	C	0.71	0.35	

OR_i = initial OR-value; OR_c* = combined OR-value obtained by "b" column interaction with "a" column; P_{int} = *P*-value of the intreraction.

Conclusions: In this study we could observe that the gene-gene interaction of the HIF-1α signaling pathway highly increases the risk of developing OA, with the exception of *COL2A1* and *HIF1AN* interaction which had a protective role against OA. Further studies are needed to validate this results.

THU0017 COMBINATION OF EGFR AND BLYS GENE EXPRESSION IN LUPUS NEPHRITIS

L.A. Mas[1,2], S. Retamozo[2,3], F. Bonisconti[1,2], E.V. Palomino[1,2], J.P. Pirola[2,3], V. Saurit[2,3], A. Alvarellos[2,3], T. Alvarellos[1,2]. *[1]Immunogenetics, Hospital Privado. Universitario de Córdoba; [2]Instituto Universitario de Ciencias Biomédicas de Córdoba; [3]Rheumatology, Hospital Privado. Universitario de Córdoba, Cordoba, Argentina*

Background: Lupus nephritis (LN) is a severe complication of Systemic Lupus Erythematosus (SLE). Non-invasive biomarkers are needed for diagnosis of LN and to identify patients at risk of a renal flare (1). Thus the presence of biomarkers associated with inflammation, tissue damage or cell activation in the urine of patients with LN may be a useful tool in the evaluation of LN patients.
The glomerular filtration rate (GFR) is considered the best overall index of renal function in health and disease. Because GFR is difficult to measure in clinical practice, most clinicians estimate the GFR (eGFR) from the serum creatinine concentration (2).
B Lymphocyte Stimulator (BLyS) is a cytokine that fosters B cell activation, antibody production, B cell - T cell interaction and plasma cell survival. These events have been demonstrated to play a role in patients with LN (3).
Objectives: We evaluated urinary levels of BLyS as biomarker for LN and their relationship with eGFR.

Methods: Urine samples (n=86) were obtained from LN patients and classified in two groups: patients with eGFR >60 (GFRhigh, n=68, 62F/6M, age: 34.07±13.24) and patients with eGFR ≤60 (GFRlow, n=18, 14F/4M, age: 35.22±13.76). RNA from urine samples was isolated using TRIzol-Chloroform technique and then reverse-transcribed using random primers. Levels of BLyS expression were evaluated using Quantitative Real Time PCR (QPCR). All amplifications were carried out in duplicate and threshold cycle (C_t) scores were averaged for calculations of relative expression values. The C_t scores were normalized against C_t scores by subtracting the corresponding β2Microglobuline (β2M) control, or $DCt=C_{t,gene}- C_{t,B2M}$.To test for differential gene expression between groups, a two sample t-test was performed to compare the DCt in the two groups.
Results: DCt is inversely proportional to BLyS's expression. We evaluated data from ΔCt analysis observing that mRNA levels of BLyS in eGFRlow (6.193±1.787) were higher than those from eGFRhigh (7.564±2.326), with a statistically significant difference between groups (p=0.0288).

	eGFRlow	eGFRhigh	
BLyS (ΔCt)	6.193±1.787	7.564±2.326	p=0.0288

Conclusions: In the present cross-sectional study, increased levels of BLyS were observed in patients with eGFR ≤60. These gene expression results might be linked to B cell activation and proliferation in kidney and thus in urine samples. Combination of eGFR and BLyS appears to be a good biomarker.

THU0018 ANGIOTENSINOGEN AS A MARKER OF INJURY IN LUPUS NEPHRITIS

L.A. Mas[1,2], S. Retamozo[2,3], M.J. Haye Salinas[3], V. Saurit[2,3], E.V. Palomino[1,2], J.L. De la Fuente[2,4], M. Angelina[2,5], J.P. Pirola[2,3], A. Alvarellos[2,3], T. Alvarellos[1]. *[1]Immunogenetics, Hospital Privado. Universitario de Córdoba; [2]Instituto Universitario de Ciencias Biomédicas de Córdoba; [3]Rheumatology; [4]Nephrology, Hospital Privado. Universitario de Córdoba; [5]Nephrology, Hospital Raúl Ferreyra, Cordoba, Argentina*

Background: Lupus Nephritis (LN) is one of the most severe forms of systemic lupus erythematosus (SLE) (1). Angiotensinogen (AGT) gene encodes the only glycoprotein known to be a precursor of the vasopresor angiotensin II (Ang II). Ang II is also a growth factor and a profibrogenic cytokine (2). In kidney transplantation AGT has been founded down expressed in biopsies with chronic allograft dysfunction (3). In LN, AGT deserves evaluation.
Objectives: To investigate AGT expression in biopsies and urines from LN patients.
Methods: 32 biopsies/urines paired from 32 LN patients was included. Kidney biopsies were evaluated according to the ISN/RPS classification system. Levels of AGT were evaluated using Quantitative Real Time PCR. Threshold cycle (C_t) scores were averaged for calculations of relative expression values. The C_t scores were normalized against C_t scores by subtracting β2Microglobuline control, or $\Delta Ct=C_{t,gene}- C_{t,B2M}$. Data expressed as ΔCt are inversely proportional to gene expression level. Nonparametric Mann Whitney test analysis and Anova with Bonferroni test were performed.
Results: 26 (81.3%) patients were female with a mean age at biopsy time of 31.9±29 years. The SLEDAI at the time of biopsy was 10.5 (IQR 0–15.7) and SLICC ≥1 in 13 (32.5%), hypocomplementemia 13/31 (41.9%) and positive DNA in 11/29 (37.9%) patients. Biopsies from patients with proteinuria ≥0.5 and renal failure (n=23), proteinuria isolated (n=14), LN remission (n=9), renal failure (n=7) and nephrotic syndrome (n=2) were performed. The mean value of ΔCt AGT gene expression in renal biopsy was 4.50 (IQR 3.51 – 5.67) and AGT in urine samples was 13.94 (IQR 11.66 – 17.89).
Conclusions: In the present study we found a potential utility of AGT mRNA levels in samples of active vs remission LN patients. Prospective studies are needed for confirming these results.

Table 1. AGT gene expression in biopsies and urines samples

	Class I/ Normal Biopsies n=3	Class II Biopsies n=6	Class IV Biopsies n=12	Class V/VI Biopsies n=10	p p

THU0019 FEATURES OF TELOMERE LENGTH DISTRIBUTION ON INDIVIDUAL CHROMOSOMES IN RHEUMATOID ARTHRITIS

M. Barkovskaya[1], A. Bogomolov[2], N. Knauer[1], E. Blinova[1], A. Sizikov[3], N. Rubtsov[2], V. Kozlov[1]. *[1]Laboratory of the Clinical Immunopathology, Research Institute of Fundamental and Clinical Immunology; [2]Laboratory of the Morphology and Function of Subcellular Components, Institute of Cytology and Genetics SB RAS; [3]Department of Clinical Rheumatology, Clinic of Immunopathology, Novosibirsk, Russian Federation*

Background: Telomeres are nucleoprotein structures,that protect the ends of chromosomes during cell divisions [1,2,3]. Previously it was found, that average telomere length in immune cells is reduced in atopic and autoimmunity disorders.This fact indicates an early immune aging in immune-mediated diseases [4,5]. The distribution of telomere repeats on different chromosomes has an individual telomere profile in humans [6] and may be a congenital feature, that accelerates immunosenescence.
Objectives: The purpose of this study was to evaluate the length of telomeres in the arms of individual chromosomes in patients with RA and healthy donors.
Methods: The study included 6 patients with RA and 6 healthy donors (the median age 51.5 (50–54) and 51.5 (49–53) years respectively). Metaphase spreads obtained from PBMCs were used in this study. Written informed consent was obtained from each person enrolled in the study. At the time of sampling, RA inpatients characterized with acute exacerbation of the disease received treatment at the Clinic of Immunopathology,Novosibirsk. RA was diagnosed by clinicians according to ACR/EULAR 2010. For measurement of the telomere length on individual chromosome arms we used Q-FISH with $(C_3TA_2)_3$ PNA-probe. Inverted DAPI banding was used for chromosome identification according to ISCN 2013. The new MeTeLen software was developed to estimate the telomere repeats relative quantity (http://www.bionet.nsc.ru/en/development/application-development/development-of-a-computer/metelen.html) in metaphase images.
Results: When comparing the telomere length, it was found, that telomere on chromosome 16 p are shorter in patients with RA than in donors. Since each person has an individual telomere profile, we also analyzed the presence of shortened telomere sequences on individual chromosome arms relative to the average length of telomeres for each subject separately. As a result, patients with RA have a larger number of significantly shortened telomeres than donors (see Table).

Comparison group	Chromosome arms with shortened telomere repeats
Healthy volunteers	12p, 19p, 2q, 20q
Patients with RA	7p, 12p,16p, 17p, 19p, 2q, 20q, 21q

Telomere length on chromosome 16 p (expressed in relative units) in patients with RA and healthy donors. Data are presented as median and interquartile range, *-significant difference (p< 0.05, Mann-Whitney U test).

Conclusions: The revealed features of telomeric profiles of patients with RA may be an indication of a proliferative stress, that occurs as a result of the mass immune cell proliferation in the immunopathology. It can be assumed, that the presence of a great number of shortened telomeres can promote cell death through apoptosis. The observed shortening of the telomere length on chromosome 16 p in RA may be relevant in its pathogenesis. It is known, that telomere shortening can lead to increased gene expression near the telomere DNA region. Thus, in 16 p 13 a number of genes is localized, that are associated with RA or may be involved in its development.

THU0020 INCREASED EXPRESSION OF CCN4/WISP1 IN OSTEOARTHRITIC ARTICULAR CARTILAGE IS EPIGENETICALLY REGULATED AND DISRUPTS CARTILAGE HOMEOSTASIS

M. van den Bosch[1], Y.F. Ramos[2], W. den Hollander[2], N. Bömer[2], R.G. Nelissen[3], J.B. Bovée[4], A.B. Blom[1], I. Meulenbelt[2]. *[1]Experimental Rheumatology, Radboud university medical center, Nijmegen; [2]Department of Molecular Epidemiology; [3]Department of Orthopedics; [4]Department of Pathology, Leiden University Medical Center, Leiden, Netherlands*

Background: Previously, we described increased expression of Wnt-1-induced signaling protein 1 (*Wisp1*) in murine synovium and cartilage after induction of two experimental osteoarthritis (OA) models. *Wisp1* is a downstream target of the canonical Wnt signaling pathway that has been shown to play a pivotal role in the etiopathology of OA. In line with this, we have observed increased breakdown of the articular cartilage after overexpression of *Wisp1* in naïve mouse knee joints, whereas *Wisp1*$^{-/-}$ mice revealed decreased cartilage degeneration in three independent experimental OA models compared to wild type controls. Together, these data indicate a direct correlation between *Wisp1* and OA in mice.
Objectives: In the current study we set out to characterize the relation between expression of *WISP1* and human OA.
Methods: Articular cartilage from preserved and degenerated OA areas was collected from 39 Caucasian end-stage OA patients. Cartilage from non-OA-diagnosed individuals was collected after femoral neck fractures. Cartilage degeneration was classified according to the Mankin scoring system. DNA was isolated to determine correlation between *WISP1* expression and methylation profiles using Generalized Linear Mixed Model (GLMM). RNA expression levels were determined with microarray analysis and RNA sequencing. Immunohistochemical staining was used to determine WISP1 protein expression. Recombinant WISP1 was added to human chondrocyte microparticles, and cartilage extracellular matrix deposition was determined by measuring cartilage microparticle size and Safranin O/Fast Green staining.
Results: We observed increased WISP1 expression in cartilage of OA patients compared to non-OA-diagnosed controls. Moreover, within OA patients, both WISP1 mRNA and protein expression were significantly increased in OA-affected cartilage compared to preserved regions of the same joint, and WISP1 expression significantly correlated with Mankin score. Interestingly, we found that positional CpG dinucleotides were hypomethylated in cartilage of OA-affected areas as compared to unaffected areas from the same joint, which correlated with increased RNA expression as determined with both microarray analysis and RNA sequencing analysis. Of note, methylation levels of a CpG affecting *WISP1* transcription were found to highly significantly correlate to a single nucleotide polymorphism (SNP) at the *WISP1* locus. Next, to investigate effects of increased WISP1 levels on chondrocyte microparticles, we added human recombinant WISP1. This resulted in a significantly decreased deposition of cartilage extracellular matrix as reflected by decreased microparticle circumference, and a strongly decreased proteoglycan content, suggesting that increased WISP1 levels are detrimental to cartilage.
Conclusions: The expression of WISP1, both RNA and protein, is increased in OA-affected as compared to preserved articular cartilage. This increased expression is inversely correlated with methylation levels of a positional CpG for WISP1, which was found to be under the influence of a SNP at the *WISP1* locus. Together, our results suggest that tight regulation of *WISP1* expression via methylation is essential to maintain cartilage homeostasis.

THU0021 THE ANALYSIS OF PRF1, STX11, UNC13D AND STXBP2 GENE IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS WITH MACROPHAGE ACTIVATION SYNDROME

P. Wei[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: We investigated the clinical characteristics of 34 cases with systemic juvenile idiopathic arthritis (SJIA) and macrophage activation syndrome (MAS) and analyzed PRF1, UNC13D, STX11 and STXBP2 gene so as to figure out the genetic pathogenic mechanism.
Methods: The clinical characteristics of 34 cases with sJIA and MAS were retrospectively analyzed, and the coding sequences of PRF1, UNC13D, STX11 were amplified. DNAMAN software and NCBI BLAST were used to compare sequences. The chi-square test was employed to compare the distribution of allele and genotype frequencies between SLE patients and healthy controls.
Results: Among the 34 cases, 69% were males, and the average age was 6 years. 85% (29/34 cases) of the cases underwent genetic testing and four SNPS loci were detected: PRF1 c. 1061 c > T (rs885822); UNC13D c. 659 c > T (rs3744007); STXBP2 c. 1483 T > c (rs10001) and STXBP2 c. 1616 A > G (rs6791). Compared with control group, genotype and allele frequencies of PRF1 rs885822 and STXBP2 rs10001 among the MAS cases were of significant difference (rs885822: allele frequency 2 =4.52, p=0.03; genotype frequency: 2 =5.52, p=0.02. rs10001: allele frequency 2 =21.33, p=0.00; genotype frequency: 2 =19.58, p=0.00). There were no significant differences in genotype and allele frequencies of UNC13D rs3744007 and STXBP2 rs6791 between MAS group and control group (rs3744007: allele frequency 2 =1.89, p=0.17; genotype frequency: 2 =1.59, p=0.45. rs6791: allele frequency 2 =1.69, p=0.19; genotype frequency: 2 =2.09, p=0.35). The main characteristics of the cases were persistent fever, progressive hepatosplenomegaly, a sharp decline in blood cells, effusion, significantly increased serum liver enzymes, hyperlipidemia, etc. Some children had mucosal bleeding, neurological dysfunction, etc. More than 82% children had upper respiratory tract infection before MAS onset. 90% of children had remission, while three cases developed multiple organ failure and died.
Conclusions: Macrophage activation syndrome is fatal complication caused by immune imbalance. Early detection and treatment is the key to improve the prognosis. The SNP PRF1 rs885822 and STXBP2 rs1001 may be concurrent with the pathogenesis of SJIA-MAS. The SNP UNC13D rs3744007 and STXBP2 rs6791 may not play a role in SJIA-MAS.

THU0022 REPLICATION ANALYSIS OF GENE-GENE INTERACTION BETWEEN HLA-DQA2 AND HLA-DQB2 VARIANTS IN ITALIAN RHEUMATOID ARTHRITIS PATIENTS

R. Bassi Andreasi[1], M.F.J. Khan[1], E. Galuppi[2], M. Govoni[2], M. Rubini[1]. *[1]Biomedical and Specialty Surgical Sciences; [2]Medical Sciences, University of Ferrara, FERRARA, Italy*

Background: Rheumatoid Arthritis (RA) is a complex and multifactorial disease, caused by multiple interactions between genetics and environmental factors. In the context of RA genetics, the Human Leukocyte Antigen (HLA) exerts a primary role. Approximately 90% of RA patients show alleles at the HLA-DRB1 locus, codifying for 5 Amino Acids, known as "*shared epitope*" (SE). SE is associated with increased risk to develop RA and more severe phenotype, but it does not entirely explain HLA contribution to disease risk.
Moreover, it is generally accepted that occurrence risk could be determined by specific gene-gene interactions. A study carried out in USA (NARAC) reported a particular interaction between SNPs in the HLA class II region: HLA-DQA2 (rs9275595) and HLA-DQB2 (rs10807113). Results showed 11 fold increased risk to develop RA in patients carrying both variants (Liu *et al.*, 2011), while single variants did not significant contribute to the RA risk (Odds ratio, OR, respectively, 1.6 and 1.0).
Gene-gene interaction between HLA-DQA2 and HLA-DQB2 SNPs is remarkable, considering that glycoproteins codified by these genes combined each other and create a quaternary structure.
Objectives: To replicate NARAC study evidence in Italian population, we genotyped rs9275595 (HLA-DQA2) and rs10807113 (HLA-DQB2) variants using a case/control model.
Methods: The study included a cohort of 316 Italian RA patients and a matched group of 443 healthy control individuals. All subjects were genotyped for HLA-DQA2 T>C (rs9275595) and HLA-DQB2 A>C (rs10807113) using TaqMan technology and Real-Time PCR.
Results: Replication test performed in our Italian RA cohort did not identify significant interaction between two variants analyzed.
However, considering the single variant rs9275595, the results showed a significantly increased risk to develop RA. Taking T/T genotype as the reference, C/C homozygotes showed significant association with a 3.82 fold increased risk of RA (OR=3.821 95% CI (2.017–8.351) p-value=0.00063). The SNP acted under an additive model: T/C heterozygotes showed significant OR=1.988 (95% CI 1.458–2.711, p-value=0.00002).
Conclusions: The results of this study do not confirm the gene-gene interaction previous reported in the NARAC cohort (Liu *et al.*, 2011). However, outcomes suggest that HLA-DQA2 rs9275595 could contribute to RA pathogenesis in the Italian population.

THU0023 SYNOVIAL FLUID MIRNAS MULTIMARKER ANALYSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Shumnalieva[1], D. Kachakova[2], S. Monov[1], R. Kaneva[2], Z. Kolarov[1], R. Rashkov[1]. *[1]Department of Internal Medicine, Clinic of rheumatology, Medical University - Sofia; [2]Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Medical University - Sofia, Sofia, Bulgaria*

Background: Recent epigenetic studies reveal the pathogenic role of micro-ribonucleic acids (microRNAs) and their targets in the inflammatory process in rheumatoid arthritis (RA). miRNAs play crucial role in controlling and modulating immunity and their abnormal expression has been linked to the deregulated function of regulatory T cells, to the chronic synovial inflammation and bone destruction[1–3].
Objectives: To perform a multimarker analysis of synovial fluid (SF) expression levels of miR-146a, miR-155 and miR-223 in RA patients in regard to their role as diagnostic biomarkers.
Methods: Total RNA was isolated from the SF of 48 RA patients and 11 healthy controls (HCs) and expression levels of miR-146a, miR-155 and miR-223 were determined by quantitative real-time polymerase chain reaction (qPCR), SybrGreen technology. Relative changes of gene expression levels of the miRNAs were calculated by $2^{-\Delta\Delta Ct}$method and SPSS were used for statistical analysis. RNU6B gene was used as a reference control for normalization. Receiver operating characteristic (ROC) curve analysis using RQ values was constructed in order to evaluate the diagnostic accuracy of these miRNAs in SF for distinguishing RA patients from HCs.
Results: miR-146a, miR-155 and miR-223 showed overexpression in RA SF compared to HCs (in 70.83%, 79.17% and 79.17% of the patients, respectively) and could be used to differentiate RA patients from HCs ($p=4.8x10^{-4}$, $p=8x10^{-5}$ and $p=2.8x10^{-4}$, respectively). The ROC curve analysis showed diagnostic accuracy for miR-146a with area under the curve (AUC)=0.769, 95% CI=0.600÷0.938, p=0.006, with sensitivity of 75% and specificity of 72.3%; AUC for miR-155 was 0.858 (95% CI=0.757÷0.959, $p=2.3x10^{-4}$) with sensitivity of 81.3% and specificity of 81.8%; AUC for miR-223=0.841 (95% CI=0.724÷0.958, $p=4.6x10^{-4}$), with sensitivity of 87.5% and specificity of 72.7%. The diagnostic accuracy improved when performing a multimarker analysis with AUC for the combination of miR-146a and miR-155=0.871 (0.776–0.967, $p=1.4x10^{-4}$), AUC for miR-146a and miR-223=0.867 (0.753–0.982, $p=1.6x10^{-4}$), AUC for miR-155 and miR-223=0.907 (0.823–0.991, $p=2.6x10^{-5}$). AUC for the combination of all three miRNAs was 0.915 (0.840–0.990, $p=2.02x10^{-5}$) with 89.6% sensitivity and 81.8% specificity.
Conclusions: Local miRNA expression levels could serve as diagnostic biomarkers in RA patients. The multimarker analysis of the expression levels of miR-146a, miR-155 and miR-223 in SF has better diagnostic accuracy than their single use in the clinical practice.

THU0024 WHOLE GENOME LINKAGE AND EXOME SEQUENCING ANALYSES IN AN AUTOSOMAL RECESSIVE TAKAYASU ARTERITIS FAMILY

I. Karacan[1], S.N. Esatoglu[2], E. Tahir Turanlı[1,3], A. Tolun[4], E. Seyahi[2]. *[1]Istanbul Technical University, Dr. Orhan Ocalgiray Molecular Biology-Biotechnology and Genetics Research Centre, Institute of Science, Engineering and Technology, Molecular Biology, Biotechnology and Genetics Program; [2]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; [3]Istanbul Technical University, Department of Molecular Biology and Genetics; [4]Boğaziçi University, Department of Molecular Biology and Genetics, Istanbul, Turkey*

Background: Takayasu arteritis (TA) is a rare chronic inflammatory disease of the aorta and its major branches, seen predominantly in females. Its etiology is unknown, however, there is a growing body of evidence to suggest genetic contribution to the pathogenesis of the disease: a) The disease is relatively frequent in Asia, b) Several familial cases of TA have been published (1) and even, autosomal recessive inheritance pattern has been suggested (2), c) Genetic association with HLA-B*52 across multiple ethnicities has been confirmed (3), and d) A multi-ethnic genome-wide association studies (GWAS) study in TA established additional genetic susceptibility loci (4–5).
Objectives: We studied a consanguineous family consisting of two affected and one unaffected sibs and their healthy parents in order to identify the causative mutation or linked loci.
Methods: Whole genome single nucleotide polymorphism (SNP) genotyping was performed for five family members using Illumina OmniExpress-24 BeadChip targeting ~700,000 SNP markers. Using genotyping data, we performed multi-point parametric linkage analysis assuming recessive inheritance and complete penetrance. Also, exome sequencing was performed for index patient to search for a rare, homozygous deleterious variant in the possibly linking regions.
Results: Whole-genome linkage analysis resulted in 25 genomic regions with LOD score above 1.50. Within the family members, all candidate regions shared homozygosity by only affected individuals. Causative variant search in linkage regions identified seven homozygous candidate variants in which five of them were located in 19q13.33. Candidate non-synonymous variants were found in *ANXA8L*, *EHBP1L1*, *MYH14*, *KCNJ14*, *SYNGR4*, *TULP2* and *SHANK1* genes.
Conclusions: This is the first whole genome linkage analysis in a TA family with recessive inheritance. Linkage and following exome sequencing analyses revealed seven possible variants that may be causative to disease. Further variant and candidate gene investigations are still in process.

Cytokines and inflammatory mediators

THU0025 IL-6 TRANS-SIGNALING CAUSES ACCELERATED ATHEROSCLEROSIS IN DISEASE PRONE ANIMALS

R. Davies[1], H.S. Jin[1], K. Sime[1], J.O. Williams[2], C.R. Thompson[1], G.W. Jones[1], K. Allen-Redpath[1], S.A. Jones[1], T.R. Hughes[1], S. Rose-John[3], A.S. Williams[1], E.H.S. Choy[1]. *[1]Institute of Infection and Immunity; [2]Cardiff School of Biosciences, Cardiff University, Cardiff, United Kingdom; [3]Institüt of Biochemistry, Christian-Albrecht Universität, Kiel, Germany*

Background: Cardiovascular (CV) disease is a major cause of mortality in patients with rheumatoid arthritis (RA). CV risk is increased early in the disease course. Subclinical inflammation and dyslipidaemia are often seen in RA before patients become symptomatic, suggesting the presence of subclinical CV disease. Inflammation, as measured by acute phase reactants, is associated with CV disease in RA. Interleukin (IL)-6 is a major driver of the acute phase response in RA. Notably, systemic elevations in inflammatory cytokines including IL-6 correlate with CV risk. Importantly, IL-6 regulates both immune homeostasis and inflammatory processes linked with chronic disease progression. Control of these processes is regulated by two modes of IL-6 signaling; classical IL-6 receptor signaling and IL-6 trans-signaling. Cellular responses controlled by IL-6 trans-signaling are mediated via soluble IL-6 receptor (sIL-6R) and is widely considered to promote deleterious pro-inflammatory outcomes [1]. We hypothesize that atherosclerosis may predate diagnosis of RA, and is accelerated by IL-6 trans-signaling during active arthritis. Here, we investigate this hypothesis using the established ApoE-deficient (*apoE*$^{-/-}$) mouse model of atherosclerosis.
Objectives: To examine the effect of IL-6 classical and trans-signaling on atherosclerosis by administering IL-6 or Hyper-IL-6 (a IL-6: sIL-6R fusion protein) to *apoE*$^{-/-}$ mice.
Methods: Male *apoE*$^{-/-}$ mice were fed a high-fat diet for 8 weeks starting at 8 weeks of age. Mice were divided into 4 groups. Group 1 received IL-6 (160 ng twice weekly, delivered i.p.), and Group 2 and 3 received Hyper-IL-6 (500 ng and 1 μg delivered i.p. twice weekly) for 8 weeks. Group 4 received PBS twice weekly for 8 weeks. Serial transverse 7 um brachiocephalic artery cross-sections were cut and stained with haematoxylin and oil red-O. Lesion size was determined by computer-assisted morphometry, using Image J on stained sections. Brachiocephalic plaque size in mice treated with PBS, IL-6 and Hyper-IL6 were compared using ANOVA and post-hoc Tukey t test.
Results: Mice treated with Hyper-IL-6 1μg had significantly larger brachiocephalic plaques (mean plaque area 0.73±0.04 mm^2) than those administered PBS (0.018±0.01 mm^2, p <0.001), and IL-6 (0.033±0.017 mm^2, p =0.015; Fig.1A). Similarly, mice administered Hyper-IL-6 [1μg] had a significantly higher percentage of the brachiocephalic artery occupied by plaques (45.3±18.1%) compared to those administered PBS (10.38±6.7%, p <0.001) or IL-6 (20.1±10.2%, p =0.002) (Fig.1B). Mice administered Hyper-IL-6 [0.5μg] had significantly higher percentage plaque (27.7±16.2%) than PBS administered mice, p=0.015. There was no significant difference in total cholesterol, HDL, LDL, triglycerides, free fatty acids or cholesterol:HDL ratio between the groups.

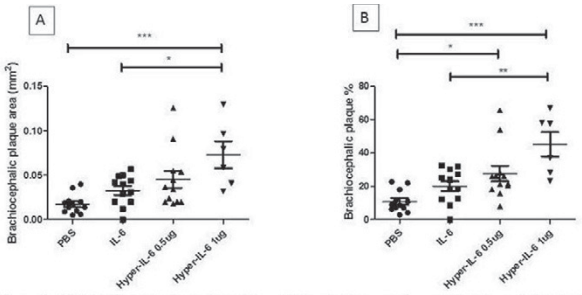

Figure1. (A) Significantly larger brachiocephalic plaque area in *apoE*$^{-/-}$ mice administered Hyper-IL-6 1μg compared to mice administered IL-6 or PBS. B) Significantly higher brachiocephalic plaque percentage in *apoE*$^{-/-}$ mice administered Hyper-IL-6 compared to PBS, and significantly higher brachiocephalic plaque percentage in *apoE*$^{-/-}$ mice administered hyper-IL-6 1μg compared to IL-6.

Conclusions: IL-6 trans-signaling leads to accelerated atherosclerosis in disease susceptible animals. This effect is independent of changes in serum lipid profiles.

THU0026 OSM IS MORE EFFECTIVE THAN IL-6 AT INDUCING ENDOMT OF HUMAN DERMAL MICROVASCULAR CELLS

K. Nevin[1], L. Stawski[2], M. Feeney[1], N. Wisniacki[1], M. Trojanowska[2].
[1]*Immuno-Inflammation Therapeutic Area Unit, GlaxoSmithKline, Stevenage, United Kingdom;* [2]*Arthritis Centre, Boston University, Boston, United States*

Background: Oncostatin-M (OSM) and interleukin-6 (IL-6) are members of the IL-6 superfamily and signal via glycoprotein 130 (gp130). OSM signals with either the type I receptor complex, gp130/ Leukemia Inhibitory Factor Receptor (LIFR), or the type II receptor complex, gp130/OSM receptor (OSMR), whilst IL-6 signals via gp130 with the IL-6 receptor (IL-6R) or by trans signalling with soluble IL-6R (sIL6-R). Endothelial cells (ECs) express both gp130 and OSMR [Brown TJ et al 1991], however it is unclear whether ECs express IL-6R [Romano M et al 1997; Nilsson MB et al 2005]. Endothelial to mesenchymal transition (EndoMT) is the phenotypic transition of ECs into mesenchymal cells where ECs lose their specific EC markers, detach from the endothelial layer and initiate the expression of mesenchymal cell products. EndoMT is associated with vascular dysfunction, one of the early manifestations of systemic sclerosis. The role of OSM and IL-6 in EndoMT has not yet been fully elucidated.

Objectives: To determine the effect of OSM and IL-6/sIL-6R on microvascular EC migration, proliferation and EndoMT.

Methods: Human dermal microvascular ECs (HDMECs) were treated with human recombinant proteins OSM (1–100 ng/mL), IL-6 (10–100 ng/mL) and sIL-6R (10–100 ng/mL). Cell migration and proliferation were measured with Live-Cell imaging system over 50 hours and analysed using a two-way ANOVA. Secretion of Collagen type I protein was measured at 48 hours by western blot analysis of media supernatant from HDMEC cultures. Changes in VE-Cadherin and F-actin expression were examined by immunofluorescence over 72 hours.

Gene expression was measured at 3 hours using quantitative RT-PCR analysis and analysed by Student's paired T-Test.

Results: OSM and IL-6, with or without IL-6R, significantly increased ($P<0.001$, n=3 donors) HDMEC migration and proliferation and secretion of extracellular matrix (ECM) protein Collagen I compared to the control group. OSM, but not IL-6 with or without sIL-6R, reduced expression of EC marker VE-Cadherin and increased expression of elongated F-actin stress fibres (n=2 donors). OSM significantly affected ($P<0.05$, n=3 donors) expression of EndoMT genes *SNAIL1*, *SNAIL2*, *SNAIL3* and *TWIST* [Figure 1] and ECM genes *MMP1*, *MMP2 TIMP1* and *TIMP2* compared to the control. Many of the gene changes in response to OSM were further augmented by co-stimulation with sIL-6R. IL-6 with or without sIL-6R only significantly affected ($P<0.05$, n=3 donors) EndoMT genes *SNAIL1* and *SNAIL3* and ECM gene *TIMP1*.

Conclusions: OSM induced a stronger EndoMT phenotype in HDMECs in comparison to IL-6, suggesting that OSM is capable of initiating EndoMT activity in microvascular cells. The augmented effects observed for OSM with sIL-6R also suggests that OSM is capable of binding the sIL-6R and initiating signalling in HDMECs *in vitro*.

THU0027 CLUSTERIN IS ELEVATED IN SERUM AND MUSCLE TISSUE IN IDIOPATHIC INFLAMMATORY MYOPATHIES AND IS ASSOCIATED WITH DISEASE ACTIVITY

T. Lennerová, L. Vernerová, M. Klein, M. Tomčík, H. Mann, V. Hrušková, K. Pavelka, J. Vencovský, L. Šenolt. *Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*

Background: Clusterin (also known as apolipoprotein J) is a molecular chaperone that participates in inflammatory and apoptotic processes. Recent data indicate its possible protective role in the development of chronic autoimmune disorders.

Objectives: The aim of this study was to analyse the skeletal muscle expression of clusterin and its serum levels in patients with idiopathic inflammatory myopathies (IIM) and in healthy donors, and to examine the association of clusterin with disease activity.

Methods: Clusterin mRNA expression in skeletal muscle specimens, obtained by muscle biopsy (mini-invasive Bergstrom technique), was determined using qPCR in 10 patients with IIM and 10 healthy subjects. Serum concentrations of clusterin were measured by ELISA (Biovendor) in 65 patients with IIM (27 dermatomyositis (DM), 28 polymyositis (PM), 10 immune-mediated necrotizing myopathy (IMNM)) and in 54 healthy individuals. Disease activity was assessed using myositis intention to treat index (MITAX), myositis disease activity assessment visual analogue scales (MYOACT), health assessment questionnaire (HAQ) and global disease assessment evaluated by doctor and patient. Data are presented as mean ± SD.

Results: Clusterin mRNA expression in skeletal muscles was increased in patients with IIM compared to healthy donors (p=0.029). In addition, serum clusterin levels were significantly higher in all IIM patients than in healthy subjects (87.1±22.8 vs 68.4±12.4, $p<0.0001$) and also in individual subsets of patients in comparison to the control group (DM: 87.7±24.7, PM: 86.1±23.2, IMNM: 88.15±18.0, $p<0.0001$ for all). Clusterin levels in all patients with IIM positively correlated with MYOACT (r=0.337, p=0.008), MITAX (r=0.357, p=0.004) and global disease assessment evaluated by doctor (r=0.309, p=0.015). In patients with DM, positive correlations with MYOACT (r=0.499, p=0.009), MITAX (r=0.491, p=0.009), HAQ (r=0.470, p=0.014), global disease assessment evaluated by doctor (r=0.559, p=0.004), γ-glutamyl transpeptidase and asparate aminotransferase were found (r=0.504, p=0.007; r=0.429, p=0.025, respectively). PM and IMNM subsets showed no significant association.

Conclusions: We demonstrate increased local and systemic expression of clusterin in IIM patients compared to healthy individuals and its association with disease activity, especially in dermatomyositis.

THU0028 TYPE I INTERFERON SIGNATURE IN THE PERIPHERAL BLOOD AND CXCL4 PLASMA LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS

N.I. Vlachogiannis, V.-K. Bournia, A. Nezos, P.F. Christopoulos, M. Patsouras, P.G. Vlachoyiannopoulos, C.P. Mavragani, P.P. Sfikakis. *Joint Academic Rheumatology Program, National and Kapodistrian University of Athens Medical School, Athens, Greece*

Background: Type I Interferon (IFN) pathway is activated in Systemic Sclerosis (SSc) and represents a therapeutic target currently being tested in clinical trials, while higher IFNα levels have been also associated with pulmonary fibrosis in these patients. On the other hand, *in vitro* experiments using plasmacytoid dendritic cells from patients with SSc suggest an interplay between the chemokine (C-X-C motif) ligand 4 (CXCL4), a potential biomarker in SSc, and type I IFN. [1]
Objectives: To test the hypothesis that type I IFN-induced gene expression in the peripheral blood associates with particular clinical and laboratory features, including plasma CXCL4 levels, in patients with SSc.
Methods: Forty six patients with limited and 19 with diffuse SSc (60/65 women, aged 54±14 years, disease duration ranging between 0.5–27 years) and 20 healthy controls were examined. Peripheral whole blood samples (3ml) were subjected to cDNA synthesis and the expression of 3 genes (IFIT1, MX1, IFI44) that are preferentially induced by type I IFN was quantified by real time PCR. Type I IFN individual scores were calculated as described [2]; scores were arbitrarily considered as high when exceeding the mean value plus 3SD of the corresponding healthy control scores. Plasma CXCL4 levels were determined by ELISA.
Results: A high type I IFN score (i.e.>8) ranging from 8.4 to 145 was found in 21/65 (32.3%) patients with SSc, compared with none of 20 healthy controls (p:0.002). SSc patients with high type I IFN scores demonstrated higher erythrocyte sedimentation rate and lower diffusing lung capacity for carbon monoxide (DLCO) levels than the remaining patients (p:0.002 and p:0.02, respectively, by Mann-Whitney U test). Other disease variables, including extent of skin involvement and autoantibodies, were not associated with high type I IFN score. Individual type I IFN scores positively correlated with the corresponding CXCL4 plasma levels (Spearman's r: 0.53, p-value: 0.02).
Conclusions: A prominent type I IFN signature was observed in the peripheral blood of one third of patients with SSc in association with upregulated inflammatory response, reduced DLCO levels and higher CXCL4 plasma levels. Further prospective data are required to establish the role of type I IFN as an additional novel biomarker in SSc.

THU0029 BACTERICIDAL/PERMEABILITY-INCREASING PROTEIN DOWNREGULATES THE INFLAMMATORY RESPONSE TO PATHOGENIC CRYSTALS IN VITRO AND IN VIVO

A. Scanu[1], R. Luisetto[2], F. Oliviero[1], P. Galozzi[1], R. Ramonda[1], L. Punzi[1]. *[1]Rheumatology Unit, Dept. of Medicine, University of Padova; [2]Dept. of Surgical Oncological and Gastroenterological Sciences, Padova, Italy*

Background: Bactericidal/permeability-increasing protein (BPI) is a cationic protein mainly produced by polymorphonuclear cells (PMN) which exerts an antimicrobial activity by damaging bacterial membranes and interacts with specific cell surface receptors, such as toll-like receptors (TLRs). BPI has been detected in synovial fluid of patients with different arthritis, including crystal-induced arthritis.
Objectives: To evaluate the effects and mechanisms of action of BPI in *in vitro* and *in vivo* models of crystal-induced inflammation.
Methods: The human monocytic cell line THP-1 was primed for 3 h with phorbole myristate acetate (300 ng/ml), reincubated overnight, and treated with sterile synthetic monosodium urate (MSU) (0.5 mg/ml) or calcium pyrophosphate (CPP) (0.1 mg/ml) crystals for 24 h in presence or absence of BPI (5 μ g/ml). In some experiments, cells or crystals were pretreated with BPI for 2 h before stimulation. BPI inhibition experiments were carried out with antibody against TLR2 or TLR4. Cell supernatants were tested by ELISA for interleukin (IL)-1β and IL-8 production. Chemotactic effect of culture supernatants was evaluated in chemotaxis chamber by the migration of freshly isolated peripheral blood PMN.
As regard the study in vivo, air pouches were raised on the backs of CD1 mice (n=7 per condition). 2 mg of MSU crystals in 1 ml of PBS were injected into the pouch in the presence or absence of 0.1 mg of BPI for 3 h. Controls received 1 ml of PBS. After the sacrifice, pouch fluids were recovered by washing with 2 ml of PBS. Leukocyte count in lavage fluids was obtained using a hemocytometer and the percentage of PMN was determined by May-Grünwald-Giemsa staining. IL-1β, chemokine (C-X-C motif) ligand 1 (CXCL1) and IL-6 levels were measured in exudates by ELISA.
Results: Exposure of THP-1 cells to different types of crystals increased the production of IL-1β (MSU: 406.62±12.00 pg/ml; CPP: 357.07±25.17 pg/ml) and IL-8 (MSU: 3798.56±24.64 pg/ml; CPP: 3427.74±22.33 pg/ml). The release of both cytokines induced by crystals was significantly diminished in the presence of BPI (76% IL-1β, 58% IL-8), and tended to be more pronounced when cells, but not crystals, were pretreated with the protein (90% IL-1β, 65% IL-8). The presence of antibody anti-TLR2 or anti-TLR4 did not affect the BPI inhibitory effect. Supernatants of crystal-stimulated cells increased the migration of PMN cells which was reduced in the presence of BPI.
The injection of MSU crystals into the subcutaneous pouches of mice induced leukocyte infiltration (10.2±3.39 x 10^5 cells/ml) comprising 68.6±8.75% of PMN. IL-1β (32.33±6.35 pg/ml), CXCL1 (467.07±27.47 pg/ml) and IL-6 (624.61±29.41 pg/ml) were measured in lavage fluids. The co-injection of MSU crystals and BPI inhibited leukocyte influx by 60% and PMN infiltration by 87% and, in turn, the levels of all assessed cytokines were reduced (81% IL-1β, 70% CXCL1, 35% IL-6).
Conclusions: This study shows that BPI reduces the crystal-induced inflammatory process *in vitro* and *in vivo* by inhibiting pro-inflammatory cytokine release and PMN recruitment. The mechanism of action of BPI may include the direct interaction with activated cells in a TLR-independent manner.

THU0030 IL-2IC SUPPRESSES CIA IN MICE BY THE TH1/TH17 IMMUNE RESPONSES DUE TO ENHANCEMENT OF BOTH TREG NUMBERS AND TREG FUNCTIONS

Y. Yokoyama[1], T. Iwasaki[2], S. Kitano[1], T. Furukawa[1], A. Satake[3], K. Matsui[1], H. Sano[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo; [2]Department of Pharmacy, Hyogo University of Health Sciences, Kobe; [3]1st Department of Internal Medicine, Kansai Medical University, Hirakata, Japan*

Background: Interleukin-2 (IL-2) induces regulatory T cells (Tregs) and reduces disease activity such as graft versus-host disease and systemic lupus erythematosus. IL-2/anti-IL-2 monoclonal antibody immune complex (IL-2IC) increases the half-life of IL-2 *in vivo* and specifically induces Tregs. We previously demonstrated that administration of IL-2IC suppressed collagen-induced arthritis (CIA) in mice (EULAR 2015).
Objectives: To clarify complex regulatory network of IL-2IC in autoimmune arthritis, we examined the suppression mechanism of IL-2IC induced Tregs to Th1 and Th17.
Methods: Male DBA/1 mice were immunized by injection of 200μg of Type II collagen emulsified with an equal volume of complete Freud adjuvant intradermally at the base of the tail of mice (first immunization). Second immunization was given 21 days after first immunization. IL-2ICs were prepared by mixing 5μg of anti-IL-2 antibody (clone JES6–1D) with 1μg of mouse IL-2 for 15 minutes. The mice were injected with either PBS as a control or IL-2IC (5μg /mouse) intraperitoneally for 3 days. Mouse paws were scored for arthritis using a macroscopic scoring system ranging from 0 to 4 (0, no swelling or redness; 1, swelling/redness of paw or one joint; 2, two joints involved; 3, more than two joints involved; and 4, severe arthritis of the entire paw and joints). The arthritic score for each mouse is the sum of the scores of all four paws. Peripheral blood cells were stained with anti-CD25 (PC61), anti–CD4 (RM4–5), anti-Foxp3 (FJK-16s) and CD4+CD25+Foxp3+ Tregs were analyzed by flow cytometry. Th1 and Th17 cells infiltrating in the synovium were examine by immunohistochemistry stained with anti-IFN-g and IL-17 mAb. CD4+CD25+ Treg cells were analyzed for suppressive activity against proliferation of effector CD4+ T cells. For intracellular cytokine staining, spleen cells which were removed in day 28, were stimulated with PMA, ionomycin, and breferdin for 6 hours and intracellular cytokine staining were performed by using anti-IFN-γ, anti-IL-10, anti-IL-17, and analyzed by flow cytometry.
Results: To define the effects of IL-2IC on established CIA, IL-2IC was administered for 3 days from day 21 to day 23 after the first immunization (day 0 to day 2 after the second immunization) of CIA. To define the effect of IL-2IC on early stages of disease induction we administered IL-2IC from day 0 to day 2 after first immunization. We observed a significant decrease in both the incidence and severity of arthritis in these CIA mice. Injection of IL-2IC effectively elicited more than 2-fold expansion of CD4+CD25+Foxp3+ Tregs in peripheral blood cells than control mice. Th1 and Th17 cells infiltrations in the synovium were significantly inhibited by IL-2IC treatment. *In vitro* suppression assay demonstrated significant augmentation of the suppressive capacity of CD4+CD25+Treg cells in IL-2IC treated mice. Intracellular cytokine staining revealed that IL-10 production by CD4+ cells in IL-2IC treated spleen increased four folds than in controls, and IFN-γ-producing helper T cells (Th1) and IL-17-producing helper T cells (TH17) were significantly decreased.
Conclusions: These observations indicate that IL-2IC not only induce Tregs, but also augments Treg function by enhancing IL-10 production. Thereby Tregs suppress Th1 and Th17 cells.

THU0031 THERAPEUTIC TREATMENT OF ANTI-FRACTALKINE MONOCLONAL ANTIBODY INHIBITS JOINT DESTRUCTION IN COLLAGEN-INDUCED ARTHRITIS MODEL

K. Hoshino-Negishi[1], M. Ohkuro[2], T. Nakatani[1], W. Ikeda[1], Y. Kuboi[1], N. Ishii[1], T. Yamauchi[1], N. Yasuda[1], T. Imai[1]. *[1]Research & Development, KAN Research Institute. Inc., Kobe-Shi; [2]Research Project Promotion Group, EA Pharma Co., Ltd., Kawasaki-ku, Japan*

Background: In the Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) monoclonal antibody (mAb) demonstrated a promising efficacy in active rheumatoid arthritis (RA) patients who were inadequately controlled by MTX and/or TNF-a inhibitors. However, the effect of anti-FKN mAb on joint destruction remains to be elucidated. In RA, synovium-infiltrated monocytes/macrophages cause synovitis and cartilage damage. Osteoclasts are generated from osteoclast precursor cells (OCPs) and cause bone erosion. FKN is expressed on endothelial cells and fibroblast-like synoviocytes in synovium in both experimental arthritis model and RA patients. FKN is also expressed on osteoblasts in neonatal mouse calvariae. CX3CR1, the receptor for FKN, is expressed on monocytes/macrophages and OCPs. Therefore, the interaction of FKN and CX3CR1 might play important roles in migration, differentiation and activation of these cells, leading to cartilage damage and bone erosion.
Objectives: We examined the efficacy of an anti-FKN mAb on collagen-induced arthritis (CIA) in mice, especially on joint destruction.
Methods: For the induction of CIA, DBA/1J mice were immunized with bovine type II collagen. Anti-FKN mAb or control IgG was injected twice a week from the day of the 1st immunization (for the prophylactic treatment) or after the onset of CIA (for the therapeutic treatment). The clinical arthritis score was defined as the sum of the scores of four paws. Plasma concentrations of IL-6, TNF-a, serum amyloid A (SAA), Tartrate-Resistant Acid Phosphatase type 5b (TRAP-5b), Cartilage Oligomeric Matrix Protein (COMP) and Matrix Metalloproteinase 3 (MMP-3) were measured using ELISA. Radiological score was measured by the soft x-ray images of limb bones. Alcian blue/Alizarin red and Tartrate-Resistant Acid Phosphatase (TRAP) staining were performed for histopathological analysis of ankle joints.
Results: In the prophylactic treatment, anti-FKN mAb markedly reduced the clinical arthritis score, soft x-ray score, and plasma levels of TRAP-5b, COMP and MMP-3, whereas plasma levels of IL-6, TNF-a and SAA were not significantly reduced compared with control IgG-treated mice. Histopathological analysis demonstrated almost complete suppression of joint destruction and dramatic reduction in the number of TRAP-positive cells by the treatment of anti-FKN mAb. Importantly, therapeutic treatment of anti-FKN mAb also significantly ameliorated clinical arthritis score and soft x-ray score. Synovitis, pannus formation, cartilage degradation and bone erosion were also strongly suppressed and the number of TRAP-positive cells in joint was also decreased by the therapeutic treated of anti-FKN mAb.
Conclusions: Anti-FKN mAb demonstrated a remarkable efficacy in the arthritis score without affecting systemic inflammatory parameters and inhibited the joint destruction with the marked reduction of osteoclasts in CIA model. These results suggest that inhibition of FKN/CX3CR1 axis by a humanized anti-FKN mAb, E6011, is an attractive therapeutic strategy for the treatment of both inflammatory synovitis and joint destruction of RA.

THU0032 THE ROLE OF S100A9 IN PAIN RESPONSE DURING EXPERIMENTALLY INDUCED ACUTE SYNOVITIS

E.J.W. Geven, E.N. Blaney-Davidson, E.L. Vitters, A.W. Sloetjes, B. Walgreen, A.B. Blom, P.L.E.M. van Lent. *Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands*

Background: Synovitis-associated pain is an important aspect of arthritis pathology. Several inflammatory mediators released by the synovium have been implicated in the regulation of pain, including S100A8 and S100A9 which may regulate pain either via direct stimulation of TLR4 on the nerve endings in the synovium or via stimulation of the dorsal root ganglia (DRG), thereby enabling an increased phagocyte infiltration.
Objectives: To investigate the role of S100A9 in the pain response after induction of an acute synovitis using streptococcal cell walls (SCW) as a trigger, comparing $S100A9^{-/-}$ mice and their WT controls.
Methods: Acute synovitis was induced by a single i.a. injection of SCW in the knee joint of C57Bl6 (WT) mice and $S100A9^{-/-}$ mice, control mice received an i.a. saline injection. Serum S100A8/A9 levels were investigated by ELISA and expression of S100A8 and S100A9 in synovium and DRG by immunohistochemistry. Joint swelling and cell influx was assessed by ^{99m}Tc accumulaiton and histology, respectively. Pain response were investigated Incapacitance Tester (weight bearing), Catwalk (gait analysis) and von Frey's filaments (mechanical allodynia). Gene expression of inflammatory mediators and neuron activation markers in DRG were determined by q-PCR.
Results: A single i.a. injection of SCW resulted in increased synovial expression of S100A8 and S100A9 and subsequent increased serum S100A8/A9 levels (2.6-fold, $P<0.001$) 1 day p.i., which returned to basal levels at 7 days p.i. The increased expression of S100A9 did not contribute to the development of inflammation since joint swelling and cell influx were similar in WT and $S100A9^{-/-}$ mice 1 day p.i. Using the Incapacitance Tester, WT mice showed a marked and significant decrease in percentage of weight bearing on the SCW injected hindpaw (28%) compared to saline injection (47%, $P<0.001$) 1 day p.i., whereas $S100A9^{-/-}$ mice did not. In addition, gait analysis showed that the stand-phase of the unaffected paws were significantly increased in WT mice 1 day p.i., which will reduce the load on the inflamed paw, while in $S100A9^{-/-}$ mice these parameters were not altered. No difference in mechanical allodynia was observed, both mouse strains showed a similar reduction of paw withdrawal threshold (4.2 and 4.5 fold decrease respectively). Analysis of DRG showed no increased phagocyte infiltration after SCW injection as determined by S100A8 and S100A9 immunohistochemistry and no change in gene expression of MCP-1, KC, IL-1β or TNF was measured. However, expression of neuron activation markers NAV1.7, ATF3 and GAP43 were significantly increased at 1 day after SCW injection in WT mice as compared to saline injected mice (P =0.022, 0.004 and 0.030, respectively) while SCW injection in $S100A9^{-/-}$ mice did not show increased expression, which is in line in with the reduced pain response observed earlier in $S100A9^{-/-}$ mice.
Conclusions: These findings show that S100A9, which is released from the synovium upon inflammation, is an important mediator of inflammatory pain response in the knee, and that during the acute phase of inflammation is likely regulated via direct activation of TLR4 on nerve endings in the synovium and not via increased infiltration of phagocytes in the DRG.

THU0033 LOCAL INJECTION OF ADIPOSE-DERIVED MESENCHYMAL STROMAL CELLS IN EXPERIMENTAL INFLAMMATORY OA RESULTS IN INTERLEUKIN-1β-MEDIATED ATTRACTION OF PMNS AND REDUCED S100A8/A9 RELEASE

S. van Dalen, A. Sloetjes, M. Helsen, B. Walgreen, E. Geven, P. van Lent. *Experimental Reumatology, Radboud university medical center, Nijmegen, Netherlands*

Background: Recent studies have shown that mild synovitis in early phases of osteoarthritis (OA) is conducive to development of joint damage. OA synovitis is characterized by elevated levels of pro-inflammatory factors like S100A8, S100A9, interleukin-6 (IL-6), and interleukin-1 beta (IL-1β). S100A8/A9 was found to be crucial in mediating joint destruction in inflammatory experimental OA. Previously we found that adipose-derived mesenchymal stromal cells (ASCs) exhibit immunosuppressive characteristics and reduce joint pathology after local application into mouse knee joints with experimental inflammatory OA. This protective effect is only perceived after intra-articular injection in early but not late stage OA, suggesting that the effect may be mediated by an inflammatory milieu.
Objectives: To examine the working mechanism of ASCs after early injection in experimental OA.
Methods: Experimental OA was induced by injection of collagenase into murine knee joints (CiOA). Total knee joints were stained with haematoxylin/eosin and the PMN-specific antibody NIMP-R14. ASCs were isolated from murine adipose tissue and stimulated for 24h with IL-1β or S100A8/A9. Gene expression in stimulated cells was analyzed using qPCR. Protein levels of chemokines and cytokines were measured in culture supernatant using Luminex. Migration of MACS isolated bone marrow (BM-) PMNs towards ASC-conditioned medium (CM) was examined using Transwell inserts. ASCs were co-cultured with BM-PMNs and analyzed using histology and Luminex.
Results: ASC injection into day 7 CiOA knee joints (when synovitis and IL-1β and S100A8/A9 levels are highest) caused a strong attraction of mainly PMN-like cells and their clustering around ASCs in the synovium shortly after injection (6h), which was confirmed by immunohistochemistry. IL-1β stimulation of ASCs in vitro strongly increased gene expression of PMN-attracting chemokines KC, CXCL5, and CXCL7 as well as protein levels of KC, whereas S100A8/A9 did not. The migration of BM-PMNs through Transwell inserts towards CM of IL-1β-stimulated ASCs was significantly increased (from 5% to 10%) when compared to CM of non-stimulated ASCs. Next, ASCs were co-cultured with BM-PMNs in the presence or absence of IL-1β. After 6h, a clear clustering of neutrophils around ASCs was observed, with a significant increase in the number of ASCs clustering with PMNs, as well as a significantly elevated number of clustering PMNs per ASC after IL-1β stimulation. Interestingly, association of PMNs with ASCs lead to a significantly lowered release of KC protein by ASCs (69% and 76% lower after 24h and 48h respectively), as well as a significantly reduced release of S100A8/A9 protein by the PMNs. This coincided with lowering of S100A8/A9 levels in washouts of inflamed synovium 6h and 48h after injection of ASCs in day 7 CiOA knee joints.
Conclusions: Local application of ASCs in inflamed CiOA knee joints results in attraction and clustering of PMNs with ASCs in the synovium. This presumably runs via IL-1β-mediated up-regulation of chemokine release by ASCs, and ultimately results in significantly lowered S100A8/A9 levels.

THU0034 THE INFLAMMATORY POTENTIAL OF CALCIUM PYROPHOSPHATE CRYSTALS DEPENDS ON THEIR CAPACITY TO INDUCE NF-κB AND MAPK PATHWAYS

F. Renaudin[1,2], L. Campillo-Gimenez[1], P. Gras[3], C. Combes[3], M. Cohen-Solal[1,4], F. Lioté[1,4], H.-K. Ea[1,4]. *[1]UMR1132, Bioscar, Inserm; [2]University Paris Diderot, Paris; [3]Ensiacet, CIRIMAT, Inpt-Ups-CNRS, Toulouse; [4]Pôle locomoteur, Service de Rhumatologie, centre Viggo Petersen, AP-HP, Hôpital Lariboisière, Paris, France*

Background: Calcium pyrophosphate (CPP) crystal-induced inflammation is mainly driven by interleukin (IL)-1β. IL-1β production involves a two-step process including the formation of pro-IL-1β through NF-κB activation and its maturation inti active IL-1β through NLRP3 inflammasome activation. Two CPP crystal phases, namely monoclinic and triclinic CPP dehydrated (m- and t-CPPD) crystals are identified in synovial fluids. We have recently demonstrated that m- and t-CPPD display different inflammatory potentials marked by a differential level of IL-1β production and other pro-inflammatory mediator expression.
Objectives: We aimed to assess the intracellular pathways upstream CPP crystal-induced IL-1β production, according to the different inflammatory properties of CPP crystal phases.
Methods: Four synthesized and pyrogen-free CPP crystals [a-CPP (amorphous), m-CPPD or tetrahydrated (m-CPPT) and t-CPPD] (Gras P et al. 2014) and monosodium urate (MSU) crystals were used, *in vitro*, to stimulate THP-1 cell line or mouse bone marrow-derived macrophages (BMDM) in the presence or not of pharmacological inhibitors: Bay-117085 (Bay, NF-κB inhibitor); SB203580 (SB, MAPK p38 inhibitor); SP600125 (SP, JNK inhibitor) and PD98059 (PD, p42/44 MAPK inhibitor). The expression of pro- and anti-inflammatory cytokine genes was assessed by qRT-PCR, and IL-1β or IL-8 production by ELISA; MAPK phosphorylation by immunoblot. NF-κB activation was quantified in THP-1 cells containing a gene reporter plasmid under control of NF-κB transcriptional factor. *In vivo*, we used murine air pouch model to assess the effects of NF-κB inhibition in CPP crystal-mediated inflammation.
Results: We previously demonstrated that *in vitro* m-CPPD crystals were the most inflammatory CPP crystals and induced a higher production of mature IL-1b associated to a higher expression of NLRP3 protein, and a higher IL-8 production and expression of inflammatory cytokine genes (IL-1β, IL-6, IL-8, IL-33, TNF, COX-2) than t-CPPD, m-CPPT and MSU crystals. a-CPP crystals did not have inflammatory property. m-CPPD crystals induced a higher NF-kB activation and a higher phosphorylation p38, p42/44 and JNK MAPKs than t-CPPD and MSU crystals. In parallel, we showed that inhibition of NF-κB completely abrogated mature IL-1b and IL-8 secretion and pro-IL-1β synthesis induced by all CPP crystals. Inhibition of JNK and p42/44 MAPK with SP and PD respectively, decreased both IL-1β secretion and NF-κB activation induced by CPP crystals. *In vivo* IL-1β and IL-8 production and neutrophil infiltration induced by m-CPPD crystals were dramatically decreased by NF-κB inhibitor.
Conclusions: Our results showed that IL-1β and IL-8 production induced by CPP crystals is completely dependent of NF-κB signaling. They suggested that the inflammatory potential of different CPP crystals relied on their capacity to activate both MAPK and NF-κB pathways. Differential level of NF-κB activation is partially dependent of MAPK phosphorylation. Additional studies are ongoing to investigate the underlying mechanisms.

THU0035 CYTOKINE PROFILING OF AQUEOUS HUMOR IN BEHÇET'S DISEASE PATIENTS WITH ACTIVE OCULAR INVOLVEMENT

A. Soriano[1,2], S. Croci[3], L. Cimino[4], M. Bonacini[3], E. Calò[3], A. Zerbini[3], M. Parmeggiani[3], L. Fontana[4], C. Salvarani[5]. *[1]Department of Internal Medicine, Rheumatology Unit, Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia, Italy, Reggio Emilia; [2]Campus Bio-Medico University of Rome, Rome; [3]Clinical Immunology, Allergy and Advanced Biotechnologies Unit; [4]Ocular Immunology Unit; [5]Department of Internal Medicine, Rheumatology Unit, Arcispedale Santa Maria Nuova – IRCCS, Reggio Emilia, Italy*

Background: Behçet's disease (BD) is a systemic inflammatory disorder with unknown etiology. Uveitis and retinal vasculitis occur in 60–80% of patients during the disease course. Previous data on cytokine profiling in aqueous humor (AH) of patients with active BD-related uveitis suggested that both T helper (Th) 1 and Th17 cells are involved in immunopathogenesis [1]. Furthermore, higher levels of Natural Killer T (NKT) cells (CD3+ CD56+) have previously been found in AH of patients with BD-related uveitis as compared to other types of uveitis [2]. However, data on magnitude and patterns of cytokines in BD-related uveitis remain scarce.
Objectives: To examine cytokine production as well as frequency of NK and NKT cells in AH from BD patients with active uveitis as compared to patients with active Vogt-Koyanagi-Harada (VKH) disease-related uveitis.
Methods: AH from 8 adult patients with BD (1990 ISGB criteria [3]) and active uveitis, and from 7 patients with active VKH were analyzed. Definition of "active" uveitis included ≥2 cells in the anterior chamber (Hogan scale, 1950) and/or 2+ vitritis (Nussenblatt scale, 1990), papillitis, macular edema and retinal vasculitis with active "photo fundus". AH from 5 subjects undergoing cataract surgery were included as controls. Cytokines' concentrations were determined with Bio-Plex Pro-Human cytokine 27-plex assay. Frequency of NK and NKT cells was determined by flow cytometry using anti-CD3, -CD56, -CD16 antibodies.
Results: Higher levels of IL-1b, IL-1RA, IL-5, IL-7, IL-6, G-CSF, IFN-g, IP-10, TNF-a IL-8 and MIP1a were found in AH from patients with BD and VKH compared to controls. G-CSF and IFN-g were detected in AH from BD and VKH patients, but not in the control group. Lower levels of GM-CSF were found in BD and VKH patients, while IL-6 levels were 3000-fold increased, as compared to controls. No differences were detected between BD and VKH patients in terms of cytokine levels. However, AH from 4 BD patients showed a peculiar distinct cytokine pattern, when analyzed by unsupervised cluster analysis. Intriguingly, a higher amount of neutrophils/mL was found in AH from these 4 BD cases. Frequency of NKT (CD3+ CD56+) cells was higher in BD patients as compared to VKH, while that of NK (CD56+ $CD3^{neg}$) cells was similar and that of T cells ($CD56^{neg}$CD3+) was lower. Finally, no difference was found between NK subsets in terms of proportion of CD16+ cells in both BD and VKH groups.
Conclusions: AH of both BD and VKH groups showed increased levels of IL-6, G-CSF and IFN-g, which might suggest their potential role in the immunopathogenesis of these types of endogenous uveitis. However, a distinct cytokine profile able to distinguish the two conditions remains to be identified. Additionally, our preliminary results confirm the previous observation of increased NKT cells levels in BD uveitis as compared to VKH.

THU0036 ROLES OF IL-8 IN RANK-L- AND ACPA-MEDIATED OSTEOCLASTOGENESIS

A. Cîrciumaru, Y. Liu, A. Krishnamurthy, S.M. Mia, V. Joshua, M. Engström, V. Malmström, M. Sun, H. Wähämaa, B. Rethi, A. Catrina. *Karolinska Institute, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden*

Background: We have shown previously in various experimental models that anti-citrullinated protein antibodies (ACPAs) can contribute to bone erosion and arthralgia through IL-8 dependent mechanisms.
Objectives: In cell cultures osteoclasts (OCs) played a prominent role in the ACPA-induced IL-8 secretion and therefore we decided to characterize in detail the autocrine regulation of OC differentiation by IL-8 in the presence or absence of ACPAs.
Methods: Peripheral blood CD14-positive monocytes were used to generate OCs in the presence of M-CSF and RANKL. Expression levels of IL-8 and CXCR1/2 were monitored during OCs maturation using intracellular flow cytometry, cytometric bead array, immunohistochemistry and RT-PCR. Inhibition of IL-8 and its receptors were performed in OC cultures using IL-8 neutralizing antibodies and small molecule CXCR1 and CXCR2 antagonists (Reparixin, SB-332235), in the presence or absence of polyclonal ACPAs. OC numbers were counted using light microscope after TRAP staining.
Results: Macrophages and developing OCs secreted high levels of IL-8 in response to the cytokine M-CSF. IL-8 expression kinetic was characterized by transient peaks when new cytokine was added, followed by very low level of steady-state production. In the presence of ACPAs IL-8 production increased 3–4 fold during late phases of OC differentiation. With the help of IL-8 neutralizing antibodies or inhibitors acting on the IL-8 binding chemokine receptors CXCR1 and CXCR2 we showed that the M-CSF induced IL-8 plays a crucial role in OC differentiation in the presence of exogenous RANK-L. In the presence of ACPAs OC differentiation was further enhanced in response to the ACPA-mediated increase in IL-8 production. The CXCR1 and CXCR2 inhibitors Reparixin and SB-332235 significantly inhibited the RANKL-mediated osteoclastogenesis at 100μM and 10μM respectively, both in the presence or absence of ACPAs. By using the inhibitors at low concentrations we could counteract the ACPA-mediated increase in OC development without interfering with steady state OC differentiation.
Conclusions: Our findings further support an important role for IL-8 in bone biology and in the ACPA-mediated OC differentiation both under physiological conditions and in the presence of ACPAs. Together with previous data showing in vivo, our data indicated that small molecule CXCR1 and CXCR2 antagonists could provide novel therapeutic tools for targeting OCs in ACPA+ individuals.

THU0037 IMMUNOGENICITY IN A TERTIARY CARE HOSPITAL: OUR EXPERIENCE

A.G. Valle[1], M. Garijo Buffort[2], M. Retuerto Guerrero[2], C. Iñiguez[2], E. Díez[2], C. Moriano[2], A. López[2], M. Martín[2], C. Álvarez[2], T. Pérez Sandoval[2].
[1]Rheumathology, Hospital Can Misses, Ibiza; [2]Rheumathology, Complejo Asistencial Universitario, León, Spain

Background: The drugs called Anti-TNF inhibitors are capable of inducing an immune response (immunogenicity) Its effectiveness may be affected by the development of Anti-Drug Antibodies (Ab)
Objectives:
- To assess the frequency of appearance of Anti-Drug Antibodies: Infliximab (IFX), Adalimumab (ADA), etanercept (ETN)
- To classify the failures of response
- To analyse the relationship between anti-TNFα antibodies and concomitant treatment with DMARDs
- To observe whether there is a link between risk factors and drug levels

Methods: This is a retrospective, descriptive, observational study of patients with Rheumatoid Arthritis (RA), Spondyloarthritis (SpA), Psoriatic arthritis (PsA), Seronegative arthritis (SA) and Enteropathic arthritis (EA) with active disease and that were treated in the "University Health Care Hospital of León" between Jan-2015 and Jan-2016. Using ELISA Technology and the kits Promonitor®, it was possible to detect serum levels of IFX ADA, ETN (reference values>2.5μg/mL, 5–8μg/mL and 0.8–1.2μg/mL respectively) and of anti-drug antibodies. The samples were collected the same day of the administration, prior to it, always in a trough level. The gathered data was: demographic data, activity, time-to-disease progression, prior treatment with biologics, concomitant DMARDs, duration of the biologic treatment and dosage, quantization levels, anti-TNF antibodies, cardiovascular risk factors (CVRF) and smoking habits.
Results: Variables to study:
N=40: IFX 50%, ADA 30%, ETN 20%.
Age 53.6±3.7 years old [95% CI], Women: 55%, time-disease progression: 12.3±2.7 years old.
Type of disease: RA 47.5%, SpA 15%, PsA 20%, SA 7.5%, EA 10%.
DAS28: 3.5±0.4, BASDAI 4.7±0.5, BASFI 4.3±1.4.
Prior treatment with biologics (30%): IFX 15%, ADA 66%, ETN 12.5%.
Frequency of administration: IFX 8.6±0.36 weeks, ADA 2.25±0.36 weeks, ETN 1.1±1.0 weeks.
Reasons for requesting the levels:
- Secondary failure (82%): IFX 90%, ADA 66.7%, ETN 75%
- Primary failure (17%): IFX 5%, ADA 33%, ETN 25%
- Infusion reactions (2.5%)

Drug levels within the therapeutic range: IFX 10%, ADA 41%, ETN 50%.
Formation of anti-TNF Ab of the sample: IFX 30%, ADA 16%, ETN 0%.
DMARDs: presence of 62.5% (MTXsc 64%, MTXvo 20%, Leflunomide, Sulfasalazine e Hydroxychloroquine 16%).
Conclusions: We found the following conclusions:
- In the data collected, we observe that the IFX (30%) is the most immunogenic drug, followed by the ADA (16%) and being the ETN (0%) the one that so far has not presented anti-drug Ab, outcomes in agreement with the medical literature
- The main reason for requesting has been the secondary failure (90%)
- The suboptimal levels of the drug and the presence of specific ab are correlated with the loss of clinical response. In our case, the proper range of drug is only objective in 10% of the patients treated with IFX, 41% with ADA and 50% with ETN
- The concomitant use of DMARDs in our study has not been shown to decrease levels of Ab, being the MTX the most used in our patients (84%). We observed no correlation between the occurrence of Ab, the use of DMARDs or the type of disease
- The monitoring of the levels of anti-TNF drug may be useful to individualize the treatment, to avoid possible side effects and to make decisions regarding the continuation or change of therapy.

THU0038 BIMEKIZUMAB DUAL INHIBITION OF IL-17A AND IL-17F PROVIDES EVIDENCE OF IL-17F CONTRIBUTION TO CHRONIC INFLAMMATION IN DISEASE-RELEVANT CELLS

A. Maroof[1], R. Okoye[1], T. Smallie[1], D. Baeten[2], S. Archer[1], C. Simpson[1], M. Griffiths[1], S. Shaw[1]. *[1]UCB Pharma, Slough, United Kingdom; [2]UCB Pharma, Brussels, Belgium*

Background: IL-17A and IL-17F share structural homology and have similar biological function[1]. Although the contribution of IL-17A to immune-mediated inflammatory diseases has been widely reported[1–3], the role of IL-17F is less well characterised in human tissue inflammation. Bimekizumab, a humanised monoclonal IgG1 antibody, was developed to neutralise both IL-17A and IL-17F potently and selectively, and is under clinical development as a treatment for psoriatic arthritis (PsA) and other immune-mediated conditions such as psoriasis.
Objectives: To assess the involvement of IL-17F in chronic inflammation in tissue from patients with PsA and disease-relevant cells, and to determine the effect of dual neutralisation of IL-17A and IL-17F in suppressing inflammation, compared with blockade of IL-17A.
Methods: Synovial and lesional skin tissue from patients with PsA was probed by immunostaining for expression of IL-17F protein. Normal dermal fibroblasts and synoviocytes, in the presence of TNFα, were stimulated with recombinant IL-17A and IL-17F to assess the inflammatory response. Using cytokine-specific blocking antibodies, the individual and combined effects of IL-17A and IL-17F were explored with: pro-inflammatory cytokine expression in a complex *in vitro* model (synoviocytes from patients with PsA and normal dermal fibroblasts were treated with pro-inflammatory mediators from supernatant [SN] of sorted Th17 cells), microarray and cell migration studies.
Results: IL-17F expression was observed in tissue biopsies from patients with PsA. In normal dermal fibroblasts, normal synoviocytes and synoviocytes from patients with PsA, stimulation with recombinant IL-17F promoted production of pro-inflammatory mediators, such as IL-6 and IL-8, though to a lesser extent than with recombinant IL-17A. Treatment of Th17 SN-stimulated synoviocytes from patients with PsA with bimekizumab (neutralising IL-17A and IL-17F) led to greater reductions of IL-6 (42% lower $p<0.05$) and IL-8 (35% lower $p<0.05$) production than IL-17A inhibition. Bimekizumab treatment of Th17 SN-stimulated normal dermal fibroblasts also reduced production of IL-6 (35% lower $p<0.0001$) and IL-8 (57% lower $p<0.0001$) more than IL-17A alone. Combining IL-17A + IL-17F monoclonal antibodies produced similar results to bimekizumab. Levels of expression of 27 inflammation-linked genes, including *CXCL1*, *CXCL2*, *CXCL3* and *IL-15RA*, were lower with dual neutralisation of IL-17A and IL-17F by bimekizumab versus inhibition of IL-17A. Suppression of migration of neutrophils (Fig.) and monocytes, both involved in tissue destruction in immune-mediated diseases, was substantially greater with bimekizumab treatment than with single blockade of IL-17A.

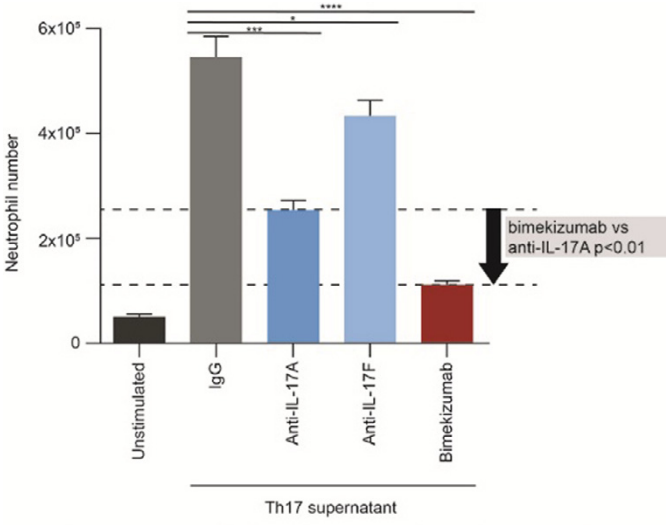

Fig. Quantification of neutrophil migration following treatment with cytokine-specific antibodies and bimekizumab. * represents a significant reduction of cell migration vs IgG control, *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001

Conclusions: Dual neutralisation of IL-17A and IL-17F provides evidence for the contribution of IL-17F to inflammation in joints and skin beyond IL-17A alone. As a result, dual inhibition of IL-17A and IL-17F by bimekizumab may provide an effective treatment for immune-mediated inflammatory diseases such as PsA.

THU0039 LIPIDOMICS ANALYSIS OF HDL PARTICLE IN INFLAMMATORY RHEUMATIC DISEASES: ALTERATION OF PHOSPHOLIPID COMPOSITION AND ROLE OF INFLAMMATION

C. Giraud[1], F. Capel[2], F. Dutheil[3], B. Pereira[4], M. Soubrier[1], A. Kontush[5], M. Lhomme[6], J.L. Sebedio[2], A. Tournadre[1]. *[1]Rheumatology, CHU Gabriel Montpied; [2]Unité nutrition humaine, UMR 1019/Inra; [3]AME2P, Blaise Pascal University; [4]Biostatistic/ "Delegation Recherche Clinique et Innovation", CHU Gabriel Montpied, Clermont Ferrand; [5]INSERM UMR_s 1166 – Ican, Université Pierre et Marie Curie – Paris 6; [6]ICANalytics, ICAN, Paris, France*

Background: Rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylsosing

spondylitis (SA) are associated with an increased cardiovascular (CV) mortality. Quantitative abnormalities in lipid profiles are insufficient to explain this excess of CV risk and a qualitative approach of HDL composition is required to identify loss of atheroprotective functions and to correctly identify patients at risk. Atheroprotective functions of HDL are directly linked to the structure of HDL mainly composed of phospholipids (PL).

Objectives: The main objective of this study is to analyze the PL composition of HDL in patients with chronic inflammatory rheumatic diseases and to compare to matched healthy controls.

Methods: HDL structure was assessed in patients with active RA (ACR criteria), PsA (CASPAR criteria) and SA (ASAS criteria) patients before initiating first biologic and in healthy controls matched for age, sex and body mass index. Dyslipidemia treatment or pathology which could interfere with lipid profile were excluded. Demographics data, disease activity, cardiometabolic profile and plasma samples were collected. HDL particle were isolated from plasma after two step ultracentrifugation using gradient of density. Lipidomics analysis were performed using liquid chromatography coupled with mass spectrometry. Phospholipid composition between patients and controls was compared using multivariate analyses to take into account possible confounding variables determined according to univariate results and clinical relevance (age, tobacco consumption, steroids use). Multidimensional analyses as factorial mixed data analysis (FMDA) were performed to complete these analyses.

Results: 19 RA, 19 PsA and 12 SA were analyzed (table 1). 220 phospholipids species were identified among which 2 major classes were modified in rheumatic diseases. Phosphatidylcholine (PC) decreased in RA and PsA ($p<0.01$ and <0.05 respectively) while lysophosphatidylcholine (LPC) increased significantly ($p<0.01$, and <0.05 respectively). Some phospholipids species as PC 40: 8 ($p<0.001$), LPC 16:0 ($p<0.001$), LPC 18:0 ($p<0.001$) were identified as discriminant marker of HDL composition in rheumatic disease as compared to controls.

Conclusions: Phospholipids composition of HDL is altered in RA and PsA. These alterations could explain a loss of atheroprotective functions and the excess of CV risk observed in RA and PsA patients. Chronic inflammation, through the activation of phospholipase A2 type II which hydrolyze PC into LPC, could modify the structure of HDL phospholipids and thus could impact HDL functionality such as cholesterol efflux, LDL oxidation modulation, anti-inflammatory and vasculoprotective properties. These preliminary data suggest the major role of inflammation in these alterations.

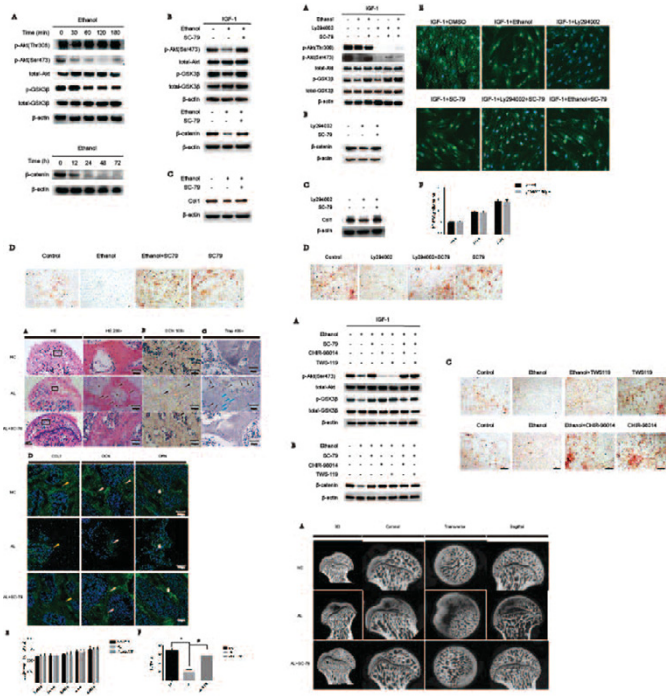
THU0040 NOVEL AKT ACTIVATOR SC-79 IS A POTENTIAL TREATMENT FOR ALCOHOL-INDUCED OSTEONECROSIS OF THE FEMORAL HEAD



C. Yixuan. *Orthopedics, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China*

Background: Alcohol is known to be one ofthe leading risk factors for osteonecrosis of the femoral head. However, the underlying etiology and protective strategiesof alcohol-induced osteonecrosis of the femoral headhavenot been clarified.

Objectives: The aim of this study was to explore the molecular mechanism of alcohol-induced osteonecrosis of the femoral head, and to investigate the protective effect of SC-79 on the disease.

Methods: In vitro, we employed RT-PCR, alizarin red staining, alkaline phosphatase activity testing, western blot, immunofluorescence staining to investigate the effect of ethanol on hBMSCs. In vivo experiments, immunofluorescence staining, TRAP, TUNEL and micro-CT were performed to investigate the development of ONFH.

Results: In vitro, we found that ethanol could significantly impair the expression of osteogenic genes of RUNX2 and OCN, downregulate osteogenic differentiation, impair IGF-1 induced membrane recruitment of the Akt, suppress the Akt-Ser473 phosphorylationand the subsequent activation of Akt/GSK3β/β-catenin signaling in bone mesenchymal stem cells. Functional studies further confirmed this signaling was the critical mediator during the ethanol-induced inhibitory effects on osteogenesis of BMSCs.Thus, the dephosphorylation of Akt-Ser473 in Akt/GSK3β/β-catenin signaling pathway might be a potential mechanism in the pathogenesis of alcohol-induced osteonecrosis of the femoral head.SC-79, a novel Akt activator was introduced in this study to block the dephosphorylation effect of ethanol on Akt-Ser473 both in vitro and in vivo. In the rat model of alcohol-induced osteonecrosis of the femoral head, micro-CT and histopathological analyses revealed obvious osteonecrosis changes in alcohol-administrated rats while significantly less developed in SC-79 injected rats. OPN, OCN and COL1 immunofluorescence staining revealed that osteogenic response of femoral heads was markedly reduced after alcohol administration, but significantly reversed by SC-79 treatment.

Conclusions: Hence, we discovered alcohol-induced osteonecrosis of the femoral headwas associated with the suppression of the Akt-Ser473 in Akt/GSK3β/β-catenin pathway in BMSCs. The administration of SC-79, to elevate Akt activation, might be a clinical strategy to prevent the development of alcohol-inducedosteonecrosis of the femoral head.

THU0041 PROGRANULIN AND DERIVATIVES CAN BE EMPLOYED AS LATENT DUAL-FUNCTION CHONDROGENIC AND ANTI-INFLAMMATORY THERAPEUTICS FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

C.M.A. Schultz, Y. Chernajovsky. *Bone & Joint Research Unit, Queen Mary, University of London, London, United Kingdom*

Background: Rheumatoid Arthritis (RA) is a debilitating inflammatory disease of the joints afflicting around 1% of Western populations. Some of the best treatments are anti-TNF agents, but these only achieve remission in 60% of patients and cause deleterious side effects. Progranulin (PGRN), a cysteine-rich, multi-domain growth factor was reported to bind TNF-receptors (TNFR) blocking pro-inflammatory signalling[2], as well as stimulating chondrogenesis[3]. PGRN is cleavable and its peptides have pleiotropic effects, some of which may be beneficial and others refractory to ameliorating RA. Granulin A (GRN A) was shown to interact with cartilage ECM protein COMP[4]. Atsttrin – comprising 3 fused PGRN regions, was shown to ameliorate arthritic disease[2]. The latency associated peptide (LAP) of TGFβ1 can be fused to short peptides and cytokines via a MMP cleavage site to facilitate targeting to inflamed sites such as RA joints, reducing side effects and enhancing *in vivo* half-life[1]. We hypothesised that a peptide based on PGRN could be fused to LAP and used to both block TNF and stimulate cartilage regeneration in RA joints in a targeted way.

Objectives: To produce a panel of PGRN derivatives fused to LAP. To determine the chondrogenic and anti-TNF capacities of the fragments in the presence and absence of MMP activation. To evaluate their efficacy in the CIA model of RA.

Methods: Micromass cultures of C28/I2 chondrocytes and C3H10T1/2 mesenchymal cells were employed to determine the ability of PGRN fragments to stimulate chondrogenesis. HT-29 and WEHI-164 TNF sensitive cells were used to evaluate the anti-TNF capacity of LAP-PGRN fragments. Co-immunoprecipitation was used to characterise interactions between PGRN fragments and TNFRII. DBA/1 fibroblasts transduced with lentivirus encoding LAP-PGRN fusions were delivered to DBA/1 mice with CIA to assess anti-arthritic effects.
Results: PGRN, LAP-PGRN, LAP-GRN A and LAP-Atsttrin were cloned and expressed in mammalian expression systems. PGRN elevated sulphated proteoglycan production in micromass cultures of C28/I2 human chondrocytes, and also stimulated proliferation of C3H10T1/2 cells. Furthermore, PGRN reduced TNF-mediated catabolism of extracellular matrix in established chondrogenic C3H10T1/2 micromass cultures. LAP-PGRN, LAP-GRN A and LAP-Atsttrin potentiated BMP2 mediated chondrogenesis in C3H10T1/2 micromasses. PGRN failed to protect WEHI-164 fibroblasts or HT-29 colorectal carcinoma cells from TNF-mediated cytotoxicity despite interacting with TNF receptor *in vitro* by co-immunoprecipitation. LAP-PGRN, LAP-GRN A and LAP-Atsttrin all failed to protect WEHI-164 cells from TNF-mediated cytotoxicity, even after MMP1 cleavage and release. CIA disease progression was reduced in DBA/1 mice treated with autologous fibroblasts overexpressing murine Etanercept or PGRN relative to control treatment. LAP-Atsttrin was more effective than LAP-PGRN and LAP-GRN A at reducing arthritic symptoms relative to LAP-Empty controls.
Conclusions: These findings suggest that PGRN could be used as a targeted dual-function chondrogenic and anti-inflammatory treatment for RA, but these effects are not elicited directly through the TNF pathway.

THU0042 LONGITUDINAL IP-10 SERUM LEVELS ASSOCIATE WITH THE COURSE OF DISEASE ACTIVITY AND ACHIEVING DMARD-FREE SUSTAINED REMISSION IN RHEUMATOID ARTHRITIS

A. van Hooij[1], D. Boeters[2], E. Tjon Kon Fat[3], S. van den Eeden[1], P. Corstjens[3], A. van der Helm-van Mil[2], A. Geluk[1]. *[1]Department of Infectious diseases; [2]Department of Rheumatology; [3]Department of Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands*

Background: Although rheumatoid arthritis (RA) is a chronic autoimmune disease that is persistent in the majority of patients, 10–15% of the RA patients achieve disease modifying anti-rheumatic drugs (DMARD)-free sustained remission over time. Biological mechanisms underlying the persistence of inflammation in RA are yet unidentified. It is well established that increased serum levels of IFN-γ-induced protein 10 (IP-10) are associated with (acute) increased inflammatory responses against mycobacterial pathogens causing leprosy and tuberculosis, thereby providing useful diagnostic tools in these infectious diseases. Based on previous genetic susceptibility studies, we hypothesize that there is an overlap between inflammatory responses observed in these mycobacterial diseases and those observed in RA. Therefore, we determined the association between serial IP-10 serum levels and achieving DMARD-free sustained remission as well as disease activity scores (DAS)-remission.
Objectives: To 1) assess the association between IP-10 levels over time in patients that have persistent RA versus patients that achieve DMARD-free sustained remission, and 2) determine the association between IP-10 levels and DAS.
Methods: 139 serum samples of 34 RA-patients (1987-criteria), obtained at the time of diagnoses and at yearly intervals thereafter, were studied. 15 patients had persistent RA and 19 patients achieved DMARD-free sustained remission after a median follow up of 2.7 years. IP-10 serum levels were measured using a previously developed, user-friendly lateral flow assay. Baseline and change in IP-10 levels over time were compared between patients with persistent RA and those achieving DMARD-free sustained remission. The association between the change in IP-10 level and the change in DAS was studied; in addition the course of the absolute IP-10 levels and the DAS over time was plotted for individual patients.
Results: IP-10 serum levels varied from 316 – 53,685 pg/ml between RA-patients. Patients that had persistent arthritis or achieved DMARD-free sustained remission over time did not differ in baseline IP-10 levels (median persistent RA 1991 pg/ml and median DMARD-free sustained remission 3292 pg/ml, p=0.19). However, a significant decrease in IP-10 levels over time was observed in patients achieving DMARD-free sustained remission (p=0.003), whereas IP-10 levels remained stable in patients with persistent RA. Changes in IP-10 levels correlated well with changes in DAS scores (p=0.05). Also at the level of individual patients, a strong correlation between IP-10 levels and DAS over time was observed.
Conclusions: These longitudinal data indicate that IP-10 levels are associated with perseverance of RA as well as with disease activity. Rapid diagnostic tests measuring IP-10 levels can therefore be helpful in monitoring of RA patients.

THU0043 TARGETED MEDICINE: THERAPEUTIC USE OF FUNCTIONAL CYTOKINE ASSAYS IN COMPLEX INFLAMMATORY ARTHRITIS

E.E.P. Htut[1], L. Ceron-Gutierrez[2], R. Doffinger[2,3], J. Rees[1]. *[1]Rheumatology; [2]Immunology, Addenbrooke's Hospital; [3]National Institute of Health Research, Cambridge Biomedical Research Centre, Cambridge, United Kingdom*

Background: Functional cytokine assays have been limited to experimental models of inflammatory arthritis without translation into clinical therapy.
Objectives: To illustrate the successful use of functional cytokine assays in providing targeted treatment for complex inflammatory arthritis.
Methods: A 24 year old male presented in 2014 with a florid asymmetrical polyarthritis associated with an elevated acute phase response (ESR 50, CRP 42, ALP 132). He had no history of psoriasis, inflammatory bowel or eye disease and no family history.
Vasculitis and viral arthritis screen, ACE, ANA, Anti dsDNA, RF and CCP were negative. He was positive for HLA B27 without evidence of spondyloarthropathy on imaging. He was noted to have a monoclonal gammopathy of uncertain significance with normal bone profile, unremarkable urinary BJP and whole body CT scan. His joint symptoms responded to corticosteroid therapy with the addition of hydroxychloroquine and methotrexate. In 2015, his clinical condition had significantly deteriorated with worsening joint inflammation, 3 kg weight loss with a sudden rise in acute phase response, without proven infection. His functionality declined with long term sickness from work.
Biochemical tests revealed: Hb 123, MCV 87.2, Plt 393, Neutrophil 7.76, ESR 86, Alb 31, Calcium 2.68, ALP 387 (noted to be of bony origin), CRP 286, Ferritin 1161, PT 13, and APTT 39. Renal function, protein electrophoresis, blood film, haemolytic screen, viral and autoimmune liver screens were unremarkable. Hydroxychloroquine and methotrexate were temporarily with-held at this stage, although he was maintained on prednisolone 20 mg, with a partial response in his joint symptoms. An infiltrative pathology was a concern and was subsequently excluded.
The next therapeutic step would have been an anti-TNF agent. Nevertheless, due to his atypical and complex disease course, cytokine assays were performed to further characterise his disease profile and provide targeted treatment. Results showed an elevated IL6 production; IV Tocilizumab was selected for the treatment of his inflammatory arthritis. He has had a remarkable response in terms of his systemic and joint symptoms as well as considerable biochemical improvement. He was able to de-escalate his corticosteroid regime and return to work.
Results: TNF alpha, IL1 beta, and IL-6 are important inflammatory mediators and targets of intervention in the treatment of Rheumatoid arthritis. They may be induced *in vivo* and *in vitro* using Toll like receptor mediated innate activation. Active Whole Blood Cytokine Profiling was performed for the patient and compared to healthy controls. Innate activation of whole blood with various TLR agonists including LPS (TLR4), PAM3 (TLR1/2), Imiquimod (TLR7) revealed low induction of TNF alpha and IL1 beta in the patient when compared to controls. In contrast, the patient showed an elevated IL-6 production. Patient's cytokine levels in serum and in non-activated whole blood were normal.
Conclusions: Our case highlights the potential progression to personalised medicine in achieving optimal patient outcome delivered in a cost-effective way. Functional cytokine assays in the appropriate context and within selected patient groups can help to achieve disease remission by allowing targeted treatment.

THU0044 CHONDROITIN SULPHATE INHIBITS MONOCYTE CHEMOATTRACTANT PROTEIN-1 RELEASE FROM 3T3L1 ADIPOCYTES: A NEW TREATMENT OPPORTUNITY FOR OBESITY-RELATED METABOLIC SYNDROMES?

E. Montell[1], T.V. Stabler[2], V.B. Kraus[3]. *[1]Pre-Clinical R&D Area, Bioiberica, Barcelona, Spain; [2]Duke Molecular Physiology Institute; [3]Duke Molecular Physiology Institute. Division of Rheumatology, Duke University School of Medicine, Durham, United States*

Background: Monocyte chemoattractant protein-1 (MCP-1) overproduction from inflamed adipose tissue is a major contributor to obesity-related metabolic syndromes. We have recently published that chondroitin sulphate (CS) can attenuate the monosodium urate (MSU) crystal mediated THP-1 macrophage inflammatory response reflected by reduced release of pro-inflammatory cytokines IL-1β and TNFα. We have also recently determined that the CS inhibitory effect is not acting at the inflammasome but upstream, most likely by inhibiting activation of NF-κB.
Objectives: We sought to determine whether CS had a similar inhibitory effect on MCP-1 release from lipopolysaccharide (LPS) stimulated adipocytes.
Methods: We cultured 3T3-L1 embryonic fibroblasts and induced their differentiation into adipocytes using an established protocol. We then treated the adipocytes with LPS to induce inflammation and thus MCP-1 release. At the same time we added varying concentrations of CS (Bioibérica, Spain) in a physiologically relevant range (10–200 μg/ml) and 24h after we measured MCP-1 release (R&D Systems, Minneapolis, MN, USA). We also cultured THP-1 monocytes and tested whether CS (200 μg/ml) could inhibit cell migration induced by human recombinant MCP-1. Monocyte chemotaxis in response to 24h exposure to

varying concentrations (0, 3.125–100 ng/ml) of recombinant human MCP-1 (R&D Systems) was tested using the CytoSelect 96-well cell migration assay (Cell Biolabs, San Diego, CA, USA). All experiments were run a single time with each treatment group run in triplicate. After normalization for cell viability, cell culture results were expressed as fold change from the media only negative control (no CS, no LPS). One-way ANOVA with Bonferroni's post-hoc test and post-hoc linear trend were performed on cell culture results using Graphpad Prism software (La Jolla, CA, USA).

Results: We found that LPS (1μg/ml) caused a significant rise in MCP-1 release ($p<0.0001$) from 3T3-L1 adipocytes. CS in physiologically achievable concentrations (100–200 μg/ml) produced a dose dependent reduction ($p<0.01$ at 100 μg/ml and $p<0.001$ at 200 μg/ml) of MCP-1 release from 3T3-L1 adipocytes in response to LPS. Recombinant MCP-1 (25–100 ng/ml) caused a dose dependent increase ($p<0.001$ at 25ng/ml and $P<0.0001$ at 100ng/ml) in cell migration of THP-1 monocytes. CS at the highest test concentration (200 μg/ml) had no effect on MCP-1 mediated THP-1 migration.

Conclusions: Our data demonstrate that CS inhibits the release of MCP-1 from 3T3-L1 adipocytes that have been stimulated with LPS, but has no effect on the chemotactic action of MCP-1 on THP-1 monocytes. Furthermore, our work data strongly suggests that it is the inhibition of MCP-1 release by CS that underlies this effect and not a direct inhibition of the chemotactic action of MCP-1 by CS. Given the importance of MCP-1 over-production in obesity-related metabolic syndromes, inhibiting the release of MCP-1 from adipocytes by CS, and thus blocking the recruitment of macrophages to adipose tissue, could provide a new treatment opportunity for these syndromes.

THU0045 IL-21 AND IL-22 ARE INVOLVED IN BONE DESTRUCTION IN RHEUMATOID ARTHRITIS PATIENTS

E. Kuca-Warnawin[1], W. Kurowska[1], A. Radzikowska[1], G. Pracon[2], T. Burakowski[1], M. Olszewska[3], I. Slowinska[4], I. Sudol-Szopinska[2], W. Maslinski[1]. *[1]Department of Pathophysiology and Immunology; [2]Department of Radiology; [3]Department of Anesthesiology and Intensive Care; [4]Department of Rheumoorthopaedic Surgery, National Institute of Geriatrics, Rheumatology, and Rehabilitation, Warsaw, Poland*

Background: Inflammatory process in bone marrow (BM) observed on MRI scans of rheumatoid arthritis (RA) patients (called bone marrow oedema) was shown to proceed joint destruction in RA. Our previous studies supported the concept that BM actively participate in the pathogenesis of RA by TLR triggered B cell activity (1), increased number of activated T cells and increased level of proinflammatory cytokines (2,3). Cytokines play a key role in the bone destruction of rheumatoid arthritis.

Objectives: To investigate the levels of IL-21 and IL-22 in RA BM plasma and their association with bone destruction.

Methods: BM samples were obtained from RA and osteoarthritis (OA) patients during total hip replacement surgery. Levels of IL-17AF, IL-21, IL-22, RANKL and cathepsin K in BM plasma were determined by specific ELISA tests. We analyzed pelvic radiographs of 22 patients with RA admitted to the NIGRR and subjected to total hip replacement. Radiographs were taken a day or two before surgery. In our study we assessed hip joint changes semi-quantitatively with the use of the proposed scoring system including primary RA (juxta-articular osteoporosis, axial joint space narrowing, inflammatory cyst presence, bony erosion) and late RA changes (axial migration of the femoral head, femoral head deformation, avascular necrosis of femoral head, femoral head subluxation).

Results: We found increased levels of activated T cell associated cytokines IL-21 (924.8 pg/ml vs 688.6 pg/ml, $p<0.05$) and IL-22 (94.5 pg/ml vs 65.8 pg/ml, $p<0.05$) in BM plasma of RA patients in comparison to osteoarthritis (OA) patients. Interestingly levels of both of these cytokines strongly correlated positively with concentration of osteoclastogenesis/osteoclast activity marker RANKL and cathepsin K. Surprisingly level of IL-17AF did not correlate with RANKL or cathepsin K. Furthermore, concentration of IL-21 was statistically significantly higher in patients with more severe radiologically assessed bone destruction. Median value of concentration of IL-21 in RA patients with small bone destruction was 797.4 pg/ml, with mild bone destruction was 1037.8 pg/ml, with severe bone destruction (1079.0 pg/ml).

Conclusions: Our results show an association between BM plasma levels of IL-21 and IL-22 and bone destruction, supporting the hypothesis that IL-21 and IL-22 are important pathogenic factors of this disease. Therapy targeting IL-21 and IL-22 may be of value in preventing bone erosions in patients with RA.

THU0046 CALCIUM PYROPHOSPHATE AND MONOSODIUM URATE CRYSTAL-INDUCED PROSTAGLANDIN E2 PRODUCTION INVOLVES NF-κB ACTIVATION AND ROS PRODUCTION, INDEPENDENTLY OF INTERLEUKIN-1BETA AXIS

F. Renaudin[1,2], L. Campillo-Gimenez[1], C. Combes[3], M. Gosset[4], M. Cohen-Solal[1,5], F. Lioté[1,5], H.-K. Ea[1,5]. *[1]UMR1132, Bioscar, Inserm; [2]University Paris Diderot, Paris; [3]CIRIMAT, Université de Toulouse, INPT, UPS, CNRS, Ensiacet, Toulouse; [4]EA 2496, UFR Odontologie, Paris Descartes, Montrouge; [5]Service de Rhumatologie, centre Viggo Petersen, AP-HP, hôpital Lariboisière, Paris, France*

Background: Monoclinic and triclinic calcium pyrophosphate dihydrated (mCPPD and tCPPD) and monosodium urate (MSU) crystals are responsible in human for relapsing acute arthritis. CPP and MSU crystal-triggered inflammation depends on several inflammatory mediators including interleukin (IL)-1β and prostaglandin (Pg) E2. IL-1β production is governed by NF-κB, NLRP3 inflammasome and caspase-1 activation. PgE_2 derives from arachidonic acid (AA) synthesis, which is regulated by cytosolic phospholipase A2 ($cPLA_2$), and cyclooxygenase-(COX) 2 activation. CPP crystal-induced IL-1β production is well documented, but CPP crystal-induced PgE2 production remains unclear.

Objectives: To evaluate how CPP crystals induce PgE_2 production and the role of IL-1β in this process.

Methods: Synthetic and pyrogen-free m-CPPD, t-CPPD and MSU crystals were used to stimulate human monocyte cell line (THP-1 cells) and primary bone marrow-derived macrophages (BMDM) of wild type (wt) and NLRP3 inflammasome deficient ($nlrp3^{-/-}$) mice. Pharmacological inhibitors were used to assess the role of oxidative stress (N-acetyl-L-cysteine, NAC) and NF-κB pathway (Bay-117085). PgE_2 and IL-1β production were quantified by ELISA, gene expression by qRT-PCR, $cPLA_2$ by immunoblot. NF-κB activation was assessed in THP-1 cells containing a reporter gene under control of NF-κB p65 promotor. *In vivo*, CPP crystal-induced PgE2 production was evaluated in the air pouch model in the presence or not of NF-κB inhibitor or NAC.

Results: *In vitro*, m- and t-CPPD and MSU crystals rapidly induced the production of PgE_2 and IL-1β by THP-1 cells and BMDM. PgE_2 production was associated with $cPLA_2$and NF-κB activation along with increased expression of COX-2 (20 fold) and its receptor EP2 and EP4 genes. While CPP crystal-induced IL-1β production was abolished in THP-1 cells by treatment with caspase-1 inhibitor and in $nlrp3^{-/-}$ BMDM, CPP crystal-induced PgE_2 was not modified suggesting IL-1β- and NLRP3-independent pathways. Interestingly, CPP crystal-induced PgE_2 production was completely abrogated by NF-κB inhibitor treatment and significantly decreased by the antioxidant NAC; in both case, COX-2 gene expression was dramatically inhibited. *In vivo*, treatment with NAC or Bay strongly inhibited IL-1β and PgE_2 production and cellular infiltrate induced by CPP crystals.

Conclusions: PgE_2 production mediated by CPP and MSU crystals is activated by NF-κB signaling, independently of NLRP3/IL-1β production axis. Moreover, ROS production, known as a NLRP3 activator in response to CPPD or MSU crystals, is also involved in the regulation of PgE_2 production. The relations between these different pathways are under investigation.

THU0047 RESVERATROL AND ITS PRECURSOR POLYDATIN INHIBIT CRYSTAL-INDUCED INFLAMMATION IN VITRO BY DECREASING OXIDATIVE STRESS AND IL-1BETA ACTIVATION PATHWAY

Y. Zamudio-Cuevas[1], F. Oliviero[2], E. Belluzzi[2], A. Scanu[2], L. Andretto[2], P. Galozzi[2], M. Favero[2], R. Ramonda[2], P. Spinella[3], G. Ravagnan[4], A. Lopez-Reyes[5], L. Punzi[2]. *[1]Instituto Nacional de Rehabilitación, Mexico City, Mexico; [2]Rheumatology Unit, University of Padova; [3]Clinica Nutrition Unit, University of Padova, Padova; [4]Istituto di Farmacologia Traslazionale (IFT) – CNR, Roma, Italy; [5]Instituto Nacional de Rehabilitación, Mexico City, Mexico*

Background: Resveratol (RES) and its natural precursor polydatin (PD) are polyphenol compounds that display a broad variety of beneficial effects including anti-apoptotic and anti-inflammatory properties.

Objectives: This study aimed to investigate the role of RES and PD in the inflammatory process induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals in vitro. Their effect was evaluated though IL-1β, NLRP3 inflammasome, reactive oxygen species (ROS), nitric oxide (NO) and the phagocytosis index assessment.

Methods: A monocytic cell line (THP-1) was primed for 3 hours with phorbol myristate acetate (PMA) (100ng/ml) and stimulated with synthetic MSU (0.05mg/ml) and CPP (0.025mg/ml) crystals. RES and PD were added to cultures at, respectively, 100μM and 200μM. Experiments were carried out either adding RES and PD along with crystals, or pretreating cells (2 hs) with polyphenols and removing them before crystal stimulation. IL-1β were evaluated in cell supernatants and at intracellular level by ELISA assay. IL-1β and NLRP3 expression was assessed by RT-PCR. Reactive oxygen species (ROS) and NO were measured by cytometric analysis using fluorogenic probes (CellROX Deep Red Reagent and DAF-FM, respectively). Crystal phagocytosis index was calculated at different time points using polarized light microscopy.

Results: RES and PD inhibited IL-1b induced by crystals both at extracellular

and intracellular level. This inhibition was more pronounced after polyphenol cell pretreatment. In this case cytokine production was completely suppressed both in control and in stimulated cells. Cell pretreatment was extremely effective also in reducing mRNA expression of IL-1 after crystal stimulation while NLRP3 expression was to some extent affected by RES. RES and PD had a slight inhibitory effect on crystal phagocytosis when added along with the stimulus, while pretreated cells did not show any difference in the phagocytosis index. ROS production induced by MSU crystals was more pronounced (4 fold increase) with respect to CPP crystals (2 fold increase). RES was more effective than PD in inhibiting ROS production ($p<0.05$ crystals vs crystals+RES). The pretreatment showed a more marked decrease of ROS than the simultaneous treatment and the effect reached significance for both PD and RES. Similar inhibitory effects have been obtained when NO production was considered.

Conclusions: Our results demonstrated that RES and PD are effective in inhibiting crystal-induced inflammation affecting IL-1 production and NLRP3 expression and activation. Data obtained after cell pretreatment allow us to hypothesize that these polyphenols act on specific signaling pathway preventing inflammation, and that this action is independent from crystal phagocytosis.

THU0048 SOLUBLE URIC ACID INCREASED THE EXPRESSION OF ABCG2 AND PDZK1 IN HUMAN INTESTINAL CELL LINES THROUGH THE TLR4/NLRP3/CASPASE-1 AND PI3K/AKT SIGNALING PATHWAYS

M. Chen, X. Lu, H. Wu. *Department of Rheumatology, the Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou, China*

Background: Hyperuricemia is the key pathophysiological basis of gout[1]. The most common reason generating hyperuricemia is verified the obstacle of urate excretion by current researches[2]. The intestine is known as the most important organ involved the excretion of uric acid besides the kidney[1]. ABCG2 has an outsized genetic contribution to extra-renal underexcretion and causes a compensatory increase in urinary urate output[3]. PDZK1 is a kind of an important structural protein regulated ABCG2 function, by potential molecular interaction with ABCG2[4].

Objectives: The present study was undertaken to explore the effect and its related mechanisms of soluble uric acid on the urate excretion PDZK1 and ABCG2 in HT-29 and Caco-2 cell lines

Methods: HT-29 and Caco-2 cell lines were used as a well-established model of human intestinal epithelial cells. Cells were pretreated with or without inhibitors and then stimulated with soluble uric acid. siRNA transfection was used to assess the interaction between ABCG2 and PDZK1. qRT-PCR and western blotting were used to measure mRNA and protein levels, respectively. Subcellular fractionation methods and immunofluorescence were used to examine the proteins in different subcellular compartments. Flow cytometry experiments examined the function of ABCG2.

Results: Soluble uric acid significantly up regulated the expression of PDZK1 and ABCG2 in human intestinal cell lines. It also activated TLR4/NLRP3/caspase-1 inflammasome and PI3K/AKT signalling pathway through the phosphorylation of the ser473 pAkt. The increased expression of PDZK1 and ABCG2 was suppressed by a block of TLR4 (TAK-242) and caspase-1 inhibitor (acetyl–YVAD–chloromethylketone) and partly reduced by wortmanning, a specific inhibitior of PI3K. Additionally, lipopolysaccharide (LPS), the potent inducer of inflammatory responses mediated through TLR4, activated TLR4/NLRP3/caspase-1 inflammasome and up regulated the expression of ABCG2 and PDZK1. Besides, the stimulation of soluble uric acid facilitated the translocation of ABCG2 from intracellular compartment to plasma membrane and increased the transport activity. Furthermore, PDZK1 knockdown via siRNA significantly inhibited the expression and transport activity of ABCG2 regardless of the activation by soluble uric acid.

Conclusions: The PI3K/AKT and TLR4/NLRP3/caspase-1 signaling pathways modulate ABCG2 and PDZK1 expression stimulated by soluble uric acid in human intestinal cells. PDZK1 plays a pivotal role in the regulation of ABCG2.

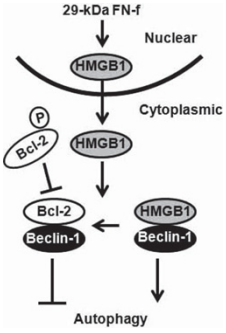
THU0049 29-KDA FIBRONECTIN FRAGMENT SUPPRESSED HMGB1-DEPENDENT AUTOPHAGY PATHWAY IN HUMAN ARTICULAR CHONDROCYTES



M. Choi[1], I.Y. Park[1], K.M. Son[2], H.S. Hwang[1], H.A. Kim[1]. *[1]Hallym University Sacred Heart Hospital; [2]Hallym University Dongtan Sacred Heart, Gyeonggi-do, Korea, Republic Of*

Background: Fibronectin fragments found in synovial fluid induce the catabolic responses in cartilage. High mobility group protein Box 1 (HMGB1), a damage-associated molecular pattern (DAMP), resides in the nucleus, translocates into the cytosol in response to various stimuli, and is subsequently released into the extracellular space.

Objectives: In this study, we investigated the effect of 29-kDa fibronectin fragment (29-kDa FN-f) on HMGB1-mediated autophagy pathway in primary human chondrocytes.

Methods: Human articular chondrocytes were enzymatically isolated from articular cartilage. The mRNA and protein levels of HMGB1 were measured by quantitative real-time PCR (qRT PCR) and Western blot analysis. The translocation of nuclear HMGB1 into cytoplasm was determined by western blot and immunofluorescence microscopy. Activation of mammalian target of rapamycin (mTOR), protein kinase B (Akt) and 1A/1B-light chain 3 (LC3) was measured by western blot analysis. Interaction of HMGB1 and Beclin-1 were evaluated by immunoprecipitation (IP). Release of HMGB1 into extracellular medium was measured by ELISA.

Results: HMGB1 was significantly reduced in human osteoarthritis (OA) cartilage compared to normal cartilage. qRT PCR and Immunoblotting assay revealed that 29-kDa FN-f significantly reduced expression of HMGB1 at the mRNA and protein levels and also led to the translocation of the nuclear HMGB1 into the cytoplasm, together with decreased levels of Beclin-1 and phosphorylated Bcl-2. Using IP analysis, we demonstrated that in the presence of 29-kDa FN-f the association of HMGB1 and Beclin-1, which led to HMGB1-dependent autophagy pathway, was decreased, whereas the association of Bcl-2 and Beclin-1 was increased. In addition, prolonged treatment with 29-kDa FN-f significantly increased the release of HMGB1 into the culture medium. A variety of evidence, including down-regulated LC3-II, an autophagy marker, and increased phosphorylated 4EBP1 and p70S6K, substrates of mTOR, revealed that 29-kDa FN-f subsequently suppressed autophagy in primary chondrocytes by activating Akt/mTOR signaling pathway.

Conclusions: These results demonstrated that 29-kDa FN-f has a harmful impact on chondrocytes through suppressing HMGB1-dependent autophagy pathway and releasing HMGB1, DAMP, to extracellular space.

THU0050 MICRORNA-365 INHIBITS IL-1β-INDUCED CATABOLIC FACTOR EXPRESSION BY TARGETING HIF-2α IN HUMAN PRIMARY CHONDROCYTES

M.H. Lee[1], J.-I. Hong[1], H.S. Hwang[1], K.M. Son[2], H.A. Kim[1]. *[1]Hallym University Sacred Heart Hospital, Kyunggi; [2]Hallym University Dongtan Sacred Heart Hospital, Gyeonggi, Korea, Republic Of*

Background: MicroRNAs, small noncoding RNA molecules, are involved in the pathogenesis of various diseases such as cancer and arthritis. Endothelial PAS

domain protein-1/hypoxia-inducible factor-2α (EPAS-1/ HIF-2α) is a catabolic transcription factor that regulates osteoarthritis (OA) cartilage destruction.
Objectives: In this study, we examined whether microRNA-365 (miR-365) affects interleukin (IL)-1β-induced expression of catabolic factors in chondrocytes via regulation of HIF-2α.
Methods: Total RNA was isolated from normal and OA cartilage tissues and human chondrocytes. miR-365 expression was quantified by TaqMan assay. The effects of miR-365 on HIF-2α and HIF-2α-modulated genes were assessed by quantitative real-time reverse polymerase chain reaction (qRT-PCR), Western blot analysis, and enzyme-linked immunosorbent assay (ELISA). Direct interaction of miR-365 with the 3' untranslated region (UTR) of HIF-2α mRNA was examined using a luciferase reporter assay. Nitrite concentration was measured in culture medium using a Griess assay.
Results: miR-365 levels were significantly decreased in human OA cartilage relative to normal cartilage. Overexpression of miR-365 significantly suppressed IL-1β-induced expression of HIF-2α in human articular chondrocytes. Pharmacological inhibition of various IL-1β-associated signaling pathways revealed mitogen-activated protein kinase and nuclear factor-κB as the primary pathways driving IL-1β-mediated decreases in miR-365 and subsequent increase in HIF-2α expression. Using a luciferase reporter assay encoding the 3'UTR of human HIF-2α mRNA, we showed that overexpression of miR-365 significantly suppressed IL-1β-induced up-regulation of HIF-2α. Furthermore, miR-365 overexpression significantly suppressed IL-1β-induced expression of catabolic factors, including cyclooxygenase-2, inducible nitric oxide synthase, and matrix metalloproteinase-1, -3 and -13, and nitric oxide (NO) production in chondrocytes.

Conclusions: MiR-365 regulates IL-1β-stimulated catabolic effects in human chondrocytes by modulating HIF-2α expression.

THU0051 ASSOCIATION BETWEEN BIOACTIVE TNF AND EULAR RESPONSE TO TNF INHIBITORS IN RHEUMATOID ARTHRITIS

J. Poudroux[1], H. Marotte[1], J.-E. Gottenberg[2], S. Paul[3]. *[1]Rheumatology, CHU Saint Etienne, Saint Priest en Jarez; [2]Rheumatology, CHU Strasbourg, Strasbourg; [3]Immunology, CHU Saint Etienne, Saint Priest en Jarez, France*

Background: ROC study provided data to manage rheumatoid arthritis (RA) treatment after a failure to a first TNF blocker (1). We previously reported that high circulating TNF bioactivity was associated with good clinical response (2).
Objectives: To explore ability of TNF bioactivity to predict response to second TNF blocker.
Methods: Here, we assessed TNF bioactivity in 130 RA patients from the group rotation to a second TNF blocker at the time of randomisation and after 6 months. Clinical and biological data were recorded at baseline and 6 month with Eular response assessed at 6 month.
TNF bioactivity was assessed with HEK-Dual TNF cells adapted from our previous work (2). Due to non-normalised distribution, non parametrical analysis were performed.
Results: Baseline circulating TNF bioactivity was similar according to Eular response. However, circulating TNF bioactivity at 6 month was associated with clinical response with low TNF bioactivity in responders. A ROC analysis suggested a cut-off at 0.320 with a sensitivity at 92% and a specificity at 41%.
Conclusions: After a failure of a first TNF blocker, circulating TNF bioactivity is not able to predict response to a second TNF blocker despite a lower level in responders compared to non-responders.

THU0052 LEVELS OF INFLAMMATORY SEROLOGIC BIOMARKERS IN HLA-B27 AND HLA-B15 POSITIVE PATIENTS WITH SPONDYLOARTHRITIS

J. Londono[1], A.M. Santos[2], J.C. Rueda[2], P. Peña[2], I. Briceño[3], E.-L. Saldarriaga[2], J.-I. Angarita[2], E. Calvo[4], M. Avila[2], N. Martinez-Rodriguez[5], H. Cubides[2], V. Parra[2], J.F. Medina[6]. *[1]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá; [2]Reumatología; [3]Faculltad de Medicina, Grupo Genética Humana, Universidad de la Sabana, Chia; [4]Departamento de Imágenes diagnósticas, Universidad Nacional, Bogotá, Colombia; [5]Departamento de Investigación de Salúd Comunitaria, Hospital Infantil de México Federico Gomez, Ciudad de Mexico, Mexico; [6]Unidad de Entrenamiento Clínico, Facultad de Medicina, Universidad de Navarra, Pamplona, Spain*

Background: A main challenge in spondyloartritis (SpA) management was the availability of reliable biomarkers related with disease activity, or predicting joint damage and the response to treatment. Although erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are currently used as biomarkers for disease activity, they lack sensitivity, specificity and reproducibility. With the understanding of SpA pathogenesis, additional biomarkers like metalloproteinase 3 (MMP-3), interleukin (IL)-1a, IL-6, lipopolysaccharide-binding protein (LBP), tumour necrosis factor a (TNFa), macrophage colony stimulating factor (M-CSF), interferon gamma (INF-g), IL-17 and IL-23, had been proposed
Objectives: We aimed to evaluate the associations of MMP-3, IL-1a, IL-6, M-CSF, LPB, IL-17 and IL-23 levels in SpA patients positive for HLA-B27 or HLA-B15
Methods: 178 patients (100 men and 78 women) with SpA according to ASAS criteria were included in the study. HLA typing was performed by PCR using the Biorad® HLA-SSP ABDR plates. The levels of TNFa, IL-1a, IL-6, INF-g and IL-17 were measured by a cytometric bead-array (CBA Flex Set) using a FACS Canto II Flow CytometerÔ. Enzyme-linked immunosorbent assay (ELISA) was used to determine serum levels of IL-23, M-CSFand MMP-3. CRP and LBP levels were measured by chemiluminescence. Statistical analysis was made with SPSS v19. For comparison of quantitative variables with a normal distribution we used the Student's *t*-test. Categorical variables were presented in frequency charts and percentages, and the Chi-squared test and Fisher's exact test were used when necessary, for comparing groups. Two-tailed P-value <0.05 was considered statistically significant
Results: Of the 178 patients, 70 were positive for HLA-B27, 34 for HLA-B15 and 74 had other HLA-B. According to ASAS classification criteria, 152 patients had axial SpA (axSpA) manifestations, 161 had peripheral SpA (pSpA) manifestations, and 148 patients had mixed axial and peripheral manifestations. Figure 1 shows the mean levels of inflammatory serologic biomarkers in these subgroups of patients

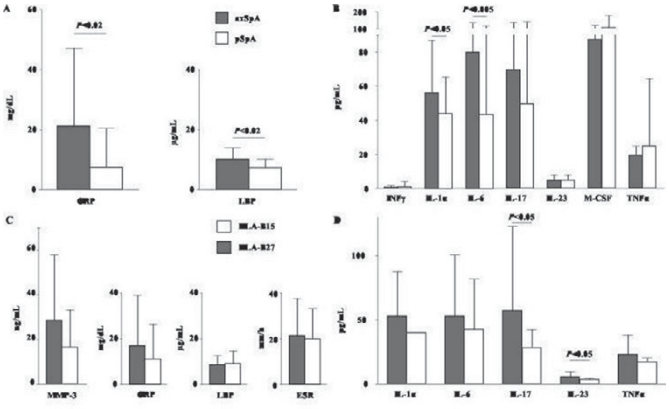

Figure 1. A. Disease activity biomarkers (CRP: C-reactive protein; LBP: lipopolysaccharide-binding protein) in axial spondyloarthritis (axSpA) and peripheral spondyloarthritis (pSpA); B. Cytokines (INFγ: interferon gamma; IL: interleukin; M-CSF: macrophage colony stimulating factor; TNFα: tumour necrosis factor alpha) in axSpA and pSpA; C. Disease activity biomarkers (MMP-3: metalloproteinase 3; ESR: erythrocyte sedimentation rate) in HLA-B27 and HLA-B15 positive SpA patients, D. Cytokines in HLA-B27 and HLA-B15 positive SpA patients

Conclusions: High levels of IL-17 and IL-23 were associated with the presence of HLA-B27, which mainly correlates with an axial presentation of the disease as

compared to HLA-B15 patients. Accordingly, the genotype (presence of HLA-B27 or HLA-B15) and phenotype (axial or peripheral involvement) may help physicians when considering a targeted therapy of SpA patients with IL-17 inhibition in a context of personalized medicine

THU0053 SELECTIVE ACTIVATION OF AN AMPK-CREB-NRF2-DEPENDENT PATHWAY BY CELECOXIB INDUCES VASCULOPROTECTIVE GENES AND MITIGATES AGAINST CARDIOVASCULAR RISK

F. Alrashed, D. Calay, C.C. Thornton, A. Bauer, A. Kiprianos, D.O. Haskard, A. Seneviratne, J.J. Boyle, J.C. Mason. *Rheumatology and Vascular Sciences, Imperial College London, London, United Kingdom*

Background: Although concern remains about the athero-thrombotic risk posed by COX-2-selective inhibitors (COXIBs), the recent PRECISION trial demonstrated non-inferiority of moderate dose celecoxib when compared to naproxen and ibuprofen with respect to cardiovascular safety, with fewer actual CV events recorded for celecoxib. Moreover, celecoxib proved significantly safer than either comparator in regard to gastrointestinal events[1]. Given the markedly different cardiovascular risk associated with celecoxib and rofecoxib, we investigated the hypothesis that, in addition to cyclo-oxygenase inhibition, celecoxib specifically activates COX-2-independent AMP kinase (AMPK) signalling to exert protective effects in the vascular endothelium.

Objectives: To investigate COX-2-independent vasculoprotective signalling pathways activated by celecoxib in human endothelium.

Methods: *In vitro* studies of celecoxib, rofecoxib, ibuprofen and naproxen were performed on human umbilical vein and human aortic endothelial cells (HUVEC and HAEC). Inhibition of signalling pathways was achieved using siRNA. The vascular effects of celecoxib *in vivo* were studied in C57Bl/6 mice fed celecoxib (1000 ppm) or control chow (48 hrs). Aortic tissue was snap-frozen and sections studied by immunofluorescence confocal microscopy.

Results: At therapeutically relevant concentrations celecoxib (1–10μ M) induced the vasculoprotective protein heme oxygenase-1 (HO-1) in HUVEC and HAEC (EC) ($p<0.01$). In contrast, rofecoxib and the commonly used non-selective NSAIDs ibuprofen and naproxen failed to induce HO-1. Celecoxib derivative 2,5-dimethyl-celecoxib (DMC), which lacks COX-2 inhibition, also upregulated HO-1, implicating a COX-2-independent mechanism. Immunoblotting demonstrated that celecoxib and DMC induce AMPK$\alpha^{(Thr172)}$ and CREB-1$^{(Ser133)}$ phosphorylation leading to Nrf2 nuclear translocation ($p<0.05$). These responses were not seen with ibuprofen or naproxen, while siRNA depletion of AMPKα abrogated celecoxib-mediated CREB and Nrf2 activation ($p<0.05$). Acting via the same pathway, celecoxib induced additional cytoprotective genes including H-ferritin. *In vivo*, celecoxib similarly increased HO-1 and H-ferritin in murine aortic endothelium when compared to control-fed mice ($p<0.05$). Functionally, celecoxib treatment inhibited TNF-α-induced NF-κB p65$^{(Ser536)}$ phosphorylation by increasing AMPK activity. This attenuated VCAM-1 upregulation via induction of HO-1, as revealed by HO-1 siRNA ($p<0.05$). Similarly, celecoxib prevented the IL-1-mediated increase of IL-6 mRNA ($p<0.01$). These responses were not seen with ibuprofen or naproxen.

Conclusions: Celecoxib induces anti-inflammatory, anti-oxidant proteins HO-1 and H-ferritin in human vascular endothelium via a novel AMPK-CREB-Nrf2-dependent pathway. This mechanism may contribute to the important and marked differences in cardiovascular risk between celecoxib and rofecoxib. Understanding mechanisms underlying NSAID heterogeneity may ultimately lead to the development of safer anti-inflammatory drugs.

THU0054 UTILITY OF SEROLOGICAL PARAMETERS IN GIANT CELL ARTERITIS FOR PREDICTING DISEASE COMPLICATIONS

K. Lakota[1,2], J. Feichtinger[3,4], B. Burja[1], T. Kuret[1], P. Žigon[1], Ž. Rotar[1], R. Ješe[1], S. Sodin-Šemrl[1,2], S. Čučnik[1,5], G. Thallinger[3,4], M. Tomšič[1,6], A. Hočevar[1]. *[1]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana; [2]FAMNIT, University of Primorska, Koper, Slovenia; [3]Institute of Molecular Biotechnology, Graz, Austria, Graz University of Technology; [4]OMICS Center Graz, BioTechMed Graz, Graz, Austria; [5]Faculty of Pharmacy; [6]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Background: Giant Cell Arteritis (GCA) is a systemic vasculitis affecting primarily large and medium sized arteries. Immediate high dose steroid treatment may prevent urgent complications, such as vision loss and cerebrovascular insults[1–3]. However, there is a clear lack of data on predicting serological markers and their association to clinical complications.

Objectives: To investigate serological parameters that support clinicians in predicting complications in a large, clinically well-characterized set of untreated GCA patients at time of diagnosis.

Methods: The study included 98 GCA patients (67% female) with a median (IQR) age 74.1 (67.3–78.8) years and a median (IQR) symptome duration time of 30 (20–90) days). Healthy blood donors (HDs, n=52, 61.5% female, median (IQR) age of 41.95 (20.4–63.1) years) served as controls. GCA complications studied were visual disturbances (including permanent loss of vision), relapses, peripheral artery involvement and claudication. Levels of 27 serum analytes were measured using Luminex xMAP Technology. Interleukin-6 (IL-6) and serum amyloid A (SAA) levels were tested using ELISA and nephelometry, respectively.

Results: The highest, significantly elevated analytes in GCA vs. HDs were SAA (85-fold > HDs mean values), IL-23 (63-fold) and IL-6 (11-fold). IL-13, α-fetoprotein and MMP-2 were significantly decreased in GCA, while levels of IL-2, IL-17A and TNF-α were unchanged. PCA analysis revealed a signature analyte profile positioning towards the HD cluster. SAA, CRP, haptoglobin, ESR, thrombocyte # and matrix metalloproteinase-1 (MMP-1) all negatively associated with visual disturbances, confirming our previous data. Age showed significant association to permanent visual loss, with older patients being more affected[3]. SAA, CRP and ESR at presentation were found to be predictive of relapsing disease, while MMP-2 negatively associated with relapse. VCAM-1, α-fetoprotein, MARCO and IL-27 were all negatively associated with peripheral artery involvement. MMP-2 and MARCO showed positive association with claudication, while IL-18 was negatively associated.

Conclusions: In our large study of untreated GCA patients we highlight the importance of using serological acute phase parameters, MMPs and other analytes for predicting complications.

THU0055 LOW MOLECULAR WEIGHT BAFF SIGNALING INHIBITORS AMELIORATE IL-6, IL-10 AND IGG PRODUCTION IN VITRO AND IN VIVO MODELS OF AUTOIMMUNE DISEASES

K. Yoshimoto[1], K. Suzuki[1], K. Sugahara[2], T. Takeuchi[1]. *[1]Keio University School of Medicine, Tokyo; [2]Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan*

Background: In our previous study, we reported that soluble BAFF (sBAFF) robustly enhanced IL-6 production by peripheral monocytes of patients with primary Sjogren's syndrome (pSS) and that the expression level of a BAFF receptor (BR3) was significantly elevated in pSS monocytes. We also found that the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the serum IgG level of pSS patients. Investigation of the interaction of monocytes and B cells showed that IgG production by B cells was enhanced by sBAFF-stimulated monocytes. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in IgG overproduction by B cells which is often observed in pSS, and that BAFF signaling via BR3 is a possible therapeutic target to treat pSS. A high throughput screening of a low molecular weight compound library successfully discovered two pyrrolopryimidine derivatives, BIK12 and BIK13, which inhibit sBAFF binding to BR3. We found that these compounds inhibited not only IL-6 production by BAFF-stimulated monocytes, but also IgG production by B cells co-cultured with the monocytes.

Objectives: To elucidate the mechanism of inhibitory activities of these compounds on BAFF signaling pathways, we measured production of IL-10 as well as IL-6 by monocytes *in vitro*, both of which work for B cell activation. In addition, we analyzed *in vivo* effects of the compounds on production of autoantibody and cytokines in autoimmune disease model mice.

Methods: Peripheral monocytes and B cells were prepared from healthy individuals. The monocytes were stimulated with sBAFF and cultured *in vitro* with or without peripheral B cells in the presence of BIK-12 or BIK-13. The amounts of IL-6, IL-10 and IgG were measured by ELISA. BIK-13 was administered intraperitoneally to MRL/lpr mice, an animal model of autoimmune diseases, three times a week for 6 months. Serum levels of an anti-ds DNA antibody, IL-6 and IL-10 were measured by ELISA.

Results: sBAFF enhanced the production of not only IL-6, but also IL-10 by peripheral monocytes *in vitro*. As expected, BIK12 and BIK-13 significantly suppressed production of IL-6 and IL-10 by BAFF-stimulated monocytes *in vitro* in a dose dependent manner. Notably, IgG production by B cells co-cultured *in vitro* with sBAFF-stimulated monocytes was significantly suppressed by these compounds. The compounds did not exhibit toxicities to the cells in the dose range. These data suggest that BAFF signaling via BR3 lead to production of IL-6 and IL-10 in monocytes, and the cytokines in turn mediates the signal to B cells resulting in IgG overproduction. Interestingly, serum levels of an anti-dsDNA antibody, IL-6 and IL-10 in MRL/lpr mice received BIK13 simultaneously declined as compared to control mice. These data collectively suggest that the compound was also efficacious *in vivo*.

Conclusions: BIK-13, a pyrrolopyrimidine derivative, suppressed IgG production

by B cells through affecting monocytes. IL-6 and/or IL-10 may intermediate the effect. Our findings strongly suggest that BAFF signaling via BR3 is a possible therapeutic target for drug discovery to treat pSS or other intractable autoimmune diseases which accompany hypergammaglobulinemia. Moreover, these compounds may provide novel tools to explore the pathological mechanism of the development of these autoimmune diseases.

THU0056 FREE FATTY ACIDS PROMOTE INFLAMMATION VIA OSTEOBLASTS AND OSTEOCLASTS FROM PATIENTS WITH RHEUMATOID ARTHRITIS OR OSTEOARTHRITIS

K. Frommer[1], A. Schäffler[2], U. Lange[1], S. Rehart[3], J. Steinmeyer[4], M. Rickert[4], U. Müller-Ladner[1], E. Neumann[1]. *[1]Dept. of Internal Medicine and Rheumatology, Kerckhoff-Klinik, Justus-Liebig-University of Giessen, Bad Nauheim; [2]Dept. of Internal Medicine III, Endocrinology, Diabetes, Metabolism, Justus-Liebig-University of Giessen, Giessen; [3]Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt; [4]Dept. of Orthopaedics and Orthopaedic Surgery, University Hospital Giessen and Marburg, Giessen, Germany*

Background: Various inflammatory cardiovascular and metabolic diseases such as atherosclerosis, coronary heart diseases and type 2 diabetes are associated with chronically elevated free fatty acid (FFA) levels. With inflammation being a factor in pathological bone loss, FFA may also be contributors to bone loss in osteoarthritis (OA) and/or rheumatoid arthritis (RA).

Objectives: To investigate whether FFA have an influence on osteoblasts and osteoclasts from patients with RA or OA, in a way that may alter bone degradation in these diseases.

Methods: Primary osteoblasts (OB) were isolated from cancellous bone of OA and RA patients undergoing knee joint surgery. Osteoclasts (OC) were differentiated from peripheral blood mononuclear cells (PBMC). OB and OC were stimulated with the saturated FFA palmitic acid (PA) and the unsaturated FFA linoleic acid (LA) (100 μM each). Immunoassays were used to quantify protein secretion. mRNA expression levels were quantified by real-time PCR. Mineralization activity was quantified using Alizarin Red S staining, differentiated OC were quantified by counting TRAP-positive multinuclear cells (>2 nuclei). Toll-like receptor (TLR) 4 and TLR2 were blocked by neutralizing antibodies.

Results: When stimulated with FFA, OB from RA and OA patients secreted higher amounts of the proinflammatory cytokine IL-6 (up to 9-fold) and the chemokines IL-8 (up to 221-fold), GRO-a (from below detection level to detectable levels) and MCP-1 (up to 16-fold). Differences in the degree of response were more dependent on the patient than the disease. RANKL as well as OPG, OB-secreted modulators of OC differentiation, as well as OB differentiation markers (e.g. osterix, osteocalcin) were not influenced by FFA on mRNA or protein level. The effect of FFA on mineralization activity of OB varied between patients, yet overall there was no significant difference between FFA-treated and untreated OB. Expression of the two Wnt signaling molecules, axin-2 and b-catenin, was not changed by PA or LA, suggesting no involvement of the Wnt signaling pathway in the effects observed by FFA in OB. On the other hand, TLR4 blockade significantly reduced PA-induced IL-8 secretion by OB (by 93%), while blocking TLR2 had no effect. In both RA and OA OC, IL-8 secretion was significantly enhanced by PA and LA, with a clear time-dependency within the differentiation process for RA OC but not for OA OC. The number of TRAP positive multinuclear cells decreased for RA OC by approx. 50%, which was in agreement with the reduced TRAP secretion by a factor of 2–3 at d14. mRNA expression of various osteoclast activity markers (CLCN7, CTSK, TCIRG) was not altered.

Conclusions: Inflammation is promoted by FFA via both OB and OC from patients with RA or OA, thus possibly indirectly contributing to bone loss while no direct effect on OB/OC activity could be observed. In OB, these effects are probably mainly mediated by TLR4, while TLR2 and Wnt pathways do not play a role.

THU0057 LIPID PROFILING OF PLASMA IN RHEUMATOID ARTHRITIS PATIENTS BY LIQUID CHROMATOGRAPHY–TANDEM MASS SPECTROMETRY

K. Murakami[1], I. Murakami[1], A. Ioan-Facsinay[2], M. Giera[3], M. Hashimoto[4], A. Yoshida[1], T. Usui[1], N. Kuramoto[1], R. Nakashima[1], Y. Imura[1], H. Yoshifuji[1], K. Ohmura[1], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Rheumatology; [3]Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands; [4]Department of the Control for Rheumatic Diseases, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Background: Previously it has been described that lipid and lipid mediators are present in synovial fluid from patients with rheumatoid arthritis (RA). It is, however, currently unknown to what extent these lipid mediators are involved in disease pathophysiology.

Objectives: The aim of this study is to clarify which lipid mediators in plasma correlate with disease activity of RA.

Methods: We obtained blood from RA patients registered in the KURAMA (Kyoto University Rheumatoid Arthritis Management Alliance) cohort. None of the patients was treated with glucocorticoids or NSAIDs, both of which could affect lipid metabolism. Targeted lipidomics, using a LC–MS/MS (liquid chromatography–tandem mass spectrometry) platform was used for the identification of lipids present in the patients' plasma. SDAI (simplified disease activity index) was examined in this cohort and lipidomics profiling and disease status were combined. Data were statistically analyzed by Spearman's rank correlation coefficient test or multivariate regression analysis.

Results: Twenty-six RA patients were enrolled; female ratio: 84%, mean age: 63.0 years old, mean disease duration: 18.7 years and mean SDAI 5.26. In this group, patients age was significantly correlated with SDAI (p value =0.005, Spearman's rho =0.552). By LC-MS/MS analyses, 23 lipid components were identified and quantified. Multivariative regression analysis (Standard Least Squares) revealed that 19,20-diHDPA (Dihydroxydocosapentaenoic acid) and 14,15-diHETE (Dihydroxyeicosatetraenoic acid) significantly explained SDAI score independently of sex and age.

Among the composite measure for SDAI, the best correlated component with TJC (tender joint count) was LA (Linoleic acid, p=0.002, rho = -0.611), that with patient VAS (visual analogue scale) was 19,20-diHDPA (p=0.032, rho =0.440), and that with CRP was DHA (Docosahexaenoic acid, p=0.021, rho = -0.452).

Additionally, principal component analysis was carried out. In the first primary component (PC1), absolute eigenvecotor values of AdA (Adrenic acid), ALA (Alpha-linolenic acid), DHA, DPA (Docosapentaenoic acid) and LA are more than 0.25, among which DHA was strongly correlated with PC1 (p<0.0001, rho =0.902). PC1 positively and significantly explained TJC count independent of sex and age.

Table. Parameter Estimates by Standard Least Squares (Role variant = SDAI)

	Lower 95%	Upper 95%	Std. Beta	p value
Intercept	-39.2	-6.63	0	0.008
19,20-diHDPA	4.54	16.55	0.707	0.003
14,15-diHDPE	-26.4	-6.24	-0.62	0.003
Age	0.08	0.56	0.455	0.013
Sex				0.475

Conclusions: Since 19, 20-diHDPA (metabolized from DHA) and 14,15-diHETE (from EPA, eicosapentaenoic acid) are both generated by cytochrome P450-catalyzed epoxidation followed by conversion to the vicinal diols by epoxide hydrolase, such kind of enzymes might be key molecules connecting lipid metabolism and RA. Although a replication study is inevitable, a certain kinds of lipid and lipid mediator profiles may be associated with disease activity, especially analgesic descriptors such as tender joint count.

THU0058 S100A11 PROTEIN IS UP-REGULATED IN PATIENTS WITH IDIOPATIC INFLAMMATORY MYOPATHIES AND IS ASSOCIATED WITH DISEASE ACTIVITY

L. Andres Cerezo[1], H. Hulejová[1], B. Šumová[1], T. Lennerova[1], M. Klein[1], H.F. Mann[1], J. Zámečník[2], K. Pavelka[1], J. Vencovský[1], L. Šenolt[1]. *[1]Department of Rheumatology, 1st Faculty of Medicine, Charles University Prague, Institute of Rheumatology; [2]Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University Prague, University Hospital Motol, Prague, Czech Republic*

Background: S100A11 (calgizzarin) is a member of the S100 protein family that participates in regulating number of biologic functions and is associated with oncogenesis and inflammation. Recent data suggest involvement of S100A11 in myocardial damage.

Objectives: The aim of our study was to analyze the expression of S100A11 in patients with idiopathic inflammatory myopathies (IIMs) and its potential association with disease activity parameters and IIMs-related clinical features.

Methods: immunohistochemistry in patients with polymyositis/dermatomyositis (PM/DM, n=5/6) and control individuals with myasthenia gravis (MG, n=5). S100A11 in plasma was measured by ELISA (Biovendor) in 112 patients with IIMs (PM, n=41; DM, n=41; and cancer associated myositis (CAM), n=30) and in 42 healthy controls (HC). Patients with PM/DM fulfilled Bohan and Peter diagnostic criteria and CAM was defined as cancer occurring within 3 years of the diagnosis of myositis. Clinical disease activity was assessed by myositis disease activity assessment (MYOACT), physician and patient's global activity using visual analogue scales (VAS), manual muscle testing (MMT) and health assessment questionnaire (HAQ). Muscle enzymes CK, LD, ALT, AST and CRP were measured by routine laboratory techniques. Autoantibodies were detected by immunoprecipitation.

Results: S100A11 protein was up-regulated in the muscle from patients with IIMs compared to MG. In PM/DM patients, S100A11 was accumulated in the cytoplasm of regenerating and necrotizing muscle fibers and on the sarcolemma of most fibers. Only some mononuclear infiltrate cells showed S100A11 positivity. In patients with MG, S100A11 was detected on the sarcolemma only. Moreover, S100A11 was increased in plasma of patients with IIMs compared to HC (3.82 [1.47–72.9] vs. 2.84 [1.67–11.18] ng/ml; p=0.0076). When divided into groups, patients with DM and CAM showed significant elevation of plasma S100A11 compared to HC (4.10 [2.22–50.81] and 4.52 [1.53–9.11] vs. 2.84 [1.67–11.18] ng/ml; p=0.004 and p=0.02, respectively). Levels of S100A11 did not differ between PM and HC. In all patients, S100A11 correlated with LD (r=0.300, p=0.001), CK (r=0.217, p=0.025) and AST (r=0.343, p<0.001), with MYOACT (r=0.279, p=0.005) and with muscle, pulmonary and skin disease activity (r=0.199, p=0.040; r=0.224, p=0.025 and r=0.307, p=0.001). S100A11 levels were elevated in autoantibody-positive group compared to autoantibody-negative group of patients with IIMs (5.22 [1.45–69.29] vs 3.44 [1.58–12.12], p=0.010).
Conclusions: S100A11 is up-regulated in the circulation of patients with IIMs and correlates with disease activity. Accumulation of S100A11 in the muscle of patients with myositis may indicate its potential role in the process of cell necrosis and fiber regeneration.

THU0059 ONCOSTATIN M INDUCES INFLAMMATION AND DIFFERENTIALLY REGULATES TNF ALPHA-INDUCED PRO-INFLAMMATORY MECHANISMS AND NOTCH SIGNALLING IN THE RA JOINT

M.M. Hanlon[1], D. Veale[2], S. Wade[1], M. Biniecka[2], U. Fearon[1], T. McGarry[1]. *[1]Molecular Rheumatology, Trinity Biomedical Sciences Institute, Trinity College Dublin; [2]Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, University College Dublin, Dublin, Ireland*

Background: Oncostatin M (OSM) is a pleiotropic cytokine, highly expressed in the RA joint that displays both agonistic and antagonistic effects depending on the inflammatory microenvironment. This study examines the effect of OSM on inflammation, the Notch-1 signalling pathway which plays a critical role in vascular development and angiogenesis and finally on TNFα-induced pro-inflammatory mechanisms in Rheumatoid Arthritis.
Objectives: To examine the effect of OSM on cytokine/chemokine production, angiogenesis and the Notch-1 signalling pathway in synovial fibroblasts and endothelial cells and whether OSM potentiates the effects of TNFα-induced pro-inflammatory effects.
Methods: Primary RA synovial fibroblasts (RASFC) isolated from RA synovial biopsies obtained at time of knee arthroscopy and human dermal microvascular endothelial cells (HMVEC) were grown to confluence. RASFC and HMVEC were cultured with OSM (10ngml) alone or in combination with increasing concentrations of TNFα (0.01–1ng/ml). IL-6, IL-8, RANTES, GROα and MCP-1 cytokines/chemokines were quantified in culture supernatants by ELISA. Functionally, angiogenesis and invasion were assessed by matrigel tube formation and Transwell invasions assays respectively, and VEGF in cell lysates quantified by Real-time PCR. Finally, Notch-1, its ligands Delta-like-ligand 4 (DLL-4) and Jagged-1 (Jag-1) and downstream transcriptional repressors – Hey-1 and Hey-2 were quantified by Real-time PCR.
Results: OSM alone significantly induced IL-6 and MCP-1 while inhibiting IL-8 and GROα in RASFC and HMVEC culture supernatants, compared to basal control. OSM alone induced RANTES expression in HMVEC with little effect observed for RASFC. OSM potentiated the effect of increasing concentrations of TNFα on IL-6 and MCP-1 secretion from RASFC and HMVEC. Conversely OSM significantly inhibited TNFα-induced IL-8 and GROα secretion from both RASFC and HMVEC. Interestingly, OSM significantly inhibited TNFa-induced RANTES expression in HMVEC yet conversely potentiated this effect in RASFC. At a functional level, OSM induced both RASFC and HMVEC invasion and induced network formation and VEGF expression in HMVEC. OSM significantly induced Notch-1 in RASFC and HMVEC in a time dependent manner, but interestingly differentially regulated the Notch-1 ligands, with induction of Jag-1 only observed in RASFC, and induction of DLL-4 only observed in HMVEC. Finally OSM differentially regulated Notch-1 downstream transcriptional repressors in HMVEC, significantly inducing Hey-2 while simultaneously inhibiting Hey-1.
Conclusions: OSM is a pleiotropic cytokine that displays divergent effects with both pro- and anti-inflammatory mechanisms within the inflamed joint, effects that appear to be dependent on cell type and the inflammatory microenvironment. Targeting OSM or downstream signalling pathways may lead to new potential therapeutic strategies or adjuvant therapies, particularly for those patients who have sub-optimal responses.

THU0060 T CELL-DERIVED IL-17A AND IL-17F DRIVE BONE FORMATION FROM HUMAN PERIOSTEAL STEM CELLS: IMPLICATIONS FOR ENTHESOPHYTE FORMATION

M. Shah[1,2], A. Maroof[1], R. Al-Hosni[3], P. Gikas[4], N. Gozzard[1], S. Shaw[1], S. Roberts[1,2]. *[1]UCB Pharma, Slough; [2]University College London; [3]Institute of Orthopaedics and Musculoskeletal Science; [4]The Royal Orthopaedic Hospital, London, United Kingdom*

Background: Pathological bone formation associated with spondyloarthropathies (SpA) is a major cause of structural tissue damage causing permanent disability. A paucity of *in vitro* models that faithfully replicate human skeletal biology has impeded research into the cellular and molecular triggers for this osteoimmunological phenomenon. Nevertheless, clinical and animal studies have defined IL-17 signalling as a key regulator of SpA disease; however, the role of IL-17 in bone pathology is unclear. IL-17-producing γδ-T cells have a critical function in periosteal bone formation for fracture repair[1]. The periosteum has also been implicated in pathological bone formation during SpA disease progression[2].
Objectives: To investigate IL-17 signalling in the context of pathological bone formation using a biomimetic human periosteum derived stem cell (hPDSC) model of osteogenic differentiation.
Methods: hPDSCs were obtained through enzymatic digestion of periosteal biopsies from patients undergoing orthopaedic surgery. Expanded cultures were then treated with recombinant human IL-17A, IL-17F, or both over 96h. The expression of gene markers was then evaluated. Alternatively, hPDSCs were stimulated using a biomimetic protocol in combination with IL-17A and IL-17F, or human T-cell supernatants (SNs) (as a surrogate disease-like inflammatory milieu). Antibodies with strong-affinity to IL-17A, IL-17F, or bimekizumab (a humanised monoclonal IgG1 antibody with strong affinity for both IL-17A and IL-17F) were used to define the role of these cytokines in the SNs. Expression of osteogenic markers and matrix mineralisation was assessed to define *in vitro* bone formation.
Results: Under basal conditions IL-17A and IL-17F significantly up-regulated *IL-6* expression. Additionally, IL-17A and IL-17F transiently enhanced the expression of the osteogenic transcription factor *RUNX-2*. When IL-17 cytokines were combined in a biomimetic differentiation protocol, both IL-17A and IL-17F promoted osteogenic differentiation. Importantly, IL-17F enhanced the expression of most osteogenic markers to a greater extent than IL-17A alone following 9 days' exposure. Conversely, IL-17A treatment resulted in elevated *in vitro* mineralisation vs IL-17F. Th17 and γδ-T cell SNs potently enhanced hPDSC osteogenic differentiation and mineralisation. Whilst *IL-6* expression and *in vitro* bone formation were blocked by neutralisation of IL-17A or IL-17F, dual neutralisation of IL-17A and IL-17F in the inflammatory milieu exhibited the greatest effect on most of the tested parameters.
Conclusions: These data show that both IL-17A and IL-17F enhance *in vitro* osteogenic differentiation and bone formation from hPDSCs. The source of these cytokines has not been established but is likely to involve entheseal resident γδ-T cells. We propose that following their release, IL-17A and IL-17F drive pathological bone formation resulting in enthesophytes at the enthesis/periosteum interface. Current therapeutics display limited efficacy in blocking enthesophyte formation, hence inhibition of both IL-17A and IL-17F offers an attractive therapeutic strategy to prevent this debilitating feature of SpA.

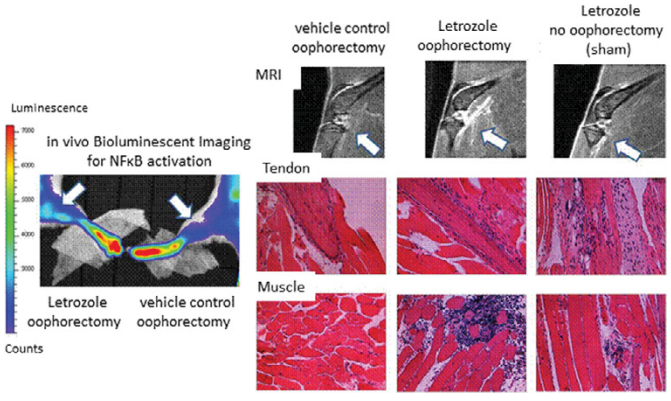
THU0061 REGULATION OF OSTEOCLAST RECRUITMENT AND ACTIVATION BY RESOLVIN D1

H.A. Benabdoune, P. Rondon, Q. Shi, J.C. Fernandes, H. Fahmi, M. Benderdour. *Research Centre, Sacré-Coeur Hospital of Montreal, Room K-3045, Montreal, Canada*



Background: Resolvin-D1 (RvD1) is a derivative of omega-3 fatty acids and a potent anti-inflammatory agent synthesized during the resolution phase of inflammation. In human cartilage, we recently reported that RvD1 strongly inhibited a number of factors involved in inflammation, catabolism, oxidative stress, and apoptosis.
Objectives: The overall objective of this study is to further investigate RvD1 effects on bone metabolism in vitro.
Methods: First, murine macrophages RAW267.4 were used to assess osteoclasts (OC) recruitment and bone resorption. RAW264.7 cells were incubated with 50 ng/ml LPS with or without RvD1 (0 - 10 μM) for 48 hours. Cell viability was verified with the MTS test. OC phenotype *markers, namely* TRAP and cathepsin-K, were assessed by western blot, enzymatic staining and immunocytochemistry. Levels of TNF-α, IL-1β, IL-6, IL-10, were measured by ELISA, and PGE_2 levels by EIA. NO release was measured by Greiss reaction.
To investigate bone resorption, RAW264.7 cells were seeded in hydroxyapatite plates, then treated with 50 ng/ml LPS with or without RvD1 (0.5 and 1 μ M) for 48 hours. Plot formation was assessed by Von Kossa staining.

Second, human osteoblasts (Ob) were obtained from post-surgery discarded trabecular bone of osteoarthritic (OA) patients who underwent total knee arthroplasty. First passage human OA Ob were treated either with RvD1 (0.1 - 1 μM) alone, or with 20 nM VitD3 with or without RvD1 (0.1 - 1 μ M), for 48 hours. Cell viability was evaluated with the MTS test. Alkaline phosphatase (PAL) activity and osteocalcin (OCN) release was determined by colorimetric reaction and ELISA, respectively.
Results: In RAW264.7 cells, our results clearly show that RvD1 strongly reduces OC recruitment and activation as indicated by the inhibition of TRAP and cathepsin K expression as well as TNF-α, IL-1β, IL-6, PGE_2 and NO release, as well as the concurrent enhancement of IL-10 levels. Besides, RvD1 decreases bone resorption through the inhibition of plots formation in hydroxyapatite matrix. In human OA Ob, RvD1 partially decreases VitD3-induced PAL activity, while it maintains OCN expression at control levels.
Conclusions: Our in vitro results clearly show that RvD1 may play an important role in the regulation of bone metabolism. Additionally to our previous data, our findings suggest that RvD1 may offer a novel and original perspective to make a real contribution to musculoskeletal and bone diseases therapy.

THU0062 NOVEL ANIMAL MODEL OF AROMATASE INHIBITOR-INDUCED ARTHRALGIA SUGGESTS AN ESTROGEN-INDEPENDENT INFLAMMATORY MECHANISM

N.A. Young[1], E. Thomas[1], B. Snoad[1], J. Sharma[1], M. Mobeen[1], A.C. DeVries[2], A. Bratasz[3], M. Lustberg[4], W. Jarjour[1], R. Reinbolt[4].
[1]Rheumatology and Immunology; [2]Department of Neuroscience; [3]Small Animal Imaging Core; [4]Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, United States

Background: Aromatase Inhibitors (AIs) block physiological estrogen production in peripheral tissues and significantly improve overall survival rates of post-menopausal, hormone receptor-positive breast cancer patients by reducing tumor recurrences. However, half of patients taking these drugs develop aromatase inhibitor induced arthralgia (AIIA), which is characterized by severe pain and inflammation in various joints. Since AIIA leads to suspension of therapy in 20% of patients, reducing incidence may provide sustained AI treatment and enhanced long-term survival.
Objectives: In order to establish a better understanding of the inflammatory mechanism and to create a platform that can be used to explore interventional strategies, our objective in this study was to design a novel animal model of AIIA.
Methods: Female BALB/C-Tg (NFκB-RE-luc)-Xen mice, which have a firefly luciferase cDNA reporter gene under the regulation of 3 κB responsive binding sites, were oophorectomized and treated with AI (letrozole) by daily subcutaneous injections. Control groups included oophorectomized mice receiving vehicle control injections and non-oophorectomized mice treated with AI. Bioluminescent imaging of hind limbs was performed after 3 weeks on the in vivo imaging system (IVIS) to measure NFκB activation. At 5 weeks, knee joints and surrounding tissue were imaged on the BioSpec 94/30 micro-MRI. Legs were collected for histopathological analysis and serum cytokine levels were measured at experimental endpoint.
Results: Bioluminescent imaging showed significantly enhanced NFκB activation in the hind limbs compared to oophorectomized controls receiving vehicle treatment. Analysis of knee joints and legs by MRI imaging showed enhanced signal detection in the joint space and surrounding tissue following AI treatment. Surprisingly, enhanced MRI detection was also demonstrated in non-oophorectomized mice that were treated with AI. Histopathological analysis further demonstrated mild inflammation in the synovial tissue and joint damage in mice treated receiving AI both with and without oophorectomy. Moreover, tenosynovitis and inflammatory muscle tissue infiltrates were detected in AI-treated mice and serum cytokine levels of IL-2, IL-4, IL-6, and CXCL1 were significantly elevated.

Conclusions: Collectively, these data establish a novel mouse model of AIIA and suggest that the pathogenesis of AI-induced inflammation is estrogen-independent. Future studies will be directed into the characterization of this inflammatory mechanism to provide insight into potential therapeutic strategies directed at mitigating this adverse inflammatory burden.

THU0063 IL-1 FAMILY CYTOKINES AND RECEPTORS IN IGG4-RELATED DISEASE

R. Capecchi[1], P. Italiani[2], I. Puxeddu[1], F. Pratesi[1], A. Tavoni[3], D. Boraschi[2], P. Migliorini[1]. *[1]Clinical and Experimental Medicine, Clinical Immunology Unit, university of Pisa, pisa; [2]Institute of Protein Biochemistry, National Research Council, Naples; [3]Clinical and Experimental Medicine, University of Pisa, Clinical Immunology Unit, university of Pisa, pisa, Italy*

Background: IgG4-related disease (IgG4-RD) is a fibroinflammatory condition that can affect almost any organ, characterized by lymphoplasmocytoid infiltrate, obliterative phlebitis and storiform fibrosis often associated with eosinophilia and increased levels of IgG4. Cytotoxic CD4 T cells producing IL-1b [D1], TGFb1 and IFN-gare detectable in peripheral blood of patients and high IL-18 expression has been found in affected organs.
Objectives: To evaluate the role of IL-1 family cytokines in IgG4-RD, by analyzing cytokines and receptors in sera.
Methods: Nine patients fulfilling the proposed criteria (Umehara, 2012) for the diagnosis of IgG4-RD were recruited. Cytokines of the IL-1 family (IL-1a, IL-1b, IL-33, IL-18), soluble receptors (sIL-1R1, sIL-1R2, sIL-1R3, sIL-1R4) and antagonists (IL-1Ra, IL-18BP) were measured in sera by multiarray ELISA assay. Free IL-18 was calculated using the law of mass action.
Results: Most patients had a multiorgan disease; retroperitoneum, salivary glands, pancreas and lymph nodes were most frequently affected. IL-18 ($p=0.007$) and free IL-18 ($p<0.0001$), sIL-1R1 ($p=0.0005$), sIL-1R2 ($p=0.0013$), and sIL-1R4 ($p=0.0006$) were significantly increased in IgG4-RD sera compared with healthy controls.
Conclusions: In IgG4-RD patients, at variance with other autoimmune or autoinflammatory conditions, the increase in IL-18 levels is not counterbalanced by IL-18BP, leading to high levels of free IL-18.The free cytokine may affect T cell subset balance and induce IFN-g production. The parallel increase of sIL-1R1 and sIL-1R2 suggests an efficient dampening of inflammatory IL-1bsignaling at the tissue level, while high levels of sIL-1R4 may be associated with vascular remodeling and fibrosis, as observed in animal models of obesity and in human cardiovascular disorders.

THU0064 ADAM-10 AS A TOCILIZUMAB TREATMENT PREDICTIVE FACTOR IN RHEUMATOID ARTHRITIS

T. Isozaki, S. Nishimi, A. Nishimi, S. Ishii, T. Tokunaga, H. Furuya, K. Wakabayashi, T. Kasama. *Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan*

Background: A disintegrin and metalloproteinases (ADAMs) are a family of transmembrane and secreted proteins. ADAM-10 has been reported to be the enzyme responsible for the release of a number of chemokines and cytokine receptors. We have shown that ADAM-10 is overexpressed on rheumatoid arthritis (RA) synovial tissue endothelial cells (ECs) and lining cells compared with osteoarthritis and normal tissues. We also demonstrated that ADAM-10 mediates EC migration and tube formed.
Objectives: In order to demonstrate for ADAM-10 in clinical side, we focused on ADAM-10 as predictive factor for treatment with biologics in RA.
Methods: The serum was collected from patients before the initial treatment with biological therapies. Fifteen patients were treated with adalimumab (ADA), and 20 patents were treated with tocilizumab (TCZ). ADAM-10 and fractalkine/CX3CL1 were measured by enzyme-linked immunosorbent assay at 0, 12, 24 and 54 weeks. Clinical disease activity was evaluated by clinical disease activity index (CDAI). Following biological therapies, we defined biologic-responders as patients whose DAS28 scores decreased by more than 1.2 at 24 weeks. ADAM-10 baseline was also compared between responders and nonresponders at 24 weeks.
Results: There were no significant differences were observed in the mean age, gender ratio, dosages of predonisolone and methotraxate between ADA and TCZ groups. In ADA group, baseline DAS28 for the 15 patients was 4.8±0.3 (2.5–7.2).

On the other hands, baseline DAS28 for the 20 patients was 4.8±0.3 (2.5–6.8) in TCZ group. There were no differences between ADA and TCZ groups. RA patients with an insufficient response to ADA or TCZ showed highly significant improvement of DAS28 after 12 weeks (2.9±0.3 and 2.2±0.4, respectively), and 24 weeks (2.5±0.4 to 2.2±0.2, respectively). ADAM-10 highly correlates with CDAI, and fractalkine/CX3CL1. Serum ADAM-10 levels were no remarkable change after treatment with ADA despite decrease of disease activity of RA. On the other hand, serum ADAM-10 levels in patients who were treated with TCZ were significantly diminished following successful treatment and clinical improvement (baseline 408±88 pg/ml and 54 weeks 138±51 pg/ml, $p<0.05$). Univariate logistic regression analysis, baseline of DAS28 (ESR), baseline of CDAI, and ADAM-10 were selected as significant variables for improvement of DAS28 (ESR) at 24 weeks. Multiple regression analysis showed that ADAM-10 was only identified as independent predictive variable for improvement of DAS28 (ESR) at 24 weeks. ADAM-10 baseline in TCZ responder was significantly higher than TCZ nonresponders at 24 weeks (620±134 pg/ml and 109±25 pg/ml, respectively, $p<0.05$).

Conclusions: This study indicates that ADAM-10 is correlated with RA disease activity, and is higher in TCZ responders. These results suggest that ADAM-10 may be a predictor of treatment effectiveness for RA with TCZ.

THU0065 CYTOKINES AND LIPOCALIN-2 IN PREGNANT WOMEN WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

T.T. Pedersen[1], M.H. Fenstad[2], T.S. Moksnes[1], M. Wallenius[1], T.H. Flo[3], M. Haug[3]. *[1]Norwegian National Advisory Unit on Pregnancy and Rheumatic diseases; [2]Dep. of Immunology and Transfusion Medicine, St. Olavs Hospital; [3]Centre of Molecular Inflammation Research and Dep. of Cancer Research and Molecular Medicine, NTNU, Trondheim, Norway*

Background: Rheumatoid arthritis (RA), and especially seronegative RA, is often ameliorated by pregnancy, while systemic lupus erythematosus (SLE) is prone to flare and associated with pregnancy complications. Cytokines and chemokines are of great importance for immune processes during pregnancy. The inflammatory marker Lipocalin-2 (LCN2) has become increasingly relevant as a potential clinical biomarker of rheumatic diseases (1). LCN2 is produced in the maternal-fetal interface during normal pregnancies and correlates with the presence and severity of preeclampsia (2).

Objectives: To obtain a better understanding of immune regulation and the disparate immune responses in pregnant women with RA and SLE. In this pilot study, we analyzed levels of multiple cytokines, chemokines and LCN2 in women with seropositive RA, seronegative RA, SLE and healthy controls during pregnancy and postpartum.

Methods: The Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases collect serum samples in a biobank from women with inflammatory rheumatic diseases before pregnancy, during pregnancy week 10–12, week 23–25, week 30–32 and 6 weeks, 6 months and 12 months postpartum. Control serum samples were collected from healthy pregnant women at matching time-points. We analyzed serum cytokine and chemokine levels using a multiplex assay. A sandwich ELISA was used to measure LCN2. In this pilot study we included pregnant women with SLE (n=4), seropositive RA (n=4), seronegative RA (n=2) and healthy pregnant controls (n=4). The total cohort consists so far of 18 pregnant women with SLE and 23 pregnant women with RA.

Results: We observed lower LCN2 levels during pregnancy in SLE patients, compared to controls and RA patients. LCN2 levels in seropositive RA patients and controls were found to be comparable during pregnancy, whereas pregnant women with seronegative RA showed higher LCN2 levels. Levels of IFNγ, IL-6 and IP-10 were higher in SLE than in RA patients during the course of pregnancy. IL-17 was slightly higher only in seropositive RA patients compared to controls. TNFα was slightly higher in both SLE and RA patients compared to controls, levels of anti-inflammatory IL-10 were very low or undetectable in all groups.

2. Trimester	Controls	SLE	Seropos RA	Seroneg RA
LCN2 (ng/ml)	285,5 (±74,7)	126,5 (±44,6)	232,6 (±67,4)	330,2 (±3,2)
IFNγ (pg/ml)	15,0 (±22,4)	40,4 (±65,1)	6,9 (±5,2)	26,1 (±9,9)
IL-6 (pg/ml)	3,4 (±1,9)	5,9 (±2,0)	3,8 (±1,5)	5,3 (±1,0)
IP-10 (pg/ml)	60,3 (±14,5)	138,3 (±92,1)	61,7 (±8,9)	64,9 (±7,3)
IL-17 (pg/ml)	1,3 (±1,3)	2,3 (±2,2)	4,8 (±9,0)	0,6 (±0,2)
TNFα (pg/ml)	2,2 (±2,5)	4,2 (±5,4)	3,3 (±3,5)	3,2 (±0,7)

Conclusions: We found interesting differences in cytokine, chemokine and LCN2 levels during pregnancy in women with SLE, seropositive RA and seronegative RA. The results need confirmation in the total cohort and will be further explored for a better understanding of the disparate immune modulation of RA and SLE during pregnancy.

THU0066 OSTEOCLAST DIFFERENTIATION GENE EXPRESSION PROFILING REVEALS CCL4 MEDIATES RANKL-INDUCED OSTEOCLAST MIGRATION

W. Xuan[1], X. Feng[2], Y. Shi[1], F. Wang[3], M. Zhang[1], W. Tan[1]. *[1]Rheumatology; [2]Traditional Chinese Medicine; [3]Department of Cardiology, the First Affiliated Hospital of Nanjing Medical University, China, nanjing, China*

Background: The migration of osteoclast from circulation and bone marrow into bone surface has suggested as a novel therapeutic point for bone erosion in RA.

Objectives: We explored the mechanisms involved in osteoclast migration.

Methods: Gene expression profiling was identified by microarray analysis and validated by Real-time PCR during differentiation of bone marrow-derived macrophages (BMMs) into osteoclast (OCs). RANKL induced osteoclast precursor cell line RAW264.7 migration and invasion in the presence and absence of anti-CCL4 antibody was measured in vitro. Intracellular signaling pathway was assessed by Western blotting. Osteoclast formation was identified by TRAP staining.

Results: A panel of 11 chemokines signal was significant increase in osteoclastic differentiation of BMMs by Microarray. High expression of CCL4 was validated in primary BMMs and RAW264.7 cell line during differentiated into OCs. RANKL induced osteoclast precursor cell migration and invasion was decreased upon addition of anti-CCL4 antibody. OCs formation and OCs related genes expression were not affected by CCL4 inhibition. Neutralization of CCL4 promoted the PI13K phosphorylation at 45 to 60min after RANKL stimulation in RAW264.7.

Conclusions: CCL4 regulates RANKL-induced OCs migration, suggesting that CCL4 inhibition could be bone protective in RA

THU0067 NLRP3 INFLAMMASOME ACTIVITY IN MONOCYTES IS REGULATED BY 12/15-LIPOXYGENASE

Y. Kusche, K. Barczyk-Kahlert, J. Roth. *Institut Der Immunologie, Münster, Germany*

Background: Activation of the NLRP3 inflammasome is a major inflammatory pathway in monocytes in response to various exogenous and endogenous stimuli. However, negative regulation of inflammasome activity is not well understood. Glucocorticoids (GC) are drugs of choice for the treatment of many inflammatory diseases. Recently, we could show that treatment of monocytes with GC leads to re-programming towards a specific population involved in resolution of inflammation. Gene analysis has shown up-regulated expression of 12/15-lipoxygenase (12/15-LOX) in GC-and LPS/GC-treated monocytes. 12/15-LOX reacts with polyunsaturated-fatty-acids to generate anti-inflammatory lipid-mediators, which contribute to resolution of inflammation.

Objectives: The aim of our study was to determine the contribution of 12/15-LOX on the inflammatory response on murine monocytes.

Methods: Bone marrow-derived monocytes were isolated from wild-type (wt) C57BL/6 and 12/15-LOX$^{-/-}$ mice and stimulated with GC and/or LPS as well as various inhibitors or stimulants. Gene expression was analyzed using qRT-PCR. Protein expression was examined by Western-Blot, Flow-Cytometry and ELISA. T-cell response was analyzed by co-culture of stimulated monocytes with allogenic T-cells.

Results: 12/15-LOX$^{-/-}$ monocytes showed slightly higher secretion of IL-1β as compared to wt cells after LPS stimulation. The differences between wt and 12/15-LOX$^{-/-}$ were much more pronounced when monocytes were additionally exposed to ATP. LPS treatment markedly enhanced expression of pro-IL-1β in 12/15-LOX$^{-/-}$ monocytes. No differences could be observed between wt and 12/15-LOX$^{-/-}$ monocytes in secretion of other proinflammatory mediators as well as the expression of inflammasome components. However, expression of cleaved caspase-11 was up-regulated in 12/15-LOX$^{-/-}$ monocytes exposed to LPS. Additionally, inhibition of caspase-11, caspase-1 and 5-LOX significantly reduced the high secretion of IL-1β in 12/15 LOX$^{-/-}$ monocytes. Interestingly, 12/15-LOX$^{-/-}$ rather than wt monocytes stimulated with LPS led to enhanced T-cell proliferation.

Conclusions: Our results demonstrate that 12/15-LOX plays a regulatory role during inflammatory immune response by counteracting the NLRP3 inflammasome activity through down-regulation of caspase-11 and 5-LOX activity. Thus, we identified a novel negative regulatory pathway of inflammasome activity.

Rheumatoid arthritis - prognosis, predictors and outcome

THU0068 THE RISK OF INDIVIDUAL AUTOANTIBODIES, AUTOANTIBODY COMBINATIONS AND AUTOANTIBODY LEVELS FOR ARTHRITIS DEVELOPMENT IN CLINICALLY SUSPECT ARTHRALGIA

R.M. Ten Brinck, H.W. van Steenbergen, M.A. van Delft, M.K. Verheul, R.E. Toes, L.A. Trouw, A.H. van der Helm-van Mil. *Rheumatology, Leiden University Medical Centre, Leiden, Netherlands*

Background: Autoantibody testing is helpful to predict progression to arthritis in subjects at risk. Previous longitudinal studies mainly focussed on autoantibody-positive arthralgia patients. Consequently predictive values of autoantibodies were evaluated relative to each other. This study assessed risks of having anticitrullinated protein antibodies (ACPA), rheumatoid factor (RF) and/or anti-carbamylated protein antibodies (anti-CarP) for arthritis development in arthralgia patients considered at risk for RA by rheumatologists based on clinical characteristics (Clinically Suspect Arthralgia, CSA).
Objectives: To assess risks of having anticitrullinated protein antibodies (ACPA), rheumatoid factor (RF) and/or anti-carbamylated protein antibodies (anti-CarP) for arthritis development in arthralgia patients considered at risk for RA by rheumatologists based on clinical characteristics (CSA).
Methods: Baseline ACPA, RF and anti-CarP antibodies of 241 patients, consecutively included in the CSA-cohort, were studied in relation to development of clinical arthritis during a median follow-up of 103 (IQR 81–114) weeks.
Results: ACPA, RF and anti-CarP antibodies were all univariably associated with arthritis development, hazard ratios (95% CI) were 8.5 (4.7–15.5), 5.1 (2.8–9.3) and 3.9 (1.9–7.7). Only ACPA, and not RF or anti-CarP, was independently associated (HR 5.1, 2.0–13.2). Relative to autoantibody-negative CSA-patients, ACPA-negative/RF-positive patients had HRs of 2.6 (1.04–6.6), ACPA-positive/RF-negative patients 8.0 (2.4–27.4), and ACPA-positive/RF-positive patients 10.5 (5.4–20.6, Figure). PPVs for development of clinical arthritis within two years were: 38% for ACPA-negative/RF-positive, 50% for ACPA-positive/RF-negative, and 67% for ACPA-positive/RF-positive patients. Higher ACPA-levels were not significantly associated with increased progression to clinical arthritis, in contrast to higher RF-levels. Autoantibody levels were stable during follow-up.

Conclusions: ACPA conferred the highest risk for arthritis development and had an additive value to RF. However, >30% of ACPA-positive/RF-positive CSA-patients did not develop arthritis during two-year follow-up. Thus CSA and information on autoantibodies is insufficient to accurately identify imminent autoantibody-positive RA.

THU0069 HOW MANY RHEUMATOID ARTHRITIS PATIENTS IN REMISSION EXPERIENCE PAIN? WHAT TYPES AND WITH WHAT FREQUENCY WERE PAINKILLERS RECEIVED? IS REACHING REMISSION A REALISTIC GOAL?

E. Torikai, M. Suzuki, Y. Matsuyama. *Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: The primary treatment goal in rheumatoid arthritis (RA) patients is to reach remission. Earlier diagnosis, advancements in disease-modifying antirheumatic drugs, and improved treatment strategies have enabled increasing numbers of RA patients to achieve remission. However, the definition of remission involves the fulfillment of specific criteria, which include a number of swollen and tender joints, the erythrocyte sedimentation rate (ESR), and the visual analog scale of pain (VAS pain). Some patients with RA in remission wished to take painkillers because they experienced pain and physical limitations in their daily life or at work. Is reaching remission a realistic goal?
Objectives: To evaluate VAS pain and patient's global assessment (PGA) in those with RA in remission, and to determine the types and frequency of which painkillers were received.
Methods: In a study of 554 RA patients with a definite RA diagnosis according to 1987 ACR criteria, we enrolled 235 patients (82% females). All patients had DAS28-ESR <2.6, defined as clinical remission, and had no acute pain as a result of operation or trauma. The mean age and disease activity were 53.6 years and 2.67, respectively. Seventy-one percent of patients were treated with MTX, 30.2% with glucocorticoids, and 38.4% with a biological agent. We evaluated VAS pain and PGA and investigated why patients experienced dissatisfaction with VAS pain and PGA. Moreover, we elucidated how many patients used painkillers and what types of painkillers were used.
Results: The mean values of clinical and laboratory data were described as follows: 28 swollen joints, 0.69; 28 tender joints, 1.56; RF, 157 IU/mL; C-reactive protein, 0.14 mg/dL; ESR, 19 mm/h; and health assessment questionnaire disability index score, 0.618. Steinblocker stages (I/II/III/IV) were (166/51/18/0), respectively and Steinblocker classes (I/II/III/IV) were (155/68/12/0), respectively. The mean VAS pain was 1.81. Thirty-five (14.9%) of 235 patients had VAS pain >3 (Fig. 1). The mean PGA was 1.54. Seventeen patients (7.2%) reported PGA >3 (Fig. 2). Reasons for VAS pain or PGA of >3 were musculoskeletal pain (48.6%), neuropathic pain (23.1%), psychological reasons (9.3%), and other (19%). Thirty-one patients (13.2%) were treated with painkillers such as NSAIDs (46.2%), acetaminophen (22.5%), pregabalin (18.6%), tramadol (4.1%), and other (8.6%). The mean values for VAS pain and PGA were improved after using painkillers by 0.73 and 0.36, respectively. There was a significant difference in the improvement rate of VAS pain and PGA between pre-use and post-use of pain-killer (Fig. 3).

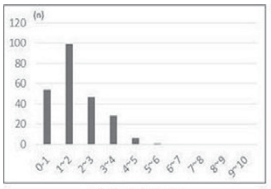

Fig.1 VAS pain

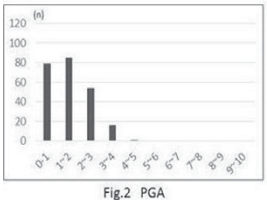

Fig.2 PGA

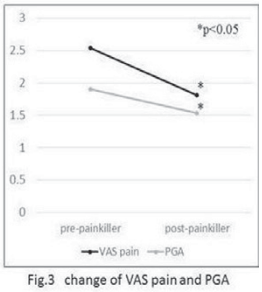

Fig.3 change of VAS pain and PGA

Conclusions: VAS pain and PGA are important for understanding the patients' functional disabilities and problems. We should attend to patients' demands and make an informed decision to form a realistic goal for RA treatment. Given that VAS pain and PGA were improved because of the use of painkillers in the current study, we suggest that the ability to appropriately prescribe painkillers is an important method with which to satisfy RA patients in remission.

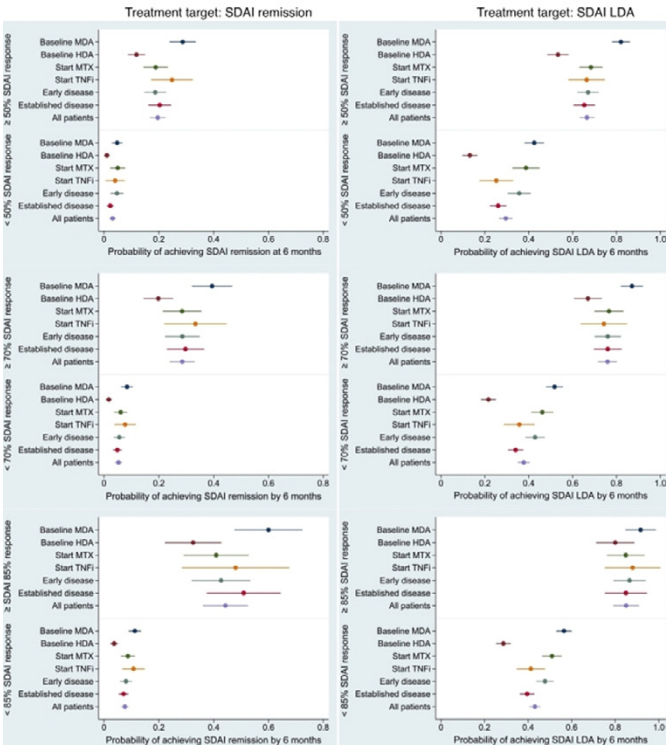
THU0070 TREAT-TO-TARGET IN RA: WHAT LEVEL OF TREATMENT RESPONSE IS NECESSARY BY 3 MONTHS IN ORDER TO ACHIEVE THE TREATMENT TARGET BY 6 MONTHS? RESULTS FROM A REAL LIFE STUDY

V. Norvang[1], I.C. Olsen[1], E.K. Kristianslund[1], T. Uhlig[1], T.K. Kvien[1], D. Aletaha[2], J. Smolen[2], E.A. Haavardsholm[1]. *[1]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [2]Division of Rheumatology, Department of Internal Medicine 3, Medical Universitiy of Vienna, Vienna, Austria*

Background: When initiating therapy with disease-modifying anti-rheumatic drugs



(DMARDs) in patients with rheumatoid arthritis (RA), treatment adoptions are recommended if no improvement in disease activity is seen within 3 months, or if the treatment target has not been reached by 6 months.[1] A pooled analyses from several pivotal RCTs showed that RA patients who did not achieve a minor treatment response by 3 months were unlikely to reach the treatment target by 6 months.[2]

Objectives: To examine what level of treatment response is needed after 3 months of therapy in order to achieve the treatment target of remission (REM) or low disease activity (LDA) by 6 months in a routine clinical setting.

Methods: Data were provided by NOR-DMARD, a prospective, multicentre, observational study. We selected RA-patients enrolled between December 2000 and November 2012, who were biological DMARD-naïve and had a moderate or high disease activity (MDA or HDA, respectively) according to the Simplified Disease Activity Index (SDAI) when initiating therapy. All analyses were performed for the total group of included patients (n=1610), as well as for the following sub-groups: disease duration over (n=895) or under (n=681) 12 months, baseline SDAI MDA (n=825) or HDA (n=785), DMARD-naive patients starting methotrexate (MTX) (n=537) and patients starting tumour necrosis factor inhibitor (TNFi) (n=248). We used a diagnostic test approach, created receiver operating characteristic curves and generated sensitivities, specificities and likelihood ratios (LRs) for all improvement cut-points (0–100%) at the 3-month visit. Furthermore, we tested the ability of established response criteria (SDAI 50/70/85 response) at 3 months to predict the desired target of SDAI remission or SDAI LDA at 6 months.

Results: At inclusion median (IQR) disease duration was 2 (0.2–8.8) years and mean (SD) SDAI was 28.3 (12.8). At 6 months 46.8% of all patients had achieved LDA and 10.8% had reached remission. Not achieving a minor treatment response (SDAI 50% response) by 3 months was associated with decreased probability of reaching remission at 6 months (LR- 0.27), but gave little prognostic information regarding the probability of reaching LDA (LR- 0.49). Patients with HDA at baseline who did not achieve at least 50% improvement in disease activity by 3 months had very low probability of reaching the treatment target by 6 months (LR- 0.15 for remission and LR- 0.30 for LDA). SDAI 85% response at 3 months was predictive of reaching the treatment target at 6 months (LR+ 6.56 for remission and LR+ of 6.45 for LDA). For the total group of patients, a reduction in SDAI of 60.2% was needed at 3 months to predict LDA at 6 months with 80% specificity, while 69.2% improvement was necessary to predict remission.

SDAI response at 3 months and probability of achieving the treatment target by 6 months

Conclusions: These results from a routine clinical setting confirm results from RCTs demonstrating a predictive association between treatment response at 3 months and achievement of the treatment target by 6 months in RA-patients. Assessments at 3 months can inform clinicians to continue or adjust ongoing DMARD-therapy in a treat-to-target strategy aiming for remission or LDA by 6 months.

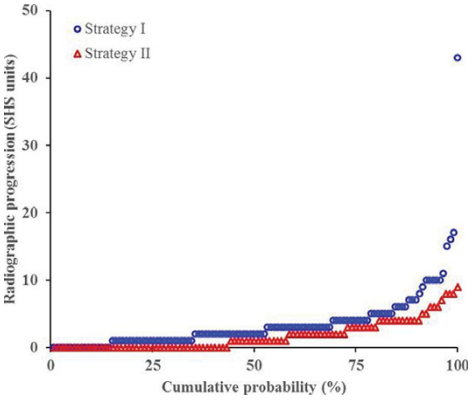
THU0071 RADIOGRAPHIC PROGRESSION IN EARLY RHEUMATOID ARTHRITIS PATIENTS FOLLOWING INITIAL COMBINATION VERSUS STEP-UP TREAT TO TARGET THERAPY IN DAILY CLINICAL PRACTICE: RESULTS FROM THE DREAM REGISTRY



L.M. Steunebrink[1], G.A. Versteeg[2], H.E. Vonkeman[1], P.M. ten Klooster[3], M. Hoekstra[4], M.A. van de Laar[1]. *[1]Arthritis Center Twente, Department of Rheumatology, Department Psychology, Health & Technology, Medisch Spectrum Twente, University of Twente; [2]Arthritis Center Twente, Department of Rheumatology, Department Psychology, Health & Technology, Medisch Spectrum Twente, University of Twente; [3]Department Psychology, Health & Technology, University of Twente, Enschede; [4]Department of Rheumatology, Isala, Zwolle, Netherlands*

Background: Early and aggressive targeted treatment with disease modifying anti-rheumatic drugs (DMARDs) has been shown to lead to substantial reductions in disease activity (1,2) and radiologic damage in patients with early rheumatoid arthritis (RA) (3,4).

Objectives: The aim of this study was to compare the first-year radiographic progression rates between a treat-to-target (T2T) strategy with initial combination therapy (strategy II) versus an initial step-up monotherapy (strategy I).

Methods: A total of 128 patients from strategy II was individually matched with 128 patients from strategy I on sex, age (± 5 yrs.) and baseline disease activity (± 0.5 on the DAS28). Differences in radiographic progression scores and the number of patients experiencing a minimal clinically important difference (≥5 SHS points; MCID) between both strategies were tested with Mann Whitney U test and chi-square test. Next, linear and logistic regression analyses were performed to examine which baseline variables were associated with radiographic progression scores and the probability of experiencing an MCID within 1 year.

Results: Patients with initial combination therapy had slightly higher baseline disease activity scores and pain scores, but better mental health scores. Patients with initial monotherapy had significantly more, and more frequently clinically relevant, radiographic progression after one year. Experiencing a MCID was associated with fewer tender joints (p=0.05) and higher ESR (p=0.02) at baseline.

Conclusions: Excellent radiographic outcome was achieved for patients treated according to a protocolled T2T strategy in daily clinical practice. Patients treated with initial monotherapy had significantly more short-term radiographic progression than patients treated with initial combination therapy.

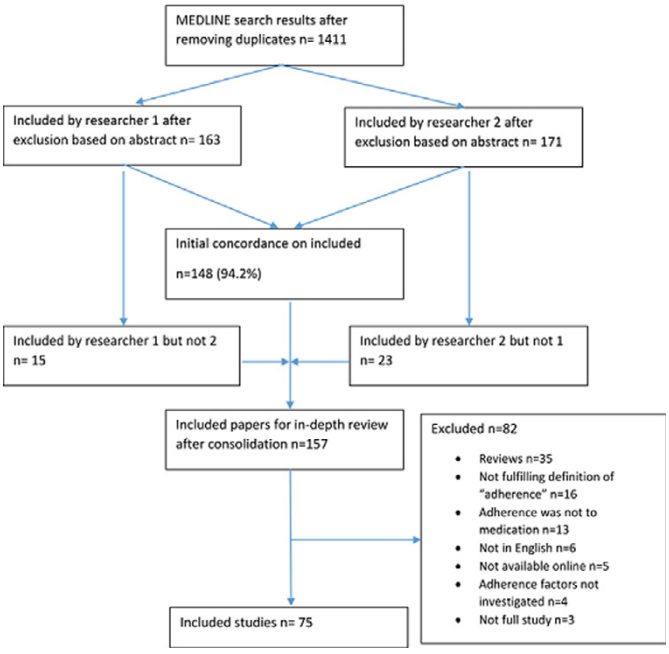
THU0072 RISK OF REVISION, PROSTHETIC JOINT INFECTION AND DEATH FOLLOWING TOTAL HIP OR KNEE ARTHROPLASTY IN PATIENTS WITH RHEUMATOID ARTHRITIS – A NATIONWIDE COHORT STUDY FROM DENMARK

R.L. Cordtz[1,2], L.E. Kristensen[2], S. Overgaard[3], A. Odgaard[4], H. Lindegaard[5], L. Dreyer[1,2]. *[1]Center for Rheumatology and Spine Diseases, Gentofte, Rigshospitalet; [2]The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen; [3]Dept. of Orthopaedic Surgery and Traumatology, Odense University Hospital, Odense; [4]Dept. of Orthopaedics, Herlev and Gentofte Hospital, Copenhagen; [5]Dept. of Rheumatology, Odense University Hospital, Odense, Denmark*



Background: Studies have shown that rheumatoid arthritis (RA) patients are at increased risk of prosthetic joint infection (PJI) but with non-uniform results for mortality risk, following total hip and knee arthroplasty (THA and TKA, respectively). The impact of biological DMARD (bDMARD) treatment on the risk of these outcomes is unknown.
Objectives: To investigate the risk of revision, PJI and death following THA and TKA in 1) RA compared with osteoarthritis (OA) patients and 2) RA patients treated with bDMARDs compared with those not.
Methods: Register-based cohort study linking the National Patient Register, DANBIO, Danish Hip Arthroplasty Register and Danish Knee Arthroplasty Register.
Follow-up: from date of THA/TKA to date of any of the outcomes, to 10 years of follow-up or end of 2014, whichever came first.
Statistics: Fine-Gray competing risks analyses to calculate confounder adjusted sub-Hazard Ratios (aSHR) with 95% confidence intervals (95% CI) for revision and PJI; Cox proportional hazard models to calculate aHR for risk of death.
Results: We identified 3913 RA and 120 499 OA patients. In DANBIO, 360 bDMARD and 1586 not-bDMARD treated RA patients were eligible for analysis. See Table for results.
Conclusions: We report an increased risk of death and PJI but a lower risk of revision in patients with RA compared with OA following THA and TKA. In RA patients, prednisolone, but not bDMARD treatment within the year prior and/or following THA and TKA was associated with an increased risk of death.

THU0073 FACTORS ASSOCIATED WITH TREATMENT ADHERENCE IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

E.T. Goh[1], A.J.X. Soo[1], J. Galloway[2], S. Norton[2], E. Nikiphorou[2]. *[1]University College London; [2]King's College London, London, United Kingdom*

Background: Nonadherence to treatment in rheumatoid arthritis (RA) has been shown to negatively impact on treat to target goals and disease outcomes. Identifying and targeting potential factors influencing nonadherence is therefore crucial in optimising patient management.
Objectives: To determine factors associated with nonadherence in patients with RA.
Methods: An electronic search was performed by two independent reviewers using MEDLINE and focusing on articles published from inception to January 2017. The search strategy combined the thesaurus (MeSH) and expanded keyword searches of two concepts: RA and treatment adherence. Inclusion criteria included observational studies and clinical trials examining potential factors associated with nonadherence. Exclusion criteria included articles not in English or without online access and those with a focus on forms of therapy other than medication. Agreement between raters at the screening stage was high (97%, kappa=.87).
Results: The primary search yielded 1411 papers, from which 75 were eventually identified as suitable for full review (Figure). Of the 75 papers, 65 were based on observational studies and 10 on clinical trials. Factors associated with nonadherence were broadly categorized into patient-related factors (socio-demographic factors, patient perceptions [beliefs/knowledge/attitudes]), disease-related factors (disease duration/severity, comorbidities, functional disability) and treatment-related factors (drug type/ method of administration/duration/regimen complexity, combination therapy). The majority (70% of all included studies) of studies reported significant associations between patient-driven factors and nonadherence. Adherence was found to be negatively associated with socioeconomic status, health literacy, and beliefs/perceptions/knowledge of the disease and treatment. Studies reported poorer mental health state (n=6) and greater disability/pain (n=7) to be implicated in nonadherence. Disease duration was largely non-significant in treatment adherence, although a few studies reported a negative correlation (n=3). Combining biologics with DMARDs was associated with improved adherence. However, considering non-biologic DMARDs only, adherence rates were higher amongst monotherapy users. One study identified polypharmacy to be negatively associated with adherence. Drug side effects were associated with nonadherence (n=7).

Figure. Study selection process & outcomes.

Conclusions: Patient-related factors including personal perceptions were among key contributors to nonadherence to medication in RA patients. This highlights the need for addressing patient-driven perceptions, along with disease and treatment

THU0074 BODY MASS INDEX IN EARLY RHEUMATOID ARTHRITIS IN UNDERWEIGHT PATIENTS IS ASSOCIATED WITH MORE PROGRESSION OF EROSIONS OVER 15 YEARS AND IN OBESE PATIENTS WITH LESS PROGRESSION OF JOINT SPACE NARROWING

S. Ajeganova[1], K. Forslind[2], B. Svensson[2], I. Hafström[1]. [1]*Department of Medicine Huddinge, Karolinska Instiutet, Stockholm;* [2]*Department of Clinical Sciences, Lund University, Lund, Sweden*

Background: Previous short-term follow-up studies and subanalyses of clinical trials in rheumatoid arthritis (RA) have suggested that low body mass index (BMI) is associated with more radiographic joint progression and high BMI with less. The effect of BMI on progression of erosion score (ES) and joint space narrowing (JSN) could be different in underweight and obese patients.
Objectives: To investigate the association between BMI in early RA with radiographic damage during 15 years; to examine if known predictors of a worse radiographic outcome could explain differential radiographic outcome in low and high BMI groups.
Methods: Four hundred and seventy-three patients from the BARFOT study included from 1992 to 1999 who performed their 15-year assessment were studied. The patients were assessed at inclusion and after 1, 2, 5, 8 and 15 years. The groups were defined by BMI (kg/m^2) at inclusion: BMI $\leq$20, (n=27), BMI 20$<$25 (n=210), BMI 25$<$30 (n=179), and BMI$\geq$30 (n=57). X-rays of hands and feet were scored by the Sharp-van der Heijde scoring method (SHS). Linear mixed models with SHS, ESR, CRP, SJC and TJC as outcome, and BMI at inclusion as predictor was used, adjusted for age, sex, initial treatment, ACPA and smoking.
Results: At baseline, total score of SHS, ES and JSN did not differ between BMI groups. There were more women and smokers in BMI$\leq$20 group and older patients in BMI$\geq$30 group. The baseline disease characteristics were similar in the BMI groups.
For the patients with BMI$\leq$20 at inclusion, BMI was associated with a higher predicted SHS progression during follow-up, effect size 5.11 (95% CI 1.72 to 15.15) p=0.005, while for the patients with BMI$\geq$30 at inclusion, BMI was associated with lower SHS, effect size 0.92 (0.86 to 0.99) p=0.028. The directions of association between BMI at inclusion and ES and JSN were similar to that for the total SHS. The effect size of the association with erosion progression was however significant only in the BMI$\leq$20 group, 1.15 (2.72 to 6.42) p=0.025 (in the BMI$\geq$30 group 0.95 (0.90–1.00) p=0.074). On the other hand, association between BMI and JSN progression was significant only in the BMI$\geq$30 group, 0.93 (0.87 to 0.99) p=0.033 (in the BMI$\leq$20 group 2.53 (0.83–7.67) p=0.096).
There were no associations between BMI and radiographic damage in BMI 20$<$25 and BMI 25$<$30 groups.
We found no significant association between BMI and ESR, CRP, SJC, TJC over time in the BMI$\leq$20 group. In the BMI$\geq$30 group, BMI was associated with a higher predicted CRP during follow-up, effect size 1.06 (1.01 to 1.12) p=0.028, but not with ESR and SJC. Compared to the patients with BMI 20–25, patients with BMI$\geq$30 had higher TJC over 15 years, 3.17 (1.06 to 9.27) p=0.038.
Conclusions: Underweight at onset of RA is associated with more radiographic damage up to 15 years and obesity with less joint damage, independent of sex, ACPA and smoking status. The effect of BMI is not explained by measures of disease activity.

THU0075 THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND DISABILITY IS MEDIATED BY PAIN AND FATIGUE IN EARLY RHEUMATOID ARTHRITIS

S. Twigg[1,2], E.M.A. Hensor[1], P. Emery[1], A.W. Morgan[1], A. Tennant[3] on behalf of Yorkshire Early Arthritis Register. [1]*Leeds Institute Rheumatic and Musculoskeletal Medicine, University of Leeds;* [2]*National Institute for Health Research- Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [3]*Swiss Paraplegic Research, Nottwil, Switzerland*

Background: Disability in early rheumatoid arthritis (RA) is correlated with disease activity. However, the relationship between these two clinical outcomes is relatively under-investigated. Understanding how disability is driven by disease activity will allow targeted interventions to improve function in early RA, alongside the suppression of inflammation.
Objectives: To identify mediators in the relationship between disease activity and disability in early RA.
Methods: Cases with new consultant-made diagnoses of RA were recruited to Yorkshire Early Arthritis Register within 24 months of symptom onset. At the baseline assessment, clinical variables were collected including the 3 variable disease activity score from counts of 28 tender and swollen joints and C-reactive protein (DAS28), Health Assessment Questionnaire (HAQ) and visual analogue scores (VAS) of pain and fatigue. Structural equation models (SEM) were constructed to evaluate the relationship between DAS28, HAQ, pain, symptom duration (SD), age and fatigue.
Results: Of 721 cases included, 482 were female and 239 male. Median age was 58 for both genders and median HAQ was 1.25 and 1.00 for women and men, respectively. A path model within a SEM framework (Figure 1) was a good fit to the data (Chi square 7.528, df=6, p=0.2748; CFI 0.997; RMSEA 0.027). However, the model could not be applied simultaneously to both genders; although estimates of regression coefficients did not vary between males and females (metric invariance), model intercepts were different. In earlier models, age was not a significant predictor and regressions of fatigue on DAS28 were not significant: the effect of DAS28 upon fatigue was fully mediated by pain. Standardised coefficients of direct and indirect effects of DAS28 on HAQ are shown in Table 1, together with Sobel tests for significance of mediator variables. The greatest effect upon HAQ was the direct effect from DAS28, but some of the effect of DAS28 on HAQ was partially mediated by pain. Furthermore, the effect of pain upon HAQ was also partially mediated through fatigue. According to the Sobel test, pain and fatigue were significant mediators in both females and males.

Table 1 Total, Direct and Indirect effects upon HAQ

Standardised effect upon HAQ	Females			Males		
	Estimate	SE	p	Estimate	SE	p
DAS28 total	0.412	0.040	<0.001	0.508	0.053	<0.001
DAS28 indirect	0.139	0.024	<0.001	0.163	0.033	<0.001
DAS28- direct	0.282	0.046	<0.001	0.344	0.060	<0.001
DAS28 via pain and fatigue	0.038	0.010	<0.001	0.032	0.014	0.025
DAS28 via pain	0.101	0.024	<0.001	0.131	0.033	<0.001
Sobel test statistic (fatigue via pain)	3.280	0.002	0.001	2.279	0.002	0.022
Sobel test statistic (Pain)	3.920	0.085	<0.001	3.253	0.122	0.001

SE, standard error.

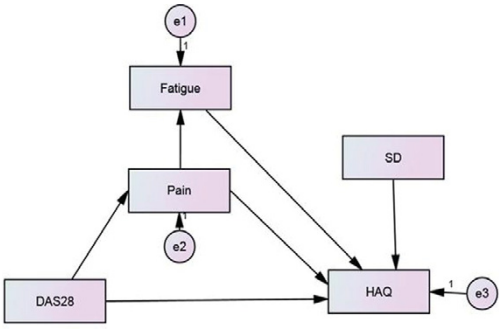

Figure 1. Path diagram to show the relationship between disease activity and disability mediated by pain and fatigue.
SD, symptom duration; e1-3, error terms (representing the unexplained variance in outcomes)

Conclusions: DAS28 dominates the impact upon HAQ in early RA; pain is shown to be an important mediator of the effects of DAS28 on HAQ, while fatigue is important as a mediator of the effect of pain on HAQ. This adds to previous evidence that pain is a driver of fatigue in RA (1) and suggests that interventions to manage pain could be important adjuncts to supression of inflammation in early RA, in order to optimise function.

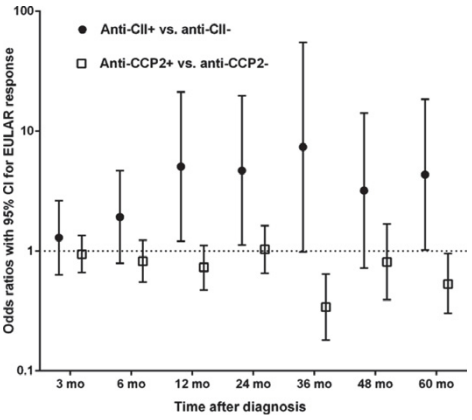
THU0076 DISEASE-MODIFYING TREATMENT REGIMENS HAVE BEEN INSUFFICIENT TO REDUCE THE INCIDENCE OF SYSTEMIC AA AMYLOIDOSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS IN CONTRAST TO A SIGNIFICANT REDUCTION IN THOSE WITH JUVENILE IDIOPATHIC ARTHRITIS

T.A.-B. Youngstein[1], T. Lane[1], J. Gilbertson[1], J. Pinney[1], T. Rezk[1], R. Manwani[1], C.C. Quarta[1], A. Wechalekar[1], S. Mahmood[1], S. Sachchithanantham[2], M. Fontana[1], C. Whelan[1], J.D. Gillmore[3], P.N. Hawkins[1], H.J. Lachmann[1]. [1]*National Amyloidosis Centre, UCL Division of Medicine;* [2]*National Amyloidosis Centre, UCL Division of Medicine, London;* [3]*National Amyloidosis Centre, National Amyloidosis Centre, UCL Division of Medicine, London, London, United Kingdom*



Background: The UK National Amyloidosis Centre has the largest known cohort of individuals with AA amyloidosis, with 660 cases since 1990. A third present in end stage renal failure (33%), with a median survival of 133 months from diagnosis[1]. Over 27 years the rate of new cases has remained remarkably constant with a median of 24 diagnoses per annum (IQR 18.5–30.5) but responsible for a decreasing proportion of new cases of systemic amyloidosis from 35% in the first 5 years to 6% in the last 5 years of the cohort.
Objectives: We sought to determine to what extent advances in treatment of the inflammatory arthritides have influenced the aetiology of AA Amyloidosis over time.
Methods: Retrospective analysis of the UK National Amyloidosis Centre AA

Amyloidosis database containing baseline demographic and clinical data. Data was analysed using a Chi-squared test (GraphPad Prism 7.0).
Results: Between 1990–2000 there were 188 new cases of AA Amyloidosis of which 51 (27.1%) had an underlying diagnosis of rheumatoid arthritis (RA), median age at diagnosis of amyloid was 60 years. 37 (19.7%) had a diagnosis of Juvenile Idiopathic Arthritis (JIA), median age 29 years. Between 2007 and 2017 there were 270 new diagnoses of AA Amyloidosis, of whom 57 had RA (21.1%), median age 66 years, and 5 (1.9%) had JIA, median age 37 years. Since the widespread use of combination disease-modifying and biologic therapy there has been a significant reduction in the incidence of JIA-associated AA Amyloidosis ($p<0.0001$). In contrast, the incidence of RA-associated AA Amyloidosis is unchanged ($p<0.1357$).
Conclusions: Advances in the treatment of JIA have significantly reduced the incidence of AA Amyloidosis in this cohort. In contrast, despite largely the same medication and similar treatment targets, RA continues to be responsible for a substantial proportion of new cases of AA Amyloidosis. One possible explanation for this may be that current assessment of disease activity in RA is sufficient to identify those at risk of joint damage or radiological progression of disease but insufficient for identifying peristent subclinical biochemical inflammation. One approach for reducing this risk may be the routine measure of the AA Amyloid precursor protein, serum Amyloid A protein (SAA) in those with RA, as it is well established that levels of SAA of below 10mg/L prevents the accumulation of AA Amyloid in those with inflammatory disease.

THU0077 ANTI-COLLAGEN TYPE II ANTIBODIES ARE ASSOCIATED WITH AN ACUTE ONSET RHEUMATOID ARTHRITIS PHENOTYPE AND PROGNOSTICATE LOWER DEGREE OF INFLAMMATION

V.A. Manivel[1], M. Mullazehi[1], L. Padyukov[2], H. Westerlind[3], L. Klareskog[2], L. Alfredsson[3], S. Saevarsdottir[2], J. Rönnelid[1]. *[1]Immunology genetics and Pathology, Uppsala University, Uppsala; [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital and Karolinska Institutet; [3]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*

Background: Anti-collagen II antibody (anti-CII) positive RA patients present with early but not persistent signs of inflammation and joint erosions. This early anti-CII-dependent phenotype coincides with high anti-CII levels around the time of RA diagnosis, whereafter anti-CII levels drop. Our previous studies showed that this phenotype is associated with *in vitro* cytokine production by monocytes, activation of granulocytes, and enhanced chemokine production by monocyte/granulocyte cocultures, stimulated with anti-CII containing immune complexes. These *in vitro* findings argue that elevated anti-CII levels at time of RA diagnosis are functionally related to the corresponding acute onset RA phenotype.
Objectives: Our previous comparison done in a small RA cohort (n=274) describe that anti-cyclic citrullinated peptide 2 (anti-CCP2) positive patients have a severe long-term prognosis but anti-CII positive patients have transient inflammation. In the present study we wanted to extend this in a large RA cohort with clinical follow-up data, and to relate to HLA-DRB1* alleles.
Methods: Anti-CII and anti-CCP2 were measured at baseline in 773 patients from the Swedish Epidemiological Investigations in Rheumatoid Arthritis (EIRA) study with clinical follow-up data from the Swedish Rheumatology Quality (SRQ) registry, and 1476 patients with HLA-DRB1* information. Comparisons were done concerning CRP, ESR, TJC, SJC, DAS28, DAS28CRP, pain-VAS, global-VAS and HAQ at 8 occasions during 5 years, and association to HLA-DRB1* alleles.
Results: Anti-CII was detected in 6.6% (97/1476), and anti-CCP2 in 57.9% (855/1476) of the patients. There was no significant difference in treatment strategy at diagnosis for patients with and without those antibodies. Anti-CII associated with elevated CRP, ESR, SJC, DAS28 and DAS28CRP at diagnosis and up to six months, whereas anti-CCP2 associated with SJC and DAS28 from 6 months to 5 years, but not earlier. The anti-CII-associated phenotype was strong, and predominated also in anti-CII/anti-CCP2 double positive patients. Compared to baseline levels, anti-CII was asscociated with improvements in CRP, ESR, SJC, TJC and DAS28 over time, whereas anti-CCP2 was associated with deteriorations in SJC and DAS28 over time, compared to antibody negative patients. Anti-CII positive patients achieved EULAR good or moderate response more often than negative patients whereas the opposite was found for anti-CCP2 positive patients (figure). Anti-CII was positively associated with HLADRB1*01 and HLADRB1*03, with significant interaction, and double positive individuals had >14 times higher mean anti-CII levels than HLA double negatives. Whereas smoking associated with elevated anti-CCP2 levels, smokers has lower anti-CII levels.

Conclusions: Anti-CII seropositive RA represents a distinct phenotype, in many respects representing the converse to the clinical, genetic and smoking associations described for ACPA. Although not diagnostically useful, early anti-CII determinations predict favourable inflammatory outcome in RA. The combined analysis of anti-CII and ACPA/anti-CCP2 may be a new two-dimensional tool for predicting the prognosis and chosing therapy in newly diagnosed RA patients.

THU0078 CONCOMITANT USE OF CONVENTIONAL SYNTHETIC DMARDS AND RESPONSE TO BARICITINIB

A. Kavanaugh[1], C. Helt[2], D. Muram[2], J. Alam[2], V. Arora[2], A.L. Pinto Correia[2], I. de la Torre[2], R. van Vollenhoven[3]. *[1]UC San Diego School of Medicine, la Jolla; [2]Eli Lilly and Company, Indianapolis, United States; [3]Amsterdam Rheumatology & Immunol Center, Amsterdam, Netherlands*

Background: Baricitinib (BARI), an oral JAK1/JAK2 inhibitor, is in development for patients (pts) with moderate to severe rheumatoid arthritis (RA).[1,2]
Objectives: This post-hoc analysis of two phase 3 studies assessed whether concomitant use of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) altered the response or safety outcomes to BARI in RA pts and evaluated the effect of concomitant corticosteroid use on the efficacy of BARI.
Methods: Pts with ≥6 swollen and tender joints and no prior biologic DMARD use were enrolled. In RA-BEAM (NCT01710358), methotrexate (MTX)-inadequate responder (IR) pts were randomised to PBO once daily (QD), BARI 4 mg QD, or adalimumab 40 mg biweekly.[1] In RA-BUILD (NCT01710358), csDMARD-IR pts were randomised to placebo (PBO) or BARI (2 or 4 mg) QD.[2] Pts continued background csDMARD (including MTX) therapy. This post-hoc analysis included the PBO (N=716) and BARI 4 mg (N=714) pts and assessed the number and type of concomitant csDMARDS and concurrent corticosteroid use.
Results: 71%, 21%, and 6% of PBO pts were taking MTX alone, MTX + ≥1 other csDMARD, and non-MTX csDMARDs, respectively; in BARI 4 mg pts, the

rates were 74%, 18%, and 6%, respectively. Oral corticosteroids were used in 56% of PBO and 55% of BARI pts at baseline; pts continued use throughout the studies. The differences in clinical efficacy between BARI 4 mg and PBO at 12 weeks was similar regardless of the number or type of csDMARDs concomitantly used (Table) or the concomitant use of corticosteroids (data not shown). The rates of serious adverse events and discontinuation due to adverse events were comparable regardless of the number or type of csDMARDs used (Table) or corticosteroid use.

ACR20/50/70=20%, 50%, and 70% improvement in American College of Rheumatology criteria; csDMARDs=conventional synthetic disease-modifying antirheumatic drugs; DAS28-ESR=Disease Activity Score 28-erythrocyte sedimentation rate; MTX=methotrexate; SDAI=Simple Disease Activity Index.

Conclusions: BARI has demonstrated clinical safety and efficacy in a wide range of pts, regardless of the number of concomitant csDMARDs or concomitant use of corticosteroids.

THU0079 EVALUATION OF SYNOVITIS IN THE FOOT AND THE ANKLE NOT INCLUDED IN THE 28-JOINT DISEASE ACTIVITY SCORE USING ULTRASONOGRAPHY AND HISTOLOGICAL FINDINGS IN THE PATIENTS WITH RHEUMATOID ARTHRITIS

A. Abe, H. Ishikawa. *Rheumatology, Niigata Rheumatic Center, Shibata, Japan*

Background: In the treatment of rheumatoid arthritis (RA), the early diagnosis and early medical treatment via tight control have become increasingly important with the advent of biological therapy. Ultrasonography (US) for the affected joints enables the evaluation of synovial hypertrophy, effusion and bone erosion in real time. US is a reliable method that can detect more erosive sites than radiography. US is now utilized widely and is a reliable tool of rheumatologists for diagnosing RA and evaluating the disease activity.

Objectives: This study was conducted to clarify the relationship between the systemic disease activity, local disease activity using US and a synovial histopathological evaluation.

Methods: Between March 2011 and September 2015, 668 joints were surgically treated on the whole, and synovial biopsies were performed at the time of surgery. Among them, a total of 118 toes and 21 ankles, which are not included in the 28-joint disease activity score (DAS28), were investigated. Just before surgery, the US probe was placed on the dorsal aspect of the ankle and/or the toes to evaluate the activity of local synovitis. The maximum grade of power Doppler (PD) signal was determined, ranging from 0 to 3. The serum C reactive protein (CRP), matrix metalloproteinase-3 (MMP-3) and DAS28 values were also examined just before surgery. A histopathological examination of the gathered synovium at the surgical site was performed using the Rooney score (RS). Biological disease-modifying antirheumatic drugs were used in 45 cases, namely infliximab in 7 cases, etanercept in 16, adalimumab in 7, tocilizumab in 6, abatacept in 4, certolizumab pegol in 1, and golimumab in 4.

	DAS28	CRP (mg/dL)	MMP-3 (ng/mL)	RS
PD0 (n=82)	3.07 (1.07)	0.40 (0.67)	106.96 (193.69)	18.38 (3.35)
PD1 (n=32)	3.43 (1.19)	0.67 (1.08)	117.11 (92.83)	22.38 (6.58)
PD2 (n=20)	3.41 (0.89)	0.61 (0.71)	124.81 (52.61)	32.85 (6.96)
PD3 (n=5)	3.13 (0.52)	0.78 (0.76)	150.46 (123.87)	29.40 (4.51)

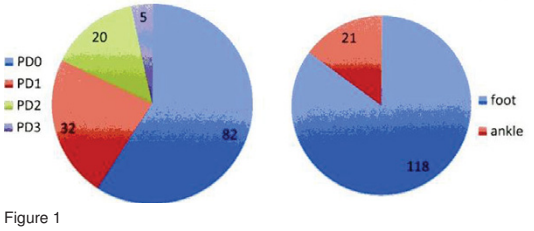

Figure 1

Results: The PD score was grade 0 in 82 cases, 1 in 32 cases, 2 in 20 cases and 3 in 5 cases. The total RS and its item scores except for "proliferating blood vessels" correlated well with the PD signal intensity. The systemic disease activity, as indicated by DAS28, CRP and MMP-3, had no significant correlation with the local PD signal intensity. However, the DAS28, CRP and MMP-3 values and each RS item score, except for "proliferating blood vessels", were significantly lower in the PD grade 0 group than in the PD grades 1, 2 and 3 groups.

Conclusions: No PD signal intensity in the ankle and foot indicates systemically well-controlled disease activity. US is an excellent tool for determining local synovitis as well as the systemic disease activity in patients with RA.

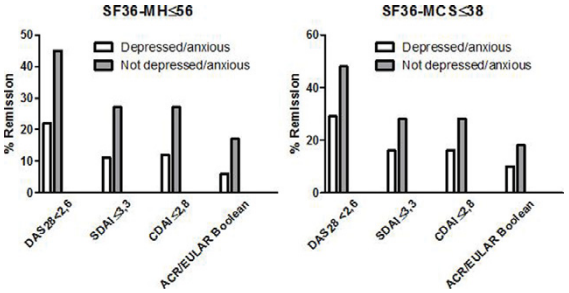
THU0080 DEPRESSION AND ANXIETY REDUCE THE LIKELIHOOD OF ACHIEVING REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL LIFE DATA FROM THE NOR-DMARD STUDY

B. Michelsen[1,2], E.K. Kristianslund[2], K.M. Fageli[2], E. Lie[2], H.B. Hammer[2], G. Haugeberg[1,3], T.K. Kvien[2]. *[1]Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand; [2]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo; [3]Dept. of Rheumatology, Martina Hansens Hospital, Bærum, Norway*



Background: Depression and anxiety are reported to predict poorer treatment outcomes in rheumatoid arthritis (RA).[1] Whether this can be confirmed in larger prospective observational studies using various remission criteria remains to be explored.

Objectives: To investigate the predictive value of baseline depression/anxiety on the likelihood of achieving remission in RA as well as the associations between baseline depression/anxiety and the components of the remission criteria at follow-up.

Methods: From the prospective, multi-center NOR-DMARD study we included RA patients starting first-time tumour necrosis factor inhibitors (TNFi) and DMARD naïve RA patients starting methotrexate (MTX) between year 2006 and 2012. The following two criteria for depression/anxiety were assessed: 1) the Medical Outcomes Survey Short Form-36 (SF-36) Mental Health subscale (MH)≤56 and 2) the SF-36 Mental Component Summary score (MCS)≤38.[2] The predictive value of baseline depression/anxiety on remission after 3 and 6 months treatment was explored in prespecified logistic regression models adjusted for age, sex, disease duration and smoking and the associations between baseline depression/anxiety and the different components of the remission criteria at follow-up in prespecified multiple linear regression models adjusted for age, sex, disease duration and smoking.

Results: A total of 1450 RA patients were included (mean (SD) age 54.4 (13.5) years, median (25th-75th percentile) disease duration 0.4 (0.0–5.0) years, 68.7% females and 28.6% current smokers). According to the SF-36MH≤56/SF-36MCS≤38 criteria 18.1/29.9% of the patients were depressed/anxious at baseline, respectively. Lower percentages of patients with versus without baseline depression/anxiety achieved remission at 3 and 6 months treatment (unadjusted analyses, figure). Baseline depression/anxiety negatively predicted remission after 3 and 6 months (adjusted analyses, table 1 and 2).

The findings were confirmed in separate subgroup analyses of TNFi/MTX treated patients. Baseline depression/anxiety were associated with increased patient's and evaluator's global assessment and 28 tender joint count at 3 and 6 months, but not with level of acute phase reactants or 28 swollen joint count.

Abstract THU0080 – Table 1. Odds ratio (95% CI) for remission in patients with versus without baseline depression/anxiety according to the SF36-MH ≤56 criterion

Months	DAS28<2.6	SDAI≤3.3	CDAI≤2.8	ACR/EULAR Boolean
3	0.48 (0.32–0.73), p<0.001	0.43 (0.25–0.74), p=0.003	0.38 (0.22–0.65), p<0.001	0.27 (0.13–0.57), p=0.001
6	0.36 (0.24–0.56), p<0.001	0.35 (0.20–0.60), p<0.001	0.38 (0.23–0.63), p<0.001	0.31 (0.16–0.61), p=0.001

Abstract THU0080 – Table 2. Odds ratio (95% CI) for remission in patients with versus without baseline depression/anxiety according to the SF36MCS ≤38 criterion

Months	DAS28ESR <2.6	SDAI ≤3.3	CDAI ≤2.8	ACR/EULAR Boolean
3	0.67 (0.49–0.93), p=0.02	0.51 (0.34–0.78), p=0.002	0.47 (0.32–0.70), p<0.001	0.35 (0.21–0.59), p<0.001
6	0.45 (0.32–0.63), p<0.001	0.46 (0.31–0.69), p<0.001	0.48 (0.33–0.69), p<0.001	0.46 (0.29–0.72), p=0.001

Conclusions: Depression and anxiety may reduce likelihood of remission based on composite scores in RA and should be taken into account in individual patients when making a shared decision on a treatment target.

THU0081 DIFFERENCES IN PATIENT-REPORTED OUTCOMES BETWEEN BARICITINIB AND COMPARATORS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS WHO ACHIEVED LOW DISEASE ACTIVITY OR REMISSION

B. Fautrel[1], M. van de Laar[2], B. Kirkham[3], R. Alten[4], R. Cseuz[5], S. Van der Geest[6], B. Zhu[7], F. De Leonardis[8], P. Taylor[9]. *[1]University Pierre et Marie Curie, Paris, France; [2]Arthritis Centre Twente, Medisch Spectrum Twente, Enschede, Netherlands; [3]Guys Hospital, London, United Kingdom; [4]Schlosspark Klinik, Berlin, Germany; [5]Revita Private Clinic for Rheumatology, Budapest, Hungary; [6]Eli Lilly & Company, Utrecht, Netherlands; [7]Eli Lilly and Company, Indianapolis, United States; [8]Eli Lilly & Company, Geneva, Switzerland; [9]University of Oxford, Headington, United Kingdom*

Background: Achieving remission is the ideal goal in treating rheumatoid arthritis (RA). In a randomised phase 3 trial, high remission and low disease activity (LDA) rates were achieved with baricitinib (BARI). However, little is known about the differences in patient reported outcomes (PROs) among patients (pts) who have already achieved these targets.

Objectives: To compare PROs between BARI, adalimumab (ADA), and placebo (PBO) in pts with RA who achieved LDA or remission in the Phase 3 RA-BEAM study.

Methods: 1305 pts with RA and background treatment with methotrexate were randomised to receive PBO (n=488), ADA (n=330), or BARI 4 mg (n=487) for 52 wks (24 wks for PBO). In each treatment group, pts in remission (DAS28-ESR$<$2.6) and with LDA (DAS28-ESR$\leq$3.2) at wk 24 were assessed from baseline for the following PROs: Pain VAS, HAQ-DI, WPAI, Morning Joint Stiffness (MJS), and FACIT-F. Sensitivity analyses were conducted for pts in remission or LDA by DAS28-CRP, SDAI, or CDAI. The assessment of response at wk 24 was determined by using the observed data, and the missing values for PRO measures were imputed by using mLOCF.

Results: Among pts in LDA, significantly greater improvements in Pain VAS and HAQ-DI scores were observed with BARI than ADA and PBO, and significantly greater improvements in MJS were observed with BARI and ADA than PBO. Significantly greater residual pain and HAQ-DI scores were observed with PBO. Among pts in remission, significantly greater improvements in pain and HAQ-DI scores were also observed with BARI than PBO. Patients in remission or LDA showed greater numerical improvement and less residual impairment in other PROs with BARI and ADA than PBO (Table 1). Consistent results were observed using other composite measures to define LDA and remission.

