteoporosis, fractures, thrombotic stroke or MI, and death were observed with increasing cumulative oCS use ($p$ <0.05 for trend). RA patients receiving an average daily dose >7.5 mg/day had an increased adjusted OR (95% CI) for diabetes (1.49; 1.21–1.84), osteoporosis (1.41; 1.20–1.66), fractures (1.22; 1.03–1.45), thrombotic stroke or MI (1.61; 1.27–2.04), and death (1.49; 1.27–1.74).

**Conclusions:** Patients with RA experienced an increased incidence of diabetes, osteoporosis, fractures, hypertension, thrombotic stroke or MI, GI perforation or bleeding, and death compared with age- and sex-matched controls. Increasing cumulative oCS doses and average daily oCS doses were associated with increased odds of diabetes, osteoporosis, fractures, thrombotic stroke or MI, and death.

## THU0173 FILGOTINIB (GLPG0634), AN ORAL JAK1 SELECTIVE INHIBITOR IS EFFECTIVE AS MONOTHERAPY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: RESULTS FROM A 24-WEEK PHASE 2B DOSE RANGING STUDY

A. Kavanaugh[1], L. Ponce[2], R. Cseuz[3], O. Reshetko[4], M. Stanislavchuk[5], M. Greenwald[6], A. Van der Aa[7], F. Vanhoutte[7], C. Tasset[7], P. Harrison[7]. *[1]University of California San Diego, La Jolla, United States; [2]Consulta Privada Dra. Ponce, Temuco, Chile; [3]Revita Reumatológiai Kft, Budapest, Hungary; [4]Regional Clinical Hospita, Saratov, Russian Federation; [5]Innitsya Regional Clinical Hospital, Vinnitsya, Ukraine; [6]Desert Medical Advances, Palm Desert, United States; [7]Galapagos NV, Mechelen, Belgium*

**Background:** Filgotinib (GLPG0634) is a novel oral, selective JAK1 inhibitor that was evaluated in a 24-week phase 2B study as monotherapy in active rheumatoid arthritis (RA) with inadequate response to methotrexate. The primary endpoint of proportion of patients achieving ACR20 response after 12 weeks of treatment was met.

**Objectives:** To present the results of the 24-week analysis.

**Methods:** Patients with active RA were randomized 1:1:1:1 in a double blinded manner to receive either placebo (PBO) or one of three doses of filgotinib (50mg, 100mg or 200mg) as a once daily regimen for 24 weeks (DARWIN 2 study). At Week 12 all patients on PBO and on 50mg daily whose tender and swollen joint counts did not improve by at least 20% (non-responders (NR)) were reassigned to 100mg daily.

**Results:** Of 283 randomized and treated patients, mean duration of RA of 9 years and DAS28(CRP) at baseline between 6.0–6.2. At Week 12, a statistically significant higher ACR20, ACR50, ACR70, DAS28(CRP) and CDAI response versus PBO was observed in filgotinib groups. These responses were similar or continued to improve through 24 weeks (Table 1). Increase in filgotinib dose from Week 12 improved efficacy in PBO and 50mg NR groups (at Week 24 ACR20 55% and 60% respectively). Serious Adverse Events and Treatment-Emergent Adverse Events (TEAE) were distributed over the dose groups including PBO: TEAE 39% PBO and 41% filgotinib groups. Infections occurred in 10% PBO and 19% filgotinib groups. No opportunistic infections, cancers or deaths occurred. In filgotinib groups, for the first 4 weeks, a dose dependent decrease in mean neutrophil and a small reduction in platelet counts was seen; mild increase in mean creatinine was apparent. These changes subsequently plateaued and remained stable up to Week 24. A dose dependent increase in haemoglobin was seen during the first 12 weeks and levels remained stable up to Week 24. Over 24 weeks no meaningful difference in transaminase changes was apparent.

Table 1. Summary of the efficacy responses after 12 and 24 weeks treatment

| | Placebo (n=72) | 50mg (n=72) | 100mg (n=70) | 200mg (n=69) |
|---|---|---|---|---|
| 12 weeks | | | | |
| ACR20, NRI[1], % | 29 | 67*** | 66*** | 73** |
| ACR50, NRI, % | 11 | 35** | 37*** | 44*** |
| ACR70, NRI, % | 3 | 8 | 19** | 13* |
| DAS28(CRP), LOCF[3], mean change from BL[2] | –1.0 | –1.8*** | –2.0*** | –2.3*** |

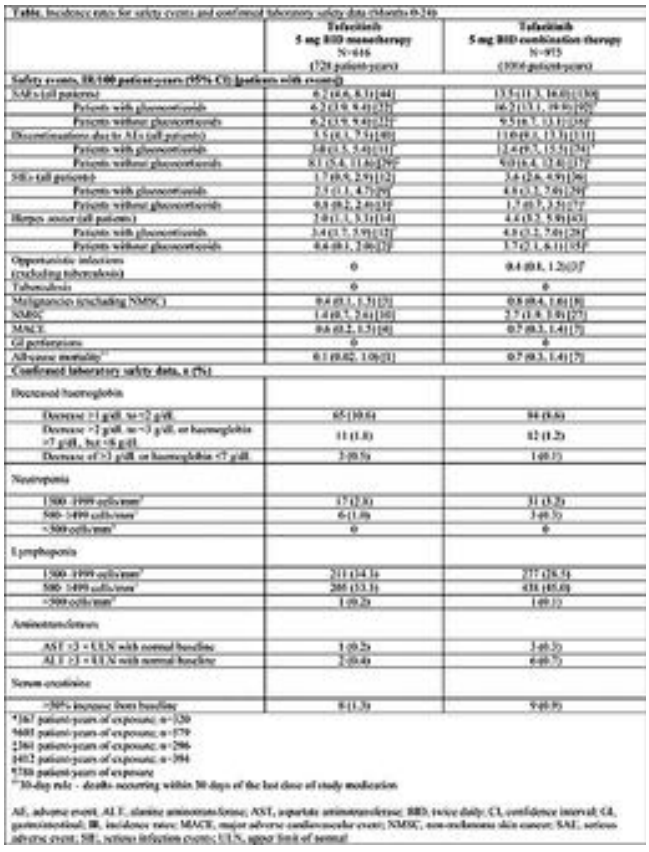
## THU0174 A SAFETY ANALYSIS OF TOFACITINIB 5 MG TWICE DAILY ADMINISTERED AS MONOTHERAPY OR IN COMBINATION WITH BACKGROUND CONVENTIONAL SYNTHETIC DMARDS IN A PHASE 3 RHEUMATOID ARTHRITIS POPULATION



A. Kivitz[1], B. Haraoui[2], J. Kaine[3], V. Castellano[4], E. Bananis[4], C.A. Connell[5], H. Fan[5], L. Takiya[6]. *[1]Altoona Center for Clinical Research, Duncansville, United States; [2]Institut de Rhumatologie de Montréal, Montréal, Canada; [3]Sarasota Arthritis Research Center, Sarasota; [4]Pfizer Inc, Collegeville; [5]Pfizer Inc, Groton; [6]Pfizer Inc, New York, United States*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of RA. In Phase 3 studies, tofacitinib demonstrated safety and efficacy at 5 and 10 mg BID when used as monotherapy or with conventional synthetic (cs) DMARDs (csDMARDs).

**Objectives:** To examine the safety profile of tofacitinib 5 mg BID as monotherapy and combination therapy in the Phase 3 clinical development RA program.

**Methods:** Safety data for tofacitinib were obtained from six double-blind Phase 3 studies of 6–24 months' duration and stratified by whether tofacitinib was administered as monotherapy (NCT00814307, ORAL Solo; NCT01039688, ORAL Start) or with csDMARDs (NCT00960440, ORAL Step; NCT00847613, ORAL Scan; NCT00856544, ORAL Sync; and NCT00853385, ORAL Standard). Patients in ORAL Start were methotrexate (MTX)-naïve while patients in all other studies had an inadequate response to cs or biologic DMARDs. Endpoints included: serious adverse events (SAEs), discontinuations due to adverse events (AEs), serious infection events (SIEs), opportunistic infections, herpes zoster (HZ), malignancies, major adverse cardiovascular events, gastrointestinal perforations, all-cause mortality and laboratory safety data.

**Results:** Tofacitinib 5 mg BID was administered as monotherapy in 616 patients (243 from ORAL Solo and 373 from ORAL Start, mean age 51.1 years [yrs], mean RA duration 4.9 yrs, 49.8% received glucocorticoids [GC]) and combination therapy in 973 patients (mean age 53.4 yrs, mean RA duration 8.9 yrs, 57.8% received GC). Incidence rates (IRs) for SAEs, discontinuations due to AEs, SIEs and HZ were generally lower in patients receiving tofacitinib monotherapy vs combination therapy. A similar trend was observed when patients were stratified by GC use; however confidence intervals were wide and overlapping for some outcomes (Table). IRs for SIEs and HZ were greater for patients who received GC compared with those who did not, irrespective of whether tofacitinib was given as monotherapy or in combination. Similar proportions of patients in the monotherapy and combination therapy groups had confirmed laboratory decreases in haemoglobin, neutrophil and lymphocyte counts, and increases in liver enzymes and serum creatinine (Table).

**Conclusions:** In this analysis, IRs for SAEs, discontinuations due to AEs, SIEs and HZ were lower in the tofacitinib 5 mg BID monotherapy group vs the combination therapy group; however, IRs should be interpreted with caution as the data are from controlled studies of limited duration and MTX-naïve patients with shorter disease duration were included in the monotherapy group only.

## THU0175 COMPARISON OF TWO COMMONLY USED INTRA-ARTICULAR STEROID PREPARATIONS IN ACUTELY SWOLLEN KNEE JOINT IN PATIENTS WITH CHRONIC ARTHRITIS – A RANDOMIZED CONTROLLED TRIAL

A. Kumar, V. Dhir, S. Singh, A. Sharma, S.S. Khanna. *Internal Medicine, Rheumatology Division, Post Graduate Institute of Medical Education and Research, Chandigarh, India*

**Background:** Rheumatoid arthritis (RA) and Spondyloarthropathies (SpA) are the commonest chronic inflammatory arthritides and intra-articular corticosteroid therapy is commonly used to control flares in one or few joints. However, it is surprising that despite more fifty years of experience with intra-articular corticosteroids use and evidence to attest their usefulness, evidence in the form of controlled trials to evaluate individual agents and their comparison remains sparse.
**Objectives:** To compare the efficacy of intra-articular injection of methylprednisolone acetate with triamcinolone acetonide in treatment of acutely swollen knee joint in patients with chronic arthritis (RA and SpA) over a follow up period of 24 weeks using time to relapse and patient reported outcomes between the two groups.
**Methods:** Patients with RA/SpA and swollen knee joint were recruited in this double-blind, randomized controlled trial. They were randomized in 1:1 ratio to receive either intra-articular methylprednisolone acetate (80 mg) or triamcinolone acetonide (80 mg) and followed up over a period of 24 weeks with follow-up visits at 4,12 and 24 weeks. Patients continued to take their DMARDs and other medications, with the dose of oral corticosteroids kept $\leq$7.5 mg/day prednisolone or equivalent. At each visit, relapse in the target joint was assessed using clinical measures, which included joint tenderness and swelling. Numerical rating scales for joint swelling and pain in the target joint, disease activity (using DAS28 (3)/BASDAI) and functional status assessment using the Health assessment questionnaire (HAQ) were secondary outcomes.
Trial #CTRI 006187.
**Results:** This study included 100 patients of RA and SpA (RA:SpA=89:11,M:F=24:76) with mean age being 41.9 (± 25.2) years and mean disease duration 5.38 years. Among these, 50 patients each received intra-articular methylprednisolone 80 mg or triamcinolone acetonide 80 mg. After 24 weeks follow-up, there was no significant difference in the relapse rate or time to relapse between the two groups, each group having 9 relapses (relapse rate in the two groups was 18.4% vs.18.8%) with an average time to relapse of 6.44 (±8.24) weeks and 7.44 (±9.74) weeks in methylprednisolone and triamcinolone groups (p=0.991). Reduction in NRS-pain was 5.50 and 5.38 and in NRS-swelling was 5.52 and 5.45 respectively in methylprednisolone and triamcinolone groups at 24 weeks. The reduction in DAS28 at 24 weeks was 1.78 in both the groups. There was no significant difference in functional status between the two groups, the average reduction in HAQ scores being 0.85 and 0.86 in methylprednisolone and triamcinolone groups respectively
**Conclusions:** Our study suggests that there is no significant difference between intra-articular methylprednislone and triamcinolone in terms of efficacy.

## THU0176 EFFICIENCY OF COMPLEX THERAPY OF RHEUMATOID ARTHRITIS USING RAMIPRIL

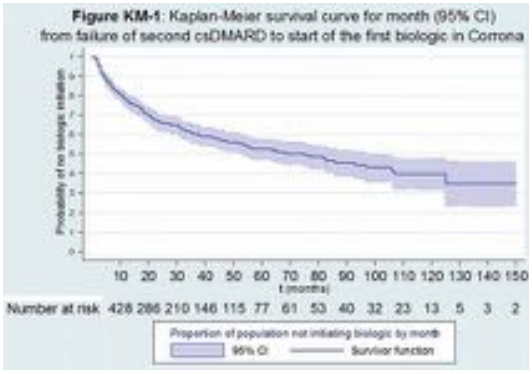
B.A. Rebrov, E.B. Komarova, I.I. Blaginina, A.B. Blagodarenko. *internal medcine, SI "Lugansk State Medical University", Lugansk, Ukraine*

**Background:** Angiotensin II (AnII) is not only involved in the pathogenesis of endothelial dysfunction (ED) due vasoconstrictor effect, but also has a powerful pro-inflammatory and remodeling properties, stimulating the production of proinflammatory cytokines (TNFα, IL-1, IL-6 et al.), adhesion molecules (ICAM-1), and growth factors (vascular endothelial growth factor - VEGF), which play an important role in the pathogenesis of rheumatoid arthritis (RA). The use of ACE inhibitors in vivo and in vitro on cell cultures demonstrated anti-cytokine and anti-inflammatory effect.
**Objectives:** to study the effectiveness of combined therapy of RA with ramipril use
**Methods:** The study included 84 patients with RA. Mean age was 40.12 ± 10.2 years. Mean RA disease duration was 4.22 ± 3.43 years. The concentration of ICAM-1, VEGF and TNFα in blood was determined by enzyme immunoassay. Endothelial regulation of vascular tone was studied in all the patients (by Celermayer-Sorensen method, 1992), which revealed the presence of ED in examined patients: reduction of endothelium-dependent vasodilation (EDVD) till less than 10%, endothelium-independent vasodilation (EIVD) – till less than 15%, the coefficient of the sensitivity of the endothelium to the (transverse strain) shere stress (K) <0.59. The average value of the examined EDVD RA patients was 9.2 ± 2.3%, ENVD – 13.9 ± 2.9%, K – 0.37 ± 0.21.
All the patients studied were randomly divided into two groups: I - 43 patients received standard RA therapy according to protocols of rheumatic diseases treatment, II - 41 patients received 12 months complex treatment, which included standard therapy with an ACE inhibitor addition - ramipril 2.5 -5 mg per day. The initial dose was 2.5 mg/day for a week, then the dose was increased to 5 mg/day under the blood pressure control. Patients of the I and II groups were not statistically different in all investigated indices prior to treatment.
**Results:** The dynamics of indicators of ED in the groups (Table. 1) revealed that all parameters in the both groups significantly improved ($p<0.001$) after treatment, but the increase was significantly more in group II ($p<0.05$). The positive dynamics of immune inflammation RA activity markers (CRP, TNFα, DAS28) after the treatment was in both groups, but the gain power was statistically more significant in group II ($p<0.05$). It should be noted, that DAS28 in group II decreases by more than 1.2 (according to the EULAR criteria for the RA treatment effectiveness), while in group I - only by 0.65.
Thus, inclusion of ramipril in the complex therapy of RA led to an improvement in endothelial regulation of vascular tone, helped to reduce blood levels of ICAM-1 by 16%, VEGF by 36%, CRP by 13%, TNFα by 12% as opposed to standard therapy.

Table 1. Dynamics of ED indices post treatment in the studied groups, Me (LQ; UQ)

| Indices | I group (n = 43) | | | II group (n = 41) | | | U | p |
|---|---|---|---|---|---|---|---|---|
| | Prior treatment | Post treatment | Gain (%) | Prior treatment | Post treatment | Gain (%) | | |
| EDVD, % | 9.3 (8.7; 9.7) | 9.4 (9.1; 10.7) | 1 | 9.2 (8.6; 10.3) | 11.3* (9.7; 11.8) | 23 | 3.6 | <0.001 |
| EIVD, % | 14.1 (13.6; 15.5) | 14.3 (13.3; 16.6) | 1 | 14.2 (13.6; 15.6) | 17.4* (16.1; 17.9) | 21 | 2.29 | 0.02 |
| K | 0.38 (0.29; 0.47) | 0.4 (0.34; 0.68) | 5 | 0.36 (0.28; 0.59) | 0.68* (0.5; 0.74) | 89 | 2.53 | 0.01 |
| ICAM-1, pg/ml | 8.2 (7.8; 10.1) | 8.3 (7.1; 9.3) | 1 | 8.03 (7.5; 10.1) | 6.7* (5.6; 7.34) | -17 | 4.48 | <0.001 |
| VEGF, pg/ml | 457 (324; 579) | 472 (290; 567) | 3 | 498 (341; 636) | 305* (191; 389) | -39 | 4.03 | 0.002 |

Source: Authors
* - differences are reliable after the treatment within one group by Wilcoxon test, $p < 0.05$



**Conclusions:** The use of ramipril in the treatment of RA for one year contributed to the effective reduction of markers of autoimmune inflammation, improved endothelial dysfunction, and significantly reduced the activity index of the disease compared with standard therapy.
**Disclosure of Interest:** None declared

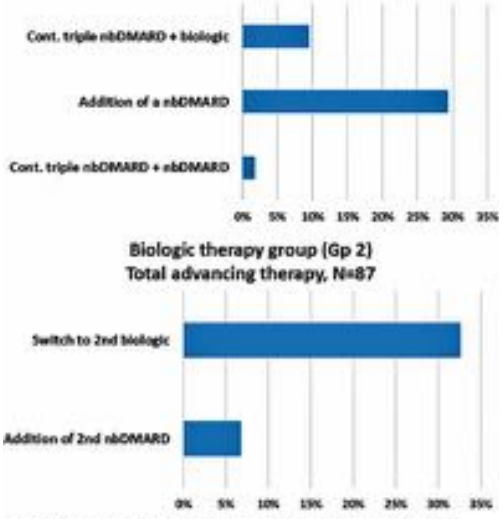
## THU0177 DELAY IN INITIATION OF BIOLOGICS AMONG BIO-ELIGIBLE PATIENTS WITH RHEUMATOID ARTHRITIS IN US: EVIDENCE FROM THE CORRONA REGISTRY

D.A. Pappas[1,2], C. Karki[1], M. Liu[1], J.M. Kremer[3], J.D. Greenberg[1,4], V. Garg[5]. *[1]Corrona, LLC, Southborough, MA; [2]Columbia University, New York, NY; [3]Albany Medical College and The Center for Rheumatology, Albany, NY; [4]NYU School of Medicine, New York, NY; [5]AbbVie, Inc., Abbott Park, IL, United States*

**Background:** Biologic agents can help achieve low disease activity or remission in patients with rheumatoid arthritis (RA) who do not respond adequately to therapy with one or two conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) (1).

**Objectives:** To understand the prevalence of RA patients with inadequate response to therapy with 2 csDMARDs and describe time to initiation of a biologic agent for this patient population.
**Methods:** Patients enrolled in the Corrona RA registry as of January 2015 were included in this analysis. "Inadequate response" to 2 csDMARDs was defined as being on moderate or high disease activity (CDAI >10) six months after the initiation of 2 csDMARDs. The index visit was defined as the first visit after 6m of being on moderate or high CDAI after the initiation of 2 csDMARDs. The population of biologic naïve patients at index visit, with at least 6 months of additional follow up were observed longitudinally to calculate the time to initiation of a biologic agent. Kaplan-Meier method was used to estimate the time to biologic initiation.
**Results:** 2723 RA patients treated with 2 csDMARDs for at least 6 months were identified. At the time of the index visit: 1774 (65.1%) patients had responded to 2 csDMARDs, 192 (7.1%) had started a biologic, and 135 (4.9%) patients with inadequate response to 2 csDMARDs and did not have at least 6 months of additional follow up post-index visit. The final number of inadequate responders to 2 csDMARDs included in this analysis was 622 (22.9%) patients (79.1% female, 60.9±12.7 mean age, 9.0±9.9 mean duration of RA, 19.5±8.9 mean CDAI at index visit). The median follow up time for this population was 32.5 months. Among the 622 patients, 227 initiated a biologic during the follow up time. The median time to initiation of a biologic was 75 months (95% CI: 53–97 months). Among the 227 patients who initiated the biologic, the mean (SD) time to initiation was 17.7 (±21.7) months (figure 1). While for some patients disease activity fluctuated between low/remission and moderate/high until the initiation of a biologic agent, for 57.3% of patients remained persistently in moderate or high disease activity over the follow-up.



**Conclusions:** A significant percentage of RA patients treated with 2 csDMARDs did not respond adequately to such therapy in the population studied. Prolonged time until the initiation of a biologic agent was noted for this patient population.

## THU0178 NEED TO ADVANCE THERAPY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TRIPLE NBDMARD VS BIOLOGIC COMBINATION THERAPY: RESULTS FROM THE CORRONA REGISTRY

D.A. Pappas[1,2], C. Karki[1], H. Litman[1], J.D. Greenberg[1,3], J.M. Kremer[4], V. Garg[5]. *[1]Corrona, LLC, Southborough, MA; [2]Columbia University; [3]NYU School of Medicine, New York, NY; [4]Albany Medical College, Albany, NY; [5]AbbVie, Inc., Abbott Park, IL, United States*

**Background:** Some studies have suggested that efficacy of triple non-biologic disease modifying anti-rheumatic drug (nbDMARD) therapy for Rheumatoid Arthritis (RA) is similar to biologic combination therapy (1).
**Objectives:** To examine the difference in need to advance therapy after treatment with triple nbDMARD (Group 1) or TNF inhibitors in combination with methotrexate (MTX)) (Group 2).
**Methods:** RA patients enrolled in Corrona between 10/2001 – 8/2015 initiating either triple nbDMARD therapy or a biologic agent in combination with MTX and with at least 1 follow-up visit were included. Group 1 included patients who started either concurrently or sequentially MTX, hydroxychloroquine and sulfasalazine. TNF inhibitors could be started concurrently with or added to MTX in Group 2. Advancement of therapy was compared for the two groups after propensity score (PS) matching and defined as discontinuing one or more of triple nbDMARD and adding a biologic/adding another nbDMARD for Group 1 and adding a second nbDMARD/switching to a different biologic for Group 2. Index visit was defined as initiation of triple therapy for Group 1 and date of biologic initiation for Group 2. Kaplan-Meier estimates were used to determine time to advancement of therapy.
**Results:** There were 236 and 2,938 in Gp 1 and 2 respectively. After PS matching, N=221 were included in each group. Groups were well balanced with a mean age of 58.5 yrs vs 58.6 yrs, mean disease duration of 10.5 yrs vs 10.6 yrs and mean clinical disease activity index (CDAI) of 15.9 vs 16.1 for groups 1 and 2 resp. About 76% (95% CI: 69.5%, 81.3%) of the Gp 1 patients continued on initial therapy compared to 82% (95% CI: 76.4%, 86.8%) in Gp 2 at 12 months of follow-up. Median time to therapy advancement was 49 months (95% CI: 35, 59) for group 1 and 69 months (95% CI: 46, 100) for group 2. About 40% of patients in triple nbDMARD group had to advance therapy during 12 months of follow-up, vs 39% in group 2. Types of first advancement of therapy is shown in table 1.

**Figure 1: Categories of advancement of therapy in triple nbDMARD and biologic therapy group during follow-up**

nbDMARD: non-biologic disease modifying anti-rheumatic drug

**Conclusions:** Therapy with a biologic agent resulted in a numerically but not statistically significant prolonged time to advancement therapy compared to triple nbDMARD therapy. Future examination of the need to advance therapy with a larger sample size may provide further insights for treatment practices.

## THU0179 DISCONTINUATION OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS IN RHEUMATOID ARTHRITIS PATIENTS WITH LOW DISEASE ACTIVITY

D.J. Go[1], K. Shin[2], H.J. Baek[3], Y.M. Kang[4], S.W. Kang[5], S.H. Park[6], J.B. Jun[7], Y.J. Lee[8], Y.W. Song[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital; [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Borame Medical Center, Seoul; [3]Division of Rheumatology, Department of Internal Medicine, Gachon University Gil Hospital, Incheon; [4]Division of Rheumatology, Department of Internal Medicine, Kyungpook National University Hospital, Daegu; [5]Division of Rheumatology, Department of Internal Medicine, Chungnam National University Hospital, Daejeon; [6]Division of Rheumatology, Department of Internal Medicine, Catholic University of Korea, Seoul St Mary's Hospital; [7]Division of Rheumatology, Department of Internal Medicine, Hanyang University, Hospital for Rheumatic Disease, Seoul; [8]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

**Background:** Although nonsteroidal anti-inflammatory drug (NSAIDs) is effective in relieving joint pain in rheumatoid arthritis (RA) patients, long-term use of NSAIDs can cause adverse effects on gastrointestinal or cardiovascular organs. When patients discontinue daily use of NSAIDs, there is often a dichotomous clinical response in patient-reported outcomes (PRO).
**Objectives:** We aimed to examine the clinical outcome especially joint pain, and its associated factors in RA patients with low disease activity (LDA) after discontinuing NSAIDs.
**Methods:** This study was a 16-week, multi-center prospective open-label trial conducted at eight rheumatology clinics in Korea. RA patients who achieved LDA (DAS28 <3.2) who were on NSAIDs for more than 2 consecutive months, discontinued the NSAID. Acetaminophen (AAP) was used as the rescue medication. During the study period, changes of DAS28 and PRO including pain visual analogue scale (VAS) and Routine Assessment of Patient Index Data 3 (RAPID-3) score were assessed. NSAIDs were restarted when patient's 1) pain was uncontrolled with AAP and 2) PRO were aggravated. The endpoint was to analyze the group of patients who continued to withdraw NSAIDs within the study period. Patients were further classified to have "sustained effectiveness" who met the following: 1) 16-week pain VAS ≤30 mm or increase less than 20% from baseline and 2) 16-week RAPID-3 score ≤6 or increase less than 20% from baseline.
**Results:** A total of 121 RA patients with LDA were enrolled in the study. Four patients were lost to follow-up. At the end of the study, 18 (15.3%) patients had restarted NSAIDs owing to uncontrolled pain. In general, there was a difference in pain VAS between baseline (median 15 mm (IQR 5–20)) and 16 weeks (median 17 mm (IQR 5–40)) ($p$=0.022). Changes of DAS28 and RAPID-3 were insignificant in patients taking on-demand AAP (n=99) (0 versus 16 weeks; DAS28, $p$=0.111; RAPID-3; $p$=0.339). Moreover, 60% of the total patients (73/117) ended up to show sustained effectiveness without restarting NSAIDs. By using a multivariate logistic regression model, we found out that joint swelling was the detrimental factor compromising sustained effectiveness (OR 0.312, 95% C.I. 0.125–0.777, $p$=0.012).
**Conclusions:** Discontinuation of NSAIDs can be attempted in RA patients with LDA, especially in those without swollen joints at the time point of its cessation.
**Disclosure of Interest:** None declared

## THU0180 LACK OF EARLY CHANGE IN DISEASE ACTIVITY SCORE PREDICTS THE LIKELIHOOD OF ACHIEVING LOW DISEASE ACTIVITY AT MONTH 6: TOFACITINIB MONOTHERAPY VERSUS METHOTREXATE IN METHOTREXATE-NAÏVE PATIENTS WITH RHEUMATOID ARTHRITIS

E. Keystone[1], R.F. van Vollenhoven[2], B. Wilkinson[3], L. Fallon[4], L.-J. Hwang[5], D. Chapman[5], R. DeMasi[5], E.B. Lee[6]. *[1]Mount Sinai Hospital, Toronto, Canada; [2]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [3]Pfizer Inc, Groton, United States; [4]Pfizer Canada, Montreal, Canada; [5]Pfizer Inc, New York, United States; [6]Seoul National University, Seoul, Korea, Republic Of*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Treatment guidelines recommend targeting remission or low disease activity (LDA), herein defined as Disease Activity Scores ≤3.2 based on 28 joint counts (DAS28≤3.2) and adjusting therapy after 3–6 months[1] (Mos). Predicting the likelihood of clinical response may help inform early treatment decisions.
**Objectives:** To understand the relationship between timing and magnitude of early changes in DAS28, erythrocyte sedimentation rate (DAS28-4[ESR]) and the likelihood of achieving LDA at Mo 6 in RA patients (pts) naïve to methotrexate (MTX).
**Methods:** In a Phase 3 study (ORAL Start; NCT01039688), MTX-naïve RA pts were randomised 2:2:1 to the following monotherapies: tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID or MTX. Conditional probability of pts achieving LDA at Mo 6 were calculated, given failure to achieve DAS28-4(ESR) improvement from baseline (range ≥0.3 to 1.8) at Mo 1 or 3. One-year data with non-responder imputation for missing values was used.
**Results:** 948 pts received treatment; tofacitinib 5 mg BID (n=370), tofacitinib 10 mg BID (n=394) or MTX (n=184); results previously reported.[2] In this post-hoc analysis, of those patients who failed to achieve DAS28-4(ESR) improvement from baseline ≥1.2 at Mo 3, 6.8% for tofacitinib 5 mg BID, 11.3% for tofacitinib 10 mg BID and 6.2% for MTX achieved LDA at Mo 6 (Table). A minority of pts (74/353 [20.9%]) receiving tofacitinib 5 mg BID failed to achieve DAS28-4(ESR) improvement ≥1.2 from baseline at Mo 3, while a greater proportion failed for MTX (65/171 [38.0%]). Failure to achieve DAS28-4(ESR) improvement from baseline at Mo 3 (range ≥0.30–1.8) for tofacitinib 5 mg BID and MTX was associated with a low probability (≤10%) of achieving LDA at Mo 6. For tofacitinib 5 mg BID, failure to achieve lower thresholds of DAS28-4(ESR) improvement (range ≥0.3 to 0.9) at Mo 1 was associated with lower probability of LDA at Mo 6 than higher DAS28-4(ESR) thresholds (≥1.2–1.8) (Table).

| Given failure to achieve DAS28-4(ESR) improvement at Month 1 or 3 | | Percentage of patients achieving LDA at Month 6 | | |
|---|---|---|---|---|
| DAS28-4(ESR) improvement≥ | Month | Tofacitinib 5 mg BID | Tofacitinib 10 mg BID | MTX* |
| 0.3 | 1 | 3.9 | 14.3 | 12.7 |
| | 3 | 0.0 | 15.4 | 5.0 |
| 0.6 | 1 | 9.8 | 18.2 | 12.8 |
| | 3 | 0.0 | 8.7 | 5.0 |
| 0.9 | 1 | 12.1 | 15.4 | 10.9 |
| | 3 | 6.0 | 11.4 | 7.8 |
| 1.2 | 1 | 14.7 | 19.5 | 10.0 |
| | 3 | 6.8 | 11.3 | 6.2 |
| 1.5 | 1 | 18.5 | 21.1 | 10.6 |
| | 3 | 8.7 | 11.1 | 6.5 |
| 1.8 | 1 | 22.6 | 23.5 | 12.8 |
| | 3 | 10.0 | 10.7 | 7.5 |

BID, twice daily; DAS28-4(ESR), disease activity score, erythrocyte sedimentation rate; LDA, low disease activity.
*MTX dose – starting dose of 10 mg per week (mg/wk), with increments of 5 mg/wk every 4 weeks to 20 mg/wk by Week 8. Mean dose of MTX was 18.6 mg/wk

**Conclusions:** Failure to achieve DAS28-4(ESR) improvement ≥1.2 from baseline at Mo 3 was associated with a low probability of achieving LDA at Mo 6 (≤6.8%) for tofacitinib 5 mg BID and MTX. For the minority of MTX-naïve RA pts treated with tofacitinib 5 mg BID or MTX who failed to achieve a minimal clinical response (DAS28-4[ESR] improvement ≥1.2) by Mo 3, another treatment option can be considered at Mo 3, as there is a low probability of reaching LDA at Mo 6.

## THU0181 EFFICACY AND SAFETY OF CONCOMITANT METHOTREXATE AND LEFLUNOMIDE USE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS. CROSS -SECTIONAL STUDY

H. Sánchez Pérez, M. García González, L. Expósito Pérez, E. Trujillo, E. Delgado Frías, J. Bethencourt Baute, S. Bustabad. *Rheumatology, Hospital Universitario de Canarias, Tenerife, Spain*

**Background:** Treatment of RA is based on the use of DMARDs, both synthetic and biological,and the mayor goal is to achieve clinical remission. Several Scientific Societies (EULAR, ACR, SER) recommend that all patients with RA should be treated with DMARDs as soon as the clinical diagnosis is established. Methotrexate (MTH) is the first line treatment. In case of unsatisfactory response (development of toxicity or failure), it is recommended to use Leflunomide (LEF), Sulfasalazine or an anti-TNF agent as a second line treatment, in monotherapy or associated with MTH
**Objectives:** To describe the current situation, baseline characteristics and reasons for discontinuing or changing treatment of RA patients seen during 1 year in our department,that were or had been treated with concomitant MTH-LEF therapy
**Methods:** Observational cross-sectional study. Clinical records of RA patients, attended in our Rheumatology Department during 2014 who were or had been treated with MTH-LEF, were reviewed. Demographic (age and sex), clinical (years of disease progression, RF/ACPA, ESR/CRP, NTJ/NSJ, DAS28) and treatment

variables (duration in months, other treatments, reasons for discontinuing or changing)were analyzed
**Results:** 483 patients were analyzed, 104 were finally included. Mean age was 55.18 years (±11,82), 88.6% were women. 39.4% were currently receiving MTH-LEF therapy, with a mean disease course in years of 6.15 (±5.03) and a mean duration of treatment in months of 22,84 (±17.45).53.7% took corticosteroids and 12.2% NSAIDs on a daily basis. RF/ACPA was positive in 85.4%/51.2%; mean NTJ/NSJ was 0.41 (±1.16)/0.32 (±069); the mean value of ESR/CRP was 32.13 (±17.99)/6.92 (±10.61). According to DAS28 score, 14.6% of patient were in remission, 70.7% at low disease activity, 12.2% at moderate disease activity and 2.4% at high disease activity. *Patients no longer with MTH-LEF therapy* had similar baseline characteristics except for ACPA positive in a higher % (77.97% vs. 51.2%,p=0.05). No differences in drug dosing were found, being the higher doses the most used ones (MTH>15 mg/week, LEF 20 mg/day). The main reason for combined therapy discontinuation was inefficacy (54%), followed by adverse effects in 35% (gastrointestinal intolerance 36.36%, nonspecific skin disorders 18.18% and hematological disorders, cough, headache and others) and low clinical activity (11%). No significant differences between patients according to the reason for discontinuation of treatment were observed. Higher drug dose use was not found in patients who experienced adverse effects (as it would have been expected). A longer disease course was found in patients presenting inefficiency as so a higher positive % of RF/ACPA
**Conclusions:** The 39.4% of patients responded to the MTH-LEF therapy, avoiding the use of biological agents. It appears to be a valid alternative for our patients, since 85.3% of them had low clinical activity. However, it had to be discontinued in up to 60.6% of patients, noting in this group a higher % of ACPA+ patients. The main causes for treatment discontinuation were ineffacy and gastrointestinal intolerance. No significant differences were seen regarding the therapy discontinuation cause, although it seems to be more common in RF/ACPA positive patients and we observed a longer disease course if inneficacy happened. No differences in drug dosing were found.

## THU0182 EX VIVO FUNCTIONAL COMPARISON OF BARICITINIB AND TOFACITINIB FOR CYTOKINE SIGNALING IN HUMAN LEUKOCYTE SUBPOPULATIONS

I. McInnes[1], R. Higgs[2], G. Rocha[2], X. Zhang[2], J. Lee[2], T. Wehrman[3], W.L. Macias[2], S. Zuckerman[2], P. Taylor[4]. *[1]University of Glasgow, Glasgow, United Kingdom; [2]Eli Lilly and Company, Indianapolis; [3]Primity Bio, Fremont, United States; [4]University of Oxford, Headington, United Kingdom*

**Background:** Baricitinib (bari) and tofacitinib (tofa) are selective JANUS kinase inhibitors (JAKi). In biochemical assays, bari exhibits greatest potency against JAK1 and JAK2, whereas that for tofa is against JAK1 and JAK3.
**Objectives:** To determine whether differences in JAKi specificity translate to differences in cellular signal transduction in leukocyte subpopulations stimulated by cytokines, indicated by inhibition of signal transducers of activator transcription (STATs) phosphorylation.
**Methods:** Peripheral blood mononuclear cells (PBMC) were obtained from healthy donors (n=6). Leukocyte preparations were incubated with JAKi using a 7 point dose range, 2.44–10,000 nM, for 1 hour before cytokine stimulation. The half maximum inhibitory concentration ($IC_{50}$) values were determined by plotting the mean fluorescence intensity of cytokine-stimulated and nonstimulated samples in phenotypically gated leukocyte subpopulations.[1]
**Results:** $IC_{50}$ values for bari and tofa were similar for interleukin-6 (IL-6) across leukocyte subsets. Differences were observed for other cytokines. The $IC_{50}$ across leukocyte subpopulations stimulated with the same cytokine varied 2–3 fold per compound (Table). The most significant differences between JAKi $IC_{50}$ values were for cytokines that use JAK1/3. Tofa was a more potent inhibitor of IL-2, IL-4, IL-15, and IL-21 induced STAT phosphorylation than bari. Both compounds inhibited IL-10 stimulation of pSTAT3 and IFN-α stimulation of pSTAT1, pSTAT3, and pSTAT5 similarly. Inhibition of IFN-α pSTAT3 and pSTAT5 were similar for both JAKi, although less potent in inhibiting STAT1 phosphorylation. Bari and tofa inhibited GM-CSF (JAK2) and G-CSF and IFNg signaling, with bari exhibiting a greater effect in monocytes than tofa.
**Conclusions:** The differences in $IC_{50}$ for key cytokine stimuli suggest fundamental functional differences across classes of JAKi. The potency of JAKi varied between different leukocyte subpopulations and is STAT substrate dependent. At the clinical level, therefore, these agents should not be considered biologically equivalent. A practical consequence is that determination of JAKi potency on $IC_{50}$ based solely on a nongated whole blood assay would not detect differential responses of leukocyte subpopulations by JAKi.

$IC_{50}$ Values for baricitinib and tofacitinib in cytokine-stimulated human PBMC preparations

## THU0183 TREATMENT WITH TOFACITINIB INHIBITS HUMAN NAÏVE B LYMPHOCYTE DEVELOPMENT AND FUNCTION IN VITRO

J. Thiel, K. Fischer, R.E. Voll, R. Lorenzetti, B. Bannert, N. Venhoff, M. Rizzi. *Rheumatology/Clinical Immunology, University Hospital Freiburg, Freiburg, Germany*

**Background:** B cells are pivotal to the pathogenesis of many autoimmune diseases including rheumatoid arthritis (RA). Tofacitinib, a JAK inhibitor, is effective and safe in the treatment of RA. Tofacitinib interferes with signal transduction via cytokine receptors using the common γ-chain.
**Objectives:** Despite of extensive data on T lymphocytes, the impact of tofacitinib on B lymphocytes is poorly understood. In this study we assess the effect of tofacitinib on the differentiation of naive B-lymphocytes and their function.
**Methods:** Sorted human B cells from cord blood or buffy coat were stimulated in the presence of increasing doses of tofacitinib. B cell phenotypes were determined by flow cytometry. Immunoglobulin concentrations were measured by ELISA. The expression of B cell fate determining genes PRDM1, IRF4, XBP1, and AICDA was analyzed by quantitative RT-PCR.
**Results:** Tofacitinib treatment strongly impaired plasmablast development, immunoglobulin secretion and induction of PRDM1, IRF-4, and XBP-1 from naive B cells. Interestingly, class switch and AICDA induction from activated naive B cells was only slightly reduced. B cells purified from buffy coats, including naive and memory B cells, stimulated in the presence of tofacitinib, showed only a moderate reduction in plasmablast formation, immunoglobulin secretion and proliferation.
**Conclusions:** We demonstrated that tofacitinib has a direct impact on human naive B-lymphocytes, independently from its effect on T lymphocytes, by impairing their development into plasmablasts and immunoglobulin secretion. Tofacitinib predominantly affects naive B lymphocytes, while its effect on total peripheral B cells containing naive and memory B cells is less pronounced. Our data are of clinical importance as they suggest that vaccinations should be performed prior to tofacitinib treatment. Furthermore, impairement of B cell function by tofacitimib may directly contribute to its therapeutic effects. This fact has implications for the potential use of tofacitinib in B cell-mediated diseases.

## THU0184 REPAIR OF BONE EROSION IN RHEUMATOID ARTHRITIS BY DENOSUMAB: AN HR-PQCT STUDY

J. Yue[1], J.F. Griffith[2], L. Shi[1], D.F. Wang[3], J. Shen[4], P. Wong[1], E.K. Li[1], T.Y. Zhu[5], L. Qin[6], L.-S. Tam[1]. *[1]Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hongkong; [2]Department of Imaging and Interventional Radiology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong; [3]Department of Imaging and Interventional Radiology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hongkong; [4]Department of Medicine & Therapeutics; [5]Bone Quality and Health Center of the Department of Orthopedics & Traumatology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong; [6]Department of Orthopedics & Traumatology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hongkong, Hong Kong*

**Background:** Blockade of receptor activator of nuclear factor kappa B ligand (RANKL), using denosumab retards bone damage in RA. Whether RANKL blockade allows repair of existing bone erosions is so far unclear.

**Objectives:** To compare the reparative effect of denosumab and alendronate on erosions in female RA patients with low bone mass using HR-pQCT.
**Methods:** This is a post-hoc analysis of a randomized-controlled trial. 40 patients with bone erosions were randomized in a 1:1 ratio to receive either subcutaneous denosumab (60mg) once or oral alendronate (70mg) weekly for 6 months. The size of individual bone erosions and the presence and degree of marginal osteosclerosis around the second metacarpophalangeal joint of the non-dominant hand were measured both semi-quantitatively and quantitatively at baseline, 3- and 6-months.
**Results:** At baseline, the mean (±SD) width, depth and volume of the bone erosion were similar for both groups (Table). At 6 months, erosion size significantly decreased in the denosumab group, and significantly increased in the alendronate group. The between group differences in all size criteria were statistically significant at 6 months (all $p<0.01$). The degree of marginal osteosclerosis was similar between both groups at baseline. At 6-month, more than half of the patients (57.1%) in the alendronate group showed no osteosclerosis (grade 0). In contrast, most patients (80.9%) in the denosumab group showed osteosclerosis (grade 1 or 2). Mean (±SD) pixel attenuation of the erosion margin was similar between both groups at baseline. Mean pixel attenuation was significantly increased at 6 months in the denosumab group though unchanged in the alendronate group. Between group differences for change in mean pixel attenuation between baseline and 6 months were also significant ($p<0.05$).

| Parameter | Alendronate | | Denosumab | |
|---|---|---|---|---|
| | Baseline (n=21) | 6 months (n=21) | Baseline (n=21) | 6 months (n=21) |
| Shape and size of erosion | | | | |
| Width (mm) | 2.91±1.64 | 3.22±1.59* | 3.16±1.21 | 2.69±1.28** |
| Depth (mm ) | 1.86±0.94 | 2.48±1.08** | 1.46±0.68 | 1.15±0.66** |
| Volume ($mm^3$) | 4.72±5.62 | 5.39±6.07* | 4.97±7.60 | 4.06±6.76** |
| Change in width (mm) | | 0.19±0.26 | | –0.23±0.24## |
| Change in depth (mm) | | 0.32±0.35 | | –0.16±0.086## |
| Change in volume ($mm^3$) | | 1.38±1.40 | | –0.91±1.054## |
| Marginal osteosclerosis | | | | |
| Grade 0 | 10 (47.6%) | 12 (57.1%) | 13 (61.9%) | 4 (19.1%) |
| Grade 1 | 9 (42.9%) | 8 (38.1%) | 8 (38.1%) | 12 (57.1%) |
| Grade 2 | 2 (9.5%) | 1 (4.8%) | 0 | 5 (23.8%) |
| Pixel attenuation (HU) | 2252±1635 | 2091±1423 | 1647±710.5 | 2066±946.5** |
| Change in pixel attenuation (HU) | | –161.6±577.6 | | 418.9±611.1# |

All data expressed as mean ± SD or n (%). Pixel attenuation refers to the mean pixel attenuation of the area surrounding the bone erosion. *$p<0.05$, **$p<0.01$, within group comparison between baseline and 6 months. #$p<0.05$, ##$p<0.01$, comparison between alendronate and deonsumab groups.

**Conclusions:** Bone erosions in RA patients treated with denosumab show evidence of limited repair in contrast to bone erosions in patients treated with alendronate, indicating a favourable impact of RANKL inhibitor on the local bone remodeling.
**Disclosure of Interest:** None declared

## THU0185 TOFACITINIB, AN ORAL JAK INHIBITOR, IN THE TREATMENT OF RHEUMATOID ARTHRITIS: SAFETY AND CLINICAL AND RADIOGRAPHIC EFFICACY IN OPEN-LABEL, LONG-TERM EXTENSION STUDIES OVER 7 YEARS

J. Wollenhaupt[1], J. Silverfield[2], E.B. Lee[3], K.K. Terry[4], K. Kwok[5], I. Lazariciu[6], C. Nduaka[7], C.A. Connell[4], R. DeMasi[5], L. Wang[4]. *[1]Schoen-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany; [2]Healthpoint Medical Group, Tampa, United States; [3]Seoul National University College of Medicine, Seoul, Korea, Republic Of; [4]Pfizer Inc, Groton; [5]Pfizer Inc, New York, United States; [6]Quintiles, Saint-Laurent, Canada; [7]Pfizer Inc, Collegeville, United States*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA).
**Objectives:** To report tofacitinib safety, tolerability and clinical response over 84 months (mo), and radiographic data over 12 mo, in long-term extension (LTE) studies.
**Methods:** Data were from two open-label studies (NCT00413699 [ongoing; database unlocked at March 2015 data-cut] and NCT00661661]) of patients (pts) with RA who completed randomised Phase (P)1/2/3 tofacitinib studies. Pts received tofacitinib 5 or 10 mg BID as monotherapy or with background DMARDs; data were pooled. Primary endpoints: AEs and lab safety. Confirmed data are reported for decreased Hgb, neutrophil and lymphocyte counts, and increases >50% from BL in creatinine. Secondary endpoints: DAS28-4(ESR), HAQ-DI and mTSS. Safety data were included up to 96 mo and efficacy up to Mo 84 ($n\leq30$ post-Mo 84).
**Results:** 4867 pts were treated (mean [max] duration: 1107 [2895] days). BL data were from P1/P2/P3 index studies for 90.9% of pts. Total tofacitinib exposure was 14926 pt-years (py); 79.2% of pts maintained initial dose. In total, 2132 pts (43.8%) discontinued (AEs: 1051 [21.6%]; insufficient clinical response: 153 [3.1%]). Most common AE classes: infections and infestations (67.6%) and musculoskeletal/connective tissue disorders (37.3%). Most common AEs: nasopharyngitis (18.1%), upper respiratory tract infection (16.2%) and bronchitis (11.7%). SAEs occurred in 26.8% of pts (incidence rate [IR] 9.7/100 py [95% CI 9.2, 10.2]), and serious infection events (SIEs) in 8.4% of pts (IR 2.8/100 py [95% CI 2.5, 3.0]). Malignancies excluding NMSC were reported in 3.0% of pts (IR 1.0/100 py [95% CI 0.8, 1.1]). IRs for SIEs and malignancies through Mo 96 did not increase vs reported data through Mo 84.[1] Decreased Hgb (>30% decrease from BL/Hgb <8 g/dL) occurred in <1.0% of pts. Increased aminotransferases (>3×ULN) occurred in 5.4% (ALT) and 3.1% (AST) of pts. Moderate to severe neutropenia (absolute neutrophil count [ANC] 0.5–$1.5\times10^3/mm^3$) was noted in 1.5% of pts; there were no confirmed cases of ANC <$0.5\times10^3/mm^3$. Confirmed absolute lymphocyte counts <$0.5\times10^3/mm^3$ occurred in 1.3% of pts. Increases >50% from BL in creatinine were seen in 2.4% of pts. Mean DAS28-4(ESR) was 6.29 at BL, 3.74 at Mo 1 and 3.20 at Mo 84. Mean HAQ-DI score was 1.42 at BL, 0.81 at Mo 1 and 0.78 at Mo 84. Radiographic data were available for 1099 pts. Mean mTSS was 24.0 at BL (last P1/P2/P3 index value), 25.1 at Mo 6 and 24.3 at Mo 12. Mean change from BL in mTSS was 0.3 at Mo 6 and 0.2 at Mo 12.
**Conclusions:** Consistent safety and sustained efficacy over 84 mo was seen in pts with RA receiving tofacitinib 5 or 10 mg BID in LTE studies. Changes in mTSS were minimal at Mo 12 in LTE studies.

## THU0186 DOES EARLY STEROID USE INCREASE THE LIKELIHOOD OF ACHIEVING REMISSION AT 6 MONTHS IN EARLY RA? RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT

K.M. Andersen[1], S.J. Bartlett[2,3], D. Lin[4], O. Schieir[5], G. Boire[6], B. Haraoui[7], C. Hitchon[8], S. Jamal[9], E. Keystone[4], J. Pope[10], D. Tin[11], C. Thorne[11], V.P. Bykerk[1,12] on behalf of CATCH Investigators. *[1]Rheumatology, Hospital for Special Surgery, New York; [2]Johns Hopkins University, Baltimore, United States; [3]McGill University, Montreal; [4]Mount Sinai Hospital; [5]University of Toronto Dalla Lana School of Public Health, Toronto; [6]Universite de Sherbrooke, Sherbrooke; [7]Institut de Rheumatologie, Montreal; [8]University of Manitoba, Winnipeg; [9]University of British Columbia, Vancouver; [10]University of Western Ontario, London; [11]Southlake Regional Health Center, Newmarket; [12]Rheumatology, Mount Sinai Hospital, Toronto, Canada*

**Background:** In RA, synthetic glucocorticoids (steroids) are often used as "bridge therapy" to rapidly control symptoms while allowing slower-acting DMARDs time to reduce disease activity. Whether early use of steroids in conjunction with conventional DMARDs has an added benefit for achieving early remission is unknown.
**Objectives:** To describe the frequency of early steroid use in a national observational cohort of ERA patients seen by rheumatologists in routine clinical practice and to estimate the extent to which early use of steroids is associated with achieving early remission at 6 months.
**Methods:** We analyzed baseline and 6-month follow up data from the prospective multi-center Canadian early ArThritis CoHort (CATCH). The study sample included participants meeting 1987 or 2010 ACR/EULAR criteria for RA, symptom duration ≤12 months, with DAS28 moderate-high disease activity at enrolment and medication information and follow-up DAS28 scores at 6 months. Mixed-effects logistic regression was used to estimate independent effects of early steroid use on remission status at 6 months after adjusting for sociodemographics (age, sex, education, comorbidities, smoking), and RA characteristics (symptom duration; presence of erosions, DAS28 and HAQ at baseline) including treatment at enrolment. A random effect for study center was specified to appropriately account for dependencies in the data.
**Results:** The analytic sample included 1170 CATCH participants and was mostly female (n=855; 73%) with a mean [SD] age of 54 [15] and symptom duration of 6 [3] months. At entry, 640 (55%) used steroids (oral only 264 [23%]; parental only 295 [25%]; both: 81 [7%]). Patients receiving steroids were older, male, had shorter symptom duration, a higher DAS28, and more swollen and tender joints ($p<0.003$). Steroids were most commonly used with MTX (frequency [%]: 513 [80%]; MTX mono: 194 [30%]; MTX combo; 319 [50%]; biologics: 10 [2%]; other treatment strategies: 117 [18%]). At 6 months, 393 (34%) were in DAS28 remission. After adjusting for treatment and other covariates, neither oral not parenteral steroids were independently associated with remission status at 6 months, though there was a trend ($p=.07$) for patients receiving both oral and parenteral steroids to have a lower odds of being in remission (see table).

Impact of early steroid use on remission status at 6 months

| | Odds Ratio | 95% Confidence Interval |
|---|---|---|
| Oral only | 0.79 | 0.53–1.17 |
| Parenteral only | 0.85 | 0.59–1.23 |
| Oral and parental | 0.56 | 0.31–1.04 |

**Conclusions:** Findings from this large national ERA cohort showed that steroids were commonly used as early adjunctive therapy in routine practice and that patients receiving steroids were more likely to be older, male, have higher disease activity and more affected joints. Early steroid use (oral or parenteral) was not independent associated with early remission at 6 months, although use of both may be a negative prognostic indicator.

## THU0187 SAFETY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR: INTEGRATED DATA ANALYSIS FROM THE GLOBAL CHRONIC PLAQUE PSORIASIS CLINICAL TRIALS

R.G.B. Langley[1], A.D. Cohen[2], P. Foley[3], C.E.M. Griffiths[4], M. Lebwohl[5], C. Leonardi[6], K. Winthrop[7], J. Proulx[8], S.T. Rottinghaus[9], R. Wolk[8], J.R. Thompson[8], S. Tatulych[8], L. Mallbris[10], R. Swanson[11]. *[1]Department of Medicine, Dalhousie University, Halifax, Canada; [2]Department of Quality Measures and Research, Clalit Health Services, Tel Aviv, Israel; [3]University of Melbourne, Parkville, Australia; [4]Dermatology Centre, Salford Royal Hospital, University of Manchester, Manchester, United Kingdom; [5]Kimberly and Eric J. Waldman Department of Dermatology, Icahn School of Medicine at Mount Sinai, New York; [6]St Louis University Department of Dermatology, St Louis; [7]Oregon Health and Science University, Portland; [8]Pfizer Inc; [9]Formerly of Pfizer Inc, Groton; [10]Formerly of Pfizer Inc, Collegeville; [11]Pfizer Inc, New York, United States*

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis that is being investigated for psoriasis.
**Objectives:** To report pooled trial safety data in patients with psoriasis to expand knowledge around the safety profile of tofacitinib in inflammatory diseases.
**Methods:** The 1-year randomised controlled trials (RCT) group included patients with psoriasis who received ≥1 dose of tofacitinib 5 or 10 mg BID in three 1-year Phase 3 RCTs. The integrated safety group included patients with psoriasis who received ≥1 dose of tofacitinib in four Phase 3 studies (5 or 10 mg BID) or a long-term extension (LTE) study. In the LTE study, patients entered following one Phase 2 study or the Phase 3 studies and received 10 mg BID (for 3 months), then 5 or 10 mg BID (ongoing, database not locked, data cut-off April 4, 2014). Incidence rates (IR; patients with events/100 patient-years) were calculated for the 1-year RCT and integrated safety groups. For the integrated safety group, data were pooled across doses.
**Results:** In the 1-year RCT group, 2436 patients received tofacitinib (5 mg BID, n=1217; 10 mg BID, n=1219), with a median of 253 days of tofacitinib exposure (range: 1–431, first and third quartiles: 168, 364). In the integrated safety group, 3623 patients received tofacitinib, with a median of 527 days of tofacitinib exposure (range: 1–1344, first and third quartiles: 261, 766). Serious infection IRs were 1.37 and 2.42 respectively for 5 and 10 mg BID in the 1-year RCT group, and 1.68 in the integrated safety group. Herpes zoster IRs were 1.00 and 2.32 for 5 and 10 mg BID in the 1-year RCT group, and 2.55 in the integrated safety group. Malignancy (excluding non-melanoma skin cancer [NMSC]) IRs were 1.12 and 0.81 for 5 and 10 mg BID in the 1-year RCT group, and 1.00 in the integrated safety group. NMSC IRs were 0.63 and 1.27 for 5 and 10 mg BID in the 1-year RCT group, and 0.74 in the integrated safety group. Major adverse cardiovascular event IRs were 0.50 and 0.23 for 5 and 10 mg BID in the 1-year RCT group, and 0.37 in the integrated safety group. In the 1-year RCT group, 95% confidence intervals for 10 vs 5 mg BID hazard ratios included 1 for each of these events.
**Conclusions:** Serious infection, herpes zoster and NMSC IRs were numerically, but not statistically, higher with 10 vs 5 mg BID. IRs were similar in the RCT group and the integrated safety group, indicating that IRs are stable over time. Tofacitinib was well tolerated in patients with plaque psoriasis – including up to 44 months of exposure for some patients in the ongoing LTE study at data cut-off.

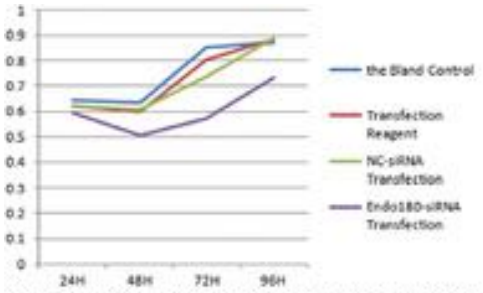
## THU0188 EFFICACY AND SAFETY OF ADD-ON TREATMENT OF TACROLIMUS VERSUS LEFLUNOMIDE IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO METHOTREXATE: A 24-WEEK DOUBLE-BLINDED RANDOMIZED NON-INFERIORITY STUDY



K. Shin[1], H.J. Baek[2], Y.M. Kang[3], S.W. Kang[4], H.S. Cha[5], J.B. Jun[6], S.H. Park[7], Y.J. Lee[8], Y.W. Song[9]. *[1]Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul; [2]Division of Rheumatology, Department of Internal Medicine, Gachon University Gil Hospita, Incheon; [3]Division of Rheumatology, Department of Internal Medicine, Kyungpook National University Hospital, Daegu; [4]Division of Rheumatology, Department of Internal Medicine, Chungnam National University Hospital, Daejeon; [5]Division of Rheumatology, Department of Internal Medicine, Sungkyunkwan University, Samsung Medical Center; [6]Division of Rheumatology, Department of Internal Medicine, Hanyang University, Hospital for Rheumatic Disease; [7]Division of Rheumatology, Department of Internal Medicine, Catholic University of Korea, Seoul St Mary's Hospital, Seoul; [8]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam; [9]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul National University Hospital, Seoul, Korea, Republic Of*

**Background:** Tacrolimus (TAC) is used as a disease modifying antirheumatic drug (DMARD) in rheumatoid arthritis (RA). Combination of TAC with methotrexate (MTX) has been shown to be effective and safe in RA, yet comparative clinical studies are insufficient to date.
**Objectives:** To investigate the efficacy and safety of TAC versus leflunomide (LEF) when combined with MTX in RA patients
**Methods:** The PLATINUM-X study is a 24-week multi-center, double-blinded randomized non-inferior (phase 4) study targeting RA patients with moderate to active disease activity (DAS28(ESR) >3.2) that had a inadequate clinical response to MTX. Patients were randomized into the TAC or LEF (add-on) group. The initial daily dose of TAC and LEF were 1.5 mg and 10 mg, respectively for 4 weeks, then increased to 3 mg, 20 mg until the end of the study. Clinical (DAS28, Korean (K-) HAQ) and laboratory data were obtained at 4, 8, 16, and 24 weeks. The primary endpoint was to compare DAS28 in both groups at 24 weeks. Non-Inferiorly was established if the upper limit of the 95% confidence interval (CI) for DAS28 difference was less than 0.7. Secondary endpoint variables included DAS28, K-HAQ as well as swollen/tender joint counts at each visit. Safety profiles were assessed at each patient's visit. The per protocol set was used for statistical analysis.
**Results:** Eighty seven patients were screened in 9 centers, and 75 patents were randomized into 2 groups. Baseline demographics of patients were comparable with baseline DAS28 being 4.54 ± 0.61 and 4.91 ± 1.01 in the TAC and LEF group, respectively. TAC was non-inferior to LEF in terms of reduction of DAS28 at 24 weeks (mean difference -0.0565, CI -0.6513, 0.5384). Improvement of DAS28, K-HAQ throughout each visit was not statistically different between the 2 groups. Yet, reduction in tender joint count was significant in the TAC group compared with LEF (-5.97 ± 4.89 versus -3.08 ± 5.55 at 24 weeks, $p$=0.0145). There was more numbers of adverse events (AE) or adverse drug reactions in the LEF group (89 in LEF and 64 in TAC); 6 patients presented transaminitis in the LEF group compared with 2 in TAC.
**Conclusions:** The efficacy of TAC plus MTX is non-inferior to LEF combined the MTX, with reasonable safety profile in RA patients with moderate to active disease activity (cris.nih.go.kr KCT0000781).

## THU0189 INCREASED EXPRESSION OF THE COLLAGEN INTERNALIZATION RECEPTOR ENDO180 IN FIBROBLAST-LIKE SYNOVIOCYTES OF PATIENTS WITH RHEUMATOID ARTHRITIS

L. Yan, F.L. Kai, G.X. Hua. *Division of Rheumatology, Department of Internal Medicine, The 3rd Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** Hyperproliferative and invasiveness are the characteristics of fibroblast-like synoviocytes in rheumatoid arthritis (RA-FLSs), which contribute mainly to RA disease progression and ultimately to joint destruction. Endo180 is a recycling endocytic receptor that has functions to regulate cell migration and bind to internalize collagens. However, the expression of Endo180 in RA-FLSs and its underlying mechanisms remain unclear.
**Objectives:** The aim of this study was to examine the expression of Endo180 in RA-FLSs and the role it played in RA pathological process.
**Methods:** Tissues were collected from RA patients with joint replacement surgery or arthroscopy and RA-FLSs were obtained by tissue culture;Westren blotting was used to measure the expression of Endo180 in RA-FLSs. Chemically synthesized small interference RNA (siRNA) specifically targeting Endo180 gene was transfected into RA-FLSs by cationic liposome; The interference efficiency of Endo180-siRNA on the production of Endo180 RNA and protein was determined by RT-qPCR and Western blotting respectly; The proliferative inhibition rate was examined by CCK8 assay and the migration of RA-FLSs were examined by Transwell assay.
**Results:** Expression of Endo180 was obviously higher in fibroblast-like synoviocytes in RA than OA and the traumatic patients. And its expression level has positive correlation with disease activity described as DAS28. The proliferative inhibition rate was obviously higher in the Endo180-siRNA group than the control groups ($P<0.05$) after transfection for 48h (16.31%±1.17%), 72h (23.53%±2.62%), 96h (18.01%±1.96%). Transwell migration assay demonstrated the RA-FLSs through the transwell membrane in Endo180-siRNA group (21.27±6.35) were lesser than the NC-siRNA group (80.20±11.12) ($P<0.05$) and the blank control group (82.17±10.36) ($P<0.05$).

Knocking-down Endo180 in RA-FLSs decreases cell proliferation. RA-FLSs were transfected with Endo180-siRNA or a negative control for 24h, 48h, 72h, and 96h respectively and the cell proliferation was assessed by the CCK8 assay.

**Conclusions:** Endo180 may play a role in the regulation of proliferation and migration of RA-FLSs, which may provide beneficial therapeutic effects in RA.

## THU0190 A SIX-WEEK PROGRESSIVE RESISTANCE TRAINING CLASS IMPROVES FUNCTION AND FATIGUE IN RA PATIENTS

B. Berntzen[1], L. Erwood[1], T. Bellerby[1], E. Price[2], D. Collins[2], L. Williamson[2]. *[1]Great Western Hospital, Swindon, United Kingdom; [2]Rheumatology, Great Western Hospital, Swindon, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is associated with adverse changes in body composition and physical function that persist despite pharmaceutical treatment. Randomised control trial evidence has shown that Progressive Resistance Training (PRT) is safe and efficacious in restoring lean mass and function in patients with RA. We set up our own PRT programme for RA patients to explore whether similar results could be achieved in an NHS setting.
**Methods:** RA patients were invited to attend a PRT programme of six, weekly class held under the supervision of a Senior Physiotherapist. Newly diagnosed and established RA were included. The exercises used within the circuit are: wall slides, chest press, leg extension, rowing, balance board work, triceps extensions, bicep curls, clam, bridging, standing calf raises and step ups. Classes included up to 10 patients at a time. Data collected at induction and after six weeks included demographics, BMI, percentage body fat, grip strength, 60 second Sit to Stand test, HAQ and FACIT (fatigue) scores. After the six-week PRT programme patients were encouraged to continue at home or referred to their local gym.
**Results:** Of 34 RA Patients invited, 27 started and 21 completed the 6 week PRT course. Mean age 54 (range 17–78) years; 71% F; 50% RF positive. 11 (32%) patients were diagnosed within 3 months of starting the class. There was no difference in results between recently diagnosed and established RA patients. After six weeks there was a significant improvement in: HAQ mean (range) 1 (0–2.9) vs 0.8 (0–2.5) p=0.03; Body Fat Composition mean (range) 38.0% (21.5%>51%) vs 36.9% (26.3%>48.2%) p=0.02; Sit to Stand mean (range) 20.0 (8–36) vs 23 (9–42) p=0.02. There was a trend towards improvement mean (range) in: handgrip strength 22.0 (2–54) vs 25.8 (5–54) p=0.21 and FACITF score 29.5 (18–49) vs 35.6 (19–49) p=0.05.

| | BMI | Sit to stand (60 secs) | Grip strength right (kg) | Grip strength left (kg) | FACITF | Body fat % | HAQ |
|---|---|---|---|---|---|---|---|
| Baseline mean | 30.9 | 20.0 | 22.5 | 22.0 | 29.5 | 38.0 | 1 |
| 6 week mean | 30.3 | 23.0 | 27.3 | 25.8 | 35.6 | 36.9 | 0.8 |
| p | 0.49 | 0.02 | 0.08 | 0.21 | 0.05 | 0.02 | 0.03 |

**Conclusions:** We present an effective model for PRT workable in the NHS, which encourages patient to take control of their own exercise regimes. The class setting fosters motivation, confidence and a belief in exercise as part of effective treatment. This brief intervention was associated with significant improvement in various aspects of physical function, Grip strength, HAQ and Fatigue scores.

## THU0191 JAK-STAT PATHWAY STIMULATION, A NEW CAUSE OF INFLAMMATORY ARTHRITIS

M. Shaikh[1], R. Gilliver[2], A. Ostor[3]. *[1]Rheumatology Research Unit, Addenbrooke's Hospital, Cambridge University Hospitals; [2]Rheumatology; [3]Rheumatology Research Unit, Cambridge University Hospitals, Cambridge, United Kingdom*

**Background:** Downregulation of the JAK-STAT signalling pathway with agents such as tofacitinib (a JAK inhibitor) is emerging as effective in the management of rheumatoid arthritis. It is conceivable therefore that upregulation of this pathway could result in inflammatory arthritis. The thrombopoietin receptor agonists eltrombopag and romiplostim, used to treat immune thrombocytopaenia (ITP), stimulate the JAK-STAT pathway. A frequent side effect of these drugs is arthralgia, in up to 26% of patients.
**Objectives:** To highlight thrombopoetin receptor agonists as a potential cause of inflammatory arthritis.
**Methods:** We present a 62-year-old male who developed florid inflammatory arthritis following initiation of eltrombopag for ITP.
**Results:** Mr H was first diagnosed with ITP in 1997, with splenectomy in 1998. Rituximab treatment in 2014 was ineffective for his persistent thrombocyopaenia. Eltrombopag was commenced and titrated to 50mg daily. Three months later he developed new left knee pain with an effusion. Following a dose increase to 50/75mg (alternate days), the arthritis progressed to involve the shoulders, wrists and hands bilaterally. He noted joint stiffness, worse in the mornings, particularly in the small joints of the hands with associated swelling and difficulty making a fist. On examination, he displayed bilateral swollen wrists, metacarpophalangeal and proximal interphalangeal joints with reduced range of movement. Blood tests showed CRP <5mg/L, ESR 16mm, uric acid 326μmol/L, with rheumatoid factor, anti-CCP antibodies and ANA all being negative. Plain radiographs identified moderate degenerative changes in the hands, however MRI of the left knee showed a significant joint effusion. Ultrasonography showed moderately severe synovitis of the right wrist and mild synovitis of the left wrist, with increased power Doppler signal. Three months after eltrombopag dose reduction to 50mg daily, the arthritis in the hands improved such that he could form a fist. Eltrombopag was reduced and weaned, leading to further improvement in his symptoms.
**Conclusions:** To our knowledge this is the first case of a patient developing inflammatory arthritis following treatment with JAK stimulation. Interestingly, our patient was seronegative for both rheumatoid factor and anti-CCP, but had synovitis on ultrasound. The temporal and dose-related correlation between eltrombopag initiation and inflammatory arthritis, in the absence of other causes, suggests an association. Mechanistically this is likely to be via the binding of eltrombopag to dendritic cell thrombopoietin receptors with subsequent JAK2-STAT5 activation. Conversely inhibition of JAK signalling by methotrexate or the JAK inhibitors tofacitinib and baracitinib is used in the treatment of inflammatory arthritis. While most rheumatologists are aware of the therapeutic benefits of JAK inhibitors, the effects of potential stimulators of the pathway are less well known. It is possible that increasing use of these drugs may result in a rise in inflammatory arthritis.

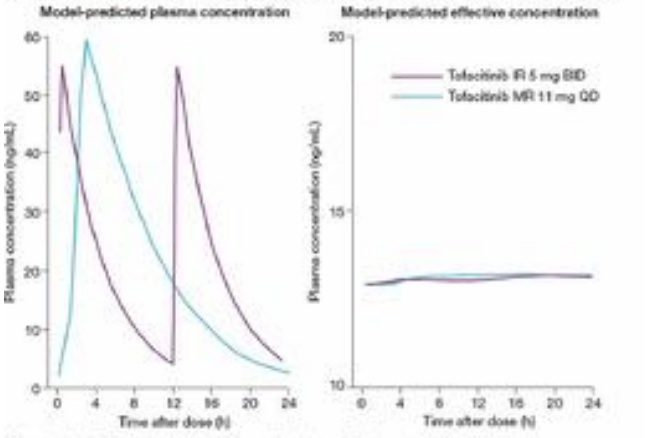
## THU0192 EVALUATING PHARMACOKINETIC PREDICTORS OF TOFACITINIB CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS

M. Lamba[1], D. Furst[2], A. Dikranian[3], M. Dowty[1], M. Hutmacher[4], D. Conrado[1], T. Stock[5], C. Nduaka[5], S. Krishnaswami[1]. *[1]Pfizer Inc, Groton; [2]University of California, Los Angeles; [3]San Diego Arthritis Medical Clinic, San Diego; [4]Ann Arbor Pharmacometrics Group, Ann Arbor; [5]Pfizer Inc, Collegeville, United States*



**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). A extended-release (XR) formulation to provide a once-daily (QD) dosing alternative to the available 5 mg twice daily (BID) immediate-release (IR) formulation has been developed.[1]

**Objectives:** To determine the most relevant pharmacokinetic (PK) parameter driving the clinical response of tofacitinib to inform clinical development of the MR formulation.

**Methods:** Clinical efficacy data (Disease Activity Score [DAS] and ACR 20/50/70 responses) from 5 Phase 2 RA dose-ranging studies of IR 1–30 mg BID and IR 20 mg QD across ~1500 patients were analysed. Dose- and exposure-response (E-R) models were developed to characterise the time course of changes in DAS, including quantifying the delay between concentration and response, and to compare the predictive abilities of various PK parameters (total drug exposure as measured by area under the concentration-time profile [AUC], and peak [$C_{max}$] and minimum [$C_{min}$] plasma concentrations). Non-clinical efficacy data from a dose-fractionation study of multiple IR QD and BID doses using the murine collagen-induced arthritis (mCIA) model were also analysed to delineate the predictive ability of PK parameters. The relationship between tofacitinib exposure metrics and incidence of safety outcomes was explored using linear logistic models.

**Results:** The E-R model yielded an equilibration half-life of 3.2 weeks for changes in DAS, substantially longer than the PK half-life of tofacitinib (~3 hours). Application of this model to plasma PK profiles of MR and IR yielded superimposable predicted effective concentrations for both regimens (Fig 1). In a dose-ranging Phase 2 study, analyses of the IR 20 mg QD dose (similar AUC to the IR 10 mg BID dose, but 86% lower $C_{min}$ and ~2-fold higher $C_{max}$) demonstrated similar efficacy to the IR 10 mg BID dose. DAS mean (standard error) change from baseline was -1.72 (0.14) for IR 20 mg QD vs -1.82 (0.15) for IR 10 mg BID; ACR 20/50/70 rates were 56/36/24% for IR 20 mg QD vs 58/28/12% for IR 10 mg BID at Week 12. Statistical comparison of PK parameters favoured AUC as a better predictor ($p<0.05$) of DAS changes than $C_{max}$ or $C_{min}$, with little added value of $C_{max}$ or $C_{min}$. In the mCIA model, BID and IR QD E-R curves were well aligned for AUC as the predictor, as demonstrated by concordance of concentrations producing 50% of maximum response. Comparing the predictive ability of AUC, $C_{max}$ and $C_{min}$ for safety events of interest (eg serious infections) also supported AUC as the most relevant PK parameter (data not shown).

**Figure 1. Predicted Steady-State Tofacitinib Concentration-Time Profiles in Plasma and in the Virtual Effect Compartment Following IR 5 mg BID Doses and MR Doses in RA Patients**

BID, twice daily; IR, immediate release; MR, modified release; RA, rheumatoid arthritis

**Conclusions:** These analyses support AUC as the relevant predictor of tofacitinib clinical response and inform clinical development of an MR formulation of tofacitinib for QD dosing.

## THU0193 RESPONSE TO BARICITINIB AT 4 WEEKS PREDICTS RESPONSE AT 12 AND 24 WEEKS IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM TWO PHASE 3 STUDIES

M. Weinblatt[1], P. Taylor[2], Y. Tanaka[3], E. Keystone[4], M. Schiff[5], R. Fleischmann[6], L. Yang[7], V. Arora[7], S. de Bono[7], T. Holzkaemper[7], D. Schlichting[7], T. Takeuchi[8]. *[1]Brigham and Women's Hospital, Boston, United States; [2]Univ of Oxford, Headington, United Kingdom; [3]Univ Occup Environ Health, Fukuoka, Japan; [4]Mt Sinai Hospital, Toronto, Ontario, Canada; [5]Univ Colorado Hospital Rheum, Greenwood Village; [6]Univ Texas SW Medical Center, Dallas; [7]Eli Lilly & Co., Indianapolis, United States; [8]Keio Univ, Tokyo, Japan*

**Background:** Baricitinib (bari), a JAK1 and JAK2 inhibitor, showed significant improvements across multiple measures of disease activity as early as week (wk) 1 that were maintained through wk 52 in ph 3 studies of patients (pts) with active RA.[1,2]

**Objectives:** To determine if, in bari-treated pts, early changes in disease activity predicted later achievement of low disease activity (LDA) or remission.

**Methods:** 1305 pts with inadequate response to methotrexate (MTX) were randomized in RA-BEAM (3:3:2, oral PBO/4 mg bari QD/SC injection adalimumab [ADA] Q2W, 52 wks); 584 MTX-naïve pts were randomized in RA-BEGIN (4:3:4, oral MTX QW/4 mg bari QD/4 mg bari QD+MTX QW, 52 wks). Improvement from baseline (BL) to wk 4 was used to predict LDA or remission defined by Disease Activity Score (DAS28) and Simplified Disease Activity Index (SDAI) at wks 12/24 (bari 4 mg arm, both studies). Early responder and early nonresponder were predefined as Clinical Disease Activity Index (CDAI) improvement ≥6 and <6, respectively, at wk 4.

**Results:** Compared to PBO or ADA (RA-BEAM) or MTX (RA-BEGIN), treatment with bari was associated with rapid decrease in DAS28 and CDAI from wk 1.[1,2] By wk 4, 86% (RA-BEAM) and 85% (RA-BEGIN) of bari pts had a CDAI decrease ≥6. In both studies, LDA/remission rates at wks 12/24 were higher in pts with CDAI improvement ≥6 compared to pts with CDAI improvement <6 from BL to wk 4 (Table). Negative predictive values (NPV) for remission at wks 12/24 associated with CDAI improvement <6 from BL to wk 4 exceeded 90%, indicating that pts with CDAI improvement <6 were highly unlikely to achieve remission; NPV for LDA exceeded 80%.

Table 1. LDA and remission After 12 and 24 weeks of 4 mg baricitinib treatment in RA-BEAM and RA-BEGIN

| Decrease from BL to Wk 4 | LDA (DAS28-ESR ≤3.2) | | Remission (DAS28-ESR <2.6) | |
|---|---|---|---|---|
| | Wk 12 | Wk 24 | Wk 12 | Wk 24 |
| CDAI | RA-BEAM | | | |
| <6 | 2/63 (3.2) | 7/61 (11.5) | 0/63 (0) | 3/61 (4.9) |
| NPV | 96.8 | 88.5 | 100 | 95.1 |
| ≥6 | 111/399 (27.8) | 143/382 (37.4) | 50/399 (12.5) | 81/382 (21.2) |
| CDAI | RA-BEGIN | | | |
| <6 | 0/24 (0) | 4/24 (16.7) | 0/24 (0) | 2/24 (8.3) |
| NPV | 100 | 83.3 | 100 | 91.7 |
| ≥6 | 34/129 (26.4) | 53/124 (42.7) | 21/129 (16.3) | 32/124 (25.8) |

Data are n/N (%) of patients achieving clinical outcome of interest except NPV. NPV = negative predictive value (%).

**Conclusions:** In RA-BEAM/RA-BEGIN, lack of early clinical response to bari 4 mg (failure to achieve CDAI improvement ≥6 at 4 wks) was associated with low rates of LDA/remission at wks 12/24. These results are consistent with similar analyses from previous ph 3 studies of bari.[3] The majority of bari pts had improvement in CDAI ≥6 at wk 4; these decreases were associated with improved clinical responses at wks 12/24. Early identification of pts (4 wks) who are not likely to achieve LDA/remission may be useful in tailoring therapy to individual pts.

## THU0194 A NOVEL REVERSIBILE BRUTON'S TYROSINE KINASE (BTK) INHIBITOR (BMS-986142) PROVIDES FAVORABLE SAFETY, PHARMACOKINETIC, AND PHARMACODYNAMIC PROFILES IN HEALTHY SUBJECTS

S.K. Lee, J. Xing, I. Catlett, R. Adamczyk, A. Griffies, A. Liu, B. Murthy, M. Nowak. *Bristol-Myers Squibb Company, Princeton, United States*

**Background:** BTK is an attractive, novel therapeutic target for autoimmune disease, based on the established mechanistic data via B cell receptor (BCR)-dependent and Fc receptors (FcR)-dependent pathways (Whang et al. Drug Discov Today, 2014;19:1200–4). BMS-986142, a new small molecule reversible inhibitor of BTK, is being developed for the treatment of rheumatoid arthritis (RA) and auto-immune diseases. To support clinical development of BMS-986142, it is important to demonstrate sufficient pharmacodynamic (PD) activity, acceptable pharmacokinetic (PK) profile, and low drug-drug interaction potential with methotrexate (MTX) prior to testing in patients.
**Objectives:** Here we present the outcomes from two phase 1 studies investigating safety, tolerability, PK, PD, and its effect on MTX PK following oral administration of BMS-986142 in healthy subjects.
**Methods:** In Study 1, healthy volunteers (18–50 y) were randomized to receive single doses of BMS-986142 (5 to 900 mg or placebo) or multiple doses of BMS-986142 (25 to 350 mg or placebo once daily [QD] for 14 days) to assess the safety, tolerability, PK, and PD (as measured by CD69 inhibition). In Study 2, safety and tolerability was assessed in healthy males (18–50 y) receiving single doses of MTX alone (7.5 mg) and in combination with BMS-986142 (350 mg QD) while assessing the effect of BMS-986142 on the PK of MTX.
**Results:** BMS-986142 was well tolerated in both studies. In Study 1, a grade 3 SAE (psychosis, 75 mg BMS-986142) not related to study drug was reported in 1 subject; 1 grade 3 AE (blood creatinine phosphokinase elevation, placebo) was also reported. Three drug related grade 1 AEs (headache-SAD, 900mg; back pain-MAD, 200 mg; cough-MAD, placebo) were reported in Study 1. There were no grade 3 AEs reported in Study 2. AEs reported at least twice among all dosing groups are presented in the table. BMS-986142 was rapidly absorbed with peak concentrations occurring within 2 hours and gradually eliminated with a half-life of up to 11 hours, enabling QD dosing in the patient studies. BMS-986142 showed linear PK following either a single- or multiple-dose administration. A dose- and concentration-dependent decrease in CD69 expression was observed following the administration of BMS-986142. Daily administration at 350 mg led to near complete coverage above the IC50 for CD69 inhibition throughout the dosing interval without time-dependent changes. BMS-986142 did not affect the PK of MTX, as the peak concentrations and total exposure were comparable when administered with and without BMS-986142 (adjusted geometric mean ratios [90% CI]: $C_{max}$, 1.046 [0.910, 1.202]; $AUC_{(0\text{-}T)}$, 1.041 [0.950, 1.139]).

| | SAD | | MAD | | |
| | Placebo n=12 | BMS-986142 n=36 | Placebo n=8 | BMS-986142 n=24 | BMS-986142 n=12 |
| Subjects with AEs | 2 | 8 | 4 | 8 | 4 |
| Dizziness | 0 | 1 | 0 | 0 | 2 |
| Headache/tension headache | 1 | 5 | 1 | 1 | 2 |
| Nausea | 0 | 1 | 0 | 0 | 2 |
| Diarrhea | 0 | 1 | 0 | 1 | 0 |
| Cough | 0 | 1 | 1 | 1 | 0 |
| Upper respiratory infection | 0 | 2 | 0 | 1 | 0 |
| Thermal burns | 0 | 1 | 0 | 1 | 0 |

**Conclusions:** BMS-986142 was found to be safe and well tolerated at the doses tested in two phase 1 studies in healthy subjects. It showed favorable PK/PD profile including lack of interaction with MTX and can be safely administered in RA patients that are on background MTX. Overall, BMS-986142 has the potential to show clinical activity in treating autoimmune diseases.

## THU0195 PREFERENTIAL INHIBITION OF IL-6 RELATIVE TO IL-7 SIGNALING PATHWAYS BY ABT-494: EXPOSURE-RESPONSE ANALYSIS OF EX-VIVO DATA FROM TWO PHASE 1 CLINICAL TRIALS AND COMPARISON TO TOFACITINIB

M.-E. Mohamed[1], D. Koenig[2], H.S. Camp[1], S. Jungerwirth[1], A.A. Othman[1]. *[1]AbbVie, North Chicago, United States; [2]AbbVie, Ludwigshafen, Germany*

**Background:** ABT-494 is a Janus activated kinase (JAK) inhibitor that demonstrated robust efficacy in Phase 2 clinical trials in rheumatoid arthritis and is currently being evaluated in Phase 3. ABT-494 has a higher in vitro potency against JAK1 compared to JAK2 and JAK3 isoforms. Selectivity of ABT-494 towards JAK1 has the potential to provide an improved safety profile compared to less selective JAK inhibitors.
**Objectives:** The objective of this work was to characterize the effects of ABT-494 on IL-6 and IL-7 signaling pathways and to compare the in-vivo potency of ABT-494 versus tofacitinib in inhibiting these different pathways in humans.
**Methods:** Data from two Phase 1 clinical studies of ABT-494 immediate-release capsules were included in this analysis. In the first study, single doses of ABT-494 (1, 3, 6, 12, 24, 36, and 48 mg) or placebo were administered to healthy subjects. In the second study, multiple doses of ABT-494 (3, 6, 12, and 24 mg), placebo, or tofacitinib (5 mg) were administered to healthy subjects twice daily for 14 days and multiple doses of ABT-494 (6, 12, and 24 mg) or placebo were administered twice daily to subjects with mild to moderate rheumatoid arthritis. Blood samples were collected to measure plasma concentrations of ABT-494 or tofacitinib and the degree of inhibition of IL-6-induced STAT3 phosphorylation (pSTAT3) and IL-7-induced STAT5 phosphorylation (p-STAT5) as measures of in-vivo inhibition of JAK1 and JAK1/JAK3, respectively, in whole blood. Non-linear mixed-effects modeling was conducted to characterize the relationships between ABT-494 or tofacitinib pharmacokinetics and ex-vivo IL-6-induced pSTAT3 and IL-7-induced pSTAT5. The dataset included 68 subjects who received ABT-494, 23 subjects who received placebo, and 9 subjects who received tofacitinib.
**Results:** Dose dependent inhibition of IL-6-induced pSTAT3 and IL-7-induced pSTAT5 relative to baseline was observed, with maximum inhibition occurring at 1 hour after ABT-494 dose administration. The relationships between ABT-494 or tofacitinib plasma concentrations and IL-6-induced pSTAT3 and IL-7-induced pSTAT5 were adequately described using direct $E_{max}$ models. The relationship between ABT-494 plasma concentrations and the ex-vivo pharmacodynamic effects were consistent in healthy volunteers and rheumatoid arthritis patients. The model-estimated plasma $EC_{50}$ [95% bootstrap confidence interval] values for inhibition of IL-6-induced pSTAT3 and inhibition of IL-7-induced pSTAT5 were 61 [48 to 77] nM and 125 [106 to 143] nM, respectively, for ABT-494 versus 119 [87 to 160] nM and 79 [69 to 91] nM, respectively, for tofacitinib.
**Conclusions:** ABT-494 is more potent than tofacitinib in inhibiting IL-6-induced pSTAT3 (mediated predominantly through JAK1) and is less potent than tofacitinib in inhibiting IL-7-induced pSTAT5 (mediated through JAK1 and JAK3). These results are consistent with higher in vitro potency of ABT-494 against JAK1 compared to JAK3. Results from the ongoing Phase 3 trials will determine whether the improved selectivity profile of ABT-494 will translate into improved benefit to risk profile compared to less selective JAK inhibitors.

## THU0196 GENOME-WIDE TRANS-ANCESTRY META-ANALYSIS OF HERPES ZOSTER IN RHEUMATOID ARTHRITIS AND PSORIASIS PATIENTS TREATED WITH TOFACITINIB

N. Bing[1], H.Y. Zhou[1], B.H. Zhang[1], M. Nagaoka[2], H. Valdez[3], M. Vincent[1], J.D. Clark[1]. *[1]Pfizer Inc, Cambridge, United States; [2]Pfizer Japan Inc, Tokyo, Japan; [3]Pfizer Inc, New York, United States*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of RA. Rates of HZ were higher than seen with other agents used to treat RA in the tofacitinib RA development programme, especially in Japan and Korea.[1] Higher than expected HZ rates were also noted in tofacitinib PsO studies in Japan. Thus, it is important to identify the mechanisms of increased risk of HZ infection for patients (pts) receiving tofacitinib.
**Objectives:** To determine if the increased risk of HZ infection with tofacitinib is associated with genetic risk factors, and whether such factors can inform the mechanisms of increased rate of HZ with tofacitinib and the variation of HZ infection rate across ethnicities.
**Methods:** We performed a trans-ethnic and trans-indication meta-analysis of a genome-wide association study in 5246 tofacitinib-treated pts in RA and PsO Phase 2, 3 and long-term extension (LTE) studies (data cut-off April 2014; LTE ongoing, database not locked), by evaluating ~8 million genetic variants on HZ

event (case vs control) and time to HZ event via logistic and Cox regressions, respectively.
**Results:** After adjusting for age, baseline absolute lymphocyte count, genetically defined ethnicity and concomitant methotrexate use (RA only), we identified 5 loci associated with either increased HZ event rate and/or shorter time to HZ event at a genome-wide significance ($p<5x10^{-8}$). Two associations were noteworthy based on biological plausibility. A SNP near CD83 (and LINC01108) was associated with increased risk of HZ events (meta-analysis OR=3.7, $p=2.1x10^{-8}$). Frequency of the risk allele was low (<3%) in Caucasian pts and rare (<0.1%) in Japanese pts. CD83 is expressed on multiple immune subsets, is a marker of dendritic cell maturation and B-cell activation and is down-regulated in dendritic cells by VZV infection, suggesting a plausible mechanism for increased HZ risk in pts treated with tofacitinib. The second SNP was near *IL-17RB* and was associated with faster rate of HZ onset (meta-analysis HR=3.6, $p=7.6x10^{-10}$); this was driven by a risk allele common in Japanese pts (~17% in general Japanese population) but occurring in <0.2% of Caucasian pts. *IL-17RB* is highly expressed on iNKT2 and iNKT17 cells, whereas iNKT1 cells are *IL-17RB* negative and dependent on JAK-dependent IL-15. iNKT cell deficiency with low production of IFN-gamma by iNKT cells was linked to disseminated VZV in response to vaccination in 2 case reports, despite generally intact immune systems. Overexpression of IL-25, the ligand for IL-17RB, also led to recurrence of VZV, suggesting that the ratio of iNKT1 to iNKT2 and 17 cells is important.
**Conclusions:** Genetic analysis of ~5300 pts treated with tofacitinib identified multiple loci associated with an increased risk of HZ. The risk allele of one SNP was significantly more prevalent in Japanese pts. A possible iNKT cell skewing mechanism was suggested and will be evaluated in future studies.

## THU0197 CONVENTIONAL DMARD THERAPY AND IMPROVEMENT OF DISEASE ACTIVITY IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Rheumatology; [2]Psychology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA). This strategy is being used last years in Colombia. On the other hand a multidisciplinary care team (MCT) model was generated in order to improve outcomes.
**Objectives:** The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 24-month period in patients with conventional DMARD therapy in a large cohort of patients from a Colombian specialized in RA center with a MCT model.
**Methods:** A descriptive retrospective study was performed. Records of patients using conventional DMARD treatment from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. A MCT model means that a patient should be seen by other specialties such as physiatrist, physical and occupational therapy, nutritionist and psychologist at least 3 times a year. We divided patients in three groups: low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission (REM). Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
**Results:** 767 patients were included in this study, 615 (80%) women and 152 (20%) men. Average age was 63 ± 11 years. Concerning to treatment of entire cohort, 76 (6.8%) patients were using Leflunomide alone, 47 (6%) and Metothrexate alone, 164 (21%) Leflunomide plus Metothrexate, 43 (6%), Leflunomide plus other DMARDs, 84 (11%), Metothrexate plus others DMARDs 168 (22%) and 261 (34%) "only" DMARDs without Leflunomide or Metothrexate. At 24 months was observed an increase in percentage of patients in remission/LDA (up to 85%) and a decrease in percentage of patients in MDA/SDA disease activity statistically significant. At beginning DAS28 was 4.07 ± 1.03 and after 24 months of follow-up DAS28 was 2.7 ± 0.72, showed improvement (p<0.00).

| ACTIVITY LEVEL | TIME 0 n (%) | 6 MONTHS n (%) | 12 MONTHS n (%) | 24 MONTHS n (%) |
|---|---|---|---|---|
| REM | - | 230 (29) | 397 (51) | 416 (54) |
| LDA | 194 (25) | 255 (33) | 200 (26) | 243 (31) |
| MDA | 438 (57) | 263 (34) | 163 (21) | 106 (14) |
| SDA | 135 (17) | 19 (2.5) | 7 (0.91) | 2(0.26) |

**Conclusions:** There is a global improvement of DAS28 in a cohort of RA patients receiving only conventional therapy, treated and followed under T2T strategy recommendations and a MCT model. We show real-world data on conventional DMARD utilization in patients with RA in a low income developing country, these observations could be used by decision makers in order to consider health decisions.

## THU0198 BARICITINIB EFFECTS ON LIPID AND NMR-MEASURED LIPOPROTEIN PROFILES IN A PHASE 3 STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Taylor[1], E. Keystone[2], Y. Tanaka[3], D. van der Heijde[4], J. Zhong[5], S. Thanabalasundrum[6], G. Ruotolo[6], D. Schlichting[6], T.P. Rooney[6], W.L. Macias[6], S. Zuckerman[6], S. de Bono[6], M. Weinblatt[7]. *[1]Univ of Oxford, Headington, United Kingdom; [2]Mt Sinai Hospital, Toronto, Ontario, Canada; [3]Univ Occup Enciron Health, Fukuoka, Japan; [4]Leiden Univ Medical Centre, Leiden, Netherlands; [5]Quintiles Transnational INC, Durham; [6]Eli Lilly & Company, Indianapolis; [7]Brigham and Women's Hospital, Boston, United States*

**Background:** Baricitinib (bari), a JAK1 and JAK2 inhibitor, was efficacious compared to placebo (PBO) and adalimumab (ADA) in a 52-week (Wk) Ph 3 study in patients (pts) with active rheumatoid arthritis (RA) and an inadequate response (IR) to methotrexate (MTX)[1].
**Objectives:** To evaluate changes in lipid and lipoprotein profile over 52 wks of treatment with bari or ADA compared with PBO in the aforesaid study.
**Methods:** MTX-IR pts with active RA were randomized 3:3:2 to bari 4mg once daily (QD), PBO, or ADA 40mg biweekly. Lipid profile was evaluated at baseline and at Wks 12, 24, and 52 and nuclear magnetic resonance (NMR)-measured lipoprotein particle size and number at baseline and Wk 12.
**Results:** Treatment with both bari and ADA resulted in significant mean increases from baseline to Wk 12 in total cholesterol (PBO -0.2%, bari 15%, ADA 7%), triglycerides (PBO 1%, bari 17%, ADA 12%), LDL-C (PBO -0.6%, bari 16%, ADA 9%), and HDL-C (PBO 0.8%, bari 17%, ADA 8%). These increases persisted through Wk 52. The NMR lipoprotein profile revealed similar changes for bari and ADA relative to PBO regarding an increase in large LDL, a decrease of all types of small LDL, and increases in IDL, VLDL and subfractions, and total HDL as well as large and small HDL particles (Table 1). Significant increases in total LDL particle numbers were not observed with either bari or ADA.

NMR analyses (mean change from baseline ± SD)

| | Wk 12 | | |
|---|---|---|---|
| | PBO (N=488) | Bari (N=487) | ADA (N=330) |
| Total LDL particles† | –22.4±236.1 | 15.0±282.3 | –33.9±257.4* |
| Large LDL particles | –2.8±158.0 | 81.9±191.7*** | 42.2±182.2*** |
| Small LDL particles | –21.3±285.8 | –81.0±327.3*** | –82.7±349.7*** |
| Medium small LDL particles | –2.9±60.2 | –16.6±67.6*** | –15.5±74.4*** |
| Very Small LDL particles | –18.5±228.7 | –64.4±263.0*** | –67.2±278.6*** |
| Total HDL particles§ | –0.03±4.2 | 4.8±5.3*** | 2.0±4.6*** |
| Large HDL particles | 0.0±2.2 | 1.0±2.7*** | 0.4±2.2** |
| Medium HDL particles | 0.1±2.8 | 0.7±3.5*** | –0.4±3.1 |
| Small HDL particles | –0.2±4.1 | 3.1±5.2*** | 2.0±4.3*** |
| IDL particles† | 1.7±38.6 | 14.0±48.5*** | 6.6±40.4* |
| Total VLDL particles† | –1.7±24.7 | 12.0±28.8*** | 6.1±23.8*** |
| Large VLDL particles | –0.1±2.9 | 1.0±3.3*** | 0.5±2.7** |
| Medium VLDL particles | –0.8±15.7 | 5.5±18.2*** | 3.2±13.7*** |
| Small VLDL particles | –0.8±15.0 | 5.6±17.1*** | 2.3±17.2* |

†Values for LDL and VLDL particles are nmol/L; §Values for HDL particles are μmol/L; Within-treatment p-values, *p≤0.05, **p≤0.01, ***p≤0.001.

**Conclusions:** The increase in LDL-C and HDL-C with both bari and ADA is accompanied by an increase in large LDL, total HDL particles and a decrease in small LDL. The nature of these changes may potentially indicate a more atheroprotective profile than that of the PBO group.

## THU0199 TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN THE TREATMENT OF RHEUMATOID ARTHRITIS: CHANGES IN LYMPHOCYTES AND LYMPHOCYTE SUBSET COUNTS AND REVERSIBILITY AFTER UP TO 8 YEARS OF TOFACITINIB TREATMENT

R. van Vollenhoven[1], E. Choy[2], E.B. Lee[3], A. Hazra[4], A. Anisfeld[5], I. Lazariciu[6], P. Biswas[5], M. Lamba[7], S. Menon[7], J. Hodge[5], J.D. Clark[8], L. Wang[7], S. Krishnaswami[7]. *[1]Amsterdam Rheumatology and Immunology Centre and VU University Medical Centre, Amsterdam, Netherlands; [2]CREATE Centre, Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom; [3]Seoul National University, Seoul, Korea, Republic Of; [4]Pfizer Inc, Collegeville; [5]Pfizer Inc, New York, United States; [6]Quintiles, Saint-Laurent, Canada; [7]Pfizer Inc, Groton; [8]Pfizer Inc, Cambridge, United States*

**Background:** Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Cytokines involved in lymphocyte development, function and homeostasis are known to signal through JAKs.
**Objectives:** To characterise the effects of tofacitinib treatment on absolute lymphocyte counts (ALCs) and lymphocyte subset counts (LSCs) and their reversibility after treatment discontinuation.
**Methods:** ALCs were collected as part of safety monitoring procedures throughout the tofacitinib RA clinical programme. Short-term (ST) changes were evaluated in five Phase (P) 2 studies (tofacitinib 1–30 mg twice daily [BID]; treatment duration 6 weeks–6 months). Long-term (LT) changes were assessed in an LT substudy (LSS) of NCT00413699 (study ongoing; database not locked) in which patients (pts) had received tofacitinib 5 or 10 mg BID for up to 8 years. Reversibility of changes in ALCs was evaluated in pts who permanently discontinued tofacitinib due to lymphopenia as defined by a confirmed ALC $<500$ cells/mm$^3$. Reversibility of changes in LSCs was evaluated in a P2 study (NCT00147498) through a 6-week withdrawal phase after 6 weeks' tofacitinib treatment and in the LSS during a 4 week temporary withdrawal phase in pts with an ALC $\leq$1000 cells/mm$^3$ and $\geq$40% decrease in ALC vs baseline (NCT00413699).
**Results:** In total, there were 1432 and 4867 pts from P2 and LT extension (LTE) studies, respectively. Approximately 1050 pts from LTE study NCT00413699 were enrolled into the LSS for evaluation of ALCs and LSCs (median tofacitinib exposure of 5 years). Pre-treatment baseline for natural killer (NK) cells, B cells, T cells (CD3+, CD4+ and CD8+) were available for 130, 133, 133, 52 and 52 pts, respectively. Effects of tofacitinib on ALCs and LSCs are summarised in Table 1. Tofacitinib treatment resulted in a transient increase in ALC at Month 1, followed by a gradual decline to stabilise below baseline levels by ~4 years. Magnitude and time course of changes in CD4+ and CD8+ T cells mirrored those of ALC. CD4+ and CD8+ cell counts were well correlated with ALC. LT treatment showed higher NK cell counts vs baseline, in contrast to decreases seen after ST dosing. B cell counts increased with ST treatment but returned toward baseline with LT treatment.

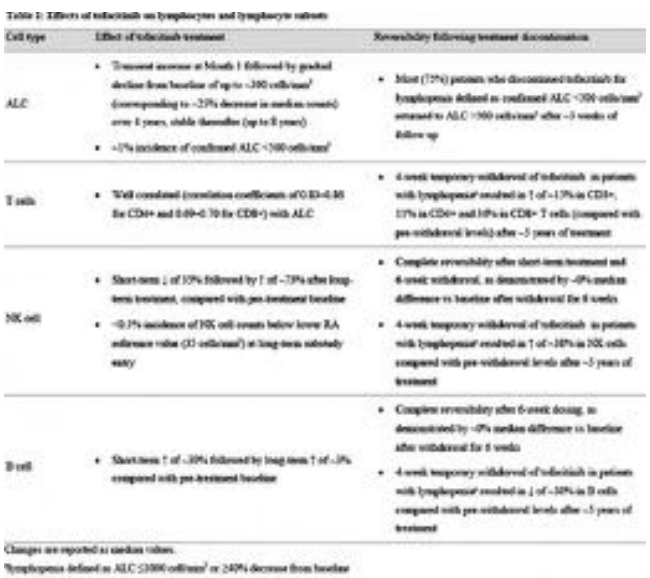

Table 1: Effects of tofacitinib on lymphocyte and lymphocyte subsets

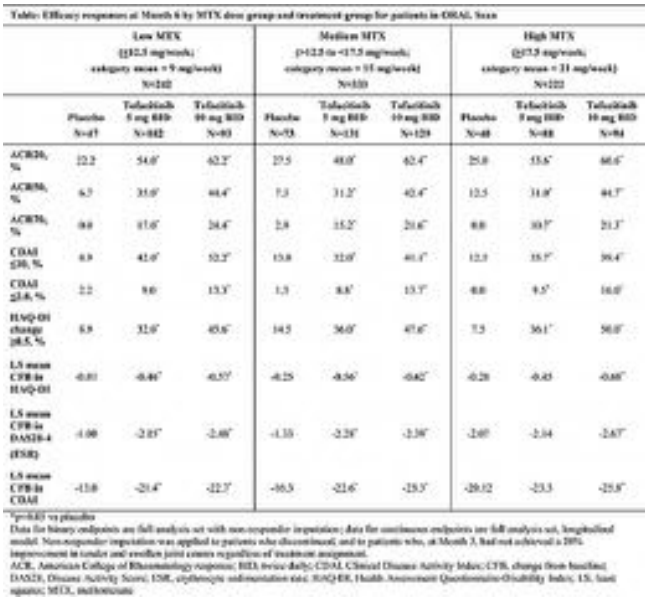
| Cell type | Effect of tofacitinib treatment | Reversibility following treatment discontinuation |
|---|---|---|
| ALC | • Transient increase at Month 1 followed by gradual decline from baseline of up to ~300 cells/mm³ (corresponding to ~23% decrease in median count) over 4 years, stable thereafter (up to 8 years)<br>• ~1% incidence of confirmed ALC <500 cells/mm³ | • Most (75%) patients who discontinued tofacitinib for lymphopenia defined as confirmed ALC <500 cells/mm³ returned to ALC >500 cells/mm³ after ~3 weeks of follow up |
| T cells | • Well correlated (correlation coefficients of 0.83–0.86 for CD4+ and 0.69–0.70 for CD8+) with ALC | • 4-week temporary withdrawal of tofacitinib in patients with lymphopenia* resulted in ↑ of ~13% in CD3+, 15% in CD4+ and 10% in CD8+ T cells (compared with pre-withdrawal levels) after ~5 years of treatment |
| NK cell | • Short-term ↓ of 10% followed by ↑ of ~73% after long-term treatment, compared with pre-treatment baseline<br>• ~0.1% incidence of NK cell counts below lower RA reference value (33 cells/mm³) at long-term substudy entry | • Complete reversibility after short-term treatment and 4-week withdrawal, as demonstrated by ~0% median difference vs baseline after withdrawal for 8 weeks<br>• 4-week temporary withdrawal of tofacitinib in patients with lymphopenia* resulted in ↑ of ~38% in NK cells compared with pre-withdrawal levels after ~5 years of treatment |
| B cell | • Short-term ↑ of ~10% followed by long-term ↑ of ~5% compared with pre-treatment baseline | • Complete reversibility after 6-week dosing, as demonstrated by ~0% median difference vs baseline after withdrawal for 8 weeks<br>• 4-week temporary withdrawal of tofacitinib in patients with lymphopenia* resulted in ↓ of ~30% in B cells compared with pre-withdrawal levels after ~5 years of treatment |

Changes are reported as median values.
*Lymphopenia defined as ALC ≤1000 cells/mm³ or ≥40% decrease from baseline
ALC, absolute lymphocyte count; NK, natural killer; RA, rheumatoid arthritis



**Conclusions:** Tofacitinib treatment was associated with decreases in ALC. Changes in CD4+ and CD8+ T cell counts were reflected in ALC, while B cell and NK cell counts tended to return to or exceed baseline levels. Reversibility is observed following ST and LT dosing.

## THU0200 EFFECT OF METHOTREXATE DOSE ON THE EFFICACY OF TOFACITINIB: TREATMENT OUTCOMES FROM A PHASE 3 CLINICAL TRIAL OF PATIENTS WITH RHEUMATOID ARTHRITIS

R. Fleischmann[1], P. Mease[2], S. Schwartzman[3], L.-J. Hwang[4], K. Soma[5], C. Connell[5], L. Takiya[6], E. Bananis[6]. *[1]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas; [2]Swedish Medical Center and University of Washington School of Medicine, Seattle; [3]Hospital for Special Surgery; [4]Pfizer Inc, New York; [5]Pfizer Inc, Groton; [6]Pfizer Inc, Collegeville, United States*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). ORAL Scan was a 2-year, randomised, Phase 3, clinical trial that evaluated tofacitinib therapy with background methotrexate (MTX) in patients (pts) with RA and an inadequate response (IR) to MTX.[1]
**Objectives:** To study the effect of MTX dose on tofacitinib efficacy in pts from the ORAL Scan study.
**Methods:** In ORAL Scan, MTX-IR pts with RA were randomised 4:4:1:1 to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or placebo with advancement to 5 mg BID or to 10 mg BID at Month (Mo) 3 or Mo 6, in combination with background MTX. MTX dose was stable throughout the study and was categorised as Low ($\leq$12.5 mg/week), Medium ($>$12.5 to $<$17.5 mg/week), or High ($\geq$17.5 mg/week). Endpoints evaluated at Mo 6 included ACR response rates, proportion of pts achieving low disease activity measured by Clinical Disease Activity Index (CDAI $\leq$10), CDAI defined remission rate (CDAI $\leq$2.8), proportion of pts achieving an improvement $\geq$0.5 in Health Assessment Questionnaire-Disability Index (HAQ-DI), and least squares mean change from baseline in HAQ-DI, Disease Activity Score (DAS28-4[ESR]) and CDAI. Binary variables were evaluated with non-responder imputation, and continuous variables were analysed using a longitudinal model. Regression analyses were conducted to evaluate efficacy responses by MTX dose group and other covariates.
**Results:** 797 pts were randomised and treated (tofacitinib 5 mg BID, n=321; tofacitinib 10 mg BID, n=316; placebo, n=160). In total, 242 pts were included in the Low MTX (9 mg mean) dose group, 333 in the Medium MTX (15 mg mean) dose group, and 222 in the High MTX (21 mg mean) dose group. Baseline demographics and disease characteristics were generally similar across MTX dose groups, though weight, BMI, glucocorticoid (GC) use and CDAI were higher in the High MTX dose group. At Mo 6, greater efficacy was seen with tofacitinib compared with placebo for all endpoints across the 3 MTX dose groups (Table). Efficacy for placebo-treated pts was generally numerically greater in the Medium and High MTX dose groups than in the Low MTX dose group. Efficacy with tofacitinib appeared similar regardless of MTX dose group. Regression analyses demonstrated a lack of effect of BMI, GC use and MTX dose groups on efficacy assessments.
**Conclusions:** In this post-hoc analysis, clinical efficacy of tofacitinib at Mo 6 was greater than placebo, and appeared similar regardless of MTX dose, as in these pts, tofacitinib was added to patients that had an inadequate response to MTX. Higher MTX doses did not appear to result in additional efficacy to tofacitinib than

lower doses. A randomised clinical trial is needed in which different doses of MTX are added to tofacitinib in MTX-naïve pts in order to examine the effect of MTX dose on tofacitinib efficacy.

## THU0201 WEAK CORRELATION BETWEEN A MULTI-BIOMARKER DISEASE ACTIVITY SCORE AND CLINICAL RESPONSE WITH BARICITINIB IN A PHASE 2B STUDY IN RHEUMATOID ARTHRITIS

R. Fleischmann[1], M. Genovese[2], E. Keystone[3], M. Weinblatt[4], J. Rancourt[5], E. Nantz[5], D. Schlichting[5], S. Zuckerman[5], W.L. Macias[5], P. Taylor[6]. *[1]Univ. of Texas SW, Dallas; [2]Stanford Univ., Palo Alto, United States; [3]Mt. Sinai Hosp., Toronto, Canada; [4]Brigham and Women's Hosp., Boston; [5]Eli Lilly & Company, Indianapolis, United States; [6]Univ. of Oxford, Headington, Oxford, United Kingdom*

**Background:** Regular disease activity assessment should be a key component of rheumatoid arthritis (RA) care. In patients with moderate-to-severe RA and inadequate response to methotrexate (MTX-IR) treated with baricitinib (bari) 1, 2, 4, or 8 mg in a Phase 2b double-blind study, bari demonstrated clinically and statistically significant improvements at 12 wks including DAS28-CRP <2.6 for 1 (14%), 2 (15%), 4 (37%), and 8 (22%) mg versus placebo (4%; PBO).[1] (Elevated high-sensitivity C-reactive protein (hsCRP) >1.2xULN or erythrocyte sedimentation rate (ESR) >28 mm/h was required at study entry.[1]) In the same study, only modest, statistically significant improvements in a multi-biomarker disease activity score (MBDA)[2] were observed.[3]

**Objectives:** To investigate how MBDA correlates with clinical endpoints in the previously reported study.[3]

**Methods:** Post-hoc statistical analysis was conducted on combined bari 1, 2, 4, and 8 mg (n=189) and paired low (1, 2 mg; n=91) and high (4, 8 mg; n=98) doses using partial correlation analyses, which controls for effects of association with other variables, to assess the relationship between MBDA and absolute change from baseline in 13 disease activity measures.

**Results:** Mean MBDA improved from baseline to Wk 12 for each dose versus PBO,[3] but the two highest correlations were only of moderate strength: hsCRP [a component of MBDA] (r=0.60) and DAS28-CRP (r=0.43). For all other measures, associations with MBDA were significant ($p<0.05$) but of weak magnitude; swollen joint count (SJC) was not significant (Table). The low- and high-dose pairs had mostly weak correlations (not shown); the strongest correlation was with hsCRP (r=0.50, 0.68, respectively; both $p<0.001$).

| Disease activity measures | r† |
|---|---|
| hsCRP | 0.60** |
| DAS28-CRP | 0.43** |
| ESR | 0.32** |
| DAS28-ESR | 0.27** |
| SDAI | 0.27** |
| HAQ-DI | 0.24** |
| Patient's Global Assessment of Arthritis Pain | 0.23** |
| Physician's Global Assessment of Disease Activity | 0.23** |
| American College of Rheumatology Change from Baseline (ACR-N)‡ | –0.20* |
| Patient's Global Assessment of Disease Activity | 0.18* |
| TJC (68 joints) | 0.17* |
| CDAI | 0.16* |
| SJC (66 joints) | 0.04 |

†Pearson partial correlation coefficient (r) assessed relationship between MBDA score and absolute changes from baseline at Wk 12 in the combined dose group. **$p\leq0.001$, *$p<0.05$. P-value calculation based on Pearson correlation inference test. ‡ACR-N measures % improvement from baseline.

**Conclusions:** In MTX-IR patients treated with bari for 12 wks, significant changes in clinical response measures were seen but were not strongly correlated with MBDA. The highest correlations, although statistically significant, were of moderate strength. MBDA score changes did not have a strong correlation to clinical measures with bari. If these observations are corroborated they would suggest that caution is required when assessing clinical response to bari using the MBDA.

## THU0202 CLINICAL OUTCOMES OF RHEUMATOID ARTHRITIS PATIENTS RECEIVING TOFACITINIB MONOTHERAPY IN THE OPEN-LABEL LONG-TERM EXTENSION

R. Fleischmann[1], J. Wollenhaupt[2], L. Wang[3], A. Maniccia[4], K. Kwok[4], L. Takiya[5], R. van Vollenhoven[6]. *[1]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, United States; [2]Schoen-Klinik Hamburg-Eilbek Teaching Hospital, Hamburg, Germany; [3]Pfizer Inc, Groton; [4]Pfizer Inc, New York; [5]Pfizer Inc, Collegeville, United States; [6]Amsterdam Rheumatology and Immunology Centre and VU University Medical Centre, Amsterdam, Netherlands*

**Background:** Treatment options delivering sustained efficacy when given as monotherapy in RA are limited.[1] Tofacitinib is an oral JAK inhibitor for the treatment of RA. Tofacitinib monotherapy demonstrated efficacy in adult patients (pts) with RA in two Phase (P) 3 index studies (ORAL Solo[2] and ORAL Start[3]).

**Objectives:** To present data through Month 84 for safety and Month 60 for efficacy for pts who stayed on tofacitinib monotherapy in long-term extension (LTE) studies.

**Methods:** Data were pooled from two tofacitinib LTE studies (NCT00413699 [ongoing; database unlocked as of Mar 2015 data cut-off] and NCT00661661 [completed; Apr 2014]). Pts from P 1/2/3 tofacitinib index studies received tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background conventional synthetic DMARDs in LTE. For tofacitinib and permitted concomitant RA medications, dose adjustments were allowed for inadequate efficacy or for safety reasons. In this analysis, pts were assigned to tofacitinib 5 or 10 mg BID groups based on average total daily dose in LTE (<15 mg/day or ≥15 mg/day, respectively). Monotherapy was defined as those pts who received tofacitinib

without other DMARDs throughout the LTE. Baseline values were those of the index studies for pts enrolling in LTE within 14 days of index study; for all others, baseline was start of LTE. Safety was evaluated through Month 84 and efficacy through Month 60 due to limited sample size.

**Results:** 1750 pts initiated LTE on tofacitinib monotherapy; 1552 (89%) stayed on monotherapy throughout LTE (495 on 5 mg BID; 1057 on 10 mg BID). For pts staying on monotherapy, mean (max) treatment duration was 1248 (2892) and 1011 (2377) days for 5 and 10 mg BID, respectively. Efficacy responses for tofacitinib monotherapy were stable through Month 60 (Table 1). In the 5 and 10 mg groups, 66% and 82% of pts, respectively, stayed on initial dose throughout LTE. The proportion of pts staying on steroids decreased from 56% to 40% and 41% to 35%, in the 5 and 10 mg groups respectively, from baseline to Month 60. Rates of discontinuation due to lack of efficacy and adverse events (AEs), and of serious infection and malignancy (excluding non-melanoma skin cancer) were low (Table 1).

Table 1: Efficacy responses over time and safety endpoints in patients receiving tofacitinib monotherapy

Efficacy responses

Safety endpoints in patients receiving tofacitinib monotherapy up to data cut-off

| | Tofacitinib 5 mg BID N=495 | Tofacitinib 10 mg BID N=1057 |
|---|---|---|
| Exposure, patient years | 1709 | 2957 |
| Discontinuations, n (%) | 223 (45.1) | 390 (36.9) |
| Due to lack of efficacy | 17 (3.4) | 22 (2.1) |
| Due to AEs | 112 (22.6) | 181 (17.1) |
| Discontinuations due to AEs, IR (95% CI) | 7.2 (6.3, 8.0) | 6.3 (5.4, 7.1) |
| Serious infection, IR (95% CI) | 2.5 (1.8, 3.4) | 2.4 (1.9, 3.0) |
| Malignancies (excluding NMSC), IR (95% CI) | 1.0 (0.4, 1.6) | 0.8 (0.5, 1.1) |

ACR, American College of Rheumatology response; AE, adverse event; BID, twice daily; CI, confidence interval; DAS28-4(ESR), disease activity score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, incidence rate (patients with event per 100 patient-years); N, number of evaluable patients; NMSC, non-melanoma skin cancer

**Conclusions:** In this analysis of pts receiving tofacitinib monotherapy in the LTE studies, nearly 90% of pts stayed on monotherapy, most did not have tofacitinib dose adjustments or add a DMARD and efficacy was sustained over 60 months, with low rates of discontinuation due to lack of efficacy or AEs. Safety was consistent with what has been reported previously.

## THU0203 BARICITINIB TARGETS THE TYPE I IFN/STAT-MEDICATED ACTIVITIES OF HUMAN T CELLS AND DENDRITIC CELLS

S. Kubo, S. Nakayamada, K. Nakano, Y. Tanaka. *The First Department of Internal Medicine, University of Occupational and Environmental Health, Fukuoka, Japan*

**Background:** The JAK/STAT pathway is a potent therapeutic target in autoimmune diseases. We previously reported that tofacitinib, a JAK1/3 inhibitor, suppressed pro-inflammatory cytokine production and co-stimulatory molecule expression on dendritic cells via suppression of IFN/STAT signal and directly inhibited lymphocyte proliferation. To date, baricitinib, a JAK1/2 inhibitor, has shown dramatic effect in the treatment of rheumatoid arthritis. However, the exact targets of the cells and cellular signaling by baricitinib remain unclear.

**Objectives:** To elucidate the mechanisms of action of baricitinib, we shed light on the JAK/STAT signal on human T cells and dendritic cells.

**Methods:** The effects of baricitinib and tofacitinib on the human $CD4^+$ T cells proliferation, phosphorylation of STAT, the maturation of human monocyte-derived dendritic cells, and the cytokine production of human plasmacytoid dendritic cells were investigated.

**Results:** Human T cells were proliferated after stimulation with anti-CD3 and anti-CD28 antibody. However, the T cell proliferation was significantly suppressed by the addition of baricitinib in a dose dependent manner. Both IFN-$\alpha$ and IL-6 induced phosphorylation of STAT1, STAT3 and STAT4 in human T cells. IL-12 induced phosphorylation of STAT4. IL-21 induced phosphorylation of STAT3 and STAT4. However, IL-23 did not induce the phosphorylation of STAT. Baricitinib, as well as tofacitinib, inhibited the phosphorylation of STAT1, STAT3 and STAT4 induced by IFN-$\alpha$, IL-6 and IL-21. Interestingly, the inhibition effect of baricitinib on phosphorylation of STAT4 which was induced by IFN-$\alpha$ was stronger than that of tofacitinib. On the other hand, CD80/CD86 and HLA-DR of human monocyte-derived dendritic cells (MoDCs) were significantly induced at 48 hour after lipopolysaccharide (LPS) stimulation. The CD80/CD86 expression in MoDCs was suppressed by the addition of baricitinib in a concentration-dependent manner, while the expression of HLA-DR was not affected. The induction of CD80/CD86 expression by LPS stimulation was also suppressed by tofacitinib. Moreover, the expression of CD80/CD86 which was induced by LPS was completely suppressed by the addition of an anti-type-I IFN receptor antibody. Baricitinib and tofacitinib suppressed the production of type-I IFN from plasmacytoid dendritic cells; however, it did not affect TNF-$\alpha$ production.

**Conclusions:** Tofacitinib and baricitinib inhibited not only lymphocyte proliferation but also T cell stimulatory capacity of human dendritic cells through suppression of type-I IFN and STATs signaling. Baricitinib characteristically inhibited the activation of IFN/STAT4 signal stronger than that of tofacitinib. Taken together, the different mode of action among JAK inhibitors may affect the clinical effects in patients not only with rheumatoid arthritis but other immune-mediated diseases.

## THU0204 RETENTION RATE OF BIOLOGIC AGENTS AFTER REMISSION INDUCED WITH AND WITHOUT CONCOMITANT GLUCOCORTICOID TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROPENSITY SCORE MATCHED ANALYSIS

S. Asai, T. Kojima, N. Takahashi, K. Funahashi, N. Ishiguro on behalf of TBCR Study Group. *Department of Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Concomitant glucocorticoids effectively increase remission rate in patients with early rheumatoid arthritis (RA) treated with synthetic DMARDs.[1] However, it remains unclear whether concomitant glucocorticoids have additive effects over biologic agents after achieving remission in the patients with RA. Given that drug retention reflects a good balance between effectiveness and tolerability, assessing the retention rate and reasons for discontinuation is important for drug evaluation.

**Objectives:** To compare retention rate of biologic agents for the patients who achieved clinical remission with and without concomitant glucocorticoid treatment [GC(+) and GC(–) groups, respectively], and investigate the predictors of drug discontinuation due to insufficiency in the GC(+) group.

**Methods:** A cohort study was performed using a multicentre registry. A total of 404 patients with RA achieved clinical remission defined as a DAS28-CRP $<2.6$ within the first year of treatment with the first biologic agents. Of all patients, 202 (50%) received concomitant glucocorticoids at achieving remission. Propensity score matching was performed given concerns of treatment-selection bias, and a total of 128 matched pairs of patients were identified. The first year follow-up time point after registration, which almost reflected the time of achieving remission, was considered the baseline in this study. The cumulative retention rate of the first biologic agents was estimated using Kaplan-Meier curves and compared with the log-rank test, and the impact of baseline characteristics on the drug discontinuation due to insufficiency in the GC(+) group was assessed with Cox proportional hazards models.

**Results:** There was good balance across all baseline characteristics after propensity score matching (Table 1). Six of the 128 patients (4.7%) in the GC(–) group discontinued the first biologic agents due to insufficiency during the follow-up period, while 31 of the 128 patients (24.2%) in the GC(+) group did so. According to Kaplan-Meier estimates, the discontinuation rate due to insufficiency for the GC(+) group was significantly higher than that for the GC(–) group (37% vs. 7%, respectively, at 5 years, $P<0.001$) (Fig. 1A). The number of patients who discontinued biologic agents due to adverse events (infection) during the follow-up period was 10 (6) and 11 (6) in the GC(–) and (+) group, respectively.

According to Kaplan-Meier estimates, there was no significant difference among the GC(–) and (+) group in the discontinuation rate due to adverse events (11% vs. 16%, respectively, at 5 years, *P*=0.676) (Fig. 1B). Multivariate analysis using Cox proportional hazards models revealed that Steinbrocker stage (III+IV vs. I+II) (HR: 3.37, 95% CI: 1.09–10.44, *P*=0.035) independently predicted drug discontinuation due to insufficiency in the GC(+) group.

**Table 1** Baseline characteristics of patients after propensity score matching

| Characteristics | GC (-) (n=128) | GC (+) (n=128) | P value |
|---|---|---|---|
| Age, median (IQR) years | 59 (49-66) | 59 (50-65) | 0.945 |
| Female, % | 84 | 83 | 1.000 |
| Disease duration, median (IQR) years | 7(3-16) | 7 (2-14) | 0.548 |
| RF positive, % | 82 | 81 | 0.867 |
| Steinbrocker stage III+IV, % | 63 | 63 | 1.000 |
| Steinbrocker class III+IV, % | 13 | 16 | 0.595 |
| DAS28-CRP, median (IQR) | 2.0 (1.4-2.3) | 2.0 (1.6-2.3) | 0.358 |
| TNF inhibitors, % | 87 | 88 | 0.850 |
| Concomitant MTX, % | 79 | 78 | 1.000 |
| MTX dosage, median (IQR) mg/week* | 8 (6-10) | 8 (6-8) | 0.964 |
| GC dosage, median (IQR) mg/day† | - | 4.0 (2.5-5.0) | - |

GC = glucocorticoid; IQR = interquartile range; RF = rheumatoid factor; DAS28-CRP = Disease Activity Score in 28 joints using the C-reactive protein; TNF = tumor necrosis factor; MTX = methotrexate. *Median among patients receiving the drug. †Prednisolone mg/day or equivalent. Median among patients receiving the drug.

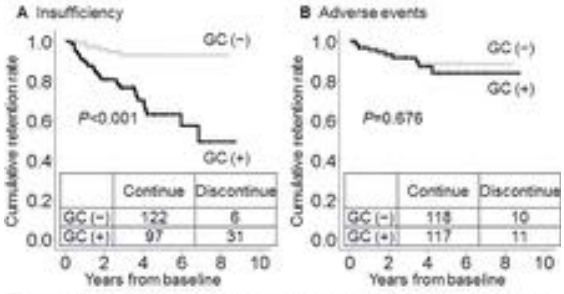

**Figure 1** Kaplan-Meier curves for time to discontinuation due to **A**, insufficiency, and **B**, adverse events stratified by use of glucocorticoids.

**Conclusions:** The patients who achieved remission with concomitant glucocorticoid treatment, especially with Joint destruction existing at achieving remission, had a high risk of subsequent discontinuation of biologic agents due to insufficiency.

## THU0205 ASSOCIATION BETWEEN CONCURRENT METHOTREXATE AND TRIMETHOPRIM-SULFAMETHOXAZOLE USE AND THE RISK OF HOSPITALISATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE POPULATION STUDY

T.-T. Chuang, C.-H. Yang, C.-F. Kuo, S.-F. Luo, K.-H. Yu, L.-C. See. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

**Background:** Concurrent use of methotrexate (MTX) and trimethoprim-sulfamethoxazole (TMP-SMX) has been linked to the development of cytopenia as a result of reduced renal clearance of MTX. However, the risk of adverse outcomes has not been estimated in a population setting.

**Objectives:** This study aimed to examine the risk for emergency department visits or hospitalisation after concurrent use of MEX and TMP-SMX in patients with rheumatoid arthritis (RA) in Taiwan using the National Health Insurance (NHI) data.

**Methods:** This was a retrospective cohort analysis of RA patients identified from the entire NHI database which contains essentially all residents in Taiwan. The case definition of RA was based on a rheumatologist diagnosis with a verification of expert panel commissioned by the Administration of National Health Insurance. Overall we identified 30,285 RA patients between 2000 and 2010. RA patients filled prescription for MTX in 453,114 person-quarters in which 9018 person-quarters they also filled a prescription for TMP-SMX. The main outcome measure was emergency department visit or hospital admission in person-quarters with concurrent fills of MTX and TMP-SMX compared with the rates in person-quarters with MTX prescription only. Multivariable logistic regression was used to adjust for age, sex, comorbidity, and socioeconomic status with a Generalised Estimating Equation (GEE) model to calculated the crude ORs (95% CIs) and adjusted ORs.

**Results:** Hospitalisations were more common in person-quarters with MTX and TMP-SMX use (688 events/8330 quarters) compared with quarters with MTX use alone (20,616 events/423,480 quarters) with a crude OR of 1.49 (95% confidence interval [CI], 1.36–1.62] and an adjusted OR of 1.45 (95% CI, 1.33–1.58). However, the risk for emergency department visits associated with MTX and TMP-SMX use (536 events/8,482 person-quarters) was not higher (21,115 events/422,981 person-quarters). The crude OR was 1.08 (95% CI, 0.97–1.19) for emergency department visits and the adjusted OR was 1.05 (95% CI 0.95–1.15]).

**Conclusions:** MTX use along with TMP-SMX is associated with an increased risk for hospitalisations which suggests a significant drug interaction between MTX and TMP-SMX in RA patients.

**Disclosure of Interest:** None declared

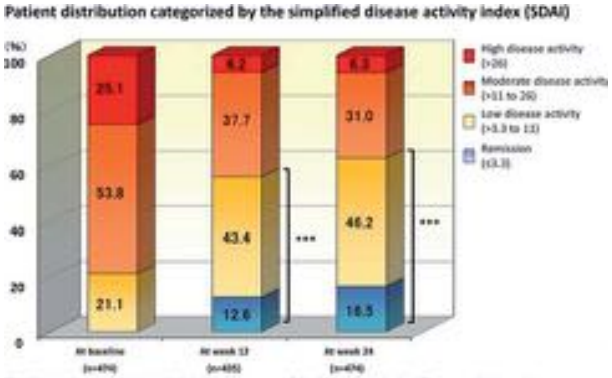
## THU0206 POST-MARKETING SURVEILLANCE OF EFFICACY AND SAFETY OF TACROLIMUS ADD-ON THERAPY IN JAPANESE RHEUMATOID ARTHRITIS PATIENTS WITHOUT AN ADEQUATE RESPONSE TO BIOLOGICAL DMARDS

T. Takeuchi[1], K. Ishida[2], K. Shiraki[2], T. Yoshiyasu[2]. *[1]Keio University; [2]Astellas Pharma Inc., Tokyo, Japan*



**Background:** Tacrolimus (TAC) is an immunosuppressive macrolide that blocks T-cell activation by specifically inhibiting calcineurin; it is widely administered after organ transplantation. TAC was approved in Japan for the treatment of rheumatoid arthritis (RA) in 2005. The emergence of biological disease–modifying anti-rheumatic drugs (DMARDs) has made remission an achievable goal for RA treatment. However, in some patients, biological DMARDs fail to achieve adequate suppression of disease activity or the efficacy of biological DMARDs is reduced. Therapeutic options for such patients include dose increases of biological DMARDs, switching to other biological DMARDs, and add-on use or dose increase of conventional anti-rheumatic drugs. The usage of add-on TAC has been reported in some studies [1,2].

**Objectives:** We report the results of post-marketing surveillance to evaluate the safety and efficacy of TAC add-on therapy with biological DMARDs in Japanese RA patients without an adequate response to biological DMARDs in a real clinical setting.

**Methods:** The observation period of this study was 24 weeks. Six hundred twenty-four patients were included in the safety population and 566 patients were included in the efficacy population. An inadequate response to biological DMARDs was defined as meeting all of the following conditions: Simplified Disease Activity Index (SDAI) >3.3 when TAC was started; both tender joint count and swollen joint count were the same or increased compared to those at 4 to 8 weeks prior to TAC; and biological DMARDs were used for at least 8 weeks prior to TAC. Efficacy was mainly evaluated using the SDAI and EULAR (European League Against Rheumatism) response criteria. SDAI improvement was defined as SDAI ≤11.

**Results:** Mean age was 61.9 years and mean disease duration was 10.5 years. The mean TAC dose was 1.3 mg during the observation period. Adverse drug

**Patient distribution categorized by the simplified disease activity index (SDAI)**

The SDAI analysis population included 474 patients out of the 566 patients in the efficacy population and excluded the patients who were missing baseline data and any week 12 and week 24 data (after tacrolimus administration).
Missing data at the final evaluation point of week 24 were input using the last observation carried forward.
***p<0.001 (McNemar test vs baseline).

reactions (ADRs) occurred in 94 patients and serious ADRs were observed in 11 patients. Infections occurred in 21 patients and serious infections were observed in 8 patients. SDAI remission rate was 16.5% at week 24, SDAI improvement rate was 62.7% at week 24, and the mean SDAI was decreased from 20.0 at baseline to 10.8 at week 24. Interestingly, 40 patients (33.6%) out of 119 patients with high disease activity at baseline achieved SDAI improvement at week 24. Based on EULAR response criteria, moderate to good response rate was 64.7% at week 24.

**Conclusions:** TAC is well tolerated and effective when used as an add-on to biological DMARDs in Japanese RA patients who do not achieve an adequate response to biological DMARDs in a real clinical setting.

## THU0207 DIACEREIN IN COMBINATION WITH METHOTREXATE VERSUS METHOTREXATE ALONE IN THE TREATMENT OF EARLY RHEUMATOID ARTHRITIS

W. Louthrenoo[1], S. Nilganuwong[2], R. Nanagara[3], B. Siripaitoon[4]. *[1]Chiang Mai University, Chiang Mai; [2]Mahidol University, Bangkok; [3]Khonkaen University, Khonkaen; [4]Prince of Songkla University, Songkhla, Thailand*

**Background:** Diacerein is currently registered as a drug for the treatment of osteoarthritis. Evidence from in vitro studies and animal models of rheumatoid arthritis (RA) [1–3] suggest that it may also be a treatment option in early RA.

**Objectives:** To evaluate the efficacy and safety of diacerein in early RA patients with inadequate response to methotrexate (MTX).

**Methods:** Active early RA patients, according to the 1987 ACR revised criteria for RA, were invited to join this randomised, double-blind, placebo-controlled, multicentre phase II study. Inclusion criteria were insufficient response to MTX ($\geq$7.5 mg/week), $<$2 years disease duration, DAS28 $>$4.0, tender joint count $\geq$6/68 and swollen joint count $\geq$6/66. After a one-month run-in period on stable MTX therapy, eligible patients were randomised to receive either diacerein (DAR) 50 mg or matching placebo (PBO) twice daily in addition to MTX. Study assessments were scheduled at baseline (W0), then every 4 weeks through 24 weeks of treatment (W24). The primary endpoint was the ACR20 response criteria at W24. Secondary endpoints included EULAR response criteria for RA, MCII ($\geq$15 mm improvement in pain on VAS) and PASS ($<$41 mm of pain on VAS) response criteria.

**Results:** On 45 patients screened, 40 were randomised (ITT data set), and received at least one dose of study medication (safety data set). Five patients prematurely discontinued the study due to consent withdrawal (DAR: 2; PBO: 1) or unacceptable increase in disease activity (DAR: 2). Both groups were homogeneous at baseline for demographic and disease characteristics, except for a lower tender joint count in the DAR group (16.5±8.8 vs 24.6±13.2, p=0.0220). The efficacy analysis performed on the ITT data set showed that all parameters improved throughout the study in both groups. At W24, 13 patients in the DAR group and 9 patients in the PBO group responded to the ACR20 criteria (p=0.2036), while 15 patients in the DAR group reached a good or moderate EULAR response vs 5 patients in the PBO group (p=0.0016). The DAS28 improved from baseline by 1.26±1.37 and 0.85±1.17 in the DAR and PBO groups, respectively (p=0.1199). At W24, the MCII was met by 13 patients in the DAR group vs 9 patients in the PBO group (p=0.0388), while 16 and 10 patients reached the PASS, respectively (p=0.0014). Rescue medication consumption (paracetamol) was similar in both groups. The sensitivity analysis performed on the per protocol set (DAR: 19; PBO: 20) confirmed the results of the primary analysis. Thirty-one patients reported one or more adverse events (DAR: 16, PBO: 15). The most frequent adverse event (AE) was chromaturia (DAR: 8, PBO: 2), followed by diarrhoea (DAR: 4, PBO: 4) and upper respiratory tract infection (DAR: 2, PBO: 5). Gastrointestinal disorders accounted for 37.5% of all AEs (DAR: 8, PBO: 7). One serious AE was reported in each group (DAR: hip fracture; PBO: pharyngotonsillitis); both were not related to the study medication.

**Conclusions:** Diacerein 100 mg was shown to have efficacy in reducing RA signs and symptoms when combined with MTX. However, more powered clinical trials are needed to confirm these pilot findings.

## THU0208 EFFECT OF DOUBLE FILTRATION PLASMAPHERESIS ON MRI-BONE EROSION IN RA

X. Yu[1], L. Zhang[2], L. Wang[1]. *[1]Department of Rheumatology and Immunology, Traditional Chinese Medicine-Western Medicine Hospital of Cangzhou of Hebei, Cangzhou; [2]Medical Unit, 66019 Troops of Chinese People's Liberation Army, Beijing, China*

**Background:** The primary goal of treating the patient with rheumatoid arthritis (RA) is to maximise long-term health-related quality of life (1). The functional limitation caused by disease activity is reversible in RA patients, caused by joint structure damage is irreversible (2). The progressive structural damage contributes the life-long disability in RA patients (3).

**Objectives:** The current study was conducted to investigate whether the combination therapy of Double Filtration Plasmapheresis (DFPP), Leflunomide and Methotrexate improves bone erosion found through magnetic resonance imaging (MRI) in patients with long-standing rheumatoid arthritis (RA).

**Methods:** Seventy-two RA patients with high active disease of $>$3 years' duration were randomized to receive DFPP in combination with leflunomide and methotrexate (DFPP group), and leflunomide plus methotrexate (no-DFPP group). The primary end point was the improvement in MRI-detected bone erosion over 12 months. Secondary end points include subclinical remission by MRI and clinical remission in DAS44.

**Results:** The study achieved a significant improvement in MRI-detected bone erosion. Bone erosion score of the patients in DFPP group was 11.29±9.55 (mean±SD) at month 12, compared with 14.37±9.55 at baseline ($P<0.001$) and 16.88±8.33 at month12 of the patients in no-DFPP group ($P<0.001$). The patients with a decreased erosion score were reached 84.21% at month 12 in the DFPP group. This study showed significantly greater subclinical remission and clinical remission rates in the DFPP group than in the no-DFPP group ($P<0.001$). Patients with synovitis scores were 0 reached 65.79% of the patients in DFPP group, compared with 0 in no-DFPP group at month 12. The patients with 0 score in synovitis and bone edema reached 55.26% in the DFPP group at month 12. Clinical remission in DAS44 achieved 71.05% at month 12 of the patients in DFPP group, compared with 5.88% of the patients in no-DFPP group. A sustained DAS44 remission for at least 6 months reached 57.89% of the patients in DFPP group at month 12, compared with 0% of the patients in no-DFPP group.

**Conclusions:** The combination therapy of DFPP and DMARDs in long-standing RA patients achieved significant improvement in MRI bone erosion, repair of erosion. The DFPP combination therapy in RA patients had better responses in improving MRI bone erosion and reaching clinical remission and subclinical remission than DMARDs therapy.

## THU0209 CHARACTERIZATION OF CHANGES IN LYMPHOCYTE SUBSETS IN BARICITINIB-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS IN A PHASE 3 STUDY (RA-BEAM)

Y. Tanaka[1], R. Fleischmann[2], M. Schiff[3], T. Takeuchi[4], E. Keystone[5], M. Weinblatt[6], S. Zuckerman[7], M. Issa[7], S. Thanabalasundrum[7], B. Augendre-Ferrante[7], S. de Bono[7], D. Schlichting[7], T.P. Rooney[7], W.L. Macias[7], P. Taylor[8]. *[1]U Occup Environ Health, Fukuoka, Japan; [2]U Texas SW Med Center, Dallas; [3]U Colorado Hospital Rheum, Greenwood Village, United States; [4]Keio Univ, Tokyo, Japan; [5]Mt Sinai Hospital, Toronto, Canada; [6]Brigham and Women's Hospital, Boston; [7]Eli Lilly & Co., Indianapolis, United States; [8]U of Oxford, Headington, United Kingdom*

**Background:** Baricitinib (bari; an oral JAK 1/JAK 2 inhibitor) is in development for patients (pts) with active RA. In healthy subjects, absolute lymphocyte counts (ALC) increased after bari administration, returning to baseline (BL) by 24 hrs.[1]

**Objectives:** To examine changes in ALC and lymphocyte (LYM) subsets in pts with active RA treated with bari (4 mg QD), placebo (PBO), or adalimumab (ADA, 40 mg Q2W).

**Abstract THU0209** – Table 1. ALC/LYM subsets at BL, Wks 4, 12, and 24 (Observed Mean Count)

| | PBO (N=488) | | | | Bari (N=487) | | | | ADA (N=330) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | BL | Wk 4 | Wk 12 | Wk 24 | BL | Wk 4 | Wk 12 | Wk 24 | BL | Wk 4 | Wk 12 Wk 24 |
| ALC, cells/μL | 1820 | 1750 | 1800 | 1800 | 1810 | 2160*** | 1860 | 1830 | 1810 | 2010*** | 2180*** 2140*** |
| T cells, cells/μL | 1300 | 1259 | 1309 | 1301 | 1294 | 1487*** | 1314 | 1286 | 1314 | 1426*** | 1533*** 1553*** |
| B cells, cells/μL | 215 | 208 | 215 | 212 | 209 | 316*** | 309*** | 296*** | 211 | 284*** | 303*** 306*** |
| NK cells, cells/μL | 214 | 215 | 215 | 211 | 223 | 290*** | 188*** | 191** | 211 | 220 | 230* 232* |

*p≤0.05, **p≤0.01, ***p≤0.001 vs PBO. Reference ranges: ALC = 800–4280; T cells = 603–2990; B cells = 107–698; NK cells = 95–640.

**Methods:** 1305 pts with active RA despite MTX treatment were randomized 3:3:2 to PBO, bari, or ADA. ALC, T, and B cell subsets (T: Th1, Th17, CD4, CD8, T reg, CD3+CD4+CD127-/loCD25+; B: switched/nonswitched memory, mature naive, immature transitional), and natural killer (NK) cells were quantified by flow cytometry at BL and wks 4, 12, and 24. Wk 4 phlebotomy was postdose bari or PBO; wks 12 and 24 were predose.

**Results:** ALC and T cells/subsets increased with bari and ADA at wk 4 (generally within normal ranges), returning to near BL at wks 12 and 24 in bari but remaining elevated in ADA (Table). B cells/subsets increased at wks 4 in bari and ADA and remained elevated through wk 24. NK cells were increased at wk 4 in bari and were below BL but within the normal range at wks 12 and 24; NK cells were increased at wks 12 and 24 in ADA. The percentages of pts with ≥1 low NK cell count were 20.5%, 32.6%, and 20.6% in PBO, bari, and ADA, respectively; percentage of pts with ALC CTCAE grade ≥2 were 14.1%, 9.9%, and 10.0%. Through wk 24, serious infection rates were 1.4%, 1.0%, and 0.6% for PBO, bari, and ADA; rates were 1.0%, 1.3%, and 0%, respectively, in pts with ≥1 low NK cell count and 2.9%, 4.2%, and 0% in pts with ≥1 ALC CTCAE Grade ≥2 value. Rates of herpes zoster (HZ) were 0.4%, 1.4%, and 1.2% for PBO, bari, and ADA; rates were 0%, 0.6%, and 0%, respectively, in pts with ≥1 low NK cell count and 1.4%, 2.1%, and 0% in pts with ≥1 ALC CTCAE Grade ≥2 value (no statistically significant differences between treatment groups).

**Conclusions:** Changes in ALC and subpopulations with bari in RA-BEAM were largely within normal ranges and are consistent with previous data.[2] Sustained increases in B cells were observed in bari and ADA. Sustained increases in ALC/T cells were only seen in ADA. A modest reduction in NK cells at wks 12 and 24 with bari was not associated with serious infection or HZ.

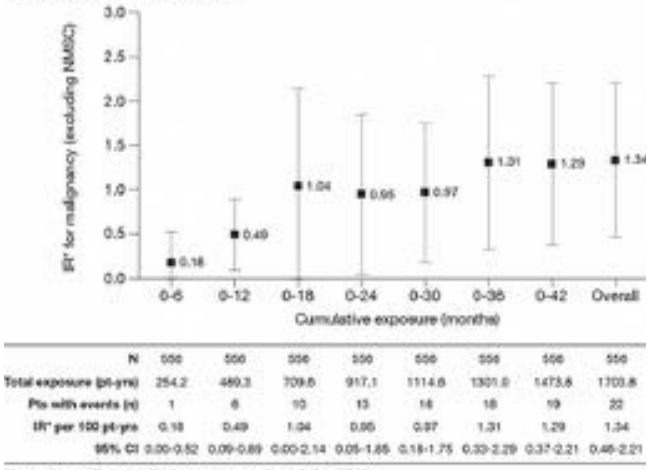
## THU0210 MALIGNANCY DATA IN TOFACITINIB-TREATED JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Tanaka[1], T. Takeuchi[2], H. Yamanaka[3], N. Sugiyama[4], T. Yoshinaga[4], K. Togo[4], J. Geier[5], M. Boy[5], C.A. Connell[5]. *[1]University of Occupational and Environmental Health, Kitakyushu; [2]Keio University; [3]Tokyo Women's Medical University; [4]Pfizer Japan Inc, Tokyo, Japan; [5]Pfizer Inc, Groton, United States*



**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

**Objectives:** To evaluate age- and sex-standardised incidence rates (ASRs) for malignancy (excluding non-melanoma skin cancer [NMSC]) in Japanese RA (JRA) patients (pts) in the tofacitinib clinical programme.

**Methods:** Malignancy data were pooled from 2 Phase (P)2, 1 P3 and 1 open-label long-term extension RA studies conducted in Japan (April 2014 data-cut). Cumulative ASRs were calculated (6-month intervals). Crude incidence rates and standardised incidence ratios (SIRs) were calculated for tofacitinib clinical trials in Japan and Japan Medical Data Center (JMDC) RA sub-populations. General population data[1] were used to calculate ASRs and SIRs. Three sets of criteria for malignancy events (A, B and C) were defined for sensitivity analysis for the JMDC claims data. Compared with Malignancy criteria A, Malignancy criteria B and C included a more restricted definition of malignancy events in order to exclude possible false diagnoses of malignancy.

**Results:** Of 556 tofacitinib-treated JRA pts (1705 patient-years [pt-yrs] of exposure); 22 pts had malignancies. Overall, post-tofacitinib exposure in JRA pts, cumulative ASR (95% confidence interval [CI]) for malignancy (excluding NMSC) was 1.34 (0.46–2.21) pts with events/100 pt-yrs of exposure, and the SIR (95% CI) was 2.13 (1.33–3.22) which overlapped with the SIRs for several JMDC cohorts (Figure).

**Figure.** Cumulative incidence rate* for malignancy (excluding NMSC) for tofacitinib-treated RA patients in Japanese clinical trials

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| N | 556 | 556 | 556 | 556 | 556 | 556 | 556 | 556 |
| Total exposure (pt-yrs) | 254.2 | 469.3 | 709.6 | 917.1 | 1114.6 | 1301.0 | 1473.6 | 1705.8 |
| Pts with events (n) | 1 | 6 | 10 | 13 | 16 | 18 | 19 | 22 |
| IR* per 100 pt-yrs | 0.18 | 0.49 | 1.04 | 0.95 | 0.97 | 1.31 | 1.29 | 1.34 |
| 95% CI | 0.00-0.52 | 0.09-0.89 | 0.00-2.14 | 0.05-1.85 | 0.18-1.75 | 0.33-2.29 | 0.37-2.21 | 0.46-2.21 |

*Age and sex adjusted to the Japanese general population, 2010
CI, confidence interval; IR, incidence rate; NMSC, non-melanoma skin cancer; Pts, patients; pt-yrs, patient-years; RA, rheumatoid arthritis

**Conclusions:** SIRs for malignancies (excluding NMSC) in tofacitinib-treated JRA pts were comparable with JMDC RA sub-populations. Ongoing post-marketing surveillance will further evaluate malignancy among JRA pts treated with tofacitinib.

THU0211 **THE COMBINATION OF CHINESE HERBAL PREPARATION ZHENG QING FENG TONG NING WITH METHOTREXATE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

Z. Feng[1,2,3], M. Cao[1,3], L. Duan[1,3], Z. Wu[1,3]. *[1]The First Affiliated Hospital of Shenzhen University, Shenzhen; [2]School of Medicine, Jinan University, guangzhou; [3]Shenzhen Institute of Geriatric Medicine, Shenzhen, China*

**Background:** Traditional Chinese Medicine (TCM) and TCM preparations for the treatment of rheumatoid arthritis (RA) present its unique advantages, which show the characteristics of overall adjustment, multi-level and multiple targets, and with fewer side effects. Base on its potent immunosuppressive and anti-inflammatory properties, Sinomenine (SIN) or its preparations are taken into consideration for the treatment of RA. A kind of SIN preparations Zheng Qing Feng Tong Ning (ZQFTN) tablet combined with methotrexate (MTX) which was used to treat active RA. And there are several clinical researches showed that ZQFTN plus MTX significantly improved symptoms and prevented disease progression compared to MTX monotherapy. Owning to minor species and inconsistent assessment methods, the results always are paradoxical.
**Objectives:** To assess the efficacy and safety of the combination of Chinese herbal preparation ZQFTN and MTX for the treatment of RA.
**Methods:** Randomized controlled trials (RCTs) data of traditional Chinese preparation ZQFTN combined with MTX versus MTX alone for the treatment of RA were collected by searching the Pubmed, Embase, SpringerLink, CNKI and Wanfang databases up to December 2015. Study selection, data extraction, data synthesis, and data analyses were performed according to the Cochrane standards.
**Results:** Ten RCTs involving 909 participants were included in this meta-analysis. Majority of the included RCTs had poor methodological quality. Compared with MTX, ZQFTN combined with MTX exhibited better therapeutic effects for the treatment of RA (OR=0.29; 95%CI: 0.17 to 0.50). In addition, ZQFTN combined with MTX caused more significant decrease in erythrocyte sedimentation rate (ESR) (MD=-7.40; 95%CI: -13.15 to -1.66), rheumatoid factor (RF) (MD=-14.02; 95%CI: -16.21 to -11.84), C reactive protein (CRP) (MD=-4.47; 95%CI: -7.17 to -1.78), and disease activity score in 28 joints (DAS28) (MD=-0.56; 95%CI: -0.74 to -0.37). Gastrointestinal discomfort and abnormal liver function were more frequently observed in RA patients treated with the combination of ZQFTN and MTX compared to MTX alone (OR=0.45; 95%CI: 0.22 to 1.01 for gastrointestinal discomfort; OR=0.24; 95%CI: 0.09 to 0.63 for abnormal liver function). No significant difference in low leucocyte account (OR=0.43; 95%CI: 0.17 to 1.11) was observed between the two groups. However, erythra with itching was more frequently reported in the MTX monotherapy group compared to the ZQFTN and MTX combination group (OR=4.43; 95%CI: 1.37 to 14.32). Additionally, publication bias was not identified based on the Begg's funnel plots and Egger's regression test.
**Conclusions:** Our study suggests that ZQFTN combined with MTX are more effective than MTX alone for the treatment of RA. However, the adverse effects of the combination of ZQFTN and MTX should be further assessed. Due to the poor methodological quality of included trials, well designed, multi-center, and large-scale RCTs are necessary to further confirm our conclusion.

## Basic science in paediatric rheumatology

THU0212 **MODEL OF ARTHRITIS WITH THE TYPICAL SYSTEMIC MANIFESTATIONS IN WISTAR RATS**

P.F. Litvitskiy[1], V.N. Sakharov[2], E.I. Alexeeva[3], N.A. Mayansky[4]. *[1]Pathophysiology Department; [2]Pathophysioligy Department, I.M. Sechenov First Moscow State Medical University, Russia; [3]Pediatric Rheumatology Department; [4]Laboratory Department, Scientific Center of Children's Health, Moscow, Russian Federation*

**Background:** Autoinflammatory component rather than autoimmune one is to be leading mechanism in the pathogenesis of the systemic juvenile idipathic arthritis (sJIA). Macrophage activation sydrome (MAS) ifatal complication of sJIA also is a result of a hyperactivation of monocytes/macrophages [1, 2]. Given those data, macrophage (M1 and M2) reprogramming becomes a very promising strategy to achieve remission of the disease. Existing animal models of arthritis (particularly collagen-induced arthritis) are not adequate for experimental implementation of this approach, because a key element of their pathogenesis is the formation of autoaggressive antibodies. For a long time, adjuvant arthritis in rats was meant to be the most close (but still not optimal) animal model to investigate the pathogenesis of rheumatoid arthritis and juvenile idiopathic arthritis [3].
**Objectives:** To create the model of arthritis with the typical systemic manifestations caused by the use of a macrophage M1 phenotype differentiation stimulus in Wistar rats.
**Methods:** Day 0: Rats (8 male Wistar rats, 8 month old) were injected intracutaneously (right footpads) with 0,1 ml of complete Freund's adjuvant (CFA, 5 mg/ml, DIFCO LABORATORIES, Michigan, USA) and injected intraperitoneally (i.p.) with 5 μg/kg body weight of lipopolysaccharide (LPS, 10 μg/ml, Medgamal, Russia). In control groups equivalent volumes of physiological 0.9% sodium chloride solution were used. Day 18: rats were reinjected i.p. with LPS (10 μg/kg body weight). Day 39: rats were reinjected intracutaneously (left footpads) with 0,1 ml of CFA and reinjected i.p. with LPS (10 μg per animal).
**Results:** The temperature over the hind paw joints was found to significantly increase ($p<0,05$) for at least 5 days in the group of LPS+CFA (main group) in comparison with the group of CFA only. This effect was confirmed to depend on the degree of inflammation in the joints as significant differences (p=0,019) were observed between left and right hind paws in the main group on the Day 42.
Metatarsal joint diameters were increased significantly ($p<0,05$) for at least 5 days (after Day 39) in the main group and remained increased (non-significantly) until the end of the study.
Pain assessment was performed by the method [4, 5], the severity of local changes in the region of inflamed joints [4]. More pronounced pain and arthritis symptoms after Day 39
**Conclusions:** Our novel animal model of arthritis (combined stimulation by M1 stimulus LPS and CFA) is cheap and easy to reproduce. The model allows to investigate systemic mechanisms of arthritis that pathogenetically are close to the systemic manifestations of arthritis in humans.

## Paediatric rheumatology

THU0213 **ADALIMUMAB IN COMBINATION WITH METHOTREXATE FOR THE TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS: THE SYCAMORE TRIAL**

A.V. Ramanan[1], A.D. Dick[2], A.P. Jones[3], A. McKay[3], P.R. Williamson[3], S. Compeyrot-Lacassagne[4], B. Hardwick[3], H. Hickey[3], D. Hughes[5], P. Woo[4], D. Benton[1], C. Edelsten[4], M.W. Beresford[6]. *[1]University Hospitals Bristol NHS Foundation Trust; [2]Bristol Eye Hospital, Bristol; [3]Department of Biostatistics, University of Liverpool, Liverpool; [4]Great Ormond Street Hospital for Children NHS Foundation Trust, London; [5]Bangor University, Bangor; [6]University of Liverpool, Liverpool, United Kingdom*

**Background:** Uveitis associated with Juvenile Idiopathic Arthritis (JIA) is a major cause of morbidity with potentially sight-threatening complications. Despite current screening and (pre-biologic) therapeutic options, 10–15% of children develop bilateral visual impairment. Tumour necrosis factor alpha plays a pathogenic role in JIA-uveitis. No controlled trials have determined the impact of biologic therapy in JIA-associated uveitis.
**Objectives:** To compare the clinical effectiveness of adalimumab in combination with methotrexate (MTX) versus MTX alone, with regard to controlling disease activity in refractory uveitis associated with JIA.
**Methods:** Patients aged 2 to 18 years with active JIA-associated uveitis, despite stable methotrexate (MTX) treatment for at least 12 weeks, were randomly assigned to adalimumab or placebo in a ratio of 2:1. All patients were treated up to a maximum period of 18 months, with follow up of 2 years from randomisation. All patients received a stable dose of MTX and in addition either adalimumab (20 mg for patients weighing $<30$ kg or 40 mg for patients weighing $\geq 30$ kg, subcutaneous injection every 2 weeks) or placebo.
Primary endpoint was "time to treatment failure" defined by the "Standardisation of the Uveitis Nomenclature" criteria. Ten secondary efficacy endpoints were assessed including quality of life variables and arthritis disease activity measures. Adverse events from both arms were collected. Post-hoc analyses investigated "time to treatment response" and the proportion of responders, failures or those who had no change at three and six months. Statistical analysis of the primary outcome used the log rank test to compare treatment groups with a hazard ratio and 95% confidence interval also being reported.
**Results:** The trial was stopped early for reasons of efficacy after 90 patients had been randomised and the interim analysis met the pre-specified statistical stopping guidelines. The final analysis of the primary outcome showed a positive treatment effect in favour of adalimumab: hazard ratio (HR) 0.25 (95% CI 0.12–0.49); $p<0.0001$. Adverse events were experienced by 88.3% (53/60, 694 events) of patients in the adalimumab group and 90% (27/30, 144 events) of patients in the placebo group. Events were consistent with the known adalimumab profile. Post-hoc analyses showed significant differences showing favourable response to Adalimumab with respect to both the time to treatment response HR 3.15 (95% CI 1.42 to 7.00); $p<0.0027$ and the proportion of responders at both three and six months (p=0.0014 for each timepoint).
**Conclusions:** This trial, the largest of its kind to be conducted in JIA-associated

uveitis, provides evidence of efficacy of adalimumab treatment used in addition to methotrexate in this population. The safety profile of adalimumab was consistent with that previously reported for adalimumab.

## THU0214 SAFETY OF ADALIMUMAB IN PEDIATRIC PATIENTS WITH POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS, ENTHESITIS-RELATED ARTHRITIS, PSORIASIS, AND CROHN'S DISEASE

G. Horneff[1], M.M.B. Seyger[2], D. Arikan[3], J. Kalabic[4], J.K. Anderson[3], A. Lazar[4], D.A. Williams[3], C. Wang[3], R. Tarzynski-Potempa[3], J.S. Hyams[5]. *[1]Asklepios Clinic, Sankt Augustin, Germany; [2]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [3]AbbVie Inc., North Chicago, IL, United States; [4]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany; [5]Connecticut Children's Medical Center, Hartford, CT, United States*

**Background:** Adalimumab (ADA) is a tumor necrosis factor (TNF) inhibitor used for treatment of chronic immune diseases. The safety of ADA treatment in pediatric patients (pts) is particularly important since prolonged treatment for these conditions is often required.
**Objectives:** To evaluate the safety of ADA, alone or in combination with concomitant therapy, in pediatric pts with polyarticular juvenile idiopathic arthritis (pJIA), enthesitis-related arthritis (ERA), psoriasis (Ps), and Crohn's disease (CD)
**Methods:** Safety data from 6 clinical trials and their open-label extension studies were analyzed. Pts treated for pJIA (NCT00048542, NCT00775437, and NCT00690573) and ERA (NCT01166282 [interim week-52 data]) received ADA 24 mg/m$^2$ body surface area every other week (eow) or 20 mg eow ($<$30 kg) to 40 mg eow ($\geq$30 kg). Pediatric pts treated for Ps (NCT01251614) received ADA 0.4 mg/kg (up to 20 mg) or 0.8 mg/kg (up to 40 mg) at week 0, then eow from week 1. Pediatric pts treated for CD (NCT00409682) received open-label ADA induction therapy (160 mg and 80 mg at weeks 0 and 2, respectively, if $\geq$40 kg; 80 mg and 40 mg if $<$40 kg), followed by double-blind maintenance dosing (high dose: 40 mg eow if $\geq$40 kg or 20 mg eow if $<$40 kg at week 4; low dose: 20 mg eow if $\geq$40 kg or 10 mg eow if $<$40 kg at week 4); weekly dosing was allowed for disease flare at week 12 or later; pts received high-dose eow or weekly ADA during an open-label extension (NCT00686374). Events (E) per 100 pt-years (PY) were calculated using adverse events (AEs) reported after the first ADA study dose through 70 days after the last study dose.
**Results:** The analysis included 577 pediatric pts, representing 1423.3 PY of ADA exposure (Table). Over 90% of pts across indications reported treatment-emergent AEs. Common AEs were headache (13.8, 46.9, and 23.8 E/100 PY for pJIA and ERA, Ps, and CD, respectively), nasopharyngitis (12.4, 57.6, and 14.1 E/100 PY, respectively), and upper respiratory tract infection (30.1, 24.7, and 14.9 E/100 PY, respectively). The rates of serious AEs (E/100 PY) were 13.4 for pts with pJIA and ERA, 7.4 for pts with Ps, and 32.3 for pts with CD. One death was reported from an accidental fall (pt with Ps). There were no reports of malignancies, demyelinating disorders, cardiovascular events, pulmonary embolism, reactivation of hepatitis B, Stevens-Johnson syndrome, or erythema multiforme.

Table. Treatment-Emergent Adverse Events Occurring in ≥1% of Patients in Pediatric Adalimumab Clinical Trials

| Treatment-Emergent Event | pJIA and ERA[a] N=216 Exposure, PYs=797.8 | | Pediatric Ps N=111 Exposure, PYs=313.5 | | Pediatric CD N=152 Exposure, PYs=184.4 | |
|---|---|---|---|---|---|---|
| | n (%) | E (events per 100 PY) | n (%) | E (events per 100 PY) | n (%) | E (events per 100 PY) |
| Any AE | 205 (94.9) | 420.8 (52.7) | 103 (92.8) | 328.8 (32.9) | 151 (99.3) | 2630 (82.0) |

—, analysis only in the CD population; ADA, adalimumab; AE, adverse event; CD, Crohn's disease; ERA, enthesitis-related arthritis; pJIA, polyarticular juvenile idiopathic arthritis; Ps, psoriasis; PYs, patient-years.
[a]The ERA study includes interim week-52 data.
[b]Investigator-assessed as possibly or probably related to study drug.
[c]Some were serious.
[d]Events included hypersensitivity (n=36), urticaria (n=27), asthma (n=16), eye pruritus (n=3), rash (n=3), bronchospasm (n=2), generalized pruritus (n=2), injection site urticaria (n=2), drug hypersensitivity (n=1), facial edema (n=1), generalized rash (n=1), and wheezing (n=1). One event of anaphylactic reaction was reported as an immune system disorder.
[e]Events included anemia (n=24), leukopenia (n=17), neutropenia (n=13), lymphopenia (n=11), macrocytic anemia (n=11), microcytic anemia (n=11), and pancytopenia (n=11). 13 events were serious (leukopenia, n=2 and neutropenia, n=2 [JIA]; anemia, n=9 [CD]).
[f]Events included liver disorder (n=2), hepatotoxicity (n=1), and hepatocellular injury (n=1) in the pJIA and ERA group, and 1 serious event of hepatitis in the CD group.

**Conclusions:** The safety profile of ADA in pediatric pts with pJIA, ERA, Ps, or CD was similar across indications, and no new safety signals specific to the pediatric population were identified.

**Acknowledgement:** AbbVie funded the studies (NCT00048542, NCT00775437, NCT00690573, NCT01166282, NCT01251614, NCT00409682, and NCT00686374); contributed to their design; and was involved in the collection, analysis, and interpretation of the data, and in the writing, review and approval of the abstract. ## THU0215 LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (SJIA): 5-YEAR FOLLOW-UP OF AN OPEN-LABEL TRIAL

N. Ruperto[1], H.I. Brunner[2], P. Quartier[3], T. Constantin[1], E. Alexeeva[1], R. Schneider[2], I. Kone-Paut[1], K. Schikler[2], K. Marzan[2], N. Wulffraat[1], S. Padeh[1], V. Chasnyk[1], C. Wouters[1], J.B. Kuemmerle-Deschner[1], T. Kallinich[1], B. Lauwerys[4], E. Haddad[2], E. Nasonov[1], M. Trachana[1], O. Vougiouka[1], K. Leon[5], A. Speziale[6], K. Lheritier[6], A. Martini[1], D. Lovell[2] on behalf of PRINTO/PRCSG. *[1]PRINTO-Istituto Gaslini, Genoa, Italy; [2]PRCSG, Cincinnati, United States; [3]Necker-Enfants Malades Hospital, Paris, France; [4]Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium; [5]Novartis Pharmaceuticals Corporation, East Hanover, United States; [6]Novartis Pharma AG, Basel, Switzerland*

**Background:** SJIA is a distinct and debilitating form of arthritis associated with elevated cytokine (interleukin [IL]-1 and IL-6) levels.[1] Studies have shown that biologics (IL-1 and IL-6 inhibitors), including canakinumab (CAN), a selective, human anti-IL-1β monoclonal antibody, are more effective than conventional medications (NSAIDs, corticosteroids, methotrexate) in the treatment of SJIA patients (pts).[1,2] However, little is known about long-term efficacy and safety of biologics in SJIA.
**Objectives:** To assess long-term efficacy and safety of CAN treatment in a 5-year (yr) follow-up of SJIA pts.
**Methods:** This was an open-label extension study of SJIA patients participating in the clinical trials of CAN, with details reported earlier.[3] Pts (age, 2–20 yrs) received subcutaneous (sc) CAN (4 mg/kg) every 4 wks. Baseline is defined as the starting point of the extension trial. Efficacy measurements were done every 3 months including adapted paediatric response criteria (aACR), clinical inactive disease, clinical remission on medication (12 months of continuous clinical inactive disease) and juvenile arthritis disease activity score (JADAS). Safety was assessed monthly.
**Results:** Overall, 147 pts had a median treatment duration of 3.2 yrs, and 82 (56%) were exposed to CAN for $>$3 yrs (total treatment exposure of $\sim$365 pt-yrs). At 3 month of CAN therapy, 50% of pts had inactive disease, increasing to 49% at last assessment. Of the 107 pts with an aACR 30 at entry to the extension, 61.7% had aACR 100, with 86.0%, 87.9% and 91.6% having aACR 70/50/30 responses, respectively at last assessment. Clinical remission on medication was achieved in 43.0% of pts. Median JADAS10-CRP at baseline was 8.2 (indicating moderate disease activity), and at last assessment, median change from baseline was –0.2, with a median score of 1.8, indicating low disease activity, with similar results noted for JADAS27-CRP. Most common adverse event (AE) was infection (2.0 infections/100 pyr) typically involving the upper respiratory tract. Overall, 47 (32.0%) pts had $>$1 serious AE (SAE; mostly infections, macrophage activation syndrome [MAS] or SJIA flare), 10 cases of MAS (43.8 events/100 pyr) were reported, and 18 (12.2%) pts discontinued due to an AE. No deaths were reported.
**Conclusions:** In patients previously treated with CAN in pivotal trials, response to treatment was sustained or improved during long-term treatment in the extension study. Safety profile of CAN was consistent with safety findings from previous studies.

## THU0216 SAFETY AND EFFECTIVENESS OF ADALIMUMAB±METHOTREXATE FOR THE TREATMENT OF POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS (PJIA): STRIVE REGISTRY

N. Ruperto[1], D.J. Lovell[2], C. Wallace[2], M. Toth[2], I. Foeldvari[1], J. Bohnsack[2], D. Milojevic[2], E. Rabinovich[2], D. Kingsbury[2], K. Marzan[2], P. Quartier[3], K. Minden[1], E. Chalom[2], G. Horneff[1], R.M. Kuester[1], J. Dare[2], M. Heinrich[4], H. Kupper[4], J. Kalabic[4], A. Martini[1], H.I. Brunner[2] on behalf of PRINTO and PRCSG. *[1]Printo-IRCCS, Genova, Italy; [2]PRCSG, Cincinnati, United States; [3]Hopital Necker-enfants Malades, Paris, France; [4]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany*

**Background:** JIA is the most common chronic inflammatory rheumatic diseases of childhood. Due to their long-term safety and efficacy, biologic disease modifying antirheumatic drugs (DMARD) are commonly necessary for control of pJIA patients (pts).
**Objectives:** To evaluate 6-year (y) safety and 2 y effectiveness profile of Adalimumab with or without methotrexate (ADA±MTX) when used in current clinical practice for the treatment of moderately to severely active pJIA.
**Methods:** This is a 6 y interim analysis of an ongoing, multicenter, non-interventional, observational registry of pts with moderately to severely active pJIA with up to10 y safety follow-up. Included pts are treated with either ADA±MTX or MTX alone as part of their routine clinical care enrolled in the US, EU, and Australia. MedDRA observational adverse events (AEs) were recorded from the first day in the registry through last contact, irrespective of the duration of registry treatment. Effectiveness was assessed by 27-joint juvenile arthritis disease activity score (JADAS27), based on CRP.
**Results:** As of January 2014, enrollment was complete. As of June 1, 2015 cut-off date, 846 pts (543 in ADA±MTX and 303 in MTX groups) were treated in the registry. There were 39 pts who rolled over from the MTX to the ADA±MTX arm. At registry entry mean pJIA disease duration was 1.4 y and 3.7 y for MTX and ADA±MTX arms, respectively. At baseline (BL), mean AJC71 was 5.8 and 5.3 for MTX and ADA±MTX arms, respectively, and Childhood Health Assessment Questionnaire Disability Index (CHAQ-DI) was 0.6 for both arms. At data cutoff, the mean duration of study exposure was 1.81 y and 2.15 y for MTX and ADA±MTX arms, respectively. Overall, 206 pts (68%) in the MTX and 216 pts (39.8%) in the ADA±MTX arms discontinued registry drug through 6 y. The main reasons for registry drug discontinuation for the MTX arm: pts required additional therapy (32.3%), other (11.9%), lack of efficacy (10.9%), AEs (8.3%), or pts achieved JIA remission (7.6%), and for ADA±MTX arm: lack of efficacy (16%), lost to follow-up (7.2%), other (5.9%), and AEs (5.3%). Frequencies and rates of treatment-emergent AEs were similar to those reported for observational AEs (Table). There were no reports of deaths, malignancies, opportunistic infections, active TB, oral candidiasis, or CHF. Mean JADAS27 (CRP) improved from 12.2 at BL to 9.7, 5.2, 4.4, 3.5, 2.2 at months 1, 6, and 12, 18, 24 for pts in the MTX and from 11.8 at BL to 7.0, 4.-2, 4.2, 3.6, 3.9 in the ADA±MTX arms, respectively (observed data).
**Conclusions:** Overall, ADA±MTX was well-tolerated in these pts with pJIA with no new safety signals. Discontinuations from the registry drug were relatively high through 6 y, but greater in the MTX only arm.