PRO Measures	Baseline	Residual Mean Value at Wk 24	Observed Change at Wk 24	Baseline	Residual Mean Value at Wk 24	Observed Change at Wk 24	Baseline	Residual Mean Value at Wk 24	Observed Change at Wk 24

THU0082 LUNG INVOLVEMENT IN ACPA POSITIVE SUBJECTS: A PILOT STUDY ON THE ROLE OF LABORATORY, FUNCTIONAL AND IMAGING MARKERS

B. Lucchino[1], M.C. Gerardi[1], C. Iannuccelli[1], M.P. Guzzo[1], M. Di Paolo[2], M. Bonini[2], F. Vaccaro[2], P. Palange[2], F. Vullo[3], D. Diacinti[3], G. Valesini[1], M. Di Franco[1]. *[1]Department of Internal Medicine and Medical Specialities; [2]Department of Public Health and Infectious Diseases; [3]Department of Radiology, Sapienza university of Rome, Roma, Italy*

Background: The ACPA-positive Rheumatoid Arthritis (RA) is a complex disease. Signs of immune activity against citrullinated proteins may be present years before the onset of clinical manifestations. Recent findings suggest that the lung may represent an early site of autoimmune-related injury in ACPA-positive patients without signs of arthritis.

Objectives: The purpose of the present study was to evaluate the presence of subclinical pulmonary abnormalities in ACPA-positive subjects without arthritis and in RA-patients through laboratory, functional and imaging markers.

Methods: Eleven ACPA-positive subjects without arthritis, 10 patients naïve to therapy with early ACPA-positive RA ($<$6 months duration) and 9 with established ACPA-positive RA ($<$36 months duration) were consecutively enrolled. Subjects underwent baseline pulmonary function tests (PFTs), DLCO measurement and CPET. The evaluation of Surfactant protein D (SP-D) serum levels was performed in all the patients and in 9 healthy controls matched for age and sex with an ELISA test. Twenty-four subjects underwent chest high-resolution computer tomography (HRCT), in order to evaluate parenchymal or airways abnormalities.

Results: The cohort consisted of 7 men and 23 women, mean age 48,93 (DS+/-12.1). PFTs resulted abnormal only in 2 patients. A DLCO reduction was observed in 54.5% of ACPA-positive subjects without RA, in 60% and in 55.6% of patients with early and established RA, respectively. In RA patients, an inverse correlation between disease duration and DLCO/Va (r=-0.50; p=0.03) was observed. The exercise tolerance at CPET was reduced in 54.5% of ACPA-positive subjects without RA, in 20% of patients with early RA and in 55.6% of those with established RA. Serum SP-D levels were higher in established RA (p=0.079), in ACPA-positive subjects and early RA than in healthy controls. ACPA levels positively correlated (r=0.45;p=0.01) with CPET parameters of ventilation inefficiency, suggesting a ventilation/perfusion mismatch. A negative correlation between ACPA and SP-D levels and CPET metabolic parameters was also observed. The presence of pulmonary nodules was the most common alteration founded at HRCT, equal to 28% in ACPA-positive subjects without arthritis, in 66% and 87% of patients with early and established RA, respectively. In the last group, all patients showed parenchymal abnormalities. There was also a significant (p=0.022) higher frequency of lung abnormalities in patients with established disease compared with the other two groups.

Conclusions: The early lung involvement in RA is often subclinical and baseline PFT's are scarcely informative. Although preliminary, these findings suggest that DLCO, CPET parameters and SP-D can represent early markers of the subclinical lung injury. Furthermore, lung abnormalities detectable at HRCT seem to develop early in the course of the disease. However, additional studies are needed to clarify lung abnormalities in RA.

THU0083 THE RELEVANCE OF ELEVATED CRP AS AN INCLUSION CRITERION IN CLINICAL TRIALS IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Scoville[1], J. Subotícki[2], S. Zhong[2], E. Keystone[3]. *[1]Idaho Falls Arthritis Clinic, Idaho Falls; [2]AbbVie, N Chicago, United States; [3]Mount Sinai Hospital, Univ of Toronto, Toronto, Canada*

Background: Elevated C-reactive protein (CRP) is often used as an entry criterion in clinical trials (CT) of patients (pts) with rheumatoid arthritis (RA), resulting in the potential exclusion of pts with active disease and high screen failure rates[1].

Objectives: To assess the relevance of requiring an elevated CRP ($\geq$1 mg/dL) as an inclusion criterion for clinical, functional, and radiographic outcomes.

Methods: This *post hoc* analysis used data from 2 randomized CTs in RA pts with an inadequate response to methotrexate (MTX). In DE019, pts on background MTX received adalimumab (ADA) or placebo (PBO)[2]; in MUSICA, pts received either 7.5 or 20 mg MTX, along with ADA[3]. Data from MUSICA were used

to confirm observations from DE019. Pts were subgrouped by CRP level at entry (CRP <1 mg/dL, ≥1 mg/dL). Baseline (BL) demographics and disease characteristics were summarized for each group. Clinical efficacy was assessed through swollen/tender joint count (S/TJC) at 66/68 joints, pain, patient global assessment (PtGA), physician global assessment (PhGA), CRP, clinical disease activity index (CDAI), 28-joint disease activity score based on CRP (DAS28-CRP), and proportions of pts achieving ACR20/50/70. Functional outcomes were assessed by the disability index of the health assessment questionnaire (HAQ-DI), and radiographic outcomes by the modified total Sharp score (mTSS). Outcomes were assessed in pts with CRP <0.8 mg/dL in DE019, which included pts with CRP levels as low as 0.75 mg/dL Observed data are reported at week 24.

Results: In DE019, 183 pts (89 and 94 in the ADA and PBO arms, respectively) had CRP <1 mg/dL and 224 pts (118 and 106, respectively) had CRP ≥1mg/dL. Pts with elevated CRP had higher BL disease activity compared with those with CRP <1 mg/dL at entry (not shown). After 24 wks of treatment with ADA, pts in both CRP subgroups experienced significant improvements in most clinical and functional outcomes vs PBO (Table). In pts with CRP <0.8 mg/dL, the ACR20 response rate difference (30.4, p<.001) and the difference in ΔmTSS (-1.3, p<.05) for ADA vs PBO treatment were still significant. Compared to pts with CRP <1 mg/dL, pts with elevated CRP experienced greater clinical and functional improvements. However, within the ADA subgroups, pts with elevated CRP had smaller differences vs PBO in mTSS, perhaps reflecting higher joint damage at BL. In general, similar trends were observed in MUSICA (not shown).

Disease characteristics at Week 24 in patients with CRP <1 or ≥1 mg/dL at entry in DE019

Change from baseline values and least square mean differences (using ANCOVA) are reported for continuous endpoints. p-values for binary endpoints are calculated based on chi-square test or Fisher's exact test. ***, **, *: p < .001, .01 and .05, respectively for differences between treatment groups for change from BL. Missing values are not imputed.
[a]n=82, [b]n=76, [c]n=72, [d]n=102, [e]n=99, [f]n=78, [g]n=84 .
TJC68, tender joint count at 68 joints; SJC66, swollen joint count at 66 joints; PtGA, patients global assessment of disease activity; PhGA, physician's global assessment of disease activity; HAQ-DI, disability index of health assessment questionnaire; CRP, C-reactive protein; DAS28-CRP, 28-joint disease activity score based on CRP; CDAI, clinical disease activity index; mTSS, modified total Sharp score; ACR20/50/70, 20, 50 and 70% improvement in the American College of Rheumatology criteria

Conclusions: While pts with elevated CRP at entry experienced larger improvements from BL in clinical and functional outcomes upon treatment, significant improvements in most outcomes were also observed in those without elevated CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not be required to see differences between active and inactive treatment.

THU0084 AGREEMENT BETWEEN THE DAS28-ESR AND THE DAS28-CRP AND FACTORS RELATED TO THE DISCREPANCIES BETWEEN DISEASE ACTIVITY LEVELS ACCORDING TO THESE 2 SCORES IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE ESPOIR COHORT

C. Gaujoux-Viala[1,2], M. Belkacemi[3], A. Cantagrel[4], B. Fautrel[5], B. Combe[6].
[1]Rheumatology, Nîmes University Hospital; [2]EA2415, Montpellier University, Nîmes; [3]IURC, EA2415, Montpellier; [4]Rheumatology, Toulouse University Hospital, Toulouse; [5]Rheumatology, Pitié-Salpêtrière Hospital, APHP, Paris; [6]Rheumatology, Lapeyronie Hospital, Montpellier, France

Background: DAS28 is often used as a treatment decision tool in patients with rheumatoid arthritis (RA) in the daily clinic. Although different versions of DAS28 have previously been validated, and although disease activity thresholds are the same, it is not clear whether DAS28-ESR and DAS28-CRP can be used interchangeably in individual patients.

Objectives: The aims of our study were to examine the agreement between these two DAS28 versions in individual early RA patients in the daily clinic and to idenditify factors related to the discrepancies between disease activity levels according to these 2 scores.

Methods: Baseline and 6 months data from 677 patients with early RA (ACR EULAR 2010) were extracted from the French cohort of early arthritis ESPOIR (at least 2 swollen joints for less than 6 months, DMARD naïve) and were used to calculate DAS28-ESR and DAS28-CRP. Disease activity levels according to the DAS thresholds and EULAR responses were assessed. Intraclass correlation coefficient [ICC] and weighted kappa (k) were calculated. The Bland-Altman method was used to examine the bias between the DAS scores and the 95% limits of agreement (LoA). Multivariate logistic regression was used to determine the patient and RA features independently associated with discrepancies between disease activity levels according to DAS28-ESR and DAS28-CRP.

Results: The mean value of DAS28-CRP (5.04±1.16 at M0 and 3.38±1.33 at M6) was smaller than that of mean DAS28-ESR (5.33±1.24 at M0 and 3.51±1.42 at M6). Agreement between the scores was excellent: ICC=0.93 at M0 and M6. Agreement between disease activity levels according to the 2 scores was good: k=0.70 at M0 and 0.75 at M6. Agreement between EULAR responses at M6 according to the 2 scores was good: k=0.78. At M0, the bias of DAS28-CRP was -0.28 (LoA -1.16, 0.59) and -0.14 (LoA -1.17, 0.89) at M6.There were discrepancies between disease activity levels according to the 2 scores in 122 (18.6%) patients at M0 with clear difference in moderate (88 patients for DAS28-CRP vs 29 for DAS28-ESR) and high disease activity (18 patients for DAS28-CRP vs 80 for DAS28-ESR), and in 171 (28.1%) patients at M6 with clear difference in remission (42 patients for DAS28-CRP vs 29 for DAS28-ESR) and high disease activity (9 patients for DAS28-CRP vs 32 for DAS28-ESR). At M0, presence of erosion (OR 95% CI=1.76 [1.07–2.90]), better mental component of the SF36 (OR 95% CI=2.14 [1.38–3.31]), fewer tender joint counts (TJC) and better physical component of the SF36 (PCS) (with significant interaction between TJC and PCS) were associated with discrepancies between disease activity levels according to the 2 scores. At M6, only being male (OR 95% CI=1.62 [1.09–2.41]) was associated with discrepancies.

Conclusions: DAS28-CRP significantly underestimated disease activity compared to DAS28-ESR. Agreement was high between the 2 scores, good for disease activity levels and EULAR responses. In the individual patient, however, the two scores may differ considerably. The scores should not be used interchangeably in the daily clinic without caution.

THU0085 TIME TO REMISSION AND THE ACHIEVEMENT OF SUSTAINED REMISSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: SITE VARIATION ANALYSIS IN THERAPEUTIC STRATEGY FROM THE CANADIAN EARLY ARTHRITIS COHORT (CATCH)

C. Barnabe[1], O. Schieir[2], G. Hazlewood[3], J. Pope[4], C. Hitchon[5], S. Bartlett[6], G. Boire[7], E. Keystone[2], D. Tin[8], B. Haraoui[9], V. Bykerk[10], C. Thorne[8] on behalf of Canadian Early Arthritis Cohort (CATCH) Investigators. *[1]University of Calgary, Calgary; [2]University of Toronto, Toronto; [3]Medicine, University of Calgary, Calgary; [4]Western University, London; [5]University of Manitoba, Winnipeg; [6]McGill University, Montreal; [7]University of Sherbrooke, Sherbrooke; [8]South lake Regional Health Centre, Newmarket; [9]Universite de Montreal, Montreal, Canada; [10]Hospital for Special Surgery, New York, United States*

Background: Treatment response in ERA reflects individual prognostic factors and therapeutic selection which may be influenced by provider experience and beliefs. This may lead to variations in rates of and time to remission across centres involved in multi-site cohorts.

Objectives: We compared therapeutic strategies across Canadian ERA clinics in relation time to CDAI and DAS28 remission, and frequency of attaining sustained remission.

Methods: Data were analyzed for patients with >1 year of follow-up, enrolled at sites with >40 patients at baseline and >30 patients with 2 years of follow-up data. We determined time to remission and frequency of sustained remission (2 consecutive visits at least 6 months apart), using DAS28 and CDAI scores. Treatment strategy was determined as initial and ever use of oral methotrexate monotherapy, subcutaneous methotrexate monotherapy, methotrexate-based combinations, non-methotrexate DMARDs, triple therapy, or biologic therapy.

Results: 1,749 participants from 13 centers with mean age 54 years, 73% female, mean DAS28 4.9 (SD 1.4) and mean CDAI 25.6 (SD 14.6) were included. There were significant differences between centers in participant characteristics (gender, age, symptom duration, body mass index, comorbidities, smoking status, education, ethnicity, marital status, seropositive status, erosions). The

initial therapeutic strategies were oral methotrexate monotherapy 16% (site range 0%>55%), subcutaneous methotrexate monotherapy 15% (0%>45%), methotrexate-based combination therapy 30% (10%>47%), non-methotrexate DMARDs 19% (4%>44%), triple therapy 11% (0%>60%), and biologics 2% (0%>18%). At 60 months of follow-up, the frequency of use of these strategies was relatively stable except for biologics which increased to 21% (0%>80%). The mean and median time to DAS28 remission was 12.4 months (SD 12.1, range 8.6 to 17.2) and 9 (IQR 3, 18) months respectively. The mean and median time to CDAI remission was 14.8 (SD 13.5, range 10.3 to 21.2) and 9 (IQR 6, 18) months respectively. The frequency of sustained DAS28 remission was 50% (site range 20–70%), and CDAI 35% (12–58%). At the two sites with the highest rates of sustained remission and shortest time to remission, patients had fewer comorbidities and the initial treatment strategy was preferentially methotrexate-based combination therapies, and with eventual advancement to biologics in 7 and 39% in patients. In contrast, the patients at the site with the lowest rates of sustained remission and longest time to remission had long symptom duration at treatment initiation, highest body mass index and proportion with ≥2 comorbidities, worse socioeconomic status and higher baseline DAS28. This site also had the highest proportion of patients treated with biologics at the baseline visit, escalating to 80% by 60 months.

Conclusions: Treatment strategy and patient characteristics vary across CATCH sites and contribute to variable rate and frequency of achieving sustained remission.

THU0086 THE USE OF A BLINDED TRUNCATED ULTRASOUND POWER DOPPLER JOINT COUNT VALIDATES EFFICACY DATA FROM AN EARLY PHASE OPEN LABEL DRUG STUDY TREATING RHEUMATOID ARTHRITIS

C. Wiesenhutter[1,2], *[1]Department of Family Medicine, University of Washington, Seattle; [2]Coeur d'Alene Arthritis Clinic, Coeur d'Alene, United States*

Background: Small open label pilot trials generate important information on tolerability, toxicity, pharmacokinetics, and antigenicity in the early phase investigation of new compounds in the treatment of rheumatoid arthritis (RA). However, because the standard disease activity measures (DAMs), such as the disease activity score in 28 joints (DAS28) have a major subjective component, the efficacy data acquired in such trials is generally felt to be much less reliable than that obtained in blinded trials. Incorporating more objective DAMs, and performing them in a blinded fashion, might enhance the validity of efficacy data in such an early clinical setting.

One possible disease activity measure to fulfill this role would be an ultrasound power Doppler joint count (UPD) which has been shown to correlate with conventional clinical measures[1].

Objectives: To determine whether the blinded use of a truncated (low joint count) UPD in an early phase RA trial correlates with other DAMs in the trial and contributes to validation of efficacy of the drug.

Methods: The results of an open label trial in which Staph Protein A (PRTX-100, Protalex Inc.) was given to patients with active RA has been previously reported[2]. Standard disease activity measurements were obtained. In addition, an UPD was performed utilizing a truncated methodology in which three sites at the dorsal wrist and three dorsal metacarpal sites were analyzed bilaterally for a total of twelve sites studied. There were a total of 117 UPDs performed on eleven patients. UPD were acquired in less than five minutes per study. These UPDs were stored digitally and subsequently read in duplicate in a blinded fashion after completion of the study by the investigator (CW). Each joint site was subjectively scored from 0 (normal) to 3 (severe) with a possible total score of 0 -36 Intra-observer reliability was determined by two-way random intra-class correlations (ICC). Significant changes of UPD and clinical DAMs from baseline to single time points were assessed by the Wilcoxon signed rank test and correlations were performed by the Spearman's rho test (p). Effect size was determined by standardized mean difference (SMD).

Clinical assessments and UPDs were obtained weekly for the first month, then monthly for five more months.

Results: Intra-observer UPD score reproducibility was high (ICC =0.886). Significant reductions ($p<0.05$) in UPD and the DAS28 were found at day 22 and on all subsequent visits. Correlations between UPD and DAMs total scores were moderate to strong. However, the total differences from baseline and visits did not correlate, except for CRP (n=67 p=0.471, $p<0.001$). Also, some individual time points showed differences such as baseline vs day 196 (see table). SRMs for both UPD and DAMs were high, but higher for the DAS28 (1.00–2.16) than for the UPD (0.83–1.10).

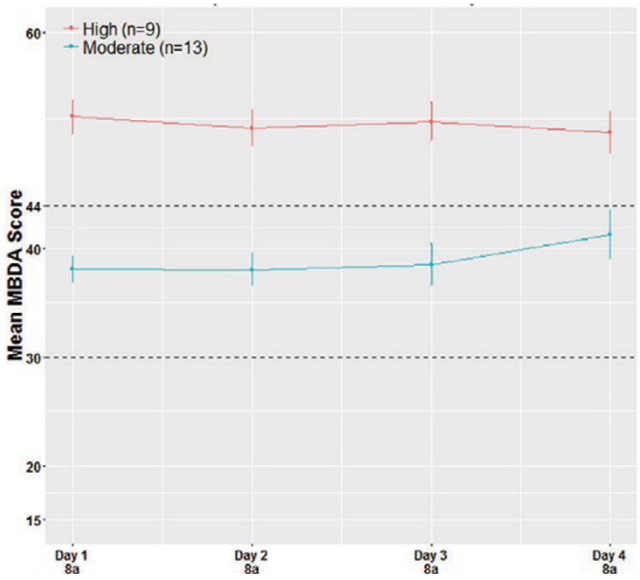
THU0087 DAILY AND DIURNAL VARIATION AND DETERMINATION OF THE MINIMALLY IMPORTANT DIFFERENCE IN RHEUMATOID ARTHRITIS PATIENTS WITH MODERATE TO HIGH MULTI-BIOMARKER DISEASE ACTIVITY SCORES



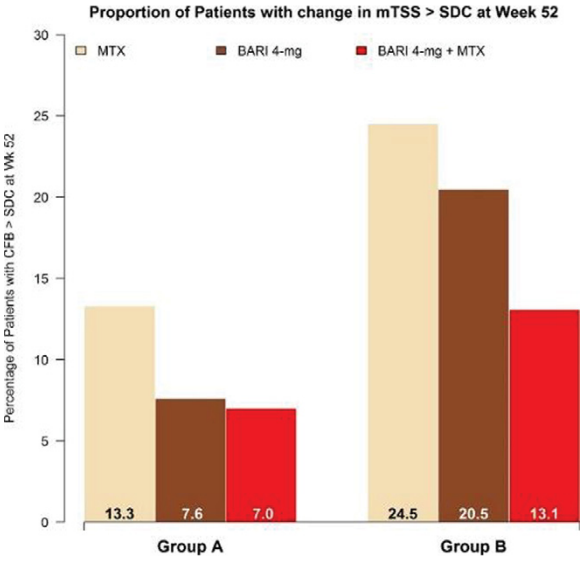
D. Chernoff[1], R.J. Bolce[1], C.C. Hwang[1], X. Wang[1], A. Kivitz[2], J.R. Curtis[3]. *[1]Crescendo Bioscience Inc., South San Francisco; [2]Altoona Center for Clinical Research, Duncansville; [3]The University of Alabama at Birmingham, Birmingham, United States*

Background: The Multi-Biomarker Disease Activity (MBDA) score has been validated as a disease activity metric in rheumatoid arthritis (RA) patients. Patients initiating new therapy or changing therapy frequently have moderate to high MBDA scores. Understanding short term biological variation of MBDA scores in these patients is important in order to determine a minimally important difference (MID).

Objectives: To evaluate biological variation in MBDA scores over a 24-hour period and from day to day in patients with clinically stable RA with moderate to high MBDA scores at baseline and to determine the MID in these patients.

Methods: We performed an analysis of 22 RA patients with moderate or high baseline MBDA scores. Adults with clinically stable seropositive RA (>8 weeks without DMARD and/or biologic medication changes and ≤10 mg prednisone per day) who had MBDA scores of moderate (MBDA 30–44) or high (MBDA >44) were eligible. Serum samples were obtained 5 times over the first 24-hour period (8 AM, 12 PM, 4 PM, 8 PM, and 8 AM); at 12 PM in the next 24-hour period; and at 8 AM the next 2 consecutive days, for a total of 8 timepoints. An additional midnight sample was excluded from the analysis because this timepoint is not relevant to normal clinical practice hours. Diurnal variation was calculated using 5 timepoints over the first 24 hours. Daily variation was determined using 4 timepoints taken at 8 AM on successive days. Combined diurnal and daily variation was calculated using 8 timepoints over 4 days. For each patient, absolute changes in MBDA scores were calculated for all possible pairs of timepoints for: a) diurnal variation (total 220 pairs), b) daily variation (total 132 pairs) and c) diurnal and daily variation (total 616 pairs). MID was calculated as the 90th percentile of absolute

Figure 1. Mean (SE) MBDA Scores over Four Days for Patients with Moderate (n=13) or High (n=9) MBDA Scores at Baseline



changes using all diurnal and daily variation data. Bootstrapping was used to validate the result.
Results: Of patients included in the analysis, 13 had moderate MBDA scores and 9 had high MBDA scores at baseline. Baseline demographics were: 73% women, mean age 61.8 (SD: 12.1) years, mean MBDA score 43.9 (SD: 8.3), and mean CDAI 20.2 (SD: 17.1). No patients were on glucocorticoids. Based on the analysis of the absolute change of MBDA score in the data with daily and diurnal variation combined, the mean was 3.4 (SD: 3.8), the median (Q1, Q3) was 2 (1, 5), and the MID was calculated as 7. Similar results were obtained using a bootstrap method. Minimal variability in mean MBDA scores was observed over 4 days for patients with moderate and high baseline MBDA scores (Figure 1).
Conclusions: Based upon the short term biologic variability of moderate and high MBDA scores, the MID was 7 units. An absolute change exceeding this threshold is unlikely due to diurnal and daily biological variation of the MBDA scores.

THU0088 STRUCTURAL DAMAGE PROGRESSION IN PATIENTS TREATED WITH METHOTREXATE, BARICITINIB MONOTHERAPY OR BARICITINIB + METHOTREXATE BASED ON THEIR LEVEL OF CLINICAL RESPONSE IN THE PHASE 3 RA-BEGIN STUDY

D. van der Heijde[1], P. Durez[2], G. Schett[3], E. Naredo[4], M. Østergaard[5], G. Meszaros[6], N. Bello[6], I. De la Torre[6], P. Lopez-Romero[6], D. Schlichting[7], E. Nantz[7], R. Fleischmann[8]. *[1]Leiden University Medical Centre, Leiden, Netherlands; [2]UCL-Saint Luc, Bruxelles, Belgium; [3]Universitätsklinikum Erlangen, Erlangen, Germany; [4]Hospital Universitario Fundación Jimenez Diaz, Madrid, Spain; [5]Copenhagen Centre for Arthritis Researc, Copenhagen, Denmark; [6]Eli Lilly & Company, Madrid, Spain; [7]Eli Lilly & Company, Indianapolis; [8]U Texas SW Medical Center, Dallas, United States*

Background: Baricitinib (BARI), an oral inhibitor of Janus kinase (JAK) 1 and JAK 2, is being developed for the treatment of rheumatoid arthritis (RA). RA-BEGIN was a phase 3 double-blind, three-arm multicentre study of BARI administered as monotherapy or in combination with methotrexate (MTX) to patients (pts) with early active RA who had no or limited treatment with DMARDs. Methotrexate (MTX) monotherapy was the active comparator.
Objectives: To evaluate the proportion of pts with structural damage progression, defined as change from baseline (CFB) greater than the smallest detectable change (SDC) in mTSS at week (wk) 52, depending on their disease state as measured by DAS28-CRP.
Methods: Pts were classified into two groups based on DAS28-CRP. Group A included pts who achieved sustained DAS28-CRP $\leq$3.2 at weeks 16, 20 and 24. Pts who did not achieve DAS28-CRP $\leq$3.2 consecutively at weeks 16, 20 and 24 and pts with missing DAS28-CRP at any of those 3 visits were included in Group B. The proportion of pts with CFB mTSS > SDC at wk 52 was estimated for each treatment arm for the two defined groups of response. The SDC in mTSS in the RA-BEGIN population at wk 52 was 1.4. Missing mTSS at wk 52 were imputed using linear extrapolation based on baseline data and the most recent radiographic data prior to the missed radiograph. No formal statistical tests were performed and comparisons are merely descriptive. All analyses were post-hoc.
Results: Out of the 584 pts of the modified-ITT population (all randomised pts who received at least 1 dose of study drug) in the RA-BEGIN study, 212 were classified in Group A: 21.4% (45/210), 42.1% (67/159), and 46.5% (100/215) for MTX, BARI and BARI+MTX, respectively. The odds ratios for sustained DAS28-CRP $\leq$3.2 response (weeks 16, 20 and 24) to BARI and BARI+MTX vs. MTX, were respectively 2.8 (95% CI 1.7–4.4) and 3.3 (95% CI 2.1–5.1). Pts classified in Group A maintained an adequate level of response up to wk 52. Further, pts in Group A (sustained DAS28-CRP $\leq$3.2) on either BARI + MTX or BARI, were less likely to show structural progression than patients who achieved sustained DAS28-CRP $\leq$3.2 on MTX. Pts in Group B on MTX or BARI monotherapy were more likely to show structural progression than patients who did not achieve a sustained DAS28-CRP $\leq$3.2 response on BARI + MTX (Figure 1).
Footnote: Group A: Patients who achieved sustained DAS28-CRP $\leq$3.2 (NRI) at weeks 16, 20 and 24 (N=212); Group B: Complement group
Conclusions: In patients who achieved sustained low DAS28-CRP scores, progression rates compared to MTX were reduced to a similar degree with BARI as monotherapy or in combination with MTX. Compared to MTX in patients who did not achieve sustained low DAS28-CRP scores, progression rates were reduced most markedly with combination therapy.

THU0089 M-DAS28, DAS28 (CRP) AND RAPID3 SCORES AT BASELINE ARE GOOD PREDICTORS OF RADIOGRAPHIC DISEASE PROGRESSION AT 1 AND 2 YEARS: DATA FROM THE AMPLE TRIAL

E. Keystone[1], H. Ahmad[2], Y. Yazici[3], E. Muratti[4], J. Ye[2], M. Bergman[5]. *[1]University of Toronto, Toronto, Canada; [2]Bristol-Myers Squibb, Princeton; [3]New York University School of Medicine, New York, United States; [4]Bristol-Myers Squibb, Montreal, Canada; [5]Drexel University College of Medicine, Philadelphia, United States*

Background: Clinicians rely on time-efficient, validated disease activity assessments to help predict disease progression accurately in patients (pts) with RA. The utility in predicting structural damage progression for the Routine Assessment of Patient Index Data 3 (RAPID3)[1] is largely unknown, while that of DAS28 (CRP)[2] and modified (M-)DAS28 have been previously reported.[3]
Objectives: This *post hoc* analysis examined the relationship between baseline disease activity measures and their ability to predict structural damage progression in the Phase III AMPLE (NCT00929864) trial.[4]
Methods: AMPLE was a randomized, investigator-blinded study in which MTX-experienced pts with active RA $\leq$5 years received SC abatacept 125 mg weekly or adalimumab 40 mg every 2 weeks in combination with stable-dose MTX. Logistic regression analysis was used to correlate the effect of disease activity at baseline on radiographic (X-ray) progression at Months (M) 12 and 24. Disease activity was assessed using M-DAS28,[3] DAS28 (CRP), RAPID3, CDAI and SDAI. Radiographs were scored using the modified Sharp/van der Heijde scoring system; progression was defined as change from baseline in total score greater than the smallest detectable change, which was calculated as SD/square root (2) x 1.96 (where SD is standard deviation of paired differences of change from baseline in total score between two readers).
Results: Logistic regression analysis was carried out for all randomized and treated pts (abatacept, n=318; adalimumab, n=328). For these patients, M-DAS28, DAS28 (CRP) and RAPID3 at baseline were significant predictors of radiographic progression at M12 and M24, baseline SDAI was a significant predictor at M12 but not M24 and baseline CDAI was not a significant predictor at either time point

Logistic regression model and area under ROC curves for the impact of disease activity at baseline on radiographic progression at M12 and M24 (all randomized and treated patients)

Disease activity measure	M12			M24		
	OR (95% CI)	p value	AUC	OR (95% CI)	p value	AUC
CDAI	1.02 (1.00, 1.04)	NS	0.5762	1.01 (0.99, 1.03)	NS	0.5416
SDAI	1.02 (1.00, 1.04)	<0.05	0.5963	1.02 (1.00, 1.03)	NS	0.5634
DAS28 (CRP)	1.47 (1.15, 1.90)	<0.01	0.6271	1.31 (1.03, 1.67)	<0.05	0.5911
RAPID3	1.26 (1.08, 1.47)	<0.01	0.6270	1.16 (1.01, 1.34)	<0.05	0.5871
M-DAS28	1.51 (1.25, 1.83)	<0.001	0.6624	1.36 (1.13, 1.63)	<0.01	0.6208

AUC = area under the curve; M = month; NS = not statistically significant; OR = odds ratio; ROC = receiver operating characteristic.

(Table). Receiver operating characteristic curves showed that M-DAS28, DAS28 (CRP) and RAPID3 had higher predictive value (area under the curve) than CDAI or SDAI for radiographic progression at M12 and M24 (Table). There was no impact of treatment arm on predictors of radiographic outcomes.

Conclusions: In this *post hoc* analysis, disease activity scores at baseline according to M-DAS28, DAS28 (CRP) and RAPID3 were good predictors of radiographic progression at M12 and M24 and were more predictive than other measures of disease activity tested, with M-DAS28 demonstrating the greatest degree of prediction.

THU0090 INFLUENCE OF AGE AT DISEASE ONSET ON CLINICAL, FUNCTIONAL, AND ULTRASONOGRAPHIC OUTCOMES IN A MONOCENTRIC EARLY RHEUMATOID ARTHRITIS COHORT

E. Galuppi, I. Farina, C. De Giorgio, C.A. Scirè, M. Govoni. *Department of Medical Sciences, UOC Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna, Ferrara, Italy*

Background: Rheumatoid Arthritis (RA) onset may occur at any age and peaks in the fifth decade. Because the mean age of general population is continually increasing and since older age could impact on outcomes, late-onset RA (LORA) will probably become a relevant issue for health care system in the next future. A better characterization of LORA could help rheumatologist in the therapeutic decision-making process tailored on the individual patient.

Objectives: To investigate the relationship between age at disease onset and clinical, ultrasonographic and functional outcomes.

Methods: Early RA (ERA) patients fulfilling 2010 ACR/EULAR, with available clinical ad ultrasonographic follow-up of at least 1 year, who consecutively attended our Early Arthritis Clinic between 2009–2014, were retrospectively analyzed. Patients were pooled into 3 groups by age at RA onset: <45 years (young-onset RA [YORA] group 1), 45 to 60 years (intermediate-onset RA [IORA] group 2), and >60 years (late-onset RA [LORA] group 3). At baseline biological, functional and ultrasonographic data were recorded. The following items were compared at baseline and after 12 months from diagnosis: $DAS28_{CRP}$ remission rate, functional disability using the Health Assessment Questionnaire (HAQ), power doppler (PWD) score, Methotrexate (MTX) treatment, use of glucocorticoids (GCs).

PWD MSUS REM	reference	1.21 (0.40-3.69)	0.72	1.18 (0.51-2.73)	0.69
HAQ score <0.5	reference	0.75 (0.33-1.73)	0.51	1.24(0.61-2.53)	0.53

aOR: odds ratio adjusted for gender, baseline $DAS28_{CRP}$, MTX use, glucorticoid use, serology.

Results: The main baseline demographic and disease characteristics of the whole sample of ERA (n=223) and the 3 age groups- YORA (46), IORA (81) and LORA (96)- are summarised in Table 1. Age at RA-onset was independently associated with $DAS28_{CRP}$ remission at 1 year (Table 2).

Conclusions: In a cohort of ERA, older age at disease onset is associated with a more active pattern disease at the beginning but with a greater probability of $DAS28_{CRP}$ remission at 1 year.

THU0091 HIGH MULTI-BIOMARKER DISEASE ACTIVITY SCORE IS ASSOCIATED WITH HIGH RISK OF RADIOGRAPHIC PROGRESSION IN SIX STUDIES

J.R. Curtis[1], C.H. Brahe[2], M. Ostergaard[2], M.L. Hetland[2], K. Hambardzumyan[3], S. Saevarsdottir[3], X. Wang[4], E.H. Sasso[4], T.W. Huizinga[5]. *[1]Univ. of Alabama at Birmingham, Birmingham, United States; [2]Copenhagen Center for Arthritis Research, Copenhagen, Denmark; [3]Karolinska Univ. Hospital and Karolinska Institutet, Stockholm, Sweden; [4]Crescendo Bioscience Inc., South San Francisco, United States; [5]Leiden Univ. Medical Center, Leiden, Netherlands*

Background: The multi-biomarker disease activity (MBDA) test uses a validated algorithm with 12 serum protein biomarkers to assess disease activity in patients with RA. The MBDA score has previously been found to be a predictor of risk for radiographic progression (RP).

Objectives: To evaluate data from six cohorts to collectively establish the relationship between the MBDA score and risk for RP.

Methods: Clinical, MBDA score and radiographic data were analyzed for 6 cohorts with N>100: Leiden, SWEFOT Year 1, SWEFOT Year 2, OPERA Year 1, and AMPLE Year 1 (abatacept and adalimumab arms) (see Figure). Analyses used published results when available or patient-level data when not (i.e., for Leiden; and for OPERA CRP analyses). Frequency of RP over one year was determined by category of MBDA score (low, moderate [30–44], high on a scale of 1–100) at the start of the year for four cohorts and by category of MBDA score at the end of the year for AMPLE cohorts (as published). RP was defined using the threshold for change in total modified Sharp score (ΔmTSS) specific to each study (2 to >5 TSS units). Positive and negative predictive values (PPV and NPV) were determined for each study by comparing patients with high MBDA score (>44), DAS28-(ESR/CRP) (>5.1 or >4.09) or CRP (>3 mg/dL) vs. those in a not-high category. Relative risk (RR) for RP was determined for each study, and in a meta-analysis of the non-overlapping patient groups with MBDA scores available at the start of the year (Leiden, SWEFOT Year 1 and OPERA Year 1). Results of multivariate analyses and analyses that combined MBDA score with other risk factors for RP were summarized.

Results: The 6 study cohorts included patients receiving csDMARDs alone or with adalimumab, infliximab or abatacept. Overall rates of RP were 10–26%. In each study, RP was most frequent among patients with a high vs. not-high MBDA score (>44 vs. ≤44). For high MBDA scores, NPVs were 93–97% and PPVs were 18–32%, with RR values of 3.6–9.5 (P=0.002 to <0.0001) (Figure). In a meta-analysis of the Leiden, SWEFOT Year 1 and OPERA Year 1 cohorts, RR was 5.1 (P<0.0001) for MBDA categories, and 1.4 (P=0.23) and 1.6 (P=0.01) for categories of DAS28-CRP or CRP, respectively. Previously published multivariate analyses in the Leiden and SWEFOT Year 1 cohorts showed that MBDA score was an independent predictor of RP compared with other predictors. In the Leiden cohort, MBDA score was the strongest predictor and high MBDA score

Association between radiographic progression (RP) and high MBDA score (>44)

Cohort	N	RP cutoff	Overall % RP	PPV for MBDA >44	NPV for MBDA >44	Relative Risk[1] (95% CI)	P-value
Leiden	163	>5.0	17%	31%	93%	4.3 (1.9, 9.5)	<0.0001
OPERA Year 1	164	≥2.0	26%	31%	97%	9.5 (1.4, 66.3)	0.0009
SWEFOT Year 1	235	>5.0	18%	21%	97%	7.1 (1.0, 49.9)	0.008
Meta-analysis (LEIDEN + OPERA Year 1 + SWEFOT Year 1)						5.1[3] (2.5, 10.1)	<0.0001
SWEFOT Year 2	133	>5.0	13%	32%	95%	6.2 (2.4,16.5)	0.0001
AMPLE Year 1 (Aba)	181	>2.2[4]	10%	18%	96%	4.5 (1.6,13.1)	0.003
AMPLE Year 1 (Ada)	186	>2.2[4]	11%	24%	93%	3.6 (1.6,8.1)	0.002

PPV, positive predictive value; NPV, negative predictive value. 1. Relative risk = PPV/(1-NPV). 2. Random-effect model used for meta-analysis. 3.Aggregated relative risk. 4. ΔTSS cutoff for RP was defined in Fleischmann et al (*Arthritis Rheumatol* 2016;68:2083–9) as >smallest detectable change (SDC), however no value was specified; SDC for AMPLE was specified as 2.8 and 2.2 in prior AMPLE publications (Weinblatt 2013; Schiff 2014).

DOI: 10.1002/art.40021; Published data only, from Fleischmann et al(*).

discriminated between high and low risk for RP among patients with high SJC (>5) or high DAS28-CRP, with PPV as high as 57%.
Conclusions: High MBDA scores were associated with increased risk for RP in 6 study cohorts, including patients treated with csDMARDs, TNFi and abatacept. Based on high NPVs (≥93%), the MBDA score used alone had clinical value for identifying patients with little or no risk of RP. Combining the MBDA score with clinical measures yielded PPVs approaching 60%, suggesting that biomarkers can help stratify patients by their risk for RP.

THU0092 CHORONIC PAIN INCREASES INDEPENDENT OF THE DISEASE ACTIVITY AND DEPRESSION IN FEMALES WİTH RHEUMATOİD ARTHRITIS

F.G. Yurdakul, A. Kılıçarslan, H. Bodur. *Department of Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital, Ankara, Turkey*

Background: Chronic pain is a key component of rheumatoid arthritis (RA). Although pain is reduced with the control of inflammation at the first years of the disease, pain increases over time with different pathways just as central sensitization. Fatigue, sleep problems and depressive symptoms with chronic pain are common problems in patients with RA (1,2).
Objectives: We aimed to investigate the frequency of widespread pain, sleep disorders, fatigue, and depressive symptoms in RA patients. Furthermore discrepancy of these symptoms and disorders were analyzed between female and male RA patients.
Methods: One hundred and sixty one RA patients (female: 119, male: 42) and 68 healthy controls (female: 52, male: 16) were enrolled in the study. Widespread pain index (WPI) with nineteen body parts that was identified by 2010 fibromyalgia diagnostic criteria was interrogated. Pain visual analog scale (VAS), Health Assessment Questionnaire (HAQ), Physician global assessment (PhGA), Fatigue severity scale (FSS), Pittsburgh sleep quality index (PSQI), Beck depression inventory (BDI) were evaluated in both RA patients and healthy controls. Morning stiffness (MS), Rheumatoid arthritis quality of life (RAQOL) and disease activity score 28 (DAS28) were assessed in RA patients. Data were analyzed in female and male RA patients.
Results: The mean PhGA, HAQ, BDI, FSS, WPI values of RA patients were worse than healthy controls (p=0.012, 0.000, 0.008, 0.033, 0.044 respectively). There was no difference between RA and healthy controls in terms of sleep disorders. The mean age, disease duration, MS, swollen joint count, C-reactive protein, PhGA and BDI were similar in female and male RA patients. WPI, VAS pain, tender joint count, HAQ, RAQOL, FSS, PSQI, and DAS 28 were higher in females (Table 1).

Table 1. Clinical features in female and male RA patients

	Female RA patients (n=119)	Male RA patients (n=42)	p
Widespread pain index	4.70±4.97	2.65±3.99	0.04*
PhGA	2.87±2.16	2.09±1.63	0.08
DAS28	3.39±1.39	2.68±1.11	0.01*
CRP	10.77±13.62	12.59±14.20	0.24
Tender Joint Count	10.92±13.47	6.78±13.09	0.03*
Swollen Joint Count	0.88±2.67	0.31±0.69	0.690
HAQ	1.06±0.83	0.68±0.66	0.04*
RAQOL	14.34±10.06	7.59±8.83	0.00*
FSS	35.57±19.24	22.21±14.41	0.00*
PSQI	8.02±5.58	5.00±4.20	0.00*
BDI	15.71±13.34	11.28±12.56	0.06

PhGA: Physician global assessment, DAS: Disease activity score, CRP: C Reactive protein, HAQ: Health Assessment Questionnaire, RAQOL: Rheumatoid arthritis quality of life, FSS: Fatigue severity scale, PSQI: Pittsburgh sleep quality index, BDI: Beck depression inventory.

Conclusions: RA is a disease that increases fatigue, depressive symptoms and widespread pain.DAS 28 scores were higher due to the increased pain scores and tender joint count that are subjective parameters in female RA patients. Pain scores in females are significantly higher than in males, and pain exacerbated by central sensitization pathway in women may lead to sleep disorders and fatigue, but not increase depressive symptoms.

THU0093 PERSISTENCE OF POWER DOPPLER ULTRASOUND-DETECTED RESIDUAL SYNOVITIS IN CONSECUTIVE ULTRASOUND EXAMINATIONS IN RHEUMATOID ARTHRITIS PATIENTS IN CLINICAL REMISSION PREDICTS UNFAVORABLE OUTCOME OVER ONE YEAR

G. Mouterde[1], C. Lukas[1], N. Filippi[1], G. Marin[2], N. Molinari[2], J. Morel[1], B. Combe[1]. *[1]Rheumatology department; [2]Department of Statistics, Lapeyronie hospital, Montpellier, France*

Background: Some studies revealed an association of Power Doppler (PD) ultrasound (US)-detected residual synovitis (PDUSS) and risk of relapse and radiographic progression (RP), in individual patients in rheumatoid arthritis (RA). However, the longitudinal relationship between clinical remission and repeated US residual lesions during follow-up is not so well-known.
Objectives: The aim of this study was to evaluate the ability of PDUSS in consecutive examinations to predict unfavorable outcome (i.e. clinical relapse or RP) at 1 year.
Methods: RA patients ≥18 years fulfilling 2010 ACR-EULAR criteria, treated with synthetic or biologic (b) DMARDs and in clinical remission (DAS28-ESR<2.6 and no clinically active synovitis) for less than 6 months, were included in the longitudinal prospective SONORE study (ClinicalTrials.gov identifier: NCT02618954). Clinical and biological characteristics of patients were collected at baseline, and every 3 months during 1 year. RA treatment had to be stable during follow-up. A standard US examination on 40 joints for the presence of synovial hypertrophy and PD signal was performed by an independent investigator blinded to clinical and radiographic data at each visit during 1 year. Presence of US synovitis was defined by a PD signal≥1 in at least one joint. Radiographs of hands, wrists and feet were scored at baseline and 1 year. Outcome measures: RP was defined by an increase ≥1 point of the modified total Sharp score. A relapse was defined by a DAS28>3.2 at ≥1 follow-up visits AND a change of DMARDs, excluding change due to safety issues; or an increase in the DMARD or Corticosteroid (CS) dosage (≥5mg/d). Baseline variables, including PDUSS and its persistence during the follow-up, were assessed for their association with time to progression to unfavorable outcome using univariate then stepwise multivariate Cox regression analyses to obtain adjusted HRs.
Results: The 115 included patients had a mean (SD) age of 58.9 (±12.8) years, mean disease duration of 9.3 (±9.3) years, a mean duration of remission of 2.1 (±2.3) months. 74.8% were female, 79.1% of the patients were anti-CCP positive, 51.4% had erosive disease. The mean DAS28-ESR was 2.03 (±0.63). 59.2% received methotrexate, 59.9% bDMARD and 11.7% CS. PDUSS was detected in ≥1 joint in 75 patients (72.1%) at baseline. 41/75 (54.7%) had persistence of at least one PDUSS during the follow-up. 26 (23.2%) had a relapse (after a mean duration of 9.1 (±2.6) months) or a RP at 1 year. In multivariate analysis, persistence of at least one PDUSS during the follow-up (HR=5.24 [1.74–22.5], p=0.009) and baseline number of tender joints (HR=1.32 [0.95–1.68], p=0.052) were predictors of relapse or RP at 1 year. Duration of remission, other baseline US findings including baseline PDUSS, autoantibodies, and erosive disease had no additional predictive value.
Conclusions: Persistence of a PDUSS during the follow-up, rather than baseline PDUSS, predicts unfavorable outcome at 1 year in RA patients in clinical remission. This suggests that initial US findings are not sufficient to justify therapeutic change, but that the persistence of a residual PDUSS requires careful follow-up, and might even potentially merit strategy adaptation.

THU0094 FACTORS ASSOCIATED WITH RADIOGRAPHIC REMISSION (RR) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) WHILE NON-BIOLOGICALDISEASE MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS) USING

O. Iaremenko, G. Mykytenko. *Internal Diseases at Stomatological Faculty, O.O. Bogomolets National Medical University, Kyiv, Ukraine*

Objectives: To assess the factors associated with RR achievement in patients (pts) with RA while non-biological DMARDs using.
Methods: A cohort of 174 pts with RA (50.6% with early RA) was prospectively assessed at baseline and 2 years by the Disease Activity Score (DAS28) and the Sharp–van der Heijde Score (SHS). Mean age at inclusion was 52.0±0.91 yrs, disease duration – 51.3±4.82 month. 82.7% of the pts were women; 62.6% were positive for rheumatoid factor (RF) and 75.9% - for antibodies against cyclic citrullinated peptides (aCCP). Pts were treated with methotrexate (MTX) (mean dose – 11.6±0.29 mg/w, n=157), leflunomide (LF) (19.2±0.28 mg/d, n=95), sulfasalazine (SS) (2 g/d, n=76) or combination of DMARDs (CD) (n=74). After 2 yrs of DMARDs therapy 41 pts (23.5%) reached RR (ΔSHS≤0.5). No one pts using low dose of MTX (7.5 mg/week) achieved remission so they were excluded from further analysis. According to RR achievement in 2 yrs pts were divided into

2 groups (41and 92 pts who achieved RR and didn't respectively). After 2 yrs the factors associated with RR achievement in pts with RA while non-biological DMARDs using were assessed.

Results: Before study, pts in both groups were comparable by all demographic, clinical and X-ray characteristics, frequency of DMARDs prescribed. They differed only in frequency of RF-positivity (39.0 and 57.6% respectively in pts achieved RR and didn't, $p<0.05$), aCCP-positivity (21.7 and 73.3% respectively, $p<0.001$) and aCCP level (6.06±0.88 and 105.3±22.7 U/ml respectively, $p<0.001$).

There was strong and moderate positive correlation between RR achivement and aCCP-negativity ($r=0.57$, $p<0.05$), low aCCP level ($r=0.45$, $p<0.05$) and ΔDAS28 ($r=0.35$, $p<0.05$).

Results of multinomial logistic regression analyses (SPSS, V.22, IBM) showed that RF-negativity was the only independent predictor of RR achievement ($B=3.14$, $p<0.05$).

41.7% pts in RR achieved clinical remission by DAS28 as well. Only 19.7% pts achieved clinical remission without RR ($p<0.05$ vs pts achieved clinical and RR) and 12.5% pts achieved RR without clinical response (DAS28>5.1, ΔDAS28≤1.2 or any value of DAS28 with ΔDAS28≤0.6; $p<0.01$).

After 2 years of treatment the mean value of ΔDAS28 in comparison groups (with and without RR) did not differ (2.79±0.28 vs 2.33±0.17 respectively) so there was a discrepancy between clinical and radiological outcome.

Conclusions: Baseline predictors associated with achieving of radiographic remission in pts with RA are RF- and aCCP-negativity, low level of aCCP, but independent predictor of radiographic remission achievement is the only RF-negativity.

The discrepancy between the frequency of clinical and radiographic remission achievement in RA patients is observed.

After 2 yrs of non-biological DMARDs treatment 41.7% pts with RA achieves radiographic and clinical remission at the same time.

THU0095 IMPACT OF ULTRASOUND-DETECTED TENOSYNOVITIS AND SYNOVITIS ON DISEASE FLARE, DISABILITY AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RA IN CLINICAL REMISSION: RESULTS OF THE STARTER STUDY

G. Sakellariou[1], G. Filippou[2], E. Bellis[3], C.A. Scirè[4], G. Carrara[5], A. Iagnocco[6] on behalf of STARTER study group and US Study Group of the Italian Society for Rheumatology. *[1]IRCCS Policlinico San Matteo Foundation, Pavia; [2]University of Siena, Siena; [3]Ospedale Mauriziano, Torino; [4]Italian Society for Rheumatology, Milan; [5]Italian Society for Rheumatology, Milano; [6]Università degli Studi di Torino, Torino, Italy*

Background: In patients with RA in remission subclinical ultrasonographic (US) synovitis (-S) relates to flare and radiographic progression. The impact of tenosynovitis (-T) on flare, disability and radiographic progression is not known.

Objectives: To evaluate the predictive role of US-detected tenosynovitis and synovitis in RA patients in remission on flare, disability and radiographic progression over 12-months.

Methods: STARTER is a multicentre cohort study of the US Study Group of the Italian Society for Rheumatology. Participants were selected on the basis of a reliability exercise and the availability of high-end equipment with high frequencies probes. Patients with RA in remission underwent clinical and US evaluation. US -T and -S were assessed categorically by Grey Scale (GS) and power Doppler (PD) at 11 joints, extensor and flexor tendons in both hands. Patients were assesed at baseline, 6 and 12 months. The primary outcome was flare within 12 months (defined as increase in DAS28>1.2 or >0.6 if final DAS28>3.2). The secondary outcomes were progression of disability (increase ≥2.3 in the Health Assessment Questionnaire (HAQ)) and radiographic progression (increase in the total Sharp van Der Hejide score (SHS) ≥4.3) at 12 months. Logistic models were used to measure the relationship between GS-T/-S, PD-T/-S and outcomes, results were presented as odds ratios (OR) and 95% confidence interval (CI), adjusted for pre-specified confounders.

Table 1

	OR (95% CI)	Adj OR (95% CI)
ΔDAS28 >1.2 or >0.6 if final DAS28 >3.2		
PD-T	0.59 (0.16,2.15)	0.47 (0.12,1.82)
PD-S	1.64 (0.93,2.90)	1.59 (0.86,2.92)
PD-T + PD-S	*2.75 (1.45,5.20)*	*2.09 (1.06,4.13)*
GS-T	1.59 (0.53,4.72)	1.37 (0.42,4.41)
GS-S	2.18 (0.97,4.92)	1.88 (0.79,4.46)
GS-T + GS-S	*2.88 (1.34,6.14)*	*2.25 (1.00,4.06)*
ΔHAQ ≥0.23		
PD-T	0.64 (0.13,3.03)	0.81 (0.16,4.01)
PD-S	0.79 (0.37,1.68)	0.71 (0.32,1.54)
PD-T + PD-S	1.49 (0.68,3.26)	1.33 (0.57,3.11)
GS-T	0.77 (0.22,2.73)	0.64 (0.17,2.45)
GS-S	0.83 (0.34,1.97)	0.61 (0.24,1.54)
GS-T + GS-S	0.93 (0.42,2.02)	0.64 (0.27,1.53)
ΔTotal SHS ≥4.3		
PD-T	0.82 (0.09,7.37)	0.54 (0.05,5.76)
PD-S	1.61 (0.71,3.64)	1.60 (0.68,3.79)
PD-T + PD-S	1.53 (0.60,3.93)	1.09 (0.38,3.11)
GS-T	0.78 (0.08,7.88)	0.67 (0.06,7.50)
GS-S	2.38 (0.72,7.84)	1.78 (0.49,6.48)
GS-T + GS-S	1.91 (0.59,6.15)	1.24 (0.34,4.49)

Results: 361 patients (72.3% f, mean age (sd) 56.1 (13.3), median disease duration (IQR) 7.1 years (3.6–13.5)) were included, complete radiographs were available for 189/361 (52.3%) patients. 98/326 (30.6%) patients had a flare within 12 months, 70/340 (20.59%) had an increase in HAQ and 39/189 (20.6%) radiographic progression. Results are presented in Table 1. Flare was predicted only if –T and –S, assessed by both GS and PD, were concurrently present, while both –T and-S and their combination did not predict HAQ or SHS progression.

Conclusions: In patients with RA in clinical remission, US-detected synovial and tenosynovial inflammation relates to the risk of flare, while in a short term follow-up the effect on disability and radiographic progression is limited. These results might have been influenced by the short follow-up and limited power for secondary outcomes. US might integrate the clinical management of RA patients in clinical remission.

THU0096 MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) IS ASSOCIATED WITH THE PROGRESSION OF STRUCTURAL BONE DAMAGE IN RHEUMATOID ARTHRITIS PATIENTS IN REMISSION

G. Schett[1], S. Finzel[2], M. Hagen[1], M. Englbrecht[1], J. Haschka[3], C. Figuereido[4], J. Fogagnolo Cobra[4], J. Rech[1]. *[1]University of Erlangen-Nuremberg, Erlangen; [2]University Medical Center Freiburg, Rheumatology and Clinical Immunology, Freiburg, Germany; [3]St.Vincent Hospital, Vinforce Study Group, Medical University of Vienna, Vienna, Austria; [4]Institutio de Rheumatologia, Sao Paolo, Brazil*

Background: Due to an increasing number and an earlier use of effective disease modifying anti-rheumatic drug (DMARD) therapy a growing number of rheumatoid arthritis (RA) patients reaches a state of clinical remission of disease. Whether clinical remission completely protects from structural bone damage, however, is still a matter of debate as conventional radiographic methods have their limitation in the sensitivity to characterize bone damage. Furthermore, residual activity of inflammation associated with the generation of inflammatory markers may characterize a subset of RA patients in remission, associated with higher prevalence and/or progression of bone damage.

Objectives: To test whether residual systemic inflammation is associated with structural bone damage and the progression of structural bone damage in RA patients in sustained remission.

Methods: RA patients (i) fulfilling the 2010 EULAR/ACR classification criteria of RA, (ii) having a positive anti-citrullinated protein antibody (ACPA) status and (iii) being in DAS28-ESR remission for 6 months were included. High-resolution peripheral quantitative computed tomography (HR-pQCT) of the right hand was done at baseline and after 1year. Erosion numbers and erosion volumes were assessed in the metacarpophalangeal joints. Vectra-DA tests measuring the serum levels of twelve different inflammation markers (CRP, SAA, IL-6, TNFR1, MMP-1, MMP-3, EGF, VEGF-A, VCAM-1, YKL-40, leptin and resistin) were performed in the baseline samples. MBDA score was calculated according to previously defined algorithms with low MDBA score defined as <30 units and moderate to high scores as ≥30 units (1).

Results: 100 ACPA+ RA patients in sustained remission were investigate (mean±SD age: 57±14 ys; disease duration: 4.8±4.9 ys; DAS28: 1.7±0.5;63% females; 100% MTX treatment, 38% MTX+TNFi treatment). 65 patients had low (<30), 25 patients has moderate (≥30–44 and 10 patients had high (>44) MBDA scores. Patients in the different MBDA categories had similar age, sex, disease duration, DAS28 scores and DMARD treatment. Baseline HR-pQCT analysis showed that erosion numbers and volumes were significantly ($p<0.001$) higher in patients with high MBDA scores. Higher erosion numbers (>10) and larger erosions (>10 mm^3) were exclusively found in patients with moderate to high MBDA scores. MBDA scores were correlated to erosion numbers ($p<0.001$) and volumes ($p=0.0018$). Longitudinal analysis showed significant progression of erosions only in patients with high MBDA scores. Furthermore, progression (>5mm^3 increase in volume) over 1 year was confined to methotrexate treated patients, while tumor necrosis factor inhibitor treated patients were protected from progression even in case of moderate to high MBDA scores. However there were only 4 patients treated with TNFi that had a high MBDA score.

Conclusions: These data show that residual disease activity assessed by MBDA score is associated with structural damage and progression of structural damage in RA patients in sustained remission.

THU0097 CHANGE IN SELF-REPORTED PAIN REFLECTS PSYCHOLOGICAL AND FUNCTIONAL STATE RATHER THAN INFLAMMATORY BURDEN IN UNITED STATES LATINOS WITH ESTABLISHED RHEUMATOID ARTHRITIS

G. Karpouzas, E. Hernandez, C. Cost, S. Ormseth. *Rheumatology, Harbor-UCLA Medical Center, Torrance, United States*

Background: Pain represents the cardinal complaint in patients with rheumatoid arthritis (RA). It may reflect inflammation, structural damage, or aberrant processing and regulatory mechanisms.
Objectives: We evaluated whether changes in pain reflect inflammatory burden variation or non-inflammatory factors in Latinos with established RA in the United States (US).
Methods: We evaluated 271 patients from a single academic center with complete data in parameters of interest on 2 visits, 12 months apart. Demographics, serologies, swollen and tender joint assessments, sedimentation rate, fatigue-VAS (visual analogue scale), pain-VAS, depression assessment (Patient Health Questionnaire-PHQ9), functional disability (Health Assessment Questionnaire, HAQ-DI), presence of erosions and irreversible articular damage (IAD, including subluxation, fusion, arthrodesis, or prosthesis) were recorded. Principal components factor analysis with varimax rotation determined latent variables of symptom change. Multinomial logistic regression modeling with forward stepwise entry determined parameters associated with clinically meaningful change in pain compared to no change
Results: Two factors met acceptance criteria (Eigenvalues $\geq$1) with values of 2.57 and 1.31 respectively (Table 1). Following rotation, factor 1 loadings comprised change in fatigue, pain, depression scores, and functional disability, representing non-inflammatory factors. Conversely, factor 2 encompassed changes in tender and swollen joints and ESR, representing inflammation. Clinically relevant improvement in pain significantly correlated with respective improvements in fatigue, depression, functional disability and tender joints (Table 2); worsening pain was negatively associated with change in disability or fatigue.

Table 1: Principal Component factor analysis with change variable loadings

	Factor 1*	Factor 2*
Fatigue change	0.814	-0.019
Pain change	0.757	0.216
PHQ9 change	0.716	0.024
HAQ-DI change	0.569	0.328
Swollen joint count change	0.095	0.828
Tender joint count change	0.238	0.696
Sedimentation Rate change	0.003	0.642
* Factor 1 explains 30.6% of variance and factor 2 explains 24.8%		

Table 2: Factors associated with clinically meaningful change in self-reported pain

	parameters	B	Std Error	p-value	OR	95% CI
Worsening	Intercept	-1.437	0.213	0.000		
	PHQ9 change	-0.011	0.034	0.752	0.989	0.925-1.058
	TJC change	-0.026	0.025	0.314	0.975	0.927-1.025
	HAQ-DI change	-1.254	0.358	0.000	0.285	0.142-0.575
	Fatigue change	-0.223	0.073	0.002	0.800	0.693-0.923
Improving	Intercept	-1.186	0.192	0.000		
	PHQ9 change	0.088	0.035	0.012	1.092	1.020-1.169
	TJC change	0.066	0.028	0.016	1.069	1.012-1.128
	HAQ-DI change	0.627	0.317	0.048	1.871	1.005-3.483
	Fatigue change	0.204	0.067	0.002	1.226	1.075-1.339
Reference category is no change						

Conclusions: In Latinos with established RA, change in pain reporting reflects alterations in non-inflammatory parameters such as fatigue, depression and functional disability rather than inflammation. Active screening and consideration of those factors may inform therapeutic interventions, balance patient and physician expectations, and optimize patient satisfaction and clinical outcomes.

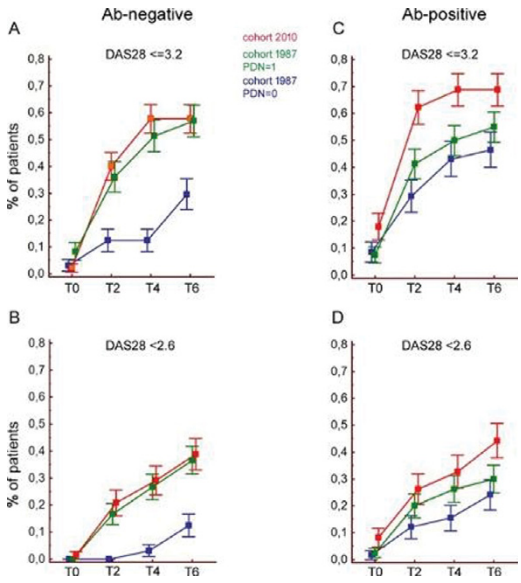
THU0098 THE NAILFOLD CAPILLAROSCOPY IN RHEUMATOID ARTHRITIS: QUANTITATIVE ANALYSIS AND CLINICAL AND SEROLOGICAL CORRELATION



G. Cuomo, E. Frongillo, L. Pirro, A. Del Mastro, C. Romano. *Dipartimento Assistenziale Integrato di Medicina Interna, UOC Medicina Interna - Università degli Studi della Campania - Luigi Vanvitelli, Napoli, Italy*

Background: Nailfold videocapillaroscopy (NVC) abnormalities have been reported in patients with Rheumatoid Arthritis (RA). Nevertheless only few studies evaluated the grades of the detected alterations (1,2). In 1994, Hachulla et al., showed microvascular permeability alterations in RA, to confirming the existence of a microangiopathy (3). In addition, Meyer et al. showed modifications of the normal blood flow velocity and microvascular dysfunction in RA (4).
Objectives: The aim of this study was to evaluate, in RA patients and healthy controls (HC), the microcirculatory abnormalities through NVC, applying a qualitative and quantitative method. We also correlated abnormalities with clinical and immunological features
Methods: Thirty-five HC (35 females, 7 males, median age 55, range 32–70) and 70 RA patients (61 females, median age 58 years, range 30–75; median disease duration 12 years, range 1–20) consecutively admitted to our outpatient clinic, were examined. All patients underwent a full clinical-serological characterization. Both patients and controls underwent NVC, with optical probes of 200X (VideoCap 2.5). We excluded patients who showed conditions known to compromise microcirculation, such as diabetes, hypertension, overlap with other connective tissue diseases or certain pharmacological treatments. The following NVC parameters were evaluated with a semiquantitative method: capillary enlargement (ectasias), microhemorrhages, mean capillary density, capillary tortuosity (5).
Results: NVC alterations were detected in 55 of 70 (68.6%) RA patients: 40 (57%) patient showed ectasic capillaries; 21 (30%) decrease of the mean capillary density; 12 (17%) microhemorrhages; 46 (65.7%) capillary tortuosity. No patient had megacapillaries and/or neoangiogenic abnormalities.
A statistically significant difference between HC and RA patients was found for the detection of ectasias ($p<0,0001$) and for the decrease of the mean capillary density ($p<0,001$).
No differences emerged in RA patients between NVC pattern and/or immunological (ANA, ACPA, Rheumatoid Factor) and/or serological profile (ESR, CRP, lipid profile).
Nevertheless we found a correlation between NVC abnormalities (microhrmorrhages) and activity disease evaluated by DAS28 (p=0.0037)
Conclusions: Our study confirms the presence of a sub-clinical microvascular involvement in RA patients either with or without microvascular clinical manifestations.
In our opinion capillaroscopy can be considered a valid technique in inflammatory joint diseases to analyze microvascular circulation. Moreover, the correlation of NVC specific alteration with disease activity suggests the importance of these features in the assessment of RA patients.

THU0099 THE 2010 CLASSIFICATION CRITERIA AND A MORE AGGRESSIVE TREATMENT STRATEGY IMPROVE CLINICAL OUTCOMES IN SEROPOSITIVE BUT NOT SERONEGATIVE RHEUMATOID ARTHRITIS

G. Crepaldi, S. Bugatti, F. Benaglio, G. Sakellariou, A. Manzo, C. Montecucco, R. Caporali. *Department of Rheumatology, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

Background: Current guidelines recommend an early and intensive treatment in patients diagnosed with rheumatoid arthritis (RA), and the 2010 ACR/EULAR Classification Criteria were developed with the aim of allowing earlier diagnosis and treatment (1,2). Recent studies highlighted some differences in disease activity between seropositive and seronegative RA patients at disease onset (3).
Objectives: To investigate whether the application of the 2010 ACR/EULAR Classification Criteria and a more aggressive treatment strategy improve clinical outcomes in patients with early RA irrespective of the autoantibody status.
Methods: 584 early, treatment-naïve RA patients were recruited in the years 2005–2014. RA diagnosis was made according to the ACR 1987 criteria in 2005–2010 (n=360, cohort 1987), and to the 2010 ACR/EULAR criteria in 2011–2014 (n=224, cohort 2010). Patients were classified in autoantibody (Ab)-negative (negative rheumatoid factor (RF) and/or anticitrullinated peptide antibody (ACPA) and Ab-positive (RF and/or ACPA positive). Methotrexate (MTX) was used at the initial dosage of 10 mg/week in cohort 1987, and 15 mg/week in cohort 2010, and progressively increased if low disease activity (LDA) (DAS28$\leq$3.2) was not met. The frequency and predictors of LDA and clinical remission (DAS28$<$2.6) over 6 months were assessed by Cox regression.
Results: In Ab-negative patients, LDA and clinical remission were achieved in 62.8% and 37.2% of the cases, and the 2010 cohort did not show significantly improved outcomes (HR [95% CI] 0.86 [0.611.23] for LDA; 1.04 [0.651.69] for remission) (Figure 1A,B). In contrast, in Ab-positive patients, the application of the 2010 classification criteria and higher dosages of MTX were associated with increased frequency of LDA after adjustment for confounders (age, sex, prednisone, baseline DAS28; HR [95% CI] 1.39 [1.012]) (Figure 1C). Clinical remission was achieved in 41.3% of the cases, compared to 29.6% in the 1987 cohort (p=0.17) (Figure 1D).
Conclusions: Early diagnosis and a more aggressive treatment strategy with MTX lead to significantly improved outcomes in autoantibody positive RA. The management of seronegative patients remains suboptimal.

THU0100 IN EARLY INFLAMMATORY ARTHRITIS A LYMPHOID PATHOTYPE SIGNFICANTLY ASSOCIATES WITH REQUIREMENT FOR BIOLOGIC THERAPY AT 12 MONTHS FOLLOW UP: RESULTS FROM THE PATHOBIOLOGY OF EARLY ARTHRITIS COHORT (PEAC)

G. Lliso-Ribera[1], F. Humby[1], S. Kelly[1], M. Bombardieri[1], M. Lewis[1], R. Hands[1], V. Rocher[1], F. Bene[1], A. Nerviani[1], C. Buckely[2], P. Taylor[3], I. McInnes[4], C. Pitzalis[1]. *[1]Experimental Medicine and Rheumatology, Queen Mary University London, London; [2]Centre for Translational Inflammation Research, University of Birmingham, Birmingham; [3]Kennedy Institute of Rheumatology, University of Oxford, Oxford; [4]Experimental Medicine and Rheumatology, University of Glasgow, Glasgow, United Kingdom*

Background: Early aggressive treatment in RA equates to better long term outcomes, however targeting aggressive therapies including biologics to patients with the worse prognosis is critical to deliver acceptable risk/benefit ratios and health economic improvements. Such an approach requires prognostic biomarkers, whether the well recognised heterogeneity in synovial pathobiology in early RA translates to specific disease outcomes is currently unknown.
Objectives: The aim of this study was to investigate whether in a treatment naïve early inflammatory arthritis cohort, baseline synovial pathotype significantly associates with disease outcome at 12 months.
Methods: 166 consecutive DMARD naïve patients recruited as part of PEAC at Barts Health NHS Trust with synovial tissue suitable for analysis were included. At baseline patients were classified as RA (2010 ACR/EULAR criteria) or undifferentiated (UA). All patients underwent a baseline synovial biopsy of a clinically active joint along with collection of demographic data. Patients were subsequently treated with DMARD +/- steroid therapy with aim for low disease activity (DAS <3.3). At 6 month follow up patients were escalated to biologic therapy if fulfilling UK NICE guidelines. At 12 months patients were classified as: (i) no treatment, (ii) DMARDs, and (iii) Biologic +/- DMARDs. Sequentially cut sections of baseline synovial biopsies underwent immunohistochemical staining and semi-quantitative scoring (0–4) to determine the degree of CD20+Bcells, CD3+T cells, CD68+ lining (l) and sublining (sl) macrophage and CD138+ plasma cell infiltration. Sections were categorised into 3 pathotypes, (i) Fibroid: (CD68 SL<2 and or CD3, CD20, CD138<1), (ii) Myeloid: (CD68SL>2, CD20<1 and or CD3>1) and (iii) Lymphoid: (grade 2–3 CD20+ aggregates, CD20>2).
Results: 79% were classified as RA and 21% as UA. Mean disease duration was 9.27 months. 92% (153/166) patients had follow-up at 12months. 29% (44/153) of patients were classified as fibroid, 34% (52/166) as myeloid and 37% (57/166) as lymphoid. At baseline patients with a lymphoid pathotype had a significantly higher CRP and DAS28 and were significantly more likely to be sero positive for for RF and ACPA ($p<0.05$), suggesting that a lymphoid pathotype is associated with higher levels of disease activity. At 12 months follow up a significantly higher proportion of patients classified as lymphoid vs myeloid or fibroid (58% vs 21% vs 21%) required biologic therapy.
Conclusions: Results demonstrate that in an early inflammatory arthritis cohort a lymphoid pathotype significantly associates with higher disease activity at baseline, sero positivity for RF and ACPA and a requirement for more aggressive therapy at 12 month. This supports a direct role for synovial lymphoid structures in disease pathogenesis and suggests a role as a prognostic biomarker facilitating early stratification of aggressive therapeutic intervention.

N=153	Fibroid (44)	Myeloid (52)	Lymphoid (57)	p-value
No treatment (14) n (%)	6 (42%)	6 (42%)	2 (14%)	<0.05*
DMARD (101) n (%)	30 (29%)	38 (37%)	33 (32%)

THU0101 CARDIOVASCULAR MAGNETIC RESONANCE IMAGING CHARACTERISATION OF CARDIOVASCULAR ABNORMALITIES IN INDIVIDUALS AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS

G.J. Fent[1], L. Hunt[2,3], K.S. Mankia[4,5], B. Erhayiem[1], J.R. Foley[1], P. Garg[1], P.P. Swoboda[1], J. Andrews[4,5], J.P. Greenwood[1], P. Emery[4,5], S. Plein[1], M.H. Buch[1,5]. *[1]Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, UK; [2]NIHR Leeds Musculoskeletal Medicine, University of Leeds, United Kingdom; [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, United Kingdom; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine; [5]NIHR Leeds Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: Inflammation is the primary contributor to excess cardiovascular (CV) disease in rheumatoid arthritis (RA), with evidence of subclinical abnormalities observed even in treatment-naïve, early RA [1]. Preliminary reports suggest citrullinated proteins are present in atherosclerotic plaque [2]. It is unclear whether immunological changes of anti-citrullinated protein antibody (anti-CCP+) positive individuals "at risk" of developing RA are associated with CV abnormality.
Objectives: To perform a pilot study to explore whether subclinical CV abnormalities are present in anti-CCP+ individuals at risk of developing RA.
Methods: Sixteen consecutive patients with non specific MSK symptoms but no synovitis, detectable anti-CCP antibody and 30 age-matched healthy controls (HC) underwent a multi-parametric 3.0T (Philips Achieva) cardiovascular magnetic resonance (CMR) study. Neither group had any history of CV disease. At-risk individuals were categorised as low and high absolute risk for RA development (<50% and ≥50% respectively) according to a published risk model [3]. CMR post-processing was performed using CVI [42] (Circle Cardiovascular Imaging, Canada).
Results: HC and at risk individuals were well matched for baseline characteristics (table 1). Aortic strain values (distensibility, strain and stiffness index β) were lower, indicating increased aortic stiffness, in at-risk individuals than HC, numerically most pronounced those classified high risk (table 2). There were no differences in LV mass and function, late gadolinium enhancement, myocardial T1 (measure of myocardial composition) or LV S prime (longitudinal LV systolic function) (table 2).

Table 1. Baseline characteristics

	All 'at risk' RA patients (n= 16)	Healthy controls (n=30)	p value
Age (years)	53±11	50 ± 15	0.59
Males	4/16 (25%)	10/30 (33%)	0.57
Systolic BP (mmHg)	121±17	120±13	0.82
Diastolic BP (mmHg)	64±11	64±11	0.81
BMI (kg/m^2)	28±5	27±6	0.47
Diabetes	2/16	0/30	0.05
Active smoker	1/16 (6%)	3/30 (10%)	0.68
Ex-smoker	11/16 (69%)	5/30 (17%)	0.001
Mean absolute pre-	45%	-	-

Table 2. Results table

	All 'at risk' RA individuals (n= 16)	Low 'at risk' RA individuals (n=10)	High 'at risk' RA individuals (n=6)	Healthy controls (n=30)	p value
Aortic Distensibility (10^{-3}mmHg)	3.6±1.4	4.1±1.5	2.8±0.5	4.7 ± 2.0	0.05
Aortic strain	0.20±0.06	0.21±0.07	0.18±0.03	0.25 ± 0.09	0.03
Aortic stiffness index, β	3.5±1.0	3.2±1.0	4.0±0.8	2.7 ± 0.8	0.007
Myocardial native T1	1215±35	1213±36	1218±37	1202 ± 36	0.25
Late Gadolinium enhancement	1/16	0/6	1/10	1/30	-
LV ejection fraction (%)	62±4	62±5	63±3	62±5	0.94
RV ejection fraction (%)	55±6	54±4	58±7	54±6	0.47
Indexed LV mass (g/m^2)	46±10	45±8	49±14	49±8	0.29
Indexed LV volume (ml/m^2)	83±12	81±13	87±12	80±11	0.34
LV S prime (s-1)	1.1±0.1	1.2±0.1	1.0±0.1	1.1±0.1	0.37

Conclusions: Anti-CCP+ individuals with non-specific MSK symptoms (in particular, a high risk group), exhibit increased aortic stiffness. This suggests presence of CV abnormalities prior to development of RA and implies a role of autoantibody-mediated development of atherosclerosis. These findings warrant further investigation in larger scale studies.

THU0102 CLINICAL DISEASE ACTIVITY MEASURES ARE IMPORTANT DRIVERS OF MAJOR CHANGE IN MEDICAL TREATMENT IN US VETERANS ENROLLED IN THE VETERANS AFFAIRS RHEUMATOID ARTHRITIS (VARA) REGISTRY

G.W. Cannon[1,1], C.-C. Teng[2], N.A. Accortt[3], D. Collier[3], S. Mehrotra[2], B.C. Sauer[2]. *[1]Rheumatology; [2]Salt Lake City Va Medical Center, Salt Lake City; [3]Amgen, Thousand Oaks, United States*

Background: Current guidelines encourage the measurement of rheumatoid arthritis (RA) disease activity and directing therapy to achieve a low disease state or remission (treat-to-target). Many RA patients with documented moderate to severe disease activity remain on their current therapy without change.

Objectives: This study investigated Veterans Affairs (VA) clinical data to identify patient factors associated with a major change in RA therapy and to determine the relative importance of these different factors.

Methods: US Veterans enrolled in the VARA registry were included if they had: 1) high/moderate disease activity (DAS28≥3.2) at index date, 2) 18 months of VA data prior to the index date and 3) two or more other DAS28 measured during the preceding 18 months separated by at least three months. A major change was report if within 7 days before to 90 days after the index date there was either: 1) initiation or escalation of DMARDs, 2) initiation or increase dose of prednisone and/or 3) ≥2 joint injections.

Baseline DAS28 was estimated during the observation period prior to the index date using an area under the curve calculation and compared to the DAS28 at the index date. Patients were categorized as have a worsening or improvement of disease if the DAS28 at index date was 0.6 higher or lower than the average DAS28 during the observation period respectively. Other patients were categorized as no change in DAS28.

Analyses of clinical variables including components of the DAS28 and patient and physician reported measures were compared in patients with and patients without a major change in therapy.

Results: Of 941 patients who met study criteria, only 388/941 (41.2%) had a major change of therapy. Patients with worsening DAS28 were more likely to have a major change 183/369 (49.5%) than no DAS28 change 170/454 (37.4%) and improved DAS28 35/118 (29.6%) (P<0.001). Clinical variables were strongly associated with changes in therapy among patients with worsening disease activity and not as strongly associated with change in therapy in those with no change disease activity. Clinical variables were not significantly associated with major change in patients with disease improvement, though that group had the smallest sample size. Ten representative clinical variables with the highest association with major change are included below.

	Comparison of Patients with Major Change to Patients without Major Change					
Demographic elements	DAS28 worsening (n=369)		DAS 28 no change (n=454)		DAS 28 improved (n=118)	
Major Change at Index Date - Number (%)	183/369 (49.5%)		170/454 (37.4%)		35/118 (29.6%)	
Age at RA Disease Onset - Mean (SD)	52.4±13.7		51.4±13.7		50.9±12.9	
Age at Index Date - Mean (SD)	65.3±10.6		65.6±11.0		64.0±10.8	
Male - Number (%)	328 (88.9%)		410 (90.3%)		99 (84.0%)	
Clinical Variables from VARA registry	RR (CI 95)	p-value	RR (CI 95)	p-value	RR (CI 95)	p-value
DAS28 Score At Index Date	1.25 (1.11 - 1.42)	<0.001	1.30 (1.12 - 1.51)	0.001	1.23(0.82 - 1.82)	0.318
Baseline DAS28 Score during 18 months observation period	1.20 (1.05 - 1.37)	0.009	1.27 (1.09 - 1.47)	0.002	1.27 (0.86 - 1.87)	0.219
Swollen Joint Count	1.03 (1.00 - 1.04)	0.031	1.05 (1.01 - 1.08)	0.006	1.06 (0.99 - 1.12)	0.070
Tender Joint Count	1.02 (1.00 - 1.04)	0.027	1.01 (0.98 - 1.03)	0.530	0.98 (0.91 - 1.07)	0.671
Modified Health Assessment Questionnaire (MD HAQ)	1.08 (0.87 - 1.37)	0.051	1.03 (0.81 - 1.31)	0.743	0.90 (0.50 - 1.61)	0.722
Pain Score	1.07 (1.01 - 1.13)	0.028	1.04 (0.99 - 1.10)	0.145	0.93 (0.83 - 1.05)	0.257
Patient Global Assessment	1.01 (1.00 - 1.01)	0.093	1.01 (1.00 - 1.02)	0.014	1.00 (0.98 - 1.01)	0.560
Physician Global Assessment	1.00 (0.99 - 1.01)	0.474	1.01 (1.00 - 1.02)	0.002	1.01 (0.99 - 1.02)	0.402
Erythrocyte Sedimentation Rate	1.01 (1.00 - 1.01)	0.073	1.00 (1.00 - 1.01)	0.582	1.00 (0.99 - 1.02)	0.630
C-reactive Protein	1.04 (1.00 - 1.08)	0.056	1.08 (1.00 - 1.17)	0.990	1.08 (0.92 - 1.28)	0.344

Conclusions: More than half of the patients with moderate disease activity did not have a major change in therapy. The likelihood of a major change in therapy increased with worsening disease activity. The clinical variables assessed were more strongly associated with change in therapy in patients with worsening of disease. Clinical disease activity measures are highly associated with the decision to initiate major changes. Future work will investigate the potential added value of administrative variables. This work emphasizes the need for methods to systematically collect and utilize clinical disease activity measurements, particularly longitudinally, to improve the treat-to-target strategy.

THU0103 ANTI-RA33 AUTOANTIBODIES ARE ASSOCIATED WITH THERAPEUTIC RESPONSES TO METHOTREXATE AND ANTI-TNF TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Steiner[1], D. Sieghart[1], P. Studenic[1], T. Horn[2], D. Aletaha[1], J. Smolen[1]. *[1]Internal Medicine III-Rheumatology, Medical University Vienna; [2]Phadia Austria GmbH, Thermo Fisher Scientific, Vienna, Austria*

Background: Besides the determination of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA), anti-RA33 antibodies (which are directed to the nuclear antigen hnRNP-A2) could be of additional diagnostic and/or prognostic value in patients with rheumatoid arthritis (RA) because they are also found in RF/ACPA negative patients (1, 2).

Objectives: So far, published data on anti-RA33 antibodies refer only to the IgG isotype. It was therefore the aim of this study to measure the prevalence of anti-RA33 IgG, IgM and IgA antibodies in patients with RA and to determine their potential prognostic value regarding prediction of response to treatment.

Methods: A total of 255 patients were tested for the presence of IgG, IgM and IgA anti-RA33 antibodies by a newly developed EliA® (Thermo Fisher Scientific). All patients had initially been treated with conventional synthetic drugs (mostly methotrexate) and were subsequently treated with at least one TNF inhibitor. Therapeutic responses to MTX and TNF blocking biologicals were calculated in an inception cohort (n=104) who had started their DMARD therapy at our clinic. To define therapeutic responses the simplified disease activity index (SDAI)50 and American College of Rheumatology (ACR)20 responses were calculated.

Results: Among the 255 patients, 11% tested positive for anti-RA33 IgG antibodies, 15% for IgM antibodies and 6% for IgA antibodies. Altogether, 62 patients (24%) had at least one type of anti-RA33 antibody: 24 patients were RF-negative, 26 were ACPA-negative and 18 were RF/ACPA double negative. Thus, in 32 patients (13%), anti-RA33 was the only antibody specificity. Regarding response to anti-TNF therapy (Figure 1A), in the group of patients testing positive for anti-RA33 antibodies of any isotype (with or without concomitant RF and/or ACPA) the percentage of SDAI50 responders (24%) was significantly lower (p=0.0117) than in anti-RA33 negative (but RF/ACPA positive) patients (42% responders) and similar to the group of completely seronegative patients (21% responders). In contrast, regarding responses to MTX (Figure 1B) the percentage of SDAI50 responders was significantly higher (p<0.0001) among anti-RA33 positive patients (with or without RF and/or ACPA) (59% responders) compared to anti-RA33 negative (but RF/ACPA positive) patients (37% responders) and seronegative patients (24% responders).

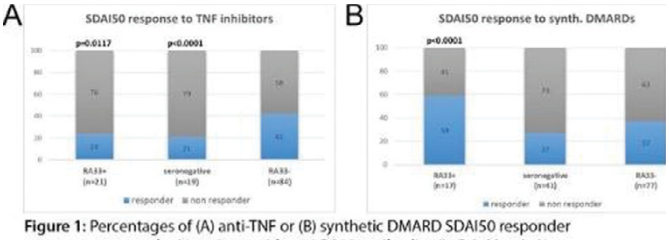

Figure 1: Percentages of (A) anti-TNF or (B) synthetic DMARD SDAI50 responder versus non responder in patients with anti-RA33 antibodies (IgG, IgM or IgA), seronegative patients (RA33-RF-ACPA-) compared to RA33 negative patients.

Conclusions: In agreement with previous findings (1,2) anti-RA33 antibodies reduced the diagnostic gap left by ACPA and RF and thus the percentage of seronegative patients by 13%. Importantly, the presence of anti-RA33 antibodies was associated with a favourable response to MTX on the one hand and with a diminished response to TNF inhibitors on the other hand. Therefore, these antibodies appear to have some prognostic value for prediction of therapeutic responses and could become helpful tools in therapeutic decision making.

THU0104 BOTH MRI AND HAQ-DI CAN PREDICT RELAPSES FOLLOWING ALL TREATMENT WITHDRAWAL IN MTX-NAÏVE PATIENTS WITH RA IN REMISSION AFTER 12 MONTHS OF ABATACEPT THERAPY IN THE AVERT TRIAL

H. Ahmad[1], J. Baker[2], M. Østergaard[3], P. Emery[4], T. Huizinga[5], J. Ye[1], S. Banerjee[1], P. Conaghan[4]. *[1]Bristol-Myers Squibb, Princeton; [2]Philadelphia VA Medical Center & the University of Pennsylvania, Philadelphia, United States; [3]Copenhagen Center for Arthritis Research, Rigshospitalet and University of Copenhagen, Copenhagen, Denmark; [4]University of Leeds and Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; [5]Leiden University Medical Center, Leiden, Netherlands*

Background: Factors predictive of relapse need to be identified to aid therapy withdrawal decisions for patients with RA achieving remission with treatment. AVERT (NCT01142726) was a Phase IIIb, randomized, active-controlled trial in patients with early RA.[1] After a 12-month, double-blind treatment period with abatacept + MTX, or abatacept or MTX monotherapy, patients with DAS28 [CRP] <3.2 could enter a 12-month withdrawal period (all treatment stopped).
Objectives: To evaluate *post hoc* whether MRI scores, patient characteristics and disease activity at Month 12 were predictors of clinical relapse at Month 18 and Month 24 after treatment withdrawal in AVERT.
Methods: Synovitis, erosion and bone oedema in the dominant hand and wrist MRI were scored at Month 12 using the RA MRI scoring system (RAMRIS). Patient characteristics (pain, age, weight, HAQ-DI) and disease measures (CRP, SJC28, TJC28, DAS28 [CRP], CDAI, SDAI) were recorded at Month 12. The influence of these factors on the proportion of patients who relapsed (doubling of TJC28 and SJC28, and DAS28 [CRP] ≥1.2 increase relative to Month 12) by Month 18 and Month 24 was assessed.
Results: A total of 172 patients achieving DAS28 remission (DAS28 [CRP] <2.6) at Month 12 in any treatment group were included in the analysis. Numbers of patients who relapsed at Month 18 and Month 24 were 100 and 113, respectively. Of the patient characteristics, disease activity and imaging factors analysed at Month 12, only MRI synovitis, erosion and oedema scores, as well as HAQ-DI scores, were significantly associated ($p<0.05$) with relapse status at both Month 18 and Month 24 (Table).
Conclusions: MRI and HAQ-DI scores in patients in DAS28 remission predicted clinical relapses 6 and 12 months after complete drug withdrawal in the AVERT trial. The clinical decision on whether to withdraw therapy in MTX-naïve patients with RA in remission may benefit from an assessment of imaging and physical function prior to drug withdrawal.

THU0105 PREDICTION OF RESPONSE TO CERTOLIZUMAB-PEGOL IN RHEUMATOID ARTHRITIS (PRECEPRA) BY FUNCTIONAL MRI OF THE BRAIN – AN INTERIM ANALYSIS OF AN ONGOING INVESTIGATOR INITIATED PHASE III TRIAL

H. Schenker[1], A. Hess[2], L. Konerth[2], M. Sergeeva[2], J. Prade[2], A. Kleyer[1], M. Reiser[1], A. Hueber[1], M. Englbrecht[1], E. Feist[3], R.E. Voll[4], B. Bannert[4], C. Baerwald[5], J. Rösch[6], A. Doerfler[6], G. Schett[1], J. Rech[1]. *[1]Department of Internal Medicine 3, University of Erlangen-Nuremberg; [2]Institute of Pharmacology and Toxicology, University of Erlangen, Erlangen; [3]Department of Rheumatology and Immunology, Charité, Berlin; [4]Clinic for Rheumatology and Clinical Immunology, University of Freiburg, Freiburg; [5]Department of Rheumatology, University of Leipzig, Leipzig; [6]Department of Neuroradiology, University of Erlangen-Nuremberg, Erlangen, Germany*

Background: Tumor necrosis factor inhibitors (TNFi) signify a major advance in the treatment of rheumatoid arthritis (RA). However, treatment success initially remains uncertain as one third of patients do not respond adequately to TNFi.
Objectives: We investigated whether brain activity associated to arthritis measured by functional magnetic resonance imaging (fMRI) can function as a predictor of response to TNFiin RA patients.
Methods: This is an interim analysis of the first 50 patients of the PreCePRA trial, a multi-center, double-blind, placebo-controlled fMRI trial on patients with RA. [1] [2] Active RA patients failing csDMARDs with a DAS28-ESR >3.2 and at least three tender and/or swollen joints received a baseline brain BOLD fMRI scan upon joint compression at screening. Patients werethen randomized into a 12-week double-blinded treatment phase with placebo (arm 1) or 200mg certolizumab-pegol eow (arm 2; fMRI Bold signal>2000 voxel i.e. $2cm^3$, arm 3; fMRI Bold signal <2000 voxel). LDA 3mo. Primary end point was DAS28-ESR low disease activity at 12 weeks. A 12 weeks follow-up phase in which patients were switched from the placebo to the treatment arm folowed the blinded phase. fMRIwas carried out at baseline as well as after 12 and 24 weeks of or placebo.
Results: In 31 patients (responders) baseline signal volume i.e. sum of significantly coupled voxels after the FDR thresholding was significatly higher compared to 19 patients (non-responders) ($p<0.001$) allowing discrimination between the two groups prior to treatment. In responders we detected an persitent decrease of the BOLD volume from baseline to week 12 and week 24 ($r^2=0.561$) whereas the BOLD volume in non-responders persitently increased ($r^2=0.589$).

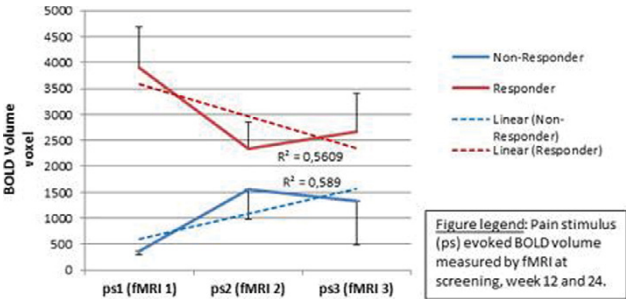

Figure legend: Pain stimulus (ps) evoked BOLD volume measured by fMRI at screening, week 12 and 24.

Conclusions: Based on this interim analysis we conclude that high BOLD volumes in fMRI, indicating high-level brain representation of pain in arthritis. These data represent the first encouring signal of the PreCePRA brain fMRI study supporting the concept that increased RA-related brain activity is related to response to TNFi.

THU0106 ROUTINE CLINICAL ASSESSMENT OF JOINT DAMAGE TO EVALUATE OUTCOME IN RHEUMATOID ARTHRITIS

H. Bernelot Moens, A. terAvest, D. Berendsen, C. Haagsma. *Rheumatology & Clinical Immunology, Ziekenhuisgroep Twente, Almelo, Netherlands*

Background: Early treatment of rheumatoid arthritis (RA) with treat-to-target strategies aims to reduce disease activity and to prevent joint damage. Assessment of the quality of care is commonly based on measurements of disease activity, functioning and well being. In clinical trials, radiographic scores are widely used to assess structural joint damage, but these are not applicable in routine care and limited to hands and feet. Only a few studies evaluated clinical assessment of irreversible joint damage (e.g. surgery) as outcome. The RA articular damage (RAAD) score counts structural damage in all joints that that are affected by RA[1]. It correlates with radiographic damage[2]. We have applied this score since 2014 in routine care.

Abstract THU0104 – Table 1. MRI and HAQ-DI Scores at Month 12 in Patients With vs Without Relapse by Month 18 and Month 24*

	Patients with vs without relapse at Month 18		Patients with vs without relapse at Month 24	
Score	Estimated difference in scores at Month 12 (95% CI)	p value	Estimated difference in scores at Month 12 (95% CI)	p value
MRI synovitis	1.051 (0.291, 1.810)	0.0070	1.088 (0.256, 1.920)	0.0107
MRI erosion	3.244 (1.694, 4.795)	<0.0001	3.076 (1.550, 4.601)	0.0001
MRI oedema	1.503 (0.650, 2.356)	0.0007	1.423 (0.644, 2.202)	0.0004
HAQ-DI	0.194 (0.050, 0.338)	0.0088	0.201 (0.050, 0.353)	0.0095

*Month 18: 92 with relapse, 63 without relapse; Month 24: 103 with relapse, 52 without relapse.

Objectives: Evaluate the feasibility of a simple clinical joint damage score and describe the increment over time in RA patients with varying disease duration.
Methods: Cross-sectional study in all patients with a clinical diagnosis of RA visiting the outpatient clinic in 2015 and 2016. Rheumatologists and nurses from the outpatient department of a large regional hospital received a single training to perform the RAAD score. Scores of 0 (no damage), 1 (mild) or 2 (severe: ankylosis, luxation or joint surgery) were assigned to 35 joints (maximum score: 70) with a disease activity score, and stored in the electronic patient record system. Baseline data including ACR 2010 criteria were also registered.
Results: In 1007 (67.3%) of 1496 RA patients seen over 2 years RAAD-scores were performed. 652 (64.7%) were female, average age (SD, range) was 62.6 (13.1, 19–95), disease duration 9.9 (9.6, 0–65) years. Rheumatoid factor and ACPA were positive in 70.6% and 70.3% respectively.
RAAD scores related to disease duration illustrate that at disease onset 86%, and after 20 years 37% of the patients has no joint damage (Table). Distribution over joints shows the classical predominance of damage in MCP, PIP and MTP joints (Image). Structural damage in shoulders or elbows was present in 8.3% and 12.5%, in knees and hips in 10,3% each. Despite current treatment strategies, irreversible joint damage of more than 5 joints is present in 6.3% within 10 years.

Table 1. Accumulation of irreversible joint damage score with disease duration, number (%)

RAAD-score	1st year (N=69)	2–4 yrs (N=228	5–9 yrs (N=253)	10–19 yrs) (N=239)	≥20 yrs (N=218)
0 (no joint damage)	59 (86)	158 (69.3)	145 (57.3)	81 (33.9)	80 (36.7)
1–5	8 (12)	65 (28.5)	92 (36.4)	103 (43.1)	42 (19.3)
6–10	2 (3)	4 (1.8)	11 (4.3)	34 (14.2)	28 (12.8)
11–20			4 (1.6)	13 (5.4)	36 (16.5)
>20		1 (0.4)	1 (0.4)	8 (3.3)	32 (14.7)
Average (range)	0,4 (0–6)	0,9 (0–23)	1,6 (0–37)	2,2 (0–18)	9,0 (0–59)

Conclusions: Clinical assessment of joint damage is a feasible parameter of long term outcome in RA. Reflecting overall joint damage, the RAAD-score provides a broader view than radiographic scoring of hands and feet and is easy to apply in routine care. Given the slow increment a single assessment per 5 years may suffice to compare structural joint damage across cohorts of patients.

THU0107 ASSOCIATION OF GLOBAL DNA METHYLATION WITH MTX RESPONSE AND ADVERSE EVENTS IN EARLY RHEUMATOID ARTHRITIS

H. Gosselt[1], M.D. Rotte[1], M. Chisholm[1], M. Hazes[2], R.D. Jonge[3], S. Heil[1].
[1]Clinical Chemistry; [2]Rheumatology, Erasmus Medical Center, Rotterdam; [3]Clinical Chemistry, VUMC, Amsterdam, Netherlands

Background: Methotrexate (MTX) is a first-line therapy in early Rheumatoid Arthritis (RA). However, ~30% of treated patients do not respond to the medicine or need to abrogate treatment because of severe adverse events. Since MTX interferes with the folate cycle and thereby influences the methylation cycle, we hypothesize that methylation status at start therapy is associated with response and adverse events after three months of MTX treatment enabling personalized medicine.
Objectives: Examine global methylation status of early Rheumatoid Arhtritis patients before and after 3 months of MTX use between responders and non-responders and patients that do or do not experience adverse events.
Methods: To assess global methylation status, DNA was isolated at baseline from whole blood of 120 patients from the Treatment in the Rotterdam Early Arthritis Cohort (tREACH), a multicenter, stratified single-blind clinical trial of patients with early RA. Methylation status of 7 CpG sites within Long-interspersed nuclear elements (LINE-1) were analyzed and quantified by Matrix Assisted Laser Desorption Ionization time of flight Mass Spectrometry (MALDI-TOF MS). Results were compared between MTX responders and non-responders based on a low disease activity (DAS28 <3.2) at three months of treatment and patients experiencing ≤2 or ≥3 adverse events. Gastrointestinal adverse events were assessed separately.
Results: No statistical differences in the mean of 7 LINE-1 CpGs were observed between responders and non-responders, nor in patients experiencing ≤2 or ≥3 adverse events. However, methylation status of specific CpG sites within LINE-1 did show significant changes. Baseline CpG_2 methylation levels were positively correlated with the DAS28 score at t3 (p=0.018) and baseline methylation levels in CpG_5 and CpG_8.9 were significantly higher in patients experiencing ≥3 adverse events (p=0.018 and p=0.034, respectively). Besides, CpG_5 methylation levels were particularly increased in patients experiencing gastrointestinal adverse events (p=0.038).
Conclusions: Global methylation status is associated with non-response and adverse events to MTX in early RA patients and can therefore be implemented in future prediction models.

THU0108 SUBCLINICAL CENTRAL NERVOUS SYSTEM DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS: DISEASE ACTIVITY AND CYTOKINES

I. Tekeoğlu, S. Sağ, A. Kamanlı, M.S. Sağ, K. Nas. *Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya, Turkey, sakarya, Turkey*

Background: We aimed in this study to investigate blood-brain barrier (BBB) dysfunction in RA patients who had no neurological symptoms, and were receiving synthetic DMARD treatment.
Objectives: We investigated correlations between cranial MRI images and brain specific proteins (S100 Beta, GFAP), cytokines (IL-1 beta, IL-17) in plasma which had important roles in disease activity.
Methods: In our study, 57 patients (46 females and 11 males) were included included in RA group, and 34 patients (24 females and 10 males) in the control group. All of RA patients were receiving synthetic DMARD treatment. Demographic characteristics of all patients were recorded. Disease activity was evaluated by using DAS-28. Mini-mental test (MMT) was used for evaluation of cognitive functions, and Fazekas scale was used to evaluate cranial MR lesions. S100 beta, GFAP, claudin, IL-17, and IL-1 beta levels were measured in peripheral blood of both groups.
Results: Demographic characteristics were similar between the groups, and there was no statistically significant difference in gender, age, and body mass index (BMI) between patient and control groups (p>0.05). S100 beta, and GFAP levels were significantly higher in RA group (p<0.05). No difference was determined in hyperintense lesions diagnosed in cranial MR between patient and control groups (p>0.05). There were positive correlations between IL-17 S100 beta and GFAP, and IL-1 beta and S100 beta.
Conclusions: In our study, we have shown that blood-brain barrier may be damaged subclinically in RA patients, brain specific proteins related to BBB dysfunction may be increased in the peripheral blood, and BBB dysfunction may be related to cytokines which play an important role in disease pathogenesis. In conclusion, cytokines which circulate in the peripheral blood in RA may cause subclinical BBB damage. Further large scale studies with long-term follow-up are required which will support this hypothesis.

THU0109 UPDATED ESTIMATION OF THE EQ5D QUALITY OF LIFE QUESTIONNAIRE UTILITY VALUES THROUGH HAQ-DI MAPPING FOR SPAIN

I. Gorostiza[1], L. Ansola[2], E. Galindez[3]. *[1]Research Unit; [2]Research Unit; [3]Rheumatology, H. Universitario Basurto, Vizcaya, Spain*

Background: Rheumatoid arthritis (RA) deeply affects the quality of life (QoL) of patients. The preferred approach to evaluate treatment efficiency is to value health as patient preferences known as utilities, and subsequently, calculate Quality-Adjusted Life Years gained. A new 5-level of severity EQ5D has recently released and a new tariff proposed for Spain (Ramos-Goñi,2016). Although QoL questionnaires are not of routine use in clinical practice, it is possible to estimate it using the Health Assessment Questionnaire Disability Index (HAQ-DI)
Objectives: To develop a function that allows the estimation of EQ5D-5L utility values from HAQ-DI updated to the newest proposed tariff for Spain

Methods: Patients with RA from two teaching hospitals, participating in a prospective observational study completed the HAQ-DI and EQ5D-5L at 0–6-12 month follow-up visits. Inclusion criteria: ACR RA diagnosed patients, on biologic treatment and whose disease activity remained stable at least for 3 months EQ5D-5L is a standardized, generic instrument for describing and valuing health and QoL, consisting in a five-dimensional descriptive system (mobility, self-care, usual activities, pain/discomfort and anxiety/depression) and a visual analogue scale. A country-specific tariff converts patient's answer to a 0–1 (full health) utility index. HAQ-DI is a self-completed questionnaire used to assess the functional ability using 20 items, distributed across 8 dimensions and resulting in a four-level disability scale (0–3). In addition, socio-demographic and clinical data where recorded.To estimate the EQ5D-5L utility index OLS models were built. As this index is bounded to the [-0.416, 1] interval, Tobit models were also considered. Hereafter, the index was transformed to the open interval (0,1) and estimated through beta regression with a logit link. To determine the relationship grade between the index and the HAQ-DI scale and obtain residuals without trend, GAM models were used. Best fitting models were determined by AIC, MAE and RMSE. All analyses were performed using R software

Results: 217 questionnaires fulfilled by 77 patients. Mean (SD) age was 57.0 (12.9), 87% women, AR duration 13.7 (7.1), mean DAS28 2.72 (1.00) and HAQ-DI 0.77 (0.60). Baseline EQ5D index: 0.768 (0.182). All the OLS estimation models resulted in the interval limits defined by the index, so Tobit models were not considered. When considering the linear model we obtained the best results with the HAQ-DI term and its third power: EQ5D5L = 0.9232 – 0.1760×HAQ – 0.0172×HAQ^3 (AIC=–221.62; MAE=0.0974; RMSE=0.1363); for beta regression, we obtained the best model with the HAQ-DI to the first power alone: logit (EQ_01) = 2.5821 – 1.1165×HAQ (AIC=–444.4; MAE=0.0691; RMSE=0.0958). Considering the AIC and the residuals together, we obtained the best fitting model with the beta regression approach, with neither age nor sex

Conclusions: So far, only a utility function using HAQ-DI and an older EQ5D-3L version was available for Spain (Carreño,2011). This updated utility function can be used as a practical approach to predict RA patients' QoL and EQ5D utility score for Spain when clinicians/researchers need them for clinical practice or cost-effectiveness analyses and generic QoL measurements are not available

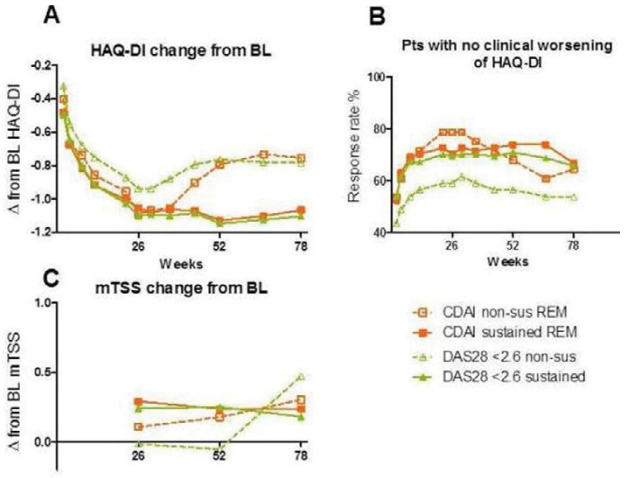
THU0110 THE IMPORTANCE OF SUSTAINED REMISSION FOR LONGTERM OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Smolen[1], C. Gabay[2], D. Aletaha[1], P. Emery[3], I. Sainsbury[4], Y. Zhang[4], A. Kavanaugh[5]. *[1]Medical Univ of Vienna, Vienna, Austria; [2]Univ of Geneva, Geneva, Switzerland; [3]Leeds Inst of Rheumatic & Musculoskeletal Medicine, Leeds, United Kingdom; [4]AbbVie, N Chicago, IL; [5]Univ of California, San Diego, CA, United States*



Background: In patients (pts) with rheumatoid arthritis (RA), the long-term impact of sustained versus (vs) transient clinical remission (REM) has not been assessed thoroughly, although REM duration has been shown to affect structural outcomes[1]. The relationship of different definitions of clinical remission (REM) with function and structural integrity has not been assessed.

Objectives: To explore the importance of sustained REM or disease control for long-term outcomes, and assess various definitions of REM in adalimumab (ADA) long-term trials.

Methods: Data are from 2 trials of ADA in early RA pts; In PREMIER, pts received ADA, methotrexate (MTX) or ADA+MTX for 2 years (yrs), after which they could enter an open label (OL) period for upto 8 yrs[2]. In OPTIMA, pts received ADA+MTX, or placebo (PBO) +MTX for 26 weeks (wks). Based on whether or not pts achieved DAS28-CRP <3.2 at wks 22 and 26, pts withdrew ADA, continued on PBO+MTX, ADA+MTX or OL ADA+MTX until Wk 78[3]. For this analysis, non-sustained REM/disease control was defined as meeting one of the following at 6 months but not 1 yr: DAS28-CRP <2.6; simplified disease activity index (SDAI) ≤3.3; clinical disease activity index (CDAI) ≤2.8. Sustained REM/disease control was defined as meeting these criteria at both 6 months and 1 yr. The mean change from baseline in health assessment questionnaire-disability index (ΔHAQ-DI), or modified total Sharp score (ΔmTSS), and the number of pts without clinical worsening of HAQ-DI (Δ≤0.22) were assessed over 78 wks for OPTIMA, or 5 yrs for PREMIER. NRI and LOCF were used for binary and continuous variables, respectively.

Results: In OPTIMA, by any of the REM criteria, pts in sustained REM had larger mean ΔHAQ-DI over time (Fig 1A) vs pts in non-sustained REM. Pts with non-sustained DAS28-CRP <2.6 vs non-sustained CDAI REM had numerically smaller ΔHAQ-DI up to Wk 52. Over time, more pts in sustained vs non-sustained REM using DAS28-CRP<2.6 (but not CDAI or SDAI criteria) did not have clinical worsening of HAQ-DI, possibly due to more suppression of inflammatory components upon achieving CDAI REM but not DAS28-CRP <2.6 in these early RA pts (Fig 1B). At Wk 78, ΔmTSS at Wk 78 was smaller for pts in sustained vs non-sustained DAS28-CRP <2.6, and similar for sustained and non-sustained CDAI REM (Fig 1C). Somewhat fewer pts at Wk 78 may have contributed to some variability. Trends were similar in PREMIER (not shown).

Conclusions: Pts who were in sustained disease control/REM had better clinical, functional and radiographic outcomes over the long- term, vs pts in a more transient state, regardless of the REM criteria used, although for CDAI REM, functional and radiographic outcomes were similar for sustained and non-sustained REM, in line with its higher stringency.

For LOCF: CDAI non-sustained REM N=28, CDAI sustained REM N=84, DAS28 <2.6 non-sustained, N=39, DAS28 <2.6 sustained, N=137; For NRI: CDAI non-sustained REM at Wk 26, N=22, at Wk 78, N=18; CDAI sustained REM at Wk 26, N=59, at Wk 78, N=56 DAS28 <2.6 non-sustained, at Wk 26, N=23, at Wk 78, N=21; DAS28 <2.6 sustained, at Wk 26, N=95, at Wk 78, N=90

THU0111 NOVEL AUTOANTIBODY PROFILES IN RHEUMATOID ARTHRITIS AND THEIR ASSOCIATION WITH RADIOGRAPHIC PROGRESSION IN THE SCOTTISH EARLY RHEUMATOID ARTHRITIS INCEPTION COHORT AND BIOBANK (SERA)

J. Nijjar[1], F. Morton[1], A. Gilmour[1], C. Paterson[1], H. Bang[2], D. van der Heijde[3], K. Raza[4], C. Buckley[4], D. Porter[5], I. McInnes[1]. *[1]University of Glasgow, Glasgow, United Kingdom; [2]Orgentec Diagnostika GmbH, Mainz, Germany; [3]LUMC, Leiden, Netherlands; [4]University of Birmingham, Birmingham; [5]NHS GGC, Glasgow, United Kingdom*

Background: Antibodies against citrullinated peptides are useful in the diagnosis of rheumatoid arthritis (RA) and are associated with poorer prognosis and greater radiographic progression. Novel autoantibodies recognising several post-translational modifications (PTM) are now emerging including anti-carbamyl, and anti-acetyl antibody classes. Less is known of their prognostic significance.

Objectives: To determine the prevalence of autoantibodies to modified vimentin and/or CCP2 (anti citrullinated (CCP), anti carbamylated (Carb), anti acetylated (Acet)) in a subset of the Scottish Early RA (SERA) inception cohort (n=212) and to correlate them with baseline and radiographic progression over 12 months.

Methods: Baseline and 12m hand and foot radiographs were scored by two readers independently, blinded to patient information and time order according to the Sharp van der Heijde score (SvH). Serum samples from the SERA biobank were analysed with recently published anti-modified protein assays. Patients with citrullinated antibodies (CCP) had antibodies to modified vimentin and/or antibodies to CCP2. Clinical, radiographic and autoantibody data were analysed in R.

Results: See Table 1.

In patients with early RA four main antibody profiles were detected: patients

Table 1

	Negative n=35	CCP n=65	CCP_Carb n=36	CCP_Carb_Acet n=76
Female (%)	74.1	72.3	66.75	52.6
Age, mean	64.1	54.9	60.5	56.7
Disease duration, mean, months	6.6	14.7	11.7	13.2
Smoked (%)	54.3	67.7	77.8	67.1
DAS28-ESR, mean (complete data)	5.5 (30)	4.7 (56)	5.1 (30)	5.2 (64)
Radiographic Scores				
Baseline Erosion score, mean	2.9	2.8	7.2	3.3
Baseline JSN score, mean	3.3	3.4	6.6	3.5
Baseline Total SvH Score, mean	6.2	6.2	13.8	6.8
Mean change in Total SvH score over 12 months	0.5	0.5	1	1.8

with anti CCP antibodies (n=65), antibodies to anti CCP and anti Carb (n=36), antibodies to all three PTM (n=76) and antibody negative patients (n=35). Overall there was low radiographic progression in this sample of the SERA cohort. EULAR non-responders had greater progression compared to good responders (Least square mean difference in SvH over 12 m of 1.6, p=0.019).
Baseline SvH erosion scores are 4.4 points higher in the CCP_Carb group compared to CCP alone (p=0.009) (Table 2 + Fig 1).

Table 2

Comparison	LS mean difference in baseline erosion score	P value
CCP_Carb vs CCP	4.4	0.009
CCP_Carb vs CCP_Carb_Acet	3.9	0.017
CCP_Carb vs Negative	4.3	0.026
Comparison	**LS mean difference in SvH change over 12 months**	**P value**
CCP_Carb_Acet vs CCP	1.3	0.016
CCP_Carb_Acet vs Negative	1.3	0.046

Total SvH 12m progression is 1.3 points higher in the triple positive group compared to the CCP group alone (p=0.016) (Table 2 + Fig 2). Total SvH progression is also higher when comparing the triple positive to the negative group (p=0.046).

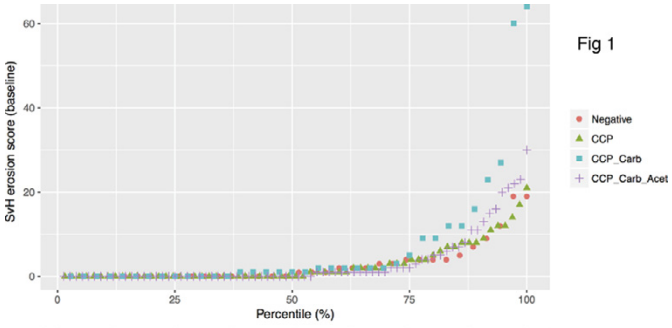

Fig 1

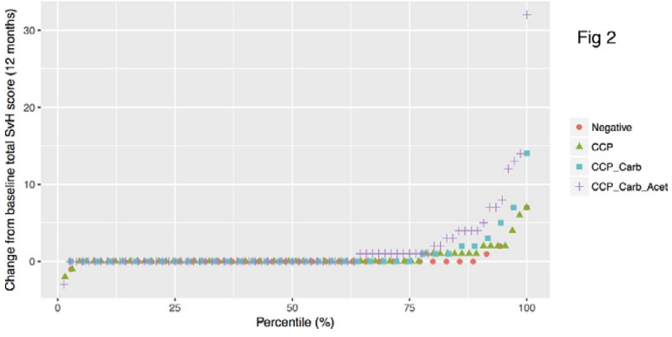

Fig 2

Conclusions: RA patients with antibodies to citrullinated peptides only have lower baseline erosions and less radiographic progression over 12m compared to those with a wider autoantibody repertoire. Baseline differences in erosion suggest that these antibodies may be pathogenic during the pre-RA disease process. Radiographic progression increases with autoantibody repertoire suggesting ongoing immune activation.

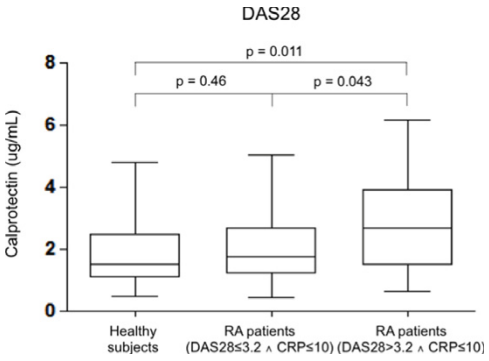
THU0112 STRESS AND DEPRESSION IN PATIENTS WITH EARLY INFLAMMATORY POLYARTHRITIS: NATURAL HISTORY AND ASSOCIATIONS WITH DISEASE ACTIVITY, DISABILITY AND PAIN OVER FIVE YEARS

J.M. Gwinnutt[1], D.P.M. Symmons[1,2], A.J. MacGregor[3,4], J.R. Chipping[3,4], T. Marshall[3,4], M. Lunt[1], S.M.M. Verstappen[1]. *[1]Arthritis Research UK Centre for Epidemiology, University of Manchester; [2]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester; [3]Norwich Medical School, University of East Anglia; [4]Rheumatology Department, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom*



Background: Stress and depression are common in patients with inflammatory polyarthritis (IP). There is little research on long term patterns of depression and stress or how these variables relate to disease activity, disability and pain.
Objectives: To describe the natural history of stress and depression over five years and to assess the association of baseline, one year prior and current disease activity, disability and pain with longitudinal stress and depression.
Methods: Patients recruited to the Norfolk Arthritis Register (NOAR) (inclusion criteria: ≥2 swollen joints for ≥4 weeks) from 2005–2008 were included in this analysis. Demographics, medication use, 51 swollen/tender joint counts (SJC51/TJC51), pain visual analogue scale, HAQ, comorbidities and the Arthritis Impact Measurement Scales 2 (AIMS2) depression and stress subscales (range 0–10; high score = worse health status) were collected at baseline and years 1, 2, 3 and 5. Rheumatoid factor (RF), anti-cyclic citrullinated peptide antibodies (anti-CCP2) and C-reactive protein (CRP) were measured in baseline blood samples. ACR/EULAR 2010 RA criteria were applied to baseline characteristics. Depression and stress over five years were described using descriptive statistics. Multivariate random effects models were applied to assess the association of baseline disease activity (SJC51/TJC51), pain and disability with depression and stress over time adjusting for baseline age, gender, RF, anti-CCP2, CRP, sDMARD use, comorbidities, depression and stress. Similar methods were used to assess one year prior and current disease activity, pain and disability's association with stress and depression. Missing data were imputed using multiple imputation.
Results: 509 patients were included (median (IQR) age: 57 (45, 68) years; 321 (63.1%) female; 305 (59.9%) ACR/EULAR RA). Baseline median (IQR) depression and stress were 2.5 (1.5, 4.5) and 4.0 (2.5, 5.5) respectively and remained constant over five years. Baseline SJC51, TJC51, pain and HAQ were not independently associated with depression or stress over five years. Current HAQ and pain, but not SJC51/TJC51, were independently associated with depression and stress (per unit increase in HAQ: depression β 0.83, 95% CI 0.69, 0.97; stress β 0.76, 95% CI 0.61, 0.90; per 1cm increase in pain: depression β 0.09, 95% CI 0.06, 0.12; stress β 0.09, 95% CI 0.05, 0.12). Higher HAQ was independently associated with increased depression and stress one assessment later (per unit increase in HAQ: depression β 0.21, 95% CI 0.09, 0.32; stress β 0.21, 95% CI 0.10, 0.33) but not pain, SJC51 or TJC51.
Conclusions: There were no associations between measures of disease activity and depression or stress. Prospectively higher HAQ scores were associated with worse psychological health a year later. This may have implications for holistic management of IP.

THU0113 SERUM CALPROTECTIN MAY REFLECT INFLAMMATORY ACTIVITY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE NORMAL C-REACTIVE PROTEIN

J. Hurnakova[1], H. Hulejova[1], J. Zavada[1], M. Komarc[2], L. Andres Cerezo[1], H. Mann[1], J. Vencovsky[1], K. Pavelka[1], L. Senolt[1]. *[1]Institute of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Department of Methodology, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic*

Background: About a half of patients with rheumatoid arthritis (RA) have normal or low C-reactive protein (CRP) levels[1–3]. Calprotectin is a promising and probably more specific biomarker of disease activity than conventionally used acute phase reactants.
Objectives: The aim of this study was to analyse levels of serum calprotectin in RA patients with clinically active disease and with low CRP (<10 mg/L).
Methods: A total of 160 RA patients and 32 healthy subjects were enrolled in this study. All patients underwent clinical examination (DAS28). The levels of calprotectin were analyzed in patients with moderate to high disease activity with low CRP levels and in healthy subjects. The discriminatory capacity of calprotectin to identify clinically active patients in spite of normal CRP was assessed using ROC curves.
Results: Out of all RA patients, 74/160 (46.3%) had low CRP and were in remission or had low activity at the same time. However, 51/160 (32%) had low CRP levels despite moderate to high disease activity according to DAS28. In these patients, calprotectin levels were significantly higher than in patients with low CRP in remission or with low disease activity at the same time (mean 2.7±1.5 vs. 2.1±1.2 μg/mL, p=0.043) and differed from that in healthy subjects (mean 2.7±1.5 vs. ± 1.9±1.2 μg/mL, p=0.011) (Figure 1). The discriminatory capacity for calprotectin to distinguish clinically active vs. inactive patients in spite of low CRP

using AUC of the DAS28 was 0.607 (95% CI 0.503 to 0.711, p=0.043) with an optimal cut-off 2.5 μg/mL.

Conclusions: The present study demonstrates that calprotectin may reflect inflammatory activity in RA patients where CRP fails to do so.

THU0114 EFFECTS OF SMOKING ON BARICITINIB EFFICACY IN PATIENTS WITH RHEUMATOID ARTHRITIS: POOLED ANALYSIS FROM TWO PHASE 3 CLINICAL TRIALS

J. Curtis[1], P. Emery[2], G. Burmester[3], V. Arora[4], J. Alam[4], D. Muram[4], L. Klareskog[5]. *[1]University of Alabama at Birmingham, Birmingham, United States; [2]Leeds MSK Biomed/Chapel Allerton Hospital, Leeds, United Kingdom; [3]Universitatsklinikum Charite, Berlin, Germany; [4]Eli Lilly and Company, Indianapolis, United States; [5]Karolinska Institutet, Stockholm, Sweden*

Background: The efficacy of some rheumatoid arthritis (RA) therapies is reduced among patients who are smokers.

Objectives: This post-hoc analysis of two phase 3 studies assessed the effects of patient smoking status on the response to baricitinib treatment in patients with RA.

Methods: In RA-BEAM (NCT01710358), patients with inadequate response to methotrexate were randomized to placebo once-daily (QD) (N=488), baricitinib 4 mg QD (N=487), or adalimumab 40 mg biweekly (N=330).[1] In RA-BUILD (NCT01721057), patients with inadequate response to conventional synthetic disease modifying antirheumatic drugs (csDMARDs) were randomized to placebo (N=228) or baricitinib (2 mg, N=229; or 4 mg, N=227) QD.[2] Patients continued background csDMARD therapy in both studies. This post-hoc analysis was conducted in the placebo (N=716) and baricitinib 4 mg (N=714) patients. Patient-reported smoking status was categorized as current (smokers) or not current (non-smokers).

Results: Among 1,430 evaluable patients who received placebo or baricitinib 4 mg, 290 (20.3%) were smokers. Smoking status at baseline did not affect the clinical results of treatment with baricitinib for 24 weeks; smokers who received placebo were numerically less likely than non-smokers receiving placebo to achieve most clinical outcomes (Table). Baricitinib's effect on modified total Sharp score was more pronounced among nonsmokers (interaction p-value =0.07).

Table 1. Efficacy outcomes at week 24 with data up to rescue

	Placebo (N=716)		Baricitinib 4 mg (N=714)	
	Smoker (n=139)	Non-Smoker (n=577)	Smoker (n=151)	Non-Smoker) (n=562)
ACR20	44 (31.7)	231 (40.0)	108 (71.5)	399 (71.0)
ACR50	24 (17.3)	119 (20.6)	76 (50.3)	270 (48.0)
ACR70	8 (5.8)	49 (8.5)	49 (32.5)	151 (26.9)
SDAI ≤3.3	5 (3.6)	19 (3.3)	24 (15.9)	88 (15.7)
SDAI ≤11	24 (17.3)	137 (23.7)	72 (47.7)	294 (52.3)
CDAI ≤2.8	4 (2.9)	24 (4.2)	24 (15.9)	89 (15.8)
CDAI ≤10	22 (15.8)	137 (23.7)	71 (47.0)	289 (51.4)
DAS28-hsCRP ≤3.2	24 (17.3)	123 (21.3)	75 (49.7)	296 (52.7)
DAS28-hsCRP <2.6	9 (6.5)	53 (9.2)	51 (33.8)	192 (34.2)
HAQ-DI ≥0.3	47 (33.8)	219 (38.0)	103 (68.2)	346 (61.6)
HAQ-DI ≥0.22	61 (43.9)	254 (44.0)	108 (71.5)	381 (67.8)
mTSS change ≤0*	68/96 (70.8)	250/356 (70.2)	78/107 (72.9)	304/363 (83.7)

Data are n (%). *mTTS data are from RA-BEAM only.

Conclusions: This analysis of smokers and non-smokers in two RA trials demonstrated that the beneficial effect of baricitinib treatment versus placebo was similar on all clinical endpoints, but may differ for structural damage progression.

THU0115 DISABILITY (HAQ) AND QUALITY OF LIFE (SF-12) AS RELATED TO ADHERENCE AND HEALTH LITERACY IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.G. Kuipers[1], M. Koller[2], F. Zeman[2], K. Mueller[2], J.U. Rueffer[3]. *[1]Rheumatology, Red Cross Hospital Bremen, Bremen; [2]Center for Clinical Studies, University Hospital Regensburg, Regensburg; [3]German Fatigue Society, Cologne, Germany*

Background: Disabilities in daily living and quality of life are key endpoints to evaluate the outcome of treatment for rheumatoid arthritis (RA). Among factors that may contribute to good outcome are adherence (i.e., the extent to which patients' behaviors corresponds with agreed recommendations from their doctor) and health literacy (patients' understanding and use of health information).

Objectives: The survey included a representative, nationwide sample of German physicians specialized in RA and patients with RA. The physician questionnaire included the disease activity score (DAS28) and medical prescriptions. The patient questionnaire included fatigue (EORTC QLQ-FA13), health assessment questionnaire (HAQ), quality of life (SF-12), health education literacy (HELP), and patients' listings of their medications.

Methods: Adherence was operationalized in various ways: patient-reported (CQR5), behavioral (correspondence between physicians and patients listings of medications), physician-assessed (five-point rating scale ranging from 1=very adherent to 5=not at all adherent) and a combined measure of physician rating (1= very adherent, 0 = less adherent) and the match between physicians' prescriptions and patients' accounts of their medications (1 = perfect match, 0 = no perfect match), leading to three categories of adherence: high, medium and low. Linear regressions were calculated using HAQ and SF-12 (physical and psychological) as dependent variables and adherence, health literacy and the set of demographic and clinical variables as predictor variables.

Results: A total of 708 pairs of patient and physician questionnaires were analyzed. The mean age of the patients, of whom 73% were women, was 60 years (SD=12).

Multiple regression analyses show, that health literacy is an independent predictor for HAQ and both SF-12 scales. Adherence by doctor is an independent predictor for both SF-12 scales while the adherence composite score is an independent predictor for HAQ and SF-12 psychological. Taking all 4 rheumatoid medications as prescribed is an independent predictor for HAQ and SF-12 physical. All models

Table 3: Multiple linear regression models

		HAQ*			SF-12 Physical			SF-12 Psychological		
MLR model*	Predictor	B (95%-CI)	p-value	R^2	B (95%-CI)	p-value	R^2	B (95%-CI)	p-value	R^2
Model 1	All 4 rheumatism agents taken as prescribed	4.41 (.45, 8.38)	.029	20 %	2.39 (.51, 4.28)	.013	16 %	.34 (-1.67, 2.35)	.741	15 %
	Adherence by doctor (ref. medium or less adherence)									
	adherent	1.79 (-3.89, 7.45)	.534		3.14 (.43, 5.86)	.023		.74 (-2.15, 3.64)	.615	
	Very adherent	3.01 (-2.56, 8.58)	.289		3.28 (.61, 5.95)	.016		3.10 (.254, 5.95)	.033	
	Health education literacy*	.330 (.229, .431)	<.001		.141 (.093, .189)	<.001		.220 (.169, .272)	<.001	
Model 2	All 4 rheumatism agents taken as prescribed	3.22 (-.87, 7.32)	.123	20 %	2.00 (.04, 3.96)	.046	15 %	-.11 (-2.20, 1.98)	.919	15 %
	Adherence composite score (ref. low adherence)									
	medium adherence	2.22 (-1.16, 6.06)	.256		.67 (-1.17, 2.51)	.476		.12 (-1.84, 2.08)	.905	
	high adherence	5.06 (.62, 9.50)	.026		1.48 (-.65, 3.61)	.172		2.74 (.47, 5.01)	.018	
	Health education literacy*	.323 (.222, .423)	<.001		.141 (.093, .190)	<.001		.223 (.171, .274)	<.001	

All models are adjusted for sex, age, drinking alcohol (y/n), smoking status (y/n) and sport activities (y/n);
B, regression coefficient; 95%-CI, 95%- confidence interval; *linearly transformed on a scale from 0 (negative/low) to 100 (positive/high)

are additionally controlled for age, sex, smoking (y/n), drinking alcohol (y/n), sport (y/n).
Conclusions: This study showed that HAQ and SF-12 were related to adherence and health literacy. This finding highlights the importance of patient education and counseling in order to increase both, medical understanding and adherence to therapy.

Rilski, Sofia, Bulgaria*

Background: Vitamin D (25(OH)D) deficiency seems a distinct risk factor influencing prevalence and severity of several autoimmune diseases. Several studies suggest that low serum concentrations of vitamin D are frequent in rheumatoid arthritis (RA) patients, and an inverse relationships have been reported between 25(OH)D serum concentrations and disease activity or disability.
Objectives: European multicentre cross-sectional study to collect data on vitamin D serum concentrations in RA patients from different countries, and to investigate the relationship with disease activity, disability and quality of life in a large population.
Methods: The survey involved 625 RA patients (mean age 55±11 years, mean disease duration 11±9 years) and 276 age and sex-matched healthy subjects from 13 European countries. Serum samples for 25(OH)D measurement were collected during winter time (December-March) and analyzed in a central laboratory using chemiluminescence immunoassay (DiaSorin). Thirty-six percent of RA patients were treated with vitamin D analogues. Patient past medical history, Rheumatoid Arthritis Impact Diseases (RAID) score, Health Assessment Questionnaire (HAQ) and DAS28-CRP were also collected. Statistical analysis was performed by non parametric tests.

Results: Mean serum concentration of 25(OH)D was found significantly lower in RA patients (17.6±9.7 ng/ml) when compared to matched controls (18.9±9.4 ng/ml) (p=0.01), Several statistically significant differences between European countries were observed (possibly linked to different latitude, sun exsposure and dietary habits) (see figure). Vitamin D deficiency (<20 ng/ml) was found in almost 66% of RA patients, and severe deficiency (<10 ng/ml) was detected in almost 25% of them; insufficiency (between 20 and 30 ng/ml) was found in 27% of RA patients. Only 6% of the RA patients were found within the normal concentrations (>30 ng/ml). Male and female RA patients showed similar 25(OH)D values. Negative statistically significant correlations were found between 25(OH)D serum concentrations and RAID (p=0.05) HAQ (p=0.04) and DAS28-CRP (p<0.001) scores in the RA patients group.
Conclusions: This European survey add new evidences that vitamin D insufficiency/deficiency is frequent in RA patients with statistically significant differences between several countries. Vitamin D serum concentrations negatively correlate with the clinimetric indexes for disease activity, disability and quality of life in the present cohort of RA European patients.

THU0117 INDEPENDENT ASSOCIATIONS OF DISEASE CHARACTERISTICS AND CARDIOVASCULAR RISK FACTORS WITH LEFT VENTRICULAR DIASTOLIC FUNCTION IN RHEUMATOID ARTHRITIS

A.M. Millen[1], L. Mokotedi[1], S. Gunter[1], C. Robinson[1], G.R. Norton[1], A.J. Woodiwiss[1], L. Tsang[1], P.H. Dessein[1,2]. *[1]Cardiovascular Pathophysiology and Genomic Research Unit, School of Physiology, University of the Witwatersrand, Parktown, Johannesburg, South Africa; [2]Rheumatology Division, Universitair Hospital Brussel, Brussels, Belgium*

Background: Heart failure contributes to the excess mortality experienced by patients with rheumatoid arthritis (RA) (1). Impaired diastolic function represents a pre-clinical cardiac alteration which is highly predictive of cardiac events and often progresses to heart failure. Diastolic dysfunction is the most common cause of heart failure in patients with a preserved ejection fraction. Whereas RA is associated with an increased prevalence of impaired diastolic function (2,3), the pathophysiological mechanisms that mediate this comorbidity await further elucidation.
Objectives: This study aimed to identify potential determinants of ventricular (LV) diastolic function in patients with RA.
Methods: LV diastolic function was determined in 176 patients with RA; 9 patients had established cardiovascular disease. LV diastolic function was determined by echocardiography from the ratio of early-to-late transmitral blood flow velocity (E/A), the ratio of E to the mean of the lateral and septal wall myocardial tissue lengthening at the mitral annulus (e') (E/e'), and the lateral e'. Relationships of comprehensively evaluated traditional cardiovascular risk factors and RA characteristics with markers of LV diastolic function were determined in confounder adjusted multivariate regression models.
Results: Disease duration (partial r=-0.23, p=0.00), rheumatoid factor status (partial r=-0.16, p=0.04) and erythrocyte sedimentation rate (partial r=-0.16, p=0.04) were associated with lower logarithmically transformed (log) E/A. Upon further adjustment for left ventricular mass index or relative wall thickness, these relationships remained significant (p≤0.05). Diastolic blood pressure was related to log E/e' (partial r=-0.16, p=0.04); this association was no longer significant after additional adjustment for left ventricular mass index (p=0.06) or relative wall thickness (p=0.06). Disease duration (partial r=-0.32, p=0.00), waist-to-hip ratio (partial r=-0.29, p=0.00) and triglycerides (partial r=-0.17, p=0.03) were related to log lateral e'. These relationships remained significant upon further adjustment for left ventricular mass index (for all p=0.00) or relative wall thickness (for all p=0.00). In sensitivity analysis among RA patients without established cardiovascular disease (n=167), the results were not materially altered.
Conclusions: Modifiable traditional cardiovascular disease risk factor and disease characteristics are consistently associated left ventricular diastolic function in RA.

THU0118 WHAT IS THE ROLE OF STEROIDS IN INDUCING DIABETES MELLITUS IN PATIENTS WITH RHEUMATOID ARTHRITIS? AN OBSERVATIONAL COHORT STUDY

A. Emamifar[1], R. Hviid Larsen[2], R. Asmussen Andreasen[1], I.M. Jensen Hansen[1,3]. [1]*Rheumatology;* [2]*Medicine, Svendborg Hospital, Odense University Hospital, Svendborg;* [3]*DANBIO, Copenhagen, Denmark*

Background: Patients with Rheumatoid Arthritis (RA) are at increased risk of Diabetes Mellitus (DM) probably due to immune system activation or RA treatment with steroids.[1] However the pathology of DM in RA is not fully understood.
Objectives: To define the prevalence of DM in our RA patients population. Furthermore, to clarify the role of steroid treatment to induce DM in the RA patients.
Methods: All patients with diagnosis of RA who were registered in Danish Danbio Registry at time of study, Nov 2016, were included. To find the concurrent DM, patients' medical records including past medical history and lab tests (Hemoglobin A1c and Blood Sugar) were reviewed. In addition, year of DM as well as RA diagnoses were extracted from Fyns Diabetes Database and Danbio respectively to the extent that data were available. Patients' drug histories were searched for information about steroid treatment if diagnosis of RA was made prior to diagnosis of DM.
Results: Of 1035 patients with diagnosis of RA, 104 (10%) patients had DM. Of 104 RA patients with DM, data regarding the year of diagnosis for both RA and DM was found in 55 patients which of them 15 patients were diagnosed with RA before DM, one patient was diagnosed with both DM and RA at the same year and 39 patients were diagnosed with RA after DM. However, only one patient, of those who were firstly diagnosed with RA, was prescribed prednisolone during the time period between diagnoses of RA and thereafter DM. Of 15 patients with prior diagnosis of RA to DM, 13 patients were diagnosed according to 1987 classification criteria (Old) for RA and 2 patients were diagnosed according to 2010 classification criteria (New). Out of 39 patients where DM was diagnosed before RA, 10 patients was diagnosed based on the old criteria and 29 patients was diagnosed based on the new RA criteria [Fig 1A and 1B]. Patients with firstly diagnosed DM were more often diagnosed according to the new RA criteria and, on the contrary, patients with latterly diagnosed DM were more often diagnosed with old RA criteria ($p<0.001$).

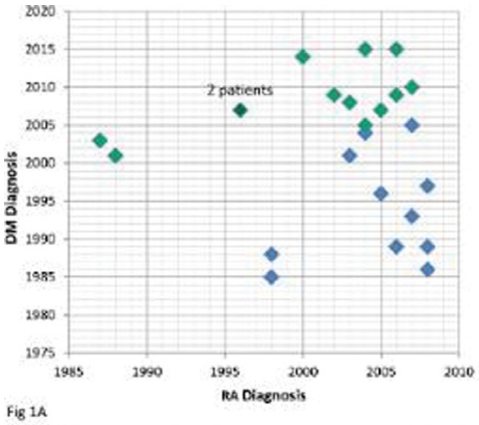

Fig 1A

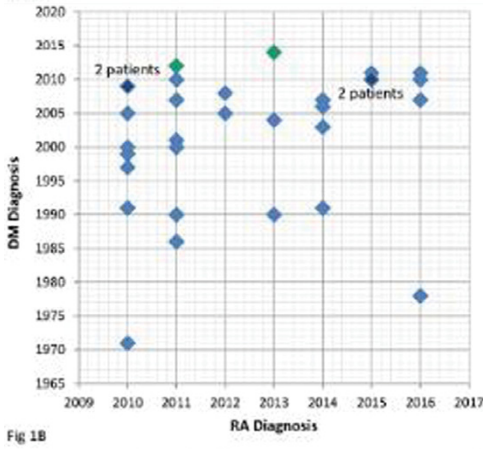

Fig 1B

Figure 1A: In 13 Rheumatoid Arthritis (RA) patients who were diagnosed according to 1987 classification criteria for RA, diagnosis of RA was made earlier than Diabetes Mellitus and **Figure 1B:** In 2 Rheumatoid Arthritis (RA) patients who were diagnosed according to 2010 classification criteria for RA, diagnosis of RA was made earlier than Diabetes Mellitus.

Conclusions: The prevalence of DM in this RA population (10%) was about twice of Danish population (5.7%). The role of steroid treatment in which to what extent increases the risk of DM is not clear, however in this study it was negligible, why we propose that the pathology of DM in RA patients most importantly deals with the role of immune system activation namely Tumor Necrosis Factor alpha and not the treatment modality i.e. steroids.

THU0119 ASSESSMENT OF RHEUMATOID CACHEXIA AND ITS ASSOCIATION WITH CLINICAL, FUNCTIONAL AND THERAPEUTIC OUTCOMES

A.L.D. Moro[1], V. Hax[1], R.C.E. Santo[2], T. Fighera[3], W. Kisaki[2], C.V. Brenol[1], R.M. Xavier[1]. [1]*Rheumatology Service, Hospital de Clínicas de Porto Alegre;* [2]*Universidade Federal do Rio Grande do Sul;* [3]*Endocrinology Service, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

Background: Rheumatoid arthritis (RA) is a chronic and inflammatory disease that besides articular symptoms leads to loss of muscle mass in presence of stable or increased fat mass (FM), condition defined as rheumatoid cachexia (RC). RC is associated with a worse prognosis, but it is still overlooked in clinical practice.
Objectives: To evaluate the prevalence of rheumatoid cachexia (RC) in patients with rheumatoid arthritis (RA) and determine its correlation with the features of RA, the level of physical activity and with the current therapy.
Methods: Ninety one RA patients in a cross-sectional study underwent total body dual-energy x-ray absorptiometry (DXA) for measurement of total and regional fat mass index (FMI; Kg/m^2), lean mass index (LMI; Kg/m^2), bone mineral content (BMC; Kg/m^2) and fat free mass index (FFMI; Kg/m^2) to assess the prevalence of RC. The associations of measures of body composition with RA features - age, diagnosis time, Health Assessment Questionnaire (HAQ), Disease Activity Score in 28 joints (DAS 28), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) -, level of physical activity (measured by International Physical Activity Questionnaire – IPAQ) and current therapy were explored.
Results: Mean age was 56.8±7.3, disease duration 9 years (3 – 18), DAS28 3.65±1.32, HAQ 1.12 (0.25 – 1.87) and use duration of biological agents was 25 months (17.8 – 52.5). 17% of the patients had FFMI below the 10th percentile and FMI above the 25th percentile of a reference population and 33% of the patients had FFMI below the 25th percentile and FMI above the 50th percentile, condition known as RC, according to the more recently used definitions. FFMI correlated negatively only with age ($r=-0.219$; $p=0.037$) and disease duration ($r_s=-0.214$; $p=0.042$). FMI correlated positively with CRP ($r_s=0.229$; $p=0.029$), ESR ($r_s=0.235$; $p=0.025$), DAS 28 ($r_s=0.273$; $p=0.009$) and HAQ ($r_s=0.297$; $p=0.004$). Among patients under biologics, 3.8% (n=1) had RC versus 23% (n=15) of those not taking biologics ($p=0.033$), according to the stricter definition.
Conclusions: The prevalence of RC was considerable and deserves additional research. Besides that, patients under biological therapy had lower prevalence of RC, suggesting a protective effect of biological agents.

THU0120 PREVALENCE OF CHRONIC KIDNEY DISIASE IN REUMATOID ARTHRITIS PATIENTS AND IT'S ASSOCIATIN WITH MULTIMORBIDITY

A.Y. Zakharova[1], E. Galushko[1], Y. Uskova[2], A. Gordeev[1]. [1]*Nasonova Reserch Institute of Rheumatology, MOSCOW, RUSSIA;* [2]*Central Clinical Hospital of Russian President Administration, Moscow, Russian Federation*

Background: RA pts commonly present with multiple concurrent chronic disease. The great importance is attached to cardiovascular diseases due to their proven association with high frequency of morbidity and death. Much attention has been paid to the potential role of high-grade systemic inflammation and classical modifiable CVD risk factors – such as hypertension, dyslipidaemia, insulin resistance/metabolic syndrome, obesity, physical inactivity and smoking. A recent meta-analysis has shown that renal impairment is a strong independent cardiovascular risk factor in the general population [1].
Objectives: To assess the prevalence and associations of CKD in RA pts (ACR/EULAR 2010y.) and relate with pts multimorbid background, RA activity and duration.
Methods: 209 RA pts (F-70,6%, mean age 67,0±11,3y), admitted to rheumatology division from 1999 to 2015, were included into analysis. RA duration was 19

[6;93] mo, average disease activity (DAS28) 5,2±1,7. CKD was defined as the presence of markers of renal impairment (proteinuria≥1+, hematuria≥2+ or leucocyturia≥2+) and/or eGFR<60 ml/min/1,73m^2 (using CKD-EPI formula) persistent beyond 3 months. The extent of multi-morbid environment was rated using Cumulative Illness Rating Score (CIRS) [2]. CIRS was calculated using the 5 score scale (0–4) to assess 14 major organ systems of the body (0–56).

Results: The prevalence of CKD was 82,3% (172), and 30,1% (63) had eGFR<60 ml/min/1,73m, and 50,2% pts had CKD stage 2. The range of proteinuria was 12,4%. In group of pts with CKD 3–5 stage the prevalence of arterial hypertension (AH) was 84%, ischemic heart disease (IHD) - 63,5%, diabetes militants 2 22%, oncology 12,7%. Mean CIRS value in RA pts was 15 [10;19] scores. The eGFR was independent of the RA duration (r=-0,01, *p*=0,86) and RA activity (r=0,09, *p*=0,17). There was found the strongest correlation of eGFR with CIRS (r=-0,61, p<0,01), age (r=0,58; *p*<0,05), AH (r=-0,34, p<0,01), IHD (r=-0,28, p<0,05), BMI (r=-0,17; r=0,35), uric acid levels (r=-0,37), as well as with hemoglobin level (r=0,19) and HAQ scores (r=0,31; r=0,32). No correlation was found between eGFR and oncology, gender, VAS score, and ESR, CRP, cholesterol (*p*>0,05).

Conclusions: CKD is a serious condition associated with premature mortality, decreased quality of life, and increased health-care expenditures, but it doesn't consider as comorbid disorder of RA. The CKD prevalence is greater among aged RA pts than in general population and it has a stronger correlation with multimorbid burden than traditional factors. Compromised renal function, apart from the age, is of dominant importance in pts management issues, limiting the range of available effective therapies, thus, aggravating RA natural course on one side, and inducing and catalyzing the severity of dysmetabolic syndrome, AH and anemia – on the other.

THU0121 ULTRASOUND IN THE ASSESSMENT OF CARPAL TUNNEL SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Di Matteo, E. Filippucci, G. Smerilli, A. Draghessi, S. Gasparini, A. Incorvaia, M. Di Carlo, W. Grassi. *Clinica Reumatologica, Università Politecnica delle Marche, Jesi (AN), Italy*

Background: Carpal tunnel syndrome (CTS) is one of the most frequent extra-articular manifestations of rheumatoid arthritis (RA). Ultrasound (US) has proven to represent a reliable tool for the diagnosis of CTS [1]. However, its role in the diagnosis of CTS in patients with RA has been poorly investigated.

Objectives: The aim of this study is to evaluate the US findings at carpal tunnel level in a cohort of patients with RA, focusing on those with a clinical diagnosis of CTS.

Methods: Patients with RA fulfilling the ACR/EULAR 2010 classification criteria were consecutively enrolled. The diagnosis of CTS was made according to the American Academy of Neurology practice parameter for CTS [2]. The MSUS assessment was carried out using a MyLab Twice (Esaote SPA) US system working with a 18–22 MHz linear probe. The power Doppler (PD) frequency was set between 7.5 and 11.3 MHz. The following grey scale (GS) US parameters were assessed at the carpal tunnel level: cross-sectional area (CSA) of the median nerve at the carpal tunnel inlet (at the level of the pisiform and scaphoid bones), presence of flexor tenosynovitis and palmar radio-carpal synovitis (both in GS and PD), presence of crystal macro-aggregates and marked bone profile irregularities. The median nerve was considered enlarged if its CSA was more than 12 mm^2. We evaluated the presence of intra-neural PD signals at the carpal inlet and scored its entity (0=no PD signal, 1=one single vessel within median nerve, 2=two or three single or two confluent vessels and 3=more than three single or more than two confluent vessels). PD was considered "positive" if grade 1 or more was found.

Results: We included 40 RA patients. CTS was diagnosed in 19 out of 80 wrists (23.8%) and in 13 out of 40 RA patients (32.5%). Enlarged median nerve was found in 3 out of 19 wrists with CTS (15.8%) and in 6 out of 61 wrists without CTS (9.8%). Flexor tenosynovitis was found in 7 out of 19 wrists with CTS (36.8%) and in 5 out of 61 wrists without CTS (8.2%). Palmar radio-carpal synovitis was found in 2 out of 19 wrists with CTS (10.5%) and in 3 out of 61 wrists without CTS (4.9%). Crystal macro-aggregates were not detected in any of the scanned wrists. Marked bone profile irregularities were found in 2 out of 19 wrists with CTS (10.5%) and in 14 out of 61 wrists without CTS (23%). Positive intra-neural PD was found in 9 out of 19 wrists with CTS (47.4%) and in 9 out of 61 wrists without CTS (14.7%).

Conclusions: These preliminary results suggest that MSUS could be a useful tool in the diagnosis of CTS also in patients with RA. Intra-neural PD and flexor tenosynovitis were the most frequently MSUS abnormalities detected in RA patients with CTS. The inflammatory involvement of the tendinous and joint structures which are part of the carpal tunnel could lead to median nerve compression and CTS symptoms and should be considered in the MSUS assessment of CTS.

THU0122 QUANTITATIVE ASSESSMENT AND ANALYSIS OF HAND MUSCLE VOLUME

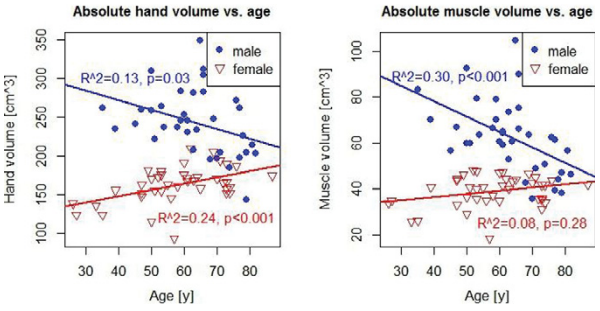
A. Friedberger[1], C. Figueiredo[2], O. Museyko[1], A. Grimm[1], I. D'Oliveira[2], T. Bäuerle[3], J. Rech[2], O. Chaudry[1], M. Uder[3], G. Schett[2], K. Engelke[1]. *[1]Institute of Medical Physics, University Erlangen-Nuremberg; [2]Department of Medicine 3, University Erlangen-Nuremberg; [3]Radiological Institute, University Hospital Erlangen-Nuremberg, Erlangen, Germany*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by bone, cartilage and muscle loss. While bone and cartilage damage have been extensively studied in the past, the effects of RA on volume and composition of hand muscles have not yet been studied. This situation is surprising, since visible hand muscle atrophy is a hallmark of RA and quantification of muscle composition is of growing interest.

Objectives: Quantitative assessment of hand muscle volume and fat using MRI.

Methods: A random forest based method was used to segment hand muscle in T1 weighted MR scans of 76 RA patients (37 males, 26–87 years, mean 61 years). The segmentation procedure is fully automated but allows for manual corrections of wrongly segmented areas. Multimodal registration of the muscle segmentation masks to MR Dixon Fat Fraction images was used for fat quantification.

Outcome parameters were absolute hand and muscle volume (V_H^{abs} resp. V_M^{abs}), relative muscle volume $V_M^{rel} = V_M^{abs}/V_H^{abs}$ and absolute and relative fat content (V_F^{abs} resp. V_F^{rel}).



Student's t-tests were performed for gender discrimination. Linear regression was used to model age dependency. Further a multivariate regression was used to model dependence on predictors BMI, RA disease duration, DMARD treatment duration, HAQ, DAS28, RF, ESR and CRP after age adjustment. Dixon sequences were not available for all patients, therefore fat analysis could only be done in 17 females.

Results: V_M^{abs} in males was significantly higher than in females (p<0.001, means: 63 cm^3 vs. 29 cm^3). Similar results were observed for V_H^{abs} (p<0.001, means: 243 cm^3 vs. 163 cm^3) and V_M^{rel} (p=0.02, means: 0.256 vs. 0.239).

The table show the results of the linear regression analysis for significant predictors of males and females, respectively. The figure shows age dependence of V_M^{abs} and V_H^{abs}.

	Age	BMI (age adj.)	Disease duration (age adj.)
Males			
V_M^{abs}	p<0.001, R^2=0.25	p<0.001, R^2=0.61	ns.
V_H^{abs}	p=0.03, R^2=0.13	p<0.001, R^2=0.50	ns.
V_M^{rel}	p<0.001, R^2=0.30	p=0.04, R^2=0.35	p=0.02, R^2=0.36
Females			
V_M^{abs}	ns.	ns.	p=0.07, R^2=0.16
V_H^{abs}	p<0.001, R^2=0.24	ns.	ns.
V_M^{rel}	ns.	ns.	p=0.06, R2=0.12

V_F^{abs} and V_F^{rel} showed no dependence on age or disease duration. V_F^{abs} but not V_F^{rel} was highly correlated with V_M^{abs} and V_H^{abs} (both: p<0.001, R^2=0.75). V_F^{rel} was positively correlated with BMI (p=0.03, R^2=0.32), a weaker but not significant effect was observed for V_F^{abs}.

Conclusions: Results for muscle volume were highly sex specific. Males showed higher V_M^{abs}, V_H^{abs} and V_M^{rel}. Nevertheless V_M^{abs} and V_H^{abs} in males showed significant decrease with age while the opposite but weaker effects were observed in females. Relative fat volume depends on BMI but is independent of muscle volume.

THU0123 NEW PERSPECTIVES IN DIAGNOSIS OF INTERSTITIAL LUNG DISEASE RELATED TO RHEUMATOID ARTHRITIS. VALIDATION STUDY OF AN ELECTRONIC STETHOSCOPE AND AD HOC SOFTWARE FOR DETECTION OF PULMONARY CRACKLES

A. Manfredi[1], M. Sebastiani[1], G. Cassone[1], A.L. Fedele[2], V. Venerito[3], M. Trevisani[4], F. Furini[5], O. Addimanda[6], E. Gremese[2], F. Iannone[3], G. Della Casa[1], S. Cerri[1], G. Sandri[1], F. Pancaldi[7], F. Luppi[1], C. Ferri[1] on behalf of InsPiRAtE study group. *[1]Policlinico di Modena, University of Modena and Reggio Emilia, Modena; [2]Catholic University of Rome, Rome; [3]University of Bari, Bari; [4]Sant'Orsola-Malpighi Hospital, Bologna; [5]University of Ferrara, Ferrara; [6]University of Bologna, Bologna; [7]Department of Sciences and Methods for Engineering, University of Modena and Reggio Emilia, Modena, Italy*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial joint swelling and tenderness, secondary to the immune-system dysfunction, often complicated by extra-articular manifestations. Among them, lung involvement is very frequent and interstitial lung disease (ILD) represents one of the deleterious complications of RA with impact on both therapeutic approach and overall prognosis. Nevertheless, diagnosis of ILD often remains missing or delayed.
Objectives: To preliminarily evaluate the predictive value of pulmonary sound recorded by an electronic stethoscope (ES) and elaborated by an ad hoc software in identification of RA-ILD diagnosed by mean of high resolution computed tomography (HRCT) in a multicenter study.
Methods: RA patients who underwent HRCT in the last 12 months were enrolled. They were all auscultated with the ES (Littmann 3200^{TM} 3M, USA), bilaterally, at dorsal level, in at least 3 pulmonary fields (medium and basal). All tracks recorded were analyzed by a suitably developed software capable of recognizing pathological crackles in lung sounds. Results were compared with radiologic findings detected in a blind manner by an expert radiologist.
Results: One hundred and six RA patients were enrolled (M/F: 1/2.5, mean age 68.7±10.3); among them 45 (42.5%) showed ILD at HRCT. Three patients were excluded because of a low quality of the sound recorded. The algorithm showed a sensitivity and specificity of 72.1% and 84.4%, respectively and a positive/negative predictive value of 69.1% and 86.3%, respectively.
Conclusions: Despite preliminary, these data suggest an important role of ES in clinical practice for an early diagnosis of ILD in RA patients and a significant reduction of inappropriate prescription of HRCT. Since very different types of ILD can occur in course of RA, with different radiologic features and localization, proper development of the measurement setup (ES and ad hoc software for the detection of PC) could further increase its predictive value, in particular to avoid incorrect records and misdiagnosis. The routinely employment of ES and proper software, combined to clinical findings (cough, dyspnea) and respiratory lung function, could increase our ability to early identify ILD in RA patients.

THU0124 OCCUPATIONAL EXPOSURE TO ASBESTOS AND RISK OF RHEUMATOID ARTHRITIS

A. Ilar[1], P. Gustavsson[1], P. Wiebert[1], C. Bengtsson[1], L. Klareskog[2], L. Alfredsson[1]. *[1]The Institute of Environmental Medicine; [2]Department of Medicine, Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden*

Background: Airborne agents are considered important environmental triggers of rheumatoid arthritis (RA) among genetically susceptible individuals. Due to the known association between silica dust and RA, we wanted to study the association between RA and another silicate mineral; asbestos.
Objectives: The aim of this study was to estimate the risk of RA from ever occupational asbestos exposure as well as years with exposure among men and women.
Methods: The study base consisted of men and women living in Sweden from 1968 until 2012. RA patients were identified from the National Patient Register, the Swedish Rheumatology Register (SRQ), the Swedish population-based case-control study EIRA or the Swedish Prescribed Drug Register. We matched ten controls from the national population register per case on age, county and sex. Data on occupational histories were collected from the national population and housing censuses carried out in 1960, 1970, 1975, 1980 and 1990. A job-exposure matrix (JEM) containing historical exposure estimates from 1955–1995 to asbestos was applied to the study participants' occupational histories.
We used unconditional logistic regression to assess the odds ratios (ORs) and 95% confidence intervals (CIs) of RA associated with ever exposure and years of exposure to asbestos. ORs were adjusted for ever exposure to silica dust, which was also generated from a JEM. One of the data sources (EIRA) contained self-reported information on potential confounders. Analyses on this data source were carried out to estimate the confounding effect from pack-years of cigarette smoking and alcohol use.
Results: 167 143 cases and 1 701 200 controls were included in the analysis. The proportion of participants who had ever worked with asbestos was 38% among male cases, 35% among male controls, 3% among female cases and 3% among female controls.
Ever vs. never asbestos exposure resulted in an OR of 1.15 (95% CI: 1.13–1.17) among men and 1.00 (95% CI: 0.96–1.04) among women. The ORs decreased to 1.09 (95% CI: 1.07–1.12) and 1.00 (95% CI: 0.96–1.04) for men and women respectively after adjusting for silica exposure. Asbestos exposed men were more likely than women to have worked with asbestos for a longer period of time, but the risk of RA did not appear to increase with years with the exposure. Male participants with 30 or more years of asbestos exposure at work had an OR of 1.10 (1.02–1.19) after adjustment for silica exposure.
1,882 male and 4,107 female study participants belonged to the EIRA study and had complete information on potential confounding factors. The OR among men went from 1.61 (95% CI: 1.32–1.97) to 1.35 (95% CI: 1.08–1.70) when we additionally adjusted for silica exposure, pack-years of smoking and alcohol use. Among women the OR went from 1.34 (95% CI: 0.93–1.93) to 1.07 (95% CI: 0.73–1.57). Risks were higher for the ACPA- RA subtype, with adjusted ORs of 1.63 (95% CI: 1.18–2.24) for men and 1.14 (95% CI: 0.66–1.98) for women.
Conclusions: Asbestos exposure is associated with RA among men, and mainly the ACPA- RA subtype. The increased risk remained after adjustments for potential confounders.

THU0125 PROGRESSION OF SUBCLINICAL ATHEROSCLEROSIS OVER ELEVEN YEARS IS INCREASED IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A. Södergren[1], K. Karp[2], E. Lundström[3], T. Smedby[4], B. Möller[5], S. Rantapää-Dahlqvist[1], S. Wållberg-Jonsson[1]. *[1]Rheumatology, Dept of Public Health and Clinical Medicine; [2]Dept of Surgical and Perioperative Sciences; [3]Dept of Public Health and Clinical Medicine, Umeå; [4]Rheumatology, Östersund; [5]Rheumatology, Luleå, Sweden*

Background: Patients with rheumatoid arthritis (RA) have an increased mortality and morbidity due to cardiovascular disease (CVD).
Objectives: In this prospective follow up over eleven years, we investigated the progression of atherosclerosis measured by intima media thickness (IMT), in relation to traditional CVD risk factors and inflammation, in patients with early RA compared to controls.
Methods: Patients from northern Sweden diagnosed with early RA are consecutively recruited into an ongoing prospective study. A subgroup aged $\leq$60 years (n=54) was consecutively included for ultrasound measurements of IMT of a. Carotis communis at inclusion (T0), and after 11 years (T11). 31 age-sex-matched controls were included. The patients were clinically assessed, SCORE, Reynolds Risk Score and Larsen score were calculated and blood samples drawn from all individuals at T0 and T11. Data and results presented in this abstract are preliminary.
Results: Patients with RA as well as controls had a significant aggravation in IMT over 11 years (0.52 at T0 and 0.68 at T11 in RA: $p<0.001$; 0.54 at T0 and 0.63 at T11 in controls: $p<0.05$; IMT in RA vs controls at T0 and at T11: $p>0.05$). The patients with RA had a significantly higher progression in IMT from T0 until T11 (0.16 vs 0.08, $p<0.001$). In simple linear regression analyses among RA-patients, the IMT at T11 was significantly associated with several variables at T0: age, systolic blood pressure, SCORE, Reynolds Risk Score, tPA, L-selectin (inversely), MCP-1 and Larsen score. The progression in IMT over 11 years was associated with age and Larsen score at T0.
Conclusions: In this prospective study, the progression of sub-clinical atherosclerosis over 11 years was significantly higher in patients with RA than in controls. The IMT at T11 was associated with several traditional cardiovascular risk factors, as well as disease severity, at time of diagnosis.

THU0126 THE EFFECT OF GLUCOCORTICOIDS ON BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

A.-B.G. Blavnsfeldt[1], M.D. Thomsen[2], S. Tarp[3], B. Langdahl[4], E. Hauge[1], A. de Thurah[1]. *[1]Department of Rheumatology, Aarhus University Hospital, Aarhus; [2]Diagnostic Centre, Silkeborg Regional Hospital, Silkeborg; [3]The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen; [4]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark*

Background: The role of glucocorticoids (GCs) in the treatment of rheumatoid arthritis (RA) is widely debated. GCs stimulate bone resorption and impair bone formation (1). Inflammatory cytokines also stimulate bone resorption, and patients with RA have a high risk of osteoporosis (OP) and fragility fractures (2). However, in patients with RA, impairment of bone formation by GCs may be counter-balanced by reduced systemic inflammation and increased physical activity.
Objectives: This systematic review aims to assess the effect of oral prednisolone and prednisone on bone mineral density (BMD) in patients with RA analyzed in randomized, controlled trials (RCT).
Methods: We performed a systematic literature search and identified double-blinded RCTs comparing prednisolone or prednisone with placebo and measuring

BMD dual-energy absorptiometry at baseline and at least once thereafter. Two authors independently reviewed references, extracted data and assessed risk of bias. We assessed quality of evidence using the GRADE methodology. Primary outcomes were mean change in BMD at the hip and lumbar spine. Secondary endpoints included RA disease activity and radiographic progression.
Results: We identified 7 studies. Studies were comparable regarding study population and intervention. Risk of bias was considered low for BMD outcomes. Data completeness was low in some studies. We found no statistically significant difference in change in BMD from 0 to 24 months neither at the lumbar spine (Standard Mean Difference (SMD) 0.02 (95% CI -0.16, 0.12)) nor at the hip (SMD -0.11 (95% CI -0.25, 0.02)). Disease activity was significantly lower in the GC groups (mean difference in DAS28 -0.32 (95% CI -0.52, -0.11). Concomitant treatment of RA differed between studies, as did OP prophylaxis. However, sensitivity analyses excluding a study with different distribution of OP prophylaxis between groups receiving GCs or placebo did not alter the estimates. Quality of evidence was rated moderate for BMD outcomes.
Conclusions: In this group of double-blinded RCT studies we found no difference in change in BMD in patients with RA who received GCs compared to those who received placebo. The interpretation of this is difficult as it challenges the well-established fact that GCs negatively impact BMD. However, our findings suggest that in a population with early RA, followed for two years, the dampening of inflammation as well as increased physical activity may outweigh the inherent effects of GCs. This concurs with our finding of lower disease activity in the groups receiving GCs.

THU0127 THE DYNAMICS OF MENTAL DISORDERS FREQUENCY IN COMPLEX DMARDS, BIOLOGICS AND ANTIDEPRESSANTS TREATMENT OF RHEUMATOID ARTHRITIS PATIENTS

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], E. Nasonov[1]. *[1]Nasonova Research Institute of Rheumatology; [2]Moscow Research Institute of Psychiatry MoH, Moscow, Russian Federation*

Background: mental disorders (MD) (anxiety/depressive (ADD) and cognitive (CD)) occur in rheumatoid arthritis (RA) patients (pts) very often, they are usually stress-related and, probably, have common pathogenesis chains with RA. In this connection the disease-modifying anti-rheumatic drugs (DMARDs) and biologics drugs treatment may be effective in ADD in RA-pts.
Objectives: to determine the frequency of MD dynamics during DMARDs, biologics and antidepressants treatment of RA-pts in prospective 5yrs study.
Methods: 128 RA-pts were enrolled in this study. All of them met the full ACR criteria. 86% RA-pts were women with a mean age of 47,4±1,0 (M±m) yrs. RA activity was assessed by DAS28 and was high (5,25±0,17 (M±m)) in the beginning of the study. 67% RA-pts were taking prednisone (5±2,7 mg/day),80% RA-pts - DMARDs, 26% - biologics (rituximab – 11%, anti-TNF-α – 10%, anti-IL6 – 5%). MD were diagnosed by psychiatrist in accordance with the ICD-10 in semi-structured interview. The severity of depression and anxiety was evaluated by Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A). CD were diagnosed with psychology and neuropsychology methods. ADD were diagnosed in 121 (94,5%) and CD – in 87 (67,9%) of RA-pts. Major depressive disorder (MDD) was found in 41 (32%), minor depressive disorder (MinDD) – in 50 (39%) and anxiety disorders (AD) – in 30 (23,4%) of RA-pts. The occurrences of MD were evaluated in one and five yrs in 105 from 121 (87%) RA-pts divided into the following treatment groups: 1 – DMARDS (n=32), 2 - DMARDs + antidepressants (sertraline or mianserine) (n=37), 3 – DMARDs + biologics (n=27), 4 - DMARDs + biologics + antidepressants (sertraline or mianserine) (n=9).
Results: *Group 1:* the frequency of MDD was increased from 24,6% to 34,8% in a year and to 42,8% in 5 yrs (p=0,09); MinDD – from 47,8% to 60,8% (p=0,19) and 50% in 5 yrs; the number of pts with AD decreased from 27,5% to 4,3% (p=0,014) and 4,8% (p=0,021) accordingly. The frequency of CD was increased from 64,3% to 78,3% (p=0,16) in 5 yrs. *Group 2:* the frequency of MDD was decreased from 47,4% to 15,7% (p=0,049) in a year and to disappearance of depressive symptoms (p<0,001) in 5 yrs; MinDD – from 26,3% to 15,8% and to disappearance (p<0,001) in 5 yrs; AD – from 26,3% to 10,5% and to disappearance (p<0,001) in 5 yrs. The frequency of CD was decreased from 78,9% to 60% (p=0,25). *Group 3:* the frequency of MDD was unchanged (40,7%, 45,4% and 42,8% accordingly); the frequency of MinDD was increased not significantly – 40,7%, 40,9% and 52,4%; but AD – was significantly decreased (from 18,5% - to disappearance in a year (p=0,042) and 5 yrs (p=0,047)). The frequency of CD was increased from 77,8% to 85%. *Group 4:* the frequency of MDD was decreased significantly from 66,7% to 16,7% in a year and to disappearance in 5 yrs (p=0,03); MinDD and AD were decreased from 16,7% both to disappearance. The occurrence of CD was decreased from 71,4% to 57,1%.
Conclusions: the results demonstrated the best positive dynamics of MD (ADD and CD) frequency in the groups of RA-pts receiving antidepressants treatment in combination with DMARDs and biologics. There was no positive dynamics of MD in patients group receiving DMARDs and mild positive dynamics of AD in the group receiving biologics.

THU0128 FEATURES OF ULTRASOUND DOPPLEROGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SUBCLINICAL HYPOTHYROID DYSFUNCTION

A. Knyazeva[1], O. Rebrova[1], N. Bludova[1], T. Meshcheryakova[2]. *[1]Internal Medcine, SI "Lugansk State Medical University"; [2]Ultrasound Department, Lugansk Clinical Regional Hospital, Lugansk, Ukraine*

Background: Now it is proved that the leading reason for the decline in life expectancy in patients with rheumatoid arthritis (RA) are cardiovascular (CV) disease. The increase in CV risk in patients with RA is associated with increased progression of atherosclerotic vascular lesions. Autoimmune inflammatory process in RA affects the vascular endothelium contributes to the appearance of CV events and increased mortality of patients with RA. It is known that when SHTD increased levels of proinflammatory cytokines. Also, when there is an increase SHTD thickness complex intima-media (CIM)
Objectives: To study the characteristics of ultrasound dopplerography in patients with RA with SHTD
Methods: The observation 139 patients with RA. The I group consisted of 91 patients with RA and SHTD, the II - 48 patients with RA without SHTD. Patients in group I and II did not differ significantly by age and duration of RA. Detection of endothelial dysfunction was performed using ultrasound dopplerography vessels in accordance with international guidelines
Results: In the study of endothelial regulation of vascular tone in both groups of patients revealed the presence of disturbances, as determined signs of reduced endothelium-dependent vasodilation (EDVD) and endothelium-independent vasodilation (EIVD) compared with regulatory measures, which EDVD brachial artery (BA) is greater than or equal to 10% and EIVD BA - 15%. Defined EDVD significant decrease in group II, in contrast to the I (T=4.5, p<0.001), which amounted to 8.3±3.0% and, respectively 10.6±2.1%. EIVD figure was in group II 12.9±3.8%, and in the I – 15.4±1.5%, which also had significant differences (T=4.5, p<0.001) (Table 1).

Table 1

Indicators	I group (n=48)	II group (n=91)	p
D_0, cm	3.8 (3.7; 3.9)	3.9 (3.7; 4.2)	0.16
D_1, cm	4.3 (4.1; 4.5)	4.3 (4.0; 4.5)	0.83
D_2, cm	4.5 (4.3; 4.7)	4.5 (4.2; 4.7)	0.09
V_0, cm/s	55.6 (52.6; 61.1)	52.6 (44.2; 58.2)*	0.002
V_1, cm/s	76.1 (71.6; 79.6)	70.8 (62.6; 76.6)*	<0.001
EDVD, %	10.6±2.1	8.3±3.0*	<0.001
EIVD, %	15.4±1.5	12.9±3.8*	<0.001
CIM, mm	0.73 (0.71; 0.79)	0.97 (0.95; 1.0)*	<0.001
C	0.45 (0.34; 0.71)	0.26 (0.18; 0.46)*	0.002

Note: * p<0.05.

It is also a distinction between the two groups in terms of the thickness of the CIM (Z=9.7, p<0.001), exceeding in group II. Determined a significant decrease in the coefficient of sensitivity to endothelial shear stress (C) in patients with RA, who was in I group of 0.45 (0.34; 0.71), and in II - 0,26 (0.18; 0.46) that there was a statistical difference in this index between the groups of patients (Z=3.6, p<0.001) due to a significant reduction in patients of group II.
The performed analysis of variance indicated that there SHTD influence on the development of disorders of vascular endothelial function in motor RA patients. The SHTD presence in group II patients significantly affected the reduction EDVD, EIVD, C (H=13.8, p<0.001; H=14.5, p<0.001; H=10.2, p=0.001).
Conclusions: The analysis indicated the presence of influence SHTD on the development of disorders of vascular-motor endothelial function in RA patients. These data show that the presence SHTD patients with RA leads to a significant increase in the risk of developing CVD. This requires a more careful study of RA patients for early detection and correction of comorbidities that worsen the clinical course of RA

THU0129 CD8+CD28- T-LYMPHOCYTES ARE ASSOCIATED WITH SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Wahlin[1], A.E. Fasth[2], K. Karp[3], K. Lejon[4], A. Södergren[1], S. Wållberg-Jonsson[1]. *[1]Public health and clinical medicine/Rheumatology, Umeå university, Umeå, Umeå; [2]Rheumatology Unit, Department of Medicine at Solna, Karolinska institutet, Stockholm; [3]Surgical and Perioperative Sciences; [4]Clinical Microbiology, Immunology, Umeå university, Umeå, Umeå, Sweden*

Background: Patients with rheumatoid arthritis (RA) have an increased mortality and morbidity due to cardiovascular disease and accelerated progression of atherosclerosis. Altered populations of T-lymphocytes are associated with atherosclerosis, and chronic infection with cytomegalovirus (CMV) affects the T-cell-population.
Objectives: To study the association between subsets of T-lymphocytes, subclinical atherosclerosis assessed by intima-media thickness (IMT) and antibodies against CMV in patients with RA.
Methods: Patients with new-onset RA (n=71), aged ≤60 years at diagnosis, were consecutively included in a study of development of atherosclerosis. Ultrasound measurement of IMT of a. carotis communis was undertaken at inclusion (T0), after five years (T5) and after 11 years (T11) (n=54). At T11, flow-cytometry was undertaken to investigate subsets of T-lymphocytes (CD45+CD3+), where CD4, CD8, CD28, CD56 and CX3CR1 was studied. CX3CR1 is the ligand of fractalkine, an adhesion molecule expressed on activated endothelial cells to attract leukocytes. Serological analysis for CMV was undertaken from samples collected at T0, T5 and T11.
Results: The percentage of CD8+T-lymphocytes lacking the co-stimulatory molecule CD28 (CD8+CD28-) was significantly (standardized beta coefficient 0.39, p-value 0.01) associated with IMT at T11 in a linear regression model including T0 variables smoking, systolic blood pressure and cholesterol. No association with IMT was seen for CD4+CD28- T-lymphocytes. CX3CR1 was expressed in 71% of CD8+CD28- T-lymphocytes, compared with 8.2% of CD8+CD28+. The prevalence of immunoglobulin G seropositivity for CMV was 47/70 (67%), 42/66 (57%) and 34/56 (52%) at T0, T5 and T11 respectively. Patients with constantly positive CMV serologies (T0, T5 and T11) had a significantly higher percentage of CD8+CD28- and CD4+CD28- T-lymphocytes. Also the proportion of cells expressing CX3CR1 was in both CD4+ and CD8+ T-lymphocytes associated with constantly positive serologies for CMV.
Conclusions:
Subclinical atherosclerosis in patients with RA was associated with CD8+CD28- T-lymphocytes in a regression model adjusted for traditional cardiovascular risk factors. Positive serologies for CMV were associated with an increased proportion of CD8+CD28- T-lymphocytes and T-lymphocytes expressing CX3CR1.

THU0130 IMPROVEMENT IN MEASURES OF DEPRESSED MOOD AND ANHEDONIA IN TWO RANDOMIZED, PLACEBO-CONTROLLED PHASE III STUDIES OF SIRUKUMAB, A HUMAN ANTI-INTERLEUKIN-6 ANTIBODY, IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Sun[1], B. Hsu[2], D. Wang[3], M. Curran[2], W.C. Drevets[1], G. Chen[4], G.M. Wittenberg[1]. *[1]Janssen Research & Development, LLC, Titusville; [2]Janssen Research & Development, LLC, Spring House, Pa; [3]Janssen Research & Development, LLC, Raritan; [4]Janssen Research & Development, LLC, la Jolla, United States*

Background: Interleukin-6 (IL-6) is one of the known neuroactive-cytokines involved in neuronal plasticity and stress coping and is associated with depression. Depressive symptoms are common in patients with rheumatoid arthritis (RA), a disease characterized by high peripheral IL-6. Previous analysis of a Phase II study[1] showed that sirukumab, a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, can help reduce depressive symptoms in RA patients.
Objectives: To further assess and validate the effects of sirukumab on relieving depressive symptoms in RA patients.
Methods: We conducted a post-hoc analysis of 2 Phase III, randomized, double-blind, placebo-controlled trials evaluating efficacy and safety of sirukumab in the treatment of RA. SIRROUND-D enrolled patients with active RA despite disease-modifying anti-rheumatic drugs and having serum C-reactive protein (CRP)≥8mg/L at baseline. SIRROUND-T enrolled patients with active RA despite anti-TNF therapy and having serum CRP≥8mg/L or erythrocyte sedimentation rate≥28mm/h at baseline. Patients using antidepressants were excluded from the analysis. Patients were grouped by presence/absence of prevalent depressed mood and anhedonia (PDMA), based on the self-reported frequencies of these 2 core depressive symptoms in the SF-36, requiring one present at least "most of the time" and the other "some of the time" in the past 4 weeks. A depression score was derived based on the 2 core depressive symptoms of SF-36. Relief of depressive symptoms in patients with PDMA was evaluated by comparing changes in the depression score from baseline to week 8 between the placebo and combined sirukumab groups directly and with adjustment for RA activity as measured by the Disease Activity Score-28 with CRP. Changes in depression score were also analyzed in RA patients who did not have an ACR50 response to sirukumab. The combined effect of anti-IL-6 treatment was estimated using meta-analysis of 2 Phase III, 1 Phase II studies of sirukumab and 1 Phase II study of the anti-IL-6 cytokine antibody siltuximab.
Results: At baseline, 19% and 22% of patients were classified as PDMA in the 2 studies, respectively. Sirukumab treatment, compared to placebo, significantly improved depressive symptoms by week 8 among PDMA patients (p=0.022 and 0.046 for the 2 studies, respectively) before adjusting for changes in RA activity. Within the sirukumab group, the reduction in depressive symptoms remained significant after adjusting for changes in RA activity ($p<0.0001$) and in ACR50 non-responders at week 8 ($p<0.0001$), while differences in improvements between the sirukumab and placebo group reduced to trends. Meta-analysis of 4 anti-IL-6 studies (1 siltuximab, 3 sirukumab) revealed that anti-IL-6 treatment helps alleviate depressive symptoms even after adjusting for changes in disease activity (Standardized Mean Difference =0.25, p=0.03).
Conclusions: Our findings are consistent with previous results from a phase II RA study. Peripheral anti-IL-6 cytokine treatment is associated with improvement in depressive symptoms in RA patients, possibly supporting a role for IL-6 dysfunction in depression.

THU0131 PREMATURE CORONARY HEART DISEASE FREQUENCY IN RHEUMATOID ARTHRITIS WHO ARE RECEIVING BIOLOGIC AGENTS: HUR-BIO REAL LIFE RESULTS

B. Armagan[1], A. Sari[1], A. Erden[1], L. Kilic[1], E.C. Erdat[2], O. Karadag[1], A. Akdogan[1], S. Apras Bilgen[1], U. Kalyoncu[1], S. Kiraz[1], I. Ertenli[1]. *[1]Hacettepe University, Department of Internal Medicine, Division of Rheumatology; [2]Hacettepe University, Department of Internal Medicine, Hacettepe University, Ankara, Turkey*

Background: Patients with rheumatoid arthritis (RA) are at increased risk of coronary heart disease (CHD) overall, as well as death from CHD. A direct impact of chronic inflamation on the vascular system, secondary effects of physical inactivity and some drugs used in the management of RA are shown as the reasons for the increase in this comorbidity (1).
Objectives: We aim to determine the frequency of CHD in the RA patients who receive biological agents.
Methods: Hacettepe University Biologic Registry (HUR-BIO) includes demographic and clinical data of patients treated with biological agent since 2005. By August 2016, 1235 RA patients were recorded in the database. Age, smoking status, comorbidities, current and previous treatments were analysed in 1000 patients. Disease activity was estimated by the 28-joint activity calculator (DAS28-ESR) and DAS28-CRP. Functional assesment was evaluated by the Health Assessment Questionnaire (HAQ). Premature CHD should be defined if clinical CHD or sudden death is documented in male younger than 55 years of age and in female younger than 65 years of age.
Results: Overall 1000 patients (79,8% female) were enrolled in this study. Mean age was 53,1±12,6 years old, mean disease duration was 12,3±9,3 years. CHD was detected 57 (5,7%) patients and female/male was 38/19. Premature CHD was observed in 38 (66,7%) patients. CHD patients had more frequently male, older, higher classical risk factors, higher baseline ESR level and higher functional disability (Table). HAQ score also remained high in CHD group at last visit. Classical cardiovascular risk factors, sex, seropositivity, disease activity score and HAQ score were similar in the premature and other CHD group. Coronary artery stenting, coronary artery bypass surgery and medical treatment was applied in 12 (21%), 20 (35,1%) and 25 (43,9%) CHD patients, respectively. There was no statistical difference in treatment of premature and other CHD.

Table 1. Characteristic of patients who have CHD or not

	CHD (n=57)	No CHD (n=943)	p
Female n (%)	38 (66,6)	19 (80,6)	0,011
Hypertansion n (%)	38 (66,6)	271 (28,7)	<0.001
Diabetes Mellitus n (%)	11 (19,3)	97 (10,3)	0.033
Smoking (current/past) n (%)	30 (52,6)	370 (39,2)	0.003
Age mean (SD)	64,7 (9,9)	52,4 (12,4)	<0.001
Baseline Erythrocyte sedimentation rate (SD)	45,7 (30,3)	36,1 (24,6)	0.009
Baseline HAQ mean (SD)	1,27 (0,64)	1,02 (0,62)	0.025
Last HAQ mean (SD)	0,84 (0,64)	0,66 (0,58)	0.024

CHD: Coronary heart disease, HAQ: Health Assessment Questionnaire.

Conclusions: As a results CHD were detected in 5,7 percents of RA patients who are receiving biological agents. Importantly, two third of these patients have

premature CHD. Classical risk factors are observed more frequently in CHD patients as expected but interestingly, no additional risk factors other than age were detected between premature and other CHD patients. This suggests that the primary factor triggers premature CHD is the underlying inflammatory rheumatic disease. The presence of CHD was determined by patient history which the limitation of our study. We did not assess to subclinical CHD in this study.

THU0132 IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE FOR PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM 2-YEAR FOLLOW UP

M.S. Sergeeva, B.S. Belov, G.M. Tarasova, E.N. Alexandrova, A.A. Novikov, M.V. Cherkasova, D.E. Karateev, E.L. Luchikhina, Y.V. Muravyev, D.V. Buhanova. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Comorbid infections have significant impact on morbidity and mortality, especially in autoimmune diseases. Prevention of infection is an integral part of supervision of these patients.
Objectives: To investigateimmunogenicity and safety of 23-valent polysaccharide pneumococcal vaccine in patients with rheumatoid arthritis (RA) treated with diseases modifying anti rheumatic drugs (DMARDs) and biologic diseases modifying anti rheumatic drugs (bDMARDs) during the 2-year follow-up.
Methods: Out of 110 subjects (81 females (73,6%), 29 males (26,4%) aged 23–76 years) included into the study, 79 were RA patients and 31 were controls with a history of ≥2 episodes of lower respiratory tract infections (bronchitis, pneumonia). 52 patients with RA were on methotrexate (MTX), 14 were on leflunomide (LEF), 13 were ontumor necrosis factor alpha inhibitors (iTNF-α)+MTX. One dose (0,5 ml) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously without discontinuation of MTX/LEF or 28–30 days prior to initiation of iTNF-α. Totally four study visits were preplanned: initial vaccination visit and 3 control visits in 1, 3 and 12 months after vaccinationfor 110 patients. 39 RA patients were followed up for 2 years (24 months). Routine evaluation during each visit included physical exams and laboratory tests. Levels of antibodies to pneumococcal capsular polysaccharide were measured using VaccZymeTM PCPIgG 2 kit (The Binding Site Group Ltd, Birmingham, UK). Post-immunization response coefficient was calculated for each participant as the ratio of AB levels during visits II, III, IV and V to baseline AB level at Visit I.
Results: Not a single caseof clinicallyor radiographically confirmed pneumonia was documented during the follow up period. Pronounced positive immune reaction after administration of the vaccine under investigation was documented in RA patients during different therapies, i.e., significant post-immunization response coefficient increase. There were 61% responders among RA patients and 70% responders among the controls during one-year follow-up. Dynamics of post-immunization response coefficient in RA patients during 2-year follow up are presented in the Table. RA patients and the control group are marked more than 2-foldsignificant increase in the content of antibodies in 3 monthsafter the vaccination. Despite the decline in their concentrationsto 12 months, it remained at the proper level and was increased to 24 month follow-up.Good tolerability of the vaccine was documented in 65% of cases, satisfactory (injection site pain, swelling and hyperemia of the skin up to 2 cm in diameter and subfebrilefever) in 35% of cases. As these reactions had no causal relationship with current RA therapy, and fully resolved within 24 hours without additional treatment, no RA therapy modification was required.Pronounced DAS28 positive dynamics in RA patients (4,27 and 2,68 at Visit I and Visit V, respectively, $p<0,001$) indicates the absence of any negative impact of vaccination on disease activity.

Table. Post-immunization response coefficient dynamics in RA patients during 2 year follow up. Me [25,75 percentile]. (n=39).

	Visit II (1 month)	Visit III (3 Month)	Visit IV (12 month)	Visit V (24 month)
RA patients	2,33* [1,6;3,8]	3,55* [2,32;6,23]	2,64* [2,03;6,39]	3,07* [1,56;6,18]

*$p<0,05$

Conclusions: Thus, all given prove the sufficient immunogenicity and safety of 23-valent pneumococcal vaccine in RA patients, getting different therapeutic regimens,during the 2-year follow-up.

THU0133 SERUM PENTRAXIN-3 IN THE ASSESSMENT OF CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Targonska-Stepniak, M. Piotrowski, R. Zwolak, M. Majdan. *Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, POLAND, Lublin, Poland*

Background: Rheumatoid arthritis (RA) is associated with the increased cardiovascular (CV) morbidity and mortality due to accelerating, progressive atherosclerosis. The chronic, systemic inflammatory process is responsible for both joint damage and increased CV risk in RA patients. Pentraxin 3 (PTX3) is an inflammatory marker, a member of long pentraxin superfamily, supposed to be involved in inflammatory process as well as in atherosclerosis.
Objectives: The goal of the study was to assess the role of PTX3 as an inflammatory marker in patients with RA and to evaluate the relationship between PTX3 and CV risk markers [carotid intima-media thickness (cIMT), QTc distance (dQTc), lipid profile].
Methods: The study group consisted of 72 consecutive RA patients, 60 (83,3%) female and 12 male (16,7%), with the mean (SD) age 53,4 (10,29) (range 21–71) and disease duration 16,8 (10,3) years (range 2–49). The activity of RA was estimated by clinical examination with the disease activity score in 28 joints (DAS28). Remission or low disease activity was observed in 35 (48,6%) patients; moderate or high disease activity (DAS28 >3,2) in 37 (51,4%) patients. Disease modifying antirheumatic drugs (DMARDs) used in the treatment included: methotrexate 61 (84,7%) patients, chlorochine or hydroxychlorochine 9 (12,5%), leflunomide 4 (5,6%), cyclosporine 1 (1,4%) patient. The majority of patients 54 (75%) were treated with biological DMARDs, currently or in the past.
Results: The mean (SD) PTX3 concentration in RA patients was 4,57 (2,83) ng/ml (range 1,43- 16,07). The mean (SD) cIMT value was 0,86 (0,2) mm (range 0,43–1,77). There were 19 (26,4%) RA patients with advanced atherosclerosis (presence of atherosclerotic plaques).
The positive, significant correlations were found between PTX3 concentration and other inflammatory markers: C-reactive protein (CRP) (R=0,5), ESR (R=0,46) and white blood cell count (WBC) (R=0,41). PTX3 concentration was also correlated with clinical disease activity markers: DAS28 value (R=0,41), as well as with tender joint count (TJC) (R=0,01), swollen joint count (SJC) (R=0,009), patient's global assessment of the disease activity (R=0,02).
The mean (SD) PTX3 concentration was significantly higher in patients with moderate/high RA activity in comparison with remission/low disease activity [5,56 (3,29) vs 3,48 (1,71) ng/ml, p=0,001] and in patients anti-CCP positive compared with anti-CCP negative [4,57 (2,58) vs 3,02 (0,85) ng/ml, p=0,04].
The mean (SD) PTX3 concentration was significantly higher in patients with definite atherosclerosis (cIMT >0,9 mm) than in patients with subclinical or no atherosclerosis [5,77 (3,02) vs 3,99 (2,58) ng/ml, p=0,04], as well as in patients with atherosclerotic plaques in comparison with no plaques (6,18 (2,83) vs 4,02 (2,64) ng/ml, p=0,0006).
There was a negative correlation between PTX3 and dQTc (R= -0,33, p=0,007).
Conclusions: The results of the study suggest a twofold role of PTX3:
1. an inflammatory marker of the joint disease activity
2. a biomarker indicating intensity of atherosclerosis, estimated by greater cIMT value and the presence of atherosclerotic plaques. The negative correlation between PTX3 and dQTc suggests the increased risk of sudden cardiac death due to shortening of dQTc.

THU0134 INTERSTITIAL LUNG DISEASE AND RHEUMATOID ARTHRITIS. MULTICENTER STUDY WITH TOCILIZUMAB

C. Fernández-Díaz [1], J. Narvaez-García [2], M. Martín-López [3], P. Rubio-Muñoz [4], S. Castañeda-Sanz [5], N. Vegas-Revenga [1], L. Dominguez-Casas [1], V. Calvo-Rio [1], M. Gonzalez-Gay [1], R. Blanco [1]. *[1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander; [2]Rheumatology, Hospital Universitario Belvitge, Barcelona; [3]Rheumatology, Hospital 12 de Octubre, Madrid; [4]Rheumatology, Hospital Universitario Germans Trias i Pujol, Barcelona; [5]Rheumatology, Hospital la Princesa, Madrid, Spain*

Background: Interstitial Lung Disease (ILD) is a severe extraarticular manifestation of rheumatoid arthritis (RA). AntiTNFα drugs and conventional disease-modifying anti-rheumatic drugs (DMARDs) such as methotrexate (MTX) have been involved in the development of ILD. IL6 has been implicated in the pathogenesis of ILD (Kobayashi J et al). However, a fatal case of exacerbation of ILD has been described with tocilizumab (TCZ) (Kawashiri SY el at).
Objectives: Our aim was to assess the efficacy and safety of TCZ in ILD associated with AR.
Methods: Multicenter study of RA patients with ILD treated with TCZ. ILD was diagnosed by high-resolution computed tomography (HRCT). TCZ was used at standard dose (8 mg/k/iv/4 weeks). We have analyzed the following variables: a) 1-point change in the degree of dyspnea according to the Modified Medical Research Council (MMRC); b) Forced Vital Capacity (FVC) improvement ≥10%; and improvement ≥10% in DLCO; c) HRCT, and d) joint assessment (DAS28 score).
Results: We studied 12 patients (9 women/3 men) with ILD related to RA.

The mean age±SD was 57.1±16.1 years. The mean evolution of RA was 9±5.8 years. The patients had previously received the following DMARDs; MTX (n=12), leflunomide (LFN) (8) sulfasalazine (SSZ) (3) hydroxichloroquine (HCQ) (1) azathioprine (AZA) (2), gold salts (2). In addition, 11 patients had previously received biological drugs: adalimumab (4) anakinra: (1), etarnecept (4), rituximab (4), infliximab (1), certolizumab (1), abatacept (1). RA was seropositive in 11 cases (92%). Besides HRCT, the diagnosis of ILD was confirmed by biopsy in 4 patients. In 2 patients ILD was drug-related: MTX (n=2). TCZ was prescribed in monotherapy (n=8) or combined with other DMARDs (4). These DMARDs were: LFN (2), MTX (1), AZA (1). In many patients the dyspnea and DLCO remain stable (Table). After a follow-up of 12 months, 2 patients withdrew TCZ, 1 patient for ILD worsening and 1 patient for joint inefficacy.

Table 1

	Baseline	3th month	6th month	12th month
MRC, n (%)		11	8	11
– No change		11 (100)	7 (87)	8 (73)
– Improvement		0	0	2 (18)
– Worsening		0	1 (13)	1 (9)
FCV, n (%)		2	5	9
– No change		2 (100)	5 (100)	6 (67)
– Improvement		0	0	2 (23)
– Worsening		0	0	1 (12)
DLCO, n (%)		2	4	9
– No change		1 (50)	3 (75)	9 (100)
– Improvement		0	0	0
– Worsening		1 (50)	1 (25)	0
HRTC, n (%)		0	2	10
– No change			1 (50)	7 (70)
– Improvement			0	0
– Worsening			1 (50)	3 (30)
DAS28 – *mean*	4.46±1.40	3.35±1.19	3.23±1.04	2.98±0.95
CRP (mg/dl) – *mean*	3.23±2.96	1.11±0.98	1.48±0.95	1.15±0.84
ESR (mm/1st h) – *mean*	45.17±28.84	16.16±10	16.16±11.41	17.47±25.45

Conclusions: In our knowledge, this is the largest series that assess the EPID associated with RA treated with TCZ. We observed that in many cases pulmonary involvement remains stable.

THU0135 THE COURSE OF LOWER EXTREMITY FUNCTION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS OVER THE FIRST FIVE YEARS

M. Mellblom Bengtsson[1], C. Book[1,2], S. Hagel[3,4], L.T. Jacobsson[5], C. Turesson[1,2]. *[1]Department of Rheumatology, Skåne University Hospital; [2]Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö; [3]Rheumatology, Department of Clinical Sciences, Lund, Lund University; [4]Department of Rheumatology, Skåne University Hospital, Lund; [5]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at Gothenburg University, Gothenburg, Sweden*

Background: Rheumatoid arthritis (RA) frequently involves joints of the feet and the knees. Disability related to arthritis in the lower extremities has a major impact in many patients, but has not been extensively studied.

Objectives: To investigate lower extremity function in early RA, using validated tests, and to assess its relation to other disease parameters.

Methods: Consecutive patients with early RA (symptom duration ≤12 months) in an inception cohort from a well-defined area were followed according to a structured protocol, with visits at inclusion and after 1, 2 and 5 years. Lower extremity function was investigated using the Index of Muscle Function (IMF) (1), a validated battery of tests by which the patient's general ability, muscle strength, muscular endurance and balance/coordination are assessed by a physiotherapist. The scores on the subscales are added for a total IMF score (IMF total) of 0–40. A subscore of the Health Assessment Questionnaire Disability Index (HAQ-DI), based on the 10 questions that are mainly dependent on function of the lower extremities (the HAQ-DI-LE (2)) was calculated, as well as a modified HAQ-DI-LE (mHAQ-DI-LE) that included only the three HAQ-DI domains in which all questions relate mainly to the lower extremities. Changes in the IMF total score and subtest scores between visits were analyzed using the Wilcoxon signed rank test. Correlations between disease parameters were assessed using Spearman's rank test.

Results: A total of 106 patients (67% women, mean age 61 years, mean baseline DAS28 4.4, median baseline HAQ-DI 0.75) were included. Data on IMF total were available for 100, 89 and 67 patients at the 1, 2 and 5-year visits. Lower extremity function improved from baseline to the 1-year visit (IMF total median 10; interquartile range (IQR) 4–16 vs. 7; IQR 3–12) (p=0.01). This was followed by a decline in lower extremity function, in particular between the 2-year and 5-year visits (IMF total median 8 (IQR 3–13) vs 9.5 (IQR 3.75–18.25); p=0.001). This was mainly due to worsening in test results for muscle strength (median 4 (IQR 1–6) vs 5 (IQR 2–9); p=0.001) and for balance/coordination (median 2 (IQR 0–4) vs 3 (IQR 2–6); p=0.001). At baseline, IMF total correlated with HAQ-DI-LE (r=0.46), mHAQ-DI-LE (r=0.49) and HAQ-DI (r=0.40) (all p<0.001), whereas there were weaker correlations with CRP (r=0.24; p=0.02) and DAS28 (r=0.28; p=0.004). There were consistent correlations between IMF total and HAQ-DI-LE, mHAQ-DI-LE and HAQ-DI at all time points, but no significant correlations for IMF total with CRP and DAS28 at the 2-year visit.

Conclusions: In early RA, there was improvement in lower extremity function during the first year, followed by a gradual decline, possibly explained by lack of complete disease control and aging. Tests of muscular function in the lower extremities may reveal aspects of RA disease severity that are not fully captured by standard disease activity measures, and may add important information regarding functional loss.

THU0136 NESFATIN-1 EXPRESSION IS ASSOCIATED WITH REDUCED ATHEROSCLEROTIC DISEASE RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Robinson[1], L. Tsang[1], A. Solomon[1], A. Woodiwiss[1], S. Gunter[1], H.-C. Hsu[1], G. Norton[1], A. Millen[1], P. Dessein[1,2]. *[1]Cardiovascular Pathophysiology and Genomic Research Unit, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa, Johannesburg, South Africa; [2]Rheumatology Division, Universitair Hospital Brussel, Brussels, Belgium*

Background: Nesfatin-1 comprises a peptide that is involved in appetite suppression, energy homeostasis and fluid regulation, and was recently documented to participate in a range of cardiometabolic pathways (1,2). There is currently a need for the identification of novel biomarkers in the elucidation of CVD risk and its stratification in persons with rheumatoid arthritis (RA). The role of nesfatin-1 in cardiovascular disease risk among RA patients is uncertain.

Objectives: We investigated the potential impact of nesfatin-1 on subclinical cardiovascular disease manifestations in patients with RA by determining the associations of nesfatin-1 concentrations with atherosclerosis and circulating levels of matrix metalloproteinase (MMP)-2 that mediates plaque stability and those of MMP-3 and MMP-9 that cause plaque vulnerability.

Methods: Nesfatin-1 concentrations were measured in 236 (114 black; 122 white) RA patients. Relationships of nesfatin-1 concentrations with ultrasound determined carotid intima-media thickness (cIMT) and plaque and MMP levels were identified in confounder adjusted multivariate regression models.

Results: Nesfatin-1 concentrations were inversely associated with c-IMT (β (SE) = -0.022 (0.008), p=0.00) and directly with MMP-2 levels (β (SE) =0.117 (0.031), p=0.00). After adjustment for conventional risk factors and RA characteristics, these associations persisted (c-IMT: β (SE) = -0.017 (0.008), p=0.04; MMP-2: β (SE) =0.116 (0.033), p=0.00). Patient characteristics did not influence the nesfatin-1-to-cIMT relation (interaction p≥0.7). By contrast, the Disease Activity Score in 28 joints (DAS28) and Clinical Disease Activity Index impacted the nesfatin-1-to-cIMT association (interaction p=0.04 and 0.02, respectively). Nevertheless, in stratified analysis, nesfatin-1 concentrations were related to those of MMP-2 in patients with no or mild (β (SE) =0.148 (0.054), p=0.00) and moderate or high disease activity (β (SE) =0.086 (0.041), p=0.04) as determined by DAS28 (cut-off value 3.6) as well as by CDAI (cut-off value =10) (β (SE) =0.130 (0.048), p=0.00 and 0.107 (0.046), p=0.02), respectively).

Conclusions: Nesfatin-1 concentrations are consistently associated with a reduced atherosclerosis burden and increased MMP-2 levels in patients with RA.

THU0137 IMPACT OF PERIODONTAL AND RHEUMATIC DISEASE MARKERS ON FIRST-DEGREE RELATIVES OF PATIENTS WITH RHEUMATOID ARTHRITIS ACCORDING TO AGE GROUP

C. Romero-Sanchez[1,2], S. Giraldo[3], J. De-Avila[1], M.A. Cano-Bermuedez[1], L. Chila-M.[1], J. Bello-Gualtero[2], P. Chalem[4], W. Bautista[3], J. Londono[5], C. Pacheco-Tena[6], G. Lafaurie[1], R. Valle-Oñate[7]. *[1]Unit of Oral Basic Investigation/School of Dentistry, Universidad El Bosque; [2]Department of Rheumatology and Inmunology, Hospital Militar Central, Bogotá, Colombia; [3]School of Medicine, Universidad Militar Nueva Granada; [4]Departamento de Reumatologia, Fundacion Instituto de Reumatologia Fernando Chalem, Bogotá D.C; [5]Spondyloarthropaty Group, Rheumatology Universidad de la Sabana, Chia, Colombia; [6]Departamento de Reumatologia, Investigacion y Biomedicina S.C., Chihuahua, Mexico; [7]Departamento de Reumatologia, Hospital Militar Central, Bogotá, Colombia, Bogotá D.C., Colombia*

Background: Rheumatoid arthritis (RA) and periodontal disease (PD) have

similar underlying pathologic processes and share a general deregulation of the inflammatory response.
Objectives: To evaluate PD markers in first-degree relatives (FDR) of consanguinity individuals of patients with rheumatoid arthritis to compared with controls and to establish an association to rheumatic activity according to age groups
Methods: 201 FDR individuals and 201 matched controls were included. Clinical evaluation of rheumatologic and periodontal condition was performed. *P. gingivalis, P. gingivalis* IgG1 and IgG2, ESR, CRP, RF, ACPAs, painful and swollen joints were assessed. A frequencies analysis, comparisons and a logistic regression model were made. The study was approved by local ethics committee.
Results: 37.3% of patients with overweight and 10.1% obsesses. Subjects with more than one swelling joint were 21 subjects <30 years, 5 between 31–40, 5 between 41 to 50 subjects and 9 subjects over 50, for more one painful joint were 73. The RF was present in 8.0%, APCA in 13%, RA33 in 1%. 67.3% had a diagnosis of PD, 81.6% had a moderate-severe p=0.003.*P. gingivalis* was in 47,9%, and *P. gingivalis* IgG1 were in 54.7%. It was evidenced that 25.3% patients presented BMI>30, where 81.8% had periodontitis p=0.006. Regression analysis on the whole group shows a risk to present BMI>25 (OR 1.67 IC-95% 1.02 – 2.74 p=0.042), ACPAs (OR 3.7 IC-95% 1.34–10.22 p=0.012), at least one pain join (OR2.51 IC-95% 1.42–4.44 p=0.001) and gingival index (OR4.57 IC-95% 1.76–11.80 p=0.002) in FDR individuals. Based on age the risk to develop PD was increasing: individuals among 30 to 40 years shows OR 2.76 (IC-95% 1.24–6.18, p=0.013); among 41 to 50 years, OR 4.72 (IC-95% 1.81–12.32, p=0.001); and for >50 years individuals an OR 6.22 (IC-95% 2.55–15.1, p=0.0001). The discriminating analysis by age rank shows that FDR individuals <30 years (n=67) exhibited high risk to have at least one pain join (OR 3.84 IC-95% 1.28–11.47 p=0.016). In subjects among 30 to 40 years (n=46), the risk was associated with periodontal pocket (OR1.44 IC-95% 1.05–4.98 p=0.021), one or more pain join (OR 3.56 IC-95% 1.22–10.40 p=0.020) which it was maintained until 50 years individuals (n=35) (OR4.32 IC-95% 1.11–16.78 p=0.0034), individuals >50 years (n=53) show high risk to present BMI>25 (OR 4.00 IC-95% 1.46–10.45 p=0.007).
Conclusions: Obesity, ACPA and periodontitis can be considered as relevant conditions associated with the development of RA in FDRs. However, the analysis based on age group shows that periodontal markers do not appear early in FDR individuals; however, clinical rheumatologic variables are manifested and maintained over time.

THU0138 DAS 28 CORRELATED POORLY WITH THE OBJECTIVE EVIDENCE OF INFLAMMATION AS DETECTED BY ULTRASOUND (US) EXAMINATION OF HANDS AND FEET IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS (RA)

C. Ciurtin, G. Brown, A. Cotton, J. Guinto, A. Jones, V. Morris. *Department of Rheumatology, University College London NHS Trust, London, United Kingdom*

Background: The Disease Activity Score including 28 joint count (DAS-28) is the most widely used outcome measure in RA. However, despite evidence that metatarsophalangeal (MTP) joints are often the first joints affected in RA, DAS-28 score does not incorporate them.
Objectives: Our study aimed to investigate the correlation between DAS-28 assessment and objective evidence of active joint inflammation using the US examination of both hands and feet, including wrists, metacarpophalangeal (MCP), proximal interphalangeal (PIP), and MTP joints.
Methods: A retrospective study was conducted, including 87 patients who were referred to the US clinic for an examination of their hands and feet in the last 6 months (46 patients with RA and 43 controls - patients with other inflammatory or degenerative arthropathies). Information about demographics, disease duration, current treatment, inflammatory markers, and DAS-28 scores was captured. The US OMERACT criteria were used for grading synovial hypertrophy, and assessing for the presence of Power Doppler (PD) signal, erosions and osteophytes. Statistical analysis methods included T-test, Mann-Whitney U test, Z score for proportions and Spearman's correlation coefficients.
Results: In the RA group, DAS-28 had a weakly positive correlation with the cumulative PD scores of their hands and feet joints (R=0.14, P=0.02), but did not correlate with PD score of MTP joints (R=0.03, P=0.09). In the control group, DAS-28 did not correlate significantly with either the total PD scores of feet (R=0.42, P=0.26) or hands and feet joints (R=0.5, P=0.25). Sensitivity of US examination of hands alone compared to hands and feet was 74.3% for the RA group, while the sensitivity of US feet to detect the presence of PD was 59.2% when compared to the US of both hands and feet.
Conclusions: We found that DAS-28 correlated poorly with objective evidence of inflammation as detected by US of the hands and feet, and this correlation was lost when only the presence of inflammation in the feet was taken into consideration. Further validation of our results in a larger study including patients stratified based on the disease duration might help understand which patient subgroups are more likely to have their disease activity significantly under-evaluated using DAS-28 outcome measure.

THU0139 DEPRESSIVE SYMPTOMS AND VITAMIN D IN PATIENTS WITH EARLY ARTHRITIS

D. Freier[1], M. Biersack[1], J. Detert[1], G.-R. Burmester[1], R. Uebelhack[2], T. Braun[1], V. Hoehne-Zimmer[1]. *[1]Rheumatology; [2]Psychiatry, Charité-University Medicine, Berlin, Germany*

Background: There is a high prevalence of depression in patients with rheumatic disorders. Especially, in rheumatoid arthritis, it is one of the most prevalent co-morbidities with 16% to 38%. Vitamin D (VD) deficiency is one of the known risk factors for depressive disorders. On the other hand, a VD deficiency has often been detected in rheumatic diseases. A possible correlation between these two co-morbidities has not been investigated so far in patients with early arthritis (EA).
Objectives: The aim of this study was to examine the association between VD deficiency and depression and/or anxiety disorders in patients who have presented themselves for the first time in the EA clinic.
Methods: Patients with a suspected EA (at least one swollen joint without previous trauma or joint infection with a symptom duration of 6 weeks to 12 months) received a screening date within five work days. The VD status (25-hydroxy-VD_3) was obtained during the first EA clinic consultation. In addition, each patient completed questionnaires on the disease history, as well as evaluated self-assessment questionnaires including the health assessment questionnaire (HAQ) and the Hospital Anxiety and Depression Scale (HADS). The hereby-obtained results of disease activity, VD-status and HADS-scores were investigated. In the observation period from June 2012 to March 2015, 75 patients fulfilled the inclusion criteria of completed results and questionnaires as well as a disease duration of less than 12 months.
Results: The mean age of this EA cohort was 51.7±16.9 years (♀ 65.3%, mean disease duration: 4.0±3.0 months). The prevalence of VD deficiency (<75 nmol/l) was 73.3%. 48.0% of EA patients showed a positive global distress score (≥13). The mean HADS global distress score in VD sufficient patients was 10.2±8.6 vs 13.3±6.9 in deficient patients. The observed difference was not statistically significant. There was neither an association between gender, age and VD status nor was there any difference in the laboratory parameters (e.g. C-reactive protein, rheumatic factor, anti citrullinated peptide, hemoglobine) or assessment of functional status (e.g. HAQ, disease activity score by 28 joints).
Conclusions: The prevalence of VD deficiency is higher in EA patients with 73% than in the general German population (vs. 60%). The prevalence of positive distress with 50% is also higher. Interestingly, no association of deficient VD levels and positive distress in the HADS was detected in our examined EA cohort. This might be explained by the early stage of disease, but further studies are necessary to evaluate this new insight.

THU0140 SPECKLE TRACKING ECHOCARDIOGRAPHY EVALUATION OF CORONARY TERRITORIES IN MEXICAN MESTIZO PATIENTS WITH RHEUMATOID ARTHRITIS

D.Á. Galarza-Delgado[1], J.R. Azpiri-López[2], I.J. Colunga-Pedraza[1], F.J. Torres-Quintanilla[2], R.E. Ramos-Cázares[1], A. Valdovinos-Bañuelos[1], A. Martínez-Moreno[3], R.I. Arvizu-Rivera[3], R. Vera-Pineda[3], J.A. Cárdenas-de la Garza[3], M.A. Garza-Elizondo[1], M.A. Benavides-González[2], F. Hervert-Cavazos[2]. *[1]Rheumatology; [2]Cardiology; [3]Internal Medicine, Hospital Universitario "Dr. José Eleuterio González", UANL, Monterrey, Mexico*

Background: The main cause of death in patients with rheumatoid arthritis (RA) is atherosclerotic cardiovascular disease. Speckle Tracking Echocardiography (STE) is an imaging technique that analyses the local and global myocardial function by assessing the myocardial deformation (strain). This technique is useful in addressing early alterations in ischemic pathologies (1,3).
Objectives: The aim of this study was to analyze if longitudinal strain abnormalities correspond with vascular territories, and compare the results between RA-patients and matched controls.
Methods: An observational cross-section case-control study was designed. Patients that fulfilled the 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, were 40–75 years old, with no overlap syndromes and no history of atherosclerotic cardiovascular disease were included. The control group was integrated by age- and sex-matched subjects, with no rheumatologic or cardiovascular diseases. A standard transthoracic echocardiogram was performed by a

board-certified echocardiographer. Affection of coronary territories was compared between groups using longitudinal strain by speckle tracking according to the European Society of Cardiology and the American Society of Echocardiography recommendations.

Results: A total of 53 RA-patients and 24 control subjects were included. Demographic characteristics for each group are shown in table 1. There was no statistical difference in global longitudinal strain between RA-patients and controls (-20.86±2.82 vs -21.19±2.46, p=0.62). Comparison of longitudinal strain values of the three vascular territories evaluated between RA-patients and controls did not reach statistical difference (Table 2).

Table 1. Demographic characteristics

	RA group (n=53)	Control group (n=24)	*p*
Age, mean ± SD	55.54±9.11	52.81±6.61	0.172
Women, n (%)	51 (96.2)	26 (96.3)	0.988
Body Mass Index, mean ± SD	27.53±5.85	28.05±4.66	0.956
Hypertension, n (%)	18 (33.96)	5 (18.5)	0.149
Type 2 Diabetes mellitus, n (%)	7 (13.2)	4 (14.8)	0.844

Table 2 – Variable comparison

	RA group (n=53)	Control group (n=24)	*p*
Global Longitudinal Strain, mean ± SD	-20.86 ± 2.82	-21.19 ± 2.46	0.620
Anterior descendent territory, mean ± SD	-21.16 ± 3.13	-21.64 ± 2.91	0.510
Circumflex territory, mean ± SD	-20.12 ± 3.28	-21.09 ± 3.1	0.207
Right coronary territory, mean ± SD	-18.98 ± 2.38	-18.79 ± 2.37	0.735

Conclusions: Contrary to previous published evidence (1, 2), there was no statistical difference in global longitudinal strain between RA patients and controls. Coronary territories are not affected in RA patients in comparison with controls. Further studies with a larger cohort are necessary to determine the usefulness of strain in the evaluation of subclinical cardiovascular disease.

THU0141 CAN WE PREDICT THROMBOTIC TENDENCY IN RHEUMATOID ARTHRITIS: A THROMBOELASTOGRAPHIC ANALYSIS

S. Türk[1], D. Üsküdar Cansu[1], H. Üsküdar Teke[2], T. Kaşifoğlu[1], M. Akay[2], M. Bilgin[3], C. Korkmaz[1]. *[1]Eskişehir Osmangazi University School of Medicine, Rheumatology; [2]Eskişehir Osmangazi University School of Medicine, Hematology; [3]Eskişehir Osmangazi University School of Medicine, Bioistatistics, Eskişehir, Turkey*

Background: Arterial and venous thromboembolism were proven to be increased in cases with rheumatoid arthritis (RA) (1). It would be interesting to predict thrombosis in these patients by a laboratory test. Rotational thromboelastography (ROTEM) is a viscoelastometric clotting test to evaluate the kinetics of clot formation and fibrinolysis which provides global information on cellular and soluble procoagulant/anticoagulant protein interactions.

Objectives: Our aim was to determine the thrombosis predisposition in RA patients by thromboelastography and to identify the possible clinical and laboratory risk factors for thrombotic tendency in RA patients.

Methods: 85 RA patients (mean age: 54.12±13 yrs; female: 66 (77.6%) diagnosed based on 2010 ACR/EULAR classification criteria were sequentially recruited. Patients were receiving either conventional synthetic disease modifying antirheumatic drugs (csDMARD) or were receiving biological treatments. Age- and gender matched 35 healthy individuals were enrolled as a control group. Complete blood count (CBC), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) levels were measured and DAS-28 scores were calculated. ROTEM was applied at the same time and clotting time (CT, seconds), clot formation time (CFT, seconds), and maximum clot firmness (MCF, mm) were determined. A shorter CT and/or CFT values and/or a higher MCF levels imply tendency towards hypercoagulability.

Results: RA patients with a higher disease activity were found to have a shorter I-CFT and a higher I-MCF (p values p=0.020, p=0.033, respectively). Correlation analysis revealed shorter I-CFT and E-CFT and higher I-MCF and E-MCF in those with more active disease, hence indicating a higher tendency to thrombosis. DAS-28 score, high level of CRP, and increased platelet count were identified as variants affecting thromboelastography in favor of thrombosis susceptibility.

Conclusions: Disease activation in RA patients may lead to hypercoagulability, independent of the ongoing medication of patients. Considering the fact that the predictive value of ROTEM parameters for further thrombosis, additional studies are needed whether pro-thrombotic state in RA may herald thrombosis in the presence of inflammation.

THU0142 MATRIX METALLOPROTEINASE-3 AND ANTIBODIES (IGG) AGAINST OXIDIZED LOW-DENSITY LIPOPROTEIN LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Gerasimova, T. Popkova, M. Cherkasova, E. Alexandrova, A. Novokov. *V.A.NASONOVA Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is associated with an unexplained increased cardiovascular risk. Matrix metalloproteinase-3 (MMP-3) is the most important protease involved in RA inflammation which may play a role in the development of cardiovascular events. Antibodies against oxidized low-density lipoprotein (oxLDL) are known to be involved in the development of inflammation and atherosclerosis. Specific role of MMP-3 and antibodies against oxLDL in cardiac pathology in RA patients (pts) is not well investigated.

Objectives: To compare MMP-3 and oxLDL-IgG antibody levels, as well as lipid profiles in pts with active RA and healthy controls.

Methods: Thirty nine RA pts (33 women and 6 men, median age 56,5 [49; 65] years), with active arthritis (mean disease duration 96 [48; 190] months; DAS28 5,8 [5,3;6,3]; HAQ 1,8 [1,3; 2,2]) were enrolled in the study. Twenty three pts (59%) received methotrexate, 5 (13%) – the combination of methotrexate with oral glucocorticoids, 10 (26%) - oral glucocorticoids monotherapy.

The control group consisted of 29 volunteers (21 women and 8 men, median age 58,5 [53; 62] years). Serum MMP-3 and oxLDL-IgG levels were measured by enzyme-linked immunosorbent assay (ELISA).

Results: Elevated MMP-3 levels were detected more frequently in RA pts (31/39 (79%)) vs healthy controls (2/29 (7%), $p<0,0001$). MMP-3 concentrations were higher in RA pts (57,0 [36,6; 114,3ng/ml), than in the control group subjects (13,4 [9,9; 20,4]mg/ml, $p<0,0001$). MMP-3 levels demonstrated significant correlation with ESR ($r=0,64$, $p<0,05$) and CRP ($r=0,52$, $p<0,05$) values.

OxLDL-IgG levels in RA pts and healthy controls did not differ significantly (290,3 [111,3; 608,6] mU/ml, and 228,1 [125,1; 338,8] mU/ml, respectively $p>0,05$). Rates of dyslipidemia were similar in RA pts (23/39 (59%) and control group subjects (15/29 (52%). Concentrations of lipids were also similar in both groups and were as follows: total cholesterol was 5,2 [4,9; 6,2] mmol/l in RA pts and 6,3 [5,1; 6,6] mmol/l in the control group; HDL cholesterol - 1,7 [1,4; 2,0] mmol/l and 1,7 [1,5; 2,1] mmol/l, LDL cholesterol - 3,3 [2,8; 4,0] mmol/l and 3,6 [3,0; 4,0] mmol/l, triglycerides - 1,3 [1,0; 1,6] mmol/l and 1,4[1,1; 1,8] mmol/l, the atherogenic index of plasma - 2,4 [1,8; 2,8] and 2,4 [1,9; 3,0], respectively. Showed no correlation between the levels of oxLDL-IgG and lipids in both groups. In the RA group, concentrations of HDL cholesterol were negatively correlated with MMP-3 ($r=-0,5$, $p<0,05$), C-reactive protein ($r=-0,53$, $p<0,05$), and DAS28 ($r=-0,4$, $p<0,05$).

Conclusions: RA pts exhibited higher serum MMP-3 levels than healthy individuals. OxLDL-IgG levels were similar in RA pts and healthy subjects. Obtained results suggest that MMP-3 and CRP may produce a negative impact on HDL-cholesterol levels in patients with active RA.

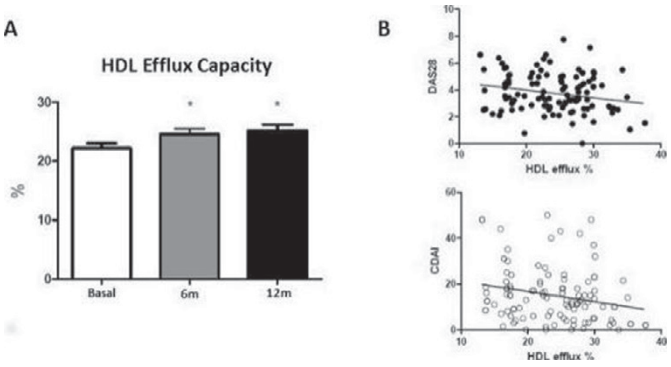
THU0143 CHOLESTEROL EFFLUX CAPACITY OF HDL IS OTHERWISE IMPROVED BY DIFFERENT BIOLOGIC-DMARDS IN RHEUMATOID ARTHRITIS



F. Cacciapaglia[1], S. Perniola[1], J. Härdfeldt[2], M. Nivuori[1], O. Magazzino[1], M.G. Giannotta[1], M. Giannini[1], M.G. Anelli[1], A. Moschetta[2], F. Iannone[1]. *[1]DETO - Unit of Rheumatology; [2]DIM - Clinica Medica "Cesare Frugoni", University of Bari, Bari, Italy*

Background: Rheumatoid arthritis (RA) patients have an increased mortality for cardiovascular (CV) events, not completely explained by impaired cholesterol levels or other traditional CV risk factor (1). Target therapy with effective control of systemic inflammation have been demonstrated to improve articular outcomes, but the effect on CV risk is still under investigation (2). The ability of high-density lipoprotein (HDL) to accept cholesterol from macrophages (HDL cholesterol efflux capacity; HDLc-EC) is a key step in reverse cholesterol transport, with significant consequences on incident atherosclerotic CV disease (3), but this marker in RA have still alternate evidence (4,5).

Objectives: To assess the effects of different biological DMARDs on HDLc-EC in RA

Methods: Disease activity data and blood samples from 40 patients with RA before and up to 12 months after starting a biologic therapy were collected. The study included patients starting intravenously administered Abatacept (ABA;n=10), Infliximab (INF;n=10), Tocilizumab (TCZ;n=10), and Rituximab (RTX;n=10), at approved dose regimens for RA treatment. HDLc-EC was measured on paired serum samples using THP-1 macrophages and a fluorometric assay for cholesterol measurement. ANOVA was used to compare paired continuous data, and Pearson' r value was calculated for correlations.

Results: Disease activity assessed by DAS28-CRP and CDAI significantly dropped during all treatments. No significant changes in total and high or light density cholesterol fractions were detected. HDLc-EC at baseline was 22±3% with a statistically significant increase up to 25±3% and 27±4% after 6 and 12 months of treatment, respectively ($P<0.001$) [Figure A]. Patients treated with INF and RTX demonstrated the higher rise in HDLc-EC, already after 6 months and lasting up to 12 months of treatment. ABA and TCZ treated patients after 6 months had a slight HDLc-EC rising, with a subsequent plateau. We observed an opposite correlation between HDLc-EC and disease activity by DAS28-CRP and CDAI (r=-0.2;P=0.01) [Figure B]. Finally, no CV events were detected during the study follow-up.

Conclusions: Biologic treatment can influence the HDLc-EC of RA patients, already after 6 months of therapy, and is associated with changes in disease activity and inflammatory status. Infliximab and Rituximab seem to have an enhanced impact on HDLc-EC. Future studies need to address the mechanisms beyond these intriguing findings.

THU0144 COGNITIVE FUNCTION OF PATIENTS WITH RHEUMATOID ARTHRITIS IS ASSOCIATED WITH DISEASE ACTIVITY BUT NOT CAROTID ATHEROSCLEROTIC CHANGES

G.-T. Kim[1], H.-S. Tag[1], Y.-K. Kim[1], S.-G. Lee[2], E.-K. Park[2], J.-H. Park[2], J.-W. Lee[3], S.-H. Kim[4], J.-H. Lee[5]. *[1]Department of Internal Medicine, Kosin University College of Medicine; [2]Department of Internal Medicine, Pusan National University Hospital; [3]Department of Internal Medicine, Busan St. Mary's Hospital; [4]Department of Internal Medicine, Inje University College of Medicine; [5]Department of Internal Medicine, Maryknoll Medical Center, Busan, Korea, Republic Of*

Background: Rheumatoid arthritis (RA) is a complex inflammatory disease that has features of atherosclerosis and cognitive decline. Although the relationship between atherosclerosis and cognitive impairment has been studied and replicated, whether cognitive deficits in RA can be attributed to their atherosclerotic changes is not well understood.

Objectives: This study investigated the cognitive function in patients with RA using the Korean version of the Consortium to Establish a Registry for Alzheimer's disease (CERAD-K) neuropsychological battery and evaluated whether cognitive function was affected by the carotid arterial atherosclerosis.

Methods: We examined seventy RA patients and forty healthy controls. RA activity was assessed by disease activity score with 28 joints-*erythrocyte sedimentation rate* (DAS28-ESR) and objective memory impairment was defined as a performance score of 1.5 standard deviations below the respective age-specific, education-specific, and sex-specific normative means for at least one of the four episodic memory tests in CERAD-K; the Word List Memory, Word List Recall, Word List Recognition, and Constructional Recall tests [1]. Carotid arteries were scanned for the presence of plaque and intima-media thickness (IMT). We assessed potential risk factors of cognitive impairment in RA patients using regression analyses.

Results: Of the CERAD-K subtests, there were a significant difference between the RA patients and healthy controls in verbal fluency (12.97±3.73 vs 15.48±4.57, respectively; p=0.004) and Boston Naming Test (11.50±2.08 vs 12.30±1.77, respectively; p=0.035). Carotid ultrasound revealed significantly more plaques in the RA patients than in the healthy controls (39% vs 15%, respectively; p=0.017). RA patients with memory impairment have significantly higher score of DAS28-ESR (4.14±0.99 vs 2.60±0.88, respectively; $p<0.001$), age (65.71±7.71 vs 58.50±11.33, respectively; p=0.009), and mean cIMT (0.56±0.10 vs 0.50±0.08, respectively; p=0.027) compared to RA patients without memory impairment. In multivariable regression analysis, CERAD-K total score showed a significant negative correlation with age (β=-0.415, $p<0.001$) or DAS28-ESR (β=-4.685, $p<0.001$), but no correlation was found between CERAD-K total score and presence of plaque or cIMT (Table 1).

Table 1. Regression analysis of mean CERAD-K total scores and clinical parameters

	Univariable analysis				Multivariable analysis		
Total (n=70)	Coefficient (β)	95% CI	P	R^2	Coefficient (β)	95% CI	P
Age (years)	-0.494	(-0.711, -0.277)	<0.001	0.232	-0.415	(-0.607, -0.224)	<0.001
Male (%)	2.121	(-5.079, 9.320)	0.559	0.005			
RF (IU/MI)	0.003	(-0.014, 0.020)	0.733	0.002			
hsCRP (mmol/L)	-0.074	(-0.284, 0.135)	0.482	0.007			
DAS28	-5.402	(-7.552, -3.252)	<0.001	0.270	-4.685	(-6.629, -2.742)	<0.001
TC	0.020	(-0.038, 0.078)	0.484	0.007			
Mean cIMT	-26.082	(-56.267, 4.103)	0.089	0.042			
Presence of plaque	-1.209	(-6.79, 4.371)	0.667	0.003			

RF: rheumatoid factor, hsCRP: high sensitivity C-reactive protein, DAS28: disease activity score 28, TC: total cholesterol, cIMT: carotid intima-media thickness

Conclusions: Our results indicate that disease activity of RA and aging contribute to cognitive impairment, but there was no association between cognitive function and clinical or subclinical carotid atherosclerotic changes in RA patients.

THU0145 IMPACT OF DIFFERENT FORMULATIONS OF "PATIENT GLOBAL ASSESSMENT" ON REMISSION CLASSIFICATION BY DISEASE ACTIVITY INDICES IN RHEUMATOID ARTHRITIS

G. Eugénio[1], R. Ferreira[1,2], C. Silva[3], C. Medeiros[1], J.A.P. Silva[1,3], C. Duarte[1,3]. *[1]CHUc-Huc; [2]UICiSA:E; [3]FMUC, Coimbra, Portugal*

Background: Patient global assessment (PGA) of disease activity is included in a large number of composite indices of disease activity and definitions of remission in Rheumatoid Arthritis (RA). However, the actual question is formulated in a variety of different ways according to the instrument considered.

Objectives: To evaluate how 6 different formulations of PGA affect patient estimates and impact upon disease activity and remission rates as assessed by 4 Disease Activity Indices.

Methods: Consecutive RA patients followed in a Rheumatology outpatient department were included in this cross-sectional study. Data collection comprised: 28 joint counts (tender and swollen), C-reactive protein (CRP) and 6 different PGA formulations. The chosen formulations were the ones stated in the: v1) Portuguese National Registry Reuma.pt, the locally used formulation; v2) ACR/EULAR provisional definition of remission (considered in this study as the "standard"); v3) CDAI and SDAI; v4) Disease Activity Score (DAS28) assessment of general health; v5) DAS28 assessment of disease activity (the currently used); v6) one, exploratory, developed by the investigators, including idiomatic cultural expressions. ACR/EULAR Boolean criteria, CDAI, SDAI, and DAS28-CRP (4v) were used to test how these 6 PGA formulations change the rates of remission. PGA differences were assessed by descriptive analyses (including patients with PGA $\leq$10 and $\leq$20mm) and Bland-Altman test.

Results: In total, 193 patients were included (82% female, mean (SD) age of 59 (13) years, mean disease duration of 12 (9) years and 31% under biologics). The average PGA ranged from 42.3 (25.3) to 48.1 (26.7)mm as measured in different formulations. The ACR/EULAR (v2) formulation yielded the largest proportion of

Table 1. Descriptive statistics of the 6 PGA's formulations (n=193)

PGA Formulation	Mean (SD)	PGA below cut-off n (%)	
		$\leq$10 mm	$\leq$20mm
v1 Reuma.pt	47.5 (28.0)	26 (13.5)	43 (22.3)
v2 ACR/EULAR	43.5 (27.9)	31 (16.1)	48 (24.9)
v3 CDAI/SDAI	47.2 (25.9)	23 (11.9)	34 (17.6)
v4 DAS28-GH	42.9 (25.3)	27 (14.0)	42 (21.8)
v5 DAS28-DA	42.3 (25.3)	28 (14.5)	44 (22.8)
v6 Investigators	48.1 (26.7)	22 (11.4)	35 (18.1)

patients scoring ≤10mm (16.1%), corresponding to a difference of up to 4.7% versus other PGAs. Similar results were found for the ≤20 cut-off (Table 1).
By using different PGA's formulations the rates of remission calculated with different indices can vary between 4.7% and 6.7% (Table 2).
Bland-Altman chart confirmed the low agreement between ACR/EULAR formulation and the other PGA formulations (p<.05), except for the DAS "general health" (p=.054).

Table 2. Remission rates according to four composite indexes with the 6 PGA's formulations (n=193)

PGA Formulation	Definition – n (%)			
	ACR/EULAR Boolean	SDAI	CDAI	DAS28 4vCRP
v1 Reuma.pt	19 (9.8)	32 (16.8)	33 (17.1)	97 (50.5)
v2 ACR/EULAR	25 (13.0)	36 (19.1)	39 (20.0)	100 (51.7)
v3 CDAI/SDAI	16 (8.3)	27 (14.1)	26 (13.5)	91 (47.3)
v4 DAS28-GH	20 (10.4)	29 (15.2)	33 (17.1)	99 (51.4)
v5 DAS28-DA	19 (9.8)	29 (15.2)	30 (15.5)	100 (51.7)
v6 Investigators	17 (8.8)	27 (14.1)	27 (14.0)	97 (50.0)
Max. dif. within definition	9 (4.7)	9 (4.7)	13 (6.7)	9 (4.7)

Conclusions: The use of different PGA formulations has clinical implications in disease activity, which, in turn, can influence therapeutic decisions. The establishment of a single standardised formulation seems warranted.

THU0146 QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS - DEMOGRAPHIC AND SOCIO-ECONOMIC ASSOCIATIONS

H. Baharuddin[1], N. Zainudin[2], H. Mohd Yusoof[2], I.S. Lau[2]. *[1]Rheumatology, Universiti Teknologi MARA; [2]Rheumatology, Hospital Selayang, Selangor, Malaysia*

Background: The primary goal of treating patients with rheumatoid arthritis (RA) is to maximise long-term HRQol.[1]Quality of life (Qol) in patients with RA may be substantially impacted by their inability to perform daily activities, a shift in family roles, more restricted employment opportunities, increased financial burden and social dependency and reduced recreational activities.[2]
Objectives: To investigate the Qol among RA patients and its association with demographic and socioeconomic details.
Methods: This is a cross-sectional study conducted in a rheumatology outpatient clinic in Malaysia. Patients who fulfilled 2010 ACR/ EULAR classification criteria for RA were asked to answer WHOQOL-BREF questionnaire and specific questions on demographics and socio-economic details, during their attendance to rheumatology clinics. WHOQOL-BREF is a self-report quality of life questionnaire on individual's perception of quality of life and health, physical health, psychological, social relationships and environment domains.
Data was analysed using SPSS 20. Student's t-test was used to analyse the mean difference between two groups and chi-square test was used to analyse between 2 categorical data. Pearson correlation was used to analyse correlation between two groups of continuous data. p<0.05 was considered significant.
Results: The mean age of patients in this study was 53.10 (±14.3) years, with majority being females (80.4%) and married (70.6%). Half of the patients were Malays (49.0%). 51.0% rated overall quality of life as good and 41.2% rated overall health as satisfied. The mean transformed scores were 55.2 (±15.9) in physical health, 57.3 (±15.9) in psychological, 59.2 (±18.1) in social relationships and 58.2 (±15.2) in environment domains.
There were significant differences in the transformed scores for Malay (65.5±15.9) and non-Malay (53.1±18.2) in the social relationship domain; t (49) =2.58, p=0.01, and for education at secondary level and above (65.9±14.9) and primary level (48.0±16.6), t(49)=-3.87, p<0.01. We found no significant association between race and education level; 17 (53.1%) Malays and 15 (46.9%) non-Malays had education level of secondary and higher, X^2(1, N=51) =0.58, p=0.48. Patients with household income of less than RM 3, 000 had significantly lower scores compared to those with higher household income, in overall perception of quality of life (3.3±0.9 vs 4.0±0.6; t(49)=-2.8, p<0.01), overall perception of health (2.9±0.9 vs 3.6±0.7, t(49)=-2.97, p<0.01), physical health domain (51.2±16.2 vs 63.8±11.6, t(49)=-2.78, p=0.01) and psychological domain (53.3±16.3 vs 66.1±10.9, t(49)=-2.85, p=0.01).
Conclusions: Patients with RA perceived their Qol to be moderate in all domains. Social relationship was perceived to be better in Malays and patients with higher educational level. Low income was significantly associated lower overall quality of life and health, physical and psychological health.

THU0147 THORAX CT FINDINGS IN A LARGE COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS: HUR-BIO REAL LIFE RESULTS

A. Sari, B. Armagan, A. Erden, L. Kilic, O. Karadag, A. Akdogan, S. Apras Bilgen, I. Ertenli, U. Kalyoncu, S. Kiraz. *Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Lungs are one of the target organs in rheumatoid arthritis (RA) patients. Interstitial lung disease (ILD), rheumatoid nodules, pleural effusion, bronchiectasia and small airway disease are common manifestations of lung involvement.
Objectives: Objective of this study was to evaluate distribution of Thorax CT findings and treatment features in RA patients registered in a biologic registry.
Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective, single center database of biological treatments including 1229 RA patients by August 2016. Demographics, clinical and serological features of patients and thorax CT results performed in Hacettepe University between 2000 and 2016 were retrospectively evaluated. Patients whose CT was reported as small airway disease or ILD by radiologists, were evaluated as a subgroup. Data included type of biological treatments before diagnose of ILD and at last control as well.
Results: Among 1229 patients (78.8% female), mean age was 53.3±12.9 and disease duration was 11.4±7.9. Thorax CT had been performed in 203 (16.5%) patients. Distribution of pathologic findings in thorax CT was represented in Table 1. 29 patients (%2.4) were diagnosed as ILD with regard to CT findings. Patients with ILD were older (64.5±6.7 vs 60.6±10.1, p=0.039) and more frequently positive for rheumatoid factor (RF) (25/27 (%92.6) vs 77/121 (%63.3), p=0.003) than patients without ILD. ILD was detected before beginning of biologics in 11 (37.9%) patients and during biologic treatment in 18 (62.1%) patients. Honeycombing was seen in 10 (34.5%) patients. First choice of biologic agent was RTX in 10 (34.5%) and TNFi in 19 (65.5%) patients. In ILD patients, mean follow-up duration was 51±31 months and first biologic was switched to another in 16 (55.2%) of patients. At the last follow-up visit 19 (65.5%) patients were on rituximab, 3 (10.3%) patients were on abatacept and 7 (24.1%) were on TNFi. Small airway disease was detected in 19 (9.3%) patients. History of smoking was present in only 4 (21.0%) of patients with small airway disease.

Table 1. Distribution of thorax CT findings

Thorax CT finding	N (%)
Interstitial thickening	13 (6.4)
Reticular densities	31 (15.3)
Ground glass opacities	33 (16.3)
Nodules	35 (17.3)
Effusion	18 (8.9)
Bronchiectasia	46 (22.7)
Traction bronchiectasia	17 (8.4)

Conclusions: Broncіectasia, rheumatoid nodules, small airway disease and ILD were the most frequent CT findings of RA patients. Rituximab was the choice of first biologic treatment in one third of patients, however two-thirds of patients were on rituximab therapy at the last follow-up visit. Lung involvement stands out as an important factor in selection of biologics.

THU0148 INCREASE OF NIGHT QT-INTERVAL DURATION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB DURING 12-MONTH FOLLOW-UP

I.G. Kirillova, D. Novikova, E. Luchikhina, E. Markelova, H. Udachkina, N. Demidova, A. Misiyuk, T. Popkova, A. Volkov, L. Denisov, D. Karateev. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Objectives: to evaluate dynamic of ECG parameters in RA pts treated with tofacitinib (TOFA) during 12-month follow-up.
Methods: After 12-m follow-up the ECG parameters by 12 lead ECG and 24h ECG was assessed in 28 RA pts treated with TOFA (22 women, median age 54 [40;62] years, disease duration 39,5 [16,5;60,0] m, moderate to high activity (DAS28–5.1 [4.6;6.0], SDAI–26 (21;34)), positive for ACCP (75%)/RF (79%), who were non-responders to MTX at least 15 mg/week and/or other synthetic DMARDs and bDMARDs. TOFA therapy was started in all pts with dose 5 mg BID per os followed by the dose escalation to 10 mg BID in 8 (29%) pts. TOFA used in combination with MTX in 27 (96%) pts, leflunomide in 1 (4%). Low-dose oral corticosteroids (<10 mg/day prednisone or equivalent) were received by 9 (35%) pts. Remission or LDA was achieved in 55% pts (DAS28), 77% (SDAI). At baseline the most of pts had multiple CVRF and subclinical organ damage (arterial hypertension-67%, overweight-57%, abdominal obesity-61%, physical inactivity-64%, smokers/ex-smokers-25%/21%, menopausal status-59%, DM type 2–7%, mSCORE≥5%>21%, subclinical carotid atherosclerosis-64%, cardiac heart failure with preserved ejection fraction-7%. Cardioprotective therapy received 16 (57%) pts (beta-blockers–7, angiotensin II receptor type 2/ACE inhibitors–11, statins–11, dihydropyridine calcium channel blockers-7).
Results: There was no difference in heart rate (HR), QTc interval duration,

QRS duration measured by 12-lead ECG in RA pts treated with TOFA (table 1). However, an increase in PQ interval duration was observed (p=0,04). There were significantly decrease of mean HR (p<0,003), increase of QRS duration (p<0,03), QTc (p<0.03), night QTc (p<0,02) in 24 h ECG ambulatory recording. HR, PQ, QTc duration were changed independently of beta-blockers therapy. The number of pts with QTc≥440 ms increased from 11% to 21% (p>0.05). A change in QTc duration correlated negatively with dynamics of DAS 28, SDAI (r=-0,4, p<0,05), DM (r=0,5, p<0,02), dBP (r=-0,4, p<0,04). There were also significantly increase number of ventricular premature beats (p<0,03).

Table 1. ECG characteristics of pts with RA treated with TOFA

	Baseline	After 12 months
12-lead ECG		
Heart rate, bpm	71 [64;81]	69 [61;78]
PQ, ms	133 [126;131]	150 [130;160]*
QRS, ms	83 [79;89]	84 [80;91]
QTc, ms	421 [406;434]	410 [398;420]
24 h ECG		
Heart rate, bpm	78 [70;84]	74 [65;80]*
QRS, ms	82 [73;91]	85 [73;92]*
QTc, ms	409 [402;425]	415 [406;427]*
QTc night, ms	414 [400;434]	420 [408;437]*
VPB pts, n (%)	18 (66)	22 (78)
Ventricular premature beats, n	14 [7;50]	280 [15;3423]*

Data are presented in median values and IR (unless otherwise noted), *p<0,05 before and after TOFA treatment (nonparametric paired Wilcoxon test).

Conclusions: A significant decrease in HR and an increase in QRS, night QTc interval duration, number of ventricular premature beats by 24h ECG were observed in RA pts treated with tofacitinib (TOFA) during 12-month follow-up. QTc duration correlated with dynamic of disease activity, DM type 2 and diastolic BP.

THU0149 A CLINICAL AND PATHOLOGICAL CHARACTERIZATION OF METHOTREXATE-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Nakano [1], A. Nawata [1,2], S. Nakayamada [1], S. Iwata [1], K. Hanami [1], S. Kubo [1], I. Miyagawa [1], M. Yoshikawa [1], K. Saito [1], Y. Tanaka [1]. *[1] The First Department of Internal Medicine; [2] Department of Pathology, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan*

Background: Methotrexate (MTX) is used as an anchor drug for the treatment of rheumatoid arthritis (RA). Patients with RA have a modestly increased risk of developing lymphoproliferative disorders (LPD). Furthermore, although sometimes spontaneous regression occurs after withdrawal of MTX, LPD developed during the treatment with MTX is broadly defined as MTX-associated LPD (MTX-LPD).
Objectives: To characterize the risk factors concerning MTX-LPD and to consider optimal treatment after occurrence of LPD in patients with RA.
Methods: We retrospectively evaluated 51 RA patients with LPD from 2006 to 2015 in our institution. MTX-LPD patients were divided into two groups; regressive LPD after MTX cessation (N=27) and persistent LPD though MTX was tapered (N=24), and the clinical characteristics, pathology and treatment outcomes were compared. EBV infection and IL-6 receptor (IL-6R) expression were analyzed by in situ hybridization and immunohistochemistry.
Results: There was no significant difference in disease duration, stage, disease activity of RA, the positive rate of Epstein–Barr virus-encoded small RNAs, EBERs (42.7 vs 50.0%) and treatment with TNF-inhibitors (40.7 vs 45.8%) between regressive LPD and persistent LPD. Age of LPD onset (59.1 vs 68.3), CRP (2 vs 5 mg/dl) and the weekly MTX dose (10.9 vs 8.4 mg/w) significantly differed between the groups. Of note, IL-6R was highly expressed in both group (75.0 vs 66.7%). Among regressive LPD, 3 patients developed DLBCL later. persistent LPD showed poorer prognosis and worse mortality than regressive LPD. An older age and anemia were poor prognostic factors. Of 51 patients, 41% achieved sustained low disease activity (LDA) with other DMARDs except MTX. Nine of 10 patients refractory to DMARDs were controlled by tocilizumab (TCZ) and kept LDA.
Conclusions: Taken together, it seems unreasonable to be lump the persistent-group into the same category as MTX-LPD. The high expression rate of IL-6R and the high responsiveness to TCZ suggest that IL-6/IL-6R is likely to play a role in the development of LPD in patients with RA.

THU0150 OPTIMIZING COMORBIDITY RISK MANAGEMENT IN RA BY TRANSLATING A NURSE-LED INTERVIEW INTO AN EASILY INTERPRETABLE TRAFFIC LIGHT SYSTEM

K. Krüger [1], R. Eder [2], C. Müller [3], R. Hecker [3]. *[1] Rheumatologisches Praxiszentrum St. Bonifatius, München; [2] Rheumapraxis am Spitaltor, Deggendorf; [3] Abbvie Deutschland Gmbh & Co. Kg, Wiesbaden, Germany*

Background: Due to its inflammatory nature, rheumatoid arthritis (RA) is associated with a variety of comorbidities and individual risk factors [1]. The benefit of a nurse-led programme on RA comorbidity management has been reported recently [2].
Objectives: To describe a new assessment tool for patient risk management and report the difference between structured versus expert guided assessment following standard of care in a construct-validation cohort.
Methods: The ongoing cluster randomized multicentre study ERIKO is longitudinally assessing individual risk profiles of patients with RA in Germany. The aim of this study is to test the benefit of applying a nurse-led scoring algorithm for individual risk profiles followed by a structured patient consultation (active arm) as compared to local standard of care.
The ERIKO-Score was calculated by rating validated assessment tools and treatment guidelines and translating their outcome into a three-level ordinal score defined by the categories low, intermediate or high risk, including nominal weights for risk management (e.g. condition is being treated with goals achieved or not). Scores were interpreted numerically by rating categories with 0, 1 and 2 points, respectively.
We included cardiovascular (CV) risk (ESC-guideline), infection risk (RABBIT risk calculator), vaccination status (guideline), fracture risk (FRAX), tooth status (PSI), depression- (PHQ-9) and health-related quality of life (hrQoL, RAID). The same risk categorization was prompted in all centres at the screening visit without providing the rating tools.
This analysis compares SOC ratings from the screening visit (month zero) with the baseline ERIKO-scores at month three in the active arm. No statistical hypothesis testing was performed in this analysis.
Results: This analysis included 283 patients from 31 centres specialized in rheumatology care randomized to the active study arm. 82.3% were female with a mean age of 57.8 years (sd 12.1) and a mean DAS28 of 2.6 (sd 1.1). The mean total ERIKO-Score was slightly higher at baseline as compared to applying the scoring algorithm on SOC ratings at the screening visit (5.33 +- 1.95 vs. 4.32 +- 2.61, respectively, table 1). The discrepancy was mainly driven by CV risk, vaccination status, tooth status and depression risk, that were more often rated worse by applying the ERIKO score than by SOC, while infection- and fracture risk were more frequently rated lower by the ERIKO-Score (table 2). The strongest discrepancy between SOC ratings and ERIKO-Score (Δ =2 points) were observed for tooth status (N=54), CV risk (N=25) and vaccination status (N=25) (table 2). SOC ratings were strongly based on expert opinion with the most frequently cited tools being vaccination guidelines (38.9%), bone mineral density measurement (BMD) (39.6%) and RABBIT-infection risk-score (23.1%).

Table 1 ERIKO Score at baseline visit (3 months)

N = 283 [5]	Ordinal Risk Rating				Numeric interpretation	
Dimension	missing [%(N)]	Low [%(N)]	Intermediate [%(N)]	High [%(N)]	Median (IQR)	Mean (sd)
CV risk	9.2 (26)	27.9 (79)	26.5 (75)	36.4 (103)	1 (2)	1.1 (0.80)
Vaccination status	9.2 (26)	15.9 (45)	50.5 (143)	24.4 (69)	1 (1)	1.1 (0.66)
Infection risk	9.2 (26)	79.9 (226)	10.2 (29)	0.7 (2)	0 (0)	0.1 (0.36)
Risk of major osteoporotic fracture	9.9 (28)	52.7 (149)	32.9 (93)	4.6 (13)	0 (1)	0.5 (0.59)
Tooth status	11.3 (32)	5.3 (15)	55.1 (156)	28.3 (80)	1 (1)	1.3 (0.56)
Depression risk	9.2 (26)	46.3 (131)	39.6 (112)	4.9 (14)	0 (1)	0.5 (0.60)
hrQoL	9.2 (26)	33.9 (96)	47.3 (134)	9.5 (27)	1 (1)	0.7 (0.64)

[5] n = 26 without data at baseline.

Table 2 Discrepancy between ERIKO-Score and ratings following SOC (baseline vs. screening)

	Δ = 1 or 2 points (total)			Δ = 2 points (low vs. high)	
Dimension	No difference [%(N)]	SOC risk lower [%(N)]	SOC risk higher [%(N)]	SOC risk lower [%(N)]	SOC risk higher [%(N)]
CV risk[a]	35.0 (99)	44.2 (125)	10.2 (29)	8.5 (24)	0.4 (1)
Vaccination status[b]	34.6 (98)	38.5 (109)	17.7 (50)	7.4 (21)	1.4 (4)
Infection risk[b]	63.6 (180)	6.0 (17)	21.2 (60)	0	3.2 (9)
Risk of major osteoporotic fracture[b]	36.8 (104)	15.2 (43)	38.9 (110)	1.4 (4)	3.5 (10)
Tooth status[a]	18.4 (52)	47.7 (135)	23.3 (66)	15.5 (44)	3.5 (10)
Depression risk[b]	48.4 (137)	30.7 (87)	11.7 (33)	3.2 (9)	3.2 (9)
hrQoL[b]	64.6 (166)	18.0 (51)	14.1 (40)	2.1 (6)	0.4 (1)

[a] n = 30 without data at screening or baseline; [b] n = 26 without data at baseline

Conclusions: A nurse-led comorbidity risk assessment in rheumatology practices seems feasible. Applying the ERIKO-Score based on validated tools led to a

higher risk grading than the predominantly expert-opinion based SOC. Construct validation of the ERIKO-Score is ongoing.

THU0151 ACPA ARE ASSOCIATED WITH LOW BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

L. Bautista Aguilar, A. Salmoral Chamizo, R. Jimenez Gasco, I. Gomez Gracia, P. Font Ugalde, M.L. Ladehesa Pineda, E.C. Lopez Medina, L. Perez Sanchez, A. Escudero Contreras, E. Collantes Estevez. *Rheumatology, Reina Sofia University Hospital/IMIBIC/ University of Cordoba, Cordoba, Spain*

Background: Several studies have related ACPA with the presence of bone erosion in rheumatoid arthtitis patients as they induce the differentiation and activation of osteoclasts

Objectives: Our main aim is to evaluate the association of ACPA with bone mineral density (BMD) in RA

Methods: Case-control study of 73 RA patients (2010 EULAR criteria) and a long standing disease of 5 years. Demographic and clinical variables were collected. BMD values using densitometry at the lumbar (CL), hip (CT) and femoral neck (CF) were collected. The presence of low bone mineral density (osteopenia: tscore$\leq$-1) and ACPA levels were compared using logistic regression analysis, adjusting variables related to BMD: age, sex, menopause, body mass index (BMI), habit Smoking, disease duration, daily corticoid doses, methotrexate treatment and inflammatory disease activity (DAS28)

Results: A group of 73 patients were included (14 men) with a mean age of 66,45±10,41 years, mean body mass index 28,48±5,22 kg/m^2, mean long standing disease of 2,28±1,75 years and mean DAS 28 of 3,17±1,18. A total of 29 patients were negative for ACPA compared to 44 patients that were positive for ACPA. Osteopenia in lumbar spine was found in 82.2% of patients 65.8% hip and 75.3% in femoral neck. Logistic regression was performed without finding statistically significant association between osteopenia and inflammatory activity (DAS 28), vitamin D levels and positive rheumatoid factor, adjusted for variables that can modify BMD. ACPA Positive (any titer) were associated with the presence of lumbar spine osteopenia (OR 7.19, 95% CI 1.77–29.17) (p=0.006), hip (OR 15.17, 95% CI 3.96–58.18) (p=0.001) and femoral neck (OR 3.76; 95% CI 1.20–11.82) (p=0.023). In addition, a simple variance analysis (ANOVA) was performed to compare T scores and ACPA levels divided into three categories: $\leq$25U/mL, 25–300U/mL and$>$300U/mL. ACPA group $\leq$25U/mL differed in mean T score values in lumbar spine, hip and femoral neck. No differences were found between ACPA positive patients with low and high levels for T score values.

Conclusions: ACPA positivity in RA is associated with an increased risk of osteopenia in lumbar spine, hip and femoral neck independently of other variables that may modify bone mineral density. These data suggest that ACPA may play a role in bone remodeling

THU0152 WHO ARE THE PATIENTS WITH RHEUMATOID ARTHRITIS (RA) WHO ARE GETTING COMORBIDITY SCREENING PROCEDURES IN ACCORDANCE WITH GUIDELINES? A STUDY OF 769 ESTABLISHED RA PATIENTS

L. Gossec, F. Foissac, M. Soubrier, F. Fayet, T. Bardin, C. Beauvais, G. Chales, I. Chary-Valckenaere, E. Dernis, L. Euller-Ziegler, R.-M. Flipo, P. Gaudin, S. Guis, T. Marhadour, X. Mariette, G. Mouterde, S. Pouplin, P. Richette, A. Ruyssen-Witrand, T. Schaeverbeke, J. Sibilia, M. Dougados. *COMEDRA working group, Paris, France*

Background: Patients with RA are either more at risk of, or less well screened for, several comorbidities including cardiovascular (CV) risk, cancer, infections and osteoporosis.[1] Recommendations have been developed on how and at what frequency to screen for comorbidities in RA patients.[2]

Objectives: to characterise patients who are being screened correctly (i.e., in accordance with recommendations).

Methods: *Study design:* This was an open long-term (3 years) extension of the COMEDRA 6 month randomized controlled trial in which patients with definite, stable RA were visiting a nurse for comorbidity assessment and screening counselling.[3] For this analysis, only the final visit data were used cross-sectionally. *Assessment of comorbidity screening:* A score was developed to quantify comorbidity screening procedures in accordance with guidelines:[4] this score gives 50 points to CV risk screening, 20 points to cancer screening, 20 points to pneumococcus and influenza vaccination and 10 points to osteoporosis screening. The score ranges 0–100 and 0 indicates optimal screening. *Factors associated with optimal screening:* demographic and disease characteristics were compared between patients considered well-screened (lowest tertile for screening score) versus other patients. *Statistical analysis:* Variables with p$<$0.20 in univariate analysis were entered into the multivariate analysis using a backward stepwise logistic regression.

Results: 769 patients were assessed: mean (±SD) age 62 (±11) years, mean disease duration 17 (±10) years; 614 (80%) were women and 535 (70%) were receiving a biologic. Disease was well-controlled (mean DAS28 2.8±1.3). The mean comorbidity screening score was 24.3 (±17.8) (range, 0–100). The 316 patients (41% of all patients) in the lowest tertile for this score (i.e., with a score $\leq$15) were less often smokers: odds ratio [95% confidence interval] 0.45 [0.28 – 0.72], were more often treated for hyperlipidemia (2.58 [1.85 – 3.61]), and were more often treated with a biologic (1.97 [1.4 – 2.76]).

Conclusions: Comorbidity screening is suboptimal in RA. Patients who were better screened were more frequently already followed-up for hyperlipidemia and were more frequently receiving biologics but more less frequently smokers. Thus it seems getting optimal screening may reflect both patient characteristics but also physician attention to comorbidity in certain situations. Empowering patients to be responsible for the comorbidity screening reminders should be explored.

THU0153 VASCULAR MORBIMORTALITY IN RHEUMATOID ARTHRITIS (RA) PATIENTS AND ITS RELATION WITH VASCULAR STUDY

L. Montolio-Chiva, M. Robustillo-Villarino, C. Vergara-Dangond, M. Aguilar-Zamora, E. Valls-Pascual, D. Ybáñez-García, A. Martínez-Ferrer, V. Núñez-Monje, J.J. Alegre-Sancho. *Rheumatology, Hospital Universitario Dr. Peset, Valencia, Spain*

Background: RA patients have a higher risk of vascular events, especially cardiac ones. Besides, mortality in these patients is 54% higher than the general population. Nowadays, we have non-invasive techniques that allow us to detect subclinical vascular damage.

Objectives: To describe subclinical vascular affection in a sample of RA patients and to explore its relationship with mortality and with the development of vascular events.

Methods: Ambispective observational study with analytical components. We included, consecutively, RA patients controlled in a tertiary hospital. We gathered demographic (sex, age, body mass index [BMI]), clinical (traditional vascular risk factors, previous vascular events), and analytical variables (atherogenic index, glomerular filtration [GF] [MDRD], CRP, ESR). Other variables were collected retrospectively from the electronic medical record. We estimated the modified SCORE. We explored the extracranial branches of the carotid artery with an Esaote MyLab70XVG ultrasound device with a linear probe (7–12mHz) and an automated program measuring intima media thickness (IMT) by radiofrequency ("Quality intima media thickness in real-time, QIMT"), and the presence of atheroma plaques, as per the Mannheim consensus, was registered. We also determined pulse wave velocity (PWV) by a validated MobilOGraph® device. We considered an IMT$>$900 $\mu$and a PWV$\geq$10m/s as pathologic values. We prospectively collected mortality and the development of new vascular events over three years. Statistical analysis was performed using SPSS 17.0 software.

Results: We included 198 patients, excluding 13 because of previous vascular events. The mean age was 65,8 years (DE 13,3) and most of them were women (76,2%). The mean BMI was 27,29 (DE 4,84). 27% were smokers, 42,7% hypertensive, 46,7% dyslipemic and 10,8% were diabetic. The mean duration of RA was 17,37 years. 74,6% of patients were seropositive (RF and/or ACPA) and 75, 5% had erosions. 74,6% received glucocorticoids, 58,4% NSAIDs, 98,9% DMARDs and 35,7% biologic therapies. The mean CRP and ESR were 9,45mg/L (DE: 32,2) and 14,04mm/h (DE:14,46), respectively. The mean modified SCORE was 1,81 (DE: 1,79).

Regarding the vascular study, 48,6% of the patients had atheroma plaques, 31,7% had a pathologic PWV with a mean value of 9,13 (DE 2,12), and 16,7% had a pathologic IMT with a mean value of 754 μ(DE 168,52).

During 3 years of follow up, we registered 26 (14,1%) vascular events: 9,7% cardiac, 2,1% cerebral and 2,2% peripheral. There were 5 deaths: 3 vascular, 1 infectious and 1 respiratory. The development of vascular events was related with the presence of atheroma plaques (p 0,008) and with pathologic PWV (p

0,028), as well as with the presence of erosions, GF, HTA and dyslipidemia. The appearance of cardiac events was related, also, with the use of NSAID (p 0,041). The presence of a pathologic IMT (p 0,032) and HTA (p 0,044) were the only variables related with death from any cause.

Conclusions: A combination of carotid ultrasonography and arterial stiffness study can help us to best identify patients with RA who have an increased risk of dying or developing a vascular event.

THU0154 ASSOCIATION BETWEEN PLASMA LIPIDS, DISEASE ACTIVITY AND PCSK9 LEVELS IN RA PATIENTS

M. Heslinga[1], G. Lambert[2], A. Thedrez[3], J. Kastelein[4], M. Nurmohamed[1,5]. *[1]Amsterdam Rheumatology and immunology Center | Reade, Amsterdam, Netherlands; [2]University of la Reúnion, Saint-Denis; [3]University of Nantes, Nantes, France; [4]Academic Medical Center; [5]Amsterdam Rheumatology and Immunology Center | VU University Medical Center, Amsterdam, Netherlands*

Background: Patients with rheumatoid arthritis (RA) are at increased cardiovascular risk with contribution of both inflammation and traditional risk factors. Dyslipidemia is an important risk factor and lipid-lowering therapy plays a key role in cardio-preventive treatment. A new class of low density lipoprotein cholesterol (LDL-C) lowering drugs, proprotein convertase subtilisin/kexin type 9 (PCSK9)-inhibitors are now emerging. In view of a lower rate of musculoskeletal side effects these drugs might be preferred over statins in patients with RA. Active inflammation in RA leads to a decline in lipid levels, but the relation between inflammation and PCSK9 levels is unknown.

Objectives: To assess PSCK9 levels in RA patients, and the relationship with lipid levels and disease activity.

Methods: PSCK9 levels were assessed using ELISA in 97 randomly selected patients. Lipid profile assessment comprised TC, HDL-C, LDL-C and triglycerides. Disease activity was assessed using disease activity score of 28 joints (DAS28).

Results: The mean age of RA patients was 54.5 years (± 10.8) and they were predominantly female (74.2%). The mean PCSK9 value in RA patients was 214.75 (± 73.3), which is similar to that in the general population [1]. PCSK9 values were associated with TC (corrected B 22.34, 95% CI 6.80–37.88, p0.005) and triglycerides (corrected B 21.02, 95% CI -0.84–42.89, p0.044) (table 2). 77 patients had low disease activity (DAS28 ≤3.2), 11 patients had medium disease activity (DAS28 >3.2 and ≤5.1) and 20 patients had highly active disease (DAS28 >5.1). Mean PCSK9 values were 213.01, 246.96 and 258.30 ng/mL, respectively. Patients with active disease had a higher PCSK9 level (corrected B 42.555 95% CI 0.769–84.341, p 0.046) compared to patients with low disease activity (table 1).

Table 1. Relation between plasma lipids, disease activity and PCSK9 levels

	B	95% CI	P-value
TC	21.86	7.03–36.69	0.004
*	21.88	6.52–37.24	0.006
**	22.34	6.80–37.88	0.005
Triglycerides	21.02	-0.84–42.89	0.059
*	19.81	-2.91–42.53	0.087
**	24.81	0.68–48.94	0.044
HDL-C	13.03	-14.97–41.03	0.358
*	14.57	-14.61–43.79	0.324
**	11.04	-20.15–42.23	0.484
LDL-C	14.23	-1.93–30.38	0.084
*	13.59	-2.81–29.99	0.103
**	15.22	-1.51–31.95	0.074
TC/HDL ratio	6.28	-4.4–16.9	0.245
*	5.95	-5.12–17.03	0.289
**	8.64	-3.36–20.64	0.156
DAS28 (low vs. high disease activity)†	45.284	4.865–85.884	0.029
*	42.028	0.652–83.405	0.047
**	42.555	0.769–84.341	0.046

*Corrected for age and gender, **Corrected for age, gender and BMI. †Low disease activity: DAS28 >3.2, and high disease activity: DAS28 ≤5.1. BMI = Body Mass Index, DAS28 = Disease activity score of 28 joints, HDL = high density lipoprotein, LDL = low density lipoprotein, TC=Total cholesterol.

Conclusions: PCSK9 levels in RA are similar to the general population. RA patients with active disease had higher PCSK9 levels compared to patients with low disease activity. Altogether, PCSK9 inhibitors could be an alternative treatment for dyslipidemia in RA patients who experience side effects of statins, albeit that a formal trial still has to be conducted in this category of patients.

THU0155 IMPACT OF BASELINE MODIFIED RHEUMATIC DISEASE COMORBIDITY INDEX (MRDCI) ON DRUG SURVIVAL AND EFFECTIVENESS OF BIOLOGICAL DRUGS IN PATIENTS AFFECTED WITH RHEUMATOID ARTHRITIS (RA), SPONDYLOARTHRITIS (SPA), AND PSORIATIC ARTHRITIS (PSA) IN REAL-WORLD SETTINGS

M. Fornaro[1], M. Di Carlo[2], S. Gentileschi[3], M.G. Giannotta[1], L. Cantarini[3], F. Salaffi[2], G. Lapadula[1], F. Iannone[1]. *[1]Department of Rheumatology, University of Bari, Bari; [2]Rheumatology Department, Polytechnic University of Marche, Jesi; [3]Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinic, Department of Medical Sciences, Surgery and Neurosciences, University of Siena, Siena, Italy*

Background: The overall assessment of patients with systemic arthritis can not exclude comorbidities, which may impact therapeutic outcomes.

Objectives: To assess the impact of baseline modified rheumatic disease comorbidity index[1] (mRDCI) on drug survival and effectiveness of biological drugs in patients affected with Rheumatoid arthritis (RA), Spondyloarthritis (SpA), and Psoriatic Arthritis (PsA) in real-world settings.

Methods: Patients (nr. 635) with RA (nr. 214), SpA (nr. 213), and PsA (nr. 208) starting a biological drug were retrospectively analysed. mRDCI was scored at baseline, and disease characteristics were recorded at entry and at last observation. Drug retention was analysed using Kaplan–Meier curves. Cox-regression models were used to estimate the association of mRDCI with drug discontinuation and clinical outcomes, the achievement of clinical remission based on 28 joint-Disease Activity Score (DAS28) <2.6 for RA and PsA, and on Ankylosing Spondylitis-C-reactive protein Disease Activity Score (ASDAS-CRP) <1.3 for SpA.

Results: Baseline mRDCI significantly correlated with the number of biological drug switches (rho 0.47). Drug persistence was significantly higher in patients with mRDCI=0 (96.4%), than in those with mRDCI ≥2 (83.9%). Compared to mRDCI ≥2 patients, those without comorbidities showed significantly higher drug survival rate in PsA (p=0.0001) or SpA (p=0.02), but not in RA (Figure 1). mRDCI was also found to be a predictor of definitive drug discontinuation (HR 1.53) and of failure to achieve DAS28 based remission in RA (HR 0.66) or PsA (HR 0.77), and ASDAS-CRP driven remission in SpA (HR 0.43).

Table 1. Baseline demographics of patients with Psoriatic Arthritis (PsA), Rheumatoid arthritis (RA), and Spondyloarthritis (SpA)

	All (n=635)	PsA (n=208)	RA (n=214)	SpA (n=213)
Age (mean ± SD)	51.1±13	51.3±12	54.2±12	47.8±13

THU0156 CLINICAL ASSESSMENT VERSUS ULTRASONOGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICAL AGENTS - THE IMPACT OF CONCOMITANT FIBROMYALGIA

M.M. Tamas[1], L.-J. Ghib[1], C.I. Bondor[2], I. Felea[3], L. Damian[3], I. Filipescu[1], A. Mociran[3], S.-P. Simon[1], L. Muntean[1], S. Rednic[1]. *[1]Rheumatology; [2]Department of Medical Informatics and Biostatistics, "Iuliu Hatieganu" University of Medicine and Pharmacy; [3]Rheumatology, Emergency County Clinical Hospital, Cluj Napoca, Romania*

Background: Concomitant fibromyalgia (FM) may increase subjective components of the disease activity scores (DAS) in rheumatoid arthritis (RA), thus leading to an improper assessment of treatment response. Ultrasonography (US) is currently used in clinical practice as an objective measure of the disease activity. The US7 German score was demonstrated to be sensitive to change, reflecting the therapeutic response in RA patients [1].
Objectives: To evaluate clinical and US parameters in RA patients with or without concomitant FM, undergoing biological therapy.
Methods: RA patients treated with various biological agents who presented in our Department of Rheumatology were consecutively enrolled. Patients underwent clinical and laboratory examinations. US was performed by an experienced sonographer, blinded to clinical evaluation. Synovitis and synovial/tenosynovial vascularity were scored semiquantitatively (grade 0–3) by gray-scale (GS) and power Doppler (PD) US. Tenosynovitis (TS) and erosions were scored for presence [1].
Patients were divided in two groups according to the difference between tender joint count (TJC) and swollen joint count (SJC): ≥7 RA-FM group, <7 RA-nonFM group, representing the "joint count" criteria for FM, after the study of Pollard *et al.* [2].
Results: Thirty-nine patients were included, 77% women, mean age 55.2±11.3 years, mean disease duration 15.25±9.4 years. Nine out of 39 (23%) patients were classified as having associated FM. Disease duration and treatment were comparable between groups.
Significantly higher values for TJC, patient global assessment (PGA), DAS 28 were found in the RA-FM group, with no differences for SJC or inflammatory markers (ESR, CRP). GS and PD-US7 scores were similar between groups (Table 1).

Table 1. Clinical and US findings in RA-nonFM and RA-FM groups

	RA-nonFM (n=30)	RA-FM (n=9)	*P* value
PGA (mm)	41.33 (18.28)	58.88 (17.63)	<0.001
TJC	3 (0–10)	12 (9–17)	<0.001
SJC	2 (0–7)	1 (0–6)	0.54
ESR (mm/h)	22.26 (18.42)	27.33 (16.87)	0.21
CRP (mg/l)	8.46 (17.84)	8.67 (9.11)	0.66
DAS28 CRP	3.33 (0.98)	5.13 (1.18)	0.015
GS Synovitis US7 score	3.80 (4.37)	2.67 (1.66)	0.96
PD Synovitis US7 score	1.67 (2.90)	1.22 (1.20)	0.59
Erosions US7 score	3.77 (2.75)	4.89 (2.85)	0.29
GS TS US7 score	0.30 (0.84)	0.44 (0.73)	0.31
PD TS US7 score	0.20 (1.10)	0.33 (0.71)	0.08

In the RA non-FM, but not in the RA-FM group, GS and PD-US7 correlated with SJC (r=0.44, *p*=0.015 – GS synovitis, r=0.47, *p*=0.008 – PD synovitis; r=0.57, *p*=0.001 – GS TS; r=0.46, *p*=0.011 – PD TS) and PD synovitis negatively correlated with the "joint count" criteria (r=-0.44, *p*=0.015).
Conclusions: Concomitant FM in RA patients undergoing biological therapy lead to higher DAS28 scores, but not to synovial inflammation on US. US-PD correlates with clinically detected synovitis in the non-FM group. US is expected to modify treatment decision and to prevent RA mistreatment especially in RA-FM patients.

THU0157 RELATIONSHIP OF MATRIX METALLOPROTEASE 3 TITER AND SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE CHIKARA STUDY

M. Tada, Y. Yamada, K. Mandai, N. Hidaka. *Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

Background: Patients with rheumatoid arthritis (RA) show a lower muscle mass[1] and higher prevalence of sarcopenia than healthy individuals. A prospective observational study (CHIKARA study, registration number: UMIN000023744) was started to clarify the influence of changes in disease activity for sarcopenia.
Objectives: We investigated the relationship between sarcopenia and disease activity at baseline in patients with RA.
Methods: We analyzed baseline data from the CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease activity in rheumatoid arthritis). Sarcopenia was diagnosed using the criteria of the Asia Working Group on Sarcopenia[2]. Muscle mass, body fat mass, total body water, bone mass, and basal metabolic rate were measured using a body composition analyzer (MC-780A; TANITA, Tokyo, Japan). We investigated correlations between sarcopenia and disease activity (DAS28-ESR, SDAI, physical function (HAQ), and laboratory data using uni- and multivariate analyses.
Results: Participants comprised 100 patients with RA (females, 78%; mean age, 66.1 years). Mean disease duration was 5.5 years, DAS28-ESR was 3.55, and the percentage of subjects with sarcopenia was 28%. Table 1 shows risk factors for sarcopenia. Sarcopenia correlated with weight, body mass index (BMI), body fat mass, muscle mass, basal metabolic rate, Steinbrocker stage, CRP bone mass, and matrix metalloprotease (MMP)-3 on univariate analysis. Glucocorticoid dosage, rheumatoid factor, and anti-CCP antibody showed no correlation with sarcopenia. BMI, body fat mass, and MMP-3 were identified as independent risk factors on multivariate analysis. MMP-3 over 90.7 ng/ml was a risk factor for sarcopenia by ROC curve analysis (odds ratio, 3.09; p=0.023).

Table 1. Risk factors for sarcopenia in patients with RA

	Univariate		Multivariate		
	R	*P*	Odds ratio	95% CI	*P*
Weight	-0.421	<0.001	–	–	–
BMI	-0.490	<0.001	0.307	0.185–0.509	<0.001
Body fat mass	-0.219	0.002	1.318	1.124–1.546	0.001
Muscle mass	-0.325	0.001	–	–	–
Basal metabolic rate	-0.419	<0.001	–	–	–
Steinbrocker stage	0.206	0.039	–	–	–
CRP	0.201	0.045	–	–	–
Bone mass	-0.374	<0.001	–	–	–
MMP-3	0.238	0.017	1.012	1.003–0.021	0.01

Conclusions: The percentage of sarcopenia was 28% in patients with RA. Low BMI, high body fat mass, and high MMP-3 represented independent risk factors for sarcopenia. A relationship between MMP-3 and sarcopenia was indicated by this study.

THU0158 IMMUNE RESPONSE EFFICIENCY AFTER VACCINATION IN RA AND SPA PATIENTS TREATED WITH BIOLOGICS AND IMMUNOSUPPRESSIVE AGENTS: A SYSTEMATIC LITERATURE REVIEW

M. Tissier[1], A. Molto[1], S. Kolta[1], O. Fogel[1], M. Dougados[1], J. Morel[2], C. Miceli-Richard[1]. *[1]Hopital Cochin Paris, Paris; [2]CHU Montpellier, Montpellier, France*

Background: One of the most effective strategies to prevent infections is vaccination, especially in patients treated with biologics and immunosuppressive (IS) agents. Nevertheless, the effectiveness of the resulting immune response in these patients has been questioned.
Objectives: To perform a systematic literature review aiming to assess evidence available regarding immune response efficiency (IRE) and the ideal schedule for vaccination in RA and SpA patients treated with Methotrexate (MTX), TNF inhibitors (TNFi), anti-CD20 (rituximab, RTX), anti-CTLA4 (abatacept, ABA) or anti-IL6 (tocilizumab, TCZ).
Methods: A systematic literature review was conducted by searching in PubMed all studies with the MeSH terms "[Rheumatoïd Arthritis" OR "Spondyloarthritis"] AND ["vaccination" OR "vaccines"] AND ["Methotrexate" OR "Abatacept" OR "Tocilizumab" OR "Rituximab" OR "Adalimumab" OR "Certolizumab" OR "Etanercept" OR "Golimumab" OR "Infliximab"], with no limitation regarding time of publication. Only studies evaluating the IRE were included. Case reports, general reviews and meta-analysis were excluded.
Results: After exclusion criteria, 35 studies (out of 60 studies retrieved) assessing IRE in RA or SpA patients were selected, under MTX (n=35), TNFi (n=18), RTX (n=8), ABA (n=4) or TCZ (n=5). The studied vaccines were mostly the trivalent seasonal Influenza (n=20), the anti-pneumococcal vaccine (n=16), and few studies regarding the tetanus toxoid vaccine (TTV) (n=2), Hepatitis A vaccine (n=1) and accidental revaccination against yellow fever (n=2). Most studies (32/35) evaluated the IRE using the antibody (Ab) titer. When studying the anti-pneumococcal and influenza vaccination, the primary outcome was mainly the seroresponse 3 to 6 weeks after vaccination (i.e. Ab ratio post/pre-vaccine) but some studies (15/35) also assessed the seroprotection rate (i.e. patients with an effective titer of protective Ab), and some (3/35) the effectiveness of seroresponse using the opsonization index rate.
Regarding the anti-pneumococcal and influenza vaccination, MTX, RTX, and ABA were reported to impair the immune response; neither TNFi nor TCZ were shown to decrease seroresponse.

Regarding TTV, one study showed persistent seroresponse in patients treated with TNFi; a second study showed no difference between MTX and RTX in response to T-cell dependant protein Ag TTV.
Two studies reported no significant difference in efficiency or tolerance in patients accidentally revaccinated against yellow fever under TNFi.
Conclusions: These observations highly suggest that an effective vaccination for patients treated with MTX, RTX, and ABA should necessitate a therapeutic window or a scheduled treatment spacing, in order to offer the best protection against Influenza and Pneumococcal infection. This might not be necessary in patients under TNFi or TCZ; nevertheless, further studies are necessary to optimize the vaccination modalities.

THU0159 RHEUMATOID ARTHRITIS MAY NOT INFLUENCE EATING BEHAVIOURS CHARACTERISTICS

N. Bulut[1], M.E. Tezcan[2]. *[1]Family Medicine; [2]Rheumatology, Kartal Research and Education Hospital, Istanbul, Turkey*

Background: Patients with rheumatoid arthritis (RA) have an increased risk of obesity and cardiovascular disease compared with the general population (1). Eating behaviours may play an important role in obesity and cardiovascular disease.
Objectives: We hypothesised that RA patients have impaired eating behaviours that may have a role in obesity. For evaluating this hypothesis, we compared eating behaviours of patients with RA, osteoarthritis (OA) and healthy controls.
Methods: One hundred and fifty-seven RA patients (M/F: 23/134) who fulfilled the 2010 American College of Rheumatology (ACR) RA classification criteria, 31 hand OA patients (M/F: 1/30) who fulfilled 1990 ACR hand OA criteria and 60 healthy controls (M/F: 9/51) were enrolled to the study who applied to Kartal Dr. Lutfi Kirdar Training and Research Hospital Rheumatology outpatient clinic. Eating behaviours was assessed by the Three-Factor Eating Questionnaire (TFEQ).Demographic data, smoking status, co-morbidities, anthropometric measurements, VAS pain score were analyzed.
Results: There were no differences between three groups in demographic features and anthropometric measurements (table1). Moreover, there were no differences between three groups in cognitive restraint and emotional eating scores.Although,healthy controls had significantly higher uncontrolled eating scores than the RA group ($p<0.05$), uncontrolled eating scores of all three groups were lower than Turkish people average scores (2) (table2).

Table 1. Demographic and Anthropometric features of study groups

	RA (n=157)	OA (n=31)	Healthy Controls (n=60)	*p*
Age	51.00 (40.00–57.50)	50.00 (46.75–62.00)	48.00 (39.25–53.75)	0.06

VAS pain (0–100)	10.00 (0.00–30.00)	10.00 (10.00–30.00)	N/A	0.07

RA, Rheumatoid Arthritis; OA, Osteoarthritis; BMI, Body mass index; VAS, Visual analog score.

Table 2. Eating behaviours of study groups

	RA (n=157)	OA (n=31)	Healthy Controls (n=60)	*p*
Uncontrolled eating scores	10.00 (8.00–12.00)	10.00 (8.00–13.00)	11.00 (9.00–14.00)	0.047
Cognitive restraint scores	16.00 (13.00–18.00)	16.00 (14.00–19.00)	14.00 (11.25–18.00)	0.075
Emotional eating scores	5.00 (3.00–8.00)	5.00 (3.75–11.00)	4.00 (3.00–7.00)	0.066

Conclusions: This was the first study using the TFEQ in patients with RA. In our study, we found that disease features of RA may had no effect on eating behaviors.

THU0160 DISEASE MODIFYING ANTIRHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS WITH INTERSTITIAL LUNG DISEASE: A PROSPECTIVE STUDY

N. Mena-Vazquez[1], C. Gómez-Cano[2], C. Aguilar-Hurtado[3], M. Rojas-Giménez[1], S. Manrique-Arija[1], C. Domic[1], C. Fuego-Valera[1], I. Ureña-Garnica[1], F.G. Jiménez-Núñez[1], G. Diaz-Cordoves[1], M.V. Irigoyen-Oyarzábal[1], M. Padín-Martín[3], A. Fernández-Nebro[1]. *[1]Department of Rheumatology at the University Regional Hospital of Malaga (HRUM). Institute for Biomedical Research in Malaga (IBIMA). Malaga University., Malaga; [2]Department of Rheumatology Hospital Valme, Sevilla; [3]Department of Radiology, Malaga, Spain*

Objectives: To describe the evolution of interstitial lung disease (ILD) in RA patients treated with disease modifying antirheumatic drugs (DMARDs) for 1 year in real clinical practice conditions.
Methods: *Design:* Prospective observational case-series. *Patients:* Patients with RA (ACR/EULAR 2010 criteria) and ILD (American Thoracic Society/European Respiratory criteria) from two centres (Regional Hospital of Málaga and Valme Hospital of Sevilla) were included. *Protocol:* All patients with RA and ILD who visited outpatient clinic from January to December 2015. They were reviewed according to a predetermined protocol for systematic data collection. Resolution Computed Tomography (HRCT),Pulmonary function test (PFT) and echocardiogram were requested for all patients.This visit was marked as v0 (index date). At 12 months (v12) the joint assessment (DAS28), echocardiogram, PTF and HRCT were again evaluated. HRCT's were assessed by the same radiologist with expertise in chest radiology. *Outcomes:* At v12:(1)improvement (ie improvement in FVC$\geq$10% or DLCO$\geq$15% and no radiological progression),(2)non-progression (stabilization or improvement in FVC$\leq$10% or DLCO$<$15% and no radiological progression),(3)progression (worsening of FVC$>$10% or DLCO$>$15% and radiological progression), or (4) death due to ILD. *Variables:* Description of ILD type (Nonspecific interstitial pneumonia/Usual interstitial pneumonia) and lung function by PTF, HRCT.Presence of PTH by echocardiogram and dyspnoea.Collection of adverse events. *Statistical analysis:* Descriptive analysis and Wilcoxon or T test between the v0 and v12. One factor ANOVA between sDMARD,bDMARD and combination therapy groups.
Results: The main characteristics at V0 of the patients (n=22) are shown in the table. Seven patients (31.8%) received a sDMARDs with a bDMARDs; 12 patients (54.5%) in monotherapy with sDMARD, with MTX being the most frequent (34.7%); 3 (13.6%) in monotherapy with bDMARDs (Table 1). Three patients (13.6%) had improvement (1 with MTX, 1 with RTX and 1 with HCX + RTX), 15 patients (68.2%) remained stable (4 with MTX, 3 with LFN, 1 with HCQ, 1 AZA, 1 ABT, 1ABT + SSZ, 2 MTX + ETN, 1 HCQ + RTX, and 1 HCQ + ADA);and 3 (13.0%) got worse of ILD (1 with MTX developed unknown lung mass, 1 with LFN and 1 with LFN + IFX). One patient died during follow-up due to respiratory infection (under treatment with RTX). No patient developed PPH. We did not find significant differences between v0 DAS28 and at 12 months (2.55 [0.75] vs 2.42 [1.22], p=0.567) or in HAQ 1.15 [0.93] vs 1.25 [0.78], p=0.450). There were no significant differences in PTF, HRCT or DAS28 at v12 between sDMARD, bDMARD and combination therapy groups. Four patients (18.2%) had adverse effects: 2 respiratory infections, 1 oral herpes simplex and 1 tooth infection.

VARIABLES	Patients
Sex (Female), n (%)	12 (54.5)
Age (years), mean (DE)	69.4 (7.0)
Smoker, n (%)	4 (18.2)
Body mass index (BMI), mean (SD	28.9 (6.0)
Disease duration (months), mean (SD)	211.9 (131.5)
ILD duration (months), mean (SD)	64.5 (47.1)
Rheumatoid factor, n (%)	21 (95.5)
Anti–cyclic citrullinated peptide, n (%)	21 (95.5)
Erosions, n (%)	16 (72.7)
DAS28, mean (DE)	2.55 (0.7)
HAQ, mean (DE)	1.15 (0.9)
Treatment	
sDMARD, n (%)	19 (86.4)
Methotrexate, n (%)	8 (36.4)
Leflunomide, n (%)	5 (22.7)
Sulfasalazine, n (%)	1 (4.5)
Hydroxychloroquine, n (%)	4 (18.2)
Azathioprine	1 (4.5)
bDMARDs, n (%)	10 (45.5)
Rituximab, n (%)	4 (18.2)
Abatacept, n (%)	2 (9.1)
Etanercept, n (%)	2 (9.1)
Infliximab, n (%)	1 (4.5)
Adalimumab, n (%)	1 (4.5)

Conclusions: Most patients with RA and ILD who are receiving treatment with DMARD (82%)remained stable or improved after at least 1 year of both synthetic and biological DMARD treatment. However, a significant percentage of patients had an adverse outcome. More prospective studies with a greater number of patients are necessary to identify the influence of DMARDs in this evolution.

THU0161 SYNDECANS ARE CORRELATED WITH HIGH TITRES OF ANTIBODIES AGAINST CITRULLINATED PROTEINS ANTIGENS (ACPAS) IN SERA FROM ACTIVE RHEUMATOID ARTHRITIS

N.A. Rodriguez-Jimenez[1], E.G. Cardona-Muñoz[2], J.I. Gamez-Nava[1], E.E. Perez-Guerrero[3], M. Ponce-Guarneros[4], E.Y. Vera-Navarrete[3], A. Nava-Zavala[1], T.A. Garcia-Cobian[2], M. Salazar-Paramo[1], L. Gonzalez-Lopez[5]. *[1]UMAE, Hospital de Especialidades Centro Medico de Occidente, Instituto Mexicano del Seguro Social; [2]Universidad de Guadalajara, Guadalajara, Mexico; [3]Doctorado en Farmacologia, Universidad de Guadalajara, Guadalajara; [4]Unidad de Medicina Familiar No. 97, IMSS, Magdalena, Jalisco; [5]Hospital General Regional No. 110, IMSS, Guadalajara, Mexico*

Background: Syndecans includes a group of proteins from the cell-surface heparan-sulfate proteoglycan family, with a relevant role in chronic inflammation of synovial tissue in patients with rheumatoid arthritis (RA) participating in the cell-matrix and cell-cell interactions. Syndecans are differentially expressed in the synovial tissue: syndecan-1 (SDC-1) is expressed mainly in mononuclear cells, syndecan-3 (SDC-3) is mainly expressed by synovial endothelial cells and syndecan-4 (SDC-4) is expressed by B lymphocytes regulating B cell development and survival. Currently, there is strong evidence that antibodies directed to citrullinated protein antigens (ACPAs) are associated with a more severe disease in RA. Nevertheless, to date, there is a lack of information about the relation between serum syndecan levels and serum concentrations of rheumatoid factor (RF) and ACPAs.
Objectives: To evaluate the association between serum SDC-1, SDC-3 and SDC-4 levels with serum concentrations of RF and ACPAs.
Methods: Eighty-one, patients with RA were included. We assessed clinical characteristics including disease activity by DAS-28, functioning by HAQ-Di. Serum concentrations of RF were measured by nephelometry, two ACPAs were measured: anti-CCP2 and anti-mutated citrullinated vimentin (anti-MCV) antibodies using ELISA. Serum levels of SDC-1, SDC-3 (ng/mL) and SDC-4 (pg/mL) were measured by ELISA. We compared the serum levels of these syndecans in the ACPA+ group (group 1) versus ACPA- group (group 2) with Student t-test. A correlation analysis (Pearson tests) was performed to identify the strength of association between concentrations of syndecans with concentrations of ACPAs and other variables.
Results: Patients with RA had a mean age of 50±11 yrs, 75% were RF+ and 64% were ACPA+. In patients with ACPAs+ were observed higher serum concentrations of SDC-3 ($p=0.003$) and SDC-4 ($p<0.001$). SDC-1 correlated significantly with anti-MCV ($r=0.53$, $p<0.001$). Serum concentrations of SDC-3 correlated significantly with anti-CCP titres ($r=0.53$, $p=0.003$) and anti-MCV ($r=0.46$, $p=0.02$); whereas SDC-4 levels correlated significantly with anti-CCP titres ($r=0.61$, $p<0.001$) and RF ($r=0.53$, $p=0.003$). Additionally, serum SDC-1 levels correlated with decrement in response to treatment with synthetic DMARDs ($r=-0.25$, $p=0.026$). SDC-1 did not correlate with serum SDC-3 ($p=0.8$) and SDC-4 ($p=0.8$); whereas serum SDC-3 and SDC-4 had a strong correlation ($r=0.8$, $p<0.001$).
Conclusions: Serum SDC-3 and SDC-4 are increased in ACPA-positive RA patients. These data suggest that syndecans might be useful as serum biomarkers for discriminate a group of patients with RA and more severe disease.

THU0162 RELATIONSHIP BETWEEN LEVELS OF HUMAN PEPTIDYL ARGININE DEIMINASE-4 WITH CHRONIC PERIODONTITIS SEVERE IN RHEUMATOID ARTHRITIS

O. Vega[1], T. Rubin de Celis[1], D. Tamayo[2], R. Flores[2], A. Madariaga[3], Y. Laura[4], R. Gamboa[5]. *[1]Rheumatology, Reumacenter; [2]Medicine; [3]Dentistry, Hospital III, EsSalud; [4]Immunology, Reumacenter, Juliaca; [5]National Hospital Guillermo Almenara, Essalud, Lima, Peru*

Background: Both Peptydil arginine deiminase of *P. gingivalis* (pPAD), and the human enzyme (hPAD), could citrullinarize peptides from the bacteria and human host in Rheumatoid Arthritis patients (RA). Chronic periodontitis (CP) could be associated with a constant generation of citrullinated proteins, and it lead to a proportional hPAD enzymatic production.
Objectives: The aim was to demonstrate the association between serum levels of hPAD4 and severe Periodontitis in patients with rheumatoid arthritis.
Methods: Patients with RA (n=127) matched with healthy controls (n=120) were studied in a cross-sectional study. Levels of human recombinant antigens for hPAD4; cyclic citrullinated peptide antibody (CCP3, IgG), Rheumatoid factor (IgM) and C-reactive protein (CRP); determined by ELISA test.
The CP was classified according to the recommendations of the International Workshop for Classification of Periodontal Diseases and Conditions. Bivariate analysis to demonstrate the associations, and non-parametric analyzes were used according to the case.
Results: There were no significant demographic diffrences between the two groups. The median hPAD4 level was 1.21 (95% CI 1.4–1.7) in RA and 0.75 (95% CI 0.94–1.26) ng/ml in controls, ($p<0.004$). The median hPAD4 level in patients with RA and CP was 1.32 (95% CI 1.39–1.9) Vs control with CP 0.7 (95% CI 0.94–1.5) ng/ml, $p<0.04$.
The frequency of CP was higher in patients with RA than in controls (66.9 vs 43%, $p<0.000$; OR: 2.65 (95% CI: 1.58–4.44); these values showed a low correlation (0.24). The median level of hPAD4 was associated with CP extension, $p<0.000$ and severity, $p<0.000$.
A significant correlation was found between levels of hPAD4 with the DAS28 ESR score ($p<0.002$). The high score of HAQ-DI (>2.0) correlated with hPAD4 levels ($P<0.001$). The group of people with higher HAQ-DI score and at the same time with greater severity of CP (n=12) showed increased levels PAD4 ($p<0.025$).
Conclusions: hPAD4 levels correlate with the severity of CP independent of the RA presence and in RA subjects with high score of disability and activity disease. The hPAD4 could be proposed as a serological marker of clinical severity in chronic diseases such as CP and RA.

[a] The date when the special reimbursement for IJD came effective
[b] The time period after the index date until Dec 31st 2014
[c] Three control subjects were matched for each patient with IJD

psoriatic arthritis (PsA). However, these findings are mainly based on materials from an era of less active treatment of the IJD's and thus progress in this theory may have happened. Further, many cases fail to fulfil any classification criteria. We found no published data on CV risk in unspecified arthritis (UA).
Objectives: To investigate the association between the five most common IJDs and CHD based on a nationwide large register data in Finland during 2000–14.
Methods: From the register maintained by the Social Insurance Institution (SII), we collected data on all Finnish patients granted a new special reimbursement (SR) on medications for the following IJDs during 2000–14: seropositive RA (ICD10 code M05), seronegative RA (M06), UA (M13), spondyloarthritis (SpA) (M45–46), and PsA (L40). For these patients, Population Register Centre matched three controls, standardized for age, sex, and place of residence. The index date was determined to be the date when the SR for IJD came effective. From the case and control groups we analysed the frequency of individuals that had SR also for CHD (ICD10 codes I20–25) at the index date, or to whom it was granted by SII during the observation period.
Results: Altogether 201 776 individuals (50 444 cases and 151 332 controls) were identified. The frequencies of the individuals having CHD by the index date and the incidences of CHD during follow-up are presented in table 1.
Conclusions: Compared to general population, CHD was overrepresented at RA diagnosis, especially in seropositive men and seronegative women, while other patients had comparable rates of CHD with the population. After the index day, the incidence of CHD was increased in all patient groups except for men with seronegative RA and women with seropositive RA or SpA. Thus, the CV risk associated to IJDs remains in this millennium, and also pertains to UA.

THU0164 SUBCLINICAL ATHEROSCLEROSIS AND CARDIOVASCULAR EVENTS IN ITALIAN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM MULTICENTER GIRRCS (GRUPPO ITALIANO DI RICERCA IN REUMATOLOGIA CLINICA E SPERIMENTALE) STUDY

P. Ruscitti[1], D.P.E. Margiotta[2], L. Navarini[2], F. Macaluso[3], D. Iacono[4], F. D'Onofrio[5], G. Emmi[6], F. Atzeni[7], M. Prete[8], F. Perosa[8], P. Sarzi-Puttini[7], L. Emmi[6], F.P. Cantatore[5], G. Triolo[3], R. Giacomelli[1], G. Valentini[4].
[1]Rheumatology Section, Department of Biotechnological and Applied Clinical Science, University of L'Aquila, L'Aquila; [2]Clinical Medicine and Rheumatology Department, Campus Bio-Medico University of Rome, Rome; [3]Rheumatology Section, Department of Internal Medicine, University of Palermo, Palermo; [4]Rheumatology Section, Department of Clinical and Experimental Medicine, Second University of Naples, Naples; [5]Rheumatology Section, Department of Medical and Surgical Sciences, University of Foggia Medical School, Foggia; [6]Department of Experimental and Clinical Medicine, University of Florence, Florence; [7]Rheumatology Section, L. Sacco University Hospital, Milan; [8]Systemic Rheumatic and Autoimmune Diseases Unit, Department of Biomedical Sciences and Human Oncology, University of Bari Medical School, Bari, Italy

Background: Several studies showed a close relationship between Rheumatoid Arthritis (RA) and accelerated atherosclerosis [1,2]. At the best of our knowledge, no such study has been carried out in a large Italian series.
Objectives: To investigate the prevalence of presence of subclinical atherosclerosis and history of cardio-cerebrovascular events (CVEs), in 1266 patients consecutively admitted to Rheumatology Units throughout the whole Italy.
Methods: From 01/01/2015 to 31/12/2015, 1266 consecutive patients admitted to GIRRCS centres, satisfying ACR/EULAR criteria for RA were investigated for: i. traditional cardiovascular risk factors: gender, age, smoking habit, cholesterol, triglycerides, glycemia, systemic arterial hypertension (SAH), metabolic syndrome (MS), type 2 diabetes (T2D); ii. RA aspects: disease duration as assessed from the first symptom, disease activity as evaluated by DAS28, radiographic damage by joint X-ray, and joint surgery; iii. subclinical atherosclerosis, as assessed by ultrasound technique and/or atherosclerotic peripheral lesions; iv. history of CVEs.
Results: We evaluated 1176 patients out of 1266, that were investigated for both CVEs and subclinical atherosclerosis. They were mostly females (80.52%), with a median age of 60 years (range 18–91 years), a median disease duration of 12 years (range 0.8–25 years), seropositive in 69.21%. Nineteen percent were in remission; 17.51% presented low disease activity; 39.45% moderate disease activity, 22.61% high disease activity.
Out of 1176 patients, 217 (18%) showed evidence of subclinical atherosclerosis: a figure lower than that reported worldwide (32.7%) [2]. Eighty-two patients (6.9%) had a history for CVEs (58 myocardial infarction, 38 heart failure, 10 ischemic transitory attack, 7 Stroke), too this figure is lower than that reported worldwide (8.5%) [3,4]. In multivariate analysis, older age (p=0.0001, OR:1.069, CI95%:1.05–1.09), MS (p=0.0001, OR:3.417, CI95%:2.16–5.40) and SAH (p=0.0001, OR:3.714, CI95%:2.23–6.17) and high disease activity (p=0.001, OR:2.117, CI95%:1.35–3.32) were significantly associated with the presence of subclinical atherosclerosis. Male gender (p=0.0001, OR:3.465, CI95%:1.94–6.185), MS (p=0.005, OR:2.542, CI95%:1.29–4.52), T2D (p=0.007, OR:2.324, CI95%:1.29–4.29) and SAH (p=0.001, OR:4.921, CI95%:2.14–11.45) and higher disease activity (p=0.003, OR:1.316, CI95%:1.15–1.68) were significantly associated with a history of CVEs.
Conclusions: This is the first Italian multicenter study on subclinical and clinical atherosclerosis in patients with RA. We pointed out a low prevalence of both subclinical atherosclerosis and history of CV events. Nonetheless, a high disease activity and presence of cardiovascular risk factors were found to play a role, similarly to other countries.

THU0165 RISK OF HERPES ZOSTER IN PATIENTS WITH RHEUMATOID ARTHRITIS IN THE BIOLOGICS ERA BASED ON THE IORRA COHORT

R. Yamaguchi[1], A. Nakajima[1], E. Inoue[2], M. Ochiai[1], Y. Shimizu[1], N. Sugimoto[1], E. Tanaka[1], K. Ikari[1], A. Taniguchi[1], H. Yamanaka[1]. *[1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan; [2]National Center for Child Health and Development, Center for Clinical Research for Development, Tokyo, Japan*

Background: A high incidence of herpes zoster (HZ) in patients with rheumatoid arthritis (RA) has been reported (1). According to our previous report on the incidence of HZ in Japanese patients with RA enrolled in the IORRA (Institute of Rheumatology, Rheumatoid Arthritis) cohort from 2005 to 2010, the standardized incidence rate (SIR) of HZ per 1,000 patient-years was 9.1 (95% confidence intervals [95% CIs]: 6.2–12.9) (2). In that study, 3.0% of patients used biologics at baseline. Subsequently, the use of biologics has increased, and many new potent disease-modifying antirheumatic drugs (DMARDs) have been introduced. The treatment strategy for RA has progressed in recent years; thus, it is important to investigate whether there is a change in the HZ incidence rate and the risk factors for HZ with the expanded use of biologics.
Objectives: To elucidate the incidence of HZ and risk factors for HZ in RA patients in the IORRA cohort.
Methods: The IORRA cohort is a large, single institute-based, observational cohort of RA patients established at the Institute of Rheumatology, Tokyo Women's Medical University, in 2000. Among patients with RA enrolled in the IORRA surveys from 2010 to 2015, the incidence of HZ was extracted based on patients' self-report and confirmed by the medical records. The SIR with 95% CIs was calculated and risk factors for HZ were analyzed using a Cox regression analysis.
Results: For 7,815 patients with RA (female, 84.7%) who were analyzed, the median [interquartile range (IQR)] age was 61.0 [49.7–68.9] years, and disease duration was 10 [4–18] years. Baseline drugs (median dose [IQR]) included prednisolone (PSL, 4 [2–5] mg/day) in 36.8%, methotrexate (MTX, 8 [6–10] mg/week) in 70.4%, and biologics in 14.7% of patients. Among 7,815 patients with 25,863 patient-years of observation (male, 3,828; female, 22,035), 340 HZ events were confirmed in 309 patients (21 patients had multiple events). The SIR per 1,000 patient-years was 8.5 (95% CI: 6.9–10.5) in total, 6.0 (95% CI: 3.7–9.2) in males, and 11.0 (95% CI: 8.7–13.7) in females. The following hazard ratios (HR) were found: unit increase of age, 1.14 (95% CI: 1.03–1.26, $p<0.05$); J-HAQ score 0.5–1.5 (reference J-HAQ score =0), 1.51 (95% CI: 1.09–2.10, $p<0.05$); MTX use, 1.58 (95% CI: 1.06–2.36, $p<0.05$); and biologics use, 1.88 (95% CI: 1.44–2.47, $p<0.01$). PSL use was not a risk factor (PSL dose <5 mg/day: HR 1.17 [95% CI: 0.91–1.51, p=0.22]; PSL dose $\geqq$ 5 mg/day: HR 1.17 [95% CI: 0.72–1.91, p=0.52]; the reference PSL dose =0 mg/day).
Conclusions: The drugs that were a risk factor for HZ were PSL and MTX in our previous study when the use of biologics was not prevalent. In this study, the drugs that were a risk factor for HZ were MTX and biologics, but not PSL in the era when the use of biologics became frequent.

THU0166 COMPARISON OF THE RISK OF COMORBIDITIES BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS AND DIABETES MELLITUS USING JAPANESE HEALTH INSURANCE DATABASE

R. Sakai[1], S. Kasai[2], M. Tsutsumino[1], H. Yamanaka[1], N. Miyasaka[3], M. Harigai[1]. *[1]Division of Epidemiology and Pharmacoepidemiology in Rheumatic Diseases, Institute of Rheumatology, Tokyo Women's Medical University; [2]Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University; [3]Tokyo Medical and Dental University, Tokyo, Japan*

Background: Patients with rheumatoid arthritis (RA) have a higher risk of comorbidities such as infections[1], cardiovascular diseases[2], and fractures[3] than general population. To understand the risk of these comorbidities in RA more precisely, it is needed to compare the risk between RA and other chronic diseases. A Dutch study[4] showed that patients with RA had comparable risk of cardiovascular diseases to diabetes mellitus (DM). Because of possible racial or ethnic difference of risks of comorbidities, it is warranted to compare the risk between RA and DM in Asian countries.
Objectives: To compare risk of hospitalized infections (HIs), cardiovascular diseases and stroke (CVDs), and fractures between RA and DM cases using Japanese health insurance database.
Methods: This retrospective longitudinal population-based study was conducted using claims data provided by the Japan Medical Data Center Co., Ltd. We defined individuals as RA cases if they met all of the following: 1) had at least 6 months of continuous enrollment in the health insurance database; 2) had at least one RA diagnostic code and at least one prescription of disease-modifying antirheumatic drugs between January 2005 and December 2013; and 3) were ≥50 years old (RA group, n=3,607). Among individuals who met above criteria 1) and had at least DM diagnostic code and at least one prescription of drugs for DM, but did not meet 2), we selected age- (±5 years), gender-, calendar year of the observation start, and observation length-matched DM cases at 1:3 ratio (RA: DM) (DM group, n=10,821). Each comorbidity was defined as follows: HIs, at least one ICD10 code and one prescription of drugs for infections with hospitalization; CVDs, at least one ICD10 code and one prescription of drugs or medical procedures for CVDs with hospitalization; fractures, at least one ICD10 code for fractures. We calculated incidence rates (IR) with 95% confidence interval (CI) of each comorbidity in the two groups up to 10 years and adjusted odds ratio (OR) of RA compared with DM for each comorbidity using generalized estimating equation.
Results: The median age was 58, and 75.1% were female in the both groups. The IR [95% CI] of HIs, CVDs, and fractures was 2.8 [2.5–3.2]/100 patient years (PY), 9.2 [7.4–11.4]/1,000 PY, 16.7 [14.2–19.6]/1,000 PY in the RA group, 2.8 [2.6–3.0]/100PY, 26.3 [24.4–28.3]/1,000PY, 10.3 [9.1–11.6]/1,000PY in the DM group respectively. The OR [95% CI] of RA (vs. DM) for HIs, CVDs, fractures was 0.9 [0.8–1.1], 0.4 [0.3–0.6], 1.3 [1.0–1.7] after adjusting for baseline characteristics.
Conclusions: This study revealed that patients with RA had significantly lower risk of CVDs than and similar risk of HIs and fractures to those with DM using health insurance database for the first time in Asia.

THU0167 ASSOCIATION OF BIOLOGIC ANTIRHEUMATIC THERAPY WITH THE RISK OF DEVELOPING TYPE 2 DIABETES IN ADULTS WITH RHEUMATOID ARTHRITIS: NEW EVIDENCE FROM REAL WORLD DATA

S.K. Paul[1], O. Montvida[2], J.H. Best[3], S. Gale[3], A. Pethoe-Schramm[4], K. Sarsour[3]. *[1]University of Melbourne, Melbourne; [2]QIMR Berghofer Medical Research Institute, Brisbane, Australia; [3]Genentech, South San Francisco, CA, United States; [4]F. Hoffmann-La Roche, Basel, Switzerland*

Background: While rheumatoid arthritis (RA) has been associated with the increased risk of developing type 2 diabetes mellitus (T2DM), few basic science studies have indicated the possible beneficial role of some biologic disease-modifying antirheumatic drugs (bDMARDs), including the interleukin-6 (IL-6) based DMARDs, on insulin resistance in patients with RA.
Objectives: To evaluate the impact of treatment with bDMARDs, including the IL-6 inhibitors, on the probability of developing T2DM in a real world setting.
Methods: From the Centricity Electronic Medical Records of GE Healthcare, a longitudinal cohort of 192,509 US adults (age≥18 years) with diagnosis of RA from January 2000 to April 2016 was selected. Patients were excluded if they had a prior history of diabetes, cancer and micro- or macro-vascular diseases at diagnosis of RA. Four mutually exclusive antirheumatic treatment groups (TGs) were identified by diagnosis date (Dx) and treatment initiation date (ID): tocilizumab (TCZ, n=843), TCZ+Other bDMARDs (TCZ+obDMARD, n=2489), non-TCZ other bDMARDs (obDMARD, n=45,262) and no bDMARD (n=143,915). Within the treatment groups, 142,225 patients had a minimum 6 months of exposure before development of T2DM or end of follow-up. Treatment-effects regression models were used to estimate the probabilities (95% CI) of developing T2DM during follow-up in the 4 TGs after adjusting and balancing with inverse-probability-weighted regression for various factors including age, sex, smoking status, body mass index, use of non-biologic DMARDs, use of statins, anaemia status and follow-up time post ID.
Results: At diagnosis, the 142,225 patients were on average 55 years old, 22% male, 71% white Caucasian, 13% with anaemia, and 32% obese with mean BMI of 29 kg/m^2. About 28%/42% were using statins/MTX at diagnosis or during follow-up before development of T2DM. During mean 4.6 years of follow-up from Dx, 2.6%/2.6%/5.3%/5.8% developed T2DM in the TCZ/TCZ+obDMARD/obDMARD/no bDMARD TGs. The adjusted probability of developing T2DM was 0.05 (95% CI: 0.04, 0.05) in no bDMARD group; with significantly lower probability of developing T2DM in TCZ [0.02 (95% CI: 0.01, 0.04)], TCZ+obDMARD [0.03 (95% CI: 0.02, 0.04)] and obDMARD [0.01 (95% CI: 0.01, 0.02)] groups (Table). Hypertension, higher BMI and Statin use were associated with significantly higher probability of developing T2DM by 0.25 (95% CI: 0.16, 0.35), 0.08 (95% CI: 0.07, 0.08) and 0.36 (95% CI: 0.27, 0.47) respectively. Patients with anaemia had 8% higher likelihood of developing T2DM (p=0.13). Among those who received any bDMARD, those who ever received TCZ had significantly lower probability of developing T2DM (0.024, 95% CI: 0.02, 0.03), compared to those who were never exposed to TCZ therapy.

Table: The probability of developing T2DM, adjusted by age, sex, BMI, anaemia; balanced on hypertension, follow-up, obDMARDs and statin usage.

	Probability (95% CI)	Difference (95% CI)
No bDMARD	0.046 (0.045, 0.048)	–
obDMARD Only	0.041 (0.039, 0.044)	-0.005 (-0.008, -0.002)
TCZ Only	0.025 (0.006, 0.043)	-0.022 (-0.04, -0.003)
TCZ+obDMARD	0.018 (0.01, 0.026)	-0.029 (-0.037, -0.02)
Among those who received any bDMARDs		
No TCZ	0.046 (0.044, 0.049)	–
TCZ	0.023 (0.017, 0.029)	-0.024 (-0.03, -0.017)

Conclusions: This study indicates the possible beneficial role of IL-6 inhibitors (TCZ) in reducing the likelihood of developing T2DM among adults without major co-morbidities at diagnosis of RA.

Rheumatoid arthritis - non biologic treatment

THU0168 PATIENTS' POSITIVE BELIEFS AND CERTAINTY PREDICT METHOTREXATE ADHERENCE IN A RHEUMATOID ARTHRITIS COHORT: THE RAMS STUDY

H.F. Hope[1], K. Hyrich[2], F. Varney[3], S. Wilkes[3], S.M. Verstappen[2], L. Cordingley[4]. *[1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Centre for Musculoskeletal Research; [2]Arthritis Research UK Centre for Epidemiology; [3]Division of Psychology and Mental Health; [4]Centre for Musculoskeletal Research and Dermatological Science, University of Manchester, Manchester, United Kingdom*

Background: Living with RA confers substantial uncertainty about the long-term outcomes of the disease and the occurrence of possible medication associated adverse events (ADEs). This latter uncertainty may be particularly apparent when new therapies are initiated and reduce patient adherence.
Objectives: The aim of this study was to evaluate whether patients' negative and/or uncertain illness beliefs during methotrexate (MTX) therapy are associated with adherence.
Methods: This was a sequential mixed-methods design study using data from the Rheumatoid Arthritis Medications Study (RAMS). RAMS is a 12 month observational study in the UK recruiting patients with RA commencing MTX for the first time. Clinical and demographic data were collected at baseline and patients were asked to complete a weekly diary recording MTX intake (adherence) and reasons for not taking MTX. In addition there was a free text section in the diary where patients could comment about any aspect of their disease or care. Six month diary data were used for the purpose of this study.Patients were categorised as non-adherent if the proportion of adherent weeks was <90%.
Phase 1:Using a random sample (n=50/417) of patient diaries with free text comments a coding system was developed to categorise illness events and beliefs contained in these data. Inter-rater reliabilities for codes rated by three judges were calculated using intraclass correlation coefficients (ICC) and unreliable codes (ICC<0.6) dropped.
Phase 2:179 of 200 diaries from adherent and non-adherent individuals were randomly selected, coded and categorised into illness belief profiles (IBPs) by three researchers blind to adherence data.Univariate logistic regression analyses adjusted for age and gender were used to investigate the association between IBPs and MTX non-adherence behaviour (<90% adherence).
Results: Phase 1: ten codes with ICCs ranging from 0.6–1.0 were used to create three IBPs (Table):"Positive & Certain" (PC), "Negative & Certain" (NC) and "Negative and Uncertain" (NU) (Fig.).
Phase II, the median age of the sample was 62 [51.8–65.6] years, 67% were women and the median disease activity score was 4.3 [3.4–5.2]. Being PC lowered the odds of non-adherence (OR 0.32, 95% CI 0.12–0.85), being NU increased the odds of non-adherence (OR 2.7, 95% CI 1.0–7.0), but being NC didn't associate with non-adherence during the first six months of therapy (OR 0.98, 95% CI 0.31–3.2).

Table 1. The reliability (ICC) of codes that contribute to the IBPs

IBP	Codes	ICC (95% CI)
Positive	Treatment response	0.73 (0.60–0.83)
	ADE cessation	0.79 (0.68–0.87)
	Positive emotion	0.77 (0.65–0.85)
	Positive attribution	0.60 (0.44–0.74)
Negative	Disease flare	0.93 (0.89–0.96)
	ADE	0.81 (0.71–0.88)
	Severity attribution	0.62 (0.46–0.75)
	Negative emotion	0.81 (0.71–0.89)
	Negative attribution	0.81 (0.71–0.88)
Certainty/Uncertainty	Certainty/Uncertainty	1.0 (1.0–1.0)

Positive & Certain (N=89)	Negative & Certain (n=148)	Negative & Uncertain (n=35)
"Pain has reduced in my joints this week"	"Methotrexate too strong, however in lot of pain in knees"	"I think the cramp may be the HCQ not the MTX"
"Can write with right hand"	"Pain is still unbearable and (MTX) not working"	"It may be the flu injection what has give me side effect"\
"Wrists much less painful"	"Ankle and wrist still painful and inflamed"	"Fingers and wrist quite painful & lots of pins and needles. Due to heat?"
"Not feeling any side effects"	"Methotrexate had no effect at all at this stage"	"Upset stomach, ate out, so could have been that?"
"Feeling better this week"	"Same as last week seems to be worse"	"Swelling of wrist-knee don't know if tabs caused it"
"Almost all pain gone - whoopee!"	"Stomach ache and nausea much worse after every meal"	"Difficult to tell if MTX side effects, still ill"

Figure. Examples of patient comments that contributed to each IBP

Conclusions: People who are uncertain about how to attribute illness events are less likely to adhere within the first six months of starting MTX therapy. Encouraging patients to actively monitor their progress with therapy and providing them with support to understand likely effects of MTX may help optimise DMARD use.

THU0169 ONE-THIRD OF PATIENTS WITH RHEUMATOID ARTHRITIS ELIGIBLE FOR A FIRST BIOLOGIC ARE NOT ADHERENT TO METHOTREXATE: RESULTS OF FORGET, A CROSS-SECTIONAL SURVEY OF 244 PATIENTS

C. Beauvais[1], V. Hautin-Monteil[2], M.-C. Ducrot[3], R.-M. Flipo[4]. *[1]Rheumatology Department, Saint Antoine Hospital, APHP, Paris; [2]Roche; [3]Agence A+A, Boulogne-Billancourt; [4]Rheumatology department, Roger Salengro Hospital, Lille, France*

Background: Adherence to Methotrexate (MTX) is not optimal in patients with rheumatoid arthritis (RA)[1]. Low adherence may lead to insufficient response and unjustified initiation of biologics.
Objectives: The objectives were 1-assess the self-reported adherence rate to MTX of RA patients insufficient responders to MTX (MTX-IR) when an initiation of biologics was being considered 2- Investigate the factors of low adherence among these patients 3- collect the physicians' estimation of their patients' adherence level.
Methods: Patient recruitment was done through rheumatologists: RA patients, MTX-IR, biologic-naive, eligible for a biologic according to the rheumatologist's opinion. The rheumatologist completed a questionnaire on his practice and estimation on the patient's level of adherence and provided the patient with a self-administered questionnaire on his disease and treatments, to be sent directly to the data center. The patient's questionnaire contained the CQR19 (Compliance Questionnaire for Rheumatology [2]. The purpose of assessing adherence was not specified to the patient.
Results: From May to July 2016, 78 rheumatologists recruited 269 patients who referred 244 self-administered questionnaires, 214 assessed for CQR 19 score; 200 questionnaires were completed by both patients and their rheumatologist. Patients were 72% women, mean age 54 years, 58% had at least 1 comorbidity, mean DAS28 score 4.07, mean RAID score 5.7/10. The percentage of non-adherent patients was 34%: adherence rate <80% according to the CQR.
Non-adherent patients had a higher RAID score (5.7 vs 5.0; p<0.01) whereas DAS 28 was not significantly different (4.14 vs 4.04). They more often presented osteoporosis (18% vs 4%, p<0.01), reported reluctance to take treatment (40% vs 24%, p<0.01), had more negative beliefs (40% vs 24%; p<0.01), and poor support from relatives (67% vs 84%, p<0.011). Good-adherent patients were more often followed in a private practice (31% vs 10%, p<0.01) and reported more information received from their rheumatologist (94% vs 85%, p<0.05). No correlation was found between adherence and age, subcutaneous versus oral route of administration or perceived tolerance.
88% of rheumatologists reported they detect adherence at every consultation, asking direct (76%) or open (46%) questions. Adherence was underestimated by rheumatologists: a 67% concordance was found between the rheumatologist's rating and the patient's reported adherence. Non-adherent patients to MTX were more often proposed biologic treatment in combination with MTX than patients with good compliance (91% vs 68%, p<0.01).
Conclusions: This survey showed for the first time that 34% of MTX-IR patients show poor adherence to MTX at the time of the initiation of a first biologic. Negative beliefs and poor support from relatives are factors of non-adherence. Studies will be needed to understand physicians' attitudes toward non-adherence and what strategy of biologics prescription they are likely to consider.

THU0170 OUTCOMES OF THE RAPID DOSE ESCALATION OF METHOTREXATE IN JAPANESE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS; RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

M. Tsutsumino[1], R. Sakai[1], M. Kihara[2], K. Amano[3], R. Yoshimi[4], M. Inoo[5], H. Dobashi[6], T. Sugihara[7], T. Hidaka[8], H. Kohsaka[2], N. Miyasaka[2], M. Harigai[1]. *[1]Tokyo Women's Medical University; [2]Tokyo Medical and Dental University, Tokyo; [3]Saitama Medical Center, Saitama; [4]Yokohama City University School of Medicine, Yokohama; [5]Utazu Hospital; [6]Kagawa University, Kagawa; [7]Tokyo Metropolitan Geriatric Hospital, Tokyo; [8]Shiminnomori Hospital, Miyazaki, Japan*

Background: Methotrexate (MTX) is the anchor drug for treatment of rheumatoid arthritis (RA), but tolerance to MTX is substantially different across ethnics and few studies have assessed efficacy and safety of rapid dose escalation regimen of MTX in Japanese patients with early RA.

Objectives: To evaluate outcomes of rapid dose escalation regimen of MTX compared with conventional treatment.
Methods: We implemented a randomized, controlled trial that enrolled patients with RA who fulfilled all of the following criteria: 20 to 70 years-old, disease duration ≤2 years, SDAI ≥11, and without prior use of MTX, tacrolimus (TAC) or biologics. Patients were randomized into rapid escalation (RE) group or conventional treatment (CT) group at 1:1 ratio. In RE group, doses of MTX were escalated up to 0.25 mg/kg/wk within 8 wks after start of MTX and increased maximum tolerable dose or 16 mg/wk until wk 12. If a patient achieved SDAI remission at wk 12, MTX was continued at the same dose. If a patient did not achieve SDAI remission at wk 12 or showed intolerance to MTX, use of TAC or TNF inhibitor (TNFi) were allowed. In CT group, patients were treated with either MTX, TAC, salazosulfapyridine, or bucillamine by the discretion of physicians until wk 12. If a patient achieved SDAI remission at wk 12, same treatment was continued. If a patient did not achieve remission at wk 12, use of TNFi was allowed. Patients were treated by the discretion of physicians at wk 24 and onward. We set two primary endpoints; the percentage of patients achieving SDAI remission and Boolean remission at wk 24. We planned to enroll 120 patients per arm based on expected SDAI remission rates at wk 24, alpha and beta errors and dropout rates.
Results: Enrollment was terminated prematurely and all patients were followed for 48 wks. Of 115 enrolled patients, 57 were randomly assigned to RE group and 58 to CT group. Baseline demographics were similar between the two groups. The median baseline values (RE vs. CT) were 24.9 and 25.9 for SDAI, 0.88 and 0.69 for HAQ, and 0.64 and 0.61 for EQ-5D, respectively. At wk 24, the percentages of patients achieving remission in RE and CT groups were 42% and 28% by SDAI criteria (p=0.1, χ^2 test), and 35% and 17% (p=0.03, χ^2 test) by Boolean criteria, respectively. Median values of HAQ at wk 24 in RE and CT groups were 0 and 0.13 (p=0.096, M-W U test), and those of EQ-5D were 0.78 and 0.77 (p=0.12, M-W U test), respectively. At wk 48, these values were not statistically different between the two groups. There were no significant differences between the two groups with incidence of severe adverse events.
Conclusions: The rapid dose escalation regimen of MTX provided significantly superior Boolean remission rate and tended to provide superior SDAI remission than conventional treatment in patients with early RA in the short term.

THU0171 INCREASED FUNCTIONAL ACTIVITY OF FOXP3+REGULATORY T CELLS IN THE PERIPHERAL BLOOD OF DMARDS-NAÏVE METHOTREXATE-TREATED PATIENTS WITH EARLY RA USING

A. Avdeeva[1], Y.P. Rubtsov[2], T.V. Popkova[1], D.T. Diykanov[2], E.L. Nasonov[1]. *[1]Nasonova Research Institute of Rheumatology; [2]Lomonosov Moscow State University, Moscow, Russian Federation*

Objectives: To analyze the effect of methotrexate (MT) therapy on the percentage and absolute number of FoxP3+ regulatory T (Treg) cells in the peripheral blood of MT-naïve patients (pts) with early RA we used Treg immunostainingwith antibodies to surface markers and Foxp3 with subsequent flow cytometric analysis
Methods: 45 MT-naïve pts with early RA (39 females, Me;IQR age 52.0 (32.5–57.5) years, RA duration 5 (4–6) months, DAS 28 5.01 (4.18–5.8), RF positive -71.1%, ACPA - positive-88.9%) were included into the study. All pts were administered subcutaneous MT as the first-line DMARD at 10 mg/week with rapid dose escalation up to 20–25 mg/week. Human blood mononuclear cells were isolated from whole venous blood by Ficoll–Hypaque centrifugation and subjected to multicolor flow cytometry analysis. Tregs were stained for different surface markers, and proportions of marker-positive subsets (FoxP3+CD25+; CD152+surface; CD152+intracellular; FoxP3+CD127-; CD25+CD127-; FoxP3+ICOS+; FoxP3+CD154+; FoxP3+CD274+) were determined; 20 healthy donors made the control group
Results: After 24 weeks of MT therapy value DAS 28 was 3.1 (2.7–3.62); SDAI 7.4 (4.2–11.4); DAS 28 remission/low disease activity was achieved in 22 (56.4%) pts, based on SDAI – in 25 (64.1%) pts; while MT failure based on EULAR response was documented in 4 (10.3%) pts. Lower percentages of FoxP3+CD25+ cells ((5.53 (4.09–6.48 vs 6.92 (5.84–7.96)), percentages and absolute number of FoxP3+ICOS+ cells ((6.91 (2.14–11.47) vs 10.83 (9.27–13.7); 0.0035 (0.0013–0.0067) vs 0.0068 (0.0039–0.009)), and percentages and absolute number of FoxP3+CD154+ cells ((0.47 (0.19–0.83) vs 1.51 (1.12–2.08); 0.0002 (0.00009–0.0005) vs 0.00087 (0.00047–0.0014)), and FoxP3+CD274+ T-cells (0.63 (0.34–1.49) vs 1.94 (1.16–2.25); 0.0003 (0.0002–0.00065) vs 0.001 (0.0006–0.0016), $p<0,05$ in all cases) were documented in early RA pts versus healthy donors.
An increase in the percentage of CD4+cells (from 45.0 (38.0–49.2) to 46.8 (39.9–53.2)); an increase in the relative and absolute number of CD152+surface 0.65 (0.22–1.67) vs 2.07 (1.11–3.81); 0.0002 (0.0001–0.0008) vs 0.0007 (0.0004–0.002); and moderate decrease in the relative and absolute number of FoxP3+ICOS+ cells 5.3 (2.1–11.3) vs 4.1 (1.6–6.6); 0.002 (0.001–0.006) vs 0.0015 (0.0006–0.003), $p<0.05$ in all cases, was registered after 24 weeks of MT therapy. After 24 weeks of MT therapy the level of CD152+surface in the RA pts group was higher compared with healthy donors 2.1 (1.11–3.81) and 0.51 (0.34–1.2); 0.0007 (0.0004–0.002) and 0.0003 (0.00014–0.0008), respectively, $p<0.05$
Treg levels and phenotype were analyzed in pts groups based on MT efficacy by 24th week of treatment. Higher percentages and absolute number of FoxP3+CD274+ cells (1.25 (0.43–2.3) 0.0004 (0.0002–0.001) were detected in patients achieving SDAI remission (n=25), compared to pts with moderate disease activity (SDAI>11 n=14) (0.44 (0.2–0.69) 0.00016 (0.0001–0.0004), $p<0.05$)
Conclusions: MT therapy in early RA pts results in increased Treg suppressor activity according to growing percentages and absolute number of CD152+surface and FoxP3+CD274+ cells, more pronounced among pts, achieving remission/low disease activity following treatment. Increased levels of these markers are indicative of improved Tregs functional activity after successful MT therapy

THU0172 IMPROVEMENT OF DISEASE ACTIVITY IN A 5-YEAR COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS AND A MULTISPECIALITY CARE MODEL RECEIVING CONVENTIONAL DMARD THERAPY

P. Santos-Moreno[1], D. Gomez[1], E. Castillo[1], R. Giraldo[1], G. Ballesteros[1], L. Villarreal[2], J. Bello[3], D. Buitrago-Garcia[3]. *[1]Rheumatology; [2]Psychology and processes; [3]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

Background: Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA), this strategy has become recognized as a standard of good practice embodying the principle that rapid attainment of remission, or low disease activity, can halt joint damage and maintain good quality of life.
Objectives: The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 5 year period in patients with conventional DMARD therapy in a large cohort of patients from a Colombian specialized in RA center with multidisciplinary care model (MCM).
Methods: A descriptive dynamic cohort study was performed. Records of patients using conventional DMARD treatment from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. MCM model means that every patient is seen by the other specialties involved in care as a minimum three times a year. We divided patients in three groups: low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
Results: We included 1443 patients, 84% were women and 16% were men. Mean age was 62±11 years; mean DAS28 at beginning was 4.0±1; regarding disease activity 57% were in moderate disease activity and 17% in severe disease activity. While at 5 year follow up mean DAS was 2.92±0.65, 48% achieved remission, 30% low disease activity, with decrease to 20% in moderate disease activity and 2% in severe disease activity.

ACTIVITY LEVEL	TIME 0 n(%)	2012-2013 n(%)	2013-2014 n (%)	2014-2016 n (%)
REM	-	380(26%)	530(37%)	698(48%)
LDA	380 (26%)	495(34%)	487(34%)	437(30%)
MDA	782 (54%)	439(30%)	401(28%)	284(20%)
SDA	281 (19%)	129(9%)	25(2%)	24 (2%)

Conclusions: There is a significant improvement of DAS28 in a cohort of RA

patients receiving only conventional DMARDs therapy, treated and followed under T2T strategy recommendations and a MCM model.

THU0173 LONG TERM SAFETY AND EFFICACY OF FILGOTINIB IN A PHASE 2B OPEN LABEL EXTENSION STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS UP TO 144 WEEKS

R. Alten[1], R. Westhovens[2], A. Kavanaugh[3], M. Genovese[4], K. Winthrop[5], M. Greenwald[6], L. Ponce[7], F. Enriquez[8], M. Stanislavchuk[9], M. Mazur[10], A. Spindler[11], R. Cseuz[12], N. Nikulenkova[13], M. Glowacka-Kulesz[14], I. Szombati[15], A. Dudek[16], L. Meuleners[17], C. Tasset[17], P. Harrison[17], A. Van der Aa[17]. *[1]Schlosspark-Klinik, Berlin, Germany; [2]University Hospitals, Leuven, Belgium; [3]University of California, la Jolla; [4]Stanford University School of Medicine, Palo Alto; [5]Oregon Health and Science University, Portland; [6]Desert Medical Advances, Palm Springs, United States; [7]Cons. Priv., Temuco, Chile; [8]Clinstile SA de CV, Col.Roma, Mexico; [9]Vinnitsya Reg Clin Hosp, Vinnitsya, Ukraine; [10]IMSP Inst. de Cardiologie, Chisinau, Moldova, Republic of; [11]Centro Méd. Priv. Reum., Tucumau, Argentina; [12]Revita Reumatológiai Kft, Budapest, Hungary; [13]Vladimir Reg Clin Hosp, Shosse, Russian Federation; [14]Silesiana Centrum Medyczne, Wroclawska, Poland; [15]Qualiclinic Kft, Budapest, Hungary; [16]AMED Medical Center, Warsaw, Poland; [17]Galapagos NV, Mechelen, Belgium*

Background: Filgotinib (GLPG0634, GS-6034) is an oral JAK1 selective inhibitor with a favorable safety and efficacy profile in two 24-week Phase 2b studies as add-on to methotrexate (DARWIN 1) or as monotherapy (DARWIN 2) in patients with active rheumatoid arthritis (RA). Three daily doses were tested (50mg, 100mg or 200mg) in comparison to placebo.
Objectives: To assess long term safety and efficacy of filgotinib 200mg daily in patients from the DARWIN 3 Phase 2 open-label extension study.
Methods: Patients who completed DARWIN 1 or 2 and enrolled in DARWIN 3 received filgotinib 200mg once daily or 100mg twice daily, depending on prior treatment assignment. The DARWIN 3 data cut off was when the last patient reached extension Week 60. For safety, all data from the first intake of filgotinib in DARWIN 1/2/3 were analysed (up to 144 weeks).
Results: 877 patients participated in DARWIN 1 or 2, 790 completed and 739 entered DARWIN 3 from 22 countries (82% females, mean age 53y). 559 patients (75.6%) completed Week 60, 9.3% discontinued due to positive Quantiferon, 7.8% due to other adverse events, 6.8% for other reasons and 0.3% due to insufficient response. Overall exposure to filgotinib was 1314 patient-years (PYE). Treatment-emergent adverse events (157.7/100PYE), serious adverse events (5.3/100PYE) and serious infections (1.9/100PYE) occurred at similar rates compared to the core studies, however infections decreased on a percentage basis from 15% (109/739, W0–12) to 5% (25/549, W85–96). 16 cases of Herpes zoster were reported (1.2/100PYE), 6 cases of malignancy (excl. NMSC) (0.5/100PYE) and 1 case of MACE (0.1/100PYE). There was no active case of tuberculosis. Three fatalities were reported (0.2/100PYE). Mean change from baseline (CFB) at Week 96 and CTCAE toxicity grading in lab parameters of special interest are shown in table 1.

Table 1. Mean CFB at Week 96 and CTCAE toxicity grading of selected lab parameters

	Mean CFB	CTCAE Grade 3–4 (%)
Hb	+6.5 g/L	0.4
Neutrophils	–1.73 giga/L	1
Lymphocytes	–0.19 giga/L	2
Creatinine	+8.2 μmol/L	0
ALT	+6.1 U/L	0.4
LDL	+13%	–
HDL	+23%	–
Tot chol/HDL	–4%	–
NK cells	–0.02 giga/L	–

Based on an observed case analysis 84% (505/601), 65% (389/601), 44% (267/601) and 51% (299/587) of patients reached ACR20, ACR50, ACR70 and DAS28(CRP) remission at Week 60 respectively.
Conclusions: With 1314 patient-years of exposure, the safety profile of filgotinib appears consistent with that of previously reported double-blind studies and the clinical response appears durable.

THU0174 DRUG RETENTION OF TOFACITINIB VERSUS BIOLOGIC ANTIRHEUMATIC AGENTS IN RHEUMATOID ARTHRITIS: OBSERVATIONAL DATA FROM THE SWISS SCQM REGISTRY

A. Finckh[1], L. Herzog[2], A. Scherer[2], J. Dudler[3], B. Moeller[4], A. Ciurea[5], R. Mueller[6], P. Hasler[7], P. Exer[8], I. von Muehlenen[8], D. Kyburz[9], C. Gabay[1], P. Zufferey[10] on behalf of the Physicians of the SCQM. *[1]HUG, Geneva; [2]SCQM Foundation, Zurich; [3]HFR, Fribourg; [4]Inselspital, Bern; [5]USZ, Zurich; [6]KSSG, St Gallen; [7]KSA, Aarau; [8]Rheuma-Basel Practice; [9]USB, Basel; [10]CHUV, Lausanne, Switzerland*

Background: The oral Janus kinase inhibitor tofacitinib (Tofa) was licensed in Switzerland in 2013 for the treatment of moderate to severe rheumatoid arthritis (RA) patients having failed methotrexate. Besides Tofa, rheumatologists in Switzerland have the choice between 7 alternative bDMARDs licensed with similar indications, including 5 TNF inhibitors (TNFi) and 2 bDMARDs with other modes of action (OMA-bDMARDs).
Objectives: To compare the drug retention rate of three alternative treatment options licensed with a similar indications, namely Tofa, TNFi and OMA-bDMARDs, using data from the Swiss registry.
Methods: This is an observational cohort study within the Swiss Clinical Quality Management registry (SCQM). All therapies with Tofa, TNFi, and OMA-bDMARDs initiated in adult RA patients between August 1, 2013 and Dec 1, 2016 were considered. The exposure of interest was treatment with Tofa vs TNFi and vs OMA-bDMARDs (Abatacept or Tocilizumab). The primary outcome was drug retention defined as the time from initiation to discontinuation of treatment. We used Kaplan Meier curves to display drug retention and Cox proportional hazard models stratified by seropositivity to analyze the hazard for treatment discontinuation. We adjusted for potential confounders, including gender, age, disease duration, seropositivity, BMI, smoking status, DAS28-CRP and the total number of previous bDMARDs. We applied multiple imputation to account for missing baseline covariate data.
Results: A total of 1996 therapies were initiated during the study period (376 Tofa, 928 TNFi, 692 OMA-bDMARDs). Some differences in disease and treatment characteristics existed between the 3 groups, in particular TNFi tended to be used in patients with fewer previous bDMARDs experience, younger age and shorter disease duration. The crude overall drug retention was similar between the 3 three drug groups (p=0.24) (Figure 1A). The adjusted analysis demonstrated a slightly higher hazard of drug discontinuation with TNFi compared to Tofa [HR 1.27 (95% CI: 1.02 – 1.57, p=0.03)], while no difference was observed for OMA-bDMARDs and Tofa [HR 1.03 (95% CI: 0.83 – 1.28, p=0.76)] (Figure 1B). Complete case results were consistent with results using multiple imputation of baseline covariates. Other variables significantly associated with drug discontinuation were a higher number of previous bDMARDs (p <0.001) and increasing BMI values (p=0.03), while combination therapy with sDMARDs tended to decrease discontinuation (p=0.08)

Conclusions: The results of this observational study suggest that Tofa is a valuable alternative to treatment options in RA, with Tofa drug retention at least comparable to other available bDMARDs.

THU0175 INFLAMMATION DETECTED WITH MODERN SENSITIVE MRI ANALYSIS DEMONSTRATES THAT THERAPEUTIC RESPONSE AS EARLY AS ONE MONTH PREDICTS 12-MONTH RADIOGRAPHIC PROGRESSION: DATA FROM A STUDY USING TOFACITINIB AND METHOTREXATE IN METHOTREXATE-NAÏVE PATIENTS WITH EARLY RA

P.G. Conaghan[1,2], M.A. Bowes[3], M. Østergaard[4], G. Guillard[3], D. Chapman[5], A. Stein[6], J. Andrews[5], Z. Xie[7], A. Koenig[8], K. Soma[7], B. Wilkinson[7]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds; [3]Imorphics Ltd, Manchester, United Kingdom; [4]Copenhagen Center for Arthritis Research, Copenhagen, Denmark; [5]Pfizer Inc, New York, NY; [6]Quintiles, Morrisville, NC; [7]Pfizer Inc, Groton, CT; [8]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. A novel automated quantification method for RA MRI-detected pathology using statistical shape modelling technology (RAMRIQ) provides a tool that may be even more responsive than the sensitive RAMRIS semi-quantitative standard.[1]
Objectives: To determine if early changes in RAMRIQ were predictive of subsequent MRI and radiographic damage progression in a study of tofacitinib for the treatment of early RA in methotrexate-naïve patients with minimal radiographic progression.
Methods: We used data from an exploratory, Phase 2 randomised controlled trial comparing tofacitinib, methotrexate and the combination (n=109) in methotrexate-naïve patients with early active RA.[1] All patients met ACR classification criteria for active RA. MRI was performed at baseline and at 1, 3, 6 and 12 months. A single centralised reader read all MRI data; data for each patient were randomised by time point and read in the same sitting. We examined changes in synovitis, osteitis and erosions for RAMRIQ and RAMRIS at 1 and 3 months and performed univariate analyses on their relationship to RAMRIS, RAMRIQ and radiographic progression (modified Total Sharp Score [mTSS]) at 12 months.
Results: Reduction in RAMRIQ synovitis and osteitis at 1 and 3 months were significantly associated with reduction in RAMRIS erosion progression at 12 months (Table). Improvement in RAMRIQ synovitis and osteitis at 1 and 3 months were also associated with reduction in radiographic progression at 12 months, while RAMRIQ erosions at 1 and 3 months were not significantly associated with radiographic progression (Table). Early changes in RAMRIS erosion at 1 and 3 months were associated with radiographic progression at 12 months (Table). Treatment with tofacitinib alone or in combination with methotrexate was also associated with reduced progression in RAMRIS erosions (p=0.017 and p=0.007, respectively).

Table. Univariate analyses of the relationship between RAMRIQ and RAMRIS measurements at Month 1 and 3 and RAMRIS erosion and radiographic progression at Month 12.

p value	RAMRIS erosion progression (Month 12)	Radiographic progression (mTSS; Month 12)
Change in RAMRIQ synovitis		
Month 1	0.004	<0.001
Month 3	0.008	0.008
Change in RAMRIQ osteitis		
Month 1	0.001	<0.001
Month 3	<0.001	<0.001
Change in RAMRIQ erosions		
Month 1	-	0.075
Month 3	-	0.530
Change in RAMRIS erosions		
Month 1	-	0.001
Month 3	-	0.005

mTSS, modified Total Sharp Score; RAMRIQ, quantitative RAMRIS; RAMRIS, Rheumatoid Arthritis MRI Scoring System

Conclusions: In this study, sensitive automated detection demonstrated that change in synovitis and osteitis predict subsequent RAMRIS erosion and radiographic progression. Treatment with tofacitinib as monotherapy or in combination with methotrexate was also highly predictive of no progression of erosive damage. Because of its enhanced sensitivity, novel quantitative imaging analysis has the potential to change RA clinical trial design where assessing structural damage is an objective.

THU0176 EFFICIENCY AND SAFETY OF RAPAMYCIN COMBINED WITH LOW-DOSE IL-2 TREATMENT COMPARED WITH METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Z. Li[1], H. Niu[1], M. Chen[1], H. Yao[1], J. Luo[1], C. Gao[2], X. Li[1], C. Wang[1]. *[1]Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China; [2]Pathology, Brigham and Women's Hospital, Harvard Medical School, Brigham and Women's Hospital, Harvard Medical School, United States*

Background: The molecular target rapamycin (mTOR) signaling can regulate between effector and regulatory T cell lineage commitment [1]. Rapamycin, the inhibitor of mTOR, has appeared to be a new therapy for several autoimmune diseases, such as systemic lupus erythematosus [2].
Objectives: To evaluate whether rapamycin is beneficial in patients with Rheumatoid Arthritis (RA), and compared with Methotrexate in efficiency and safety.
Methods: Fifty-eight DMARDs-naive RA patients were enrolled, thirty-eight were treated with Rapamycin (0.5 mg every 2 days, combined with IL-2 50WIU per day for 5 days), the others with Methotrexate (10mg per week) taken as control. Clinical improvement and immunological assessments were performed at baseline, 1 and 12 weeks. Treatment group assessed CD4+ T cell subsets by flow cytometry at baseline, 1 and 12 weeks.
Results: We enrolled 58 patients. At baseline, patients had a mean DAS28 of 3.34 (0.81). Rapamycin group and Methotrexate group included 38 and 20 patients, respectively, with no significant differences in baseline characteristics. At 1 week, the mean DAS28 after Rapamycin treatment (2.43 [0.77]) and Methotrexate (2.25 [0.86]) was not significantly different (P=0.43). Same as ESR (24.74 [24.53], 21.76 [24.27], P=0.66). The dose of glucocorticoid during hospitalization of rapamycin treatment group (720.8 [554.3]) was lower than Methotrexate (1202.3 [943.1], P=0.042). The length of hospital stay of Rapamycin (14.5 [3.9]) was lower than Methotrexate (21.0 [3.8], P<0.001). Rapamycin administration resulted in an increase in the absolute counts of Treg cells from a median of 36.82 cell/ul (at week 0) to 99.80 cell/ul (at week 1) (P<0.001). The ratios of Th17/Treg cells showed a reduction from a median of 0.16 to 0.09, and the difference was significant (P=0.047). At 12 week, 5 patients treated with Rapamycin dropped out because of non-compliance. the mean DAS28 was not significantly different (2.36 [0.97], 2.16 [0.86], P=0.51). The same as the daily dose of glucocorticoid (10.21 [32.3], 9.16 [40.1], P=0.804). The absolute counts of Treg cells increased from a median of 36.82 cell/ul (at baseline) to 43.26 cell/ul after Rapamycin administration (P=0.028). The ratios of Th17/Treg had no significant difference from a median of 0.16 at baseline to 0.12 at week 12 (P=0.937). Liver enzyme elevations occurred on 2 patients after Methotrexate therapy for 1 week. However, there were no serious adverse events observed during the 12-week period of rapamycin treatment.
Conclusions: Rapamycin combined with the low-dose IL-2 appears to be a safe and effective therapy for RA, by a rapid increase of circulating Treg cells and a correction of the ratio of Th17/Treg cells, which has gotten a same response compared with Methotrexate.

THU0177 ABT-494 PHARMACOKINETICS FOLLOWING ADMINISTRATION OF THE ONCE-DAILY EXTENDED-RELEASE TABLET FORMULATION BEING UTILIZED IN THE ONGOING RHEUMATOID ARTHRITIS PHASE 3 TRIALS

M.-E.F. Mohamed[1], J. Zeng[1], I.-H. Song[2], A.A. Othman[1]. *[1]Clinical Pharmacology and Pharmacometrics; [2]Immunology Clinical Development, AbbVie, North Chicago, United States*

Background: ABT-494 is a selective Janus Kinase 1 inhibitor. In two Phase 2b studies in subjects with rheumatoid arthritis, 6 mg and 12 mg twice-daily (BID) doses of ABT-494 immediate-release formulation achieved optimal benefit-risk profiles. To enhance patients' compliance, an extended-release formulation was developed targeting to achieve comparable exposures with the 6 mg and 12 mg BID of the immediate-release formulation with once-daily (QD) administration.

Objectives: The objective of this work was to characterize the pharmacokinetics of ABT-494 with the extended-release formulation that is currently being utilized in Phase 3.
Methods: Comparison of ABT-494 pharmacokinetics from the immediate-release and extended-release formulations was conducted following multiple-dose administration in healthy subjects. Two cohorts of subjects were evaluated. In the first cohort, healthy subjects (N=12) received multiple 15 mg QD doses of the extended-release tablet formulation and multiple 6 mg BID doses of the immediate-release capsule formulation for 7 days. In the second cohort, healthy subjects (N=12) received multiple 30 mg QD doses of the extended-release tablet formulation and multiple 12 mg BID doses of the immediate-release capsule formulation for 7 days. Both evaluations were conducted following an open-label, randomized, 2-period, 2-sequence, crossover design under fasting conditions. ABT-494 plasma concentrations were measured and pharmacokinetic parameters were calculated using non-compartmental analyses.
Results: At steady-state, ABT-494 AUC0–24 ratio [and 90% confidence interval] was 0.94 [0.84 – 1.05], C_{max} ratio was 0.91 [0.74 – 1.12] and C_{min} ratio was 1.09 [0.85 – 1.40] for the 15 mg QD regimen of the extended-release formulation relative to the 6 mg BID regimen of the immediate-release formulation. Similarly, ABT-494 mean $AUC_{0–24}$ ratio was 0.97 [0.87 – 1.09], C_{max} ratio was 0.90 [0.73 – 1.11] and C_{min} ratio was 0.87 [0.75 – 1.02] for the 30 mg QD regimen of the extended-release formulation relative to the 12 mg BID regimen. All evaluated regimens were well-tolerated by healthy subjects.
Conclusions: ABT-494 regimens of 15 mg QD and 30 mg QD of the extended-release formulation, currently being utilized in Phase 3 RA studies, provide similar exposures to 6 mg BID and 12 mg BID, respectively of the immediate-release capsule formulation previously shown to provide optimal benefit-risk profiles in RA Phase 2 trials.

THU0178 LONG TERM SAFETY PROFILE OF METHOTREXATE IN PATIENTS WITH RA IN ROUTINE CARE

A.B. Nalawade[1], S.M. Akerkar[2], B.D. Pandey[3]. *[1]Rheumatology, Sancheti Institute, Pune; [2]Mumbai arthritis clinic, Mumbai; [3]Rheumatology, Fortis Hospital, Delhi, India*

Background: Methotrexate is the anchor drug used most widely as monotherapy or combination therapy with other DMARDS & biologics in treatment of RA. It is widely perceived by clinicians to have potentially dangerous adverse effects (AE). The present study was designed to assess safety of long term methotrexate in patients with RA on standard care in clinical practice.
Objectives: To evaluate the safety of long term methorexate therapy in patients with RA
Methods: RA patients on methotrexate therapy at recommended doses (15–25 mg per week) as monotherapy or in combination with other conventional dmards or biologics for over 4 years were enrolled between Jan 2016 to Dec 2016. Since the objective was to assess safety, those patients initiated on methotrexate 4 years ago but had discontinued due to adverse effects were also included. Patients were analysed with a questionnaire and review of past records from the clinic. The questionnaire included questions about duration and compliance of methotrexate therapy, any untoward effects that patient felt were due to methotrexate and direct questions related to known methotrexate side effects. Investigations were reviewed from past records.Data were presented by 1- year intervals starting from the time patient received first dose of methotrexate. Adverse events (AE), rate of discontinuation and abnormal laboratory results were analysed per 100 patient (pt.) years in 1 year intervals.
Results:

Females, no. (%)	205 (89.9%)
Age, mean ± SD (years)	48.6 (±10.8)
Disease duration, mean ± SD (years)	8.4 (±5)
Seropositive (RF and/ or ACPA)	207 (91%)
Methotrexate monotherapy (%)	55 (24%)

The cumulative exposure to methotrexate was 926 patient years. Of 228 patients, 218 continued methotrexate through 4 years. Overall 10 patients discontinued methotrexate over 4 years, 5 due to GI intolerance and 1 due skin allergy in the first year. In subsequent years 2 patients were withdrawn due to chronic cough, 1 due to raised transaminases and 1 patient after severe infection and pancytopenia. Incidence of AEs, severe AEs, infections, laboratory abnormalities and discontinuations due to AE's declined during 4 years exposure. The most common AEs included nausea and dyspepsia (24.6/ 100 pt. years in first year with declining incidence through 4 years). The second most common AE reported was infections (7/100 pt. years). Most common infections were mild UTI & respiratory tract infections.14 patients initially asymptomatic or having mild nausea reported significantly increased nausea in year 4 and beyond, all responding to reduction of methotrexate dose. The incidence of severe AE that needed hospitalisation &/ or discontinuation of methotrexate was 2.6/100 pt. years in year 1 with declining events over time. The cumulative risk of serious AE over 4 years was 1.2/ 100 pt. years.

Conclusions: Methotexate therapy was well tolerated over 4 years treatment period with a good safety profile. Most of the AE's were mild to moderate severity not needing discontinuation of methotrexate. Study has limitations since it is retrospective observational study with small patient number from two outpatient rheumatology clinics. Some AE's may have been underestimated as patient compliance not ascertained and patients with AE's may have lost to follow up. Some effects may have been overestimated as precise causality is not proven. During the 4 years methotrexate treatment, no new safety concerns emerged.

THU0179 INCIDENCE OF DEEP VEIN THROMBOSIS AFTER TOTAL HIP REPLACEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Rybnikov, E. Byalik, S. Makarov, T. Reshetnyak, A. Khramov, E. Naryshkin, D. Ivanov, V. Pavlov. *Orthopaedic, V.A.Nasonova research institute of rheumatology, Moscow, Russian Federation*

Background: The purpose of this study was to compare incidences of VTE in patients with rheumatoid arthritis (RA) and osteoarthritis (OA) after total hip arthroplasty, different strategies for prevention of VTE and evaluate their efficiency.
Objectives: To evaluate the efficiency of prevention of VTE in patients with rheumatoid arthritis and osteoarthritis after total hip replacement under comparable conditions.
Methods: A one-year prospective cohort study was performed on 173 primary THA patients operated in V.A. Nasonova Research Institute of Rheumatology for the period 2016. Of these, 91 patients with RA (52.6%) and 82 patients with OA (47.4%). For a comparative analysis of the efficiency of anticoagulant therapy, each patient group was divided into 2 subgroups by type of drug therapy. The first - nadroparin calcium (the drug therapy was started for 12 hours after the operation at a dose of 0.1 ml per 10 kg of body weight one time per day), the second - nadroparin calcium with transfer to dabigatran etexilate (the first stage of 4 hours after the operation was started therapy by nadroparin calcium, and then after the removal of the epidural catheter moved to the dabigatran etexilate).Doppler ultrasonography (DUS) was routinely performed preoperatively and on postoperative day 7, 14, then 1 time a month for diagnosing a deep venous thrombosis (DVT). Time of observation was 6 months.
Results: DVT were reported in 8 (4.8%) patients, 2 of them (1.2%) with RA and 6 (3.4%) with OA. Distal DVT developed on 8 and 17 days after total hip replacement in RA patient's group. They received nadroparin calcium only. 5 patients with VTE after surgery from OA group used nadroparin calcium and 1 patient was on combined drug therapy. Of the 8 cases of VTE - 6 (75%) were asymptomatic and 2 (25%) with development of clinical and laboratory picture. All cases of thrombosis in a group of RA was asymptomatic. In a perioperative period of clinically significant bleeding was not seen.
Conclusions: Cases of VTE in patients with RA, despite the large number of risk factors, under comparable conditions is significantly lower than patients with OA. The number of asymptomatic DVT dominates symptomatic both comparison groups. In patients with RA and OA who were from the first group have reported 6 cases of VTE and only 1 case of VTE have reported in patients who were from second group. Prevention of VTE by combination of LMWH and NOACs was more effective and safety in RA and OA patients.

THU0180 SYSTEMS BASED INVESTIGATION OF THE ANTI-IMMUNOGENIC POTENTIAL OF DMARDS FOR RHEUMATOID ARTHRITIS USING HUMAN PRIMARY CELL-BASED BIOMAP® PHENOTYPIC PROFILING

A. O'Mahony[1], E. Choy[2]. *[1]BioMAP Division, DiscoverX Corporation, South San Francisco, United States; [2]Division of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom*

Background: Biologics represent a rapidly growing class of approved and investigational drugs routinely used to treat multiple diseases, including inflammatory and rheumatic diseases[1]. Unfortunately, the success of such therapeutics is

undermined by their immunogenicity and the development of anti-drug antibodies (ADA) associated with treatment failure and hypersensitivity reactions[2]. Methotrexate (MTX) has been shown to reduce the generation of an ADA response[3]. The ability of other conventional synthetic Disease Modifying Anti-Rheumatic Drugs (csDMARDs) to mitigate unwanted immunogenicity, and prolong efficacy in patients who cannot tolerate methotrexate, is less clear.

Objectives: We previously reported that MTX markedly inhibited the production and release of soluble immunoglobulin (sIgG) by human primary B cells co-cultured with PBMC (BT system) in the *in vitro* BioMAP® phenotypic screening panel[4,5]. MTX also had anti-proliferative effects on human primary tissue and immune cell types[6]. We evaluated other csDMARDs to determine if they were broadly active or, were more similar to MTX in selectively blocking sIgG production and therefore would be more likely to reduce ADA associated with biologics.

Methods: A series of csDMARDS (sulfasalazine, hydroxychloroquine, cyclosporine, leflunomide and azathioprine) were profiled at 4 concentrations across the BioMAP Diversity PLUS™ panel to generate phenotypic activity profiles. In addition to assessing sIgG production, effects on a broad scope of disease-relevant readouts related to primary cell activation and proliferation, inflammation, wound healing, tissue/matrix remodeling, and fibrosis were also evaluated.

Results: Similar to MTX, cyclosporine, leflunomide and azathioprine strongly inhibited sIgG production at all tested concentrations. In contrast, treatment with sulfasalazine or hydroxychloroquine did not decrease sIgG indicating these compounds may not mitigate the immunogenicicty of biologics. In contrast to MTX, several csDMARDS were broadly active in many BioMAP systems. Bioinformatics analysis was used to identify distinct mechanistic signatures for these agents in the BioMAP Panel.

Conclusions: These results support application of the BioMAP *in vitro* assay systems, widely utilized for preclinical drug discovery, to determine the suitability of csDMARDS as anti-immunogenic co-treatments to extend the clinical efficacy of biologics. Clinical studies are needed to confirm these results, however, in inflammatory bowel diseases and to a less extent in rheumatoid arthritis, azathioprine has been shown to reduce immunogenicity of biologics[7].

Background: Methotrexate (MTX) is the DMARD of first choice in the treatment of rheumatoid arthritis (RA).

Objectives: To investigate the clinical characteristics and describe therapeutic approaches in RA patients ongoing MTX not achieving a DAS28 "low disease activity" score.

Methods: This is a case-control analysis including 186 patients (mean age±SD, 61±12 years, 16% males) who did not achieve a DAS28 "low disease activity" score (defined by a value ≤3.2) and 558 age- and gender-frequency-matched (1:3), randomly selected controls (mean age age±SD, 61±13 years) who achieved a DAS28 "low disease activity" from the original cohort investigated in the MARI study. The MARI study enrolled RA patients on treatment for at least 12-month with MTX. Demographic, clinical, laboratory and pharmacological characteristics of patients recorded at baseline visit were considered for the current analysis. We first compared the characteristics of patients who reached the endpoint with those of subjects who did not by univariate analyses, thereafter, we performed a multivariate model to identify predictors of not achieving the endpoint. We further investigated the therapeutic approaches in patients not achieving the endpoint.

Results: Compared to patients with a DAS28 ≤3.2, subjects not achieving the endpoint presented with a significant higher (mean±SD) weight and BMI (DAS28 ≤3.2: 25±4 versus DAS28 >3.2: 26±5, P=.022), and longer duration of symptoms (months±SD) before the RA diagnosis (11±15 versus 15±20, P=.009). A higher proportion of subjects within the group not achieving the endpoint presented with polyarticular disease (DAS28 ≤3.2: 57% versus DAS28 >3.2: 96%, P<.001), erosive arthritis (49% versus 73%, P<.001), extra-articular symptoms (3% versus 10%, P<.001), positive RF test (63% versus 73%, P=.013), and increased CRP (13% versus 53%, P<.001). The proportion of patients treated with oral MTX was 25% in the subgroup with DAS28 ≤3.2 and 15% in the subgroup with DAS28 >3.2 (P=.004). In the logistic regression analysis, the variables predictive of a DAS28 >3.2 were polyarticular disease (OR 4.0, 95% CI 2.4–6.7, P<.001), erosive arthritis (OR 2.2, 95% CI 1.4–3.4, P<.001), and increased CRP (OR 7.4, 95% CI 4.9–11.4, P<.001). In patients who did not reach the endpoint, the main therapeutic strategies were: a change in the route of administration of MTX (DAS28 >3.2: 13% versus DAS28 ≤3.2: 4%, P<.001) in favor of subcutaneous MTX, an increase of the dose of MTX (13% versus 2%, P<.001), and the prescription of a new biologic (12% versus 1%, P<.001).

Conclusions: Our results identified a number of variables potentially associated the risk of not achieving a DAS28 "low disease activity" score in RA patients ongoing MTX treatment. Longitudinal studies are warranted.

THU0182 MONOTHERAPY WITH THE JAK1-SELECTIVE INHIBITOR FILGOTINIB DISPLAYS AN ANTI-INFLAMMATORY BIOMARKER PROFILE IN RHEUMATOID ARTHRITIS PATIENTS

A. Kavanaugh[1], A. Van der Aa[2], C. Jamoul[2], W. Li[3], L. Goyal[3], Y. Pan[3], P. Harrison[2], C. Tasset[2], J. Tarrant[3], R. Galien[4]. *[1]University of California, la Jolla, United States; [2]Galapagos NV, Mechelen, Belgium; [3]Gilead Sciences, Foster City, United States; [4]Galapagos SASU, Romainville, France*

Background: Janus kinases (JAKs) are key proteins in the signal transduction of many cytokines and growth factors. The selective JAK1 inhibitor filgotinib (GLPG0634, GS-6034) has been evaluated in a 24-week phase 2B study (DARWIN 2) as monotherapy in active rheumatoid arthritis (RA) patients with inadequate response to methotrexate and has shown a good safety and efficacy profile[1].

Objectives: To gain insight into filgotinib mode of action as monotherapy in RA patients by analysing the impact of filgotinib on a broad panel of immune modulators in the serum.

Methods: RA patients received either placebo (PBO), or filgotinib monotherapy at 50mg, 100mg or 200mg once daily (QD). Serum samples were collected at baseline, week 4 and week 12 and analysed using the 18-plex bead-based immunoassay (HSTCMAG-28SK Merck-Millipore) on BioPLEX-200 instrument to measure cytokine concentration. Median % change from baseline for biomarkers are reported for week 4 and 12. Wilcoxon rank-sum test assessed the significance of difference between filgotinib treated groups and PBO.

Results: Following treatment with filgotinib at 100 mg QD and 200mg QD, there were significant reductions in cytokines important in expansion and activity of multiple T cell subsets and innate immunity compared to PBO (see Table). These changes include decreases in proinflammatory cytokines (IL-6, IL-1β, and TNFα), T_H1-related (IL-2, IFN-γ and IL-12), T_H2-related (IL-4, IL-5, and IL-13) and T_H17-related cytokines (IL-1β, IL-6, IL-17A, IL-21 and IL-23). All doses of

Table 1. Median percent change of biomarkers from baseline

MIP-1α	5	-5***	-8***	3	-7***	-6**
MIP-1β	3	-6**	-6*	3	-5^{NS}	3^{NS}
TNF-α	5	-7***	-12***	5	-11**	-14**

P values comparing % changes between filgotinib and PBO groups: NS p>0.05; *p<0.05; **p<0.01; ***p<0.001.

filgotinib also reduced the B- and T-cell development cytokine IL-7. In contrast, IL-8 was not affected by filgotinib. Reductions in MIP1α, MIP1β and GM-CSF are in line with a down modulation of innate immune activity.
Conclusions: Treatment of RA patients with filgotinib monotherapy resulted in significant reduction in the levels of a broad range of cytokines related to T_H1, T_H2, T_H17 and potentially B cells, as well as innate immunity. This observed anti-inflammatory activity of filgotinib is consistent with its efficacy in RA patients.

THU0183 IMPROVED ADHERENCE TO NEWLY PRESCRIBED DMARDS WITH CO-PRESCRIPTION WITH LOW DOSE STEROIDS IN RHEUMATOID ARTHRITIS PATIENTS ATTENDING CLINIC AT A DISTRICT GENERAL HOSPITAL IN THE UK

A. Nugaliyadde[1,2], K. Culfear[2], A. Nandagudi[2], A. Bharadwaj[2]. *[1]Department of Rheumatology, Teaching Hospital Kandy, Kandy, Sri Lanka; [2]Department of Rheumatology, Basildon and Thurrock University Hospital, Basildon, United Kingdom*

Background: Non-adherence to DMARDs is associated with disease flares and increased disability. Adherence rates to prescribed medicine regimes in people with Rheumatoid Arthritis vary from 30–80% in different studies. Improving adherence to therapy leads to better disease outcome and reduced costs associated with management of RA.
Objectives: This study was carried out as a pilot study to look at the effect of co-prescription of steroids on the adherence and side effects to newly prescribed DMARDS in patients with rheumatoid arthritis.
Methods: This is a prospective, observational cohort study, for the duration of three months per participant. Patients were selected sequentially from those attending outpatient clinic at Basildon Hospitals with a confirmed diagnosis of rheumatoid arthritis (ACR/EULAR criteria), and had been planned to start on a new DMARD by the treating physician. Baseline data included demographics, disease characteristics and data regarding steroid co- prescription including route, dose and duration. Patients were reviewed at three months to look at DMARD adherence defined by continuation of the DMARD. We looked at the side effect profile as possible contributing factor to non-adherence. The effect of co-prescription with steroids and other demographic data on treatment duration was investigated using Kaplan-Meier survival plots. Logistic regression analysis was used to investigate the effect of co- prescription of steroids on continuation of medication.
Results: Fifty one patients were recruited to the study. Median age at the time of enrolment was 61 years (IQR 46–71), 73% were females and 92% were caucasians. seventy percent of the patients were seropositive and DMARD naïve with a mean DAS CRP at recruitment of 4.13 (1.21). Seventeen (33%) patients were co-prescribed with steroids at the initiation of DMARDs. Out of these 59% (n=10) were DMARD naïve. Thirteen patients received a tapering dose of oral prednisolone with a mean starting dose of 13.8mg daily (range 3mg - 20 mg) for a mean duration of 10.8 weeks. Two patients received oral prednisolone 5mg daily for 12 week. The mean cumulative dose of oral prednisolone prescribed was 632.2mg. The two remaining patients received 120 mg of depomedrone IM.
The non adherence rate for our cohort was 35%, 6% for patients co-prescribed with steroids versus 50% for patients who were not co-prescribed with steroids. The odds ratio for likelihood of discontinuation for patients who were not co-prescribed with steroids versus patients who were, was 16 (1.94–134.5, p=0.011).
At the end of three months 25% of the whole cohort, 12% of the patients who were co-prescribed with steroids versus 32% of the patients who were not co-prescribed with steroids reported side effects to the DMARD initiated. the odds ratio for reporting side effects with steroid co-prescription was 0.28 (0.054–1.438, p=0.12).
Conclusions: Co-prescription of low dose steroids with initiation of DMARDs increases the chances of adherence and possibly reduces the side-effect profile

THU0184 ADHERENCE PROFILES TO METHOTREXATE OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) ELIGIBLE FOR BIOLOGICS: TYPOLOGIES FROM FORGET, A CROSS-SECTIONAL SURVEY OF 244 PATIENTS

C. Beauvais[1], V. Hautin-Monteil[2], M.-C. Ducrot[3], R.-M. Flipo[4]. *[1]Rheumatology Department, Saint Antoine Hospital, APHP, Paris; [2]Roche France; [3]Agence A+A, Boulogne-Billancourt; [4]Rheumatology department, Roger Salengro Hospital, Lille, France*

Background: Adherence to Methotrexate (MTX) is not optimal in RA patients [1]. Conflicting determinants of adherence have been identified in literature. Our hypothesis was that the discordant results were related to different typologies of patients.
Objectives: Determine the Methotrexate adherence profiles of patients with RA eligible for biologics.
Methods: The FORGET survey carried out in 2016 was aimed to assess the MTX adherence rate of RA patients, insufficient responders to MTX, biologic-naive, when an initiation of biologics was being considered. Non-adherence was defined as a compliance rate <80% according to the CQR19 (Compliance Questionnaire for Rheumatology) [2]. The factors tested were socio-demographic characteristics, DAS 28, RAID, CQR responses, beliefs, voluntary or involuntary dose skipping, social and medical support.
Results: Of the 244 patients analyzed, the non-adherence rate was 34%. The rather weak correlation between adherence (CQR) and the disease impact (RAID) tended to confirm the hypothesis of different profiles. Four typologies of patients were determined. Groups G1 and G2 were non-adherent patients with high (G1) or lower (G2) impact. Groups G3 and G4 were patients with good adherence with high (G3) or lower impact (G4. Significant adherence factors were found for these 4 groups (p<0.01) (table).

	Non-adherent patients		Adherent patients	
	G1	G2	G3	G4
%	14	19	33	34
CQR 19 (%)	21	40	78	88
RAID (0–10) mean	6,7	4,6	6,3	3,7
Skipped doses (%)	66	55	15	11
Skipped does without doctor's recommendation (%)	38	41	3	3
I comorbidity or more (%)	62	68	57	45
Depression (%)	31	14	12	3
Anxiety	16	9	9	1
Good information received (%)	69	83	81	93
I find constrains to take may treatment (% yes)	59	61	21	6
I tolerate my treatment badly (% yes)	47	18	16	18
I think every day about may arthritis (% yes)	83	63	88	53
I find it hard to keep may professional obligations because of my arthritis (% yes)	79	38	65	32
I feel well informed about my arthritis (% yes)	69	83	81	93
I had support from my relatives (% yes)	55	55	82	96
My treatment is doing me more harm than good (% no agreement at all)	0	22,7	36,8	71
The most important reason to take my treatment is that I can still do what I want to do (% complete agreement)	6,3	11,4	17,2	60,5
I do not expect miracles from my treatment (% no agrement at all)	0	0	10,3	23

Conclusions: Four adherence profiles to Methotrexate have been identified. Among the non-adherent patients, 2 topologies are opposed: 1- patients in state of suffering, with low support from relatives, negative beliefs and significant professional impact. 2-patients with less disease impact, who perceived their treatment with constraints although well tolerated. Detection of patients' profiles may allow targeted strategies to improve or maintain adherence.

THU0185 COMPARISON OF TOFACITINIB SAFETY AND EFFICACY IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DMARDS, OR TO ONE OR MORE BIOLOGICAL DMARDS

C. Charles-Schoeman[1], J. Kremer[2], S. Krishnaswami[3], K. Soma[4], J. Geier[4], R. Zhang[4], S. Strengholt[4], G. Burmester[5]. *[1]University of California, Los Angeles, CA; [2]Albany Medical College and the Center for Rheumatology, Albany, NY; [3]Pfizer Inc, Groton, CT; [4]Pfizer Inc, New York, NY, United States; [5]Charité – University Medicine Berlin, Berlin, Germany*

Background: Tofacitinib is an oral JAK inhibitor for the treatment (tx) of rheumatoid arthritis (RA). Studies have shown diminishing response to tx in RA patients (pts) when cycling through TNF inhibitors. Prior analyses assessed tofacitinib in csDMARD-inadequate response (IR) pts vs overall bDMARD-IR pts.

Objectives: To compare tofacitinib safety and efficacy in RA pts who have previously failed tx (lack of efficacy and/or safety reasons) with csDMARDs, with pts who failed tx with either 1 or ≥2 prior bDMARDs.
Methods: Data from pts who received ≥1 dose of tofacitinib in 19 RA studies up to 96 months (2 Phase [P] 1; 9 P2; 6 P3; 2 LTE studies [1 LTE ongoing; data as of March 2015]) were used in this analysis. Data were pooled across all 19 studies for safety assessments in the All RA population: csDMARD-IR, n=4377; bDMARD-IR, n=838 (1 bDMARD-IR, n=533; ≥2 bDMARD-IR n=305). Safety was also assessed up to 24 months in pts randomised to tofacitinib 5 or 10 mg BID or placebo (PBO) in a pooled P2/P3 randomised controlled trial (RCT) population (8 P2, 6 P3 studies; csDMARD-IR, n=3328; bDMARD-IR, n=782). Incidence rates (pts with events/100 pt-years) were calculated for serious AEs (SAEs), serious infections (SIs) and herpes zoster (HZ). Efficacy was assessed by pts achieving ACR20 response and DAS28-4(ESR) ≤3.2 at Month 3 in a pooled P3 RCT population (csDMARD-IR, n=2375; bDMARD-IR, n=664).
Results: Prior to tofacitinib tx, bDMARD-IR pts had longer RA duration, greater disease burden and more corticosteroid use vs csDMARD-IR pts. SAEs were more common among bDMARD-IR vs csDMARD-IR pts in both the P2/P3 RCT and the All RA populations; SAE rates were not higher in pts failing ≥2 bDMARDs vs 1 bDMARD (Table). Incidence rates for SIs were generally greater in pts with IR to bDMARDs vs csDMARDs in the All RA population, but generally lower in pts with IR to 1 or ≥2 bDMARDs vs csDMARDs in the P2/P3 RCT population; incidence with 5 mg BID was lower for 1 vs ≥2 bDMARDs in the P2/P3 RCT population. Incidence rates for HZ were similar between pts with IR to csDMARDs or 1 bDMARD, but appeared numerically greater in pts with IR to ≥2 bDMARDs in both the P2/P3 RCT and the All RA populations. A similar pattern was observed across tofacitinib and PBO groups. Efficacy at Month 3 in the P3 RCT population was greater with both tofacitinib doses vs PBO. Although absolute response was smaller in pts with IR to bDMARDs vs csDMARDs, generally similar efficacy was observed in pts with IR to 1 or ≥2 bDMARDs (Table).

Table. Selected safety and efficacy outcomes by prior failed treatment.

		csDMARD-IR-only	Overall bDMARD-IR	1 bDMARD-IR	≥2 bDMARD-IRs
P2/P3 RCT population (0–24 months);* incidence rate (pts with event/100 pt-years) (95% CI)

	Tofacitinib 10 mg BID	21.1***	15.8**	15.7*	16.5*
	Placebo	3.9	4.9	5.8	3.4

*p<0.05; **p<0.001; ***p<0.0001 vs placebo
[a]Placebo data up to 6 months only
Δ, change from baseline, BID, twice daily; bDMARD, biological disease-modifying antirheumatic drug; CI, confidence interval; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DAS28-4(ESR), Disease Activity Score in 28 joints with erythrocyte sedimentation rate, HZ, herpes zoster; IR, inadequate response, P, Phase, pts, patients, pt-years, patient-years; RA, rheumatoid arthritis; RCT, randomised controlled trial; SAE, serious adverse event; SI, serious infection

Conclusions: SAEs and SIEs were more common in tofacitinib- and PBO-treated pts with IR to bDMARDs vs csDMARDs; increased risk was generally not observed with increasing number of prior bDMARDs. HZ risk appeared greater with ≥2 bDMARDs vs 1 bDMARD. Efficacy was greater with tofacitinib vs PBO for csDMARD-IR and bDMARD-IR pts, with similar response observed in pts with IR to ≥2 or 1 bDMARD. These data support the use of tofacitinib in different lines of therapy, although the analysis is limited by smaller sample size in some groups.

THU0186 MAGNITUDE AND DURATION OF EARLY RESPONSE WITH TOFACITINIB: POST-HOC ANALYSIS OF TWO PHASE 3, PLACEBO-CONTROLLED STUDIES

D. Aletaha[1], A. Kivitz[2], G. Valenzuela[3], J. Tesser[4], S. Hays[5], H. Li[5], C.A. Connell[6], E. Bananis[5], A. Soonasra[5], J.S. Smolen[7]. *[1]Department of Internal Medicine 3, Medical University of Vienna, Vienna, Austria; [2]Altoona Center for Clinical Research, Duncansville, PA; [3]Integral Rheumatology & Immunology Specialists, Fort Lauderdale, FL; [4]Arizona Arthritis & Rheumatology Associates, Glendale, AZ; [5]Pfizer Inc, Collegeville, PA; [6]Pfizer Inc, Groton, CT, United States; [7]Division of Rheumatology, Medical University of Vienna and Hietzing Hospital, Vienna, Austria*

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. ORAL Solo (NCT00814307) and ORAL Sync (NCT00856544) were two Phase 3 index studies that demonstrated the efficacy of tofacitinib in adult patients (pts) with RA who were DMARD inadequate responders (DMARD-IR). Early onset of effect is a clinically meaningful endpoint.
Objectives: This post hoc analysis examined the magnitude and durability of early response to tofacitinib in ORAL Solo and ORAL Sync.
Methods: ORAL Solo and ORAL Sync were double-blind, placebo (PBO)-controlled, parallel-group studies in pts with active RA and an inadequate response to ≥1 conventional synthetic (cs) or biologic (b) DMARDs. Pts were randomised to tofacitinib 5 mg BID, tofacitinib 10 mg BID, PBO advanced to tofacitinib 5 mg BID, or PBO advanced to tofacitinib 10 mg BID, either as monotherapy in ORAL Solo or with background csDMARDs in ORAL Sync. In ORAL Solo, pts randomised to PBO were advanced to tofacitinib at Month (M) 3; in ORAL Sync, pts randomised to PBO were advanced to tofacitinib at M3 (non-responders) or M6 (all other pts). In this post hoc analysis, the following clinical efficacy data for pts on tofacitinib or PBO (prior to advancement to tofacitinib) ± csDMARDs, were evaluated at Week 2, M3 and M6 (ORAL Sync only; no M6 PBO comparison in ORAL Solo): change from baseline (CFB) in Clinical Disease Activity Index (CDAI) >12,[1] HAQ-DI CFB ≥0.22, CDAI ≥50% improvement from baseline, CDAI ≥70% improvement from baseline, CDAI ≥85% improvement from baseline, Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score improvement from baseline ≥4, Pain visual analogue scale (VAS) score CFB ≥10. This analysis was post hoc and multiplicity adjustment was done.
Results: Clinical efficacy endpoint data are summarised in the Table. At Week 2, more patients receiving tofacitinib 5 or 10 mg BID ± csDMARDs (compared with PBO ± csDMARDs) achieved a CDAI CFB >12, HAQ-DI CFB ≥0.22, CDAI ≥50% improvement from baseline and pain VAS CFB ≥10. By M3, more pts receiving tofacitinib 5 or 10 mg BID ± csDMARDs (compared with PBO ± csDMARDs) achieved the efficacy outcomes measured including improvements from baseline in FACIT-F scores ≥4, CDAI ≥50%, CDAI ≥70% and CDAI ≥85%. Responses attained at M3 were maintained or increased at M6.

Table. Clinical efficacy endpoints from Week 2 to Month 6 in ORAL Sync and ORAL Solo (FAS[a]; NRI[b])

		ORAL Solo			ORAL Sync		
Improvement from baseline, % pts (95% CI)		Tofacitinib 5 mg BID (N=241)	Tofacitinib 10 mg BID (N=243)	PBO (N=122)	Tofacitinib 5 mg BID + csDMARDs (N=312)	Tofacitinib 10 mg BID + csDMARDs (N=315)	PBO + csDMARDs (N=158)

*p<0.05 vs PBO; the normal approximation for the difference in binomial proportions was used to test the superiority of each dose of tofacitinib to PBO. [a]Included all randomised patients who took ≥1 dose of study medication. [b]Patients who withdrew for any reason before Month 6, or patients who were advanced to tofacitinib after Month 3 (only for ORAL Sync) had their values on or after withdrawing or advancing set to Non-Response in this analysis. N = total number in each treatment group, number of patients available for the analysis may vary for individual endpoints. PBO group included only those patients who had not yet advanced to tofacitinib.
Comparisons for tofacitinib vs PBO at Month 6 not available for ORAL Solo as all PBO patients advanced to tofacitinib at this time point.
BID, twice daily; CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic DMARD; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; FAS, full analysis set; NA, not available; NRI, non-responder imputation; PBO, placebo; Pts, patients; VAS, visual analogue scale.

Conclusions: DMARD-IR pts with active RA receiving tofacitinib ± csDMARDs appeared to show greater improvements compared with PBO in clinical disease

activity, HAQ-DI, and pain as early as Week 2 (first post-baseline assessment), and improvements in fatigue by M3. Responses were maintained or improved through M3 (monotherapy) or M6 (with background csDMARDs).

THU0187 DO WE TODAY ALTERNATIVE THERAPIES RHEUMATOID ARTHRITIS TWO OR MORE DISEASE-MODIFYING DRUGS? THE STORY OF HOW A SIMPLE DRUG PENTOXIFYLLINE MAY ENHANCE THE ACTION OF METHOTREXATE IN RHEUMATOID ARTHRITIS

D.S. Bublikov, D.A. Anchugina, I.E. Babushkin. *Altay State Medical University, Barnaul, Russian Federation*

Background: The treatment of patients with RA (rheumatoid arthritis) is a complicated task, because the achievement of remission and low level of activity often requires administration of 2–3 disease-modifying drugs. In such conditions we often face with the rise of treatment costs and with the increase of therapy side effects. That is why relevant is the search of the drugs increasing the effect of the "gold standard" of RA – therapy - methotrexate, and also frequently used sulphasalazine and leflunomid. Treatment of prior to "Treat to target" is difficult enough, forcing researchers around the world to look for the ways to improve the effectiveness of RA treatment.

Objectives: To explore the possibilities of reducing RA activity on the disease activity score DAS28 CRP by adding pentoxifylline to the methotrexate, sulfasalazine and leflunomide treatment.

Methods: This study included women (n=131) with RA longer than 1 year in duration, having a seropositive rheumatoid factor, and DAS28 CRP activity score of 3.2–5.1. Middle aged – 46.44±3.24 years old. All patients received a 15.50±2.50 mg oral dose of methotrexate per week, 2000±500 mg oral dose of sulfasalazine per day, 20±5 mg oral dose of leflunomide per day. Patients were divided into two groups - those who only had disease-modifying drugs (DMARDs) (n=80) and those who were treated with an oral dose of methotrexate and 1200 mg of pentoxifylline per day (n=51).

Results: The baseline for both groups of RA patients did not differ significantly in terms of the level on the DAS28 CRP (p=0.812). On 14th day of the group who were taking pentoxifylline, the DAS28 CRP disease activity score was significantly lower by 12.5% ($p<0.001$). After 28 days, the users had a DAS28 CRP disease activity score index difference. The difference between two groups is statistically significant. In the group that were treated with pentoxifylline in addition to DMARDs (p=0.001) the index was found to be 8.3% lower. For 28 days, the methotrexate group's disease activity according to the DAS28 CRP activity score significantly decreased by 14.3% from the baseline ($p<0.001$). For 28 days, the pentoxifylline + DMARDs group also achieved a statistically significant reduction in the index according to the DAS28 CRP activity score by 20.5% ($p<0.001$)

The disease activity index for the two groups for 14 and 28 days is shown in the table.

The DAS28 CRP Index in the two groups of RA patients

Groups of patients Observation time	Group DMARDs (n=80)	Group DMARDs +) Pentoxifylline (n=51)	Statistical significant differences between the two groups
Baseline	3.11±0.05	3.13±0.05	p=0.812
For 14 days	3.06±0.05	2.69±0.06	p<0.001
For 28 days	2.71±0.04	2.48±0.06	p=0.001

Conclusions: Thus, converting the monotherapy DMARDs to pentoxifylline will significantly reduce the activity of RA, while avoiding many of the adverse effects of the other combination therapies. This data requires further long-term research.

THU0188 EFFICACY AND SAFETY OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO DID NOT RESPOND TO SYNTHETIC AND BIOLOGICAL DMARDS IN CLINICAL PRACTICE

E.L. Luchikhina[1], D. Karateev[2], A. Misiyuk[1], N. Demidova[1], G. Loukina[1], D. Abdulganieva[3], A. Baranov[4], A. Babaeva[5], L. Evstigneeva[6], O. Ivanova[7], V. Mazurov[8], O. Semagina[9], A. Sizikov[10], V. Sorotskaya[11], E. Nasonov[2]. *[1]Early arthritis department; [2]Nasonova Research Institute of rheumatology, Moscow; [3]Kazan State Medical University, Kazan; [4]Yaroslavl State Medical University, Yaroslavl; [5]Volgograd State Medical University, Volgograd; [6]Ekaterinburg 1st Regional Clinic Hospital, Ekaterinburg; [7]4 Voronezh Regional Clinical Hospital, Voronezh; [8]North-western State Medical University named after I.I.Mechnikov, Saint-Petersburg; [9]Samara Regional Clinical Hospital, Samara; [10]Scientific Research Institute of Clinical immunology, Novosibirsk; [11]2nd Sity Hospital, Tula, Russian Federation*

Background: Tofacitinib (TOFA) is so far the only representative of a new class of Jak-kinase inhibitors in rheumatology. Despite extensive data on TOFA obtained from 3rd phase studies, for use in clinical practice, the information is limited.

Objectives: To study the efficacy and safety of TOFA in RA in clinical practice.

Methods: We represent the combined data from two parallel IV Phase open-label observational clinical trials, modelling clinical practice, conducted by very similar protocols in 11 rheumatology centers in Russia. Inclusion criteria were active RA, methotrexate (MTX) failure, and/or other synthetic or biologic DMARDs failure. In total, 142 pts (26 males, 116 females, age 51,5±12,2 years, disease duration 88,6±78,1 months, 86,6% RF(+), 76,6% ACPA(+), 81,7% with erosive disease, DAS28-ESR 5,89±1,03, SDAI 35,7±13,4, HAQ 1,59±0,64) were included. 32 (22,5%) pts had biologics in history. TOFA used in the dose of 5 mg BID for 6 months, with possibility to increase to 10 mg BID (carried out in 27 pts after 11,3±2,7 weeks). 115 (81%) pts received TOFA in combination with MTX (18±4,5 mg per week), 18 with leflunomide or sulfasalazine, 9 pts used TOFA in monotherapy.

Results: 129 (90,8%) pts successfully completed the six-month period of treatment. TOFA was withdrawn due to lack of response in 6 cases, adverse events (AEs) in 4 (pneumonia, arterial hypertension, skin vasculitis, mouth ulcers), withdrawal of informed consent – 2, protocol violation – 1. At month 3 SDAI score decreased to 14,6±10,9 ($p<0,01$), 55 (42,6%) pts achieved SDAI LDA and 22 (17,1%) SDAI remission; HAQ decreased to 0,95±0,61, HAQ≤0,5 observed in 36 (27,9%) pts. After 6 months, SDAI and HAQ scores decreased to 10,5±8,6 and 0,83±0,64 resp. ($p<0,01$); 81 (62,8%) pts achieved SDAI LDA and 29 (22,5%) SDAI remission; HAQ≤0,5 observed in 48 (37,2%) pts. Results of treatment in patients with and without biological DMARDs in history were similar. Pts who needed dose escalation of TOFA had worse results at month 3 compared to others (SDAI 21±10,2 and to 13,2±10,7 resp., p=0,02), but after increase of the dose to 10 mg BID at month 6 they showed a slightly better result (SDAI 9,5±7,1 and to 10,7±8,9 resp., p=0,54). Only 2 serious AEs (pneumonia and skin vasculitis) observed. We didn't see any case of Herpes zoster in our group.

Conclusions: TOFA was effective in patients with severe RA who did not respond to both synthetic and biological DMARDs (achievement of SDAI LDA in 42,6% of pts at month 3 and in 62,8% at month 6). Dose escalation to 10 mg BID can be useful in ¼ of patients who do not respond to standard dose of TOFA. TOFA has shown a good safety profile.

THU0189 SAFETY OF FOUR TREATMENT REGIMENS IN EARLY RHEUMATOID ARTHRITIS

E. Fedorenko[1], G. Lukina[2], Y. Sigidin[3], D. Karateev[3]. *[1]Moscow Clinical Scientific Center; [2]Moscow Clinical Scientific Center, V.A.Nasonova Research Institute of Rheumatology; [3]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Objectives: To compare safety data in patients (pts) with early (<2 years duration) RA who were randomised to receive 4 different regimens of treatment.

Methods: One hundred forty-one pts with RA of less than 2 years duration (122 women, mean age 51 years, mean disease duration 24 weeks, mean DAS 28 5,9; 64% RF-positive,59% ACCP-positive) were randomly allocated to receive one of the following treatment regimens: methotrexate (MTX, up to 20 mg/week,

35 pts); MTX plus prednisolone (P) 10 mg daily (MTX-P, 34 pts); MTX-P plus methylprednisolone (MP) 1000 mg intravenously on the first day of treatment (MTX-P-MP, 35 pts); leflunomide 20 mg daily (LEF, 37 pts). Duration of treatment was one year. Control points were 3, 6 and 12 months from the initiation of therapy. Safety data was assessed at the main control points.

Results: One hundred twenty-seven pts completed the study. Side effects were registered in the same number of patients in each group (9 patients; 24,3%>26%). Therapy had to be stopped in six patients due to side effects: MTX - 1 (depigmentation of the skin), MTX-P - none, MTX-P-MP - 1 (stomatitis) and LEF - 4 (dermatitis-2; pancytopenia with platelet count 43 $\times 10^9$/L, erythrocyte $2{,}9\times 10^{12}$/L, WBC 2×10^9/L-1; angioedema, periorbital edema and dermatitis with itching-1). Other side effects were mild: MTX - 8 pts (dyspepsia-1, elevation of transaminases-6, hair loss-1), MTX-P - 9 pts (Cushing's syndrome - 1, hair loss - 1, anemia - 1, elevation of transaminases - 4, arterial hypertension - 2), MTX-P-MP - 8 pts (hair loss-1,dermatitis-1, elevation of transaminases-5, Cushing's syndrome - 1) and LEF - 5 pts (elevation of transaminases-5). At baseline all groups were comparable in their demographic, clinical and radiographic characteristics.

Conclusions: In most cases side effects were moderate or minimal. The most serious side effects, leading to the discontinuation of the therapy, were registered in LEF group. There was no withdrawal of treatment in MTX-P group. Safety profile was the same in all groups.

THU0190 DERMATOLOGICAL GUIDELINES FOR MONITORING METHOTREXATE TREATMENT REDUCE DRUG-SURVIVAL COMPARED TO RHEUMATOLOGICAL GUIDELINES

H. Bernelot Moens[1], F. Busger op Vollenbroek[1], R. Janssens[2], C. Doggen[3].
[1]Rheumatology & Clinical Immunology; [2]Dermatology, Ziekenhuisgroep Twente, Almelo; [3]Health Technology and Services Research, University of Twente, Enschede, Netherlands

Background: Methotrexate (MTX) is widely used in the treatment of psoriasis and psoriatic arthritis (PsA). To prevent MTX-induced adverse events dermatological MTX guidelines advise a higher number and frequency of blood tests than rheumatological guidelines (1,2). These differences are not based on evidence indicating a higher risk for patients with psoriasis compared to PsA.

Objectives: Compare the effects of MTX monitoring strategies by rheumatologists and dermatologists.

Methods: Patients with psoriasis or PsA in a Dutch teaching hospital. Inclusion criteria: start methotrexate (MTX) between 2006 and 2012 and scheduled follow-up by dermatologist or rheumatologist. Exclusions: incomplete availability of lab data. Start and stop dates and dosing of MTX and folic acid, reasons for withdrawal of MTX, numbers and results of laboratory tests performed for MTX safety, occurrence of any serious adverse event (SAE) were retrieved from electronic records.

Results: PsA patients used higher initial and maximum doses of MTX and folic acid, but psoriasis patients had a higher frequency of abnormal liver function tests, resulting in a striking difference in withdrawal of MTX (Table). In PsA MTX was more often withdrawn for remission, and less frequently for ineffectiveness leading to longer drug survival in the first course of treatment. There were no differences in the occurrence of SAE or death between these groups. Hospital admissions related to infection were recorded in 6 (3.1%) PsA vs 4 (2.1%) psoriasis patients.

Table 1. MTX dose, lab results, and reasons for withdrawal

	Psoriasis (N=190)	Psoriatic arthritis (N=196)
Men, N (%)	86 (45.3)	95 (48.5)
Age (y), mean (SD)	52.3 (16.2)	51.8 (13.8)
Prior treatment with MTX	8 (4.2)	39 (19.9)**
MTX starting dose (mg/week)	12.2 (3.7)	15.2 (3.0)**
Folic acid starting dose (mg/week)	4.9 (0.7)	8.4 (5.6)**
Duration of first treatment course (months)	19.0 (19.5)	34.3 (30.5)**
Laboratory visits per treatment month	0.62 (0.81)	0.50 (0.34)*
Abnormal lab results per treatment month	0.14 (0.26)	0.03 (0.07)**
Abnormal lab results per laboratory visit	0.26 (0.39)	0.06 (0.11)**
Reasons for withdrawal of MTX		
Ineffectiveness	46 (24.1%)	31 (15.8%)*
Remission	14 (7.3%)	21 (10.7%)
Abnormal laboratory result	29 (15.2%)	8 (4.1%)**
Drug toxicity (mild, including infection)	47 (24.6%)	52 (26.5%)
Serious Adverse Event	2 (1.0%)	2 (1.0%)
Death (not related to MTX)	2 (1.0%)	4 (2.0%)
Other	22 (11.6%)	15 (7.6%)

Numbers: mean (SD), *P value ≤0.05; **P-value <0.001 (Fisher's exact test),

Conclusions: Monitoring by dermatologists resulted in more abnormal liver function tests and shorter drug survival of MTX. The monitoring strategy by rheumatologists was not associated with increased SAEs. This supports the safety of current rheumatological guidelines and suggests reconsideration of a higher number of liver function tests in dermatological guidelines.

THU0191 EFFECTS OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, ON PATIENT-REPORTED OUTCOMES IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

H. Yamanaka[1], Y. Tanaka[2], T. Takeuchi[3], N. Sugiyama[4], T. Hirose[4], N. Yoshii[4], Y. Morishima[4], S. Toyoizumi[4]. *[1]Tokyo Women's Medical University, Tokyo; [2]University of Occupational and Environmental Health, Kitakyushu; [3]Keio University; [4]Pfizer Japan Inc, Tokyo, Japan*

Background: Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Improvements in patient-reported outcomes (PROs) have been reported in the global population of the Phase (P)2, P3 and long-term extension (LTE) tofacitinib studies.

Objectives: To explore the effect of tofacitinib on PROs in Japanese patients (pts) with RA.

Methods: In this post hoc analysis, data from Japanese pts with RA were obtained from two 12-week randomised dose-finding P2 studies in methotrexate (MTX) inadequate responder (IR) and DMARD-IR pts (NCT00603512/A3921039 and NCT00687193/A3921040), one 24-month P3 study in MTX-IR pts (ORAL Scan; NCT00847613/A3921044) and an open-label, LTE study in pts who completed a qualifying P2 or P3 study (NCT00661661/A3921041; completed April 2014). Pts received tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO) (P2 and ORAL Scan; no PBO in LTE). In ORAL Scan, non-responder PBO pts advanced to tofacitinib at Month 3; all remaining pts were advanced at Month 6. PROs included: mean change from baseline in Pt's Global Assessment of Arthritis (PtGA; visual analogue scale [VAS]), Physician's Global Assessment of Arthritis (PGA; VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Pain (VAS), Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F), Medical Outcomes Study (MOS) Sleep Scale and Short-Form Health Survey (SF-36) domain scores. Significance was declared for $p\leq 0.05$ for the P2 and P3 studies reported here.

Results: The analysis included 238 pts from P2 studies, 118 pts from ORAL Scan and 486 pts from the LTE study. Demographics and baseline characteristics were similar between treatment groups for all studies. In P2 studies at Week 12, tofacitinib 5 and 10 mg BID demonstrated significantly greater improvements from baseline vs PBO in PtGA, PGA, HAQ-DI, Pain, FACIT-F, MOS Sleep Scale and in 4 (Physical Function [PF], Role-Physical [RP], Bodily Pain [BP] and General Health [GH]) of the 8 SF-36 domain scores (Table). Significant improvements in PtGA, PGA, HAQ-DI, Pain and FACIT-F vs PBO were seen as early as Week 2. In ORAL Scan at Month 3, statistically significant improvements from baseline in PtGA, PGA, HAQ-DI and Pain were seen for both tofacitinib 5 and 10 mg BID vs PBO (Table) and these were maintained to Month 24. Significant improvements vs PBO as early as Month 1 were seen for PGA (tofacitinib 10 mg BID) and Pain (both doses). In the LTE study, mean changes from LTE study baseline in PtGA, PGA, HAQ-DI and Pain were -32.5, -40.8, -0.5 and -32.9, respectively, for all tofacitinib doses at Week 2, and -40.7, -50.2, -0.7 and -42.4, respectively, at Week 168. Mean changes from baseline in SF-36 domain scores at Week 12 and

Week 168, respectively, were: 7.5 and 8.6 (PF); 6.9 and 6.9 (RP); 10.4 and 11.6 (BP); 5.7 and 5.4 (GH); 7.2 and 6.1 (Vitality [VT]); 5.0 and 4.5 (Social Function [SF]); 6.3 and 5.5 (Role-Emotional [RE]); and 6.1 and 4.8 (Mental Health [MH]).

THU0192 INFORMING PATIENTS ABOUT METHOTREXATE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS WITH PATIENTS IN THE UNITED KINGDOM – A SURVEY OF RHEUMATOLOGISTS' STRATEGIES

H.F. Hope[1], S.M. Verstappen[2], L. Cordingley[3], K. Hyrich[2]. *[1]NIHR Manchester Musculoskeletal Biomedical Research Unit; [2]Arthritis Research UK Centre for Epidemiology; [3]Division for Musculoskeletal Research and Dermatological Science, University of Manchester, Manchester, United Kingdom*

Background: Rheumatologists are the primary prescribers of methotrexate (MTX) for the treatment of rheumatoid arthritis (RA) in the United Kingdom (UK), however rheumatologists' views on their clinical practices are largely unknown. The authors conducted a qualitative study that highlighted a number of factors that contributed to their ability to discuss and commence MTX, which included how emotionally and cognitively prepared patients were to discuss treatments. The aim of this study was to further explore these themes with an online survey.
Objectives: The aims of this study were:1)To establish the views of rheumatologists about MTX for the treatment of rheumatoid arthritis (RA), 2)To examine if rheumatologists' views influenced discussing or commencing MTX during the initial consultation.
Methods: An online survey was designed and subsequently refined based on interviews with rheumatologists in the UK. The survey asked rheumatologists about their clinical setting, and their views and practices with respect to treating RA with MTX. Rheumatologists were asked how often specific pieces of MTX information were discussed during a consultation to commence MTX (5=Always to 1=never). They were also asked to identify the barriers to discussing these issues. The questionnaire included a factorial survey ie. two patient vignettes where we manipulated the following factors; male/female, emotionally prepared/unprepared and no/negative prior knowledge. Rheumatologists could select "information overload" as a barrier to communication with the patient. Random mixed effects models tested if these patient factors and information overload associated with 1) commencing and 2) discussing MTX.
Results: Ninety-six rheumatologists seeing approximately eight (IQR:5–12) new patients a week with 15±7 years of experience completed the survey. Rheumatologists reported they often/always discussed ten (IQR 8–11) pieces of information during a consultation (Fig 1A), and information overload was identified as a communication barrier (48%); 52% of rheumatologists expected the nurse to discuss MTX therapy (Fig 1B). Sixty rheumatologists completed one, and 56 rheumatologists two vignettes (n=116). The vignette conditions and information overload significantly associated with "Commencing MTX" (X^2=53.85, p <.0001, R^2=.21) and discussing MTX (X^2=30.9, p =.002, R^2=.19). Gender* emotional preparedness (β=-4.27, 95% CI:-7.33,-1.21), and information overload*emotional preparedness (β=-3.03, 95% CI:-5.24, -.82) associated with MTX commencement, whilst only gender*emotional preparedness with discussing MTX (β=-3.86, 95% CI:-6.82, -.90).

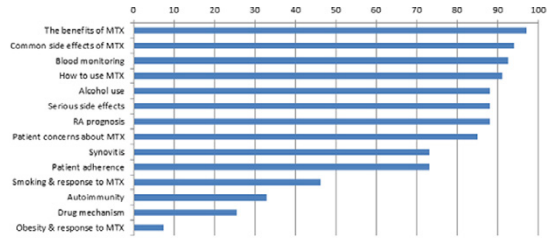

Fig.1A. The specific pieces of MTX-related information rheumatologists in the UK report they often/always discuss in clinic (%)

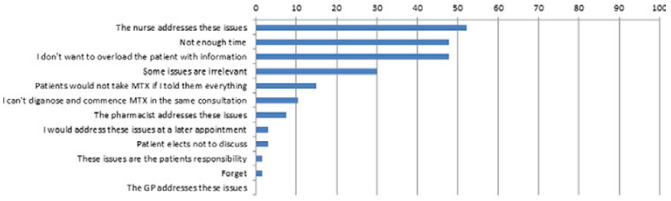

Fig.1B. The reasons rheumatologists in the UK give for not always discussing MTX-related information in clinic (%)

Conclusions: Currently UK rheumatologists convey a large amount of information to patients during early consultations. Almost half of rheumatologists identified the need to communicate large amounts of information in clinical consultations as a barrier to discussing MTX therapy. These data reflect the challenge clinicians face in trying to execute effective shared decision-making practices. Strategies to address patients' emotional responses to their diagnosis and being overloaded with MTX information are needed. Staggering presentation of information during clinical consultations may benefit some patients.

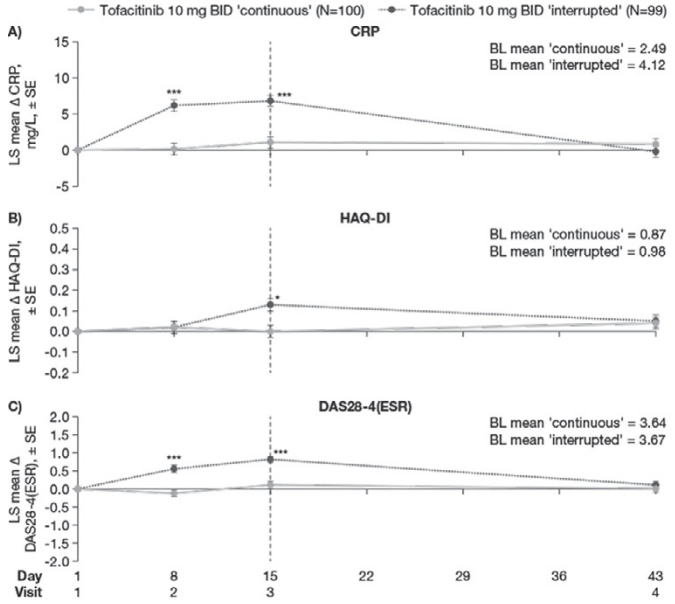
THU0193 REESTABLISHMENT OF EFFICACY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN RHEUMATOID ARTHRITIS PATIENTS AFTER TEMPORARY DISCONTINUATION



J. Kaine[1], J. Tesser[2], R. DeMasi[3], L. Takiya[3], L. Wang[4], M. Snyder[3], H. Fan[4], J. Wollenhaupt[5]. *[1]Sarasota Arthritis Research Center, Sarasota, FL; [2]Arizona Arthritis & Rheumatology Associates, Glendale, AZ; [3]Pfizer Inc, Collegeville, PA; [4]Pfizer Inc, Groton, CT, United States; [5]Schön-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany*

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).
Objectives: To assess the efficacy and safety of tofacitinib after temporary discontinuation and reinitiation of therapy in RA patients (pts).
Methods: Data were collected from a randomised, parallel-group (grp), controlled, open label, vaccine sub-study in RA pts participating in a long-term extension (LTE) study (NCT00413699). Pts were ≥18 years of age with active RA and had received tofacitinib 10 mg BID for ≥3 months. The sub-study included 2 treatment (tx) grps: "continuous tx" (tofacitinib 10 mg twice daily [BID] as monotherapy or with methotrexate [MTX]) and "interrupted tx" (tofacitinib withdrawn for 2

weeks post-randomisation [Day 1–Day 15; Visits 1–3], then tofacitinib 10 mg BID reinitiated as monotherapy or with MTX at Visit 3); randomisation was stratified by MTX use. Pneumococcal and influenza vaccines were administered to all pts on Day 8 (Visit 2; vaccine titers reported previously[1]). Blood samples were taken on Days 8, 15 (Visit 3) and 43 (Visit 4). Efficacy endpoints included change from baseline in C-reactive protein (CRP), Health Assessment Questionnaire Disability Index (HAQ-DI) and Disease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28-4[ESR]) at each visit. A mixed-effects model with repeated measures was used to evaluate treatment effect at each visit. Analyses for efficacy were exploratory, with no multiplicity adjustment for comparisons.

Results: Of the 199 pts in this analysis (continuous, n=100; interrupted, n=99), 117 received concomitant MTX. At LTE study baseline (BL) in the continuous and interrupted grps, respectively: 81.8/83.8% of pts were white, 84.8/86.9% were female and mean age was 55.0/53.9 years. BL (Day 1) values for CRP, HAQ-DI and DAS28-4(ESR) were generally similar between groups. At Day 8, mean CRP and DAS28-4(ESR) significantly increased from BL for interrupted vs continuous tx; HAQ-DI values were similar between grps (Figure). As expected at Day 15, mean CRP, HAQ-DI and DAS28-4(ESR) significantly increased from BL for interrupted vs continuous tx. After tofacitinib reinitiation for 28 days (Day 43), changes in CRP, HAQ-DI and DAS28-4(ESR) were similar between grps and approached BL levels. Adverse events (AEs) were experienced by 35.4% and 49.5% of pts receiving interrupted and continuous tx, respectively. The most frequent treatment-emergent AEs were bronchitis and upper respiratory tract infection (each AE: 6 pts) and vaccination-related immunisation reaction, myalgia and rash (each AE: 5 pts). Serious AEs occurred in 3 pts (3%) in each grp. In total, 1 pt (1%), in the interrupted tx grp, discontinued due to a study-drug related AE; no pts discontinued due to disease flare.

Figure. LS mean change from BL in RA efficacy endpoints over time from a vaccine sub-study with temporary tofacitinib dose interruption

*p<0.05, ***p<0.0001 for 'interrupted' vs 'continuous' tx
Dashed line indicates the end of the dose interruption period which began at BL
Δ, change from BL; BID twice daily; BL, baseline; CRP, C-reactive protein; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire Disability Index; LS, least squares; RA, rheumatoid arthritis; SE, standard error; tx, treatment

Conclusions: Efficacy of tofacitinib 10 mg BID can be reestablished following loss of efficacy during temporary (2 weeks) tx discontinuation in pts with RA. Pts receiving continuous tx maintained efficacy throughout the study. Further investigations are required.

THU0194 THE ROLE OF ENHANCED LIVER FIBROSIS (ELF) SCORE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH METHOTREXATE

J. Swierkot[1], M. Frankowski[2], M. Skoczynska[2], A. Starba[2], M.S. Gomulkiewicz[3], P. Wojtala[2], M. Bujak[3]. *[1]Department of Rheumatology and Internal Medicine, Medical University Wroclaw; [2]Department of Rheumatology and Internal Medicine; [3]Department of Radiology, Wroclaw University Hospital, Wroclaw, Poland*

Background: MTX is still a basic medicament used in treatment of patients with RA. One of its adverse reaction is its hepatoxicity. Previous studies have established high diagnostic accuracy of the ELF score to assess hepatic fibrosis in chronic viral hepatitis and fatty liver disease.

Objectives: The aim of the research was the evaluation of the usefulness of ELF markings, by patients treated with MTX, as an indicator which shows potential liver damage.

Methods: In the research were analyzed results of 96 patients with RA treated with MTX. Average age of patients was 60 (19–85 years old), median of body mass was 70 kg (46–140), median of BMI was 26 (16–46). Average time of taking MTX were 4 years and median of the accumulated dose was 3140 mg (12,5–27400mg). Disease activity in the moment of evaluation, evaluated by DAS 28, was 4,3 (0,98–8,42).

Achieved results ELF, PIIINP were correlated with body mass, BMI, dose of MTX, other illnesses (e.g. diabetes), taken nonsteroidal anti-inflammatory drugs and statins. In statistical analysis were used Pearson correlation and U Mann-Whitney test.

Results: The ELF values correlated with age, accumulated dose and DAS 28. Along with the increase of accumulated dose of MTX, disease activity and by older patients, were observed higher ELF values (the differences were statistically significant). The PIIINP values correlated with patients' body mass, accumulated dose of MTX and disease activity, evaluated by DAS 28. The differences were statistically significant. Along with the increase of body mass, accumulated dose and DAS 28, were observed higher values of PIIINP. Patients with diabetes had statistically higher values of PIINP (average: 11.13, median: 11,38), than patients without diabetes (average: 8.06, median: 7.15). There was observed no relationship between ELF and PIIINP results with taken nonsteroidal anti-inflammatory drugs and statins.

Conclusions: The ELF test, and one of its elements, PIIINP, may be useful in the evaluation of patients with higher probability of hepatotoxic effect of MTX. Special attention should be paid to older, obese patients, with diabetes, patients who take higher accumulated dose of MTX and with higher disease activity.

THU0195 CONSISTENT EFFICACY AND SAFETY OF TOFACITINIB IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE OR INTOLERANCE TO NON-MTX CSDMARDS

J. Tesser[1], A. Gül[2], E. Olech[3], K. Oelke[4], T. Lukic[5], C.W. Murray[6], C. Zhang[6], L. Takiya[6]. *[1]Arizona Arthritis & Rheumatology Associates, Glendale, AZ, United States; [2]Istanbul University, Istanbul, Turkey; [3]UNLV School of Medicine, Las Legas, NV; [4]Rheumatic Disease Center, Glendale, WI; [5]Pfizer Inc, New York, NY; [6]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. In clinical practice, a proportion of patients (pts) with RA may not be candidates for treatment with the conventional synthetic DMARD (csDMARD) methotrexate (MTX).[1]

Objectives: To evaluate tofacitinib 5 or 10 mg BID efficacy and safety using pooled data from 8 Phase (P) 2 and 6 P3 trials in RA pts who were (1) inadequate responders (IR)/intolerant to csDMARDs, but did not have an IR or intolerance to MTX or biologic DMARDs (ie, non-MTX csDMARD-IR population) or (2) pts with an IR/intolerance to any csDMARD including MTX but not bDMARD-IR (ie, 2nd-line population).

Methods: Month 3 efficacy outcomes included proportions of pts achieving ACR20/50/70 responses, and Disease Activity Score 28-4(ESR) (DAS28-4[ESR])<2.6 (remission), as well as change from baseline in DAS28-4(ESR) and Health Assessment Questionnaire-Disability Index (HAQ-DI) scores. No multiplicity adjustments were made. Crude incidence rates (CIR; unique pts with events/100 pt-years) based on adverse event (AE) reporting through Month 24 were calculated for treatment-emergent AEs (TEAEs), serious AEs (SAEs), discontinuations (DCs) due to AEs and AEs of special interest.

Results: In the P2/3 tofacitinib RA trials, prior csDMARDs received by the non-MTX csDMARD-IR and 2nd-line populations, respectively were: chloroquine (17.7% and 37.2%), hydroxychloroquine (13.7% and 22.7%), leflunomide (19.4% and 20.9%), MTX (7.3% and 93.3%), sulfasalazine (31.1% and 27.1%) and others (8.0% and 11.1%); pts may have received >1 prior csDMARD. The non-MTX csDMARD-IR population included 208, 247 and 82 pts receiving tofacitinib 5 and 10 mg BID or placebo (PBO), respectively; the 2nd-line population comprised 1206, 1266 and 856 pts, respectively. Baseline characteristics were generally similar between populations except for mean RA duration (5.2–7.2 years, non-MTX csDMARD-IR pts; 8.2–8.5 years, 2nd-line pts). Most pts were female (80.3–85.4%), mean age range was 49.7–52.5 years and mean DAS28-4(ESR)

score ranged from 6.2–6.5. Tofacitinib 5 and 10 mg BID achieved higher ACR responses and greater changes from baseline in DAS28-4(ESR) and HAQ-DI scores vs PBO at Month 3 in both populations (Table). Numerically higher proportions of non-MTX csDMARD-IR pts achieved efficacy outcomes vs 2nd-line population. CIRs for SAEs, DCs due to AEs and AEs of special interest were similar across groups; CIRs for TEAEs were higher with PBO vs tofacitinib. AE frequency was generally lower in the non-MTX csDMARD-IR population vs 2nd-line population.

Table. Efficacy outcomes at Month 3 and safety outcomes to Month 24

	Tofacitinib 5 mg BID		Tofacitinib 10 mg BID		PBO	
	Non-MTX csDMARD-IR	Second-line	Non-MTX csDMARD-IR	Second-line	Non-MTX csDMARD-IR	Second-line

Malignancies[#]	0.4 (0.0–2.2)	0.7 (0.3–1.4)	0.3 (0.0–1.9)	0.7 (0.3–1.5)	0.0 (0.0–19.9)	0.0 (0.0–1.6)

[a]p<0.001; [b]p<0.05 vs PBO; [#]excluding non-melanoma skin cancer; AE, adverse event; CI, confidence interval; CIR, crude incidence rate; csDMARD, conventional synthetic disease modifying antirheumatic drug; DAS28-4(ESR), disease activity score 28-4(ESR); DC, discontinuation; FAS, full analysis set; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, inadequate response; LSM, least squares mean; MACE, major adverse cardiovascular events; MTX, methotrexate; NRI, non-responder imputation; OI, opportunistic infection; PBO, placebo; SAE, serious AE; SE, standard error; SIE, serious infection event; TB, tuberculosis; TEAE, treatment emergent adverse event

Conclusions: This analysis indicates that tofacitinib is associated with similar efficacy and safety outcomes between csDMARD-IR (including MTX-IR) pts and those who are csDMARD-IR but not MTX-IR. This suggests a favourable tofacitinib benefit/risk profile for RA pts who have a contraindication to or refuse treatment with MTX and failed other csDMARDs.

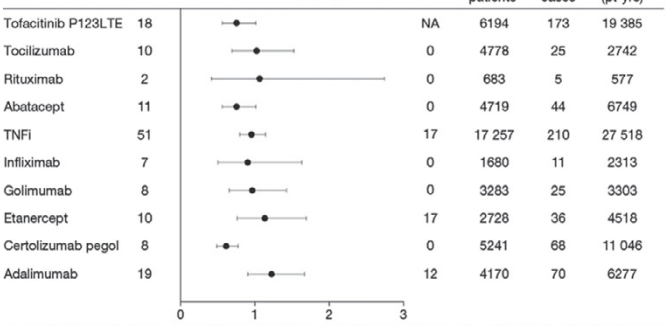
THU0196 SYSTEMATIC REVIEW AND META-ANALYSIS OF MALIGNANCIES, EXCLUDING NON-MELANOMA SKIN CANCER, IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOFACITINIB OR BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

J.J. Gomez-Reino[1], T. Checchio[2], J. Geier[3], M. Boy[2], S. Ahadieh[2], S. Menon[2], S. Krishnaswami[2]. *[1]Fundacion Ramon Dominguez, Hospital Clinico Universitario, Santiago de Compostela, Spain; [2]Pfizer Inc, Groton, CT; [3]Pfizer Inc, New York, NY, United States*



Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). The limited size of the control groups (placebo and active comparator) and limited duration of treatment within the tofacitinib RA clinical trial programme do not permit precise direct comparative assessments for adverse events of long latency, including malignancies, therefore a meta-analytic approach was taken.

Objectives: To compare the rate of malignancies in patients (pts) with moderately to severely active RA within the tofacitinib RA clinical trial programme with estimates from published trial data of approved biologic (b)DMARDS using meta-analytic methods.

Methods: Incidence rates (IR; pts with events per 100 pt-years [yrs] exposure) for tofacitinib were calculated using pooled data from randomised controlled trials (RCT) and long-term extension (LTE) studies. Two Phase (P) 1 studies, 9 P2 studies, 6 P3 studies and 2 LTE studies (one study ongoing; database unlocked at March 2015 data cut off) constituted the P123LTE dataset; pts received 1, 3, 5, 10, 15, 30 mg BID or 20 mg QD of tofacitinib. A systematic literature review of published RCT and LTE studies (through August 2014) of approved bDMARDs (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab) was conducted. IRs for the endpoint of interest (all malignancies [excluding non-melanoma skin cancers (NMSC)]) were calculated for each bDMARD utilising a random-effects meta-analytic model with a restricted Maximum Likelihood Estimator for between-study variances. Estimates of Q statistic and I^2 were generated to determine the existence and degree of heterogeneity related to the study pool.

Results: The tofacitinib P123LTE dataset included 6194 pts with a total exposure of 19 385 pt-yrs. A total of 64 bDMARD articles were extracted for analysis, representing 58 unique studies and approximately 27 000 pts. Study populations were generally consistent across studies and treatments: mean pt age ranged from 51–54 yrs; mean percentage of pts who were female was 74–84%; and mean baseline C-reactive protein level was 20–31 mg/L. The IR (95% confidence interval [CI]) of malignancy for tofacitinib in the P123LTE dataset was 0.89 (0.76, 1.04) (Figure). Estimated IRs (95% CI) of malignancy were 0.75 (0.56, 1.01) for abatacept, 1.06 (0.41, 2.74) for rituximab, 1.02 (0.69, 1.52) for tocilizumab and 0.95 (0.79, 1.14) for tumour necrosis factor inhibitors (adalimumab, certolizumab, etanercept, golimumab and infliximab) (Figure).

Figure. Incidence rates for all malignancies (excluding NMSC) with biologic DMARDs and tofacitinib across RCTs and LTE studies

The results displayed include a continuity factor (r=0.05) to account for zero incidence rates. Tofacitinib data included through March 2015. Clinical trials for non-tofacitinib studies were conducted between 1997 and 2014.
CI, confidence interval; DMARD, disease-modifying antirheumatic drug; I^2, percent of total variability due to heterogeneity; LTE, long-term extension; NA, not applicable; NMSC, non-melanoma skin cancer; pt-yr, patient-year; RCT, randomised controlled trial; TNFi, tumour necrosis factor inhibitor

Conclusions: The results of this meta-analysis indicate that the tofacitinib IR for all malignancies (excluding NMSC) in pts with moderately to severely active RA is within a similar range to those reported in published interventional studies of similar RA populations treated with approved bDMARDs.

THU0197 TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN THE TREATMENT OF RHEUMATOID ARTHRITIS: SAFETY AND EFFICACY IN OPEN-LABEL, LONG-TERM EXTENSION STUDIES OVER 8 YEARS

J. Wollenhaupt[1], J. Silverfield[2], E.B. Lee[3], K. Terry[4], K. Kwok[5], S. Abramsky[5], M. Wang[5], C. Nduaka[6], R. DeMasi[6], L. Wang[4]. *[1]Schön-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany; [2]Healthpoint Medical Group, Tampa, FL, United States; [3]Seoul National University, Seoul, Korea, Republic Of; [4]Pfizer Inc, Groton, CT; [5]Pfizer Inc, New York, NY; [6]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

Objectives: The objective of this analysis was to report tofacitinib safety, tolerability and clinical efficacy in long-term extension (LTE) studies with up to 105 months of observation.

Methods: Data were pooled from two open-label studies (NCT00413699 [ongoing; database not locked at January 2016 data-cut] and NCT00661661) of patients with RA who had participated in Phase 1/2/3 tofacitinib studies. Patients received tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background disease-

modifying antirheumatic drugs (DMARDs). Primary endpoints were adverse events (AEs) and confirmed laboratory safety data. Secondary endpoints included clinical efficacy measures (American College of Rheumatology [ACR] 20/50/70 response rates, Disease Activity Score using 28 joint counts and erythrocyte sedimentation rate [DAS28-4(ESR)], Health Assessment Questionnaire-Disability Index [HAQ-DI] and clinical disease activity index [CDAI]). Safety data were included up to Month 105 and efficacy data up to Month 90 (n≤100 at Month 96).

Results: A total of 4967 patients were treated (mean [max] duration: 1215 [3182] days). Total tofacitinib exposure was 16,711 patient-years; 77.4% of patients maintained their initial dose. In total, 2370 patients (47.7%) discontinued (AEs: 1131 [22.8%]; insufficient clinical response: 175 [3.5%]). The most common AE classes were infections and infestations (68.9%) and musculoskeletal/connective tissue disorders (39.0%). The most common AEs were nasopharyngitis (18.7%), upper respiratory tract infection (17.2%), bronchitis and urinary tract infection (12.2% each). Serious AEs occurred in 28.6% of patients and serious infection events (SIEs) in 8.8% of patients. Malignancies, excluding non-melanoma skin cancer, were reported in 3.0% of patients. Incidence rates (IR; patients with events per 100 patient-years) for AEs of interest (with 95% confidence intervals [CIs]) and laboratory observations are provided in Table 1. IRs for SIEs and malignancies through Month 105 did not increase compared with reported data through Month 96.1 No new safety risks were identified. Clinical responses were sustained from Month 1 to Month 90 (Table 2).

Table 1. Safety outcomes and laboratory observations in LTE studies (up to 105 months) of tofacitinib in patients with RA

	Tofacitinib (5 and 10 mg BID) ± background DMARDs N=4967
Incidence rates (patients with events per 100 patient-years) for AEs of interest (95% CI)	
SAEs	9.5 (9.0, 10.0)
SIEs	2.6 (2.4, 2.9)
Malignancies (excluding NMSC)	0.9 (0.8, 1.0)
Confirmed laboratory abnormalities, n (%)	
Haemoglobin ≤7 g/dL or decrease in haemoglobin of ≥3 g/dL from BL	97 (2.0)
Neutrophil <0.5 x 10^3/mm^3	0 (0.0)
Lymphocyte <0.5 x 10^3/mm^3	64 (1.3)
ALT ≥3 x ULN	292 (5.9)
AST ≥3 x ULN	167 (3.4)
Increase in serum creatinine of ≥50% from BL	147 (3.0)

AE, adverse event; ALT, alanine aminotransferase; AST, aspartate aminotransferase; BID, twice daily; BL, baseline; CI, confidence interval; DMARDs, disease-modifying antirheumatic drugs; LTE, long-term extension; NMSC, non-melanoma skin cancer; RA, rheumatoid arthritis; SAEs, serious adverse events; SIEs, serious infection events; ULN, upper limit of normal.

Table 2. Clinical outcomes in LTE studies (up to 90 months) of tofacitinib in patients with RA

	Tofacitinib (5 and 10 mg BID) ± background DMARDs		
	BL	Month 1	Month 90
		N=4907	N=171
ACR20 response rates, %	–	73.0	83.0
ACR50 response rates, %	–	49.2	56.1
ACR70 response rates, %	–	28.9	32.7
	N=4782	N=4776	N=168
DAS28-4(ESR), mean (SE)	6.29 (0.01)	3.75 (0.02)	3.38 (0.09)
	N=4924	N=4880	N=170
HAQ-DI, mean (SE)	1.42 (0.01)	0.82 (0.01)	0.76 (0.05)
		N=4802	N=169
CDAI, mean change from BL (SE)	–	-24.0 (0.20)	-28.5 (1.02)

ACR, American College of Rheumatology criteria; BID, twice daily; BL, baseline; CDAI, clinical disease activity index; DAS28-4(ESR), Disease Activity Score using 28 joint counts and erythrocyte sedimentation rate; DMARDs, disease-modifying antirheumatic drugs; HAQ-DI, Health Assessment Questionnaire-Disability Index; LTE, long-term extension; RA, rheumatoid arthritis; SE, standard error.

Conclusions: In patients with RA who remained in the LTE studies, tofacitinib (5 or 10 mg BID) with or without background DMARDs was associated with consistent safety through Month 105 and sustained clinical efficacy through Month 90.

THU0198 COMPARISON OF EFFICACY BETWEEN COMBINATION THERAPY WITH IGURATIMOD AND SULFASALAZINE WITH METHOTREXATE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: PROPENSITY SCORE ANALYSIS

K. Tokunaga[1], A. Shiraishi[2], H. Oshikawa[1], N. Hagino[3], J. Nishino[4], S. Tohma[5]. *[1]Department of Rheumatology, Japanese Red Cross Kumamoto Hospital, Kumamoto; [2]Emergency Department, Kameda Medical Center; [3]Department of Rheumatology, Teikyo University Chiba Medical Center, Chiba; [4]Department of Orthopedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo; [5]Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, Sagamihara National Hospital, Sagamihara, Japan*

Background: Iguratimod (IGU) is a small-molecule disease-modifying antirheumatic drug (DMARD) that has been shown to suppress inflammation via the inhibition of nuclear factor-kappa B activation in vitro. The efficacy of combination therapy with IGU and methotrexate (MTX) has been demonstrated in comparison with that of placebo in rheumatoid arthritis (RA). However, its efficacy in comparison with other DMARDs such as sulfasalazine (SSZ) has not been elucidated.

Objectives: To clarify the efficacy of combination therapy with IGU in comparison with that of SSZ with MTX in typical clinical practice.

Methods: We analyzed data from 16,825 RA patients registered in a large database (NinJa: National Database of Rheumatic Diseases by iR-net in Japan) from April 2011 to March 2015 (1). In this study, we compared the two groups who received IGU or SSZ in addition to methotrexate in the earlier year. We excluded patients who started receiving biologic DMARDs, and IGU or SSZ the year prior to the study period, and those whose regimens were changed to other DMARDs such as tacrolimus and bucillamine. Baseline characteristics were compared using the *t* test, Wilcoxon test, or chi-square test. Fisher analysis was conducted for both outcomes. The predicted probability of IGU treatment was calculated by fitting a logistic regression model using all clinically relevant variables as presented in Table 1. Moreover, to reduce the effect of treatment-selection bias and potential confounding in this observational study, we performed rigorous adjustment for significant differences in the baseline characteristics of patients with propensity-score matching using the following algorithm: 1:1 optimal match with a ±0.15 caliper and no replacement. We used the standardized difference to measure covariate balance, whereby a standardized mean difference of >0.1 represents meaningful imbalance. The outcome was remission rate with disease activity score 28 CRP (DAS28-CRP) in the year after initiation of IGU or SSZ therapy.

Results: The group that received IGU in addition to MTX included 66 patients; the other group that received SSZ in addition to MTX included 163 patients. Table 1 shows the results of the pre- and post-propensity score matching of patients' characteristics. Sixty-five patients were compared in each group after score matching. The remission rates of DAS28-CRP in the following year was 77.2% (44/57 patients) and 71.7% (38/53 patients; P=0.52) in the IGU and SSZ groups, respectively.

Table 1. Patients' Characteristics in Full and Propensity Score-Matched Cohorts according to Initiation of Iguratimod or Sulfasalazine

Characteristic	Full Cohort			Propensity Score-Matched Cohort		
	IGU (n = 66)	SSZ (n = 163)	SMD	IGU (n = 65)	SSZ (n = 65)	SMD
Sex, male (%)	32 (19.6)	11 (16.7)	0.077	13 (20.0)	11 (16.9)	0.079
Age per decade (mean [SD])	5.57 (1.44)	5.70 (1.15)	0.097	5.78 (1.36)	5.66 (3.24)	0.099
MTX (mg/week) (mean [SD])	9.38 (3.38)	9.34 (3.28)	0.01	9.26 (3.51)	9.42 (3.24)	0.048
PSL (mg/day) (mean [SD])	1.72 (2.53)	1.71 (2.53)	0.002	1.51 (2.32)	1.74 (2.54)	0.093
SJC 66 (mean [SD])	2.38 (3.57)	3.03 (3.68)	0.207	3.15 (4.10)	2.97 (3.67)	0.047
TJC 68 (mean [SD])	2.70 (4.61)	2.85 (4.52)	0.033	2.57 (4.91)	2.86 (4.55)	0.062

IGU: iguratimod; MTX: methotrexate; PSL: prednisolone; SD: standard deviation; SJC: swollen joint count; SMD: standardized mean difference; SSZ: sulfasalazine; TJC: tender joint count

Conclusions: Combination therapy with IGU or SSZ and methotrexate for rheumatoid arthritis did not show a significant difference in disease activity. Further studies are needed.

THU0199 TOFACITINIB IMPROVES LEFT VENTRICULAR MASS AND CARDIAC OUTPUT IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Kume, K. Amano, S. Yamada, T. Kanazawa, K. Hatta. *Rheumatology, Hiroshima Clinic, Hiroshima, Japan*

Background: Rheumatologists need to develop primary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tofacitinib (Tofa) improved arterial stiffness in RA patients. RA is associated with an increased *left* ventricular mass index (LVMI), a strong marker of cardiovascular mortality.There is no evidence that Tofa effects on left ventricular (LV) morphology and function.

Objectives: To study the effect of Tofa plus methotrexate (MTX) on LV morphology and function in MTX resistant active RA patients, in a cohort study design.

Methods: RA patients were eligible if they had active disease despite treatment with MTX. All patients have no steroids, and no previous history of CVD. Consecutive 28 patients with moderate to severe active RA patients (DAS28>3.2) despite MTX were received Tofa plus MTX. LV morphology and function was assessed with cardio-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

Results: 24 patients completed 24 weeks. Left ventricular mass index (LVMI) was attenuated significantly by Tofa (week 0-week24, –12.4±5.4 g/m^2; p=0.0002). Cardiac output (CO) was attenuated significantly by Tofa (week 0-week24,-0.87±1.2l/min). DAS28 and CRP improved significantly by Tofa (week 0-week24; DAS28: -2.26±0.91; CRP: 14.1±8.7 mg/l) ($p<0.05$). Surprisingly, the change of disease activity (DAS 28 and CRP) is no correlation with the change of LVMI or CO in this study. Observationally, 4 cases significantly improved right ventricular mass as well as left ventricular mass (20% improved right ventricular mass index from baseline).

Conclusions: Tofa improved LVMI and CO in active RA despite MTX. TCZ improves LVMI and CO independently of its effects on disease activity. Tofa might be improved right ventricular mass. JAK-STAT pathway might be an important role of LV hypertrophy. Tofa, JAK-STAT pathway blocking, may prevent cardiovascular morbidity and mortality in RA.

THU0200 RISK FOR DEVELOPING ADVERSE EFFECTS CAUSED BY SALAZOSULFAPYRIDINE IN RHEUMATIC DISEASES

K. Nakanishi[1], M. Kinjo[2]. [1]*Okinawa Hokubu Hospital, Nago;* [2]*Okinawa CHUBU Hospital, Uruma, Japan*

Background: Salazosulfapyridine is non-antimicrobial sulfonamides, which is used as a synthetic disease modified anti-rheumatic-drug (DMARD) for rheumatoid arthritis and psoriatic arthritis. Prior study suggested sulfa allergy may be more commonly seen in patients with positive anti- Ro/SS-A antibody (anti-Ro).

Objectives: To identify the risk factor for adverse effects (AEs) caused by salazosulfapyridine in patients with rheumatic diseases.

Methods: We retrospectively identified patients ≥18 years old who received salazosulfapyridine at a tertiary medical center in Japan between 2010–2015. Data were collected on the incidence of AEs, clinical features and autoantibodies.

Results: We identified 313 patients with rheumatic diseases who received salazosulfapyridine. Median age was 61 (range, 20–95); 215 of 313 (67%) were female (Table). The incidence of AEs was 15% (48/313); Median duration until developing AEs was 14 days (range, 2–50). AEs included rash (28), fever (19), elevated liver function tests (13), gastrointestinal symptoms (9), lymphadenitis (3), neutropenia and eosinophilia (1). Factors associated with AEs are female gender, positive anti-Ro or psoriatic arthritis. Multivariate logistic controlling for age, gender and anti-Ro showed that positive anti-Ro has 2.33 odds (P=0.03; 95% CI: 1.07–5.08) of having AE of salazosulfapyridine. Among patients without anti-Ro, subjects with psoriasis showed 9.95 odds (P<0.001; 95% CI: 3.51–28.2) of developing AEs than non-psoriatic patients.

Conclusions: AEs caused by salazosulfapyridine are common in patients with rheumatic diseases. Presence of anti- Ro or psoriasis may be a risk factor for AEs caused by salazosulfapyridine.

Table

	With AEs (n=48)	Without AEs (n=265)	P value
Age over 60 years — no. (%)	22 (46)	26 (56)	0.21
Female sex — no. (%)	42 (88)	173 (65)	0.002
Clinical diagnosis			
Rheumatoid arthritis — no. (%)	26 (54)	214 (81)	0.002
Sjogren's syndrome — no. (%)	15 (31)	31 (12)	0.001
Psoriatic arthritis — no. (%)	19 (40)	11 (4)	<0.001
Anti-Ro/SS-A antibody — no. (%)	14 (29)	28 (11)	0.006

THU0201 OLDER AGE, HYPOALBUMINAEMIA AND RENAL FAILURE MIGHT BE POOR PROGNOSIS FACTORS FOR LOW DOSE METHOTREXATE-INDUCED MYELOSUPPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

X.-N. Wei, D.-H. Zheng, Y.-Q. Mo, J.-D. Ma, Y.-L. Chen, L. Dai. *Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

Background: Methotrexate (MTX) serves as an anchor drug in rheumatoid arthritis (RA) and the maximal dose of MTX from EULAR recommendation is 25–30 mg/w. Small cases retrospective cohort studies reported that the mortality rate of RA patients with low dose (5–25 mg/w) MTX-induced myelosuppression was about 17–25%. However, studies of low dose MTX-induced myelosuppression are rare in Chinese RA patients.

Objectives: To perform a retrospective case series analysis of the characteristics and outcomes of RA patients with low dose MTX-induced myelosuppression in China.

Methods: RA patients hospitalized at Sun Yat-Sen Memorial Hospital from January 2001 to December 2016 were recruited. Clinical data were collected and adverse effects were recorded simultaneously. Low dose MTX-induce myelosuppression was diagnosed as white blood cell $<4\times10^9$/L together with hemoglobin <130 g/L and platelet count $<130\times10^9$/L after treatment of MTX without an alternative cause for pancytopenia. Data were showed as mean ± standard deviation.

Results: (1) There were 1137 RA patients recruited and 17 patients (1.5%) of them were hospitalized for low dose MTX-induce myelosuppression. Among these 17 patients, 53% were females, age was 68±5 years, disease duration was 12±11 years.

(2) Four (23.5%) patients had dose errors, taking MTX 5–10mg daily for 24 days (range: 5–80), MTX accumulated dose was 25–200mg before myelosuppression. Mean MTX dose in the other patients (n=13, 76.5%) was 11.0±1.7 mg/w (range: 7.5 –15), course of MTX was 10±11 months (range: 0.5–48). Four (30.8%) patients manifested myelosuppression within the first month after taking MTX, and 4 (30.8%) patients had been well on a stable drug dose (7.5–12.5) for more than one year before myelosuppression, 2 patients manifested myelosuppression after adding MTX dose to 15mg/w for 2 months.

(3) Fifteen (88.2%) patients had oral mucositis, eight of them had involvement of both oral mucosa and skin. Fever was noticed in 10 (58.8%) patients. Infections were recorded in 6 (35.3%) patients, manifested as pneumonia (n=4), sepsis (n=1), urinary tract infection (n=1) and skin soft tissue abscesses (n=1). Two patients experienced abdominal pain and melena.

(4) Among the patients with neutropenia [n=17, mean neutrophil count: $(0.74\pm0.76)\times10^9$/L, range: 0–1.83], 9 (52.9%) developed severe neutropenia with neutrophil counts below 0.5×10^9/L. Five patients developed severe thrombocytopenia (platelet count $<20\times10^9$/L), and severe anemia occurred in 4 patients (hemoglobin <65g/L). Hypoalbuminemia (30.0±2.8 g/L) was noted in all patients. Glomerular filtration rate (GFR)≤30 ml/min/1.73 m^2 was noted in 4 (23.5%) patients and GFR≤50 ml/min/1.73 m^2 in 12 (70.6%) patients.

(5) Pancytopenia recovered (n=17) after discontinuation of MTX and supplementation of folic acid (10–30mg/d). Only 3 (17.6%) patients were treated with rescue intravenous leucovorin. Thirteen (76.5%) were treated with granulocyte colony stimulating factor (G-CSF) and 7 (41.2%) required blood products. Fifteen (88.2%) required antibiotic therapy. Sixteen (94.1%) patients was recovered and discharged, only one patient die from acute brainstem infarction but not from myelosuppression.

Table 1 Characteristics of 17 RA patients with low dose MTX-induce myelosuppression

Case	Age (y)	Sex	Dose (mg/w)	Dose errors	Fever	Mucositis	Neutrophil count (×10^9/L)	Platelet count (×10^9/L)	Hemoglobin (g/L)	GFR (ml/min/1.73 m^2)	Albumin (g/L)	Outcome
1	74	F	10	+	-	+	0.32	107	87	50.0	34.2	Recovered

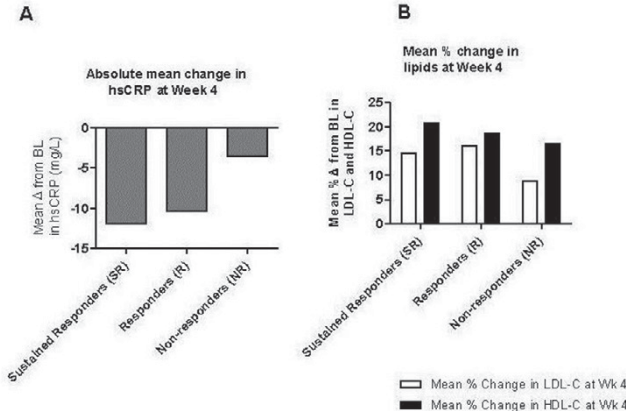
THU0202 UNAFFORDABLE CONVENTIONAL AND ABSENT BIOLOGIC DMARDS: INCREASING THE BURDEN OF RHEUMATOID ARTHRITIS IN FYROM

O. Gjeorgjieva, N. Memeti, L. Damjanovska-Krstikj. *University Rheumatology Clinic, University Sts Cyril and Methodius, Skopje, Macedonia, The Former Yugoslav Republic Of*



Background: In the developing world rheumatologists and their patients are struggling to implement treat to target therapy in established Rheumatoid Arthritis (RA)which means they can hardly establish remission and low disease activity which is the mainstay of the RA treatment. The main reason is the lack of conventional synthetic and biological (c and b) DMARDs in the therapeutic armamentarium as well as their high cost which increases already difficult burden of RA.
Objectives: The aim of the study is to evaluate the RA treatment and treatment expenses in a group of patients with established RA in FYR of Macedonia including the availability of DMARDs.
Methods: We have conducted a cross-sectional study at the University Rheumatology Clinic in Skopje, including 100 patients with established RA, who fulfilled RA classification criteria from 2010. Physical examination, laboratory analyses and DAS28 were performed and all patients filled a questionnaire with 13 questions about treatment expenses and availability.
Results: There were 82 females and 18 males, with mean age of 59 and disease duration of 8.3 (SD 7,3) years and moderate disease activity DAS28 3,9+/-1,47 and 75% of seropositive RA (double positive 30%, Ant-CCP positive 30%, RF positive 15%) with mean CRP of 21,5 mg/L They spend from 10 to 100 Euros monthly (on average 27+/-17,6) for the cs DMARDs therapy. Almost 80% think that the cs DMARDs therapy is too expensive for them and 100% of them could not afford to pay or co-pay for b DMARDs. Most of the patients (49%) are using single cs DMARDs. Double and triple c DMARD therapy is used by 32% vs 17%, respectively. Even though it is highly effective, patients consider triple cs DMARD therapy expensive and with very low compliance because of the high costs and low tolerability. Only 2% of the patiens are using b DMARDS using rituximab, the only available biologic DMARD therapy in FYROM. Around 70% are taking low dose prednisolone. Almost 50% of the patients cannot take the cs DMARD therapy with a prescription and have to buy their DMARDS without any coverage from the insurance fund and the same percent have problems to find the c DMARDs with prescription because it is not available. Almost half of the patients have heard about the b DMARDs, most of them from their rheumatologist and 54% of them would like to receive it. The patient's reasons for taking b DMARDs are presented in Graph 1.
Conclusions: High expenses and low availability of c DMARDs on prescription and the urgent need for b DMARDs are adding the burden of RA in developing countries including FYROM with the increased need for full coverage for conventional DMARDs and at least partial coverage of biologic DMARDs, especially anti-TNF agents by the insurance companies. The use of biosimilars might be highly appreciated in the future.

THU0203 CHANGES IN C-REACTIVE PROTEIN AND LIPID LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABT-494, A SELECTIVE JAK-1 INHIBITOR

M. Nurmohamed[1], Y. Zhang[2], J. Lin[2], H. Camp[2]. *[1]Amsterdam Rheumatology Immunology Ctr, VU Univ Medical Ctr, Amsterdam, Netherlands; [2]AbbVie, N Chicago, United States*

Background: In patients (pts) with rheumatoid arthritis (RA) treated with ABT-494, dose-dependent increases in levels of low and high density lipoprotein cholesterol (LDL-C and HDL-C) were observed, along with decreases in levels of C-reactive Protein (CRP). Whether these changes are due to the control of inflammation or a direct effect on CRP production in the liver is not known.
Objectives: To explore the relationship between changes in HDL-C or LDL-C and CRP with ABT-494 treatment, and to assess whether the effect on lipids is dependent on improvement of RA signs and symptoms.
Methods: Data were from two phase 2b controlled trials of ABT-494 in RA pts with inadequate response or intolerance to TNF inhibitors (TNF-IR, BALANCE-1)[1], or with inadequate response to methotrexate (MTX-IR, BALANCE-2)[2]. Pts treated with placebo or 3,6,12,18 mg ABT-494 twice daily for 12 weeks (wks) are included. Levels of high sensitivity (hs) CRP, total cholesterol (TC), LDL-C and HDL-C were measured at baseline (BL) and Wk 2,4,6, 8 and 12. Atherogenic burden at BL and Wk 12 was assessed by ratio of ApoB:ApoA1 and TC:HDL-C in 6 mg and 12 mg dose groups in both studies. Pearson's coefficients were calculated *post hoc* to assess possible correlations between HDL-C or LDL-C levels (or changes from BL) with other variables including (high sensitivity) hsCRP, at BL and Wk 12. Pts were subgrouped by response: Sustained responders (SR), pts who achieved an ACR20 response at every visit from Wk 2–12; Responders (R), pts who achieved ACR20 at least once, but not at every visit; Non-responders (NR), pts who did not achieve ACR20 at any visit.
Results: The ratios of LDL-C:HDL-C[1,2] and TC:HDL-C remained unchanged after 12 wks of treatment with ABT-494. The ratio of ApoB:ApoA1 also remained unchanged from BL to Wk 12: in BALANCE-1, 0.61 to 0.58 for the 6 mg (n=19), and 0.62 to 0.60 for 12 mg (n=11) groups, and in BALANCE-2, 0.62 to 0.64 for the 6 mg (n=18) and 0.69 to 0.66 for 12 mg (n=16) groups. An inverse relationship between LDL-C or HDL-C and hsCRP was observed throughout the treatment period. At Wk 4, among the variables tested, the strongest correlation was observed between changes from BL in hsCRP and LDL-C (-0.29, $p<0.001$) or HDL-C (-0.26, $p<0.001$). Out of 420 pts, 104 pts (25%) were ACR20 SR, 251 pts (60%) were R and 65 pts (15%) were NR. Compared to NR, SR and R had a greater absolute reduction in hsCRP (Fig. 1A). A robust percentage increase in HDL-C was observed in all 3 groups (20.8%, 18.5% and 16.4% in SR, R and NR, respectively). Compared to the SR and R (14.6% and 16%, respectively), a smaller percentage increase in LDL-C was observed in the NR (8.9%) (Fig. 1B).