## THU0217 DKK-1 LEVELS ARE ELEVATED IN PATIENTS WITH ENTHESITIS RELATED ARTHRITIS WITHOUT SACROILIAC JOINT FUSION

C. Fisher[1], L. Bourke[1], A. Radziszewska[1], D. Jadon[2], R. Sengupta[3], T. Bray[4], M. Hall-Craggs[4], D. Sen[1], Y. Ioannou[1]. *[1]Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London; [2]Rheumatology Department, Addenbrooke's Hospital, Cambridge; [3]Rheumatology Department, Royal National Hospital for Rheumatic Diseases, Bath; [4]Centre for Medical Imaging, University College London, London, United Kingdom*

**Background:** Dkk-1 is an inhibitor of the Wnt signalling pathway and therefore plays an important role in bone remodelling. Studies in adults with ankylosing spondylitis have described lower levels of Dkk-1 compared to healthy controls although this is not consistent. Higher levels have been found in some cohorts and particularly in patients with no syndesmophyte formation, suggesting that Dkk-1 may be an important factor in bony ankylosis. There has been no description of Dkk-1 in a younger population with enthesitis related arthritis (ERA).
**Objectives:** To test serum Dkk-1 levels in adolescent and young adult patients with ERA and compare between different disease phenotypes and healthy controls.
**Methods:** Patients were recruited from the adolescent and young adult clinics at University College London Hospital. Serum samples were stored at -80℃ until use. Dkk-1 levels were measured by ELISA (Quantikine, R&D Systems, Minneapolis, MN) as per manufacturer's instructions, in duplicate and correlated with clinical features and MRI results.
**Results:** Serum from 78 patients with ERA (median age 17 years) and 20 age and gender matched healthy controls was tested. Dkk-1 levels were significantly higher in patients with ERA (median=2971pg/ml, IQR 2258–3511pg/ml) compared

to healthy controls (median=1806pg/ml, IQR 1307–2950pg/ml, p=0.0014) (Figure 1A). Patients with ERA who were HLA-B27 positive had higher Dkk-1 levels (median=3081pg/ml, IQR 2337–3680) than those who were HLA-B27 negative (median=2445pg/ml, IQR 1832–3365, p=0.0488) (Figure 1B). Interestingly, there was no significant difference in Dkk-1 levels between patients with axial and those with persistently peripheral ERA or between patients on TNF inhibitors versus those naïve to biologics. There was no correlation between Dkk-1 and CRP, ESR, patient age at date of sample or disease duration. Eleven patients with ERA of the 78 tested had already developed bony fusion of their sacroiliac joints (SIJs); in this group Dkk-1 levels were unexpectedly lower (median=2214pg/ml, IQR 2103–2618pg/ml) compared to those with ERA who had no evidence of bony fusion on MRI scan (median=3042pg/ml, IQR 2321–3607pg/ml, p=0.0355) (Figure 1C).

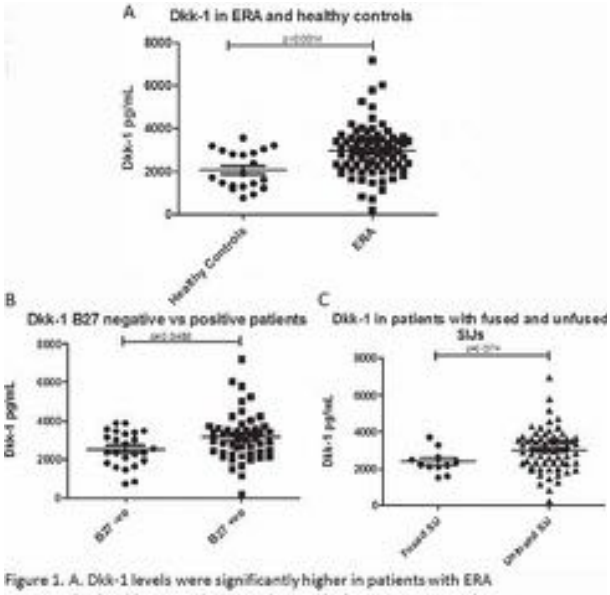

Figure 1. A. Dkk-1 levels were significantly higher in patients with ERA compared to healthy controls. B. Levels were higher in patients with ERA who were HLA-B27 positive compared to negative. C. Patients with SIJ bony fusion had significantly lower levels than those with no bony fusion.

**Conclusions:** In our study, patients with ERA had significantly higher serum levels of Dkk-1 compared to controls. Levels were even higher in those patients who were HLA-B27 positive but there was no correlation with axial disease, patient age, disease duration, CRP, ESR or TNF inhibition treatment. Patients with existing bony fusion of their SIJs had lower levels of Dkk-1, despite the numbers being relatively small. Dkk-1 levels appear elevated in ERA but may reduce with the occurrence of bony fusion. Further larger and longitudinal studies are needed to confirm these findings and to correlate changes in Dkk-1 levels with treatment and MRI findings over time.

## THU0218 COW'S MILK ALLERGY IN INFANCY AND LATER DEVELOPMENT OF JUVENILE IDIOPATHIC ARTHRITIS: A REGISTER-BASED CASE-CONTROL STUDY

P. Vähäsalo[1,2], M. Arvonen[1,2,3], T. Pokka[2,4], L. Kröger[3], L. Virta[5]. *[1]Department of Pediatrics, Medical Research Center Oulu, Oulu University Hospital and University of Oulu; [2]PEDEGO Research Unit, University of Oulu, Oulu; [3]Department of Pediatrics, Kuopio University Hospital and University of Eastern Finland, Kuopio; [4]Department of Pediatrics, Medical Research Center Oulu, Oulu University Hospital and University of Oulu, Finland, Oulu; [5]Research Department, Social Insurance Institution, Turku, Finland*

**Background:** There is discursive information about the incidence of food allergies in juvenile idiopathic arthritis (JIA). In rheumatoid arthritis antibodies from proximal gut secretions against nutritional proteins including cow's milk have been detected (1). We have earlier found a low-grade mucosal inflammatory activation in JIA patients, which resembled the findings of delayed type food allergy (2–3). Also in some case reports, JIA has been linked to food allergy. In our earlier study, we found that exposure to antibiotics was associated with later diagnosis of JIA (4).
**Objectives:** Since there is discursive information about the relation between cow's milk allergy (CMA) and JIA, we wanted to study the association.
**Methods:** The material was collected from national registers (Special Reimbursement Register, Drug Purchase Register and Population Register Center) containing all children born between 2000 and 2010 in Finland and diagnosed with JIA (N=1,298) and age-, gender- and place of birth-matched controls (N=5,179). Altogether 235 children with CMA were identified and 66 of them had JIA. A conditional logistic regression analysis was performed to evaluate the association between CMA and JIA. Additive interaction between CMA and antibiotics for JIA was evaluated by relative excess risk due to interaction (RERI), the attributable proportion due to interaction and synergy index.
**Results:** In boys, a diagnosis of CMA and usage of hypoallergenic formula in infancy associated with later development of JIA (OR 2.4, 95% CI 1.6 to 3.6) whereas in girls with CMA such an association was not found (OR 1.1, 95% CI 0.7 to 1.7). Additionally, every 10-liter purchase of hypoallergenic formula increased the risk of JIA by 2% in boys (OR 1.02, 95% CI 1.01 to 1.03), but there was no increase in girls.
The association was most evident in those boys with diagnosis of JIA at less than three years of age (OR 3.8, 95% CI 1.9 to 7.6) and in those boys who had CMA with gastrointestinal symptoms (OR 4.4, 95% CI 1.9 to 9.9). In boys with both CMA and antibiotic exposure the risk of JIA was fourfold (OR 4.0, 95% CI 2.3 to 6.9) when compared to those without any such exposure. Nevertheless, no statistically significant additive interaction between CMA and antibiotic exposure was detected.
**Conclusions:** Current associations may reflect difficulty in the maturation of intestinal immunity in boys at risk of JIA. Environmental factors related to JIA pathogenesis seem to have sex disparity.

## THU0219 PROSPECTIVE ANALYSIS OF THE IMMUNOGENIC RESPONSE IN JIA PATIENTS (PAEDIATRIC AND ADULT) ON ANTITNF TREATMENT

E. Quesada-Masachs[1], D. Álvarez-de la Sierra[2], M. Garcia Prat[2], R. Pujol-Borrell[2], M. Martínez Gallo[2], C. Modesto Caballero[1], A.M. Marín Sánchez[2]. *[1]Rheumatology; [2]Immunology, Hospital Universitario Vall d'Hebron, Barcelona, Spain*

**Background:** There is some evidence that clinical response in patients with chronic arthritis treated with antiTNF agents can be influenced by their immunogenicity. This particular has not been fully studied in patients with juvenile idiopathic arthritis (JIA)
**Objectives:** To evaluate the immunogenic response against antiTNF agents and its possible impact on treatment efficacy in patients with JIA
**Methods:** Seventy-three patients (40 children and 33 adults) fulfilling ILAR criteria of JIA were included. All of them were on treatment with Etanercept (ETN), Adalimumab (ADA) or Infliximab (IFX) +/– Methotrexate (MTX). Demographical and disease characteristics were recorded at baseline. Clinical outcome was prospectively assessed every 6 months (JADAS, patient or parents VAS, physician's VAS, CHAQ/HAQ, ESR, CRP, number of swollen, painful and limited joints). Patients were tested for the presence of both, serum drug levels and antidrug antibodies levels at baseline and every 6 months
**Results:** Thirty-one paediatric patients (77.5%) needed combined treatment (antiTNF + MTX) *vs* 18 patients (54.4%) in the adult group. Furthermore, paediatric patients followed an intensified antiTNF therapy protocol more frequently than adult patients (54% *vs* 39.33%; p=0.044). A total of 189 determinations for the assessment of immunogenic response against antiTNF therapy were analysed. No differences were found between children and adults in the prevalence of antidrug antibodies or in the circulating antiTNF levels. No antidrug antibodies were found neither in the 107 determinations of patients following ETN treatment nor in the 6 determinations of patients on IFX. Just 5 (17%) of the 29 patients on ADA treatment produced anti-ADA antibodies at least once during the follow-up period. Regarding the 77 ADA determinations, patients who were on monotherapy with ADA produced antidrug antibodies with a significant higher frequency than patients on combined treatment with MTX (37.5% *vs* 8.7% of them respectively; p=0.016). Patients on monotherapy with ADA also exhibit a significant reduced serum ADA levels than patients on ADA+MTX (4.73μg/mL *vs* 12.73μg/mL respectively; p=0.019). However, no significant differences were observed in the ETN concentration between patients on monotherapy or on ETN+MTX treatment (1.50μg/mL *vs* 1.77μg/mL respectively). No correlation was observed between drug levels or the presence of antidrug antibodies and any of the clinical or biological parameters
**Conclusions:** JIA paediatric patients needed intensified and combined with MTX antiTNF therapy more frequently than adults. In spite of this, no differences were found regarding antiTNF levels between children and adults. This fact suggest

that children need more therapy to maintain antiTNF concentrations to control the disease activity. No antibodies antiETN were detected in our patients. ADA in monotherapy seems to be more immunogenic than in combined therapy in JIA. We found no correlation between antiTNF levels or the presence of anti-antiTNF antibodies and the clinical outcome of JIA patients

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4790

## THU0220 RETROSPECTIVE STUDY EVALUATING TREATMENT DECISION AND OUTCOME OF NON-JUVENILE IDIOPATHIC ARTHRITIS (JIA)-ASSOCIATED CHILDHOOD UVEITIS

E. Sardar[1], P. Dusser[1], M. Labetoulle[2], E. Barreau[2], B. Bodaghi[3], I. Kone-Paut[1]. [1]*Paediatric Rheumatology;* [2]*Ophthalmology, Paris-Sud University Hospital, APHP;* [3]*Ophthalmology, Pitie-Salpetriere Hospital University of Paris VI, Paris, France*

**Background:** Non-infectious uveitis is the most common cause of blindness in children. Most studies have evaluated diagnosis criteria and treatment of JIA-associated uveitis.

**Objectives:** We analyzed treatment and outcome of childhood uveitis related to other causes than JIA.

**Methods:** A retrospective chart review of pediatric uveitis in patients <16y-old seen between 2001 and 2015 at a university hospital in Paris. We excluded patients with JIA-associated uveitis. Clinical characteristics, treatment and ocular complications were collected. We used the SUN [1] (Standardization of Uveitis Nomenclature) for the classification of uveitis, disease activity (inactive uveitis: rare cells or less) and treatment endpoints, improvement: defined as a 2-step decrease in the inflammation level or a decrease to grade 0, worsening: defined as a 2-step increase in the inflammation level or an increase from grade 3+ to 4+, or remission (inactivity without treatment for ≥3 months).

**Results:** Thirty patients (SR: 0,5; 51 eyes) were enrolled. Mean age of diagnosis was 9.6±3.5 years (3 to 15 y). Mean follow-up was 4 ±3 years. Main diagnoses were: idiopathic (60%), Behçet's disease (BD) (13%), sarcoidosis (10%), Vogt-Koyanagi– Harada syndrome (3%), herpes simplex virus (3%) and tubulointerstitial nephritis and uveitis (TINU) syndrome (3%).

Among idiopathic uveitis (n=27 eyes), 44% were anterior uveitis. Twenty eyes (74%) received systemic corticosteroid as first-line therapy, inducing inactivity for 2 eyes (10%) and remission for 1 eye (5%) at 5 years. DMARDs were needed for 18 eyes (66.6%). Methotrexate was used as first-line therapy in 14 eyes (77%) with 7.1% (n=1 eye) remission at 4 months.

Infliximab was used as second-line treatment in 9 eyes (60%) with 78% of improvement and 78% of inactivity but no remissions. Ocular complications occurred in 67% of patients: posterior synechia (37%), macular edema (37%), severe vision loss (26%), cataract (22%), vasculitis (19%), and band keratopathy (16%). In BD uveitis (n=6 eyes), 83% had panuveitis. All BD patients received systemic corticosteroid therapy and azathioprine among those 50% responded with inactive uveitis. Infliximab was used as second-line therapy in 3 eyes with 100% of improvement. All BD patients developed complications: vasculitis (83%), posterior synechiae (83%), vitreous hemorrhage (50%), severe vision loss (33%) and macular edema (17%). Sarcoidosis affected 4 eyes, 75% were panuveitis and all patients received systemic corticosteroids and became steroid dependent. All of these patients received methotrexate, and 50% required infliximab as a second line with remission in 1 eye and inactivity in 3 eyes. Posterior synechiae developed in 3 eyes.

**Conclusions:** Idiopathic uveitis is the most common cause of non-JIA uveitis in children. BD and sarcoïdosis are thought to be the most severe ones, but idiopathic uveitis seems very difficult to treat as two third of patients have severe complications at the end of the treatment. Most patients were steroid dependent and required a DMARD in association with infliximab. Improvement and disease inactivity were frequently obtained but remission was rare.

## THU0221 EFFICACY OF BIOLOGICAL AGENTS IN COLCHICINE RESISTANT CHILDREN WITH FMF

N. Aktay Ayaz[1], B. Sözeri[2], M. Çakan[1], Z. Gündüz[2], A. Paç Kısaarslan[2], R. Düşünsel[2], H. Poyrazoğlu[2]. [1]*Pediatric Rheumatology Unit, Kanuni Sultan Suleyman Hospital, Istanbul;* [2]*Pediatric Rheumatology Unit, Erciyes University Medical Faculty, Kayseri, Turkey*

**Background:** Familial Mediterranean fever (FMF) is the most common monogenic autoinflammatory disease diagnosed usually during childhood period. It is managed appropriately with colchicine. Hovewer, even though very rare, there are cases that can not be controlled by colchicine treatment. Ultimate goal of treatment is to control attacks and subside inflammation both during and in between attacks. There are some drugs offered for resistant cases. The anti IL-1 therapy is the most promising one.

**Objectives:** This study that is performed in two pediatric rheumatology centers in Turkey is aiming to collect and evaluate the data of children resistant to colcicine treatment and receving anti IL-1 treatment by means of eficacy and safety.

**Methods:** Two pediatric rheumatology centers had been involved to the study. The medical data were collected retrospectively. The children had been diagnosed as FMF according to the Tel-Hashomer criteria. Colchicine resistance was defined as having 3 or more attacks despite maximum dose of colchicine treatment regarding to age. The severity of the disease before and after biological treatment was performed by Pras and FMF 50 scores.

**Results:** From two pediatric rheumatology centers 26 children were enrolled to the study. The median age at onset of disease was 4 years [(IQR)2–5]. The consanguinity rate was 46.2%. Thirteen of the children had a family member with diagnosed FMF. Only 3 patients had a family history of amyloidosis. Abdominal pain (88.5%) was the most common symptom. The median number of attacks per year was 12 before colchicine treatment, the median attack number dropped to 11 per year after colchicine. The median dose of colchicine before biologic therapy was 1.5 g/day (range 1–1.5). The median duration of colchicine treatment before biologic therapy was 54 months (IQR 23.7–99 months). The median biologic treatment starting age was 11.5 years (range 8.7–16). As biological agent, nineteen patients were started with anakinra, 2 were with etanercept, 5 with canakinumab. The two patients who were under etanercept treatment were switched to anakinra due to lack of effectiveness. Of 19 patients who were commenced anakinra, 12 (63.1%) were switched to canakinumab due to painful injections, lack of effectiveness, allergy and patient's choice. There were no switches among canakinumab users. Pras scores had been changed from 10.17 to 6 in anakinra users, from 10 to 6 in canakinumab users. There was no difference of effectiveness between two drugs. The FMF 50 score showed improvement in 14 of 15 anakinra users, 15 of 15 canakinumab users. The difference of scores was not significant between both groups.

**Conclusions:** Although colchicine is the main treatment option in FMF, resistant children need additional medications. IL-1 is the major cytokine modulating inflammation in FMF. There are reports pointing out these agents as promising for resistant cases. Our study is the largest cohort of children with resistant FMF under biological treatment. Both anakinra and canakinumab had shown good and similar efficiacy in resistant cases. Long term efficacy and safety evaluations should be done with controlled trials.

## THU0222 THE DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER FOLLOWING THE INITIAL PRESENTATION OF MONOARTHRITIS

O. Tanous[1], Y. Horovitz[1], S. Shalev[1], M. Khayat[2], R. Spiegel[1]. [1]*Pediatric;* [2]*Emek Medical Center, Afula, Israel*

**Background:** Familial Mediterranean Fever (FMF) is the most common Mendelian autoinflammatory syndrome resulting from mutations in the MEFV gene [1]. Musculoskeletal involvement, mostly in the form of arthritis or arthralgia is the second common manifestation of FMF following periodic fever and abdominal pain [2,3]. The incidence and pattern of joint involvement is highly heterogeneous. Retrospective data suggest that arthritis may be the initial presentation of FMF in up to 15% of patients in certain populations [4,5].we aimed to examine whether certain "idiopathic monoarthritis" episodes are in fact the initial presentation of FMF.

**Objectives:** to prospectively investigate the prevalence of FMF in children admitted to our department with an acute episode of "idiopathic monoarthritis". In addition we aimed to identify risk factors that when associated with monoarthritis, will specifically indicate genetic testing of the MEFV gene.

**Methods:** A prospective study of 71 otherwise healthy children admitted to our pediatric department between 2010–2013 with a first episode of idiopathic monoarthritis. Demographic, clinical and laboratory data were documented and genetic assay of the five common mutations in our population of the MEFV gene were analyzed in the entire study population.

**Results:** Among the cohort 7 (10%) children harbored 2 pathogenic mutations in the MEFV gene, thus confirming diagnosis of FMF. This FMF induced arthritis group had a statistically significant female predominance compared with the idiopathic arthritis group 6 (86%) vs 19 (30%), respectively) (P=0.006, OR =14.2). In addition, associated abdominal pain during the attack 2 (28%) vs 2 (3%), respectively (P=0.04, OR=12.4) and a family history of FMF 2 (29%) vs 5 (8%), respectively (P=0.1 OR 4.7,) were more common in the FMF induced arthritis group

**Conclusions:** In Mediterranean populations where FMF is relatively common we recommend for every child with first episode of arthritis, without an identifying cause to strongly consider MEFV genetic testing of the common mutations in the relevant population.

## THU0223 DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF PATIENTS WITH JUVENILE SCLERODERMA-A SINGLE CENTER EXPERIENCE

A. Adrovic[1], S. Sahin[1], K. Barut[1], A. Koka[2], O. Kasapcopur[1]. *[1]Pediatric Rheumatology; [2]Pediatric Cardiology, Cerrahpasa Medical School, Istanbul, Turkey*

**Background:** Juvenile scleroderma (JS) is a rarely seen chronic connective tissue disorder. According to organ involvement, the disease is divided into two main forms: systemic and localized. Localized scleroderma (JLS) is characterized with sclerosis of the skin but internal organs involvement is not expected. Juvenile systemic sclerosis (JSS) is characterized by both cutaneous and internal organ involvement. Clinical features are insidious and it can take years until complete clinical picture develops.
**Objectives:** The aim of the study was to investigate main demographic and clinical characteristics of patients with JS, followed up at our department. Additionally, we aim to share our experience of this rare condition.
**Methods:** Patients with JS were included in cross-sectional study. Demographic data were taken from disease history of patients. Clinical features, laboratory results and treatment options were evaluated at last clinical visit.
**Results:** A totally of 46 patients were included in the study: 40 (86,9%) female, 6 (13%) male. The mean age of patients was 14±3 years, mean age at disease onset was 9,1±4,23 years and the mean age at diagnosis was 10,2±3,4 years. Twenty six patients (56,5%) were diagnosed with JSS and 20 (43,4%) had JLS. Skin involvement and peripheral vasculopathy were the most common clinical features. Musculoskeletal involvement takes a second place. Gastro-intestinal (GIS) involvement was present only in systemic sclerosis group. Six patients (13%) had lung fibrosis. Pulmonary hypertension was found in 6,5% of all JS patients but its percentage was higher among patients with JSS (11,5%). None of patients had neurological and renal involvement. All JSS patients were positive while 40% of JLS patients were negative for ANA. Anti Scl 70 antibody was positive only among patients with JSS. Combination of MTX+corticosteroids was used in 15 patients (32,6%). Vasoactive agent was added in therapy of 20 patients (43,5%) which all belong to JSS group. While 31 patients were in remission (67,4%), 15 (32,6%) had active disease in last visit. All patients with active disease belonged to systemic group.
**Conclusions:** Juvenile scleroderma is rarely seen multisystemic disease. Unlike adults, cardiovascular and pulmonary involvement is uncommon among children. Early diagnosis, regular follow up and appropriate treatment are of high importance in clinical course and disease prognosis.

## THU0224 PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH JUVENILE LUPUS ERYTHEMATOSUS

A. Adrovic[1], R. Dedeoglu[2], S. Sahin[1], K. Barut[1], A. Koka[2], O. Kasapcopur[1]. *[1]Pediatric Rheumatology; [2]Pediatric Cardiology, Cerrahpasa Medical School, Istanbul, Turkey*

**Background:** Juvenile systemic lupus erythematosus (jSLE) is a chronic autoimmune disease characterized with multisystemic involvement. Vital organ involvement is the most important morbidity and mortality factor. Early diagnosis of cardio-vascular and pulmonary involvement is shown to be relevant in term of reducing mortality.
**Objectives:** The aim of this study is to explore the frequency of pulmonary hypertension in patients with jSLE, using non-invasive methods (Doppler echocardiography).
**Methods:** Patients with diagnosis of jSLE followed up at our department were included in the study. Doppler echocardiography was performed at all included patients. Pulmonary arterial pressure was determineted by three different methods. Systolic pulmonary arterial pressure (SPAP) was estimated by measurement the maximal velocity of tricuspid insufficiency (TI). Diastolic pulmonary arterial pressure (DPAP) was estimated by velocity of pulmonary insufficiency at the end of diastole (PI). Mean pulmonary arterial pressure (MPAP) was determinated by pulmonary insufficiency acceleration time (AT) and the ration of AT to ejection time (ET). Systolic pulmonary arterial pressure was calculated by modified Bernoulli equation. Right atrial pressure was evaluated by measurement the right atrial volume, the degree of tricuspid regurgitation and contraction of vena cava inferior during inspiration
**Results:** A total of 38 jSLE patients were included in the study. Mean age of patient was 16±2,59 year, mean age at diagnosis was 10,6±3,5 year and mean disease duration was 57±33,6 month. Velocity of pulmonary insufficiency at the end of diastole (PI) was 1,469±0,295 m/sec and 1,214±0,128 m/sec in patients and control group, respectively. Maximal velocity of tricuspid insufficiency (TI) was 2,340±0,277 m/sec and 2,044±0,411 m/sec in patients and control group, respectively.The ration of pulmonary insufficiency acceleration time (AT) to ejection time (ET) was normal in both patients and in control group. Although estimated pulmonary arterial pressure was found to be in normal ranges (<25 mmHg) in all studies patients, it was statistical significantly higher comparing to control group. According to those results, there were no findings of pulmonary hypertension among patients with jSLE.
**Conclusions:** This study confirms that pulmonary hypertension is uncommon among patients with jSLE. Early diagnosis, regular follow up and proper therapy are thought to be important in reducing the risk of pulmonary hypertension.

## THU0225 HYPOGONADOTROPIC HYPOGONADISM IN SYSTEMIC ARTHRITIS- AN INTERESTING CASE SERIES FROM A TERTIARY CARE CENTRE

B. Chilukuri, R. Sankaralingam, S. Sankar, R. Ramamoorthy, B. Mahendran. *Institute of Rheumatology, Madras Medical College, Chennai, India*

**Background:** The musculoskeletal, cardiac, pulmonary, hepatic, reticuloendothelial, hematological, neurological manifestations of systemic arthritis are very well known. Hormonal abnormalities of systemic arthritis have not been reported thus far
**Objectives:** To study hormone profile in systemic arthritis and identify abnormalities
**Methods:** We present a case series of abnormal hormone profile in 5 consecutive cases of Systemic arthritis admitted and evaluated at Institute Of Rheumatology, Madras Medical College during Februrary 2015. All patients had high systemic disease activity – elevated ESR, CRP, ferritin, fibrinogen, thrombocytosis.
Fasting serum hormone profile was done by chemiluminescence method – Adrenocorticotropin releasing hormone (ACTH), Thyroid stimulating hormone (TSH), Follicle stimulating hormone (FSH), Luteinizing hormone (LH), Prolactin,

| Parameters | Patient 1 | Patient 2 | Patient 3 | Patient 4 | Patient 5 |
|---|---|---|---|---|---|
| AGE (years)/sex | 6/Male | 11/Male | 10/Male | 9/Male | 6/Male |

| ESR mm/hr | 70 | 50 | 60 | 94 | 64 |
| CRP in dilutions | 48 | 24 | 48 | 48 | 24 |
| Platelet count, lakhs/cumm | 8 lakhs | 4 lakhs | 6 lakhs | 5.2 lakhs | 6 lakhs |
| Serum ferritn | 2150 | 540 | 2105 | 3578 | 2210 |
| Fibrinogen | 512 | 480 | 541 | 502 | 510 |
| Prednisolone | 10 mg | 10 mg | 15 mg | 7.5mg | 5mg |
| DMARDS | Methotrexate | Methotrexate | Methotrexate | Methotrexate | Methotrexate |
| Biologics | Tocilizumab | Tocilizumab | Tocilizumab | Nil | Tocilizumab |
| ACTH, pg/ml | 7.8 | 2.4 | 13.9 | 4.8 | 6.2 |
| TSH, μIU/ml | 2.1 | 0.7 | 4.9 | 2.4 | 2 |
| FSH, mIU/ml | 0.02* | 0.06* | 0.6* | 0.2* | 0.3* |
| LH, mIU/ml | 0.01* | 0.01* | 0.01* | 0.01* | 0.01* |
| Prolactin, ng/ml | 4 | 4 | 13 | 6 | 8 |
| Testosterone, ng/dl | <2.5* | <2.5* | <2.5* | <2.5* | <2.5* |
| IGF-1, ng/ml | 137 | 103* | 164 | 241 | 156 |
| GH, ng/ml | 2.6* | 0.1* | 0.5* | 0.1* | 0.5* |

Testosterone, Insulin like growth factor-1 (IGF-1), Growth hormone (GH) were estimated.

**Results:** All 5 patients had low serum FSH,LH,GH,Testosterone levels. All 5 patients had normal ACTH,TSH,prolactin levels. * indicates LOW VALUES

**Conclusions:**

– Hypogonadotrophic secondary hypogonadism was observed in 5 consecutive patients with systemic arthritis with high disease activity.
– We are presenting this case series as no studies have so far been reported on hormone profile of patients with systemic arthtritis to the best of our knowledge.
– Further studies with more number of cases are needed to find out whether the endocrine dysfunction is disease related or drug induced.

## THU0226 OUTCOMES OF TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS RELATED UVEITIS WITH TNF-ALPHA INHIBITORS

E. Gaidar[1], M. Kostik[1], L. Snegireva[1], M. Dubko[1], V. Masalova[1], E. Serogodskaya[1], T. Nikitina[1], A. Hynes[2]. *[1]Saint- Petersbburg State Pediatric Medical University, Saint-Petersburg, Russian Federation; [2]Eye Care Physicians and Surgeons, Winchester, VA, United States*

**Background:** Uveitis is the inflammation of the uvea by definition, but for a rather long time the term "uveitis" was used to identify inflammation in any part of the eye (retinitis, chorioretinitis, scleritis, episcleritis). According to some authors one of the most common causes of uveitis in childhood is Juvenile Idiopathic Arthritis (JIA). Patients with JIA associated uveitis are usually asymptomatic at early stages. In 20–30% of cases uveitis may occur a few years before joint manifestation. As the result of those two factors we often see the delay in the treatment or not adequate treatment. Early and aggressive treatment of JIA associated uveitis can help better control inflammation and can help to eliminate inflammation before development of irreversible ophthalmic pathology.

**Objectives:** The goal of the study was to evaluate the efficacy of two anti-TNF-alpha biological agents: Adalimumab (ADA, humanized monoclonal anti-TNF-alpha antibody) and Infliximab (INF, chimeric monoclonal antibody that binds both circulating and membrane-bound TNF-alpha receptors) in the treatment of uveitis, associated with Juvenile idiopathic Arthritis (JIA). The incidence of eye involvement in JIA can be as high as 10–20%.

**Methods:** Thirty-seven children with aggressive forms of JIA with uveitis who failed immunosuppressive agents were enrolled in the study. The age of the patients at the beginning of anti-TNF-alpha treatment ranged from 5 to 17 years. All patients were divided into two groups: one group received ADA (40 mg sc every 2 weeks), and the other group was received INF (iv 5–6 mg/kg at week 0–2-6 and after every 8 weeks). Duration of treatment was 3–48 months. The efficacy of treatment was assessed by reduction of flare-ups, reduction of topical and systemic steroids, immunosuppressive drugs and reduction of activity of uveitis.

**Results:** In ADA group the remission was observed in 61% of cases, reduction of number of flare-ups was in 18% and in 14% we saw worsening of the disease due to discontinuation of non-biological drug. In INF group remission was in 78% and in 22% of the cases no improvement. The remission of uveitis was achieved in 0.5 - 4 months from the starting of ADA. Topical steroids was tapered within 1.5–3 months and none of the patient required regional injections of steroids. Therapy with ADA permitted to cease non-biological immunosuppressive agents, especially in children who received simultaneously 2 non-biological agents.

**Conclusions:** Our experience in ADA treatment of uveitis shows good result in control of uveitis independent from the severity of the disease and despite it was used as a first-, second- or third-line agent among the biologics. The speed of remission in patients with JIA associated uveitis treated with ADA and INF depends on the severity of uveitis, the time between the beginning of the disease and administration of immunosuppressive therapy. This study needs to be continued to enroll more patients and to increase the follow-up time to evaluate the long-term efficacy and safety of anti-TNF-alpha agents in JIA associated uveitis.

## THU0227 ADOLESCENT AND YOUNG ADULT CARE IN ADULT RHEUMATOLOGY CLINICS

E. Bruce[1], J. Fox[1], P. Watson[1], J. McDonagh[2,3]. *[1]Rheumatology, University Hospital of South Manchester; [2]Paediatric Rheumatology, Royal Manchester Childrens Hospital; [3]Centre for Musculoskeletal Research, Manchester University, Manchester, United Kingdom*

**Background:** The importance of transitional care for young people from paediatric to adult rheumatology is well established. However, in most rheumatology departments there will be a significantly larger cohort of older adolescents and young adults (AYAs) that enter adult services de-novo than will have transitioned from paediatric services.

**Objectives:** Our aim was to evaluate AYA care within adult Rheumatology clinics, in particular focusing on use of the HEEADDSS psychosocial interview.

**Methods:** A review of clinical correspondence for patients aged 16–25yrs attending adult rheumatology clinics at University Hospital of South Manchester, between February 2015 and May 2015 was undertaken. Data collected included demographics, diagnosis and evaluation of documentation of the components of the HEEADDSS screen.

**Results:** 193 appointments were issued for 16–25yr olds, representing 5% of the total number of appointments. 103 were new referrals, with a majority from general practice. Age distribution was even, over two thirds were female. The "did not attend" rate was 10%.

36 had a confirmed inflammatory condition, 27 were under investigation for a possible inflammatory arthritis and 47 had a non inflammatory condition. Of the HEEADDSS criteria the most often documented was education/employment at 31%, with exercise at 19%.

**Conclusions:** The AYA group is well represented within this secondary care setting. Documentation of the HEEADDSS criteria was suboptimal. There may be wider implications of this on health outcomes.

The first step towards improving care for this cohort is to establish an awareness within the adult team of the particular needs of this patient group, AYA health is not just a concern for paediatric rheumatologists.

## THU0228 EFFICACY COMPARISON WITH TOCILIZUMAB, INTERLEUKIN-1 INHIBITORS AND ETANERCEPT FOR TREATMENT OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

G. Horneff[1], A.C. Schultz[1], A. Hospach[2], G. Ganser[3], I. Foeldvari[4], A. Thon[5], R. Trauzeddel[6], F. Weller[7], K. Minden[8], J.P. Haas[9]. *[1]Asklepios, Sankt Augustin; [2]Olga Hospital, Stuttgart; [3]St Josef Stift, Sendenhorst; [4]Cenre Ped Rheum, Hamburg; [5]MMH, Hannover; [6]Helios Clinic, Berlin; [7]Prof Hess Clinic, Bremen; [8]Charite, Berlin; [9]Centre Ped Rheumatology, Garmisch-Partenkirchen, Germany*

**Background:** Since the approval of first biologics for JIA, such treatments in Germany are monitored prospectively by the BiKER registry.

**Methods:** sJIA pts documented in BIKER exposed to Etanercept (ETA), Tocilizumab (TOC) or IL-1inhibitors were identified. A 6-month therapy period was chosen as a meaningful time for early efficacy judgement. Intention to treat analysis (ITT) of JADAS10 was performed. Discontinuation due to inefficacy/intolerance was calculated as non-response.

**Results:** 205 sJIA patients (51% male) received 269 treatment courses with biologics (TOC 71, Anakina 36, Canakinumab 19, ETA 143). Median age and disease duration (ETA 3.3;TOC 3.3;IL-1i 3.0) were comparable. The choice of drug was influenced by the availability. ETA was started in 80% of pts before 2008 while in the TOC cohort all pts and in the IL-1i cohort 74% started therapy after 2008. Pre-treatment consisted of steroids in all pts, MTX in the ETA/TOC/IL-1i cohort in 88%/83%/76% and biologics preexposure was used in 2%/66%/86%. Concomitant treatment with systemic steroids was significantly less frequent with TOC (44%, $p<0,001$) and IL-1i (44%, $p<0.001$) compared to 83% with ETA. Concomitant MTX was used with ETA in 81% but significantly less frequent with TOC (64%; $p=0.004$) or IL-1i (44%; $p<0.0001$). Also other DMARDs were used less frequently with TOC (9%) and IL-1i (4%) compared to ETA (24%).

Systemic manifestations were present at baseline in: 8% ETA, 96% TOC and 38% IL-1i cohort. The mean±SD baseline JADAS was higher in the ETA cohort (20.7±9.1) than in the TOC cohort (16.2±10.6) or IL-1i cohort (7.8±8.9).

At month 6, a marked decrease of the JADAS was noted in all cohorts. ITT analysis revealed a significant advantage of TOC and Il-1i over ETA (table). Significantly more pts reached a JADAS-Remission (JADAS$\leq$1) upon TOC (OR/95CI 3.85/1.68–8.83/$p<0.001$) or upon IL-1i (OR/95CI 4.55/1.92–

| | | ETA (n=143) | TOC (n=71) | IL-1i (n=55) |
|---|---|---|---|---|
| Baseline | JADAS10 Median (IQR) | 8.2 (5.3–13.0) | 9.6 (4.9–13.3) | 8.2 (5.1–13.3) |
| Month 6 | JADAS10 Median (IQR) | 6.2 (1.1–15.6) | 0.8 (0.1–5.3) | 6.6 (0.2–2.0) |
| | JADAS MDA n (%) | 26 (29.5%) | 21 (61.8%) | 21 (65.6%) |
| | JADAS Remission n (%) | 16 (18.2%) | 15 (44.1%) | 16 (50%) |
| | Discontinuations (< Month 6) | | | |
| | Inefficacy | 23 (26.1%) | 4 (11.8%) | 7 (21.9%) |
| | Intolerance | | 1 (2.9%) | |
| | Remission | 1 (1.1%) | | |

10.77/p=0.003) than with ETA. Significantly more pts reached a JADAS-MDA (JADAS≤3.8) upon TOC (OR 3.55/1.49–8.46/p=0.003) or upon IL-1i (OR 4.5/1.87–10.84/p<0.0001) than with ETA. ETA was more often discontinued due to inefficacy before month 6 than TOC or IL-1i.
**Conclusions:** A high proportion of pts showed a significant response to treatment especially with TOC or with IL-1i. After 6 months on treatment JADAS remission criteria were reached by up to 50% of patients while 60% to 65% reached JADAS minimal disease activity desoite much less steroids and DMARD used with TOC or IL-1i. ETA has been used in earlier times but it is less effective and it's use in sJIA has markedly decreased in Germany.

Helmus[1]. *[1]Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schön Klinik Eilbek, Hamburg; [2]Uni Child Hosp, Berlin, Germany; [3]Uni Child Hosp, Istanbul, Turkey; [4]Uni Child Hosp, São Paulo, Brazil; [5]Uni Child Hosp, Riga, Latvia; [6]Uni Child Hosp, Buenos Aires, Argentina; [7]Uni Child Hosp, Moscow, Russian Federation; [8]Uni Child Hosp, Rio de Janeiro, Brazil; [9]Uni Child Hosp, Firenze, Italy; [10]Uni Child Hosp, Saint-Petersburg, Russian Federation; [11]Uni Child Hosp, Madrid, Spain; [12]Uni Child Hosp, New York, United States; [13]Uni Child Hosp, Prague, Czech Republic; [14]Uni Child Hosp, Tuebingen, Germany; [15]Uni Child Hosp, Almada, Portugal; [16]Uni Child Hosp, Ljubljana, Slovenia; [17]Uni Child Hosp, Santa Fe, Argentina; [18]Uni Child Hosp, Innsbruck, Austria; [19]Uni Child Hosp, Copenhagen, Denmark; [20]Uni Child Hosp, Chennai, India; [21]Uni Child Hosp, Tel Aviv; [22]Uni Child Hosp, Kfar Saba, Israel; [23]Uni Child Hosp, London, United Kingdom; [24]Uni Child Hosp, Pittsburgh, United States*

**Background:** Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Several adult publications looked at the differences between limited (ljSSc) and diffuse subtype (djSSc). There is rarity of data regarding this topic in pediatric jSSc. The juvenile scleroderma inception cohort is a prospective standardized register for patients with jSSc.
**Objectives:** comparison of patients characteristic at the time of inclusion with ljSSc and djSSc
**Methods:** We compered the demographics and clinical characteristics of the ljSSc and djSSc.
**Results:** Up till now 74 patients were enrolled, 54 (76%) with djSSc and 18 with ljSSc (24%). 9% in djSSc and 25% in ljSSc showed overlap features. Disease duration at time of inclusion in the cohort was 3.7 years in the djSSc and 3.3 years in ljSSc. 82% in the djSSc and 78% in the ljSSc group were female. The mean age of the onset of Raynaud symptomatic was 9.0 years in the jdSSc and 9.9 years in ljSSc group and onset of the non-Raynaud symptomatic with 9.4 in djSSc and 10.6 ljSSc. At the time of inclusion the mean modified Rodnan Skin Score was 18.5 in the djSSc and 8,4 in ljSSc (p=0.0001). Anti-Scl 70 positivity was found in 31.5% of djSSc and 30.8% in ljSSc. Only 2 patient in the djSSc group and one in the ljSSc group was anticentromere positive. Capillary changes occurred in 60.7% in the djSSc and 50% in ljSSc, but 58.2% in djSSc and only 23.5% in ljSSc had already history of ulcerations (p=0.013) and 21.8% had active ulceration in the djSSc and 5.9% in the ljSSc. 33.3% of djSSc and 72.7% of ljSSc had cardiac involvement (p=0.027). pulmonary hypertension occurred in 57.1% djSSc and 18.2% in ljSSc. 63% in djSSc and 27.3% in ljSSc group had signs of interstitial lung disease on imaging (p=0.046). Renal involvement occurred in 7.1% djSSc and 5.6% in ljSSc. 39.3% of djSSc and 22.2% of ljSSc had gastrointestinal involvement. 56.4% in djSSc and 83.35 in ljSSc had musculoskeletal involvement (p=0.04).
**Conclusions:** Patients with djSSc have younger age at onset, have more often capillary changes and active ulcerations, pulmonary hypertension and less gastorintestinal and joint involvement and more disease damage. The characteristics of the pediatric subtypes differs from adults with SSc, especially the high proportion of patients with diffuse subtype.

**Background:** Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Several adult publications looked at the differences between male and female patients with Systemic Sclerosis. There is rarity of data regarding this topic in pediatric jSSc. The juvenile scleroderma inception cohort (www.juvenilescleroderma.com) is a prospective standardized register for patients with jSSc.
**Objectives:** comparison of patients characteristic at the time of inclusion in the registry who are male or female.
**Methods:** Patients with jSSc were included worldwide to the juvenile scleroderma inception cohort. We compered the demographics and clinical characteristics of the male and female patients.
**Results:** Up till now 74 patients were enrolled, 54 with djSSc (76%) and 18 with ljSSc (24%). 14 (19%) of the patients were male (M) and 60 female (F) (81%). The mean disease duration at the time of inclusion was 9.3 in M and 9.2 in F patients. 74.4% of the M and 76.7% of the F had diffuse subset. The mean age of the onset of Raynaud symptomatic was 9.3 in M and 9.2 years in the F patients and the non-Raynaud symptomatic with 9.1 in M and 9.9 in F patients. At the time of the inclusion the mean modified Rodnan Skin Score was 20 in M and 15.1 in F patients. Anti-Scl 70 positivity was found in 42.9% in M and 32.1% in F patients. Anticentromere positivity occurred in 16.7% in M and 3.3% in F patients (p=0.027). Capillary changes were present in 50% of the M and 60% of F patients, but 50% in M and F had already history of ulcerations, but 28.6% in M and 15.5% in F had active ulceration. 57.1% of the M and 50% of the F patients had cardiopulmonary involvement. Six patients had pulmonary hypertension, they were all F. 75% of M and 46.7% of F patients had signs of interstitial lung disease on imaging. Renal involvement was around 7% in both sexes. 21.4% in M and 38.3% in F patients had gastrointestinal involvement. 92.9% of M and 55.9% in M patients had musculoskeletal involvement.
**Conclusions:** We present the data on the first 74 patients with jSSc included in our cohort. Patients with male sex have a more severe disease similar to adult male patients.

## THU0231 BELIMUMAB IN PAEDIATRIC SLE (THE PLUTO STUDY) – STUDY DESIGN AND PARTICIPATION

J. Fettiplace[1], B. Ji[1], D. Roth[2]. *[1]GSK, London, United Kingdom; [2]GSK, Philadelphia, United States*

**Background:** Belimumab, a fully human IgG1λ monoclonal antibody for B Lymphocyte Stimulator protein, was licensed in 2011 by the FDA and EMA for add-on therapy in adult patients with active systemic lupus erythematosus (SLE). As part of a paediatric investigational plan, a study of belimumab in paediatric SLE was designed and commenced in 2012 (BEL114055, ClinicalTrials.gov: NCT01649765).
**Objectives:** To outline the study design, study participation and rationale for subject selection.
**Methods:** The PLUTO study is a 52-week multi-centre, randomized parallel group, placebo-controlled double-blind study to evaluate the safety, efficacy, and pharmacokinetics (PK) of belimumab plus standard therapy in paediatric patients (5–17 yrs) with SLE. To be eligible to enrol patients need to have a clinical diagnosis of SLE according to the ACR criteria, be autoantibody positive and have a SELENA-SLEDAI score of ≥6. Patients who complete the double-blind phase (Part A), are eligible to join an open-label safety follow-up period of up to ten years (Part B). For subjects who withdraw from Part A or Part B, there is a long-term safety follow up phase (Part C).
Part A is divided into 3 Cohorts. Cohort 1 will consist of the first 12 subjects (12–17 yrs). Once the PK and safety profile of Cohort 1 is evaluated and any

potential dose adjustments are determined as a result of this analysis, additional subjects 12–17 yrs will then enrol in Cohort 3. Cohort 2 will enrol 12 patients (5–11 yrs) at the dose determined from the PK analysis of Cohort 1. Once the PK and safety profile of Cohort 2 is evaluated and any potential dose adjustments are determined as a result of this analysis, additional subjects 5–11 yrs will then enrol in Cohort 3. Cohorts 1 and 2 will be randomized in a 5:1 ratio, and Cohort 3 subjects will be randomized in a 1:1 ratio to receive belimumab or placebo on a background of standard therapy.
An Independent Data monitoring Committee (IDMC) will monitor unblinded safety, efficacy and PK data from the study.
**Results:** The study is currently enrolling and is active in the following countries: US, Canada, Argentina, Peru, Mexico, UK, Spain, Netherlands, Poland, Russia and Japan.
Subjects selected for study inclusion had active SLE indicated by skin/mucosa, musculoskeletal, haematologic, renal or CNS organ manifestations and were receiving standard concomitant SLE therapies including corticosteroids, anti-malarials and immunosuppressants. The profile of the trial population reflects a patient population who have active SLE but with an inadequate response to standard therapy and who therefore may benefit from an alternative treatment such as belimumab.
The ongoing IDMC reviews support the study continuation according to the current protocol.
**Conclusions:** The PLUTO study aims to address an area of unmet clinical need in which there are no licensed therapies. Please consider the eligibility of your paediatric SLE patients for this important study.
**Acknowledgement:** This study is funded by GSK.

## THU0232 DOES THE TIME OF BDMARD START DETERMINE THE OUTCOME OF JIA IN ADULTHOOD?

J. Klotsche[1], M. Niewerth[1], I. Foeldvari[2], E. Baerlin[3], C. Baumann[4], F.K. Striesow[5], P.M. Aries[6], M. Aringer[7], J.-P. Haas[8], G. Horneff[9], K. Minden[1,10]. *[1]German Rheumatism Research Center, Berlin; [2]Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schön Klinik Eilbek, Hamburg; [3]Internistisch-Rheumatologische Praxis, Ludwigsburg; [4]Rheumatologische Schwerpunktpraxis, Plauen; [5]Internistisch-Rheumatologische Praxis, Bonn; [6]Internistisch-Rheumatologische Praxis, Hamburg; [7]Medizinische Klinik III - Bereich Rheumatologie, Medizinische Fakultät Carl Gustav Carus an der TU Dresden, Dresden; [8]Zentrum für Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen; [9]Asklepios Kinderklinik St. Augustin GmbH, St. Augustin; [10]Kinderklinik, Charité Universitätsmedizin Berlin, Berlin, Germany*

**Background:** Biological disease modifying antirheumatic drugs (bDMARD) had great impact on the medical management of patients with juvenile idiopathic arthritis (JIA). Many patients nowadays enter adulthood in clinical remission, with normal function and without long-term sequelae. There is little information to what extent the early use of bDMARDs affects the long-term outcome of patients with JIA.
**Objectives:** To investigate if the 10-year outcome after JIA onset is associated with the time lag between JIA disease onset and first bDMARD use.
**Methods:** Outcome variables were examined in patients prospectively observed in the national JIA biologic register BiKeR and its follow-up register JuMBO since initiation a bDMARD therapy. Analyses included patients with at least one visit in JuMBO. Assessed parameters were JADAS3–10, C-HAQ, joint surgery (replacements, synovectomies), eye surgery and patient-reported outcomes. To analyze the influence of the time lag between JIA onset and first use of bDMARD, patients were assigned to one of the following three groups (G1: $\leq$2 year = early therapy, G2: intermediate, G3: $\geq$5 years = late). A general propensity score was estimated to adjust for baseline differences between the three groups. Mixed models were used to determine the association of the three groups and outcomes. Surgeries were analyzed by Cox regression analyses.
**Results:** 609 patients were ever treated with a bDMARD and successfully transferred to JuMBO. Most (91%) patients were enrolled in BiKeR on etanercept followed by adalimumab (6%), 93% had previously received a conventional synthetic (cs) DMARD. 27.9% had RF negative polyarthritis and 19.5% enthesitis-related arthritis. The first csDMARD was started 0.4 years after disease onset in the early bDMARD group (n=142), and 1.2 and 3.1 years after JIA onset in the in-between group and late group (n=274), respectively. At their last follow-up (10.2±6.2 years after JIA onset), the patients' mean age was 21.2 years. The clinical outcome 10 years after disease onset could be investigated in 478 patients. Patients with early biologic treatment were significantly more often in drug-free JADAS remission (15%) for at least 12 months, had more often an inactive disease (JADAS3–10$\leq$1, 27.6%) and no functional limitations (58.6%) compared to late treatment start. There was no significant difference in the patient-reported outcome measures. Among all 609 patients, 35 (5.8%) patients had undergone joint replacement, 100 (16.4%) synovectomy and 19 (3.2%) eye surgery. Patients on bDMARD in follow-up had a lower likelihood for joint replacement (HR=0.25, p=0.003) or synovectomy (HR=0.26, p$<$0.001). Patients with late DMARD treatment had significantly more synovectomies (HR=4.9, p$<$0.001) than patients with early treatment.
**Conclusions:** Patients who started with cs and bDMARDs within the first two years of disease are significantly more often in drug-free remission in adulthood and have less sequelae than those who started later. The data emphasize the importance of a fast disease activity control and may support the idea of a window of opportunity for JIA.

## THU0233 IMPACT OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS/STILL'S DISEASE ON ADOLESCENTS AS EVIDENCED THROUGH SOCIAL MEDIA POSTING

R.F. Modica[1], K.G. Lomax[2], P. Batzel[3], A. Cassanas[3], M. Elder[1]. *[1]Department of Pediatrics, University of Florida, Gainesville, Fl; [2]Immunology and Dermatology Medical Affairs, Novartis Pharmaceuticals Corp, East Hanover, NJ; [3]Treato, Princeton, NJ, United States*

**Background:** Systemic juvenile idiopathic arthritis (SJIA)/Still's disease is a rare form of chronic arthritis in pediatrics. The patient perspective of living with the disease is not well understood, particularly among adolescent age patients.
**Objectives:** The objective was to understand the adolescent SJIA experience as shown by their own social media posts.
**Methods:** English posts from SJIA patients were reviewed on public social media sites.
**Results:** 71 posts with a date range of 2009–2015 on 15 sites were reviewed in Nov 2015. 24 unique authors were identified: 17 SJIA patients (40 posts) and 7 mothers of SJIA patients (12 posts). Patients were aged 13–20 years. Several patients posted about similar diagnostic experiences marked by 5 stages: (1) misunderstood with their pain and fatigue being overlooked until a crisis occurs, (2) dismissed as "fakers", where their initial misdiagnosis is often "growing pains" or "fake pains", (3) misdiagnosis, often as cancer, when the symptoms acutely worsen (4) testing stage that leads to an SJIA diagnosis, and (5) focus on the difficulties of dealing with a chronic invisible disease where they feel ashamed of their arthritis and distressed at being different from their peers. Many adolescent patients, looking back at the onset of the disease when they were children, describe themselves as a "sleeping child" rather than the typical active, playing child. Patients describe trying to hide their illness from friends, but express their concerns more openly online. Patients also describe anger directed at SJIA which is described as a powerful external enemy attacking their body, using terms like "bulldozer," "dragon", and "monster'.' Many posters used superhero language or imagery in their social media posts to help them "fight" the disease and their struggle. Mothers of SJIA patients also used warrior-child imagery and language in their posts. Some SJIA patients also posted about the risk of death, or shared stories about other SJIA patients who died which is a distinct difference from non-SJIA patients. Many patients also have adopted the term "spoonie" to describe themselves as living with a chronic disease, a term that originated in the autoimmune community to refer to how people with chronic conditions manage their energy throughout the day. Only the older teenagers used the term Still's.
**Conclusions:** Adolescent SJIA patients posted openly about the difficulties of their disease causing them to be different from their healthy friends, whereas in the real world they tried to minimize or hide the effects of their disease. They frequently used superhero words and images in posts in describing their fight for health. Physicians can use these insights when counseling adolescent SJIA patients to provide a narrative that meshes with the patients' worldview and perhaps, by speaking a similar language, could increase treatment adherence.

## THU0234 CLINICAL EXPERIENCE AND DECISION MAKING IN RELATION TO THE USE OF BIOLOGICS IN ADULT JIA

N. Smith[1], T. Rapley[2], F. McErlane[3], L. Kearsley-Fleet[4], K.L. Hyrich[4,5], H.E. Foster[1,3]. *[1]Musculoskeletal Research Group, Institute of Cellular Medicine; [2]Institute of Health and Society, Newcastle University; [3]Paediatric Rheumatology, Great North Children's Hospital, Newcastle Upon Tyne; [4]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, University of Manchester; [5]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*

**Background:** Juvenile Idiopathic Arthritis (JIA) is the most common chronic inflammatory musculoskeletal disease of childhood in the UK. More than 30% of patients will continue to have active disease as adults, with some requiring a biologic for the first time after the age of 18 years. Prior to December 2015, there was no national UK approval for the use of biologics in this older population, albeit they were used in adults with JIA (British Society for Rheumatology Biologics Register BSRBR Data).
**Objectives:** This mixed methods study aimed to explore the clinical experience

and decision-making of health care professionals in relation to the use of biologics in adults with JIA.
**Methods:** An online survey of 205 healthcare professionals working in UK hospitals who have recruited adults with JIA to BSRBR-RA (response rate: 81 (39%) including rheumatology consultants (49), rheumatology specialist nurses (29), research nurses (2) and staff associates (1)), ascertained their experience in relation to four distinct areas: (1) Education, Training and Practice; (2) Factors Suggesting a Diagnosis of JIA, (3) Use and Choice of Biologics; and (4) Treatment Challenges. The survey data were analysed using descriptive statistics and free-text comments using qualitative techniques. This study had ethical approval with informed consent from all participants.
**Results:** Most (95%) survey participants currently treat adults with JIA and many (63%) also treat children. Most had not received any education or training in the specific management of adults with JIA (65%) although 56% had received some training in paediatrics (described as formal training programmes, attendance at meetings; in practice learning and colleague support). Many stated further need for training in JIA in adults (52%) and children (58%).
Participants reported using all currently approved biologics for either JIA in children or rheumatoid arthritis; etanercept, adalimumab and tocilizumab being the most common. Factors influencing choice included: National guidelines and funding; JIA disease-associated factors; patient previous treatment; previous experience of clinician; and patient choice. The challenges encountered in treating adults with JIA included: access to biologic therapy; JIA awareness and knowledge; access to support from colleagues and MDT; problems associated with transitional care services; and patient expectations. Potential improvements to aid the diagnosis and management of adults with JIA were offered and these included: Introduction of national guidelines; further education/training and support; and introduction or improvement of transition service links.
**Conclusions:** Improved access to education, training and treatment guidelines in JIA is likely to improve clinical experience and decision-making in relation to the management of adults with JIA. Future qualitative work will explore this further.
**Disclosure of Interest:** None declared

## THU0235 ADJUVITE: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED TRIAL OF ADALIMUMAB IN JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS

P. Quartier[1], V. Despert[2], S. Poignant[3], C. Elie[4], I. Kone-Paut[5], A. Belot[6], L. Kodjikian[7], D. Monnet[8], M. Weber[9], B. Bodaghi[10], A. Baptiste[4]. *[1]Pediatric Immunology-Hematology and Rheumatology Unit, Necker* ***Hospital,:*** *Paris; [2]Pediatrics, CHU, Rennes; [3]Pediatrics, CHU, Nantes; [4]Clinical Research Unit, Necker Hospital, Paris; [5]Pediatrics, CHU, Kremlin-Bicetre; [6]Pediatrics; [7]Ophtalmology, CHU, Lyon; [8]Ophtalmology, Cochin Hospital, Paris; [9]Ophtalmology, CHU, Nantes; [10]Ophtalmology, Pitie-Salpetriere Hospital, Paris, France*

**Background:** Juvenile idiopathic arthritis (JIA) patients may develop chronic, anterior uveitis. Topical steroids and methotrexate (MTX) often lack of efficacy.
**Objectives:** To asses safety and efficacty of adalimumab in patients with JIA-associated uveitis.
**Methods:** Elligible patients had chronic, "white eyes" uveitis with inadequate response to topical steroids and MTX, no previous anti-TNF antibody therapy and at least one assessable eye with inflammation quantified by laser flare photometry $\geq$30 photons/ms. Double-blind randomization at Day 1 (D1) into 2 equal groups, one treated with placebo and one with adalimumab (24 mg/m$^2$ in patients aged 4 to less than 13 years, 40 mg in patients $\geq$13), every other week subcutaneous injections. Primary objective: to demonstrate a higher response rate at Month 2 (M2) in the adalimumab arm versus the placebo arm. Response was defined as a 30% reduction of inflammation on laser flare photometry in the eye with the highest flare value at D1 and improvement or a stable appearance on slit lamp examination. From M2 to M12, all patients were allowed to receive adalimumab (open phase) (NCT01385826).
**Results:** 34 patients were screened and 31 received at least one injection of study treatment.

Table 1. Patients characteristics at study treatment onset

| | Ada (n=16) | Placebo (n=15) | All (n=31) |
|---|---|---|---|
| Female, n (%) | 15 (94) | 13 (87) | 28 (90) |
| Age, median value, years [ranges] | 10.8 [5.0–20.3] | 9.2 [4.9–29.1] | |
| Active joints, median n [ranges] | 0 [0–3] | 0 [0–4] | 0 [0–4] |
| Uveitis median duration, years [ranges] | 4.4 [0.4–18.9] | 4.8 [0.6–24.2] | |
| Laser flare (ph/ms), median [ranges] | 99 [23–322] | 70 [36–265] | |
| Bilateral uveitis, n (%) | 10 (63) | 14 (93) | 24 (78) |
| Ongoing treatments at D1 | | | |
| Oral steroids, patients n (%) | 7 (44) | 3 (20) | 10 (32) |
| Methotrexate, patients n (%) | 15 (94) | 11 (73) | 26 (84) |

At M2, in intention-to-treat (Primary objective), there were 9/16 responders in the adalimumab group and 3/15 in the placebo group ($p$=0.038, Chi-squared test; RR=2.81, CI95%=[0.94–8.45] with log-binomial model estimation). One patient stopped the trial at D14 (adalimumab group, uveitis worsening) and one at M9 (ocular hypertony). 29 patients reached M12 on adalimumab. There were 5 serious adverse events in 4 patients, all in the placebo group, 4 during the open-label phase, none related to study treatment (investigator assessment).
**Conclusions:** Adalimumab was effective in reducing ocular inflammation within 2 months and well tolerated over 12 months in patients with JIA-associated chronic uveitis and an inadequate response to topical steroids and MTX. Laser flare photometry is a valuable tool to assess early improvement.

## THU0236 BONE METABOLIC INDEX AND CLINICAL PHENOTYPE IN JUVENILE-ONSET ANKYLOSING SPONDYLITIS (JAS)

P. Zhang, Z. Hu, J. Qi, Y. Mou, Y. Jiang, J. Gu. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** Ankylosing spondylitis (AS) is a common inflammatory rheumatic disease which preferentially affects the axial structures causing spinal ankylosis, AS is more common in young adults aged 10–40, but the onset age can also be childhood. It was grouped according to onset age: those with onset symptoms before the age of 16 years were classified as Juvenile-onset Ankylosing Spondylitis (JAS), and patients with onset symptoms older than 16 at onset were classified as Adult-onset Ankylosing Spondylitis (AAS). Clinical phenotype and prognosis of JAS is different from AAS,but up to now scarce information about JAS was reported, especially the related bone metabolism mechanism.
**Objectives:** To analyse bone metabolic index (BMI) changes on patients with Juvenile-onset Ankylosing Spondylitis (JAS) and their relations with clinical index.
**Methods:** To collect the clinical data of JAS,such as C-reactive protein (CRP), blood sedimentation (ESR),the disease activity index (BASDAI),functional index (BASFI) and bone mineral density (BMD), detect the serum bone metabolism index,such as Wnt-3a, BMP-2, Dkk-1, 25 (OH) D and ICTP, then group these data and do statistical analysis.
**Results:** Osteopenia and VitD lack were widespread in JAS. Compared with controls, The elevated Wnt-3a and reduced Dkk-1 levels were not significant in JAS ($P>0.05$), and there was no significant correlation between the two indexes and other BMI, course, clinical inflammation index, BASDAI and BASFI. However,the serum ICTP and BMP-2 were increased significantly in JAS, and both the CRP and BMP-2 were positive related with serum Wnt-3a (r was 0.271 and 0.250 respectively, $P<0.05$).Correlation analysis shew there was positive correlation between serum 25 (OH) D and hip BMD in JAS (r=0.383, $P<0.01$), and there was negatively correlation between ICTP and BASDAI (r=-0.405 and -0.273 respectively, $P<0.05$).Besides,regression analysis shew that both serum 25 (OH) D and the disease course were independent prognostic factors of patients' hip BMD decreasing, where as CRP and ICTP were also independent prognostic factors of patients' BASDAI. BMI in JAS with different clinical phenotypes were compared, BMP-2 level was much higher in JAS with hip joint involvement than other groups (P=0.032), while there was no significant difference in serum 25(OH)D,ICTP,Wnt-3a and Dkk-1 level in all groups ($P<0.05$).
**Conclusions:** There is bone metabolism imbalance in JAS,and BMI can indirectly reflect the disease activity and bone loss,among which BMP pathway played an important role in the JAS with hip lesions and deserves further research.

## THU0237 DISEASE ACTIVITY IN PATIENTS WITH JUVENILE SPONDYLOARTHROPATHY ON ANTI-TNF THERAPY AS MEASURED BY THE JUVENILE ARTHRITIS DISEASE ACTIVITY SCORE (JADAS)-10 AND THE JUVENILE SPONDYLOARTHRITIS DISEASE ACTIVITY INDEX (JSPADA)

R.A. Russo, M.M. Katsicas. *Immunology & Rheumatology, Hospital de Pediatría Garrahan, Buenos Aires, Argentina*

**Background:** Juvenile Spondyloarthropathy (jSpA) is SpA that starts during childhood and adolescence. Most children with jSpA fall into the categories of

enthesitis-related arthritis (ERA), psoriatic arthritis, and undifferentiated arthritis of the ILAR classification of Juvenile idiopathic arthritis (JIA). Several disease activity scores have been developed for adults with SpA and for children with JIA (such as the Juvenile Arthritis Disease Activity Score or JADAS). However, neither of these measures has been validated in jSpA. The Juvenile Spondyloarthritis Disease Activity Index (JSpADA) has been recently developed and retrospectively validated in jSPA (1).

**Objectives:** to assess disease activity in a cohort of patients with ERA on anti-TNF therapy using the JADAS-10 and the JSpADA.

**Methods:** retrospective review of prospectively collected data. Patients with ERA treated with anti-TNF agents for $\geq$1 year and complete records were included. Information was collected on visits 0 (immediately prior to anti-TNF therapy start), 1 month after start of therapy, and every 3 months thereafter (up to 36 months) on demographics, therapeutic agents used, and disease activity measures: active joints (AJ), active enthesitis (AE), pain score, wellbeing according to the patient (VASp), disease activity according to the physician (VASphy), JADAS-10, JSpADA, and ESR. Comparisons between visits were performed using paired t-test; correlations between outcome measures was done using Spearman's correlation test.

**Results:** 24 of 28 patients treated with anti-TNF agents fulfilled inclusion criteria. They were all male, 50% HLA-B27 positive; median age at entry 13 y, disease duration 4 y; median observation period was 21 months, 207 visits were recorded. Twenty-two (92%) children showed peripheral arthritis while 17 (71%) exhibited sacroiliitis on MRI/Xrays before starting therapy. Patients received etanercept (17, 2 were later switched to infliximab and adalimumab each), adalimumab (5), or infliximab (2). At baseline patients showed (medians): AJ 4.5, ESR 15 mm/h, VASphy 1, JSpADA 2, and JADAS 9.5. AE was present in 4 (17%) and lumbar limitation (LL) in 9 (37%) children. All patients showed JSpADA $>$0 and 95% children had JADAS $>$1. After 3 months JSpADA decreased to 1.25 and JADAS-10 to 6; 5 (21%) patients achieved inactive disease (ID, JADAS-10 $\leq$1). At visit 12 months: AJ 0 (p=0.0015), ESR 7 mm/h (p=0.06), VASphy 0.5 (p=0.005), JSpADA 1 (p=0.0004), and JADAS 1.75 (p=0.02); AE was present in 0 patients and LL in 6 (25%). JADAS-10 $\leq$1 was observed in 18 (75%) patients and JSpADA $\leq$1 in 21 (87%) children during follow-up. At baseline and at visit 12 months JSpADA showed high correlations with JADAS-10 (r=0.97, 0.75) and AJ (r=0.73, 0.77); JADAS-10 also correlated with AJ (r=0.92, 0.83).

**Conclusions:** in this retrospective cohort of ERA patients with peripheral and axial active involvement there was a marked and progressive reduction in disease activity after the initiation of anti-TNF therapy. Both JSpADA and JADAS-10 demonstrated to be sensitive, feasible and useful activity measures that could be used in clinical trials or a treat to target strategy for JSpA.

## THU0238 HOW TO DIAGNOSE AND PREVENT THE EPISODES OF PFAPA SYNDROME

M. Gunes[1], S. Cekic[1], S.S. Kilic[2]. [1]*Uludag University Medical Faculty, Bursa, Turkey;* [2]*Pediatric Rheumatology, Uludag University Medical Faculty, Bursa, Turkey*

**Background:** Periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis (PFAPA) syndrome is the most frequent repetitive fever syndrome in childhood. It is characterized with fever episodes lasting for about three to six days, once every three to eight weeks.

**Objectives:** In this study, we aim to elucidate the clinical clues that will facilitate the identification of PFAPA which is a clinical diagnosis and the efficacy and safety of colchicine prophlaxis in a large cohort. Additionally, we intend to investigate the relation between MEFV gene mutations and clinical findings of PFAPA.

**Methods:** Clinical and laboratory data of 400 consecutive patients with PFAPA syndrome followed up at the department of Pediatric Immunology and Rheumatology Uludag University Faculty of Medicine, were collected from the medical records retrospectively.

**Results:** Four-hundred children (256 male, 144 female), the mean age at diagnosis was 4.2 ± 2.2 years, were involved in our study. During the episodes, the mean number of WBC was high (12724,7/mm$^3$) with predominantly neutrophils. The mean number of monocytes was found to be 1256.2/mm$^3$ and 90.2% of the patients had monocytosis. Serum amiloid A and C reactive protein levels were high in 84.6% and 77.8% of the patients, respectively. Procalcitonin was negative in 97.3% of the patients. MEFV gene heterozygous mutation was determined in 57 of the 231 patients (24.7%) tested. Colchicine prophylaxis was administered in 356 patients. The mean duration between episodes was prolonged from 18.8 to 49.5 days by prophylactic colchicine therapy. During the episodes, a single dose of 1 mg/kg methyl prednisolone was prescribed. Four patients underwent tonsillectomy.

**Conclusions:** Our study, include the largest number of patients with PFAPA syndrome in the literature. It is particularly important to assess and to demonstrate the high rate of response to colchicine prophylaxis in patients with PFAPA syndrome, especially those with MEFV variant. In blood screening neutrophilia associated with monocytosis and low procalcitonin level could contribute to diagnosis.

## THU0239 PERFORMANCE OF DISEASE ACTIVITY MEASURES IN JUVENILE SPONDYLOARTHRITIS IN A PLACEBO CONTROLLED TRIAL WITH INFLIXIMAB

S. Ramiro[1], J.C. Casasola-Vargas[2], D. van der Heijde[1], R. Landewé[3], R. Burgos-Vargas[2]. [1]*LUMC, Leiden, Netherlands;* [2]*Hospital General de Mexico, Mexico, Mexico;* [3]*ARC, Amsterdam, Netherlands*

**Background:** Several outcome measures in trials with juvenile-onset spondyloarthritis (Jo-SpA) have been borrowed from trials in juvenile idiopathic arthritis and from adult spondyloarthritis, but a proper psychometric analysis has never been conducted in patients with Jo-SpA.

**Objectives:** To assess discriminatory aspects of several disease activity outcome measures and response criteria for Jo-SpA.

**Methods:** Data from a previously reported 12-week RCT comparing infliximab (IFX) and placebo (PBO) in patients $<$18 years with Jo-SpA and onset $<$16 years of age were analyzed. The primary endpoint of the trial was the number of active joints (both swollen and tender). Several other disease activity measures and response criteria were also tested (Table). Statistics to determine how well disease activity measures could discriminate between IFX and PBO included "standardized mean difference" (SMD) and "Guyatt's effect size". Both statistics are standardized measures to compare change from baseline per group. For categorical response criteria, the chi-square test ($\chi^2$) was used. Higher numbers indicate better discriminatory capacity.

**Results:** Patients were randomised to IFX (n=12) and PBO (n=14). Of the continuous measures, the ASDAS showed the best and very good discrimination between IFX and PBO (SMD:1.98; Guyatt: 4.28) (Table). The physician's global, CRP, JADAS and JSpADA also discriminated well. The BASDAI (or its separate items), BASFI and spinal mobility measures performed worse. Of the response criteria ASAS40 and ACR Pedi 90 discriminated best between IFX and PBO (Table). ASDAS response criteria and ACR Pedi 30–70 also performed well.

**Table: Discrimination between patients on infliximab and placebo at week 12**

| CONTINUOUS OUTCOME MEASURES | | | | |
|---|---|---|---|---|
| | Infliximab mean change (SD) | PBO mean change (SD) | Guyatt's effect size | SMD |
| ASDAS | 2.4 (1.3) | 0.5 (0.6) | 4.28 | 1.98 |
| Physician's global assessment, 0-10 mm VAS | 5.2 (2.4) | 1.6 (2.2) | 2.34 | 1.56 |
| JADAS27 (0-57) | 12.7 (5.9) | 4.3 (5.7) | 2.22 | 1.46 |
| JSpADA (0-8) | 2.8 (1.2) | 0.5 (1.4) | 1.98 | 1.73 |
| CRP (mg/L) | 21.1 (8.4) | 2.3 (10.9) | 1.93 | 1.90 |
| Total enthesitis (0-51) | 8.5 (10.6) | 1.6 (5.0) | 1.71 | 0.85 |
| Patient's global assessment, 0-10 mm VAS | 4.3 (3.8) | 0.8 (2.8) | 1.55 | 1.08 |
| BASDAI total (0-10) | 3.3 (3.1) | 0.9 (2.3) | 1.41 | 0.90 |
| Pain, 0-10mm VAS | 3.3 (2.1) | -1.7 (3.2) | 1.03 | 1.80 |
| Active joint count (0-72) | 4.4 (1.7) | 2.6 (4.6) | 0.96 | 0.51 |
| | **Infliximab mean change (SD)** | **PBO mean change (SD)** | **Chi-square** | **p-value** |
| ACR Ped 90 | 8 (67%) | 1 (7%) | 10.12 | 0.001 |
| ASAS40 | 6 (55%) | 0 (0%) | 10.05 | 0.002 |
| ACR Ped 70 | 9 (75%) | 2 (14%) | 9.76 | 0.002 |
| BASDAI50 | 8 (73%) | 2 (14%) | 8.77 | 0.003 |
| ASDAS-MI | 5 (63%) | 0 (0%) | 8.65 | 0.003 |
| ACR Ped 50 | 11 (92%) | 5 (36%) | 8.55 | 0.003 |
| ASDAS-CII | 7 (88%) | 2 (20%) | 8.10 | 0.004 |
| ASDAS-ID | 7 (64%) | 1 (8%) | 7.74 | 0.005 |
| ACR Ped 30 | 11 (92%) | 6 (43%) | 6.80 | 0.009 |
| JADAS27 MDA (≤2) | 6 (50%) | 1 (7%) | 6.03 | 0.014 |
| JADAS27 inactive disease/remission (≤1) | 3 (25%) | 0 (0%) | 3.96 | 0.047 |
| ASAS20 | 7 (64%) | 4 (29%) | 3.07 | 0.080 |

**Conclusions:** Of all continuous measures tested in adult axial SpA the ASDAS discriminates best between active treatment and PBO in patients with Jo-SpA. But the child specific JSpADA also performs well.

Of all response criteria tested the child-specific ACR Pedi 30 to 90, as well as the adult ASAS40 and ASDAS response criteria work well. One of these measures should be used as primary endpoint in trials with Jo-SpA.

## SLE, Sjögren's and APS - etiology, pathogenesis and animal models

### THU0240 DYSREGULATIONS IN THE SPHINGOLIPID PATHWAY IN SLE PATIENTS

A. Checa[1], H. Idborg[2], D.G. Sar[1], P.-J. Jakobsson[3], C.E. Wheelock[1], I. Gunnarsson[3]. *[1]Department of Medical Biochemistry and Biophysics, Bioanalytical Chemistry Research Laboratory in Inflammatory Metabolomics, Karolinska Institutet, Stockholm; [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Solna; [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease with a heterogeneous presentation of symptoms from joints, skin, kidneys, central nervous system, lungs, and the cardiovascular system. There is no cure for SLE and development of novel drugs and biomarkers of effective treatment is needed. Sphingolipids are bioactive signaling molecules involved in the regulation of cell growth, differentiation and apoptosis. Dysregulation of single sphingolipids has been described in several diseases with an inflammatory component and sphingosine-1-phosphate (S1P) agonist (Fingolimod) is investigated as treatment in SLE. Therefore, the sphingolipid pathway has arisen as very important compounds to study in respect to SLE pathogenesis.
The compounds of the sphingolipid pathway are highly correlated and simultaneous measure of several sphingolipids in an "omics" like analysis is expected to provide more information than compounds individually determined.
**Objectives:** Our objective is to screen the sphingolipid pathway in patients with SLE compared to healthy controls. In addition we aim to study if the altered sphingolipids will be normalized after treatment.
**Methods:** EDTA-plasma from 107 SLE female patients were screened for 34 different sphingolipids by liquid chromatography tandem mass spectrometry (LC-MS/MS) and compared to matched healthy population-based donors (n=23). In addition, female SLE patients (n=22) were analyzed before and after induction of remission treatment.
**Results:** SLE patients were found to exhibit an altered sphingolipid profile compared to controls. Significantly ($p<0.01$) increased levels of C16:0- and C24:1-ceramides, C16:0, C18:0 and C24:1-hexosylceramides and decreased levels of S1P were found in SLE patients compared to controls. The observed higher levels of ceramide to S1P ratios in SLE patients may reflect the blockage of the pathway that is controlled by ceramidase and can be inhibited by nitric oxide. These alterations were associated with SLAM and SLEDAI clinical scores and were normalized after induction of remission treatment.
**Conclusions:** This work shows the importance of performing a holistic approach targeting the different molecules of the sphingolipid pathway. Our results show dysregulations in circulating sphingolipids in patients with SLE and normalized after treatment, suggesting that sphingolipids may be useful markers of disease progression and possible drug targets.

### THU0241 PRESENCE OF GERMINAL CENTERS IN DIAGNOSTIC BIOPSIES OF PRIMARY SJÖGREN'S SYNDROME PATIENTS IS NOT A RISK FACTOR FOR THE DEVELOPMENT OF PAROTID MALT LYMPHOMAS

E.A. Haacke[1,2], A. Vissink[3], B. van der Vegt[2], F.K. Spijkervet[3], H. Bootsma[1], F.G. Kroese[1]. *[1]Dept of Rheum & Clin Immun; [2]Dept of Pathol & Med Biol; [3]Dept of Oral & Maxillofacial Surg, UMCG, Groningen, Netherlands*

**Background:** B cell hyperactivity is a hallmark of primary Sjögren's syndrome (pSS) and plays a critical role in sustainment and progression of pSS.[1] Hyperactivity is reflected by the presence of germinal centers (GCs) in periductal lymphoid infiltrates in the salivary glands. Risselada et al[2] reviewed the presence of GCs in the salivary gland biopsies of pSS patients. On hematoxylin and eosin (HE) stained sections a mean weighted percentage of 25.1±5.0% (range 18.3–33%) of GCs positivity was present. On CD21 sections, staining follicular dendritic networks, this increased to 35.3±14.8% (range 19–58.8%).
A serious complication of pSS is the 5–10% lifetime risk of developing non-Hodgkin B cell lymphomas.[3] Most lymphomas associated with pSS are of the Mucosa Associated Lymphoid Tissue (MALT) type, which typically arise in parotid glands. Which pSS patients will develop non-Hodgkin's lymphomas is largely unknown, but several risk factors have been identified. Presence of GCs in minor salivary glands at diagnosis of pSS has been postulated as a risk factor. Theander et al[4] observed that six out of seven pSS patients that developed malignant lymphomas had GCs in their initial diagnostic minor salivary gland biopsy. However, a drawback of that study was that also lymphomas not characteristic for pSS such as follicular lymphoma and anaplastic T-cell lymphoma were included.[4]
**Objectives:** The aim of this study was to explore the possible role of GCs as risk factor for malignant lymphoma development in pSS restricting ourselves to lymphomas which are typically associated with pSS, namely parotid gland MALT lymphomas.
**Methods:** In a cohort of 56 pSS patients with parotid MALT lymphomas we were able to collect and reassess tissue sections from 14 salivary gland biopsies (11 minor, 3 parotid) taken at diagnosis of pSS, i.e. before diagnosis of MALT. Paraffin sections were analyzed for the presence of GCs on HE sections and, more sensitively, by B cell lymphoma 6 protein (BCL6) staining.
**Results:** HE stained sections of 11 diagnostic minor salivary gland biopsies revealed that GCs were present in 2/11 (18%) biopsies (Fig. 1a,c). BCL6 staining showed a small GC in one additional patient in the initial biopsy (Fig. 1b,d). Thus, GCs were present in 3/11 labial salivary gland biopsies (27%). Including diagnostic parotid gland biopsies, GCs were present in 4/14 (29%) HE stained sections and in 5/14 (36%) BCL6 stained sections. The mean interval between diagnosis of pSS and parotid MALT lymphoma was 6.0 yr (range 0.2–14.4 yr).

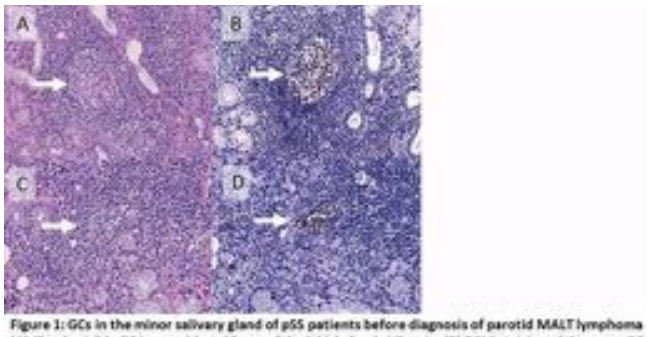

**Figure 1: GCs in the minor salivary gland of pSS patients before diagnosis of parotid MALT lymphoma**
(A) Clearly visible GC in a periductal focus of the labial gland, HE stain. (B) BCL6 staining of the same GC. (C) Conspicuous GC in a periductal focus of the labial gland, HE stain. (D) BCL6 staining shows a small GC. Arrows point to GCs.

**Conclusions:** In this study percentages of GCs in salivary gland biopsies prior to MALT lymphoma were comparable to the percentage of GCs positive biopsies in the general pSS population.[2] We therefore conclude that presence of GCs in diagnostic (minor) salivary gland biopsies is not predictive for developing pSS associated parotid gland MALT lymphomas.

### THU0242 HIGH-THROUGPUT SCREENING DISCOVERS NOVEL AUTOANTIBODIES IN AUTOIMMUNE DISEASES: THE SEROTAG APPROACH IN SYSTEMIC LUPUS, SYSTEMIC SCLEROSIS AND RHEUMATOID ARTHRITIS

P. Schulz-Knappe[1], P. Budde[1], H. Goehler[1], H.-D. Zucht[1], M. Schneider[2], S. Vordenbäumen[2], A. Lueking[1], R. Brinks[3], J. Richter[2]. *[1]Protagen AG, Dortmund; [2]Policlinic of Rheumatology, Heinrich-Heine-University; [3]Institute for Biometry and Epidemiology, German Diabetes Center, Düsseldorf, Germany*

**Background:** Diagnostic biomarkers are decision-making tools in clinical lab routine and are of growing importance for clinical management of patients. In autoimmune diseases, one class of biomarkers are autoantibodies (AAB) directed against human autoantigens. Apart from diagnostic antigens used in clinical routine, additional AAB reactivities to more than 100 human antigens are described in literature. Obviously, the autoimmune profile of humans covers a huge number of AABs, which display an enormous resource to identify novel marker candidates.
**Objectives:** Here we describe a new screening platform SeroTag for screening of novel AABs in autoimmune diseases. By offering thousands of human antigens to serum samples of several autoimmune diseases a comprehensive landscape shall be drawn to identify diseases and disease subgroups according to their intrinsic, highly differentiated autoantibody pattern.
**Methods:** SeroTag utilizes over 7,000 human proteins as antigen collection in bead-based suspension arrays (Luminex FlexMap 3D) to allow for high throughput serum sample processing with high accuracy, followed by standard and advanced data mining procedures. We screened over 4,000 serum samples from patients with autoimmune diseases such as SLE (n= >500), SSc (n= >250), RA (n= >500), and healthy individuals (n= >350) to confirm known and to discover novel autoantibodies. Recombinant antigens were covalently coupled to magnetic, color coaded beads and serum samples were incubated with 20 multiplex bead mixes

each representing hundreds of antigens. Univariate and multivariate statistical analyses were performed to reveal significant antigens and to define correlation of antigens with clinical parameters and amongst themselves.
**Results:** In SLE, SSc and RA novel autoantigens were discovered in independent discovery and validation studies. Antigens showing reproducible, significant reactivity compared to active and passive controls were selected in a stepwise marker refinement approach. Examples include BICD2 and KDM6B as novel antigens in SSc with 20–30% prevalence, TMPO and MVP in SLE with 15–25% prevalence, and several novel protein targets of anti-citrullinated peptide antibodies.
**Conclusions:** Discovery approaches for autoantigens in autoimmune diseases show great promise to further detail the autoimmune landscape. SeroTag screening is a valuable tool for "omics"-type biomarker discovery and verification. Novel autoantigens were discovered and validated in RA, SLE, SSc which show potential for improved and earlier diagnosis, differential diagnosis, and disease subgrouping.

## THU0243 INTEGRATED ANALYSIS OF MICRORNA AND MRNA EXPRESSION PROFILES RELATED TO CARDIOVASCULAR DISEASE IN MONOCYTES FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

C. Perez-Sanchez[1], M.Á. Aguirre[1], P. Ruiz-Limón[1], N. Barbarroja[1], Y. Jiménez-Gómez[1], M.C. Ábalos[1], I. Arias-de la Rosa[1], M. Galindo[2], E. Collantes-Estévez[1], M.J. Cuadrado[3], C. López Pedrera[1]. *[1]IMIBIC/Reina Sofía Hospital/University of Córdoba, Córdoba; [2]Doce de Octubre Hospital, Madrid, Spain; [3]Lupus Research Unit, St Thomas Hospital, London, United Kingdom*

**Background:** MicroRNAs (miRNAs) are endogenous small non-coding RNAs that regulate gene expression by interfering translation or stability of target transcripts. This interplay between miRNA and their mRNA might constitute an important mechanism in the regulation of the proatherothrombotic status of SLE patients.
**Objectives:** To investigate the contribution of deregulated miRNAs to the altered gene profile associated to cardiovascular disease in SLE.
**Methods:** Thirty three SLE patients and 27 healthy donors were included in the study. Gene Expression Microarray (44K, Agilent, one colour) and nCounter microRNA Expression Array (NanoString Technologies) were performed, respectively, to analyze mRNA and miRNA expression profiles on isolated monocytes. Target genes of the differentially expressed miRNAs were identified by using the Igenuity Pathway Analysis Software (IPA). To recognize the putative microRNA-mRNA target pairs and interaction networks, the subsets of miRNAs and mRNAs were characterized by the microRNA Target Filter tool of IPA. The resulting identified interactions were revalidated by RT-PCR on the whole cohort of SLE patients. The predicted microRNA-mRNA interactions were also tested by functional analyses using microRNA over expression experiments in monocytes purified from SLE patients
**Results:** Comparative analysis of the mRNA profiles showed significantly different expressions of 1222 genes in SLE monocytes in relation to healthy monocytes (658 up-regulated and 564 down-regulated). Functional analysis by using IPA showed that about 30% of altered genes were involved in inflammation and cardiovascular disease (CVD). Comparative analysis of the microRNA profiles showed significantly different expressions of 37 microRNAs in SLE monocytes (8 up-regulated and 29 down-regulated). Functional IPA analysis showed that microRNAs altered were mainly related to connective tissue disorders, inflammatory response and reproductive system disease. A total of 63 genes were inversely correlated, and predicted as CVD-related target genes of 23 differentially expressed microRNAs. Interaction networks of those genes and some microRNAs differentially expressed in SLE monocytes were also identified. Among them, we verified the overexpression of STAT3 and PPARg (which promote monocyte/macrophage differentiation and uptake of oxLDL) associated to inhibition of miR-130a-3p. Similarly, we demonstrated in our patients cohort the overexpression of CMKLR1 (chemokine receptor regulating the recruitment of inflammatory monocytes to sites of inflammation) associated with inhibition of miR-149–5p. The relationship between these identified target genes and specific miRNAs was further delineated in ex vivo studies.
**Conclusions:** We have identified novel microRNA-mRNA regulatory networks related to CVD in SLE, thus delineating a novel genetic control of the diverse biological processes and factors related to the cardiovascular pathology present in this autoimmune condition.

## THU0244 NONINVASIVE ASSESSMENT OF MACROPHAGE ACTIVATION IN EXPERIMENTAL GLOMERULONEPHRITIS USING OPTICAL IMAGING WITH NEAR-INFRARED LIGHT SERVES AS A SURROGATE OF DISEASE ONSET

S. Braehler[1], M.D. Cheung[2], D. Huang[2], W.J. Akers[3], A.H. Kim[2]. *[1]Immunobiology; [2]Rheumatology; [3]Mallinckrodt Institute of Radiology, Washington University School of Medicine, Saint Louis, MO, United States*

**Background:** Glomerulonephritis (GN) represents a major cause of morbidity and mortality in many conditions such as systemic lupus erythematosus. The standard for diagnosing GN is through renal biopsy, but this is not performed uniformly across many centers. Furthermore, it is well established that early treatment of GN improves complication and survival outcomes (1,2). While proteinuria and/or hematuria is typically the first clinical sign of GN, immunologic changes in the kidney such as macrophage infiltration is observed well before. Thus, there is an unmet need to identify a noninvasive approach for recognizing GN, especially the preclinical stages. Recent advances in deep tissue imaging using probes detected by near-infrared (NIR) wavelengths have enabled the noninvasive probing of biologic activity. Activated macrophages that infiltrate the kidney early in GN express the papain-like cysteine protease cathepsin B (3). Thus, renal macrophage activation can be assessed using an NIR probe that becomes fluorescent upon cleavage by cathepsin B.
**Objectives:** We tested whether NIR optical imaging can assess renal macrophage activation as a noninvasive marker for early-stage GN.
**Methods:** GN was induced in 129 mice by nephrotoxic serum (NTS) delivered intravenously. Proteinuria was quantitated using albumin ELISA and chromogenic creatinine assay. Presence of renal macrophages was confirmed using FACS. NIR optical imaging of anesthetized mice was performed following intravenous administration of a cleavable sensor for cathepsin B and fluorescence intensity of kidney regions quantified using the Perkin Elmer FMT4000 fluorescence molecular tomography device.
**Results:** In mice with uninflamed kidneys, we confirmed the paucity of renal macrophages. Accordingly, there was minimal renal fluorescence signal as determined by fluorescent molecular imaging of cathepsin B activity. 3 days post-NTS administration, we observed a massive influx of macrophages into the kidney by flow cytometry, which correlated with a significant increase in renal fluorescence intensity signal in NTS mice compared to control mice. This was followed by the onset of proteinuria on days 5–7 in NTS mice.
**Conclusions:** Induction of GN by NTS caused significant macrophage infiltration, which could be detected noninvasively by a cathepsin B-activatable probe and NIR optical imaging. Importantly, detection of activated macrophages preceded the onset of proteinuria by several days. These data establish the proof-of-principle that NIR optical imaging may represent a translatable approach to detecting the preclinical stages of GN.

## THU0245 INDIVIDUAL VERSUS COMBINED BLYS OR/AND APRIL NEUTRALIZATION REVEALS DEVELOPMENTAL PLASTICITY FOR PLASMA CELL SURVIVAL FACTOR REQUIREMENTS

P. Haselmayer[1], M. Vigolo[2], J. Nys[2], P. Schneider[2], H. Hess[1]. *[1]Department of Immunopharmacology, Merck KGgA, Darmstadt, Germany; [2]Department of Biochemistry, University of Lausanne, Lausanne, Switzerland*

**Background:** The role of the TNF family cytokine APRIL (a proliferation inducing ligand) in the etiology and pathogenesis of autoimmunity is incompletely understood. The inhibition of B cell survival factors in the NZBWF1 mouse model of systemic lupus erythematosus (SLE) thus far revealed similar efficacy profiles for compounds that neutralize BLyS (B lymphocyte stimulator, also known as BAFF) only, or both BLyS and APRIL (1, 2). Strategies that exclusively target APRIL are sparse, mostly confined to genetic approaches and do not dissect its temporal requirements in disease progression.
**Objectives:** Comparison of single versus dual pharmacological inhibition of BLyS and APRIL in a mouse model for the human autoimmune disease SLE.
**Methods:** Reagents that neutralize either APRIL alone (an anti-APRIL antibody), BLyS alone (BAFFR-Fc), or both BLyS and APRIL (TACI-Fc), were administered to NZBWF1 mice after the onset of autoimmunity, but before nephritis occurred.
**Results:** The inhibition of APRIL alone was inefficient, in contrast to BLyS single antagonism, which instead delayed lupus symptoms, or to the dual inhibition of BLyS and APRIL, which arrested further disease development, autoantibody production, immune complex deposition in glomeruli and prevented onset of nephritis. While studying the plasma cell compartment over time in a T-dependent hapten/carrier immunization system, developmental plasticity in terms of survival factor requirements was observed. Moreover, a maturation window for plasma

cells was identified during which APRIL predominantly mediated survival. The results indicate that plasma cells are flexible in the use of APRIL or BLyS to support their survival in the bone marrow niche.

**Conclusions:** These results suggest that targeting plasma cells by neutralization of both BLyS and APRIL might be beneficial to prevent autoantibody-mediated damages in SLE.

## THU0246 ROLE OF IGE IN THE PATHOGENESIS OF TUBULOINTERSTITIAL INFLAMMATION IN HUMAN LUPUS NEPHRITIS

V.M. Liarski[1], J. Henault[2], R. Herbst[2], R. Kolbeck[2], M. Sanjuan[2], M.R. Clark[1]. *[1]Rheumatology, University of Chicago, Chicago; [2]Respiratory, Inflammation & Autoimmunity, MedImmune, Gaithersburg, United States*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease, the most frequent severe manifestation of which is lupus nephritis (LuN). We have previously shown that tubulointerstitial inflammation (TII) is a usual feature of LuN with $T_{FH}$ cells participating in conjugates with B cells, and driving adaptive immune responses (1).

**Objectives:** To investigate the role of innate immune responses and plasmacytoid dendritic cells (pDCs) in LuN TII

**Methods:** We utilized multichannel immunofluorescent confocal microscopy, performed on 18 human biopsy samples of LuN and compared this to 7 cases of de-identified normal kidney (NK) biopsies. Control staining for Igk and IgE in addition to stains for CD20, BDCA2, IgE, and MxA (a protein, upregulated in IFN-a signature responses) were performed. To check for the presence of serum antibodies, matched human serum from 5 of the biopsies analyzed was assayed by means of ELISA for the presence of anti-dsDNA IgE antibodies.

**Results:** Control staining for Igk and IgE was performed with over 90% overlap between the two stains across NK and LuN samples. Stains for CD20, BDCA2, IgE, and MxA (a protein, upregulated in IFN-a signature responses) were performed and revealed the presence of activated $MxA^+$ pDCs in close association with IgE antibodies and $CD20^+$ cells in LuN but not NK tissue. IgE staining was present in the tubulointersititium in 16 of 18 LuN biopsies as compared to 1 out of 7 NK biopsies. Qualitative analysis indicated that tubulointerstitial staining was more prominent in all LuN cases as compared to the single NK case. Among the LuN biopsies studied, a germinal center was clearly present in one sample with the finding of IgE co-localized with B cells and surrounded by activated pDCs, similar to that seen in tonsil controls, raising the possibility of *in situ* production of IgE antibodies.

To check for the presence of serum antibodies, matched human serum from 5 of the biopsies analyzed was assayed by means of ELISA for the presence of anti-dsDNA IgE antibodies. 4 out of 5 (80%) of the samples had detectable levels of IgE anti-dsDNA antibody. Matched renal biopsies revealed interstitial staining with IgE in all of the cases.

**Conclusions:** Our data suggests that activated pDCs are present in a majority of LuN TII cases, and are closely associated with IgE antibodies and $CD20^+$ B cells. Furthermore, matched serum experiments showed the presence of detectable anti-dsDNA IgE antibodies in 4 of 5 cases. The finding of a germinal center in complex with IgE staining and activated pDCs raises the possibility of *in situ* production of IgE mediating LuN TII and participating in the pathogenesis of this disease, providing a link between the innate and adaptive immune responses and revealing a new role for IgE in autoimmunity.

## THU0247 THE EFFECT OF HYDROXYCHLOROQUINE AND IRAK4 INHIBITION ON THE IFN-A AND TNF-A PRODUCTION INDUCED BY SLE RELATED IMMUNE COMPLEXES

K. Hjorton[1], N. Hagberg[1], O. Berggren[1], J. Mo[2], J. Sandling[1], M.-L. Eloranta[1], L. Rönnblom[1]. *[1]Dept of Rheumatology, Uppsala University, Uppsala; [2]Astra Zeneca R&D, Mölndal, Sweden*

**Background:** Patients with systemic lupus erythematosus (SLE) have an ongoing interferon (IFN)-α production due to the stimulation of Toll-like receptors (TLR) 7 and 9 in plasmacytoid dendritic cells (pDCs) by immune complexes (ICs) containing self-derived nucleic acid. Such interferogenic ICs also trigger the production of TNF-α by several immune cells. Produced TNF-α in SLE contributes to organ inflammation such as nephritis and arthritis, but can also modulate the central autoimmune process as demonstrated by the induction of a lupus-like syndrome after anti- TNF-α treatment.

**Objectives:** To clarify the effect on IFN-α and TNF-α production by IC-stimulated immune cells from healthy individuals and SLE patients exposed to hydroxychloroquine (HCQ) and an IRAK4 inhibitor

**Methods:** pDC and NK cells were isolated from peripheral blood of healthy individuals and monocyte depleted PBMCs from SLE patients. Cells were stimulated with RNA-containing ICs (RNA-IC) comprised of SLE-IgG and U1snRNP particles in the presence or absence of HCQ, which blocks endosomal TLR7/9 activation, or a IL-1 receptor associated kinase (IRAK) 4 inhibitor (AZ13732754–004) acting downstream of TLR 7/9. IFN-α and TNF-α production was measured after 20 h by immunoassays or by intracellular staining using flow cytometry.

**Results:** RNA-IC induced IFN-α production selectively in pDC, whereas TNF-α was produced by both pDC and NK cells. Co-cultivation of pDC and NK cells enhanced the production of IFN-α (28-fold) and TNF-α (15-fold). TNF-α was rapidly produced by NK cells (5 h), but exhibited a delayed production in pDC (9 h). All IFN-α positive pDCs (13.6%) were TNF-α positive, whereas a fraction of pDCs (7.1%) were only TNF-α positive. HCQ completely inhibited the IFN-α and TNF-α production by pDCs, but did not affect TNF-α production by NK cells. Preliminary studies showed that cells from HCQ-treated SLE patients produced little IFN-α (mean 3 U/ml vs 27 U/ml in not HCQ-treated) in response to RNA-IC [NH1], whereas TNF-α production was maintained (mean 760 U/ml [NH2] vs 407 U/ml in not HCQ-treated). Inhibition of IRAK4 effectively blocked IFN-α production in both pDC (94%) and pDC-NK cell co-cultures (91%).

**Conclusions:** The IFN-α production induced by RNA-IC is completely blocked by HCQ and the IRAK4 inhibitor AZ13732754–004, suggesting that administration of an IRAK4 inhibitor could be an effective treatment strategy in SLE. The observation that HCQ inhibited the pDC derived TNF-α production, but not TNF-α released from other immune cells in SLE patients, may explain why HCQ treatment is only partially effective in SLE. In addition, our observation indicates that RNA-IC stimulated TNF-α production is induced by different mechanisms in pDC and NK cells. Further investigations are needed to clarify if IRAK4 inhibition has a broader inhibitory effect than HCQ on the production of proinflammatory cytokines, and if inhibition of IRAK4 should be explored as a therapeutic option in SLE.

## THU0248 THERAPEUTIC INTEREST OF ANTI-CD3 AND ANTI-BAFF MONOCLONAL ANTIBODIES IN THE NOD MODEL OF SJÖGREN'S SYNDROME

R. Felten[1], L. Chatenoud[2], L. Magne[2], M. Sawaf[3], C. Seifert[3], H. Dumortier[3], F. Monneaux[3], J. Sibilia[1], P. Schneider[4], J.-E. Gottenberg[1]. *[1]Rhumatologie et Centre national de référence pour les maladies auto-immunes, CHU Hautepierre, Strasbourg; [2]Immunorégulation et immunopathologie, Hôpital Necker, Paris; [3]Immunopathologie et chimie thérapeutique, CNRS, IBMC, Strasbourg, France; [4]Département de biochimie, Université de Lausanne, Lausanne, Switzerland*

**Background:** BAFF is an essential cytokine for autoreactive B-cell activation, survival, and autoantibody secretion. Therapeutic interest of anti-BAFF therapy is under evaluation in primary Sjögren's syndrome (pSS) with encouraging data in an open clinical trial but it has not been evaluated in an animal model of the disease. In addition, T-lymphocytes, which represent the predominant cell population infiltrating salivary glands, also contribute to its pathogenesis. Targeting T-cells with anti-CD3 antibodies is efficacious to control diabetes in NOD mice, which also represent a relevant animal model of pSS, and in patients with type I diabetes.

**Objectives:** We aimed to evaluate the therapeutic effect of anti-CD3 and anti-BAFF antibodies and their potential synergy on dryness and salivary gland infiltrates in the NOD model of pSS.

**Methods:** Female NOD mice were studied between 10 and 20 weeks. 8 mice were treated with anti-BAFF antibodies, 8 with isotype control antibodies, 6 with the combination of anti-BAFF and anti-CD3 antibodies, 5 with anti-CD3 antibodies and 12 were not treated. Dryness was assessed by measuring the stimulated salivary flow at 10 and 20 weeks. Focus score was analysed at 20 weeks. Spleen, salivary glands and blood lymphocyte sub-populations were analysed using flow cytometry.

**Results:** Only anti-BAFF antibody therapy led to a significant increase in the salivary flow (10.4μL/20 minutes/g ±1.3 with anti-BAFF antibodies, 5.7±2.7 with isotype control antibodies, p=0.003, 5.5±1.7 in non-treated mice, p=0.002) and resulted in the decrease in salivary gland infiltrates (focus score of 1.75±0.5 with anti-BAFF antibodies, 4.0±0 with isotype control antibodies, p=0.028, 4.6±1.14 in non-treated mice, p=0.015). Inhibition of BAFF resulted in a marked decrease of blood, spleen and salivary B-cells (proportion of B-lymphocytes out of total number of lymphocytes in salivary glands: 1.0%±0.9 with anti-BAFF antibodies, 7.6%±2.6 with anti-CD3 antibodies, 0.3%±0.2 with combined treatment and 12.5%±2.3 with isotype control). With anti-BAFF and/or anti-CD3, an increase in salivary glands Foxp3+ regulatory T-cells was observed (proportion of FoxP3+ T cells among total number of CD4+ T cells: 28.7%±5.9 with anti-BAFF antibodies, 27.6%±1.8 with anti-CD3 antibodies, 27.7%±1.9 with combined treatment and 20.7%±1.0 with isotype control). In addition, salivary CD3+CD4-CD8- double negative T-cells markedly increased after anti-BAFF treatment (41.0%±5.5 with anti-BAFF antibodies, 26.4%±7.8 with anti-CD3 antibodies, 37.7%±8.9 with combined treatment and 24.8%±13.5 of T-lymphocytes CD3+ with isotype control). Salivary double negative CD4-CD8- T-cells were inversely correlated with the focus score, which suggests their protective role.
**Conclusions:** Anti-CD3 therapy was not efficacious nor synergic with anti-BAFF. Anti-BAFF therapy resulted in a marked improvement of dryness and salivary gland infiltrates in the NOD model of pSS. Interestingly, BAFF inhibition resulted in the increase of regulatory T-lymphocyte populations, which might contribute to the therapeutic effect of this strategy. This study strengthens the rationale to target BAFF in patients with pSS.

## THU0249 FUNCTIONAL CLUSTERS OF AUTOANTIBODIES TARGETING TLR AND SMAD PATHWAYS DEFINE NEW SUBGROUPS IN SYSTEMIC LUPUS ERYTHEMATOSUS

M.J. Lewis[1], M.B. McAndrew[2], C. Wheeler[2], N. Workman[2], P. Agashe[2], J. Koopmann[3], E. Uddin[2], L. Zou[1], R. Stark[2], J. Anson[2], A.P. Cope[4], T.J. Vyse[5]. *[1]Experimental Medicine & Rheumatology, Queen Mary University of London, London; [2]Oxford Gene Technology, Oxford; [3]MedImmune, Cambridge; [4]Academic Department of Rheumatology; [5]Dept of Genetics & Molecular Medicine, King's College London, London, United Kingdom*

**Background:** The molecular targets of the vast majority of autoantibodies in systemic lupus erythematosus (SLE) are unknown. Multiple recent failures of new therapies in SLE clinical trials demonstrate the need for improved classification of SLE based on pathogenesis.
**Objectives:** To identify novel autoantibodies in SLE for the development of an improved assay for diagnosis and identification of autoantibody clusters for classification of SLE subgroups.
**Methods:** We used a baculovirus-insect cell expression system to create an advanced protein microarray with 1545 full-length human proteins. All proteins were expressed with a biotin carboxyl carrier protein (BCCP) folding tag, so that only correctly folded proteins were bound to the array. Sera were assayed from three independent cohorts of SLE individuals (total n=277) and age, gender and ancestry-matched controls (n=280).
**Results:** We confirmed 116 proteins (FDR<0.01) as autoantigens in SLE, of which 13 had been previously reported, hence we identified 103 novel SLE autoantigens. The 116 SLE autoantigens clustered into four distinct groups by unsupervised hierarchical clustering. The presence of these four clusters was confirmed by principal component analysis. Protein-protein interaction network analysis showed that the autoantigens in each of the four clusters were functionally linked. The original SLE autoantigens Ro60, La, and SMN1/Sm complex formed a distinct antigen cluster (SLE1a), extended by a second cluster (SLE1b) of proteins involved in RNA/DNA/chromatin processing. The largest two clusters of novel autoantigens revealed two networks of interconnected proteins: the receptor-regulated SMAD2, SMAD5 and proteins linked to TGF-β signalling (SLE2); and the TLR adaptor MyD88 and multiple key proteins involved in TLR signalling, regulation of NF-κB, and lymphocyte development (SLE3). ROC curve analysis of antibody biomarker panels showed improved diagnostic sensitivity/specificity compared to conventional anti-nuclear (ANA) and anti-dsDNA antibody tests. Of particular clinical importance, autoantibodies from cluster SLE1b and SLE3 enabled detection of SLE individuals who were negative for ANA or anti-dsDNA antibody tests.
**Conclusions:** Novel autoantibodies, especially from cluster SLE1b and SLE3, identified in this study may improve diagnosis of SLE, through identification of SLE patients who are negative for ANA or dsDNA antibodies. SLE patients clustered into four groups with autoantibody responses against networks of proteins with related cellular or immunological functions, suggesting that different pathogenic mechanisms underlie the four SLE subgroups. Thus the autoantigen clusters may be clinically useful for stratifying SLE patients for specific therapies: SLE patients with TLR signaling autoantigens might preferentially benefit from B cell targeting therapies; SLE patients with autoantibodies against SMAD2/5 and related pathway autoantigens might benefit from TGF-β targeting therapies.

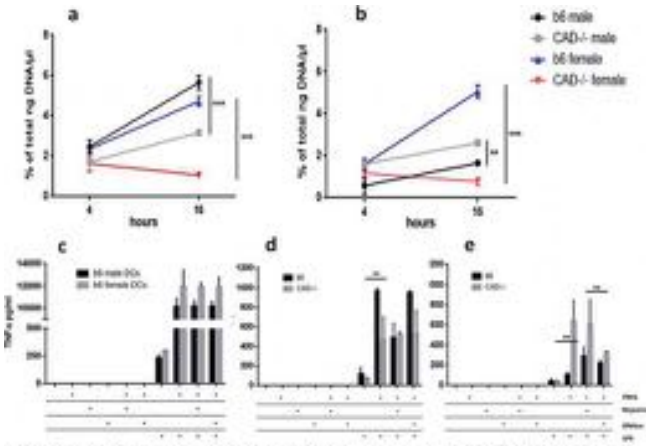
## THU0250 DYSREGULATION OF AUTOPHAGY IN SYSTEMIC LUPUS ERYTHEMATOSUS IS CORRELATED TO TRANSCRIPTIONAL INTERFERON SIGNATURES AND PROVIDES CANDIDATE BIOMARKERS

L. Chiche[1], G. Penaranda[2], P. Savori[2], N. Jourde-Chiche[3], P. Halfon[2], C. Camus[2]. *[1]Internal Medicine; [2]Biology, Hopital Europeen; [3]Nephrology, Hopital Conception, Marseille, France*

**Background:** Autophagy, a lysosome-mediated catabolic process that allows cells to degrade unwanted cytoplasmic constituents and to recycle nutrients, is also involved in innate and adaptive immune responses. It is induced by different stress signals including cytokines such as interferons (IFN). In systemic lupus erythematosus (SLE), a pivotal role for IFN is supported by gene expression studies. A dysregulation of autophagy has been recently reported in SLE patients and hydroxychloroquine (HCQ), its main treatment, is an inhibitor of autophagy.
**Objectives:** The aim of this study was to evaluate autophagy pathways and identify autophagy-related (A-R) biomarkers in SLE patients.
**Methods:** After identification of A-R transcripts (PubMed, KEGG), candidate A-R transcripts were selected through a data-driven approach. Publicly available datasets related to "human/blood/SLE" gene expression profiles and restrained to types of platforms (illumina or affymetrix) as well as tissue (whole blood (WB) or PBMC) were retrieved from GEO database. Candidate A-R transcripts corresponded to those with a significant differential expression between SLE patients (n=157) and matched healthy controls (adjusted p-value <0.05) in the LUPUCE cohort dataset. Fold change (FC) analyses across multiple SLE datasets and interferon inducibility (interferome database) of these candidates allowed the selection of a final panel. Finally, the relative expression of this panel of A-R transcripts (ΔΔCT) was determined by RT-qPCR on WB samples from SLE patients (n=32) and their controls (n=14). Results were correlated with clinical (SLEDAI score) and biological (including IFN modular transcriptional signatures) characteristics as well as treatments of SLE patients (Brown-Mood test).
**Results:** Overall, 97 A-R transcripts were identified through the literature search and 12 SLE datasets from GEO database (WB n=8, PBMC n=4). Among SLE patients from the LUPUCE cohort study, 16 genes (corresponding to 23 A-R Transcripts) were differentially expressed, of which 9 with a significant FC (>1.3): 8 overexpressed (RGS19, MAP1LC3B, ATG7, RAB24, APP, TGM2, TNFSF10/TRAIL and STAT1) and 1 underexpressed (CASP8). The expression levels of a panel of 5 of these candidates (TRAIL, STAT1, CASP8, WIPI1, ATG7) were determined by PCR and only TRAIL and STAT1 exhibited significant overexpression in SLE patients compared to controls (p=0.0105 and 0.0001 respectively). For TRAIL, expression was significantly lower in patients with completely inactive disease (SLEDAI=0) compared to other SLE patients with moderate to important disease activity (p=0.0338). For these 2 genes, no clinical of biological differences were observed between high expressers (> mean ΔCT ± 2SD) and other SLE patients, except that high STAT1 and TRAIL expressers had significantly higher modular transcriptional type I and II IFN signatures, and a trend for being less treated by HCQ was observed for high STAT1 expressers (p=0.075).
**Conclusions:** An exploratory transcriptome data-driven approach identified autophagy-related transcripts as candidate biomarkers in SLE, and suggests that autophagy is induced by type I IFN via the JAK1-STAT1 pathway and may present a potential therapeutic target in this disease.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2790

## THU0251 ABSENCE OF CASPASE-ACTIVATED DNASE AFFECTS NETOSIS AND ITS MODULATION OF DENDRITIC CELL ACTIVATION IN A SEX-DEPENDENT MANNER



A. Del Mastro[1,2], R. Caricchio[2]. *[1]Division of Clinical Immunology, University of Naples Federico II, Naples, Italy; [2]Division of Rheumatology, Temple University, Philadelphia, United States*

**Background:** NETosis is an antimicrobial cell death program of neutrophils characterized by the release of Neutrophil Extracellular Traps (NETs). NETs consist of processed chromatin associated with cytoplasmic proteins and granules. NETs behave as alarmins and can directly activate Dendritic Cells (DCs) or modulate their LPS-mediated activation. Interestingly recent data demonstrate a role for NETosis in Systemic Lupus Erythematosus (SLE) and other autoimmune diseases. The underlying mechanisms are not completely clear, but defective NET-DNA degradation seems to be important. Caspase-activated DNAse (CAD) is an intracellular DNAse activated by caspases during apoptotic cell death whose absence leads to the lupus-like disease in genetically predisposed mice.
**Objectives:** Our aim was to determine the role of CAD in NETs release.

Specifically whether its absence may influence LPS-mediated DCs activation via NETs modulation. We also investigated weather NETosis in the absence of CAD was sex-biased. The latter in view of the relevance of sex in lupus

**Methods:** Neutrophils from the bone marrow of C57bl/6 (b6) and b6.CAD (CAD)–/– mice were treated with 50 nM phorbol myristate acetate (PMA) to induce NETosis. NET-DNA was detected in supernatants by spectrophotometry after 4 and 16 hours. Pretreatment with heparin (50 ug/ml) or physiological concentrations of DNAse (20 ng/ml) was used to respectively neutralize NET-histones and degrade NET-DNA. NETting neutrophils were also visualized and counted by Immunofluorescence. Bone marrow-derived Dendritic Cells (BMDCs) were co-cultured for 20 hours with neutrophils previously treated for 4 hours as mentioned before, in presence or absence of 25 ng/ml LPS. Neutrophils and BMDCs were also treated separately as controls. DCs activation was studied by quantifying TNF-alpha from supernatants by ELISA and by staining cells were stained for flow cytometry to detect CD11b+CD11c+CD86+ DCs.

**Results:** We found that in CAD–/–, NET-DNA was lower than b6 at 4 and 16 hours, and DNAse was not as effective as in b6 in degrading NET-DNA. NETting neutrophils didn't produce any detectable TNF-alpha. LPS-mediated DC activation was enhanced in the presence of NETting neutrophils from b6 males and CAD–/– males and females. Interestingly we found that for b6 females, heparin pretreatment increased the response. In contrast for CAD–/– females, the response was reduced by DNAse. Finally in males, NETs in the absence of CAD led to lower LPS-mediated DC activation. The latter showed decreased activation only with heparin pretreatment.

NET-DNA from $5x10^5$ neutrophils /well in 24-well plates after treatment with PMA 50 nM alone (a) and 30' pretreatment with DNAse 20 ng/ml (b). TNF-α detected from $5x10^5$ DCs cultured alone (c) and with $5x10^5$ pre-treated neutrophils in males (d) and females (e): neutrophils were treated for 4 hours with PMA 50 nM with or without heparin 50 µg/ml or DNAse 20 ng/ml; after 4 hrs pre-treatment, LPS 25 ng/ml was added and supernatants were processed after 20 hours.

**Conclusions:** We show that CAD activity is important for the proper release of NETs, its absence confers resistance to DNAse and its role is sex-biased. Indeed we show that NETs protect only b6 females from enhanced LPS-induced DC activation, and activation is significantly higher in absence of CAD and resistant to NET inhibition. Finally in males, histones seem to have a significant role in DC activation in b6, while in females the role of DNA seems to be more relevant in both strains. Further studies are needed to characterize the molecular features of these differences.

## THU0252 DECREASED EXPRESSION OF IMMUNOREGULATORY PROTEIN PROGRAMMED DEATH LIGAND-1 (PD-L1) IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PLACENTA

A.M. Stevens [1,2], M. Yuasa [1], G. Deutsch [3,4]. *[1]Center for Immunity and Immunotherapies, Seattle Children's Research Institute; [2]Pediatrics, University of Washington; [3]Laboratory Medicine, Seattle Children's; [4]Pathology, University of Washington, Seattle, United States*

**Background:** The increased rates of preeclampsia, pre-term birth, and intra-uterine growth restriction in SLE pregnancy are only partially explained by the vascular effects of anti-phospholipid antibodies. SLE patients themselves are on average born preterm, suggesting a heritable defect in maternal-fetal tolerance. PD-L1 is one candidate gene, in that it has been implicated in the both autoimmunity and maternal-fetal tolerance: PD-L1 is expressed on healthy antigen presenting cells to downregulate inflammatory responses, and also on placental trophoblasts at the maternal-fetal interface, where it inhibits alloreactive T cells. Peripheral blood antigen presenting cells from SLE patients are deficient in PD-L1 expression compared to remission or healthy controls. Little is known about placental costimulatory molecules in women with autoimmune diseases.

**Objectives:** This study tested the hypothesis that placental PD-L1 expression is abnormally regulated in SLE pregnancy.

**Methods:** Expression of PD-L1 was quantified by immunohistochemistry in placentas from 6 SLE patients, 7 rheumatoid arthritis patients (RA) and 9 healthy control women obtained from the Global Alliance for the Prevention of Prematurity and Stillbirth Repository. PD-L1 mRNA expression was assayed by RT-PCR and normalized to GAPDH expression. PD-L1 on peripheral CD14+/CD11c+ monocytes was assayed by flow cytometry. Significant differences between groups were tested by T-test.

**Results:** By immunostaining, PD-L1 expression in SLE placentas was low compared to control groups. PD-L1 mRNA expression correlated with protein expression, although the differences were not significant. A limited analysis of CD45 and CD43 co-expression suggested that a subset of maternal T lymphocytes expressed PDL-1 but that fetal cells did not. The mean gestational age was lower in SLE (27 weeks, range 18–39) compared to RA (38, range 29–40) and controls (34, range 19–40), but there was not a strong correlation between gestational age and PD-L1 expression ($R^2$ 0.18). Three SLE patients exhibited placental insufficiency, with relatively low PD-L1 expression (18 compared to 24 in healthy SLE). On peripheral blood monocytes, PD-L1 expression was low in juvenile SLE patients compared to healthy controls (55% of SLE monocytes v. 93% of healthy monocytes, p=0.001). Although in the normal range, mothers of SLE patients also had relatively low PD-L1 expression compared to control mothers (87% v. 94%, p=0.04).

Table 1. Relative mean PD-L1 expression in placenta

| | | Controls | SLE | P* | RA | P** |
|---|---|---|---|---|---|---|
| Protein | Mean | 39 | 21 | 0.012 | 37 | 0.63 |
| | Fetal | 39 | 16 | | 36 | |
| | Maternal | 41 | 23 | | 34 | |
| mRNA | | 109 | 72 | 0.21 | 300 | 0.08 |

*SLE versus controls; **RA versus controls.

**Conclusions:** Placental PD-L1 expression is dysregulated in women with SLE. Inadequate expression of PDL-1 in the placentas of patients with SLE could result in loss of maternal-fetal tolerance, *contributing to the high rate of pregnancy complications in SLE.*

**Disclosure of Interest:** None declared

## THU0253 A POLYMORPHISM UPSTREAM MIR1279 GENE IS ASSOCIATED WITH PERICARDITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND CONTRIBUTES TO DEFINITION OF A GENETIC RISK MODEL PROFILE

C. Perricone [1], C. Ciccacci [2], F. Ceccarelli [1], E. Cipriano [1], S. Rufini [2], C. Politi [2], A. Latini [2], C. Alessandri [1], F.R. Spinelli [1], G. Novelli [2], G. Valesini [1], P. Borgiani [2], F. Conti [1]. *[1]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma; [2]Department of Biomedicine and Prevention, Section of Genetics, University of Rome "Tor Vergata", Rome, Italy*

**Background:** MicroRNAs have emerged as important regulators of gene expression in post-transcriptional level. These are a class of small non-coding molecules, which could contribute to the pathogenesis of autoimmune diseases, including systemic lupus erythematosus (SLE). Recently, it has been demonstrated that the rs1463335 SNP in MIR1279 gene region was associated with decreased levels of TRAF3IP2 expression. We have previously demonstrated an association between TRAF3IP2 polymorphisms and SLE, especially with the development of pericarditis (1).

**Objectives:** Thus, we aimed to investigate the role of the MIR1279 rs1463335 SNP in SLE, with particular regards to pericarditis development. Furthermore, we aimed at constructing a pericarditis genetic risk profile for SLE patients considering others risk alleles that we had previously found associated with pericarditis development (1, 2).

**Methods:** We recruited 315 Italian SLE patients and 278 healthy controls. Rs1463335 SNP, located upstream MIR1279 gene, was analyzed by allelic discrimination assay. MIR1279 gene was further sequenced in 50 patients. Genotyping of rs7574865 (STAT4), rs2542151 (PTPN2), rs2241880 (ATG16L1) and rs33980500 (TRAF3IP2) SNPs were also performed. A case/control association study and a genotype/phenotype correlation analysis were performed and a risk profile model for pericarditis in SLE was built.

**Results:** The full sequencing of the MIR1279 gene in SLE patients did not reveal any novel or known variation. The variant allele of the rs1463335 SNP was significantly associated with susceptibility to pericarditis (P=0.017, OR=1.67). Patients carrying the A allele were more susceptible to develop the pericarditis with an allele-additive effect: patients carrying the variant homozygous genotype have a higher risk than patients carrying the heterozygous genotype (P=0.013, OR=3.28 vs P=0.06, OR=2.4, respectively). A risk profile model for pericarditis considering the risk alleles of MIR1279 and other three genes (STAT4, PTPN2 and TRAF3IP2) showed that patients with 4 or 5 risk alleles have a significantly higher risk to develop pericarditis (OR=4.09 with P=0.001 and OR=6.04 with P=0.04 respectively). Anti-Sm antibodies were the only parameter associated

with the development of pericarditis. A multivariate analysis by binary regression analysis, considering as dependent variable the presence/absence of pericarditis and as independent variables all the studied SNPs associated with pericarditis, was performed. In a stepwise approach including anti-Sm, MIR1279, STAT4, TRAF3IP2 and PTPN2 SNPs, this model explains about 25% ($R^2$ Cox &Snell) of the variability involved in the susceptibility to pericarditis.
**Conclusions:** We describe for the first time the contribution of a MIR1279 SNP in pericarditis development in SLE patients and a genetic risk profile model useful to identify patients more susceptible to develop pericarditis in SLE. This approach could help to improve the prediction and the management of this manifestation.

## THU0254 IN VIVO UBIQUINOL (COQ10) SUPPLEMENTATION REDUCES THE ATHEROTHROMBOTIC STATUS OF ANTIPHOSPHOLIPID SYNDROME PATIENTS

C. Perez-Sanchez[1], M.Á. Aguirre[1], I. Arias-de la Rosa[1], P. Ruiz-Limón[1], N. Barbarroja[1], M.C. Ábalos[1], Y. Jiménez-Gómez[1], P. Segui[1], E. Collantes-Estévez[1], J.M. Villalba[2], L. Fernández-del Rio[2], J.A. Gonzalez-Reyes[2], M.J. Cuadrado[3], C. López-Pedrera[1]. *[1]IMIBIC/Reina Sofía Hospital/ University of Córdoba; [2]Department of Cell Biology, Physiology and Immunology/University of Córdoba, Córdoba, Spain; [3]Lupus Research Unit, St Thomas Hospital, London, United Kingdom*

**Background:** Previous studies have demonstrated the presence of an oxidative perturbation in antiphospholipid syndrome (APS) patient's leukocytes, which was directly related to an inflammatory and proatherothrombotic status, and relied on alterations in mitocondrial dynamics and metabolism, which was prevented and/or reversed by in vitro treatment with coenzyme Q10 (CoQ10).
**Objectives:** 1) To investigate the beneficial effects of in vivo ubiquinol (Q, reduced form of CoQ10) supplementation on atherothrombosis prevention in APS patients, through the implementation of a prospective, randomized, double-masked, placebo-controlled study. 2) To characterize the cellular and molecular mechanism involved.
**Methods:** The study was conducted on 32 APS patients randomized to receive either Q (200 mg/day) or placebo for one month. Blood was drawn at time 0 and at the end of the treatment. Studies were performed in plasma and purified leukocyte subsets. Endothelial activity was evaluated by Laser-Doppler measurement of post ischemic reactive hyperemia. Carotid intimae media thickness (CIMT) was measured as atherosclerosis marker.
**Results:** Twenty nine out of the 32 APS patients completed the intervention, which increased significantly plasma Q levels. Endothelial function improved notably. Q treatment decreased expression of a number of protrombotic and proinflammatory mediators, and produced a reduction in both, the levels of peroxides and the percentage of monocytes with altered mitochondrial membrane potential ($\Delta\Psi m$). Electron Microscopy analyses indicated that Q treatment promoted an increase in monocytes' mitochondrial size. MiRNA profiling by Nanostring technology revealed 22 microRNAs reduced in APS patients. Among them, 10 were upregulated by effect of Q treatment. Functional classification of those miRNAs revealed a preponderance of target mRNAs involved in cardiovascular disease. Gene profiling showed differential expression of 33 atherosclerosis-related genes in APS patients, of which 16 were changed by effect of Q. Using bioinformatic tools, interaction networks of those genes and microRNAs were also identified (i.e. downregulation of PDGFB, IL-1A and SERPINE1 was associated to upregulation of miR150–5p; in parallel, downregulation of TGFB2 and MMP-1 was linked to the upregulation of miR-145–5p).
Correlation studies demonstrated that reduced expression prothrombotic and proinflammatory mediators, and increased miRNA expression, were related to the increased plasma Q levels and improved endothelial function. Q effects were particularly relevant in APS patients showing pathologic CIMT and thrombotic recurrences, who showed a better response to Q treatment.
**Conclusions:** 1) Q supplementation significantly improved endothelial function, and reduced mitochondrial dysfunction, oxidative stress and the expression of prothrombotic/proinflammatory proteins. 2) Underlying epigenetic mechanisms seem to be involved. Our results support the potential impact of Ubiquinol in the prevention of atherothrombosis in APS patients.

## THU0255 IDENTIFICATION OF NOVEL REGULATORY NETWORKS RELATED TO ATHEROTHROMBOSIS IN MONOCYTES FROM ANTIPHOSPHOLIPID SYNDROME THROUGH INTEGRATED ANALYSIS OF MICRORNA/MRNA/PROTEIN EXPRESSION PROFILES

C. Perez-Sanchez[1], M.Á. Aguirre[1], P. Ruiz-Limón[1], N. Barbarroja[1], Y. Jiménez-Gómez[1], I. Arias-de la Rosa[1], M.C. Ábalos[1], E. Collantes-Estévez[1], M.J. Cuadrado[2], C. López-Pedrera[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Córdoba, Spain; [2]Lupus Research Unit, St Thomas Hospital, London, United Kingdom*

**Background:** MicroRNAs have a functional role in numerous physiological and pathological processes by regulating the expression of their target genes. A number of miRNAs have been involved in the pathogenesis of antiphospholipid sindrome (APS). However, the miRNA-mRNA regulatory network involved in the regulation of the proatherothrombotic status in APS patients is far from being fully understood.
**Objectives:** To identify and characterize novel regulatory miRNA/mRNA/protein networks related to atherothrombosis in monocytes from APS.
**Methods:** Twenty one APS patients and 27 healthy donors were included in the study. A multi-step approach combining microarray miRNA (Nanostring technology) and mRNA expression profile (44K, Agilent, one color) and bioinformatics analysis was adopted to identify the APS specific miRNA-mRNA regulatory networks. Target genes of the differentially expressed miRNAs were identified by using the Igenuity Pathway Analysis Software (IPA). To recognize the putative miRNA-mRNA target pairs and interaction networks, the subsets of miRNAs and mRNAs were characterized by the miRNA Target Filter tool of IPA. The resulting identified interactions were validated by RT-PCR and western blot on the whole cohort of APS patients and by functional analyses using miRNA overexpression experiments in monocytes purified from APS patients.
**Results:** Comparative analysis of the mRNA profiles showed significantly different expressions of 519 genes in APS monocytes (352 up-regulated and 167 down-regulated). Functional analysis by using IPA showed that about 33% of altered genes were involved in inflammation and cardiovascular disease (CVD). Comparative analysis of the miRNA profiles showed significantly different expressions of 22 miRNAs in APS monocytes (3 up-regulated and 19 down-regulated). Functional IPA analysis showed that miRNAs altered were mainly related to connective tissue disorders, inflammatory response and reproductive system disease. A total of 56 genes were inversely correlated, and predicted as CVD-related target genes of 19 differentially expressed miRNAs. An interaction network of those genes and miRNAs differentially expressed in APS monocytes were also identified. Interestingly, a few number of miRNAs (i.e. miR-30b, miR-145, miR-199, miR-17, miR-26a) regulate idependently multiple gene targets belonging to the cluster of genes related to inflammation and atherogenesis, (i.e. VEGF, TGFβ, LDLR, PPARD, IL1, IL2, IL12, VCAM1, ITGA, CACNB2, MMP3). Transfection assays validated regulatory relationships between those miRNAS and a number of targets at both RNA and protein levels.
**Conclusions:** Our system biology approach introduced and nominated 1) important deregulated miRNAs involved in atherothrombosis in monocytes from APS; 2) Significant and confident deregulated mRNAs which were anti-correlatively targeted by deregulated miRNAs; and 3) dysregulated proteins in association with deregulated miRNA-mRNAs interactions. These results introduce a possible mechanism of function of deregulated miRNAs and mRNAs in atherothrombosis-related APS that could be used as potential therapeutic targets.

## THU0256 COMPLEMENT C3 EXACERBATES TLR7-MEDIATED SKIN INFLAMMATION BUT NOT SYSTEMIC AUTOIMMUNITY

C. Giacomassi, G.S. Ling, N. Buang, J. Strid, M. Botto. *Centre for Complement and Inflammation Research (CCIR), Department of Medicine, Imperial College, London, United Kingdom*

**Background:** Short–term topical application of a Toll-like receptor 7 (TLR7) agonist, Imiquimod (IMQ), is a widely used murine model of psoriasis. Recently long–term epicutaneous application (4–8 weeks) of IMQ has been shown to elicit lupus-like manifestations. Importantly the topical application of IMQ induced more potent systemic effects than the intraperitoneal administration, indicating that activation of the TLR7-signalling in the skin plays a key role.
**Objectives:** Since complement activation is known to have a crucial role in the regulation of local inflammation and in the pathogenesis of lupus, we investigated whether C3 played a role in the induction of the cutaneous lesions as well as in the lupus-like syndrome triggered by IMQ
**Methods:** BALB/c wild-type (WT) and C3-deficient (BALB/c.$C3^{-/-}$) mice were treated with topical application of 5% IMQ cream for either 7 consecutive days (short-term) or 3 days /week for 11 weeks (long-term).
**Results:** After 7 days, skin thickening (ear thickness at day 7: WT 60.14 mm ± 1.625, n=7, vs BALB/c.$C3^{-/-}$ 50.88 mm ± 2.460, n=8, p value=0.0094) and local neutrophil recruitment (cell number at day 7: 52.3±6.736, n=7, vs BALB/c.$C3^{-/-}$ 30.33±4.192, n=7, p value=0.0170) were significantly reduced in

the absence of C3. The expansion of IL17$^+$ $\gamma\delta^+$ T cells in the draining lymph nodes was also significantly impaired (day 7: WT 59.06% ± 2.961, n=7, *vs* BALB/c.C3$^{-/-}$ 46.21% ± 2.023, n=8, p value=0.0029*)*. Long-term IMQ treatment resulted in the development of similar low titres of auto-antibodies in both groups of mice (anti-RNP: WT 29.75±11.33, n=5 *vs* BALB/c.C3$^{-/-}$ 97.28±41.53, n=5, p=0.1553; anti-ssDNA: WT 9.252±3.367, n=5, *vs* BALB/c.C3$^{-/-}$20.70±12.03, n=5, p=0.386; anti-chromatin: WT 12.59±7.001, n=5, *vs* BALB/c.C3$^{-/-}$ 16.72±12.60, n=5, p=0.781). In addition, the kidney histology scored by a trained histopathologist evidenced no difference in the glomerulonephritis severity.

**Conclusions:** Collectively, these data suggest that C3 acts as a potential mediator of IMQ-induced skin inflammation. However, the different local tissue response does not result in an altered autoimmune response in the C3-deficient mice. The study of the involvement of other complement components is currently in progress.

## THU0257 DIAGNOSTIC ACCURACY OF MULTIPLEX BEAD-BASED IMMUNOASSAY FOR ANTINUCLEAR ANTIBODIES (ANA) TESTING IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

E. Aleksandrova[1], Z. Verijnikova[1], A. Novikov[1], T. Panafidina[1], N. Seredavkina[1], T. Popkova[1], N. Ayzina[2], E. Nasonov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology; [2]Diagnostic Center of Laboratory Research, Moscow, Russian Federation*

**Background:** ANA are a large family of autoantibodies directed at various cellular constituents. The measurement of ANA is a useful tool to confirm the diagnosis of SLE. New automated bead-based arrays can simultaneously and rapidly determine a profile of multiple ANA. Clinical performance of multiplexed technologies for detection of ANA specificities in SLE is not validated.

**Objectives:** To evaluate the diagnostic accuracy of multiplex bead-based immunoassay for the detection of ANA profile in SLE.

**Methods:** We studied 94 patients (pts) (80 F, age 35.9 [16.0–65.0] years, disease duration 113.5 [2.0–576.0] months) with SLE (ACR criteria, 1997), 50 pts with other systemic autoimmune rheumatic diseases, 20 pts with non-autoimmune rheumatic diseases and 30 healthy controls. Serum samples were analyzed for SLE-associated ANA (anti-dsDNA, anti-Sm, anti-chromatin, anti-SS-A/Ro 52 kDa and 60 kDa, anti-SS-B/La, anti-RNP-70, anti-ribosomal P) using automated multiplex bead-based immunoassay system BioPlex® 2200 (ANA Screen; Bio-Rad Laboratories Inc., USA). The following ANA values were considered positive: anti-dsDNA≥10.0 IU/mL, other antigen-specific ANA ≥1.0 AI (Antibody Index).

**Results:** The detection of anti-dsDNA, anti-Sm, anti-ribosomal P antibodies by BioPlex assay demonstrated the highest overall specificity (0.95, 0.97, 0.99, respectively), and positive likelihood ratio (LR) (10.40, 9.67, 15.0, respectively) for diagnosis of SLE (Table 1). BioPlex assay for anti-RNP-70, anti-SS-A/Ro, anti-chromatin antibodies was a useful diagnostic test in SLE (positive LR 2.80, 2.31, 4.15, respectively). Anti-SS-B/La antibodies testing had no value in SLE diagnosis (positive LR 1.20). The frequency of 1 ANA in SLE pts was 79.8%,2 ANA – 28.7%, 3 ANA – 15.6%, 4 ANA – 10.6%, 5 ANA – 5.3%, 6 ANA – 1.1%. Simultaneous detection of ≥3 ANA increased the specificity of multiplex immunoassay up to 0.98–1.00, and positive LR – to a maximum value.

Table 1
Diagnostic accuracy of multiplex bead-base immunoassay for ANA detection in SLE (n=94)

| Antibody | Sensitivity | Specificity | Positive LR | Negative LR |
|---|---|---|---|---|
| anti-dsDNA | 0.52 | 0.95 | 10.40 | 0.51 |
| anti-Sm | 0.29 | 0.97 | 9.67 | 0.73 |
| anti-chromatin | 0.54 | 0.87 | 4.15 | 0.52 |
| anti-SS-A/Ro | 0.37 | 0.84 | 2.31 | 0.75 |
| anti-SS-B/La | 0.12 | 0.90 | 1.20 | 0.98 |
| anti-RNP-70 | 0.14 | 0.95 | 2.80 | 0.91 |
| anti-ribosomal P | 0.15 | 0.99 | 15.00 | 0.86 |

**Conclusions:** The detection of ANA profile by multiplex bead-based immunoassay has a high specificity and positive likelihood ratio for diagnosis of SLE. Additional investigations are required to evaluate the usefulness of multiplex ANA testing for monitoring disease activity and for determining prognosis of SLE.

## THU0258 DRVVT AND APTT RATIOS FOR LABORATORY DETECTION OF LUPUS ANTICOAGULANT – TO NORMALIZE OR NOT TO NORMALIZE THAT IS THE QUESTION

E.C. Hannson, E.-M. Norberg, M. Berndtsson, J.P. Antovic. *Karolinska University Hospital & Institutet, Stockholm, Sweden*

**Background:** The laboratory testing of lupus anticoagulant (LA) is based on the guidelines given by ISTH-SSC and CLSI. Both guidelines advocate using diluted Russel viper venom (dRVVT) test in combination with activated partial thromboplastin time (aPTT) assay and the results should be expressed as ratio to the pooled normal plasma (PNP). Since reagents used for testing may differ between lots as well as between manufacturers, those guidelines recommend normalization of the results. However some authors suggest not using the normalization step to decrease the complexity of already very complicated LA testing.

**Objectives:** To investigate how the normalization of dRVVT and aPTT-ratios based on PNP reference values affects the reference ranges and the number of positive and negative results for the presence of LA.

**Methods:** Double centrifuged plasma samples from healthy subjects (N=49) were analyzed on Behring Coagulation System BCS XP. All samples were analyzed with the dRVVT-based assay, using LA screen and LA confirm from Life Diagnostics, as well as with aPTT assays - PTT-LA from Diagnostica Stago as screen and Actin FS from Siemens Healthcare Diagnostics as the confirm step. Ratios were calculated for both dRVTT and aPTT before and after normalization using mean of run-specific PNP value. Our laboratory reports the dRVVT-ratio and aPTT–ratio as: negative <1.2, weakly positive 1.2–1.4, and positive >1.4. We also investigated 362 previously analyzed samples to figure out how the normalization step influences the results.

**Results:** Ratios for PNP were 1.06±0.01 and 1.26±0.02 for dRVVT and aPTT respectively. Out of 49 healthy subjects without the normalization step, 34 would have been reported as negative (15 as weakly positive) with dRVVT and 3 would have been reported as negative (8 as positive and 38 as weakly positive) with aPTT. After normalization 45 samples would have been reported as negative (3 and 1 as weakly positive with dRVVT and aPTT respectively). The normalization step led to a decrease in the amount of positive diagnosis (from 58% to 44% and 77% to 41% using dRVVT and aPTT respectively) and at the same time the number of samples tested negative increased (7% to 15% and 6% to 34% for dRVVT and aPTT respectively).

**Conclusions:** Our findings indicate that without the normalization step only 6% of healthy subjects would be reported as negative for the presence of LA. The introduction of the normalization step decreases the number of false positive results and this is particularly true for the aPTT based assay. Since false positive results lead not only to unnecessary patients' discomfort, but also generate an increased cost due to prolonged follow up of the patients, an additional step using normalization which is relatively simple and inexpensive is definitely justified for the laboratory diagnosis of LA.

## THU0259 INDUCTION OF APOPTOSIS AND AUTOPHAGY IN CIRCULATING PBMC BY MICROPARTICLES FROM PATIENTS WITH SYSTEMIC LUPUS ERYTEMATOSUS

F. Miranda, C. Barbati, C. Alessandri, F.R. Spinelli, F. Ceccarelli, S. Truglia, G. Valesini, F. Conti. *Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, la Sapienza Università di Roma, Roma, Italy*

**Background:** Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease characterized by heterogeneous clinical manifestation and a complex pathogenesis. Lymphocytes from patients with SLE display multiple alterations, including increased cell activation, abnormal apoptosis and impairment of autophagic pathway. Recently, evidence from genetic, cell biology and animal models suggested that autophagy, a major pathway for organelle and protein turnover, may play a pivotal role in the occurrence and development of SLE. Some studies showed altered profile of circulating microparticles (MPs) in SLE patients. These MPs are released constitutively and may increase as a result of cellular activation and apoptosis. Originally considered as inert debris, MPs are now known to display diverse pro-inflammatory and pro-thrombotic activities, and they are implicated in the intercellular communications. MPs can influence the course of rheumatic and other immune-mediated diseases.

**Objectives:** The aim of our study was to evaluate the possible role of MPs purified from SLE patients on the modulation of apoptosis and autophagy in *peripheral blood mononuclear cells* (*PBMCs*) isolated from healthy donors.

**Methods:** PBMCs from healthy donors were isolated by Ficoll-Hypaque density-gradient centrifugation, cultured and treated with 0.5,2.5,5 *10$^6$ MPs purified by 10 sera of active SLE for 16 h. Apoptosis was measured using FITC-conjugated annexin V (AV) and a propidium iodide (PI) apoptosis detection kit. Acquisition was performed on a FACS Calibur. Autophagy was measured by Western blot for LC3II.

**Results:** MPs appeared capable of inducing apoptosis. Indeed, PBMCs showed significantly higher apoptosis if treated with MPs compared with untreated cells (percentage of apoptotic cells treated with 5, 2.5 and 0.5*10$^6$ MPs: 15, 10, 9 *vs.* 7%, *P*=0.0001, P=ns, P=ns, with respectively). Moreover, MPs increased autophagy in a dose response manner (LC3-II/β-actin ratio: 1.2, 1, 0,6 *vs.* 0.5, with 5, 2.5 and 0.5*10$^6$ MPs, respectively *P*=0.0001).

**Conclusions:** We demonstrated that MPs from SLE patients induce apoptosis in PBMCs, thereby possibly decreasing the number of circulating leucocytes. The mechanisms underlying such phenomena are not known. Some authors suggested that MPs, through the arachidonic acid pathway, may induce apoptosis.

Indeed, this pathway, together with the sphingomyelinic, increase the concentration of ceramide, thus leading into apoptosis mediated by the activation of caspase 8 and by the release of downstream pro-apoptotic factors. Moreover, available data do not exclude the possibility that components of MPs other than arachidonic acid, may also contribute to the ceramide-mediated apoptosis. Finally, this is the first study addressing the relations between MPs and autophagy, suggesting an increase of this cellular event after exposure to MPs. Since an augmented autophagy has been implicated in autoimmunity, it could be of interest to target MPs in order to re-balance the autophagic processes.

**Disclosure of Interest:** None declared

## THU0260 IL-25 AXIS IS ACTIVATED AND ASSOCIATED WITH AN ILC2 AND M2 INFLAMMATORY STATE IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

G. Guggino[1], F. Ciccia[1], A. Rizzo[2], L. Saieva[1], C. Schinocca[1], P. Cipriani[3], R. Giacomelli[3], R. Alessandro[1], G. Triolo[1]. *[1]University of Palermo; [2]Azienda Ospedaliera Villa Sofia Cervello, Palermo; [3]University of L'Aquila, L'Aquila, Italy*

**Background:** Type 2 innate lymphoid cells (ILC2) and M2 polarized macrophages are activated and produce cytokines in response to IL-25/IL-17RB, although the relevance of this axis to immune responses in primary Sjoren's syndrome (pSS) is unknown.

**Objectives:** We sought to investigate the role of the IL-25/IL-17RB axis and ILC2 and M2 macrophages in patients with pSS.

**Methods:** Expression analysis of IL-17B, IL-25, IL-33 and IL-17RB was performed by TaqMan real-time PCR and immunohistochemistry on salivary glands from 50 patients and 20 controls. Analysis of IL-17RB expression and the frequencies of natural type 2 innate lymphoid cells (nILC2), inflammatory ILC2 (iILC2), and M2-polarized macrophages were assessed by means of flow cytometry among salivary gland (SGMC) and peripheral blood (PBMC) mononuclear cells. Clusters of ILC2 cells and M2 macrophages were also studied by immunohistochemistry and confocal microscopy. The role of IL-25 on ILC2 was investigated in *ex vivo* studies.

**Results:** IL-25 and IL-17RB, but not IL-25, were significantly over-expressed in the MSG of pSS patients and correlated with the focus score and the degree of lymphoid organization. IL-17RB was mainly expressed by T lymphocytes, ILC2 cells and macrophages. No significant increased expression of IL-33 was observed in pSS. Significant increase in the frequency of iILC2, but not of nILC2, was observed in both PBMC and SGMC. Clusters of ILC2 cells, resembling fat associated lymphoid clusters (FLAC), and M2 polarization were also observed in pSS salivary glands and correlated with the focus score. IL-25 stimulation of isolated SGMC and PBMC resulted in the expansion of iILC2.

**Conclusions:** These findings suggest that IL-25 may promote, by interacting locally and sistemically with IL-17RB$^+$ cells, an iILC2 and M2 inflammatory state in pSS. Blockade of the IL-25 axis could be clinically relevant in pSS.

**Disclosure of Interest:** None declared

## THU0261 T FOLLICULAR REGULATORY CELLS FROM PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME EXPRESS LOWER LEVELS OF CTLA-4

G.M. Verstappen[1], O.B.J. Corneth[2], R.W. Hendriks[2], A. Vissink[3], H. Bootsma[1], F.G.M. Kroese[1]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Pulmonary Medicine, Erasmus MC, Rotterdam; [3]Oral and Maxillofacial Surgery, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands. Within circulating CD4$^+$ T cells, the proportion of Tfh cells (CD45RA$^-$FoxP3$^-$CXCR5$^+$PD-1$^+$) is increased in pSS patients, compared with healthy controls (HCs). Increased levels of circulating Tfh cells are associated with higher systemic disease activity, as measured by serum IgG titers and the European League Against Rheumatism (EULAR) Sjögren's syndrome Disease Activity Index (ESSDAI). However, it is unknown if the proportion of T follicular regulatory (Tfr) cells is also altered. Tfr cells may play an important role in pSS pathogenesis, since the ratio between T follicular regulatory (Tfr) cells (CD45RA$^-$FoxP3$^+$CXCR5$^+$PD-1$^+$) and Tfh cells seems to dictate B cell responses.[1]

**Objectives:** To analyze the Tfr/Tfh ratio in pSS patients and HCs and to assess the functional suppressive capability of Tfr cells by means of their expression of the inhibitory immune receptor cytotoxic T-lymphocyte-associated protein 4 (CTLA-4).

**Methods:** Twenty-four pSS patients (23 female, mean age 44, median ESSDAI 8), diagnosed according to the revised AECG criteria, and 24 sex- and age-matched healthy controls were included. Cryopreserved peripheral blood mononuclear cells were analyzed by flow cytometry for expression of CD3, CD4, CD45RA, FoxP3, CXCR5, PD-1 and CTLA-4. Besides the frequency of positive cells, median expression levels per cell of CTLA-4 were measured using median fluorescence intensity. Statistical analysis were performed using the Mann–Whitney U or the Spearman's Rho test.

**Results:** In addition to the increase in Tfh cells, we found an increased proportion of Tfr cells within the pool of circulating CD4$^+$ T cells in pSS patients, compared with HCs ($p<0.001$). Unexpectedly, the Tfr/Tfh ratio was significantly higher in pSS patients, compared with HCs ($p<0.001$), pointing towards an immune suppressive equilibrium. However, expression levels of CTLA-4 on Tfr cells from pSS patients were significantly decreased ($p<0.001$), which suggests that Tfr cells from pSS patients have a lower suppressive capability. Furthermore, lower expression levels of CTLA-4 on Tfr cells were associated with an increase in the Tfh cell proportion ($r^2$=-0.382, p=0.066). CTLA-4 expression levels were also decreased on total Treg cells (CD45RA$^-$FoxP3$^+$) from pSS patients ($p<0.001$).

**Conclusions:** Although both the proportion of Tfr cells and the Tfr/Tfh ratio are increased in pSS patients, the decreased expression of CTLA-4 by Tfr cells suggests that Tfr cells from pSS patients have a lower suppressive capacity. This may contribute to the expansion of Tfh cells and consequently to hyperactivity of B cells in pSS. Limitation of Tfh cell expansion by immunomodulatory treatment may reduce this B cell hyperactivity.

## THU0262 IMPAIRED SUPPRESSIVE CAPACITY OF REGULATORY B CELLS IN PRIMARY SJOGREN'S SYNDROME

H. Zhang[1], W. Lin[2], H. Chen[1], Y. Fei[1], W. Zhang[1], F. Zhang[1]. *[1]Rheumatology, Peking Union Medical College Hospital, Beijing; [2]Rheumatology, Hebei General Hospital, Shijiazhuang, China*

**Background:** primary Sjogren's syndrome (pSS) is a chronic systemic autoimmune disorder that typically affects exocrine glands. B cell hyperactivity is a cardinal feature in pSS[1]. Besides the antibody-producing, regulatory B cells (Breg) has recently been shown to contribute to the maintenance of immunological tolerance[2,3]. The role of the Breg cells in pSS is not well understood.

**Objectives:** In this study, we investigated the levels of Breg cells in peripheral blood in patients with pSS, primary biliary cirrhosis (PBC) as well as in healthy controls (HC) and explore the characteristic and function of Breg cells in pSS patients.

**Methods:** Newly diagnosed pSS patients (n=70) were enrolled, 50 healthy volunteers and 25 PBC patients were recruited as healthy and disease controls. To analyze the percentages of Breg cells and the level of IL-10 secreted by Breg cells, PBMCs were surface and intracellular stained, and detected by flow cytometry. The expression of IL-10 in B cells were determined by real-time PCR. The function of Breg cells was tested by co-culturing isolated CD19$^+$CD24$^{hi}$CD38$^{hi}$ Breg cells with purified CD4$^+$CD25$^-$T cells (Teff cells) from pSS patients or HC at a ratio of 1:1. The cytokines in culture supernatants were measured by cytometric beads array.

**Results:** The frequency of circulating Breg cells in pSS patients was significantly increased, compared with PBC patients and HC (6.88 ± 2.48%, 1.95 ± 1.04%, and 1.52±0.65%, respectively; $p<0.0001$). The percentages of IL-10$^+$ Breg cells was much lower in pSS patients, compared to PBC and HC (16.04 ± 9.03%, 81.40 ± 21.00%, 31.00 ± 7.79%, respectively; $p<0.05$), while the expression of IL-10 in B cells was much higher in pSS patients than that in HC (13.48 ± 18.90, 3.55 ± 0.71, respectively; $p<0.05$). When autologous or heterologous Teff cells/Breg cells were co-cultured, IFN-$\gamma$, TNF-$\alpha$, IL-4, IL-17 in supernatants secreted by HC or pSS Teff cells significantly suppressed by healthy Breg cells, not by Breg cells in pSS patients ($p<0.05$).

**Conclusions:** This preliminary study showed that the frequency of Breg cells was significantly increased in pSS patients. Although the expresssion of IL-10 mRNA in B cells was much higher, the secretion of IL-10 of Breg cells from pSS patients was decreased and less effective in the control of Teff cell proliferation. Unlike HC, the suppressive capacity of Breg cells was impaired in pSS. The malfunctioning Breg cells may play an important role in pathogenesis of pSS.

## THU0263 KPT-350, A SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE) COMPOUND, EFFECTIVELY REDUCES INTERFERON-ALPHA ACTIVATION AND AUTOREACTIVE PLASMA CELLS IN MURINE LUPUS

J. Rangel-Moreno[1], W. Wang[2], T. Owen[2], J. Barnard[2], B. Klebanov[3], Y. Landesman[3], S. Tamir[3], S. Shacham[3], J. Anolik[2]. [1]*Department of Medicine, Division of Allergy, Immunology and Rheumatology;* [2]*University of Rochester Medical Center, Rochester;* [3]*Karyopharm Therapeutics, Inc., Newton, United States*

**Background:** There is great interest in developing new treatment approaches for systemic lupus erythematosus (SLE), but the biologic therapies under investigation have yielded disappointing results. Recently the nuclear export protein XPO1 (Exportin 1/CRM1) has surfaced as an attractive target for the treatment of inflammatory disorders like SLE. Selective Inhibitor of Nuclear Export (SINE) compounds are potent, orally-available, and well-tolerated XPO1 (Exportin 1/CRM1) agonists. *In vitro* and *in vivo*, SINE compounds exert apoptotic and anti-inflammatory effects by mediating nuclear retention of important XPO1 cargos like the NFκB pathway regulatory protein, IκB (figure).
**Objectives:** This study evaluated the efficacy of the SINE compound KPT-350 on disease progression, interferon-α (IFN-α) production by plasmacytoid dendritic cells (pDCs) and autoantibody production by plasma cells (PCs) in a murine model of SLE.
**Methods:** Cohorts of nephritic NZB/W F1 lupus-prone female mice, with established disease (elevated anti-dsDNA antibody titer and proteinuria) were treated with low or high dose KPT-350 (5 or 7.5 mg/kg, respectively) or a vehicle control three times per week for 8 weeks (n=8/group). Proteinuria was monitored and kidney histology assessed. Spleen, bone marrow (BM) and kidney cells were harvested and analyzed by flow cytometry. Antibody secreting cells (ASCs) and germinal centers (GCs) were enumerated and measured by ELIspot and immunofluorescent staining. Serum samples and RNA were collected for Luminex assay and qPCR. Effects on pDC production of IFN-α were assessed using *in vitro* cultures of BM cells stimulated with CpG 2216 10ng/ml for 5 hours.
**Results:** Both high and low doses of KPT-350 prevented nephritis progression with a statistically significant reduction in urine protein levels in treated groups ($p<0.05$ beginning at 6 weeks). Moreover, nephritis was improved histologically (GN score: 3.3±1.2 vehicle vs. 1.0±-0 SINE; interstitial nephritis: 2±-1.1 vehicle vs. 0±-0 SINE; lipoid infiltrate score: 1.3±-0.6 vehicle vs. 0±-0 SINE). In the spleen, levels of GC B cells ($CD19^+PNA^+CD95^+$) and IgG and anti-DNA ASCs were dramatically reduced. ASCs were also reduced in the BM and became undetectable in the kidney. Importantly, serum anti-DNA antibodies decreased with treatment but total IgG levels remained intact. KPT-350 inhibited the production of IFN-α by pDCs in a strong, dose-dependent fashion (% of vehicle: 1 uM 88%, 10 uM 66%, 100 um 39%, and 1000 uM 0%). Additionally, IFN-α regulated chemokines in the serum of treated mice were decreased (MCP-1: 250±-90 pg/mL vehicle vs. 54±-26 pg/mL SINE, p=0.049), as were the renal mRNA levels of three PC survival factors: BAFF (38% of vehicle, $p<0.05$), APRIL (19% of vehicle, $p<0.05$) and IL6 (40% of vehicle).

**Conclusions:** SINE compounds influence the generation, survival and function of PCs and other immune cells through a multifactorial mechanism involving pDCs, GCs and ASCs. It is likely that a common process, namely inhibition of the canonical NFκB pathway, underlies KPT-350's effect. Collectively, our findings suggest that, by simultaneously modulating IFN-α activation and NFκB signaling, SINE compounds might slow disease progression in SLE.

## THU0264 A SELECTIVE JAK1 INHIBITOR, FILGOTINIB SUPPRESSES LYMPHOCYTIC INFILTRATION IN SALIVARY GLAND OF NON OBESE DIABETIC MICE VIA SUPPRESSION OF BAFF PRODUCTION OF SALIVARY GLAND EPITHELIAL CELLS

J. Lee[1], J. Lee[2], S.-Y. Baek[2], J.H. Koh[1], M.-K. Chung[1], H. Jeon[1], S.H. Kim[1], J.H. Yoo[1], H. Kim[1], S.-K. Kwok[1], J.H. Ju[1], S.-H. Park[1]. [1]*Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul St. Mary's Hospital;* [2]*Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University of Korea, Seoul, Korea, Republic Of*

**Background:** Interferon (IFN) signatures are upregulated in patients with primary Sjogren's syndrome (pSS) and interferons are considered to play a pathogenic role in pSS. Therefore, Janus kinase (JAK) which mediates interferon signaling pathway may be a good therapeutic target
**Objectives:** We set out to investigate whether a selective JAK1 inhibitor, filgotinib would ameliorate disease-related parameters in non-obese diabetic (NOD) mice, an animal model SS
**Methods:** Filgotinib (1.5mg/kg) or vehicle (saline) was intraperitoneally injected three times per week from 8 weeks after birth. Salivary flow rate (SFR) was addressed on 8, 12, 16 and 20 weeks. Histologic analysis was performed on 20 weeks. The effect of filgotinib on the expressions of B cell activating factor (BAFF) and chemokines (CXCL10 [IP-10], CXCL3 [fractalkine], CCL-2 [MCP-1]) in human salivary gland epithelial cell (SGEC) line or primary epithelial cells of patients with pSS was determined *in vitro*.
**Results:** The SFR of NOD mice in both groups decreased over time. Of note, SFRs of filgotinib-treated mice were greater than those of controls. Histologic evaluation of the salivary gland revealed that the lymphocytic infiltration of salivary gland was markedly reduced in the mice treated with filgotinib. Filgotinib suppressed STAT1 phosphorylation in IFN-treated SGECs. In addition, IFN-induced BAFF and chemokine production of SGECs or primary epithelial cells were abrogated by filgotinib treatment.
**Conclusions:** Filgotinib suppresses SFR decrease and lymphocytic infiltration of salivary glands of NOD mice by inhibiting inhibiting IFN signaling pathway, thus suppressing BAFF and chemokine production of salivary gland epithelial cells. JAK inhibition may be a novel therapeutic approach for SS.
**Disclosure of Interest:** None declared

## THU0265 B CELL PHENOTYPIC CHANGES IN ANTI-NUCLEAR ANTIBODY POSITIVE INDIVIDUALS PRIOR TO THE ONSET OF SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASE

J. Wither[1], N.-H. Chang[1], B. Noamani[1], D. Bonilla[1], S. Johnson[1,2], L. Lisnevskaia[3], E. Silverman[4], A. Bookman[1], C. Landolt-Marticorena[1]. [1]*University Health Network;* [2]*Mount Sinai Hospital, Toronto;* [3]*Lakeridge Health Services, Oshawa;* [4]*Hospital for Sick Children, Toronto, Canada*

**Background:** Patients with systemic autoimmune rheumatic diseases (SARD) often have a prolonged pre-clinical phase during which they are anti-nuclear antibody $(ANA)^+$ but lack clinical symptoms. It has been proposed that progression from asymptomatic autoimmunity to clinical disease is accompanied by immunologic changes that could be used as predictors of disease development. Previous studies indicate that a number of B cell phenotypic changes are seen in SARD patients including changes in the proportions of various naïve and memory B cell subsets, increased B cell activation and elevated levels of plasmablasts/plasma cells.
**Objectives:** To determine whether $ANA^+$ individuals who lack sufficient symptoms for a SARD diagnosis have B cell phenotypic changes similar to those seen in SARD.
**Methods:** Healthy controls (HC) and $ANA^+$ individuals who: 1) lacked clinical symptoms of SARD (ANS); 2) had at least one clinical symptom of SARD (UCTD); or 3) had a recently diagnosed steroid and immunosuppressive naïve SARD (SLE, SS, SSc, MCTD, DM) were recruited. PBMCs were isolated over a Ficoll gradient, stained with various combinations of fluorescently labeled antibodies and analyzed by flow cytometry. Anti-nuclear antibodies were measured through the hospital laboratory. Whole blood IFN signature and BAFF RNA levels were measured by NanoString.
**Results:** B cell phenotypes were examined for 32 HC, 38 ANS, 28 UCTD, and 59 early SARD (24 SS, 26 SSc, 6 SLE, 2 MCTD, 1 DM) patients. Patients with early SARD had a number of changes in their naïve and memory B cell subsets, as previously reported for patients with established disease, including: increased proportions of mature naïve B cells (SSc); increased proportions of T1T2 cells (SLE and SS); and trends to decreased proportions of switched memory B cells ($CD27^+IgD^-$) in all SARD. Similar decreases in the proportion of switched memory B cells were seen in ANS and UCTD patients, and as seen for the SARD patients, these cells were activated with elevated levels of CD86 as compared to HC. Significantly increased activation of the $CD27^-IgD^-$ memory compartment was also seen in ANS, UCTD, SLE and SjD patients. Although significantly increased proportions of plasmablasts and/or $CD138^+$ plasma cells

were seen in all SARD patients (except those with SSc), these were not seen in ANS and UCTD patients. Nevertheless, in pre-SARD individuals (ANS + UCTD) there was a significant positive correlation between the size of these cell subsets, as well as the proportion of T1T2 cells, and ANA titer and the number of different anti-nuclear antibodies specificities. As observed for early SARD patients, there was a trend to increased BAFF levels as compared to HC in pre-SARD individuals, which achieved statistical significance in UCTD patients. However, there was no association between the levels of BAFF and any of the B cell phenotypes, whereas the IFN signature was positively associated with the proportion of T1T2 cells.

**Conclusions:** B cell phenotypic abnormalities precede the onset of clinical disease in ANA$^+$ individuals and have a pattern suggesting ongoing activation through T-B collaboration.

## THU0266 CGAMP AND CGAS ARE EXPRESSED IN A SUBSET OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ASSOCIATE WITH DISEASE ACTIVITY

J. An[1], L. Durcan[1], R.M. Karr[1], J.J. Woodward[2], K. Elkon[1]. [1]*Rheumatology;* [2]*Microbiology, University of Washington, Seattle, United States*

**Background:** Type I interferon (IFN-I) is strongly implicated in the pathogenesis of Systemic Lupus Erythematosus (SLE) and "interferonopathies" such as Aicardi-Goutieres Syndrome (AGS). A recently discovered DNA-activated IFN-I pathway, cyclic GMP-AMP (cGAMP) synthase (cGAS), which is crucial in viral immunity, has been linked to AGS and mouse models of SLE. Whether this pathway plays a role in human SLE is unknown.

**Objectives:** Given the pivotal role played by interferon in the pathogenesis of SLE, our initial aim was to determine whether cGAS expression and subsequent cGAMP production contribute to IFN-I production in SLE. A further objective was to establish whether there is a specific disease phenotype associated with activation of this pathway.

**Methods:** There were three phases to this work. Initially, we evaluated cGAS mRNA expression by QPCR from stored cDNA in 51 SLE patients and 20 normal controls. Peripheral blood mononuclear cells (PBMC) were obtained from a second cohort comprising 17 SLE patients, 10 RA patients and 9 healthy volunteers. Extracts from these PBMC were tested for cGAMP by a Multiple Reaction Monitoring (MRM) assay developed on a mass spectrometer coupled with Ultra-Performance Liquid Chromatogram (UPLC). In a third cohort, cGAS and cGAMP were examined in the same SLE patients (n=31). Disease activity was determined by SELENA-SLEDAI and organ involvement, serology and medications recorded. Categorical variables were compared using Fischer's exact test, mean data was compared using a t-test or the Wilcoxon Sum-Rank test for normal or non-normally distributed data respectively.

**Results:** Phase 1 revealed that cGAS expression in PBMC was significantly higher in SLE patients (n=51) when compared to normal controls (n=20) (p=0.0045). cGAS expression positively correlated with IFN response gene (ISG) expression in SLE patients ($p=1.8 \times 10^{-5}$). When PBMC from healthy controls were incubated with IFN-I, cGAS mRNA increased in a dose response manner consistent with it being an IFN stimulated gene. Targeted measurement of cGAMP by mass spectrometery detected cGAMP in 14.6% (7/48) SLE patients but not in any of the normal (n=19) or RA (n=22) controls. Disease activity was significantly higher in SLE patients with cGAMP detected versus those in which it was not detected (SLEDAI=7.0, SD 5.09 versus 3.52, SD 2.78, p=0.0102).

**Conclusions:** Although cGAS appears to be a prominent cytosolic DNA sensor responsible for inducing IFN in response to infection, its role in human autoimmune diseases is unknown. Here, we describe for the first time, evidence of cGAS/cGAMP activation in human SLE. We demonstrated high disease activity associated with activation of this pathway. The inducing stimulus, cell type of production and overall importance in generating the IFN signature in SLE remain to be determined.

## THU0267 THE OXIDATIVE STRESS MARKERS AS RISK FACTOR FOR ENDOTHELIAL DYSFUNCTION IN PRIMARY AND SECONDARY ANTIPHOSPHOLIPID SYNDROME

L. Stojanovich[1], N. Stanisavljevic[1], D. Marisavljevic[1], V. Dopsaj[2], B. Todic[3]. [1]*Head of the Department for scientific research, University Hospital Center Bezanijska Kosa;* [2]*Faculty of Pharmacy Belgrade, University of Belgrade;* [3]*Internal medicine, University Hospital Center Bezanijska Kosa, Belgrade, Serbia*

**Background:** The oxidative stress markers as risk factor for endothelial dysfunction in primary and secondary antiphospholipid syndrome.

**Objectives:** Antiphospholipid syndrome (APS) may manifest as a primary (PAPS) or as a secondary disease (SAPS). It is featured by clinical manifestations in the presence of antiphospholipid antibodies (aPL). Antioxidant status has been evaluated in patients with SLE, with conflicting results.

**Methods:** The study involved 152 APS patients (95 PAPS, 57 SAPS) and 41 age/sex-matched controls. Brachial artery responses to reactive hyperaemia (endothelium-dependent dilatation) [FMD] and sublingual nitroglycerine (endothelium-independent dilatation) [NMD] were measured by using high-resolution vascular ultrasound. Markers of oxidative stress, including lipid hydroperoxydes (LOOH), advanced oxidation protein products (AOPP), total thyol groups and paraoxonase 1 activity (PON1) were determined by spectrophotometric method.

**Results:** FMD in patients with PAPS and SAPS was significantly lower than those of the controls ($p<0.001$ and $p<0.001$, respectively) without difference in NMD. FMD impairment was similar in both APS groups. Risk factors for endothelial impairment were age ($p<0.05$), obesity (p=0.048) and hypertension (p=0.020) but not aPL. We also found statistically significant difference in prevalence of FMD and NMD impairment in PAPS patients with longer disease duration. LOOH and AOPP concentrations were significantly higher and thyol groups lower in APS patients comparing to control group as the same relations between SAPS to PAPS groups. APS patients with fetal losses had higher AOPP (p=0.002) as well as patients diagnosed with thrombosis (p=0.011). Impairment of FMD was found in APS patients with higher LOOH and AOPP concentrations (p=0.044 and 0.015, respectively). There was no difference between impairment of FMD and NMD according to aPL category (except LA positivity to FMD impairment in PAPS group) or clinical APS manifestation.

**Conclusions:** Endothelial dysfunction is present in APS patients with marked oxidative imbalance. Oxidative stress is more prominent in SAPS than in PAPS group. Endothelial dysfunction is doubtlessly present in APS patients with oxidative imbalance as additional risk factor among other risk factors for clinical event. AOPP could be relevant prognostic factor for APS manifestations since it contribute to endothelial dysfunction and correlate to clinical APS manifestations.

## THU0268 DECREASED EXPRESSION OF MIR-130A AND MIR-708 IN TYPE-1 CLASSICAL DENDRITIC CELLS OF SJÖGREN'S SYNDROME PATIENTS INDICATES THEIR DYSREGULATION

M.R. Hillen, S.L. Blokland, E. Chouri, A.P. Lopes, A.A. Kruize, C.E. Hack, M. Rossato, T.R. Radstake, J.A. van Roon. *Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the salivary and lachrymal exocrine glands that leads to dryness of mouth and eyes. Type-1 classical dendritic cells (cDCs) are very potent antigen presenting cells known to induce strong T-cell proliferation and cytokine production. Despite the fact that especially cDC1s are candidate key players in the activation of local T and B-cells in pSS, they have rarely been studied in pSS.

**Objectives:** Considering the critical role of micro-RNAs (miRNAs) in regulation of gene expression, we investigated miRNA expression in isolated cDC1s of pSS patients.

**Methods:** Two independent cohorts (discovery and validation) were established including a total of 29 pSS patients. 17 healthy controls (HC) were included as control group. cD1c+CD19- cells were isolated from peripheral blood using MACS and we performed miRNA profiling of 758 miRNA targets using the OpenArray platform in the donors included in the discovery cohort. A selection of the miRNAs found to be differentially expressed in pSS versus HC was measured in the validation cohort. We performed pathway enrichment with the experimentally supported targets of the validated miRNAs.

**Results:** A total of 24 miRNAs were downregulated in pSS patients versus HC in the discovery cohort (all at least $p<0.05$ and 2log expression difference). Of these, 16 targets were selected to be validated in validation cohort. Two miRNAs, miR-130a and miR-708, were significantly downregulated in pSS patients in both cohorts ($p<0.05$). Pathway enrichment showed that the experimentally supported targets of these miRNAs are mainly involved in vesicle trafficking and a number of growth-factor signalling pathways ($p<0.05$, FDR corrected), including epidermal growth factor (EGF) signalling and endocytosis. We are currently linking the miRNA expression data to RNAseq data and performing functional experiments with primary DCs to dissect the effects of miRNA dysregulation in these cells.

**Conclusions:** We here for the first time show differentially expressed miRNAs in an isolated immune cell subset of pSS patients. In addition, this is the first evidence for dysregulation of primary peripheral blood type-1 cDCs in pSS. Considering threimportant role of miRNAs in cell function, this suggests that targeting aberrant miRNA expression may provide tools to modulate cDC activity.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4074

## THU0269 A MULTITUDE OF DOWNREGULATED MIRNAS IN PLASMACYTOID DCS OF SJÖGREN'S SYNDROME PATIENTS INDICATES NUMEROUS DYSREGULATED SIGNALLING PATHWAYS

M.R. Hillen, E. Chouri, S.L. Blokland, A.A. Kruize, F.P. Lafeber, M. Rossato, J.A. van Roon, T.R. Radstake. *Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

**Background:** Plasmacytoid dendritic cells (pDCs) are indicated to be key players in the pathogenesis of primary Sjögren's syndrome (pSS) and important producers of type-1 interferon (IFN). This is based on their increased presence in pSS salivary glands, potential role in experimental animal models and the presence of an IFN signature in pSS patients, which is associated with disease activity measures. MicroRNAs (miRNA) are key regulators of cellular function and may play a pivotal role in pDC function.
**Objectives:** To unravel the role of miRNAs in pDCs of pSS patients, we investigated the expression of miRNA in these cells in pSS patients.
**Methods:** Two independent cohorts (discovery and validation) were established including a total of 30 pSS patients. 15 healthy controls (HC) were included as control group and divided over the two cohorts. CD304-expressing pDCs were isolated from peripheral blood using MACS and profiling of 758 miRNA was performed using the OpenArray platform in the donors included in the discovery cohort. miRNAs found to be differentially expressed in the discovery cohort were subsequently measured in an independent validation cohort. Experimentally supported targets of validated miRNAs were used to perform pathway enrichment.
**Results:** A total of 24 miRNAs were significantly downregulated in pSS patients versus HC in the discovery cohort (all $p<0.05$ and $>2$log fold difference). 15 miRNAs were selected to be measured in the validation cohort, ten of these miRNAs were subsequently validated ($p<0.05$). Pathway enrichment indicated that these miRNAs are mainly involved in regulation of growth factor signalling and cell cycle (FDR corrected, $p<0.05$), including MTOR and PI-3K pathways. We are currently studying the involvement of these miRNAs in pDC function by linking miRNA expression to RNA sequencing data and *in vitro* functional assays.
**Conclusions:** We here for the first time show differential expression of miRNAs in isolated pDCs of pSS patients. Considering the strong potential of miRNAs in regulation of cell function, these data suggest a significant contribution to pDC function. Further analysis of the pathways in which these miRNAs are involved will expand our understanding on the role of pDCs in pSS.
**Disclosure of Interest:** None declared

## THU0270 ACTIVATION OF PLASMACYTOID DENDRITIC CELLS BY APOPTOTIC PARTICLES - MECHANISM FOR THE LOSS OF IMMUNOLOGIC TOLERANCE IN ANDROGEN-DEPLETED SJÖGREN'S SYNDROME

M. Ainola[1], P. Porola[1], Y. Takakubo[2], B. Przybyla[3], T. Tolvanen[4], A. Hänninen[5], Y. Konttinen[1,6], D. Nordström[1,6]. *[1]Clinicum, Faculty of Medicine, University of Helsinki, Helsinki, Finland; [2]Department of Orthopaedic Surgery, Yamagata University, Yamagata, Japan; [3]Hematology and Cancer Center, Helsinki University Central Hospital; [4]Department of Pathology, University of Helsinki, Helsinki; [5]Department of Medical microbiology and immunology, University of Turku, Turku; [6]Internal Medicine, Helsinki University Central Hospital, Helsinki, Finland*

**Background:** Sjögren's syndrome (SS) is a common autoimmune disease targeting salivary and lacrimal glands. It is strongly female-dominant characterized by low estrogen (E) levels combined with a local intracrine dihydrotestosterone defect (DHT) [1, 2]. It is assumed that the primary effect in SS is the abnormal apoptosis of salivary gland cells, combined with increased production and abnormal handling of the apoptotic particles [3].
**Objectives:** The working hypothesis was that these hormonal defects lead to increased apoptosis of the epithelial cells and pro-inflammatory plasmacytoid dendritic cell (pDC) mediated host responses. Apoptosis induced particles contain SS autoantigens, which may affect immune cells.
**Methods:** Apoptotic particles were collected by different centrifugation steps. The expression and localization of SS autoantigens ($\alpha$-fodrin and SS-A) was analysed with flow cytometry. Isolated apoptotic particles were used to stimulate pDCs. The effect of the particles on TLR7/9 expression in pDCs was studied with qPCR and the elicited cytokine/interferon (IFN) profile with xMAP and ELISA measurements. To study the effects of sex steroids, pDCs were cultured without and with various concentrations of dehydroepiandrosterone (DHEA), DHT and 17-$\beta$-estradiol (E2).
**Results:** Apoptosis-induced apoptotic particles contained SS-autoantigens and hy1-RNA. These particles were internalized by pDCs, which stimulated the TLR expression and the production of proinflammatory cytokines TNF-$\alpha$, interleukin-6 (IL-6) and IL-8. On the contrary, type I IFN production was not induced. Androgens inhibited the particle-induced increase of TLR9 expression in pDCs.
**Conclusions:** Apoptosis of epithelial cells leads to translocation of SS-autoantigens and single-stranded hy1-RNA to apoptotic blebs and membrane particles. The apoptotic particles are internalized by pDCs, which in response mature and produce proinflammatory cytokines. Androgens affect to redistribution of autoantigens and diminish the particle-elicited increase of TLR expression in pDCs. Apoptosis of salivary gland cells lead to formation of apoptotic particles, which might affect immunotolerance, production of autoantibodies and onset of autoinflammation. This event might describe how the immunologic tolerance is broken in the early stages of SS.

## THU0271 IMPAIRMENT OF GAS6/MERTK SYSTEM IN LUPUS NEPHRITIS

M. Bellan[1,2], M. Quaglia[1,3], F. Goegan[1], S. Pagani[1], L. Salmi[1], L. Castello[1,4], R. Bonometti[1,2], D. Sola[1,2], A. Gibbin[1,2], M. Pirisi[1,2], G.C. Avanzi[1,4], P. Stratta[1,3], P.P. Sainaghi[2]. *[1]Translational Medicine, Università del Piemonte Orientale UPO; [2]Internal Medicine Division; [3]Division of Nephrology; [4]Division of Emergency Medicine, AOU Maggiore della Carità, Novara, Italy*

**Background:** Growth Arrest-Specific 6 (Gas6) and its receptor MERTK have been involved in the regulation of inflammation and apoptosis.
**Objectives:** We evaluated if an impairment of Gas6/MERTK signalling system could be associated with Systemic Lupus Erythematosus (SLE) disease activity and, specifically, with kidney involvement.
**Methods:** Gas6 and the soluble, cleaved form of MERTK (sMER) plasma concentration were measured in 59 SLE patients and in 46 healthy controls. Clinical and laboratory data were collected.
**Results:** SLE patients had significantly higher plasma sMER concentrations (10,40 ng/ml [IQR 7,92–13,83] vs 2,65 ng/ml [2,38–3,23]) while healthy subjects showed only slightly higher plasma Gas6 concentrations than patients (22,8 ng/ml [IQR 19,2–24,7] vs 14,7 ng/ml [11,8–20,5]). Moreover, only sMER, but not Gas6, was significantly different being higher in SLE patients with renal involvement (11,3ng/mL [9,7–13,9ng/mL] vs 7,8 ng/mL [6,2–12,2ng/mL]). At univariate analysis sMER concentration was related to clinical and laboratory indexes of disease activity as SLEDAI, haemoglobin, ESR, proteinuria and creatinine plasma concentration but, at multiple regression analysis only 24 h urine protein concentration fitted the model (R=0,9751 F11,314; $p<0,002$).
**Conclusions:** An increased sMER concentration can be detected in SLE patients, particularly those who showed renal involvement. Interestingly sMER is directly related to the degree of proteinuria, This observation suggests an increased cleavage of MERTK; on this basis an impairment of MERTK-mediated apoptotic bodies clearance could be supposed.

## THU0272 INCOMPLETE AND SYSTEMIC LUPUS ERYTHEMATOSUS REVEAL A DIFFERENT PATTERN OF INTERFERON-STIMULATED GENES UP-REGULATION

M.Y. Md Yusof[1,2], Y. El-Sherbiny[1], A. Psarras[1], E.M. Hensor[1,2], M. Wittmann[1], P. Emery[1,2], E.M. Vital[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Type I interferons (IFN-I) play a central role in the pathogenesis systemic lupus erythematosus (SLE). IFN-I activity has been used as a biomarker by measuring interferon-stimulated gene (ISG) transcripts in the peripheral blood of SLE patients, but its relationship with clinical features still remains unclear. Incomplete lupus erythematosus (ILE) describes individuals with new onset of features suggestive of SLE, but do not fulfil diagnostic criteria. Up to 20% of these patients eventually progress to SLE.
**Objectives:** To investigate ISG expression in patients with ILE and explore possible qualitative differences between established and early stages of SLE.
**Methods:** A meta-analysis of known ISGs indicated 33 genes of importance [1]. The expression of 33 ISGs was measured using qPCR in PBMCs from individuals with SLE (n=54), ILE (n=27), and healthy controls (HC; n=14). SLE was defined using 2012 ACR/SLICC criteria. ILE was defined as ANA +ve, 1–2 clinical ACR/SLICC criteria, and symptom duration $<12$ months. Factor analysis (FA) was used to reduce expression data to a limited set of factors, which were compared between patient groups using ANCOVA test.
**Results:** FA on SLE patients indicated two factor scores explaining 80% of the data variance. The majority of variability was explained by Factor F1; however, Factor F2 appeared more relevant to the presence of fully established SLE. F1 and F2 were significantly different between patient groups; p=0.005 and p=0.044 respectively. F1 was similarly high in both SLE [SLE:HC=4.22 (1.80, 9.88), p=0.001] and ILE [ILE:HC=2.96 (1.20, 7.32), p=0.019]. In contrast, F2 was increased only in SLE [SLE:HC=1.38 (0.95, 2.00), p=0.086] but not in ILE [ILE:HC=1.02 (0.69, 1.51), p=0.917]; a significant difference was observed

between SLE and ILE patients [SLE:ILE=1.35 (1.04, 1.77), p=0.026].In total, 16 and 14 genes loaded onto F1 and F2 respectively. Most of the genes were involved in IFN signalling pathways. Genes related to apoptosis and ubiquitination were present in both F1 and F2. Additionally, F1 loaded genes were mainly associated with antiviral immunity, complement regulation, and Th2 responses; genes loaded onto F2 were associated with regulation of IFN-I, dsDNA binding, chemotaxis, and Th1 responses.

**Conclusions:** IFN-I activity is present in ILE. However, the majority of measured ISG expression (F1) cannot distinguish ILE and SLE. F1 represents genes that distinguish healthy individuals, but show little variation at different stages of disease development. We define a subset of ISGs (F2), the expression of which is only increased in patients with confirmed clinical SLE. ISG expression is not unidimensional: qualitative differences in expression of distinct ISGs can contribute to clinical progression after disease initiation.

## THU0273 DECREASED INTERLEUKIN-35 IS ASSOCIATED WITH HIGHER RISK OF PREGNANCY MORBIDITY IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

N. Liu [1], S. Zhang [2], C. Li [3], H. Zhu [4], A. Al-Hussaini [5], X. Wei [6], X. Zhang [7], L. Zhu [7], Q. Lu [7], R. Mu [7], Z. Li [2]. *[1] Rheumatology and Immunology, Peking University People's Hospital, Western District; [2] Peking University People's Hospital; [3] Peking Universtity People's Hospital; [4] Peking Univisity People's Hospital, Beijing, China; [5] School of Dentistry, Cardiff University; [6] School of Dentistry, Cardiff University, Cardiff, United Kingdom; [7] Peking University People's Hospital, Beijing, China*

**Background:** Antiphospholipid syndrome (APS) is an autoimmune disease characterized mainly by recurrent pregnancy failures and/or thrombosis [1]. Interleukin (IL)-35, a new member of IL-12 family, was demonstrated to play a role in the immunopathogenesis of several autoimmune diseases [2,3]. The expression of IL-35 was observed to be abnormal in idiopathic recurrent pregnancy loss [4].

**Objectives:** To determine the expression of IL-35 and assess its association with clinical /laboratory features in patients with APS.

**Methods:** Serum IL-35 was detected by the enzyme-linked immunosorbent assay (ELISA). 126 patients with APS, 38 patients with primary pregnancy morbidity, and 69 healthy controls were enrolled in the study. Clinical and laboratory features of APS patients were recorded. The Mann-Whitney U test was used to evaluate differences of non-normal distribution data and the Student's t test was used for normal distribution data. The differences in the frequency of clinical /laboratory characteristics were assessed by the Chi-square ($\chi^2$) test. The relevances between IL-35 and clinical/laboratory features were further analyzed by the Spearman test (measurement data) or Chi-square ($\chi^2$) test (qualitative data).

**Results:** Serum IL-35 was significantly decreased in APS patients (median 14.73, IQR 0–28.09 pg/ml) and patients with primary pregnancy morbidity (16.00, 10.56–25.00 pg/ml), compared to healthy controls (28.87, 20.16–47.47 pg/ml; all $p<0.001$). Female APS patients with decreased IL-35 had higher risk of pregnancy morbidity than those with normal IL-35, with an odds ratio (OR) of 2.565 (95% confidence interval (CI) 1.138–5.785, $p=0.022$), especially events of fetus death $\geq$ the 10th week (OR=6.545, 95% CI 6.03–21.101; $p<0.001$). In contrast, the frequency of thrombosis was significantly lower in APS patients with decreased IL-35 and the OR value was 0.382 (0.185- 0.789; $p=0.009$).

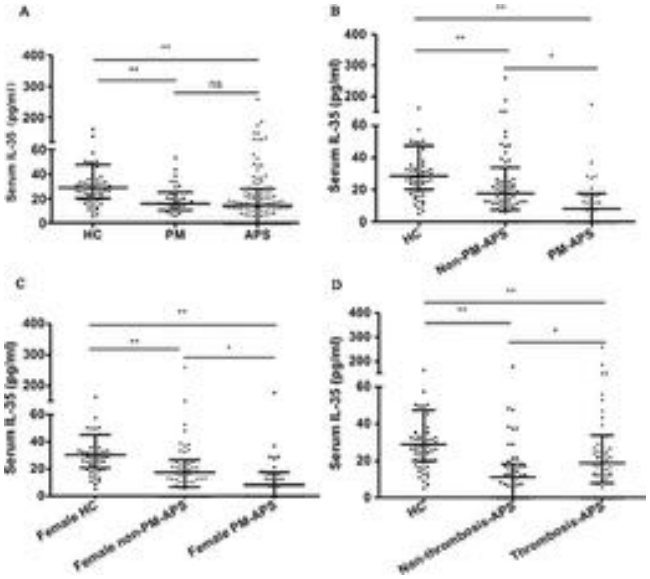

Figure 1

**Conclusions:** Serum IL-35 was decreased in APS patients and was associated with pregnancy morbidity and thrombosis, raising the hypothesis of its complicated pathogenic roles in APS.

## THU0274 UPREGULATION OF NOD2 INVOLVED IN THE INFLAMMATORY RESPONSE BY ACTIVATION OF MAPK SIGNALING PATHWAY IN LUPUS NEPHRITIS

O. Jin, C.C. Hou, X.Q. Li, X. Zhang, M. Qiu, D. Lin, L. Fang, X. Guo, Z. Lin, Z. Liao, J. Gu. *Division of Rheumatology, The Affiliated Third Hospital of Sun Yat-san University, Guang Zhou, China*

**Background:** Nucleotide-binding oligomerization domain (NOD) - containing 2 (NOD2) is a NOD - like receptors (NLRs) which plays important role in immune regulation and inflammatory response. There are increasing evidences to show that NOD2 may contribute to the development of numerous auto inflammatory and autoimmune disorders. However, their role in lupus nephritis (LN) is not known. Here, we explored the role of NOD2 in LN.

**Objectives:** However, their role in lupus nephritis (LN) is not known. Here, we explored the role of NOD2 in LN.

**Methods:** Immunohistochemistry was applied to observe the expression of NOD2 in renal biopsies. Real-time quantitative polymerase chain reaction (RT-qPCR) was used to detect the level of NOD2 mRNA in the biopsies. In vitro studies, HK-2 cells (renal tubular epithelial cell-line) were cultured with different inflammatory stimulation, western blot was used to investigate their expression of NOD2 and the following activation of MAPK pathway signals (ERK1/2, p38 and JNK), real-time qPCR was applied to observe the mRNA levels of downstream pro-inflammatory mediators (IL-1b, IL-8, MCP-1, TGF-b1, IL-6).

**Results:** (1) Immunohistochemistry staining demonstrated that the expression of NOD2 in LN is higher than that of normal control (P=0.002), and the mRNA level of NOD2 in renal tissue of LN patients was higher than that of normal control (P=0.001). (2) In vitro studies, the urine and serum from onset LN patients can significantly promote higher NOD2 expression in HK2 cells than that from healthy control ($P<0.001$). In addition, TGF-b1, LPS and muramyl dipeptide (MDP) can also induce higher NOD2 expression in HK2 cells ($P<0.001$, respectively). (3) The activation of NOD2 increased phosphorylation of ERK1/2, p38 and JNK. Moreover, the activation of NOD2 induced the release of pro-inflammatory mediators including IL-1b, IL-8, MCP-1, TGF-b1, IL-6.

**Conclusions:** Our study showed NOD2 expression was increased in LN patients. The activation of NOD2 can promote the activation of MAPK signaling pathway and release of downstream pro-inflammatory mediators. NOD2 may participate in the pathogenesis of LN.

## THU0275 PHARMACODYNAMIC MODELING OF BTK OCCUPANCY VERSUS EFFICACY IN RA AND SLE MODELS USING THE NOVEL SPECIFIC BTK INHIBITOR M2951

P. Haselmayer [1], M. Camps [2], L. Liu-Bujalski [3], F. Morandi [4], J. Head [4], S. Zimmerli [5], L. Bruns [1], A. Bender [5], P. Schroeder [6], R. Grenningloh [5]. *[1] Immunology, Merck KGaA, Darmstadt, Germany; [2] Immunology, Merck Serono, Geneva, Switzerland; [3] Medicinal Chemistry; [4] Biomolecular Pharmacology; [5] Immunology; [6] Translational Pharmacology, EMD Serono, Billerica, United States*

**Background:** Bruton's tyrosine kinase (BTK) is a clinically proven target in several hematological indications. Due to its role in mediating the signaling of both B cell receptors (BCR) and Fc receptors (FcR), BTK is also a potential target for the treatment of autoimmune disease such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), where B cell and innate immune cell activation are key drivers of pathology.

**Objectives:** We are developing M2951, a novel,highly selective BTK inhibitor that

is suitable for the treatment of chronic diseases. This work aimed at characterizing its efficacy in various cellular assays in vitro as well as in disease models for RA and SLE. Based on in vivo efficacy and target occupancy data, a PKPD model describing the correlation of BTK inhibition and disease severity reduction was built.
**Methods:** The BTK inhibitor M2951 was characterized in various biochemical and cellular assays to demonstrate its potency and specificity. To determine disease-modifying activity, M2951 was tested in NZB/W F1 mice which had been infected with e replication-deficient adenovirus expressing IFN-alpha in order to synchronize disease onset. Efficacy was determined by measuring proteinuria and histological kidney damage. Furthermore, M2951 was tested in a collagen-induced arthritis model (CIA) in the mouse. Paw scores were used to measure efficacy. A biochemical assay was developed that allowed to measure the degree of BTK occupancy in blood cells and splenocytes was developed. This assay was used to build a translational PKPD model linking target occupancy to efficacy.
**Results:** M2951 potently inhibits BCR- and FcR-mediated signaling and subsequent activation and function of B cells and certain myeloid cells. In mouse models of RA and SLE, M2951 displayed robust efficacy as demonstrated by a marked reduction of disease severity. In the NZB/W F1 IFN-α-accelerated SLE model, efficacy correlated with B cell inhibition, reduction of autoantibodies, and decreased circulating memory B and T cells. In addition to SLE, RA-like symptoms were inhibited in a collagen-induced arthritis model. In order to translate preclinical efficacious doses to humans, we determined the degree of target occupancy necessary to achieve disease reduction. Pharmacodynamic modeling showed that BTK occupancy of 60 and 80% was linked to 80% and near complete disease inhibition, respectively, in both the RA and SLE models.
**Conclusions:** In summary, these results demonstrate the potential of M2951 to treat autoimmune disease and may inform rational dose decisions as M2951 is advanced for development in rheumatologic diseases.

## THU0276 INCREASED OXIDATIVE DNA DAMAGE AND IMPAIRED GENE REPAIRING PATHWAY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Donmez[1], G.E. Pamuk[2], O. Doganlar[3], O.N. Pamuk[1]. *[1]Rheumatology; [2]Hematology; [3]Trakya University Medical Faculty, Edirne, Turkey*

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease and may affect multiple organs and systems. Definite etiology and pathogenesis of disease is unknown. Apoptosis, defective clearance of apoptotic materials, uncontrolled DNA damage related to oxidative stress play important roles in the pathogenesis of SLE.
**Objectives:** In this study we aimed to evaluate some parameters related to oxidative stress, apoptosis and gene repairing system in SLE and lupus nephritis (LN) patients.
**Methods:** The study included 10 patients with active SLE, 10 patients with active LN and 10 healthy controls. The demographical and clinical features of patients were obtained from medical charts. RNA isolation from peripheral blood was performed according to protocol of RNA kit. RT-PCR was used to analyze gene expressions of SOD, CAT, glutathione synthetase, survivin, BCL-2, CCN D1 and that of genes in the apoptotic pathway. To compare the features of study groups, one-way ANOVA test was performed and Duncan test was used as posthoc analysis.
**Results:** 8-hydroxy-deoxyguanosine (8-OHdG) which is the most common stable product of oxidative DNA damage caused by ROS is significantly higher in SLE (618±293) and LN groups (732±303) than in healthy controls (333±128) (p values $<0.01$). In addition, genomic template stability (GTS) in SLE and LN groups were significantly lower than in healthy controls (p values $<0.001$). Telomer length was used to assess overal biological aging. In our SLE and LN patients, telomer length is shortened than in healthy controls (p values $<0.01$).
We also evaluated the antioxidant system gene expression. We detected that main antioxidant system gene expression like SOD, SOD2, GS and GPX were significantly decreased in LN patients than in SLE and healthy controls. In the contrary, gene repair pathway related gene expression such as TDG, SMUG1 and RAD18 were significantly increased in SLE and especially in LN groups when compared to healthy controls (p values $<0.05$).
In LN patients, p53 gene was expressed significantly more than in SLE and controls. This gene was also expressed significantly more in SLE than in controls ($p<0.05$).
The expression of apoptosis associated genes like BAX, APAF, CYTC, CASPASE3 were elevated in LN than in SLE and healthy controls (p values $<0.01$). Apoptosis inhibitor genes like survivin, livin, XIAP and BCL2 were expressed signficantly higher in LN patients than in SLE and controls (p values $<0.01$). These genes were also expressed higher level in SLE patients than in controls ($p<0.05$).
**Conclusions:** In SLE patients, particularly in LN group, oxidative DNA damage is increased and antioxidant gene expression is decreased. Gene repair pathway is also impaired in SLE and LN. Although, genes related to inhibition of apoptosis is elevated, this elevation is not enough to eliminate the activation of apoptosis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3028

## THU0277 EVALUATION OF POLYMORPHISMS OF STAT4, TRAF31P2 AND HCP5 IN SJÖGREN SYNDROME: ASSOCIATION WITH DISEASE SUSCEPTIBILITY AND CLINICAL ASPECTS

S. Colafrancesco[1], C. Perricone[1], R. Priori[1], G. Picarelli[1], C. Ciccacci[2], P. Borgiani[2], A. Latini[2], G. Novelli[2], G. Valesini[1]. *[1]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma; [2]Genetica, Dipartimento di Biomedicina e Prevenzione, University of Rome Tor Vergata, Rome, Italy*

**Background:** Primary Sjögren syndrome (pSS) is a systemic inflammatory condition characterized by lymphocytic infiltrates in exocrine glands. STAT4 is one of the genes involved in "interferon (IFN) signature" and a single nuclear polymorphism (SNP), rs7574865 has been found associated with pSS. Other SNPs in TRAF3IP2 (rs33980500 and rs13193677) and HCP5 (rs3099844) genes, have been previously associated with the susceptibility to systemic lupus erythematosus (SLE), and seem to influence the disease phenotype.
**Objectives:** To evaluate the association of different SNPs [STAT4 (rs7574865), TRAF3IP2 (rs33980500), HCP5 (rs3099844)] with the susceptibility to pSS and their role in modulation of clinical and laboratory features.
**Methods:** One hundred thirty-five consecutive patients with pSS (AECC) were enrolled and clinical and laboratory data collected. Three hundred age and sex-matched healthy subjects were used as controls. Genomic DNA was isolated from peripheral blood mononuclear cells (Qiagen blood DNA mini kit). Genotyping was performed by allelic discrimination assays (Applied Biosystems, Foster City, CA, USA).
**Results:** Clinical and laboratory features are reported in table.

| Clinical features | Number (%) | Laboratory features | Number (%) |
|---|---|---|---|
| Sex (M/F) | 5/130 | ANA | 116/135 (85.9) |
| Age (mean ± SD), yrs | 59±12.1 | Anti-Ro/SSA | 81/135 (60) |
| Age at diagnosis (mean ± SD), yrs | 53,2±12,2 | Anti-La/SSB | 56/135 (41.4) |
| Xerophthalmia | 124/135 (91.8) | Hypergammaglobulinemia | 44/135 (32.5) |
| Xerostomia | 124/135 (91.8) | Rheumatoid factor | 46/135 (34) |
| Glandular swelling | 27/135 (20) | Leucopenia | 28/135 (20.7) |
| Arhritis | 16/135 (11.8) | Hypocomplementemia | 11/135 (8.1) |
| Lymphoma | 4/135 (2.9) | Monoclonal component | 13/135 (9.6) |
| | | Cryoglobulinemia | 6/135 (4.4) |

Deviations from Hardy–Weinberg equilibrium were not observed. The SNPs rs7574865 of STAT4 and rs3099844 of HCP5 were found associated with pSS at both the genotypic and allelic level ($p<0.001$, OR=1.84, 95%CI=1.28–2.65 and $p<0.05$, OR=2.28, 95%CI=1–3.7, respectively) and the data was confirmed after adjustment for other variables. STAT4 was found associated with the presence of monoclonal component (p=0.021). HCP5 was associated with the presence of leukopenia (p=0.021, OR=2.91, 95%CI=1.15–7.38) and lymphoma ($p<0.001$).
**Conclusions:** This study confirms the association between the rs7574865 polymorphism of STAT4 and the susceptibility for pSS, and shows for the first time the association with a variant of HCP5. STAT4 was associated with monoclonal component supporting the role of IFN signature in autoantibodies production. Furthermore, HCP5 seem to be able to influence the disease phenotype predisposing to the development of leukopenia and lymphoma. These data need to be validated on larger cohorts of patients.
**Disclosure of Interest:** None declared

## THU0278 INCREASED PLATELET AGGREGATION BY VON WILLEBRAND FACTOR ACTIVITY CORRELATES WITH ANTI-DSDNA ANTIBODY LEVELS AND ACUTE PHASE REACTANTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. Nossent[1,2], W. Raymond[2], G.Ø. Eilertsen[1]. *[1]Department of Clinical Medicine, UiT The Artic University of Norway, Tromsø, Norway; [2]School of Medicine & Pharmacology, University of Western Australia, Perth, Australia*

**Background:** Von Willebrand Factor (vWF) typically is released in response to endothelial damage or dysfunction to promote thrombus formation. In Systemic Lupus Erythematosus (SLE) patients vWF protein levels (vWF:Ag) predict cardiovascular events [1], but endothelial dysfunction in SLE is an incompletely understood multifactorial process [2].
**Objectives:** To investigate whether vWF functional activity (VWF:RCo) is related to clinical disease activity, markers of inflammation, vascular risk factors and events in SLE.
**Methods:** A cross sectional study in patients (n=90) that fulfilled ACR classification criteria for SLE and had detailed clinical information and serology collected at an extended outpatient visit. VWF functional activity was determined by ristocetin induced platelet aggregation (vWF:RCo), while vWF protein level was measured by turbidimetric assay (vWF:Ag). Variables included in this study were: SLEDAI2K;

SLICC-DI; immunosuppressive drug usage (n=33); anticoagulant therapy (n=33); antiphospholipid antibody status (aPL) and syndrome (APS) and levels for anti-dsDNA Ab, B-cell activating factor (BAFF), IL-6 and TNFα, acute phase reactants and plasma Factor VIII [3, 4].

**Results:** Platelet aggregation by vWF was significantly higher in SLE patients compared to healthy controls (n=10) (median vWF:RCo, 123% vs 78%, p=0.004) as were vWF:Ag levels (142% vs 107%, p=0.001). VWF:RCo correlated with levels of ESR (Rs 0.332, p=0.01), anti-dsDNA Ab (Rs 0.26, p=0.02), LDH (Rs 0.26, p=0.016), ceruloplasmin (Rs 0.367, $p<0.01$), C1-inhibitor (Rs 0.24, p=0.02), total cholesterol (Rs 0.23, p=0.03) and correlated inversely to transferrin (Rs -.317, $p<0.01$). VWF:RCo levels were unrelated to SLEDAI2K, CRP and IL-6 or TNFα levels and were not significantly different in patients with a previous cardiovascular event, vasculitis, antiphospholipid Ab, or in current smokers.

**Conclusions:** The association between vWF dependent platelet aggregation, acute phase proteins and increased anti-dsDNA antibody levels suggest that anti-dsDNA Ab mediated inflammation contributes to endothelial dysfunction in SLE.

## THU0279 MSCS ALLEVIATE CLINICAL AND EXPERIMENTAL SJOGREN'S SYNDROME BY INHIBITING IL-12 PRODUCTION OF APCS

B. Shi, J. Qi, R. Feng, Z. Zhang, W. Chen, W. Li, X. Tang, G. Yao, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Mesenchymal stem cells (MSCs) have been demonstrated to be effective in treating clinical and experimental Sjogren's syndrome (SS). However, the underlying mechanisms of benefit effects of MSCs on pSS remain unclear. IL-12 was mainly generated from monocytes, dendritic cells (DCs) and macrophages, and regarded as a pro-inflammatory cytokine in autoimmune diseases, including SS.

**Objectives:** In this study we test whether the therapeutic effects of MSCs on SS is mediated by reducing IL-12 production.

**Methods:** $1\times10^6$ human umbilical cord derived MSCs were injected into NOD mice (experimental Sjogren's syndrome, ESS) via tail vein. 4 weeks later, the salivary flow rates were detected. Splenocytes were collected and CD11c+ and CD11b+ cells were sorted by magnetic beads. Lacrimal and salivary glands were collected for histologic analysis. Serum IL-12 was quantified by ELISA inprimary Sjogren's syndrome (pSS) patients and healthy controls. 5 patients with pSS received MSCs transplantations. Whole blood was collected before MSCs treatment and 4 weeks later. CD14+ cells from pSS patients and healthy controls were isolated by magnetic beads. The CD14+ cells were induced to generate DCs or macrophages. Expression of IL-12 was detected by RT-PCR. Human THP-1 cells were induced towards macrophage or DC. THP-1 cells, THP-1-induced macrophages and DCs were co-cultured with MSCs, respectively. IL-12 levels in supernatants were detected by ELISA. IL-12 gene expression was quantified by real-time PCR.

**Results:** MSCs transplantation improved salivary flow rates and decreased lymphocyte infiltrations in lacrimal and salivary glands, proving its effectiveness in alleviating symptoms of NOD mice. *In vivo* transplantation of MSCs into NOD mice also reduced serum IL-12 levels, and IL-12 mRNA in CD11c+ and CD11b+ cells. Serum IL-12 levels were significantly increased in pSS patients. MSCs transplantation also decreased IL-12 levels in pSS patients after 4 weeks. CD14+ monocytes, monocyte-derived DCs and macrophages from pSS patients generated significantly more IL-12 than that from healthy individuals. MSCs significantly reduced IL-12 production by human THP-1-induced DCs, macrophages or monocytes *in vitro*. Moreover, MSCs also decreased IL-12 production in mouse Raw246.7 cells (mouse macrophage), mouse CD11c+ cells and CD11b+ cells *in vitro*.

**Conclusions:** IL-12 over-production by APCs may contribute to the pathogenesis of pSS and ESS. MSCs may alleviate clinical and experimental Sjogren's syndrome through decreasing IL-12 production.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.2371

## THU0280 IL-12 EXACERBATES SJOGREN'S SYNDROME THROUGH INDUCING LYMPHOCYTE INFILTRATIONS INTO SALIVARY GLANDS AND IMBALANCE OF LYMPHOCYTE SUBSETS

B. Shi, J. Qi, R. Feng, Z. Zhang, W. Chen, W. Li, X. Tang, G. Yao, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Primary Sjogren's syndrome (pSS) is characterized by inflammation of exocrine glands and functional impairment of the salivary and lacrimal glands, accompanied by the disorders of immune system, including increased pro-inflammatory cytokines, decreased anti-inflammatory cytokines, and turbulence of immune cell homeostasis. IL-12 is a pro-inflammatory cytokine relating to autoimmune diseases. However, the role of IL-12 in pSS and the underlying mechanism is still not fully understood.

**Objectives:** We aimed to explore the role of IL-12 in the pathogenesis of pSS.

**Methods:** Serum IL-12 was detected in pSS patients and healthy controls. The percentages of T cell subsets, B cells and plasma cells in peripheral blood were analyzed. NOD mice (experimental Sjogren's syndrome model, ESS) were treated with recombinant IL-12 protein, anti IL-12 MAb or same volume of saline, respectively. One week later, the salivary flow rate was detected. Histopathology of submandibular gland, lacrimal gland, lung and kidney were observed by HE staining. Immunochemistry was performed to identify the phenotype of the infiltrated lymphocytes. Flow cytometry was used to detect the proportion of lymphocyte subsets of splenocytes.

**Results:** IL-12 levels were significantly higher in pSS patients. Th1, Th17 and Tfh cell percentages were significantly higher in pSS, while Treg percentage was decreased. Th1/Th2 and Th17/Treg ratios were also higher in pSS patients. Besides, plasma cell percentages were also higher in pSS patients. All of the above data suggested the disturbance of both cellular and humoral immune balances in pSS patients. In vivo IL-12 treatment in NOD mice significantly increased salivary gland swollen severity, decreased salivary flow rates, and promoted lymphocyte infiltration in salivary glands, pulmonary interstitium and renal medulla. Immunochemistry staining showed that most of the infiltrated lymphocytes into the organs were CD4+, and a majority of the CD4+ cells were IL17A+, suggesting IL-12 induced Th17 cell infiltrations in multiple organs of NOD mice. On the other hand, anti IL-12 decreased the percentages of Th1, Th17 and Tfh cells, and corrected the imbalance of Th1/Th12 and Th17/Treg ratio. The anti IL-12 also reduced the salivary gland swollen and lymphocyte infiltration, whilst increased salivary flow rates.

**Conclusions:** IL-12 deteriorated the pathogenesis of ESS partially by promoting lymphocyte infiltration into the affected organs and disturbance of lymphocyte subsets. Targeting IL-12 may be a potential therapeutic strategy for SS patients.

**Disclosure of Interest:** None declared

## THU0281 ARTESUNATE INHIBITS TYPE I INTERFERON INDUCED PRODUCTION OF MACROPHAGE MIGRATION INHIBITORY FACTOR IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

X. Feng, W. Chen, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Macrophage migration inhibitory factor (MIF) is a key regulator of both atherosclerosis and systemic lupus erythematosus (SLE), yet the factors participating in its production remain unclear.

**Objectives:** In this study, the relationship between type I interferon (IFN) and MIF levels in SLE patients were examined, and the effect as well as the mechanism of artesunate (ART), an anti-malarial agent extracted from Chinese herbs, on the regulation of MIF were explored.

**Methods:** Serum and peripheral blood cells from SLE patients and healthy controls were collected, with MIF levels measured by ELISA and type I IFN inducible gene expressions detected by real-time PCR. Associations between two factors were assessed by Spearman correlation analysis. ART at different concentrations was added to human umbilical vein endothelial cells (HUVECs) cultures with or without prior IFNα-1bstimulation and to SLE peripheral blood mononuclear cells (PBMC) cultures, with dexamethasone or fludarabine, a selective inhibitor of signal transducer and activator of transcription (STAT) 1, applied as positive treatment controls. Protein levels of STATs and phosphorylated (p-) STATs in HUVECs were determined by western blotting.

**Results:** Serum MIF levels were elevated in SLE patients and positively associated with disease activity ($r$ =0.86, $p$ <0.0001) and accumulated damage ($r$ =0.34, $p$ =0.048). Meanwhile, increased MIF levels were closely associated with IFN scores in SLE patients ($r$ =0.74, $p$ =0.0002). *In vitro* experiments showed that IFNα-1b had a direct impact on MIF production. ART could inhibit IFN inducible gene (LY6E and ISG15) expressions in HUVECs and PBMC cultures, and suppress IFNα-1b induced MIF production. Over-expression of p-STAT1, but not p-STAT3 or STAT5, was detected after IFNα-1b stimulation, which was completely reversed at the presence of ART.

**Conclusions:** MIF could be regulated by type I IFN in SLE patients. ART counteracts the effect of IFNα to inhibit MIF production by blocking STAT1 phosphorylation, thus may have therapeutic potential for SLE-associated atherosclerosis.

**Disclosure of Interest:** None declared

## SLE, Sjögren's and APS - treatment

### THU0282 EXPOSURE-RESPONSE ANALYSES OF EFFECTS OF VENETOCLAX, A SELECTIVE BCL-2 INHIBITOR, ON B AND TOTAL LYMPHOCYTE COUNTS IN FEMALE SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

M. Minocha[1], A.K. Jones[1], P. Lu[2], A.A. Othman[1]. [1]*AbbVie, North Chicago, IL;* [2]*AbbVie, Worcester, MA, United States*

**Background:** B-cell Lymphoma 2 (Bcl-2) is an anti-apoptotic protein that plays a critical role in hemostasis of auto reactive lymphocytes (B and T cells) thought to be involved in various autoimmune diseases such as SLE. Abnormalities in the Bcl-2 mediated lymphocyte apoptotic process have been implicated in development of these autoimmune diseases. Venetoclax is an orally bioavailable, selective Bcl-2 inhibitor currently under evaluation for treatment of SLE and several oncology indications.
**Objectives:** The objective of this work was to quantitatively characterize the relationship between venetoclax plasma concentrations and time course of the reduction in B and total lymphocyte counts following single and multiple dosing of venetoclax in female subjects with SLE
**Methods:** Serial pharmacokinetic and lymphocyte count data from a double-blind, randomized, placebo-controlled Phase 1 study of venetoclax (single doses of 10, 30, 90, 180, 300 and 500 mg or two cycles of 30, 60, 120, 240, 400 and 600 mg or matching placebo once daily for seven days followed by 21 day washout) in female subjects with SLE (N=98) were analyzed using non-linear mixed-effects modeling.
**Results:** Venetoclax plasma concentrations in subjects with SLE were characterized using a two-compartment pharmacokinetic model with first-order elimination. Venetoclax resulted in reduction of B and total lymphocytes and the effect was consistent between the two cycles of treatment for the multiple dose evaluation. An indirect response model with venetoclax stimulating B lymphocytes turnover was utilized to describe venetoclax exposure/ B lymphocytes relationship. The slope for stimulation of the first order rate constant of B lymphocytes turnover was estimated at 0.02 [95% CI: 0.01, 0.03] $day^{-1}$/(ng/mL) following multiple dosing. An $E_{max}$ model with an effect site (to introduce time-delay) was used to describe venetoclax effect on total lymphocytes. The maximum effect was estimated to be 60% relative to baseline with an estimated $EC_{50}$ of 225 [95% CI: 146 to 383] ng/mL. Baseline B and total lymphocytes were identified as covariates for venetoclax slope and $EC_{50}$, respectively. For the cyclic regimens of 120 and 600 mg, the model predicted typical reduction from baseline at day 7 of 26% and 77%, respectively, for B lymphocyte (for a baseline value of $0.18x10^9$ cells/L) and 15% and 37%, respectively, for total lymphocytes (for a baseline value of $1.7x10^9$ cells/L)
**Conclusions:** The current analyses demonstrate that B lymphocytes are more sensitive than total lymphocytes to the effects of venetoclax and these effects were quantitatively characterized in female subjects with SLE using an exposure-response modeling approach. The developed models will be utilized to guide the design of future trials of Bcl-2 inhibitors in subjects with SLE, including dose selection and assessment of cyclic versus continuous dosing.

### THU0283 ANTICOAGULATION AND LONG-TERM OUTCOMES IN PATIENTS WITH RENAL ARTERY STENOSIS AND ANTIPHOSPHOLIPID SYNDROME

A. Casian[1], S. Sangle (joint first author)[1], S. ManouStathopoulou[2], N. Jordan[3], D. D'Cruz[1]. [1]*Lupus Unit;* [2]*Medicine, Guy's and St. Thomas' NHS Foundation Trust, London;* [3]*Rheumatology, Addenbrooke's Hospital, Cambridge, United Kingdom*

**Background:** Our previous data [1],[2],[3] showed that renal artery stenosis (RAS) is more prevalent in antiphospholipid syndrome (APS) (26%) compared to the general hypertensive population (8%),and anticoagulation with INR$\geq$3 was associated with initial reduction of chronic kidney disease (CKD) and hypertension.
**Objectives:** To characterise the long-term outcomes and associations with anticoagulant treatment for patients with renal artery stenosis and antiphospholipid syndrome.
**Methods:** We identified 37 patients with RAS and APS fulfilling Sapporo criteria [4]: anticardiolipin IgG/IgM titer$>$40 units or $>$99th percentile (or +lupus anticoagulant) on $\geq$2 occasions $\geq$6 weeks apart AND vascular thrombosis (or pregnancy morbidity). RAS was diagnosed by magnetic resonance angiography (MRA).
**Results:** 15 patients had APS alone and 22 APS associated with autoimmune conditions (13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37 (83.8%) were female and median follow-up was 10.4 years. 25/37 (67.6%) had previous thrombosis. 7/37 (18.9%) had bilateral RAS, 3 artery occlusion. 6/37 (16.2%) had concurrent coeliac stenosis. Recanalization of RAS occurred after hydroxychloroquine in 3/37 and 9/37 (24.3%) underwent angioplasty +/– stenting. MRA was repeated in 11/37 (29.7%) after 2 years. 23/37 (62.2%) were anticoagulated, with 9/37 (24.3%) on antiplatelet therapy. 13/37 (35.1%) received hydroxychloroquine, 10/22 (45.5%) immunosuppressives and 18/37 (48.6%) antihypertensives. 9/37 (24.3%) died after a median of 10 years since RAS diagnosis. 21/37 (56.8%) developed CKD: 6 endstage renal failure (ESRD) and 15 with median eGFR 39 mls/min.

| Patient group | CKD (eGFR$<$60 mls/min) | ESRD | Death |
|---|---|---|---|
| Anticoagulant therapy (23) | 15/23 | 4/23 | 5/23 |
| No anticoagulation (14) | 6/14 | 2/14 | 4/14 |
| p value | 0.3 | 1.0 | 0.7 |
| APS alone (15) | 7/15 | 3/15 | 1/15 |
| APS+ autoimmune disease (22) | 14/22 | 3/22 | 5/22 |
| p value | 0.3 | 0.7 | 0.4 |
| Medical therapy (28) | 13/28 | 3/28 | 7/28 |
| Renal angioplasty (9) | 8/9 | 3/9 | 2/9 |
| P value | 0.05 | 0.14 | 1 |

**Conclusions:** The majority of patients with RAS and APS were female, developed CKD and did not benefit from renal angioplasty. Anticoagulation was not associated with longterm reduction of ESRD or death, suggesting a non-thrombotic pathogenic process underlying RAS, such as intimal hyperplasia. Treatment of associated vascular risk factors and autoimmune disease is paramount. Anticardiolipin antibodies and renal MRA are useful screening tests for lupus patients with difficult blood pressure control.

### THU0284 DYNAMICS OF B LYMPHOCYTE SUBSETS IN SLE PATIENTS TREATED WITH RITUXIMAB

A.A. Mesnyankina, E.N. Aleksandrova, S.K. Soloviev, A.P. Aleksankin, S.I. Glukhova, A.A. Novikov, E.V. Suponitskaya, E.A. Aseeva, E.L. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Objectives:** to study B-cell subsets dynamics in SLE patients receiving rituximab (RTX) therapy with following 6 months observation.
**Methods:** The study included 16 SLE pts (1m/15f) with high (SLEDAI2K$>$10 - 13 pts.) and moderate (SLEDAI2K$<$10- 3 pts.) disease activity. Out of them 7 pts with lupus nephritis and 3 pts with neurolupus. RTX was administered to pts who failed to respond to glucocorticoids (GCs) and cytostatics (CTs). B-cells subsets were assessed before RTX administration (month 0), and at month 3 and month 6 of RTX therapy. RTX was administered at 500 to 2000 mg doses depending on disease activity. We investigated the absolute and relative number of CD19+ B cells, the total population of memory B cells (CD19+CD27+), "preswitch" (CD19+IgD+CD27+) and "postswitch" (CD19+IgD-CD27+) memory B cells, naive (CD19+IgD+CD27-) and transitional (CD19+IgD+CD10+CD38++CD27-) B cells, plasmablasts (CD19+CD38+++IgD-CD27+CD20-), short-lived plasma cells (CD19+CD38+), long-lived plasma cells (CD19+CD138+), and double-negative B-cells (CD19+CD27-IgD) were measured. All B cell subsets were analyzed by technique of multicolor flow cytofluorometry using panel of monoclonal antibodies to surface membrane markers of B-lymphocytes.
**Results:** Following initiation of RTX SLE clinical and lab activity indices have decreased in all 16 pts by month 3 and month 6 of follow up (SLEDAI-2K 0 month –Me 15 [11;19], 3 month -Me 7 [3;10], 6 month –Me 5 [4;9], $p$$<$0.05), as well as decrease of absolute count CD19 B-cell subpopulation (0 month – Me 0,11 [0,0741; 0,2], 3 month - Me 0,0017 [0; 0,003], 6 month - Me 0,0045 [0,0005; 0,01], $p$$<$0.05). B-cell repopulation by 6 month in 11 out of 16 pts was due to "naive" B-cells Me 0,00085 [0; 0,008], double negative Me 0,001 [0; 0,0025] and "postswitch" memory B-cells Me 0,0013 [0,0001; 0,003]. SLE exacerbation by 6 month was documented in 5 pts, in 3 out of them B-cell repopulation occurred. A correlation between baseline high SLE activity before RTX infusions (SLEDAI-2K 5 pts – Me 20 [18;24], 11 pts. Me 12 [8;12]) and SLE exacerbation at 6 month after initiation of RTM therapy ($p$$<$0,05, r=0,54) was found.
**Conclusions:** Decrease in clinical and lab SLE activity was documented in all 16 pts by 3 month after one course of RTM therapy. In 3 out of 5 exacerbated pts at 6 month B-cell repopulation was found, but without significant correlation with counts of B-cells subpopulations during the whole follow up period.

## THU0285 DALAZATIDE, AN INHIBITOR OF THE KV1.3 CHANNEL ON ACTIVATED EFFECTOR MEMORY T CELLS, HAS IMMUNOTHERAPY POTENTIAL IN SYSTEMIC LUPUS ERYTHEMATOSUS

A.M. Stevens[1,2], M. Yuasa[2], D. Peckham[3], C. Olsen[4], S.P. Iadonato[3], P. Probst[3]. *[1]Pediatrics, University of Washington; [2]Center for Immunity and Immunotherapies, Seattle Children's Research Institute; [3]Kineta, Inc; [4]KPI Therapeutics, Inc., Seattle, United States*

**Background:** T cell activation depends upon a calcium signaling cascade that is regulated by voltage-gated potassium channels. Effector memory T cells ($T_{EM}$), which are implicated in the immunopathogenesis of a panel of autoimmune diseases, express the potassium channel Kv1.3. Dalazatide is a potent peptide inhibitor of the Kv1.3 channel that has recently shown efficacy in a Phase 1b plaque psoriasis trial. Evidence suggests that inflammatory cytokine producing $T_{EM}$ cells might be involved in the immunopathology of lupus nephritis.
**Objectives:** Provide proof-of-principle *ex vivo* data for therapeutically targeting chronic T cell activation in systemic lupus erythematosus (SLE) by using dalazatide to block the Kv1.3 channel and to evaluate the effect of dalazatide on the *in vitro* inflammatory cytokine production of $T_{EM}$ cells from SLE patients.
**Methods:** Peripheral blood mononuclear cells from pediatric and adult SLE patients as well as healthy controls were studied. T lymphocyte subsets were assayed *ex vivo* for Kv1.3 expression by flow cytometry. The effect of dalazatide on phorbol myristate acetate (PMA)/ionomycin-induced inflammatory cytokine expression by $T_{EM}$ cells was evaluated by intracellular cytokine staining.
**Results:** Kv1.3 expression by $CD8^+$ $T_{EM}$ cells was significantly higher in patients with active lupus nephritis when compared to patients with inactive SLE or healthy controls. Dalazatide inhibited IFN-$\gamma$, IL-17 and TNF-$\alpha$ production by both $CD4^+$ and $CD8^+$ $T_{EM}$ cells from SLE patients in a dose-dependent manner. Higher levels of dalazatide-mediated inhibition were observed in IFN-$\gamma$ and TNF-$\alpha$-expressing $CD4^+$ $T_{EM}$ cells from patients with active SLE when compared to samples from SLE patients with inactive disease.
**Conclusions:** *Ex vivo* studies suggest that dalazatide inhibition of Kv1.3 may be a therapeutic target for SLE. In addition, Kv1.3 expression may be a useful biomarker of disease activity in SLE.

## THU0286 THE EFFICACY AND THE LONG-TERM PROGNOSIS OF RITUXIMAB FOR REFRACTORY THROMBOTIC MICROANGIOPATHY ASSOCIATED WITH CONNECTIVE TISSUE DISEASES

A. Kondo, H. Dobashi, Y. Takeuchi, T. Kameda, M. Izumikawa, S. Nakashima, H. Ozaki, R. Wakiya, N. Kadowaki. *Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan*

**Background:** Recently, it has been described in many reports that B cell has important roles in connective tissue disease (CTD). Rituximab (RTX), anti-CD20 monoclonal antibody is widely known as effective for patients with several autoimmune hematological disorders including thrombotic microangiopathy (TMA) through not only B cell depletion but reducing antigen-presenting cell function, complement hyperactivation, release of inflammatory cytokines and abnormal auto-reactive T cell response through co-stimulatory signals.[1)] TMA is developed in CTD occasionally. CTD-TMA especially with normal activity of von Willebrand factor cleaving protease, a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member-13 (ADAMTS-13) is often resistant for plasma exchange (PE) conducted for thrombotic thrombocytopenic purpura with ADAMTS-13 inhibitor and lack of ADAMTS-13 activity as a first-line treatment.[2)] It has been reported that the autoantibodies other than ADAMTS-13 inhibitor, complement hyperactivation, and excessive inflammatory cytokines production associated with refractory TMA.[3)]
**Objectives:** We investigate the efficacy and the long-term prognosis of RTX treatment for refractory TMA associated with CTD.
**Methods:** We enrolled 7 CTD-TMA patients (SLE; 3, SS; 2, MCTD; 1, DM; 1) with refractory to PE treatment between 2006 and 2015. We examined the ADAMTS-13 activity, its inhibitor and ultra-large von Willebrand factor multimers (UL-VWFMs) at TMA onset. RTX was given 375mg/$m^2$ per a dose. We defined complete response (CR) as platelet counts $>150\times10^9$/l for more than 3 consecutive days, with normal levels of serum LDH and an absence of TMA-related symptoms. We considered CR continued more than 30 days after RTX treatment as remission. In addition, we investigated as follow subjects; duration from initial RTX treatment to CR, duration of sustained CR, relapse and adverse events.
**Results:** No abnormality of ADAMTS-13 activity was observed 6 patients. The thrombocytopenia was improved immediately within 2–3 weeks after the initiation of RTX and hemolytic anemia and neuropsychiatric manifestations were improved following after the recovery of thrombocytopenia, respectively. 6 patients could achieve CR. They who achieved CR all have sustained long-term remission by only 1 or 2 doses of RTX administration and there was no relapse. RTX was partial response for 1 patient with insufficient recovery of thrombocytopenia but detectable serum haptoglobin and she was reported with controllable bacterial pneumonia.
**Conclusions:** We suggest that RTX treatment has efficacy with high response rate and long-term remission for the refractory CTD-TMA patients. Moreover, RTX treatment can be the first-line treatment for CTD-TMA.

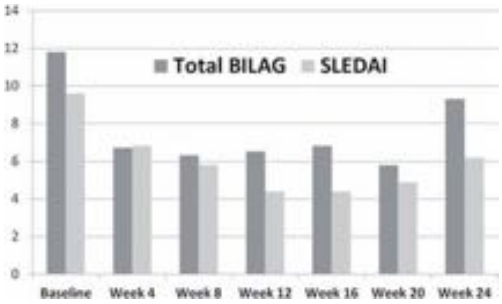
## THU0287 GLUCOCORTICOIDS WITHDRAWAL IN SYSTEMIC LUPUS ERYTHEMATOSUS: MYTH O REALITY?



C. Tani[1], L. Carli[1,2], R. Vagelli[1], V. Signorini[1], S. Vagnani[1], D. Totti[1], M. Tristano[1], M. Mosca[1]. *[1]Clinical and Experimental Medicine, university of Pisa, Pisa; [2]GenOMeC PhD, University of Siena, Italy*

**Background:** Glucocorticoids (GC) minimization is a pursued goal in the management of systemic lupus erythematosus (SLE) and is a target in patients (pts) management [1]. However, real-life data show that the vast majority of SLE pts are receiving long-term GC therapy despite being considered in clinical remission by their treating physician [2]. Few data are available on treatment discontinuation and tapering protocols in routine clinical practice.
**Objectives:** To analyze the clinical characteristics and the disease outcome of a group of GC free SLE pts
**Methods:** GC-free SLE pts were selected from the lupus clinic database; this is an electronic database where demographic, clinical and serological data, as well as therapies of patients referring to the clinic, are prospectively collected and regularly updated. Disease activity is defined by the clinician's judgement as well as by the SELENA-SLEDAI and the ECLAM scores, damage accrual is computed according to the SLICC-DI score.
**Results:** Out of 410 pts followed at the clinic, 210 had a regular follow-up (at least 3 yearly assessments) and were included in the study. Out of these,46 (21.9%) pts were GC free for at least 3 months and were included in the present analysis. Forty-one (89%)were female and the mean age at enrolment was 43.3±13; 16 pts had a history of lupus nephritis (35%). At the last visit, the median duration of GC withdrawal was 24 months (3–141 months) and 84% were GC free for at least 12 months. Thirty-eight pts (82.6%) were taking antimalarials,32 patients were also immunosuppressant free.At GC stopping, mean disease duration was 11.6±8 years (2 to 35), being less than 5 years in 17%; 21 patients (46%)were in clinical and serological remission, 23 (50%) had serological activity (low complement and/or anti-dsDNA), 2 (4%) had mild hematological abnormalities. Organ damage (SLICC$\geq$1) was present in 12 pts (26%). After GC withdrawal, disease flares were observed in 8 pts (17%): one severe flare (lupus nephritis onset),7 minor flares (3 articular, 2 cutaneous,2 hematological) requiring a short course of GC therapy. Additionally, shortly after GC stopping, fatigue was reported by 3 pts. Interestingly, only two pts (4.3%) accrued further damage during the follow-up (cancer and coronary artery disease) over a period of 60 and 72 and months respectively. No differences in patients' age, disease duration, disease activity or ongoing therapies at GC stopping were observed between pts who flared *vs* those without flares. Additionally, serological activity at GC withdrawal was not associated with an increased risk of disease flare.
**Conclusions:** In our cohort GC withdrawal was successfully attempted in 20% of cases. A severe flare was observed in only one patient; interestingly, a very low damage accrual was recorded. No clinical or serological variables predictive of disease flare after GC stopping were identified. Our data support that GC withdrawal is an achievable goal in SLE patients in routine clinical practice and represent a feasible target in the disease management.

## THU0288 IMMU-115 (HUMANIZED ANTI-CD74 ANTIBODY) FOR SUBCUTANEOUS (SC) ADMINISTRATION: A PHASE IB STUDY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

D.J. Wallace[1], M.H. Weisman[1], W.A. Wegener[2], H. Horne[2], D.M. Goldenberg[2]. [1]*Cedars-Sinai Medical Center, Los Angeles, CA;* [2]*Immunomedics, Inc., Morris Plains, NJ, United States*

**Background:** IMMU-115 (milatuzumab), a humanized antibody targeting the CD74 antigen present on antigen-presenting cells (APC), is being studied in hematological malignancies, but dysregulation of APCs may also occur in nonmalignant disorders. IMMU-115 could thus potentially help control underlying immune responses responsible for autoimmunity.
**Objectives:** To evaluate a weekly dosing regimen of SC IMMU-115 in patients with SLE and moderately active disease.
**Methods:** Phase I, open-label study of adults with SLE (ACR Revised Criteria) and positive ANA (titer $\geq$1:80) who have moderate disease activity but not severe flares (at least 2 BILAG B's, but no A's) despite standard SLE medications incuding at least 5 mg/day prednisone. Patients continued background lupus medications and received SC IMMU-115 administered for 4 consecutive weeks, with disease activity assessed by BILAG2004 and SELENA-SLEDAI every 4 weeks until week 24.
**Results:** Ten patients (9F/1M; median age, 37; median 7 years from diagnosis) have now received 250 mg SC IMMU-115 injections once-weekly for 4 weeks. They were on prednisone (5–20 mg/day, n=10), antimalarials (n=7), and immunosupressives (n=2) with mean SLEDAI 9.6 and BILAG-B activity in the musculoskeletal (n=10), mucocutaneous (n=9), cardiorespiratory (n=1), and renal (n=1) body systems. All patients showed improvement in at least one body system, having eliminated most muscoloskeletal B's (9/10, 90%) and mucocutaneous B's (7/9, 78%) by week 8, with the single cardiorespiratory B eliminated by week 20, and the renal B vacillating between B and C over the study. Four patients developed new B-level disease after treatment at weeks 8, 12 and 20 (all cardiorespiratory) and week 24 (neuropsychiatric). Overall, mean total BILAG (scored using B=5, C=1, D/E=0) decreased 43% with treatment, while mean SLEDAI decreased 54%, with both measures still decreased at week 24 (see Figure). Nine patients had adverse events, all Grade 1–2 (mild-moderate) and predominantly injection site (N=7) or constitutional/flu-like (N=9) reactions managed with supportive medication (steroids, antihistamines, anti-pyretics). Routine safety and other laboratories (B and T cells, monocytes, dendritic cells, serum immunoglobulins, cytokines, ANA and other autoantibodies, CRP, C3) were unremarkable. One patient developed anti-IMMU-115 antibodies (HAHA) of uncertain clinical significance, resolving within 3 months. IMMU-115 serum levels with the current assay were not detectable ($<$0.5 $\mu$g/mL).

**Conclusions:** SC IMMU-115 appeared safe with manageable toxicity in the first cohort of patients with SLE and moderately active disease, all of whom received 250 mg doses given weekly for 4 weeks. Already at this first planned dose level there was evidence of treatment efficacy with suppression of initial disease activity extending 24 weeks in most patients. As such, patients are currently being randomized in a double-blinded placebo-controlled expansion phase in order to confirm the activity of SC IMMU-115 in this population.

## THU0289 LONG TERM USE OF HYDROXYCHLOROQUINE IN PATIENTS WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME: A RETROSPECTIVE COHORT STUDY

E. Nuri[1], M. Taraborelli[2], L. Andreoli[1], M. Gerosa[3], L.M. Argolini[3], P.L. Meroni[3,4], A. Tincani[1]. [1]*Rheumatology, University of Brescia and Spedali Civili of Brescia;* [2]*Rheumatology, Spedali Civili of Brescia, Brescia;* [3]*Rheumatology, Ospedale Gaetano Pini and University of Milan;* [4]*Laboratory of Immuno-Rheumatology, Istituto Auxologico Italiano, Milan, Italy*

**Background:** A potential role of hydroxychloroquine (HCQ) use in patients with antiphospholipid antibodies (aPL) has been suggested by some retrospective cohorts and in animal models based on its potential beneficial effects on autoantibody effect and titer, endothelial function and glucose or lipid metabolism [1–3].
**Objectives:** To evaluate the impact of HCQ on aPL titers, on glucose and cholesterol levels and its role in the prevention of thrombotic recurrences in Primary Antiphospholipid Syndrome (PAPS).
**Methods:** Patients with PAPS, diagnosed according to 2006 Classification Criteria without any Connective Tissue Disease, that received HCQ (HCQ+) but no immunosuppressive drugs, were matched with similar patients that did not received HCQ (HCQ-) according to the following characteristics: same gender, follow-up duration, disease onset, age at the beginning of the follow-up ±10 years and initial date of the follow-up ± 5 years.
**Results:** Seventy-two patients (36 HCQ+ and 36 HCQ-) with a mean follow-up of 77 (±SD 49) months between 1992 and 2015 were studied. No significant variations in demographical, clinical, serological features were observed between the two groups except for of anti-extractable nuclear antigen antibodies (19% in HCQ+ versus 0% in HCQ-,p:0.014). Anti-β2Glycoprotein I IgG titers were significantly lower in HCQ+ than in HCQ- patients at the end of the follow-up (Student t,p:0.018). The variations of all the aPL titers in the two groups are shown in Figure 1. No differences in glucose and cholesterol levels were detected. Eight percent of HCQ+ and 17% of HCQ- patients experienced a thrombosis during the follow-up. Among patients with a history of thrombosis the annual incidence of recurrences was lower (0,87%) in HCQ+ patients than in HCQ- (2,17%).

Table 1. Prevalence of medium-high titer antiphospholipid antibodies over follow-up

| Antiphospholipid antibodies medium-high titers | Variation between beginning and end of follow-up in HCQ+ (%) | Variation between beginning and end of follow-up in HCQ– (%) |
|---|---|---|
| Anticardiolipin IgG | –25% | –4% |
| Anticardiolipin IgM | –0% | +11% |
| Anti-β2 Glycoprotein IgG* | –30% | –7% |
| Anti-β2 Glycoprotein IgM | –28% | –6% |

*Statistically significant (p=0.04).

**Conclusions:** This study showed a strong reduction of aPL titers and of the incidence of recurrences in patients treated with HCQ, supporting a possible role of this drug in the treatment of patients with PAPS.

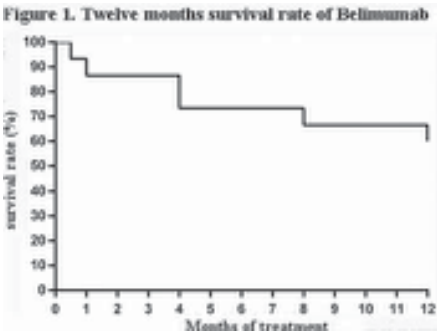
## THU0290 TWELVE MONTHS SURVIVAL RATE AND CAUSES OF WITHDRAWAL OF BELIMUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS IN A REAL LIFE SETTING

F.R. Spinelli, F. Ceccarelli, F. Morello, L. Massaro, C. Alessandri, G. Valesini, F. Conti. *Dipartimento di Medcina Interna e Specialità Mediche - Reumatologia, Sapienza Università di Roma, Rome, Italy*



**Background:** Systemic Lupus Erythematosus (SLE) is a chronic disease requiring long-term treatment. Even though immunosuppresive therapy has significantly improved the survival, a great percentage of SLE patients exhibit a persistently active disease or deal with disease flares during the follow-up. Belimumab (BLM), an anti-*B Lymphocyte Stimulator* (BLyS), is currently the only biological drug approved for the treatment of active SLE patients not responding to standard of care, without active kidney or neuropsychiatric involvement.
**Objectives:** Aim of the study was to analyse 12 months survival of BLM treatment and causes of withdrawal in a monocentric cohort of SLE patients followed-up in a daily practice setting.
**Methods:** The study was proposed to all the patients who were due to start BLM. After the informed consent was obtained, demographic, clinical and serological data, indication to BLM and concomitant therapies were registered. At baseline and after 3, 6 and 12 months of follow-up, disease activity (SLE Disease Activity Index – SLADAI 2K), C3 and C4 levels, anti-dsDNA status and weekly dose of glucocorticoids were recorded. At each visit adverse events and causes of withdrawal were also evaluated. Data were expressed as mean±standard deviation; after 3, 6 and 12 months, difference in SLEDAI 2K, C3 and C4 and prednisone-equivalent dose compared to baseline were evaluated by Student t test. The treatment survival was evaluated by Kaplan-Meier analysis. P value $<$0.05 were considered significant.
**Results:** We enrolled to the study 15 Caucasian females with mean age of 41.3±10.1 years and mean disease duration of 19.2±9.2 years. Indication for starting BLM were: mucocutaneous involvement (n=5, 33.3%), arthritis (n=10, 66.7%) and lung involvement (1 patient, 6.7%). At baseline, all the patients were taking prednisone; 88.7% hydroxychloroquine, 33.3% mycophenolate mofetil, 20% azathioprine, 20% cyclosporine, 20% methotrexate and 6.7% thalidomide.

Table 1 summarizes the trend of SLEDAI 2K, C3 and C4, prednisone dose and percentage of patients positive for anti-dsDNA during the follow-up.
The Kaplan-Meier (Figure 1) shows a 12 months survival rate of 60%. In 13.3% of patients adverse events were the cause of BLM withdrawal (severe infection in one patient and acute infusion reaction in another one). In 2 patients (13.3%) BLM was discontinued for lack of efficacy on articular and skin manifestations, after 4 and 8 months respectively; one patient developed a severe neuropsychiatric flare after the second BLM infusion and was admitted in our hospital for depression and suicidal thoughts. The other patient was lost during the follow-up.

Table 1. SLEDAI 2K, C3 and C4, prednisone dose and anti-dsDNA status during the follow-up

| | T0 | T3 | T6 | T12 |
|---|---|---|---|---|
| N° of patients | 15 | 13 | 11 | 9 |
| PDN mg/sett[#] | 80.7±39.2 | 51±17.2* | 45±18,5* | 30.9±26.1* |
| SLEDAI 2K[#] | 7±2.8 | 5.9±2.7 | 5.6±2.7 | 3.7±3.1** |
| C3[#] | 71.7±18.5 | 71.2±16.8 | 70.9±12.1 | 73.3±18.3 |
| C4[#] | 16.4±6.6 | 12.4±5.8 | 9.9±4.3 | 12.3±8.5 |
| aDNA+ (%) | 100 | 41.6** | 30** | 28.5** |

[#] mean ± standard deviation; *p<0.05; **p<0.005.

**Conclusions:** In our monocentric cohort of SLE patients treated in a real life setting, the main causes of BLM withdrawal were the lack of efficacy or disease flare.

## THU0291 ENDOTHELIAL PROGENITOR CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS: EFFECT OF B LYMPHOCYTE STIMULATOR AND ITS INHIBITION

F.R. Spinelli, C. Barbati, L. Massaro, F. Ceccarelli, F. Miranda, S. Truglia, C. Alessandri, F. Conti, G. Valesini. *Dipartimento di Medicina Interna e Specialità Mediche - Reumatologia, Sapienza Università di Roma, Rome, Italy*

**Background:** Cardiovascualar disease is the main comorbidity in Systemic Lupus Erythematosus (SLE). Circulating endothelial progenitor cells (EPCs) are bone marrow-derived cells, able to differentiate into mature endothelial cells. Several studies demonstrated a reduction and functional impairment of EPCs in SLE patients, contributing to the endothelial dysfunction characterizing these patients. Belimumab (BLM), a human monoclonal antibody anti-B Lymphocyte Stimulator (BLyS) is the first biological drug approved for the treatment of SLE patients. In murine models of atherosclerosis, treatment with a BLyS inhibitor slowed the progression and reduced the size of atherosclerotic plaque.
**Objectives:** to evaluate the effect of BLyS inhibition on EPCs both *ex vivo* – in SLE patients receiving BLM– and *in vitro*.
**Methods:** We enrolled consecutive patients with SLE diagnosed according to 1997 ACR criteria. Patients with known cardiovascular disease were excluded. As control, we studied age and sex-matched healthy subjects. SLE disease activity was evaluated by SLEDAI 2K at baseline and after 4 and 12 weeks of BLM; blood samples were collected at the same time-point. Peripheral blood mononuclear cells (PBMC) isolated by Ficoll density-gradient centrifugation were incubated with fluorescein isothiocyanate-labeled anti-CD34 monoclonal antibodies and phycoerythrin-labeled anti VEGF-R2/KDR; acquisition was performed by flow cytometry: EPCs were defined as CD34/KDR double-positive cells. For *in vitro* studies, recovered cells isolated from healthy donors' PBMC were plated on dishes coated with human fibronectin. Apoptosis was investigated after 6, 12, 24 and 48 hours of incubation with BLyS at different concentration – 5, 20 and 100 ng/ml – and re-evaluated after 6 hours of co-incubation with BLM at 173 and 300 μg/ml. Kolmogorov-Smirnov showed the normal distribution of EPCs; data were expressed as mean±standard deviation. To test the hypothesis that BLM may increase EPCs number we used one-tailed T-test. A p value <0.05 was considered statistically significant.
**Results:** We enrolled 18 female patients (mean age 41.3±10.1 yrs, mean disease duration 19.2±9.2 yrs). Number of EPCs was significantly lower in SLE patients compared to NHS (p<0.0001). Of the 18 patients, 10 (mean age 44.9±9.6 yrs, mean disease duration 15.6±10.0 yrs) started BLM for refractory disease (mean baseline SLEDAI 2K 7.1±3.1). After 4 and 12 weeks, SLEDAI 2K tended to decrease (p=ns). Baseline EPC number was significantly lower compared to NHS (p=0.002). After 4 weeks, mean EPC number increased to 0.026±0.015 (p=0.038 vs baseline; p=n.s. vs NHS). At week 12 we observed a slight decrease of EPC number compared to week 4 (0.021±0.015 p=ns).
*In vitro* studies demonstrated that 20 ng/ml of BLyS induced apoptosis of EPC after 6 hours of incubation; this effect was reverted by the addiction of 173 and 300 μg/ml of BLM. BLM alone did not induce apoptosis of EPC.
**Conclusions:** This study confirms a reduction of EPCs number in SLE patients compared to NHS. Treatment with BLM significantly increased EPCs number. *In vitro* data suggest a direct role of BLM by demonstrating a pro-apoptotic effect of BLyS that was reverted by the addition of the human anti-BLyS in EPCs culture. These results furhter support a contribution of BLyS and B cells in the promotion of atherosclerosis.

## THU0292 C-PEPTIDE AND MODIFIED HOMA-INDEX IN DIFFERENT CARBOHYDRATE METABOLISM DISTURBANCES DURING GLUCOCORTICOID THERAPY

G. Nurullina, F. Valeeva. *Kazan Medical State University, Kazan, Russian Federation*

**Background:** Glucocorticoid administration can lead to profound metabolic side-effects, including peripheral insulin resistance (IR), impaired glucose tolerance (IGT) and hyperglycemia and diabetes mellitus (DM). Homeostatic model (HOMA) is a validated method of IR evaluation.
**Objectives:** To evaluate the role of C-peptide and modified HOMA-index in different carbohydrate metabolism disturbances (CMD) during glucocorticoid therapy.
**Methods:** 165 patients were included: 53 patients with systemic lupus erythematosus (LE), 35 - with systemic vasculitis (SV); 67 - with chronic glomerulonephritis (CGN). 98 patients received glucocorticoid pulse-therapy (GC-PT) (1 course of 3 sessions) and 67 received oral GC. All patients underwent standard clinical and laboratory tests, glucose tolerance test (GTT), C-peptide evaluation, also HOMA-IR was calculated.
**Results:** Oral GCT group revealed increased prevalence of CMD and DM – in 21 (31.1%) and 19 (28.4%) patients, respectively, compared to GC-PT group (p=0.038 and p=0.049, respectively). All patients receiving GC-PT (both with CMD and normoglycemia) demonstrated significant increase of C-peptide level and HOMA-IR index on during maximal blood glucose level, that is 4–6 hours after GC-PT (p<0.05). In patients with CMD HOMA-IR index normalization was insignificant; there were significant differences between the evaluated parameters before and after GC-PT, which indicates a more pronounced IR in these patients. C-peptide level in patients with DM, which developed after GC-PT, was significantly elevated compared to patients without CMD both at baseline (1050 vs. 410 pmol/l, respectively) and after GC-PT course (1796 vs. 1152 pmol/l, respectively) (p<0.05). During maximal blood glucose levels C-peptide was significantly elevated in patients with CMD, compared to patients without CMD (3170 vs. 2430 pmol/l; p<0.05), which substantiates the development of severe IR in patients with CMD and DM. HOMA-IR index in patients with DM was significantly elevated compared to patients without CMD at baseline (5.04 vs. 2.2; p<0.05), during maximal blood glucose level (15.2 vs. 5.84; p<0.05) and after GC-PT course (10.4 vs. 4; p<0.05) and in patients with IGT compared to patients without CMD – during maximal blood glucose levels (17.47 vs. 5.84; p<0.05) and after GC-PT course (9.67 vs. 4; p<0.05). C-peptide level was significantly elevated in patients receiving oral GC therapy and demonstrating impaired fasting glucose, IGT and DM compared to patients without CMD both at baseline (681.2, 877.9, 1106.1 vs. 384.7 pmol/l; p<0.05) and after OGTT (1411, 3296.7, 4981.7 vs. 839.2 pmol/l; p<0.05). C-peptide elevation after oral GTT was accompanied by a significant increase in HOMA-IR index compared to control group in patients with impaired fasting glucose, IGT and DM (6.37 vs. 9.04, 16.21, 19.84; p<0.05).
**Conclusions:** CMD is more prevalent after oral GC therapy compared to GC-PT. In both groups C-peptide levels and HOMA-IR index were elevated in patients with IGT and DM both at baseline and after oral GTT, compared to patients without CMD and fasting glucose impairment, which proposes a presence of IR in that group of patients. HOMA-IR index can be utilized for the prognosis and early diagnostics of profound CMD in patients receiving intensive GC therapy and prolonged oral GC therapy.

## THU0293 SAFETY, PHARMACOKINETICS, ENZYME ACTIVITY, AND IMMUNOGENICITY OF RSLV-132, A NOVEL RNASE FUSION PROTEIN DEVELOPED TO REDUCE RNA-CONTAINING IMMUNE COMPLEXES IN SYSTEMIC LUPUS ERYTHEMATOSUS

D. Burge[1], J. Doedens[1], J. Eisenman[1], K. Elkon[2], C. Gabel[1], J. Posada[1]. *[1]Resolve Therapeutics; [2]Rheumatology, University of Washington, Seattle, United States*

**Background:** RNA-associated with immune complexes (ICs) is recognized to

play a central role in driving interferon production and systemic inflammation in systemic lupus erythematosus (SLE). To date, therapeutic strategies which have sought to block interferon directly or to target various B-cell regulatory proteins have met with mixed success. Given the proximal point of nucleic acid-containing ICs in the inflammatory cascade, reduction in associated RNA is expected to render the ICs less pathogenic. RSLV-132 is a fully-human Fc fusion protein consisting of the Fc domain of IgG1 fused to human RNase 1 that is designed to enzymatically digest RNA-containing ICs.

**Objectives:** This multiple ascending dose study of RSLV-132 in SLE patients was carried out to assess the safety, pharmacokinetics (PK), serum enzyme activity, and immunogenicity of this novel biologic in SLE.

**Methods:** A phase 1b, multicenter, randomized, double-blind, placebo-controlled study evaluated 4 dose cohorts (0.3 – 10.0 mg/kg) administered by intravenous infusion. Each cohort consisted of 8 subjects (6 received RSLV-132 and 2 received placebo). Three to five doses were given over 29 days. Serum samples were collected and analyzed for PK analysis, anti-drug antibody (ADA) assessment, autoantibody profiles, and RNase catalytic activity assessment.

**Results:** A total of 61 adverse events (AEs) were recorded in the 32 subjects during the study. One grade 3 event (cholecystitis; unrelated) occurred in a subject in the 0.3 mg/kg group There were no deaths in the study. The PK analysis demonstrated a linear increase in serum RSLV-132 concentration with a terminal half-life of approximately 19 days. None of the subjects in the study were positive for ADA. RNase catalytic activity increased in a proportional manner up to approximately 100 ug/ml at $C_{max}$ in the 10 mg/kg dose cohort, and very closely paralleled the drug concentration curve detected by ELISA. SLEDAI scores were recorded during the study and of the evaluable subjects (SLEDAI $>0$) a greater proportion of RSLV-132-treated subjects (44%) saw a reduction in SLEDAI scores than in the placebo group (33%). Given the small size of the study this trend will need to be confirmed in larger studies.

**Conclusions:** RSLV-132 is a promising, novel biologic for the treatment of SLE. An excellent safety profile was observed in the current study. The PK profile showed good dose-proportionality and the observed half-life will support bi-weekly dosing going forward. High serum RNase activities were achieved and sustained over the entire course of the study with no evidence of an ADA response. The results of this study support continued development of RSLV-132 in SLE.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.2744

## THU0294 AN INTERNATIONAL CONSENSUS EXERCISE TO CLASSIFY SLE DAMAGE ITEMS ACCORDING TO THEIR LIKELY ASSOCIATION WITH STEROIDS

J. Little, M. Lunt, B. Parker, I.N. Bruce on behalf of the Systemic Lupus International Collaborating Clinics (SLICC). *Centre for Musculoskeletal Research, Institute of Inflammation and Repair, University of Manchester, Manchester, United Kingdom*

**Background:** Corticosteroids (CS) have been identified as a key factor associated with long term damage in systemic lupus erythematosus (SLE). The Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index (SDI) has been extensively validated and a previous analysis (Gladman et al J Rheumatol 2003;30:1955–9) suggested that SDI items can be grouped according to their likely association with CS.

**Objectives:** To generate international expert consensus opinion on which SDI items have an association with the use of CS.

**Methods:** We performed a Delphi exercise amongst SLICC members and associates. A survey requested expert opinions on how each SDI item was influenced by CS use on a Likert scale. The scale ranged from -3 to +3 where -3 = I believe that CS have a strong protective link with this item, 0 = I believe that CS have no effect on this item, +3 = I believe that CS have a strong causal link with this item. A second Delphi round presented each participant with their previous rating and the group median for that item, providing the opportunity for revision. A preliminary univariate analysis of CS exposure against damage was performed within the SLICC Inception Cohort to assess the appropriateness of these groupings and if any other items needed reclassifying.

**Results:** Of 43 members/associates, 36 respondents returned 26 complete forms (60.5%). All 26 completed the second round (100%) after which adequate consensus was reached. Four items (cataract, osteoporosis, avascular necrosis and diabetes mellitus) were assessed to be highly likely to be related to CS (median & mode =3, Table 1). Ten other items were "probably"/"possibly" CS related by expert opinion. The remaining items were felt not to be associated with CS. The univariate analysis supported these groupings and identified a significant association between CS exposure and the muscle atrophy/weakness item (e.g. OR (95% CI) 6.81 (1.91–24.27) if on steroids for all of intervening follow up period c.f. some or none of the period). It was agreed that muscle atrophy/weakness should be reclassified into the 'definite association' group.

**Conclusions:** A consensus exercise based on expert opinion and initial analysis in an international inception cohort has generated a preliminary classification of the 42 SDI items according to their likely association with CS. This classification system requires further validation but will facilitate studies examining the impact of CS exposure on SLE populations.

**Acknowledgement:** The Systemic Lupus International Collaborating Clinics (SLICC) acknowledge funding support of UCB Pharma for this study.

Table 1. Groupings of SLICC/ACR Damage Items (SDI) according to likely association with the use of CS (highly likely, probable and possible causative role groups shown only)

| CS have a causative association the SDI item | SDI item | Likert scale rating | |
|---|---|---|---|
| | | Median (range) | Mode (%) |
| Definite | Cataract | 3 (2,3) | 3 (69.23) |
| | Osteoporosis | 3 (2,3) | 3 (92.31) |
| | Avascular necrosis | 3 (2,3) | 3 (76.92) |
| | Diabetes | 3 (2,3) | 3 (76.92) |
| Definite (in final consensus) | Muscle atrophy or weakness | 2 (–2,3) | 2 (50.00) |
| Probable | Angina or coronary artery bypass | 2 (1,3) | 2 (46.15) |
| | Myocardial infarction | 2 (0,3) | 2 (50.00) |
| Possible | Cognitive impairment | 1 (–1,3) | 1 (42.31) |

## THU0295 ANIFROLUMAB REDUCES DISEASE ACTIVITY IN MULTIPLE ORGAN DOMAINS IN MODERATE TO SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

J.T. Merrill[1], R. Furie[2], V.P. Werth[3], M. Khamashta[4], J. Drappa[5], L. Wang[5], G. Illei[5]. *[1]Oklahoma Medical Research Foundation, Oklahoma City; [2]Northwell Health, Great Neck; [3]Philadelphia VA Medical Center and University of Pennsylvania, Philadelphia, United States; [4]Graham Hughes Lupus Research Laboratory Division of Women's Health, London, United Kingdom; [5]MedImmune, Gaithersburg, United States*

**Background:** As reported elsewhere, anifrolumab was evaluated in a Phase IIb study of SLE patients with moderate to severe disease activity, in which 305 patients received intravenous infusions of anifrolumab (300 mg, 1000 mg) or placebo every 4 weeks for 1 year. Both doses demonstrated increased rates of reduction in global disease activity, although a more favorable risk-benefit profile was observed with the 300-mg dose.

**Objectives:** To compare the impact of anifrolumab on individual organ domains in patients with moderate to severe SLE who participated in the Phase IIb study.

**Methods:** At Week 52, changes from baseline in organs domain activity were assessed using the British Isles Lupus Assessment Group (BILAG) and SLE Disease Activity Index 2000 (SLEDAI-2K). Improvement in a BILAG organ domain was defined as the transitioning from "A" or "B" to a lower score. Improvement in a SLEDAI domain required a lower score at Day 365 compared with baseline in at least one of its components.

**Results:** The majority of patients had baseline involvement of the mucocutaneous and/or musculoskeletal domains of SLEDAI-2K and BILAG. Compared with placebo, a greater percentage of patients in the anifrolumab-treated group improved in these frequently involved organs: [Mucocutaneous: SLEDAI-2K: placebo 38/100 (38.0%) vs. 300 mg 61/99 (61.6%; $p<0.001$) vs. 1000 mg 51/102 (50.0%; $p=0.082$); BILAG: 24/87 (27.6%) vs. 49/84 (58.3%; $p<0.001$) vs. 33/82 (40.2%; $p=0.069$); Musculoskeletal: SLEDAI-2K: 42/99 (42.4%) vs. 55/97 (56.7%; $p=0.032$) vs. 50/98 (51.0%; $p=0.197$); BILAG: 47/95 (49.5%) vs. 64/94 (68.1%; $p=0.005$) vs. 54/91 (59.3%; $p=0.149$)]. Trends suggesting potential benefits were observed in most of the other less frequently active domains including SLEDAI-2K cardiorespiratory, vascular, hematological, and constitutional, and BILAG cardiorespiratory and constitutional domains. Of those patients who had involvement in the SLEDAI-2K immunological domain at baseline [positive anti-double-stranded-DNA (anti-dsDNA) and/or low complement level], a greater number of patients in the anifrolumab groups [placebo: 4/53 (7.5%); 300 mg: 9/43 (20.9%; $p=0.068$); 1000 mg: 18/59 (30.5%; $p=0.004$)] had lower scores at Day 365, representing a normalization of anti-dsDNA and/or hypocomplementemia. However, among patients who had a normal anti-dsDNA and/or normal complements at baseline a slightly greater number of patients treated with 300 mg anifrolumab had an increase in the score representing the development of a new anti-dsDNA or hypocomplementemia compared with baseline [placebo: 7/79 (8.9%); 300 mg: 11/82 (13.4%), 1000 mg: 6/79 (7.6%)].

**Conclusions:** Anifrolumab treatment resulted in greater rates of improvement than placebo in multiple organs, with greatest impact seen with 300 mg anifrolumab.

## THU0296 LOW BM, LOW HDL CHOLESTEROL AND CURRENT STEROID DOSE MIGHT CONTRIBUTE TO SUBCLINICAL ATHEROSCLEROSIS IN SLE PATIENTS WITH LOW DISEASE ACTIVITY

J.-Y. Jung, H.-A. Kim, C.-H. Suh. *Rheumatology, Ajou University of Medical School, Suwon, Korea, Republic Of*

**Background:** Systemic lupus erythematosus (SLE) patients have increased risk of advanced atherosclerosis and cardiovascular disease. The mechanism of premature atherosclerosis in SLE is not completely understood, and systemic inflammation representing disease activity and traditional risk factors such as overweight and dyslipidemia have been regarded to contribute. Many SLE patients have low disease activity or sporadic occurrence of mild symptoms after a period of vigorous manifestations derived from autoimmune activation.
**Objectives:** Previously we evaluated subclinical atherosclerosis of SLE patients with mild disease activity by Doppler ultrasound 4 years ago[1]. This time we checked them again and assessed which features affects their changes.
**Methods:** We assessed carotid artery intima-media thickness (cIMT) and carotid plaque by Doppler ultrasonography among sixty-one female SLE patients who were enrolled in the previous work 4 years ago, and analyzed the changes with clinical characteristics.
**Results:** The SLE disease activity index of the participants was 4.2 ± 3.9, and 25(OH)$D_3$ level was elevated than previous study (25.7 ± 6.9 vs 12.7 ± 8.6 ng/mL, $p<0.001$), while other features were similar. The mean cIMT of SLE patients was 0.39 ± 0.09 mm and 11 patients had carotid plaques, which were not significantly different with previous study. Twenty one patients had the increased cIMT, while 35 patients had decreased cIMT. And new carotid plaque was developed in 7 SLE patients, while the carotid plaque of 10 SLE patients was resolved. The patients with increased cIMT had lower body mass index (BMI) (19.8 ± 1.8 vs 21.7 ± 3.1 kg/$m^2$, $p$=0.007), longer disease duration (102.0 ± 42.2 vs 74.8 ± 55.2 months, $p$=0.006) and higher total steroid dose (18.5 ± 21.6 vs 10.5 ± 22.9 g, $p<0.001$) compared with those not. The patients having new carotid plaque had lower high-density lipoprotein (HDL) cholesterol levels (41.6 ± 10.2 vs 55.6 ± 15.5 mg/dL, $p$=0.024) and were taking higher doses of current steroid (8.9±9.5 vs 3.6±4.5mg, $p$=0.008). On multiple regression analysis, BMI (0.62 [0.42–0.91], $p$=0.01) and HDL cholesterol (0.94 [0.89–1.0], $p$=0.02) were revealed to affect cIMT increment, and current steroid dose (1.14 [1.01–1.28], $p$=0.04) were revealed to affect plaque development.
**Conclusions:** BMI have been known to affect atherosclerosis and vitamin D deficiency has been known to associate with cardiovascular disease. In contrast of other studies, our data showed BMI contributed negatively cIMT increment. The result about BMI was regarded that very low BMI might have a harmful effect to atherosclerosis, considered that mean BMI was much lower (21.0 ± 2.8 kg/$m^2$) than other studies[2].The follow up study for SLE patients with low disease activity showed low BMI and HDL cholesterol might be a risk factor for subclinical atherosclerosis and current steroid dose could be associated with plaque development.

## THU0297 PHYSICAL ACTIVITY IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: EFFECTS ON FATIGUE AND DEPRESSIVE BEHAVIOR FOR IMPROVED QUALITY OF LIFE

L. Stojanovich, G. Bogdanovic, A. Djokovic. *Head of the Department for scientific research, University Hospital Center Bezanijska Kosa, Belgrade, Serbia*

**Background:** Because of the fact that systemic lupus erythematosus (SLE) causes joint and muscle pain, fatigue, depression, the very thought of exercising can be a challenge for patients. Although exercise can be beneficial and can significantly improve the quality of life.
**Objectives:** The aim of the study is to determine the form of physical activity in SLE patients that could improve their quality of life. Although exercise can be beneficial and can significantly improve the quality of life.
**Methods:** This prospective study included 60 patients diagnosed with SLE in stable condition. A randomly selected group of 30 women had aerobic training on a bicycle ergometer for a period of 15 minutes, 3 times per week for 6 weeks, while the second group of 30 women did exercise for 30 minutes, 3 times per week during the same period. FSS (fatigue Severity Scale), Short Form 36 (SF36) questionnaire on the quality of life and Beck depression inventory (BDI) were analyzed at baseline and after 6 weeks.
**Results:** Fatigue was present in all patients (FSS score 53.8 ± 5.7; min 39, max 63) before starting the exercise. Fatigue was present in 11 patients (18.3%) after the physical activity while 49 (81.7%) patients did not experience it (FSS score 29.1 ± 7.8; min 18, max 45). Before starting the exercise the largest number of patients, 40 (66.67%) of them, was in a moderate depressed state, while after physical activities the greatest number of patients, 37 (61.66%), had a mild mood disturbance. There are high statistical differences ($p<0.001$) in values of all areas of quality of life questionnaire SF36 before and after the implementation of physical activity. Comparing the different types of physical activities there were not any statistically significant differences ($p>0.05$) in values of FSS and BDI questionnaire. A statistically significant difference was observed in terms of reducing the parameters of pain, general health and mental health in a group that had a physical activity on a bicycle ergometer evaluated by the SF36 questionnaire ($p<0.05$).
**Conclusions:** Our study has shown that a continuous physical activity in SLE patients significantly improves their quality of life by reducing fatigue and depressive reactions without negative impacts on the activity of their disease. The type of physical activity was not relevant.

## THU0298 TYPE I INTERFERON PREDICTS BIOLOGICAL EFFECT OF BELIMUMAB ON RHEUMATOID FACTOR POSITIVE B-CELLS IN SJÖGREN'S SYNDROME: RESULTS FROM THE BELISS TRIAL

L. Quartuccio[1], C.P. Mavragani[2], A. Nezos[2], S. Gandolfo[1], A. Tzioufas[2], S. De Vita[1]. *[1]Department of Biological and Medical Sciences, Rheumatology Clinic, University Hospital of Udine, Udine, Italy; [2]Department of Physiology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece*

**Background:** B-lymphocyte Stimulator (BLyS, or BAFF), a survival factor for B cells, has been previously implicated in the pathogenesis of Sjögren's syndrome (SS) and SS related lymphoproliferation (1–2). It has been also previously shown to be induced by both type I and II Interferons (IFNs) also implicated in the pathogenesis of SS (3). Belimumab, an anti-BAFF monoclonal antibody that targets BAFF, was recently found to be effective and safe in SS in the phase II BELISS trial (4–5).
**Objectives:** To explore the possible effect of belimumab on IFN-induced peripheral blood gene expression in the phase II BELISS trial. Additionally, to evaluate whether baseline IFN signature could serve as a predictor of clinical and serological responses following belimumab treatment.
**Methods:** Twelve patients who were enrolled in the phase II BELISS trial were studied for peripheral blood IFN signature at baseline, at w28 (10/12), and at w52 (4/12). Patients were all females, median 47.5 yrs (35–79), all positive for anti-SSA/SSB and for rheumatoid factor (RF), with a median ESSDAI score of 7 (2–27) at BELISS study entry. Peripheral blood mononuclear cells from all study participants were subjected to Real-Time PCR for 3 interferon inducible genes (MX-1, IFIT-1, IFI44) preferentially induced by type I IFN and 2 interferon inducible genes preferentially induced by type II IFN (MIG-1, GBP1). Both type I and II IFN scores were determined, as previously described.
**Results:** No statistically significant changes were observed between baseline and w28 or w52 type I IFN scores (mean±SE: 17.8±3.2 vs 19.9±3.7 vs 20.2±1.2, respectively, $p>0.05$ for all comparisons by paired sample t-tests). Baseline type I IFN scores were correlated with changes in rheumatoid factor from baseline to w52, baseline mental component score of SF-36 (r=0.7/p=0.007, and r=0.8/p=0.003, respectively, by Pearson's test). When patients were subdivided in two groups, i.e. low IFN score and high IFN score, based on the baseline mean of IFN score, a significant differences were found between low and high IFN score groups as regards baseline to w52 changes in IgG (p=0.004, by Mann-Whitney), IgA (p=0.004, by Mann-Whitney), IgM levels (p=0.03, by Mann-Whitney) in favour of high IFN score group, while changes in RF levels tended to be significant (p=0.08, by Mann-Whitney). No significant changes or associations with type II IFN scores were observed.
**Conclusions:** Type I IFN-induced peripheral blood gene expression may affect the magnitude of biological effect of belimumab in SS, and in particular on RF-positive B-cell clones. Patients showing higher IFN signature may be the optimal target for belimumab in SS.

## THU0299 B CELL COMPARTMENT AND PHARMACODYNAMICS OF BELIMUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS: EARLY CLINICAL EFFICACY BY DEPLETION OF CD27- AND INCREASE OF CD27+ B CELLS

L. Quartuccio[1], G. De Marchi[1], F.M. Rossi[2], F. Zuliani[1], M. Bond[1], L. Picco[1], P. Masolini[1], F. Rizzolio[3], S. De Vita[1]. *[1]Department of Biological and Medical Sciences, Rheumatology Clinic, University Hospital of Udine, Udine; [2]Centro di Riferimento Oncologico (CRO), Clinical and Experimental Onco-Hematology Unit; [3]Centro di Riferimento Oncologico (CRO), Experimental and Clinical Pharmacology Unit, Aviano (PN), Italy*

**Background:** Belimumab, a human anti-BAFF monoclonal antibody that inhibits soluble BAFF, is effective in systemic lupus erythematosus (SLE), and leads to a partial B cell depletion. However, which subset of B cells may be the main therapeutic target of belimumab in SLE is still unclear.
**Objectives:** Primary objective of this study was to evaluate the effect of belimumab on the expression of BAFF receptor (BAFFR) on B cells through 12 months of belimumab treatment in SLE, and to correlate BAFFR expression with changes in B cell subsets.
**Methods:** Twelve consecutive patients with SLE (all female, age 44±7,8 yrs, 12,6±5,4 yrs of disease duration) undergoing belimumab therapy were studied. All patients received at least two immunosuppressors before belimumab. All patients were taking glucocorticoids at baseline [median (range): 7,5 (0–40) mg/day of prednisone or equivalent)], and 11/12 also at least one immunosuppressor. Median SLEDAI-2k score at baseline was 8,5 (range 8–15). Samples were collected and analysed at baseline (T0), month +3 (T3), +6 (T6), +9 (T9) and +12 (T12) for clinical and biological parameters. B cells subsets were characterized by multiparametric flowcytometry on a BD FACSCanto flowcytometer. The expression of BAFFR was also analysed as Mean Fluorescence Intensity (MFI). Parametric or non-parametric tests were used, as appropriate based on variable distribution. Data is reported as mean±standard error.
**Results:** A transient statistically significant increase of BAFFR MFI was observed from T0 to T3 (p=0,004) and from T0 to T6 (p=0,066) with a subsequent decrease until T12 (table 1). Interestingly, this course was similar to that observed in CD19+CD27+ cell subset (table 1), that showed a transient significant increase at T3 (p=0,014) and T6 (p=0,025) in 9/12 patients, with a subsequent slightly significant decrease from T6 to T12 (p=0,05) in all patients. Globally, a decrease of CD19+ cells was observed from T0 to T12 (p=0,19, table 1). This course is consistent with that observed in the CD27- B cell subset, that showed a decrease from T0 to T3 (p=0,14) and from T0 to T6 (p=0,14), and the decrease was persistent from T6 to T12 (p=0,6). SLEDAI-2k score decreased from T0 to T3 (p=0,007), to T6 (p=0,003) and to T12 (p=0,03) (table 1).
**Conclusions:** BAFF depletion differently acts on B cell subsets, CD19+27+ subset being able to increase BAFFR and transiently expand themselves, while CD19+27- being more sensitive to BAFF deprivation, and faster decreasing. Thus, early clinical response may be related to the changes in the CD27+/CD27- B cell ratio.

## THU0300 RISK FACTORS FOR ADVERSE PREGNANCY OUTCOME IN FIRST-LINE TREATED PREGNANCIES IN ANTIPHOSPHOLIPID ANTIBODIES-POSITIVE WOMEN ACCORDING TO DIFFERENT TREATMENT STRATEGIES: RESULTS FROM OUR 30 YEARS'EXPERIENCE PREGNANCY CLINIC

M.G. Lazzaroni[1], L. Andreoli[1], F. Lupoli[1], E. Aggogeri[1], E. Bettiga[2], S. Zatti[3], A. Lojacono[3], F. Ramazzotto[3], M. Fredi[1], A. Tincani[1]. *[1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia; [2]Obstetrics and Gynecology, University of Parma, Parma; [3]Obstetrics and Gynecology, Spedali Civili and University of Brescia, Brescia, Italy*

**Background:** Antiphospholipid antibodies (aPL) are risk factors for Adverse Pregnancy Outcome (APO). The therapeutic strategy to adopt in aPL patients during pregnancy should in fact consider different clinical and serological risk factors. In addition to conventional therapy, some recent evidences suggest a possible role of hydroxychloroquine.
**Objectives:** To review our approach in first-line treated pregnancies in aPL patients in our 30 years' experience Pregnancy Clinic (1985 -2015) to find out which clinical and serological risk factors have influenced the choice of treatments and which should be considered in the future for possible additional treatments.
**Methods:** We reviewed 120 first-treated pregnancies that were prospectively followed in our center by a multispecialistic team of Rheumatologists and Obstetricians. Patients were classified as Primary Antiphospholipid Syndrome (PAPS) according to revised criteria and as Incomplete PAPS or aPL carriers according to their clinical history or aPL status. Patients with concomitant systemic autoimmune diseases were excluded. aPL profile was defined as the combination of the 3 criteria tests for aPL (Lupus Anticoagulant, anti-cardiolipin, anti-Beta2 Glycoprotein I). APO was defined as at least one of the followings: miscarriage (<10th week), fetal death (≥10th week), severe preterm delivery (≤34th week) with or without preeclampsia (PE), HELLP syndrome or perinatal death.
**Results:** The type of therapy was divided in three main categories: combination therapy with low molecular weight heparin (LMWH) and LDA (68,57%), single therapy with low dose aspirin (LDA) (31,26%) and therapy with corticosteroids plus LDA (21,18%).
We collected 16 APO (13%): 11 (75%) in the category of LMWH+LDA. Analyzing APO vs. non-APO pregnancies we found no differences in variables that could predict an APO (history of thrombosis, a previous APO or a triple positive aPL profile) in any of the 3 categories (Table 1). Moreover, we found an increased rate of non criteria aPL manifestations in APO patients in LMWH+ASA category (31% vs. 4%, p:0.002; OR 2.19, 95%CI 2.20–61.6), but not in the other 2 categories of treatment.

| | Pregnancies with APO (n=16) | Pregnancies without APO (n=104) | P Value |

| Non-criteria PAPS (n6=) | 1 (6%) | 5 (5%) | |
| aPL carriers (n=1) | 0 (0%) | 1 (1%) | |
| Single positive (n=8) | 2 (13%) | 6 (6%) | |
| Double positive (n=13) | 1 (6%) | 12 (12%) | |
| **Triple positive (n=0)*** | **0 (0%)** | **0 (0%)** | **1.000** |
| **Previous APO (n=19)*** | **3 (19%)** | **16 (15%)** | **0.717** |
| **Non-criteria aPL manifestations° (n=5)*** | **1 (6%)** | **4 (4%)** | **0.517** |

**Table 1** *variables considered for univariate analysis with Fisher's exact test [p<0.05]
°non-criteria aPL manifestations were defined as the presence of at least one of the followings: (livedo reticularis, thrombocytopenia, headache, hemolytic anemia, cardiac valvulopathy, epilepsy).

**Conclusions:** Non-criteria aPL manifestations are a risk factor for APO ande can determine failure to conventional treatment with LMWH plus LDA during pregnancy in aPL patients regardless of clinical diagnosis, serological profile or obstetric history. These patients may represent a more severe phenotype of disease and may deserve an immunomodulatory treatment to increase the probability of success during pregnancy.

## THU0301 A PHASE II TRIAL OF RETINOIDS ON LUPUS NEPHRITIS IN A SINGLE CENTER

M. Funauchi, Y. Nozaki, K. Kinoshita. *Hematology and Rheumatology, Kindai Universtiy Faculty of Medicine, Osaka, Japan*

**Background:** Although immunosuppressants such as corticosteroids or cyclophosphamide can suppress the progression of LN, a major manifestation of systemic lupus erythematosus (SLE), some cases are resistant to those agents, and severe adverse reactions (ARs) may occur. Therefore, development of new effective drugs with fewer ARs is important. Recently, all-trans retinoic acid (ATRA), one of natural retinoids, has been reported to differentiate regulatory T cells and suppress Th17 cells in the models of autoimmune diseases. We have reported that ATRA improved proteinuria, survival rate as well as renal pathology in lupus-prone mice (ref). On the other hand, AM80, a synthetic retinoid, has been reported to suppress the expression of inflammatory cytokines in collagen-induced arthritis and EAE.
**Objectives:** Effectiveness and safety of these retinoids for the treatment of LN were examined.
**Methods:** Twenty-three patients with LN who fulfilled the ACR's revised criteria for classification of SLE were enrolled. Those unable to prevent pregnancy for more than 2 years, and who had been newly given any immunosuppressants within 8 weeks before this study were excluded. ATRA (10 mg/day) was administered to 9 patients (group A) and AM80 (4 mg/day) to 14 (group B) for 6M. Six in group B dropped out due to ARs, and effectiveness was analyzed using data of 8 patients. Through the study, the dose of steroid was not increased but allowed to be reduced if the clinical course was improved. Urinary protein (UP), serum albumin (Alb) and creatinine (Cr) levels, titer of the serum anti-double-strand DNA antibody (ADNA), serum complement levels (C3, C4) and activity (CH50) were determined every month.
**Results:** In group A, Average of UP decreased at 6M after the treatment (3.2 to 0.4 g/g Cr, $p<0.05$), Alb tended to elevate (3.2 to 3.8 g/dl), and Cr did not change. ADNA tended to reduce from 23.5 to 15.5 IU/ml, and C3, C4 and CH50 tended to elevate. In group B, UP tended to reduce at 6M (2.3 to 1.3), while Alb and Cr did not change. ADNA reduced from 37.6 to 18.8 at 3M and kept the similar value at 6M. Serum C3, C4 and CH50 tended to elevate until 6M. In group A, ARs occurred in 3 cases (leucopenia, fatigue and myalgia), while skin rash occurred in 4, bone pain in 3, hair loss in 3, and faintness, hypertension and fever in one case each in group B. AM80 was discontinued in 6 cases due to bone pain, faintness, hypertension and fever within 2M. Dose of steroid tended to reduce at 6M (A:17.1 to 15.0, B:13.6 to 13.2 mg/day).
**Conclusions:** This is the first report of on effectiveness and safety of retinoids for LN. Although the difference did not reach significance due to lack of number, UP and ADNA tended to reduce, Alb elevate, and complements tended to elevate in the both groups. Dose of steroid was reduced in some cases. Number of the cases was not enough mainly because of the exclusion criteria of contraception. Bone pain occurred relatively frequently and caused dropout in AM80 group, although it was not so severe. These findings suggest that retinoids might have a role in improvement of LN resistant to conventional therapy, and ancillary role of retinoids to high-dose steroids or immunosuppressants should be also tested in future.

## THU0302 VALIDATION OF HIGHLY SENSITIVE FLOW CYTOMETRY AS A BIOMARKER FOR RITUXIMAB IN SLE: A RATIONALE FOR MORE INTENSIVE TREATMENT TO IMPROVE CLINICAL OUTCOMES

M.Y. Md Yusof[1,2], D. Shaw[2], A. Rawstron[3], P. Emery[1,2], E.M. Vital[1,2]. *[1]Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [3]Haematological Malignancy Diagnostic Service, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Rituximab is effective for SLE in open label series however level of clinical response varies and was not superior to standard of care in randomised trials. We previously showed that clinical response was associated with the depth of initial B cell depletion and relapse was associated with early plasmablast repopulation [1].
**Objectives:** To validate B cell depletion as a predictor of response to rituximab in SLE as a basis to develop more effective B cell targeted therapy.
**Methods:** The published discovery cohort included 38 renal and extra-renal lupus patients. A validation cohort of 46 new patients was recruited. All patients received an initial cycle of 2 infusions of 1000mg rituximab, each preceded by 100mg methylprednisolone. Rituximab was repeated on clinical relapse. Concomitant therapy with cyclophosphamide was not used. Oral immunosuppressants were continued if used at baseline. Oral prednisolone doses varied. B cell depletion using a protocol optimized to detect low numbers of B cell subsets and plasmablasts was measured at baseline, after both infusions of rituximab (6 weeks) and at early B cell repopulation (6 months). Complete depletion was defined as total B cell count $<0.0001x10^9$/L
**Results:** Depletion and response data were available for 84/100 patients. Overall complete depletion rate was 54%.

| Cohort | Depletion | Non response | Response | p |
|---|---|---|---|---|
| Discovery (n=38) | Incomplete | 7/22 (32%) | 15/22 (68%) | 0.012 |

| Validation (n=46) | Incomplete | 6/17 (35%) | 11/17 (65%) | 0.014 |
| | Complete | 2/29 (7%) | 27/29 (93%) | |
| Combined (n=84) | Incomplete | 13/39 (33%) | 26/39 (67%) | 0.001 |
| | Complete | 2/45 (4%) | 43/45 (96%) | |

Incomplete depletion was predicted at baseline by low complement C4 (p=0.044) but not baseline BILAG score or immunosuppressant use. In original cohort there was a significant association between plasmablast repopulation ($>0.0008x10^9$/L) and time to relapse <18 months (p=0.024). Follow up for relapse was limited to 22/36 responders in the validation cohort at the time of analysis, with a trend to the same association (p=0.119).
**Conclusions:** We have validated depth of B cell depletion as a predictor of response to rituximab in SLE. Clinical trials using more intensive rituximab treatment regimens, or alternative CD20 molecules are likely to increase clinical response rates to B cell depletion in clinical trials. B cell subsets should be monitored in the routine care of SLE patients receiving rituximab and repeat infusions considered if early depletion is incomplete or plasmablast repopulation is detected at 6 months.

## THU0303 LONGITUDINAL PATTERNS IN SLE RESPONSE TO STANDARD OF CARE THERAPY: IMPLICATIONS FOR SLE CLINICAL TRIAL DESIGN

M. Kim[1], J.T. Merrill[2], K.C. Kalunian[3], B.H. Hahn[4], A. Roach[5], P.M. Izmirly[6] on behalf of the Lupus Foundation of America Collective Data Analysis Initiative Group. *[1]Dept. of Epidemiology & Population Health, Albert Einstein College of Medicine, Bronx; [2]Clinical Pharmacology Research Program, Oklahoma Medical Research Foundation, Oklahoma City; [3]Dept. of Medicine, University of California San Diego, La Jolla; [4]Dept. of Medicine, University of California Los Angeles, Los Angeles; [5]Dept. of Education and Research, Lupus Foundation of America, Washington DC; [6]Dept. of Medicine, New York University School of Medicine, New York City, United States*

**Background:** Most clinical trials of new treatments for systemic lupus erythematosus (SLE) have shown weak discrimination between investigational agents and placebo when added to standard of care (SOC). Given that targeted biologics are unlikely to be effective in all patients, it is challenging for these experimental therapies to exceed the high response rates observed with SOC alone in placebo arms. The design of future SLE trials may be improved by considering strategies for reducing placebo response rates and obtaining a better understanding of the within-patient variability in disease activity during follow up.
**Objectives:** The goal of this study was to evaluate longitudinal patterns of response in SLE patients who received placebo plus SOC in two completed 52-week clinical trials. Baseline characteristics discriminating early and persistent responders from non-responders to SOC were also examined to identify patient populations who may benefit most from experimental therapies and could be targeted for enrollment in future trials.
**Methods:** Data was obtained from the Collective Data Analysis Initiative (CDAI) of the Lupus Foundation of America and included 147 patients from the placebo plus SOC arms of two randomized Phase II/III trials in moderately-to-severely active lupus patients without acute nephritis. A BILAG-based response was evaluated at weeks 12, 24, 36, 48, and 52. Both cross-sectional and longitudinal analyses of response patterns were performed. Clinical variables, including background medications and baseline factors associated with disease severity, that discriminated persistent responders from non-responders were identified using logistic regression.
**Results:** The cross-sectional response rates ranged from 37% - 46% between 12 - 52 weeks for patients treated with placebo plus SOC, similar to the placebo response rates estimated in most non-nephritis lupus trials. The response rate decreased to 14.3% (95% CI: 8.6% - 19.9%) when the criterion was complete response, i.e., response at all visits between 12 - 52 weeks. Agreement between response status at 12 weeks and 36–52 weeks was low (kappa =0.15 - 0.25); furthermore only 31% of initial 12 week responders maintained response at all subsequent visits. Factors contributing to non-response to SOC at all visits included more severe disease, as suggested by more organ systems active at baseline, and low C3 levels at baseline. Less aggressive immunosuppression was also associated with non-response.
**Conclusions:** An endpoint based on a sustained rather than cross-sectional response may reduce high placebo response rates in SLE trials that continue aggressive SOC and may improve discrimination between effective experimental

treatments and SOC. Although there is increasing interest in conducting efficient 12 or 24 week early phase trials, the observed lack of stability in response to SOC over time highlights a potential weakness with shorter studies that use an endpoint of improvement. Our data also confirm earlier reports that the likelihood of response in the placebo group depends on the severity of disease and the aggressiveness of background treatments.

## THU0304 ADHERENCE TO HYDROXYCHLOROQUINE AS ASSESSED BY MEASUREMENTS OF DRUG AND METABOLITE BLOOD LEVELS IN AN INTERNATIONAL PROSPECTIVE STUDY OF SLE PATIENTS IN FLARE

N. Costedoat-Chalumeau[1], F. Houssiau[2], P. Izmirly[3], V. Le Guern[1], S. Navarra[4], M. Jolly[5], G. Ruiz-Irastorza[6], E. Hachulla[7], N. Agmon-Levin[8], Y. Shoenfeld[8], F. Dall'Ara[9], J. Isenberg[18]. *[1]Cochin Hospital, Internal Medicine, Paris, France; [2]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Rheumatology and Internal Medicine, Bruxelles, Belgium; [3]NYU Langone Medical Center, Center for Musculoskeletal Care, New York, United States; [4]University of Santo Tomas Hospital, Rheumatology, Manila, Philippines; [5]Rush University Medical Center, Rush Lupus Clinic, Chicago, United States; [6]Hospital Universitario Cruces, Internal Medicine, Barakaldo, Spain; [7]Claude Huriez Hospital, Internal Medicine, Lille, France; [8]Sheba Medical Center, Zabludowicz Center for Autoimmune Diseases, Tel-Hashomer, Israel; [9]Spedali Civili e Università degli Studi di Brescia, Rheumatology and Internal Medicine, Brescia, Italy; [10]Pierre-Zobda-Quitman Hospital, Internal Medicine, Martinique, France; [11]Hospital Clínic de Barcelona, Autoimmune Diseases, Barcelona, Spain; [12]Haut Lévêque Hospital, Internal Medicine, Pessac; [13]Dupuytren Hospital, Internal Medicine, Limoges; [14]Pitié-Salpêtrière Hospital, Internal Medicine, Paris, France; [15]Montreal General Hospital, Lupus Clinic, Montreal, Canada; [16]St Louis Hospital, Clinical Immunology, Paris, France; [17]The Karolinska University Hospital, Medicine, Unit for Clinical Research Therapy, Inflammatory Diseases, Stockholm, Sweden; [18]University College London, Centre for Rheumatology, London, United Kingdom; [19]Hopital Pitié-Salpêtrière, Pharmacology, Paris; [20]European Georges Pompidou Hospital, Internal Medicine, Paris, France; [21]Johns Hopkins Center, Rheumatology, Baltimore, United States*

**Background:** Non-adherence to treatment, a major cause of continued lupus activity and flares, may be difficult to recognize.

**Objectives:** In this international prospective study, we evaluated adherence to hydroxychloroquine (HCQ) in SLE patients with flares (NCT01509989).

**Methods:** This study included 305 SLE patients (SLICC criteria) from 10 countries, all of whom had been prescribed HCQ for ≥2 months and were having a disease flare (SELENA-SLEDAI Flare Index). Adherence to HCQ was assessed by self-questionnaires (MASRI, Morisky), physician's assessment (VAS 0–100), and blood concentrations of HCQ and its main metabolite desethylchloroquine ([HCQ] and [DCQ]). Non-adherence was defined by MASRI <80%, Morisky<6, [HCQ] <200ng/ml and/or undetectable [DCQ].

**Results:** 305 patients (288 women; mean age 38 ± 12ys) met the inclusion criteria. The median SLE duration was 11ys [range 1–46]; 108 patients (35%) had a history of lupus nephritis.

At enrollment, the median SELENA-SLEDAI score was 8 [2–30] and the flare was considered severe in 43%. The HCQ dosage was 400mg/d in 72%, 200mg/d in 15%, or another dosage in 13%. The median [HCQ] was 718ng/ml [0–4345]. In addition, steroids were prescribed in 76%, and immunosuppressives in 46%.

Severe non-adherence defined by [HCQ] <200ng/ml was found in 44 patients (14.4%). 12 additional patients with very low median [HCQ] of 235ng/ml [210–343] had an undetectable [DCQ] indicating a very recent resumption of treatment. Thus, 56 patients (18.4%) were objectively defined as severely non-adherent. Table 1 shows that the treating physician believed that 75% of these non-adherent patients were taking at least 50% of their prescribed HCQ dose, strongly suggesting that doctors were often unaware of non-adherence. The median VAS evaluating the adherence from the doctor's point of view was 75 [0–98] in objectively non-adherent patients vs 87 [0–100] in other patients. The doctor's opinion, therefore, was poorly informative.

Good adherence to treatment with HCQ (MASRI ≥80%) was self-reported by 77% of the patients, including by 43% of those objectively severely non-adherent. On the other hand, the investigators felt that only 12% of patients took less than 50% of HCQ, with severe non-adherence confirmed in 39%. Conversely, while intake was estimated at ≥75% (65%), 15% of these patients were objectively severely non-adherent.

Non-adherent patients defined by self-questionnaires (MASRI<80% or Morisky <6) and/or drug blood levels, represented 47% of this cohort.

**Conclusions:** These data demonstrate that blood HCQ and DCQ measurements objectively identify significant non-adherence to HCQ in nearly 20% of SLE patients. Non-adherence was often unrecognized by the doctor, suggesting usefulness of blood assays to more accurately determine adherence.

| | Non-adherent (n = 56) | Others (n = 249)* | Total (n = 305)* |
|---|---|---|---|
| **Reported adherence by the patients** | | | |
| - Mean MASRI | 69 [0-75] | 90 [0-100] | 86 [0-100] |
| - N of patients with MASRI ≥ 80% | 24/56 (43%) | 205/243 (84%) | 229/299 (77%) |
| **Perceived adherence by physician on a VAS (0 to 100)** | | | |
| - Median VAS [range] | 75 [0-98] | 87 [0-100] | 85 [0-100] |
| - N of patients with VAS 0-24 | 9 (16%) | 5 (2%) | 14 (5%) |
| - N of patients with VAS 25-49 | 5 (9%) | 17 (7%) | 22 (7%) |
| - N of patients with VAS 50-74 | 12 (21%) | 60 (24%) | 72 (24%) |
| - N of patients with VAS 75-100 | 30 (54%) | 167 (67%) | 197 (65%) |

**Legends:** HCQ: hydroxychloroquine. DCQ: desethylchloroquine. N: number. MASRI is a self-questionnaire assessing adherence from the patient's point of view. A MASRI ≥80% is considered a good adherence to treatment. VAS: Visual Analogue Scale. This represents the rating of the patient's adherence from the physician's point of view. A VAS of 0 means that the physician believes that the patient did not take any HCQ tablet in the last month, and 100% means that he/she thinks that the patient never missed a single dose.
Non-adherence was defined by [HCQ] <200ng/ml and/or undetectable concentration of DCQ.
"Others" included patients perfectly adherent as well as less adherent patients with a blood level of HCQ >200 ng/ml and a measurable DCQ.
*: 1 missing data regarding [HCQ] and [DCQ]

## THU0305 PHARMACOKINETICS OF SWITCHING FROM INTRAVENOUS TO SUBCUTANEOUS BELIMUMAB FOR PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

S.Z. Sheikh[1], N.L. Fox[2], A.E. Hammer[3], H. Struemper[4], J. Groark[5], D. Roth[5], D. Gordon[5]. *[1]University of North Carolina, Chapel Hill, NC; [2]GlaxoSmithKline, MD; [3]GlaxoSmithKline, RTP, NC; [4]PAREXEL, Durham, NC; [5]GlaxoSmithKline, Philadelphia, PA, United States*

**Background:** The ability to self-administer subcutaneous (SC) belimumab would enhance treatment options for patients with SLE.

**Objectives:** The pharmacokinetics (PK) across the change in administration from monthly belimumab intravenous (IV; 10 mg/kg) to weekly self-administration of belimumab 200 mg SC was examined in patients with SLE.

**Methods:** Study 200339 (NCT02124798) enrolled adults with SLE who had received at least three monthly belimumab 10 mg/kg IV doses plus standard care, or who completed the open-label continuation phase of a randomised, controlled trial of belimumab SC (prefilled syringe). The target period between the last IV dose and first SC dose was 1 to 4 weeks. Open-label belimumab 200 mg SC (1 mL) was self-administered weekly (thigh or abdomen) using an autoinjector under clinic observation at Weeks 1, 2, 4, 8 and at home at Weeks 3, 5, 6, 7. PK samples were collected prior to SC administration at Weeks 1, 2, 4 and 8.

**Results:** 95 patients enrolled: 91 completed the study. All except two patients transitioned from belimumab IV administration. Overall, 94% (89/95) of patients successfully self-administered belimumab at Weeks 1 and 2. A total of 736 injections were attempted over the 8-week treatment period, and 720 (98%) were concluded to be successful. Median serum belimumab trough concentration at Week 8 was 113 μg/mL (Figure). Following the switch from IV to SC, steady-state trough belimumab levels were attained on average by Week 2 (Figure). Median % changes from Week 1 to Week 8 were -51%, -23%, 1% and -3% for subjects with investigator-reported IV to SC switching time intervals of ≤1.5 weeks, 1.5–2.5 weeks, 2.5–3.5 weeks and >3.5 weeks, respectively.

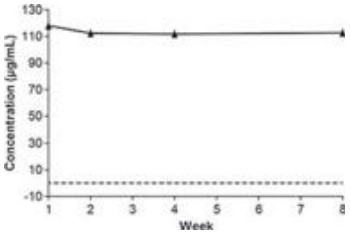

Figure 1. Median belimumab serum concentration. Dashed line: lower limit of quantification (0.1 μg/mL)

**Conclusions:** Patients with SLE successfully self-administered belimumab SC using a novel autoinjector. With a protocol-specified 1–4-week interval between

the last IV and the first SC administration, baseline (Week 1) belimumab concentrations were on average similar to their eventual steady-state concentration. Since bioequivalent exposures were previously demonstrated for belimumab SC administration with autoinjector and prefilled syringe[1], the pharmacokinetically stable transition from IV to SC administration demonstrated here, is also assumed to hold for belimumab SC administered with the prefilled syringe. The median Week 8 belimumab concentration of 113 μg/mL confirms that steady-state average concentrations over the dosing interval (CavgSS) for weekly belimumab 200 mg SC are similar to the CavgSS of 110 μg/mL for belimumab 10 mg/kg IV every 4 weeks[2]. The appropriate dosing interval between IV to SC dosing appears to be 1–4 weeks to start SC treatment when exposure is close to SC steady-state levels.

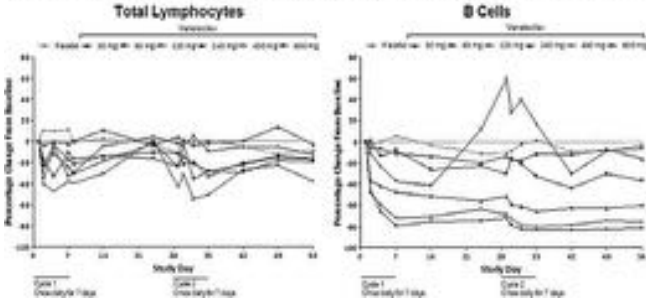
## THU0306 SAFETY, TOLERABILITY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF THE BCL-2 INHIBITOR VENETOCLAX (ABT-199) IN A PHASE 1 SINGLE AND MULTIPLE ASCENDING DOSE STUDY IN FEMALE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

P. Lu[1], R. Fleischmann[2], C. Curtis[3], S. Ignatenko[4], M. Desai[5], S.L. Wong[5], K.M. Grebe[1], J. Zeng[5], J. Medema[1], J. Stolzenbach[5]. *[1]AbbVie Inc., Worcester, MA; [2]University of Texas Southwestern Medical Center, Dallas, TX; [3]Compass Research Center, Orlando, FL, United States; [4]Charité Research Organisation, Berlin, Germany; [5]AbbVie Inc., North Chicago, IL, United States*



**Background:** Apoptosis eliminates auto-reactive T and B cells during immune responses; failure of elimination is important in development of systemic lupus erythematosus (SLE). Elevated Bcl-2 expression may contribute to cell death abnormalities for auto-reactive cells. Venetoclax (ABT-199) is a selective, small-molecule Bcl-2 inhibitor.

**Objectives:** To examine safety, tolerability, pharmacokinetics, and pharmacodynamics (PD) of venetoclax in female patients (pts) with SLE

**Methods:** This was a single and multiple ascending dose (MAD), double-blind, randomized, placebo (PBO)-controlled, phase 1 study (NCT01686555) in women aged 18–65 y with SLE for >6 mo, receiving stable SLE therapy. Twelve cohorts were planned (N=96); in each cohort, 6 pts received venetoclax and 2 received PBO. Pts in cohorts 1–6 received single doses of venetoclax 10, 30, 90, 180, 300, and 500 mg, respectively, or matching PBO. Pts in MAD arms (cohorts 7–12) received 2 cycles (once daily for 1 wk, then 3 wk off in each cycle) of venetoclax 30, 60, 120, 240, 400, and 600 mg, or matching PBO, beginning after safety evaluation of the single-dose venetoclax 90-mg cohort.

**Results:** In 98 enrolled pts, adverse events (AEs) were reported for 62% of pts receiving venetoclax and 48% receiving PBO; common AEs were headache (23% vs 24%, respectively) and gastrointestinal disorders (diarrhea [8% vs 4%], nausea [16% vs 12%], vomiting [8% vs 4%]). Most drug-related AEs were mild to moderate; no serious AE was reported with venetoclax. There were no deaths and no clinically relevant abnormalities of vital signs or electrocardiograms. Exposure to venetoclax was dose proportional, with a half-life of ~7–17 h after single doses. PD effects of Bcl-2 inhibition included dose-dependent reductions of total lymphocytes and B cells (Figure) after single and multiple venetoclax doses up to 600 mg. B cells were most sensitive to Bcl-2 inhibition, with up to 80% reduction from baseline in high-dose groups. Similar sensitivity was observed across B cell subsets. Total lymphocytes and T cells showed modest reduction; recovery of total lymphocytes occurred during the dosing interval of cyclic multiple dose regimens (Figure). Levels of neutrophils, platelets, reticulocytes, hemoglobin, and safety laboratory values showed no consistent patterns or marked changes across single- and multiple-dosing groups.

Figure. Percentage changes from baseline in total lymphocytes and B cells during multiple dosing of venetoclax

**Conclusions:** In female SLE pts, venetoclax was well tolerated in single and multiple doses; exposure appeared consistent with findings in cancer pts. PD assessments showed venetoclax-mediated reductions of lymphocytes and subsets.

## THU0307 REPOSITORY CORTICOTROPIN INJECTION (RCI) ATTENUATES DISEASE ACTIVITY IN PATIENTS WITH PERSISTENTLY ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) REQUIRING CORTICOSTEROIDS: RESULTS FROM A 44-WEEK OPEN-LABEL EXTENSION STUDY

P. Becker[1], R. Furie[2], M. Mitrane[3], E. Zhao[1]. *[1]Research & Development, Mallinckrodt Pharmaceuticals, Ellicott City; [2]Northwell Health, Hofstra Northwell School of Medicine, Great Neck; [3]Manhattan BioPharm Consultants LLC, New York, United States*

**Background:** We recently reported results from a pilot 8-week randomized double-blind placebo (PBO)-controlled study of RCI in subjects with persistently active SLE involving skin and/or joints despite moderate dose corticosteroids for ≥4 weeks[a]. Although the primary endpoint of this study (resolution of disease active for SLEDAI rash or arthritis with no worsening of other organ systems by BILAG) was not met, RCI therapy (40U daily or 80U every other day SC) led to improvement in several measures of disease activity, including total hybrid SLEDAI (hSLEDAI), total BILAG, CLASI Activity scores, and Tender and swollen joint count, as compared with PBO.

**Objectives:** To describe the topline results of a 44-week open-label extension (OLE) of this study of RCI in persistently active SLE.

**Methods:** 33/38 subjects completed the double-blind phase of the study and opted to enroll in the OLE. Of these 33, 22 had received RCI and 11 PBO during the prior 8 weeks. The dose of RCI could be adjusted beginning at week 9, with the goal of achieving a stable dose (16, 40 or 80U SC, 1–3x/week) to control disease activity no later than Week 28. Beginning at Week 20, investigators were encouraged to taper background prednisone. Disease activity was assessed monthly by hSLEDAI, BILAG, CLASI, Tender & swollen joint counts, and physician's global assessment (PGA).

**Results:** 20 subjects completed the OLE, 13/22 from the RCI/RCI and 7/11 from the PBO/RCI groups. No unexpected adverse events were observed.

| | RCI/RCI (n=22) | PBO/RCI (n=11) |
|---|---|---|
| OLE baseline, mean (SD) | | |
| Total hSLEDAI | 5.8 (3.02) | 9.1 (3.42) |
| Total BILAG | 6.8 (4.31) | 13.5 (8.82) |
| PGA | 28.73 (21.05) | 39.09 (27.24) |
| CLASI activity (of those >0) | 4.8 (4.25) (n=17) | 7.0 (7.00) (n=9) |
| Tender & swollen joint count (of those >0) | 4.6 (1.67) (n=5) | 5.0 (2.94) (n=4) |
| Prednisone (mg/day) | 8.98 (1.67) | 16.36 (8.09) |
| Results, proportion (%) | | |
| SLEDAI rash or arthritis domain 0 & no new BILAG prior to steroid taper | 5/10 (50%) | 2/7 (28.6%) |
| SRI (week 52) | 10/13 (76.9%) | 6/7 (85.7%) |
| Prednisone to <7.5 mg/day (week 52) | 9/13 (69.2%) | 3/7 (42.9%) |
| Prednisone decreased >50% | 7/13 (53.8%) | 4/7 (57.1%) |
| Severe flares (SFI) (week 52) | 2/22 (9.1%) | 3/11 (27.3%) |
| Change from OLE baseline at week 52, mean (SD) | | |
| Total hSLEDAI | –1.5 (2.79) | –4.7 (3.77) |
| Total BILAG | –1.2 (5.58) | –7.0 (8.35) |
| PGA | –9.92 (16.02) | –14.14 (13.70) |
| CLASI Activity | –3.0 (4.92) | –2.8 (1.6) |
| Tender & swollen joint count | –2.0 (5.66) | –2.5 (4.95) |

**Conclusions:** These data demonstrate that subjects in the RCI/RCI group had a durable response to therapy over 52 weeks, whereas those in the PBO/RCI group experienced improvements in disease activity during the OLE that were generally comparable to the improvements seen with RCI treatment from the blinded phase of the trial.

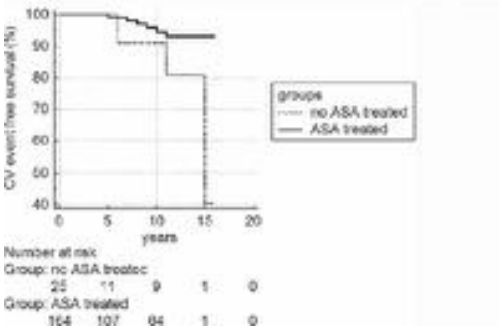
## THU0308 HYDROXYCHLOROQUINE IMPROVES PREGNANCY OUTCOME IN WOMEN WITH ANTIPHOSPHOLIPID ANTIBODIES WITHOUT OTHER UNDERLYING CONNECTIVE TISSUE DISEASE

S. Sciascia[1], S. Baldovino[2], D. Roccatello[2], M.J. Cuadrado[3]. *[1]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare; [2]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare, Torino, Italy; [3]Lupus unit, Guy's and St. Thomas' NHS Foundation Trust, London, UK, London, United Kingdom*



**Background:** Low-dose aspirin and/or heparins represent the treatment of choice for the management of pregnant women with antiphospholipid antibodies (aPL). However, despite these treatments, maternal, fetal, and neonatal complications related to the presence of aPL may still occur.
**Objectives:** To assess pregnancy outcome in women with aPL without other underlying connective tissue disease (CTD) who were treated with hydroxychloroquine (HCQ) in addition to conventional treatment during pregnancy.
**Methods:** Eighty-nine pregnancies in 48 women with persistent aPL were included in this observational, retrospective, cohort study: (group 1) 17 pregnancies that occurred in 13 women were treated with HCQ for at least 6 months before pregnancy, and the therapy continued throughout gestation; (group 2) 72 pregnancies that occurred in 35 women with aPL that were not treated with HCQ were included as controls. All the patients were tested positive for aPL in the absence of conclusive clinical signs/symptoms of CTD.
**Results:** HCQ-treatment was associated with a higher rate of live births (82% group A vs 58% group B; p=0.05). Placenta-mediated complications (pre-eclampsia and abruption placentae) were not observed in group 1 but occurred in 5 cases of group 2. Pregnancy duration was longer in group 1 than group 2 (36.4 [6–40] vs 33.5 [6–40] weeks; p=0.04).
**Conclusions:** Despite the limit of the small sample size, our observations support that HCQ may improve pregnancy outcome in women with aPL.
**Disclosure of Interest:** None declared

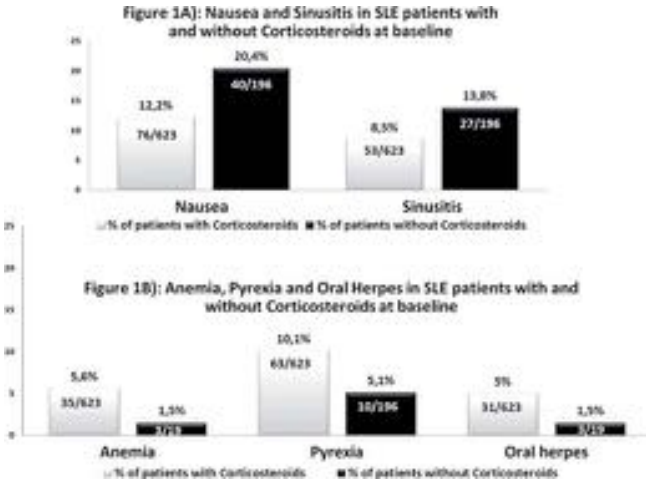
## THU0309 LOW-DOSE ASPIRIN AS PRIMARY PROPHYLAXIS FOR CARDIOVASCULAR EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONG-TERM FOLLOW UP

S. Fasano, M. Iudici, I. Pantano, L. Pierro, G. Valentini. *Rheumatology Unit, Second University of Naples, Naples, Italy*

**Background:** Cardiovascular (CV) morbidity and mortality are significantly greater in Systemic Lupus Erythematosus (SLE) patients than in the general population. Acetylsalicylic acid (ASA) is known to be associated with a decrease in the incidence of CV events in high-risk patients from general population [1].
**Objectives:** We previously investigated ASA efficacy as primary prophylaxis in 167 SLE patients followed for 7 patient-years [2]. Here, we report data collected in 189 patients followed for 8,2 patient-years.
**Methods:** SLE patients consecutively admitted to a tertiary center, who, at admission, satisfied 1992 ACR and/or 2012 SLICC classification criteria for SLE and had not experienced any CV event, were enrolled into the study. Low-dose ASA (100 mg/day) was prescribed to each patient at first visit. Fourteen patients (7%) refused to take it. At each 6-monthly visit, ASA side effects, ASA discontinuation and occurred CV events were recorded.
**Results:** 189 consecutive SLE patients were followed-up for a median of 8 years (range 1–15). Among them, 164 regularly took the medication (ASA-treated) and 25 refused to take or discontinued it (non-ASA-treated patients). Six CV events occurred in the 164 ASA-treated (4.2/1000 person-years), 4 in the 25 non-ASA-treated patients (25.4/1000 person-years) (p=0.003). No relevant side effect related to ASA treatment was recorded.

**Figure 1**. Rate of CV events over time in ASA- and non-ASA treated patients.



**Conclusions:** Present data further support the role of ASA in the primary prophylaxis of CV events in SLE patients.

## THU0310 RELATIONSHIP BETWEEN CORTICOSTEROIDS AND UNFAVORABLE MEDICAL EFFECTS. A STUDY UNDER THE SHARE SYSTEM BASED ON THE CLINICAL TRIAL BELIMUMAB IN SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (BLISS-76)

S. Emamikia[1], C. Gentline[1], M. Backheden[2], K. Chatzidionysiou[1], L. Arnaud[1], R.F. van Vollenhoven[1]. *[1]ClinTRID, Karolinska Institute; [2]Dept. of Learning, Informatics, Management and Ethics, Unit for Medical Statistics, Stockholm, Sweden*

**Background:** Corticosteroids (CSs) are used to control moderate to severe manifestations in Systemic Lupus Erythematosus (SLE) patients. CSs have rapid and strong favorable effects in controlling the disease manifestations but have very significant side-effects and long-term adverse consequences when used at high doses for prolonged periods of time. However, detailed quantitative information on the relationship between CS exposure (dosage and duration) and side-effects in the literature is limited.
**Objectives:** To obtain a better understanding of the exact relationship between exposures to CSs and possible adverse events (AEs).
**Methods:** Data from the BLISS-76 clinical trial, which are owned by the sponsor company GSK, were accessed through an agreement under the SHARE mechanism, whereby investigators are granted access for performing pre-specified analyses within the dataset [1]. We focused our analyses on AEs that were frequently reported or where a causal relationship with CSs could be suspected. We studied the relationship between AEs CSs at baseline (BL) as well as during the trial.
**Results:** Among the 819 patients included in BLISS-76, 623 (76.1%) were treated with CSs at BL. Significantly higher proportions of the following AEs: anemia, pyrexia and oral herpes were found in patients treated with CSs at BL compared to those who were not (5.6% vs. 1.5%, p=0.018; 10.1% vs. 5.1%, p=0.031; 5.0% vs. 1.5%, p=0.039, respectively). In contrast, the reverse was observed for nausea and sinusitis (12.2% vs. 20.4%, p=0.007; 8.5% vs. 13.8%, p=0.038, respectively) (Figure 1). The following AEs: cataract, glaucoma/ocular hypertension, osteopenia, musculoskeletal disorders, myalgia, cardiac disorders, hypertension, type 2 diabetes/hyperglycaemia, hypercholesterolaemia/hyperlipidaemia, peptic ulcer, skin ulcer and cushingoid, were numerically but not statistically more frequent in patients with CSs at BL compared to those without.

**Conclusions:** The SHARE mechanism is a useful tool for allowing detailed independent analyses of sponsored clinical trial data. Our results suggest that anemia, pyrexia and oral herpes are associated with CS-exposure in a large clinical trial of patients with SLE. Notably,the use of CSs was associated with reduced occurrence of nausea and sinusitis.

## THU0311 IL3R-ALPHA AS A NOVEL THERAPEUTIC TARGET IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Oon[1,2,3], H. Huynh[4], T.Y. Tai[4], M. Ng[4], K. Monaghan[4], M. Biondo[4], G. Vairo[4], E. Maraskovsky[4], A.D. Nash[4], N.J. Wilson[4], I.P. Wicks[1,2,3]. *[1]The Walter and Eliza Hall Institute; [2]The Royal Melbourne Hospital; [3]The University of Melbourne; [4]CSL Limited, Parkville, Australia*

**Background:** Despite currently available therapies, a significant morbidity, and mortality remains in SLE. Major therapeutic targets have been the auto-antibody producing B cell, and more recently, type I IFN, which is produced by pDCs activated via TLR7 and TLR9 stimulation by SLE immune complexes. Alternate ways of reducing type I IFN, such as by modulating pDCs, are now emerging (1, 2). We have developed a novel mAb targeting the IL-3Rα, CSL362, which both depletes IL-3Rα expressing cells, and neutralizes signaling through IL-3.
**Objectives:** Our objective was to explore the potential utility of CSL362 as a therapeutic in SLE, via its effects on multiple pathogenic cell types and cytokines.
**Methods:** *In vitro* studies were undertaken in a heterogenous population of SLE donors, and healthy and autoimmune disease controls, and major findings confirmed *in vivo* in cynomolgus macaques. The effect of CSL362 on peripheral blood mononuclear cell types was evaluated by flow cytometry, on cytokine production by ELISA or Luminex assays, and on gene expression by qRT-PCR.
**Results:** CSL362 potently and specifically depleted $CD123^{hi}$ pDCs and basophils (average depletion 86.07%±2.07 (SEM), $p<0.05$, n=72 for pDCs, and 59.39%±3.57, $p<0.05$, n=71 for basophils). This occurred mainly through antibody-dependent cell-mediated cytotoxicity, although neutralization of IL-3 alone with the Fab fragment of CSL362 resulted in pDC, but not basophil, depletion at higher doses. Through pDC depletion, TLR7-, TLR9- and SLE serum- stimulated IFNα production, and IFN-inducible gene expression was markedly reduced (average reduction in TLR9-stimulated IFNα production 99.36%±0.39, $p<0.05$, n=29). Additionally, TLR7- and TLR9-induced plasmablast expansion was inhibited by CSL362. This depended upon depletion of pDCs by CSL362, which decreased not only IFNα, but IL-6, production that was required for plasmablast expansion. Importantly, we found that IFN-inducible gene expression and plasmablast expansion were more effectively inhibited by CSL362 than by IFNα blocking mAbs. This may be because pDC depletion by CSL362 reduced production of cytokines other than IFNα, such as IL-6, and interferon types other than type I. Indeed, CSL362 reduced production of type III IFN, a cytokine which has been postulated as a cause of ongoing disease activity despite type I IFN blockade (3). Administration of a single subcutaneous dose of CSL362 to cynomolgus macaques confirmed pDC and basophil depletion, correlating with a decrease in IFN-inducible gene expression, that lasted several weeks post dose, with no major adverse events observed.
**Conclusions:** The unique ability of CSL362 to affect the major pathogenic targets of type I IFN and the B cell, and newer targets such as the basophil (4), IL-3 (5) and type III IFN, presents a strong rationale for its therapeutic evaluation in SLE.

## THU0312 PHYSICAL FATIGUE IS VERY IMPORTANT AS CLINICAL OUTCOME FOR IMPROVEMENT BY TREATMENT ACCORDING TO PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

S. Arends[1], P.M. Meiners[2], F.G. Kroese[1], E. Brouwer[1], F.K. Spijkervet[2], A. Vissink[2], H. Bootsma[1]. *[1]Rheumatology and Clinical Immunology; [2]Oral and Maxillofacial Surgery, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Besides ocular and oral dryness, fatigue is a prominent symptom in patients with primary Sjögren's syndrome (pSS).
**Objectives:** To investigate the importance of fatigue in relation to other symptoms and to evaluate the effect of rituximab treatment on fatigue in pSS patients with active disease.
**Methods:** The present analysis was based on data from our follow-up study of treatment with rituximab.(1) Twenty-eight pSS patients were treated with rituximab (1000 mg at days 1 and 15) and evaluated for 60 weeks. Subjective symptoms of dryness, physical fatigue, and limb pain were scored on a scale of 0–10 according to the ESSPRI. Mental fatigue was also scored on a scale of 0–10. Patients were asked to rank their symptoms of dryness, physical fatigue, pain, and mental fatigue in order of importance; from most to least eligible for improvement. In addition, the importance for improvement of each symptom was scored on a scale of 0–10. Fatigue was assessed in more detail with the Multidimensional Fatigue Inventory (MFI). Systemic disease activity was assessed with the ESSDAI.
**Results:** At baseline, 24 of the 28 (86%) pSS patients reported physical fatigue as most eligible for improvement, followed by pain and dryness. Mental fatigue was ranked as least eligible for improvement by 50% of the patients. However, for all these 4 domains, patients found it very important to get rid of their symptoms, reflected by median scores of importance of 8 or higher. The highest scores were given for physical fatigue (median 10, IQR 9–10).
Rituximab treatment resulted in a significant improvement in all clinical assessments. At 16 and 24 weeks of follow-up, physical fatigue showed 31% and 25% improvement in median values at group level, pain 36 and 29%, dryness 29% and 36%, and mental fatigue 36% and 9%, respectively. Regarding MFI domains, most improvement was reported in general (25% and 25%) and physical (19% and 16%) fatigue. In comparison, systemic disease activity assessed with ESSDAI improved 73% at group level. At 60 weeks of follow-up, all clinical assessments had returned to baseline values.
Before rituximab treatment, 18% of the patients had physical fatigue score $<5$, representing patient-acceptable symptom state (PASS). At 16–24 weeks, this proportion of patients increased to 21–36%. The proportion of patients with low disease activity according to ESSDAI increased from 29% at baseline to 75–79% at 16–24 weeks.
**Conclusions:** Fatigue is a very important symptom in pSS patients with active disease, which particularly concerns physical fatigue. Rituximab treatment resulted in a significant improvement of all patient-reported symptoms. However, the large majority of patients still experienced physical fatigue above the cut-off value for the PASS. Therefore, clinical attention for this prominent symptom is warranted in future clinical trials in pSS.

## THU0313 DOUBLE-BLIND, RANDOMIZED STUDY OF VAY736 SINGLE DOSE TREATMENT IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME (PSS)

T. Dörner[1], M. Posch[2], F. Wagner[2], A. Hüser[2], T. Fischer[1], L. Mooney[3], O. Petricoul[3], P. Maguire[3], P. Pal[4], J. Doucet[3], M. Cabanski[3], E. Kamphausen[3], S.J. Oliver[3]. *[1]Charité Hospital; [2]Charité Research Organisation, Berlin, Germany; [3]Translational Medicine; [4]Novartis Pharma AG, Basel, Switzerland*

**Background:** VAY736 is a novel, defucosylated, human IgG1 mAb targeting the receptor for B cell activating Factor of the TNF family (BAFF-R), providing both enhanced antibody-dependent cellular cytotoxicity (ADCC)-mediated depletion of B cells and blockade of BAFF:BAFF-R signaling that drives B cell differentiation, proliferation and survival.
**Objectives:** To clinically evaluate the clinical efficacy of the dual mechanisms of action of VAY736 in patients with pSS, a highly BAFF-driven, systemic autoimmune disease involving lymphocytic infiltration and progressive dysfunction of exocrine glands along with various extra-glandular manifestations.
**Methods:** A single center, randomized, parallel group, double-blind, placebo-controlled trial recruited 27 seropositive pSS patients with EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) $\geq 6$ and residual salivary flow over a 10-month period and randomized for treatment with intravenous VAY736 at either a single high dose, (n=12), a single lower dose (n=6), or with placebo (n=9). Outcomes were measured at baseline and at weeks 6, 12 and 24. The primary outcome was change in ESSDAI at week 12. Secondary outcomes included the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), Short Form-36 (SF-36), Multidimensional Fatigue Inventory (MFI) and global VAS assessments. Additional outcomes included salivary flow rates, Ocular Staining Score (OSS), high resolution salivary gland ultrasound (US) de Vita scores, serum markers of B cell hyperactivity and flow cytometry-determined lymphocyte subsets.
**Results:** Data analyses included all patients. VAY736 was safe and well-tolerated with no drug-related SAE, drop outs or discontinuations. Mean age was 50.5 years with 4 males, 2 in placebo and 1 in each treated arm. Baseline mean ESSDAI scores (range) were 11.5 (6–18), 14.5 (6–31) and 11.1 (6–19) in the high dose, lower dose and placebo arms, respectively. Rapid, profound depletion of circulating B cells was observed in all VAY736-treated patients. The primary endpoint of ESSDAI was reduced within 12 weeks but did not reach clinical or statistical significance. Improvements in VAY736-treated subjects were seen across the clinical secondary outcome measures, particularly for scores of patient and physician global assessments and SF-36 physical. Of note, the higher dose group had more sustained effects on clinical outcomes (e.g., ESSPRI, MFI) at

weeks 6 and 12, while maximal effects in the lower dose group were more evident at the earlier week 6 time point, suggesting reduced VAY736 tissue exposure in some patients by week 12. PD measurements (serum BAFF levels, circulating B cells) confirmed target engagement. A trend in improvement of US scores occurred in the high dose group. There were no consistent changes in salivary flow rate or OSS. Analyses of additional biomarkers are pending.

Baseline/Change from baseline at week 12 as Mean (SD); combined treatment arms represented by VAY736 data
ESSDAI/ESSPRI: EULAR Sjögren's Syndrome Disease Activity Index/ Patient Response Index
MFI: Multidimensional Fatigue Index
Phys/Pat VAS: Physician/Patient Global Visual Analog Scale
SF36: Short Form 36
*For ESSDAI: Bayesian 95% Credibility Interval was presented as CI

**Conclusions:** Despite a limited, single infusion, VAY736 achieved in this early phase trial trends in the primary outcome and across all secondary outcomes. Thus, this treatment was safe and suggests a positive therapeutic effect for this dual mechanisms of action in pSS that warrant further evaluation.

### THU0314 CLINICAL AND IMMUNOLOGICAL CONSEQUENCES OF TOTAL GLUCOSIDES OF PAEONY TREATMENT IN SJÖGREN'S SYNDROME: A RANDOMIZED CONTROLLED TRIAL

Y. Zhou, L. Jin, F. Kong, H. Zhang, Z. Chen, G. Wang, X. Li, X. Li. *Rheumatology and Immunology, Anhui Provincial Hospital, Hefei, Anhui, China*

**Background:** Sjögren's syndrome (SS) is an autoimmune disease and the treatment of SS remains symptomatic. The total glucosides of paeony (TGP) is the active compound extracted from the roots of Paeonia lactiflora Pall. TGP can reduced production of IFN-γ, IL-6 and IL-12, and inhibited dendritic cells. Recently, TGP had been approved in the treatment of rheumatoid arthritis by China State Food and Drug Administration. However, the therapeutic effects of TGP on SS and the mechanisms behind were largely unknown.
**Objectives:** To investigate the clinical and immunological consequences of total glucosides of paeony (TGP) treatment in patients with Sjögren's syndrome (SS).
**Methods:** Forty-five patients with primary SS participated in a randomized, double-blinded, placebo-controlled clinical trial. Patients were assigned randomly to TGP or placebo group in a ratio of 2:1 and followed up for 24 weeks. Clinical assessment was performed by EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), stimulated and unstimulated salivary flow rate, and Schirmer test at week 4, 12, 18 and 24. The proportion of B cells and levels of serum IL-6, TNF-α, IFN-γ and BAFF were measured before and after treatment. This trial was registered on www.chictr.org, with the register number of ChiCTR-TRC-12002325.
**Results:** ESSPRI in the patients who got 3 to 6 score at baseline was significantly reduced in TGP group at 18- and 24-week changed from (4.81±0.60) to (4.15±1.27) ($P$=0.012) and (4.20±1.46) ($P$=0.027). Stimulated salivary flow rate increased at week 24 from (1.80±0.39) to (2.01±0.51) ($P$=0.031) and unstimulated salivary flow rate increased from (1.30±0.92) to (1.55±0.90) ($P$=0.011) in TGP group, but the placebo group showed no significant difference. Erythrocyte sedimentation rate (ESR) was decreased significantly compared to the placebo group at 12- and 24-week from (40.9±18.0) to (29.4±12.2) ($P$=0.003) and (30.4±17.3) ($P$=0.024). The percentage of naive B cells decreased in TGP group from (77.34±12.20)% to (64.59±15.60)% ($P$=0.005) while memory B cells increased at week 24 from (21.79±11.97)% to (34.21±15.48)% ($P$=0.006). The concentrations of TNF-α and IFN-γ decreased in TGP group at week 24 from (32.51±26.67) to (24.22±13.56) ($P$=0.017) and (10.71±8.94) to (6.55±4.88) ($P$=0.022), respectively.
**Conclusions:** TGP appears to improve the glandular secreting function and ameliorate the inflammatory process.
**Acknowledgement:** We thank the patients who participated in the study and Lansen Pharmaceutical Co. Ltd. (Shenzhen, China) which kindly provided drugs. ## SLE, Sjögren's and APS - clinical aspects (other than treatment)

### THU0315 SERUM PROTEIN PATTERN OF SYSTEMIC LUPUS ERYTHEMATOSUS USING PROXIMITY EXTENSION IMMUNOASSAY

A. Petrackova[1], A. Smrzova[2], M. Schubertova[2], P. Schneiderova[1], T. Dyskova[1], M. Skacelova[2], F. Mrazek[1], P. Horák[2], E. Kriegova[1]. *[1]Dept. of Immunology, Palacky University Olomouc; [2]Dept. of Internal Medicine III - Nephrology, Rheumatology and Endocrinology, University Hospital, Olomouc, Czech Republic*

**Background:** Systemic lupus erythematosus (SLE) is a severe autoimmune connective tissue disorder. Current knowledge about the serum protein pattern associated with SLE is still limited.
**Objectives:** To identify SLE-associated serum protein signature using innovative multiplex Proximity Extension ImmunoAssay (PEA).
**Methods:** We investigated the serum levels of 92 inflammation-related proteins in 76 Czech patients with SLE and 24 age-matched healthy control subjects (C) using a highly sensitive multiplex PEA (Proseek Multiplex, Olink Bioscience, Sweden). Statistical tests (Student t-test, Benjamini-Hochberg correction, Principal component analysis (PCA)) were performed using GenEx (Sweden), $P$-value $<0.05$ was considered as significant.
**Results:** When comparing SLE to control subjects, serum levels of 30 proteins were deregulated ($P<0.05$ after multiple comparisons). PCA revealed three proteins distinguishing SLE and C: sirtuin 2 (SIRT2; SLE *vs* C fold change: 2.1, $P$=0.000005), interleukin 18 (IL18; 1.5, $P$=0.00002) and sulfotransferase 1A1 (ST1A1; 2.2, $P$=0.00007). Interestingly, SIRT2 and ST1A1 were not reported in SLE yet; from neuroinflammation there is evidence that SIRT2 regulates NFκB signalling and Toll-like receptors, ST1A1 contributes to resistance to anti-inflammatory treatment. Among other highly-deregulated proteins, we observed elevation of many inflammatory mediators (IL-18R1, CCL4, CSF1, SLAMF1, CD40 and TNFRSF9), and also of Caspase 8, a metalloprotease STAMBP and Axin-1, a modulator of Wnt-signalling pathway ($P<0.0005$) in SLE. Subanalysis of protein pattern in patient phenotypes is ongoing.
**Conclusions:** This first study using PEA identified SLE-associated serum signature, with many of novel proteins not yet reported in SLE. Their exact function and suitability as biomarkers in SLE deserves further investigation.

### THU0316 ISCHEMIC HEART DISEASE AMONG SLE PATIENTS: A CASE-CONTROL STUDY

A. Abu Much[1,2], A. Watad[1], D. Bracco[2], A.D. Cohen[3], H. Amital[1]. *[1]Department of Medicine "B", Sheba Medical Center, Tel hashomer; [2]Sackler Faculty of Medicine, Tel Aviv university; [3]Clalit Health Services, Tel Aviv, Israel*

**Background:** Ischemic heart disease (IHD) is a well identified cause of mortality in SLE patients due to accelerated premature atherosclerosis attributed to both traditional cardiovascular risk factors and to the inflammatory effect of SLE itself (1,2).
**Objectives:** To investigate the incidence and prevalence of IHD among Middle Eastern SLE patients derived from a large, national real-life database.
**Methods:** Using data from the largest HMO in Israel, the Clalit Health Services, we selected for patients with SLE. These patients were compared with age and sex matched controls with regards to the prevalence of IHD in a case-control study. Chi-square and t-tests were used for univariate analysis and a logistic regression model was used for multivariate analysis.
**Results:** The study included 5,018 patients with SLE and 25,090 age and

Logistic regression for IHD (n=30,108)

| Variable | OR | 95% CI | P-value |
|---|---|---|---|
| SLE | 3.774 | 3.344–4.260 | <0.001 |

CI, confidence interval; OR, odds ratio; SES, socioeconomic status.

sex-frequency matched controls. The prevalence of IHD in patients with SLE was increased compared to controls (11.3% and 3.1%, respectively, P<0.001). In a multivariate analysis SLE was associated with IHD (OR 3.77, 95% confidence interval 3.34–4.26).

**Conclusions:** Our data supports that SLE is an independent risk factor for IHD. When evaluating by gender, the risk seems even more substantial in females.

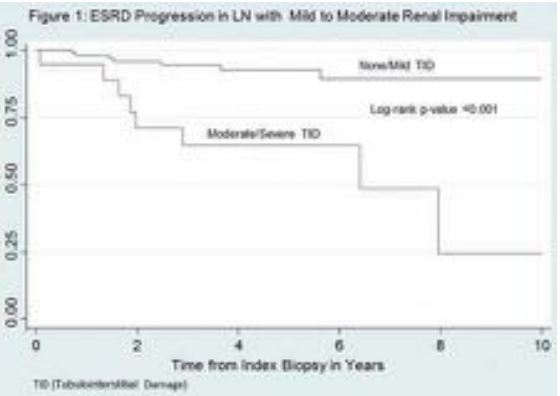
## THU0317 TUBULOINSTERSTIAL DAMAGE IS AN INDEPENDENT PREDICTOR OF END STAGE RENAL DISEASE IN LUPUS NEPHRITIS PATIENTS WITH MILD TO MODERATE RENAL IMPAIRMENT



B. Jovanovic[1], H.N. Khan[1], W. Mowrey[1], P. Izmirly[2], D. Schwartz[1], J. Buyon[2], C. Putterman[1], B. Goilav[1], A. Broder[1]. *[1]Montefiore Medical Center; [2]New York University, New York, United States*

**Background:** Tubulointerstitial damage (TID) is associated with progression to end stage renal disease (ESRD) in lupus nephritis (LN)[1,2]. However, it has not been established whether the association of TID and ESRD holds true in individuals with preserved or only moderately impaired renal function.

**Objectives:** To determine if TID predicts progression to ESRD in LN patients with mild to moderate renal impairment at the time of kidney biopsy.

**Methods:** We identified all adult and pediatric SLE patients (by ACR and/or SLICC criteria) who had an index biopsy consistent with LN between January 2005 and July 2015. Demographic data, comorbidities, medications, laboratory data, ESRD onset, and deaths through December 2015 were ascertained from medical chart reviews, the United States Renal Data Systemic Report, and National Death Index. Renal impairment was defined as mild (chronic kidney disease [CKD] stage 1 or 2, estimated glomerular filtration rate [eGFR] $\geq$60 mL/min/1.73m$^2$), or moderate (CKD stage 2, eGFR$\geq$30 and $<$60 mL/min/1.73m$^2$). TID was defined as the presence of moderate to severe tubular atrophy and/or interstitial fibrosis as reported on the renal biopsies in accordance with the 2003 ISN/RPS criteria. Time to ESRD onset was defined as time from the index biopsy date to incident ESRD date; non-ESRD patients were censored at time of death or the last visit. Kaplan-Meier survival curves and Cox proportional hazards models were used to evaluate whether TID was predictive of ESRD progression adjusting for eGFR (as a continuous variable) and LN class.

**Results:** Of the 131 LN patients with mild to moderate renal impairment (8 (6%) Class II, 58 (44%) Class III/IV, 38 (29%) Class V, and 27 (21%) mixed), 16 (12%) progressed to ESRD. Eighty six percent of ESRD progressors had proliferative or mixed LN vs. 51% of non-ESRD, p=0.02. There were no significant differences with respect to age, sex, race, comorbidity scores, complement levels, anti-dsDNA, or protein to creatinine ratio at index biopsy between ESRD and non-ESRD groups. Median (IQR) baseline eGFR was 65 (51, 75) mL/min/1.73m$^2$ in the ESRD group and 97 (69, 127) mL/min/1.73m$^2$ in the non-ESRD group, p=0.001. TID was present in 12% of biopsies with eGFR$\geq$60 mL/min/1.73m$^2$ and in 35% of biopsies with GFR between 30 and 60 mL/min/1.73m$^2$. Moderate to severe TID was associated with a high risk of ESRD progression (Figure 1, log-rank p-value$<$0.001), HR=8.3, 95% CI: (2.6, 27), p-value$<$0.001, adjusted for eGFR and proliferative or mixed LN. Similarly, TID remained a significant predictor when the analyses were limited to patients with a eGFR$>$60 mL/min/1.73m$^2$, HR=5.6, 95% CI: (1.3, 22.9), p=0.02, adjusted for eGFR.

**Conclusions:** TID was found in a significant proportion of clinically-indicated kidney biopsies in LN patients with mild to moderate renal impairment. The presence of TID was a strong predictor of ESRD progression in these patient independent of eGFR or biopsy class. Further studies are needed to identify factors associated with the presence of TID to develop effective prevention strategies.

## THU0318 THE PREGNANCY EXPERIENCE OF 85 WOMEN WITH SLE FOLLOWED IN A SPECIALIST LUPUS CLINIC COMPARED TO THE GENERAL POPULATION

C.-L.M. Murphy, S. Croca, A. Rahman, I. Giles. *Rheumatology, University College Hospital, London, United Kingdom*

**Background:** SLE affects women of childbearing age. Research suggests that patients with SLE have similar rates of pregnancy as other women but a higher rate of pregnancy loss [1]. Parity may be reduced due to infertility eg. secondary to antiphospholipid syndrome, pregnancy loss or personal choice. Concerns over teratogenic medication, disability and child health have been cited as personal reasons [2].

**Objectives:** Our aim was to carry out a retrospective analysis of the pregnancy experience of women with SLE followed up for a mean of 18 years in a specialist clinic.

**Methods:** Pregnancy data were collected on 85 women with SLE via questionnaire between June and December 2015. Questions focused on parity, number of pregnancies, miscarriages, stillbirths, termination of pregnancy and number of live births. Questions related to pregnancy complications included pre-eclampsia, intrauterine growth retardation (IUGR), abruption placenta, gestational diabetes, caesarean sections (CS) and preterm labour $<$37 weeks. Data on smoking and serology were obtained from the medical records.

**Results:** Of 85 women with SLE, the mean age was 45 years and mean follow-up was 18±11 years. Ethnicity was 53% white, 10.5% Asian, 27% Afro-Caribbean and 9% other. 20% were current/previous smokers. 43.5% were anti-Ro positive. 14% were LA positive, 15% were aCL positive and 8% were anti-β2GPI positive. The questionnaire results are summarised in Table 1, with comparison to UK population figures where they are available.

Table 1

| | SLE (n=85) | UK population average |
|---|---|---|
| Never pregnant | 36.5% | Unknown |
| No children | 47% | 20% at age 45* |
| Miscarriage rate | 22% | 15–20% |
| Elective TOP | 20% | ≈36% by age 45 |
| Average family size (for the 45 who had children) | 1.5 | 1.82 children |
| Number with >3 children | 11% | 14.3%* |

*Office of National Statistics UK.

Among the 45 parous women, there were 83 live births. 80% (36/45) had 1–2 children. 15% had 3 (7/45) children and 4% (2/45) had 4 children. No patient had more than 4 children.

Miscarriages occurred in 22% (19/85); 18% (8/45) had preterm labour, 4.4% (2/45) had hypertension during pregnancy, 9% (4/45) had CS, 4.4% had low birth weight. Other adverse pregnancy outcomes included placental abruption (2.2%), ectopic pregnancy (2.2%), IUGR (2.2%) and stillbirth (twins) (2.2%).

**Conclusions:** The major finding of this study was that almost half the respondents had no children, more than double what one would expect in UK women of the same mean age. This was primarily due to never having been pregnant rather than increased rate of TOP or miscarriage. Further research into the social and/or medical reasons for this avoidance of pregnancy is required. Pregnancy morbidity amongst those who had been pregnant was common especially miscarriage and pre-term labour.

## THU0319 SUBOPTIMAL VITAMIN D LEVELS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Ramos, J.L. Andreu, M. Bascuas, M. Cuadros, M. Espinosa, B.J. Flores, J. Campos, J. Sanz. *Rheumatology, H.U. Puerta de Hierro Majadahonda, Majadahonda, Spain*

**Background:** Systemic lupus erythematosus (SLE) is a systemic autoimmune

disease that mainly affects women of childbearing age. Recent studies suggest a high prevalence of vitamin D insufficiency and deficiency in patients with SLE. Inadequate levels of vitamin D could determinate not only skeletal problems but also a potentiation of autoimmune activity in SLE.
**Objectives:** The purpose of this study was to determine the prevalence of vitamin D insufficiency and deficiency in SLE patients attended in a tertiary care center.
**Methods:** Consecutive patients with SLE seen in the Lupus Clinic of a Rheumatology Service belonging to a high complexity center in the Spanish Public Health System were included. Patients had to fulfill the 1997 ACR criteria for the classification of SLE. Different epidemiological, clinical, laboratory and serological variables were recorded. Levels of vitamin D and PTH, as well as serum levels of calcium, phosphorus, and alkaline phosphatase were systematically determined in all patients serum. Serum vitamin D levels at 25 nmol/L and 75 nmol/L were the cut-off values for vitamin D deficiency and vitamin D insufficiency, respectively. The local ethical committee authorized the study. Descriptive statistics was used to present the results; chi-square test, Student t test, and Mann-Whitney U test were used to establish statistical significance. A $p<0.05$ was considered significant. Statistical analyses were performed by using Stata v12.0.
**Results:** One hundred and twenty patients were included, with a mean age of 51 years. Eighty-nine percent were women and 89% were caucasian. The average time of disease evolution was 13 years. Seventy-six percent of patients were taking hydroxychloroquine, 42% were taking glucocorticoids, and 37% of them were taking calcium plus vitamin D supplements.
Nine percent of patients had vitamin D deficiency and 56% had vitamin D insufficiency. Elevated levels of PTH were detected in 18% of patients with vitamin D insufficiency and in 45% of patients with vitamin D deficiency. There were no statistically significant differences between them and patients with optimal levels of vitamin D. Likewise, no statistically significant association was observed between suboptimal vitamin D levels and skin involvement, photosensitivity, use of photoprotection, use of glucocorticoids, use of antimalarial or use of anticonvulsants.
**Conclusions:** Despite taking vitamin D and calcium supplements, vitamin D deficiency and insufficiency are common among SLE patients. Therefore, it might be advisable to monitor serum vitamin D levels in order to adjust the dose of vitamin D prescribed.

## THU0320 CARDIOVASCULAR RISK PROFILES IN A LUPUS COHORT: THOSE THAT ARE MISSED

D. Boulos[1], R. Koelmeyer[2], E. Morand[1], A. Hoi[1]. [1]*Rheumatology, Monash Health;* [2]*School of Clinical Sciences, Monash University, Melbourne, Australia*

**Background:** Risk prediction models for Cardiovascular Disease (CVD) are based on known risk factors and are used to guide therapy. Amongst these, the Framingham Risk Equation ("Framingham Score")[1] is perhaps most well-known and attempts to moderate risk by targeting ideal lipid and blood pressure levels in those identified as high-risk (defined as an estimated 10-year CVD risk>15%). Systemic Lupus Erythematosus (SLE) is associated with increased CVD risk despite these patients not conforming to conventional CVD risk profiles. Petri *et al* have described a novel SLE-specific cardiovascular risk equation ("SLE Score")[2] that incorporates SLE disease parameters in addition to conventional risk factors.
**Objectives:** To determine the prevalence of high CVD risk amongst a SLE cohort, and to assess the characteristics of patients who might be missed when using conventional CVD risk assessments.
**Methods:** Using data collected via the Monash Lupus Clinic, patients meeting ≥4/11 ACR diagnostic criteria for SLE were studied. A cross-sectional analysis using the most recent data for each patient was used to categorise patient risk via both the "Framingham Score" and "SLE Scores". The characteristics of patients identified as "high-risk" by the SLE Score only (termed the "missed group") were compared to those identified by the Framingham score (the "conventional group") using non-parametric tests (Mann-Whitney U test for continuous and Fisher's exact test for categorical variables).
**Results:** Of 184 patients screened, 146 (79%) had complete data for calculation of the CVD risk scores. Overall, 22 (15%) and 44 (30%) of patients were determined to be at "high-risk" based on the Framingham and SLE Scores respectively. Traditional risk factors such as smoking (18.5%), diabetes (2%) and hypertension (18.5%) were generally lower in this lupus cohort than similar age-matched population rates.[3] Using the SLE Score, 18% (n=27) of patients were newly assigned as high-risk. The "missed group" lacked traditional risk factors, being more likely to be female (81% vs 50%; p-value 0.03), younger (mean age 54 vs 69 years $p<0.01$), with lower blood pressure (systolic BP 132 vs 143; p=0.05) and body-mass index (24.1 vs 28.0 kg/m$^2$; p value 0.02). Of the 49 participants deemed high-risk via either score, 12 (25%) and 2 (4%) were appropriately treated to target BP and lipid targets respectively.
**Conclusions:** In this cross-sectional comparison between cardiovascular risk prediction models, a significant proportion of patients were re-classified as high-risk using a formula that incorporates SLE disease-related parameters. Females were underrepresented using the Framingham Risk Equation, and conventional risk factors were not increased in SLE patients- suggesting a disease specific CVD risk profile. Further evaluation of the disease-specific risk calculator is warranted in long-term prospective studies, including focus on appropriate blood pressure and lipid levels.

## THU0321 THE ASSOCIATION BETWEEN ECHOCARDIOGRAPHIC PARAMETERS AND MORTALITY IN PATIENTS WITH LUPUS NEPHRITIS

D.V. Monova[1], S. Monov[2], K. Kirilov[3], E. Peneva[1]. [1]*Department of Internal Diseases, Medical Institute;* [2]*Department of Rheumatology, Medical University;* [3]*Department of Cardiology, Medical Institute, Sofia, Bulgaria*

**Background:** Systemic lupus erythematosus (SLE) is an inflammatory autoimmune disease that affects multiple organs, with a broad spectrum of manifestations and a clinical status marked by periods of exacerbation and remission, with a variable course and prognosis. Cardiac abnormalities are common in lupus patients even when clinically asymptomatic from cardiac aspect. Echocardiography is an excellent non-invasive tool for cardiac evaluation.
**Objectives:** The aim of this study is to investigate the relationship between echocardiographic parameters and mortality in lupus nephritis (LN) patients.
**Methods:** A total of 258 LN patients who underwent echocardiography during year 1998–2015 were enrolled into this study. In all patients a structural and functional cardiovascular alterations has been described. Association with all-cause and cardiac mortality were examined by the Cox proportional hazards model with adjustments for demographic factors, laboratory variables, medication use and echocardiographic parameters.
**Results:** The median duration of follow-up was 191,72 ± 82,54 months. The frequency of heart complications in LN patients is quite variable and depends on follow-up period. Among 258 LN patients, 94 (36,43%) died during the follow-up period. Of them, 44 patients (46,81%) died of cardiac disease. Disease duration of SLE and proteinuria were risk factors associated with the descent of E/A (E: the peak velocity at rapid left ventricular filling; A: the peak velocity during left atrial contraction) ratio ($p<0,05$). In the multivariate analysis, the presence of cardiac manifestation, high systolic blood pressure (SBP) and serum level of C-reactive protein (CRP), low serum level of albumin, low estimated glomerular filtration rate (eGFR) and decreased left ventricular ejection fraction (LVEF) ($p<0,05$) were independently associated with increased all-cause mortality. Meanwhile, factors correlated independently with an increase in cardiac mortality included the presence of cardiac manifestation, low eGFR, increased left ventricular mass index (LVMI) ($p<0,05$) and decreased LVEF ($p<0,05$).
**Conclusions:** Patients with LN have a higher risk of myocardial involvement, which can result in ventricular dysfunction. Decreased LVEF is associated with all-cause and cardiac mortality, whereas, increased LVMI is an independent risk factor for cardiac mortality in LN patients. These findings indicate the need for rigorous cardiac follow up in patients with LN.