Figure 1

Conclusions: Atherogenic burden did not increase in pts treated with ABT-494 for 12 wks. Compared to non-responders, pts with a clinical response experienced a larger increase in lipids and a larger decrease in hsCRP. Limited data from these phase 2 studies suggest that there might not be an increased risk of cardiovascular events. Results from the larger phase 3 trials can provide more information.

THU0204 RELATIONSHIPS BETWEEN METHOTREXATE DOSAGES AND CLINICAL VARIABLES IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO ACHIEVED REMISSION WITH METHOTREXATE MONOTHERAPY: A STUDY USING THE IORRA OBSERVATIONAL COHORT STUDY

M. Tochihara[1], Y. Katsumata[1], E. Inoue[1,2], Y. Kawaguchi[1], E. Tanaka[1], A. Nakajima[1], K. Ikari[1], A. Taniguchi[1], H. Yamanaka[1]. *[1]Institute of Rheumatology, Tokyo Women's Medical University; [2]National Center for Child Health and Development, Tokyo, Japan*

Background: Considerable variability exists in the way rheumatologists prescribe methotrexate (MTX) therapy in patients with rheumatoid arthritis (RA), including the dosage [ref.1]. Start higher doses or fast dose escalation are associated with higher efficacy, but also with more toxicity. In addition, factors such as renal function, body size, and age of the patient can affect the optimal dosage of MTX.
Objectives: We aimed to study the relationships between MTX dosages and clinical variables in patients with RA who achieved remission with MTX monotherapy.

Methods: The "Institute of Rheumatology, Rheumatoid Arthritis (IORRA)" is a single-center prospective observational cohort study established at our institute in 2000. Data (physicians' and patients' disease assessments, laboratory data, and many other patient information) were collected from approximately 5,000 RA patients biannually. More than 99% of RA patients treated at our institute were enrolled in this cohort, and >98% of patients answered and mailed their questionnaires back to us every time. Among the RA patients who were registered in the IORRA cohort study from 2011 through 2015, 603 patients fulfilled the American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) Boolean-based definition of remission in RA, at least once and used only MTX as disease-modifying antirheumatic drugs (DMARDs) including biological DMARDs for 5 years. Relationships between MTX dosages and gender, disease duration, height, body weight, body mass index, body surface area, serum creatinine (SCr), estimated glomerular filtration rate (eGFR), creatinine clearance (by Cockcroft-Gault Equation), rheumatoid factor, and anti-cyclic citrullinated peptide antibody when remission was first reached by each patient were analyzed by univariate analyses using Pearson correlation coefficient and Welch's *t* test. Subsequently, a multiple regression analysis was performed.
Results: Univariate analyses detected several candidate clinical variables associated with MTX monotherapy dosages in RA patients who achieved remission: height, body weight, body surface area, SCr, eGFR, and CCr (p =0.004, 0.050, 0.241, <0.001, <0.001, and <0.001, respectively). Subsequently, a multiple regression model developed a best-fit model with the following variables; age, height, body weight, and SCr (standardized partial regression coefficient = -0.20, 0.10, 0.07, and -0.22, respectively), while its adjusted coefficient of determination was 0.114.
Conclusions: There were significant relationships between MTX monotherapy dosages and age, height, body weight, and renal function in RA patients who achieved remission. However, the low coefficient of determination indicated the model accounted for limited variability with the specified variables.

THU0205 EFFECTS OF THE JAK1-SELECTIVE INHIBITOR FILGOTINIB ON MULTIBIOMARKER DISEASE ACTIVITY SCORES IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO METHOTREXATE

M.C. Genovese[1], W. Li[2], L. Goyal[2], Y. Pan[2], A. Van der Aa[3], C. Jamoul[3], P. Harrison[3], C. Tasset[3], R. Galien[4], J. Tarrant[2]. *[1]Division of Immunology & Rheumatology, Stanford University School of Medicine, Palo Alto; [2]Gilead Sciences, Foster City, United States; [3]Galapagos NV, Mechelen, Belgium; [4]Galapagos SASU, Romainville, France*

Background: Filgotinib (GLPG0634, GS-6034) is an oral selective JAK1 inhibitor that has been evaluated in a 24-week phase 2B study (DARWIN 1) on the background of methotrexate (MTX) treatment in active rheumatoid arthritis (RA) patients who were MTX inadequate responders[1].
Objectives: To evaluate the effect of filgotinib compared to placebo on a multi-biomarker disease activity (MBDA) score that measures 12 disease-related biomarkers of inflammation and joint injury in RA patients taking background MTX.
Methods: Serum samples of RA patients who were on a stable dose of MTX and received either placebo (PBO) or filgotinib 100mg or 200mg once daily (QD), were tested for MBDA components (Crescendo Biosciences, CA, US) at baseline, week 4 and week 12. Median % change from baseline for MBDA score and individual components are reported for week 4 and week 12. Wilcoxon rank-sum test assessed the significance of difference between filgotinib treated groups *vs.* PBO.
Results: Baseline MBDA scores and component values (median; interquartile range) were similar in PBO (55; 45–64), 100mg QD (58; 42–66), and 200mg QD (59; 50–67.5) treatment groups. Filgotinib treated patients had reductions in the MBDA score from baseline at both the 100mg and 200mg QD dose levels, but not in the PBO group. At both weeks 4 and 12, these reductions in the filgotinib treated groups were significantly different from the PBO group. Most of the individual components contributed to the decrease in MBDA score, but the largest reductions were observed for serum amyloid A (SAA), C-reactive protein (CRP), and IL-6, and the biomarkers of joint-damage, matrix metalloproteinase 3 (MMP3), MMP1, vascular endothelial growth factor (VEGF), and YKL40 (human cartilage glycoprotein 39). There was an increase in leptin and no change in epidermal growth factor (EGF) concentrations.

Table 1. Median percent change from baseline of MBDA score and component concentrations

	Week 4			Week 12		
	PBO (N=62)	Filgotinib 100mg QD (N=63)	Filgotinib) 200mg QD (N=68)	PBO (N=65)	Filgotinib 100mg QD (N=62)	Filgotinib par 200mg QD (N=68)
MBDA SCORE	-1	-20***	-24***	-5	-19***	-24***
CRP	15	-57***	-71***	-8	-66***	-78***
EGF	14	-18^{NS}	-8^{NS}	0	-10^{NS}	0^{NS}
IL-6	-15	-34**	-60***	-20	-41**	-63***
LEPTIN	0	8^{NS}	18^{NS}	6	14^{NS}	23*

VCAM-1	5	-10***	-15***	0	-8**	-16***
VEGF	3	-16***	-25***	-2	-16***	-26***
YKL-40	2	-12*	-32***	-7	-17^{NS}	-33***

p-values comparing % changes between filgotinib and PBO groups NS, p>0.05; *p<0.05; **p<0.01; ***p<0.001.

Conclusions: RA patients treated with filgotinib in combination with MTX had significant reductions in the MBDA score that was driven by key RA biomarkers encompassing both inflammation and joint injury. These findings are consistent with the filgotinib efficacy observed in RA patients over 12 weeks.

THU0206 THE JAK1-SELECTIVE INHIBITOR FILGOTINIB REDUCES MULTIPLE MARKERS OF INFLAMMATION LINKED TO VARIOUS PATHOLOGIC CELL TYPES AND PROCESSES IN RHEUMATOID ARTHRITIS PATIENTS

P. Taylor[1], R. Westhovens[2], A. Van der Aa[3], C. Jamoul[3], W. Li[4], L. Goyal[4], Y. Pan[4], P. Harrison[3], C. Tasset[3], J. Tarrant[4], R. Galien[5]. *[1]University of Oxford, Oxford, United Kingdom; [2]University Hospitals, Leuven; [3]Galapagos NV, Mechelen, Belgium; [4]Gilead Sciences, Foster City, United States; [5]Galapagos SASU, Romainville, France*

Background: JAK1, 2, 3 and TYK2 are cytoplasmic tyrosine kinases that mediate intracellular signaling of many cytokines and growth factors. Filgotinib (GLPG0634, GS-6034) is a JAK inhibitor with high selectivity for JAK1 over other JAK family members. Filgotinib has a favorable safety and efficacy profile in two Phase 2B studies in active rheumatoid arthritis (RA) patients who were methotrexate (MTX) inadequate responders.
Objectives: To assess the effect of filgotinib on a background of MTX treatment on markers of inflammation in RA patients.
Methods: Serum samples from RA patients who were on a stable dose of MTX and received either placebo (PBO), filgotinib 100mg or 200mg once daily (QD), were collected at baseline, week 4 and week 12 and analyzed for 35 soluble serum biomarkers by validated single-plex or multiplex immunoassays. Median % changes from baseline for biomarkers are reported. Wilcoxon rank-sum test assessed the significance of difference between filgotinib treated groups and PBO.
Results: Filgotinib treatment induced a dose-dependent and significant decrease

in a variety of biomarkers implicated in RA pathogenesis including inflammation (IL-1β, IL-6, TNFα and SAA), matrix degradation and cartilage destruction (MMP1 and MMP3), immune cell trafficking (CXCL10, ICAM-1 and VCAM-1) and angiogenesis (VEGF). Cytokines involved in T_H1 (IFN-γ, IL-2, IL-12) and T_H17 (IL-1β, IL-6, IL-21, IL-23) cell subset differentiation and activity were significantly decreased. Additionally, decrease in the B-cell chemoattractant CXCL13 and the myeloid growth factor GM-CSF supports the anti-inflammatory effects of filgotinib treatment.

Table 1. Median percent change of biomarkers at week 12 from baseline for PBO and 200mg QD dose

	PBO (N=78)	Filgotinib 200mg QD (N=75)		PBO (N=78)	Filgotinib 200mg QD (N=75)		PBO (N=78)	Filgotinib 200mg QD (N=75)

IL-13	-1	-8**	LEPTIN	6	23*	VEGF	-2	-26***
IL-17A	2	-18*	MCP-1	4	-8^{NS}	YKL-40	-7	-33***
IL-1β	-2	-26***	MIP-1α	1	-8**			

p-values comparing % changes between filgotinib and PBO groups: NS, $p>0.05$; *$p<0.05$; **$p<0.01$; ***$p<0.001$.

Conclusions: Treatment with filgotinib decreased several factors that have key roles in RA for matrix degradation, cartilage destruction, angiogenesis, leukocyte adhesion and recruitment. The changes were accompanied by decreases in cytokines that promote and activate T_H1, T_H17, B-cells and myeloid cells that are important in RA. These findings provide insights into filgotinib mechanism of action and are consistent with its efficacy observed in RA patients.

THU0207 THE EFFECT OF THE USE OF GLUCOCORTICOIDS ON HEALTH ASSESSMENT QUESTIONNAIRE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL REMISSION –DATA FROM KANSAI CONSORTIUM FOR WELL-BEING OF RHEUMATIC DISEASE PATIENTS (ANSWER COHORT)-

R. Hara[1], T. Fujimura[1], M. Hashimoto[2], M. Furu[2], W. Yamamoto[2], T. Hirano[3], K. Ebina[4], S. Yoshida[5], K. Nagai[5], H. Amuro[6], Y. Son[6], T. Onishi[7], K. Akashi[7], M. Katayama[8], T. Kira[9], N. Shimmyo[1], A. Kido[1], Y. Akai[1], T. Fujimoto[1], Y. Tanaka[1]. *[1]The Center for Rheumatic Diseases, Nara Medical University, Nara; [2]Department of the Control for Rheumatic diseases, Graduate School of Medicine, Kyoto University, Kyoto; [3]Department of Respiratory Medicine, Allergy and Rheumatic Disease, Graduate School of Medicine, Osaka University; [4]Department of Orthopaedic Surgery, Osaka University, Graduate School of Medicine; [5]Department of Internal Medicine (I), Osaka Medical College; [6]First Department of Internal Medicine, Kansai Medical University, Osaka; [7]Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe; [8]Department of Rheumatology and Clinical Immunology, Osaka Red Cross Hospital, Osaka; [9]Department of the Control for Rheumatic diseases, Nara Medical University, Nara, Japan*

Background: In the treatment of patients with rheumatoid arthritis (RA), glucocorticoids (GCs) with csDMARDs remain an important treatment option given their capacity to increase clinical, structural and functional efficacy. On the other hand, it is reported that GCs usage even at low dosage significantly deteriorated functional capacity in patients with low disease activity state. In these previous study, disease activity and subsequent joint destruction have no small influence on functional disability.

Objectives: To investigate the effect of the use of glucocorticoids (GCs) in patients with RA who had maintained clinical remission on functional ability.

Methods: Among 2,649 patients with RA who achieved DAS-ESR<2.6 after 2013 in the multi-center cohort, 1,171 patients who had maintained DAS-ESR<2.6 were eligible. Clinical and demographic characteristics were collected at baseline. We calculated odds ratio (OR) (95% confidence interval) of the use and dose of GCs to predict the yearly progression of HAQ-DI score adjusted for age, sex, BMI, disease duration, RF titer, ACPA titer, CRP, MMP-3, DAS28-ESR, HAQ-DI, use of MTX and use of biologic DMARDs as covariates in multiple logistic regression model.

Results: Characteristics of patients at baseline were as follows (median (IQR), proportion). The age was 61 (48–68) years, female was 70.6%, disease duration was 4.5 (1.7–10.7) years, RF-positive was 64.4%, ACPA-positive was 70%, DAS28-ESR was 2.0 (1.6–2.6), HAQ-DI score was 0.125 (0–0.5). Of the 1,171 patients, 235 (20.1%) patients had been treated with oral GCs when achieving clinical remission. CRP (0.06 (0–0.2) vs 0.03 (0–0.1), p=0.03), MMP-3 (106.1 (73.2–172.8) vs 49.5 (36.5–77.2), p<0.001), SDAI (2.9 (1.5–5.9) vs 2.6 (1.0–4.8), p=0.003), DAS28-CRP (1.6 (1.3–2.0) vs 1.5 (1.2–1.9), p=0.008), patients' global assessment (mm) (15 (5–31) vs 11 (3–25), p=0.006), physicians' global assessment (mm) (6 (3–12) vs 5 (0–10), p=0.001) and HAQ-DI (0.38 (0–0.88) vs 0.13 (0–0.38), p<0.001) were significantly higher and disease duration was significantly longer (year) (8.9 (3.2–19.6) vs 4.1 (1.6–9.3), p<0.01) in the GCs group compared to the non-GCs group. One hundred and fifty-eight (67.2%) patients had been treated with GCs during follow up, and median dose was 4.5 (2.5–5.5) mg/day. Two hundred and eighty-seven (24.5%) patients' yearly change of HAQ-DI score incresed. The adjusted OR of the use of GCs at baseline was 2.06 (1.21–3.51). The adjusted OR of the daily dose of GCs <5mg was 1.61 (0.73–3.56), whereas that of GCs≧5mg was 2.65 (1.11–6.34) in patients with keeping GCs use.

Conclusions: The use of GCs in RA patients with sustained remission was the risk factor of progression of HAQ-DI score dose-dependently.

THU0208 METHOTREXATE POLYGLUTAMATES LEVELS IN ERYTHROCYTES WERE GENETICALLY AFFECTED IN RA PATIENTS WITH LOW DISEASE ACTIVITY FOR LONG PERIOD

S. Kumagai[1,2], M. Nishida[2], Y. Uemura[1], M. Izumi[2], K. Abe[2], K. Yoneda[2], Y. Noda[2], S. Sendo[3], A. Ohishi[3], M. Shinohara[3], G. Tsuji[2]. *[1]Shinko Institute for Medical Research; [2]Center for Rheumatic DIseases, Shinko Hospital; [3]Graduate School of Medicine, Kobe University, Kobe, Japan*

Background: Detection of the intracellular levels of polyglutamated MTX (MTX-PGn) can predict response of MTX or possibly its adverse effects. As efficacy and toxicity of MTX differs among individual patients, we had proposed a predictive model for MTX efficacy consisting of 9 SNPs (2015 EULAR). In the present study, we measured erythrocyte MTX-PGn in RA patients with low disease activity for long time receiving a stable dose of MTX, investigated their associations with genetic polymorphisms, and speculated MTX dose required to reach possible effective MTX-PG levels.

Objectives: To investigate if erythrocytes MTX-PGn concentration is associated with the 9 SNPs in 7 genes reportedly related to MTX-efficacy in RA patients with low disease activity.

Methods: The study was cross-sectional using 121 adult patients with RA in Shinko Hospital. All patients enrolled had received a stable dose of MTX (mean 8.9±0.3 mg/week), and kept lower disease activity (DAS28-CRP <2.7, mean 1.9±0.4) for at least 3 months. Concentrations of MTX-PG with 1 - 5 glutamate residues (PG1- PG5) in erythrocytes were quantitated by LC-ESI-MS/MS as described by den Boer et al. Nine SNPs in 7 genes previously found to associate with efficacy of MTX by us were genotyped by RT-PCR (Applied Biosystems, Inc.). First, association of the 9 SNPs with concentrations on MTX-PGn was analyzed by one-way layout (Wilcoxon signed-rank test). Secondly, multivariate logistic regression analyses were performed to estimate roles of MTX dose and polymorphisms in concentrations of MTX-PGn.

Results: Total PGn concentrations were 82.1±31.7 nmol/L (m±SD) and positively correlated with MTX dose (Rs =0.4104, p<0.001), but range of concentration was rather wide even if the dose was same. By one-way layout, GGH c.452C>T was associated with PG1, PG2, and total PG, SLC19A1 c.80G>A with total PG, and SLC28A3_c.267G>A with PG3. Three SNPs (FPGS c. 192T>C, EPHX1_c.357G>A, SLC28A3_c.267G>A) were related to MTX doses. Next, we investigated roles of MTX dose and 9 SNPs in maintenance of MTX-PGn concentrations as by multiple regression analyses. As PG1 levels were related to GGH c.452C>T but not to MTX dose, PG1 levels were 38.2±19.6 and 54.8±21.5 nmol/L in CC and CT genotypes, respectively (P=0.0291). MTX dose was strongly associated with PG3 levels as well as with those of PG4. MTX-PG3 levels were regressed as follows; MTX-PG3 (nmol/L) = -0.035 +[2.04 * MTX dose] + [2.34 * SLC19A1 c.80G>A] + [-2.01 * FPGS c.*192T>C]. When upper and lower limits of them were defined, we can speculate MTX dose to reach the effective levels for individual patients. However, the ranges of effective levels were rather wide, suggesting that effectiveness of MTX may depend on not only concentrations of MTX-PG but also responsiveness to MTX-PG.

Conclusions: We measured erythrocyte MTX-PGn in RA patients with low disease activity and investigated for their associations with MTX dose and genetic polymorphisms. We could speculate MTX dose required to reach possible effective MTX-PG levels in individual patient.

THU0209 LYMPHOCYTE SUBSETS IN BIOPSY SPECIMEN ARE ASSOCIATED WITH SPONTANEOUS REGRESSION OF LYMPHOPROLIFERATIVE DISORDERS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE

T. Kameda[1], M. Izumikawa[1], M. Inoo[2], I. Onishi[2], N. Kurata[2], S. Nakashima[1], H. Shimada[1], H. Ozaki[1], R. Wakiya[1], A. Kondo[1], N. Kadowaki[1], H. Dobashi[1].

Background: Patients with rheumatoid arthritis (RA) have a high risk for lymphoproliferative disorders (LPDs). An LPD in a patient treated with methotrexate (MTX) is known as MTX-associated LPD (MTX-LPD), which is classified among immunodeficiency-associated lymphoproliferative disorders (ID-LPD) as "other iatrogenic ID-LPD" in the 2008 World Health Organization Classification of Tumours of Haematopoietic and Lymphoid Tissues (1). We previously reported that MTX is an independent risk factor for LPD onset in Japanese patients with RA (2). In MTX-LPD, MTX withdrawal can result in spontaneous regression of LPD. In addition, limited evidence indicates that Epstein–Barr virus infection is related to spontaneous regression of MTX-LPD. No biomarker has been identified that predicts spontaneous regression of MTX-LPD.
Objectives: To identify a biomarker that predicts spontaneous regression of MTX-LPD in RA patients.
Methods: We enrolled RA patients from Kagawa Prefecture, Japan, who developed MTX-LPD during the period from June 2010 through December 2016. RA was diagnosed in accordance with the American College of Rheumatology 1987 classification criteria and was treated with disease-modifying antirheumatic drugs, including MTX. The patients were divided into two groups: those followed-up after discontinuation of MTX alone (MTX withdrawal group) and those who received chemotherapy at 1 month or later after MTX discontinuation (chemotherapy group). The following variables were compared between groups: change in peripheral lymphocyte subsets after MTX discontinuation, serum soluble interleukin-2 receptor, and lymphocyte subsets and Epstein–Barr virus–encoded RNAs in a biopsy specimen from a lesion.
Results: We enrolled 43 MTX-LPD patients (29 in the withdrawal group and 14 in the chemotherapy group). From among these groups, we selected 32 patients for analysis of changes in peripheral lymphocyte subsets (23 in the withdrawal group and 9 in the chemotherapy group) and 22 for analysis of lymphocyte subsets in a lesion specimen (11 each in the withdrawal group and chemotherapy group). Peripheral lymphocyte counts were significantly higher after MTX discontinuation in the withdrawal group. Analysis of lymphocyte subsets from lesion specimens revealed significantly higher CD8-positive lymphocyte counts in the chemotherapy group than in the withdrawal group.
Conclusions: Lymphocyte count differed before and after MTX discontinuation, and a higher CD8-positive lymphocyte count in a lesion specimen was associated with spontaneous regression of MTX-LPD. These findings may help identify a predictive marker for MTX-LPD treatment and management.

THU0210 CHANGES IN HEMOGLOBIN LEVELS UPON TREATMENT WITH ABT-494, A SELECTIVE JAK-1 INHIBITOR, AND RELATION TO BASELINE LEVELS OF C-REACTIVE PROTEIN

V. Strand[1], M. Genovese[1], J. Kremer[2], M. Schiff[3], Y. Li[4], J. Sokolove[4].
[1]Stanford Univ, Palo Alto; [2]Albany Medical College, Albany, NY; [3]Univ of Colorado, Denver, CO; [4]AbbVie, N Chicago, IL, United States

Background: Patients (pts) with rheumatoid arthritis (RA) often have inflammation-related anemia of chronic disease, partially due to IL-6 and its induction of hepcidin. High levels of the inflammatory marker C-reactive protein (CRP) are largely induced by IL-6. Treatment with JAK inhibitors has been associated with both rise and fall in hemoglobin (Hb) levels, possibly due to inflammation control and inhibition of JAK2 (which is involved in erythropoiesis), respectively [1,2].
Objectives: To examine the association of changes in Hb upon treatment with ABT-494 with baseline (BL) CRP levels.
Methods: This *post hoc* analysis used data from two phase 2b randomized controlled trials (RCT) of ABT-494: in RA pts with inadequate responses or intolerance to TNF inhibitors (TNF-IR, BALANCE-1)[3], and in pts with inadequate responses to methotrexate (MTX-IR, BALANCE-2)[4]. The analyses included pts receiving ABT-494 at 6 or 12 mg. Pts were subgrouped by quartiles of BL CRP. For each RCT, and for the pooled data from both, changes from BL in Hb (g/dL) were determined after 12 weeks (wk) of treatment with ABT-494, for the overall population and for pts who achieved ACR20 or DAS28-CRP $\leq$3.2 responses at Wk 12. For ACR20 and DAS28-CRP $\leq$3.2, non-responder imputation was used. For changes in Hb, data are as observed. Significance was determined by ANCOVA.
Results: In pooled data from 110 and 100 pts from BALANCE-1 and -2 respectively, higher BL CRP was associated with smaller mean decreases in Hb at Wk 12 (p=.074). In the MTX-IR trial, pts in the highest CRP quartile had a mean increase from BL in Hb (+0.28 g/dL) vs pts in the lower quartiles who had mean decreases in Hb ($p<.01$). In both RCTs, ACR20 or DAS28-CRP $\leq$3.2 responders had smaller decreases in Hb vs non-responders at Wk 12. Among DAS28-CRP $\leq$3.2 responders, pts in the higher CRP quartiles had significantly smaller mean decreases in Hb vs pts in the lower quartiles ($p<.01$ for MTX-IR and $p<.05$ for TNF-IR pts). Responders in the highest BL CRP quartile also had a mean increase in Hb (+0.31 and + 0.54 g/dL for MTX-IR ACR20 and DAS28-CRP $\leq$3.2 responders respectively, + 0.15 g/dL for TNF-IR DAS28-CRP $\leq$3.2 responders) (Fig. 1A–D). While similar trends between BL CRP levels and changes in Hb at Wk 12 were observed among ACR20 or DAS28-CRP $\leq$3.2 non-responders, the differences in Hb levels between the quartiles were not significant. Despite the small mean changes, the mean Hb values remained within the normal range for females (lower limit of normal 11.5 g/dL)

Figure 1. Hb levels at BL and Week 12 in patients by baseline CRP quartile in patients who achieved an ACR20 or LDA response.

Q1 is the lowest, and Q4 the highest quartile. Q1 was within the normal range, for which the upper limit is 5 mg/L. CRP quartile cutoffs are as follows: In MTX-IR, Q1: ≤2.5 mg/L, Q2: >2.5 and ≤5.9 mg/L, Q3: >5.9 and ≤18.3 mg/L, Q4: >18.3 mg/L; in TNF-IR, Q1: ≤3.1 mg/L, Q2: >3.1 and ≤7.0 mg/L, Q3: >7.0 and ≤16.7 mg/L, Q4: >16.7 mg/L.

Conclusions: Upon treatment with ABT-494, pts with the highest CRP (a potential surrogate for IL-6) at BL had a mean increase in Hb compared to decreases in those with lower CRP. This effect was more apparent in pts with clinical responses. This suggests that effective treatment of RA-associated inflammation with ABT-494 may counterbalance the small Hb reduction associated with JAK inhibition.

THU0211 META-ANALYSIS OF SERIOUS INFECTIONS WITH BARICITINIB, TOFACITINIB AND BIOLOGIC DMARDS IN RHEUMATOID ARTHRITIS

V. Strand[1], S. Ahadieh[2], R. DeMasi[3], S. Krishnaswami[2], J. Geier[4], S. Menon[2], J.J. Gomez-Reino[5]. *[1]Division of Immunology/ Rheumatology, Standford University, Palo Alto, CA; [2]Pfizer Inc, Groton, CT; [3]Pfizer Inc, Collegeville, PA; [4]Pfizer Inc, New York, NY, United States; [5]Fundacion Ramon Dominguez, Hospital Clinico Universitario, Santiago de Compostela, Spain*

Background: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Baricitinib is a JAK inhibitor being investigated for RA. Serious infection events (SIEs) have been reported in RA randomised controlled trials (RCTs) but limited head-to-head data are available to directly compare rates of these events for tofacitinib vs biologic (b)DMARDs and baricitinib.
Objectives: We present an updated meta-analysis of published RCTs and corresponding long-term extension (LTE) studies to contextualise the risk of SIEs[1] with tofacitinib and extend this work to include the JAK inhibitor baricitinib.
Methods: An initial systematic literature search (Medline, Embase, PubMed and regulatory submission documents) was conducted for SIEs with tofacitinib and bDMARDs (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab).[1] A subsequent systematic literature review of RCTs was conducted using Medline, BIOSIS, Embase and conference abstracts to evaluate SIEs with baricitinib. Incidence rates (IRs; patients with events per 100 patient-years) were calculated for each agent, utilising a random effects meta-analytic model using R (version 2.15.2 for tofacitinib and bDMARDs; version 3.2.2 for baricitinib) with a Restricted Maximum Likelihood Estimator for between-study variances. Risk ratios and risk differences were calculated for each agent vs control across RCTs up to rescue of patients randomised to receive placebo using the random effects Mantel-Haenszel method.
Results: Six RCTs with baricitinib were included in this updated analysis. In the original analysis, 70 RCTs and 18 LTE studies met inclusion criteria for tofacitinib and bDMARDs. The table provides a summary of the meta-analyses conducted for SIE IRs (with and without LTE), risk ratios and risk differences relative to control. The IRs (95% confidence interval [CI]; heterogeneity [I^2]) for baricitinib were 4.75 (2.32, 9.74; I^2=19%) for 2 mg and 3.67 (2.33, 5.78; I^2=36%) for 4 mg. The analysis of risk ratios (p values 0.22 for 2 mg; 0.95 for 4 mg) and risk differences (p values 0.41 for 2 mg; 1.00 for 4 mg) did not reveal a significant difference from control for both doses of baricitinib, which is consistent with analyses of tofacitinib and bDMARDs. There were limited data to assess SIE incidence for baricitinib (4 mg) monotherapy vs in combination with methotrexate (MTX); the RA-BEGIN study showed IRs of 3.77 (1.7, 8.4) and 2.33 (0.97, 5.59), respectively. Pooled IR estimates for tofacitinib from the development programme were 1.70 (0.91, 2.92) and 1.79 (1.00, 2.95) for 5 and 10 mg BID monotherapy, respectively; when administered in combination with MTX, the IRs were 3.44 (2.41, 4.76) and 3.42 (2.42, 4.70) for 5 and 10 mg BID, respectively.

Table: Serious infection incidence rates, risk ratios and risk differences for tofacitinib vs biologic DMARDs and baricitinib[1]

Drug	Incidence rate (95% CI), per 100 pt-yr		Risk ratio (95% CI)	Risk difference (95% CI), %
	RCT+LTE	RCT	RCT	RCT
Abatacept	3.04 (2.49, 3.72)	2.97 (2.17, 4.07)	1.18 (0.45, 3.09)	0.4 (-0.72, 1.51)
Rituximab	3.72 (2.99, 4.62)	3.45 (2.73, 4.36)	1.01 (0.46, 2.22)	-0.42 (-1.63, 0.79)
Tocilizumab	5.45 (4.26, 6.96)	5.39 (4.05, 7.18)	1.82 (1.22, 2.73)	1.51 (0.68, 2.33)
Infliximab	6.11 (5.24, 7.12)	6.42 (5.50, 7.50)	0.83 (0.33, 2.06)	-0.52 (-3.56, 2.53)
Etanercept	4.06 (3.26, 5.08)	3.90 (2.76, 5.52)	1.00 (0.07, 15.24)	0.00 (-9.39, 9.39)
Certolizumab	7.59 (5.80, 9.94)	7.59 (5.80, 9.94)	2.18 (1.06, 4.50)	1.96 (0.8, 3.12)
Golimumab	5.31 (4.09, 6.89)	5.31 (4.09, 6.89)	1.3 (0.43, 3.90)	0.68 (-0.31, 1.67)
Adalimumab	5.04 (3.80, 6.69)	5.47 (3.92, 7.64)	2.27 (0.84, 6.13)	1.16 (-0.34, 2.67)
TNF inhibitors	4.90 (4.41, 5.44)	5.50 (4.86, 6.23)	1.50 (1, 2.25)	0.94 (0.25, 1.63)
Tofacitinib 5 mg, P2/P3	NA	2.71 (2.00, 3.58)[a] 2.35 (1.36, 4.06)[b]	1.34 (0.43, 4.15)	0.27 (-0.36, 0.9)
Tofacitinib 10 mg, P2/P3	NA	2.72 (2.04, 3.56)[a] 2.80 (1.95, 4.01)[b]	1.67 (0.60, 4.65)	0.42 (-0.22, 1.05)
Tofacitinib P123LTE (All doses)	2.74 (2.51, 2.99)[a]	NA	NA	NA
Baricitinib 2 mg	NA	4.75 (2.32, 9.74)	1.13 (0.24, 5.35)	-0.35 (-1.72, 1.02)
Baricitinib 4 mg	NA	3.67 (2.33, 5.78)	0.82 (0.34, 1.97)	-0.21 (-1.11, 0.69)

[a] Estimate from pooled patient-level data
[b] Estimate from random effects meta-analytic model

CI, confidence interval; DMARDs, disease-modifying antirheumatic drugs; JAK, Janus kinase; LTE, long-term extension; NA, not applicable; P2/P3, Phase 2 and Phase 3 studies; P123LTE, Phase 1, 2, 3 and LTE studies; pt-yr, patient year; RCT, randomised controlled trial; risk ratio, relative risk compared with placebo; risk difference, risk difference compared with placebo; TNF, tumour necrosis factor

Conclusions: The results from these meta-analyses suggest that the risk of SIEs (IRs, risk ratios and risk differences) with tofacitinib is comparable with published rates for bDMARDs and baricitinib in patients with moderate to severe RA.

THU0212 THE IMPROVEMENT OF ULTRASONOGRAPHIC FINDINGS FOR 24 WEEKS MAY PREDICT REMISSION AT 52 WEEKS IN JAPANESE RHEUMATOID ARTHRITIS PATIENTS TREATED WITH IGURATIMOD THERAPY

Y. Kanayama[1], H. Nagasaka[2], M. Shimotake[2], F. Miyachi[2], K. Fujita[2], A. Nagata[2]. *[1]Orthopedic Surgery and Rheumatology; [2]Clinical technology, Toyota Kosei Hospital, Toyota, Japan*

Background: Iguratimod (IGU) suppressed tumor necrosis factor-alpha-induced production of interleukin (IL)-6, IL-8, and monocyte chemoattractant protein 1 via inhibition of nuclear factor kappa B activation in cultured human synovial cells and human acute monocytic leukemia cells. We reported the clinical efficacy of IGU at ACR2014 and EULAR2015. However there is still few studies of improvement of ultrasonographic findings in rheumatoid arthritis (RA) treated with IGU.
Objectives: To evaluate the efficacy of IGU therapy in patients with RA using ultrasonography (US).
Methods: Participants comprised 54 Japanese RA patients who had recently received IGU. All patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments from baseline to 52 weeks, and US assessments at baseline, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 26 (0–78) synovial sites (22 joints) in the following joints: bilateral first to fifth metacarpopharangeal (MCP) joints (dorsal recess); first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) (dorsal recess) joints; and the wrists (dorsal radial, median and ulnar).
Results: The patients included 16 males and 38 females. The mean age was 65.4±11.6 years; the mean disease duration was 9.3±10.8 years; and the number of MTX combination, other DMARD excluded combination, IGU monotherapy and Biologics combination were each 32, 10, 8 and 4 cases.
Clinical findings related to RA were as follows: tender and swollen joint count, 4.2±2.9 and 3.2±2.1; patient's and physician's global assessment of disease activity, 40.2±24.0 and 40.2±19.9mm; CRP, 1.0±1.2 mg/dL; ESR, 31.2±18.2 mm/h; DAS28-ESR, 4.37±0.88 and SDAI, 16.4±7.0. The mean DAS28-ESR improved to 3.43±0.94 and 2.98±0.88 at Week 12 and 24 ($p<0.001$, $p<0.001$) and the mean SDAI improved to 8.8±6.1 and 6.3±5.2 at Week 12 and 24 ($p<0.001$, $p<0.001$) significantly. The mean GS score changed from 16.8±12.5 at baseline to 15.8±11.2 (p=0.458) and 14.8±10.3 (p=0.103) at week12 and 24. The mean PD score changed from 7.6±6.8 at baseline to 5.8±6.0 (p=0.053) and 5.3±5.4 (p=0.05) at week12 and 24. In the achieved remission for DAS28-ESR at Week52 (n=16) and not achieved or discontinued IGU patients (n=38), the respective changes in GS and PD scores from baseline to 12 or 24 weeks were as follows: ΔGS score: -3.7±0.8 vs 0.1±6.8 (p=0.068) at 12 weeks and -5.8±5.7 vs -0.4±9.8 (p=0.008) at 24 weeks; and ΔPD score: -3.4±5.6 vs -1.1±5.2 (p=0.065) at 12 weeks and -4.9±6.3 vs -1.2±6.1 (p=0.013) at 24 weeks (Fig.1). Areas under the receiver operating characteristic curves for the ΔGS and ΔPD score at each time point for remision achievement at 52 weeks were each 0.643 and 0.648 from week0 to 24 and 0.725 (cut-off index -3, odds ratio 5.60, sensitivity 0.74, specificity, 0.67) and 0.706 (cut-off index -1, odds ratio 4.71, sensitivity 0.63, specificity, 0.73) from week0 to 24 (Fig.2).

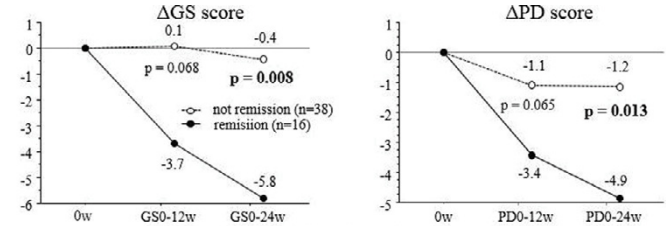

Figure 1 : Respective changes in ΔGS and ΔPD score from baseline to Week 24 in the achieved remission for DAS28-ESR at Week52 and not achieved or discontinued IGU patients

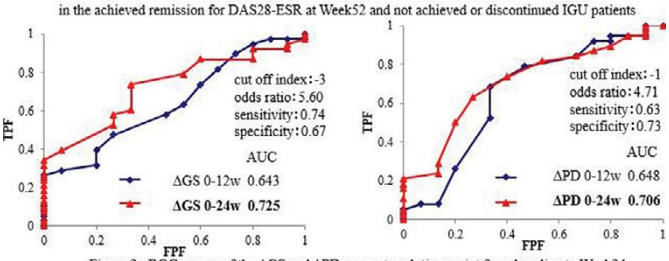

Figure 2 : ROC curves of the ΔGS and ΔPD score at each time point from baseline to Week24 for predicting the achieved remission at Week 52 after starting IGU therapy

Conclusions: The IGU therapy improved not only the disease activity not also the inflammatory synovitis. The present study provides evidence supporting t the improvement of GS and PD score from baseline to week24 may predict whether the achieved remission or not at Week 52.

THU0213 COMPARATIVE EFFICACY AND SAFETY OF BARICITINIB 2 MG AND 4 MG IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Y.H. Lee, Y.H. Seo, G.G. Song. *Rheumatology, Korea University Medicial Center, Seoul, Korea, Republic Of*

Background: Baricitinib is a potent, selective JAK1 and JAK2 inhibitor. Baricitinib has been investigated in phase II and phase III studies of active patients with rheumatoid arthritis (RA). who showed an inadequate response to disease-modifying antirheumatic drugs (DMARDs), including methotrexate (MTX) and biologics. However, due to the lack of adequate multiple comparisons, the comparative efficacy and safety of baricitinib in various treatment regimens with different dosages or in combination with DMARDs or MTX remains unclear.
Objectives: This study aimed to assess the relative efficacy and safety of once-daily baricitinib 2 mg and 4 mg administration in patients with active RA.
Methods: We performed a literature search using MEDLINE, EMBASE, the Cochrane Controlled Trials Register, and the EULAR and ACR conference proceedings. In this network meta-analysis, randomized controlled trials (RCTs) examining the efficacy and safety of baricitinib in patients with active RA were included. A Bayesian network meta-analysis was conducted to combine the direct and indirect evidence from the RCTs.
Results: Seven RCTs involving 3,461 patients met the inclusion criteria. There were 10 pairwise comparisons, including 7 direct comparisons and 5 interventions. The ACR20 response rate was significantly higher in the baricitinib 4 mg in combination with disease-modifying antirheumatic drugs (DMARD) group than in the placebo+DMARD group (OR 3.13, 95% CrI 2.32–4.33). Compared with the placebo+DMARD group, the baricitinib 4 mg, baricitinib 2 mg+DMARD, and adalimumab 40 mg+MTX groups showed a significantly higher ACR20 response rate. The ranking probability based on the surface under the cumulative ranking curve (SUCRA) indicated that baricitinib 4 mg+DMARD was likely to elicit the best ACR20 response rate (SUCRA =0.7930), followed by baricitinib 4 mg (SUCRA =0.7034), baricitinib 2 mg+DMARD (SUCRA =0.6304), adalimumab 40 mg+MTX (SUCRA =0.3687), and placebo+DMARD (SUCRA =0.0045). By contrast, the safety based on the number of treatment-emergent adverse events (TEAEs) did not differ significantly among the 5 interventions.
Conclusions: Baricitinib 2 mg and 4 mg administered once daily was an efficacious intervention for active RA that had no significant risk of TEAE development.

THU0214 LONG-TERM OUTCOME OF IGURATIMOD, CONVENTIONAL SYNTHETIC DISEASE-MODIFYNG ANTI-RHEUMATIC DRUD DEVELOPED IN JAPAN, IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL-WORLD CLINICAL SETTING

Y. Hirano, M. Isono, Y. Okada, Y. Oishi. *Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan*

Background: Iguratimod (IGU) is csDMARDs developed in Japan and used in Japanese daily practice since 2012. Although IGU was developed as an anti-inflammatory drug at first, anti-rheumatic effect was found in experiments using type II collagen-induced arthritis model mice[1)]. Main mode of action of IGU was thought to be inhibition of NF-kB resulted in decreased production of IL-6, IL-8 and TNF-alpha[2)]. Clinical trials performed in Japan showed that efficacy of IGU was equal to sulfasalazine when used as monotherapy in patients with rheumatoid arthritis (RA)[3)]. Additive efficacy to MTX was also shown in double-blind randomised trial in RA patients [4)]. Although several short-term results were published[5)], long-term results in daily clinical setting is lacking.
Objectives: To investigate long-term outcome of IGU in patients with RA.
Methods: 120 RA patients treated with IGU in our institute from April 2013 to June 2016 were included. Patients' characteristics, factors influencing to prescribing of IGU (why was IGU chosen as treating csDMARDs?), drug continuation rates (Kaplan-Meier) were investigated. Time course of disease activity (DAS28-CRP & SDAI) was also investigated using 65 cases who passed 2 years after starting of IGU.
Results: Baseline characteristics was as below. Mean age was 64.9 years old, %female was 74.2%, mean RA duration was 10.0 years and MTX was concomitant in 50.0% of cases. 82% of patients had factors influencing to prescribing IGU and intolerance of dose escalation of MTX was 1st reason (23.3%), old age over 80 years old was 2nd reason (16.7%) and economical reason was 3rd (14.2%) (Table1). Drug continuation rates were 71.1% at 1 year, 48.9% at 2 years and 43.1% at 3 years (Fig1). Time course of disease activity (baseline-6 months-1 year-2 year) was 3.6–3.0–3.0–3.0 in DAS28-CRP. In 15 cases in remission of DAS28-CRP at 2 years, 2 were classified with high disease activity and 9 were moderate disease activity at baseline (Fig2).

Table 1. Factors Influencing to Prescribing of Iguratimod (120 RA patients)

	Number of Cases	%
Intolerance of MTX doze escalation	28	23.3
Old age (over 80 years old)	20	16.7
Economical difficulties	17	14.2
Chronic Infection	13	10.8
Interstitial Pneumonia	13	10.8
Chronic Kidney Disease	12	10.0
Severe Lung Disease Except for Interstitial Pneumonia	10	8.3
Past History of Malignant Lymphoma or Lymphoproliferative Disease	9	7.5
Strong Anxiety for Side Effect of Biologics by Patients	7	5.8
Past History of Severe Adverse Event of Biologics	6	5.0
Treating Malignant Tumor	4	3.3
Others	1	0.8
Total	140*	

* There were RA patients who have 2 or more factors.

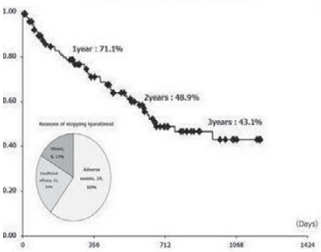

Fig1. Drug Continuation Rate of Iguratimod in 120 RA Patients (Kaplan-Meier method)

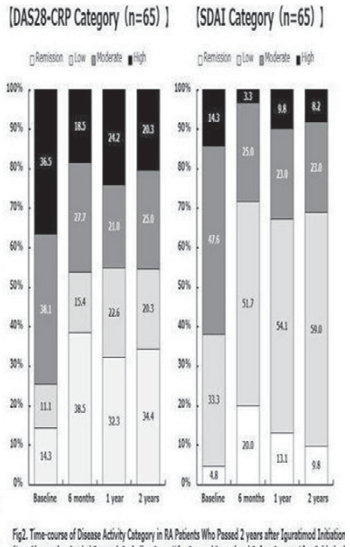

Fig2. Time-course of Disease Activity Category in RA Patients Who Passed 2 years after Iguratimod Initiation (Last Observation Carried Forward, Including Cases Who Stopped Iguratimod Before 2 years After Initiation)

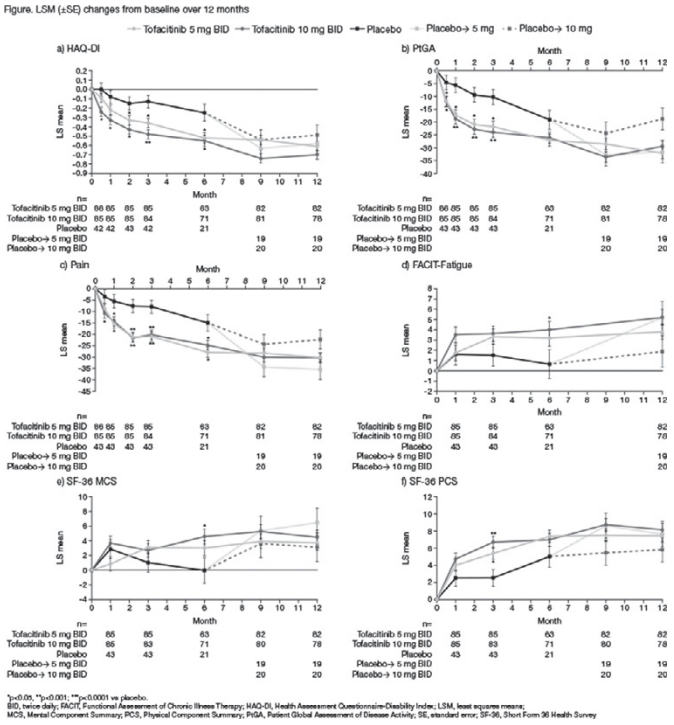

Conclusions: Efficacy of IGU in RA patients who had intolerance of MTX dose escalation or usage of biologics was observed. Although biological DMARDs is effective in RA patients, the cost is very expensive. IGU is comparative cheap (¥9,200/month) and suitable for RA patients with economical difficulties. As IGU decreased TNF-alpha production via inhibition of NF-kB, MTX+IGU may have similar mode of action with MTX+TNF inhibitor. Drug continuation rates were decreased over time and escape of efficacy may occur in some patients. Otherwise, IGU was very effective in some cases. Some of RA patients with high disease activity decreased disease activity greatly to remission state at 2 years after initiation of IGU.

THU0215 EFFECTS OF TOFACITINIB ON PATIENT-REPORTED OUTCOMES IN A PHASE 3 STUDY OF CHINESE PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO DMARDS

Z. Li[1], Y. An[1], G. Li[2], L. Wang[3], K. Kwok[4], Q. Wu[2] on behalf of China ORAL group. *[1]Peking University People's Hospital; [2]Pfizer Inc, Beijing, China; [3]Pfizer Inc, Groton, CT; [4]Pfizer Inc, New York, NY, United States*

Background: Rheumatoid arthritis (RA) worsens patients' health-related quality of life.[1] Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of RA. Improvements in patient-reported outcomes (PROs) have been reported in the global population of Phase 3 tofacitinib trials.[2]
Objectives: To explore the effect of tofacitinib administered with conventional synthetic DMARDs (csDMARDs) on PROs in Chinese patients with RA and an inadequate response to DMARDs.
Methods: This was a post-hoc analysis of data from Chinese patients in the 12 month, double-blind Phase 3 study ORAL Sync (NCT00856544), with patients randomised 4:4:1:1 to tofacitinib 5 mg BID, tofacitinib 10 mg BID, placebo (PBO)→tofacitinib 5 mg BID or PBO→tofacitinib 10 mg BID, with csDMARDs. Non-responders (defined as those who did not achieve a 20% improvement in both of the swollen or tender joint counts) receiving PBO advanced blindly to tofacitinib at Month 3; all remaining PBO patients advanced to tofacitinib at Month 6. Least squares mean changes from baseline were reported for Health Assessment Questionnaire-Disability Index (HAQ-DI), patient assessment of arthritis pain (VAS), patient global assessment of disease activity (PtGA), Functional Assessment of Chronic Illness Therapy (FACIT) Fatigue scale, Short Form-36 Health Survey (SF-36), EuroQol five dimensions questionnaire (EQ-5D), and Work Limitations Questionnaire (WLQ), using a mixed-effects model for repeated measures. All patients receiving ≥1 dose of study treatment with ≥1 post-baseline assessment were included.
Results: Overall 216 patients were included (n=86, tofacitinib 5 mg BID; n=86, tofacitinib 10 mg BID; n=22, PBO→tofacitinib 5 mg BID; n=22, PBO→tofacitinib

10 mg BID). There were no major differences in demographics or baseline characteristics between treatment groups. At Month 3, tofacitinib resulted in significantly greater changes in HAQ-DI (5 mg BID, $p<0.05$; 10 mg BID, $p<0.001$), PtGA (5 mg BID, $p<0.05$; 10 mg BID, $p<0.001$), Pain (5 mg BID, $p<0.001$; 10 mg BID, $p<0.001$) and SF-36 Physical Component Summary (PCS) scores (5 mg BID, $p<0.05$; 10 mg BID, $p<0.001$) vs PBO (Figure). Numeric improvements in FACIT-Fatigue, SF-36 Mental Component Summary (MCS) [Figure] and EQ-5D health state profile (utility scores) were observed at Month 3 with tofacitinib vs PBO. There were no improvements in WLQ observed at Month 3 with tofacitinib vs PBO. Improvements were generally maintained at 6 and 12 months (Figure). The proportion of patients achieving HAQ-DI improvement $\geq$0.22 from baseline at Month 3 was significantly higher with tofacitinib vs PBO (5 mg BID, $p<0.05$; 10 mg BID, $p<0.05$).

*p<0.05, **p<0.001, ***p<0.0001 vs placebo.
BID, twice daily; FACIT, Functional Assessment of Chronic Illness Therapy; HAQ-DI, Health Assessment Questionnaire-Disability Index; LSM, least squares means; MCS, Mental Component Summary; PCS, Physical Component Summary; PtGA, Patient Global Assessment of Disease Activity; SE, standard error; SF-36, Short Form 36 Health Survey

Conclusions: Tofacitinib 5 and 10 mg BID administered with csDMARDs significantly improved PROs including SF-36 PCS, PtGA, physical function and pain vs PBO. These improvements were maintained for up to 12 months in Chinese patients with RA.

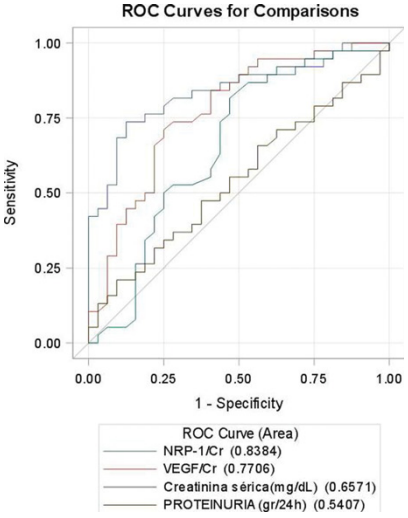
SLE, Sjögren's and APS - etiology, pathogenesis and animal models

THU0216 URINARY NEUROPILIN-1: A NEW BIOMARKER APPROACH IN THE PROGNOSIS OF LUPUS NEPHRITIS



M. Torres-Salido[1], C. Solé-Marcé[1], M. Vidal[2], J. Cortés-Hernández[1], J. Ordi-Ros[1]. *[1]Vall Hebron Institute Research (Vhir); [2]Renal Pathology, Vall d'HEBRON Hospital, Barcelona, Spain*

Background: Lupus nephritis (LN) affects up to 50% of patients with SLE and is a major cause of morbidity, despite modern therapeutic approaches [1,2]. To date, renal biopsy is still the gold standard for diagnosing and classifying the degree of renal inflammation and scarring, but its invasiveness makes it unsuitable for serial monitoring. A novel biomarker to predict the evolution of renal inflammatory injury is still needed. Neuropilin-1 (NRP-1) has important functions in adult tissues, being involved in axonal guidance, vascular endothelial sprouting, regeneration and organ repair and immunosupression [3].

Objectives: Evaluate the protein and expression levels of NRP-1 at the time of the renal flare in patients with lupus nephritis and determine whether they could predict the disease progression.

Methods: Urine and serum of 70 patients with LN with nephrotic proteinuria, 25 patients with chronic non-lupus related nephopathy, and 25 healthy controls were analyzed by qPCR-RT and ELISA to determinate the levels of mRNA/protein of NRP-1. Immunohistochemistry of protein levels were done in renal biopsy (N=5). Urine and serum from 39 other patients with LN with nephrotic proteinuria were collected prospectively during two years.

Results: Increases in mRNA expression and protein concentration of NRP-1 were identified in urine samples of LN patients in flare compared with the different control groups. However, significant NRP-1 levels were found in LN patients that gone into remission compared with patients in non-remission after one year of treatment ($p<0.0001$). Urinary VEGFA, VEGFR1, VEGFR2 and SEMA3A mRNA and protein levels were also determinate. Results were confirmed with immunohistochemistry in renal biopsies (N=5). We observed a strong correlation with NRP-1 protein levels and VEGFA protein levels ($r=0.466$, $p<0.0001$). Areas under the receiver operating characteristic curve of urinary NRP-1 and VEGFA protein levels to distinguish between remission and non-remission patients were 0.8384 and 0.7706, respectively (Figure 1). In a prospective study (N=39), urinary protein NRP-1 and VEGFA levels decreased in LN patients going to complete remission; but no those with non-response that maintain their low levels during all the follow-up.

Conclusions: For first time, we demonstrate that urinary levels of NRP-1 might reflect the evolution of renal inflammatory injury and could be used as novel biomarker to predict the recovery of LN.

THU0217 DNA METHYLATION ANALYSIS IN MULTIPLE CELLULAR COMPARTMENTS DEMONSTRATES A UNIVERSAL DNA METHYLATION INTERFERON SIGNATURE IN MULTIPLE CELLULAR COMPARTMENTS AND PREDOMINANT B-CELL HYPERMETHYLATION IN TWINS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C.J. Ulff-Møller[1,2], F. Asmar[3], Y. Liu[2], A.J. Svendsen[4], F. Busato[2], K. Grønbæk[3], J. Tost[2], S. Jacobsen[1]. *[1]Copenhagen Lupus and Vasculitis Clinic, Rigshospitalet, Copenhagen, Denmark; [2]Laboratory for Epigenetics and Environment, Centre National de Génotypage, CEA – Institut de Génomique, Evry, France; [3]Department of Haematology, Rigshospitalet, Copenhagen; [4]Epidemiology, Biostatistics and Biodemography, University of Southern Denmark, Odense, Denmark*

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune

disease. High monozygotic twin discordance implies a role for non-genetic effects in disease pathogenesis. Previous epigenome-wide association studies (EWAS) have demonstrated a role for DNA methylation in SLE, but different immune cell subsets have so far been insufficiently characterised. The disease discordant twin model is a powerful design for detecting SLE-associated DNA methylation variation.

Objectives: To investigate genome-wide DNA methylation changes in sorted CD4+ T-cells, monocytes, granulocytes and B-cells from twin pairs with at least one SLE-affected twin.

Methods: Altogether 15 SLE twin pairs participated in the study, of which 6 pairs were monozygotic (MZ) and 9 were dizygotic (DZ), including 2 concordant pairs (1 MZ, 1 DZ). Disease activity was evaluated using the SLE disease activity index (SLEDAI). Peripheral blood was processed using gradient density centrifugation for the granulocyte fraction and the mononuclear cell fraction was sorted serially for CD14+ monocytes, CD4+ T-cells and B-cell enrichment using a RoboSep device (Stemcell Technologies). DNA was extracted using the DNA/RNA/miRNA Universal kit (Qiagen). Genome-wide DNA methylation was evaluated using the Infinium HumanMethylation450K BeadChip (Illumina). Paired analyses were performed using a Wilcoxon test with $p<0.01$ and median differential methylation $>7\%$ considered as statistically significant. Top differentially methylated genes were validated using pyrosequencing.

Results: In paired analyses of discordant SLE twins without restriction to probe category, we found 176, 510, 393 and 2882 differentially methylated CpGs in CD4+ T-cells, monocytes, granulocytes and B-cells, respectively. Restricted to the promoter and transcription start sites, there were 55, 327, 247 and 1628 genes in CD4+ T-cells, monocytes, granulocytes and B-cells with differentially methylated CpGs, respectively. In all cell types, there was a profound hypomethylation of interferon-regulated genes, including *IFI44L, DTX3L, PARP9* and *IFITM1*, which was more pronounced in twins with recent flare within the past 2 years. In contrast to the other cell types, hypermethylation was predominantly observed in B-cells. Using Ingenuity Pathway Analysis, the top upstream regulators of hypermethylated genes in B-cells were *TNF, miR-146a-5p* and *EP300*. Hypomethylation of CpGs was validated in all cell types at the genes *IFI44L, PARP9, IFITM1, LGALS3BP, LOXL1, MIR10A, PLSCR1* and *RSAD1*, in B-cells and granulocytes at *TACSTD2* and at *MIR146B* in B-cells. Hypermethylation of CpGs was validated in B-cells alone for *CXCR5, DDR1* and *TRAF5*.

Conclusions: Robust hypomethylation of interferon-regulated genes is common to all major cellular compartments in SLE twins. The finding of hypermethylated CpGs in B-cells is novel and might be of interest to SLE pathogenesis.

THU0218 CIRCULATING MICRORNAS AS BIOMARKERS FOR DIAGNOSIS AND TYPIFYING THE ATHEROTHROMBOTIC STATUS IN ANTIPHOSPHOLIPID SYNDROME

C. Perez-Sanchez[1], I. Arias-de la Rosa[1], M.A. Aguirre[1], P. Ruiz-Limon[1], N. Barbarroja[1], Y. Jimenez-Gomez[1], M.C. Abalos-aguilera[1], E. Collantes-Estevez[1], M. Teresa-Herranz[2], J. Lozano-Herrero[2], C. Martinez[2], R. Gonzalez-Conejero[2], M.J. Cuadrado[3], C. Lopez-Pedrera[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba; [2]IMIB-Arrixaca /University of Murcia/ Internal Medicine Service, Morales Meseguer Hospital, Murcia, Spain; [3]Lupus Research Unit and St. Thomas Hospital, London, United Kingdom*

Background: The course of antiphospholipid syndrome (APS) may rapidly progress from asymptomatic to severe manifestations. Thus, timely diagnosis is essential to improve accuracy of therapy. The role of circulating microRNAs (miRNAs) as potential biomarkers of disease has not yet been analysed in APS.

Objectives: To investigate the contribution of circulating miRNAs to the pathogenesis of APS and their potential role as non-invasive biomarkers of the disease.

Methods: Ninety APS patients and 42 healthy donors (HD) were included in the study. Clinical and inflammatory parameters were analysed. As a complement to standard clinical follow-up, the ankle-brachial index (ABI) and carotid intima-media thickness (CIMT) were determined. miRNA expression profiling was performed in plasma by PCR-Array, and the Ingenuity Pathways analysis software (IPA) was used to identify specific miRNAs and target proteins associated to the pathogenesis of APS. RT-PCR and ELISA/Bioplex of selected genes and proteins were used to validate microarray data. The diagnostic value of specific miRNAs signatures (ratios) as disease biomarkers was evaluated by ROC curves analysis. To assess the specificity of these signatures in APS, the expression of the selected miRNAs was analysed in plasma from 23 thrombotic patients without associated autoimmune disease. Monocytes isolated from HD and endothelial cells (ECs) were treated in vitro with antiphospholipid antibodies (aPL-IgGs) purified from the serum of APS patients, and the changes promoted on the levels of selected miRNAs and their potential targets were analysed.

Results: The PCR-Array identified 39 circulating miRNAs differentially expressed, including 19 up-regulated and 20 down-regulated in APS. IPA analysis recognized 11 miRNAs as potential modulators of target genes involved in the physiopathology of APS. Logistic Regression and ROC curve analyses identified a signature of 10 miRNA ratios as biomarkers for diagnosis of APS with great accuracy (AUC:0.81), along with 2 miRNA ratios as biomarkers for typifying the atherothrombotic status (pathologic CIMT) of APS (AUC:0.76). Patients with thrombosis but without associated autoimmune disease displayed a specific miRNA profile, distinct from that of APS patients. The miRNA signature was related to clinical features of APS such as the occurrence of foetal loss and the type of thrombosis suffered, and correlated with parameters linked to autoimmunity (aPL-IgG titers), inflammation, and thrombosis (ABI, ESR, TF, PAI-1, MCP-1, VEGF-A and VEGF-R1). In vitro treatment of monocytes and endothelial cells with aPL-IgG antibodies promoted a significant deregulation in the secreted levels of the selected miRNAs and atherothrombotic target proteins.

Conclusions: miRNA levels in the serum of APS patients -modulated by aPL-IgG antibodies- are potential novel biomarkers for diagnosis and typifying of their atherothrombotic status, thus constituting a useful tool in the prevention and management of the disease.

THU0219 AUTOANTIBODY PROFILE OF CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM A TERTIARY CARE CENTRE IN NORTH INDIA

S. Guleria[1,1], A. Sharma, A. Gupta, A. Rawat, D. Suri, S. Singh. *Pediatric allergy and immunology, Pgimer Chandigarh, Chandigarh, India*

Background: Juvenile dermatomyositis (JDM) is a rare childhood autoimmune inflammatory muscle disorder that can result in severe disability or death. Children with JDM can have autoantibodies in their sera like other autoimmune diseases [1]. Over the last few years, few novel Myositis Specific Antibodies (MSA) have been identified. Some phenotypical associations have been described with these autoantibodies like anti p-140 (anti NXP2) has been shown to have correlation with calcinosis in children with JDM [1–2].

Objectives: To study autoantibody profile and to look for phenotypical associations of autoantibodies in JDMS.

Methods: Cross-sectional retrospective study. All children diagnosed to have JDM, registered from 1995 to 2015 in Pediatric Rheumatology Clinic at Post Graduate Institute of Medical Education and Research Chandigarh, India and who were tested for autoantibodies were included in the study. Clinical findings, antinuclear antibodies (ANA), autoantibody for MSA and myositis associated autoantibodies (MAA) were noted from the careful scrutiny of case records. Immunoglobulin G (IgG) antibodies against Jo1, threonyl-tRNA synthetase (PL7), alanyl-tRNA synthetase (PL12), glycyl-tRNA synthetase (EJ), Signal Recognition Particle (SRP), Mi-2, MDA-5, Transcriptional intermediary factor 1-γ (TIF-1γ), Ku, PMScl 100, Scl 70 and SSA/Ro 52 have been done by Immunodot. Evaluation for anti p-140 or Nuclear Matrix Protein (NXP2) and anti 200/100 or 3-Hydroxy-3-Methyglutaryl-Coenzyme (HMG CoA reductase) was done using ELISA.

Results: Antinuclear antibody (ANA) testing was done in 97 patients. Forty six (47.4%) tested positive. In addition, MSA and MAA were assessed. Anti-SRP antibodies were present in 4 (11.4%) children, anti-MDA5 in 3 (8.6%), anti-Mi2 in 1 (2.9%) and 1 patient tested positive for anti-SSA/Ro52 antibodies. All 4 children with anti-SRP were girls, had polycyclic course and 2 of them developed calcinosis. Patients with anti-MDA5 had predominant skin involvement, less severe muscle disease and followed a monocyclic course. Two of them had arthritis/arthralgia at the time of presentation. The only patient with anti-Mi2 had normal muscle strength/endurance at the time of follow up. None of the patients had anti synthetase antibodies (anti-Jo1, anti-PL-7, anti-PL-12, anti-EJ), anti-ku or anti-Scl-70. None of the subjects tested positive for anti-NXP2 or anti- HMG CoA.

Conclusions: Prevalence of autoantibodies in children with JDM in our study is similar to what has been described previously. Type of autoantibodies, though, is not similar. This may be due to ethnic differences of the population. Autoantibodies were tested in children while they were on treatment. This may have resulted in lower positivity. Evaluation of autoantibody profile at the time of diagnosis may assist in predicting the course of disease and response to treatment.

THU0220 SELETALISIB, A NOVEL SELECTIVE PI3KΔ INHIBITOR WITH THERAPEUTIC POTENTIAL IN INFLAMMATION AND AUTOIMMUNITY

A. Payne, M. Juarez, G.I. Johnston, E. Helmer, M. Thomson. *UCB Pharma, Slough, United Kingdom*

Background: PI3Kδ is predominantly expressed in lymphocytes; the role it plays in immune disease has encouraged the development of inhibitors targeting

its kinase activity. Inhibitors of PI3Kδ have been approved or are in clinical development for the treatment of B cell malignancies; their therapeutic potential in inflammatory and autoimmune disease is being explored. Seletalisib is a selective and potent PI3Kδ inhibitor that has been profiled in preclinical and early clinical studies.
Objectives: To assess the therapeutic potential of seletalisib in inflammatory and autoimmune disease.
Methods: *In vitro* cell-based studies were performed on blood samples taken from healthy volunteers (HV) or from patients with primary Sjogren's Syndrome (pSS) and/or psoriasis. In addition, samples were analysed from a single ascending dose study in HV (NCT02207595) and a multiple ascending dose study in HV and psoriasis patients (NCT02303509). T and B cell responses in the presence and absence of seletalisib were assessed by flow cytometry or a Meso-Scale discovery assay (Meso-Scale Diagnostics, MD, USA), following activation of the T cell- or B cell-receptor by receptor cross-linking or via stimulation with specific antigens. The functional selectivity of seletalisib was assessed in the BioMap system (DiscoverX, CA, USA). Translational studies used flow cytometry and/or immunofluorescence to demonstrate the presence of active PI3K signalling in diseased tissue, through expression of phosphorylated-AKT (pAKT) or -ribosomal protein S6 (pS6). The effect of seletalisib on PI3K signalling was determined by phospho-flow cytometry. Target engagement was determined through measurement of basophil degranulation in healthy subjects, and assessment of lesion severity score in skin biopsies from patients with psoriasis that were treated with seletalisib.
Results: Preclinical studies showed seletalisib potently inhibited T cell differentiation and function (IC_{50} range: 2–31 nM). Further, it blocked activation and proliferation of B cells (IC_{50} range: 16–49 nM). When profiled in a wide range of primary cell assay systems, including fibroblasts, epithelial, endothelial and vascular smooth muscle cells, seletalisib showed significant activity only in those systems containing lymphocytes, demonstrating its functional selectivity towards PI3Kδ-expressing cells. Expression of the PI3K pathway in lymphocytes was shown at the site of disease in clinical samples both from patients with psoriasis and pSS. Seletalisib inhibited PI3K signalling, measured by a reduction in pAKT and pS6 expression, in T cells derived from patients with psoriasis.
In first-in-man studies, mean seletalisib plasma concentration-time profiles increased with increasing dose after single and multiple dosing, with no major deviations from dose proportionality. There was no unexpected accumulation or loss of exposure after multiple dosing (time-independent pharmacokinetic (PK) profile) and apparent $t_{1/2}$ values (approx. 20h) were supportive of once-daily dosing. Inhibition of basophil degranulation in healthy subjects and effects on the cellular composition in lesional skin biopsies from patients with psoriasis, provided indications of target engagement, following treatment with seletalisib.
Conclusions: Seletalisib is a potent, selective PI3Kδ inhibitor with an attractive preclinical and human PK profile; clinical studies are ongoing.

Background: The miRNAs of the miR-200 family are critical regulators of oncogene and tumor suppressor genes. Preliminary data from a limited number of patients with SS-associated lymphoma suggested that the expression of miR200b-5p in MSGs may be downregulated in lymphoma.
Objectives: To validate whether low miR200b-5p MSG-levels are associated with SS-related lymphomas and if they are deregulated before lymphoma development, suggesting a possible prognostic value.
Methods: miR200b-5p expression was analyzed by quantitative real-time PCR in total RNA from MSG tissues obtained from 77 SS patients and 9 patients with non-SS sialadenitis associated with sarcoidosis, HCV infection (4 each) or HBV (1 that was also diagnosed with MALT lymphoma). with chronic sialadenitis associated with sarcoidosis, HCV (4-each) or HBV infection (1 who was also diagnosed with MALT-lymphoma). SS-patients included 28 that did not develop lymphoma during follow-up (without lymphoma; median follow-up time since biopsy performance, range: 6yrs, 1–12.75yrs), 18 that developed lymphoma in the future (prelymphoma; median follow-up time till lymphoma diagnosis, range: 3.59yrs, 0.42–8.5yrs, 15-MALT, 2-NMZL, 1-DLCBL) and 32 with SS-associated lymphoma at the time of biopsy (lymphoma; 25-MALT, 2-NMZL, 2-DLCBL, 1-BALT, 1-LP and 1-SLL). In 15 cases, we had sequential MSG-samples from prelymphoma patients who transitioned to lymphoma (12-MALT, 2-NMZL, 1-DLCBL).
Results: Tukey's multiple comparison revealed that miR200b-5p levels were significantly down-regulated in MSG tissues of prelymphoma and lymphoma SS-patients (mean relative expression±SE: 0.37±0.10 and 0.26±0.06, respectively) compared to SS-patients without lymphoma (0.67±0.07; $p \leq 0.05$ and $p \leq 0.0001$ for pre- and lymphoma, respectively) or non-SS sialadenitis (0.85±0.28, $p \leq 0.05$ and $p \leq 0.01$, respectively). Interestingly, low miR200b-5p levels were detected in HBV patient that had MALT lymphoma (0.17). The expression of miR200b-5p was not found to differ between patients with SS without lymphoma and non-SS sialadenitis, or SS-associated pre-lymphoma and lymphoma. The analysis of the 15 cases of SS patients that had sequential samples before and on lymphoma diagnosis revealed that miR200b-5p levels do not significantly change over transition to lymphoma. The miR200b-5p expression levels were negatively correlated with the biopsy focus score (r:-0.6550, $p < 0.0001$), whereas they were not associated with the site or the number of involved sites, the type or the stage of lymphoma.
Conclusions: The significantly low levels of miR200b-5p in MSG tissues of patients with SS-associated prelymphomas and lymphomas suggest that miR200b-5p deregulation is implicated in SS-lymphomagenesis. The downregulation of miR200b-5p in prelymphoma samples and the lack of change over transition to lymphoma suggest that it can serve as a prognostic marker for future lymphoma development. The prognostic value of miR200b-5p in SS-associated lymphomas, the expressing cell types and affected molecular pathways are under investigation.

THU0222 PROPHYLACTIC AND THERAPEUTIC ADMINISTRATION OF AN ANTI-CD40 ANTAGONIST ANTIBODY BLOCKS AND REVERSES PROTEINURIA AND NEPHRITIS IN NZB/W-F1 MICE

S. Perper, S. Westmoreland, Z. Liu, M. Duval, J. Seagal, B. McRae, S. Clarke.
Abbvie, Worcester, United States

Background: The CD40-CD40L pathway is a potential target for the treatment of autoimmune diseases, as CD40 is a costimulatory receptor on antigen presenting cells (APCs) critical for the induction and maintenance of an immune response through binding CD40L on T cells. In the absence of CD40, both humoral and cellular responses to foreign antigens are severely impaired. In particular, disruption of this pathway prevents the development of disease in lupus-prone mice.
Objectives: The objective of this work is to evaluate whether prophylactic and therapeutic treatment with an antagonistic anti-CD40 antibody prevents and reverses nephritis and other manifestations of lupus in lupus-prone mice.
Methods: NZB/W-F_1 mice were i.p. administered anti-CD40 prophylactically or therapeutically at various doses once or twice per week. Prophylactic treatment of NZB/W-F_1 mice began at 26 weeks of age and continued for 9 weeks, while therapeutic treatment was initiated in NZB/W-F_1 mice after they developed severe proteinuria (urine protein $\geq$300 mg/dL). Proteinuria was monitored weekly by urinalysis, and at study termination blood and spleen cells were analyzed by flow cytometry. Additionally, histological analysis of kidney, spleen, and salivary glands were performed, as well as gene transcription analysis of the kidney by microarray.
Results: As expected, prophylactic and therapeutic administration reduced the number of splenic germinal center (GC) B cells and T follicular helper cells (Tfh). Prophylactic treatment blocked development of proteinuria and extended survival in NZB/W-F_1 mice. Significantly, therapeutic anti-CD40 treatment reversed established, severe proteinuria in NZB/W-F_1 mice and extended their survival. In agreement, the kidneys and salivary glands of treated mice exhibited reduced inflammation compared to control mice, and the kidneys exhibited lower CD40, IFN-I and chemokine gene signatures compared to controls. Interestingly, anti-CD40 decreased expression of genes in kidney belonging to the "hepatic fibrosis" pathway, possibly explaining the improvement of kidney function.
Conclusions: Anti-CD40 treatment prevents the onset and reverses ongoing nephritis and sialadenitis in NZB/W-F_1 mice. Resolution of ongoing nephritis results in restoration of low or normal urine protein levels. Thus, treatment with an antagonistic anti-CD40 is a strong candidate for clinical study in SLE.

THU0223 ELEVATED MTORC1 SIGNATURE IN B CELLS FROM SJÖGREN'S SYNDROME PATIENTS CORRELATES WITH B CELL HYPERACTIVITY THAT IS ABROGATED BY MTOR INHIBITION: A NOVEL THERAPEUTIC STRATEGY TO HALT B CELL HYPERACTIVITY IN PSS?

S.L. Blokland[1,2], M.R. Hillen[1,2], C.G. Kommer-Wichers[1,2], A.A. Kruize[1], J.C. Broen[1,2], J.A. van Roon[1,2], T.R. Radstake[1,2]. *[1]Rheumatology & Clinical Immunology; [2]Laboratory of Translational Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: A hallmark feature of primary Sjögren's syndrome (pSS) is B cell hyperactivity, including presence of autoantibodies, aberrant presence of B cells and plasma cells in the salivary glands, elevated serum IgG levels and increased risk of lymphoma development. The mTOR pathway is essential for cell growth,

survival and proliferation of B cells and mTOR inhibition has been shown to be effective in immune B cell suppression in transplant patients and in treatment of B cell lymphomas. Interestingly, in a pSS mouse model mTOR targeting inhibited lymphocytic infiltration in the lacrimal gland. However, mTOR activation in B cells has not been studied in pSS patients.
Objectives: To study the mTOR pathway in B cells of pSS patients as a potential therapeutic target to inhibit B cell hyperactivity.
Methods: Expression of mTOR pathway genes (MTOR, RPTOR, RICTOR, DEPTOR, AKT1, IGF1R, IGF1, PTEN) were assessed on an OpenArray platform in purified peripheral blood B cells and monocytes from pSS patients (n=12), non-Sjögren's sicca patients (n=17) and healthy controls (HC, n=9). Correlations with clinical parameters including lymphocytic focus score, ESSDAI and serum IgG levels were assessed. Flow cytometry analysis for B cell subset distribution was performed to assess potential effects of B cell subset distribution on gene expression differences. Culture experiments were performed to study inhibition of the mTORC1 pathway (phosphorylated S6, kinase activity downstream of mTORC1) in association with inhibition of B cell proliferation and IgG production by mTOR inhibition.
Results: RPTOR and IGF1R expression were significantly increased in B cells from pSS patients (p=0.019 and p=0.018, respectively) and correlated with serum IgG levels (r=0.429, p=0.020, and r=0.462, p=0.012). Differences in expression of mTOR pathway genes were not found in monocytes. To indicate the mTOR signature a cumulative mTORC1 score was calculated consisting of Z scores (AKT1 + IGF1R + IGF1 + RPTOR + MTOR – PTEN – DEPTOR) which was significantly elevated in pSS (p=0.027), correlating with serum IgG levels (r=0.463, p=0.011). Frequencies of memory and naïve B cells did not differ between pSS patients and HC in this cohort (p=0.415). Activation of B cells in culture resulted in phosphorylation of S6, which indicates increased mTORC1 activity, in accordance with B cell proliferation and IgG production in both HC and pSS patients. Inhibition of mTOR by rapamycin decreased pS6 (n=4, n=2 HC, n=2 pSS, MFI 1400±335 vs 935±306, p=0.060), strongly reduced B cell proliferation (n=6, n=3 HC, n=3 pSS, 80.8±9.9 vs 19.1±15.8%, $p<0.001$), reduced IgG+ B cells (n=6, n=3 HC, n=3 pSS 39.5±15.5 vs 11.1±5.7%, p=0.001) and decreased IgG production (n=4, n=2 HC, n=2 pSS, 160±180 pg/mL vs 25.3±13.0 pg/mL p=0.060).
Conclusions: Presence of an mTORC1 signature in B cells from pSS patients correlating with B cell hyperactivity indicates a role for mTORC1 in B cell activation in this disease. The fact that B cell proliferation and IgG production is effectively inhibited by rapamycin suggests that mTOR inhibition represents a potential therapeutic strategy for pSS.

THU0224 ASSOCIATION OF IRAK-M WITH NEUROPSYCHIATRIC SYMPTOMS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

S. Sacre, R. Thwaites, K. Davies. *Brighton and Sussex Medical School, University of Sussex, Brighton, United Kingdom*

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease, where a breakdown in immune tolerance leads to sustained inflammation and tissue damage. Patients exhibit multi-organ involvement with a diverse range of symptoms that include arthritis, nephritis, neuropsychiatric events and dermatological complaints. Interleukin-1 receptor-associated kinase M (IRAK-M), a negative regulator of toll-like receptor (TLR) signalling has previously been associated with SLE in a murine study [1]. Deficiency of IRAK-M was observed to exacerbated disease in a SLE model in C57BL/6-lpr/lpr mice [2].
Objectives: This study aimed to investigate the expression of IRAK-M in monocytes from SLE patients compared with healthy control donors and measure downstream cytokine production upon TLR stimulation.
Methods: The study was approved by the Brighton East Research Ethics Committee and the *National Research Ethics Service* Committee North West – Lancaster. Whole venous blood was collected from 39 SLE patients and 19 healthy donors. Peripheral blood mononuclear cells were purified from whole blood after which monocytes were isolated using $CD14^+$ selection beads. Expression of IRAK-M was determined relative to the geometric mean of the housekeeping genes glyceraldehyde 3-phosphate dehydrogenase and hypoxanthine phosphoribosyltransferase 1 by quantitative polymerase chain reaction. Cultured monocytes were stimulated with TLR ligands. Cytokine production was measured by enzyme-linked immunosorbent assay.
Results: IRAK-M expression was increased in the SLE patient group, however many of the patients did not show elevated expression compared to healthy donors. When stratified by disease symptoms, a clear correlation was observed between low expression of IRAK-M and neuropsychiatric symptoms which was not evident when evaluating other SLE symptoms. Interestingly, TLR activation led to elevated cytokine production in SLE patient monocytes that correlated with the basal level of IRAK-M expression in individual donors. Further investigation revealed that SLE monocytes demonstrated a reduced upregulation of IRAK-M after TLR activation compared to healthy donors.
Conclusions: Increased expression of IRAK-M was not unexpected in the SLE group due to the systemic inflammatory nature of the disease. However, not all patients presented with increased levels of IRAK-M and upon activation were less able to upregulate IRAK-M compared to healthy donors, suggesting a reduced capacity to resolve inflammation. This was reflected in the elevated cytokine production observed from SLE monocytes. Thus, low expression of IRAK-M in SLE monocytes is linked to elevated inflammatory cytokine production and may be a biomarker for neuropsychiatric symptoms in SLE patients.

THU0225 ROLE OF THE IL-12/IL-35 BALANCE IN SJÖGREN'S SYNDROME

O. Fogel[1], E. Rivière[2], R. Seror[2], G. Nocturne[2], S. Boudaoud[3], B. Ly[3], J.-E. Gottenberg[4], V. Le Guern[1], J.-J. Dubost[5], J. Nititham[6], K. Taylor[6], P. Chanson[2], P. Dieudé[7], L. Criswell[6], C. Miceli[1], X. Mariette[2]. *[1]Hopital Cochin; [2]Hopital Bicêtre; [3]Inserm UMR1184, Paris; [4]Hopital de Hautepierre, Strasbourg; [5]Hopital Montpied, Clermont-Ferrand, France; [6]UCSF, San Francisco, United States; [7]Hopital Bichat, Paris, France*

Background: An interferon (IFN) signature is involved in the pathogenesis of primary Sjögren's syndrome (pSS), but whether the signature is type 1 or 2 remains controversial. Mouse models and genetic studies suggested the involvement of T helper 1 and type 2 IFN pathways. Likewise, polymorphisms of interleukin 12A gene (*IL-12A*), which encodes for IL-12p35, have been associated with pSS. IL-12p35 subunit is shared by 2 heterodimers, IL-12 and IL-35.
Objectives: To confirm the genetic association of *IL-12A* polymorphism and pSS and elucidate the involvement of the IL-12/IL-35 balance in pSS by functional studies.
Methods: The genetic study involved 673 patients with pSS from 2 French pSS cohorts and 585 healthy French controls. Functional studies were performed on sorted monocytes, stimulated or not. IL-12A mRNA and IL-12 and IL-35 protein levels were assessed by qRT-PCR and by ELISA and a multiplex kit for IL-35 and IL-12, respectively.
Results: We confirmed the association of the *IL-12A* rs485497 polymorphism and pSS and found an increased serum protein level of IL-12p70 in pSS patients carrying the risk allele (p=0.016). Serum level of IL-12p70 was greater in patients than controls (p=0.0001), especially patients with more active disease (p=0.05); conversely IL-35 level was decreased in patients (p=0.0001) especially in patients with a more active disease (p=0.05).
Conclusions: Our findings emphasize the involvement of the IL-12/IL-35 balance in the pathogenesis of pSS. Serum IL-35 level was associated with low disease activity, in contrast to serum IL-12p70 level, which was rather associated with a more active disease.
Acknowledgements: We thank Dr Odile Devergne (Université Paris Descartes, AP-HP, Hôpital Necker, Paris) for her expertise on the IL-35 ELISA kit to ensure the quality and reproducibility of this test.

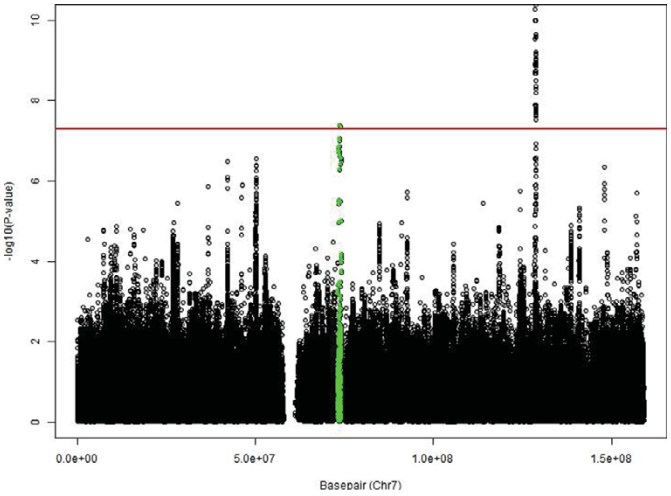
THU0226 DIFFERENTIAL SUSCEPTIBILITY OF TH17 AND T REGULATORY CELLS TO APOPTOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS – THE MODULATORY EFFECTS OF STATIN

J. Sun, J. Frostegard, A. Liu. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*



Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder. Patients with SLE have accelerated cardiovascular disease. Recent studies show there are more Th17 while less T regulatory (Treg) cells in the SLE patients. Th17/Treg imbalance may contribute to the pathogenesis of SLE.
Objectives: To investigate the underlying mechanisms of Th17/Treg imbalance, we test the proportion and susceptibility of Th17 and Treg to apoptosis, and the modulatory effects of statin in the SLE patients.
Methods: Totally 17 SLE patients and 20 gender- and age-matched control subjects were enrolled for this study. Peripheral blood mononuclear cells were isolated, either analyzed ex vivo, or cultured in the conditions to induce Th17 and/or Treg polarization. The proportion of Th17/Treg cells and frequency responding to apoptosis were analyzed by multiple color flow cytometry. Cytokines in cell culture supernatants and plasma were tested by ELISA. T cell polarization-related transcription factors were detected by quantitative real time PCR.
Results: The proportion of Th17 ($CD4^+IL17^+$) cells were higher in SLE patients,

both in ex vivo and in the Th17-polarizing cultures. While the frequencies of Treg ($CD4^+CD25^+CD127^{dim/-}$) cells were lower in the corresponding populations. Higher levels of IL17 and IL6 were detected in plasma of SLE patients. Responding to CD95-induced apoptosis the frequency of $CD4^+IL17^+$ cells from SLE patients was substantially lower, but that of $CD4^+CD25^+CD127^{dim/-}$ cells from Treg-polarizing cultures was considerably higher. With treatment of atorvastatin, $CD4^+IL17^+$ cell population in cultures derived from SLE patients showed an increased susceptibility to CD95-induced apoptosis. However, the $CD4^+CD25^+CD127^{dim/-}$ cell population had reduced response to apoptosis. Accordingly, the ratio of transcription factor RORC/FoxP3 decreased in T cell cultures of SLE patients.
Conclusions: Th17 cells were more resistant than Treg cells to CD95-induced apoptosis in SLE as compared to control subjects. Statins counteracted the dysregulated susceptibility of SLE T cells to apoptosis. Our findings reveal a novel mechanism underlying the imbalance of Th17/Treg and show a potential interest to the treatment of the patients with SLE.

Background: Recent genome-wide association studies (GWAS) have identified more than 50 loci associated with systemic lupus erythematosus but they explain less than 30% of the heritability of the disease. Meta-analysis including new populations can contribute to identify additional genetic risk factors.
Objectives: The aim of the presents study was to identify additional genetic risk loci for SLE.
Methods: We performed a meta-analysis using data from a recent large scale GWAS from 4,036 cases and 6,959 controls from Caucasian European ancestry [1] and a newly genotyped cohort of 907 SLE patients and 1,524healthy controls from Spain. Genetic association was tested at the single-marker level using linear regression and at the pathway-level using Fisher's modified method.
Results: Combining the two cohorts we identified genome-wide significant association ($P<5E-8$) at five new loci: three SNPs at intragenic regions and two intergenic loci at chromosomes *7q11.23* (Manhattan plot for chromosome 7 is shown in Figure; new SLE risk region SNPs highlighted in green) and *17q21.31*.

Several of the new associated genes are functionally associated with B cell regulation. After multiple test correction, *B Cell Receptor signaling*, *Biopeptides* and *Cell surface interactions at the vascular wall* pathways were also significantly associated with SLE risk.
Conclusions: In conclusion, we have identified five new risk loci for SLE through a meta-analysis including a new GWAS.

THU0228 INTRA-RENAL ACTIVATION OF ADAPTIVE IMMUNE EFFECTORS IS ASSOCIATED WITH HIGHER DISEASE SEVERITY IN LUPUS NEPHRITIS

C. Pamfil[1], N. Demoulin[2], M. Jadoul[2], S. Aydin[3], F.A. Houssiau[1,4], B. Lauwerys[1,4]. *[1]Pôle de pathologies rhumatismales systémiques et inflammatoires, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain; [2]Department of Nephrology; [3]Department of Pathology; [4]Department of Rheumatology, Cliniques universitaires Saint-Luc, Brussels, Belgium*

Background: Chronic renal impairment remains a feared complication of lupus nephritis (LN). Yet, little is known about mechanisms and markers of disease severity in the lupus kidney.
Methods: We performed high-throughput transcriptomic studies (Illumina HumanHT12 v4 Expression Beadchips) on archived (- 80 degrees) kidney biopsies from 32 SLE patients and 8 controls (pre-transplant donors). Unsupervized clustering and differential gene expression studies were performed using GeneSpring software. Pathway analyses were carried on using DAVID and GSEA. Clinical and biological data were retrieved from the patients' medical records. Immunohistochemistry experiments (CD3, CD20, CD21) were performed on the same samples, and on an additional cohort of 37 SLE kidney biopsies. Syndecan-1 (SDC1) was used as a marker of renal tubular cell response to stress.
Results: Compared to controls, LN samples overexpressed transcripts involved in interferon signature, apoptosis, chemokines, antigen presentation, T and B cell activation.
Unsupervized clustering studies isolated 14 SLE samples based on their gene expression features. These samples were characterized by a significantly lower estimated GFR at the time of biopsy (T0) (50.7 versus 97.4 ml/min/1.72m^2), but also at follow-up (49.1 versus 85.8 ml/min/1.72m^2) compared to the other SLE samples. Yet, apparent renal disease duration at T0, disease duration at last follow-up (median 91.5 versus 86 months), double-stranded DNA antibody titers at T0 and other relevant characteristics (histological scores, proteinuria, numbers of subsequent flares) were not different between both groups.
From a transcriptomic point of view, these 14 samples were characterized by the overexpression of transcripts and pathways involved in adaptive immune responses: antigen presentation, T cell differentiation and B cell activation.
Immunohistochemistry studies confirmed a significant association between the presence of CD3 and CD20 positive cells in the interstitial space and lower estimated GFR at baseline in the same, but also in an independent set of samples. The presence of CD3 and CD20 positive cells was also associated with lower SDC1 expression on renal tubular cells. Low SDC1 expression on renal tubular cells was strongly associated with impaired kidney function at baseline.
Conclusions: LN kidney biopsy samples from patients with lower estimated GFR are characterized by the overexpression of transcripts pointing to the activation of a local antigen-dependent immune response. Activation of "second wave" immune effectors in the LN kidney is a known feature of the disease, and impacts kidney function through alterations in the function of renal tubular cells.

THU0229 DNA HYPOMETHYLATION AND DECREASED HYDROXYMETHYLATION IS ASSOCIATED WITH DECREASED ANTIOXIDANT RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS

E. Grau Garcia[1], C.M. Feced Olmos[1], M. Fernandez Matilla[2], E. Labrador Sánchez[1], F.M. Ortiz-Sanjuan[1], N. Fernández-Llanio[2], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortes[1], J.J. Fragio Gil[1], I. Martínez Cordellat[1], R. González Mazarío[1], I. Chalmeta Verdejo[1], L. Gonzalez Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Vicens Bernabeu[1], J.E. Oller Rodriguez[1], J.A. Castellano Cuesta[2], V. Fornés Ferrer[3], D. Hervás Marín[3], L. Olivares González[4], R. Rodrigo Nicolás[4], J.A. Román Ivorra[1]. *[1]Rheumatology Department, HUP la Fe; [2]Rheumatology Section, Hospital Arnau de Vilanova; [3]Biostatistics Unit; [4]Molecular, Cellular and Genomic Biomedicine, IIS la Fe, Valencia, Spain*

Background: Systemic lupus erythematous (SLE) shows increased DNA demethylation. An intermediate step to DNA demethylation is the DNA hydroxymethylation, where 5-mC is oxidized into 5-hmC. Hydroxymethylation is not completely understood and it may be related to oxidative stress in SLE patient.
Objectives: To analyze the association between the hydroxymethylation and demethylation, with the antioxidant response and SLE pathophysiology.
Methods: We analyzed in 142 SLE patients and 34 healthy controls the serum concentration of glutathione (GSH) and glutathione disulphide (GSSG) by UPLC-MS/MS, superoxide dismutase (SOD) and total antioxidant capacity (TAC) by colorimetric methods. 5-mC and 5-hmC levels were measured by colorimetric methods. Complete blood-test was made and clinical data by personal interview was collected. Biostatistical analysis with R (3.3.2.) was performed.
Results: There is a correlation between the methylation and hydroxymethylation rate ($P<0.001$), and both were lower in patients than in controls (P=0.024; $P<0.001$). GSH and GSSG values were lower in patients (P=0.033 y P=0.003), but GSH/GSSG ratio was not statistically different in both groups. SOD levels were higher in patients (P=0.001), but TAC did not show significant differences. Higher demethylation is associated to lower TAC values in patients and healthy controls (P=0.005; P=0.01). In patients, decreased SOD values are associated with higher demethylation and lower hydroxymethylation rates ($P<0.001$; P=0.007). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P=0.001; $P<0.001$). We did not observe any association between 5-mC or 5-hmC levels and GSH, GSSG or GSH/GSSG ratio. Higher demethylation is associated to vascular symptoms (defined by RELESSER study) and lupus anticoagulant (AL) positivity (P=0.041; P=0.015), and lower hydroxymethylation to mucocutaneous damage (defined by RELESSER study) and AL positivity (P=0.015; P=0.009). Lower levels of GSH and GSSG were associated to increased accumulated damage assessed by SLICC (P=0.01; P=0.005), and lower SOD values with longer disease duration (P=0.001).
Conclusions: We observed higher demethylation and lower hydroxymethylation in SLE patients than in controls, related to increased SOD activity. Moreover higher demethylation leads to lower TAC levels. These epigenetic disorders are related to antioxidant response disruptions in SLE patients, probably because of the chronic inflammatory condition. Our results suggest that epigenetic processes are involved in SLE physiopathology.

THU0230 HIF1A (RS11549465) AND AKNA (RS10817595) GENE POLYMORPHISMS ARE ASSOCIATED WITH PRIMARY SJÖGREN'S SYNDROME

G. Hernandez-Molina[1], J.M. Rodríguez-Pérez[2], J. Fernández-Torres[3], G. Lima[1], N. Pérez-Hernández[2], A. López-Reyes[3], G.A. Martínez-Nava[3]. *[1]Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran; [2]Department of Molecular Biology, Instituto Nacional de Cardiologia; [3]Synovial Fluid Laboratory, Instituto de Rehabilitacion, Mexico City, Mexico*

Background: HIF-1α is the main transcriptional regulator of cellular and developmental response to hypoxia, and also participates in the integration of the T cell receptor and cytokine receptor-mediated signals of CD4+ helper cells. Another transcription factor also involved in the immune responses is the AT-hook transcription factor (AKNA).
Objectives: To evaluate the allele and genotype frequencies of polymorphic sites of *HIF1A* and *ANKA* genes in primary Sjögren's syndrome (pSS).
Methods: We included 110 patients with pSS and 141 ethnically matched healthy controls. Three *HIF1A* gene polymorphisms *(Pro582Ser, Ala588Thr, and C191T) and two AKNA genes polymorphism (-1372C>A, and Pro624Leu*) were genotyped using TaqMan probes in a Real-Time PCR instrument. Associations between pSS and genotypes, alleles and inheritance models of the SNPs of interest were evaluated by logistic regression adjusted by age and gender.
Results: Most of the patients were females (95.4%), median age 55 years and median disease duration of 7.8 years. The *C/T* genotype and the *T* allele of the *HIF1A Pro582Ser* polymorphism protected against pSS (OR=0.22; 95% CI=0.09–0.52; $P<0.01$; and OR=0.26; 95% CI=0.12–0.58; $P<0.01$; respectively). Whereas under a recessive model adjusted by age and gender, the *AKNA -1372C>A* polymorphism A/A genotype was associated with an increased risk of pSS (OR=2.60; 95% CI=1.11–6.12; *P*=0.03). Parotid enlargement was associated with the *HIF1A* gene polymorphism (rs11549465), conferring protection for the C/T genotype vs. C/C (OR=0.22; 95% CI 0.05–0.90, *P*=0.03). The allele T of the same polymorphism was also associated with parotid enlargement (OR=0.24, 95% CI=0.65–0.95; *P*=0.04). We did not find any association with any other clinical or serological feature.
Conclusions: We identified *HIF1A Pro582Ser T* allele and *C/T* genotype as well as *AKNA -1372C>A* polymorphism A/A genotype as genetic factors associated with pSS. Further studies in other populations are needed to validate our findings and to shed some light on their functional implications.

THU0231 IL-17 POLARIZATION OF MAIT CELLS DERIVE FROM THE ACTIVATION OF TWO DIFFERENT PATHWAYS

G. Guggino[1], F. Ciccia[2], M. Lo Pizzo[2], D. Di Liberto[2], L. Saieva[2], P. Ruscitti[2], P. Cipriani[3], G. Sireci[2], R. Alessandro[2], F. Dieli[2], R. Giacomelli[3], G. Triolo[2]. *[1]DIBIMIS; [2]University of Palermo, palermo; [3]University of L'Aquila, L'Aquila, Italy*

Background: Primary Sjogren Syndrome (pSS) is a chronic inflammatory disorder affecting exocrine glands. Both IL-23 and the downstream cytokines IL-17 and IL-22 are recognised as key players in the disease. Therefore, the identification of the cellular sources and inducers of IL-17 is crucial in the understanding of the drivers of inflammation in pSS. Mucosal-associated invariant T (MAIT) cells recognize riboflavin derivatives presented by the MHC class I-like molecule MR1.
Objectives: Recently, MAIT cells have been implicated in the pathogenesis of autoimmune disorders and found expanded in salivary glands of pSS patients. Their expression of IL7R and IL23R, makes them potential contributors to the pathogenesis of pSS.
Methods: Mononuclear cells from 16 patients with pSS and 14 subjects with non Sjogren Syndrome secca syndrome (nSS) were isolated from blood and salivary glands. We assessed the phenotype and cytokine expression of MAIT cells by surface and intracellular flow cytometry analysis. The function of MAIT cells was assessed upon *in vitro* stimulation with recombinant IL-7, IL-23 or their specific ligand lumazine (a Vitamin B2 precursor previously reported to be recognized by and specifically activate MAIT cells).
Results: MAIT cells were reduced in frequency in peripheral blood but not in minor salivary glands of patients with pSS, compared with nSS. *In vitro* stimulation of MAIT cells from pSS patients induced cytokine production which was dependent on priming with IL-7, IL-23 or specific antigen (lumazine) stimulation. Particularly, IL-7 and IL-23 guarantee IL-17 polarization of MAIT cells by two different pathways via the activation of STAT3 or RORc respectively.
Conclusions: This study confirms a potential role for MAIT cells in pSS and, for the first time, links IL-7 and IL-23 to the IL-17 polarization of MAIT cells in these patients.

THU0232 INHIBITING THE ACTIVATION OF COMPLEMENT C5 BY MESENCHYMAL STEM CELLS IN THE TREATMENT OF LUPUS NEPHRITIS

H.-J. Ma[1,2], C. Liu[1], Z.-Y. Zhang[1], R.-H. Feng[1], W.-C. Li[1], L.-Y. Sun[1]. *[1]Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing; [2]Department of Rheumatology, The First Affiliated Hospital of Xinxiang Medical University, Weihui, China*

Background: Excess activation of the complement system is involved in the development and progression of systemic lupus erythematosus (SLE). Allogeneic umbilical cord mesenchymal stem cells (UC-MSC) transplantation has achieved good clinical efficacy for refractory SLE, however, the exact mechanism is unclear. Our previous work found that deposits of C5a and C5b-9 were significantly enhanced in severe lupus nephritis (LN), which suggested that antagonists of C5 might contribute to the treatment of LN, in other words, effective therapy for LN may be involved in inhibiting the activation of C5.
Objectives: To observe the clinical effect of UC-MSC on SLE model mice (B6.lpr), and explore the mechanism of MSC inhibiting the activation of complement C5 in lupus mice.
Methods: 26-week-old female B6.lpr mice were randomly allocated in four groups, which were given the following treatments, CTX (200mg/kg), UC-MSC ($1x10^6$), C5aRa (W-54011, 1mg/kg), and an equal volume of 0.5%DMSO. 24 hours urine and peripheral blood were collected periodically. All mice were sacrificed at 40 weeks of age.Urine protein to creatinine ratio was used to estimate daily urine protein excretion. Plasma creatinine was measured by a biochemical analyzer. Plasma levels of C3, C5a, soluble C5b-9, and anti-dsDNA

antibody were determined by ELISA. Histopathological evaluation of renal lesions was undertaken by HE, PAS, PASM and Masson staining under light microscopy. Podocyte foot processes were assayed by the transmission electron microscopy. Depositions of C5a, C5b-9, and MBL were detected by immunohistochemistry assay. Immunofluorescence was utilized to detect the expression of C5aR1, IgG, IgM, IgA, C3, C1q, and properdin in the glomeruli.

Results: At the end point, proteinuria of mice in the former three groups was significantly reduced when compared with the control mice, and renal function was also improved in both MSCT and CTX groups. Plasma level of C3 was significantly elevated in mice of MSCT and C5aRA groups. Furthermore, mice in MSCT group appeared a remarkably decreased C5a in the circulation. Compared to control mice, no significant difference was found in plasma levels of anti-dsDNA and SC5b-9, although there were decline trends in other three groups. Pathological analysis showed that the proliferation of glomerular cells and foot process fusion were significantly inhibited in MSCT treated mice. Immunohistochemistry showed that deposits of C5a and C5b-9 were significantly decreased in the MSCT group. Immunofluorescence examination showed that the expression of IgG, C3, C1q, and properdin was significantly decreased in MSCT treated mice, meanwhile, the expression of MBL was also significantly reduced in these mice.

Conclusions: The activation of the complement system was obviously involved in the glomerulonephritis in lupus mice. Allogeneic UC-MSC transplantation can effectively improve the clinical outcome of lupus mice. Possible mechanism of MSCT might be related to inhibit the activation of complement C5 in the circulation and local kidney via interrupting the classical, alternative, and lectin pathways. The potential involved contributors of UC-MSC are currently under study.

THU0233 IN VITRO INDUCED REGULATORY T-CELLS CAN AMELIORATE SEVERITY OF PRISTANE INDUCED LUPUS (PIL)

H. Leiss, B. Jacobs, I. Gessl, A. Puchner, J. Smolen, G. Stummvoll.
Rheumatology, Medical University Vienna, Vienna, Austria

Background: Pristane induced lupus (PIL) is a well-established murine model for environmentally induced systemic lupus erythematosus (SLE). Mice develop specific autoantibodies and show symptoms of SLE including arthritis, diffuse proliferative immune complex glomerulonephritis and haemorrhagic pulmonary capillaritis.

Objectives: To investigate the therapeutic effects of in vitro -induced regulatory T cells (iTreg) in the murine model of PIL.

Methods: BALB/c mice were injected i.p. with either 0.5ml of pristane (PIL) or PBS (controls). Naive $CD4^+$ thymocytes were sorted and cultured and cell suspensions with >80% of $CD4^+FoxP3^+$ cells (iTreg) were injected intravenously (i) once when PIL was induced ($5x10^6$ iTreg (iTreg-single)) or (ii) every 4 weeks ($1x10^6$ iTreg, iTreg-rep). Animals were monitored for paw swelling and grip strength. After 8 months histological analysis evaluated for cartilage degradation, number of osteoclasts and the extent of inflammation and bone erosion. Glomerulonephritis and pneumonitis were quantified using the kidney biopsy score and a newly adapted histomorphometric image analysis system; inflammatory tissue was further analyzed by tissue cytometry. Serum levels of anti-dsDNA, anti-histone and anti-chromatin antibodies were measured by ELISA.

Results: Monthly injections of $1x10^6$ iTreg reduced the clinical as well as the histological severity of PIL-arthritis, seen by a higher mean grip strength (2.96±0.02 vs. 2.73±0.06, $p<0.01$), less mean paw swelling (0.04±0.02 vs. 0.36±0.07, $p<0.01$) and retardation of the symptom onset (Figure A). 62% of PIL-mice and 33% of iTreg-rep mice had erosive arthritis. There was a significant reduction of arthritis severity in all histological parameters (inflammatory area in mm^2 0.19±0.06 vs. 0.69±0.11; erosive area in mm^2 0.01±0.01 vs. 0.07±0.02; number of osteoclasts 2±1.13 vs. 9.14±2; cartilage degradation in mm^2 0.06±0.01 vs. 0.19±0.03, all $p<0.01$, Figure B). The single boost of $5x10^6$ iTreg could not prevent joint manifestations. However, a slight retardation in "loss of grip strength" and a significantly less erosive area was observed. In regards to the cellular composition of the inflammatory tissue in paws, a significantly increased relative amount of CD4+Foxp3+ cells was seen in the iTreg-rep group compared to the PIL group (in % 5.2±2.3 vs. 0.6±0.2, $p<0.01$).

Repeatedly injected mice (iTreg-rep) had significant less pulmonary involvement (perivascular inflammatory area in mm^2/mm^2 lung area 0,003±0,001 vs. 0,007±0,001, $p<0.01$) and renal disease (glomerular activity score 1,17±0,31 vs. 2,43±0,39, $p<0.05$) compared to PIL (Figure C). Corresponding, iTreg-rep mice had significantly lower serum levels of disease-associated auto-antibodies (Figure D).

Conclusions: Repeated injections of iTreg ameliorate the clinical and histological severity of PIL- manifestations. A single boost of iTreg at the time of disease induction does not prevent manifestations, but retards the onset of symptoms. Thus iTreg have significant positive effects on PIL, which may have consequences for future approaches in treating SLE.

THU0234 EPIGENETIC CELL COUNTING: A NOVEL TOOL TO QUANTIFY IMMUNE CELLS IN SALIVARY GLANDS DETECTS ROBUST CORRELATIONS OF TFH CELLS WITH IMMUNOPATHOLOGY

J.A. van Roon[1,2], F.M. Moret[1,2], S.L. Blokland[1,2], A.A. Kruize[2], G. Bouma[3], A. van Maurik[3], S. Olek[4], U. Hoffmueller[4], T.R. Radstake[1,2]. *[1]Laboratory of Translational Immunology; [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; [3]Immunoinflammation TAU, GlaxoSmithKline, Stevenage, United Kingdom; [4]Epiontis GmbH, Berlin, Germany*

Background: Histological analysis of salivary glands for decades has been a valuable tool in the characterization of patients with primary Sjögren's syndrome (pSS) and non-Sjögren's sicca (nSS) patients. Importantly, it has helped in understanding the immunopathology of sicca patients. Nonetheless, standardization of histological assessments, e.g. to quantify lymphocytic foci or germinal centers is lacking, contributing to improper classification of disease and assessment of risk of lymphoma for example. Also, detailed and reproducible quantification of the heterogeneity of inflammatory cells and their contribution to immunopathology is lacking. Recent progress in epigenetics has revealed that cell-specific DNA methylation profiles can be applied to reliably quantify numbers of cells in blood and tissues.

Objectives: To investigate whether epigenetic cell counting can serve as a novel reliable tool to quantify immune cells in salivary glands of sicca patients.

Methods: DNA was isolated from frozen tissue sections of 13 nSS, 12 probable SS, 29 pSS and 7 overlap SS patients. Bisulfite conversion of demethylated DNA sites was followed by cell specific qPCR that was used to calculate the percentage of cell subsets related to the total number of cells quantified by housekeeping gene expression. Percentages of epigenetically counted cells were correlated to gene expression generated by RNA-Seq analysis of matched salivary gland tissue and histological and clinical parameters (LFS, %IgA+ plasma cells, serum IgG, SSA positivity).

Results: Strongly increased percentages of epigenetically quantified percentages of CD3, CD4, CD8, B cells, T follicular helper (Tfh) cells and Treg cells in pSS vs nSS patients were observed (all $p<0.001$, CD8 $p<0.01$). These inflammatory cell types all strongly correlated with LFS (all at least $p<0.001$, CD8 $p=0.014$), local B cell hyperactivity (% IgA+ cells, all $p<0.001$, except CD8 $p=0.06$ and B cells, $p=0.127$) and systemic B cell hyperactivity (all at least $p<0.01$, except CD8 $p=0.051$). Th17 cells were not significantly different between nSS and pSS patients. Only CD8 T cells were significantly increased in probable SS patients as compared to nSS patients ($p<0.05$). Percentages of CD3 and B cells positively correlated with CD3 and CD19 RNA expression ($r=0.608$, $p<0.0001$; $r=0.597$, $p<0.0001$, resp.). Interestingly, percentages of Tfh cells correlated with CXCL13 ($r=0.789$, $p<0.0001$), IL7R, CXCR5 and ICOS RNA expression (all $p\leq0.001$) and were strongly associated with autoimmunity (SSA positivity, $p<0.001$).

Conclusions: Epigenetic cell counting is a promising novel tool to reproducibly and easily quantify immune cells in the (inflamed) labial salivary gland of sicca patients with relatively low amount of tissue needed (<1 mm^3). Considering the potential of this technique to include a huge number of (cell-specific) biomarkers we believe this opens up new standardized ways for salivary gland analysis with high relevance for patient classification, understanding of immunopathology and clinical trials.

THU0235 EXOSOME-DELIVERED MIR-146A REGULATES SENESCENCE OF BONE MARROW- MESENCHYMAL STEM CELLS FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS THROUGH TARGETING IRAK1 AND TRAF6

J. Ji, Y. Wu, X. Kong, Z. Zhang, Z. Gu[1,1]. *Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China*

Background: Exosomes are membrane nano-vesicles secreted by a multitude of cells that harbor biological constituents such as proteins, lipids, mRNA and microRNA. Recent study suggests that microRNAs can be transferred between cells and mediate target gene repression. Our research group revealed the senescence of bone marrow-mesenchymal stem cells from systemic lupus erythematosus patients,which participated in the development of SLE. However, the relationship between senescence of MSCs and miRNAs remains unclear.
Objectives: In this study, we investigated whether exosomes act as intercellular messengers delivering microRNA that modulate the senescence of BM-MSCs from SLE patients and its possible mechanism.
Methods: Tewelve female SLE patients and healthy subjects were enrolled in the study. All patients were females, and their age distribution was similar to that of the cases. Serum were collected from these persons. All BM-MSCs were Isolated by density gradient centrifugation. Serum-derived exosomes were extracted by Total Exosome Isolation reagent and confirmed by transmission electron microscope and western blot. The internalization of exosomes was detected by immunofluorescence. QRT-PCR was used to distinguish the difference of expression of miR-146a in exosomes between normal group and SLE group. Different exosomes stimulated normal BM-MSCs, then detecting expression of miR146a by qRT-PCR, detecting expression of IRAK1 and TRAF6 by WB, observing the activity of β-gal of cells, the changes of cytoskeletal structure by F-actin staining and the distribution of cell cycle by flow cytometry. We used miRNA mimics and miRNA inhibitor to interfere the expression of miR-146a.
Results: Serum-derived exosomes could be taken up by BM-MSCs through the plasma membrane due to treatment of BM-MSCs with exosomes. After stimulation of exosomes in normal MSCs, miR146a was decreased, but, IRAK1 and TRAF6 was activated. And, the cell volume and the number of SA-β-gal positive in SLE BM-MSCs was increased. The organization of cytoskeleton was neatly disordered. The rate of cell proliferation was decreased. The miR-146a mimics in SLE BM-MSCs can significantly reverse the senescence.
Conclusions: Exosomes-delivered miR-146a in the serum of SLE patients can promote the senescence of BM-MSCs through targeting IRAK1 and TRAF6. Exosomes play an important role in the pathogenesis of SLE.

THU0236 ANTIBODIES TOWARDS ATP-BINDING CASSETTE TRANSPORTER ABCA1: A NEW MECHANISM FOR ATHEROSCLEROSIS IN SLE?

M. Fernandes Das Neves[1,2], J.R. Batuca[3], F. Batista[2], C. Favas[2], H. Célia[2], J. Delgado Alves[2]. *[1]CEDOC - Chronic Disease Research Center, NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon; [2]Medicine IV, Professor Doutor Fernando Fonseca Hospital, Amadora; [3]CEDOC - Chronic Disease Research Center, NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Background: Systemic Lupus Erythematosus (SLE) is considered an independent risk factor for cardiovascular disease and patients with SLE have an increased burden of atherosclerotic vascular disease[1]. High-density lipoproteins (HDL) are the plasma lipoproteins responsible for reverse cholesterol transport[2]. HDL protective effect on cardiovascular disease is attributed to the cholesterol efflux capacity as well as to its anti-oxidant and anti-inflammatory properties[3]. Dyslipidemia is frequent amongst patients with SLE, characteristically with low HDL levels.
ATP-binding cassette transporter ABCA1, also known as the cholesterol efflux regulator protein, is a ubiquitous cholesterol transporter that is highly expressed in macrophages. Its main function is to donate cholesterol to apolipoprotein A-I (ApoA-I) in lipid-poor HDL particles. As such, ABCA1 closely influences HDL levels and its role in atherosclerosis has been increasingly studied[4].
Objectives: This study was undertaken to determine if antibodies against ABCA1 can be detected in patients with SLE through enzyme-linked immunosorbent assay (ELISA).
Methods: Patients with SLE were divided in two groups: group A, with low damage (based on less than 4 SLICC criteria), and group B, with high damage (based on the presence of at least 4 SLICC criteria). Groups A and B were compared with a control group. 48 patients were enrolled (13 in group A and 35 in group B), and 18 age and gender-matched healthy controls were included in the control group. IgG anti-ABCA1 and anti-HDL antibodies were assessed by home-made ELISAs, using commercially available ABCA1 synthetic peptide and HDL from healthy donors.
Results: There were no differences between group A and the control group. Group B had higher titers of anti-ABCA1 antibodies when compared with group A (p=0.016) and the control group (p=0.022). For positivity we considered values superior to 3 standard deviations above the mean of healthy controls. Four patients showed positive anti-ABCA1 titers (11.4%).
Conclusions: This is the first time that naturally occurring antibodies against ABCA1 are detected by ELISA. These antibodies are increased in patients with SLE that have higher damage, measured by SLICC classification criteria. Future studies will determine their pathogenic role and the potential use of a standardized ELISA to detect anti-ABCA1 antibodies in clinical practice.

THU0237 WHOLE TRANSCRIPTOME ANALYSIS OF APL TREATED HUVECS MAPS PROINFLAMMATORY AND PROCOAGULANT PATHWAYS

M.D. Patsouras[1], S. Foutadakis[2], E. Alexopoulou[2], M. Agelopoulos[2], D. Thanos[2], A.G. Tzioufas[1], P.G. Vlachoyiannopoulos[1]. *[1]Department of Pathophysiology, Medical School National Kapodistrian University; [2]Biomedical Research Foundation Academy, Athens, Greece*

Background: Antiphospholipid syndrome is an autoimmune thrombophillia characterized by recurrent thromboembolism and or pregrancy morbidity in the presence of antiphospholipid antibodies (aPL). β2GPI which is the major autoantigen in the syndrome forms complexes with anti-B2GPI autoantibodies that activate platelets, monocytes and endothelial cells. Previous studies have shown that anti-β2GPI-β2GPI complexes activate TLR4 and TLR6 on endothelial cells leading to NFκB, MAPK activation and Tissue Factor and proinflammatory cytokine expression.[1,2]
Objectives: To evaluate the whole transcriptome of endothelial cells that have been stimulated with aPL-B2GPI complexes.
Methods: Human umbilical Vein Endothelial cells (HUVECs) were isolated from 2 APS patients and 4 Healthy control women upon delivery. Healthy donor HUVEC were stimulated with IgG isolated from APS patients with high aPL titers and healthy individuals in the presence of B2GPI. Consequently total mRNA was isolated, cDNA libraries were created and whole transcriptome sequencing (RNASeq) was performed. Gene expression data were validated in protein levels with immunohistochemistry in placenta tissues from APS patients and healthy individuals.
Results: Whole transcriptome analysis of HUVECs stimulated with aPL-β2GPI complexes and IgG from healthy individuals revealed 680 differentially expressed genes, among which 377 were upregulated and 303 downregulated in the aPL stimulated endothelial cells. Characteristic examples of the upregulated genes are IL-6, IL-8, VCAM1, SELE and TGFB2 and TGFBR1. Bioinformatics analysis revealed that the upregulated genes belong mainly to the cytokine-cytokine receptor interaction (hsa053323), MAPK signaling pathway (hsa04010), TNF signaling pathway (hsa04668) and NOD-like receptor pathway (hsa04621). Characteristic examples of the downregulated genes include the CBX4, CBX8, BCOR and HDAC7 genes. Interestingly some of the proteins encoded by these genes play role in the epigenetic modification of DNA. Immunohistochemical staining on placenta biopsies from APS patients and healthy individuals for IL-6, IL-8, IL-18, NFkB, TF, TNF-a, E-SELECTIN, MAPK8, TGFB2 and TGFBR1 showed increased intensity in the signal of endothelial cells on APS specimens validating thus the RNASeq results in the tissues.
Conclusions: RNASeq of endothelial cells treated with aPL and B2GPI reveals a thoroughly analysed proinflamatory and procoagulant phenotype. Moreover differential expression of DNA modifying proteins suggests the possible epigenetic regulation of gene expression on endothelial cells in APS syndrome. Ongoing experiments aim to analyze histone acetylation and methylation status of the promoters of the selected genes that were shown to be differentially expressed.

THU0238 P-GLYCOPROTEIN MONOCLONAL ANTIBODY IMPROVES LUPUS-LIKE SYNDROME IN MRL/LPR MICE

M. Wang, P. Zeng, G. Zhou, J. Lv, Q. Wang. *Department of Rheumatology and Immunology, Peking University Shenzhen Hospital, Shenzhen, Guangdong 518036, CHINA., Shenzhen, China*

Background: Preventing steroid resistance and maintaining disease control are significant challenges to overcome in treating SLE patients[1]. P-glycoprotein (P-gp) of membrane transporters, a product of the multiple drug resistance (MDR)-1 gene, is known to play a pivotal role in the acquisition of drug resistance to chemotherapy in autoimmune diseases[2].Inhibition of P-gp could overcome such drug resistance[3,4]. So we observed the effect of P-gp monoclonal antibody on MRL/lpr lupus mice.

Objectives: To investigate the efficacy of P-glycoprotein monoclonal antibody in the treatment of the MRL/lpr mice.

Methods: Twenty four 14- week- old MRL/lpr female mice were divided into 3groups:group 1 (G1)were treated with P-glycoprotein monoclonal through caudal vein, group 2 (G2)were treated with P-glycoprotein monoclonal three times and group 0 (G0)were treated with 0.5ml normal saline as controls. Twenty-four hours proteinuria and body weight were assessed every two weeks.Enzyme linked immunosorbent assay (ELISA)was used to measure the levels of serum anti-dsDNA antibodies. The histopathology changes of the kidneys were observed.

Results: From the 22th week,the body weight of groups Gl and G2 increased significantly than that of the group G0 ($p<0.05$). At the 22th weeks,the 24 hours proteinuria in group Gl (1.9±1.1)mg and G2 (1.4±0.9)mg was decreased than that in group G0 (3.1+1.9)mg ($p<0.05$), and at the 26th weeks,that of groups G1 (2.4±1.4)mg and G2 (1.8±1.1)mg was also significantly decreased than in group G0 (5.3±2.2)mg ($p<0.01$). At week 26,serum creatinine decreased significantly in both groups G1 (7.0±2.9)umol/L and G2 (6.1±2.5)umol/L than in group G0 (12.7±1.3)umol/L ($p<0.05$). One week after treatment, the levels of anti-dsDNA antibodies in group Gl (43±19)x10^2 U/ml and G2 (45±32)x10^2 U/ml were both significantly decreased than those of the group G0 (87±39)x10^2 U/ml ($p<0.05$),and at the 26th weeks the difference between group G2 (35±11)xl0^2 U/ml and G0 (59±35)x10^2 U/ml was statistically significant. The nephron crescent formation in group G1 (0.11±0.05)and G2 (0.09±0.01)was significandy lower that of the group G0 (0.23±0.07) ($p<0.05$), and that of group G2 was significantly less that of group Gl ($p<0.05$).

Conclusions: P-glycoprotein monoclonal antibody is very effective in treating MRL/lpr mice.It is safe and free of rejection reactions.

Table 1. Effects of P-gp monoclonal antibody on the levels of anti-dsDNA antibodies, serum creatinine and the routine blood test of MRL/lpr mice ('X±s)

Group	Number	ds-DNA ($\times10^2$U/ml)	Scr (μmol/ml)	WBC ($\times10^9$/L)	HB (g/L)	PLT ($\times10^9$/L)
G1	8	48±19	8.3±2.4*	7.8±3.6*	124±8	118±97*
G2	8	35±11#	6.1±3.5#	5.9±4.2#	138±13	132±85#
G0	8	59±35	13.2±.8	3.1±2.9	110±11	76±61

Notes: *G1 vs G0 $p<0.05$, #G2 vs G0 $p<0.05$.

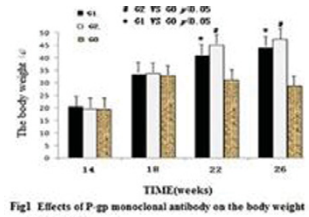

Fig1 Effects of P-gp monoclonal antibody on the body weight of MRL/lpr mice

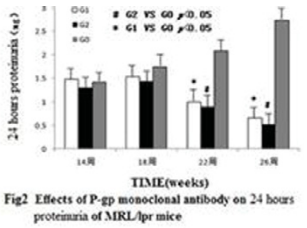

Fig2 Effects of P-gp monoclonal antibody on 24 hours proteinuria of MRL/lpr mice

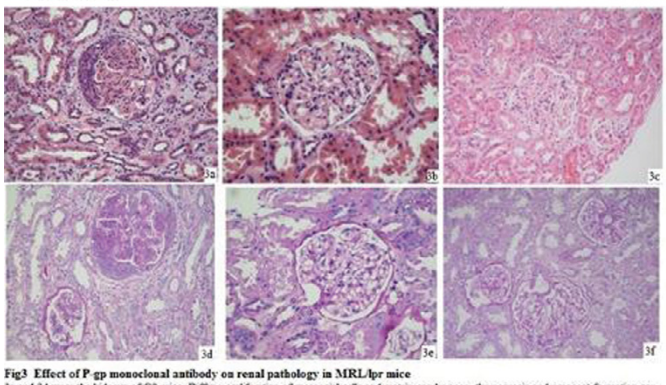

Fig3 Effect of P-gp monoclonal antibody on renal pathology in MRL/lpr mice
3a and 3d were the kidneys of G0 mice. Diffuse proliferation of mesangial cells and matrix can be seen, the necrosis and crescent formation can be seen in a few capillarie. Tubular lumen dilated and renal tubular epithelial cells shedding. Renal interstitial inflammatory cell infiltration, Arteriolar wall thickening and lumen stenosis. 3b and 3e were the kidneys of G1 mice. The mesangial cells and stroma were mildly proliferated, the basement membrane was thickened,but no crescent and no thickening of the epithelium. There was no inflammatory cell infiltration and fibrosis in the renal interstitium. 3c and 3f were the kidneys of G2 mice. There was no obvious inflammatory cell infiltration in the renal interstitium

THU0239 SERUM HMGB1 AND TLR4 LEVELS AS NOVEL BIOLOGICAL MARKERS FOR THE ACTIVITIES OF NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Q. Huang[1], C. Yuan[2], H. Ren[1], M. Yang[1]. *[1]Department of Rheumatology; [2]Department of Neurology, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) is a severe complication of SLE, including a variety of neurological and psychiatric features. Previous studies have demonstrated the close relationship between NPSLE and inflammation. HMGB1-TLR4 signaling pathway is the up-stream pathway of NF-κB, which could upregulate the expression of various cytokines and other inflammatory mediators.

Objectives: The objective of the study was to explore the potential mechanism of HMGB1-TLR4 axis in SLE.

Methods: The study population consisted of 107 SLE patients and 43 age- and sex-matched healthy controls. 73 SLE patients had active disease. 36 of these had NPSLE. The serum anti-NR2A antibodies levels were measured by ELISA. Clinical and serological parameters were assessed according to routine procedures. HMGB1 and TLR4 levels were measured by ELISA.Statistical analyses were performed by using the chi-square test and the t-test.

Results: CNS manifestations accounted for 94% (34/36 patients), while involvement of the PNS was 6% (2/36patients). The majority of the manifestations were Seizure disorders (n=17; 47.2%),Headache (n=12; 33.3%), Cognitive dysfunction (n=10; 27.8%), Psychoses (n=8; 22.2%).Within the group of active patients those with NP manifestations had higher HMGB1 levels (0.451 (0.292 to 0.583)) compared to active patients with non-NP manifestations (0.356 (0.098 to 0.436)). In patients with NP (0.429 (0.313 to 0.526)) and non-NP (0.375 (0.196 to 0.478)) manifestations during active periods of the disease, TLR4 levels significant increased in comparison to the controls. TLR4 levels were significantly higher in active patients (0.401 (0.196 to 0.526)) compared to quiescent patients. There was a significant positive correlation between levels of HMGB1 and TLR4 in the total patients group ($P<0.0001$, r=0.939).We observed a correlation between HMGB1 levels and SLEDAI ($P<0.0001$, r=0.804). Also, TLR4 levels showed a significant correlation with SLEDAI ($P<0.0001$, r=0.809). HMGB1 levels correlated with anti-dsDNA levels ($P<0.0001$, r=0.558). Similarly, TLR4 showed a correlation with anti-dsDNA levels ($P<0.0001$, r=0.522).We observed a negative correlation in the total SLE group between C3, C4 and HMGB1 levels ($P<0.0001$, r=-0.545 and $P<0.0001$, r=-0.270 respective. Also, TLR4 showed a significant negative correlation with C3 and C4 ($P<0.0001$, r=-0.559 and $P<0.0001$, r=-0.285 respectively).

Conclusions: Our data suggest that HMGB1-TLR4 axis plays an important role in the pathogenesis of SLE as well as NPSLE.

THU0240 DEFECTIVE REGULATION BY ATP-GATED IONOTROPIC P2X7 RECEPTOR DRIVES T FOLLICULAR HELPER CELL EXPANSION IN SYSTEMIC LUPUS ERYTHEMATOSUS

R. Gualtierotti[1], C.E. Faliti[2,3], M. Gerosa[1,4], F. Grassi[3,5], P.L. Meroni[1,4,6]. *[1]Lupus Clinic, Division of Rheumatology, ASST G. Pini; [2]Istituto Nazionale Genetica Molecolare "Romeo ed Enrica Invernizzi", Milan, Italy; [3]Institute for Research in Biomedicine, Università della Svizzera Italiana, Bellinzona, Switzerland; [4]DISCCO, Department of Clinical Science and Community Health; [5]Department of Medical Biotechnology and Translational Medicine (BIOMETRA), University of Milan; [6]IRCCS Istituto Auxologico Italiano, Milan, Italy*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune

disease of unknown aetiology. The deregulated activation of T follicular helper (Tfh) cells in secondary lymphoid organs may play a pivotal role in the activation of B cells and production of autoantibodies. Both murine and human Tfh cells were shown to be sensitive to extracellular ATP via purinergic P2X7 receptor. P2X7 is a non-selective ionic channel that in the presence of high concentrations of ATP or prolonged stimulation opens to a pore permeable to molecules up to 900 Da and causes cell death. Mice deleted for P2rx7 show a significantly worsened outcome of pristane-induced SLE. Expansion of circulating Tfh (cTfh) cells has been correlated with increased levels of autoantibodies and more severe clinical manifestations in SLE.

Objectives: Our aim was to investigate the possible role of P2X7 receptor activity in driving cTfh expansion in a cohort of SLE patients. Patients with primary antiphospholipid syndrome (PAPS) and healthy donors (HD) served as normal controls.

Methods: Forty-two adult patients with SLE (SLEDAI >4), 14 patients with primary antiphospholipid syndrome (PAPS) and 34 sex- and age-matched healthy donors (HD) were included. Circulating Tfh cells were isolated as a CCR7loPD1+ cells. In 32 patients with SLE, we investigated permeability of Tfh cells to Yo-Pro-1 staining over time at FACS upon stimulation with the P2X7 selective agonist BzATP and the presence of a correlation (Spearman's rho) between Tfh cells expansion and Yo-Pro uptake. We analysed *in vitro* differentiation of CXCR5+PD1+ Tfh cells and sensitivity of this pathway to BzATP in CD4 naïve cells isolated from 4 SLE and 4 healthy donors in the presence of a mixture of Activin A and IL-12, with or without BzATP.

Results: As previously reported, SLE patients had a significant expansion of the CCR7loPD-1+ cTfh cells [SLE (n=42): 38.3±12.8% versus HD (n=34]): 21.6±4.5%, ****$p<0.0001$]. There was no significant difference in the representation of cTfh cells between PAPS patients ([n=14] 22.6±6.6%) and HD (p=0.6714). The analysis of BzATP induced Yo-Pro-1 permeability revealed a significantly increased resistance to P2X7-mediated cell death in SLE patients as compared to HD and PAPS patients (fold increase of Yo-Pro-1-positive cells at 450 sec, HD [n=28]: 5±2.3%; SLE [n=32]: 3±1.7%, ****p=0.003; PAPS [n=14]: 5±2.9%, **p=0.0042). Furthermore, Spearman's rho showed a significant correlation between the percentage of cTfh cells and the degree of Yo-Pro uptake (r -0.37). *In vitro* generation of Tfh cells from HD naïve cells revealed a significant response to inhibition by BzATP, which was not present when SLE naïve cells were used.

Conclusions: The CCR7loPD-1+ cTfh cells are significantly expanded in SLE but not PAPS patients compared to HD. The degree of expansion correlates with diminished sensitivity to P2X7-mediated cell death. This defective regulation is present also within *in vitro* differentiation of Tfh from naïve cells isolated from SLE patients. Our data suggest a selective defect of P2X7-mediated control of Tfh cell generation and expansion in SLE.

THU0241 DECREASED CIRCULATING CXCR3+CCR9+ TH CELLS ARE ASSOCIATED WITH ELEVATED LEVELS OF THEIR LIGANDS CXCL10 AND CCL25 IN THE SALIVARY GLAND OF PATIENTS WITH SJÖGREN'S SYNDROME TO POTENTIALLY FACILITATE CONCERTED MIGRATION

S.L. Blokland[1,2], M.R. Hillen[1,2], S. Meller[3], B. Homey[3], G.M. Smithson[4], A.A. Kruize[1], T.R. Radstake[1,2], J.A. van Roon[1,2]. *[1]Department of Rheumatology & Clinical Immunology; [2]Laboratory for Translational Immunology, UMC Utrecht, Utrecht, Netherlands; [3]Department of Dermatology, University of Düsseldorf, Düsseldorf, Germany; [4]Takeda Pharmaceuticals International, Takeda Pharmaceuticals International, CA, United States*

Background: Primary Sjögren's syndrome (pSS) is characterized by dryness and lymphocytic infiltration in the salivary glands. Both CXCR5+ T follicular helper (Tfh) cells and CCR9+ Tfh-like cells and their specific chemotactic ligands CXCL13 and CCL25 are present at increased levels in the salivary glands of pSS patients. Recently, we and others found that CCR9+ Th cells are elevated in pSS peripheral blood and co-express CXCR3 and other chemokine receptors, known to be differentially expressed by Th cell subsets. CCR9+ Th cells play an important role in mucosal immunity and have been shown to produce high levels of IFN-γ, like CXCR3+ Th1 cells. Since ligands of CXCR3 (CXCL9/10/11) are abundantly expressed in the salivary glands of pSS patients the potential role of this receptor in conjunction with CCL25 was studied in comparison with other chemokine receptors.

Objectives: To study potential chemokine interactions causing enhanced migration of CCR9+ T cells into the salivary glands in pSS.

Methods: CXCL10, CCL25, CXCL13, CCL17 and CCL20 mRNA and protein expression in the salivary gland of pSS and non-Sjögren's sicca (nSS) patients was assessed (mRNA: n=9 vs n=9 and protein: n=26 vs n=34, respectively). Frequencies of CXCR3, CCR9, CXCR5, CCR4 and CCR6 expressing Th cells in blood of pSS patients and healthy controls were assessed by flow cytometry (n=11 vs n=11). Chemotaxis assays (n=3 HC, n=5 pSS) were performed to study migration induced by CXCL10 and CCL25.

Results: CCL25, CXCL10 and CXCL13 expression were increased in pSS compared to nSS patients, both at mRNA and protein level (all $p\leq0.02$). CCL17 and CCL20 expression were low and detectable in only few patients. Protein levels of CXCL10 and CXCL13 correlated with lymphocytic focus scores and all 3 chemokines correlated with serum IgG levels in pSS (all $p<0.05$). CCL25 protein levels strongly correlated with CXCL10 (r=0.545, p=0.004) but not with CXCL13. A relative decrease of CXCR3+ cells was found in the CCR9+ Th subset in the peripheral blood of pSS patients (p=0.04), which was most pronounced in the effector and effector memory subsets (64% vs 26%, p=0.03 and 51% vs 27% p=0.01, respectively). CCR4 or CCR6-expressing CCR9+ Th cells and CXCR3 or CCR6-expressing CXCR5+ Th cells were not decreased. To test the hypothesis that CXCR3 ligands and CCL25 facilitate migration, co-migration of lymphocytes in response to CXCL10 and CCL25 was studied. CXCL10 and CCL25 induced synergistic Th cell chemotaxis in vitro (p=0.02 and $p<0.01$ as compared to CCL25 or CXCL10 only, respectively).

Conclusions: The decreased frequency of CXCR3+CCR9+ Th cells in blood of pSS patients may be due to a concerted action of overexpressed ligands at the site of inflammation. Elevated expression of ligands CXCL10 and CCL25 in the salivary gland and the synergistic effect on chemotaxis in vitro indicate a potential role for these chemokines in formation of lymphocytic infiltrates in exocrine glands of pSS patients.

THU0242 BIOLOGICAL PATHWAY ANALYSIS IN PRIMARY SJÖGREN'S SYNDROME ASSOCIATED LYMPHOMA

S. Al-Ali[1,2], A. Skelton[3], S. Cockell[3], J. Tarn[1], K. James[4], S. Bowman[5], B. Griffiths[6], D. Young[1], U. Registry[1], W.-F. Ng[1]. *[1]Institute of Cellular Medicine, Newcastle University, Newcastle Upon Tyne, United Kingdom; [2]Department of Biology, College of Science/University of Basrah, Basrah, Iraq; [3]Bioinformatics Support Unit; [4]School of Computing Science, Newcastle University, Newcastle Upon Tyne; [5]University Hospital Birmingham, Birmingham; [6]Freeman Hospital, Newcastle Upon Tyne, United Kingdom*

Background: Lymphoma development is a serious complication of Primary Sjögren's syndrome (pSS). To date, the biological processes that may be involved in pSS-associated lymphoma are not fully understood.

Objectives: The aim of our study is to use microarray gene expression data from a well-defined cohort of pSS patients to identify biological processes that may be relevant to pSS-associated lymphoma.

Methods: pSS patients and healthy controls from the UK primary Sjögren's syndrome registry (UKPSSR) were used in this study. All patients fulfilled the AECG criteria. Whole genome gene expression data from whole blood RNA samples (n=144) stratified into five clinical subsets (pSS=61, pSS with lymphoma=16, pSS with other cancers=21, pSS with paraproteinemia=23 and healthy controls=23) were used for the pathway analysis. A list of 68 differentially expressed genes in pSS-associated lymphoma compared with pSS (non lymphoma) were uploaded into the Ingenuity Pathway Analysis (IPA) analytic tool. Similar approach was also used for comparison between the lymphoma and other pSS subject groups. Finally, we also examined the regulators and pathways involved in the genes from the gene expression signature in pSS-associated lymphoma we have previously described (*BMS1*, *NUDT14* and *MGST3*) [1].

Results: In pSS-associated lymphoma the top canonical pathway was "Aryl Hydrocarbon Receptor (AHR) signaling," which includes *MGST3*. Several other canonical pathways also included the genes of the 3-gene biosignature of pSS-associated lymphoma. The downstream effects and gene-gene interactions were explored through molecular networks analysis. Furthermore, important upstream regulators of the 3 biosignature genes include *NFE2L2*, *PPARA* and *TOCF1* were identified.

The pathway analyses of the other pSS subgroups showed 67 common canonical pathways showed among all the pSS subgroups. Focusing on pSS-associated lymphoma versus healthy controls, 94.9% of the canonical pathways in this comparison were in common with the canonical pathways identified when comparing pSS-associated lymphoma with pSS. The "Interferon Signaling pathway" was the top pathway for all pSS subgroups comparing with healthy controls. In addition, all the non-lymphoma pSS subgroups showed similar patterns in the downstream analysis which differ from the pSS-associated lymphoma group.

Conclusions: The pathway analysis revealed different possible pathways that might be involved in lymphoma development in pSS and indicates a unique gene expression signature exist in pSS-associated lymphoma. These results might provide a deeper understanding and a direction for future studies to investigate lymphoma development in pSS patients.

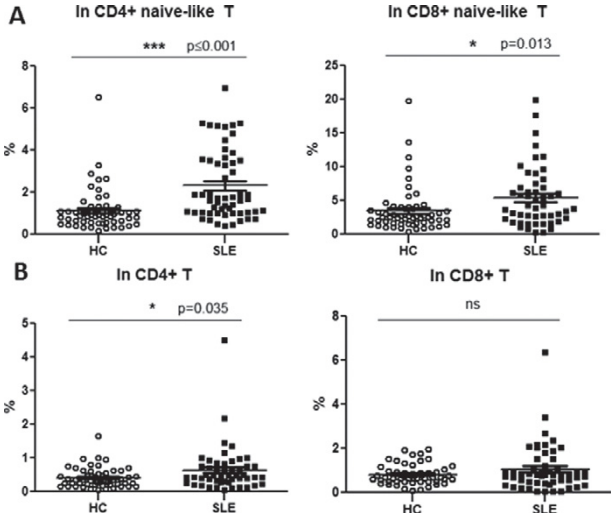
THU0243 CAN THE INCREASE OF LOBULES / FOCI RATIO BE HISTOPATHOLOGICAL EVIDENCE OF PRIMARY SJÖGREN'S SYNDROME



B. Ünal[1], V. Yazısız[2], G.Ö. Elpek[1], M. Göçer[3], M.E. Terzioğlu[2]. *[1]Pathology; [2]Rheumatology; [3]Internal Medicine, Akdeniz University, ANTALYA, Turkey*

Background: Minor salivary gland biopsy from the lip region is commonly used for primary Sjögren's syndrome (SS) diagnosis. It is accepted that changes of histopathology is the most important component of diagnostic criteria. In this study, we analyzed the relationship between histopathological changes and laboratory findings/clinical features in SS patients and control group.
Objectives: The aim of this study was to determine the histopathological changes in minor salivary tissue for SS diagnosis
Methods: A total of 69 minor salivary gland biopsies (29 Sjögren's syndrome and 40 controls) were included in the study. Biopsies were evaluated by a blind pathologist unaware of the diagnosis. Histopathological findings were noted as ductal dilatation, fat tissue percentage ($<$10% or $>$10%), acinar atrophy, ductal/ acinar ratio and lobules/foci ratio. It was evaluated whether there was a relationship between histological changes and age, gender, ANA, anti-SSA, anti-SSB, RF and Chisholm scores.
Results: The lobules/foci ratio of patients with Sjögren's syndrome was significantly higher than the control group ($p<0.001$). The cutoff value of the lobules/foci ratio for SS diagnosis was 0.8. Furthermore, there was a significant correlations between the lobules/foci ratio greater than 0.8 and antibodies (ANA, RF, anti-Ro) positivity and Chisholm score ($p<0.01$). Other histopathological findings such as ductal dilatation, fat tissue percentage, acinar atrophy, and ductal/atherine ratio do not distinguish SS from non-SS.
Conclusions: The results of this study revealed that only the lobules/foci ratio from histopathological changes has a strong relation with SS diagnosis. It can be important for pathologists to distinguish SS.

THU0244 THE ROLE OF STEM CELL-LIKE MEMORY T CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Y.J. Lee, H. Kwon, E.B. Lee. *Seoul National University, Seoul, Korea, Republic Of*

Background: The stem cell-like memory T (Tscm) cell, a special subset of memory T cell, has a potential to self-renew and differentiate into wide spectrum of T cells[1]. However, the role of Tscm in autoimmune disease such as systemic lupus erythematosus (SLE) remains to be unknown.
Objectives: To investigate the levels of Tscm cells in SLE patients compared with healthy controls and to understand the functional characteristics of the Tscm cells from SLE patients.
Methods: Fifty two SLE patients and 57 healthy controls (HCs) were enrolled. To detect Tscm cells which are designated as $CD3^+$ $CD4^+$/$CD8^+$ $CD45RO^-$ $CCR7^+$ $CD62L^+$ $CD45RA^+$ $CD27^+$ $CD28^+$ $CD127^+$ $CD122^+$ $CD95^{hi}$, flow cytometry was performed after staining peripheral blood mononuclear cells (PBMCs, $1x10^7$ cells/mL) with fluorescence-conjugated antibodies. To ascertain the differentiation ability of Tscm cells, different subsets of T cells including naïve-like T, central memory T, effector memory T and follicular helper T cells (Tfh) were evaluated after stimulating the isolated Tscm cells with anti-CD3/CD28 antibodies for 6 days. To investigate the function of the Tfh cells derived from Tscm cells, secreted IgG antibodies were measured from the supernatants by ELISA after incubating Tfh –containing differentiated Tscm cells with autologous B cells and SEB for 6 days.
Results: Among the naive-like T ($CD3^+$ $CD4^+$ $CCR7^+$ $CD45RO^-$ $CD45RA^+$ $CD62L^+$) cells, the proportion of $CD4^+$ and $CD8^+$ Tscm cells was significantly higher in SLE patients than HCs (for $CD4^+$ T cells, 2.29±0.22 (SLE) vs 1.11±0.13 (HC), p-value$\leq$0.001; for $CD8^+$ T cells, 5.36±0.63 (SLE) vs 3.41±0.44 (HC), p-value=0.013). Among the total $CD4^+$ T cells, the ratio of Tscm to $CD4^+$ T cells was higher in SLE patients than in healthy controls (0.63±0.10 (SLE) vs 0.40±0.04 (HC), p-value=0.035) (Fig 1). SLE and HC Tscm cells could differentiate into naive-like T, central memory T, effector memory T cells and renewed themselves in response to α-CD3/CD28 stimuli. In addition, in response to the same stimuli, SLE Tscm cells could differentiate into more Tfh cells than HC Tscm cells could (for $CXCR5^+$ $ICOS^+$ $PD\text{-}1^+$ cells in $CD4^+$ T cells, 9.30% (SLE) vs 5.41% (HC) and for $Bcl\text{-}6^+$ cells in $CD4^+$ T cells, 34.29% (SLE) vs 19.20% (HC)). Tscm-derived Tfh cells could help B cells produce antibodies *in vitro* (12007.81±4457.54 (SLE) vs 2082.18±517.82 (HC)).
Conclusions: Proportions of Tscm cells among T cells is increased in SLE patients compared with HCs and the Tscm cells may help maintain SLE by its ability to differentiate into Tfh cells.

THU0245 MAMMALIAN TARGET OF RAPAMYCIN PATHWAY MIGHT CONTRIBUTE THE MINOR SALIVARY GLAND CHANGES IN BOTH SJOGREN'S SYNDROME AND SYSTEMIC SCLEROSIS PATIENTS

Z.Z. Gumus[1], F. Cakalagaoglu[2], Z. Soypacaci[3], M. Ozmen[4], D. Solmaz[4], S. Gucenmez[4], O. Gercik[4], S. Akar[4]. *[1]Internal Medicine; [2]Pathology; [3]Nephrology; [4]Rheumatology, Izmir Katip Celebi University Ataturk Education and Research Hospital, Izmir, Turkey*

Background: The *Mammalian Target of Rapamycin* (mTOR), a multiprotein complex, controls cell growth, proliferation, survival and plays an important role in immunity and inflammation. *Transforming Growth Factor-β1* (TGF-β1) leads to an increase in mTOR levels by protein kinase B (PKB or Akt) pathway. *Phosphatase and tensin homolog* (PTEN) affects mTOR pathway by inhibiting Akt. Recently, increased activities of TGF-β1 and mTOR were established in a mouse model of SSc. However the role of mTOR pathway, which might be a potential treatment target, in the human salivary gland inflammation is not evaluated systematically before.
Objectives: Therefore, we aimed to examine the activity of mTOR pathway and TGF-β1 in human minor salivary gland biopsies of Sjogren's Syndrome (SjS) and systemic sclerosis (SSc) patients.
Methods: Immunohistochemical technique was used to analyze the expression of mTOR, PTEN and TGF-β1 in human minor salivary gland biopsies of SjS, SSc and SjS-SSc overlap patients. Immunohistochemical staining was evaluated by light microscopy and staining intensity was scored semi-quantitatively (Figure 1). The biopsy specimens were also examined for the degree of fibrosis.
Results: Formalin fixed sections of minor salivary gland biopsies of 58 SjS (57 female [98.3%]), 14 SSc (13 female [92.8%]) and 23 SjS-SSc overlap patients (all female) were included in the study. All biopsy specimens of SjS and overlap patients had a focus score of $\geq$1. There is no significant difference regarding mTOR expression between groups (P=0.622). mTOR expression was found in 94.4% in SjS group, 100% in overlap and 90% in SSc patients. PTEN protein was expressed in 87.2% of patients with SjS, 57.9% of overlap and 100% of SSC patients and the difference was statistically different (P=0.023). Although ductal epithelial TGF-β1 expression was similar between groups (P=0.345), acinar

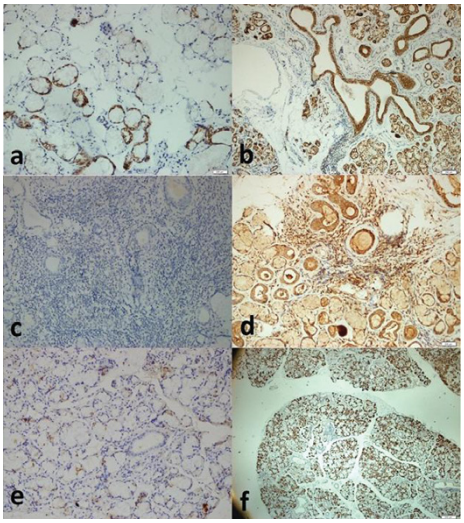

Figure 1. Minor salivary gland biopsy pictures with different stainings of mTOR [1 positive (a) and 3 positive staining (b)], PTEN [negative staining (c) and score 2 (d)] and TGF-β1 [negative staining (e) and score 3 (f)].

cell expression is more frequent in SSc (72.7%) and overlap patients (85.7%) in comparison with SjS (58.2% and *P*=0.004). Additionally, most of the acinar TGF-β1 staining was strong positive in SSC patients (45.5% vs 19.0% and 3.6%).
Conclusions: The results of our study showed that mTOR may be one of the common pathways for the pathology/inflammation observed in both SjS and SSc. Thus, there may be a room for mTOR inhibitors for the treatment of both diseases. Additionally PTEN and TGF-β1 expression, in particular acinar TGF-β1 might be a distinctive feature of SSc.

SLE, Sjögren's and APS - clinical aspects (other than treatment)

THU0246 THE IMPACT OF CLASSIFYING SLE PATIENTS WITH THE SLICC-2012 VERSUS THE ACR-1997 CLASSIFICATION CRITERIA ON EARLY DIAGNOSIS, SEVERITY, AND DAMAGE: DATA FROM THE COMMUNITY-BASED CRETAN LUPUS REGISTRY

I. Gergianaki[1,2], A. Fanouriakis[3], C. Adamichou[2], G. Spyrou[4], P. Sidiropoulos[2], D. Boumpas[1,3,5,6,7], G. Bertsias[1,2]. *[1]Laboratory of Autoimmunity and Inflammation, Institute of Molecular Biology-Biotechnology, FORTH; [2]Rheumatology, Clinical Immunology and Allergy, University of Crete School of Medicine, Iraklio; [3]4th Department of Medicine, Attikon University Hospital, National and Kapodistrian University of Athens Medical School, Athens; [4]Laboratory of Autoimmunity and Inflammation, University of Crete School of Medicine, Iraklio; [5]Laboratory of Autoimmunity and Inflammation, Biomedical Research Foundation of the Academy of Athens, Athens, Greece; [6]Medical School, University of Cyprus, Nicosia, Cyprus; [7]Joint Rheumatology Program, Attikon University Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece*

Background: Systemic Lupus Erythematosus (SLE) often poses challenges to diagnosis in clinical practice and classification in research. The 2012 SLICC criteria have been recently introduced, with validation studies suggesting greater sensitivity yet equal or lower specificity compared to the 1997 ACR criteria. However, the prognostic significance of classifying SLE patients with the $SLICC^{2012}$ versus the ACR^{1997} criteria is not known.
Objectives: To evaluate the impact of $SLICC^{2012}$ versus ACR^{1997} SLE classification in terms of clinical characteristics and outcome.
Methods: Both the $SLICC^{2012}$ and the ACR^{1997} classification criteria were applied to adult SLE patients enrolled in the community-based Cretan Lupus Registry over the period 1999–2013. Classified cases were assessed at the end of 2013 in terms of disease severity (determined by the severity of manifestations and the use of lupus treatments) and organ damage (assessed by the SLICC/ACR damage index). Cases who fulfilled both criteria during the observation period were categorized according to which set of criteria was satisfied first and then compared for the frequency of individual criteria.
Results: At the end of the observation period (year 2013), fewer SLE patients had been classified with the $SLICC^{2012}$ (n=602) as compared with the ACR^{1997} (n=750) criteria. The female-to-male ratio (12.6:1 versus 13:1) and the mean (±SD) age at the time of diagnosis (42±15 versus 43±15 years) were comparable between $SLICC^{2012}$ and ACR^{1997}-classified cases, respectively. Lupus was classified as mild, moderate and severe in 50%, 33% and 17% of the ACR^{1997}- as compared to 42%, 34% and 23% of the $SLICC^{2012}$-classified patients ($p<0.001$). Damage occurred in 30.5% of the ACR^{1997} versus 36% of the $SLICC^{2012}$ cohort (p=0.01) despite comparable disease duration. Patients who fulfilled both sets of criteria (n=512) were categorized into three groups based on which criteria were fulfilled first, i.e. group 0 (concurrently: 87% of cases), group 1 ($SLICC^{2012}$ after ACR^{1997}: 5%), and group 2 ($SLICC^{2012}$ before ACR^{1997}: 8%). We found that malar rash and neurologic disorder were significantly more prevalent in group 1 (malar rash: 54.3%, 80.8% and 48.8% in groups 0, 1 and 2, respectively, p=0.02; neurologic disorder: 3.7%, 15.4% and 0%, respectively, p=0.05). Conversely, group 1 patients had significantly lower frequency of non-scarring alopecia (51.3%, 23.1% and 68.3%, respectively, p=0.02) and synovitis (23.9%, 0% and 29.3%, respectively, p=0.012).
Conclusions: Application of the $SLICC^{2012}$ criteria may result in classification of SLE patients with more severe disease compared to those who fulfill the ACR^{1997} criteria, which may have important implications in terms of trial design; however, these data need to be validated. Lack of inclusion of malar rash in the $SLICC^{2012}$ criteria and of non-scarring alopecia in the ACR^{1997} criteria may delay the classification of SLE patients.

THU0247 THE PRESENCE OF ANTI-RO AND ANTI-LA ANTIBODIES IS ASSOCIATED WITH TUBULOINTERSTITIAL DAMAGE IN LUPUS NEPHRITIS

A. Londono Jimenez[1], W.B. Mowrey[2], A. Broder[3]. *[1]Department of Medicine, Montefiore Medical Center/Albert Einstein College of Medicine; [2]Epidemiology and Population Health, Albert Einstein College of Medicine; [3]Division of Rheumatology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, United States*

Background: Moderate-to-severe tubulointerstitial damage (TID) is associated with poor renal outcomes in lupus nephritis (LN) independent of glomerular pathology[1]. Specific antibody profiles associated with TID in LN have not been identified. Unlike glomerular damage, TID is not associated with anti-dsDNA or complement levels[1]. An association between TID and the presence of anti-Ro/La antibodies has been proposed in Sjögren's syndrome[2]. Whether these antibodies are associated with TID in LN is not known.
Objectives: To study an association between anti-Ro/La antibodies and moderate-to-severe TID in LN.
Methods: We identified all patients who fulfilled ACR and/or SLICC criteria for SLE. Patients were included if they had an index renal biopsy consistent with LN between January 2005 and July 2015 and had complete data on TID and anti-Ro/La. Medical history, demographic and laboratory data were ascertained from chart review. TID was defined as the presence of moderate or severe tubular atrophy and/or interstitial fibrosis from the renal biopsy reports.
Results: of the 157 LN patients, 39 (25%) had moderate/severe TID (Table). As expected, moderate/severe TID was associated with older age, class III/IV±V LN and lower estimated glomerular filtration rate (eGFR) at biopsy. Anti-Ro antibodies were present in 55 (47%) of patients with none/mild TID and 17 (44%) of patients with moderate/severe TID (p=0.74). Both anti-Ro and anti-La antibodies were present in 11 (9%) of patients with none/mild TID vs 11 (28%) of patients with moderate/severe TID (p=0.003). In the logistic regression model adjusted for age, eGFR and LN class, the presence of both anti-Ro and anti-La antibodies was associated with a 3-fold increase in the odds of TID, OR 3.1, 95% CI (1.1–9.1), p=0.04.

Baseline characteristics by TID (none/mild vs. moderate/severe)

	None/Mild TID (n=118)	Moderate/Severe TID (n=39)	p-value
Age, median (IQR), years	26 (17, 37)	41 (25, 53)	<0.001
Men, n (%)	21 (18)	10 (26)	0.29
Black Race, n (%)	55 (47)	22 (56)	0.29
Hispanic ethnicity, n (%)	41 (40)	12 (38)	0.79
Charlson comorbidity index, median (IQR)	3 (1, 4)	3 (1, 4)	0.09
Creatinine (mg/dL), median (IQR)	0.8 (0.6, 1.2)	1.6 (1, 2.6)	<0.001
eGFR mL/min/1.73m^2, median (IQR)	91 (61, 127)	42 (26, 75)	<0.001
Protein/Creatinine ratio (mg/mg), median (IQR)	2.2 (1.0, 4.9)	2.1 (1.5, 5.5)	0.68
LN class n (%)			0.008
I/II	10 (9)	0	
III/IV ± V	71 (61)	34 (87)	
V	35 (30)	5 (13)	
Low C3, n (%)	83 (75)	23 (70)	0.51
Low C4, n (%)	76 (70)	22 (67)	0.69
Elevated dsDNA, n (%)	70 (68)	21 (66)	0.81
Anti-Ro, n (%)	55 (47)	17 (44)	0.74
Anti-Ro and anti-La, n (%)	11 (9)	11 (28)	0.003

Conclusions: The presence of anti-Ro and anti-La antibodies is associated with moderate/severe TID, independent of age, LN class and eGFR. Understanding the role of anti-Ro/La in the mechanisms underlying TID in LN may lead to novel preventive and therapeutic strategies.

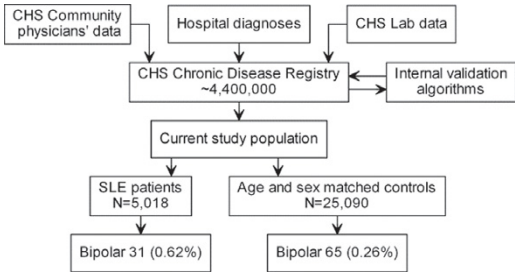
THU0248 THE ASSOCIATION BETWEEN SYSTEMIC LUPUS ERYTHEMATOSUS TO BIPOLAR DISORDER – A REAL-LIFE STUDY

S. Tiosano[1,2], O. Gendelman[1,2], D. Comaneshter[3], H. Amital[1,2], A. Cohen[3,4], D. Amital[5]. *[1]Sackler School of Medicine, Tel-Aviv University, Tel-Aviv; [2]Internal Medicine 'B', Sheba Medical Center, Ramat-Gan; [3]Chief physician's office, Clalit Health Services, Tel-Aviv; [4]Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva; [5]Ness Ziona Beer Yaacov Mental Health Center, Beer Yaacov, Israel*



Background: Systemic Lupus Erythematosus (SLE) is a chronic, autoimmune disease that has a wide variety of physical manifestations, including neuropsychiatric features. Bipolar Disorder (BD) is a chronic, phasic affective disorder that may present as depression or as mania. Neuropsychiatric symptoms in SLE develop in 20%>70% of SLE patients during the course of the disease and in half of these patients they precede the diagnosis of SLE[1–4]. In half of the patients, neuropsychiatric manifestations occur prior to the diagnosis of SLE[5].

Objectives: The objective of this study was to investigate the association between SLE and Bipolar Disorder (BD) using big data analysis methods.
Methods: Patients with SLE were compared with age- and sex-matched controls regarding the proportion of BD in a cross-sectional study. Chi-square and t-tests were used for univariate analysis and a logistic regression model was used for multivariate analysis, adjusting for confounders. The study was performed utilizing the chronic disease registry of Clalit Health Services medical database.
Results: The study included 5,018 SLE patients and 25,090 matched controls. BD was found in a higher proportion among SLE patients compared to controls (0.62% vs. 0.26%, respectively, $p<0.001$). BD patients had a greater proportion of smokers compared to non-BD patients (62.5% vs 23.5%, respectively, $p<0.001$). In a multivariate analysis, smoking and SLE were both found to be significantly associated with BD.

Multivariate logistic regression model of covariates associated with Bipolar disorder

	OR	CI	p
Age	1.01	1.00, 1.02	0.137
Gender: Female	1.63	0.96, 2.97	0.087
SES:			
Medium vs. Low	1.06	0.66, 1.69	0.816
High vs. Low	1.17	0.67, 1.98	0.575
Smoking	4.80	3.16, 7.39	<0.001
SLE	**1.74**	**1.11, 2.66**	**0.012**

SES: Socioeconomic status, SLE: Systemic lupus erythematosus.

Conclusions: SLE was found to be independently associated with BD. These findings may imply that an autoimmune process affecting the central nervous system among lupus patients facilitates the expression of concomitant BD.

THU0249 SUBCLINICAL HAND ARTHROPATHY IN PATIENTS WITH SYSTEMIC LUPUS ERITHEMATOSUS

C.A. Guillen-Astete, M. Revenga-Martinez, A. Zea-Mendoza. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

Background: As well as other systemic inflammatory diseases with joint compromise, there is an interest to identify the presence of synovitis in systemic lupus erythematosus (SLE) patients, in every follow up consultation. In SLE, the research about subclinical synovitis (that, which is clinically unnoticed but demonstrable by means of image studies) is quiet limited. The majority of studies focused on the use of ultrasound (US) assessment of patients with SLE included non selected patients so many of them counted with patients with chronic synovitis or even deformities. Due to that their results are difficult to compare and the real prevalence of subclinical synovitis is still unknown.
Objectives: To determine the prevalence of synovitis in a selected cohort of patients without clinical evidence of arthritis or synovitis.
Methods: We performed a prospective study on 96 SLE patients grouped as follows: Group 0 (20) without no historical or present joint symptoms, Group 1 (34) with intermittent joint pain and Group 2 (42) with intermittent arthritis without deformities or erosions. A systematic US study of the carpal, 2nd and 3rd MCP joint of the non dominant hand were performed to all patients. US findings were expressed according to the nomenclature EULAR recommendations for synovitis, power Doppler signal and composite synovitis index.
Results: Six patients from group 0 showed any grade of synovitis (30%), 13 from group I (38.2%) and 18 from group II (42.8%). From the whole group of subjects, those with at least a synovitis finding was 37 (38.5%).
Into the 2nd MCP joint, 4 patients (20%) from group 0 showed any grade of synovitis, one of them (5%) with power Doppler (PD) signal. The composite index of synovitis and PD signal (CSI) was 0.3 DE 0.36. In group 1, 9 patients (26.5%) showed any grade of synovitis, 4 of them also showed PD signal (11.8%). The CSI for this group was 0.44 DE 0.48. In group 2, 15 patients (14.3%) showed any grade of synovitis and 6 of them also showed PD signal (14.3%). The CSI for this group was 0.59 DE 0.55. Globally, we detected synovitis in 28/96 patients (29.2%) and PD signal in 11 (11.5%).
Into the 3rd MCP joint, 5 patients (25%) from group 0 showed any grade of synovitis, one of them (5%) also had PD signal. The CSI for this group was 0.3 DE 0.36. In group 1, 8 patients had synovitis (23.5%), 3 of them also showed PD signal (8.8%). The CSI for this group was 0.38 De 0.46. In group 2, 15 patients showed any kind of synovitis (35.7%), 4 of them with PD signal (9.5%). CSI index for this group was 0.57 DE 0.61. Globally there where 27/96 patients with synovitis (28.1%) and 8 with PD signal.
Into the carpal dorsal aspect, 5 patients of group 0 has synovitis (25%) and 3 PD signal (15%). CSI was 0.5 DE 0.54. In group 1, 12 patients had synovitis (35.3%) and 5 PD signal (14.7%) CSI was 0.58 DE 0.54 In group 2, 16 patients has synovitis (38.1%) and 8 PD signal. CSI was 0.61 DE 0.51. Globally, 33/96 has synovitis (34.4%) and 16 PD signal (16.7%).
Conclusions: As far as our knowledge goes, this is the first US prevalence study in SLE patients where all deforming and erosive arthritis have been excluded. We have demonstrated that approximately one third of patients without joint symptoms had any grade of synovitis detectable by ultrasonography. The prognosis meaning of our findings will require further prospective initiatives.

THU0250 EFFECT OF FETAL UMBILICAL ARTERY DOPPLER ON PREDICTION OF ADVERSE PREGNANCY OUTCOMES IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Z. Zhan, D. Chen, Q. Qiu, Y. Yang. *Department of Rheumatology, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Pregnancies in women with SLE resulted in an increase of adverse pregnancy outcomes (APOs). The predictive value of fetal umbilical artery Doppler examinations for APOs has been reported, while not widely be assessed in SLE pregnant women.
Objectives: To ascertain the predictive value of fetal umbilical artery Doppler for fetal APOs in SLE pregnancies.
Methods: A fetal Doppler ultrasound examination was performed on all fetuses during the third trimester (28～36 weeks of gestation) and the term pregnancy (37～42 weeks of gestation). The Doppler flow parameters of umbilical arteries were recorded, including pulsatility parameter (PI), resistance index (RI), the peak value of umbilical arteries at end-systole (Vmax, also abbreviate as S) and the peak value of umbilical arteries at end-diastole (Vmin, also abbreviate as D). The value of S/D was automatically calculated. Clinical data and pregnancy outcomes were also analyzed retrospectively.
Results: In total, 109 cases of pregnant SLE women performed fetal umbilical artery Doppler at the third trimester and 82 at the term pregnancy. Among the 109 cases, 65 resulted in one or more APOs, including 45 with premature delivery, 23 with intrauterine growth restriction (IUGR), 16 with fetal distress, 8 with neonatal lupus (NLE) and 3 with congenital malformation. Fetus with APOs had higher S/D values compared with fetus without APOs (2.9±0.9 VS. 2.4±0.5, P=0.001). In addition, other Doppler indexes did not differ significantly across groups. The area under the receiver operating characteristic curve was 0.7 (P=0.003) for S/D values, with the optimal cutoff of 2.8. At this cutoff, sensitivity (46.2%) and specificity (90.9%) had the best combination, whereas the positive and negative predictive values were 83.3% and 52.1%, respectively. Among the 82 cases with term pregnancy, 23 resulted in APOs, including 11 with IUGR, 15 with fetal distress, 4 with NLE and 1 with congenital malformation. All of the Doppler indexes (S/D, PI, RI, Vmax and Vmin) in fetus with APOs were higher than those without APOs, but no statistical significance were found between the 2 groups.
Conclusions: Umbilical artery Doppler was a good monitor method for APOs in the third trimester. S/D values were sensitive and specific predictors for APOs in pregnancies complicated by SLE. Women with more than 2.8 S/D could start strict monitoring to rapidly identify and treat obstetric complications.

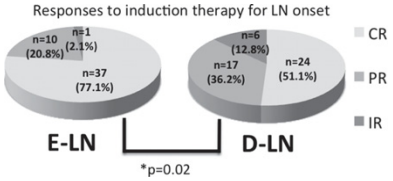
THU0251 DIFFERENT RESPONSES TO INDUCTION THERAPY IN TWO ONSET CATEGORIES OF LUPUS NEPHRITIS

M. Nakano[1], A. Mimori[2], R. Kamei[1], K. Suga[1], A. Yashima[1], S. Yamada[1], Y. Takahashi[1], H. Yamashita[1], H. Kaneko[1]. *[1]Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo; [2]Division of Nephrology and Rheumatology, Iwate Prefectural Central Hospital, Morioka, Japan*



Background: We previously reported different clinical features, serological profiles and activities in two onset categories of lupus nephritis (LN): LN that

developed as a flare of systemic lupus erythematosus (SLE) after treating the prior non-renal SLE conditions successfully (delayed, D-LN) and LN manifesting at the time of SLE onset (early, E-LN).[1)] More frequent flares and higher serum titers of anti-dsDNA antibody during the LN flares were observed in D-LN than E-LN groups, suggesting that D-LN may reflect intractable SLE conditions. However, we had not analyzed whether there is a difference in the response to treatment between the two groups.

Objectives: This study investigated possible differences in the response to induction therapy between E-LN and D-LN.

Methods: We retrospectively examined 95 LN (48 E-LN, 47 D-LN) patients who attended our hospital between January 1991 and May 2016. All of them were diagnosed with SLE according to the American College of Rheumatology criteria and were shown to have LN on renal biopsy. First, we compared the clinical features of E-LN and D-LN, such as sex, age at SLE and LN onset, urinary protein, serum creatinine, serum anti-dsDNA titer, serum C3, prevalence of serum anti-Sm, renal biopsy histological types and induction therapy options at LN onset. Then we compared the response to therapy at 24 weeks for LN onset and flares between the two groups. The response to treatment was classified into complete response [CR; urine protein to creatinine ratio $<$50 mg/mmol and normal or near-normal (within 10%)GFR], partial response [PR; $\geq$50% reduction in proteinuria to sub-nephrotic levels and (near-) normal GFR], and insufficient response [IR; anything else]. We analyzed the data using chi-square test, Fisher's exact test and the Mann–Whitney *U*-test. We further evaluated predictors of treatment response at LN onset using univariate and forward stepwise multivariate Cox regression analysis.

Results: Higher serum C3 (56.4±22.4 *vs.* 46.3±22.7 mg/dl, p=0.03) were observed in D-LN groups. The proportion of histological types (I or II/III or III+V/IV or IV+V/V: 6/7/26/9 *vs.* 4/5/26/12, p=0.77) and induction therapy options at LN onset were similar between the two groups. However, the response to the therapy for LN onset was better in E-LN than D-LN (CR/PR/IR: 37/10/1 *vs.* 24/17/6, p=0.02) (Fig). Univariate Cox regression analysis indicated that severe proteinuria, elevated serum creatinine, class IV or IV+V on renal biopsy and D-LN were associated with non-CR (PR+IR) to induction therapy for LN onset ($p<0.05$). Multivariate Cox regression analysis including variables identified as significant in univariate analyses showed that severe proteinuria [hazard ratio (HR) 1.35, p=0.007] and D-LN [HR 4.96, p=0.003] were independent predictors of non-CR to the induction therapy. LN flares were observed in 13/48 E-LN and 20/47 D-LN patients, and IR was observed in 15.4% (2/13) of E-LN and 40.0% (8/20) of D-LN patients.

Conclusions: In this study, the relatively poorer treatment response was observed in D-LN compared with E-LN patients and D-LN was a predictor of poorer treatment response independent of renal histology and the severity of nephritis at LN onset.

THU0252 NAILFOLD CAPILLAROSCOPY IN SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND CRITICAL APPRAISAL

S. Wijnant[1], F. Ingegnoli[2], K. Melsens[1], K. Thevissen[3], F. De Keyser[1,3], S. Decuman[1], E. Deschepper[4], O. Distler[5], U. Müller-Ladner[6], Y. Piette[3], V. Riccieri[7], N. Ughi[2], E. Vandecasteele[8], M. Cutolo[9], V. Smith[1,3]. *[1]Department of Internal Medicine, Ghent University, Ghent, Belgium; [2]Department of Clinical Sciences and Community Health, ASST Gaetano Pini, Division of Rheumatology, University of Milan, Milan, Italy; [3]Department of Rheumatology, Ghent University Hospital; [4]Department of Public Health, Biostatistics Unit, Ghent University, Ghent, Belgium; [5]University Hospital Zurich, Zurich, Switzerland; [6]Rheumatology and Clinical Immunology, University of Giessen/Kerckhoff-Klinik, Bad Nauheim, Germany; [7]Department of Internal Medicine and Clinical Specialities, Sapienza University, Rome, Italy; [8]Department of Cardiology, Ghent University Hospital, Ghent, Belgium; [9]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

Background: Systemic lupus erythematosus (SLE) is a rheumatic disease with common vascular involvement. Nailfold capillaroscopic changes have been described in SLE. Although, until today there is no clear role yet for capillaroscopy in classifying or staging the disease.

Objectives: To systematically review and critically appraise the literature on capillaroscopic changes described in SLE.

Methods: A sensitive search, on behalf of the EULAR study group on microcirculation in Rheumatic Diseases, was developed in Web Of Science, PubMed and Embase to identify all original research studies in which SLE patients had capillaroscopy. Two reviewers identified titles, abstracts and full texts. Exclusion criteria were: ACR criteria for SLE were not met, less than 5 patients were included in the study, there was no information on capillaroscopy in SLE, no original research or non-English language. All included articles underwent quality appraisal. Results were summarised according to density, dimensions, morphology, haemorrhages, semi quantitative assessment, qualitative assessment (see table) and correlation of capillaroscopic changes with clinical and laboratory parameters.

Results: From 172 articles captured, 36 articles were included in this review. The following capillaroscopic parameters were significantly more prevalent in SLE patients compared to healthy controls (see table): tortuous capillaries, abnormal morphology, haemorrhages, nailfold capillaroscopic score, "non-specific patterns" and "scleroderma like pattern". Hairpin shaped capillaries were significantly more prevalent in healthy controls compared to SLE patients. For clinical and laboratory parameters, Raynaud's phenomenon (RP), gangrene and 24 hours proteinuria were significantly correlated with capillaroscopic changes.

				Significant	Non-significant	Conclusion
Quantitative evaluation	Density	Mean density		4 studies	4 studies	Non-conclusive
		Avascularity		2 studies	0 studies	
	Dimensions	Diameter	Mean limb diameter	4 studies	2 studies	Non-conclusive
			Mean width	2 studies	2 studies	
			Enlarged width	4 studies	0 studies	
			Giant	1 study	0 studies	
		Length		3 studies	2 studies	Non-conclusive
	Morphology	Normal morphology		3 studies	0 studies	Significant more hairpin morphology in healthy controls compared to SLE patients and more tortuous capillaries in SLE patients compared to healthy controls
		Abnormal morphology		5 studies	0 studies	Significant more abnormal morphology in SLE patients compared to controls
	Haemorrhages			2 studies	0 studies	Significant more haemorrhages in SLE patients compared to controls
	NFC score			2 studies	0 studies	Significant higher NFC score in SLE patients compared to controls
Qualitative evaluation	Other patterns			1 study	0 studies	Significant more nonspecific and scleroderma-like pattern in SLE patients compared to controls

Conclusions: This first systematic review on capillaroscopy in SLE attests conclusive significant differences in morphology, haemorrhages, semi quantitative assessment, qualitative assessment and some clinical and laboratory parameters. Further large scale research is ongoing through the EULAR study group on microcirculation in Rheumatic Diseases to further define its role.

THU0253 TRIPLE POSITIVITY TO ANTIPHOSPHOLIPID ANTIBODIES IN PRIMARY ANTIPHOSPHOLIPID SYNDROME: INCREASED RISK OF ARTERIAL THROMBOSES AND ABORTIONS

F. Signorelli, G. Balbi, R.A. Levy. *Rheumatology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil*

Background: Triple positivity (TP) to antiphospholipid antibodies (aPL) has been associated with increased risk of thrombotic and gestational events in different populations of antiphospholipid syndrome (APS) patients. Nonetheless, the majority of the studies evolved APS secondary to systemic lupus erythematosus (SLE).

Objectives: To investigate whether TP increases the risk of criteria and non-criteria manifestations in primary APS (pAPS) patients.

Methods: A cross-sectional study was performed in a group of 74 outpatients who fulfilled APS classification criteria (Sydney; N=67) or with thrombocytopenia and persistent circulating aPL, but no criteria manifestations of APS (N=7), seen in our department. Clinical and serological features collected during medical

Table 1. Demographic and clinical characteristics

Variable	Triple positivity (N=19)	No triple positivity (N=55)	P value

examination and by chart review were correlated to the presence or not of aPL TP.
Results: Nineteen out of 74 pAPS patients had aPL TP (25.7%). Demographic and clinical characteristics are shown in Table 1. In a bivariate analysis, TP was associated with the presence of combined thrombotic and obstetric manifestations (p=0.008), three or more abortions (abortion 3+; p=0.043), and livedo (p=0.023). In a multivariate regression analysis, the model was adjusted to age, sex, race and variables with p<0.10 in the bivariate analysis (arterial thrombosis, abortion 3+, livedo, thrombocytopenia, and thrombotic+obstetric). After the analysis, arterial thrombosis (OR 5.74; CI95% 1.31–25.05; p=0.02) and abortion 3+ (OR 12.55; CI95% 1.01–156.54; p=0.049) were associated with TP.
Conclusions: In our cohort of primary APS patients, triple positivity was associated with arterial thromboses and the occurrence of 3 or more abortions, with increased risk over 5 and 12 folds, respectively.

THU0254 COMPARISON OF URBAN VERSUS RURAL ENVIRONMENT ASSOCIATED SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): RISK AND CLINICAL FEATURES

I. Gergianaki[1,2], A. Fanouriakis[3], C. Adamichou[2], G. Spyrou[4], P. Sidiropoulos[2], D. Boumpas[1,3,5,6,7], G. Bertsias[1,1,2,2]. *[1]Laboratory of Autoimmunity and Inflammation, Institute of Molecular Biology-Biotechnology, FORTH; [2]Rheumatology, Clinical Immunology and Allergy, University of Crete School of Medicine, Iraklio; [3]4th Department of Medicine, Attikon University Hospital, National and Kapodistrian University of Athens Medical School, Athens; [4]Laboratory of Autoimmunity and Inflammation, University of Crete School of Medicine, Iraklio; [5]Laboratory of Autoimmunity and Inflammation, Biomedical Research Foundation of the Academy of Athens, Athens, Greece; [6]Medical School, University of Cyprus, Nicosia, Cyprus; [7]Joint Rheumatology Program, Attikon University Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece*

Background: SLE originates from the complex interplay between genetic, epigenetic and environmental factors but the effects of the latter remain elusive. Very few studies have examined the impact of the place of residence (urban/rural) on SLE clinical profile and outcomes.
Objectives: To evaluate the effect of rural versus urban place of residency with regards to: i) SLE occurrence; ii) delay in diagnosis; iii) clinical manifestations, severity and non-reversible organ damage; iv) comorbidities and hospitalizations.
Methods: We employed data from the Lupus Epidemiology & Surveillance project in Crete (750 adult SLE patients with ≥4 ACR-1997 classification criteria). Crete is a Mediterranean island with genetically stable and homogenous population in ethnicity and sociodemographic characteristics, with no significant inequalities regarding access to healthcare facilities; 61% of the inhabitants live in rural (<10,000 people) and 47% in urban areas (>10,000 people). Demographics and residency history were retrieved from face interviews. In 200 patients with exclusively urban or rural residence, a subanalysis was performed in relation to disease risk, diagnosis age, disease severity, renal and neuropsychiatric involvement, and organ damage (SLICC damage Index [SDI]).
Results: SLE prevalence (December 2013) varied across the four geographical prefectures of Crete (Figure 1) and was significantly higher in urban ($165/10^5$) than rural ($123/10^5$) areas (p<0.001). The relative risk of SLE in urban versus rural regions was 2.0 (95% Confidence Interval 1.5–2.9). Notably, patients in urban regions had lower age of diagnosis (38.0±13.4 *vs.* 44.5±14.8 years, p=0.005) and female-to-male ratio (6.5:1 *vs.* 11:1) than those in rural regions. Delay >2 years between symptoms onset and SLE diagnosis occurred in 42% of patients from rural areas as compared to 32% of those from urban areas (p=0.01). Acute cutaneous lupus was more prevalent in the rural environment (83.9% vs. 72.6%, p=0.05) whereas the opposite trend was noted for discoid rash (2.3% vs. 16.8%, p=0.001). Nephritis occurred less frequently (10.3% *vs.* 12.4%) and neuropsychiatric disease was more prevalent (14.9% *vs.* 10.6%) in rural than urban patients albeit non-significantly. Prevalence of mild, moderate, and severe disease was 42%, 40%, and 18% in patients from rural areas, the respective figures being 55%, 28% and 18% in those from urban areas (p=0.12). Hospitalization due to active lupus did not differ between the two groups. At last follow-up, 45.3% of the patients living in urban and 51.9% of patients in rural areas had no organ damage (p=0.89). Concurrent allergic diseases were more frequent in urban patients (30.9% *vs.* 14.3%, p=0.045), particularly allergic rhinitis (8.8% *vs.* 2.3%, p=0.05).

Conclusions: SLE may be more prevalent in urban than rural regions and urbanization is associated with increased risk of SLE and earlier age of disease onset.
Our results suggest an important effect of the environment on SLE occurrence and characteristics, which warrants further investigation.

THU0255 COMPARISON OF REMISSION AND LUPUS LOW ACTIVITY STATE AS PREDICTORS OF ORGAN DAMAGE

M. Petri[1], L.S. Magder[2]. *[1]Johns Hopkins University School of Medicine; [2]University of Maryland, Baltimore, United States*

Background: Outcome measures that combine control of SLE activity and prednisone reduction are clinically relevant. A clinical goal in SLE is to reduce risk of long-term organ damage.
Objectives: We assessed whether two recently proposed disease activity outcomes were predictive of future damage.
Methods: For each month of follow-up in a large SLE cohort, we determined whether the patient was in Clinical Remission (as defined by the DORIS work group) or low lupus disease activity state (LLDAS) (as defined by Franklyn et al.). Clinical Remission was defined as a PGA<0.5, clinical SLEDAI=0 and no prednisone or immunosuppressants. Clinical Remission on Treatment allowed for prednisone≤5mg/day and immunosuppressant use. LLDAS was defined as a SLEDAI ≤4, PGA ≤1.0, no major organ activity, and no new activity. LLDAS on treatment allowed for prednisone use ≤7.5 mg/d and immunosuppressants. Damage was defined using the SLICC/ACR index.
Results: There were 81,118 person-months observed among 2,026 patients (92% female, 53% Caucasian, 39% African-American). Table 1 shows the rates of damage, per person month, in subgroups defined by Remission or LLDAS.

Table 1. Rates of new damage, in subgroups defined by past levels of disease activity

Percentage of prior months in:	Number of person-months observed	Number of months with an increase in SLICC/ACR damage	Rate of damage per 100 person-months	Rate ratios	P-values
Clinical Remission					
None	35,772	406	1.13	1.0 (Ref)	
Not none, but <25%	14,358	102	0.71	0.60 (0.48, 0.75)	<0.0001
25% to 50%	6573	50	0.76	0.66 (0.46, 0.94)	0.023
50% to 75%	3845	27	0.70	0.63 (0.42, 0.97)	0.035
75%+	1,641	10	0.61	0.58 (0.30, 1.15)	0.12
Clinical Remission on Treatment					
None	16,491	250	1.52	1.0 (Ref)	
Not none, but <25%	20,169	170	0.84	0.54 (0.44, 0.67)	<0.0001
25% to 50%	14,344	103	0.72	0.46 (0.36, 0.60)	<0.0001
50% to 75%	8396	54	0.64	0.43 (0.30, 0.60)	<0.0001
75%+	2,789	18	0.65	0.45 (0.27, 0.75)	0.0019
LLDAS					
None	30,366	343	1.13	1.0 (Ref)	
Not none, but <25%	10,880	106	0.97	0.86 (0.69, 1.07)	0.18
25% to 50%	5012	40	0.80	0.70 (0.51, 0.98)	0.037
50% to 75%	8494	60	0.71	0.63 (0.48, 0.83)	
75%+	7,527	46	0.61	0.54 (0.40, 0.73)	<0.0001
LLDAS on Treatment					
None	7,656	117	1.53	1.0 (Ref)	
Not none, but <25%	10,555	134	1.27	0.83 (0.65, 1.06)	0.14
25% to 50%	12,686	129	1.02	0.66 (0.51, 0.85)	0.0013
50% to 75%	18,151	133	0.73	0.48 (0.37, 0.61)	0.0010
75%+	13,141	82	0.62	0.40 (0.30, 0.54)	<0.0001

Damage rates were relatively low when LLDA was achieved at least 50% of the time. These rates were similar to those experienced by patients who met a more stringent treatment restriction with Remission on Treatment at least 50% of the time.
Conclusions: The equivalence of LLDAS and DORIS remission on treatment is welcome news, as LLDAS on treatment >50% of the time is an easier goal to achieve (3 times more person-months observed in our cohort) and more realistic as a clinical trial outcome.

THU0256 DEVELOPMENT AND VALIDATION OF A SCORE TO PREDICT THE RISK OF SEVERE INFECTION IN SLE

B. Tejera Segura[1], I. Rúa-Figueroa[2], J. Pego-Reigosa[3], V. del Campo Pérez[3], D. Isenberg[1], A. Rahman[1]. *[1]University College London Hospital, London, United Kingdom; [2]Hospital Universitario Dr.Negrín, Las Palmas de Gran Canaria; [3]Complejo Hospitalario Universitario de Vigo, Vigo, Spain*

Background: Infection is a major cause of morbidity and mortality in SLE patients. It would be helpful to have a tool to predict the risk that an individual patient with SLE will develop serious infection.
Objectives: To develop a predictive risk calculator algorithm (SCORE) that

assesses the probability of serious infection (i.e. leading to hospitalization) in SLE patients and to test it in an independent cohort.
Methods: The SCORE was developed using data from the RELESSER (Spanish Society of Rheumatology Lupus Registry) cohort of 3658 SLE patients. A Cox regression model for repeated events (Andersen-Gill) was applied to assess which demographic and clinical factors were independently associated with increased risk of developing serious infection (Table 1). The SCORE was then validated using retrospective data from the UCLH (University College London Hospital) cohort including 699 SLE patients. Median SCORE values were compared between sub-groups of patients using the U-Mann-Whitney test.
Results: Among 699 SLE UCLH patients, 98 (14%) developed serious infection. We compared these patients with 111 SLE controls who have never suffered serious infection. The characteristics of both groups are summarized in table 2. The infection group were more likely to have suffered previous infection (P=0.001) and/or hospitalized for SLE (P<0.001) and had renal and joint disease (P=0.005). Over a quarter of the infection group died from their infection. Median (Md) SCORE at diagnosis in SLE patients with infection was 4.27 (IQR 3.18) which was significantly higher than in the control group (Md 2.55, IQR 3.79) (z=3.341; P=0.0008). Md SCORE before infection in patients was 5.3 (IQR 3.68) which was significantly higher than SCORE at diagnosis (z=-5.733; P≤0.001) in those patients. By ROC analysis, we defined three possible cut-offs to distinguish patients with and without infection. The area under the ROC curve was 0.66 (CI 95% 0.56 to 0.71). A cut-off for SCORE at diagnosis >3.18 identified patients who would develop serious infection with sensitivity (S)76.5% and specificity (SPC) 50.5%. For SCORE >3.79, S was 64.3% and SPC 57.7%. For SCORE >4.24, S was 64.3% and SPC 60.4%.

TABLE 1 – FACTORS INCLUDED IN THE "SCORE"

Risk factor	B	P-value	HR
Age at diagnosis (>46 years old)	0.1163	0.001	1.12
Latin American ethnicity	0.427	0.001	2.40
Corticosteroids (>10 mg/day) at time of calculating SCORE	0.2878	0.001	1.33
Sex=male	0.3692	0.0001	1.49
Previous hospitalization (for SLE)	1.0049	<0.00001	2.73
Katz index	0,062	0.002	1.06
Prior infection at any time	0.8739	<0.0001	2.40

Table 2

	SLE-infection (n=98)	SLE-non infection (n=111)	P value
Gender	Females: 90 (91.8) Males: 8 (8.2%)	Females: 103 (92.8%) Males: 8 (7.2%)	ns
Mean age (diagnosis of SLE)	30.5 (27)	31 (18)	ns
Ethnicity	Caucasian 48 (49%) Latin American 3 (3.06%) African/Caribbean 28 (28.6%) Asian 7 (7.1%) Other 12 (12.2%)	Caucasian 72 (64.9%) Latin American 2 (1.8%) African/Caribbean 20 (18.02%) Asian 6 (5.4%) Other 12 (10.8%)	ns
Median length of follow-up (IQR)	9.5 (14) yrs	14 (9) yrs	**0.001**
Previous treatment	Steroids (at any time) 89 (90.8%)	Steroids (at any time) 61 (55%)	**<0.001**
	MMF 25 (25.5%)	MMF 23 (20.7%)	ns
	AZA 46 (47%)	AZA 29 (26.1%)	**<0.001**
	Cyclophosphamide 20 (20.4%)	Cyclophosphamide 13 (11.7%)	**0.01**
	Biological treatment 24 (24.5%)	Biological treatment 22 (19.8%)	ns
Patients with >1 Infection	18 (18.4%)		

Conclusions: We have developed a SCORE for predicting risk of serious infection in SLE and validated it in an independent cohort. Given the potential mortality from such infections, this SCORE could be clinically useful though the moderate sensitivity and specificity necessitate caution and further prospective studies.

THU0257 ENHANCED ACTIVATION OF NLRP3 INFLAMMASOMES IN PATIENTS WITH SJÖGREN'S SYNDROME

J.N. Kim, S.-K. Kim, J.-Y. Choe. *Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of*

Background: There has been data about pathogenic role of NLRP3 inflammasome in Sjögren's syndrome. However, linkage between their clinical features and NLRP3 inflammasome has not been clearly defined.
Objectives: The aim of this study is to identify the association of NLRP3 inflammasome with clinical features in patients with primary Sjögren's syndrome.
Methods: A total 25 female patients with Sjögren's syndrome and gender-matched 25 healthy controls were consecutively enrolled. The mRNA expression for target genes including NLRP3, ASC, caspase-1, IL-1b, and IL-18 in peripheral blood mononuclear cells (PBMCs) were measured using real-time polymerase chain reaction. Serum IL-1b and IL-18 expression were also measured by ELISA method. Clinical information and disease activity and damage for Sjogren's syndrome such as EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and Sjögren's Syndrome Disease Damage Index (SSDDI) were collected at the time of enrollment. Statistical analysis were applied including Spearman's correlation coefficient and Mann-Whitney t-test.
Results: Patients with Sjögren's syndrome was found to be highly expressed in mRNA IL-1b and its protein, compared to controls (p<0.001 and p=0.001, respectively). The mRNA levels of caspase-1 and ASC were significantly higher than those in controls (p=0.021 and p=0.008, respectively), but not mRNA level of NLRP3. The mRNA level of IL-1b is closely related with mRNA level of NLRP3 and ESR (r =0.549, p<0.001 and r =0.577, p=0.003, respectively). Serum IL-1b protein expression in Sjögren's syndrome was found to be associated with mRNA level of caspase-1. Based on SSDDI, patients with SSDDI ≥1 was older and higher IL-1b and NLRP3 mRNA expression, compared to those with SSDDI =0 (p=0.035, p=0.005, and p=0.016, respectively).
Conclusions: This study confirmed that activation of NLRP3 inflammasome might implicated the pathogenesis of Sjögren's syndrome.
Disclosure of Interest: None declared

THU0258 SERUM PARAOXONASE 3 LEVELS ARE DECREASED AND PARAOXONASE 3 ACTIVITY IS REDUCED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AS COMPARED TO HEALTHY CONTROLS

A. Dhooria[1], K. Priyanka[2], A. Sharma[1], I. Verma[2], A. Lal[3], S. Singh[1]. *[1]Internal Medicine; [2]Biochemistry; [3]Radiodiagnosis, PGIMER, Chandigarh, India*

Background: Premature atherosclerosis is a well recognised comorbidity in patients with SLE (1). Elevated levels of circulating Oxidised Low Density Lipoprotein (OxLDL) have been described in SLE patients, especially in those with a history of cardiovascular disease (2). Paraoxonase 3 (PON 3) is believed to play a role in prevention of atherosclerosis by contributing towards the anti oxidant actions of high density lipoprotein (HDL).
Objectives: To determine serum PON3 levels and PON 3 activity in patients with SLE and compare them with healthy controls.
Methods: Serum PON 3 levels and PON3 activity were determined in 100 patients of SLE with no prior history of coronary artery disease and they were compared with those of 50 healthy controls who did not have diabetes, hypertension or coronary artery disease. Serum PON3 concentration was determined by enzyme-linked immunosorbent assay (ELISA) using anti-PON3 antibody specific for human PON3. PON 3 activity was estimated using Spectrophotometric assay which quantified the hydrolysis of dihydrocoumarin at 270 nm (3).
Results: PON 3 levels were lower in SLE patients (P<0.001) and PON 3 activity was reduced (p<0.001) as compared to healthy controls. In subgroup analysis of SLE patients, PON 3 activity and levels did not correlate with disease activity. On Univariate analysis, serum creatinine (r^2=0.06, p<0.002), age (r^2=0.03, p=0.035), and SLE status (r^2=0.27, p<0.001) contributed to PON3 levels. On Univariate analysis, serum creatinine (r^2=0.15, p<0.001), AST (r^2=0.04, p=0.01), ALT (r^2=0.16, p<0.001) and SLE status (r^2=0.77, p<0.001) contributed to PON3 levels. On multivariate analysis, only SLE status predicted PON 3 levels (P<0.001) and PON 3 activity (p<0.001).

Parameter	SLE patients	Healthy controls	P value
Serum Creatinine (mg/dl)	0.55 (0.19)	0.58 (0.19)	<0.001
Aspartate aminotransferase (U/L)	22 (11)	21 (18)	0.02
Alanine aminotransferase (U/L)	12.45 (13)	26.5 (15)	<0.001
Alkaline Phosphatase (U/L)	70 (34)	63.5 (49)	0.408
Total cholesterol (mg/dl)	155 (67)	168.5 (25)	0.076
Low density lipoprotein (mg/dl)	84.5 (44)	102 (28)	0.023
High density lipoprotein (mg/dl)	41 (21)	43 (11)	0.329
Triglyceride (mg/dl)	136 (96)	129 (64)	0.359
Very low density lipoprotein (mg/dl)	27 (19)	26 (12)	0.344
Paraoxonase 3 activity*	38.43 (37.64)	69.54 (27.80)	<0.001
Paraoxonase 3 levels**	0.54 (0.32)	2.41 (1.06)	<0.001

All values are in Median (Interquartile Range). *μmol ml^{-1} min^{-1}, **μg ml^{-1}.

Conclusions: PON3 levels are reduced and PON 3 activity is decreased in patients with SLE as compared to healthy controls, the difference was attributable to the disease itself. This may contribute to premature atherosclerosis in these patients.

THU0259 RESPIRATORY SYMPTOMS IN PRIMARY SJÖGREN'S SYNDROME, A CROSS-SECTIONAL STUDY OF THE OASIS COHORT

A. Dumusc[1], B. Fisher[2], F. Barone[2], A. Richards[3], A. Poveda[3], J. Higham[3], S. Rauz[2], S. Bowman[1]. *[1]University Hospitals Birmingham NHS Foundation Trust; [2]Institute of Inflammation and Ageing, University of Birmingham; [3]Birmingham Dental Hospital, Birmingham, United Kingdom*

Background: In previous studies, 5 to 35% of patients with primary Sjögren's syndrome (pSS) are reported to have respiratory symptoms (RS). Pulmonary involvement varies from a dry cough due to airway dryness to life-threatening interstitial lung disease.
Objectives: To evaluate RS prevalence in patients with pSS and compare characteristics of pSS patients with and without RS to those in patients without pSS suffering from ocular or oral dryness.
Methods: Cross-sectional study of patients at the time of their inclusion in the OASIS cohort between 2014 and September 2016. This UK prospective research cohort includes patients with suspected pSS or known pSS and aims to collect long-term high quality data with regular clinical, dental and ophthalmological assessments. We asked systematically all the patients if they had any RS. In case of clinically significant RS, pulmonary function tests (PFTs) were requested, and if needed, a high-resolution chest tomography (HRCT) was performed. We included in the analysis only patients fulfilling the AECG (2002) criteria for pSS and excluded patients with secondary Sjögren's syndrome. Characteristics of pSS patients with and without RS and non-pSS patients with sicca symptoms were compared. For statistical analysis, we used unpaired t test, Mann-Whitney test, Fisher's exact test and Chi-square test when appropriate. $P \leq 0.05$ was considered statistically significant.
Results: Among the 157 patients included in the cohort, 70 fulfil the AECG criteria for pSS and 63 have sicca symptoms without pSS. In the pSS/sicca non-pSS groups, 25.7%/15.9% had RS (cough 10.0%/7.9% and breathlessness 15.7%/6.3%) and 5.7%/1.6% an abnormal chest clinical examination respectively. PSS patients with pre-existing lung disease (n=11) had significantly more RS than pSS patients without it (n=59): 54.5% versus 20.3% (p=0.03).
PSS patients with RS or abnormal chest clinical examination (n=21) had a higher ESSDAI index value (mean ±SD) than patients without them (n=49) (7.8±5.7 versus 5.0±4.9, p=0.04), essentially due to a higher constitutional domain score (1.7±2.1 versus 0.6±1.5, p=0.01) and a higher respiratory domain score (1.3±2.8 versus 0, $p<0.01$). They also had a higher ESSPRI index value (mean ±SD), which is a patient reported outcome: 7.4±1.7 versus 6.0±2.1 (p=0.05). There were no differences between pSS patients with and without RS in terms of demographic characteristics, objective measurements of tear and saliva production, histological focus scores and auto-immunity profiles.
In this same group of pSS patients, 10 PFTs and 9 HRCTs were requested and showed abnormal results in 60.0% and 55.6% respectively. A reduced gas transfer was the most common finding in PFTs (DLCO mM/min/kPa, % predicted value, mean ±SD: 66.7±11.7). Among these patients, 2 patients were diagnosed with interstitial lung disease. Both had abnormal PFTs and HRCT.
Conclusions: One third of pSS patients presented with respiratory symptoms or abnormal chest clinical examination at inclusion in our cohort. These patients had higher ESSDAI and ESSPRI index values but did not differ in terms of objective saliva and tear production measurements and auto-antibody profile. Reduced gas transfer was the most common abnormal finding in PFTs.

THU0260 LOW PLASMA CONCENTRATIONS OF APOLIPOPROTEIN M CORRELATE TO DISEASE ACTIVITY AND ENDOTHELIAL DYSFUNCTION IN SLE

A. Bengtsson[1], H. Tydén[1], C. Lood[1], B. Gullstrand[1], B. Dahlbäck[2], A. Jönsen[1]. *[1]Rheumatology, Institution of Clinical Sciences, Lund University, Lund; [2]Clinical Chemistry, Institution of Translational Medicine, Malmö, Sweden*

Background: ApoM is an antiatherogenic and vasculoprotective 25kDa apolipoprotein suggested to play a role in keeping endothelial barrier integrity.
Objectives: The aims of the current study were to determine the impact of SLE disease activity on apoM levels and investigate if apoM levels reflect endothelial function in SLE.
Methods: Plasma concentrations of apoM were measured with ELISA in two SLE cohorts, all patients fulfilling ≥4 American College of Rheumatology (ACR) classification criteria for SLE, and 100 healthy controls (HC). Patients in cohort I had active disease as evaluated with SLEDAI scores. In cohort II endothelial function was measured by EndoPAT 2000 and correlated to apoM levels. A low Reactive Hyperemia Index (RHI) value indicated endothelial dysfunction (ED).
Results: In cohort I, the plasma levels of apoM were found to be significantly decreased in SLE ($p<0.0001$), and the apoM concentrations correlated inversely to disease activity (SLEDAI, r= -0.29, p=0.0063. ApoM was also significantly lower in patients with active nephritis, leukopenia, anti-DNA antibodies or rash compared to patients without these manifestations.
In cohort II, using linear regression analysis, there was a positive correlation between apoM levels and the RHI value, indicating endothelial dysfunction, in the younger SLE patients: β=0.94 CI 95% 0.22,1.65 r=0.32 p=0.011.
Conclusions: SLE related inflammation may have an impact on lower plasma apoM, which may affect the endothelium and the process towards cardiovascular disease.

THU0261 PREGNANCY COURSE AND OUTCOME IN SLE PATIENTS COMPARED TO PATIENTS WITH OTHER CONNECTIVE TISSUE AND INFLAMMATORY RHEUMATIC DISEASES - DATA FROM A PROSPECTIVE COHORT STUDY

A. Strangfeld[1], C. Bungartz[1], A. Weiß[1], M. Schneider[2], J. Richter[2], A. Zink[1,3], R. Fischer-Betz[2]. *[1]German Rheumatism Research Centre, Berlin; [2]Department of Rheumatology & Hiller Research Unit, University Hospital, Düsseldorf; [3]Charité University Medicine, Berlin, Germany*

Background: Patients with systemic lupus erythematosus (SLE) are at increased risk for pregnancy complications and adverse pregnancy outcomes. During the past decades, advances in drug treatment and management during pregnancy made successful pregnancy in patients with SLE possible. Less is known about pregnancy course in other connective tissue diseases (OCTD).
Objectives: To compare pregnancy courses and outcomes in SLE patients with those in OCTD patients and patients with other inflammatory rheumatic diseases.
Methods: The German Rhekiss register is designed as nationwide, web-based longitudinal observational cohort study. Pregnant patients with confirmed diagnose of inflammatory rheumatic disease are eligible to be enrolled until the 20th week of pregnancy regardless of drug treatment. At baseline, sociodemographic parameters, prior pregnancies, comorbidities and antibody status are reported. During pregnancy, rheumatologists and patients report drug treatments, course of the maternal disease, development of fetus and complications once per trimester. After delivery, the pregnancy outcome and child development during the first two years of life are collected.
Results: Until October 2016, data of 392 patients were available and grouped according to their disease in SLE patients, those with other connective tissue disease (OCTD) and patients with all other diagnoses (allO). 121 women had already completed their pregnancy with known outcome. Of them, most patients in the OCTD group were diagnosed with undifferentiated connective tissue disease

	SLE	Other connective tissue diseases	All other diagnoses
Patient characteristics at enrolment			
Pregnancies, n	**85**	**71**	**236**
Maternal age [years]	31.8 (4.4)	32.9 (3.9)	32.4 (4.3)
Disease duration [years]	7.3 (5.9)	5.8 (6.05)	8.3 (7.6)
BMI > 30, n (%)	4 (8.7)	1 (2.6)	10 (8)
Disease activity (physician global) [0-10] in the first trimester	1.5 (1.3)	1.7 (1.5)	2.6 (2.2)
Rheumatoid factor positive, n (%)	9 (14.8)	12 (25.5)	48 (34.5)
Lupus anticoagulant positive, n	6	1	1
Anticardiolipin antibody positive, n	13	3	1
Anti-β2-GP-1 positive, n	10	3	2
Antiphospholipidsyndrome, n	10	1	1
SLEDAI	1.7 (2.3)	-	-
RAID [0-10]	1.8 (1.6)	1.9 (2.0)	2.1 (2.0)
Outcomes of pregnancies			
Completed pregnancies, n	**32**	**25**	**64**
Miscarriages, n (wk of gestation)	2 (wk 9/12), 1 elective (wk21)	2 (wk 14 & 21)	2 (wk 5 & 10)
No. of patients with flares during pregnancy			
1 – 2 flares	2	5	37
3 – 4 flares	0	0	10
5 – 6 flares	0	0	4
Life births, n: **preterm** (< 37th wk)	5 + 2x twins	2 + 1x twins	7 + 1x twins
at term (≥ 37th wk)	19 + 3x twins	20	53 + 1x twins
Mean birth weight [gramm] of singletons born at term	3123	3234	3477
Serious complications during pregnancy (n patients)	HELLP Syndrome (1) severe preeclampsia (1) serious bleedings (2) preterm labour (1) serious infection (2) thrombotic embolism (1)	HELLP Syndrome (2) preeclampsia (2) preterm rupture of membranes (1) serious infection (1)	*none*
Non-serious complications (n patients)	gestational diabetes (2) infections (1)	gest. diabetes (1) infections (1)	gest. diabetes (3) infections (4)
Congenital malformation / complication	multiple anomalies → elective termination palatine cleft (suspected Pierre-Robin-Syndrome) hämangioma at leg congenital megaureter	sacral agenesis hexadactylus (both sides)	hip dysplasia sacral hämangioma
Postpartal maternal complications	cerebral insult serious pyelonephritis hypertensive crisis	*none*	*none*
Neonatal complications (n children)	serious infections (3) lethal sepsis (1) serious icterus (1)	serious infection (3) serious respiratory distress (3) hypoglycaemia (1)	non-serious infection (1) serious respiratory distress (1)

If not otherwise indicated values are mean (SD). wk= week of gestation.

(9), Sjögren Syndrome (5) and mixed connective tissue disease (5). The allO group included rheumatoid arthritis (28), psoriatic arthritis (10), spondyloarthritis (11), and JIA (8). The proportion of children born at term was lowest in patients with SLE (79%), compared to OCTD (91%) and allO patients (88%). The table shows selected baseline and outcome parameters.

In early pregnancy, more patients with SLE reported low disease activity and a higher proportion was diagnosed by the rheumatologist as having mild disease than in the other diagnoses groups. During pregnancy, flares occurred rarely in SLE and OCTD patients, whereas a substantial proportion of patients in the allO group had multiple flares. However, serious complications during and after pregnancy occurred more often in SLE and OCTD patients, as well as congenital anomalies and complications. Due to the low number of events and completed pregnancies, associations to suspected risk factors couldn't be analyzed yet.

Conclusions: Although most patients with SLE or OCTD had a favorable course and outcome of pregnancy, compared to patients with other inflammatory rheumatic diseases substantially more complications and adverse pregnancy outcomes occurred. The association to specific risk factors predicting adverse pregnancy outcomes could not yet be analyzed. At the time of the EULAR congress we expect at least twice as much completed pregnancies.

All patients with SLE and OCTD should be tightly screened during pregnancy with timely and adequate adjustment of drug treatments.

THU0262 CHANGES IN SONOELASTOGRAPHIC CHARACTERISTICS IN SJÖGREN'S SYNDROME – A FIVE-YEAR FOLLOW UP

B. Hofauer, M. Bas, N. Mansour, A. Knopf. *Otorhinolaryngology/Head and Neck Surgery, Klinikum Rechts Der Isar, Technical Universitiy Munich, Munich, Germany*

Background: The role of sonography in the evaluation of salivary gland alterations in patients with suspected Sjögren's Syndrome (SS) and its benefit with regard to the diagnosis is part of continuing investigation. Studies on sonoelastographic alterations in the salivary glands of patients with SS have been published during the last years and were able to prove significant differences compared to patients with sicca-symptoms without fulfilling the AECG classification criteria [1, 2]. The available knowledge on longitudinal changes in sonoelastographic characteristics is still limited.

Objectives: Which variations of sonoelastographic salivary gland alterations can be observed during the five-year follow up of patients with primary Sjögren's Syndrome?

Methods: Patients with primary Sjögren's Syndrome (pSS) diagnosed according to the AECG classification criteria were included in this study. The EULAR SS Patient Reported Index (ESSPRI) was applied for the evaluation of patient's symptoms and the EULAR SS Disease Activity Index (ESSDAI) for systemic features. During 2011 and 2016 the sonoelastographic alterations of the salivary glands in patients with primary Sjögren's Syndrome were evaluated. Acoustic Radiation Force Impulse (ARFI) imaging (=shear wave velocity), Real Time Tissue Elastography (RTTE) and Virtual Touch Tissue Imaging (VTTI) were applied for the sonoelastographic evaluation in addition to B-Mode sonography (BMUS). Results of BMUS, RTTE and VTTI were graded with appropriate scoring systems.

Results: Fifty patients diagnosed with pSS were included (45 female, age: 56 years SD =16). In 2011 the mean ESSPRI score was 8.3 (SD =4.6) and the mean ESSDAI score was 5.6 (SD =7.5). Initially, the mean ARFI value of parotid glands was 2.99m/s (SD =0.93) and the mean ARFI value of the submandibular glands was 2.15m/s (SD =0.57). Clinical examination and sonoelastographic evaluation was repeated after five years in 2016, revealing a mean ESSPRI score of 6.1 (SD =3.2, p=0.002) and a mean ESSDAI score of 4.6 (SD =7.0, $p<0.001$). After five years a significant decline of ARFI values could be observed in the parotid gland (2.33m/s, SD =0.70, $p<0.001$) while no significant changes of the ARFI of the submandibular gland could be observed. Results of RTTE and VTTI did not change significantly. The mean time interval between onset of first symptoms and first sonographic examination in 2011 was 57.3 months (SD =60.8).

Conclusions: The five-year sonoelastographic follow up of salivary gland alterations in patients with pSS revealed a decline in the severity of sonoelastographic alterations of the parotid gland in ARFI imaging, indicating a certain capability for modulation of salivary gland affection in pSS.

THU0263 PREVALENCE OF REMISSION AND ITS EFFECTS ON ORGAN DAMAGE AND QUALITY OF LIFE IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C.C. Mok, L.Y. Ho, S.M. Tse, K. Chan. *Medicine, Tuen Mun Hospital, HK, Hong Kong*

Background:

Objectives: To study the effect of disease remission on organ damage and quality of life in Chinese patients with systemic lupus erythematosus (SLE).

Methods: Patients who fulfilled the ACR classification for SLE were studied. Their remission status at last visit was determined by the European consensus (DORIS definition): (1) Complete remission (clinical SLEDAI=0, serology inactive); and (2) Clinical remission (clinical SLEDAI=0, serology active). These two categories were further divided into those who required ongoing immunosuppressive treatment (prednisone $\leq$5mg/d or other immunosuppressive agents) and who did not. The increase in SLE organ damage (SDI) score since 5 years prior to recruitment was compared between patients who were and were not in remission for $\geq$5 years. Participants were randomly selected for assessment of quality of life by using both the validated version of SF36 and the LupusPRO (version 1.8) and comparison was made between those who did and did not achieve remission for $\geq$5 years by the independent Students' t-test.

Results: 769 SLE patients were studied (92% women; age 46.4±14.6 years, SLE duration 12.6±8.1 years). At last visit, clinical remission was present in 259 (33.7%) patients (median 43 months) and complete remission (clinically and serologically inactive) was present in 280 (36.4%) patients (median 51 months). Clinical/complete remission for $\geq$5years was achieved in 64 (8.3%) and 129 (16.8%) of the patients, respectively. 53 (6.9%) patients in remission $\geq$5 years were taken off all medications including HCQ (drug-free). Compared with patients who did not remit, those remitted $\geq$5 years were older (49.9±13.2 vs 45.7±15.8; p=0.004), and had significantly lower prevalence of renal involvement, leukopenia or thrombocytopenia. Significantly fewer patients who remitted for $\geq$5 years were maintained on prednisolone compared to others (31% vs 68%; $p<0.001$). The increase in SDI scores over the preceding 5 years was 0.17±0.53 in patients who had complete/clinical remission off-therapy (except HCQ) for $\geq$5 years (N=88), 0.25±0.51 in those remitted for $\geq$5 years but maintained on immunosuppressive medications (N=105), 0.41±0.84 in those remitted for $<$5 years (N=346) and 0.67±1.10 in those who did not remit (N=230), respectively. The increase in SDI was statistically higher in those remitted for $\geq$5 years than $<$5 years (p=0.007) or those who did not remit ($p<0.001$). Logistic regression showed that patients with remission for $<$5 years or who did not remit had an increase in the risk of new damage accrual as compared to those with remission for $\geq$5 years (OR 2.42 [1.50–3.89]; $p<0.001$), adjusted for age, sex, SLE duration, SDI scores 5 years prior and the daily maintenance prednisolone dose at last visit. Among 453 patients who had QOL assessment, remission for $\geq$5 years was associated with significantly higher higher physical component and mental component scores of the SF36 than those who did not remit. Patients with remission for $\geq$5 years had significantly higher scores in the individual health-related domains (except cognition) of the LupusPRO than those who did not remit.

Conclusions: Durable remission can be achieved in a quarter of patients with SLE. Patients with remission for $\geq$5 years have significantly less damage accrual and better QOL. Prolonged remission is an appropriate parameter for outcome assessment in SLE.

THU0264 RESPONSIVENESS OF LUPUSPRO V1.8 AMONG CHINESE PATIENTS WITH LUPUS

C.C. Mok[1], J. Block[2], M. Jolly[2]. [1]*Medicine, Tuen Mun Hospital, HK, Hong Kong;* [2]*Medicine and Behavorial Sciences, Rush University Medical Center, Chicago, United States*

Background: LupusPRO v1.7 is a patient reported outcome tool for patients with systemic lupus erythematosus (SLE) that has undergone psychometric validation and responsiveness studies in the US.

Objectives: To report results on responsiveness of LupusPRO among Chinese patients with SLE.

Methods: 430 patients with SLE meeting the ACR classification criteria were recruited in Hong Kong, China at a single center for this observational study. LupusPRO scores from two visits one year apart were analyzed for responsiveness and Minimal Clinically Important Difference (MCID) against patient report and physician assessed anchors of changes in health. Two patient reported anchors were used (Global change in health and item 2 of Short Form 36 form). Physician assessed anchors of change in health were disease activity (Physician global assessment-PGA, SELENA-SLEDAI) and damage (SLICC-SDI/ACR). Change in PGA of $\geq$0.3 and SELENA-SLEDAI of $\geq$4 in either direction was used to define worsening in disease activity. Our primary outcomes of interest were was summary HRQOL and HRQOL domains, as non HRQOL domains tend not to change over short time periods. Analysis of variance was used to compare changes in LupusPRO summary and domain scores against the anchors.

Results: Mean (SD) age of participants was 42 (14) years. Ninety five percent were women. Mean (SD) PGA, SELENA-SLEDAI and SDI at baseline were 0.5 (0.5), 2.9 (3.0) and 0.7 (1.2) respectively. Summary HRQOL, and HRQOL

domains (Lupus Symptoms, Physical Health, Pain-Vitality, Emotional Health and Body Image) were responsive to changes in patient reported and physician assessed health status (disease activity and damage) (Table 1). Procreation and Cognition domains showed responsive trends with patient reported change in health status, while Lupus Medications domain was responsive additionally to changes in Damage.

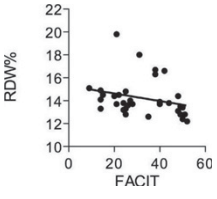
THU0265 IDENTIFYING THE LINKS BETWEEN IRON DEFICIENCY AND FATIGUE IN ADOLESCENTS AND YOUNG ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS



C. Wincup[1], Y. Ioannou[1], T. Richards[2], F. Josephs[1], L. Suffield[1], A. Rahman[1]. *[1]Department of Rheumatology; [2]Division of Surgery & Interventional Science, University College London, London, United Kingdom*

Background: Between 80–90% of patients with systemic lupus erythematosus (SLE) report fatigue to be the single most troublesome and debilitating symptom of their illness.[1] Recent studies have found that functional iron deficiency and iron deficiency anaemia have been linked with fatigue and decreased cognitive performance.[2] Increased red blood cell distribution width (RDW) is an early indicator of iron deficiency that can be useful in assessing iron stores in patients with SLE who may have an elevated serum ferritin due to underlying inflammation.

Objectives: To investigate the relationship between early iron deficiency (measured by RDW) and fatigue in adolescents and young adults with SLE.

Methods: Adolescent and young adult patients with SLE were recruited prospectively between November 2016 and January 2017. All patients were asked to complete the Functional Assessment of Chronic Fatigue Illness Therapy (FACIT) Fatigue Scale v4, in which a numerical score between 0–52 is generated. Lower scores indicate more fatigue. Standard measures of lupus disease activity including Erythrocyte Sedimentation Rate (ESR), C-Reactive Protein (CRP), Complement C3 levels, anti-double stranded DNA binding (anti-dsDNA) and SLEDAI were recorded. Haemoglobin (Hb) and RDW were also measured. Anaemia was defined by World Health Organisation criteria (male Hb $<$130g/L and female Hb $<$120g/L). Non-parametric analysis was performed using Spearman's rank with a p-value $<$0.05 felt to be significant.

Results: 33 patients aged between 16.7 and 27.5 years (median age 20) were included. 85% of the patients were female. Their FACIT scores were lower than those published for healthy individuals of the same age group - median 24, IQR 22–44 for SLE vs median 43, IQR 35–48 for healthy. There was no statistically significant correlation between FACIT Fatigue score and SLEDAI (p=0.92), anti-dsDNA (p=0.36), C3 levels (p=0.37), ESR (p=0.30) or CRP (p=0.85). Interestingly a statistically significant negative correlation between FACIT Fatigue score and RDW was observed (p=0.012; r=-0.43). A correlation between FACIT Fatigue score and Hb was noted although this was not statistically significant (p=0.079). 12 of the 33 patients were found to be anaemic (11 female, 1 male). Analysis of the sub-group of 21 non-anaemic patients found FACIT Fatigue Score and RDW continue to show a statistically significant association (p=0.026; r=-0.49).

Conclusions: Fatigue is a common and debilitating symptom described by young patients with SLE. Standard serological and clinical markers of disease activity did not correlate with the burden of fatigue. Increased RDW has been shown for the first time to correlate with increased fatigue in patients with lupus, suggesting that iron deficiency may play a significant role in the manifestation of this troublesome symptom. A trial of therapeutic iron infusions in the treatment of fatigue in SLE is planned.

THU0266 DAMAGE INDEXES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SECONDARY ANTIPHOSPHOLIPID SYNDROME: DIAPS VS SLICC/ACR DAMAGE INDEX

D. Potarniche[1], D. Mazilu[2], I. Saulescu[2], A. Borangiu[2], L. Groseanu[2], C. Constantinescu[2], V. Vlad[1], F. Berghea[2], V. Bojinca[2], D. Opris-Belinski[2], A. Balanescu[2], D. Predeteanu[2], R. Ionescu[2]. *[1]"Sfanta Maria" Clinical Hospital; [2]"Sfanta Maria" Clinical Hospital, "Carol Davila" University of Medicine, Bucharest, Romania, Bucharest, Romania*

Background: Systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are systemic autoimmune diseases that have overlaping irreversible organ damages. Since SLICC/ACR Damage Index (SDI) misses key features of APS, the Damage Index in patients with Thrombotic Antiphospholipid Syndrome (DIAPS) was proposed.

Objectives: To assess the differences in indexes available for measuring organ damage in a cohort of patients with SLE and secondary APS.

Methods: Clinical records of patients with SLE and secondary APS were reviewed. Data on medical history and clinical manifestations were collected. The two damage indexes, SDI and DIAPS, were applied. Comparison between the two indexes was done for each organ system affected.

Results: Sixty five clinical charts were reviewed, 5 had been excluded for incomplete information. SDI and DIAPS was recorded in 60 patients. Patient's mean age was 45.05±14.61 years, with mean disease duration of 9.47±6.96 years. Mean SDI in our cohort was 4,15±2.58 and mean DIAPS – 4.08±3.41. SDI correlated significant to DIAPS (R=0.826, p$<$0.000). Neuropsyhiatric manifestations were found in 25 patients (41.7%). Their mean SDI value was 4.92±2.73 and DIAPS value of 5.52±3.47. DIAPS value was higher in the subgroup of patients with neuropsyhiatric (p=0.006) and respiratory system damage (p=0.037). This difference was not observed regarding SDI value. DIAPS value correlated significantly to neurological (R=0.397, p=0.002) and pulmonary damage (R=0.364, p=0.004), but not to SDI value. No diferrences were observed between the two scores regarding perypheral vascular manifestation (DIAPS p=0.221, SDI p=0.136) and renal involvement (DIAPS p=0.062, SDI p=0.078).