## THU0322 ALTERED QUALITY OF LIFE IS MAINLY ASSOCIATED WITH PATIENT REPORTED OUTCOMES IN PRIMARY SJÖGREN'S SYNDROME PATIENTS: DATA FROM A LARGE THERAPEUTIC TRIAL

D. Cornec[1], V. Devauchelle-Pensec[1], X. Mariette[2], S. Jousse-Joulin[1], J.-M. Berthelot[3], A. Perdriger[4], X. Puéchal[5], V. Le Guern[5], J. Sibilia[6], J.-E. Gottenberg[6], L. Chiche[7], E. Hachulla[8], P.-Y. Hatron[8], V. Goeb[9], G. Hayem[10], J. Morel[11], C. Zarnitsky[12], J.J. Dubost[13], P. Saliou[1], J.O. Pers[1], R. Seror[2], A. Saraux[1]. [1]*CHU Brest, Brest;* [2]*Hôpitaux Universitaires Paris-Sud, le Kremlin-Bicêtre;* [3]*CHU Nantes, Nantes;* [4]*CHU, Rennes;* [5]*Hôpital Cochin, Paris;* [6]*CHU, Strasbourg;* [7]*Hôpital Européen, Marseille;* [8]*CHU, Lille;* [9]*CHU, Amiens;* [10]*Hôpital Bichat, Paris;* [11]*CHU, Montpellier;* [12]*CH, le Hâvre;* [13]*CHU, Clermont, France*

**Objectives:** To identify the main determinants of quality of life (QoL) alteration in patients with active primary Sjögren's syndrome (pSS) participating in a large therapeutic trial.
**Methods:** At the inclusion visit in the TEARS trial, 120 patients with active pSS completed the Short Form survey 36 (SF36), a validated tool measuring the level of QoL. The association of demographic data, patient-reported outcomes (including the EULAR SS Patient Reported Index (ESSPRI) score), objective measurements of dryness and autoimmunity, and the physician evaluation of systemic activity (using the EULAR SS Disease Activity Index (ESSDAI) score) with SF36 physical and mental components were assessed by univariate then multivariate linear regression analyses.

Table 1. Determinants of the Physical Component Summary (PCS) of the SF36 score

| | | Univariate | | Mutivariate model 1 | | Mutivariate model 2 | |
|---|---|---|---|---|---|---|---|
| | | Beta | P | Beta | P | Beta | P |
| General characteristics | Gender (male) | 2.963 | 0.410 | | | | |
| | Age | −0.017 | 0.792 | | | | |
| | BMI>25 | −3,917 | 0,027 | −1.661 | 0.249 | −2.217 | 0.143 |
| | Disease duration | −0,247 | 0,102 | | | | |
| PROs | ESSPRI | −0,301 | <0.001 | N/A | | −0.263 | <0.001 |
| | Global VAS | −0,17 | 0,001 | 0.015 | 0.763 | N/A | |
| | Pain VAS | −0,191 | <0.001 | −0.150 | <0.001 | N/A | |
| | Fatigue VAS | −0,196 | <0.001 | −0.069 | 0.105 | N/A | |
| | Global dryness VAS | −0.053 | 0.215 | | | | |
| | Oral dryness VAS | −0,092 | 0,011 | −0.025 | 0.444 | N/A | |
| | Ocular dryness VAS | −0,058 | 0,059 | −0.041 | 0.124 | N/A | |
| *Objective tests* | Schirmer's test ≤5 mm | 0.287 | 0.873 | | | | |
| | UWSF ≤0.01 mL/min | 3,32 | 0,064 | 1.481 | 0.333 | 1.998 | 0.20 |
| | Abnormal SG biopsy | −0.038 | 0.988 | | | | |
| | Anti-SSA/SSB | 0.307 | 0.889 | | | | |
| *Systemic activity* | Physician VAS | −0.036 | 0.239 | | | | |
| | ESSDAI | −0,335 | 0,007 | −0.161 | 0.128 | −0.185 | 0.10 |

**Results:** SF36 results showed a marked alteration of QoL in this population of patients with active pSS. The strongest predictors of a low QoL (for both physical and mental components, Table 1) were patient-reported symptoms, best assessed using the ESSPRI, with pain and ocular dryness intensity displaying independent association with QoL. Conversely, systemic activity level was not associated to QoL alteration, even in the subset of patients with moderate to high systemic activity as defined by the ESSDAI.
**Conclusions:** pSS cardinal symptoms (dryness, fatigue and pain) are the major predictors of QoL alteration and should be targeted in future therapeutic trials in addition to systemic involvement.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3654

## THU0323 PREDICTORS OF DISEASE SEVERITY, LYMPHOMA AND DEATH: PREVALENCE IN PATIENTS REGISTERED ON THE UNITED KINGDOM PRIMARY SJÖGREN'S SYNDROME REGISTRY

E. Lea[1], B. Hargreaves[1], D. Lendrem[2], S. Mitchell[1], V. Hindmarsh[1], S. Bowman[3], B. Griffiths[1], W.F. Ng[1] on behalf of UK Primary Sjögren's Syndrome Registry (UKPSSR). *[1]Newcastle upon Tyne Hospitals; [2]Newcastle University, Newcastle upon Tyne; [3]University Hospital of Birmingham, Birmingham, United Kingdom*

**Background:** There has been much research aimed at elucidating key biological and clinical features which predict severity of disease and development of lymphoma in patients with primary Sjögren's syndrome (pSS). Key biological predictors identified include the presence of leukopenia or lymphopenia, hypocomplementaemia, cryoglobulinaemia, monoclonal gammopathy; key clinical predictors include younger age at time of symptom onset or diagnosis, peripheral neuropathy, salivary gland enlargement and skin involvement (particularly palpable purpura) [1–4]. The UK Primary Sjögren's Syndrome Registry (UKPSSR) is a MRC funded patient cohort, devised to facilitate research into pSS to improve understanding of the condition.
**Objectives:** Ascertain the prevalence of putative clinical predictors amongst UKPSSR patients. Explore the relationship between demographics, clinical parameters, disease severity and lymphoma development.
**Methods:** Patients were identified on the UKPSSR (n=868), those with insufficient data were excluded from analysis (n=36). Frequency of the predictors was calculated for remaining 832 patients. Patients were assigned a value for each predictor: 1 for present, 0 for absent. These values were then added to provide the prevalence of each predictor within the cohort, and a cumulative score for each patient. Each patient had 2 cumulative scores: one for disease severity and risk of death, the other for risk of lymphoma. Patients with a recorded age of pSS symptom onset (n=739) were analysed to investigate the relationship between age of onset and development of lymphoma. SPSS used for statistical analysis.
**Results:** Pearson Chi-squared analysis found a statistically significant (p=0.004) increased incidence of lymphoma in patients presenting with symptoms of pSS before the age of 35. Predictors of lymphoma development were more common in patients whose symptoms started between age 20–34 (p=0.05). Patients with diagnosed lymphoma had a higher cumulative lymphoma risk score than patients who did not have lymphoma (p=0.05). Predictors of severe disease were found to be more common in patients whose symptoms began before age 35 (p=0.05).
**Conclusions:** This analysis corroborates the findings of previous research showing an increased lymphoma prevalence in patients presenting with pSS at a younger age [4]. It also finds a statistically significant link between poor prognostic features and development of lymphoma as described in the literature [2,3]. Further statistical analysis will aim to establish the link between each predictor and the development of systemic manifestations of pSS, baseline and cumulative ESSDAI scores and lymphoma.

| Predictor of disease severity | Number | % |
|---|---|---|
| Cytopenia | 274 | 32.9 |
| Hypocomplementaemia (C3 or C4) | 133 | 16.0 |
| Cryoglobulinaemia | 8 | 1.0 |
| Peripheral neuropathy | 90 | 10.8 |

## THU0324 OBESITY INTERFERES WITH THE INFLAMMATORY STATUS IN LUPUS PATIENTS

F.M.M. Santos[1], J.C. Lino[2], K.C. Correia[3], R. Reis[4], M.V. Andrade[5], R.W. Telles[3], M.I. Correia[6], C.C. Lanna[3] on behalf of Lupus Erythematosus Systemic Research Group (GPLES). *[1]Rheumatology, Medical School and Hospital das Clínicas, Universidade Federal of Minas Gerais; [2]Nutrition; [3]UFMG, Belo Horizonte, Brazil; [4]Statisctic; [5]Medical clinic; [6]Cirurgical, UFMG, Belo Horizonte, Brazil*

**Background:** High frequency of obesity among SLE patients has been described, however, it is unknown whether obesity can modify the inflammatory status of those individuals.
**Objectives:** To analyze the profile of cytokines and evaluate whether obesity interferes with the inflammatory status of SLE patients.
**Methods:** Cross-sectional study included 189 women with SLE and 70 controls, older than 18 years, were included in the study. Data related to clinical and laboratory manifestations besides medication use were assessed. Disease activity was measured by SLEDAI-2K and irreversible cumulative damage by SLICC-ACR/DI. Nutritional status was assessed by body mass index (BMI). Serum concentrations of IL6, IL10, IL17, TNFα, soluble TNFα receptors 1 (sTNFR1) and 2 (sTNFR2) were analyzed using high sensitivity cytometric bead array and adipokines (leptin and adiponectin) by ELISA kits. Multiple linear regression method was performed for multivariate analysis. In order to adjust the multivariate models the following variables were included: age, menopause, disease activity, use of antimalarial drugs, immunosuppressive and current dose of corticosteroids.
**Results:** In lupus patients group, mean (SD) values of age and disease duration were, respectively, 37.5 (10.0) and 9.1 (6.3) years. Considering BMI, 72 (38.1%) patients were classified as eutrophic, 64 (33.9%) as overweight and 53 (28.0%) as obese. The mean (SD) cumulative dose of prednisone was 32.9 (26.1) g, and of the current daily dose of prednisone was 10.4 (12.9) mg. The median (IQR) disease activity and damage index scores were 2 (0–6) and 0 (0–1), respectively. Serum levels of cytokines were higher in lupus patients when compared to controls [IL6 ($p<0.001$), sTNFR1 (p=0.028), sTNFR2 (p=0.003), IL10 ($p<0.001$), leptin (p=0.044) and adiponectin ($p<0.001$)]. Only the IL17 levels (p=0.518) did not differ statistically between the two groups. Higher BMI correlated with age (rs =0.335; p = <0.001), age at diagnosis (rs=0.319; $p\leq0.001$) and with less years of education (rs= -0.204; p=0.005). No correlation was observed between BMI and disease activity (rs: 0.116 p=0.113) as well as with damage index (rs:-0.080 p=0.309). Higher concentrations of IL6 (rs=0.246, p=0.002), IL17 (rs=0.195, p=0.014) and leptin (rs=0.430; $p<0.001$) were positively and independently correlated with BMI.
**Conclusions:** This study showed higher serum levels of cytokines and adipokines in SLE patients. Also, higher BMI was correlated with higher concentrations of IL6, IL17 and leptin in the study group, suggesting that BMI could interfere, regardless of disease activity, with the inflammatory profile of women with SLE.

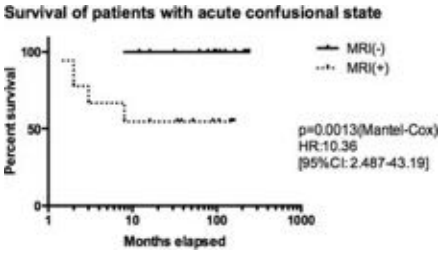
## THU0325 LONG-TERM OUTCOME OF PATIENTS WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME: A RETROSPECTIVE MULTICENTER STUDY



F. Dall'ara[1], M. Taraborelli[2], R. Reggia[1], M. Fredi[2], L. Andreoli[1], M. Gerosa[3], A. Hoxha[4], L. Massaro[5], M. Tonello[4], P. Cacoub[6], N. Costedoat-Chalumeau[7], F. Franceschini[2], P.L. Meroni[3], J.C. Piette[6], A. Ruffatti[4], G. Valesini[5], E.N. Harris[8], A. Tincani[1]. *[1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia; [2]Rheumatology and Clinical Immunology, Spedali Civili of Brescia, Brescia; [3]Division of Rheumatology, Department of Clinical Sciences and Community Health, Ospedale Gaetano Pini, University of Milan, Milan, Italy, Milan; [4]Rheumatology Unit, Department of Medicine - DIMED, University of Padua, Padua, Italy, Padua; [5]Internal Medicine and Medical Specialties Department, Policlinico Umberto I, "La Sapienza" University of Rome, Rome, Italy, rome, Italy; [6]Internal Medicine Department, Centre de référence maladies auto-immunes et systémiques rares, AP-HP, Hospital "Pitié-Salpêtrière", "Pierre et Marie Curie Paris VI" University, Paris, France; [7]Internal Medicine Department, Cochin Hospital, "René-Descartes Paris V" University, Paris, France, Paris, France; [8]Vice Chancellor Emeritus, University of the West Indies, Kingston 7, Jamaica, West Indies, Jamaica*

**Background:** Data on the long-term outcome in primary antiphospholipid syndrome (PAPS) patients are still very limited.
**Objectives:** To assess the long-term frequency of recurrences, organ damage, severe comorbidities, mortality and evolution in connective tissue disease (CTD) in PAPS patients.
**Methods:** Medical records of PAPS patients followed in 6 centers for ≥15 years were retrospectively reviewed. Chi square for categorical and Student t test for continuous variables were used. $P<0.05$ was considered significant.
**Results:** One hundred and fifteen patients (88% females) followed between 1983 and 2014 with a mean age at diagnosis of 33 (±10) years and mean follow-up of 19 (±3.5) years were studied. Fifty-one patients (44%) had at least a thrombotic event during follow-up for a total of 75 events and an annual incidence of 3.5%. Thromboses were more frequent in patients with previous thrombotic history (p:0.002,OR:4.8, 95%CI:1.6–14.7). There was a tendency towards anticoagulant treatment being not protective against recurrences (p:0.063). Six patients (5%) had a catastrophic event. Fifty-two women had 87 pregnancies, successful in 78% of cases. Twenty-nine percent of patients had functional damage. Damage was significantly associated with a thrombotic history (p:0.004,OR:13.9,95%CI:1.8–288.4) and to arterial events ($p<0.001$,OR:7.9,95%CI:2.7–24.3) especially stroke, but not to demographics, serology or treatment. Twenty-four major bleeding episodes were recorded in 18 patients, all on anticoagulants. Severe infections affected 6 patients (5%) with 1 fatality. A solid cancer was diagnosed in 8 patients (7%). One patient (1%) with a chronic bowel ischemia died for sepsis. Eleven percent of patients developed a CTD and 14% another autoimmune disease.
**Conclusions:** Despite therapy, a high proportion of patients experienced new thrombotic events,while pregnancy outcome was significantly improved. Organ damage developed in a significant proportion of patients and was associated with arterial events. The risk of evolution in CTD has to be considered.

## THU0326 BRAIN MRI IN PATIENTS WITH ACUTE CONFUSIONAL STATE OF DIFFUSE PSYCHIATRIC/NEUROPSYCHOLOGICAL SYNDROMES IN SYSTEMIC LUPUS ERYTHEMATOSUS

G. Abe[1], Y. Arinuma[1], Y. Sakuma[1], H. Kikuchi[2], S. Hirohata[1]. *[1]Rheumatology and Infectioud diseases, Kitasato University School of Medicine, Sagamihara; [2]Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan*

**Background:** Neuropsychiatric systemic lupus erythematosus (NPSLE), especially diffuse psychiatric/neuropsychological syndromes (diffuse NPSLE), is one of the most difficult complications of the disease. For the evaluation and the diagnosis of central nervous system manifestations, including NPSLE, brain MRI is a very useful tool to detect the various abnormalities. We previously disclosed that patients with diffuse NPSLE and MRI abnormalities have more severe inflammation in the central nervous system compared with those without MRI abnormalities, as evidenced by poorer prognosis. Of note, acute confusional state (ACS) is the most recalcitrant manifestation in diffuse NPSLE. However, it remains unclear whether abnormalities in brain MRI still have any influences in patients with ACS.
**Objectives:** The aim of this study is to explore the differences in clinical characteristic between ACS patients with and without MRI abnormalities.
**Methods:** Thirty-six patients with ACS admitted to our University Hospitals from 1992 to 2015 were exhaustively enrolled in this study. Their medical charts and brain MRI scans were reviewed. The relationship of MRI abnormalities with various parameters was analyzed.
**Results:** As many as 19 of 36 patients (52.8%) had abnormal MRI findings. MRI findings improved after treatment in 14 of 19 patients for whom follow-up studies were available. Among the 5 patients without improvement of MRI findings, 4 patients died from active NPSLE itself. MRI abnormalities were not correlated with the age at the onset of ACS, the disease duration of SLE, the presence of anti-DNA antibody, anti-phospholipid antibodies, or anti-ribosomal P antibodies, and the levels of IL-6 in sera or cerebrospinal fluid. Notably, MRI abnormalities were significantly associated with the presence of serum anti-Sm antibodies (p=0.0005). Finally, the presence of MRI abnormalities in patients with ACS significantly increased the mortality (p=0.0013, HR=10.36 [95% CI: 2.487–43.19]) (figure).

**Conclusions:** These results demonstrate that patients with ACS of diffuse NPSLE with MRI abnormalities have more severe inflammation in the central nervous system, as evidenced by poorer prognosis. The data also indicate that anti-Sm in involved in the development of MRI abnormalities in ACS.
**Disclosure of Interest:** None declared

## THU0327 COMPARISON OF IMMUNOENZYMATIC ASSAY AND CRITHIDIA IMMUNOFLUORESCENCE TEST FOR THE DETECTION OF ANTI-DOUBLE STRAND DNA ANTIBODIES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Orsolini[1,2], M.R. Snyder[3], C.S. Crowson[2], J.L. Frinack[3], M.G. Kevin[2]. *[1]Rheumatology, University of Verona, Verona, Italy; [2]Rheumatology; [3]Immunology Lab, Mayo Clinic, Rochester, United States*

**Background:** Anti double strand DNA (dsDNA) antibodies are one of the immunologic hallmarks used to identify patients with systemic lupus erythematosus (SLE). However, they can be seen in patients with other connective tissue diseases (CTDs) on occasion. These auto-antibodies can also be drug-induced by medications such as anti-TNF$\alpha$ agents. Different methods are available for their detection. In the past, radioimmunoassays (RIA) and immunofluorescence by Crithidia (CLIFT) were commonly used. More recently, immunoenzymatic assays (ELISA) have been widely utilized.
ELISA assays are much faster, cheaper and easier to perform than other methods such as CLIFT and now are the most common method used by immunology laboratories.
The Crithidia test is still used in clinical practice, often for the purpose of confirmation after ELISA or further testing if ELISA is negative, but its real usefulness needs to be more clearly defined.
**Objectives:** Investigate the relation between dsDNA Abs measured by CLIFT and ELISA. Define the clinical role for CLIFT testing.
**Methods:** 1000 consecutive adult patients tested for anti dsDNA by ELISA in Mayo Clinic Rochester immunology lab from September to December 2015 had their sera tested also by CLIFT. Laboratory, clinical data and history were reviewed. For ELISA we used Quanta Lite dsDNA ELISA kit by Inova Diagnostic, taking as stated by the manufacturer for negative value below 30 IU/ml, for borderline between 30 and 75 IU/ml and for positive above 75 IU/ml. For CLIFT we used Crithidia Luciliae Kit by Kallestad, considering positive the samples with immunofluorescence signal from the kinetoplast or from both the kinetoplast and the nucleus.
**Results:** CLIFT showed a very high specificity (99%) but a low sensitivity (14%) for patients with SLE. ELISA had specificity close to CLIFT (92–95%) but with a substantially better sensitivity (36–47%). ELISA performed better considering borderline as negative (positive predictive value [PPV] with borderline as negative 68% vs 63% as positive).

Table 1. Samples by ELISA and CLIFT results, SLE samples out of total samples for each group, with percentage

| | ELISA | | | |
|---|---|---|---|---|
| | Negative | Borderline | Positive | Total |
| Crithidia | | | | |
| Negative | 119/817 (15%) | 26/49 (53%) | 57/93 (61%) | 202/959 (21%) |
| Positive | 4/7 (57%) | 1/3 (33%) | 27/31 (87%) | 32/41 (78%) |
| Total | 123/824 (15%) | 27/52 (52%) | 84/124 (68%) | 234/1000 (23%) |

**Conclusions:** CLIFT is very specific but its low sensitivity limits its usefulness.
New generation ELISA has good performance, with high specificity and good sensibility.
A negative test by ELISA is most of the time negative also by Crithidia, and among the rare ELISA-/CLIFT+ few patients have SLE, so there's no need to run Crithidia in ELISA negative patents.
Among the ELISA positive, Crithidia could add value for some patients with SLE, but always keeping in mind the limit of sensitivity.

## THU0328 A COMPREHENSIVE EVALUATION OF SERUM AUTOANTIBODIES IN PRIMARY SJÖGREN'S SYNDROME

C. Capaldo[1], G. Carvajal Alegria[2], B. Bendaoud[1], S. Jousse-Joulin[2], A. Saraux[2], J.-O. Pers[1], V. Devauchelle-Pensec[2], Y. Renaudineau[1]. *[1]Immunology, CHRU Morvan; [2]Rheumatology, CHRU Cavale Blanche, Brest, France*

**Background:** Conventional antibodies are well described and studied in primary Sjögren syndrome, nevertheless patients can also present unconventional autoantibodies.
**Objectives:** The objective of this study was to investigate the prevalence of a large panel of conventional and unconventional autoantibodies (Ab) in a well-characterized population of patients with primary Sjögren's syndrome (pSS).
**Methods:** Two hundred and twenty six pSS patients benefiting from a comprehensive clinical and radiological assessment were recruited. A new technique based on chemiluminescence (ISYS-IDS) was selected, in 44 patients, to assay 17 autoantigens including SSA/Ro (52+60 kDa), SSB/La, dsDNA, centromere, Sm, U1-snRNP, Scl70, Jo1, cardiolipin, β2-GPI, CCP2, PR3, MPO, GBM, transglutaminase (IgA), and deaminated gliadin (IgA&IgG). If positive, the presence of Ab was validated by another technique. The study was completed by the search for anti-nuclear Ab (ANA) on HEp-2 cells and rheumatoid factors (RF) against human and rabbit IgG.
**Results:** Search for conventional Ab showed ANA (71.7% at 1:320), anti-SSA/Ro Ab (61.1%), anti-SSB/La Ab (31.0%, all anti-SSA+) and IgM RF (44.2%). The triple Ab association (ANA+SSA+RF) rather than the SSA/SSB association was associated with an earlier diagnosis, an active immunological profile (hypergammaglobulinemia, erythrocyte sedimentation rate) and a salivary gland involvement (lymphocyte infiltration, ultrasonography and enlargement). Three patients out of 44 (6.8%) had unintended Ab in current practice directed against centromere, Jo1, and dsDNA plus IgG deaminated gliadin Ab but without associated clinical signs.
**Conclusions:** The ability to combine a wide range of autoantibodies can lead to defining new subgroups of pSS patients for precise disease characterization, patient stratification and response prediction.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3392

## THU0329 RETROSPECTIVE ANALYSIS OF CLINICAL FEATURES, DISEASE COURSE AND OUTCOME OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN KYRGYZSTAN

G. Koilubaeva[1], E. Aseeva[2], S. Soloviev[2], E. Nasonov[2], T. Reshetnyak[2], A. Djumagulova[1], V. Eralieva[1], E. Karimova[1]. *[1]Rheumatology, National Center of Cardiology and Internal Medicine Named After Academician M. Mirrahimov, Bishkek, Kyrgyztan; [2]Rheumatology, Federal State Research Institution (FSRI) named after V.A. Nasonova, Moscow, Russian Federation*

**Background:** Systemic lupus erythematosus (SLE) is a devastating disease affecting different organs, ultimately leading to organ failure and death. To date, there are no data regarding the real-life picture of SLE in Kyrgyzstan.
**Objectives:** To define retrospectively the pattern of clinical features, disease course and outcome of patients with SLE in Kyrgyzstan.
**Methods:** The retrospective study comprised of 107 consecutive patients with confirmed SLE, who underwent inpatient care in the department of rheumatology of the National Center of Cardiology and Internal Medicine (NCCIM) from 2001 to 2011. Subsequently enrolled patients were followed-up on a regular basis. Study protocol included clinical, instrumental, laboratory and immunological parameters obtained from specially designed registry database of NCCIM (BLIPS 8, ADS-Limathon). All patients fulfilled the revised ACR criteria for SLE. Age, gender, disease activity index (SLEDAI-2K), SLICC Damage Index (SDI) and other parameters obtained at the time of first hospitalization and subsequently in 75 cases out of 107 after 5 years of follow-up observation were included for the statistical analysis. Immunological analysis included determination of anti-dsDNA and anti-Sm antibodies "ANA-LIA-Max 17". Date and cause of death were determined according to the primary medical records.
**Results:** Vast majority of patients (79.4%) enrolled in this study were from the northern part of the country. The study included 91.5% women and 8.4% men with a mean age 30 years and mean disease duration - 2.0 years. It took from 6 months to 3 years since the onset of symptoms to the verification of the diagnosis. Majority of patients (49.5%) were with subacute variant of the disease. Based on disease activity index, patients with moderate and high grade of disease activity were 46.7% and 44%,respectively. Within 5-year follow-up observation of 75 out of 107 patients the remission was achieved in 3.7%, and the low grade disease activity in 6.4% patients. In all cases upon a significant decrease in disease activity, there was a statistically significant increase in SDI score for 1 or higher points. Various irreversible organ damages were found in almost half of the cases (47.6%) at a mean of 2.0 years from the onset of the disease. Majority of patients showed low (28.7%) and moderate (28.3%) SDI score. During observation 27 (36%) of 107 patients died. The main causes of death were active SLE and its complications involving different organ damages: kidney (29.6%), lung (22%) and combined central nerves system (CNS) and kidney (11%). Overall mortality from the concomitant infection was 18.7%, prominently from the infection of the respiratory system, among them 42.7% with severe pneumonia and progressive respiratory failure.
**Conclusions:** The study identified that progressive organ damages and infectious complications involving respiratory system were associated with poor prognosis and outcome of patients with SLE in Kyrgyzstan.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1617

## THU0330 VALIDIITY OF PROTEIN-TO-CREATININE RATIO IN AN UNTIMED URINE SPECIMEN AND ESTIMATED GLOMERULAR FILTRATION RATE AS MEASURES OF PROTEINURIA AND RENAL FUNCTION IN PATIENTS WITH LUPUS NEPHRITIS

H. Nishina, Y. Katsumata, M. Hanaoka, Y. Kawaguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** In 2006, the American College of Rheumatology (ACR) Ad Hoc Committee on Systemic Lupus Erythematosus (SLE) recommended the urinary protein level in a spot (untimed) urine specimen (determined as urinary protein-to-urinary creatinine ratio; spot P/C ratio) over a 24-hour urine protein excretion. In addition, the committee stated that renal function refers to the estimated glomerular filtration rate (GFR) and selected the MDRD study equation. However, several subsequent reports suggested that the spot P/C ratio may be inaccurate in the assessment of the degree of proteinuria in lupus nephritis (LN). In addition, there is no consensus as to which estimating equation is preferred for estimated GFR in LN.
**Objectives:** We aimed to evaluate the validity of spot P/C ratio and estimated GFR by the modified MDRD study equation as measures of proteinuria and renal function in patients with LN.
**Methods:** A total of 61 patients with active LN who were admitted to our hospital from 2010 through 2015 were included. LN was pathologically confirmed in 51 patients and renal biopsy was not performed in the other 10 patients. In addition, 22 SLE patients without active LN in whom spot P/C ratio, 24-hour urine protein excretion, estimated GFR, and 24-hour urine creatinine clearance were measured were also included. All the patients met the revised ACR classification criteria for SLE. Clinical and laboratory data were retrospectively collected from the electronic medical records and statistically analyzed.
**Results:** The spot P/C ratio and the 24-hour urine protein excretion were moderately correlated (n=64, Pearson's $r$ =0.62). However, the Bland-Altman plot demonstrated proportional bias (progressive deviation with values). Agreement of the spot P/C ratio $\geq$0.5 and the 24-hour urine protein excretion $\geq$0.5 g was moderate (Cohen's $\kappa$ =0.56) whereas that of $\geq$0.2 was almost perfect ($\kappa$ =0.83). Measured 24-hour urine creatinine excretion ranged from 220 mg to 2120 mg; the mean and median values were 860 mg and 840 mg, respectively. Among the 10 patients in whom serial data could be obtained in more than 3 times, the spot P/C ratio and the 24-hour urine protein excretion were highly correlated ($r$ =0.87 to 0.99), except for 2 patients ($r$ = -0.30 and 0.68, respectively). In these serial samples derived from the 8 patients, there was substantial agreement between the spot P/C ratio and the 24-hour urine protein excretion about whether increased or decreased compared to previous data ($\kappa$ =0.65). The estimated GFR by the modified MDRD study equation and the body surface area (BSA) corrected 24-hour urine creatinine clearance were moderately correlated (n=81, $r$ =0.62). However, the Bland-Altman plot demonstrated both fixed and proportional bias. Agreement of the estimated GFR and the BSA-corrected 24-hour urine creatinine clearance $\geq$60 (ml/min/1.73 $m^2$) was moderate ($\kappa$ =0.48).
**Conclusions:** Our results supported the validity of spot P/C ratio and estimated GFR by the modified MDRD study equation as convenient screening and monitoring measures of proteinuria and renal function in patients with LN. However, agreement between these convenient measures and measures based on 24-hour urine collection is not always good. Spot P/C ratio and estimated GFR should be used with attention to their limitation.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1896

## THU0331 OUTCOME OF PREGNANCY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS, PREVALENCE OF MATERNAL, OBSTETRIC, AND FETAL COMPLICATIONS

H. Alkoky, N. Baghdadi, J. Al Saleh. *dubai health authority, Dubai, United Arab Emirates*

**Background:** Systemic lupus erythematosus (SLE) is a chronic disease affecting mainly women in childbearing age. Studies have shown that pregnancy in SLE women puts the mother and the fetus at risk of serious adverse events [1]. The prevalence of these events is under reported in the Arab countries. This study is to examine the pregnancy outcomes in patients with SLE.
**Methods:** We have retrospectively analyzed the medical files, and electronic medical records of all pregnant patients with SLE attended our Rheumatology Clinic between 2007 to 2014. All patients met ACR classification criteria for SLE. We have excluded patients diagnosed with DM, hypertension, chronic kidney disease before the onset of lupus.
We captured the following data: patient demographic number of pregnancies after the onset of SLE, pregnancy outcomes, maternal complications during and after pregnancy.
**Results:** We identified 150 pregnancies in 64 patients with lupus, and 57 (89%)

patients were Arabs. The total number of live birth was 105 (70%). An adverse fetal event was observed in 48 (32%) pregnancies. Total number of miscarriages was seen 43 (28.6%), six (4%) were induced abortions. Two died in utero (1%) and there was one neonatal death (1%). 44 (29%) were born below 2,500g, four were premature (less than 37 weeks) (3%), intrauterine growth retardation was observed in 19 (12.6%) and four born with malformation (3%). Obstetric complications occurred in 30 (20%) pregnancies, 5 (3%) had pre-eclampsia, 5 (3%) had gestational diabetes, and one had postpartum hemorrhage (1%). Maternal complications were detected in 20 (13.3%) pregnancies, lupus flare was observed in 18 (12%), five had thrombosis (3%), and no death.

**Conclusions:** Pregnancy in lupus is often associated with an adverse maternal and fetal outcome independent by disease activity.

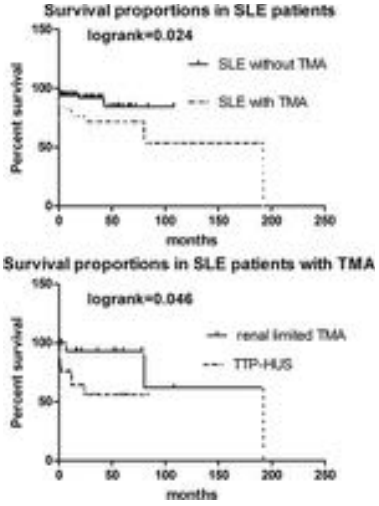
## THU0332 THE PREDICTIVE RISK FACTORS AND PROGNOSES OF THROMBOTIC MICROANGIOPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS



J. Li, Z. Zhang. *Rheumatology and Clinical Immunology Department, Peking University First Hospital, Beijing, China*

**Background:** Systemic lupus erythematosus (SLE) with thrombotic microangiopathy (TMA) has been reported in numerous patients with high mortality and poor renal prognosis. The risk factors and prognoses of these patients remain unknown.

**Objectives:** The aim of this study is to investigate the predictive risk factors of TMA in SLE patients and analyze the prognoses.

**Methods:** Clinical and laboratory parameters of 42 patients (SLE with TMA) and 84 patients (active lupus patients without TMA) were retrospectively analyzed. Clinical and laboratory data was also compared between 17 patients with renal-limited TMA and 25 patients with TTP-HUS. Logistic regression and Kaplan-Meier survival curves were statistically tested with the logrank test. HRs and their 95% CIs were calculated using the multivariate Cox proportional-hazards model.

**Results:** SLE patients with TMA suffered more neurological and cardiac involvements, as well as poor renal function. More plasma was exchanged (42.9% vs. 2.4%) and infused (64.3% vs. 40.5%) in these patients. Serological creatinine and C-reactive protein were independent risk factors for TMA. TMA patients presented poorer outcome (P=0.024), while a longer survival was expected in renal-limited TMA patients (P=0.046). In lupus patients with TMA, serum creatinine value (hazard ratio=1.005, P=0.014) and C-reactive protein levels (hazard ratio=1.009, P=0.058) predicted poor outcome.

**Conclusions:** Serum creatinine value and C-reactive protein levels were predictive for lupus with TMA. Renal-limited TMA patients presented relatively better outcome than patients with TTP-HUS.

Torrente[24], L. Silva[25], A. FNebro[26], I. Rua[27] on behalf of RELESSER-EASSER. *[1]H; [2]IBI, Vigo; [3]H, Coruña; [4]H, GMarañon; [5]H, 12Oct; [6]H, Sierrallana; [7]U, Vigo; [8]H, GTrias; [9]H, Torrejon; [10]H, Povisa; [11]H, Navarra; [12]H, P.Asturias; [13]H, Salamanca; [14]H, Valdecilla; [15]H, León; [16]H, PHierro; [17]H, Basurto; [18]H, GCanaria; [19]H, Tenerife; [20]H, VMacarena; [21]H, Zaragoza; [22]H, Murcia; [23]H, Paz; [24]H, Hospitalet; [25]H, Guadalajara; [26]H, Málaga; [27]H, Negrin, Spain*

**Background:** Mortality in SLE has improved over the last decades. Outcome measures as damage become more important.

**Objectives:** To study damage manifestations and the timing of their appearance.

**Methods:** In the 1st transverse phase of RELESSER, accumulated information on 400 variables per patient at the time of the last evaluation was collected. We evaluated damage manifestations in each system and the temporal relationship of their appearance with the time of SLE diagnosis.

Cumulative incidence function for damage was estimated.The impact on mortality was studied controlling for sex, race, age at diagnosis and delay of diagnosis of SLE by Cox regression.

**Results:** 2,662 SLE patients had the dates of presentation of each event of damage: 2,417 (91.0%) women, 2,402 (92.8%) Caucasian, mean age (±SD) 34.0 (±13.6) years at the time of diagnosis. The mean follow-up time was 115.6 (±50.8) months. 112 (4.2%) patients died.

At the time of the study 917 (34.4%) patients had at least 1 damage manifestation, the mean number of systems per patient with at least 1 damage manifestation was 0.54 (±0.92) and the mean SDI score was 0.65 (±1.2).

The systems more frequently damaged were musculoskeletal (MS) (11.9%), ophtalmic (7.8%) and cardiovascular (CV) (5.9%).In the 1st year after SLE diagnosis, the cumulative incidence (CI 95%) of damage in at least 1 system was 7.4% (6.4–8.4), at 5 years 18.9% (17.3–20.4) and after more than 10 years 29.2% (27.3–31.1).The systems damaged at earliest stages, 1 year after SLE diagnosis, were: MS 1.7% (1.2–2.2), neuropsychiatric 1.3% (0.8–1.7), renal 1.2% (0.8–1.6) and CV 0.9% (0.6–1.3).

The rate of increase of damage is significantly higher ($p<0.001$) short time after SLE diagnosis. The proportion of patients with damage in at least 1 system at 5 and 10 years was 18.9% (17.3–20.4) and 29.2% (27.3–31.1). While in the 1st year 7.4% of patients present damage in any system, only 2.9% per year do so since the 1st to the 5th year after diagnosis and, between the 5th and 10th year there was only an annual increase of damage of 2.1%.Risk of death is multiplied by 2.04 (1.7–2.3) at the time that a new system is damaged. Significant impact on neuropsychiatric, renal, pulmonary, CV systems and malignancy was found, with multiplicative risk factors of 2.0, 1.8, 2.8, 1.7 and 2.7 respectively.

**Conclusions:** Damage occurs already in early stages of the disease. It appears early in MS, neuropsychiatric and kidneys. The increase of damage is greater in the 1st year after SLE diagnosis. The accumulation of visceral damage increases the mortality rate.

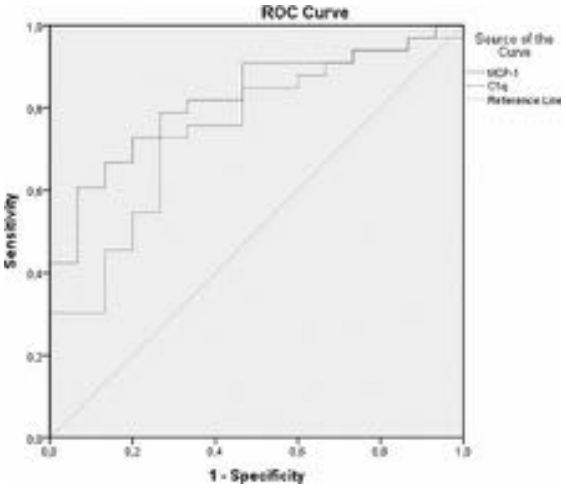
## THU0334 A LONGITUDINAL ANALYSIS OF CHANGE IN LUPUS NEPHRITIS IN AN INTERNATIONAL INCEPTION COHORT USING A MULTISTATE MARKOV MODEL APPROACH

J.G. Hanly on behalf of Systemic Lupus International Collaborating Clinics (SLICC). *Rheumatology and Medicine, Dalhousie University and Nova Scotia Health Authority, Halifax, Canada*

**Background:** Patients with lupus nephritis (LN) may have improvement or deterioration in renal status over time.



**Objectives:** To capture bidirectional change we used a reversible multistate

Markov model to study transitions in glomerular filtration rate (GFR) and proteinuria (PrU) in a prospective, international, inception cohort of SLE patients receiving standard of care.
**Methods:** Patients were evaluated at enrollment and annually. LN was identified from the ACR classification criteria and/or renal biopsy. Data included medications, estimated GFR (eGFR) and PrU (ePrU), disease activity (SLEDAI-2K), organ damage [(SLICC)/ACR damage index (SDI)] and lupus autoantibodies including IgG anticardiolipin (aCL) and lupus anticoagulant (LAC). GFR states were defined: state 1 (eGFR: >60 ml/min); state 2 (eGFR: 30–60 mL/min); and state 3 (eGFR: <30 ml/min). Similarly, PrU states were defined: state 1 (ePrU: <0.25 gr/day); state 2 (ePrU: 0.25–3.0 gr/day); and state 3 (ePrU: >3.0 gr/day). Multistate models were used to provide estimates of relative transition rates and state occupancy probabilities for various time periods.
**Results:** Of 1,826 SLE patients, 89% were female, 49.2% Caucasian with mean±SD age 35.1±13.3 years. The mean disease duration at enrollment was 0.5±0.3 years and follow-up was 4.6±3.4 years. LN occurred in 700/1,826 (38.3%) patients. There was no observed change in eGRF state for 2303/2430 (94.8%), 136/255 (53.3%) and 26/55 (47.3%) visits when the previous eGFR state was 1, 2 and 3 respectively. The corresponding values for ePrU states were 1167/1460 (79.9%), 547/983 (55.6%) and 59/205 (28.8%). For both outcomes the likelihood of improvement (states 2 to 1 and 3 to 2) was greater than deterioration (states 1 to 2 and 2 to 3). The transition from state 3 to ESRD was more likely with eGFR (54%) than ePrU (9%). Probability estimates of transitioning between eGFR and ePrU states, ESRD and death at 1, 2 and 5 years were determined. At year one the highest probability was for patients to remain in the initial eGFR (95%, 55%, 42%) or ePrU (81%, 56%, 31%) state. Following 2 and 5 years, the estimated probability for improvement in either eGFR or ePrU was higher than deterioration. Multivariate analysis identified older age ($p<0.001$), race/ethnicity (Hispanic, Asian and African ancestry) ($p<0.001$), higher ePrU state ($p<0.001$) and higher renal biopsy chronicity score (p=0.013) as predictors for deterioration in eGFR states and male sex (p=0.04) for improvement. For ePrU, multivariate analysis identified race/ethnicity (Hispanic, Asian and African ancestry) (p=0.009), earlier calendar year (p=0.017), SDI without renal variables (p=0.058) and higher renal biopsy chronicity score (p=0.015) as predictors for deterioration. Male sex (p=0.016), positive LAC (p=0.007) and ISN/RPN class V nephritis (p=0.012) and mycophenolic acid (p=0.003) were associated with lower improvement rate.
**Conclusions:** In lupus nephritis, the expected improvement and deterioration in renal outcomes can be estimated by multistate modeling and is predicated by identifiable risk factors. New therapeutic interventions for LN should meet or exceed these expectations.

## THU0335 ANTI C1-Q ANTIBODIES AND URINARY MONOCYTE CHEMOATTRACTANT PROTEIN-1 LEVELS AS BIOMARKERS FOR RENAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.A. Gómez-Puerta[1], B.L. Ortiz Reyes[1], C. Perez Koller[2], T. Urrego[1], A.L. Vanegas[3,4], C.H. Muñoz[3,4], M. Restrepo Escobar[3], L.A. González[3], G.M. Vasquez[1]. *[1]Grupo de Inmunología Celular e Inmunogenética, Universidad de Antioquia, Medellín; [2]Inova Diagnostics, Werfen, Bogotá; [3]Sección de Reumatología, Universidad de Antioquia; [4]Hospital Universitario de San Vicente Fundación, Medellín, Colombia*

**Background:** Some previous studies in Caucasian, Asian, and African-american patients have shown that the anti-C1q antibodies and urine levels of MCP-1 (uMCP-1) were significantly greater in patients with LN. However, information in Mestizo and Afro-Latin American patients is very limited.
**Objectives:** Our aim was to evaluate diagnostic value of Anti-C1q and uMCP-1 as a potential markers for the diagnosis of LN in Colombian SLE patients
**Methods:** We examined serum levels of anti-C1q and uMCP-1 in 67 consecutive SLE patients (ACR criteria 1997) from Hospital San Vicente Fundación, at Medellín, Colombia. A fresh urine sample from each patient was collected in a sterile container. Serum Anti-C1q antibodies and uMCP-1 were measured by ELISA techniques (Inova, San Diego, and R&D system, Minneapolis, EEUU, respectively). Several clinical and serological features were analyzed as well as disease activity (SLEDAI). Descriptive statistics were used to describe data. Mann-Whitney tests were used to compare data and Spearman'srho for correlations. Additionally, ROC curves relating the specificity and sensitivity profiles of the 2 biomarkers were done
**Results:** 67 SLE patients were recruited (89% female) with median age of 33.5± 12.0 yrs and median disease duration of 6.76 ± 6.80 years. Mestizo (71%) and Afro-latin American (26%) were majority. Hematologic disease (89%), arthritis (86%), cutaneous involvement (80%), and renal disease (66%) were among most common manifestations. Sixty-three percent of patients were positive for anti-C1q and 56% had elevated levels of uMCP-1 (mean levels 1678 ±3722 pg/ml). Mean SLEDAI score was 10.0 ± 9.0. We found significant association between anti C1q antibodies and several clinical features including serositis, proteinuria, renal and hematological involvement and with several serological markers including anti-dsDNA, low complement and higher SLEDAI score. Patients with LN had higher levels of anti-C1q antibodies than patients without LN (mean levels of 91.3 ± 85.4 vs 31.7 ± 38.7, p value=0.002). uMCP-1 levels were significantly higher in patients with LN than in patients without LN (2399 ± 4566 vs 472 ± 596 pg/ml, p value=0.017) and in patients with proteinuria (2537 ± 4731 vs 553 ± 688, p value=0.025). There was no correlation between anti-C1q levels and uMCP-1. An ROC curve constructed for anti-C1q and uMCP-1 and renal in all SLE patients showed that uNGAL had a good level of sensitivity and specificity with an AUC of 0.74 for anti-C1q and 0.82for uMCP1 (see figure).

ROC curve on Anti-C1q and uMCP-1. Solid line for Anti-C1q, dotted line for MCP-1.

**Conclusions:** Although further confirmatory testing is underway, LN patients had almost 3 times and 5 times higher levels of Anti-C1q and uMCP-1, respectively than patients without LN. Anti-C1q antibodies and uMCP-1 may be a good biomarkers for LN in Mestizo and Afro-Latin american SLE patients, and can be a useful marker to identify patients with higher risk of renal involvement

## THU0336 OUTCOMES IN PATIENTS WITH ISCHEMIC STROKE REGARDING TITER AND PERSISTENCE OF ANTIPHOSPHOLIPID ANTIBODIES

J.Y. Pyo, S.W. Lee, J.J. Song, S.-K. Lee, Y.-B. Park. *Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea, Seoul, Korea, Republic Of*

**Background:** Stroke and transient ischemic attack (TIA) are the most common neurologic manifestation of antiphospholipid syndrome (APS). The international consensus criteria for APS classification require persistent antiphospholipid antibodies (aPL) positivity (at least 12 weeks apart) and medium or high titer for anticardiolipin antibody (aCL) associated with clinical manifestations [1]. To confirm the diagnosis of a patient who comes with stroke/TIA and positive aPL as definite APS, we serially check the positivity of aPL in addition to titer of aCL. However, significance of persistence and moderate or high titer of aPL on the clinical relevance is not identified.
**Objectives:** To evaluate the effect of persistent and medium or high titer of aPL positivity on recurrence in patients with ischemic stroke/TIA.
**Methods:** We reviewed medical records of 99 patients with ischemic stroke/TIA who had at least one or more positive aPL (ie, positivity for anticardiolipin antibodies [aCL], $\beta_2$-glycoprotein I antibodies [$\beta_2$-GPI], lupus anticoagulant

| | aPL carriers (n=53) | Definite APS (n=46) | Total (n=99) | p-value |
|---|---|---|---|---|
| 1st attack age (years) | 43.2±13.8 | 44.0±13.0 | 43.6±13.4 | 0.758 |
| Female sex (%) | 19 (35.8% | 28 (60.9% | 47 (47.5%) | 0.013 |
| F/U duration (months) | 43.8±39.2 | 60.4±53.3 | 51.6±46.8 | 0.078 |

| Prior CVD | 1 (1.9%) | 0 (0%) | 1 (1.0%) | 0.349 |
| Cardiac diseases | 13 (24.5%) | 6 (13.0%) | 19 (19.2%) | 0.148 |
| Abortion Hx. | 4 (7.5%) | 4 (8.78%) | 8 (8.1%) | 0.834 |
| T.chole | 183.1±45.1 | 175.5±43.8 | 179.6±44.5 | 0.400 |
| TG | 152.7±142.3 | 121.6±100.2 | 138.0±124.5 | 0.231 |
| HDL | 43.5±10.4 | 42.8±14.2 | 43.2±12.3 | 0.764 |
| LDL | 105.2±33.2 | 105.8±28.8 | 105.5±31.1 | 0.923 |
| Recurrence | 16 (30.2%) | 14 (30.4%) | 30 (30.3%) | 0.979 |
| Duration to recurrence (months) | 35.2±48.3 | 33.7±43.5 | 34.5±45.3 | 0.931 |

antibodies [LA]). We divided these patients into two groups according to the most recent revised classification (Sydney consensus conference), and designated as "definite APS" who fulfilled the laboratory criteria, and "aPL carriers" who had transient or low titer aPL. We compared the subsequent ischemic stroke/TIA events between the two groups.
**Results:** Of the 99 patients, 46 (46%) were classified as definite APS and 53 (54%) as aPL carriers. There was no increased risk of subsequent ischemic/TIA events in definite APS group compared with aPL carriers group. The overall event was 14 (30.4%) in APS group and 16 (30.2%) in aPL carriers group during 60.4 months and 43.8 months follow up period respectively. 38 patients were having anticoagulation for treatment and 60 patients were on anti-platelet treatment without anticoagulation, but there was no difference on recurrence events regarding the treatment. Among definite APS group, there was no difference in recurrence events according anticoagulation vs anti-platelet agent.
**Conclusions:** The persistence and medium or high titer of aPL enables to diagnose APS in ischemic stroke/TIA patients, but does not predict increased risk for subsequent ischemic stroke/TIA.

## THU0337 RAYNAUD PHENOMENON IS ASSOCIATED WITH MYOCARDIAL FIBROSIS IN PRIMARY SJÖGREN SYNDROME, ASSESSED BY A CARDIAC MAGNETIC RESONANCE APPROACH: A PROSPECTIVE PILOT STUDY AT A SINGLE CENTER

K. Sugiyama[1], H. Kobayashi[1], Y. Kobayashi[2], Y. Nagasawa[1], N. Ikumi[1], T. Nozaki[1], H. Inomata[1], H. Shiraiwa[1], H. Karasawa[1], M. Iwata[1], N. Kitamura[1], Y. Matsukawa[1], M. Takei[1]. *[1]Nihon University School of Medicine, Tokyo; [2]St. Marianna University School of Medicine, Kanagawa, Japan*

**Background:** Primary Sjögren syndrome (pSS) shares many clinical, inflammatory, and immunological features with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Both SLE and RA are characterized by a high risk of cardiac involvement. However, there are limited data on the risk of overt cardiac involvement in pSS.
**Objectives:** We sought to use a cardiac magnetic resonance imaging (CMR) approach to assess cardiac involvement and determine its association with disease characteristics in pSS patients without cardiac symptoms.
**Methods:** Consecutive pSS patients, according to ACR classification criteria (2012), without a history or clinical findings of hypertension, cardiovascular disease, diabetes, or dyslipidemia underwent contrast CMR. Late gadolinium enhancement (LGE) was used for the assessment of myocardial fibrosis. Using a black-blood T2-weighted image (T2-WI), myocardial inflammation could be assessed. Sjögren syndrome disease activity index (ESSDAI) was determined. Eighty percent patients had documentation of a minor salivary gland biopsy. Salivary gland biopsy data were classified by focus score (FS). We investigated the patients in terms of prevalence of CMR abnormalities and explored possible associations between CMR abnormalities and pSS disease characteristics.
**Results:** Thirty-seven female pSS patients were enrolled (mean age: 55.5 ± 7.0 years). On an average, cardiovascular risk was low for the group, with patients demonstrating no ECG abnormalities, and the patients had generally low traditional cardiovascular risk factors, with a mean Framingham 10-year hard cardiovascular risk score of 4 ± 2%. The mean ESSDAI was 3.3 ± 2.1. Thirteen patients (35%) demonstrated myocardial abnormalities. Myocardial edema was seen in 5 patients (13%) on T2-WI. LGE was found in 11 patients (29%), 3 of whom demonstrated edema on T2-WI. The main finding observed in 7 among 11 LGE-positive patients (63%) was a linear LGE pattern without coronary distribution. A patchy nodular LGE pattern was observed in 4 among 11 patients (37%). The patients with CMR abnormalities showed no significant difference of ESSDAI, compared with those with no CMR abnormalities. Antibodies to La/SSB antigens were significantly higher in LGE-positive than LGE-negative patients (p=0.003). Raynaud phenomenon was significantly associated with LGE-positive and T2-WI-positive patients (p=0.001 and p=0.04, respectively). Other pSS characteristics such as disease duration, commodities, and cardiovascular risk factors were not significantly associated with myocardial abnormalities. The greatest relative difference between LGE-positive and -negative patients was observed in FS >3, with an adjusted odds ratio of 3.0. After adjusting for confounding by age, pSS duration, and anti-SSB antigen, the association of LGE with Reynaud phenomenon remained significant (p=0.02).
**Conclusions:** Subclinical myocardial involvement, as detected by CMR, was frequent in pSS patients without cardiac symptoms. Our results suggest that Raynaud phenomenon has a role in promoting cardiac involvements in patients with pSS.

## THU0338 CYSTIC LUNG DISEASE IN SJÖGREN'S SYNDROME: AN OBSERVATIONAL STUDY

S. Lechtman, M.-P. Debray, B. Crestani, C. Bancal, M. Hourseau, A. Dossier, J.-F. Alexandra, M.-P. Chauveheid, T. Papo, K. Sacre. *Paris-7 UNIVERSITY, APHP, Bichat Hospital, Paris, France*

**Background:** Assessments of the prevalence of pulmonary involvement in Sjögren's syndrome (SS) vary considerably in the literature. Moreover some publications found that lung involvement in SS is usually mild and stable while others describe a far more severe disease complication with a 5-year mortality of more than 15%. This is indicating that more studies of prevalence and severity of pulmonary involvement in SS are needed
**Objectives:** To analyze the prevalence, characteristics and outcome of cystic lung disease associated with Sjögren's syndrome (SS).
**Methods:** From June 2010 to February 2015, 90 SS patients (60.1±14.8 years; 88 (97.8%) female, 62 (68.9%) primary SS) had a systematic chest CT-scan. The presence of thin-walled cysts was analyzed by one experienced radiologist. Demographic data, clinical history, laboratory findings, and pulmonary function tests were extracted from medical records.
**Results:** Twenty-one (23.3%) patients had cysts on CT scan performed 40.5±54.5 months after SS diagnosis. Cysts number ranged from 1 to 25, were often bilateral (52.4%) and mostly located in the middle lung zone (76.2%). Cysts were isolated (n=6, 28.6%) or associated with other lesions including bronchiectasis (n=5, 23.8%), micronodules (n=5, 23.8%), ground-glass opacity (n=4, 19%) and/or air trapping (n=3, 14.3%). Most patients with cysts (57.1%) had no respiratory symptoms. When comparing SS patients with and without cysts, patients with cysts tended to be older (65.3±15.3 versus 58.5±14.4 years, p=0.06). Smoking habits were similar in both groups. Anti-SSB antibodies were more frequently detected in patients with cysts (57.1% vs 26.1%, p=0.02). Pulmonary function tests were normal in most cases (52.6%) or displayed only mild small airways obstruction and reduced diffusion capacity to carbon monoxide. Four (19%) patients with cysts had a past history of associated pulmonary disease including interstitial lung disease. During follow-up (25.1±17.7 months) no patient developed specific lung disease or lymphoproliferative disorders.
**Conclusions:** Cystic lung disease is frequent, benign, associated with anti-SSB/La antibodies and has no impact on outcome in SS
**Disclosure of Interest:** None declared

## THU0339 NON-CALCIFIED CORONARY ARTERY PLAQUE ASSOCIATES WITH ADVERSE LIPOPROTEIN PROFILES IN SYSTEMIC LUPUS ERYTHEMATOSUS

L. Durcan[1,2], A. Arbab-Zadeh[3], M. Connelly[4], J. Otvos[4], L.S. Magder[5], M. Petri[2]. *[1]Rheumatology, University of Washington, Seattle; [2]Rheumatology; [3]Cardiology, Johns Hopkins, Baltimore; [4]Labcorp, Raleigh; [5]Epidemiology and Public Health, University of Maryland, Baltimore, United States*

**Background:** Systemic lupus erythematosus (SLE) associates with excess cardiovascular (CV) disease and related mortality. This is contributed to, but cannot be fully explained, by traditional CV risk factors, treatments and SLE-specific factors. Coronary artery calcium scores (CAC), by computed tomography (CT) have been shown to predict atherosclerotic burden and CV events. Non-calcified plaque (NCP), common in SLE, can also be quantified and may be more metabolically active and unstable. Routine lipids are unhelpful in distinguishing SLE patients with or without either CAC or NCP. Nuclear magnetic resonance (NMR) spectroscopy allows determination of the size and concentration of lipoprotein classes and subclasses.
**Objectives:** To determine whether differences in NMR lipoprotein parameters can distinguish SLE patients with and without CAC. An additional aim was to establish whether NMR parameters associate with quantified NCP or calcified plaque.
**Methods:** As part of a longitudinal lupus cohort, SLE patients had coronary CT angiography performed. The burden of atherosclerosis was evaluated (CAC, NCP). CAC scores were calculated according to the Agatston system. NCP was also categorized and scored for each patient. Lipoprotein particle numbers

| Biomarker | Calcified Plaque | | NCP | |
|---|---|---|---|---|
| | Correlation Coefficient | P-value | Correlation Coefficient | P-value |
| Medium VLDL (nmol/L) | 0.07 | 0.56 | –0.00 | 0.97 |
| Small VLDL (nmol/L) | 0.00 | 0.99 | –0.05 | 0.68 |
| LDL (nmol/L) | 0.14 | 0.26 | 0.26 | 0.034 |
| IDL (nmol/L) | 0.05 | 0.66 | –0.02 | 0.89 |
| Large LDL (nmol/L) | 0.09 | 0.44 | 0.15 | 0.22 |
| Small LDL (nmol/L) | 0.02 | 0.89 | 0.14 | 0.22 |
| HDL (total) (μmol/L) | 0.17 | 0.17 | 0.16 | 0.20 |
| Large HDL (μmol/L) | –0.04 | 0.75 | –0.03 | 0.83 |
| Large HDL (μmol/L) | 0.10 | 0.42 | –0.07 | 0.57 |
| Small HDL (μmol/L) | 0.11 | 0.36 | 0.21 | 0.086 |
| VLDL size (nm) | 0.21 | 0.082 | 0.25 | 0.038 |
| LDL size (nm) | 0.09 | 0.49 | –0.05 | 0.70 |
| HDL size (nm) | –0.08 | 0.50 | –0.13 | 0.30 |
| Triglyceride (mg/dL) | 0.24 | 0.043 | 0.20 | 0.10 |
| Lipoprotein Insulin Resistance Score | 0.21 | 0.080 | 0.24 | 0.044 |

and size were evaluated by NMR. The initial statistical analysis compared those with and without calcified and NCP using t-tests. Further evaluation involved the calculation of correlation coefficients to evaluate the relationship between lipoprotein abnormalities and the burden of calcified and NCP.
**Results:** 69 SLE patients were evaluated, 49 (71%) African-American and 20 (29%) Caucasian. Significant NCP was present in 41 (59%) and CAC in 14 (20%). Individuals with NCP had significantly larger VLDL particles (44.8 ±5.5 nm versus 47.7 ±6.1 nm, p=0.042). Considering the volume and extent of CAC and NCP; (Table 1) higher triglycerides were observed with increasing levels of CAC. Increasing volumes of NCP were associated with higher LDL particle number and larger VLDL size. The lipoprotein insulin resistance scores were also positively associated with NCP. Table 1:Spearman Correlation for lipoprotein parameters and quantified coronary artery plaque.
**Conclusions:** The mechanisms underlying atherosclerosis in SLE are poorly understood. NCP is highly prevalent in SLE and may be contributed to by differences in LDL, VLDL and insulin resistance measures, not evaluated in routine lipid profiles. Further longitudinal analysis will determine whether these abnormalities associate with progression of disease and can be considered prognostic markers.

## THU0340 RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS EXHIBIT SIMILAR DEGREE OF SEVERITY OF SUBCLINICAL ATHEROSCLEROSIS. RESULTS FROM A CROSS-SECTIONAL STUDY IN A POPULATION OF NORTHWESTERN SPAIN

L. Riancho-Zarrabeitia, A. Corrales, N. Vegas-Revenga, L. Domínguez-Casas, V. Portilla, R. Blanco, M.A. González-Gay. *Hospital Universitario Marqués de Valdecilla, Santander, Spain*

**Background:** Chronic inflammation plays a central role in the development of atherosclerosis, being especially relevant in patients with rheumatic diseases. Patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) are more prone to suffer cardiovascular events than the general population.
**Objectives:** Our aim was to study the prevalence of subclinical atherosclerosis in patients with RA and SLE and determine the differences between these conditions.
**Methods:** We evaluated 99 SLE patients and 206 sex- and age-matched RA patients without previous history of cardiovascular events. Subclinical atherosclerosis was defined by the presence of carotid plaque according to Manheim Consensus Conference criteria and/or intima-media thickness ≥0.90 mm. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7–12 MHz linear transducer and the *automated software guided technique radiofrequency – Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). After the univariate analysis, multivariate regression models were fitted to adjust for potential confounders.
**Results:** The mean age was 52 ± 13 years in RA and 51±13years in SLE (p=0.77). Demographic data and traditional cardiovascular risk factors are summarized in table 1.
Regarding carotid plaques, there were no statistically significant differences. The frequency of carotid plaques was 40.2% among patients with RA and 44.4% in SLE patients. Bilateral plaques were present in 26% patients with RA and in 21.2% of those with SLE.
An IMT ≥0.90 mm was observed in 9.8% RA patients and in 6.3% of SLE patients (p= NS).
After adjusting for traditional cardiovascular risk factors and disease duration, there were no differences in the frequency of carotid plaques (OR SLE vs RA 1.52; CI 0.88–2.62) or in the frequency of IMT ≥0.90 mm (OR 0.75; CI 0.27–2.07).

| | SLE, % (n=99) | RA, % (n=206) | P |
|---|---|---|---|
| Female | 93.9 | 95.1 | 0.784 |
| Age (mean ± SD), years | 51.4±13.4 | 51.9±13.5 | 0.768 |
| Disease duration (mean ± SD), years | 11.1±8.5 | 8.6± 8.3 | 0.015 |
| Hypertension | 25.3 | 31.9 | 0.284 |
| Dyslipidemia | 19.2 | 42.2 | <0.001 |
| Diabetes | 1.0 | 8.3 | 0.009 |
| Smokers | 24.2 | 33.8 | 0.084 |
| Former smokers | 27.3 | 17.6 | |
| Family history of premature CV disease | 29.6 | 19.2 | 0.055 |
| Carotid plaque | 44.4 | 40.2 | 0.535 |
| Plaque unilateral | 23.2 | 13.7 | 0.104 |
| Plaque bilateral | 21.2 | 26.5 | |
| IMT ≥0.90 mm | 6.3 | 9.8 | 0.383 |

**Conclusions:** The frequency of subclinical atherosclerosis is similar in patients with SLE and RA after adjusting for traditional cardiovascular risk factors.

## THU0341 CORRELATION BETWEEN ESSDAI AND CLINESSDAI IN A REAL-LIFE COHORT OF SJÖGREN'S SYNDROME PATIENTS

L. Quartuccio[1], C. Baldini[2], E. Bartoloni[3], F. Carubbi[4], R. Priori[5], A. Alunno[3], R. Gerli[6], G. Valesini[7], R. Giacomelli[8], S. Bombardieri[9], S. De Vita[10] on behalf of GRISS group. *[1]Department of Biological and Medical Sciences, Rheumatology Clinic, University Hospital of Udine, Udine; [2]Rheumatology Unit, University of Pisa, Pisa; [3]Rheumatology Unit, University of Perugia, Perugia; [4]Rheumatology Clinic, University of L'Aquila, L'Aquila; [5]Rheumatology Clinic, University la Sapienza, Rome; [6]University of Perugia, Rheumatology Unit, Perugia; [7]University of Rome la Sapienza, Rheumatology Clinic, Rome; [8]University of L'Aquila, Rheumatology Unit, L'Aquila; [9]University of Pisa, Rheumatology Unit, Pisa; [10]University of Udine, Rheumatology Clinic, Udine, Italy*

**Background:** ClinESSDAI has been recently proposed as a valid tool for the assessment of disease activity in Sjögren's syndrome (SS) and it seems very close to the original ESSDAI (1, 2). The rationale of developing ClinESSDAI was to provide an accurate evaluation of disease activity independently of B-cell biomarkers, and it has been proposed to be used in biological/clinical studies to avoid data colinearity, in clinical trials, as secondary endpoint, to detect change independently of biological effect of the drug, and in clinical practice to assess disease activity for visits where immunological tests have not been done. However, validation in real-life cohorts is lacking, since 702 fictive vignettes derived from 96 real cases of primary SS of the ESSDAI development study were used.
**Objectives:** Primary objective of the study was to correlate ClinESSDAI and ESSDAI scores in large real-life cohorts of primary SS patients.
**Methods:** SS patients from 5 independent cohorts were studied. All patients fulfilled the American-European Consensus Group Criteria for primary SS. ESSDAI and ClinESSDAI scores were calculated at SS diagnosis. The whole population comprised 966 patients with primary SS (mean age 52±14, 95.4% female). Patients positive for anti-SSA antibodies were 684 (70.8%), for anti-SSB antibodies were 353 (46.5%), and negative for both anti-SSA/SSB antibodies were 271 (28.1%). Correlation between ClinESSDAI and ESSDAI scores was evaluated by Spearman's test.
**Results:** ClinESSDAI score significantly correlated with ESSDAI score in the first cohort (p<0.0001, r=0.972). Both ClinESDDAI and ESSDAI scores significantly correlated with all the single domains of the ClinESSDAI and ESSDAI, respectively, showing very similar results, even if the level of correlation was moderate to low in all the domains for both tools (table 1). Importantly, ClinESSDAI also significantly correlated with the biological domain of the ESSDAI score (table 1). Interestingly, focus score, available in 363/966 (37.6%) patients, did not correlate with both ClinESSDAI and ESSDAI scores (p=0.63, and p=0.426, respectively), while age at diagnosis inversely correlated with ClinESSDAI and ESSDAI scores (p<0.0001, r=-0.151, p<0.0001, r=-0.17, respectively).

Table 1

| ESSDAI Domain | ESSDAI | | ClinESSDAI | |
|---|---|---|---|---|
| | P | Spearman's rho | P | Spearman's rho |
| Constitutional | <0.0001 | 0.365 | <0.0001 | 0.386 |
| Lymphadenopathy | <0.0001 | 0.497 | <0.0001 | 0.498 |
| Glandular | <0.0001 | 0.323 | <0.0001 | 0.311 |
| Articular | <0.0001 | 0.393 | <0.0001 | 0.454 |
| Cutaneous | <0.0001 | 0.354 | <0.0001 | 0.346 |
| Pulmonary | <0.0001 | 0.276 | <0.0001 | 0.262 |
| Renal | <0.0001 | 0.183 | <0.0001 | 0.193 |
| Muscular | 0.031 | 0.069 | 0.014 | 0.079 |
| PNS | <0.0001 | 0.285 | <0.0001 | 0.291 |
| CNS | 0.0004 | 0.125 | <0.0001 | 0.136 |
| Hematological | <0.0001 | 0.391 | <0.0001 | 0.351 |
| Biological | <0.0001 | 0.327 | <0.0001 | 0.225 |

**Conclusions:** ClinESSDAI is a valid tool to assess systemic disease activity in primary SS.

## THU0342 PREGNANCY OUTCOME IN JAPANESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY OF 134 PREGNANCIES

M. Tochihara, Y. Katsumata, Y. Okamoto, Y. Kawaguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** Most previous studies reported less successful fetal outcome and more frequent maternal obstetric complications in systemic lupus erythematosus (SLE) pregnancy, whereas the impact of pregnancy on SLE remains controversial. On the other hand, because there have been only a few small published studies focusing the pregnancy outcome in Japanese patients with SLE, available information is currently still insufficient for Japanese women and their partners.
**Objectives:** We aimed to investigate the pregnancy outcome in Japanese patients with SLE in more than twice larger size than previous reports.
**Methods:** The questionnaires about past pregnancies were delivered to all

the Japanese women with SLE seen at our university clinic in November and December 2013. All the patients met the revised ACR classification criteria for SLE. Respondents were asked to answer the questionnaires while referring to the Maternal and Child Health Handbook, which consists of records of pregnancy, delivery, child development, and healthcare, and is filled in by obstetricians, pediatricians, and public health nurses. Clinical and laboratory data were also retrospectively collected from the medical records. Integrated data were statistically analyzed and also compared to available corresponding data in general Japanese populations.

**Results:** A total of 77 patients answered about 134 pregnancies: 18, 7, and 109 pregnancies occurred before, concomitant with, and after SLE diagnosis, respectively. In cases with pregnancies after SLE diagnosis, SLE was clinically quiescent in 105 of 109 pregnancies. Of the 116 pregnancies concomitant with or after SLE diagnosis, 81 (70%) resulted in a live birth, 14 (12%) in induced abortion, 19 (16%) in spontaneous abortion, and 2 (2%) in stillbirth. Among the 81 live births, low birth weight (LBW), fetal growth restriction (FGR), and preterm birth occurred in 43 (53%), 9 (11%), and 27 (33%) pregnancies, respectively. In general Japanese populations, these incidences were reported to be 10%, 3 to13%, and 5 to 13%, respectively. Although immunosuppressants other than steroids, namely tacrolimus, cyclosporine, and azathioprine, were continued during 9 pregnancies, these incidences were not significantly different compared to those without immunosuppressants. Of the 7 live birth pregnancies before SLE diagnosis, there were no LBW, FGR, or preterm birth. Of all, there were 2 cases of neonatal lupus. Of the 116 pregnancies concomitant with or after SLE diagnosis, pregnancy-induced hypertension (PIH) occurred in 24 (21%) pregnancies, which reportedly occurred in 3 to 5% in general Japanese populations. Maternal obstetric complications (including PIH and excluding SLE flare) more frequently occurred in the pregnancies concomitant with or after SLE diagnosis than in the pregnancies before SLE diagnosis (49/116 vs. 3/18, $p$ =0.04). Of the 109 pregnancies after SLE diagnosis, 16 (15%) pregnancies were associated with SLE flares, but their predictors were not clarified.

**Conclusions:** The present study showed that LBW, preterm birth, and maternal obstetric complications such as PIH were associated with SLE pregnancies among Japanese women. Concurrent use of tacrolimus, cyclosporine, and azathioprine during pregnancy was not associated with poor fetal outcome. SLE flares occurred in 15% of the pregnancies, but their predictors were not clarified.

## THU0343 RECURRENT THROMBOSIS IN YOUNG PATIENTS WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME: THE RELEVANCE OF THE ANTIPHOSPHOLIPID ANTIBODY PROFILE

M. Rodrigues[1], C. Nalli[2], L. Andreoli[2], E. Balestreri[2], A. Zanola[2], F. Allegri[2], A. Pedrini[2], G.L. Norman[3], M. Mahler[3], A. Tincani[2]. *[1]Rheumatology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal; [2]Rheumatology and Clinical Immunology, Spedali Civili of Brescia, Brescia, Italy; [3]Inova Diagnostics, San Diego, CA20673, United States*

**Background:** Recurrence of thrombosis in patients with Primary Antiphospholipid Syndrome (PAPS)is a major event yielding to poor prognosis.The identification of risk factors for recurrence is crucial to improve secondary prophylaxis strategies.

**Objectives:** To determine the risk factors for rethrombosis in patients with PAPS.

**Methods:** Retrospective analysis of a monocentric cohort of patients with thrombotic PAPS defined according to the updated Sapporo Criteria. aPL were determined by Lupus Anticoagulant (LA), anti-cardiolipin (aCL) IgG/IgM and anti-β2 glycoproteinI (anti-β2GPI) IgG/IgM. A positive result by all 3 assays was defined as triple positivity.Retrospective collection of serum samples was possible for 107 patients (66%).Ninety-two patients with positive anti-β2GPI IgG (57%) were selected for testing IgG against the domain I of β2GPI (anti-DI)using the chemiluminescence immunoassay in BIO-FLASH®system (INOVA Diagnostics, San Diego, CA, USA; cut-off 20CU). High titre anti-DI was defined as above 60CU.Patients were grouped by the number of events (single – S or recurrent – R). Comparisons between groups were performed using chi square and Mann-Whitney. Multivariate logistic regression was used to identify independent determinants of R events.Variables identified as having p-value $<0.1$ in univariate analysis were included. Anti-DI was not included because data were not available for the whole cohort. P-values $<0.05$ were considered statistically significant.

**Results:** The study included 162 PAPS patients (118 female, median age 48 years; venous thrombosis, VT – 103, arterial thrombosis, AT – 59). During the follow-up 70 recurrences were observed in 53 patients (VT – 36, AT – 34). Patients with rethrombosis more frequently had cardiac disease (hypertensive cardiopathy, valvular dysfunction, patent foramen ovale) (43% vs 21% p=0.007) and arterial hypertension (53% vs 33% p=0.01). Recurrent events were significantly associated with triple positivity (64% vs 44% p=0.01), LA (83% vs 62% p=0.008) and anti-β2GPI IgM (77% vs 60% p=0.03). Patients with rethrombosis less frequently received hydroxychloroquine (HCQ) (11% vs 41% $p<0.001$), OA (19% vs 46% p=0.009) and anti-platelet treatment (37% vs 59% $p<0.001$). The logistic regression analysis showed that triple positivity (OR 3.57 95%CI 1.32–9.65), cardiac dysfunction (OR 3.51 95%CI 1.35–9.15), HCQ (OR 0.22 95%CI 0.08–0.64), OA (OR 0.06 95%CI 0.02–0.24) and anti-platelet treatment (OR 0.01 95%CI 0.03–0.34) remained significant. Triple aPL positivity was more frequent in younger patients (under 50 years, n=118) who had recurrent events (71% vs 51% p=0.05), while no differences were found in terms of traditional cardiovascular risk factors. In the subgroup of anti-β2GPI IgG positive patients, recurrence was associated with the presence of high titre anti-DI in the whole cohort (80% vs 50% p=0.006) and in patients below the age of 50 (80% vs 55% p=0.03). Anti-DI levels were significantly higher in patients with recurrence (median 316CU vs 61CU p=0.02).

| | Single (n= 105) | Recurrent (n=53) | p |
|---|---|---|---|
| Demography | | | |
| Age at last visit, median (25th, 75th percentile) years | 47,8 (37,6 – 56,9) | 54,5 (42,7 – 65,7) | NS |
| Age at first event, median (25th, 75th percentile) years | 36,0 (24,0 – 45,5) | 42,0 (31,0 – 53,0) | NS |
| Sex, no.female | 79 (75%) | 39 (73%) | NS |
| Disease duration, median (25th, 75th percentile) months | 89,9 (42,2 – 169,9) | 108,5 (35,3 – 174,3) | NS |
| Clinical features | | | |
| Thrombosis (first event) | | | |
| Arterial | 39 (36%) | 20 (38%) | NS |
| Venous | 70 (64%) | 33 (62%) | NS |
| Thrombotic Risk Factors | | | |
| Cardiac disease | 23 (21%) | 23 (43%) | 0,007 |
| Arterial hypertension | 23 (21%) | 22 (42%) | 0,016 |
| - Untreated hypertension | 32 (29%) | 22 (42%) | NS |
| Diabetes mellitus | 3 (3%) | 4 (7%) | NS |
| Obesity | 23 (21%) | 13 (24%) | NS |
| Smoking | 37 (34%) | 13(25%) | NS |
| Hypercholesterolemia | 34 (31%) | 17 (32%) | NS |
| Hypertriglyceridemia | 10 (9%) | 6 (11%) | NS |
| Hyperhomocysteinemia | 26 (24%) | 12 (23%) | NS |
| Inherited thrombophilia | 36 (33%) | 16 (30%) | NS |
| Laboratory Profile | | | |
| LA | 68 (62%) | 44 (83%) | 0,008 |
| - Isolated LA | 6 (5%) | 4 (7%) | NS |
| aCL IgG | 72 (66%) | 36 (68%) | NS |
| aCL IgM | 82 (75%) | 38 ( 71%) | NS |
| β2GPI IgG | 82 (75%) | 38 ( 72%) | NS |
| β2GPI IgM | 66 (61%) | 41 (77%) | 0,034 |
| β2GPI IgG anti-DI (n=92) | 41 (56%) | 25 (83%) | NS |
| β2GPI IgG anti-DI: high-titer (>60 CU) (n=92) | 31 (50%) | 24 (80%) | 0,008 |
| Single positivity | 24 (22%) | 8 (15%) | NS |
| Double positivity | 36 (33%) | 11 (21%) | NS |
| Triple positivity | 48 (44%) | 34 (64%) | 0,016 |

**Conclusions:** Patients with thrombotic PAPS still develop recurrence despite treatment.Triple positivity and high titre anti-DI conferred an increased risk of rethrombosis irrespective of traditional risk factors.

## THU0344 OSTEOPOROSIS AND VERTEBRAL FRACTURES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. García-Carrasco[1,2], A. Rojas-Villarraga[3], N. Molano-González[4], P. Soto-Santillán[1], C. Mendoza-Pinto[1]. *[1]Systemic Autoimmune Diseases Research Unit, Hospital General Regional No. 36-CIBIOR Instituto Mexicano del Seguro Social; [2]Medicine School, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico; [3]Center for Autoimmune Diseases Research -CREA-, School of Medicine and Health Sciences; [4]Center for Autoimmune Diseases Research -CREA-, School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia*

**Background:** Observational studies have indicated a high but heterogeneous prevalence of low bone mineral density (BMD) and vertebral fractures (VR) in patients with systemic lupus erythematosus (SLE).

**Objectives:** To evaluate the relationship between SLE and BMD, osteoporosis and the risk of vertebral fracture.

**Methods:** A systematic review and meta-regression analyses were carried out according to the Preferred Reporting Items for Systematic Meta-Analyses (PRISMA) guidelines. Articles were identified from electronic databases (PubMed, Embase, VHL, SciELO and the Cochrane Library). The search was conducted using MesH terms, Boolean operators and keywords, which included “systemic lupus erythematosus”, “osteoporosis”, “bone mineral density”, and “vertebral fractures”. Prospective longitudinal and cross-sectional studies were considered for review without language restrictions. Articles were screened for suitability. Those selected were evaluated by two investigators, who extracted information on study characteristics, outcomes of interest, and risk of bias, and summarized the strength of evidence. Data was extracted when studies met inclusion criteria and were of sufficient quality. BMD, reported as the mean ± standard deviation

evaluated by dual-energy X-ray absorptiometry (DXA), was analyzed including information on SLE cases and controls, treatment, menopausal status and fractures by meta-regression analysis adjusted by anatomical region. Data were analyzed using the Metafor package in R (3.0.2 version).
**Results:** In total 49 articles were identified and analyzed (12, 593 SLE cases/six anatomical regions and 14,235 controls/six anatomical regions). SLE women, but not SLE men, had a lower BMD than healthy controls ($p<0.0001$). When only SLE patients were analyzed, the BMD did not significantly differ between patients who had or had not received corticosteroid (CTS) therapy. Unsurprisingly, postmenopausal SLE patients had a lower BMD (lumbar spine and total hip) compared with premenopausal patients ($p<0.0001$). The BMD did not differ in patients with and without fractures.
**Conclusions:** This systematic review and meta-regression analysis shows that women with SLE had a higher risk of low BMD than healthy controls. The data did not show that CTS therapy had an impact on BMD.

## THU0345 PRESENCE OF IMMUNOGLOBULIN (IG) A ANTIBODIES AGAINST CARDIOLIPIN AND β2-GLYCOPROTEIN-I IN THE ABSENCE OF IGG AND IGM IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Frodlund, J. Wetterö, T. Skogh, C. Sjöwall. *IKE, Faculty of Health Sciences, Linköping University, Linköping, Sweden*

**Background:** The antiphospholipid (Hughes) syndrome (APS) is characterized by vascular thrombosis and/or pregnancy morbidity and twice repeated confirmed presence of anti-cardiolipin and/or anti-β2-glycoprotein-I antibodies of IgM/IgG isotype and/or a positive lupus anticoagulant test. These tests and isotypes are found in the 1997 update of the American College of Rheumatology (ACR) classification criteria for systemic lupus erythematosus (SLE). As antiphospholipid antibodies are associated with increased morbidity and mortality in SLE, it is of major concern to screen new patients early for these antibodies. Despite limited scientific evidence, however, IgA isotype was added as a formal laboratory criterion in the 2012 SLICC criteria.
**Objectives:** Herein, we thus evaluated a well-characterized Swedish SLE cohort with regard to the presence of IgM, IgA and IgG isotypes of anti-cardiolipin or anti-β2-glycoprotein-I antibodies in relation to disease phenotype, organ damage, smoking habits, medical treatment, APS and thromboembolic events. We aimed to define the frequency of each isotype separately in order to disclose if any specific features are associated with the presence of isolated IgA antiphospholipid antibodies.
**Methods:** Serum samples from 254 patients (88% women) of the "Clinical Lupus Register in Northeastern Gothia" were included. All cases had a clinical diagnosis of SLE and met the 1982 ACR classification criteria and/or the Fries' diagnostic principle (*i.e.* positive ANA + manifestations in $\geq$2 typical organ systems). 211 (83%) were prevalent cases, whereas 43 (17%) had a newly diagnosed SLE at the time for blood sampling. 200 healthy blood donors and 100 patients with early rheumatoid arthritis (RA) served as controls. Anti-cardiolipin and anti-β2-glycoprotein-I antibodies (IgM, IgA and IgG) were analyzed at Linköping Clinical immunology unit using a fluoroenzyme-immunoassay (Phadia-250 instrument, Thermo-Fisher Scientific Phadia AB, Uppsala, Sweden). Cut-off limits for positive antibody tests were set at $>$99th percentile of healthy blood donors.
**Results:** Among the SLE patients: 45 (18%) fulfilled APS classification; 69 (27%) were positive for at least one isotype (IgM/IgA/IgG) and 34 (13%) for IgA of either anti-cardiolipin or anti-β2-glycoprotein-I antibody. 24 (9%) SLE cases were positive for IgA anti-cardiolipin, 12 of whom were positive in the absence of IgM/IgG class antibodies. 28 (11%) SLE cases were positive for IgA anti-β2-glycoprotein-I, 13 of whom were positive in the absence of IgM/IgG. 7 (2.8%) SLE patients were positive for isolated IgA anti-cardiolipin and/or anti-β2-glycoprotein-I antibodies and fulfilled APS classification, whereas 9 SLE cases (3.5%) were positive for isolated IgA anti-cardiolipin and/or anti-β2-glycoprotein-I antibodies without meeting APS classification. 7% of the RA cases were positive with regard to at least one isotype of anti-cardiolipin or anti-β2-glycoprotein-I antibodies.
**Conclusions:** We demonstrate that IgA anti-cardiolipin and/or anti-β2-glycoprotein-I antibodies can be found in almost 1/7 of Swedish SLE patients, either in the absence of IgM/IgG (47%) or in combination with other isotypes (53%). In 7 of these cases, the presence of isolated IgA antiphospholipid antibodies was associated with APS. Analyses of associations with disease outcome, phenotype, drugs and smoking habits are ongoing.

## THU0346 FURTHER VALIDATION OF SIMPLE INDEX AS A SIMPLE DISEASE ACTIVITY ASSESSMENT TOOL FOR SLE

N. Gandhi[1], M. Jolly[1], A. Nevares[2], W. Sequeira[1]. *[1]Rheumatology, Rush University Medical Center, Chicago; [2]Rheumatology, Cleveland Clinic, Celveland, United States*

**Background:** An easy, quick tool, requiring minimal training or physician input for disease activity (DA) assessment in SLE, would have potentially greater uptake for routine use among rheumatologists and primary care physicians. Furthermore, integration into busy work flow processes would be easier for the same reason. Most DA tools for SLE are complex, require training and physician time; and are not performed during routine care visits for most SLE patients. SIMPLE (Simple Disease Assessment for People with Lupus Erythematosus) [1] is a numeric composite index based on patient reported questions and two laboratory values, and requires minimal input from health care provider which can be provided by nurse or a physician extender. Here, we prospectively evaluate the correlation of SIMPLE index with physician based DA measure.
**Objectives:** Prospectively validate SIMPLE index as a DA measure compared to traditional physician based DA assessment tools.
**Methods:** 72 consenting patients meeting ACR classification criteria for SLE were recruited from two academic center clinics. Primary outcome of interest was correlation between Simple Index (SI) and SELENA-SLEDAI (SS). Secondary outcome of interest was correlation between SI and Physician Global Assessment (PGA). Patients filled the self-reported components of SI in the waiting room prior to their visit. PGA and SS were assessed at the same visit by the physician. Descriptive and spearman correlational analyses were obtained. Stratified analysis by fibromyalgia status (FMS) was also conducted. P value of $\leq$0.05 was considered significant on two tailed tests. We considered correlation coefficient of $<$0.30, 0.30 to 0.49 and $>$0.50 as weak, moderate and strong correlation, respectively.
**Results:** Mean (SD) age was 40.8+12.4 yrs, and 87.5% participants were women. Ethnic background of the participants was as follows: 52.8% Blacks, 25% Whites, 8.3% Hispanic, 6.9% Asians and 6.9% others. Median (IQR) SI was 21.7 (17.2). Median (IQR) values of PGA and total SS were 0.5 (1.0) and 4.0 (6.0), respectively. Spearman correlation coefficient between SI and PGA and SS were 0.507 (p 0.001), 0.568 (p 0.001), respectively. In a sub analysis excluding fibromyalgia patients, these correlations were 0.538 (p 0.001, n=60), 0.633 (p 0.001, n=59) respectively.
**Conclusions:** SIMPLE index is strongly correlated with PGA and SS in SLE patients, and the correlation is even stronger in SLE patients without FMS. SIMPLE index is quick, easy and requires negligible health care team input, which can be from a physician extender or a nurse or any physician. SIMPLE Index has the potential to be widely used in varied health care access levels and systems in different parts of the world. SIMPLE Index can potentially serve as a quality of care measure. Larger and longitudinal studies that include patients with greater DA and to test its responsiveness are currently ongoing.

## THU0347 IS BALANCE AFFECTED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS?

M. Alkan Melikoglu, F. Bagcier. *ATATURK UNIVERSITY FACULTY of MEDICINE, Rheumatology, Erzurum, Turkey*

**Background:** Systemic Lupus Erythematosus (SLE) is a multisystem disease that has a broad range of manifestations. Balance as a complex task may be affected in SLE and this may cause postural instability and fall risk.
**Objectives:** The aim of this study was to determine the fall risk in cases with SLE with an objective computerized technique and to evaluate the potential related risk factors for falls in these cases.
**Methods:** Female patients with SLE (1997 ACR revised classification criteria for SLE) and female healty controls were included. Patients who were not able to tolerate posturography, with a history of orthopedic surgery and with known balance problems were excluded. The age, disease duration, anamnesis of falls, fear of falling and drugs used were recorded. Disease activity (with SLE disease activity index SELENA modification) and damage (with Systemic Lupus International Collaborating Clinics/ACR Damage Index) were evaluated. For the evaluation of fall efficacy, we used the Falls Efficacy Scale International (FES-I). Fall risk analysis was performed by Tetrax Interactive Balance System which is a computerized posturography device. By this method, fall risk is obtained as a numeric value (0–100) and as ranges indicating low, moderate or high risk of fall. We investigated age, disease duration, fall anamnesis, fear of falling, drug usage, FES-I, disease activity and damage as possibe related factors to fall risk. Mann–Whitney U, chi square and Spearman correlation tests were used for statistical analysis.
**Results:** 48 cases with SLE and 30 controls were included. The mean ages of the cases and controls were 37,8±12,6 and 39,1±15,7 years, respectively. Symptom duration of the cases was 6,1±4,2 months. 7 cases (15%) had anamnesis of

falls during the last 12 months, whereas only 1 control (3%) had this anamnesis ($p<0,05$). Fear of falling was reported by 40% of the cases and 30% of the controls ($p<0,05$). FES-I scores were found to be significantly higher in cases than controls (22±11 and 16±9 respectively; p=0,040). With the computerized system used, significantly higher fall risk results were recorded in patients with SLE than the controls (59,3±29,5 and 35,8±26,9, respectively; $p<0,001$). Low, moderate and high fall risks were recorded as 31%, 15% and 54% of the cases and 53%, 23% and 23% of the controls and this distribution was also significantly worse in cases than controls ($p<0,05$). No significant correlation was found between fall risk and other factors including age, disease duration, fall anamnesis, fear of falling, drug usage, disease activity and disease damage except FES-I which was significantly correlated both with fall risk assessment and fall risk category in cases ($p<0,05$).

**Conclusions:** With an objective computerized technique, fall risk was found to be higher in cases with SLE than controls in our study. The higher fall risk in these patients seems to be affected by the disease itself, rather than its other characteristics. An increased awareness of the potential fall risk and future studies investigating the possible coexisting balance problems in SLE may contribute to the management.

## THU0348 ASSESSMENT OF SUBMANDIBULAR GLAND ULTRASONOGRAPHY IN EARLY-STAGE SJÖGREN'S SYNDROME

N. Hashimoto[1], S. Uchiyama[2], M. Kitano[3], T. Nakazawa[4], T. Iwasaki[5], T. Hashimoto[1]. *[1]Hashimoto Rheumatology Clinic; [2]OMM Medical Center, Osaka; [3]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya; [4]Osaka Saiseikai Nakatsu Hospital, Osaka; [5]Department of Pharmacy, Hyogo University of Health Sciences, Kobe, Japan*

**Background:** Sjögren's syndrome (SS) is a chronic inflammatory autoimmune disease characterized by lymphocyte infiltration in salivary and lacrimal glands. Recently, salivary gland ultrasonography proved valuable for the assessment of salivary gland involvement in SS and seemed to exhibit good diagnostic properties. We previously reported that submandibular gland ultrasonography (SGUS) is a useful noninvasive and inexpensive procedure for the evaluation of the structural changes of salivary gland involvement in SS patients (International Symposium on SS 2002, EULAR 2009, EULAR 2012, EULAR 2015). However, the usefulness of SGUS for the evaluation of early-stage SS patients with normal salivary flow was unknown.

**Objectives:** The aim of this study was to examine the usefulness of SGUS in early-stage SS patients with normal salivary flow.

**Methods:** We observed 9 non-SS patients with anti-SS-A antibodies sero-positive, 13 SS patients with low salivary flow (L/SS) and 16 SS patients with normal salivary flow (N/SS). SS was diagnosed according to the American College of Rheumatology (ACR) classification criteria for SS. SS was divided into two groups according to salivary flow using Gum test [L/SS ($\leq$10mL/10min) and N/SS ($>$10mL/10min)]. All patients were examined RF, FANA, anti-SS-A/SS-B antibodies in serum and labial salivary gland biopsies for the diagnosis of SS. All patients were performed US scans by a single examiner who was blinded to the clinical data and used an US with a 7.5-MHz liner array transducer (SSA-350A; Toshiba, Tokyo, Japan). US staging scores were assessed by glandular size, inhomogeneity and contrast of diagastric muscle (0: normal, 1: mild, 2: moderate, 3: severe structural damage). PD grading scores were graded by pulsed wave pattern in power Doppler US at the internal SG facial arteries (0: normal, 1: intermittent wave pattern, 2: disappearance of wave pattern).

**Results:** The whole salivary flow was significantly decreased in L/SS (4.4±2.8mL/10min) patients than in non-SS (19.0±7.6mL/10min, $p<0.001$) and N/SS (19.1±8.0mL/10min, $p<0.001$) patients. All patients were anti-SS-A antibodies sero-positive. There were no significant differences among non-SS, N/SS and L/SS patients in the frequency of sero-positive antibodies such as RF, FANA and anti-SS-B. However, the size of SG was significantly smaller in L/SS (216.1±59.7mm$^2$) than in non-SS (325.9±66.2mm$^2$, $p<0.005$) and N/SS (311.3±98.7 mm$^2$, $p<0.005$). US staging scores and PD grading scores were significantly higher in L/SS (2.85±0.38, 1.62±0.51) than in non-SS (0.89±1.05, 0.33±0.71, $p<0.001$) and N/SS (1.44±1.15, 0.44±0.51, $p<0.001$) patients.

**Conclusions:** SUSG findings reflect salivary gland functions and is useful for the diagnosis of SS with low salivary flow but not for early-stage of SS patients with normal salivary flow.

**Disclosure of Interest:** None declared

## THU0349 EARLY SYMPTOMS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) RECALLED BY 337 SLE PATIENTS

N. Leuchten[1], B. Milke[1], B. Winkler-Rohlfing[2], D. Daikh[3,4], T. Dörner[5], S. Johnson[6,7], M. Aringer[1] on behalf of the SLE Classification Criteria Steering Committee. *[1]Department of Medicine III, University Medical Center Carl Gustav Carus, TU Dresden, Dresden; [2]Lupus Erythematodes Selbsthilfegemeinschaft e.V., Wuppertal, Germany; [3]Department of Medicine, University of California; [4]Department of Veterans Affairs Medical Center, San Francisco, United States; [5]Department of Medicine, Rheumatology, and Clinical Immunology, Charité University Hospital, Humboldt University, Berlin, Germany; [6]Department of Medicine, Toronto Scleroderma Research Program, Toronto Western Hospital; [7]University Health Network, Mount Sinai Hospital, University of Toronto, Toronto, Canada*

**Background:** EULAR and ACR have jointly funded a project to develop systemic lupus erythematosus (SLE) classification criteria, aiming at earlier and more accurate classification of the disease. This abstract reports on an early phase of that project, aimed at collecting potential candidate criteria. Since SLE patients usually experience the onset and diagnosis as a critical life event, memories of this time appear remarkably accurate.

**Objectives:** The objective of this study was to identify early symptoms of SLE from the patient perspective.

**Methods:** As approved by the local ethics committee, we conducted a cross-sectional survey of German SLE patients. An anonymous self-report questionnaire was published in the "Schmetterling" the quarterly journal of the "Lupus erythematodes Selbsthilfegemeinschaft", the German SLE patient association. Patients were asked for year of and age at their initial diagnosis. The questionnaire included typical organ manifestations, symptoms and autoantibodies. In addition, patients were asked to add additional symptoms in free text. For each symptom, boxes were provided to indicate the presence of the symptom before diagnosis, in the first year of diagnosis and at the time of completion of the questionnaire.

**Results:** 333 patient questionnaires were completed and mailed. Of the respondents, 93% were female. The respondents' mean age at diagnosis was 36 years, their mean disease duration was 17 years. 83% reported to be definitely ANA-positive. Joint, skin and kidney involvement were reported at 82%, 66% and 33%, respectively. 22% of patients reported fibromyalgia. For the time before and shortly after diagnosis, more than 50% of the patients reported fatigue (89%), joint pain (87%), sensitivity to sunlight (79%), myalgias (76%), rash (71%), fever (54%), Raynaud's (52%) and hair loss (51%). Approximately one third (37%) affirmed shortness of breath. Free text symptoms reported frequently before or early in diagnosis are listed in Table 1.

Table 1. Free text symptoms frequently present before or early in diagnosis

| | |
|---|---|
| Diarrhea/abdominal pain | n=33 (10%) |
| Headache/migraine | n=33 (10%) |
| Sicca symptoms | n=33 (10%) |
| Depression/mood disorder | n=26 (8%) |
| Cognitive impairment | n=25 (8%) |
| Dizziness/vertigo | n=20 (6%) |
| Serositis | n=18 (5%) |
| Polyneuropathy/paresthesias | n=16 (5%) |
| Sleep disturbance | n=12 (4%) |

**Conclusions:** For a Caucasian European SLE patient population, the overall characteristics suggested meaningful representation. While many symptoms were reported as expected, a significant number of patients volunteered gastrointestinal complaints and symptoms of the central and peripheral nervous system.
Solicitation of self reported information from the patient perspective has not been widely used in the development of classification criteria for SLE. These data add to the information on early SLE symptoms that may help improve classification of early SLE.

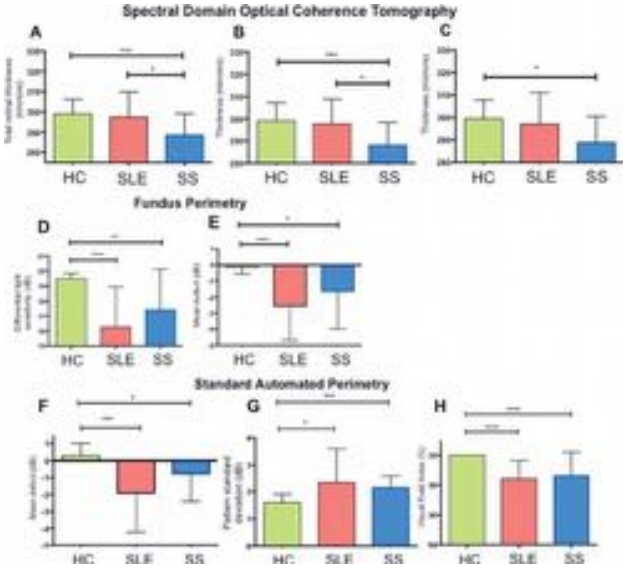
## THU0350 MORPHOLOGICAL ALTERATION OF THE RETINAL POSTERIOR POLE AND FUNCTIONAL EYE IMPAIRMENT IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOUS AND SJÖGREN SYNDROME



P. Conigliaro[1], C. Canofari[1], G. Draghessi[2], P. Triggianese[1], C. Valeri[2], L. Novelli[1], G. Aloe[2], M. Cesareo[2], R. Perricone[1]. *[1]Clinic of Rheumatology, Allergology and Clinical Immunology; [2]Ophthalmology Unit, Department of Experimental Medicine and Surgery, University of Rome "Tor Vergata", Rome, Italy*

**Background:** Systemic Lupus Erythematous (SLE) and Sjögren Syndrome (SS) are autoimmune diseases that may exhibit several manifestations including an ocular involvement. Ocular involvement may be underestimated or be subclinical since current treatments as hydroxycloroquine and steroid may exert both beneficial and side effects on eyes.

**Objectives:** To assess the eye involvement in patients affected by autoimmune diseases as SLE and SS.

**Methods:** 48 patients affected by autoimmune diseases (29 SLE, 19 SS) without an active eye involvement were prospectively and consecutively enrolled.

Morphological and functional eye assessment included: complete ophthalmogical examination, Spectral Domain Optical Coherence Tomography examination, fundus perimetry (FP), standard automated perimetry (SAP). 25 age and sex-matched healthy controls (HC) were also evaluated.
**Results:** SS patients displayed a reduction of mean retinal thickness in the posterior pole compared with HC and SLE (p=0.0003 and p=0.03, Fig.1A). This reduction was demonstrated in superior and inferior hemifield compared with HC (p=0.001 and p=0.007) and in superior hemifield compared with SLE (p=0.01) (Fig.1B-C). The FP mean differential sensitivity in SLE and SS patients was reduced compared with HC (p<0.0001 and p=0.001, Fig.1D). The FP mean defect values in SLE and SS patients were higher than HC (p<0.0001 and p=0.03, Fig.1E). A negative correlation was demonstrated in SLE between age and FP mean differential sensitivity (p=0.0005, r= -0.7). FP alteration in SLE was prevalent in those patients that were not on steroid treatment. In SS a higher proportion of patients with alteration in FP received a cumulative hydroxycloroquine dose higher than 1000g (p=0.02). The SAP demonstrated in SLE and SS patients a significant increase of the mean defect (MD) and the pattern standard deviation (PSD) compared with HC (MD: p=0.001 and p=0.01, PSD: p=0.02 and p=0.0002; Fig.1F-G). Visual field index (VFI) values were reduced in both SLE and SS patients compared with HC (p<0.0001 for both comparisons, Fig.1H). SLE patients with kidney involvement displayed a significant increase of the MD and the PSD compared with those without kidney involvement (p=0.04 and p=0.01, respectively). Likewise, VFI values were reduced in SLE with nephritis compared with that in patients without a kidney involvement (p=0.04).

**Conclusions:** In a small cohort of patients with autoimmune diseases without an overt active eye involvement a morphological alteration of the retinal posterior pole and functional impairment was demonstrated suggesting a subclinical involvement thatmight be concealed by the treatment.
**Disclosure of Interest:** None declared

## THU0351 VITAMIN D INSUFFICENCY IS ASSOCIATED TO FATIGUE IN NON-SUPPLEMENTED WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN A MEDITERRANEAN REGION

T.C. Salman-Monte[1], P. Corzo[1], F. Castro[1], L. Polino[1], V. Torrente-Segarra[2], J. Carbonell-Abello[1]. *[1]Rheumatology Department, Hospital del Mar, Barcelona; [2]Rheumatology Department, Hospital General Hospitalet-Moisès Broggi, St Joan d'Espi, Spain*

**Objectives:** It has been previously reported that vitamin D deficiency is more prevalent among SLE patients than in the general population. We sought to determine the prevalence of vitamin D insufficiency and deficiency and their related factors, its relationship to SLE symptoms and disease activity on a group of supplemented and non-supplemented female SLE patients from the Mediterranean region.
**Methods:** We performed a cross-sectional study including female SLE patients who regularly attended the outpatient Lupus Unit at Parc de Salut Mar-IMAS in Barcelona, from January 2012 and May 2014. Collected data were: sociodemographics; vitamin D supplementation; fatigue degree visual analog scale; pharmacological treatment; main SLE serological markers, Indexes, scales; and plasma levels of 25-hydroxy vitamin D
**Results:** One-hundred and two consecutive female SLE patients were included. Vitamin D overall insufficiency and deficiency were exhibited by 46% and 22.5% of patients, respectively. Vitamin D insufficiency was found in 50% of supplemented and 60% of non-supplemented patients. Among non-supplemented female SLE patients, it was found that patients with Vitamin D insufficiency showed more fatigue (p=0.009) and received more oral corticosteroids (p=0.02) than those with normal levels. Patients with Vitamin D insufficiency (supplemented and non-supplemented) received more oral corticosteroids than those without insufficiency (p=0.008).

| Variable | 25(OH)D <30 ng/mL (n=16) | 25(OH)D ≥30 ng/mL (n=24) | p-value |
|---|---|---|---|
| BMI (kg/m$^2$)* | 23.9 [21.3–29.2] | 23.7 [21.7–30.2] | 0.672 |
| Sun blocker** | 12 (75%) | 18 (75%) | 1.000 |
| Vitamin D diet intake | 14 (87.5%) | 18 (75%) | 0.439 |
| SLEDAI* | 3.3 [0–5.5] | 3.4 [0–7.5] | 0.967 |
| MHAQ* | 0.39 [0–0.68] | 0.33 [0–0.75] | 0.859 |
| VAS fatigue* | 63.5 [51.5–80.0] | 39.5 [20.0–59.7] | 0.009 |
| Anti-dsDNA UI/mL* | 208 [35–265.7] | 141 [30–176.2] | 0.318 |
| ESR (mm/h)* | 14 [4.2–23] | 14.7 [5.5–20.2] | 0.881 |
| CRP (mg/dl)* | 0.4 [0.2–0.4] | 0.3 [0.2–0.2] | 0.233 |
| Corticosteroids** | 9 (56.2%) | 5 (20.8%) | 0.021 |
| Mean Corticosteroids dosage* | 6.4 [0–10] | 0.9 [0–0] | 0.020 |
| Photosensitivity | 15 (93.8%) | 22 (91.7%) | 1.000 |

*N* (%)/Mean ± SD; Med [P25–P75]. *Comparisons performed with Mann-Whiney U test. **Comparisons performed with Chi-Square test or Fisher exact test.

**Conclusions:** Vitamin D insufficiency is highly prevalent among female SLE patients, even in southern regions. Non-supplemented female SLE patients showed more fatigue and received more oral corticosteroids than those with normal levels of Vitamin D. This data was not found in supplemented patients despite having a high prevalence of Vitamin D insufficiency (up to 50%). Further studies with longer follow-up and larger population are needed to confirm our observations.

Sacco Univ, Milan, Italy; [38]Privado Hosp, Córdoba, Argentina; [39]Sao Paulo Federal Univ, Sao Paulo, Brazil*

**Objectives:** To analyse the diagnostic approach used in the largest international cohort of patients with primary Sjögren syndrome (pSS)
**Methods:** The Big Data Sjögren Project is a multicentre registry formed in 2014 by experts participating in the EULAR-SS Task Force. By January 2016, the database included 8315 consecutive patients fulfilling the 2002 criteria. The main features at diagnosis/recruitment (time of criteria fulfilment) were collected and analysed
**Results:** The cohort included 7753 (93%) women (mean age at diagnosis 53 years). Sicca symptoms were reported in more than 90% of patients at diagnosis (92% for dry eye and 92.5% for dry mouth). The diagnostic tests used included the determination of anti-Ro/La antibodies in 8250 (99%) patients, Schirmer test in 6205 (75%), salivary gland biopsy in 5988 (72%), salivary flows in 4941 (59%), corneal stainings in 3304 (40%), scintigraphy in 2578 (31%) and sialography in 873 (10%) patients. The mean number of diagnostic tests included in the 2002 AE criteria was 4.85 ± 1.44 (of a maximum of 8 different tests), and was higher in patients with negative ANA (5.18 vs 4.80 in ANA+, p<0.001) or negative RF (5.06

vs 4.81 in RF+, $p<0.001$), and was also higher in American patients vs European or Asian patients (5.28 vs 4.83 and 4.63, respectively). A correlation was found between the number of tests carried out and the number of 2002 criteria finally fulfilled (R=0.48)

**Conclusions:** We found a heterogeneous diagnostic approach of pSS with respect to the number of 2002AE diagnostic tests carried out; the approach varied significantly according to geographic origin and baseline immunological profile

## THU0353 SERUM TWEAK LEVELS IN PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

R. Svobodova[1], P. Kozelek[2], M. Posmurova[2], V. Peterova[3], H. Hulejova[1], L. Senolt[1], M. Olejarova[1]. *[1]Department of Rheumatology; [2]Psychiatric Clinic of 1st Medical faculty Charles University; [3]Neurologic Clinic of 1st Medical faculty Charles University, Prague, Czech Republic*

**Background:** Systemic lupus erythematosus (SLE) is autoimmune disease involving various organs including the nervous system. Neuropsychiatric SLE (NPSLE) occurs in 30 - 40% of SLE patients. One of the most common manifestations of NPSLE is cognitive dysfunction (CD) which occurs in 21 - 81% of SLE patients. TWEAK is a TNF family ligand that mediates pleotropic effects through its receptor Fn14, including the stimulation of inflammatory cytokine production and induction of neuronal death. Recent studies in animal models and human SLE patients suggest TWEAK as a potential mediator of NPSLE.

**Objectives:** To examine potential association between serum TWEAK levels and NPSLE, mainly cognitive dysfunction in patients with SLE, to determine a possible association with other types of organ involvement and specific autoantibodies (antineuronal, antiphospholipid, anti-dsDNA, antinuclear, anti-P protein, etc), and a correlation with disease activity.

**Methods:** The SLE patients (fulfilling ACR classification criteria for SLE) have undergone a complete neuropsychiatric examination for the presence NPSLE including brain MRI. CD has been assessed according to the ACR classification of NPSLE. The activity of the disease was evaluated using the diseases activity index (SLEDAI). Serum TWEAK levels were measured by ELISA.

**Results:** We analyzed 90 SLE patients. The neuropsychiatric involvement and cognitive dysfunction with moderate to severe disability was diagnosed in 58 (64.4%), 53 (58.8%) patients, resp. The headache, cranial neuropathy and epilepsy were the most frequent neurological manifestations. Active disease was present in 44 patients (48.8%). In contrast to recent studies no significant differences were found in the serum TWEAK levels between patients with and without NPSLE. There were also no differences in serum TWEK levels between patients with and without CD. We did not observe any association of serum TWEAK levels with different organ SLE manifestations, presence of antibodies or disease activity.

**Conclusions:** NPSLE and CD were found to be frequent SLE manifestations in our cohort. However, serum TWEAK levels do not seem to be a reliable biomarker for NPSLE or other manifestations in patients with SLE. Further studies in patients with new NPSLE manifestation prior to initiating therapy may be needed.

## THU0354 THROMBOCYTOPENIA IN PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES: A PARADOXICAL THROMBOTIC RISK FACTOR

R. Hisada, M. Kato, E. Sugawara, K. Ohmura, I. Nakagawa, K. Oku, T. Bohgaki, O. Amengual, T. Horita, S. Yasuda, T. Atsumi. *Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo City, Japan*

**Background:** Thrombocytopenia is a non-criteria manifestation of antiphospholipid syndrome (APS). Antiphospholipid antibodies (aPL) have been shown to activate platelet through multiple mechanisms. In patients with idiopathic/immune thrombocytopenia, aPL have been shown to increase the risk of thrombosis. Conversely, it remains unclear whether thrombocytopenia increases the risk of thrombosis in patients who have aPL.

**Objectives:** To evaluate the relationship between thrombocytopenia and thrombosis in patients who have aPL.

**Methods:** A single center retrospective study comprising 670 consecutive patients who underwent testing for aPL including lupus anticoagulant, anticardiolipin antibodies (IgG and M), anti-β2-glycoprotein I antibodies (IgG and M), and phosphatidylserine-dependent antiprothrombin antibodies (IgG and M) between January 2004 and December 2006. Excluded were patients who had been followed-up for $\leq$1 year.

**Results:** Of 524 patients included in this study, 187 had systemic lupus erythematosus, 70 rheumatoid arthritis, and 33 primary APS. At least one of aPL was positive in 241 patients. The prevalence of thrombocytopenia was not different in aPL positive and negative patients (24% vs 18%, p=0.11). In aPL positive group, patients with thrombocytopenia experienced arterial thrombosis (46% vs. 17%, $p<0.001$), venous thrombosis (27% vs. 7%, $p<0.001$), and recurrent thrombosis (10% vs. 2%, p=0.006) more frequently than patients without thrombocytopenia. Lupus anticoagulant (56% vs. 35%, p=0.006) and phosphatidylserine-dependent antiprothrombin antibodies (57% vs 34%, p=0.001) were more prevalent in patients with thrombocytopenia than in those without. Higher aPL score (Otomo K, et al. Arthritis Rheum 2012), were detected higher (p=0.001) in patients with thrombocytopenia than in those without. In aPL negative group, conversely, patients with and without thrombocytopenia similarly experienced thrombosis (23% vs 16%, p=0.23).

**Conclusions:** Our data indicate that thrombocytopenia is associated with the risk of thrombosis in aPL positive patients providing new insight into the pathophysiology of aPL mediated platelet activation.

**Disclosure of Interest:** None declared

## THU0355 CLINICAL TRIAL SIMULATION IDENTIFIES FACTORS FOR PATIENT ENGAGEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS NEPHRITIS TRIALS IN AFRICAN-AMERICANS

S.S. Lim[1], D. McKinnell[2], M.E. Pierson[3], F.S. O'Brien[3]. *[1]Emory University School of Medicine, Atlanta, United States; [2]Deloitte UK Life Sciences Advisory, London, United Kingdom; [3]AstraZeneca, Gaithersburg, United States*

**Background:** Clinical trials of patients with systemic lupus erythematosus (SLE) and lupus nephritis (LN) can be confounded by difficulties in engaging patients. Identifying factors of non-engagement informs strategies to increase involvement and compliance.

**Objectives:** We generated qualitative data on the engagement and experience of patients in clinical trials, which can be used to improve the design and conduct of future trials.

**Methods:** A unique approach was used simulating key study visits for an upcoming study involving patients with active SLE/LN and clinical staff from an indigent care hospital in Atlanta, GA. Patients underwent a consent procedure (30–45 minutes), simulated SLE/LN screening visit (2.5 hours), and simulated SLE/LN first dosing visit (4.5–5 hours). Patients and site staff were interviewed to obtain sentiments and perceptions relating to the simulated visits.

**Results:** *Demographics:* Six African-American patients (1 male, 5 female) aged 27–60 years with moderate to severe SLE/LN were recruited. Although the sample size was small, it provided value owing to its targeted clinical context. Patients differed in cognitive ability and health literacy. *Communication:* Patients expressed a preference for obtaining general disease and specific trial information from the Internet and stated that both strong online and community support were important. Patients valued help and support to discuss their conditions and options with family and friends. For support groups, the use of lupus community leaders was suggested for communicating the importance and relevance of clinical trial participation. Study sponsors were also advised to engage the lupus community through lupus community leaders. Despite completing full informed consent procedures, not all patients understood the degree of commitment at the time of study enrollment; in addition, a few patients thought the study might cure their disease. Patients suggested developing condensed and/or electronic versions of the informed consent form in text or audio format. Staff mentioned using electronic patient-reported outcome tools, which the patients found acceptable to complete. *Patient needs:* The extent of disruption to patients' lives due to study participation was cited as a major factor for potential study withdrawal. Limited flexibility in work schedules and inflexible commitments such as child care, leading to financial burden were raised as significant concerns. Although patients were generally happy with their current disease management, they were willing to consider changing their medications for a better outcome. Some patients were motivated by being part of developing a possible cure. The simulation also considered infusion visits, which required coordination between relevant parties, with post-infusion observation times potentially shortened. The duration of study visits (2+ hours) was a concern for patients and made them particularly sensitive to wait times between procedures.

**Conclusions:** Insights and techniques from this study at an urban indigent care lupus clinic with large numbers of African-Americans can be applied to the design of future clinical trials for patients with SLE/LN in high-risk populations to potentially improve recruitment, retention, compliance and advocacy.

## THU0356 COMPARISON BETWEEN JUVENILE-, ADULT-, AND LATE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

S.V. Monov[1], D.V. Monova[2], E.A. Peneva[2], R.P. Shumnalieva[1]. *[1]Department of Rheumatology, Medical University; [2]Department of Internal Diseases, Medical Institute, Sofia, Bulgaria*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune, immune-complex, multi-system, chronic inflammatory disease of the connective tissue. Late onset SLE (LSLE) represents a specific sub-group of the disorder, beginning after 50 years of age.
**Objectives:** The objective of this study is to evaluate the association of clinical features and prognosis with age at disease onset in patients (pts) with SLE. This article discusses the prevalence, clinical course, serological features, prognosis and treatment of LSLE.
**Methods:** Medical records of 301 SLE consecutive pts were reviewed and classified into three groups according to their ages at disease presentation. Sociodemographic, clinical and laboratory data, concomitant diseases were found at the time of diagnosis of SLE. Categorical data were analyzed by chi-square test and potentially associated factors were tested by multinomial logistic regression.
**Results:** Among the pts studied, 33 (10,96%) were juvenile (J) onset ($\leq$18 years), 236 (78,41%) were adult (A) onset ($>$18 and $\leq$50 years) and 32 (10,63%) were LSLE ($>$50 years). The incidence of LSLE was significantly higher in women than in men ($p<0,001$), but the predominance of women among LSLE (4:1) was reduced when compared with that observed in JSLE or ASLE. JSLE were more likely to be untreated before admission ($p<0,001$) and have mucocutaneous manifestations ($p<0,001$), but musculoskeletal symptoms ($p<0,05$) and leukopenia ($p<0,05$) were less frequent, while comorbidities were much higher in pts with LSLE ($p<0,001$). Arthritis, fever, serositis, sicca symptoms, Raynaud's syndrome, Sjögren's syndrome, lung disease, neuropsychiatric symptoms, hemolytic anemia and thrombosis were more frequently found in LSLE, while malar rash, discoid lupus, photosensitivity, vasculitis and glomerulonephritis are less common in LSLE compared with JSLE or ASLE. Most LSLE pts have a positive anti-nuclear antibody test, but anti-double-stranded DNA, anti-C1q antibodies, anti-ribosomal antibodies, hypocomplementaemia and anti-Sm antibodies were found more frequently in JSLE and less frequently in than ASLE or LSLE. Rheumatoid factor, anti-Ro/SS A and anti-La/SSB are more often positive in LSLE.
The diagnosis of LSLE is often delayed and treatment is determined by the presence of concomitant diseases, NSAID's, antimalarials or low doses of glucocorticoids are used for the less severe forms. Immunosuppressives and higher doses of glucocorticoids are the treatments of choice for more severe organ involvements and complications.
The probability of survival was reduced in LSLE patients. With respect to this, the 10-year and 15-year survival probability were 78,2% and 58,4% in the LSLE group and 94,7% and 90,4% in patients with JSLE, respectively. Infections are the main cause of death in LSLE pts.
**Conclusions:** Our results indicate that SLE pts present with different clinical and serological manifestations according to age at disease onset. LSLE has specific features with misleading signs and symptoms, but its clinical course seems milder compared with that in younger pts. Considering that the LSLE pts had simultaneously easily controllable diseases and high incidence of comorbidities, a different treatment strategy from JSLE pts should be considered. Our data support the claim of a reduced probability of survival in the older age-group of SLE patients.

## THU0357 DIFFUSE ALVEOLAR HEMORRHAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS - A SINGLE CENTER RETROSPECTIVE CLINICAL ANALYSIS FROM INDIA

S.K. Appani, P.K. Devarasetti, R.V. Irlapati, L. Rajasekhar. *Rheumatology, Nizams Institute of Medical Sciences, Hyderabad, India*

**Background:** Diffuse Alveolar hemorrhage (DAH) a rare life threatening manifestation of Systemic Lupus Erythematosus (SLE) with high mortality.[1,2]
**Objectives:** To characterize the profile of SLE patients with DAH in our cohort.
**Methods:** Medical charts of patients with SLE and DAH from 2008 to 2015 in our institute were reviewed. Clinical, laboratory, treatment, outcome details were noted. Statistical analysis carried out with SPSS software (version 21). Independent sample T test was done to compare survivors and non-survivors.
**Results:** Nineteen (1.32%) of 1438 SLE patients had DAH. Their mean age was 24.2±7.8 years, mean duration of hospital stay 16.1±7.5 days, mean SLE disease activity index (SLEDAI) (19.2 ±8.7). Seven had DAH at initial diagnosis of lupus, 4 had recurrent episodes of DAH. Ten (52.6%) patients died. Clinical manifestations included fever (84.2%), cough (78.9%), dyspnea (100%), hemoptysis (73.7%). Organ involvement include nephritis in (14/19) 73.7%, CNS involvement (6/19) 31.6%, arthritis (9/19) 47.4%, mucocutaneous (13/19) 68.4%, myocarditis (5/19) 26.3%, pulmonary arterial hypertension (7/19) 36.8%, serositis (8/19) 42.1%, renal failure (8/19) 42.1%, autoimmune hemolytic anemia in (2/19) 10.5% patients. Leucopenia (10/19) 52.6%, thrombocytopenia (11/19) 57.9%, low complements in 14/15 patients, dsDNA positive in (16/19) 84.2%, aCL antibody positivity in 4/14, raised serum procalcitonin in 3/14. Mean erythrocyte sedimentation rate (ESR) was 52.9±41.6 mm first hour, mean creatinine 1.6±1.5 mg/dl. Concomitant infection was seen in 7 (36.8%) patients. Respiratory tract infection was seen in 5 (4 had bacterial, 1 had strongyloides) and 2 had systemic infection. Eleven (57.9%) required mechanical ventilation. All patients received intravenous methylprednisolone pulses, cyclophosphamide in (16/19) 84.2%, IVIg in 2, Rituximab in 1, plasmapheresis in 1 patient. Median follow up of survivors is 33 months, 2 lost to follow up.
Univariate analysis showed age and high ESR as independent risk factors associated with DAH. Mortality was associated with requirement of mechanical ventilation.
**Conclusions:** DAH in SLE is rare, but associated with high mortality. It occurs in patients with high disease activity. Requirement of mechanical ventilation is associated with higher mortality.

## THU0358 HIP JOINT AVASCULAR NECROSIS IN A MULTI-ETHNIC SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

S.S. Shaharir[1], R. Mohd[2], R. Mustafar[2], N.S. Shahril[3]. *[1]Rheumatology; [2]Nephrology, National University of Malaysia, Kuala Lumpur; [3]Rheumatology, Putrajaya Hospital, Putrajaya, Malaysia*

**Background:** Avascular necrosis of bone (AVN) is a well known complication in patients with systemic lupus erythematosus (SLE).
**Objectives:** To determine the prevalence of avascular necrosis (AVN) involving hip joint among SLE patients and its associated factors.
**Methods:** Consecutive SLE patients attending outpatient follow-up clinics in National University of Malaysia and Putrajaya Hospital, Malaysia from 2004 until 2014 with confirmed avascular necrosis of hip joint on magnetic resonance imaging (MRI) were reviewed. Demographics and disease characteristics of patients with AVN complications were compared with other lupus controls.
**Results:** A total of 300 patients were reviewed and majority of them were Malays (175, 58.3%) followed by Chinese (107, 35.7%), Indian (15, 5%) and others (3, 1%). Eighteen patients (6%) had hip joint AVN and more than two-thirds were bilateral (14 patients, 77.8%). The median onset of AVN was 3 (IQR 4.25) years from diagnosis of lupus. A higher proportion of patients who did not received hydroxychloroquine (HCQ) developed AVN compared to those receiving HCQ (50% vs 24.8%, p=0.02). On the other hand, prednisolone dose $\geq$60mg daily for at least 2 weeks were associated with a higher prevalence of AVN (55.6% vs 23.4%, p=0.005). Positive antiphospholipid antibody (aPL) was also associated with higher prevalence of AVN (55.6% vs 27%, p=0.01). Multivariable logistic regression analysis revealed that the independent predictors of AVN were prednisolone dose $\geq$60mg OD [OR 3.7 (95% CI 1.3–9.9)] and aPL positivity [OR3.1 (95% CI 1.1–8.3)]. HCQ use was independently associated with lower prevalence of AVN [OR 0.3 (95% CI 0.1–0.9)].
**Conclusions:** Hip joint AVN was significantly associated with positive aPL, prednisolone dose $\geq$60mg daily for at least 2 weeks while HCQ use was demonstrated to be associated with lower hip AVN prevalence.

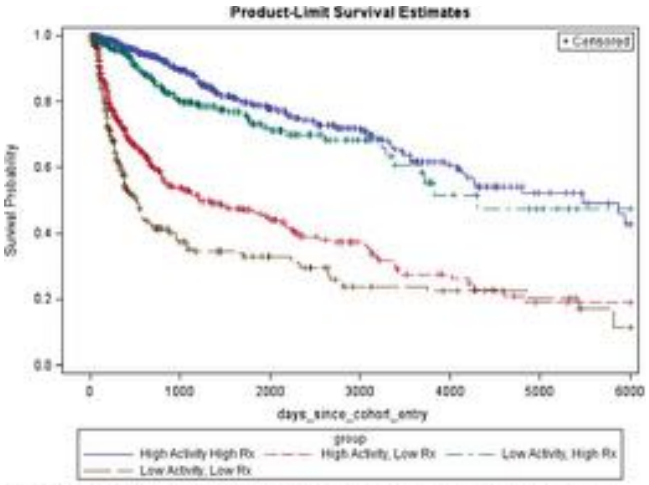
## THU0359 ANTI-B2GLYCOPROTEIN-1 IGA ANTIBODIES INDEPENDENTLY AND DIFFERENTIALLY CONTRIBUTE TO THROMBOTIC RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS ABOVE AND BEYOND ACL AND LA: LESSONS FROM A CONTEMPORARY MULTIETHNIC PATIENT COHORT

T. Aung, G. Miller, S. Ormseth, R. Moran, G. Karpouzas. *Harbor-UCLA Medical Center, Torrance, United States*

**Background:** Lupus anticoagulant (LA), IgM and IgG anticardiolipin (ACL), and anti-beta2 glycoprotein 1 (b2GPI) Ab, positive twice 12 weeks apart, constitute laboratory diagnostic criteria of the Antiphospholipid Syndrome (APLS) in patients with or without SLE. IgA ACL and b2GPI Ab subclasses are not included in this classification.
**Objectives:** We investigated the prevalence and contribution of various (sub)classes of APLs to thrombotic events in a multiethnic cohort of SLE patients. We further evaluated the independent contribution of a-b2GPI IgA to thrombotic events above and beyond criteria APL subclasses and clinical risk factors.

**Methods:** A total of 401 patients (232 latinos, 109 African Americans, 25 Caucasians and 35 Asians) fulfilling ≥4 1996 criteria for SLE, and follow-up in a single center between 2008 and 2015 were included. LA was assessed with both aPTT and DRVVT. ACL and a-b2GPI subclasses were tested using commercial ELISA kits and positivity was defined according to manufacturer specifications. Logistic regression models assessed incremental thrombotic risk by higher numbers of APL Abs. Hierarchical forward stepwise regression models evaluated incremental thrombotic risk by a-b2GPI IgA, after accounting for clinical factors (step 1, table 1), and other APL (sub)classes (step 2).
**Results:** Of 401 patients, 92 (23%) had 1 APL Ab class, 12 (3.1%) had 2, and 10 (2.7%) had 3 APLs; LA and a-b2GPI IgA were the most prevalent (14% and 13.7% respectively). Other ACL and a-b2GPI subclasses were uncommon (<2.8%). Sixty-nine (17.2%) subjects had 109 events (57 venous, 35 arterial, 14 obstetric, and 3 glomerular thrombosis); APLS was diagnosed in 34 (49.3%). Higher number of APLs yielded increased thrombotic risk compared to none [OR of 6.6, 9.9, and 27.8 for 1, 2, and 3 respectively, all with p<0.0001]; triple APL positivity bore higher event risk than single [OR=4.2, p=0.047]. In the final model (table 1), SLE duration and hypertension contributed to thrombotic risk (p<0.0001, and p=0.055 respectively), whereas age, gender, smoking, history of nephrotic syndrome, and oral contraceptives did not. Presence of ACL (IgG or IgM) and LA significantly raised risk in the entire cohort, with variation at the ethnic group level, whereas addition of a-b2GPI IgG and IgM did not; a-b2GPI IgA independently contributed an additional 3-fold risk (p=0.001), for the entire cohort, as well as all individual ethnic subgroups. Inclusion of a-b2GPI-IgA in the consensus criteria would have established an APLS diagnosis in an additional 12 subjects (+17.4%, p=0.0005).

**Table 1**: Contributions of clinical factors and various (sub)classes of APLs on thrombotic risk in patients with SLE



| | Factors | B | SE | Wald | OR | 95% CI | p-value |
|---|---|---|---|---|---|---|---|
| Step 1 | SLE Duration | 0.07 | 0.02 | 12.8 | 1.07 | 1.03-1.1 | *<0.0001* |
| | Gender | 0.78 | 0.38 | 4.3 | 2.20 | 1.04-4.54 | *0.038* |
| Step 2 | SLE duration | 0.07 | 0.02 | 10.9 | 1.07 | 1.03-1.20 | *0.001* |
| | Gender | 0.75 | 0.41 | 3.3 | 2.12 | 0.94-4.76 | 0.07 |
| | ACL IgG/IgM (+) | 1.90 | 0.64 | 8.9 | 6.70 | 1.90-23.21 | *0.003* |
| | LA (+) | 1.96 | 0.33 | 34.8 | 7.10 | 3.90-13.60 | *<0.0001* |
| Step 3 | SLE duration | 0.06 | 0.02 | 8.5 | 1.06 | 1.02-1.1 | ***0.004*** |
| | Gender | 0.75 | 0.42 | 3.1 | 2.12 | 0.92-4.80 | 0.08 |
| | ACL IgG/IgM (+) | 1.66 | 0.67 | 6.2 | 5.30 | 1.40-11.60 | ***0.013*** |
| | LA (+) | 2.03 | 0.34 | 35.2 | 7.62 | 3.90-14.90 | ***<0.0001*** |
| | a-b2GPI IgA (+) | 1.14 | .38 | 9.1 | 3.13 | 1.50-6.56 | ***0.003*** |

**Conclusions:** A-b2GPI IgA and LA were the most prevalent APLs in a contemporary multiethnic cohort of SLE patients. Higher numbers of APLs yielded higher thrombotic risk, and so did triple positivity compared to single. A-b2GPI IgA presence significantly enhanced event risk above and beyond clinical factors and all other APL subclasses.
**Disclosure of Interest:** None declared

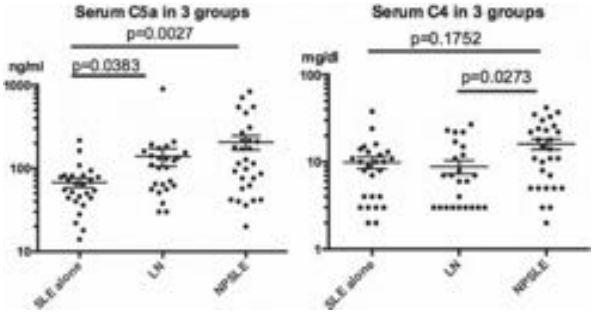
## THU0360 APPLICATION OF NEW DEFINITIONS OF REMISSION IN SLE: DURABLE REMISSION IS RARE

T.R. Wilhelm [1,2], M. Petri [1], L.S. Magder [3]. *[1] Rheumatology, Johns Hopkins University School of Medicine, Baltimore, United States; [2] Videncenter for Reumatologi og Rygsygdomme, Rigshospitalet Glostrup, Copenhagen, Denmark; [3] Epidemiology & Public Health, University of Maryland, Baltimore, United States*

**Background:** Remission is the ultimate goal in SLE. However, after more than 50 years of research on this topic, no agreement on the definition of remission has been widely accepted. Developing definition(s) of remission was one of the primary research recommendations of the treat-to-target (T2T/SLE) international task force. Definitions of remission were agreed on by an international collaboration from the DORIS working group [1].
**Objectives:** In this study, we applied four DORIS definitions of remission to a large cohort to determine the time to remission, duration of remission and predictors of remission.
**Methods:** The four DORIS definitions of remission are Clinical Remission, Complete Remission, Clinical ROT (remission on treatment) and Complete ROT. Any definition requires the clinical Systemic Lupus Disease Activity Index (cSLEDAI), meaning without serology, to be 0 and the Physician Global Assessment (PGA) to be <0.5 (0–3 VAS). For Remission, prednisone intake has to be 0 and immunosuppressives are not allowed. For ROT, prednisone intake has to be ≤5 mg per day and immunosuppressives are allowed. Clinical Remission and Clinical ROT are regardless of serology, whereas Complete Remission and Complete ROT require negative anti-ds DNA and normal complement. 2263 patients were included in our analyses. Patients entered the cohort from 1987 to 2014 and were seen at least quarterly. Patients not in remission at cohort entry were followed prospectively. We used the Kaplan-Meier approach to estimate the distribution of time to remission after cohort entry. Once remission was achieved, patients were followed prospectively until relapse occurred. The Kaplan-Meier approach was used to estimate the distribution of time from remission to relapse. Cox regression was used to identify baseline factors associated with time to remission, adjusting for baseline level of disease activity and baseline treatment.
**Results:** The median time to remission is 8.7, 11, 1.8 and 3.1 years for Clinical Remission, Complete Remission, Clinical ROT and Complete ROT, respectively. High baseline treatment is the major predictor of a longer time to remission, followed by high baseline activity (Figure). The median duration of remission is just three months. Surprisingly, this is quite similar for all the definitions. African-American ethnicity, baseline low C3 and baseline hematologic activity are negative predictors for time to remission for all definitions. Baseline anti-dsDNA and baseline low C4 are negative predictors for Complete Remission and for Complete ROT. Baseline low C4 is also a negative predictor for Clinical Remission. In multivariable models, income and education were not significant after controlling for race. Furthermore, we did not find a significant association for sex, age group and the use of hydroxychloroquine.

Kaplan-Meier Estimates of probability of not being in clinical remission, by time since cohort entry, stratified by baseline disease activity and treatment (High baseline disease activity defined as PGA ≥1 or SLEDAI ≥3. High baseline treatment defined as Prednisone >5 or Immunosuppressant use.)



**Conclusions:** Our results provide further insights into the frequency and duration of remission in SLE and call attention to the major role of baseline activity and baseline treatment in predicting remission.

## THU0361 SERUM C5A IS INCREASED IN LUPUS NEPHRITIS AS WELL AS IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS THROUGH DIFFERENT MECHANISMS

Y. Sakuma [1], T. Nagai [1], T. Yoshio [2], S. Hirohata [1]. *[1] Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Sagamihara; [2] Rheumatology and Clinical Immunology, Jichi Medical University, Tochigi, Japan*

**Background:** Neuropsychiatric manifestation in systemic lupus erythematosus (NPSLE) is one of the most serious complications of the disease. We have recently demonstrated that the breakdown of blood brain barrier (BBB) plays a crucial role in the development of diffuse psychiatric/neuropsychological manifestations (diffuse NPSLE), allowing influx of neuron-reactive autoantibodies from systemic circulation into the brain (ref). Notably, C5a, a split product of C5, has been recently shown to cause BBB damages. Moreover, association of C5a with some forms of glomerulonephritis has been implicated.
**Objectives:** The present study therefore explored the levels of C5a in sera from patients with NPSLE and lupus nephritis (LN).
**Methods:** Serum specimens were obtained from 29 patients with NPSLE including 18 patients with diffuse NPSLE and 9 patients with neurologic syndromes (focal NPSLE), 25 patients with LN, 26 patients without NPSLE or LN (SLE alone), and from 21 healthy individuals. Cerebrospinal fluid (CSF) specimens were obtained from 29 patients with NPSLE on the same day of the collection of serum specimens. The levels of C5a, C5, C3 and C4 were measured by enzyme-linked immunosorbent assay. The BBB function was evaluated by CSF /serum albumin ratio (Q albumin).
**Results:** Serum C5a was significantly increased in 80 SLE patients compared with that in healthy individuals. Serum C5a was significantly elevated in NPSLE as well as in LN compared with that in SLE alone (figure), whereas there were no significant differences in serum C5 among these 3 groups. Serum C4, but not serum C3, was significantly lower in LN than that in NPSLE (figure), indicating the activation of complement classical pathway in LN, but not in NPSLE. Q albumin was significantly elevated in diffuse NPSLE compared with that in focal NPSLE, whereas there were no significant differences in CSF C5a and in serum C5a between these 2 groups. Notably, Both CSF C5 and CSF C5a were significantly

correlated with Q albumin, whereas serum C5a, but not serum C5, was inversely correlated with Q albumin in NPSLE patients.

**Conclusions:** These results have disclosed that serum C5a was elevated in NPSLE as well as in LN through different mechanisms. Moreover, the data indicate that CSF C5a and C5 were elevated in NPSLE due to BBB damages. Finally, it is suggested that C5a might be consumed during the process of BBB damages.

## THU0362 ADVERSE PREGNANCY OUTCOMES AND ASSOCIATED FACTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Z. Zhan, D. Chen, Y. Yang, L. Liang. *Department of Rheumatology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

**Background:** Compared to the general population, pregnant women with systemic lupus erythematosus (SLE) tended to suffer a higher risk of adverse pregnancy outcomes (APOs). Since SLE often affected women of reproductive age, pregnancy outcomes and the associated factors had always been a major concern.

**Objectives:** To investigate the maternal and fetal outcomes among pregnant patients with SLE, and to evaluate the clinical predictors of adverse pregnancy outcomes.

**Methods:** We collected the clinical data from 251 SLE patients with 263 pregnancies between Jan 2001 to Dec 2015 and then conducted retrospective analysis. APOs included pregnancy loss (spontaneous or therapeutic abortion, fetal death, and neonatal death), adverse fetal outcomes [fetal malformation, preterm delivery, and neonatal lupus erythematosus (NLE)], obstetrical complications [pregnancy induced hypertension (PIH), intrauterine growth retardation (IUGR), and fetal distress]. Associated factors for APOs were analyzed by Logistic regression model.

**Results:** The mean age of patients was 28.6±3.9 yrs, apart from newly diagnosed ones, the mean duration was 5.8±4.0 yrs. Of all the 263 pregnancies, 188 were from previously diagnosed SLE patients and 75 were from newly diagnosed (during pregnancy or puerperium) patients. Successful delivery and pregnancy loss occurred in 71.5% (188/263) and 29.5% (75/263), respectively. Pregnancy loss included therapeutic abortion in 60 (22.8%), spontaneous abortion in 6 (2.3%), fetal death in 7 (2.7%), and neonatal death in 2 (0.8%). Adverse fetal outcomes included 4 cases (1.5%) with fetal malformation, 56 (21.3%) with premature and 12 (4.6%) with NLE. Obstetrical complications included 35 cases (13.3%) with PIH, 32 (12.2%) with IUGR, 21 (8.0%) with fetal distress. Pregnancy loss in newly diagnosed SLE patients was significantly higher than those in previously diagnosed ones (45.3% vs. 21.8%; $P<0.001$). In multivariate analysis, hypocomplementemia (OR=3.60, 95%CI 1.30–9.94, P=0.01), hypoproteinemia (OR=3.21, 95%CI 1.23–8.30, P=0.02), antiphospholipid antibodies positivity (OR=8.393, 95%CI 1.73–40.84, P=0.01), anti-DNP antibody positivity (OR=5.64, 95%CI 1.24–28.36, P=0.03), and hypertension (OR=14.597, 95%CI 1.51–141.60, P=0.02) were independent risk factors for APOs. Usage of hydroxychloroquine (OR=0.27, 95%CI 0.11–0.73, P=0.01) during pregnancy was a protective factor for APOs.

**Conclusions:** The rate of APOs is still high in SLE patients complicated with pregnancy. Pregnancy loss in newly diagnosed SLE patients is significantly higher than those in previously diagnosed ones. Hypocomplementemia, hypoproteinemia, antiphospholipid antibodies positivity, anti-DNP antibody positivity and hypertension are important risk factors for APOs. Usage of hydroxychloroquine during pregnancy is protective.

# Spondyloarthritis - etiology, pathogenesis and animal models

## THU0363 POSITION 97 (P97) OF HLA-B, A RESIDUE IMPLICATED IN ANKYLOSING SPONDYLITIS PATHOGENESIS, PLAYS A KEY ROLE IN CELL SURFACE FREE HEAVY CHAIN EXPRESSION VIA INTERACTIONS WITH β2-MICROGLOBULIN

L. Chen, H. Shi, J. Yuan, P. Bowness. *Botnar Research Centre, Oxford, United Kingdom*

**Background:** Polymorphisms of position 97 (P97) residue in HLA-B are strongly associated with Ankylosing Spondylitis (AS).[1] Position 97 residue locates in the α2 domain of HLA-B*27 and contributes to the C/F pocket that accommodates the C-terminal of peptide ligands.[2] Mutation of Asparagine (N) at P97 to Aspartic acid (D) has been reported to decrease HLA-B*27:04 cell surface expression.[3] We hypothesized that variations of residues at P97 might contribute to AS pathogenesis through altering cell surface HLA-B*27 expression.

**Objectives:** In this study, we studied the effect of P97 residue variants on cell surface expression of HLA-B*27.

**Methods:** Flow cytometry was used to measure surface expression of HLA-B*27 in C1R and HeLa cells expressing wildtype HLA-B*27 (N97) and six mutants at position 97 (N97T, N97S, N97V, N97R, N97W and N97D). TAP-deficient T2, Tapasin-deficient 220 cells, ERAP1-silenced and β2m-silenced C1R cells were used to identify protein interactions. β2m-deficient HCT15 cells and β2m-knockout HeLa cells were used to study the effect of P97 residues on HLA-B*27 expression in the absence of β2m. Surface expression of HLA-B*7/ HLA-B*51 and their P97 mutants in C1R and HeLa cells was also studied.

**Results:** Mutation of P97 to AS risk residue Threonine, but not to the protective residues (Serine and Valine) or the non-associated residues (Arginine and Tryptophan), increased surface free heavy chain (FHC) expression in C1R and HeLa cells. The HLA-B*27-N97D mutation significantly reduced both of HLA-B*27 FHC and classical complex expression on the surface of C1R and HeLa cells. Only β2m, not TAP, Tapasin or ERAP1, was essential for the reduction of cell surface HLA-B*27 FHC expression in HLA-B*27-N97D mutant. The expression of HLA-B*7 and HLA-B*51 was also affected by P97 residue mutations.

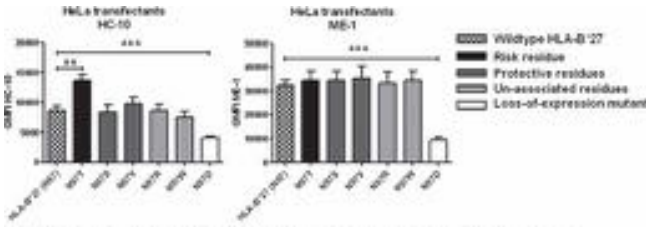

**Figure 1 P97 amino acid variants affect HLA-B*27 expression on the cell surface.** HeLa cells were transfected using lentivirus to express HLA-B*27(N97) and six mutants at position 97 (N97T, N97S, N97V, N97R, N97W and N97D). HLA-B*27 free heavy chain (HC-10 antibody) and classical HLA-B*27 complex (ME-1 antibody) cell surface expression is shown. All experiments were repeated three times. Results are expressed as mean and standard deviation. P value was determined using unpaired two-tailed t-test (** = P<0.01, *** = p<0.001).

**Conclusions:** The P97 residue affects HLA-B*27 free heavy chain and classical complex cell surface expression, in which β2m plays a key role. Cell surface expression of HLA-B*7 and HLA-B*51 is also affected by residue variations at P97. The association of P97 amino acid polymorphisms with AS is, at least in part, explained by its effect on HLA-B*27 free heavy chain cell surface expression.

## THU0364 RARE ERAP1 ALLOTYPE COMBINATIONS DO NOT EXPLAIN THE ERAP1 ASSOCIATION WITH ANKYLOSING SPONDYLITIS

L.H. Appleton, A.R. Roberts, M. Vecellio, B.P. Wordsworth. *Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Science, University of Oxford, Oxford, United Kingdom*

**Background:** Single nucleotide polymorphisms (SNPs) in *ERAP1* are strongly associated with ankylosing spondylitis (AS) (1,2). ERAP1 is an aminopeptidase involved in the generation of optimal peptide epitopes for presentation by T-cells in the context of major histocompatibility complex (MHC) class I molecules such

as HLA-B27. One small study (17 AS cases and 19 controls) suggested that the frequencies of functionally different *ERAP1* allotypes differ between patients and controls in AS (3,4). In this study 13 ERAP1 alleles were identified, many of which were rare and previously unreported; allotype *001 was reported in 44% of cases and 8% controls; allotype *002 in 3% of cases and 45% of controls; allotype *005 in 11% of cases and 29% of controls. The authors also reported that the frequencies of particular allotype combinations differed greatly between AS and controls. For example, the allotype combination *001+*005 was found in 53% of cases, but no controls. This allotype combination (and several other less common combinations) were reported exclusively in AS cases, and were shown in parallel *in vitro* experiments to be associated with poor processing of peptides and altered HLA class I expression. The results of these unexpected *ERAP1* associations clearly required verification in a larger population sample in view of their potentially dramatic implications for understanding one of the most enduring mysteries of the pathogenesis of AS, namely its association with HLA-B27.

**Objectives:** Our study was performed in a much larger sample to assess the veracity of previous suggestions that rare *ERAP1* alleles and allotype combinations are associated with AS.

**Methods:** We genotyped 213 AS families and 46 control families using KASP™ technology for 5 SNPs (M349V, K528R, D575N, R725Q, Q730E) to infer *ERAP1* allotypes. Allotype and genotype frequencies were compared.

**Results:** Several of the reported rare variants were not observed in our sample. We did not confirm the previously reported *ERAP1* associations with rare allotype combinations; the *001 allotype was seen in 17.1% of cases and 23.9% controls. Allotype *002 was seen in 34.7% of cases and 25% controls. The *005 allotype, which was common in the previous report among cases, was not seen in either of our AS cases or controls. The *001+*005 allotype combination, which was observed in 53% of cases in the previous small study was completely absent from both our larger sample of 213 cases and 46 controls.

**Conclusions:** We were unable to confirm the suggested association of AS with rare *ERAP1* allotype combinations in this much larger population study. We were also unable to confirm the diversity of *ERAP1* haplotypes previously suggested. Further investigation will be required to clarify the correlation of *ERAP1* allotype combinations with both functional effects and their potential association with AS.

## THU0365 LIGHT RS1077667 G>A GENE POLYMORPHISM IS ASSOCIATED WITH SUSCEPTIBILITY TO ANKYLOSING SPONDYLITIS IN A CHINESE HAN POPULATION

B. Yang, L. Wang. *Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China*

**Background:** Single-nucleotide polymorphisms (SNPs) are single base-pair changes which will lead to the structural changes of mRNA and get involved in the pathogenesis process of ankylosing spondylitis (AS). LIGHT is indicated to be a inflammatory mediator in AS. Meanwhile the SNP rs1077667 G>A, which was located on LIGHT, is associated with the expression of LIGHT.

**Objectives:** This study explored the relationship between AS and the SNP rs1077667 G>A in a Han Chinese population. Meanwhile we explored the relationship between the SNP and the laboratory characteristic of AS patients.

**Methods:** A case-control study with 497 subjects diagnosed AS and 387 healthy controls to compare their genotype and gene frequencies was delivered. SNP is identified by high-resolution melting methods (HRM). Clinical characteristics of patients with AS and controls were registered at the same time.

**Results:** Statistical significance was found in both co-dominant model (GG vs. GA vs. AA) (P=0.000004) and allele [p=4.59E-08, OR (95%CI) = 0.740 (0.663–0.827)] between LIGHT rs1077667 G>A and the risk of AS. However, no significant association was found between the SNP and the laboratory indexes.

**Conclusions:** This is the first study to address the association between the LIGHT rs1077667 G>A polymorphisms and AS, and it suggests a potential pathogenic factor for AS.

## THU0366 ASSOCIATION OF CHROMOSOME 1Q32 WITH ANKYLOSING SPONDYLITIS IS INDEPENDENT OF BOWEL SYMPTOMS AND FAECAL CALPROTECTIN

R.L. Roberts[1], M. Wallace[1], A. Harrison[2], D. White[3], N. Dalbeth[4], L. Stamp[5], D. Ching[6], J. Highton[7], T. Merriman[8], P. Robinson[9], M. Brown[10], S. Stebbings[7]. *[1]Department of Surgical Sciences, Dunedin School of Medicine, Dunedin; [2]Regional Rheumatology Unit, Hutt Hospital, Wellington; [3]Department of Rheumatology, Waikato Hospital, Hamilton; [4]Department of Medicine, University of Auckland, Auckland; [5]Department of Medicine, University of Otago, Christchurch; [6]Department of Rheumatology, Timaru Hospital, Timaru; [7]Department of Medicine, Dunedin School of Medicine; [8]Department of Biochemistry, University of Otago, Dunedin, New Zealand; [9]Faculty of Medicine and Biomedical Sciences, University of Queensland; [10]Diamantina Institute, Princess Alexandra Hospital, Brisbane, Australia*

**Background:** Colonoscopic, endoscopic, and histological studies have demonstrated that intestinal inflammation, similar to the ileo-colitis seen in Crohn's disease (CD), is a common feature of ankylosing spondylitis (AS). More recently, the existence of a shared genetic basis to CD and AS has been demonstrated [1,2].

**Objectives:** To test whether the association of known CD risk loci with AS is primarily due to the presence of bowel inflammation in AS patients.

**Methods:** 286 Caucasian patients fulfilling the modified New York criteria for AS and with no history of inflammatory bowel disease were assessed non-invasively for bowel inflammation using faecal calprotectin and the Dudley Inflammatory Bowel Symptom Questionnaire (DISQ) [3]. All patients and 568 matched healthy controls were genotyped with TaqMan® SNP genotyping assays for the confirmed CD risk loci [2], 1q32 (rs11584383),*JAK2* (rs10758669), *CDKAL1* (rs6908425), *IL12B* (rs100454310), *ZPBP2* (rs2872507), *MUC19/LRRK2* (rs11175593), *STAT3* (rs744166), and *IL23R* (rs1343151, rs10489630, rs11209026). Chi square testing was used to test for association.

**Results:** Minor alleles of 1q32 SNP rs11584383 (p=0.002, OR=0.69, 95% CI 0.55–0.87), and *IL23R* SNPs rs11209026 (p=0.011, OR=0.53, 95% CI 0.32–0.87) and rs1343151 (p=0.027, OR=0.77, 95% CI 0.61–0.97) all conferred protection against AS. However, only the association of 1q32 SNP rs11584383 remained significant after Bonferroni correction for multiple testing (p=0.02). The Cochran's Q test found no significant difference between ORs after stratification of AS patients by DISQ score and faecal calprotectin ($P_{difference} > 0.09$).

**Conclusions:** Previously, the association of CD risk loci with susceptibility to AS has been attributed to the co-occurrence of asymptomatic intestinal inflammation which is well recognised and supports the concept that CD and AS are two extremes of a related genetic and phenotypic disease spectrum. However, our study provides preliminary evidence that the association of the confirmed CD risk locus 1q32 SNP rs11584383 with AS is independent of bowel inflammation.

## THU0367 IDENTIFICATION OF DIFFERENTIALLY METHYLATED GENES IN PURIFIED DISEASE-RELEVANT BLOOD CELL POPULATIONS IN PATIENTS WITH SPONDYLOARTHRITIS

J. Tost[1], A. Bugge Tinggaard[1], S.-F. Wang-Renault[1], F. Busato[1], M. Dougados[2,3], C. Miceli-Richard[3,4]. *[1]Laboratory for Epigenetics & Environment, Centre National de Génotypage, CEA - Institut de Génomique, Evry; [2]Inserm (U1153), Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité; [3]Rheumatology Department, Paris Descartes University, Cochin Hospital, AP-HP; [4]Immunoregulation Unit, Pasteur Institute, Paris, France*

**Background:** Spondyloarthritis (SpA) is a complex disease involving genetic, epigenetic and environmental contributions to disease risk. However, associated polymorphisms explain only 25% of SpA heritability suggesting that a significant inherited component of SpA is not being detected by screening genetic polymorphisms and suggests an important role for epigenetic factors such as DNA methylation. However, no comprehensive analysis of genome-wide DNA methylation in disease relevant blood cell populations has so far been performed in SpA allowing to experimentally verify this hypothesis.

**Objectives:** This study aimed to perform a genome-wide DNA methylation analysis in sorted CD4 and monocytes from SpA patients compared with controls.

**Methods:** In the exploratory cohort, 24 SpA patients and 16 age and sex-matched controls were analyzed. SpA patients were monocentrically recruited between October 2014 and May 2015 in the department of rheumatology (Cochin hospital). These patients had an active disease despite NSAIDs intake and were eligible for a TNF-blocker treatment. The mean BASDAI (± SD) was 53.2±23.7; ASDAS 3.2±1.1 and CRP 13±16.6. Among these patients, 23 fulfilled the ASAS classification criteria (imaging arm) with sacro-iliitis on X-rays (n=16) or objective signs of inflammation on MRI (n=21). Only one patient fulfilled the clinical arm. Genome-wide DNA methylation patterns were analyzed in cell-sorted (MACS)

monocytes and CD4 T-lymphocyte populations from SpA patients and controls using the Illumina 450K Infinium Human Methylation 450K BeadChip allowing the simultaneous quantitative monitoring of more than 480,000 CpG positions.
**Results:** In CD4 cells 122 CpGs in 82 promoter regions of genes were found to be differentially methylated using stringent quality thresholds including several genes involved in disease-relevant signaling cascades such as Wnt-signaling and genes in which genetic polymorphisms have previously been associated with susceptibility to SpA. With 158 CpGs located in 86 promoter regions, slightly more genes were found to be differentially methylated in monocytes. Differentially methylated loci included again genes in Wnt signaling and bone metabolism, osteoblast or chondrocyte-specific genes as well as genes that have previously been shown to be implicated in related diseases such as psoriasis. A single gene was found differentially methylated in both monocytes and T-lymphocytes underlining the importance to perform these epigenetic analyses in purified cell populations. Validation of these differentially methylated positions in 12 genes at single-nucleotide resolution is ongoing in monocytes and CD4 lymphocytes from 12 additional patients and 12 additional controls using the highly quantitative pyrosequencing technology.
**Conclusions:** This study is the first to analyze genome-wide DNA methylation in purified disease-relevant blood cell populations in SpA bringing into evidence a moderate number of promoters whose deregulation might contribute to the pathogenesis of SpA. Integration with RNA expression data will allow defining the functional impact of the DNA methylation patterns to better understand the molecular changes in SpA and potentially identify novel targets for therapeutic intervention.

## THU0368 IL-22 IMPACT ON HUMAN BONE MARROW MESENCHYMAL STEM CELLS FUNCTIONS; A NOVEL PATHWAY THAT MAY CONTRIBUTE TO ABERRANT NEW BONE FORMATION IN HUMAN SPA

Y. El-Sherbiny[1,2], A. El-Zayadi[1,3], S. Churchman[1,2], T. Baboolal[1], R. Cuthbert[1], J. El-Jawhari[1], A. Alase[1], A. Badawy[3], E. Jones[1,2], D. McGonagle[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR-Leeds Musculoskeletal and Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Department of Obstetrics and Gynecology, Mansoura University Hospitals, Mansoura, Egypt*

**Background:** The spondyloarthropathies (SpAs) including ankylosing spondylitis (AS) show a propensity for florid new bone formation following bouts of inflammation. However, in other skeletal diseases such as rheumatoid arthritis, inflammation predictably leads to diffuse bone loss and periarticular erosion.[1] Anti-TNF therapies effectively alleviate spinal inflammation in SpA but fail to arrest the new bone formation.
SpAs are genetically and therapeutically linked to IL-23, which in turn regulates IL-22. it is a master regulator of stem cell niches in the intestine, liver, endometrium and skin[2] but to the best of our knowledge, no data on its influence upon human osteoprogenitors or MSCs has been described.
**Objectives:** We hypothesized that IL-22, a master regulator of stem cells in other niches, might also regulate mesenchymal stem cell (MSC) osteogenesis in an inflammation-dependent context.
**Methods:** Bone marrow samples were obtained after informed consent (n=10), and MSCs isolated and culture expanded for 2–4 passages. Cells were analysed using flowcytometry for ISCT criteria and expression IL-22R ±IFNG and TNFa stimulation. IL-22 effects were tested with and without inflammatory cytokines (IFNG and TNFa) on: MSC proliferation using colorimetric XTT assay, MSC migration using transwell migration assays, the expression of trascriptional factors of MSC adipo-, osteo- or chondro-genic potential using qRT-PCR, and on osteogenic differentiation assay evaluated by colorimetric calcium assay.
**Results:** Interestingly, IL-22R expression was detected in MSCs intracellularly and showed a mean 1.8±0.12 fold increase post IFNG and TNFa stimulation.
MSC stimulation with combined IL-22, IFNG and TNFa but not single cytokines increased MSC proliferation (p=0.008) and migration (p=0.037) compared to unstimulated MSCs.
Osteogenic, adipogenic but not chondrogenic transcription factors were upregulated by IL-22 ($p<0.05$). Moreover, Inflammatory stimuli (IFNG+TNFa±IL-22) did not affect the chondro- and adipogenic transcription factors but did temper the increase of pro-osteogenic *RUNX2*. Mature bone markers, particularly *BGLAP*/osteocalcin were rarely detectable in the presence of inflammation. The inflammatory milieu also downregulated all tested chondrogenic markers *ACAN*, *COL2A1* and *COL10A1* compared to unstimulated and IL-22 stimulated MSCs.
Notably, MSC osteogenesis was enhanced following IL-22 exposure (p=0.031 for calcium production). The combination of IFNG and TNFa with or without IL-22 suppressed MSC osteogenesis (p=0.0313 for both).
**Conclusions:** This is the first study to show that IL-22 is involved in MSC proliferation/migration in inflammatory environments with MSC osteogenesis occurring only in IFNG/TNFa absence. Given the genetic link with SpA, these physiological MSC bone responses need evaluation in pathological post-inflammation osteogenesis in human SpA.

## THU0369 IL-17A+ AND IL-22+ T CELLS INCREASE DURING ANTI-TNFα TREATMENT IN SPONDYLOARTHRITIS – A LINK TO RADIOGRAPHIC PROGRESSION?

T. Andersen[1], M. Hvid[2], T. Kragstrup[3], H. Gleerup[4], A.G. Jurik[5], R. Østgård[5], B. Deleuran[2]. *[1]Biomedicine, Aarhus University, Aarhus C; [2]Aarhus University, Aarhus, Denmark; [3]Biomedicine, Aarhus University, Aarhus; [4]Regional Hosp. Silkeborg, Silkeborg; [5]Aarhus University Hospital, Aarhus, Denmark*

**Background:** The pro-inflammatory Th17 associated cytokines IL-17A and IL-22 have been proposed as important mediators in spondyloarthritis (SpA).
Treatment of SpA has been improved dramatically with the introduction of tumor necrosis factor (TNF)α inhibitors. Despite good clinical efficacy, anti-TNFα fail to affect bone formation and radiograpchic progression in SpA. Th17 cells and cytokines might be involved in this lack of response to anti TNF-α antibodies.
**Objectives:** To investigate the association of Th17 cells with changes in clinical and MRI activity in SpA patients treated with anti-TNFα. Furthermore, to investigate the involvement of the Th17 cytokines IL-17A and IL-22 on bone anabolic pathways in SpA.
**Methods:** Percentage of IL-17A and IL-22 producing T cells were assessed in peripheral blood mononuclear cells from 30 SpA patients at baseline, after 12 and 52 weeks of anti-TNFα therapy using intracellular flow cytometry. Clinical activity was evaluated using the Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). MRI grading was performed on the whole spine and in the sacroiliac joints (SIJ). Correlation analyses were performed to investigate the association between percentages of Th17 cells and disease progression during the course of treatment.
Normal human osteoblasts and fibroblast like synoviocytes (FLS) were stimulated with IL-17A, IL-22, TNFα and supernatants from CD4+CD45RO+CCR6+ cells to determine the bone modulatory activity of Th17 cytokines.
**Results:** Percentages of IL-17A producing and IL-22 producing, and CCR6 expressing CD4+CD45RO+ T cells were increased at baseline compared with healthy controls. These subsets increased during 52 weeks of anti-TNFα therapy, despite clinical response with the composite scores ASDAS decreasing from 3.6 (3.0–4.0) to 1 (0.5–1.9) and BASDAI decreasing from 63.50 (52–71) to 15 (3- 31). High baseline percentages of IL-17A and IL-22 producing CD4+CD45RO+ T cells correlated with greater improvement in ASDAS and BASDAI score. Both baseline percentages of IL-17A and IL-22 producing CD4+CD45RO+ T cells were associated with increased levels of chronic MRI changes at baseline (both $p<0.05$). Additionally, IL-17A producing CD4+CD45RO+ T cells at baseline were associated with chronic MRI changes in the SIJ at 12 months ($p<0.01$).
IL-17A, IL-22 and TNFα stimulation increased mineral deposition from normal human osteoblasts. IL-22 in combination with TNFα inhibited the secretion of Dkk-1 from SpA FLS, whereas neither TNFα nor IL-17A were able to affect Dkk-1 secretion from SpA FLS.
**Conclusions:** Th17 cells increased during anti-TNFα therapy, regardless of clinical improvement. Th17 cell percentages at baseline predict clinical response and are associated with chronic MRI changes at baseline and outcome at 52 weeks. Not only IL-17A, but also IL-22 are able to affect bone formation and bone remodelling pathways, but only IL-22 induce Dkk-1 in FLS.
Hereby, the consistently elevated percentages of Th17 cells, despite good disease control in this group of SpA patients, could provide a link to the ongoing ectopic bone formation seen in SpA.

## THU0370 DISEASE ACTIVITY, NOT DRUG EXPOSURE, AFFECTS PREGNANCY OUTCOMES IN INFLAMMATORY ARTHRITIS

E. Fishman[1], J. Cush[2], K. Dao[3]. *[1]Texas A&M Health Science Center College of Medicine, Bryan; [2]Department of Rheumatology, Baylor Research Institute; [3]Texas Health, Dallas, United States*

**Background:** Pregnancy is commonly encountered in women who have immune mediated inflammatory arthritis such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), juvenile arthritis (JIA) or ankylosing spondylitis (AS). They are often diagnosed with these diseases during their fertile years; yet, data is scant on how disease activity and drug exposure affects maternal outcomes.
**Objectives:** Our goals were to chart medication use during pregnancy and to determine what is more likely to cause adverse fetal outcomes (AFOs): disease activity or drug exposure.
**Methods:** This is an observational study at a single clinic of females aged 18–45 years, diagnosed with RA, JIA, AS or PsA who had: 1) >12 months follow-up; 2) documented pregnancy during this period; and 3) clinic visits that qualified as being preconception (within 12 months of conception), pregnancy (1st, 2nd or 3rd

trimester) and post-partum (within 12 months after delivery). Drug exposure was classified as occurring preconception (PRE- ≥1 month before conception), at risk (RISK- 1st trimester plus 1 month preconception) or during 2nd and 3rd trimesters of pregnancy (PREG). Data collected included therapies (DMARDS, biologics, steroids, NSAIDS), modified health assessment questionnaire (mHAQ), tender joint count (TJC), swollen joint count (SJC), pain score, and global arthritis score (GAS) calculated from TJC (0–28) + pain (0–10) + mHAQ (0–24) where remission (REM) <3; low activity 3–7; mod activity 8–19; high activity >20 Maternal disease activity was further classified as flared or improved (defined: 20% change in TJC+SJC or >3 increase in joint count if PRE count <2). Fetal outcomes were classified as live births or AFOs: preterm labor, miscarriages, preeclampsia, fetal growth restrictions, or malformations. A $\chi^2$ test of homogeneity was calculated to determine if AFOs were more likely a result of drug exposure or maternal disease activity during pregnancy.

**Results:** 26 pregnancies (8 RA, 6 PsA, 4 AS, 8 JIA) were observed in 20 patients (7 RA, 5 PsA, 3 AS, 5 JIA). This number represents 7.5% of all clinic women who were fertile with these diagnoses. Mean age at delivery was 31.6 years and disease duration was 10.8 yrs. During PRE the most common drugs used were TNFi (62%), methotrexate (20%), other DMARDS (12%), other Biologics (8%), Prednisone (23%), and NSAIDs (81%). Drug use was relatively unchanged in PREG: TNFi (58% same), DMARDS (15% same), Prednisone (23% same), NSAIDs (31% less) and no drugs (15% more). Of the 10 PRE patients in REM, 5/10 stayed in REM or LDAS during PREG; 3/10 were in MDAS or HDAS POST pregnancy. Of the 16 PRE patients with GAS ≥4, only 4/16 improved to REM or stayed in LDAS during PREG; 10/16 were in MDAS or HDAS POST pregnancy. There were 4 AFOs (2 preterm, 2 miscarriage), but no malformations. The 4 AFOs occurred in women with high flare rates during pregnancy, and none of the women in remission or low disease activity states had an AFO (p=0.1422). There was no significant correlation between the different drug therapies and AFOs (p=0.5885).

**Conclusions:** These observational data show that during pregnancy, patients with inflammatory arthritis, the majority still require drugs to control their disease. Only 15% of women were able to get off of therapy. While fetal outcomes were primarily favorable, AFOs were seen in patients with the highest disease activity, and not by drug exposure.

## THU0371 INCREASED FREQUENCY OF REGULATORY CD19+CD24HIGH CD38HIGH B CELLS IN PATIENTS WITH ANKYLOSING SPONDYLITIS (AS)

M.-B. Bautista-Caro[1], I. Arroyo-Villa[1], E. de Miguel[1], D. Peiteado[1], C. Plasencia-Rodríguez[1], A. Villalba[1], A. Puig-Kröger[2], P. Sánchez-Mateos[2], E. Martín-Mola[1], M.E. Miranda Carus[1]. *[1]Rheumatology, Hospital La Paz - IdiPaz; [2]Immunology, Hospital Gregorio Marañón, Madrid, Spain*

**Background:** CD19+CD24$^{high}$CD38$^{high}$ B cells have been described to have a regulatory capacity and their frequency is altered in the peripheral blood of patients with various autoimmune diseases. The pathogenesis of AS is not well understood, and evidence suggesting the implication of either autoinflammatory or autoimmune mechanisms has been reported. In addition, increased frequencies of circulating B cells bearing a regulatory phenotype has recently been described in spondyloartrhitis (1).

**Objectives:** To study the frequency of circulating CD19+CD24$^{high}$ CD38$^{high}$ B cells (Breg) in patients with Ankylosing Spondylitis (AS), and test the regulatory capacity of this B cell subset.

**Methods:** Peripheral blood was drawn from AS patients naïve for TNF blockers (AS/nb) (n=37) and healthy controls (HC) (n=37), that were matched with patients for age and gender. After isolation by Ficoll-Hypaque gradient, PBMCs were stained with antibodies to CD3, CD4, CD19, CD24, and CD38, and examined by flow cytometry. For functional studies, total CD19+ B cells were isolated from PBMCs of 3 HC by magnetical sorting. Breg-depleted CD19+ B cells were obtained after total CD19+ B cells were depleted of CD19+CD24$^{high}$CD38$^{high}$ B cells by cytometry in a FacsVantage sorter (Beckton Dickinson). Total CD19+ B cells or Breg-depleted CD19+ B cells were established in culture and stimulated through their BCR. Secretion of IFNγ was determined by ELISA in culture supernatants.

**Results:** When compared with healthy controls, AS/nb patients demonstrated a significantly increased frequency of CD19+CD24$^{high}$CD38$^{high}$ B cells (Breg). The frequency of circulating Breg was increased not only in AS/nb patients with high or very high disease activity (ASDAS-CRP) >2.1 but also in AS patients with low activity or no activity (ASDAS-CRP<2.1). The frequency of circulating Breg cells did not correlate significantly with ASDAS-CRP, ASDAS-ESR, BASDAI, CRP or ESR values. Functional in vitro studies showed that the secretion of IFNγ was significantly higher in Breg-depleted CD19+ as compared with total CD19+ B cells, indicating that Breg have the capacity to downmodulate B cell pro-inflammatory cytokine secretion.

**Conclusions:** An increased frequency of circulating CD19+CD24$^{high}$CD38$^{high}$ B cells is observed in AS/nb patients, that is not related with disease activity. Functional in vitro studies confirmed that CD19+CD24$^{high}$CD38$^{high}$ B cells are able to downmodulate B cell pro-inflammatory cytokine secretion.

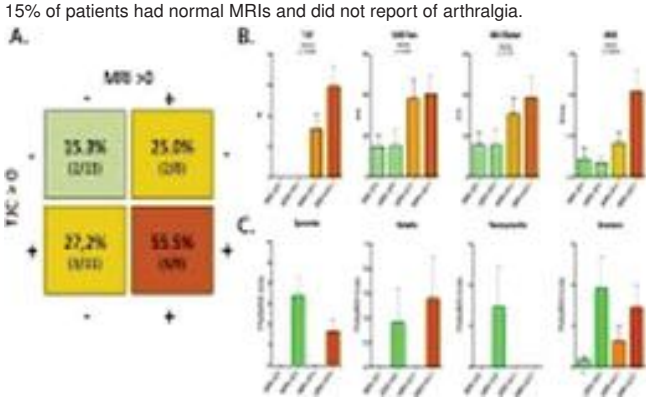
## THU0372 SUBCLINICAL JOINT INFLAMMATION IN PSORIASIS PATIENTS WITHOUT CONCOMITANT PSORIATIC ARTHRITIS- A CROSS-SECTIONAL AND LONGITUDINAL ANALYSIS

F. Faustini[1,2], D. Simon[1], I. Oliveira[1], A. Kleyer[1], J. Haschka[1,3], M. Englbrecht[1], A. Cavalcante[4], S. Kraus[1], T. Tabosa[4], C. Figueiredo[1], A. Hueber[1], R. Kocijan[1,3], A. Cavallaro[5], G. Schett[1], M. Sticherling[6], J. Rech[1]. *[1]Rheumatology and Immunology, University Erlangen-Nuremberg, Erlangen, Germany; [2]Rheumatology, Karolinska University Hospital, Stokholm, Sweden; [3]Medical Department II, St Vincent Hospital, Vienna, Austria; [4]CSD Clinica Som Diagnosticos, Belem, Brazil; [5]Department of Radiology; [6]Department of Dermatology, University Erlangen-Nuremberg, Erlangen, Germany*



**Background:** Psoriasis is a chronic inflammatory disease affecting 2–3% of the population [1,2]. Up to 30% of psoriasis patients develop psoriatic arthritis (PsA), and usually musculoskeletal symptoms start after the onset of skin disease. Psoriatic skin disease has a higher prevalence than arthritis what raises the question whether psoriasis patients without PsA are indeed spared from joint inflammation [3].

Detecting subclinical joint inflammation could help identify which patients with skin disease would benefit of treatment covering both skin and musculoskeletal inflammation.

**Objectives:** To search for subclinical inflammatory joint disease in psoriasis patients without arthritis, and to determine whether such changes are associated with the later development of PsA.

**Methods:** Eighty-five subjects without arthritis (55 with psoriasis and 30 healthy controls) received high field magnetic resonance imaging (MRI) of the hand. MRI scans were scored according to the PSAMRIS method [4]. Psoriasis patients received complete clinical investigation, high-resolution peripheral quantitative computed tomography (HR-pQCT) to detect erosions and enthesiophytes and were followed up for at least one year for the development of PsA.

**Results:** 47% of psoriasis patients showed at least one inflammatory lesion on MRI. Synovitis was the most prevalent inflammatory lesion (38%), while osteitis (11%), tenosynovitis (4%) and periarticular inflammation (4%) were less frequent. The mean (±SD) PSAMRIS synovitis score was 3.0±2.5 units. Enthesiophytes and bone erosions were not different between psoriasis patients with or without inflammatory MRI changes. The risk for developing PsA was as high as 55% if patients had subclinical synovitis and symptoms related to arthralgia, but only 15% of patients had normal MRIs and did not report of arthralgia.

**Conclusions:** Prevalence of subclinical inflammatory lesions is high in patients with cutaneous psoriasis. Arthralgia associated with MRI synovitis constitutes a high-risk constellation for the development of PsA.

## THU0373 DEGRADATION FRAGMENTS OF COLLAGEN I AND V ARE EARLY DISEASE MARKERS IN β-GLUCAN TRIGGERED SPONDYLOARTHRITIS IN SKG MICE

N.S. Gudmann[1], N. Fox[2], M. Karsdal[1], A.C. Bay-Jensen[3], J. Schmitz[2], A.S. Siebuhr[1]. *[1]Nordic Bioscience, Herlev, Denmark; [2]Eli Lilly, Indianapolis, United States; [3]Nordic Bioscience, Herlev, Andorra*

**Background:** Spondyloarthritis (SpA) is a slowly progressing, chronic inflammatory disease predominately affecting the axial skeleton. It is caracterized by excessive extracellular matrix (ECM) remodeling of the affected tissues. It is proposed that serological biomarkers of ECM remodeling can be used in assessment of SpA progression, diagnosis and treatment efficacy.
**Objectives:** In this study we investigated the turnover of selected ECM proteins in a β-glucan triggered SpA SKG mouse model. Turnover of type I, II, III and V collagen were evaluated in serum by biomarkers reflecting MMP-derived degradation fragments of the collagens (C1M, C2M, C3M and C5M, respectively).
**Methods:** Fifty SKG mice were included in the study for the SpA model. Additionally ten BALB/c mice were included as a reference of regular healthy mice. The BALB/c mice and ten SKG mice were sacrificed at week 0. The remaining SKG mice (n=40) were induced with 3 mg/kg β-glucan at week 0. 10 animals were sacrificed each at week 1, 3, 6 and 8. All groups were observationally scored weekly for the development of arthritis and skin inflammation, and body weight. Blood was collected via cardiac puncture at termination. The biomarkers (C1M, C2M, C3M and C5M) were assessed by competitive ELISAs in serum. Differences between biomarker levels in Naive SKG mice compared to other groups were evaluated by Kruskal-Wallis multiple comparison test.
**Results:** Clinical scoring revealed that the disease progressed throughout the study, starting with mild manifestations at week 1 in the β-glucan induced SKG mice. The biomarkers of interstitial tissue C1M, C3M and C5M were in general elevated compared to naïve SKG mice (Fig. A, C, D). The C5M levels were increased from an average of 2.2ng/ml to 4.6ng/ml already one week after β-glucan induction ($p<0.001$) and the levels remained elevated in all β-glucan induced mice compared to SKG naïve mice throughout the study (Fig. D). C1M was significantly increased from an average of 25.6ng/ml to 34.7ng/ml at week 1. This level was further increased at week 8 of which the average level was 48.5ng/ml ($p<0.0001$; Fig. A). C3M levels were significantly increased from an average of 14.6ng/ml in SKG naïve mice to 22.7ng/ml three weeks after β-glucan induction ($p<0.01$) and they were further increased to an average of 30.9ng/ml after eight weeks ($p<0.0001$; Fig. C)). In contrast cartilage turnover reflected by C2M (Fig. B) did not change significantly after β-glucan induction at any time point. There were no significant differences between biomarker levels of BALB/c mice compared to the SKG naïve mice.

**Conclusions:** The turnover of type I, III and V was significantly altered in this mouse model of SpA. This indicates an unbalanced turnover of the interstitial tissue. Levels of C1M and C5M were significantly increased already at week 1 after β-glucan induction, while symptoms were still weak. This suggests that C1M and C5M may be useful to assist early diagnosing. In contrast levels of C2M reflecting cartilage degradation were unaltered upon β-glucan induction, suggesting that cartilage turnover was not significantly affected in this model.

## THU0374 A LONGITUDINAL STUDY OF GUT INFLAMMATION AND THE DEVELOPMENT OF INFLAMMATORY BOWEL DISEASE IN ANKYLOSING SPONDYLITIS

E. Klingberg[1], H. Strid[2,3], A. Ståhl[4], A. Deminger[1], H. Carlsten[1], L. Öhman[4], H. Forsblad-d'Elia[1,5]. *[1]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at the University of Gothenburg, Göteborg; [2]Department of Internal Medicine, Södra Älvsborgs sjukhus, Borås; [3]Institute of Medicine, Departments of Internal Medicine and Clinical Nutrition, Sahlgrenska Academy at University of Gothenburg; [4]Microbiology and Immunology, Sahlgrenska Academy at the University of Gothenburg, Göteborg; [5]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden*

**Background:** Patients with ankylosing spondylitis (AS) have an increased risk of developing inflammatory bowel disease (IBD). There is however a lack of knowledge regarding the incidence of IBD in AS and what predicts the development from subclinical gut inflammation to IBD.
**Objectives:** To determine the intra-individual variation in fecal calprotectin (FC) over 5 years in relation to AS disease activity, disease manifestations and medication and to study the 5–year incidence of IBD in AS and identify predictors for its' development.
**Methods:** At baseline FC was assessed in 204 AS patients (NY-criteria) without diagnosed IBD. FC was then reexamined in 164 of the patients at the 5-year follow-up. The patients answered questionnaires regarding gastrointestinal symptoms, medication, physical function and disease activity. Ileocolonoscopy was performed at the 5-year follow-up if FC remained ≥200 mg/kg after 3 weeks NSAID-pause. The medical records were checked for colonoscopies, episodes of gut inflammation or diagnose of IBD during the follow-up period.
**Results:** The characteristics of the 164 AS patients [median (IQR)]: 74♀/90♂, age 54 (46–67) ys, symptom duration 27 (18–39) ys, BASDAI 3.2 (1.8–5.2), $ASDAS_{CRP}$ 2.1 (1.3–2.7), BASFI 2.3 (1.0–4.1) and BASMI 3.4 (2.4–4.6).
At the 5-year follow-up FC was elevated (>50 mg/kg) in 63% of the patients, but not associated with gastrointestinal symptoms. In 24% of the patients FC was >200 mg/kg. The intra-individual variation in FC during the 5-year follow-up was less than ±200 mg/mg in 80% (131/164) of the patients. FC was correlated with CRP ($r_S=0.219$; p=0.005), ESR ($r_S=0.172$; p=0.027), $ASDAS_{CRP}$ ($r_S=0.207$; p=0.008), hemoglobin ($r_S=-0.200$; p=0.01), BASMI ($r_S=0.207$; p=0.008) and BASFI ($r_S=0.154$; p=0.048).
Users of NSAIDs had higher FC than non-users [93 (44–215) vs. 40 (23–120) mg/kg; p=0.011], whereas DMARD users had lower FC than non-users [45 (29–87) vs. 110 (40–250) mg/kg; $p<0.001$]. Users of infliximab, adalimumab and golimumab had lower FC than non-users [48 (23–135) vs. 89 (40–210) mg/kg; p=0.022], whereas users of etanercept had higher FC [200 (93–555) mg/kg]. In linear regression DMARD-use (B= -111.6, SE=41.0, p=0.007) and BASMI (B=41.9, SE=10.7, $p<0.001$) remained independently associated with log-transformed FC.
Totally 1.5% (3/204) had been diagnosed with Crohns disease (CD) and 0.5% with lymphocytic colitis at the five-year follow-up. Furthermore 3% had demonstrated a picture of subclinical CD and 2% a picture of subclinical chronic colitis at ileocolonoscopy. A high FC and presence of mucus in diarrhea were the main predictors of the development of CD.
**Conclusions:** FC was elevated in approximately two-thirds of the patients both at baseline and at the five-year follow-up and positively associated with disease activity at both time points. The results supports a link between gut and joint disease in AS.
Use of NSAIDs and etanercept was associated with a higher FC, whereas use of other TNF-blockers and DMARDs was associated with a lower FC. The five-year incidence of CD was 1.5%, and an elevated FC was a main predictor thereof.

## THU0375 ASDAS-BASED REMISSION WAS LESS FREQUENT THAN BASDAI-BASED REMISSION, AND BOTH WERE RELATED TO CRP AND SMOKING IN EARLY AXIAL SPONDYLOARTHRITIS. THE DESIR COHORT

D. Wendling[1], X. Guillot[2], L. Gossec[3], C. Prati[1], A. Saraux[4], M. Dougados[5].
*[1]Rheumatology, CHU Jean Minjoz; [2]Rheumatology, CHU, Besançon; [3]Rheumatology, Pitié Salpétrière Hospital, Paris; [4]Rheumatology, CHU, Brest; [5]Rheumatology, Cochin Hospital, Paris, France*

**Background:** Remission is the final goal for treat to target strategy in axial spondyloarthritis (axSpA). No clear definition is currently recognized, but ASDAS-CRP inactive state or BASDAI threshold (1) have been proposed. The frequency of remission using these definitions and factors associated with remission are unknown in early axSpA.
**Objectives:** To evaluate the percentage of patients in remission in early AxSpA, comparing different definitions of remission, and to evaluate factors associated with remission at inclusion in the DESIR cohort and after 24 months.
**Methods:** DESIR is a prospective observational cohort of patients with recent onset (less than 3 years) inflammatory back pain, beginning before 45 years, suggestive of axial SpA. For each of three definitions of remission (ASAS partial remission (PR), ASDAS-CRP less than 1.3 (ASDAS-R), BASDAI less than 3.6 (1) (BASDAI-R)), the ability to detect patients in remission according to the two other definitions was assessed using ROC curves and Areas Under the Curve (AUC). Data at baseline (M0) and M24 were analyzed, to look for factors (clinical, biological and imaging) associated with remission in uni and multivariate analysis by logistic regression.
**Results:** 706 patients were evaluated at M0 and 577 at M24. At M0, the percentage of patients in remission was 4% (PR), 8% (ASDAS) 34% (BASDAI), and at M24: 15%, 24% and 54% respectively, in the whole population and in Amor, ESSG and ASAS classified patients, but lower in mNY patients (data not shown). BASDAI less than 3.6 detected best patients in PR and ASDAS-R, with AUC of 0.84 and 0.86 respectively. In univariate analysis at M0, lower ESR and CRP, DKK-1, low BMI, male gender, absence of psoriasis, less smoking, HLA-B27 positivity, ASAS criteria fulfillment, positive sacro iliac imaging, less analgesics use and less subsequent use of anti TNF at M24 were associated with remission (ASDAS-R, BASDAI-R). No association was found with age, disease duration, enthesitis, uveitis, IBD, NSAID use, mSASSS. In multivariate analysis, remission was associated with lower ESR, less smoking, use of analgesics. At M24, low ESR and CRP, female gender, less smoking, less NSAID use, lower NSAID score, ASAS criteria fulfillment, lower biologics use and lower systemic steroid use were associated with remission in univariate analysis. In multivariate analysis, remission was associated with less smoking, less analgesics, ASAS clinical arm fulfillment, less NSAIDs (ASDAS-R), low CRP (ASDAS-R), low BMI (BASDAI-R) (Table 1).

Table 1

| Remission | ASDAS-R ASDAS <1.3 | r, p | BASDAI-R BASDAI <3.6 | r, p |
|---|---|---|---|---|
| M0 (N=706) | CRP | –0.59*** | ESR | –0.04* |
| | Smoking | –1.5** | Smoking | –0.93* |
| | Analgesics | 1.55*** | Analgesics | 1.39** |
| M24 (N=577) | CRP | –0.6*** | BMI | –0.14** |
| | Smoking | –1.08* | Smoking | –1.16** |
| | ASDAS clinical | 1.76* | ASAS clinical | 1.28* |
| | NSAIDs | –1.4** | | |
| | Analgesics | –2.02*** | Analgesics | –1.74*** |

**Conclusions:** In this population suggestive of early SpA, acute phase reactants and analgesics were associated with remission at baseline and M24, but smoking appears as a major marker of disease activity and remission in early AxSpA.

## THU0376 PREVALENCE OF PERIPHERAL AND EXTRA-ARTICULAR DISEASE IN ANKYLOSING SPONDYLITIS VERSUS NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: A META-ANALYSIS

J.J. De Winter[1], L.J. van Mens[1], D. van der Heijde[2], R. Landewé[1], D.L. Baeten[1,3]. *[1]Department of Clinical Immunology and Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center/University of Amsterdam, Amsterdam; [2]Department of Rheumatology, Leiden University Medical Center, Leiden; [3]Department of Experimental Immunology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands*

**Background:** Axial spondyloarthritis (axSpA) is a common chronic inflammatory disease with predominantly axial symptoms. Besides axial symptoms, the disease is characterized by peripheral (arthritis, enthesitis, dactylitis), and extra-articular (uveitis, psoriasis, inflammatory bowel disease (IBD)) disease manifestations. A much debated question is whether the radiographic form (defined as ankylosing spondylitis or AS) and the non-radiographic form (nr-axSpA) of axSpA represent subsets of the same disorder or if they are distinct disease entities (1–4). Hypothesizing that AS and nr-axSpA reflect subsets of a single disease entity and have similar disease burden, we performed a meta-analysis of published studies of axial SpA in order to assess if the prevalence of peripheral and extra-articular disease manifestations is similar in AS and nr-axSpA.
**Objectives:** The objective of this meta-analysis was to assess the prevalence of peripheral and extra-articular disease manifestations in AS and nr-axSpA.
**Methods:** We performed a systematic literature search to identify publications describing the prevalence of peripheral and extra-articular disease manifestations in patients with AS and nr-axSpA. We assessed the risk of bias, between-study heterogeneity and extracted data. Pooled prevalence and prevalence differences were calculated.
**Results:** Eight studies including 2236 AS patients and 1242 nr-axSpA patients were included. Seven out of 8 studies were longitudinal cohort studies. There was a male dominance in AS (70.4%; 95% CI 64.4–76.0%) but not in nr-axSpA (46.8%; 95% CI 41.7–51.9), which was independent from HLA-B27 prevalence. HLA-B27 prevalence was similar in AS (78.0%; 95% CI 73.9–81.9%) and nr-axSpA (77.4%; 95% CI 68.9–84.9%). The pooled prevalence of arthritis (29.7% (95% CI 22.4–37.4%) versus 27.9% (95% CI 16.0–41.6%)), enthesitis (30.4% (95% CI 3.7–65.8%) versus 34.1% (95% CI 4.7–71.0%)), dactylitis (6.0% (95% CI 4.7–7.5%) versus 6.0% (95% CI 1.9–12.0%)), psoriasis (10.2% (95% CI 7.5–13.2%) versus 10.9% (95% CI 9.1–13.0%)) and IBD (4.1% (95% CI 2.3–6.5%) versus 6.4% (95% CI 3.6–9.7%)) were similar in AS and nr-axSpA. The pooled uveitis prevalence was higher in AS (23.0% (95% CI 19.2–27.1%)) than in nr-axSpA (15.9% (95% CI 11.8–20.4%)).
**Conclusions:** Peripheral and extra-articular manifestations are equally prevalent in AS and nr-axSpA, except for uveitis, which is slightly more prevalent in AS. These data support the concept that AS and nr-axSpA belong to one pathogenic entity with similar disease manifestations.

## THU0377 ARE PATIENTS WITH ANKYLOSING SPONDYLITIS REALLY DIFFERENT FROM NON-RADIOGRAPHIC AXIAL SPA: RESULTS FROM CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS REGISTRY

P.J. Mease[1,2], C. Karki[3], J.B. Palmer[4], M. Liu[3], R. Pandurengan[3], V. Herrera[4], J.D. Greenberg[3,5]. *[1]Swedish Medical Center; [2]University of Washington School of Medicine, Seattle, WA; [3]Corrona, LLC, Southborough, MA; [4]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [5]NYU School of Medicine, New York, NY, United States*

**Background:** Only a few european studies have shown that most of the clinical features and assessments of axial spondyloarthritis (ax-SpA) are similar in patients with/without radiographic changes[1]. However, some differences might be observed which might be prognostic factors of more severe disease.
**Objectives:** To describe the demographic, clinical, patient reported outcomes (PROs) and treatment characteristics of ax-SpA population in the Corrona registry, a large national cohort of psoriatic arthritis (PsA)/SpA patients in the US.
**Methods:** The study included ax-SpA patients enrolled in the registry between 3/2013–7/2015. Ax-SpA population was further stratified into two cohorts: ankylosing spondylitis (AS) and non-radiographic Axial SpA (nr-axSpA) based on the NY modified criteria for AS (1984) and ASAS criteria for ax-SpA without sacroiliac radiographic changes respectively. Descriptive analyses on patient characteristics (demographics, clinical, patient reported outcomes and treatment) were evaluated at enrollment into the registry. Chi-square and t-tests were used for continuous and categorical variables respectively to evaluate the differences.
**Results:** Of the 407 patients identified with ax-SpA, 310 were diagnosed with AS and 97 with nr-axSpA. Patients with AS were slightly older (mean: 49yrs vs 44 yrs) and mostly males (65% vs 57%) compared to patients with nr-axSpA respectively. Both cohorts had similar functional disability measured by health assessment questionnaire, HAQ (mean: 0.6 vs 0.6), quality of life measured by EQ-5D (mean: 0.7 vs 0.7) and mean percentage of overall activity impairment measured by WPAI (26.8% vs 31.6%). About 7.6% of AS patients had fibromyalgia compared to 9.7% of nr-axSpA (p-value: 0.5). While clinical features (BASDAI, BASFI, ASDAS) did not differ between the AS and nr-axSpA patients, signs of inflammation measured by acute phase reactants were significantly higher in patients with AS compared to nr-axSpA (mean ESR: 14.4 vs 8.9 respectively, $p<0.05$) (figure 1), which are consistent with other national cohorts (1). In addition, patients with nr-axSpA

**Figure 1: Clinical features in AS and nr-AxSpA patients in Corrona**

were more likely to have enthesitis (47.4% vs. 29.0%) and dactylitis (12.4% vs. 9.0%) respectively. Although there were some differences in the history of biologic use (65% and 74% resp.), current biologic use (61.3% and 63.9%) and use of prednisone (5.5% and 6.2%) was similar in both groups.

**Conclusions:** This is the first characterization of axial SpA patients from the US Corrona registry with stratification into ankylosing spondylitis and non-radiographic axial SpA. Patients with nr-axSpA were younger and more likely to be female compared to patients with AS. Both groups had similar clinical characteristics, quality of life, disability and work impairment.

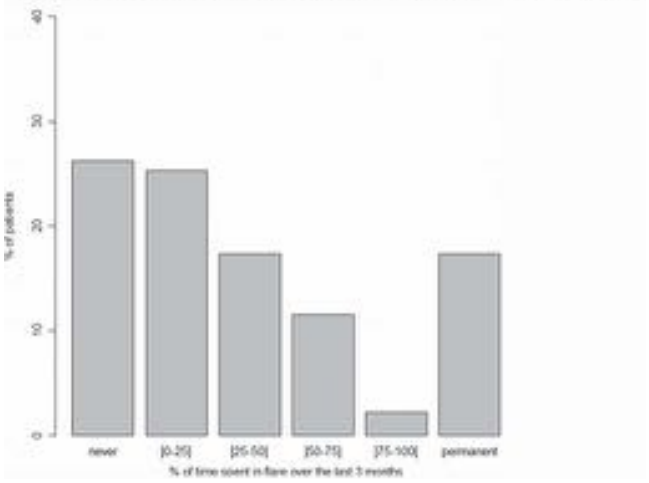
## THU0378 HOW FREQUENT WERE PATIENT REPORTED FLARES IN ANKYLOSING SPONDYLITIS PATIENTS BEFORE THE WIDE USE OF ANTITNF AND WHAT IS THE VALIDITY OF PATIENT REPORTED FLARES? A CROSS-SECTIONAL ANALYSIS OF 234 PATIENTS

C. Jacquemin[1], W. Maksymowych[2], A. Boonen[3], L. Gossec[1]. *[1]Rheumatology, Paris 6 University, Pitié-Salpêtrière Hospital, Paris, France; [2]Rheumatology, University of Alberta, Alberta Hospital, Edmonton, Canada; [3]Internal medicine, Maastricht University Medical Center, Maastricht, Netherlands*



**Background:** Axial Spondyloarthritis (axSpA) is characterized by alternated periods of flares and remission. This fluctuating disease activity varies from one patient to another in terms of symptom intensity and flares frequency and may lead to poor outcomes.

**Objectives:** The objective of this study was to assess the frequency of patient reported flares, and the validity of this concept through their related factors and through the relation between time spent in flare and disease activity assessed by BASDAI.

**Methods:** This was a cross-sectional study in 2004 from the Canadian FOllow-up Research Cohort of Ankylosing SpondyliTis (FORCAST). Participants had definite Ankylosing spondylitis (AS) according to modified New-York criteria. Current flare status (yes/no), number of flares over the past 3 months and average duration of a flare (in weeks) were assessed by self-report. Disease activity was assessed by BASDAI and BASFI was also collected. Only patients with complete data for flare questions were included in this analysis. Descriptive statistics were performed and univariate and multivariate logistic regression analysis compared patients with at least 1 flare over 3 months to those without flares, for disease activity, treatment, and demographic characteristics. Association between disease activity and percentage of time spent in flare was assessed by Spearman correlation.

**Results:** 234 patients were analyzed including 169 (72.2%) men, with a mean age of 45.5 (±11.8) years and a mean disease duration of 21.7 (±11.7) years. Their mean BASDAI and BASFI (0–10) were respectively 4.4 (±2.3) and 3.4 (±2.6); 55 (23.5%) were taking conventional disease modifying drugs and 18 (7.69%) were taking antiTNF. Overall, 117 (50%) of patients were currently in flare and 174 (74.3%) reported at least one past flare. In those with flares, the median number of flares per patient over 3 months was 3 (interquartile range, 2, 4.5), their median duration was 2 weeks (1, 3) and the median time spent in flare was 25% (0, 66.7) over 3 months (figure). In multivariate analyses patients flaring had

**Distribution of patients according to the percentage of time spent in flare over the last 3 months**

a significantly higher BASDAI (OR=1.84, p<0.001), were more often treated by NSAIDs (OR=6.65, p=0.02) and less often by anti-TNF (OR=0.16, p<0.01) than the no flare group. Patients reporting only past flares also had higher BASDAI (OR=1.59, p<0.01) and were less often treated by anti-TNF (OR=0.14, p=0.01). There was a significant correlation between the percentage of time spent in flare and the BASDAI score (r=0.58, p-value <0.0001).

**Conclusions:** In this cross-sectional study assessment of patients in 2004 little treated with anti-TNF, flares were very frequent and long; patients reported spending a mean of 25% of their time in flare. As expected patients reporting at least one recent flare had higher disease activity, were more likely to be taking NSAIDs and were less likely to be taking anti-TNF. The time spent in flare was well-correlated with BASDAI. These results indicate the validity of the concept of flares as assessed by a single question in axSpA.

## THU0379 CLINICAL DISEASE ACTIVITY MEASURES ARE ASSOCIATED WITH RADIOGRAPHIC SPINAL PROGRESSION IN EARLY AXIAL SPONDYLOARTHRITIS

D. Poddubnyy[1], M. Protopopov[1,2], H. Haibel[1], J. Braun[3], M. Rudwaleit[4], J. Sieper[1]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Kazan State Medical University, Kazan, Russian Federation; [3]Rheumazentrum Ruhrgebiet, Herne; [4]Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany*

**Background:** It has been shown in the past that elevated C-reactive protein (CRP) [1] and the composite Ankylosing Spondylitis Disease Activity Score (ASDAS) [2,3] are associated with radiographic spinal progression in axial spondyloarthritis (axSpA). It is not clear, however, whether patient-reported measures of disease activity might also play a predictive role.

**Objectives:** To investigate the association between patient-reported measures of disease activity and radiographic spinal progression over two years in early axSpA.

**Methods:** Altogether 178 patients with definite axSpA (100 with ankylosing spondylitis and 78 with non-radiographic axSpA) from the German Spondyloarthritis Inception Cohort (GESPIC) were included in the current study. Spinal radiographs (cervical spine lateral views, lumbar spine lateral and anteroposterior views) were scored according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) system and for the presence of syndesmophytes. Clinical and lab data were collected at baseline and every 6 months thereafter. Time-averaged values (over 2 years) of the patient global assessment of disease activity (PG), BASDAI and its components, CRP and CRP-based ASDAS, were calculated.

**Results:** In the logistic regression analysis there was a significant association between time-averaged patient global and syndesmophyte formation (table): the adjusted odds ratio (OR) was 1.30 (1.01–1.69) meaning a 30% increase of the chance for new syndesmophytes formation over two years with an increase of PG by 1 point (on a 0–10 scale). The time-averaged BASDAI demonstrated no significant association with radiographic spinal progression, but duration and severity of morning stiffness were both significantly associated with syndesmophytes formation with a similar strength of association as the patient global (table). Similar trends although not always significant were observed for the mSASSS worsening by 2 points and more after two years. CRP and ASDAS did show an already known association with radiographic spinal progression in early axial SpA.

**Conclusions:** Higher patient global assessment of disease activity, duration and severity of morning stiffness are clinical parameters, which are associated with

**Table:** Crude and adjusted* odds ratios for the association between disease activity parameters and radiographic spinal progression in patients with early axial spondyloarthritis.

| Disease activity measure (time-averaged) | Crude OR (95% CI) | Adjusted OR (95% CI)* |
|---|---|---|

## THU0380 A SINGLE DETERMINATION OF C-REACTIVE PROTEIN DOES NOT SUFFICE TO DECLARE A PATIENT WITH A DIAGNOSIS OF AXIAL SPA "CRP-NEGATIVE"

R. Landewé[1], T. Nurminen[2], O. Davies[3], M. Turina[1], D. Baeten[1]. *[1]Clinical Immunology and Rheumatology, Amsterdam Rheumatology & Immunology Center, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands; [2]UCB Pharma, Monheim, Germany; [3]UCB Pharma, Slough, United Kingdom*

**Background:** Four TNF-inhibiting biologicals (TNFi) have been approved by European regulatory authorities for active non-radiographic (nr) and radiographic (r; also termed ankylosing spondylitis) axial (ax) SpA.[1–4] To be eligible to receive TNFi treatment, nr-axSpA patients (pts) must have either a positive MRI showing inflammation of the sacroiliac joints or a positive CRP assessment (CRP >upper limit of normal [ULN]). CRP is also considered a predictor of treatment response in axSpA.[5] However, many axSpA pts are classed as CRP-negative despite levels close to the ULN.

**Objectives:** These analyses investigated the reproducibility of negative CRP test results in pts with active axSpA who were intolerant to or had insufficient response to NSAID treatment.

**Methods:** The 204-week (wk) phase 3 RAPID-axSpA trial (NCT01087762) evaluated the efficacy and safety of certolizumab pegol (CZP) in axSpA pts, and was double-blind and placebo (PBO)-controlled for the initial 24 wks. At screening, pts were either MRI or CRP (>ULN [7.9mg/L]) positive. PBO-treated pts continued on stable conventional medication and were re-randomized to CZP at Wk16 (ASAS20 non-responders) or Wk24 (ASAS20 responders). These analyses considered CRP data for all PBO-randomized (n=107) pts up until re-randomization to CZP (Wk16 or Wk24). CRP was assessed at screening, baseline and at 9 time points to Wk24. Descriptive methods and linear mixed models (LMM) were used to investigate time trends and variability of CRP, and empirical best linear unbiased prediction (EBLUP) to estimate prediction limits of CRP. Log(CRP+1) transformation was used for modelling.

**Results:** Of 106 pts with baseline CRP assessments, 26 (25%) had negative CRP tests at baseline, of whom 13 (50%) had ≥1 positive CRP test to Wk16 (Table). Of the 80/106 (75%) pts with positive CRP at baseline, 25 (31%) had ≥1 negative CRP test to Wk16.

LMM did not reveal statistically significant changes in mean CRP to Wk24 in pts randomized to PBO. EBLUP analysis showed that even for a pt with a CRP score of 2mg/L at a single evaluation, the 80% prediction interval for the next assessment (4 wks apart from the first) included 7.9mg/L, indicating that there was >10% chance of a positive CRP test upon re-evaluation. The 4-wk interval prior to re-evaluation was selected because residual autocorrelation was observed between assessments at shorter intervals.

The EBLUP result was supported by descriptive evaluations, with 10.8% of CRP assessments ≤3mg/L testing positive (>7.9mg/L) at their subsequent assessment (4 wks apart from the first). This increased to 53.1% when the original CRP assessment was between ≥6 and ≤7.9mg/L.

**Table:** Likelihood of finding positive CRP tests after an initial negative CRP test

| Proportion of subsequent* CRP-tests positive | Screening CRP test negative (n=26) | Baseline CRP test negative (n=26) |
|---|---|---|
| 0% | 42% | 50% |
| >0–20% | 0% | 4% |
| >20–40% | 23% | 15% |
| >40–60% | 12% | 15% |
| >60–80% | 8% | 4% |
| >80–<100% | 4% | 8% |
| 100% | 12% | 4% |

*CRP was assessed at screening, baseline and at 6 time points post-baseline to Wk16.
16 patients had negative CRP tests at both screening and baseline assessments.
Positive: CRP >7.9mg/L; Negative: CRP ≤7.9mg/L.

**Conclusions:** In axSpA pts with a clinical indication to initiate TNFi treatment, but with a negative CRP test (<ULN), the CRP test should be repeated at least once after a number of weeks, since there is a substantial chance of finding a positive result at subsequent testing.

## THU0381 THE INCIDENCE OF HERPES ZOSTER INFECTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: ANALYSIS FROM KOREAN NATIONAL HEALTH INSURANCE SERVICE–COHORT SAMPLE DATABASE

D.-H. Lim[1], S.M. Ahn[1], S. Hong[1], Y.-G. Kim[1], C.-K. Lee[1], B. Yoo[1], T.-H. Kim[2]. *[1]Division of Rheumatology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine; [2]Division of Rheumatology, Department of Internal Medicine, Hanyang University Hospital for Rheumatic Disease, Seoul, Korea, Republic Of*

**Background:** Herpes zoster (HZ) infection occurs more commonly in patients with underlying autoimmune disease, partially due to immunosuppressive treatment. However, little is known about the incidence of HZ in patients with ankylosing spondylitis (AS), especially who were treated with conventional disease modifying anti-rheumatic drugs (cDMARDs) or TNF inhibitors.

**Objectives:** The aims of our study were to investigate the incidence of HZ in AS patients and to determine whether use of cDMARDs or TNF inhibitors could increase the risk of HZ infection in AS patients.

**Methods:** We used database of the Korean National Health Insurance Service–Cohort Sample (1,025,340 individuals) from 2002 to 2013, which was age-, gender-, district- and income stratified random sample. We evaluated HZ incidence among three groups (non-DMARD users, cDMARDs [sulfasalazine, methotrexate] users and TNF inhibitor users) based on drug exposure episodes. Cox proportional hazard analysis was performed to investigate the association between treatment group and HZ infection.

**Results:** Among 1,079 patients with AS, we identified 54 HZ infections. Crude incidence rates were 11.0 per 1000 patient-years (95% CI, 8.2–14.3) in all AS patients; 9.1 (95% CI, 6.2–12.8) in non-DMARD users, 16.7 (95% CI, 9.1–28.0) in

Table 1. Hazard ratio of herpes zoster in ankylosing spondylitis patients according to the treatment regimens

| Exposures | Crude hazard ratio (95% CI) | Adjusted hazard ratio (95% CI)[a] |
|---|---|---|
| Non-DMARD | 1.00 [Reference] | 1.00 [Reference] |
| Conventional DMARD | 3.11 (1.47–6.58) | 3.70 (1.68–8.14) |
| TNF inhibitors | 2.60 (1.09–6.19) | 3.52 (1.37–9.01) |
| Etanercept | 2.57 (0.84–7.91) | 3.93 (1.21–12.76) |
| Infliximab | 1.71 (0.23–12.75) | 2.00 (0.27–15.04) |
| Adalimumab | 2.53 (0.56–11.39) | 3.40 (0.66–17.53) |
| Switching | 6.43 (0.82–50.40) | 6.27 (0.72–54.77) |

[a]Adjusted for gender, age and baseline corticosteroid use.

cDMARDs users and 14.1 (95% CI, 6.1–27.8) in TNF inhibitor users, respectively. Adjusted hazard ratio (HR) of HZ infection was higher in cDMARDs users and TNF inhibitor users than in non-DMARD users (Table). In subgroup analysis, TNF inhibitor increased the risk of HZ infection more significantly in female (adjusted HR =8.01; 95% CI, 1.97–32.54) and patients older than 50-yr (adjusted HR =7.29; 95% CI, 1.88–28.21), but not in patients exposed to baseline corticosteroid (95% CI, 0.53–32.84) compared to non-DMARD users.

**Conclusions:** The incidence of HZ in AS patients was 11.0 per 1000 patient-years which is similar to the previously reported incidence in general Korean population. cDMARDs or TNF inhibitors increased the risk of HZ infection in AS patients, especially in female and older patients, which can be considered as target of HZ vaccination in AS population.

## THU0382 DEVELOPMENT OF SPA-FEATURES IN PATIENTS WITH CHRONIC BACK PAIN OVER A ONE-YEAR COURSE: DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY (SPACE)-COHORT

Z. Ez-Zaitouni[1], M. van Lunteren[1], P. Bakker[1], M. Reijnierse[2], I.J. Berg[3], R. Landewé[4], M. van Oosterhout[5], A. Ortolan[6], D. van der Heijde[1], F. van Gaalen[1]. *[1]Rheumatology; [2]Radiology, LUMC, Leiden, Netherlands; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Rheumatology, AMC, Amsterdam; [5]Rheumatology, GHZ, Gouda, Netherlands; [6]Rheumatology, University of Padova, Padova, Italy*

**Background:** Little is known on the development of SpA-features over time in patients with recent onset chronic back pain (CBP).

**Objectives:** To explore whether patients with suspicion of axial spondyloarthritis (axSpA) develop spondyloarthritis (SpA)-features over time in the SPACE-cohort, and to study the effect of gaining features on the clinical diagnosis and classification according to the Assessment of SpondyloArthritis international Society (ASAS)-criteria for axSpA.

**Methods:** SPACE is an inception cohort study in which CBP pts (≥3 months, ≤2 years, onset <45 years) from various rheumatology centres across Europe are included. Baseline (BL) and one-year (FU) data were used for this study. Pts underwent a full diagnostic work-up consisting of MRI and radiographs of the sacroiliac joints (MRI-SI and X-SI), acute phase reactants, HLA-B27, and assessment of all other SpA-features. For the purpose of this study positive SpA-features were accumulated according to the principle of "once a feature always a feature" meaning pts were not able to "lose" features over time. Total number of SpA-features was calculated excluding sacroiliac imaging and HLA-B27 status. Clinical diagnosis (axSpA yes/no) of pts was provided by the treating rheumatologist with use of local reading and the ASAS-criteria for axSpA (based on central scoring and agreement of 2/3 readers) were used for classification.

**Results:** A total of 270 pts with CBP with both baseline and one-year follow-up visits were included: 36.7% were male, mean age (SD) at inclusion was 31.2 (8.0) years, mean number of SpA-features (SD) at BL and one-year FU were 2.8 (1.5) and 3.5 (1.6), respectively. After one year 49.3% of pts had gained one or more features. Most common features were IBP (BL: 77.0%, FU: 88.2%), good response to NSAIDs (BL: 48.5%, FU: 70.6%), elevated CRP/ESR (BL: 29.5%, FU: 43.3%), and positive family history for SpA (BL: 48.9%, FU: 52.6%).

For 16 out of the 270 pts information on diagnosis at either BL or FU was missing. In the remaining 254 patients, rheumatologists diagnosed 150 (59.1%) and 66 (26.0%) patients with axSpA and no axSpA at both time points, respectively. In 15.0% (38/254) of patients the diagnosis changed; 16 patients with no axSpA diagnosis at BL were diagnosed with axSpA at FU of which 11/16 (68.8%) had acquired one or more features. In 22 patients with axSpA at BL rheumatologists reconsidered their diagnosis at FU. In the 150 patients diagnosed with axSpA, 108/150 (72%) of patients already fulfilled the ASAS-criteria at BL and 79 (52.7%) patients gained a minimum of one feature, which led to a new the axSpA classification for 9 patients at FU.

**Figure 1.** Number of acquired SpA-features (after medical history taking, physical examination and measurement of acute phase reactants; excluding sacroiliac imaging and HLA-B27 status) at one-year follow-up (FU) in patients with and without axSpA diagnosis.

| Diagnosis | Number of features gained after one year | | | | | |
|---|---|---|---|---|---|---|
| | 0 | 1 | 2 | 3 | >3 | Total |
| AxSpA baseline and FU | 71 | 50 | 18 | 9 | 2 | 150 |
| AxSpA only at FU | 5 | 9 | 2 | - | - | 16 |
| AxSpA only at BL | 11 | 8 | 2 | 1 | - | 22 |
| No AxSpA baseline and FU | 40 | 23 | 2 | 1 | - | 66 |
| Total | 127 | 90 | 24 | 11 | 2 | 254 |

**Conclusions:** In patients with CBP of short duration almost half developed at least one new SpA-feature within one year, however the impact on diagnosis and classification was limited.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.1851

## THU0383 DOES CHANGE IN DISEASE ACTIVITY OVER ONE YEAR RESULT IN CHANGE IN HEALTH-RELATED QUALITY OF LIFE IN AXIAL SPONDYLOARTHRITIS PATIENTS?

M. Van Lunteren[1], Z. Ez-Zaitouni[1], P. Bakker[1], H. Dagfinrud[2], R. Landewé[3], M. van Oosterhout[4], R. Ramonda[5], F. van Gaalen[1], D. van der Heijde[1]. *[1]Rheumatology, LUMC, Leiden, Netherlands; [2]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [3]Rheumatology, AMC, Amsterdam; [4]Rheumatology, GHZ, Gouda, Netherlands; [5]Rheumatology, University of Padova, Padova, Italy*

**Background:** Treatment target of patients with axial Spondyloarthritis (axSpA) is based on assessment of disease activity (remission) while the ultimate goal is improvement of Health Related Quality of Life (HRQoL). Therefore it is important to know if a change in disease activity is indeed related to a change in HRQoL.

**Objectives:** To assess the association between the change in disease activity and change in HRQoL between baseline and one year in patients with early axSpA.

**Methods:** The Spondyloarthritis Caught Early (SPACE) study is a prospective cohort study in patients with chronic back pain (≥3 months, ≤2 years, onset <45 years) recruited from various rheumatology centres across Europe. The 36-item Short-Form (SF-36) was completed by patients to assess HRQoL at baseline and 1 year. After recoding and recalibration, raw scale scores were converted in scale scores ranging from 0 (worst) to 100 (best). Physical (PCS) and Mental Component Summary (MCS) scores were calculated by adjusting converted scale scores for country, gender, and age, and were compared to the general population mean of 50 with a standard deviation (SD) of 10. The Ankylosing Spondylitis Disease Activity Score (CRP based; ASDAS) was calculated to assess disease activity. Linear regression models were made with change of ASDAS between baseline and 1 year (ΔASDAS) as a determinant and the change of PCS (ΔPCS) or MCS (ΔMCS) as an outcome. The models were adjusted for age. Fulfilment of the imaging or clinical arm and gender were tested for interaction.

**Results:** A total of 86 patients fulfilled the ASAS axSpA criteria; 50 patients fulfilled the clinical arm and 36 patients the imaging arm. Mean age was 29.3 years (SD 7.7), 48.8% was male, and mean duration of back complaints was 13.8 months (SD 7.4). Patients had a mean PCS of 27.0 (SD 15.8, IQR 17.8–38.1), mean MCS of 49.3 (SD 13.0, IQR 40.0–59.4), and mean ASDAS of 2.4 (SD 1.0, IQR 1.6–3.0) at baseline. At 1 year the mean PCS increased to 36.0 (SD 13.9) and the MCS remained stable at 49.7 (SD 12.1), and mean ASDAS decreased to 2.0 (SD 0.8). As the MCS was not different from the general population, only the effect of ASDAS on PCS was determined. In the univariable model (Figure 1), a decrease of 1 unit of ASDAS between baseline and 1 year resulted in an increase of 9.7 (SE 1.5) in the PCS score over 1 year. Fulfilment of the clinical or imaging arm and gender were effect modifiers (2-way interaction) in the model for PCS ($p=0.10, R^2=38.6\%$). Results were stratified for these variables. The effect of ΔASDAS on ΔPCS was most pronounced in men (fulfilling the imaging arm (-15.8; SE 2.7) and fulfilling the clinical arm (-11.8; SE 4.0)). It was still significant but to a lesser extent in women fulfilling the clinical arm (-6.9; SE 2.1) but not in women fulfilling the imaging arm (-1.2; SE 4.8).

**Figure 1:** Association between the change in ASDAS and the change in Physical (PCS) at baseline and 1 year among axial Spondyloarthritis patients in the SPACE cohort (n=86)

Abbreviations: Physical Component Summary (PCS), Ankylosing Spondylitis Disease Activity Score, CRP-based (ASDAS)

**Conclusions:** Although improvement in ASDAS is correlated to improvement in the physical component of HRQoL, the impact of this correlation largely depends on gender and arm of the ASAS criteria: impact is highest in men fulfilling the imaging arm.

## THU0384 PERFORMANCE OF THE ASAS CLASSIFICATION CRITERIA FOR AXIAL AND PERIPHERAL SPONDYLOARTHRITIS – A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

A. Sepriano[1,2], R. Rubio[1], S. Ramiro[1], R. Landewé[3], D. van der Heijde[1]. *[1]LUMC, Leiden, Netherlands; [2]CEDOC, NMS, Lisbon, Portugal; [3]ARC, Amsterdam, Netherlands*

**Background:** The Assessment of SpondyloArthritis international Society (ASAS) has developed and validated classification criteria for axial spondyloarthritis (axSpA) and peripheral SpA (pSpA). Following their release, the ASAS criteria

have been "challenged" in different cohorts, thus warranting a review of the so-far accumulated evidence on the criteria validity and applicability.
**Objectives:** To summarize the evidence on the performance of the ASAS classification criteria for axSpA (also imaging and clinical arm separately), pSpA and the entire set of SpA, when tested against the Rheumatologist's diagnosis ("reference standard").
**Methods:** A systematic literature review was performed to identify eligible studies. Only studies with full-text available were included and, thereafter, raw data was obtained from the authors of the selected publications. A meta-analysis was performed to obtain pooled estimates for sensitivity, specificity, positive (LR+) and negative (LR-) likelihood ratios, by fitting random effects models. With a series of sensitivity analyses we assessed the possible effects of: i) target population (original validation study inclusion criteria *vs* different inclusion criteria); iii) setting (hospital *vs* community); and iii) disease duration (<2 years *vs* ≥2 years).
**Results:** Of the 1,647 retrieved articles, 8 fulfilled the inclusion criteria (N=5,042 patients). The entire set of the ASAS SpA criteria yielded a high pooled sensitivity (73%) and specificity (88%), but with limited available data (Table). Similarly good results were found for the axSpA criteria (sensitivity: 82%; specificity: 88%) in a larger number of studies. Splitting the axSpA criteria in "imaging arm only" and "clinical arm only" resulted in much lower sensitivity (30% and 23% respectively) but retaining very high specificity (97% and 94% respectively). The "imaging arm only" compared to the "clinical arm only" had a much higher LR+ (9.6 *vs* 4.5, respectively). The pSpA criteria were less tested than the axSpA and have shown a similarly high pooled specificity (87%) but lower sensitivity (63%). Sensitivity analyses yielded consistently good results for the axSpA criteria (sensitivity (range): 78% - 86%; specificity (range): 86% - 93%). For pSpA there were few studies therefore hampering sensitivity analyses.

**Table.** Results of the meta-analysis

| | Number of studies | Number of patients | LR+ (95% CI) | LR− (95% CI) | Sensitivity (95% CI) | Specificity (95% CI) |
|---|---|---|---|---|---|---|
| ASAS SpA criteria | 2 | 1,750 | 6.3 (3.2; 12.4) | 0.31 (0.13; 0.70) | 0.73 (0.47; 0.89) | 0.88 (0.81; 0.93) |
| ASAS pSpA criteria | 1 | 749 | 4.7 (3.5; 6.3) | 0.43 (0.30; 0.62) | 0.62 (0.47; 0.76) | 0.87 (0.81; 0.91) |
| ASAS axSpA criteria | 6 | 4,293 | 8.9 (3.8; 12.4) | 0.19 (0.15; 0.27) | 0.82 (0.76; 0.87) | 0.88 (0.79; 0.94) |
| axSpA criteria (imaging arm +/- clinical arm) | 5 | 3,426 | 13.6 (4.8; 38.7) | 0.45 (0.37; 0.56) | 0.57 (0.47; 0.66) | 0.96 (0.88; 0.99) |
| axSpA criteria (clinical arm +/- imaging arm) | 5 | 3,426 | 6.0 (2.9; 12.4) | 0.56 (0.43; 0.72) | 0.49 (0.34; 0.64) | 0.92 (0.82; 0.96) |
| axSpA criteria (imaging arm only) | 5 | 3,426 | 9.8 (4.4; 20.7) | 0.72 (0.59; 0.88) | 0.26 (0.16; 0.40) | 0.97 (0.94; 0.99) |
| axSpA criteria (clinical arm only) | 5 | 3,426 | 4.5 (2.3; 8.8) | 0.81 (0.72; 0.91) | 0.23 (0.17; 0.29) | 0.94 (0.89; 0.96) |

**Conclusions:** Accumulated evidence from more than 5,000 patients confirms the good performance of the various ASAS SpA criteria as tested against the Rheumatologist's diagnosis. The clinical and imaging arm have high specificity but lack sensitivity if applied separately, indicating that the full set of axSpA criteria is the preferred set.

## THU0385 PATIENT AND PHYSICIAN AGREEMENT IN ALL BATH ANKYLOSING SPONDYLITIS DISEASE ACTIVITY INDEX QUESTIONS IS EXCELLENT EXCEPT FOR ENTHESITIS

L. Ghukasyan, A. Moltó, A. Etcheto, M. Dougados. *Rheumatology Department, Hopital Cochin, Paris, France*

**Background:** The BASDAI is a validated and widely used instrument to assess disease activity in SpA. Despite being a self-administered questionnaire, in daily practice, physicians often ask the questions themselves to the patients. To the authors best knowledge no data has been reported evaluating the agreement between patient and physician for the BASDAI.
**Objectives:** To assess the agreement between patients and physicians reported BASDAI in axial SpA patients in daily practice.
**Methods:** Patients with axial SpA according to the treating rheumatologist were included. First, patients were asked to fill out the BASDAI questionnaire in the waiting room. Thereafter, and being unaware of the results reported by the patients, the rheumatologist collected another BASDAI by reading out loud the questions to the patient and giving explanations if needed. Agreement for the total score and for each question was calculated by the intraclass correlation coefficient and its 95%CI. Evaluation of the agreement for the axial BASDAI (i.e. removing questions 3 and 4) was performed identically.
**Results:** Fifty patients were included, aged 44 (±10) y and 32 (64%) males. Mean disease duration was 15 (±10) y and among them 34 (69,4%) had a radiographic sacroiliitis.
Agreement between patient and physician was excellent both for the BASDAI and axial BASDAI: ICC 0.91 [95% CI, 0.84–0.95] and ICC 0.94 [95% CI, 0.90–0.97], respectively. The lowest agreement was found for question 4 (i.e. referring to enthesitis) with an ICC [95%CI] =0.51 [0.28 – 0.69].
**Conclusions:** An excellent agreement was found between patients and physicians for the BASDAI and its axial version. However, the question for enthesitis yielded only a moderate agreement, even in a group of patients with long-standing disease, and therefore used to fill this questionnaire. This should encourage physicians to use BASDAI as a self-administered questionnaire.
**Acknowledgement:** This research was conducted while the first author Liana Ghukasyan was an ARTICULUM Fellow.

## THU0386 THE ASSOCIATION OF SERUM TRAIL LEVELS AND METABOLIC PARAMETERS IN PATIENTS WITH AS AND PSA

D. Temiz Karadağ[1], F.C. Eraldemir[2], Ö. Özdemir Işık[1], S. Tekeoğlu[1], A. Yazıcı[1], A. Cefle[1]. *[1]Internal Medicine, Rheumatology, Kocaeli University Medical School; [2]Biochemistry, Kocaeli University Medical School, Kocaeli, Turkey*

**Background:** Tumour necrosis factor-related apoptosis-inducing ligand (TRAIL), is a pro-apoptotic, multi-functional cytokine.Several studies have suggested that autoimmun diseases, diabetes mellitus, hyperlipidemia and cardiovascular diseases were associated with circulating TRAIL concentrations.
**Objectives:** The aim of this study was to investigate, whether TRAIL levels were associated with metabolic features in patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA).
**Methods:** We compared the relationship between the serum levels of TRAIL with body mass index, waist circumference, fasting plasma glucose, insulin, HOMA, hemoglobin A1C, cholesterol levels in 53 patients with AS, 42 patients with PsA and 53 healthy controls. We also analysed the association ofTRAIL with inflammatory parameters (CRP, ESR, TNF-α)and disease acitivity (BASDAI, BASFI, DAS28-ESR). None of the patients included in this study had diabetes mellitus or CVD.
**Results:** Serum levels of TRAIL were not different in patients with PsA (5,06±3,23 pg/ml), AS (4,36±2,49 pg/ml) and HC (3,85±2,2 pg/ml, *p=0,155*).Serum TRAIL had a direct and significant correlation with waist circumference (*p=0,005*), TNF-α (*p=0,000*) and CRP (*p=0,021*).When we analysed the results in patients with AS;serum TRAIL levels directly correlated with TNF-α (*p=0,003*),LDL (*p=0,041*) and total cholesterol (*p=0,026*).Serum TRAIL levels were higher in HLAB-27 positive patients than negative patients (*p=0,001*). TNF-α levels were higher in AS than PsA and healthy controls (*p=0,038*).TNF-α was inversely associated with BASDAI (*p=0,029*) and BASFI (*p=0,046*).

Table 1

| | AS (n=53) | PsA (n=42) | Healthy controls (n=53) | *p* |
|---|---|---|---|---|
| Age (mean ± SD) | 31.8±6.8 | 44±11.8 | 31.4±5 | 0.00 |
| Sex , M/F (ratio, %) | 41/12 (77.4%) | 12/30 (28.6%) | 38/15 (71.7%) | 0.00 |
| Waist circumference, cm (mean ± SD) | 89.6±13.3 | 97±12 | 84.4±10.6 | 0.00 |
| BMI, kg/m$^2$ (mean ± SD) | 26.3±5.2 | 30±5.7 | 24.3±2.9 | 0.00 |
| Fasting glucose, mg/dl (mean ± SD) | 89.2±12.5 | 95.86±21.8 | 82.13±6.9 | 0.00 |
| Insulin, IU/ml (mean ± SD) | 12.9±9.2 | 14±9.4 | 9.4±5.5 | 0.002 |
| HOMA (mean ± SD) | 2.9±2.24 | 3.65±4.2 | 1.9±1.2 | 0.00 |
| Hemoglobin A1C (mean ± SD) | 5.6±0.98 | 6.1±0.97 | 5.38±0.49 | 0.00 |
| Total cholesterol, mg/dl (mean ± SD) | 182.7±37 | 204±52.9 | 179.94±28.4 | 0.008 |
| LDL-cholesterol, mg/dl (mean ± SD) | 111±30.2 | 129±42.4 | 110.8±26.8 | 0.015 |
| HDL-cholesterol, mg/dl (mean ± SD) | 44.35±12.3 | 48.4±12.6 | 47.9±12 | 0.057 |
| Trigliserid, mg/dl (mean ± SD) | 136.2±82.2 | 148±113 | 106±62.4 | 0.042 |
| CRP, mg/dl (mean ± SD) | 0.63±0.9 | 2.1±10.9 | 0.038±0.2 | 0.00 |
| ESR, mm/h (mean ± SD) | 13.8±11.2 | 17.7±14.2 | 5.5±4.7 | 0.00 |
| TNF-α, pg/ml (mean ± SD) | 31.27±9.33 | 17.59±9.34 | 12.9±5.7 | 0.038 |
| TRAIL, pg/ml (mean ± SD) | 4.36±2.49 | 5.06±3.23 | 3.85±2.2 | 0.155 |
| BASDAI/BASFI (mean, ± SD) | 2.9±2.1/2.2±1.7 | – | – | |
| DAS28-ESR | – | 2.54±1.08 | – | |

**Conclusions:** Our results showed that, serum TRAIL levels were associated with TNF-α, LDL-cholesterol and total cholesterol in patients with AS.Serum TRAIL concentrations were higher in HLAB-27 positive patients.Further studies are needed to clarify the underlying basis, because it seems there is a complex interaction between inflammatory processes and metabolic disorders.

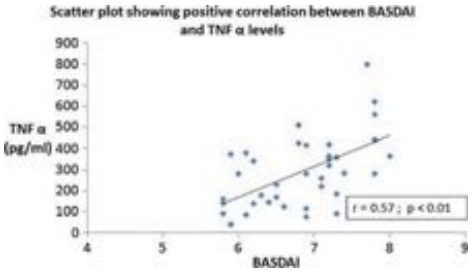
## THU0387 SERUM LEVELS OF TNF ALPHA AND VEGF AS MARKERS OF DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS



B. Mahendran, R. Sankalingam, K. Mohanasundaram, S. Sankaran, M. Mani, B. Chilukuri. *Rheumatology, Madras Medical College, Chennai, India*

**Background:** Monitoring of disease activity in axial spondyloarthritis is difficult due to lack of specific markers of inflammation. Conventional markers of inflammation namely ESR and CRP, seldom correlates with disease activity. To help in the early diagnosis and monitoring of axial spondyloarthritis, there has been a growing need for new biomarkers of disease activity.
**Objectives:** To investigate the role of serum vascular endothelial growth factor (VEGF) and tumor necrosis factor alpha (TNF α) as markers of disease activity in patients with Axial Spondyloarthritis (axSpA).
**Methods:** 40 patients with axSpA (28 with Ankylosing Spondylitis and 12 with non-radiological axSpA; mean age 29 years, mean duration 5 months) were included in this study. ESR, CRP, BASDAI/BASFI, serum TNF α and VEGF levels were assessed at baseline and after 12 weeks of therapy with either etanercept or NSAIDs (20 patients in each group). 20 healthy age and sex matched controls were also recruited for the study.
**Results:** Patients with axSpA had higher levels of serum TNF α (mean 341pg/ml) and VEGF (mean 797pg/ml) when compared with healthy controls (mean 72.5 pg/ml, $p<0.001$ and mean 269 pg/ml, $p<0.001$). There was significant reduction in serum TNF α and VEGF levels after 12 weeks of treatment with etanercept (mean 161pg/ml, $p<0.001$ and mean 442 pg/ml, $p<0.001$ respectively) but not with NSAID (p=0.29, p=0.25). Both TNF α and VEGF had a positive correlation with BASDAI (r=0.57, $p<0.01$ and r=0.44, $p<0.01$) and BASFI (r=0.61, $p<0.01$ and r=0.33, p=0.03) at baseline. The levels of TNF α and VEGF showed no correlation with ESR and CRP (p=0.48, p=0.07 and p=0.21, p=0.06 respectively)at baseline. There was no correlation between BASDAI and levels of ESR, CRP (p=0.27 and p=0.49 respectively).

Table 1. Comparison of parameters in Etanercept group (Before and after treatment)

| Parameter | Healthy control | Etanercept group (before treatment) (N=20) | Etanercept group (after treatment) | P value paired data | P value between control and before treatment group |
|---|---|---|---|---|---|
| Age (yrs) | 26 (6.1) | 27.3 (7.5) | 27.5 (7.5) | NA | 0.55 |
| BASDAI | – | 7.0 (0.6) | 3.9 (0.6) | <0.001[a] | NA |
| BASFI | – | 6.9 (0.5) | 3.8 (0.5) | <0.001[a] | NA |
| ESR (mm/hr) | – | 27.6 (16.8) | 11.4 (6.9) | <0.001[a] | NA |
| CRP (mg/L) | – | 5.5 (2.5) | 4.2 (1.2) | 0.04[a] | NA |
| TNF α (pg/ml) | 72.5 | 341.25 (142.8) | 169.5 (125.1) | <0.001[a] | <0.001[a] |
| VEGF (pg/ml) | 269.7 (142.6) | 791 (287.7) | 442.5 (208.5) | <0.001[a] | <0.001[a] |

[a]Statistically significant.

**Conclusions:** Serum levels of TNF α and VEGF serve as better markers of disease activity when compared with ESR and CRP in axSpA. Significant reduction in VEGF levels with treatment makes it a potentially new therapeutic target in axSpA

## THU0388 THE ASSOCIATIONS BETWEEN AGE WITH THE CLINICAL AND RADIOLOGICAL ACTIVITY IN SPONDYLOARTHRITIS

P.H. Li, C. Ho, H.Y. Chung, C.S. Lau. *Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong*

**Background:** Spondyloarthritis (SpA) is an umbrella term which includes several inflammatory arthritides sharing common clinical features, such as sacroiliitis, spondylitis, peripheral arthritis/enthesitis and other extra-articular manifestations. Although typically presenting at a young age, SpA is often a relentlessly progressive disease even in this new era of biologics.
In the last few years, much research has been generating on discovering new and more sensitive modalities in the use of magnetic resonance imaging (MRI) for assessing SpA. The advent of MRI has enabled clinicians to detect objective features of active inflammation, thereby allowing earlier diagnosis and more quantitative assessment of disease severity.
Despite these rapid advancements, there have been few reports on examining the association between age and disease activity in SpA, especially with the use of these various new modalities of imaging. In this cross-sectional analysis, we examine the associations between age and the clinical and radiological disease activities in axial SpA using radiographs as well as different modalities of MRI.
**Methods:** One hundred and twenty one patients fulfilling the Assessment of SpondyloArthritis International Society Classification Criteria for axial SpA were included in analyses. Patient demographics, disease activity and radiographic scores, as well as magnetic resonance imaging (MRI) with diffusion weighted imaging derived apparent diffusion coefficient values ((DWI(ADC)), were compared between patients older than and younger/equal to 40 years of age at a cross-sectional level. Variables with significant differences in univariate analyses were used as dependent variables in multivariate linear regression models adjusted for potential confounding/contributing factors.
**Results:** Multivariate analysis showed that increasing age was significantly associated with higher Bath Ankylosing Spondylitis Functional Index (B=0.04, $p<0.01$) and Bath Ankylosing Spondylitis Metrology Index scores (B=0.03, $p<0.01$); as well as higher modified Stoke Ankylosing Spondylitis Spine Score (B=0.57, $p<0.01$). On MRI, increasing age was associated with a lower SpondyloArthritis Research Consortium of Canada MRI index (B=(-0.2), p=0.01) and DWI(ADC) (B=(-0.01), $p<0.01$) of the SI joints, but higher DWI(ADC) values of the axial spine (B=0.01, p=0.01).
**Conclusions:** Increasing age in SpA was associated with greater functional impairment and structural damage, more inflammation of the axial spine, but less inflammation of the SI joints. Our findings are consistent with the traditional belief of SpA being an "ascending disease" and highlights the importance of different modalities of MRI in the diagnosis and disease monitoring of SpA.

**Disclosure of Interest:** None declared

## THU0389 COMPARING DIFFUSION WEIGHTED IMAGING (DWI) WITH CLINICAL PARAMETERS AND SHORT TAU INVERSION RECOVERY (STIR) SEQUENCE IN DETECTING SPINAL AND SACROILIIAC (SI) JOINTS INFLAMATION IN SPONDYLOARTHRITIS (SPA)

H.Y. Chung[1], C.S. Lau[2], P. Li[1]. [1]*Division of Rheumatology and Immunology, Queen Mary Hospital, Hong Kong;* [2]*Division of Rheumatology and Immunology, University of Hong Kong, Hong Kong, Hong Kong*

**Background:** DWI has been proposed for SpA diagnosis and disease monitoring1,2. The clinical correlation and effectiveness of this imaging when compared to the traditional STIR sequence is still under evaluation.
**Objectives:** To compare DWI with with clinical features, and traditional STIR sequence in detecting spinal and SI joints inflamation in SpA patients.
**Methods:** One hundred and ten patients fulfilled ASAS Axial SpA criteria were recruited consecutively from two rheumatology centers in Hong Kong. Clinical, radiological and blood parameters were collected. DWI and STIR MRI were performed simultaneously and results were scored according to the Spondyloarthritis Research Consortium of Canada (SPARCC) for comparison. The Apparent Diffusion Coefficient (ADC) values were also calculated.
**Results:** DWI showed no correlation with clinical features. When compare with STIR sequence, it correlated well with STIR sequence at the SI joints level (CC 0.76, $p<0.001$), but weakly at the spinal level (CC 0.23, p=0.02). At SI joints level, presence of inflammation by both STIR sequence and DWI were associated with increase in maximum (B=0.24, p=0.02 in STIR; B=0.37, $p<0.001$ in DWI) and mean ADC values (B=0.17, p=0.003 in STIR; B=0.15, p=0.01 in DWI). Maximum (B=0.19, p=0.04) and mean spinal ADC values (B=0.18, p=0.01) were also positively associated with DWI detected spinal inflammation. STIR sequence had no association with ADC values. Presenec of Modic lesion showed positive correlation with STIR (B=7.12, p=0.01) but not spinal ADC values.
**Conclusions:** Both STIR sequence and DWI perform similiarily in detecting active sacroiliitis. At spinal level, ADC values appear to be independent of other imaging/clinical assessment and are not affected by degenerations.

**Background:** Spondyloarthritis (SpA) has been considered relatively rare in Japan, with an estimated incidence rate of 0.48/100,000 person-years and an estimated population prevalence of less than 0.01%. However, in daily practice, we have diagnosed SpA more frequently after recent increase in awareness of this disease entity, suggesting presence of potentially severe under-diagnosis in the previous time periods. Further improvement of awareness of this disease entity is necessary to allow patients to receive appropriate treatments. In this study, we aim to characterize distinguishing clinical features of SpA in Japanese patients, which should then allow us to improve both under-diagnosis and misdiagnosis of this increasingly treatable disease entity.
**Objectives:** To evaluate clinical characteristics commonly manifested in Japanese SpA patients in COMOSPA database.
**Methods:** Descriptive statistics of patient demographics and clinical characteristics of SpA were provided in the Japanese subgroup comparing with those in rest of Asian countries and non-Asian countries. Prevalence of characteristics were compared across regions using ANOVA (continuous variables) or $\chi^2$ test (categorical variables) to identify clinical features that were more characteristic of Japanese SpA patients. These analyses were conducted using the COMOSPA database.
**Results:** 161 Japanese patients, 933 non-Japanese Asian patients, and 2890 non-Asian patients were included in the study. Mean age and male percentage for Japanese patients were 48.9 years old and 59.3%, respectively. As a baseline characteristic, Japanese patients weighed less than other groups (65.0 vs. 66.6 vs. 78.3kg, $p<0.001$). Radiographic axial SpA patients were significantly fewer in Japanese patients (50.9 vs. 76.4 vs. 61.1%, $p<0.001$). Percentage of the patients with inflammatory back pain was lower in Japanese patients (71.9 vs. 88.6 vs. 85.1%, $p<0.001$) as well. In contrast, peripheral arthritis consistent with SpA was more common in Japanese patients (75.0 vs. 46.2 vs. 63.6%, $p<0.001$), as well as dactylitis (26.9 vs. 7.2 vs. 17.6%, $p<0.001$), enthesitis (48.1 vs. 23.5 vs. 42.1%, $p<0.001$) and nail involvements (25.5 vs. 3.3 vs. 13.5%, $P<0.001$). Psoriasis was also more common in Japanese patients (38.5 vs. 6.2 vs. 20.0%, $p<0.001$). HLA-B27 was less frequently positive in Japanese patients (29.2 vs. 80.0 vs. 49.9%, $p<0.001$). Functional status measured by BASFI (Bath Ankylosing Spondylitis Functional Index) and disease activity measured by BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) tended to be lower in Japanese patients compared to non-Asian patients.
**Conclusions:** Japanese SpA patients demonstrated unique clinical pictures compared to other Asian and non-Asian countries. These results allow us to improve both under-diagnosis and misdiagnosis of the disease.

## THU0391 AXIAL DISEASE IN PSORIATIC ARTHRITIS (ADIPSA) STUDY: SERUM-SOLUBLE BONE-TURNOVER BIOMARKERS OF PSORIATIC ARTHRITIS PHENOTYPES

D. Jadon[1,2], R. Sengupta[1], A. Nightingale[3], M. Lindsay[3], H. Lu[3], A. Jobling[3], J. Dunphy[1], E. Korendowych[1], J.T. Elder[4], R.P. Nair[4], G. Shaddick[3], N.J. McHugh[1]. *[1]Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath; [2]Rheumatology, Addenbrooke's Hospital, Cambridge; [3]Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom; [4]Medicine, University of Michigan, Ann Arbor, United States*

**Background:** Psoriatic spondyloarthritis (PsSpA), peripheral-only psoriatic arthritis (pPsA) and ankylosing spondylitis (AS) are characterised by differing patterns of osteoproliferation and bone resorption, which may be reflected by levels of serum-soluble bone-turnover biomarkers.
**Objectives:** To investigate four such potential biomarkers (Dkk-1, M-CSF, MMP-3 and OPG) as predictors of: (i) PsSpA occurrence; (ii) axial radiographic severity; (iii) psoriatic arthritis mutilans (PAM) occurrence.
**Methods:** A prospective single-centre cross-sectional study (ADIPSA) recruited pPsA (n=127; fulfilling CASPAR criteria), PsSpA (n=118; psoriasis with radiographic sacroiliitis and/or spondylitis) and AS (n=157; fulfilling modified New York criteria) cases, and assessed them clinically, radiographically, and in terms of serum biomarkers. Serum was obtained from two other centres of clinically characterised psoriasis-only (PsC; n=200) cases, and sex/age-matched healthy controls (HC; n=50). ELISA was used to measure serum Dkk-1, M-CSF, MMP-3 and OPG concentrations. Multivariable regression analyses compared serum concentrations across disease groups.
**Results:** OPG is a biomarker of axial disease in spondyloarthritis (SpA) cases; concentrations were significantly lower in SpA cases with axial disease (RAD) than in those without (non-RAD) (adjusted odds ratio, $OR_{adj}$ 0.20 per ng/ml increase in concentration; 95%CI 0.05, 0.80; p=0.02), independently of having psoriasis.
Dkk-1 is a biomarker of axial disease in SpA cases, with a pattern for increasing concentration along a spectrum of increasing axial involvement. Dkk-1 concentrations were significantly higher in SpA cases with axial disease than in those without ($OR_{adj}$ 1.22; 95%CI 1.05, 1.42; p=0.01), independently of having psoriasis, and significantly lower in PsSpA than AS cases ($OR_{adj}$ 0.85; 95%CI 0.74, 0.98; p=0.02).
M-CSF is a biomarker of arthritis. Compared with HC, M-CSF concentrations were significantly lower in pPsA ($OR_{adj}$ 0.14; 95%CI 0.06, 0.32; $p<1x10^{-5}$), PsSpA

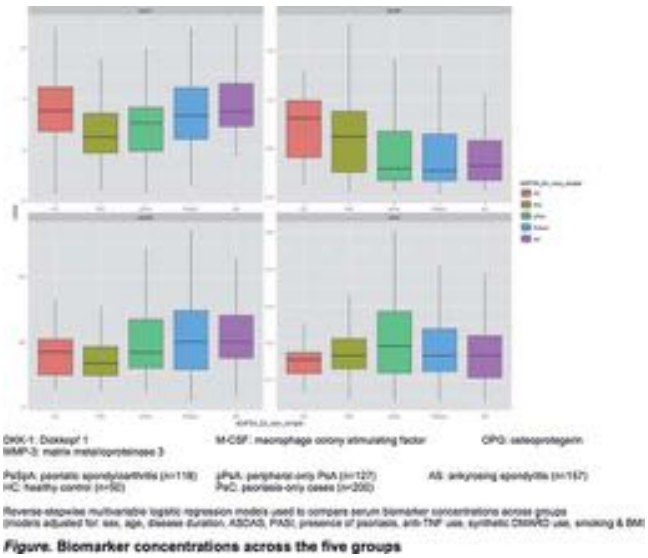

**Figure. Biomarker concentrations across the five groups**

($OR_{adj}$ 0.07; 95%CI 0.03, 0.17; $p<1x10^{-8}$), and AS ($OR_{adj}$ 0.37; 95%CI 0.16, 0.85; $p<1x10^{-7}$). Similarly, M-CSF concentrations were significantly lower in PsA than PsC cases ($OR_{adj}$ 0.44; 95%CI 0.24, 0.82; p=0.01).
MMP-3 is a biomarker of arthritis. Compared with HC, MMP-3 concentrations were significantly higher in pPsA ($OR_{adj}$ 1.06; 95%CI 1.01, 1.10; p=0.02), PsSpA ($OR_{adj}$ 1.06; 95%CI 1.01, 1.11; p=0.02), and AS ($OR_{adj}$ 1.06; 95%CI 1.01, 1.11; p=0.01). Similarly, MMP-3 concentrations were significantly higher in PsA than PsC cases ($OR_{adj}$ 1.02; 95%CI 1.01, 1.03; p=0.0004).
There were no significant associations between biomarkers and either morphology or radiographic severity (mSASSS or PASRI).
Biomarker levels were no different in PsA cases with/without PAM.
**Conclusions:** OPG and Dkk-1 appear to be biomarkers of axial disease in SpA patients (pPsA, PsSpA, AS), independently of cutaneous psoriasis status. M-CSF and MMP-3 appear to be biomarkers of arthritis, but don't differentiate SpA phenotypes. No biomarkers for PAM occurrence in PsA were found. The high concentration of Dkk-1 in AS and PsSpA, supports previous evidence that Dkk-1 is dysfunctional in axial SpA.

## THU0392 BONE MINERAL DENSITY CHANGES IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS

E. Gubar[1], T. Dubinina[1], A. Dyomina[1], A. Godzenko[2], O. Rumyantseva[1], A. Smirnov[1], S. Glukhova[1], M. Urumova[1], S. Erdes[1], E. Nasonov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology; [2]Riussian Medical Academy of Postgraduate Education, Moscow, Russian Federation*

**Background:** Bone loss in patients (pts) with early axial spondyloarthritis is insufficiently studied.
**Objectives:** To assess 1-year bone mineral density (BMD) changes at the femoral neck (FN) and lumbar spine (LS) in pts with early axial spondyloarthritis (axSpA).
**Methods:** 47 pts (20 men and 27 women) with axSpA and <5 years duration of inflammatory back pain (ASAS 2009 criteria) of the Russian CORSAR cohort were observed. Pts included had baseline and 1-year-visit BMD measurements. Pts matched the ASAS criteria and were observed according to ASAS guidelines. At baseline, the median age was 27.0 (24.0–31.0) years, disease duration 22.0 (10.0–34.0) months. 90% of pts were HLA-B27 positive. 46% of pts alongside inflammatory back pain also had peripheral arthritis. Median BASDAI was 3.5 (2.1–5.2), ASDASCRP 2.3 (1.4–3.2), ESR 9.0 (5.0–24.5) mm/h, CRP 3.9 (1.0–19.7) mg/L. Femoral neck (FN) and lumbar spine (LS) (L2–4) BMD were measured in all pts using dual-energy x-ray absorptiometry (DXA). Low BMD was defined as Z score ≤-2 SD (at least in one investigated site). MRI of sacroiliac joints (SIJs), LS and hip joints (HJs) (in case of hip joint involvement) were performed using Signa Ovation 0.35 T scanner (matrix 288x192).
**Results:** In all 47 pts, baseline median Z-score was -0.6 (-1.3 – 0.2) SD for the FN and -0.7 (-1.8 – 0.3) SD for the LS. Z-score for the FN was significantly lower in women: -1.0 (-1.5 – -0.3) SD and 0.0 (-0.75 – 0.4) SD, respectively, p=0.0065. At baseline examination low BMD at least in one of the sites was evidenced in 8 (17%) pts (4 men and 4 women). While all 8 pts had low LS BMD, 3 of them had also low FN BMD. At baseline examination of the 47 pts association between lumbar spine MRI-spondylitis and low BMD was revealed. MRI-spondylitis was evidenced in 8 (17%) pts: 3 (62.5%) of them had low FN and/or LS BMD, while 5 (62.5%) pts of this group had normal BMD values. In contrast, within the group of pts without the LS MRI inflammation (n=39) nobody had low BMD (p=0.0006). Initially, there was found a relationship between high ASDAS activity and low BMD: 11.5% of pts with high ASDASCRP values had low BMD. In contrast, within the group of pts with low or moderate ASDASCRP values nobody had low BMD (p=0.054).
Among the 8 pts with low baseline BMD, 1-year BMD normalized in 3 pts (all women and all initially had low LS BMD). In one patient (male) with normal baseline BMD values low LS BMD at the 1-year visit was observed. Therefore, at 1-year visit fewer pts had low BMD than at baseline examination (n=8, 17% vs n=6, 12.8%, respectively). In males the lowering of LS BMD at 1-year visit was evidenced with much higher confidence than in females (5 among 20 pts, 25%, vs 1 among 27 pts, 3.8%, respectively; p=0.043).
Neither at baseline examination nor at 1-year visit any correlation was detected between low BMD and disease duration, high disease activity according to BASDAI, raised CRP or ESR levels, the presence of MRI-sacroiliitis or MRI-coxitis.
**Conclusions:** In the Russian cohort of axSpA pts there was found an association between active MRI-spondylitis of the LS and BMD reduction in LS and/or FN. The findings corroborate the hypothesis that low BMD in pts with early axSpA is a result of inflammation. Males more often than females had lowered LS BMD after 1 year of observation.

## THU0393 INCREASED 18F-FLUORIDE UPTAKE LESIONS AT VERTEBRAL CORNERS ON POSITRON EMISSION TOMOGRAPHY PREDICT NEW SYNDESMOPHYTES DEVELOPMENT IN ANKYLOSING SPONDYLITIS

E.-K. Park[1], S.-G. Lee[1], D.-W. Koo[1], J.-H. Park[1], G.-T. Kim[2], H.-S. Tag[2], J.-W. Lee[3]. *[1]Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital; [2]Internal Medicine, Kosin University College of Medicine; [3]Internal Medicine, Busan St. Mary's Hospital, Busan, Korea, Republic Of*

**Background:** 18F-fluoride uptake on positron emission tomography (PET) represents osteoblastic activity. Previous cross-sectional studies showed that increased 18F-fluoride uptake lesions at vertebral corners were associated with both inflammation and structural changes on magnetic resonance imaging (MRI) and radiography, respectively, in patients with ankylosing spondylitis (AS) [1,2]. But, longitudinal studies that investigated the association between increased 18F-fluoride uptake lesions and future syndesmophytes formation are lacking.
**Objectives:** We aimed to demonstrate that increased 18F-fluoride uptake lesions on PET predict the development of new syndesmophytes.
**Methods:** In 12 patients with AS, 18F-fluoride PET-MRI (Philips Healthcare, Cleveland, OH, USA) was performed at baseline and radiography was performed at baseline and 2 years. We recorded 18F-fluoride uptake lesions on PET, acute (type A) and advanced (type B) corner inflammatory lesions (CILs) and fat lesions on MRI and syndesmophytes on radiography. An increased 18F-fluoride uptake lesion was defined as an uptake greater than the uptake in the adjacent normal vertebral body (Figure 1).

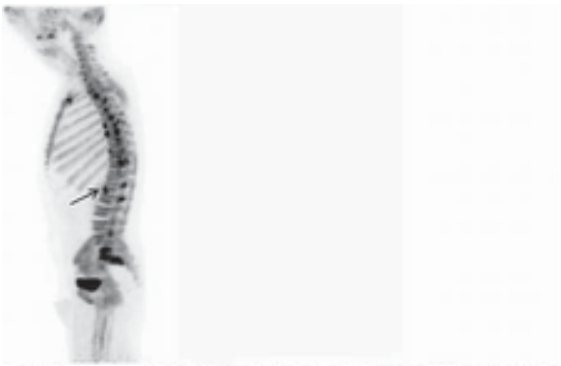

Figure 1. Increased 18F-fluoride uptake lesions at L1 lower and L2 upper anterior vertebral corners (arrow) on positron emission tomography in a 43-year old patient with ankylosing spondylitis

**Results:** Of 231 anterior vertebral corners without syndesmophyte at baseline, 13 type A CILs (5.5%), 2 type B CILs (0.9%) and 20 fat lesions (8.7%) on MRI and 6 increased fluoride uptake lesions (2.6%) on PET were observed. After 2 years, 16 new syndesmophytes (6.9%) in 8 AS patients (66.7%) occurred. New syndesmophytes developed significantly more frequently in anterior vertebral corners with increased 18F-fluoride uptake lesions (50%) or fat lesions (25%) at baseline, as compared with those without either feature (5.8% and 5.2%, respectively). In generalised linear latent mixed models after adjusting within-patient correlation, baseline increased 18F-fluoride uptake lesion significantly predicted the development of new syndesmophytes (OR=20.6, 95% CI=2.7–156.1, p=0.003). Fat lesions were also associated with new syndesmophytes development (OR=9.3, 95% CI=2.1–40.2, p=0.003), but this association was not observed in CILs.
**Conclusions:** Our findings indicate that increased 18F-fluoride uptake lesions can predict future new syndesmophytes formation in patients with AS. 18F-fluoride PET may be used to estimate structural damage in these patients.

## THU0394 MRI ASSESSMENT OF AXIAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE-RELATED SPA: AGE AT DISEASE DIAGNOSIS, NOT EXTENT AND SEVERITY OF AXIAL DISEASE, RELATES TO HLA-B27

G. De Marco[1,2], D. McGonagle[1,2], G. Lettieri[1,2], S.Z. Aydin[3], M. Merashli[1,2], J. Hamlin[4], H. Marzo-Ortega[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Division of Rheumatology, University of Ottawa, Ottawa, Canada; [4]Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Up to 20% of inflammatory bowel diseases (IBD) cases may have an associated form of Spondyloarthropathy (SpA). Axial disease in SpA may vary from sporadic back pain to advanced spinal fusion, undistinguishable from Ankylosing Spondylitis (AS). Magnetic resonance imaging (MRI) is well established in the assessment of spinal disease in SpA, but axial MRI data in IBD are still sparse. In AS and axial Psoriatic Arthritis (PsA), it has previously been shown that the extent and severity of inflammatory changes of bone marrow oedema (BMO) on MRI is related to HLA-B27.
**Objectives:** The aims of this study were to describe the prevalence and extent of BMO lesions and their relationship with HLA-B27 status in IBD-related SpA with axial symptoms.
**Methods:** Consecutive MRI scans [thoracic spine (TS), lumbar spine (LS) and sacroiliac joints (SIJs)], from patients attending the Leeds Combined Rheumatology and Gastroenterology service between 2005–2015, were assessed retrospectively. Scans had been performed as part of clinical assessment for inflammatory back pain. All subjects had histological diagnosis of IBD and fulfilled ASAS classification criteria for SpA, HLA-B27 status and demographics were also collected. MRI scans were scored by consensus by two expert readers, blinded to the clinical characteristics of the patients. We used the semiquantitative (0–3) Leeds MRI Scoring System for BMO lesions representative of inflammation in the spine and SIJs, whereby a lesion graded as moderate (grade 2) is considered clinically significant. Concordant data from the two readers were used to report on definite lesions.
**Results:** MRI scans from 43 patients were available for analysis; mean age 43.4 yrs (SD 13.2, range 18.1–80.9), 25 were females (58.1%). Mean age at SpA diagnosis was 37.1 yrs (SD 11.9, range 17.1–63). HLA-B27 was positive in 15 subjects (34.9%) and was associated with younger age at SpA diagnosis (p=0.015). The median MRI score and number of BMO lesions were 2 (IQR 0–7 and 0–5, respectively), 13 patients (30.2%) scored zero, 14 subjects (32.6%) showed at least 1 clinically relevant lesion (grade $\geq$2). Gender, current age or age at MRI scan were not associated with HLA-B27. MRI total (whole axial skeleton) and partial (TS, LS and SIJs single analysis) score, number of BMO lesions and severe lesions (total axial skeleton and TS-LS-SIJs single analysis) were not different according to HLA B27 status.
**Conclusions:** Although the majority of IBD-related SpA do not carry HLA B27, diagnosis at a younger age was related to HLA-B27 status. Axial BMO lesions in IBD disease showed the whole spectrum of changes noted in AS. Unlike AS and axial PsA, no association was found between the extent and severity of MRI-determined axial disease and HLA-B27.

## THU0395 THE PREVALENCE OF INFLAMMATORY AND STRUCTURAL LESIONS ON MRI OF THE SACROILIAC JOINTS IN PATIENTS WITH VERY EARLY PERIPHERAL SPONDYLOARTHRITIS

G. Varkas[1,2], P. Carron[1], H. Cypers[1,2], L. Van Praet[1], D. Elewaut[1,2], L. Jans[3], F. Van den Bosch[1]. *[1]Department of Rheumatology, Ghent University Hospital; [2]VIB Inflammation Research Center, Ghent University; [3]Department of Radiology, Ghent University Hospital, Ghent, Belgium*

**Objectives:** To assess the prevalence of inflammatory and structural lesions on MRI of the sacroiliacal joints (SIJ) in patients with peripheral spondyloarthritis (PSpA) in a very early stage of the disease.
**Methods:** Baseline data originated from the double-blind RCT with golimumab in 60 patients (CRESPA), who were diagnosed with PSpA and had a symptom duration <3 months. MRI SIJ was performed at baseline. Peripheral arthritis, dactylitis or enthesitis combined with $\geq$1 SpA feature (uveitis, psoriasis, IBD, preceding infection, HLAB27 or sacroiliitis on imaging) was necessary for inclusion. However, all patients already fulfilled the classification criteria without data on imaging of the SIJ. Bone marrow edema (BME) of the SIJ was quantified using the Spondyloarthritis Research Consortium of Canada (SPARCC) scoring system. Besides BME of the SIJ, all MRIs were also scored for other inflammatory lesions such as enthesitis and capsulitis. Structural MRI lesions of the SIJ such as subchondral sclerosis, erosions, periarticular fat and ankylosis were also assessed. Hip evaluation consisted of the presence of joint effusion, BME, enthesitis and cortical aberrations.
**Results:** Although not the reason for encounter, 7 out of 60 patients reported ever having inflammatory back pain (IBP) at inclusion or in the past, with median Visual analogue scores (VAS) of 2.0 (range 0.0- 9.0) for back pain. Overall, 35% of patients (21/60) exhibited BME of the SIJ and fulfilled the definition of a positive MRI by ASAS, with median SPARCC score of 8.0 (range 2.0–37.0). Only 3 out of 7 patients with IBP exhibited BME on MRI SIJ. Therefore, almost 86% of patients (18/21) with active sacroiliitis did not exhibit symptoms of IBP. Median VAS back pain in patients with sacroiliitis compared to patients without sacroiliitis respectively reached 2.0 and 1.0 (P=NS). Pelvic enthesitis was present in 23.8% (5/21) of patients with an ASAS positive MRI SIJ and in 10.3% (4/39) of patients with negative MRI. None of the patients exhibited enthesitis of the L5 spinous process, iliac crest, anterior superior iliac spine or ramus pubis. The MRI features of PSpA patients are presented in Table 1.

Table 1

| | ASAS MRI+ (n=21) | | ASAS MRI– (n=39) | |
|---|---|---|---|---|
| | Unilateral | Bilateral | Unilateral | Bilateral |
| Inflammatory lesions of the SIJ, n (%) | | | | |
| BME | 16 (76.2) | 5 (23.8) | 1 (2.6) | 0 |
| Capsulitis | 7 (33.3) | 0 | 0 | 0 |
| Retroarticular enthesitis | 5 (23.8) | 1 (4.8) | 1 (2.6) | 0 |
| Chronic lesions of the SIJ, n (%) | | | | |
| Sclerosis | 1 (4.8) | 2 (9.5) | 0 | 0 |
| Fat metaplasia | 2 (9.5) | 4 (19.0) | 1 (2.6) | 0 |
| Erosions | 3 (14.3) | 8 (38.1) | 4 (10.3) | 0 |
| Ankylosis | 2 (9.5) | 0 | 0 | 0 |
| Pelvic enthesitis, n (%) | | | | |
| Symphysis | 1 (4.8) | | 1 (2.6) | |
| Ischial tuberosity | 2 (9.5) | 0 | 1 (2.6) | 2 (5.4) |
| Posterior superior iliac spine | 3 (14.3) | 0 | 0 | 0 |
| Greater trochanter | 0 | 1 (4.8) | 0 | 2 (5.4) |
| Gluteus posterior | 1 (4.8) | 0 | 0 | 0 |
| Hip, n (%) | | | | |
| Joint effusion/ BME | 4 (19.0)/ 1 (4.8) | 0/0 | 4 (10.3)/ 1 (2.6) | 1 (4.8)/0 |
| Bony changes of the cortex | 1 (4.8) | 1 (4.8) | 2 (5.4) | 0 |

**Conclusions:** Even in early diagnosed peripheral SpA patients, over 1/3 exhibited BME suggestive of acute sacroiliitis and structural lesions of the SI joints. Our findings underscore the importance of sacroiliitis as the cornerstone feature within the SpA-concept, even in asymptomatic patients.
**Disclosure of Interest:** None declared

## THU0396 VISCERAL ADIPOSE TISSUE AND CARDIOVASCULAR RISK IN SPONDYLOARTHRITIS: RESULTS FROM THE DESIR AND COMOSPA COHORTS

H. Che[1], C. Souffir[2], A. Molto[2], S. Kolta[2], A. Etcheto[2], P. Richette[3], M. Dougados[2], C. Roux[2], K. Briot[2]. *[1]Rheumatology, Lapeyronie Hospital, Montpellier, Montpellier; [2]Rheumatology, Cochin hospital, INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité; [3]Rheumatology, Lariboisiere Hospital, Paris, France*

**Background:** Spondyloarthritis (SpA) is associated with an increased cardiovascular risk. Abdominal adiposity, especially visceral adipose tissue (VAT) is emerging as a independent cardio-metabolic risk factor.
**Objectives:** Our study aimed at assessing association between VAT and cardiovascular risk factors in patients with early or long-standing SpA.
**Methods:** This study was performed in patients recruited from 2 cohorts of SpA: COMOSPA (long-standing SpA) and DESIR (early SpA).
VAT was measured by total body dual energy X-ray absorptiometry in patients with SpA, at baseline in the COMOSPA cohort; at baseline and after 2 years of follow-up in the DESIR cohort. We also collected the following items: demographic data, disease characteristics, current treatment, inflammation biomarkers, cardiovascular risks (BMI, smoking status, hypertension, diabetes, hypercholesterolemia and hypertriglyceridemia) and cardiovascular events (history of ischemic cardiovascular disease).
We, first, compared VAT values in these 2 groups of patients, then, searched for an association between VAT and cardiovascular risks, and finally, studied 2-year VAT variations for patients in the DESIR cohort.
**Results:** 82 patients and 129 patients from COMOSPA and DESIR cohorts were included respectively. In COMOSPA, patients were mostly males (68.3% vs. 55.6%), older (46.3±12.8 vs. 33.0±8.6 years old), with a longer duration of disease (12.0±11.2 vs. 1.5±0.9 years), and received more frequently TNF-blockers (64.6% vs. 30.2%), as compared to DESIR cohort (all p<0.02).
SpA patients of COMOSPA cohort had more frequently hypertension (34.1% vs. 3.1%, p<0.01), dyslipidemia (43.9% vs. 7.0%, p<0.01), current smoking (34.1% vs. 32.6%, p<0.01) and tended to have a higher BMI (26.5±5.4 vs. 23.7±3.5 kg/m$^2$, p=0.06) than patients from the DESIR cohort.
Mean VAT was higher in patients of COMOSPA cohort than in DESIR cohort (140.6±75.2 vs. 79.2±44.0 cm$^2$, p<0.01) after adjustment for age.
In patients of COMOSPA cohort, VAT was significantly associated with the presence of dyslipidemia (p=0.02) and high level of LDL cholesterol (p<0.01), after adjustment for age, gender and BMI, in univariate analysis.
In patients of DESIR cohort, baseline VAT was significantly associated with high level of CRP (p=0.04), high consumption of NSAIDs (assessed by NSAIDs score) (p=0.04) and presence of hypertension (p=0.05), after adjustment for age, gender and BMI, in univariate analysis. In patients of DESIR cohort, VAT tended to increase over 2 years from baseline (79.2 vs 82.6 cm$^2$, +1.8%, p=0.054); this variation was significantly associated with SpA responding to

ASAS criteria (p=0.01), presence of hypercholesterolemia (p<0.01), presence of hypertriglyceridemia (p<0.01) and 2-year changes of BMI (p<0.01). 2-year VAT variation was similar in patients receiving TNF-blockers or not.
**Conclusions:** This study shows that VAT is higher in patients with long–standing SpA than with early SpA. VAT is associated with to the presence of cardiovascular risk factors, after adjusting on age and BMI in both settings. In addition to BMI, assessing VAT could be a complimentary tool for the assessment of cardiovascular risk in SpA patients.

## THU0397 SAFETY OF TUMOR NECROSIS FACTOR INHIBITOR IN ANKYLOSING SPONDYLITIS PATIENTS WITH OCCULT HEPATITIS B VIRUS INFECTION

H.-J. Jeong, C.-B. Choi, J.-B. Jun, T.-H. Kim. *Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of*

**Background:** Tumor necrosis factor inhibitors (TNFi) are being widely used for treatment of ankylosing spondylitis (AS). It is known to increase the risk of hepatitis B virus (HBV) reactivation in hepatitis B surface antigen (HBsAg)-positive patients and possibly also in patients with occult HBV infection (HBsAg-negative/hepatitis B core antibody (HBcAb)-positve).
**Objectives:** The aim of this study was to evaluate the effects of TNFi therapy on HBV reactivation in AS patients with occult HBV infection.
**Methods:** AS patients treated with TNFi at our institution were retrospectively reviewed. Clinical datas before and after using TNFi including 3 serologic markers for HBV: HBsAg, HBcAb and hepatitis B surface antibody (HBsAb), type and duration of TNFi, and liver function tests. Definite HBV reactivation was defined as reappearance of HBsAg in a previously HBsAb-negative individual and possible HBV reactivation was defined as serum alanine aminotransaminase (ALT) elevation (>2 times upper normal limit) in patients with occult HBV infection.
**Results:** A total 295 of AS patients on TNFi therapy were assessed excluding 7 (2.4%) patients who were HBsAg-positive. Fifty-seven (19.8%) patients who were HBcAb-positive (occult HBV infection) and 231 (80.2%) patients who were HBcAb-negative were analyzed. The mean age of patients with occult HBV infection was 48.96 ± 11.26 years, which was significantly higher than patients who were HBcAb-negative (35.86 ± 9.61). Duration of TNFi therapy, type and number of TNFi used, proportion of patients with abnormal liver function test, and HLA-B27 positivity did not differ significantly between the 2 groups. None of the patients showed definite HBV reactivation during TNFi therapy. However, 5 (2.2%) HBcAb-negative patients converted to HBcAb-positive after TNFi therapy. Their follow up ALT levels remained within normal ranges. Two (3.5%) of the 57 patients with occult HBV infection showed possible HBV reactivation with elevation in ALT levels. One of these patients had also on methotrexate and liver function normalized with discontinuation of methotrexate.
**Conclusions:** TNFi therapy was safe in AS patients with occult HBV infection. Nevertheless, close monitoring is necessary for detection of HBV reactivation in patients with occult HBV infection.

## THU0398 OBSERVATIONAL STUDY ON THE QUALITY OF LIFE OF ITALIAN AXIAL SPONDYLOARTHRITIS PATIENTS (QUASAR): BASELINE DATA

I. Olivieri[1], R.M. D'Attino[2], G. Gualberti[2], R. Merolla[2] on behalf of QUASAR Study Group. *[1]Ospedale San Carlo, Potenza; [2]Abbvie srl, Medical Department, Campoverde di Aprilia (LT), Italy*

**Background:** Quality of Life (QoL) is reduced in patients (pts) with axial spondyloarthritis (axSpA) who suffer from pain, stiffness and fatigue in their most productive years of life. Currently, data on QoL and impact on daily activities in axSpA pts classified according to the ASAS criteria are limited. No medical research in Italy has been conducted in AxSpA pts
**Objectives:** To assess the evolution of QoL in pts suffering from axSpA over a 12-month period and disease impact on daily life activities
**Methods:** QUASAR is a multicenter, longitudinal, observational study on adult axSpA pts in Italy. This interim analysis reports baseline data. Inclusion criteria were diagnosis of axSpA (either non radiographic [nr-axSpA] or ankylosing spondylitis [AS]) based on the ASAS classification criteria and ability to understand and complete the questionnaires. The following clinical parameters were recorded: CRP, HLA-B27, pain, stiffness, disease activity (BASDAI and ASDAS), Patient and Physician Global Assessment (PtGA/PGA), comorbidities and treatment. Subjects were asked to complete the ASQoL, WPAI, MARS, EQ-5D questionnaires and a VAS on satisfaction with the treatment during routine visits. Descriptive statistics (mean±Standard Deviation [SD] or frequencies) are presented for baseline clinical characteristics, disease activity and QoL. Mann-Whitney test, t-test, $\chi^2$ were used to calculate differences between pts groups
**Results:** A total of 512 pts (mean age 47.8±13.1 years; males 62.1%) were enrolled. 19% had a family history of SpA and 21% of psoriasis. 97 pts (18.9%) had a diagnosis of nr-axSpA. 246 (61.5%) subjects out of the 400 typed were HLA-B27 positive (48.7% and 62.7% of nr-axSpA and AS pts, respectively). Time to diagnosis since symptom onset was 5.4±2.9yrs for all pts, 3.8±3.1yrs for nr-axSpA and 5.8±2.8yrs for AS pts. 59.8% of nr-axSpA and 58.3% of AS pts had pain at the first visit. Low back pain was the most frequent type (73.3% of all pts) followed by cervical pain (35%) and dorsal pain (23.3%). 52.6% of nr-axSpA and 56.1% AS pts had morning stiffness. The following table shows the baseline demographic and characteristics of the pts involved in QUASAR:

Table 1

| | Overall | Nr-axSpA | AS | p-value |
|---|---|---|---|---|
| Age (years) | 47.8±13.1 | 42.5±13.5 | 49.0±12.6 | <0.001 |
| Male gender | 62.1% | 52.6% | 64.3% | 0.032 |
| HLA-B27 | 61.5% | 48.7% | 62.7% | 0.237 |
| CRP | 0.8±2.2 | 0.7±1.3 | 0.8±2.3 | 0.669 |
| Pain | 58.6% | 59.8% | 58.3% | 0.789 |
| PGA | 2.8±2.7 | 2.8±2.6 | 2.7±2.7 | 0.627 |
| PtGA | 3.6±2.7 | 4.1±2.6 | 3.6±2.7 | 0.545 |
| BASDAI | 3.2±2.5 | 3.6±2.5 | 3.2±2.4 | 0.861 |
| ASDAS | 13.2±9.0 | 14.4±9.0 | 12.9±9.0 | 0.138 |
| ASQoL | 5.8±5.5 | 6.2±5.6 | 5.7±5.4 | 0.429 |
| EQ-5D VAS | 66.3±21.8 | 64.0±23.1 | 66.9±21.4 | 0.926 |

Values reported are mean ± SD, if not indicated otherwise; p value refers to comparison between nr-axSpA and AS pts.

Extra Articular Manifestations (EAM) were as follows: psoriasis 17.6%, uveitis 15.8%, ulcerative colitis (UC) 4.1% and Crohn's disease 6.5%. EAMs were present in 24.7% and 15.9% (psoriasis), 15.5% and 15.9% (uveitis), 5.2% and 3.9% (UC), 4.1% and 7.0% (Crohn's disease) of nr-axSpA and AS pts
**Conclusions:** QUASAR is the first prospective Italian study with a large sample size that reports an overall similar burden of disease in nr-axSpA and AS patients, documented by pain, CRP, PGA/PtGA, BASDAI, ASDAS, ASQOL, and EQ-5D VAS. Our data support the importance of early diagnosis and treatment of axSpA

## THU0399 THE ANKYLOSING SPONDYLITIS DISEASE ACTIVITY INDEX (ASDAS) TO ASSESS DISEASE ACTIVITY IN PSORIATIC ARTHRITIS

J. Hermann, R. Husic, J. Gretler, A. Haidmayer, A. Lackner, W.B. Graninger, C. Dejaco. *Internal Medicine, Medical University of Graz, Graz, Austria*

**Background:** Psoriatic arthritis (PsA) belongs to the spondyloarthritides and disease activity can be evaluated by the Disease Activity Index for Psoriatic Arthritis (DAPSA) and the Composite Psoriatic Disease Activity Index (CPDAI) [1]. The Ankylosing Spondylitis Disease Activity Score (ASDAS) is a composite disease activity score for ankylosing spondylitis covering peripheral involvement in both versions selected by ASAS international society ($ASDAS_{CRP}$ and $ASDAS_{ESR}$)[2].
**Objectives:** To evaluate the possible importance of $ASDAS_{CRP}$ and $ASDAS_{ESR}$ to assess disease activity in PsA.
**Methods:** In a cross-sectional study patients attending our outpatient clinic and fulfilling CASPAR criteria of PsA underwent a complete rheumatologic assessment to calculate the disease activity score CPDAI and DAPSA for PsA as well as the $ASDAS_{CRP}$ and $ASDAS_{ESR}$ after informed consent was obtained. On the same day a rheumatologist unaware of the clinical status of the patients performed B-mode and power Doppler (PD) sonography of peripheral joints, of tendon sheets and entheses according to the MASEI, and of perisynovial tissue of finger joints. Results were graded semi-quantitatively and sum scores were calculated for PD signals and for pathological B-mode and PD findings together (GLUS, range 0–832). Descriptive statistics were used to summarise the data and correlations were analysed by the Spearman's rank correlation test.
**Results:** 67 of 84 included patients (49 male, 18 female; mean age 51 (SD 12) years; median disease duration 7 years (IQR 4–18) could be evaluated. We found a strong correlation of the DAPSA and CPDAI score and a low but significant

Table 1. Correlation of the PsA composite and ultrasound scores with the ASDAS

| | $ASDAS_{CRP}$ (r, 95% CI) | $ASDAS_{ESR}$ (r, 95% CI) |
|---|---|---|
| CPDAI | 0.67 (0.51–0.79)*** | 0.58 (0.38–0.72)*** |
| DAPSA | 0.74 (0.60–0.83)*** | 0.71 (0.56–0.81)*** |
| PD sum score | 0.24 (–0.01–0.46)* | 0.29 (0.05–0.50)* |
| GLUS | 0.30 (0.06–0.51)* | 0.37 (0.13–0.56)** |

*p<0.05; **p<0.005; ***p<0.0001. r: correlation coefficient; CI: confidence interval; PD sum score: semi-quantitative score of joints, entheses, tendons and perisynovial tissue with power Doppler signals; GLUS: global ultrasound score.

correlation of the GLUS and the PD sum score with the $ASDAS_{ESR}$ and $ASDAS_{CRP}$ (table). We observed only a moderate association of the DAPSA with the GLUS (r=0.52, 95%CI 0.32–0.68) and the association of the CPDAI with the GLUS and the PD sum score (r=0.25, 95%CI 0.003–0.47 and r=0.19, 95%CI -0.06–0.42, respectively) was even lower than the correlation of the GLUS and the PD sum score with the $ASDAS_{ESR}$ and the $ASDAS_{CRP}$. In PsA-patients with clinically defined remission 25.0% of the patients fulfilled the CPDAI and 29.1% the DAPSA remission criteria. However, in patients with clinically defined remission 50.0% and 54.2% fulfilled the $ASDAS_{ESR}$ and $ASDAS_{CRP}$ criteria for inactive disease.

**Conclusions:** This cross-sectional study shows that the ASDAS might also be a valuable tool to measure disease activity and to define clinical remission in PsA.

## THU0400 RELATIONSHIP BETWEEN HEALTH QUALITY OF LIFE AND OTHER INDICATORS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

J.L. Garrido-Castro[1], C. Gonzalez-Navas[1], J. Castro-Jimenez[1], P. Font-Ugalde[2], E. Collantes-Estevez[2]. *[1]Maimonides Institute of Biomedical Research of Cordoba; [2]Reina Sofia Universtiy Hospital, Cordoba, Spain*

**Background:** Axial spondyloarthritis (AxSpA) is an inflammatory disease that mainly affects the spine. As the disease progresses, there is a reduction of quality of life (QOL) in patients due to loss of mobility and function, and also by episodes of inflammation and stiffness (disease activity).

**Objectives:** To Analyze relationship between QOL of patients with AxSpA and other commonly used indicators in assessing these patients.

**Methods:** 100 patients with AxSpA (67% male, age 48.38±11.05, disease duration 14.37±10.74, HLAB27 + 85%) were included. QOL of patients was assessed by the Ankylosing Spondylitis Quality of Life index (ASQoL). Mobility was evaluated by conventional metrology and by a new motion capture system (UCOTrack) and UCOASMI as its metrological index [1]. PRO questionnaries were completed to evaluate activity, function and overall status. Structural damage was scored by mSASSS index. To analyze relationship, Spearman tests, ANOVA and multiple linear regression were performed.

**Results:** ASQoL showed statistically significant correlations with BASFI, BAS-G, ASDAS and UCOASMI. No significant correlations between QOL and structural damage, neither B27+, or having nr-AxSpA were found. Table shows results groupped by sex, B27, duration, nr-AxSpA (mSASSS <5 Duration>5 years) high activity level and poor mobility with statistical significance. Variables that were independently associated with ASQOL, in a multivariable linear regresion, were gender (p=0.027), BASDAI (p=0.008) and BASFI (p<0.001) $R^2$ =0.676. Repeating this analysis, but including mobility measures obtained by motion capture, variables that were independently associated with ASQoL were BASDAI (p=0.000) lateral flexion defined by the position of shoulders and hips (p=0.004) and tilt of C7-L4 (p=0.023) $R^2$ =0.609.

**Conclusions:** QOL in AxSpA is influenced by the activity of the disease, and by decreased mobility. Women perceive a lower QOL. The best measure related to QOL is lateral bending. Improving patient mobility through exercise and finding appropriate treatment to decrease disease activity, you can improve QOL of patients with AxSpA.

## THU0401 SEVERE BONE MARROW EDEMA ON SACROILIAC JOINT MRI INCREASES THE RISK OF LOW BMD IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

K.Y. Kang[1], Y.S. Hong[2]. *[1]Division of Rheumatology, Internal Medicine; [2]Catholic University of Korea, Seoul, Korea, Republic Of*

**Background:** Patients with axSpA have an increased risk of low bone mass. AS patients have a high prevalence of osteoporosis, which is observed in both early and advanced cases. A recent study showed that nr-axSpA patients show significantly greater bone loss than patients with mechanical back pain.

**Objectives:** To determine the association between inflammatory and structural lesions on sacroiliac joint (SIJ) MRI and BMD and to identify risk factors for low BMD in patients with axial spondyloarthritis (axSpA).

**Methods:** Seventy-six patients who fulfilled the ASAS axSpA criteria were enrolled. All underwent SIJ MRI and BMD measurement at the lumbar spine, femoral neck, and total hip. Inflammatory and structural lesions on SIJ MRI were scored. Laboratory tests and assessment of radiographic and disease activity were performed at the time of MRI. The association between SIJ MRI findings and BMD was evaluated.

**Results:** Among the 76 patients, 14 (18%) had low BMD. Patients with low BMD showed significantly higher bone marrow edema (BME) and deep BME scores on MRI than those with normal BMD (p<0.047 and 0.007, respectively). Inflammatory lesions on SIJ MRI correlated with BMD at the femoral neck and total hip. Multivariate analysis identified the presence of deep BME on SIJ MRI, increased CRP, and sacroiliitis on X-ray as risk factors for low BMD (OR: 5.6, 14.6, and 2.5, respectively).

**Conclusions:** The presence of deep BME on SIJ MRI, increased CRP levels, and severity of sacroiliitis on X-ray were independent risk factors for low BMD.

**Disclosure of Interest:** None declared

## THU0402 RADIOGRAPHIC PROGRESSION IS ASSOCIATED WITH INCREASED CARDIOVASCULAR RISK IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

K.Y. Kang, S. Bahk. *Division of Rheumatology, Internal Medicine, Catholic University of Korea, Seoul, Korea, Republic Of*

**Background:** A recent study showed that patients with chronic inflammatory arthritis have an increased risk of cardiovascular disease (CVD). Axial sponayloarthritis (axSpA) is also thought to carry an increased cardiovascular (CV) risk, but it is unclear whether axSpA patients have a higher risk of CVD than the general population.

**Objectives:** To compare the cardiovascular disease (CVD) risk between axial spondyloarthritis (axSpA) patients and matched controls, and to identify factors associated with increased CVD risk in axSpA patients.

**Methods:** This cross-sectional study enrolled 185 axSpA patients who fulfilled the ASAS criteria and 925 ageand sex-matched controls. None of the subjects had a previous history of CVD or diabetes mellitus. Traditional CVD risk factors were assessed and the 10 year CVD risk was calculated using the Framingham risk score (FRS). Estimated 10 year CVD risk was compared between axSpA patients and matched controls. Disease activity and radiographic progression in the sacroiliac joint and spine of axSpA patients were evaluated at the time of CVD risk assessment.

**Results:** HDL cholesterol levels were lower in axSpA patients than in matched controls (p=0.004); however, systolic blood pressure was higher (p<0.001). The FRS was 5.0 ± 6.6% for controls and 6.3 ± 8.7% for axSpA patients (p=0.046). Both the grade of sacroiliitis on X-ray and the number of syndesmophytes correlated with the FRS (p=0.009 and p=0.001, respectively), but disease activity variables did not. The FRS was significantly higher in axSpA patients with a greater number of syndesmophytes (p=0.035). Multivariate analysis identified the grade of sacroiliitis and number of syndesmophytes as being independently associated with the FRS (p=0.003 and p=0.042, respectively).

**Conclusions:** The FRS was higher in axSpA patients than in a matched general population. Radiographic progression in the spine and sacroiliac joints was associated with a high estimated 10 year CVD risk.

**Disclosure of Interest:** None declared

## THU0403 PERFORMANCE OF MODIFIED MINIMAL DISEASE ACTIVITY (MDA) CRITERIA IN PATIENTS WITH PERIPHERAL SPONDYLOARTHRITIS: POST-HOC ANALYSIS OF ABILITY-2

L.C. Coates[1,2], S. Abraham[3], W. Tillett[4], P.J. Mease[5], S. Ramiro[6], Y. Xia[7], X. Wang[8], A.L. Pangan[8], I.-H. Song[8]. *[1]Leeds Teaching Hospitals NHS Trust; [2]University of Leeds, Leeds; [3]NIHR/Wellcome CRF, Imperial college Healthcare NHS trust, London; [4]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; [5]Swedish Medical Center and University of Washington, Seattle, United States; [6]Leiden University Medical Center, Leiden, Netherlands; [7]University of Illinois at Chicago, Chicago; [8]AbbVie Inc, North Chicago, United States*

**Background:** Due to lack of validated outcome measures in non-psoriatic peripheral spondyloarthritis (pSpA), recent studies in this patient (pt) population have used varying endpoints [1]. Thus, developing new pSpA-specific indices may be worthwhile. Minimal Disease Activity (MDA) has been validated in psoriatic arthritis but not in pSpA.

**Objectives:** To evaluate the performance of a modification of the MDA criteria (excluding psoriasis) in pSpA patients (pts) from the ABILITY-2 study [2].

**Methods:** This post-hoc analysis evaluated the validity of a modified MDA (mMDA) in pSpA. ABILITY-2 was a 12-week trial comparing adalimumab (ADA) with placebo (PBO) in pSpA followed by a 144 week extension. The mMDA for pSpA was defined as achieving at least 4 or 5 out of the following 6 criteria: (1) tender joint count (TJC, 78 joints) $\leq$1; (2) swollen joint count (SJC, 76 joints) $\leq$1; (3) pt pain visual analog scale (VAS) $\leq$15 of 100 mm; (4) pt global activity (PtGA) VAS $\leq$20 of 100 mm; (5) health assessment questionnaire–disability index (HAQ-DI)$\leq$0.5; and (6) tender entheseal points $\leq$1. Enthesitis was assessed by the Leeds Enthesitis Index (LEI) or the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index for this analysis. The proportion of pts achieving the 4 different versions of mMDA were evaluated (either 4 or 5 of 6 using LEI and either 4 or 5 of 6 using SPARCC). The correlations between mMDA and the novel pSpA response criteria [PSpARC] remission from ABILITY-2 and Ankylosing Spondylitis Disease Activity Score Inactive Disease [ASDAS ID] were evaluated by tetrachoric correlation ($r_{tet}$).

**Results:** Of the 163 pts (82 ADA, 81 PBO) who completed wk 12, significantly greater proportion of pts receiving ADA achieved mMDA (regardless of the definition) compared with PBO (P<0.001 for all comparisons, Table 1a). The proportion of mMDA responders at yrs 1, 2, and 3 was numerically higher in pts initially randomized to ADA. The mMDA response showed a stronger positive correlation with PSpARC remission ($r_{tet}$>0.9) than ASDAS ID ($r_{tet}$>0.75) at wk 12, and yrs 1–3. Among pts who fulfilled the 4/6 criteria (LEI or SPARCC), approximately 20–30% of pts did not meet TJC and SJC criterion (Table 1b). However, the 5/6 criteria (LEI or SPARCC) were more stringent with approximately 5% and 13% not meeting the TJC and SJC criterion, respectively.

Table 1a. Proportion of patients achieving modified MDA*

| Modified MDA | Week 12 (DB) | | Year 1 (OLE) | | Year 2 (OLE) | | Year 3 (OLE) | |
|---|---|---|---|---|---|---|---|---|
| | ADA (n=82) | PBO (n=81) | ADA (n=71) | PBO>ADA (n=74) | ADA (n=62) | PBO>ADA (n=68) | ADA (n=54) | PBO>ADA (n=58) |

*n (%)

Abbreviations: MDA=Minimal Disease Activity; DB=double-blind period; OLE=Open-Label Extension; ADA=Adalimumab; PBO=Placebo; LEI=Leeds Enthesitis Index; SPARCC=Spondyloarthritis Research Consortium of Canada; TJC78=Tender Joint Count (78 joints); SJC76=Swollen Joint Count (76 joints); Pt Pain=Patient global assessment of Pain; VAS=Visual Analog Scale; PtGA=Patient Global assessment of disease Activity; HAQ-DI=Health Assessment Questionnaire-Disability Index based on 20 questions.

**Conclusions:** All 4 versions of mMDA discriminated between ADA and PBO treatment groups; both entheseal indices performed similarly. The mMDA (particularly the 5/6 versions which closely represents the concept of MDA) could be an appropriate treatment target in pSpA pts.

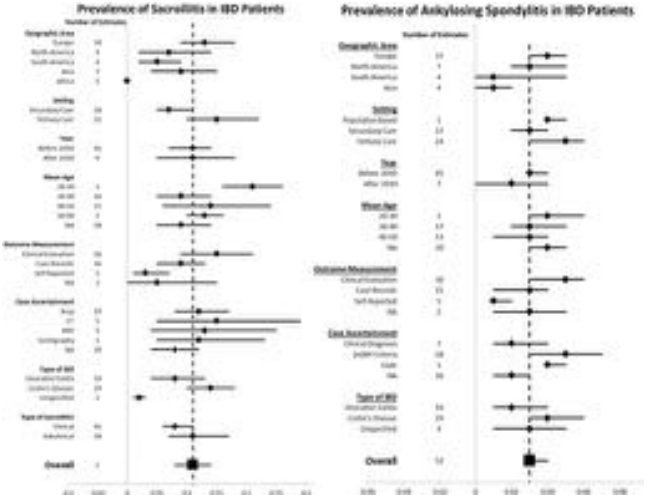
## THU0404 THE PREVALENCE OF AXIAL AND PERIPHERAL SPONDYLOARTHRITIS IN INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW & META-ANALYSIS

M.C. Karreman[1,2], J.J. Luime[1], J.M. Hazes[1], A.E. Weel[1,2]. *[1]Rheumatology, Erasmus University Hospital; [2]Rheumatology, Maasstad Hospital, Rotterdam, Netherlands*



**Background:** Inflammatory Bowel Disease (IBD) is a chronic disease that affects up to 0.5% of the population, comprising both Crohn's Disease (CD) and ulcerative colitis (UC). Various extra-intestinal manifestations can occur, among which spondyloarthritis (SpA). SpA can manifest with both axial and peripheral manifestations, but prevalence estimates of these manifestations differ widely.

**Objectives:** To provide a pooled estimate of the prevalence of axial and peripheral manifestations of SpA in patients with IBD and to identify factors that might influence the prevalence estimates.

**Methods:** We systematically searched Embase, Pubmed, OvidSP, Scopus and Web-of-science databases from inception to May 2014. All articles addressing the prevalence of axial and/or peripheral manifestations of spondyloarthritis in adult IBD patients were included. Risk of bias was assessed using a quality assessment tool including items on selection bias, non-response bias, sample size and misclassification of SpA diagnosis.

**Results:** Out of 4846 studies, 60 studies were included. Sample size varied from 9 to 4454. Methodological quality of the included studies was moderate, with only a slight majority scoring positively on the individual items of the quality assessment tool. With regard to axial manifestations, the pooled prevalence of sacroiliitis was 0.11 (95% CI 0.08–0.014), whereas the pooled prevalence for ankylosing spondylitis was 0.03 (95% CI 0.03–0.04). For peripheral arthritis the pooled prevalence was 0.14 (95% CI 0.12–0.16). Few estimates were available for the prevalence of enthesitis (range from 0.01 to 0.54) and dactylitis (range from 0 to 0.04). For both axial and peripheral manifestations, the prevalence was higher in patients with CD than in patients with UC.

Heterogeneity between studies was large, which might be explained by methodological quality as well as difference in geographic area, clinical setting and the use of criteria for case ascertainment as shown in figure 1 for the prevalence of SI and AS.

**Conclusions:** Spondyloarthritis is a common extraintestinal manifestation in IBD. Peripheral arthritis is slightly more common with a pooled prevalence of 0.14 than axial manifestations as sacroiliitis (pooled prevalence 0.11) and ankylosing spondylitis (pooled prevalence 0.03). For both axial and peripheral manifestations, the prevalence is higher in patients with CD than in patients with UC.

**Disclosure of Interest:** None declared

## THU0405 ABILITY OF GENERAL PRACTITIONERS TO DISTINGUISH BETWEEN INFLAMMATORY AND NON-INFLAMMATORY SYMPTOMS IN PATIENTS AT RISK OF SPONDYLOARTHRITIS: THE APPSPA STUDY

M.C. Karreman[1,2], J.M. Hazes[1], A.E. Weel[1,2]. [1]*Rheumatology, Erasmus University Hospital;* [2]*Rheumatology, Maasstad Hospital, Rotterdam, Netherlands*

**Background:** Over the last couple of years early arthritis clinics provided quick access for patients with inflammatory arthritis. However, although early access to specialized care is now available, adequate referrals are also required to shorten the doctors' delay. Therefore, general practitioners (GPs), the ones who refer, should be aware of symptoms distinguishing between inflammatory and non-inflammatory disease in patients at risk for spondyloarthritis (SpA).
**Objectives:** To describe GP's ability to recognize symptoms suggestive of spondyloarthritis.
**Methods:** The AppSpA study was set up, a cross-sectional study focusing on awareness and knowledge of SpA in GPs and patients at risk for SpA. For the present study a single survey was developed and send out to GPs in various regions of the Netherlands. This survey was based on a study by Jois et al, which looked into recognition of symptoms of inflammatory back pain. Since we were also interested in the ability of GPs to recognize peripheral manifestations of SpA, we added some extra questions.
**Results:** 183 of the 950 GPs completed the survey, leading to a participation rate of 19.3%. Of the participating GPs the mean age was 47.2 years (SD 10.3) and 47.5% were male. Mean time working as a GP was 15.4 years (SD 13.5).
Almost all GPs (94.5%) indicated to be familiar with the term SpA, but 55.5% associated it only with axial manifestations. Up to one third of the GPs associated the term SpA with psoriatic arthritis (23.7%) and Inflammatory Bowel Disease (33.5%).
With regard to the recognition of signs of inflammatory pain, especially morning stiffness and pain relieve by NSAIDs were recognized (Table 1), whereas pain improvement with exercise was recognized in less than 25% of cases. When we focus on the peripheral manifestations of SpA; out of six signs for inflammatory peripheral disease, only 43.2% of GPs recognized at least three of these symptoms. For the eight axial signs, 60.6% recognized at least four symptoms.
If GPs thought about inflammatory symptoms, the majority asked for the presence of psoriasis (83.6%) and inflammatory bowel disease (72.1%). GPs less often ask about other SpA related symptoms such as uveitis (61.8%), enthesitis (19.1%) and dactylitis (19.1%).

**Table 1. Proportion of GPs who identified correct signs of inflammatory joint and back pain (n=183)**

| Signs of inflammatory disease | Peripheral | Axial |
|---|---|---|
| Insidious onset of complaints, n (%) | 53 (29.0) | 90 (49.2) |
| Symptom duration>3 months, n (%) | 57 (31.2) | 93 (50.8) |
| Pain improved with exercise, n (%) | 25 (13.7) | 38 (21.3) |
| Pain not relieved by rest, n (% | 30 (16.4) | 40 (21.9) |
| Pain relieved by NSAIDs, n (%) | 160 (87.4) | 150 (82.0) |
| Morning Stiffness>30min, n (%) | 141 (77.1) | 138 (75.4) |
| Nocturnal Pain, n (%) | Not Asked | 143 (78.1) |
| Alternating Buttock Pain, n (%) | Not Asked | 37 (20.2) |

**Conclusions:** Overall, recognition of inflammatory disease by GPs is suboptimal, where GPs are more aware of axial manifestations compared to peripheral manifestations. The recognition of these signs and symptoms of SpA in primary care needs improvement in order to facilitate the necessary referrals to rheumatologists.

## THU0406 LACK OF INFORMATION FOR PATIENTS AT RISK FOR SPONDYLOARTHRITIS: THE APPSPA STUDY

M.C. Karreman[1,2], J.M. Hazes[1], A.E. Weel[1,2]. [1]*Rheumatology, Erasmus University Hospital;* [2]*Rheumatology, Maasstad Hospital, Rotterdam, Netherlands*

**Background:** Patients with psoriasis (PSO) and inflammatory bowel disease (IBD) are at risk for developing spondyloarthritis (SpA). To overcome diagnostic delay, physicians treating patients with these conditions should be aware of this increased risk to minimize doctors' delay in referring patients to specialized care. However, as patients' delay could also be an issue, patients themselves should also be aware of their risk to develop SpA. Since the need to empower patients in order to effectively manage their disease has recently been included in several guidelines for rheumatic diseases, involving patients in their disease becomes more and more important.
**Objectives:** To assess whether patients with PSO or IBD are aware of the risk of developing SpA and if so how they became aware.
**Methods:** A cross-sectional study was set up including PSO and IBD patients between 18 and 55 years of age. Patients were invited to participate either by their GP or by the patient organizations for PSO and IBD. Patients willing to participate completed a set of questionnaires regarding their disease, level of awareness and presence of musculoskeletal complaints.
**Results:** 552 PSO patients completed the questionnaires, of which 43.1% indicated to be aware of the possibility of developing a rheumatic condition already before the study-invitation. Of these 238 patients, 34% indicated to have gained this knowledge by themselves. Another 13.5% was informed by their GP and 24.4% by their medical specialist, while 18.5% learned from family or neighbors. Of the IBD patients, 344 completed the questionnaires, of which 41.9% was aware of the possibility of developing a rheumatic condition before the invitation for the study. The majority of patients was informed by their medical specialist (40.3%) or gained this knowledge by themselves (39.6%). Only 1.4% was informed by their GP and 9.7% learned from family or neighbors. For both PSO and IBD, patients who were recruited via the patient organizations were significantly more aware than patients recruited via the GPs.

**Table 1. Level of Awareness in Patients with Psoriasis or IBD**

| | Psoriasis (n=552) | IBD (n=344) |
|---|---|---|
| % Awareness | 43.1 | 41.9 |
| % Informed by GP | 13.5 | 1.4 |
| % Informed by medical specialist | 24.4 | 40.3 |
| % Via surroundings | 18.5 | 9.7 |
| % Looked it up themselves | 34.0 | 39.6 |
| % Patient organization | 8.4 | 2.8 |
| % Other | 1.3 | 6.3 |

**Conclusions:** Less than half of the patients with psoriasis or IBD are aware of the possibility of developing a rheumatic condition. If patients are aware, the majority gained this knowledge by themselves and 60% were not informed by a medical professional. More awareness could be achieved if medical professionals like the GP or the medical specialist would have more knowledge about symptoms of SpA and are trained in informing their patients about the increased risk of developing SpA. Public awareness campaigns to inform patients at risk could also be beneficial in minimizing patients' delay. Patient organizations could play a role in this awareness campaigns, since they already seem to inform their patients well.
**Acknowledgement:** This survey is part of initiative to develop a communication platform which was financially supported by AbbVie.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2358

## THU0407 BASELINE RESULTS FROM PROOF – A 5-YEAR OBSERVATIONAL STUDY OF LONG-TERM DISEASE OUTCOME IN AXIAL SPONDYLOARTHRITIS

R.D. Inman[1], J. Sieper[2], D. Poddubnyy[2], S. Akar[3], S. Munoz-Fernandez[4,5], M. Hojnik[6]. [1]*Toronto Western Hospital, Toronto, Canada;* [2]*Charité Universitätsmedizin Berlin, Berlin, Germany;* [3]*Izmir Katip Celebi University School of Medicine, Izmir, Turkey;* [4]*Hospital Universitario Infanta Sofía;* [5]*Universidad Europea de Madrid, Madrid, Spain;* [6]*AbbVie, Ljubljana, Slovenia*

**Background:** Axial spondyloarthritis (axSpA), encompassing ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) without advanced structural lesions in the sacroiliac joints (SIJ), is a relatively new disease concept. The natural disease course of axSpA, including progression of structural damage over time, has not yet been systematically studied in large patient (pt) groups.
**Objectives:** To report the baseline data of PROOF, a large study currently being conducted in 29 countries across the world, evaluating long-term outcomes in pts with axSpA classified by ASAS criteria.
**Methods:** PROOF is a multi-country prospective observational study evaluating axSpA pts in rheumatology clinical practice over 5 years. Pts with axSpA fulfilling ASAS classification criteria were eligible, if diagnosed $\leq$12 months prior to study enrolment. Investigator's confidence with the diagnosis of axSpA is ascertained on a numeric rating scale (NRS 0–10) at enrolment and end of follow-up. Assessments of disease activity (BASDAI, ASDAS-CRP), physical function (BASFI), quality of life (SF-12v2), productivity (WPAI-SHP), and pelvic X-ray are scheduled at yearly follow-up visits. X-rays are graded according to NY criteria by local and central readers.
**Results:** 2084 pts with axSpA fulfilling ASAS criteria have been enrolled in PROOF study, 1259 pts with AS (60%) and 825 pts with nr-axSpA (40%) according to the investigators. The level of confidence with the diagnosis of axSpA was 8.7±1.8. The imaging criterion was fulfilled by 85% of pts (40% MRI, 51% X-ray, 9% both), 15% of pts were classified through the clinical arm. HLA-B27 was tested in 85% of pts and found to be positive in 68% of cases (70% with AS and 60% with nr-axSpA). Overall, pts were in their mid-thirties, had a long delay in referral to rheumatologist and recently diagnosed axSpA. Comparison of demographic and clinical characteristics between pts with AS and nr-axSpA is shown in Table 1. Pelvic x-rays were reportedly done in 1635 (78%) pts within 6 months of the baseline visit; to date both local and central readers have scored x-rays of 1344 pts (82% of available). Of the 1344 pts, 83.3% retained their classification (AS or nr-axSpA) after the central reading,

**Table 1.** Baseline demographics and disease characteristics of patients in PROOF study

| Characteristic, measure | AS | nr-axSpA | P-value[a] |
|---|---|---|---|
| Subdiagnosis by investigators, *n (%)* | 1259 (60.4) | 825 (39.6) | NA |
| Age, years, *mean ± SD* | 34.9 ± 10.9 | 34.2 ± 9.8 | 0.4 |

| HLA-B27 positive[b], % | 89.8 | 59.6 | 0.0001 |
| Time from onset of back pain, months, *mean ± SD* | 64.8 ± 89.7 | 50.0 ± 71.0 | <0.0001 |
| Time from first physician visit for back pain, months, *mean ± SD* | 55.5 ± 78.2 | 45.7 ± 66.1 | 0.0008 |
| Time from first physician visit for back pain to first referral to rheumatologist, months, *mean ± SD* | 46.0 ±72.4 | 38.0 ± 63.3 | 0.003 |
| Time from diagnosis of axSpA, months, *mean ± SD* | 3.1 ± 3.4 | 2.6 ± 3.2 | 0.004 |
| CRP, mg/L, *mean ± SD* | 17.4 ± 23.5 | 11.6 ± 20.0 | <0.0001 |
| ESR, mm/h, *mean ± SD* | 23.9 ± 20.6 | 16.5 ± 17.5 | <0.0001 |
| BASDAI, *mean ± SD* | 4.4 ± 2.3 | 4.7 ± 2.3 | 0.01 |
| ASDAS-CRP, *mean ± SD* | 3.0 ± 1.1 | 2.8 ± 1.1 | <0.0001 |
| BASFI, *mean ± SD* | 3.4 ± 2.5 | 3.2 ± 2.4 | 0.35 |
| HRQoL based on SF-12v2, PCS, *mean ± SD* | 40.8 ± 8.7 | 41.5 ± 8.9 | 0.14 |
| HRQoL based on SF-12v2, MCS, *mean ± SD* | 43.7 ± 10.3 | 43.0 ± 10.6 | 0.27 |
| WPAI-SHP, Total activity impairment, %, *mean ± SD* | 44.0 ± 27.6 | 43.3 ± 27.9 | 0.65 |
| Subdiagnosis based on local x-ray reading, *n (%)*[c] | 1035 (62.6) | 618 (37.4) | NA |
| Subdiagnosis based on central x-ray reading, *n(%)*[d] | 902 (67.1) | 442 (32.9) | NA |

[a]Baseline characteristics and disease measures were compared using Wilcoxon test for quantitative variables and Chi-square test for qualitative variables.
[b]HLA-B27 test was done in 85% of all patients.
[c]Missing n=291/1635 (currently being queried), [d]Missing n=73/1617 (in progress).
Abbreviations: AS=Ankylosing spondylitis; nr-axSpA=non-radiographic axial spondyloarthritis; NA=Not Applicable; CRP=C-reactive protein; ESR=Erythrocyte sedimentation rate; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; ASDAS-CRP=Ankylosing Spondylitis Disease Activity Score containing CRP; BASFI=Bath Ankylosing Spondylitis Functional Index, HRQoL=Health-related quality of life; SF-12v2=Short form 12-item health survey; PCS=Physical component summary score; MCS=Mental component summary score. WPAI-SHP=Work productivity impairment Questionnaire-specific health problem.

while 16.7% were classified differently. Based on the kappa value, there was a substantial agreement on the grading of x-rays between the local and central readers: kappa=0.63 (95% CI, 0.59–0.68).
**Conclusions:** PROOF is the largest observational study in pts with axSpA classified by ASAS criteria so far. It provides insights into the clinical practice worldwide and aims to assess long-term outcomes of axSpA. Baseline results confirmed comparable clinical features and disease burden between AS and nr-axSpA, highlighted a long delay in referral to rheumatologists, and showed a good agreement between the SIJ x-ray grading by local and central readers.
**Acknowledgement:** AbbVie funded the PROOF study, contributed to its design and participated in data collection, analysis and interpretation of the data, and in writing, review, and approval of the publication. Medical writing support was provided by Deepa Venkitaramani, PhD, of AbbVie.

## THU0408 PREVALENCE OF RENAL IMPAIRMENT IN PATIENTS WITH SPONDYLOARTHRITIS: RESULTS FROM THE INTERNATIONAL COMOSPA STUDY

M. Couderc[1], M. Soubrier[1], B. Pereira[2], A. Molto[3], M. Dougados[3].
*[1]Rheumatology; [2]Biostatistic Unit, Clermont Ferrand Universitary Hospital, Clermont-Ferrand; [3]Rheumatology, Hopital Cochin- assistance publique des Hopitaux de Paris, Paris, France*

**Background:** Renal impairement in spondyloarthritis (SpA), although uncommon, may include secondary renal amyloidosis (AA type), non-steroidal anti-inflammatory drug (NSAID) nephropathy, and glomerulonephritis. Data on the prevalence of renal impairement in SpA are relatively rare and usually come from small or retrospective studies.
**Objectives:** To assess the prevalence and associations of renal dysfunction in patients with SpA.
**Methods:** COMOSPA was an international (22 participating countries from four continents) multicentric study on comorbidities in SpA. Renal function was assessed from the estimated glomerular filtration rate (eGFR) using the Modification of Diet in Renal Disease (MDRD) equation. SpA characteristics, risk factors for renal impairment were collected. NSAID use was assessed by the currently (last 3 months) intake. Logistic regression models were constructed from variables which were significantly associated with an eGFR of $<$60ml/min/1.73m$^2$ or clinically relevant.
**Results:** Of the 3984 recruited patients, after excluding of outliers and patients for whom eGFR was not available, 2098 (52.6%) were analysed (male gender: 63.5%; age: 45.3 years; disease duration: 8.6 years; HLAB27+: 53.7%; BASDAI: 3.6/10). A total of 153 patients (5.2%, mean age 53.6 years) had an eGFR $<$60 ml/min/m$^2$. In univariate analysis, renal impairment was associated with age ($p<0.001$), HLAB27 positivity ($p<0.001$), several cardiovascular risk factors (history of hypertension [$p<0.001$], systolic blood pressure [p=0.03], diabetes [p=0.005] and the Framingham Risk score [$p<0.001$]), disease activity scores (BASDAI [p=0.001], ASDAS-CRP [$p<0.001$]), functionnal parameters (BASFI [$p<0.001$], HAQ [$p<0.001$]), inflammatory biomarkers (ESR and CRP, both $p<0.001$), but not with disease duration, disease sevrity (bamboo spine, hip replacement) or NSAID current intake.
**Conclusions:** Renal impairment is not rare in SpA and is associated with age, disease severity and inflammation but not with cardiovascular risk factors or NSAID currently use.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2279

## THU0409 IS DISEASE ACTIVITY ASSOCIATED WITH WORK PRODUCTIVITY LOSS, PRESENTEEISM, AND ABSENTEEISM IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS? RESULTS FROM THE SPACE COHORT

M. Van Lunteren[1], P. Bakker[1], Z. Ez-Zaitouni[1], J. van der Vijver[1], C. Fongen[2], R. Landewé[3], M. van Oosterhout[4], R. Ramonda[5], F. van Gaalen[1], D. van der Heijde[1]. *[1]Rheumatology, LUMC, Leiden, Netherlands; [2]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [3]Rheumatology, AMC, Amsterdam; [4]Rheumatology, GHZ, Gouda, Netherlands; [5]Rheumatology, University of Padova, Padova, Italy*

**Background:** Disease activity has an important impact on work productivity in patients with Ankylosing Spondylitis (AS). However, knowledge is limited if this impact exists in early axial Spondyloarthritis (axSpA) patients and if it is similar in different subgroups of patients such as male vs. female patients.
**Objectives:** To investigate if the impact of disease activity, assessed by ASDAS (AS Disease Activity Score, CRP based), on work productivity is similar according to gender, age, medication use, profession, HLA-B27 positivity, and duration of back pain at baseline in early axSpA patients.
**Methods:** The SPACE-cohort includes patients (chronic back pain $\geq$3 months, $\leq$2 years, onset $<$45 years) recruited from 5 European centres. Patients who fulfilled the ASAS criteria for axSpA were included in this analysis. Work Productivity and Activity Impairment questionnaire (WPAI) was completed by patients at baseline to assess the impact of axSpA on Work Productivity Loss (WPL; i.e. total work impairment due to disease), presenteeism (i.e. decreased functionality at work due to disease), and absenteeism (i.e. absence at work due to disease) in the past 7 days. Higher scores indicate greater impairment (ranged 0–100). ASDAS was used to assess disease activity. Gender, age, medication use, profession, HLA-B27 positivity, and duration of back pain were tested for effect modification (cut-off of $p<0.20$) one by one in a linear regression model. Continuous variables were split by their median.
**Results:** In total, 87 axSpA patients working at baseline were included; 53 patients of them fulfilled the clinical arm and 34 patients the imaging arm of the ASAS axSpA criteria. Patients were on average 30.8 years old (SD 7.6), 52.9% was male, and had a mean duration of back pain of 13 months (SD 7.1). They worked on average 29.5 (SD 15.8) hours and missed 3.0 (SD 8.0) hours per week at work due to axSpA. Mean WPL, presenteeism, and absenteeism were 34.3% (SD 28.5), 31.4% (SD 25.3), and 8.2% (SD 20.1) respectively. Patients had a mean ASDAS of 2.3 (SD 0.9). The univariable model (Figure 1) shows that one point increase in ASDAS resulted in an increase of 19.3%, 16.9%, 8.7% in WPL, presenteeism, and absenteeism, respectively. Fulfilment of the clinical or imaging arm was not an effect modifier (not shown). Gender and duration of

back pain were effect modifiers in the associations between ASDAS and WPL, presenteeism, and, absenteeism. Results were stratified for these variables. The associations remained statistically significant in all stratified models, except in the model of absenteeism for males (p=0.207).
**Conclusions:** Disease activity is positively associated with WPL, presenteeism, and absenteeism in early axSpA patients. The same level of disease activity seems to have more adverse impact on work productivity in women than in men, and irrespective of that, in patients with relatively long disease duration. In addition to disease activity, gender, and disease duration are relevant contextual factors in explaining WPL in patients with early axSpA.

## THU0410 THE ASSOCIATION BETWEEN DISEASE ACTIVITY AND IILLNESS PERCEPTIONS IN EARLY AXIAL SPONDYLOARTHRITIS PATIENTS IN THE SPONDYLOARTHRITIS CAUGHT EARLY (SPACE)-COHORT

M. Van Lunteren[1], M. Scharloo[2], A. Kaptein[2], Z. Ez-Zaitouni[1], P. Bakker[1], C. Fongen[3], R. Landewé[4], M. van Oosterhout[5], M. Lorenzin[6], F. van Gaalen[1], D. van der Heijde[1]. *[1]Rheumatology; [2]Medical Psychology, LUMC, Leiden, Netherlands; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Rheumatology, AMC, Amsterdam; [5]Rheumatology, GHZ, Gouda, Netherlands; [6]Rheumatology, University of Padova, Padova, Italy*

**Background:** Studies in patients with rheumatic diseases report that negative views of illness are associated with poorer disease outcomes, such as more disability and pain. Little is known about illness perceptions in patients with early axial Spondyloarthritis (axSpA).
**Objectives:** To describe illness perceptions and to explore the association between illness perceptions and disease activity in patients with early axSpA at baseline.
**Methods:** The Spondyloarthritis Caught Early (SPACE) cohort includes patients (chronic back pain ≥3 months, ≤2 years, onset <45 years) recruited from 5 participating centres in Europe. Patients completed the Revised Illness Perception Questionnaire (IPQ-R). The illness identity dimension asked patients if they have experienced a certain symptom (15 in total) and if they believed these symptoms are related to axSpA. The other illness perception dimensions and causal attributions (15 causes) used 5-point Likert scales to score all items ranging from 1 (strongly disagree) to 5 (strongly agree). For the IPQ-R dimensions, see Figure 1. Disease activity was assessed by ASDAS (Ankylosing Spondylitis Disease Activity Score, CRP based). Univariable linear regression models were built for each IPQ-R dimension as dependent and ASDAS as independent variable adjusted for age and gender. Results were stratified when gender was an effect modifier (p<0.10). P-values <0.05 were considered to be statistically significant.
**Results:** Only patients fulfilling the ASAS classification for axSpA (n=119) were included. These patients had a mean age of 29.7 (SD 7.9) years and 50.4% was male. The mean disease duration was 13.0 (SD 7.3) months and the mean ASDAS 2.4 (SD 1.0). Patients reported 4.2 (SD 2.3) symptoms to be associated with axSpA on average, see Figure 1. Pain, joint stiffness, fatigue, and sleeping problems were the most reported symptoms according to patients in the illness identity dimension. All other dimensions showed a mean of approximately 3, except psychological attributions, risk factors, immunity and accident of the causal section, which had a mean of approximately 2. Patients with axSpA attributed their complaints mostly to heredity, chance or bad luck, or stress and worries. Six dimensions of the IPQ-R were associated with ASDAS. A stronger illness identity (β=0.63, p=0.003), stronger beliefs in severe consequences (β=0.32, p<0.001), less illness coherence (β=-0.24, p=0.003), more negative emotions towards their complaints (β=0.22, p=0.003), stronger beliefs of psychological attributions as a cause only in men (β=0.22, p=0.034), and the belief of immunity as a cause (β=0.17, p=0.010) were statistically significantly associated with a higher ASDAS.
**Conclusions:** Negative illness perceptions, such as experiencing more symptoms, believing in severe consequences, less illness coherence, and negative emotions towards axSpA, are associated with disease activity in patients with early axSpA.

## THU0411 FATIGUE IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND LOW VITALITY IN THOSE WITH PSORIATIC ARTHRITIS: RESULTS FROM A LARGE REAL-WORLD SURVEY IN EUROPE AND THE USA

P.G. Conaghan[1], A. Deodhar[2], V. Strand[3], R. Alten[4], E. Sullivan[5], S. Blackburn[5], H. Tian[6], K. Gandhi[6], S. Jugl[7]. *[1]University of Leeds, Leeds, United Kingdom; [2]Oregon Health & Science University, Portland, OR; [3]Stanford University, Palo Alto, CA, United States; [4]Schlosspark-Klinik, University Medicine, Berlin, Germany; [5]Adelphi Real World, Manchester, United Kingdom; [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [7]Novartis Pharma AG, Basel, Switzerland*

**Background:** Many patients diagnosed with AS or PsA experience chronic fatigue or low energy which can persist during treatment and affect health related quality of life (HRQOL) and the ability to work.
**Objectives:** To assess self-reported fatigue in patients with AS and vitality in those with PsA, HRQOL and employment status.
**Methods:** In this fatigue and HRQOL study of a cross-sectional survey from 5 European countries and the USA, physicians with 3–30 years' experience were eligible if treating patients with AS or PsA. Inclusion of patients was not restricted by treatment. Patients reported HRQOL (EQ-5D and SF-36), Work Productivity and Activity Impairment Questionnaire (WPAI) as well as other items. AS patients rated their fatigue using BASDAI (BASDAI-Fatigue). In PsA the SF-36 vitality domain (VT) was used to assess fatigue. Fatigue was classified in AS as non-severe (BASDAI-Fatigue <5) to severe (BASDAI-Fatigue ≥5). In PsA tertiles using SF-36 VT were applied to stratify fatigue: low (>65 to 100), moderate (45 to 65) high (0 to <45).
**Results:** Results are presented from 910 patients with AS (613 EU/297 USA) and 1136 with PsA (762/374) who completed questionnaires.
Among AS patients who answered the BASDAI-Fatigue item, 42.0% [373/889] reported severe and 58.0% [516/889] non-severe fatigue. Tertiles of fatigue in PsA were defined based on responses from 1108 patients, who answered the SF-36 VT as: 33.6% [372/1108] low, 35.4% [392/1108] moderate and 31.0% [344/1108] high fatigue.
AS patients reporting severe fatigue had significantly worse HRQOL than those with non-severe fatigue: EQ-5D utility (0.64 vs 0.89); SF-36 physical component summary (PCS) (52.7 vs 82.3); mental component summary (MCS) (54.4 vs 75.9) scores. All SF-36 domains were also significantly lower (all $p$ <0.0001).
PsA patients with high fatigue reported significantly worse HRQOL than those with low or moderate fatigue: EQ-5D (0.60 vs 0.93 and 0.81 respectively); SF-36 PCS (49.7 vs 90.2 vs. 74.1); SF-36 MCS (48.4 vs 84.4 vs. 67.3). All SF-36 domains were significantly worse, omitting VT as this was used for PsA fatigue classification. (all $p$ <0.0001)
Patients with AS reporting severe fatigue had significantly greater overall work impairment due to their disease than those with non-severe fatigue (WPAI (mean): 41.7% vs 13.7%; $p$ <0.0001). Similar significant associations were evident with PsA patients with high, low, moderate fatigue: 43.1% vs 8.9% and 20.0% respectively ($p$ <0.0001).
Among 156 AS patients reporting additional information on retirement or unemployment, 98 had severe and 58 non-severe fatigue. Those with severe fatigue had significantly higher rates of retirement or unemployment due to AS (49.0% vs. 22.4%; p=0.0012).
**Conclusions:** This large analysis of patient-reported data shows that fatigue is common in AS and PsA with a substantial number reporting high/severe fatigue. Fatigue significantly affects HRQOL, social functioning, work productivity and therefore impacts patients' daily life as well as societal costs.

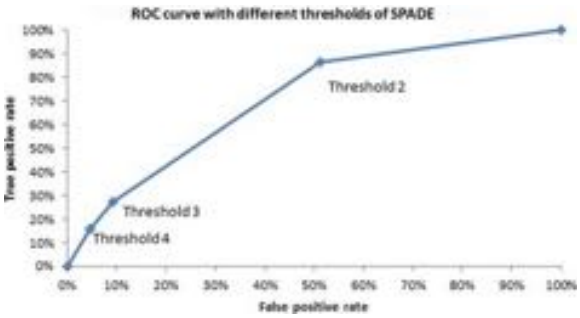
## THU0412 MASES CORRELATES LINEARLY WITH DISEASE ACTIVITY AND INVERSELY WITH PATIENT RELATED OUTCOMES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS WITHIN THE SCQM COHORT

R. Mueller[1], T. Kaegi[1], N. Graf[2], J. von Kempis[1], J.J. Luime[3]. [1]*Division of Rheumatology, Kantonsspital St. Gallen, St. Gallen;* [2]*Graf Biostatistics, Winterthur, Switzerland;* [3]*Department of Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands*



**Background:** Enthesitis is one of the potential extra-axial manifestations found in patients with spondyloarthritis (SpA). Enthesitis can be quantified using the MASES (Maastrich Ankylosing Spondylitis Enthesitis *Score*), consisting 13 predefined entheses assessed for tenderness. There are few data on the MASES outside of RCTs. To better understand the impact of enthesitis real live data are needed.
**Objectives:** To analyse (i) cross-sectionally the correlation of enthesitis with clinical, personal outcome parameters and (ii) longitudinally the development of enthesitis under treatment in patients with axial spondyloarthritis.
**Methods:** We included all patients from the Swiss national registry SCQM with axial spondyloarthritis and valid MASES at baseline. Patients were analysed for demographics at baseline, physical assessments (BASMI, BASFI, BASDAI) and patient centered outcomes (SF36). Continuous variables were compared using a Student's T-test, categorical variables with $\chi^2$ test. Spearman's Rho or linear regression were employed for correlational analyses. Patients were analysed for changes in MASES depending on the initial MASES scores and the therapeutic strategy employed: synthetical DMARDs vs. TNF antagonists.
**Results:** 3241 patients were included into the study. 45.9% of the patient had no entheseal affection at baseline (MASES =0). 59.7% of the patients were HLA B27 pos. and 60.5% of the patients were suffering from axial disease as defined by the New York criteria. The frequency of patients achieving higher MASES scores decreased linearly ($R^2$: 0.4823, p=0.0058). Moderate associations were found for BASDAI, BASFI, patient's and physician's assessments of disease activity patients assessment of pain, the SF 36 mental and physical component score (Spearman's Rho: 0.403, 0.328, 0.326, 0.381, 0.352, -0.215, -0.326, respectively). The average response of MASES after 1 year increases linearly with higher average MASES scores (slope -0.41, $R^2$ =0.78). Patient with a MASES of zero at baseline developed an increase of MASES during follow up (average after 12 month: 0.48). Patients treated with TNF antagonists or DMARDs had a mean change of -1.15 and -1.03 at 12 months, respectively (p=0.967).
**Conclusions:** Almost half of the axial SpA patients suffered from entheseal involvement. Half of the patients with a MASES of zero at baseline developed an entheseal involvement during follow up. Higher MASES scores correlate with parameters indicative of disease activity and patient related outcomes. In those with MASES over 1 the score decreased under treatment during follow up. However, changes of MASES under TNF antagonist or DMARD treatment did not differ in our cohort. In conclusion, a focussed analysis on enthesitis and its therapeutic strategy in SpA is needed.

## THU0413 UTILITY OF THE SPADE TOOL TO IDENTIFY AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH CHRONIC BACKPAIN

S. Habibi[1], S. Doshi[2], R. Sengupta[1,3]. [1]*Rheumatology, Royal National Hospital for Rheumatic Diseases;* [2]*Medical Physics, Royal United Hospital;* [3]*University of Bath, Bath, United Kingdom*

**Background:** Many referral strategies have been devised to optimize the early diagnosis of axial spondyloarthritis (AxSpA). These result in the diagnosis of AxSpA in 30 to 40% of patients. Strategies to reduce the delay in diagnosis of AxSpA and optimise the appropriateness of referrals to secondary care should be explored. The Spondyloarthritis Diagnosis Evaluation (SPADE) tool (www.spadetool.co.uk) has been designed to assist healthcare professionals define the probability of axial spondyloarthritis (AxSpA) in patients <45 years of age with chronic back pain and no definite changes on radiographs. The probability of AxSpA derived from the 'SPADE Tool' is displayed on a chart with clear instructions for the user on what action should be taken next.
**Objectives:** To assess the performance of the SPADE tool in the secondary care setting.
**Methods:** The RNHRD runs a weekly Early Back Pain (EBP) clinic. Data on all patients (AxSpA and Mechanical back pain) has been collected. The SPADE tool which consists of questions pertaining to clinical features, CRP, HLA-B27 and MRI findings was applied on all EBP patients utilizing data they were referred with (before Specialist advised investigations- MRI scan results) to obtain the probability of SpA as one of the 4 categories: Category 1-improbable, category 2-additional tests needed (HLA-B27 or MRI, consider referral to a specialist), category 3 (probable SpA) and category 4 (definitive SpA). A physicians diagnosis of AxSpA was used as the gold standard. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were estimated using observed ratios of patient numbers from this sample. 95% CIs on the NPV were generated by assuming a binomial model for x, where x is the number of patients with SpA who are not referred at a given SPADE threshold.
**Results:** N=87 (49 males); 44 (50.5%) had SpA subsequently diagnosed; 6/27 in category 1, 26/44 in category 2, 5/7 in category 3 and 7/9 in category 4. Estimates of PPV, NPV, sensitivity and specificity obtained by using each of the SPADE categories as a threshold for referral are given in the table.

| Threshold | Sensitivity (%) | Specificity (%) | PPV (%) | NPV (%) |
|---|---|---|---|---|
| 1 | 100 | 0 | 51 | |
| 2 | 86 | 49 | 63 | 78 [95% CI: 58, 91%] |
| 3 | 27 | 91 | 75 | 55 [95% CI: 43, 67%] |
| 4 | 16 | 95 | 78 | 53 |

**Conclusions:** The SPADE tool is a valuable resource to assist clinicians define the probability of SpA in patients with chronic back pain. The high NPV, especially with the referral threshold set at 2 or 3, implies that the test is most useful in ruling out SpA. Note that the prevalence of AxSpA in this sample is likely to be higher than in the target population (primary care), meaning that these estimates of NPV are likely to be underestimates. The tool needs to be validated in a primary care setting.
**Acknowledgement:** The funding for the SPADE tool was provided through a Medical Education grant from Abviee

**Background:** Making the diagnosis of axial spondyloarthritis (axSpA) may be difficult. Antibodies against CD74 have been shown to be present in 2/3 of patients with long established axial SpA.
**Objectives:** InterSpA is an international multicenter study, conducted to compare the sensitivity and specificity of anti-CD74 and HLA-B27 in patients with axSpA of recent onset.
**Methods:** Patients between 18 and 45 years suffering from inflammatory back pain (IBP) for maximally 2 years were recruited. The presence of ankylosing spondylitis, additional inflammatory rheumatic disorders and biologic therapy were exclusion criteria. MRI of sacroiliac joint was performed in all patients; HLA-B27 was detected by genotyping and anti-CD74 using a CE certified kit of Aesku Diagnostics (Wendelsheim, Germany). The sensitivity of anti-CD74 and HLA-B27 were calculated in patients fulfilling the imaging arm of ASAS criteria, in all patients fulfilling ASAS criteria and in 100 blood donors. Both the MRI reading as well as the laboratory procedures were performed blinded.
**Results:** 205 patients suffering from IBP were recruited. There were 40 recruiting failures. The remaining 165 patients had a mean age of 29.4 years, a mean duration of IBP of 12.6 months, 50% of the patients were female. Sacroiliitis was diagnosed by the local and an independent expert reader in 71/123 (57.7%). So far complete data sets are available of 91 patients. Of these, 16 fulfilled the ASAS criteria of axSpA by a pathologic MRI only, 40 by both MRI and presence of HLA-B27 and 20 by HLA-B27 only. The sensitivities of IgA anti-CD74, IgG anti-CD74 and HLA-B27 were 71.4%, 26.8% and 75% in the 56 axSpA patients with a pathologic MRI, 73.7%, 23.7% and 81.6% in all 76 patients fulfilling ASAS criteria, and 3%, 5% and 8% in the blood donors. The likelihood ratios are 23.8

(IgA anti-CD74), 5.4 (IgG anti-CD74) and 9.4 (HLA-B27) when considering the patients with a pathologic MRI only, and 24.6 (IgA anti-CD74), 4.7 (IgG anti-CD74) and 10.2 (HLA-B27) when considering all patients fulfilling ASAS criteria.
**Conclusions:** Considering their specificity and sensitivity, IgA anti-CD74 is a useful addition to our diagnostic tools for axSpA.

## THU0415 THE EFFECT OF SMOKING ON CLINICAL AND STRUCTURAL DAMAGE IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

V. Villaverde-Garcia[1], T. Cobo-Ibáñez[2], D. Seoane-Mato[3], P. Díaz del Campo-Fontecha[3], M. Guerra[3], G. Candelas-Rodríguez[4], J.D. Cañete[5]. *[1]Rheumatology Dpt, H.U. Móstoles. Madrid. Spain; [2]Rheumatology Dpt, H.U. Infanta Sofía. San Sebastián de los Reyes. Madrid. Spain; [3]Research Unit, Spanish Society of Rheumatology; [4]Rheumatology Dpt, H.U. Clínico San Carlos, Madrid; [5]Rheumatology Dpt, H.U. Clinic and IDIBAPS, Barcelona, Spain*

**Background:** Although it has been widely accepted that smoking has a negative effect on AS and aSpA patients, the findings were limited by small sample size and conflicting data.
**Objectives:** To examine the impact of smoking on clinical and structural damage in patients with AS and aSpA.
**Methods:** A systematic literature review was performed by 2 reviewers, a librarian and a methodologist. Studies were identified by a sensitive search strategies in the main bibliographic databases (Medline, Embase and Cochrane Library) up to November 2014. We selected articles that analysed, in AS and aSpA patients, the smoking impact on disease activity, structural damage, functional status and quality of life. Any type of study except case series or case reports was eligible. Two reviewers (VVG and TCI) screened the titles and abstracts of the retrieved articles independently. VVG reviewed the selected articles in detail and collected the data from the studies included by using *ad hoc* standard forms. A hand research was completed by reviewing the included studies references. The evidence level was assessed with the Oxford Centre for Evidence-based Medicine Levels of Evidence.
**Results:** Of 341 studies identified, 13 were selected for inclusion: 7 case-control and 6 cohort studies. These studies provided data from over 4.163 patients. All studies evaluated patients with AS and only two evaluated patients with AS and aSpA, being the quality of the studies moderate-low. Current smokers with AS, had a higher disease activity (BASDAI $>4$) [OR=1.83; IC95% 1.13 a 2.98; p=0.015], poorer quality of life (ASQoL$>7$) [OR=2.00, IC95% 1.25 a 3.22, p=0.004] and more pain (numerical scale NRS) [OR=2.00, IC95% 1.23 a 3.27, p=0.005], independently of age, sex, duration of the disease and social support. Smoking was significantly associated with progression of functional disability in patients with AS for less than ten years of disease duration (HAQ-S increased 0.0545 units/yr among smokers compared to nonsmokers, p=0.004).In patients with aSpA, smoking was associated with an earlier onset of inflammatory back pain [regression coefficient (B)= -1.46; IC 95% -2.87 a -0.06, p=0.04], higher disease activity (ASDAS-PCR B=0.20; IC95% 0.02 a 0.38; p=0.03; BASDAI B=0.50; IC95% 0.17 a 0.83; p=0.003), worse functional status (BASFI B=0.38; IC95% 0.07 a 0.69; p=0.02), more frequent inflammation and more structural damage in MRI (OR=1.91; IC95% 1.34 a 2.72, p$<$0.001) and plain radiography (OR=1.56; IC95% 1.08 a 2.26, p=0.02), and poorer quality of life (Euro-QoL) [B=1.38; IC95% 0.69 a 2.07, p$<$0.001].
**Conclusions:** Smoking cessation should be recommended in AS and aSpA patients, not only at the disease onset, but also along the follow-up. However, the available evidence is insufficient and limits the recommendation strength (NE 4, GR C). Larger-scale studies with longitudinal follow-up in disease activity, functional ability and structural damage in AS and aSpA patients, are necessary. This systematic literature review was performed to inform the aSpA and psoriatic arthritis guideline (ESPOGUIA) of the Spanish Society of Rheumatology.

## THU0416 PREVALENCE OF COMORBIDITIES AND RISK FACTORS IN SPONDYLOARTHRITIS IN LATIN AMERICA: A COMPARATIVE STUDY WITH GENERAL POPULATION: DATA FROM THE MULTINATIONAL ASAS-COMOSPA STUDY

W. Bautista-Molano[1,2], R. Landewé[3], A. Moltó[4], R. Burgos-Vargas[5], J. Maldonado-Cocco[6], R. Valle-Oñate[7], D. van der Heijde[1]. *[1]Rheumatology Department, Leiden University Medical Center, Leiden, Netherlands; [2]Rheumatology Department, School of Medicine, HMC/UMNG, Bogotá, Colombia; [3]Rheumatology Department, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [4]Rheumatology B Department, Paris Descartes University, Cochin Hospital, AP-HP, Paris, France; [5]Servicio de Reumatología, Hospital General de México and Universidad Nacional Autónoma de México, Mexico City, Mexico; [6]Rheumatology Section, Instituto de Rehabilitación Psicofísica and Argentine Rheumatologic Foundation "Dr Osvaldo Carcia Morteo", Buenos Aires, Argentina; [7]Rheumatology Department, School of Medicine, Hmc/Umng, Bogota, Colombia*

**Background:** Increased risk of some comorbidities has been reported in spondyloarthritis (SpA). Knowledge about the prevalence and data related to these comorbidities and risk factors in Latin America is limited.
**Objectives:** To determine the prevalence of several comorbidities and risk factors for these comorbidities in patients with SpA in three Latin American countries, and to compare this prevalence with the rates in the general population investigating whether the prevalence is increased.
**Methods:** Data of 390 consecutive patients with SpA enrolled in the international cross-sectional ASAS-COMOSPA study from Argentina, Colombia and Mexico were analysed. The prevalence rates (95% CI) of arterial hypertension (AHT), tuberculosis (TB), and malignancies (colon, melanoma, lung, lymphoma, prostate, cervix and breast) were estimated with continuity correction according to the method described by Wilson. The data from Colombian general population (adjusted per gender and age group) were obtained from the CARMELA study for AHT, from the National Health Surveillance Public System for TB and HBV and from the GLOBOCAN project for malignancies. The prevalence (95% IC) in SpA patients was compared with the prevalence rates in the Colombian general population by calculating age and gender-specific prevalences for AHT, TB and HBV, and calculating gender-specific prevalences for malignancies. SPSS Statistics 22 was used to perform the statistical analysis.
**Results:** In total 64% were male, mean age of 45 (14.7) years and disease duration of 7.0 (8.1) years. The most common comorbidities were AHT (25.3%), hypercholesterolemia (21.8%), osteoporosis (9.4%) and gastrointestinal ulcer (7.8%). The prevalence of AHT was 25.3% (95% CI 21.2 to 29.4) and was significantly higher compared with the general population 13.4% (95% CI 11.5 to 15.2). The overall prevalence of TB was 3.33% (95% CI 1.8 to 5.7) and the prevalence of HBV infection was 1.03% (95% IC 0.3 to 2.7), both increased as compared with the general population (0.03% and 0.01% respectively). There was not an increased prevalence of cancers compared with general population.
**Conclusions:** In patients with SpA, we found a higher prevalence of hypertension, tuberculosis and hepatitis B infections in three Latin America countries as compared with general population data. A systematic evaluation and screening of these comorbidities and risk factors may help to properly monitor and detect these conditions in SpA patients.

## THU0417 SERUM LEVELS OF GDF15 ARE ELEVATED IN SPONDYLOARTHRITIS, AND NEGATIVELY LINKED WITH BONE EROSION

Y. Song, Y. Cui, H. Lin, G. Zhang, H. Zeng, Y. Zeng. *Goungdong General Hospital, Goungzhou, China*

**Background:** In order to assess disease activity and predict outcomes of patients with spondyloarthritis (SpA), it is necessary to discover useful serum biomarker reflecting inflammation, fat deposition, erosion and ankylosis [1]. GDF15 was previously fond related to inflammation [2] and worked as a protective factor in inflammatory pathology. In rheumatology arthritis patients, serum level of GDF15 could predict the presence of joint erosions [3].
**Objectives:** The objective was to assess associations between GDF15 and radiographic features, including X-ray and MRI of the sacroiliac joint in SpA patients.
**Methods:** SpA was defined according to 2009 ASAS criteria. Sera from 53 patients with SpA and 18 healthy controls were measured GDF15 levels using ELISA. Inflammation was assessed by ESR, CRP and MRI of the SIJ, using the Spondyloarthritis Research Consortium of Canada (SPARCC) score and a method of dichotomy to assess fat deposition, bone erosion and ankylosis. Radiographs of the pelvis were scored by using the modified New York (mNY) score.
**Results:** Serum GDF15 levels were higher in SpA patients in comparison with controls (208.4 ± 173.7 vs 339.2 ± 295.0 pg/ml and P=0.005 Figure). Among

SpA, patients who suffered from bone erosion on MRI had lower levels of GDF15 (423.4± 288.1 vs 284.3± 275.6 pg/ml and P=0.022).In addition, correlation analysis showed there was a negative correlation between serum GDF15 and bone erosion (r= -0.433, p=0.007) in SpA patients whose X-rays were 0-III according to mNY criteria. Moreover, GDF15 levels of those patients were related to CRP levels ((r=0.328, p=0.044). No significant correlations were found between SPARCC score, fat deposition and ankylosis and GDF15 levels, but CRP and ESR levels were significantly correlated with SPARCC score (r=0.291, p=0.036 and r=0.474, p=0.0004) in SpA.

Figure1 Serum GDF15 levels in SpA patients and Controls

**Conclusions:** Our study suggested that serum GDF15 levels were higher in SpA patients than healthy controls.GDF15 was correlated with CRP which was correlated with SPARCC score, suggesting GDF15 may not directly related to bone edema in SpA. GDF15 was negatively related to bone erosion, which may play a protective role in process of bone erosion.

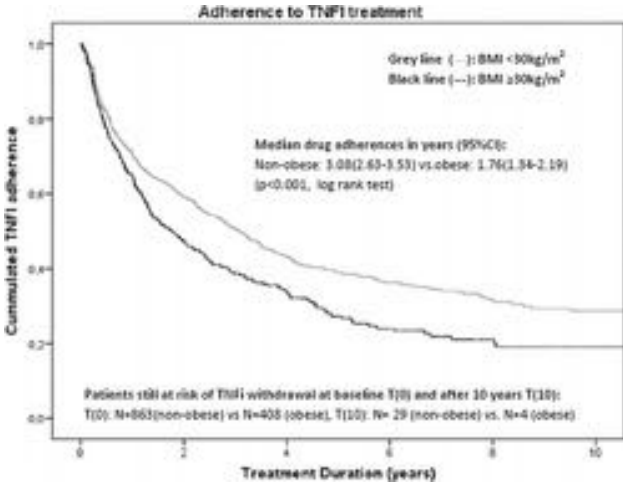
## Psoriatic arthritis

### THU0418 OBESITY IMPAIRS THE RESPONSE TO TUMOUR NECROSIS FACTOR-ALPHA INHIBITORS IN PSORIATIC ARTHRITIS: RESULTS FROM THE DANBIO AND ICEBIO REGISTRIES



P. Højgaard[1,2], B. Glintborg[3], L.E. Kristensen[2], T.J. Love[4,5], B. Gudbjornsson[4,5], L. Dreyer[1,2,6]. *[1]Department of Rheumatology, Gentofte Hospital, Rigshospitalet, Copenhagen; [2]The Parker Institute, Frederiksberg Hospital, Frederiksberg; [3]Department of Rheumatology, Gentofte Hospital, Rigshospitalet and the DANBIO registry, Copenhagen, Denmark; [4]Center for Rheumatology Research (ICEBIO), Landspitali, University hospital of Iceland; [5]Faculty of Medicine, University of Iceland, Reykjavík, Iceland; [6]Faculty of Medicine, University of Copenhagen, Copenhagen, Denmark*

**Background:** TNF-α inhibitor (TNFI) treatment fails among half of patients with psoriatic arthritis (PsA) treated in routine care. Obesity is a frequent, pro-inflammatory condition in PsA that may affect pharmacokinetics, immunological processes and patient-reported outcomes.

**Objectives:** To investigate the impact of obesity on disease activity, treatment response and drug adherence among PsA patients initiating their first TNFI treatment course in routine care.

**Methods:** Observational cohort-study based on the Danish (DANBIO) and Icelandic (ICEBIO) registries. Kaplan-Meier plots, Cox regression and logistic regression analyses studied the impact of obesity (body mass index (BMI) $\geq$30kg/m$^2$) on drug adherence and TNFI response. Six-month response was defined according to ACR20/50/70 and EULAR criteria. Sub-analyses stratified according to gender and TNFI (adalimumab/etanercept/infliximab) were performed.

**Results:** Among 1943 patients (1750 Danish, 193 Icelandic) included in the study, 1271 (65%) had available BMI and 408 (32%) of these were obese (327 (80%) Danish, 81 (20%) Icelandic). Prescription rates were: adalimumab (39%), etanercept (26%), infliximab (24%), golimumab (7%) and certolizumab (4%). Median follow-up-time was 1.5 years, IQR: 0.5–3.9. At baseline obese patients smoked less (23% vs 30%), were older (49±12 vs 47±13 years, (mean (SD)) and had higher disease activity measured as DAS28 (4.6±1.2 vs 4.4±1.2), tender joint count (6 (3–13) vs 5 (2–11); median, (IQR)), C-reactive protein (9 (5–19) vs 7 (3–18)), HAQ score (1.1 (0.8–1.6) vs 0.9 (0.5–1.4)), Visual-Analogue-Scale (VAS) patient global (72 (54–87) vs 65 (50–80)) and VAS pain (66 (48–76) vs 60 (38–74)), compared with non-obese (all $p<0.05$). Obese patients had shorter treatment adherence than non-obese (Figure 1), especially among men (5.9 (4.1–7.7) vs 2.5 (1.7–3.2)); median years (95%CI), ($p<0.01$). Similar results were found when Icelandic and Danish patients were analyzed separately. Obesity was an independent predictor of TNFI withdrawal both overall: HR 1.6 (95%CI 1.3–2.0), in men: HR 1.8 (1.3–2.5), women: HR 1.5 (1.1–2.0) and for every TNFI:

adalimumab: HR 1.6 (1.2–2.2), etanercept: HR 2.0 (1.3–3.3), infliximab: HR 1.6 (1.1–2.5). The EULAR good-or-moderate response rate was significantly lower in obese than non-obese (55% vs 65%), (p=0.02). In men, obesity reduced the chance of both EULAR good response: OR 0.5 (95%CI 0.3–0.9) and EULAR good-or-moderate, ACR20 and ACR50 responses (all OR 0.4 (0.2–0.8)). Obesity also predicted a poorer EULAR good-or-moderate response overall (OR 0.6 (0.4–0.9)), in women (OR 0.5 (0.3–0.9)) and for all TNFI types (data not shown).

**Conclusions:** Obesity is associated with increased disease activity and attenuates response and adherence to TNFIs in PsA.

**Acknowledgement:** Thank you to Elinborg Stefansdottir who assisted in the achievement of Icelandic data, to Niels Steen Krogh from Zitelab for extraction of data and to Peder Frederiksen and Robin Christensen for statistical advises. Thanks to all Danish and Icelandic Departments of Rheumatology for providing data to DANBIO and ICEBIO.

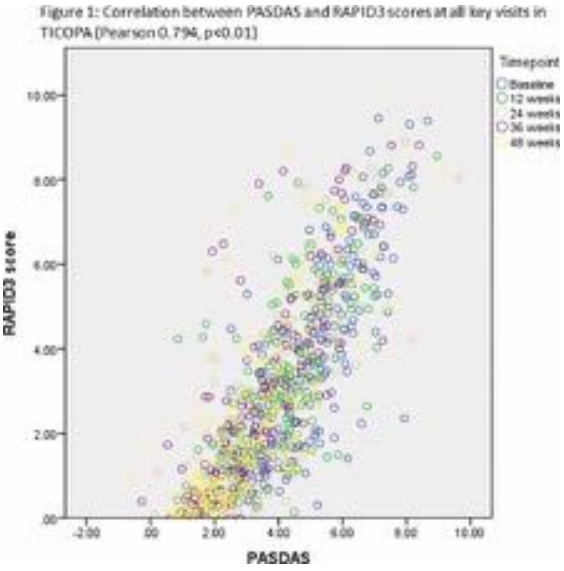
### THU0419 RAPID3 PERFORMS WELL IDENTIFYING TREATMENT EFFECT IN THE TIGHT CONTROL OF PSORIATIC ARTHRITIS STUDY

L.C. Coates[1,2], W. Tillett[3], T. Pincus[4], A. Kavanaugh[5], P.S. Helliwell[1,2]. *[1]Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; [3]Royal National Hospitals for Rheumatic Diseases, Bath, United Kingdom; [4]School of Medicine, Rush University, Chicago; [5]Rheumatology, Allergy and Immunology, University of California, San Diego, San Diego, United States*

**Background:** RAPID3 is a patient completed outcome measure assessing disease activity in inflammatory arthritis consisting of the health assessment questionnaire (HAQ) and two VAS scales. It is feasible for use in clinical practice and has been well validated in rheumatoid arthritis (RA) and other conditions, but there is little data on its use in psoriatic arthritis (PsA).

**Objectives:** To investigate the responsiveness and discrimination of RAPID3 and a modified version with skin VAS in the Tight Control of Psoriatic Arthritis (TICOPA) trial.

**Methods:** Data from the TICOPA trial were used to assess the performance of the RAPID3 index. RAPID3 was calculated using the HAQ-DI, patient completed pain VAS and global disease activity VAS. Due to concerns about skin involvement in PsA, we also calculated a novel RAPID3Ps score which also included a skin activity VAS to see if performance was superior.