Conclusions: SDI may underestimate APS related damage in patients with SLE and secondary regarding neurological and pulmonary organ involvement. Given the implications for high morbidity and mortality, DIAPS may be the appropriate damage score to be used.

THU0267 METABOLIC SYNDROME AND HEALTH-RELATED QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS

D.P.E. Margiotta, F. Basta, M. Vadacca, G. Dolcini, F. Pignataro, A. Vernuccio, C. Mazzuca, L. Navarini, A. Afeltra. *Unit of Allergology, Immunology and Rheumatology, Università Campus Bio-Medico di Roma, Rome, Italy, Rome, Italy*

Background: Systemic Lupus Erythematosus (SLE) is associated to a huge prevalence and incidence of cardiovascular diseases (CVDs) due to accelerated atherosclerosis. Several evidences demonstrated that metabolic syndrome (MeS) could contribute to CVDs burden in SLE. In general population, MeS components and, according to some reports, MeS itself are associated to worsened Health related Quality of Life (HR-QoL). In SLE patients, a severe decline of HR-QoL has been widely demonstrated.

Objectives: In the study, we evaluated the association between MeS, HR-QoL and QoL-related factors, such as depression, fatigue and physical activity.
Methods: We conducted a cross-sectional study with retrospective evaluation of disease activity, damage and therapies cumulative dosage. MeS was defined according to International Federation of Diabetes (IFD) criteria. All patients were evaluated to explore MeS IFD criteria and other CVD risk factors (familiar history, lifestyle, smoking). SLE disease activity and damage were evaluated using SELENA-SLEDAI and SDI indices, respectively. Disease flares were retrospectively assessed by SFI index. HR-QoL was quantified by SF-36 instrument. We used Beck Depression Inventory (BDI) to assess depression and Facit-Fatigue to evaluate fatigue. Physical activity was quantified using International Physical Activity Questionnaire (IPAQ) and expressed according to categorical IPAQ total score. Patients also completed Pittsburgh Sleep Quality Index (PSQI) exploring sleep pathology.
Results: We enrolled 55 SLE patients (2 male and 53 female). Mean age was 45±12.5. MeS prevalence was 23.6% and obesity (according to IFD definition) was recorded in 36.4% of patients. SLE patients with MeS presented reduced scores in SF-36 summary components MCS and PCS compared to patients without MeS (p 0.002 and p 0.04, respectively). The SF-36 individual components significantly decreased in MeS were the Mental Health, the Physical Rose and the Social Role (p 0.003, p 0.03, p 0.05, respectively). In multiple linear regression the values of MCS was significantly associated only to obesity (p 0.01), while neither MeS it self nor any MeS components were associated to PCS values. BDI score was significantly higher and Facit-Fatigue score was reduced in SLE patients meeting MeS criteria compared to subjects without MeS ($p<0.0001$, p 0.005, respectively). A greater proportion of SLE patients with MeS presented almost mild depression (p 0.03). We found to be physically inactive, according to IPAQ score, the majority of SLE patients with MeS compared to patients without MeS ($p<0.0001$). In multiple logistic regression, factors related to MeS were the Number of flares in the previous one year [OR (95% CI) 13.7 (1.7–107.8)], to have a BDI>13 (to have almost mild depression) [OR 0.05 (0.004–0.87)] and to be physically inactive (IPAQ=1) [OR 33.5 (2.3–496.4)].
Conclusions: HR-QoL seems to be compromised in SLE patients with MeS, especially in mental components. Moreover, SLE patients with MeS often presented depression, are burdened by more severe fatigue and frequently are physically inactive. The presence of MeS in SLE was associated to the number of flare and, above all, to the physical inactivity, while not having depression seems exert a protective effect on MeS.

Sapienza University, Roma; [11]Rheumatology Clinic. University of Udine, Udine, Italy*

Background: Celiac disease (CD) is an inflammatory and immune-mediated gluten-dependent enteropathy occurring in genetically susceptible individuals. CD is recognized to affect between 0.6% and 1% of worldwide population, with wide regional differences. Disease clinical features are protean and highlight the systemic nature of the disease. In recent years, an increased prevalence of CD has been also reported in patients with connective tissue diseases (CTDs). This association may be due to a shared genetic predisposition, to immunological mechanisms and/or exposure to a common triggering event. However, this observation remains controversial since data are usually based on descriptive case reports. Different methods of antibody detection and enrolled population sample size may contribute to result discordance. Moreover, CD diagnosis is often delayed because disease clinical spectrum may be atypical mimicking rheumatologic conditions and autoimmune disease itself may display typical symptoms of CD. Undoubtedly, awareness of CD occurrence in CTDs is important to prevent potential long-term systemic complications related to an unrecognized CD in these patients.
Objectives: To evaluate the prevalence of overt and subclinical CD and features of the disease in a large cohort of patients with systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and primary Sjögren's syndrome (pSS) with a multicenter prospective study involving 9 Italian Rheumatology Units.
Methods: Data from consecutive 580 SLE, 354 pSS and 524 SSc patients were collected. Disease-specific features were registered in patients with known CD. Remaining patients were tested for IgA transglutaminase (Eu-tTG® human IgA new, Eurospital S.p.A., Trieste). Anti-endomysium (EMA) IgA and IgG were tested in IgA tTG positive and borderline patients. Esophagogastroduodenoscopy with duodenal biopsy was proposed in IgA tTG+/EMA+, IgA tTG-/EMA+ and IgA tTG±/EMA+ patients.
Results: CD prevalence was 1,7% in SLE, 7% in pSS and 1,3% in SSc patients. Higher frequency of elevated liver enzymes was detected in SLE-CD and of herpetiform dermatitis in SSc-CD patients in comparison to the other groups ($p<0.05$ for both). Interestingly, pSS-CD and SSc-CD patients were younger and had a lower age at diagnosis in comparison to pSS and SSc without CD ($p<0.05$ for all). Of interest, higher prevalence of CD was detected in SSc patients with diffuse form in comparison to limited SSc (86% vs 14%, p=0.002).
Conclusions: The results of the present large multicenter study confirm higher prevalence of CD in CTD patients, especially in pSS. Screening of CD may be considered in younger patients with CTD and lower age at diagnosis. The strong association of CD with the diffuse type of SSc is of note and suggests that different, still unexplored, pathogenic mechanisms may characterize the two subsets of the disease.

THU0269 ELECTROCARDIOGRAPHIC NONSPECIFIC ST-T ABNORMALITIES ARE ASSOCIATED WITH HIGHER MODIFIED FRAMINGHAM RISK SCORE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITHOUT CLINICAL CARDIOVASCULAR DISEASE

E. George, T. Perez-Recio, L. Geraldino-Pardilla. *Department of Rheumatology, Columbia University College of Physicians & Surgeons, New York, United States*

Background: Cardiovascular disease (CVD) is a leading cause of mortality in systemic lupus erythematosus (SLE). Traditional CVD risk scores underperform in SLE. Interestingly, a high prevalence of nonspecific ST-T changes (NST-T) has been recently reported in lupus patients[1,2]. These electrocardiographic findings are known to increase the risk for myocardial infarction, coronary artery disease, CVD, and all-cause mortality[3] in the general population, but in SLE this association remains unknown. Therefore, we sought to define the association of NST-T with the modified Framingham Risk Score (mFRS) as a surrogate outcome for CVD[4].
Objectives: To evaluate if NST-T are associated with higher mFRS in SLE patients without clinical cardiovascular disease.
Methods: Adult SLE patients without clinical CVD continuously seen at the Columbia University Lupus Center between April 2016 and January 2017, meeting 1997 American College of Rheumatology classification criteria for SLE were studied. Twelve-lead electrocardiogram (EKG), high sensitivity C-reactive Protein (hsCRP), demographics, disease-specific characteristics, medication use, and CVD risk factors were ascertained. Univariable and multivariable linear regression models were constructed to test the association of NST-T with the mFRS.
Results: Seventy-four lupus patients were studied (baseline characteristics in table 1). In univariable analysis, patients with NST-T had a significantly higher mFRS (0.44, p=0.018). There were no confounders identified in the analysis. However after adjusting for variables associated with the mFRS: smoking, diabetes, hsCRP, Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index [SDI], aspirin use, this association remained statistically significant (0.38, p=0.05). Image 1 shows the association of mFRS with NST-T vs no NST-T.

Age, years ± SD	39±13
Female, n (%)	67 (90%)
Hispanic, n (%)	56 (77%)
African American, n (%)	14 (19%)
Body mass index	30±8.3
Median Disease Duration, years (IQR)	6.5 (4–12)
Median SLEDAI (IQR)	4 (2–8)
Moderate-Severe Disease activity (SLEDAI ≥6), n (%)	23 (31%)
Median SDI, n (%)	0 (0–1)
hsCRP median (IQR)	2.4 (1–6.5)
ESR , Median (IQR)	37 (23–51)
Anti-DNA, n (%)	44 (60%)
Anti-SSA, n (%)	42 (59%)
Anti-Smith, n (%)	21 (30%)
Ever smoker, n (%)	16 (22%)
Hypertension, n (%)	22 (30%)
Diabetes, n (%)	6 (8%)
mFRS, median (IQR)	0.5 (0–1.8)
NST-T abnormalities, n (%)	27 (38%)

Conclusions: Non Specific ST-T changes are independently associated with a higher mFRS in SLE patients without clinical CVD.

THU0270 HOMOCYSTEINE, ANTIPHOSPHOLIPID ANTIBODIES AND RISK OF VASCULAR EVENTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Stojan, W. Fu, M. Petri. *Rheumatology, Johns Hopkins University, Baltimore, United States*

Background: SLE patients have higher plasma total homocysteine concentrations compared to healthy controls. Hyperhomocysteinemia in SLE is a potentially modifiable, independent risk factor for stroke and thrombotic events, hypertension, and coronary artery calcification.
Objectives: We investigated the association of homocysteine levels with the presence of antiphospholipid antibodies as well as the potentially additive thrombotic risk in patients with antiphospholipid antibodies who have hyperhomocysteinemia.
Methods: To analyze the association between hyperhomocysteinemia and the presence of antiphospholipid antibodies in SLE, 844 patients with homocysteine measurements were included in the analysis. 237 patients had at least one measurement over 15 umol/L. Patients were followed quarterly after cohort entry. The association of hyperhomocysteinemia with antiphospholipid antibodies is detailed in Table 1.

Table 1. Homocysteine and antiphospholipid antibody positivity

	Homocysteine (umol/L)		Odd ratios (95% CI)	P value	Adj. Odd ratios (95% CI)	Adj. P value
	≥15 (%)	<15 (%)				
Anti-cardiolipin	43.24	57.62	0.56 (0.37,0.84)	0.0049	0.54 (0.36,0.81)	0.0033
Anti-B2 Glycoprotein	16.98	29.69	0.48 (0.28,0.82)	0.0076	0.46 (0.27,0.8)	0.0054
Lupus anticoagulant	19.82	29.29	0.6 (0.36,0.98)	0.0404	0.54 (0.33,0.91)	0.0190

To analyze the prevalence of vascular events among SLE patients with antiphospholipid antibodies based on homocysteine levels, 571 patients with positive antiphospholipid antibodies and at least one homocysteine measurement were included in the analysis. There were 166 patients with at least one homocysteine measurement over 15 umol/L.
The lupus anticoagulant was assessed by dRVVT with mixing studies and confirmatory tests. Anticardiolipin and anti-beta2 glycoprotein 1 were measured by ELISA (INOVA). Vascular events were defined as stroke, myocardial infarction, digital gangrene, and deep vein thrombosis.
Results:

Table 2. Prevalence of vascular events among SLE patients with antiphospholipid antibodies based on homocysteine levels

	Abnormal Homocysteine >15 umol/L N (%)	Normal Homocysteine N (%)	P value
Superficial Thrombosis	4 (2.41)	12 (2.96)	0.7176
Deep vein thrombosis	37 (22.29)	58 (14.36)	0.0257
Stroke	17 (10.24)	30 (7.41)	0.3139
Myocardial infarction	13 (7.83)	11 (2.72)	0.0099
Digital Gangrene	4 (2.41)	8 (1.98)	0.7523

Conclusions: SLE patients with elevated homocysteine were less likely ($p<0.05$) to have any of the antiphospholipid antibodies. Among patients with SLE who have antiphospholipid antibodies, elevated homocysteine is associated with a significantly higher prevalence of myocardial infarction and deep vein thrombosis ($p<0.05$).

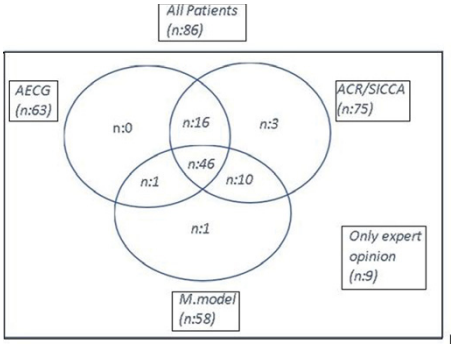
THU0271 THE PERFORMANCE OF DIFFERENT CLASSIFICATION CRITERIA IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME AND ANALYSIS OF THEIR CONTRIBUTION FOR DEFINITIVE DIAGNOSIS, WHEN EITHER CRITERIA USED ALONE OR IN COMBINATION

Z. Kosuva Ozturk[1], G. Kenar[2], H. Yarkan Tugsal[2], B. Zengin[2], G. Can[2], F. Onen[2], M. Birlik[2]. [1]*Internal Medicine;* [2]*Rheumatology, Dokuz Eylul University School of Medicine, Izmir, Turkey*



Background: Many classification criteria sets have been proposed for primary Sjögren's Syndrome (pSS),consisting of variable features of the disease.Despite increasing number of criteria sets, expert opinion is still keeping its importance for the diagnosis of pSS.
Objectives: We aimed to compare the performance of 3 classification criteria sets for pSS, to determine the agreement between each other and expert opinion and to investigate diagnostic contribution with any combined use of these criteria.For those assessments, American-European Consensus Criteria (AECG), American Collage of Rheum (ACR)/Sjögren Int. Clinical Alliance (SICCA) criteria and *L.S. Martin et al.* criteria named Mathematical model (M.model) had chosen.The M.model is a criteria set known to be noninvasive and proposed as highly specific.
Methods: 86 patients (F: 96%, mean age: 51.7±11.8) following up in our clinic with the diagnosis of pSS were enrolled to the study.Expert opinion had been taken as gold standard for pSS diagnosis. Patients were questioned for eye/mouth dryness. Antinuclear antibody (ANA), complement (C3, C4), anti-Ro and anti-La, serum protein electrophoresis, rheumatoid factor (RF), break-up time (BUT) and Schirmer, minor salivary gland biopsy results were analysed cautiously. The aforementioned criteria sets, were implemented to assess the classification. The percentage of exact agreement and Kappa test was calculated.
Results: Number of patients classified as pSS according to ACR/SICCA, AECG and M.model criteria were 75 (87%), 63 (73%) and 58 (67%) respectively. 9 patients (10%) did not fulfill any of these 3 criteria but they were diagnosed as pSS according to expert opinion (Image 1). The Kappa test was moderate between the ACR/SICCA and AECG criteria and slightly low between the M.model with the AECG and ACR/SICCA criteria (Table 1). According to our proposed combination model, number of patients classified as pSS, either AECG or M.model was 74(86%); either AECG or ACR/SICCA model was 76(88%); either ACR/SICCA or M.model was 77 (89.5%) (Table 2). In the triple combination of our model, if all 3 criteria used concomitantly, only 46 (51%) of patients fulfill the criteria simultaneously; however if any of 3 criteria sets used 77 (89.5%) patients fulfill as pSS.

Table 1

	AECG	ACR/SICCA	M.MODEL
AECG		%83 K: 0.50	%68 K: 0.25
ACR/SICCA	%83 K: 0.50		%75 K: 0.34
M.MODEL	%68 K: 0.25	%75 K: 0.34	

Table 2

	Classsification criteria	(n)	(%)
According to 1 criteria	ACR/SICCA	75	87,2
	AECG	63	73,2
	M. model	58	67,4
According to either of 2 criteria	ACR/SICCA or M.model	77	89,5
	AECG or ACR/SICCA	76	88,3
	AECG or M. model	74	86
According to either of 3 criteria	AECG or ACR/SICCA or M.model	77	89,5
According to concomitant use of 3 criteria	AECG + ACR/SICCA + M.model	46	51.6

Conclusions: In this study, ACR/SICCA classification criteria for pSS was found the most compatible criteria set with expert opinion, when it used alone. The combination of either ACR/SICCA or M.model was found to be the most sensitive binary combination for classification with similar results as triple combination.This study showed that a small group of patients could not be classified as pSS even if the criteria sets were used with concomitant combinations. It was determined that experienced specialists were largely need to recognize and distinguish these patients.

THU0272 VISFATIN IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: AN IMMUNE METABOLIC INTERPLAY

H.E.S. Mansour[1], H.M. Farouk[1], M.A. Abdulrahman[1], N.O. El-Azizi[1], N.M. Lotfy[2], A.S.M. Farouk[1]. *[1]Internal Medicine & Rheumatology; [2]Clinical patholgy & Immunology, Facilty of Medicine- Ain Shams University, Cairo, Egypt*

Background: Visfatin is a proinflammatory cytokine (adipocytokine) that is secreted in excess from adipose tissue in obese individuals, and it has numerous metabolic and autoimmune implications: it stimulates the secretion of IL-6, IL-8, IL-10, IL-18 and TNF-α. In SLE patients these may influence disease activity and delays remission (1).
Objectives: To assess the possible effects of obesity & serum visfatin levels on SLE patients and its clinical relevance on disease process, activity and occurrence of insulin resistance.
Methods: This study was performed on 60 SLE patients satisfying the 1997 American College of Rheumatology revised criteria (ACR) and 60 apparently normal individuals with matched age and sex as control groups. All subjects were classified according to BMI into 4 groups (non-obese and obese SLE patients, non-obese and obese control persons). All patients were subjected to full history & clinical examination, assessment of SLE disease activity was done using BILAG-2004 index, laboratory investigations were done (CBC, ESR, fasting blood glucose, renal and liver function tests, lipids profile, fasting plasma insulin, calculation of insulin resistance by HOMA score, measurement of serum visfatin level by ELISA kit) and diagnosis of metabolic syndrome according to WHO definition.
Results: There were statistically significant higher grades of cardiorespiratory manifestations of BILAG score in obese compared to non-obese SLE patients. 40% of obese lupus patients were hypertensive, while only 16.6% of non-obese SLE patients A statistically significant higher prevalence of metabolic syndrome in obese compared to non-obese SLE patients. There were statistically significant higher levels of total serum cholesterol; serum triglyceride, fasting blood sugar, fasting insulin, insulin resistance and serum visfatin; but lower level of HDL in obese SLE patients compared to non- obese SLE. The same observations were recorded on comparing non-obese SLE patients to non-obese controls & obese SLE to obese controls. A statistically significant higher level of insulin resistance and prevalence of metabolic syndrome were found among obese SLE patients when compared to obese controls and non-obese SLE patients compared to non-obese controls. Regarding serum visfatin levels obese SLE patients have significantly higher serum visfatin levels than non-obese SLE patients than obese controls than non-obese controls.In all SLE patients there were statistically significant positive correlations between serum visfatin levels and each of: BMI, waist circumference, haematological manifestations, total BILAG score of disease activity, serum triglycerides, liver functions (ALT, AST, alkaline phosphatase and total serum proteins). While a significant negative with HDL level.
Conclusions: Obesity (BMI) is an independent risk factor in SLE patients that increases the SLE disease activity and complications. Visfatin is an adipocytokine its level significantly increased in obese SLE patients & it is positively correlated with disease activity.

THU0273 PREVALENCE AND FACTORS ASSOCIATED WITH FATIGUE IN FEMALE SLE PATIENTS AT THE HOSPITAL DEL MAR / PARC DE SALUT MAR

I. Carrión-Barberà, T. Salman-Monte, S. Castell, F. Castro, P. Corzo, F. Ojeda, L. Polino, E. Beltrán, C. Pérez, J. Carbonell. *Rheumatology, Hospital del Mar, Barcelona, Spain*

Background: In patients with SLE, subjective parameters are very important as they have a great impact on the quality of life. Among them, fatigue is the most prevalent symptom in SLE, as it occurs in more than 90% of patients (1). Likewise, approximately 50% of patients consider fatigue the most disabling symptom of the disease (2). Despite its high prevalence and impact on quality of life, fatigue has not been extensively studied in patients with SLE.
Objectives: To determine the prevalence of fatigue in our cohort as well as the factors with which it is associated, its relationship with demographic variables, vitamin D levels, treatments, SLE symptoms and disease activity.
Methods: A cross-sectional study was carried out including female patients with SLE (ACR 1997 criteria) who regularly attended the Parc de Salut Mar-IMAS in Barcelona between January 2012 and May 2014. We collected sociodemographic data, vitamin D supplementation, the VAS fatigue, pharmacological treatment, main serological markers of SLE, and plasma levels of 25-hydroxy vitamin D. The association between fatigue and the different variables was evaluated by the Spearman's rho correlation coefficient for the continuous and the Mann-Whitney U test for the categorical variables.
Results: One hundred and two consecutive female patients were included. The fatigue variable was evaluated through a fatigue VAS with a mean score of 52.84 (range 0–100), a median of 59.00 and a standard deviation of 29.86. A statistically significant relationship was found between fatigue and age, MHAQ, SLICC and photosensitivity in the entirety of the 102 patients. As for the relationship between fatigue and vitamin D insufficiency (25-OH vit. D≤30 levels), the sample was divided into patients receiving vitamin D supplementation (N=60) and without supplementation (N=40), finding a significant relationship between fatigue and vitamin D insufficiency in the group without supplementation.

Table 1. Correlation between fatigue and the different SLE variables studied

Age**	Correlation coefficient	0.289
	p-value	0.003
	N	102
MHAQ**	Correlation coefficient	0.484
	p-value	0.000
	N	102
SLICC**	Correlation coefficient	0.256
	p-value	0.009
	N	102
25-0H-VitD**	Correlation coefficient)	-0.356
	p-value	0.024
	N (not supplemented)	40
Photosensitivity*	55.32 [30–80]	p-value = 0.043
	N	102

Significant value $p<0.05$. Med [P25–P75]. *Mann-Whitney U test; **Spearman's rho test.

Conclusions: Fatigue is highly prevalent among female patients with SLE. A statistically significant association was found between the presence of fatigue, on the one hand, and age, MHAQ, SLICC, photosensitivity, and vitamin D insufficiency in the group of patients without supplementation on the other. It is necessary to carry out further studies with a larger sample and with validated fatigue measurement scales to confirm our findings.

THU0274 FOOTPRINTS OF NEUTROPHIL EXTRACELLULAR TRAPS ARE ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Jeremic[1], O. Djuric[2], B. Bonaci Nikolic[3]. *[1]Institute of Rheumatology, Belgrade; [2]Insttute of Epdemiology; [3]Institute of Allergy and Clinical Immunology, Belgrade, Serbia*

Background: Impaired removal of apoptotic waste in patients with systemic lupus erythematosus-SLE has been long known as important factor that trigger autoimmune response. Neutrophil extracellular traps could be another source of autoantigens in patients with SLE.
Objectives: The aim of this study was to compare NETs markers (free DNA, myeloperoxidase) and dnase I in SEL patients and healthy controls, as well to assess their relationship with serological markers of SLE disease activity (C3 and C4 complement components, anti-dsDNA antibodies) and SLEDAI score (clinical disease activity index).
Methods: We analysed 111 sera obtained from 84 SEL patients (60 patients had 1 sample and 24 patients had 2 or 3 samples) and 50 healthy blood donors. Serum levels of myeloperoxidase, B-cell activating factor-BAFF, cell free DNA, complement components C3 and C3, antibody to dsDNA by CLIFT end ELISA assays, netolitic activity and DNAse I were measured. The group of 35 patients was selected (11 with *de novo* disease) for which clinical data were recorded.
Results: SLE patients had significantly higher concentration of free serum DNA (1.69±0.23 vs. 1.42±031 ng/mL, p=0.0003), dnase I (10.4±6.9 vs. 5.8±5.7 U/mL, $p<0.05$), anti-MPO antibodies (13.8±43.4 vs. 0.9±0.3 U/mL, $p<0.001$) and myeloperoxidase activity (1607±2353 vs. 560.3±182.5 RU, $p<0.05$) in comparison to healthy controls. The ability of sera to degrade NETs was similar in both groups. Free DNA, dnase I, BAFF and anti-MPO levels as well myeloperoxidase activity showed significant correlation with anti-dsDNA antibodies measured by ELISA test. None of studied parameters showed correlation with C3 and C4 complement components. C3 and anti-dsDNA antibodies measured by indirect immune fluorescence were independent predictors of SLEDAI score in multivariate analysis, while BAFF and dnase I were significant in univariate analysis. Free cDNA was predictor of SLEDAI score higher than 7 in univariate analysis.
Conclusions: Increased amount of NETs markers found in lupus sera confirms their role in SLE pathogenesis. Determination of NETs markers could be useful serological parameter to follow disease activity in SLE patients.

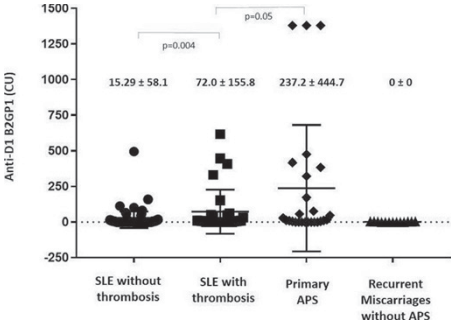
THU0275 IMPORTANCE OF SERUM TITERS OF ANTIBODIES AGAINST DOMAIN 1 OF B2 GLYCOPROTEIN 1

J.A. Gómez-Puerta[1,2], T. Urrego[2], A. Hernández[3], S. Ruiz Giraldo[3], C. Rua[4], J. Duque Botero[3], M. Velázquez[5], A.P. Cadavid[5], A.L. Vanegas-García[1,6], C.H. Muñoz[1,6], L.A. González[1], G. Vásquez[1,2]. *[1]Grupo de Reumatología; [2]Grupo de Inmunología Celular e Inmunogenética; [3]Departamento de Medicina Interna; [4]Grupo de Investigación en Trombosis; [5]Grupo de Reproducción, Universidad de Antioquia; [6]Grupo de Reumatología, Hospital San Vicente Fundación, Medellín, Colombia*

Background: There is an increasing interest in the study of domain reactivity of antibodies against β2 glycoprotein I (anti-B2GPI) in patients with antiphospholipid syndrome (APS). Antibodies targeting domain 1 of the molecule (anti-D1) as the most relevant autoantibody subpopulation. Previous information of anti-D1 B2GPI comes from APS cohorts with Caucasian, Asian, and African-American patients. However, there are no studies in Mestizo and Afro-Latin American patients.
Objectives: Our aim was to evaluate the prevalence of Anti-D1 B2GPI antibodies in a cohort of Colombian patients with systemic lupus erythematosus (SLE) with and without thrombosis, primary APS and patients with previous history of recurrent miscarriages (RM) without APS criteria.
Methods: In this cross-sectional study we measured Anti-D1 B2GPI antibodies in a group of patients from Rheumatology Department, Coagulation clinic and Recurrent Pregnancy Loss Program at the Reproduction Group at Hospital San Vicente Fundación and Universidad de Antioquia, respectively, at Medellín, Colombia. Anti-D1 B2GP1 antibodies were tested using a chemiluminescent immunoassay (QUANTA Flash B2GPI IgG, Inova Diagnostics). Mann-Whitney tests were used to compare data.
Results: One hundred and seventy seven (median age 33.5±12.1 years; 89% women) patients were included. One hundred thirty eight patients had SLE (78%), 27 primary APS (15%) and 13 RM (7%). Fifty five (31%) out of 177 patients had history of thrombosis and 41 (23%) of pregnancy losses. Overall, Anti-D1 B2GPI antibodies were positive (>20 CU) in 35 (20%) of patients. Anti-D1 B2GPI were positive in 23%, 17% and 0% of patients with primary APS, SLE and RM, respectively. Overall, serum Anti-D1 B2GPI were significantly higher in patients with than without previous thrombosis (149.1±336.1 vs 16.3±61.8 CU, p<0.0001) and in patients (SLE or primary APS) with previous history of pregnancy losses (40.2±123.1 vs 21.0±74.5 CU, p=0.04). Anti-D1 B2GPI were significantly higher in patients with primary APS vs SLE with thrombosis, and in patients with SLE with thrombosis vs SLE without thrombosis (Figure). No clinical associations were found among Anti-D1 B2GPI antibodies and other APS features.



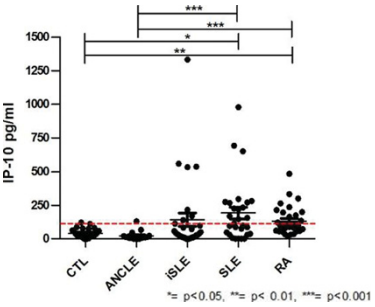


Figure 1. Mean serum levels of Anti-D1 B2GPI in a cohort of 177 patients.

Conclusions: Serum titers of Anti-D1 B2GPI antibodies were more than 9 times and 2 times higher in patients with thrombosis and pregnancy losses, respectively. In addition, serum titers were significantly higher in patients with primary APS than in SLE patients with thrombosis. Whether Anti D1- B2GPI antibodies titers are useful to differentiate patient with primary and secondary APS requires further analysis.

THU0276 INTERFERON-RELATED CHEMOKINE IP-10 IS A POTENTIAL BIOMARKER IN INCOMPLETE SYSTEMIC LUPUS ERYTHEMATOSUS

W. Lambers[1], K. De Leeuw[1], M. Jonkman[2], H. Bootsma[1], J. Westra[1]. *[1]Rheumatology and Clinical Immunology; [2]Dermatology, UMCG, Groningen, Netherlands*

Background: Incomplete SLE (iSLE) is the designation of patients who display symptoms that are typical for SLE, but with insufficient criteria to fulfil the diagnosis. Unfortunately, predictive biomarkers for SLE development are lacking. Increased IFN-type I production is an important factor in the pathogenesis of SLE. Interferon-regulated chemokines therefore could possibly be useful as biomarkers for disease progression to SLE. Candidate biomarkers IFN-γ induced protein 10 (IP-10) and monocyte chemo attractant protein (MCP-1) have shown to be increased in SLE and to correlate with disease activity.
Objectives: To determine possible candidate biomarkers IFN-γ induced protein 10 (IP-10) and monocyte chemo attractant protein (MCP-1) in patients with iSLE.
Methods: Serum samples were collected of 30 iSLE patients, 29 SLE patients, and 17 ANA-negative patients with histologically proven cutaneous lupus erythematosus (ANCLE). Outcomes were compared with 25 age- and gender-matched controls (CTL) and 31 rheumatoid arthritis (RA) patients as disease control group. Levels of IP-10 and MCP-1 were measured using ELISA.
Results: IP-10 was significantly increased in SLE and RA patients compared with CTL and ANCLE. IP-10 levels were increased in 23% of iSLE patients. These patients had higher SLE disease activity index (SLEDAI) and more frequently decreased C3 level and joint involvement compared to those with normal IP-10 levels. Regarding MCP-1 levels, no significant differences were found between any of the groups and no correlations with clinical markers was found.

Conclusions: Levels of IP-10, but not MCP-1, might be useful as a predictive biomarker for progression to SLE in patients with iSLE, although future prospective longitudinal analyses are needed to confirm this hypothesis.

THU0277 REASONS FOR DEFICIENCY OF PHYSICAL INACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L. Lipovskiy, C. Baerwald, O. Seifert. *Rheumatology Unit, Department of Internal Medicine, University Hospital Leipzig, Leipzig, Germany*

Background: Systemic lupus erythematosus (SLE) is associated with musculoskeletal complaints, fatigue and reduced quality of life. Physical exercise can play a crucial role in the treatment of rheumatic diseases, optimizing both physical and mental health.
Objectives: To characterize physical activity (PA) and its impact on SLE patients.
Methods: 85 SLE outpatients (92% female; age 44.2±12.5; 57.5% with SLEDAI score ≤5, 42.5% with SLEDAI score ≥6) were included in this study. The following questionnaires were utilized: painDETECT, visual analog scale for pain (VAS 0 - 100 mm), short-form health survey (SF - 36, quality of life), the FACIT-Fatigue Scale and the Health Assessment Questionnaire (HAQ - DI). PA was assessed for every patient using the long form of International Physical Activity Questionnaire (IPAQ - LF) and the Metabolic Equivalent of Task (MET) minutes per week (min/wk) (physiological measurement expressing calories of physical activities). The participants were classified in 3 groups according to the PA levels conferring to the guidelines of IPAQ. Physical inactivity was defined as fewer than 150 min/week spent in moderate or vigorous physical activities. Furthermore, the patient reasons "to be not physical active" and their opinion regarding the influence of PA on disease-related symptoms (on a scale of 0–10) were obtained.
Results: 10.6% of SLE patients were physically inactive (525.2±277.3 MET-Min/wk), 31.8% had a moderate physical activity, and 57.6% were physically active. Physical inactivity was associated with higher fatigue (FACIT-F, p<0.04) and lower "vitality" (SF-36, p<0.03) scores. Moreover, the subjective impact of fatigue on PA was significantly higher in physically inactive patients compared to physically active patients (the patient's score: 7.75±1.25 vs. 5.5±0.94, p<0.04). Moderate and severe pain (more than 40 mm VAS) was also associated with physical inactivity (OR 12.38, 95% CI 1.69 to 144.3, p=0.0056). In contrast, HAQ-DI was not related to levels of PA. Although physical inactivity correlated

with a higher total disease activity score (SLEDAI ≥6) (OR 9.9, 95% CI 2.1 to 49.9, p=0.0056), neither of the single SLEDAI items and organ manifestations including musculoskeletal manifestations was associated with physical inactivity. Interestingly, the study could not detect any statistical difference in organ manifestations and SLEDAI scores between patients with moderate and high PA. According to the patient's report, the main SLE-related reasons "not to be physically active" for all three groups were "lupus flare" (35.6%), "fatigue" (26.9%) as well as "joint complaints" (15.7%). The main general barriers for PA were "comorbidity" (35,6%) and "lack of motivation" (26,9%). Furthermore, the subjective impact of "bad weather conditions" on physical activity was significantly greater in physically inactive patients compared with the two other groups (the patient's report: 6.58±2.3 vs. 3.49±0.7, p<0.03).

Conclusions: The main reason for the patients not to be physically active was fatigue and pain. The study also indicates that not only somatic symptoms could decrease the levels of PA in SLE patients. Further research on psychological factors is needed. The study underlines the need for management strategies that specifically target physical activity as a part of an overall SLE management program.

THU0278 COMPARISON OF THE 2016 ACR/EULAR AND THE 2002 AECG CLASSIFICATION CRITERIA IN A COHORT OF PATIENTS WITH SUSPECTED PRIMARY SJÖGREN'S SYNDROME

M. Le Goff[1], D. Cornec[2], S. Jousse-Joulin[2], D. Guellec[2], S. Costa[2], T. Marhadour[2], R. Le Berre[2], S. Genestet[2], B. Cochener[2], S. Boisrame-Gastrin[2], Y. Renaudineau[2], J.-O. Pers[2], A. Saraux[2], V. Devauchelle-Pensec[2]. *[1]Rheumatology; [2]CHRU Brest, Brest, France*

Background: New consensual classification criteria for primary Sjögren's syndrome (pSS) have been recently developed and endorsed by ACR and EULAR. They differ substantially from previously used AECG criteria in that they consider systemic involvement (defined as ESSDAI score ≥1) as well as sicca symptoms as entry criteria before applying a weighted score. Evaluation of the concordance and differences between the two sets of criteria in independent patient populations is mandatory to establish how future clinical studies using the new criteria will be comparable to previously published studies. Major salivary gland ultrasonography (SGUS) has demonstrated promising diagnostic performance in previous studies, but was not included in these new classification criteria.

Methods: This cross-sectional study was conducted in the monocentric Brittany cohort (DIApSS cohort) of patients with suspected pSS (sicca symptoms, parotidomegaly or extraglandular manifestations suggestive of pSS). All patients had standardized clinical examination, basic biology, immunological tests and minor labial salivary gland biopsy. SGUS in mode B was performed by the same experienced operator, who was blinded to the diagnosis. Agreement between the two sets of criteria was assessed using Cohen's κ coefficient and the characteristics of discordant patients were detailed.

Results: 290 patients were prospectively included between 2006 and 2016. Mean age was 55.6±13.2 years, 92.1% were female and mean duration of the symptoms 6.0±6.6 years. More patients fulfilled ACR/EULAR criteria (n=125, 43.1%) than AECG criteria (n=114, 39.3%). 114 patients (39.3%) fulfilled both criteria, 11 (3.8%) fulfilled ACR/EULAR only, 0 AECG only and 165 (56.9%) none of the criteria. Concordance between both criteria was good (kappa=0.9). Compared to patients fulfilling both criteria, patients fulfilling ACR/EULAR but not AECG criteria (n=11) had similar age, similar symptom duration, but less frequent sicca symptoms (eye dryness 18.2% versus 96.5%; mouth dryness 54.5% versus 97.4%, p<0.01 for both), and less frequent salivary gland dysfunction (salivary flow ≤0.1 ml/min: 20% versus 70.9%, p<0.01).They had characteristic features of pSS, with frequent systemic involvement at diagnosis (90.9%), positive salivary gland biopsy (90.9%), abnormal SGUS (44.4%) and presence of anti-SSA/SSB autoantibodies (45.4%). 46.5% of them had a diagnosis of pSS according to the physician. Among patients negative for the two sets of criteria, 12% had an abnormal SGUS and 10.3% received a clinical diagnosis of pSS based on physician opinion.

Conclusions: Agreement between AECG criteria and new ACR/EULAR criteria is good suggesting that they select quite similar patients. ACR/EULAR criteria display a slightly higher sensitivity and are able to detect more patients with systemic involvement, but some of these patients did not have pSS according to the physician diagnosis. As previously demonstrated for AECG criteria, SGUS inclusion into ACR/EULAR criteria may further enhance their sensitivity.

THU0279 ARE THE PULMONARY INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS ASSOCIATED WITH A HIGHER PREVALENCE OF COMORBIDITIES?

M. Cebanu[1], V. Salaru[2], V. Sadovici[3], M. Pasali[3], N. Loghin-Oprea[3], M. Mazur[3], L. Mazur[4], G. Ciobanu[1]. *[1]Emergency Medicine; [2]Family Medicine; [3]Rheumatology; [4]Cardiology, State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

Background: Patients with systemic lupus erythematosus have a very high burden of comorbidities. Identification and management of these comorbidities are critical for optimal medical care to this population.

Objectives: To assess the prevalence of comorbidities in SLE patients with pulmonary involvement.

Methods: In a cross-sectional study, patients who fulfiled the SLICC (2012) classification criteria for SLE, were recruited from Rheumatology Departement. Data collection included demographics, disease duration, physician-rated indices of disease activity (by SLAM), damage (by SLICC/ACR DI) and Charlson comorbidity Index. The pulmonary involvement was assessed by chest X-ray, EcoCG Doppler and pulmonary functional tests.

Results: The study included 106 patients (97 women, 9 males) with a mean age (±SD) of 41,1±12,6 yrs, mean disease duration of 90,3±87,3 months. The disease activity by SLAM was 11±5,17 points and mean SLICC/ACR DI 1,9±2,4 points (66% of patients had at least 1 point). Pulmonary assessment revealed that 45 (42,5%) patients had different types of pulmonary involvement due to lupus: pleuritis - 24 patients, pneumonitis – 1 patient, pulmonary embolism – 4 patients, interstitial lung disease – 15, shrinking lung syndrome – 1 and pulmonary arterial hypertension – 9 patients. The most frequent comorbidities in study group were: arterial hypertension - in 57 (53,7%) cases, from which 33 (57,9%) patients had pulmonary involvement and 24 (42,1%) without, obesity (BMI>30 kg/m^2) had 29 (27,4%) patients, from which 17 (58,6%) with lung involvement and 12 (41,4%) without, anemia (Hb<110g/l) had 24 (22,6%) patients, from them 14 (58,3%) with lung disease and 10 (41,7%) patients - without, heart failure (I-II NYHA) had 23 (21,7%) patients, from them 20 (86,9%) were with lung implication, thyroiditis had 22 (20,8%) and 15 (68,2%) of them were with pulmonary involvement, diabetes mellitus type II had only 6 (5,7%) patients and half of them had lung disease. Assessing the impact of associated diseases through Charlson comorbidity index, we found that the score for patients diagnosed with damage to the respiratory system was twice as big vs. patients without respiratory impairment from SLE (6,3±2,4 vs. 3,4±1,4 points). Also, Charlson comorbidity score ≥1 was identified as a risk factor for lung involvement (OR 5,5294, 95% CI 2,367 – 12,91, p<0,01). Evaluation of disease activity by SLAM showed that patients with lung involvement have a higher disease activity vs. patients without (13,9±6,0 vs. 8,9±4,0, p<0,05).

Conclusions: On the one hand, according to our results patients with SLE and pulmonary involvement have a higher prevalence of comorbidities comparative with patients without them. Hypertension was found to be the most common comorbidity and it was determined in 73,3% of patients with impaired respiratory system (p<0,01). On the other hand, association of comorbidities (Charlson comorbidity score ≥1) was identified as a risk factor for lung lesions.

THU0280 COMPARISON OF CLASSIFICATION CRITERIA FOR SJÖGREN'S SYNDROME FROM 2002 AND 2016 IN AN INCIDENT COHORT DIAGNOSED 2007 TO 2011 FROM STOCKHOLM COUNTY SWEDEN

M. Kvarnström, M. Wahren-Herlenius. *Dep. of Medicine, Unit of Experimental Rheumatology, Karolinska Institutet, Karolinska Uniververity Hospital, Stockholm, Sweden*

Background: The current American-European Consensus Criteria (AECC) from 2002 has been the most widely used and applied all over the world. New classification criteria for Sjögren's syndrome was published in 2016, designed in a collaboration between ACR and EULAR. They are made up of a scoring system in which 4 points are required for classification. The weight/score is as follows:

- Labial salivary gland biopsy with focal lymphocytic sialadenitis and focus score of ≥1 foci/4 mm^2 – 3
- Anti-SSA/Ro positive – 3
- Ocular Staining Score ≥5 (or van Bijsterveld score ≥4) in at least 1 eye – 1
- Schirmer's test ≤5 mm/5 minutes in at least 1 eye – 1
- Unstimulated whole saliva flow rate ≤0.1 ml/minute – 1.

Objectives: Comparison of classification criteria for Sjögren's syndrome from 2002 and 2016 in a 5 year cohort of incident patients diagnosed 2007 to 2011 from Karolinska University Hospital, Stockholm County, Sweden.

We wanted to examine the consistency between the different classification criteria.

Methods: We compared a cohort of all diagnosed patients with primary Sjögren's syndrome during the years 2007 to 2011 at the Dep. of Rheumatology at Karolinska University Hospital in Stockholm Sweden. Data on the item Ocular Staining Score ≥5 was not available since it is not included in AECC. The cohort consisted of 199 patients all fulfilling the 2002 AECC. Another eight patients did

not fulfill the criteria but were regarded as possible Sjögren's syndrome under development by the rheumatologist who investigated them.
Results: 196 of the 199 pSS patients also fulfilled the new criteria from 2016. The three patients who did not only had SSB autoantibodies and no positive biopsy. Of eight patients with suspicion of Sjögren's syndrome under development, three fulfilled the new criteria.
Conclusions: The classification criteria for Sjögren's syndrome from 2002 and 2016 are consistent. This study indicates a possibility that the new criteria may be more sensitive early in the disease development, as long as the classification is not based on autoantibody positivity against SSB.

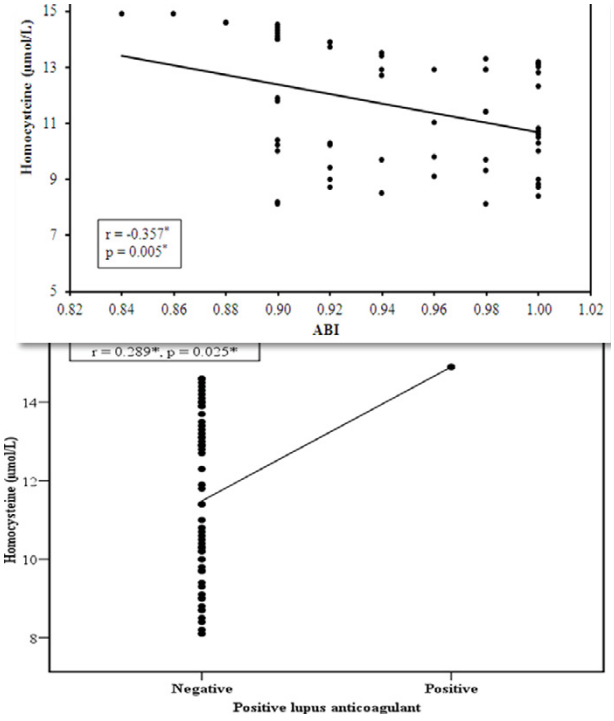
THU0281 LONG-TERM PROGNOSIS AND PREDICTINGFACTORS OF CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTI-CENTER COHORT STUDY FROM CSTAR REGISTRY

M. Li[1], Z. Wang[1], Y. Wang[2], X. Zeng[1] on behalf of CSTAR. [1]*Peking Union Medical College Hospital;* [2]*Chinese Academy of Medical Science, Beijing, China*

Objectives: To investigate the long-term outcomes, both mortality and damage, and related prognostic factors of patients with systemic lupus erythematosus (SLE) in the CSTAR (Chinese SLE Treatment and Research group) registry cohort.
Methods: All of the patients were enrolled from April 2009 to February 2010. They were followed up at clinic and were telephone interviewed at the endpoint. Demographic data, clinical manifestations, activity (SLEDAI-2K), damage scores (SLLIC/Damage Index), and medications were collected. Data were censored at the last clinic visit or telephone interview. Survival rates were studied by Kaplan-Meier method, and COX proportional hazard model was adopted to perform the analysis of predicting factors for mortality.
Results: A total of 2104 patients were recruited at baseline, and 1494 patients were successfully followed up. The cumulative 1, 3 and 5-year survival ratesfrom diagnosis were 99.0%, 98.1% and 97.1%. 78 patients died during follow-up, and the main death causes were infection (34.6%), active disease (26.9%), cardiovascular and cerebrovascular events (6.41%) and malignancy (5.13%). At entry, 247 patients presented with irreversible organ damage and it increased to 398 patients at the endpoint. The major accumulated organ damages were renal (25.9%), musculoskeletal (20.2%), neuropsychiatric (12.4%), and pulmonary (10.8%) damage. Cox regressionshowed that male, late onset age (≥50y), onset to diagnosis time ≥1 year, previous organ damage, renal involvement, pulmonary arterial hypertension, neuropsychiatric involvement, serositis and the number of involved organ systems ≥3predict for higher mortality.

Table 1: Independent predictors of mortality obtained by univariate analysis

Univariate analysis	HR	95%CI	*p*
Age at onset ≥ 50 years	3.935	2.111-7.334	<0.001
Onset to diagnosis ≥ 1 year	1.996	1.251-3.186	0.004
Gender	2.082	1.119-3.873	0.021
Baseline organ damage*	2.846	1.757-4.610	<0.001
Renal involvement*	2.434	1.425-4.156	0.001
Hematologic involvement*	1.605	0.978-2.635	0.061
Interstitial lung disease*	2.167	0.973-4.823	0.058
Pulmonary arterial hypertension*	4.126	2.107-8.081	<0.001
Neuropsychiatric involvement*	2.290	1.169-4.486	0.016
Serositis*	2.580	1.605-4.148	<0.001
No. of involved organ systems (1) *	1.793	0.719-4.466	0.210
No. of involved organ systems (2) *	2.045	0.805-5.195	0.133
No. of involved organ systems (≥3) *	5.638	2.339-13.589	<0.001



* Performed after controlling of gender, onset age and time from onset to diagnosis

Conclusions: Long-term survival rates have improved for Chinese SLE patients. Early diagnosis, preventing fromthe emerging systemic organ involvements and organ damagecould be the treating target for the management of SLE patients in China.

THU0282 HOMOCYSTEINE: ANY ROLE IN PERIPHERAL VASCULAR DISEASE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS?

N. Mohannad[1], M. Tayel[2], M.H. Megallaa[3]. [1]*Internal Medicine, Rheumatology Unit, Alexandria University Hospitals, Alexandria University;* [2]*Internal Medicine, Rheumatology Unit;* [3]*Internal Medicine, Alexandria University, Alexandria, Egypt*

Background: Many are the independent risk factors for premature atherosclerosis in general & peripheral vascular disease (PVD) in particular in SLE patients. Plasma homocysteine (HCY) is a known risk factor for atherosclerosis. Atherosclerosis can lead to many cardiovascular diseases as myocardial infarction, stroke and claudication
Objectives: To compare the occurrence PVD of the lower extremity of SLE patients (pts) with age and sex matched controls and evaluate the role of HCY level in its occurrence
Methods: Body mass index (BMI), blood pressure, lipid profile, titers of autoantibodies [ANA, anticardiolipin antibodies ACL (IgM, IgG)], C3, C4, plasma HCY level were assessed, SLEDAI and (SLICC/ACRDI)were calculated. PVD evaluation was done by measuring Ankle Brachial Index (ABI) with values <0.9 considered diagnostic of PVD; in 60 SLE pts and 30 age-matched controls. Patients with previous hypertension, diabetes, other collagenic diseases & smokers were excluded
Results: Eighty-eight percent of the pts were women. The mean age (SD) was 30.40 (11.46) years & mean disease duration 3.61 (4.92)years. 50 pts were asymptomatic, 5 had mild & 5 had moderate claudications.SLE pts had significant higher total cholesterol (TC), LDL than controls 224.1±57.8 vs 181.1±41.1 mg/dl & 162.7±57.0 vs 119.5±13.4 (<0.001*) respectively, higher HCY 11.6±2.1 & 6.4±0.1 μmol/L (p<0.001*) & lower HDL 47.2±13.1 &52.6±3.7 mg/dl (p=0.004*). Low ABI was found in 30% of SLE pts but none of the controls (p=0.001*) & was correlated with higher HCY level (p=0.005*), TC & LDL (p<0.001* & p<0.001*), but not TG (p=0.748) or asymptomatic pts, presence of mild or moderate claudications (p=0.468,1.000, 0.154), still its value negatively correlated with lupus anticoagulant (LA) (p=0.002), ACL IgM (p<0.001*), the presence of lupus nephritis (LN) (p<0.001*) & SLICC/ACRDI (p=0.017*) but not with disease duration (dd) (p=0.535), Anti ds DNA (p=0.364), ACL IgG (p=0.8940), C4 (p=0.168) or SLEDAI (p=0.074).No correlation was found between HCY level and pts' age, dd, age at diagnosis, BMI, Anti ds DNA, ACL IgG, C4 & SLEDAI (p=0.521, 0.098, 0.946, 0.502, 0.346, 0.335, 0.325, 0.787). A positive correlation was found between HCY level and LA, ACL IgM, TC, LDL, the presence of LN & SLICC/ACRDI with a p value of 0.025*, <0.001*, <0.001*, 0.003*, 0.001*, 0.001* & negative one with HDL p=0.023*

Conclusions: 83.3% of SLE pts were asymptomatic or had atypical symptoms of PVD still 30% of the patients had low ABI. ABI can be a more reliable, non-invasive test to assess PVD than the conventional methods of pulse palpation or history of claudication in SLE pts.Both traditional & nontraditional risk factors of atherosclerosis are important but HCY can play a role, among other factors, as independent risk factor of PVD in SLE

Background: Resilience is the human capacity to respond positively to adverse situations, enabling individuals to achieve, maintain, or recover physical or emotional health after devastating illness, losses, or other stressful situations. Resilience may be an important factor in health promotion.
Objectives: The aim of this study was to evaluate resilience and possible associated factors in patients with systemic lupus erythematosus (SLE).
Methods: In a cross-sectional study, 123 SLE women and 133 age-matched controls were evaluated using the Spanish version of Wagnild and Young's Resilience Scale (WYRS, 1993). SLE patients underwent a structured interview to collect sociodemographic data, including socioeconomic status measured by the Graffar method. The Center for Epidemiologic Studies Depression Scale (CES-D) was used to measure depressive symptoms.
Results: The median age and duration disease of SLE women was 45 (IQR: 34–54) years and 11 (IQR: 8–15) years, respectively. Thirty-three percent had depressive symptoms (CESD score $\geq$16). Resilience scores did not differ between patients and controls (median 80 IQR: 75–87 vs.80 IQR: 74–85;p=0.38). However, patients with SLE had a higher personal competence factor than controls. Personal competence factor correlated negatively with age and socioeconomic status (R= -0.220, p: 0.05 and R= -0.357, $p<0.001$) and positively with educational level (R=0.324, $p<0.001$). Less resilience (lower WYRS scores) correlated with depressed mood (higher CESD scores) (R= -0.537, $p<0.001$).
Conclusions: Resilience in patients with SLE did not differ from that of controls. Age, socioeconomic status and depressive symptoms correlated with low resilience. Educational level correlated with higher resilience.

Objectives: To correlate the main features at diagnosis with survival in a multicenter international cohort of patients with primary Sjögren syndrome (SS).
Methods: The Big Data Sjögren Project was formed in 2014 to take a "high-definition" picture of the main features of primary SS by merging international SS databases (9302 consecutive patients recruited from 21 countries of the 5 continents)
Results: Data about survival at the last visit was available in 6240 patients (5831 women, mean age at diagnosis of 53yrs, 82% White). After a mean follow-up of 7.1yrs, 407 (6%) patients died. Patients who died were more frequently men (10% vs 6%, p=0.004) and White (96% vs 81%, $p<0.001$), had a higher mean age at diagnosis (64 vs 52yrs. $p<0.001$) and a higher frequency of abnormal ocular (95% vs 87%, $p<0.001$) and oral (90% vs 79%, $p<0.001$) tests in comparison with survivors; sicca symptoms and salivary gland biopsy were unrelated to survival. Immunologically, patients who died showed a higher frequency of RF (52% vs 46%, p=0.039) and cryoglobulins (18% vs 7%, $p<0.001$). Logistic regression identified as independent variables the age at diagnosis (OR 1.07), male gender (OR 1.77), abnormal ocular (OR 5.79) and oral (OR 2.10) tests, and cryoglobulins (OR 3.10). Time-adjusted multivariate Cox proportional-hazards regression analysis confirmed age at diagnosis (OR 1.12, CI95% 1.10–1.14), male gender (OR 2.12, CI95% 1.36–3.29) and cryoglobulins (OR 2.43, CI95% 1.72–3.42) as independent variables related to death.
Conclusions: An older age at diagnosis, male gender and serum cryoglobulins were the principal risk factors associated with death in this large multiethnic cohort of patients with primary SS.

THU0285 USE OF CONTRACEPTIVE METHODS IN A SINGLE CENTER COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS FROM ARGENTINA

R.A. Gomez, F.M. Paniego, M. Garcia Carrasco, D. Dubinsky, G. Nasswetter. *Rheumatology, Hospital de Clinicas Jose de San Martin, Ciudad Autónoma de Buenos Aires, Argentina*

Background: Systemic Lupus Erythematosus (SLE) may associate with flares, an unfavorable course and the need of teratogenic treatment during pregnancy. Not every contraceptive method (CM) may be used in this patients. There are guidelines for their use according to existing morbidity and SLE activity[1].
Objectives: Describe the use of CM in a cohort of outpatients with SLE
Methods: Descriptive, observational, cross-sectional study. Patients $\geq$16 years old with SLE (SLICC 2012) and $\geq$1 visit during the last year of our database were included. Those with menopause were excluded. We analyzed demographic data; disease duration; antiphospholipid antibodies (aPL) and antiphospholipid syndrome (APS) (Sapporo 2006); socioeconomic status (Graffar scale); disease activity (SELENA-SLEDAI) and accrual damage (SLICC); use of teratogens: Methotrexate (MTX), Mycophenolate (MYC), Cyclophosphamide (CYC), biologic drugs (BD), self-reported sexual status (active/non active) and CM: intrauterine device (IUD), condom (Cdm) and hormonal contraceptive pill (CP).
Results: 132/219 were included. Female 91.6%, age: 30.1 (16–49) years, disease duration: 38.5 (1–324) months, SELENA-SLEDAI: 3.5 (0–29), SLICC: 0.5 (0–5).
Sexual status and use of CM: were available for 120 patients. Sexually active (SA) 73%, female 77%. CM in SA patients: 74%: 5% CP, 77% Cdm and 18% IUD.
CM in female patients stratified by Graffar (GF): GF I (n=1): none SA; GF II: (n=19): 84% SA, 75% of them used CM (75% Cdm, 25% IUD); GF III (n=33): 82% sexually active, 81% used CM (86% Cdm, 14% IUD), GF IV (n=41) 75% SA, 68% used CM (9% CP, 71% Cdm, 19% IUD), GF V (n=4) 100% SA, 50% used CM (50% CP, 50% Cdm); GF NA (n=11) 55% SA, 83% used CM (80% Cdm, 20% IUD).
CM in female patients stratified by SLE activity: SLEDAI $<$3 (n=62): 76% SA, 77% of them used CM (3% CP, 83% Cdm, 14% IUD); SLEDAI 3–12 (n=42): 81% SA, 76% used CM (8% CP, 69% Cdm, 23% IUD); SLEDAI $>$12 (n=60): 60% SA, 67% used CM (100% Cdm).
CM in female patients using teratogenic drugs: MTX (n=8): 100% SA, 75% of them used CM (17% CP, 66% Cdm, 17% IUD); MYC (n=20): 80% SA, 88% used CM (71% Cdm, 29% IUD); CYC (n=3): 33% SA, 100% used CM (100% Cdm); Belimumab (n=1): 100% SA, 100% surgical CM (tubectomy).
aPL was evaluated in 96/132 patients. 17/96 had positive aPL and 5/17 fulfilled APS criteria. 2/17 patients had no CM data available, none with APS. 9/17 patients with aPL were female, 55% SA and all of them used Cdm. 3/5 patients with APS were female, all SA, 66% used Cdm.
Conclusions: Condom was the most reported CM. Use of CM was more frequent in the upper social stratus (GF I-III) respect to the lower (GF IV-V).
The proportion of sexually active female patients was similar in those using teratogenic drugs compared with who had not used them.
The self-reported sexual status was similar despite of SLEDAI stratification, being similar in patients with low or high disease activity.
We deem necessary education, counseling and evaluation of use of the CM in every visit of patients with SLE.

THU0286 RECURRENCE OF ARTERIAL AND VENOUS THROMBOSES IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

G. Balbi, F. Signorelli, R.A. Levy. *Rheumatology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil*

Background: Antiphospholipid syndrome (APS) is the thrombophilia associated with the highest risk of recurrence of both arterial and venous thromboses. (1,2) In addition to the standard of care (lifelong oral anticoagulation), identification of other risk factors is important to provide better care and to reduce the incidence of rethrombosis.
Objectives: To investigate the risk factors associated with recurrence of arterial and venous thromboses in primary APS patients.
Methods: A cross-sectional study was performed in a group of 80 outpatients who fulfilled APS classification criteria (Sydney). The patients were regularly seen in our department, and clinical and serological features were collected during visits and by chart review. They were classified as recurrent or not, and these groups were compared. Recurrence was defined as the presence of 2 or more thrombotic events during lifetime. Patients with 1 thrombotic event were classified as "no recurrent". No history of thrombosis was the only exclusion criteria.
Results: Of 80 pAPS patients, thirty-five had arterial thrombosis and 54 had venous thrombosis. Of them, thirty-six had recurrent thromboses (11 arterial and 25 venous). Demographic and clinical characteristics of the arterial group are shown in Table 1. In a bivariate analysis, recurrent arterial thromboses were associated with hypertension (p=0.016) and positivity to lupus anticoagulant (LA; p=0.033), and recurrent venous thrombosis correlated to obesity (BMI$\geq$30 kg/m^2; p=0.003). In a multivariate regression analysis, the model of recurrent arterial thromboses was adjusted to age, sex, and variables with p$<$0.10 in the bivariate analysis (age, hypertension, dyslipidemia, and positivity to lupus anticoagulant). Hypertension (OR 9.02; CI95% 1.05–77.5; p=0.045) and age (OR 1.16; CI95% 1.01–1.33; p=0.035) increased the risk of relapse of arterial thrombosis.

Table 1. Demographic and clinical characteristics of patients with recurrent and non-recurrent arterial thromboses (N=35)

Variable	Arterial recurrence (N=11)	No arterial recurrence (N=24)
Age	53.5±7.7	41.9±11.7
Female gender	10 (90.9)	18 (75)
Caucasian	8 (72.7)	14 (58.3)
Time first manifestation (mo)	185 (120–300)	150 (59,3–204)
Risk factors		
Hypertension	8 (72.7)	7 (29.2)
Diabetes	1 (9.1)	1 (4.2)
Dyslipidemia	8 (72.7)	9 (37.5)
Obesity (BMI$\geq$30 kg/m^2)	4 (36.4)	7 (29.2)
Premature CVD	3 (27.3)	2 (8.3)
Smoking	5 (45.5)	9 (37.5)
Non criteria		
Livedo	4 (36.4)	9 (37.5)
Thrombocytopenia	1 (9.1)	4 (16.7)
Valvulopathy	1 (11.1)*	2 (13.3)**
Raynaud phenomenon	4 (36.4)	6 (25.0)
Migraine	6 (54.5)	12 (50.0)

*N=9; **N=15. Mo = months. CVD = cardiovascular disease. Values showed as N (%) for categorical variables, Mean ± SD for normal distribution and Median (interquartil range) for asymmetric distribution.

Conclusions: This data suggests that hypertension, a traditional cardiovascular risk factor, is associated with increased risk of recurrent thrombosis and, therefore, should be controlled in pAPS patients. Besides, each additional year of age is associated with the risk of 16% of a new arterial thrombotic event.

THU0287 CENTRAL ARTERIAL STIFFNESS MEASURED BY THE AUGMENTATION INDEX IS INCREASED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND IS DETERMINED BY THE LEVELS OF IGM-β2-GLYCOPROTEIN AND THE SMALL-DENSE HDL PARTICLES

S. Parra[1,2], N. Amigo[3], M. Heras[4], D. Ibarreche[5], M. Benavent[6], A. Navarro[6], E. Garcés[6], A. Castro[1,2]. *[1]Autoimmune diseases unit, Sant Joan's university Hospital; [2]Institut investigacions Sanitaries Pere i Virgili, Reus, Spain; [3]Centre for Omic Sciences, Institut Investigacions Sanitaries Pere i Virgili; [4]Lipid resarch unit (URLA), Rovira i Virgili university; [5]Unitat de medicina vascular i del metabolisme (UVASMET), Sant Joan University Hospital; [6]Internal medicine, Sant Joan's university Hospital, Reus, Spain*

Background: Patients affected by Systemic Lupus Erythematosus (SLE) show an increase in cardiovascular mortality and morbidity. The accelerated atherosclerosis observed in patients with SLE cannot be entirely explained by the traditional cardiovascular risk factors. Patients with SLE show increased subclinical atherosclerosis determined by an increased carotid arterial thickness, endothelial dysfunction and central arterial stiffness. Analysis of lipoproteins by magnetic nuclear resonance (MNR) provide information of those lipoproteins associated with subcinial atherosclerosis in SLE.
Objectives: To investigate the metabolic and immunological factors associated with the presence of central arterial stiffness determined by the Augmentation Index (AIx) as well as the detailed analysis of the lipid profile performed by magnetic nuclear resonance (MNR)
Methods: Descriptive cross-sectional study of 69 women with SLE compared with a control group of 34 age matched healthy women. On the same day of the study, blood extraction, physical examination and augmentation index (AIx) obtained by Peripheral Arterial Tonometry were performed. The carotid intima-media thickness (IMTc) was also performed on the same day of the study to correlate the arterial stiffness with another subclinical atherosclerosis marker. Analysis of lipoprotein populations by NMR (Liposcale,Biosfer Teslab) were performed.
Results: Patients with SLE showed significant increased arterial stiffness respect the control group (20.30 (21.54)% vs 10.84 (11.51)%, *P*=0.0021)The values of AIx were well correlated with Framingham risk score (r=0.486, P <0.001) as well as the IMTc (r=0.456, P<0.001). The classic cardiovascular risk factors associated with the AIx were the SBP levels (r=0.456, P<0.001) and age (r=0.456, P <0.001). Patients under antimalarial drugs showed significant decreased AIx (11.74 (11.28) vs 24.97 (20.63); *P*=0.024. Immunological variables associated with AIx were levels of C4 (r=0.259; *P*=0.046) and the IgM-β2-glycoprotein levels (r=0.284, P=0.284).As for the lipoprotein populations, AI values correlated with ApoB plasma levels, remnant particles, the number of large, medium and small VLDL particles, the number of small LDL particles and the number of small-dense HDL particles. In the multivariate analysis we found that age (β=0.377 (0.117–0.636), *P*=0.005) IgM-B2-GLP levels (β=0.303 (0.026–0.580),*P*=0.033) and the small-dense HDL particles (β=1,463 (0.605–2.322), *P*=0.001).
Conclusions: SLE patients show increased central arterial stiffness respect healthy population. Patients treated with antamalarial drugs show lower arterial stifness. In multivariate analyses variables that predicted levels of AIx were age, levels of IgM-β2-glycoprotein and the number of small-dense HDL particles.

THU0288 COMPARISON OF THE CLINICAL, SEROLOGICAL, AND PROGNOSTIC DIFFERENCES AMONG JUVENILE-, ADULT-, AND LATE-ONSET LUPUS NEPHRITIS IN KOREAN PATIENTS: A CASE-CONTROL STUDY

S.-S. Lee[1,1], J.-H. Kang, J.-E. Kim, K.-E. Lee, D.-J. Park. *Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of*

Objectives: SLE patients present with different clinical and serological manifestations according to the age at disease onset. However, it is not known whether there is an association between disease onset age and the clinical presentation of lupus nephritis (LN). Therefore, we investigated whether LN patients could be distinguished based on the time of disease onset and, if so, whether the groups differed in their clinical, laboratory features and long-term prognosis in ethnically homogeneous Korean patients.
Methods: We enrolled 117 SLE patients with available clinical data at the time of renal biopsy for LN from the lupus cohort at Chonnam National University Hospital. We divided the LN patients according to the age at LN diagnosis into three groups [juvenile-onset LN (JLN), diagnosed at $\leq$18 years; adult-onset LN (ALN), diagnosed at 18–50 years; and late-onset LN (LLN), diagnosed at $>$50 years] and compared the baseline demographic, clinical, histological, and relevant laboratory findings. We also compared the treatment and long-term prognosis of LN according to those three groups.
Results: Of the 114 LN patients, 20 (17.5%), 84 (71.8%), and 13 (11.1%) had JLN, ALN, and LLN, respectively. LLN patients were less educated than ALN and JLN patients (p <0.001). Hypertension and diabetes mellitus at the onset of LN were more common in LLN patients than ALN or JLN patients (p<0.001 and?p=0.037, respectively). Regarding the laboratory findings, LLN patients had a higher white blood cell count and lower eGFR than ALN or JLN patients (p<0.011 and 0.002, respectively). Histologically, LLN patients had more chronicity indices and a higher chronic score (p =0.006, p =0.019, p<0.001 and p<0.001, respectively). Anti-Ro antibodies were found more frequently in ALN patients and less frequently in JLN patients (p =0.024) and lower complement levels were more common in JLN patients and less common in LLN patients (p<0.011 and 0.002, respectively). During a mean follow-up of 76.5 months, the development of chronic kidney disease and death from any cause were higher in LLN patients than in JLN and ALN patients (p =0.028 and p =0.038, respectively).
Conclusions: LN patients present with different clinical and serological manifestations according to age at disease onset. Interestingly, LLN patients had more chronicity at the time of renal biopsy, and more deterioration of kidney function and death on long-term follow-up, than JLN and ALN patients. Therefore, LLN patients should be monitored and managed carefully to avoid poor outcomes.

THU0289 B-CELL ACTIVATING FACTOR GENE EXPRESSION IN URINARY SAMPLE AND RENAL BIOPSY FOR MONITORING DISEASE ACTIVITY IN LUPUS NEPHRITIS

S. Retamozo[1,2], L. Mas[3], M.J. Haye Salinas[4], V. Saurit[4], F. Caeiro[4], A. Diller[5], J. De La Fuente[6], M. Angelina[7], N.R. Benzaquen[4], J.P. Pirola[4], A. Alvarellos[4], T. Alvarellos[3]. *[1]Rheumatology, Hospital Privado Universitario de Córdoba; [2]INICSA, CONICET; [3]Molecular Biology; [4]Rheumatology; [5]Pathology; [6]Nephrology, Hospital Privado Universitario de Córdoba; [7]Nephrology, Hospital Raul A Ferreyra, Cordoba, Argentina*

Objectives: To evaluate BLyS as biomarker in disease activity in urinary sample and renal biopsy from patients with LN.
Methods: Retrospective study. Between June 2009 and October 2013, 32 patients with SLE and LN fullfilling SLE classification criteria of ACR 1997 were included. The renal biopsies were evaluated according to the ISN/RPS classification system. The gene expression levels of BLyS were quantified using Quantitative Real Time PCR (QPCR). The relative quantification method was used for analysis, where Ct was normalized to an endogenous control β2Microglobulina (β2M) (ΔCt BLyS). The data expressed as ΔCt are inversely proportional to gene expression level. The value of BLyS is expressed as median (M) and interquartile range (IQR) for filing a non-normal distribution.
Results: 26 (81.3%) patients were female with a mean age at diagnosis of 26.9±13 years and 31.9±29 years at the time of renal biopsy. The SLEDAI at the time of biopsy was 10.5 (IQR 0–15.7) and SLICC ≥1 in 13 (32.5%), hypocomplementemia 13/31 (41.9%) and positive DNA in 11/29 (37.9%) patients. Biopsies from patients with proteinuria ≥0.5 and renal failure (RF) (n=23, 71.9%), proteinuria isolated (n=14, 43.8%), LN remission. The value of the BLyS gene expression in renal biopsy was 8.09 (IQR 7.37–9.16) and BLyS in urinary sample was 6.45 (IQR 5.62–7.76).
Conclusions: BLyS detection in urinary samples could be a potential biomarker for predicting lupus nephritis activity. Our data confirm that the BLyS as urinary biomarker is present in patients with active renal disease especially in patients with proliferative glomerulonephritis.

THU0290 CLINICAL BACKGROUND FACTORS RELATED TO SILENT OSTEONECROSIS OF THE FEMORAL HEAD UPON INITIATION OF STEROID THERAPY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

T. Kuroda[1], N. Tanabe[2], H. Sato[1], T. Nakatsue[1], Y. Wada[1], M. Nakano[3], I. Narita[1]. *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences; [2]Department of Health and Nutrition, Faculty of Human Life Studies, University of Niigata Prefecture; [3]Department of Medical Technology, School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan*

Background: Osteonecrosis of the femoral head (ONF) occurs frequently (3–40%) in patients who receive corticosteroid therapy for SLE. MRI can accurately visualize pathological abnormalities of the femoral head, being much more sensitive than plain radiography. To analyze the risk factors associated with steroid-induced ONF, the best approach would be to examine early changes in the femoral head using MRI and any early clinical events attributable to steroid therapy. For treatment of SLE, a number of strategies may be selected according to the clinical conditions of patients, and treatments may differ slightly among hospitals. Therefore, for better clarification of the background factors associated with ONF, the optimum approach would be to analyze the treatment strategy, selection of steroid, initial dose of steroid and drugs used together with steroid in a cohort of patients treated at a single hospital.
Objectives: To clarify the factors related to silent ONF in patients with SLE treated at a single institution.
Methods: One hundred six patients (12 males and 94 females) with SLE were selected on the basis of having been newly diagnosed and requiring high-dose prednisolone, including pulse therapy with methylprednisolone, as the initial treatment. All the patients initially underwent plain radiography and MRI at the start of corticosteroid treatment to detect any early changes in the femoral head, and subsequent examinations were performed three months later. Laboratory parameters were evaluated at the start of steroid treatment and one month thereafter. All statistical analyses were performed with SPSS v. 13 (SPSS Inc., Chicago, IL, USA). Differences demonstrated by 2-tailed tests were considered statistically significant at *P* (two-sided) <0.05, and marginally significant at *P*=0.05–0.10.
Results: By three months after the start of corticosteroid treatment, asymptomatic ONF was diagnosed by MRI in 30 patients (28.3%), being bilateral in 17 and unilateral in 13. Serological activity (C3, C4, CH50 and anti-ds DNA antibody), renal function (eGFR, serum creatinine and urinary protein), anti-phospholipid antibodies, and SLEDAI were not correlated with asymptomatic ONF. BMI, BSA, and the initial dose of prednisolone per unit body weight, BMI and BSA were also not correlated with asymptpmatic ONF. No preventive effect of ONF was observed by pretreatment with statins. However, patients with angiitis and a elevated total cholesterol level at 4 weeks after the start of steroid treatment tended to show a higher incidence of ONF. Patients with a higher triglyceride level both before and 4 weeks after the start of steroid treatment showed a significantly higher frequency of asymptomatic ONF (P<0.001).
Conclusions: Asymptomatic ONF is common in patients with SLE. A high triglyceride level is a significant risk factor for ONF, and large epidemiologic surveys would help to shed light on early events such as silent ONF in patients receiving steroid therapy.

THU0291 GENDER INFLUENCE ON CLINICAL, BIOLOGICAL AND IMMUNOLOGICAL ASPECTS OF SYSTEMIC LUPUS ERYTHEMATOSUS

T. Ben Salem, M. Tougorti, I. Naceur, I. Ben Ghorbel, M. Lamloum, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

Background: Systemic lupus erythematosus (SLE) is more frequent in women but seems to be more severe in men.
Objectives: The aim was to study gender influence on clinical, biological and immunological features of SLE
Methods: It's a retrospective study conducted in an internal medicine department. Patients with systemic lupus erythematosus (ACR revised criteria) were included. Data were recorded and compared using SPSS. Variables with a p≤0.05 were considered to be statistically significant.
Results: A total of 246 SLE patients were included; 224 female and 19 male (sex ratio F/M was 11.78). Mean ages at disease onset and at SLE diagnosis were comparable for men and women respectively 35.63±14.31 vs 32.7±13.36 years and 35.8±14.3 vs 34.5±13.6 years.
SLE diagnosis was made earlier in men with an average delay (from first sign of the disease to diagnosis) of 6.1 months vs 21.4 months (p=0.02). Clinically, photosensitivity was significantly more frequent in women (81.4% vs 58.8%; p=0.03). Women complained from alopecia more frequently than men but the difference was not statistically significant (35.1% vs 14.3%; p=0.09). Arthritis were two times more frequent in women (50.7% vs 25%; p=0.04). Lupus nephritis us well us lupus pancreatitis were significantly more frequent in men, respectively 66.7% vs 41.6% (p=0.039) and 11.1% vs 1.4% (p=0.047). There were no differences according to gender in neurological involvement and seritis. No significant differences were observed between men and women concerning hematological disorders. Anti-DNA, anti-Sm, anti-RNP, anti-SSA, anti-SSB, anti-cardiolipin and anti-B2GP1 antibodies frequencies were similar in both genders.
Conclusions: SLE diagnosis was made earlier in men than women, this could be explained by more severe disease in men [1]. However this hypothesis has been highly controversial [2]. Cutaneous and joints manifestations seem to be more frequent in women whereas serious manifestations like lupus nephritis and neurological involvements were more frequent in men [3–4]. In our study, only lupus nephritis and pancreatitis were more frequent in men.

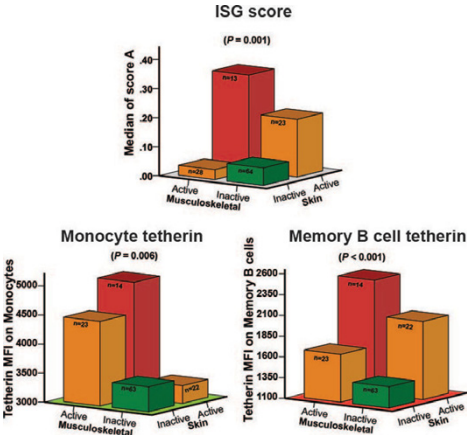
THU0292 DIAGNOSTIC ACCURACY OF ULTRASOUND AND ULTRASONOGRAPHIC FEATURES OF SALIVARY GLANDS IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME



V. Milic, G. Radunovic, N. Damjanov. *Institute of Rheumatology, Belgrade, Serbia*

Objectives: To analysis ultrasonography (US) changes of salivary glands (SG) in patients with primary Sjogren's syndrome (pSS) and assessment of their accuracy for diagnosis pSS.
Methods: This study included 205 pSS patients (mean age 53.9±11.5, disease duration 5.6 years) and 87 healthy controls (mean age 52.3±14.7). All pSS patients fulfilled the AECG diagnostic criteria. The disease activity was measured by EULAR SS disease activity index (ESSDAI). Parotid and submandibular glands on both sides were assessed for size, parenchymal echogenicity and inhomogeneity, posterior glandular border and presence of intraglandular lymph nodes. Inhomogeneity of the salivary glands were graded according to the De Vita scoring system [0) homogenous glands; 1) mild inhomogeneous - isolated hypoechogenic areas; 2) evident inhomogeneous - scattered hypoechogenic areas, and/or multiple punctate or linear densities; 3) grossly inhomogeneous – large or confluents hypoechogenic areas, and/or to linear densities, and/or multiple cysts. The global SGUS score (0–6) was the sum of the scores of each pair of salivary glands. Statistical analysis was performed by SPSS v16. Data were compared using *t*-test, χ^2 test and Mann-Whitney U test. The optimal cut-off value for SGUS score was calculated as the area under the receiver operating characteristic curve (AUC-ROC).
Results: Xerophtalmia and xerostomia were presented in 185/205 (90.2%) and 186/205 (91.2%), respectively. According to ESSDAI, the majority of pSS patients 88/205 (43%) had moderate disease activity. Seventy-eight per cent of pSS patients were anti-SSA antibody positive, 44% anti-SSB/La antibody positive. Biopsy of LSG was positive in 140/172 (81.4%) pSS patients. US abnormalities were established in 197 (96%) pSS patients and in 16 (18%) controls ($p<0.0001$). Pathological sizes of salivary glands were more frequently in pSS patients than controls, 111 (54.2%) vs. 3 (3.4%) patients, respectively ($p<0.0001$). The echogenicity of the salivary glands was pathological changes in 142 (69.3%) pSS patients and in only 5 (5.7%) control group ($p<0.0001$). The pathological glandular border was frequently in pSS patients than control group, 48 (23.4%) vs. 2 (2.3%), $p<0.0001$. No differences were detected between the two groups of patients for enlarged intraglandular lymph nodes. Most of pSS patients had pathological inhomogeneity, 197/205 (96.1%) vs. 16/85 (18.4%) in control group ($p<0.0001$). The median SGUS was significantly higher in pSS patients in comparison with control group [median (range) 4 (0–6) vs. 0 (0–2), $p<0.0001$]. Forty-five percent of pSS patients had SGUS score 4. The SGUS cut-off ≥ 2 showed specificity of 89.5% and sensitivity 89.3%. Diagnostic accuracy of the parenchymal inhomogeneity was very good (AUC-ROC 0.89), followed by the glandular echogenicity (AUC-ROC 0.81), the glandular size (AUC ROC 0.75), the posterior border (AUC ROC 0.60), and the presence of intraglandular lymph nodules (AUC ROC 0.49), respectively.
Conclusions: Our findings confirm that most of established pSS patients had pathological SGUS features. Among US parameters, parenchymal inhomogeneity was the most discriminant feature for diagnosis of SS. There is the growing evidence that ultrasound should be considered as the useful method for evaluation of salivary glands in pSS patients.

THU0293 B-CELL RESPONSES TO TYPE I INTERFERON DEFINE DISEASE ACTIVITY IN SLE AND CAN BE MEASURED BY CELL SURFACE TETHERIN (CD317)

Y.M. El-Sherbiny[1,2], M.Y. Md Yusof[1,2], A. Psarras[2], E. Hensor[1,2], R. Tooze[3], G. Doody[3], M. Wittmann[1,2], P. Emery[1,2], E.M. Vital[1,2]. [1]*National Institute of Health Research Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust;* [2]*Leeds Institute of Rheumatic and Musculoskeletal Medicine;* [3]*Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, United Kingdom*

Background: SLE is a Type I interferon (IFN-I) mediated disease with autoreactive B cells. Whole blood interferon-stimulated gene (ISG) expression is used to measure IFN-I status but does not consistently correlate with clinical features and therapy response. ISG expression may be influenced by differing response in individual cell subsets as well as IFN-g. Tetherin is a cell surface protein encoded by the interferon-stimulated gene *BST2*.
Objectives: To evaluate tetherin expression as a novel cell-specific flow cytometric biomarker for IFN-I response.
Methods: *In vitro,* we tested response of expression of *BST2* and 30 other ISGs to stimulation with IFN-a and IFN-g, as well as dose response of *BST2* and tetherin protein in B cells. Sorted cells (Monocyte, T, NK, naïve and memory B, plasmablast) from 8 controls and 10 SLE patients were used to test variation in expression of 31 ISGs between cell subsets and whether tetherin measured by flow cytometry is a cell specific marker for IFN-I response. Samples from 156 SLE patients, 30 ACPA+ANA- RA (DAS28>3.2) patients and 22 healthy controls (HC) were used in 3 clinical validation studies of tetherin vs. ISG score against diagnosis, disease activity (BILAG-2004) and plasmablast repopulation after rituximab.
Results: Some ISGs' expression in B cells increased in response to both IFN-a and IFN-g. Others, which included *BST2*, were selective for IFN-a. An 18-gene ISG score derived from this latter group was calculated for comparison with tetherin.
Results from cell sorting showed that ISG Score was highest in monocytes; other subsets were 75–85% lower ($p<0.001$). SLE-associated increase in expression (SLE:HC ratio) varied between 2.56 (T cells) to 4.93 (plasmablasts).
Diagnosis: ISG score differentiated HC from SLE with ratio 3.58 (1.94 – 6.61) and large effect size 0.14 (partial eta squared). Using tetherin for cell specific IFN response revealed marked differences between subsets. Monocytes did not differentiate HC and SLE at all with ratio 1.19 (0.87 – 1.61) and effect size 0.03. Memory B cells had medium-large effect size of 0.11 with ratio 1.59 (1.21 – 2.09). Comparing SLE and RA the largest effect size was for plasmablast Tetherin at plasmablasts at 0.23, with ratio 2.20 (1.66 – 2.93).
Disease activity: ISG score was associated with cutaneous disease activity (BILAG A/B) but not musculoskeletal (Fig 1). Monocyte tetherin was associated with musculoskeletal disease activity but not cutaneous. Memory B cell tetherin was associated with disease activity in both these organs. Memory B cell tetherin was increased with renal (p=0.005) or haematological (p=0.005) activity with no differences in ISG score for these domains (p=0.152, p=0.989 respectively).
Plasmablast numbers after rituximab were associated with Memory B cell tetherin (R=0.38, p=0.047) but not ISG score (R=0.24, p=0.219).

Conclusions: ISG expression in unsorted blood is influenced by IFN-g and cellular composition of the sample as well as IFN-I. Flow cytometric measurement of surface tetherin is a cell-specific assay for IFN-I that avoids these problems. Memory B cell tetherin was better associated with plasmablast numbers and clinical features of disease than monocyte tetherin or ISG score.

Vasculitis

THU0294 DIFFERENTIAL PATTERNS OF ATROPHY IN HIPPOCAMPUS AND BRAINSTEM BETWEEN CHRONIC PROGRESSIVE NEURO-BEHCET'S DISEASE AND ALZHEIMER'S DISEASE

H. Kikuchi[1], K. Asako[1], T. Yanagida[1], H. Kono[1], S. Hirohata[2]. [1]*Department of Internal Medicine, Teikyo University School of Medicine, Tokyo;* [2]*Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Kanagawa, Japan*

Background: Central nervous system involvement is one of the most serious complications in Behçet's disease (BD). This condition is referred to as neuro-Behçet's disease (NB) and can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical course and responses to corticosteroid treatment. Cerebellar ataxia, such as gait disturbances and dysarthria, is one of the representative manifestations in CPNB. Accordingly, brainstem atrophy is frequently observed in CPNB, but not in ANB. Notably, progressive neurobehavioral changes mimicking those in Alzheimer's disease (AD) are also frequently observed in CPNB, but these changes cannot be accounted for by brainstem atrophy.

Objectives: In the present study, volumes of the hippocampus were examined to identify the responsible lesions for neurobehavioral changes in CPNB, and patterns of atrophy in the hippocampus and brainstem were compared between patients with CPNB and AD.
Methods: The subjects were 32 patients, including 13 with CPNB (11 males and 2 females, age 51.2±12.1 years old [mean ± SD]), 13 with Behçet's disease without NB (non-NB) (10 males and 3 females, age 54.4±11.4 years old), and 6 with AD (5 males and 1 female, age 78.8±7.5 years old). All patients with BD satisfied the international classification criteria for BD. CPNB was defined as intractable, slowly progressive neurobehavioral changes and/or cerebellar ataxia accompanied by persistent elevation of interleukin-6 of >20 pg/mL in cerebrospinal fluid on two different occasions at an interval of at least 2 weeks. All patients with AD satisfied Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV criteria. Brain magnetic resonance imaging (MRI) was obtained from each subject. The areas of the midbrain tegmentum and pons were measured on mid-sagittal sections of T1-weighted images using image analysis software (Image J ver.1.45: NIH, USA). Severity of gray matter loss in the hippocampal region and whole brain were investigated using Voxel-Based Specific Regional Analysis System for Alzheimer's Disease (VSRAD) software (Eisai Co., Ltd) to determine the degrees of hippocampal region atrophy (Z score) and whole-brain atrophy (WBAI). Thus, the 1/Z score is positively correlated with the hippocampus volume. The ratio of the degree of brainstem atrophy to that of hippocampal atrophy was evaluated by the brainstem area value divided by the 1/Z score (BA/H score) in each patient.
Results: The brainstem area was significantly decreased in CPNB (461.8±87.3 [mean ± SD]) compared with that in AD (661.9±56.1) and non-NB (666.1±50.6) (Figure A). VSRAD analysis showed that Z score was significantly increased in CPNB (1.46±0.70) and AD (3.13±1.21) compared with that in non-NB (0.77±0.40) (Figure B). Of note, the BA/H score, reflecting the brainstem/hippocampus volume ratio, was much lower in CPNB than in AD [663.5±311.8 vs 2018±667.6, p=0.001] (Figure C).

Conclusions: These results indicate that the hippocampus, in addition to the brainstem, is a common target lesion in CPNB, and this accounts for the progressive neurobehavioral dysfunction in this disease. Moreover, the data emphasize that brainstem atrophy is disproportionately greater than hippocampal atrophy in CPNB, in contrast to AD.

THU0295 CLINICAL FEATURES OF TAKAYASU'S ARTERITIS FROM AN INCEPTION COHORT: EARLY DISEASE IS CHARACTERIZED BY "SYSTEMIC INFLAMMATION"

F. Alibaz-Oner on behalf of Turkish Takayasu Arteritis Study Group.
Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

Background: There is only retrospective and very limited data for the long term prognosis of Takayasu's Arteritis (TAK), a rare large-vessel vasculitis. In this study, we aimed to present the preliminary results of a Takayasu Inception Cohort settled for long term, prospective follow-up of only newly-diagnosed patients with TAK.
Methods: Patients fullfilling the American College of Rheumatology 1990 criteria for TAK and diagnosed in the last 12 months were included to the study. Patients' data were recorded in an electronic database of an international "Takayasu's Arteritis Registry" requiring baseline and at least annual visits. Data is compared with an historical Turkish cohort previously published (Bıçakçıgil, et al, 2009).
Results: The study included 128 patients (age: 38.9±13.1 years, F/M: 112/16) with TAK from 15 tertiary Rheumatology centers in Turkey. The mean symptom duration of patients was 5.2 years at diagnosis. According to the angiographic classification, 59.2% of the study group had type I and only 17.2% had type V disease. When we compared our results to our retrospective cohort (previously published by Turkish Takayasu Arteritis Study Group), constitutional symptoms (72.2% vs 66%) and limb claudication (62.3% vs 48%) were observed to be more frequent, whereas pulselessness (35.6% vs 88%) was less in the inception cohort.(Table 1) Carotidynia was present only in the inception cohort. Similarly, mucocutaneous symptoms also seem to be a feature of newly-diagnosed disease (26.4% vs 8.8%). Regarding comorbidities at diagnosis, the rate of dyslipidemia was 22%, diabetes mellitus 6%, smoking 28.5% and obesity (BMI>30) 15.8% among TAK patients. All patients were given oral corticosteroid (CS) therapy (0.5–1 mg/kg) at diagnosis, 10 patients (7.8%) also having CS pulses. In addition to CSs, 55 patients (43%) were given methotrexate, 14 patients (11%) azathioprine and 5 (4%) cyclophosphomide at disease-onset.

Table 1. Clinical characteristics of Inception and Retrospective Cohorts from Turkey

	Inception Cohort (n=128)	Retrospective Cohort (Bıçakçıgil et al.) (n=248)
Constitutional symptoms	91/126 (72.2%)	163/248/ (66%)
Limb claudication	66/106 (62.3%)	119/248 (48%)
Carotidynia	26/104 (25%)	–
Pulseless	37/104 (35.6%)	218/248 (88%)
Musculoskeletal manifestations	66/124 (53.2%)	104/248 (42%)
Mucocutaneous manifestations	32/121 (26.4)	22/248 (8.8%)
Respiratory manifestations	40/122 (32.8%)	22/184 (12%)
Neurologic manifestations	58/124 (46.8%)	156/248 (63%)
Cardiac involvement	23/106 (21.7%)	141/248 (57%)
Ophthalmologic involvement	29/125 (23.2%)	57/248 (36%)

Conclusions: Our results suggest that, in an inception cohort, signs and symptoms of "systemic inflammation" is more prominent in newly-diagnosed TAK patients, whereas vascular extent and damage accumulates during the disease course. The long term follow-up of our inception cohort will better show the actual course and predictors of prognosis in TAK.

THU0296 THE ROLE OF ULTRASOUND IN THE MANAGEMENT OF GIANT CELL ARTERITIS (GCA) IN ROUTINE CLINICAL PRACTICE

S. Monti[1,2], A. Floris[3], C. Ponte[4], S. Vaggers[2], W.A. Schmidt[5], A.P. Diamantopoulos[6], C. Pereira[2], R. Luqmani[2]. *[1]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, Pavia, Italy; [2]NDORMS, Rheumatology Department, Nuffield Orthopaedic Centre, University of Oxford, Oxford, United Kingdom; [3]Rheumatology, University Clinic and AOU of Cagliari, Cagliari, Italy; [4]Rheumatology, Hospital de Santa Maria, Rheumatology research Unit Instituto de Medicina Molecular, Lisbon Academic Medical Centre, Lisbon, Portugal; [5]Rheumatology, Immanuel Krankenhaus Berlin, Medical Centre for Rheumatology Berlin-Bu, Berlin, Germany; [6]Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway*

Background: Colour Doppler sonography (CDS) is an emerging diagnostic tool for giant cell arteritis (GCA), however, its use in routine practice is still not widespread.
Objectives: To develop a protocol using CDS and explore its value in the routine care of patients with GCA.
Methods: We developed a structured scanning protocol for CDS of temporal and axillary arteries (total of 8 anatomical sites scanned per patient) based on previously published methods. We tested the protocol on consecutive patients referred to a single rheumatology centre, with suspected or established GCA, between July 2014 and September 2016. We defined a positive scan by the presence of halo in at least one branch of a temporal artery (TA) or one axillary artery (AX). We report data from the first 293 consecutively scanned cases.
Results: We assessed 293 patients (mean age 72±10, female/male 196/97), of whom 118 had clinically confirmed GCA. Amongst new referrals with confirmed diagnosis of GCA, 44% had a positive scan; two patients with a positive scan did not have GCA. 82% of new referrals patients showed exclusive TA involvement, 25% concomitant AX, and 4% exclusive AX involvement. High-dose glucocorticoid therapy had already been started in 78% of these patients for an average of 17±33 days. Amongst this group, the sensitivity of CDS was 46% (95% IC 37%>55%), specificity 98% (95% CI 93%>99.8%), positive predictive value 96% (88%>99.6%), and negative predictive value 60% (95% IC 52%>68%). During the period of observation, the rate of temporal artery biopsies (TAB) decreased significantly from 42% to 25% (p=0.002). During follow up, CDS was positive in 21% of 89 routine scans in asymptomatic individuals, compared to 58% in patients with confirmed clinical flares (45% of whom had negative inflammatory markers). Over time, the number of halos per patient reduced; only new or flaring patients showed a halo in >4 sites. Halo size at the TA did not change significantly (average thickness 0.6±0.1 mm), however, the size of AX artery halos significantly reduced from first referral (1.6±0.4 mm) to follow up (1.4±0.2, p=0.01) or during subsequent flares (1.4±0.2, p=0.02).
Conclusions: We have developed and tested a standardised methodology for CDS evaluation of GCA. CDS provides a high positive predictive value for a diagnosis of GCA in unselected patients from routine clinical practice, although prior high dose glucocorticoid therapy is likely to reduce its sensitivity. CDS allows for a significant reduction of TAB. We explored the role of CDS to detect disease flares and demonstrated a significant reduction in the extent of abnormalities, and of the size of halo of the AX arteries during follow up or flares. These findings could have a significant impact on the management of patients with suspected and confirmed GCA.

THU0297 A NOVEL ULTRASOUND SCORING SYSTEM FOR GIANT CELL ARTERITIS

S. Monti[1,2], C. Ponte[3], G. Carrara[4], F. Rumi[4], A. Hutchings[5], B. Dasgupta[6], R. Luqmani[1]. *[1]NDORMS, Rheumatology Department, University of Oxford, Oxford, United Kingdom; [2]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, Pavia, Italy; [3]Rheumatology, Hospital de Santa Maria, CHLN, Lisbon, Portugal; [4]Epidemiology Unit, Italian Society of Rheumatology, Milan, Italy; [5]Department of Health Services Research and Policy, London School of Hygiene and Tropical Medicine, London; [6]Rheumatology, Southend University Hospital, NHS Foundation Trust, Westcliff-on-Sea, United Kingdom*

Background: Colour duplex sonography (CDS) can be used for giant cell arteritis (GCA) to detect inflammatory oedema of the vascular wall, known as "halo". A standardized, quantitative score to grade the severity and extension of vascular involvement detected by CDS has not yet been developed.
Objectives: To develop and test different scoring models of CDS findings in patients with new onset GCA, and to correlate the models with final diagnosis, histologic findings, and outcome.
Methods: We selected patients with a positive CDS and a confirmed diagnosis of GCA from the Temporal Artery Biopsy vs Ultrasound in Diagnosis of GCA (TABUL) study (1). We designed CDS models combining different ultrasonographic information based on available evidence, or hypothesized clinical relevance of size, anatomical distribution, and extent of halos, summing up to a final numeric score.
Results: We included 135 GCA patients (male/female: 43/92), age 73.3±8. Fourty four patients (24%) had a positive CDS, but not a final diagnosis of GCA. We designed 8 different CDS models (Figure 1). Models 1, 4, 6, and 7 were significantly associated with a confirmed diagnosis of GCA (Table 2). Model 7 better discriminated patients with GCA from non-GCA: area under the curve (AUC): 0.844 (0.766–0.923). All, except models 5 and 8, correlated with a temporal artery biopsy (TAB) result diagnostic for GCA. Most models correlated with histologic findings involving the media or transmural infiltrate, but not with small vessel or adventitial involvement. None of the models correlated with permanent ischaemic sequelae, however, the low number of events might have affected the results.

Figure 1. Ultrasound scoring models

Model	Scoring formula
Model 1	Sum of sites with halos in TA and AX
Model 2	Defined as either bilateral halo on any TA branches OR bilateral halo on AX
Model 3	(Number of sites with halo on TA * average halo thickness among TA branches) + (number of sites with halo on AX * average halo thickness on AX)
Model 4	(Number of sites with halo on TA * maximum halo thickness among TA branches) + (number of sites with halo on AX * maximum halo thickness among AX)
Model 5	(Average halo thickness among TA + add "1" if bilateral halo on TA) + (average halo thickness among TA + add "1" if bilateral halo on AX)
Model 6	(Maximum halo thickness among TA + add "1" if bilateral halo on TA) + (maximum halo thickness among AX + add "1" if bilateral halo on AX)
Model 7	(Maximum thickness among TA * 2 if bilateral) + (maximum halo thickness among AX * 2 if bilateral)
Model 8	(Average thickness among TA * 2 if bilateral) + (average halo thickness among AX * 2 if bilateral)

TA: temporal artery; AX: axillary artery; * multiply by.

Conclusions: The CDS findings that better correlate with a diagnosis of GCA, and TAB findings are: the number of positive sites, the size of the halo (maximum, rather than average thickness), and the presence of bilateral halos, variably combined into a unique score. We plan to test these models in a new cohort of patients with suspected GCA, to determine their validity.

THU0298 LONG TERM OUTCOME OF PATIENTS WITH TAKAYASU ARTERITIS- A SINGLE CENTRE STUDY

R. Goel[1], D. Danda[1], G. Joseph[2], A. Nair[1], V. Jayseelan[3], L. Jayaseelan[3], S. Kumar[4], P. Bacon[5]. *[1]Clinical Immunology and Rheumatology; [2]Cardiology; [3]Biostatistics; [4]Child Health, Christian Medical College, Vellore, Tamil Nadu, Vellore, India; [5]School of Immunity and Infection, University of Birmigham, Birmigham, United Kingdom*

Background: Takayasu Arteritis (TA), a large vessel vasculitis is characterised by a variable clinical course and outcome that differs across populations. Most studies are limited by small sample size.
Objectives: (i) To study treatment outcome in our TA patients with a follow up of ≥12 months (ii) Construct a prediction model for subset of patients with sustained inactive disease.
Methods: Consecutive patients with TA attending our clinics between 1998 and April 2016 were recruited. Details of baseline demography, clinical profile, angiography, disease extent using DEI.Tak, laboratory parameters and TADS (Takayasu arteritis damage score) were recorded. At each follow up visit, disease activity was assessed by Indian Takayasu Activity score (ITAS-2010 (CRP) and imaging, while damage was assessed by TADS for patients who followed up for ≥12 months (retrospectively for 179 and prospectively for 72 patients). Treatment response was classified as complete response (CR), partial response and no-response. Sustained inactive disease was defined as maintenance of CR throughout the follow up with steroid dose reduced to ≤5mg/day. Relapse was defined as return of active disease after CR. Statistical analysis was performed using SPSS-16. Intergroup comparisons were performed by nonparametric test. Logistic regression was used for determining independent associations. Optimal cut off values were determined using receiver operating curve and prediction model was constructed. Efficacy of medications was compared by Cox proportional hazards model.
Results: Baseline details were noted for 503 patients: mean age at onset of 25.6±11.1 years, disease duration 12 (6–48) months, diagnostic delay 6 (3–24) months) and 77.9% were females.
Among 251 patients with follow up of at least 12 months, 95.2% received steroids along with II line immunosuppressant in 93.6% (mycophenolate in 63.7%). Tocilizumab was given induction or rescue therapy to 44 patients. Revascularisation procedures were performed in 71.7%. Complete (ITAS 2010 = 0, CRP <6mg/L, angiowise non-progression) and partial response was achieved in 176 patients (70.1%) and 42 (16.7%) respectively within 6 months.
During a median follow up of 42 (IQR: 24–81) months, 116 (46.2%) maintained complete response till their last follow up with cumulative relapse free survival of 83%, 70% and 55% at 1, 2 and 3 years respectively. A model including baseline CRP≤6.1mg/L, type 4 disease and DEI.Tak <9 predicted sustained inactive disease with an AUC of 70.2 (63.3–77.2, p=0.000). Initial steroid dosage of 0.5mg/kgday was similar to 1mg/kg/day in terms of response or relapse. Overall, there were only 15 (5.9%) patients who never responded to treatment. There were 2 fatalities. At the last visit, 176 (70.5%) had stable disease. Damage progression (delta TADS) was lower in patients with sustained inactive disease than the rest, p=0.000.
Conclusions: Medical management arrested disease activity, damage progression and mortality in our cohort. Low baseline CRP and DEI.Tak scores and type 4 disease independently predicted sustained inactive disease.

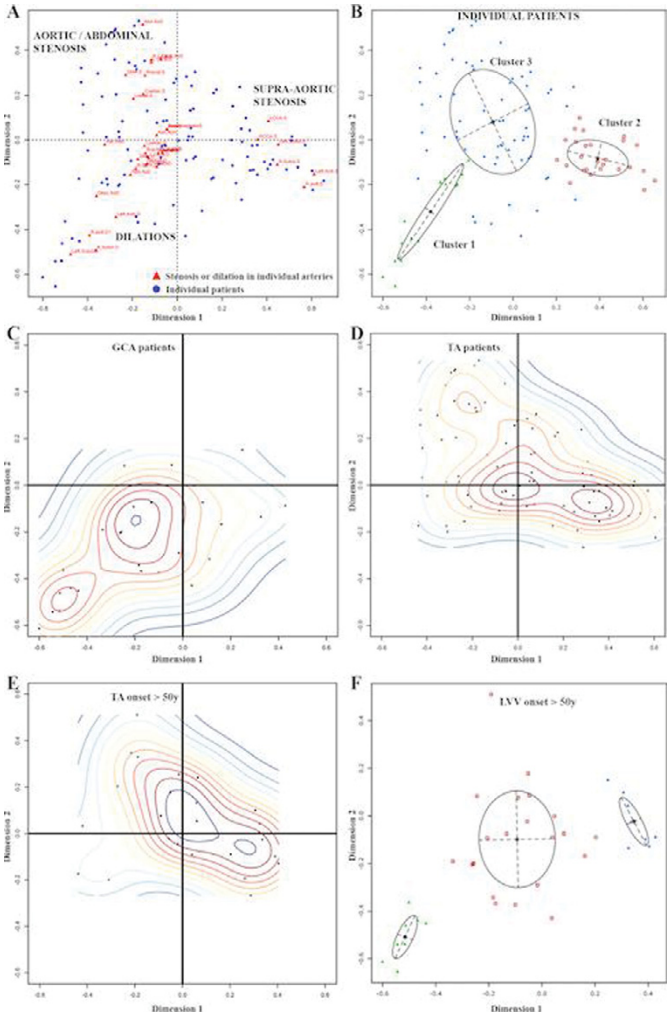
THU0299 UNDERSTANDING THE HETEROGENEITY OF LARGE-VESSEL VASCULITIDES

E. Tombetti[1], A. Ambrosi[2], C. Godi[2], B. Ariff[1], A.A. Manfredi[2], J. Mason[1]. *[1]Imperial College London and Imperial College NHS Trust, London, United Kingdom; [2]San Raffaele Hospital and Vita-Salute University, Milan, Italy*



Background: Adult large-vessel vasculitides (LVV) are rare conditions, currently classified as two different diseases, Takayasu arteritis (TA) and giant cell arteritis (GCA), on an empirical basis. Insight into phenotypic and pathogenic differences between the two is scarce at best. Arterial involvement, despite being the central disease feature, has been poorly addressed by research. We have developed two novel, imaging-based scores (the arteritis stenosis score [ASS] and arteritis dilation score [ADS]). ASS and ADS define stenotic and aneurysmal disease in a

Abstract THU0297 – Table 2. Correlation of the different models with clinical and histologic variables

Comparison between satisfying (1) or not satisfying (0) the considered variable.

core-set of 17 arteries and respectively represent the sum of stenosis and dilation scores in individual arteries[1].
Objectives: To use ASS, ADS and the stenosis and dilation scores of individual arteries to describe a cohort of LVV patients and identify heterogeneity between patients.
Methods: The ASS, ADS and individual artery scores have been derived from 110 LVV (81 TA, 29 GCA) patients. Model-based clustering optimising the Bayesian Information Criterion and principal component analysis were performed.
Results: Arterial involvement was shown to be differed in GCA and TA: TA has higher ASS than GCA (median, IQR: 20, 11–29 Vs 5, 0–11; $p<0.001$) and lower ADS (0, 0–5 Vs 6, 0–13; $p=0.019$). The scatterplot of ASS and ADS revealed incomplete overlap of arterial involvement in GCA and TA. No differences were seen in TA with disease onset before or after 40 yrs. Age at onset, ASS and ADS did not correlate in TA, suggesting stenotic and aneurysmal arterial remodelling are independent. In GCA, ASS and ADS were negatively correlated ($\rho=-0.401$; $p=0.031$) and ADS correlated with age at onset ($\rho=0.383$; $p=0.040$), suggesting the existence of a biologic "switch" between arterial stenosis and dilation, regulated by age at onset.
We accounted for geographical distribution of lesions by evaluating the scores of individual arteries with correspondence analysis. Arterial involvement was symmetric with tripolar segregation: stenosis in the supra-aortic branches, stenosis in the aorto-abdominal district and arterial dilation (Fig 1A). When patients exhibited the first two components, three different clusters were recognised (Fig 1B), with different ASS, ADS and damage as assessed by the TA damage score ($p<0.001$ for all tests). 27/29 (93%) of GCA patients were included in cluster 1 and 3, while 77/81 (95%) of TA clustered in 2 and 3. Of interest, density graphs showed (i) a different distribution of arterial involvement in GCA and TA (Fig 1C-D), and (ii) potential for identification of novel disease subsets (2 in GCA and 3 in TA). A comparable distribution was seen in TA with onset before or after 40 yrs (Fig 1E). Lastly, when patients with disease onset after 50 yrs (11 TA, 28 GCA) were studied, a trimodal distribution was observed, suggesting discrete phenotypes of arterial involvement exist, rather than a continuum (Fig 1F).

Conclusions: Arterial involvement differs in TA and GCA, although some overlap exists. Elderly TA is similar to juvenile TA, while a potential biologic "switch", yet to be identified, regulating the final outcome of arterial remodelling and influenced by ageing, is present in GCA. Three main patterns of arterial involvement appear to exist. LVVs represent the composition of different discrete subsets rather than a phenotypic continuum.

THU0300 CENTRAL NERVOUS SYSTEM INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS (WEGENER) IN A LARGE SERIES OF PATIENTS WITH ANCA-ASSOCIATED VASCULITIDES (AAV).REVAS STUDY-GEAS-SEMI

R. Solans-Laqué[1], M. Rodriguez-Carballeira[2], M. Castillo[3], G. Fraile[4], J. Rios[5], X. Solanich[6], F. Martinez-Valle[1], L. Saez[7], F. Pasquau[8], E. Fonseca[9] on behalf of REVAS Study group. *[1]Internal Medicine, Vall Hebron University Hospital, Barcelona; [2]Internal Medicine, Mutua Hospital, Terrassa; [3]Internal Medicine, Virgen Rocio Hospital, Sevilla; [4]Internal Medicine, Ramon y Cajal Hospital; [5]Internal Medicine, la Paz University Hospital, Madrid; [6]Internal Medicine, Bellvitge University Hospital, Hospitalet; [7]Internal Medicine, Miguel Servet University Hospital, Zaragoza; [8]Internal Medicine, Marina Baixa Hospital, Alicante; [9]Internal Medicine, Cabueñes Hospital, Gijon, Spain*

Background: GPA is a necrotizing systemic vasculitis that usually involves ENT, lung and kidneys. Neurological manifestations appear in 25–50% of patients, usually involving peripheral nervous system. CNS involvement, has been reported in only 7–11% of cases
Objectives: to describe the clinical features and outcome of patients with GPA and CNS involvement in a large series of patients with AAV
Methods: multicenter retrospective-longitudinal study that encompassed patients diagnosed with AAV between Jan 1995 and Nov 2014 in 21 Centres from Spain (REVAS Study). Statistical anlysis was performed using SSPS vs20 package
Results: 455 patients (188 GPA, 167 MPA and 100 EGPA) were included. Mean age at diagnosis was 55.7±17.2y. ANCA were positive in 86.8% of cases (35.8% C-ANCA, 51% P-ANCA). Median time to diagnosis was 4 weeks (IQR 10). Median follow-up time was 80 months (IQR 105). Neurological involvement was documented in 156 (34.5%) patients, but only 33 (7.3%) presented CNS involvement at disease onset. From those patients, 20 (60.6%) had GPA. Mean age at diagnosis of patients with GPA and CNS involvement was 51.1±16.7y. ANCA were positive in all cases (15 C-ANCA-PR3, 5 P-ANCA-MPO). Headache was the main neurological symptom (60%) followed by sensory (45%) and motor impairment (35%). MRI and/or angio-CT scan were performed in all cases. Cerebral ischaemic lesions were observed in 10 patients, and granulomatous lesions in 9, including pachymeningitis (n=6), spinal cord pachymeningitis (n=2) and isolated granulomatous lesions (n=1). Lumbar puncture was performed in 8 (40%) patients and revealed CSF abnormalities in 70. Diagnosis was confirmed by meningeal biopsy (n=2), ENT biopsies (n=5) and renal biopsy (n=2) in patients with CNS granulomatous lesions, and by renal, pulmonary or peripheral nerve biopsy in patients with CNS ischemic lesions. Headache was predominant in patients with granulomatous lesions, while sensory and motor impairment were predominant in patients with ischemic lesions. Mean BVAS at disease onset was 29.2±9.7, significantly higher than in GPA total cohort (18.2±9.2). Renal involvement was more common in patients with ischaemic lesions than in those with granulomatous (80% vs. 40%, $p<0.001$), and ENT involvement in patients with granulomatous forms (70% vs. 50%, $p<0.005$). Most patients (70%) received oral CF for induction therapy. Two patients received rituximab. For maintenance therapy, 25% of patients received AZA, 20% MMF and the remaining CF. 70% of patients received TM-SX. During follow-up, 58.8% and 40% of patients developed bacterial and opportunistic infections, respectively. Infections were related to oral CF therapy ($p=0.029$). Long-term neurological sequelae were noted in patients with ischaemic lesions (40%) and spinal cord pachymeningitis (100%)
Conclusions: Patients with GPA and CNS involvement have more severe disease at presentation and more treatment-related side effects than patients without CNS involvement. Long-term neurological sequelae are more frequent in patients with ischaemic lesions and spinal cord pachymeningitis

THU0301 SAFETY FOLLOWING INITIATION OF RITUXIMAB IN GRANULOMATOSIS WITH POLYANGIITIS (GPA) OR MICROSCOPIC POLYANGIITIS (MPA): INTERIM ANALYSIS OF THE RITUXIMAB IN ANCA-ASSOCIATED VASCULITIS REGISTRY (RAVER)

J. Niles[1], N. Allen[2], J.A. Block[3], C.L. Koening[4], C.A. Langford[5], A. Abril[6], A.S. Lee[6], P.A. Merkel[7], L.E. Mertz[8], P.A. Monach[9], L.W. Moreland[10], P.H. Nachman[11], T. Peikert[8], R.F. Spiera[12], D. Wallace[13], F. Erblang[14], M.D. Cascino[15], P. Duncombe[16], V. Malik[14], P. Brunetta[15]. *[1]Massachusetts General Hospital, Boston, MA; [2]Duke University Medical Center, Durham, NC; [3]Rush University Medical Center, Chicago, IL; [4]University of Utah, Salt Lake City, UT; [5]Cleveland Clinic Foundation, Cleveland, OH; [6]Mayo Clinic, Jacksonville, FL; [7]University of Pennsylvania, Philadelphia, PA; [8]Mayo Clinic, Rochester, MN; [9]Boston Medical Center, Boston, MA; [10]University of Pittsburgh School of Medicine, Pittsburgh, PA; [11]University of North Carolina, Chapel Hill, NC; [12]Hospital for Special Surgery, New York, NY; [13]Wallace Rheumatic Disease Research Center, Los Angeles, CA, United States; [14]F. Hoffmann La-Roche, Ltd., Basel, Switzerland; [15]Genentech, Inc., South San Francisco, CA, United States; [16]prn Statistical Consulting Services, Ltd., Ely, United Kingdom*

Background: Therapy-related serious adverse events (SAEs) are important causes of morbidity in patients with GPA or MPA. Long-term safety data of rituximab in GPA/MPA are limited.
Objectives: To characterize safety events in an observational registry of patients with GPA/MPA initiating rituximab.
Methods: This interim analysis of RaVeR, an ongoing open-label real-world study of adult patients with GPA or MPA initiating rituximab (dose/frequency determined by investigator), was conducted when 50% of patient-years (PY) were collected (July 2015). Safety events included serious infections (SI), infusion-related reactions (IRR), serious cardiac events, malignancies, and other serious events. Crude incidence rates (IR) and 95% CI were calculated. Trial registration number: NCT01613599
Results: 97 patients (291 PY) received rituximab, of whom 70% received rituximab retreatment. Median follow-up was 2.4 years. Overall, 91% of patients were ANCA-positive and 78% had GPA. 17 patients (17.5%) had a history of plasmapheresis or dialysis; 20 (20.6%) were receiving rituximab plus cyclophosphamide at baseline. 33 patients had 71 SAEs (32.4/100 PYs [95% CI: 25.32–40.89]). 11 patients had 20 SIs (9.13/100 PYs [95% CI: 5.58–14.10]). 9 patients (9.3%) experienced 13 serious cardiovascular (CV) events (5.93/100 PYs [95% CI: 3.16–10.15]), 12 of which were reported as unrelated to rituximab. Of the 13 CV events, 9 were atrial arrhythmias and most patients had associated renal or CV disease history. There were no serious IRRs or SAEs within 24 hours of rituximab infusion. There were 6 deaths (2.74/100 PYs [95% CI: 1.01–5.96]); causes of death included septic shock, interstitial lung disease, congestive heart failure, cardio-respiratory arrest and 2 deaths of unknown etiology. The severe disease flare rate was 5.94/100 PYs (95% CI: 3.16–10.15). Among patients who received rituximab retreatment, the IRs of SAEs (26.1/100 PYs) and SIs (7.29/100 PYs) were not increased compared with the overall cohort.

Table. Observed safety events of interest

	Number of events	IR per 100 PY (95% CI)
All SAEs	71 in 33 pts (34%)	32.42 (25.3 to 40.9)
Serious infections	20 in 11 pts (11%)	9.13 (5.58 to 14.1)
Serious cardiac events	13 in 9 pts (9%)	5.93 (3.16 to 10.15)
Serious vascular events	6 in 5 pts (5%)	2.74 (1.01 to 5.96)
Malignancies	2 in 2 pts (2%)	0.91 (0.11 to 3.30)

IR, incidence rate; PY, patient-year; SAE, serious adverse event.

Conclusions: In this interim analysis of patients with GPA/MPA treated with rituximab, SAEs were not increased compared with comparable cohorts of patients with renal involvement. Safety events did not increase with rituximab retreatment. These results are consistent with the known safety profile of rituximab and provide preliminary long-term, practice-level safety data for rituximab in GPA/MPA.

THU0302 HISTOLOGY FINDINGS IN GIANT CELL ARTERITIS (GCA) AND THEIR RELATIONSHIP WITH THE ULTRASOUND RESULTS: ANALYSIS OF DATA FROM THE TABUL STUDY (TEMPORAL ARTERY BIOPSY VS ULTRASOUND IN DIAGNOSIS OF GIANT CELL ARTERITIS)

C.B. Ponte[1,2], S. Monti[3], S. Singh[4], A. Hutchings[5], A. Diamantopoulos[6], B. Dasgupta[7], W.A. Schmidt[8], R.A. Luqmani[9]. *[1]Department of Rheumatology, Hospital de Santa Maria; [2]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [3]Department of Rheumatology, IRCCS Policlinico S. Matteo Foundation, University of Pavia, Pavia, Italy; [4]Nuffield Department of Surgical Sciences, University of Oxford, Oxford; [5]Department of Health Services Research and Policy, London School of Hygiene and Tropical Medicine, London, United Kingdom; [6]Department of Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway; [7]Department of Rheumatology, Southend University Hospital, NHS Foundation Trust, Southend-on-Sea, United Kingdom; [8]Department of Rheumatology, Immanuel Krankenhaus Berlin, Medical Centre for Rheumatology Berlin-Buch, Berlin, Germany; [9]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

Background: Although temporal artery biopsy (TAB) has been the gold standard for diagnosis of GCA, ultrasound has superior sensitivity but lower specificity. Occasionally, histological evidence of inflammation is restricted to the *vasa vasorum*, the periadventitial small vessels, or both, which could limit the diagnostic sensitivity of ultrasound for GCA. Moreover, false positive ultrasound results have been described in patients with arteriosclerosis on histology.
Objectives: To compare histologic findings with ultrasound results from patients with suspected GCA included in the TABUL study (a multinational study to assess the relative performance of ultrasound and TAB for diagnosing GCA).
Methods: All patients with newly suspected GCA underwent an ultrasound of both temporal and axillary arteries, followed by a TAB, within 7 days of commencing glucocorticoid therapy. TAB pathological diagnoses were analysed and the different histologic features were compared with the ultrasound results using Chi-square or Fisher exact tests.
Results: Results for TAB and ultrasound were available in 388 patients (69% with a final clinician's diagnosis of GCA). An artery was definitely obtained in 363 (94%) TABs; the pathological diagnosis was GCA in 104 (29%) cases, arteriosclerosis in 35 (10%), normal in 203 (56%) and other conditions in 21 (6%). All TABs compatible with GCA also had a final clinician's diagnosis of GCA (73% with positive ultrasound). Table 1 shows that ultrasound positivity occurred more frequently in patients where the media was the predominant site of inflammation (p=0.01). The ultrasound result was positive in 9 (26%) cases where TAB was consistent with arteriosclerosis, 8 (89%) of whom had a final clinician's diagnosis of GCA. The ultrasound was positive in 64 (32%) cases where TAB was normal, 52 (81%) of whom had a final clinician's diagnosis of GCA.

Table 1: Relationship between the histologic features of patients with a TAB diagnosis of GCA and ultrasound results

Histologic features (n patients)	Ultrasound positive (n=76)	Ultrasound negative (n=28)	*p value*
Predominant site of inflammatory cellular infiltrate			
Predominant intima infiltrate (n=8)	7 (87.5%)	1 (12.5%)	*0.679*
Predominant IEL infiltrate (n=13)	10 (76.9%)	3 (23.1%)	*1.000*
Predominant media infiltrate (n=21)	20 (95.2%)	1 (4.8%)	*0.010*
Predominant adventitia infiltrate (n=19)	11 (57.9%)	8 (42.1%)	*0.099*
Predominant *vasa vasorum* infiltrate (n=4)	2 (50%)	2 (50%)	*0.293*
Predominant transmural infiltrate (n=39)	26 (66.7%)	13 (33.3%)	*0.254*
Histologic specific findings			
Presence of giant cells (n=74)	58 (78.4%)	16 (21.6%)	*0.056*
Presence of vessel complete occlusion (n=24)	17 (70.8%)	7 (29.2%)	*0.778*
Presence of IEL fragmentation (n=86)	61 (70.9%)	25 (30.1%)	*0.386*
Presence of intimal hyperplasia (n=91)	65 (71.4%)	26 (28.6%)	*0.506*

TAB = temporal artery biopsy; IEL= internal elastic lamina

Conclusions: Amongst patients with suspected GCA, ultrasound is more likely to be positive when histological inflammation is predominantly present in the intima-media. No significant correlation between histologic findings and negative ultrasound results was found, but the small number of cases with predominant *vasa vasorum* infiltrates in our cohort limited this analysis. There was only one false positive ultrasound in patients with arteriosclerosis on TAB.

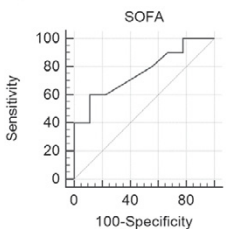
THU0303 CLINICAL FEATURES AND PROGNOSIS OF ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT AT DIAGNOSIS

S. Fukui, N. Iwamoto, T. Shimizu, M. Umeda, A. Nishino, T. Koga, S.-Y. Kawashiri, Y. Hirai, K. Ichinose, M. Tamai, H. Nakamura, T. Origuchi, A. Kawakami. *Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

Background: Kidneys are major organs targeted by antineutrophilic cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Clinical manifestations, laboratory data, and prognosis of AAV with renal involvement at diagnosis are not elucidated.



Objectives: We compared clinical features of AAV with renal involvement with patients without renal involvement.
Methods: We conducted an observational study of 104 patients with AAV (12 eosinophilic granulomatosis with polyangiitis, 23 granulomatosis with polyangiitis (GPA), 66 microscopic polyangiitis, 3 renal limited vasculitis) between in 2008 to 2016 in Nagasaki University Hospital. Using medical records, we analyzed the patients' baseline variables, laboratory data, clinical symptoms, and therapeutic outcomes after treatments including episodes of relapses, initiations of dialysis, and death. Renal involvement was defined as the state with estimated glomerular filtration rate <60 mL/min/1.73 m^2 or microscopic hematuria (2+ or greater) which were not caused by renal diseases except for AAV.
Results: Sixty-nine patients had renal involvement. Patients with renal involvement group had higher median age at diagnosis than patients without renal involvement group (75 years vs. 66 years, $p<0.001$). Patients with renal involvement included fewer GPA patients compared to other AAV types. Patients with renal involvement had lower hemoglobin levels (10.3 g/dL vs. 12.3 g/dL) and lower platelet levels ($23.7x10^4/\mu L$ vs. $28.7x10^4/\mu L$). Patients with renal involvement had higher erythrocyte sedimentation rate (78mm/h vs. 20mm/h), MPO-ANCA titers (116 U/mL vs. 58 U/mL) and urine protein levels (0.81 g/gCr vs. 0.15 g/gCr). Patients with renal involvement had lower C3 levels, but CH50 and C4 levels did not differ between in two groups. There were no differences in treatments including doses of prednisolone and use of methylprednisolone pulse and cyclophosphamide between in two groups. Multivariable regression analysis revealed that age at diagnosis is the most significant explanatory variable to renal involvement. Nineteen percent of patients with renal involvement had initiations of dialysis. Multivariable analysis demonstrated estimated glomerular filtration rate at diagnosis is the most significant explanatory variable to initiations of dialysis (p=0.010). Receiver operating characteristic curve showed the cutoff level of estimated glomerular filtration rate to distinguish initiations of dialysis was 37mL/min/1.73 m^2 (sensitivity=79%, specificity=70%, area under the curve=0.80). Assessed by a log-rank test, overall survival rate did not differ between in two groups (p=0.29).
Conclusions: Patients with renal involvement had higher age at diagnosis. Patients with renal involvement included fewer GPA patients. Patients with renal involvement had lower C3 levels. Estimated glomerular filtration rate at diagnosis is the most significant explanatory variable to initiations of dialysis.

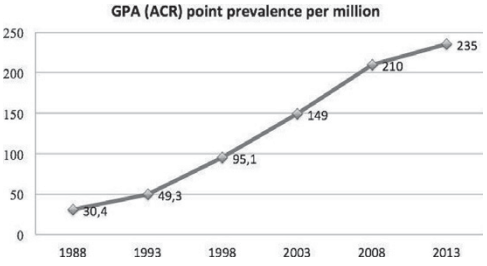
THU0304 VASCULITIS PATIENTS ADMITTED TO INTENSIVE CARE UNIT: IMPLICATIONS FROM A SINGLE-CENTER RETROSPECTIVE STUDY

A. Watad[1], O. Shovman[2], N.L. Bragazzi[3], Y. Shoenfeld[4], H. Amital[5], Y. Haviv[6]. *[1]Internal Medicine B; [2]Department B, Sheba Medical Center, Tel Aviv, Israel; [3]Department of Health Sciences, Genova university, Genoa, Italy; [4]Zabludowicz center for Autoimmune Diseases; [5]Sheba Medical Center, Tel Aviv, Israel; [6]Department of General Intensive Care, Sheba Medical Center, Tel Aviv, Israel*

Background: Vasculitides are a heterogeneous group of disorders that are characterized by the inflammation of the vasculature vessels. Vasculitides may present as a life-threatening condition and cause higher rates of morbidity and mortality. There are few studies assessing the outcome and prognosis of patients with vasculitides admitted to the intensive care (ICU).
Objectives: To assess the outcome of vasculitides patients required admission to ICU and to identify factors associated with mortality
Methods: A retrospective study was carried out, including all patients who were diagnosed with vasculitides and admitted to the ICU of the Sheba Medical Center, Tel-Hashomer, throughout the years 2000–2014. Continuous variables were computed as mean±standard deviation, whilst categorical variables were recorded as percentages, where appropriate. Student's t-test and chi-squared analyses were performed for investigating the impact of the clinical variables on mortality.
Results: Twenty-five vasculitides patients admitted to the ICU were included in the present study (mean age 52±14y, sex ratio M/F: 12/13). The mortality rate among these patients was 48%. Leading causes for ICU admission were: infection (64%), vasculitides exacerbation (34%), and hemorrhage (16%). Variables significantly associated with mortality were: the use of Rituximab prior to admission ICU (p=0.039), involvement of the hemodynamic system (p=0.024), the SOFA score (p=0.041), blood infections during the first week at ICU (p=0.018) and persisting after the first week (p=0.007).

Figure 1. Receiver Operating Characteristic (ROC) analysis of the predictive power of the Sequential Organ Failure Assessment (SOFA) score, in predicting the mortality of vasculitis patients admitted at intensity care unit (ICU), in terms of sensitivity and specificity.



Conclusions: Our study confirms the high mortality rate among vasculitides patients and mainly among those requiring admission to ICU. SOFA score and pre-admission treatment with rituximab have been found to be predictive of mortality.

THU0305 EPIDEMIOLOGY OF ANCA-ASSOCIATED VASCULITIS IN NORTHERN NORWAY

A.T. Nilsen[1], R.A. Watts[2], W. Koldingsnes[1]. *[1]Department of Rheumatology, University Hospital of North Norway, Tromsø, Norway; [2]Norwich Medical School, University of East Anglia, Norwich, United Kingdom*

Background: The ANCA-associated vasculitides (AAV) have increased in prevalence since the 1980s, with granulomatosis with polyangiitis (GPA) being most prevalent in Caucasian population in circumpolar areas. This was also shown in a study on GPA in northern Norway between 1984 and 1998, which further showed an increasing incidence [1].
Objectives: The present study aimed to investigate the subsequent 15-year period in the same region, now including all the AAVs.
Methods: The study area has 11 hospitals, no private specialist in rheumatology or nephrology, and an adult population of 371 928. We retrospectively searched all hospital databases, using ICD-10 codes potentially compatible with AAV. Patients diagnosed with AAV from 1999 through 2013 according to the European Medicines Agency (EMEA) algorithm, and for GPA also the subgroup fulfilling the American College of Rheumatology (ACR) 1990 criteria, were included. For prevalence data, patients residing in the area, but with AAV diagnosis prior to 1999, were included too.
Results: Using the EMEA algorithm, 90 incident cases were classified as GPA, 39 as microscopic polyangiitis (MPA) and 14 as eosinophilic granulomatosis with polyangiitis (EGPA). Within the GPA group, 78 patients also met the ACR criteria. The results for incidence and prevalence are given in Table 1:

		Annual incidence/million				Point prevalence at 31. Dec		
		1999–2003	2004–2008	2009–2013	Total period	2003	2008	2013
ACR	GPA	11,4	16,7	12,5	13,6	149	210	235
EMEA	GPA	11,4	19,9	15,7	15,8	149	226	261
EMEA	MPA	2,7	6,5	11,0	6,8	10,8	31,9	63,3
EMEA	EGPA	2,7	2,7	1,6	2,3	13,5	18,6	30,4
EMEA	All AAV	16,8	29,0	28,2	24,9	173	276	354

Conclusions: The GPA incidence and prevalence in this study are the highest reported. Though the incidence has stabilized, prevalence is still increasing, albeit at a decelerating rate (Graph 1). Moreover, the total AAV prevalence doubled in the last 10 years, exceeding previous estimates. Incidence of MPA and EGPA are both within the range found elsewhere. But the MPA incidence appears to be rising reminiscent of GPA before the turn of the century.

THU0306 PREVALENCE AND CHARACTERISTICS OF NEUROPATHY IN PATIENTS WITH ANCA ASSOCIATED VASCULITIDES: DATA FROM THE DCVAS STUDY

A. Bischof[1,2,3], V.K. Jaeger[4], M.P. Collins[5], R.D.M. Hadden[6], R. Luqmani[7], R. Suppiah[8], A. Craven[7], T. Daikeler[9]. *[1]Neurology, University of California San Francisco, San Francisco, United States; [2]Neurology, University Hospital Basel, Switzerland; [3]Immunology Clinic; [4]Rheumatology, University Hospital Basel, Basel, Switzerland; [5]Neurology, Medical College of Wisconsin, Milwaukee, United States; [6]Neurology, King's College Hospital, London; [7]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; [8]Rheumatology, Auckland District Health Board, Auckland, New Zealand; [9]Rheumatology, University Hospital Basel, Switzerland, Basel, Switzerland*

Background: Epidemiological data on vasculitic neuropathy (VN) in ANCA associated vasculitides (AAV) are scarce and controversial. The Diagnostic and

Classification Criteria for Primary Systemic Vasculitis (DCVAS) study is a large multinational, observational case control study collecting detailed data from patients with primary vasculitides at inclusion.
Objectives: To describe the prevalence, associations with other disease characteristics and patterns of VN in patients with AAV at initial presentation.
Methods: Patients included in the DCVAS study and having completed 6 months follow-up until December 2016 were screened. All patients with a diagnosis of AAV confirmed by an independent expert team were included. VN was diagnosed by clinical features, neurophysiology and/or nerve biopsy. AAV organ manifestations were identified by described symptoms or by the items from the vasculitis damage index. Laboratory parameters and histology were retrieved from the database. Data were analysed descriptively.
Results: By Dec 2016, 1268 patients with a physician submitted diagnosis of AAV had their case summaries reviewed by an expert panel and the diagnosis of AAV confirmed in 839. 484 (58%) had GPA, 195 (24%) MPA, 150 (18%) EGPA and 10 (1.2%) an unclassified AAV. Of these patients, 247 (29.4%) had findings compatible with VN. Mean age in patients with and without VN was 58.7 (SD 15) and 55.4 (SD 17) years, respectively. 133 (53.9%) of patients with VN and 289 (48.8%) without VN were female. VN was diagnosed by biopsy in 5.7%, by the presence of mononeuritis multiplex in 10.1% and by the description of new onset peripheral neuropathy in the context of AAV in 84.2%. Frequency of VN was 19.4% in GPA, 24.1% in MPA and 68.0% in EGPA. 5.6% of patients had motor, 27.9% sensory, 36.4% had sensorimotor neuropathy, and 7.4% had neuropathy exclusively documented on VDI. VN was associated with older age (p=0.008), the presence of MPO-ANCA (p=0.005), skin ($p \leq 0.001$), musculoskeletal ($p \leq 0.001$), cardiac (p=0.001) and multiorgan (>5 organs) involvement (p=0.05) and with the absence of renal (p=0.002), gastrointestinal (p=0.03) and eye involvement ($p \leq 0.001$).
Conclusions: VN has a high prevalence in patients with AAV. In EGPA, more than half of the patients suffered from peripheral nerve involvement. A typical clinical scenario (e.g. older age, MPO positivity, skin and joint/muscle involvement) may help to identify patients at risk of neuropathy. DCVAS was not primarily designed to assess VN, therefore these data should be interpreted with caution.

THU0307 NMR-BASED SERUM METABOLOMICS OF PATIENTS WITH TAKAYASU ARTERITIS (TA): RELATIONSHIP WITH DISEASE ACTIVITY

A. Jain[1], D. Kumar[2], R. Misra[1], P.A. Bacon[3], A. Guleria[4], D.P. Misra[4], S. Singh[4], D. Dubey[4], S. Chaurasia[4], S. Kumar[4], U. Kumar[4], S.K. Mishra[4], A. Zanwar[4], A. Rawat[4]. *[1]Clinical Immunology, SGPGIMS; [2]CBMR, Lucknow, India; [3]Department of Rheumatology, Birmingham, United Kingdom; [4]Affiliation not provided*

Background: Takayasu arteritis (TA) is a chronic large vessel vasculitis of unknown etiopathogenesis. The serological and radiological parameters currently used to assess the disease activity are not highly specific and there is a pertinent need for a biomarker discovery. In our previous study [1], NMR based serum metabolomics had revealed distinctive metabolic signatures in patients with TA compared to age/sex matched healthy controls. In this study we sought to investigate whether these distinctive metabolites correlate with disease activity.
Objectives: To identify the discriminatory serum metabolic profiles and their correlation with disease activity.
Methods: Patients with TA fulfilling ACR criteria were assessed for disease activity by ITAS 2010, with a score of 4 or more, considered as active. The serum metabolic profiles of active and inactive TA patients were obtained at 800 MHZ NMR spectrometer and were compared using multivariate orthogonal partial least-squares discriminant analysis (OPLS-DA) to identify metabolites that changed in response to disease activity [based on PLS-DA VIP (variable importance on projection) score >2.0 and permutation test, p-value <0.01].
Results: 88 patients were categorized into active (34) and inactive (54) groups. Median age in active and inactive groups was 25 years and 27 years respectively. Female to male ratio was 3.4:1 in the active group and 5:1 in the inactive group. Majority had class V disease. Mean duration of illness was 4.0±3.5 years in active TA and 6.5±5.5 years in inactive TA group. An exquisite separation in OPLS-DA score plot showed metabolic differences between active and inactive TA patients (Fig. 1A). The key metabolite entities identified with highest discriminatory potential (VIP score >2) were glucose, glutamine, glycine, N-acetyl glycoprotein (NAG), choline, and low/very-low density lipoproteins (LDL/VLDL). Of them glucose, glycine, and NAGs were elevated in the sera of active TA patients, whereas glutamine, choline and LDL levels were decreased in these patients. Receiver operating characteristic (ROC) curve analysis revealed NAG has the highest potential to discriminate active from inactive TA patients (area under the ROC curve was 0.75 (p-value <0.0001) (Fig. 1B, 1C).
Conclusions: The study revealed discriminatory metabolites between active and inactive TA patients and evaluated the possibility of NAG as a clinical biomarker for activity judgment in this disease. However, more work needs to be done to validate the results in a large cohort of patients in a longitudinal manner.

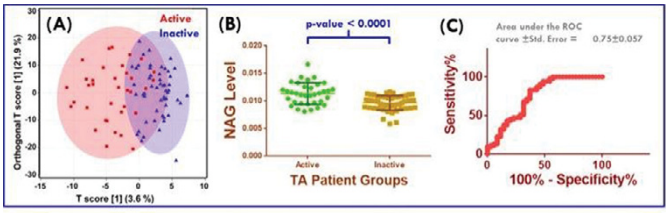

Figure 1: **(A)** 2D score plot obtained from OPLS-DA analysis of 1D ^{1}H NMR spectra. **(B)** Scatter plot showing the serum levels of NAG in active and inactive Takayasu arteritis (TA) patients. The center line refers to the median; whereas the dark lines above and below the center line indicate the 25th and 75th percentiles. **(C)** The receiver operating characteristic (ROC) curve analysis performed to evaluate the specificity, sensitivity, and area under ROC curve (AUC) of NAG peak, showing discriminatory potential of NAG metabolite, based on univariate (box plot) and ROC curve analysis.

THU0308 EXTENSIVE ANALYSIS OF T CELL RECEPTOR GAMMA (TCRG) GENE REARRANGEMENTS REVEALS A SIMILAR REPERTOIRE IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA) AND IN HYPEREOSINOPHILIC SYNDROME (HES)

C. Baldini[1], S. Galimberti[2], E. Ciabatti[2], I. Petrini[3], G. Tarrini[2], M. Latorre[4], E. Elefante[1], F. Ferro[1], R. Grossi[2], N. Pisanti[2], M. Petrini[2], M. Mosca[1]. *[1]Clinical and Experimental Medicine, Rheumatology Unit; [2]Clinical and Experimental Medicine, Hematology Unit; [3]Translational Research and New Technology in Medicine, General Pathology; [4]Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy*

Background: Hypereosinophilia-associated syndromes are a heterogeneous group of diseases characterized by sustained and elevated blood eosinophilia with evidence of eosinophil-induced organ damage. Classically, Eosinophilic granulomatosis with polyangiitis (EGPA) and Hypereosinophilic syndrome (HES) present several overlapping clinical and laboratory features, making it challenging to correctly insert patients in restricted and well-defined categories with specific and more effective therapeutic approaches. Therefore, great efforts are ongoing searching for novel biomarkers able to differentiate these two disorders in daily practice.
Objectives: To detect T cell receptor gamma (TCRG) clonal rearrangements in EGPA and HES, comparing the frequency distribution of V region and J region segment utilization in the study population.
Methods: In this single center study, we included consecutive patients with a diagnosis of EGPA and HES. Inclusion criteria were: documentation of a persistent peripheral eosinophilic count of ≥1.5 x109/L and signs or symptoms of organ involvement. Clinical and laboratory data of the patients were collected. Sequence-based determination of the frequency distribution of TCRG Gene Rearrangements was performed using next-generation sequencing with the Illumina MiSeq (LymphoTrack TRG assay, Invivoscribe).
Results: We included 21 patients (9 with EGPA and 12 with HES). Four EGPA patients were MPO-ANCA positive. We detected TCRG clonal rearrangements in 44% (4/9) patients with EGPA and in 42% (5/12) patients with HES (p-value = n.s). No association was observed between TCRG clonal rearrangements and ANCA status in EGPA patients. Recurrent TCRG gene rearrangements were observed; in particular, Vg10JgP1 (5 cases) and Vg4Jg1/2 (4 cases) were detected in both EGPA and HES, whereas Vg9Jg1/2 (2 cases) and Vg10Jg1/2 (2 cases) were found only in patients with HES.
Conclusions: Even if preliminary, this study reveals a similar T cell receptor gamma repertoire in EGPA and HES, thus suggesting a possible antigen-driven inflammatory response underlying hypereosinophilia in both EGPA and HES. Moreover, our results would suggest that the TCR clonality cannot be used as a tool for the differential diagnosis between EGPA and HES.

THU0309 TREATMENT WITH METHOTREXATE AND RISK OF RELAPSES IN PATIENTS WITH GIANT CELL ARTERITIS IN CLINICAL PRACTICE

D. Freites Núñez, J. Font, C. León, I. Morado, L. Rodríguez-Rodríguez, L. León, Z. Rosales, B. Fernández, J. Jover, L. Abásolo. *Reumatologia, Hospital Clinico San Carlos, Madrid, Spain*

Objectives: To assess the incidence rate of relapses and to analyze the risk of relapses in patients with *Giant Cell Arteritis* (GCA) treated with and without

Methotrexate (MTX), in clinical practice. Other factors associated were also investigated.
Methods: An inception cohort of GCA was assembled in the out-patient clinic at Hospital Clinico San Carlos, including patients from the date of diagnosis (Jan-1991 until Sept-2013), and followed-up until Sept-2014. Main outcome: relapses defined as after an objective improvement, patient has again symptoms or signs of GCA with high ESR and the need to increase corticosteroids at least 10mg. The independent variable was exposure to MTX over time. Covariables: Sociodemographic, clinical, and treatment. Incidence rates of relapses (IR) per 100 patient-years with their 95% confidence intervals [CI] were estimated using survival techniques. Time of exposure comprised the period from diagnosis until: lost of follow-up, main outcome, exposure to MTX or the end of the study. MTX influence on IR was analyzed by multivariable Cox models.
Results: 168 patients were included (675 patient-years). 80% of them were female, with a mean age of 76±7 years. 65% of the patients were on MTX, with mean dose of 10 mg/week. 31% of patients had relapses with an IR of 12 [9.6–14.9]. The median number of relapses was 1 [1–2], with a median lag time of 1.6 [0.6–6.3] years. In the multivariate analysis, exposure to MTX had less risk of flaring compared to those never on MTX ($p<0.05$). Other variables included in the final model were: visual alterations, constitutional symptoms or malaise at clinical presentation of GCA.
Conclusions: The use of MTX seems to decrease the risk of recurrences. We also found other factors influencing on flares.

THU0310 FREQUENCY OF RELAPSES AND TREATMENT DISCONTINUATION DURING LONG-TERM FOLLOW-UP OF PATIENTS WITH GIANT CELL ARTERITIS

C. Tsalapaki, A. Lazarini, K. Antonatou, K. Thomas, K. Klavdianou, C. Koutsianas, D. Vassilopoulos. *Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens School of Medicine, Hippokration General Hospital, Athens, Greece*

Background: There are limited data regarding the long term outcomes of patients with giant cell arteritis (GCA) in the modern therapeutic era.
Objectives: To evaluate relapse, treatment discontinuation and complication rates in GCA patients during long term follow-up.
Methods: A retrospective systematic chart review of GCA patients who were followed in an Academic Rheumatology Unit between 2002 to 2016 was performed. Demographic, clinical, laboratory and treatment data were collected and analyzed.
Results: 53 GCA patients were included in the study. 62% (n=33) were women with a mean age at diagnosis of 73±8.8 years and median duration of symptoms of 1.3 months. 41 patients (77%) had biopsy proven GCA while in 5 patients (9%) there was evidence of large vessel involvement. At presentation, the most common symptoms were headache (60%), fever (51%), scalp tenderness (47%), jaw claudication (39%), visual disturbances (23%), polymyalgia rheumatica symptoms (9%) and vision loss (6%). Regarding laboratory data at baseline, the median ESR and CRP were 101 mm/h and 50 mg/dl respectively while the mean hemoglobin (Hb) and platelet (PLT) count was 11.3±1.2 g/dl and 381.000±134.000, respectively. All patients were initially treated with tapering doses of pos steroids (mean start prednisolone dose: 42±12 mg/day) while 2 patients (4%) were given IV steroid pulses. During follow-up (3.1±2.7 years), for patients with did not adequately respond or could not tolerate steroids, non-biologic (n=12, 23%) or biologic DMARDs (n=4, 7%) were added. Relapses requiring change in immunosuppressive therapy occurred in more than half of patients (n=28, 53%); among these 67% were laboratory and 56% clinical relapses. Osteoporosis (17%), cataracts (7%), fractures (4%) and avascular necrosis (2%) developed during chronic steroid treatment. At the last follow-up visit, 39% (n=21) of patients had discontinued steroids and 31% (n=17) all treatments. Comparing the group of patients who had discontinued treatment (D/C group) to those who were unable to stop therapy (continued therapy group), there were no statistically significant differences (age, duration of symptoms at diagnosis, initial steroid dose, baseline and follow-up ESR, CRP, Hb and platelet values, relapses, co-administration of DMARDs, comorbidities), except from gender (females: D/C group=41%, continued therapy group=72%, p=0.03). Kaplan-Meier analysis also showed that the median time to discontinuation of treatment was longer in females compared to males (log rank p=0.018).
Conclusions: In this long-term follow-up study, relapses occurred in more than half of GCA patients while only one out of three patients were able to discontinue all therapies. Among different variables, only male sex was associated with earlier treatment discontinuation.

THU0311 FECAL MICROBIOTA IN BEHÇET'S SYNDROME PATIENTS WITH MUCOCUTANOUS AND UVEITIS INVOLVEMENT

D. Tecer[1], F. Gogus[1], A. Kalkancı[2], M. Erdogan[2], S. Coban[3], M. Hasanreisoglu[4], T. Karakan[5]. *[1]Department of Physical Medicine and Rehabilitation, Division of Rheumatology; [2]Department of Medical Microbiology; [3]School of Medicine phase 3 student; [4]Department of Ophthalmology; [5]Department of Gastroenterology, Gazi University, Faculty of Medicine, Ankara, Turkey*

Background: Innate immunity has a major role in the pathogenesis of Behçet's syndrome. The gut microbiota is an active component of the immune system. It plays an important role in the formation of the immune system in the early life and in the continuation of immune homeostasis through the life. Dysbiosis, imbalance in the gut microbiota, can lead to many serious metabolic and inflammatory pathologies
Objectives: We aimed to investigate the gut microbiota structure in Behçet's syndrome patients with mucocutanous and uveitis involvement only.
Methods: 6 patients with Behçet's syndrome with uveitis, 12 patients with familial Mediterranean fever (FMF) and 9 patients with Crohn's disease (CD) and 10 healthy controls were included. Patients, positive and healthy controls were excluded if they had one of the following combined diseases/situations: a) gastrointestinal surgical history (e.g. bariatric surgery, gastrectomy or colectomy), b) antibiotic or probiotics use in the last 3 months, c) specific dietary restriction, d) malignancy, e) additional autoimmune disease or inflammatory bowel disease. Total DNA was extracted from fecal samples using the QIAamp DNA stool Mini Kit following the manufacturer's instructions (Qiagen). Next generation sequencing of 16SrRNA gene was performed using Ion Torrent Technology. Partial 16S rRNA ene sequences were amplified from extracted DNA using the 16S Metagenomics Kit (Life Technologies). The integrity of the PCR amplicons was analyzed by gel electrophoresis. PCR products were purified using AMPure XP DNA purification beads and Invitrogen DynaMaq magnet apparatus. DNA concentration of the amplified sequence was equalized through the Qubit System (Life Technologies). The libraries was created by using the Ion Plus Fragment Library Kit. Barcodes were also added to each sample using the Ion Express Barcode Adapters Kit. Emulsion PCR was carried out using the Ion One Touch 2 machine. Sequenciing of the amplicon libraries was carried out on a 318 chip the Ion Torrent Personal Genome Machne System and Ion PGM Hi-Q kit. 16S rRNA sequences were analyzed by Ion Reporter Software.
Results: In healthy subjects, fecal microbiota consisted predominatly of Bacteroidetes (53.2%) including Bacteroides and Prevotella genuses. Firmicutes such as Bacilli, Clostridia, followed, consisting 31.2% of the bacterial community. Fecal bacterial flora of patients with Behçet's syndrome consisted of Firmicutes (45%), Proteobacteria (23%) such as Enterobacteriaceae and Prevotellaceae, and Bacteriodetes (10%). FMF cases were found to be colonized by Firmicutes (39.3%), Bacteriodetes (32.2%) and Proteobacteria (13.6%) predominantly. CD cases were colonized by Enterobacteriacea (43%), and other Proteobacteria groups, followed by Bacteriodetes (15.4%) and Firmicutes (8.8%).
Conclusions: Fecal flora of patients with Behçet's syndrome and of positive control groups (FMF and CD) differed significantly from that of healthy controls. In a subgroup of patients with Behçet's disease with uveitis and muscucutaneaous involvement only, firmicutes species seem to be the dominant bacterial fecal flora.

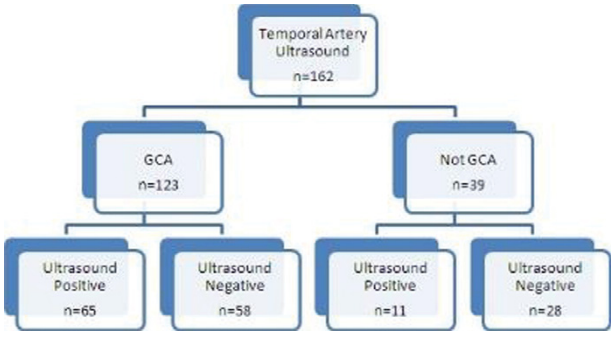
THU0312 PERFORMANCE CHARACTERISTICS AND PREDICTORS OF TEMPORAL ARTERY ULTRASOUND AND BIOPSY FOR THE DIAGNOSIS OF GIANT CELL ARTERITIS IN A REAL WORLD POPULATION; A PROSPECTIVE COHORT STUDY



R. Conway[1], S. Di Bello[1], L. O'Neill[1], G.M. McCarthy[2], C.C. Murphy[3], D.J. Veale[1], U. Fearon[4], R.P. Killeen[5], E.J. Heffernan[5], E.S. Molloy[1]. *[1]Rheumatology, St Vincents University Hospital; [2]Rheumatology, Mater Misericordiae University Hospital; [3]Ophthalmology, Royal College of Surgeons in Ireland; [4]Molecular Rheumatology, Trinity College Dublin; [5]Radiology, St Vincents University Hospital, Dublin, Ireland*

Background: The diagnosis of giant cell arteritis (GCA) remains a clinical one. Temporal artery (TA) ultrasound (US) has been proposed as a new diagnostic tool in GCA.
Objectives: To assess the performance characteristics of TA US and biopsy in routine clinical practice.
Methods: All patients presenting with suspected GCA to our institutions are recruited to a prospective registry. Patients who had both a TA US and biopsy performed at the time of presentation were included in the current study. US was performed by 2 radiologists. The performance characteristics of both tests were compared to physician diagnosis at six months following presentation. Predictive factors for positive US and biopsy were explored in univariate and multivariable logistic regression analyses.
Results: 162 patients were included, 123 (76%) with GCA. Mean (SD) duration of glucocorticoids was 6.6 days (19.4) at the time of TA US and 6.2 days (8.4) at the time of TA biopsy. US had a sensitivity of 52.8% (95% CI 43.7, 61.9) and specificity of 71.8% (95% CI 54.9, 84.5). There were 11 false positive US results; 5 with migraine, 2 other vasculitides, 2 local infections, 2 malignancies. Biopsy

had a sensitivity of 48.8% (95% CI 39.7, 57.9) and specificity of 97.4% (95% CI 84.9, 99.9). A hypothetical sequential strategy of US followed by biopsy in the case of negative US had a sensitivity of 78.9% (95% CI 70.1, 85.5) and specificity of 71.8% (95% CI 54.9, 84.5), equivalent to a simultaneous testing strategy. Time on glucocorticoids did not significantly impact the results of US or biopsy. The only factor independently predictive of a positive US was male sex (OR 5.53, 95% CI 2.72 to 11.22, p<0.001). The only factor independently predictive of a positive biopsy was jaw claudication (OR 2.40, 95% CI 1.11, 5.21, p=0.027).

Table 1. Performance Characteristics of Ultrasound, Biopsy, and Combination Strategies

Strategy	Sensitivity	Specificity	PPV	NPV	PLR	NLR
Ultrasound alone	52.8	71.8	85.6	32.6	1.87	0.66
Biopsy alone	48.8	97.4	98.0	37.6	19.02	0.53
Sequential (Biopsy only if US positive)	22.8	97.4	96.6	28.6	8.88	0.79
Sequential (Biopsy only if ultrasound negative)	78.9	71.8	89.8	51.9	2.80	0.29
Simultaneous	78.9	71.8	89.8	51.9	2.80	0.29
Procedure, glucocorticoid duration						
Ultrasound, all, n=162	52.8	71.8	85.6	32.6	1.87	0.66
Ultrasound, 0 days, n=80	51.9	76.9	82.4	43.5	2.25	0.63
Ultrasound, >0 ≤3 days, n=27	46.2	100	100	6.0	Infinity	0.54
Ultrasound, >3 ≤7 days, n=25	60.0	40.0	80.0	20.0	1.00	1.00
Ultrasound, >7 ≤14 days, n=18	64.3	50.0	81.8	28.6	1.29	0.71
Ultrasound, >14 days, n=12	44.4	100	100	37.5	Infinity	0.56
Biopsy, all, n=162	48.8	97.4	98.0	37.6	19.02	0.53
Biopsy, 0 days, n=53	46.9	100	100	55.3	Infinity	0.53
Biopsy, >0 ≤3 days, n=24	66.7	83.3	92.3	45.5	4.00	0.40
Biopsy, >3 ≤7 days, n=38	47.1	100	100	18.2	Infinity	0.53
Biopsy, >7 ≤14 days, n=29	47.8	100	100	33.3	Infinity	0.52
Biopsy, >14 days, n=18	37.5	100	100	17.0	Infinity	0.63

Conclusions: TA US is a useful tool in the diagnosis of GCA; however false positive tests occur in 7% and thorough clinical assessment remains crucial. Prior glucocorticoid treatment has no clear impact on results.

THU0313 INFERIOR AND SUPERIOR VENA CAVA THROMBOSIS IN BEHCET S DISEASE. MOROCCAN EXPERIENCE

F.Z. Alaoui[1], M. Moudatir[2]. *[1]Internal medicine; [2]12 rue la saone, Polo, University hospital ibn rochd, Casablanca, Morocco*

Background: Behcet's disease (BD) is a systemic disorder with a vascular tropism where the vessels might be affected. Venous thrombosis is the most common vascular complication. Among its locations, vena cava thrombosis (VCT) are rare but can be life-threatening.
The purpose of this work is to specify the frequency of VCT in the course of Behcet's disease in morocco and to analyse epidemiological, clinical and therapeutic modalities.
Objectives: This retrospective study was conduced in the internal medicine department of the University Hospital IbnRochd of Casablanca, over a period of thirty-five years between 1980 and 2016.
Methods: Where included 1618 cases of Behcet's disease, all diagnosed in our service and meeting the diagnosis criteria as defined by the international study group (ISG) for Behcet's disease.
Results: 52 patients with VCT – 47 men and 4 women - were gathered during this period, representing a rate of 3.30% of 1572 cases, with a mean age of 35 years (ranges 17–54).
The diagnosis of VCT and BD was concomitant in 10 cases and occurred during the course of the disease in 42 cases after an average of 6 years of evolution.
Among the localization. Inferior VCT is the most frequent localization (32 patients, including 15 cases of Budd- Chiari syndrome). The superior VCT was reported in 24 patients, whereas 5 patients had both a superior and inferior VCT.Vena cava thrombosis was associated with deep venous thrombosis (DVT) of the lower limbs in 24 cases and with an aneurysm in 7 cases (pulmonary artery: 4 cases, femoral artery: 2 cases, abdominal aorta; 1 case).
Regarding the therapeutic modalities, 41 patients were under anti-coagulant treatment, 45 patients received corticosteroids and 51 of the patients were under immunosuppressive agents (cyclophosphamide,azathioprine).
The evolution was significantly improved after the introduction of the immunosuppressive therapy, which were firstly initiated in 2006.
Conclusions: Vena cava thrombosis in the context of Behcet's disease is a very serious pathology threatening the patient's vital and functional prognosis.
Preventive measures, early diagnosis and effective treatment are the keys to a successful management of such complications' risks.

THU0314 RADIOLOGIC ACTIVITY IS THE MAJOR DETERMINANT FOR PHYSICIANS WHILE DECIDING ACTIVE DISEASE IN TAKAYASU ARTERITIS

G. Kenar[1], P. Cetin[2], H. Yarkan[1], B. Zengin[1], G. Can[1], M. Birlik[1], F. Onen[1]. *[1]Rheumatology, Dokuz Eylul University School of Medicine, Izmir; [2]Rheumatology, Dumlupınar University, Kutahya, Turkey*

Background: There are no valid follow-up parameters in the assessment of disease activity in Takayasu arteritis (TA).
Objectives: We investigated the impact of incorporation of vascular imaging into ITAS in the assessment of disease activity in TA.
Methods: 52 patients who fulfilled the ACR criteria were included in the study. PGA, Kerr et al.'s criteria and ITAS2010/ITAS-A scores were evaluated in all patients in serial visits. All the patients were followed using 3–6 monthly B-mode/Doppler ultrasonography (USG) and 6–12 monthly magnetic resonance angiography (MRA).
Radiological activity (Rad) was defined based on the presence of any of the 3 parameters including new vessel involvement by any technique (5 points),increase in vessel wall thickness on USG (3 points) and vessel wall edema on MRA (3 points).Then we incorporated these scores with ITAS-A to obtain a composite disease activity index (ITAS2010-A-Rad) (Table 1). Active disease was defined as ITAS-A-Rad >4 points.
Results: Total 410 visits of 52 TA patients (mean age 50.7 yrs, F: 92.3%, mean follow-up duration:6.4±2.9 yrs) were evaluated. Radiological assessment was done in 359 visits (by USG in 271 and by MRA in 190). Patients were categorized as having active disease in 194 visits (47.4%) according to PGA and 72 visits (17.5%) according to Kerr et al. criteria.The agreement between them was fair (66%, κ: 0.29). Radiological activity was determined in 105 out of 359 visits (29.2%). The total agreement between radiological activity and Kerr at al. criteria was 83% (κ: 0.58). It was found to be 76% (κ: 0.52) between radiological activity and PGA.
Mean ITAS-A-Rad scores were found to be significantly higher in visits with active disease compared to visits with inactive disease according to both PGA and Kerr et al. criteria (Table 2). The ITAS-A-Rad was significantly correlated with all the other activity parameters including ITAS2010, ITAS-A, and APRs.
There were 43 visits with new vessel involvement by any radiologic technique; all visits included patients with active disease based on both PGA and Kerr et al. criteria. Whereas in 50% of these visits, patients had normal CRP, and %49 had normal ESR.
The agreement between ITAS2010 and PGA was fair (69%, κ: 0.38).When APR was added (ITAS-A), it did not improve (68%, κ: 0.34). But the agreement between

Table 1. The definition of ITAS-A-Rad Score

Clinical	ITAS2010			0–
Laboratory	APR	ESR	0 for ESR<20 1 for 21–39 2 for 40–59 3 for >60 mm/h	0–3
		CRP	0 for CRP≤5 1 for 6–10 2 for 11–20 3 for >20mg/l	
Radiology	Radiological activity	New vessel involvement with any radiological method		5
		B-mode Doppler USG	Progression on vessel wall thickness	3
		MRA	Presence of vessel wall edema	3
Total	ITAS-A-RAD Score			

ITAS-A-Rad Score >4 –> Activity.

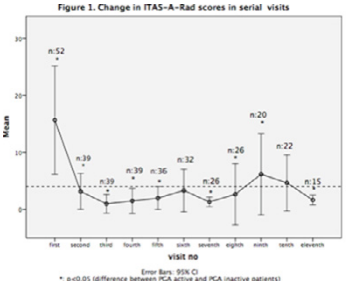

Table 2. Response to change: The mean ITAS-A-Rad scores in serial visits

	ITAS-A-Rad score (mean±SD)		
Visit no	PGA: active	PGA: inactive	P
1	16.72±6.3	5.25±4.9	<0.001*
2	6.23±4.6	1.92±3.8	<0.001*
3	5.11±3.3	1.40±1.63	<0.001*
4	4.11±2.47	1.60±1.72	<0.001*
5	6.36±5.6	1.36±1.7	<0.001*
6	3.20±2	2.95±39	0.29
7	4±2.3	1.76±2.7	<0.001*
8	5.3±3.8	1.3±1.77	<0.001*
9	4.33±6.02	1.21±2.3	0.02*
10	6.67±4.5	1.5±2.3	0.06
11	4±2.7	1.10±0.99	0.028*

ITAS-A-Rad and PGA (72%, κ: 0.50) and also Kerr et al. criteria (82%, κ: 0.56)was found to be moderate. Interestingly, when only USG (ITAS-A-USG) or only MRA (ITAS-A-MRA) was used, the agreement with PGA was remained unchanged (73%, κ: 0.45 and 76%, κ: 0.52, respectively).
When responsiveness to change of ITAS-A-Rad score was evaluated by serial visits of patients, it was found that the mean value of the score was discriminative for activity according to PGA in 9 of 11 visits (Figure 1).
Conclusions: The results of this study suggest that ITAS-A-Rad may be used to be a valuable follow-up parameter in the assessment of disease activity.

THU0315 CENTRAL NERVOUS SYSTEM INVOLVEMENT IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS: A SINGLE CENTER EXPERIENCE

G.E. Fragoulis[1], S. Lionaki[2], A. Venetsanopoulou[1], P.G. Vlachoyiannopoulos[1], H.M. Moutsopoulos[1], A.G. Tzioufas[1]. *[1]Pathophysiology Department; [2]Nephrology Department, University of Athens, School of Medicine, Athens, Greece*

Background: Peripheral nerve involvement is relatively frequently encountered in patients with granulomatosis with polyangiitis (GPA). Central nervous system (CNS) manifestations are reported to occur in about 10% of GPA patients.
Objectives: We aimed to estimate the prevalence of CNS involvement in Greek patients with GPA, describe the related clinical characteristics, and identify possible predicting factors for its occurrence. We also compared the clinical picture and long term outcomes of GPA patients with and without CNS involvement.
Methods: The medical charts of all patients with ANCA-associated and biopsy proven small vessel vasculitis (AAV), diagnosed in our hospital between 1995–2015, were retrospectively reviewed and GPA patients with CNS involvement were identified. Demographics, serological and clinical features, at the time of AAV diagnosis, of CNS involvement and during the follow-up time, were recorded. Comparisons of disease characteristics and outcomes, including patient survival, relapse rate and treatment-related adverse events, were performed between GPA patients with and without CNS involvement.
Results: 77 patients with GPA were identified in our AAV registry. Of these, nine (11.7%) developed CNS manifestations, either at clinical presentation (33.3%) or during the follow-up (66.7%). At the time of CNS involvement, all patients were characterized by increased acute phase reactants and all but one patients had vasculitic manifestations in several other organs/systems and increased titers of ANCA. CNS symptomatology included: sensor and/or sensorimotor symptomatology (33.3%), severe headache and hearing loss (33.3%), delirium and seizures (22.2%), diplopia (11.1%) and cerebellar symptoms (11.1%). Findings from MRI were: cerebral ischemic lesions (55.6%), focal dural thickening with enhancement (22.2%), orbital mass formation (11.1%) and mastoiditis causing facial nerve palsy bilaterally (11.1%). Patients with CNS involvement, compared to those without, at initial AAV diagnosis, experienced vasculitic manifestations of the ENT system more frequently (77.8% *versus* 25.4%, p=0.004) and they had a lower disease activity, as assessed by the BVAS score, while during the overall course of the disease experienced lung vasculitis less frequently (44.4% vs. 79.4%, p=0.02). Comparisons between GPA patients with and without CNS manifestations did not reveal any differences in long-term outcomes including relapse rate rate/100 person-months, (95% CI) [1.812 (0.920–3.229) Vs 1.033, (0.757–1.378), respectively] (p=0.171), survival (Mantel-Cox test, p=0.244) and treatment-related adverse events
Conclusions: CNS involvement was recorded in 11.7% of our GPA patients, either during the initial phase or as a late disease sequela. ENT involvement and low BVAS score at disease onset were more common in GPA patients with CNS manifestations. Based on our results, CNS involvement did not affect the long term outcomes of GPA patients.

THU0316 EPIDEMIOLOGY OF TAKAYASU ARTERITIS IN NORTHERN ITALY

G. Restuccia[1], L. Boiardi[1], P. Macchioni[1], M. Catanoso[1], P. Mancuso[2], C. Salvarani[1]. *[1]Rheumatology, Arcispedale S Maria Nuova; [2]Servizio interaziendale di epidemiologia, Azienda unità sanitaria locale, Reggio Emilia e Arcispedale S Maria Nuova, Reggio Emilia, Italy*

Background: Takayasu arteritis (TAK) is a large vessel vasculitis of unknown etiology, predominantly affecting the aorta and/or its major branches and occurring before the age of 40 years.TAK has been described worldwide with an annual incidence in Europe ranging from 0.4 to 1.3 /1.000.000. TAK is more common in female. In the largest study from Japan, the female to male ratio was eight to one. In a recent Swedish epidemiologic study no male were identified. There are no epidemiological studies regarding Takayasu arteritis in Italian population.
Objectives: To investigate the epidemiology of Takayasu arteritis in a Northern Italy area.
Methods: All patients with incident TAK diagnosed between 1997 and 2015 living in the Reggio Emilia area were identified by capture and re-capture checking at computerized discharge diagnosis codes (ICD10) and at outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital and by examining the Reggio Emilia district database for rare diseases.The Reggio Emilia population is predominantly of Caucasian origin (92.5%) with a yearly increase in general population of 0.5% (from 438.588 inhabitants in 1997 to 533.827 in 2015).
Results: There were 5 women satisfyng ACR 1990 criteria for TAK diagnosis during the 18 years study period. The overall age and sex-adjusted 18 years incidence per 100.000 persons aged <40 years was 2.2. (95% CI:0.71 to 5.09). The overall age-and sex-adjusted 20 years incidence per 100,000 women aged <40 years was 4.5. (95% CI:1.46 to 10.48). Median age at disease onset was 36y and at diagnosis was 39 years. The prevalence of TAK in the general population on December 31 2015 was 0.9 (95% CI: 0.31 to 2.19) while in female population aged <40 years was 4.4 (95% CI 1.47 to 10.54). All patients are still alive on December 31 2015.
Conclusions: As observed in other epidemiological studies, TAK is a rare disease also in Northern Italy with a large prevalence of female.
Disclosure of Interest: None declared

THU0317 CARDIOVASCULAR RISK FACTORS AND COMORBID DISEASES IN TAKAYASU ARTERITIS

H. Masyan[1], N.S. Esatoglu[2], A.M. Celik[1], V. Hamuryudan[2], H. Yazıcı[2], E. Seyahi[2]. *[1]Department of internal medicine; [2]Department of internal medicine, Division of Rheumatology, Cerrahpasa medical faculty, Istanbul, Turkey*

Objectives: Cardiovascular complications are the main causes of morbidity and mortality in the course of Takayasu arteritis (TA).In addition to the occlusive vasculitis,hypertension and accelerated atherosclerosis are possibly other factors playing role in the ethiopathogenesis of these complications.Although,strict management of traditional cardiovascular risk factors is advocated to diminish the effect of cardiovascular complications,we still do not know whether traditional risk factors and other comorbid conditions are increased or operative.In this study we looked at the frequency of traditional atherosclerotic risk factors and comorbid conditions among patients with TA and suitable diseased and healthy controls.
Methods: We studied 88 (77F,11M) consecutive TA patients and 71 (66F,5M) SLE patients,between May and November 2016.In addition,age and gender matched, 96 (80F, 16M) healthy controls were included.Study participants were interviewed with the help of a standardized questionnaire that assess the presence or absence of traditional atherosclerotic risk factors and several comorbid conditions according to the Charlson comorbidity index.Additionally,Framingham coronary heart disease risk score was calculated.
Results: Smoking was more frequent among the healthy controls,whereas hypertension and family history of cardiovascular diseases were more common among TA patients.Patients with SLE were found to have less hyperlipidemia.The Framingham risk scores did not differ among the groups.Pericardial/pleural and renal diseases were more frequently observed in SLE patients,whereas cardiovascular diseases and chronic lung diseases were more common in TA patients.Inflammatory bowel diseases were only observed in TA patients.

	Takayasu arteritis (n=88; 77F/11 M)	SLE (n=71; 66 F/5 M)	Healthy controls (n=96; 80 F/16 M)	P value
Age, mean ± SD	44±12	42±12	45±11	NS
Age at disease onset, mean ± SD	31±12	29±11	–	NS
Smoking (current and past), n (%)	27 (31)	30 (42)	47 (49)	<0.05
Hyperlipidemia, n (%)	32 (44)	15 (25)	41 (48)	0.018
Hypertension, n (%)	47 (53)	23 (32)	22 (23)	<0.01
Diabetes mellitus, n (%)	8 (9)	6 (7)	15 (16)	NS
Median [IQR] Framingham risk score	3 [1–9]	3 [1–5]	3 [2–7]	NS
Familial history of cardiovascular diseases, n (%)	41 (47)	15 (21)	22 (23)	<0.01
Cardiovascular diseases, n (%)	47 (53)	13 (18)	1 (1)	<0.01
Valvular heart disease, n (%)	34 (39)	12 (17)	7 (7)	<0.01
Chronic pulmonary diseases, n (%)	11 (13)	1 (2)	5 (6)	<0.05
Pleural/pericardial diseases, n (%)	7 (8)	14 (20)	0	<0.01
Renal diseases, n (%)	10 (11)	19 (27)	8 (8)	<0.05
Other accompanying rheumatologic diseases and amyloidosis, n (%)	10 (11)	15 (21)	1 (1)	<0.01
Inflammatory bowel diseases, n (%)	9 (11)	0	0	<0.01
Inflammatory upper/lower back pain, n (%)	21 (24)	23 (32)	6 (6)	<0.01
Family history of rheumatologic diseases, n (%)	26 (30)	25 (35)	4 (4)	<0.01

Conclusions: Traditional atherosclerotic risk factors are not increased in TA.Comorbidities in these patients are mainly due to the complications of vascular involvement.The frequency of inflammatory bowel diseases and inflammatory upper/lower back pain is substantially high and deserves further research. Moreover, the increased incidence of cardiovascular and rheumatologic diseases among the first-degree relatives of TA patients suggest that genetic mechanisms may play role in TA

THU0318 CORONARY ARTERY DISEASE IN PATIENTS WITH BEHÇET'S DISEASE: A RETROSPECTIVE, SINGLE CENTER STUDY

H. Chen[1], Y. Zhang[2], W. Chen[3], J. Liu[1], L. Wang[1], F. Zhang[1], W. Zheng[1]. *[1]Rheumatology, Peking Union Medical College Hospital, BEIJING; [2]Oncology and immunology, The fourth hospital of Hebei Medical University, Hebei; [3]Cardiology, Peking Union Medical College Hospital, BEIJING, China*

Background: Behçet's disease (BD) is a chronic inflammatory disease affecting various size of arteries and veins. Coronary artery disease (CAD), a life-threatening condition, is rarely reported in patients BD.
Objectives: To investigate the clinical characteristics of BD patients complicated with CAD, and to elucidate the potential risk factors of CAD in BD patients.
Methods: We retrospectively reviewed all the medical records of BD patients who were admitted to our institute from 2001 to 2016. CAD was defined as aneurysm, stenosis and (or) occlusion of coronary arteries confirmed by angiography or contrast-enhanced computer tomography. BD patients with CAD and age- and gender-matched BD patients without CAD (at 1:3 ratio) were enrolled. Demographic, clinical and laboratory data were systemically collected, analyzed and compared between two groups.
Results: In total, 19 patients, including 17 male and 2 female, were complicated with CAD. The mean onset age of BD was 34 and the mean duration from the onset of BD to the diagnosis of CAD was 4.1 year. Angina pectoris (8/19) and acute myocardial infarction (8/19) were the most common cardiac symptoms, arrhythmia was presented in one patient, and three patient remained asymptomatic. Coronary artery aneurysm, stenosis and occlusion were presented in 9, 13 and 3 patients, respectively. Smoking (7/19) was frequently observed, while hypertension (3/16), diabetes mellitus (2/19), obesity (1/19) and alcohol consumption (1/19) were rarely present. Additionally, seven arterial and two venous extra-cardiac vasculopathies were presented. Oral ulceration (19/19) and skin lesions (16/19) were the most common BD-associated symptoms. Comparing with BD patients without CAD, patients with BD presented with higher ESR (mean, 34.4 vs 16.3 mm/hr, p=0.0018) and CRP (mean, 36.4 vs 12.2 mg/L, p=0.002), more frequency of skin lesions (84% vs 55%, p=0.0334) and pathergy reactions (37% vs 26%, p=0.0103). Furthermore, multivariate analysis confirmed that elevated CRP was a independent risk factor of CAD (OR 1.032, 95% CI 1.011–1.053, p=0.003).
Conclusions: CAD, a rare complication of BD, predominately affect male patients. BD patients with CAD presented with active BD disease symptoms and elevated inflammatory markers, which implicated aberrant vascular inflammation was the key mechanism of CAD in BD patients. CRP, but not traditional CAD risk factors, was the risk factor of CAD in BD patients.

THU0319 MR ANGIOGRAPHY FOR EVALUATION OF VASCULAR INFLAMMATION IN ELDER PATIENTS WITH LARGE VESSEL VASCULITIS

I. Smitienko[1], P. Novikov[2], E. Atyasova[1]. *[1]Medical Center "Petrovskie Vorota"; [2]Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Objectives: The aim of the study was to evaluate the feasibility of MR angiography (MRA) for evaluation of vascular inflammation in elder patients with large vessel vasculitis.
Methods: 16 patients with established on PET with 18F-FDG large vessel vasculitis (14 female and 2 male; average age 66 years) were enrolled in our study. 14 patients had got giant cell arteritis (just only 3 biopsy-proven cases), 2 patients with isolated aortitis of thorax aorta and 2 cases of PMR-associated arteritis. The average duration of any disease was 8 months. All patients underwent MRA with or without contrast enhancement of aorta and its branches at 1.5 Tesla (Siemens Magnetom Essenza). All patients had repeated MRA at 6 and 12 months. All images were studied by one specialist. We evaluated the role of mural oedema as a sign of activity of vasculitis. The results of MR-angiography were compared with clinical and laboratory data, ultrasound and PET with 18F-FDG.
Results: A total of 42 MRA were obtained in 16 patients. Significant mural oedema of thorax aorta or large arteries was shown by imaging in 20 of 42 cases (48.0%) and correlated with clinical and laboratory signs of vasculitis activity, progressive arterial stenosis detected by ultrasound and increased uptake of 18F-FDG on PET. 12 patients with high degree of inflammation on MRA were streroid-naïve. In 22 cases (52%), MRA had showed mild or moderate oedema of the arteries' wall. Low-moderate activity of vascular inflammation in our patients was associated with moderate or high of immunosuppressive therapy (prednisolone 40–60 mg/day). However, gradual reduction in the intensity of immunosuppression in 4 patients with mild mural oedema was associated with development of relapse of large vessel vasculitis. Notably, contrast enhancement did not improve significantly edema imaging.
Conclusions: Visualisation of artery wall oedema by MRA may be a usefull approach to detect persisting inflammation in elder patients with large vessel vasculitis.

THU0320 DIFFERENT PATTERNS OF VASCULAR INVOLVEMENT IN PET/CT ACCORDING TO CRANIAL SYMPTOMS IN BIOPSY PROVEN GIANT CELL ARTERITIS, A PRELIMINARY STUDY

J. Mestre Torres[1], I. Navales[2], F. Martínez[1], J. Loureiro[1], S. Bujan[1], C. Pérez[1], M. Simó[2], R. Solans[1]. *[1]Internal Medicine; [2]Nuclear Medicine, Hospital Vall d'Hebron, Barcelona, Spain*

Background: GCA is the most frequent vasculitis in patients over 50 years old. It involves large vessels (LV) such as aorta, carotid, vertebral and subclavian arteries. After the development of new imaging techniques, extracranial LV involvement has been increasingly described. Past studies showed a trend in worse prognosis in those patients with aortitis at diagnosis but larger studies are needed to determine the clinical implications of these results. Correlation between symptoms at diagnosis and PET evaluation has not been done.
Objectives: To evaluate aortic and supraaortic involvement in a new onset GCA cohort through PET/CT. To compare aortic and supraaortic involvement in patients with and without cranial ischemic symptoms.
Methods: Prospective study including all newly diagnosed biopsy-proven GCA patients in 2016 according to ACR criteria. PET/CT was performed during initial evaluation. Clinical data, blood tests and PET/CT results were recorded. Ischemic symptoms included jaw claudication (JC) and visual symptoms. Analysis was made using Stata IC/14. Patients were compared according to clinical presentation (presence vs absence of ischemic symptoms) with Fisher exact test.
Results: 18 patients were included (63.6% were women). At diagnosis age was 77.4±8.7 years (mean ± SD). Patients presented headache (78.6%), polymyalgia rheumatica (14.3%), constitutional syndrome (42.8%), JC (42.9%) and visual symptoms (35.7%). On physical examination pulse was decreased in 78.6% of patients. Blood tests showed anemia in 71.4% with an ESR 90.41±33mm/h (mean ± SD). PET/CT was performed after (median, intercuartilic range) 6.5 days (2 - 10 days). Analysis of vascular uptake was semiquantitative. Aortic involvement was present in 42.9% of patients. Supraaortic and vertebral arteries were involved in 42.8%. Baseline characteristics were similar to other cohorts. At the time of diagnosis, proportion of aortitis was significantly lower (p=0.049) in patients with ischemic symptoms when compared to those without. We could not find any differences between these two groups when analyzing the presence of increased vascular uptake in carotid and vertebral arteries. Limitations of the study are the small size of the cohort and the variability of the PET/CT protocols among literature. However, we think this study is important because it shows the differences between these two subgroups of GCA.
Conclusions: In this study, patients with cranial ischemic symptoms showed less involvement of large vessels when compared to those GCA patients that presented with systemic symptoms. These results suggest that there may be different physiopathological subsets leading to GCA. Further studies are needed to better understand these mechanisms.

THU0321 ALTERATIONS IN THE PERIPHERAL B CELL COMPARTMENT IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (CHURG-STRAUSS SYNDROME)

M. Rizzi, M. Engesser, R.E. Voll, A. Troilo, I. Janowska, N. Venhoff, J. Thiel. *Rheumatology/Clinical Immunology, University Hospital Freiburg, Freiburg, Germany*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) belongs to the group of ANCA associated vasculitides. While the combination of asthmatic symptoms and vasculitis characterize the disease clinically, eosinophilia and increased serum IgE concentrations are serologic hallmarks. The role of B lymphocytes in EGPA has not been defined so far, but therapeutic response to rituximab in EGPA points towards a role of B-cells in the pathogenesis of EGPA.
Objectives: To characterize the peripheral B cell compartment in patients with EGPA, to analyze the in vivo potential of B lymphocytes to class-switch to IgE, and to assess in vitro the differentiation of naïve B cells to IgE-secreting plasmablasts.
Methods: Laboratory work-up included ANCA-status, eosinophils, IgE, IgG, IgA, IgM, and peripheral $CD19^+$ B-cell count. B cell subpopulations (naïve, marginal zone, class-switched B cells and plasmablasts) were analyzed by staining PBMCs with fluorescent-labeled monoclonal antibodies against: CD27, CD20, CD38, IgD, IgG, IgA, IgE, CD21, and BAFF-R. For in vitro differentiation assays magnetically isolated B lymphocytes from EGPA patients and aged matched healthy controls were stimulated with CD40L and IL-21 and IL-4 in enriched Iscoves' medium supplemented with 10% FCS, 1 μg/mL insulin, 2.5 μg/mL apo-transferrin, 1% nonessential amino acids, 2 mmol/L glutamine, and 1 μg/mL reduced glutathione. Starting the culture with equal number of B cells, the absolute number of plasmablasts, and IgE class switched cells after 9 days was determined by counting the events in the $CD27^{high}CD38^{high}$ gate or the $IgG/A/D^-IgE^+$ gate by flow cytometry. IgE secretion in the supernatant was measured by ELISA.
Results: 18 patients (8 females, median age 59 years) with EGPA diagnosed according to ACR and CHC-criteria were included into the study. 22% of patients were ANCA-positive. Immunosuppressive therapy was azathioprine in 11 patients, methotrexate in 3 patients, and leflunomid or mycophenolate in one patient each and two patients received no immunosuppressive treatment. 7 patients had a history of a prior cyclophosphamide therapy. Median lymphocyte count was

normal ($1.2x10^3/\mu l$; normal range 1.1 to $3.2x10^3/\mu$ l) but peripheral B cell numbers were markedly diminished ($37/\mu l$, normal range: 100 – $500/\mu l$). While the percentage of naïve B cells (53%) and marginal zone like B cells (10.5%) were within normal range, the percentage of class-switched memory B cells was high (28.2%). To assess the in vitro class switch capacity to IgE the number of IgE class-switched cells after 9 days of culture was determined by counting the events in the IgG/A/D-IgE+ gate. The percentage of IgE-switched cells was 6.8% (range: 0.3%>34%) and not statistically different from healthy controls.

Conclusions: In the EGPA-patients we report we observed markedly diminished B-cells despite of normal lymphocyte counts. Within the B cell compartment, there was a shift towards later B cell maturation stages. The in vitro B-cell development to IgE class-switched cells was not increased in EGPA-patients pointing towards a non-B cell intrinsic mechanism.

THU0322 DESCRIPTIVE STUDY OF ASIAN INDIAN PATIENTS WITH RHEUMATOID VASCULITIS IN RETROSPECT: A SINGLE, TERTIARY CARE CENTRE EXPERIENCE

J. Mathew[1], A. Ganapati[1], R. Goel[1], S. Pulikool[1], A.J. Mathew[1], R. Janardhana[1], M. Gowri[2], D. Danda[1]. *[1]Rheumatology; [2]Biostatistics, Christian Medical College, Vellore India, Vellore, India*

Background: Rheumatoid vasculitis (RV) is a severe extra-articular manifestation of rheumatoid arthritis (RA), with high morbidity and mortality reported in literature

Objectives: To describe the Asian Indian perspective on RV patients, their clinico-laboratory features and their outcome along with the factors affecting them

Methods: A retrospective review of electronic medical records of 8984 RA patients from January 2007 to August 2016, was done for those satisfying Scott & Bacon criteria for RV[1]. Probable RV was defined as patients not satisfying Scott & Bacon Criteria, but were managed like RV after exclusion of alternate diagnosis. Birmingham Vasculitis activity score (BVAS) version 3[2] was used for monitoring activity of RV

Results: 63 patients of RV were identified, with a study period prevalence of 0.7%, in our RA cohort. 33 (52.4%) patients were female. Mean age of patients was 50.7±11.5 years with median duration of RA being 6 years. Involvement of Peripheral Nervous System (PNS) was the commonest manifestation of RV in 52/63 (82.5%) patients followed by skin in 34/63 (53.9%) patients. Rheumatoid Nodule was seen in 14/ 63 (22.2%) patients. Percentage of current and ex-smokers combined,was same as rheumatoid nodule prevalence. 52 (82.5%) patients had biopsy evidence of vasculitis.26/51 (50.9%)patients were started on mycophenolate mofetil, 13/51 (25.5%)patients on cyclophosphamide, 8/51 (15.7%) patients on azathioprine, 4/51 (7.8%) patients on Methotrexate as immunosuppressive (IS) agent along with mean dose of 46.6±13.7 (0.86±0.23mg/kg/day) prednisolone. Additionally, Rituximab & IVIg were used in 2 patients each respectively. 3 months after initiation of immunosuppression 26/50 (52%) patients on follow-up were in remission and 39/47 (82.9%) patients attained remission at 6 months. Mean time to achieve remission was 151.1±86.3 days. All IS agents were equally effective in inducing remission at 3 and 6 months and showed statistically similar BVAS reduction at 3 and 6 months from baseline (t test & chi-square test). 7 (11.2%) deaths noted in the cohort at their respective last visit during 195.3 patient years cumulative follow up. Multiple regression analysis showed that at baseline, presence of PNS involvement, eosinophilia, thrombocytosis, higher BVAS score and higher steroid requirement were predictors of persistently active vasculitis and absence of eye involvement and higher hemoglobin % at baseline were predictors for remission, at 3 months ($p<0.05$). 4/50 (8%) patients had relapse of vasculitic symptoms. 2 and 5 year survival rates were 96.2% and 83.9% respectively

Conclusions: Our cohort of Asian Indian RV was compartively younger with lesser RA duration, less percentage of ever-smokers, lesser rheumatoid nodule prevalence, higher PNS involvement with better survival/mortality rates compared to published literature. All IS agents showed equal rates of BVAS remission & BVAS reduction at 3 and 6 months of treatment

THU0323 THE INCIDENCE RATES OF ANCA-ASSOCIATED VASCULITIDES IN NORTHERN GERMANY (SCHLESWIG-HOLSTEIN) REMAIN STABLE BETWEEN 1998 TO 2014

K. Herlyn[1], W.L. Gross[2], E. Reinhold-Keller[2]. *[1]Rheumatology, Private Practice, Lübeck; [2]Rheumatology, Klinikum Bad Bramstedt, Bad Bramstedt, Germany*

Objectives: To assess the incidence of ANCA-associated vasculitides (AAV) in a stable population by registering all newly diagnosed patients in a large region in Northern Germany. To investigate the epidemiology and pattern of AAV over seventeen years in a prospective study.

Methods: Between 1/1/98 and 31/12/14 all newly diagnosed cases of AAV (Granulomatosis with polyangiitis (GPA), microscopic polyangitis (MPA), eosinophilic granulomatosis with polyangitis (EGPA)) as defined by the Chapel Hill Consensus Conference 1992 were identified in a large mixed rural/urban northern German region consisting of 2,83 million habitants in a population-based prospective study. The following sources were explored on a regular basis: (a) departments of all hospitals, including their outpatient clinics; (b) all departments of pathology, and (c) the reference immunological laboratories serving the catchment area. All cases were re-evaluated by the authors.

Results: Within the observation period of seventeen years 551 patients were identified as having a new diagnosis of AAV in the catchment area, the incidence rate was 12 (range 8 -16)/million/year. GPA represents 70% of the AAV with an incidence rate of 7.9 (range 6–12)/million/year (95% CI 1;11 - 5*;19*), MPA with an incidence rate of 2.4 (range 1–5)/million/year (CI 0;3 – 1;9) and EGPA 1.1 (range 0–2)/million/year (CI 0;4).

Incidence rates of GPA were on average three times higher than those of MPA and seven times higher than CSS. The incidence rates were stable between 1998 and 2014, our observations did not reveal significant differences. Gender differences were not observed. People diagnosed with MPA were on average 66.4 years old.

Conclusions: Results of our unique population based vasculitis register over seventeen years assessing the incidence of AAV in a region of 2.83 million habitants in northern Germany demonstrate stable incidence rates for AAV. Variances between years have been observed, but no pattern or periodicity. Compared to other studies investigating small regions or referral centers the incidence rates for AAV were comparable to the incidence rates observed in Norway, Sweden and the United States, lower than those in United Kingdom, but higher than in Spain and Vilnius. The incidence rates of MPA are significantly higher in Japan, whereas GPA and CSS have rarely been diagnosed.

THU0324 NEUTROPHILS IN GIANT CELL ARTERITIS: MONITORING DISEASE PROGRESSION DURING THERAPY TAPERING

T. Kuret[1], K. Lakota[1,2], P. Žigon[1], M. Ogrič[1], Ž. Rotar[1], R. Ješe[1], S. Sodin-Šemrl[1,2], S. Čučnik[1,3], M. Tomšič[1,4], A. Hočevar[1]. *[1]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana; [2]FAMNIT, University of Primorska, Koper; [3]Faculty of Pharmacy; [4]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Background: Giant Cell Arteritis (GCA) represents a medical emergency due to risk of permanent vision loss and/or cerebrovascular insults. Polymyalgia rheumatic (PMR) frequently coexists with GCA[1]. No diagnostic or prognostic markers are yet known for GCA and predicting relapses during steroid therapy tapering is difficult. Biomarkers, such as serum amyloid A (SAA) and interleukin-6 (IL-6) provide added value for monitoring inflammation and a recent investigational study indicated the potential use of neutrophils and their surface markers in GCA pathogenesis[2].

Objectives: To determine the percentage of neutrophils, T and B cells, and the mean fluorescence intensity (MFI) of L-selectin (CD62L) and integrin αM (CD11b) on $CD16^+$ neutrophils in peripheral blood of newly diagnosed, untreated GCA and PMR patients vs. healthy controls (time 0) and at GCA follow-up (7, 30 and 90 days after therapy).

Methods: Flow cytometry of stained, lysed and fixed whole blood[2] was performed in 10 GCA patients (6 followed longitudinally), 7 PMR patients and 5 healthy controls (7-colour immunophenotyping kit, Miltenyi). Levels of SAA and IL-6 were measured in sera of GCA patients (n=6) using nephelometry and ELISA, respectively.

Results: Percentage of neutrophils was significantly higher at time 0 in GCA and PMR patients compared to healthy controls. Expression of both CD62L and CD11b on $CD16^+$ neutrophils was also higher in GCA and PMR patients, as compared to healthy controls. Longitudinally, GCA patients showed an initial decrease in percentage of neutrophils at day 7 in comparison with time 0, increasing on days 30 and 90, while both T ($CD4^+$) and B cells exhibited a significant elevation in % at day 7, with a decline at days 30 and 90. The MFI of neutrophil CD62L steadily decreased from day 0 (85.80±45.45) to day 7 (71.99±29.93) and day 30 (57.61±42.17), while showing a substantial increase on day 90 (88.54±60.35). CD11b expression diminished initially and remained reduced on day 90. Levels of SAA and IL-6 declined sharply from day 0 to 7 (>10-fold drop) and day 30, with gradual elevation of both on day 90.

Conclusions: Neutrophil CD62L may represent a good surface marker for monitoring disease progression following glucocorticoid tapering. SAA and IL-6 exhibit a sharp decrease at early time points, increasing at day 90. In the future, a larger, longer study of neutrophils and their CD62L expression could support clinicians in their decision when and how to re-evaluate therapy in GCA patients.

THU0325 RELATIONSHIP OF THE INITIAL SYMPTOMS TO THE DIAGNOSIS DELAY AND POOR PROGNOSIS IN PATIENTS WITH TAKAYASU ARTERITIS

K. Matsumoto, Y. Kaneko, K. Izumi, K. Yamaoka, T. Takeuchi. *Internal Medicine, Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan*

Background: Clinical courses of Takayasu arteritis are of great variety. Its non-specific initial symptoms can cause the delay in diagnosis and lead to poor prognosis. However, the symptoms of very early phase of Takayasu arteritis and their effects on diagnosis delay and prognosis are unclear.
Objectives: To clarify the characteristics of initial symptoms of Takayasu arteritis, the delay in diagnosis, and its relationship with prognosis.
Methods: The consecutive patients with Takayasu arteritis with analysable information in our hospital were enrolled. Initial symptoms, laboratory findings before diagnosis, the duration from symptom onset to diagnosis, and prognosis were investigated. Initial symptoms were divided into 7 groups; cranial symptoms (dizziness, syncope, headache, neck pain, hemi-paralysis, and jaw claudication), visual symptoms (vision loss and visual field loss), extremities symptoms (claudication of extremities, coldness of limbs, bilateral difference in blood pressure, and limb numbness), cardiac/aortic symptoms (dyspnea on exertion, palpitation, and chest compression), hypertension, general illness (fever, fatigue, body weight loss, and arthralgia), and abnormal medical examinations (heart murmur, bruit on any extremities, and abnormal chest X-ray). Poor outcome was defined as a cardiovascular surgery or death.
Results: A total of 98 patients were enrolled with the median observation period of 12.1 years (range, 1 month to 59 years). Eighty-seven (88.7%) were female and the mean age at diagnosis was 37 years. The mean duration from the initial symptoms to diagnosis was 600 days. Thirty-four (34.7%) patients had poor outcomes. The initial symptoms before diagnosis were cranial symptoms in 25%, visual symptoms in 5%, extremities symptoms in 20%, cardiac/aortic symptoms in 7%, hypertension in 9%, general illness in 26%, and abnormal medical examinations in 8%. The duration from symptom onset to diagnosis was 792, 52, 567, 752, 1318, 293 and 1014 days (p=0.10), respectively; the rate of poor outcome was 28, 25, 38, 86, 75, 22, and 25% (p=0.010), respectively. The duration from symptom onset to diagnosis was longer in the patients with poor prognosis than those without (837 vs 493 days, p=0.06). The patients with extremities symptoms were younger (29.6 vs 38.9 years, p=0.026) than those with the other symptoms, and patients with cardiac/aortic symptoms were older (49.7 vs 36.3 years, p=0.044). The patients without general illness showed lower levels of C-reactive protein (3.26 vs 5.86 mg/dl, p=0.048), erythrocyte sedimentation rate (38.3 vs 66.6 mm/h, p=0.01), and platelet counts ($29.4*10^4$ vs $34.0*10^4/\mu l$, p=0.09), and resulted in poor outcome more frequently than those with (42.6 vs 22.6%, p=0.058).

Conclusions: The initial symptoms of Takayasu arteritis before diagnosis varied widely, and majority of them were non-specific. Lacking inflammatory signs were related with delayed diagnosis and poor prognosis.

Objectives: To evaluate the efficacy of adalimumab (ADA) in short and long term follow-up in refractory uveitis of Behçet's disease (BD)
Methods: Multicenter study. Ocular inflammation was evaluated according to "SUN working Group" (Am J Ophthalmol 2005;140:509–516), and the macular thickening with OCT. A comparison was carried out between baseline, and follow-up visits. Results are expressed as mean±SD or median [IQR]. Continuous variables were compared with Wilcoxon test.
Results: We studied 74 patients/132 affected eyes (39M/35W); mean age 38.7±11.3. The ocular pattern was panuveitis (n=45), posterior uveitis (n=14), anterior uveitis (n=14) and intermediate uveitis (n=1). Before ADA, systemic treatment with corticosteroids, iv metilprednisolone (n=23), Cyclosporin A (58), azathioprine (33), metotrexate (31) and other drugs (28) was used. The dose of ADA was 40 mg/2 weeks/ sc in monotherapy (n=22) or combined (n=52). Most patients showed a rapid and progressive improvement (TABLE). The 24 patients (37 affected eyes) with CME showed a significant improvement.
ADA was optimized in 23 (31.1%) that were in remission for 15.3±9 months. Interval of administration was increased to 3 (n=6), 4 (13), 5 (1), 6 (1) and 8 weeks. After a mean follow-up of 13.0±9.7 months after optimization, 21 patients were stable and 2 had a severe flare. In 4 patients ADA was stopped after 35.2±9.3 months in remission. The main adverse effects observed were lymphoma (n=1), pneumonia (1), and 2° bacteriemia by E. Coli (1)

THU0327 ASSOCIATION BETWEEN THE TC/HDL RATIO AND DISEASE ACTIVITY IN PATIENTS WITH TAKAYASU ARTERITIS

L. Pan[1], J. Du[2], H. Liao[1]. *[1]Rheumatology and Immunology; [2]Beijing An Zhen Hospital, Capital Medical University., Beijing, China*

Background: Accelerated atherosclerosis has become the main cause of morbidity in patients with autoimmune diseases such as RA and SLE [1]. The Cholesterol/High-density Lipoprotein Cholesterol (TC/HDL-C) ratio is a high discriminatory power index for coronary heart disease. A high TC/HDL-C ratio has been intensively used as a predictor of CVDs [2]. EULAR Task Force recommended that the TC/HDL-C ratio should be regarded as an important prognostic indicator for future cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) [3]. However, the relationship between the TC/HDL-C ratio and disease activity of Takayasu arteritis (TAK) is unclear.
Objectives: To investigate changes in the TC/HDL-C ratio and to evaluate the relationship between the TC/HDL-C ratio and disease activity of TAK.
Methods: A retrospective study of 103 patients with TAK and 73 healthy controls was performed. We compared the triglyceride (TG), TC, low-density lipoprotein cholesterol (LDL-C), HDL-C and TC/HDL-C ratio between patients and healthy controls, and we analyzed correlations between the lipid parameters and indexes

of TAK activity. A ROC curve was used to determine the predictive value of TC/HDL-C ratio in patients group.

Results: The TG level was higher in patients with TAK than in the controls (p=0.000). The TC, LDL-C, and HDL-C levels were significantly lower in patients with TAK than in the controls (p=0.000, p=0.000, and p=0.000, respectively). The HDL-C level was significantly lower in the active TAK group than in the inactive TAK group (p=0.005). The TC/HDL-C ratio was significantly increased in patients with disease activity (p=0.001), and it exhibited a positive relationship with the high-sensitivity C-reactive protein level (r=0.234, p=0.003) and Kerr score (r=0.219, p=0.031). In addition, the TC/HDL-C ratio of 3.698 was determined as a predictive cut-off value of TAK (sensitivity 61.0%, specificity 78.6%, area under the curve=0.743) (Figure 1).

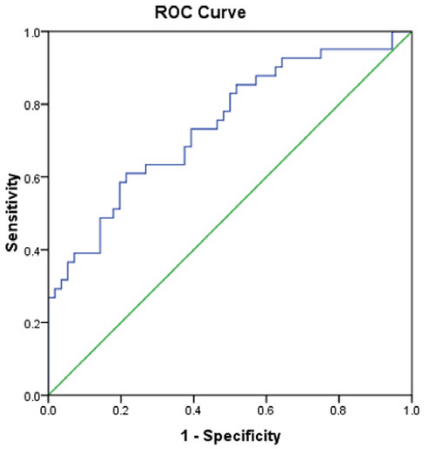

Figure 1.Receiver-operating characteristic curve for the TC/HDL-C ratio.
The area under the curve was 0.743, with sensitivity and specificity of 61.0%and 78.6%

Conclusions: For the first time, we showed that serum levels of TC, LDL-C, and HDL-C were significantly lower in patients with TAK, and the TC/HDL-C ratio has a positive relationship with the disease activity of TAK, suggesting that the TC/HDL-C ratio may be a potential indicator for monitoring the disease activity of patients with TAK.

THU0328 PREDICTORS OF SEVERE DAMAGE IN ANCA-ASSOCIATED VASCULITIS: DATA FROM A MONOCENTRIC INCEPTION COHORT

M. Felicetti, R. Padoan, M. Cerchiaro, M. Zen, L. Punzi, F. Schiavon. *Department of Medicine DIMED, Operative Unit of Rheumatology, University of Padova, Padova, Italy*

Background: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are multi-systemic diseases associated with anti-neutrophil cytoplasmic antibodies (ANCA). Patients develop severe and irreversible damage, even in early stages of the disease, but data about prognostic factors are limited.

Objectives: To assess items and predictors of severe damage in a monocentric cohort of ANCA-associated vasculitis (AAV) patients, classified as GPA or MPA.

Methods: Clinical and serological data of patients, followed-up in a daily practice setting, were retrospectively revised. Severe damage, defined as a Vasculitis Damage Index (VDI) ^{3} 5, was assessed after 12 months and at last examination (LE). The five most important items, predictors of severe damage and their increase rate were analysed at the beginning and at the last examination.

Results: 69 patients were included, 53 (76.8%) classified as GPA and 16 (23.2%) as MPA. According to EUVAS classification 7 (10.1%) were affected by limited disease, 14 (20.3%) by early systemic disease, 35 (50.7%) by generalized disease and 13 (18.9%) by severe disease. Patients were middle aged at diagnosis (54.6±15 years) with a diagnostic latency of 9.6±16.4 months, mostly caucasian (98.6%) and equally represented in sex (female 53.6%). Mean follow-up was 54.5±41.9 months. The number of flare/year at LE was significantly higher in anti-PR3 patients if compared to anti-MPO (1.0±1.1 vs 0.3±0.5, p=0.028).

The VDI items most frequently observed are listed in Figure 1.

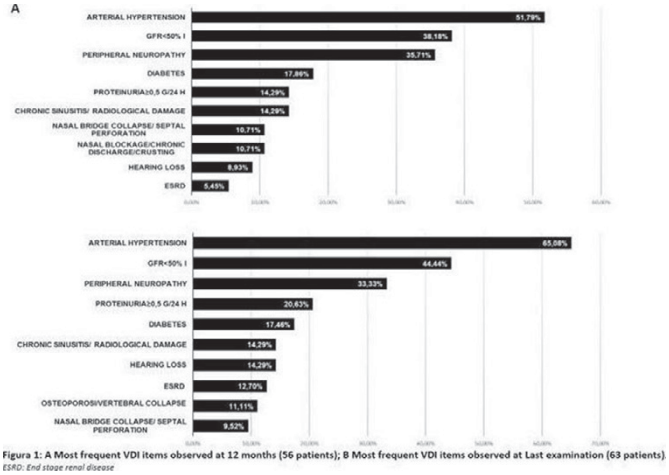

Figura 1: A Most frequent VDI items observed at 12 months (56 patients); B Most frequent VDI items observed at Last examination (63 patients).
ESRD: End stage renal disease

We measured their frequencies and increase rate from diagnosis to the LE: arterial hypertension increased from 3 (4.7%) to 41 (65.1%) (+60.3% (IC 95% 48–71%), p<0.0001), GFR<50% from 1 patient (1.6%) to 28 (44.4%) (+42.8 (IC 95: 31–55), p<0.0001), neuropathy from 4 (6.3%) to 22 (34.9%) (+28.6% (IC 18–41), p<0.0001), diabetes from 0 (0%) to 11 (17.5%) (+17.5% (IC 10–29); p=0.0011) and proteinuria>0.5 g 24 h from 1 (1.6%) to 13 (20.6%) (+19% (IC 11–31); p=0.0006).

Severe damage, defined as VDI≥5, increased over time, being present in none patient at diagnosis and in 14 (25.9%) at last examination.

At univariate analysis, number of flares/year (p=0.012), BVASv3 at diagnosis (p=0.03), steroid pulses therapy (p=0.04) and steroid cumulative dose (p=0.03) were identified as predictive factors of severe damage in the first year. Conversely, creatinine at LE (p=0.04), numbers of hospitalizations (p=0.009) and steroid cumulative dose at LE (p=0.47) were found to be predictors of long-term severe damage. Interestingly, ANCA pattern did not influence damage severity and only slightly differences in VDI items was noted between anti-PR3 and anti-MPO positive patients.

Conclusions: Our results highlights that knowing severe damage predictors is key in short and long term treat to target patient's management.

Background: The aim of this study was to determine the demographic, clinical,

laboratory and management characteristics along with the clinical course of Budd-Chiari syndrome (BCS) associated with Behçet's disease (BD).
Methods: Sixty patients with BD with BCS (40 male, 20 female) were identified in 23 rheumatology centers (Group I). A total of 169 consecutive patients (100 male, 69 female) with BD who did not have clinically apparent BCS during the follow-up were evaluated as the control group (Group II).
Results: Comparison of the demographic and clinical findings between the Group I and the Group II were as follows: The mean age of disease onset was 23.1 +/- 6.7 years vs. 26.8±0.6 years (p=0.013), mean age at diagnosis was 27.2±0.9 vs. 30.4±0.6 years (p=0.008), arthritis was 10% vs. 28.4% (p=0.002), papulopustular skin lesion was 48.3% vs 69.2% (p=0.003), central nervous system (CNS) involvement 10% vs. 3% (p=0.03), cardiac involvement was 16.7% vs. 2.4% ($p<0.001$), superficial thrombophlebitis was 23.3% vs. 4.7% ($p<0.001$), and deep vein thrombosis was 58.3% vs. 15.4% ($p<0.01$). On diagnosis 50% of BD patients with BCS were classified as Child-Pugh A. Inferior vena cava obstruction was observed in 38.3% and portal vein thrombosis was seen in 3.3% of the patients with BCS. Mortality in BCS patients with BD was 18.3%. BCS related treatment after diagnosis in patients with BD were as follows: 71.7% of patients were treated with monthly cyclophosphamide intravenous pulses, 53.3% received intravenous pulse corticosteroids, 55.9% used azathioprine, 54.2% had warfarine treatment, and 50.8% were treated with low molecular weight heparin.
Conclusions: This study shows a higher frequency of cardiac and CNS involvement, superficial thrombophlebitis, papulopustular skin lesion, deep vein thrombosis in BD patients with BCS. Arthritis was observed less common in BD patients with BCS. The mean age onset was lower in patients with BCS. Medical treatment with immunosuppressive agents and anticoagulation appears to be the treatment of choice in BD patients with BCS. The majority of the patients with BCS were Child–Pugh class A on diagnosis. The inferior vena cava is frequently involved and, often associated with deep vein thrombosis and cardiac involvement.

THU0330 MYCOBACTERIAL CORD FACTOR ANALOG INDUCES HIGH IL-6 SECRETION AND MINCLE RECEPTOR EXPRESSION IN PATIENTS WITH TAKAYASU ARTERITIS

N. Gupta[1], J. Kabeer Doss[2], H. Mohan[2], R. Goel[2], D. Danda[2]. *[1]CHRistian Medical College, VELLORE, Vellore, India; [2]Clinical Immunology & Rheumatology, CHRistian Medical College, VELLORE, Vellore, India*

Background: Association between Takayasu Arteritis (TA) and Tubcerculosis (TB) has been in vogue for years. Scientific evidence for this association is limited.
Objectives: To study pro-inflammatory cytokine responses and mRNA expression in patients with TA on exposure to Trehalose-6,6-dibehenate (TDB), a synthetic analogue of mycobacterial cord factor in comparison with healthy controls.
Methods: Patients with type V TA satisfying 1990 ACR criteria and age and sex matched healthy controls were recruited. 10 ml blood was collected in heparin coated tube. PBMCs were separated by density gradient centrifugation. PBMCs were cultured with and without 5μg/ml and/or 50 μg/ml of TDB for 48 hours in RPMI medium at 5% co2 incubator. IL-6, TNF-αand IL-17 were measured in cell culture supernatant. RNA was extracted from the cells and quantification of gene expression was performed using sequence specific primers with SYBR green in Step One Plus™ Real-Time PCR Systems (Applied Biosystems).
Results: Twenty two TA patients and 21 age and sex matched healthy controls were recruited. Baseline characteristic of cases included median (range) age:26.5 years (15–49), male:femaleratio of 5:17, ITAS-CRP2010: 7 (1–26) and DEITAK: 7.5 (1–21). Both patients and controls showed response by secreting IL-6 and TNF-α upon stimulation withTDB. Relative induction of IL-6 was significantly higher in TA [31.88 (0.74–168)] as compared to healthy controls [1.931 (0.644–8.21); $p<0.002$]. IL-17 was undetectable even upon TDB stimulation. Relative mincle expression was significantly upregulated by TDB in TA1.03 (0.623–1.346) fold, as compared to healthy controls 0.43 (0.36–0.57) fold ($p<0.05$). Relative gene expressions of IL-6, IL-8, TNFα, IFN-gand BCL-10 were not significantly different between TA and healthy controls.
Conclusions: Stimulation with TDB led to higher secretion of IL-6 and increased mincle expression in PBMCs of TA patients as compared to healthy controls.

THU0331 MYELOPEROXIDASE DEPLETION IS A SELECTIVE FEATURE OF TAKAYASU ARTERITIS AND PREDICTS THE CLINICAL OUTCOME

A.A. Manfredi, G.A. Ramirez, V. Canti, E. Tombetti, M. Baldini, E. Baldisera, P. Rovere-Querini, N. Maugeri. *San Raffaele Scientific Institute, Milano, Italy*

Background: Takayasu's arteritis (TA) is a rare large-vessel vasculitis characterized by persistent remodelling of the vessel walls. The role of innate immune cells in TA is poorly understood. Biomarkers to be used for assessment of TA activity and clinical outcome are missing. A trimodal pattern of myeloperoxidase (MPO) distribution (simultaneous occurrence of neutrophils with complete depletion, reduced and normal content of the enzyme) is detectable in the very early phase of acute myocardial infarction and has been associated with a burst of neutrophil interaction with activated platelets[1]
Objectives: Here, we aimed at characterizing the phenotype of neutrophils and platelets in patients TA and correlating these biological findings with clinical data.
Methods: neutrophil MPO expression has been studies in 93 subjects, including 21 TA patients, 20 age- and sex-matched healthy donors that served as controls, 25 patients with chronic stable atherosclerosis (CSA), eight patients with giant cell arteritis (GCA), five patients with gramulomatosis with polyangitis (GPA), four patients with eosinophilic GPA (EGPA) and ten patients with polymyalgia rheumatica (PMR). Blood samples were collected and processed as described[1–3]. Neutrophil MPO content, platelet P-selectin and High-Mobility Group B1 (HMGB1) in platelet derived microparticles (PDμP) release were assessed by flow cytometry. TA patients were then followed up for a median time of 3.43 years.
Results: The trimodal distribution of neutrophils MPO content was identified in 17/21 TA, 1/8 GCA, 0/10 PMR, 0/25 CSA, 0/5 GPA and 0/4 EGPA patients; moreover in 0/20 healthy controls (ANOVA, F=15.22, $p<0.0001$). Neutrophil MPO content and the presence of neutrophils with complete MPO depletion in TA patients correlated inversely with i) platelet P-selectin expression ($p<0.01$), ii) the fraction of $HMGB1^{+}$-PDμP ($p<0.01$) and iii) disease duration, implicating an association of platelet and neutrophil activation with the disease natural history. In fact, the Kaplan Mayer analysis reveals that TA patients that had neutrophils with complete MPO depletion are at a significantly increased risk of ischemic complications during the follow up (long-rank=4.864, p=0.027, HR=36.15 abd CI-95%=0.15–7.51).
Conclusions: Neutrophils and platelets are significantly activated in TA. Paroxysmal neutrophils activation, leading to complete MPO depletion, is a common feature and predict ischemic events and as such the clinical disease outcome.

THU0332 CARDIAC INVOLVEMENT IN POLYARTERITIS NODOSA: A RETROSPECTIVE PATHOLOGICAL STUDY OF 37 AUTOPSY CASES

O. Zimba[1], M. Bagriy[2]. *[1]the Department of Internal Medicine, Danylo Halytsky Lviv National Medical University, Lviv; [2]Department of Pathological Anatomy, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*

Background: Cardiac involvement is a significant cause of the death and disability in systemic vasculitis. The comprehensive analysis of histopathologic findings in polyarteritis nodosa (PN) can help better understand mechanisms of excessive cardiovascular risk in patients with systemic vasculitis.
Objectives: To investigate the variation of cardiac pathological findings in autopsy cases of PN.
Methods: A retrospective analysis of cardiac pathological changes was performed in 37 autopsy cases of PN over period of 15 years. There were 28 males and 9 females, ranging from 23 to 85 years. The median age at disease onset was 35, 7 years; the median duration of disease was 2.1 years with a range of 2 month to 7 years.
Results: The destructive-productive vasculitis of the coronary arteries have been found in 30 cases (81.1%) of PN. The vessels most affected were myocardial, and epicardial medium and small-sized arteries. Histologically, the remodelling of coronary artery tree in PN had a wide range of acute and chronic changes that likely were depended on the duration of the disease. There were three types of pathological findings: (1) arteritis with predominantly destructive changes; (2) arteritis with predominantly proliferative changes; (3) destructive-productive arteritis. The early phase of PN has been characterized by abnormalities of vessels wall from mucoid swelling to fibrinoid necrosis. The most common was panarteritis with involvement of all layers of the arterial wall, and inflammatory responses with intramural, and perivascular infiltrates, mainly composed of lymphocytes, and neutrophils. However, endo-, meso-, and periarteritis also were observed in some cases. The most remarkable lesions in coronary arteries were the nodules visible to the naked eye along coronary arteries. They were present in 9 cases (30%), and can be described as well-demarcated nodular thickening of the artery walls with size from 0.1 to 0.4 cm. The pathological basis of nodules are areas of focal inflammation, destruction and aneurysmal dilatations of artery wall. In cases of chronic course of PN, the intimal hyperplasia due to proliferation of endothelial cells have been observed. Interestingly, that this productive endarteritis with luminal narrowing of coronary arteries was common in patients who were exposed to different types of occupational xenobiotic (silica dust, pesticides, insecticides, solvents, heavy metals). In 5 (16.7%) cases, luminal occlusion due to intimal proliferation, fibrosis and thrombus formation

led to the myocardial infarction, and death. Pathological manifestation of cardiac involvement in PN included the left ventricular hypertrophy due to renovascular arterial hypertension in 26 cases (70.3%). In addition, interstitial myocarditis was observed in 4 cases (10.8%).

Conclusions: Our date suggest that cardiac involvement is common in polyarteritis nodosa (81.1%), and coronary vasculitis affecting medium and small-sized arteries with wide range of acute and chronic changes can be the life-threatening condition.

THU0333 ARE THE DEMOGRAPHIC AND CLINICAL FEATURES OF POLYARTERITIS NODOSA SIMILAR BETWEEN THE UK AND TURKEY?

O. Karadag[1,2], A. Erden[1], E.D. Batu[1], S. Gopaluni[2], A. Sari[1], B. Armagan[1], I. Ertenli[1], S. Ozen[1], D. Jayne[2]. *[1]Hacettepe University Vasculitis Centre, Ankara, Turkey; [2]Vasculitis and Lupus Clinic Addenbrooke's Hospital, University of Cambridge, Cambridge, United Kingdom*

Background: Polyarteritis Nodosa (PAN) is the first described but the least frequent primary systemic vasculitis. Various subgroups of necrotizing vasculitis have separated out from PAN, and are now defined such as HBV-related, cutaneous PAN or monogenic forms of vasculitis. There is a paucity of information on the current phenotypes and, ethnic and geographic differences of PAN.

Objectives: This study compares the demographic and clinical features between two PAN cohorts.

Methods: A retrospective survey of databases from two vasculitis centres between 1990–2016 for PAN patients fulfilling the EMEA Vasculitis Classification algorithm. All paediatric patients met the Ankara 2008 (EULAR/PReS endorsed) criteria for childhood PAN. Patients with typical angiographic and/or histopathologic findings consistent with PAN were included. Demographics, and clinical characteristics, Disease Extent Index (DEI) and Vasculitis Damage Index were recorded. A subgroup analysis based on disease extent between the UK patients with Turkish (TR) patients was performed.

Results: 93 (M/F: 51/42) patients (UK: 47, TR: 46) were recruited into the study. The mean age was 46.7 (20.7) years. Three were HBV-related, 20 (21.5%) had paediatric onset, 16 (16.5%) were cutaneous PAN.

Turkish patients had younger disease of onset (28.7 (17.8) vs. 43.0 (18.0), $p<0.001$). Twelve (26%) of Turkish patients had a monogenic disease (FMF association in 7, DADA2 in 5).

Cutaneous PAN was more frequent in the UK group (12 pts vs. 4pts, p=0.031) whereas renal involvement was increased in the TR group (Table). In contrast to systemic involvement, female predominance was seen in cutaneous PAN (40.3% vs. 68.8%, p=0.037). DEI was similar in both systemic involved groups (6.1 (2.4) vs. 6.5 (2.3), p=0.428). No difference was found between paediatric and adult onset patients except for frequency of cutaneous lesions (100% vs. 64.3%, p=0.002).

During a median 67.5 (32–126) months follow up, 13 patients deceased. No difference was found between the groups regarding relapse rate, death and vasculitis damage index (Table).

Table: Demographic and clinical characteristics of PAN patients

	All patients n: 93	UK cohort (n:47)	Turkish cohort (n: 46)	p
Age at time of study	46.7 (20.7)	52.5 (19.6)	33.6 (17.1)	**<0.001**
Age at diagnosis, years	35.8 (19.2)	43.0 (18.0)	28.7 (17.8)	**<0.001**
Time to diagnosis, months	2 (1-6)	2 (1-5)	3 (2-8)	**0.041**
Sex, male, %	54.8	44.7	65.2	**0.047**
Any constitutional symptoms, %	87.7	87.1	88.1	0.898
Any cutaneous manifestations, %	71.7	68.1	75.6	0.426
Musculoskeletal manifestations, %	78.0	76.7	82.6	0.278
Neurologic manifestations, %	38.8	32.5	54.3	0.089
Testicular pain/tenderness (men only), %	20.3	28.5	16.7	0.310
Renal involvement, %	58.0	40.4	76.1	**<0.001**
Gastrointestinal manifestations, %	47.1	48.8	45.0	0.733
Follow up, months	67.5 (32-126)	79.0 (35.0-143.0)	65 (29.5-108)	0.669
Response to treatment, % • Complete • Partial • No response	 58.5 30.8 10.8	 60.4 30.2 9.4	 54.5 31.8 13.7	0.838
Any relapse,%	57.1	58.9	52.9	0.675
Death, %	14.0	12.7	15.2	0.733
VDI	1 (0-1)	1 (0-1)	1 (0-2)	0.632

Values are labeled as mean (SD or median (IQR 25%-75%), VDI: Vasculitis Damage Index

Conclusions: Even though, the Turkish group had a younger disease onset and higher additional monogenic disease; disease extent, relapse rate, death, and damage index were similar in both groups. Among the cutaneous PAN group there was a female predominance. A multi-centre GWAS study could highlight the impact of genetic background on disease presentation and severity.