Results from the RAPID3 measures were correlated with the PsA disease activity score (PASDAS) a composite disease activity score already validated by GRAPPA. Change in the RAPID3 measures and other outcome measures were compared between the tight control arm and the standard care arm of the TICOPA study using t-test for continuous variables and chi-squared for categorical measures of disease state.

**Results:** RAPID3 scores strongly correlated with PASDAS (Pearson correlation 0.794, $p<0.01$) at all baseline and follow up visits. The change in score at follow up was also moderately correlated with the change in PASDAS (0.636, $p<0.01$). Correlation was similar for the RAPID3Ps at 0.831.

When looking at differentiation between treatment groups, change in RAPID3 score at 48 weeks was highly discriminant (t value -3.43, $p<0.001$) and was higher than all other PsA measures (DAPSA and other individual outcome measures) except for PASDAS (t value -3.75, $p<0.001$) as shown in the table.

Looking at specific cutpoints, RAPID3 “near remission” was also highly discriminant between treatment groups (chi squared 7.48, p=0.006) although with a lower value than the minimal disease activity criteria for PsA (chi squared 10.11, p=0.001).

| Measure | Tight Control | | | | Standard Care | | | | T value | p |
|---|---|---|---|---|---|---|---|---|---|---|
| | Baseline | Mean change | SRM | ES | Baseline | Mean change | SRM | ES | | |
| PASDAS | 5.27 | –2.49 | –1.45 | –1.77 | 4.96 | –1.38 | –0.83 | –1.09 | –3.75 | 0.00 |
| RAPID3 | 4.18 | –2.16 | –1.07 | –1.06 | 3.59 | –1.01 | –0.47 | –0.52 | –3.43 | 0.00 |
| Phy Global | 44.10 | –32.26 | –1.57 | –1.62 | 40.80 | –19.83 | –0.86 | –1.27 | –3.34 | 0.00 |
| Pt Global | 56.15 | –33.60 | –1.05 | –1.20 | 51.54 | –18.64 | –0.56 | –0.69 | –3.12 | 0.00 |
| pain VAS | 53.42 | –31.92 | –1.05 | –1.18 | 47.33 | –17.79 | –0.56 | –0.68 | –2.82 | 0.01 |
| DAPSA | 31.24 | –19.01 | –1.08 | –0.94 | 30.04 | –11.45 | –0.69 | –0.53 | –2.61 | 0.01 |
| fatigue | 48.85 | –21.44 | –0.73 | –0.78 | 46.39 | –13.20 | –0.46 | –0.46 | –1.84 | 0.07 |
| TJC | 12.33 | –6.62 | –0.65 | –0.56 | 13.22 | –3.34 | –0.28 | –0.24 | –1.57 | 0.12 |
| SJC | 7.57 | –6.27 | –0.96 | –0.97 | 6.82 | –4.50 | –0.57 | –0.58 | –1.22 | 0.22 |

**Conclusions:** RAPID3 shows good correlation with other validated measures of disease activity in PsA and addition of a psoriasis measure does not seem necessary in this population. The RAPID3 score and "near remission" definition are able to effectively discriminate between two active treatment groups in an interventional trial.

**Acknowledgement:** We acknowledge all collaborators and participants in the TICOPA trial.

**Disclosure of Interest:** None declared

## THU0420 APREMILAST, AN ORAL PHOSPHODIESTERASE 4 INHIBITOR, IS ASSOCIATED WITH LONG-TERM (52-WEEK) IMPROVEMENTS IN BASDAI IN PATIENTS WITH PSORIATIC ARTHRITIS: POOLED RESULTS FROM 3 PHASE III, RANDOMIZED, CONTROLLED TRIALS

P. Mease[1], H. Marzo-Ortega[2], A. Poder[3], F. Van den Bosch[4], J. Wollenhaupt[5], E. Lespessailles[6], M. McIlraith[7], L. Teng[7], S. Hall[8]. *[1]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; [3]Clinical Research Centre Ltd, Tartu, Estonia; [4]UZ Gent, Gent, Belgium; [5]Schön Klinik Hamburg Eilbek, Hamburg, Germany; [6]University of Orléans, Orléans, France; [7]Celgene Corporation, Summit, United States; [8]Monash University, CabriniHealth, Melbourne, Australia*

**Background:** In the PALACE psoriatic arthritis (PsA) trials, the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score was obtained as an exploratory measure in a subset of patients (pts) considered by investigators to have axial involvement, although PsA spondylitis was not confirmed by more objective measures such as MRI.

**Objectives:** Assess the impact of apremilast 30 mg BID (APR) on BASDAI over 52 wks using PALACE 1 (NCT01172938), 2 (NCT01212757), and 3 (NCT01212770) pooled data of pts with active PsA despite prior conventional DMARDs and/or biologics.

**Methods:** APR was evaluated in a subset of pts with baseline (BL) BASDAI ≥4 ("subset") over 16, 24, and 52 wks.

**Results:** BL BASDAI ≥4 was reported in 454/1493 (30%) pts. Mean PsA duration was similar between the subset and the rest of the PALACE 1–3 population (BL BASDAI <4: n=1039). Slightly higher percentages of the subset had a history of palmoplantar, nail, scalp, or plaque psoriasis; mean BL psoriasis BSA and % with BSA ≥3% were slightly increased. The subset had higher mean BL values for CRP (1.12 vs 0.93), pain VAS (63.6 vs 53.8), pt's global disease assessment (62.2 vs 53.5), and physician's global disease assessment (PhGA) (59.0 vs 53.0) and markedly worse mean HAQ-DI (1.41 vs 1.08), SF-36v2 PF (30.6 vs 35.8), and FACIT-F (25.7 vs 31.8); TJC was higher (25.1 vs 19.1) and SJC (12.4 vs 10.9) was less differentiated. DAS-28 scores were comparable. Despite disease activity differences, BL concomitant oral DMARDs were similar in both groups: 1 in 61.0% and 2 in 5.5% (subset) vs 1 in 57.8% and 2 in 6.4% (rest of PALACE 1–3 population); MTX was the most common DMARD. In the subset, 73.6% had only been treated with oral DMARDs pre-study and 44.9% with only 1 DMARD; 25.1% had prior biologic use and 9% prior biologic failure, slightly higher percentages vs the other group. Small increases in BL NSAID and analgesic use were noted in the subset. Mean BL BASDAI scores in the subset were 6.6 in APR and 6.4 in placebo (PBO)pts. APR resulted in a greater mean decrease in BASDAI score vs PBO at Wk 16 (–1.53 vs –0.91; *P*=0.0173) and Wk 24 (–1.64 vs –0.74; *P*=0.0002); other disease measures significantly improved, including marked HAQ-DI, PhGA, and fatigue improvements (Table). Long-term improvement was seen across measures, with mean Wk 52 BASDAI reduction of –2.18 (Table) and mean HAQ-DI improvement of –0.464.

**Outcomes at Wk 24 and Wk 52 in Pts With BASDAI ≥4 at BL**

| | Wk 24 (LOCF) | | Wk 52 (Data as Observed) |
|---|---|---|---|
| | APR 30 mg BID n=156 | PBO n=151 | APR 30 mg BID n=125 |
| BASDAI score, mean BL | 6.6 | 6.4 | 6.6 |
| BASDAI score, mean change from BL | –1.64* | –0.74 | –2.18 |
| SJC, mean change | –5.5* | –2.4 | –8.5 |
| HAQ-DI, mean change | –0.301* | –0.117 | –0.464 |
| SF-36v2 PF, mean change | 4.98* | 1.76 | 7.06 |
| Pain VAS, mean change | –12.6* | –7.9 | –22.1 |
| FACIT-F, mean change | 4.38* | 1.29 | 6.77 |
| Pt's global assessment, mean change | –10.9 | –5.7 | –19.8 |
| Physician's global assessment, mean change | –22.1* | –7.4 | –34.3 |

*P≤0.05; †P≤0.0001 vs PBO; based on an analysis of covariance model for the change from BL, with treatment group, BL DMARD use, and study as factors, and BL value as the covariate. Pt's global assessment of pain APR30 vs PBO at Wk 24, P=0.0590. At Wk 24, missing values were handled using LOCF; Wk 16 data were carried forwarded to Wk 24 for pts who early escaped at Wk 16; the n represents the number of pts randomized at BL and with a BL BASDAI value ≥4. For Wk 52, the n represents the number of pts randomized to APR30 at BL and with a BL BASDAI value ≥4 and an outcome measure at Wk 52; the n may vary slightly for each end point. LOCF=last observation carried forward; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; SJC=swollen joint count; HAQ-DI=Health Assessment Questionnaire-Disability Index; SF-36v2 PF=36-item Short-Form Health Survey version 2 Physical Functioning domain score; VAS=visual analog scale; FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue.

**Conclusions:** In this post-hoc analysis, pts reporting BASDAI ≥4 appear to have added disease burden, with greater disability, pain, fatigue, and global disease ratings; this may not be captured by some disease activity measures, and effective treatment strategies may not have been available. APR resulted in long-term improvements in BASDAI scores and other measures. Further evaluation objectively assessing presence of inflammatory spine disease in PsA and its response to APR is warranted.

## THU0421 SERUM-BASED SOLUBLE MARKERS MAY DIFFERENTIATE PSORIATIC ARTHRITIS FROM OSTEOARTHRITIS

V. Chandran[1,2], A.V. Perruccio[1,3], S. Li[1], F. Abji[1], R. Gandhi[3], D.D. Gladman[1,3]. *[1]Krembil Research Institute; [2]Medicine, Laboratory Medicine and Pathobiology, Institute of Medical Science; [3]University of Toronto, Toronto, Canada*

**Background:** It is often difficult to differentiate psoriatic arthritis (PsA) from osteoarthritis (OA) in clinical practice.

**Objectives:** To aid clinical diagnosis, we aimed to identify soluble biomarkers that differentiate PsA from OA.

**Methods:** Serum samples from 201 patients with OA (mean age 65 years, 43.3% males, no history of inflammatory disease), 77 patients with PsA satisfying CASPAR criteria (mean age 45 years, 54.5% males) and 76 healthy controls (mean age 37 years, 50% males) were obtained from the respective biobanks of the Arthritis Program, University Health Network, and the University of Toronto PsA Program. Samples were obtained at the time of joint replacement surgery (OA) or at the time of clinical assessment (PsA, healthy controls), and stored at -80°C until laboratory assays were conducted. Soluble markers of cartilage metabolism (COMP, hyaluronan), metabolic syndrome (adiponectin, adipsin, resistin, HGF,

insulin, leptin) and inflammation/immune response (CRP, IL-1b, -6, -8, TNF-α, MCP-1, NGF) were assayed in the samples using Luminex multiplex assay. Marker levels in serum were compared across the 3 groups using the Kruskal-Wallis test. Pair-wise comparisons were made with Wilcoxon rank sum test. To identify markers that differentiate PsA from OA, multivariate logistic regression analyses with backward elimination, adjusted for age and sex, were constructed using markers determined to be significant at a $p \leq 0.1$ from univariate analyses. Discriminative ability was assessed by way of receiver operating characteristic (ROC) curves based on findings from multivariate models. The final model was further validated in an independent set of 73 PsA and 75 OA samples using predicted probabilities estimated using coefficients from the model developed on the training set.

**Results:** Univariate analyses revealed the following markers significantly differed across groups ($p<0.001$): COMP, hyaluronan; resistin, HGF, insulin, leptin; CRP, IL -6, -8, TNF-α, MCP-1, NGF. When comparing PsA to OA, the following markers significantly differed ($p<0.001$): COMP, hyaluronan; resistin, HGF, insulin; CRP, IL-6, -8, TNF-α, MCP-1, NGF. Multivariate analysis demonstrated that COMP (OR 1.24, 95% CI 1.06, 1.46), resistin (OR 1.26, 95% CI 1.07, 1.48), MCP-1 (OR 1.10, 95% CI 0.07, 1.48) and NGF (OR $<0.001$, 95% CI $<0.001$, 0.25) were independently associated with PsA vs. OA. The area under the ROC curve (AUROC) for this model was 0.99. Internal cross-validation of the model consistently identified MCP-1 as a PsA marker. Further validation of the model including COMP, resistin, MCP-1 and NGF showed an AUROC of 0.98.

**Conclusions:** A panel of 4 biomarkers (COMP, resistin, MCP-1, NGF) may distinguish PsA from OA. Clinical utility of these markers will need to be determined in prospective studies.

**Disclosure of Interest:** None declared

## THU0422 APREMILAST MONOTHERAPY AS THE FIRST SYSTEMIC TREATMENT IN DMARD-NAÏVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: 3-YEAR TREATMENT RESULTS

A.F. Wells[1], C.J. Edwards[2], A.J. Kivitz[3], P. Bird[4], D. Nguyen[5], K. Shah[5], L. Teng[5], J.A. Aelion[6]. *[1]Rheumatology and Immunotherapy Center, Franklin, United States; [2]University Hospital Southampton, Southampton, United Kingdom; [3]Altoona Center for Clinical Research, Duncansville, United States; [4]Combined Rheumatology Practice, Kogarah, Australia; [5]Celgene Corporation, Summit; [6]West Tennessee Research Institute, Jackson, United States*

**Background:** Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the immune response that causes joint inflammation and other manifestations of psoriatic arthritis (PsA), including skin disease. Primary findings from the PALACE 4 study (NCT01307423) demonstrated greater efficacy with APR vs. placebo in DMARD-naive patients with active PsA.[1,2]

**Objectives:** Describe the long-term efficacy and safety of APR monotherapy in DMARD-naïve patients in PALACE 4 for up to 156 weeks.

**Methods:** Patients were randomized (1:1:1) to placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20). Patients whose swollen joint count (SJC) and tender joint counts (TJC) had not improved by ≥20% at Week 16 were considered non-responders and required to be re-randomized (1:1) to APR30 or APR20 if they were initially randomized to placebo, or continued on their initial APR dose. At Week 24, all patients remaining on placebo were re-randomized to APR30 or APR20. Double-blind treatment continued to Week 52 with open-label APR for up to 4 additional years.

**Results:** A total of 527 patients were randomized and received ≥1 dose of placebo (n=176), APR30 (n=176), and APR20 (n=175). Of the patients entering the third year of therapy, 88.0% (272/309) completed the Week 156 visit. At Week 52, 58.0% (119/205) of patients receiving APR30 and 55.4% (107/193) receiving APR20 achieved a 20% improvement in modified American College of Rheumatology (ACR20) response (Table). At Week 156, rates of improvement in PsA signs and symptoms and physical function were sustained, as shown by modified ACR20/ACR50/ACR70 responses, mean percent change in SJC/TJC, mean change in Health Assessment Questionnaire-Disability Index (HAQ-DI) score, proportion of patients with HAQ-DI exceeding the minimal clinically important differences (MCID) ≥0.30 threshold, achievement of Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) of 0 and dactylitis count of 0, and 75% and 50% reduction from baseline Psoriasis Area and Severity Index (PASI-75 and PASI-50) responses (Table). During Weeks >104 to ≤156, the most common adverse events (AEs) among APR-exposed patients were upper respiratory tract infection (3.2%) and nasopharyngitis (3.9%); serious AEs occurred in 5.2% of APR patients, and no opportunistic infections occurred. In general, no change in the types of AEs and no increase in the incidence and severity of AEs were seen with longer-term exposure.

| | Outcomes at Weeks 52 and 156 | | | |
|---|---|---|---|---|
| | Week 52 | | Week 156 | |
| | APR30 n=207* | APR20 n=194* | APR30 n=143* | APR20 n=133* |
| ACR20, n/m† (%) | 119/205 (58.0) | 107/193 (55.4) | 84/141 (59.6) | 79/131 (60.3) |
| ACR50, n/m† (%) | 61/205 (29.8) | 54/191 (28.3) | 50/141 (35.5) | 51/131 (38.9) |
| ACR70, n/m† (%) | 32/206 (15.5) | 23/192 (12.0) | 33/143 (23.1) | 26/130 (20.0) |
| SJC, mean % change | −76.1 | −70.5 | −84.3 | −78.1 |
| TJC, mean % change | −59.4 | −52.4 | −65.7 | −63.6 |
| HAQ-DI (0-3), mean change | −0.35 | −0.28 | −0.38 | −0.35 |
| HAQ-DI MCID ≥0.30†, n/m (%) | 98/207 (47.3) | 89/194 (45.9) | 69/143 (48.3) | 66/133 (49.6) |
| MASES of 0, n/m (%)† | 65/127 (51.2) | 52/132 (39.4) | 50/79 (63.3) | 55/91 (60.4) |
| Dactylitis count of 0, n/m (%)† | 74/102 (72.5) | 72/102 (70.6) | 60/71 (84.5) | 65/73 (89.0) |
| PASI-75, n/m (%)† | 34/119 (28.6) | 42/112 (37.5) | 32/82 (39.0) | 33/77 (42.9) |
| PASI-50, n/m (%)† | 64/119 (53.8) | 65/112 (58.0) | 46/82 (56.1) | 46/77 (59.7) |

*Data as observed; n/m=number of responders/number of patients with sufficient data for evaluation. *The n reflects the number of patients treated with APR30 and APR20 regardless of when patients started taking APR (Baseline, Week 16, or Week 24) and who had data available at the specific time point; actual number of patients available for each end point may vary. †Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. ‡Pre-specified MCID threshold, based on the literature (Mease PJ, et al. Ann Rheum Dis. 2004;63(Suppl 1):391) at the time of protocol development and definition of analysis. §Examined among patients with enthesitis at baseline and data at the specific time point. Mean MASES at baseline were 3.5 (APR30) and 4.1 (APR20). ¶Examined among patients with dactylitis at baseline and data at the specific time point. Dactylitis mean counts at baseline were 3.6 (APR30) and 3.1 (APR20). #Examined among patients with psoriasis involvement of the body surface area ≥3% at baseline and data at the specific time point.

**Conclusions:** Over 156 weeks, APR monotherapy demonstrated sustained response and improvements in PsA signs and symptoms, including SJC, TJC, enthesitis, dactylitis, physical function, and psoriasis. APR continued to demonstrate an acceptable safety profile and was generally well tolerated.

## THU0423 TIME TO REBOUND IN JOINT SYMPTOMS FOLLOWING DISCONTINUATION OF TNFI THERAPY AFTER ACHIEVING LOW DISEASE ACTIVITY OR REMISSION IN PSORIATIC ARTHRITIS PATIENTS ENROLLED IN THE US CORRONA REGISTRY

L.R. Harrold[1], B. Stolshek[2], S. Rebello[1], D. Collier[2], A. Mutebi[2], S.W. Wade[3], W. Malley[1], J.D. Greenberg[1], C.J. Etzel[1]. *[1]Corrona, LLC, Southborough; [2]Amgen, Inc., Thousand Oaks; [3]Wade Outcomes Research Consulting, Salt Lake City, United States*

**Background:** The treatment goal for patients (pts) with psoriatic arthritis (PsA) is to suppress disease activity. Little is known about clinical outcomes in pts who stop TNFi therapy after achieving low disease activity (LDA) during routine care.

**Objectives:** We evaluated time to rebound (i.e., increase in joint symptoms after therapy discontinuation) in pts with PsA who achieved LDA prior to stopping TNFi therapy as well as changes in measures of disease activity at the first visit following TNFi discontinuation.

**Methods:** In the Corrona registry, we identified pts with PsA who initiated a TNFi (adalimumab, etanercept, infliximab, golimumab), achieved LDA based on Clinical Disease Activity Index (CDAI) ≤10 on TNFi therapy, discontinued TNFi altogether while still in LDA (persistence on conventional disease modifying medication was allowed) and had at least 1 follow-up visit while off TNFi. Demographic and clinical characteristics were assessed at discontinuation date (index date). To assess time to rebound, pts were followed until earliest of the following events: rebound of symptoms (CDAI >10), initiation of another biologic/small molecule or last follow-up visit. Kaplan-Meier curves were generated for time to rebound (CDAI >10). To assess impact of TNFi discontinuation, change in disease activity measures including CDAI, modified Health Assessment Questionnaire (mHAQ), pt and physician global assessments, and pt pain were assessed between discontinuation and first post-index visit.

**Results:** There were 94 pts (57% female, 51% biologic-experienced at TNFi initiation) who met study criteria. At TNFi discontinuation, mean (standard deviation [SD]) age and disease duration were 52.6 (12.7) and 9.8 (7.4) years, respectively. Over time, 67 (73%) pts had a rebound in symptoms, with median time to rebound of 8 months (95% CI 6–12). At first post-index visit, there was a significant mean increase in all measures of disease activity except mHAQ (Table).

Table 1. Disease activity measures at index (TNFi discontinuation), first post-index visit, and change during interval

| Disease activity measure | Index: Mean (SD) | Follow-up visit: Mean (SD) | Mean change (SD) | p-value |
|---|---|---|---|---|
| CDAI | 4.3 (3.1) | 7.5 (7.7) | –3.2 (6.9) | *<0.0001* |
| mHAQ | 0.24 (0.35) | 0.27 (0.38) | –0.03 (0.26) | 0.328 |
| Physician Global | 9.9 (10) | 14.7 (14.9) | –4.8 (15.4) | 0.003 |
| Pt. Global | 23.2 (21.4) | 29.6 (25.6) | –6.5 (23.7) | 0.01 |
| Pt. Pain | 26.4 (24.9) | 32.1 (26.7) | –5.6 (20.7) | 0.01 |

**Conclusions:** Rebound of symptoms in PsA patients occurred frequently with the majority of patients having worsening of disease activity by the next visit after TNFi discontinuation. These results suggest careful consideration before stopping these agents after achievement of low disease activity.

## THU0424 TREATMENT WITH TNF ALPHA BLOCKERS IS ASSOCIATED WITH REDUCED PROGRESSION OF ATHEROSCLEROTIC PLAQUES IN PATIENTS WITH PSORIATIC DISEASE – A PROSPECTIVE STUDY

L. Eder[1], V. Chandran[2], R. Cook[3], D.D. Gladman[4]. *[1]Women's College Research Institute, Women's College Hospital; [2]Rheumatology, Toronto Westen Hospital, Toronto; [3]University of Waterloo, Waterloo; [4]Rheumatology, Toronto Western Hospital, Toronto, Canada*

**Background:** Patients with psoriatic disease are at high risk for cardiovascular morbidity. The strong link between inflammation and atherosclerosis highlights the role of suppression of inflammation as a potential strategy for prevention of cardiovascular events.
**Objectives:** To assess whether the use of TNFα blockers is associated with reduced rate of progression of atherosclerotic plaques in psoriatic disease patients.
**Methods:** Patients with psoriasis only (PsC) or psoriatic arthritis (PsA) from a large psoriatic disease cohort were enrolled. Baseline evaluation included clinical assessment of cardiovascular risk factors, joint and skin disease activity and medication use. Patients were followed every 6–12 months according to a standard protocol. Treatment with any TNFα blocker for at least 50% of the follow-up period was defined as the primary predictor. Ultrasound assessment of the carotid arteries was performed and Total Plaque Area (TPA) was measured at baseline and after 2–3 years. The average annual change in TPA was calculated by subtracting the baseline from the follow-up TPA divided by the number of years between the visits. This measure represented the annual progression rate of atherosclerosis and was considered the outcome of interest. The association between treatment with a TNFα blocker and progression of atherosclerosis was assessed by multivariate linear regression analysis after adjusting for cardiovascular risk factors, statin therapy and treatment with Disease Modifying Anti Rheumatic Drugs (DMARDs).
**Results:** A total of 319 patients with psoriatic disease (66.4% PsA, 33.6% PsC) were included in the analysis. Their mean age was 54.5±11.8 years and 56.3% were men. The mean duration of follow up was 2.9 years. 61.7% of the patients had at least one atherosclerotic plaque at baseline. Progression in atherosclerosis was observed in 46% of the patients, while in the remaining 54% no change/regression in atherosclerosis was found. Men had a significantly higher annual progression rate of atherosclerosis compared with women (annual TPA 2.4 vs. 0.6 $mm^2$, $p<0.001$, respectively). Since a statistically significant interaction between sex and several of the co-variates, including TNFα blocker therapy, was found, separate regression models were constructed for men and women. In men, TNFα blocker therapy was associated with a reduced adjusted rate of atherosclerosis progression (β=-2.25 95% Confidence Interval (CI) -3.45, -1.05, $p<0.001$). Additional predictors of atherosclerosis progression in men were baseline TPA (β =5.72, 95% CI 3.81, 7.62), current smoking (β=1.86, 95% CI 0.19, 3.54) and LDL cholesterol level (β=0.81, 95% CI 0.07, 1.56). In contrast, neither TNFα blocker therapy ($p=0.71$) nor any of the cardiovascular risk factors assessed predicted progression rate of atherosclerosis in women. No difference was found in atherosclerosis progression between PsA and PsC ($p=0.73$).
**Conclusions:** TNFα blocker therapy is associated with reduced progression rate of atherosclerosis in patients with psoriatic disease. The lack of association in women may be explained by reduced power due to minimal progression of atherosclerotic plaques in women in general or by alternative underlying mechanisms of cardiovascular morbidity in women.

## THU0425 THE EARLY DIAGNOSIS OF PSORIATIC ARTHRITIS: STANDARDIZED EVALUATION OF SPECIFIC ENTHESES, TENDONS AND CAPILLARIES IN PATIENTS WITH FRESH DIAGNOSED PSORIASIS

D. Becker-Capeller[1], S. El-Nawab-Becker[2], C. Iking-Konert[3]. *[1]Rheumatology, Private Practice; [2]Rheumatologische Schwerpunktpraxis, Stade; [3]Rheumatology, Medical University of Hamburg (UKE), Hamburg, Germany*

**Background:** Early diagnosis of psoriatic arthritis (PsA) is a challenging topic. PsA is not a mild disease. Untreated it is to compare with rheumatoid arthritis. PsA leads in a high percentage to joint damage, to a poor functional status and to a reduced quality of life. Due to cardiovascular complications patients with PsA die earlier than the general population. Today effective treatment can be started earlier but early diagnosis is still a big problem.We have classification criteria (Caspar, Gepard) and the enthesitis-synovial concept is part oft he international ASAS classification criteria, but we have no early- disease-diagnostic criteria. The fact that skin lesions normally precedes the manifestation of PsA (80%) makes the cooperation between dermatologists and rheumatologists crucial.
**Objectives:** Our hypothesis is that tendonitis and enthesitis of the feet and capillary abnormalities in early PsA can be diagnosed in a very early stage of the disease long before joints involvement is occurring.
**Methods:** We investigated 51 consecutive patients with psoriasis diagnosed and referred by the collaborating dermatologists, without joint problems. Psoriasis must be diagnosed for the first time and should not last longer than 2 years. (All dermatologists in the area participated). No specific dermatological treatment should be started except topics. We performed PW-doppler ultrasound examination of the peronaeus tendons, the tibialis posterior muscle tendons, the tibialis anterior tendons and the attachement oft he Achillles tendons on both sides as well as nailfold capillaroscopy oft he 2.-4.finger of the right hand. A control group of 10 healthy controls was examined.
**Results:** Demographic data and specific assessments (Caspar, Gepard, PASI, DLQI, DAS28) were obtained from the psoriasis group. 20% of the study group had a nail psoriasis, more than 50% were suffering from psoriasis capitis. Our data reveal a large number of grade 1 (75%) and 2 (35%) (range grade1–3) tendonitis abnormalities in the peronaeus- and tib. posterior tendons. Joint effusions could be mostly seen in the talo-tibial joint, whereas the Achilles tendons and the bursa achillea were not often affected. Capillaroskopy results showed torsions/twist-signs in 18% in psoriasis- patients/nail psoriasis -patients which did not differ from the results of the control group. Hair-Pin capillaries occurred significantly more often in the control-group. No dactylitis could be detected in these early cases.
**Conclusions:** Tendonitis of the foot-ankle region occurs strikingly more often than expected in early stages of psoriasis. Ultrasonic of the ankle region is easy to perform in rheumatologic practises. Capillaroscopy is more time consuming and should be reserved for special diagnostic questions.
We have a simple tool to modify the natural course of PsA by early diagnosis. But that works only in a tight interdisciplinary setting (tight junction) between rheumatologists and dermatologists.

## THU0426 ACHILLES ENTHESITIS DEFINED BY ULTRASOUND IS NOT ASSOCIATED TO CLINICAL ENTHESITIS IN PATIENTS WITH PSORIATIC ARTHRITIS

B. Michelsen[1], A.P. Diamantopoulos[1,2], D.M. Soldal[1], H.B. Hammer[3], A. Kavanaugh[4], G. Haugeberg[1,5,6]. *[1]Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand; [2]Dept. of Rheumatology, Haugesund Rheumatism Hospital, Haugesund; [3]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Dept. of Rheumatology, Allergy, Immunology, Univeristy of California San Diego, San Diego, United States; [5]Dept. of Rheumatology, University of Science and Technology, Trondheim; [6]Dept. of Rheumatology, Martina Hansens Hospital, Baerum, Norway*

**Background:** Clinical examination may overestimate Achilles enthesitis. Ultrasonography (US) is a valuable tool for assessment of musculoskeletal inflammation including subclinical enthesitis.
**Objectives:** The aim of our study was to compare clinical and US evaluation of Achilles enthesitis in patients with psoriatic arthritis (PsA).
**Methods:** Patients with PsA were included consecutively in a clinical setting during 1.5 years. The Achilles insertion was examined by clinical assessment of tenderness by a trained nurse, and an experienced ultrasonographer performed US evaluation of 1) inflammatory activity defined as power Doppler (PD) signal, tendon thickening, hypoechogenicity and bursal swelling as well as 2) structural damage defined as erosions at tendon insertion, calcifications and enthesophytes. US sum scores of inflammatory activity and structural damage were assessed. Demographic variables and US scores were assessed by descriptive statistics. Proportions were analysed by Chi-Square test. Correlations were assessed by Spearman's rank correlation test (non-parametric distribution of the data).
**Results:** A total of 141 PsA patients were included. They all fulfilled the CASPAR criteria. Mean (SD) age was 52.4 (10.2) years, disease duration 9.5

(6.6) years, BMI 28.3 (4.3) kg/m$^2$, 50.4% were females, 10.6% used steroids, 57.4% conventional synthetic disease modifying drugs (csDMARDs), 32.6% tumor necrosis factor inhibitors (TNFi) and 20.6% both TNFi and csDMARDs.
Of 282 Achilles tendons, 88 (33.2%) were tender on palpation. By US, 6 (17%) had hypoechogenicity, 37 (13.1%) thickening, 2 (0.8%) PD activity, 14 (5%) bursal swelling, 112 (39.7%) calcifications, 77 (27.3%) enthesophytes and 4 (1.4%) erosions at tendon insertion. Inflammatory activity was found in 55 (19.5%) of the examined Achilles tendons and 148 (52.5%) had structural damage on US sum scores. No significant correlation was found between US sum scores and tenderness on palpation. 36 (18.6%) of the Achilles tendons showed subclinical inflammation on US. No significant difference of percentages of patients with Achilles inflammatory activity or structural damage was found when comparing patients currently treated or not with TNFi, csDMARDs and steroids.
**Conclusions:** We report lack of association between palpation tenderness and US signs of Achilles enthesitis in PsA. US showed structural damage in 52.5% and subclinical inflammation in 18.6% of the examined Achilles tendons.

## THU0427 STUDY OF PREVALENCE AND PREDICTORS OF MINIMAL DISEASE ACTIVITY (MDA) STATE IN A SPANISH POPULATION WITH PSORIATIC ARTHRITIS. MAAPS STUDY

R. Queiro, J.D. Cañete, J.C. Torre, J.A. Román-Ivorra, J. Sanz, C. Montilla, J. Salvatierra, J. Calvo, S. Gómez, M. Montoro, A. Cábez. *Rheumatology, Coordinator Center, HUCA, Oviedo, Spain*

**Background:** Biological therapies have greatly improved the management of psoriatic arthritis (PsA). Minimal disease activity (MDA) has become the optimal target in the treatment of PsA, waiting for a standardized definition of remission. Knowing the proportion of PsA patients in the MDA state could inform on the quality of management of these patients.
**Objectives:** To determine the prevalence of MDA (Coates et al.) in patients with PsA in Spain as well as its potential predictors. To evaluate the association between MDA and the impact of disease, as evaluated by the PsA Impact of Disease questionnaire (PsAID).
**Methods:** This was a non-interventional, cross-sectional, multicenter study, which aimed to evaluate the prevalence of MDA in a Spanish population with PsA. The study was carried out at 25 rheumatology outpatient clinics between May/2014 and Feb/2015. A total of 238 adult patients diagnosed with PsA (CASPAR criteria) with at least one year disease duration and treated with biological and non-biological *DMARDS* were included. Finally, 227 were considered evaluable. Clinical, demographic, treatment data, physical function (HAQ) and quality of life (PsAID) were obtained. According to the latter, the patient acceptable symptoms state (PASS) has been defined as a PsAID value $<4$. All patients gave informed consent. An Ethics committee board approved the final version of this study.
**Results:** Overall, 133 out of 227 (58.6%) subjects achieved MDA at study entry. Seventy-seven (37.9%) and 137 (64.4%) patients reached joint and skin remission, respectively. However, a fair relationship between MDA and joint remission (k=0.390) and a slight relationship between MDA and skin remission (k=0.178) were observed. Patients in MDA state had better functional capacity by HAQ (0.35 ± 0.47) vs non-MDA patients (0.79 ± 0.63), $p<0.001$. These patients also had a significantly lower impact of the disease as measured by PsAID: MDA patients (3.34 ± 3.05) vs non-MDA patients (7.13 ± 5.21), $p<0.001$. In multivariate logistic regression analysis, male gender (OR 2.74, p=0.001), sedentary lifestyle (OR 3.13, p=0.002), familial history of PsA (OR 0.38, p=0.036), CRP level (OR 0.92, p=0.010) and use of corticoids (OR 0.33 p=0.007) were predictors of MDA. Painful entheses count $\leq 1$ was the MDA criterion met by the highest proportion of patients (80.5%), whereas reaching a global disease activity VAS score $\leq 20$ was achieved by only 43.2% of them.
**Conclusions:** MDA was achieved by nearly 60% of patients in this study reflecting clinical practice in agreement with results from earlier studies. These patients had better functional state and most of them reached an acceptable symptoms state according to the PsAID. Our results of predictors to achive MDA should be confirmed in further prospective studies.

## THU0428 PSORIASIS ARTHRITIS IS ASSOCIATED WITH PERIARTICULAR BONE LOSS OF THE METACARPALS

A. Pfeil[1], H.H. Thodberg[2], L. Krojniak[1], D.M. Renz[3], L. Reinhardt[1], P. Oelzner[1], G. Wolf[1], J. Böttcher[4]. *[1]Department of Internal Medicine III, Friedrich Schiller University Jena, Jena, Germany; [2]Visiana, Holte, Denmark; [3]Institute of Diagnostic and Interventional Radiology, Friedrich-Schiller-Univerisity Jena, Jena; [4]Institute of Diagnostic and Interventional Radiology, SRH Waldklinikum Gera, Gera, Germany*

**Background:** The BoneXpert is a new Digital X-ray Radiogrammetry method measures the cortical bone thickness of the metacarpals.
**Objectives:** The aim of this study was to quantify cortical bone loss in patients with Psoriasis Arthritis (PsA) and to compare these findings with the PsA modified van der Heijde Sharp Score.
**Methods:** The study includes 104 PsA patients. The BoneXpert method was used to measure the Metacarpal Index ($MCI_{BX}$) at the metacarpal bones (II to IV). Additionally, the T-Score of the MCI ($T\text{-}Score_{MCI}$) was calculated. Radiographic severity was evaluated by the PsA modified van der Heijde Sharp Score (Joint Space Narrowing Score and Erosion Score).
**Results:** For the total PsA study cohort the $T\text{-}Score_{MCI}$ was significantly reduced with -1.289 ± 1.313 SD. The MCI presented a negative correlation to the Joint Space Narrowing Score ($r = -0.558$; $p<0.001$) and Erosion Score ($r = -0.714$; $p<0.001$) of the PsA modified van der Heijde Sharp Score. In this context, a severity dependent and PsA-related periarticular demineralization as measured by the $MCI_{BX}$ was quantified. The highest reduction was observed for the $MCI_{BX}$ with -28.5% ($p<0.01$) regarding to the Erosion Score and with -21.1% ($p<0.01$) for the Joint Space Narrowing Score.
**Conclusions:** Patients with PsA presented also periarticular demineralisation and severity dependent bone loss as measured by the BX using the $MCI_{BX}$. The BX-parameters seem to function as surrogate marker of radiographic progression in PsA and potentially differentiate between different stages of disease manifestation affecting bone structures.

## THU0429 THE RISK OF INCIDENT LIVER DISEASE AMONG PATIENTS WITH PSORIASIS, PSORIATIC ARTHRITIS, AND RHEUMATOID ARTHRITIS

A. Ogdie[1,2], S. Grewal[3], J. Takeshita[3], D. Shin[3], R. Carr[4], J. Gelfand[5]. *[1]Medicine/Rheumatology; [2]Center for Clinical Epidemiology and Biostatistics; [3]Dermatology; [4]Medicine/Hepatology, University of Pennsylvania, Philadelphia, Pa; [5]Dermatology, University of Pennsylvania, Philadelphia, United States*

**Background:** Cross-sectional studies have suggested that psoriasis, psoriatic arthritis (PsA), and rheumatoid arthritis (RA) are associated with liver disease. Little is known about the risk for incident liver disease among patients with these diseases from a population-based perspective.
**Objectives:** To examine the risk for incident liver disease among patients with psoriasis, PsA, and RA compared to the general population
**Methods:** We conducted a population-based cohort study in the United Kingdom using The Health Improvement Network (THIN) data from 1994–2014. Patients age 18–89 with codes for PsA, RA, or psoriasis were matched to up to 5 controls from the general population on practice and start date in the practice. Patients with prior liver disease were excluded. Cox proportional hazards models were used to estimate hazard ratios (HR) with 95% confidence intervals (CI). A priori we hypothesized an interaction with disease modifying antirheumatic drug (DMARD) use. Patients with psoriasis who received a DMARD or phototherapy were identified as having "severe" psoriasis.
**Results:** Among patients with PsA (N=12,308) RA (N=54,251), psoriasis (N=197,130) and controls (N=1,279,754), 10,415 incident cases of liver dis-

**Abstract THU0429** – Table 1

| | | N | Incident liver disease diagnosis | Mean cohort time | Person years (PY) | Incidence (per 10,000 PY) | Age/Sex adjusted HR (95% CI) | Fully adjusted HR (95% CI) |
|---|---|---|---|---|---|---|---|---|
| Control | | 1,279,754 | 8,140 | 6.50 | 8,319,520 | 9.78 | Ref | Ref |
| PsA | No DMARD | 5,786 | 64 | 6.12 | 35,390 | 18.08 | 1.80 (1.40–2.30) | 1.37 (1.02–1.85) |
| | DMARD | 6,522 | 70 | 5.83 | 38,018 | 18.41 | 1.87 (1.48–2.37) | 1.66 (1.29–2.14) |
| RA | No DMARD | 21,396 | 189 | 5.71 | 122,204 | 15.47 | 1.60 (1.39–1.85) | 1.50 (1.27–1.77) |
| | DMARD | 32,855 | 227 | 6.13 | 201,351 | 11.27 | 1.19 (1.04–1.36) | 0.97 (0.83–1.13) |
| Psoriasis | Mild | 186,006 | 1,593 | 6.21 | 1,155,765 | 13.78 | 1.40 (1.33–1.48) | 1.37 (1.29–1.46) |
| | Severe | 11,124 | 132 | 5.31 | 59,018 | 22.37 | 2.32 (1.95–2.75) | 1.94 (1.61–2.35) |

ease were identified. After adjusting for age, sex, body mass index, drinking, smoking, NSAID use, systemic glucocorticoid use, and diabetes, the HR were significantly elevated for all groups except patients with RA who received a DMARD: PsA without a DMARD 1.37 (95%CI: 1.02–1.85), PsA with a DMARD 1.66 (95%CI: 1.29–2.14), RA without a DMARD 1.50 (1.27–1.77), RA with a DMARD 0.97 (0.83–1.13), psoriasis without a DMARD 1.37 (1.29–1.46), and severe psoriasis 1.94 (1.61–2.35). Among all patients, 38% of new liver disease was attributed to fatty liver disease, 19% was alcoholic liver disease, and 8% was viral mediated liver disease. Among patients with PsA prescribed a DMARD and patients with severe psoriasis, fatty liver disease accounted for more than half of new diagnoses of liver disease.

**Conclusions:** Patients with PsA, RA, and psoriasis have a significantly increased risk for development of liver disease even after accounting for risk factors and among patients not prescribed a DMARD. These results suggest systemic inflammation may play a role in the development of liver disease beyond the relationship with treatment-related toxicity.

## THU0430 IXEKIZUMAB PROVIDES IMPROVEMENTS THROUGH 52 WEEKS IN PHYSICAL FUNCTION, QUALITY OF LIFE, AND WORK PRODUCTIVITY IN BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG-NAIVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

A.B. Gottlieb[1], M.E. Husni[2], C.L. Shuler[3], R. Burge[3], C.-Y. Lin[3], C.H. Lee[3], D.D. Gladman[4]. *[1]Tufts Medical Center, Boston; [2]Cleveland Clinic, Cleveland; [3]Eli Lilly and Company, Indianapolis, United States; [4]University of Toronto, Toronto, Canada*

**Background:** Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. PsA has a negative impact on patients' quality of life, physical function, and work productivity. Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. In this phase 3 trial (SPIRIT-P1), previously reported results showed that IXE treatment resulted in significant improvements (compared with placebo [PBO]) at Week [Wk] 24 in the patient-reported outcome (PRO) measures of Health Assessment Questionnaire – Disability Index (HAQ-DI), Short Form-36 Health Survey Physical Component Summary (SF-36 PCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS), and Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP; presenteeism, work productivity, activity impairment).

**Objectives:** To evaluate whether an effect of IXE on improvement of PROs is also observed at Wk 52.

**Methods:** A total of 417 biologic disease-modifying antirheumatic drug (bDMARD)-naive patients with active PsA were randomly assigned 1:1:1:1 to subcutaneous administration of 80-mg IXE every 4 wks (Q4W) or 2 wks (Q2W), each with a 160-mg starting dose at Wk 0; adalimumab (ADA) 40 mg Q2W (active comparator); or PBO in the Double-Blind Treatment Period (DBTP; Wks 0 through 24). Of these patients, 381 continued into the Extension Period (EP; Wks 24 through 52). PBO- and ADA-treated patients were randomly re-assigned (1:1) to 80 mg IXEQ4W or IXEQ2W at Wk 16 (inadequate responders) or Wk 24; ADA-treated patients started IXE after an 8-wk wash-out period at Wk 24 (inadequate responders) or Wk 32. Investigators were blinded as to criteria for inadequate response. Analyses for the EP were conducted on the EP Population, defined as all patients who received at least 1 dose of study drug during the EP.

Missing values were imputed by nonresponder imputation for categorical data and modified baseline observation carried forward for continuous data.

**Results:** Baseline demographics and clinical characteristics were generally similar between treatment groups; population mean baseline (Wk 0) scores for HAQ-DI, SF-36 PCS, and EQ-5D VAS (Table) indicated impaired physical function and quality of life. Physician-assessed clinical efficacy was shown by 69% of patients treated with IXE for 52 wks achieving American College of Rheumatology (ACR) 20 response. Patients receiving IXE (Q4W or Q2W) for 52 wks reported similar improvements in HAQ-DI, SF-36, EQ-5D VAS, and WPAI-SHP (presenteeism, work productivity, activity impairment) (Table) to Wk 24 results, and the percentage of IXE patients with improvement from baseline HAQ-DI score $\geq$0.35 achieving minimally clinically important difference for HAQ-DI was sustained at Wk 52 (Table) compared with Wk 24. At Wk 52, patients receiving ADA/IXE also showed similar improvements in ACR20 response and most PRO measures (Table) to Wk 24 results.

**Conclusions:** IXE provided sustained improvement through 52 wks in physical function, quality of life, and work productivity in bDMARD-naive patients with active PsA.

## THU0431 SUSTAINED IMPROVEMENTS IN SKIN SYMPTOMS, PHYSICAL FUNCTIONING, AND QUALITY OF LIFE WITH SECUKINUMAB VERSUS USTEKINUMAB IN PATIENTS WITH MODERATE-TO-SEVERE PSORIASIS AND CONCOMITANT PSORIATIC ARTHRITIS: 52 WEEK RESULTS FROM THE CLEAR STUDY

A.B. Gottlieb[1], D. Thaçi[2], A. Blauvelt[3], V. Bhosekar[4], M. Milutinovic[5], C. Karyekar[6] on behalf of the CLEAR Study Group. *[1]Tufts Medical Center, Boston, United States; [2]University Hospital Schleswig-Holstein, Lübeck, Germany; [3]Oregon Medical Research Center, Portland, United States; [4]Novartis Healthcare Pvt Ltd, Hyderabad, India; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, East Hannover, United States*

**Background:** Psoriatic arthritis (PsA) is an inflammatory arthritis associated with psoriasis.[1] In the prospective, randomised, double-blind CLEAR study (NCT02074982), secukinumab, a human anti-interleukin (IL)-17A monoclonal antibody, demonstrated superior efficacy (Psoriasis Area and Severity Index [PASI] 90) over ustekinumab (an IL-12/23 inhibitor) in patients with moderate-to-severe plaque psoriasis.[2] We previously reported that secukinumab improved skin symptoms and physical functioning at 16 weeks (wks) in the subgroup with concomitant PsA.[3]

**Objectives:** To report 52 wk results in the subgroup with concomitant PsA.

**Methods:** Patients were randomised 1:1 to receive subcutaneous (s.c.) secukinumab 300 mg or ustekinumab (patients $\leq$100 kg, 45 mg sc; $>$100 kg, 90 mg s.c.). Secukinumab administered at baseline (BL), Wks 1, 2, and 3, and every 4 wks from Wk 4 and ustekinumab at BL, Wk 4, and every 12 wks from Wk 16. The primary endpoint was the proportion of patients achieving $\geq$90% reduction from BL in PASI score at Wk 16. PASI 75, PASI 90, PASI 100, and IGA mod 2011 responses over time, and changes from BL in the HAQ-DI, WPAI, and DLQI were analysed in the subgroup with concomitant PsA. Analyses used non-responder imputation for efficacy assessments and observed data for PROs.

**Results:** Of the total 676 patients randomised, 610 (93.7%) completed 52 wks of study (secukinumab group, 312 [94.8%]; ustekinumab group, 298 [92.5%]). In overall population, the PASI 90 response was achieved by 79.0% vs. 57.6% ($P<0.0001$) and 74.9% vs. 60.6% ($P=0.0001$) patients receiving secukinumab vs. ustekinumab at Wk 16 and Wk 52, respectively. Concomitant PsA was reported in 69/337 (20.5%) and 54/339 (15.9%) patients in the secukinumab and ustekinumab groups, respectively. In the subgroup with concomitant PsA, a higher proportion of patients in the secukinumab group achieved a PASI 90 response at Wk 52 vs. ustekinumab; 77.6% vs. 63.5% ($P<0.05$), respectively. The mean change from baseline in HAQ-DI at Wk 52 was –0.30 with secukinumab vs. –0.13 with ustekinumab. A higher proportion of patients receiving secukinumab achieved HAQ-DI response (minimum clinically important difference) vs. ustekinumab at Wk 52 (39.4% vs. 23.5%, respectively). Greater improvements were observed in other parameters with secukinumab vs. ustekinumab in the PsA subgroup (Table).

**Conclusions:** The significant efficacy of secukinumab vs. ustekinumab in clearing psoriasis was sustained through 52 wks in patients with moderate-to-

**Table. Clinical Response and PROs with Secukinumab in the PsA Subgroup at Wk 52**

## THU0432 APREMILAST, AN ORAL PHOSPHODIESTERASE 4 INHIBITOR, IS ASSOCIATED WITH LONG-TERM (104-WEEK) IMPROVEMENT IN FATIGUE IN PATIENTS WITH PSORIATIC ARTHRITIS: POOLED RESULTS FROM 3 PHASE III, RANDOMIZED, CONTROLLED TRIALS

A. Kavanaugh[1], D.D. Gladman[2], C.J. Edwards[3], A. Poder[4], F. Lioté[5], P. Bird[6], G. Schett[7], D. Nguyen[8], L. Teng[8], P.J. Mease[9]. *[1]University of California, San Diego, School of Medicine, La Jolla, United States; [2]Toronto Western Research Institute, Toronto, Canada; [3]University Hospital Southampton, Southampton, United Kingdom; [4]Clinical Research Centre Ltd, Tartu, Estonia; [5]University Paris Diderot, Paris, France; [6]University of New South Wales, Kogarah, Australia; [7]University of Erlangen-Nuremberg, Erlangen, Germany; [8]Celgene Corporation, Summit; [9]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States*

**Background:** Fatigue, a common symptom affecting individuals with psoriatic arthritis (PsA), is associated with decreased quality of life and loss of work productivity.[1] The 2014 OMERACT PsA Working Group identified fatigue measurement as an important outcome to consider including in PsA core assessments.[2] The PALACE 1 (NCT01172938), 2 (NCT01212757), and 3 (NCT01212770) studies compared apremilast (APR) efficacy/safety, including fatigue level, with placebo (PBO) in patients (pts) with active PsA despite prior conventional DMARDs and/or biologics.

**Objectives:** Report APR treatment impact on fatigue over 104 wks in a pooled analysis of the PALACE 1–3 studies.

**Methods:** Pts were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use. The PBO-controlled phase continued to Wk 24, with a Wk 16 early escape option. At Wk 24, all remaining PBO pts were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Wk 52; pts could then continue to receive open-label APR up to an additional 4 years. Fatigue was assessed using FACIT-F v4 and SF-36v2 Vitality domain (VT).[3] Total FACIT-F scores range from 0–52; lower scores denote higher fatigue levels. As a point of reference, mean fatigue scores of 40.1–43.6 in the general population,[4,5] 35.8 in PsA pts,[6] and 23.9 in anemic cancer pts[5] have been reported, and FACIT-F MCID in PsA has not been determined; this analysis used FACIT-F MCID in rheumatoid arthritis pts (3–4).[7] SF-36v2 VT, a subscale of SF-36v2, measures physical and mental impact of fatigue on individuals.[8] Scores are norm-based; group values <47 represent a below-average range vs the general population.[9]

**Results:** Baseline mean FACIT-F (29.4–30.9) and SF-36v2 VT (40.6–40.8) scores were below population norms. Long-term improvement in fatigue was seen in APR pts at Wks 52 and 104 (mean FACIT-F=35.0), marking a shift toward population FACIT-F norms (Table). APR30 mean change was 5.6, with 50.9% of pts achieving FACIT-F MCID. Similarly, improvements in SF-36v2 VT scores were observed at Wks 52 and 104 with ≈60% of pts achieving MCID. Over 104 wks, most AEs were mild/moderate; in general, no increase was seen in AE incidence/severity with longer term exposure.

| | FACIT-F v4 and SF-36v2 VT at Wks 52 and 104 | | | |
|---|---|---|---|---|
| | Wk 52 | | Wk 104 | |
| | APR30 n=559* | APR20 n=541* | APR30 n=454* | APR20 n=430* |
| **FACIT-F v4** | | | | |
| Baseline score, mean | 29.2 | 31.2 | 29.5 | 31.2 |
| Mean score at time point | 34.8 | 35.1 | 35.0 | 35.7 |
| Mean change from baseline score | 4.8 | 3.9 | 5.6 | 4.5 |
| Mean % change from baseline score | 35.4 | 21.5 | 44.5 | 26.1 |
| Pts achieving MCID, % | 50.6 | 48.0 | 50.9 | 50.5 |
| **SF-36v2 VT** | | | | |
| Baseline score, mean | 40.6 | 41.6 | 40.8 | 41.5 |
| Mean score at time point | 45.3 | 45.9 | 46.5 | 46.3 |
| Mean change from baseline score | 4.7 | 4.3 | 5.6 | 4.8 |

Data as observed. *The n represents the number of pts who completed 52 wks and 104 wks of treatment, respectively, regardless of when apremilast was started (baseline, Wk 16, or Wk 24), with a baseline value and value at the specific time point.

**Conclusions:** APR-treated pts experienced improvements in fatigue, as measured by FACIT-F and SF-36 VT scores. Over 104 wks, clinically meaningful improvements were maintained. APR demonstrated an acceptable safety profile and was generally well tolerated up to 104 wks.

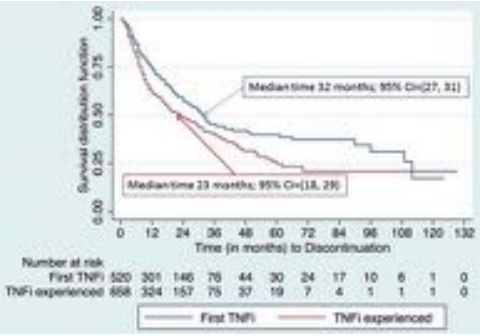
## THU0433 PERSISTENCY WITH TNFI IN BIOLOGIC EXPERIENCED VERSUS BIOLOGIC NATIVE PSA PATIENTS ENROLLED IN CORRONA REGISTRY

C.J. Etzel[1,2], B. Stolshek[3], S. Rebello[4], D. Collier[3], A. Mutebi[3], S.W. Wade[5], W. Malley[1], J.D. Greenberg[6,7], L.R. Harrold[6,8]. *[1]Biostatistics, Corrona, LLC, Southborough, MA; [2]Epidemiology, UT MD Anderson, Houston, TX; [3]Amgen, Inc., Thousand Oaks, CA; [4]Epidemiology, Corrona, LLC, Southborough, MA; [5]Wade Outcomes Research Consulting, Salt Lake City, UT; [6]Corrona, LLC, Southborough, MA; [7]NYU School of Medicine, New York, NY; [8]Medicine, UMass Medical School, Worcester, MA, United States*



**Background:** Little is known about the long-term use of TNFi for the management of PsA in routine clinical practice in the US.

**Objectives:** To assess overall persistence with TNFi and evaluate differences based on patients' prior use or non-use of TNFi in the US Corrona registry.

**Methods:** We identified all PsA initiators of a TNFi (adalimumab, etanercept, infliximab, golimumab) with at least 1 follow-up visit from October 2002 to December 2014. Patients were followed until the earliest of: discontinuation of the TNFi, initiation of another biologic or small molecule therapy or last follow-up

visit. Patient characteristics (demographic and clinical characteristics) at the index date (TNFi initiation) were evaluated. Kaplan-Meier curves were used to describe time to discontinuation, with censoring for all patients with a ≥1year gap between office visits. The log rank test was used to assess for differences in persistence (defined as remained on index TNFi) based on prior TNFi use.

**Results:** A total of 1241 patients initiated a TNFi during the study period, with mean (standard deviation [SD]) age and disease duration of 50.7 (12.1) years and 8.3 (8.5) years, respectively. The mean (SD) swollen and tender joint counts were 3.3 (4.8) and 4.7 (6.4). Forty-four percent of patients (n=549) were TNFi-naïve at initiation. Overall, 46% of patients (n=572) discontinued TNFi during follow-up with 83.2%, 66.9%, 52.4%, 40.6% and 36.1% of patients persistent at 6, 12, 24, 36 and 48 months respectively; median time to discontinuation was 27 months (95% CI: 24, 31). Based on the log rank test, persistence was greater in patients on their first TNFi –than in patients with prior TNFi use (Figure).

**Conclusions:** Over half of all PsA patients included in this study were persistent to TNFi at 24 months post-initiation. TNFi-naïve patients had greater persistence compared to TNFi–experienced patients.

## THU0434 SERIOUS INFECTIONS IN PSORIASIS PATIENTS WITH PSORIATIC ARTHRITIS IN THE PSORIASIS LONGITUDINAL ASSESSMENT AND REGISTRY STUDY

C. Ritchlin[1], A. Gottlieb[2], A. Menter[3], P. Mease[4], S. Kalia[5], F. Kerdel[6], S. Kafka[7], J. Morgan[7], W. Langholff[8], S. Fakharzadeh[7], K. Goyal[7]. *[1]U of Rochester, Rochester; [2]Tufts Med Ctr/Tufts Sch of Med, Boston; [3]Baylor U Med Ctr, Dallas; [4]Swedish Med Ctr; U of Washington, Seattle, United States; [5]U of British Columbia, Vancouver, Canada; [6]Florida Academic Derm Ctrs, Miami; [7]Janssen Scientific Affairs, LLC; [8]Janssen R & D, LLC, Horsham, United States*

**Objectives:** To describe the rates of serious infections (SI) in psoriasis (PsO) patients with psoriatic arthritis (PsA) from PSOLAR.

**Methods:** PSOLAR is an international, disease-based, observational study in which patients eligible for, or receiving conventional systemic & biologic agents for the treatment of PsO are followed prospectively. The characteristics & cumulative incidence rates of SIs occurring within 91 days of biologic administration, for patients who reported PsA,including a subset with PsA confirmed by a joint-specialist are summarized. Cohorts were defined as & attribution was based on treatment exposure in the following order (regardless of sequence & duration): (1) ustekinumab (UST) (2) other sponsor biologic (primarily infliximab [IFX]) (3) non-sponsor biologic (primarily adalimumab/etanercept [ADA/ETN]), & (4) non-biologic therapies (NB) (including immunodulators [eg MTX, cyclosporine], phototherapy, & topical therapy). Exposure to any therapy higher in the order precluded inclusion in the lower cohorts. Multivariate analyses using Cox hazard regression were used to identify predictors of time to first SI (using exposure within 91 days for biologics [compared to no biologic use] & for immunomodulators [compared to no immunomodulator use]).

**Results:** As of Aug 23, 2014, PSOLAR was fully enrolled with 12093 patients (40388 total patient-years [PY] of follow-up).Number of patients with reported PsA was overall 4316: 1489 UST, 776 IFX, 1680 ADA/ETN, 371 NB; of these patients, 1719 had confirmed PsA (664 UST, 356 IFX, 576 ADA/ETN, 123 NB). Baseline demographics & medical history were generally balanced across cohorts & were comparable to confirmed PsA subset; however, in overall PsA sub-group, more patients in NB cohort were ≥65yrs of age (UST 9.9%, IFX 13.9%, ADA/ETN 12.5%, NB 25.6%)& had a medical history of cancer (UST 3.3%, IFX 3.5%, ADA/ETN 3.9%, NB 8.4%).In the overall PsA subgroup (15 029 PY of follow-up), rates of SIs/100 PY were: UST 1.12, IFX 3.36, ADA/ETN 2.49, and NB 2.20. Among the confirmed PsA subset, rates/100 PY were: UST 1.06, IFX 2.83, ADA/ETN 2.58, NB 1.63. In the overall PsA sub-group, increasing age, male gender, current/prior smoking, history of significant infection, diabetes, & use of biologics (other than UST as a combined group) were associated with increased risk for SI; no increased risk was observed with UST & immunomodulators. In patients with confirmed PsA, diabetes, history of significant infection, more severe skin PsO, & use of biologics other than UST (as a combined group) were significantly associated with increased infection risk; UST & immunomodulators were not associated.

Inherent bias with respect to observational data may apply. Variability in size & clinical features was noted among treatment groups.Incidence rates are not adjusted for differences. Individual biologics beyond UST were not evaluated individually in statistical analyses.

**Conclusions:** Results suggest a higher risk of SIs with biologics (as a combined group), other than UST, in comparison with no biologic usage; increased risk was not observed with UST or immunomodulators.

## THU0435 DAS-28 REMISSION AND IMPROVEMENTS IN SKIN DISEASE OVER 3 YEARS OF TREATMENT WITH APREMILAST: RESULTS FROM THE PALACE 3 STUDY IN DMARD/BIOLOGIC-EXPERIENCED ACTIVE PSA PATIENTS

C.J. Edwards[1], F.J. Blanco[2], J. Crowley[3], M. McIlraith[4], K. Shah[4], L. Teng[4], C.A. Birbara[5]. *[1]University Hospital Southampton, Southampton, United Kingdom; [2]NIBIC-Hospital Universitario A Coruña, Galicia, Spain; [3]Bakersfield Dermatology, Bakersfield; [4]Celgene Corporation, Summit; [5]University of Massachusetts Medical School, Worcester, United States*

**Background:** Treatment goals for active psoriatic arthritis (PsA) include long-term control of both skin and joint symptoms. Achievement of remission in 28-joint count Disease Activity Score (DAS-28) using C-reactive protein (CRP), clinically important changes in DAS-28 (CRP), reduction in swollen joint count (SJC), or decrease in skin disease may be used as goals of treatment.[1] PALACE 3 (NCT01212770) included PsA patients with active joint disease with an active skin lesion at the time of enrollment.

**Objectives:** Assess long-term treatment responses across PsA manifestations in patients treated with apremilast (APR) for 3 years.

**Methods:** Patients were stratified by baseline DMARD use (yes/no) and psoriasis involvement of the body surface area (<3%/≥3%) and randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). After a PBO-controlled phase of 24 wks, all patients were treated with APR30 or APR20 and could enroll in long-term follow-up. Efficacy assessments in years 2 and 3 were conducted at Wks 65, 78, 91, 104, 117, 130, 143, and 156.

**Results:** 505 patients were randomized and received ≥1 dose of study medication (PBO: n=169; APR30: n=167; APR20: n=169). A total of 89% (249/281) of patients starting the third year of APR therapy completed the Wk 156 visit. Patients treated with APR30 demonstrated sustained decreases in disease activity at Wk 156, as shown by mean decreases in DAS-28 (CRP) of –1.58; 79.1% achieved a good/moderate EULAR response and 41.0% achieved DAS-28

| | Outcomes at Wk 156 | |
|---|---|---|
| | APR30 n=140* | APR20 n=114* |
| DAS-28 (CRP), mean change | −1.58 | −1.54 |
| DAS-28 (CRP) <2.6, n/m (%) | 57/139 (41.0) | 51/113 (45.1) |
| SJC, mean % change | −78.3 | −76.4 |
| TJC, mean % change | −65.0 | −65.3 |
| HAQ-DI (0-3), mean change | −0.39 | −0.41 |
| HAQ-DI MCID, ≥0.30, n/m (%) | 65/140 (46.4) | 61/114 (53.5) |
| ACR20, n/m† (%) | 89/138 (64.5) | 72/112 (64.3) |
| ACR50, n/m† (%) | 56/137 (40.9) | 52/113 (46.0) |
| ACR70, n/m† (%) | 29/137 (21.2) | 26/113 (23.0) |
| PASI-75, n/m (%)‡ | 33/68 (48.5) | 22/58 (37.9) |
| PASI-50, n/m (%)‡ | 46/68 (67.6) | 34/58 (58.6) |

Data as observed. n/m=number of responders/number of patients with sufficient data for evaluation.
*The *n* reflects the number of patients treated with APR30 and APR20, regardless of when APR was started (baseline, Wk 16, or Wk 24), and who had data available at Wk 156; actual number of patients available for each end point may vary. †Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. ‡Examined among patients with psoriasis involvement of ≥3% of the body surface area at baseline and having data at Wk 156.

(CRP) remission. Sustained relief across PsA manifestations, including SJC, a marker of inflammation, was also demonstrated (Table); at Wk 156, APR30 resulted in a mean 78.3% decrease in SJC, 65.5% of patients had a swollen joint count of 0 or 1. Decreases in disability and maintenance of functionality were demonstrated by sustained decreases in HAQ-DI scores (Table). Continued effect on skin disease was shown by decreases in skin involvement, as measured by the PASI; 54.7% of APR30 patients had a baseline PASI >5 and 27.3% had a baseline PASI >10; at 156 wks, 64.7% had a PASI <3, and 83.8% had a PASI of ≤5. PASI-75 and PASI-50 also signified clinically significant relief (Table). No new safety concerns were identified after 156 wks of APR treatment. During Wks >104 to ≤156 of APR exposure, adverse events (AEs) occurring in ≥5% of patients were nasopharyngitis and urinary tract infection; most AEs were mild or moderate in severity. Serious AEs occurred in 7.8% of APR patients during Wks >104 to ≤156, similar to rates seen for the earlier study periods; few discontinuations due to AEs (2.1%) occurred over Wks >104 to ≤156.

**Conclusions:** Over 156 wks, among patients continuing in the study, APR demonstrated sustained and clinically important improvements in PsA signs/symptoms, including physical function and associated psoriasis. APR was generally well tolerated and continued to demonstrate an acceptable safety profile with long-term use.

## THU0436 A RETROSPECTIVE NON-INTERVENTIONAL MULTI-CENTRE STUDY EVALUATING TREATMENT REGIMENS USED IN PSORIATIC ARTHRITIS PATIENTS IN AUSTRALIA- THE PSA REAL STUDY

D. Nicholls[1], A. Nakayama[2], H. Griffiths[3], G. Littlejohn[4], P. Bird[5], L. Roberts[6], J. de Jager[7], J. Zochling[8], S. Richter[9], S. Louw[10], K. Tymms[11] on behalf of the OPAL Consortium. *[1]Coast Joint Care, Maroochydore; [2]Rheumatology Department, Canberra Hospital, Canberra; [3]Barwon Rheumatology Service, Geelong; [4]Monash Rheumatology, Clayton; [5]Combined Rheumatology Practice, Sydney; [6]Monash Medical Centre, Clayton; [7]Gold Coast Rheumatology, Southport; [8]Menzies Institute for Medical Research, Hobart; [9]Celgene Pty Ltd; [10]McCloud Consulting Group, Sydney; [11]Canberra Rheumatology, Canberra City, Australia*

**Background:** Psoriatic arthritis (PsA) is a spondyloarthritis spectrum disease with prominent involvement of skin and joints. The management of PsA patients is often complex and there is no uniformity across the medical profession. The majority of PsA studies have been prospective clinical trials involving a homogenous and restricted patient population. This may not reflect real clinical practice where patients have co-morbidities and other clinical characteristics that preclude them from participating in clinical trials.

**Objectives:** To provide a cross sectional analysis of disease activity and management of PsA patients in the Australian population.

**Methods:** This was a retrospective non-interventional multi-centre study using the Audit4 clinical audit program, with de-identified and routinely collected clinical data sourced from participating rheumatology practices in the OPAL consortium (Optimising Patient outcomes in Australian rheumatoLogy) across Australia during November 2015[1]. Data collected included baseline characteristics, prevalence and duration of cDMARD and bDMARD treatments, DAS28-CRP results, and reasons for stopping therapy.

**Results:** A total of 3422 clinician diagnosed PsA patients were included in this study: 60% were female, mean age 54 years (±14) and mean disease duration 10 years (±9). Of patients with a valid treatment record (n=2948), 46% were on cDMARD monotherapy, 19% on bDMARD monotherapy, 13% on combination bDMARD and cDMARD therapy, 11% on combination cDMARD therapy and 10% were on no DMARDs. Of those with DAS28 CRP results (n=494), the highest mean DAS 28 CRP was 3.32 (±1.57) on combination cDMARD therapy, and the lowest DAS 28 CRP was 2.19 (±0.89) on bDMARD monotherapy. The most common reasons for cessation of cDMARD monotherapy was adverse reactions (41%), for bDMARD monotherapy lack of efficacy (26%) and combination bDMARD and cDMARD therapy either completed treatment or drug no longer required (37%).

**Conclusions:** Cross sectional analysis of this large cohort managed in rheumatology clinical practice suggests most are receiving DMARD therapies with less disease activity on bDMARD monotherapy. Adverse reactions and lack of efficacy remain common reasons for cessation of cDMARD and bDMARD monotherapy in PsA.

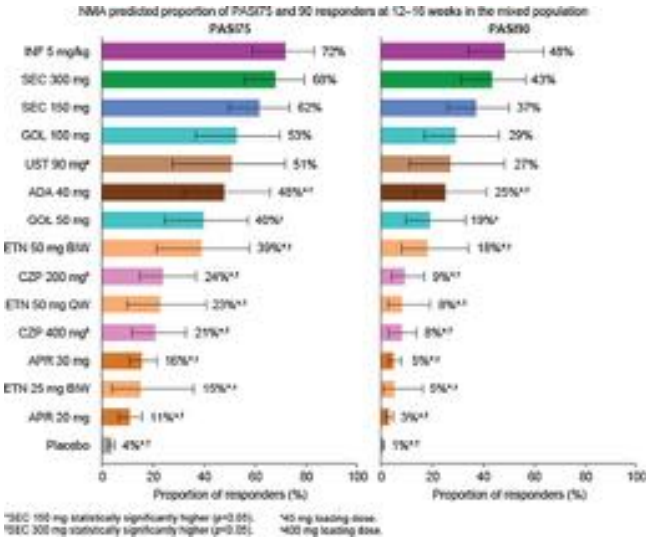
## THU0437 SECUKINUMAB FOR THE TREATMENT OF PSORIATIC ARTHRITIS: COMPARATIVE EFFECTIVENESS RESULTS VERSUS LICENSED BIOLOGICS AND APREMILAST FROM A NETWORK META-ANALYSIS

I.B. McInnes[1], P. Nash[2], C. Ritchlin[3], H. Thom[4], S. Kanters[5], E. Palaka[6], K. Gandhi[7], S. Mpofu[8], S. Jugl[8]. *[1]University of Glasgow, Glasgow, United Kingdom; [2]University of Queensland, Brisbane, Australia; [3]University of Rochester, New York, United States; [4]University of Bristol, Bristol, United Kingdom; [5]Redwood Outcomes, Vancouver BC, Canada; [6]Novartis Ireland Ltd, Dublin, Ireland; [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [8]Novartis Pharma AG, Basel, Switzerland*



**Background:** Secukinumab (SEC) is approved for the treatment of active PsA in adults who have responded inadequately to DMARD therapy. The FUTURE 1 and 2 RCTs which included biologic-naïve and biologic-experienced patients, demonstrated superiority of SEC 150 mg and 300 mg over placebo. As no direct trial comparisons are yet available there is a need for comparative effectiveness assessment.

**Objectives:** Comparative assessment of SEC via network meta-analysis (NMA) vs. licensed biologics and apremilast in adults with active PsA who had failed conventional DMARD therapy.

**Methods:** A systematic review of the literature (November 2015) identified 20 relevant RCTs. NMAs were conducted following health technology assessment guidance using Bayesian fixed-effects models. PASI and ACR responses and their credible intervals (CrIs), which can be interpreted similarly to CIs, were modelled using a conditional binomial likelihood NMA with probit link function. The results of pairwise comparisons are presented for SEC using relative risks (RRs) [95%CrI]. Non-responder imputation data were used for all comparators except golimumab QM (GOL) and infliximab 5 mg/kg Q2M (INF) for which only last observation carried forward data were available. Analyses were performed in biologic-naïve, biologic-experienced, and mixed populations at week 16 for ACR and at weeks 12–16 for PASI.

**Results:** At week 16 in the biologic-naïve population, ACR20 responses were statistically significantly higher for SEC 150 mg (61%) and 300 mg (58%) than for ustekinumab QM (UST) 45 mg (RR 1.95 [1.29–2.86] and RR 1.84 [1.21–2.74], respectively), and for SEC 150 mg vs UST 90 mg (RR 1.52 [1.03–2.16]). ACR20 responses were statistically significantly higher for SEC 150 and 300 mg vs. apremilast BID (APR) 20 mg (RR 2.51 [1.52–4.29] and RR 2.37 [1.39–4.12] respectively), and for SEC 150 mg vs. APR 30 mg (RR 1.72 [1.09–2.71]). Comparisons between SEC and anti-TNFs did not show statisticall significance. For ACR50 and 70, both SEC doses showed the same pattern of significance as for ACR20. Sensitivity analyses using the mixed population were in general agreement with these observations.

For PASI50, 75, and 90 at weeks 12–16 in the biologic-naïve population, only a small evidence network with SEC, GOL 50/100mg, adalimumab 40 mg (ADA) and INF was available and there were no statistically significant differences between SEC and these comparators. In the mixed population, SEC was statistically significantly superior to ADA, APR 20/30 mg, certolizumab pegol (CZP) 200/400 mg, etanercept (ETN) 25/50 mg BIW and 50 mg QW, and (SEC 300 mg only) GOL 50 mg.

**Conclusions:** SEC shows statistically significantly higher results vs. UST and APR in ACR20, 50 and 70, with at least comparable response rates across all ACR and PASI endpoints vs. all therapies included in this NMA. For PASI50, 75, and 90 responses, SEC had high response rates with statistically significant results vs. ADA, APR, CZP, ETN, and (SEC 300 mg only) GOL 50 mg.

## THU0438 ENTHESITIS IN PSORIATIC ARTHRITIS AND NEED FOR BIOLOGICAL THERAPY

M. Bascuas, J.L. Andreu, I. Millan, M. Cuadros, C. Ramos, M. Espinosa, B.J. Flores, J. Campos, J. Sanz. *Rheumatology, H.U. Puerta de Hierro Majadahonda, Majadahonda, Spain*

**Background:** Psoriatic arthritis (PsA) is a potentially destructive inflammatory chronic arthropathy, with a wide range of clinical manifestations. Currently, biological therapy (BT) is the second step of treatment after an inadequate response to conventional disease-modifying anti-inflammatory drugs.
**Objectives:** The goal of our study was to identify baseline characteristics of patients with PsA associated with the need for BT use during the follow-up.
**Methods:** This is a single-centre, case-control study. Unselected PsA patients diagnosed after December 31st, 1999 and fulfilling CASPAR classification criteria were included. Reviewing medical records identified epidemiological, clinical, analytical and imaging features. The main outcome was the need of BT during the follow-up. The local ethical committee authorized the study. Chi-square, Student t test, and Mann-Whitney U test were used to establish statistical significance in the univariate analysis. Logistic regression was used for the multivariate analysis. A $p<0.05$ was considered significant.
**Results:** One hundred and fifty-nine patients were included (75 women and 84 men), with a mean age of 48 years. During the follow-up, 66 patients (41%) needed BT (BT+ patients). No significant differences in age, sex, race, presence of cardiovascular risk factors, smoking, alcohol consumption, initial joint pattern, presence of dactylitis, presence of onychopathy, HLA B27 positivity, presence of radiographic erosions, presence of axial radiographic involvement, mean C-reactive protein, or mean erythrocyte sedimentation rate were found in BT+ patients when compared with BT negative (BT–) patients. Twenty per cent of BT– patients had enthesitis at the beginning, compared with 39% of BT+ patients [Odds ratio 2.53 (CI 95%: 1.25–5.12); p=0.009]. Mean time from the onset of symptoms to the first appointment with a rheumatologist was significantly associated with the need for further use of BT (20 weeks in BT– patients versus 108 weeks in BT+ patients; $p<0.001$). Multivariate analysis showed that the delay in rheumatology consultation and presence of enthesitis were independent factors significantly associated with the need for BT.
**Conclusions:** In PsA patients, the initial presence of enthesitis is an independent risk factor associated with the need for biological therapy during the follow-up.
**Disclosure of Interest:** None declared

## THU0439 52-WEEK EFFICACY AND SAFETY OF APREMILAST AND SWITCH FROM ETANERCEPT IN PATIENTS WITH MODERATE TO SEVERE PSORIASIS: RESULTS FROM THE LIBERATE STUDY

K. Reich[1], J. Soung[2], M. Gooderham[3], Z. Zhang[4], K. Nograles[4], R.M. Day[4], L. Ferris[5], M. Goodfield[6]. *[1]SCIderm Research Institute and Dermatologikum Hamburg, Hamburg, Germany; [2]Southern California Dermatology, Santa Ana, United States; [3]Skin Centre for Dermatology and Probity Medical Research, Peterborough, Canada; [4]Celgene Corporation, Summit; [5]University of Pittsburgh, Pittsburgh, United States; [6]Leeds General Infirmary, Leeds, United Kingdom*

**Background:** Psoriasis is a chronic systemic inflammatory disease often treated with conventional systemic and biologic drugs that may variously be ineffective, inaccessible, or pose significant safety and tolerability risks.
**Objectives:** The phase IIIb LIBERATE (Evaluation in a Placebo-Controlled Study of Oral Apremilast and Etanercept in Plaque Psoriasis) study (NCT01690299) evaluated the efficacy and safety of apremilast or etanercept vs. placebo in biologic-naive patients (pts) with moderate to severe plaque psoriasis.
**Methods:** In this double-blind, double-dummy study, pts were randomized (1:1:1) to placebo (PBO), apremilast 30 mg BID (APR), or etanercept 50 mg QW (ETN) through Wk16; thereafter, all pts switched to or continued APR (PBO/APR, ETN/APR, APR/APR). The primary endpoint was achievement of a ≥75% reduction from baseline in Psoriasis Area and Severity Index (PASI) score (PASI-75) at Wk16 with APR vs. PBO; secondary endpoint was PASI-75 achievement at Wk16 with ETN vs. PBO. Additional physician global assessments (PGA) of disease activity were conducted using the static (sPGA), lattice system (LS-PGA), and scalp (ScPGA) instruments; nail disease was also evaluated (Nail Psoriasis Severity Index [NAPSI]). Responses were assessed at Wks16 and 52 using the last-observation-carried-forward (LOCF) methodology.
**Results:** 250 pts received ≥1 dose of study drug, had both baseline PASI and ≥1 post-treatment PASI evaluations, and were included in the analysis set (PBO n=84; APR n=83; ETN n=83). At baseline, 166 (66.4%; PBO n=58; APR n=54; ETN n=54) pts had an ScPGA score ≥3 (moderate to very severe) and 148 (59.2%; PBO n=46; APR n=52; ETN n=50) had a NAPSI score ≥1. At Wk16, PASI-75 achievement was significantly greater ($P<0.0001$) with APR (39.8%) or ETN (48.2%) vs. PBO (11.9%). Although this study was not designed/powered for APR vs. ETN comparisons, Wk16 PASI-75 achievement was not significantly different between APR and ETN ($P=0.2565$, post hoc). At Wk16, APR and ETN produced significantly greater achievement of 0 or 1 ratings (clear or almost clear) vs. PBO in sPGA and LS-PGA and in ScPGA (clear or minimal) (Table). Improvements in nail psoriasis were also achieved with APR and ETN at Wk16 (Table). At Wk52, PASI-75 response was sustained in APR/APR (50.6%) and ETN/APR (55.4%) pts; PASI-75 response was 46.4% in PBO/APR pts (Table). sPGA, LS-PGA, and ScPGA responses achieved at Wk16 were generally sustained through Wk52 with APR (Table). Continued APR treatment over 52wks resulted in further improvements in nail psoriasis (Table). Adverse events were consistent with known safety profiles of APR and ETN.

**LIBERATE Efficacy Outcomes**

| Pts Achieving Response, % (LOCF) | PBO n=84 | APR n=83 | ETN n=83 |
|---|---|---|---|
| **Wk16** | | | |
| PASI-75 | 11.9 | 39.8* | 48.2* |
| sPGA 0 or 1[‡] | 3.6 | 21.7* | 28.9* |

## THU0440 IXEKIZUMAB PROVIDES SUSTAINED IMPROVEMENT UP TO 52 WEEKS OF DISEASE ACTIVITY AS ASSESSED BY COMPOSITE MEASURE SCORES IN BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG (BDMARD)-NAIVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

L.C. Coates[1], M.E. Husni[2], C.L. Shuler[3], H. Carlier[3], C.-Y. Lin[3], J. Mou[3], C.H. Lee[3], P.J. Mease[4]. *[1]University of Leeds, Leeds, United Kingdom; [2]Cleveland Clinic, Cleveland; [3]Eli Lilly and Company, Indianapolis; [4]Swedish Medical Center, and University of Washington, Seattle, United States*

**Background:** Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory

disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. PsA can be progressive and destructive, resulting in physical deformities, impaired function, decreased quality of life, and increased mortality. Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. Results are presented from a phase 3 trial (SPIRIT-P1; NCT01695239) with IXE in patients with active PsA.

**Objectives:** To explore the impact of IXE, as assessed by disease activity composite measures, up to 52 weeks (wks).

**Methods:** A total of 417 bDMARD-naive adult patients with active PSA, were randomly assigned 1:1:1:1 to subcutaneous administration of either 80-mg IXE every 4 wks (Q4W) or every 2 wks (Q2W), each with a 160-mg starting dose at Wk 0; adalimumab (ADA) 40 mg Q2W (active comparator); or placebo (PBO) in the Double-Blind Treatment Period (DBTP; Wks 0 through 24). Of these patients, 381 continued into the Extension Period (EP; Wks 24 through 52). PBO- and ADA-treated patients were randomly re-assigned (1:1) to 80 mg IXEQ4W or IXEQ2W at Wk 16 (inadequate responders) or Wk 24; ADA-treated patients started IXE, after an 8-wk wash-out period, at Wk 24 (inadequate responders) or Wk 32. Investigators were blinded as to the criteria for inadequate response. Disease activity was measured at Wks 24 and 52 by composite measures including the following: minimum disease activity (MDA) as measured with the Psoriasis Area and Severity Index ($MDA_{PASI}$) and with the static Physician Global Assessment of psoriasis ($MDA_{sPGA}$), and modified Composite Psoriatic Disease Activity Indices (CPDAI-12 and CPDAI-14 [see Table 1 footnote]). Analyses for the DBTP were conducted on the Intent-to-Treat Population, defined as all randomly assigned patients; analyses for the EP were conducted on the EP Population, defined as all patients who received at least 1 dose of study drug during the EP. In the DBTP, treatment comparisons were made by a logistic regression model for categorical data with missing values imputed by nonresponder imputation; a mixed model for repeated measures analysis was used for continuous data.

**Results:** At Wk 24, CPDAI-12 and CPDAI-14 total scores (assesses domains of peripheral arthritis, skin disease, enthesitis, dactylitis [and spinal disease for CPDAI-14 only]) for patients receiving IXEQ4W, IXEQ2W, or ADA, were significantly improved compared with results for patients receiving PBO (Table 1). Similarly, at Wk 24, significantly more patients receiving IXEQ4W, IXEQ2W, or ADA achieved $MDA_{sPGA}$ and $MDA_{PASI}$ compared with patients receiving PBO (Table 1), and percentages of patients receiving IXEQ4W or IXEQ2W who achieved $MDA_{sPGA}$ and $MDA_{PASI}$ were sustained through Wk 52 (Table 2). Results for $MDA_{sPGA}$ were similar to results for $MDA_{PASI}$ within each treatment group.

## THU0441 EFFECT OF CONCOMITANT CONVENTIONAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (CDMARDS) ON THE EFFICACY AND SAFETY OF IXEKIZUMAB IN BIOLOGIC DMARD-NAIVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

L.C. Coates[1], A.B. Gottlieb[2], C.L. Shuler[3], C.-Y. Lin[3], S. Samanta[3], S.R. Moriarty[3], C.H. Lee[3], P.J. Mease[4]. *[1]University of Leeds, Leeds, United Kingdom; [2]Tufts Medical Center, Boston; [3]Eli Lilly and Company, Indianapolis; [4]Swedish Medical Center and University of Washington, Seattle, United States*

**Background:** Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. Results are presented for the phase 3 trial (SPIRIT-P1) with IXE treatment of patients with active PsA.

**Objectives:** To evaluate the efficacy and safety of IXE when used alone or in combination with concomitant conventional DMARDs (cDMARDs).

**Methods:** A total of 417 bDMARD-naive adult patients were randomly assigned 1:1:1:1 to subcutaneous administration of 80-mg IXE every 4 wks (Q4W) or every 2 wks (Q2W), each starting with a 160-mg dose at Wk 0; adalimumab (ADA) 40 mg Q2W (active comparator); or placebo (PBO) during the Double-Blind Treatment Period (DBTP; Wks 0 through 24). Of these patients, 267 were receiving a concomitant cDMARD at baseline, 149 were not, and 1 did not receive study drug; patients were stratified by cDMARD use, and were to remain on their cDMARD through the DBTP. At Wk 24, efficacy was evaluated by American College of Rheumatology (ACR) response; and progression of structural damage was assessed by the modified Total Sharp Score (mTSS). Safety assessments included the percentage of patients experiencing treatment-emergent adverse events (TEAEs), serious adverse events (SAEs), and discontinuations due to adverse events (AEs). Efficacy analyses were conducted on the Intent-to-Treat Population, defined as all randomly assigned patients; safety analyses were conducted on the Safety Population, defined as all randomly assigned patients who received at least 1 dose of study drug. Fisher's test was used for treatment comparisons in ACR and AE data, and an analysis of covariance model was used for mTSS data. Missing values were imputed by nonresponder imputation for ACR data and by linear extrapolation for mTSS data.

**Results:** At Wk 24, compared with patients receiving PBO, significantly more patients receiving IXEQ4W or IXEQ2W (with/without concomitant cDMARD) achieved ACR20/50/70 responses (see Table for ADA results). Patients receiving IXEQ2W (with/without concomitant cDMARD) or IXEQ4W or ADA (with concomitant cDMARD) showed significantly less progression in mTSS from baseline compared with patients receiving PBO (Table). No treatment-by-subgroup effects were observed for ACR20/50/70 or mTSS (Table footnotes). In patients receiving concomitant cDMARDs, significantly more patients receiving IXE or ADA experienced ≥1 TEAE, compared with patients receiving PBO; the percentages of patients with SAEs or discontinuations due to an AE were comparable among treatment groups (Table).

**Table: Effect of Concurrent Use of Conventional DMARDs on Efficacy and Safety of Ixekizumab**

| Baseline use of cDMARD? | Placebo N=106 Yes n=69 | Placebo N=106 No n=37 | ADA/Q2W N=101 Yes n=67 | ADA/Q2W N=101 No n=34 | IXEQ4W N=107 Yes n=68 | IXEQ4W N=107 No n=39 | IXEQ2W N=103 Yes n=63 | IXEQ2W N=103 No n=40 |

Abbreviations: ACR=American College of Rheumatology; ACR20=at least 20% improvement in ACR assessments from baseline; ACR50=at least 50% improvement in ACR assessments from baseline; ACR70=at least 70% improvement in ACR assessments from baseline; ADA=adalimumab; AE=adverse events; ANCOVA=analysis of covariance; cDMARD=conventional disease-modifying antirheumatic drug; IXE=ixekizumab; LSM=least squares mean; N,n=number of patients; NRI = nonresponder imputation; mTSS=modified Total Sharp Score; SAEs=serious adverse events; SE=standard error; TEAEs=treatment-emergent adverse events.

* Treatment-by-subgroup interaction p-values are .321 (ACR20), .454 (ACR50), and NA (ACR70, because 0 PBO patients without cDMARD achieved ACR70). Treatment-by-subgroup interaction p-values are based on a logistic regression model with effect of treatment, subgroup, and the treatment-by-subgroup interaction, and are tested at the significance level of 0.10.

† Treatment-by-subgroup interaction p-value is .727. Treatment-by-subgroup interaction p-value is from an ANCOVA model with treatment, baseline score, subgroup, and interaction of treatment by subgroup included as factors.

‡ Patients with ≥1 event.

§ Statistical analyses presented are for the baseline use of cDMARD – "yes" or "no" subgroup within each treatment group, and the respective baseline use of cDMARD – "yes" or "no" subgroup within the placebo group.

* p< .05; ** p≤.01; *** p≤.001; p-values for ACR20/50/70 and AEs are based on Fisher's exact test; p-values for mTSS are from an ANCOVA model with treatment and baseline scores.

**Conclusions:** IXE demonstrated efficacy in improvement of PsA signs and

symptoms and structural inhibition in bDMARD-naive patients with/without concomitant cDMARD use. With concomitant cDMARD use, although significantly more patients receiving IXE or ADA experienced ≥1 TEAE, compared with patients receiving PBO, the frequency of SAEs and discontinuations due to an AE were comparable among all treatment groups.

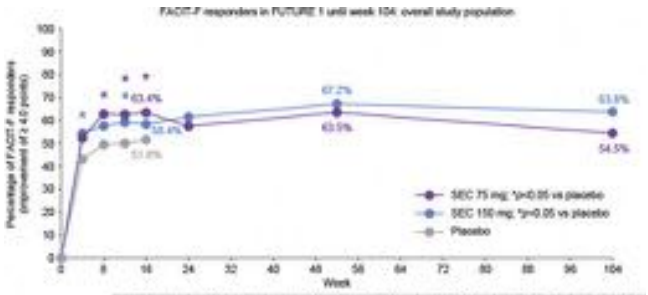
## THU0442 REDUCTION IN FATIGUE IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS ARE SUSTAINED OVER 2 YEARS: LONG-TERM RESULTS OF TWO PHASE 3 STUDIES WITH SECUKINUMAB



L. Gossec[1], T.K. Kvien[2], P.G. Conaghan[3], M. Østergaard[4], J. Cañete[5], C. Gaillez[6], S. Mpofu[6], E. Davenport[7], S. Jugl[6]. *[1]Paris 06 University, Paris, France; [2]Diakonhjemmet Hospital, Oslo, Norway; [3]University of Leeds, Leeds, United Kingdom; [4]Copenhagen Center for Arthritis Research (COPECARE), Rigshospitalet, Denmark; [5]Hospital Clinic de Barcelona e IDIBAPS, Barcelona, Spain; [6]Novartis Pharma AG, Basel, Switzerland; [7]RTI Health Solutions, Durham, NC, United States*

**Background:** Fatigue is an important symptom associated with active psoriatic arthritis (PsA) and can impact on health-related quality of life (HRQoL) and social functioning. Secukinumab (SEC) has resulted in rapid improvements in signs and symptoms, physical functioning and HRQoL in patients with active PsA vs placebo (PBO) in the FUTURE 1 (F1) and FUTURE 2 (F2) studies. Rapid improvements in fatigue were reported in F2.

**Objectives:** To assess 1- and 2-year data on the effects of SEC on fatigue in patients with PsA, including both biologic-naïve patients and those with an inadequate response to TNF therapy (TNF-IR) and to investigate correlations between fatigue and baseline characteristics or clinical endpoints.

**Methods:** Patients with active PsA (F1, N=606; F2, N=397) received SEC or PBO every 4 weeks. Patients receiving PBO who did not meet predefined response criteria at week 16 were re-randomized at week 24 to active treatment. Fatigue was assessed at baseline and weeks 4, 8, 12, 16, 24, 52 and 104 using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale. A change in FACIT-F score of ≥4 from baseline was used to define fatigue response. Logistic regression was used to explore the relationship between fatigue response (weeks 16 and 52) and baseline characteristics and clinical response criteria. The FACIT-F response analyses were based on observed data with no imputation; the FACIT-F score analyses used mixed-effect model repeated measure imputation.

**Results:** Improvements in fatigue compared with PBO were observed for all SEC doses in from week 4 onwards. A fatigue response at week 16 was achieved by 58.4% (F1) and 70.0% (F2) of patients receiving SEC 150 mg, compared with 51.6% (F1) and 43.2% (F2) of those receiving PBO (see figure for F1 data). For SEC 300 mg, a 16 week response was achieved by 50.5% (F2). Responses were sustained at week 52 for 150 mg (F1, 67.2%; F2, 68.5%) and 300 mg (F2, 60.2%) and at week 104 for 150 mg (F1, 63.8%). Sustained responses were also seen in both biologic-naïve (F1, n=425; F2, n=258) and TNF-IR patients (F1, n=181; F2, n=104). Logistic regression analyses of pooled data from F1 and F2 found age and baseline HAQ-DI scores were associated with fatigue response (weeks 16 and 52). Achieving a fatigue response was moderately to strongly correlated with clinical response criteria (including ACR, HAQ-DI and PASI scores at weeks 16 and 52).

| | Week 4 | Week 8 | Week 12 | Week 16 | Week 24 | Week 52 | Week 104 |
|---|---|---|---|---|---|---|---|
| SEC 75 mg, n/m | 99/189 | 120/191 | 119/190 | 123/194 | 111/193 | 113/178 | 79/143 |
| SEC 150 mg, n/m | 105/193 | 110/191 | 113/191 | 111/190 | 116/192 | 123/183 | 97/152 |
| Placebo, n/m | 65/197 | 96/194 | 91/192 | 97/188 | .. | .. | .. |

n, number of patients with sufficient data for evaluation; m, number of responders.

**Conclusions:** SEC provided rapid and sustained improvements in fatigue for up to 104 weeks in patients with active PsA, regardless of prior biologic exposure. Achieving a fatigue response was moderately to strongly correlated with improvement in clinical response criteria, indicating a relationship between fatigue and PsA disease activity. SEC-induced sustained improvements in fatigue may be important for improving HRQoL in patients with PsA. Analysis of factors predictive of fatigue response may help to clarify the drivers of fatigue; this study highlights the importance of age and physical functioning.

## THU0443 UNMET NEEDS IN PSORIATIC ARTHRITIS: ONE THIRD OF THE PATIENTS WITH QUIESCENT DISEASE ACCORDING TO THE RHEUMATOLOGIST'S OPINION DO NOT ACHIEVE MINIMAL DISEASE ACTIVITY

L.J. Van Mens[1], A.W. van Kuijk[2], D.L. Baeten[1]. *[1]Amsterdam Rheumatology and Immunology Center, AMC; [2]Amsterdam Rheumatology and Immunology Center, Reade, Amsterdam, Netherlands*

**Background:** Several new drugs, including ustekinumab, apremilast, and secukinumab, became available for the treatment of psoriatic arthritis (PsA) over the last years, broadening our possibilities to treat the disease effectively. The new therapeutic modalities open a new perspective for patients not responding to conventional DMARDs and TNF inhibitors (TNFi). As achieving the lowest possible level of disease activity in all domains of disease is associated with better long-term outcomes, the new therapeutic modalities may potentially also benefit patients with partial but not full disease control with cDMARDs and/or TNFi.[1] Therefore, defining an acceptable disease state in routine clinical practice is becoming increasingly important to identify who could potentially benefit from treatment adjustment.

**Objectives:** The aim of the study was to assess how many patients with quiescent disease according to the treating rheumatologist have an acceptable disease state defined as minimal disease activity.

**Methods:** This cross-sectional study was performed in 2 rheumatology outpatient clinics and included a total of 250 PsA patients between Feb 2013 and June 2015. Key inclusion criteria were fulfillment of the CASPAR criteria and quiescent disease in the opinion of the treating rheumatologists, defined by the fact that the rheumatologist did not consider to modify the current treatment. Patients were systematically evaluated by an independent research physician for current disease activity including clinical assessments and patient reported outcomes (PRO). Minimal disease activity (MDA) was defined as the fulfillment of ≥5 of the following: TJC68≤1, SJC68≤1, PASI≤1, VASpain≤15mm, VASptglobal≤20mm, HAQ≤0.5, tender entheseal points≤1.

**Results:** One third (88/250) of the PsA patients with quiescent disease according

Table 1

| | All pts | MDA+ | MDA- | p-value (<0.05 = sign.) |
|---|---|---|---|---|
| N | 250 | 162 | 88 | |
| Patient characteristics mean (SD) | | | | |
| Age | 55 (11) | 53 (12) | 59 (10) | 0.000 |
| Gender (%♀) | 33% | 50% | 26% | 0.002 |
| Age at arthritis onset | 43 (12) | 41 (12) | 45 (11) | 0.021 |
| PRO scores median (IQR) | | | | |
| HAQ | 0.25 (0–0.63) | 0.0 (0–0.38) | 0.75 (0.5–1.38) | 0.000 |
| DLQI | 1 (0–3) | 0 (0–1) | 2 (0–5) | 0.000 |
| SF-36 PCS | 46 (39–54) | 51 (46–54) | 38 (31–43) | 0.000 |
| VAS pt global (mm) | 10 (3–29) | 6 (1–11) | 37 (23–56) | 0.000 |
| WPAI (daily activities) | 1 (0–4) | 1 (0–2) | 4 (2–7) | 0.000 |
| Laboratory median (IQR) | | | | |
| ESR (mm/hr) | 6 (4–11) | 5 (3–9) | 8 (5–16) | 0.000 |

to the treating rheumatologist did not fulfill MDA criteria (MDA-). A high TJC, VASpain and VASptglobal were the items most frequently contributing to the failure to achieve MDA (not achieved in 83%, 82% and 80%). However, also objective signs of disease activity were higher in MDA- vs MDA+ patients: a SJC>1 occurred in 35% vs 7% (p=0.000), enthesitis>1 in 14% vs 3% (p=0.002), and PASI>1 in 43% vs 26% (p=0.002). There was no difference in treatment use (including cDMARD and TNFi) between MDA- and MDA+. See table 1 for additional patient characteristics.

**Conclusions:** One third of the PsA patients with quiescent disease according to the treating rheumatologist do not achieve the MDA criteria. These patients have higher disease activity both on subjective and objective disease activity measurements. As this is associated with worse PROs, further research should evaluate if treatment adjustments may be beneficial for this patient group with residual disease activity.

## THU0444 SUBCLINICAL ULTRASONOGRAPHIC ENTHESITIS IN PATIENTS WITH PSORIASIS IS ASSOCIATED WITH RISK MARKERS FOR PSORIATIC ARTHRITIS

L. Eder[1], A. Polachek[2], C.F. Rosen[3], V. Chandran[2], D.D. Gladman[2]. *[1]Women's College Research Institute, Women's College Hospital; [2]Rheumatology, Toronto Western Hospital; [3]Dermatology, University Health Network, Toronto, Canada*

**Background:** Enthesitis is considered a primary feature of psoriatic arthritis (PsA). PsA has a period of pre-clinical disease in which enthesitis can be detected in patients with psoriasis only by sensitive imaging modalities such as ultrasound. In this study we consider the presence of subclinical enthesitis detected by ultrasound in psoriasis patients as a proxy for PsA-risk.

**Objectives:** We aimed to estimate the prevalence of subclinical enthesitis in patients with psoriasis without clinical arthritis and to assess their relation with known risk markers for PsA.

**Methods:** 178 patients with a diagnosis of psoriasis confirmed by a dermatologist were enrolled. Patients with clinical signs suggestive of PsA were excluded. Information about demographics, co-morbid conditions and psoriasis phenotype was recorded. Musculoskeletal ultrasound assessment of 12 entheseal sites was performed according to a standard protocol. Enthesis thickness, structure, calcification/bone proliferation, erosion, bursa and power Doppler signal in the cortical bone profile, tendon and bursa were scored according to the MAdrid Sonographic Enthesitis Index (MASEI). A cut-off of ≥20 was used to define "subclinical enthesitis". The association between the presence of subclinical enthesitis and patients' characteristics was assessed using logistic regression analysis adjusting for age.

**Results:** A total of 19 of 178 patients (10.7%) were found to have subclinical enthesitis on ultrasound (MASEI≥20). The most frequently affected sites were the attachments of the distal patellar tendon (46.7%), Achilles tendon (44.1%) and plantar fascia (38%). 37 patients (20.8%) had one or more entheseal sites with positive power Doppler signal. Patients with subclinical enthesitis were more likely to be older (p=0.002), obese (p=0.01), diabetic (p=0.005), have nail pitting (p=0.006) and work in physically demanding occupations (p=0.01). Moreover, patients with subclinical enthesitis were more likely to report morning stiffness (p=0.008); however, no association was found with other musculoskeletal symptoms or patient reported outcomes estimating the degree of pain, function, fatigue and quality of life. On multivariate analysis the presence of ultrasonographic enthesitis was associated with obesity (Odds Ratio (OR) 14.3, 95% Confidence Interval (CI) 1.7, 118, p=0.01), current smoking (OR 5.1, 95% CI 1.3, 19.4, p=0.02), physically-demanding occupation (OR 4.3, 95% CI 1.3, 13.8, p=0.01), diabetes mellitus (OR 5.5, 95% CI, 1.1, 28.1, p=0.04) and psoriatic nail pitting (OR 4.3, 95% CI 1.5, 11.9, p=0.006).

**Conclusions:** The presence of subclinical enthesitis is associated with known risk markers of PsA including: nail pitting, obesity and occupation-related mechanical stress. These findings reinforce the use of ultrasound for investigation of pre-clinical PsA in patients with psoriasis.

**Disclosure of Interest:** None declared

## THU0445 VALIDATION OF THE CONTEST QUESTIONNAIRES TO SCREEN FOR PSORIATIC ARTHRITIS IN PRIMARY CARE PSORIASIS PATIENTS

M.C. Karreman[1,2], A.E. Weel[1,2], M. van der Ven[2], M. Vis[2], I. Tchetverikov[3], M. Wakkee[4], T.E. Nijsten[4], J.M. Hazes[2], J.J. Luime[2]. *[1]Rheumatology, Maasstad Hospital; [2]Rheumatology, Erasmus University Hospital, Rotterdam; [3]Rheumatology, Albert Schweitzer Hospital, Dordrecht; [4]Dermatology, Erasmus University Hospital, Rotterdam, Netherlands*

**Background:** Various screening tools have been developed and validated over the years in order to enhance early recognition of psoriatic arthritis (PsA) among psoriasis patients, but their performance remains suboptimal. In 2014 the CONTEST-group developed a new screening tool consisting of the most discriminating questions from 3 existing tools (PEST, PASE, TOPAS) which was externally validated in 2 psoriasis cohorts from dermatology. Validation in a primary care setting has yet to be performed.

**Objectives:** To externally validate the CONTEST questionnaire in psoriasis patients in primary care.

**Methods:** Data from the SENSOR study was used, a cross-sectional study in adult psoriasis patients with regular spells of musculoskeletal complaints from primary care. In this study, patients completed the PEST and PASE screening-questionnaires before clinical evaluation. Within CONTEST 3 TOPAS questions are used that were not included in our study. These questions were therefore replaced by similar questions: ToPAS 2A was replaced by PEST 3, ToPAS 2B by nail assessment by a dermatologist and ToPAS 7 by data from the manikin in the PEST. We calculated sensitivity, specificity and area under the curve (AUC) for the CONTEST with a cutoff of 4, as well as the CONTEST-w (weighted version, cutoff of 8) and the CONTEST-jt (including the PEST manikin, cutoff of 5). Performance was also calculated selecting the patients in the same way as the CONTEST study, i.e. only inviting patients with a positive PEST and/or PASE questionnaire for clinical evaluation. As a reference standard we used a clinical diagnosis of PsA made by a rheumatologist and enthesitis confirmed by ultrasound (presence of Power Doppler). Results from our dataset were compared with data from the development cohort and with the performance of the PEST.

**Results:** For this analysis 473 psoriasis patients at risk for PsA were available. Compared with the development cohort sensitivity was considerably lower in our dataset (0.30–0.51) than in the development of the CONTEST (0.86). Specificity was higher in our dataset (0.75–0.87) compared with the CONTEST development (0.35–0.48). While AUCs were around 0.7 for all three versions, comparable with the AUCs found in the development of CONTEST. Comparing these results with the performance of the PEST in our population, it shows that the sensitivity is lower for the CONTEST (0.30–0.51) than for the PEST (0.68), while the specificity is slightly higher (0.75–0.87 vs 0.71).

**Table 1. Performance (AUC, Sensitivity and Specificity) of the CONTEST questionnaires in the development study and in the SENSOR dataset**

| | AUC | | | Sensitivity | | | Specificity | | |
|---|---|---|---|---|---|---|---|---|---|
| | Development | SENSOR | SENSOR selection* | Development | SENSOR | SENSOR selection* | Development | SENSOR | SENSOR selection* |
| CONTEST | 0.69 | 0.69 | 0.60 | 0.86 | 0.53 | 0.64 | 0.35 | 0.75 | 0.5 |
| CONTEST-w | 0.74 | 0.67 | 0.60 | 0.86 | 0.30 | 0.36 | 0.48 | 0.87 | 0.73 |
| CONTEST-jt | 0.70 | 0.69 | 0.60 | 0.86 | 0.51 | 0.62 | 0.37 | 0.78 | 0.55 |
| PEST | 0.91 | 0.71 | NA | 0.92 | 0.68 | NA | 0.78 | 0.71 | NA |

* Only selecting patients with a positive PEST and/or PASE questionnaire

**Conclusions:** External validation of the CONTEST questionnaire in primary care psoriasis patients with regular spells of musculoskeletal symptoms resulted in lower sensitivity and higher specificity compared to the development cohort, while AUCs were comparable. When only selecting patients with at least one positive screeningtool, the sensitivity slightly increases while the specificity slightly decreases. However, the performance of the CONTEST questionnaires does not seem to exceed the performance of the PEST in a primary care setting.

## THU0446 MANAGEMENT OF PSORIATIC ARTHRITIS IN EAST OF ENGLAND

M. Joy, G. Kasavkar, A. Bharadwaj, A. Nandagudi. *Rheumatology, Basildon and Thurrock NHS Trust, Basildon, Essex, United Kingdom*

**Background:** Currently there are many guidelines for the management of psoriatic arthritis which advocate the use of DMARDs (Disease Modifying Anti-Rheumatic Drugs) such as the EULAR (2011) and the BSR (2012) guidelines. These guidelines are based on systematic reviews comparing DMARD to placebo rather than head to head trials.

**Objectives:** The purpose of the survey is firstly to establish whether clinicians in our region were managing psoriatic arthritis in line with recommendations, and secondly, to explore the reasons behind choice of DMARDs or biologic agent.

**Methods:** An anonymous regional survey of 25 clinicians was conducted based around the diagnosis, classification and management of psoriatic arthritis.

**Results:** The most popular classification for PsA is the Moll and Wright's

criteria (39%). Methotrexate is the first choice DMARD in oligoarthritis (77%) and polyarthritis (96%). The reasons being: evidence based (31%) prior experience (31%) and to manage the skin condition (38%). The majority favour leflunomide (60%) over sulphasalazine (32%) as second line DMARD. Factors influencing this choice consisted of: evidence (52%); prior experience (28%); safety (12%); likelihood of improving the skin condition (8%). Of the 76% of clinicians who stated they regularly use outcome measures, 67% used PsARC of which 50% use it sometime, 43% always, and 7% rarely. DAS is used by 19% while 14% noted tender or swollen joint counts. Only few clinicians actively subcategorise dactlitis (17%) and enthesitis (36%). The majority (83%) didn't distinguish between PsA and Ankylosing Spondylitis. Popular first choice biologic agents were adalimumab (58%): golimumab (13%): certolizumab (13%). The reasons being: prior experience (37%), articular efficacy (21%), and extra-articular efficacy (16%).

**Conclusions:** The majority of clinicians use PsARC for outcome measurement although not many use it frequently. This may be due to a relatively small cohort of patients on biologic treatment who would need this score to meet criteria to continue biologic therapy. The majority of clinicians didn't distinguish between PsA and Ankylosing Spondylitis which may affect management.There is a general consensus in the East of England region regarding first line DMARD therapy as Methotrexate despite the lack of evidence. There are only few randomised controlled trials showing articular efficacy of DMARDs in psoriatic arthritis but they do show symptomatic benefit. Over half of clinicians use Adalimumab as the first line biologic agent. BSR guidelines (2012) recommend the use of an anti TNF monoclonocal antibody in those who require rapid control of skin psoriasis. Other suggested considerations included cost effectiveness and patient preference which were not stipulated in this survey. The reasons for biologic choice vary but at least a third of all clinicians rely on their prior experience.

## THU0447 MEASURING OUTCOME IN PSORIATIC ARTHRITIS: CORRELATION BETWEEN DIFFERENT SKIN SCORES

M. Elmamoun[1], C. Loftus[2], A. Szentpetery[1], P. Gallagher[1], L. Barnes[2], O. FitzGerald[1]. [1]*Department of Rheumatology, St. Vincent's University Hospital;* [2]*Department of Dermatology, St. James's Hospital, Dublin, Ireland*

**Background:** Psoriatic arthritis (PsA) is a heterogeneous disease that includes features of peripheral arthritis, spondylitis, dactylitis, enthesitis, and skin and nail disease. PsA affects about 30% of patients with psoriasis (PsO).[1]

Measuring outcome in psoriatic arthritis (MOPsA) is a web-based tool, freely available to use (see https://mopsa.ie), that collects clinical information about all domains affected in PsA including skin disease and patient reported outcome measures (PROMs). MOPsA also calculates the composite psoriatic disease activity index (CPDAI) and minimal disease activity (MDA).[2,3]

Assessment of skin disease in rheumatology clinics can be challenging. Availability of patient self-assessment questionnaires that correlate with, and possibly can replace, physical examination would address this challenge.

**Objectives:** Our aim was to correlate skin-related patient self-assessment questionnaires and skin sores assessed by physicians using MOPsA.

**Methods:** 189 patients with PsA, fulfilling CASPAR criteria, were recruited in this study. 137 patients from rheumatology clinic and 52 patients from dermatology clinic. We calculated the following skin scores: Dermatology Quality of Life Index (DLQI), Psoriasis Symptom Inventory (PSI), Body Surface Area (BSA) and Psoriasis Area Severity Index (PASI). GraphPad Prism version 6 was used for statistical analysis.

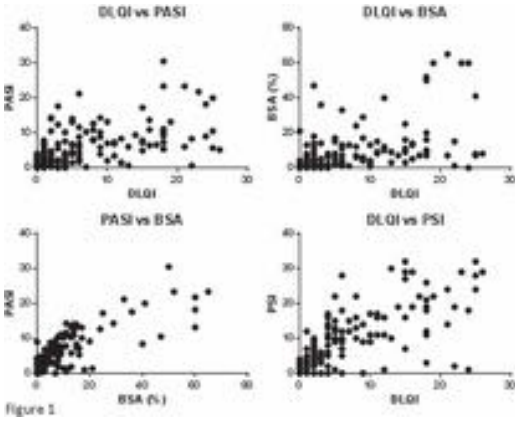

Figure 1

**Results:** Data from 189 patients with skin scores were included in this analysis. Mean ± SD age of 44.61 (± 12.54), 99 (52%) patients were males. 96 (51%) patients had nail involvement. Mean ± SD DLQI was 5.57 (± 6.93), PSI 7.36 (±8.68), BSA 7.27 (± 12.17), and PASI 4.57 (± 5.56).

There was strong correlation between PASI and BSA (r=0.8502, P<0.0001) and between PASI and DLQI (r=0.7256, P<0.0001), but moderate correlation between PASI and PSI (r=0.5812, P<0.0001). There was strong correlation between BSA and DLQI (r=0.7048, P<0.0001) but moderate correlation between BSA and PSI (r=0.6246, P<0.0001 respectively). Finally, there was strong correlation between DLQI and PSI (r=0.7873, P<0.0001).

**Conclusions:** Our analysis confirms the correlation between PASI and DLQI. The strongest correlation was between PASI and BSA. DLQI correlates very well with all three parameters (PASI, BSA and PSI). These preliminary results suggest that the combination of BSA and DLQI might work equally well to PASI and DLQI when accurately accessing skin involvement in rheumatology clinics.

## THU0448 SECUKINUMAB FOR THE TREATMENT OF PSORIATIC ARTHRITIS: COMPARATIVE EFFECTIVENESS RESULTS VERSUS ADALIMUMAB UP TO 48 WEEKS USING A MATCHING-ADJUSTED INDIRECT COMPARISON

P. Nash[1], I.B. McInnes[2], P. Mease[3], H. Thom[4], S. Cure[5], E. Palaka[6], K. Gandhi[7], S. Mpofu[8], S. Jugl[8]. [1]*University of Queensland, Brisbane, Australia;* [2]*University of Glasgow, Glasgow, United Kingdom;* [3]*Swedish Medical Center and University of Washington, WA, United States;* [4]*University of Bristol, Bristol;* [5]*MAPI group, Uxbridge, United Kingdom;* [6]*Novartis Ireland Ltd, Dublin, Ireland;* [7]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States;* [8]*Novartis Pharma AG, Basel, Switzerland*

**Background:** Secukinumab (SEC) is approved for the treatment of active PsA in adults with inadequate response to DMARDs. The FUTURE 2 (F2) trial showed superiority of SEC 150 mg and 300 mg over placebo for the primary outcome of ACR20 response at week 24 and for multiple secondary outcomes, with efficacy sustained to week 52. The ADEPT trial compared adalimumab 40 mg (ADA) with placebo in biologic-naïve patients. In F2, patients could switch from placebo (from week 16); for both trials all had switched after week 24. In the absence of direct comparison or a continuous common placebo arm, matching-adjusted indirect comparison (MAIC) can assess relative efficacy. MAIC adjusts for differences in patient characteristics at baseline, reducing the effective sample size (ESS) for the therapy arm in one trial, but matching this with the population of the therapy arm from another trial, thus simulating head-to-head comparison.

**Objectives:** To assess the relative efficacy of SEC 150 mg and 300 mg vs. ADA using F2 and the published ADEPT trial.

**Methods:** Patient-level data from the SEC arms of the F2 trial (n=200 across SEC doses) were weighted to match patient baseline characteristics for the ADA arm of ADEPT (n=151). Logistic regression was used to determine weights for age, body weight, sex, race, methotrexate use, presence of psoriasis (≥3% body surface area), mean PASI score, dactylitis, enthesitis, mean HAQ-DI and previous biologic therapy. Weighted outcomes from F2 (ESS: n=36 for SEC 150 mg; n=38 for SEC 300 mg) were compared with data from ADEPT (both trials used non-responder imputation). Pairwise comparisons using relative risks (RRs) were

performed and results are presented as RR (95% CI) and probability of response (95% CI) for ACR20, 50 and 70 at week 48. For PASI75 and 90, ADA week 48 results are compared with SEC week 52 data (the nearest data point).
**Results:** In the MAIC, both SEC doses had higher mean ACR20, 50 and 70 responses than ADA, with statistical significance for SEC 150 mg (RR: 1.41 [1.14–1.76], $p$=0.002) and SEC 300 mg (RR: 1.31 [1.03–1.66], $p$=0.027) at ACR20 and for SEC 300 mg (RR: 1.41 [1.03–1.92], $p$=0.032) at ACR50. The ACR20, 50 and 70 response rates were 79.6% (72–88), 57.1% (47–67) and 32.4% (23–42) respectively for SEC 150 mg; 73.5% (64–83), 61.4% (51–71) and 42.9% (33–53) for SEC 300 mg; and 56.3% (48–64), 43.7% (36–52) and 29.8% (23–37) for ADA. Findings were consistent across sensitivity analyses which also showed significance for SEC 300 mg at ACR70.
PASI 75 and 90 response rates were numerically better for SEC 300 mg: 71.1% (57–86) and 52.2% (36–68) than ADA: 58.0% (46–70) and 46.4% (35–58). SEC 150 mg rates were 51.2% (38–64) and 40.8% (28–54) respectively.
**Conclusions:** When adjusted for patient baseline characteristics, SEC was associated with numerically higher response rates for joint and skin outcomes with statistically significantly higher responses vs. ADA for ACR endpoints at week 48. The next level of evidence will be a head-to-head to substantiate these findings.

## THU0449 ASSESSMENT OF DISABILITY LEVELS IN A COHORT OF 1,489 PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS, AND THE EFFECT OF APREMILAST TREATMENT: POOLED DATA FROM 3 PHASE III, RANDOMIZED, CONTROLLED TRIALS

P.J. Mease[1], J. Wollenhaupt[2], S. Hall[3], F. Van den Bosch[4], E. Lespessailles[5], M. McIlraith[6], L. Teng[6], C.J. Edwards[7]. *[1]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; [2]Schön Klinik Hamburg Eilbek, Hamburg, Germany; [3]Monash University, CabriniHealth, Melbourne, Australia; [4]UZ Gent, Gent, Belgium; [5]University of Orléans, Orléans, France; [6]Celgene Corporation, Summit, United States; [7]University Hospital Southampton, Southampton, United Kingdom*

**Background:** Psoriatic arthritis (PsA) reduces physical function and QoL; a treatment goal is to improve/maintain functionality. PALACE 1 (NCT01172938), 2 (NCT01212757), and 3 (NCT01212770) compared apremilast (APR) efficacy/safety with placebo (PBO) in patients (pts) with active PsA despite prior conventional DMARDs and/or biologics, providing one of the largest databases (N=1,489) examining physical disability in pts with moderate/severe PsA.
**Objectives:** Assess APR 30 mg BID (APR30) treatment impact on disability using the HAQ-DI over 104 wks with PALACE 1–3 pooled data.
**Methods:** Pts were randomized (1:1:1) to PBO, APR30, or APR 20 mg BID (APR20) stratified by baseline (BL) DMARD use (yes/no). At Wk 24, all remaining PBO pts were re-randomized to APR30 or APR20. HAQ-DI scores were collected at BL and Wks 16, 24, 40, 52 65, 78, 91, and 104. Mean change, proportion reaching MCID, and disability levels were calculated; HAQ-DI cutoff levels were ≤1.0 (clinically significant disability[1]), ≤0.5 (MDA criteria[2]), and ≤0.25. Score shift categories were examined in 0.25 increments to clarify pt disability level. Wk 16 data, compared with PBO, are analyzed by intent-to-treat/LOCF methodology. Other data shown are as observed to Wk 104. Mean change and MCID outcomes are for all pts receiving treatment with APR30 at any time during the study; for disability level and category shift assessments, data are shown for pts randomized to APR at BL.
**Results:** Pts exhibited significant BL physical disability (mean HAQ-DI=1.2); 60% of APR30 pts had a score >1.0, and 31% >1.5, noting marked difficulty/need for assistive devices in performing activities of daily living. Major disability was noted in 19% with BL HAQ-DI >1.75. As early as Wk 16, physical function improved with APR30; pts exhibited a mean HAQ-DI change of –0.23 (vs –0.08 PBO; $P$<0.0001), 56% achieved HAQ-DI ≤1.0 at Wk 16 (vs 48% PBO pts), and 29% achieved HAQ-DI ≤0.5 (vs 25% PBO pts). Fewer PBO vs APR30 pts reached the MCID of –0.13 (prespecified analysis; 37% vs 47%; $P$<0.005) or –0.30 (prespecified analysis)/–0.35[3] (post hoc analysis) (26% vs 36% for both; $P$<0.005). At Wk 52, decreases in disability were maintained (APR30 mean change in HAQ-DI=–0.33); 48% of APR30 pts achieved MCID –0.30 and –0.35. Importantly, at Wk 52, 58% of all APR30 pts achieved HAQ-DI ≤1.0, 34% ≤0.5, and 24% ≤0.25 (Table). Among pts with greater BL disability (HAQ-DI ≥1.5), 64% improved by ≥1 shift category and 47% by ≥2. At Wk 104, 50% of APR30 pts achieved MCID of –0.30 and –0.35, with 64% achieving HAQ-DI ≤1.0, 38% ≤0.5, and 28% ≤0.25; LOCF analysis confirmed Wk 104 results.

| Pts Achieving Improvement in Physical Function by HAQ-DI Level | | |
|---|---|---|
| Pts Achieving HAQ-DI Disability Threshold, % | Wk 52* APR30 n=377 | Wk 104* APR30 n=306 |
| ≤1.0 | 58 | 64 |
| ≤0.5 | 34 | 38 |
| ≤0.25 | 24 | 28 |
| **Pts Achieving HAQ-DI MCID Levels, %** | **APR30 n=567** | **APR30 n=456** |
| ≥0.30 | 48 | 50 |
| ≥0.35 | 48 | 50 |

Health Assessment Questionnaire-Disability Index (HAQ-DI) ≤1.0=disability not clinically significant; ≤0.5=disability remission.
*Wk 52 and Wk 104 were based on data as observed.

**Conclusions:** In APR30 pts, physical function improved at Wk 16 and was sustained with long-term treatment. Most pts achieved HAQ-DI MCID –0.30 or –0.35 and HAQ-DI scores ≤1.0, with many obtaining HAQ-DI ≤0.5, defined as minimal disease in recent criteria. These data indicate improvement and long-term maintenance of functionality with APR treatment.

## THU0450 ALL-CAUSE MORTALITY AND MALIGNANCIES IN PSORIASIS PATIENTS WITH PSORIATIC ARTHRITIS IN THE PSORIASIS LONGITUDINAL ASSESSMENT AND REGISTRY STUDY

P. Mease[1], A. Gottlieb[2], A. Menter[3], C. Ritchlin[4], S. Kalia[5], F. Kerdel[6], S. Kafka[7], J. Morgan[7], W. Langholff[8], S. Fakharzadeh[7], K. Goyal[7]. *[1]Swedish Med Ctr; U of Washington, Seattle; [2]Tufts Med Ctr/Tufts Sch of Med, Boston; [3]Baylor U Med Ctr, Dallas; [4]U of Rochester, Rochester; [5]U of British Columbia, Vancouver; [6]Florida Academic Derm Ctrs, Miami; [7]Janssen Scientific Affairs, LLC; [8]Janssen R & D, LLC, Horsham, United States*

**Objectives:** To describe characteristics&incidence rates of all-cause mortality & malignancies (excluding NMSC) in PsO patients with PsA from PSOLAR.
**Methods:** PSOLAR,an international, disease-based, observational study in which patients eligible for, or receiving conventional systemic & biologic agents for PsO are followed prospectively.Characteristics & safety for patients who reported PsA, including a narrower subset with PsA confirmed by a joint-specialist,are summarized. Cohorts were defined as & attribution was based on treatment exposure prior to/during registry, in the following order (regardless of sequence & duration): (1) ustekinumab (UST) (2) other sponsor biologic (primarily infliximab [IFX]) (3) non-sponsor biologic (primarily adalimumab/etanercept [ADA/ETN]),& (4) non-biologic therapies (NB) (including immunomodulators {IMM} [eg. MTX, CsA], phototherapy, & topical therapy). Exposure to any therapy higher in the order precluded inclusion in the lower cohorts. Multivariate analyses using Cox hazard regression were used to identify predictors of time to first malignancy & mortality [compared to no biologic use] & for IMM [compared to no IMM use].
**Results:** As of Aug 23, 2014, PSOLAR is fully enrolled with 12093 patients (40388 total patient-years [PY] of follow-up).Number of patients with reported PsA overall was 4316: 1489 UST, 776 IFX, 1680 ADA/ETN, 371 NB; of these patients, 1719 had confirmed PsA (664 UST, 356 IFX, 576 ADA/ETN, 123 NB). Baseline demographics & medical history were generally balanced across cohorts; however, in overall PsA sub-group, more patients in the NB cohort were ≥65 yrs of age (UST 9.9%, IFX 13.9%, ADA/ETN 12.5%, NB 25.6%) & had a medical history of cancer (UST 3.3%, IFX 3.5%, ADA/ETN 3.9%, NB 8.4%). In the overall PsA subgroup, cumulative incidence rates/100PY for all-cause mortality were UST 0.28, IFX 0.30, ADA/ETN 0.52, NB 0.70; age, obesity, history of cardiovascular disease (CVD), history of diabetes& smoking were predictors of time to mortality. Cumulative incidence rates/100PY for malignancy were UST 0.57, IFX 0.67, ADA/ETN 0.64, & NB 1.01; age & history of malignancy were predictors of time to first malignancy. Biologic & IMM use were not predictors for mortality or malignancy. Among the confirmed PsA subset, cumulative incidence rates per 100PY for all-cause mortality UST 0.21, IFX 0.36, ADA/ETN 0.38, NB 0.25 & for malignancy UST 0.52, IFX 0.54, ADA/ETN 1.02, NB 1.25. Inherent bias with observational data may apply. Variability in size & clinical features was noted among groups. Incidence rates are not adjusted for differences (adjustment for

key factors are included in statistical analyses). Small numbers of patients in the confirmed PsA subset precluded assessment of risk factors.
**Conclusions:** Unadjusted rates of all-cause mortality&malignancies for biologics were generally comparable among both PsA subsets. Advanced age, history of malignancy were predictors of time to first malignancy & age, obesity, CVD history, diabetes history & smoking were predictors for time to mortality based on overall PsA subset; biologics & IMM were not predictors for mortality or malignancy.

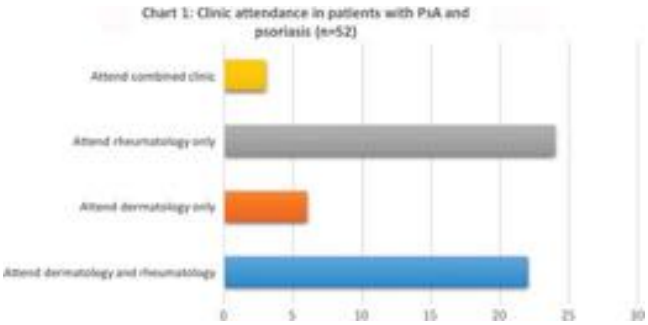
## THU0451 COMPARING FOUR SCREENING TOOLS FOR PSORIATIC ARTHRITIS AMONG SUBJECTS DIAGNOSED WITH PSORIASIS



R.M. Baddoura[1], R. Tomb[2], A. Ghanem[2], E. Halaby[2], N. Mansour[3], N. Ayoub[3], F. Stephan[3], B. Soutou[3], F. El Sayed[3], A. Ammoury[3], H. Megarbane[3], J. Helou[3]. *[1]Rheumatology; [2]Dermatology; [3]St Joseph University, Beirut, Lebanon*

**Background:** Screening psoriatic arthritis remains a challenge. A few dedicated tools have been developed in different settings however direct comparative data is limited.
**Objectives:** To compare screening properties of a new instrument [PsoQ], inspired by both ASAS recommendations for early diagnosis of spondyloarthritis and ACR criteria for rheumatoid arthritis, to three others developed in the setting of dermatology practice [PAQ, PASE and PEST].
**Methods:** Consecutive subjects diagnosed with psoriasis by the dermatologist were submitted the four questionnaires. Subjects with scores above the reported threshold values and a set value for the new instrument, designated as screened positive, were offered rheumatological assessment to search for psoriatic arthritis. Screening properties of the four tools were compared.
**Results:** 371 patients with a mean (SD) age of 39.1 (16.9) were included [204 women (54.9%)]. Predominant psoriasis phenotype was psoriasis vulgaris (78%); prevalence of nail involvement was 15.6% and of scalp lesions 33.7%.
103 patients (27.0%) were screened positive using either of the four questionnaires: 25 (6.8%) using the PAQ questionnaire, 55 (14.8%) with the PASE questionnaire and 41 (11.1%) by the PEST questionnaire. 52 (14.0%) reported features of inflammatory back pain and 32 (8.6%) reported features of inflammatory peripheral arthritis and accordingly 68 (18.3%) were screened positive by the PsoQ. In total, 10 patients were identified as psoriatic arthritis (prevalence 2.7% (95%CI: 1.1%; 4.3%). Predominantly axial phenotype was present in 5 subjects and peripheral arthritis phenotype in five.
Sensitivities (SE) and specificities (SP) of the four questionnaires ranged between 70% and 100% for SE and between 83.9% and 94.4% for SP. SE was the highest using PsoQ (100%) while SP was the highest using PAQ7 (94.4%).
Positive predictive values (PPV) were low, between 12.7% and 20.0% while negative predictive values (NPV) were high, between 98.6% and 100.0%. The highest PPV was achieved with PAQ7 (20%) and the highest NPV (100%) was obtained with PsoQ.
Positive likelihood ratios (PLR) were moderate ranging from 5.3 to 8.8 and negative likelihood ratios (NLR) ranged between 1.9 and 4.5.
**Conclusions:** The four tools showed similar screening properties. Subjects with scores above threshold values need referral for rheumatological assessment.

## THU0452 PSORIATIC ARTHRITIS AND PSORIASIS: THE ONGOING NEED FOR A MULTIDISCIPLINARY APPROACH TO MANAGEMENT

S. McCusker[1], J. Leman[2], S. Bawa[1], M.-M. Gordon[1]. *[1]Rheumatology; [2]Dermatology, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom*

**Background:** Psoriasis is a common inflammatory condition of the skin, associated with significant morbidity. Around 20% of patients with psoriasis suffer from psoriatic arthritis (PsA) (1). SIGN guidelines recommend a multidisciplinary approach in the assessment and management of patients with PsA or psoriasis. There is currently a combined clinic in Glasgow for review of patients with severe psoriasis and PsA, whilst most patients continue to attend separate dermatologist or rheumatologist led clinics.
**Objectives:** To review the population groups attending separate dermatologist and rheumatologist led clinics, to establish adherence to SIGN guidelines with regards to management, and to gauge the potential unmet demand for patients who may benefit from review in a combined clinic.
**Methods:** All patients attending tertiary PsA or psoriasis clinics in March 2015 were invited to complete a questionnaire on their disease, demographics and clinic attendance. Patients attending the PsA clinic completed a DLQI (Dermatology Life Quality Index), those attending the psoriasis clinic completed a PEST (Psoriasis Epidemiology Screening Tool) score.
**Results:** 48 patients attending the PsA clinic and 34 patients attending the psoriasis clinic were included (n=82). 63% (n=52) had both PsA and psoriasis. 14 (17%) patients saw their GP for annual review.
38% (n=18) and 21% (n=10) of patients attending the PsA clinic had been offered referral to physiotherapy and occupational therapy respectively. 22 (42%) of the 52 patients with psoriasis and PsA attended both rheumatology and dermatology, with 4% (n=3) attending the combined clinic (chart 1). 87% (n=45) of patients with a diagnosis of both psoriasis and PsA would find a combined clinic useful.
A PEST score of $\geq$3 is considered positive, and referral to a rheumatologist is recommended (1). 50% of patients attending the psoriasis clinic had a PEST score $\geq$3. 59% of these patients had been referred to, or were currently attending, a rheumatology clinic. 10 patients attending the PsA clinic had a DLQI $\geq$6, these patients should be referred to a dermatologist (1). 60% of these patients had seen a dermatologist.
Leflunomide is the recommended systemic drug of choice in patients with PsA. 1 patient in the PsA group was receiving leflunomide. Methotrexate was the most commonly used systemic therapy in 20 patients in the PsA group and 6 patients in the psoriasis group.
Adalimumab was the most commonly used biologic in both groups (n=17).

**Conclusions:** Currently there are multiple rheumatology and dermatology clinics for the management of PsA and psoriasis throughout Greater Glasgow and Clyde, with only one combined clinic.
Despite clear recommendations for a multidisciplinary approach to the management of psoriasis and PsA, only 4% of our patients attend a combined clinic, fewer than a third have been reviewed by a physiotherapist or occupational therapist and only 17% have an annual GP review. 41% of patients attending the psoriasis clinic with a positive PEST score had not seen a rheumatologist while 40% of patients with a DLQI $\geq$6 attending the PsA clinic had not seen a dermatologist. This audit suggests the need to consider greater access to combined clinics, to allow a multidisciplinary approach to management.

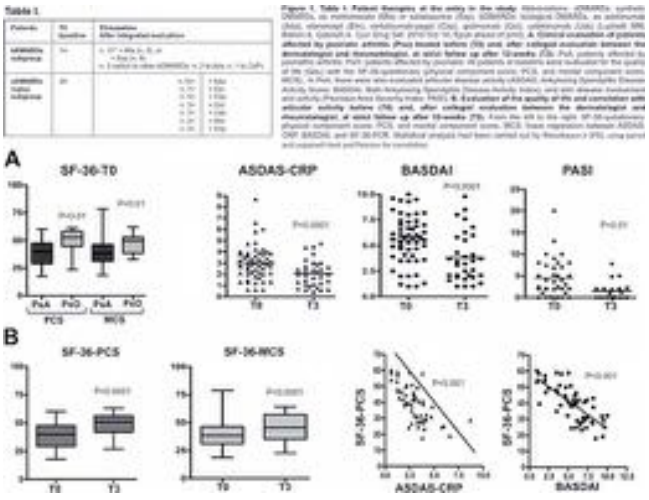
## THU0453 HIGH PREVALENCE OF PSORIATIC ARTHRITIS MISDIAGNOSES IN PSORIASIS PATIENTS IN RUSSIAN DERMATOLOGICAL CLINICS BASED ON PSORIASIS EPIDEMIOLOGY SCREENING TOOL (PEST), RHEUMATOLOGICAL EVALUATION AND THE CASPAR CRITERIA

M. Chamurlieva, T. Korotaeva, E. Loginova. *Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation*



**Background:** According to official Russian Federation statistics the mean annual incidence of psoriatic arthritis (PsA) in patients (pts) with psoriasis (PsO) is 2.5%. Lower estimates may reflect a missed diagnosis of PsA. The efficiency of PsA screening approach in PsO pts in Russian dermatological clinics remains unknown.
**Objectives:** to evaluate the prevalence and misdianosis of PsA in PsO pts in dermatological clinics according to the PEST questionnaire, rheumatological evaluation and the CASPAR criteria.
**Methods:** 103 consecitive unselected pts (male-47/female-56) with plaque PsO mean age 44±13.69 years (yrs.), BSA 9.32±13.55%, PASI 15.39 ± 12.51, DQLI 9.42±6.8 with no known diagnosis of inflammatory arthritis were included. All pts completed the PEST questionnaire before being consulted by a dermatologist. A total score PEST$\geq$3 is indicative of PsA, PEST$<$3 is non-PsA. All pts were subsequently evaluated by a rheumatologist to confirm/exclude PsA. The CASPAR criteria are considered to be the "gold standard" for the diagnosis of PsA. The sensitivity (Sen.) and the specificity (Sp.) of the PEST, (%) were calculated.

**Results:** 60 out of 103 pts (58.2%) had PEST≥3 but after rheumatological assessment according to the CASPAR criteria PsA confirmed in significantly fewer cases – in 47 out of 60 pts (78.3%) and in 13 out of 60 pts (21.6%) PsA was overdiagnosed (false-positive). 43 out of 103 pts (63.4%) had PEST<3 but even so in 14 out of 43 pts (32.5%) PsA was undiagnosed and then confirmed after rheumatological assessment according to the CASPAR criteria (false-negative). So finally the prevalence of PsA in a series of 103 plaque PsO pts was 59.2% (61 pts). PsA was misdiagnosed in 27 out of 103 pts (26.2%). PEST Sen./Sp. were 77%/69% accordingly.
**Conclusions:** In dermatological clinics the PEST questionnaire is a proper approach that is available for PsA screening. But PEST alone is limited due to high amounts of misdiagnoses. All pts should follow up with a rheumatologist and the CASPAR criteria despite the PEST results. For proper diagnosis of PsA among PsO pts need interdisciplinary collaboration with rheumatologists.

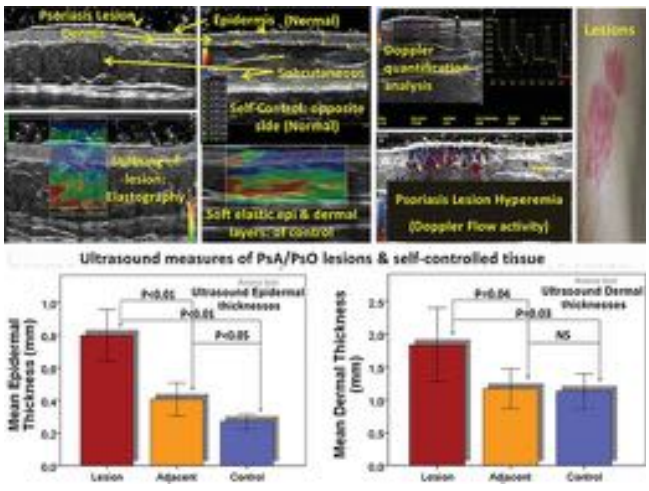
## THU0454 THE MULTIDISCIPLINARY APPROACH IS THE BEST OPTION TO ACHIEVE THE IMPROVEMENT OF DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS AFFECTED BY PSORIATIC ARTHRITIS: PRELIMINARY RESULTS OF A MONOCENTRIC STUDY

W. Capeci, M.M. Luchetti, A. Campanati, D. Benfaremo, G. Ganzetti, E. Molinelli, M. Rossini, A. Farinelli, M. Ciferri, A. Offidani, A. Gabrielli. *Scienze Cliniche e Molecolari, Università Poiltecnica delle Marche, Ancona, Italy*



**Background:** Psoriatic arthritis (PsA) is a chronic arthritis, included in the spondyloarthritis group, characterized by the coexistence of skin and joint inflammation. The delayed diagnosis and therapy may result in an increased rate of progression of clinical damage, affecting significantly the quality of life (QoL) (1). An integrated clinical examination of PsA patients, carried out by the dermatologist and rheumatologist, is actually considered the optimal approach to manage the PsA disease.
**Objectives:** Evaluation of the effect of the multidisciplinary integrated approach, performed by dermatologist and rheumatologist, in: a) the early diagnosis of PsA, and b) the quality of life before and after therapeutic integrated approach.
**Methods:** Since January 2015, we examined 145 consecutive patients complaining articular symptoms and/or psoriasis in the outpatient clinics and in the clinical ward of the dermatology and internal medicine departments. Among them, 53 patients were diagnosed as PsA and 21 by psoriasis (Pso). At baseline, after collegial evaluation, the treatment strategy was planned depending on articular activity-involvement (peripheral or axial), systemic inflammation (C-reactive protein, CRP, and erythrocyte-sedimentation rate, ESR, levels), and skin involvement. Moreover, at baseline and after 12-weeks, articular disease was assessed by Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), following ASAS (Assessment of SpondyloArthritis international Society) indications, and skin disease by the Psoriasis Area Severity Index (PASI). QoL was assessed using the Short Form-36 questionnaire (SF-36).
**Results:** At baseline, QoL was significantly worse in PsA than Pso patients, as assessed by mean SF-36 (physical component score, PCS, and mental component score, MCS) (Fig.1A). Female patients had significantly worse SF-36 MCS than male patients globally considered (37.4±8.4 vs 46.1±12.3, p=0.03), also in the PsA patient's group alone (35.8±8.1 vs 44±13.7, p=0.01). After the integrated evaluation in: a) 33 PsA naïve patients a biological drug was prescribed; b) 3 patients switched to another biological drug; c) 11 patients assuming already a biological drug a synthetic DMARD was added; d) 6 a synthetic DMARD alone was prescribed (Fig. 1, Table I). At 12 weeks, 33 patients had been evaluated at follow-up. It was observed a significant improvement in articular disease as well as skin disease activity (Fig. 1). Consistently, a significant improvement was obtained also in QoL (Fig. 1) and a significant statistical correlation resulted between articular activity and QoL. In fact, a significant correlation between ASDAS-CRP and BASDAI with SF-36 PCS was observed (Fig. 1).
**Conclusions:** In our work, we demonstrate that the multidisciplinary treatment and follow-up approach in patients with PsA has achieved a significant and, most importantly, fast improvement in disease activity and patient reported QoL after 12 weeks. Thus this reinforces the importance of a shared choice of the therapy and it encourages further studies to assess the long-term outcomes and feasibility.

## THU0455 EVALUATING PSORIATIC SKIN LESIONS IN PSORIASIS AND PSORIATIC ARTHRITIS: ULTRASOUND AS A COMPLEMENTARY MEASURE

Y. Kisten[1], E. af Klint[1,2], N. Györi[1], H. Rezaei[1,2], L. Eidsmo[3], M. Ståhle[3], R. van Vollenhoven[1,4]. *[1]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska Institute; [2]The Rheumatology Unit and Clinic, Karolinska University Hospital; [3]Dermatology and Venereology Unit, Karolinska Institute, Stockholm, Sweden; [4]Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands*

**Background:** Currently, the diagnosis and assessment of psoriatic arthritis (PsA) and psoriasis (PsO) skin lesions are mostly done by visual inspections, and when in doubt, supplemented by biopsies. Although PsA is primarily assessed by physical examination, the utility of ultrasound (US) is beneficial.
**Objectives:** The aim of this proof of concept study was to determine the performance of ultrasound (using advanced imaging software applications) in assessing skin lesions and inflammation in selected PsA and PsO patients.
**Methods:** A rheumatologist and dermatologist assessed the PsA and PsO patients respectively. PsA examination included the standard clinical joint assessments, and we thereafter evaluated the hands & wrists and symptomatic joints with US for synovitis & tenosynovitis (including nail beds & tendons). Blinded by the clinical results and treatment plans, the epidermal, dermal and subcutaneous tissue thicknesses of 2 of the most affected psoriasis lesions were US scanned using high frequency B-Mode, automated Color Doppler quantification (CDQ; measured over 4 seconds) and elastography applications (measuring lesion size, depth, hyperemia and tissue elasticity). The skin tissue adjacent to the psoriasis lesions, as well as the unaffected skin on the contralateral side (self-control) was measured.
**Results:** A total of 270 skin depth measurements (2 of the most affected lesions, 3 intervals apart, at 3 different sites described above) of 5 PsA/PsO patients were analyzed. Epidermal thickness differed significantly between the adjacent and control tissue layers [F (2,27) =30.95, MSE =0.76, p<0.001]. Similar findings were evident for dermal thickness differences [F (2,27) =5.05, MSE =1.59, p=0.014]. In contrast and as expected, subcutaneous tissue thicknesses showed no significant differences. US using color Doppler revealed the presence of hyperemia in 80% of the examined lesions by CDQ resulted in flow averages ranging from 0.016–0.655 for minimum ratios to 0.103–0.241 for maximum ratios. Of these Doppler active lesions, 60% were echogenic (some with acoustic shadowing). Contrary, 20% of the psoriasis lesions showed no obvious Doppler activity, displaying reduced tissue stiffening on elastography (suggesting healed lesions). Two of 10 (20%) lesions showed no abnormal findings (soft on elastography) having no acoustic shadows, and low-level CDQ activity (minimum 0.016:0.034 and maximum 0.103:0.135 ratios). Ultrasound displayed the presence of synovitis, tenosynovitis, and nail-bed hyperemia together with altered microcirculation & hand psoriasis skin perfusion in PsA patients.

**Conclusions:** Ultrasound metrics of skin tissue (plaque characteristics, tissue depth & elasticity, and Doppler activity quantification) has potential as a complementary measure for the clinical assessment of PsA and PsO.
**Disclosure of Interest:** None declared

## Osteoporosis

### THU0456 MAJOR RISK FACTORS OF FEMORAL NECK OSTEOPOROSIS IN RHEUMATOID ARTHRITIS PATIENTS

E. Taskina, L. Alekseeva, I. Dydykina, M. Podvorotova, P. Dydykina, E. Petrova, N. Dyomin, A. Smirnov, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** Osteoporosis (OP) is 2–3 times more frequent in rheumatoid arthritis (RA) patients as compared to general population with associated 1,5–2,5 – fold increased risk of fractures. Femoral neck fracture is the most unfavorable prognosis and outcome in these patients, compromising their quality of life.
**Objectives:** To identify major risk factors of femoral neck OP in female RA patients.
**Methods:** The study included 206 female RA patients (ACR criteria), aged 20–75 years (mean age 56,6±11,2 years). An individual patient's file contained social and demographic data, anthropometric parameters, case history, clinical examination and lab findings, traditional OP risk factors, patient's joint status and comorbidities. Hand and distal feet X-ray was taken in each case. Van der Heijde modified Sharp method was used to score the erosions and joint space narrowing in hands and feet. Axial bone mineral density (BMD) was measured using DEXA scan. DEXA T-score was used in post-menopausal women, and Z-score – in menstruating women.
**Results:** Femoral neck OP was diagnosed in 68 patients (33%), while in 138 (67%) no OP was found. Patients with and without OP were of comparable age (58,7 ± 12,3 vs 55,5 ± 10,2 years, $p$=0,06), but differed in disease duration (12 (7; 22) vs 11 (7; 15) years, $p$=0,04) and total Sharp score (181,5 (92; 267) vs 112 (59; 173), $p$=0,006). OP patients were taking higher average daily dose of glucocorticosteroids (GC) during the previous year (5 (2,5; 7,5) vs 2,5 (1,3; 5) mg/day, $p$=0,03) and were prescribed greater number of intra-articular (i/a) GC injections vs patients without OP (8 (3; 18) vs 6 (2; 10), $p$=0,04, respectively). Analysis of traditional OP risk factors identified lower body weight in OP patients (62,8 ± 11,4 vs 69,6 ± 12,4 kg, $p$<0,001) and post-menopause status in the majority of them (89,7 vs 74,6%, RR =1,2, 95% CI 1,06–1,36, $p$=0,007). Higher incidence of femoral neck fractures within the immediate family members was found in OP patients family history (16,4 vs 2,9%, RR =5,57, 95% CI 1,82–17,07, $p$=0,001). Multifactorial analysis identified the following major femoral neck OP risk factors: total Sharp score, average daily GC dose during the previous year, total number of intra-articular GC injections, and menopause; the contribution of these variables in OP development was assessed (discriminant function coefficients: 0,006; 0,37; 0,07; 2,91, respectively) to suggest a model (with the area under the ROC curve equal to 0,926), allowing prediction of femoral neck OP with high accuracy, equal to 89,7%.

| Factors | Discriminant function coefficient |
|---|---|
| Total Sharp score | 0,006 |
| Total number of i/a GC injections | 0,07 |
| Average daily GC dose in the previous year | 0,37 |
| Menopause | 2,91 |
| Weight | -0,09 |
| Constant | 3,73 |

**Conclusions:** The degree of erosive joint destruction in hand and feet (based on total Sharp score), average daily GC dose during the previous year, total number of intra-articular GC injections, and menopause are major risk factors of femoral neck OP in female patients with RA.

### THU0457 COMPREHENSIVE DISEASE CONTROL WITH LESS RELAPSE AND RADIOGRAPHIC PROGRESSION AT ONE YEAR BY INTENSIVE THERAPY WITH ADDITIONAL SHORT-COURSE OF TOCILIZUMAB: A REAL-WORLD, PROSPECTIVE COHORT STUDY IN CHINESE PATIENTS WITH RHEUMATOID ARTHRITIS

X.-Y. Wang, Y.-Q. Mo, J.-D. Ma, L.-F. Chen, J. Jing, D.-H. Zheng, L. Dai. *Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** Tocilizumab (TCZ) was the first approved non-TNFα bDMARD for rheumatoid arthritis (RA) in China since November 2013. However, the mean course of TCZ for most Chinese RA patients is about 3–6 months because of self-paid and expensive price, similar to the situation of other biological originator DMARDs or their biosimilar.
**Objectives:** To investigate the efficacy and safety of additional short-course of TCZ combined with csDMARDs on disease activity and 1-year radiographic progression of RA patients.
**Methods:** One hundred and ten RA patients with moderate to high disease activity were treated with csDMARDs and followed up regularly at baseline, week 4, 12, 24 and 52. Thirty-seven of them were willing to receive additional 3–6 consecutive doses of intravenous TCZ 8 mg/kg every 4 weeks. One-year radiographic progression was defined as mTSS≥0.5. Comprehensive disease control (CDC) was defined as DAS28(4)-CRP<2.6, health assessment questionnaire (HAQ)<0.5 and mTSS<0.5. Relapse was defined as leaving DAS28 theraputic target corresponding to a DAS28(4)-ESR score of >3.2.
**Results:** Seventy-four RA patients who have finished 52 weeks follow-up were qualified for statistics. Patients in TCZ+csDMARDs group (n=23) were with significant higher disease activity by DAS28(4)-ESR than those in csDMARDs group (n=51) at baseline ($p$<0.05, Table 1), and there was no significant difference of other baseline characteristics and csDMARDs therapy during follow-up between two groups (all $p$<0.05). There was 35% patients in TCZ+csDMARDs group reached remission at week 4 which was significantly greater than those in csDMARDs group (8%, $p$=0.006), and the rates of patients reached therapeutic target (DAS28[4]-ESR<3.2), remission (DAS28[4]-ESR<2.6) or deep remission (DAS28[4]-ESR<1.98) at week 12 in TCZ+csDMARDs group were also significantly higher (Fig. 1). The ratio of patients with EULAR good response at week 12 in TCZ+csDMARDs group was significantly higher than that in csDMARDs group (74% vs. 35%, $p$=0.010), consistent at week 24 (87% vs. 49%, $p$=0.002) and week 52 (70% vs. 43%, $p$=0.046). For patients who have reached therapeutic target during follow-up, 65% (22/34) of them in csDMARDs group and 33% (7/21) in TCZ+csDMARDs group relapsed within 52 weeks ($p$=0.029).The one-year radiographic progression rate at week 52 in TCZ+csDMARDs group was significantly lower than those in csDMARDs group (13% vs. 49%, $p$<0.05) and 52% patients in TCZ+csDMARDs group achieved CDC at week 52 which was significantly greater than those in csDMARDs group (24%, $p$=0.030). No significant difference of adverse events during follow-up was found between two groups (all $p$<0.05).

**Table 1** The baseline characteristics, treatments and adverse effects between TCZ+csDMARDs group and csDMARDs group

| | TCZ+csDMARDs group (n=23) | csDMARDs group (n=51) | P |
|---|---|---|---|
| **Baseline characteristics** | | | |
| Female, n (%) | 18 (78) | 40 (78) | 1.000 |
| Age (years) | 53 (37-65) | 50 (39-57) | 0.629 |
| Disease duration (months) | 20 (5-96) | 36 (12-84) | 0.259 |
| Positive RF, n (%) | 18 (78) | 41 (80) | 1.000 |
| Positive anti-CCP antibody, n (%) | 19 (83) | 42 (82) | 0.752 |
| DAS28 (4)-CRP, median (IQR) | 5.0 (4.6-6.4) | 4.7 (4.0-5.7) | 0.079 |
| DAS28 (4)-ESR, median (IQR) | 6.0 (5.5-7.0) | 5.4 (4.6-6.4) | **0.045** |
| **csDMARDs therapy during follow-up** | | | |
| MTX+LEF, n (%) | 20 (87) | 40 (78) | 0.527 |
| MTX+HCQ, n (%) | 2 (9) | 6 (12) | 1.000 |
| MTX+HCQ+SASP, n (%) | 1 (4) | 1 (2) | 1.000 |
| Glucocorticoid, n (%) | 10 (43) | 30 (59) | 0.184 |
| Others, n (%) | 0 (0) | 4 (8)* | - |
| **Adverse effects** | | | |
| Upper respiratory tract infection, n (%) | 3 (13) | 4 (8) | 0.670 |
| Elevated aminotransferase (1~2 folds of ULN), n (%) | 6 (26) | 7 (14) | 0.206 |
| Elevated aminotransferase (over 2 folds of ULN), n (%) | 1 (4) | 3 (6) | 1.000 |
| Neutropenia, n (%) | 2 (9) | 4 (8) | 1.000 |

*Four patients with MTX intolerance due to gastrointestinal discomfort were treated with LEF+HCQ (n=2), LEF+SASP and HCQ+SASP, respectively. ULN, upper limit of normal range.

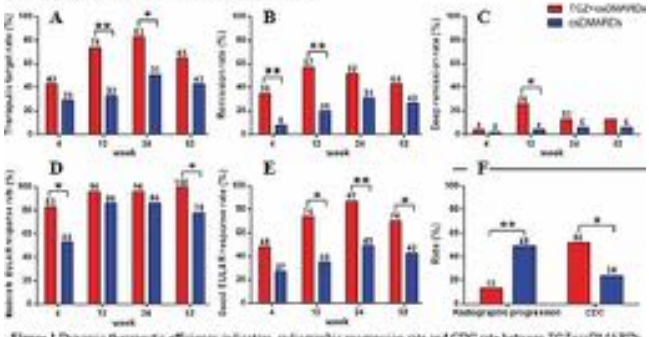

**Figure 1** Dynamic therapeutic efficiency indicators, radiographic progression rate and CDC rate between TCZ+csDMARDs group and csDMARDs group. *$p$<0.05, **$p$<0.01. Therapeutic target, remission and deep remission were defined as DAS28 (4)-ESR<3.2, 2.6 and 1.98, respectively

**Conclusions:** Intensive therapy with additional short-course of TCZ combined with csDMARDs could induce more CDC with less relapse and radiographic progression at one year which implies an alternative cost-effective strategy of biologics for RA patients especially in developing countries.

## THU0458 INFLUENCE OF ORAL PREDNISOLONE ON EFFECT OF DENOSUMAB ON OSTEOPOROSIS IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS; 12 MONTHS OF FOLLOW-UP – A MULTICENTER REGISTRY STUDY

Y. Kanayama[1], Y. Hirano[2], N. Takahashi[3], S. Asai[3], N. Ishiguro[3], T. Kojima[3] on behalf of TBCR-BONE Study Group. *[1]Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [2]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [3]Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Denosumab (DMB) is a fully human monoclonal antibody to the receptor activator of nuclear factor-kappaB ligand (RANKL) that blocks its binding RANK, inhibiting the development and activity of osteoclasts, decreasing bone resorption, increasing bone density and reducing fracture risk. Osteoporosis (OP) is more frequent in patients with rheumatoid arthritis (RA) than in the general population due to active systemic inflammation as well as the use of glucocorticoid and immobility. However efficacy of denosmab is not clear in patirnts with glucocorticoid- induced OP in RA. Therefore we investigated the influence of oral prednisolone on effect of DMB in patients with Japanese RA from initiation to 12 months at this time.
**Objectives:** This prospective study investigated the efficacy of DMB for 12 months on glucocorticoid- induced OP in RA patients.
**Methods:** Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed DMB from Tsurumai Biologics Communication Registry (TBCR)-BONE between October 2013 and October 2014 were enrolled. The final study cohort of 67 patients received continuous DMB therapy more than 12 months. The DMB dose was 60mg at once every 6 months. In all cases native or activated vitamin D has been used. We reviewed the results for 6 and 12 months about the increase and decrease of bone mineral density (BMD) of lumbar spine (LS) and total hip (TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen (PINP) and tartrate-resistant acid phopshatate form 5b (TRACP-5b)
**Results:** In the patients receiving oral prednisolone group (n=26, R-PSL) and not receiving group (n=41, N-PSL), the number of female was each 24 (92%) and 40 (98%) cases (p=0.555). The mean age was 68.5 ± 7.9 and 69.9 ± 7.2 years old (p=0.657); disease duration was 16.3 ± 9.9 and 16.0 ± 13.3 years (p=0.532); the body mass index was 19.9 ± 3.5 and 19.6 ± 2.9 (p=0.852) and the FRAX was 32.7 ± 18.3 and 21.6 ± 13.5 (p=0.007). Clinical findings related to RA and OP at baseline were as follows; CRP 1.1 ± 1.3 and 0.4 ± 1.0 mg/dl (p=0.017); DAS-CRP 3.20 ± 1.13 and 2.39 ± 1.22 (p=0.003); m-HAQ 1.20 ± 0.83 and 0.73 ± 0.72 (p=0.026); PINP 60.4 ± 37.0 and 55.0 ± 32.7 μg/l (p=0.433); TRACP-5b 502 ± 245 and 488 ± 206 mU/dL (p=0.852); LS-BMD 0.86 ± 0.18 and 0.83 ± 0.17 g/cm$^2$(p=0.296) and TH-BMD 0.60 ± 0.11 and 0.60 ± 0.08 g/cm$^2$ (p=0.892). The rate of decreased PINP from baseline to 6 and 12 months were each -29.4% vs -40.2% (p=0.289) at 6 month and -13.7% vs -41.4% (p=0.118) at 12month and TRAC-5b were -28.5% vs -35.1% (p=0.849) at 6 month and -21.4% vs -31.6% (p=0.401) at 12month in the R-PSL group vs N-PSL group. The rate of increased LS-BMD from baseline to 6 and 12 months were each 3.4% vs 4.5% (p=0.305) at 6 month and 4.7% vs 6.8% (p=0.175) at 12month and TH-BMD were 3.0% vs 3.0% (p=0.816) at 6 month and 3.9% vs 3.9% (p=0.898) at 12month in the R-PSL group vs N-PSL group (Fig. 1). The rate of patients who did not increase LS-BMD and TH-BMD for 12 months were each 17.4% vs 15.4% (p=0.836) and 17.4% vs 5.0% (p=0.179) in the R-PSL group vs N-PSL group (Fig. 2).

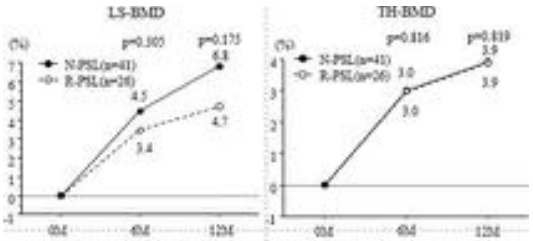

Figure 1: The rate of increased LS-BMD and TH-BMD from baseline to 6 and 12 month

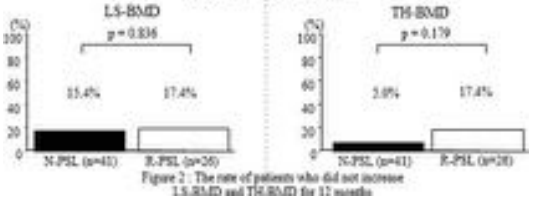

Figure 2 : The rate of patients who did not increase LS-BMD and TH-BMD for 12 months

**Conclusions:** DMB was effective in OP of RA patients. Oral prednisolone use did not influence the efficacy of DMB in the short period of 6 and 12 months.

## THU0459 COMPARISON BETWEEN THE AMERICAN RECOMMENDATIONS AND THE JAPANESE GUIDELINES FOR GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

T. Furuya, S. Momohara, A. Taniguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** In 2014, the Japanese Society for Bone and Mineral Research (JSBMR) updated their guidelines for the management and treatment of glucocorticoid-induced osteoporosis (GIO) and incorporated a new scoring method that does not use the Fracture Risk Assessment Tool (FRAX®).
**Objectives:** In this study, using the JSBMR guidelines (1) and the American College of Rheumatology (ACR) 2010 recommendations (2) for the prevention and treatment of GIO, we compared our evaluations of Japanese patients with rheumatoid arthritis (RA) who were treated with glucocorticoids.
**Methods:** The Institute of Rheumatology Rheumatoid Arthritis (IORRA) study, which began in 2000, was a prospective cohort study of RA patients conducted at the Institute of Rheumatology, Tokyo Women's Medical University (Tokyo, Japan). Applying ACR recommendations and JSBMR guidelines, we evaluated 1,752 of these Japanese patients who were over the age of 50 years (mean age 63 years) and had been treated with glucocorticoids. The ACR recommendation is to prescribe osteoporosis treatments for patients treated with ≥7.5 mg/day prednisolone or whose 10-year risk of major osteoporotic fractures is >10%. The Japanese GIO guidelines identify age, glucocorticoid dose, lumbar bone mineral density, and prior fragility fractures as factors predictive of bone fracture, and the fracture risk for an individual can be calculated as the sum of the scores for each risk factor with a score of 3 representing the optimal cut-off score for pharmacological intervention.
**Results:** Among the female RA patients older than 50 years who were treated with glucocorticoids (n=1,438), in accordance with the ACR recommendations and the Japanese guidelines, 1,183 (82%) and 1,119 (78%) patients, respectively, should have received osteoporosis treatments (Table). Among the male RA patients older than 50 years who were treated with glucocorticoids (n=314), the ACR recommendations and the Japanese guidelines propose that 217 (69%) and 267 (85%) patients, respectively, should have received osteoporosis treatments (Table). Among the male patients, the Japanese guidelines would recommend significantly more patients receive osteoporosis treatments compared with the ACR recommendations ($P<0.0001$).

| Recommendations/guidelines | Female (n=1,438) | Male (n=314) |
|---|---|---|
| ACR | 182 (12.7%) | 3 (1.0%) |
| JSBMR | 118 (8.2%) | 53 (16.9%) |
| ACR and JSBMR | 1001 (69.6%) | 214 (68.2%) |
| None | 137 (9.5%) | 44 (14.0%) |

**Conclusions:** The updated Japanese GIO guideline appears to be a simple and useful tool to use when treating Japanese RA patients with glucocorticoids. The ACR recommendations may have underestimated the need for osteoporosis treatment in male patients with RA compared with the Japanese guideline, although prospective studies are necessary to conclude.

## THU0460 WHAT IS THE BEST LUMBAR SPINE VERTEBRAE COMBINATION TO PREDICT MAJOR OSTEOPOROTIC FRACTURE? THE OSTEOLAUS COHORT STUDY

H. Mraihi[1], O. Lamy[1,2], M. Metzger[2], S. Soares[2], B. Aubry-Rozier[2], D. Stoll[2], D. Hans[2] on behalf of Osteolaus Cohort. *[1]Departement of Internal Medicine; [2]Rheumatology service, Bone and Joint Department, Lausanne University Hospital, Lausanne Switzerland., Lausanne, Switzerland*

**Background:** The international guidelines recommend to use the average bone mineral density (BMD) over L1 to L4 in the management of osteoporosis and prediction of fracture. Exclusion of certain vertebrae is recommended according to specific rules (ISCD position). The spine Trabecular Bone score (TBS), a surrogate of bone micro-architecture, has been newly introduced into international guidelines and the FRAX® tool for clinical use in conjunction with BMD and clinical risk factors.

**Objectives:** The aim of this study is to test several TBS vertebrae combinations in regard to major osteoporotic fracture prediction.

**Methods:** The osteoLaus cohort (Lausanne, Switzerland) included 1500 woman 50 to 80 years old. All women had a detailed questionnaire related to clinical risk factors and treatment known to influence bone metabolism, BMD measurement (hip, spine and whole body), vertebral fracture assessment and TBS. The primary outcome was the prevalence of major osteoporotic fracture (MOF) according to TBS per-vertebral combination. Appropriate statistics and necessary adjustment for confounding factors were performed. L1-L4 TBS was used as reference value.

**Results:** Out of 1'466 women included in the study (mean age 64.5±7.6 years, BMI 25.7±4.4), 12.7% suffered from MOF. The odd ratios per standard deviation decreased (OR) were 1.53 (1.29 – 1.80) and 1.80 (1.50 – 2.15) for the spine and total femur BMD respectively. Adjusted (age & glucocorticoids status) OR and area under the curve of different combination of vertebrae can be found in the following table for TBS.

| | OR (95% CI) | AUC (95% CI) | p<0.05 vs L14TBS | p<0.05 vs L12TBS |
|---|---|---|---|---|
| **L1–2 TBS** | **2.16 (1.80–2.58)** | **0.73 (0.69–0.76)** | ns | – |
| L1–3 TBS | 2.09 (1.74–2.50) | 0.72 (0.68–0.75) | ns | ns |
| *L1–4 TBS* | *1.98 (1.65–2.36)* | *0.71 (0.67–0.75)* | – | *ns* |
| L2–3 TBS | 1.92 (1.61–2.29) | 0.70 (0.66–0.74) | ns | 0.04 |
| L2–4 TBS | 1.81 (1.52–2.17) | 0.69 (0.65–0.73) | 0.001 | 0.001 |
| L3–4 TBS | 1.53 (1.29–1.82) | 0.68 (0.65–0.72) | 0.0002 | 0.0002 |

**Conclusions:** It seems that excluding L4 tends to improve the fracture risk prediction. TBS is very sensitive to vertebra positioning (e.g. projection). To compensate for the natural lordosis of the spine, one has to lift the legs of the patient. L4 is often still angled which could explained such results. Further prospective studies are needed to confirm these results.

## THU0461 REBOUND-ASSOCIATED VERTEBRAL FRACTURES AFTER DENOSUMAB DISCONTINUATION: A SERIES OF 8 WOMEN WITH 35 SPONTANEOUS VERTEBRAL FRACTURES

B. Aubry Rozier, D. Stoll, E. Gonzalez Rodriguez, D. Hans, O. Lamy. *Lausanne University Hospital, Lausanne, Switzerland*

**Background:** Osteoporosis (OP) treatments are given for a limited period of time because of a risk/benefice balance. Reversibility of OP treatment is observed by the measurements of bone markers turnover (BMTs) and bone mineral density (BMD). The effect on vertebral fracture (VFx) is difficult to evaluate. The OP treatment discontinuation is associated with an increase of BMTs and a more or less rapid decrease of BMD. Denosumab (Dmab) discontinuation is associated with a severe rebound effect on BTMs and BMD for near 24 months. A recent publication suggests an increase of VFx [1].

**Methods:** We report the cases of 8 postmenopausal women. They received Dmab 60mg every 6 months for 2 to 8 doses. The 8 women were on calcium and vitamin D. A wide biological assessment excluded a secondary cause of OP. VFx were documented by MRI.

**Results:** Five OP women without any prior fragility fracture were treated every 6 months with 4 to 6 Dmab doses. Dmab was stopped because there was no more OP on BMD (3 women 55, 56 and 59 y old), the aromatase inhibitors were stopped (77y old) and according to the wish of the patient (77y old). 9 to 16 months after Dmab discontinuation, they presented respectively 5 (D11, D12, L2-L4), 7 (D9, D12-L5), 2 (D11 and D12), 3 (D12-L2) and 9 (D5-D9 and D11-L2) symptomatic spontaneous (SS) VFx.

A 65 y old woman with osteoporosis and 3 prevalent VFx was treated every 6 months with 8 Dmab doses. Ten months after Dmab discontinuation she presented 2 SSVFx (D12, L3).

These 62 y old woman (osteopenia, treated with *aromatase* inhibitors) received 2 Dmab doses every 6 months. The subsequent Dmab dose was forgotten. Twelve months after the last Dmab dose she presented a D10 SSFx.

A 71 y old woman (one prevalent VFx and one hip fracture) received 2 Dmab doses with a delay of 11 months because of a lack of compliance. Eleven months after the last Dmab dose she presented 5 SSVFx (D12, L2-L5).

**Conclusions:** These 8 cases show a severe increased risk of vertebral fractures in the 9 to 16 months after the last injection of Dmab. The occurrence of these fractures can be explained by the severe rebound effect observed after denosumab discontinuation. It is urgent to: 1) inform the health authorities and patients of this risk; 2) determine treatment regimens before or at the time of denosumab discontinuation.

## THU0462 THE PREDICTORS OF FRACTURE IN PATIENTS WITH COELIAC DISEASE: AN OBSERVATIONAL STUDY

R. Sinha, M. Bukhari. *Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom*

**Background:** Coeliac disease and other malabsorptive diseases have been associated with a low bone mineral density secondary to a variety of factors including calcium absorption. We have previously shown that there is a fivefold propensity for having Osteoporosis (OP) compared to controls with a predilection for spinal osteoporosis (1). However this does not translate completely to predicting fragility fractures. The FRAX™ tool uses the femoral neck to predict fractures on a population basis and ignores the lumbar spine.

**Objectives:** We set out to determine the predictors of fragility fractures in a large observational cohort. Specifically we set out to determine if the lumbar spine bone mineral density (BMD) is a predictor for fragility fractures.

**Methods:** Patients referred for bone mineral density (BMD) estimation in a scanner in the North west of England between 2004 and 2014 with a history of coeliac disease were identified from a dual X-ray absorptiometry (DEXA) database. Demographics and other risk factors were also recorded. Initially those that sustained a fracture were compared ot those that had not sustained a fracture using the chi squared test for categorical variables and Students T test for continuous variables. Fragility fractures were also recorded. Initially univariate logistic regression models were modelled predicting fractures in the cohort and a multivariate model was subsequently fitted. Variables included age at scan, gender, body mass index (BMI), family history of fracture, alcohol, smoking, glucocorticoid exposure, rheumatoid arthritis in addition to BMD in the lumbar spine (L1-L4) and the femoral neck.

**Results:** 788 patients were scanned in the referral period. Mean age at scan was 55.4 year (SD 14.4), 576 (73.1%) were female, 159 (20.2%) had sustained a fracture. Patients who had sustained a fracture were more likely to be female 127/576 (22%) vs 32/212 (15%) (p=0.03), older 59.2 years (SD14) vs 54 years (SD 14) (p<0.001) and have concomitant rheumatoid arthritis 5/159 (3%) vs 6/629 (1%) (p=0.04). They also had lower BMD in both the lumbar spine and the femoral neck. Results of the univariate analysis are shown in table 1. Significant predictors are denoted with an asterisk (*).

Table 1

| Predictor | Odds ratio | 95% CI |
|---|---|---|
| Age at scan in decades | 1.27 | 1.18, 1.44* |
| Female gender | 1.59 | 1.04, 2.43* |
| Lumbar spine BMD | 0.06 | 0.02, 0.15* |
| Femoral neck BMD | 0.05 | 0.01, 0.17* |
| Rheumatoid arthritis | 3.37 | 1.02, 11,2* |
| smoking | 1.10 | 0.76, 1.62 |
| Excess alcohol | 1.50 | 0.71, 3.16 |
| Family history of fracture | 0.92 | 0.54, 1.56 |
| Steroid exposure | 1.18 | 0.78, 1.79 |
| Body mass index kg/m$^2$ | 0.98 | 0.96, 1.02 |

In the multivariate model, the only variables that predicted fractures in this cohort were the BMD in the lumbar spine (OR 0.09 95%CI 0.03,0.25) and age at scan OR 1.19 (95%CI 1.04,1.37) per decade.