THU0334 EVALUATION OF SUBCLINICAL VASCULAR DAMAGE IN PATIENTS WITH POLYMYALGIA RHEUMATICA: A CROSS-SECTIONAL STUDY USING AN INTEGRATED, NON-INVASIVE APPROACH OF COLOR DOPPLER ULTRASOUND AND CARDIO-ANKLE VASCULAR INDEX (CAVI) MEASUREMENT OF ARTERIAL STIFFNESS

P. Sessa[1], I.M. Rutigliano[1], R. Scrivo[1], V. Silvestri[2], F. Ciciarello[3], G. La Torre[4], F. Conti[1], R. Priori[1], C. Alessandri[1], V. Riccieri[1], M. Di Franco[1], B. Gossetti[2], G. Valesini[1]. *[1]1) Department of Internal Medicine and Medical Specialties; [2]2) P. Stefanini General and Specialist Surgery Department; [3]3) Department of Cardiovascular Science; [4]4) Department of Public Health and Infectious Diseases, University of Rome la Sapienza, Roma, Italy*

Background: The association of chronic inflammatory rheumatic disorders with an increased risk of vascular disease, especially cardiovascular and cerebrovascular disease, is a consolidated matter, but data on polymyalgia rheumatica (PMR) are still inconsistent.

Objectives: The aim of our cross-sectional study was to investigate the presence of vascular damage in patients with PMR by analyzing subclinical vascular disease through validated, non-invasive cardiovascular disease markers.

Methods: We enrolled patients with PMR diagnosed according to the EULAR classification criteria and, as controls, patients with major cardiovascular risk factors (MCVRF) including hypertension, diabetes, hypercholesterolemia, cigarette smoking, and obesity. In all of them we performed color Doppler ultrasound to evaluate the common carotid intima-media thickness (IMT), the prevalence of carotid artery stenosis and of anterior-posterior abdominal aortic diameter (APAD); we also assessed the cardio-ankle vascular index (CAVI) to measure arterial stiffness and contextually the ankle-brachial index (ABI) to investigate the presence of lower-extremity peripheral arterial disease.

Results: Forty-eight patients with PMR and 56 with MCVRF were included. Demographic parameters were balanced between groups. A significant increase of IMT (1.03±0.23 *vs* 0.89±0.20; p=0.02), CAVI (8.59±1.23 vs 7.59±0.93; p=0.01) and APAD values (22.03±4.86 *vs* 19.14±4.65; p=0.03) was found in PMR patients with respect to MCVRF controls. No differences were reported with regards to the prevalence of carotid artery stenosis or ABI values between the two groups. No significant correlation between disease duration or duration of glucocorticoid treatment and IMT or CAVI values was found in PMR patients. Results of bivariate analysis showed a significant correlation between IMT and CAVI in both PMR and MCVRF patients (r^2=0.845 and 0.556, respectively; $p<0.001$).

Conclusions: Our study adds new information on cardiovascular risk in PMR patients, showing an increase in subclinical cardiovascular lesions and paving the way for further studies to define the utility and modality of cardiovascular screening for primary prevention in these patients.

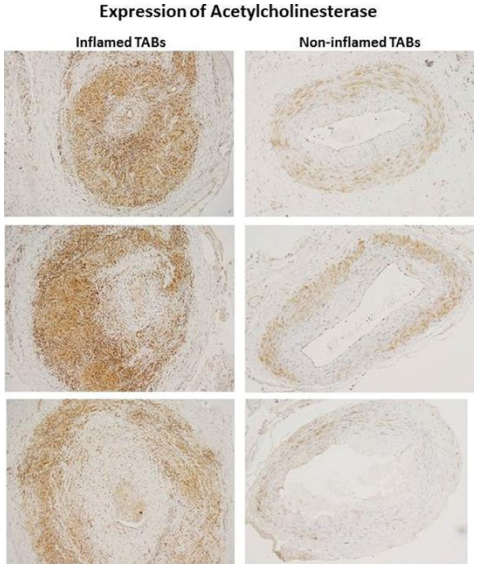
THU0335 ACETYLCHOLINESTERASE IS HIGHLY EXPRESSED IN THE INFLAMED VESSEL WALL OF PATIENTS WITH GIANT CELL ARTERITIS

P. Therkildsen[1], B.D. Nielsen[1], K.K. Keller[1], T. Steiniche[2], L.C. Gormsen[3], I.T. Hansen[1], E.-M. Hauge[1]. *[1]Department of Rheumatology; [2]Department of Histopathology; [3]Department of Nuclear Medicine and PET Centre, Aarhus University Hospital, Aarhus, Denmark*



Background: The temporal artery biopsy (TAB) remains the gold standard in the diagnosis of giant cell arteritis (GCA) and is part of the ACR Classification criteria for GCA. However, TABs are false-negative in 10–60% of cases [1]. Cellular studies have shown that activated immune cells upregulate the acetylcholinesterase (AChE) expression [2]. If AChE is upregulated in the active GCA vessel wall, it may potentially improve the TAB as a diagnostic tool.

Objectives: To investigate the *in-situ* expression of acetylcholinesterase (AChE) in the vessel wall of patients with biopsy-positive GCA and compare to non-GCA patients.

Methods: In this histological case-control study, TABs from a total of 24 TAB-positive GCA and 44 TAB-negative non-GCA patients (21 patients with a final diagnosis of PMR, 23 patients with other diagnosis) were retrospectively selected from TABs performed between January 2012 and December 2015. A total of 295 TABs were assed for inclusion. Only positive TABs showing clear transmural inflammation were included. Patients treated with >7 days of prednisolone prior to the TAB were excluded. Clinical data were obtained from electronic patient records to confirm or dismiss clinical diagnosis. *TAB-HE-stains* were reviewed by a pathologist with expertise in vasculitis. Immunohistochemical methods were used to determine the AChE expression. The histological inflammation and AChE

expression were assessed and graded on 0–1-2 scale, blinded to histological and clinical data. Solitary AChE staining of the media was not included in the assessment.

Results: 24 positive and 44 negative TABs, with corresponding clinical positive and negative GCA diagnosis, were included in this study. We found that 10/24 positive TABs showed high AChE expression (grade 2) and 14/24 showed moderate AChE expression (grade 1). No AChE expression was observed outside the media in negative TABs from non-GCA patients (i.e. grade 0). The AChE expression was in 79% agreement with the degree of histological inflammation with a kappa value of 0.58. Prednisolone treatment for up to 7 days did not suppress the AChE expression. Neither the AChE expression, nor the histological inflammation showed correlation to any clinical or biochemical findings.

Conclusions: Our study shows that high to moderate AChE expression was observed in all 24 biopsies from TAB-positive GCA patients and that the AChE expression was in good agreement with the histological inflammation. No non-specific AChE expression was observed outside the media in any of the 44 TABs from TAB-negative non-GCA patients. This indicates that AChE could play a significant role in the inflammatory process in GCA and may be a potential biomarker in inflammatory diseases such as GCA.

THU0336 GIANT CELL ARTERITIS (GCA) IN OCTOGENARIAN PATIENTS

R. Solans-Laqué[1], E. Fonseca[2], B. Escalante[3], A. Martinez-Zapico[4], G. Fraile[5], M. Conesa[6], M. Abdilla[7], M. Monteagudo[8], J. Lasso[9], E. Calvo[10], B. Gracia[3], M. Castillo[11], J. Mestre[1] on behalf of REVAS Study Group (GEAS-SEMI).
[1]Internal Medicine, Vall Hebron University Hospital, Barcelona; [2]Internal Medicine, Cabueñes Hospital, Gijon; [3]Internal Medicine, Lozano Blesa Hospital, Zaragoza; [4]Internal Medicine, Central Hospital (HUCA), Asturias; [5]Internal Medicine, Ramon y Cajal Hospital, Madrid; [6]Internal Medicine, Miguel Servet Hospital, Zaragoza; [7]Internal Medicine, Alzira Hospital, Valencia; [8]Parc Taule Hospital, Sabadell; [9]Internal Medicine, Alcañiz Hospital, Teruel; [10]Internal Medicine, San Jorge Hospital, Huesca; [11]Internal Medicine, Virgen Rocio Hospital, Sevilla, Spain

Background: GCA is the most common systemic vasculitis in elderly people. It is characterized by granulomatous involvement of the major branches of the aorta with predilection for the temporal arteries. Headache is the most frequent initial complaint, and permanent visual loss the most feared complication.

Objectives: to describe the initial manifestations and outcome of CGA in octogenarian patients, and to investigate if there are some differences compared to younger patients

Methods: demographic, clinical and histological features, treatment and outcome of all patients with biopsy-proven GCA recruited at 11 different Hospitals from Spain (REVAS Study) were analysed. Statistical analysis was performed using SPSS vs. 20

Results: among the 418 patients included in the study, 180 (27.5%) were older than 80 y at disease onset (mean age 83.77±3.1, range 80–92y). Cardiovascular risk factors (hypertension, hypercholesterolemia, diabetes) were more prevalent in octogenarian patients than in younger (73% vs. 50%, p=0.018). Headache was the most frequent initial complaint (78.5%), followed by polymyalgia rheumatica (49.6%), jaw claudication (48.7%) and toxic syndrome (43.5%). A total of 28 (24.35%) patients suffered permanent visual loss, due to anterior ischemic optic ischemic neuropathy (n=26) or central retina vein thrombosis (n=4). When compared with younger patients, neither headache, nor jaw claudication, nor scalp tenderness and polymyalgia, were more common in octogenarian patients. Only fever was less common in patients >80 y at diagnosis than in younger (27.7% vs. 72.3%, p=0.006), and permanent visual loss was most prevalent among octogenarian patients (24.3% vs. 15.7%, OR 1.73, 95CI 1.1–2.9, p=0.04). We found an inverse correlation between fever and permanent visual loss (p=0.001). Blindness was significantly correlated with jaw claudication (p=0.006) and amaurosis fugax (p=0.001). We did not found any significant correlation between blindness and vascular risk factors. Regarding to LAB, ESR was higher in octogenarian patients (p=0.006) as well as thrombocytosis >400.000 platelets/mm (p=0.026). No differences were found related to anaemia prevalence. Inflammatory infiltrate with lumen occlusion and giant cells were significantly more prevalent in temporal artery biopsies from patients with permanent bilateral visual loss (p=0.007 and p=0.01, respectively). No differences were found related to treatment. All patients received oral prednisone at tapering dosage, 85.9% calcium and vitamin D supplementation, and 60% bifosfonates. We did not found differences related to treatment-side effects (osteoporotic fracture, diabetes, infections) between octogenarian patients and the younger.

Conclusions: octogenarian patients with GCA have an increased risk of developing permanent visual compared to younger patients. The presence of jaw claudication and amaurosis fugax must prompt to initiate corticosteroid treatment quickly. No differences were found related to treatment side effects in octogenarian patients.

THU0337 CLASSIFICATION OF ANTINEUTROPHILIC CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS AND CLINICAL IMPACT AND OUTCOME

S. Deshayes[1], A. Aouba[1], K. Kathy[2], D. Mariotte[2], T. Lobbedez[3], N. Martin Silva[1]. *[1]Department of Internal Medicine; [2]Department of Immunology; [3]Department of Nephrology, CHU Côte de Nacre, Caen, France*

Background: Antineutrophilic cytoplasmic antibody (ANCA)-associated vasculitis (AAV) have overlapping manifestations. Classifications based on clinical criteria or ANCA specificity have emerged to individualize homogenized group of patients in terms of clinical forms and outcomes.

Objectives: The aim of our study was to retrospectively re-evaluate the clinical impact and outcome of our monocentric AAV patients' cohort, according to classifications based on clinical criteria and/or ANCA specificity.

Methods: A retrospective monocentric study carried out in Caen university hospital led to identify proteinase-3 (PR3) or myeloperoxidase (MPO)-ANCA AAV patients (via an ELISA technique), respectively from March 1997 to June 2016, and from September 2011 to June 2016. Patients with eosinophilic granulomatosis with polyangiitis were excluded. AAV were classified between granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA), and limited or severe forms according to respectively European Medicines Agency vasculitis algorithm and WGET group. Categorical variables were reported as percentages and compared using Chi^2 or Fisher's tests according to expected frequencies. Continuous variables were expressed as means and analyzed using Student's t-test. Associations between survival, or relapse free survival, and AAV classifications were evaluated by the log-rank test. A p-value <0.05 was considered to be statistically significant.

Results: A total of 150 GPA/MPA were included.

Table 1

	anti-MPO GPA (n=20)	anti-PR3 GPA (n=74)	anti-MPO MPA (n=43)	anti-PR3 MPA MPA (n=13)
Male %	35	54	67	54
Renal involvement %	75	61	88	92
Ear-nose-throat involvement %	65	77	12	0
Lung involvement %	70	80	70	31
Skin involvement %	25	30	21	38
Neurological involvement %	45	24	23	31
Rheumatologic involvement %	55	62	37	54
Limited vasculitis, %	40	23	12	23
Relapse %	50	50	21	8
Death %	0	23	19	31
Initial BVAS, median ± SD	20±7.2	18.5±7.4	17±5.1	15±7.5
Age at diagnosis (years), median ± SD	66.5±11	60±17	62±13	70±21
Follow-up (months), median ± SD	49±47	55±65	50±37	33±108

As expected, ear-nose throat involvement were significantly higher in PR3-ANCA vs MPO-ANCA, and GPA vs MPA (p<0.001). Survival was significantly higher in

Abstract THU0337 – Table 2

p (significant higher parameter)	Male	Renal involvement	Lung involvement	Rheumatologic involvement	Limited vasculitis	Initial BVAS
PR3 vs MPO	0.71	**0.011** (MPO)	0.74	**0.03** (PR3)	0.74	0.38
GPA vs MPA	0.09	**<0.001** (MPA)	**0.03** (GPA)	**0.02** (GPA)	0.08	**0.035** (GPA)
MPO GPA vs PR3 GPA	0.14	0.25	0.38	0.57	0.13	0.64
MPO GPA vs MPO MPA	**0.02** (MPA)	0.27	0.99	0.19	**0.018** (GPA)	**0.048** (GPA)
MPO MPA vs PR3 MPA	0.52	1	**0.005** (MPO)	0.35	0.38	0.88

anti-MPO GPA but relapse-free survival was lower, compared to anti-MPO MPA (p=0.038 and p=0.015, respectively), without difference in treatments. Relapse-free survival was lower in GPA, compared to MPA (p<0.001). Among GPA patients, there was significantly more deaths in PR3 than MPO patients (p=0.02), but without significant difference between ANCA types for all other considered criteria, including survival (p=0.06).

Conclusions: The clinicopathological classification appeared as the strongest criteria for distinguish homogeneous forms and prognosis of AAV. Besides their diagnostic value, ANCA may not exhibited further great interest, especially in GPA.

Disclosure of Interest: None declared

THU0338 CLINICAL PRESENTATION AND OUTCOMES OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: ANCA-NEGATIVE VERSUS ANCA-POSITIVE

E. Zagvozdkina, P. Novikov, S. Moiseev. *Sechenov First Moscow State Medical University, Moscow, Russia, Moscow, Russian Federation*

Objectives: The aim of the prospective study was to compare clinical presentation at diagnosis and long-term outcomes of eosinophilic granulomatosis with polyangiitis (Churg-Strauss) (EGPA) patients according to antineutrophil cytoplasmic antibody (ANCA) status.

Methods: EGPA was classified according to the Revised CHCC Nomenclature and ACR1990 criteria. Activity of vasculitis was evaluated using BVAS. A minor relapse was defined as an increase in at least one new or worse minor item and no major BVAS items. A major relapse was an increase in at least one major BVAS item.

Results: We followed 93 patients with EGPA for a mean±SD of 6.3±6.5 years. Their mean±SD age was 46.6±13.8 years, and 96.8% patients had a history of asthma. The most common EGPA manifestations at diagnosis included ENT manifestations (88.2%), fever (78.5%), peripheral neuropathy (73.1%), lung involvement (59.1%) and skin lesions (49.5%). Thirty seven of 93 patients (39.8%) were ANCA-positive. These patients had significantly more frequent myalgia and mononeuritis multiplex, than the ANCA-negative patients. The difference in occurrence of kidney disease between the two groups did not reach statistical significance. However, all three patients with rapidly progressive kidney failure were ANCA-positive. BVAS at diagnosis and VDI at the end of the follow-up were significantly higher for ANCA-positive patients. The follow up duration was 587.7 patient-years. The incidence of all vasculitis relapses was 14 per 100 patient-years, including major and minor vasculitis relapses (5.3 and 8.7 per 100 patient-years, respectively). The 3- and 5-year relapse-free survival rate was 65.4% (95% CI 54.6–76.2) and 43.1% (95% CI 30.4–55.7), respectively. The frequency of vasculitis relapses was 21.0 per 100 patient-years in the ANCA-positive group versus 19.6 per 100 patient-years in the ANCA-negative group (P=0.4).

Table 1. Main clinical characteristics at diagnosis of the 71 patients with EGPA, according to ANCA status

Manifestations	ANCA+ (n=37)	ANCA- (n=34)	P
Fever	30 (81.1)	25 (73.5)	0.57
Myalgia	22 (59.5)	10 (29.4)	**0.02**
ENT	33 (89.2)	30 (88.2)	1.00
Lung	24 (64.9)	19 (55.9)	0.47
Cutaneous	24 (64.9)	15 (44.1)	0.10
Peripheral neuropathy	30 (81.1)	21 (61.8)	0.11
Mononeuritis multiplex	17 (45.9)	6 (17.6)	**0.01**
Cardiovascular	13 (35.1)	10 (29.4)	0.62
Gastrointestinal	4 (10.8)	4 (11.8)	1.00
Renal	11 (29.7)	5 (14.7)	0.16
BVAS at diagnosis, mean ± SD	16.86±6.44	12.62±5.52	**<0.01**
VDI at the end of the follow-up	2.43±1.57	1.76±1.16	**<0.01**

Conclusions: The characteristics of EGPA patients differ according to their ANCA status, although long-term outcomes were similar in both groups. EGPA is characterized by relapsing course of disease. The minor vasculitis relapses predominated in the structure of relapses.

THU0339 FECAL CALPROTECTIN LEVELS AS AN INDICATOR OF ACTIVE DISEASE IN BEHÇET'S SYNDROME PATIENTS WITH GASTROINTESTINAL INVOLVEMENT: A CONTROLLED STUDY

S.N. Esatoglu[1], I. Hatemi[2], Y. Ozguler[1], G. Hatemi[1], H. Uzun[3], A.F. Celik[2], H. Yazici[1]. *[1]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; [2]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Gastroenterology; [3]Istanbul University, Cerrahpasa Medical School, Department of Biochemistry, Istanbul, Turkey*

Background: Elevated fecal calprotectin (FC) levels indicate activity in Crohn's disease (CD) and ulcerative colitis and are used as non-invasive biomarkers in these diseases. Gastrointestinal involvement of Behçet's syndrome (GIBS) shows clinical and endoscopic similarities to CD. A previous study suggested that FC may help to diagnose GIBS patients (1), but we are not aware of any studies addressing its role in identifying disease activity in such patients.

Objectives: To determine whether FC helps to distinguish active GIBS patients from those in remission.

Methods: We collected fecal and serum specimens before colonoscopy from 39 GIBS patients who agreed to participate (Table). Twenty-six patients were asymptomatic whereas 13 had abdominal pain and/or diarrhea. We also filled disease activity index for intestinal Behçet's disease (DAIBD) and Crohn's disease activity index (CDAI) in each patient. Active gastrointestinal (GI) involvement was defined as having ulcers on colonoscopy. We included 22 active and 25 inactive CD patients as controls. We used 150 μg/g as the cut-off for a positive FC level. None of the patients were receiving NSAIDs that could increase FC levels.

Results: Among the 39 GIBS patients, 14 had active ulcers on colonoscopy (8/13 symptomatic and 6/26 of asymptomatic). FC level was >150 μg/g in 12/14 active GIBS patients and in 6/25 patients in GI remission (OR: 19, 95% CI: 3 to 110). The median FC and CRP levels were higher among active GIBS patients whereas serum calprotectin levels were not different (Table). Among CD patients, 16/25 active patients and 3/22 patients in remission had a FC level >150 μg/g (OR: 11, 95% CI: 11 to 49). There was a high correlation between FC and CDAI scores (r=0.64, p<0.001) and a very high correlation between FC and DAIBD scores (r=0.71, p<0.001), while FC was not correlated with serum calprotectin and CRP levels. Among the 6 GIBS patients who had high FC levels despite being in remission for GI involvement, 2 had active mucocutaneous lesions, 1 had concomitant macrophage activation syndrome (MAS), 1 had polycythemia vera with trisomy 8 and 2 were started high dose corticosteroids. Repeat FC levels could be obtained in 3 of these patients, after the resolution of MAS and mucocutaneous lesions, and were <150 in all 3.

Table 1. Demographic, clinical and laboratory features of active GIBS patients and in GIBS patients who are in remission

	Active GIBS (n=14)	GIBS in remission (n=25)	*P* value
Gender, M/F	5/9	10/15	0.15
Mean±SD age, years	47.5±7.2	40±11	0.03
Median (IQR) FC, μg/g	301 (176–957)	30 (30–134)	*<0.001*
FC ≥150 μg/g, n (%)	12 (86)	6 (24)	*<0.001*
Median (IQR) serum calprotectin, ng/mL	98 (39–128)	69 (54–101)	0.5
Median (IQR) serum CRP, mg/dL	2 (1–5)	3 (2–15)	0.07
Median (IQR) CDAI scores	52 (4–189)	30 (0–92)	0.2
Median (IQR) DAIBD scores	40 (4–81)	20 (0–37)	0.1

Conclusions: FC seems to be a useful non-invasive tool for identifying active GI involvement in GIBS patients. Whether the presence of other BS manifestations can cause false positive results in GIBS patients in remission remains to be studied. On the other hand, serum calprotectin levels do not seem to be useful in identifying active disease in GIBS patients.

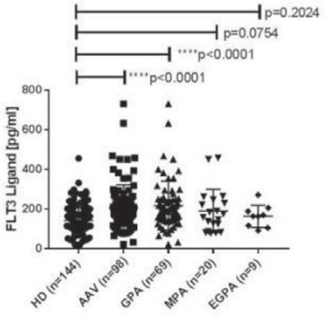
THU0340 ADRENAL INSUFFICIENCY DURING GLUCOCORTICOID TREATMENT IN PATIENTS WITH POLYMYALGIA REUMATICA OR GIANT CELL ARTERITIS

T. Laursen[1], H. Locht[1], B. Jensen[1], S. Borresen[2], U. Feldt-Rasmussen[2], L. Hilsted[3], E.M. Bartels[4]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet; [2]Department of Endocrinology, Rigshospitalet; [3]Department of Clinical Biochemistry, Rigshospitalet; [4]The Parker Institute, Department of Rheumatology, Copenhagen, Denmark*



Background: Adrenal insufficiency secondary to long-term systemic glucocorticoid treatment is a well-recognized problem. However, the extent and prevalence of this phenomenon has not been thoroughly explored.
Objectives: To investigate the prevalence of adrenal insufficiency in patients with polymyalgia reumatica (PMR) and giant cell arteritis (GCA) during treatment with low doses of prednisolone (<10mg/day) assessed by the adrenal response to a 250 microgram Synachten® test. To explore whether potential adrenal insuffiency was associated with duration of steroid treatment.
Methods: Outpatients were examined when prednisolone doses were between 2.5 and 10 mg/day for >6 months. Adrenal function was evaluated after a 48-hour pause of prednisolone, using a 250 μg Synachten® (ACTH) test where plasma cortisol levels were measured at baseline and 30 minutes after Synacthen injection. Adrenal insufficiency was defined as plasma cortisol <420 nmol/l after 30 minutes according to the validated Roche Elecsys®Cortisol II assay. Accummulated doses of prednisolone for the individual patients were calculated. A multiple regression analysis was used to test for an association between the plasma cortisol after 30 minutes and the accumulated dose of prednisolone.
Results: Forty-eight patients (35 women) completed the Synachten® test. Seven (14.6%) patients exhibited adrenal insufficiency. Median age was 74 years (Range: 57–89 years). Median accumulated dose was 3.402 mg (Range: 820–21.200mg). Median plasma cortisol after 30 minutes was 562 nmol/l (Range: 92–989 nmol/l). In patients with adrenal insufficiency, median plasma cortisol was 122 nmol/l (Range: 56–275 nmol/l) at baseline and 207 (Range: 92–420 nmol/l) after 30 minutes. In patients without adrenal insufficiency, median plasma cortisol was 359 (Range: 9–710 nmol/l) at baseline and 584 nmol/l (Range: 429–989 nmol/l) after 30 minutes. Accumulated doses of prednisolone did not differ in patients with and without adrenal insufficiency (p=0.49). Plasma cortisol after 30 minutes was not associated with accumulated dose of prednisolone (estimate –0.01, 95% CI: –0.02 to 5.39, p=0.06), when adjusting for sex and age.
Conclusions: Iatrogenic adrenal insufficiency was prevalent among patients with PMR or GCA treated with low dose prednisolone. Adrenal function was not associated with the accumulated dose of prednisolone, or the duration of steroid treatment. A Synacthen® test is a valuable tool to evaluate the adrenal function, when steroid treatment is tapered in these patients. Latent symptoms of adrenal insufficiency may explain why some patients are reluctant to discontinue steroid treatment even after the inflammatory condition has gone into remission.

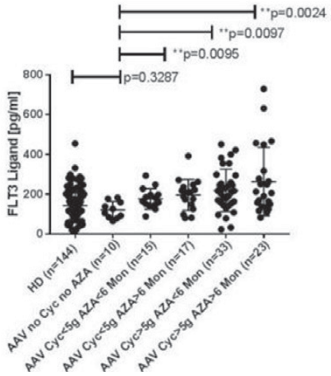
THU0341 FLT3 LIGAND CONCENTRATIONS ARE ELEVATED IN ANCA-ASSOCIATED VASCULITIDES (AAV) AND ARE INFLUENCED BY IMMUNOSUPPRESSIVE THERAPY



N. Venhoff, J. Thiel, R.E. Voll, A.C. Venhoff, U. Salzer. *Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Medical Faculty, University of Freiburg, Freiburg, Germany*

Background: The cytokine Flt3 ligand is an important cofactor for early hematopoiesis by mainly driving the development of lymphoid and early B-cell precursors. In the periphery functions of Flt3 are more pleiotropic involving the differentiation of regulatory T-cells, dendritic cells as well as peripheral B-cells. Besides its well-known roles in hematological disorders and as an indicator of bone marrow (BM) output capacity, the possible involvement of FLT3 ligand in autoimmune disorders was only discovered recently.
Objectives: Our primary aim was to analyze if FLT3 ligand serum concentrations are affected in AAV patients. Secondary aims were to correlate the FLT3 ligand serum concentrations with clinical and laboratory parameters. And, since FLT3 ligand concentrations are elevated in different states of bone marrow failure, we also wanted to evaluate FLT 3ligand as a marker for treatment related BM toxicity in AAV patients.
Methods: We performed a cross sectional study using a sandwich ELISA to determine FLT3 ligand concentrations in the serum of 98 well characterized AAV patients (69 GPA, 20 MPA and 9 EGPA) and 144 healthy controls (HC). Statistical evaluation was done using Mann-Whitney or unpaired, two-tailed Student's t-test.
Results: In patients with AAV, FLT3 ligand concentrations were significantly elevated (207 pg/ml +/- 116.2 in AAV versus 142.5 pg/ml +/- 65.98 in HC; p<0.0001). Disease specific analysis revealed significantly elevated FLT3 ligand concentrations in GPA (217.6 pg/ml +/- 123; p<0.0001), but no significant differences for MPA and EGPA when compared to HC. FLT3 ligand concentrations did not correlate to serological or clinical markers of disease activity, however, overall disease activity was low in the studied cohort. To assess the influences of treatment regimen on FLT3 ligand concentrations, we focused our analysis on treatment histories of cyclophosphamide (CYC) and azathioprine (AZA) and grouped the patient cohort according to the cumulative CYC dose (< or >5g) and/or duration of AZA therapy (< or >6 months). AZA and CYC naïve patients (n=10) showed FLT3 concentrations comparable to HC (121 pg/ml +/- 42.3), but in patients with low dose CYC and short term AZA therapy FLT3 concentrations were significantly higher (176.6 pg/ml +/- 51.6), both compared to treatment naïve patients and HC (p=0.0095 vs. AZA/CYC naïve, p=0.0105 vs HC). Intensified treatment was associated with even further increased concentrations of FLT 3 ligand with highest concentrations found in patients treated with >5g CYC cumulative dose or AZA treatment for >6 months (263.4 pg/ml +/- 172.6; p=0.0024 vs. AZA/CYC naïve, p<0.0001 vs HC).

Elevated FLT3 serum concentrations in ANCA-associated vasculitides

FLT3 ligand serum concentrations are influenced by therapy

Conclusions: Flt3 ligand concentrations are elevated in patients with AAV, especially in patients with GPA. The elevation more likely reflects the therapeutic regimen and history than disease activity as we could show that patients with more intensive treatment including both CYC and AZA show higher FLT3 ligand serum levels when compared to patients with less intense therapy.

THU0342 UTILIZING "REAL LIFE" DATA IN ORDER TO EVALUATE THE ASSOCIATION BETWEEN GIANT CELL ARTERITIS AND AUTOIMMUNE THYROID DISEASE

Y. Yavne[1], S. Tiosano[2], A. Watad[2], D. Comaneshter[3], Y. Shoenfeld[2], A.D. Cohen[3,4], H. Amital[5]. *[1]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv; [2]Department of Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer; [3]Chief Physician's Office, Clalit Health Services, Tel Aviv; [4]Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva; [5]Department of Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Aviv, Israel*

Background: In 1977, How et al.[1] described the case of a simultaneous presentation of giant cell arteritis (GCA) and hypothyroidism. In the following decades, numerous studies have attempted to determine whether a significant interaction exists between GCA and autoimmune thyroid dysfunction, with conflicting results[2–5].
Objectives: To evaluate whether a genuine association exists between GCA and autoimmune thyroid disease.
Methods: Utilizing the medical database of Clalit Health Services, we compared the proportion of autoimmune thyroid disease between patients with GCA and age- and gender-matched controls in a cross-sectional study. Univariate analysis was performed using Chi-square and student *t-test* and a multivariate analysis was performed using a logistic regression model.
Results: 5,663 GCA patients and 23,308 age- and gender-matched controls were

included in the study. The proportion of hypothyroidism amongst GCA patients was increased in comparison with controls (18.2% vs. 6.91%, respectively, *p-value* <0.001), as was hyperthyroidism (2.56% and 1.19% respectively, *p-value* <0.001). After controlling for confounders, GCA demonstrated a robust independent association with hypothyroidism on multivariate logistic regression (OR 1.297, 95% CI 1.187–1.418, Table 1). In contrast, when a similar model was performed in order to assess the nature of the association between GCA and hyperthyroidism, it was found to be non-significant, with an OR of 1.097.

Table 1. Multivariate logistic regression of covariates associated with hypothyroidism

Characteristic	OR	CI	P
Age	1.03	1.02–1.03	<0.001
Gender (Female)	3.32	2.93–3.79	<0.001
BMI	1.02	1.01–1.03	<0.001
SES:			
Medium vs. Low	1.42	1.28–1.58	<0.001
High vs. Low	1.63	1.45–1.83	<0.001
GCA	1.30	1.12–1.42	<0.001

BMI: Body Mass Index, kg/m^2, SES: Socioeconomic status, GCA: Giant Cell Arteritis.

Conclusions: GCA patients have a higher proportion of hypothyroidism in comparison with matched controls. A significant association between GCA and hyperthyroidism was not found. Physicians treating GCA patients should consider screening for thyroid dysfunction on a regular basis.

THU0343 THE EFFECT OF ADALIMUMAB ON CLINICAL MANIFESTATIONS AND PRO-INFLAMMATORY CYTOKINES MILIEU IN PATIENTS WITH BEHCET'S DISEASE

Y. Braun-Moscovici, Y. Tavor, D. Markovits, K. Toledano, A. Rozin, M.A. Nahir, A. Balbir-Gurman. *Rheumatology Department, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, Haifa, Israel*

Background: Behcet's disease is a multisystemic chronic relapsing inflammatory disease, classified among the vasculitides. The aetiology of Behcet's disease is unknown. Several cytokines, among them TNF-α, are involved in the pathogenesis of the disease.

Objectives: We aimed to assess efficacy and safety of Adalimumab (ADA) in patients with active Behcet's arthritis not responding to one or more DMARDS and to assess the impact of treatment on the cytokine milieu.

Methods: Eligible patients (pts) with active arthritis were enrolled in a 24 weeks single center prospective open-label study. Pts who relapsed within 12 weeks following ADA discontinuation could enter a 3 year extension study. The efficacy was assessed by 68 tender and 66 swollen joint count, patient visual analogue scale (VAS) for pain, physician overall disease activity VAS, health assessment questionnaire (HAQ), Behçet's Disease Current Activity Form (BDCAF), C reactive protein (CRP) and erythrocyte sedimentation rate (ESR). TNF-α,IL-1β, IL-6, INF-γ, IL-10 and IL-17a were evaluated at baseline, after 24 and 48 weeks of treatment, by ProcartaPlex Human High Sensitivity – Immunoassay kit. Trough ADA serum levels and anti-drug antibodies were measured at baseline, week 24 and 48.

Results: Ten pts (6 females),age (mean, standard deviation –SD) 45 (8.4) years, with a disease duration of 11.6 (10) years, were enrolled and treated with subcutaneous ADA 40mg every 2 weeks for 24 weeks. The results are described in Table1. A statistically significant improvement was observed in swollen joint count, physician VAS and BDCAF and in IL-6 levels, but not in tender joint count or HAQ. Resolution of oral and urogenital ulcers was achieved in all pts. Significant reduction of pain was reported by 40% of pts. No relapse of uveitis or other disease manifestations occurred during the study. The reduction in IL-6 levels correlated with the physician VAS and BDCAF but not with HAQ. No correlation was found between change in IL-10 level and VAS pain. The levels of INF-γ, IL-17A, TNF-α were undetectable in all pts. IL-1β was elevated in 1 patient only. ADA serum trough levels were in the therapeutic range in 7/10 pts. One patient developed high antidrug antibodies titer and ADA serum trough level of 0 with a concomitant increase in VAS pain and IL-6 concentration. Another patient with low ADA trough levels and no antibodies improved after providing ADA weekly. The disease relapsed in 9/10 pts, within 4–6 weeks following ADA interruption, 7 pts enrolled into the extension study.

	Baseline mean (SD)	24 weeks mean (SD)	P
Swollen joints	4.6 (4.2)	0.6 (0.4)	0.006
Tender joints	19 (18.7)	12.6 (10.9)	Non significant (NS)
Physician VAS	51.5 (18.5)	24.5 (16)	0.002
Patient pain VAS	72 (19)	56 (33)	NS
BDCAF	5.4 (1.6)	2.1 (1.4)	0.001
HAQ	1.76 (0.8)	1.6 (0.9)	NS
IL-6 pg/ml	10.06 (13.4)	2.02 (0.8)	0.042

Conclusions: ADA treatment was well tolerated and achieved a significant improvement in arthritis and mucocutaneous manifestations and lowered IL-6 serum concentration in all study pts but only 40% reported significant pain reduction. A subset of pts with insufficient improvement in joint tenderness and generalized pain may require comprehensive pain management besides anti-inflammatory therapy.

THU0344 A RHEUMATOLOGY LED PATHWAY FOR THE INITIAL MANAGEMENT OF GCA IMPROVES DIAGNOSTIC OUTCOMES COMPARED TO THE GENERALIST

Z. Farah, M. Gulati, M. Matheou, H. Alam, S. Hamdulay. *Rheumatology, Northwick Park Hospital, London, United Kingdom*

Background: Giant Cell Arteritis (GCA) is a medical emergency requiring prompt and appropriate management to prevent complications. The British Society of Rheumatology (BSR) has set out guidelines on the appropriate management of suspected GCA targeting both primary and secondary-care physicians. Hospitals increasingly use care-pathways to facilitate appropriate initial management of GCA by non-rheumatologists. Evidence is limited, however, on the impact of such interventions on patient care.

Objectives: To evaluate the impact of designing a GCA care-pathway for non-rheumatologists (acute and general physicians) on patient care in terms of: (i) duration from referral to temporal artery biopsy (TAB) and rheumatology review; (ii) glucocorticoid therapy burden; and (iii) proportion of referrals with a final diagnosis of GCA

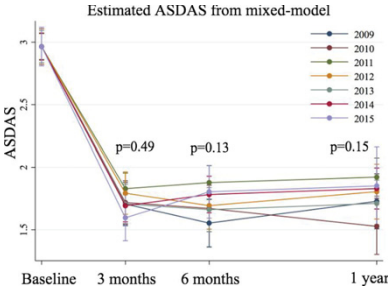
Methods: We performed a retrospective study of all patients diagnosed with GCA between 3 periods: prior to introducing a GCA pathway (2007–2009), rheumatology led GCA pathway (2010–2012), and non-rheumatology led GCA pathway (2012–2016). We identified patients from a TAB database and collected general demographic data, initiation of glucocorticoid therapy, referral for TAB and rheumatology clinic, date of TAB and clinic review, biopsy findings, and final diagnosis.

Results: Table 1 summarises the main findings. After introducing the rheumatology-led pathway (2010–2012), rate of referrals for TAB per month declined to 0.78, the proportion of patients having a TAB within 14 days of referral reached 100%, and the proportion of patients with a positive biopsy increased to 30% suggesting appropriate use of the pathway and an improvement in care. However introducing a non-rheumatology led GCA pathway (2012–2016), led to increased referral numbers. The proportion of TAB within 14 days decreased, and the proportion with a positive biopsy declined (17%).

Abstract THU0344 – Table 1

	Before GCA Pathway	Rheumatology Led GCA Pathway (1st Cycle)	Non-Rheumatology Led GCA Pathway (2nd Cycle)
Dates	Pre-2010 (Jan 07–Sep 09)	2010 to 2012 (Jan 10–Mar 12)	2016 (Nov 12–June 16)
Study Design	Retrospective	Retrospective	Retrospective
Source of Data	Histology database, electronic records	Histology database, electronic records	Histology database, electronic records
Number of Patients Biopsied	54	21	129
Number of Months	33	27	44
Rate of Biopsies (pts/month)	1.64	0.78	2.93
Days from referral to TAB; Median (min-max)	5 (0–56)	5 (0–13)	9 (0- 45)
Proportion with TAB within 14 days	87%	100%	66.2%
Proportion with a positive biopsy for GCA	26%	30%	17%
Mean Age (years)	73	73	71
Gender Ratio (M:F)	18:36 (F 66.7%)	4:17 (F 80.9%)	48:81 (F 62.7%)
OUTCOME	GCA Pathway introduced	Pathway continued	Pathway review

The non-rheumatology led GCA pathway was associated with higher glucocorticoid burden. In this cohort, 23/55 (41.8%) patients who were found not to have GCA received more than 21 days of high dose steroids (40–60mg Prednisolone) whilst awaiting rheumatology review. 4 patients whose final diagnosis was not GCA received high dose steroids for more than 30 days (max 109 days).



Conclusions: 1. Availability of a rheumatology-led GCA pathway leads to improved care for patients with suspected GCA

2. Easy access for referral of patients with headache as assessed by the non-specialist can lead to over-use of the pathway and inappropriate referrals

3. Non-rheumatology-led GCA pathway can lead to a high glucocorticoid burden, especially in an elderly demographic with other comorbidities

Spondyloarthritis - treatment

THU0345 REAL-LIFE EFFECTIVENESS OF TNF INHIBITORS IN AXIAL SPONDYLARTHRITIS: ARE CHANGING NATIONAL POLICIES ON CHOICE OF TNF INHIBITOR REFLECTED IN RESPONSE TO TREATMENT?

E.K. Kristianslund[1], K.M. Fagerli[1], E. Lie[1], A. Wierød[2], S. Kalstad[3], E. Rødevand[4], F. Krøll[5], P. Mielnik[6], T.K. Kvien[1], I.C. Olsen[1]. *[1]Department of Rheumatology, Diakonhjemmet Hospital, Oslo; [2]Department of Rheumatology, Drammen Hospital, Drammen; [3]Department of Rheumatology, University Hospital of North Norway, Tromsø; [4]Department of Rheumatology, St. Olavs Hospital, Trondheim; [5]Revmatismesykehuset, Lillehammer; [6]Department of Rheumatology, Førde Central Hospital, Førde, Norway*

Background: Tumour necrosis factor inhibitors (TNFi) have revolutionized treatment of axial spondylarthritis (axSpa). The five different available TNFi have not been compared directly, and whether effectiveness differs between agents is unknown. In Norway national authorities consider the different TNFi equivalent, and since 2009 the least expensive drug following an annual national tender has been the drug-of-choice in the publicly funded healthcare system. This has lead to variations across different years in drug use where choice of TNFi has been predominantly based on national price policy and not clinical characteristics.

Objectives: Comparing response to TNFi during the first year of treatment of axSpA in biologics-naïve patients over years with highly varying uptake of different TNFi.

Methods: We included the 981 biologics-naïve patients with axSpA from the NOR-DMARD register who started their first TNFi from 2009 through 2015. The preferred drugs in national recommendations were: 2009 adalimumab, 2010 golimumab, 2011 etanercept, 2012 etanercept, 2013 golimumab, 2014 certolizumab, 2015 certolizumab/biosimilar infliximab (CT-P13). We compared the estimated change in Ankylosing Spondylitis Disease Activity Score (ASDAS) between treatment years at 3, 6 and 12 months after treatment start using a mixed model with subject-specific random intercept, adjusting for baseline disease activity, age, sex and treatment centre.

Results: Demographics, drug uptake and baseline characteristics for each year 2009–2015 are listed in table 1. The preferred drug was started in 57–91% of patients. There was a trend towards lower ASDAS and disease duration over time. There were no differences in treatment effectiveness between the years, regardless of the substantial differences in type of TNFi used (figure).

Conclusions: Real-life data do not show differences in response to TNFi despite large annual variation in type of TNFi prescribed, indicating similar effectiveness of the available TNFi in patients with axSpA. This supports the practice of selecting drug based on cost and feasibility of use, as is the current practice in Norway. Further adoption of this principle can provide access to TNFi treatment to more patients, as it reduces costs and healthcare resources are limited.

THU0346 CONCOMITANT FIBROMYALGIA IN AXIAL SPONDYLOARTHRITIS HAS A NEGATIVE IMPACT ON TNF ALPHA BLOCKERS TREATMENT EFFECT IN REAL LIFE

A. Moltó, A. Etcheto, L. Gossec, S. Perrot, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: Coexisting fibromyalgia (FM) in axial spondyloarthritis (axSpA) can represent therapeutic challenges, particularly when evaluating the treatment effect of biologics (i.e. TNF alpha blockers (TNFb)). Indeed, since FM patients often report high levels of pain and disability there is the risk of classifying such patients as refractory to TNFb (ie, as not reaching a significant improvement in disease activity).

Objectives: To evaluate the impact of concomitant FM on the TNFb treatment effect in axSpA.

Methods: *Design:* Prospective observational national study with 2 visits 3 months apart (baseline and 12 weeks after TNFb initiation) (Predict-SpA study ClinicalTrials.gov: NCT03039088). *Patients:* axSpA patients (diagnosis according to treating rheumatologist) initiating a TNFb. *Data collection:* the FiRST questionnaire (Fibromyalgia Rapid Screen Test) which screens for FM, patients and disease characteristics and effectiveness measures (e.g. ASAS response components). *Statistical analysis:* FM positive screening was defined by a FIRST score ≥5/6; the primary efficacy outcome was the ASAS 40. Non-responder imputation and baseline observation carried forward imputation (for binary and continuous outcome variables, respectively) was performed. Impact of FM on the TNFb treatment effect was evaluated by multivariable logistic regression, with ASAS 40 as the dependent variable and FM as the independent variable; were also included in the model other factors previously reported in the literature as associated with treatment efficacy (i.e. X-ray and MRI sacroiliitis, abnormal CRP (>6mg/L), HLA B-27, smoking status, previous TNFb exposure, age<40 and male gender).

Results: Among the 527 patients enrolled in the study, 508 patients were analysed. Mean age was 41.4 (±11.6), 237 (46.7%) were women, with a 6.1±8.5 mean disease duration. Among them, 192 (37.8%) were screened as FM by the FiRST questionnaire. Overall efficacy of the TNFb was good (ASAS40, 201/508 (39.6%)) though 50 patients (9.8%) patients discontinued the TNFb before the follow-up visit and were considered as non-responders.

Patients with FM presented less frequently an ASAS 40 response (87/192 (45.3%) vs 171/316 (54.1%), for the FM vs non-FM groups according to the FIRST definition. Presence of FM was independently associated with poorer ASAS40 response (adjusted odds ratio, OR =0.5 [95% CI 0.3 – 0.8]) while X-ray sacroiliitis (1.8 [1.2 – 2.8]), abnormal CRP (1.6 [1.0 - 2.4]) and absence of previous exposure to TNFb (1.7 [1.1 – 2.6]) were found to be associated with an ASAS40 response.

Conclusions: This study 1) confirms the "conventional" predisposing factors of TNFb treatment response such as X-ray sacroiliitis, abnormal CRP and absence of previous exposure to TNFb; and 2) suggests that concomitant FM influences treatment response. FM deserves to be screened in axSpA, in particular in case of a decision to initiate a TNFb therapy.

THU0347 IMPACT OF OBESITY ON THE RESPONSE TO TUMOUR NECROSIS FACTOR INHIBITORS IN AXIAL SPONDYLOARTHRITIS

R. Micheroli[1], M. Hebeisen[2], A. Scherrer[2], L. Wildi[1], P. Exer[3], G. Tamborrini[4], J. Bernhard[5], B. Möller[6], P. Zufferey[7], M.J. Nissen[8], A. Ciurea[1]. *[1]University Hospital Zurich; [2]SCQM, Zurich; [3]Rheuma-Basel; [4]UZR, Basel; [5]Bürgerspital, Solothurn; [6]Inselspital, Bern; [7]CHUV, Lausanne; [8]University Hospital Geneva, Geneva, Switzerland*

Background: Few studies have investigated the impact of obesity on response to tumour necrosis factor inhibitors (TNFi) in patients with axial spondyloarthritis (axSpA).
Objectives: To investigate the impact of different Body Mass Index (BMI) categories on TNFi response in a large cohort of patients with axSpA.
Methods: Patients within the Swiss Clinical Quality Management cohort were included if they fulfilled the ASAS criteria for axSpA, started a first TNFi after recruitement and had available BMI data as well as a baseline and follow-up visit at 1 year (±6mo) (N=632). Patients were categorized according to BMI: normal (BMI 18.5 to <25), overweight (BMI 25 to 30) and obese (BMI >30). We evaluated the proportion of patients achieving the 40% improvement ASAS criteria (ASAS40) as well as Ankylosing Spondylitis Disease Activity Score (ASDAS) improvement and status scores at 1 year. Patients having discontinued the TNFi were considered non-responders. We controlled for age, sex, HLA-B27, axSpA-type, BASDAI, BASMI, elevated CRP, current smoking and physical exercise in multiple adjusted logistic regression analyses.
Results: In comparison to normal weight and overweight patients, obese individuals were significantly older, had a longer symptom duration and higher BASFI and BASMI levels, while ASDAS levels were comparable between the 3 groups (Table 1). Data to calculate the ASAS40 response was available in 496 patients (78%). It was reached by 44%, 35% and 28% of patients with normal weight, overweight and obesity, respectively, (p=0.02; Table 2). A significantly lower odds ratio (OR) for achieving ASAS40 response was found in adjusted analyses in obese patients vs patients with normal BMI (OR 0.30, 95% confidence interval (CI) 0.11–0.73, p=0.01). Comparable results were found for the other outcomes assessed. The respective adjusted ASAS40 OR in overweight vs. normal weight patients was 0.69, 95% CI 0.38–1.24, p=0.22.

Table 1. Baseline characteristics at start TNFi

Parameter	N	BMI category		
	632	Normal (N=331)	Overweight (N=202)	Obese (N=99)
Male sex, %	632	54	74*	64
Age, years	632	37.0 (11.2)	40.6 (11.5)*	44.2 (10.9)*#
Symptom duration, years	627	11.8 (10.1)	13.0 (11.4)	15.8 (11.7)*#
HLA-B27 positive, %	579	81	77	72
BASDAI	552	5.3 (2.0)	5.7 (1.9)*	5.8 (1.8)*
ASDAS-CRP	520	3.4 (0.9)	3.5 (0.9)	3.6 (0.9)
Elevated CRP, %	587	55	49	59
BASFI	558	3.6 (2.4)	4.2 (2.4)*	4.9 (2.6)*
BASMI	541	2.0 (2.0)	2.2 (1.9)	3.0 (2.3)*

*P values <0.015 compared with patients with normal weight. #P values <0.015 compared with patients with overweight. Values are the mean (SD).

Table 2. Unadjusted response rates after 1 year of treatment with a first TNF inhibitor

Outcome	N	BMI category			P*
	496	Normal (N=258)	Overweight (N=162)	Obese (N=76)	
ASAS40	496	44	35	28	0.02
ASDAS improvement ≥1.1	425	60	46	38	0.002
ASDAS <2.1	472	56	39	31	<0.001
ASDAS improvement ≥2	425	26	24	14	0.14
ASDAS <1.3	472	30	15	10	<0.001

Values are the %. *Overall P value.

Conclusions: Obesity is associated with significantly lower response rates to TNFi in patients with axSpA.

THU0348 SAFETY AND EFFICACY OF INTRAVENOUS GOLIMUMAB IN ADULT PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: RESULTS THROUGH WEEK 28

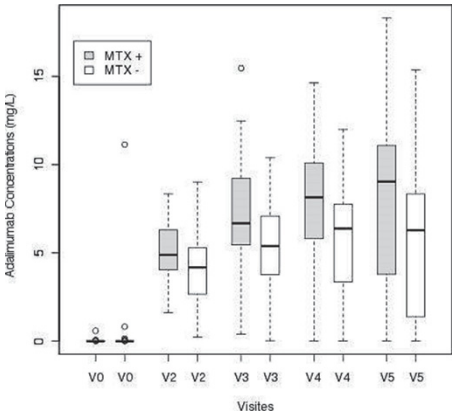
A. Deodhar[1], J.D. Reveille[2], D.D. Harrison[3], L. Kim[3], K.H. Lo[3], E. Hsia[3,4]. *[1]Oregon Health & Science University, Portland; [2]University of Texas Health Sciences Center, Houston; [3]Janssen Research & Development, LLC, Spring House; [4]University of Pennsylvania School of Medicine, Philadelphia, United States*

Objectives: Subcutaneous (SC) golimumab (GLM) is currently approved for adult patients (pts) with RA, PsA, and AS. The GO-ALIVE study was designed to evaluate the safety and efficacy of IV GLM in adult pts with active AS.
Methods: GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled trial. Pts (aged ≥18 yrs) had a diagnosis of definite AS (per modified New York criteria) and BASDAI ≥4, total back pain visual analogue scale ≥4, and CRP ≥0.3mg/dL. Pts were randomized (1:1) to IV GLM 2mg/kg at weeks (wks) 0, 4, and every 8 wks or PBO at wks 0, 4, and 12, with crossover to GLM at wk16. Up to 20% of pts could have had a prior anti-TNF agent (other than GLM), and up to 10% of pts could have complete ankylosis of the spine. The primary endpoint was ASAS20 at wk16. Major secondary endpoints were ASAS40, BASDAI50, and change in BASFI score at wk16. Some of the other statistically-controlled assessments were BASMI, and ASAS partial remission. Pts were monitored for adverse events (AEs). Data through wk28 are reported here.
Results: 208 pts were randomized and received study agent (PBO: 103; GLM: 105). Baseline demographic and disease characteristics were similar between treatment groups. 78% of pts were male, mean age was 39 yrs; mean disease duration was 5.5 yrs, 89.9% were HLA-B27 positive, 5.8% had complete ankylosis of the spine, 14.4% used a prior anti-TNF. At wk16, significantly greater proportions of GLM pts vs PBO had ASAS20 (73.3% vs. 26.2%), ASAS40 (47.6% vs. 8.7%), and BASDAI 50 (41.0% vs. 14.6%) responses (all p<0.001; Table). Reductions in BASFI were also significantly greater with GLM. ASAS20 was significantly higher with GLM than PBO as early as wk2 (37.1% vs 19.4%; p=0.005). Responses in the GLM group were maintained through wk28. PBO pts who crossed over to GLM at wk16 had improvements in clinical response at wk20 that were maintained through wk28. Through wk16, 23.3% of PBO pts and 32.4% of GLM pts had ≥1 AE. Infections were the most common type of AE (PBO, 7.8%; GLM, 11.4%). Through wk28, 34.8% of all GLM-treated pts had ≥1 AE; nasopharyngitis (5.4%) was the most common. Two pts (1.0%) had SAEs (pancreatitis, n=1; pneumonia, n=1). Both were randomized to GLM. There were no opportunistic infections, malignancies, or deaths through wk28. The rate of infusion reactions was low (1.5%). 3 pts treated with GLM had 4 reactions; none was serious or severe.

Table. Efficacy at week 16.

	Placebo	Golimumab 2 mg/kg
Patients randomized, n	103	105
Clinical efficacy		
ASAS20, n (%)	27 (26.2%)	77 (73.3%)**
ASAS40, n (%)	9 (8.7%)	50 (47.6%)**
BASDAI 50, n (%)	15 (14.6%)	43 (41.0%)**
Change from baseline in BASFI, n	98	105
mean (SD)	-0.5 (2.0)	-2.4 (2.1)**
ASAS partial remission, n (%)	4 (3.9%)	17 (16.2%)*
Change from baseline in BASMI (linear), n	96	100
mean (SD)	-0.1 (0.5)	-0.4 (0.6)**

*p < 0.01; **p ≤ 0.001
ASAS20/40, ≥20%/40% improvement in ASsessment in Ankylosing Spondylitis (ASAS) International Working Group criteria; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BASMI, Bath Ankylosing Spondylitis Metrology Index; SD, standard deviation



Conclusions: IV GLM 2mg/kg was efficacious in reducing the signs and symptoms of AS compared with PBO. GLM was well-tolerated through wk28; the safety profile was consistent with other anti-TNFs, including SC GLM.

Background: TNF inhibitors are effective in treating spondyloarthritis (SpA).

However, anti-drug antibodies (ADA) may be responsible for decreased efficacy. Methotrexate reduces adalimumab immunogenicity in rheumatoid arthritis (1).
Objectives: The aim of the study was to evaluate the effect of methotrexate on ADA detection in SpA patients receiving adalimumab.
Methods: One hundred and ten SpA patients eligible for adalimumab 40 mg S/C eow were randomized on a 1:1 ratio to receive MTX 10 mg s/c every week, 2 weeks prior (V0) adalimumab (MTX+), or adalimumab alone (MTX-). ADA detection and adalimumab concentration were assessed 4 weeks (V2), 8 weeks (V3), 12 weeks (V4) and 26 weeks (V5) after starting adalimumab (V1). The main outcome was the percentage of positive patients for ADA detection at V5 or last available visit.
Results: Patients' characteristics (sex, previous TNF inhibitors, disease duration, HLA B27 +/-, BMI) were comparable between the two groups. One hundred and seven patients were analyzed, 55 in the MTX+ group versus 52 in the MTX- group. ADA were detected at V5, in 39/107 (36.4%) patients; 13/52 (25%) in the MTX+ group versus 26/55 (47.3%) in the MTX- group (p=0.03). Adalimumab concentrations were statistically higher in the MTX+ group as compared with the MTX- group at V2, V3, V4 and V5 (Figure 1). There was no difference in terms of adverse events and efficacy between the two groups.

Conclusions: MTX reduces immunogenicity and ameliorates pharmacokinetics of adalimumab in SpA patients. The clinical impact of this combination requires longer period studies.

THU0350 EFFECT OF NSAID CONSUMPTION ON CARDIOVASCULAR EVENTS IN SPONDYLOARTHRITIS

E. Rivière[1,2], A. Etcheto[3], F. Van den Bosch[4], D. Van der Heijde[5], R. Landewé[6], M. Dougados[3], A. Molto[3] on behalf of ASAS-COMOSPA taskforce.
[1]Rheumatology, Bicêtre Hospital, INSERM U1184, le Kremlin Bicêtre; [2]Rheumatology B, Cochin Hospital; [3]Rheumatology B, Cochin Hospital, INSERM U1153, Paris, France; [4]Rheumatology, Ghent Universituy Hospital, Ghent, Belgium; [5]Rheumatology, Leiden University Medical Center, Leiden; [6]Rheumatology and Immunology Center, ARC, Amsterdam and Zuyderland Hospital Heerlen, Amsterdam, Netherlands

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) have been reported to increase cardiovascular (CV) risk. Studies on NSAIDs safety in patients with spondyloarthritis (SpA) are rare and contradictory. However, this question is highly relevant for these patients with chronic NSAIDs use and increased CV risk (1).
Objectives: The objective of this study was to determine the relationship between NSAIDs use and the occurrence of CV events, including myocardial infarction (MI) and stroke, in patients with SpA.
Methods: This is an ancillary study of the observational, cross-sectional, multicenter, international ASAS-COMOSPA study. The inclusion criteria were: age >18 years and SpA diagnosis. In order to overcome prescription bias when comparing patients who ever received/did not receive NSAIDs, a propensity score (PS) to predict NSAIDs intake was calculated. Patients who had never received NSAIDs were matched to patients who ever received an NSAID according to the PS. In this matched population, the probability for a patient to present a CV event was estimated by logistic regression. Furthermore, in the global population of the study, factors associated with the occurrence of CV event were explored by logistic multivariate analysis, here including the NSAIDs score (2) of the last three months, age and gender, and using the PS as an adjustment variable.
Results: Of the 3984 patients enrolled in the study, data on CV event occurrence were available for 3961 patients. Among them, 3548 patients received NSAIDs (89.6%) and 378 had never received NSAIDs (10.4%). Patients who had never received NSAIDs had more often inflammatory bowel disease (9.9% vs 5.3%), and a less severe disease (% of bamboo patients: 2.0% vs 7.6%). Among the 756 matched patients, 29 (3.8%) patients reported a CV event (21 MI, 13 strokes and 5 MI + stroke). The number of patients with CV event was not significantly different between the two groups, ever and never NSAIDs exposure respectively (16 (2,1%) vs 13 (1,7%), OR =1.86 [0.496–6.989]). No difference was observed between the two groups for MI and stroke compared separately (12 (1,6%) vs 9 (1,2%), OR =2.96 [0.417–21.013] and 8 (1,1%) vs 5 (0,7%), OR =0.926 [0.288–22.108] respectively). In the second model, where PS was used as a covariate, the occurrence of overall CV event was independently associated with age (OR =2.7 [2.3–3.2]) and male sex (OR =1.9 [1.2–3.0]), but not with the NSAIDs score (OR =1.0 [0.9–1.1]).
Conclusions: The use of NSAIDs does not seem to be associated with the occurence of CV event in patients with SpA, however it cannot be excluded that the study is underpowered. Further prospective studies are needed to confirm these results.

THU0351 ADALIMUMAB TAPERING WITH COMBINED METHOTREXATE CAN BE EFFECTIVE AS MAINTENANCE THERAPY IN SPA-RELATED UVEITIS

F. Lian, J. Zhou, Y. Wang, H. Xu, L. Liang, X. Yang. *Dept. of Rheumatology, 1St Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Anti-TNF agents have deeply improved the therapeutic efficacy of spondyloarthritis (SpA)-related uveitis [1]. Despite the benefits of anti-TNF drugs, patients need to stay on this treatment for a long time. There has been a clear medical need to consider the long-term safety and increased drug costs. Unanswered question for physicians is whether TNF blockers can be reduced or even stopped in SpA-related uveitis, or how can it be reduced in patients have achieved remission or LDA. The current study aimed to investigate the effectiveness and safety of adalimumab tapering strategy in SpA-related uveitis. We tried to find a way in balancing the quality of the patients' lives, the side effects and the cost-effectiveness.
Objectives: The aim of this study was to evaluate the effectiveness of tapering of adalimumab combined with MTX in patients with spondyloarthritis (SpA)-related uveitis.
Methods: We performed a retrospective analysis. SpA patients with uveitis admitted to a south China hospital were enrolled. Demographic information, clinical characteristics, laboratory findings, intraocular inflammation, visual acuity, and macular thickness were documented every 3 to 6 months.
Results: In 32 cases of SpA-related uveitis who achieved clinical remission for at least 6 months after receiving a standard dose of adalimumab in combination of MTX, adalimumab was tapered and MTX was continued. Dosing interval of adalimumab were spaced by 30% every 3 months up to complete stop. Twenty-six cases without MTX were analyzed for comparison. No significant difference of demographic characteristics and BASDAI, CRP, ESR was found between the two groups at the baseline. During the first 12 months of adalimumab tapering, the mean BASDAI remained stable in both groups. No recurrent uveitis was found in the group with combined MTX. In the group without combined MTX, 2 patients (2/26, 7.7%) presented increased anterior chamber inflammation and visual acuity. At the end of 24 months, mean BASDAI, CRP and ESR remained low in both groups. Two cases (2/32, 6.3%) in the group of combined MTX were documented increased BASDAI higher than 4, but no recurrent uveitis was observed. Altogether 5 cases (5/32, 15.6%) in the group of combined MTX had recurrent uveitis, in which 4 cases (4/5, 80%) initiated adalimumab tapering at 6 months' remission. In comparison, 8 cases (8/26, 30.8%, $p<0.001$) in the group without combined MTX had recurrent uveitis, in which 6 cases initiated

adalimumab tapering at 6 months' remission and 2 cases initiated adalimumab tapering at 9–12 months' remission. No patients had recurrent uveitis at 12 months' remission or longer in both groups. Adalimumab plus MTX were well tolerated in all patients.

Conclusions: For maintaining remission of SpA-related uveitis, adalimumab tapering can be effective when combined with MTX. Initiation of the tapering after 12 months' remission largely lower the rate of recurrence.

THU0352 TOFACITINIB TREATMENT IS ASSOCIATED WITH ATTAINMENT OF THE MINIMALLY IMPORTANT REDUCTION IN AXIAL MRI INFLAMMATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

W.P. Maksymowych[1], D. van der Heijde[2], X. Baraliakos[3], A. Deodhar[4], M. Brown[5], S.P. Sherlock[6], D. Li[7], D. Fleishaker[8], T. Hendrikx[7], K.S. Kanik[8].
[1]University of Alberta, Edmonton, AB, Canada; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Rheumazentrum Ruhrgebiet, Herne, Germany; [4]Oregon Health & Science University, Portland, OR, United States; [5]Queensland University of Technology, Brisbane, Australia; [6]Pfizer Inc, Cambridge, MA; [7]Pfizer Inc, Collegeville, PA; [8]Pfizer Inc, Groton, CT, United States

Background: Tofacitinib is an oral Janus kinase inhibitor. The minimally important changes (MICs) for the SPondyloArthritis Research Consortium of Canada (SPARCC) MRI sacroiliac joint (SIJ) and spine scores based on agreement with global change scores by readers are ≥2.5 and ≥5, respectively.[1]

Objectives: To assess whether MIC in SIJ and spine can discriminate between tofacitinib and placebo (PBO) in patients (pts) with ankylosing spondylitis (AS) and if this is concordant with clinical responses.

Methods: In this 16-week (wk), Phase 2, double-blind, dose-ranging study (NCT01786668),[2] 207 adult pts meeting modified New York AS criteria were randomised 1:1:1:1 to PBO or tofacitinib 2, 5 or 10 mg twice daily (BID) for 12 wks. Clinical endpoints included in this post-hoc analysis were: Assessment of SpondyloArthritis International Society 20% improvement (ASAS20) and ASAS 40% improvement (ASAS40) response rates, AS disease activity score major improvement (ASDAS MI; change ≥2.0 from baseline), ASDAS inactive disease (ASDAS ID; <1.3), Bath AS disease activity index (BASDAI), Bath AS functional index (BASFI) and back pain. Pts (%) achieving MIC in SIJ, spine and both SIJ and spine, in tofacitinib and PBO groups, were summarised based on observed data, and pooled tofacitinib (5 and 10 mg BID) vs PBO data were compared using Fisher's exact test. Concordance between achieving MIC and Wk 12 clinical responses was assessed. Wk 12 clinical responses were compared between pts achieving/not achieving MIC.

Results: MRI data for 164 pts were evaluated. Baseline demographics were generally balanced between treatment groups and typical of AS populations.[2] Tofacitinib 2, 5 and 10 mg BID improved mean (range) SPARCC scores vs PBO (SIJ: -2.2 [-22.0, 10.5], -3.5 [-34.5, 11.0], -3.6 [-29.0, 0.5] vs -0.7 [-9.5, 6.5]; spine: -3.2 [-34.5, 20.5], -5.5 [-36.5, 8.0], -6.7 [-32.5, 7.5] vs -0.8 [-8.0, 14.0]). Approximately 3 times more pts achieved MIC in SIJ or spine in the pooled tofacitinib group vs PBO (SIJ: 34.1% vs 11.8%, $p<0.05$; spine: 38.6% vs 11.8%, $p<0.01$). Achieving MIC in SIJ and spine correlated with clinical response. In pts on tofacitinib, ASAS20, ASAS40 and ASDAS MI responses were more likely in pts achieving MIC in SIJ or spine (Table) vs not achieving MIC. Compared with not achieving MIC, pts on tofacitinib achieving MIC in SIJ had larger improvements in BASDAI, BASFI and back pain.

Conclusions: Pts who received tofacitinib who had AS experienced clinically meaningful reductions in axial MRI inflammation. Pts achieving MIC for MRI inflammation had increased clinical response rates.

THU0353 CHANGE IN MRI STRUCTURAL LESIONS IN THE SACROILIAC JOINT AFTER TWO YEARS OF ETANERCEPT THERAPY IN COMPARISON TO A CONTEMPORARY CONTROL COHORT IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

W.P. Maksymowych[1], M. Dougados[2], R.G. Lambert[1], R. Landewe[3], A. Molto[2], P. Claudepierre[4], M. de Hooge[5], R. Bonin[6], J.F. Bukowski[6], H. Jones[6], I. Logeart[7], R. Pedersen[6], A. Szumski[8], B. Vlahos[6], D. van der Heijde[5].
[1]University of Alberta, Edmonton, Canada; [2]Paris Descartes University, Hôpital Cochin, Paris, France; [3]Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [4]Universite Paris Est Creteil, Creteil, France; [5]Leiden University Medical Center, Leiden, Netherlands; [6]Pfizer, Collegeville, United States; [7]Pfizer, Paris, France; [8]InVentiv Health, Princeton, United States

Background: Demonstrating a structural effect of TNF inhibitors in axial SpA (axSpA) is challenging.

Objectives: To compare 2 yrs of structural lesion changes on T1W MRI in the sacroiliac joints (SIJ) of pts receiving etanercept (ETN) in a clinical trial to similar pts not receiving biologics in a cohort study.

Methods: Pts had recent onset non-radiographic (nr)-axSpA fulfilling ASAS criteria. Study group: pts receiving ETN 50 mg once weekly for 2 yrs in EMBARK (NCT01258738). Control group: pts in a longitudinal cohort study not receiving biologics for 2 yrs (DESIR, NCT01648907). Outcome measure: change in structural lesions of erosion, backfill, fat metaplasia, and ankylosis. MRI images were read by 3 experienced readers unaware of image chronology and pt group, using the SpondyloArthritis Research Consortium of Canada SIJ Structural Score (SSS).[1] For each group, differences were calculated between percentages of patients experiencing increases and decreases in structural lesion scores over 2

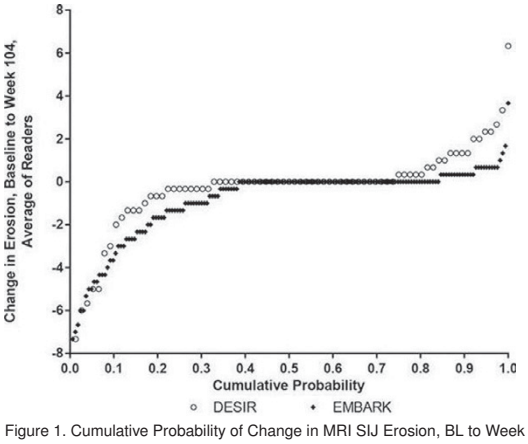

Figure 1. Cumulative Probability of Change in MRI SIJ Erosion, BL to Week 104.

Abstract THU0353 – Table 1. Observed Change in MRI SIJ Structural Lesions, BL to Week 104

Structural lesion	Cohort	Decreased n/N (%)	Increased n/N (%)	Mean Difference* (95% CI)†	Mean differences (Control – ETN) (95% CI)
Erosion	Control	14/76 (18.4)	10/76 (13.2)	-5.3% (-18.1, 7.6)	18.8% (3.5, 34.1)†§
	ETN	46/162 (28.4)	7/162 (4.3)	-24.1 (-32.1, -16.0)	17.8% (2.1, 33.6)‡§
Backfill	Control	2/76 (2.6)	10/76 (13.2)	10.5% (1.7, 19.3)	-5.5% (-16.6, 5.5)†
	ETN	1/162 (0.6)	27/162 (16.7)	16.0% (10.1, 22.0)	-3.7% (-15.2, 7.8)‡
Fat metaplasia	Control	0/76 (0)	7/76 (9.2)	9.2% (2.6, 15.9)	1.8% (-6.6, 10.2)†
	ETN	2/162 (1.2)	14/162 (8.6)	7.4% (2.7, 12.2)	-2.4% (-11.2, 6.4)‡
Ankylosis	Control	0/76 (0)	1/76 (1.3)	1.3% (-1.3, 3.9)	1.3% (-2.2, 4.9)†
	ETN	2/162 (1.2)	2/162 (1.2)	0% (-2.4, 2.4)	1.5% (-3.1, 6.2)‡

Based on 2 of 3 readers assigning same category; otherwise considered no change. Some pts started with the lowest possible score and could not decrease. *Percent pts with increase – percent pts with decrease. †One-way ANOVA. ‡Adjusted for covariates listed in Methods. § $P<0.05$.

yrs. Treatment effect was analyzed without and with adjustment for the baseline (BL) covariates of sex, symptom duration, smoking status, HLA-B27 status, ASDAS-CRP, SPARCC MRI SIJ score, and SIJ radiography score.

Results: At BL, pts with MRI images in the control (DESIR, N=76) and ETN (EMBARK, N=162) cohorts differed significantly in symptom duration, smoking status, ASDAS-CRP and SPARCC MRI SIJ score. The table presents structural lesion changes on MRI. The mean difference between control and ETN was significant for erosion (table). Figure shows cumulative probability plot.

Conclusions: This analysis confirms the slow rate of structural lesion progression in the SIJ over 2 yrs in nr-axSpA and suggests a lower rate of progression with ETN than without a TNF inhibitor.

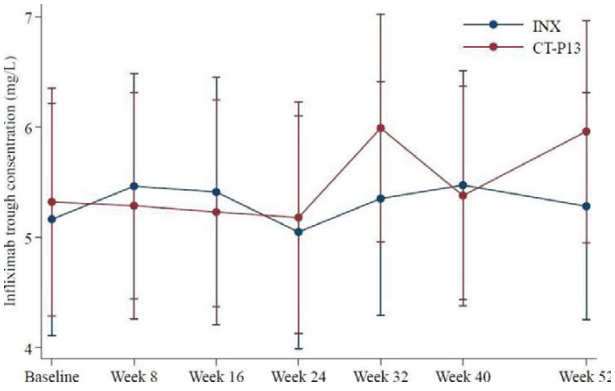
THU0354 DISEASE WORSENING AND SAFETY IN PATIENTS SWITCHING FROM ORIGINATOR INFLIXIMAB TO BIOSIMILAR INFLIXIMAB (CT-P13) IN THE RANDOMIZED NOR-SWITCH-STUDY: EXPLORATIVE ANALYSIS IN SPA PATIENTS



G.L. Goll[1], I.C. Olsen[1], N. Bolstad[2], K.K. Jørgensen[3], M. Lorentzen[4], C. Mørk[5], J. Jahnsen[3], E.A. Haavardsholm[1], T.K. Kvien[1] on behalf of the NOR-SWITCH study group. *[1]Dept of Rheumatology, Diakonhjemmet Hospital; [2]Biochemistry DNR, Oslo University Hospital, Oslo;[3]Gastroenterology, Akershus University Hospital, Lørenskog; [4]Dermatology, Oslo University Hospital, Oslo; [5]Dermatology, St Olav University Hospital, Trondheim, Norway*

Background: The NOR-SWITCH study is a 52-week randomized, double-blind, non-inferiority, phase IV switch trial in patients with Crohn's disease (CD), ulcerative colitis (UC), spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and plaque psoriasis (Ps) on stable treatment with originator infliximab (Remicade®, INX), funded by the Norwegian government. Previously, primary analyses of the pooled indications have been published[1].

Objectives: To investigate efficacy, safety and immunogenicity in SpA patients treated with continuous INX vs patients switched to CT-P13 (biosimilar infliximab, Remsima®) in the NOR-SWITCH study (explorative analyses).

Methods: Patients were randomized 1:1 to continued INX or switch to CT-P13. Serum drug levels were analyzed by automated in-house assay. The primary endpoint was disease worsening according to disease-specific composite measures and/or consensus between investigator/patient. Exploratory subgroup analyses examined disease worsening and safety in SpA. The primary endpoint was analysed by logistic regression, adjusted for diagnosis and disease duration.

Results: Demographics, occurrence of disease worsening, change in disease measures and treatment-emergent adverse events (TEAE) were similar (Table), as were serum drug levels for INX and CT-P13 (Figure).

Conclusions: Explorative analyses in the NOR-SWITCH study showed similar efficacy, drug levels and safety in SpA patients switched to CT-P13 as those on continuous INX. The study was not powered to show non-inferiority within each diagnosis.

Abstract THU0354 – Table 1. Demographics, baseline characteristics (FAS), percentage of patients with disease worsening, change in disease measures during 52 weeks follow-up (PPS)

Demographics, baseline characteristics	INX	CT-P13	
Total number of SpA patients PPS/FAS	43/45	42/46	
Age (years) mean (SD)	50.0 (10.3)	52.8 (10.8)	
Females	7 (16%)	8 (17%)	
Duration of ongoing INX treatment (years) mean (SD)	8.6 (3.1)	8.7 (3.2)	
Immunosuppressive co-medication	15 (33%)	10 (22%)	
HLA B27 pos	31 (94%)	33 (87%)	
Disease worsening			95% CI of group difference after 52 weeks
All study patients	53 (26.2%)	61 (29.6%)	-12.7–3.9%
SpA	17 (39.5%)	14 (33.3%)	-14.5–27.2%
Change in disease measures from baseline			
Physician Global Assessment of Disease Activity (0–10)	-0.1 (1.4)	-0.5 (1.3)	0.53–0.53
Patient Global Assessment of Disease Activity (0–10)	0.1 (2.2)	-0.4 (1.8)	-0.08–0.62
Log_{10} erythrocyte sedimentation rate (mm/h)	0.0 (0.3)	-0.0 (0.3)	-0.14–0.06
Log_{10} C-reactive protein (mg/L)	-0.0 (0.4)	-0.1 (0.4)	-0.11–0.15
ASDAS	0.1 (0.6)	-0.2 (0.7)	-0.27–0.24
BASDAI	0.3 (1.0)	-0.2 (1.4)	-0.50–0.47
TEAE (FAS)	116	102	

Data are n (%), mean (SD) or median (25–75 percentiles). 95% CI, 95% confidence interval of the adjusted treatment difference. BASDAI, Bath Ankylosing Spondylitis Disease Activity Index. ASDAS, Ankylosing Spondylitis Disease Activity Score. FAS, Full Analysis Set. PPS, Per Protocol Set. TEAE, treatment emergent adverse events.

THU0355 INFLUENCE OF ADALIMUMAB AND SULFASALAZINE ON STRUCTURE OF HYALINE CARTILAGE OF HIP JOINTS IN PATIENTS WITH ANKYLOSING SPONDILITIS

A. Petrov, H. Zayaeva, A. Petrov. *Medical Academy named after Georgievsky, Crimean Federal university named after V.I. Vernadsky, Simferopol, Russian Federation*

Background: The impairment of hip joints has significant prognostic value on functional status of patients with Ankylosing spondylitis (AS) [1]. One of possible yearly marker of hip joints structure damage in patients with AS may be changing in volume of hyaline cartilage [2]. But clinical significance of this marker in monitoring of hip joint structure changes during treatment is underinvestigated.
Objectives: To investigate changes in width of hyaline cartilage of hip joints in patients with AS under treatment with sulfasalazine and adalimumab during 12 month.
Methods: The 53 patients with AS (42 male, 9 female, average age is 37.6 years old, duration of disease is 14–152 month) were included into study. All patients were treated by NSAIDs and sulfasalazine (2 g per day) at least 3 month before study. In treatment of 27 patients (1st group) was added adalimumab (40 mg subcutaneously every 2 weeks), other 26 patients (2nd group) were left on previous treatment regime. Patients were observed during 12 months of treatment including measurements of pain visual analog scale (VAS) in hip movements, maximal distance between ankles, pelvic X-ray and sonography of hip joints by 10–18 MHz probe. BASRI-Hips index was applied for radiographic estimation of structural damage of hip joints [3]. During sonography width of hip joint capsule and hyaline cartilage were measured. The Mann-Whitney-U test was used for comparison of changes in clinical and sonographic data between two groups of patients.
Results: After 12 month treatment period in patients of 1st group in comparison with patients of 2nd group more significant decrease of pain VAS during hip movements (on 27.3 [18.8; 32.5] mm vs 4.7 [0.5; 9.6] mm, $p<0,01$), increase of maximal distance between ankles (on 124.3 [92.3;145.6] mm vs 3.5 [1.2; 6.5] mm, $p<0,05$) and decrease of joint capsule width (on 2.4 [1.0; 3.6] mm vs 0.4 [0.0;1.1] mm, $p<0,05$) had been determined. In patients of 1st group width of hyalinic cartilage had been increased on 0.15 [0.4; 0.22] mm, while in patients of 2nd group width of hyalinic cartilage had been decreased on 0.8 [0.0; 1.4] mm ($p<0,05$). These cartilage changes were accompanied by decrease of mean BASRI-Hips index on 1 point in 2nd group and absence of changes of BASRI-Hips index in 1st group. The correlation between changes in width of hip hyalinic cartilage and pain VAS during movement in hip joints (r=-0.52 [0.38; 061]) and maximal distance between ankles (r=+0.47 [0.32; 0.60]) had been revealed.
Conclusions: Treatment with adalimumab leads to decrease of clinical and sonographic signs of coxitis and improvement of hyaline cartilage structure. The increase of width of hip hyalinic cartilage correlates with clinical effect of treatment of coxitis in patients with AS. More prolonged observation is needed for analysis of correlation between changes in hyaline cartilage structure and radiographic progression of hip joints damage in AS.

THU0356 THE RANK OF ADMINISTRATION AND NOT THE MOLECULE HAS AN IMPACT ON THE ANTI TNF TREATMENT RESPONSE IN AXIAL SPA

A. Moltó, A. Etcheto, L. Gossec, S. Perrot, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: Five different sub-cutaneous TNF alpha blockers (TNFb) are available for the treatment of NSAID-refractory and active axial spondyloarthritis (axSpA). The efficacy of these drugs in axSpA has been well reported in several RCT and real-life studies separately or as a group, but only very few head-to-head studies have compared each molecule's treatment effect in axSpA. Also, some data suggest that TNFb treatment effect in patients failing to a first TNFb is poorer than in TNFb-naïve patients, but some other suggest that response to a second TNFb might be comparable.
Objectives: to describe TNFb prescription and treatment response of each TNFb, and to compare treatment response in TNFb- naïve/not naïve axSpA patients in a real-life setting.
Methods: Prospective, multicenter, usual care study with 2 visits (baseline and 12 weeks after TNFb initiation, Predict-SpA study, ClinicalTrials.gov: NCT03039088)). *Patients:* axSpA patients (diagnosis according to treating rheumatologist) initiating a TNFb. *Data collection:* Patients and disease characteristics at baseline. Previous exposure to TNFb was collected. Disease activity and function measures were collected at both visits. The choice of the TNFb to be started during the trial was at the treating rheumatologist's discretion. *Statistical analysis:* effectiveness was defined by the BASDAI50 response. Non-responder imputation and baseline observation carried forward imputation (for binary and continuous outcome variables, respectively) were performed for patients who discontinued the TNFb treatment between baseline and the follow-up visit.
Results: Among the 527 patients enrolled in the study, 508 patients were included in the analysis (1 patients was excluded due to missing data on all disease activity measures at baseline, and 18 patients were excluded due loss of follow-up between baseline and the follow-up visit). Mean age was 41.4 (±11.6), 237 (47%) were women, with a 6.1±8.5 mean disease duration. 377/508 (74%) were TNFb-naïve while 66 (13%), 35 (7%),19 (3.7%),8 (2%) and 3 (1%) had previously received, 1,2, 3, 4 and >4 TNFb, respectively.
In the whole study population the most frequently prescribed TNFb was etanercept (197 (39%)), followed by adalimumab (131 (26%)), golimumab (88 (17%)), infliximab 53 (10%) and certolizumab (39 (8%)); the same order was observed in TNFb naïve patients; however, in patients previously exposed to TNFb, the most frequently prescribed TNFb was infliximab (31 (24%)) followed by golimumab (29 (22%)), adalimumab (29 (22%)), certolizumab (22 (17%)) and etanercept (20 (15%)).
BASDAI50 responses were comparable for all TNFb molecules: 52%, 52%, 48%, 53% and 49% for etanercept, adalimumab, golimumab, infliximab and certolizumab, respectively.
BASDAI 50 response was comparable in patients TNFb-naïve and patients previously exposed to only 1 previous TNFb (53% vs. 52%, for naïve vs. non-naïve patients) but significantly decreased after (i.e. 37% and 36.% for patients previously exposed to 2 and to 3 or more TNFb)
Conclusions: this study suggests that the TNFb treatment response is similar across the different available molecules but this treatment response decreased in case of a previous use of two TNFb.

THU0357 NO SPECIFIC IMPACT OF CONCOMITANT FIBROMYALGIA ON THE ANTI TNF TREATMENT EFFECT IN AXIAL SPONDYLOARTHRITIS PATIENTS WITHOUT RADIOGRAPHIC STRUCTURAL DAMAGE OR OBJECTIVE SIGNS OF INFLAMMATION

A. Moltó, A. Etcheto, L. Gossec, S. Perrot, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: Currently, the European Medicine Agency (EMA) is recommending the use of anti-TNF in case of active NSAID refractory axial (ax) spondyloarthritis (SpA) only in the presence of either structural radiographic damage of the sacroiliac Joints (SIJ) or objective signs of inflammation (either elevated CRP or inflammation at MRI-SIJ) probably mainly because of the fear of a concomitant fibromyalgia (FM).
Objectives: To evaluate the interaction of a concomitant FM on the anti-TNF response with regard to the application of the EMA recommendation
Methods: *Study design:* Prospective, multicenter, longitudinal (12 weeks) open trial (Predict-SpA, ClinicalTrials.gov: NCT03039088). *Patients (pts):* axSpA requiring an anti-TNF. *Data collected:* At baseline, 1/Radiographic SIJ damage 2/ MRI-SIJ inflammation 3/ Elevated CRP 4/ FM according to the FiRST (Fibromyalgia Rapid Screen Test) questionnaire. At baseline and after 12 weeks of therapy: BASDAI. *Statistical analysis:* Non Responder Imputation (NRI), Baseline Carried Forward Technic (BOCF) in case of missing data. Interaction test between the presence of FM and the fulfillment of the EMA recommendation (defined by the presence of either structural radiographic damage of the SIJ or objective signs of inflammation (either elevated CRP or inflammation at MRI-SIJ)) on the anti TNF treatment response (BASDAI50)
Results: Of the 508 enrolled pts (females: 46.7%, age: 41.4+11.6 years old, HLA B27 positive: 57.5%, X-Ray sacroiliitis: 53.2%, inflammation at MRI-SIJ: 52.0%), only 59 had no structural damage at SIJ-X-Rays and no inflammation at MRI-SIJ (12%). A concomitant FM was noticed in 42% *vs* 37% of pts treated in accordance *vs* not with the EMA recommendation, respectively (p=0.44). The anti-TNF treatment effect was higher in the groups of pts treated in accordance (vs not) with the EMA recommendation (BASDAI 50: 52% *vs* 39%, respectively; p=0.054). There was a trend (but not statistically significant) suggesting an interaction of the concomitant FM on the anti TNF treatment response with regard

to the application of the EMA recommendation (interaction p value=0.140). In the 59 pts not treated in accordance with the EMA recommendation, the treatment effect in the sub-groups of pts without (*vs* with) concomitant FM was 38% vs 40% respectively, p=0.891. In the 449 pts treated in accordance with the EMA recommendation, the treatment effect in the sub-groups of pts without (*vs* with) concomitant FM was 56% vs 46%, p=0.042).

Conclusions: This study suggests that 1/ French rheumatologists are applying the EMA recommendation in daily practice 2/ these recommendations result in a better outcome in terms of short term symptomatic treatment effect. In this study, concomitant FM was not more frequently observed in patients without (*vs* with) objective sign of structural damage or inflammation and the impact of a concomitant FM was not more pronounced (or even lower) in pts without (vs with) objective sign of structural damage or inflammation.

THU0358 ROSUVASTATIN IMPROVES NITRIC OXIDE AND ENDOTHELIAL FUNCTION AND SUPPRESSES INFLAMMATORY DISEASE ACTIVITY IN ANKYLOSING SPONDYLITIS

A. Syngle[1], N. Garg[2], P. Krishan[2]. *[1]Cardio Rheuma, Healing Touch City Clinic, Chandigarh and Fortis Multi Speciality Hospital, Mohali, India, Chandigarh; [2]Department of Pharmaceutical Sciences and Drug Research, Punjabi University, Patiala, India*

Background: Nitric oxide (NO) regulates the synthesis of several inflammatory mediators, functions of inflammatory cells in the inflamed joint and plays a central role in the regulation of blood vessel tone[1]. Therefore, NO inhibitors represent important therapeutic advancement in the management of inflammatory diseases. Rosuvastatin improves NO and endothelial dysfunction in patients with heart failure[2] but its effect on NO has not yet been tested in Ankylosing Spondylitis (AS) patients.

Objectives: To investigate the effect of rosuvastatin on nitrite levels (NO surrogate) and its relationship with endothelial function and inflammatory measures in AS.

Methods: 40 consecutive patients (20 in Rosuvastatin (10 mg/day) and 20 in placebo arm) meeting the modified New York criteria for AS, with active disease despite treatment with conventional synthetic DMARDs were recruited. Serum nitrite estimation was carried out by Griess reaction. Flow-mediated dilatation (FMD) was assessed using AngioDefender. Inflammatory measures included– BASDAI, BASFI, ESR and CRP. Pro-inflammatory cytokines (TNF-α, IL-6 and IL-1) were measured at baseline and after 24 weeks.

Results: After 24 weeks, significant improvement in serum nitrite was observed in rosuvastatin group (5.27±0.26 to 4.11±0.19, p<0.01) compared with placebo (5.47±0.26 to 5.36±0.23, p=0.33). At 24weeks; FMD, TNF-α, and IL-6 improved significantly in rosuvastatin group compared with placebo. At 24 weeks; ESR, CRP, BASDAI and BASFI significantly improved in rosuvastatin group compared with placebo. After treatment with rosuvastatin, nitrite correlated inversely with FMD (r=-0.47, p=0.03) (Fig.1A) and positively with TNF-α (r=0.64, p=0.01) (Fig.1B), CRP (r=0.52, p=0.01) (Fig.1C) and LDL (r=0.54, p=0.01) (Fig.1D).

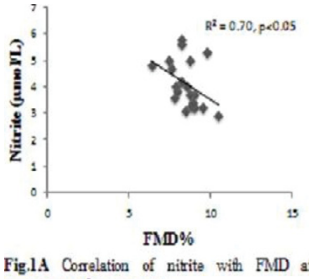

Fig.1A Correlation of nitrite with FMD after treatment with rosuvastatin

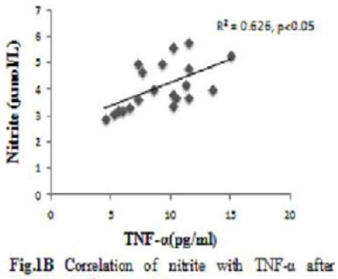

Fig.1B Correlation of nitrite with TNF-α after treatment with rosuvastatin

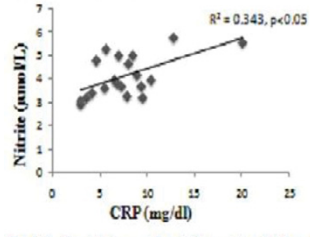

Fig.1C Correlation of nitrite with CRP after treatment with rosuvastatin

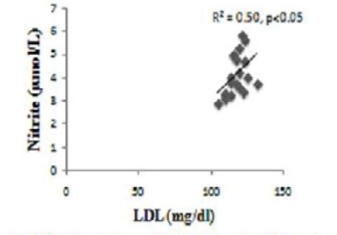

Fig.1D Correlation of nitrite with LDL after treatment with rosuvastatin

Conclusions: Rosuvastatin reduced serum nitrite concentration and improved endothelial dysfunction in AS patients. Rosuvastatin lowers the proinflammatory cytokines, especially IL-6 and TNF-α, which downregulates CRP production and thus the production of NO. Rosuvastatin also favorably improved the lipid levels in AS patients. Rosuvastatin exerts anti-inflammatory, immunomodulatory and vasculoprotective effect in ankylosing spondylitis through both cholesterol dependent and cholesterol independent pathways

THU0359 SECUKINUMAB DEMONSTRATES CONSISTENT SAFETY OVER LONG-TERM EXPOSURE (UP TO 3 YEARS) IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: POOLED ANALYSIS OF THREE PHASE 3 TRIALS

A. Deodhar[1], X. Baraliakos[2], H. Marzo-Ortega[3], J. Sieper[4], M. Andersson[5], B. Porter[6], T. Fox[5]. *[1]Oregon Health & Science University, Portland, United States; [2]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany; [3]Nihr Lmbru, Ltht&lirmm, UoL, Leeds, United Kingdom; [4]Charité University Medicine Berlin, Berlin, Germany; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corp., East Hanover, United States*

Background: Safety data for secukinumab in the treatment of ankylosing spondylitis (AS) have been reported from three Phase 3 studies: MEASURE 1 (NCT01358175)[1], MEASURE 2 (NCT01649375)[1] and MEASURE 3 (NCT02008916).[2]

Objectives: To report long-term (up to 3 years) pooled safety and tolerability data for secukinumab in AS (data cut-off: 25 June 2016).

Methods: Overall, 371, 219 and 226 patients with active AS were randomised in MEASURE 1, MEASURE 2 and MEASURE 3, respectively. Study design, efficacy and safety results of these studies have been published earlier.[1,2] Secukinumab doses differed in the studies and included intravenous 10 mg/kg or subcutaneous (75–300mg) multi-dose loading, followed by subcutaneous (s.c.) maintenance dosing (75, 150, or 300mg). Data collected up to the last patient performing the Wk 156 visit in MEASURE 1, the Wk 104 visit in MEASURE 2, and the Wk 52 visit in MEASURE 3 were pooled at the patient level. Exposure-adjusted incidence rates were calculated to account for differences in treatment exposure and analyses included all patients who received ≥1 dose of secukinumab 150 or 300mg.

Results: A total of 510 patients were included in the analysis (968.9 patient-years of exposure). The exposure-adjusted AE and SAE rates with secukinumab across the entire safety period were 159.2 and 5.4 per 100 patient-years, respectively. Nasopharyngitis, diarrhoea and headache were the most frequently reported AEs. The incidences of *Candida* infections, serious infections, inflammatory bowel disease, major adverse cardiac events, neutropenia and uveitis were low and consistent with previous reports over shorter exposure periods[1] (Table). No cases of suicidal ideation or depression were reported.

Table 1. Summary of pooled safety across 3 AS studies (Entire safety period)

	Any secukinumab dose (N=510)
Total exposure, patient-years	968.9
Minimum–maximum exposure (days)	1–1530
Death, n (%)	0
AEs by EAIR: AE per 100 Patient-years (95% CI)	
Any AE	159.2 (144.4, 175.1)
Any SAE	5.4 (4.0, 7.1)
Frequent AEs[1]	
Nasopharyngitis	13.6 (11.2, 16.5)
Diarrhoea	6.4 (4.9, 8.3)
Headache	6.7 (5.1, 8.7)
Upper respiratory tract infection	4.3 (3.1, 5.9)
AEs of special interest	
Candida infections	0.8 (0.4, 1.6)
Serious infections	0.7 (0.3, 1.5)
Inflammatory Bowel Disease	0.4 (0.1, 1.1)
Crohn's disease	0.2 (0.0, 0.7)
Ulcerative colitis	0.2 (0.0, 0.7)
MACE	0.4 (0.1, 1.1)
Neutropenia	1.2 (0.6, 2.1)
Uveitis	1.6 (0.9, 2.6)

[1]AEs that occurred in Any secukinumab group with an IR >4.0 during the entire safety period. AE, adverse event; CI, confidence interval; EAIR, exposure adjusted incidence rate per 100 patient-years; MACE, major adverse cardiac events; N, number of patients in the analysis; n, number of patients with event; SAE, serious adverse event.

Conclusions: This longer-term safety assessment of secukinumab in the treatment of AS was consistent with previous reports and did not identify any new safety signals.

THU0360 IMPROVEMENTS IN SLEEP PROBLEMS AND PAIN IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS TREATED WITH INTRAVENOUS GOLIMUMAB: 28-WEEK RESULTS OF THE PHASE III GO-ALIVE TRIAL

A. Deodhar[1], J.D. Reveille[2], E.K. Chan[3], S. Peterson[4], N. Li[4], E. Hsia[4,5], L. Kim[4], K.H. Lo[4], D.D. Harrison[4], C. Han[6]. *[1]Oregon Health & Science University, Portland; [2]University of Texas Health Sciences Center, Houston; [3]Janssen Global Services, LLC, Raritan; [4]Janssen Research & Development, LLC, Spring House; [5]University of Pennsylvania School of Medicine, Philadelphia; [6]Janssen Global Services, LLC, Malvern, United States*

Objectives: To investigate the effect of intravenously administered (IV) Golimumab (2 mg/kg), an anti-TNFα monoclonal antibody, on sleep problems, total back pain, and night back pain in adult patients (pts) with active Ankylosing Spondylitis (AS).
Methods: GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo-controlled trial. Pts (aged ≥18 years) had a diagnosis of definite AS (per modified New York criteria) and BASDAI ≥4, total back pain visual analogue scale (VAS) ≥4, and CRP ≥0.3mg/dL. At baseline, 208 pts were randomized to IV golimumab 2mg/kg (N=105) at Wks 0, 4, and every 8 wks or placebo (N=103) at Wks 0, 4, and 12, with crossover to IV golimumab at Wk 16 and through Wk 52. Sleep problems were assessed using the Medical Outcomes Study Sleep Scale (MOS-SS, range 0–100), a generic instrument designed to assess six dimensions of sleep, including 1) Sleep disturbance, 2) Somnolence, 3) Sleep adequacy, 4) Snoring, 5) Awaken short of breath or headache, and 6) Quantity of sleep/optimal sleep during the past 4 wks. The six dimensions are also used to generate the composite Sleep Problems Index. An increase in score from baseline represents improvement. Total back pain and night back pain over the past wk were assessed using VAS (0–10 cm; 0=no pain, 10=most severe pain). Wk 28 results are presented here. Unadjusted p-values of least square mean differences (LSMD) between treatment groups were based on analysis of covariance (ANCOVA) controlling for prior anti-TNF therapy.
Results: Mean changes in MOS-SS Sleep Index and 6 subscales are presented in Table 1. Improvement ($p<0.05$) in the MOS-SS sleep index and 4 subscales at Wk 8 was observed in golimumab compared to placebo, and in the sleep index and 4 subscales at Wk 16. Improvements from baseline to Wks 8 and 16 in pts' assessment of total back pain (cm) were greater ($p<0.001$) in golimumab than placebo (-2.70 vs -0.86 and -3.15 vs -1.15, respectively), and after placebo crossed over to golimumab, the differences diminished at Wk 28 (-3.14 vs -3.34, respectively). Improvements at Wks 8 and 16 from baseline in pts' assessment of night back pain (cm) were also greater ($p<0.001$) in golimumab than placebo (-3.03 vs -0.87 and -3.44 vs -0.85, respectively), and differences diminished at Wk 28 (-3.47 vs -3.42, respectively). Changes from baseline in all subscales of MOS-SS were correlated (Spearman correlations ranging between -0.10 and -0.45) with total back pain (TBP) and night back pain (NBP) at Wks 8, 16, and 28 (p values <0.05), with the exception of Snoring and both TBP and NBP at Wk 16. Change in NBP was associated with change in Sleep Problem Index at all 3 time points (p=0.002, p=0.001, and p=0.031, respectively). In the general linear model, most of the association between change in TBP and change in Sleep Problem Index was explained by the association between change in NBP and change in Sleep Problem Index.

Table 1. Summary of mean (standard deviation) changes in MOS-SS and its subscales.

	GLM	PBO	GLM	PBO	GLM	PBO*

Awaken short of breath or headache:	4.64 (12.44) p=0.043	1.15 (10.02)	4.08 (12.26) p=0.20	1.50 (11.20)	4.19 (12.50)	3.00 (11.21)
Quantity of sleep/optimal sleep:	0.13 (0.57) p=0.43	0.10 (0.52)	0.13 (0.59) p=0.019	0.01 (0.57)	0.16 (0.56)	0.19 (0.56)

*At Wk28. PBO has crossed over to GLM

Conclusions: Adult pts with active AS treated with IV golimumab showed improvements in sleep problems, total back pain, and night back pain. Night back pain improvement was associated with improvement in sleep problems.

THU0361 PRESCRIPTION PATTERNS OF BIOLOGICAL DISEASE MODIFYING DRUGS AND BIOSIMILARS IN ANKYLOSING SPONDYLITIS – A COLLABORATION BETWEEN BIOLOGICAL REGISTERS IN THE FIVE NORDIC COUNTRIES

B. Glintborg[1], K. Chatzidionysiou[2], J. Askling[2], K. Aaltonen[3], E. Kristianslund[4], B. Gudbjornsson[5], D. Nordström[3], M.L. Hetland[1], L. Dreyer[1], L.E. Kristensen[1], T.S. Jørgensen[1], K. Eklund[3], G. Grondal[5], S. Ernestam[2], J. Joensuu[3], T. Kvien[4], E. Lie[4], K. Fagerli[4], A.J. Geirsson[5], H. Jonsson[5], L. Jacobsson[2]. *[1]On behalf of the DANBIO registry, Copenhagen, Denmark; [2]On behalf of the SRQ/ARTIS registry, Stockholm, Sweden; [3]On behalf of the ROB-FIN registry, Helsinki, Finland; [4]On behalf of the NOR-DMARD registry, Oslo, Norway; [5]On behalf of the ICEBIO registry, Reykjavik, Iceland*

Background: Large-scale real life observational cohorts are needed to study effectiveness and early signals of rare safety issues of new biological disease modifying drugs (bDMARDs) and biosimilars (bsDMARDs) in ankylosing spondylitis (AS). Combining data from biological registries would facilitate this. The Nordic countries have several similarities that would justify such aggregated analyses including similar health care systems with universal access to population based health care, availability of b/bsDMARDs through a tax-paid system and the registration of use and effectiveness of bDMARDs in inflammatory diseases in a prospective manner in drug registries.
Objectives: To explore the prescription patterns of old (TNF-inhibitors) and newer bDMARDs (secukinumab, ustekinumab) including bsDMARDs (SB4, CT-P13) over time in AS in the Nordic countries in order to illustrate the potential of a common Nordic collaboration.
Methods: Data regarding the numbers of AS patients (pts) (ICD10 code M45) who initiated bDMARD treatment (irrespective of treatment course number) during the period 2011–2016 were collected from the Nordic rheumatologic biological registries SRQ (Sweden), NOR-DMARD (6 Norwegian treatment centres), DANBIO (Denmark), ROB-FIN (Finland, 2011–2015) and ICEBIO (Iceland).
Results: In total, 6,610 bDMARD treatment initiations were identified (Sweden 3654, Norway 1078, Denmark 782, Finland 789, Iceland 307).
The prescription patterns of bDMARDs changed substantially over time. In 2016, the number of pts initiating a bsDMARDs exceeded those starting an originator bDMARD (figure). Few patients were treated with ustekinumab (Denmark <10 pts, Finland <10, Sweden 26) and secukinumab (Denmark <10 pts, Sweden 57).

Figure. The 5 Nordic countries, total number of AS patients initiating bDMARD per year

	2011	2012	2013	2014	2015	2016	Total
ADA, GOL, CERT	526	523	677	751	642	330	3449
Originator IFX	160	160	128	116	76	54	694
Biosimilar IFX	0	0	4	44	369	244	661
Originator ETN	285	282	197	244	235	91	1334
Biosimilar ETN	0	0	0	0	0	378	378
Secukinumab	0	0	0	0	1	64	65
Ustekinumab	0	0	1	9	15	4	29
Total	971	965	1007	1164	1338	1165	6610

ADA: Adalimumab, GOL: Golimumab, CERT: Certolizumab Pegol , IFX: Infliximab, ETN: Etanercept

Conclusions: The use of bsDMARDs in AS is rapidly increasing. The use of drugs with new modes of action is still low, which illustrates the need for collaboration across countries to provide real life data with sufficient power for new innovative therapies in the future. The Nordic rheumatologic registries represent a unique

opportunity to study effectiveness and safety of bDMARDs, including bsDMARDs in AS.

THU0362 EFFECT OF BIOTECHNOLOGICAL DRUGS ON EXTRA-ARTICULAR MANIFESTATIONS OF ANKYLOSING SPONDYLITIS: SYSTEMATIC REVIEW

A.L.R. Pinto [1], C.V. Pessoa [1,2], L.S. Inês [1,3]. *[1]Faculty of Health Sciences, University of Beira Interior, Covilhã; [2]Rheumatology, Local Health Unit of Guarda, Guarda; [3]Rheumatology, Coimbra Hospital and Universitary Centre, Coimbra, Portugal*

Background: Treatment with biotechnological agents (infliximab, etanercept, adalimumab, golimumab and certolizumab pegol) in ankylosing spondylitis (AS) is effective. However, evidence regarding the potential efficacy of these anti-TNF drugs in the extra-articular manifestations of ankylosing spondylitis, namely in uveitis (UV), inflammatory bowel disease (IBD) and dactylitis is scarce.

Objectives: To analyze evidence on efficacy of anti-TNF drugs approved for AS treatment in UV, IBD and dactylitis associated with AS.

Methods: A systematic literature review was performed using the PubMed and Cochrane Library databases. Randomized controlled trials (RCT), meta-analyzes and observational studies (OS) reporting efficacy of anti-TNF agents in extra-articular manifestations of AS were included.

Results: Fifty studies were included (seventeen RCTs, six meta-analyses and twenty seven observational studies). From the RCT we extracted the results presented in Table 1 for uveitis and in Table 2 for IBD. None reported results for dactylitis. Of the meta-analyzes included, only one presents results. These one shows that the incidence of uveitis is lower in patients taking etanercept than placebo (incidence of 8.6 and 19.3 per 100 patients per year, respectively; p value =0.03). In OS comparing different drugs, in one the risk of developing uveitis was 1.9 times higher in patients under etanercept compared to those under adalimumab (p value =0.0223) and a risk similar to those under infliximab and those under adalimumab. In another we have a percentage of patients with uveitis, during the course of the study, under etanercept of 8.0% and under infliximab of 4.0%. In the OS, the percentage of patients with UV events with infliximab was in a range of 0.0%>3.1% with a follow-up interval between 2 years and 5 years; with etanercept was 0.9%>29.6% and a follow-up time interval between 12 weeks to 7 years; with adalimumab there is only one study with duration of 2 years reporting 3.9% UV events. Regarding IBD reported in OS, there was 3.7%>7.7% patients with events under treatment with etanercept over a follow-up time of 3.2–7 years; with adalimumab only a 2-year study reported IBD in 0.6% of cases. We did not find results regarding for other extra-articular manifestations or anti-TNF drugs.

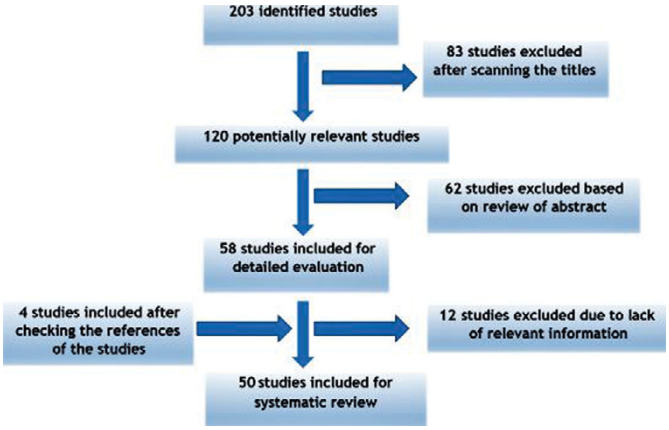

Table 1. Percentage of patients with events of uveitis on Randomized Controlled Trials

Uveitis	Randomized Controlled Trials	
	% patients with events under therapy	% patients with events under placebo
Infliximab	2,9	8,6
Etanercept	1,1	3,5
Adalimumab	No results	No results
Golimumab	No results	No results
Certolizumab pegol	0,9	2,8

Table 2. Percentage of patients with events of inflammatory bowel disease on Randomized Controlled Trials

Inflammatory Bowel Disease	Randomized Controlled Trials	
	% patients with events under therapy	% patients with events under placebo
Infliximab	No results	No results
Etanercept	1,1	0,7
Adalimumab	1,0	0,0
Golimumab	No results	No results
Certolizumab pegol	0,0	0,9

Conclusions: Efficacy of anti-TNF drugs on extra-articular manifestations of AS is under-reported in RCTs. Available data suggests possible efficacy of infliximab, adalimumab and certolizumab in UV, and of certolizumab in IBD. No evidence is available about anti-TNF efficacy in AS-associated dactylitis. Future studies with anti-TNF drugs should better report on extra-articular manifestations in AS.

THU0363 IMPACT OF ADALIMUMAB ON CLINICAL OUTCOMES, HEALTHCARE RESOURCE UTILIZATION AND SICK LEAVES IN ANKYLOSING SPONDYLITIS PATIENTS IN CENTRAL AND EASTERN EUROPE

D. Opris-Belinski [1], S. Erdes [2], S. Grazio [3], L. Šenolt [4], M. Hojnik [5], O. Nagy [6], L. Iosub [7], S. Szántó [8]. *[1]Rheumatology, Sf. Maria Clinical Hospital, Carol Davila University of Medicine, Bucharest, Romania; [2]V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; [3]Univ. Dpt. of Rheumatology, Clinical Hospital Centre Sisters of Mercy, Croatia, Zagreb, Croatia; [4]Dpt. of Rheumatology, 1st Faculty of Medicine, Charles Univ, Institute of Rheumatology, Prague, Czech Republic; [5]AbbVie, Global Medical Affairs, Ljubliana, Slovenia; [6]AbbVie, Global Medical Affairs, Budapest, Hungary; [7]AbbVie, Global Medical Affairs, Bucharest, Romania; [8]Rheumatology, Faculty of Medicine, Univ. of Debrecen, Debrecen, Hungary*

Background: Ankylosing spondylitis (AS) represents a considerable socioeconomic burden due to early disease onset, development of functional disability and life-time costs. The impact of originator adalimumab on the extent of outpatient attendance, hospitalizations and sick leave in relation to clinical outcomes is not known in Central and Eastern Europe (CEE).

Objectives: To evaluate disease activity, physical function, selected health care resource utilization and sick leaves in patients treated with adalimumab in clinical practice in CEE countries.

Methods: This was a 52-week multi-center post-marketing observational study conducted in 5 countries in CEE. Eligible AS patients were prescribed originator adalimumab according to the local practice; 5 study visits (V) were performed approx. 3 months apart. Disease activity was measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Index ($ASDAS_{CRP}$), treatment response as BASDAI50 and $\triangle ASDAS \geq -2$ (at study end), physical function by Bath Ankylosing Spondylitis Functional Index (BASFI). Data on AS related healthcare resource utilization and sick leave during the study was recorded prospectively through a systematic interview with the patient at each study visit. For pre-and post-treatment comparison, the same sort of data were recorded retrospectively at baseline visit for the 3-month period preceding adalimumab therapy, verified against chart review, then multiplied by 4 to match the prospective follow-up duration. Descriptive statistics were used; last observation carried forward data are presented herein.

Results: 452 patients were enrolled, 360 completed the study. Mean age was 42.9 (±12.1) yrs; 68.7% were male and 62.7% were employed at baseline. Average disease duration was 7.7 (±8.7) yrs. Mean BASDAI and ASDAS decreased from 6.3 (±2.1) and 4.0 (±1.1) at baseline to 2.3 (±2.0) and 1.9 (±1.1) at study end, respectively; mean BASFI from 6.2 (±2.3) to 2.6 (±2.3). BASDAI and ASDAS based treatment response was seen at study end in 72.3% and 58.9% of patients, respectively. The mean number of hospital admissions and inpatient days decreased from 2.8 (±3.9) to 0.9 (±2.8) and from 23.0 (±40.8) to 3.9 (±17.7), respectively (pre- and post-treatment). The mean number of sick leaves and sick leave days decreased from 3.2 (±8.8) to 1.1 (±5.6) and from 32.2 (±69.2) to 5.1 (±24.5), respectively (employed patients only, n=282). The reduction of hospital admissions/days, sick leaves and sick leave days were higher in treatment responders compared to non-responders. No new safety signal was detected.

Conclusions: Treatment with adalimumab in routine clinical practice in 5 CEE countries resulted in clinically meaningful improvements in disease activity and physical function as well as reduced healthcare resource utilization and sick leaves.

THU0364 IMMUNOGENICITY OF ANTI-TNF DRUGS AND CLINICAL RESPONSE IN PATIENTS WITH SPONDYLOARTHRITIS

D. Geiger[1], Y. Degboe[1], T. Barnetche[2], A. Cantagrel[1], A. Ruyssen-Witrand[1], A. Constantin[1]. *[1]Rheumatology, Centre de Rhumatologie, CHU Purpan, Place du Dr Baylac, Toulouse Cedex 9; [2]Rheumatology, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France*

Background: Antidrug antibodies (ADAb) seem to be associated with a loss of response in immune-mediated inflammatory diseases (1) and in psoriatic arthritis (2).
Objectives: To assess the effect of ADAb on clinical response in patients with spondyloarthritis (SpA) treated with anti-TNF drugs.
Methods: We conducted a systematic literature review of controlled trials and observational studies assessing the effect of ADAb on response to anti-TNF drugs (Adalimumab (ADL), Certolizumab (CTZ), Etanercept (ETA), Golimumab (GOL) and Infliximab (INF)) in patients with axial or peripheral SpA. Databases analysed were PubMed, the Cochrane library, and ACR/EULAR meeting abstracts, until January 2017. A meta-analysis was performed using the inverse variance approach and statistical heterogeneity was assessed with the Cochran Q-test and I^2 values. A statistical threshold of 5% was considered as significant.
Results: Over 1,387 publications screened, 7 studies were selected for meta-analysis (3–9). These studies were observational studies (n=6) or controlled trial (n=1); involved patients with axial or peripheral SpA (n=6) or psoriatic arthritis (n=1); included treatments with ADL (n=4), ETA (n=1), INF and INF biosimilar (n=2), or various anti-TNF drugs (n=1). ADAb rates varied between anti-TNF drugs: 0% for ETA, 13.6–31.4% for ADL, 0–28.9% for INF. Patients with ADAb were less often responders than patients without ADAb in 6 studies, more often responders in one study, while the risk ratio (RR) for response was not assessable in one study due to the absence of ADAb. The weighted pooled RR (95% CI) for response to anti-TNF drugs was 0.73 (0.54–0.98) in ADAb+ in comparison with ADAb- patients (p=0.04) (see figure). There were trends towards more infusion reactions and lower serum drug levels in patients with ADAb (data not shown).

Conclusions: According to the results of this meta-analysis, ADAb positivity is associated with a lower rate of response to anti-TNF agents in patients with SpA.

THU0365 DO EXTRA-ARTICULAR MANIFESTATIONS AFFECT THE CHOICE OF BIOLOGIC THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS? A MULTICENTRE REAL-LIFE ANALYSIS

E.G. Favalli[1], S. D'Angelo[2], A. Carletto[3], A. Becciolini[1], F. Martinis[3], G. Tramontano[2], M.G. Raimondo[4], M. Biggioggero[4], A. Marchesoni[1], M. Rossini[3], I. Olivieri[2]. *[1]Department of Rheumatology, Gaetano Pini Institute, Milano; [2]Rheumatology Institute of Lucania (IRel) - Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Potenza; [3]UOC Reumatologia, Dipartimento di Medicina, AOUI, Verona; [4]Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute, Milano, Italy*

Background: Extra-articular manifestations (EAMs), such as uveitis, inflammatory bowel diseases (IBD) and psoriasis (PsO), frequently complicate the disease course of patients with axial spondyloarthritis (axSpA), although prevalence data on this regard are still controversial. The occurrence of EAMs might also contribute to the decision of introducing a biologic therapy and even influence the choice between the available TNF inhibitors (TNFis).
Objectives: The aim of this study is to retrospectively evaluate the prevalence of EAMs in a multicentre cohort of axSpA patients treated with TNFi, investigating how these influenced the choice of treatment.
Methods: Clinical data from axSpA patients treated with a TNFi between May 2003 and May 2016 where obtained from a multicentre registry. Prevalence of EAMs (uveitis, IBD and PsO) was calculated at the time of TNFi prescription, evaluating their distribution according to drug subgroup.
Results: The study included 503 patients with axSpA (172 [34.2%] women, mean age [±SD] 40.5 [±13.2] years, mean disease duration 9.7 [±14.7] years), receiving a total of 675 lines of treatment (I-line n=503, II-line n=118, ≥ III-line n=54) with a TNFi (272 infliximab [IFX], 173 adalimumab [ADA], 89 golimumab [GOL], 141 etanercept [ETN]). At the time of TNFi introduction, 28.6% patients claimed at least one EAM (IBD 11.3%, uveitis 10.9%, and PsO 8.8%). The baseline presence of at least one EAM was associated with a more frequent prescription of an anti-TNF monoclonal antibody rather than etanercept (34.1% versus 21.9%, respectively; p=0.005). In detail, EAMs were found in 41.6, 36.9, 29.8, and 21.9% patients treated with GOL, ADA, IFX, or ETN, respectively. The prevalence of IBD was significantly higher (p=0.004) in patients treated with ADA (12.7%), IFX (14.3%), or GOL (11.2%) compared with ETN (4.9%). Uveitis was numerically more frequent in GOL (20.2%) and ADA (13.3%) rather than IFX (9.5%) and ETN (9.9%) groups. Finally, PsO prevalence was similar in patients treated with ADA (10.9%) and GOL (10.1%), and numerically lower in the ETN (7.1%) and IFX (5.9%) groups.
Conclusions: In our cohort of axSpA patients treated with TNFis, EAMs were highly represented. The presence of extra-articular involvement has been carefully taken into account when a TNFi was required to better control the disease. In particular, IBD and uveitis drove more frequently the choice toward an anti-TNF monoclonal antibody instead of the receptor.

Pini Orthopedic Institute, Milan, Milan; [11]Rheumatology and Immunology Unit, Spedali Civili, Brescia; [12]University of Padua, Padua; [13]Rheumatology Unit, University Hospital L.Sacco, Milan, Italy*

Background: Tumour necrosis factor (TNF) plays a pivotal role in controlling intracellular of bacterial infection. The BSR Biologics Register (BSRBR) has reported an increase in the occurrence of listeria and salmonella infections in anti-TNF-treated rheumatoid arthritis patients in comparison with those patients treated with non-biological DMARDs.
Objectives: The aim of this study was to determine the incidence of gastrointestinal infection in the anti-TNF-treated spondyloarthritis (SpA) patients in the GISEA registry, and identify the factors associated with its development.
Methods: The prospective GISEA registry was designed to collect real-world clinical data concerning patients with RA or SpA treated with biological drugs. The baseline information includes demographics, disease duration, HAQ-DI, DAS-28, BASDAI, BASFI and BASMI scores, steroid use, smoking history and comorbidities.
Results: Of the 3321 anti-TNF-treated SpA patients in the registry (1731 males, 52.2%; mean age 47±13 years; median disease duration three years, interquartile range [IQR] 0–8), 1065 (32%) were treated with infliximab (IFN), 1052 (32%) with adalimumab (ADA), and 1204 (36%) with etanercept (ETN). Two thousand, one hundred and five patients (63.4%) had a median of one comorbidity (IQR 0–2], the most frequent being hypertension (701), thyroid diseases (281), diabetes mellitus (207), cardiopathy (189), and osteoporosis (145). In combination with the biological drug, 919 patients (27.7%) received steroids and 2451 (79.9%) at least one DMARD. The median follow-up was three months (IQR 1–2 years). Twenty-two patients 0.7% experienced bacterial gastrointestinal infections, the most frequent being due to listeria, klebsilla and salmonella. The crude incidence rate was 2.5 per 1000 patient-years (95% CI 1.6–3.7). Univariate analysis showed that female gender (OR 3.9, 95% CI 1.5–10.0; p=0.004) and comorbidities (OR 3.4, 95% CI 1.0–3.5; p=0.049) were associated with a high risk of gastrointestinal infections, and that the use of IFN rather than ETN and ADA (p=0.712 and p=0.238) was not associated with a higher risk of gastrointestinal infections.

Furthermore, univariate models showed that age (p=0.738), disease duration p=0.090, previous DMARDs (p=0.616), and HAQ (p=0.674) and BASFI (scores p=0.850) were not statistically significant predictors of gastrointestinal infections.
Conclusions: The incidence rate of gastrointestinal infections in SpA patients treated with anti-TNF drugs is not increased. Being female and having comorbidities are predictive factors of gastrointestinal infections.

THU0367 THE INFLUENCES OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON SERUM VEGF AND BMP-2 LEVELS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

G. Gao, L. Lu, Z. Li, Y. Li. *Rheumatology, the First Affiliated Hospital of Zhengzhou Unversity, Zhengzhou, China*

Background: VEGF has been found abnormal in patients with SpA and related to disease activity [1,2]. BMP-2 has a function of promoting the osteophyte formation, and may be involved in the integration process of AS spine [3,4]. VEGF and BMP-2 interact with each other, participating in the formation of osteoblast [5]. COX-2 works together with the expressions of BMP2 and VEGF is an important factor of heterotopic ossification [6].
Objectives: To investigate the serum levels of VEGF and BMP-2 in axSPA treated with NSAIDs and their possible relationship with disease activity.
Methods: 120 patients with axSPA were randomized administered with imrecoxib or celecoxib respectively for 3 months. Serum VEGF and BMP-2 were detected. ESR, CRP, BASDAI, BASFI and SPARCC were measured.
Results: A statistically significant change was found in ESR, BASDAI, patients global assessment of disease activity, Schober test and SPARCC following treatment with imrecoxib or celecoxib (P <0.05). There were no statistically significant differences between the two groups. (P >0.05). There was statistically significant difference in serum VEGF levels before and after treatment (240.89±17.68 pg/ml vs 187.00±11.42 pg/ml, P<0.05), but no difference in BMP-2 (231.74±104.44 vs 226.80±116.26 pg/ml, P>0.05). A significant correlation was found between VEGF level and ESR, CRP, BASFI, tragus-up-wall distance and finger to floor distance, lumbar side flexion,Schober test and intermalleoar distance (r=0.628, 0.542, 0.238, 0.299, 0.353, -0.369, -0.373, -0.359, -0.274, P<0.05).And the BMP-2 levels were correlated with CRP and lumbar side flexion (r =0.213, -0.190, P<0.05). Serum VEGF levels were significantly increased in HLA-B27-positive patients than in HLA-B27-negative ones (P<0.05).
Conclusions: NSAIDs can not only improve symptoms and function, but also reduce sacroiliitis possibly by affecting the levels of VEGF and BMP. Imrecoxib and celecoxib have the same efficacy.The response to treatment was correlated with the expression of HLA-B27.

THU0368 CLINICAL AND IMAGING CHARACTERISTICS OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS REPORTING FLARE SYMPTOMS IMMEDIATELY PRIOR TO NEXT DOSE IN ROUTINE TNFI THERAPY

R. Ansell, H. Mathieson, M. Merashli, N. Busquets-Pérez, D. McGonagle, H. Marzo-Ortega. *Nihr Lmbru, Leeds Teaching Hospitals Trust and LIRMM, University of Leeds, Leeds, United Kingdom*

Background: Tumour necrosis factor inhibitors (TNFi) are highly efficacious in axial spondyloarthritis (axSpA) with significant clinical responses mirrored in resolution of MRI determined bone marrow oedema (BMO) lesions representative of active inflammation in the sacroiliac joints (SIJ) and spine. However, symptom flare suggesting loss of response is common with many patients reporting deterioration days or weeks prior to the next dose. We hypothesised that intermittent suppression of inflammation with longer acting TNFis such as adalimumab or infliximab may be associated with a greater likelihood of recurrence of MRI determined BMO lesions than shorter acting agents such as etanercept.
Objectives: To explore the relationship between symptom flare immediately prior to next treatment dose and recurrence of MRI determined BMO lesions with different TNFi in axSpA.
Methods: Proof-of-concept, single centre study. Eligible participants were adults with axSpA established on adalimumab, etanercept or infliximab describing loss of response immediately prior to next treatment dose. Loss of response was defined as subjective “flare” or “wearing off” of drug effect before the expected duration of treatment effect. Participants attended at three points: Baseline: first day of treatment cycle (day of drug dose); Endpoint 1: 3–4 days after dose; and Endpoint 2: within 48 hours of next dose. ASDAS-CRP and whole spine and SIJ MR imaging utilising 3T MRI scanner were performed at each visit. Images were scored according to the semi-quantitative Leeds MRI scoring system by two observers blinded to participant identity and date of scan.
Results: 38 participants (16 adalimumab; 12 etanercept; 10 infliximab) with a total 113 MRI scans were analysed. 71% (n=27) male; 60% (n=23) HLA-B27+ with no differences between the groups; 73.7% (n=28) fulfilled mNYC for AS; the remainder were classified as nr-axSpA. 58% (n=22) had at least 1 Grade 1 BMO lesion at baseline with lesions more commonly seen with longer acting drugs (5/12 in etanercept group; 9/16 in adalimumab group; 8/10 in infliximab group) and 11 (50%) had at least 1 Grade ≥2 lesion (Table 2). There was a trend towards number and severity of BMO lesions fluctuating through the treatment cycle (Figure 1) mimicking subjective loss of response, also reflected on the ASDAS-CRP (Table 1) but this did not reach statistical significance.

Table 1. Median (range) ASDAS-CRP by drug and visit

	Baseline	Endpoint 1	Endpoint 2
Etanercept	2.94 (1.5–4.4)	2.46 (1.8–4.0)	3.18 (1.1–4.2)
Adalimumab	2.97 (1.7–5.5)	2.17 (1.0–7.9)	2.79 (1.4–5.3)
Infliximab	3.3 (3.0–4.7)	2.93 (1.0–4.5)	3.31 (2.8–4.8)

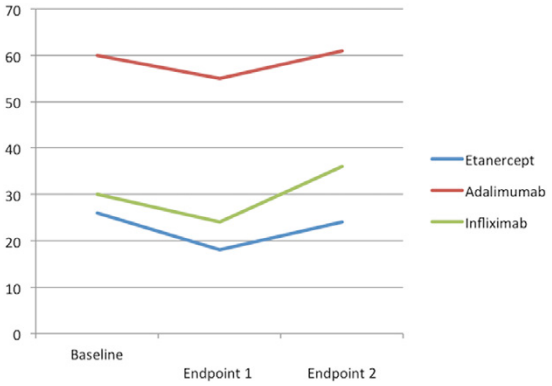

Figure 1. Total number of BMO lesions (grade 1 and ≥2).

Conclusions: This small proof-of-concept study shows subtle fluctuations on MRI changes of BMO and ASDAS-CRP corresponding to time of subjective “flare” before next scheduled TNFi dose in subjects with axSpA. Although these changes may be more common with the longer acting TNFi our data are not confirmatory. Larger studies are required to explore this concept further as these observations are potentially relevant for disease progression since cycles of inflammation and its subsequent suppression could theoretically increase the risk of new bone formation.

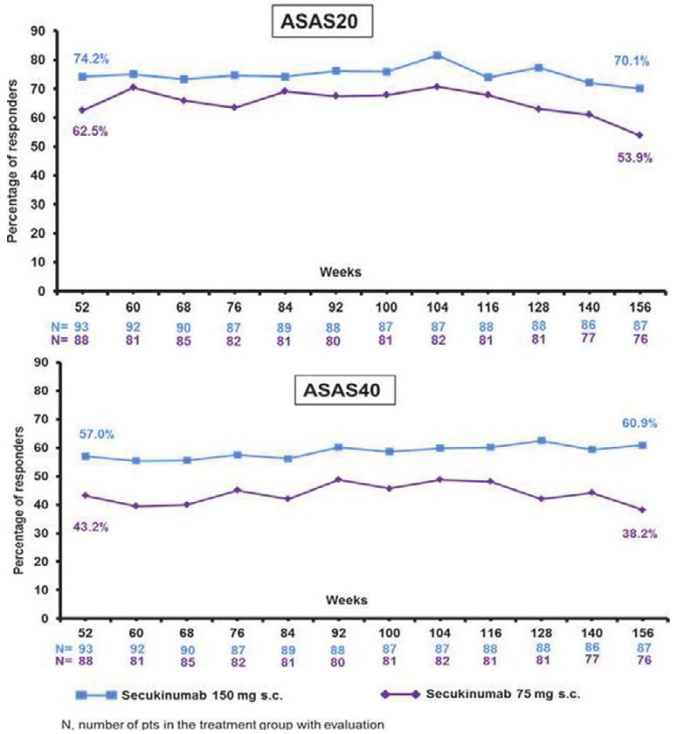
THU0369 SECUKINUMAB 150MG PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE ANKYLOSING SPONDYLITIS WITH HIGH RETENTION RATE: 3-YEAR RESULTS FROM PHASE III TRIAL, MEASURE 2

H. Marzo-Ortega[1], C.W. Legerton[2], J. Sieper[3], A.J. Kivitz[4], R. Blanco[5], M. Cohen[6], E.M. Delicha[7], S. Rohrer[7], H. Richards[7] on behalf of the MEASURE 2 study group. *[1]Nihr Lmbru, LTHT and LIRMM, UoL, Leeds, United Kingdom; [2]Low Country Rheumatology, Articularis Healthcare, Charleston, United States; [3]University Clinic Benjamin Franklin, Berlin, Germany; [4]Altoona Center for Clinical Research, Duncansville, United States; [5]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [6]McGill University, Montreal, Canada; [7]Novartis Pharma AG, Basel, Switzerland*



Background: Secukinumab improved signs and symptoms of ankylosing spondylitis (AS) over 2 years in the MEASURE 2 study (NCT01649375).[1,2]
Objectives: To report the efficacy and safety of secukinumab over 3 years from the MEASURE 2 study.
Methods: 219 patients (pts) with active AS were randomised to subcutaneous secukinumab 150mg (72 pts), 75mg (73 pts) or placebo (PBO, 74 pts). At Week (Wk) 16, PBO treated pts were re-randomised 1:1 to secukinumab 150mg or 75mg, irrespective of clinical response. Pts initially randomised to secukinumab and those who switched from PBO to secukinumab at Wk 16 were included in the analysis (secukinumab 150mg, N=106 and secukinumab 75mg, N=105). Outcome measures at Wk 156 included ASAS20 and 40, ASDAS-CRP inactive disease, ASAS5/6, BASDAI, SF-36 PCS and ASAS partial remission. Data are reported as observed. Safety analyses included all pts who received ≥1 dose of secukinumab.
Results: At 156 wks, the completion rates for secukinumab 150mg was 81.1% (86/106) and 72.4% (76/105) for 75mg. Higher discontinuation rates for 75mg were in part due to lack of efficacy or patient/guardian decision. Efficacy observed across endpoints from Wks 52 to 156 are summarised in the Table. Higher responses were observed in the 150mg group (Table and Figure). Over the entire study period, the mean exposure [±SD] to secukinumab was 914.3±315.5 days. The exposure-adjusted incidence rates with Any secukinumab for infections/infestations, Crohn's disease, malignant/unspecified tumours and major adverse cardiovascular events were 1.5, 0.6, 0.6 and 0.6 per 100 pt-years, respectively.
Conclusions: Secukinumab 150mg provided sustained improvement in the signs & symptoms along with physical functions with over 80% retention rate through 3 years in pts with AS. Safety profile remained favourable and was consistent with previous reports.[1,2]

THU0370 INCREASED INTERLEUKIN-17A CONCENTRATION REMAINS HIGH IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TUMOR NECROSIS α INHIBITORS WITHIN THE YEAR

I.Z. Gaydukova, A. Rebrov. *Hospital Therapy, Saratov State Medical University, Saratov, Russian Federation*

Background: Ankylosing spondylitis (AS) is associated with changes in the serum cytokines concentrations. During the treatment cytokines profile could change in different manner.
Objectives: The aim of the study was to evaluate the changes in concentration of interleukin-17A (IL-17A) in patients with AS, treated with tumor necrosis factor α inhibitors (anti-TNFα) during the year.
Methods: 30 patients with AS, fulfilled m. New-York criteria, with BASDAI ≥4.0 and NSAIDs non-responders were involved in the study. Mean age of AS patients at baseline was 38.35±9.19 years (M ± SD), the duration of AS was 11.4±9.6 years, 22 (73.3%) of patients – male. 20 healthy volunteers were involved as controls (mean age 40.1±7.7 years, male - 12 (60%). All AS patients were treated during the year with Remicade (infliximab, MSD®)) - 5 mg/kg at the recommended scheme. BASDAI, $ASDAS_{CRP}$ indices were calculated, C-RP, TNFα and IL-17A levels were measured before the treatment with anti-TNFα (baseline) and 52±2 weeks after the baseline. Number of patients achieved ASAS 20, ASAS 40 responses, and ASAS partial remission was evaluated. The statistics was performed with SPSS17.
Results: Baseline concentrations of TNFα and IL-17A in AS patients were higher than in healthy subjects (28.4±14.4 and 2.4±2.1, respectively, p<0.000). Significant reduction of AS activity, but not of IL-17A serum concentration was marked at week 52, Table 1.
24 (80%) achieved ASAS 20, 18 (60%) – ASAS 40, 12 (40%) of patients with

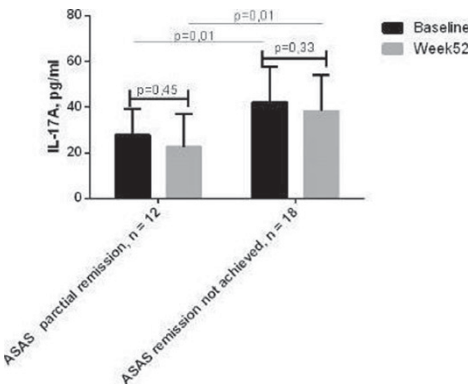

Table 1. Clinical and laboratory characteristics of AS activity at baseline and week 52, n=30

	Baseline	Week 52	p
Pain, Me [Q25;Q75]	6.0 [7.0; 9.0]	3.4 [1.0; 5.0]	<0.000
BASDAI, Me [Q25;Q75]	6.6 [4.4; 8.85]	3.2 [2.1; 7.6]	<0.000
ASDAS, Me [Q25;Q75]	3.8 [3.5; 4.4]	2.1 [1.26; 4.26]	<0.000
C-RP, mg/l, M±SD	12.3±3.9	4.3±1.7	<0.000
TNF α, pg/ml, M±SD	17.8±7.6	7.3±3.2	<0.000
IL-17A, pg/ml, M±SD	28.4±14.4	32.1±12.2	0.29

AS achieved ASAS partial remission. IL-17A was lower in patients who achieved remission compared to patients who did not achieve remission (figure).
Conclusions: Serum concentration of IL-17A remains stable in patients treated with anti-TNFα during the year. The baseline and final concentrations of serum IL-17A are higher in patients with AS who do not achieved ASAS partial remission compared to those who achieved the remission.

THU0371 THERAPY MODIFICATIONS IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH A BIOLOGIC IN THE UNITED STATES – DESCRIPTIVE ANALYSES FROM AN ADMINISTRATIVE CLAIMS DATABASE

J.A. Walsh[1], O. Adejoro[2], B. Chastek[2], G. Chun[3], Y. Park[3]. *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]Optum, Eden Prairie, MN; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States*

Background: For patients with active ankylosing spondylitis (AS), biologic therapy has been shown to be an effective treatment option. Physicians treating patients with biologic therapy may modify the treatment by adding non-biologic medications and/or escalating the dose of the biologic; however, limited data exist on how these therapy modifications are used in patients with AS receiving biologic treatment in real-world settings.
Objectives: To describe therapy modifications (adding non-biologic medications or dose escalation of the biologic therapy) in patients with active AS who newly initiated treatment with biologic therapy in the United States.
Methods: This study used US administrative pharmacy and medical claims data from the Optum Research Database. Adult patients with AS who newly initiated (no evidence of use in the 12 months prior) a biologic between January 1, 2013 and January 31, 2015, and were continuously enrolled in a commercial or Medicare Advantage health plan 12 months before (baseline period) and 15 months following the index date, defined as the date of first pharmacy fill or medical infusion, were included. To reduce confounding by patients with an early switch/discontinuation, therapy modifications were identified only in those who persisted on the index biologic for >90 days. Therapy modifications identified included initiation of add-on medications (disease-modifying antirheumatic drugs, nonsteroidal anti-inflammatory drugs [NSAIDs], opioids, corticosteroids, antidepressants, anxiolytics, sleeping aids and topical analgesics) after the first 90 days of persistence, and dose escalation of the index biologic. Dose escalation was defined as a patient receiving a dose >10% above the reference dose from the product label for ≥90 days.
Results: Of the 333 patients with AS included who persisted on their index biologic for >90 days, 88.3% initiated a subcutaneous tumor necrosis factor inhibitor (TNFi-SC; adalimumab, certolizumab pegol, etanercept or golimumab) as their index biologic and 11.7% initiated an intravenous TNFi (TNFi-IV; infliximab). During the 12-month baseline period, patients had a mean (standard deviation) number of claims of 3.9 (6.6) for opioids, followed by 2.5 (3.1) for NSAIDs, 1.9 (2.8) for corticosteroids and 1.8 (3.7) for antidepressants. Overall, 44.7% of patients received ≥1 additional medication during the period from 90 days after the index date to the end of persistence with the index biologic or 12-month post-index period. The most commonly added medications were corticosteroids (16.8%), opioids (12.9%), NSAIDs (10.2%) and antidepressants (7.2%) (Table 1). Overall, 7.2% of patients had a dose escalation of the index biologic (38.5% for TNFi-IV and 2.7% for TNFi-SC) in the immediate 12-month post-index period.

Table 1. Add-on medications initiated from 90 days after the index date to the end of persistence or 12 months among patients with AS

Additional Medication, n (%)	Total (N = 333)	TNFi-SC (n = 294)	TNFi-IV (n = 39)
Any medication	149 (44.7)	129 (43.9)	20 (51.3)
Corticosteroid	56 (16.8)	46 (15.6)	10 (25.6)
Opioid	43 (12.9)	39 (15.5)	4 (10.3)
NSAID	34 (10.2)	30 (10.2)	4 (10.3)
Antidepressant	24 (7.2)	22 (7.5)	2 (5.1)
Anxiolytic	23 (6.9)	18 (6.1)	5 (12.8)
csDMARD	15 (4.5)	13 (4.4)	2 (5.1)
Topical analgesic	13 (3.9)	9 (3.1)	4 (10.3)
Sleeping aid	9 (2.7)	8 (2.7)	1 (2.6)
tsDMARD	0 (0.0)	0 (0.0)	0 (0.0)

AS, ankylosing spondylitis; csDMARD, conventional synthetic disease-modifying antirheumatic drug; IV, intravenous; SC, subcutaneous; TNFi, tumor necrosis factor inhibitor; tsDMARD, targeted synthetic disease-modifying antirheumatic drug.
* TNFi-SC includes adalimumab, certolizumab, etanercept and golimumab.
† TNFi-IV includes infliximab.

Conclusions: In this descriptive, administrative claims-based study from the US, approximately 45% of patients with AS initiated an add-on medication while receiving biologic therapy. Further research is needed to better understand optimal therapy strategies for patients with AS.

THU0372 EFFECT OF TNFI VERSUS NSAID ON SPINAL RADIOGRAPHIC PROGRESSION OVER 4 YEARS IN EARLY ANKYLOSING SPONDYLITIS: RESULTS FROM TWO OBSERVATIONAL COHORTS IN SOUTH KOREA

J.W. Park[1], M.J. Kim[1], J.K. Park[1], Y.J. Lee[2], E.B. Lee[1], Y.W. Song[1], E.Y. Lee[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul; [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic Of*

Background: It is uncertain whether early suppression of inflammation by tumor necrosis factor inhibitor (TNFi) leads to a decreased radiographic progression in axial spondyloarthritis (axSpA).
Objectives: To compare the radiographic progression over 4 years in patients with early ankylosing spondylitis (AS) using TNFi versus nonsteroidal antiinflammatory drug (NSAID)
Methods: A total of 215 patients with early AS (symptom duration<10 years) were included based on the availability of radiographs at baseline and 2- and/or 4-years of follow up. Among them, 135 patients with TNFi were from SNUH-biologics cohort (TNFi group) and other 80 patients with NSAID were from control cohort in Seoul National University Bundang Hospital (NSAID group). Radiographic progression was assessed by two blinded readers using modified Stokes AS Spinal Score (mSASSS). Linear mixed model was applied to compare the radiographic progression between the two groups after adjustment for clinical factors. We also performed a sensitivity analysis after the propensity score matching in which age, smoking status, baseline CRP and baseline mSASSS were included as covariates.
Results: Patients in the TNFi group showed higher baseline BASDAI (6.7 vs. 3.1) and CRP (2.2 vs. 1.1mg/dL) as compared with those in the NSAID group. There were no differences between the two groups regarding age, gender, HLA-B27, smoking status and baseline radiographic damage. Overall, radiographic progression rate (95% CI) during the observation was 0.72 (0.57–0.87) unit/year. TNFi group showed significantly slower progression than NSAID group (β=-0.33 unit/year, p=0.042). This result was consistent after adjusting for age, smoking status, baseline CRP and presence of baseline syndesmophytes (β=-0.50 unit/year, p=0.001) (Table). In the subgroup analysis of patients without baseline syndesmophytes, TNFi group showed no radiographic progression over time whereas NSAID group did not (0.03 [-0.22–0.27] vs. 0.45 [0.20–0.71] unit/year). These results were not changed when the same analysis was performed in the post-matched population (78 TNFi group vs. 78 NSAID group).

Table 1. Radiographic progression over time in early AS patients using NSAID vs. TNFi

	Univariable analysis		Multivariable analysis[b]	
	Regression coefficient (95% CI)[a]	*p* value	Regression coefficient (95% CI)	*p* value
Age>40	0.82 (0.48–1.16)	<0.001	0.27 (-0.07–0.61)	0.124
Ever-smoker	0.31 (-0.01–0.62)	0.056	0.08 (-0.20–0.37)	0.568
Baseline CRP (mg/dL)	0.12 (0.05–0.18)	0.001	0.10 (0.04–0.16)	0.002
Baseline syndesmophytes	1.30 (1.00–1.62)	<0.001	1.14 (0.80–1.48)	<0.001
Group	-0.33 (-0.65–0.01)	0.042	-0.50 (-0.79–0.22)	0.001
NSAID group	0.93 (0.68–1.18)	<0.001	0.45 (0.18–0.71)	0.001
TNFi group	0.60 (0.40–0.79)	<0.001	-0.06 (-0.31–0.19)	0.648

[a]Regression coefficient indicates the progression of mSASSS over one year. [b] Gender, HLA-B27, baseline BASDAI and time-averaged NSAID index were not included because they did not show a significant ($p<0.1$) interaction with time in the univariable analysis.

Conclusions: In patients with early AS, TNFi led to a decreased radiographic progression as compared with NSAID treatment. This result suggests that early and durable suppression of inflammation using TNFi can have beneficial effect on the radiographic outcome of AS.

THU0373 USE OF CORTICOSTEROID HIP JOINT INJECTIONS IN SPONDYLOARTHRITIS PATIENTS UNDER TNF ALPHA INHIBITORS

K. Maatallah[1], A. Ben Ouhiba[1], I. Mahmoud[2], S. Belghali[3], W. Hamdi[1], M. Kchir[1], R. Tekaya[2], L. Abdelmoula[2]. *[1]Department of Rheumatology, M.T Kassab Institute; [2]Department of Rheumatology, Charles Nicolle Hospital; [3]Department of Rheumatology, Farhat Hached Hospital, Tunis, Tunisia*

Background: The hip disease is a serious complication of spondyloarthritis (SpA), engaging the functional prognosis of patients. TNF alpha inhibitors are a breakthrough for the treatment of SpA and the management of this complication.
Objectives: To assess the efficacy of TNF alpha inhibitors on hip involvement in SpA by evaluating the use of intra-articular corticosteroid infiltrations.
Methods: Observational cohort study that included 94 SpA patients with hip disease (ASAS2009). Two groups were studied. Group 1 (G1): patients under anti-TNF alpha therapy and Group 2 (G2): TNF alpha inhibitors naive patients. Clinical (BASDAI, BASFI, hip (pain/mobility), index of severity for osteoarthritis for the hip (ISH)), biological (CRP) data were assessed and the use of corticosteroid hip joint infiltration was compared. Evaluations were performed and compared between the 2 groups at baseline (T0), two years (T2) and Tn (greater than or equal to 3 years). The correlation study was made by Pearson test. A correlation was considered statistically significant if $p<0.05$.
Results: Group 1 and 2 included 48 and 46 patients respectively. The socio demographic and clinical characteristics of the disease were comparable between the two groups. Biological and radiological assessments of the two groups were comparable at T0. Group 1 had however a more active disease and a greater functional impairment. NSAIDs were prescribed in 40% of patients in G1 and 86% in G2 ($p<0.0001$). DMARDS were prescribed in 20 patients in G1 and in 22 patients in G2 ($p=0.6$). In G1 patients received infliximab, adalimumab and etanercept in 48%, 15% and 37% of cases respectively. Four patients of G1 and three of G2 patients received intra-articular corticosteroid infiltration in the year prior to the initial assessment ($p=0.7$). Assessment at T2 showed a greater improvement in clinical and biological parameters of the disease in group 1 than in group 2 with Δ (T2-T0) significantly lower in group 1 for the BASDAI ($p<0.0001$), the BASFI ($p<0.0001$) and the ISH ($p=0.017$). The number of painful hip was significantly lower in group 1 ($p<0.0001$). The evaluation at Tn showed a sustained clinical and biological efficacy of TNF alpha inhibitors in Group 1. The use of corticosteroid injections was significantly higher in group 2. Table 1 summarizes the assessment of different parameters at T2 and Tn.
Conclusions: Hip involvement is a marker of severity of spondyloarthritis. Anti-TNF alpha treatment is effective on hip disease. It reduces the use of intra articular injections of corticosteroids.

THU0374 LONG-TERM EFFECTS OF TNF-ALPHA INHIBITORS ON BONE MINERAL DENSITY AND THE INCIDENCE OF VERTEBRAL FRACTURES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

K. Beek[1], M. van der Weijden[1], W. Lems[1], C. van Denderen[2], M. Nurmohamed[1], I. van der Horst-Bruinsma[1]. *[1]Rheumatology, Amsterdam Rheumatology immunology Centre/VUmc and Reade; [2]Rheumatology, Amsterdam Rheumatology immunology Centre/Reade, Amsterdam, Netherlands*

Background: Ankylosing Spondylitis (AS) is not only characterized by pathological bone formation leading to ankylosis, but also by bone loss which may lead to vertebral fractures (VFx). TNF-alpha inhibitors (TNFi) have proven to be effective in blocking the inflammation process. A few studies also showed an increase of Bone Mineral Density (BMD) in AS patients treated with TNFi [1–3] but the incidence of VFx after two years of treatment was increased.[3–4]
Objectives: To evaluate the long-term effect of TNFi on BMD and the incidence of VFx in patients with AS.
Methods: Consecutive TNFi naive patients diagnosed with AS according to the Modified New York criteria were included. Patients were recruited from the VUmc and the Amsterdam Outpatient clinic Reade and were treated with TNFi for 4 years. BMD at hip and lumbar spine (LS) were measured at baseline, after 2 and 4 years. T-scores were categorized as "normal BMD", "osteopenia" and "osteoporosis", based on the WHO osteoporosis criteria.[5] The incidence of VFx was determined by two observers using the Genant method.[6]
Results: In total, 70 AS patients with complete datasets (67.1% male) were included. The mean age was 41.6 years and the disease duration (time since diagnosis) was 9.8 years. At baseline 42% of the patients had a decreased BMD of the hip and 34% of the spine, of whom 19 patients (27%) had both a decreased hip BMD as well as a decreased lumbar BMD. The BMD of spine and hip improved after 2 and 4 years of TNFi treatment (Table 1). In 7 patients (10%), 8 VFx were observed both at baseline and after 2 years. After 4 years of TNFi-treatment 11 VFx were observed in 9 patients.
After 4 years, 2 out of 9 patients with ≥1 VFx had a decreased BMD at hip and lumbar spine whereas the other 7 patients had a normal BMD. The majority of VFx was localized in the mid or lower thoracic spine.

Table 1, BMD measurement in spine and hip of 70 AS patients treated with TNFi

	Baseline	After 2 years of TNFi	After 4 years of TNFi
Osteopenia LS*	23 (32.9)	19 (27.1)	21 (30.0)
Osteoporosis LS	6 (8.6)	3 (4.3)	2 (2.9)
Abnormal BMD LS	29 (41.5)	21 (31.4)	23 (32.9)
Osteopenia total hip	22 (31.4)	19 (27.1)	16 (22.9)
Osteoporosis total hip	2 (2.9)	2 (2.9)	3 (4.3)
Abnormal BMD total hip**	24 (34.3)	21 (30.0)	19 (27.2)
Patients with VFx	7 (10.0)	7 (10.0)	9 (12.9)
Total number of VFx	8	8	11

*Lumbar Spine; **N=68, because 2 patients had a total hip replacement. Abnormal BMD = osteopenia and/or osteoporosis according to WHO guideline[6]. Vertebral fractures (VFx) are presented in number of patients with a VFx and the actual prevalence of VFx. Outcomes are presented in n (%).

Conclusions: The percentage of relatively young AS patients with a decreased BMD at baseline of the hip and lumbar spine was high (34–41%). After 4 years of TNFi-treatment the BMD of the lumbar spine improved in 8.6% of the patients and of the hip in 7.2% of the patients. At baseline, several vertebral fractures were found and a few additional vertebral fractures were observed after 4 years of treatment.

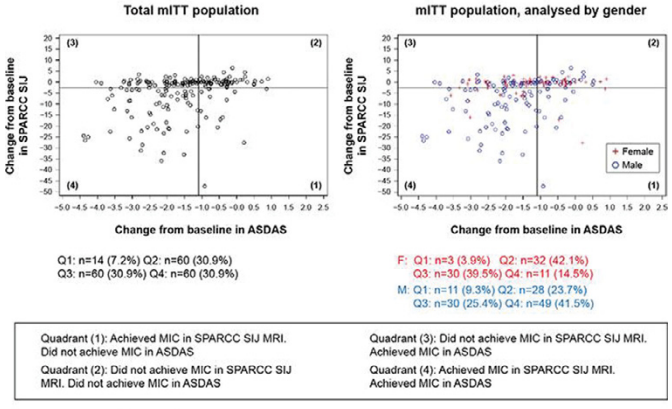
THU0375 CHARACTERISTICS ASSOCIATED WITH IMPROVEMENTS IN SPARCC SIJ AND ASDAS SCORES IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS TREATED WITH ETANERCEPT

K. de Vlam[1], A. Burden[2], M.A. Dilleen[3], C. Boone[4]. *[1]Katholieke Universiteit, Leuven, Belgium; [2]Quanticate, Hitchin; [3]Pfizer, Sandwich, United Kingdom; [4]Pfizer, SA/NV, Medical Department, Brussels, Belgium*

Background: The EMBARK trial of etanercept (ETN) (NCT01258738)[1] has demonstrated the long-term efficacy of ETN in patients with non-radiographic axial spondyloarthritis (nr-axSpA) and shown correlations between decreased inflammation and clinical outcomes.[2]
Objectives: To determine which baseline (BL) characteristics are associated with clinical improvements after 48 weeks of treatment with ETN in patients with nr-axSpA.
Methods: This post hoc analysis was performed on data from patients with nr-axSpA enrolled in the 92-week open-label phase of the EMBARK trial. The primary analysis population was the EMBARK modified intent-to-treat (mITT) population (patients who had ≥1 dose of ETN, had ≥1 on-therapy evaluation, and met the Assessment in Ankylosing Spondylitis classification criteria for axSpA). Patients' SpondyloArthritis Research Consortium of Canada (SPARCC) sacroiliac joint (SIJ) scores and Ankylosing Spondylitis Disease Activity Scores (ASDAS) were recorded, and patients were divided into 4 quadrants (Q1–4) based on the minimally important change (MIC) for each instrument (SPARCC SIJ score, change from BL [cfb] of ≥2.5; ASDAS, cfb ≥1.1). Patients in Q1 achieved MIC in SPARCC SIJ but did not achieve MIC in ASDAS. Q2 did not achieve MIC in SPARCC SIJ and did not achieve MIC in ASDAS. Q3 did not achieve MIC in SPARCC SIJ but achieved MIC in ASDAS. Q4 achieved MIC in SPARCC SIJ and achieved MIC in ASDAS. Missing data were imputed using last observation carried forward. *P*-values were obtained using the Chi-squared test (categorical variables) and the Kruskal-Wallis test (continuous variables) in order to compare BL characteristics across improvement status. Multivariable



Abstract THU0373 – Table 1. Comparison of Clinical and biological variations between the 2groups at T2 and Tn

	T2/T0			Tn/T0		
	G1	G2	p	G1	G2	p
ΔISH	-7,7 [-19, 2]	-1,6 [-19, 8]	**0,01**	-9,3 [-20, 2]	0,1 [-4, 4]	**0,005**
ΔBASFI	-2,7 [-9, 7]	1,1 [-1, 4]	**<0,0001**	-3,2 [-9, 1]	0,2 [-3, 6]	**<0,0001**
ΔBASDAI	-3 [-8, 3]	0,4 [-3, 5]	**<0,0001**	-3,4 [-9, 2]	-0,9 [-6, 4]	**0,001**
Hip pain (%)	35	75	**<0,0001**	20	67	**<0,0001**
Limitation of hip mobility (%)	71	83	0,2	50	86	**<0,0001**
ΔCRP (mg/l)	-33,6 [-132,69]	-6,1 [-72,18]	0,3	-25,5 [-89, 6]	-1 [-99,58]	**0,04**
Corticosteroids hip joint injections (n)	1	3	0,2	0	4	**0,04**

multinomial logistic regression modelling was used to calculate which BL characteristics were associated with clinical improvements when adjusted for all other BL characteristics.

Results: At screening, male patients had significantly higher median SPARCC SIJ scores compared with female patients (4.83 [range 0.0–48.0] vs 1.5 [0.0–32.0], $P<0.0001$). At wk48, 69.1% of 194 patients achieved MIC in either SPARCC SIJ scores, ASDAS or both (Q1/3/4, Figure). There was a statistically significant difference in the number of male versus female patients who achieved MIC in both scores (Q4), compared with patients who achieved MIC in only one or neither (Q1–3, Figure) ($P<0.0001$). However, multinomial logistic regression modelling showed that age ($P=0.0358$), BL ASDAS ($P<0.0001$), and screening SPARCC Spine ($P=0.0358$) and SPARCC SIJ ($P<0.0001$) scores, not gender, were significantly associated with achievement of MIC in both SPARCC SIJ and ASDAS at wk48 for the total population (after adjustment for the effects of other variables).

Figure: Numbers of Patients who Did or Did Not Achieve MIC in SPARCC SIJ Score (≥2.5 cfb) or ASDAS (≥1.1 cfb)

ASDAS, Ankylosing Spondylitis Disease Activity Scores; cfb, change from baseline; MIC, minimally important change; mITT, modified intent-to-treat; SIJ, sacroiliac joint; SPARCC, SpondyloArthritis Research Consortium of Canada.

Conclusions: Although BL summaries showed a significant difference in gender across quadrants, the BL SPARCC SIJ score was strongly correlated with gender (male patients had more inflammation). When both were included in a multivariable model, gender was non-significant. Only age, BL ASDAS, and screening SPARCC SIJ and Spine scores were associated with MIC after 48 weeks of etanercept treatment.

THU0376 REAL-WORLD USE OF SECUKINUMAB WITH AND WITHOUT A LOADING REGIMEN AMONG PATIENTS WITH ANKYLOSING SPONDYLITIS IN THE UNITED STATES: PATIENT PROFILE AND DOSING

K. Oelke[1], G. Chun[2], Y. Li[2], X. Liu[3], Y. Park[2]. *[1]Rheumatic Disease Center, Glendale; [2]Novartis Pharmaceuticals Corporation, East Hanover; [3]KMK Consulting, Inc, Morristown, United States*

Background: Secukinumab is a fully human anti–interleukin-17 monoclonal antibody approved for the treatment of patients with moderate to severe plaque psoriasis, psoriatic arthritis and ankylosing spondylitis (AS), and may be administered with or without a loading regimen of 150 mg at weeks 0, 1, 2, 3 and 4 followed by maintenance dosing every 4 weeks. The dosing pattern of secukinumab in a real-world setting of patients with AS has not been evaluated since its approval in the United States on January 15, 2016.

Objectives: To describe the demographic, clinical and treatment characteristics (loading, dose) of patients with AS who were treated with secukinumab in routine clinical practice in the United States.

Methods: Retrospective data from the Symphony Health Solutions Lx commercial claims database were used to identify AS patients who had ≥1 secukinumab treatment between January 15, 2016 and June 30, 2016. Patients eligible for inclusion were ≥18 years of age who had the diagnosis of AS and ≥1 pharmacy or medical claim in the 12 months prior to their first secukinumab treatment (index date). Patient demographics and secukinumab dosage were examined at the index date. Clinical characteristics, comorbidities and treatment history in the 12 months prior to the index date were identified and presented by use versus no use of a loading regimen of secukinumab.

Results: A total of 152 patients who initiated secukinumab were included in this study; the mean (SD) age of included patients was 45.3 (11.1) years and 53.9% were female. Of the 152 patients, 119 patients (78.3%) received a loading regimen and 33 (21.7%) did not. Patient demographics, clinical characteristics and treatment history were not significantly different between the two cohorts (Table 1). The majority of patients (65.5%) with loading initiated secukinumab with the 150-mg dose, whereas the majority of patients (60.6%) without loading initiated with the 300-mg dose. More than half of the patients in each cohort received a biologic therapy during the 12-month baseline period (loading, 65.5%; no loading, 51.5%). Other prior treatments included oral corticosteroids (30.3% for both), conventional synthetic disease-modifying antirheumatic drugs (DMARDs) (loading, 31.9%; no loading, 21.2%) and targeted synthetic DMARDs (loading, 4.2%; no loading, 12.1%). The prevalence of comorbidities was similar between the two cohorts, with the most prevalent comorbidities being hypertension (19.1%), rheumatoid arthritis (19.1%) and other skin diseases (18.4%).

Table 1. Demographics, clinical characteristics and treatment history of patients with AS treated with secukinumab with or without a loading dose of 150 mg

	Overall (n = 152)	Loading (n = 119)	No Loading (n = 33)
Age, mean (SD), years	45.3 (11.1)	46.0 (10.8)	42.6 (11.9)

Diabetes	10 (6.6)	9 (7.6)	1 (3.0)
Anxiety	8 (5.3)	6 (5.0)	2 (6.1)
Obesity	6 (3.9)	4 (3.4)	2 (6.1)

AS, ankylosing spondylitis; csDMARD, conventional synthetic disease-modifying antirheumatic drug; NSAID, nonsteroidal anti-inflammatory drug; tsDMARD, targeted synthetic disease-modifying antirheumatic drug.

Conclusions: In this retrospective, administrative claims-based study, the majority of patients with AS initiated secukinumab treatment with a loading regimen. Although only the 150-mg dose of secukinumab is approved for the treatment of AS, almost 40% of patients received the 300-mg dose, indicating a need to better understand patient and treatment characteristics for secukinumab in patients with AS. The results of this study provide early insights into real-world use of secukinumab with and without a loading regimen in patients with AS in the United States.

THU0377 LOW DOSE IL-2 THERAPY CAN RECOVERY TH17/TREG CELL BALANCE IN PATIENTS WITH SPONDYLOARTHROPATHY THROUGH INCREASING REGULATORY T CELLS NUMBERS

F. Jinnan[1], X. Dan[1], C. Qianqian[1], Q. Kaili[1], G. Chong[2], L. Xiaofeng[1]. *[1]Department of Rheumatology, The Second Hospital of Shanxi medical University, Taiyuan, China; [2]Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, American Samoa*

Background: The imbalance in the number of Th17 and Treg cells is suggested to be associated with the pathogenesis of SpA. Recent studies have shown that interleukin-23 (IL-23) and Th17 play a crucial role in the pathogenesis of SpA. However the status of CD4+CD25+Foxp3+Treg cells which exert immunoregulatory functions are remains to investigate.

Objectives: To explore the status of the immunologic balance between Th17 cells and Treg cells in patients with SPA, and to assess the effect of low dose IL-2 on the peripheral CD4+ T cells.
Methods: Two hundred and two patients, who met the Assessment of Spondyloarthritis International Society (ASAS) criteria were enrolled and given conventional therapy, including Nonsteroidal Anti-inflammatory Drugs (NSAIDs), biological agents, Sulfasalazine, glucocorticoid. Eighty seven patients were not only given conventional therapy, but also injected subcutaneously low-dose IL-2 (50 WIU/day for 5 days). Clinical and laboratory indicators were compared before and after IL-2 treatment. The $CD4^+$ T cells in peripheral blood were measured by multicolor flow cytometry. The side effects were observed in the course of therapy.
Results: The absolute number and ratio of CD4 + CD25 + FOXp3 + regulatory T cells in peripheral blood of patients with SPA was significantly decreased compared with the healthy control group, (25.13 (18.76,37.37) vs. 33.06 (22.87,42.33), $P<0.001$); Th17/Treg (0.29 (0.18, 0.49) vs. 0.20 (0.15, 0.34), P=0.001). The absolute number of Treg cells increased more than 3-times (22.70 (14.47, 30.10) vs.67.87 (48.21, 105.82), $p<0.001$) after 5 days of low-dose IL-2 treatment. Th17/Treg was significantly higher (0.32 (0.18, 0.57) vs. 0.20 (0.15, 0.34), $P<0.001$) before treatment compared with healthy controls.
Conclusions: The decrease of CD4 + CD25 + FOXp3 + Treg cells might play a key role in the pathogenesis of SpA. Low dose IL-2 therapy can restore and maintain the balance of Th17 and Treg cells by increasing Treg cells numbers selectivity. The therapy is safe. More attention should be paid on the long term benefits of low-dose IL-2 therapy in the further research.

THU0378 IMPACT OF THE ADALIMUMAB PATIENT SUPPORT PROGRAM ON CLINICAL OUTCOMES IN ANKYLOSING SPONDYLITIS: RESULTS FROM THE COMPANION STUDY

L. Bessette[1], C. Thorne[2], B. Millson[3], K. Charland[3], K. Donepudi[3], T. Gaetano[4], V. Remple[4], M. Latour[4], M.-C. Laliberté[4]. *[1]Department of Medicine, Laval University, Quebec City; [2]Southlake Regional Health Centre, Newmarket; [3]QuintilesIMS, Kirkland; [4]AbbVie Corporation, St. Laurent, Canada*

Background: Adalimumab (ADL) is a TNF-alpha inhibitor indicated for various inflammatory autoimmune diseases including ankylosing spondylitis (AS). Patients receiving ADL in Canada are eligible to enroll in the AbbVie Care patient support program (PSP) which provides them with personalized services including ongoing care coach calls (CCC). In a previous study, rheumatology patients enrolled in Abbvie Care receiving CCC demonstrated significantly greater persistence and adherence to ADL than patients that did not receive CCC (no-CCC).
Objectives: The objective of this study was to examine if ADL patients receiving CCC through the ADL PSP had an increased likelihood of achieving controlled disease state as determined by a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score <4 compared to those not receiving CCC.
Methods: A longitudinal analysis using de-identified aggregate-level data collected through the AbbVie Care PSP was performed. Probabilistic matching was used to link patient-level records from the ADL PSP database to records from the QuintilesIMS longitudinal prescription transactions database (LRx). Patients were indexed on the date of their first ADL transaction between January 2010 and October 2015. The ADL PSP database included patient measurements of the BASDAI, a measure of disease activity. To be eligible, patients had to have a baseline BASDAI measurement between 90 days before and 30 days after their index date and have had a follow-up BASDAI measurement 6 to 18 months later. Only patients that were confirmed to be persistent on ADL as confirmed through the LRx records were included in the comparison. Controlled disease (BASDAI <4) at the time of the follow-up BASDAI assessment was compared in patients having received CCC and patients without CCC. Robust Poisson regression was used to estimate the adjusted relative risk (RR) of controlled disease. Analyses were adjusted for patient age group, sex, region, prior biologic use, days lapsed between BASDAI assessments, and baseline disease control status category.
Results: A total of 249 AS patients met eligibility criteria and 123 (49%) of these had received CCC. Of the 249 patients, 184 (74%) had controlled disease (BASDAI <4) at the follow-up assessment, 98 (80%) in the CCC group and 86 (68%) in the no CCC group. In the multivariable regression analysis, there was a 23% increased likelihood of achieving controlled disease in the CCC group relative to the group without CCC (RR=1.23, 95% confidence interval: 1.06–1.42; p-value =0.0055).
Conclusions: AS patients receiving tailored services through the ADL PSP in the form of care coach calls have an increased likelihood of achieving controlled disease within 6 to 18 months. These results may help refine interventions aiming at improving clinical outcomes in AS patients.

THU0379 IMPACT OF TIME SINCE DIAGNOSIS, AGE, AND NUMBER OF PRIOR NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON 52-WEEK CLINICAL RESPONSE TO ADALIMUMAB IN PATIENTS WITH ANKYLOSING SPONDYLITIS

J. Sieper[1], A. Deodhar[2], M. Hojnik[3], Y. Zhang[4], M. Dougados[5]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Oregon Health & Science University, Portland, United States; [3]AbbVie, Ljubljana, Slovenia; [4]AbbVie Inc., N Chicago, United States; [5]René Descartes University and Hôpital Cochin, Paris, France*

Background: Ankylosing spondylitis (AS) patients (pts) were found to respond better to TNF inhibitors (TNFi) if treated early in the disease course.[1] The actual disease onset and hence disease duration is not always known. Previously, younger age was found to have the largest positive impact on clinical outcomes following 12 weeks (wks) of adalimumab (ADA) treatment.[2]
Objectives: The objective of this analysis was to examine the impact of time since diagnosis, age, and number of prior NSAIDs as surrogates for disease duration on clinical outcomes in AS pts from ATLAS trial treated with ADA for 52 wks.
Methods: ATLAS[3,4] was a phase 3 randomized double-blind placebo (PBO)-controlled trial evaluating the safety and efficacy of originator ADA in pts with active AS who failed NSAID therapy. In this post hoc analysis, pts who received at least one dose of ADA during the PBO-controlled period or open label extension and received prior NSAID(s) at baseline (BL) were categorized by BL: (1) time since diagnosis (<2 vs ≥ 2; <5 vs ≥ 5; <10 vs ≥ 10 years [y]), (2) age (<35, 35–45, and >45 y), and (3) number of prior NSAIDs (≤ 2 vs >2). The effect of time since diagnosis, age, and number of prior NSAIDs on AS outcome measures following 52 wks of ADA treatment was examined.
Results: At wk 52, 274 pts had received at least one dose of ADA and had at least one prior NSAID at BL. A majority of pts were ≥ 5 y since AS diagnosis (188 [68.6%]), ≤ 45 y of age (163 [59.5%]), HLA-B27+ (213 [77.7%]), and had ≤ 2 prior NSAIDs (158 [57.7%]). Pts with shorter time since diagnosis were generally younger (late thirties). Across all subcategories, $>70\%$ of pts were male. The BL disease activity measures were numerically similar across most categories. Following 52 wks of ADA treatment, the proportions of pts achieving ASAS20 and ASAS40 responses were numerically higher and mean decreases in BASDAI and BASFI scores from BL larger in subcategories with shorter time since diagnosis, younger age, and fewer prior NSAIDs (Table). There were significant differences in ASAS40, BASDAI, and BASFI scores between time since diagnosis (<2 vs ≥ 2 and <5 vs ≥ 5 y) and age (<35 vs >45 y) subcategories.

Table. Clinical Responses Following 52 Weeks of ADA Exposure in Patients Categorized by Time Since Diagnosis, Age, and Prior NSAID(s).

†P-values based on comparison with <35 years.
‡Change from baseline to week 52.
NSAID = Non-Steroidal Antiinflammatory drug; ASAS = Assessment of SpondyloArthritis international Society classification criteria; BASDAI = Bath Ankylosing Spondylitis Disease Activity Index; SD = Standard Deviation; BASFI = Bath Ankylosing Spondylitis Functional Index.

Conclusions: Following 52 wks of ADA treatment, shorter time since diagnosis and younger age were associated with greater clinical responses and improvements in disease activity and functionality. Although younger age (<35 vs >45 y) had significant positive impact on the clinical outcomes similar to wk 12 results, shorter time since diagnosis (<2 vs ≥ 2 and <5 vs ≥ 5 y) was also associated with better 52-wk clinical outcomes. These results suggest that early effective treatment intervention may improve long-term clinical outcomes in AS pts.

THU0380 RESULTS OF A REAL LIFE DOSE-REDUCTION STRATEGY FOR ANTI-TNFALPHA INHIBITORS IN A COHORT OF PATIENTS WITH SPONDYLOARTHRITIS

M.C. Castro-Villegas[1,2], P. Font-Ugalde[1,2,3], M. Romero-Gomez[1,2], M. Arredondo-López[3], E.C. López-Medina[1], R. Ortega-Castro[1,2], J. Calvo-Gutierrez[1,2,3], A. Escudero-Contreras[1], E. Collantes-Estévez[1,2,3].
[1]Reina Sofía University Hospital; [2]IMIBIC; [3]Universidad de Córdoba, Cordoba, Spain

Background: Published reports suggest that patients with Spondyloartrhitis (SpA) in remission under treatment with TNFalpha inhibitors (TNFi) could obtain the same benefit at lower dose of the drug.
Objectives: To evaluate effectiveness of a strategy of dose reduction of TNFi in SpA patients in clinical remission and to explore baseline characteristics predictive of maintenance of the response.
Methods: Retrospective observational study, including patients with SpA meeting ASAS criteria treated with TNFi following a dose optimization protocol (lower doses or longer intervals than aproved), from 2008 to 2015. Criteria for optimization was patients with BASDAI≤2 and/or C reactive protein level (CRP)≤5 mg/L for at least 6 months. Patients who relapsed (BASDAI>2 and/or CRP>5mg/L) returned to standard dose. Clinical/analytical parameters and drug's survival time until relapse were recorded. SPSSv.17 software was used for contrast means. Survival Kaplan-Meyer curves was analysed.
Results: 149 SpA patients treated with TNFi, 32/149 patients (21.5%) included in optimization protocol. 27 patients (84.37%) with increased interval between doses, remaining with reduced dosification. Table 1 shows baseline characteristics of patients on optimization group (mean±SD or proportion). 18/32 patients (56.2%,IC:39.01–73.4) maintained clinical remission with optimized dose at 36.5 months (median). Table 2 shows activity parametres of both relapsed and maintained response patients. There were either baseline differences or at optimization time between patients who maintained remission and not, but relapsed patients showed higher CRP at optimization time, without statistically significant differences. 72.2% (13/18) of patients on sutained remission were naive for TNFi, although no significant difference compared to switcher patients on the median survival (31.9 vs 20.9 months, P=0.9). No baseline predictor of sustained response at optimized dose were found. CRP<5 mg/L at optimization time showed a trend towards longer survival (43.4 vs 13.3 months), without differences statistically significant (p=0.09).
Conclusions: Optimization of TNFi in SpA is possible and allows up to half of patients to maintain clinical remission, but no baseline factors predictors of sustained response after optimization was found.

THU0381 CERTOLIZUMAB PEGOL IS EFFECTIVE IN UVEITIS ASSOCIATED TO SPONDYLOARTHRITIS REFRACTORY TO OTHER TUMOUR NECROSIS FACTOR INHIBITORS

M.V. Hernández[1], M. Mesquida[2], V. Llorens[2], M. Sainz de la Maza[2], R. Blanco[3], V. Calvo[3], O. Maiz[4], A. Blanco[5], A. Urruticoechea[6], J.R.D.D. Jiménez de Aberásturi[7], P. Ahijado[8], E. Judez[9], P. Tejón[10], S. Peña[11], A. Adan[2], R. Sanmartí[1]. *[1]Rheumatology; [2]Ophtalmology, Hospital Clínic, Barcelona; [3]Rheumatology, Hospital Marqués de Valdecilla, Santander; [4]Rheumatology; [5]Ophtalmology, Hospital Universitario Donostia, San Sebastián; [6]Rheumatology, Hospital Can Misses, Ibiza; [7]Rheumatology, Txagorritxu Hospital, Vitoria; [8]Rheumatology, Hospital Universitario Infanta Elena, Madrid; [9]Rheumatology, Complejo Hospitalario Universitario de Albacete, Albacete; [10]Rheumatology; [11]Ophtalmology, Hospital Universitario General de Castellón, Castellón, Spain*

Background: Uveitis is one of the most common extra-articular manifestations of patients with spondyloarthritis (SpA). In severe cases, uveitis may require the use of biological therapy, primarily tumor necrosis factors inhibitors (TNFi), being the most currently used infliximab and adalimumab. However, another TNFi such as certolizumab pegol (CZP), with indication for SpA patients, could be an effective option in cases of inefficacy or adverse events to other TNFi, as we have previously reported (1).
Objectives: Our objective is to analyze the effectiveness and the safety profile of CZP in patients with refractory SpA-associated-uveitis
Methods: Observational, multicentric, retrospective study. We selected all patients with a diagnosis of SpA (including ankylosing spondylitis (AS), psoriatic arthritis (PsA), non-radiographic axial SpA (nr-axSpA) and SpA associated to inflammatory bowel disease (IBD-SpA)) who had refractory uveitis (confirmed by an Ophthalmologist) as main extra-articular manifestation, and who received CZP for at least 6 months. Variables analyzed: age, sex, diagnosis, type of uveitis, duration since the first uveitis episode and number of eyes affected; previous treatment (NSAID, disease-modifying anti-rheumatic drugs (DMARDs), immunossuppressive or biological therapy); outcome, and time to follow-up.
Results: Twenty-four eyes of 13 patients (10 men); age 49.5±11.7 (range 29–71 years) were included in the study. Diagnosis were: seven AS, four PsA, one nr-axSpA, and one IBD-SpA. Type of uveitis: 9 anterior, 3 panuveitis, and 1 intermediate uveitis. Mean disease duration was 151±117.1 months (range 5–420). 84.6% patients had previously received biological therapy (46.1% ≥2 biological agents). 61.5% received CZP in monotherapy and 5 patients received concomitant treatment: 4 methotrexate and 1 azathioprine. In all cases CZP was started due to inefficay to previous treatment except for 2 cases whose primary reason was the occurrence of adverse events (one injection site reaction and one development of relapsing polychondritis). After a follow-up of 13.1±6.6 months (range 6–27), 9 patients are still on CZP treatment. Ten eyes showed improvement of visual acuity (41.7%), 10 remained stable and 2 worsened. During the follow-up no serious adverse events were reported. Four cases withdrew CZP treatment: 2 due to worsening of articular symptoms but with no uveitis activity; 1 due to macular edema and 1 due to uveitis activity. One patient switch to infliximab, one to golimumab, and 2 required switch to tocilizumab. In all 13 patients except 2, CZP achieved a good control of SpA activity.
Conclusions: CZP demonstrated effectiveness in patients with uveitis-associated to SpA refractory to previous TNFi treatment.

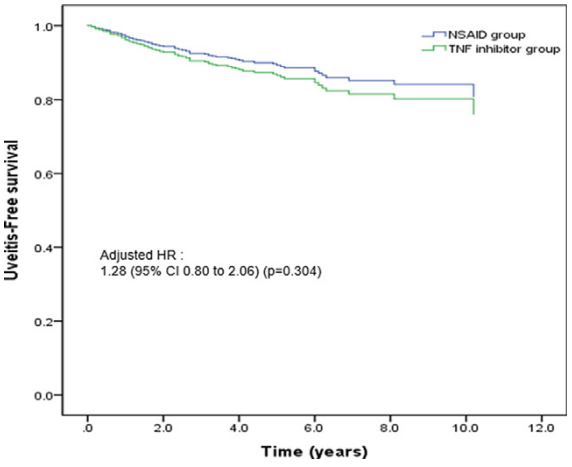
THU0382 CHANGE IN SACROILIAC JOINT STRUCTURAL RADIOGRAPHIC DAMAGE AFTER TWO YEARS OF ETANERCEPT THERAPY IN COMPARISON TO A CONTEMPORARY CONTROL COHORT IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

M. Dougados[1], W.P. Maksymowych[2], R. Landewe[3], A. Molto[1], P. Claudepierre[4], M. de Hooge[5], R.G. Lambert[2], R. Bonin[6], J.F. Bukowski[6], H. Jones[6], I. Logeart[7], R. Pedersen[6], A. Szumski[8], B. Vlahos[6], D. van der Heijde[5]. *[1]Paris Descartes University, Hôpital Cochin, Paris, France; [2]University of Alberta, Edmonton, Canada; [3]Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [4]Universite Paris Est Creteil, Creteil, France; [5]Leiden University Medical Center, Leiden, Netherlands; [6]Pfizer, Collegeville, United States; [7]Pfizer, Paris, France; [8]InVentiv Health, Princeton, United States*



Background: Despite the well-known symptomatic and anti-inflammatory effect

of TNF inhibitors in axial SpA (axSpA), demonstrating a structural effect is challenging.
Objectives: To compare 2 yrs of radiographic sacroiliac joint (SIJ) changes in pts receiving etanercept (ETN) in a clinical trial to similar pts not receiving biologics in a cohort study.
Methods: Pts had recent onset non-radiographic (nr)-axSpA fulfilling ASAS criteria. Study group: pts receiving ETN 50 mg once weekly for 2 yrs in EMBARK (NCT01258738). Control group: pts in an ongoing longitudinal cohort study not receiving biologics for 2 yrs (DESIR, NCT01648907). Outcome measure: change in x-ray SIJ score per mNY criteria (0–4 per SIJ). X-rays were read by 3 experienced readers unaware of image chronology and pt group. Primary endpoint: change (mean of 3 readers) in total SIJ score (-8 to +8). Binary endpoints: (1) shift from baseline (BL) mNY+ to wk-104 mNY- and vice versa; (2) change in SIJ score $\geq$1 (left or right SIJ); (3) change in SIJ score $\geq$1 in $\geq$1 SIJ, with change from 0 to 1 and from 1 to 0 considered no change. Treatment effect was analyzed without and with adjustment for the baseline (BL) covariates of sex, symptom duration, smoking status, HLA-B27 status, ASDAS-CRP, SPARCC MRI SIJ score, and SIJ radiography score.
Results: At BL, the control (DESIR, N=197) and ETN (EMBARK, N=164) cohorts differed significantly in all covariates listed above. The difference in change in total SIJ score for control vs ETN, adjusted for covariates, was small but significant: least-squares mean (95% CI): 0.08 (-0.03, 0.20) vs -0.14 (-0.26, -0.01); p=0.008. The table presents x-ray changes. When adjusted for covariates, the mean difference between control and ETN was significant for 2 of the 3 binary endpoints (table).
Conclusions: This analysis confirms the slow rate of radiographic SIJ progression over 2 yrs in nr-axSpA. The observed data suggest a lower rate of progression with ETN than without a TNF inhibitor.

THU0383 INCIDENCE OF UVEITIS IN NON-STEROIDAL ANTI-INFLAMMATORY DRUGS VERSUS TUMOR NECROSIS FACTOR INHIBITORS USERS AMONG PATIENTS WITH ANKYLOSING SPONDYLITIS: A RETROSPECTIVE COHORT STUDY

M.J. Kim, E.E. Lee, E.Y. Lee, Y.W. Song, E.B. Lee. *Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of*

Background: Uveitis associated with ankylosing spondylitis (AS) often recurs and may lead to ocular complications. It remains to be known whether non-steroidal anti-inflammatory drugs (NSAIDs) or TNF inhibitors (TNFi) is more effective in reducing the recurrence of uveitis in patients with AS.
Objectives: To evaluate the effect of NSAIDs and TNFi on preventing recurrence of uveitis in patients with AS.
Methods: This retrospective cohort study included 1061 patients diagnosed with AS at Seoul National University Hospital between January 2004 and December 2015. Patients' clinical factors and laboratory findings were collected from the patients' electric medical records. Patients were divided into those who were treated with NSAIDs (n=623) or TNFi (n=438) which included etanercept, adalimumab, infliximab and golimumab. The incidence rates of new-onset uveitis during each treatment was compared using Cox proportional hazard model after adjusting age, sex, disease duration, history of uveitis, smoking status, ESR, CRP, and HLA-B27. Propensity-score matched comparison was also performed as sensitivity analysis (n=168 in the TNFi group and n=168 in the NSAID group).
Results: Among the 1061 patients, those in the TNFi group had longer disease duration (11.75±7.14 vs 6.22±4.42 years), higher ESR, CRP level (40.97±33.87 vs 23.32±22.09 mm/h, 2.69±3.41 vs 1.12±1.93 mg/L, respectively) and higher proportion of patients who had previous history of uveitis before the treatment (22.4 vs 15.4%). The incidence rates of uveitis were 3.60 (95% CI 2.97 to 4.42) per 100 person-year in the NSAID group and 6.03 (95% CI 5.15 to 7.04) per 100 person-year in the TNFi group. The adjusted hazard ratio for the new-onset uveitis during the treatment in the TNFi group versus the NSAID group was 1.28 (95% CI 0.80 to 2.06) (p=0.304). When compared with NSAID group, etanercept group showed higher incidence of uveitis than the other TNFi: etanercept (HR 1.96 [1.41 to 2.74]), adalimumab (HR 0.65 [0.40 to 1.05]), infliximab (HR 0.50 [0.22 to 1.14]) and golimumab (HR 0.79 [0.25 to 2.50]). The propensity score-matched population was also consistent with the crude comparison between NSAID group and TNFi group (HR 1.29 [0.73 to 2.28]) (p=0.388).

Conclusions: The effect of TNFi on reducing the incidence of uveitis is comparable to NSAIDs in patients with AS. Uveitis occurred more commonly with treatment with etanercept compared with the other treatments.

THU0384 THE EFFECT AND SAFETY OF YISAIPU (YISAIPU) IN THE TREATMENT OF PATIENTS WITH NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN CHINA

M. Zhao[1], G. Shi[2], Y. Tao[3], X. Wang[4], S. Cao[1], Z. Lin[1], Z. Liao[1], Q. Kong[4], J. Gu[1]. *[1]Rheumatology department, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou; [2]Rheumatology department, The First Affiliated Hospital of Xiamen University, Xiamen; [3]Rheumatology department, The Second Affiliated Hospital of Guangzhou Medical University; [4]Radiology department, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease, which includes AS and nr-axSpA. Anti-TNF-α agents, such as Yisaipu (Yisaipu) are frequently used in nr-axSpA patients in China, but the related data is limited.
Objectives: The aim of this research is to assess the efficacy and safety of Yisaipu in the treatment of patients with nr-axSpA in China.
Methods: The inclusion of study population consisted of 150 patients who met the ASAS criteria for axial SpA but not the modified New York radiographic criteria for AS, had a score of $\geq$4 on the BASDAI or a score of $\geq$2.1 on the ASDAS-CRP and had been treated unsuccessfully with $\geq$1 NSAIDs for 4-week. Patients were assigned to receive Yisaipu (made in China) 50 mg/week and continued background NSAID treatment for 24 weeks (open-label study). At week 24, the

primary efficacy end point was the improvement of ASDAS-CRP. Secondary end points included ASAS 20, ASAS 40, ASAS 5/6, ASAS partial remission and BASDAI. Safety was evaluated during scheduled visits.

Results: 123 patients with active nr-axSpA were enrolled between April 19, 2014, and July 10, 2015. The mean age of the 123 nr-SpA patients was (25.3±5.9) years. The ASDAS-CRP and BASDAI decrease from 2.7±0.9 to 0.7±0.4, from 4.5±1.5 to 0.9±0.8, respectively between weeks 0 and 24. The patients achieved the ASDAS-CRP<2.1 was 96.7%. ASDAS-CRP major and important improvement were achieved by 41.4%, 79.8%, respectively at weeks 24. ASAS 20, ASAS 40, ASAS5/6 and ASAS partial remission were achieved by 75.0%, 54.8%, 64.5%, 89.3%, respectively at weeks 24. Yisaipu-treatment was associated with statistically significant improvements in all parameters, including BASFI, BASMI, PGA, PhGA, ESR and CRP concentrations. Most adverse events in the open-label phase were mild or moderate in severity.

Conclusions: Yisaipu was effective and well-tolerated during the 24-week study period and was associated with a significant improvement in the signs and symptoms of active nr-axSpA.

THU0385 ASSESSMENT OF RELATIONSHIP BETWEEN BELIEFS' ABOUT MEDICINES AND TREATMENT ADHERENCE IN ANKYLOSING SPONDYLITIS PATIENTS

M. Cinar[1], F.I. Cinar[2], E. Tekgoz[1], R. Horne[3], S. Yilmaz[1]. *[1]Department of Internal Medicine, Division of Rheumatology, University of Health Sciences, Gulhane Medical Faculty; [2]Gulhane School of Nursing, University of Health Sciences, Ankara, Turkey; [3]UCL School of Pharmacy, Centre for Behavioural Medicine, University College, London, United Kingdom*

Background: Ankylosing spondylitis (AS) is a chronic disease requiring long-term treatment. Patients' beliefs about medicines and treatment may affect their treatment adherence and treatment success.

Objectives: In this study, we aimed to investigate the relationship between beliefs about medicines and treatment adherence in AS patients.

Methods: This cross-sectional study was conducted in a single tertiary rheumatology clinic. One hundred and fifty three AS patients were enrolled to the study. Socio-demographic and medical characteristics of the patients were recorded to a patient interview form. In order to evaluate the general and personal views of the patients about drugs, the Turkish Translation of the Beliefs about Medicines Questionnaire (BMQ-T) (Cinar et al in 2016) was used. According to this survey, the beliefs about medicines are composed of the following sections: Specific Necessity, Specific Concerns, General Overuse and General Harm. Medication adherence was assessed by using the Morisky Green Levine Medication Adherence Scale (MGLS) (1986). Adherence was measured on a scale of 0 to 4, in which higher scores represent lower medication adherence and vice versa. Patients who reported a score of 0 on the MGLS were classified as adherent. All other patients were classified as nonadherent. Categorical variables were compared with Chi-square test, while continuous variables were compared with independent samples t test. To evaluate potential risk factors for non adherence, logistic regression method was used.

Results: The mean age of the patients was 35.15±8.19 years. The mean time from first symptom (disease duration) was 10.0±6.1 years. The vast majority of the patients (n=145; 94.8%) were male. One hundred patients (65.4%) were using NSAIDs and 83 patients (54.2%) were using anti-TNF. According to the MGLS scores, 56 (36.6%) patients were compatible with treatment, and 97 patients (63.4%) were found to be incompatible with the treatment. As the BMQ-T-Specific Necessity scores increased, drug compliance was also increased (p=0.006), on the other hand, as the BMQ-T-Specific Concerns, BMQ-T-General Overuse and BMQ-T-General Harm scores increased, drug compliance was decreased (p=0.023, 0.002, <0.001, respectively). There were significant positive correlations between Specific Concerns (p=0.002), General Overuse (p=0.031) and General Harm (p=0.024) score levels with the increase in patients' BASDAI score. While there was significant correlation between the disease duration and the General Overuse scores in the negative direction (p=0.016), there was significant correlation between the disease duration and the Specific Necessity scores in the positive direction (p=0.002). As 1 unit increase in the BMQ-T-Specific Necessity score decreased the risk of treatment nonadherence by 0.38 fold, on the other hand, 1 unit increase in the BMQ-T-General Harm score raised the risk to 3.21.

Conclusions: In our study, the belief of AS patients about the necessity of treatment they were using, found to increase treatment adherence, while harm potential of the treatment was decreasing the adherence. In other words, to enhance the treatment adherence of AS patients, it is essential to convince the patients about the necessity of treatment and relieve the anxiety they carry about potential adverse effects.

THU0386 USE OF BIOLOGICS AND NSAIDS IN TREATING PATIENTS WITH AXIAL SPONDYLOARTHRITIS IN THE US-BASED CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS (PSA/SPA) REGISTRY

P.J. Mease[1], D. van der Heijde[2], C. Karki[3], M. Liu[3], R. Pandurengan[3], Y. Park[4], J.D. Greenberg[3,5]. *[1]Seattle Rheumatology Associates, Seattle, WA, United States; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Corrona, LLC, Southborough, MA; [4]Novartis, East Hanover, NJ; [5]New York University School of Medicine, New York, NY, United States*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease affecting the sacroiliac joints and spine. Treatment primarily consists of first-line nonsteroidal anti-inflammatory drugs (NSAIDs) and/or biologic therapy when disease activity persists despite NSAID therapy. Although many studies have evaluated the efficacy of these treatments, there are few studies that have characterized NSAIDs and/or biologic therapy among patients with axSpA in the United States.

Objectives: To characterize patients with axSpA treated with NSAIDs only, biologics only, or both NSAIDs and biologics at the time of enrollment in the US-based Corrona PsA/SpA Registry.

Methods: This study included all patients with axSpA diagnosed by the rheumatologist aged ≥18 years enrolled in the Corrona Registry between March 2013 and September 2016 who were treated with NSAIDs only, biologics only, or both NSAIDs and biologics at the time of enrollment (baseline). Patients fulfilled the Assessment of SpondyloArthritis international Society classification criteria.[1] Demographics, clinical characteristics, disease activity measures and treatment history were collected at enrollment and described for each group.

Results: As of September 2016, 359 patients with axSpA met the study inclusion criteria; at baseline, 224 patients (62.4%) were receiving NSAIDs (92 [25.6%] with NSAIDs only and 132 [36.8%] with both NSAIDs and biologics) and 135 patients (37.6%) were receiving biologics only. Baseline characteristics were similar across all treatment subgroups with regards to age, race and body mass index. Fewer females were treated with biologics (with/without NSAIDs) compared to the NSAIDs only group. At baseline, patients treated with NSAIDs or both NSAIDs and biologics were older, had longer duration of disease with worse disease activity (measured by ASDAS and BASDAI), functional impairment (BASFI and HAQ-DI) and had worse pain and fatigue compared to those treated with biologics only (Table 1). 88–96% of patients receiving biologics (with or without NSAIDs) had prior biologic use compared to only 25% of NSAIDs only group. Patients treated with biologics only reported decreased percentage of impairment while working, overall work impairment and activity impairment at baseline compared with patients treated with NSAIDs only and both NSAIDs and biologics.

Table 1. Baseline clinical and patient-reported characteristics of patients with axSpA in the Corrona PsA/SpA Registry stratified by NSAID and biologic use

Characteristics*	NSAIDs Only (n = 92)	Biologics Only (n = 135)	NSAIDs and Biologics (n = 132)
Age, years	48.6 (15.0)	46.1 (13.6)	48.1 (13.2)
White, n (%)	81 (91.0)	120 (93.0)	118 (92.9)
Male, n (%)	53 (58.9)	88 (65.7)	91 (70.5)
BMI, kg/m^2	29.4 (6.1)	29.7 (7.1)	28.7 (6.1)
Disease duration, years	18.3 (13.0)	16.1 (12.7)	19.2 (11.5)
History of prior csDMARD use, n (%)	23 (25.0)	55 (40.7)	47 (35.6)
History of prior biologic use, n (%)	24 (26.1)	130 (96.3)	117 (88.6)
ASDAS-CRP	2.1 (0.7)	1.9 (0.8)	2.1 (0.9)
BASDAI (0-10)	4.4 (2.5)	3.7 (2.5)	4.4 (2.6)
BASFI (0-10)	3.7 (2.9)	3.1 (2.8)	3.5 (2.9)
Patient pain (VAS 0-100)	49.9 (29.5)	37.3 (28.7)	44.4 (30.5)
Patient-reported fatigue (VAS 0-100)	47.1 (29.4)	45.7 (28.6)	49.9 (30.7)
Morning stiffness, n (%)	88 (95.7)	114 (84.4)	117 (88.6)

Absenteeism (% Work time missed)	5.3 (17.8)	5.5 (15.5)	7.5 (18.6)
Presenteeism (% Impairment while working)	28.7 (28.0)	21.7 (24.3)	29.4 (26.2)
Work Productivity (% Overall work impairment)	26.1 (26.4)	22.8 (25.7)	32.5 (37.7)
Activity Impairment (% Activity impairment)	41.0 (29.9)	31.4 (30.7)	39.8 (31.6)

ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score using C-reactive protein; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BMI, body mass index; HAQ, Health Assessment Questionnaire; VAS, visual analog scale; WPAI, Work Productivity and Activity Impairment questionnaire: general health.

* All values are presented as "mean (SD)" unless otherwise stated. Current NSAID use included acetylsalicylic acid, celecoxib, diclofenac, ibuprofen, meloxicam, naproxen and others. Current biologic use included abatacept, adalimumab, anakinra, apremilast, certolizumab pegol, etanercept, golimumab, infliximab, rituximab, secukinumab, tocilizumab and ustekinumab.

Conclusions: About two-thirds of patients with axSpA were treated with NSAIDs (with or without biologics) and about three-fourths of patients were treated with biologics (with or without NSAIDs) at enrollment. Patients that were already treated with biologics without NSAIDs at enrollment showed better measures of disease activity and PROs compared with the other treatment groups. Future research will assess changes in clinical and disease characteristics over time by treatment subgroup.

THU0387 THE CLINICAL IMPORTANCE OF THE THYROID NODULES DURING TUMOR NECROSIS FACTOR-ALPHA INHIBITOR THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

R. Terlemez[1], K. Akgün[2], D. Palamar[2], H. Sarı[2]. *[1]Physical medicine and rehabilitation, Şişli Hamidiye Etfal Research and Training Hospital; [2]Physical medicine and rehabilitation, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey*

Background: TNF is a pivotal regulator of inflammation and the cytokine system. Besides this, there is no doubt that TNF has a major role in cancer biology. TNF has a dual defensive and offensive role in carcinogenesis (1). TNF-blocking treatment has led to improvements in the management of inflammatory diseases.Even though their efficacy as anti-inflammatory drugs is well-proven, there are some concerns about the adverse effects of anti-TNF therapy (2). Basic research suggests that the evaluation of infections and malignancy as major adverse effects should be performed effectively (3). However, some studies conducted so far have dubious notions that anti-TNF therapy increases the risk of cancer (3,4).
Objectives: Objective: The clinical importance of the thyroid nodules in patients with axial spondyloarthritis (ax-SpA) rests with the need to exclude thyroid malignancy. The aim of this study is to assess the risk of thyroid malignancy in ax-SpA patients receiving anti-TNF therapy.
Methods: From September 2015 until December 2015, 70 patients diagnosed with ax-SpA according to ASAS criteria, were included in the research. Forty of the patients had received anti-TNF therapy, and 30 of the patients were anti-TNF naive. A clinician from the Physical Medicine and Rehabilitation clinic performed ultrasonography on all patients to screen for thyroid nodule(s). If thyroid ultrasonography revealed an abnormal finding, the patient was referred to a radiologist.
Results: The mean (SD) age was 38±9.87 years; % 75.7 of the patients were male. None of the demographic differences between the groups were statistically significant. Fifteen of the forty patients that received anti-TNF therapy and eleven of the thirty anti-TNF naive patients had thyroid nodule(s). Four patients from the anti-TNF group underwent fine needle aspiration biopsy, and two of them were diagnosed with papillary thyroid carcinoma. None of the nodules in anti-TNF naive patients required biopsy. When compared to the normal population, the standardized incidence ratio (SIR) was found to be increased in both male (SIR: 2.03% 95 CI: 1.9 to 18) and female (SIR: 2.7% 95 CI: 2.6 to 24) cases.
Conclusions: We see a mild increase in thyroid malignancies in ax-SpA patients that received anti-TNF therapy. Consequently, the thyroid gland should also be taken into consideration while screening for malignancy before anti-TNF therapy.

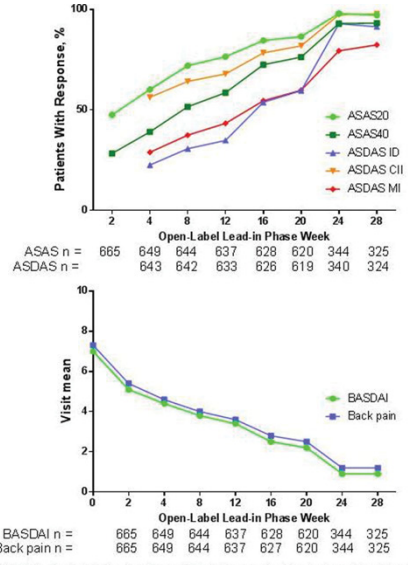
THU0388 EFFICACY AND SAFETY OF ADALIMUMAB IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE 28-WEEK OPEN-LABEL PERIOD OF THE ABILITY-3 STUDY



R. Landewé[1], J. Sieper[2], R. Inman[3], A.L. Pangan[4], X. Wang[4], J.K. Anderson[4]. *[1]University of Amsterdam, Amsterdam, Netherlands; [2]Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Toronto Western Hospital, Toronto, Canada; [4]AbbVie, North Chicago, United States*

Background: Adalimumab (ADA) significantly improved clinical response at wk 12 vs placebo in patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) in the ABILITY-1 study. The subsequent, ongoing ABILITY-3 study is assessing continuation vs withdrawal of ADA in nr-axSpA pts who respond to ADA.
Objectives: Evaluate the efficacy and safety of ADA during the open-label lead-in period of ABILITY-3.
Methods: ABILITY-3 has a 28-wk lead-in open-label ADA (40 mg every other wk) period; pts who achieve sustained remission (Ankylosing Spondylitis Disease Activity Score inactive disease [ASDAS ID] at wks 16, 20, 24 and 28) are randomized to double-blind placebo (withdrawal) or ADA (continuation) for 40 wks (ongoing). From wk 20–28, pts who did not achieve ASDAS ID were discontinued. Adult pts with nr-axSpA (fulfilling Assessment of SpondyloArthritis international Society [ASAS] criteria but not modified New York criteria) with objective evidence of inflammation in the sacroiliac joints or spine on MRI or elevated hs-CRP at screening; active disease at baseline (defined by ASDAS ≥2.1, BASDAI ≥4, and total back pain score ≥4); and inadequate response to ≥2 NSAIDs were eligible.
Results: Of 673 pts enrolled, 51% were women and mean BASDAI was 7.0±1.4 (Table). At wk 28, 305 (45%) pts were randomized (ASDAS ID: 33% at wk 12, 44% sustained at wk 28; nonresponder imputation) and 368 (55%) pts discontinued (not achieving sustained remission, n=300 [45%]; other reasons, n=68 [10%]). In observed analysis, 59%, 35%, and 22% of pts achieved ASAS40, ASDAS ID, and ASAS partial remission, respectively, at wk 12, similar to wk 12 data from ABILITY-1 pts with objective inflammation at baseline. The proportions of pts achieving ASAS20, ASAS40, ASDAS ID, ASDAS CII, and ASDAS MI increased, and mean BASDAI and back pain scores decreased over time (observed analysis; Figure). Adverse events (AEs) were reported by 468 pts (70%), most commonly nasopharyngitis (n=121 [18%]), upper respiratory tract infection (n=81 [12%]), and headache (n=56 [8%]); serious AEs occurred in 19 (3%) pts.

Table 1. Baseline Characteristics

Mean ± SD	(n=673)
Age	37.3±11.1
White, n (%)	651 (97)
Female, n (%)	343 (51)
Symptom duration, y	7.7±7.7
HLA-B27 positive, n (%)	515 (77)
TJC	6.5±10.4
SJC	1.9±4.0
MASES	3.4±3.5
PGA-disease activity	6.5±1.5 n=671
Patient-pain	7.4±1.7
BASDAI	7.0±1.4
ASDAS	3.6±0.8
hs-CRP	9.6±15.0
BASFI	5.3±2.2
HAQ-S	2.1±0.6

BASFI, Bath Ankylosing Spondylitis Functional Index; HAQ-S, Health Assessment Questionnaire for the Spondyloarthropathies; hs-CRP, high-sensitivity C-reactive protein; MASES, Maastricht Ankylosing Spondylitis Enthesitis Score; PGA, physician global assessment; SJC, swollen joint count; TJC, tender joint count.

BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CII, clinically important improvement; MI, major improvement.
Patients who did not achieve ASDAS ID were discontinued at week 20–28 visits.

Conclusions: Baseline disease activity was higher in ABILITY-3 pts than reported in prior trials. After 28 wks of open-label ADA therapy, disease activity improved and sustained remission was achieved in 44% of pts. Efficacy and safety in this nr-axSpA population were consistent with findings from ABILITY-1.

THU0389 IS THERE ANY ROLE OF IMMUNOGENICITY ON THE RESPONSE TO THE ANTI-TUMOR NECROSIS FACTOR ALPHA THERAPY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: THE FIRST RESULTS OF A PROSPECTIVE COHORT STUDY

S. Akar[1], M. Cinar[2], G. Sargin[3], O. Karadag[4], G. Kinikli[5], M. Ozmen[1], O. Gercik[1], U. Kalyoncu[4], S. Yilmaz[2], T. Senturk[3], G. Keser[6], G. Hatemi[7], F. Yargucu[6], Y. Ozguler[7], A. Cefle[8], D. Kozaci[9], D. Solmaz[1], B. Kisacik[10]. *[1]Rheumatology, Katip Celebi University Faculty of Medicine, Izmir; [2]Rheumatology, Gulhane Military Hospital, Ankara; [3]Rheumatology, Adnan Menderes University Faculty of Medicine, Aydın; [4]Rheumatology, Hacettepe University Faculty of Medicine; [5]Rheumatology, Ankara University Faculty of Medicine, Ankara; [6]Rheumatology, Ege University Faculty of Medicine, Izmir; [7]Rheumatology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul; [8]Rheumatology, Kocaeli University Faculty of Medicine, Kocaeli; [9]Biochemistry, Ankara Yildirim Beyazid University Faculty of Medicine, Ankara; [10]Rheumatology, Gaziantep University Faculty of Medicine, Gaziantep, Turkey*

Background: Although anti-tumour necrosis factor agents (anti-TNFs) are very effective in most patients with ankylosing spondylitis (AS) significant proportion of patients quit the treatment due to non-response or adverse events. The development of anti-drug antibodies (ADAs) and low serum drug levels might have a mechanistic role in loss of efficacy of or the development of adverse events in patients treated with anti-TNFs. There is limited data regarding the immunogenicity of anti-TNFs in patients with AS.
Objectives: Therefore the aim of this study was to evaluatethe relationship between the formation of ADAs, serum through drug levels and clinical response to anti-TNFs in patients with AS.
Methods: In total 350 AS patients with a new anti-TNF agent prescription in the last two weeks period were planned to include this multi-center prospective observational cohort study. Herein we are presenting the data of first 102 patients who had >3months follow-up. Clinical data and serum samples were collected at baseline and at every three months of treatment. Serum drug levels and ADAs were measured by ELISA in one center to avoid inter-assay variability.
Results: 102 biologic naïve AS patients (75 [74%] male, mean (±SD) age; 37.2±10.7 years) who started anti-TNF agents (14 infliximab [13.7%], 27 adalimumab [26.5%], 33 etanercept [32.4%] and 28 golimumab [27.5%]) were included in the present analysis. In comparison to baseline values BASDAI, ASDAS-CRP and CRP values were significantly decreased in third months of follow-up ($P<0.001$) (table). At 12 weeks of follow-up 9 patients (9%; 2 on infliximab and 7 adalimumab) had ADAs and 20 (20%; 10 on adalimumab, 4 infliximab, 4 golimumab and 2 etanercept) had no detectable drug levels.The presence of ADAs were significantly correlated with serum drug levels ($P<0.001$). Up to 12 months of follow-up none of patients treated etanercept developed ADAs. Third month BASDAI and ASDAS-CRP values were significantly higher in patients with ADAs (BASDAI values were 5.2±1.4 vs 3.0±1.8; $P<0.001$ and ASDAS-CRP values were 3.1±1.0 vs 1.9±1.1; $P<0.001$) (figure) and patients with no detectable drug levels BASDAI values were 4.1±1.8 vs 2.9±1.8; $P=0.012$ and ASDAS-CRP values were 2.7±1.3 vs 1.9±1.0; $P=0.015$).
Conclusions: ADAs against anti-TNF agents might develop as early as 12 weeks of treatment. Our results confirm that ADA development may hinder the anticipated response to anti-TNF agents in patients with AS.

Table 1. Baseline and third month's follow-up indicators of activity and response in AS patients treated with anti-TNF agents

	Baseline	Third month
BASDAI	6.8±5.2	3.2±1.9
ASDAS-CRP	4.1±2.5	2.0±1.1
CRP	23.8±32.8	7.9±13.9

THU0390 EFFECT OF REHABILITATION ON THE CHEST EXPANSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S.D. Jandric. *Department for FRM, Faculty of Medicine, University of Banjaluka, Banja Luka, Republic of Srpska, Bosnia and Herzegovina*

Background: Ankylosing spondylitis (AS) is a form of chronic inflammatory arthritis that leads to pain, stiffness, progressive spinal deformity, and spinal fusion, limitation of the spine, rib cage motion and severe functional impairment. Pulmonary function is altered in AS owing mainly to the limited chest expansion.
Objectives: The purpose of this study was to investigate the effect of rehabilitation on the limited chest expansion measured by respiratory index and relationship between duration of the rehabilitation and age, disease onset, disease duration and respiratory index in patients with AS during physical treatment and rehabilitation.
Methods: The study was designed as a retrospective study that included 47 consecutive AS patients (33 male and 14 female), average age of 52.53±11.58 years that were hospitalized and treated in rehabilitation center. Average duration of the rehabilitation was 17.77±5.92 days. Respiratory index was measured for all AS patients at the beginning and at the end of rehabilitation with a centimeter ribbon. Student's t-test and Pearson's test of correlation were used for statistically analysis.
Results: Average disease duration was 13.35±8.74 years, disease onset was at 39.64±12.87 years. Respiratory index was 1.98±1.34 cm at beginning of rehabilitation and 3.01±1.75 cm at the end of rehabilitation. The difference was statistically significant (t=8.025, $p<0.001$). Pearson's test of correlation was shown statistically significant correlation between value of respiratory index at beginning and at the end of rehabilitation (r=0.872, $p<0.001$). Duration of the rehabilitation (hospital days) statistically significant correlate with value of respiratory index at beginning rehabilitation (r=-0.289, $p<0.05$), but not with age, disease duration and disease onset ($p>0.05$).
Conclusions: The physical therapy and rehabilitation has led to the improvement the respiratory index in patients with AS, which confirms its effectiveness. The value of respiratory index at beginning rehabilitation is associated with duration of the rehabilitation. Significant limitation in respiratory index indicates longer hospital stay. These results could be having importance in planning of rehabilitation of patients with AS.

THU0391 FEMALE GENDER IS ASSOCIATED WITH A POORER RESPONSE TO TNF INHIBITORS IN ANKYLOSING SPONDYLITIS

T. Rusman, M.T. Nurmohamed, J.C. van Denderen, I. Visman, I.E. van der Horst-Bruinsma. *Amsterdam Rheumatology immunology Center |Departments of Rheumatology VU University Medical Center & Reade, Amsterdam, Netherlands*

Background: Limited data are available on the influence of gender and lifestyle factors, such as smoking, alcohol consumption and Body Mass Index (BMI) on disease activity and response to TNF inhibitors (TNFi) in ankylosing spondylitis (AS).
Objectives: This study aimed to determine whether these factors influence age at diagnosis, disease activity and response to TNFi.
Methods: In a prospective study, clinical data (age, gender, C-reactive protein, Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Score (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Metrology Index (BASMI), smoking, alcohol consumption and BMI) were collected in AS patients from a observational cohort, who started or switched treatment with TNFi. Data were collected at baseline and after 6, 12 and 24 months. Independent T-tests and linear regression analyses were performed to assess the influence of gender and lifestyle factors on age at diagnosis and disease activity.

Results: In total, 312 consecutive AS patients, 34% female, were included with a mean follow-up of 18.9 months. Most patients (172, 55%) showed significant improvement after start of TNFi of whom 86 patients (28%) had a clinically important (ASDAS decrease >1.1) and 86 (26.9%) a major clinical improvement (ASDAS decrease >2.2). BMI was significantly correlated with age at diagnosis (p=0.016; 95% CI: 0.07 – 0.65): an increase of BMI with three points delayed the AS diagnosis with one year. At baseline, smoking and gender were not correlated with the ASDAS, but BASDAI and BASMI were both inversely related to BMI. Male gender was significantly associated with a higher chance at clinical response (improvement of the BASDAI with 50% or a 2 point decrease) to TNFi (p=0.041). At one year follow-up the clinical improvement of males versus females was respectively 62% vs. 43% and at two year follow-up 59% vs. 46%. Males also showed a significantly higher ASDAS improvement after one year of follow-up compared to females (p=0.015).

Conclusions: Significantly less females had a clinical response compared to males after one and two years of TNFi treatment. A higher BMI not only prolonged the time to AS diagnosis up to one year, but also negatively influenced the BASDAI and BASMI scores. Female gender and high body weight should be taken into consideration when the efficacy of TNFi is assessed, by stratifying for these factors in the analysis.

THU0392 DO WE REALLY NEED DMARDS ADDITION TO ANKYLOSISNG SPONDYLITIS PATIENTS TREATED WITH TUMOR NECROSIS FACTOR ALPHA INHIBITORS?

T. Reitblat[1], O. Cohen[1], D. Aharoni[2], E. Hadrian[2], G. Reifman[1], Y. Braun-Moscovici[3], A. Balbir-Gurman[3]. *[1]Department of Rheumatology; [2]Laboratory Service, Barzilai Mc, Ashkelon; [3]B. Shine Rheumatology Unit, Rambam Health Care Campus and Rappaport Faculty of Medicine, Technion, Heifa, Israel*

Background: The management of systemic inflammatory diseases, such as Rheumatoid arthritis (RA) and Ankylosing spondylitis (AS) has been revolutionized with the introduction of tumor necrosis factor alpha inhibitors (TNF-I). Significant reduction in disease activity and achievment of remission resulted in halting of joint damage and improved quality of life. Unfortunately, approximatly 15–30% of patients fail to reach desirable improvement or lose drug effectiveness with time. It may be explained by immunogenicity and production of human anti chimeric antibodies (HACA). Presence of HACA against TNF-I have been associated with low levels of the drug and lose of therapeutic response. The prevalence of HACA in RA is estimated between 20–40%, and in AS between 25–64%. The difference in the pathogenesis of RA and AS as well as diverce approach in using disease modifying anti-rheumatic drugs (DMARDs) may influence HACA production and TNF-I levels in these conditions.

Objectives: To compare the incidence of HACA and Infliximab, Etanercept, Adalimumab levels in patients with RA and AS with respect to concomitant DMARDs.

Methods: Patients' with RA and AS data treated with TNF-I for at least 3 months in whom tests for HACA and Infliximab, Etanercept, Adalimumab levels were available were extracted from patients' files. Data included: demographics, concomitant treatment, and disease activity scores (BASDAI for AS and DAS-28 for RA). Serum for assessment of drugs level (ELISA) and HACA (ADAb;Promonitor, Bridging, ELISA) was obtained before the next drug administration. Univariate comparison was done using Student t test for the continuous variables and Chi square test for the categorical variables (P <.05 was considered significant).

Results: Data on 53 patients with AS (mean age 47.9±11.9 years, 41.5. % female) and 29 patients with RA (mean age 54.8±8.1 years, 75, 9% female) were available: 22 RA patients were treated with Methotrexate and 7 with other DMARDs; no one AS patient was treated with concomitant DMARDs. High level of HACA was found in 22.6% AS patients and in 34.5% RA patients (p>0.05); 86.8% patients with AS reached theurapethic level of drug compared to 69% RA patients (p=0.027). Drugs levels were similar in AS and RA patients (Table). Low disease activity (DAS28-CRP<3.2) was registered in 62.1% RA patients and in 81.4% AS patients (BASDAI <4).

Conclusions: Despite significant difference in the use of concomitant DMARDs, patients with AS and RA had similar prevalence of HACA. Moreover, higher proportion of patients in AS group reached therapeutic level of TNF-I. The data supports the hypothesis, that immune responce to TNF-I may be different in AS and RA and, therefore, the addition of DMARDs to prevent development of HACA in patients with AS may be unnecessary.

THU0393 SECUKINUMAB PROVIDES SUSTAINED REDUCTION IN FATIGUE IN PATIENTS WITH ANKYLOSING SPONDYLITIS THROUGH 3 YEARS: LONG-TERM RESULTS OF TWO RANDOMISED DOUBLE-BLIND PLACEBO-CONTROLLED PHASE 3 STUDIES

T.K. Kvien[1], A. Deodhar[2], L. Gossec[3], P.G. Conaghan[4], V. Strand[5], M. Østergaard[6], N. Williams[7], B. Porter[8], K. Gandhi[8], S. Jugl[9]. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]Oregon Health & Science University, Portland, Oregon, United States; [3]UPMC University Paris 06, Paris, France; [4]University of Leeds, Leeds, United Kingdom; [5]Stanford University School of Medicine, Palo Alto, CA, United States; [6]Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; [7]RTI Health Solutions, Durham, NC; [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [9]Novartis Pharma AG, Basel, Switzerland*

Background: In patients (pts) with ankylosing spondylitis (AS), fatigue is a common symptom negatively affecting health-related quality of life (HRQoL) and social functioning. Secukinumab (SEC), a fully human anti–IL-17A mAb, rapidly improved signs and symptoms, physical functioning, and HRQoL in pts with AS.[1,2]

Objectives: To assess the long-term effects of SEC on fatigue in TNF inhibitor (TNF)-naïve and TNF inhibitor inadequate responder/intolerant (TNF-IR) AS pts in MEASURE 1 and MEASURE 2.

Methods: 371 and 219 pts were randomized to SEC or placebo (PBO) in MEASURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and MEASURE 2 (150 or 75 mg SC), respectively. At Week (Wk) 16, non-responder PBO pts were re-randomized to SEC 150 or 75 mg SC (in MEASURE 1, PBO pts achieving ASAS20 response at Wk 16 were switched to SEC at Wk 24). Fatigue was measured at baseline (BL) and Wks 4, 8, 12, 16, 24, 52, 104 and 156 using FACIT-F, which assesses fatigue in the previous 7 days using 13 questions graded on a 0–4 scale (higher scores=less fatigue). An increase from BL in FACIT-F score of ≥4 points (based on MCID) was used to define "response". Approximately 69% of pts were TNF-naïve and 31% were TNF-IR across both trials. Analyses were based on the full analysis set and subgroups stratified by prior TNF therapy. Correlations between BL characteristics and improvements in fatigue were investigated using a logistical regression model. Only data from the approved dose (SEC 150 mg) are presented.

Results: FACIT-F was 24.5–25.6 and 22.6–24.3 at BL across groups in MEASURE 1 and 2, respectively. Improvements in FACIT-F with SEC at Wk 16 were sustained through Wk 156 in MEASURE 1 and Wk 104 in MEASURE 2 (Table). Rapid and sustained fatigue responses were also seen in subgroups stratified by prior TNF use. In the overall population, LS mean changes (±SEM) from BL in FACIT-F scores were significantly greater with SEC vs PBO at Wk 16 in both MEASURE 1 (7.60±0.99 vs 3.34±1.00, *P*=0.002) and MEASURE 2 (8.10±1.09 vs 3.27±1.09, *P*=0.018); reductions in fatigue were sustained throughout the entire follow up in both trials (MEASURE 1 Wk 156: 9.81±0.95; MEASURE 2 Wk 104: 9.27±1.13). Similar results were reported in both TNF-naïve and TNF-IR pts. Correlational analyses based on pooled data from both trials did not identify any BL factors that

Table: FACIT-F responders in MEASURE 1 and MEASURE 2 with secukinumab 150 mg[a]

	Proportion of Patients with FACIT-F Response[b], % (n/m)			
	Week 16	Week 52	Week 104	Week 156
MEASURE 1[c]				
Overall (N=87)	66.7 (58/87)	73.6 (64/87)	72.2 (57/79)	75.6 (65/86)
TNF-naïve (N=70)	70.0 (49/70)	75.7 (53/70)	70.3 (45/64)	74.3 (52/70)
TNF-IR (N=17)	52.9 (9/17)	64.7 (11/17)	80.0 (12/15)	81.3 (13/16)
MEASURE 2				
Overall (N=72)	77.6 (52/67)	80.6 (50/62)	81.4 (48/59)	–
TNF-naïve (N=44)	86.0 (37/43)	90.0 (36/40)	84.6 (33/39)	–
TNF-IR (N=28)	62.5 (15/24)	63.6 (14/22)	75.0 (15/20)	–

[a]Observed data are shown; [b]Defined as improvement (increase in FACIT-F score) by ≥4.0 points from BL; [c]Data shown are from patients who entered the MEASURE 1 long-term extension study at Week 104 (NCT01863732)
m, number of patients with sufficient data for evaluation; N, number of patients randomized to SEC 150 mg
n, number of responders

consistently predicted improvement in fatigue response at Wks 16, 52, and 104. A one-unit increase in BL BASDAI score (i.e. worsening) was a significant factor for achieving FACIT-F response at Wk 104 (P=0.02).

Conclusions: SEC provided sustained improvements in fatigue for up to 156 wks in both TNF-naïve and TNF-IR pts with AS. Fatigue response was generally higher in TNF-naïve pts.

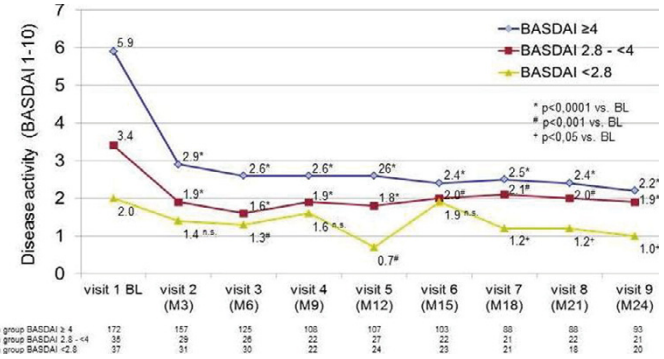
THU0394 RHEUMATOLOGISTS USE DIFFERENT CUT OFFS FOR DISEASE ACTIVITY IN REAL LIFE – THE EXPERIENCE WITH GOLIMUMAB IN ANKYLOSING SPONDYLITIS – A SUBANALYSIS FROM THE NON-INTERVENTIONAL GO-NICE TRIAL

J. Braun[1], X. Baraliakos[1], U. Kiltz[1], K. Krüger[2], G.R. Burmester[3], S. Wassenberg[4], M.H. Thomas[5]. *[1]Rheumazentrum Ruhrgebiet, Herne; [2]Rheumatologisches Praxiszentrum, München; [3]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin; [4]Rheumazentrum Ratingen, Ratingen; [5]Medical Affairs, MSD Sharp & Dohme GmbH, Haar, Germany*



Background: International recommendations for the management of axial spondyloarthritis including ankylosing spondylitis (AS) suggest a BASDAI level of disease activity of ≥4 to indicate treatment with biologics. Other cut-offs have rarely been studied so far.

Objectives: Therefore, we were interested to learn about the level of disease activity used in daily routine to start anti-TNF therapy.

Methods: In a posthoc subanalysis of the non-interventional, prospective, study GO-NICE that has been performed in a real life setting in Germany we used data from biologic naïve patients with established AS to study the initial BASDAI values before the start of therapy with Golimumab 50mg SC once monthly. Established standardized outcome measures were used.

Results: Out of a total of 543 AS-patients (pts.) documented in 126 German centers, 244 biologic-naïve pts. were eligible. A total of 134 pts. (54.9%) completed the 24 month observational period. The majority of pts. (70.5%), had a BASDAI ≥4 (group (gr.).1), while 14.3% had a BASDAI of ≥2.8 - <4 (gr.2) and 15.1% even had a BASDAI <2.8 (gr.3, Table). The patient demographics did not differ much between these 3 groups, the proportion of males was numerically somewhat lower in gr.1. The proportion of pts. with an elevated CRP was highest in gr.2 at BL. The BASDAI in gr.1,2 and 3 was initially 5.9±1.3, 3.4±0.4 and 2.0±0.8, dropped significantly to 2.2*±2.0, 1.9*±1.2 and 1.0±1.2 within 3 months (*p<0.0001 vs. BL), and decreased significantly (p<0.005) to 2.2±1.7, 1.9±1.7 and 1.4±1.0 at month 24, respectively (fig.).The BASDAI 50% improvement was 68.8%, 44.8%, and 45.2% at month 3, and increased to 84.9%, 61.9%, and 55.0% at month 24, respectively.

Conclusions: The most interesting observation of this real life study and posthoc analysis is certainly that almost a third of the pts. were included in the study who did not reach the recommended BASDAI cut-off of ≥4. Furthermore the data show that the patients with a BASDAI 2.8 - <4 seem to have significant benefit of anti-TNF treatment, while this was not really the case with in pts. with a BASDAI <2.8. This finding should lead to a reevaluation of the established BASDAI cut-off of ≥4. Future studies should also evaluate the performance of an ASDAS cut-off.

It seems likely that especially pts. with elevated CRP levels and a BASDAI <4 will benefit from this new strategy. We think that in light of the rather weak correlation of pain and "objective" parameters of inflammation such as CRP and MRI the here reported observation does make some sense. Regarding the treatment with golimumab no new safety signals were detected.

THU0395 HIGH NUMBER OF PREVIOUS BIOLOGIC USE AND COMORBIDITIES IN FIRST REAL WORLD SECUKINUMAB STUDY IN PSA AND AS – NON-INTERVENTIONAL, AQUILA STUDY IN GERMANY

U. Kiltz[1], C. Legeler[2], M. Maier-Peuschel[2], J.A. Veit[2], C. Mann[2], H.-P. Tony[3]. *[1]Rheumazentrum Ruhrgebiet, Rheumazentrum Ruhrgebiet, Herne; [2]Novartis, Nürnberg; [3]Medizinische Klinik und Poliklinik II, Universität Würzburg, Würzburg, Germany*

Background: Secukinumab has been shown to significantly improve symptoms of psoriatic arthritis (PsA)[1] and ankylosing spondylitis (AS)[2] in numerous phase III studies. Still, as randomized, controlled, clinical trials often limit their patients to a very strict and selected group, further data on real world evidence is necessary to assess efficacy in a broader patient group.

Objectives: To evaluate baseline characteristics regarding demographics, disease activity and comorbidities in patients with active PsA or AS in daily practice treated with secukinumab in Germany.

Methods: AQUILA, a non-interventional, multi-center, 52-week study enrolling 2000 patients with active PsA or AS. Patients are documented as treated in clinical practice. Here, we will report the baseline characteristics of a subgroup of 347 patients who have been enrolled in the study. At baseline patient's health status, selected comorbidities and disease history was assessed using routine parameters (among others: CRP, joint count, BASDAI). Furthermore, overall disease activity and quality of life has been documented using ASAS-HI (AS) and PsAID-12 item (PsA).

Results: 108 AS- and 239 PsA-patients were included, majority of AS patients were male, in PsA the majority was female. Previous bDMARD exposure was high in both groups, percentage of NSAID and cDMARD exposure varied (Tab). For PsA patients elevated CRP (Tab) and a high number of tender (8.4) and swollen joints (4.4) was reported. Assessed comorbidities included coronary heart disease (9.7%), stroke (2.5%), heart failure (2.9%) and depression (13.4%). Effect of PsA on patient's life at baseline was reported via PsAID-12 item with a mean score of 5.0 (±2.2). AS patients enrolled in this trial had a high disease activity with a mean BASDAI of 5.5 (±2.0) and elevated CRP (Table). Considered comorbidities were coronary heart disease (4.6%), stroke (0%), heart failure (0.9%) and depression (12%). Patient's impairments due to AS were assessed at baseline with the ASAS-HI, reporting a mean score of 8.1 (±3.6).

Conclusions: The baseline characteristics of the population are comparable with

Abstract THU0394 – Table 1. Demographics and baseline characteristics

THU0396 EFFICACY OF SWITCHING BDMARDS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

V. Navarro-Compán[1], E. de Miguel[1], A. Balsa[1], P. Diaz del Campo[2], J. Gratacós[3]. *[1]Hospital la Paz, IdiPaz; [2]Spanish Society of Rheumatology, Madrid; [3]Hospital Parc Taulí, Sabadell, Spain*

Background: bDMARDs (TNF or IL-17 inhibitors) have been shown to be efficacious in patients with axial spondyloarhritis (axSpA). However, approximately 30–50% of patients who receive a first bDMARD do not respond well. Current practice in these patients is switching to another bDMARD but the scientific evidence for this attitude is sparse.

Objectives: To evaluate the efficacy of switching bDMARDs in patients with axSpA.

Methods: A systematic literature review until February 2016 was performed using Medline, EMBASE and Cochrane databases. Furthermore, abstracts from the previous EULAR and ACR meetings were reviewed. The research question was formulated according to the PICOS method: Population (axSpA patients); Intervention (bDMARD); Outcome (clinical response); and Setting (longitudinal studies with follow-up ≥12 weeks of follow up including data from ≥50 patients). Data was extracted using a form developed for this specific purpose. The quality of the studies was assessed based on CEBM Oxford. Clinical response in patients who switched to a second bDMARD was determined and compared with the one achieved after receiving the first bDMARD (a TNFi in all cases). Results are shown as median (range) and relative frequencies (%).

Results: In total, 7 studies out of 1506 retrieved citations were included. All studies included patients with ankylosing spondylitis (AS). The study design was prospective observational (n=3), retrospective observational (n=2), open-label trial (n=1) and post-hoc analysis from two RCTs (n=1). The level of evidence for all the studies was 4. In these studies, a total of in 4678 patients received a first bDMARD and 1198 patients switched to a second bDMARD (a TNFi in all cases except in 51 patients that switched to secukinumab). Baseline characteristics of patients included in the studies were: 41 (38–44) years old, 67% (64–74) males, 78% (74–89) HLA-B27+ and BASDAI before switching 6.2 (5.3–6.5). The most frequent reason to switch bDMARD was inefficacy, followed by intolerance/adverse events. Median (range) time to assess response after switching was 6 (3–12) months. The criteria to define clinical response were heterogeneous. BASDAI50 was employed in four studies and the percentage of patients who achieved this response after the first and the second bDMARD for each study was: (63% vs 41%), (50% vs 28%), (54% vs 37%), (72% vs 56%), respectively. The response for the other three studies was based on different definitions, being as follows: BASDAI <4 (83% vs 78%), ASAS20 response (67% vs 48%) and retention rate after one year (65% vs 60%). The reason to switch bDMARD (intolerance or inefficacy) was not found as a significant predictor of treatment response in most of the studies. In addition, two studies reported data (n=137 and 11 patients) to evaluate the efficacy of switching to a third bDMARD (TNFi in both cases). The percentage of patients who responded (BASDAI50) to the third TNFi was 30% and 52%, respectively.

Conclusions: In patients with AS who do not respond to a first TNFi, switching to another bDMARD (either a TNFi or secukinumab) is efficacious in a considerable number of patients (30–50%). However, the clinical response after receiving a second bDMARD is lower to the one experienced after the first TNFi. Published data for switching to a third bDMARD is very limited.

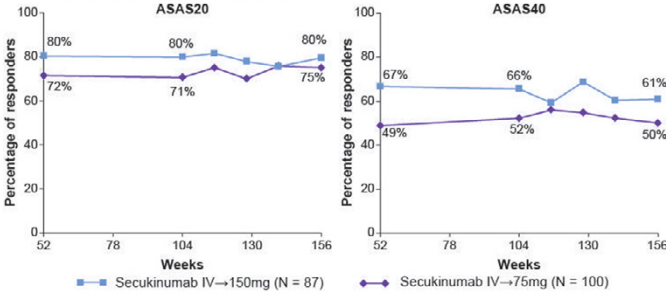
THU0397 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE ANKYLOSING SPONDYLITIS: 3-YEAR RESULTS FROM A PHASE 3 EXTENSION TRIAL (MEASURE 1)

X. Baraliakos[1], A.J. Kivitz[2], A. Deodhar[3], J. Braun[1], J.C. Wei[4], E.M. Delicha[5], Z. Talloczy[6], B. Porter[6] on behalf of the MEASURE 1 study group.
[1]Ruhr-University Bochum, Herne, Germany; [2]Altoona Center for Clinical Research, Duncansville; [3]Oregon Health & Science University, Portland, United States; [4]Chung Shan Medical University Hospital, Taichung, Taiwan, Province of China; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Rapid and sustained improvements in the signs and symptoms of ankylosing spondylitis (AS) have been reported with secukinumab, a fully human anti–IL-17A mAb, over the first 2 years (yrs) in the Phase 3 MEASURE 1 trial.[1,2]

Objectives: To report efficacy and safety of secukinumab through 3 yrs in an extension trial (NCT01863732) to the core MEASURE 1 trial.

Methods: After the 2-yr core trial, patients (pts) receiving secukinumab 150 or 75mg s.c. were invited to enter a 3-yr extension trial. Efficacy results at Week (Wk) 156 are reported for pts who were originally randomised to secukinumab. Assessments at Wk 156 included ASAS20/40, BASDAI, BASDAI50, SF-36 PCS, ASAS partial remission (ASAS PR) and ASDAS-CRP. Binary and continuous variables used multiple imputation and MMRM estimates, respectively. Analyses by anti-TNF use (naïve/intolerant to or inadequate response [IR]) was pre-specified and reported as observed. Safety analyses included all pts who received ≥1 dose of secukinumab.



Results: A total of 290/371 pts (78%) completed the 2-yr core trial. Of these, 274 pts entered the extension trial, with 260 completing 156 wks (83/87 pts [95%] in IV→150mg; 95/100 pts [95%] in IV→75mg; 82/87 [94%] pts in placebo→secukinumab). At Wk 156, clinical improvements were sustained across all endpoints (Table, Figure). Similar trends were observed regardless of prior anti-TNF use (Table). Across the treatment period (secukinumab exposure [mean±SD]: 964.3±372.1 days), exposure-adjusted incidence rate with secukinumab for serious infections, Crohn's disease and malignant/unspecified tumours was 1.1, 0.5 and 0.5 per 100 pt-yrs, respectively.

Table 1. Summary of 156-wk efficacy results

	Observed data		Missing data considered[a]

[a]Missing data of binary variables were imputed and for continuous variables MMRM estimates are shown. [b]Evaluable data available in n=86 and n=98 pts in the secukinumab IV→150mg and IV→75mg groups, respectively. [c]Least squares mean±SE for MMRM estimates and mean±SD for observed data. [d]Observed data. [e]Evaluable data available in n=70 and 75 pts (naïve) and n=16 and 23 pts (IR) in the secukinumab IV→150mg and IV→75mg groups, respectively. [#]Observed data provided for reference. IV, pts received secukinumab 10mg/kg i.v. loading at baseline, Wks 2 and 4; N, number of pts in the extension trial.

Figure. ASAS20 and ASAS40 responses through Week 156

Data presented after multiple imputation through Week 156. ASAS20 and ASAS40 responses through Week 104 have been reported previously.[2] N, number of patients in the extension trial

Conclusions: Secukinumab provided sustained efficacy in signs/symptoms and physical function in pts with active AS over 3 yrs. Secukinumab was well tolerated with a favorable safety profile consistent with that reported previously.[1,2]

THU0398 SECUKINUMAB SUSTAINS INDIVIDUAL CLINICAL RESPONSES OVER TIME IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: 2-YEAR RESULTS FROM A PHASE 3 TRIAL, MEASURE 2

X. Baraliakos[1], M. Schiff[2], K. Pavelka[3], A. Widmer[4], B. Porter[5], C. Gaillez[4] on behalf of the MEASURE 2 study group. *[1]Ruhr-University Bochum, Herne, Germany; [2]University of Colorado, Denver, United States; [3]Charles University, Prague, Czech Republic; [4]Novartis Pharma AG, Basel, Switzerland; [5]Novartis Pharmaceuticals Corporation, East Hanover, United States*

Background: The assessment of achieving, maintaining or improving clinical response to biologics in ankylosing spondylitis (AS) is a part of treat-to-target recommendations aimed at optimising treatment goals.[1]
Objectives: To evaluate patient (pt)-level secukinumab data and assess the likelihood of achieving, maintaining or improving an Assessment of SpondyloArthritis international Society (ASAS) response from Week (Wk) 2 (early response) to Wk 16 (primary endpoint) and from Wk 16 to Wk 52 or 104 (sustained effect) in pts with active AS from the MEASURE 2 trial.[2,3]
Methods: This is a *post-hoc* analysis of AS pts originally randomised to secukinumab 150mg (approved dose) who completed the 16-wk double-blind treatment period, followed by long-term uncontrolled treatment. Shift analyses on ASAS response between Wks 2 and 16 and Wks 16 and 52 or 104 were performed on subgroups of secukinumab 150mg treated pts categorised by their highest ASAS criteria response at the earlier time point (ASAS non-responder [ASAS NR], ASAS20 responder, ASAS40 responder) and evaluating whether this response was improved, sustained, or worsened at the later time point, based on observed analysis.
Results: Overall, 65, 61 and 59 pts treated with secukinumab 150mg had available data to determine ASAS responses for shift analyses from Wk 2 to 16 and Wk 16 to 52 or 104, respectively. At baseline, mean age was 41.9±12.5 years, mean time since diagnosis was 7.0±8.2 years and mean Bath Ankylosing Spondylitis Disease Activity Index score was 6.6±1.5. Approximately half of the ASAS NR pts at Wk 2 or 16 subsequently developed an ASAS 20 or 40 response at the later time point of Wk 16 or 52, respectively. A total of 79% pts improved their response from ASAS20 to ASAS40 at Wk 16 (Wk 2 to 16) and another 44% pts improved their response from ASAS20 to ASAS40 from Wk 16 to 52. A majority (64% and 84%) of ASAS40 responders at Wk 2 or 16 maintained this response at Wk 16 or 52, respectively. Similar trends were observed in responses from Wk 16 to 104 (Figure).
Conclusions: In this *post-hoc* pt-level analysis, the majority of secukinumab 150mg treated pts maintained or improved their ASAS responses over time, consistent with the sustainability of group-level ASAS responses reported previously.[2,3] In particular, the majority of pts who achieved either an ASAS20 or ASAS40 response at Wk 2 or 16 maintained or improved their response at Wks 16, 52 or 104, respectively.

THU0399 TAPERING THERAPY OF TNF-INHIBITOR FOR MRI CHANGES IN SPONDYLOARTHRITIS

Y. Song, Y. Cui, X. Zhang, H. Zeng, Y. Zeng. *Goungdong General Hospital, Goungzhou, China*

Background: TNF-inhibitors could significantly improve disease activity of SpA patients, however, there is still no answer to the effect of prolonged the interval of TNF-inhibitors on MRI changes.
Objectives: The aim of the study was to investigate whether prolonged the interval of TNF-inhibitor injection could maintain SpA at low disease activity and improve imaging changes of sacroiliac joint.
Methods: A total of 98 SpA patients were included and 67 of them received TNF-i with or without conventional DMARDs. TNF-i included Etanercept, Infliximab and Adalimumab. The full dosage treatment was defined as patients received Etanercept 50 mg per week, Infliximab 4 mg/kg at 0, 2, 6 week and Adalimumab 40 mg every two weeks. The dose of Etanercept was gradually reduced to 50 mg every two weeks, 50 mg every three weeks and then 50 mg per month. The infusion of Infliximab was reduced to every 8 weeks, every 12 weeks and then every 16 weeks. The interval of Adalimumub injection was changed from 3 weeks to 4 weeks and then to two months. After full dose treatment in the first 3 months, patients who administrated TNF-i were evaluated every 3–6 months. According to laboratory tests including ESR, CRP and IgA levels, BASDAI, BASFI, ASDAS results and sacroiliac joint SPARCC scores, the interval of TNF-i treatment was prolonged gradually. Fat metaplasia, bone erosion, sclerosis and ankylosis changes on MRI were compared between baseline, 4–6 months and 1–2 years.
Results: After 3 months of treatment, inflammatory indexes, BASDI, BASFI, ASDAS and SPARCC scores were significantly lower than baseline ($P<0.05$). After 4–6 months of treatment, ESR, CRP and IgA levels were greatly lower than before (8 (3,25) *vs.* 2 (1,3) mm/h, 4.97 (1.83,14.5) *vs.* 1.71 (1.24,2.82) mg/l, 2.96±1.34 *vs.* 2.20±1.01mg/l, Table 1, $P<0.01$). Compared to baseline, significant reduction of BASDAI and BASFI score was observed in TNF-inhibitor

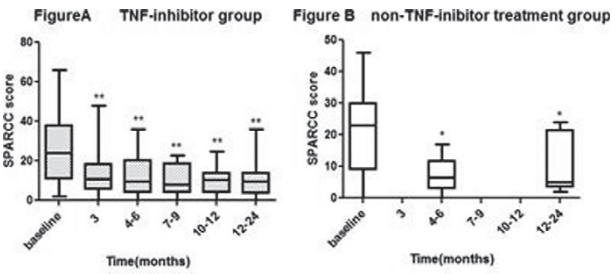

Figure 1 SPARCC score changes in TNF-inhibitor(A) and non-TNF-inhibitor(B) treatment group

Abstract THU0399 – Table 1. ESR, CRP and IgA changes before and after treatment

		Baseline	3 months	4–6 months	7–9 months	9–12 months	12–24 months
ESR (mm/h)	TNF-inhibitor	8 (3,25)	2 (1,3.75)**	2 (1,3)**	7 (2,9)	2.93 (2,6)	5.05 (2,17.75)
	non-TNF-inhibitor	10 (5,36)	–	2 (2,8)	–	–	4 (0.5,10.5)
CRP (mg/L)	TNF-inhibitor	4.97 (1.83,14.5)	1.54 (1.03,3.02)*	1.71 (1.24,2.82)**	4.89 (1.95,8.75)	2.01 (1.25,4.37)	4.21 (1.0,10.83)
	non-TNF-inhibitor	6.85 (3.11,16.05)	–	1.95 (1.59,5.34)	–	–	4.72 (1.8,7.43)
IgA (mg/L)	TNF-inhibitor	2.96±1.34	1.88±1.38	2.20±1.01**	1.92±1.63	1.78±1.32	2.45±1.63
	non-TNF-inhibitor	3.47±1.63	–	1.95±1.35	–	1.79±2.53	1.47±1.48

*P<0.05, **P<0.01.

group. The SPARCC scores in TNF-i group also decreased significantly (Figure1, $P<0.01$). There was no significant progress in fat metaplaisa, bone erosions, sclerosis and ankylosis during the follow-up period ($P>0.05$). Even though the inflammatory indexes and clinical evaluation of non-TNF-i group did not improved remarkably, SPARCC score were significantly reduced at 4–6 months and 1–2 years ($P<0.05$).
Conclusions: TNF-i could reduce clinical and imaging inflammatory degree. Prolonged the interval of TNF-i treatment could maintain low disease activity and improve bone marrow edema, whereas fat metaplasia, bone erosion, sclerosis and ankylosis were not exacerbated.

THU0400 RISK FACTORS OF SAGITTAL TRANSLATION AFTER PEDICLE SUBTRACTION OSTEOTOMY ON ANKYLOSING SPONDYLITIS

Y.-S. Park, J. Kim, J.-S. Park. *Department of Orthopaedic Surgery, Hanyang University Guri Hospital, Guri city, Korea, Republic Of*

Background: Few studies on sagittal translation and its risk factors after pedicle subtraction osteotomy (PSO) in ankylosing spondylitis (AS) patients have been conducted. There is also no study on overall evaluation of radiologic parameters as the candidate of its risk factor.
Objectives: The aim of this study was to report the cases of sagittal translation which developed after PSO in AS patients with kyphotic deformity and to analyze its risk factors
Methods: The subjects of this study were 53 AS patients (58 cases) who underwent PSO to correct their kyphotic deformity between March 2006 and August 2016. The 53 subjects consisted of 45 males and 8 females. Their mean age was 39.3 12 Tit'>7.9 (range: 29–67). After osteotomy, the patient was examined for the presence of sagittal translation in the correction site through intraoperative radiograph. The low modified Stoke AS spine score (mSASSS) was measured before the surgery. The vertebral parameters such as lumbar lordosis angle, thoracic kyphotic angle, and sagittal vertical axis, and the pelvic parameters such as pelvic incidence, pelvic tilt, and sacral slope were also measured before and after the surgery.
The subjects were grouped according to the presence and absence of sagittal translation, and their radiologic parameters were compared. In addition, the correlation between sagittal translation and each parameter was analyzed. Complications that developed during and after the surgery were also analyzed.
Results: Sagittal translation developed in 16 subjects (30%) or 17 cases (29.3%). The mean lumbar lordosis angle and the mean sagittal vertical axis of both the sagittal translation (ST) group and the non-sagittal translation (Non-ST) group were successfully corrected (p=0.000, respectively). A significant difference in preoperative mean sacral slope was observed between the groups (p=0.045). The ST group showed a significantly higher mSASSS (48.1±20.7) than the Non-ST group (36.8±16.2) (p=0.002). In the multivariate regression analysis, sagittal translation was positively correlated with mSASSS (odds ratio 1.34, P=0.002) and the preoperative sacral slope (odds ratio 1.46, P=0.009), and negatively correlated with the difference between preoperative and postoperative thoracic kyphotic angle (odds ratio 0.68, P=0.01). Both groups showed no finding of permanent neurologic complication after the surgery.
Conclusions: The incidence of sagittal translation after pedicle subtraction osteotomy was closely related with the severity of ankyloses in AS patients. Therefore, when pedicle subtraction osteotomy is performed for AS patients with severe ankyloses and high sacral slope, it is required that surgeon consider sagittal translation which could induce neurologic complication.

THU0401 ULTRASOUND EVALUATION IN FOLLOW-UP OF URATE-LOWERING THERAPY IN GOUTY PATIENTS: THE USEFUL STUDY

M. Forien[1], E. Norkuviene[2], P. Richette[3], G. Mouterde[4], H.-K. Ea[3], F. Lioté[3], M. Petraitis[2], T. Bardin[3], J. Ora[3], P. Dieudé[1], S. Ottaviani[1]. *[1]Rheumatology, Hôpital Bichat, Paris, France; [2]Rheumatology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Rheumatology, Lariboisière Hospital, Paris; [4]Rheumatology, Lapeyronie Hospital, Montpellier, France*

Background: Ultrasonography (US) has demonstrated its ability to detect urate deposition in gouty patients. Some US features have been suggested to be specific such as tophus and the double contour (DC) sign. In contrast to the usefulness of US for diagnosis, data are lacking on its role in follow-up of gout deposition after initiation of urate-lowering therapy (ULT).
Objectives: We aimed to determine the ability of US to show disappearance of urate deposits in gouty patients requiring ULT.
Methods: We performed a 6-month multicentre prospective study. To be included in the study, patients needed to have: i) a proven gout (identification of monosodic urate crystal in synovial fluid analysis or tophus aspiration), ii) presence of US features of gout (tophus and/or DC sign) at knee and/or first metatarsophalangeal joints (MTP1s). Serum uric-acid (SUA) level was assessed at baseline, M3 and M6. US evaluations were performed at baseline, M3 and M6 after starting ULT, by one local rheumatologist, blinded to SUA levels and clinical data. The primary outcome was the decrease (absolute value and percentage of decrease) of US tophus after 6 months of ULT, according to the final SUA levels. The secondary outcome was the mean percentage of joint sites with DC sign disappearance. Three stages of SUA levels were defined (high SUA levels: >360 μmol/l, low SUA: 300 -360 μmol/l, very low SUA: <300 μmol/l.
Results: A total of 79 gouty patients (mean ± SD age 61.8±14 years, 91% of males) were included. The mean disease duration was 6.3±6.1 years. Tophi were found at clinical exam in 29% of patients. Baseline SUA levels were 530±97 μmol/l. At least one US tophus and DC sign were found in 74 (93.7%) and 68 (86.1%) of patients, respectively. Allopurinol and febuxostat was started in 26 (33%) and 53 (67%) patients, respectively. A total of 67 patients were completers at 6 months. Among those M6 completers, 39 and 18 patients achieved a very low and low SUA levels, respectively. The 10 remaining patients maintained high SUA levels. Comparison of US features of gout modifications between the 3 groups of final SUA levels revealed a higher decrease of US tophus size and higher proportion of DC sign dissolution among patients with lowest SUA levels (Table 1). Additionally, final M6 SUA levels was associated with: decrease size of tophus (r=0.5093 [0.3012; 0.6711], P<0.0001), percentage of decrease of the tophus size (r=0.5352 [0.3332; 0.6902], P<0.0001) and inversely correlated with the proportion of DC sign dissolution (r=-0.624 [-0.763; -0.4298]).

Table 1. Modifications of US features of gout after 6 months of ULT

M6 SUA levels, mmol/l	SUA <300 N=39	SUA 300–360 N=18	SUA >360 N=10	P*
Delta size tophus, mean ± SD mm	-6.5±4.1	-4.4±3.0	-0.0±1.5	P=0.00046
% of decrease of tophus	-56.6±32.9	-31.5±24.3	-10.3±17.2	P=0.00028
% of joint site with DC sign dissolution	80.8	59.9	1.1	P<0.0001

*Kruskal-Wallis test. DC: double contour; SD: standard deviation; SUA: serum uric acid levels.

Conclusions: US is able to detect decrease or disappearance of US urate deposits after ULT. Additionally, the decrease of US deposits is strongly correlated with lowest SUA levels. These data suggest that US could be useful for ULT management in gouty patients.

THU0402 ULTRASONOGRAPHY AND DUAL-ENERGY CT (DECT) DO NOT PROVIDE THE SAME QUANTIFICATION OF URATE DEPOSITION IN GOUT: RESULTS FROM A CROSS-SECTIONAL STUDY

T. Pascart[1], A. Grandjean[2], L. Norberciak[3], V. Ducoulombier[2], M. Motte[2], H. Luraschi[2], M. Vandecandelaere[2], C. Godart[2], E. Houvenagel[2], N. Namane[2], J.-F. Budzik[4]. *[1]Rheumatology; [2]Hopital Saint Philibert, LOMME, France; [3]Biostatistics; [4]Radiology, Hopital Saint Philibert, LOMME, France*

Background: Gout is due to monosodium urate (MSU) deposition in joints and soft tissues. Ultrasonography (US) and dual-energy CT (DECT) have been shown to be effective in detecting MSU deposits. Both techniques can examine tophi size. DECT is effective to identify soft-tissue MSU deposits and US can show joint deposition with the double contour (DC) sign. It is unknown if these two techniques provide the same quantification of the extent of urate deposition on a given patient.
Objectives: The main objective of this study is to compare the tophus size measured by US and by DECT. The secondary objective is to evaluate the correlation between the prevalence of the US DC sign and the global volume of urate deposits measured by DECT.
Methods: This prospective cross-sectional study included patients fulfilling the 2015 ACR/EUALR criteria for gout. Patients underwent US and DECT examinations of their knees and feet. The largest US tophi was selected as the index tophus. US examination of the DC sign was performed on the femoro-patellar joints, talo-crural joints and 1st metatarsophalangeal joints. Total volume of urate deposits of knees and feet was measured by DECT. The primary endpoint was the intra-class correlation coefficient (ICC) of the volume of the index tophus measured by US and DECT [CI 95%].
Results: A total of 64 patients were included in the study, of which 35 patients presented with at least one US tophus. Patients were in average 64.5±16.3 years old, 84.4% were male, had an average ACR/EULAR score of 13.6±2.5, and disease duration was 12±14.7 years. Overall, 44 patients (68.8%) were currently taking urate lowering therapy and 22 patients (34.4%) had clinical tophi. Out of the 35 US selected largest tophi, 6 tophi were not seen in DECT. Of the tophi identified with both techniques, 21 were localized in the feet and 8 in the knees. The ICC of the tophus volume assessment by US and DECT was 0.45 [0.12–0.69]. The average volume of the largest US tophi was 2.7±6.5 cm^3 and 1.5±3.3cm^3 when measured by DECT. If the index tophus was localized in the knee, the ICC was 0.36 [0–0.82] and was 0.68 [0.37–0.86] if the tophus was in

the foot. The Spearman correlation coefficient between the DECT urate volume and the number of joints with a positive DC sign was 0.15.
Conclusions: US and DECT do not provide the same assessment of tophus size. The correlation is improved when considering tophi localized in the feet. The number of joints with positive DC sign does not correlate to the volume of urate deposition in the soft tissues measured by DECT.

THU0403 URATE-LOWERING TREATMENT AND RISK OF INCIDENT UROLITHIASIS IN PEOPLE WITH GOUT: A NESTED CASE-CONTROL STUDY

C.-F. Kuo, J.-S. Chen. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

Background: A higher risk of urolithiasis has been reported in gout patients. However, whether urate-lowering treatments, including both xanthine oxidase inhibotors and uricosuric agents, are beneficial to reduce the risk or urolithiasis in gout patients has not been examined.
Objectives: To investigate the independent associations between urate-lowering treatment (ULT) and the risk of urolithiasis in incident gout patients.
Methods: We conducted a nested case-control study based on the Taiwan National Health Insurance Research Database (NHIRD), which was used to identify 473,858 newly diagnosis gout patients during the period from January 1, 2000 through December 31, 2004. All these patients were followed until December 31, 2013. We considered patients who first diagnose incident urolithiasis after the date of entry cohort (gout onset) as cases and the diagnostic date was defined as index date. Each case was matched up to five eligible controls whose follow-up period included the case's index date by sex, birth of year and gout diagnosis year. And the index date of case was assigned to the matched controls. Odds ratios (ORs) and 95% confidence interval (CI) of urolithiasis associated with cumulative defined daily dose (cDDD) of xanthine oxidase inhibitor and uricosuric agents were main ourcome measures.
Results: Gout patients with incident urolithiasis (n=32,654) occurring after the initial diagnosis of gout aged 20–79 were age- and sex-matched 1:5 to 163,270 gout patients without urolithiasis. After adjusting for age, sex, urbanization status, income, occupation, and pertinent drugs and comorbidities, the OR of urolithiasis associated with use of ULT among gout patients were 1.04 (95% CI 1.00 to 1.07) for those with 28–90 cDDD, 0.95 (95% confidence interval 0.91–0.99) for 91–365 cDDD and 0.77 (95% confidence interval 0.73–0.82) for >365 cDDD, compared with those with a cDDD <28. The OR (95% CI) for urolithiasis associated with xanthine oxidase inhibitor use was 0.94 (0.89–0.99) for 28–90 cDDD, 0.90 (0.84–0.97) for 91–365 cDDD and 0.73 (0.63–0.83) for >365 cDDD. For uriscouric agents, the OR (95% CI) for urolithiasis among those with 28–91, 91–365 and <365 cDDD were 1.04 (1.01, 1.08), 0.94 (0.90–0.98) and 0.78 (0.73–0.84), respectively.
Conclusions: Higher ULT consumption was associated with a lower risk of urolithiasis. Xanthine oxidase inhibitors associated with reduced urolithiasis risk consistently across the range of consumption studied but for uricosuric agents inadequate cumulative dose results in a higher risk despite the risk reduced gradually with a higher cumulative dose.

THU0404 SELF-REPORTED SEVERITY OF GOUT IN A PRIMARY CARE SETTING AND ASSOCIATED FACTORS – RESULTS FROM A GOUT SURVEY IN PRIMARY CARE

A.J. Landgren, M. Dehlin, U. Bergsten, V. Sigurdardottir, P. Drivelegka, T. Zverkova Sandström, L. Jacobsson. *Department of Rheumatology and Inflammation Research, Institution of Medicine, Sahlgrenska Academy. University of Gothenburg., Gothenburg, Sweden*

Background: Patients with gout are usually seen in primary care. There are numerous reports regarding severity of gout in cohort studies and patients seen in more specialized care, less is known about the spectrum of severity of the disease in primary care.
Objectives: To describe the pattern of self-reported disease severity of gout and predictors thereof in a primary care setting.
Methods: All patients above 18 with an ICD10-diagnosis of gout at a health care visit in primary care (Jan 2015 through Aug 2016) were identified from primary care within the Western Sweden Health Care Region (WSHCR). 941 patients were identified and included in the study. They were sent a questionnaire with questions regarding comorbidities, demographics, gout characteristics and Health Assessment questionnaire (HAQ) reflecting disability. Self-reported disease severity was assessed by a three-level Likert scale (mild, moderate, severe). Possibly associated factors were analyzed by bivariate logistic regression (binary outcome: mild vs. moderate/severe) models and factors that were statistically significant were further analyzed by multivariate analysis.
Results: The response rate was 54%. Response rates were significantly lower in women overall and in men under the age of 50. Covariates that were significantly associated with more severe self-reported severity of gout in the bivariate logistic regression models (Table 1) were: female sex, hyperlipidemia, higher number of previous attacks, attack during last month, HAQ. In the multivariate analysis objective measures of gout severity such as more than ten previous attacks and attack during last month were strongly associated with the patients grading of severity, in addition to presence of hyperlipidemia (Table 1).

Table 1. Characteristics of gout patients stratified by disease severity and logistic regression models

Covariates	Mild* n=272	Moderate* n=130	Severe* n=62	Univariate analyses** OR (95% CI)#	Multivariate analyses (OR (95% CI)#
Age in years (mean)	70.8	71.9	71.8	1.01 (0.99–1.02)	N/A
Female sex (%)	12.9	18.5	22.6	1.67 (1.01–2.76)	1.54 (0.85–2.80)
Education ≤9 years (%)	24.8	27.6	46.6	1.46 (0.97–2.21)	N/A
Diabetes (%)	22.8	27.1	27.4	1.29 (0.84–1.98)	N/A
Kidney disease (%)	6.6	9.3	11.3	1.59 (0.81–3.12)	N/A
BMI (mean)	27.9	28.2	27.8	1.02 (0.97–1.06)	N/A
Hyperlipidemia (%)	29.4	44.2	46.8	2.00 (1.36–2.95)	2.13 (1.39–3.28)
Duration of gout in years (mean)	10.4	11.2	8.5	1.00 (0.98–1.01)	N/A
Total number of attacks (%):					
1	19.5	6.4	12.1	ref	ref
2–5	50.0	40.8	39.7	1.93 (1.01–3.67)	1.51 (0.77–2.96)
6–10	14.8	20.8	13.8	2.98 (1.42–6.25)	2.12 (0.97–4.62)
>10	15.6	32.0	34.5	5.00 (2.48–10.09)	3.15 (1.49–6.65)
Attack during the last month (%)	11.5	30.4	30.6	3.43 (2.10–5.61)	1.81 (1.36–2.41)

HAQ§ (mean)	0.24	0.29	0.51	1.56 (1.09–2.24)	1.20 (0.80–1.81)
Tophus (%)	14.3	21.3	4.8	1.17 (0.69–1.98)	N/A

*Self-reported disease severity. **ORs reflects yes vs no for dichotomous covariates, per year for age and duration and per unit for HAQ. #Moderate/severe vs mild, ¶Urate-lowering therapy. § Health assessment questionnaire.

Conclusions: Over 40% of patients with gout in a primary care setting rated their disease as moderate or severe. The validity of the patients rating was supported by other covariates reflecting disease severity. The observations that women and those with hyperlipidemia reported a more severe disease needs to be further explored.

THU0405 KILLING TWO BIRDS WITH ONE STONE? THE DASH DIET AND THE RISK OF GOUT: 26-YEAR FOLLOW-UP OF A PROSPECTIVE COHORT

S.K. Rai[1], T.T. Fung[2,3], N. Lu[1], S.F. Keller[1], G.C. Curhan[4,5], H.K. Choi[1,4]. *[1]Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital; [2]Department of Nutrition, Harvard T.H. Chan School of Public Health; [3]Department of Nutrition, Simmons College; [4]Channing Division of Network Medicine, Department of Medicine; [5]Renal Division, Department of Medicine, Brigham and Women's Hospital, Boston, United States*

Background: The Dietary Approaches to Stop Hypertension (DASH) diet, which reduces blood pressure and is recommended in cardiovascular disease (CVD) (1,2), has also been found to lower serum uric acid (SUA) levels, particularly among those with hyperuricemia (3). Thus, the DASH diet may be particularly useful in gout care by reducing both SUA and CVD risk, especially among patients with hypertension which affects 74% of gout patients (4), thereby "killing two birds with one stone". However, corresponding data for the risk of gout are not available. In contrast, a Western dietary pattern may increase the risk of gout.
Objectives: To prospectively examine the relation between the DASH and Western dietary patterns and the risk of gout among men.
Methods: Using the Health Professionals Follow-up Study, we prospectively examined the relation between the DASH and Western diets and incident gout in 44,444 male participants with no history of gout at baseline. Using validated food frequency questionnaires, each participant was assigned a DASH score (reflecting high intake of fruits, vegetables, nuts and legumes, low-fat dairy products, and whole grains, and low intake of sodium, sweetened beverages, and red and processed meats) and a Western pattern score (reflecting higher intake of red and processed meats, French fries, refined grains, sweets, and desserts). We identified incident cases of gout meeting the preliminary ACR survey criteria for gout, adjusting for potential confounders including age, total energy intake, body mass index (BMI), diuretic use, history of hypertension, history of renal failure, and intake of alcohol and coffee. We conducted stratified analyses to evaluate whether the association between the DASH and Western pattern scores and the risk of gout varied according to BMI, alcohol use, and hypertension status.
Results: During 26 years of follow-up, we documented 1,731 confirmed cases of incident gout. A higher DASH score was associated with a lower risk for gout (multivariable relative risk [RR] for extreme quintiles, 0.68 [95% confidence interval, 0.57 to 0.80]; P for trend <0.001) (Table 1). In contrast, a higher Western pattern score was associated with an increased risk for gout (multivariable RR for extreme quintiles, 1.42 [95% confidence interval, 1.16 to 1.74]; P for trend=0.005) (Table 1). These associations persisted regardless of BMI, alcohol use, and hypertension status, and there was no significant interaction with these variables (all P for interaction >0.17).

Table 1. Relative Risk of Incident Gout According to Quintiles of DASH and Western Dietary Pattern Scores

Variable	Frequency of Intake (serving/d)					P for trend
	Q1	Q2	Q3	Q4	Q5	
DASH Diet						
Cases/PY	396/192891	391/195970	366/196511	332/192697	246/193455	
Age-adjusted RR (95% CI)	1.0	0.96 (0.83,1.10)	0.88 (0.77,1.02)	0.81 (0.70,0.94)	0.60 (0.51,0.70)	<0.001
Multivariable RR (95% CI)	1.0	0.90 (0.79,1.04)	0.87 (0.76,1.01)	0.82 (0.70,0.95)	0.68 (0.57,0.80)	<0.001
Western Diet						
Cases/PY	287/190572	347/194533	365/196671	346/197114	386/193182	
Age-adjusted RR (95% CI)	1.0	1.19 (1.02,1.39)	1.25 (1.07,1.46)	1.18 (1.01,1.38)	1.35 (1.16, 1.57)	<0.001
Multivariable RR (95% CI)	1.0	1.09 (0.93,1.28)	1.15 (0.98,1.36)	1.12 (0.94, 1.33)	1.42 (1.16, 1.74)	0.005

Abbreviations: RR, relative risk; CI, confidence interval; PY, person-years.
Age-adjusted models adjusted for age and total energy intake.

Conclusions: The DASH dietary pattern is associated with a lower risk of gout, suggesting that its urate-lowering effect among hyperuricemic individuals translates to a lower risk of gout. Conversely, the Western dietary pattern is associated with a higher risk of gout. The DASH diet may provide an attractive preventive dietary approach for the risk of gout, particularly given the high level of cardiovascular comorbidities among this patient population.

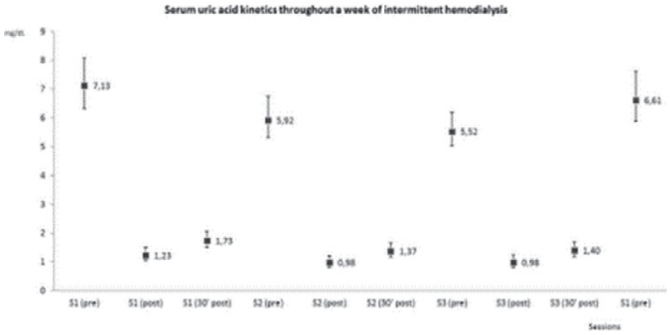
THU0406 SERUM URIC ACID LOWERING TREATMENT APPEARS UNNECESSARY DURING HEMODIALYSIS



M. Andrés[1,2], R. Soriano[1], E. Oliveira[3], C. Trigo[3], M.D. Arenas[4], E. Pascual[2,5].
[1]Departamento de Medicina Clínica, Universidad Miguel Hernández; [2]Seccion de Reumatologia; [3]Servicio de Análisis Clínicos, Hospital General Universitario de Alicante; [4]Unidad de Nefrología, Hospital Vithas Perpetuo Socorro; [5]Emeritus Professor, Universidad Miguel Hernández, Alicante, Spain

Background: Gout patients often suffer from renal disease, some ultimately developing end-stage renal disease (ESRD) and requiring hemodialysis (HD) replacement therapy. Though some reports suggested that tophi disappear after HD, urate-lowering agents are frequently continued, often based on persistent high SUA levels before HD. Also, the impact of SUA levels in the survival of patients on hemodialysis (HD) is under discussion.

Objectives: To assess the SUA reduction achieved under HD and analyze the kinetics of SUA in a week of intermittent HD.

Methods: SUA levels were determined before and after HD sessions in consecutives 96 patients with end-stage renal disease (ESRD), and compared through paired samples Student's t test. Variables related to HD were analyzed whether associated with SUA reductions ≥80% using Student's t test or ANOVA. Also, a kinetics study on selected 10 patients with hyperuricemia (SUA before HD>6.8 mg/dL) throughout intermittent HD sessions in a week period was performed; differences in SUA levels were analyzed by repeated measures ANOVA.

Results: Patients were mean aged 66.5 years (SD±13.8), 62 males (64.6%). Mean time on HD replacement was 7.1 years (±7.2). Before starting HD, 43.0% had hyperuricemia and 21.6% reported gout. Sixteen (16.4%) continued on urate-lowering agents after HD. Mean SUA levels before and after HD session was 5.2mg/dL (± 1.0) and 1.0mg/dL (±0.4), respectively. Mean SUA reduction following HD was 80.2% (95% CI 78.4–82.0); 51 patients (56.7%) showed SUA reduction ≥80%. HD-related variables Kt/v<1.3 (p=0.006) and blood efflux<400mL/min (p=0.004) significantly associated with achieving SUA reduction ≥80%. Figure shows the SUA kinetics study: SUA significantly reduced all over the period and persisted below hyperuricemia threshold (p=0.015).

Conclusions: Under HD replacement therapy SUA levels effectively reduced and persisted below saturation point, suggesting that urate-lowering therapy appears unnecessary for patients with gout and ESRD.

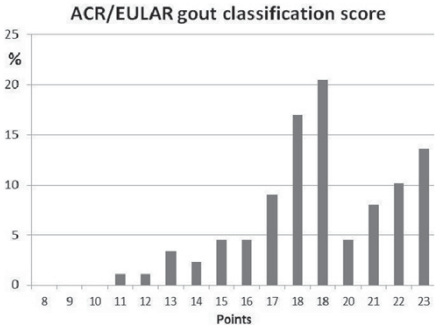
THU0407 HIGH GOUT CLASSIFICATION SCORE IS ASSOCIATED WITH ULTRASOUND FINDINGS IN PATIENTS WITH CRYSTAL-PROVEN GOUT



T. Uhlig, L.F. Karoliussen, E.A. Haavardsholm, T.K. Kvien, H.B. Hammer.
Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

Background: The recent ACR/EULAR classification (1) classify gout in patients with at least 8 out of maximum 23 points, but presence of monosodium urate crystals in a symptomatic joint/tophus alone is sufficient for gout classification without need for further scoring. It is not known how in crystal-proven patients with increased serum urate (sUA) the whole range of classification points distribute.

Objectives: To determine the distribution along the spectrum of ACR/EULAR criteria in crystal-proven patients with insufficiently treated sUA levels, and if disease factors in gout are associated with high classification scores.

Methods: Baseline data from a prospective observational study were used from patients with crystal-proven gout who presented after a recent gout flare. Included patients had at baseline insufficiently treated sUA level (>360 μmol/L [>6 mg/dl]). Demographic, clinical data and sUA levels were collected from September 2015 to December 2016 in one rheumatology department. Ultrasound of joints was assessed with one total score for double contour sign, tophus, and aggregates in several joints and tendons/entheses. The score for ACR/EULAR criteria for gout was calculated.

Results: 89 patients were included, with baseline mean (SD) age 56.0 (14.8) years, 92% males, 88% Caucasians, disease duration 7.9 (7.3) years, presence of palpable tophi 19%, ultrasound score 19.9 (13.8), serum urate 486 (90) μmol/L, creatinine 78 (18) ml/min, creatinine clearance 78 (18) ml/min, ESR 14 (14) mm/h, body mass index 29.4 (4.9) kg/m^2, comorbidity score [SCQ] 3.5 (3.2), and physical function [HAQ] 0.34 (0.51). All patients satisfied clearly the scoring arm of the classification criteria with a median (range) 19 (11 – 23) of 23 possible points (Figure 1). Patients with a median and higher score above the median (≥19 points) vs. lower score reported more gout flares during the last 12 months (p<0.001), had longer disease duration (9.2 vs. 6.2 yrs, p=0.05), and a higher ultrasound score (23.9 vs. 14.9, p=0.001). The groups with high and low scores were similar for age, gender, ethnicity, level of education, BMI, physical function, comorbidity score, sUA level and kidney function.

Conclusions: As expected, patients seen in the clinic with crystal-proven gout and at least slightly increased sUA also satisfy the scoring arm of the new classification criteria for gout, supporting their clinical use. Patients with classification points above the median had more flares in the preceding year, and a higher urate burden assessed by ultrasound, but did not have other indicators for a more severe disease.

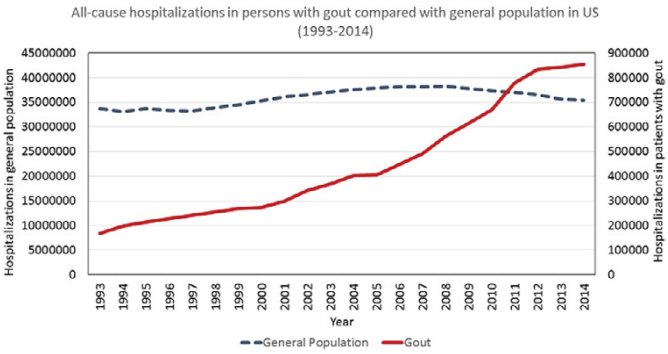
THU0408 GOUT IS AN IMPORTANT PREDICTOR OF WORK DISABILITY IN BOTH MEN AND WOMEN

V. Sigurdardottir[1,2], P. Drivelegka[1], A. Svärd[2], L.T. Jacobsson[1], M. Dehlin[1].
[1]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg; [2]Centre for Clinical Research Dalarna, Falun, Sweden

Background: Gout is the most common form of inflammatory arthritis with a prevalence of 1.5% in our area in the age group 50–59 years (1). Gout has a

substantial association with several comorbidities. Studies on the impact of gout on work disability on a population level are scarce.
Objectives: The primary objective of the study was to investigate if gout was a predictor of work absenteeism exceeding 90 days in a calendar year, controlling for comorbidites and socioeconomic status in men and women separately. Another aim of the study was to explore if urate lowering therapy (ULT) attenuated the risk of work disability for gout cases.
Methods: Gout cases were defined in the population based health care database (VEGA) of the Western Swedish Health Care Region (WSHCR) by having a first diagnosis of gout in the years 2003–2009 by ICD-10 codes (M10 and M14.0) in VEGA. Cases were included if their age at the time of diagnosis of gout was ≤62 years. Five controls for each case, matched for age, sex and place of residence were chosen from the census register by Statistics Sweden. Individuals with any work disability in the year before the index year were excluded from analysis. Data on predefined comorbidities registered previous to the index year was collected from VEGA by ICD-10 codes. Data on prescribed medications was collected from the national prescription database. Data on educational level, income and number of days per calendar year with sick-leave and disability pension was provided by Statistics Sweden. Conditional logistic regression taking into account the 1-to-5 matched design of the study was performed in individuals without work disability in the year before the index date for the outcome of ≥25% (≥90 days) work disability in the year after the index year. Possible predictors of work disability for gout cases were analyzed using logistic regression
Results: 3068 incident gout cases (females N=554 (18%)) of working age without prior work disability were matched to 15,077 population controls. After matching, 3258 controls with prior work disability were excluded leaving 11,819 controls for analysis. Of the women with gout, 69 (12.5%) became ≥25% work disabled in the year after the index-year as opposed to 117 (6.1%) of the female controls, p<0,0001. 163 men with gout (6,5%) became ≥25% disabled vs. 377 (3.8%) of male controls, p<0,0001. After adjusting for comorbidities and educational level gout increased the risk of work disability to a similar extent for men (OR 1.4, 95% CI 1.2–1.8) and women (OR 1.9, 95% CI 1.4–2.6). Cardiovascular and renal comorbidity as well as alcoholism, female sex and low educational level (less than 12 years) were important predictors of work disability in gout patients whereas receiving ULT during the time period being studied did not attenuate the risk (OR 0.8, 95% CI 0.5–1.1).



Conclusions: Gout is a significant independent predictor of work disability in both men and women. ULT did not attenuate the risk of work disability early after diagnosis for gout cases in this study, possibly explained by under-prescribing and sub-optimal dosage as previously shown in our region (1).

THU0409 NOT JUST A SWOLLEN BIG TOE: INCREASING ALL-CAUSE HOSPITALIZATIONS IN PATIENTS WITH GOUT IN THE UNITED STATES: 1993–2014

G. Singh[1], A. Mithal[2], A. Mithal[3]. [1]*Gastroenterology and Hepatology, Stanford University;* [2]*Student;* [3]*Epidemiology, ICORE, Woodside, United States*

Background: Gout is a disorder of uric acid metabolism and often presents as acute severe joint pain. However, several recent studies have highlighted systemic complications of associated hyperuricemia in patients with gout, including possible increased risk of renal and cardiovascular comorbidities.
Objectives: To study all-cause hospitalizations in patients with gout in the United States (US) from 1993 to 2014.
Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary or secondary diagnosis of gout, and compared them to total all-cause US hospitalizations during the same period. US population estimates and projections for the resident US population were obtained from the US Census Bureau.
Results: There were 789.8 million all-cause hospitalizations in 6.4 billion person-years of observation from 1993 to 2014 (123.4 hospitalizations per 1,000 person-years). During this time-period, 9,741,598 hospitalizations occurred in patients with gout (152.2 per 100,000 person-years). All-cause US hospitalizations increased from 33.7 million in 1993 to 35.4 million in 2014, an increase of 4.8% over 22 years (Figure, dotted blue line). All-cause hospitalizations in gout patients have increased from 167,441 in 1993 (64.2 per 100,000 person-year) to 854,475 in 2014 (267.9 per 100,000 person-years, a dramatic increase of over 410% (p<0.0001, Figure solid red line). In 2014, hospitalizations in gout patients accounted for over 4.6 million hospital days at a total national cost of over US $42.6 billion.

Conclusions: All-cause hospitalizations in patients with gout in the US have significantly increased by 410% in the last 22 years, almost hundred-fold of the 4.8% increase in US population all-cause hospitalization rate in the same time-period. This calls for an increase need for identification and management of serious co-morbid conditions in patients with gout.

THU0410 GOUT AND THE RISK OF INCIDENT ERECTILE DYSFUNCTION: A BODY MASS INDEX-MATCHED POPULATION-BASED STUDY

N. Schlesinger[1], N. Lu[2], H.K. Choi[2]. [1]*Medicine, Rutgers/ Robert Wood Johnson Medical School, New Brunswick;* [2]*Medicine, Harvard Medical School, Boston, United States*

Background: Gout is the most common inflammatory arthritis. Erectile dysfunction is common in the general population; however, evidence regarding erectile dysfunction among gout patients is limited.
Objectives: Our purpose was to study whether there was an increased risk of erectile dysfunction among gout patients, as compared with the general population.
Methods: We conducted a cohort study using The Health Improvement Network, an electronic medical record database in the United Kingdom. Up to five individuals without gout were matched to each case of incident gout by age, enrolment time, and body mass index. Multivariate Hazard Ratios for erectile dysfunction were calculated after adjusting for smoking, alcohol consumption, comorbidities and medication use.
Results: We identified 2290 new cases of erectile dysfunction among 38,438 patients with gout (mean age 63.6 years) and 8447 cases among 154,332 individuals in the comparison cohort over a 5-year median follow up (11.9 vs. 10.5 per 1000 person-years, respectively). Univariate (age, entry time and body mass index-matched) and multivariate Hazard Ratios for erectile dysfunction among patients with gout were 1.13 (95% CI, 1.08 to 1.19) and 1.15 (95% CI, 1.09 to 1.21), respectively. In our sensitivity analysis, restricting gout cases to those receiving anti-gout treatment (n=31,227) the magnitude of relative risk was stronger than the primary analysis; (multivariate Hazard Ratios =1.29; 95% CI, 1.22 to 1.37).
Conclusions: This population-based study suggests an increased risk of erectile dysfunction among gout patients, supporting a possible role for hyperuricemia and inflammation as independent risk factors for erectile dysfunction.

Background: Tophus burden (TB) was proposed by OMERACT as mandatory domain for chronic gout studies. Image methods although useful, frequently are not available in daily clinical practice.
Objectives: To evaluate TB clinically in a cohort of gout patients during 3 years follow-up.
Methods: We analyzed baseline and follow-up data (6, 12, 18, 20, 24, 30 and 36 months) of patients with gout (ARA/CGD/ACR-EULAR) from the GRESGO cohort; this analysis includes the patients with ≥1 clinical nodule(s) considered as tophi in the baseline visit. Index tophi size (ITS) was considered as the longer axis of the bigger tophi. TB evaluations: 1) Tophi number (T); 2) ITSt (cm) measured with tape; 3) ITSca (cm), measured with caliper; 4) ITSco, measured with compass. 5) Index tophi hardness (ITh) or consistency, by VAS (0: very soft-10 hard as a rock). This protocol was approved by the local IRB and patients signed and informed consent for their participation.
All the patients received treatment for gout and associated diseases according to published guides and available drugs. The evaluations were done by the same group of physicians (Rheumatologists and Residents). Variables: TB measures, demographic, clinical and biochemical variables. HAQ and EUROQoL and VAS for pain and general health. Inter/intraobserver variability were evaluated. Statistical analysis: t test, X2, r, kappa, Friedman and multiple correlation.
Results: 298 patients; 97%males, 203 (68%) tophaceous gout, age, age at onset and duration of the disease were: 46.4±12.7 32.4±12.4 and 14.7±9.3 years respectively. Available ULT: Allopurinol and probenecid, colchicine as prophylaxis. Mean allopurinol dose prescribed at baseline visit was 346.9±154 mg/d and 550±205 mg/d 3 years later.TB values (see table). Index tophi size had r>0.93 among the 3 evaluations (ITSt, ITSca, ITSco) and r<0.3 with ITh. Inter and intraobserver variability was 0.8 and 0.9 respectively; there was significant improvement *(p<0.001) in ITS, sUA, painful, swollen, limited to motion joints, HAQ, EuROQoL, VAS pain, VAS health (patient and physician) also improved significantly.

	Baseline	6mo	12mo	18mo	24mo	30mo	36mo
ITSt*	6.4±3.7	5.9±3.7	5.6±3.7	5.7±3.9	5.2±4.0	5.6±3.3	4.5±3.3
ITSca	5.1±2.8	4.6±2.7	4.7±2.6	4.7±2.9	4.4±2.7	4.6±2.4	3.6±1.9
ITSco	5.1±3.0	4.6±2.8	4.7±2.7	4.9±3.0	4.3±2.8	4.6±2.5	3.8±1.8
ITh	7.3±1.7	6.8±1.9	7.1±1.6	6.7±1.9	6.5±1.8	6.6±2.0	6.3±1.6
HAQ*	0.6±0.7	0.4±0.5	0.3±0.5	0.4±0.4	0.3±0.4	0.4±0.5	0.2±0.4
AGA*	8.3±12	0.8±1.3	0.6±2.6	0.3±0.8	0.2±0.6	0.2±0.4	0.3±0.6
sUA*	8.3±2.2	7.3±2.0	6.8±1.9	6.3±1.9	6.3±2.5	5.5±1.6	5.8±1.8
Allopurinol*	347±154	445±165	477±178	491±180	534±205	504±183	556±193

Values represent mean and SD. *p<0.01 ITS in cm; ITh: VAS in cm. AGA number of acute attacks in the last 6 months. sUA: mg/dL, allopurinol dose mg/day.

Conclusions: In our cohort, ITSt was the best measure for TB evaluation, the 3 ITS measures had a good correlation between them and less with ITh or consistency. Patients with tophaceous gout, improved significantly with allopurinol and probenecid during 3 years follow-up in TB (ITSt) as well according to the other OMERACT proposed domains for chronic gout.

THU0412 TREATMENT WITH NERIDRONATE IN CHILDREN AND ADULTS WITH OSTEOGENESIS IMPERFECTA: DATA FROM OPEN-LABEL, NOT CONTROLLED, THREE-YEAR ITALIAN STUDY

A. Fassio, L. Idolazzi, O. Viapiana, C. Benini, E. Vantaggiato, A. Giollo, M. Rossini, D. Gatti. *Rheumatology, Aoui Verona Reumatologia, Verona, Italy*

Background: Osteogenesis Imperfecta (OI) is a rare generalized connective tissue disease. Its main features are skeletal fragility and substantial growth deficiency [1]. Currently, bisphosphonates showed to increase bone mineral density (BMD). A positive effect on prevention of fractures both in adults and in children is reported by some studies, but generally data are still inconsistent [2].
Neridronate is an amino-bisphosphonate licensed in Italy for the treatment of OI.
Objectives: to assess the long-term efficacy and safety of the treatment in patients with OI.
Methods: the patients were divided by age into two groups and observed for 3 years: 55 patients younger than 20 years old and 114 patients older than 20 years old. Neridronate was administered by i.v. infusion at the dosage of 2 mg/kg, up to a maximum of 100 mg at three months intervals. DXA of the lumbar spine, hip and ultradistal radius were evaluated every 6 months. Blood calcium, phosphate, bone turnover markers and fasting urinary calcium/creatinine ratio, were obtained at baseline and every 3 months.
Results: the mean lumbar spine and total hip BMD and BMC significantly increased from baseline up to month 36 in both patients groups. The mean ultradistal radius BMD significantly increased from baseline to any time point in patients younger than 20 years, while, in patients older than 20 years, BMD significantly increased from baseline only at month 18, 30 and 36 respectively. The mean ultradistal radius BMC significantly increased from baseline to any time point in patients younger than 20 years, while there were no substantial or statistically significant changes from baseline to any time point in patients aged older than 20 years. The mean number of fractures observed in the 3 years of treatment was significantly lower than that observed in the 3 years before the start of treatment in both groups (table 1).
Most of AEs were symptoms of an acute phase reaction, which was reported in 47.3% of patients younger than 20 years and in 22.8% of those older than 20 years. Serious adverse events (SAEs) were reported in 19 patients (34.5%) younger than 20 years and in 26 patients (22.8%) aged older than 20 years. None of the reported SAEs in both groups was considered as treatment-related.

Table 1, Results of number of fractures per patient during treatment in the two patient populations

Number of fractures, mean ± SD (range)	Age ≤20 years	Age >20 years
Before treatment (3 years	2.7±2.37 (0–8)	0.6±1.28 (0–8)
During treatment (3 years)	0.9±1.43 (0–7)	0.3±0.56 (0–3)
– Wilcoxon signed rank test p-value	<0.001	0.003

Conclusions: long-term treatment with i.v.neridronate has positive effects on BMD, BMC, bone turnover markers and fracture risk with a good safety profile in both groups.

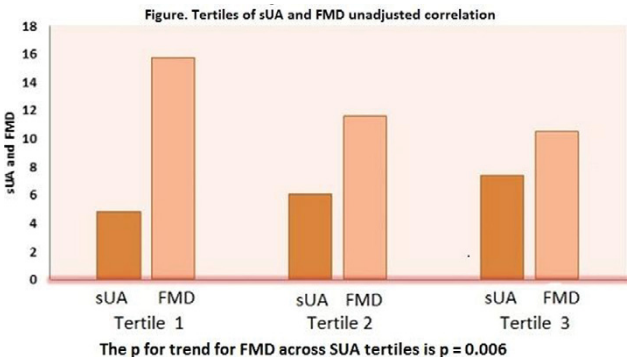
THU0413 SERUM URATE AND ITS ASSOCIATION WITH BLOOD PRESSURE AND ENDOTHELIAL DYSFUNCTION IN YOUNG ADULTS



M.B. Saddekni[1], K.G. Saag[1], T. Dudenbostel[1], D.A. Calhoun[2], S. Oparil[2], D.I. Feig[3], P. Muntner[4], P.J. Foster[1], S.R. Biggers[5], E.J. Rahn[5], P. Li[6], D.T. Redden[6], A.L. Gaffo[5]. *[1]UAB School of Medicine, Division of Clinical Immunology and Rheumatology; [2]UAB School of Medicine, Division of Cardiovascular Disease; [3]UAB School of Medicine Division of Nephrology; [4]UAB School of Public Health, Department of Epidemiology; [5]Department of Medicine, Division of Rheumatology and Immunology; [6]UAB School of Public Health, Department of Biostatistics, University of Alabama at Birmingham, Bimringham, United States*

Background: Both serum urate (sUA) and endothelial dysfunction have been associated with hypertension and cardiovascular disease. Increasing sUA level has been associated with endothelial dysfunction and higher inflammatory markers. To date, however, few studies have examined the relationship between sUA, endothelial dysfunction, and blood pressure (BP) including young and largely healthy individuals.
Objectives: To determine whether there is an association between higher sUA, endothelial dysfunction as measured by flow-mediated dilation (FMD), and BP in young adults.
Methods: We conducted a cross-sectional analysis of baseline data for consecutively enrolled individuals (age 18 – 40 years). Enrollment criteria included baseline systolic BP (SBP) ≥120 and <160 mmHg or diastolic BP (DBP) ≥80 and <100 mmHg, and sUA ≥5.0 mg/dL for men or ≥4.0 mg/dL for women. Endothelial dysfunction measured by FMD, 24- hours ambulatory BP monitoring (ABPM) and sUA level were obtained. Associations between sUA, FMD, and ABPM variables were evaluated using a general linear model. Adjustments for age, gender, race, and BMI were applied after significant univariate results.
Results: 86 participants included in the analysis. Participants recruited had a mean age (±standard deviation) of 28.5±6.9 years, 36% were female, 41% African-Americans, mean BMI was 29.2±6.8 kg/m^2, and mean sUA was 5.9±1.2 mg/dL (n=77, range from 3.9 to 8.5 mg/dL). We found no significant cross-sectional associations between sUA, FMD, and BP variables assessed by ABPM (Table). Participants in the upper tertile of sUA had significantly worse FMD than those in the lower tertiles (Figure). However, this difference was no longer significant after multivariable adjustment age, gender, race, and BMI.

Table 1. Cross-sectional correlation between sUA, FMD, and Ambulatory Blood Pressure parameters

Parameters	r	p-value
sUA and FMD	-0.112	0.351
sUA and SBP	0.037	0.766
sUA and DBP	-0.012	0.924
sUA and MAP	0.056	0.657

Conclusions: In this cross-sectional analysis of young adults, there was no evidence to support an association between sUA levels and endothelial

dysfunction or BP. Endothelial dysfunction or BP might be associated with changes in sUA when measured longitudinally in individuals, but not when measured cross-sectionally in populations. Larger studies will be needed to confirm these results.

THU0414 INCIDENCE AND PREDICTORS FOR NEPHROLITHIASIS IN GOUT PATIENTS AND THE GENERAL POPULATION

A.J. Landgren[1], L. Jacobsson[1], U. Lindström[1], T.Z. Sandström[1], E. Fjellstedt[2], P. Drivelegka[1], V. Sigurdardottir[1], L. Björkman[1], M. Dehlin[1]. *[1]Department of Rheumatology and Inflammation Research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg; [2]Department of Nephrology and Transplantation, SUS University Hospital, Malmö, Sweden*

Background: A well-known complication of gout is an increased risk for nephrolithiasis (NL). The incidence rate of NL in the general population varies in different studies between 85 and 170/100 000 person-years, with a peak incidence in the ages 40–49 years. Several medications used in gout patients could affect the risk for NL, including allopurinol, losartan, thiazide- and loop-diuretics. Effect of these medications on risk of NL in gout patients, and the general population, has only scarcely been studied.

Objectives: In this cohortstudy we investigated: 1) overall incidence of NL in gout and general population (GP) controls 2) risk for first time NL in gout patients vs general population (GP) controls, and 3) predictors for first time NL in both groups separately.

Methods: Gout patients were identified from the regional health care database in western Sweden (VEGA), containing ICD10-codes for all regional Healthcare visits from 2000. Matched (birthyear, sex, county) GP controls were selected from the population register. National registers and VEGA were used to retrieve information on comorbidities, socioeconomic factors and current medications at start of follow-up. The study population had to be above 19 years of age, without NL prior to start of follow-up, and living in the Western Swedish Health Care Region (WSHCR). Follow-up began 2006–01–01, or at the first gout-diagnosis if this occurred later, and ended at death, emigration or 2012–12–31, whichever occurred first. Incidence rates (IR) per 1000 person-years and hazardratios (HR) were calculated. Possible predictors for NL were based on risk factors presented in the literature.

Results: 29,968 gout patients and 138,678 matched GP controls were included. In gout patients there were 678 NL-events (IR: 6.2 per 1000 pyrs at risk (95% CI: 5.7–6.6)) and in GP controls 2125 (IR 3.9 per 1000 pyrs at risk (95% CI 3.7–4.0)). Risk for NL was increased in gout (HR=1.49, 95% CI: 1.35–1.64), and was higher in men compared to women (P<0.0001) in all age groups for gout cases and controls. All comorbidities and medications were more frequent in cases compared to controls (p<0.0001) at start of follow-up. Risk-factors for NL such as kidney disease (KD), obesity, diabetes were 2–4 times more common in gout patients compared to GP controls. Predictor point estimates for NL were similar in gout cases and GP controls (Figure 1), except for losartan which increased the risk of NL in GP controls (HR=1,47, 95% CI: 1.01–2.13) but not in gout patients. Loop-diuretics appeared to decrease the risk for NL in both cohorts (P<0.0001), whereas other cardiovascular (CVD) drugs had no effect.

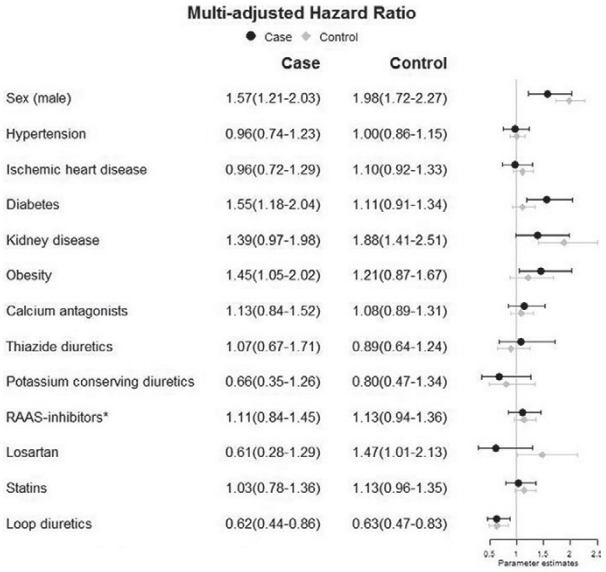

*Figure 1 Predictors for first time nephrolithiasis (NL) in patients with gout and GP controls without gout, analyzed by multivariate proportional hazards analyses, adjusting for age and other covariates in the figure, *Renin-angiotensin-aldosterone-System-Inhibitors excluding losartan*

Conclusions: The risk for NL was increased by 50% in gout patients, compared to controls. Overall pattern of predictors was similar in gout patients and population controls. In patients with gout, male sex, diabetes mellitus (DM), obesity predicted NL, whereas use of loop diuretics was protective. Overall, the most commonly used CVD drugs did not increase the risk for NL in patients with gout.

THU0415 A STRUCTURED MONITORING PROGRAM FOR DRUG ALLERGY IN PATIENTS NEWLY INITIATED ON ALLOPURINOL

B.Y. Thong[1], K.-Y. Gan[2], B.-H. Ang[2]. *[1]Rheumatology, Allergy and Immunology; [2]Pharmacy, Tan Tock Seng Hospital, Singapore, Singapore*

Background: Allopurinol allergy (drug eruption, severe cutaneous adverse reactions [SCAR] and drug induced hypersensitivity syndrome [DiHS]) develops during the first 2–12 weeks after initiation. SCAR risk factors include Chinese ethnicity, HLA-B*5801 positivity and chronic kidney disease. HLA-B*5801 testing to prevent SCAR has not been shown to be cost-effective in Singapore.

Objectives: To retrospectively study whether a structured monitoring program (SMP) can lead to early diagnosis of allopurinol allergy and prevent development of SCAR/DiHS.

Methods: SMP patients (cases) managed by rheumatologists were compared with controls managed by non-rheumatologists during the study period 1 Jan 2015 to 30 Jun 2016. Cases upon initiation of allopurinol had baseline full blood count (FBC), serum creatinine (Cr), alanine aminotransferase (ALT) and aspartate aminotransferase (AST) measured. If drug eruptions/abnormal laboratory tests developed during monitoring, allopurinol was stopped. The electronic dispensing system and computerized medical records were used for collection of patient demographics, indication for allopurinol use, initiation dose, monitoring intervals, laboratory results and clinical features of drug allergy. This was compared with the control group without an SMP. Chi square tests were used to compare differences in proportions and Mann-Whitney U test for differences in medians. P value ≤0.05 was considered statistically significant.

Results: There were 61 cases and 30 controls with comparable age (p=0.81), ethnicity (>80% Chinese) (p=0.63) and estimated glomerular filtration rate, eGFR (p=0.72). There were significantly more cases with tophaceous gout (41% vs 10%, p=0.003), while more controls tumour lysis syndrome prophylaxis (30% vs 0%, p<0.001). Median (interquartile range, IQR) starting dose of 50 (50) mg was lower among cases versus controls of 100 (200) mg (p<0.001); all cases had baseline and follow-up laboratory tests compared to controls (p<0.001). Cases were followed up at a median (IQR) of 2 (1.1) weeks after initiation then 5 (2.0) weeks after the first visit, whereas controls were reviewed 8 (8.9) weeks after initiation, then 11 (4.6) weeks after the first visit. Two patients in the SMP group with normal eGFR developed maculopapular eruption (MPE), 1 elevated ALT/AST, and 1 both MPE and elevated ALT/AST within the first 14 days of initiation. One control with lymphoma and baseline eGFR 31 ml/min/1.73m^2 developed DiHS (fever, MPE, elevated ALT/AST less than twice upper limit of normal) 43 days after initiation for tumour lysis prophylaxis. This occurred while on 2-weekly monitoring of FBC, ALT, AST. There were no cases of SCAR in both groups.

Conclusions: SMP facilitates early diagnosis of allopurinol allergy/DiHS which occurred during the first 2–6 weeks after initiation. Whether early cessation of allopurinol prevents development of SCAR, and reduces the need for HLA-B*5801 testing will require a larger prospective study.

THU0416 RAPID TOPHUS RESOLUTION IN CHRONIC REFRACTORY GOUT PATIENTS TREATED WITH PEGLOTICASE

B. Mandell[1], A. Yeo[2], P. Lipsky[3]. *[1]Department of Medicine, Cleveland Clinic, Cleveland, OH; [2]Horizon Pharma, Lake Forest, IL; [3]AMPEL BioSolutions, LLC, Charlottesville, VA, United States*

Background: It has been suggested that the velocity of resolution of tophi in persons with chronic tophaceous gout is related to the serum urate levels.[1] However, few subjects with a persistent serum urate less than 4.0 mg/dL were studied. Pegloticase is a recombinant uricase conjugated to polyethylene glycol approved in the US for treatment of patients with chronic refractory gout. It profoundly decreases serum uric acid in responders to <1 mg/dL. The results from the pegloticase clinical trials provided the opportunity to determine the impact of persistent and markedly low levels of serum urate on the velocity of tophus resolution.

Objectives: To assess the velocity of tophus resolution in subjects treated with pegloticase for chronic refractory gout.

Methods: This analysis used results from two randomized controlled trials (RCTs) of 6 months duration.[2,3] For tophus measurements, serial standardized digital photographs were analyzed by a blinded reader using computer-assisted quantitative measurement software. Subjects were defined as responders and nonresponders based upon maintenance of a serum urate <6 mg/dL during intensive monitoring periods after 3 and 6 months of treatment.

Results: During the 6 months of the RCTs, a total of 952 tophus measurements were analyzed in 87 subjects, including 341 in 30 responders; 361 in 36 nonresponders receiving pegloticase infusions; and 250 in 21 subjects receiving placebo infusions. Mean serum urate levels in these subjects were 10.1, 0.3 and 0.3 mg/dL at baseline, 3 months and 6 months in responders; 10.7, 8.9 and 9.6 mg/dL in nonresponders; and 10.2, 9.8 and 9.7 mg/dL in placebo treated patients, respectively. At baseline, the mean tophus area in responders was 581.6 +/- 742.7 mm^2 (mean ± SD; n=90 tophi); in nonresponders it was 676.5+/-1416.6 mm^2 (n=93 tophi); and in placebo treated subjects it was 672.9+/-1039.5 mm^2 (n=66 tophi). By regression analysis, the velocity of tophus resolution over the 6 months of treatment was 50.1 mm^2/month in responders; 14.0 mm^2/month in nonresponders; and 13.9 mm^2/month in placebo treated patients (responders versus nonresponders or responders vs placebo treated subjects (p=0.001)). In responders, the mean time to total tophus resolution was estimated to be 347 days (11.5 months, with a range of 5.6–36.4 months). During the 6 month treatment period, the area under the curve (AUC) of multiple serum urate measurements in responders was 6,067.9+/-6,781.6 mg/dL hr compared with 34,647.4+/-8,586.7 and 42,451.1+/-6,396.1 mg/dL·hr in nonresponders and placebo treated subjects, respectively (p<0.001). In responders, there was a significant correlation between the velocity of tophus resolution and serum urate AUC (p=0.009).

Conclusions: Pegloticase treatment causes a rapid resolution of tophi in responders as predicted from the profound and persistent serum urate lowering associated with this therapy.

THU0417 PERIPHERAL NEUROPATHY IN PATIENTS WITH GOUT. ALTERATIONS BEYOND LOCAL DAMAGE

C.O. Lopez Lopez[1], E. Corzo Dominguez[1], M.D.L.L. Montes-Castillo[1], H. Llinas[2], E. Alvarez Hernandez[2], I. Peláez Ballestas[2], R. Burgos Vargas[2], J. Vazquez-Mellado[2]. *[1]Rehabilitation; [2]Rheumatology, Hospital General de Mexico, Mexico city, Mexico*

Background: Peripheral neuropathies (PN), are peripheral nervous system disorders associated to several causes. According to distribution are classified as: Local (mononeuropathy [MNP]) or Systemic (Multiple mononeuropathy [MNPM] and polyneuropathy [PNP]). PN in gout has been scarcely described. Previous reports only consider MNP of median nerve at the wrist and MNP of the ulnar nerve at the elbow, due to tophus compression.

Objectives: To describe the frequency and characteristics of PN in patients with gout and its association to gout related variables, co-morbidity and treatment.

Methods: Consecutive patients from GRESGO, a cohort of 450 gout (ARA/CGD/ACR-EULAR) patients seen for the first time at Rheumatology department and treated according to published guidelines for gout. Variables included: demographic, clinical, biochemical data, HAQ and 3 questionnaires for PN (DN4, LANSS and MNSI) previously translated and validated in our country. We performed Nerve Conduction Studies (NCS) following AAME guidelines (Include:Sensory action potential [sural, ulnar and median nerves], Compound muscle action potential [peroneal, tibial, median and ulnar nerves] and late F-wave [tibial and ulnar nerves]). This protocol was approved by the local IRB and the patients signed an informed consent. *Statistical analysis:* Student's t test, Mann–Whitney U test and X2.

Results: We included 162 gout patients, 98% males, 72% tophaceous gout, 48% severe tophaceous gout (STG), mean age 49.4±12 years, 14±10 years of disease duration, educational level 8±4 years, BMI 27.9±4.6kg/m^2.

According to questionnaires: 56% DN4, 45% MNSI and 36% LANSS could be classified as PN. Sixty five percent had abnormal NCS: MNP: 52%, most of them (58%) neuropraxia. PNP 35% and 13% MNPM in them, axonal damage was reported in 88%. MNP localization: Median nerve/carpal tunnel (89%); peroneal nerve/fibula head (7.4%); ulnar nerve/elbow (1.8%) and tibial nerve/ankle (1.8%). For associated factors, Gout+Local PN (L-PN) patients were compared with Gout without PN as well as Gout+Systemic PN (S-PN) (see table). Hypertriglyceridemia and dyslipidemia were significantly more frequent among L-PN patients; in other hand, frequency of tophi, STG and mean HAQ values were significantly more frequent in S-PN patients, there were no significant differences among other clinical data associated with gout itself.

Table 1. Factors associated to Gout+PN. Values represent % unless specified

Variable	Gout+L-PN n=55	Gout+S-PN n=51	Gout Without PN n=56	p
Alcoholism/Smoking	85/69	82/68	85/73	NS
Chronic renal failure	18	17	16	NS
Hyperglycemia/Diabetes	25	31	21	NS
Obesity	27	23	29	NS
Hypertriglyceridemia/Dyslipidemia	**58/69**	27/41	35/40	**0.02**

HAQ*	0.38±0.49	**0.59±0.58**	0.37±0.50	**0.01**
Serum uric acid*	8.1±2.7	7.9±2.3	7.9±2.3	NS
Previous treatment:			NS	
Glucocorticoids	52	68	52 70	
Colchicine	51	46	50	
Allopurinol	71	69	70	

*Mean±SD.

Conclusions: PN is common among gout patients, PN could be diagnosed by questionnaires (particularly DN4) and NCS in 65%. L-PN (median nerve most of them) explain 52% of the cases, in 48% S-PN was found, in these group PNP is more frequent. Hypertriglyceridemia is associated with L-PN and STG to S-PN. The role of uric acid and/or crystals needs to be evaluated.

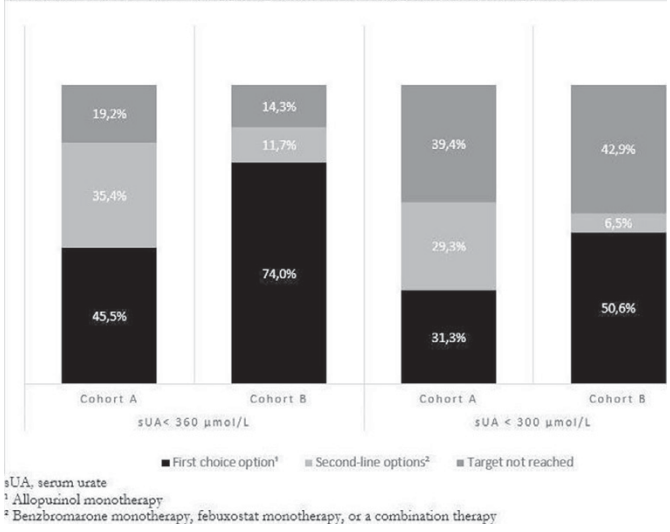
THU0418 A PROOF-OF-CONCEPT STUDY: TREATING TO THE TARGET WITH URATE LOWERING THERAPY IN REAL-WORLD GOUT PATIENTS

C.A. Janssen[1], T.L. Jansen[2], M.A. Oude Voshaar[1], H.E. Vonkeman[1], M.A. van de Laar[1]. *[1]Arthritis Center Twente, Department of Psychology, Health and Technology, University of Twente, Enschede; [2]Department of Rheumatology, Viecuri Medical Center, Venlo, Netherlands*



Background: Gouty arthritis is a common, potentially disabling and increasingly prevalent disease [1]. Last year, the European League Against Rheumatism (EULAR) task force gout updated the 2006 recommendations for the management of gout [2,3]. The guideline stresses the application of a targeted approach when initiating urate lowering therapy (ULT) in gout patients for reaching the recommended serum urate (sUA) target values. However, data on clinical outcomes of real-world gout patients treated according to this approach are limited.

Objectives: To examine the clinical outcomes achieved in two patient cohorts in which differing targeted ULT treatment approaches were employed, both aiming to reach the EULAR recommended sUA targets.

Methods: We conducted a retrospective chart review study. Gout patients were included that had been treated at the rheumatology departments of two clinical centers in the Netherlands, applying different targeted ULT treatment approaches. Patients in cohort A followed an approach combining two modes of action once allopurinol monotherapy failed to reach the predefined target, whereas patients in cohort B were treated with sequential monotherapy following allopurinol

monotherapy failure. Outcome parameters were defined to reflect the EULAR recommendations concerning ULT [3].
Results: A total of 177 patients were included in the study; 99 in cohort A and 78 in cohort B. The majority (N=146, 82.5%) of the included patients from both cohorts were able to meet the predefined sUA target of <360 μmol/L. In addition, more than half (N=104, 58.8%) of the patients reached the stringent sUA target of <300 μmol/L. The proportion of patients reaching sUA targets did not differ significantly (p=0.51) between the cohorts, with 80.8% (n=80) of the patients in cohort A reaching the primary sUA target, compared to 85.7% (n=66) in cohort B (Figure 1). In total, patients following treatment with first-line allopurinol, second-line monotherapy options or second-line combination therapy, 102/124 (82.3%), 25/31 (80.6%) and 19/21 (90.5%) respectively, reached the primary sUA target.

Figure 1: Proportion of patients reaching the EULAR recommended sUA targets in cohort A (n=99) and cohort B (n=77), applying different ULT targeted treatment approaches

sUA, serum urate
¹ Allopurinol monotherapy
² Benzbromarone monotherapy, febuxostat monotherapy, or a combination therapy

Conclusions: This chart review provides a proof-of-concept of the treat-to-target approach in gout patients when a targeted approach with ULT is applied. However, our study also shows that not all patients may reach targets using currently available treatment options. Prospective, pragmatic randomized studies to investigate differences between specific treatment regimes in gout patients, together with costs, safety and patient-reported outcome measures are needed.

THU0419 RISK OF TOTAL HIP AND KNEE REPLACEMENT IN GOUT PATIENTS PRIOR TO AND FOLLOWING DIAGNOSIS: A NATIONAL POPULATION STUDY IN TAIWAN

C.-F. Kuo, J.-S. Chen, K.-H. Yu, S.-F. Luo. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

Background: Total joint replacement (TJR) is a major surgical procedure aiming to replace damaged natural joints with artificial prosthesis to restore function and alleviate pain. Total knee replacement (TKR) and total hip replacement (THR) are two common replacement procedures, mainly as a result of osteoarthritis, rheumatoid arthritis, trauma, fracture and infection. Whether gout associates with a greater risk of TJR independent of these primary risk factors is controversial, despite tophaceous or chronic deforming gouty arthritis may lead to joint destruction and subsequent TJR
Objectives: We carried out a case control study using the National Health Insurance (NHI) database with full coverage of the general population of Taiwan to investigate the burden of TJR in gout patients at diagnosis compared to matched controls. We further followed incident gout patients and their matched controls after diagnosis to compare their subsequent risk for TJR.
Methods: The Taiwan National Health Insurance database was used to identify 74,729 new diagnosis gout patients in 2005. These were matched 1:1 to 74,729 controls by birth year and sex with people who did not have gout diagnosis or urate-lowering treatment prescription. Odds ratios (ORs) of total hip or knee replacement (THR or TJR) at diagnosis and hazards ratios (HRs) after diagnosis were estimated adjusted for gender, age at diagnosis, comorbidities, co-medications, place of residence, income and occupation.
Results: Gout was associated with adjusted ORs (95% CIs) of 0.87 (0.54 to 1.40), 1.01 (0.57 to 1.79), 0.93 (0.64 to 1.35) for the THR, TKR and TJR at diagnosis, respectively. The incidence rate of THR or TKR in the patients with gout was 1.60 and 1.76 (per 1,000 person-years) which was higher than matched controls (0.99 and 0.98, respectively). Gout was also associated with an adjusted HR (95% CI) of 1.41 (1.19 to 1.68), 1.37 (1.16 to 1.61) and 1.37 (1.22 to 1.56) for developing THR, TKR and TJR.
Conclusions: Compared to matched controls people with gout did not have an increased risk of TJR at diagnosis but the risk increased substantially after diagnosis. Whether adequate urate-lowering treatment reduces the risk requires further study.

THU0420 IMPROVED SURVIVAL OF POST-MYOCARDIAL INFARCTION PATIENTS TREATED WITH ZOFENOPRIL COMBINED WITH XANTINE OXIDASE INHIBITORS AS COMPARED TO PLACEBO OR OTHER ACE-I

C. Bentivenga [1], E.R. Cosentino [1], F. Ventura [1], G. Magri [1], I. Ricci Iamino [1], S. Bacchelli [1], E. Ambrosioni [1], D. Degli Esposti [1], N. Malavolta [1], S. Corvaglia [1], G. Vukatana [1], C. Borghi [2] on behalf of SMILE. [1] *Cardiac-Thoracic-Vascular Department, Azienda Ospedaliera Universitaria Sant'Orsola-Malpighi;* [2] *Cardiac-Thoracic-Vascular Department, University of Bologna, Bologna, Italy*

Background: Oxidative stress is increased in hyperuricemic patients with acute myocardial infarction (AMI). In these patients, use of sulfhydrylACE-inhibitors (ACEIs), such as zofenopril or captopril, and xanthine oxidase inhibitors (XOIs), may potentially result in an enhanced antioxidant effect and improved survival. However, the benefit of such combination in post-myocardial infarction has never been verified.
Objectives: To test the usefulness of the combination therapy Zofenopril + XOI in improving survival free from MACE in post-AMI patients
Methods: We re-analyzed the data of the four SMILE (Survival of Myocardial Infarction Long-term Evaluation) studies by grouping patients according to the type of ACEIs and the use of XOIs. 165 (31.4%) of the 525 patients were treated with XOIs (79 under zofenopril and 86 under placebo, lisinopril or ramipril), whereas 360 were not (192 zofenopril and 168 placebo or other ACEIs). In these four groups, we separately estimated the 1-year combined risk of major cardiovascular events (MACE, death or hospitalization for cardiovascular causes).
Results: MACE occurred in 10.1% of patients receiving zofenopril + XOIs, in 18.6% receiving placebo or other ACEIs + XOIs, in 13.5% receiving zofenopril without XOIs and in 22.0% receiving placebo or other ACEIs, but no XOIs (p=0.034 across groups). Rate of survival free from MACE was significantly larger in patients treated with zofenopril and XOIs than with other ACEIs with no XOIs [hazard ratio: 2.29 (1.06, 4.91), p=0.034]. A non-significant trend for superiority of zofenopril + XOIs combination was observed vs. zofenopril alone [1.19 (0.54, 2.64), p=0.669] or vs. placebo or other ACEIs combined with XOIs [1.82 (0.78, 4.26), p=0.169].
Conclusions: Our retrospective analysis suggests an improved survival free from MACE in post-AMI patients treated with a combination of an ACEI and urate lowering drug with antioxidant activity.

THU0421 FEMALE PRIMARY GOUT HAD ITS UNIQUE ULTRASOUND FEATURES

D.F. Lin [1], X. Guo [1], J. Cao [1], Y. Wu [2], J. Gu [1]. [1] *Rheumatology department;* [2] *Ultrasound department, the 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Primary gout is a metabolic disease occurred in male and post-menopause female in most cases. Though the ultrasound features of gout had been discovered for several years, no reports illuminated whether there would be difference presentations between different genders in the joints.
Objectives: We employed ultrasound instead of dual-energy CT to explore more refined pathological manifestations of primary gout in different genders.
Methods: All cases were confirmed as gout fulfilling 1997 ACR classification criteria. All cases excluded secondary gout induced by drug, tumor, hypertension, diabetes mellitus, renal failure. Ultrasound was performed during chronic stage of gout but not at acute attack. The process was done by 2 observers blinded to

each other, blood tests. Final diagnosis was determined by the third US expert if the 2 observers got the different conclusion. Bilateral toes, dorsal feet, ankle, knee, wrist, fingers, elbow, and shoulder were detected to find 6 features of gout suggested by OMERCT: tophus, "snow storm"-like effusion, cloudy synovium in grey scale, double-contour sign, bone erosion and Power Doppler (PD) signal. Each above positive presentations in each above range would get 1 point and the sum scores would be ranged from 0 to 84. Serum uric acid (UA) was recorded too.

Results: 1) 23 female and 139 male were recruited in the program. The female-male ratio was 1:6. Mean age and disease duration of the female subjects were elder than male ones (female:male=57.2±14.1: 44.7±14.7 years old) with longer disease duration to confim the diagnosis (female:male = 10.9:1.2 months). The average serum UA level in female was lower than male group (female:male = 413.8±162.1umol/L, 515.5±156.9umol/L, sig$<$0.05).

2) The intra-observer reliability from 20% samples random seclection showed an overall agreement of 80%, 92%, 96%, 87%, 80%, 73% for tophus, "snow storm"-like effusion, cloudy synovium in grey scale, positive double-contour sign, bone erosion and PD signal with kappa value of 0.78, 0. 92, 0.95, 0.86, 0.79, 0.72, respectively.

3) The difference showed female gout had higher frequency of tophus, bone erosion and lower frequency of effusion while the other indexes were equal:topus scores (female:male=87%:,74.1%), cloudy synovium grey scale scores (female:male=65.2%:62.6%), effusion scores (female:male=17.4%,31.7%), bone erosion scores (female:male=30.4%,16.5%), power dopplar scores (female:male=34.8%,41%), positive double-contour signs (60.9%:59.9%. The top 2 affected ranges were ankle (female:male=69.6%:55.3%), knee (female:mlae=60.9%:54.0%). Furthermore, female gout had more frequently occurred not in the less typical ranges such as fingers (female:male=34.7%:19.4%), elbow (8.7%:2.7%), which might be the cause for delayed diagnosis.

Conclusions: Though the level of serum UA was lower, Female gout had its unique ultrasound features with more tophus, bone erosion and less effusion compared to male gout. The less typical ranges were recommended for US examinations.

THU0422 SEL-212: ENHANCED SERUM URIC ACID CONTROL IN HYPERURICEMIC PATIENTS THROUGH SELECTIVE MITIGATION OF ANTI-DRUG ANTIBODIES AGAINST PEGSITICASE

E. Sands[1], A. Kivitz[2], L. Johnston[1], T.K. Kishimoto[1]. [1]*Selecta Biosciences, Watertown;* [2]*Altoona Center for Clinical Research, Duncansville, United States*

Background: Recent EULAR recommendations for refractory gout treatment with pegylated uricase (pegloticase) acknowledge the risk of allergic reactions related to the development of anti-drug antibodies (ADAs) [1]. ADAs also affect the efficacy of treatment [2]. As a novel approach to treatment, we demonstrated that co-administration of pegsiticase (another pegylated uricase) and a synthetic vaccine particle encapsulating rapamycin (SVP-R) showed improved control of serum uric acid (sUA) in uricase-deficient mice by inducing antigen-specific immune tolerance to pegsiticase [3]. Here we describe the impact of SEL-212, a combination product of SVP-R and pegsiticase, on ADA formation and sUA levels in hyperuricemic patients in a Phase 1 open-label multicenter clinical trial.

Objectives: To assess the initial safety and impact on sUA levels and ADA formation of SEL-212, which is designed to be the first non-immunogenic uricase therapy for refractory gout.

Methods: Cohorts of hyperuricemic (sUA $\geq$6 mg/dL) patients consented to a single dose of 0.4 mg/kg pegsiticase alone, SVP-R alone (0.03–0.5-mg/kg), or 0.4 mg/kg pegsiticase co-administered with SVP-R (0.03–0.3-mg/kg; SEL-212). ADAs and sUA were assessed at baseline and 7, 14, 21, and 30 days after dosing.

Results: Sixty-three patients were enrolled with a median age of 49.4 years. Mean baseline sUA was 7.4±1.3 mg/dL. Patients dosed with pegsiticase alone showed an immediate drop in sUA, which returned to baseline levels by 14–21 days in 4 of 5 subjects, correlating with the induction of ADA titers $>$1000. Patients treated with SVP-R alone showed no meaningful change in sUA.

In contrast, patients treated with SEL-212 showed a dose-dependent inhibition of anti-uricase ADAs and corresponding decrease in sUA levels through at least day 30 after a single injection. Seven of 10 patients treated with SEL-212 at a SVP-R dose of 0.1 mg/kg showed no detectable sUA at day 30, and all 10 subjects dosed with SEL-212 at SVP-R doses of 0.15 or 0.3 mg/kg showed sustained control of sUA through at least day 30. There was a strong correlation between maintenance of low uric acid levels at day 30 and with low or no ADA titers.

SEL-212 was generally well tolerated at effective dose levels. One SAE (grade 2 rash) was observed in the lowest of the three effective dose levels (0.1 mg/kg SVP-R). A second SAE was determined by the investigator to be not related to study drug. All SAEs fully resolved. No SAEs were observed with SEL-212 at the higher effective dose levels of SVP-R (0.15 or 0.3 mg/kg). The maximum tolerated dose was defined at 0.3 mg/kg.

Conclusions: Data suggest that a single dose of SEL-212 in hyperuricemic patients can tolerably, therapeutically and durably control sUA for $\geq$30 days, correlating with inhibition of ADAs. These results supported monthly dosing in an ongoing Phase 2 multi-dose study in symptomatic gout patients and the potential use of SVP-R to mitigate ADAs for other immunogenic biologics.

THU0423 THE RELATIONSHIP BETWEEN CLINICAL DISEASE ACTIVITY, SYMPTOM DURATION AND ULTRASONOGRAPHIC CHANGES IN GOUT

E. Norkuviene[1], M. Petraitis[1], I. Apanaviciene[1], D. Virviciute[2], A. Baranauskaite[1]. [1]*Rheumatology;* [2]*Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania*

Background: Ultrasonography (US) has recently been validated and used as an objective diagnostic tool for urate deposition also joint damage and was proposed as an outcome measure in gout [1–2].

Objectives: Our aim was to investigate the relationship between clinical gout activity and load of US changes.

Methods: Sixty monosodium-urate-crystal-confirmed gout patients (52 men) and 36 healthy normouricemic controls were prospectively included in one centre. The relationship between clinical symptoms and US gout-related changes investigating 36 joints and 4 tendons (m. triceps and patellar) was evaluated using Spearman's correlation.

Results: The total number of intraarticular T, periarticular T, total T, total DC, and total E found per patient on ultrasound ranged from 0–26, 0–4, 0–30, 0–29, and 0–18, accordingly.The number of acute attacks per year/per life had a significant positive correlation with the total number of intraarticular T (rs=0.518/0.652; p$<$0.0001), total number of intraarticular and periarticular T (rs=0.552/0.699; p$<$0.0001), the total number of DC (rs=0.374/0.551; p$<$0.01), the total number of erosions (rs=0.374/0.542; p$<$0.01), and the total tophus area (rs=0.420/0.549; p$<$0.01) measured on US per patient. Strong, positive correlation was observed between the number of subcutaneous tophi and total US tophus area (rs=0.628), total number of DC (rs=0.612) and erosions (rs=0.526), found per patient on US, all p$<$0.0001. Disease duration significantly positively correlated with the load of US T, E and DC (p$<$0.0001) in the investigated sites. There was no correlation between CRP and US, also no correlation between the uric acid concentration and US changes: total number of T (rs=0.193, p=0.139), DC (rs=0.179, p=0.170) or E (rs=0.063, p=0.634) found per patient. The tophus area measured in two first metatarsophalangeal joints (MTP) positively correlated with subcutaneous tophus count (rs=0,404; p=0,001), the US intraarticular T count (rs =0,732; p$<$0,0001) total US DC count (rs =0,477; p$<$0,0001) total intraarticular tophus area (rs =0,829; p$<$0,0001)and total tophus area other than first MTP joints (rs =0,603; p$<$0.0001).

Conclusions: Ultrasonographic gout -related changes strongly positively correlate between each other and with subjective also objective signs of disease activity, increasing with disease duration in gout. The size of tophi inside the first metatarsophalangeal joints could be representative of the total body urate load and could be chosen as an outcome measure for the longitudinal gout studies.

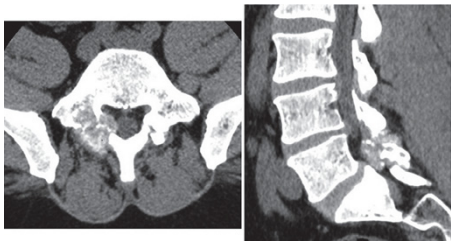
THU0424 GOUT AT THE SPINE: A RETROSPECTIVE STUDY WITH DUAL-ENERGY COMPUTED TOMOGRAPHY



E. Chotard[1], J.M. Sverzut[2], F. Lioté[1,3], T. Bardin[1,3], H.-K. Ea[1,3]. [1]*AP-HP, hôpital Lariboisière, Service de Rhumatologie, centre Viggo Petersen, Paris;* [2]*Centre cardiologique du Nord, Service de Radiologie, St Ouen;* [3]*INSERM UMR1132, Bioscar, University Paris Diderot, Paris, France*

Background: Gout is due to monosodium urate (MSU) crystal deposition after chronic hyperuricemia. Although MSU crystal deposition can occur in every joint and peri-articular structure, spine involvement is scarcely reported. Dual energy computed tomography (DECT) is a performant tool to assess urate deposits, especially in deep structures such as intervertebral discs and apophyseal joints.

Objectives: to describe spinal DECT features of urate monosodium deposits compared to peripheral joint DECT.

Methods: Patient with gout diagnosis (MSU crystal identification by polarized microscopy or fulfilling "Nijmegen's criteria" (1)) who had undergone DECT were included from November 2012 to June 2016. Images were analyzed by

a trained musculoskeletal radiologist. For each DECT, clinical and biochemical characteristics of each patient were collected retrospectively.
Results: 22 patients (men 77%), mean age 62.5 years and mean BMI 28.4 kg/m^2 were included. Mean gout duration was 108.0±114.4 months, mean of last available serum uric acid level was 520±193 μmol/l, and 15 patients had at least one clinical tophus. Mean estimated glomerular filtration rate (MDRD formula) was 47±27 ml/min/1.73 m^2. One patient was on hemodialysis and one had received kidney transplant.
A total of 39 DECT has been performed: 28 of peripheral joints and 11 of the spine (9 lumbar, 1 sacroiliac and 1 cervical). Spinal DECT were done in 10 patients to explore recurrent inflammatory pain (n=3 lumbar, 1 cervical and 1 buttock) or mechanical back pain (n=2 lumbar). 4 spinal DECT were performed in asymptomatic patients with extended peripheral tophi. Spinal MSU crystal deposits were disclosed by DECT in 83% (5/6) and 25% (1/4) of symptomatic and asymptomatic patients, respectively. In all painful patients, MSU crystal deposition was considered as a likely explanation of spinal symptoms. MSU crystal depositions was identified in apophyseal joints (n=5), cervical intervertebral disc (n=1) and yellow or interspinous ligaments (n=4). All involved apophyseal joints were eroded (figure 1). No vertebral bone erosion was observed. Calcification of spinal tophus was observed in 4 patients. DECT identified peripheral deposits in 15/18 (83.3%) patients. In peripheral DECT, bone erosions were observed in 71.4% and joint effusion in 32.1% of DECT positive peripheral joints. MSU crystal depositions were observed in tendons, cartilages or synovial membranes in 82.1% of positive DECT joints and in soft tissues in 64.3% of positive patients. MSU crystal deposits were calcified in 7 cases.

Conclusions: MSU crystal depositions at the spine are present in 60% of patients in this retrospective DECT study. DECT can represent a performing imaging procedure for their detection in symptomatic patients. Further studies are needed to assess the clinical utility of DECT of the spine in gout.

THU0425 THE FIRST METATARSOPHALANGEAL JOINT (MTP1) IS NOT THE MAIN LOCALIZATION OF GOUT AT DIAGNOSIS IN SUB-SAHARAN AFRICA

F. Kemta Lekpa, M.S. Doualla, H. Namme Luma. *Service de Médecine Interne, Douala General Hospital, Douala, Cameroon*

Background: Numerous data in sub-Saharan Africa suggest that MTP1 is not the hallmark of gout (1–5).
Objectives: We carried out this study with the aim to determine the joint most involved at the time of diagnosis of gout in Cameroon.
Methods: We performed a cross-sectional study in all outpatients seen at the Rheumatology unit of the Douala General Hospital, Cameroon, between 2004 and 2014. We included patients with diagnosis of gout according to ACR criteria 1977.
The main characteristics of gout at diagnosis were collected, particularly the joints involved.
A $p<0.05$ was significant.
Results: At the end of this study, 511 patients (415 men and 96 women) with the diagnosis of gout were included. The mean age was 55.9±10.8 years.
Joint pain (n=508, 99.4%) was the leading reason for consultation at the time of diagnosis. The knees (n=300, 62.6%)), ankles (n=187, 39.0%) and MTP1 (n=128, 26.7%) were the most affected joints. Table 1 presents the frequency of the joints affected, comparing our results with those of the other African series.
There was no difference between MTP1 and others joints location (particularly knees and ankles) according to age, sex, place of residence, duration of disease, uric acid level, and associated comorbidities ($p>0.05$).
Conclusions: MTP1 is not the joint most involved at the time of diagnosis of gout in sub-Saharan Africa. Diagnosis of gout should be considered before any inflammatory knee and ankle pain in patients from sub-Saharan Africa. Genetic studies would provide a better understanding of this feature.

THU0426 LONG-TERM ADHERENCE TO URATE-LOWERING THERAPY IN GOUT: DO NOT BLAME ON THE PATIENTS

F. Perez-Ruiz, I. Urionagüena, S.P. Chinchilla. *Rheumatology Division, Hospital Universitario Cruces and Biocruces Health Research Institute, Baracaldo, Spain*

Background: adherence to urate-lowering treatment (ULT) in patients with gout is reported to be lower than 50% in the first year, below 20% at 2-year, and worse than in other chronic conditions such as hypertension, diabetes, or hyperlipidemia.
Objectives: to evaluate adherence to ULT both overall and during follow-up, to compare it to the adherence to medications for associated comorbidities, and to explore potential causes for non-adherence to ULT.
Methods: transversal study of a nested cohort of patients in a gout clinic in the hospital setting who were scheduled for a follow-up visit during 6 consecutive months in 2016. General data of patients, along with variables related to gout and to comorbid conditions are systematically retrieved at first visit; prescribed ULT, doses, adherence, and serum urate levels were obtained during the follow-up visits. Adherence was retrieved as medication possession rate (MPR) according to pharmacy offices from government electronic databases (including >98% of the general population). Also, MPRs of drugs prescribed for hypertension, diabetes (only oral), and hyperlipidemia were obtained; if more than one drug prescribed for any of the previous, the best adherence per comorbidity treatment was entered. Good adherence was considered as MPR>80 percent of that prescribed, target serum urate (sUA) as <0.36 mmol/L. Patients are educated at first visit and encouraged to be adherent from baseline through follow-up visits.
Results: adherence data were available from 209 patients who were scheduled for a follow-up visit during the observation period; 14 (6.7%) patients did not atend the visit. This sample was formed by 90% male, only 55% had received ULT previous to first visit, median age was 65 years at follow-up visit, 47% and 44% showed poliarticular and tophaceous disease at baseline, respectively. MPR overall showed a median of 89% (IQR 79–94, N=209) for ULT (72% had MPR>80), and 89% (IQR 81–94, N=119), 88% (IQR 79–94, N=65), and 82% (IQR 77–93, N=28) for hypertension, hyperlipidemia, and diabetes respectively ($p<0.05$ only for diabetes).
Adherence was lower for patients who did not attend the scheduled visit (median MPR 58% vs. 86%, MPR >80, 21% vs. 75%, $p<0.01$). Adherence was lower during the first year (80%, N=67) compared to 2nd and 3rd year period (86%, N=67) or 4 year or over (89%, N=75). MPR>80 was 57%, 76% y 81% for the same periods of follow-up, respectively. Good adherence was associated to a rate of target serum urate of 90%, compared to 72% for patients showing MPR<80.
Male gender and un-attendance to scheduled visit were statistically associated to MPR<80 in multivariate analysis, and numerically to increasing age and overall comorbidity.
Conclusions: adherence to ULT measured as MPRs in a cohort of educated patients is good, sustained during follow-up, and similarly good to that for comorbid conditions (hypertension, hyperlipidemia, and diabetes); therefore, we cannot blame poor adherence on the patients anymore. Targeting absenteeism could be an opportunity for further improvement.

THU0427 AMBIENT AIR POLLUTION AND RISK OF ACUTE GOUT FLARES; A TIME-SERIES STUDY

H.J. Ryu[1], M.R. Seo[1], H.J. Choi[1], J. Cho[2], H.J. Baek[1]. [1]*Rheumatology;* [2]*Occupational and Environmental Medicine, Gachon University Gil Medical Center, Incheon, Korea, Republic Of*

Background: Air pollution is caused by substances that consists of solid particles, liquid droplets, or gases including carbon monoxide (CO), nitrate (NO), sulfur dioxide (SO_2), ozone (O_3), lead, toxic product from tobacco smoke and particulate matter (PM). Inhaled air pollutants can induce oxidative stress and this can contribute to trigger or exacerbate systemic inflammation and autoimmunity. The relations of air pollution with rheumatic diseases have been reported, especially in rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis and juvenile idiopathic arthritis. Gout is an inflammatory disease caused by deposition of monosodium urate (MSU) crystals. Acute gout flares is initiated with activation of the NLRP3 inflammasome and release of IL-1β by MSU crystals. PM $<10\mu m$ in diameter (PM_{10}) exposure has been reported to activate NLRP3 inflammasome in airway epithelial cells. The influence of air pollutants including PM_{10} to acute gout flares has not yet been known.
Objectives: To investigate the association between air pollution and acute gout flares
Methods: We obtained data from the National Health Insurance Database between 2007 and 2015 in Incheon, Republic of Korea by Health Insurance Review and Assessment (HIRA) service. The HIRA data included age, gender, national health insurance type, diagnosis code based on the International Classification of Diseases version 10 (ICD–10), visit date, procedure code, and prescription code. We studied the subjects of age $\geq$19 years who visited emergency department (ED) due to acute gout flare between 2008 and 2015. Acute gout flare was defined as an ED visit due to gout (ICD-10, M10) with any prescription of non-steroidal anti-inflammatory drugs (NSAIDs), acetaminophen, steroids, or colchicine. Comorbidities and prescription history were collected. The data of ambient PM_{10}, O_3, NO_2, CO, and SO_2 levels were obtained from the Ministry of Environment data sources. We performed time-series study. The generalized additive models with Poisson distribution were used to investigate the association between single air pollutant level and acute gout flares. To examine the delayed effect of air pollutant exposure before the ED visit day on acute gout flare, we established cumulative lag models (averaging levels of consecutive days).
Results: The total number of ED visits for acute gout flare from 2008 to 2015 in Incheon was 139,665, including 48.8% of 40–59 year-old men. The ED visits for acute gout attack were most likely to occur in summer (29.1%). Among the ED cases of acute gout flares, 11.0% had a prescription history of allopurinol or febuxostat for the six months before the visit. The relative risks (RRs) of PM_{10} and O_3 at lag0–7 were 1.02 (1.01–1.03) and 1.07 (1.06–1.08), respectively. NO_2, CO, and SO_2 did not show significant association with acute gout flares. Acute gout flares showed more significant association with O_3 in the cases with hypertension and use of NSAIDs, colchicine, or statins. PM_{10} was more significantly associated with acute gout flares in the cases with congestive heart failure.
Conclusions: Ambient air pollution can induce acute gout flares and its influence on acute gout flares may increase according to the comorbidities or medications.

THU0428 ON THE INCIDENCE OF GOUT FLARES IN PRIMARY CARE: A RETROSPECTIVE COHORT STUDY

H. Janssens[1], M. Janssen[2], J. Fransen[3], M. Flendrie[4]. [1]*Department of Primary and Community Care, Radboud University Medical Centre, Nijmegen;* [2]*Rheumatology, Rijnstate Hospital, Arnhem;* [3]*Radboud University Medical Centre;* [4]*Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

Background: From rheumatologist point of view (secondary care) there is a serious concern about suboptimal treatment of gout patients in primary care with warnings for worse prognostic consequences.(1) Some refer even to a "state of suboptimal gout care" promoted by "substantial gaps between rheumatologists and primary care providers" in their approaches to gout care:(2) the strategy of "treating-to-target" (to lower serum uric acid (SUA) levels $<$0.36mmol/L) versus "treating-to-avoid-symptoms" (often without addressing hyperuricemia).(3) Most studies on gout care in the primary care setting checked patients for prescribed urate lowering treatment (ULT), SUA assessments or reached SUA target levels, omitting the major patient related clinical end point of gout, flare frequency.(4)
Objectives: To quantify the occurrence of flares and the use of ULT, in primary care patients with gout, and to analyze patient characteristics related to low or high flare frequency.
Methods: A retrospective cohort study (setting one Dutch primary care center with an integrated medical praxis and pharmacy). Electronic medical records of ca. 5800 enlisted patients were used to select all patients with gout, to analyze their ULT use, and to assess flare frequency in a 2-year time window (2014–2015). Flare was defined as each pharmacy delivery of an anti-inflammatory drug or pain killer linked to a morbidity code for gout. Associations were studied between high or low flare frequency and patient characteristics by univariate logistic regression.
Results: Of 173 included patients (prevalence 3%; mean age 66.4 yr; 75.7% men) 38.7% used ULT persistently during the 2-year time-window. Median time after initial diagnosis was 8.0 yr (IQR 3.0–14.5). Mean total numbers of flares in two years was 2.7 (SD: 4.7), median 1.0 (IQR: 0.0–4.0). Of the patients not receiving ULT (n=106, 61.3%) 41.5% had never, 25.5% one or two, and 6.6% more than six flares during two years. No associations were found between patient characteristics (e.g. age, time after initial diagnosis, crystal diagnosis, ULT use, cardiovascular co-morbidity, diuretic use) to differentiate patients with "no-or-1-flare" and "2-or-more-flares" per two years.
Conclusions: Occurrence of flares in this stringently observed primary care cohort of patients with gout was very low, even if most patients did not use prophylactic ULT. Only 6.6% of patients experienced $>$6 flares in two years. Patients, in particular those not using ULT and with a low flare frequency (the majority), may reflect individuals with a distinctive (moderate) disease activity. They probably do not fulfill the general accepted advancing course of gout with ongoing and increasing flare frequency, MSU deposition, tophus formation, and joint damage. Immediate lifelong ULT for them may not be automatically indicated. Our study shows that suboptimal gout management in the perception of rheumatologists (secondary care) does not lead to an abundant number of gout flares in primary care patients. This urges to caution when recommendations based upon secondary care guide lines are advised for primary care patients with gout.

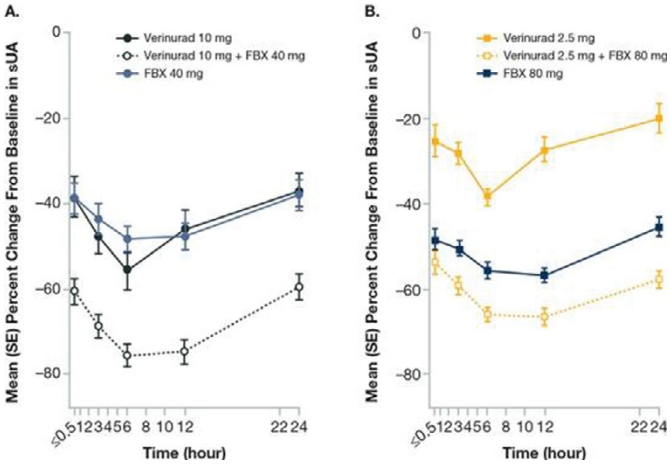
THU0429 CLINICAL SIGNIFICANCE OF INCREASED SERUM LEVELS OF FGF23 IN FIBROUS DYSPLASIA

H. Florez[1], S. Mandelikova[1], X. Filella[2], A. Monegal[1], N. Guañabens[1], P. Peris[1]. [1]*Rheumatology Department;* [2]*Clinical Biochemistry Department, Hospital Clinic, Barcelona, Spain*



Background: Fibrous dysplasia of bone (FD) is an uncommon skeletal disorder, caused by missense mutations of the *GNAS1* gene and is characterized by the development of fibro-osseous lesions that replace normal bone. FD can present with a broad spectrum of clinical manifestations, including the development of hypophosphatemic osteomalacia which is due to the production of the phosphaturic hormone fibroblast growth factor 23 (FGF-23) by the dysplastic bone tissue. Nevertheless, the prevalence of this clinical complication is not well known.
Objectives: To analyse the serum levels of FGF-23 in patients with FD and determine their relationship with the extension and activity of the disease, as well as with serum phosphate levels.
Methods: Twelve patients (7F:5M) with FD with a mean age of 50.67±16.4 years (24–79) were included. The clinical reports of the patients were reviewed, with special attention to the extension and activity of the disease, number and location of the affected bones, clinical complications and treatments received. Serum FGF-23 values were recorded in all subjects (determined by Immunotopics, CA, USA [measuring FGF23 C- terminal], normal value $<$130 RU/ml), as well as serum phosphate and calcium values, bone turnover markers and their evolution with treatment.
Results: Serum levels of FGF-23 were increased ($>$130 RU/ml) in 6/12 patients (50%). In patients with and without high FGF-23 levels the number of affected bones (2.2±2 *vs.* 1.9±1, respectively) and the skeletal locations of FD were similar as was the age in both groups of patients (48.2±14 *vs.* 53.2±19 years). In addition, FD disease activity and extension were similar in the two groups as were the bone turnover marker values (FAO, PINP and CTx). Strikingly, differences between serum phosphate values were not observed between the two groups (FGF23 $>$130: 3.9±0.9 mg/dl *vs.* FGF23 $<$130: 3.5±0.6 mg/dl). Indeed, none of the patients with high FGF-23 levels had low serum phosphate values. Following bisphosphonate (zoledronate) treatment, there were no significant changes in FGF-23 values. Nevertheless, an increase of 123% was found in one patient receiving denosumab, although hypophosphatemia was not associated.
Conclusions: Patients with FD frequently present elevated FGF-23 values with no effects on serum phosphate levels, thereby suggesting the presence of an alteration in processing this protein in the dysplastic bone tissue in this disease. The role of denosumab treatment in FD and its repercussion on FGF-23 levels need further study.

THU0430 PHARMACOKINETICS, PHARMACODYNAMICS, AND TOLERABILITY OF CONCOMITANT MULTIPLE DOSE ADMINISTRATION OF VERINURAD (RDEA3170) AND FEBUXOSTAT IN HEALTHY ADULT MALE SUBJECTS

J.T. VanderLugt[1], M. Gillen[2], X. Yang[3], J. Hall[3]. *[1]Jasper Clinical Research & Development, Kalamazoo, MI; [2]AstraZencea, Gaithersburg, MD; [3]Ardea Biosciences, Inc., San Diego, CA, United States*

Background: Verinurad (RDEA3170) is a novel selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia.
Objectives: This Phase 1, single-blind, multiple dose, drug-drug interaction (DDI) study evaluated the pharmacokinetics (PK), pharmacodynamics, and tolerability of verinurad in combination with febuxostat (FBX) in healthy male volunteers.
Methods: Subjects were randomized to receive once-daily doses of FBX or verinurad or placebo alone for 7 days, FBX + verinurad or FBX + placebo on days 8–14, and the alternative single agent (FBX or verinurad or placebo) on days 15–21. Subjects received either the combination of verinurad 10 mg + FBX 40 mg or verinurad 2.5 mg + FBX 80 mg. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21, and assayed for verinurad, FBX, and uric acid. Baseline samples were drawn on Day –1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).
Results: Of 23 randomized subjects, 20 completed the study. FBX 40 mg had no apparent effect on the plasma C_{max} and AUC for verinurad 10 mg, whereas FBX 80 mg increased the plasma C_{max} and AUC for verinurad 2.5 mg by 25% and 33%, respectively. Verinurad had no effect on FBX PK. Renal clearance of verinurad was unchanged by FBX.
The mean maximal reduction in serum uric acid (sUA) was 76% with verinurad 10 mg + FBX 40 mg compared with verinurad 10 mg (56%) or FBX 40 mg (49%) alone (Figure 1A) and was 67% with verinurad 2.5 mg + FBX 80 mg compared with verinurad 2.5 mg (38%) or FBX 80 mg (57%) alone (Figure 1B). Consistent with the mechanism of action (MOA) of verinurad, 24-hr fractional excretion of uric acid (FEUA) increased (2.5 mg: 7.6%; 10 mg: 12.8%) vs baseline (6.5% and 6.0%, respectively). Renal clearance of uric acid (CL_{UR}) increased similarly (2.5 mg: 9.0 mL/min; 10 mg: 12.3 mL/min) vs baseline (8.3 and 7.3 mL/min, respectively). The increases were maintained for 24 hours with verinurad 10 mg + FBX 40 mg (FEUA: 11.8%; CL_{UR}: 13.6mL/min). Consistent with its MOA, FBX 40 mg and 80 mg decreased the amount of uric acid excreted in urine (246 and 221 mg, respectively, vs baseline: 695 and 818 mg), FEUA (4.79 and 4.18%, respectively, vs baseline: 6.31 and 6.54%), and CL_{UR} (4.91 and 4.96 mL/min, respectively, vs baseline: 7.71 and 8.73 mL/min). No serious AEs, discontinuations due to AEs, or clinically significant laboratory or ECG abnormalities were noted during the study.

Figure 1: Mean (SE) percent change from baseline in sUA at steady state following verinurad 10 mg or FBX 40 mg or the combination (A) or verinurad 2.5 mg or FBX 80 mg or the combination (B)

Conclusions: No DDI was found with the verinurad 10 mg + FBX 40 mg combination and only a modest one with verinurad 2.5 mg + FBX 80 mg. Both combinations were safe and well tolerated and resulted in greater reduction of sUA than either verinurad or FBX alone. These results support the continued development of this novel approach for the treatment of gout and hyperuricemia.

THU0431 COMPARATIVE EFFECTIVENESS OF ALLOPURINOL VERSUS FEBUXOSTAT FOR PREVENTING INCIDENT RENAL DISEASE IN OLDER ADULTS: AN ANALYSIS OF MEDICARE CLAIMS DATA

J. Singh, J. Cleveland. *University of Alabama at Birmingham, Birmingham, United States*

Background: Large scale randomized studies are underway to assess whether compared to placebo, each XO-inhibitor, allopurinol or febuxostat, can prevent renal function loss. This evidence is needed and will confirm their nephroprotective potential. However, neither study will answer a key question: Does the renal protective effect of allopurinol differ from that of febuxostat?
Objectives: To assess the comparative effectiveness of allopurinol vs. febuxostat for preventing incident renal disease in elderly.
Methods: In a retrospective cohort study using Medicare claims data, we included patients newly treated with allopurinol or febuxostat (baseline period of 183 days without either medication). We used 1:5 propensity-matched Cox regression analyses to compare the hazard ratio (HR) of incident renal disease with allopurinol use and allopurinol dose vs. febuxostat (reference category). Sensitivity analyses included multivariable-adjusted regression models.
Results: There were 31,465 new allopurinol or febuxostat treatment episodes in 26,443 patients; 8,570 ended in incident renal disease. Crude rates of incident renal disease per 100,000 person-days were 53 with allopurinol vs. 93 with febuxostat. Crude rates of incident renal disease per 100,000 person-days were lower with higher daily dose: allopurinol $<$200, 200–299 and $\geq$300 mg/day with 65, 48 and 43; and febuxostat 40 mg and 80 mg/day with 93 and 89, respectively. In propensity-matched analyses, compared to febuxostat use, allopurinol use was associated with lower HR of incident renal disease, 0.61 (95% confidence interval (CI): 0.49, 0.77). Compared to febuxostat 40 mg/day, allopurinol doses $<$200, 200–299 and $\geq$300 mg/day were associated with lower HR of incident renal disease, 0.75 (95% CI: 0.65, 0.86), 0.61 (95% CI: 0.52, 0.73) and 0.48 (95% CI: 0.41, 0.55), respectively. Sensitivity analyses using multivariable-adjusted regression confirmed these findings.
Conclusions: Allopurinol was more effective than febuxostat in preventing incident renal disease in elderly patients. Future studies need to examine the mechanism of this renal benefit of allopurinol.

THU0432 PHARMACOKINETICS, PHARMACODYNAMICS, AND TOLERABILITY OF CONCOMITANT MULTIPLE DOSE ADMINISTRATION OF VERINURAD (RDEA3170) AND ALLOPURINOL IN ADULT MALE SUBJECTS WITH GOUT

J. Hall[1], M. Gillen[2], X. Yang[1], S. Liu[1], S. Walker[2], V. Clauson[1], M. Kankam[3]. *[1]Ardea Biosciences, Inc., San Diego, CA; [2]AstraZeneca, Gaithersburg, MD; [3]Vince and Associates Clinical Research, Inc., Overland Park, KS, United States*

Background: Verinurad (RDEA3170) is a novel selective uric acid reabsorption inhibitor in clinical development for the treatment of hyperuricemia and gout.
Objectives: This Phase 1, single-blind, multiple dose, drug-drug interaction study evaluated the pharmacokinetics (PK), pharmacodynamics, and tolerability of verinurad in combination with allopurinol (ALLO) in adult male subjects with gout.
Methods: Adult males with gout, aged 18–75 years, with serum uric acid (sUA) $\geq$8 mg/dL were randomized to receive once-daily oral doses of ALLO 300 mg or verinurad 10 mg alone for 7 days, ALLO 300 mg + verinurad 10 mg on Days 8–14, and the alternative single agent (verinurad 10 mg or ALLO 300 mg) on Days 15–21. Colchicine 0.6 mg was taken once daily from day –14. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21 and assayed for verinurad, ALLO, oxypurinol (OXY), colchicine, and uric acid. Baseline samples were drawn on Day –1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).
Results: Subjects (N=12) were mostly white (58.3%) with mean (SD) age of 51 (10) years. Following multiple doses, ALLO had no effect on C_{max} and AUC of verinurad. ALLO C_{max} was increased 33% but AUC was unaltered by verinurad. The C_{max} and AUC for OXY, the active metabolite of ALLO, were reduced 32% and 38%, respectively, by verinurad. Colchicine plasma exposures were unaltered by verinurad. ALLO had no effect on urinary excretion of verinurad, whereas urinary excretion of OXY was increased 19% by verinurad.
The mean maximal decrease in sUA was 65% with verinurad + ALLO compared with verinurad (51%) or ALLO (43%) alone (Figure). Consistent with the mechanism of action (MOA) of verinurad, 24-h fractional excretion of uric acid (FEUA) and clearance of uric acid (CL_{UR}) were increased in the absence (9.2% and 11.5 mL/min, respectively) or presence of ALLO (7.9% and 11.8 mL/min) vs baseline (4.5% and 5.7 mL/min) or ALLO alone (3.7% and 5.0 mL/min). Consistent with its MOA, ALLO decreased the amount of uric acid excreted in 24-h urine (363 mg) compared with baseline (683 mg), verinurad alone (739 mg) or verinurad + ALLO (522 mg) but had no effect on FEUA or CL_{UR}. No

serious AEs, discontinuations due to AEs, or clinically significant laboratory or ECG abnormalities were noted.

Figure: Mean (SE) percent change from baseline in sUA at steady state following verinurad 10 mg or ALLO 300 mg or in combination

Conclusions: Although a modest drug–drug interaction was found between verinurad and ALLO, the combination was safe and well tolerated at the studied doses and resulted in greater reduction of sUA than either alone. These results support the evaluation of verinurad + ALLO as an alternative once-daily treatment option for hyperuricemia and gout.

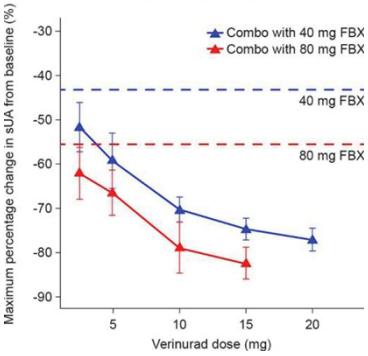
THU0433 PHARMACODYNAMIC AND PHARMACOKINETIC STUDY OF VERINURAD (RDEA3170) IN ADULT MALE SUBJECTS WITH MILD, MODERATE, AND SEVERE RENAL IMPAIRMENT: A PHASE 1, OPEN-LABEL STUDY

W.B. Smith[1], J. Hall[2], J.K. Berg[3], M. Kazimir[3], A. Yamamoto[2], S. Walker[4], C. Lee[2], T.C. Marbury[5]. *[1]Volunteer Research Group, Knoxville, TN; [2]Ardea Biosciences, Inc., San Diego, CA; [3]DaVita Clinical Research, Minneapolis, MN; [4]Astrazeneca, Gaithersburg, MD; [5]Orlando Clinical Research Center, Orlando, FL, United States*



Background: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia.
Objectives: This Phase 1, single-dose, open-label study investigated the pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in adult subjects with mild, moderate, or severe renal impairment and matched controls with normal renal function (NCT02219516).
Methods: Adult males aged 18–85 years were enrolled with a screening serum uric acid (sUA) 4.5–10 mg/dL and creatinine clearance calculated by Cockcroft-Gault formula of 60 to <90 mL/min (mild renal impairment), 30 to <60 mL/min (moderate impairment), 15 to <30 mL/min (severe impairment), or ≥90 mL/min (matched controls). Oral verinurad 15 mg was administered once under fasted conditions. Serial blood and urine samples were taken 30 min before and up to 72 hours postdose. Safety assessments included laboratory, ECG, and vital sign parameters as well as adverse event (AEs) reporting.
Results: PD data were based on 7–8 subjects per group. Verinurad decreased sUA in all groups, with greatest changes in the normal function and mild renal impairment groups. Mean (SD) maximal % change in sUA from baseline (Emax) was -38.3 (14.8)%, -36.9 (13.6)%, -20.5 (6.64)%, and -12.6 (6.94)%, respectively, in the normal function and mild, moderate, and severe renal impairment groups. Increase in the amount of excretion of uric acid due to verinurad treatment decreased in subjects with moderate and severe renal impairment. Plasma Cmax and AUC of verinurad increased with decreasing renal function. Verinurad at the 15 mg dose was well tolerated, with no serious AEs, no subject withdrawals due to AEs, and no Renal Events Adjudication Committee (REAC)-adjudicated renal events during treatment. One patient in each renal impairment group had treatment-emergent AEs considered possibly related to verinurad, which were categorized as gastrointestinal in nature. There were no clinically meaningful changes noted in laboratory values or vital signs.
Conclusions: The sUA lowering effect of verinurad was observed across the spectrum of renal function. Consistent with the verinurad renal-dependent mechanism of action, decreasing sUA lowering was demonstrated with increasing renal impairment. Verinurad safety and tolerability were similar across all stages of renal impairment.

THU0434 PHARMACODYNAMIC EFFECTS AND SAFETY OF VERINURAD (RDEA3170) IN COMBINATION WITH FEBUXOSTAT VERSUS FEBUXOSTAT ALONE IN ADULTS WITH GOUT: A PHASE 2A, OPEN-LABEL STUDY

R. Fleischmann[1], P. Winkle[2], J. Hall[3], S. Valdez[3], S. Liu[3], X. Yan[3], L. Hicks[3], M. Hernandez-Illas[4]. *[1]University of Texas, Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX; [2]Anaheim Clinical Trials, Anaheim, CA; [3]Ardea Biosciences, Inc., San Diego, CA; [4]4QPS MRA (Miami Clinical Research), Miami, FL, United States*

Background: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia.
Objectives: This Phase 2a, randomized, open-label, multicenter study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with febuxostat versus febuxostat alone in adults with gout (NCT02246673).
Methods: Patients aged ≥18 and ≤75 years with gout and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 5 cohorts to receive febuxostat (40 mg and 80 mg) alone and in combination with verinurad (dose range 2.5 mg to 20 mg; 4 treatment periods per cohort, each treatment period 7 days). Medications were administered once daily ~30 min after breakfast. Colchicine 0.6 mg for gout flare prophylaxis was initiated at approximately Day -14 (start of urate-lowering therapy [ULT]) washout) or Day -7 if not on ULT. Serial blood and urine samples were measured at preset intervals on Days -1, 1, 7, 14, 21, and 28 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, electrocardiograms, and vital sign parameters.
Results: Sixty-four patients were randomized (n=12–14 per cohort). Serum PD data pooled across cohorts demonstrated maximal % decrease in sUA from baseline (Emax) at 8–12 h after dosing. Addition of verinurad to febuxostat decreased sUA in dose-dependent manner (Figure 1). Greater sUA reductions were observed for dose combinations of verinurad ≥5 mg with febuxostat 40 mg versus febuxostat 80 mg alone. The rate of urinary uric acid excretion was reduced by febuxostat alone, but comparable to baseline levels with verinurad combined with febuxostat. Verinurad plasma exposures increased with verinurad dose and were comparable for febuxostat 40 mg and 80 mg doses. No drug-drug interaction on verinurad and febuxostat plasma PK parameters was observed. Verinurad at doses from 2.5 mg to 20 mg was well tolerated, with no serious AEs, withdrawals due to AEs, or renal-related events. The most frequent treatment-emergent AE possibly related to study medication was pain in extremity, in 2 patients receiving verinurad. Laboratory values and vital signs showed no clinically meaningful changes. There were no cases of serum creatinine elevation ≥1.5x baseline.

Figure 1. Maximum sUA percentage change

Conclusions: Verinurad coadministered with febuxostat dose-dependently decreased sUA while maintaining urine uric acid levels comparable to baseline. All dose combinations of verinurad and febuxostat in this study were generally well tolerated with no serious AEs or renal-related events during combination treatment.

THU0435 PHARMACODYNAMICS, PHARMACOKINETICS, AND SAFETY OF VERINURAD (RDEA3170) IN COMBINATION WITH FEBUXOSTAT VERSUS FEBUXOSTAT ALONE AND VERINURAD ALONE IN JAPANESE ADULTS WITH GOUT OR ASYMPTOMATIC HYPERURICEMIA: A PHASE 2A, OPEN-LABEL STUDY

M. Shiramoto[1], S. Liu[2], Z. Shen[2], J. Hall[2]. *[1]SOUSEIKAI PS Clinic, Fukuoka, Japan; [2]Ardea Biosciences, Inc., San Diego, CA, United States*

Background: Verinurad (RDEA3170) is a high-affinity URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia.

Objectives: This Phase 2a, randomized, open-label, single-site study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with febuxostat versus febuxostat alone and verinurad alone in Japanese male adults with gout or asymptomatic hyperuricemia (NCT02317861).
Methods: Japanese male patients aged ≥20 and ≤70 years with gout or asymptomatic hyperuricemia and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 6 cohorts to receive febuxostat (10 mg, 20 mg, and 40 mg) alone, febuxostat in combination with verinurad (dose range 2.5 mg to 10 mg); verinurad (2.5 mg to 15 mg) alone; or benzbromarone (50 mg) alone (4 treatment periods per cohort, each treatment period 7 days). The study drugs were administered once daily in the morning after breakfast. Serial blood and urine samples were measured at preset intervals on Days -1, 1, 2, 7, 8, 14, 15, 21, 22, 28 and 29 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, electrocardiograms, and vital sign parameters.
Results: Seventy-two patients with gout (n=37) or hyperuricemia (n=35) were randomized in this study. Addition of verinurad (2.5 mg to 10 mg) to febuxostat (10 mg, 20 mg, or 40 mg) decreased sUA in dose-dependent manner (Figure). Verinurad coadministered with febuxostat increased the amount of uric acid recovered in urine (Aeur), compared with baseline and the same dose of febuxostat administered alone, yet comparable with benzbromarone. Plasma Cmax and AUC exposures of verinurad and febuxostat exhibited dose proportional increases within the investigated dose range. No clear PK drug-drug interaction of verinurad and febuxostat with each other was observed. Verinurad at doses from 2.5 mg to 15 mg was well tolerated, with no serious AEs or withdrawals due to AEs. One treatment-emergent AE (diarrhea) was considered possibly related to both verinurad and febuxostat. Laboratory values and vital signs indicated no clinically meaningful changes.

Figure: Maximum percent change from baseline in sUA following varying verinurad doses in combination with FBX versus FBX 10, 20, or 40 mg alone

Conclusions: Verinurad coadministered with febuxostat dose-dependently decreased sUA while maintaining Aeur comparable to benzbromarone. All dose combinations of verinurad and febuxostat in this study were generally well tolerated.

THU0436 CLINICAL SIGNIFICANCE OF DELTA NEUTROPHIL INDEX IN THE DIFFERENTIAL DIAGNOSIS BETWEEN SEPTIC ARTHRITIS AND ACUTE GOUT ATTACK WITHIN 24 HOURS AFTER HOSPITALISATION

J.Y. Pyo, S.M. Jung, J.J. Song, Y.-B. Park, S.-W. Lee. *Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

Background: The most important differential diagnoses of acute monoarticular arthritis are septic arthritis and acute gout attack. Identifying infection is crucial in preventing the devastating outcome of septic arthritis.
Objectives: The delta neutrophil index (DNI) is a value that corresponds to the fraction of circulating immature granulocytes. As DNI reflects the burden of infection, we evaluated this index as a differentiating marker between septic arthritis and acute gout attack.
Methods: The medical records of 149 patients with septic arthritis and 194 patients with acute gout attack were reviewed. A specific cell analyser, ADVIA 2120, was used to measure DNI. Clinical and laboratory markers associated with predicting septic arthritis were assessed by using logistic regression.
Results: Patients with septic arthritis showed higher levels of DNI than those with acute gout attack (3.3 vs. 0.6%, $P<0.001$). Similar results were observed in patients without monosodium urate (MSU) crystal confirmation or those with normouricemia (3.3 vs. 0.5 and 3.1 vs. 0.7%, respectively; $P<0.001$ for both). A DNI level of 1.9% was determined as the cut-off value for predicting septic arthritis. In the multivariate analysis, DNI was the most powerful independent value for predicting septic arthritis (odds ratio 14.003).

Table 1. Comparison of variables between patients with acute gout attack and those with septic arthritis

Variables	Patients with acute gout attack (n=194)	Patients with septic arthritis (n=149)	Total (n=343)	p-value
Age, years	65.0±15.0	60.9±16.4	63.2±15.8	0.016
MSU crystals confirmed, n (%)	81 (41.8%)	N/A	81 (23.6%)	N/A
Positive culture, n (%)	N/A	98 (65.8%)	97 (28.3%)	N/A
WBC count, /mm^3	9600.0±3000.0	11,200.0±4700.0	10,300.0±3900.0	<0.001
DNI, %	0.6±0.9	3.3±4.0	1.8±3.0	<0.001
ESR, mm/h	61.7±33.8	78.2±32.5	69.3±34.2	<0.001
CRP, mg/L	76.5±68.7	126.6±104.0	98.7±89.6	<0.001
BUN, mg/dL	29.5±21.9	22.7±14.7	26.6±19.4	0.001
Creatinine, mg/dL	1.9±1.9	1.2±1.7	1.6±1.8	<0.001
Uric acid, mg/dL	7.6±2.5	4.4±1.6	6.3±2.7	<0.001

Table 2. Multivariate analysis of the predictive values for septic arthritis in patients with acute gout attack and those with septic arthritis*

Variables	Odds ratio	95% Confidence interval	p-value
WBC count ≥14,000.0/mm^3	1.888	0.563, 6.337	0.303
DNI ≥1.9%	14.003	5.683, 34.508	<0.001
ESR ≥70.0 mm/h	2.505	1.109, 5.657	0.027
CRP ≥106.0 mg/L	3.032	1.276, 7.209	0.012
Uric acid ≥7.0 mg/dL	0.031	0.011, 0.086	<0.001

Conclusions: This study showed the possibility of using DNI as a differentiating marker between septic arthritis and acute gout attack at the crucial early phase. DNI showed its relevance regardless of confirmation of MSU crystal deposition or serum level of uric acid.

THU0437 IMPACT OF DIURETICS ON THE URATE LOWERING THERAPY IN PATIENTS WITH GOUT: ANALYSIS OF AN INCEPTION COHORT

L. Ranieri[1], C. Contero[2], M. Andrés[1,2]. *[1]Seccion de Reumatologia, Hospital General Universitario de Alicante; [2]Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain*

Background: Use of diuretics is a common bystander in patients with gout, and it has been reported to impair response to allopurinol [1,2] and likely lead to treatment failure and refractoriness. However, after the introduction of new urate-lowering therapies (ULT) and treat-to-target strategies, whether this inconvenient effect of diuretics persists has not received critical attention to date.
Objectives: To analyze the impact of the diuretic therapy on the response to ULT in patients with gout.
Methods: Retrospective analysis of an inception cohort in patients with crystal-proven gout (Jan2014-Nov2016). Patients were classified according to the use of diuretics (loop and/or thiazide) at baseline. The primary outcome variables were the reduction of serum uric acid (SUA) levels and the achievement of different objectives of SUA (6, 5, and 4mg/dL); as secondary outcome variable the maximum dose of ULT was registered, as well as other clinical, analytical, and ULT-related data. A comparative analysis was performed according to the use of diuretics, using Student's t and chi-2 tests. Also, the analysis was stratified according to the ULT used.
Results: The inception cohort included 225 patients with an average age of 65 years (SD 14.1), being 86.2% of them men. The median duration of gout at inclusion was 4 years (p25–75 1–10) and 21.3% presented tophi. At baseline, the median (p25–75) SUA and estimated glomerular filtration rate were 8.2 mg/dL (7.2–9.2) and 75.9 mL/min (27.2–88.3), respectively. A total of 98 patients

Outcome variable	Diuretic therapy		p
	No	Yes	
Whole sample (N=209)	N=117	n=92	
– SUA reduction (mg/dL), mean (SD)	3.2 (2.1)	3.7 (2.5)	0.196
– SUA<6 (%)	80.0%	75.9%	0.458
– SUA<5 (%)	61.0%	50.6%	0.126
– SUA<4 (%)	31.4%	28.9%	0.575
Allopurinol (n=158)	N=92	N=66	
– SUA reduction (mg/dL), mean (SD)	3.1 (1.9)	3.2 (2.0)	0.813
– SUA<6 (%)	80.6%	74.2%	0.337
– SUA<5 (%)	60.2%	43.9%	0.043
– SUA<4 (%)	28.0%	21.2%	0.334
– Maximum dose (mg/day), mean (SD)	316.5 (126.9)	278.6 (121.8)	0.053
Febuxostat (n=33)	N=14	N=19	
– SUA reduction (mg/dL), mean (SD)	3.7 (3.4)	5.6 (3.1)	0.147
– SUA<6 (%)	70.0%	82.4%	0.456
– SUA<5 (%)	70.0%	76.5%	0.711
– SUA<4 (%)	60.0%	58.8%	0.952
– Maximum dose (mg/day), mean (SD)	80.0 (16.3)	80.0 (25.3)	0.348

(43.6%) were on diuretics mainly for hypertension (64.7%), heart failure (9.4%), and renal failure (5.9%). Follow-up data was available from 209 patients (92.9%), with a median 9 months of follow-up (4–14). ULT used was allopurinol in 172 patients (82.6%), febuxostat in 34 (16.5%), and benzbromarone in only 2 cases (0.9%). Regarding the baseline characteristics, patients on diuretics were older, had higher rates of females, hypertension, diabetes, and cardiovascular disease, and showed higher SUA and lower glomerular filtration rate. The table shows the outcomes comparison according to diuretic treatment, globally and stratified by type of ULT (excluding the two cases of benzbromarone). Except for a lower achievement of SUA<5 in the allopurinol subgroup, no significant differences were found either globally or by type of ULT.

Conclusions: Despite its high rate, diuretics currently seem to not have a significant impact on the achievement of the different objectives of treatment of patients with gout.

THU0438 LACK OF PREDICTIVE VALUE OF THE NIAID/FAAN CRITERIA TO IDENTIFY SUBJECTS WITH EVIDENCE OF IMMUNE ACTIVATION AFTER RECEIVING PEGLOTICASE FOR CHRONIC REFRACTORY GOUT

L. Calabrese[1], A. Kavanaugh[2], A. Yeo[3], P. Lipsky[4]. *[1]Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH; [2]Division of Rheumatology, Allergy, & Immunology, UCSD, la Jolla, CA; [3]Horizon Pharma, Lake Forest, IL; [4]AMPEL BioSolutions, LLC, Charlottesville, VA, United States*

Background: The NIAID/FAAN criteria have been widely applied to identify anaphylaxis despite having only modest specificity.1,2

Objectives: To evaluate the predictive value of the NIAID/FAAN criteria to identify evidence of immune activation in subjects with chronic refractory gout treated with pegloticase in randomized clinical trials (RCTS) who experienced infusion reactions (IRs), by assessing the capacity of biochemical testing for immunologic activation to confirm the likelihood of anaphylaxis.

Methods: During the RCTs supporting the approval of pegloticase for treatment of chronic refractory gout, subjects remained on therapy despite becoming nonresponders, which reflected the development of anti-drug antibodies (ADA); ~60% of subjects continued to receive pegloticase despite elevated ADA titers and many had IRs. In subjects receiving pegloticase every 2 weeks (q2w), 22/85 (25.9%) had a total of 43 IRs and 34/84 (40.5%) receiving pegloticase every 4 weeks (q4w) had a total of 70 IRs. 21/22 (95.5%) and 29/34 (85.3%) subjects with IRs in the q2w and q4w groups, respectively, were nonresponders. The 113 total IRs were categorized post hoc as to whether they met NIAID/FAAN criteria for anaphylaxis. Six IRs in 6 subjects met criteria, 53 IRs in 33 subjects had only one feature and were designated as "hypersensitivity", and 54 IRs in 29 subjects had no features and were designated "other". The clinical courses of these IRs and whether they were associated with elevated tryptase levels as a measure of mast cell degranulation or complement consumption as a measure of immune complex activity were assessed.

Results: Of a total of 852 infusions in subjects receiving q2w pegloticase, 43 (5.0%) were associated with IRs as were 70 of 830 infusions (9.5%) in subjects receiving q4w pegloticase. Of the 70 IRs associated with q4w administration, 3 (4.3%) met the criteria for anaphylaxis, 31 (44.3%) for hypersensitivity and 36 (51.4%) were other. The respective values for subjects receiving pegloticase q2w were 3/43 (7.0%),22/43 (51.1%), and 18/43 (41.9%). A total of 14 IRs (12.4%) were associated with elevated tryptase and 31 (27.4%) with decreased complement CH50 levels. Immunologic abnormalities were not significantly different in the 3 groups, with 16.7%, 17.0% and 7.4% of anaphylaxis, hypersensitivity and other IRs, respectively, having increased tryptase; and 0%, 30.2%%, and 27.8%, respectively, having decreased complement. No subjects were classified as experiencing anaphylaxis by investigators, none required hospitalization, and 60.7%, continued to receive pegloticase.

Conclusions: Post-hoc designation of pegloticase-treated subjects as meeting NIAID/FAAN criteria for anaphylaxis was not associated with a higher frequency of biochemical evidence of immune activation or a more severe clinical course. In pegloticase-treated subjects, the NIAID/FAAN anaphylaxis criteria did not identify subjects with IRs associated with elevated tryptase and decreased complement CH50 levels.

THU0439 MORE OBESITY AND HIGHER SERUM URIC ACID IN EARLY-ONSET GOUT PATIENTS IN SOUTH CHINA

Q.-H. Li[1], L.-X. Chen[2], Y.-H. Li[1], D.-H. Zheng[1], Y.-Q. Mo[1], L. Dai[1], J.-J. Liang[1], X.-N. Wei[1]. *[1]Department of Rheumatology; [2]Department of Internal Medecine, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

Background: Gout incidence increases in a linear fashion with age until 70 years. It was reported that there was a trend of earlier gout onset. Few studies about clinical features of early-onset gout in China are reported.

Objectives: To investigate the characteristics of early-onset gout in south China.

Methods: Patients with primary gout were recruited between June 2012 and December 2016. Face to face interview was carried out to collect demographic information, clinical characteristics of gout and comorbid diseases. The patients with gout onset before age 30 were defined as early-onset group. The other gout patients were enrolled as control group.

Results: (1) Five hundred and one gout patients were recruited, including 99 (19.8%) in the early-onset group and 402 (80.2%) in the control group. The onset age of the early-onset group was 24.2±5.8 (range 14–30) and the control group was 51.7±13.9 (range 31–84). There was no significant difference of gout duration between early-onset group and control group (P<0.05, Table 1). (2) Compared with the control group, the early-onset group presented lower frequency of flare in last year, higher serum uric acid and higher proportion of sUA>10mg/dl (P<0.05, Table 1). Body mass index (BMI) and prevalence of obesity were higher in the early-onset group (P<0.05, Table 1). The early-onset group exhibited lower prevalence of hypertension, diabetic mellitus, urolithiasis and chronic kidney disease (CKD) (P<0.05, Table 1). (3) There were 20 patients (20.2%) with tophi in the early-onset group. Compared with the 79 early-onset gout patients without tophi, the patients with tophi presented higher age (39.6±8.9 VS 29.1±6.2, P<0.001), duration of gout (12.6±4.8 VS 4.5±4.8, P<0.001), number of involved joints (12.5±9.3 VS 4.3±3.7, P<0.001) and prevalence of CKD (30.0% VS 10.1%, P=0.034), and lower BMI (23.7±3.7 VS 26.6±4.1 kg/m^2, P=0.004). Logistic regression demonstrated that higher disease duration [OR 1.30, 95% CI (1.15, 1.46), P<0.001] and lower BMI [OR 0.80, 95% CI (0.67, 0.96), P=0.015] were associated with tophi in the early-onset gout patients.

Table 1. Comparison of variables between early-onset group and control group

	Early-onset group (N=99)	Control group (N=402)	P
Age, years	30.4±8.2	57.9±13.5	<0.001
Female, %	1.0%	12.7%	<0.001
Age of onset, years	24.2±5.8	51.7±13.9	<0.001
Duration of gout, years	6.2±5.8	6.2±5.6	0.953
Frequency of flare in last year	6.4±7.5	9.3±10.9	0.022
sUA, mg/dl	10.6±2.4	8.9±2.5	<0.001
>10mg/dl, %	59.6%	32.8%	<0.001
No. of involved joints	5.9±6.0	5.9±5.5	0.981
Tophi, %	20.2%	26.1%	0.397
Alcohol overuse, %	35.4%	34.1%	0.811
BMI, kg/m^2	26.1±4.2	24.8±3.9	0.004
Obesity, %	27.3%	15.5%	0.005
Dyslipidemia, %	51.5%	54.0%	0.666
Hypertension, %	14.1%	44.0%	<0.001
DM, %	6.1%	24.6%	<0.001
Urolithiasis, %	19.2%	33.6%	0.007
eGFR, ml/min/1.73m^2	84.8±51.0	62.9±19.7	<0.001
CKD, %	14.1%	45.6%	<0.001

sUA: serum uric acid; BMI: body mass index; DM: diabetic mellitus; eGFR: estimated glomerular filtration rate; CKD: chronic kidney disease.

Conclusions: Early-onset gout exhibited higher sUA and was associated with obesity but not with hypertension, diabetic mellitus and renal insufficiency. Longer disease duration and lower BMI were associated with tophi in the early-onset gout patients.

THU0440 TEMPORAL TRENDS OF VENOUS THROMBOEMBOLISM RISK BEFORE AND AFTER DIAGNOSIS OF GOUT. A GENERAL POPULATION-BASED STUDY

L. Li[1,2], N. McCormick[1,2], E.C. Sayre[1], J. Esdaile[1,2], D. Lacaille[1,2], H. Xie[1,3], H.K. Choi[1,4], J.A. Avina-Zubieta[1,2]. *[1]Arthritis Research Canada, Richmond; [2]The University of British Columbia, Vancouver; [3]Simon Fraser University, Burnaby, Canada; [4]Harvard Medical School, Boston, United States*

Background: Data on the risk of venous thromboembolism (VTE, including deep venous thrombosis and pulmonary embolism) in patients with gout are scarce.

Objectives: 1) To estimate the overall risk of VTE in an incident gout cohort; 2) To estimate the temporal trends of VTE before and after gout diagnosis compared with the general population.

Methods: We conducted a matched cohort study using a population based administrative health database that includes all outpatient visits, hospital admissions, vital statistics, and dispensed medications for all residents in British Columbia, Canada. Gout cases were defined using one ICD-9/10 code (274/M10) from a

physician or hospital visit. To ensure incident gout, we required that all cases have ≥10 years of prior registration without a gout diagnosis. Gout cases were matched 1:1 with controls on age, sex, and cohort entry time. Prior VTE events were excluded after matching. VTE was defined using ICD-9/ICD-10 codes plus use of oral anti-coagulant. We calculated incidence rate ratios (IRRs) and age, sex, and entry time matched multivariable hazard ratios (HRs) for the risk of VTE. Sensitivity analyses were conducted to assess for unmeasured confounders (e.g., obesity).

Results: Among 105,307 individuals with newly diagnosed gout (61% male, mean age of 58 yrs), we observed 1,212 VTE events (mean follow-up time of 5.3 yrs). The fully adjusted HR was 1.27 (95% CI, 1.16–1.39) (Table 1). Our results remained significant in the sensitivity analyses (OR of 2.0 between gout and unmeasured confounder and a 50% prevalence for obesity). There were 437 incident VTE events within 3 yrs prior to the gout diagnosis. Compared to controls, during the 3rd, 2nd, and 1st yrs before gout diagnosis, the fully adjusted HRs for VTE in patients with imminent gout were 1.51, 1.58 and 1.73. The corresponding HRs in the 1st, 2nd, 3rd, 4th, and 5th yrs after gout diagnosis were 1.54, 1.39, 1.38, 1.37, and 1.32, respectively.

Table 1

	Gout (N)	Control (N)	No. of VTE events		IRRs (95% CI)	Age-, sex-adjusted (95% CI)	Fully adjusted* (95% CI)
			Gout	Control			
Before gout diagnosis

*Adjusted for Charlson comorbidity index, cancer, alcoholism, hypertension, sepsis, trauma, healthcare utilization, NSAIDs, HRT, glucocorticoid and fractures, surgery within 1 year before entry cohort.

Conclusions: Patients with gout have an increased risk of VTE. The risk increases gradually before gout diagnosis, peaks in the year prior to gout diagnosis, and then progressively declines. Our findings suggest that hyperuricemia or gout associated inflammation may be a contributing factor for VTE.

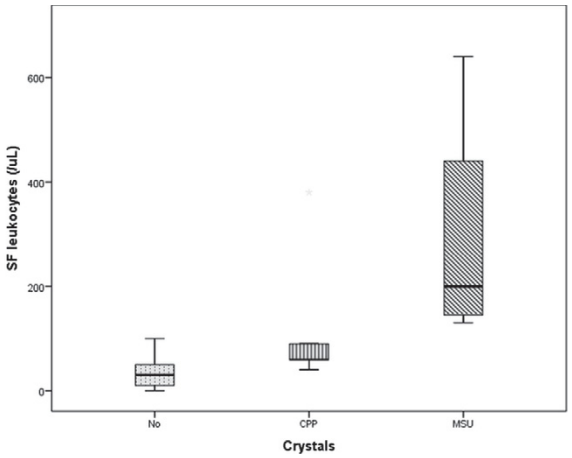
THU0441 SYNOVIAL FLUID LEUKOCYTE COUNT AND ITS ASSOCIATION WITH CRYSTAL DEPOSITION IN ASYMPTOMATIC HYPERURICEMIA: A PRELIMINARY REPORT



M. Andrés[1,2], J.A. Bernal[2], M.D. Arenas[3], E. Pascual[2,4]. *[1]Departamento de Medicina Clínica, Universidad Miguel Hernández; [2]Seccion de Reumatologia, Hospital General Universitario de Alicante; [3]Unidad de Nefrología, Hospital Vithas Perpetuo Socorro; [4]Emeritus Professor, Universidad Miguel Hernández, Alicante, Spain*

Background: Joint deposits of monosodium urate (MSU) crystals in asymptomatic hyperuricemia (AH) may associate with more severe forms of atherosclerosis [1]. It likely relates with crystal-driven subclinical inflammation, a phenomenon well described in gout [2] but to date not assessed in AH.

Objectives: To assess the synovial fluid (SF) leukocytes count in patients with AH depending on the presence of crystals.

Methods: Consecutive patients with AH were selected from nephrology clinics. Hyperuricemia threshold was established at serum uric acid (SUA) ≥7mg/dL; those on current urate-lowering therapy were excluded. Ultrasound (US) of knees, ankles and first metatarsophalangeal joints was performed blinded to clinical and laboratory data, in order to perform US-guided aspiration and obtain SF samples. These samples were analyzed in fresh by two observers, using a compensated polarized light microscope equipped with two viewing stations. The second observer was in addition unaware of US findings. The presence of leukocytes and crystals was established by consensus. SF leukocyte count was performed using a Neubauer counting camera. Mann-Whitney's U and Kruskal-Wallis' H were used to compare difference in leukocyte counts between groups.

Results: To end of January 2017, 30 patients have been assessed, with SF samples available from 27 (three showed no joint effusion at US). Median age was 70 years (p25–75 59.8–75.5), and 16 of them (60%) were males. Median (p25–75) SUA and estimated glomerular filtration rate were 8.1 mg/dL (7.6–8.5) and 37.0 mL/min (31.0–47.5), respectively. Seven (25%) were on diuretics. After microscopy evaluation, MSU crystals were found in four patients (14.8%), calcium pyrophosphate (CPP) crystals in five (18.5%), and no crystals in 18 (66.7%). Figure shows median leukocytes count according to crystal group: 200/mm^3 (138–540) in MSU group; 60/mm^3 (50–235) in CPP group; and 30/mm^3 (10–53) in those with no crystal at SF. A statistically significant difference was found between the three groups (p=0.001), and comparing MSU crystals and no crystals groups (p<0.001); no difference was found between MSU and CPP groups (p=0.111).

Conclusions: In a preliminary report, MSU crystal deposition in patients with AH leads to higher SF leukocyte count, indicating low-grade inflammation. Despite low numbers and being an ongoing study, this significant finding might contribute to explain the severe atherosclerosis data recently reported in AH patients with silent crystal deposits.

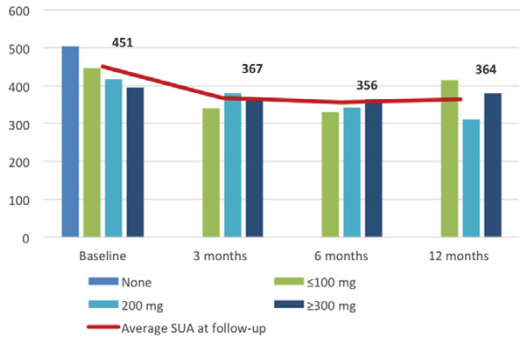
THU0442 EHEALTH SUPPORTED COLLABORATIVE CARE MODEL FOR GOUT INVOLVING RHEUMATOLOGY, PHARMACY, AND DIETETICS: PROOF-OF-CONCEPT OBSERVATIONAL STUDY

M.A. De Vera[1,2], A. Howren[1], N. Tsao[1], H. Choi[3], A. Kydd[4], R. Friesen[5], K. Shojania[2,4]. *[1]Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver; [2]Arthritis Research Canada, Richmond, Canada; [3]Department of Medicine, Massachusetts General Hospital, Boston, United States; [4]Division of Rheumatology, University of British Columbia; [5]Providence Health, Vancouver, Canada*

Background: Sub-optimal quality of care for gout, the most common inflammatory arthritis, has called for novel models to improve care and outcomes of patients.



Objectives: Our objective was to evaluate the feasibility of the "Virtual Gout Clinic Study" (VGCS) a collaborative approach to gout management involving rheumatology, pharmacy, and dietetics that take advantage of eHealth, namely, shared access of electronic medical records (EMRs), to support this unique, decentralized model of care.

Methods: *Design:* We conducted a 1-year, proof-of-concept, longitudinal observational study with a target of 30 patients. *Eligibility:* Patients with gout were eligible if they were: 1) seen in 1 of 4 rheumatology practices with 8 rheumatologists participating across British Columbia, Canada; 2) experienced ≥1 flare in the past year; 3) have a serum uric acid (SUA) level ≥360 μmol/L within the previous 2 months. *Follow-up:* Within the *VGCS*, patients receive follow-up with their rheumatologist on an as needed-basis, monthly telephone consults from the study pharmacist, and 1 telephone consult with the dietician. In this decentralized model of care, health care professionals are not co-located but have access to the patient's EMR to facilitate remote communication and collaboration. *Outcomes:* Prospective data was collected at baseline, 3, 6, and 12 months. The primary outcome measure was SUA at 12-months, specifically below recommended target level of 360 μmol/L. Secondary outcomes included patient reported outcome measures including the Compliance Questionnaire Rheumatology, Health Assessment Questionnaire Disability Index, and EQ-5D, as well as information on interventions provided within the *VGCS*.

Results: Overall, 33 individuals with gout participated in the *VGCS*. There were 22 males (88%) and mean age was 60.8±15.3 years. 29, 28, and 25 patients have completed follow-up at 3, 6, and 12 months respectively. At baseline, 22 (67%) patients were prescribed urate-lowering therapy (ULT; 21 with allopurinol and 1 with febuxostat). The remaining 11 patients initiated ULT during the study period. Figure 1 shows mean SUA decreased over baseline, 3, 6, and 12 months from 451 μmol/L, 367 μmol/L, 356 μmol/L, and 364 μmol/L, respectively, with 67% of patients having SUA <360 μmol/L at 12 months. A total of 126 pharmacist and 24 dietician consults have been provided. Pharmacist interventions included: uptritration of allopurinol dosage for 15 patients, restarting of ULT for 4 non-adherent patients, discontinuation of unnecessary medications for 12 patients, and renewals of prescription medications using solely electronic communications for 4 patients.

Conclusions: These findings provide evidence for the feasibility and effectiveness of the *VGCS*. With respect to feasibility, we successfully established the shared EMR framework between rheumatologists and study pharmacist and dietitian and demonstrated utility with respect to facilitating communication and collaborative

Figure 1. SUA according to allopurinol dose (baseline to 12 months)

care between health care providers and providing outcomes data. With respect to effectiveness, findings show declining SUA over follow-up with over two-thirds of patients achieving target at the end of follow-up.

THU0443 HYPERURICEMIA IS ASSOCIATED WITH INCREASED CORONARY ARTERY CALCIFICATION IN MEN BUT NOT WOMEN

M.I. Dehlin[1], P. Drivelegka[1], V. Sigurdardottir[1], O. Angerås[2], L.T. Jacobsson[1], H. Forsblad d'Elia[1,3]. *[1]Dept of rheumatology and inflammation research, Institution of medicine, Sahlgrenska Academy, University of Gothenburg; [2]Department of Cardiology, Sahlgrenska University Hospital, Gothenburg; [3]Departments of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden*

Background: Hyperuricemia is closely associated to cardiovascular disease although it has not been defintively established whether it is a marker or a causative agent. Serum uric acid (sUa) is strongly linked to the metabolic syndrome, hypertension (HT), dyslipidemia (DL) and higher BMI and higher levels are seen in men compared to women. Coronary artery calcification (CAC) is associated with future risk of atherosclerotic CV events in addition to these traditional cardiovascular risk factors (CVRF). CACs are present in atherosclerotic arteries and can be quantified and scored non-invasively by computed tomography. The Swedish CArdioPulmonarybioImage Study (SCAPIS) extensively characterizes a Swedish cohort of 30 000 men and women aged between 50 and 64 years. A comprehensive pilot study in 1111 individuals was completed in 2012. In this pilot study we have examined the relation between CACs and sUa

Objectives: Examine the association bewteen sUa and CAC in men and women seperately.

Methods: In the SCAPIS pilot study we identified 1106 (552 males) individuals who were screened for traditional CVDRFs, such as HT, DL, diabetes mellitus (DM), smoking, physical activity (PA), educational level (EDU), BMI, high sensitive CRP (hsCRP). CACs, reflecting calcification of coronary arteries, was determined according to Agatston[1]. We measured sUa and related quartiles to CACs with multiple logistic regression analyses adjusting for traditional CVDRFs. CAC was defined positive if ≥1.

Table 1. Baseline characteristics of the study population divided by sex

Variables	Male, n=552	Female, n=556
Age, years, mean, (SD)	57.8 (4.5)	57.6 (4.3)
BMI, mean, (SD)	27.7 (4.0)	26.9 (3.7)
hsCRP, (mean, SD)	2.3 (3.3)	2.4 (3.7)
CAC positive, (%)	305 (55%)	142 (26%)
Smoking status, never	226 (41%)	249 (45%)
Smoking status, previous	242 (44%)	222 (40%)
Smoking status, active	82 (15%)	81 (15%)
Hypertension (%)	178 (32%)	190 (34%)
Diabetetes mellitus (%)	45 (8%)	23 (4%)
Dyslipidemia (%)	160 (29%)	128 (23%)

Table 2. Quartiles of sUa and age as predictors for presence of CAC (>0 CACs score) in male and female in multivariate logistic regression analyses adjusted for age, smoking, BMI, DM, DL, HT, hsCRP, EDU and PA

sUa, μmol/L,	Male		sUa, μmol/L,	Female	
	Odds ratio, multivariate*, (CI)	p-value		Odds ratio, multivariate*, (CI)	p-value
31–305, Ref			143–229, Ref		
306–350	2.1 (1.2–3.7)	0.01	230–262	0.9 (0.5–1.7)	0.7
351–404	1.8 (1–3.3)	0.04	263–305	1 (0.5–2)	0.9
405–665	2 (1–3.8)	0.04	306–702	1.2 (0.6–2.3)	0.6
Age 50–55, Ref					
Age 56–60	2.2 (1.4–3.6)	0.001		3.6 (2–6.5)	<0.0001
Age 61–66	3.8 (2.2–6.3)	<0.0001		4.3 (2.4–7.9)	<0.0001

Results: Age, BMI, smoking status, hsCRP, HT and DL showed no differences between sex while presence of CAC and diabetes was twice as common in men (Table 1). The three upper quartiles of sUa, (>306 μmol/L), all significantly ($p<0.05$) predicted presence of CACs in men even adjusting for HT, DL, DM, smoking, PA, EDU, BMI, hsCRP and age in multivariate logistic regression, but not in women (Table 2).

Conclusions: Higher levels of sUa is associated with presence of CACs in men but not in women. This may merely reflect the earlier onset of atherosclerosis in men or possibly suggest biological differences in the effect of sUa on calcification of coronary arteries between sexes.

THU0444 INTEGRATED SAFETY OF LESINURAD, A NOVEL URIC ACID REABSORPTION INHIBITOR FOR THE TREATMENT OF GOUT

M.A. Becker[1], R.T. Keenan[2], P.P. Khanna[3], R. Malamet[4], K. Bos[4], J. Li[4], J. Hu[5], W.B. White[6]. *[1]University of Chicago, Chicago; [2]Duke University School of Medicine, Durham; [3]University of Michigan, Ann Arbor; [4]AstraZeneca Pharmaceuticals, Wilmington; [5]Formerly Ardea Biosciences, Inc, San Diego; [6]University of Connecticut School of Medicine, Farmington, United States*

Background: Lesinurad is a selective uric acid reabsorption inhibitor recently approved at 200 mg daily in combination with a xanthine oxidase inhibitor (XOI) for treatment of hyperuricemia associated with gout in patients who have not achieved target serum uric acid on an XOI (allopurinol or febuxostat) alone.

Objectives: To investigate the safety profile of lesinurad (LESU), we integrated safety data based on: (1) 3 large, pivotal, placebo-controlled, 12-month phase III (core) trials evaluating LESU 200 mg and LESU 400 mg in combination with an XOI; and (2) 2 extension studies, in which LESU-treated patients continued to receive LESU + XOI at the same dose and initially placebo-treated patients were randomized to receive LESU 200 mg or LESU 400 mg in addition to the XOI provided in the preceding core trial.

Methods: Safety data were pooled from the 3 core studies and 2 12-month extension studies using descriptive statistics for patients receiving ≥1 dose of study medication. To adjust for varying treatment durations, treatment-emergent adverse events (TEAEs) are expressed as exposure-adjusted incidence rates (number of subjects with events per 100 person-years [PY]).

Results: In the core studies, adverse event rates were comparable for XOI alone and LESU 200 mg + XOI groups for any TEAEs, serious TEAEs, and TEAEs leading to discontinuation (Table 1). Adverse event rates were higher with LESU 400 mg + XOI. Major adverse cardiovascular event (MACE) rates, which included cardiovascular death, myocardial infarction, or stroke, in the core studies were 0.71 (95% CI 0.15, 2.08), 0.96 (0.26, 2.47), and 1.94 (0.84, 3.82) per 100 PY for XOI

Table 1. Pooled Analysis of Exposure-Adjusted Adverse Event Incidence Rates in 3 Pivotal Placebo-Controlled 12-Month Phase III Studies Evaluating Lesinurad 200 mg and 400 mg in Combination with Xanthine Oxidase Inhibitors

Adverse Event Category [n (rate)]	XOI alone (N=516) (PY=408.5)	LESU 200 mg + XOI (N=511) (PY=396.3)	LESU 400 mg + XOI (N=510) (PY=390.5)
Any TEAE	363 (88.9)	386 (97.4)	407 (104.2)
Any TEAE with RCTC toxicity Grade 3 or 4	48 (11.8)	52 (13.1)	67 (17.2)
Any TEAE possibly related to randomized study medication	80 (19.6)	98 (24.7)	118 (30.2)
Any TEAE possibly related to XOI	52 (12.7)	49 (12.4)	66 (16.9)
Any TEAE possibly related to prophylaxis	52 (12.7)	56 (14.1)	61 (15.6)
Any serious TEAE	29 (7.1)	24 (6.1)	44 (11.3)
Any fatal TEAE	0 (0)	2 (0.5)	3 (0.8)
Any TEAE leading to randomized study medication discontinuation	28 (6.9)	32 (8.1)	48 (12.3)

Table 2. Pooled Analysis of Exposure-Adjusted Adverse Event Incidence Rates in 3 Pivotal Placebo-Controlled 12-Month Phase III Studies + 2 Extension Studies Evaluating Lesinurad 200 mg and 400 mg in Combination with Xanthine Oxidase Inhibitors

Adverse Event Category [n (rate)]	LESU 200 mg + XOI (N=666) (PY=926.5)	LESU 400 mg + XOI (N=666) (PY=917.9)
Any TEAE	531 (57.3)	552 (60.1)
Any TEAE with RCTC toxicity Grade 3 or 4	93 (10.0)	115 (12.5)
Any TEAE possibly related to randomized study medication	158 (17.1)	187 (20.4)
Any TEAE possibly related to XOI	77 (8.3)	101 (11.0)
Any TEAE possibly related to prophylaxis	76 (8.2)	81 (8.8)
Any serious TEAE	63 (6.8)	84 (9.2)
Any fatal TEAE	7 (0.8)	7 (0.8)
Any TEAE leading to randomized study medication discontinuation	68 (7.3)	86 (9.4)

LESU, lesinurad; PY, patient years; RCTC, Rheumatology Common Toxicity Criteria; TEAE, treatment-emergent adverse event; XOI, xanthine oxidase inhibitor. Exposure-adjusted incidence rates are expressed as subjects with events per 100 person-years.

alone, LESU 200 mg + XOI, and LESU 400 mg + XOI, respectively. Renal-related TEAE rates in the core studies were 5.6, 7.3, and 15.4 per 100 PY, respectively. Longer exposure in the core + extension studies did not result in increases in any TEAEs, serious TEAEs, or TEAEs leading to discontinuation (Table 2). MACE rates were low in the core + extension studies, at 1.05 (95% CI 0.50, 1.93) and 1.48 (0.81, 2.48) in the LESU 200 mg + XOI and LESU 400 mg + XOI groups, respectively. Renal events in the core + extension studies were lower in the LESU 200 mg + XOI than LESU 400 mg + XOI group at 8.6 and 14.6, respectively.

Conclusions: Lesinurad at the approved dose of 200 mg once daily demonstrated a consistent, acceptable safety profile. There were no new safety concerns in the extension studies.

THU0445 GOUTY ARTHRITIS: DECISION MAKING FOLLOWING DUAL ENERGY CT SCAN IN CLINICAL PRACTICE, A RETROSPECTIVE ANALYSIS

M. Gamala[1], S. Linn-Rasker[2], M. Nix[2], B. Heggelman[2], J. van Laar[1], P. Pasker-de Jong[2], J. Jacobs[1], R. Klaasen[2]. *[1]University Medical Center, Utrecht; [2]Meander Medical Centre, Amersfoort, Netherlands*

Background: Gout is associated with joint damage, and increased cardiovascular morbidity; it is important to diagnose and treat it. However, although clinical presentation may be strongly suggestive of gout, joint aspiration and microscopy not always yield the diagnosis. The latest technique to visualize monosodium uric acid MSU depositions and thus to diagnose gout is Dual Energy CT scan (DECT).[1]

Objectives: To establish whether DECT is a diagnostic tool, i.e. associated with initiation or discontinuation of a urate lowering drug (ULD). Second, whether DECT results (gout deposition y/n) can be predicted by clinical and laboratory variables.

Methods: Digital medical records of 147 consecutive patients with clinical suspicion of gout at the outpatient clinic of the Department of Rheumatology of Meander Medical Centre, Amersfoort, the Netherlands who underwent DECT between January 1, 2013 and December 31, 2014 were analyzed retrospectively. Collected were clinical data including medication before and after DECT, lab results, and results from diagnostic joint aspiration and DECT. The relationship between DECT results and clinica, and laboratory results was evaluated by univariate regression analyses; predictors showing a $p<0.10$ were entered in a multivariate logistic regression model with the DECT result as outcome variable. A manual backward stepwise technique was applied.

Results: 87 patients were diagnosed with gout based on demonstration of MSU crystals in synovial fluid (SF) or positive DECT result. In 30 patients, DECT was the only conformation of gout; in 29 of them ULD was started and in 1 it was intensified. Following DECT, the current ULD was stopped in 3 patients. The clinical and laboratory variables associated with the DECT result are presented in table 1. In the multivariable regression model, cardiovascular disease y/n (OR 3.07, 95% CI 1.26–7.47), disease duration in years (OR 1.008, 95% CI 1.001–1.016), frequency of attack per year (OR 1.23, 95% CI 1.07–1.42), creatinine clearance in ml/min (OR 2.03, 95% CI 0.91–1.00) were independently associated with positive DECT results.

Table 1. Univariate model analyses of predictors of positive DECT results

	OR (95% CI)	p
Gender (reference: male gender)	0.48 (0.24–0.99)	0.04
Body Mass Index (per kg/m^2)	1.03 (0.96–1.11)	0.36
Cardiovascular disease yes/no	2.72 (1.36–5.42)	0.04
Diabetes mellitus yes/no	3.69 (1.26–10.71)	0.01
Urate lowering therapy use at the moment of DECT yes/no	2.6 (1.15–6.28)	0.02
Disease duration years	1.01 (1.005–1.02)	0.01
Frequency of attacks per year	1.2 (1.08–1.33)	0.01
Uric acid levels between flares (per μmol/L)	1.004 (1.001–1.007)	0.008
Creatinine clearance (per ml/min)	0.95 (0.92–0.99)	0.01
Joint involvement at the moment of DECT: MTP1 or other joints	1.69 (1.05–3.37)	0.1
Past first metatarsophalangeal (MTP1) joint involvement yes/no	3.37 (1.69–6.72)	0.01
MSU crystals at microscopy yes/no	1.62 (1.23–2.17)	0.001

Conclusions: DECT has impact on clinical decisions on ULD therapy. It may be a useful diagnostic imaging tool for patients who cannot undergo joint aspiration because of contraindications or with difficult to aspirate joints, or those who refuse joint aspiration.

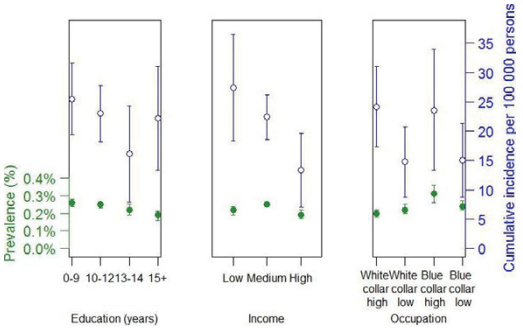
THU0446 PREVALENCE AND INCIDENCE OF NON-GOUT CRYSTAL ARTHROPATHY IN SOUTHERN SWEDEN FROM THE SOCIOECONOMIC PERSPECTIVE



M. Hameed[1], A. Turkiewicz[2], T. Saxne[3], L. Jacobsson[4], M. Englund[5], M.C. Kapetanovic[6]. *[1]Department of Clinical Sciences, Lund, Section for Rheumatology, Lund University, Lund and Skåne University Hospital, Section for Rheumatology in Lund and Malmö, Sweden, Malmö; [2]Lund University, Faculty of Medicine, Department of Clinical Sciences Lund, Orthopedics, Clinical Epidemiology Unit, Lund, Sweden; [3]Department of Clinical Sciences, Lund, Section for Rheumatology, Lund University, Lund, Section for Rheumatology in Lund and Malmö, Lund; [4]Department of Rheumatology & Inflammation Research, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg; [5]Lund University, Faculty of Medicine, Department of Clinical Sciences Lund, Orthopedics, Clinical Epidemiology Unit; [6]Department of Clinical Sciences, Lund, Section for Rheumatology, Lund University, Lund and Skåne University Hospital, Section for Rheumatology in Lund and Malmö, Sweden, Lund, Sweden*

Background: Recently, we reported the prevalence of gout to be 1.7% among adults in the Skåne region in southern Sweden (1). Few epidemiological data are available on non-gout crystal arthropathy and none for this region.

Objectives: The objective of this study was to study the prevalence and incidence of non-gout crystal arthropathy (including chondocalcinosis, acute/subacute/chronic calcium pyrophosphate/hydroxyapatite or other crystal deposition disease) in southern Sweden from the socioeconomic perspective.

Methods: The Skåne Healthcare Register includes information on all health care visits with given ICD10-coded diagnoses for all citizens in the region (total population 1.3 million). SHR was searched for all adult (≥18 years) residents in Skåne region in year 2014, who between 1998 and 2014 had received at least one diagnosis of non-gout crystal arthropathy (ICD-10 code M11.0- M11.9) by any physician. The crude point prevalence at December 31st 2014 and the cumulative incidence in the calendar year 2014 were calculated. In addition, we examined the 2014 age- and sex- standardized point prevalence and cumulative incidence of non-gout crystal arthropathy according to occupation (white collar /blue collar with high or low skilled occupations), income (low/middle/high) and level of education (primary school/high school/university).

Results: The crude 2014 point prevalence and 2014 cumulative incidence (95% CI) of non-gout crystal arthropathy were 0.23% (0.22% - 0.24%) and 21.5 (18.6–24.3) cases per 100 000 persons at risk, respectively. Compared to women, men had numerically but not significantly higher prevalence (0.26% vs 0.20%) and incidence (24.6 vs 18.5 per 100 000 persons). This pattern remained regardless of age. The mean (SD) age of a person with prevalent non-gout crystal arthropathy was 71.5 (14.4) years. Both prevalence and incidence increased with increasing age and were highest in individuals ≥85 years (prevalence 1.4%), but decreased with years of education. Persons with middle income and blue collar high skilled occupation (e.g. skilled agricultural, forestry and fishery workers and craft and related trades workers) had the highest point prevalence and incidence of non-gout crystal arthroplasty (figure).

Conclusions: Although considerably less prevalent than gout in southern Sweden non-gout crystal arthropathy affects about 0.2% of the adult population, i.e. a similar prevalence as for psoriatic arthritis in the same region. The prevalence increases with age and is highest among individuals aged 85 years or higher. There is a socioeconomic gradient with more affected individuals among people with lower level of education, middle income, and more manual work.

THU0447 CO-MORBID GOUT IS ASSOCIATED WITH INCREASED CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH TYPE 2 DIABETES, BUT NOT CARDIOVASCULAR EVENTS OR MORTALITY

M. Mian[1], S.K. Patel[2], B. Wai[1], P.M. Srivastava[1], R.R.C. Buchanan[1,2], L.M. Burrell[1,2]. *[1]Department of Medicine, Austin Health; [2]Department of Medicine, University of Melbourne, Melbourne, Australia*

Background: Gout is an inflammatory arthropathy characterised by elevated serum uric acid levels. In Australia, gout has a prevalence of 1.7 - 4%.[1] This increased to ~10% in community based Australian patients with type 2 diabetes, although elevated serum uric acid did not predict cardiovascular (CV) or all-cause mortality.[2] To date, the long-term outcomes of patients with diabetes and comorbid gout being followed up in the hospital out-patient setting have not been studied.
Objectives: To compare cardiovascular risk factors and long-term outcomes and mortality in patients with type 2 diabetes according to the presence or absence of gout.
Methods: 1,405 patients with type 2 diabetes were prospectively recruited from the outpatient setting at Austin Hospital. Baseline cardiovascular risk factors and comorbidities were identified. Patients were classified as having gout if they gave a history of gout or were taking medication for the treatment of gout. For statistical analysis, patients with diabetes (Group 1) were compared to those with diabetes and gout (Group 2). Cardiovascular events and long-term CV mortality were assessed over a 10 year period.
Results: There were 1,329 patients with diabetes (Group 1; 95%) and 76 with diabetes and gout (Group 2; 5%). Patients with gout were older (68±11 vs. 64±12y, p=0.004), more likely to be male (80% vs. 59%, p<0.0001), with higher triglyceride levels (2.6 vs 1.9 mmol/L, p=0.002), lower HDL (1.05 vs. 1.24 mmol/L, p<0.0001), higher BMI (33 vs. 31, p=0.026), and were more likely to have nephropathy (55% (n=35) vs. 26% (n=311), p<0.0001) with increased albumin creatinine ratio (3.4 vs 1.8 g/mmol, p=0.002). Despite the worse cardiovascular risk profile in those with gout and diabetes, cardiovascular events and all-cause mortality were not significantly different between the groups (Group 1, 27% (n=333) vs. 35% (n=23) in Group 2, p=0.201).
Conclusions: Although patients with comorbid gout and type 2 diabetes have a worse cardiovascular risk factor profile compared to those with diabetes alone, this was not associated with increased cardiovascular morbidity or all-cause mortality. These results suggest that elevated uric acid and gout are markers rather than determinants of CV mortality.

THU0448 CHARACTERIZATION OF PATIENTS WITH CHRONIC REFRACTORY GOUT WHO DO AND DO NOT HAVE CLINICALLY APPARENT TOPHI: RESPONSE TO PEGLOTICASE

N.L. Edwards[1], J. Singh[2], O. Troum[3], A. Yeo[4], P. Lipsky[5]. *[1]Department of Medicine, University of Florida, Gainesville, FL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Keck School of Medicine, University of Southern California, Los Angeles, CA; [4]Horizon Pharma, Lake Forest, IL; [5]AMPEL BioSolutions, LLC, Charlottesville, VA, United States*

Background: The term "chronic refractory gout" defines a subset of chronic gout patients who are either intolerant of or unresponsive to standard uric acid (UA) lowering therapy (ULT). Subjects (N=85) meeting this definition were enrolled in a study of pegloticase (8 mg every 2 weeks [q2w], the approved dose), a mammalian recombinant uricase conjugated to polyethylene glycol that is approved for the treatment of gout refractory to conventional oral ULT. Of this group of subjects, 73% had clinically apparent tophi, whereas 27% did not.
Objectives: To determine the clinical characteristics and response to pegloticase therapy in patients with chronic refractory gout with and without clinically apparent tophi.
Methods: This analysis used results from two pivotal randomized controlled trials[1] to assess the clinical characteristics and the efficacy of pegloticase (8 mg q2w) in patients with chronic refractory gout with or without tophi at baseline. The results for serum urate (UA), flares, Patient Global Assessment (PGA), tender and swollen joints (TJC and SJC), bodily pain, Health Assessment Questionnaire-Disability Index (HAQ-DI), and the Arthritis-Specific Health Index (ASHI) and Bodily Pain from the Medical Outcomes Study Short Form 36 item (SF-36) were determined for each group.
Results: The analysis included patients with chronic refractory gout, 62 with tophi at baseline and 23 without tophi. Chronic refractory gout patients in the two groups were similar at baseline, with the only significant differences in mean values between tophaceous and nontophaceous gout groups as follows: TJC, 14.2 vs 5.00 (P=0.01); SJC, 10.9 vs 3.4 (P=0.003); ASHI, 50.4 vs 64.7 (P=0.03); and HAQ-DI, 1.3 vs 0.6, respectively (P=0.001). Other measures of disease impact and comorbidities were not significantly different between groups. Treatment with pegloticase 8 mg q2w resulted in significant and comparable reductions in serum UA in both groups. Comparison of results from baseline and after 6 months of treatment for patients with tophi at baseline indicated significant reductions in serum UA (P<0.0001), flares (P<0.0001), PGA (P<0.0001), TJC and SJC (both P<0.0001), HAQ-DI (P=0.02), and SF-36 Bodily Pain (P<0.0001). Results for patients without clinically apparent tophi at baseline indicated significant improvements in serum UA (P<0.0001), flares (P=0.004), PGA (P=0.009), TJC (P=0.01), SJC (P=0.003), SF-36 Bodily Pain (P=0.03), and ASHI (P=0.0001).
Conclusions: These results indicate that chronic refractory gout patients may present with or without clinically apparent tophi. Tophaceous patients are distinguished by more tender and swollen joints, greater disability, and greater arthritis severity, but otherwise are similar to nontophaceous patients. Both groups had significant clinical benefit over 6 months of treatment with pegloticase.

THU0449 EVIDENCE BASED DEVELOPMENT OF CRITERIA FOR COMPLETE RESPONSE IN PATIENTS WITH CHRONIC REFRACTORY GOUT

N. Schlesinger[1], P. Khanna[2], A. Yeo[3], P. Lipsky[4]. *[1]Department of Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Rheumatology, University of Michigan, Ann Arbor, MI; [3]Horizon Pharma, Lake Forest, IL; [4]AMPEL BioSolutions, LLC, Charlottesville, VA, United States*

Background: Preliminary criteria for remission in gout patients have recently been proposed. These include serum urate, acute flares, tophus, pain and patient global assessment.[1] These preliminary criteria were based on consensus exercises and have not yet been tested in a large clinical trial database of chronic gout patients. Because of the availability of clinical results from subjects with chronic refractory gout treated with pegloticase (8 mg every 2 weeks), a mammalian recombinant uricase conjugated to polyethylene glycol that is approved in the US for treatment of adult patients with chronic gout refractory to oral urate lowering therapy[2], the utility of these proposed criteria could be assessed.
Objectives: To test the utility of the preliminary criteria to discern a complete response (CR) in subjects with chronic refractory gout treated with pegloticase (8 mg every 2 weeks).
Methods: Data from two randomized clinical trials (RCT) evaluating the impact of pegloticase therapy in subjects with chronic refractory gout were examined.[2] Of this group of subjects, 42% had persistently lowered serum urate and 58% did not meet the urate-lowering endpoint of this RCT. Initially, individual patient data was reviewed to establish the frequency with which subjects, who were responders to pegloticase, met the proposed remission criteria. Mixed modeling was then employed on data from these subjects to determine the components of the model that best correlated with time of maximum benefit.
Results: Of 34 pegloticase responders, 25 (73.5%) met the published criteria[1] of remission. However, pain assessment was often an outlier; data obtained by visual analogue scale and Medical Outcomes Study Short Form-36 questionnaire often differed. Mixed modeling was, therefore, carried out using the data obtained from the subjects meeting criteria for remission to determine the components that best correlated with time to maximum benefit. Other clinical outcome measures assessed in the clinical trial were also analyzed. Besides serum urate levels in the mixed modeling analysis, the components of response that best correlated with time of maximum benefit included assessment of tophi (analyzed photographically), number of swollen joints, number of tender joints and patient global assessment. Using these criteria, 25 of the responders (73.5%) and 29.4% of the entire pegloticase-treated population met criteria for a CR. The median time to reach a CR was 252 days (range: 126–966 days). Of interest, when a decrease in serum urate was omitted, 6 (12.2%) of the pegloticase nonresponders also met criteria for a CR. Patients receiving placebo did not achieve the composite outcome measure considered as CR.
Conclusions: These results have defined criteria for achieving CR in individuals with chronic refractory gout treated with pegloticase and suggest that most individuals who persistently lowered their serum urate levels while on pegloticase reached criteria for CR in a median of 8.4 months. This composite CR definition can serve as an evidence-based target aiding the design and endpoints of future clinical trials.

THU0450 HOSPITAL READMISSIONS FOR GOUT IN THE UNITED STATES: A NATIONAL DATABASE STUDY

N. Annapureddy[1], A. Saha[2], P. Poojary[3,4], K. Chauhan[4], G. Nadkarni[4].
[1]Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville; [2]Department of Public Health; [3]Department of Public Health; [4]Division of Nephrology, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Gout is associated with significant burden and risk of readmission. Little is known about readmissions among Gout patients on a national level in the United States.
Objectives: The aim of this study was to describe unplanned hospital readmission rates among adult gout patients and assess predictors of readmission.
Methods: We analyzed the 2013 National Readmission Database (NRD) to quantify readmission rates among Gout patients. The NRD includes weighted discharge data from 21 geographically diverse states accounting for 49.3% of the U.S. population. It includes approximately 14 million un-weighted discharges (49.1% of all U.S. discharges) corresponding to 36 million annual discharges nationwide. NRD data is from patients with non-Medicare payers (Medicaid, private, self-pay, or other). Gout hospitalizations were identified using the International Classification of Diseases, ninth Revisions, Clinical Modification (ICD-9-CM) diagnosis code 274.0x. All hospitalizations for patients age $\geq$18 were included. In efforts to exclude routine readmissions, we excluded those admissions related to pregnancy, those for chemotherapy, admissions where the patient was readmitted the same day as they were discharged, who had deaths during the same index hospitalizations, hospitalizations for less than 24 hours, and those with missing discharge. We utilized Chi-square tests, t tests and Wilcoxon rank-sum tests as appropriate. Survey logistic regression was used to assess the relationship between potential predictors for readmissions and the odds of at least one 30-day unplanned readmission. This analysis was chosen given the NRD data, which involves nested, weighted observations that are inherently stratified in clusters to produce national estimates.
Results: A total of 10708 index hospitalizations which had Gout as the primary diagnosis were included in the analysis. Among those with a primary Gout diagnosis, there were 1212 30-days readmissions (11.3%). 14.3% percent of patients with Gout as the primary diagnosis on index hospitalization were readmitted with the same diagnosis. The next most common readmission diagnoses were congestive heart failure (CHF), septicemia, and acute and unspecified renal failure (Figure 1A). In multivariable analysis of index hospitalizations with Gout as the primary diagnosis, CHF (OR 1.25, 95% CI, 1.05–166), chronic kidney disease (CKD) (OR 1.54, 95% CI, 1.23–1.92), atrial fibrillation (AF) (OR 1.33, 95% CI, 1.10–1.78), deep venous thrombosis (DVT) (OR 1.29, 95% CI, 1.03–1.88), APR-DRG severity level 3 and 4 (OR 1.51, 95% CI, 1.01–2.38 and OR 2.10, 95% CI, 1.06–4.58), discharge to specialized care (OR 1.47, 95% CI, 1.07–2.02), discharge to home health care (OR 1.35, 95% CI, 1.03–1.77), and discharge against medical advice (OR 3.85, 95% CI, 1.50–9.91), were significantly associated with 30-days readmission after adjusting for demographics, comorbidities, hospital characteristics, payer type, and the APR-DRG severity scale (Figure 1B).
Conclusions: In a national readmissions database, 11.3% of patients admitted with a primary diagnosis of Gout were readmitted within 30 days. Significant predictors of readmission included CHF, CKD, AF, APR-DRG severity level 3 or 4 and any discharge other than routine.

THU0451 A METHOD FOR COUNTING CALCIUM PYROPHOSPHATE CRYSTALS IN THE SYNOVIAL FLUID

P. Montagna, R. Brizzolara, S. Soldano, M. Cutolo, M.A. Cimmino. *Department of Internal Medicine, University of Genova, Genova, Italy*

Background: Identification of calcium pyrophosphate dihydrate (CPP) crystals in the synovial fluid (SF) from inflamed joints provides a definitive diagnosis of CPP deposition disease (CPPD) (1). CPP crystals may also be found in non-inflamed joints, allowing diagnosis also during asymptomatic periods (2). SF analysis and CPP crystals count could be used to evaluate disease activity during follow-up. It is more difficult than the count of monosodium urate (MSU) crystals, already tested in a previous work (3), for CPP crystals show different shapes, are often very minute and non-birefringent.
Objectives: To study an objective method for counting CPP crystals in the SF.
Methods: The SFs aspirated from the knees of 15 consecutive patients (8 men) affected by CPPD diagnosed according to the EULAR definition were analysed. Cytological evaluation included SF leukocyte and differential count. For crystal detection, a small drop of fresh SF was placed on a glass slide and examined by compensated polarized microscopy (400x). To facilitate crystal count, the slide was divided into 4 equal parts drawing a cross with a pencil. The count was performed by continuous viewing and for each field both the number of birefringent and non-birefringent crystals was noted. Two observers evaluated separately 6 SFs and repeated the count after 24 hours. SFs were divided into 4 groups: SFs with $<$50, from 50 to 400, from 401 to 1200, and $>$1200 crystals.
Results: Mean time needed for the count was 60 minutes. Inter-reader agreement was 0.68 (0.47–0.88) for CPP crystals, 0.68 (0.50–0.85) for the birefringent ones and 0.60 (0.38–0.81) for the non-birefringent. Intra-reader agreement was 0.48 (0.17–0.78) for the first examiner and 0.30 (0.14–0.74) for the second. In 7 patient the SF was aspirated from an inflamed knee. Crystal number did not correlate with the presence of knee inflammation (r=0.41; p=0.19), the SF volume (r=0.14; p=0.61), the number of leukocytes (r=0.36; p=0.19), the % of PMN (r=0.25; p=0.37), and the presence of intracellular crystals (r=0.31, p=0.27). Actively inflamed joints had a higher SF volume [11 ml (10–20 ml) vs. 2 ml (1–10 ml), p=0.03] and a higher percentage of PMN [72% (0–94%) vs. 12% (0–68%), p=0.028]. SF with intracellular crystals showed also a higher percentage of PMN (57.1%±34.3% vs. 3%±6% p=0.006).
Conclusions: Our preliminary results indicate that CPP crystal count is less reliable and more time-consuming that that of MSU crystals. Non-birefringent crystals show lower inter-reader agreement than birefringent ones.

THU0452 IMMEDIATE AND LONG TERM EFFICACY OF ANAKINRA IN ACUTE FLARES DUE TO HYDROXYAPATITE CALCIFICATIONS: A REAL-LIFE EXPERIENCE OF 13 CASES

P. Zufferey, R. Valcov, A. So. *DAL, CHUV, Lausanne, Switzerland*

Background: Calcifications composed of hydroxyapatite (HA) crystals can induce acute and severe pain accompanied by signs of acute inflammation. In a previous pilot study, we have shown that anakinra was effective in acute flare of calcific periarthritis of the shoulder in the short term
Objectives: The goal of this retrospective observational study was to confirm these results in a larger set of patients, extending the observation to other localizations and to report on the long-term follow-up.
Methods: All consecutive patients with an acute flare due to HA deposition and treated with anakinra between March 2011 and November 2016 were included. Flare was defined as symptoms of acute pain at rest present for $<$10 days. None of the patients had corticosteroid therapy in the last 2 weeks, none had responded to at least 48 hours of high doses of NSAIDs or other rheumatologic diseases explaining the symptoms. Clinical evaluation consisted of patient assessment of pain by VAS (10mm scale) at days 0, 1, 3, 21 and joint mobility. CRP and ESR measurements, ultrasound and x-ray examinations were performed before the

treatment and at least once again after the treatment. Anakinra 100mg daily was administered for 1 to 3 consecutive days. Other baseline demographic data and long-term follow up data were collected from the patients' charts and after phone call to the patients

Results: 13 patients fulfilled the inclusion criteria. 12 had a flare at the shoulder, 1 at the first MCP of the hand. The acute inclusion flare was the first episode in 9/13 subjects. At baseline, mean pain VAS:8.8/10 Active and passive motion was severely restricted in all patients. Local inflammation was sufficiently severe to induce an elevation of the CRP and ESR in 10/12 patients. By ultrasound, the mean size of calcifications was 17 mm. Only one had an arc-shaped aspect with shadowing, the others were fragmented. *Short term follow-up:* Pain diminished drastically and rapidly, typically within hours, in most patients after the first injection and was almost absent at day three (mean VAS 1.7/10), stable at 3 weeks (mean VAS: 2.1). At follow-up ultrasound, the calcification disappeared in none of the patients but, in most cases, a reduction (50% mean size reduction) and a fragmentation was observed.*Long term follow-up:* The median duration was 24 months, (range 4 to 74 months). Only 2/ 12 patients experienced an acute relapse. These two patients already suffered from chronic shoulder pain and had prior flares before the treatment with anakinra. Mild chronic pain, essentially related to movement (mean VAS: 2.7), was still present in 5 patients. Two patients regularly took NSAIDs; the others did not use any painkiller

Conclusions: This study suggests that IL-1β inhibition may be an interesting therapeutic approach in acute flares in relation with hydroxyapatite calcification. Moreover this treatment does not seem to be associated with rebound or recurrence of flares in the long term.

THU0453 HEART AND CAROTID CHANGES IN FIFTY-THREE GOUT PATIENTS TREATED WITH XANTHINE OXIDASE INHIBITORS: A FOLLOW-UP STUDY

R.N. Gancheva[1,2], A. Kundurdjiev[1,2], M. Ivanova[1,2], T. Kundurzhiev[2,3], Z. Kolarov[1,2]. *[1]Medical Faculty; [2]Medical University; [3]Faculty of Public Health, Sofia, Bulgaria*

Background: Gout connects to cardiovascular (CV) morbidity and higher risk of death due to CV events. A few ultrasound studies assess the way in which heart and vessels change over time in gout patients (pts). It is still unclear whether treatment with allopurinol or febuxostat reduces to some extent target organ damage.

Objectives: We aimed to establish heart and vessels alterations developing over time in gout pts and to find out whether treatment with allopurinol or febuxostat is associated with a change in these structures.

Methods: A total of 53 gout pts were examined and divided into two groups: 31 gouty arthritis without tophi, 24 males and 7 females aged 55.8±12.3 years and 22 gouty tophi, 20 males and 2 females aged 59±9 years. Pts underwent multimodal ultrasound examination at study entry and one year and six months thereafter. Aortic root diameter (Ao), left atrium (LA) size, thickness of the interventricular septum (IVS) and of posterior wall (PW) of the left ventricle, end-diastolic volume index (EDVi), end-systolic volume index (ESVi), stroke volume index (SVi), fractional shortening (FS), and ejection fraction (EF) were recorded with 2.5 MHz transducer. Intima-media thickness (IMT) and rigidity of the common carotid arteries, judged by the values of the common carotid artery resistive index (CCARI), were examined with 10 MHz transducer. Statistical analyzes were done by chi-square or Fisher's exact test, One-Sample Kolmogorov-Smirnov, Shapiro-Wilk and Paired-Samples T-test. Within-subjects effects and between-subjects effects were assessed by the Repeated Measures ANOVA.

Results: At the two time points of pts' examination there was no deviation in Hb (p=0.412), Ht (p=0.866), serum uric acid (p=0.877), serum albumin (p=0.515), eGFR (p=0.793), EDVi (p=0.248), ESVi (p=0.345), SVi (p=0.357), FS (p=0.516) and CCARI (p=0.244), but PW tended to be thicker (p=0.067). Ao (p=0.008), LA (p=0.001), IVS (p=0.007) increased, and EF (p=0.026) decreased between the two examinations. In gouty arthritis without tophi and in gouty tophi Ao (mean±SD; 39.42±5.00 vs 39.14±3.77, p=0.471), LA (mean±SD; 39.10±5.11 vs 43.86±5.95, p=0.088), IVS (mean±SD; 12.77±1.58 vs 13.47±1.54, p=0.910) and IMT (mean±SD; 0.93±0.17 vs 1.05±0.17, p=0.237) changed similarly over time, but the reduction in EF was more pronounced in gouty tophi (p=0.031). In pts not taking allopurinol an increase in LA (p=0.012), IVS (p=0.006) and IMT ($p<0.001$) was registered. In those treated with allopurinol Ao (p=0.011), LA (p=0.022) increased, EF (p=0.016) decreased and no change in IVS (p=0.523) and IMT (p=0.165) was found. Pts who had not received febuxostat tended to have greater Ao (p=0.063), larger LA (p=0.003), thicker IVS (p=0.046), thicker IMT ($p<0.001$) and lower EF (p=0.034). In contrast, no change was registered in Ao (p=0.559), LA (p=0.332), IVS (p=0.125), EF (p=0.689) and IMT (p=0.163) in treated with febuxostat.

Conclusions: Over time in gouty arthritis without tophi and gouty tophi similar changes in the heart and carotids develop, but heart pumping function is more affected in the later stage of the disease. Heart and carotids morphology and function are preserved in pts treated with febuxostat. In the allopurinol group cardiac morphological and functional alterations occur with no change in IMT.

THU0454 ROLE OF PHYSICAL EXERCISE IN PATIENTS WITH HIP ARTHROPLASTY FOR ASEPTIC NECROSIS OF THE FEMORAL HEAD

R.I. Marcu, S. Patru, A.C. Bighea, D. Matei. *Medical Rehabilitation, University of Medicine and Pharmacy, Craiova, Romania*

Background: Necrosis of the femoral head has a slow but progressive evolution, increasing degradation of the joint, worsening instability, with permanent pain and reduced walk perimeter. In the advanced stages of the disease, the only effective treatment is replacement of the joint (hip arthroplasty).

Objectives: The objective of our study was to examine the effects of a two weeks kinetic program on pain and functional status in patients with hip arthroplasty for aseptic necrosis of the femoral head.

Methods: We conducted an observational, prospective, randomized study on a sample of 47 patients with hip arthroplasty for aseptic necrosis of the femoral head. Patients were randomly assigned to a control group (23 patients) who received only analgesics and NSAID's when needed (group 1) and a study group (24 patients) whose therapeutic program included daily physical exercise (group 2). Patients were initially evaluated and after two weeks of rehabilitation treatment. The clinical and functional parameters assessed were: pain on a visual analogue scale (100 mmVAS), physical impairments (muscular strength and mobility of hip joint) and disabilities (Tinetti Gait Scale, D'Aubigné Scale and movement capacity).

Results: The scores for functional parameters improved: pain- 42.6% (group 2) and 33.4% (group 1) (p=0.000054); physical impairments: muscular strength- 8.3% (group 2), without improving by group 1, mobility: 41.8% (group2) and 21.4% (group 1); disabilities: Tinetti Gait Scale- 33.6% (group 2) and 22.1% (group 1), D'Aubigné Scale- 35.8% (group 2) and 22.4% (group 1), movement capacity- 55.8% (group2) and 31.9% (group 1). The results were statistic significant ($p<0.05$).

Conclusions: Improvement of pain, physical impairments and disabilities for the study group certifies the efficacy of the rehabilitation program including physical exercise in patients with hip arthroplasty for aseptic necrosis of the femoral head and motivates the continuation of the study on a longer period of time and on a larger number of patients. Rehabilitation program must begin right after patients underwent surgery for hip replacement.

THU0455 RENAL SAFETY OF LESINURAD: A POOLED ANALYSIS OF PHASE III AND EXTENSION STUDIES

R. Terkeltaub[1], R. Malamet[2], K. Bos[2], J. Li[2], D.S. Goldfarb[3], M. Pillinger[4], D. Jalal[5], J. Hu[6], K. Saag[7]. *[1]University of California, San Diego; [2]AstraZeneca Pharmaceuticals, Wilmington; [3]New York University School of Medicine; [4]New York University Langone Medical Center, New York; [5]University of Colorado Anschutz Medical Center, Aurora; [6]Formerly Ardea Biosciences, Inc, San Diego; [7]University of Alabama at Birmingham, Birmingham, United States*

Background: Lesinurad (LESU) is a selective uric acid reabsorption inhibitor approved in the United States and European Union at a 200 mg daily dose in combination with a xanthine oxidase inhibitor (XOI) for treatment of hyperuricemia associated with gout in patients unable to achieve target serum uric acid on an XOI (allopurinol or febuxostat) alone.

Objectives: To investigate the renal safety of LESU, data were pooled from 3 pivotal, placebo-controlled, 12-month phase III (core) studies evaluating lesinurad 200 mg (LESU200) and 400 mg (LESU400) in combination with an XOI and from 2 extension studies, where patients continued LESU+XOI at the same dose or were randomized from placebo to LESU200 or LESU400 plus an XOI.

Methods: Renal-related and kidney stone safety data were pooled from core studies to compare LESU200+XOI and LESU400+XOI with an XOI alone and from core studies + extension studies to evaluate the impact on renal safety of extended LESU+XOI treatment. Renal-related treatment-emergent adverse events (TEAEs) were a customized list of 36 preferred terms selected from the Medical Dictionary for Regulatory Activities (MedDRA) Renal and Urinary Disorders System Organ Class (SOC), the Investigations SOC, and the Acute Renal Failure MedDRA Standardized MedDRA Query (SMQ). Descriptive statistics are provided for patients receiving $\geq$1 dose of study medication. To adjust for varying treatment duration, TEAEs are expressed as exposure-adjusted incidence rates (EAIRs; number of subjects with events per 100 person-years).

Results: In the core studies, EAIRs for any renal-related TEAE, serious renal-related TEAEs, and renal-related TEAEs leading to discontinuation were similar with an XOI alone and LESU200+XOI and lower than with LESU400+XOI (Table 1). Similar results were found for kidney stone and serious kidney stone TEAEs. The most common renal-related TEAE was increased serum creatinine (sCr). EAIRs for sCr elevations $\geq$1.5x baseline were higher with LESU+XOI than XOI alone (Table 1). Overall, 75% and 84% of sCr elevations in the XOI alone and LESU+XOI groups, respectively, were resolved at last study assessment; 75% and 66% resolved without interruption of medication. Exposure to extended

LESU+XOI treatment in the core+extension studies did not show an increase from core studies in EAIRs for any renal-related or kidney stone adverse event category (Table 2).

Table 1. Exposure-Adjusted Renal-Related and Kidney Stone Adverse Event Incidence Rates in Core Studies

	XOI alone (N=516) (PY=408.5)	LESU200+XOI (N=511) (PY=396.3)	LESU400+XOI (N=510) (PY=390.5)
Renal-Related Adverse Event Category [n (rate)]			
Any TEAE	23 (5.6)	29 (7.3)	60 (15.4)
Serious TEAE	2 (0.5)	0	5 (1.3)
Any TEAE leading to randomized study medication discontinuation	5 (1.2)	6 (1.5)	17 (4.4)
sCr elevations ≥1.5 x baseline	12 (2.9)	29 (7.3)	73 (18.7)
Kidney Stone Adverse Event Category [n (rate)]			
Kidney stone TEAEs	9 (2.2)	3 (0.8)	13 (3.3)
Serious kidney stone TEAEs	1 (0.2)	0	3 (0.8)

LESU, lesinurad; XOI, xanthine oxidase inhibitor; sCr, serum creatinine; PY, patient years. Exposure-adjusted incidence rates are expressed as subjects with events per 100 person-years.

Table 2. Exposure-Adjusted Renal-Related and Kidney Stone Adverse Event Incidence Rates in Core+Extension Studies

	LESU200+XOI (N=666) (PY=926.5)	LESU400+XOI (N=666) (PY=917.9)
Renal-Related Adverse Event Category [n (rate)]		
Any TEAE	80 (8.6)	134 (14.6)
Serious TEAE	4 (0.4)	13 (1.4)
Any TEAE leading to randomized study medication discontinuation	17 (1.8)	32 (3.5)
sCr elevations ≥1.5 x baseline	75 (8.1)	156 (17.0)
Kidney Stone Adverse Event Category [n (rate)]		
Kidney stone TEAEs	10 (1.1)	18 (2.0)
Serious kidney stone TEAEs	1 (0.1)	5 (0.5)

LESU, lesinurad; XOI, xanthine oxidase inhibitor; sCr, serum creatinine; PY, patient years. Exposure-adjusted incidence rates are expressed as subjects with events per 100 person-years.

Conclusions: Lesinurad at the approved dose of 200 mg once daily combined with XOI demonstrated comparable rate of adverse events to XOI alone. There was no clinically relevant increase in these adverse events with the extension of treatment beyond 1 year.

THU0456 RATE OF HOSPITALIZATION FOR HEART FAILURE IS LOWER IN PATIENTS WITH CONTROLLED GOUT VERSUS UNCONTROLLED GOUT

R. Morlock[1], P. Chevalier[2], A.B. Klein[3]. *[1]YourCareChoice, Ann Arbor, United States; [2]QuintilesIMS, Zaventem, Belgium; [3]AstraZeneca Pharmaceuticals, Gaithersburg, United States*

Background: Hyperuricemia is associated with worsened outcomes in patients with heart failure (HF). However, little is known about the association between gout and HF.

Objectives: To assess the impact of gout control on the rate of hospitalization for acute HF in a prevalent gout population.

Methods: This retrospective database analysis used data from the Clinical Practice Research Datalink-Hospital Episode Statistics (UK) from Jan 1, 2009 to Dec 31, 2011. Patients were required to have evidence of "prevalent established gout" (ie, treated with urate-lowering therapy [ULT] or eligible for ULT based on ACR guidelines) between Jan 1, 2009 and Dec 31, 2009 and be aged ≥18 on index date (Jan 1, 2010). Follow-up extended from Jan 1, 2010 to Dec 31, 2011. HF rate was calculated as the percentage of eligible patients having ≥1 HF-related hospitalization over the course of the calendar year. In each calendar year, patients were considered to have controlled gout if they had no elevated serum uric acid (sUA; ≥6 mg/dL), no diagnosis of tophus, and no flare documented. Uncontrolled gout was defined as ≥1 elevated sUA or 1 tophus diagnosis during the year. In this analysis patients with no documented sUA were considered not evaluable. To mitigate the limited availability of sUA data, a sensitivity analysis was conducted using an alternate definition of control status: if sUA was available, controlled was defined as no elevated sUA, no flare, and no tophi and uncontrolled was defined as ≥1 elevated sUA, tophus, or flare; if sUA was unavailable, controlled was defined as medication possession ratio (MPR)>80% and uncontrolled defined as 0%<MPR≤80%. Here, patients with no documented sUA and MPR=0% were not evaluable. The odds ratio of HF was modeled in each post-index year using logistic regression models, with adjustment for control status (in previous or current year), gender, age, and Charlson Comorbidity index as covariates.

Results: A total of 29,758 eligible gout patients were identified. Within the subset of patients with available sUA (4762 in 2010 and 4385 in 2011), the HF rate was consistently lower in patients whose gout was controlled in the ongoing year (adjusted OR: 0.253 in 2010 [P=0.032]; 0.268 in 2011 [P=0.019]). The sensitivity analysis conducted using MPR as a proxy for control in a larger population (26,999 patients in 2010 and 26,176 patients in 2011) yielded similar results (OR: 0.387 in 2010 [P<0.001]; 0.462 in 2011 [P<0.001]).

Conclusions: This study suggests that patients with controlled gout have a lower risk of being hospitalized for HF. Further studies would be required to validate this finding on larger samples.

THU0457 LESS THAN HALF OF PATIENTS TREATED WITH HIGH-DOSE ALLOPURINOL REACH SUA TARGET

R. Morlock[1], D.C. Taylor[2], S. Baumgartner[3]. *[1]YourCareChoice, Ann Arbor; [2]Ironwood Pharmaceuticals, Inc., Cambridge; [3]drB Consulting, Spokane, United States*

Background: Although allopurinol is FDA approved for up to 800 mg per day and EMEA authorized for up to 900 mg per day, most patients receive 300 mg per day or less.

Objectives: To describe physician, patient, and treatment characteristics in gout patients treated with allopurinol and to assess the proportion of patients reaching serum uric acid (sUA) target by allopurinol dose.

Methods: Patient data from a quantitative survey of physicians were utilized and results confirmed through chart review. Initial and current dose of allopurinol, presence of co-morbid conditions, sUA lab results, physician specialty, and patient characteristics were assessed. Data on number of patients achieving target sUA≤6mg/dL were also collected. Descriptive characteristics are presented as proportions or means and standard deviations (SD). Multivariate and descriptive statistics are used to describe patients with sUA≤6 mg/dL.

Results: A total of 251 rheumatologists and 250 primary care physicians were interviewed. Of 2505 patients with gout, 1437 (57%) were treated with allopurinol. Use of high-dose allopurinol significantly differed by country with less than 6.5% of patients in France, Germany, and Spain given >300mg, whereas 10.2%, 19.5%, and 33.6% of patients in Italy, the US, and the UK, respectively, received a daily dose >300mg ($p<0.01$). Over 12 months the percentage of patients achieving sUA ≤6.0 mg/dL differed across the 6 countries. Looking across all countries, only 43.8% and 44.7% of patients achieved sUA <6.0mg/dL with 301–599mg and ≥600mg of allopurinol QD, respectively. A multivariable-adjusted model found patients with tophi (OR 3.42; $p<0.01$), co-existing alcoholism (OR 1.73; $p<0.05$), COPD (OR 2.01; $p<0.05$), smoking cessation treatment (3.49; $p<0.05$), and from the UK (OR 3.98; $p<0.01$) were more likely to be using >600mg of allopurinol. Regardless of allopurinol dose, the co-variates UK vs. other countries (OR 3.51; $p<0.01$), time on therapy >24 months (OR 1.39; $p<0.01$), and chart-documented co-existing hypertension (OR 1.36; $p<0.05$) were predictive of achieving sUA <6 mg/dL. Whereas physician sub-specialty [general practitioners vs. rheumatologists (OR 0.56; $p<0.01$)], having tophi (OR 0.72; $p<0.05$), and chart-documented co-existing alcoholism (OR 0.67; $p<0.05$), hyperlipidemia (OR 0.74; $p<0.05$), and kidney stones (OR 0.49; $p<0.05$) were found to be associated with not achieving sUA <6 mg/dL. After adjusting for confounding factors, over a 12-month period, there was no difference in achieving sUA <6 mg/dL for those treated with high- vs. low-dose allopurinol.

Conclusions: Allopurinol is approved for up to 800mg in the US and 900mg in the EU but the majority of patients are treated with ≤300mg per day. Less than 50% of patients achieve sUA <6mg/dL at any dose of allopurinol. These data suggest a need for consideration of new treatment options on top of allopurinol for uncontrolled gout patients.