**Conclusions:** In univariate analysis, many risk factors are associated with fracture in this cohort, but in multivariate analysis, the best predictor of fracture was the BMD in the lumbar spine. This is not included in the FRAX™ tool and would make estimating the fracture risk in this cohort difficult. Further modelling in other cohorts is needed to validate this finding.

## THU0463 VIEWPOINTS OF DENTAL SURGEONS ON THE USE OF BISPHOSPHONATES IN RHEUMATOLOGY PATIENTS

C. Daron[1], C. Deschaumes[2], M. Soubrier[1], S. Mathieu[1]. [1]*Rheumatology, Hopital Gabriel Montpied;* [2]*Odontology, Hopital Estaing, Clermont Ferrand, France*

**Background:** While typically prescribed in oncology, bisphosphonates (BP) are also used in rheumatology, particularly in osteoporosis treatment. The most serious complication of BP is osteonecrosis of the jaw (ONJ). In the 2012 guidelines for good clinical practices, the French Society of Stomatology and Maxillofacial Surgery reported a much lower incidence of ONJ in BP-treated patients for rheumatologic diseases (0.001–0.1%) than in oncology (1–10%).
**Objectives:** We recorded the viewpoints of dental surgeons in the Auvergne region of France on these treatments.
**Methods:** A questionnaire was sent to 880 dental surgeons. This questionnaire comprised four independent sections:
– characteristics of the participating dental surgeons;
– evaluation of everyday practice during dental surgery consultations;
– evaluation of practices for patients already treated with BP for rheumatologic indications;
– evaluation of practices for patients meant to start BP treatment for rheumatologic indications.
**Results:** We obtained 382 responses (43.4%), finally analyzing 376 respondents with available data. Of these, 58.7% were men ($n$=221) and 198 were aged between 46 and 65 years (52.6%). In total, 156 had attended an in-service training course (ISTC) on the topic (41.5%).
Our results demonstrated that 237 dental surgeons systematically asked their patients if they were treated with BPs (63.0%); this percentage was higher among those who had been practicing for less than 10 years ($p<0.004$), who worked in a group practice (71.3%, $p<0.001$) or who had attended an ISTC on the topic (71.6%, $p<0.001$).
For patients on BPs, 84.5% of the practitioners felt uncomfortable about performing dental surgery ($n$=318) and 11% about non-surgical dental care ($n$=41). These results did not differ significantly according to overall practice experience or practice structure, nor for practice location. Of the respondents, 67% stated that their practice differed depending on the BP administration (*per os* or i.v.) route. Dental panoramic radiography was systematically performed prior to all work by 55.3% of dentists ($n$ =208). 81.6% did not discontinue BP *per os* prior to dental surgery ($n$ =307).
Of the practitioners, 53.7% felt uncomfortable when a rheumatologist asked whether the patient's dental status allowed for BP prescription ($n$=202). This percentage was higher among those who had not attended any ISTC (62.6% *vs.* 50.7%; $p<0.03$). On completion of dental work, 27.4% of the practitioners waited 1–3 months before approving the initiation of BP treatment ($n$ =103).
In all, 71 practitioners reported at least one case of dental complication under BP treatment (18.8%), consisting of 49 ONJs, 12 healing problems, and three bone sequestrae. Four dental surgeons stated the complications arose in patients under treatment for cancer.
**Conclusions:** This original study reveals that dental surgeons are uncomfortable about giving dental care to patients receiving BPs. Closer collaboration and better information-sharing between rheumatologists and dental surgeons appears necessary to facilitate the use of BPs in rheumatology.
**Disclosure of Interest:** None declared

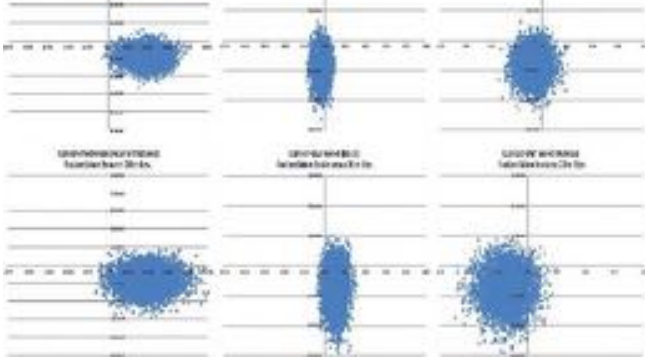
## THU0464 OSTEOPOROSIS, NOT OSTEOARTHRITIS, COULD PREDICT THE OCCURRENCE OF SARCOPENIA IN THE NEAR FUTURE: A 4-YEAR FOLLOW-UP OF THE ROAD STUDY



N. Yoshimura[1], S. Muraki[1], H. Oka[2], S. Tanaka[3], H. Kawaguchi[4], K. Nakamura[5], T. Akune[5]. [1]*Dept. of Joint Disease Research, 22nd Century Medical and Research Center;* [2]*Dept. of Medical Research and Management for Musculoskeletal Pain;* [3]*Dept. of Orthopaedic Surgery, Sensory and Motor System Medicine, The University of Tokyo;* [4]*JCHO Tokyo Shinjuku Medical Center, Tokyo;* [5]*National Rehabilitation Center for Persons with Disabilities, Saitama, Japan*

**Objectives:** The present 4-year follow-up study of the general population was conducted to clarify whether the presence of musculoskeletal diseases, such as, osteoporosis (OP), knee osteoarthritis (KOA), and lumbar spondylosis (LS) could predict the occurrence of sarcopenia (SP) in the near future.
**Methods:** The second survey of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study, a large-scale population-based cohort study, was conducted between 2008 and 2010. We enrolled 1,099 participants (aged ≥60 years; 377 men and 722 women) from the second survey of the ROAD study who had completed assessments of handgrip strength, gait speed, skeletal muscle mass by using bioimpedance analysis, and bone mineral density by using dual X-ray absorptiometry. The third survey was conducted between 2012 and 2013. Of the 1,099 individuals who were enrolled from the second survey, 767 (69.8%; 253 men and 514 women) had completed assessments identical to those in the second survey. SP was defined as per the algorithm of the Asian Working Group for Sarcopenia, while OP at the lumbar spine L2–4 and/or femoral neck was defined according to the World Health Organization criteria. KOA and LS were diagnosed as grade 3 or higher of the Kellgren-Lawrence scale.
**Results:** Among the 767 subjects who completed both the second and third surveys of the ROAD study, the prevalence rates of OP, KOA, and LS in the second survey were 20.5% (men, 3.6%; women, 28.9%), 32.7% (men, 23.1%; women, 37.4%), and 49.8% (men, 46.0%; women, 51.7%), respectively. The cumulative incidence of SP during the 4-year period between the second and third surveys was 2.0%/yr (men, 2.2%/yr; women, 1.9%/yr). After adjustment for confounding factors such as age (yr), gender (0: men, 1: women), regional differences (0: mountainous area, 1: coastal area), and body build (0: normal; body mass index (BMI) ≥18.5 and ≤27.5 kg/m$^2$, 1: emaciation; BMI <18.5 kg/m$^2$, 2: obesity; BMI >27.5 kg/m$^2$), a logistic regression analysis using the occurrence of SP as the objective variable and the presence of OP as the explanatory variable indicated that the presence of OP was significantly associated with the occurrence of SP (odds ratio, 2.51; 95% confidence interval, 1.23–5.11; $p$ =0.011). By contrast, the presence of KOA, and LS was not significantly associated with the occurrence of SP (KOA: 1.32, 0.72–2.41, $p$ =0.369; LS: 1.08, 0.60–1.94, $p$ =0.792).
**Conclusions:** This prospective study suggests that the presence of OP could predict the incidence of SP in the near future, but KOA and LS could not. Treatment of OP might reduce the risk not only of osteoporotic fracture but also of SP.
**Disclosure of Interest:** None declared

## THU0465 FRACTURE LIAISON SERVICE REDUCES RE-FRACTURE RATE, COST-EFFECTIVE AND COST SAVING IN WESTERN AUSTRALIA

C.A. Inderjeeth[1], W. Raymond[1], E. Geelhoed[2], A. Briggs[3], K. Briffa[3], D. Oldham[4], J. McQuade[5], D. Mountain[6]. [1]*Rehabilitation & Aged Care, Sir Charles Gairdner Hospital;* [2]*School of Population Health, The University of Western Australia;* [3]*Physiotherapy & Exercise Science, Curtin University of Technology;* [4]*North Metropolitan Health Service, Department of Health WA;* [5]*Arthritis & Osteoporosis Foundation of WA;* [6]*Accident & Emergency Department, Sir Charles Gairdner Hospital, Perth, Australia*

**Background:** Osteoporotic fractures impose significant morbidity, mortality and economic burden (1). Earlier research showed low rates of secondary prevention for patients discharged from Emergency Department (ED) with a fracture (2). The Fracture Liaison Service (FLS) aimed to identify, review and then manage these patients following their discharge from the ED.
**Objectives:** Determine the economic benefits of a FLS in a Western Australian hospital.
**Methods:** Patients aged >50yrs whom presented to the Emergency Department at Sir Charles Gairdner Hospital (SCGH) after a fracture were invited to the FLS. A retrospective control group from SCGH and a prospective control group from Fremantle Hospital were the comparators.
A health economic analysis from the Payer's Perspective (WA Health) examined recurrent fracture rates and quality of life (EQ-5D). Bottom-up costing included medications, investigations, GP visits and the cost of fracture determined by the literature or the AR-DRG 2013/14 prices for hospital presentation and admission. The mean incremental cost effectiveness ratios were bootstrapped (5000 iterations). Cost-effectiveness acceptability curves were generated and the willingness-to-pay was $50,000AUD.
**Results:** This FLS reduced the rate of re-fracture compared to the retrospective cohort and other tertiary centre by 9.2 - 10.2%, equating to cost savings of approximately $750,168 - $810,400/1,000 patient-years in the first year compared to control cohorts. There was no difference in the QALYs gained across groups over 12 months.
The FLS compared to SCGH retrospective cohort had a mean incremental cost of $6,168 (95CI $133, $18,626) per 1% reduction in the 12 month recurrent fracture risk. The FLS compared to other sites had a mean incremental cost of $6,782 (95CI -$2,562, $25,686) per 1% reduction in the 12 month recurrent fracture risk. The FLS compared to SCGH retrospective cohort had a mean incremental cost of

$859 (95CI -$4,074, $4,864) per QALY gained at 12 months. The FLS compared to other sites had a mean incremental cost of -$119 (95CI -$1,665, $700) per QALY gained at 12 months.
Figure 1 demonstrates that the FLS is cost-effective in delivering a reduction in the fracture rate at 12 months. However, the QALY gained (EQ-5D) was no different at 12 months between the study groups.
**Conclusions:** This FLS demonstrated to be effective in reducing rates or recurrent fracture(s) and resulted in significant cost effectiveness and cost-saving.

## THU0466 OSTEOPOROSIS-RELATED ANKLE FRACTURE: SHOULD WE CONSIDER IT?

Á. Prior-Español[1], S. Rodríguez-Muguruza[1], A. Florido[2], I. Casas[3], J. Sanint[1], Y. García-Mira[1], M. Martínez-Morillo[1], L. Mateo[1], J. Cañellas[1], X. Tena[1], J.A. Hernandez-Hermoso[2], A. Olivé[1], S. Holgado[1]. *[1]Rheumatology; [2]Orthopedic; [3]Epidemiology, Universitary Hospital Germans Trias i Pujol, Badalona, Spain*

**Background:** Osteoporosis is defined as a systemic skeletal disease characterized by low mineral density and microarchitectural changes in the bone which increase its fragility and fracture risk. Ankle fracture is one of the most common fractures; however the relation with osteoporosis is still being debated. The diagnosis and treatment of osteoporosis is not always adequate.
**Objectives:** To determine the relation of ankle fractures to osteoporosis
**Methods:** Retrospective study 2008–2014. Center: Tertiary academic hospital with a referral area of 850,000 inhabitants. The medical charts, bone mineral density (BMD), radiographs and electronic data bases of patients with ankle fracture were reviewed. Demographic data (age, gender), BMD, mechanism of injury (high or low energy trauma), fracture pattern (single malleolus, bimaleollar and trimalleolar fracture) and treatment of fracture and osteoporosis were collected. Patients were divided into younger age ($\leq$60years) and older age ($>$60 years) groups.
**Results:** A total of 299 patients with ankle fractures were included. The mean age was 49.5 years (DS 26.5). There were 131 (43.8%) male and 168 (56.2%) female patients. Among these patients, 84 (28.1%) were in the older age group (74% female and 26% male) and 216 (72.2%) were in the younger age group (51% male and 49% female). Bimaleolar fracture was the most common pattern in both groups (62.7% and 50.5%). Proportion of low energy trauma and conservative treatment was higher in elderly group compared to younger group (63.9% vs 38%, p 0.002/20.5% vs 8.3%; p 0.003). Of note 34 (11.7%) of patients underwent a dual-energy X-ray absorptiometry (DXA): 17 (50%) in the elderly group and 17 (50%) in younger (82% were older than 50 years). In the older group only 1 (5.9%) patient had a normal BMD, 8 (47.1%) had osteopenia and 8 (47.1%) had osteoporosis. Compared with younger patients, osteoporosis was more frequent in older group (10.8% vs 1.4%; p$<$0.005). Older patients had a higher proportion of new fractures than younger (23.8% vs 12.6%; p 0.016), between 3 and 60 months after the ankle fracture. The new fractures were: 9 Colles', 4 vertebral, 4 hip and 3 in other location.
**Conclusions:** Ankle fracture was more common in females in the older group. DXA was performed in a very low percentage of cases. The features of ankle fractures and the higher ratio of new fractures in the older group suggest a possible link with osteoporosis. Patients with ankle fracture should be studied in order to diagnose osteoporosis. These patients may have a benefit of treatment.

## THU0467 OSTEOPOROSIS AND CELIAC DISEASE IN PATIENTS WITH DISTAL RADIUS AND ANKLE FRACTURES

A.M. Hjelle[1], G. Tell[2], E. Apalset[3], P. Mielnik[1], J. Bollerslev[4]. *[1]Dept of Rheumatology, Helse Førde, Førde; [2]Departement of Global Public Health and Primary Care, University of Bergen, Norway; [3]Dept of Rheumatology, Haukeland University Hospital, Bergen; [4]Section of Specialized Endocrinology, Oslo University Hospital, Oslo, Norway*

**Background:** Patients suffering a distal radial fracture have a high prevalence of osteoporosis [1]. Ankle fractures have traditionally not been considered to be an osteoporotic fracture, however more recent studies suggest otherwise [2, 3]. Patients with celiac disease (CD) have low bone mineral bone density (BMD), and overall findings indicate an increased risk of fracture [4, 5].
**Objectives:** To investigate and compare the prevalence of osteoporosis in patients with acute distal radius or ankle fracture and describe risk factors for osteoporosis in the two groups.
**Methods:** 400 consecutive patients over the age of 40 with acute distal radius or ankle fracture were included in this study after referral from the orthopedic department at Forde General Hospital in Sogn og Fjordane county, Norway. BMD of the hips and spine was measured and history of previous fracture, comorbidities, medication, physical activity, smoking habits, body mass index (BMI) and nutritional factors were registered. Serum analysis to detect secondary osteoporosis including IgA tissue transglutaminase was performed.
**Results:** The prevalence of osteoporosis was 44.7% in the patients with distal radius fracture (n=293) compared to 23.4% in the ankle fracture group (n=107). Significant risk factors for having osteoporosis when having suffered a distal radius fracture were older age, female gender, lower BMI, and celiac disease (defined as either known celiac disease AND/OR positive IgA tissue transglutaminase). Elevated PTH or low vitamin D was not significant. The patients with radius fracture and osteoporosis had a higher prevalence of celiac disease (7.6%) than the ones with radius fracture and osteopenia or normal BMD (0.6%). In the ankle fracture patients with osteoporosis there were no celiac disease cases, versus 3.7% in the ankle fracture patients with osteopenia/normal BMD. In the ankle fracture group, low BMI was a significant risk factor for being osteoporotic, but no other significant risk factors were found.
**Conclusions:** The prevalence of osteoporosis was higher among persons suffering a distal radius fracture than among those with acute ankle fracture. Several well-known risk factors for osteoporosis were associated with being osteoporotic among subjects suffering a distal radius fracture, but only BMI was associated with osteoporosis in the ankle fracture group.

## THU0468 OSTEOPOROSIS AND OSTEOCALCIN LEVELS IN PATIENTS WITH GOUT

A. Doğru[1], A. Balkarlı[2], C.C. Karatay[3], V. Cobankara[4], M. Sahin[1], S.E. Tunc[1]. *[1]Department of Internal Medicine, Division of Rheumatology, Suleyman Demirel University, Faculty of Medicine, Isparta; [2]Department of Internal Medicine, Division of Rheumatology, Antalya Training and Research Hospital, Antalya; [3]Department of Internal Medicine; [4]Department of Internal Medicine, Division of Rheumatology, Pamukkale University, Faculty of Medicine, Denizli, Turkey*

**Background:** Gout is a rheumatic disease characterized by the deposition of monosodium urate crystals in the joints and surrounding tissues. Gout is the most common inflammatory arthritis in men. It affects 1–2% of the adult population. Comorbid conditions and drugs used in gout are thought to increase the risk of osteoporosis but unlike some other forms of rheumatic diseases, gout is not believed to cause osteoporosis.
**Objectives:** In our study, we aimed to investigate the osteoporosis and osteocalsin levels in patients with gout.
**Methods:** 70 patients diagnosed with gout and 53 age-sex match controls were included in the study. Cardiovascular diseases, chronic renal disease, diabetes mellitus, hypertension, thyroid disease, bone disorders, eating disorders, gastrointestinal surgery or disease history, steroid use, alcohol use, patients with family history of osteoporotic fracture were excluded. The t and z scores from lumbar spine (L2-L4) and femur (neck, ward, trochanter, total) were determined by Dual energy X-ray absorptiometry (DEXA). Osteocalcin levels was measured by electrochemiluminescent immunoassay (ECLIA).
**Results:** Osteoporosis according to t- scores of lumbar vertebrae L2-L4 was found to be significantly higher in patients with gout compare to control group (p=0.02). There was no correlation between osteoporosis and the frequency of gout attacts, tophi and disease duration. Osteocalcin levels were detected to be significantly increased in the gout patients compare to control group (p=0.004). Vitamin D levels were similar in gout and control group (p=0.14). Alkaline phosphatase, parathyroid hormone levels were found to be significantly lower in control group compare to gout group (p=0.001).

Table 1. Gout patients and control group results

| Parameter | Gout (n=70) | Control (n=53) | p |
|---|---|---|---|
| Osteoporosis , n (%) | 16 (22.9%) | 5 (9.4%) | 0.02* |
| Osteopenia, n (%) | 35 (50%) | 23 (43.4%) | NS |
| Osteocalcin (ng/ml) | 26.6 (14.9–53.8) | 18 (14.2–25.2) | 0.004* |
| Vitamin D (ng/ml) | 20.3 (13.2–25.6) | 16 (11–25) | NS |
| Parathyroid hormone (pg/ml) | 57.9 (42–86) | 43.7 (33.8–55) | 0.001* |
| Alkaline phosphatase (U/L) | 76 (63.2–92.5) | 62 (48–76.5) | 0.001* |

Values are presented as median (25–75 interquartile ranges. *P$<$0.05, NS: non significant.

**Conclusions:** Gout may increase the risk of osteoporosis and serum osteocalcin

levels in clinical practice may be a useful biomarker for osteoporosis. Long-term randomized controlled prospective studies with larger populations are required for the clarification of the relationship between gout and osteoporosis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5014

## THU0469 COMPARISON OF DORSAL AND LUMBAR PAIN IN PATIENTS WITH AND WITHOUT NON-ACUTE VERTEBRAL FRACTURES IN TERMS OF THERAPEUTIC APPROACH AND URGENT CARE BURDEN

C.A. Guillen-Astete, A. Boteanu. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** Among people over 65 years old, many circumstances increase the frequency and intensity of back pain including osteoarthritis, less muscle mass and kyphosis. Acute vertebral fracture (VF) is also a cause of intense spine pain and a relevant cause of consultation due to its locomotive impairment and need of potent pharmacological analgesia.
**Objectives:** To compare the frequency of healthcare demand and intensity of analgesic treatment of patients with lumbar or dorsal pain according to the existence or not of a vertebral fracture excluding the acute event.
**Methods:** A retrospective comparative study was conducted. Registries of patients who consulted in our A&E department by lumbar or dorsal pain, older than 65 years old from November 2013 to November 2015 were identified and grouped according to the presence or absence of a known VF. Records of patients who were diagnosed by the first time of vertebral fracture during the medical attention were excluded. Main outcome variables were number of consultations/year and type of treatment according to the WHO pain ladder.
**Results:** The inclusion criteria were achieved in 1528 registries. Among them, 76 registries were incomplete or unavailable. Of the remaining 1452 registries, 168 (11.5%) presented a previously documented vertebral fracture (PDVF) and the remaining did not (nVF). Average age in the PDVF and nVF group was 75.9 SD 3.3 and 73.6 SD 4.2 years old, respectively ($P$=0.0001). Average number of consultations was 1.58 SD 0.23 consultations/year in PDVF group and 1.02 SD 0.11 consultations/year in nVF group (95%CI of difference 0.5391–0.5809; $P$=0.0001; T Student's test). Among patients with PDVF, MD group had an average of 1.60 SD 0.26 consultations/year and CRVF group had an average of 1.60 SD 0.32 ($P$=0.29). The odds ratio of to require a further consultation within a month of first assessment was 2.24 when PDVF group was compared with nVF group (CI95% 1.54–3.26; $P$<0.0001). At discharge, 42 (25.0%) patients of PDVF group and 652 (50.7%) of nVF group were sent to primary care units and 98 (58.3%) patients of PDVF group and 210 (16.3%) of nVF group were sent to secondary care units ($P$=0.0001 for both comparison, Fisher's exact test). The odds ratio of be discharged without need of further follow up was 0.40 when compared PDVF and nVF group (CI95% 0.26–0.62; $P$<0.0001). 53.5% of PDVF patients and 23.4% of nVF patients were treated at discharge with 2º scale WHO-pain ladder drugs ($P$=0.0001). 29.1% of PDVF group and 23.4% of nVF group were treated with 3rd scale WHO-pain ladder drugs ($P$=0.0001). The odds ratio of be treated with major opiods at discharge was 78.02 when compared PDVF with nVF group (CI95% 38.57–161.86; $P$<0.0001). Among patients with PDVF, 21.3% of patients of the MD group and 41.5% of patients of the CRVF were treated with drugs of the 3rd scale WHO-pain ladder (OR 2.61; 95%CI 1.32–5.17, $P$=0.0057)
**Conclusions:** Patients with non-acute vertebral fractures have a higher index of urgent consultations per year, are more probably to be treated with major opiods and generates a higher burden of primary or secondary care appointments. As far as we know, this is the very first study which measures the impact of VF in an urgency environment.

## THU0470 HOSPITAL UTILISATION AND MORTALITY OF TRAUMATIC HIP AND NON-HIP FRACTURES IN PATIENTS WITH OSTEOPOROSIS IN WESTERN AUSTRALIA: A TEN-YEAR STUDY USING LINKED ADMINISTRATIVE DATA

C.A. Inderjeeth[1], W. Sun[2,3], A. Briggs[4], L. Miller[2], P. Kelly[3], W. Pyper[5], A. Huska[6]. [1]*Rehabilitation & Aged Care & Rheumatology, University of WA and North Metropolitan Health WA;* [2]*Epidemiology Branch, Department of Health, Perth;* [3]*School of Public Health, University of Sydney, Sydney;* [4]*School of Physiotherapy and Exercise Science, Curtin University;* [5]*Health System Economic Modelling;* [6]*Health Strategy and Networks, Department of Health, Perth, Australia*

**Background:** Osteoporosis is common. Traumatic fracture is more likely in those with osteoporosis at significant cost. Given the burden of the osteoporotic fracture and need to prioritise fracture prevention and management initiatives in WA, we sought to further investigate the 10-year linked data from the previous study to examine hospital utilisation and mortality associated with traumatic fractures in those with osteoporosis.[1]
**Objectives:** To compare hospital utilisation and mortality outcomes of "traumatic" hip with non-hip fractures in patients with osteoporosis in Western Australia (WA) over 10 years.
**Methods:** *Design:* Retrospective cohort study (2002 to 2011).
*Setting:* Population-based data linkage of the WA Hospital Morbidity Data System and Mortality Registry.
*Participants:* WA residents aged ≥50 years hospitalised with an index "traumatic" fracture and osteoporosis. Index fractures sites included hip, spine, pelvic, rib or "other" fracture sites.
*Main outcome measures:* Index hospitalisations, hospital readmission due to any subsequent fractures, length of stay (LOS), admission costs, characteristics of hospital stay and mortality.
**Results:** Specific fracture sites for index cases were identified in 974 patients (18% of all index cases) due to coding inconsistencies. Index hip and spine fractures were the most common fractures requiring hospitalisations, with index hip being the most expensive to treat ($40,570 per person on average) and the cost accounted for 65% of total cost of index cases. Non-hip fractures accounted for 68% of admissions and have similar hospital utilisation as hip fracture in terms of LOS (30 days on average), requirement for hospital transportation (over 60%) and rate of readmission. The risk of readmission following index spine fracture was 1.5-fold higher (95%CI=1.14–1.98) than index hip fractures. No significant mortality difference was found between hospitalised hip and non-hip cases. The 1 year, 5 years and 10 years cumulative probability of death for hip fracture was 21%, 61% and 84%, respectively.
**Conclusions:** Fracture prevention strategies need to target all with osteoporosis (marker of frailty) to reduce incidence of first fracture (including traumatic). Although mortality and readmission were similar for hospitalised hip and non-hip fracture patients, hip fracture accounted for 32% of index fractures and 65% of costs. Better coding system of osteoporotic fracture in the hospital data in Australia is required to monitor the disease progression in the aging population.

## THU0471 AN OPPORTUNITY TO BREAK THE FRAGILITY FRACTURE CYCLE: 10 MONTHS OF A FRACTURE LIAISON SERVICE

D. Rosa-Gonçalves[1], R. Vieira[1], G. Terroso[1], R. Matos[2], R. Pinto[2], C. Vaz[1], L. Costa[1]. [1]*Rheumatology;* [2]*Trauma and orthopaedic surgery service, Centro Hospitalar São João, Oporto, Portugal*

**Background:** A Geriatric Trauma Unit (GTU) was created in our hospital to optimize the acute treatment of patients with fragility fractures. The rheumatology department assists in subsequente evaluation of these.
**Objectives:** To report the results of the evaluation after 10 months of a fracture liaison service (FLS).
**Methods:** All patients over 65 years-old admitted to the GTU with a fragility hip fracture were systematically identified on a daily, prospective basis. The protocol was first implemented on March 2015 and we describe all patients included until December 2015. After a first evaluation during the hospital admission, patients are referred to the outpatient clinic for further characterization, generally within 3 months. The investigations included were dual-energy x-ray absortiometry (DXA, GE-Lunar), FRAX® including DXA and laboratory blood tests. A descriptive study was performed.
**Results:** 208 cases of fragility hip fracture in patients above 65 years were identified, 78.9% women. Mean age (sd) of 83 years old (7.6). The most frequently affected segment of the hip was the trochanteric region (n=109, 52.4%), followed by the femoral neck (n=75, 36.1%). Most patients (68.8%) underwent surgical intervention within the first 48 hours. Regarding risk factors for osteoporosis (OP), there was a high prevalence of selective serotonin reuptake inhibitor consumption (n=40, 20.1%) as well as antiepileptics (n=10, 5%) and corticosteroids (n=9, 4.5%). Another highly prevalent risk factor was diabetes (n=49, 23.5%). Regarding the body mass index we found that the majority of patients (42.3%) had values within normal limits. Benzodiazepines use, clearly associated with falls, was reported by 44% of patients (n=91). In our analysis only 13.5% (n=28) of the patients had past or current use of bisphosphonates (BP) and only 5.8% of those reporting previous fragility fracture were ever treated for OP. The prevalence of previous fragility fracture was 25.3% (n=47), most commonly hip fracture (n=19, 10.2%). Prior to fracture, 62.5% of patients were independent for daily activities. However, within 3 months after the fracture, only 32% of these patients regain their autonomy. We have recorded 22 deaths, 12 cases during hospitalization.
Full assessment of bone health was conducted in 44 patients. In 34% (15/44) of the cases, the densitometric criteria for OP were not met and 20 (45.5%) patients had radiographic signs of vertebral fragility fracture. Only 9 patients had 25-OH vitamin D levels above 30 ng/mL and 19 (43%) patients had deficiency levels. Using the FRAX toll, the absolute risk of major osteoporotic fracture was higher than 20% in 8 (18%) patients and the absolute risk of hip fracture was higher than 3% in 30 (68%) patients. Regarding treatment implementation, all patients received calcium and vitamin D supplementation and 35 (84%) patients started anti-osteoporotic treatment (33 BP and 2 denosumab).
**Conclusions:** FLS are key pieces in the secondary fracture prevention as they facilitate patient care by automatically including all patients with a fragility fracture

within a health-care system able to implement the adequate strategies to prevent future fractures as well as fracture-related complications.

## THU0472 EVALUATION OF TRABECULAR BONE SCORE IN PATIENTS WITH A DISTAL RADIUS FRACTURE

H.S. Gong, Y.H. Shin. *Department of Orthopaedic Surgery, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

**Background:** Studies have shown that trabecular bone score (TBS) is associated with vertebral and non-vertebral fractures in postmenopausal women, and it may have value for assessing microarchitectural deterioration other than low bone mass. There are limited data on the TBS in patients with a distal radius fracture (DRF), which often occurs in the osteopenic or even normal bone mineral density (BMD) ranges.
**Objectives:** The purpose of this study was to compare BMD and TBS in patients with a DRF and propensity score-matched control patients.
**Methods:** We compared BMD and TBS in 269 women with a DRF older than 50 years of age with age- and body mass index (BMI)-matched control patients who had no history of fractures. BMD was measured at the lumbar spine and at the femur using a GE Lunar Prodigy scanner. TBS was calculated on the same spine image. The differences of BMD and TBS between the two groups were assessed. A multivariate logistic regression analysis was used to analyze the odds ratio for the occurrence of DRF for variables such as age, BMI, lumbar or total femur BMD, and the TBS.
**Results:** Patients with a DRF had significantly lower BMDs at the femur (neck, trochanter and total) than control patients ($p$=0.004, 0.001 and 0.010, respectively). However, BMDs at the lumbar spine and TBS were not significantly different between the groups ($p$=0.367 and 0.708, respectively). Multivariate analysis indicated that only total femur BMD was significantly associated with the occurrence of DRF (odds ratio, 0.102; 95% confidence interval, 0.018 – 0.569; $p$=0.009).
**Conclusions:** TBS is not different between women with a distal radius fracture and those without a history of fractures. This result suggests that the TBS measured at the lumbar spine, which is mainly trabecular, may not reflect early microarchitectural changes in the distal radius, which is mainly cortical. BMD at the femur is the reliable evaluation of bone frailty in patients with a DRF.

## THU0473 CORRELATION BETWEEN METACARPAL CORTICAL BONE MINERAL DENSITY MEASURED BY DUAL X-RAY DENSITOMETRY AND RADIOGRAMMETRY ON EARLY ARTHRITIS PATIENTS

I. Llorente[1], L. Merino[1], A.M. Ortiz[2], S. González[3], E. Escolano[3], J.A. García Vadillo[2], E.F. Vicente[2], R. García Vicuña[2], I. González[2], S. Castañeda[2].
*[1]Rheumatology, Hospital de la princesa, IIS-IP; [2]Rheumatology; [3]Radiology, Hospital la Princesa, IIS-IP, Madrid, Spain*

**Background:** Low bone mass at metacarpal (MC) diaphysis measured by radiogrammetry (DXR) has been described as a poor prognostic factor in rheumatoid arthritis (RA). However, this technique is not available in our environment. Our group has previously described the measurement of bone mineral density (BMD) at metacarpophalangeal joints (MCP) by dual X-ray absorptiometry (DXA). This measurement showed an acceptable correlation with the DXR at MC bones. However, DXR at MC bones mainly assesses cortical bone, whereas DXA at MCP mainly analyzes trabecular bone. Therefore, we have developed a procedure to evaluate MC's (2nd to 4th) bone mass of the nondominant hand through DXA.
**Objectives:** To study the correlation between BMD at 2nd to 4th MC of the nondominant hand measured by DXA with data obtained by DXR.
**Methods:** We studied 171 patients belonging to the Princesa Early Arthritis Register Longitudinal (PEARL) Study (84% women, 55.4 years at symptoms onset; 56.7% fulfilled RA 2010 criteria; 52% RF+ and 43.5% ACPA+). Demographic, clinical and laboratory data were collected per protocol. Hand X-rays were performed at baseline and after one year of follow-up, as well as nondominant hand BMD assessment by DXA (Hologic© QDR4500, Elite).
The standard Hologic© software allows to design regions of interest (ROI) tailored to the researcher needs. In order to develop ROIs in DXA similar to that in DXR, the ROI generator was placed on every MC mid third of the diaphysis (aprox 17x17 mm). The ROI was rotated to be aligned to the MC longitudinal axis, avoiding overlap between adjacent ROIs.
The BMD by DXA was the average of 3 successive measurements. The BMD by DXR was measured with standardized software Sectra (Linköping, Sweden) on hand digital X-ray (GE© DX Definium 8000).
Statistical analysis was performed using Stata 12 for Windows, including linear correlations according to the Spearman test between the BMD values of MC by DXA and DXR and BMD by DXA at global hand and MCP joints. In addition, a multivariate analysis was performed to determine which variables accounted for the differences between MC bone mass measured by DXR and DXA.

**Results:** 248 BMD measurements (154 at baseline and 94 at second visit) of the 3 regions described whose values are shown in Table 1.

| | MC-DXR | MC DXA | Total Hand DXA | MCP DXA |
|---|---|---|---|---|
| BMD (g/cm$^2$; mean ± SD) | 0.529±0.074 | 0.427±0.060 | 0.327±0.041 | 0.265±0.040 |
| Difference with MC-DXR | – | 0.104±0.074* | 0.206±0.060* | 0.268±0.053* |
| Correlation with MC-DXR | – | 0.865* | 0.824* | 0.717* |

MC: metacarpal bone; DXR: bone radiogrammetry; DXA: dual X-ray absorptiometry; MCP: metacarpophalangeal joints. *p<0.0001.

**Conclusions:** As shown in table 1, MC bone mass measured by DXA shows the lowest absolute difference and the best correlation with MC bone mass by DXR. Female gender (beta coefficient =0.013; p=0.039), patients older than 65 years (beta coefficient =0.014; p=0.019) and patients with higher body mass index (beta coefficient =0.002 by kg/m$^2$; p=0.019) were significantly associated with lower differences between the values of MC by DXA and DXR.

## THU0474 THE INFLUENCE OF OSTEOPOROTIC HIP FRACTURE AFTER TOTAL KNEE ARTHROPLASTY: A PROPENSITY-MATCHED COHORT STUDY

J. Chen, T. Li, Y. Hao, H.C. Chong, S.J. Yeo. *Singapore General Hospital, Singapore, Singapore*

**Background:** Total knee arthroplasty (TKA) is an effective treatment for end stage knee osteoarthritis but the postoperative rehabilitaion period can be as long as one year[1]. During this period, patients may have increased risk of osteoporotic hip fracture after a fall[2]. Currently, there is a lack of literature reporting the effect of hip fracture on functional outcome in TKA.
**Objectives:** This study aims to investigate: 1) the incidence of osteoporotic hip fracture within one year after undergoing TKA; and 2) the influence of hip fracture on functional outcome in TKA.
**Methods:** Between March 1999 and February 2012, 2456 male patients and 10,452 female patients underwent a primary TKA at a tertiary hospital. Within one year after TKA, 25 patients had an ipsilateral hip fracture after a fall. A propensity score matching algorithm was used to select a 3:1 control group without hip fracture, with adjustment for potential confounders of functional outcome in TKA such as patients' age, gender and Body Mass Index. The operated knee was assessed using the Knee Society Function Score (KSFS), Knee Society Knee Score (KSKS) and Oxford Knee Score (OKS) at two years after TKA; while the general health of the patients was evaluated using the Physical Component Score (PCS) and Mental Component Score (MCS) of SF-36®. The Student's unpaired t-test was used to compare the two groups for continuous variables.
**Results:** The incidence of hip fracture within one year after undergoing TKA was 0.16% (4 out of 2456) among male patients and 0.20% (21 out of 10,452) for female patients. The average age of these 25 patients was 71 ± 8 years old. There were 15 patients with neck of femur fractures and 10 patients with intertrochanteric fractures. Among them, 7 had a fall within 3 months after TKA and 6 each between 4–6 months, 7–9 months as well as 10–12 months after TKA. At two years after TKA, the KSFS was 50 ± 24 in the hip fracture group versus 68 ± 21 in the control group (p=0.002); while the KSKS was 83 ± 12 and 87 ± 8 respectively (p=0.090). Similarly, the OKS was 36 ± 7 in the hip fracture group versus 41 ± 5 in the control group (p<0.001). The PCS was 37 ± 12 in the hip fracture group versus 47 ± 11 in the control group (p<0.001); while the MCS was 55 ± 10 and 54 ± 11 respectively (p=0.662).
**Conclusions:** In the country where the authors practise, the incidence of hip fracture after a fall was 0.16% for males and 0.44% for females among the general population. The incidence of hip fracture within one year after undergoing TKA among male patients was comparable to the general population, however it was two fold lower than the general population for female patients. Nonetheless, those patients who had an osteoporotic hip fracture during the rehabilitation period after TKA had poorer function at two years follow up, with significantly lower KSFS, OKS and PCS. The authors recommend additional caution against hip fracture within one year after TKA.

## THU0475 INCOMPLETE AND INCONSISTENT: INVESTIGATION OF OSTEOPOROSIS IN A DISTRICT GENERAL HOSPITAL

K.M. Achilleos, S. Mujahid, P. Long, F. Hayes. *Rheumatology Department, Southend University Hospital, Essex, United Kingdom*

**Background:** Osteoporosis is a disease of low bone density, micro-architectural destruction, increased bone fragility and susceptibility to low trauma fractures1, leading to increased morbidity and mortality with a 2–3 fold increased risk of further fractures[1–2]. Prompt diagnosis and optimal management of osteoporosis prevents further fractures[1–2]. The aim of screening is to identify those with greatest risk of sustaining a low trauma fracture who would benefit from intervention, as well as identifying other pathology including malignancy, presenting similarly. It is well documented that the majority of patients presenting with fragility fractures are neither appropriately assessed nor treated for osteoporosis[3–4].
**Objectives:** To assess compliance in screening for secondary causes of osteoporosis in all patients admitted with Neck of femur (NOF) fracture, comparing this to local CCG (Clinical Commissioning Group) guidelines.
**Methods:** Retrospective data collection from electronic records of all patients admitted from May- July 2015 who sustained a NOF fracture. Data was collected re: screening for myeloma, hyperparathyroidism, coeliac and thyroid disease, with baseline full blood count, liver function tests, renal function, Vitamin D, bone profile and testosterone within 48hours of admission.
**Results:** A total of 85 patients were identified as having sustained a NOF fracture during this period. 68% were female. The majority were postmenopausal (mean age: 85yrs; range: 73–99 yrs). Full blood count and renal function were performed in all, liver function tests in 64% and bone profile and vitamin D in 36% and 34% respectively. C-reactive protein was performed in 40% vs ESR in 1.2%. Only 3 and 4 patients were assessed for parathyroid and thyroid dysfunction respectively. No patient was fully screened for myeloma or coeliac disease. Of the 27 male patients all were over 70years old and none had their testosterone levels checked.
**Conclusions:** Overall, recommended screening tests for osteoporosis were inconsistent and incomplete, which is in keeping with the current literature. Patients that were cared for in the orthopaedic and geriatric setting who have sustained a NOF fracture should have the above baseline tests.
We have recommended a single tick box to encompass the above "osteoporosis bloods" on our electronic requesting system. All patients with a confirmed fracture should also be referred to our fracture liaison nurse for further evaluation and instigation of treatment. Junior doctors undergoing an orthopaedic rotation should have training in evaluating for secondary causes of osteoporosis.

## THU0476 EFFICACY OF DENOSUMAB FOR THE TREATMENT OF OSTEOPOROSIS IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

K. Oh[1,2], O. Namiki[3], Y. Toyoshima[4], K. Inagaki[5], K. Kanbe[6], J. Chiba[6]. *[1]Orthopedic, Showa University Northern Yokohama Hospital, Yokohama; [2]Orthopedic and Rheumatology, Tokyo Women's Medical University Medical Center East, Tokyo; [3]Department of Orthopedic, Showa University Northern Yokohama Hospital, Yokohama; [4]Orthopedic, Showa University; [5]Department of Orthopedic, Showa University school of medicine; [6]Department of Orthopedic and Rheumatology, Tokyo Women's Medical University Medical Center East, Tokyo, Japan*

**Background:** Recent studies have reported that RA patient with osteoporosis administered Denosumab (DMAB) was associated with significant increases of low bone mineral density (BMD) at lumbar spine and femoral neck.
DMAB increases cortical bone more effective than any other drug for treatment of osteoporosis.
**Objectives:** Therefore, we investigated efficacy of DMAB in the patient with RA for 12 months at lumbar spine, femoral neck, and radius.
**Methods:** Sixty RA patients with osteoporosis were administered DMAB between April 2014 and October 2015, 45 patients were evaluated for 12 months in our institute. The following items were examined just before administered and at the time of 6 months and 12 months after administration: BMD of lumbar/femur/radius, Biomarker (total P1NP, TRACP-5b), radiograph of the hand.
Also, comparisons were performed on the basis of efficacy of DMAB at the time of 12 months in radius between the patients with the poorly effected group (NR group), and the patients with the well-effected group (R group).
**Results:** After treatment of DMAB at 12 months, 5.2 percent increase of BMD at the lumbar spine was obtained, 4.2 percent increase at the femoral neck.
However, there was not significant change at the distal third of the radius.
Comparing the NR group to the R group, there was statistically significant difference in Larsen grade at the wrist.
**Conclusions:** DMAB significantly increases bone mineral density in the patient with RA.
However, in the patient with severe joint destruction, DMAB could not increase BMD at the radius.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.1128

## THU0477 EFFECT OF RECENT SPINAL CORD INJURY ON THE OPG/RANKL SYSTEM AND ITS RELATIONSHIP WITH BONE LOSS AND ANTIOSTEOPOROTIC RESPONSE TO DENOSUMAB THERAPY. PRELIMINARY RESULTS

L. Gifre[1], J. Vidal[2], S. Ruiz-Gaspà[3], E. Portell[2], A. Monegal[1], A. Muxi[4], N. Guañabens[1], P. Peris[1]. *[1]Metabolic Bone Diseases Unit. Rheumatology Department, Hospital Clinic Barcelona, Barcelona; [2]Spinal Cord Unit, Neurorehabilitation Institute Guttmann, Badalona; [3]CIBERehd; [4]Nuclear Medicine Department, Hospital Clinic Barcelona, Barcelona, Spain*

**Background:** Spinal cord injury (SCI) has been associated with a marked increase in bone loss and bone remodeling, especially short-term after injury. However, the pathogenesis and clinical management of this process remain unclear, as well as the role of the key regulators of bone remodeling, the OPG/RANKL system.
**Objectives:** To analyze the role of the regulators of bone remodeling, OPG and RANKL, in the bone loss associated with recent SCI as well as the effect of antiosteoporotic therapy with denosumab in these bone regulators in a prospective study.
**Methods:** Twenty-three male patients (aged 18 - 67 years [mean 36 ± 16 years]) with recent (<6 months) complete SCI were prospectively included (43.5% paraplegic, 56.5% tetraplegic). Patients were followed every 6 months. All patients received calcium and vitamin D supplementation. Antiosteoporotic therapy with denosumab was recommended when patients developed densitometric osteoporosis during follow-up. Serum levels of OPG and RANKL (Biomedica, Vienna, Austria), bone turnover markers (PINP, bone ALP, sCTX) and bone mineral density (BMD) at the lumbar spine and total hip were assessed at baseline (99±30 days after SCI), prior to initiating antiosteoporotic treatment (14±4 months post-SCI) and during antiosteoporotic therapy with denosumab (6 months after initiating treatment). The results were compared with a healthy control group.
**Results:** At baseline, SCI patients showed a significant increase in RANKL serum levels compared to controls (3.4±1.7 vs. 2.3±1.6 pg/mL, p=0.022) which correlated with days-since-SCI (r=0.589, p=0.005) and became undetectable after denosumab treatment in 67% of the patients (p=0.001). OPG serum levels were similar to controls at baseline (87.7±38.7 vs. 71.7±25.4, p=0.1) and did not change with denosumab treatment. No differences were observed in RANKL and OPG levels on comparing tetraplegic vs. paraplegic patients. Neither were RANKL or OPG levels related to the increase in bone loss and bone turnover markers after SCI. Patients with undetectable RANKL serum levels after denosumab treatment did not present further sublesional bone loss but increased total hip BMD (+2.5±1.3%, p=0.005), and bone markers markedly decreased (PINP: -53%, p=0.007; sCTX: -68%, p=0.005).
**Conclusions:** This study shows that short-term after SCI there is an increase in RANKL serum levels which become undetectable after denosumab treatment. The preventive effect of denosumab on sublesional bone loss further suggests a contributory role of RANKL in this clinical process.

## THU0478 ASSESSING COMPLIANCE WITH ROYAL COLLEGE OF PHYSICIANS GUIDELINES IN GCA/PMR PATIENTS WITH GLUCOCORTICOID INDUCED OSTEOPOROSIS

L. Curran[1], D. Aggarwal[2], K.M. Achilleos[3], A. Bharadwaj[4], A. Nandagudi[4]. *[1]Chelsea & Westminster Hospital; [2]Charing Cross Hospital, London; [3]Rheumatology Department, Southend University Hospital; [4]Rheumatology Department, Basildon University Hospital, Essex, United Kingdom*

**Background:** The Royal college of physicians (RCP) guidelines recommend that all patients placed on long term glucocorticoids (GCs) are at risk of osteoporosis, especially when the dose exceeds ≥10mg of Prednisolone or equivalent for >3months[1]. Patients with Giant cell arteritis (GCA) and Polymyalgia Rheumatica (PMR) are particularly at risk.
**Objectives:** To assess our departmental compliance with the RCP guidelines for glucocorticoid induced osteoporosis (GIO) published in 2002. Following review of the International Osteoporosis Foundation and the European Calcified Tissue Society and American college of Rheumatology (ACR) guidelines for GIO, we also looked into use of FRAX tool for risk assessment.

**Methods:** Retrospective data collection of 50 patients diagnosed with either GCA or PMR was selected at random since 2010. Documentation of smoking history, alcohol intake, height and weight, history of falls and started dose of GCs were also noted. Data regarding DXA results, other imaging e.g. spinal x-rays, biochemistry and the use of the FRAX assessment tool were obtained. The use of bisphosphonate, calcium/vitamin D supplementation and steroid sparing agents were also recorded.
**Results:** The majority of the patients were postmenopausal (mean age 75.2years, Range: 59–92) females (68%) with a diagnosis of PMR (72%). Ninety percent were over the age of 65years. The modal starting dose was 60mg of prednisolone in GCA patients and 15mg in those with PMR. Nine patients (18%) were identified as having an additional risk factor for osteoporosis such as thyrotoxicosis or premature menopause. History of falls was documented in 22%. Fourteen percent had a prior history of fragility fracture, of those 2% were <65years of age. Steroid sparing agent (Methotrexate (18%) and azathioprine (10%)) was commenced in 28%. None of the patients had a baseline FRAX assessment. Calcium and vitamin D supplementation was prescribed in 90%, of which 78% had this checked prior to administration. Adherence for bone protection was documented in 44%.
**Conclusions:** The documentation of risk factors and DXA requests was inconsistent for various age groups. Bone protection was commenced in the majority of patients; especially calcium and vitamin D were prescribed in almost all patients. Based on the RCP guidelines, International Osteoporosis Foundation and the European Calcified Tissue Society and ACR guidelines for GIO, local departmental guidelines have been designed to ensure appropriate investigations and bone protection is considered all these patients. There is a need for new national guidelines incorporating FRAX tool.

## THU0479 PILOT STUDY OF BONE MASS IN HEART TRANSPLANT RECIPIENTS

L. Bautista Aguilar[1], A. Salmoral Chamizo[1], I. Gomez-Gracia[1], R. Jimenez Gasco[1], P. Font[1], J.M. Arizon[2], M. Ruiz Ortiz[2], E. Collantes Estévez[1].
*[1]Department of Rheumatology, Reina Sofia University Hospital; [2]Heart Transplant Unit, Reina Sofía University Hospital, Cordoba, Spain*

**Objectives:** Our objective was to describe changes in bone mineral density (BMD), incidence of fractures and levels of bone remodeling markers in the first year post-heart transplant (postHTX).
**Methods:** We included patients aged ≥18 years with heart transplant performed in our institution from 01.01.2013 to 31.07.2015, excluding those on antiresorptive or bone forming treatment and pregnant women. Before heart transplant (preHTX) and in the one year postHTX visit, the following data were registered: body mass index, risk factors for osteoporosis, biochemical parameters of bone metabolism, presence of osteopenia or osteoporosis in the densitometric analysis of lumbar spine and femoral neck, presence of fractures in the X-ray of the spine and echocardiographic left ventricular ejection fraction (LVEF).
**Results:** All 17 patients (age 48±16 years, 12 male) included in the study were treated with calcineurin inhibitors and steroids (mean dose 15 mg/day). At the preTX visit, body mass index was 24,7±3,8 kg/m$^2$, obesity was present in 4 patients, DM in 1, kidney stones in 3, excessive alcohol consumption in 1, and 11 patients were ex-smokers. Low BMD was present in 14/17 patients (82%) in the preTX visit: 12 osteopenia (8 men and 4 women) and 2 osteoporosis (1 man and 1 woman); and 15/17 patients (88%) in the one year postTX visit: 9 osteopenia (6 men and 3 women) and 6 osteoporosis (3 men and 3 women). One patient died before the first year postHTX visit. Twelve patients (80%) had a vitamin D blood level <20 ng/ml at the one year postHTX visit. A man presented a spinal fracture in the follow-up. Mean LVEF was 25±6% (preHTX) and 75±8% (postHTX).
**Conclusions:** In this pilot study, 82% of heart transplant recipients had a low BMD preHTX and 88% at the one year postHTX visit. Moreover, 80% of patients had a vitamin D deficiency at the one year postHTX visit. Larger studies are required to fully evaluate this morbidity and describe clinical predictors.

## THU0480 COMPARATIVE EFFECTIVENESS OF EDUCATIONAL PROGRAMS FOR OSTEOPOROSIS

L.P. Evstigneeva[1], O. Lesnyak[2]. *[1]Department of Rheumatology, Sverdlovsk Regional Hospital #1, Ekaterinburg; [2]Department of Family Medicine, Northwestern State Medical University, Saint Petersburg, Russian Federation*

**Background:** Educational programs may be beneficial in a variety of important factors for the prevention, treatment and management of osteoporosis.
**Objectives:** To evaluate the influence of the three different educational interventions on knowledge, dietary calcium, physical activities and adherence to treatment of osteoporosis.
**Methods:** 117 patients (middle age 63.3 ± 8.1 years old, 95.7% are women) with osteoporosis have been included in this study. All patients were randomized to three groups. The patients of intervention group (n=39) had an osteoporosis school program (4 lessons with using interactive methods in groups of sevens to tens). The patients of the control group (n=38) received brochures with general information about osteoporosis. The patients of the comparison group (n=40) received lecture (1 x 1.5 h) about osteoporosis. Average changes from baseline in knowledge, dietary calcium, physical activities and time of physical exercises was evaluated in 3, 6 and 12 months. Adherence to treatment was evaluated in 12 months.
**Results:** After educational programs level of knowledge was increased in patients of the intervention group in 3, 6 and 12 months by 23,8%, 22,9%, 21,1%, in the group of brochures – by 0.5%, 1.8%, 4.7%, correspondingly, $p<0.01$. In the group received lecture level of knowledge was increased by 18.0%, 15.8%, 14.6% ($p<0.05$ when compared with the brochure at visits 3 and 6 months). The use of dietary calcium was increased in 3, 6 and 12 months in the intervention group by 188.5 mg, 211.8 mg and 238.1 mg, in group received lecture by 146.8 mg, 106.4 mg, 84.4 mg, in control group received brochures by 66.0 mg, 80.4 mg and 68.3 mg ($p<0.05$ when compared intervention group with the control group at visits 3 months). Physical activity was increased in 3, 6 and 12 months in intervention group by 1.7, 1.9, 0.9 scores and was significantly higher, than in group received lecture (0.2, 0.2, 0.1 scores) and in control group received brochures (0.1, 0.2, 0 scores). Time of physical exercises was increased by 45.1, 54.2 and 49.9 min in week in the intervention group and was significantly more than in the groups received lecture or brochures. Adherence to pathogenetic osteoporosis treatment was higher in the intervention group: 56.4% of intervention group, and 30.0% of the group received lecture, and 13.2% of group received brochures took pathogenetic medication regularly during the year ($p<0.01$ when compared the intervention group with the control group).
**Conclusions:** Educational program with using interactive methods in small groups increases knowledge about of osteoporosis, dietary calcium, physical activities and increases adherence to treatment of pathogenetic medication more than brochure and lecture.

## THU0481 PREVALENCE OF ASYMPTOMATIC MORPHOMETRIC VERTEBRAL DEFORMITIES IN HIV-INFECTED PATIENTS

M. Llop Vilaltella[1], W.A. Sifuentes Giraldo[1], M. Vázquez Díaz[1], C. Medina Quiñones[1], C.C. Macía Villa[1], S. Bañón-Escandell[2], J.L. Casado Osorio[2].
*[1]Rheumatology; [2]Infectious Diseases, University Hospital Ramon y Cajal, Madrid, Spain*

**Background:** Patients infected with the human immunodeficiency virus (HIV) have a high rate of low bone mineral density (BMD) of multifactorial origin, that involve traditional risk factors, activity of the infection and highly active antiretroviral therapy (HAART). An increased risk of fractures has been reported in these patients but few studies have estimated the true prevalence of asymptomatic morphometric vertebral deformities (MVD).
**Objectives:** To determine the prevalence of MVD in HIV-infected patients followed in a Spanish tertiary center, taking into account both traditional risk factors as those associated with their underlying disease.
**Methods:** We performed a cross-sectional study in HIV-infected patients with age 50 years treated in our center during the period 2014–2015. Demographics and traditional risk factors were collected through a specific survey. BMD was determined by X-ray absorptiometry dual-energy (DXA) at the lumbar spine and hip. Blood and urine samples were collected for biochemical analysis of bone metabolism. WHO definitions were used to classify DXA results. MVD were assessed on lateral X-rays of thoracic and lumbar spine using the Genant's semiquantitative method: 1) reduction of any height of the vertebral body between 20–25%: grade I (mild); 2) between 26–40%: grade II (moderate); and 3) >40%: grade III (severe).
**Results:** A total of 75 patients were included, 54 males (72%), with a mean age of 54.8 years (range: 50–70). MVD was detected in 15 cases (20%): 4 grade I, 6 grade II and 5 grade III. All patients received HAART during the study period. Femoral neck BMD was normal in 39%, 52% were in range of osteopenia and 9% osteoporosis. Variables independently associated with development of MVD were female gender (13% vs 31%, p=0.13), daily calcium intake (490 mg/d vs 594 mg/d, p=0.16), serum phosphorus (2.79 mg/dL vs 3.17 mg/dL, p=0.02) and low BMD in total hip (0.69 vs 0.75, p=0.05) (Table 1). Significant association was also found with disease duration (mean time in patients with MVD: 264.7 months,

p=0.09). No correlation was found with age, a fact that can be attributed to limited sample size and age of patients (50–70 years).

Table 1. Comparison of the characteristics of HIV-infected patients with and without MVD

| | VMD (n=15) | Non-VMD (n=60) | p-value |
|---|---|---|---|
| Mean age (years) | 53,5 | 51,4 | 0,24 |
| Female gender | 13% | 31% | 0,13* |
| Body mass index | 24,3 | 23,9 | 0,93 |
| Nadir CD4+ level | 254 | 191 | 0,12 |
| Duration of HIV infection | 264,7 | 227,2 | 0,09* |
| Total length of HAART | 206,3 | 184 | 0,32 |
| BMD total hip | 0,69 | 0,75 | 0,05* |
| T-score femoral neck | –1,63 | –1,1 | 0,03* |
| Osteopenia/osteoporosis femoral neck | 85% | 55% | 0,02* |
| BMD lumbar spine | 0,88 | 0,89 | 0,48 |
| T-score lumbar spine | –1,8 | –1,6 | 0,63 |
| Osteopenia/osteoporosis lumbar spine | 85% | 59% | 0,08* |
| Vitamin D3 level | 33,4 | 32,6 | 0,81 |
| Parathormone level | 52,7 | 51,8 | 0,82 |
| Serum phosphorous level | 2,79 | 3,17 | 0,02* |
| Serum calcium level | 9,71 | 9,53 | 0,54 |
| Daily calcium intake | 490 | 594 | 0,16* |
| Previous peripheral fractures | 27% | 35% | 0,76 |
| Family history of hip fracture | 7% | 10% | 0,69 |

**Conclusions:** We found a high prevalence of asymptomatic MVD in our series (20%). X-rays of thoracic and lumbar spine should be performed as a screening method in HIV-infected patients with risk factors, such as long-term infection, low calcium intake, low serum phosphorus levels and female gender.

## THU0482 PREDICTORS OF FRACTURES IN PATIENTS WITH UNTREATED EARLY MENOPAUSE: AN OBSERVATIONAL STUDY

M.H. Dobrzynska[1], R. Sinha[2], M. Bukhari[3]. *[1]Medical School, Lancaster University, Lancaster; [2]Salford Royal Hospital, Salford; [3]Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom*

**Background:** A previous case-control study demonstrated that untreated early menopause (menopause before 45 years of age) predisposes to a lower bone mineral density (BMD) at the femoral neck and the lumbar spine and that the condition increases ten year risk of sustaining a major osteoporotic fracture (1). However, less has been published on the predictors of fractures within this group of patients.
**Objectives:** This study aims to investigate the predictors of fractures in patients with untreated early menopause.
**Methods:** A cohort of patients attending for a DEXA scan in the North-West of England between June 2004 and July 2013 who were diagnosed with untreated early menopause was identified. These patients were divided into two groups: women with a history of post-menopausal fragility fracture and women with no history of fragility fracture. Characteristics of these two groups were compared using the chi squared test for categorical variables and stduents T test for continuous variables. Logistic models were used to describe the associations between known risk factors of fracture (FRAX risk factors and BMD, adjusting for the time from menopause).
**Results:** A total of 2,171 females with untreated early menopause were included in the study. The mean age was 63.56 (±SD12.57). The mean age at menopause was 41.12 (±SD3.85) and the mean years from menopause was 22.44 (±SD12.54). Of those women, 1308 (60.25%) had no fractures and 863 (39.75%) had a fracture. The age at scan of patients with a fracture (66.79±11.50) was significantly different from the age of patients without a fracture (61.43±12.70), p-value 0.000. The mean years from menopause was significantly different in the fracture group (25.84±11.70) as compared to the group without fractures (20.19±12.58), p-value 0.000. The body mass index, age at menopause, history of smoking, rheumatoid arthritis as well as alcohol use were not significantly different between the two groups. The mean femoral neck BMD was significantly lower in females with fracture than those with no fracture: 0.79g/cm$^2$ vs. 0.84g/cm$^3$, respectively, p-value 0.000. The mean lumbar BMD was significantly lower in fracture patients as compared to patients without fractures: 0.97g/cm$^2$ vs. 1.04g/cm$^2$, respectively, p-value 0.000. Prevalence of steroid use was relatively higher in patients without fractures as compared to those with fractures: 22.63% and 17.61% respectively, p-value 0.005. Logistic regression analysis, adjusted for age at scan and years from menopause, revealed a significant association between having a fracture and steroid use OR0.70 (95% CI 0.55, 0.88) as well as between having a fracture and having lower BMD in the lumbar spine OR 0.24 (95% CI 0.13, 0.47).
**Conclusions:** This study demonstrates that steroid use and low lumbar BMD, but not other FRAX predictors, are associated with fracture in patients with an early untreated menopause. These observations can guide measures on enhancing bone health in this patient group.

## THU0483 INCREASED INFECTION RISK WITH CONCOMITANT USE OF RANKL-INHIBITOR, DENOSUMAB AND TNF-INHIBITORS OR OTHER BIOLOGICS: FACT OR FICTION?

P.S. Chhibar, G. Ehresmann. *Rheumatology, Internal Medicine, Keck School of Medicine, University of Southern California, Los Angeles, United States*

**Background:** Patients with autoimmune diseases are at increased risk of early onset osteoporosis because of prolonged exposure to corticosteroids. RA patients may also develop early-onset osteoporosis secondary to the disease process itself. Same patients are more likely to be on TNF inhibitors or other biologics which cause them to be at an increased risk of infections. Denosumab is an anti-RANK ligand inhibitor used to treat osteoporosis. Receptor activator of nuclear factor kappa-B ligand (RANKL) is also expressed on activated T and B lymphocytes. Therefore, a RANKL inhibitor such as denosumab may increase the risk of infections.(1) In the Freedom Trial, the denosumab group reported more serious infections leading to hospitalization than in the placebo group.(1) It is unknown if biologic agents will increase the risk of infections when denosumab is used concomitantly.
**Objectives:** To determine rate of infections in patients on combination therapy with denosumab and either TNF inhibitors or other biologics.
**Methods:** We identified 40 patients in the rheumatology clinic on denosumab and either a TNF inhibitor or a biologic agent for 1 to 4 years. A retrospective chart review was conducted at the Keck Medical Center of USC to record if the patients developed infections.
**Results:** The mean age of the population was 65 ± 20 years, among which 98% were females. 75% had Rheumatoid Arthritis (RA), 10% Systemic lupus erythematosus (SLE), 2.5% SLE and Sjogren's, 2.5% SLE with Antiphospholipid Syndrome (APLS), 2.5% RA and SLE, 2.5% Microscopic Polyangiitis, 2.5% Psoriatic arthritis, and 2.5% Neurologic Behcet's disease. Prior to initiation of denosumab, patients either failed bisphosphonate therapy or became intolerant. The addition of denosumab showed a trend of improvement of T scores in lumbar spine and hip. 40% of our patients developed some infection, which is lower than 52.9% in the FREEDOM trial.(1) 70% (28/40) patients were on TNF inhibitors. 35% of these developed infections. 30% (12/40) patients were on other biologic agents. 50% of these patients developed infections. Urinary tract infection (UTI) accounted for the most common infection (12%). 12% of our patients required hospitalization for infections, compared to 4% in the Freedom trial. 17.5% of these had developed infections before denosumab. 9% had been hospitalized before denosumab for infections.

| Infections | Infection rate x/n (%) | Average time to develop infections (months) |
|---|---|---|
| Overall rate | 16/40 (40%) | |
| UTI | 5/40 (12.5%) | 15 |
| Bronchitis/Pneumonia | 4/40 (10%) | 16 |
| Wound infection | 3/40 (7.5%) | 16 |
| Sialadenitis | 1/40 (2.5%) | 28 |
| Herpes Zoster/HSV-II | 3/40 (7.5%) | 17 |

**Conclusions:** In conclusion, data from this study demonstrates that 40% patients developed infections. However, 17.5% of patients who developed infections in our study had developed infections before starting denosumab. It is therefore unclear weather the overall infection rate can be attributed solely to the combination of denosumab and biologics. Since we did not see any infections within the first year, there may be a cumulative effect of increased infection risk, if any. Antibiotic prophylaxis, while on denosumab and biologics, may be considered in patients with recurrent infections in the past.

## THU0484 ZOLEDRONIC ACID INFUSION AND EFFECT ON RENAL FUNCTION AND CALCIUM IN OSTEOPOROSIS

R. Laxminarayan[1], N. Sayed[1], M. Nisar[1], G. Swamy[2], H. Rachael[1]. *[1]Rheumatology, Queen's Hospital, Burton on Trent; [2]Orthopaedics, Royal Derby Hospital, Derby, United Kingdom*

**Background:** Zoledronic acid is a commonly used intravenous bisphosphonate. Predominantly it is excreted through the kidney. Use of zoledronic acid is contra-indicated in patients with eGFR of <30. Effect of zoledronic acid on kidney function after repeated infusions in a real life scenario is not well described. Zoledronic acid related hypocalcaemia is well recognized. But frequency of this complication in real life and its link to renal function has not been studied.
**Objectives:** The aim of our study was to assess the effect of zoledronic acid on

the renal function, calcium level and link between renal function and calcium level in patients treated with yearly zoledronic acid infusion for primary or secondary prevention of fractures in osteoporosis.

**Methods:** A retrospective review of patients receiving zoledronic acid infusions between August 2008 and August 2015 was carried out. Patients receiving the treatment for osteoporosis and who had received at least one infusion were included. All the patients had calcium level and renal function measured before and a week after the infusion. Calcium level >2.5 mMol/L was considered elevated and <2.1 as low. The e GFR measures were classified into categories of >60 (normal), 45–59 (mild impairment) and 30–44 (moderate impairment). Pre and post infusion calcium values were matched to assess the effect on the calcium. Parametric analysis was carried out to compare the means.

**Results:** 200 patients were identified on the database. 175 patients were analysed based on our inclusion criteria. 175 patients received 354 infusions. Baseline eGFR, calcium and post infusion eGFR and calcium levels are detailed in the table below. There was no significant difference between pre and post infusion eGFR or calcium levels. We also did not find any significant correlation between baseline eGFR and post infusion calcium level.

| | eGFR | | Calcium (mmol/L) | | p |
|---|---|---|---|---|---|
| | Pre infusion | Post infusion | Pre infusion | Post infusion | |
| 1st infusion (n=175) | 60.505 (41.7–90) | 60.326 (36.6–90) | 2.399 (1.98–2.75) | 2.342 (1.91–2.88) | >0.5 |
| 2nd infusion (n=103) | 58.09 (36.6–76.5) | 60.129 (28.4–90) | 2.386 (2.21–2.74) | 2.369 (2.1–2.88) | >0.5 |
| 3rd infusion (n=76) | 60.187 (35.5–88.5) | 58.808 (37.8–83.6) | 2.380 (2.16–2.7) | 2.360 (2.13–2.66) | >0.5 |

**Conclusions:** 1. Only one patient's post infusion eGFR dropped to 28.4 after the second infusion. This improved to baseline a week later.

2. Only one patient had calcium below 2.1 post infusion (1.91). The post infusion calcium returned to normal after a week.

3. There was no significant drop in post infusion eGFR compared to baseline particularly in those who had mild or moderate renal impairment.

4. Calcium level did not come down significantly following zoledronic acid infusion.

5. Baseline eGFR had no significant effect on post-infusion calcium level.

6. This real life experience reinforces the safety of zoledronic acid infusion outside trial environment.

## THU0485 AN ADVANCED ECHOSOUND APPROACH FOR FEMORAL NECK DENSITOMETRY

M. Muratore[1], F. Conversano[2], M. Peccarisi[3], P. Pisani[2], T. De Marco[3], R. Franchini[2], E. Casciaro[2], E. Quarta[1], L. Quarta[1], O.E. Casilli[1], S. Casciaro[2]. *[1]Rheumatology, "Galateo" Hospital, San Cesario di Lecce, ASL-LE; [2]Institute of Clinical Physiology, National Research Council; [3]Echolight srl, Lecce, Italy*

**Background:** Dual X-ray absorptiometry (DXA) currently represents the most common method for osteoporosis diagnosis and it is considered the gold standard for bone mineral density (BMD) measurements. However, DXA has also some important limitations that prevent its use for population screenings and this has led to the investigation of alternative ultrasound (US) approaches. In this context, we have recently introduced a new US methodology for osteoporosis diagnosis, which is based on a closely integrated processing of echographic images and corresponding "raw" radiofrequency (RF) signals ("echosound approach" [1]). The basic idea underlying this approach is that the RF signals acquired during an echographic scan of the investigated bone district can be employed to assess the bone health status through comparisons with previously derived reference spectral models. The implemented RF signal analysis method is also integrated with echographic imaging, which provides both the identification of the regions of interest and the simultaneous acquisition of a statistically significant number of US signals for each frame.

**Objectives:** To assess the accuracy of an advanced echosound approach, which was specifically tailored and optimized for femoral neck densitometry.

**Methods:** A total of 289 female patients (55–80 y) underwent both a femoral DXA and an echographic scan of proximal femur. Specific attention was paid to ensure adherence to correctness criteria for DXA scanning and data analysis as reported in the guidelines of the International Society for Clinical Densitometry [2]. The algorithm adopted for US data analysis was based on the echosound approach and included an additional dedicated signal compensation, which was specifically implemented to better account for the physiological variability in soft tissue thickness and corresponding US attenuation. The diagnostic agreement between DXA and US was assessed by accuracy calculation, Cohen's *k*, Pearson correlation coefficient (*r*), root mean square error (*RMSE*), and Bland-Altman analysis, whereas the method precision was assessed by the root mean square (*RMS*) average of the *SD* (*RMS-SD*) of repeated measurements, the root mean square coefficient of variation (*RMS-CV*), and the least significant change for a 95% confidence level (*LSC95*).

**Results:** By assuming DXA output as the gold standard reference, the overall US accuracy in patient classification was 93.1% ($k$ =0.882, $p<0.0001$). A strong correlation was also found between US-estimated BMD values and DXA-measured ones ($r$ =0.86, $p<0.001$), with a low residual error (*RMSE* =0.044 g/cm$^2$). The average difference between paired BMD measurements was -0.002 ± 0.089 g/cm$^2$ (bias ± 2 SDs). US method precision, expressed as *RMS-SD*, resulted to be 0.003 g/cm$^2$ (*RMS-CV* =0.29%; *LSC95* =0.008 g/cm$^2$).

**Conclusions:** The proposed echosound approach for femoral neck densitometry showed an excellent agreement with corresponding DXA diagnoses and an optimal measurement reproducibility, indicating a potential for an effective clinical routine adoption.

## THU0486 PERSISTENCE WITH ANTI-OSTEOPOROTIC THERAPY IN PATIENTS WITH RHEUMATIC DISEASE

S. Mizuki, K. Kushimoto, H. Yamasaki, K. Yoshida, K. Oryoji, K. Kamada, E. Yokota. *The Centre for Rheumatic Diseases, Matsuyama Red Cross Hospital, Matsuyama, Ehime, Japan*

**Background:** Osteoporotic fragility fractures decrease physical performance and disability-free life expectancy. Patients with rheumatic disease develop osteoporosis due to local cytokine production, low levels of physical activity, and glucocorticoid therapy. Rheumatologists need to proactively manage osteoporosis in patients with rheumatic disease to extend their healthy and disability-free life years. While studies have reported that approximately 50% of postmenopausal patients with osteoporosis discontinue anti-osteoporotic therapy within 1 year, there is a paucity of data on treatment continuation and discontinuation in patients with rheumatic disease.

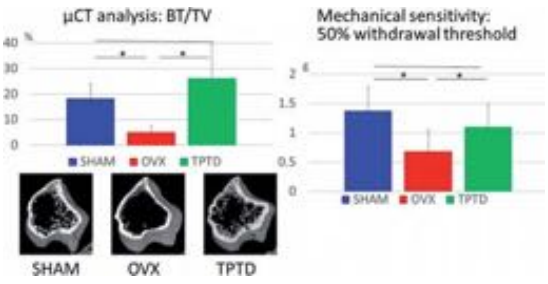
We conducted a retrospective analysis of the status of oral anti-osteoporotic therapy in patients with rheumatic disease using the prescription database at a single rheumatology specialty center from June 2007 to May 2010, a period before teriparatide, a recombinant form of parathyroid hormone, and denosumab, a monoclonal antibody to receptor activator of nuclear factor kappa B ligand, were approved for clinical use.

**Objectives:** To estimate persistence with oral anti-osteoporotic therapy in patients with rheumatic disease and identify factors influencing the persistence and reasons for discontinuation.

**Methods:** Based on prescription database, we identified patients who started treatment with alendronate, risedronate, or selective estrogen receptor modulators during the study period. Patients who continued treatment after June 1, 2010, were "censored". Patients who did not receive a prescription for 190 or more days during the study period were classified as "discontinued". Persistence were estimated using Kaplan-Meier survival analysis. Multivariate Cox proportional hazard analysis was carried out to identify factors influencing the persistence. Reasons for discontinuation were abstracted from medical charts.

**Results:** Analysis of prescription database identified 557 patients (477 females and 80 males). Of these, 378 had rheumatoid arthritis, and 112 had systemic lupus erythematosus, dermatomyositis, systemic sclerosis, vasculitis syndrome, or other connective tissue diseases. Mean age at the start of anti-osteoporotic therapy was 62.1 years, and 481 patients (86.4%) received a mean prednisolone dose of 8.4 mg/day. Persistence with anti-osteoporotic therapy was 71.9%, 61.1%, 50.1% after 1, 2, and 3 years, respectively. Factors associated with persistence were the diagnosis of connective tissue disease and use of glucocorticoids. Among patients who discontinued therapy, the most frequent reason for discontinuation of anti-osteoporotic therapy was onset of adverse events (32.4%).

**Conclusions:** Patients with rheumatic disease receiving anti-osteoporotic therapy had a higher persistence than postmenopausal patients with osteoporosis. These results suggest that rheumatologists should take a proactive stance on managing osteoporosis in patients with rheumatic disease.



**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4191

## THU0487 TERIPARATIDE IMPROVED BONE LOSS AND HYPERALGESIA IN A MOUSE MODEL OF OSTEOPOROSIS

S. Kato[1,2], H. Wakabayashi[2], Y. Naito[2], G. Miyamura[2], A. Sudo[2]. *[1]Orthipaedic surgery, Ise Red Cross Hospital, Ise city Mie; [2]Orthipaedic surgery, Mie University Graduate School of Medicine, Tsu city-Mie, Japan*

**Background:** Osteoporosis may cause not only fractures but also chronic back pain in elderly women. Bente reported that postmenopausal women with severe osteoporosis who were prescribed teriparatide (TPTD) in standard clinical practice had a reduction in back pain. However, there have been no reports regarding the effect of TPTD on pain in animal models of osteoporosis.
**Objectives:** The objective of the current study was to investigate the effect of TPTD on pain-related behavior in ovariectomized (OVX) mice.
**Methods:** Female ddY mice (8 weeks old) were ovariectomized and assigned to 3groups; SHAM-operated mice treated with vehicle (SHAM), OVX mice treated with vehicle (OVX), OVX mice treated with TPTD (TPTD).
Starting immediately after surgery, vehicle or 40μg/kg TPTD was injected subcutaneously 5 times a week for 4 weeks.
The proximal tibial metaphysis were analyzed three-dimensionally by μCT 4 weeks after surgery (each group; 8 mice).
Mechanical sensitivity was tested using von Frey filaments 4 weeks after surgery. To evaluate the withdrawal threshold, each von Frey filaments was applied once, starting with 0.008g and increasing until a withdrawal response was reached, which was considered a positive response. The lowest force producing a response was considered the withdrawal threshold. To evaluate the 50% withdrawal threshold, seven von Frey filaments were applied to the middle of the plantar surface. Testing was initiated with the 0.6g filament. In the absence of a clear paw withdrawal response, increasingly stronger filaments were presented consecutively, until one of them was found to elicit such a response. If the 0.6 g filament elicited a response, filaments with decreasing strength were presented until determination of the first one which failed to cause paw withdrawal. Data was collected using the up-down method.
To identify osteoclasts in hindlimb bone, we used the tartrate-resistant acid phosphatase (TRAP) method. TRAP-positive multinucleated cells were scored as osteoclasts. Measurements were made within an area the proximal tibial metaphysis starting immediately below the growth plate. Histomorphometry was conducted to quantify the number of osteoclasts.
**Results:** μCT analysis of the proximal tibial metaphysis showed that bone volume/tissue volume (BV/TV) and trabecular number (Tb.N) were significantly less in the OVX group than in the SHAM group, whereas trabecular separation (Tb.Sp) was significantly greater in the OVX group than in the SHAM group. In the TPTD group, BV/TV and Tb.N were significantly greater than in the OVX group, whereas Tb.Sp was significantly less than in the OVX group.
The withdrawal threshold was significantly lower in the OVX group than in the SHAM group, and it was significantly higher in the TPTD group than in the OVX group. Similarly, the 50% withdrawal threshold was significantly lower in the OVX group than in the SHAM group, and it was significantly higher in the TPTD group than in the OVX group.
The number of osteoclasts was significantly higher in the OVX group than in the SHAM group, whereas it was higher in the TPTD group than in the OVX group, but there were no significantly changes.

**Conclusions:** TPTD prevented ovariectomy-induced bone loss. In addition, mechanical hyperalgesia in hindlimbs significantly improved in OVX group compared with TPTD group. The results suggest that TPTD prevented postmenopausal osteoporotic pain.

## THU0488 NEW ZOLEDRONATE DATABASE SIGNIFICANTLY IMPROVES PRE-ASSESSMENTS AND WAITING TIMES TO REPEAT INFUSIONS – RESULTS FROM A QUALITY IMPROVEMENT PROJECT

S. Vasireddy, C. Allman, J. Farrant, M. Ammori, N. Khan, L. Bromilow. *Bolton NHS Foundation Trust, Bolton, United Kingdom*

**Background:** IV Zoledronate is used to treat osteoporosis patients who failed an oral bisphosphonate. Checking adjusted calcium (Ca), serum creatinine (Cr), estimated GFR, vitamin D and PTH before infusion can help optimise treatment outcomes. Previous audit demonstrated that our department was failing to reach 100% pre-infusion assessment (92% had Ca, Cr and eGFR; 85% Vitamin D and 74% PTH). Our previous zoledronate data was on an MS Excel spreadsheet with no audit or next due date functionality (service target: to deliver annual infusions within a month of due date). A database with these functionalities is not commercially available.
**Objectives:** We aimed to develop such a database, and demonstrate its Quality Improvement/audit functionality through analysis of waiting times to repeat infusions, and re-audit of pre-infusion assessments.
**Methods:** The new database was created in MS Access 2010 and introduced in Oct 14. Fields included Ca, Cr, eGFR, vit D and PTH. Functions were created to automatically generate next due date, and to view a list of patients in order of next due date. Waiting times were compared for repeat infusions before and after database was introduced. A proportion of all consecutive patients receiving infusions (first and repeat) since database started were selected for analysis of pre-infusion assessment. Biochemistry laboratory ranges were used for interpreting Ca (2.20–2.60mmol/l) and PTH (1.1–7.4 pmol/L); and to stratify total 25 hydroxy vit D (nmol/L; as used in previous audit: <25 = deficiency; 26–50 = insufficiency; 51–75 = adequate; 76–250 = optimal). EGFR (ml/min) was stratified according to the Chronic Kidney Disease stage (>90 = 1; 60–89=2; 30–59=3; 15–29=4; <15=5). Data were transferred to MS Excel 2010 for processing and descriptive statistics.
**Results:** 68 consecutive patients before Oct 14 and 65 consecutive patients from Oct 14 to Jan 16 who received repeat infusions were eligible for comparison. Improvements included more receiving infusion within target date (23.5% v 35.4%); and reduced waiting time (days) beyond target (mean 62.6 v 38.2; median 31 v 18). 35 consecutive patients who received zoledronate between Oct 14 and Feb 15 were identified for analysis of pre-assessments (27 women, 8 men; mean age 76.6±9.4yrs, range 52–91yrs). 35 (100%) had Cr and eGFR, 34 (97%) had Ca and vit D, and 25 (71%) had PTH. Mean Ca was 2.34±0.1mmol/l (range 2.2–2.59); Cr 88.5±17.4umol/l (59–122); eGFR 67.1±13.5ml/min (41–90); Vit D 77.2±30.5 (32–203) and PTH 5.1±2.3pmol/L (2–9.9). Vit D was deficient in 0, insufficient in 3 (8.8%), adequate in 15 (44.1%) and optimal in 14 (41.2%) (1 insufficient sample). eGFR was normal in 8 (22.8%); CKD2 in 19 (54.3%); CKD3 in 8 (22.9%) and none in CKD4 or 5.
**Conclusions:** Introduction of the purpose-built new database has achieved significant reduction in waiting times, and improvements in pre-infusion assessment (100% Cr and eGFR, and 97% Ca and Vit D compared to previous audit's 92% for Cr, eGFR and Ca and 85% for Vit D). The re-audit also confirmed overall improvement in Vit D levels (85% v 46% adequate or optimal), and 100% safety with respect to acceptable Ca and eGFR pre-infusion. We expect further improvements in waiting times for repeat infusions on a later re-audit when all patients entered on the database for first infusion complete a repeat infusion.

## THU0489 DAILY TERIPARATIDE TREATMENT AFTER BISPHOSPHONATE THERAPY IN OSTEOPOROSIS OF PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Hirano[1], M. Isono[1], J. Fukui[1], J. Hasegawa[1], N. Ishiguro[2], T. Kojima[2]. *[1]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [2]Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Ithough medication of rheumatoid arthritis (RA) has been improved by early intensive treatment using MTX and biological DMARDs for decades, treatment of concomitant disease in RA patients, such as osteoporosis (OP), will be more important to improve activity of daily living of RA patients. We reported efficacy of daily teriparatide (TPTD) on OP in RA patients in EULAR 2014[1)] and EULAR 2015[2)]. Although many drugs for OP treatment can be used in clinical practice, information of effect of switching drugs are lacking and needed. Better switching strategy in OP treatment are not well understood.
**Objectives:** This study investigated the efficacy of TPTD after bisphosphonate (BP) treatment in OP of RA patients (RA-OP).
**Methods:** 49 females with RA-OP were included in this study. 2 years had passed after the initiation of TPTD. 32 cases were treated using BP before TPTD (BP-G) and 17 cases were treatment-naïve or treated using only activated-vitamin D3 (N-G). Bone mineral density of lumbar spine (LSBMD) and total hip (THBMD) were measured every 6 month. Bone turnover markers (BTMs) were measured every 6 month (BAP, P1NP, NTX, TRACP-5b). Data were compared between BP-G and N-G.
**Results:** There were no significant differences in most of baseline characteristics between two groups except for CRP value at baseline (0.52mg/dl in BP-G and 0.68mg/dl in N-G).Used BPs were risedronate in 26 cases, alendronate in 4 cases and minodronate in 2 cases. There were no significant differences in LSBMD and THBMD at baseline between 2 groups. Baseline BAP in BP-G were significantly low compared with that in N-G (15.1μg/l vs. 18.6μg/l). Baseline NTX in BP-G were also significantly low compared with that in N-G (15.2 nmolBCE/L vs. 21.6 nmolBCE/L). P1NP and TRACP-5b were comparable between two groups. Mean LSBMD and THBMD in both group were significantly increased during TPTD treatment (Fig1). %increase of LSBMD and THBMD were compared between two groups and there were no significant differences (Fig2). Four BTMs

were increased during TPTD treatment in both group. Although there were no significant differences in % increase of BAP, P1NP and TRACP-5b during TPTD treatment, %increase of NTX in BP-G was significantly high compared with that in N-G (84.3% in BP-G and 57.4% in N-G at 6 month).

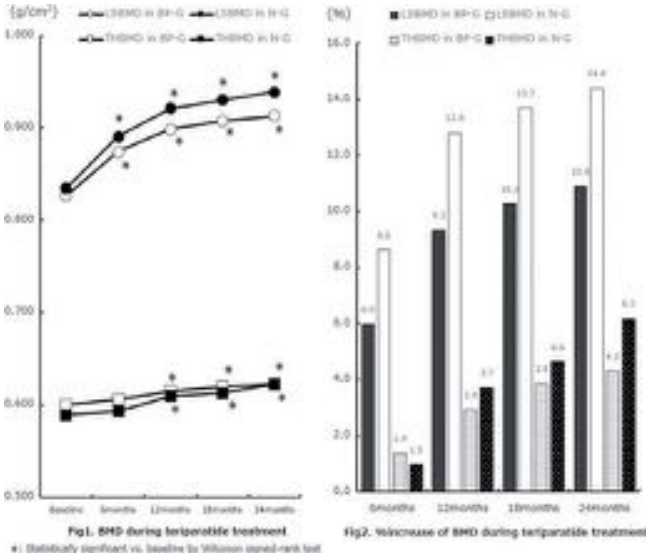

Fig1. BMD during teriparatide treatment

Fig2. %increase of BMD during teriparatide treatment

**Conclusions:** TPTD was effective in not only N-G but also BP-G. Although bone turnover was slightly inhibited and slow in BP-G, TPTD upregulated bone turnover preferably and resulted in increase of BMD in not only N-G but also in BP-G. This study suggested that TPTD was one of options after BP treatment in RA-OP.

## Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis

### THU0490 ASYMPTOMATIC GOUT IN CHRONIC KIDNEY DISEASE: PREVALENCE STUDY USING DUAL ENERGY CT AND ULTRASOUND

N.F.L. Conijn[1], E.J. Hoorn[2], G.S. Muradin[3], M.R. Kok[4], M. Vis[1].
*[1]Rheumatology; [2]Nephrology; [3]Radiology, Erasmus Medical Center; [4]Rheumatology, Maasstad ziekenhuis, Rotterdam, Netherlands*

**Background:** Gout is a metabolic disorder of purine metabolism with primary manifestations of acute and chronic arthritis and tophus formation. Asymptomatic gout is defined as tophus formation without any clinical symptoms of arthritis. Detection of asymptomatic gout may be important, as it can cause bone erosions and joint destruction. Reduced kidney function is an important risk factor for gout[1]. The prevalence of hyperuricemia and gout increases with decreasing estimated glomerular filtration rate (eGFR) independent of other risk factors for gout[1]. Dual Energy CT (DECT) and ultrasound (US) are novel radiological techniques to detect monosodium urate (MSU) crystals.

**Objectives:** The aim of this study was to assess the prevalence of asymptomatic gout in patients with chronic kidney disease (CKD) stages 4 or 5, this is an eGFR $<30mL/min/1.73m^2$.

**Methods:** Patients with CKD stages 4 or 5 were recruited from a nephrology outpatient clinic in a university hospital. Exclusion criteria were a history of arthritis or gout, the use of urate lowering drugs and the use of more than 7.5 mg prednisone/day. The joints of the feet, ankles and knees were examined with US and DECT. The OMERACT criteria for gout lesions on US were used: tophi, MSU deposits and double contour sign[2]. A DECT was scored positive if at least one tophus was present[3].

**Results:** Twenty-five patients were included. Patients were recruited from a population of 387 patients with CKD stages 4 or 5, 208 were excluded because they did not meet the in-/exclusion criteria, 58 were not treated at the outpatient clinic anymore at time of inclusion and the rest declined participation. The mean (SD) age of the participants was 65 (12), 18 were man and the mean (SD) duration of CKD was 5.3 (3.8) years.

| | | US: Double contour | | US: MSU depositions | | US: Tophi | | Positive DECT | | Any gout sign on US or DECT | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | NO | YES | NO | YES | NO | YES | NO | YES | NO | YES |
| Serum uric acid groups | <0.42 | 4 | 1 | 3 | 2 | 5 | 0 | 4 | 1 | 3 | 2 |
| | ≥0.42 | 13 | 5 | 11 | 7 | 15 | 3 | 16 | 2 | 9 | 9 |
| Total N (%) | | 17 (74) | 6 (26) | 14 (61) | 9 (39) | 20 (87) | 3 (13) | 20 (87) | 3 (13) | 12 (52) | 11 (48) |

Table 1. Findings on ultrasound and DECT compared for uric acid group. Serum uric acid is in mmol/L, <0.42 is a normal serum uric acid, ≥0.42 is a high serum uric acid.

Twelve out of 25 patients (48%) had any sign of gout on DECT or US, nine patients (36%) had MSU depositions, four (16%) had a tophus, seven (28%) had a double contour sign and three patients (13%) had a positive DECT. Patients with MSU depositions were older (73 vs. 60 years, p=0.007). Gout signs were far more common in the high uric acid group, this is an uric acid of 0.42 or higher (table 1), although this did not reached a statistical significance.

**Conclusions:** Our study shows a high prevalence of gout in patients with CKD. To our knowledge this is the first study that assessed the prevalence of asymptomatic gout in patients with CKD stages 4 or 5. Radiological signs of gout were more frequently found in patients with higher uric acid. The relevance of these findings needs further research.

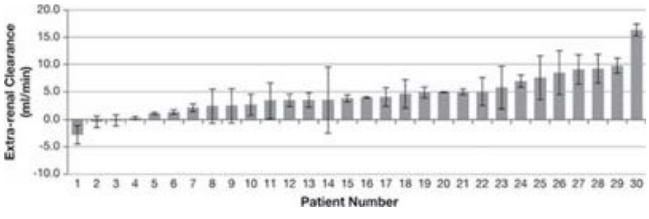
### THU0491 A NOVEL METHOD OF ESTIMATING EXTRA-RENAL CLEARANCE OF URIC ACID



D. Hyndman, S. Liu, J. Hall, J.N. Miner. *Ardea Biosciences, Inc., San Diego, United States*

**Background:** Serum uric Acid (sUA) concentration is a function of uric acid production and both renal and extra-renal clearance. Decreased renal clearance is well understood as a contributing factor in gout. Extra-renal clearance, however, has not been as well characterized. Estimating extra-renal clearance would allow the classification of patients with gout as having high or low extra-renal clearance. Additionally, since production must equal the sum of urinary excretion and extra-renal elimination, determining the amount of extra-renal elimination would allow estimation of the rate of uric acid production. With this information, subjects could be characterized by all three parameters that determine sUA levels.

**Objectives:** To estimate the extra-renal uric acid clearance of patients with gout.

**Methods:** sUA and 24-hour urinary uric acid excretion (24hrUUE) were measured in 30 patients with gout in the absence and presence of a specific URAT1 inhibitor that lowers uric acid by increasing renal uric acid excretion. In these patients, at least a 1 mg/dl decrease in sUA was achieved with the URAT1 inhibitor at steady state. Extra-renal clearance was calculated by dividing the drug-induced increase in 24hrUUE by the drug-induced decrease in sUA and adjusting units to yield ml/min. This calculation was performed twice for each patient as two sets of measurements for each patient were taken. The two calculated clearance values were then averaged.

**Results:** The average estimated extra-renal clearance of the 30 patients with gout was 4.4 ml/min. Maximum extra-renal clearance was 16 ml/min, while some patients apparently had no measurable extra-renal elimination (Figure).

**Conclusions:** Estimated extra-renal elimination varies greatly among patients with gout. Some patients have very low estimated extra-renal clearance which likely contributes to high sUA concentration.

## THU0492 URIC ACID TRANSPORT KINETICS IN THE KIDNEY: DETECTION OF RENAL SECRETION AND THE MECHANISM OF LOW FEUA

S. Liu, D. Hyndman, J.N. Miner. *Ardea Biosciences, Inc., San Diego, United States*

**Background:** Approximately 70% of urate is excreted by the kidney. Renal excretion is governed by reabsorption and secretion in the proximal convoluted tubule. However, there is little direct evidence that renal uric acid secretion occurs in humans, and it is unknown if higher renal uric acid reabsorption or low renal uric acid secretion contributes to the low fractional excretion of uric acid (FEUA) observed in patients with gout.
**Objectives:** The objectives of the study were to test the hypothesis that uric acid secretion occurs in humans, to distinguish uric acid secretion from incomplete reabsorption, and to determine if insufficient secretion and/or enhanced reabsorption are responsible for low FEUA.
**Methods:** Patients with gout in a Phase II study were treated once daily with 40 and 80 mg of febuxostat (FBX), with each treatment lasting 1 week. FBX is a xanthine oxidase inhibitor that reduces uric acid production and lowers serum uric acid (sUA). sUA and FEUA were measured at baseline and at the end of each treatment. sUA (X-axis) and FEUA (Y-axis) were plotted to evaluate the kinetics of renal uric acid handling (Figure).
**Results:** Forty-five male patients with gout, with a mean (SD) age of 49±9.3 years and BMI of 32±3.9 kg/m$^2$, participated in this study. As has been observed in previous publications, decreasing sUA led to a decrease in FEUA. However, this effect reached a plateau at low sUA levels for those who had low (<3.5%) baseline FEUA; the FEUA did not decrease further when the FBX dosage was increased from 40 mg to 80 mg (Figure). The FEUA response to decreasing sUA reaches a plateau at an FEUA of ~ 2.5%. In contrast, the curve for fractional excretion of glucose reaches zero at lower plasma glucose levels.[1] Since a prominent difference in renal handling of uric acid and glucose is that glucose is not secreted while uric acid is believed to be secreted, we suggest that the plateauing of the FEUA curve at the lower sUA range is due to renal uric acid secretion. Preliminary modeling of transporter kinetics also suggests that the observed relationship between sUA and FEUA requires secretion. In addition, the sUA level at which the FEUA begins to rise (equivalent to the renal glucose threshold) is higher for those whose baseline FEUA was low, and this observation is consistent with the hypothesis that patients with gout with low FEUA have higher reabsorption capacity. To determine the ultimate contribution of secretion to low FEUA, sUA will need to be lowered even further.

**Conclusions:** We provide direct evidence for renal uric acid secretion occurring in humans. This method can also be used to determine the relative importance of candidate renal secretory transporters in the secretion of uric acid. Higher reabsorption capacity appears to contribute to low baseline FEUA.

## THU0493 RACIAL DISPARITIES IN THE RISK OF STEVENS-JOHNSON SYNDROME AND TOXIC EPIDERMAL NECROLYSIS AS URATE-LOWERING DRUG ADVERSE EVENTS IN THE US

N. Lu[1], S. Rai[2], R. Terkeltaub[3], S. Kim[4], M. Menendez[5], H. Choi[1]. *[1]Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, United States; [2]Department of Experimental Medicine, University of British Columbia, Vancouver, Canada; [3]Division of Rheumatology, Allergy and Immunology, VAMC/UCSD, La Jolla, United States; [4]Division of Pharmacoepidemiology and Pharmacoeconomics, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, Canada; [5]Department of Orthopaedic Surgery, Massachusetts General Hospital, Harvard Medical School, Boston, United States*

**Background:** Although uncommon, the most feared adverse event of urate-lowering drugs (ULDs) is allopurinol hypersensitivity syndrome (AHS), primarily manifesting as Stevens-Johnson Syndrome (SJS) and Toxic Epidermal Necrolysis (TEN). *HLA-B*5801* allele carriage (a strong determinant of AHS) varies substantially among races, which may lead to major racial disparities in the risk of SJS/TEN in the context of ULD adverse events (ULDAEs). Such information could immediately help risk stratification to prevent these severe ULDAEs.
**Objectives:** To examine potential racial disparities in the risk of SJS/TEN in the context of ULDAEs in a large, racially diverse, and generalizable population.
**Methods:** Using the Nationwide Inpatient Sample (NIS, 2009–2013), a database representative of all US hospitalizations, we examined the racial distribution of hospitalized SJS/TEN (principal discharge diagnosis) as ULDAEs (ICD-9-CM Classification of External Causes); this combination implicates allopurinol, which is the only ULD established to cause SJS/TEN. Our reference groups were the US Census population, US allopurinol users (from the NHANES), and ULDAE hospitalizations without SJS/TEN (from the NIS).
**Results:** We identified 606 patients hospitalized for SJS/TEN as ULDAEs meeting our criteria between 2009–2013 (mean age, 68 years; 44% male). Of these 606 patients, there was a substantial over-representation of Asians (27%) and Blacks (26%), and an under-representation of Whites (29%) and Hispanics (% too-low-to-report), compared with the US Census population (5%, 12%, 67%, and 15%, respectively). The hospitalization rate ratios for SJS/TEN among Asians, Blacks, and Whites were 11.9, 5.0, and 1.0 (referent), respectively. These associations persisted using other national referents (allopurinol users and ULDAE cases without SJS/TEN).

| Race | White | Black | Asian |
|---|---|---|---|
| **Among US Adults According to Race** | | | |
| Hospitalizations, N | 175 | 155 | 143 |
| Hospitalizations per 1,000,000 US adults | 0.22 | 1.30 | 2.84 |
| Hospitalization rate ratio (95% CI) | 1.0 (ref) | 5.0 (4.0 to 6.2) | 11.9 (9.6 to 14.8) |
| **Among US Allopurinol Users According to Race** | | | |
| US adults with allopurinol use, N | 1,840,829 | 283,564 | 52,936 |
| Hospitalizations, N | 175 | 155 | 143 |
| Hospitalizations per 1,000,000 with allopurinol users | 19.0 | 106.3 | 638.5 |
| Hospitalization rate ratio (95% CI) | 1.0 (ref) | 5.7 (4.8 to 7.1) | 32.6 (26.3 to 40.4) |
| **Among NIS Hospitalizations for ULDAE According to Race*** | | | |
| Hospitalizations for ULDAE with SJS/TEN, N (%) | 175 (29) | 155 (26) | 163 (27) |
| Hospitalizations for ULDAE without SJS/TEN, N (%) | 10,012 (60) | 2,840 (18) | 985 (6) |
| Crude OR (95% CI) | 1.00 (Ref) | 2.9 (2.5 to 4.7) | 8.3 (5.0 to 13.7) |
| Age-Sex-Adjusted OR (95% CI) | 1.00 (Ref) | 2.6 (1.7 to 4.6) | 8.5 (5.1 to 14.0) |
| Age-Sex-CAD-CKD-Diabetes-Adjusted OR (95% CI) | 1.00 (Ref) | 2.8 (1.7 to 4.5) | 8.1 (5.0 to 13.3) |

SJS/TEN = Stevens-Johnson Syndrome or Toxic Epidermal Necrolysis; ULDAE = Urate-Lowering Drug Adverse Event
CAD = coronary artery disease; CKD = chronic kidney disease
*Hispanics, other races, and those with missing race data are not reported as their unweighted cell size was 10 or fewer, in which case individual group reporting is not allowed according to the Healthcare Cost and Utilization Project Data Use Agreement.

**Conclusions:** These national data indicate that Asians and Blacks have a substantially higher risk of SJS/TEN as ULDAEs than Whites (or Hispanics), correlating well with corresponding frequencies of *HLA-B*5801* in the US population (i.e.,7.4%, 4%, 1%, and 1% among Asians, Blacks, and Whites, Hispanics, respectively). As no other ULDs available in the US have been established to cause SJS/TEN, these findings support the use of vigilance in these minorities when considering allopurinol.

## THU0494 SKIN EVENTS WITH FEBUXOSTAT IN GOUT PATIENTS WITH PREVIOUS SKIN REACTIONS TO ALLOPURINOL. A RETROSPECTIVE REVIEW

N. Quilis[1], M. Andrés[1], P. Vela[1,2], E. Pascual[1,2]. *[1]Seccion de Reumatologia, Hospital General Universitario de Alicante; [2]Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain*

**Background:** Allopurinol is the most used urate-lowering agent for patients with gout. However, 10% of patients show intolerance to this drug, often at skin, which can be severe. Febuxostat is a novel non-purine selective xanthine oxidase inhibitor that has been proposed for allopurinol-intolerant patients due to its different structure. However, data regarding safety in those with previous skin reactions to allopurinol is still limited (1,2).
**Objectives:** To assess the cutaneous safety of febuxostat when used in patients with previous skin reactions to allopurinol.
**Methods:** Retrospective review of patients with crystal-proven gout treated with febuxostat in our Unit until December 2015. Those with previous skin reaction to allopurinol were selected. We registered epidemiological (age, gender), clinical (skin events) and laboratory variables (serum uric acid, glomerular filtration rate). The primary study variable was the rate of patients also presenting skin reactions with febuxostat. A descriptive analysis with estimation of the 95% confidence interval (95%CI) was performed.
**Results:** Out 102 gout patients treated with febuxostat in our Unit, we identified 24 patients with prior allopurinol-related skin events. The median age was 68.5 years (p25-p75 53.7–71.0), being 18 males (75%). Most used starting dose of febuxostat was 80mg/d (n=16), others were 5mg/d (n=1), 40mg/d (n=4) or 120mg/d (n=3). Median glomerular filtration rate at that time was 77.2 mL/min (62.7–68.6). We have identified five patients (20.8%; 95%CI 3–38%) who also

Characteristics of patients developing skin reactions with both allopurinol and febuxostat (5/24)

| Gender | Age | Allopurinol start | | Febuxostat start | | Rash with febuxostat | Outcome with benzbromarone |
|---|---|---|---|---|---|---|---|
| | | Dosage (mg/d) | GFR (mL/min) | Dosage (mg/d) | GFR (mL/min) | | |
| Female | 70 | 50 | 78 | 120 | 77.2 | Nonspecific | No rash |
| Male | 69 | N/A | 90 | 40 | 90.5 | SJS | No rash |
| Female | 68 | 100 | 52 | 80 | 80.3 | Nonspecific | No rash |
| Male | 45 | 50 | 90 | 80 | 90.9 | Nonspecific | No rash |
| Female | 41 | 300 | 40 | 5 | 40.9 | Nonspecific | No rash |

GFR: glomerular filtration rate; SSJ: Stevens-Johnson syndrome.

developed skin reactions with febuxostat (see table): in four cases a nonspecific rash, but one suffered from a Stevens-Johnson syndrome. None of these patients presented skin reactions to benzbromarone.

**Conclusions:** In our series, one out five patients with previous skin reaction to allopurinol also developed after febuxostat. Larger studies are needed to confirm these results, but this finding strengths caution when using febuxostat in this subgroup of patients.

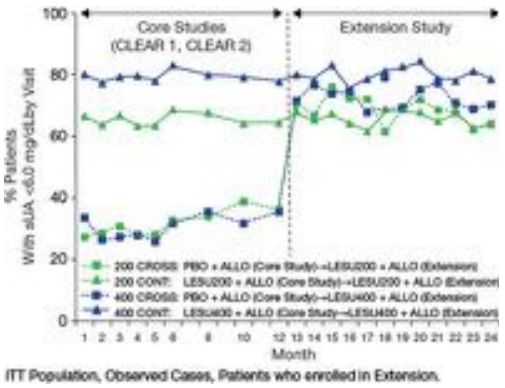
## THU0495 EXAMINATION OF SERUM URIC ACID (SUA) LOWERING AND SAFETY WITH EXTENDED TREATMENT WITH LESINURAD AND ALLOPURINOL IN SUBJECTS WITH GOUT

K.G. Saag[1], M.A. Becker[2], C. Storgard[3], M. Fung[3], N. Bhakta[3], S. Adler[4], J. Hu[3], T. Bardin[5]. *[1]Rheumatology, University of Alabama, Birmingham; [2]University of Chicago, Chicago; [3]Ardea Biosciences, Inc., San Diego; [4]Astrazeneca, Gaithersburg, United States; [5]Lariboisière Hospital, Paris, France*



**Background:** Two replicate, randomized, core Phase III trials (CLEAR 1 and 2) reported significantly more subjects treated with lesinurad 200 mg (LESU200) or 400 mg (LESU400) combined with allopurinol (ALLO) achieved target sUA <6.0 mg/dL at 6 and 12 months than ALLO+placebo (PBO) ($P<0.0001$). The safety profile of LESU200+ALLO was comparable to ALLO+placebo, except for higher rates of predominantly reversible serum creatinine (sCr) elevation.

**Objectives:** Assess long-term safety and efficacy of LESU+ALLO therapy in subjects enrolled in the CLEAR 1and 2 extension study (NCT01808131).

**Methods:** Efficacy was assessed for those completing the core study and either 1) continuing core LESU+ALLO treatment (200CONT, 400CONT) or 2) crossing over from core ALLO+PBO to either ALLO+LESU200 (200CROSS) or LESU400 (400CROSS). Core LESU200+ALLO or LESU400+ALLO subjects and 200CONT and 400CONT extension groups are reported for safety. Efficacy endpoints included proportions of subjects with target sUA <6.0 mg/dL and mean sUA levels (ITT–observed cases). Treatment-emergent adverse events (TEAEs) were calculated as exposure-adjusted incidence rates (EAIRs; events per 100 person-years [100-PY]).

**Results:** For efficacy, the 200CONT (n=239) and 400CONT (n=232) groups receiving treatment for up to 24 months, and 200CROSS (n=121) and 400CROSS (n=122) groups, receiving treatment for up to 12 months, were analyzed. Proportions of subjects with sUA <6.0 mg/dL during core and extension are shown (Figure). Mean (SD) sUA (mg/dL) for 200CONT, 200CROSS, 400CONT and 400CROSS groups, respectively, were 6.96 (1.14), 6.92 (1.33), 6.80 (1.20) and 6.99 (1.14) at baseline of the core studies, and 5.71 (1.80), 6.68 (1.57), 5.06 (1.94) and 6.68 (1.38) at the end of the 12-month core studies. After 12 months in the extension study when all patients received lesinurad, mean (SD) sUA was 5.75 (1.77), 5.78 (1.92), 5.01 (1.95), and 5.25 (1.77), respectively.

For safety, pooled analysis on a total of 405 and 401 subjects (LESU200, LESU400 respectively), from the core studies and 239 and 232 (200CONT, 400CONT, respectively) from the extension studies, was conducted. EAIRs (per 100-PY) of TEAEs and serious TEAEs at any time during core or extension studies were 54.2 and 5.8 for LESU200 and 57.2 and 8.3 for LESU400. EAIRs of renal-related TEAEs and serious renal-related TEAEs were 7.4 and 0.5 for LESU200 and 14.2 and 0.8 for LESU400. EAIRs of kidney stone incidence rates were 0.5 and 2.0 per 100-PY for LESU200 and LESU400, respectively. EAIRs of sCr elevations ≥1.5x baseline was 7.8 and 17.0 per 100-PY for LESU200 and LESU400, respectively; resolution of sCr elevations by analysis cutoff occurred in 91.7% and 87.8% of cases, respectively.

ITT Population, Observed Cases, Patients who enrolled in Extension.

**Conclusions:** Subjects treated with LESU+ALLO therapy through 2 years continued to be at sUA target; those crossing over from ALLO monotherapy had increased proportions reach target. Safety during continued treatment was consistent throughout the core and extension studies.

## THU0496 ASSOCIATIONS OF PLASMA URIC ACID AND PURINE METABOLITES WITH BLOOD PRESSURE IN CHILDREN: THE KOALA BIRTH COHORT STUDY

L.E. Scheepers[1], A. Boonen[1], W.D. Pijnenburg[2], J. Bierau[3], J.A. Staessen[2,4], C.D. Stehouwer[5], C. Thijs[2], I.C. Arts[6]. *[1]Rheumatology, CAPHRI, Maastricht University; [2]Epidemiology, Maastricht University; [3]Clinical Genetics, MUMC+, Maastricht, Netherlands; [4]Studies Coordinating Centre, Research Unit Hypertension and Cardiovascular Epidemiology, KU Leuven, Department of Cardiovascular Diseases, Leuven, Belgium; [5]Internal Medicine, CARIM, MUMC+; [6]Epidemiology, CARIM, CAPHRI, and MaCSBio, Maastricht University, Maastricht, Netherlands*

**Background:** Elevated uric acid concentrations have been associated with high blood pressure (BP) in adults and children. An increased production of uric acid by the enzyme xanthine oxidoreductase (XOR), which is accompanied by the generation of reactive oxygen species, is a putative underlying mechanism that has so far scarcely been studied. We hypothesize that a higher XOR activity leads to increased concentrations of downstream purine metabolites, resulting in higher ratios of xanthine/hypoxanthine, uric acid/xanthine, and uric acid/hypoxanthine (figure 1).

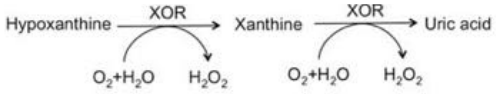

**Figure 1. Purine metabolism**
During the final stage of the purine metabolism, xanthine oxidoreductase (XOR) breaks down hypoxanthine to xanthine, and xanthine to uric acid, while reactive oxygen species are formed. These free radicals inactivate the vasodilator nitric oxide.

**Objectives:** The objectives were therefore to study the association between (i) the purine metabolites uric acid, hypoxanthine, and xanthine and (ii) the ratios of the three different purine metabolites as proxy measures for uric acid production, with systolic (SBP) and diastolic blood pressure (DBP).

**Methods:** Cross-sectional analyses were performed in a subset of 246 children from the Dutch Koala Birth Cohort Study. This cohort originates from two recruitment groups: pregnant women with either a conventional lifestyle or recruited through alternative channels. During a home visit, a nurse collected a venous blood sample and measured BP three times after a 5-minute rest, with an automated BP monitor. Furthermore, parents were in instructed to measure their child's BP on three consecutive days, in the morning and evening, using the same monitor. Purine metabolites were determined with UPLC-MS/MS. Data were analysed using a multivariable generalized estimating equations model, including repeated BP measurements, with an exchangeable correlation structure. Analyses were adjusted for sex, age, BMI, recruitment group, place and mode of delivery (hospital *vs.* at home; natural *vs.* caesarean section), maternal smoking during pregnancy (active and passive), total physical activity, and dietary intake at four years of age (total energy intake [kcal], energy from carbohydrates and protein [%] and fibre intake [grams]).

**Results:** At a mean age of 7.1 yrs, mean plasma concentrations were 202.8 μmol/L (SD 37.7) for uric acid, 4.60 μmol/L (SD 6.93) for hypoxanthine, and 0.53 μmol/L (SD 0.17) for xanthine. Average BP was 104.3 mm Hg (SD 10.0) systolic and 63.4 mm Hg (SD 10.6) diastolic. Higher ratios of uric acid/xanthine and xanthine/hypoxanthine were associated with higher DBP (adj. β 0.01 mm Hg; 95%CI 0.00 to 0.02; $P$=0.03; and adj. β 0.11 mm Hg; 95%CI 0.01 to 0.21; $P$=0.03), respectively, but not with SBP. Uric acid, xanthine, and hypoxanthine concentrations and the ratio uric acid/hypoxanthine were not associated with SBP nor DBP ($P\geq0.05$).

**Conclusions:** In multivariable-adjusted analyses, DBP in children was significantly associated with the ratios of uric acid/xanthine and xanthine/hypoxanthine, and might, as hypothesized, be proxies for uric acid production. The ratio uric acid/hypoxanthine was not associated with BP, may be explained by differential excretion or autofeedback (of non XOR metabolism).

## THU0497 ULTRASOUND IN GOUT: WHICH JOINTS SHOULD BE EVALUATED CONCERNING DIFFERENCES BETWEEN THE EARLY AND LATE GOUT?

E. Norkuviene[1], M. Petraitis[1], I. Apanaviciene[1], D. Virviciute[2], A. Baranauskaite[1]. [1]*Dept. of Rheumatology, Lithuanian University of Health Sciences;* [2]*Inst. of Cardiology of Kaunas Medical University, Kaunas, Lithuania*

**Background:** The sensitivity of ultrasound (US) signs of monosodium urate (MSU) deposition in symptomatic joints is only 60% with negative predictive value of 62% while multiple joins examination gives better sensitivity and better negative predictive value with less specificity though [1]. The 12 sites' combination assessment has been proposed by Naredo and colleagues with 84, 6% sensitivity and 83, 3% specificity in late gout [2]. Does it fit in the early gout?
**Objectives:** To compare the frequencies and specificity of US dual contour sign (DC), tophus (T) in early versus late gout using multiple investigation of joints and tendons, most often affected by gout, in order to define the most suitable test for diagnosis of both early and late stage of the disease.
**Methods:** Prospective single centre case - control study was performed. Crystal - proven gout compared according healthy controls. Systematic US assessment of 36 joints and 4 tendons (patellar and triceps) was done by rheumatologist, blinded to study group and clinical findings. The reliability of the US assessment was checked in a web – based exercise, evaluated by kappa coefficient. The early (symptoms $\leq$2 years) and rest gout was compared according frequency of DC and T in different anatomical sites using chi – square test. The specificity and sensitivity of T and DC in total investigated sites, in 10, 6 and 4 anatomical areas has been compared.
**Results:** 50 patients with gout (16 early, 34 late gout) and 36 age matched healthy controls were investigated. In late gout US T sign was most often found in I MTF (79,4%), patellar tendon (39,7%), triceps tendon (38,2%), wrist (33,8%), II MCP, II MTF joint; DC sign - in I MTF (45,6%), knees (38,2%), ankles (35,2%), II MCP (27%), II MTP, III MTP. In early gout the most often T was in I MTF (65, 7%) and wrist (21,9%), DC – in I MTF (25%), ankles (22%), II MTF. There were no T found in II MCP and PIP joints, 0,6% in the rest MCP, less T found in m. triceps and patellar tendons than in late gout ($p<0,001$ and $p<0,01$ accordingly). There were less DC found in total MCP, II MCP, total PIP and knees joints in early than in late gout with $p<0,001$; $<0,05$; $<0,01$; $<0,01$ accordingly. The best balance between sensitivity (91%) and specificity (81%) has been noticed with 6 US abnormalities in 4 joints. The intrareader reliability was good (mean kappa 0,712).
**Conclusions:** Our results suggest, that US signs of urate deposition in metacarpophalangeal and proximal interphalangeal joints, m. triceps and patellar tendons are very seldom found in gout with symptoms duration up to two years and might be the symptoms of late disease. Bilateral assessment of first metatarsophalangeal joint for tophus, dual contour sign and knee femoral cartilage for dual contour sign shows best balance between sensitivity and specificity diagnosing both early and late gout.

## THU0498 GENDER DIFFERENCES IN THE PHENOTYPE OF GOUT AND ITS EFFECT ON CLASSIFICATION USING THE ACR-EULAR CRITERIA

J. Fransen[1], T. Neogi[2], T. Jansen[3], H.R. Schumacher[4], N. Dalbeth[5], W. Taylor[6] on behalf of the SUGAR Investigators. [1]*Rheumatology, Radboud University Medical Centre, Nijmegen, Netherlands;* [2]*Rheumatology, Boston University Schools of Medicine and of Public Health, Boston, United States;* [3]*Rheumatology, Vie Curi Medical Centre, Venlo, Netherlands;* [4]*Rheumatology, University of Pennsylvania and VA Medical Center, Philadelphia, United States;* [5]*Medicine, University of Auckland, Auckland;* [6]*Medicine, Univerity of Otago, Wellington, New Zealand*

**Background:** Gout is a quite prevalent disorder in affluent countries, with the prevalence in males being 3–4 times higher than in females [1]. In practice, gout may be perceived as a "males" disorder and it has been suggested that the phenotype of gout differs between males and females, due to selection bias or by nature of the disease.
**Objectives:** To analyse whether there are differences between males and females in the phenotype of gout and in the performance of the ACR-EULAR classification criteria.
**Methods:** We used the multi-country SUGAR data set in which the ACR-EULAR classification criteria were constructed and validated [2]. In SUGAR, patients with at least one swollen joint or subcutaneous tophus conceivably being due to gout were consecutively included. Presence of MSU crystals in synovial fluid or tophus aspirate was the gold standard for gout, as assessed at inclusion, using microscopy by certified examiners in all included patients. Gout manifestations were standardly assessed without knowing the results of the microscopy. Gout manifestations included in the ACR-EULAR classification criteria were compared between male and female MSU positives. Sensitivity and specificity of the ACR-EULAR criteria, calculated without MSU results, were compared between males and females. To preserve power, the development and validation data sets of SUGAR were combined.
**Results:** There were 983 subjects included (71% male), of whom 52% (509/983) were MSU crystal-positive. Sixty-three percent (440/702) of the males and 25% (69/281) of the females were MSU crystal-positive, respectively ($p<0.0001$). There were no large ($>10\%$) or significant ($p<0.05$) differences between male and female MSU positives regarding: previous or current involvement of MTP1, mono/oligo/poly-arthritis, joint erythema, painfulness for touch, tophus, largest pain increase within 24 hours, highest level of Serum Uric Acid (SUA) level without treatment, current level of SUA, occurrence of erosions on X-ray, or double contour sign on ultrasound. Male MSU positives more frequently reported: disablement (98% versus 87%; $p<0.0001$), symptom resolution within 14 days (84% versus 65%; p=0.0002), complete resolution (86% versus 70%; p=0.0004). In the complete sample of 983 subjects, the classification system lead to a median (P25-P75) score of 5 (2–8) in females and 9 (6–14) in males ($p<0.0001$). Sensitivity and specificity of the classification system to detect MSU crystal positivity were 86% and 79% in the complete sample, and 87% and 89% for females and 85% and 70% for males.
**Conclusions:** Male and female gout patients are similar on most important aspects of the gout phenotype. The ACR-EULAR classification criteria perform well in both males and females; sensitivity is the same in males and females, while specificity was better in females.

## THU0499 NEUTROPHIL EXTRACELLULAR TRAPS (NETS): A SHARED FEATURE OF ACUTE MICROCRYSTALLINE ARTHRITIS

M. Bardelli[1], S. Lorenzini[1], C. Baldi[1], A. Simpatico[1], A. Gamberucci[2], G. Berti[1], E. Garcia Gonzalez[1], M. Galeazzi[1], E. Selvi[1]. [1]*Department of Medical Sciences, Surgery and Neurosciences, A.O.U. Siena;* [2]*Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy*

**Background:** Neutrophil extracellular traps (NETs) are web-like structures, composed of nucleic acids, histones and granular enzymes, including myeloperoxidase and elastase, that have a physiological crucial role in innate immunity response by trapping microbes. In addition, NETs have been identified as regulators of many inflammatory and autoimmune disorders, including crystal-induced arthritis.[1,2] In particular, a key role in the pathogenesis of gout flares has been postulated for NETs. During gout attacks, NET aggregates should package MSU crystals with a concomitant degradation of proinflammatory cytokines, leading to the rapid resolution of the inflammatory phase.[3]
**Objectives:** To evaluate NET expression in synovial fluid from acute CPPD arthritis and to compare NET release between acute MSU and CPPD arthritis.
**Methods:** Synovial fluid was collected from patients with active gout or pseudogout attack (n=5 for each group) and immediately centrifuged (805 rad) to separate cells from supernatant.
*Polymorphonuclear leukocytes* were counted and immediately processed for morphological evaluation under transmission electron microscopy (Zeiss EM 109; 4000x). NET expression was evaluated by fluorescence microscopy using SYTOX Green (Life Technologies) and neutrophil elastase specific antibody (ABCAM). Fluorometric quantification of NET components, DNA and neutrophil elastase, was performed in supernatant (Cary Eclipse Varian; exc/em 503/526). Results were normalized to cells/mm$^3$. Peripheral blood neutrophils from healthy donors stimulated with PMA were used as positive controls whereas PMA-untreated neutrophils were used as negative ones.
All the experiments were performed according with Helsinki guidelines.
**Results:** Extracellular material morphologically compatible with NETs was observed by electron microscopy in samples from both acute MSU and CPPD arthritis. NET structures were confirmed by the presence of extracellular DNA and neutrophil elastase at immunofluorescence.
Fluorometric quantification of extracellular DNA and neutrophil elastase showed an increased NET release in both gout and pseudogout samples compared

with negative controls ($p<0.01$). No significant differences in NET release were measured between acute MSU and CPPD arthritis samples.
**Conclusions:** Beyond confirming NETs in acute MSU arthritis, we have evidence of NET release in synovial fluid from acute CPPD arthritis. Our preliminary data suggest that the release of NETs could be a common physiophatological pathway to both crystral induced arthropaties.
**Disclosure of Interest:** None declared

## THU0500 FREQUENCY OF IL-1 GENE CLUSTER POLYMORPHISM AND ITS RELATIONSHIP WITH CLINICAL FINDINGS IN PATIENTS WITH GOUT

B. Can[1], A. Balkarli[2], L. Elmas[3], C.C. Karatay[4], E. Tepeli[3], A. Kaya[5], V. Cobankara[5]. *[1]Rheumatology; [2]Antalya training and research hospital, Antalya; [3]Department of Medical Biology; [4]Department of Internal Medicine; [5]Rheumatology, Pamukkale University School of Medicine, Denizli, Turkey*

**Background:** IL-1β has role in promotion of acute gout inflammation. The relationship of IL-1 with comorbid conditions and many other disorders has been investigated previously. Gout is an auto-inflammatory disease. Activation of IL-1 gene can contribute to pathogenesis.
**Methods:** The study included 70 patients with gout and 106 age- and sex-matched healthy volunteers. By using genomic DNA isolated from patients and healthy volunteers, 5 polymorphic gene regions (rs16944, rs2234650, rs1800587, rs1143634 and rs315952) were analyzed by using PCR. Genotyping was performed by using Melting Curve Genotyping analysis.
**Results:** Mean age was 57.73 ± 10.2 years in the patient group and 57.42 ± 8.53 years in the control group. The frequency of IL1 rs16944 gene polymorphism of heterozygous (AG) genotype was found to be increased in the patient group compared to controls (61.4% vs. 40.6%; p=0.01). Genotype distribution of remaining gene polymorphisms was similar in both groups. When each gene polymorphism was assessed regarding allele frequency, no significant difference was detected between patient and control groups ($p>0.05$). It was seen that CRP values (p=0.011) and number of attacks per year (p=0.035) were higher in patients with rs2234650 wild type (CC).The haplotype analysis was performed for rs2234650, rs1143634 and rs315952 which could have significant association with disease. Similar haplotype distribution was observed in both groups.

Table 1. Mean laboratory and clinical values according to polymorphisms

| Polymorphism | | CRP | LDL | PLT | BMI | Number of attack per year |
|---|---|---|---|---|---|---|
| | | mg/dl | mg/dl | K/uL | kg/cm$^2$ | |
| rs16944 | Wild | 0.52±0.85 | 121±24.8 | 259.5±94.8 | 29.5±1.9 | 2±0.8 |
| | Heterozygous | 2.62±14.58 | 112.6±46.6 | 254.4±83.6 | 28.7±3.8 | 1.7±0.7 |
| | Mutant | 0.66±1.43 | 111±47 | 228.2±58.4 | 29.2±3.6 | 1.7±0.7 |
| rs1143634 | Wild | 0.40±0.46 | 105.7±38.5 | 254.4±85.2 | 29.2±3.8 | 1.8±0.7 |
| | Heterozygous | 5.72±21.91 | 117.7±49.2 | 221.4±56.3 | 28.2±3.7 | 1.6±0.6 |
| | Mutant | 0.41±0.39 | **165.7±70.3** *p=0.045* | 279.2±36.0 | 29.5±2.8 | 1.5±0.5 |
| rs1800587 | Wild | 0.40±0.48 | 106.1±36.8 | 246.7±78.8 | 28.9±3.4 | 1.7±0.7 |
| | Heterozygous | 5.44±21.36 | 114.4±51.8 | 274.7±84.5 | 29.6±4.4 | 1.9±0.8 |
| | Mutant | 0.43±0.46 | 145.2±62 | 244.5±50.9 | 27.7±3.0 | 1.4±0.5 |
| rs2234650 | Wild | **4.83±20.36** *p=0.011* | 99.3±35.4 | 262.6±101 | 28.9±2.8 | **2±0.75** *p=0.035* |
| | Heterozygous | 0.37±0.54 | 123.06±50.9 | 233.7±54.6 | 27.6±4.20 | 1.6±0.7 |
| | Mutant | 0.55±1.23 | 122.05±49.8 | 235.5±48.8 | 30.1±4.2 | 1.5±0.7 |
| rs315952 | Wild | 2.60±13.95 | 116.5±50.2 | 254.8±82.5 | 29.3±3.7 | 1.8±0.7 |
| | Heterozygous | 0.28±0.42 | 102.24±31.1 | **215.4±61.3** *p=0.014* | **27.8±3.7** *p=0.049* | 1.4±0.6 |
| | Mutant | 0.38±0.35 | 111±34.7 | 283±17.9 | 30±2.44 | 0.95±0.5 |

**Conclusions:** Although there was no significant difference in the distribution of IL-1 gene polymorphism, it is seen that the presence of some genotypes could affect clinical course of gout.

## THU0501 ZOLEDRONIC ACID TREATMENT IN BONE MARROW EDEMA SYNDROME

B.J. Flores, J. Sanz Sanz, J. Campos Esteban, M.C. Ramos Giráldez, M. Espinosa Malpartida, M. Bascuas, M. Cuadros, J.L. Andreu, C.M. Isasi Zaragoza, H. Godoy Tundidor, M.M. Jiménez Palop, M.D.C. Barbadillo Mateos, L. Villa Alcázar, J. Mulero Mendoza. *Rheumatology, Hospital Puerta de Hierro, Madrid, Spain*

**Background:** Bone marrow edema (BME) syndrome describes a clinic-radiological entity in which transient subacute or chronic joint pain is associated with characteristic MRI findings (Thiryayi et al.). The etiology remains unknown and can result in significant disability (Guerra et al). Recently, it has been shown that biphosphonates can be used to achieve a reduction in BME (Ringe et al).
**Objectives:** Our objective was to review the cases of patients diagnosed with BME syndrome in the last 6 years which had also received at least one dose of zoledronic acid
**Methods:** We accessed the hospital's Pharmacy database to obtain the zoledronic acid prescriptions from January 2010 to December 2015. Subsequently we selected all the patients with diagnosis of BME syndrome (chronic joint pain AND hypointense on T1-weighted and hyperintense on T2 or STIR sequences). Pain intensity (grade 0: No pain, grade 1: Mild, grade 2: Moderate and grade 3: severe) was measured at baseline, and at 3 and 12 months after treatment with zoledronic acid. MRI changes in bone edema were assessed according to the following scale: Grade 0: No change in edema, Grade 1: Decrease <50% of the initial edema, grade 2: Decrease in >50% of the initial edema, grade 3: Disappearance of bone edema. Functionality was assessed based on whether the patient had returned to his/her daily activities. Finally, complete response was defined as patient fulfilling the following characteristics: Disappearance of pain, or recovery of daily life activities and >50% decrease on bone edema from baseline on MRI.
**Results:** 17 patients met the inclusion criteria (8 male/9 female), with a mean age of 54 years. Most commonly affected site was the ankle 9 cases (52.9%), followed by the hip: 5 cases (29.4%). 16/17 patients had baseline moderate to severe pain, and 12 months after treatment pain disappeared in 13/17. In those patients with post treatment MRI in the first 3 months (8/17), bone edema had disappeared in 5 patients (62%) and the rest of the MRIs showed a reduction of edema greater than 50%. Finally, 13 of 17 patients (76.4%) had a complete response.

Table 1. Evolution of pain, edema on MRI and functionality of patients

| | All (n=17) | Male (n=8) | Female (n=9) | Ankle (n=9) | Hip (n=5) | Knee (n=1) | Foot (n=2) |
|---|---|---|---|---|---|---|---|
| Pain (grades): Basal | | | | | | | |
| G 0: No pain | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| G 1: Mild | 1 (5.8%) | 0 | 0 | 1 | 0 | 0 | 0 |
| G 2: Moderate | 13 (76.4%) | 7 | 6 | 6 | 4 | 1 | 2 |
| G 3: Severe | 3 (17.7%) | 1 | 2 | 2 | 1 | 0 | 0 |
| 3 months | | | | | | | |
| G 0: No pain | 7 (41%) | 3 | 4 | 5 | 1 | 1 | 0 |
| G 1: Mild pain | 8 (47%) | 4 | 4 | 3 | 3 | 0 | 2 |
| G 2: Moderate | 2 (11.6%) | 1 | 1 | 1 | 1 | 0 | 0 |
| G 3: Severe | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 12 months | | | | | | | |
| G 0: No pain | 13 (76.4%) | 7 | 6 | 7 | 4 | 1 | 1 |
| G 1: Mild pain | 3 (17.7%) | 1 | 2 | 2 | 0 | 0 | 1 |

**Conclusions:** The present study shows that zoledronic acid may be a reasonable therapeutic option in bone marrow edema syndrome, as >75% of the treated patients had a complete response. This is the largest series of patients with bone marrow edema treated with zoledronic acid, but more prospective studies are needed.

## THU0502 COMPARISON OF LOW DOSES OF SYSTEMIC CORTICOSTEROIDS THERAPY IN DIABETIC PATIENTS WITH OLIGOARTICULAR OR POLYARTICULAR GOUT FLARES: AN OBSERVATIONAL RETROSPECTIVE STUDY

C.A. Guillen-Astete[1], A. Boteanu[1], M. Villarejo-Botija[2]. *[1]Rheumatology Department; [2]Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** ACR and EULAR recommendations in management of gout flares with oligoarticular involvement points that systemic corticosteroids should be strongly considered in patients with oligoarticular gout flares. However, some considerations must be taking into account before been used, especially in diabetic patients with an unstable glycemic control of with history of hyperglycaemic states after corticoids administration. Instead of avoiding its use, some clinicians use doses lesser than recommended in such patients with different results.
**Objectives:** To compare the effectiveness of different doses of corticoids in diabetic patients with acute oligoarticular gout flares fixed to weight and colchicine doses.
**Methods:** An observational retrospective study was performed. Electronic charts of diabetic patients who consulted to our A&E department from 2013 and 2015 and were diagnosed by oligoarticular gout flare were identified and revised. Registries included patients with oligoarticular gout flares who were not treated with parenteral corticoids or joint infiltrations. They were grouped according to the corticoids dose received fixed by weight and colchicine treatment. Main outcome variables were: need of further consultation before 14th day, VAS-pain score at 7th and 14th day, hyperglucemic states and time off work, where applied. Treatments with systemic corticoids were classified in two arbitrary groups: up to 0.30mg/kg/day (Group I) and 0.31 to 0.49mg/kg/day (Group II). Patients who were treated with higher doses were considered regular doses and were excluded.

**Results:** During the period of observation, 81 registries of diabetic patients diagnosed by gout flares with more than a joint involved were detected. Among them, only 62 had complete registries of weight (diabetic control at primary care facility) and complete follow up assessment after gout flare. 29 and 32 patients were included in groups I and II, respectively. Table 1, summarizes the results of the study.

| Variable | Group I <0.31mg/Kg/day | Group II 0.31-0.49mg/Kg/day | Statistics |
|---|---|---|---|
| Age and SD | 55.0 SD 8.1 | 57 SD 6.4 | *P*=0.286 |
| Male proportion | 27/29 (93.1%) | 31/32 (96.9%) | *P*=0.600 |
| Time after tappering | | | |
| • <7 days | 2 | 2 | |
| • 7-30 days | 22 | 24 | *P*=1.000 |
| • >30 days | 5 | 6 | |
| Colchicine therapy | | | |
| • None | 1 | 2 | |
| • 0.5mg/day | 9 | 8 | |
| • 1mg/day | 11 | 13 | *P*=1.000 |
| • 2mg/day | 8 | 9 | |
| Proportion of patients who asked for medical assessment before 14th day | 13 (44.8%) | 8 (25.0%) | *P*=0.068 |
| VAS pain score and SD at 7th day | 4,3 SD 2,2 | 3,1 SD 1,9 | *P*=0.025 |
| VAS pain score and SD at 14th day | 4,1 SD 2,5 | 2,0 SD 0,5 | *P*=0.0001 |
| Hyperglucemic state during treatment | 1 (3.45%) | 1 (3.13%) | N.A. |
| Time off work (where corresponds) | 6.3 SD 2.6 d/patient | 5.1 SD 1.9 d/patient | *P*=0.051 |

Table 1. Demographic data and results according to doses of prednisone per Kg/day.

**Conclusions:** In diabetic patients with oligoarticular or polyarticular gout flares the therapeutic approach with prednisone doses higher than 0.3mg/kg/day seems to be associated with a lower tendency of need of new clinical assessment, and a better pain control without a higher frequency of hyperglucemic states.

## THU0503 MAJOR CARDIOVASCULAR EVENTS IN PATIENTS WITH RECURRENT GOUT, CARDIOVASCULAR AND CHRONIC KIDNEY DISEASE, INITIATING ON ALLOPURINOL OR FEBUXOSTAT

J. Foody[1], R. Turpin[2], B.A. Tidwell[3], D.F. Eisenberg Lawrence[2], K.L. Schulman[3]. *[1]Brigham and Women's Hospital, Harvard Medical School, Boston; [2]Takeda Pharmaceuticals U.S.A., Inc., Deerfield; [3]Outcomes Research Solutions, Inc., Waltham, United States*

**Background:** Chronic management of hyperuricemia with xanthine oxidase inhibitors has been shown to reduce long term incidence of gout flares, but their resultant impact in highly comorbid populations is unclear.
**Objectives:** To compare major cardiovascular event (MCE) rates in patients with gout, moderate to severe chronic kidney disease (CKD), and cardiovascular disease (CVD) after initiation of uric-lowering therapy (ULT), with allopurinol (ALO) or febuxostat (FBX).
**Methods:** Gout patients (ICD-9-CM 274.xx), aged ≥18, with a baseline diagnosis of stage 3/4 CKD, CVD [coronary artery disease (CAD), cerebrovascular disease (CBV), peripheral vascular disease (PVD)] and/or heart failure (HF), and ≥2 baseline gout flares were selected from the MarketScan® database (January 2009-June 2013) after initiating ULT with either ALO or FBX. Patients were followed until disenrollment, discontinuation of the qualifying ULT or initiation of the alternate study agent. MCE included myocardial infarction, stroke, transient ischemic attack, non-traumatic lower extremity (LE) amputation, and coronary, cerebrovascular, or LE revascularization. Cox proportional hazard models assessed MCE risk as a function of demographics, CVD and HF history, including CVD hospitalization, gout severity, resource intensivity and history of arrhythmia/conduction disorder.
**Results:** A total of 352 patients (148 FBX, 204 ALO) met eligibility criteria (69% male; mean age 71).A majority of patients (74%) had stage 3 CKD and, by definition, all patients had CVD (68% CAD, 15% CBV, and 23% PVD) and/or HF (53%) with no significant differences between cohorts. Mean daily dose was 51 mg in FBX and 198 mg in ALO cohorts. Mean baseline flares per patient were significantly higher in the FBX cohort (2.5 vs. 2.3, p=0.005). A total of 28 MCE occurred in 5.4% and 9.8% of FBX and ALO patients respectively. A total of 15 patients (4.3%) had a CAD-specific MCE, 4 (1.1%) a CBV-specific MCE, and 10 (2.8%) a PVD-specific MCE. The MCE rate per 1000 PY (95% CI) was 75.8 (33–149) in the FBX cohort vs. 128.1 (78–198) in the ALO cohort. Cox model results suggest significantly lower MCE risk in patients initiating on FBX (hazard ratio (HR) 0.4; 95% confidence interval (CI) 0.1–0.9, p=0.035) and those with a HF history (HR 0.4, 95% CI 0.16–0.93, p=0.034). Model results suggest increased risk associated with PVD history (HR 5.3; 95% CI 2.3–12.0, p<0.0001), baseline CVD/HF hospitalization (HR 3.2; 95% CI 1.4–8.0, p=0.008), residing in the western US (HR 4.3; 95% CI 1.4–13.8, p=0.013) and higher baseline expenditure (HR 1.1; 95% CI 1.0–1.1, p=0.006).
**Conclusions:** Patients with recurrent gout, moderate to severe CKD and CVD/HF initiating on FBX had a significantly lower rate of MCE than patients initiating on ALO. It is unclear if this is due to a selective prescribing of drugs from the same therapeutic class to patients with different prognostic characteristics (channeling bias) greater clinical effectiveness of FBX or due to ALO under-dosing in renally impaired patients.

## THU0504 COMORBIDITIES AND THE EFFECTIVENESS OF CORTICOSTEROIDS IN PATIENTS WITH GOUTY ARTHRITIS

E. Mikhnevich[1], T. Pavlovich[2], J. Shishko[2]. *[1]Department of Internal Medicine; [2]University of Medicine, Minsk, Belarus*

**Background:** The choice of an optimal anti-inflammatory therapy (AIT) targeting to cut a gouty attack in the shortest terms is based on the assessment of the severity of gouty arthritis (GA), which involves a visual analog scale (VAS) for pain, number of inflamed joints (NIJ) and their sizes, the time since the onset of a gout attack till the beginning of an AIT.
**Objectives:** To determine the influence of comorbidities on the effectiveness of corticosteroids (CS) in patients with GA inadequately responding to previous AIT.
**Methods:** 220 patients with GA were included into the study. The diagnosis was based on GA criteria (ACR, 1977). 88.2% of patients were males. The mean age was 54.5 ± 9.4 years, the mean duration of disease – 8.2 ± 6.8 years. At the beginning, the patients received either NSAIDs or Colchicine with the mean duration of 10.7 ± 5.7. Because of their non-effectiveness, the treatment with CS i.v. or i.m., excepting long-acting CS, was started in clinical setting. The effectiveness of the CS was evaluated after 5 days: 47.3% (n=104) of patients had no signs of inflammation in the joints, and 52.7% (n=116) of them retained the signs of active arthritis. 28 patients continued the same CS, and 88 patients were added a long-acting CS i.m., i.a. or CS per os. Comorbidities included: eGFR <60 ml/min, cardiovascular (CV) pathologies (hypertension (HT), chronic heart failure II-III FC (CHF), ischemic heart disease (IHD), including coronary disease and arrhythmias), diabetes mellitus (DM), elevation of hepatic enzymes, infections.
**Results:** The patients with a little effect of CS as compared to the group of patients with the satisfactory effect had the longer duration of the previous AIT (p<0.001), higher VAS scores (p<0.005), greater NIJ (p<0.000) and the prevalence of polyarthritis ($\chi^2$ =15.21; p=0.0001).
Among the patients without a significant effect of CS, as opposed to the patients who responded positively to the CS treatment, more cases of eGFR <60 ml /min. were detected (52.6% and 29.8%; OR - 2.71; 95% CI, 2.11 – 3.48; p=0.0004). In the same group, we noted the prevalence of CV pathologies in general (86.2% and 75%; OR - 2.08; 95% CI, 1.39 – 3.13; p=0.035), in particular, CHF (24.1% and 9.6%; OR =2.99, 95% CI 2.35 - 3.81, p=0.004) and IHD (41.4% and 23.1%; OR =2.02, 95% CI 1.58 - 2.58, p=0.004), but not HT (p>0.05). No statistically significant difference in the number of patients with DM between the groups was found (23.3% and 13.5%; $\chi^2$ =3.42; p=0.062). At the same time, elevation of hepatic enzymes by more than 2-fold was observed more frequently in patients with a good effect of CS ($\chi^2$ =5.70, p=0.017). The proportions of patients with the presence of infections were distributed quite equally in both groups (7.4% and 6.1%; p>0.05).
**Conclusions:** Refractoriness to anti-inflammatory drugs in patients with gout along with the parameters of GA severity may also be due to comorbid disorders, such as kidney failure and CV disease (CHF, IHD). Therefore, the assessment of the GA severity for the optimal anti-inflammatory approach might include the assessment of these comorbidities. Their presence should be an indication to an early use of either a monotherapy or combinations of CS that would meet the targets of treatment.

## THU0505 THE DEVELOPMENT OF A NEW EUROPEAN REGULATORY GUIDELINE ON THE CLINICAL INVESTIGATION OF MEDICINAL PRODUCTS FOR THE TREATMENT OF GOUT

E. Rook on behalf of Rheumatology/Immunology Working Party, European Medicine Agency. *Medicine Evaluation Board, Utrecht, Netherlands*

**Background:** The EMA's Committee for Medicinal Products for Human Use (CHMP) prepares scientific guidelines in consultation with regulatory authorities in the EU Member States, to help applicants prepare marketing-authorisation applications for human medicines, including in the domain of rheumatology. These guidelines are developed by the Rheumatology/Immunology Working Party (RIWP), which is composed of European experts selected from or associated with national agencies.

**Objectives:** There is a need of new and safe treatment options for the prevention and treatment of gout attacks, and several are under development. Moreover, the EULAR an ACR have updated their recommendations for the diagnosis and treatment of gout. Imaging techniques become increasingly important in diagnosing and monitoring of gout. Therefore, a CHMP guidance is developed to promote drug development and European consensus on the choice of the endpoints and design of the studies.
**Methods:** Development and release for consultation of the concept paper by the RIWP. The draft guideline will be open for public consultation during the EULAR 2016 Congress (http://www.ema.europa.eu/docs/en_GB/document_library/Scientific_guideline).
**Results:** The development plan and endpoints will mainly be related to the mode of action of the drug. This may either urate lowering therapy (ULT), or anti-inflammatory drugs. For ULT products, serum uric acid (SUA) could serve as a surrogate endpoint. The primary endpoint is defined as SUA levels below a target level of 6 mg/dl, for a period of 3 consecutive months. For tophaceous gout patients SUA levels <5 mg/dl are considered a more appropriate primary endpoint. Tophi can be included as secondary endpoint. At present, imaging of tophi by e.g. ultrasound is considered as supportive evidence, since it's validation has been limited thus far to case series of selected patients. The treatment goal of anti-inflammatory drugs could be the acute treatment of flares. The primary endpoint should reflect a clinically relevant reduction in pain, in a relatively short time frame of 12–24 hrs. A specific goal of anti-inflammatory drugs could be the prophylaxis of flares upon initiation of ULT. The primary endpoint should be the mean number of flares within 3–6 months after the start of ULT. In general, parallel, randomised, double-blind, active-controlled trials should be performed for both ULT and anti-inflammatory drugs.
In addition, long-term anti-inflammatory treatment options may be developed for refractory gout patients with chronic gouty arthropathy, without symptom-free intervals. A suitable primary endpoint could be the reduction of pain, with the improvement of function (e.g. measured by HAQ-DI or Patient's Global Assessment) as co-primary endpoint.
The development of treatment options for *asymptomatic* hyperuricaemia is beyond the scope of this guideline.
**Conclusions:** A European regulatory guideline for the development of new treatment options of gout is under development. The guideline is open for public consultation.

## THU0506 CARDIOVASCULAR RISK AND ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH GOUT: EXPERIENCE IN A MULTIHOSPITAL SPANISH GROUP

E. Calvo Aranda[1], O. Carrión[2], A. Abdelkader[2], J. González[1], F. Aramburu[1], M. Valero[1], S. Rodriguez[1], C. Marin[1], C. Sangüesa[1], I. Amil[1], F. Saiz[2], P. García de la Peña[1]. *[1]Rheumatology; [2]Vascular Surgery, HM Hospitales, madrid, Spain*

**Background:** Several reports have shown the relationship between gout and increased cardiovascular risk (CVR). There is a lack of research in Spain about endothelial and cardiac dysfunction in gout
**Objectives:** Analyze CVR factors in gouty patients in our sample with vascular assessment, cardiological tests and laboratory parameters
**Methods:** Prospective cohort study with collection of clinical data, family history (FH) of gout and cardiovascular disease (CVD), and treatments received (calcium channel antagonists [CCA], ACE inhibitors [ACE-i], angiotensin receptor blokers [ARB], beta blockers [BB] or thiazides. A history of hypertension, diabetes (DM), dyslipidemia (DL), smoking, thrombotic events, ischemic heart disease (IHD) were also collected. Body mass index (BMI), serum uric acid (SUA), sedimentation rate (ESR), conventional/ultrasensitive RCP [cRCP, hsCRP], ferritin, total cholesterol (CHOL) and subtypes (HDLc, LDLc), triglycerides (TG), vitamin D and homocysteine were measured. Patients were referred to Vascular Surgery Department for ultrasound examination with search of carotid plaques and study of intima-media thickness (IMT), and also were to Cardiology Department for echocardiogram (ECHO-CG) and electrocardiogram (ECG)
**Results:** 150 patients, 97% men and 3% women. Average age at time of study and diagnosis: 56 (23–92) and 47 years (15–79), respectively. Age at symptoms onset: 45 years (15–77). 22.5% had tophi and 11.3% urate stones. FH: 42% had gout history and 41% CVD history. Classical CVR factors: hypertension 47.3%; DM-2 4.6%, glucose intolerance 0.6%; DL 56.7% (CHOL: 37, TG: 15, both: 33); smokers 20.6% and quitters 37.6%, 21 pack/year (1–90); 1 patient had suffered stroke; 4 thrombosis; 17 IHD (11 angina, 6 myocardial infarction). 75% overweight/obesity, BMI 28 (19–40). Analytical parameters: ESR 10 mm/h (1–68), hs-CRP 2.7 mg/dL (0.1–57.7), c-CRP 2.3 mg/L (0–14.8); SUA 6.9 mg/dL (2.4–11.8); ferritin 259 ng/ml (11–2000); COL-t: 187 mg/dL (102–321, 6 not collected [NC]), HDLc 47 mg/dL (15–88; 22 NC), LDLc 113 mg/dL (15–248) TG 145 mg/dL (53–603); vitamin D 24.7 ng/mL (5.6–23.6; 28.6% <20); homocysteine 24.7 mmol/L (4–40; 32% >15 mmol/L). ECHO-CG: 6 valvular disease, 13 left ventricular hypertrophy, 45 had >1 finding, 5 NC. ECG was normal in 79 patients; 9 right bundle branch block (BBB), 1 left BBB, 4 IHD signs, 2 repolarization abnormalities and 6 arrhythmia; 13 had ≥2 findings, 9 showed other findings, 54 NC. Vascular examination: carotid IMT greater than corresponding adjusted by age group in 75% and 79% of patients (right and left, respectively); both: 65%. Carotid plaques 23%. Treatments: ACA 2.6%, ACE-i 2%, ARB 4.6%, BB 2%, thiazides 3.3%
**Conclusions:** 75% of our patients have overweight/obesity. High percentage of subjects with hyperhomocysteinemia and/or vitamin D deficiency. Marked prevalence of increased IMT and carotid plaques, and outstanding number of cardiac abnormalities in ECHO-G/ECG. Further statistical studies will quantify the value of these early findings, that seem very relevant

## THU0507 EVIDENCE OF THE USE OF COLCHICINE ARE MORE NUMEROUS IN CARDIOLOGY AND HEPATO-GASTROENTEROLOGY THAN IN RHEUMATOLOGY: A SYSTEMATIC LITERATURE REVIEW OF CLINICAL TRIALS

F. Kemta Lekpa[1], A.F. Kwimatouo Lekpa[2]. *[1]Rheumatology, Douala General Hospital, Douala; [2]Pharmacie et Médicaments, Public Health Ministry, Yaoundé, Cameroon*

**Background:** Colchicine has been used for millennia to treat acute gout flare, but numerous other conditions have been proposed for the use of this "*eau médicinale*", including familial Mediterranean fever, Behçet's disease and pericarditis.
**Objectives:** To investigate the efficacy and safety of colchicine whatever the indication.
**Methods:** A literature search of MEDLINE, EMBASE and Cochrane library databases was performed for human studies without language restriction from inception to January 2016, using the followings key-words: "colchicine", "clinical trial", "clinical controlled trials", "randomized controlled trials". We did not impose any date or language restrictions in the search. We also handsearched reference lists of identified studies.
**Results:** The process of selection of studies is presented in Figure 1. Of the 477 articles reviewed, 106 were analyzed including 77 randomized controlled trials, 2 nonrandomized controlled trials and 27 open studies. The subjects studied were chronic liver disease (n=13), primary biliary cirrhosis (n=11), post cardiac surgery syndromes (n=11), pericarditis (n=9), coronary syndromes and other heart disease (n=6), Familial Mediterranean fever (n=5), Behçet's disease

Table 1. Main clinical trials with colchicine and their efficacy

| | Diseases | RCT available YES/NO | Efficacy YES/NO |
|---|---|---|---|
| Rheumatology | Gout | YES | YES |
| | Familial Mediterranean fever | YES | YES |
| | Behçet's disease | YES | YES |
| | Knee osteoarthritis | YES | Mixed |
| Cardiology | Acute and recurrent pericarditis | YES | YES |
| | Post cardiac surgery syndromes | YES | YES |
| | Coronary heart disease | YES | Mixed |
| Hepatology and gastroenterology | Primary biliary cirrhosis | YES | YES |
| | Primary sclerosing cholangitis | YES | NO |
| | Other chronic liver diseases | YES | Mixed |
| | Constipation | YES | YES |
| Pneumology | Lung fibrosis | YES | NO |
| | Asthma | YES | NO |
| Dermatology | Psoriasis | YES | NO |
| Others | Amyloidosis | YES | YES |

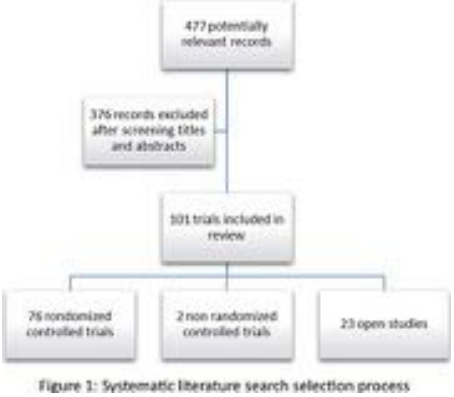

Figure 1: Systematic literature search selection process

(n=5), amyloidosis (n=4), gout (n=3), knee osteoarthritis (n=3), constipation (n=3), lung fibrosis (n=3), psoriasis and psoriatic arthritis (n=3), asthma (n=3), primary sclerosing cholangitis (n=2), low back pain (n=2), proliferative vitreoretinopathy (n=2), recurrent aphthous stomatitis (n=2). Other indications have been evaluated in one clinical trial (Graves' ophthalmopathy, oral mucositis during hematological malignancies, Peyronie's disease, hidradinitis suppurativa, acne vulgaris, chronic bullous dermatosis, actinic keratosis, cutaneous leukocytoclastic vasculitis, finger clubbing and hypertrophic osteoarthropathy, pustulosis palmaris and plantaris, scleroderma, penile condylomata acuminate, mixed cryoglobulinemia, allergic rhinitis, delayed urticaria). Table 1 summarizes the main directions of colchicine in clinical trials. The most common adverse events were gastrointestinal intolerance.
**Conclusions:** Although acute gout is the major indication for use of colchicine, only 3 clinical trials are available for gout and no for other crystal-induced arthritis. Evidence are limited for knee osteoarthritis, low back pain and psoriatic arthritis. Clinical trials published are dominated by the treatement of heart diseases (especially pericarditis), systemic diseases (primary biliary cirrhosis, Familial Mediterranean fever, Behçet's disease) and others chronic liver diseases.
**Disclosure of Interest:** None declared

## THU0508 IMPROVEMENT IN TREAT TO TARGET SERUM URATE LEVELS: RESULTS FROM A COMPARISON BETWEEN THE GEMA AND THE GEMA-II AUDITS

F. Perez-Ruiz[1], M. Andres[2], C. Diaz-Torne[3], E. de Miguel[4], C. Moragues[5], F. Sivera[6], M. Jimenez-Palop[7], C. Sanchez-Piedra[8]. *[1]Rheumatology Division, Hospital Universitario Cruces and Biocruces Health Research Institute, Baracaldo; [2]Rheumatology Division, Hospital Universitario de alicante, Alicante; [3]Rheumatology Division, Hospital Santa Creu i San Pau, Barcelona; [4]Rheumatology Division, Hospital Universitario La Paz, MAdrid; [5]Rheumatology Division, Hospital Bellvitge, Barcelona; [6]Rheumatology Division, Hospital de Elda, Elda; [7]Rheumatology Division, Hospital Universitario Puerta de Hierro; [8]Unidad de Investigación, Sociedad Española de Reumatología, Madrid, Spain*

**Background:** The prior GEMA (1) audit included patients before the EULAR 2006 recommendations were published (2), showing poor adherence to the EULAR recomendations in both crystal-based diagnosis and target urate levels.
**Objectives:** 1) assess the current quality of care in gout patients in Spain and 2) compare the current management with previous audit data.
**Methods:** The GEMA-II study included patients from EULAR 2006 to ACR 2012 guidelines. Agreement on diagnosis and treatment of gout with the EULAR 2006 recommendations was assessed. The selection of patient's files for review was performed selecting a stratified 2-stage sampling of centers according to national population statistics. A random sample in each unit with a diagnosis code of gout (ICD, R9) was centrally selected. The sample size was estimated according to previous results and expected outcomes. The main co-principal variables were >50% improvement in the rate of gold-standard diagnosis and >50% improvement in the rate of patients at target serum urate levels.
**Results:** Data from 511 randomly selected clinical records from 38 units were included. Out of the 38 units, 93% reported having a polarized microscopy facility at the office. sUA at final visit was available in 479/511 (93.7%). Samples from the two audits (GEMA and GEMA-II) did not differ in age, sex distribution or time from onset to first visit.
Crystal-based diagnosis was performed in 209/803 (26.0%) and 162/511 (31.7%) in the GEMA and GEMA-II studies (p=0,030, 5.7% improvement, not reaching endpoint >50%). By contrast, the pre-defined improvement >50% for the rate of patients achieving target serum urate (<6 mg/dl) was achieved (Table) for the overall population, independently of the aprioristic perception of the rate of target sUA or the presence of gold-standard diagnosis. A post-hoc analysis showed that in the subgroup of patients on urate-lowering medications, the improvement in the rate of patients achieving sA target was 49.31%, very close to the >50% improvement (Table).
Both crystal based diagnosis and rate of sUa in target were higher in Units with dedicated crystal-arthritis office and also in those that had presented the EULAR 2006 recommendations at least once.

Table 1

| All patients | | | Patients on urate-lowering treatment | | |
|---|---|---|---|---|---|
| sUA (mg/dl) | <6 mg | ≥6 mg | sUA (mg/dl) | <6 mg | ≥6 mg |
| GEMA (N=701) | 286 (40.8) | 415 (59.2) | GEMA (N=642) | 274 (42.7) | 368 (57.3) |
| GEMA-II (N=479) | 294 (61.4) | 185 (38.6) | GEMA-II (N=450) | 285 (63.3) | 165 (37.7) |

**Conclusions:** Overall the improvement in the rate of patients achieving target serum urate over a 6-year period exceeded 50%. The rate of gold-standard diagnosis improved, but did not reach the expected outcome. Interest in recommendations and dedicated crystal arthritis offices were associated with best results.
These preliminary data show for the first time that substantial improvement has been achieved in treat to target serum urate levels strategy for gout in the Rheumatology community.

## THU0509 OPTICAL COHERENCE TOMOGRAPHY DESCRIPTION OF TOPHI IN GOUT SHOWS THAT IRREGULAR TOPHUS MORPHOLOGY, OEDEMA AND ABSENCE OF CAPSULE ARE ASSOCIATED WITH SYMPTOMATIC DISEASE

G. Abignano[1,2], F. Del Galdo[1,2], D. McGonagle[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** The basis as to why chronic gout related tophi may be completely asymptomatic is not understood. In experimental settings coating of gouty crystals may be associated with the prevention of inflammatory responses (1).
**Objectives:** We used optical coherence tomography (OCT) in patients with gout to test the hypothesis that tophus related pain was due to the disruption of tophus capsule.
**Methods:** Eight consecutive patients with tophaceous gout were recruited. Each patient received detailed clinical assessment by a Rheumatologist including physical examination, history, current therapy, presence, number and site of tophi and whether or not each tophus was symptomatic. Tophi were photographed and scanned using Vivosight OCT scan (Michelson Diagnostics, Kent, UK). OCT of corresponding regions of the opposite side were undertaken for comparison and for subclinical tophi evaluation. One hundred slices OCT scans allowed post-processing 3D reconstructions of the visualized superficial tophus morphology (smooth or irregular) and presence or absence of tophus capsule were assessed. VAS pain scores for individual tophi were subsequently collected and correlated with imaging.
**Results:** Thirty seven tophi from eight patients with tophaceous gout were scanned. Four patients had tophi located at fingers, one at toes, two at both sites. Two patients of the third group had additional sites involved in form of multiple aggregates located at knees, heels, elbows. VAS score ranged from 0 to 9 (median=2). Eleven of the 37 tophi were symptomatic (VAS score range: 4–9), the remaining 26 were mildly or not symptomatic (VAS score 0–3). Most of the tophi (28/37) had a smooth border, 9 had an irregular aspect. Tophi with smooth border seemed to be surrounded by a "pseudo-capsule" ($p<0.05$). Tophi with irregular aspect were associated with optical density changes possibly consistent with oedema ($p<0.05$). A relationship between irregular tophi and pain was evident (p=0.0025). On the contrary, presence of smooth tophi with capsules were not associated with significant pain.
**Conclusions:** These findings suggest that non-painful tophi in patients with tophaceous gout have a different morphology and a capsule which provides support for the idea that a capsule prevents pain and inflammation. Capsular disruption is linked to flares and the hypothesis that initial serum urate lowering therapy may lead to capsule disruption should be further investigated.

## THU0510 A LONGITUDINAL DUAL ENERGY COMPUTED TOMOGRAPHY STUDY ON THE EFFECT OF URATE LOWERING THERAPIES ON THE REDUCTION OF TOPHUS BURDEN IN PATIENTS WITH CHRONIC GOUT

H. Ellmann[1], S. Bayat[1], I. d'Òliveira[1], M. Englbrecht[1], E. Araujo[1], S. Mendonca[2], A. Cavallaro[3], M. Lell[3], B. Manger[1], G. Schett[1], J. Rech[1]. *[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [2]Americas Medical City, Rio de Janeiro, Brazil; [3]Department of Radiology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany*

**Background:** Dual energy computed tomography (DECT) allows reliably detecting and quantifying tophus burden in patients with chronic gout. Longitudinal studies on the effect of uric acid lowering drug therapy on tophus burden assessed by DECT are currently lacking with the exception of a small study performed in patients treated with pegloticase (1)
**Objectives:** To assess the effects of uric acid lowering drug therapy to reduce tophus volume in patients with chronic gout
**Methods:** Follow-up DECT scans were performed in 94 patients with DECT+ chronic gout receiving stable treatment with either allopurinol, febuxostat, benzbromaron or pegloticase, or had life-style intervention only with no concomitant uric acid lowering drug therapy. Baseline and follow-up scans of both feet captured tophus volume by *Syngo DE Gout* software (Siemens). Artefacts were manually excluded. Changes in tophus volume were calculated in a descriptive (tophus volume at baseline minus tophus volume at follow-up) and inferential way (Wilcoxon signed-rank test). Demographic data, medication and blood values (CRP, creatinine, serum urate) were recorded at the time of DECT scan.

**Results:** 94 patients (75 men and 19 women) were analyzed. Mean disease duration until the first DECT examination was 3.3 years and mean interval between both DECT examinations was 1.5 years. The overall baseline serum uric acid level decreased from 7.3 ± 2.5 mg/dl to 5.9 ± 2.8 mg/dl at follow up. Baseline tophus volume decreased by 77% with allopurinol ($p<0.001$, r=-0.50), 35% with febuxostat (p=0.001, r=-0.51) and 90% with pegloticase (p=0.005, r=-0.58). Only 2 patients were treated with benzbromaron showing numerical decrease of tophus volume at a similar range as seen with allopurinol (-75%). Life-style intervention also led to a moderate (-31%), though significant (p=0.007, r=-0.40), decrease in tophus burden.

| Parameters | No therapy N = 20 | Allopurinol N = 28 | Febuxostat N = 25 | Pegloticase N = 12 | Uricosurics N = 2 | Discontinuation N = 6 |

| p- value# | 0.007 | <0.001 | 0.001 | 0.005 | 0.317 | 0.093 |

Results are mean ± SD for continuous and n/N for categorical variables. SD, standard deviation.
* Disease duration until first DECT in years
† Interval between DECT1 and DECT2 in months, corresponds the application period
‡ Absolute urate reduction/Baseline urate volume
# Asymptotic significance

**Conclusions:** Sustained uric acid lowering drug therapy leads to significant reduction of DECT tophus burden in chronic gout patients. Tophus reduction depends on initial tophus volume.

## THU0511 FACTORS ASSOCIATED WITH PRECLINICAL ATHEROSCLEROTIC CHANGES IN CAROTID ARTERY IN MEN WITH GOUT

H. Tag[1], G. Kim[1], E. Park[2], D. Koo[3], J. Lee[4], S. Kim[5]. *[1]Division of Rheumatology, Dept. of Internal Medicine, Kosin University College of Medicine; [2]Division of Rheumatology, Dept. of Internal Medicine, National University Hospital; [3]Division of Rheumatology, Dept. of Internal Medicine, Pusan National University Hospital; [4]Division of Rheumatology, Dept. of Internal Medicine, Busan St. Mary's Hospital; [5]Division of Rheumatology, Dept. of Internal Medicine, Inje University College of Medicine, Busan, Korea, Democratic People's Republic Of*

**Background:** Although a number of studies have reported that hyperuricemia and gout are independent risk factors for the development of cardiovascular disease (CVD), little is known about the relationship between hyperuricemia or gout and arterial stiffness.

**Objectives:** This study sought to compare carotid arterial stiffness in gout patients and healthy controls, and evaluate the predictive factors for arterial stiffness in male patients with gout using carotid ultrasonography.

**Methods:** In this cross-sectional study, 69 male gout patients and 64 male healthy controls without any known CVD were prospectively analyzed. Carotid artery stiffness index β (β-index) and the intima-media thickness (IMT) were measured as surrogate markers of preclinical atherosclerosis. We also measured serum uric acid, high sensitivity C-reactive protein (hsCRP), erythrocyte sedimentation rate (ESR), lipid profiles, and renal function. Adjusted comparison of the β-index and cIMT in both groups and their associations with clinical parameters were investigated.

**Results:** The gout group showed higher ESR, Cr, prevalence of HT and DM than the control group ($p<0.05$). However, HDL was higher in the control group ($p<0.05$). β-index and cIMT were higher in the gout group, but only β-index showed a statistically significant difference (11.12 ± 5.19 vs 8.68 ± 3.67, p=0.002). Multiple regression analyses showed that duration of gout was significantly associated with increased β-index and cIMT in the gout group (Table 1).

Table 1) Multiple regression analyses of clinical factors possibly affecting the β-index and cIMT in gout group

| | β-index | | cIMT | |
|---|---|---|---|---|
| | β ± SE | p | β ± SE | p |
| Age | 0.122 ± 0.070 | 0.087 | 0.002 ± 0.002 | 0.296 |
| PY of smoking | -0.051 ± 0.040 | 0.210 | -0.001 ± 0.001 | 0.579 |
| Duration of gout | 0.222 ± 0.110 | 0.049 | 0.009 ± 0.003 | 0.004 |

## THU0512 INSULIN RESISTANCE AS AN INDEPENDENT PREDICTOR OF SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH GOUT

J.H. Kim, H. Jeon, S.H. Kim, H. Kim, J. Yoo, M.K. Chung, J.H. Koh, J. Lee, S.-K. Kwok, J.H. Ju, S.-H. Park. *Rheumatology, Seoul Saint Mary's Hospital, Seoul, Korea, Republic Of*

**Background:** Gout is linked with metabolic disorders those are important risk factors of cardiovascular diseases.

**Objectives:** The aim of the present study was to identify independent predictor of subclinical atherosclerosis in patients with gout by measuring presence of atherosclerotic plaque and prevalence of erectile dysfunction (ED).

**Methods:** We analyzed 80 patients with gout and 70 healthy controls. Carotid plaque and ED were assessed by using ultrasound measurement of carotid plaque and the five-item version of the International Index of Erectile Function questionnaire in participants, respectively. Logistic regression analysis was performed to estimate the effect of variables on presences of carotid plaque or ED on all of the study subjects and patients with gout.

**Results:** Gout patients had more ED (55.3% vs. 41.4%, $p<0.047$) and carotid plaque (59.2% vs. 17.1%, $p<0.007$) compared to controls. After adjustment of compounding factors, only HOMA-IR was significantly associated with ED (OR: 1.82, 95% CI: 1.05–3.15) whereas was not with carotid plaque (OR: 1.02, 95% CI: 0.99–1.47). Gout showed significant association with carotid plaque after multivariate analysis (OR: 13.39, CI: 1.93–92.88). Older age ($p<0.001$), higher HOMA-IR (p=0.048) and lower GFR (p=0.038) were observed in patients with presence of ED than without ED in gout patients. And gout patients with carotid plaque were older (p=0.003) and had higher insulin level (p=0.035) and HOMA-IR (p=0.039) than without plaque. Logistic regression analysis showed that HOMA-IR was an independent predictor for the presence of both ED (OR: 1.62, 95% CI: 1.03–2.82) and carotid plaque (OR: 1.40, 95% CI: 1.04–1.63).

**Conclusions:** In our study, insulin resistance was an independent predictor of subclinical atherosclerosis in patients with gout.

**Disclosure of Interest:** None declared

## THU0513 DETECTION OF SUBCLINICAL TOPHI IN PATIENTS WITH GOUTY ARTHRITIS: A DUAL-ENERGY COMPUTED TOMOGRAPHY STUDY

I.J. Kim[1], J.Y. Hwang[2], J. Lee[1]. *[1]Dept. of Rheumatology; [2]Dept. of Radiology, Ewha Womans University Mokdong Hospital, Seoul, Korea, Republic Of*

**Background:** Tophi are generally considered as manifestations of chronic gout, but subclinical tophi in intra- and extra-articular structures have been shown to occur in early gout and asymptomatic hyperuricemia. Since occurrence of tophi is linked to joint destruction, it is important to detect tophi early before clinical detection.

**Objectives:** The aim of our study was to evaluate the utility of dual-energy CT (DECT) in detecting subclinical tophi in patients with gouty arthritis.

**Methods:** DECT scans of feet in 65 patients with gout without apparent clinical tophi were evaluated for presence of tophi. Plain X-ray of feet, clinical and laboratory data were obtained simultaneously at the time of the DECT evaluation. Total volumes of tophi in both feet were quantified using an automated software program of DECT.

**Results:** Subclinical tophi were detected in 63 (96.9%) patients and in 341 (18.7%) joints, and median 3 (1 to 22) joints per patient were positive for tophi. The most common sites for tophi were first metatarsophalangeal joints (17.6%), followed by ankle joints (10.9%). Tophi in Achilles tendons were present in 10.8% of patients. Patients with early gout (disease duration <2 years) had tophi in 99 (13.6%) joints. Mean number of tophi was significantly lower in patients with early gout compared to those with chronic gout (3.8 versus 6.2, p=0.038). Mean volume of tophi was not significantly different between early gout and chronic gout.
**Conclusions:** Tophi frequently occur in both intra- and extra-articular structures of gouty arthritis patients despite absence of clinically apparent tophi. DECT is an excellent imaging modality for detecting subclinical tophi.

## THU0514 SEASONAL VARIATIONS OF EPISODES OF ACUTE GOUTY ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

J.-B. Jun[1], K.Y. Park[2], H.J. Kim[3], H.S. Ahn[3], S.H. Kim[2], S.-Y. Yim[2].
*[1]Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul; [2]Physical Medicine and Rehabilitation, Ajou University School of Medicine, Suwon; [3]Preventive Medicine, College of Medicine, Korea University, Seoul, Korea, Republic Of*

**Background:** Acute gouty arthritis is the inflammatory arthritis with abrupt and intermittent nature of attack.
**Objectives:** The aim of this study was to analyze the seasonal variations of episodes of acute gouty arthritis.
**Methods:** We searched MEDLINE, EMBASE, the Cochrane library, and KoreaMed for all articles published before November 2015. Studies with quantitative data on episodes of acute gouty arthritis by months and/or seasons were included. Meta-analysis for episodes of acute gouty arthritis was done by seasons and months. Subgroup analyses by the confirmatory methods of acute gouty arthritis were done by seasons.
**Results:** Ten studies published between 1920 and 2015 were included, containing a total of 29,863 subjects. Plotting of episodes of acute gouty arthritis by months showed higher episodes during the period from March to July than other months. The risk ratio of episodes of acute gouty arthritis in spring was 1.21 (95% CI: 0.95 to 1.55, $I^2$=86%; $p$=0.12), 1.32 (95% CI: 0.98 to 1.78, $I^2$=90%; $p$=0.07), 1.27 (95% CI: 1.02 to 1.59, $I^2$=81%; $p$=0.03) when compared to summer, fall and winter, respectively. Therefore, spring had significantly higher episodes of acute gouty arthritis than winter. Subgroup analyses by confirmatory methods of episodes of acute gouty arthritis were as follows: 1) The risk ratio of acute gouty arthritis confirmed by the presence of monosodium urate in synovial fluid in spring was 1.46 (95% CI: 1.22 to 1.76, $I^2$=0%; $p$<0.0001), 1.28 (95% CI: 1.07 to 1.54, $I^2$=7%; $p$=0.007), 1.24 (95% CI: 0.93 to 1.65, $I^2$=59%; $p$=0.15) when compared to summer, fall and winter, showing that spring had significantly higher episodes of acute gouty arthritis than summer and fall; 2) The risk ratio of acute gouty arthritis confirmed by the presence of inflammation in synovial fluid was 1.53 (95% CI: 1.31 to 1.80, $I^2$=0%; $p$<0.00001), 1.44 (95% CI: 1.07 to 1.93, $I^2$=69%; $p$=0.02), 1.28 (95% CI: 1.05 to 1.55, $I^2$=40%; $p$=0.01) when compared to summer, fall and winter, showing that spring had significantly higher episodes of acute gouty arthritis than 3 other seasons.
**Conclusions:** This seems to be the first systematic review and meta-analysis on seasonal variations of acute gouty arthritis. Based on our study, the acute gouty arthritis might be developed more frequently during the period from spring. Increase in physical activity, dehydration, and seasonal variation of cortisol level could be related with this seasonal variation of episodes of acute gouty arthritis.

## THU0515 INCREASED CAROTID INTIMA-MEDIA THICKNESS WAS RELATED WITH ELEVATED SERUM HOMOCYSTEINE LEVEL IN PATIENTS WITH HYPERURICEMIA

J.H. Park, S.T. Choi, J.-S. Song. *Internal Medicine, CHUng-Ang University College of Medicine, Seoul, Korea, Republic Of*

**Background:** Hyperuricemia is known to be associated with metabolic syndrome and cardiovascular disease (CVD). It was reported that elevated level of homocysteine (Hcy) in patients with gout was related with decreased renal function. A high level of Hcy is regarded as a risk factor for CVD, since Hcy is related with endothelial cell damage, which can lead to inflammation in the blood vessels and atherosclerosis. However, there was no report about the relationship between Hcy and atherosclerosis in patients with hyperuricemia.
**Objectives:** In this study, we investigated whether or not carotid intima-media thickness (IMT) was increased in patients with hyperuricemia. We also evaluated the correlation between serum Hcy level and carotid IMT in hyperuricemic patients.
**Methods:** This study includes 1,228 patients who visited the Health Promotion Center of Chung-Ang University Hospital from January 2013 to August 2015. Serum Hcy, uric acid, fasting glucose, blood urea nitrogen (BUN) and creatinine (Cr), cholesterol profiles, C-reactive protein (CRP) and other laboratory findings were tested. Serum Hcy level was measured by a competitive immunoassay using direct chemiluminescent (Siemens Centaur Immunoassay Systems, USA). Carotid IMT was measured by B-mode carotid ultrasonography. Hyperuricemia was defined as the serum uric acid above 7.0 mg/dL, and hyperhomocysteinemia was defined as the serum Hcy above 15.0 μmol/L.
**Results:** The mean ages of hyperuricemic and normouricemic patients were not significantly different (51.19 ± 15.08 vs. 51.57 ± 17.01, $p$=0.833), however, the male ratio in hyperuricemia group was higher than that in normouricemia group (160/167, 96% vs. 732/1,061, 69%, $p$ <0.001). Patients with hyperuricemia showed significantly higher levels in serum Hcy than normouricemic individuals (13.65 ± 4.47 μmol/L vs 11.68 ± 3.65 μmol/L, $p$<0.001). Carotid IMT in hyperuricemia group was significantly thicker than that in normouricemia group (1.13 ± 0.66 mm vs 1.03 ± 0.53, $p$ =0.029). In patients with hyperuricemia, carotid IMT was correlated with serum Hcy level ($\gamma$=0.209, $p$=0.007), estimated glomerular filtration rate (eGFR), serum BUN and Cr levels ($\gamma$= -0.318, $p$<0.001; $\gamma$=0.229, $p$=0.003; $\gamma$=0.311, $p$<0.001, respectively), however, it was not correlated with serum uric acid level, glucose level and cholesterol profiles. It was shown that serum Hcy level was correlated with eGFR, serum BUN and Cr levels in hyperuricemic patients ($r$= -0.490, $p$<0.001; $r$=0.369, $p$<0.001; $r$=0.487, $p$<0.001, respectively), whereas it was uncorrelated with cholesterol profiles. The patients with high serum Hcy showed higher level of IMT than the patients with low serum Hcy (1.18 ± 0.68 mm vs 1.02 ± 0.52 mm, $p$<0.001). In multiple linear analyses, carotid IMT was affected by eGFR ($\beta$= -0.289, $p$=0.001), however, it was not influenced by glucose level and cholesterol profiles in patients with hyperuricema.
**Conclusions:** Carotid IMT was higher in patients with hyperuricemia than in those with normouricemia, and it was correlated with serum Hcy level in patients with hyperuricemia. This study suggests that decreased renal function in patients with hyperuricemia leads to elevated serum Hcy level, which in turn leads to atherosclerosis.

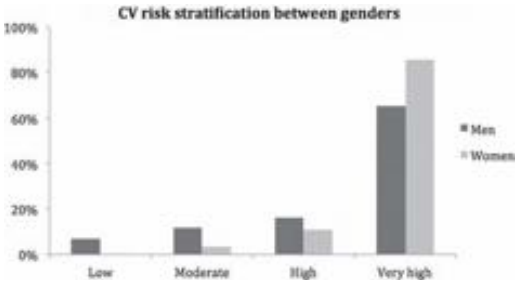
## THU0516 SERUM URIC ACID IS POSITIVELY ASSOCIATED WITH PULMONARY FUNCTION IN KOREAN HEALTH SCREENING EXAMINEES: A CROSS-SECTIONAL STUDY

J. Hwang[1], J.-U. Song[2], H. Jung[3], H. Kim[3], J. Lee[3], H.-S. Cha[3], E.-M. Koh[3], J.K. Ahn[2]. *[1]National Police Hospital; [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine; [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of*



**Background:** Serum uric acid (SUA) is an end product from the action of xanthine oxidase on purine or purine-containing compounds. Recently, much attention has been paid to the role of uric acid in disease modification. A recent study supports the view that hyperuricemia may be an independent risk factor for impaired pulmonary function in the general population. On the other hand, in view of its antioxidant properties, uric acid potentially has important beneficial effects within the respiratory system. The double-edged characteristics of SUA and mixed results from previous studies have complicated determination of whether SUA plays a pulmonary-protective or pulmonary-destructive role.
**Objectives:** The aim of this study was to determine whether level of SUA, a potent antioxidant, is linked to pulmonary function in health screening examinees without overt clinical disease.
**Methods:** We performed a cross-sectional study on 69,928 Koreans without overt medical conditions who underwent a health examination in 2010.
**Results:** A total of 30,572 male (43.7%) and 39,356 female eligible subjects were enrolled in our study. The overall prevalence of hyperuricemia among Korean health screening examinees was 25.5% in males and 8.5% in females. The median age of subjects was 40 (range 35–46) years. Increasing age was positively associated with SUA level. In sex-stratified analyses of SUA level, mean SUA level was positively associated with a quartile increase in FVC% and FEV1% in both genders ($P$ <0.001). There were also a significant positive correlation between SUA level and spirometric measures (FEV1% or FVC%) in both genders (FVC%, $r$ =0.361; FEV1% $r$ =0.314 in men and FVC%, $r$ =0.413; FEV1%, $r$ =0.382 in women). Multiple regression analysis was performed to assess whether FEV1% and FVC% were independently associated with the prevalence of hyperuricemia. The adjusted ORs for hyperuricemia comparing quartiles 2, 3, and 4 to quartile 1 (the reference group, highest quartile) of FVC% in men were 0.876 (95% CI, 0.809–0.949), 0.631 (0.574–0.695), and 0.311 (0.278–0.349), respectively. The adjusted ORs for hyperuricemia comparing quartiles 2, 3, and 4 to quartile 1 of FEV1% in men were 0.791 (95% CI, 0.729–0.859), 0.565 (0.513–0.623), and 0.302 (0.270–0.337), respectively ($p$ for trend <0.001). Similarly, the adjusted ORs of hyperuricemia in women decreased significantly across quartiles 2 to 4 of FEV1% and FVC % compared with the highest quartile as the reference group ($P$ for trend <0.001).
**Conclusions:** SUA was positively associated with FVC% and FEV1% in a healthy Korean population. This finding has important implications for the hypothesis that hyperuricemia might have a favorable effect on lung function. Longitudinal follow-

up studies and prospective interventional studies are required to confirm this positive association between SUA and lung function.

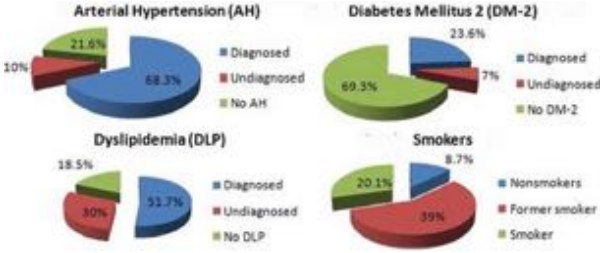
## THU0517 WOMEN WITH GOUT SHOW A POORER CARDIOVASCULAR PROFILE AFTER STRUCTURED ASSESSMENT

J.A. Bernal[1], M. Andrés[1], F. Sivera[2], L. Carmona[3], P. Vela[1,4], E. Pascual[1,4]. *[1]Rheumatology, Hospital General Universitario de Alicante, Alicante; [2]Rheumatology, Hospital General Universitario de Elda, Elda; [3]Instituto de Salud Musculoesquelética, Madrid; [4]Universidad Miguel Hernández, Elche, Spain*

**Background:** Cardiovascular (CV) disease affects gout patients. This is thought to result from a combination of an increase in CV risk factors and crystal-led inflammation. Despite being more prevalent in men, gout also has an impact on the CV risk of women (1). To date, few studies have focused on gender differences on gout, especially in terms of CV assessment.
**Methods:** Observational, cross-sectional study. Consecutive newly-diagnosed crystal-proven gout patients seen in a tertiary hospital underwent a structured CV assessment which included risk prediction tools, carotid ultrasound and CV risk stratification according to current European guidelines. Gout features were also registered. A gender comparison in the different variables was performed, employing chi-2 tests for binary variables, and Student's t or Mann-Whitney's tests for quantitative variables.
**Results:** A total of 199 patients - 28 (14.1%) women and 171 (85.9%) men - were analyzed. Women were significantly older than men (72.7± 11.1 years in women vs 62± 13.0 in men, $p<0.001$). In terms of CV risk factors, women had more commonly high blood pressure (89.3% vs 64.9%, p=0.01), diabetes (53.6% vs 18.7%, $p<0.001$), diuretic use (78.6% vs 38.2%, $p<0.001$), and chronic kidney disease (71.4% vs 21.3%, $p<0.001$). Smoking background was more frequent in men (20% vs 66%, $p<0.001$), and dyslipidemia rates were similar. Uric acid levels at diagnosis were higher (8.97 vs 7.82 mg/dL, p=0.001) in women. Regarding gout features, men showed longer disease duration (median (p25–75) 1 year (0–3.0) in women and 5 years (2.0–15.0) in men, p=0.005) and reported more gout attacks (2 attacks (1.0–3.5) in women and 5 (3.0–20.0) in men, p=0.001), with no differences between genders in the proportion of patients with tophi. No significant differences in carotid plaques were noted (50% in women and 33.6% in men, p=0.32), but ultrasound was often deemed unnecessary in women because they already presented a very high CV risk at assessment (64.3% of women and 33.7% of men, p=0.002). At final CV risk stratification, women tended to show higher CV risk than men (Figure 1).



**Conclusions:** The CV profile of women with gout seems worse than male patients in this series. Differences in gout pathogenesis between genders likely explain these results. This finding highlights the need for an optimal CV management when dealing with female gout patients.

## THU0518 NEW CARDIOVASCULAR RISK FACTORS SCREENING IN PATIENTS WITH GOUT

J.C. Ordóñez[1], M. Andres[1], J.A. Bernal[1], F. Sivera[2], L. Carmona[3], P. Vela[4], E. Pascual[5]. *[1]Rheumatology, Hospital General Universitario de Alicante, Alicante; [2]Rheumatology, Hospital General de Elda, Elda; [3]Instituto de Salud Musculoesquelética, Madrid; [4]Rheumatology, Hospital General Universitario de Alicante, Departamento de Medicina Clínica, Universidad Miguel Hernández; [5]Rheumatology, Hospital General Universitario de Alicante, Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain*

**Background:** Gout is a disease triggered by the crystallization of uric acid in the joints secondary to persistent hyperuricemia, that leads to chronic inflammation. Patients with gout frequently have comorbidities including cardiovascular (CV) disease, kidney failure, diabetes mellitus etc. In fact, some these can increase the levels of uric acid and contribute to develop gout, and also deteriorate the CV profile of these patients. Therefore, their control and identification is essential for a proper management.
**Objectives:** To assess the prevalence of unknown cardiovascular risk factors (CVRF) in patients with gout.
**Methods:** Cross-sectional analysis of a inception cohort of gout patients recruited by consecutive sampling in our rheumatology unit. Gout was diagnosed by visualization of monosodium urate crystals in synovial fluid or tophus sample. A structured CV assessment included CVRF, measurement of blood pressure, anthropometry and lab tests. Arterial Hypertension (AH) was defined by previous diagnosis, blood pressure ≥140/90mmHg and/or use of antihypertensive agents. Type 2 Diabetes Mellitus (DM-2) was defined by previous diagnosis, fasting blood glucose ≥126 mg/dL, glycosylated hemoglobin ≥6.5%; presence of microangiopathic complications was also registered. Dyslipidemia (DLP) was defined by previous diagnosis, use of hypolipidemic agents, or total cholesterol>200 mg/dL and/or triglycerides >150 mg/dL. A descriptive analysis of the results is presented.
**Results:** The study involved 199 patients. The mean age was 63.4 (SD ±13.2) years, with 171 (85.9%) men. At inclusion the prevalence of CVRF was: AH in 136 patients (68.3%), DLP in 13 (51.8%), and DM-2 in 47 (23.6%). Seventy-six (38.6%) were found obese, smoking background was present in 40 (20.1%), use of diuretics (loop and/or thiazide) in 87 (43.7%), and chronic renal failure in 57 (28.6%). After structured assessment, the following undiagnosed CVRF were found: DLP in 59 patients (29.6%), AH in 20 (10.1%) and DM-2 in 14 (7%). New CVRF were found in 94 (46.7%) patients, among them 52 (26.1%) had one CVRF, 13 (6.5%) had 2 CVRF, and even 3 CVRF were identified in 2 cases (1.0%). The final prevalence of CVRF in included gout patients is shown in the Figure.

**Conclusions:** Half of our patients showed at least one unknown CVRF, mostly DLP followed by hypertension and DM-2. This finding highlights the need for active screening for new CVRF in patients diagnosed with gout, due to the potential impact on the proper CV management.

## THU0519 XANTHINE OXIDASE GENE VARIANTS AND THEIR ASSOCIATION WITH BLOOD PRESSURE AND INCIDENT HYPERTENSION: A POPULATION STUDY

L.E. Scheepers[1], F. Wei[2], K. Stolarz-Skrzypek[3], S. Malyutina[4], V. Tikhonoff[5], L. Thijs[2], E. Salvi[5], C. Barlassina[5], J. Filipovský[6], E. Casiglia[5], Y.P. Nikitin[7], K. Kawecka-Jaszcz[3], P. Manunta[8], D. Cusi[9], A. Boonen[1], J.A. Staessen[2], I.C. Arts[10]. *[1]Rheumatology, CAPHRI, Maastricht University, Maastricht, Netherlands; [2]Cardiovascular Diseases, Studies Coordinating Centre, Research Unit Hypertension and Cardiovascular Epidemiology, KU Leuven, Leuven, Belgium; [3]Cardiology, Interventional Electrocardiology and Hypertension, Jagiellonian University Medical College, Kraków, Poland; [4]Institute of Internal and Preventive Medicine, Novosibirsk, Russian Federation; [5]Clinical and Experimental Medicine, University of Padova, Padova, Italy; [6]Internal Medicine II, Charles University, Pilsen, Czech Republic; [7]Internal and Preventive Medicine, Novosibirsk, Russian Federation; [8]School of Nephrology, University Vita-Salute San Raffaele; [9]Institute of Biomedical Technologies, Italian National Centre of Research, Milan, Italy; [10]Epidemiology, CARIM, CAPHRI, and MaCSBio, Maastricht University, Maastricht, Netherlands*

**Background:** Uric acid has been associated with blood pressure and hypertension. During the final stage of purine metabolism xanthine oxidoreductase (XOR) produces uric acid, while at the same time reactive oxygen species are formed. We hypothesized that uric acid production, as assessed indirectly from *XOR* variants, is associated with hypertension (figure 1).
**Objectives:** The aim of the present study is to investigate the association of variants in the *XOR* gene with blood pressure and the development of hypertension.
**Methods:** Analyses were conducted in the prospective Flemish FLEMENGHO and European EPOGH study. Among 2769 participants (48.3% men; mean age

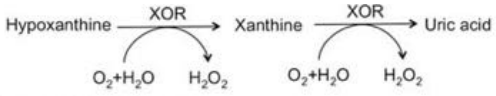

**Figure 1. Purine metabolism**
During the final stage of the purine metabolism, xanthine oxidoreductase (XOR) breaks down hypoxanthine to xanthine, and xanthine to uric acid, while reactive oxygen species are formed. These free radicals inactivate the vasodilator nitric oxide.

40.7 years) we genotyped 25 *XOR* SNPs and measured blood pressure at baseline and follow-up (median 8.8 years). The relation between variants of the *XOR* gene with changes in pulse pressure and mean arterial pressure over time; and incidence of hypertension, were analysed using multivariable mixed models and cox-regression, respectively.

**Results:** Compared with major allele homozygotes, pulse pressure increased approximately 2 mm Hg more in minor allele carriers of rs11904439 (*P*=value 0.01), whereas mean arterial pressure and diastolic blood pressure increased approximately 1 mm Hg less in minor allele carriers of rs2043013 (*P*=0.01). In 2050 participants normotensive at baseline, hazard ratios contrasting risk of hypertension in minor allele carriers *vs.* major allele homozygotes was 1.31 (95% confidence interval [CI] 1.03–1.68) for rs11904439 and 1.69 (95% CI 1.11–2.57) for rs148756340. With the false discovery rate set at 0.25, the aforementioned associations retained significance. The changes in systolic blood pressure from baseline to follow-up and the serum levels of uric acid at baseline (n=1949) were not associated with *XOR*.

**Conclusions:** In conclusion, pending confirmation in appropriately powered cohort studies, our findings suggest that variation in uric acid production, as captured by genetic variation in *XOR*, might be a predictor of changes in pulse pressure, mean arterial pressure and in the risk of hypertension.

## THU0520 TREATMENT OF GOUT – FACTORS AFFECTING INITIATION AND PERSISTENCE OF URATE LOWERING THERAPY

M.I. Dehlin[1], E. Hoxha Ekström[2], M. Petzold[3], U. Strömberg[2], G. Telg[4], L. Jacobsson[5]. *[1]Dept of rheumatology and inflammation research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg; [2]Gothia Forum; [3]Health Metrics & Swedish National Data Service, University of Gothenburg, Gothenburg; [4]AstraZeneca, Södertälje; [5]Dept of rhaumatology and inflammation research, Institution of medicine, Sahlgrenska academy, University of Gothenburg, Gothenburg, Sweden*

**Background:** Gout is the most common inflammatory arthritic disease. Treatment has been available since the 1950's and studies from different countries have demonstrated insufficient treatment with urate lowering therapy (ULT); however, contemporary data are scarce.

**Objectives:** The aims of the present observational registry study were to determine; 1) the proportion of patients receiving ULT after gout diagnosis and predictors thereof, and 2) the proportion of patients stopping ULT temporarily and predictors thereof.

**Methods:** All incident cases of patients with gout in the Western Swedish Health Care Region (WSHCR) during 2005–2013, age ≥18 years, were identified in the healthcare consumption database VEGA. WSHCR covers approximately 20% of the total Swedish population. Incident case of gout was defined as a visit with gout diagnosis (ICD-10-CM M10, M14.0–14.1), not preceded by a gout diagnosis during the previous 12 months. First dispense of ULT (allopurinol, febuxostat and probenecid) was identified in the Swedish Prescribed Drug Register. Age, comorbidities (ischemic heart disease, cardiac arrhythmias, congestive heart failure, peripheral vascular disease, cerebrovascular disease, COPD and diabetes), renal disease and renal function (calculated eGFR based on demographics and serum-creatinine), at time of gout diagnosis and at time of first ULT dispensation, were identified in VEGA. Temporary ULT stop was defined as no collection of ULT within 125 days from last dispense. Two binary outcomes were addressed: (i) receiving ULT within 30 days since diagnosis and (ii) temporary ULT stop 125 days after first ULT dispensation. The effects of sex, age, comorbidity, renal disease and renal function, respectively, were estimated by logistic regression. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated.

| | Predictors of receiving ULT treatment within 30 days post gout diagnosis | | | Predictors of temporary ULT treatment stop within 125 days after treatment start | | |
|---|---|---|---|---|---|---|
| | % of total (n= 18404) for * | OR | 95% CI | % of total (n = 7,165) for * | OR | 95% CI |
| Female*/ Male | 26.99% | 1.39 | 1.33 - 1.28 | 25.25% | 1.03 | 1.01 - 1.26 |
| Age | 30.55% | 1.44 | 1.33 - 1.56 | 26.45% | 0.59 | 0.59 - 0.65 |
| <60*/ >60 | | | | | | |
| **eGFR reduced kidney function 0*/1 | 62.46% | 1.82 | 1.67 - 1.97 | 88.22% | 0.68 | 0.62 - 0.76 |
| Renal disease 0*/1 | 89.98% | 1.51 | 1.36 - 1.68 | 53.96% | 0.74 | 0.63 - 0.86 |
| Comorbidity 0*/>= 1 | 54.54% | 1.60 | 1.49 - 1.72 | 49.05% | 0.82 | 0.56 - 0.68 |

* Reference group
** eGFR ULT n = 12,094, temp stop n = 3,078

Figure 1a-d. 1a) proportion of patients with ULT dispense post gout diagnosis, 1b) predictors of receiving ULT treatment within 30 days post gout diagnosis, 1c) proportion of patients with temporary ULT treatment stop at 125 days since start of ULT, 1d) predictors of temporary ULT treatment stop within 125 days after treatment start.

**Results:** In total, 18 404 incident cases of gout were identified, whereof 4107 (22.3%) and 6272 (34.08%) received ULT within 30 days and 365 days post-diagnosis, respectively (Fig 1a-b). Male sex, age ≥60, reduced kidney function by eGFR, presence of renal disease and presence of ≥1 comorbidities all moderately but significantly ($p<0.05$) predicted receiving ULT within 30 days (Fig 1a-b). 7165 (39%) of the cases were followed-up after their first ULT dispense (not necessarily within 30 days since diagnosis) and 2809 (39.2%) and 4670 (65.18%) had a temporary stop in the ULT treatment after 125 and 365 days, respectively (Fig 1c-d). The odds of a temporary stop was significantly ($p<0.05$) but moderately predicted by male sex, age <60, normal kidney function by eGFR, non-presence of renal disease and total lack of comorbidities (Fig 1c-d). The likelihood of starting or temporary stopping ULT did not significantly change during the study period (data not shown)

**Conclusions:** We found that only a minority of patients started ULT within one year after gout diagnosis, and the majority of these stopped therapy within one year. Age, renal disease and other comorbidities only moderately improved these results. Thus, there is still room for considerable improvement with regard to ULT in the treatment of gout.

## THU0521 PREVALENCE OF GOUT AND ULT TREATMENT IN WESTERN SWEDEN – A REGISTER STUDY

M.I. Dehlin[1], P. Drivelegka[1], V. Sigurdardottir[2], A. Svärd[2], L. Jacobsson[1]. *[1]Dept of rheumatology and inflammation research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg; [2]Rheumatology Clinic, Falun Hospital, Falun, Sweden*

**Background:** Gout is the most common inflammatory arthritic disease worldwide. The prevalence varies due to cultural, ethnical and genetic differences in populations, which emphasizes the need for national/regional data on occurrence. There are major insights in the pathogenesis and effective treatments have been available for decades. Despite this several earlier reports state sub-optimal treatment with urate lowering therapy (ULT) of this common and severe disease. Contemporary data on whether this has improved recently are overall few and completely lacking from the Nordic countries.

**Objectives:** In the present study we measured the prevalence of gout in western Sweden and the proportion thereof treated with ULT.

**Methods:** We identified all individuals with one or more ICD-10 diagnosis of gout (M10, M14) in the Western Swedish Health Care Region (WSHCR), Sweden, 2002-01-01 to 2012-12-31 through VEGA, a diagnosis register entailing all visits to physicians in primary and secondary care and hospitalizations in the region with diagnosis according to the Swedish version of ICD-10. WSHCR has 1 600 000 inhabitants, roughly 20% of the population of Sweden and is representative for the country as a whole with regard to demographics and health status. All cases were linked to Statistics Sweden (for death and possible emigration before Dec 2012) and the National Drug Prescription Register (for dispensation of ULT prescriptions during 2012). The point prevalence of gout Dec 2012 was calculated using the number of people aged 20 and above fulfilling our case definitions for gout who were alive and living in WSHCR 2012-12-31 as the numerator and the total population aged 20 and above of WSHCR by 2012–12–31 as the denominator. Dispensation of ULT prescriptions during 2012 were identified for allopurinol, febuxostat and probenecid. The presence of ≥1 dispensation was regarded as ULT treatment in 2012.

**Results:** The prevalence of gout in the Swedish population aged 20 years and above was 1,7% overall and increased with age and male sex (Fig 1), and was more than 3% in males above 50 years of age. Only 43% of the patients received

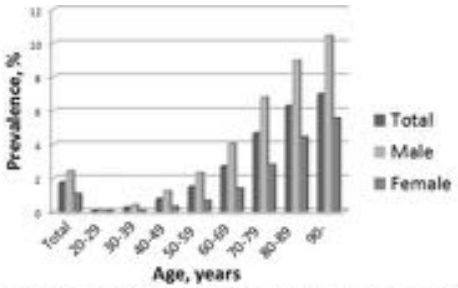

Fig 1 Prevalence of gout i WSHCR by 2012-12-31, age above 20 years in total and by age and sex

treatment with ULT in 2012, almost exclusively allopurinol (99%). Of these 43%, the majority (59%) received a dose of only 100 mg allopurinol daily.
**Conclusions:** Gout is the most common inflammatory arthritic disease in Sweden with an overall prevalence of 1.7%. Treatment with ULT is still in 2012 insufficient with low a low proportion being treated and those treated receiving low doses.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3916

## THU0522 INCREASING INCIDENCE OF GOUT IN WESTERN SWEDEN – A REGISTER STUDY

M.I. Dehlin[1], P. Drivelegka[1], V. Sigurdardottir[2], A. Svärd[2], L. Jacobsson[1]. *[1]Dept of rheumatology and inflammation research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg; [2]Rheumatology Clinic, Falun Hospital, Falun, Sweden*

**Background:** Gout is the most common inflammatory arthritic disease worldwide. The prevalence varies due to cultural, ethnical and genetic differences in populations, which emphasizes the need for national/regional data on occurrence. While there are several studies on the prevalence of gout only few have addressed the incidence of gout and there are no contemporary studies in Sweden and the neighbouring Nordic countries.
**Objectives:** In the present study we measured the incidence of gout in 2012 and its trends from 2004 to 2012 in the Western Swedish Health Care Region (WSHCR) in Sweden.
**Methods:** We identified all incident cases of gout from 2004 through 2012 through VEGA, a diagnosis register covering all visits to physicians in primary and secondary care and hospitalizations in WSHCR. WSHCR has 1 600 000 inhabitants, roughly 20% of the population of Sweden, and is representative for the country as a whole with regard to demographics and health status.
For the analyses of incidence trends an incident case of gout was defined as having a visit with a first ICD-10 diagnosis of gout (M10, M14) not preceded by a diagnosis of gout for the three calendar years before. Cumulative incidence per year was calculated using the number of incident gout cases aged 20 and above by calendar year (from 2004 to 2012) as the numerator and the total person-years aged 20 and above of WSHCR by the end of each year as the denominator. We calculated standardized estimates (direct method) using the whole Swedish population aged $\geq$20 years in 2012 as standard population Calculation of incidence trend was performed using logistic regression. Incidence in 2012 was based on cases with their first diagnosis of gout 2012 without any such diagnosis during the12 preceding years (2000–2011). All cases were linked to Statistics Sweden (for death and possible emigration before Dec 2012).
**Results:** The incidence of gout increased steadily and significantly (p for trend $<$0.001) from 2004 to 2012 with a 50% increase in the total population. The male to female ratio of gout incidence was consistently two to three fold from 2004 to 2012 (Fig. 1). The incidence of gout in Sweden 2012 was 190 cases per 100 000 person-years.

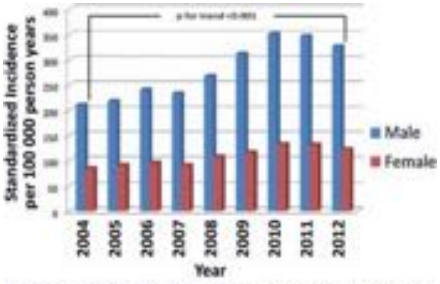

Fig 1 The standardized incidence of gout in the population aged 20 years and above by sex in western Sweden from 2004 to 2012

**Conclusions:** Gout is an increasing health care problem all over the world and also in western Sweden where the incidence of gout increased significantly over the last decade being approximately three times higher than that for rheumatoid arthritis. This increase might reflect changes in the disease panoramic and cultural changes.

## THU0523 COMORBIDITY PATTERN AT THE TIME OF GOUT DIAGNOSIS: A POPULATION- AND REGISTER-BASED CASE-CONTROL STUDY FROM WESTERN SWEDEN

P. Drivelegka[1], L. Jacobsson[1], V. Sigurdardottir[2], A. Svärd[2], M. Dehlin[1].
*[1]Department of rheumatology and inflammation research, Institute of Medicine, Sahlgrenska Academy at the University of Gothenburg, Gothenburg;*
*[2]Rheumatology Clinic, Falun Hospital, Falun, Sweden*

**Background:** Gout is the most common form of inflammatory arthritis and is linked with an increased occurrence of several comorbidities that impair quality of life and influence mortality. Population based data from European countries are scarce and the majority of them include limited categories of comorbidities without specifically addressing them to the time of gout diagnosis.
**Objectives:** To examine the occurrence of comorbidities possibly related to gout at the time of first gout diagnosis compared with matched controls from the general population.
**Methods:** Using the regional population-based health care data base in Västra Götaland region in western Sweden, the National prescribed drugs register and the census register, we identified all patients who attended any inpatient, outpatient or primary care clinic in the region and received at least one ICD10-coded diagnosis (M10, M14.0, M14.1) corresponding to gout during 2000 through 2012. In this study, we included only incident cases with first ICD-coded diagnosis of gout between January 1st 2006 and December 31st 2012 (N=14.137, mean age 66.5, 66.3% men). Each case was matched by year of birth, sex and county to 5 general population comparators, alive and without gout at the date of the index patients' first gout diagnosis, identified in the population register (N=65.899). Comorbidities (previously suggested to be related to gout) were defined by at least one visit to a physician in primary or specialized care with corresponding ICD-coded diagnosis or having dispensed a prescription for a medication strongly supporting such diagnosis prior to the index date in cases and controls respectively. The treatment with diuretics and cyclosporine was defined by having dispensed a prescription of these agents within 6 months prior to gout diagnosis. Comorbidities were grouped as "possibly causal", "metabolic" and "cardiovascular" (CVD) (table).
**Results:** Among "possibly causal" comorbidities, exposure to diuretics (thiazide, loop and potassium-sparing) (48,1%) and renal disease (11,6%) were the overall most frequent and 1,5 to 2,5-fold more common in gout at diagnosis vs controls, whereas diagnosis of psoriasis was not (table).
Among "metabolic", diagnosis of diabetes or obesity was only modestly more frequent in gout vs controls, whereas hyperlipidemia and hypertension were both very frequent in gout (33,9% and 64,9% respectively) and more common, probably reflecting a high CVD comorbidity in gout (table).
Among "CVD comorbidities", different aspects of cardiovascular disease were all common (>5%) and highly associated with gout at diagnosis with exception of thromboembolism (table).

| Comorbidities | Gout Cases Prevalence, % | Controls Prevalence,% | Prevalence Ratio | 95% Confidence interval |
|---|---|---|---|---|
| **Possibly causal** | **52,6** | **30,0** | **1,76** | **1,71-1,8** |
| Psoriasis | 0,7 | 2,7 | 0,28 | 0,23-0,34 |
| Organ transplantation | 0,9 | 0,4 | 2,16 | 1,75-2,67 |
| Use of cyclosporine | 0,4 | 0,1 | 6,18 | 4,22-9,07 |
| Renal impairment | 11,6 | 7,9 | 1,48 | 1,4-1,57 |
| Use of diuretics | 48,1 | 21,3 | 3,26 | 3,2-3,33 |
| Alcoholism | 2,4 | 2,2 | 1,09 | 1,0-1,22 |
| **Metabolic** | **68,7** | **49,8** | **1,38** | **1,35-1,41** |
| Diabetes | 10,6 | 9,2 | 1,15 | 1,0-1,22 |
| Hypertension | 64,9 | 44,3 | 1,47 | 1,43-1,50 |
| Obesity | 4,1 | 3,9 | 1,04 | 1,0-1,14 |
| Hyperlipidemia | 33,9 | 22,7 | 1,5 | 1,44-1,54 |
| **Cardiovascular** | **35,0** | **25,9** | **1,35** | **1,31-1,39** |
| Ischemic heart disease | 19,0 | 13,0 | 1,46 | 1,40-1,53 |
| Heart failure | 13,7 | 4,3 | 3,2 | 3,06-3,4 |
| Atrial fibrillation | 15,8 | 7,8 | 2,09 | 2,0-2,19 |
| Stroke | 8,6 | 7,2 | 1,2 | 1,13-1,28 |
| Thromboembolism | 5,5 | 6,0 | 0,91 | 0,84-1,0 |

**Conclusions:** The majority of gout patients has at least one comorbidity at the time of gout diagnosis and compared to the general population, a higher prevalence of a wide range of comorbidities, such as renal impairment, organ transplantation, cardiovascular diseases and the diseases reflecting the metabolic syndrome.
**Disclosure of Interest:** None declared

## THU0524 THE EFFECTIVENESS OF METHOTREXATE IN PATIENTS WITH RESISTANT CHRONIC CALCIUM PYROPHOSPHATE CRYSTAL ARTHRITIS

P. Frallonardo, F. Oliviero, M. Lorenzin, A. Ortolan, L. Punzi, R. Ramonda.
*Department of Medicine DIMED University of Padova, Rheumatology Unit, University of Padova, Padova, Italy*

**Background:** Calcium pyrophosphate deposition (CPPD) disease is a chronic arthropathy caused by calcium pyrophosphate (CPP) crystal formation and deposition in joints (1). It can be divided into different clinical subtypes: asymptomatic CPPD, osteoarthritis with CPPD, acute CPP crystal arthritis, and chronic CPP crystal inflammatory arthritis (2). In this latter form, colchicine (Co), nonsteroidal anti-inflammatory drugs (NSAIDs), and glucocorticoids (GCs) are commonly used with good effects.Some unresponsive cases, however, need alternative pharmacological treatments. Some authors suggested that methotrexate (MTX) could represent a good option in refractory patients (3).

**Objectives:** The aim of this study was to evaluate the effectiveness of MTX in patients with severe chronic CPP polyarthritis, who did not respond to NSAIDs and/or Co and GCs.
**Methods:** Twenty one outpatients (11 male; mean age 63.38 ±5.27) with resistant chronic CPP arthritis, were treated with MTX in dose between 7.5–12.5 mg/week. All patients fulfilled the EULAR diagnostic criteria for CPPD (2). Tender (TJC) and swollen joints count (SJC), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) were assessed at baseline, before MTX initiation (M0), and at three, six and nine months (M3, M6, M9). Clinical and biologic side effects of MTX were evaluated. The statistical analysis was performed using Friedman with Dunn's Multiple Comparison Test.
**Results:** At M0 the mean of TJC and SJC were 18.00±3.41 and 10.38±1.96, respectively. These parameters decreased considerably at M3 (TJC=9.62±2.52; SJC=7.95±2.84), reaching a significance at M6 (TJC=4.62±1.88; SJC=3.05±2.06) and at M9 (TJC=1.38±1.28;SJC=0.67±0.66) with respect to M0 ($p<0.0001$). These clinical features were associated to a significant improvement of ESR and CRP levels. The ESR decreased from 52.38±11.47 (M0) to 18.38±12.64 (M9) mm/hour ($p<0.001$) while CRP levels decreased from 3.00±1.27 (M0) to 0.28±0.22 (M9) mg/dl ($p<0.0001$). No relevant side biological and clinical effects were reported. No patients interrupted or reduced the dose of MTX.
**Conclusions:** This study confirms that MTX is a valid therapeutic alternative in severe chronic CPP arthritis patients, refractory to previous conventional drugs. According to this study, we observed an excellent response, with a good safety profile. Further additional studies are necessary to expanding the knowledge and identifying the patients in which MTX could be effective.

## THU0525 COUNTING SYNOVIAL FLUID MONOSODIUM URATE CRYSTALS MAY BE USEFUL IN THE MANAGEMENT OF PATIENTS WITH GOUT

P. Montagna, R. Brizzolara, C. Ferrone, S. Soldano, M. Cutolo, M.A. Cimmino.
*Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

**Background:** Gout is the most common form of arthritis, and its prevalence is increasing. The mainstay of its diagnosis is the identification of monosodium urate (MSU) crystals in the synovial fluid (SF) (1,2). In a recent study we tested a feasible and reliable technique for counting MSU crystals in the SF (3). This method could provide useful information for the management of patients with gout.
**Objectives:** To investigate correlations between MSU crystals count in SF and clinical characteristics of gout patients.
**Methods:** Forty-four consecutive patients (6 women) affected by gout diagnosed according to the ACR preliminary criteria were studied. Their SFs were examined: for crystal count, 20 ml of fresh SF were placed on a microscope slide and examined by compensated polarized microscopy (400x). The slide was divided into 4 equal parts drawing a cross with a pencil. Crystal count was obtained by continued viewing and in each quadrant the crystals were counted up to a maximum of 400 (maximum number of crystals/patient was 1600). Clinical information included: acute inflammation at the time of SF aspiration, disease duration, number of attacks, number of affected joints, presence of radiographic erosions, presence of tophi, chronic renal failure, type of antiinflammatory and urate lowering treatment (ULT), ESR, CRP, creatinine and serum uric acid (SUA). In five patients, crystal count was repeated after ULT.
**Results:** Mean age was 65.5±11.7 yrs and median disease duration was 6 years (range 0.1–35 years). Aspirated joints were the knee (40 SFs), elbow (1 SF), 1st metatarsophalangeal joint (2 SFs), and ankle (1 SF). Median crystal count was 273 (range 3–1600). Joints with recent (<1 week) inflammation tended to have a higher SF crystal count than the asymptomatic ones (491 [range 3–1600] vs. 100 [range 4–1600]; p=0.1). The number of crystals in the SF correlated with SUA (p=0.04), but not with ESR and CRP. No correlations were found with clinical features. In the 5 patients on ULT, mean MSU crystals count decreased from 871 to 473 (p=0.05).
**Conclusions:** SF MSU crystals count is not associated with the clinical features of gout, correlates with SUA, and decreases with ULT.

## THU0526 EFFICACY AND SAFETY OF FEBUXOSTAT IN 73 GOUTY PATIENTS WITH STAGE 4/5 CHRONIC KIDNEY DISEASE: RESULT FROM A RETROSPECTIVE 9 MULTICENTER STUDY

P.-A. Juge[1], M.-E. Truchetet[2], E. Pillebout[3], S. Ottaviani[4], C. Vigneau[5], C. Loustau[2], D. Cornec[6], T. Pascart[7], R. Snanoudj[8], F. Bailly[9], T. Schaeverbeke[2], A. Saraux[6], P. Dieudé[4], R.-M. Flipo[7], P. Richette[1], F. Lioté[1], T. Bardin[1], G. Chales[5], H.-K. Ea[1]. *[1]Hopital Lariboisiere, Paris; [2]CHU Bordeaux, Bordeaux; [3]Hopital St Louis; [4]Hopital Bichat, Paris; [5]CHU Rennes, Rennes; [6]CHU Brest, Brest; [7]CHU Lille, Lille; [8]Hopital Necker; [9]Hopital de la Pitie Salpetriere, Paris, France*

**Background:** Although allopurinol reminds the first urate lowering therapy (ULT), its limited dosage in gouty patients with stage 4 or 5 chronic kidney disease (CKD 4/5) prevents to achieve serum uric acid (sUA) level target (<60 mg/l). Febuxostat is a nonpurine xanthine oxidase inhibitor with predominant hepatic metabolism and can be used without dosage adaptation in gouty patients with CKD. However, its safety and efficacy in advanced CKD have been reported in only one study and no data was available in patients with kidney transplantation.
**Methods:** In this retrospective 9 multicenter study, clinical records of all gouty patients with estimated glomerular filtration rate (eGRF) ≤30 ml/min/1.73 $m^2$ (MDRD formula) at febuxostat initiation and at least 3 month-long follow-up period were selected. Items to collect (demographic data, co-morbidity, renal disease, gout history and former treatments, increasing serum urate drugs, laboratory data and any adverse effects-AEs) were approved by all participant centers. Analysis variables were: sUA level at initiation and last available sUA level; variation of eGFR; the percentage of patients who achieved sUA level <60 mg/l and 50 mg/l; and all AEs with specific attention to cardiovascular events.
**Results:** Seventy-three gouty patients (mean age 70.19 ± 11.84, 61 men) from 9 french different rheumatology and nephrology departments were included. 31 patients (41.47%) suffered from vascular CKD and 18 patients (24.66%) had had renal transplant. Mean duration of gout was 6 years. 32 patients (43.48%) had tophi, 28 (38.36%) gout arthropathies. Diuretics were used in 57 patients (78.08%). Cardiac dysfunction was present in 9 patients (16.4%). 72 patients had hypertension, 22 diabetes melitus, 48 dyslipidemia, 28 (38.36%) had past history of vascular events (stroke, heart infraction). Mean sUA level and eGFR at febuxostat initiation were 98.6 ± 28.5 mg/L and 21.5 ± 6.2 ml/min (6–30ml/min), respectively. Febuxostat initiation dosage was 80 mg daily for 47 patients (68.12%), 80mg every 2 days for 17 patients (24.64%) and 120 mg daily for 5 patients (7.25%). At the last visit (mean follow-up was 68.4 weeks (12–260)) mean sUA level was 50.5 mg/L ± 23.3. Forty-seven patients (64.38%) achieved sUA level target <60 mg/L and 42 (57.53%) had sUA level ≤50 mg/L. Renal function improved in 16 patients (23.88%), was unchanged in 20 (29.85%) and worsened in 31 (46.27%). 18 patients experienced flares under febuxostat treatment. AE was observed in 1 patient who had suffered from limb edema. No cardiovascular event was reported during the time of the febuxostat treatment.
**Conclusions:** Febuxostat appears efficient in gouty patents with stage 4/5 CKD or renal transplants. However, safety data is not clear regarding renal function. Further studies with larger sample are warrant to assess this point.
**Disclosure of Interest:** None declared

## THU0527 LESINURAD, A SELECTIVE URIC ACID REABSORPTION INHIBITOR, IN COMBINATION WITH XANTHANE OXIDASE INHIBITORS: SUA AND FLARES COMPOSITE ENDPOINT FROM PHASE III STUDIES IN GOUT PATIENTS (CLEAR 1, CLEAR 2 AND CRYSTAL)

P.P. Khanna[1], S. Baumgartner[2], J. Robinson[2], E. Tafesse[3], R. Morlock[2]. *[1]Rheumatology, University of Michigan, Ann Arbor; [2]Ardea Biosciences, Inc., San Diego; [3]AstraZeneca, Wilmington, United States*

**Background:** Lesinurad (RDEA594) is a selective uric acid reabsorption inhibitor (SURI) investigated for treatment of gout in combination with xanthine oxidase inhibitors (XOI).
**Objectives:** Investigate efficacy as assessed by a composite endpoint of serum uric acid (sUA) target and no flares in gout patients with inadequate response to XOIs alone from three Phase 3 clinical trials examining treatment with lesinurad in combination with allopurinol (ALLO) or febuxostat (FBX).
**Methods:** CLEAR 1 (NCT01510158), CLEAR 2 (NCT01493531) and CRYSTAL (NCT01510769) were 12-month, randomized, double-blind, Phase III trials to evaluate lesinurad (LESU; 200 mg or 400 mg oral, qd) in combination with ALLO vs ALLO + placebo (PBO) (CLEAR 1 and 2) or in combination with FBX vs FBX+PBO (CRYSTAL). A post-hoc composite endpoint defined as the proportion of patients reaching target sUA level (<6 mg/dL in CLEAR 1 and CLEAR 2 and <5 mg/dL in CRYSTAL) and no gout flares was assessed monthly starting at month 7 (after flare prophylaxis was to be discontinued) in each study and in a pooled analysis.
**Results:** CLEAR 1 (N=603), CLEAR 2 (N=610), and CRYSTAL (N=324) patients, respectively, were primarily male (94.0%, 96.2%, and 95.4%); mean ± SD age was 51.9 ± 11.3, 51.2 ± 10.9, and 54.1 ± 11.0 years and duration since gout diagnosis was 11.8 ± 9.4, 11.5 ± 9.3, and 14.7 ± 10.9 years. Most CLEAR 1 and CLEAR 2 patients (90.5% and 84.1%) received ALLO 300 mg daily (range: 200–600 mg and 200–900 mg, respectively). For CLEAR 1 and CLEAR 2,

LESU at both doses in combination with ALLO significantly increased proportions of patients achieving the composite endpoint (sUA target <6.0 mg/dL and no flares) vs ALLO+PBO at all visits, with approximately twice as many LESU patients achieving the composite endpoint ($p<0.001$). For CRYSTAL, LESU at both doses in combination with FBX increased proportions of patients achieving the composite endpoint (sUA target <5.0 mg/dL and no flares) vs FBX+PBO at all visits, with approximately 40% more LESU patients achieving the composite endpoint (p=0.374 to p=0.002). A pooled analysis of LESU at both doses in combination with ALLO or FBX significantly increased proportions of patients achieving the composite endpoint sUA target vs ALLO+PBO or FBX+PBO at all visits, with approximately twice as many LESU patients achieving the composite endpoint ($p<0.001$). Sensitivity analysis comparing gout flares requiring treatment (rather than all flares) and sustained achievement of composite endpoint were also carried out.

**Conclusions:** Significantly greater proportions of patients responded to the combination of lesinurad (200 or 400 mg) + XOI, with approximately twice as many achieving the composite endpoint of sUA target and no flares compared with patients treated with XOI+PBO. Combination therapy with lesinurad + XOI represents an option for gout patients who warrant additional therapy

## THU0528 HOW KIDNEYS, HEART AND LIVER CHANGE WHEN TOPHI ARE PRESENT?

R.N. Gancheva[1], A. Kundurdjiev[2], M. Ivanova[1], T. Kundurzhiev[3], Z. Kolarov[1]. *[1]Clinic of Rheumatology; [2]Clinic of Nephrology, University Hospital "Sv. Iv. Rilski"; [3]Faculty of Public Health, Medical University, Sofia, Bulgaria*

**Background:** Gout is related to metabolic, cardiovascular and renal disorders. Whether pathological changes in the main substrate – kidneys, heart and liver are more pronounced in the presence of tophi is still unknown.

**Objectives:** To determine ultrasonographic parameters of the kidneys, heart and liver echogenicity.

**Methods:** A total of 132 gout patients (pts) were examined cross-sectionally and were divided into two groups: 78 gouty arthritis without tophi, 63 males and 15 females aged 56.46±12.38 years and 54 gouty tophi, 53 males and 1 female aged 58.83±11.46 years. All pts underwent a complex multimodal ultrasonography done by one investigator, who was unaware with clinical data. The following parameters were measured: renal length and resistive index (RRI) – an indicator of renal blood flow, thickness of the interventricular septum (IVS) and posterior wall (PW) of the left ventricle in end-diastolic phase, left ventricular muscle mass (LVMM), left ventricular end-diastolic volume (LVEDV), left ventricular end-systolic volume (LVESV), stroke volume (SV), ejection fraction (EF), fraction of shortening (FS), left atrium (LA), aortic (Ao) root and liver echogenicity. Data were analyzed by Kolmogorov-Smirnov, t-test, chi-square tests and multiple logistic regression.

**Results:** Pts were age matched (p=0.267) and had similar mean serum levels of uric acid (p=0.078). Also, in the groups no significant difference in the proportion of pts with flare was estimated – 20 (25.6%) of gouty arthritis without tophi and 22 (40.7%) of gouty tophi (p=0.067), but gouty tophi were with higher CRP (mean±SD; 24.35±34.86 vs 12.11±20.43 mg/l, p=0.002), lower Hb (p=0.001), Hct (p=0.015) and serum albumin ($p<0.001$). Further, we did not establish difference in renal length (p=0.553), but gouty tophi were with higher RRI (mean±SD; 0.68±0.06 vs 0.65±0.05, p=0.003). Comparing gouty tophi to gout without no difference was found in IVS (mean±SD; 12.57±1.84 vs 12.27±1.84 mm, p=0.366), PW (mean±SD; 12.49±1.90 vs 12.13±1.84 mm, p=0.277), LVMM (p=0.292), Ao root (p=0.786) and SV (p=0.070), but a tendency of significantly reduced FS was observed (mean±SD; 37.22±4.26 vs 38.61±3.52%, p=0.050). Gouty tophi were with larger LA (mean±SD; 40.84±5.93 vs 37.96±4.90 mm, p=0.003), higher LVEDV (mean±SD; 55.77±22.40 vs 44.76±24.83 ml/m$^2$, p=0.012), higher LVESV (mean±SD; 17.69±9.98 vs 13.78±8.33 ml/m$^2$, p=0.018) and lower EF (mean±SD; 66.93±5.85 vs 68.94±4.16%, p=0.024). In both groups the proportion of pts with hepatic steatosis was large – 55 (74.3%) of gouty arthritis without tophi and 38 (76%) of gouty tophi (p=0.832). We conducted a multiple logistic regression in which LA, LVEDV, LVESV and EF were included. The factor for development of tophi was LA. Its increase by 1 mm raised the subject's risk of having tophi with an OR=1.102 (95% CI; 1.026–1.184, p=0.008).

**Conclusions:** When tophi were present renal blood flow was reduced and LA was larger. Furthermore, LA was independently associated with the development of tophi. In gouty tophi higher LVEDV and LVESV with the lack of significant difference in SV can be explained with the activation of compensatory mechanisms. Probably, chronic inflammation is one of the causes for the pathological alterations.

## THU0529 IMPACT OF AN EDUCATIONAL PROGRAM FOR THE MANAGEMENT OF GOUT DIRECTED TO PRIMARY CARE PHYSICIANS

S.P. Chinchilla[1], I. Urionagüena Onaindia[1], F. Perez-Ruiz[1,2], J. Ugarriza Ortueta[3]. *[1]Rheumatology, Hospital Universitario Cruces. OSI Ezkerraldea-Enkarterri Cruces; [2]BioCruces Health Research Institute, Barakaldo; [3]University of the Basque Country (UPV/EHU), Bilbao, Spain*

**Background:** Gout is the most frequent inflammatory arthritis in males, and therefore a common cause for consultation in both primary care and specialist settings. Despite its frequency, the diagnosis and treatment for this condition are far from desirable (1, 2). There is evidence of gout management improvement through educational programs targeted at primary care physicians (3).

**Objectives:** To measure the impact in diagnostic and therapeutic attitudes towards patients with gout, in primary care physicians, before and after performing an educational intervention based on a clinical case.

**Methods:** Through a training program aimed at general physicians with interest in musculo-skeletal diseases, an initiative of the Sociedad Española de Reumatología [Spanish Rheumatology Society] and the Sociedad Española de Médicos de Atención Primaria [Spanish Society for Primary Care Physicians], sessions were held in 6 Spanish locations. In the sessions, a general physician presented a clinical case about a patient with hyperuricaemia, intermittent arthritis, condrocalcinosis in knee joints and several associated comorbidities. In first place, 5 questions with multiple-choice answers were formulated, regarding the diagnosis and treatment deemed appropriate. Later, the case was evaluated and discussed by a rheumatologist, and the same questions were repeated.

Answers were recorded by electronic means.

**Results:** A total of 195 physicians, divided in 6 locations, attended the sessions. Statistically significant results for each evaluated area are summarized below:

Diagnosis: initially 21.8% of the attendants deemed arthrocentesis necessary for the diagnosis, but complementary investigations appeared to be more important (67.3%). Afterwards, a significant increase in the need for arthrocentesis was observed (46.7%).

Comorbidities: 52.6% of the attendants decided to prescribe a non-steroidal anti-inflammatory drug (NSAID) to the fictional patient, with chronic kidney disease. After the discussion, the broad majority of assistants opted for alternatives such as steroids (41.23%) and only 4.74% still preferred NSAIDs.

Initial complexity for diagnosis: a small percentage (12.7%) considered that a solid diagnosis was not possible without a sample of synovial fluid. This percentage rose up to 55.5% after the intervention.

Prophylaxis: Colchicine-based prophylaxis was prescribed initially by 57.4% of physicians, and after the session, by most of them (71.6%).

Urate lowering drugs: A change was observed in the use of urate lowering medications, from an initial 64.7%, up to 85.1% after the discussion.

There was a reduction in the number of referrals to specialists, but it was not statistically significant.

**Conclusions:** Through educational initiatives for primary care physicians it is possible to optimize the perception of diagnosis and treatment of patients with gout.

## THU0530 SPATIOTEMPORAL GAIT PARAMETERS AND PLANTAR PRESSURE DISTRIBUTION DURING BAREFOOT WALKING IN PEOPLE WITH GOUT AND ASYMPTOMATIC HYPERURICAEMIA: A CROSS-SECTIONAL OBSERVATIONAL STUDY

S. Stewart[1], N. Dalbeth[2], A.C. Vandal[3], K. Rome[4]. *[1]Health and Rehabilitation Research Institute, Auckland University of Technology; [2]Faculty of Medical and Health Sciences, The University of Technology; [3]Department of Biostatistics & Epidemiology; [4]Health & Rehabilitation Research Institute, Auckland University of Technology, Auckland, New Zealand*

**Background:** Chronic foot- and lower limb-related impairment are frequently reported by people with gout who also demonstrate altered gait and plantar pressure patterns when assessed during shod walking [1]. The impact of gout on plantar pressure distribution without the confounding effect of footwear is unknown. People with asymptomatic hyperuricaemia, who lack any symptoms or

clinical features of gouty arthritis also report disabling foot pain and lower limb disability compared to normouricaemic controls [2]. However, it unclear whether their gait and plantar pressure patterns also differ from healthy individuals.
**Objectives:** To identify spatiotemporal gait parameters and plantar pressure distribution during barefoot walking in people with gout and people with asymptomatic hyperuricaemia by comparing them to normouricaemic controls.
**Methods:** A total of 87 participants were included: 24 with gout, 29 with asymptomatic hyperuricaemia and 34 age- and sex-matched controls. Spatiotemporal parameters of gait were assessed during level barefoot walking using a GAITRite® walkway. Peak plantar pressure and pressure time integrals were recorded using a TekScan MatScan®. Results were adjusted for age and body mass index.
**Results:** Compared to controls, participants with gout demonstrated increased step time (0.60 vs. 0.64 s, *P*=0.022) and stance time (0.74 vs. 0.80 s, *P*=0.022), and reduced velocity (1.03 vs. 0.91 m/s, *P*=0.050). Participants with gout also walked with decreased peak pressure at the heel (294.3 vs. 268.2 kPa, *P*=0.012) and hallux (233.3 vs. 208.4 kPa, *P*=0.036) and increased peak pressure (95.4 vs. 130.8 kPa, $P<0.001$) and pressure time integrals (23.5 vs. 32.7 kPa*s, *P*=0.005) at the midfoot (Figure 1). Compared to controls, participants with asymptomatic hyperuricaemia demonstrated increased support base (0.08 vs. 0.11 cm, *P*=0.002), double support time (0.16 vs. 0.26 s, $P<0.001$) and cadence (101 vs. 107 steps/min, *P*=0.028) and reduced swing time (0.46 vs. 0.43 s, *P*=0.019) and single support time (0.46 vs. 0.43 s, *P*=0.020) as well as increased pressure at the midfoot (95.4 v 120.1 kPa, *P*=0.013), first metatarsal (211.5 vs. 239.7 kPa, *P*=0.015) and second metatarsal (292.6 vs. 321.3 kPa, P=0.007) (Figure 1).

**Conclusions:** During barefoot walking, people with gout walk slower with plantar pressure patterns suggestive of apropulsive and antalgic gait strategies. Individuals with asymptomatic hyperuricaemia also demonstrate altered barefoot gait patterns when compared to normouricaemic controls. Clinicians may consider dynamic gait outcomes when assessing and managing foot and lower limb related pain and disability in individuals with gout and asymptomatic hyperuricaemia.

## THU0531 NOD2/CARD15 GENE MUTATIONS IN PATIENTS WITH GOUTY ARTHRITIS

A. Karaarslan[1], S. Kobak[2], A. Berdeli[3]. *[1]Ortopedics; [2]Rheumatology, Sifa University Faculty of Medicine; [3]Genetics and Molecular Medicine, Ege University Faculty of Medicine, Izmir, Turkey*

**Background:** Gouty arthritis is a chronic erosive autoinflammatory disease. NOD2/CARD15 molecule has been shown to play important roles in the etiopathogenesis of many inflammatory diseases, resulting in predisposition to the diseases. NOD2/CARD15 is a cytoplasmic molecule which plays a role in controlling apoptosis as well as inflammatory processes by recognizing some microbial components.
**Objectives:** The aim of this study was to identify the frequency of NOD2/CARD15 gene mutation in gouty arthritis patients and determine its possible correlation with disease phenotype.
**Methods:** The study included 93 patients with gouty arthritis and 51 healthy controls matched for age, gender and ethnicity. NOD2/CARD15 gene mutations (R702W and G908R, 3020insC) were studied by PCR method.
**Results:** Of the 93 patients included in the study, 72 were male and 21 were female. The mean patient age was 54.2±14.2 years, mean duration of the disease was 3.1 ± 2.9 years. In the clinical and laboratory evaluations of gouty arthritis patients; first MTP joint involvement was detected in 72 (77.4%), ankle arthritis in 43 (46.2%), knee arthritis in 20 (21.5%), finger joint involvement in 18 (19.5%) patients, increased serum levels of uric acid in 76 (81.7%) and CRP in 42 (45.2%) patients, and elevated ESR in 45 (48.4%) patients. Totally 4 (9%) heterozygous mutations were detected in the NOD2/CARD15 G908R and NOD2/CARD15 R702W genes, while no mutation was detected in the NOD2/CARD15 C3020ins gene. When compared with the control group, statistically significant difference was not detected for each of three regions (908,702,3020ins) (p=0.452, p=0.583 and p=0.350, respectively). In the patient group, statistically significant correlations were not detected in clinical and laboratory findings (first MTP arthritis, ankle arthritis, increased serum uric acid, ESR and CRP values) of the patients with and without mutations for each of the three regions ($p>0.05$)
**Conclusions:** Similar frequency of NOD2/CARD15 gene mutations was detected in patients with gouty arthritis in comparison to healthy control group. Again, no correlation was observed between clinical as well as laboratory findings and NOD2/CARD15 gene mutation. Prospective studies with large series of patients are needed to be carried out on this topic.

## THU0532 GENETIC ANALYSIS FOR P2X7R RS3751142 AND CARD8 RS2043211 POLYMORPHISMS FOR SUSCEPTIBILITY OF GOUT IN MALE KOREAN POPULATION

S.-K. Kim[1], S.W. Lee[2], S.-S. Lee[3], D.H. Oh[4], D.-J. Park[3], H.-S. Kim[5], J.R. Choi[4], W.T. Chung[2], J.-Y. Choe[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu; [2]Division of Rheumatology, Department of Internal Medicine, Dong-A University College of Medicine, Busan; [3]Department of Rheumatology, Chonnam National University Medical School, Gwangju; [4]Department of Internal Medicine, Pohang Saint Mary's Hospital, Pohang; [5]Division of Rheumatology, Department of Internal Medicine, Soonchunhyang University Seoul Hospital, Seoul, Korea, Republic Of*

**Background:** The NLRP3 inflammasome, a member of the NLR family, is a key player in the production of uric acid-mediated IL-1β and is an important cytoplasmic protein complex involved in gouty inflammation. Recent single-nucleotide polymorphism (SNP) studies suggested that genetic alternations of several target molecules such as CARD8 and P2X7R contribute to the process of NLRP3 inflammasome activation.
**Objectives:** The aim of this study was to determine the association between P2X7R rs3751142 and CARD8 rs2043211 polymorphisms and gout susceptibility in male Korean subjects.
**Methods:** This study enrolled a total 242 male patients with gout and 280 healthy controls. The polymorphisms of two individual genes including rs3751142 (C>A) in the P2X7R gene and rs2043211 (A>T) in the CARD8 gene were assessed using Taq-Man analysis. Statistical analyses were performed using the Chi-square test, Kruskal-Wallis test, and logistic regression analyses.
**Results:** A difference in genotypic frequency of the P2X7R rs3751142 and CARD8 rs2043211 genes was not detected between gout and control patients. Clinical parameters including age, onset age, disease duration, body mass index, and serum uric acid levels were not different among the three genotypes for either P2X7R or CARD8 ($p>0.05$ for all). A pair-wise comparison of P2X7R rs3751142 and CARD8 rs2043211 genotype combinations revealed a protective effect of P2X7R/CARD8 AA/AA against gout susceptibility (OR=0.023, 95% CI 0.874–0.999).
**Conclusions:** This study revealed that genetic variability of the P2X7R rs3751142 and CARD8 rs2043211 genes might, in part, be associated with susceptibility for gout.

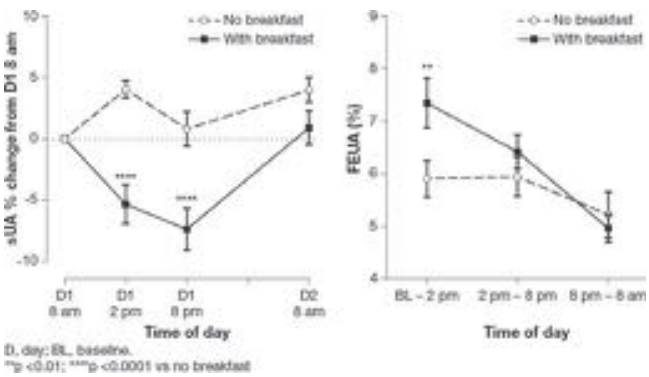
## THU0533 COMPARATIVE EFFICACY OF METHOTREXATE AND COLCHICINE IN CPPD AND CHRONIC ARTHRITIS PATIENTS

S. Vladimirov, M. Eliseev, O. Zhelyabina, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*



**Background:** Methotrexate is commonly used in patients with calcium pyrophosphate deposition (CPPD) condition, although data on methotrexate use for chronic arthritis in CPPD pts are controversial [1], and it's not clear yet, whether methotrexate can be used as an alternative to colchicine in this group of pts.
**Objectives:** The comparison of efficacy of methotrexate and colchicine in CPPD pts with chronic arthritis, in whom colchicine monotherapy was not sufficient

**Methods:** Results of controlled prospective crossover observational study, including 10 pts (8 females and 2 males) with chronic arthritis associated with CPPD are presented. The inclusion criteria were: age >18 y., the diagnosis of CPPD (by Ryan/*McCarty criteria*), chronic arthritis and low efficacy of NSAIDs. All patients were initially prescribed colchicine 1 mg/day for 3 months with a 1 month "wash-out" period before prescription of methotrexate s/c 20 mg/week for another 3 months. Pts' mean age was 62.5±11.5 y. Average disease duration was 12.4±12.0 y. For evaluation and monitoring was used to measure disease activity scores based on 44 joints (DAS44), together with the count of swollen and tender joints, pain intensity by VAS, health assessment by HAQ, and serum hsCRP at baseline, after first 3 mo of treatment, after 1 mo of "wash-out" period and after the second 3 mo treatment period. Statistica 10.0 package and Biostatistics were used for statistical processing of data. *P* values <0.05 were considered statistically significant.
**Results:** At baseline average DAS44 score was 2.47±0.27, swollen joints – 2.0±0.6, tender joints – 2.4±1.1, pain by VAS – 55.2±12.3 mm, serum level of hsCRP – 3.89±3.82 mg/L, HAQ score – 1.1±0.3. After 3 mo of colchicine therapy average DAS44 score was 1.76±0.28 ($p$=0.004), swollen joints– 1.4±0.5 ($p$=0.048), tender joints – 1.6±1.35 ($p$=0.023), pain by VAS – 42.0±13.2 mm ($p$=0.023), serum level of hsCRP – 3.13±2.85 mg/L ($p$=0.75), HAQ score – 0.95±0.3 ($p$=0.041). After 3 mo of colchicines monotherapy good results were documented in 7 pts (4 pts did not have arthritis, 3 patients showed significant reduction in disease activity (by DAS44) and intensity of pain. Insufficient efficacy was obvious in 3 pts. After 1 mo "wash-out" phase DAS44 score was 2.08±0.26, swollen joints – 1.6±0.5, tender joints – 1.7±1.4, pain by VAS – 46.5±9.8 mm, level of hsCRP – 3.38±1.74 mg/L, HAQ score – 1.3±0.34. After 3 mo of methotrexate therapy DAS44 score was 1.39±0.45 ($p$=0.027), swollen joints – 0.7±0.5 ($p$=0.023), tender joints – 0.6±0.5 ($p$=0.007), pain by VAS – 26.0±18.97 mm ($p$=0.045), serum level of hsCRP – 2.87±2.06 mg/L ($p$=0.75), HAQ score – 0.8±0,6 ($p$=0.045). In 2 out of 3 pts with insufficient colchicine efficacy the arthritis was resolved by methotrexate therapy. Meanwhile 2 pts with favorable outcome after colchicine therapy developed exacerbation after methotrexate phase.
**Conclusions:** Colchicine 1 mg/day and methotrexate 20mg/week demonstrate comparable efficacy. Methotrexate 20mg/week should be viewed as first-line choice in chronic arthritis pts associated with CPPD when colchicines efficacy is insufficient

## THU0534 SKIPPING BREAKFAST INCREASES SERUM URIC ACID LEVELS

S. Liu, J.N. Miner. *Ardea Biosciences, Inc., San Diego, United States*

**Background:** Lifestyle intervention is an important component in uricemic control. Diets with low purine and fructose content, as well as limited alcohol consumption, are recommended for people with hyperuricemia/gout.[1] It has been reported that a 2-day fast can lead to higher serum uric acid (sUA) levels, with a concomitant decrease in urinary uric acid excretion.[2] This work explores whether a shorter fast, such as simply skipping breakfast, affects sUA levels.
**Objectives:** To study the effect on sUA of skipping breakfast.
**Methods:** Two successive experiments were conducted with the same group of healthy subjects (N=30). In the first experiment the subjects consumed all three meals during the day, whereas in the second experiment the subjects did not eat breakfast but had the other two meals as usual. sUA and fractional excretion of uric acid (FEUA) were measured throughout the 24 hr experiment period. In addition, corresponding sUA levels were simulated based on the measured FEUA in order to evaluate the contribution of FEUA to the effects of breakfast on measured sUA.
**Results:** At 6, 12 and 24 hr after breakfast (~8 am), the mean±SE change from baseline (pre-breakfast) in sUA was -0.3±0.09, -0.4±0.1 and +0.1±0.09 mg/dL, respectively, when the group ate breakfast (Figure). These changes average to a decrease in sUA of 0.2±0.08 mg/dL over 24 hrs. In comparison, the change in sUA from baseline was +0.3±0.05, +0.1±0.09 and +0.3±0.07 mg/dL at 6, 12 and 24 hr when they did not eat breakfast. These changes average to an elevation in sUA of 0.2±0.05 mg/dL over 24 hrs. As a result, the difference in sUA (no breakfast - breakfast) was +0.4±0.09 mg/dL ($p<0.0001$). In the first 6 hrs after breakfast, FEUA were 7.3±0.45 with breakfast and 5.7±0.33 without breakfast (Figure, $p<0.01$). However, when sUA levels are simulated based on the observed FEUA, the difference in FEUA between breakfast and no breakfast cannot fully explain the difference in their observed sUA.

D, day; BL, baseline.
**p <0.01; ****p <0.0001 vs no breakfast

**Conclusions:** Skipping breakfast leads to a 0.4 mg/dL elevation in sUA over 24 hr. A decreased FEUA is partially responsible for the difference in sUA; however, there are likely other mechanisms involved as well. Routinely skipping breakfast might lead to even higher elevations in sUA.

## THU0535 QUALITY OF LIFE IN PATIENTS WITH GOUT IN SOUTH WESTERN SYDNEY

S.-N. Luong [1,2], V. Thakkar [1,2], G. Hassett [1], H. Mannan [2], K. Pile [1,2].
*[1]Rheumatology, South Western Sydney Local Health District; [2]School of Medicine, Western Sydney University, Sydney, Australia*

**Background:** Gout is the most common type of inflammatory arthritis in men, with an Australian population prevalence of 0.39% (1, 2). Due to ageing and rising obesity, the global burden of gout is increasing. Global disability adjusted life years (DALYs) for gout rose from 76 000 in 1990 to 114 000 in 2010 (2). Patients with severe gout are known to have low health-related quality of life (HRQOL), especially in regards to physical function (3).
**Objectives:** To determine HRQOL in gout patients of South Western Sydney, and the utility of the Gout Impact Scale (GIS). To compare GIS in patients with acute versus non-acute gout, and high frequency of gout attacks versus low frequency of gout attacks. To compare Short Form 36 version 2 (SF36v2) in our gout cohort with normals and other chronic diseases.
**Methods:** Postal cross-sectional survey study of adult patients diagnosed with gout recruited from 3 public hospitals and a private clinic. SPSS software facilitated analysis.
**Results:** 133/184 patients recruited with a 72.3% response rate. The overall impact of gout on their life was 5.9/10, higher in acute gout vs non-acute gout, mean 6.8 vs 5.2, $p<0.02$. Of patients with gout attack in the last 3 months, the severity of pain was 6.8/10. Patients with more frequent attacks of gout had higher overall severity of gout than those with less frequent attacks, mean 7.5 vs 5.2, $p<0.002$.
Patients with acute gout had higher mean scores for gout concern overall (GCO), gout medication side effects (GMSE), unmet gout treatment need (UGTN), well being during attack (WBDA) and gout concern during attack (GCDA), compared to non-acute gout, $p<0.02$. There was a moderate correlation between GCDA and GCO ($\tau_b$ =0.566, $p<0.0001$) and GCDA and WBDA ($\tau_b$=0.508, $p<0.0001$)
Patients with more frequent attacks had higher mean scores for GCO, GMSE, UGTN, WBDA and GCDA, compared to those with less frequent attacks, $p<0.002$.
Gout patients scored significantly lower in all 8 domains of SF36v2 compared to Australian normative data and diabetics. There was a moderate correlation between WBDA and the mental component summary of SF36v2 ($\tau_b$ =-0.406, $p<0.0001$).

**Conclusions:** Results of the Gout Impact Scale made sense with greater impact of gout in patients with acute gout or more frequent attacks in all 5 scales, suggesting it is a robust instrument in the diverse gout population. The impact of gout was not confined to just physical domains, but had a significant negative impact on psychological health.

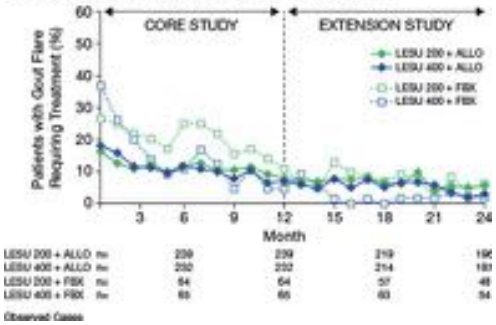
## THU0536 REMISSION AND RE-TREATMENT OF PATIENTS WITH PAGET'S DISEASE OF BONE TREATED WITH ZOLENDRONIC ACID – A SINGLE CENTER 10 YEAR EXPERIENCE

S. Fernandes, J. Borges, C. Silva, E. Simões, M. Micaelo, F. Barcelos, H. Madeira, J. Vaz Patto, L. Cunha Miranda, M. Sousa, S. Cortes, A. Faustino.
*Rheumatology, Instituto Portugues de Reumatologia, Lisbon, Portugal*



**Background:** Treatment of Paget's Disease of Bone (PDB) has been revolutionized by the use of zolendronic acid (ZA). Patients usually have a dramatic response to treatment with normalization serum alkaline phosphataise (ALP) levels and a longer period of clinical remission, compared with other class agents. Data from long-term use are scarse.
**Objectives:** Evaluate the effectiveness and safety of ZA in PDB patients, as well as remission, re-treatment rates and side effects in our outpatient population since 2005.
**Methods:** A retrospective study of PDB patients treated with 5 mg ZA intravenous infusion at our day-care center. Follow up time, demographic and clinical characteristics, previous therapeutic agents, rate of response, number and reasons of re-treatment(s) and rates of adverse events were collected. A descriptive statistic analysis was made.
**Results:** 48 patients, 60% female, mean age of 75 years, with a median time since the diagnosis of 12.3 years. The disease was poliostotic in 73% of the patients and pelvis (65%), skull (29%) and spine (27%) were the most common pagetic localizations. Deafness was present in 12.5% and 65% had hip involvement. 44% patients had been treated with another biphosphonate agent previously. Response rates were 97.9% at 1 year, 87.2% after 2 years and 95.1% after 3 years. The mean ALP levels before ZA infusion was 290 UI/L and after 112 UI/L. Sixteen patients needed a re-treatment in the period of follow up, minimum of 1 year after the ZA infusion and maximum of 8 years after. 56.3% due to raised of ALP levels and 43.8% due pain/ hip involvement. Four patients needed a third infusion due to hip involvement, and 2 of them a forth infusion due to the same reason. All of the patients re-treated due to hip involvement had severe hip involvement at time of diagnosis. In our population, 2 patients achieved 10 years remission, 5 patients 9 years remission and 10 patients 8 years remission with a single ZA infusion. Recording adverse effects were: 14.6% *Flu like* symptoms (7 patients), 2% assintomatic hypocalcemia (1 patient) and no reports of osteonecrosis or fractures. All of these effects were reported after the first ZA infusion.
**Conclusions:** In our population, we find high long-term sustained remission rate. Only sixteen patients needed re-treatment. Patients maintained sustained remission up to 10 years of a single ZA infusion. Incidence of adverse events was similar to the reported in the literature.

## THU0537 CLINICAL RESPONSE OF TOPHUS AND FLARES TO EXTENDED USE OF LESINURAD IN COMBINATION WITH A XANTHINE OXIDASE INHIBITOR IN PATIENTS WITH GOUT

T. Bardin[1], N. Dalbeth[2], R. Terkeltaub[3], C. Storgard[4], M. Fung[4], J. Hu[4], F. Perez-Ruiz[5]. *[1]Lariboisière Hospital, Paris, France, Paris, France; [2]University of Auckland, Auckland, New Zealand; [3]University of California; [4]Ardea Biosciences, Inc., San Diego, United States; [5]Hospital Universitario Cruces and Biocruces Health Research Institute, Vizcaya, Spain*

**Background:** Three randomized, double-blind, Phase III trials reported that greater proportions of patients treated with lesinurad 200 mg (LESU200) or 400 mg (LESU400), combined with the xanthine oxidase inhibitor (XOI) allopurinol (ALLO; CLEAR 1 and 2) or febuxostat (FBX; CRYSTAL), achieved serum uric acid (sUA) targets at 6 months versus xanthine oxidase inhibitor (XOI) + placebo (PBO).
**Objectives:** To evaluate the impact of long-term treatment with lesinurad + XOI on tophus and flares for at least 1 year and up to 2 years.
**Methods:** Patients completing 12 months in the core CLEAR and CRYSTAL studies could enroll in respective uncontrolled, open-label extension studies (NCT01808131; NCT01808144). Patients randomized to LESU200 + XOI or LESU400 + XOI in the core studies who continued on combination therapy in the extension studies were analyzed. Efficacy endpoints included: (1) proportions of patients with complete resolution (CR) of ≥1 target tophus (i.e. measurable tophus on hands/wrists and/or feet/ankles 5–20 mm in longest diameter), (2) percent reductions in the total area of all target tophi, and (3) proportions of patients experiencing gout flares requiring treatment (GFRT).
**Results:** A total of 239 (LESU200+ALLO) and 232 (LESU400+ALLO) patients continued in the CLEAR extension; 64 (LESU200+FBX) and 65 (LESU400+FBX) patients continued in the CRYSTAL extension. Proportions of patients with CR of ≥1 target tophus increased from end of core study (1 year) to 2 years: from 25.0% to 43.8% in LESU200+ALLO and 30.3% to 36.4% in LESU400+ALLO, and from 26.6% to 53.1% in LESU200+FBX and 35.4% to 58.5% in LESU400+FBX (LOCF). Percent reduction in the total area of all target tophi versus baseline changed from end of core study to 2 years: from 11.6% to 41.8% in LESU200+ALLO and 42.7% to 49.3% in LESU400+ALLO, and from 54.8% to 68.3% in LESU200+FBX and 58.6% to 72.4% in LESU400+FBX (LOCF). Proportions of subjects with a GFRT per month decreased during continued combination treatment in both extension studies (Figure).The proportions of patients with a GFRT during Months 1, 12, and 24 were, respectively, 16.3, 7.9, and 5.6 in LESU200+ALLO; 18.1, 6.9, and 3.0 in LESU400+ALLO; 26.6, 10.9, 6.3 in LESU200+FBX; and 36.9, 4.6, 1.9 in LESU400+FBX. Extended treatment with LESU + XOI did not result in increased exposure-adjusted incidence rates of adverse events (AEs), AEs leading to discontinuation of lesinurad, serious AEs, or clinical laboratory abnormalities.

Figure. Patients With Gout Flares Requiring Treatment (GFRT) During Core Study and Extended Treatment With Lesinurad + XOI

**Conclusions:** The CLEAR and CRYSTAL extension studies showed that patients treated with lesinurad + XOI for up to 2 years exhibited continued increases in the rate of complete resolution of tophi and reduction in tophus area, as well as decreased rates of GFRT.

## THU0538 DECREASING URIC ACID LEVEL IS ASSOCIATED WITH IMPROVING GLOMERULAR FILTRATION RATE IN CHRONIC KIDNEY DISEASE PATIENTS WITH/WITHOUT GOUT

T.-S. Lin[1,2], C.-Y. Huang[2], S.-C. Hsieh[1]. *[1]Department of Internal Medicine, National Taiwan University Hospital, Taipei; [2]Department of Internal Medicine, National Taiwan University Hospital Yunlin Branch, Yunlin County, Taiwan, Province of China*

**Background:** Hyperuricemia was a risk factor for hypertension, metabolic syndrome, type 2 diabetes mellitus, cardiovascular disease, and chronic kidney disease. Uric acid lowering therapy was indicated when hyperuricemic patients with established diagnosis of gout. Clinical trials have demonstrated that xanthine oxidase inhibitor decreased the progression of chronic kidney disease in gout patients. Uric acid lowering therapy was not suggested in asymptomatic hyperuricemic patients due to lack of evidence.

**Objectives:** To evaluate the association between the change of uric acid level and renal function in chronic kidney disease patients with/without gout.
**Methods:** This is a retrospective cohort study. The data source was the electronic records of National Taiwan University Hospital and its branch Hospital during 2011 to 2015. Patients were included if they have chronic kidney disease stage 2, 3, and 4 according to K-DOQI staging and receive follow-up for more than 6 months. Multiple variables linear regression models were applied for evaluating the association between the change of uric acid level and eGFR. The variables including age, gender, hypertension, type 2 diabetes mellitus, dyslipidemia, gout, and initial uric acid level were analyzed. We performed a subgroup analysis of the patients with decreasing uric acid level.
**Results:** Total 272 patients were included. There were 154 (56.6%) females and 118 (43.4%) males. The mean age was 57.9±14.7 (SD) years. The mean uric acid level was 6.5±1.9 (SD) mg/dL. The mean duration of follow-up was 128.7 ±55.3 (SD) weeks. 52 (19%) patients had the diagnosis of gout. In multivariable linear regression models, the change of eGFR was affected by the change of uric acid level (β= -0.249, $P$ <0.001). In the subgroup analysis of the patients with decreasing uric acid level, the change of eGFR was also affected by the change of uric acid level (β= -0.214, $P$ =0.011).
**Conclusions:** The decreasing uric acid level is associated with increasing eGFR in chronic kidney disease patients even after adjusting the status of gout. The causal relationship between the uric acid level and renal function should be interpreted carefully.

## THU0539 POPULATION-SPECIFIC RESEQUENCING REVEALS ASSOCIATION OF THE ABCC4/MRP4 GENE WITH GOUT IN NEW ZEALAND MĀORI AND PACIFIC MEN

T. Merriman[1], J. Boocock[1], E. Stahl[2], M. Cadzow[1], A. Phipps-Green[1], R. Topless[1], J. Harre Hindmarsh[3], D. Mount[4], L. Stamp[5], N. Dalbeth[6], H. Choi[4], C. Tanner[1]. *[1]Biochemistry, University of Otago, Dunedin, New Zealand; [2]Institute for Genomics and Multiscale Biology, Icahn School of Medicine at Mount Sinai, New York, United States; [3]Ngati Porou Hauora Charitable Trust, Te Puia Springs, New Zealand; [4]Harvard Medical School, Boston, United States; [5]Medicine, University of Otago, Christchurch; [6]Medicine, University of Auckland, Auckland, New Zealand*

**Background:** Genetic variants in uric acid transporters that control serum urate levels have been identified in Europeans by genome-wide association studies [1]. However there is no evidence for association with serum urate (or gout) with the organic anion transporters (OAT) 1–3 (*SLC22A6, SLC22A7* and *SLC22A8*) and multi-drug resistance protein 4 (MRP4) encoded by *ABCC4*; all four transporters have been implicated in uric acid secretion [2]. The Māori and Pacific (Polynesian) population of New Zealand (NZ) has the highest prevalence of gout worldwide and exhibits lower fractional excretion of uric acid (FEUA) than Europeans.
**Objectives:** To identify any Polynesian population-specific genetic variants in the *SLC22A6–8* and *ABCC4* genes associated with gout.
**Methods:** All participants had ≥3 self-reported Māori and/or Pacific grandparents. From the total sample set of 1808 individuals, 191 hyperuricaemic (highest urate levels) and 202 normouricaemic (lowest urate levels) individuals were selected and resequenced over a total of 24.3 kb of promoter, exon and 3' and 5' untranslated region DNA within the four genes. Replication genotyping for *rs4148500* was done using Taqman over the remaining 1415 individuals. Logistic regression association analysis with gout or hyperuricaemia (≥0.36 mmol/L in women, ≥0.42 mmol/L in men) as outcome, or linear regression with FEUA or serum urate as outcome, was performed adjusting by age, sex and Polynesian ancestry.
**Results:** A total of 39 common variants were detected with one in *ABCC4* (*rs4148500*) significantly associated with hyperuricaemia and gout. There were substantial differences in allele frequency between Western (Samoan, Tongan, Niuean, Tokelaun) and Eastern (NZ and Cook Island Māori) Polynesian samples – adjusting for ancestry revealed evidence for association with gout in the resequenced samples (OR=1.62, $P$=0.012 for *rs4148500*). The association of *rs4148500* with gout was replicated (OR=1.25, $P$=0.033) and was restricted to males ($OR_{Males}$=1.43, $P$=0.001; $OR_{Females}$=0.98, $P$=0.89). The gout risk allele was associated with FEUA in males (b=-0.570, $P$=0.01) and there was a trend towards association with serum urate in the male controls (b=0.013, $P$=0.07). The Ensembl database revealed that the variant was monomorphic (for the protective major allele) in Europeans.
**Conclusions:** This is the first report of a genetic factor specifically contributing to the increased risk of gout in men of Māori and Pacific ancestry in NZ. Association of *ABCC4* with gout and FEUA is consistent with the established role of MRP4 as a unidirectional urinary uric acid efflux pump of uric acid [3].

## THU0540 AUTOLOGOUS OSTEOBLASTIC CELLS VERSUS CONCENTRATED BONE MARROW IMPLANTATION IN OSTEONECROSIS OF THE FEMORAL HEAD: A RANDOMIZED CONTROLLED SINGLE BLIND STUDY

V. Gangji[1], M. Toungouz[2], C. Lechanteur[3], Y. Beguin[3], E. Baudoux[3], V. De maertelaer[4], S. Pather[5], R. Katz[5], J. Ino[6], D. Egrise[7], M. Malaise[8], J.-P. Hauzeur[8]. *[1]Rheumatology Dept; [2]Hemobiology and Transfusion Dept, Hôpital Erasme, Brussels; [3]Haematology, CHU Sart Tilman, Liège; [4]Faculty of Medicine, Université Libre de Bruxelles; [5]Radiology Dept, Hôpital Erasme, Brussels; [6]R&D, Bone Therapeutics, Gosselies; [7]Nuclear Medicine Dept, Hôpital Erasme, Brussels; [8]Rheumatology Dept, CHU Sart Tilman, Liège, Belgium*

**Background:** Non traumatic osteonecrosis (ON) of the femoral head is characterized by epiphyseal necrosis leading to femoral head collapse and hip replacement. ON can be seen as a vascular, mesenchymal and bone cells disease. Indeed, it was shown that implantation of bone marrow concentrate (BMC) containing mesenchymal stem cells (MSC) could delay ON progression and improve symptoms. Then, the possibility was raised that a cell-based medicinal product consisting in a population of autologous osteoblastic cells (OB) could be more efficacious than BMC in early stages ON of the femoral head.
**Objectives:** This study was undertaken to evaluate the efficacy of OB cells implantation in a randomized comparison with BMC implantation in early stages (prefractural ARCO stage 1 or 2) ON of the femoral head.
**Methods:** Patients with stage 1 or 2 ON were included in a randomized controlled single blind trial. Hips were randomized to receive a core decompression procedure followed by BMC or OB cells implantation. In the BMC group, 410.6±84.9 ml of BM was harvested from the iliac crest and concentrated to 41.8±10.9 ml. In the OB group, MSC were isolated from BM aspirate (48.8±17.7 ml), expanded and differentiated *ex vivo* under autologous conditions to obtain a population of OB cells (18.6±4.3x$10^6$ cells). Hip pain, WOMAC score and X-Rays were assessed at 3, 6, 12, 24 and 36 months. The primary endpoint was the proportion of responders at 24 months. A responder was defined as the absence of progression to a fractural stage (stage 3 or 4) and a clinically significant pain improvement.
**Results:** From 72 hips randomized, 60 hips (30 hips per group) were analyzed as the ITT efficacy cohort (50.6±11.8 years). Baseline demographic data, risk factors, location and size of ON and symptoms were not statistically different between groups. At 24 months, 70% versus 40% of hips ($p$<0.05) and at 36 months, 60% versus 33% of hips ($p$<0.05) in OB and BMC groups respectively were considered as responders. The rate of progression to stage 3 or 4 was in favor of the OB group. At 24 months, 20% versus 40% of hips (NS) and at 36 months, 20% versus 47% of hips ($p$<0.05) in OB and BMC groups respectively progressed to stage 3 or 4. A decrease in hip pain was observed in the OB group compared to the BMC group at 24 months (NS) and 36 months ($p$<0.05). Finally, patients treated with OB cells demonstrated a decrease in joint symptoms at 24 and 36 months according to the WOMAC score. Overall, 117 SAE (47 in the BMC group and 70 in the OB group) were reported of which 4% (5 SAE) were possibly related to the procedure or the cell therapy products.
**Conclusions:** This study showed that OB cells implantation in ON lesion could be more efficacious than BMC treatment to delay the evolution to subchondral fracture and to reduce pain in ON of the femoral head.

## Fibromyalgia

### THU0541 PAIN FROM STRUCTURAL PATHOLOGY IS A RISK FACTOR FOR LATER GENERALIZED PAIN: A POPULATION BASED COHORT STUDY

E. Bondesson[1,2,3], F. Larossa Pardo[2], M.E. Sandberg[2,4], A. Jöud[2,5]. [1]*Department of Clinical Sciences, Lund University;* [2]*Epidemiology and Register Centre South;* [3]*Department of Pain Rehabilitation, Skåne University Hospital, Lund;* [4]*Institute of Environmental Medicine, Karolinska Institutet, Stockholm;* [5]*Department of Occupational and Environmental Medicine, Lund University, Lund, Sweden*

**Background:** Generalized pain in the form of chronic widespread pain (CWP) and fibromyalgia is common in the general population [1] and is also a frequent comorbidity in several diseases. Chronic pain from structural pathology (e.g. inflammation or injury) has been proposed as a mechanism behind generalization of pain, likely through the mechanism of central sensitization [2].
**Objectives:** The aim was to study if patients with rheumatoid arthritis (RA), endometriosis or inflammatory bowel disease (IBD), diseases with a known component of pain from structural pathology and with diverse etiology, have an increased risk of later developing generalized pain.
**Methods:** This prospective cohort study used the Skåne Healthcare Register, covering routinely collected data on all types of care in the region of Skåne, southern Sweden (population approx. 1.3 million). The cohort included all patients in specialized and primary care between 2004 and 2014. The primary outcome, later generalized pain, was defined as a diagnosis of *pain, unspecified* (ICD-10 R52.9) or *fibromyalgia* (ICD-10 M79.7) which follows the stricter ACR-10 criteria. We used Poisson regression to calculate the incidence rate ratio (IRR), we adjusted for sex and age at study inclusion.
**Results:** During the study period 696,539 eligible individuals aged 18 or older living in the Skåne region and consulting health care at least once during the period were included in the study. After excluding patients with prevalent pain (n=1264) 695,275 individuals remained. Generalized pain was more common in women than in men (71% female). Out of 10,165 patients exposed to RA 5% later developed generalized pain, for endometriosis and IBD the corresponding percentage was 5% and 3% respectively. Among the 673,040 unexposed participants 2% developed generalized pain during the study period.

Incidence rate ratios for developing generalized pain

| | N (%) exposed cases | IRR (95% CI) | |
|---|---|---|---|
| | | Crude | Adjusted* |
| Rheumatoid arthritis | 518 (5.1%) | 3.0 (2.8–3.3) | 2.5 (2.3–2.7) |
| Endometriosis | 185 (5.2%) | 2.4 (2.0–2.7) | 2.4 (2.0–2.7) |
| IBD | 273 (2.4%) | 1.7 (1.5–1.9) | 1.7 (1.5–1.9) |

*For sex and age at inclusion.

The IRR for later generalized pain in patients with RA was 2.5 (95% CI: 2.3 - 2.7) compared to the unexposed, for endometriosis patients the IRR was 2.4 (95% CI: 2.0 - 2.7) and for IBD-patients 1.7 (95% CI: 1.5 - 1.9) when adjusted for age and sex. Restricting the outcome to only the patients with fibromyalgia, rendered equal or higher IRR for all studied diseases.
**Conclusions:** This study shows that pain from structural pathology, caused by diverse etiological factors, may predispose for later generalized pain. The understudied disease of endometriosis is a risk factor of almost equal magnitude as RA, which has, to the best of our knowledge not been shown before. These results have implications for both clinical practice, underlining the importance of optimizing pain control, and further research regarding the etiology of generalized pain and fibromyalgia.

### THU0542 PAIN CATASTROPHIZING AND SELF-EFFICACY AS DETERMINANTS OF SUBJECTIVE AND OBJECTIVE PHYSICAL FUNCTION IN WOMEN WITH FIBROMYALGIA: THE AL-ÁNDALUS PROJECT

F. Estévez-López[1,2], I.C. Álvarez-Gallardo[2], V. Segura-Jiménez[2,3], A. Soriano-Maldonado[2], M. Pulido-Martos[4], M. Borges-Cosic[2], V.A. Aparicio[5,6], A. Carbonell-Baeza[3], M. Delgado-Fernández[2], R. Geenen[1]. [1]*Department Psychology, Faculty of Social and Behavioural Sciences, Utrecht University, Utrecht, Netherlands;* [2]*Department of Physical Education and Sport, Faculty of Sport Sciences, University of Granada, Granada;* [3]*Department of Physical Education, Faculty of Education Sciences, University of Cádiz, Cádiz;* [4]*Department of Psychology, School of Humanities and Sciences of Education, University of Jaén, Jaén;* [5]*Department of Physiology, Faculty of Pharmacy, Faculty of Sport Sciences, and Institute of Nutrition and Food Technology, University of Granada, Granada, Spain;* [6]*Department of Public and Occupational Health, EMGO+ Institute for Health and Care Research, VU University Medical Centre, Amsterdam, Netherlands*

**Background:** A discrepancy between subjective (i.e., patients' perceptions) and objective (i.e., clinical observations) of physical function (PF) has been reported in fibromyalgia (FM). This discordance, with a worse subjective PF than objective PF, may have negative consequences for health-related outcomes such as the ability to pursue valued activities in daily life. Therefore, it seems important to find modifiable factors associated with this discrepancy between objective and subjective PF in FM.
**Objectives:** The present cross-sectional study examined 1) the existence of discordance between subjective and objective PF, 2) the independent association of catastrophizing and self-efficacy with subjective and objective PF, and 3) the independent association of catastrophizing and self-efficacy with the discrepancy between subjective and objective PF.
**Methods:** A total of 427 FM women filled out the Pain Catastrophizing Scale, Chronic Pain Self-efficacy Scale, and PF subscales of the SF-36 (SF-36-PF) and of the Revised FM Impact Questionnaire (FIQ-R-PF). Objective PF was measured by performance-based tests: the Senior Physical Fitness Test Battery plus handgrip strength test. Subjective and objective PF were transformed to standardized z-scores ([value-mean]/standard deviation; using means and standard deviations of a general population sample, *n*=230). These scores reflect the deviation of FM patients from the general population in standard deviation units.
**Results:** In one-way analysis of variance (ANOVA), subjective PF was poorer than objective PF ($P<.001$). Linear regression analysis (adjusted by age, body mass index, years since FM diagnosis, and educational level) showed that high pain catastrophizing and low self-efficacy were independently associated with high subjective and objective PF. Linear regression analysis revealed that high pain catastrophizing (for SF-36-PF and FIQ-R-PF) and low self-efficacy (for the SF-36-PF) were associated with a greater discrepancy between subjective and objective PF.
**Conclusions:** Subjective PF is worse than objective PF in FM. High catastrophizing and low self-efficacy are not only independently associated with low subjective and objective PF but also with a greater discordance between subjective and objective PF in FM. Our findings suggest that clinical trials that combine cognitive therapy (focused on increasing subjective PF and self-efficacy and reducing catastrophizing) and physical exercise (focused on enhancing objective PF) have potential to be effective in FM.

### THU0543 EVALUATION OF THE FIBROMYALGIA RAPID SCREENING TOOL (FIRST) QUESTIONNAIRE TO SCREEN FIBROMYALGIA ASSOCIATED WITH INFLAMMATORY RHEUMATIC DISEASE

A. Fan[1], B. Pereira[2], A. Tournadre[1], Z. Tatar[1], S. Malochet-Guinamand[1], M. Soubrier[1], J.-J. Dubost[1]. [1]*Rheumatology department;* [2]*Biostatistics Unit, CHU Clermont-Ferrand, Clermont-Ferrand, France*

**Background:** Fibromyalgia (FM) is prevalent in patients with chronic inflammatory rheumatic diseases (CIRd), where it hampers diagnosis and activity assessment. No tool for screening FM associated with CIRd has ever been evaluated. The Fibromyalgia Rapid Screening Tool (FiRST) is a brief and simple self-complete questionnaire that has been validated for screening FM in patients with diffuse chronic pain.
**Objectives:** The purpose of this study was to evaluate how well FiRST performs on screening for FM associated with CIRd.
**Methods:** This single-center cross-sectional study was conducted between September 2014 and April 2015 on all patients with chronic pain presenting for rheumatoid arthritis (RA), spondyloarthritis (SpA), and connective tissue disease (Sjögren's syndrome (SS), systemic lupus erythematosus (SLE), scleroderma (Scl), myositis). Diagnosis of FM was based on ACR–90 classification criteria (to minimize interfering overlap between rheumatic disease-related pain and FM-related pain) and expert opinion.
**Results:** The population included 605 patients: 279 RA, 271 SpA (52 psoriatic arthritis, 126 radiographic axial SpA, 64 non-radiographic axial SpA, 29 peripheral SpA), 57 connective tissue disease. In total, 51 patients had FM meeting the ACR–90 criteria, and 93 patients were given a diagnosis of FM by the expert. When tested against the ACR–90 classification criteria, FiRST demonstrated a sensitivity of 74.5%, a specificity of 80.4%, a positive predictive value of 26.6% and a negative predictive value of 97.1%. Specificity was significantly weaker

in the connective tissue disease group (RA: 84.4%, SpA: 80.2%, connective tissue disease: 59.6%; $p<0.001$). When tested against expert opinion, FiRST demonstrated a sensitivity of 75.8%, a specificity of 85.1%, a positive predictive value of 48.3% and a negative predictive value of 95%. FiRST underperformed on sensitivity in the SpA group compared to the connective tissue disease group (66% *vs* 94.4%; $p=0.004$). Performances varied according to item in the self-complete questionnaire.

**Conclusions:** The FiRST self-questionnaire performs less well in inflammatory rheumatic diseases than in primary fibromyalgia, but nevertheless it remains a simple and rapid tool to help rheumatologist and general practitioner detects fibromyalgia associated with inflammatory rheumatic disease.

**Disclosure of Interest:** None declared

## THU0544 IMPAIRED PULMONARY DIFFUSING CAPACITY IN PATIENTS WITH FIBROMYALGIA

M. Rizzi[1], F. Atzeni[2], A. Andrea Airoldi[1], I.F. Masala[3], F. Francesca Frassanito[1], C. Macaluso[1], F. Salaffi[4], P. Sarzi-Puttini[2]. *[1]Pulmonary Department University Hospital L. Sacco; [2]Rheumatology Unit, L. Sacco University Hospital, Milan; [3]Orthopedic Unit, Santissima Trinità Hospital, Cagliari; [4]Department of Reumatology, Polithecnic University of Marche, Jesi (Ancona), Italy*

**Background:** Fibromyalgia syndrome (FM) is a chronic pain disorder characterised by symptoms of morning stiffness, fatigue, depression, non-restorative sleep and reduced cognitive performance, some of which are worsened by emotional distress, meteorological changes, insomnia and strenuous activity.Some of the patients' symptoms, as well as their physical and psychological characteristics, can be attributed to autonomic nervous system (ANS) dysfunction. It has been demonstrated that ANS dysfunction in patients with type 1 diabetes mellits can induce functional alterations in the regulation of pulmonary microvascular tone and the distribution of pulmonary blood filling.

**Objectives:** The aim of this study was to evaluate whether pulmonary diffusing capacity is impaired in patients with FM as it is in those with other diseases characterised by ANS dysfunction such as type 1 diabetes.

**Methods:** Forty-five consecutive anti-nuclear antibody (ANA)-negative female Caucasian patients aged 50.1±5.6 years with FM and compared with 45 healthy female control volunteers matched in terms of age and body mass index (BMI). The autonomic function have been evaluated by means of standard electrocardiography (ECG), finger blood pressure respiration, and muscle sympathetic nerve activity (MSNA) at rest and during a stepwise tilt test up to 75°. Their autonomic profiles were drawn up on the basis of MSNA, plasma catecholamine levels, and spectral indices of cardiac sympathetic and vagal modulation, and sympathetic vasomotor control computed by means of the spectrum analysis of RR and systolic arterial pressure (SAP) variability. Lung volumes and dynamic spirometry parameters were assessed by means of plethysmography. All the patients were clinical evaluated and completed the fibromyalgia impact questionnaire (FQI) and Compositive Autonomic Symptom Score (COMPASS) questionnarie.The number of tender points (TPs) was counted using Wolfe's protocol, which gives a total score of 0–18, and the intensity of somatic pain was assessed using a 100 mm visual analogue scale (VAS).The severity of Raynaud's phenomenon was evaluated using the Raynaud's Condition Score (RCS), an ordinal scale ranging from zero to10 that measures the level of difficulty experienced by patients.

**Results:** There was no difference in lung volumes between the FM patients and healthy controls, but the carbon monoxide diffusion capacity of the lung (DLCO) (83±4 *vs.* 96±5; $p<0.001$), Kco (84±5 *vs* 98±5; $p<0.001$), alveolar-capillary membrane (DM) (12.7±2.4 *vs* 13.6±1.8; $p<0.05$) and pulmonary capillary blood volume (Vc) (48±3.9 *vs* 65±7; $p<0.001$) were significantly reduced in the patients.The COMPASS-31, RCS and pain VAS scores significantly correlated with DLCO, alveolar-capillary membrane (Kco) and Vc with the correlation being particularly close in the case of Vc. Furthermore, univariate Cox proportional hazard analysis showed that the three scores were all significantly associated with an increased risk of impaired DLCO (respectively, $\chi^2$ 16.21, $p<0.0005$; $\chi^2$ 7.09, $p<0.005$; $\chi^2$ 6.37, $p<0.01$).

**Conclusions:** FM impairs DLCO mainly as a result of a reduction in Vc, and that this defect is inversely proportional to the severity of the dysfunction suggestiong a relationship between impaired DLCO and autonomic nerve dysfunction.

## THU0545 COMPARATIVE EFFICACY AND TOLERABILITY OF DULOXETINE, PREGABALIN, AND MILNACIPRAN FOR THE TREATMENT OF FIBROMYALGIA: A BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Y.H. Lee, Y.H. Seo, S.J. Choi, G.G. Song. *Rheumatology, Korea University Medicial Center, Seoul, Korea, Republic Of*

**Background:** Duloxetine, milnacipran, and pregabalin are the only drugs approved by the Food and Drug Administration (FDA) for fibromyalgia. The recommended dosages are duloxetine 60 mg once a day, milnacipran 100 mg/day in two divided doses; may be increased to 200 mg/day, and pregabalin 150 to 300 mg/day in two divided doses. However, data on the relative efficacy and safety of the drugs approved by the FDA with different dosages are limited, because it is difficult to integrate information regarding the relative efficacy and safety of all tested drugs at different doses due to the lack of multiple comparisons in classical meta-analysis.

**Objectives:** The aim of this study was to assess the relative efficacy and tolerability of duloxetine, pregabalin, and milnacipran at the recommended doses in patients with fibromyalgia.

**Methods:** Randomized controlled trials (RCTs) examining the efficacy and safety of duloxetine 60 mg, pregabalin 300 mg, pregabalin 150 mg, milnacipran 200 mg, and milnacipran 100 mg compared to placebo in patients with fibromyalgia were included in this Bayesian network meta-analysis.

**Results:** Nine RCTs including 5,140 patients met the inclusion criteria. The proportion of patients with >30% improvement from baseline in pain was significantly higher in the duloxetine 60 mg, pregabalin 300 mg, milnacipran 100 mg, and milnacipran 200 mg groups than in the placebo group (pairwise odds ratio (OR) 2.33, 95% credible interval (CrI) 1.50–3.67; OR 1.68, 95% CrI 1.25–2.28; OR 1.62, 95% CrI 1.16–2.25; and OR 1.61; 95% CrI 1.15–2.24, respectively). Ranking probability based on the surface under the cumulative ranking curve (SUCRA) indicated that duloxetine 60 mg had the highest probability of being the best treatment for achieving the response level (SUCRA =0.9431), followed by pregabalin 300 mg (SUCRA =0.6300), milnacipran 100 mg (SUCRA =0.5680), milnacipran 200 mg (SUCRA =0.5617), pregabalin 150 mg (SUCRA =0.2392), and placebo (SUCRA =0.0580). The risk of withdrawal due to adverse events was lower in the placebo group than in the pregabalin 300 mg, duloxetine 60 mg, milnacipran 100 mg, and milnacipran 200 mg groups. However, there was no significant difference in the efficacy and tolerability between the medications at the recommended doses.

**Conclusions:** Duloxetine 60 mg, pregabalin 300 mg, milnacipran 100 mg, and milnacipran 200 mg were more efficacious than placebo. However, there was no significant difference in the efficacy and tolerability between the medications at the recommended doses.

## THU0546 CROSS-SECTIONAL ANALYSIS OF THE ASSOCIATIONS BETWEEN FIBROMYALGIA AND OTHER CHRONIC CO MORBIDITIES

A. Lichtenstein[1], S. Tiosano[1,2], D. Comaneshter[3], A.D. Cohen[3,4], H. Amital[2,5]. *[1]Sackler School of Medicine, Tel-Aviv University, Tel-Aviv; [2]Department of Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Ramat-Gan; [3]Chief Physician's Office, Clalit Health Services, Tel-Aviv; [4]Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva; [5]Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel*

**Background:** The Fibromyalgia syndrome (FMS) has been linked to chronic organic and psychiatric conditions, however large population studies that systematically investigated this claim are scarce (1).

**Objectives:** To evaluate the association of FMS with other common chronic diseases such as psychiatric, rheumatic, cardiovascular, pulmonary and malignant disorders.

**Methods:** Utilizing the database of "Clalit" health services, the largest health maintenance organization (HMO) in Israel serving roughly 4,000,000 members, we carried out a cross-sectional study. Fibromyalgia patients were compared to age- and sex- matched controls regarding the coexistence of other chronic diseases. Chi-square and t-tests were used for univariate analysis and a logistic regression model was used for multivariate analysis.

**Results:** The study included 14,296 patients with Fibromyalgia and 71,324 age-

Table 1. Logistic regression for grouped diagnoses ($n$ = 85,620)

| | Psychiatric diseases | Rheumatic diseases |
|---|---|---|
| Age | 1.04 (1.03, 1.04) | 1.03 (1.03, 1.03) |
| Male | 0.67 (0.59, 0.76) | 0.72 (0.57, 0.87) |
| SES – Medium vs. low | 0.99 (0.94, 1.03) | 1.02 (0.95, 1.10) |
| SES - High vs. low | 0.90 (0.84, 0.95) | 1.08 (0.99, 1.17) |
| Smoking | 1.64 (1.60, 1.68) | 1.29 (1.22, 1.36) |
| BMI | 1.01 (1.01, 1.01) | 1.02 (1.01, 1.02) |
| Having co morbid Fibromyalgia | 3.17 (3.13, 3.21) | 3.72 (3.65, 3.79) |

Notes:
SES=Socioeconomic status ; BMI= body mass index
P<0.01

and sex- matched controls. The proportion of psychiatric disorders (anxiety, bipolar disease, depression, psychoses.) in patients with FMS was significantly higher compared with their proportion in controls (30.1% vs. 12.2% respectively, $p<0.001$, OR =3.09, 95% CI: 2.96–3.22). The proportion of rheumatic disorders was also significantly higher in FMS patients compared to controls (10.8% and 3.15% respectively, $p<0.001$, OR =3.73, 95% CI: 3.49–3.99). A multivariate logistic regression model demonstrated that FMS was significantly associated with psychiatric disorders and rheumatic diseases after controlling for confounders, including age, sex, socioeconomic status (SES) and BMI (psychiatric multivariate OR =3.17, $p<0.01$ 95% CI: 3.13–3.21; rheumatic multivariate OR =3.72, $p<0.01$ 95% CI: 3.65–3.79). In contrast, 1365 (1145 controls, 220 FMS) chronic heart failure patients and 1970 (1668 controls, 302 FMS) chronic renal failure patients were not found to be significantly associated with FMS (CHF: OR =0.96, $p<0.566$ 95% CI: 0.83–1.11; CRF: OR =0.90, $p<0.098$ 95% CI: 0.80–1.02).

**Conclusions:** Patients with the FMS have a greater proportion of psychiatric and rheumatic disorders than matched controls. Consequently, physicians treating patients with chronic illnesses in general and rheumatic or psychiatric conditions in particular, should be aware of this high co morbidity rate.

## THU0547 IS PAIN CATASTROPHISING ASSOCIATED WITH IMPAIRED CONDITIONED PAIN MODULATION IN PEOPLE WITH CHRONIC WIDESPREAD PAIN?

D. Rice[1,2], R. Parker[2,3], G. Lewis[2], P. McNair[2]. [1]*Waitemata Pain Service, Waitemata District Health Board;* [2]*Auckland University of Technology;* [3]*Department of Physiotherapy, Waitemata District Health Board, Auckland, New Zealand*

**Background:** Fibromyalgia (FM) may be considered part of a clinical continuum with chronic widespread pain, which is its cardinal symptom [1]. These conditions are associated with abnormal nociceptive system processing, which is characterised by central sensitisation and signs of allodynia and hyperalgesia [2, 3]. Deficient endogenous pain inhibition has been implicated in the aetiology of FM [4], which may be measured by assessing conditioned pain modulation (CPM). Psychological factors such as pain catastrophising may also play a role in the heightened pain experience in FM. There is evidence that pain catastrophising may be associated with reduced CPM efficacy [5]. However, it is not yet known whether the CPM dysfunction in FM occurs at a spinal or supraspinal level and if this is related to pain catastrophising.

**Objectives:** The aims of the present study were to: (1) compare the function of the CPM response in healthy controls and individuals with chronic widespread pain; (2) to explore the relationship between pain catastrophizing and CPM efficacy; and (3) to examine the level of the nervous system where CPM dysfunction may occur in individuals with chronic widespread pain.

**Methods:** Twenty-three people with chronic widespread pain (19 of which met the criteria for FM) and 22 age- and gender-matched healthy control participants took part. Pain beliefs and depression were assessed using the Pain Catastrophising Scale (PCS) and the Depression, Anxiety, and Stress Scale (DASS), respectively. CPM efficacy was assessed by comparing the nociceptive flexion reflex (NFR) area and pain ratings elicited by electrostimulation of the dominant foot (the test stimulus) before and during a cold pressor test applied to the contralateral hand (the conditioning stimulus).

**Results:** The chronic widespread pain group had significantly higher scores in the PCS and DASS ($P<0.05$). In the chronic widespread pain group, test and conditioned reflex areas ($P=0.06$) and verbal pain ratings ($P=0.09$) were not significantly different. In contrast, the control group had a significantly smaller reflex area ($P=0.001$) and a lower verbal pain rating ($P=0.02$) during conditioning compared to the test stimulus alone. There were no significant correlations between catastrophising and CPM efficacy using either VAS or nociceptive NFR measures in either the widespread pain or control group ($P>0.05$).

**Conclusions:** This study suggests that, compared to healthy controls, people with chronic widespread pain have a dysfunctional CPM response and therefore, impaired endogenous pain inhibition. However, there was no evidence of a relationship between pain catastrophising and CPM efficacy at either spinal or supraspinal levels.

## THU0548 SLEEP ARCHITECTURE AND CLINICAL PARAMETERS IN FIBROMYALGIA AND OSTEOARTHRITIS

W.K. Yeung[1], K. Morgan[2], F. McKenna[1]. [1]*Rheumatology, Trafford General Hospital, Manchester;* [2]*Sleep Research Centre, University of Loughborough, Loughborough, United Kingdom*

**Background:** Non restorative sleep (NRS) is a characteristic symptom of fibromyalgia (FM). A number of studies have reported abnormalities of sleep architecture on polysomnography (PSG) including alpha wave intrusion (AWI) during delta wave sleep (DWS). However, AWI in DWS has also been reported in other conditions including depression or in chronic fatigue. We have compared FM patients with patients who had sleep disturbance from osteoarthritis (OA) and a group of normal healthy control subjects (NHC) to determine if there are specific abnormalities of sleep architecture in FM related to clinical parameters.

**Methods:** We studied 19 newly diagnosed FM patients (mean age 41yrs, range 19–58yrs), 17 with OA (mean age 46yrs, range 19–63yrs) with localized pain and sleep disturbance, and ten NHC (mean age 38yrs, range 23–61yrs). All participants were female. The diagnosis was confirmed by a consultant rheumatologist. None were being treated for anxiety or depression or had taken antidepressant, psychoactive or sedative drugs for at least 2 weeks prior to analysis. All completed pain score (VAS), Brief Pain Inventory (BPI), Fatigue Severity Scale (FSS), Epworth Sleepiness Scale (EPS), Pittsburgh Sleep Quality Index (PSQI), Centre for Epidemiologic Studies Depression Scale (CESD), State and Trait Anxiety Scale (STAS), Multidimensional Scales of Health Locus of Control and Perceived Social Support (HLC), and 2 weeks actigraphy and 2 consecutive nights of polysomnography (PSG) at home, scored by a trained sleep researcher. Each frequency band was decomposed and power averaged using spectral analysis.

**Results:** Sleep efficiency was significantly worse in FM and OA ($p=0.025$). Sleep stage transitions (SST) were significantly increased in FM and OA ($p=0.019$) with a marked increase in SST per hour ($p=0.002$) compared with NHC with no significant difference between FM and OA. Alpha waves were increased during stage 3 sleep (DWS) in both FM and OA compared with NHC but also with no difference between FM and OA. There was a numerical increase in spindle frequency during non REM sleep compared with NHC, more in FM than OA but with wide variation ($1.12 \pm 0.8$; $0.98 \pm 0.39$; $0.61 \pm 0.27$ mpl). Pain scores in FM and OA groups were significantly different to NHC; mean difference in BPI of 6.07 and 4.83 respectively ($p<.001$). FM had significantly greater fatigue and EPS than OA (M diff14.41, $p<.001$; 3.42, $p=.033$) and NHC (M diff=29.87, $p<.001$; 3.99, $p=0.34$). PSQI was significantly greater than HC in both FM and OA (10.19 and 7.18, $p<.001$). The difference between FM and OA was significant ($p=.023$). There were highly significant differences between the 3 groups for CESD (FM 23.11; OA16.06; NHC4.8, $p<0.001$), STAS (49.6; 39.8; 31.9, $p<0.001$), HLC ($p<0.001$), and neuroticism (15.7; 13.5; 9.3 $p<0.01$).

**Conclusions:** Patients with FM had a similar duration of sleep to this group of OA patients but had a significant difference in subjective sleep quality, with significantly increased fatigue and sleepiness. They also had more anxiety, depression and neuroticism. AWI in DWS in FM is not specific and is similar in disturbed sleep from OA, but increased spindle frequency may be a feature of FM. We hypothesise that psychological factors in FM are linked to both sleep quality and fatigue and NRS may result from an increased rate of SST with frequent fluctuation between light and deep sleep.

## THU0549 FATIGUE AND THE ROLE OF SLEEP IN FIBROMYALGIA: OBJECTIVE AND SUBJECTIVE MEASURES

M.P. Guzzo[1], M. Fernandes[2], C. Iannuccelli[1], F. Lucidi[3], L. Mallia[2], B. Lucchino[1], A.C. Di Lollo[1], G. Valesini[1], C. Violani[2], M. Di Franco[1]. [1]*Dipartimento di Medicina Interna e Specialità Mediche;* [2]*Dipartimento di Psicologia;* [3]*Dipartimento di Psicologia dei Processi di Sviluppo e Socializzazione, Sapienza, University of Rome, Rome, Italy*

**Background:** Fibromyalgia (FM) is a chronic widespread pain syndrome associated with symptoms such as sleep disorders, fatigue, depression, anxiety and cognitive alterations with a severe impairment of the life quality.

**Objectives:** The aim of this study is to examine the relationship between subjective and objective assessment of sleep quality and to analyze the predictors of fatigue in an Italian cohort of FM patients.

**Methods:** Adult outpatients diagnosed with FM, fulfilling both ACR/EULAR 1990 and 2010 criteria were enrolled (1,2). The objective measure of sleep was assessed through an actigraph (AMI Motionlogger Watch), a device which records the parameters of sleep based on electronic measure of the continuous motion detected by an accelerometer. During the study period the patients were invited to wear the actigraph on the non-dominant wrist for one week and concurrently to complete a sleep diary. After seven days the patients returned the actigraph and answered a structured interview conducted by a trained junior psychologist. Subjective quality of sleep was assessed by the Sleep Disorder Questionnaire (SDQ) (3) and the patients filled out psychometric scales as the Brief Symptom Inventory (BSI) for anxiety and depression (4) and the Checklist of Individual Strength (CIS20) for perceived fatigue (5). Both pharmacological and not pharmacological treatments were not changed 1 month before and during the study.

**Results:** Twenty-one female patients completed the study, mean age of 46.9 years (range 32–68) and mean disease duration of 7.5 years (range 1–27). The majority of 21 FM patients interviewed (76.2%) described their sleep quality as poor or very poor (mean value 3.10 ±0.89 SD on 4 point Likert scale). All patients (100%) reported insomnia complaints, and 18 (81%) met the DSM V (Diagnostic and Statistical Manual of Mental Disorders) criteria for a diagnosis of Difficulties Initiating and Maintaining Sleep (DIMS). The patients' perception about the number of slept hours (M=5.7) was significantly lower (t=3.292, $p<0.005$) than the actigraphic data (M=6.8). Total Sleep Time (TST) measured through actigraphy was directly correlated with the intensity of perceived fatigue (r=.481; $p<0.05$). A multiple regression analysis considering TST, Total Time in Bed (TTB), depression, and type of fatigue self management, showed TST as the variable that gave a major and unique contribute to the prediction of perceived fatigue. Mean values of TST and TTB both negatively correlated with FM duration (respectively r=-.589, $p<0.005$; r=-.565, $p<0.008$).
**Conclusions:** These findings confirm the high prevalence of sleep disturbances in FM and suggest that sleep quality and duration could play an important role in the perceived fatigue severity. Intervention programs for FM should include sleep regulation.

## THU0550 EARLY MULTIDISCIPLINARY INTERVENTIONS TO PROMOTE WORK PARTICIPATION IN PEOPLE WITH REGIONAL MUSCULOSKELETAL PAIN: A SYSTEMATIC REVIEW

A. Cochrane[1], N.M. Higgins[1], O. FitzGerald[2], P. Gallagher[3], J. Ashton[4], R. Breen[5], A. Brennan[6], O. Corcoran[7], D. Desmond[1]. *[1]Department of Psychology, National University of Ireland Maynooth, Maynooth; [2]School of Medicine and Medical Sciences, University College Dublin; [3]School of Nursing and Human Sciences, Dublin City University; [4]Physiotherapy Services, Beaumont Hospital; [5]Royal College of Physicians in Ireland; [6]Physiotherapy Services, AMNCH, Dublin; [7]Rheumatology Services, Waterford Regional Hospital, Waterford, Ireland*

**Background:** Musculoskeletal disorders are amongst the leading causes of disability in the working age population. Whilst there is a growing body of evidence suggesting that early targeted multidisciplinary interventions can promote work retention and prevent disability, the evidence is far from conclusive as to which interventions are the most effective.
**Objectives:** To review randomised controlled trials evaluating the effectiveness of early interventions in promoting work participation in adults with regional musculoskeletal pain (RMSKP).
**Methods:** CENTRAL, MEDLINE, EMBASE, Scopus, PEDro and OT Seeker (1990 to April 2015) were searched. Reference lists of identified articles and reviews were hand searched. Only RCTs reporting on work-related outcomes were eligible for inclusion. The intervention had to include two or more elements of the biopsychosocial model delivered as an integrated programme. Participants were either experiencing difficulties at work or had less than three months sick leave as a result of their RMSKP at enrolment. Each RCT was assessed independently by two reviewers for risk of bias. Results were analysed by hazard ratios for return to work data, while continuous outcomes were analysed as mean difference (MD) with 95% confidence intervals.
**Results:** 19 RCTS were included; the considerable variation in the components employed in the interventions limited the option to pool the data statistically using meta-analysis. There was some evidence that programmes involving a stepped care approach (4 studies) increased the probability of return to work at the 12-month follow-up [HR 1.29 (95% CI, 1.03 to 1.61), p=0.03]. However, preliminary analyses indicate a lack of consistent evidence for effects on reducing sickness absences, pain reduction and functional improvement across the intervention types.
**Conclusions:** The lack of agreement as to what constitutes "early" in the context of treating RMSKP may have contributed to the rather ambiguous findings. In addition, the different health and social insurance systems across the trials have made it difficult to generalise the results. There remains a need to establish the active components that promote work retention in this population, and to identify the patients who are most likely to benefit from an integrated and cost-effective intervention.

## THU0551 NOVEL SJÖGREN'S AUTOANTIBODIES FOUND IN FIBROMYALGIA PATIENTS WITH SICCA AND/OR XEROSTOMIA

A. Lichtbroun. *Rutgers Medical School, Piscataway, NJ, United States*

**Background:** A significant proportion of patients with fibromyalgia complain of dry eyes and mouth. The 2010 preliminary criteria for fibromyalgia even includes dry eyes and mouth as part of the somatic symptoms severity complex used to diagnose this condition. A significant proportion of Sjögren's (Sjö) patients also complain of fibromyalgia symptoms and there is literature that questions the interplay of these two disorders. Recently, novel autoantibodies, SP-1, CA6, and PSP, have been described in early Sjögren's syndrome (SS). These early markers present themselves before the classic autoantibodies, such as Ro, La, ANA, and RF. A recent paper found that 76% of patients with idiopathic xerostomia and exophthalmia for less than 2 years were positive for the early markers, while only 31% had antibodies to Ro and La. The authors concluded that SP-1, CA6, and PSP may be useful markers for identifying patients with SS at an early stage of the disease.
**Objectives:** This study aims to examine the relationship between SS and fibromyalgia by testing patients with fibromyalgia, that also complain of xerostomia and sicca symptoms, for Sjö markers Ro, La, SP-1, CA6, and PSP.
**Methods:** Beginning in April 2013, a cohort of patients was identified that presented with symptoms of fibromyalgia, meeting both the 1990 and 2010 preliminary criteria. These patients were further questioned about xerostomia and sicca symptoms. Patients that admitted to using artificial tears at least biweekly, drinking water excessively, or have previously experienced a blocked tear duct, but did not meet the strict diagnostic criteria for SS and did not have elevated inflammatory markers ESR or CRP, were selected for this study. Serum from study patients was sent to a tertiary lab, Immco Diagnostics, for testing of the classic (Ro, La) and early Sjö (SP-1, CA6, PSP) markers. Patients testing positive for the Sjö markers were provided with literature on the disease and offered appropriate treatment options, such as hydroxychloroquine.
**Results:** As of January 2016, 210 patients were selected for this study and tested for the Sjö markers. 91.0% of the patients were female and 8.6% of the patients were male. The average patient age was 56.5. 171 of the study patients were tested for both the early and classic markers, while 39 were tested for only the early markers. Of the patients that were evaluated for both the early and classic Sjö markers, 29.8% (51) tested positive for SS. 39 (22.8%) of the patients were positive for the early Sjö markers, 9.4% (16) were positive for the classic Sjö markers, and 2.3% (4) were positive for both the early and late Sjö markers. Further analysis of all the patients that tested positive for the early Sjö markers (n=47), found 74.5% (35) were positive for SP-1, 8.5% (4) were positive for CA6 and 44.7% (21) were positive for PSP. 68.1% (32) of these patients were positive for only one of the early markers and 15 (31.9%) were positive for more than one early marker.
**Conclusions:** In this cohort of fibromyalgia patients, about 1/3 of patients that were tested for both the early and classic Sjö markers tested positive for SS, with the majority of those patients being positive for one or more of the early Sjö markers. This suggests that autoimmunity, specifically early Sjögren's syndrome, may be a confounding variable in the pathophysiology of fibromyalgia.

## THU0552 HAPLOTYPES OF VITAMIN D RECEPTOR GENE: BOTH RISKY AND PROTECTIVE FOR FIBROMIYALGIA (FMS)

A. Balkarli[1], M. Akyol[2], E. Tepeli[3], H. Balkarlı[4], S. Temel[5], V. Cobankara[6]. *[1]Rheumatology, Antalya training and research hospital; [2]Department of Medical Biology, Akdeniz University Hospital, Antalya; [3]Department of Medical Biology, Pamukkale University Hospital, Denizli; [4]Department of Orthopedics and Traumatology, Akdeniz University Hospital, Antalya; [5]Internal Medicine; [6]Rheumatology, Pamukkale University School of Medicine, Denizli, Turkey*

**Background:** Clinical observations suggest that vitamin D may influence fibromyalgia etiology. FMS and vitamin D deficiency share a similar symptom profile; the relationship between these conditions is unclear. Vitamin D receptor is a crucial mediator of the symptoms of vitamin D deficiency. Thus, vitamin D receptor gene polymorphisms or haplotypes may contribute to vitamin D resistance.
**Objectives:** This study evaluated the clinical relationship between FMS and vitamin D gene among Turkish FMS patients.
**Methods:** 73 patients with FMS were diagnosed according to the ACR 2010 criteria; the control group included 61 healthy unrelated volunteers. The rs2228570 (Fok I), rs1544410 (Bsm I), rs7975232 (Apa I) and (rs731236) Taq I polymorphisms were examined using PCR-RFLP.
**Results:** In individual SNP analyses, none of the snps have been found to be associated with FMS (p values are 0.491, 0.477, 0.207, and 0.736 respectively). However, it has been detected that there is a strong association between haplotypes of VDR gene polymorphisms and FMS. As a result of this study, the effect of haplotypes is shown to be both risky and protective. P value of risk haplotypes ATC (rs2228570, rs1544410, rs7975232) is 0,015 (26,5%) and

TTT is 0,0068 (12,8%). The p value of collected risk haplotypes (ATC, TTT) is 0,006 (39,3%) and (ATC, TGT, and TTT) 0,000009 (58,7%). Frequent protective haplotype TTC is 0,0385 (6,8%). The p value of collected protective haplotypes (ATT, TCG, and TTC) is 0,008 (38%).

Table 1. Haplotype analysis of VDR gene polymoprhisms (1 = Bsm1, 2 = Fok1, 3 = Taq1)

| Haplo No. | Haplotype Bsm1-Apa1-Fok1 | Control (%) | Case (%) | P | OR (95% CI) | RR (95% CI) | Risk/Protective |
|---|---|---|---|---|---|---|---|
| 1 | ATT | 31.7 | 38.4 | 0.327 | 0.74 (1.33–0.42) | 0.83 (1.21–0.56) | R |
| 2 | ATC | 26.5 | 14.5 | 0.015 | 2.37 (4.82–1.17) | 2.01 (3.59–1.13) | P |
| 3 | TGT | 19.4 | 10.5 | 0.077 | 2.05 (4.61–0.91) | 1.85 (3.71–0.92) | P |
| 4 | TTT | 12.8 | 2.6 | 0.0068 | 5.50 (21.52–1.41) | 4.92 (18.4–1.34) | P |
| 5 | TGC | 5.2 | 12.3 | 0.075 | 0.39 (1.14–0.13) | 0.39 (1.13–0.16) | R |
| 6 | TTC | 1.1 | 6.8 | 0.0385 | 0.15 (1.17–0.02) | 0.16 (1.19–0.02) | R |
| 2+4 | ATC+TTT | 39.3 | 17.1 | 0.006 | 3.1 (5.99–1.61) | 2.28 (3.73–1.39) | P |
| 2+3+4 | ATC+TGT+TTT | 58.7 | 27.6 | 0.000009 | 3.73 (6.74–2.06) | 2.13 (3.04–1.49) | P |
| 1+5+6 | ATT+TGC+TTC | 38 | 57.5 | 0.0008 | 0.39 (0.68–0.22) | 0.60 (0.82–0.44) | R |

**Conclusions:** The present study is the first study evaluating VDR gene in patients with FMS. Our results suggest that haplotypes in VDR are strongly associated with fibromyalgia expressing both risk and protective effect. Our findings may help guide future research needed to define the role of vitamin D in FMS.

## THU0553 RELATIONSHIP BETWEEN ACTIVE DISEASE AND FIBROMYALGIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Kılıcaslan[1], F.G. Yurdakul[1], H. Bodur[2]. *[1]Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital; [2]Physical Medicine and Rehabilitation, Yildirim Beyazit University, Ankara, Turkey*

**Background:** Rheumatoid arthritis (RA) is an inflammatory disease characterized by erosive synovitis. Fibromyalgia syndrome (FMS) known with widespread pain, fatigue, sleep disturbances and mood disorders. FMS frequency increased in patients with RA.
**Objectives:** This study aimed to assess the prevalence of FMS in patients with RA and to analyse the relationship between disease activity and FMS.
**Methods:** The study included 151 RA patients and 77 controls without inflammatory rheumatic diseases. RA patients and the control group were evaluated with 2010 ACR criteria for FMS. Participants were divided into 4 groups according to presence of RA and FMS (Group 1: RA+, FMS+; Group 2: RA+, FMS-; Group 3: RA-, FMS+; Group 4: RA-, FMS-). Demographic characteristics, laboratory results, VAS pain, DAS 28, and HAQ scores were compared between 4 groups. RA patients were classified as in remission or without according to the DAS 28 score (DAS 28$\leq$2.6 and$>$2.6 respectively) and FMS evaluated.
**Results:** The mean age and sex distribution were similar between the RA patients and controls. FMS was found in 35.1% of RA patients and 19.5% of controls ($p<0.05$). The highest VAS pain and DAS 28 scores were in the group 1 and group 3 between the sub-groups (Table 1). FMS were compared between controls, RA patients in remission and active disease. FMS ratio was 19.5%; 8.1%; 53.9% respectively ($p<0.05$). Four parameters (ESR, tender joints, swollen joints, patient global assessment) of DAS 28 were higher in RA patients with active disease ($p<0.05$).

Table 1. The evaluation of disease activity and pain in patients who were divided into four groups according to the presence rheumatoid arthritis and fibromyalgia

| | VAS pain | DAS 28 | HAQ |
|---|---|---|---|
| Group 1 (RA+, FMS+), n=53 | 6,2±2* | 4,4±1* | 1,63±0,68* |
| Group 2 (RA+, FMS–), n=98 | 2,3±2,1 | 2,6±1 | 0,62±0,64 |
| Group 3 (RA–, FMS+) n=15 | 7±1,7* | 3,4±1* | 0,72±0,60 |
| Group 4 (RA–, FMS–) n=62 | 2±2 | 1,7±0,5 | 0,32±0,44 |

VAS: Visual Analog Scale, DAS 28: Disease Activity Index 28, HAQ: Health Assessment Questionnaire, RA: rheumatoid arthritis, FMS: Fibromiyalgia Syndrome. *P<0.05.

**Conclusions:** FMS is more common in the patients with RA than the general population therewithal FMS found more common in the patients with active RA. When DAS 28 parameters are analyzed, objective values (ESH; swollen joint) were higher as subjective values (pain) in this group. In conclusion increased widespread pain and disruption of the sleep quality because of inflammation may facilitate the diagnosis of FMS.

## THU0554 POLYMORPHISMS OF TRANSIENT RECEPTOR POTENTIAL VANILLOID (TRPV) 2 AND TRPV3 GENE POLYMORPHISMS WERE ASSOCIATED WITH FIBROMYALGIA IN A KOREAN POPULATION

J.-H. Kang[1], D.-J. Park[2], S.-H. Kim[3], S.-S. Nah[4], J.H. Lee[5], S.-K. Kim[6], Y.-A. Lee[7], S.-J. Hong[7], H.-S. Kim[8], H.-S. Lee[9], H.A. Kim[10], C.-I. Joung[11], S.-H. Kim[12], S.-S. Lee[1]. *[1]Rheumatology, Chonnam National University Medical School and Hospital; [2]Rheumatology, Chonnam National University Medical School, Gwangju; [3]Rheumatology, Inje University Haeundae Paik Hospital, Busan; [4]Rheumatology, Soonchunhyang University, College of Medicine, Cheonan; [5]Rheumatology, Maryknoll Medical Center, Busan; [6]Rheumatology, Catholic University of Daegu, Daegu; [7]Rheumatology, Kyung Hee University; [8]Rheumatology, Soonchunhyang University, College of Medicine; [9]Rheumatology, Hanyang University College of Medicine, Seoul; [10]Rheumatology, Ajou University Hospital, Suwon; [11]Rheumatology, Konyang University Medical School, Daejeon; [12]Rheumatology, Keimyung University, Daegu, Korea, Republic Of*

**Objectives:** Researchers continue to gather evidence that transient receptor potential vanilloid (*TRPV*) channels contribute towards pain signaling pathways. However, it is unknown whether polymorphisms of the *TRPV* gene are associated with fibromyalgia (FM). For the first time, we investigated the association between the polymorphisms of the *TRPV2* and *TRPV3* genes with FM susceptibility and the severity of the symptoms.
**Methods:** A total of 409 patients with FM and 423 controls were enrolled from 10 medical centers that participated in the Korean nationwide FM survey. The alleles and genotypes at three positions [rs3813768 (C>G), rs8121 (C>T), and rs1129235 (C>A)] in the *TRPV2* gene, and two positions [rs7216486 (G>A) and rs395357 (C>T)] in the *TRPV3* gene, were genotyped.
**Results:** The frequencies of the alleles and genotypes of individual *TRPV2* and *TRPV3* genes were not significantly associated with FM susceptibility. However, the GTA haplotype of *TRPV2* showed a defense against FM susceptibility ($P$=0.035). In addition, polymorphisms of *TRPV3* were associated with symptom severity in FM patients. The single nucleotide polymorphism (SNP) rs395357 of *TRPV3* was associated with the scores of the Brief Fatigue Inventory (BFI) ($P$=0.017) in FM patients. Furthermore, haplotypes of *TRPV3* were associated with the BFI and the SF-36 mental health summary scores ($P$=0.036, respectively)
**Conclusions:** This study was the first to evaluate the associations of *TRPV* gene polymorphisms with FM. Our results suggest that certain *TRPV2* haplotypes may have a protective role against FM, and also that some genotypes and haplotypes of *TRPV3* contribute towards the symptoms of FM.

## THU0555 NEGATIVE AFFECT IN CHRONIC PAIN: THE HEART OF THE MATTER

C. Costa[1], A.T. Pereira[2], A.M.F. Pinto[3], M. Marques[4], A. Macedo[4], J.A.P. da Silva[1]. *[1]Rheumatology Department, University Hospital of Coimbra; [2]Psychological Medicine Department; [3]Psychological Medicine Department/ Rheumatology University Clinic, Faculty of Medicine, University of Coimbra; [4]Psychiatry Department, University Hospital of Coimbra, Coimbra, Portugal*

**Background:** A large body of studies supports the concept of a frequent comorbidity between chronic pain conditions and psychological distress/disorders, especially depression. However, most of the studies have focused on specific chronic pain conditions and not on the potential differences or similarities between them.
**Objectives:** We aimed to explore the prevalence and severity of depressive symptoms, tension/anxiety (TA), anger/hostility (AH) and fatigue/inertia (FI) among fibromyalgia (FM) and rheumatoid arthritis (RA) patients and healthy controls (HC).
**Methods:** Participants were recruited at rheumatology and gynecology practices in Coimbra and all met the classification criteria for FM and RA or, in the case of HC, the pre-established criteria of a zero score in the London Fibromyalgia Epidemiological Study Screening. The Portuguese versions of the following measures were completed by all participants: Beck Depression Inventory (BDI-II) and Profile of Mood States (PoMs). The samples' characteristics were examined. Descriptive analyses were performed in order to explore the severity of depressive symptoms across samples according with the recommended cut-off points. Differences between samples with respect to depressive symptoms and mood states was tested for significance via Fisher's Exact test and one-way independent ANOVA.
**Results:** 302 participants composed the total sample [103 FM (34.11%), 98 RA (32.45%) and 101 HC (33.44%)]. Differences between samples were found regarding age ($F=30.598$; $p<.001$) and education years ($F=25.883$; $p<.001$). 17.5% of FM patients reported severe depressive symptomatology against 3.3%

of RA patients and 2.1% of HC. Similarly the percentage of FM patients with moderate depressive symptoms (24.8%) was substantially greater than the percentage of RA patients and HC (7.7% and 4.3% respectively). Both FM and RA patients reported higher levels of mild depressive symptoms (24.7% and 11%), when compared to HC (just 3.2%). The majority of HC (90.4%) reported minimal depressive symptoms, a percentage relatively close to RA patients (78%) but considerably different from FM patients (33%). Fischer's Exact test pointed to significant differences between samples regarding the prevalence of depressive symptoms ($p<.001$). Further analyses revealed that FM, RA and HC differed significantly in the mean scores of BDI-II and its dimensions, with FM patients scoring higher than RA and HC. No significant differences were found between the latter two, except for the somatic/anxiety dimension, with RA patients scoring higher than controls. Significant differences between samples were also found for TA, AH and FI. In all of these dimensions, FM patients scored significantly higher than RA and HC. Once more, RA patients and HC did not differ significantly in the mean scores of PoMS dimensions.

**Conclusions:** Results revealed that FM participants not only evidenced more depressive symptoms than RA patients and HC but also greater levels of TA, AH and FI. In turn, RA patients present scores that are, overall, similar to those of HC. Such findings reinforce not only the extreme emotional suffering that FM patients experience but also the need for interventions designed to manage depressive/anxious symptoms and emotion regulation difficulties.

## THU0556 ASSESSMENT OF PERIPHERAL SMALL FIBER NERVE IN FIBROMYALGIA

J.W. Lee[1], G.T. Kim[2], E.K. Park[3], S.G. Lee[4], H.O. Kim[5]. *[1]Rheumatology Department, Busan St. Mary's hopital; [2]Kosin University; [3]Pusan National Univeristy Hospital; [4]Pusan national University Hospital, Busan; [5]Kyung Sang National University Hospital, Jinju, Korea, Republic Of*

**Background:** Fibromyalgia (FM) is related to the features of small fiber neuropathy (SFN). Sudoscan is a non-invasive device measures sweat gland dysfunction employing electrochemical skin conductance (ESC) and is useful for assessing peripheral small fiber nerve function. Little is known about the dysfunction of peripheral small fiber nerve in patients with FM.

**Objectives:** The aim of this study was to evaluate the prevalence and characteristics of SFN in patients with FM compared with a control group and to identify factors associated with SFN in FM.

**Methods:** 66 patients with FM (age: 53 ± 9 years old) to meet 2010 ACR preliminary diagnostic criteria and 66 healthy controls were enrolled. Each FM patient was required to fast 8 to 10 hours before blood samples. Serum fasting glucose, fasting insulin, Serum 25-(OH) D and the 75-gram two-hour oral Glucose tolerance test (GTT) were measured. Height and weight were measured and used to calculate Body mass index (BMI). Overt diabetes patients were excluded using their past and medication history. The small fiber neuropathy Symptoms Inventory Questionnaire (SFN-SIQ) was used to record neuropathic symptoms. Clinical assessments included fibromyalgia impact questionnaire (FIQ), Beck Depression Inventory (BDI), and The State-Trait Anxiety Inventory (STAI). All subjects underwent the examination of Sudoscan.

**Results:** The mean feet and hands ESC were significantly lower in the FM group than the control group.(table 1).

Table 1. Comparison of Mean feet and hands ESC between FM and control group

| | FM (n=66) | Control (n=66) | p-value |
|---|---|---|---|
| Mean feet ESC (μS) | 62.2±17.9 | 72.2±13.0 | <0.001 |
| Mean hands ESC (μS) | 54.3±19.6 | 65.63±15.4 | <0.001 |

Values are expressed as mean ± SD for 66 subjects in each group.

Mean Hands ESC was irrelevant to age, BMI, SFN-SIQ, FIQ, fasting glucose, fasting insulin, homeostasis model assessment of insulin resistance (HOMA-IR), and vitamin D and 2 hour GTT glucose level. However, Mean feet ESC showed significant correlation with fasting insulin ($r= -0.34$, $p<0.01$) and HOMA-IR ($r= -0.37$, $p<0.01$).

**Conclusions:** Sudomotor function was significantly lower in patients with FM than the control group. Mean feet ESC was correlated with hyperinsulinemia and HOMR-IR in patients with FM, which implies that SFN associated with insulin resistance may play an important role in FM pain.

## THU0557 RELIABILITY AND VALIDITY OF TURKISH VERSION OF THE FIBROMYALGIA RAPID SCREENING TOOL (FIRST)

R. Çeliker[1], L. Altan[2], A. Rezvani[3], I. Aktaş[4], N. Taştekin[5], E. Dursun[6], N. Dursun[6], S. Sarıkaya[7], S. Özdolap[7], K. Akgün[8], C. Zateri[9], M. Birtane[5]. *[1]Physical Medicine and Rehabilitation, Acibadem University, Faculty of Medicine, Istanbul; [2]Physical Medicine and Rehabilitation, Uludag University Medical faculty, Bursa; [3]Physical Medicine and Rehabilitation, Fatih Sultan Mehmet Teaching and Research Hospital; [4]Physical Medicine and Rehabilitation, Bezmialem University, Faculty of Medicine, Istanbul; [5]Physical Medicine and Rehabilitation, Trakya University, Faculty of Medicine, Edirne; [6]Physical Medicine and Rehabilitation, Kocaeli University, Faculty of Medicine, Kocaeli; [7]Physical Medicine and Rehabilitation, Bulent Ecevit University, Faculty of Medicine, Zonguldak; [8]Physical Medicine and Rehabilitation, Istanbul University, Cerrahpaşa Faculty of Medicine, Istanbul; [9]Physical Medicine and Rehabilitation, Canakkale Onsekiz Mart University, Faculty of Medicine, Çanakkale, Turkey*

**Background:** Fibromyalgia is a challenging chronic pain condition accompanied by several comorbidites. Since patients are encountered in various health care settings, there is a need for short, easy to use, psychometrically validated screening tool

**Objectives:** This study aims to evaluate reliability and validity of Turkish version of Fibromyalgia Rapid Screening Tool (FiRST) by correlating this tool with 2013 American College of Rheumatology alternative diagnostic criteria (ACR AltCr) and Hospital Anxiety and Depression Scale (HADS).

**Methods:** A convenience sample of 269 subjects recruited from outpatient Physical Medicine and Rehabilitation clinics were included in the study. Patients were asked to complete the questionnaire including FiRST (twice), 2013 AltCr and HADS. The reliability of the FiRST scale was examined by test-retest method. For criterion validity of FiRST scale, we used ACR 2013AltCr for comparison. The concordance between ACRAltCr and FiRST and the relationships between variables were evaluated. The sensitivity, specificity, positive and negative likelihood ratios of FiRST was calculated according to ACR 2013 AltCr criteria. Logistic regression analysis was carried out to find the confounding effect of HADS on FiRST to discriminate the patients with FMS

**Results:** The test-retest reliability coefficient of FiRST scale was r=0.875. FiRST was similar to ACR 2013 AltCr in defining patients with FMS. FiRST score was correlated with subscores of ACR 2013AltCr. Each point increase in FiRST global score increased odds of suffering FM approximately 10 times compared to HADS

**Conclusions:** Turkish version of FiRST is a reliable instrument for identifying patients with FMS

**Disclosure of Interest:** None declared

## THU0558 FIBROMYALGIA SYMPTOMS IN A SAMPLE OF LEBANESE NURSES: PREVALENCE AND PREDICTIVE FACTORS

N. Ziade[1], S. Zoghaib[2], M. Zoghbi[3]. *[1]Rheumatology, Hotel Dieu de France; [2]Medicine; [3]Family Medicine, Saint-Joseph University, Beirut, Lebanon*

**Background:** Nurses work in a physically and emotionnally stressful envirnment, which could lead to increased fibromyalgia symptoms.

**Objectives:** To estimate the prevalence of fibromyalgia symptoms in nurses from Hotel Dieu de France and North Center Hospitals and to determine predictive factors.

**Methods:** The study was conducted using a questionnaire distributed to all registered nurses working in the two hospitals in November 2014. For fibromyalgia screening, we used the validated French version of London fibromyalgia epidemiology study screening questionnaire (LFESSQ). The screening was considered positive if a subject met four criteria of pain and two criteria of fatigue items (LFESSQ-6). To estimate the positive predictive value of LFESSQ-6, a sample of nurses screened positive were then examined by a rheumatologist to clinically confirm the diagnosis of fibromyalgia. The prevalence of fibromyalgia in nursing was estimated by applying the positive predictive value to LFESSQ-positive subjects detected by the questionnaire. They were also asked about their demographics, their work environment, personal and family history, as well as the frequency of episodes of depressed mood through the Patient's Health Questionnaire-2 (PHQ-2). The statistical analysis was based on a logistic regression model used for the multivariate analysis to identify predictive factors of fibromyalgia.

**Results:** 485 questionnaires were distributed, with a response rate of 76.3%. 16.8% of the study sample met the criteria of LFESSQ-6. The subsequent rheumatology consultation confirmed the diagnosis of fibromyalgia in 57.14% of positively screened. Applying the positive predicted value in the nursing population, the prevalence of fibromyalgia was estimated of 9.6% using the screening by the LFESSQ -6. The factors that were significantly associated with a positive screening fibromyalgia were: the number of children and sports activities as protective factors on the one hand, and dissatisfaction with salary, lack of group cohesion, and the frequency of episodes of depressed mood as risk factors on the other hand

**Conclusions:** Our results suggest that fibromyalgia is prevalent in the nursing population. Some risk factors are modifiable: depression measured by the PHQ-2, dissatisfaction with salary and a lack of group cohesion. Protective factors were the number of children and the sports activities.

## THU0559 FREQUENCY OF FIBROMYALGIA SYNDROME IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

G. Tugrul[1], N. Cuzdan Coskun[2], T. Sarpel[3], M. Sert[1], E. Nazlican[4].
*[1]Department of Internal Medicine, Division of Endocrinology and Metabolism; [2]Physical Therapy and Rehabilitation, Division of Rheumatology; [3]Physical Therapy and Rehabilitation; [4]Department of Public Health, Cukurova University, Balcali Hospital, Adana, Turkey*

**Background:** Fibromyalgia Syndrome (FS) is a chronic condition with widespread pain. Increased FS prevalence was observed in patients with Diabetes Mellitus (DM) in several of former studies.[1,2]
**Objectives:** The aim of this study is to assess the frequency of FS in patients with Type 2 DM. Additionally; we aimed to evaluate the association of pain severity with disease control of DM.
**Methods:** Patients with Type 2 DM who were followed in Endocrinology Clinic of Cukurova University Hospital were included in the study. FS was diagnosed according to 2013 Alternative Criteria set by American College of Rheumatology. Patients with anemia, hyper- and hypothyroidism, malignancy, pregnancy and rheumatologic conditions were excluded. Patients' pain during morning and sleep was evaluated by Visual Analog Scale (VAS). Fasting blood glucose and Hba1c levels were measured to assess disease control of DM.
**Results:** Ninety-two patients (61 female, 31 male) with Type 2 DM were included in the study. Mean age of the patients was 57.84 ± 10.01 years. FS was diagnosed in 4.3% of the patients. No significant difference was observed between Hba1c levels of Type 2 DM patients with and without FS ($P$=0.87). Mean VAS scores of the patients during morning and sleep were detected as 2.97±2.96 and 2.51±2.73 respectively. There was a weak negative correlation between VAS morning scores and Hba1c levels in diabetic patients (r=-0.24, $P$=0.04). There were no correlations of VAS sleep scores with fasting glucose and Hba1c levels ($P$=0.54, $P$=0.34 respectively).
**Conclusions:** According to the results of the present study, when diagnosis is based on 2013 alternative criteria of ACR, FS frequency in patients with Type 2 DM is found to be similar to that of among healthy populations. Yet, better control of blood glucose levels might decrease daily pain in diabetic patients.

## THU0560 TNX-102 SL FOR THE TREATMENT OF FIBROMYALGIA: COMPARISON OF 30% PAIN RESPONDER ANALYSIS WITH OMERACT DRAFT COMPOSITE RESPONDER ENDPOINT ANALYSES

R.M. Gendreau[1], L. Arnold[2], D. Clauw[3], J. Gendreau[4], B. Vaughn[5], B. Daugherty[6], S. Lederman[6]. *[1]Gendreau Consulting, LLC, Poway; [2]University of Cincinnati, Cincinnati; [3]University of Michigan, Ann Arbor; [4]Tonix Pharmaceuticals, Poway; [5]Rho Inc., Chapel Hill; [6]Tonix Pharmaceuticals, New York, United States*

**Background:** Novel responder definitions for fibromyalgia (FM) clinical trials have been proposed by the Outcome Measures in Rheumatology (OMERACT) FM subcommittee. These definitions include key symptom and functional domains relevant to FM patients, and were validated using outcome data from 12 previous registration trials of 4 other medications (Arnold L et al, Arth Rheum 64:885, 2012.) TNX-102 SL* is a proprietary sublingual formulation of cyclobenzaprine designed for rapid absorption and bedtime use. It showed improvements in pain and other symptoms in a Phase 2B study. This study was a 12-week, randomized, double-blind, placebo-controlled trial conducted at 17 US sites, designed to evaluate TNX as a potential treatment for FM. 205 participants were randomized (TNX=103; placebo=102).
**Objectives:** This current presentation is a retrospective analysis of the trial results using the two preferred response definitions proposed by the OMERACT committee.
**Methods:** The two OMERACT responder definitions are: the FM30 Short, which defines a responder as ≥30% reduction in pain, ≥10% improvement in physical function plus a ≥30% improvement in either sleep or fatigue, and the FM30 Long, which defines a responder as ≥30% reduction in pain, ≥10% improvement in physical function plus ≥30% improvement in any two of the following measures: sleep, fatigue, depression, anxiety or cognition.
**Results:** TNX improved multiple domains of FM. The table below compares a pain responder analysis (≥30% improvement in pain based on daily diary) to the alternative composite responder definitions proposed by OMERACT.

| Responder definition/Result (pain based on diary) | Physical function measure | Additional symptom measures | Result |
|---|---|---|---|
| 30% Pain responder | None | None | 34.0% vs. 20.6%; p=0.033 |
| FM30 Short Ver 1 | SF-36 physical function | 1 | 23.3% vs. 11.8%; p=0.038 |
| FM30 Short Ver 2 | SF-36 PCS score | 1 | 25.2% vs. 11.8%; p=0.015 |
| FM30 Long Ver 1 | SF-36 physical function | 2 | 21.4% vs. 9.8%; p=0.031 |
| FM30 Long Ver 2 | SF-36 PCS score | 2 | 23.3% vs. 9.8%; p=0.011 |

1: either FIQ sleep or FIQ energy; 2: any 2 out of FIQ sleep, FIQ energy, FIQ depression or FIQ anxiety.

Additional improvements noted over placebo included: FIQ-R total score (-17.2 vs. -9.1, p=0.015),PGIC response rate (30.1% vs. 16.7%, p=0.025), PROMIS sleep (-9.5 vs -6.1, p=0.004), sleep based on daily diary (change from baseline to week-12, 1.9 vs. -1.0; p<0.001) and FIQ-R sleep item (-2.9 vs. -1.2; p<0.0001). Systemic adverse events reported were similar to placebo. The most common local adverse event was transient tongue or mouth numbness occurring in 44% of TNX patients.
**Conclusions:** Bedtime TNX improved multiple domains of FM. Analysis by composite responder criteria developed by OMERACT suggests that the improvements in FM symptoms seen with TNX are not limited to an analgesic response, since these composite criteria all require improvement in other somatic and functional symptoms.
*TNX-102 SL is an Investigational New Drug and has not been approved for any indication.

## THU0561 ADALIMUMAB IN PATIENTS WITH ACTIVE AND INACTIVE, NON-INFECTIOUS UVEITIS: VISUAL I AND VISUAL II TRIALS

A.P. Brézin[1], A.D. Dick[2,3,4], G.J. Jaffe[5], S. Ohno[6], K. Namba[6], H. Goto[7], N. Inomata[8], A.P. Song[9], M. Kron[10], A. Camez[10], S. Tari[11], Q.D. Nguyen[12].
*[1]Université Paris Descartes, Hôpital Cochin, Paris, France; [2]University of Bristol, Bristol Eye Hospital, Bristol; [3]National Institute for Health Research (NIHR) Biomedical Research Centre at Moorfields Eye Hospital; [4]University College London, Institute of Ophthalmology, London, United Kingdom; [5]Duke University, Durham, United States; [6]Hokkaido University Graduate School of Medicine, Sapporo; [7]Tokyo Medical University; [8]AbbVie GK Japan, Tokyo, Japan; [9]AbbVie Inc., North Chicago, United States; [10]AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany; [11]AbbVie, Inc., North Chicago; [12]Truhlsen Eye Institute, University of Nebraska Medical Center, Omaha, United States*

**Background:** Uveitis causes an estimated 10–15% of cases of blindness in western countries and there is an unmet need for effective therapies for patients (pts) with non-infectious uveitis who are at risk for long-term side effects from chronic corticosteroid use.
**Objectives:** To assess adalimumab (ADA) efficacy and safety in patients with active and inactive, non-infectious uveitis.
**Methods:** Adults with non-infectious intermediate, posterior, or panuveitis were enrolled in two global phase 3, double-masked trials, VISUAL I (pts with active uveitis despite ≥2 weeks (wks) of prednisone (PS), 10–60 mg/d) and VISUAL II (pts with inactive disease dependent on 10–35 mg/d of PS, to maintain inactivity). Pts were randomized 1:1 to receive placebo (PBO) or ADA subcutaneously (80 mg wk 0, followed by 40 mg every other wk from wk 1 up to 80 wks). In VISUAL I, all pts received a PS burst followed by taper to 0 mg by wk 15. In VISUAL II, PS taper to 0 mg was mandatory by wk 19. Integrated data (main study and Japan sub-study) from VISUAL I and VISUAL II trials are reported. The primary endpoint was time to treatment failure (TF) at or after wk 6 for VISUAL I or at or after wk 2 for VISUAL II. Nine ranked secondary endpoints were assessed and adverse events (AEs) were monitored.
**Results:** The intent-to-treat (ITT) analyses included 233 (217 main study, 16 Japan sub-study) and 258 (226 main study, 32 Japan sub-study) pts from VISUAL I and VISUAL II, respectively (VISUAL I and VISUAL II: female: 58% and 61%; mean age, 43.2 years (y) and 43.1 y; mean duration of uveitis, 46 months (mt) and 59 mt). Risk of TF was reduced by 44% (VISUAL I) and 48% (VISUAL II) in ADA-treated pts compared to PBO group (VISUAL I: HR=0.56, 95% CI, 0.40–0.76,

$P<0.001$; VISUAL II: HR=0.52, 95% CI, 0.37–0.74, $P<0.001$). Median time to TF was 3 mt for PBO, 4.8 mt for ADA (VISUAL I) and 5.6 mt for PBO, not estimable for ADA (>18 mt, as more than half of the pts did not achieve TF by wk 80; VISUAL II). ADA-treated pts had fewer TF criteria than PBO in both studies and treatment effects were numerically in favor of ADA for most of the secondary efficacy variables (Table). ADA and PBO AE rates were similar (VISUAL I: 1063 vs 960 events/100 pt-y, VISUAL II: 854 vs 884 events/100 pt-y) in both studies, respectively.

Table. Summary of Ranked Secondary Efficacy variables (Intent -to-treat population)

| | VISUAL I | | VISUAL II | |
|---|---|---|---|---|
| Ranked Secondary endpoints[a] | Placebo N=114 | Adalimumab N=115 | Placebo N=107 | Adalimumab N=131 |
| 1. Change in SC inflammation Left eye / Right eye | 0.56 / 0.65 | 0.55 / 0.56 | 0.63 / 0.63 | 0.66 / 0.64 |
| Difference, mean (95% CI) | -0.23 (-0.46, -0.00), P=0.053[b] | | -0.15 (-0.36, 0.06), P=0.164[b] | |

## THU0562 A SURVEY OF RESISTANCE TO COLCHICINE TREATMENT IN FRENCH PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

A. Corsia[1], S. Georgin-Lavialle[2], G. Grateau[2], V. Hentgen[3], A. Faye[4], P. Quartier[5], I. Koné-Paut[1] on behalf of French FMF Working group: Nicolas Schleinitz, Yvan Jamilloux, Eric Hachulla, Frédéric Retornaz, Jean-François Alexandra, Gilles Hayem, Meinzer Ulrich. [1]*Pediatric Rheumatology, Bicêtre hospital, le Kremlin Bicêtre;* [2]*Internal Medicine, Tenon Hospital, Paris;* [3]*André Mignot Hospital, Versailles;* [4]*General Pediatrics, Robert Debré Hospital;* [5]*Necker Hospital, Paris, France*

**Background:** Colchicine is the standard treatment of FMF, preventing attacks and inflammatory complications in more than 90% of cases. Some patients, especially those carrying 2 M694V mutations in *MEFV* gene, may require doses higher than recommended overcoming disease manifestations. True resistance to colchicine may be exceptional but is still not defined on a consensus basis.
IL 1 targeting drugs are effective but are expensive alternative treatments requiring rigorous indications in FMF.

**Objectives:** To survey when and how physicians consider resistance to colchicine in FMF patients and to report how they handle this situation in their practise.

**Methods:** We performed a retrospective chart review of patients identified through reference centers and networks of inflammatory diseases expert physicians. We asked them to report their patients with a clinical diagnosis of FMF and at least one pathogenic *MEFV* mutation, in whom they considered resistance to colchicine. Patients with concomitant SPA or Crohn's disease were excluded. We collected their clinical data, genotypes, and more detailed information on colchicine treatment dose adjustment and compliance. Finally we tried to analyse the reason(s) to consider their patients as resistant to treatment and we collected the alternative attitudes treatments used.

**Results:** We identified 42 patients from 7 to 86 years old (mean age (±SD): 28,2 ± 22.1 years old) recruited from 10 centers. Thirty six of them could be fully analysed and consisted of 14 males and 22 females with a clinical diagnosis of FMF and, in whom 15 were children before 16 years. Sephardim Jews were the most represented. (n=23, 64%). All patients carried pathogenic mutations in the exon 10 of the *MEFV* gene except one girl and a woman with a complex allele including *MEFV* deletion. The mean (±SD) maximal dose of colchicine given in adult patients was 1.8± 0.65 mg, and it was 1.7 ± 0.6 mg (0.1 ± 0.01 mg/kg) in paediatric patients. The level of CRP in between attacks was evaluated in 40 patients and reached a mean of 35,8 mg/L. Fourty percent of patients declared to be fully observant to colchicine treatment. The main reasons to consider resistance to colchicine treatment were: >6 attacks/year (44%), >4 attacks in the last 6 months (20%), persistent inflammation (41%) and other reasons (44%). Twenty percent of patients were intolerant to an increase of colchicine dose. Concomitant treatments to overcome FMF symptoms were essentially NSAIDS, steroids, and analgesics. Sixty five percent of these patients are currently treated with IL-1 targeted drugs including anakinra (48%) and canakinumab (17%).

**Conclusions:** Our study has confirmed that resistance to colchicine treatment is rare (0–10% of patients, per investigating center) and more likely observed in patients carrying severe *MEFV* genotypes. In most cases the mean reasons to consider resistance to treatment were severe clinical symptoms and persistent subclinical inflammation, however low compliance to high doses of colchicine seems to play a major role. Patient's education and additional behavioural approaches preventing disease flares could probably reduce the use of biologics.

## THU0563 CHARACTERIZATION OF A GROUP OF 6 PATIENTS WITH MEVALONATE KINASE DEFICIENCY: SYMPTOMS AND TREATMENT WITH IL-1 INHIBITORS

A. Kozlova[1], N. Kuzmenko[1], S. Zimin[2], T. Varlamova[1], A. Shcherbina[1]. [1]*Immunology, Federal Research and Clinical Center of Pediatric Hematology, Oncology and Immunology;* [2]*Immunology, Children's Clinical Hospital N9, Moscow, Russian Federation*

**Background:** Mevalonate kinase deficiency (MKD) is a rare autosomal recessive autoinflammatory disease caused by mutations in MVK gene. MKD patients typically have an early onset of symptoms including recurrent episodes of high fever, abdominal pain, diarrhea and vomiting, arthralgia and lymphadenopathy. However not all patients have typical clinical picture of MKD.

**Methods:** We conducted a retrospective analysis of clinical features of six patients (4 females, 2 males) with MKD (confirmed by identification of MVK gene mutations). Four patients received therapy with inhibitors of IL-1 (Anakinra and/or Canakinumab). One of the patients died from amyloidosis and macrophage activation syndrome (MAS) prior to treatment initiation, her diagnosis was verified *post mortem*.

**Results:** All patients had the first symptoms of disease within the first 6 months of life. During the course of the disease all patients had periodic fever and peripheral lymphadenopathy (mainly cervical group), as well as abdominal pain, nausea/vomiting. Five patients had diarrhea, sometimes with blood, one patient suffered from severe constipation. Rash was seen in five patients, myalgia, artralgia were observed only in four. Oral ulcers were noted in two children. Two patients had neurological involvement. Interestingly, five out of six patients had rhinitis during attacks. One patient during the attack had periorbital edema and hyperemia, which; to our knowledge, have not been reported previously in MKD. One patient developed amyloidosis and MAS before treatment initiation, which led to her death. In patients receiving anti-IL-1 therapy AIDAI index decreased from 49.5±14,6 before to 1,75±1,3 after 6 month of therapy (p=0.003).

**Conclusions:** MKD symptoms can be variable and sometimes atypical, which requires physician's awareness. In our small cohort of MKD patients anti IL-1 therapy was highly effective.

## THU0564 TREATMENT OF FAMILIAL MEDITERRANEAN FEVER WITH ANAKINRA IN PATIENTS UNRESPONSIVE TO COLCHICINE

A.-C. Pecher, A. Igney-Oertel, L. Kanz, J. Henes. *Universitätsklinikum Tübingen, Tübingen, Germany*

**Background:** Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease, characterized by self-limiting periodic fever attacks with typical clinical features and oversecretion of proinflammatory cytokines as interleukin-1 (IL1).
**Objectives:** The standard of care since the early 1970s is oral colchicine, which can help to prevent attacks. Unfortunately, 5–10% of the patients are unresponsive. In these cases there is no further approved treatment. MEFV, the underlying gene mutated in FMF, encodes pyrin, which takes part in the process of IL1 secretion. In this report we analyzed the benefit of anakinra, an IL1 receptor antagonist, in patients who were unresponsive to colchicine.
**Methods:** This is a single center retrospective case series of 13 patients. Anakinra was applied subcutaneously at a standard dose of 100mg per day. There are no defined criteria for responders as well as non-responders to a certain treatment in FMF. We therefore defined colchicine resistance in analogy to other studies (1) as increasing frequency of attacks (>1/month and/or >1.5-fold of the time of best response) or as increasing inflammatory proteins i.e. CRP and SAA (>1.5-fold from upper limit). Disease activity was evaluated by laboratory parameters and clinical symptoms based on patient's and physician's assessment. Complete response (CR) was defined as no attacks and acute phase reactants below the upper limit. Partial response (PR) was defined as FMF-50 response, meaning reducing the attack rate by 50% and/or decreasing acute phase reactants, i.e. CRP or SAA, by 50%.
This retrospective case series was approved by the ethics committee of Eberhard-Karls-university, Tübingen.
**Results:** All results presented in mean±SD.
13 patients were included, median age at starting anakinra was 30.5±8.5 years, six patients were female. Nine patients had homozygous exon ten mutation, three patients had heterozygous exon 10 mutations of the MEFV-gene, one patient showed no detectable mutation. All patients were taking therapeutic oral doses of colchicine before starting treatment with anakinra. During treatment the attack rate declined from 15.8±13.1 per year to 4.1±6.6 (p=0.047). This was also the case for laboratory parameters: SAA decreased from 287.1 ± 428.4 mg/l to 10.9±12.0 mg/l (p=0.006) after three months and to 53.8±73.4 mg/l (p=0.125) after six months of treatment. CRP decreased from 6.8±7.7 mg/dl to 0.8±0.8 (p=0.005) after three months, respectively 0.7±0.9 (p=0.029) after six months. We didn't observe any major complications.
**Conclusions:** This report, to our knowledge, analyses the largest group of adults with FMF, treated with anakinra after failure of colchicine. All 13 patients of our case series responded to anakinra, four of them with CR. Interestingly, all of them showed a homozygous MEFV exon 10 mutation, which goes along with higher IL1 rates and more often are not responsive to colchicine (2). Here we could show, that anakinra is an effective treatment option for patients with FMF. Still, further prospective studies should be performed to evaluate the dosage and long-term efficacy as well as safety of anakinra.

## THU0565 CLINICAL RELEVANCE OF TREATMENT FAILURE AS ASSESSED BY THE 25-ITEM VISUAL FUNCTIONING QUESTIONNAIRE IN PATIENTS WITH INTERMEDIATE-, POSTERIOR- AND PAN-UVEITIS: RESULTS FROM THE VISUAL-1 TRIAL

A. Brézin[1], N. Chen[2], S. Tari[2], M. Skup[2], A. Joshi[2]. [1]*Université Paris Descartes, Hôpital Cochin, Paris, France;* [2]*AbbVie Inc., North Chicago, IL, United States*

**Background:** Time to treatment failure is the primary endpoint in the VISUAL-1 clinical trial (NCT01138657) of patients with non-infectious intermediate-, posterior- and pan-uveitis (NIIPPU); however, the relationship between the treatment failure (TF) criteria and patient-reported outcome of visual functioning is not well understood.
**Objectives:** To examine the relationship between TF and vision-related quality of life (QoL) as assessed by the Visual Functioning Questionnaire 25 (VFQ-25) among patients with NIIPPU.
**Methods:** The VISUAL-1 clinical trial was a randomized, placebo-controlled, 80-week study designed to investigate the efficacy and safety of adalimumab in patients with active NIIPPU. Patients were examined at scheduled study visits for TF at and after week 6. TF was assessed using 4 criteria: presence of inflammatory, chorioretinal, and/or inflammatory retinal vascular lesions, anterior chamber (AC) cell grade, vitreous haze (VH) grade, and visual acuity (VA). Patients with TF due to 1, 2, 3, and 4 of these components met 1 of 4 criteria, 2 of 4 criteria, 3 of 4 criteria, and all 4 criteria, respectively. The VFQ-25 measures 12 health domains (11 vision-related; 1 general health–related) and was used to assess the effect of ocular disease on vision-related QoL from the patient's perspective. VFQ-25 total score was the mean of 11 vision-related domains. Scores ranged from 0 (worst vision) to 100 (best vision). Analyses were conducted for patients with 1, 2, 3, and 4 components, and for patients with no component (non-failure). Changes in VFQ-25 total and subdomain scores from best state prior to week 6 to final visit were calculated for each component, at least 1 component, and no component (non-failure). Analysis of covariance (adjusting for best state prior to week 6) was used to assess the association between VFQ-25 score and 1, 2, 3, or 4 components. Missing data were imputed using last observation carried forward.
**Results:** Data from 203 patients were analyzed. Unadjusted mean change in VFQ 25 total score was -4.92 for at least 1 component compared with 0.19 for non-failure; unadjusted mean change was –3.90, –5.09, –11.1, and –13.88, for 1, 2, 3, and 4 components, respectively. Adjusted change in VFQ-25 score from best state prior to week 6 to final visit was –3.9 ($P<.0001$) for each additional component. When assessing patients by component, the greatest change in VFQ-25 total score was seen for VA (–7.99) followed by VH grade (–3.29), AC cell grade (–2.8), and retinal vascular lesion (–2.76). In general, results were similar for the VFQ-25 subdomain scores.
**Conclusions:** Clinically meaningful decreases in VFQ-25 scores among patients experiencing TF were substantial[1] supporting TF as a relevant outcome from the patient perspective. Among causes for TF, the loss of VA had the greatest impact on the QoL, the other causes for TF had a lesser effect.

**Background:** In non-infectious no anterior uveitis, adalimumab (ADA) is the only biologic that has shown efficacy in phase III randomized, double blind studies, such as VISUAL I and VISUAL II. (Brezin AP et al Arthritis Rheumatol 2015;67 (suppl 10): 2038 & Nguyen QD et al Arthritis Rheumatol 2015; 67 (suppl 10): 1388).
After a 80 mg loading dose, maintenance dose is the standard for other indications, 40 mg/sc/2 weeks.
**Objectives:** Our objective is to test a series of Behcet's síndrome uveítis, and proving if once remission was obtained, it was posible to "optimize" the maintenance dose.
**Methods:** Multicenter study of 174 patients with Behcet's síndrome refractory uveitis. All of them had insufficient response or intolerance to conventional treatment with corticosteroids and at least 1 systemic immunosuppressive drug. 71 patients started treatment with ADA and once remission was achieved, it was optimized in 23 of them.