THU0458 READY OR NOT? CHANGES IN THE CLINICAL PROFILE OF GOUT PATIENTS OVER THE LAST 25 YEARS

S.P. Chinchilla[1,2], I. Urionagüena[3], F. Perez-Ruiz[1,2,3]. *[1]University of the Basque Country, Bilbao; [2]Arthritis Research Group, BioCruces Health Research Institute; [3]Rheumatology Division, Hospital Universitario Cruces, Barakaldo, Spain*

Background: The number of publications associated to gout, as well as the prevalence of the disease, has increased in recent years. Gout is a rising cause of hospital admissions and emergency consults. More so in patients with comorbidities, it has even replaced rheumatoid arthritis as the principal rheumatological condition causing admissions (1). Some questions arise in this setting: What are the characteristics of our patients? How have they changed over the past years?
Objectives: To analyze possible changes in the epidemiologic, clinical and biochemical profiles of gout patients during a period of 25 years.
Methods: Data was collected from a prospective cohort of gout patients, from a crystal arthritis clinic in a tertiary hospital, with a reference population of half a million inhabitants. A period of 25 years was reviewed, between 1992 and 2016 (n =1137), with further division into five quinquennia (Q) for comparison purposes. When entering the cohort, epidemiologic, clinic, laboratory and imaging data are systematically collected. Variables susceptible to change in time were considered: age, gender, gout specific clinical data (articular pattern, presence of tophi), previous admissions due to gout, comorbidities and association with other conditions. Quantitative variables were analyzed with ANOVA and Bonferroni correction; qualitative variables with chi-square test. Inclusion of patients to the cohort was approved by the hospital ethics committee. Results from extreme quinquennia are reported (1stQ: 1992–1996/5thQ 2011–2016 or 2ndQ: 1997–2001/4th: 2006–2010). All results are statistically significant unless stated otherwise.
Results: Differences were observed amongst the periods of five years and age at first visit (1stQ: 54.1±10.9/5thQ: 64.6±13.8 years); gender (1stQ: 2.6%/5thQ: 12.2% of women, respectively). There were no differences when comparing with years of disease evolution before the first visit.
Initial comorbidities: important differences pertaining the prevalence of cardiovascular disease were observed (2ndQ: 26.3%/5thQ: 43.2%), as well as renal disease (1stQ: 16.7%/5thQ: 45.2%), hypertension (1stQ: 27.3%/5thQ: 75.1%) and hyperlipidaemia (1stQ: 50.6%/5thQ: 61.2%) –although this was not the case for Diabetes Mellitus. There was difference amongst periods and association with acute episodes of calcium pyrophosphate arthritis (1stQ: 3.8%/5thQ: 5.9%).
Initial clinical characteristics: differences were found in presentation with tophi (2ndQ: 23.6%/4thQ: 40.1%); polyarticular disease (1stQ: 32.9%/5thQ: 41.3%); hospital admission on the year prior to inclusion (1stQ: 14.5%/5thQ: 24.4%); use of diuretics (1stQ: 6.4%/5thQ: 45.9%); and uricaemia, the latter with no relevant clinical significance.
Conclusions: The profile of gout patients has notably changed in the past 25 years: we have elder, more complex patients, with higher rates of hospital admissions, with severe forms of disease and important comorbidities. When considering these results, we believe that a substantial proportion of gout patients will require specialized attention in the coming years.

THU0459 EXPLORING DUAL MODULATION OF GLUT9 AND OAT3, AN APICAL AND BASOLATERAL TRANSPORTERS IN PROXIMAL TUBULES AND EXPERIMENTAL MICE

S.H. Lee, S.B. Kim, D.-S. Oh. *The K-herb Research Centre, Korea Institute of Oriental Medicine, Daejeon, Korea, Republic Of*

Background: Uric acid homeostasis is a set of the balance in glomerular filtration, tubular secretion, reabsorption, and excretion. In the course of cascade, two kinds play a pivotal role; efflux transporters in apical at renal proximal tubular membrane, uptake ones in basolateral at membrane. The former has been of interest in the targets for uricosuric effects, however, dual modulation of the two could keep uric acid balance in stable ways.
Objectives: The aim of this study was to assess the uptake of seven test articles in the course of the expressions of apical/basolateral transporters in potassium oxonate (PO)-treated kidney epithelial cell lines (Caco-2, MDCK, LLC-PK1) and ICR mice.
Methods: The selected cell lines were treated with potassium oxonate (0.25 mM) and then modulated by seven test articles, the commercial herbal products (SITK01 through SITK06 and SITT01) at dose range of 0.015–1 mg/mL. To determine efficacious dose range by each test article, three cell lines, Caco-2, MDCK and LLC-PK1 cells were assessed with MTT assay. Forty eight ICR mice were injected intraperitoneally with PO at a dose of 200 and 400 mg/kg and then blood draws were conducted 0, 6, 12, 24, 72 hours after PO administration. The levels of uric acid and transporters were also measured by ELISA assay and Western blotting analysis in those cell lines.
Results: Treatment of SITK01 through SITK03 and SITT01 at concentration (250 mg/mL) decreased the cell viability. The PO-stimulated kidney epithelial cells with SITK01 through SITK03 treatment increased GLUT9 by 2.5 folds and decreased OAT3 by 1.5 folds (versus controls, p=0.012, and p=0.017, respectively). In PO-treated mice, uric acid levels were increased through GLUT9 and OAT3 transporters. The results indicated that SITK01, SITK02, and SITK03 showed the potential on uricosuric effects in a dual modulation of apical/basolateral sides of kidney epithelial tubular membranes.

Table 1. Protein expression of transporters in apical and basolateral membranes of proximal tubular epithelial cells and potassium oxonate-treated experimental mice

Membrane domain	Functions	Transporters	Caco-2	MDCK	LLC-PK1	Potassium Oxonate-treated mice
Apical	Palpation of excretion	SLC22A12 (URAT1)				++
		SLC2A9 (GLUT9)	+	++	++	++
		ABCG2 (BCRP)				
Basolateral	Inhibition of reabsorption	SLC22A6 (OAT1)		+	++	
		SLC22A8 (OAT3)	+++	+++	+	++

Conclusions: The present findings demonstrated that three commercial herbal products showed potentials to reduce hyperuricaemia-induced condition by changing protein expression levels in a transporter-uptake assay. The OAT3 and GLUT9 could be further investigated as the uricosuric group-targets on the bilateral sides at kidney epithelial tubular membranes.

THU0460 BARRIERS TO GOUT CARE: A SYSTEMATIC REVIEW AND THEMATIC SYNTHESIS OF 120 PROVIDERS AND 480 GOUT PATIENTS FROM QUALITATIVE STUDIES

S.K. Rai[1,2], H.K. Choi[1,2], S. Choi[3], A. Townsend[1,4], M.A. De Vera[1,5]. *[1]Arthritis Research Canada, Vancouver, Canada; [2]Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, United States; [3]Faculty of Medicine, University of British Columbia, Vancouver, Canada; [4]Exeter Medical School, University of Exeter, Exeter, United Kingdom; [5]Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, Canada*

Background: Despite gout's well-known pathogenesis and the availability of effective urate-lowering therapy (ULT), management remains poor. However, limited research has sought to improve care among this patient population. An in-depth understanding of provider and patient perspectives on barriers to the delivery of optimal gout care is critical to informing the development of evidence-based interventions to effectively improve disease management and patient outcomes.
Objectives: To systematically review and thematically synthesize qualitative studies to date reporting provider and patient barriers to gout management.
Methods: We conducted a mapped search of MEDLINE, EMBASE, Cumulative Index to Nursing and Allied Health Literature, and Social Sciences Citation Index databases and selected qualitative studies reporting provider and patient perspectives on gout management. Thematic synthesis was used to combine the source studies and identify key themes across studies. Two authors independently read and annotated the data and after discussion agreed on an initial coding framework. Concepts were organized into descriptive themes, and the relationships between these descriptive themes were further explored to develop higher-order analytical themes.
Results: Our search strategy retrieved 2,750 articles after the removal of duplicates. After full-text review, 20 studies spanning several geographic settings worldwide (i.e., the US, the UK, New Zealand, Australia, and the Netherlands) met all inclusion criteria and were included in our systematic review. Of these, 16 studies reported gout patient perspectives (n=480 patients), while only 7 studies reported provider perspectives (n=120 providers, including general practitioners, rheumatologists and other specialists, and allied health professionals). Thematic synthesis identified three predominant interlocking analytical themes among providers: (a) knowledge gaps and management approaches, (b) perceptions and beliefs about gout patients, and (c) system barriers to optimal gout care (Table 1). We further identified four predominant themes among gout patients: (a) limited gout knowledge (e.g., the "curable" nature of gout), (b) attitudes toward taking medication, (c) interactions with healthcare providers, and (d) practical barriers to chronic medication use (Table 1).

Table 1. Illustrative Provider and Patient Quotations from Source Studies

Analytical Theme	Quotation	Reference
Provider Barriers		
Knowledge gaps and management approaches	"I think that there is lack of knowledge by both patients and health professionals. I just thought you just had gout flare ups and then it just went away, so there is definitely a need for education and better training."	Spencer *et al.*
Perceptions and beliefs about gout patients	"Adherence to uric acid-lowering therapy is not a problem in patients with gout, since they are well aware of the fact they will get new gout attacks if they do not take their medication."	Spaetgens *et al.*
System barriers to optimal gout care	"It's another thing, too, the time issue. Cause if you're really, really busy, you don't spend time to talk to the patient, you don't have time, if we're busy."	Humphrey *et al.*
Patient Barriers		
Limited gout knowledge	"I think I have accepted the fact that there is no cure. It is up to me just to minimize it, I think. I don't think there is any cure because I haven't talked to anybody who has had it and say they don't get it anymore. Is that possible?"	Lindsay *et al.*
Attitudes toward taking medication	"So I know gout's never going to kill me, right. So I don't want to be taking – I don't want to be rattling around full of tablets all the time".	Richardson *et al.*
Interactions with healthcare providers	"I don't think they gave you enough. It kind of wasn't even the basics. There were no follow-ups or anything and I was going regularly. There must have been time in there. I didn't know about uric acid levels or what I should aim for. In my mind, I never had it explained."	Te Karu *et al.*
Practical barriers to chronic medication use	"I'm frequently too busy with school pressures to worry about taking medication regularly."	Katz *et al.*

Conclusions: Our thematic synthesis identified several barriers to gout care, particularly knowledge gaps among both providers and patients as well as implementation barriers to the provision of optimal care. Knowledge translation initiatives emphasizing the "curable" nature of gout targeting both providers and patients as well as strategies to reduce system barriers and support regular medication use are urgently needed to improve gout care.

THU0461 ACCURACY OF HUMASENS-PLUS POINT-OF-CARE URIC ACID METER USING CAPILLARY BLOOD OBTAINED BY FINGERTIP PUNCTURE

S. Fabre[1], P. Clerson[2], J.-M. Launay[3], J.-F. Gautier[4], T. Vidal-Trecan[4], J.-P. Riveline[4], A. Platt[5], A. Abrahamsson[6], J.N. Miner[7], G. Hughes[5], P. Richette[1], T. Bardin[1]. *[1]Rheumatology department, Hôpital Lariboisière, Paris; [2]Soladis Clinical Studies, Roubaix; [3]Biochemistry department; [4]Diabetology department, Hôpital Lariboisière, Paris, France; [5]Personalised Healthcare Unit, AstraZeneca, Cambridge, United Kingdom; [6]Personalised Healthcare Unit, AstraZeneca, Mölndal, Sweden; [7]Research and development, Ardea Biosciences Inc., San Diego, CA, United States*

Background: A key factor in the success of gout management is the long-term lowering of uricemia below predetermined targets (300 or 360µ mol/l). Monitoring of uricemia in gout patients is therefore important, and is presently done in the laboratory on plasma samples obtained after venous puncture. An accurate uric acid (UA) meter allowing rapid testing by the health care professionals and self-measurement by the patient should improve management of gout.

Objectives: This study aimed to assess the reliability of immediate UA measurement in capillary blood samples obtained from fingertip puncture using the HumaSens^{Plus} point-of-care meter (meter) compared with that of a standard laboratory assay (lab).

Methods: Capillary UA levels were measured from 236 consenting diabetic patients using the commercially available HumaSens^{Plus} UA meter (European Conformity marked and approved for EU market use). Each patient also had a plasma UA measurement in the biochemistry laboratory using an uricase automated colorimetric assay. Since the UA meter has a dynamic range of 180–1190µ mol/l, when the values were out-ranged (meter reading LO or HI), they were individually compared to corresponding plasma measurements. Agreement between capillary and plasma UA levels was assessed by Intraclass Correlation Coefficient (ICC) and Bland-Altman graphic representation. Best capillary UA threshold for detection of hyperuricemia (plasma UA>360µmol/l) was determined from a ROC curve, relationship between methods were identified by regression. Impact of potential confounding factors (biological parameters/treatments) was searched. A total of 206 paired measurements were required for estimation of an ICC of 0.80 with a precision of 0.10 at alpha risk of 0.05%. To better understand discrepancies between meter and lab, results were compared to reference plasma UA measurements by liquid chromatography-mass spectrometry (LC-MS) in a subgroup of 77 patients who gave complementary consent.

Results: Fourteen capillary samples were read LO by the meter: 11 were confirmed by lab to be below 180µmol/l and 3 were above (189, 206 and 428µmol/l). Two capillary samples were read HI and were measured at 303 and 213µmol/l by lab. In the remaining 222 samples with meter and lab values, ICC was 0.90 [0.87–0.92] and Bland-Altman curve showed acceptable agreement over all the tested values. Best meter threshold for detection of hyperuricemia by the HumaSens^{Plus} meter was 330µmol/l (sensitivity 0.89, specificity 0.89, area under the ROC curve 0.95). Based on regression, plasma uricase of 360µmol/l corresponded to 343µmol/l. Among the biological parameters tested, only hematocrit impacted capillary uric acid measurements, however negligibly. No medication appeared to significantly affect test results. Plasma uricase measurements were better correlated to LC-MS measurements (r=0.98 [0.96–0.99]) than capillary measurements (r=0.84 [0.75–0.90]).

Conclusions: Results of the HumaSens^{Plus} meter were reasonably comparable to those of the laboratory assay. It is easy to use and may be useful in clinic and in epidemiologic studies.

THU0462 MORTALITY IN PATIENTS WITH GOUT: A SYSTEMATIC REVIEW

S. Mitchell[1], H. Liedgens[2], E. Johannes[3]. *[1]Decision Resources Group, Bicester, United Kingdom; [2]Head Health Economics and Outcomes Research Market Access, SBU Europe; [3]Head Market Access Europe, Grünenthal GmbH, Aachen, Germany*

Background: Gout is a chronic, progressive, inflammatory disease characterised by elevated serum uric acid (sUA) levels (1). In Europe the prevalence of gout ranges from 0.9–2.5%, and is increasing (2). Published data indicate that gout is an independent risk factor for both all-cause and cardiovascular (CV)-related mortality (3, 4).

Objectives: To conduct a systematic review to identify studies reporting the association between gout and mortality (all-cause and CV-related).

Methods: Relevant publications were identified by interrogating electronic databases; Medline & MEDLINE In-Process, EMBASE and the Cochrane Library (accessed 3 May 2016). Eligibility criteria included adult patients with a definitive diagnosis of acute/chronic gout (self-reported/physician diagnosed), with no restriction on publication date, study design or geography.

Results: Nineteen studies met the pre-defined inclusion criteria and were reviewed. The studies were conducted in: the US (n=8); Taiwan (n=5); Canada (n=3); Spain (n=1); Singapore (n=1); and the UK (n=1). In addition to patients having a diagnosis of acute/chronic gout, 6 of the 19 studies were conducted in the following patient subgroups: renal transplant (n=1); chronic kidney disease (n=2); patients with a recent acute myocardial infraction (n=2); and patients with heart failure (n=1). There were several consistent finding across the 19 studies: (i) gout was associated with an increase in both all-cause mortality (reported hazard ratios [HR] ranged from 1.13 to 2.37) and CV-related mortality (reported HR ranged from 1.10 to 3.88) compared with patients without gout; (ii) the increased risk in all-cause mortality was primarily driven by an increase in CV-related mortality; (iii) the increased mortality risk was higher in females than males. One study reported that the presence of tophi was independently associated with a higher risk of all-cause mortality. Notably one study reported that patients who received urate-lowering therapy (ULT) have a statistically significant lower all-cause mortality and CV-related mortality risk relative to patients who do not receive ULT.

Conclusions: This systematic review confirms that gout is associated with an increased risk of all-cause and CV-related mortality; this was consistently reported across the eligible studies. The findings highlight the risk associated with gout and emphasise the need for appropriate treatment of this curable disease.

THU0463 EPIDEMIOLOGY OF GOUT AND HYPERURICEMIA IN NEW CALEDONIA

T. Bardin[1], E. Magnat[2], P. Clerson[3], P. Richette[4], B. Rouchon[2]. *[1]Rheumatology, Hôpital lariboisière, Paris, France; [2]Agence Sanitaire et Sociale, Nouméa, New Caledonia; [3]Soladis Clinical Studies, Roubaix; [4]Rheumatolofy, Hôpital Lariboisière, Paris, France*

Background: New Caledonia is a Pacific island of 270.000 inhabitants with mixed ethnicities, including Melanesians (39.1%) and Polynesians (10.2%) and people from European ancestry (27.2%).

Objectives: To determine the prevalence of gout and hyperuricemia in the various ethnicities and to characterize associated factors.

Methods: A 3-degree random sample of the population aged 18 to 60 years old was redressed according to the 2014 New Caledonia census. Face-to-face interviews were performed by trained nurses who used a predefined questionnaire along with planned physical measurements. All participants underwent capillary measurement of creatinine level (StatSensor) and all men and only women older

than 40 years underwent uricemia testing (HumaSens). Gout was defined by a validated algorithm (1). Hyperuricemia was defined by capillary level equivalent to plasma uric acid level (PUA) >6 mg/dl (2) and/or urate lowering drug (ULD) prescription.
Results: 1.144 participants (mean age 37.7 years; 50.4% men) were included. Prevalence of gout in the entire redressed sample was 3.3% (95% CI 2.2–4.9). The prevalence was 4.1% (1.8–8.9), 2.6% (1.4–4.7), 6.7% (2.5–16.8), and 1.9% (0.5–6.6) for Europeans, Melanesians, Polynesians and other ethnicities, respectively. After adjustment for age and sex, Polynesians showed higher risk for gout than Europeans (adjusted odds ratio [aOR] 4.57 [95% CI 1.3–16.7]). Prevalence of hyperuricemia, determined in 658 participants, was 67.0% (95% CI 61.9–71.6). Prevalence of hyperuricemia was greater for Polynesians (aOR 9.17 [3.2–26.4]), Melanesians (aOR 4.02 [2.2–7.2]) and other ethnicities (aOR 2.18 [1.1–4.5]) than Europeans. On univariate analysis, factors associated with gout were hyperuricemia, male gender, age, BMI, waist circumference, renal failure, hypertension, diabetes, history of major episodes of depression and cancer but not dietary factors or physical activity, despite a consistent association with BMI. Among gout and non-gout patients, 45.9% and 0.7% were receiving ULT. Overall, 29.6% of patients receiving ULD had proper control of PUA levels (≤6 mg/dl).
Conclusions: As compared with Europe, in New Caledonia, the prevalence of gout and hyperuricemia was high, including in patients with European descent, as was previously reported for New Zealand (3). The prevalence of gout and hyperuricemia differed by ethnicity. For Melanesians, the prevalence of hyperuricemia was higher but risk of gout similar to that for Europeans, so factors (e.g., genetics) other than those involved in hyperuricemia may intervene in the risk of gout.

Background: Gout progresses through three stages: hyperuricemia, deposition of monosodium urate (MSU) crystals, and innate immune system response to MSU crystals. Genome wide association studies (GWAS) have provided insight into the molecular control of progression to hyperuricemia. However, less is known about the progression from hyperuricemia to gout.
Objectives: To conduct a GWAS for gout (where an immune response to MSU crystals has occurred) using 5,835 cases - the largest GWAS of gout to date.
Methods: The GWAS comprised 3 data sets: NZ/Eurogout (2,365 clinically-ascertained cases; 1,485 controls), the Health Professionals Follow-Up (HPFS) and Nurses' Health Studies (NHS) (1,038 cases, self-ascertained using ACR criteria; 1,095 controls), and UK Biobank (2,432 cases, ascertained by self-report of gout, hospital records, and/or use of urate-lowering therapy; 102,989 controls). The NZ/Eurogout samples were genotyped using the Illumina CoreExome v24 bead chip array (547,644 markers), the HPFS/NHS samples using the Illumina OmniExpress v12 bead chip array (730,525 markers), and the UK Biobank samples using an Affymetrix Axiom array (820,967 markers). UK Biobank genotypes had been imputed to ~73.3M SNPs. Neither the NZ/Eurogout nor NHS/HPFS genotype sets were imputed. Markers common to all three data sets (279,939) were associated with gout (adjusted for sex, age) within each data set separately using PLINK 1.9. An inverse-variance weighted meta-analysis was done with meta v4.4 in R.
Results: There were seven loci with genome-wide significant ($P<5x10^{-8}$) evidence for association with gout: *SLC2A9* (OR=1.67), *ABCG2*(OR=1.72), *GCKR* (OR=1.24), *SLC17A1-A4* (OR=1.20), *SLC22A12* (OR=1.21), *PDZK1* (OR=1.14), *TRIM46* (OR=1.18).
Conclusions: All seven loci have been previously associated with serum urate levels in GWAS. Our data emphasise the relative importance of genetic control of serum urate, compared to the genetic control of MSU crystal formation or the innate immune response, in determining gout.

THU0465 CALCIUM PYROPHOSPHATE DEPOSITION DISEASE AND OSTEOARTHRITIS: TWO FACES OF THE SAME MEDAL? AN ULTRASONOGRAPHIC AND MICROSCOPY STUDY

V. Picerno[1], A. Scanu[2], A. Adinolfi[1], C.A. Scirè[3], B. Frediani[1], L. Punzi[2], G. Filippou[1]. *[1]University of Siena, Siena; [2]University of Padua, Padua; [3]University of Ferrara, Ferrara, Italy*

Background: Calcium pyrophosphate deposition disease (CPPD) and Osteoarthritis (OA) are frequently associated and CPPD with OA is recognized as a clinical subtype [1]. However, the differences in pathogenetic, microscopic and clinical aspects between the two diseases are not clear and how CPPD and OA could affect each other is still a matter of debate.
Objectives: To assess the differences between CPPD and OA in terms of anatomic alterations of the joint, evaluated with US, and characteristics of the synovial fluid (SF) of knees affected by CPPD and/or OA.
Methods: consecutive patients reaching the outpatient clinic for the presence of knee pain and with any amount of joint effusion were eligible for the study. Patients with diagnosis or suspicion of chronic inflammatory rheumatic conditions were excluded. All enrolled patients underwent US of the knee for the assessment of joint effusion (JE), synovial hypertrophy (SH), synovial power Doppler (PD), femuro-tibial osteophytes (FTO) and alterations of the femoral hyaline cartilage (FHC), using a semiquantitative score (0: normal to 3: severe alteration) and finally a US guided aspiration of the SF. SF was examined by optical and polarized light microscopy to determine total and differential white blood cell (WBC) counts, and for crystal identification. The concentration of the main inorganic ions involved in CPP crystal formation ($P_2O_7^{4-}$, PO_4^{3-}, Ca^{2+} and Mg^{2+}) was assessed by fluorometric and colorimetric assays. CPP crystal detection was also used for the classification of patients. Further, in CPPD patients, a count of the CPP crystals detectable in a single slide was carried out. Depending on the variables, chi-square, Mann Whitney and Spearman Ro tests were used for statistical analysis.
Results: 49 patients (28 women), mean age 70.29 yo (SD±10.93) were enrolled in the study; 23 subjects presented OA and 26 CPPD (23.07% acute arthritis, 77.6% CPPD with OA). At US, a statistically significant difference between CPPD and OA was found only for the grade of effusion, being more abundant in CPPD patients. On the contrary, no differences were found regarding SH, PD, FTO, FHC. SF analysis showed that CPPD patients presented a higher volume of SF, a higher total WBC count with a higher polymorphonuclear (PMN) cells percentage and lower monocytes percentage than patients with OA. Further, both total cell count and PMN percentage were positively correlated with the number of crystals in the SF. On the other hand, no statistically significant differences were found in the content of inorganic ions between the two groups.
Conclusions: According to these results, patients with CPPD and OA present some distinct features, mainly regarding the characteristics of the SF, compared to patients with OA alone. These differences may reflect different underlying pathogenetic pathways for the two diseases. Surprisingly, the concentration of inorganic ions in the two populations was similar.Further studies are necessary in order to better understand the link between CPPD and OA and the role of ions concentration in the SF for the formation of crystals.

THU0467 SAFETY AND EFFICACY OF FEBUXOSTAT IN ADVANCED CKD PATIENTS WITH HYPERURICEMIA

Y.-J. Oh, E.S. Park, S.S. Ahn, K.Y. Lee, S.-J. Byun, J.Y. Pyo, S.M. Jung, S.-W. Lee, Y.-B. Park, J.J. Song. *Internal medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

Background: In chronic kidney disease (CKD) patients, hyperuricemia is a common finding and might be one of modifiable risk factors for renal progression. However, dosing adjustments and increased risk of serious side effects of uric acid lowering agents in patients with reduced renal function lead to undercorrection of hyperuricemia, especially in patients with advanced CKD. Febuxostat is highly

effective and well-tolerated to treat hyperuricemia in CKD patients. Although several evidences demonstrated the usefulness of febuxostat in hyperuricemic CKD patients, clinical studies aimed at the CKD patients with inappropriately controlled hyperuricemia by allopurinol have been relatively lacking.
Objectives: The study objective is to evaluate the safety and efficacy of febuxostat in patients, who had CKD with severe renal impairment and did not meet with the target uric acid levels using allopurinol.
Methods: Data were collected from 168 patients who had CKD with more than stage 3b and changed from allopurinol to febuxostat due to uncontrolled hyperuricemia between 2005 and 2014 at Yonsei University Medical Center. Uric acid and creatinine were analyzed at baseline and during the first 6 and 12 months after conversion of febuxostat. Estimated glomerular filtration rate was calculated using the formula of MDRD equation. The patients were defined as a well-controlled state when the uric acid values of the study subjects reached within 6.0 mg/dL.
Results: The mean age was 60.7±14.6 years, and 129 patients (76.8%) were male. The number of patients was 25 (14.9%) in CKD stage 3b, 75 (44.6%) in stage 4, 8 (4.8%) in stage 5, 38 (22.8%) in patients treated with maintenance dialysis, 22 (13.1%) in patients underwent kidney transplantation. The mean estimated GFR (eGFR) and uric acid levels at baseline was 23.1±17.3 ml/min/1.73m^2 and 8.3±2.4 mg/dL, respectively. Most of the patients was treated with 40 or 80mg of febuxostat during the study period. The mean uric acid levels at 6- and 12-month after febuxostat treatment were significantly reduced compared to uric acid levels at baseline (5.2±2.1 mg/dL at 6-month and 4.9±2.2 mg/dL at 12-month, $p<0.001$, respectively). More than 70% of study subjects reached to the target of uric acid levels less than 6mg/dL at 6- and 12-months after treatment of febuxostat [122 (72.6%) patients at 6-month and 133 (79.2%) patients]. The creatinine levels at baseline and 6-month were comparable (3.42±2.03 vs. 3.38±2.16 mg/dL at baseline and 6-month, p=0.61), meanwhile, the creatinine levels were significantly increased after 12-month compared to those at baseline (3.69±2.46 mg/dL, $p<0.01$). Abnormality of liver function test was observed in only one patient during the follow up period. None of the patients did not discontinue drug due to adverse events.
Conclusions: Present study demonstrated that substantial hyperuricemic CKD patients treated with febuxostat were achieved the target of uric acid levels without adverse events. Febuxostat is an effective and safe uric acid lowering drug in allopurinol-intolerant patients with advanced CKD.

Fibromyalgia

THU0468 DIAGNOSTIC EXPERIENCE OF PATIENTS WITH FIBROMYALGIA – A SYSTEMATIC SYNTHESIS OF QUALITATIVE STUDIES

A.M. Mengshoel[1], J. Sim[2], B. Ahlsen[1], S. Madden[3]. *[1]Institute of Health and Society, University of Oslo, Oslo, Norway; [2]Institute for Primary Care and Health Sciences, Keele University, Staffordshire; [3]Faculty of Medical Science, Anglia Ruskin University, Chelmsford and Cambridge, United Kingdom*

Background: In recent years, the evidence-based practice (EBP) movement has become embraced by clinicians and scientists world-wide. A guiding principle of the EBP is that the best evidence available should inform clinical practice. At the same time, patients' experiences should be taken into consideration in the clinical disicion-making. Over the years, the diagnosis of fibromyalgia (FM) has been subject to numerous debates among scientists and clinicians. Despite that a diagnosis may lead to a biographical disruption, be a starting point for patients to make sense of their illness, and shape expectations for the future, the diagnostic debates have not been appreciably informed by how patients themselves perceive the diagnosis.
Objectives: To examine how individuals experience the process and consequences of receiving a diagnosis of fibromyalgia
Methods: A systematic literature search of qualitative studies up to May 2016 was performed. A systematic search was carried out in Medline (*n*=562), PsychInfo (n=430), Cinahl, AMED (*n*=95), and Social Science Citation Index (*n*=486) up to May 2016, supplemented by items from the authors' knowledge of the literature. Duplicates, quantitative studies, studies addressing chronic pain with no specification of diagnosis or including patients with other diagnoses, editorials, reviews, conference reports and dissertations were excluded. After this reading 93 qualitative studies of patients' experience were read to identify whether they included information about patients' diagnostic experience. Twenty-six papers, one book and a book chapter were included. Information about diagnostic experiences were extracted and subjected to an interpretive analysis in accordance with principles of meta-ethnography.
Results: Years were normally spent consulting specialists in an attempt to confirm the reality of symptoms and make sense of the illness. In this process, the reality of the illness was questioned. Great relief was expressed at finally achieving the FMS diagnosis. However, relief waned when therapies proved ineffective. Health professionals and others again questioned whether individuals were genuinely ill, that the illness had a psychological nature, and whether they were doing their best to recover. For the patients, the diagnosis did not provide a meaningful explanation of their suffering and had limited power to legitimate illness. The patients felt blamed for their failure to recover which meant their personal credibility and moral identity were put at stake.
Conclusions: The FMS diagnosis has limitations in validating and making sense of patients' illness experiences and in providing social legitimation of their illness. Social relationships are strained during the diagnostic process and in the course of ineffective therapies.

THU0469 COMPARATIVE EFFECTIVENESS OF TAI CHI VERSUS AEROBIC EXERCISE FOR FIBROMYALGIA: A RANDOMIZED CONTROLLED TRIAL

C. Wang[1], C. Schmid[2], R. Fielding[3], W. Harvey[1], K. Reid[3], L.L. Price[1], J. Driban[1], R. Kalish[1], R. Rones[4], T. McAlindon[1]. *[1]Tufts Medical Center, Boston; [2]Brown University School of Public Health, Providence; [3]Tufts University; [4]Center for Mind-Body Therapies, Boston, United States*

Background: Fibromyalgia is a complex disorder with strong psychological and pain components. Tai Chi is an integrated mind-body approach that enhances both physical and mental health and has great potential to treat fibromyalgia (1–2).
Objectives: We aimed to investigate whether Tai Chi is more effective with longer lasting effects than aerobic exercise.
Methods: We conducted a 52-week, single-blind, randomized trial of Tai Chi vs. aerobic exercise for fibromyalgia (ACR 1990 and 2010 diagnostic criteria). Participants were randomized to 1 of 4 Tai Chi interventions: 12 or 24 weeks of Tai Chi once or twice per week, or aerobic exercise held twice per week for 24 weeks. The primary endpoint was change in the Revised Fibromyalgia Impact Questionnaire (FIQR) score at 24 weeks. Secondary endpoints included change in patient's global assessment, the Hospital Anxiety and Depression scale (HADS), Sleep Quality Index (PSQI), arthritis self-efficacy scale (ASES-8), and quality of life. The comparative efficacy of the five groups was determined using longitudinal models based on the intent-to-treat principal.
Results: The mean age of subjects was 52 years (SD 12), mean years of body pain of 9 years (SD 8), 92% were women, and 61% were white. Treatment groups did not differ in baseline outcome expectation. The average of all 4 Tai Chi groups, compared to aerobic exercise, showed significant improvements in FIQR scores, patient's global, anxiety, and self-efficacy. All other outcomes favored Tai Chi over aerobic exercise (Table 1). The Tai Chi treatment with the same dosage as the aerobic group demonstrated an even larger effect for FIQR and for most other outcomes. The benefit of Tai Chi was consistent across instructors.
Conclusions: Tai Chi is more effective than aerobic exercise and can be considered as an important therapeutic option for patients with fibromyalgia.

Positive scores indicate improved outcome in second listed group. Boldface indicates statistically significant differences between groups.

THU0470 WORK AND PROFESSIONAL RECOGNITION IN FIBROMYALGIA PATIENTS – A NATIONAL FRENCH WEB BASED SURVEY ON SICK LEAVE IN 1870 FIBROMYALGIA FEMALE PATIENTS

F. Laroche[1], D. Azoulay[1], J. Guérin[1], J. Coste[2], S. Perrot[3]. [1]*Pain Department, Hospital University Saint Antoine;* [2]*Biostatistics, Hospital University Hotel Dieu;* [3]*Pain Department, Hospital University Cochin, Paris, France*

Background: Fibromyalgia (FM) induces work limitations with an increase of number of days of sick leave 3 to 4 fold higher (1, 2).
Objectives: Our objectives were to analyze work status, to determine risk factors for sick leave and to compare women working to women in sick leave during the past 12 months in a female population with FM.
Methods: 1870 female workers suffering from FM were selected from a large internet-based national survey of 4516 responders (Fibromyalgie-SOS Association website in France in 2014). Women having a FIRST score ≥5/6 were included.
Results: 1870 patients participated to the survey: 955 with full time job, 149 with part time job (related to FM status) and 766 on sick leave (7% 1–3 months, 27.3% 3–12 months and 62% >12 months). Fibromyalgia Impact questionnaire (FIQ) score was slightly lower in the 1104 patients currently working compared to the 766 on sick leave (56 versus 58.7), but not clinically different. 64,5% of the population have been on sick leave during the last 12 months (average duration: 37 mean days for full time job and 122 among those with part time job).
Women being in sick leave were older (p<0,0001), single (p=0,0321), had less financial income (p<0,0001), used more antidepressants (p=0,0085) and more anti epileptics (p=0,0102). Recognition of FM by occupational physicians or social security doctors were lower among the workers (p<0.0001).
In the 1104 currently working, more than 33% have never been visiting their occupational physician and 44,2% rarely. They reported no support from these doctors (p=0,0011) particularly those having not being on sick leave. Independent criteria of sick leave were transportation time (p=0.0131), work difficulties (p=0.0031), hinders career progress (p=0.0196), sedentary occupation and repetitive work (p=0.0195).
Conclusions: These data on a large fibromyalgia population shows that clinical status and also professional factors may influence work ability and sick leave.
The work factors include work difficulties, transportation time, sedentary and repetitive occupation. These results should be taken into account by the work professionals in order to facilitate work capacity in FM patients.

THU0471 THE EFFECTS OF TAPPING THERAPY ON PAIN, SYMPTOM SEVERITY, DYSFUNCTIONS IN DAILY LIFE, DEPRESSION, AND QUALITY OF LIFE IN PATIENTS WITH FIBROMYALGIA: A RANDOMIZED CONTROLLED TRIAL

H.J. Suh[1], S.T. Choi[2], J.-S. Song[2], S.H. Shin[3]. [1]*Seoul National University Hospital;* [2]*Internal Medicine, CHUng-Ang University College of Medicine;* [3]*Kyung Hee University Nursing Science, Seoul, Korea, Republic Of*

Background: Fibromyalgia is a disorder characterized by chronic widespread musculoskeletal pain, often accompanied by fatigue, cognitive disturbance, psychiatric symptoms, and multiple somatic symptoms. Various pharmacological and non-pharmacological therapies have been tried in the management of fibromyalgia. However, unfortunately, management remains a challenge.
Objectives: Taping therapy has been shown to be effective for pain relief in various musculoskeletal diseases. However, there was no trial for the patients with fibromyalgia. In this study, we evaluated the effects of taping therapy in patients with fibromyalgia.
Methods: This study is a randomized controlled trial with 60 fibromyalgia patients. All patients were satisfied with the 2010 American College of Rheumatology diagnostic criteria for fibromyalgia. Participants were randomized to the Kinesio taping group (n=30) and to the non-elastic paper taping group (n=30) for the control. Taping experiment was performed for three weeks (twice a week) through the one-to-one meeting. Pain, symptom severity, dysfunctions in daily life, depression, and quality of life (QoL) were assessed with the widespread pain index (WPI), severity score (SS), fibromyalgia impact questionnaire (FIQ), Beck depression inventory (BDI), and the EQ-5D INDEX and EQ-5D VAS, respectively.
Results: The mean ages of taping group and the control group were 54.3±12.0 years and 53.2±12.7 years, respectively, and female patients were 25/30 (83.3%) and 27/30 (90.0%) in both groups, respectively, and there were no differences between two groups in the medication use such as anti-depressants and muscle relaxants. Patients showed significant improvements after Kinesio taping therapy in pain (10.50±3.98 vs. 5.70±2.73, $p<0.001$), symptom severity (7.93±2.24 vs. 5.27±1.98, $p<0.001$), dysfunction in daily life (65.03±18.75 vs. 43.25±18.87, $p<0.001$), depression (18.17±8.55 vs. 13.00±6.75, $p<0.001$) and QoL (EQ-5D INDEX, 9.10±1.54 vs. 7.67±1.40, $p<0.001$; EQ-5D VAS, 38.33±24.65 vs. 56.67±27.93, $p<0.001$), respectively. In the control group, however, the significant improvement was detected only in pain (10.53±3.87 vs. 9.27±3.57, $p=0.012$). The changes before and after treatment in the Kinesio taping group revealed significant differences from those in the control group: pain ($p<0.001$), symptom severity ($p<0.001$), dysfunction in daily life ($p<0.001$), depression ($p=0.001$) and QoL ($p<0.001$ and $p<0.001$), respectively. There was no serious adverse event.
Conclusions: This study shows that Kinesio taping therapy has effects on pain, symptom severity, dysfunctions in daily life, depression, and quality of life in the patient with fibromyalgia. Taping therapy could be a useful non-pharmacological management modality for the fibromyalgia patient.

THU0472 FAST3 (FIBROMYALGIA ASSESSMENT SCREENING TEST): A COMPOSITE INDEX BASED ON MDHAQ PROVIDES CLUES TO THE PRESENCE OF SECONDARY FIBROMYALGIA IN PATIENTS WITH A PRIMARY DIAGNOSIS OF RHEUMATOID ARTHRITIS AT HIGHER LEVELS THAN IDENTIFIED IN THE MEDICAL RECORD: A CROSS SECTIONAL STUDY FROM ROUTINE CARE

I. Castrejon[1], K. Gibson[2], J.A. Block[1], T. Pincus[1]. [1]*Rheumatology, Rush University Medical Center, Chicago, United States;* [2]*Rheumatology, Liverpool Hospital, Sydney, Australia*

Background: Secondary fibromyalgia (FM) is reported in 17% of RA patients[1], but may be under-recognized in patients with classical RA findings. A FAST3 (fibromyalgia assessment screening test) index based on 3 MDHAQ (Multidimensional Health Assessment Questionnaire) scores gives similar results to ACR fibromyalgia criteria based on a widespread pain questionnaire,[2] to assist in recognizing patients with secondary FM[3].
Objectives: To study patients with a primary diagnosis of RA seen in routine care for the proportion identified as having secondary FM according to a physician diagnosis in the medical record versus a FAST3 Index of MDHAQ scores.
Methods: All patients complete an MDHAQ/RAPID3 at all visits in the waiting area in routine care. The MDHAQ includes 0–10 scores for physical function, pain, and patient global estimate, compiled into RAPID3, as well as a 0–48 RADAI self-report score of painful joints, and 0–60 symptom checklist. FAST3 has been developed previously as the 0–3 sum of 1 point each for 3 MDHAQ scores: pain VAS ≥6, RADAI ≥16, and symptom checklist ≥16.[3] FAST scores of ≥2/3 had >80% agreement with ACR FM criteria based on a widespread pain questionnaire[2] to identify secondary FM.[3] A random visit for each patient with a primary diagnosis of RA with complete data was studied. The number with a diagnosis of secondary FM in the medical record was compared to the number with FAST3 scores of 0, 1, 2, 3, and with each of the 3 FAST3 components. Receiver-operating characteristic (ROC) curves were generated to estimate sensitivity and specificity for each cut-point of the FAST3 score, using a diagnosis of secondary FM by the physician as the external criterion.
Results: 287 patients with RA were studied, of whom 10 (3.3%) had a diagnosis of secondary FM by the physician in the medical record and 61 (22%) had FAST3 scores of 2 or 3 (Table), including 6 of 10 identified as having FM in the medical record. Overall, FAST3 was 0 in 161 RA patients (56%), 1 in 59 (20.6%), 2 in 46 (16%), and 3 in 21 (7.3%) (Table). Overall, 55 additional RA patients were identified by FAST3 versus the medical record as having possible secondary FM. The ROC area was 0.73 (95% CI, 0.57–0.89) (data not shown).

Table 1. FAST3 (fibromyalgia assessment screening tool) Index and 3 individual components according to diagnosis of fibromyalgia by rheumatologist in medical record

	Clinical FM-No	Clinical FM-Yes	Total
Total	277	10	
FAST (fibromyalgia assessment screening tool) Index			
0	159 (57%)	2 (20%)	161
1	57 (21%)	2 (20%)	59
2	42 (15%)	4 (40%)	46
3	19 (7%)	2 (20%)	21
Individual component measures			
Pain >6	92 (33%)	7 (70%)	99
Pain <6	185 (67%)	3 (30%)	188
RADAI >16	68 (25%)	6 (60%)	74
RADAI <16	209 (75%)	4 (40%)	213
Symptom checklist >16	38 (14%)	3 (30%)	41
Symptom checklist <16	239 (86%)	7 (70%)	246

Conclusions: The same MDHAQ used to score RAPID3 may also provide a FAST3 score as a screening tool for secondary FM in RA (and other) patients (including primary FM). Secondary FM may be under-diagnosed by clinicians in routine care. Further validation of FAST3 in other settings is needed.

THU0473 POLYSYMPTOMATIC DISTRESS SCALE, WIDE SPREAD PAIN INDEX, AND SYMPTOM SEVERITY SCALES, AND THEIR CORRELATES IN 169 PATIENTS WITH FIBROMYALGIA SYNDROME

K. Yaseen[1], S. Kaouk[2], D. Bork[3], W.S. Wilke[3], C. Gota[3]. *[1]Internal Medicine, Cleveland Clinic; [2]Rheumatology, John Carroll University; [3]Rheumatology, Cleveland Clinic, Cleveland, United States*

Background: The polysymptomatic distress scale (PSD) is considered a measure of FM severity and ranges from 0 to 31. It is calculated by adding the two components of the American College of Rheumatology (ACR) 2010 fibromyalgia (FM) criteria, widespread pain index (WPI) and symptoms severity scale (SS).
Objectives: Determine the relationship between depression, anxiety, function disability and pain related disability, with fibromyalgia severity as measured by PSD and its subsets, WPI and SS.
Methods: All consecutive FM patients who met the ACR 2010 criteria completed the following questionnaires: PSD, patient health related questionnaire (PHQ-9), a measure of depressive symptoms, general anxiety disorder questionnaire (GAD-7), health assessment questionnaire disability index (HAQ-DI), and pain disability index (PDI).
Results: Of 169 patients, 85.7% were women, mean age 42.3 (13.3), BMI 29.3 (7.1), PHQ-9 13.7 (5.2), GAD-7 10.2 (9.1), HAQ-DI 1.6 (2.9), PDI 6 (2.1), WPI 14.3 (2.7), SS 10 (1.6). In univariate analysis PSD correlated significantly ($p<0.01$) with PHQ-9 (0.576), PDI (0.422), and GAD-7 (0.356). Widespread pain index correlated significantly with PHQ-9 (0.313), GAD-7 (0.239), HAQ-DI (0.259), and PDI (0.296). Symptom severity scale correlated significantly with PHQ-9 (0.496), GAD-7 (0.337), HAQ-DI (0.275), PDI (0.340). A linear regression analysis model, which included PHQ-9, GAD-7, PDI and HAQ-DI predicted 0.269 of PSD variance, p=0.001, and only PDI remained significantly correlated with PSD. A similar model predicted 0.348 of SS variance, ($P<0.0001$), and only PHQ-9 remained significantly correlated with SS. This model did not significantly predict WPI variability.
Conclusions: Depression, anxiety, pain disability and functional disability predict a small variance of fibromyalgia severity measured by PSD. In regression analysis, pain disability measured by PDI is the only variable that remains independently correlated with PSD. None of these variables predicted WPI, while depression measured by PHQ-9 remains independently correlated with SS, indicating that PSD subsets measure different dimensions of FM.

THU0474 A CROSS-SECTIONAL STUDY INTO THE EFFECTIVENESS OF THE FIBROMYALGIA RAPID SCREENING TOOL FOR DETECTING FM IN PATIENTS WITH CHRONIC ARTHRITIS UNDERGOING FULL AND TAPERED BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUG THERAPY

L. Valor, D. Hernández Flórez, T. del Río, I. Janta, J. Martínez Barrio, J.G. Ovalles B., B. Serrano, R. González Benítez, C. Sáenz Tenorio, J.C. Nieto, C. González, I. Monteagudo, F.J. López-Longo. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: The determination of fibromylagia (FM) in patients presenting diffuse, chronic arthritis is fraught. The Fibromyalgia Rapid Screening Tool (FiRST) is a validated questionnaire with high sensitivity and moderate specificity shown to be able to identify up to 89% of FM cases, even when accompanied by anxiety, depression or functional disability. Decisions to embark upon a course of full or tapered biological disease-modifying antirheumatic drugs (bDMARD) are influenced in part by patient self-assessment scores as well as concomitant pathologies.
Objectives: To evaluate the prevalence of FM using the FiRST questionnaire in bDMARD-treated chronic arthritis patients.
Methods: This cross-sectional study included 325 patients [178 (54,8%) females and 147 (45,2%) males] diagnosed with chronic arthritis and treated with bDMARD. Patients were consecutively recruited from the Biological Therapy Unit from January to March 2015 all having undergone full or tapered bDMARD for at least 1 year. Dosage tapering had been applied to patients considered to be in remission. All patients self-completed the FiRST questionnaire with a score>5/6 considered positive. Clinical assessment was carried out by one specialist only. Demographic, clinical and laboratory variables were recorded with pathology-specific indices used to assess disease status, i.e.DAS28-ESR, DAS28-CRP, SDAI, CDAI, BASDAI, BASFI, ASDAS-CRP. Patient pathologies were classified as peripheral arthritis (PerAR: RA, PsA, PerSpA) or axial spondyloarthropathy type (AxSpA).
Results: A total of 68/325 (21%) patients scored >5/6 in the FiRST. Disease duration and previous bDMARD usage were not significant regarding scores <5/6. In the PerAR vs. AxSpA group, we observed that 19% (n=43) and 35% (n=25) scored FiRST>5/6, respectively (p=NS). Fifteen per cent of patients with tapered bDMARD registered scores >5/6 against 85% of patients in full bDMARD dosage (p=0.001). There were a higher number of remission patients in the PerAR group as defined under DAS28-ESR, SDAI and CDAI [(96%, 94% and 94%) (p=0.01, p=0.04, p=0.032), respectively]. Association was found in the PerAR subgroups between tapered bDMARD and remission in RA patients only, as defined under DAS28-VSG, SDAI and CDAI (p=0.026, p=0.04, p=0.043, respectively). In the AxSpA tapered bDMARD subset, 86% of patients were considered to be in clinical remission as set out under BASDAI (p=0.019).
Conclusions: No difference was observed between the PerAR and AxSpA groups for FiRST>5/6. Fewer patients undergoing tapered bDMARD dosage recorded FiRST scores >5/6. Therefore, early identification of chronic arthritic patients presenting FiRST>5/6 may prove to be an important step in furthering understanding of clinical activity in diffuse arthritis as well as offering improved diagnostic and therapeutic outcomes to bDMARD-treated patients with possible concomitant FM.

THU0475 EVALUATION OF PELVIC FLOOR STRENGTH AND URINARY INCONTINENCE IN WOMEN WITH FIBROMYALGIA

M.A.G. Pontes Filho[1], H.C.S.C. Fusco[2], E.A.G. Ferreira[2], A.P. Marques[2]. *[1]Reumatologia, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo; [2]Fisioterapia, Fonaudiologia e Terapia Ocupacional, Universidade de São Paulo, Sao Paulo, Brazil*

Background: Fibromyalgia (FM) is characterized by the *American College of Rheumatology* as chronic widespread pain referred for at least 3 months. In 2010, a new diagnostic criteria was proposed and includes symptoms such as fatigue, sleep disorder and memory. Currently, pelvic floor dysfunctions and urinary incontinence (UI) are considered public health problems with high prevalence and great impact on quality of life (QoL) and on women's self-esteem. Physiotherapists have been working to create a new treatment proposal that can cover all aspects of FM, however there are few studies that include pelvic floor evaluation and urinary continence of this population.
Objectives: To assess the strength of the pelvic floor and urinary loss in women with FM.
Methods: We evaluated 126 sexually active women, aged between 19 and 65 years, with and without medical diagnosis of FM, matched for age and menopausal status, in a single center. The exclusion criteria were sexually transmitted or neurological diseases, pregnancy and use of medications with urinary side effects (urinary loss or retention). We collected in a single interview personal and gynecological data, applied the King Health Questionnaire (KHQ) for incontinent women and accomplished the evaluation of pelvic floor muscle strength according to the Oxford Classification Modified and perineometry. The participants signed the Informed Consent Form. We used for statistical analysis t test for independent variables and Mann-Whitney Test for the others.
Results: The FM patients presented the weaker pelvic floor ($p<0.001$) and had lower values in perineometry (p=0.04) than control women. Regarding urinary loss, 64.5% reported UI against 26.6% of women without FM. In the KHQ evaluation, in General Health and Emotions domains, women with FM presented worse performance ($p<0.001$ and p=0.046, respectively).
Conclusions: Urinary incontinence is a frequent finding in FM, and it could be related to the degree of strength of the pelvic floor muscles. This condition affects negatively QoL, especially with regard to emotions and general health.

THU0476 EVALUATION OF SEXUAL FUNCTION IN WOMEN WITH FIBROMYALGIA

M.A.G. Pontes Filho[1], H.C.S.D.C. Fusco[2], R.T. Cônsolo[2], E.A.G. Ferreira[2]. *[1]Reumatologia, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo; [2]Fisioterapia, Fonaudiologia e Terapia Ocupacional, Universidade de São Paulo, Sao Paulo, Brazil*

Background: Fibromyalgia (FM) is defined by the *American College of Rheumatology* as a syndrome of unknown etiology, characterized by chronic and widespread musculoskeletal pain. In 2010, a new diagnostic criteria was proposed and involves not only pain but symptoms such as depression, muscle fatigue, non-restorative sleep and urinary disorders. This may lead to a lack of interest or difficulty in the sexual act, which tends to be aggravated by depression, which is manifested by low self-esteem, decreased desire and orgasm, and pain during sexual intercourse.

Objectives: Compare the sexual function of women with and without FM.
Methods: Sexually active women aged between 19 and 65 years with and without medical diagnosis of FM in a single center, matched for age and menopausal status, were evaluated. The exclusion criteria were pregnancy and use of medications with urinary side effects (urinary loss or retention). In a single interview the participants signed the Informed Consent Form and answered questions about personal and gynecological data. The protocol The Sexual Quotient – Female Version (QS-F) was applied to assess sexual performance. We used for statistical analysis t test for independent variables and Mann-Whitney Test for the others.
Results: In this study, 126 women were evaluated with age of 43.73±10.48 years. Most of the patients were married, representing 58.7%. A total of 50% participants had 1 or 2 children, 22.2% between 3 and 4 children and 27.8% had no children. Regarding the age of menarche and manopausal status, no differences were observed between groups (p=0.70 and p=0.08, respectively). The QS-F score revealed significantly lower scores for women with FM when compared to the healthy group ($p<0.001$). We observed the same results in the domains: Desire and Sexual Interest ($p<0.001$), Excitation Phase (p=0.019) and Satisfaction and Orgasm ($p<0.001$). Regarding the Pain and Comfort domain, no differences were observed between the groups (p=0.307). However, when they were questioned about dyspareunia in the physiotherapeutic evaluation, it was observed that 51.6% of FM patients reported pain in sexual act against only 26.6% of healthy women (p=0.005).
Conclusions: Women with FM performed poorly on QS-F general score and in most domains, except for pain and comfort. When they were questioned in the physiotherapeutic evaluation about dyspareunia, we observed that women with FM had more pain in sexual intercourse, which may occurred due to the way the question was asked. As consequence, women with FM report worse sexual performance, especially with regard to desire, arousal phase and orgasm rate.

THU0477 DOES FIBROMYALGIA AFFECT PHYSICAL ACTIVITY OF THE PATIENTS?

M. Alkan Melikoglu[1], S. Dogantekin[2]. *[1]Rheumatology, ATATURK UNIVERSITY FACULTY of MEDICINE, Rheumatology; [2]Physical medicine and Rehabilitation, ATATURK UNIVERSITY FACULTY of MEDICINE, Erzurum, Turkey*

Background: Fibromyalgia syndrome (FMS) as a chronic pain condition can cause impaired physical activity level of the patients.
Objectives: The purpose this case-control study was to evaluate the physical activity levels of patients with FMS and to assess a possible relation between physical activity and disease characteristics.
Methods: Seventy patients with FMS and 50 age-gender matched controls were included in the study. The demographic features and duration of symptoms of the participants were recorded. The level of pain was evaluated using the visual analogue scale (VAS). The Fibromyalgia Impact Questionnaire (FIQ) scoring system was used for the evaluation of the impact of FMS. Also for assessing the physical activity in our participants, we used The International Physical Activity Questionnaire (IPAQ). Mann–Whitney U and Pearson correlation tests were used for group comparisons and was used for correlation analyses.
Results: The mean age of the patients and healthy controls were 41,90±8,53 years and 41,52±9,01 years, respectively. Symptom duration of the patients was 61,0±45,8 months. The patients with FMS presented significantly less transportation-related, recreational and total physical activity levels, besides reporting significantly less time spent walking and less time spent in vigorous activities than healthy controls ($p<0,05$). Also, in patients with FMS, there was a negative correlation between pain and the scores of self-reported moderate or vigorous physical activity ($r =- 0.41$, $p<0.01$). However, we couldn't find any correlation between FIQ and IPAQ scores.
Conclusions: Patients with FMS are physically less active than healthy individuals of similar profile. This reduced activity seems to be associated with pain, but not with the impact of the disorder. In the approach to the patient with FMS, considering the patient's physical activity behavior can contribute to the management of the disorder. In future studies assessing the effect of exercise in FMS, consideration of the patients' physical activity level may contribute to a complete evaluation of the patients.

THU0478 DETERMINATION OF COMORBIDITIES IN FIBROMYALGIA SYNDROME

U. Bilge[1], T. Kaşifoğlu[2], N.S. Yaşar Bilge[2], H. Balcıoğlu[1], Y.E. Sarı[1], M. Kayhan[1], I. Ünlüoğlu[1]. *[1]Eskişehir Osmangazi University Faculty of Medicine Department of Family Medicine, Eskişehir Osmangazi University Faculty of Medicine Department of Family Medicine; [2]Eskişehir Osmangazi University, Eskişehir Osmangazi University Faculty of Medicine Department of Internal Medicine Division of Rheumatology, Eskişehir, Turkey*

Background: Although fibromyalgia syndrome is diagnosed by excluding other possible diagnosis based on the patient's clinical features, in recent the studies, it was shown that comorbid diseases affect the course of fibromyalgia.
Objectives: The aim of this study is to evaluate the comorbid diseases of patients with fibromyalgia and to determine the rates of comorbid diseases
Methods: In this study, age, gender and comorbid diseases of patients above 18 years and diagnosed with fibromyalgia by a were evaluated in the database system of the hospital retrospectively.
Results: A total of 509 patients were examined in our study. 51 of the patients were male, 458 were female (mean age was 50.24±12.32). Of the patients, 345 (67.8%) had at least one comorbid disease while 164 (32.2%) had no comorbid disease. In the study, 187 of the patients (36.7%) had cardiovascular diseases, 157 of the patients (30.8%) had endocrine diseases, 63 of the patients (12.4%) had rheumatologic diseases, 30 of the patients (5.9%) had neurological diseases, 14 of the patients (2.8%) had other autoimmune diseases, 10 of the patients (2.0%) had cancers, 129 of the patients (25.3%) had mental disorders, 45 of the patients (8.8%) had chronic lung diseases, 37 of the patients (7.3%) had osteoporosis, 11 of the patients (2.2%) had other diseases (chronic pancreatitis, chronic renal failure, nephrotic syndrome, deep vein thrombosis, hepatitis serology positivity, pulmonary thromboembolism, organ transplantation).
Conclusions: FMS is an important disease that is increasing in frequency in recent years. FMS, which can be seen with many diseases, is in fact related to physicians from many branches, and it is useful to evaluate FMS patients with their comorbid conditions on their follow-up.

THU0479 THE PREVALENCE OF XEROSTOMIA IN PATIENS WITH FIBROMYALGIA

N.M. Lloves Schenone, A. Secco, V. Durigan, S. Scarafia, F.E. Romanini, M. Mamani. *Servicio de Reumatología, Hospital Bernardino Rivadaiva, Buenos Aires, Argentina*

Background: Fibromyalgia (FM) is a rheumatic disease characterized by diffuse, chronic musculoskeletal pain, of non-articular origin, which is evidenced by the palpation of painful points in specific anatomical areas and is usually accompanied by non-repairing sleep, Tiredness, morning stiffness, cognitive alterations, among others.
FM affects approximately 0.5 -5% of the population, having a maximum prevalence between 40 and 50 years. No racial or socioeconomic predisposition has been determined to date.
Sicca syndrome whose term encompasses xerophthalmia, xerostomia, xeroderma and xerovagina, has been described in patients with FM. Xerostomia is the sensation of dry mouth due to lack or decrease of saliva. There are no clinical studies that determine the prevalence of xerostomia in patients with FM and on the other hand the reduction of salivary flow in these patients has not been studied with objective tests.
Objectives: The aim of this study was to determinate the frecuency of xerostomia in patients with diagnosis of Fibromyalgia and describe their clinical and epidemiologic characteristics.
Methods: Patients were included according 1990 and 2010 ACR Classification criteria. Patients taking drugs that cause xerostomia were excluded as well as the ones presenting other rheumatologic diseases. Xerostomia was assessed by interrogation and physical examination, and a sialometry was performed in order to determinate the decrease of salival flow. A sialometry was positive if the saliva flow was under 1.5 ml in 15 minutes. In case of presenting positive sialometry patients were studied to rule out Sjogren Syndrome with laboratory and minor salivary gland biopsy.
Results: 50 patients were recruited during the study. The 100% of them were women. The mean age was 47 years old (DS+-8.5), while the mean time of evolution of FM was 6 years. 29 patients reported xerostomia of which 4 presented positive sialometry. No positive sialometry was found in the group that did not referred xerostomia. Smoking was more prevalent in patients with FM who did not

report xerostomia with respect of those who reported xerostomia (31.8% vs 6.9%, p 0.02). There were not associations between xerostomia and hypothyroidism, diabetes or menopause. The presence of Sjogren Syndrome was rule out in those 4 patients whose sialometry was positive.

Conclusions: The prevalente of xerostomía was 51%. No statistically significant associations were found in patients who reported xerostomia. A decrease in objective salivary flow was not demonstrated in patients with FM.

THU0480 MULTICENTER, PROSPECTIVE, CONTROLLED DOUBLE-BLIND STUDY COMPARING FIB-19-01, A PHYTOTHERAPY TREATMENT FOR FIBROMYALGIA, TO A DIETARY SUPPLEMENT AND TO CONVENTIONAL TREATMENT IN PATIENTS SUFFERING FROM FIBROMYALGIA

P. Bertin[1], D. Baron[2], M. Barmaki[3], I. Russ[4], C. Maindet-Dominici[5], P. Fardellone[6], P. Ginies[7], T. Conrozier[8], J. Nizard[9]. *[1]Rheumatology, CHU Limoges, Limoges; [2]Rheumatology, CH Lannion, Lannion; [3]Pain, Clinique MutualisteEugène André, Lyon; [4]Pain, Hopital residence du Parc, Marseille; [5]Pain, CHU Grenoble, Grenoble; [6]Rheumatology, CHU Amiens, Amiens; [7]Pain, CHU Montpellier, Montpellier; [8]Rheumatology, Nord Franche Comté Hospital, Trevenans; [9]Pain, CHU Nantes, Nantes, France*

Background: Current therapeutic modalities for fibromyalgia syndrome (FMS) do not provide satisfactory results to a high percentage of patients and new approaches have to be explored.

Objectives: This randomised, double-blind, controlled study was aimed to assess the efficacy and safety of adding a new treatment of herbal medicine, specifically developed to improve the quality of life of patients with FMS (Fib-19–01), to the current therapeutic regimen.

Methods: In this double-blind, placebo-controlled study, females with FMS, insufficiently improved by their current treatments, were randomised in one of the 3 following arms: Patients of arm 1 received Fib-19–01, 1 tablet twice a day. Those of arm 2 received a food supplement claimed to have analgesic properties (FSAP), in a double-blind way, and patients of arm 3 continued the previous treatment. without adding anything else (NoT). All continued the conventional treatment throughout the 6 months of follow-up. Inclusion criteria: women suffering from FMS (ACR criteria) with a Fibromyalgia Index Questionnaire FIQ $>$46. The primary endpoint was the change in FIQ score between baseline (Day 0) and month 6 (M6). Secondary Criteria included variation between D0 and M6 of the following scores: Pichot scale, Pittsburgh Sleep Quality Index (PSQI) index, SF-12 mental and social, SF-12 physical, HAD scales for depression and anxiety. Statistical analysis: Comparison intra-group (D0-M6) and intergroup on the ITT population.

Results: The ITT and per protocol populations were constituted of 101 and 75 patients. They were not statistically different and were in accordance with that expected (age 49, BMI 25, high percentage of antidepressant and anticonvulsant treatments). FIQ decrease throughout the follow-up was significant only in the Fib-19–01 group; ($p<0.001$). In intergroup comparison, improvement was higher for Fib-19–01 (-13.5) than in the 2 other groups (-5.4 and -5.6) but the difference did not reach statistical significance (p=0.08). Analysis of variance in repeated measurements of FIQ showed a significant difference between Fib-19–01 and FSAP (p=0.03). On the secondary criteria, only Fib-19–01 patients were improved for PICHOT scale ($p<0.001$), PQSI (p=0.02), SF12 mental and social ($p<0.001$), HAD anxiety (p=0.003) and depression (p=0.004). In intergroup comparison Fib-19–01 was superior to FSAP for Pichot scale (p=0.013), mental and social SF12 (p=0.018), HAD depression (p=0.013). No significant difference was found between FSAP and NoT groups. Therefore, in this study FSAP acts as a placebo which gives the results of this study a level of evidence I. All treatments were well and similarly tolerated.

Conclusions: A 6-month treatment with Fib-19–01 improved all FMS scores excepted the physical SF 12, as opposed to FSAP and conventional treatment alone, which did not significantly improve any. This study showed that Fib-19–01 has a therapeutic effect in the FMS chiefly on the components "fatigue", "emotion and social life" and "depression" of the disease, without safety concern.

THU0481 VALIDATION OF THE PROPOSED 2016 REVISION TO 2010 ACR PRELIMINARY FIBROMYALGIA DIAGNOSTIC CRITERIA IN A TERTIRAY CARE SETTING

S. Ahmed, A. Aggarwal, A. Lawrence. *Clinical Immunology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*

Background: The 2010 Fibromyalgia Diagnostic Criteria was designed for primary care[1]. The 2011 modification was a simplified version for self-reporting of fibromyalgia[2]. The 2016 revision combines both, and is supposed to be used also in tertiary setting[3]. This requires validation.

Objectives: To validate the Proposed 2016 revision with respect to (1) expert physician diagnosis and (2) 1990 ACR Classification Criteria.

Methods: Patients referred to a tertiary care centre with suspicion of Fibromyalgia were evaluated using the Proposed 2016 revision. Patients with other rheumatological diseases were excluded. Considering the expert physician opinion and American College of Rheumatology (ACR) 1990 Classification as gold standards, sensitivity, specificity, and likelihood ratios were calculated. Also, validated Hindi language versions of Brief Patient Health Questionnaire (BPHQ), Generalised Anxiety Disorder-7 (GAD7), and Toronto Alexithymia Scale-20 (TAS20) were filled up by the participants.

Results: Out of 101 patients, 77 were diagnosed as Fibromyalgia by the expert. The 2016 criteria and ACR1990 criteria were met by 79 and 67 patients respectively. The 2016 had high sensitivity but much lower specificity as compared with either the expert diagnosis or ACR1990 criteria (Table 1). Visual Analogue Scale (VAS) for pain, BHPQ, GAD7, and TAS20 scores were 7.2±2.3, 14.1±5.1, 11.3±5.5 and 58.0±14.0 (Mean±SD) respectively. Patients with or without fibromyalgia as per each of the three criteria had no significant difference in these scores.

Table 1. Sensitivity, Specificity, Likelihood ratios as compared to other criteria as gold standard, and agreement with the same

	2016 modification vs Expert opinion	2016 modification vs ACR 1990 criteria	ACR 1990 criteria versus Expert opinion
Sensitivity	87%	89.5%	79.2%
Specificity	50%	44.1%	75%
Positive likelihood ratio	1.74	1.60	3.17
Negative likelihood ratio	0.26	0.24	0.28
Kappa	0.38	0.37	0.47

Conclusions: Non-tender point based criteria have been validated in primary care. However, in tertiary care where patients are referred to as fibromyalgia, there are mimics with similar comorbidities as evident by high BPHQ, GAD7 and TAS20 scores. Even after exclusion of other rheumatological conditions, the 2016 Criteria has poor specificity. Thus, it should be used as a screening tool than a diagnostic criterion in tertiary care.

THU0482 EVOLUTION OF COMORBID FIBROMYALGIA FREQUENCY IN AXIAL SPONDYLOARTHRITIS PATIENTS STARTING AN ANTI-TNF AGENT, AND CORRELATION TO ANTI-TNF EFFICACY. THE PREDICT-SPA STUDY

S. Perrot, A. Moltó, A. Etcheto, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, L. Gossec, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: Fibromyalgia (FM) is a frequent comorbid condition in axial spondyloarthritis (axSpA). It is not known how FM comorbidity may respond to the management of SpA, and especially to anti-TNF agents.

Objectives: To evaluate the change of comorbid FM status of axSpA patients starting an anti-TNF treatment.

Methods: A prospective multicenter national study involving 39 rheumatology centers in France, analyzing 519 patients with axSpA requiring anti-TNF therapy (ClinicalTrials.gov: NCT03039088). Patients were screened for FM with the FiRST questionnaire before and after 3 months of anti-TNF. Kappa coefficient was calculated to determine the agreement of the FiRST at M0 and M3. Response to anti-TNF (BASDAI50 response was compared according to positive screening for FM or not, at both time-points using chi2 tests.

Results: Of the 519 enrolled pts, 504 (with complete data on the FiRST questionnaire) were analyzed at M3. A positive screening for comorbid FM was found in 192 pts (38%) at M0 and in 127 (25%) pts at M3. Correlation between FiRST at M0 and M3 was weak with a Kappa coefficient correlation of 0.4 [0,3 - 0,5].
Four groups were identified: group [+/+] with comorbid FM at M0 and M3: N=93 (18%; group [+/-] with comorbid FM at M0 but not at M3: N=99 (20%); group [-/-] without comorbid FM at M0 and M3: N=278 (55%); group [-/+] without comorbid FM at M0 but at M3: N=34 (7%)
Changes in the status of comorbid FM (disappearance or appearance) was observed in 134 pts (26%). In the 193 pts with baseline comorbid FM, after 3 months of anti-TNF treatment, comorbid FM was no longer found in 99 (51%)%.Efficacy at M3 was significantly better, according to BASDAI 50, in patients without comorbid FM at M3 (Table).

	FM status according to the FIRST questionnaire at M0/M3 (N total=504)			
	+/+	+/–	–/–	–/+
Number of patients	93	99	278	34
Number of patients reaching BASDAI 50 at M3	26 (28%)	61 (61.6%)	162 (58.3%)	8 (25.5%)

Conclusions: There is a high frequency of comorbid FM screened by the FiRST in active axSpA, decreased by 51%f after 3 months of anti-TNF treatments. Persistence of FM after 3 months of anti-TNF treatment is associated with lower anti-TNF response. Further studies are required to analyze the impact of screening FM before starting anti-TNF therapy in axSpA.

THU0483 CHARACTERISTICS OF PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS AND COMORBID FIBROMYALGIA. DIFFERENCES ACCORDING TO FIBROMYALGIA SCREENING (FIRST QUESTIONNAIRE) AND FIBROMYALGIA CLASSIFICATION (ACR1990)

S. Perrot, A. Moltó, A. Etcheto, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, L. Gossec, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: Fibromyalgia (FM) can be a comorbid condition in axial spondyloarthritis (axSpA). FM screening questionnaires and classification criteria fulfillment may demonstrate different prevalence and patients' characteristics may differ.
Objectives: To evaluate frequency of comorbid FM, and the differences between axSpA patients with/without comorbid FM according to screening (FiRST) and classification tools (ACR1990 FM criteria).
Methods: A multicenter national study involving 39 rheumatology centers in France included 519 patients with axSpA starting an anti-TNF treatment (PredictSpA study; ClinicalTrials.gov: NCT03039088). Patients (pts) were screened for FM with the FiRST questionnaire and classified as FM by ACR 1990 criteria. Demographic characteristics, comorbidities, axSpA characteristics, CRP and imaging were recorded in all patients. Kappa coefficient (and its 95% CI) was calculated to compare FiRST and ACR1990 criteria. Baseline characteristics associated with FM were evaluated by univariable and multivariable logistic regression (including the variables with a p value$<$0.20 in the univariable analysis).
Results: In the 519 pts (females: 46%, age: 42±12 years, mean BASDAI 5.7±2.0, mean ASDAS-CRP 3.3±0.9), a comorbid FM was screened in 38% and diagnosed in 16% of pts. Agreement between FiRST and ACR1990 was poor, with a Kappa coefficient of 0.2 [0.2–0.3].
In the multivariable analysis, comorbid FM (by the FiRST questionnaire) in axSpA patients was independently associated with a lower education level, more sick leave, more heel pain, more frequent second line anti-TNF. Comorbid FM defined by the ACR1990 classification criteria was independently associated with heel pain and inversely associated with B27 haplotype. (Table)

Table 1

Number of patients	Fibromyalgia according to FiRST questionnaire		Odds-ratio [95% CI]
	yes (199)	no (320)	
Education level (> high school)	72 (37%)	163 (51%)	0,6 [0,4- 0,9]
Sick leave (yes)	108 (54%)	134 (42%)	1,5 [1,0 - 2,2]
Heel pain (yes)	127 (64%)	151 (47%)	1,6 [1,1–2,5]
Etanercept at baseline (yes)	63 (32%)	137 (43%)	0,6 [0,4–0,9]

Table 2

Number of patients	Fibromyalgia according to ACR 1990 criteria		Odds-ratio [95% CI]
	yes (84)	no (435)	
HLA B27 (positive)	27 (32%)	272 (63%)	0.39 [0.22–0.68]
Heel pain (yes)	61 (73%)	217 (50%)	2.03 [1.16–3.56]

Conclusions: FM is frequently associated with active axSpA, with poor correlation between screening (FiRST) and diagnosis (ACR1990) test. Several characteristics are associated with comorbid FM, depending on FM classification and screening tools.

THU0484 RO60 EXPRESSION DECREASES WITH AGE IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF CHILDREN AND ADOLESCENTS AND CORRELATES WITH TLR7 STIMULATION IN PDCS OF PREPUBERTAL CHILDREN

A. Radziszewska, K. Webb, H. Peckham, Y. Ioannou. *Arthritis Research UK Centre for Adolescent Rheumatology at University College London, Great Ormond Street Hospital and UCLH, University College London, London, United Kingdom*

Background: Auto-antibodies to the RNA binding protein Ro60 are present in patients with autoimmune disorders such as systemic lupus erythematosus (SLE). In addition to its established role as an auto-antigen, Ro60 has been found to bind Alu RNA retroelements whereby it may target Alu retroelement RNA for degradation suggesting a novel putative function of this auto-antigen. If Ro60 modulates the amount of cellular RNA then one may hypothesise an association with toll-like receptor (TLR) 7 stimulation threshold.
Objectives: To measure the physiological levels of intracellular Ro60 protein in healthy children and adolescents and investigate a possible link between Ro60 protein expression and interferon-α (IFN-α) production after TLR7 stimulation.
Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from blood from 48 healthy children and adolescents (age range 6.7–17.9 years old). Cell lysates from thawed PBMC samples were tested for Ro60 expression by Western blot. PBMCs were also stimulated for 20 hours with TLR7/8 agonist R848, at 1ug/ml in the presence of brefeldin A, and plasmacytoid dendritic cell (pDC) IFN-α expression was measured using flow cytometry. Statistical tests to measure correlation between IFN-α expression in (pDCs) and PBMC Ro60 expression were performed using SPSS.
Results: Ro60 expression in PBMCs correlated negatively with age (Spearman's rho = -0.317, p=0.032). When participants were divided into two groups based on their self-reported puberty status, Ro60 expression was higher in the pre-pubertal group (p=0.02). There was, however, no difference in Ro60 expression between males and females (p=0.44) or when sexes were stratified according to pubertal status. pDC IFN-α production after TLR 7 stimulation, did not correlate with ex vivo PBMC Ro60 expression overall (Spearman's rho =0.159, p=0.302) however a moderate positive correlation was observed in pre-pubertal samples only (Spearman's rho =0.554, p=0.021).
Conclusions: Ro60 expression decreases with age in healthy young people. These findings need to be confirmed in a larger cohort and further studies are necessary to investigate the link between Ro60 expression and TLR7 signalling across different age groups as well as in patients with SLE.

THU0485 POLYMORPHISM OF SOME GENES INVOLVED IN IMMUNE AND INFLAMMATORY RESPONSES IN BELARUSIAN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS AND OTHER ARTICULAR PATHOLOGY

H.A. Yatskiu[1], N.V. Nikitchenko[1], N.V. Savina[1], T.D. Kuzhir[1], A.M. Tchitchko[2], A.V. Sukalo[2], R.I. Goncharova[1]. *[1]Institute of Genetics and Cytology, National Academy of Sciences of Belarus; [2]Belarusian State Medical University, Minsk, Belarus*

Background: Etiology and pathogenesis of juvenile idiopathic arthritis (JIA), which prevails among pediatric rheumatic diseases, are insufficiently clear. The study of molecular-genetic basis of JIA is of great interest for revealing genetic predisposition and early diagnosis.
Objectives: The present study aimed to analyze seven SNPs in five genes involved in immune and inflammatory responses: *TNFα* (rs1800629, rs361525), *PTPN22* (rs24766012), *MIF* (rs755622, rs5844572), *CTLA4* (rs5742909), *STAT4* (rs7574865), as well as in two DNA repair genes *XPD* (rs1799793) and *XRCC1* (rs25487) in different conditions.

Methods: 94 patients diagnosed with JIA (mean age 8.78±5.21), 95 children with articular syndrome (mean age7.90±4.81) and 164 hospital controls without any signs of autoimmune or inflammatory diseases (mean age13.99±2.68) were included in the study. The JIA patients were divided into subgroups according to IIAR classification criteria; among them 63 patients were diagnosed with oligoarthritis and 16 with RF- polyarthritis. Genomic DNA was extracted from blood samples by means of phenol-chloroform method. SNPs were genotyped using PCR-RFLP or fragmental analysis.
Results: The allele frequencies for all SNPs in the hospital control group were similar to those characteristic of other Europeans. No differences were found between the frequencies of the TNFα risk alleles across all three groups. Hence, both SNPs in the TNFα locus were not associated with JIA and other articular pathologies in our study. The same is true for -318C>T *CTLA4* polymorphism. Unlike these genes, *PTPN22* C1858T polymorphism influenced developing arthritis in children since heterozygous CT genotype was associated with articular pathology (rather than JIA) in the total group (OR=1.87, 95% CI [1.06–3.30], p=0.04), especially in males (OR=3.50, 95% CI [1.61–7.63], p=0.0016). In the latter case, it was effective even being combined with any genotypes in the -308G>A TNFα locus (OR=2.73, 95% CI [1.19–6.24], p=0.018). When analyzing *MIF* polymorphisms (rs755622 and rs5844572), the evident trend to increased carrying genotypes containing the risk allele *MIF*-173C was observed in females with JIA as compared to controls and significantly elevated frequency of this risk allele in females with RF- polyarthritis as compared to males (p =0.037). In females with JIA, increased frequency of heterozygous *MIF*-794 $CATT_{7,8}$ genotype as compared to the controls (OR =7.78, 95% CI [0.95 – 63.8], p=0,056) was also revealed. *STAT4* polymorphism (rs7574865) demonstrated subtype-related association with JIA due to increased frequency of the minor allele in patients with polyarthitic form of JIA as compared to both hospital controls (p=0.01; OR =2.45; 95% CI [1.19–5.04]) and other articular pathology (p=0.001; OR =3.37; 95% CI [1.56–7.28]). The same SNP was also associated with developing arthritis in females. As to role of DNA repair genes, carriers of *XPD* heterozygous Asp/Asn genotype had an enhanced risk of JIA in females (OR=2.14; 95% CI [1.05–4.35]; p=0.05).
Conclusions: Thus, the gender- and subtype-specific associations of some SNPs studied with developing joint pathologies including JIA are found in the Belarusian child population.

Paediatric rheumatology

THU0486 ANGIOPOETIN-2 AS A NEW VALUABLE MARKER OF DISEASE ACTIVITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

J. Świdrowska-Jaros, E. Smolewska. *Department of Pediatric Rheumatology, Medical University of Lodz, Lodz, Poland*

Background: Angiopoetin-2 (ANG-2) is one of the main angiogenesis modulators. As synovial angiogenesis is considered to be an important early step in the course and pathogenesis of juvenile idiopathic arthritis (JIA), it may be a valuable marker of activity of the disease.
Objectives: To evaluate ANG-2 serum and synovial fluid levels in JIA patients and its possible correlation with disease activity and the degree of ultrasound-detected synovial angiogenesis.
Methods: Serum levels of vascular markers were measured in 63 patients with JIA (aged 1,5–17) and 31 age-matched healthy controls. Synovial fluid was collected from 17 JIA patients. Disease activity (low, medium and high) was assessed by JADAS-27 scale. Ultrasound examination of inflamed joints was performed in each JIA patient and synovial angiogenesis was evaluated by means of Power Doppler ultrasonography (PDUS) and the 4th grade vascularity scale (0–3).
Results: ANG-2 serum levels were higher in children with JIA comparing to the healthy controls (5,5±1,2 ng/ml vs. 1.9±1.4 ng/ml). Serum concentration of ANG-2 in JIA children increased with disease activity (1,4±0,9 ng/ml vs. 1,4±1,0 ng/ml vs. 1,8±2,2 ng/ml), whereas Ang-2 levels in the synovial fluid were the highest in the high disease activity (3,4±2,5 ng vs. 12,5±9,5 ng/ml vs. 26,4±9,0 ng/ml, $p<0,05$). Concentration of ANG-2 in serum correlate with the synovial vascularization obtained by PDUS (0–3, accordingly 1,5±0,8 ng/ml vs. 1,3±0,9 ng/ml vs. 1,5±1,0 ng/ml vs. 13,2±8,7 ng/ml, $p<0,01$) The same pattern was observed for ANG-2 levels in synovial fluid and PDUS grade (0–3, accordingly 3,8±1,0 ng/ml vs. 5,1±4,1 ng/ml vs. 13,5±2,0 ng/ml, $p<0,01$).
Conclusions: ANG-2 might be a valuable marker in JIA children with high disease activity. Together with ultrasound examination, it may add more information about disease severity, what may be helpful in introducing the correct therapy.

THU0487 REAL-LIFE TREATMENT WITH CANAKINUMAB IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS – FIRST EXPERIENCE FROM THE BIKER REGISTRY

G. Horneff[1], F. Dressler[2], A. Thon[3], K. Minden[4] on behalf of BIKER collaborative group. *[1]Paediatrics, Asklepios, Sankt Augustin; [2]MMH Hannover, Hannover; [3]Paediatrics, MMH Hannover; [4]Charité, Berlin, Germany*

Background: Canakinumab (CAN) had demonstrated its efficacy and safety in SJIA pts (1).
Objectives: To report on the experience with CAN treatment in SJIA in the clinical practice in Germany.
Methods: Data on patients' and disease characteristics, disease activity and safety reports from the German BIKER registry were analysed.
Results: Until Dec. 2016, 37 pts exposed to CAN were identified. In 12 pts used CAN as first biologic, 25 pts were pretreated: Tocilizumab 15, Anakinra 11, Etanercept 9, Adalimumab 9. 3 patients in the pre-exposed cohort had experienced a macrophage activation syndrome. Pts' and disease characteristics are outlined in table 1. Pts pretreated were older, had a longer disease duration and more comorbidities than naïve patients. The proportion of pts with active arthritis, active systemic features and both were comparable. Disease activity at baseline was higher in the naïve cohort suggesting some clinical benefit from pretreatment. Dosing of CAN was comparable (*3.9+/-0.4 vs. 3.5+/-0.7mg/kg)* as well as the median treatment duration (0.8vs.1year). Treatment efficacy at last follow up was better in the naïve cohort with more pts reaching a PedACR 30/50/70/90 response while JADAS- or ACR-remission rates were comparable. Treatment was discontinued by 42% in the naïve and 48% in the exposed cohort. Reasons were inefficacy (n=7;19%), intolerance (n=2;5%) and remission (n=7;19%) of the disease and other (n=2;5%).

Table 1. Baseline characteristics

	Biologics naive	Biologics pre-exposed
N (female gender)	12 (17%)	25 (52%)
Age at JIA onset (years); mean ± SD; Median (IQR)	4.4±4.0; 3.0 (2.0–4.9)	6.0±4.8; 3.7 (2.6–7.1)
Age start of Canakinumab (years); mean ± SD; Median (IQR)	7.1±4.9; 5.6 (3.1–10.2)	9.8±4.8; 10.6 (5.5–14)
Disease duration (years); mean ± SD; Median (IQR)	2.8±4.1; 0.7 (0.3–3.9)	3.8 ± 4.2; 1.9 (0.6–8.7)
Concomitant treatment at baseline: NSAIDS/Steroids/MTX	6 (50%)/6 (50%)/3 (25%)	10 (40%)/11 (44%)/4 (16%)
Patients with active joints	7 (58.3%)	10 (47.6%)
Patients with active systemic features	7 (58.3%)	10 (47.6%)
Patients with active arthritis and systemic features	4 (36.4%)	4 (19.1%)
Active joint count	1.8±1.7; 2.5 (0–3)	2.1±3.3; 0 (0–3)

JADAS10	15.7±8.3	10.5±7.9

Conclusions: First experience with CAN for treatment of sJIA in clinical practice is presented. A high proportion of pts gained significant improvement. JADAS remission was reached by about 50% and ACR remission by 25–57% in both biologics pre-exposed and naïve pts while few pts discontinued treatment in remission so far. Intolerance was rare. The further long term surveillance of sJIA pts exposed CAN is intended by the registry.

THU0488 THE IMPACT OF OLIGOARTICULAR AND POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS OVER THE FIRST FIVE YEARS FOLLOWING DIAGNOSIS

S.J.W. Shoop-Worrall[1,2], S.M. Verstappen[1], J.E. McDonagh[2,3,4], W. Thomson[2,5], K.L. Hyrich[1,2] on behalf of CAPS. *[1]Arthritis Research UK Centre for Epidemiology, the University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, Central Manchester University Hospitals NHS Foundation Trust and University of Manchester Partnership; [3]Centre for MSK Research, the University of Manchester; [4]Manchester Academic Health Science Centre; [5]Arthritis Research UK Centre for Genetics and Genomics, the University of Manchester, Manchester, United Kingdom*

Background: Information regarding longer-term outcomes in JIA largely pre-date the introduction of biologic therapies and have been cross-sectional.
Objectives: The aim of this study was to assess outcomes over the first 5 years of disease in children diagnosed with oligoarticular and polyarticular JIA since 2001.
Methods: Children with oligoarthritis, rheumatoid-factor (RF) negative or positive polyarthritis were selected if recruited to the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort, between October 2001 and January 2011. The following outcomes were assessed annually to five years and included in this analysis: functional ability (Childhood Health Assessment Questionnaire (CHAQ)), the absence of limited joints, overall psychosocial health (psychosocial scale on the Child Health Questionnaire (CHQ)) and the proportion of children with CHQ psychosocial scores two standard deviations below the population mean (CHQ psychosocial$<$30).
Outcomes were assessed descriptively over time and differences between subtypes were assessed by applying multilevel (patient-level) zero-inflated negative binomial (CHAQ), logistic (absence of limited joints, percent CHQ psychosocial$<$30) and linear (CHQ psychosocial) regression analyses, adjusting for gender, age at presentation and hospital.
Results: Of 832 children, 70% were female, 68% had oligoarticular, 28% RF-negative and 5% RF-positive polyarticular JIA. Eighty four percent had ever been treated with NSAIDs, 74% corticosteroids, 55% with DMARDs and 21% with biologics within follow-up.
Baseline CHAQ was good to moderate (median 0.8, IQR 0.1 to 1.4) and only 21% of children had no limited joints reported at this time. CHQ psychosocial scores (median 50, IQR 39 to 55) were moderate, with 11% children scoring at least two standard deviations under the population mean. Overall improvements were evident in all outcomes over the first year then remained stable with no further improvements at the cohort level evident to five years.
Patients with RF-negative polyarthritis experienced significantly poorer outcomes across all variables than those with oligoarthritis. Those with RF-positive polyarthritis recorded similar CHAQ scores to patients with RF-negative polyarthritis but had the lowest odds of no limited joints (OR: 0.4, 95% CI 0.3 to 0.7) and the poorest CHQ psychosocial scores (4.8 points worse and 4.7 times the odds of scores $<$2 standard deviations of population mean), compared with those with oligoarthritis.
Conclusions: On average, the largest improvement in functional ability, limited joints and psychosocial health occur in the first year following diagnosis, perhaps confirming the importance of early treat-to-target strategies. Patients with polyarticular JIA subtype have poorer parent and physician-reported outcomes than those with oligoarthritis.

THU0489 ADIPOSITY AND INFLAMMATORY ACTIVITY IN JUVENILE IDIOPATHIC ARTHRITIS COULD THEY BE RELATED?

G. Diaz-Cordoves Rego[1], R. Galindo-Zavala[2], E. Nuñez-Cuadros[2], S. Manrique-Arija[1], N. Mena Vazquez[1], C. Domic-Bueno[1], M. Rojas-Gimenez[1], C. Fuego-Varela[1], R. Caparros-Ruiz[1], L. Cano-Garcia[1], A. Fernandez-Nebro[1]. *[1]Rheumatology, University Regional Hospital of Malaga (HRUM). Institute Biomedical Research In Malaga (IBIMA). Malaga University. Málaga, Spain; [2]Paediatric Department, Universitary Children Hospital of Malaga, Málaga, Spain*

Background: Adults with rheumatoid arthritis have been shown to have a reduction in lean mass and increased adiposity, despite presenting normal Body Mass Index (BMI). Several studies have shown increased adiposity induces a proinflammatory state which lead to a worse response to treatment. There are few publications about this subject in juvenile idiopathic arthritis (JIA)
Objectives: Describing body composition and anthropometric parameters in JIA patients, and evaluating relationship between adiposity and inflammatory in these children.
Methods: Observational cross-sectional study, in JIA patients from 4 to 15 years, monitored by a Pediatric Rheumatology Unit. Monoarticular forms were excluded. Anthropometric, clinical and treatment data were recorded. DXA (measuring bone and fat mass) were obtained. Fat Mass Index (FMI) was defined as fat mass (kg)/height (m^2) and fat-free mass index (FFMI) as lean mass (kg)/height (m^2). JADAS27 index was used to evaluate inflammatoty activity.
Results: We analyzed 80 patients, whose characteristics are shown in table 1. The most frequent JIA subtype was oligoarticular (16.3% extended,47.5% persistent) followed by polyarticular (25.1%). Twenty five percent of patients had uveitis. Fifty percent them had inactive disease with treatment, 26% had activity and 23% were inactive without treatment. Regarding the treatment, 52.5% were on methotrexate and 30% on a biological drug (22.5% antiTNFα, 5% antiIL-1, 2.5% antiIL-6). Disease duration average was 6.6 years (± 3.7SD). JADAS27 index mean score was 2 (±4SD), CRP 4.7mg/l (±9,5SD), ESR 8.7mm (±7,2SD) and CHAQ 0.17 (± 0,38SD). Anthropometric parameters are shown in table 1. Mean JADAS27 index score in patients with normal BMIwas lower (1.7±3.6 SD) than mean JADAS27 index score in overweight and obese patients (3.3±6.0SD), although this difference was not significantly (p=0.255). In multiple linear regression, an increase of 0.3 JADAS27 was observed for each unit of FMI increase (p=0.03). This relationship was maintained in the multivariate analysis (B0.015; p0.01) independently of JIA subtype and received treatment.

Variable	n=80
Age in years, median (±SD)	10,7 (3,3)
Sex,female; n (%)	56 (70)
Race caucasian,n (%)	76 (95)
BMI Median kg/m^2 (±SD)	18,2 (4,2)
BMI Percentile, median (±SD)	42,0 (29,9)
Waist perimeter, median,cm (±SD)	64,8 (11,3)
Hip perimeter cm (±SD)	77 (13,6)
Index waist/hip (±SD)	0,84 (0,06)
Obesity*, n (%)	6 (7,5)
Overweigh*, n (%)	12 (15)
Abdominal obesity,n (%)	12 (15)
Total fat (kg),median (±SE)	11,36 (8,9)
Total Lean (kg),median (±SD)	26,1 (8,9)
Total mass (kg),median (±SD)	38,8 (16,7)
Trunk fat/total fat, median (±SD)	0,42 (0,5)
Legs fat/ total fat, median (±SD)	0,42 (0,44)
FMI (%) median (±SD)	7,5 (5,3)
FFMI (%) median (±SD)	17,8 (3,8)

Conclusions: In JIA patients, there is a linear relationship between FMI and disease activity measured by JADAS27, but most patients had a normal BMI. The establishment of this relationship (fat-inflammatory activity) would be transcendental due to the need to optimize the recommendations in the JIA approach.

THU0490 MULTICENTRE STUDY OF LUPUS NEPHRITIS URINARY BIOMARKERS IN ADULT AND PAEDIATRIC PATIENTS

P. Costa Reis[1,2], K. Maurer[2], L. Schanberg[3], J.M. Burnham[2], E. von Scheven[4], K. O'Neil[5], M. Klein Gitelman[6], M. Petri[7], K.E. Sullivan[2]. *[1]Hospital de Santa Maria, Lisbon, Portugal; [2]The Children's Hospital of Philadelphia, Philadelphia; [3]Duke University, Durnham; [4]University of California San Francisco, San Francisco; [5]Indiana University, Indianapolis; [6]Children's Hospital of Chicago, Chicago; [7]Johns Hopkins University, Baltimore, United States*

Background: Glomerulonephritis is an important cause of morbidity and mortality in patients with systemic lupus erythematosus, particularly in children. Presently, renal histology is used for the diagnosis of lupus nephritis (LN), but it only offers a description of a confined area of the kidney and is seldom repeated for monitoring due to its invasiveness. Urinary biomarkers that reflect LN activity and have prognostic value are much needed to guide the judicious use of immunosuppressive drugs in these patients.
We focused on three potential LN biomarkers: HER2, TWEAK and VCAM1.
HER2 (Human Epidermal Growth Factor Receptor 2) controls cell proliferation by regulating the intracellular levels of miR-26a and miR-30b, which inhibit the expression of cell-cycle related genes. HER2 was recently shown to be dramatically overexpressed in the kidneys of LN patients and in NZM2410 mice.
TWEAK (TNF-related weak inducer of apoptosis) is involved in pro-inflammatory responses, angiogenesis and fibrosis. TWEAK is increased in the kidneys of LN patients.
VCAM1 (vascular cell adhesion molecule 1) participates in the acute phase of inflammation, controlling leukocyte infiltration. Urinary VCAM1 has emerged as a reliable indicator of the LN activity index.
Objectives: To determine the clinical value of urinary HER2, TWEAK and VCAM1 as biomarkers of LN activity.
Methods: A multicentre study is being performed in an adult and paediatric cohort. All patients have biopsy-proven LN. Clinical data and urine samples are being collected in each visit. Controls are age and sex matched individuals without renal disease. Flares are identified with the SELENA-SLEDAI flare index. Urine supernatants are analysed by commercial enzyme-immunoassays for HER2, TWEAK and VCAM1.
Results: Currently, we have studied 83 LN paediatric patients and 38 controls.

The majority are female (85%). The average age is 15±2.5 years. This cohort includes Hispanic (36%), Asian (29%), African-American (21%) and Caucasian (11%) children. LN class III or IV was diagnosed in 67% of patients. Nearly all were treated with hydroxychloroquine and steroids (95%). Other drugs used include mycophenolate mofetil (85%), cyclophosphamide (43%), rituximab (27%) and tacrolimus (2%).

A significant increase in urinary HER2, TWEAK and VCAM1 levels was found in LN patients (p=0.005; p=0.006; p=0.01, respectively) when compared to controls. HER2 levels reflected disease activity, increasing during flares.

In an adult cohort of LN patients (N=126) composed mainly of females (80%) with an average age of 46±13 years, we also found a significant increase of urinary HER2 when compared to controls (p=0.002).

A strong correlation between the urinary levels of HER2, TWEAK and VCAM1 was not found.

Conclusions: Urinary HER2, TWEAK and VCAM1 were significantly increased in a paediatric cohort of LN patients. In addition, significantly higher urinary HER2 levels were also found in an adult LN cohort. This on-going study will further evaluate if these urinary markers, alone or in combination, can reflect disease activity and predict renal flares, analysing their potential value in clinical practice.

THU0491 COMPARISON OF CLINICAL AND SEROLOGICAL FEATURES OF JUVENILE AND ADULT-ONSET NEUROPSYCHIATRIC LUPUS IN SPANISH PATIENTS

S. Garrote Corral, A. García Fernández, W.A. Sifuentes Giraldo, A.L. Boteanu, M.L. Gámir Gámir, A. Zea Mendoza. *Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Neuropsychiatric (NP) manifestations are a main cause of morbidity and mortality in juvenile-onset systemic lupus erythematosus (jSLE). Some studies suggest that they are more frequent and severe in jSLE than in adult-onset SLE (aSLE).

Objectives: To compare the clinical and serological profile of pediatric and adult patients with neuropsychiatric lupus (NPSLE) treated in a Spanish tertiary center.

Methods: A retrospective study of patients with jSLE (age of onset: 0–18y) and aSLE (age of onset: >18y) seen in our center during the period 1988–2016 was performed. Case definitions of the American College of Rheumatology were used to identify NPSLE manifestations. Demographics, clinical and serological data were obtained through a review of their medical records.

Results: A total of 69 patients with NPSLE were included, aSLE 41 (59%) and jSLE 28 (41%), the comparison of groups is presented in the table. Most of them were Caucasian (92%), mean age at diagnosis in adults was 36.4 years (range: 19–68) and 13.9 years (range: 8–18) in children. The proportion of males was higher in the latter group. The mean duration of the disease was significantly greater in adults, as well as the time from SLE diagnosis to NP manifestation onset, although without significant difference. Central NP manifestations were the most frequent in both groups (aSLE 93%, jSLE 96%) regarding to the peripheral manifestations (aSLE 12%, jSLE 11%). The most frequent manifestations in aSLE were headache (29%), cerebrovascular disease (27%), seizures (17%) and myelopathy (15%), whereas in jSLE were seizures (46%), headache (29%), mood disorder/depression (25%), psychosis (18%) and autonomic disorders (18%). A significant group of patients presented ≥2 central manifestation during their evolution (aSLE 32%, jSLE 41%), with the mean number of manifestations in adults being 1.36 (range: 1–3) and in children 1.44 Range: 1–4). Patients with jSLE developed lupus nephritis (LN) with a significantly higher frequency, as well as higher titres of anti-DNA antibodies, erythrocyte sedimentation rate (ESR) and hypocomplementemia. During the study period there was mortality in 2 cases of aSLE and 2 jSLE (5% and 7%, respectively).

	Juvenile NPSLE	Adult NPSLE	p-value
No. of patients	28 (41%)	41 (59%)	–
Women:men	20:8	39:2	0.0060*
Time of disease (months)	19.8	232.5	0.0001*
NP manifestations at onset	7 (25%)	11 (27%)	0.8651
Time from diagnosis to NP manifestation (months)	42.4	87.1	0.1268
Lupus nephritis	16 (57%)	9 (22%)	0.0028*
Antiphospholipid syndrome	5 (18%)	10 (24%)	0.5182
ANA ≥1/1280	8 (29%)	11 (27%)	0.8736
Anti-DNA ab (IU/ml)	178.9	39.4	0.0005*
Anti-Ro/SSA ab	10 (36%)	17 (41%)	0.6308
Anticardiolipin ab	4 (14%)	10 (24%)	0.3054
Anti-ß2 glycopotein I ab	5 (18%)	7 (17%)	0.9328
Lupus anticoagulant	8 (29%)	10 (24%)	0.6977
Cryoglobulins	6 (21%)	3 (7%)	0.0874
ESR (mm/h)	53.8	35.7	0.0199*
CRP mg/l	4.6	4.7	0.9687
C3 low (<80 mg/dl)	22 (79%)	16 (39%)	0.0012*
C4 low (<16 mg/dl)	22 (79%)	13 (32%)	0.0001*

Conclusions: Our results corroborate that juvenile patients with NPSLE present higher disease activity compared to adults. There was no significant diference in the time from SLE diagnosis to NP manifestation onset, but tended to be shorter in jSLE. The spectrum of NPSLE was varied both groups and an important proportion developed ≥2 manifestation. Mortality continues to be important in NPSLE in both age groups.

THU0492 MACROPHAGE ACTIVATION SYNDROME AS THE INITIAL MANIFESTATION OF JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS

S. Sato, Y. Uejima, E. Suganuma, T. Takano, S. Fujinaga, Y. Kawano. *Saitama Children's Medical Center, Saitama, Japan*

Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening complication of autoimmune diseases in children. Little is known about the association between MAS and the onset of juvenile systemic lupus erythematosus (jSLE).

Objectives: The aim of this study was to determine the frequency and clinical features of MAS as the initial complication of jSLE.

Methods: During 2004 and 2016, we retrospectively reviewed the clinical and laboratory features of 46 jSLE patients diagnosed at the Saitama Children's Medical Center. Patients who were complicated with MAS at the same time as jSLE. These patients were compared with a control group composed of jSLE patients without MAS. The MAS was diagnosed according to preliminary guidelines.

Results: Fifteen patients (32.6%) developed MAS during the initial stage of jSLE. Fever, leukopenia, thrombocytopenia, hyperferritinemia hypofibrinogenemia, increased aspartate aminotransferase (AST), and increased lactate dehydrogenase (LDH) were more frequently observed in patients having jSLE with MAS than in those having jSLE without MAS. No differences were observed in serum C3 and C4 levels, or erythrocyte sedimentation rate (ESR) ($P<0.05$). Especially, Seven patients (46.7%) had *neurologic* symptoms that were significantly higher in those with MAS ($P<0.01$). All patients received corticosteroids when jSLE with MAS diagnosis was established, among whom seven received pulse methylprednisolone therapy. Two patients were treated with IVIG. Nine patients with MAS were treated with immunosuppressants, including cyclophosphamide and mycophenolate mofetil, *azathioprine*. No patient involved in this study died.

Conclusions: MAS can be the initial manifestation of jSLE. MAS may be an underrecognized complication of jSLE. MAS with jSLE should be suspected in patients with high fever, cytopenia, and a liver disorder. In addition, we found that in jSLE with MAS patients, they had more neurologic symptoms compared to jSLE without MAS. Early diagnosis and intensive therapy is essential to improve the clinical outcome.

THU0493 STUDY OF LONG-TERM OUTCOME OF CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM A SINGLE-CENTRE IN NORTH INDIA

A. Sharma, A. Gupta, A. Rawat, D. Suri, S. Singh. *Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India*

Background: Juvenile dermatomyositis (JDM) is a rare inflammatory myopathy seen in children. There have been few studies on long-term outcome in children with JDM

Objectives: To assess long-term outcome of JDM using validated measures of outcome

Methods: All children diagnosed to have JDM for more than 2 years and registered in Pediatric Rheumatology Clinic at PGIMER, Chandigarh, India, were deemed eligible for recruitment. Study period was from January 1, 2015 to June 30, 2016. Those who were not on regular follow-up were called for assessment which was done by a single observer using Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing 8 (MMT8), Myositis Disease Activity Assessment Tool (MDAAT), abbreviated cutaneous assessment tool (aCAT), Myositis Damage Index (MDI) and Childhood Health Assessment Questionnaire (CHAQ).

Results: Thirty-five children were enrolled in this study, 22 (62.9%) were on regular follow-up. Mean age was 13.9yrs (range 4–29yrs). Mean age at diagnosis was 7.51yrs with median interval between onset of symptoms and diagnosis

being 5 months. Mean duration of disease at the time of enrolment was 7.18yrs. Disease course was monocyclic in 24 (68.6%). Muscle strength was normal in 71.4%. Severe involvement defined as MMT8 score below 64 was seen in 8.6%. Cutaneous activity was determined by aCAT with 40% children having some form of cutaneous activity. Based on MYOACT, 31.4% children had evidence of disease activity at the time of cross-sectional assessment with skin being the commonest organ system involved in 28.6% followed by muscles in 22.9%. Twenty-one (60%) children had some form of cutaneous damage. Calcinosis in 12 (34.3%) and lipodystrophy in 8 (22.9%). Twenty four subjects had an MDI score of $\geq$1 suggesting damage in at least one organ system. Most commonly affected organs were skin, endocrine and muscles in 20, 12 and 9 subjects respectively. Nine (25.7%) subjects in our study had some form of a physical dysfunction suggested by a CHAQ score above 0. Previous studies on long-term outcomes in children with JDM have either not used validated outcome measures or have used fewer measures [1–3].

Conclusions: Highlight of our study is the use of validated outcome measures for evaluation of long-term outcomes. After mean disease duration of 7.18 yrs, 1/3rd subjects had evidence of disease activity with almost 1/10th having moderate to severe activity. About 2/3rd had damage in at least one organ system. Skin was the most common organ affected by activity as well as damage. About 1/4th had reduced physical functioning. Thus, JDM is not a disease where one time treatment would suffice and regular long-term follow-up is required. Counselling of the caregivers is also critical for them to adhere to follow-up. Larger long-term studies using validated outcome measures are required to confirm these findings.

THU0494 CLINICAL FEATURES OF CHILDREN WITH KAWASAKI DISEASE IN DIFFERENT AGE GROUPS IN SOUTHWEST CHINA

L. Shi[1], J. Li[1], D. Qie[2], L. Qiao[2]. *[1]Peking University International Hospital, Beijing; [2]West China Second University Hospital, Chengdu, China*

Background: Kawasaki disease (KD) is a systemic vasculitis characterized by acute and prolonged fever. The prevalence of coronary artery abnormality (CAA) is as high as 11%. The young infants usually have the increased risk of CAA, but do not have the typical clinical manefestations of KD.

Objectives: To explore clinical features of children with KD in different age groups to improve the prognosis of KD.

Methods: A total of 218 children with kawasaki disease were divided into the infants group, the toddlers' group, the pre-school age group and the school age group. Retrospective analysis of clinical data were performed among the groups. Categorical data were compared with each other statistically by Chi-square analysis. Statistical significant was defined as $P < 0.05$. Due to the insufficient cases of school age group and five cases of patients with entire clinical data, the analysis was focused on the other three groups and excluded the five cases in the following statistical analysis.

Results: (1) Among the 218 KD patients, the male to female ratio was 1.5:1 and the recurrence rate was 1.8%. Seven cases (3.2%) were diagnosed as atypical KD, and 84 (38.5%) patients accepted intravenous gamma globulin (IVIG) treatment after the sixth day of KD onset. The incidence of IVIG-resistent KD was 8.7% and the rate of coronary dilation was 11.5%. (2) Fever was the most common clinical feature (100%). The bilateral bulbar conjunctiva injection and the change in mucosa of oropharynx were 85.4% and 81.2% respectively. Moreover, cough (40.5%), diarrhea (16.9%) and vomiting (8.5%) were also very common in the present KD patients. (3) Patients from the toddlers' group were more common to develop lymphadenopathy and skin rash (χ^2=7.784, P=0.02; χ^2=10.794, P=0.005), but were less frequently to be documented with cough and diarrhea (χ^2=7.334, P=0.026; χ^2=18.447, P=0.000). (4) The incidence of increased platelets was more common in the infants group (χ^2=7.552, P=0.023). Comparing with the urine test among three groups, the toddlers' group had a higher incidence of sterile pyuria (χ^2=10.653, P=0.005), and infants younger than 12 months old had a lower incidence of proteinuria and positive urine ketone (χ^2=15.507, P=0.000; χ^2=40.336, P=0.000).

Conclusions: The respiratory tract, the digestive and urinary systems are involved commonly in Kawasaki disease, and patients from different age groups showed different clinical features, which should be pay more attention to promote the prognosis.

THU0495 EFFECTIVENESS OF CHILDHOOD VACCINATIONS IN CAPS PATIENTS TREATED WITH CANAKINUMAB: RESULTS FROM AN OPEN-LABEL PHASE 3 EXTENSION STUDY

P. Brogan[1], M. Hofer[2], J. Kuemmerle-Deschner[3], B. Lauwerys[4], A. Speziale[5], X. Wei[6], R. Laxer[7]. *[1]Infection, Immunology, and Rheumatology, UCL Institute of Child Health, and Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom; [2]Unité Romande de Rhumatologie Pédiatrique, Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [3]University Hospital Tuebingen, Tuebingen, Germany; [4]Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium; [5]Novartis AG, Basel, Switzerland; [6]Novartis Pharma, Beijing, China; [7]University of Toronto, The Hospital for Sick Children, Toronto, Ontario, Canada*

Background: Canakinumab (CAN) has been shown not to impair antibody production following vaccination in children in an open-label phase 3 study (NCT01302860).[1] Here we present the results from the extension of this study.

Objectives: To evaluate the presence of protective antibody levels following immunisation with inactivated vaccines in CAPS patients during extension study.

Methods: Patients who completed the core study were allowed to continue into the extension study on the standard dosing regimen of 2 mg/kg subcutaneous CAN every 8 weeks or on last dose/dosing regimen received in the core study. Vaccination response was evaluated using post-vaccination antibody titres at 4 and 8 weeks after immunisation. Patients were considered assessable for an antibody response to a specific vaccination if they had a measurement of antibody titre 0–14 days post-vaccination (pre-vaccination assessment) and at least 1 subsequent measurement of antibody titre at 4 weeks and/or 8 weeks post-vaccination. However, for patients with adequate pre-dose antibody titres and maintained during the trial, the specific patient vaccination was deemed non-assessable.

Results: During the extension phase, of 17 patients ($\leq$6 years), 4 received 8 types of vaccinations against *Corynebacterium diphtheriae*, *Bordetella pertussis*, *Neisseria meningitidis*, *Clostridium tetani*, influenza type A and type B, *Haemophilus influenzae* B, *Streptococcus pneumoniae*, or hepatitis B. Of 20 unique patient-vaccination cases, 17 were assessable for a vaccination response, whereas for the remaining 3, pre-dose antibody titre was not available. For 16 (94.1%) assessable cases, post-vaccination antibody titres increased above protective levels. For one patient who received Tetravec formulation (diphtheria, tetanus and acellular pertussis combination), the response observed for 1 (vaccination against *Clostridium tetani*) of the 3 vaccines included in Tetravac represented optical density rather than antibody concentrations and hence considered non-evaluable. For 19/20 patient-vaccinations, including those without pre-dose antibody titres, protective levels were observed during the study, which were maintained throughout the extension study.

Conclusions: Canakinumab appeared to have no effect on post-vaccination antibody production following the administration of non-live vaccines in CAPS patients.

THU0496 PULMONARY SYMPTOMS AS THE FIRST PRESENTATION OF KAWASAKI DISEASE IN CHILDREN

A. Gupta, A. Kumar, D. Suri, S. Singh. *Pediatrics, Postgraduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India*

Background: Kawasaki disease (KD) is a medium vessel vasculitis which predominantly affects children less than 5 years of age. Though principal clinical features are mucocutaneous, KD in children may have multiple systemic manifestations, including pulmonary, which may create diagnostic difficulties for the treating physician.

Objectives: We describe our experience of managing children with uncommon pulmonary presentation of KD.

Methods: Five hundred and sixty five (565) children were diagnosed with KD during the period from January 1993 to December 2016 in Pediatric Rheumatology Clinic, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India. Nine children had pulmonary presentation of KD. A retrospective case review with respect to clinical presentation, radiological findings and treatment was done.
Results: Pulmonary presentation of KD was seen in 1.6% patients. Mean age at diagnosis of KD was 2.9years (range 9months – 4 years). 77.8% patients had no features suggestive of KD either on history or at presentation. First sign of KD was noted at a mean duration of 17.6 days (range 6–28 days) from the onset of symptoms. Periungual desquamation was the most common clinical sign seen in 66.6% patients followed by erythematous rash and perianal desquamation in 33.3% patients each.
Persistent fever, thrombocytosis and elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were seen in all patients. Microbiological investigations showed evidence of infection in only 2 patients – methicillin sensitive staphylococcus aureus in pus and positive mycoplasma agglutinin titre in one patient each. Parenchymal consolidation was the most common radiological finding (100%) followed by pleural effusion (55.5%), empyema (33.3%) and pneumothorax (11.1%). Coronary artery abnormalities were evident on echocardiography in 22.2% patients with dilatation of right coronary artery and left main coronary artery in 1 patient each.
All patients received intravenous antimicrobials for pneumonia. Intravenous immunoglobulin (IVIG) at 2g/kg was given after a mean duration of 24 days of onset of fever. Fever, which was unresponsive to intravenous antimicrobials, responded to IVIG therapy in all except 2 patients which required a second dose of IVIG. 55.5% patients required intercostal drainage tube (ICDT) insertion, 2 patients required streptokinase and 1 patient each required video assisted thoracoscopic surgery (VATS) and decortication. Mean follow up period was 15.9 months (range 0–62 months).
Conclusions: Pulmonary involvement in patients with KD is uncommon and is less commonly recognized. Unresolving pneumonia in a child who continues to be febrile despite adequate antimicrobials with elevated inflammatory markers can be a clue towards the diagnosis of KD. Early recognition can prevent delays in diagnosis and shorten the hospital stay.

THU0497 RHEUMATOLOGICAL MANIFESTATIONS OF X-LINKED AGAMMAGLOBULINEMIA: PROFILE OF 17 CASES FROM A TERTIARY CARE CENTER IN NORTH INDIA

A. Gupta, D. Suri, A. Gupta, A. Rawat, S. Singh. *Department of Pediatrics, Postgraduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India*

Background: X-linked agammaglobulinemia (XLA) is characterized by recurrent bacterial sino-pulmonary infections. Arthritis can be seen in 10–30% patients of hypogammaglobulinemia (1) and is usually a mono- or oligoarthritis of large joints, but polyarthritis has also been defined.
Objectives: We describe our experience of managing children with XLA who presented with rheumatological manifestations.
Methods: Sixty two children were diagnosed with XLA during the last 10 years in Primary Immunodeficiency Clinic, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India. Seventeen children had rheumatological manifestations. A retrospective case review with respect to clinical presentation, musculoskeletal findings and treatment was done.
Results: Rheumatological manifestations were seen in 27.4% patients of XLA. Thirteen out of 17 patients had a proven mutation in *Btk gene*. Mean age at symptom onset was 3.3 years (range 6 months – 13 years) and mean age at diagnosis of XLA was 5.6 years (range 1.5- 10 years). Rheumatological manifestations were seen at a mean age of 8.7 years (range 1.5- 20 years). In 2 patients, arthritis preceded the diagnosis of XLA while 10 patients developed rheumatological manifestations after the diagnosis of XLA. Arthritis as an initial presentation of XLA was seen in 5 patients.
Oligoarthritis was the most common presentation seen in 15 patients. Knee was the most commonly involved joint (11 patients) followed by ankle joint in 5 patients and shoulder, wrist and hip arthritis in 2 patients each. One patient each had arthritis involving proximal interphalangeal joints of both hands, clinical evidence of sacroiliitis and spondylodiscitis involving L4–5 and L5-S1 vertebrae. Three patients manifested as septic arthritis (fever, redness, warmth and pus in joint) involving shoulder, ankle and knee joint respectively.
Joint aspiration and/or arthrotomy had been performed in 8 patients, however cultures were sterile in all. Microbiological investigations for mycoplasma infection (viz. culture and polymerase chain reaction) in joint fluid/pus could not be performed due to unavailability. All patients received replacement intravenous immunoglobulin (IVIG - 400 mg/kg body weight) and co-trimoxazole prophylaxis. Eight patients received macrolide antimicrobials (erythromycin or azithromycin) for clinical suspicion of mycoplasma arthritis.
One patient expired during the course of his illness while four patients were lost to follow up. Arthritis showed clinical improvement after IVIG replacement therapy in remaining 12 patients with resolution of arthritis after first dose in 11 patients and after 6 months of replacement therapy in 1 patient. None of the patients had recurrence of joint symptoms on follow up, however radiological evidence of spondylodiscitis persisted in one patient.
Conclusions: Arthritis is a relatively frequent manifestation in patients with hypogammaglobulinemia. Family history and history of recurrent infections in a child with arthritis may provide a clue towards the diagnosis of primary immunodeficiency. Prompt institution of regular IVIG replacement therapy results in resolution of arthritis and prevents its recurrence.

THU0498 PFAPA SYNDROME IN LARGE PEDIATRIC POPULATION: A SINGLE CENTER EXPERIENCE

E. Pehlivan, A. Adrovic, S. Sahin, K. Barut, O. Kul, O. Kasapcopur. *Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey*

Background: Periodic fever, aphthosis, pharyngitis, and adenitis (PFAPA) syndrome is an auto-inflammatory condition of unknown etiology. It is the second most common auto-inflammatory disease in our country, following familial Mediterranean fever. Previous studies showed that tonsillectomy represents efficient treatment options.
Objectives: Our aim was to explore the main clinical features, response to tonsillectomy and long–term outcome of PFAPA pediatric patients in a single cohort. We assessed association of MEFV gene mutation with disease characteristics and treatment response.
Methods: We reviewed medical records of patients who were diagnosed with PFAPA syndrome between the January 2010 and June 2016. All of the recorded 562 patients were called by the telephone and 365 (65%) of them were reached. Demographic, clinical and therapeutically features were taken from the patients' medical records. Data on clinical course and the disease outcome were collected by using a structured questionnaire which was fulfilled during the phone conversation between investigator and patients parents.
Results: A total of 365 patients with PFAPA were examined: 154 (42%) of them were female. The mean age at disease onset, at diagnosis and at the investigation was 22.79±18.8, 41.7±21.7 and 77.14±31.35 months, respectively. The most common disease feature at the disease onset was: recurrent fever in 365 (100%), cryptic tonsillitis in 365 (100%) and aphtous stomatitis in 317 (88%). Sixty three (17%) patients met the criteria for both PFAPA and FMF. MEFV gene mutation analysis was performed in 93 (25%) patients and 51 of them (54%) had a heterozygous mutation in exon 10. Surgical treatment was performed in 158 (43%) patients. Complete clinical remission was achieved in 127 (80.3%) patients. Six (3%) showed no response to surgical treatment while 25 (15.8%) patients had a partial response. In patients with partial clinical response, frequency of fever attacks decreased significantly from 17.5 to 7.3 attack per year ($p<0.05$). Among patients who did not respond to tonsillectomy,11 (52.4%) were carrier of MEFV heterozygous mutation in exon 10. There was a statistically significant difference between patients with and without coexistence of FMF features, according to surgical treatment response ($p<0.05$).The mean age of resolution of PFAPA symptoms in patients who underwent tonsillectomy was 52±22.4 months and in patients without tonsillectomy 66±22.6 months.
Conclusions: Although PFAPA symptoms usually resolve before age of eight, some patients' complaints persist. FMF should be considered in tonsilloadenoidectomy unresponsive PFAPA patients, especially in endemic regions like Turkey. Tonsilloadenoidectomy seems to be an effective treatment option for pediatric PFAPA patients.

THU0499 ANTI-MULLERIAN HORMONE IN A COHORT OF YOUNG ADULT WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS

C. Di Mario[1], M.R. Gigante[1], A. Musto[1], A. Barini[2], A. Barini[2], B. Tolusso[1], G. Ferraccioli[1], E. Gremese[1]. *[1]Institute of Rheumatology; [2]Institute of Biochemistry and Clinical Biochemistry, Fondazione Policlinico Universitario A. Gemelli, Catholic University of the Sacred Heart, Rome, Italy*

Background: Juvenile Idiopathic Arthritis (JIA) represents one of more common chronic disease of the childhood, affects young people before sixteen and persists into their reproductive years. It is reported in one study that fertility was not impaired in JIA women but potentially it can be compromised by pharmacological treatments such as the prolonged immunosuppressive therapy used in young women patients (1). The Anti-Müllerian Hormone (AMH) is secreted from granulosa ovary cells and serum levels of Anti-Müllerian Hormone are used as a measure of ovarian reserve, reflecting the number of primary follicles.

Objectives: The aims of this study were to evaluate AMH serum levels in a cohort of young adult women affected from JIA, to compare these levels between patients and healthy controls and to assess whether the presence of the disease and the influence of previous exposure to disease-modifying antirheumatic drugs (DMARDs) and of other disease parameters may affect the ovarian reserve.
Methods: Forty women with a diagnosis of JIA, aged 18 to 25 years and with regular menses, and 20 healthy women age-matched were evaluated. Anti-Müllerian Hormone serum levels were measured according to a 2-stage enzyme-linked immunosorbent assay (ELISA) technique using a commercially available kit (AMH Gen II ELISA; Beckman Coulter). Clinical and demographic characteristics, disease duration, previous and current therapies disease activity score on 44 joints (DAS), health assessment questionnaire (HAQ) were performed at the time of blood sample.
Results: JIA patients had a mean age of 21.4±3.2 years, a disease duration of 11.5±6.6 years, a DAS of 1.22±0.58, and 12 (30%) were smokers. No significant differences were found in our cohort of JIA and healthy subjects in AMH serum levels (5.6±0.4 vs 6.6±0.6 ng/ml, respectively, p=0.5).
Considering the JIA cohort, 23 patients (57.4%) were treated with methotrexate (MTX) for a mean period of 2.1±3.1 years and 20 (50%) with anti-TNF drugs for 4.3±2.3 years. Twelve JIA women (30%) were treated with both MTX and anti-TNF. No correlations were found between AMH serum levels and patients age (p=0.6), disease duration (years) (p=0.67) and duration of therapy with MTX (p=0.5) or anti-TNF (p=0.11).
Dividing JIA patients according to MTX use, no differences were observed between MTX users and non users patients in AMH levels (6.0±0.5 vs 5.1±0.5 ng/ml, respectively, p=0.22), age, disease duration and other clinical characteristics. Patients expose to anti-TNF had AMH serum levels tendentially higher then non users patients (6.3±0.6 vs 4.9±0.5 ng/ml, respectively p=0.07).
Conclusions: In our JIA group of young adult JIA women, ovarian reserve seems not be changed by the presence of the disease, the long disease duration and the use of immunosuppressive drugs. These findings could be important for adult JIA patients.

THU0500 PHOTOBIOSTIMULATION OF CHRONIC CERVICAL PAIN IN JUVENILE POLYARTHRITIS

C. Ailioaie, L.M. Ailioaie. *Dept. of Medical Physics, Iasi, Romania, "Al. I. Cuza" University, Iasi, Romania*

Background: Chronic pain management in juvenile arthritis constitutes a special provocation not only for the medical doctors, but also for the patients and parents. Despite the extensive use of the biological agents with high efficacy, combined with the multimodal therapies, chronic pain still remains an important issue for the public health, with implications on the activities of daily living and the scholar performances. Lasers could be used for transmitting biological messages and initiating metabolic changes within living cells: no more pain, much more energy, will contribute to muscular and joints repair.
Objectives: Aim of the present study was to evaluate the effects of photobiostimulation combined with DMARDs in patients with juvenile polyarthritis and chronic cervical pain.
Methods: 62 patients diagnosed with juvenile polyarthritis (ILAR criteria), 11.4 years mean age were randomly divided in Group I (42 patients treated with local laser biostimulation and methotrexate), comparatively with a Group II - control (20 patients) treated with methotrexate and *placebo* laser, for a period of 9 months. Group I received local laser biostimulation with a dose of 2.5 J/cm^2 in 14 latero-cervical painful points, corresponding to the 7 cervical vertebrae, 1 point on the insertion of sternocleido-mastoidian muscle on the styloid processus, and 1 point on each loco-regional submandibular lymphatic ganglions, using a GaAlAs laser probe of 670 nm, 25 mW output power and a modulation frequency of 10 Hz. 45 joules were applied daily as laser treatment, 10 sessions per month, repeated 3 times, in the 9 months. For all the patients, the main medication was methotrexate in a dose of 0.6 mg/kg (maximum 20 mg) per week, steroids and symptomatic drugs, when necessary. Tutors and the older children have signed the informed consent. Measurement of the subjective pain was on VAS (0 – 100 mm), and objective pain was assessed with an electronic device, the Algometer Commender. The range of motion for flexion/extension, and the rotation to the left/right of the cephalic extremity was measured with Dualer IQ Inclinometer.
Results: In the end of study, the level of chronic pain estimated with Commander Algometer decreased by 74.6% in Group I, compared with only 41% in the control Group, and the range of motion in the affected cervical segment assessed with Dualer Inclinometer increased by 66% in the first Group, compared with only 34% in *placebo* group.
Conclusions: Laser biostimulation proved to be an effective method for the complex management of chronic pain in juvenile polyarthritis.

THU0501 EFFICACY AND SAFETY OF METHOTREXATE AS MAINTENANCE THERAPY FOR CHILDREN WITH ANTI–N-METHYL-D-ASPARTATE RECEPTOR (NMDAR) ENCEPHALITIS: EXPERIENCE OF A SINGLE CENTER

D. Ramos-Bello, A.N. Rangel-Botello, G. Aguilera Barragan-Pickens, T.A. Luna-Zúñiga, A.J. Pedro-Martínez, G. Martínez-Flores, A. Bravo-Oro, C. Abud-Mendoza. *Unidad regional de Reumatología y Osteoporosis, Hospital Central "Dr. Ignacio Morones Prieto" y Facultad de Medicina de la Uaslp, SLP, SLP, Mexico*

Background: Autoimmune-mediated encephalitis (A-ME) in children remains as a diagnostic and therapeutic challenge (1). These patients have a 12% risk of relapse, which is usually more severe (2). We previously proposed the therapy with methotrexate (MTX) for this condition (3), and we are offering now additional data on its potential benefits.
Objectives: To describe the outcome of children with A-ME receiving MTX for at least one year after stabilization of symptoms.
Methods: In this retrospective study we recruited 11 patients (7 females) with A-ME, a mean age of 7.5 years (range 8 months - 14 years), and with a median follow up of 22 months. In all cases, anti-NMDAR antibodies (subunit NR1) were detected in the CSF. Data from these patients were collected by consulting medical records. Relapse of encephalitis was defined as new onset of symptoms occurring after at least 2 months of remission, in the absence of other CNS disease.
Results: Patients presented with seizures (n=10), behavioral changes (n=11), psychosis (n=11), speech problems (n=10), and autonomic/breathing dysregulation (n=9). Patients were initially treated with methylprednisolone pulses (n=11), rituximab (n=6), intravenous immunoglobulins (n=4), cyclophosphamide (n=3) and MTX (n=11). Complete remission was observed in all cases, and maintenance therapy with MTX (10 mg/m^2 BSA) was started in all them, with gradual tapering until it was stopped. Interestingly, no relapses have been observed in any case during the mean follow up. One patient had mild oral ulcers and other showed mild elevation of liver enzymes; both events remitted after discontinuing the treatment for a couple of weeks.
Conclusions: Since relapses in patients with A-ME are a relatively frequent, the immunosuppressive therapy to prevent them is fully justified (4). Moreover, MTX therapy in pediatric patients is safe and usually well tolerated (3,5,6). The recommended dose is less than 15 mg/m^2 BSA or 1 mg/kg, with a maximal dose of 40 mg and with folic acid supplementation. In this regard, our study suggests that MTX administration (10 mg/m^2 BSA) during at least one year is a viable and effective therapy for maintenance treatment of A-ME. Accordingly, we did not detect relapses in the 11 patients studied with a median follow up time of 22 months and with an acceptable safety profile.

THU0502 EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH STILL'S DISEASE: A POOLED ANALYSIS OF SJIA DATA BY AGE GROUPS

E. Feist[1], P. Quartier[2], B. Fautrel[3], R. Schneider[4], P. Sfriso[5], P. Efthimiou[6], L. Cantarini[7], K. Lheritier[8], K. Leon[9], C. Karyekar[9], A. Speziale[8]. *[1]Charite-Universitätsmedizin, Berlin, Germany; [2]Necker-Enfants Malades Hospital; [3]Pitie Salpetriere Hospital, Paris, France; [4]PRCSG, Cincinnati, United States; [5]University of Padova, Padova, Italy; [6]Weill Cornell Medical College, New York, United States; [7]University of Siena, Siena, Italy; [8]Novartis Pharma AG, Basel, Switzerland; [9]Novartis Pharmaceuticals Corporation, East Hanover, United States*

Background: Still's disease presents in paediatric and adult patients (pts) as a disease continuum with similar symptoms and pathophysiology.[1,2]
Objectives: To evaluate the efficacy and safety of canakinumab (CAN), a selective human anti-IL1 β monoclonal antibody, in SJIA pts from pooled data across 3 age groups (grps): children, adolescent and adults (the latter representing adult-onset Still's disease [AOSD] population).
Methods: Data of CAN treated pts were pooled from 4 SJIA studies (NCT00426218, NCT00886769, NCT00889863, NCT00891046). CAN was ad-

ministered at 4 mg/kg every 4 weeks (wk). Efficacy parameters (adapted ACR [aACR] paediatric responses, juvenile idiopathic arthritis [JIA] ACR responses, pts with inactive disease), CRP levels over 12 wk and safety were assessed by age grp. One study [NCT00426218] was excluded for efficacy outcomes.
Results: 216 children (2–<12 years [y]), 56 adolescents (12–<16 y) and 29 adults (≥16 y) were analysed for efficacy outcomes. The efficacy parameters across the 3 age grps were largely comparable (Table 1). The safety profile of CAN was similar across age grps (Table 2). One death was reported (adolescents grp). Clinical, laboratory and immunogenicity data showed no notable differences between the age grps.

Table 1. Responses by age grp and time point

Age group	%	aACR paediatric; n/N (%)		JIA ACR; n/N (%)	
		Day 15	Day 85	Day 15	Day 85
Children	≥30	158/216 (73.1)	90/133 (67.7)	169/216 (78.2	93/133 (69.9)
	≥70	109/216 (50.5)	77/133 (57.9)	111/216 (51.4)	77/133 (57.9)
	≥100	46/216 (21.3)	42/133 (31.6)	47/216 (21.8)	42/133 (31.6)

Opportunistic infections	3 (1.3)	4 (6.7)	1 (3.3)
Neutropenia	11 (4.7)	2 (3.3)	0
SAE (at least 1)	81 (34.8)	25 (41.7)	9 (29.0)

Conclusions: Pooled analyses indicate similar efficacy of CAN across all the age grps of children, adolescents and adult SJIA pts. There were no meaningful differences in safety profiles across the different age grp. These analyses suggest similar efficacy of CAN in AOSD pts as observed in the SJIA pts.

THU0503 IDENTIFICATION OF OPTIMAL SUBCUTANEOUS (SC) DOSES OF TOCILIZUMAB IN CHILDREN WITH POLYARTICULAR-COURSE JUVENILE IDIOPATHIC ARTHRITIS (PCJIA)

F. De Benedetti[1], N. Ruperto[2], D. Lovell[3], A.V. Ramanan[4], R. Cuttica[5], J.E. Weiss[6], M. Henrickson[3], H. Schmeling[7], J. Anton[8], K. Minden[9], J. Hsu[10], K. Bharucha[11], S. Wimalasundera[12], A.K. Kadva[11], R. Upmanyu[12], N.L. Mallalieu[10], A. Martini[2], H. Brunner[3]. *[1]IRCCS Ospedale Pediatrico Bambino Gesù, Rome; [2]PRINTO Coordinating Ctr, Genoa, Italy; [3]PRCSG, Cincinnati Children's Hosp Med Ctr, Cincinnati, United States; [4]Bristol Royal Hosp for Children, Bristol, United Kingdom; [5]Hosp Gral de Niños Pedro Elizalde, Buenos Aires, Argentina; [6]Hackensack U Med Ctr, Hackensack, United States; [7]Alberta Children's Hosp/U Calgary, Calgary, Canada; [8]Hosp Sant Joan de Deu, Barcelona, Spain; [9]Charité U Med Berlin, Berlin, Germany; [10]Roche Innovation Ctr, New York; [11]Genentech, S San Francisco, United States; [12]Roche Products Ltd, Welwyn Garden City, United Kingdom*

Background: Efficacy and safety of intravenous (IV) tocilizumab (TCZ) have been shown in patients (pts) with pcJIA.[1]
Objectives: Determine appropriate dosing regimens of SC TCZ in pcJIA.
Methods: Pts were aged 1–17 y with pcJIA, inadequate response/intolerance to MTX and TCZ-naive or receiving TCZ IV with adequate disease control. TCZ SC was administered open label by body weight (BW)–based dosing modeled on IV dosing in pcJIA and SC dosing in adult rheumatoid arthritis: pcJIA pts <30kg received TCZ 162mg every 3 wks (Q3W) and pts ≥30kg received TCZ 162mg Q2W for 52 wks. Safety, efficacy (exploratory) and model-computed pharmacokinetic (PK) and pharmacodynamic (PD) parameters were assessed.
Results: 52 pts were enrolled; 27 <30kg and 25 ≥30kg BW; 85% and 56% were TCZ naive. Since no notable difference in steady state PK occurred in naive vs non-naive pts, pooled data are shown. Median C_{min} was similar between BW groups and higher than with TCZ IV (TCZ IV median C_{min}: 3.2 μg/mL for 10mg/kg <30kg BW and 7.3 μg/mL for 8mg/kg ≥30kg BW) ensuring adequate exposure from SC doses. Median C_{max} was lower from SC than IV dosing. Changes in PD parameters for TCZ-naive pts were consistent with those for TCZ IV. JADAS-71 generally improved (Table), with trends consistent with those for TCZ IV. Infections were the most frequent adverse event (AE), reported in 36 pts; 2 serious infections occurred in 1 pt. Injection site reactions occurred in 15% pts in the <30kg group and 44% pts in the ≥30kg group. The most common symptoms were erythema, swelling, hematoma, pain and pruritus. No serious hypersensitivity, AE leading to withdrawal, opportunistic infection, serious hepatic AE or death occurred. Overall there were 4 serious AEs in 3 pts (7.9/100 pt-y, consistent with that for TCZ IV).

	TCZ 162mg SC Q3W, BW <30kg (n=27)	TCZ 162mg SC Q2W, BW ≥30kg (n=25)
Model-computed steady state PK parameters, median [range]		
C_{min}, μg/mL	13.4 [0.2, 52.3]	12.7 [0.2, 23.8]
C_{max}, μg/mL	62.4 [39.4, 121.1]	29.7 [7.6, 50.3]
$AUC_{12weeks}$, μg/mL×day	2998 [1465, 7708]	1933 [324, 3098]
Change from baseline to week 52[a] in PD markers and efficacy, median [range]; TCZ-naive pts		
IL-6, pg/mL	27.3 [3.5, 173.9], n=11	12.2 [–6.2, 30.9], n=9
sIL-6R, ng/mL	612.1 [399.4, 808.4], n=14	429.3 [245.5, 585.6], n=11
CRP, mg/L	–1.3 [–17.0, 0.5], n=21	–0.8 [–22.9, 0.0], n=12
ESR, mm/h	–11.0 [–40.0, 0.0], n=21	–6.0 [–35.0, 0.0], n=12
JADAS-71	–16.8 [–40.3, –4.4], n=21	–12.9 [–48.1, –2.3], n=12

[a]Week 51 for Q3W group. AUC, area under the concentration curve; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; IL-6, interleukin-6; sIL-6R, soluble IL-6 receptor.

Conclusions: The BW-based TCZ SC dosing regimens for pcJIA provided adequate exposure to support efficacy comparable to that for TCZ IV, with an acceptable benefit-risk profile.

THU0504 QUANTIFYING PHYSICAL EDUCATION ATTENDANCE AND ITS RELATIONSHIP TO PAIN SEVERITY AND FATIGUE IN ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS – RESULTS FROM THE GERMAN NATIONAL PAEDIATRIC RHEUMATOLOGICAL DATABASE

F. Milatz[1], M. Niewerth[1], N. Geisemeyer[1], J. Peitz[2], C. Rietschel[3], T. Lutz[4], A. Holl-Wieden[5], K. Minden[1,6]. *[1]Epidemiology Unit, German Rheumatism Research Center Berlin, Berlin; [2]Pediatric Rheumatology Centre, Asklepios Clinic, Sankt Augustin; [3]Pediatric Rheumatology, Clementine Children's Hospital, Frankfurt/Main; [4]Medical Centre for Children and Adolescents, University Hospital Heidelberg, Heidelberg; [5]Children's Hospital, University Hospital Würzburg, Würzburg; [6]Children's University Hospital, Charité University Hospital, Berlin, Germany*

Background: Regular physical education (PE) can help adolescents achieve the recommended amount of daily physical activity and provide immediate health benefits, by positively affecting musculo-skeletal development, mental health and social behavior. Adolescents with juvenile idiopathic arthritis (JIA) are less physically active and have lower fitness levels than their healthy peers [1]. Moreover, pain and fatigue are one of the most frequent complaints and identified as one of the causes behind impaired (social) functioning [2].
Objectives: To describe the participation rate in PE and to assess its relationship to pain and fatigue in adolescents with JIA.
Methods: Cross-sectional data of adolescents with JIA recorded in the National Paediatric Rheumatological Database (NPRD) in the year 2015 were considered for the analyses. Disease characteristics were provided by rheumatologists along with patient-reported outcomes and participation in PE. Relationship to PE was assessed by using spearman's correlation.
Results: In 2015, a total of 3,289 adolescents with JIA (females 66%, mean disease duration 5 years, persistent oligoarthritis 30%) aged 13 to 17 were recorded. About 60% of the patients reported to participate in PE "always" (56% of girls, 69% of boys), whereas about 18% stated to be fully exempt from participating in PE (20% of girls, 14% of boys). Significant differences were observed among JIA subtypes, whereby patients with enthesitis-related arthritis participated more frequently than patients with rheumatoid factor-positive polyarthritis (64% vs. 46%). The mean pain level was 2.1, the mean fatigue level 1.8. Participation in PE was negatively correlated with self-reported pain intensity ($r=-0.43$) and fatigue ($r=-0.32$). Significant associations were found between PE attendance and age, sex, disease duration, functional status as well as disease activity measured by CHAQ and JADAS3–10, respectively ($p<0.05$).
Conclusions: 6 of 10 adolescents with JIA participate in PE always, whereby higher rates of self-reported attendance are associated with less severe pain and fatigue. Since exercise programs in JIA lead to significant improvements in quality of life, it is likely that physical education attendance plays an important role in pain reduction and social functioning improvement in JIA.

THU0505 LOW LITERACY BUT NOT PARENTAL SMOKING OR BREAST FEEDING WORSENS OUTCOME IN JUVENILE IDIOPATHIC ARTHRITIS IN A LOW INCOME POPULATION

F.A.C. Rocha[1], J.I. Vasques[1], L.N. Rocha[1], M.G. Aguiar[1], J.P.E. Accioly[1], C.N. Lechiu[1], L.H.A. Costa[1], M.F.C.D. Silva[2], A.R.X. Feitosa[2], H.A.L. Rocha[3], C.N. Rabelo Jr.[2]. *[1]Internal Medicine, Universidade Federal Do Ceara; [2]Pediatric Rheumatology, Hospital Geral de Fortaleza; [3]Health Department, Universidade Federal Do Ceara, Fortaleza - CE, Brazil*

Background: JIA data from underdeveloped regions are scant. We evaluated JIA patients living in low latitude (3º43'S), highly exposed to sunlight. We have shown their mean serum vitamin D levels as the higher ever reported, being not associated to disease status. Here are data on monthly income, breastfeeding, parental smoking, and literacy in this JIA cohort.
Methods: Clinical and demographic data [n (%)] from 165 JIA patients followed between May 2015 - Dec 2016 in two reference outpatient centers in Fortaleza-CE Brazil were consecutively collected. Family income (more or less than 300 US$/month), breast feeding (more or less than 3 months), literacy [more or less than 8 school-years (SY)], and parental smoking (present/absent) were compared using Juvenile Arthritis Disease Activity Score (JADAS27), Childhood Health Assessment Questionnaire (CHAQ) and presence of deformities as prognostic outcomes.
Results: Mean age was 14±4.9 years with 94 (56.9); 63 (38), 40 (24), 37 (22.4), 19 (11.5), 5 (3), and 1 (0.6) of the polyarticular, enthesitis-related, oligoarticular, systemic, undifferentiated, and psoriatic categories, respectively. Mean total CHAQ was 0.4±0.58 with a trend to be higher in polyarticular (0.55±0.69) than oligoarticular (0.3±0.4) category as well as higher JADAS 27 and more deformities in the former. Among 97 respondents, all but one patient was ever breastfed with 71 (73) for more than 3 months; 15 (17) out of 86 mothers were smokers and 28 (33.7) out of 83 smoked among family respondents; 49 (56.3) out of 87 parents had less than 8 SY and only 3 had superior level; 32 (37.6) out of 85 respondents earned less than 300US$. Lower literacy was associated to worse CHAQ ($p=0.021$). Neither maternal/family smoking nor breastfeeding time was associated to outcome. Lower income *per se* did not affect outcome.
Conclusions: This is the largest JIA database coming from an equatorial region reporting social and environmental aspects. Low literacy predominates, meaning more than half with less than elementary school, affecting prognosis. There is a low income profile and most family constituents do not smoke. Different from other countries, polyarticular category prevails despite low mean CHAQ *vis-à-vis* data from wealthy regions. Breast feeding for more than 1 month is almost universal and having breastfed for more than 3 months did not appear to influence prognosis

THU0506 ASSOCIATION OF NEUTROPHIL-TO-LYMPHOCYTE RATIO, PLATELET-TO-LYMPHOCYTE RATIO, PLATELET INDICES AND SERUM AMYLOID A LEVELS IN CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER

F. Dörtbaş[1], E. Comak[2], E. Isıyel[3]. *[1]Rheumatology, Emsey Hospital, Istanbul; [2]Pediatric Nephrology and Rheumatology, Akdeniz University, Antalya; [3]Pediatric Nephrology and Rheumatology, Kocaeli Derince Training and Research Hospital, Kocaeli, Turkey*

Background: Familial mediterranean fever (FMF) is an autosomal recessive, inherited, autoinflammatory disease characterized by recurrent, self-limited bouts of fever and inflammation. Persistent subclinical inflammation was related to increased risk of developing the serious complications, such as life- threatening amyloid a (AA) amyloidosis. The neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR) and platelet indices [mean platelet volume (MPV) and platelet distribution width (PDW)] are simple, inexpensive, and useful markers to determine inflammation. Although, there have been a lots of data regarding inflammatory markers in FMF, little information was available the relationship between NLR, PLR, MPV and serum amyloid A levels.
Objectives: The aim of this study was to investigate association of NLR, PLR, platelet indices and serum amyloid A levels in children with FMF
Methods: The medical records of children with FMF were reviewed retrospectively. Information including demographic features, clinical and laboratory findings, SAA and C-reactive protein (CRP) levels, type of MEFV mutation were collected from the hospital's computerized database following approval by the local ethics commitee. The NLR and PLR were calculated from a complete blood count. Children (<7 years old) was excluded from study due to age related features of neutrophil-to-lymphocyte ratio.
Results: Our study group included 127 children (60 males, 67 females) with FMF, diagnosed according to the Turkish pediatric FMF criteria. Their mean age was 11.35±3.69 years, their mean age at time of disease onset was 8.73±3.93 years, and their mean follow up period was 28.32±2.90 months. Thirty two children (25.2%) were homozygous, 56 children (44.0%) were compound heterozygous and 39 children (30.7%) were heterozygous for MEFV gene. In study population, the mean SAA levels, C-reactive protein (CRP) levels and e*rythrocyte* sedimentation rate (ESR) were 9.21±13.88 mg/L, 1.38±2.31 mg/dl and 16.64±12.59 mm/hour, respectively. Significant positive correlations were found between SAA, ESR, CRP and NLR ($r=0.2$, $p=0.02$; $r=0.28$, $p=0.001$; $r=0.32$, $p=0.001$, respectively). Hovewer, we did not find any significant correlation between SAA, ESR, CRP and platelet indices (MPV, PDW) and PLR (all $p>0.05$).
Conclusions: Our finding suggest that simply calculating NLR from complete blood count may be used as an additional indicator of inflammation in children with FMF. But, platelet indices and PLR cannot be used as a laboratory markers predicting inflammation in these children.

THU0507 LONG-TERM EXPERIENCE WITH ADALIMUMAB FOR THE TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS. 5- YEAR DATA FROM THE GERMAN BIKER REGISTRY

A. Klein[1], K. Minden[2], I. Foeldvari[3], G. Ganser[4], J.P. Haas[5], R. Trauzeddel[6], A. Hospach[7], F. Weller-Heinemann[8], G. Horneff[1] on behalf of BIKER collaborative group. *[1]Asklepios, Sankt Augustin; [2]Charité, Berlin; [3]Private office, Hamburg; [4]Ped Rheumatol, Sendenhorst; [5]German Ped Rheum Centre, Garmisch-Partenkirchen; [6]Chidrens Hospital, Helios Klinikum Berlin Buch, Berlin; [7]Paediatric Rheumatology, Olgahospital, Stuttgart; [8]Paediatric Rheumatology, Klinikum Bremen Mitte, Bremen, Germany*

Background: Since the approval of Adalimumab (ADA) for treatment of juvenile idiopathic arthritis (JIA), it has become a valuable option, which significantly improved the outcome of patients.
Objectives: To report efficacy (as observed) and safety of ADA in clinical practice.
Methods: Data from the German BiKeR register from 2011 to 2016 are reported. Baseline patient characteristics, treatment response and safety data were compared. Treatment response was analyzed using JIA-ACR criteria, JADAS score and improvement of functional status (Childhood Health Assessment Questionnaire disability index, CHAQ), JIA-ACR-scores, JADAS10-minimal disease activity (MDA), JADAS-remission and ACR-inactive disease criteria were analysed.
Results: 589 non-systemic JIA patients exposed to Adalimumab with at least one follow-up report were identified in the German BIKER registry, representing 1143.9 patient years (PY) of exposure to ADA and 1206.5 observation years including 90 days after discontinuation. At Baseline, 58.2% received combination with methotrexate (MTX). Patients on combination treatment had more frequently ANA, less frequently HLA-B27, had higher JADAS 10 and more often received systemic steroids (9.9% vs. 22.2%, p=0.0002). ADA dosage was 0.8mg/kg in both cohorts.
At month 12 JIA-ACR 30/50/70/90 and JADAS-MDA/-remission/ACR-inactive disease was reached by 66/63/49/33/50/24/27% on monotherapy with ADA and 68/63/45/28%/50/28/27 on combination of ADA and MTX (not significant). Response rates at month 24 were 67/66/54/35/65/32/29% on ADA monotherapy and 67/61/46/31/57/35/30% on ADA+MTX combination cohort (not significant).
The rate (/100PY) of all adverse events (AE)/serious AE/infections/serious infections/uveitis events was 52.3/2.2/16.4/4.6 upon monotherapy and 65.3/5.1/2.3/16.4/6.2 upon combination. Only rates for any AE were significantly higher upon combination (p=0.008) as well as rate of elevated transaminase (p=0.01). Rate of patients with an uveitis event was higher upon combination (9.6% vs. 5.3%, p=0.007)

Table 1

	ADA monotherapy	ADA + MTX	P
N, female (%)	223 (70)	343 (70)	n.s.

THU0508 PSYCHOLOGICAL FEATURES OF CHILDREN WITH RHEUMATIC DISEASES

I. Chyzheuskaya[1], L. Byelyaeva[1], R. Filonovich[2], L. Zajtseva[2]. *[1]Pediatrics, Belarusian Medical Academy of Postgraduate Education; [2]Pediatrics, 4th City Children's Clinical Hospital of Minsk, Minsk, Belarus*

Background: Rheumatic diseases (RD) in children are characterized by a wide spectrum of clinical manifestations, and variability of flow, the defeat of many body systems, including the musculoskeletal system, which often leads to early disability. The disease brings the children not only physical suffering and psychological distress as a result of the pathological process may be sufficiently stable defects in appearance, affecting the minds of the growing person.
Objectives: To study the psychological characteristics of children with rheumatic diseases.
Methods: 167 patients with RD were examined in the period from 2008 to 2015. In the I group included 115 children with juvenile idiopathic arthritis (JIA) (mean age 11,9±3,4 years), II group consisted of 34 children with juvenile scleroderma (JS) (mean age 12,4±2,8 years), III - 18 children with systemic lupus erythematosus (SLE) (mean age 13,1±1,7 years). As control group examined 30 healthy children aged 9–17 years (mean age 12,93±0,4 years). To investigate the expression of reactive anxiety (RA) and personal anxiety (PA) in children older than 9 years was used scale Ch.D.Spielberg. In order to study the intensity of anxiety was used M.Luscher color test. To identify the individual psychological characteristics of the individual patient questionnaire used G.J.Eysenck for teenagers, consisting of 60 questions, including the scale of extroversion, introversion, neuroticism and the scale of "the scale of lies". Testing patients and interpretation of the results was carried out together with a psychologist.
Results: The test Spielberg results indicate that significantly more ($P<0.001$), medium and high levels of anxiety both reactive and personal, occurred in children with RD. This suggests the presence of children with RD border states with the threat of self-assessment features, reducing the threshold of resistance to stressful situations. The average RA and PA indices were significantly higher ($P<0.001$) in children with RD in comparison with indicators of reactive and personal anxiety in children in the control group (46,09±0,88 points for the JS, 43,77±1,37 points for JIA, 45,07±1,83 points for SLE and 27,6±0,62 points for the control group, respectively, RA; 42,22±1,68 points for the JS, 37,84±1,27 points for the JIA, 44,76±0,88 points for SLE and 28,7±0,51 points, respectively, RA for the control group).
Results of the study with the help of M.Lusher's color test revealed the intensity of anxiety in children with JS, SLE and JIA. Evaluation results of the study showed that children and adolescents with RD clearly manifested trend bias pri-mary colors on the 6,7,8 positions, and more - in the first place.
In order to identify characteristics of temperament in patients aged 13–17 years were asked to complete a questionnaire G.J.Eysenck for undergrowth Cove. The majority of surveyed teens both clinical groups manifest emotional instability (73.3% of patients with JS and 70% of patients with JIA) and features typical of introversion (60% of patients with SS and 68% of patients with JIA) (verified differences were found) between the groups. According to G.J.Eysenck, high rates of introversion in conjunction with emotional instability correspond to the alarm state.
Conclusions: As a result, psychometric studies found that the characteristic of emotional tension, anxiety, isolation for children with RD.

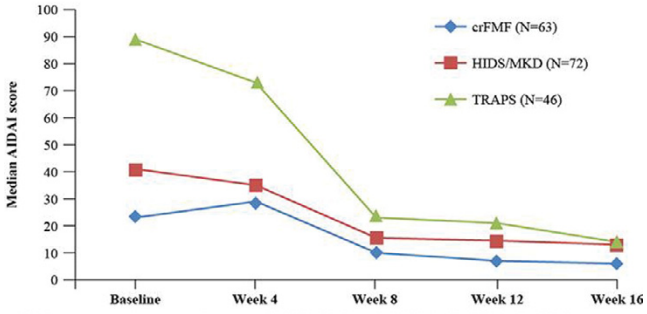
THU0509 IMPROVEMENT OF DISEASE ACTIVITY IN PATIENTS WITH COLCHICINE-RESISTANT FMF, HIDS/MKD AND TRAPS ASSESSED BY AUTOINFLAMMATORY DISEASE ACTIVITY INDEX (AIDAI): RESULTS FROM THE CLUSTER TRIAL

I. Kone-Paut[1], M. Piram[1], S. Benseler[2], M. Hofer[3], H. Lachmann[4], H.M. Hoffman[5], M. Gattorno[6], J. Frenkel[7], J.B. Kuemmerle-Deschner[8], S. Ozen[9], J. Levy[10], C.S. Karyekar[11], F. De Benedetti[12]. *[1]APHP, CHU de Bicêtre, Univ Paris Sud, le Kremlin Bicêtre, France; [2]Alberta Children's Hospital, Calgary, Canada; [3]University of Lausanne, Lausanne, Switzerland; [4]UK National Amyloidosis Centre, London, United Kingdom; [5]University of California, la Jolla, United States; [6]G. Gaslini Institute, Genoa, Italy; [7]University Medical Center, Utrecht, Netherlands; [8]University Hospital Tuebingen, Tuebingen, Germany; [9]Hacettepe University, Ankara, Turkey; [10]BIOP, Reinach, Switzerland; [11]Novartis Pharmaceuticals Corporation, East Hanover, United States; [12]IRCCS Ospedale Pediatrico Bambino Gesú, Rome, Italy*

Background: AIDAI is a novel validated tool for assessment of disease activity in autoinflammatory diseases.[1] CLUSTER study (NCT02059291) demonstrated that canakinumab (CAN; an anti- IL-1β antibody) is efficacious in resolving active flare and in preventing new flare in patients (pts) with colchicine resistant familial Mediterranean fever (crFMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and TNF receptor-associated periodic syndrome (TRAPS).[2]



Objectives: To assess AIDAI score and evaluate correlation between AIDAI and disease/response characteristics over 16 weeks (wks) of CAN treatment in CLUSTER.
Methods: CLUSTER study design and results have been presented.[2] AIDAI was calculated as the sum of 12 items[1] for 30 consecutive days. AIDAI score was calculated if the first score was recorded ≥29 days before baseline (BL). Missing items were imputed beyond last evaluable measurement by LOCF. Proportion of pts with inactive disease (ID; AIDAI score <9) was calculated at Wk 16. Correlation analysis of AIDAI with C-reactive protein (CRP), serum amyloid A (SAA), physician global assessment (PGA) and sheehan disability score (SDS), and child health questionnaire–psychological/physical (CHQ–PsCS/PCS) and short form 12–physical/mental (SF12–PCS/MCS) component summaries were performed at BL and Wk 16, with significance set at $p<0.05$.
Results: Median AIDAI scores decreased over time (Fig 1). Proportion of pts with ID at Wk 16 was 52% in crFMF, 40% in HIDS/MKD and 46% in TRAPS cohorts. AIDAI at Wk 16 correlated significantly with: SDS in all 3 cohorts; PGA in HIDS/MKD and TRAPS; SF12–MCS in crFMF and HIDS/MKD (Table 1). CRP and SAA did not correlate with AIDAI.

Table 1. Correlation between AIDAI and disease activity/response variables at Week 16

	Correlation coefficient (95% CI)		
	crFMF (N=63)	HIDS/MKD (N=72)	TRAPS (N=46)
CRP	–0.12 (–0.36; 0.14)	0.23 (–0.01; 0.45)	0.12 (–0.19; 0.42)
SAA	–0.01 (–0.27; 0.25)	–0.05 (–0.30; 0.21)	0.06 (–0.26; 0.37)
PGA	0.23 (–0.02; 0.46)	**0.35§ (0.12; 0.55)**	**0.73* (–0.54; 0.85)**
CHQ – PsCS	–0.18 (–0.56; 0.26)	–0.25 (–0.55; 0.11)	–0.33 (–0.72; 0.22)
CHQ – PCS	–0.33 (–0.66; 0.11)	**–0.46§ (–0.70; –0.14)**	–0.48 (–0.80; 0.04)
SF12 – PCS	–0.26 (–0.57; 0.11)	–0.23 (–0.68; 0.35)	**–0.52‡ (–0.81; –0.03)**
SF12 – MCS	**–0.45‡ (–0.70; –0.10)**	**–0.55‡ (–0.84; –0.03)**	0.09 (–0.43; 0.56)
SDS	**0.47† (0.22; 0.67)**	**0.37§ (0.10; 0.59)**	**0.41‡ (0.06; 0.67)**

*$p<0.0001$; †$p<0.001$; §$p<0.01$; ‡$p<0.05$.

Fig 1. Median AIDAI scores over 16 weeks

AIDAI score was calculated as the sum of all 12 daily items (YES=1 or NO=0) during 30 days.
Missing AIDAI assessments between first and last AIDAI assessments were imputed as NO.
Missing AIDAI assessments after last AIDAI assessment were imputed as NO.
LOCF, last observation carried forward.

Conclusions: CAN demonstrated rapid and sustained disease control assessed with AIDAI over 16 wks. Approximately half of crFMF and TRAPS pts, and 40% of HIDS/MKD patients had inactive disease after 16 wks of treatment. AIDAI improvements at Wk 16 correlated with patient and physician driven evaluations (PGA, SF12–MCS and SDS). CRP and SAA are indicators of response to treatment, rather than a disease activity parameter.

THU0510 UKRAINIAN REGISTRY OF JIA PATIENTS RECEIVING BIOLOGICS: IMPLEMENTATION INTO CLINICAL PRACTICE AND RECENT DATA

I.V. Biliavska[1], V.M. Kovalenko[1], O.P. Bortkevych[1], O.O. Garmish[1], Y.E. Boyko[2], L.I. Omelchenko[1], O.A. Oshlyanska[1], T.V. Marushko[1], L.F. Bogmat[3], N.S. Shevchenko[3]. [1]*Task Force, Ukrainian association of Rheumatologists, Kyiv;* [2]*Task Force, Ukrainian association of Rheumatologists, Lviv;* [3]*Task Force, Ukrainian association of Rheumatologists, Kharkiv, Ukraine*

Background: The situation with a treatment of juvenile idiopathic arthritis (JIA) is complicated in Ukraine. Mainly due to financial reason biological therapy is hardly accessible for Ukrainian patients. Nevertheless, some patients with JIA receive biologics within governmental programme. Clinical data of these patients were scattered and not systematized until 2014. The Task Force of Ukrainian Association of rheumatologists, by analogy to other European registries, has developed a registry of JIA patients receiving biologics. Ukrainian register of JIA patients is an observational, prospective, non-interventional clinical study.
Objectives: The main aim of Ukrainian register of JIA patients is an assessment of long-term safety, efficacy and cost of biological treatment of JIA. in the routine clinical practice.
Methods: 33 clinical sites from different regions of Ukraine are participating. Inclusion criteria: i) diagnosis of JIA: ii)age ≤2 years old, iii)planned start of biological therapy due to JIA; iv)negative screening for tuberculosis; v)provided informed consent. Patients have undergone standard clinical assessment every 3 months. Disease activity is measured using JADAS27 in all age groups. ANA, HLAB27, RF and anti-CCP detection are highly recommended. Uveitis and other comorbid conditions should also be fixed.
Results: 339 patients were enrolled into the study during 3 years. 64% of patients are girls. Mean age–10.98±4.41 years, with mean disease duration –5.81±3.48 years. The duration of the period between diagnosis and biologics start was 54.31±40.28 months. Comorbid conditions were found in 41.03% patients. In 14.65% of the patients uveitis was diagnosed. Most common JIA subtypes in patients receiving biologics are pJIA with negative RF (45%), sJIA (20%), enthesitis-associated JIA (11%) and persistent oligoarthritis (11%). 67.3% of enrolled patients received adalimumab (ADA); 27.9%>tocilizumab (TOZ) and 4.8%>etanercept, respectively. During observational period biologics was discontinued in 19.8% of patients due to different reasons: adverse events were observed in 6.7% (ADA) and 16.7% (TOZ), insufficient efficiency of 23.3% (ADA) and 33.3% (TOZ), remission - 6.7% (ADA); drug absence - 63.3% (ADA) and 50% (TOZ), respectively. Comparative analysis of ADA and TOZ efficacy was performed in the 144 patients with pJIA with negative RF. Administration either ADA or TOZ resulted in statistically significant reducing of disease activity according to JADAS27. In ADA group after 3 months of administration JADAS27 decreased from 16.3±10.3 to 10.0±7.8 ($p<0.00001$). In TOZ group after 3 months of administration JADAS27 reduced from 22.2±12.2 to 13.1±9.1 ($p=0.0012$). The functional disability of the patients also statistically significant decrease in both treatment group starting from 3 months of administration: 1.1±0.8 to 0.7±0.7 ($p=0.0081$) in ADA and 1.6±1.0 to 1.0±0.7 in TOZ, respectively.
Conclusions: Ukrainian national registry of JIA patients provides real-life long-term data concerning safety, efficacy, outcomes and comparative analysis of biologics in Ukrainian population of JIA patients. Data collection continues and the data received expected to be a background for clinical decision-making in future.

THU0511 TOCILIZUMAB IS A PROMISING TREATMENT OPTION FOR THERAPY RESISTENT JUVENILE LOCALISED SCLERODERMA PATIENTS

I. Foeldvari[1], J. Anton[2], M. Friswell[3], B. Bica[4], J. de Inocencio[5], A. Aquilani[6], N. Helmus[1]. [1]*Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schön Klinik Eilbek, Hamburg, Germany;* [2]*Sant Joan de Déu Hospital, Barcelona, Spain;* [3]*Great North Children's Hospital, Newcastle, United Kingdom;* [4]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil;* [5]*Pediatric Rheumatology Unit University Hospital 12 de Octubre, Madrid, Spain;* [6]*Ospedale Bambino Gesù, Rome, Italy*

Background: Juvenile localised scleroderma (jlSc) is an orphan disease. Most patient respond to treatment ot methotrexate or mycophenolate. In case of nonresponse or partial response, based on the promising tocilizumab (TOC) data of adult systemic sclerosis studies, TOC seems to be a promising option. There is no publication regarding the effectiveness of tocilizumab in jLS.
Objectives: To assess the effectivity of TOC in jlSC patients, who had nonresponse or partial response on conventional therapy.
Methods: Participants of the pediatric rheumatology email board were asked, if they follow patients with jlSc, who are treated with TOC. Clinical characteristics and the response to TOC was assessed.
Results: Six centers responded to the survey from the email board, with around 800 participatns, and reported 11 patients. The mean age of the patients at disease onset was 5.5 years. Disease duration at time of the intiation of TOC was 53.5. months (range 9 to 109). 5 patients had linear subtype, 3 of them with facial involvement, 2 of them Parry Romberg and one of them coup de sabre. Three had generalized subtype, 2 mixed subtype and 1 limited subtype/morphea. Before starting TOC patients received 10/11 Methotrexate, 7/11 Mycophenolate, 1 abatacept and 1 anti-TNF therapy. Reason to start TOC was in 9 patients increase in Localised Scleroderma Activity Index [1] (mLoSSI). In two patients increased extracutaneous activity was the indication, in one increased activity of arthritis and in the other increased activity of the central nervous system involvement.

The mean duration of tocilizumab therapy was 14.75 months. 2 patients received s.c. accoding the poly JIA dosing and all other i.v. There were diferent i.v doses applied, 5 of them 8mg/kg every 4 weeks, one of them 8 mg /kg every three weeks, 1 every two weeks and 1 pateints received 10 mg /kg every 3 weeks. 3/11 received TOC as monotherapy. 8/11 as combination therapy, 6 of them with Methotrexate and one of each with Mycophenolate or Tacrolimus. Therapy success was refelected by a decreased mLoSSI in 8/11 patients and in 6 patients by a decrease in the Localosed Scleroderma Skin Damage Index [1] (LoSDI). No new lesion occured during the treatment and in the patients with Parry Romerg subtype (n=2) no increase in the facial atrophy occured. In 8/8 patients physician global (VAS 0–100) decreased and in 8/8 the patients global disease activity (VAS 0–100) decreased. In 3/3 patients, were it was applicable, the number of acitve joints decreased, in one patients the limb discrepancy decreased. The mean modified Rodnan skin score assessed in 8 patients decreased from the mean value of 9.6 to 5.5.

Conclusions: In this small cohort of patients TOC seems to be a promising rescue medication in methotrexate/mycophenolate nonresponsive patients. A prospective controlled study would be important to prove the seen effect in a controlled way.

THU0512 FLUORESCENCE OPTICAL IMAGING IN JUVENILE PATIENTS WITH AND WITHOUT INFLAMMATORY PEDIATRIC RHEUMATIC JOINT DISEASES

M. Beck[1], J. Klotsche[1], A.-M. Glimm[2], S. Ohrndorf[2], S. Werner[2], G. Horneff[3], M. Backhaus[2], R. Trauzeddel[4], K. Minden[1], H. Girschick[5]. *[1]Deutsches Rheuma Forschungszentrum; [2]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin, Berlin; [3]Asklepios Kinderklinik Sankt Augustin GmbH, Sankt Augustin; [4]Department of Pediatric Rheumatology, Helios Klinikum Berlin-Buch; [5]Children's Hospital, Vivantes Hospital im Friedrichshain, Berlin, Germany*

Background: Imaging techniques play an important role in making a diagnosis and in the evaluation of treatment effectiveness as well as in the outcome assessment of juvenile idiopathic arthritis (JIA). Fluorescence optical imaging (FOI) has been shown to visualize inflammation in arthritis of wrist and finger joints. FOI is a simple and cost-effectively imaging technique that is well tolerated by the patients.

Objectives: Firstly, to determine the association and agreement of FOI with ultrasonography (US) and physician's assessment of swollen and active joints. Secondly, to estimate the predictive power of FOI to distinguish between patients with and without inflammatory pediatric rheumatic joint diseases.

Methods: A total of 95 patients were enrolled in three pediatric rheumatology centers in Berlin, Germany. FOI and US (in greyscale (GS) and power Doppler (PD)) were performed in each patient. The FOI software automatically generated the PrimaVista mode (PVM). Furthermore, three phases (P1, P2, P3) were defined dependent on the signal intensity in the fingertips. Each joint was scored semiquantitatively (0=no signal up to 3=strong signal, more than 50% of affected joint area) in each of the three phases and PVM. US was additionally graded by a semiquantitative score of each joint for synovitis (synovial thickening and joint effusions) in GS and hyperperfusion in PD mode. The joints were defined as active if the FOI or US reached a score of at least 1, respectively. We report the results on 27 patients in this interim analysis.

Results: The mean disease duration was 3.5 years (SD=3.2), the mean cJADAS-10 was 11.0 (SD=12.3), the mean number of active joints in the hand was 3.4 (SD=5.8). Half of the patients had polyarthritis (51.8%) and one third had a non-inflammatory rheumatic disease. A total of 810 joints in 27 patients could be analyzed. Among those, 140 (17.3%) had a positive US synovitis score, 87 (10.7%) a positive US power Doppler signal, 93 (11.5%) a clinically active joint and 133 (16.4%) a positive FOI PVM. Taking the US synovitis score as reference, the FOI PVM had a sensitivity of 40%, a specificity of 86% and an overall agreement of 79%. Taking the active joint count as reference, the FOI PVM had a sensitivity of 46%, a specificity of 88% and an overall agreement of 83%. The area under curve was 0.91 for US power Doppler, 0.84 for US GS synovitis, 0.76 and 0.93 for FOI PVM and P2 for the ability to distinguish between patients with and without inflammatory rheumatic diseases. FOI and US scores correlated highly with the cJADAS-10 and the physicians global. In contrast, the patient-reported outcomes pain and fatigue did not show any correlation with FOI and US scores.

Conclusions: FOI and US had a comparable predictive power to distinguish between patients with and without inflammatory rheumatic diseases in pediatric/juvenile patients. The agreement between active joint count, US and FOI was high. FOI may provide a cost-effective method to evaluate inflammation in finger and hand joints.

THU0513 NEONATAL MANIFESTATIONS OF IMMUNE-MEDIATED RHEUMATIC DISEASES: A RETROSPECTIVE LONGITUDINAL STUDY IN A TERTIARY HOSPITAL

J. Bernardo[1], I. Brito[1], H. Guimarães[2], M. Guimarães[3], R. Fonseca[1]. *[1]Rheumatology; [2]Pediatrics; [3]Gynecology and Obstetrics, Faculty of Medicine of the University of Porto, Porto, Portugal*

Background: Autoimmune rheumatic diseases such as systemic lupus erythematosus (SLE), antiphospholipid antibody syndrome (APS) and Sjögren's syndrome (SS) are part of a clinical spectrum eligible to affect women in child-bearing ages, affecting neonatal outcomes. Cardiac, cutaneous, haematological, hepatic complications and, more rarely, pulmonary complications have been described.

Objectives: This project aims to describe the occurrence of neonatal lupus manifestations and possible associated clinical factors among women with immune-mediated rheumatic diseases.

Methods: A retrospective longitudinal study was performed including pregnant women with immune-mediated rheumatic diseases seen in a multidisciplinary group for autoimmune diseases during pregnancy between January 2010 and December 2015. Clinical and demographic data as well as and pregnancy outcomes and neonatal manifestations were collected through consultation of clinical files. Patients with and without neonatal lupus were compared using Mann-Whitney, qui-square and fisher tests (SPSS 24.0). Significance level was set as <0.05.

Results: We included 151 gestations from a total of 140 women with a mean age of 32,5±4,4 years; 4 gestations were twin pregnancies. Within these 151 gestations, 54 (35,8%) women had SLE, 17 (11,3%) had Sjögren's syndrome, 17 (11,3%) had rheumatoid arthritis, 41 had APS (27,2%), 11 (7,3%) had Behçet's disease, 4 (2,6%) had systemic sclerosis, 8 (5,3%) had mixed connective tissue disease and 16 (10,6%) had other immune-mediated diseases. 35 (23,2%) had anti-SSA/La antibodies, 18 (11,9%) had anti-SSB antibodies, 6 (4,0%) had anti-URNP antibodies and 43 (28,5%) had anti-nuclear antibodies. During follow-up, 142 (94,0%) babies were born and 7 (4,6%) abortions and 2 (1,3%) foetal losses occurred. 6 (4,2%) neonates were born with neonatal lupus and 1 (0,7%) died *in uterus* with a complete heart block. Out of the 6 babies with manifestations, 4 (66,7%) were cardiac, 2 (33,3%) were cutaneous, 1 (16,7%) was hepatic, 2 (33,3%) were haematological and 1 (16,7%) was pulmonary. Neonatal lupus manifestations occurred more frequently in mothers with SS (23.5% vs 2.2%; p=0.003), anti-SSa/Ro (20% vs 0%; $p<0.001$), and anti-SSb/La (27.7% vs 1.5%; $p<0.001$).

Conclusions: Our study proved a link between immune-mediated rheumatic diseases and specific neonatal outcomes.

THU0514 PREDICTIVE VALUE OF SUBCLINICAL SYNOVITIS DETECTED BY DOPPLER ULTRASOUND IN RELATION TO FLARE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS TREATED WITH BIOLOGIC THERAPY AFTER TAPERING BIOLOGIC THERAPY

J.C. Nieto-González[1], A. Boteanu[2], J.C. López-Robledillo[3], P. Collado[4], A. Rodríguez[2], D. Clemente[3], M.L. Gámir[2], I. Monteagudo[1], E. Naredo[5]. *[1]Rheumatology, Hospital G.U. Gregorio Marañón; [2]Rheumatology, Hospital Universitario Ramón y Cajal; [3]Rheumatology, Hospital Infantil Universitario Niño Jesús; [4]Rheumatology, Hospital Universitario Severo Ochoa; [5]Rheumatology, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain*

Background: Anti-TNF therapy is effective and safe in JIA. Changes in anti-TNF doses are common when remission is achieved[1]. Subclinical synovitis on Doppler mode (PD) detected by ultrasound can predict flares in adult RA, but it is not yet clear in JIA[2]

Objectives: The aim of this study is to evaluate the predictive value of subclinical synovitis detected by PD-US in relation to flares in patients with JIA on remission under anti-TNF when therapy is tapered. The preliminary results were presented at the EULAR congress 2015 in Rome (FRI0520).

Methods: Observational, prospective and multicenter study. We included JIA patients on remission at least 6 months with anti-TNF, ETN and ADA, in whom anti-TNF was tapered due to clinical decision. ETN was tapered by increasing the injection 3 days and ADA by increasing a week. Patients were clinically assessed every 3 months and also with PD-US at baseline. Bilateral US assessment included joints and tendons. Adult synovitis definitions and semiquantitative scoring system were used, no synovitis definitions are available for JIA. We collected demographics (date of birth, JIA subcategory, previous and current treatments. Flare was defined as clinical signs and/or symptoms of arthritis that required increase of systemic therapy

Results: We included 57 patients, with 19 patients (33.33%) having a flare

during the 12 months follow-up. 38 patients (66.67%) were receiving ETN and 19 (33.3%) ADA, of which 11 patients (28.95%) had a flare with ETN and 8 patients (42.11%) with ADA. Table 1 shows demographics. Median time to flare was 5.73 months (IR 2–93–8.9). Concomitant methotrexate was lower in patients with flare (26.32% vs 71.05%). In 18 patients (31.58%), a previous tapering was done and median time of remission before being included was 22 months (IR 15.5–28.5). US does not predict flare in our cohort. Global synovitis score at baseline was 4 (IQR 1.3–10.8) and 0 in BM and PD respectively, and tenosynovitis was 0 both BM and PD

	All patients (n: 57)	Patients with flare (n: 19)
Gender; women (%)	39 (68.42)	10 (52.63)
Time of remission previous to tapering median months (IR)	22 (15.5–28.5)	35 (35)
Biologic therapy (ETN/ADA)	38/19	11/8
Concomitant DMARD, n (%)	32 (56.14)	5 (26.32)
Previous tapering, n (%)	18 (31.58)	5 (26.32)
JIA subcategories: n (%)		
Persistent oligoarticular JIA	15 (26.32)	5 (33.33)
Extended oligoarticular JIA	14 (24.56)	4 (28.57)
RF– polyarticular JIA	15 (26.32)	5 (33.33)
RF+ polyarticular JIA	2 (3.51)	1 (50)
Enthesitis related JIA	3 (5.26)	2 (66.6)
Psoriatic JIA	8 (14.04)	2 (25)

Conclusions: Anti-TNF tapering was safe in our JIA patients in more than half of patients after 1 year follow-up. US did not predict flares in our patients. Concomitant treatment with methotrexate was more frequent in patients who remained on remission

THU0515 DISABILITY AND LOWER QUALITY OF LIFE IS ASSOCIATED WITH SOCIOECONOMIC PASSIVITY IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

K. Rebane[1], L. Ristolainen[2], H. Relas[3], T. Orenius[2], H. Kautiainen[4], R. Luosujärvi[5], K. Aalto[6], H. Säilä[2]. *[1]Children's Hospital, University of Helsinki and Helsinki University Central Hospital; [2]ORTON Research Institute, ORTON Foundation; [3]Unit of Primary Health Care and Department of General Practice, Helsinki University Hospital Helsinki; [4]Helsinki University Central Hospital; [5]Unit of Primary Health Care and Department of General Practice, Helsinki University Central Hospital; [6]Children's Hospital, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland*

Background: Health related quality of life of adult patients with juvenile idiopathic arthritis (JIA) is shown to be significantly lower compared to the general population.[1,2]

Objectives: We aimed to recognize young adults with JIA who are socioeconomically passivated and to assess which areas of self-rated health are associated with the emergence of passivity symptoms.

Methods: We studied 195 young adults with JIA using questionnaires addressing demographics, health behavior, and physical activity. The HAQ questionnaire was used to assess functional ability, quality of life was assessed with RAND-36, depressive symptoms were assessed with BDI-II, and self-esteem was evaluated by using the Rosenberg scale. Patients were classified as active if they were engaged in studying, working, maternal leave or military service; and as passive, if they were unemployed or on disability pension.

Results: 80% of the patients were female, mean age was 23 years, and disease duration was approximately 15 years. Patients in the passive group participated less in leisure time non-physical activities (p =0.033), they felt more disturbed during their leisure time (p =0.010). Leisure time physical activity did not reveal statistically significant differences between the groups. The majority of the patients in the passive group (58%) had only basic education (p<0.001), they visited their doctor more frequently (p=0.019) and they used oral prednisolone more often (p<0.018). Approximately 70% of the patients received disease modifying antirheumatic drugs, and nearly half of the patients were treated with biologicals in both of the groups. Mean disability scores on HAQ were higher in the passive group (p=0.012). Depressive symptoms did not differ between the groups. Self-esteem was lower in the passive group (p=0.002). Results in health related quality of life revealed statistically significant differences between the groups: physical functioning (p=0.049), social functioning (p =0.020), and emotional well-being (p=0.047) were significantly lower in the passive group.

Conclusions: Patients being socioeconomically more passive showed higher degrees of disability, reporting lower physical functioning, self-esteem, emotional well-being, and social functioning. Those patients should be recognized earlier and activating interventions should be provided.

THU0516 LONGER TERM OUTCOMES OF CRMO IN A TERTIARY ADOLESCENT AND YOUNG ADULT RHEUMATOLOGY CENTRE IN THE UK

K.E.N. Clark, F. Josephs, N. Daly, Y. Ioannou, C.L. Murphy, D. Sen.
Rheumatology, University College London Hospitals, London, United Kingdom

Background: Chronic relapsing multifocal osteomyelitis (CRMO) is a rare autoinflammatory bone condition presenting primarily in children and adolescents. It characteristically affects the epiphysis and metaphysis of long bones, and presents with bony pain, local swelling and warmth.

Objectives: The aim of this study was to collate our tertiary adolescent rheumatology centre's experience of managing patients with CRMO, and establish their longer term outcomes, possible by the fact we have a cohort of patients with CRMO under long-term follow-up.

Methods: We carried out a retrospective case note review of all patients who are known to our service with a diagnosis of CRMO, presenting between age 13–20.

Results: In total 17 patients were identified as having CRMO, presenting between 1999 and 2015. 10 patients were female, and 7 patients male. The median age of initial symptoms, and age of presentation was 12 years (range1–16 years).

Median duration of follow up is 4.75 years (range 1–16.5 years). Since initial diagnosis, 3 patients evolved into a SAPHO (synovitis, acne, pustolosis, hyperostosis, osteitis) phenotype, 3 an ERA (enthesitis related arthritis) phenotype and 2 patients developed oligoarticular juvenile idiopathic arthritis (JIA).

35% of patients have a purely unifocal disease, and 65% have multifocal disease as confirmed by whole body MRI. 70.5% patients had recurrent episodes of inflammation, while 29.5% of patients had only one flare and then reached remission (either clinical or confirmed with MRI). 15 patients had their diagnosis confirmed with biopsy, while 2 did not due to site of disease. Their diagnosis is assumed based on clinic impression, and typical radiographic findings.

Sites of disease confirmed in our patients include lower limbs (70% patients), upper limbs (35% patients), clavicle (29.4%), mandible (17.6%) and spine/pelvis (23.5%).

All patients were treated with NSAIDs. In terms of treatments used since diagnosis, 76% patients have been on methotrexate (MTX), 47% had one infusion of pamidronate, and 23% required more than one infusion of pamidronate. Other medications include sulfasalazine (SSZ), azathioprine, risedronate and anti-TNFs (adalimumab, etanercept and infliximab).

On last clinic review, with or without imaging, 35% of patients continue to have active disease. Currently 29% patients are on MTX alone, 23% patients are on adalimumab and MTX, and 35% are only maintained on NSAIDS. Of those without active disease 5 patients (45%) are not on any DMARD or biologic therapy.

Conclusions: We present here our experience of managing adolescent patients with CRMO.

The perceived wisdom is that CRMO is a self-limiting disease which eventually goes into remission. However our centre's experience is that nearly 50% of our patients have a disease which evolves into another systemic autoimmune disease, mainly SAPHO, polyarticlar or enthesitis related JIA. Previous case series have suggested only 0–30% of patients' disease evolves. This may be a reflection of our older cohort of patients, who are only referred to our service with ongoing disease.

The majority of patients have a recurrent and multifocal course of disease. The most common site of disease was in the lower limbs. All patients were treated with NSAIDS, and a combination of DMARDS, bisphosphonates and biologic agents have been used, which has resulted in remission of disease in the majority of patients.

THU0517 LARGE VESSEL VASCULITIS IN INFANTS - A CASE SERIES

L. Das[1], J.H.T. Tan[1], X.C. Gao[1], S.F. Hoh[1], T. Arkachaisri[1,2]. *[1]Rheumatology and Immunology Services, Department of Paediatric Subspecialties, KK Women's and Children's Hospital; [2]Duke-NUS Medical School, Singapore, Singapore*

Background: Large vessel involvement following recrudescent or recalcitrant Kawasaki Disease or other vasculitidies in young children have been limited to few case reports and outcomes are still unclear.

Objectives: To describe and compare the characteristics and outcomes of 6 patients with large vessel vasculitis diagnosed between 2013 to 2015 in KK Hospital, Singapore

Methods:

Demographic and disease characteristic information were collected and median, interquartile range (IQR) & percentiles were used to describe the data.

Results: 6 patients were included in the analysis. Median age was 3.75 months

(IQR 3.75, 4). Other than 1 Filipino 2 year old girl (patient C), all other infants were of Chinese Singaporean origin and were less than age 1 year at onset; 4 male and 1 female. All patients were found to have multiple areas of irregular, thickened vessel walls with enhancement, involving the aorta and additional medium sized arteries on Magnetic Resonance Angiography (MRA).
Only patients C and F presented with prolonged fever and or less than 1 clinical feature of KD. C developed a unilateral enlarged lymph node on recrudescence of fever 1 month after the initial event. She was then found to have dilated CA (dCA) and consequently abnormal MRA. Other patients had significant KD Index scores and complete KD presentations.
Of the 4 patients who received only 1 dose of IVIG; C and F had diagnosis change from atypical KD to Takayasu Arteritis and G developed rhinovirus and then rotavirus as reason for prolonged fever. Patient A received IV steroids and then Infliximab. All patients received steroids. Patients A and B both developed a psoriasiform rash post-Infliximab which resolved on follow up.
Patient F and Patient B died 3 months and 17 months after diagnosis. Patient F, presented with fever, fussiness and enteritis aged 4 months. Her symptoms recurred 2 weeks after onset. Due to differential hypertension, she received an echocardiogram and subsequently MRA and cardiac catherization. Cause of death at age 7 months was small bowel perforation with arteritis and consequent intra-abdominal sepsis.
Patient B, presented with complete features of KD at age 2 months. His course was noted for recrudescence 2 weeks and 4 weeks after initial IVIG. He developed giant coronary aneurysms with abnormal MRA findings; developed myocardial infarction at age 8 months and proceeded to require a Left Ventricular Assist Device but died age 13 months from multi-organ failure.
3/6 (50%) developed aneurysms, D and F were giant. 4 surviving patients, had improvement in all vessels but continued activity in the aorta on follow up MRA, they remain on Methotrexate with no active clinical findings.

Table 1: Patient characteristics

ID	Hg# (g/DL)	WBC count (10^9/L)	Platelet count (10^9/L)	CRP (mg/L)	Time to initial MRA (weeks)	Follow up MRA (months)	Immunosuppression
A	10.8	11.3	357	130	2	20	ifx
B	8.9	24.76	595	178.4	4	8	ifx
C	9.9	15.34	532	64.4	4	8	mtx
D	9.6	26.23	270	108.3	2	died	n
E	8.6	19.99	750	175.2	1	died	ctx
F	11.7	18.54	497	142	4	6	ifx, mtx

#Hg Hemoglobin, IFX infliximab , MTX methotrexate, CTX cyclophosphamide

Conclusions: Extensive involvement of the systemic arteries and aorta in all patient were noted on initial MRA. Follow up imaging, showed improvement in all vessels. After 1 year of follow up, complete resolution occurred only in medium vessels.
Mortality in this patient cohort was 2/7 (28.6%).
This is an observational case series and our findings will need to be reproduced in larger groups of patients.

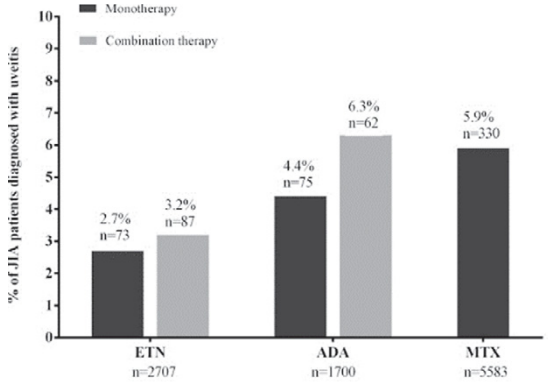
THU0518 BIOLOGICAL THERAPY IN NON-SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS PATIENTS FOLLOWED IN ADULT RHEUMATOLOGY DEPARTMENT: HUR-BIO REAL LIFE RESULTS

L. Kilic[1], A. Sari[1], B. Armagan[1], A. Erden[1], Ö. Karadag[1], A. Akdogan[1], S. Apras Bilgen[1], S. Kiraz[1], S. Ozen[2], U. Kalyoncu[1], A.I. Ertenli[1]. *[1]Department of Rheumatology; [2]Department of Pediatric Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disorder in childhood and more than one-third of patients have active inflammation during adult years that can cause disability.
Objectives: To define the demographic and clinical characteristics of non-systemic JIA (ns-JIA) patients under biological therapy followed in adult rheumatology department.
Methods: Hacettepe University Biologic Registry (HUR-BIO) is a single center biological registry since 2005. HUR-BIO database includes demographic and clinical characteristics of patients, disease activity parameters, history of articular prosthesis. The use of biological agents in routine rheumatology practice has been approved by the Ministry of Health since 2003.
Results: In this study, 95 (72.6% women) ns-JIA patients were included. The demographic and clinical characteristics of the patients were shown in the table. The first biological agents were; Etanercept (63.2%), adalimumab (16.8%), infliximab (12.6%) and the others 7 (7.4%). After a mean follow-up of 60 (48) months, 42 (44.2%) patients required biologic switch. The last visit HAQ scores of 75 patients were known and 16 (21.3%) patients had HAQ score $\geq$1.0 (female 15/54 vs. male 1/21, p=0.029). The last visit DAS-28 score of 72 patients was known and 46 (63.9%) patients had remission or low disease activity. 14 patients (14.7%) had history of articular prosthesis and were all female. Patients with history of articular prosthesis were older [39.1±10.1 vs. 29.6±10.3 years, p<0.0001], had longer disease duration [25.7±6.6 vs. 17.2±11.9 years, p=0.001] and had longer time until the biological therapy [19.6±8.4 vs. 11.5±11.6 years, p=0.002]. The time until the biological therapy of 38 ns-JIA patients diagnosed after 2003 was shorter [3.2±2.9 vs. 19.4±10.6 years, p<0.001].

Table 1. The Demographic and Clinical Characteristics of the ns-JIA Patients

	All Patients (n=95)	Female (n=69)	Male (n=26)	p
Age mean (SD)	31.0 (10.8)	32.2 (10.9)	28.0 (10.0)	0.025
Age at first symptom, mean (SD)	9.9 (5.0)	9.5 (4.0)	10.9 (4.9)	0.22
Age at diagnosis, mean (SD)	12.5 (6.7)	12.3 (7.3)	13.2 (4.5)	0.62
Disease duration (year), mean (SD)	18.5 (11.6)	19.9 (11.2)	14.6 (12.1)	0.012
Time until the biological therapy (year) mean (SD)	12.7 (11.5)	14.2 (11.5)	8.7 (11.0)	0,01
History of hip or knee prosthesis, n (%)	14 (14.7)	14 (20.3)	0	0.01
RF or anti-CCP (+), n (%)	42 (44.2)	34 (49.3)	8 (30.8)	0.11
Biological switch, n (%)	42 (44.2)	32 (46.4)	10 (38.5)	0.64
Last visit HAQ mean (SD)	0.51 (0.62)	0.62 (0.67)	0.22 (0.35)	0.005
Last visit DAS-28 mean (SD)	2.85 (1.56)	3.14 (1.47)	2.18 (1.59)	0.009



RF: romatoid factor, CCP: cyclic citrillinated peptide, ns-JIA: non-systemic JIA, HAQ: Health Assessment Questionnaire, SD: Standard deviation.

Conclusions: Structural damage and history of articular prosthesis was more common in female ns-JIA patients receiving biological therapy. Functional disability and disease activity were also higher in female patients. On the other hand, the follow-up ns-JIA patients had a good level of remission and low disease activity.The shorter duration until the time of biological treatment in patients diagnosed after 2003 indicates that both pediatric and adult rheumatologists have begun to treat these patients more effectively.

THU0519 ETANERCEPT, ADALIMUMAB AND METHOTREXATE UTILIZATION BY JUVENILE IDIOPATHIC ARTHRITIS PATIENTS AND THE OCCURRENCE OF UVEITIS

K. Roshak[1], J.M. Sopczynski[2], R.M. Suehiro[3], L. Marshall[3]. *[1]Drexel University, Philadelphia; [2]R&d Bt Bi, Predictive Informatics; [3]Medical Affairs, Pfizer, Collegeville, United States*

Background: Juvenile idiopathic arthritis (JIA) is a chronic arthritis with an onset before 16 years of age, that persists for at least 6 weeks, and has an unknown etiology.[1] Uveitis is a serious and common extra-articular manifestation of JIA, affecting 12–30% of patients (most commonly female with ANA+ oligoarthritis JIA category).[2,3] JIA-associated uveitis can be treated with biologic disease modifying antirheumatic drugs (bDMARDs), including TNF inhibitors (TNFi) such as etanercept (ETN), infliximab (IFX), and adalimumab (ADA), after failure of first-line treatments, such as topical corticosteroids and/or conventional synthetic DMARDs (csDMARDs), such as methotrexate (MTX).[2] Of note, reports exist that ETN use has been associated with uveitis flares or new-onset uveitis while an observational study reported similar uveitis flare rates for both ADA and ETN.[4,5]
Objectives: To conduct an analysis on the occurrence of uveitis in patients with JIA treated with ETN, ADA, or MTX. Combination therapy of ETN, ADA, and MTX was also assessed.
Methods: International Statistical Classification of Diseases (ICD)-9 diagnosis codes in a Truven MarketScan® claims database were used to identify JIA patients diagnosed with uveitis over a 5-year interval. The analysis assessed the proportion of JIA patients (aged 0–19 years) treated with ETN, ADA, or MTX, as monotherapy or in combination. The percentage of patients diagnosed with uveitis and the time interval for uveitis diagnosis in patients with JIA was determined.
Results: A total of 22,789 patients with JIA where included in this analysis and exhibited a mean age of 11.4 years, were predominantly female (69%), and mean JIA disease duration was 3 years. This total included 19,814 patients with chronic, or not otherwise specified, polyarticular JIA. A total of 2581 (11.3%) patients, of mean age 10.2 years, of which 73% were female, were diagnosed with uveitis. The numbers of JIA patients receiving biologic and/or MTX therapy and proportions with a uveitis diagnoses are shown in the Figure.
Conclusions: This analysis showed a similar occurrence of uveitis in JIA patients treated with ETN or ADA, either as monotherapy or in combination with MTX.

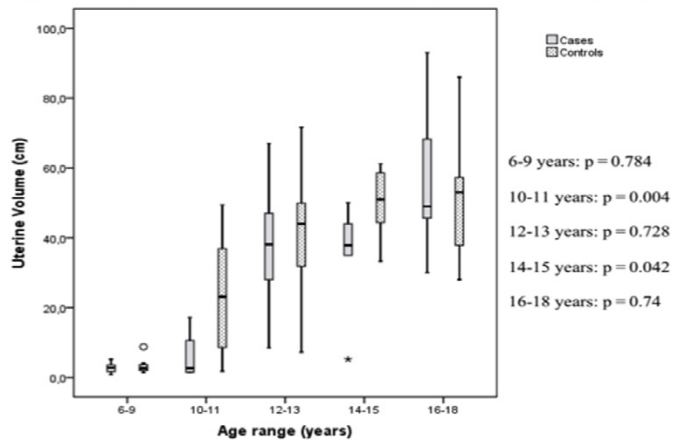
THU0520 PELVIC ULTRASOUND IN THE ASSESSMENT OF SEXUAL MATURITY IN GIRLS WITH JUVENILE IDIOPATHIC ARTHRITIS

L.M. Gonçalves[1], S.H. Machado[2], R.M. Xavier[3], P.J.C. Maróstica[4], C. Kopacek[5], I.R.S. Lucena[6]. *[1]Student, PUCRS; [2]Pediatrics rheumatology, HCPA; [3]Rheumatology service; [4]Pediatrics service, Hcpa/UFRGS; [5]Endocrinology service, HCSA; [6]Radiology service, HCPA, Porto Alegre, Brazil*



Background: Delayed puberty is common in children with chronic illnesses such as Juvenile Idiopathic Arthritis (JIA),especially in cases with an earlier age of onset.Its etiology is multifactorial and includes low weight,complications arising from the disease itself and the adverse effects of treatment.
Objectives: To compare uterine and ovarian size as well as artery pulsatility between girls with juvenile idiopathic arthritis (JIA) and healthy participants using abdominal pelvic ultrasound,and identify these findings and pubertal staging,sex hormones and disease characteristics in girls with JIA.
Methods: This study involved 44 girls with JIA and 59 healthy controls aged between six and 18 incomplete years.Pelvic ultrasound was used to determine uterine volume and length,the corpus/cervix ratio,ovarian volume and length,and the pulsatility index (PI) of uterine arteries.Hormone levels were also measured in girls with JIA.
Results: All US parameters were associated with Tanner stages in the control group ($p<0.001$).Uterine and ovarian measures were smaller in girls with JIA than in the control group.The mean PI of uterine arteries was higher in girls with JIA.Comparisons by age group revealed that uterine volumes were smaller in girls with JIA aged between 10 and 11 years (p=0.004) and 14 to 15 years (p=0.042),and the corpus/cervix ratio was smaller in girls aged 10 to 11 years (p=0.007).US measures were not associated with disease factors in the JIA group.LH and estradiol levels were found to be positively associated with ovarian and uterine size ($p<0.001$),but negatively correlated with the mean PI of uterine arteries ($p<0.01$).
Conclusions: Pelvic US is a sensitive method for the assessment of sexual maturation in girls,and can identify developmental delays in girls with JIA which may not be detected by Tanner staging.

Table 1. Comparison of abdominal pelvic US findings between control participants and patients with JIA

Variables*	Patients (n=?44)	Control participants (n=?59)	p
Uterine volume (cm^3)	10.5 (2.4–40)	36.6 (8.8–50.9)	0.009
Uterine length (cm)	4.92±1.83	5.91±1.80	0.008
Corpus to cervix ratio (cm)	1.18±0.25	1.36±0.27	0.001
Endometrium (mm)	1.4 (0–5.2)	5.4 (1.4–7.2)	0.016
Left Ovarian Length (cm)	2.60±0.69	3.04±0.84	0.006
Left Ovarian Volume (cm^3)	3.3 (1.5–5.2)	5.0 (3.0–7.1)	0.004
Right Ovarian Length (cm)	2.79±0.71	3.17±0.75	0.013
Right Ovarian Volume (cm^3)	2.9 (1.5–6.3)	5.9 (3.0–9.1)	0.006
Mean uterine PI	4.6 (2.7–6.5)	2.5 (1.9–5.1)	0.025

PI, pulsatility index. *Described as median (25th-75th percentile) or mean ± standard deviation.

Figure 1 – Comparison of uterine volume between groups across different age ranges

Conclusions: Pelvic US is a sensitive method for the assessment of sexual maturation in girls,and can identify developmental delays in girls with JIA which may not be detected by Tanner staging.

THU0521 ENTHESITIS-RELATED ARTHRITIS: NON-PERIPHERAL PATTERN IS ASSOCIATED WITH TH17 CELLS

M. Katsicas, C. Carrara, A. Bernasconi, J. Rossi, R. Russo. *Immunology & Rheumatology, Hospital de Pediatría Garrahan, Buenos Aires, Argentina*

Background: Enthesitis-related arthritis (ERA) is a category of juvenile idiopathic arthritis. Different proinflammatory cytokines linked to the Th1 and Th17 T- cell subsets have been implicated in its pathogenesis. Limited data are currently available about the relationship between disease activity and the clinical pattern and the percentage of Th1and Th17 T- cell subsets.
Objectives: To analyze Th1 and Th17 cell subsets in patients with ERA and to compare with age-matched healthy controls. To assess the association between disease activity and disease clinical pattern with Th1and Th17 cells subsets
Methods: Patients with ERA (according to ILAR criteria) were included in a cross sectional study. Disease activity measures were collected in random visits: active joint count (AJ), pain score (0–10), presence of active enthesitis (AE), sacroiliac pain (SIP), lumbar pain (LP),lumbar limitation (LL) by Schöber's test, wellbeing according to the patient using a visual analogue scale (VASp, 0–10), disease activity according to the physician (VASphy, 0–10), JADAS-10, JSpADA, and ESR/CRP were evaluated. Patients were classified based on the disease pattern (peripheral and non-peripheral) depending on the presence or absence of AJ and/or AE. Functional capacity was also assessed by CHAQ. Presence of radiologic sacroiliitis (MRI/X-rays) and treatment with TNF inhibitors (TNFi) were recorded. Th-17 and Th-1 cells were quantified by flow cytometry in PBMCs stimulated with PMA/IO. Age-matched healthy children without disease or medication were recruited as normal control. Comparison between groups (Mann-Whitney Utest) and correlation tests as appropiate
Results: Twenty-nine patients (90% M) fulfilled inclusion criteria. HLA-B27 was positive in 13 (45%). Median age at observation was 12 years and median disease duration was 2.1 years. Activity and functional measures were (medians): AJ 1, pain 0.25, VASp 0.5, VASphy 1, JADAS-10 7, JSpADA 1.75, ESR 15 mm/h, and CHAQ $\geq$0,5=8 patients (27%). AE was present in 1 (3%), SIP in 7 (24%), LP in 6 (21%), and LL in 12 (41%) children. Nineteen (65%) patients showed JADAS >1 and 21 (76%) JSpADA>0. Radiologic sacroilitis was recorded in 21 (72%) children. Fourteen (48%) patients were treated with TNFi. Th1cell percentage in ERA was 8.5±3.4% (range, 4–17.4) while healthy controls was 5.8±3.8% (range, 1.2–14.2), p=0.023. Th17cell% in ERA was 0.90±0.44 (range, 0.39–2.34%) while controls was 0,55±0.38 (range, 0,17–1,61%); p=0.004. There was no difference between T-cells% and active/inactive disease. Eighteen (62%) children showed peripheral pattern, while 11 (38%) exhibited non-peripheral. Peripheral and non-peripheral groups showed Th17%cells 0.90 (0.39–1.74) vs 1.14 (0.64–2.44) respectively (p=0.018).Significant correlations were Th1 with AJ (r=0.45 p=0.004) and Th17with LP (r=0.83 p=0,0001), LL (r=0.47 p=0.03).
Conclusions: Th1 and Th17 cells subsets were significantly higher in ERA compared with healthy controls. However, T-cells showed no significant difference between patients with active versus inactive disease. Interestingly, non-peripheral pattern showed higher Th17% cells respect to patients with peripheral disease.Our results suggest that Th17 evaluation could help identify different phenotypes that benefit from Th-17 blocking strategies.

THU0522 CORRELATION BETWEEN SERUM CALPROTECTIN (MRP8/14), CLINICAL AND ULTRASOUND ASSESSMENT IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

M. Romano, V. Gerloni, M. Gattinara, O. De Lucia, P.L. Meroni. *Rheumatology, G.Pini Istitute, Milan, Italy*

Background: MRP8/14 (also known as calprotectin) has been widely studied as

potential predictor of disease activity and response to treatment in inflammatory diseases. In Juvenile Idiopathic Arthritis (JIA), MRP8/14 levels are highly predictive of disease flares in systemic JIA. In a more heterogeneous group of JIA patients (pts), MRP8/14 levels have been shown to predict response to MTX. High levels of baseline MRP8/14 are associated with good response to anti-TNF treatment, whereas elevated MRP8/14 levels at time of discontinuation are associated with higher chance to flare. In clinical practice, ultrasound could be usefull to define the state of disease activity. Indeed, PD-US assessment of synovial vascularization has been shown to be more sensitive than serum markers of inflammation in the identification of active disease in JIA.

Objectives: To explore the association between calprotectin, clinical and US assessment in JIA pts.

Methods: A total of 30 consecutive pts (aged under 18 years) with oligo or poly JIA were assessed by US, clinical examination and MRP8/14 serum levels. Serum MRP8/14 was measured by ELISA in all pts and in 20 age matched healthy controls. Ultrasonographic B-mode and power Doppler assessment of 44 joints each pts were performed. Patients were evaluated using Wallace criteria.

Results: 30 consecutive non systemic JIA pts (F 18) were evaluated: 13 persistent and 8 extended oligoarticular, 6 polyarticular (1 RF positive), 2 ERA, 1 psoriatic JIA. Median age at disease onset was 10.6 yrs (mean 10.8, range 2–16). Mean disease duration was 5.4 yrs (range 0.1–15.9). Mean active joints was 2 (range 0–26). 14 pts were active according to Wallace criteria and 16 pts were active according to US evaluation. Ultrasonographic B-mode and power Doppler assessment was significantly correlated with clinical examination (Mcnemar test p=0.683, Cohen's K 0.602). The majority of our enrolled pts were in phase of oligoarticular involvement with minimal disease activity (median active joints=0). No statistically significant difference in serum MRP8/14 was found between all JIA pts and healthy controls (p=0.33). No statistically significant difference in serum MRP8/14 was found between active (according to clinical examination) JIA pts and healthy controls (p=0.69) and between inactive JIA pts and healthy control (p=0.23). Concentrations of MRP8/14 in active and inactive pts according to Wallace were not significantly different (p=0.75). No statistically significant difference in serum MRP8/14 was found between active and inactive pts according to US assessment (0.85). Only 6 pts (4 out of 6 with polyarticular course) showed calprotectin levels higher than normal. We found a correlation between calprotectin and CRP (Spearman r 0.4380, p=0.01) and between calprotectin and ESR (Spearman r 0.3800, p=0.05).

Conclusions: To our knowledge this is the first study to examine the correlation between MRP8/14 levels, clinical and US assessment in JIA. Serum levels of MRP8/14 (a biomarker of activation of the innate immune system) are not significatively different in oligoarticular JIA from healthy controls. Calprotectin high levels, could be related with a poliarticular disease either in clinical activity or in subclinical remission. However our study need to be extended to a larger number of pts followed prospectively.

THU0523 MORTALITY AND CAUSES OF DEATH AMONG JUVENILE IDIOPATHIC ARTHRITIS PATIENTS IN FINLAND

M. Kyllonen [1,2], H. Kautiainen [3], K. Puolakka [4], P. Vahasalo [1,5]. *[1] Pedego Research Unit, Oulu University; [2] Internal Medicine, Oulu University Hospital, Oulu; [3] General practise and Primary health care, Helsinki University, Helsinki; [4] South Karelia Central Hospital, Lappeenranta; [5] Pediatrics, Oulu University Hospital, Oulu, Finland*

Background: Juvenile idiopathic arhritis (JIA) is an inflammatory arthritis that begins before 16 years of age and persists more than 6 weeks. The prevalence of JIA is approximately 1 to 2 per 1,000 children. Only 40–60% of JIA patients had inactive disease at follow-up (1).

An increase rate of mortality has been observed in JIA. A follow-up study (1960–1993) in the United States reported early deaths especially in systemic JIA (2). The same was found in an follow-up study in Scotland (3). However two follow -up studies in United States and one study in Germany showed no increased mortality (4,5,6).

Objectives: To explore mortality rates and causes of death in JIA patients in Finland compared with the general population.

Methods: All incidents patients with JIA during 2000–2014 were collected from the nationwide register of special reimbursements for disease-modifying antirheumatics drugs, maintained by the Social Insurance Institution of Finland. The National Population Registry identified three age, sex and residence matched controls for each case. Death certificate data up to 2015 were obtained from the Statistics of Finland.

Results: Altogether 4,180 JIA patients (62% girls) were identified. Mean age at diagnosis was 8.3 years. The average follow-up was 6.6 years (IQR 3.1–10.5). These patients were compared with 12,511 controls.

During 28.941 follow-up years, 11 JIA patients (6 girls, 5 boys) and 23 controls (12 girls, 11 boys) died.

Mean age at death was 20.3 years (range 11–30) in the JIA patients and 23.1 years (range 9–29) years in the control group. (p=0.17).

Cumulative mortality in the patients with JIA was 0.4% (95% CI 0.2–0.8%) compared to 0.3% (95% CI 0.2–0.5%) in the controls, hazard ratio was 1.44 (95% CI 0.70–2.95).

Accidents were the most common (54%) cause of death in the patients with JIA, but suicide (39%) in the controls. Alcohol, drug abuse and depression contributed more to deaths in the control (39%) than in JIA group (1%), p=0.053.

Conclusions: Juvenile idiopathic arthritis is not associated with a higher mortality rate in children and young adults.

THU0524 VITAMIN D DEFICIENCY AND RISK FOR CARDIOVASCULAR DISEASE IN JUVENILE IDIOPATHIC ARTHRITIS

M.H. Abu-Zaid [1], A.M. El-Barbary [1], R.A. Gaber [2], H.H. Abdelnabi [3]. *[1] Rheumatology and Rehabilitation, Faculty of Medicine Tanta University Egypt; [2] Biochemistry; [3] Pediatric, Faculty of Medicine Tanta University, Tanta, Egypt*

Background: Vitamin D is not a classic vitamin but rather a prohormone which converted primarily in the liver into its major circulating form, 25-hydroxy-vitamin D [25(OH) D]. Serum levels of vitamin D have been found to be low in juvenile idiopathic arthritis (JIA) as in several autoimmune diseases [1]. There are some evidences of an association between serum vitamin D and cardiovascular disease risk [2].

Objectives: To assess the association between serums levels of 25-hydroxy-vitamin D and cardiovascular disease risk factors in juvenile idiopathic arthritis

Methods: A prospective cross-sectional study was done on 30 patients with JIA according to the criteria of the International League of Associations for Rheumatology (ILAR) and 30 healthy volunteers matched for age and gender. Patients with other causes of dyslipidemia or those whom receiving vitamin D supplements or lipid-lowering medications were excluded from this study.

Systolic and diastolic blood pressure was measured to all patients and controls

Also; all patients and controls underwent laboratory tests of plasma 25(OH)D, Serum High-Density Lipoprotein (HDL), Low-Density Lipoprotein cholesterol (LDL). Echocardiography, carotid intima media thickness (cIMT), flow mediated dilatation of the brachial artery (FMD) also was done to all patients and controls.

Vit D levels were then correlated in each subgroup with the other clinical, laboratory and radiological parameters. We predefined Vit D insufficiency as being $<$50 nmol/l and Vit D deficiency as being $<$25 nmol/l.

Results: The mean serum vitamin D levels of all patients were 23.8 nmol/l ±16.59. Only 7patients (23.3%) have adequate vitamin D levels (50–75 nmol/l). While Vitamin D insufficiency (serum vitamin D: 25 – 50 nmol/l) and deficiency (serum vitamin D level $<$25 nmol/l) were found in 9 (30%) and 14 patients (46.7%), respectively. JIA patients had significantly lower vitamin D levels as compared to controls ($p<0.01$). JIA patients had higher systolic and diastolic blood pressure than controls although these differences were not statistically significant ($p>0.05$) and all levels were still in normal values. Subjects with vitamin D deficiency or insufficiency had significantly lower values for HDL cholesterol and significantly elevated values for LDL cholesterol as compared to controls and patients with adequate vitamin D levels, with significant positive correlation between 25(OH)D and HDL cholesterol, and significant inverse correlation between 25(OH)D and LDL levels.

Patients with lower levels of vitamin D had significantly higher cIMT and lower FMD ($p<0.01$) With significant positive correlation between 25(OH)D and FMD, and significant inverse correlation between 25(OH)D and cIMT, while there were no significant differences in echocardiography results.

Table 1

Vit D levels	HDL	LDL	cIMT	FMD
	r=0.8493	r= -0.6032	r= -0.6616	r=0.8527

Conclusions: Vitamin D deficiency is a cardiovascular risk factor in juvenile idiopathic arthritis.

THU0525 SAFETY OF ADALIMUMAB ± METHOTREXATE FOR THE TREATMENT OF POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS (PJIA): STRIVE REGISTRY

N. Ruperto[1], H. Brunner[2], K. Nanda[2], M. Toth[2], I. Foeldvari[1], J. Bohnsack[2], D. Milojevic[2], C. Rabinovich[2], D. Kingsbury[2], K. Marzan[2], P. Quartier[1], K. Minden[1], E. Chalom[2], G. Horneff[1], R. Kuester[1], J. Dare[2], M. Bereswill[3], J. Kalabic[3], H. Kupper[3], A. Martini[1], D. Lovell[2]. *[1]PRINTO-IRCCS Gaslini, Genova, Italy; [2]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, United States; [3]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany*

Background: JIA is the most common chronic inflammatory rheumatic disease of childhood. TNF inhibitors are used for long-term control of pJIA disease.
Objectives: To evaluate the 7 year (y) safety of Adalimumab treatment with or without methotrexate (ADA±MTX) when used in current clinical practice for treatment of patients (pts) with active pJIA.
Methods: This is a 7 y interim analysis of an ongoing, multicenter, non-interventional, observational registry of pts with pJIA with up to10 y safety follow-up. Included pts were treated with ADA±MTX or MTX alone as comparison arm according to routine clinical care in PRINTO/PRCSG centres in EU, USA and Australia. MedDRA observational adverse events (AEs) were recorded from 1st day in the registry through last contact, irrespective of duration of registry treatment.
Results: In January 2014, enrollment was complete. As of June 1, 2016 cut-off date, 838 pts (301- MTX arm and 537 - ADA±MTX arm) were treated in the registry. There were 39 pts who rolled over from MTX to ADA±MTX arm. At registry entry mean pJIA disease duration was 1.3 y and 3.7 y and mean AJC71 was 5.8 and 5.2 for MTX and ADA±MTX arms, respectively. CHAQ disability index was 0.6 for both arms. Mean duration of study drug exposure in registry was 2.0 y (range: 0.0 – 7.1) and 2.5 y (range: 0.0 – 7.9) for MTX and ADA±MTX arms, respectively. Mean duration of observation in registry was 3.9 y (range: 0.0 – 7.2) and 3.5 y (range: 0.0 – 7.9) for MTX and ADA±MTX arms, respectively. Overall, 213 pts (70.8%) in MTX and 225 pts (41.9%) in ADA±MTX arms discontinued registry drug through 7 y. Main reasons (not exclusively) for registry drug discontinuation for MTX arm: pts required additional therapy (32.6%), other (13.3%), lack of efficacy (11.6%), AEs (9.3%), or pts achieved JIA remission (8.6%); for ADA±MTX arm: lack of efficacy (17.9%), other (7.3%), lost to follow-up (5.6%), AEs (5.4%), or pts achieved JIA remission (5.0%). Frequencies and rates of treatment-emergent AEs (from 1st dose date of registry drug in registry up to last dose + 70 days in registry, excluding AEs occurring during treatment interruption) were similar to those reported for observational AEs (from 1st day in registry up to last contact irrespective of drug treatment duration) (Table). Rate of serious infections was similar between MTX and ADA±MTX arms. One pt (0.2%) reported an event of opportunistic infection (fungal oesophagitis) in ADA±MTX arm. No reports of deaths, malignancies, active tuberculosis, oral candidiasis, demyelination, or congestive heart failure.

Table. Overview of the Observational Adverse events

	MTX		ADA±MTX			
			ADA only		ADA + MTX#	
	N=301 n (%)	PYs=1170.3 E (E/100 PYs)	N=160 n (%)	PYs=517.0 E (E/100 PYs)	N=377 n (%)	PYs=1338.5 E (E/100 PYs)
Any AE	157 (52.2)	505 (43.2)	66 (41.3)	216 (41.8)	178 (47.2)	553 (41.3)
AE at least "possibly drug related" per the investigator	87 (28.9)	197 (16.8)	30 (18.8)	66 (12.8)	88 (23.3)	177 (13.2)
Severe AE	17 (5.6)	23 (2.0)	14 (8.8)	22 (4.3)	25 (6.6)	41 (3.1)
Serious AE	32 (10.6)	52 (4.4)	21 (13.1)	39 (7.5)	56 (14.9)	95 (7.1)
AE leading to discontinuation of study drug or study	28 (9.3)	36 (3.1)	13 (8.1)	19 (3.7)	25 (6.6)	40 (3.0)
Infectious AE	87 (28.9)	179 (15.3)	38 (23.8)	75 (14.5)	105 (27.9)	187 (14.0)
Serious infectious AE	14 (4.7)	17 (1.5)	6 (3.8)	8 (1.5)	22 (5.8)	30 (2.2)
Injection site-related AE	6 (2.0)*	8 (0.7)	5 (3.1)	6 (1.2)	24 (6.4)	32 (2.4)

E, events; PYs, patient years (Observation time irrespectively of study drug treatment duration). *3 patients experienced injection site-related AEs with etanercept injections. During the registry, 52 (17.3%) pts in MTX arm and 45 (8.4%) pts in ADA arm started with a biologic DMARD. #MTX was used at any point of time during the course of the registry.

Conclusions: Overall, ADA±MTX was well-tolerated in these pts with pJIA with no new safety signals. The retention rate for registry drug was higher in ADA±MTX arm compared to MTX arm.

THU0526 SHORT AND LONG-TERM FOLLOW-UP OF TOCILIZUMAB FOR SEVERE JUVENILE IDIOPATHIC ARTHRITIS-ASSOCIATED UVEITIS

N. Vegas-Revenga[1], V. Calvo-Río[1], M. Santos-Gómez[2], I. Calvo[3], M. González-Fernández[3], B. López-Montesinos[3], M. Mesquida[4], A. Adan[4], M. Hernández[4], O. Maíz[5], A. Atanes[6], B. Bravo[7], C. Modesto[8], G. Díaz-Cordovés[9], N. Palmou-Fontana[1], J. Loricera[1], M. González-Vela[1], R. Demetrio-Pablo[1], L. Domínguez-Casas[1], C. Fernández-Díaz[1], J. Hernández[1], M. González-Gay[1], R. Blanco[1]. *[1]HUMV, Santander; [2]H, Torrelavega; [3]H Fe, Valencia; [4]H Clinic, Barcelona; [5]H, Donostia; [6]HUAC, A Coruña; [7]H Nieves, Granada; [8]H V d'Hebron, Barcelona; [9]H, Málaga, Spain*

Objectives: To assess the efficacy of tocilizumab (TCZ) at short and long term follow-up for severe juvenile idiopathic arthritis-associated uveitis.
Methods: Multicentre study of 25 patients who had inadequate response to traditional treatment with corticosteroids and at least one conventional immunosuppressive drug including biological therapy. The outcome variables were the degree of inflammation, visual acuity and macular thickness. The results are expressed as mean±SD for normally distributed variables, or median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.
Results: We studied 25 patients (21 women/4 men); mean age 18.6±8.3. Uveitis was bilateral in 22. JIA subsets were oligoarthritis (n=17), polyarthritis (5), psoriatic (2) and enthesitis-related arthritis (1). Ocular sequelae at TCZ onset were cataracts (13), glaucoma (7), synechiae (10), band keratopathy (12), maculopathy (9), and amblyopia (5). Pattern of uveitis was: anterior (17), panuveitis (4), intermediate (2) and posterior (2). Before TCZ, they had received corticosteroids, conventional immunosuppressive drugs and biologics, including adalimumab (24), etanercept (8), infliximab (7), abatacept (6), rituximab (2), anakinra (1), and golimumab (1). TCZ dosage regimen was 8 mg/kg IV/4 weeks (21), every 2 weeks (2), every 8 weeks (1), or 2.9 mg/kg sc every week (1). All outcome variables showed a rapid and maintained improvement (Table 1) after

Abstract THU0526 – Table 1

	Baseline	1st week	2nd week	1st month	3rd month	6th month	1st year	2nd year	3rd year
Visual acuity mea±SD	0.57±0.35	0.55±0.35	0.56±0.35	0.59±0.33	0.6±0.32*	0.63±0.32*	0.63±0.35*	0.59±0.32*	0.45±0.34*
Anterior chamber cells median [IQR]	1 [0–1]	0.75 [0–1]*	0.5 [0–1]*	0 [0–0.5]*	0 [0–0]*	0 [0–0]*	0 [0–0]*	0 [0–0]*	0 [0–0]*

*p<0.05 compared with basal.

a follow up of one year (n=21), 2 years (n=11), and 3 years (n=5). A reduction in the daily median dose of prednisone from 10 mg [0–15 mg] to 0 [0–0 mg] in 3 years, ($p<0.05$) was observed. After a median follow-up of 20.5±11.7 months in 4 patients, the interval between TCZ doses was increased to 5 weeks (n=2), 6 weeks (1) and 7 weeks (1) because of remission. TCZ had to be withdrawn due to articular inefficiency (1) or articular and ocular inefficiency (1). The main adverse effects were severe autoimmune thrombocytopenia, autoimmune anemia and thrombocytopenia, pneumonia, viral conjunctivitis and bullous impetigo in 1 patient each.

Conclusions: TCZ is useful at short and long term follow-up for severe Juvenile Idiopathic Arthritis-associated uveitis. It is possible to optimize the TCZ dose.

THU0527 PEDIATRICIAN AND ADULT RHEUMATOLOGIST COLLABORATING IN A MULTIDISCIPLINARY REUMA-PED CLINIC. IS THIS TRANSITIONAL CARE MODEL EFFECTIVE?

P. Collado[1], A. Rubio[1], R. Diaz-Delgado[2], C. Calvo[2], R. Mustienes[1], F. Rey[1], C. Bonilla[1], E. Cruz[1]. *[1]Rheumatology; [2]Pediatric, Hospital Universitario Severo Ochoa, Madrid, Spain*

Background: Transitional care should be a planned movement of adolescents with chronic diseases from child-centred to adult-oriented health care system. Recently a EULAR/PReS taskforce has developed the first international set of recommendations and standards for transitional care[1].

Objectives: To describe the results from a specific transitional care programme.

Methods: The current transitional care programme includes a multidisciplinary PED-REUMA clinic (MPRC) weekly and a non-defined period of rheumatologic follow-ups by the same rheumatologist of MPRC. The transitional care team is composed of two pediatricians, one adult rheumatologist -as transition coordinator-, a clinical nurse specialist and administrative support, as well as a psychologist and physiotherapists. Clinical information and therapies were collected throughout the disease course, and the HEADSS method of psychosocial interviewing has been included recently.

Population of the present study included young patients (YP) from that programme who are going to transfer to adult-oriented health care system. Descriptive study of socio-demographics and clinic features was included, as well as patients' adherence. YP confidence to be transferred and satisfaction with the current transitional process were measured using on a scale of 0 to 10. In patients suffering from juvenile idiopathic arthritis (JIA), clinical status of disease activity and clinical remission and CHAQ were tested before transfer.

Results: Twenty-seven YP with female predominance (63%) were included. The average age was 21±3 yo at time of a planned transfer and 16±3.4 yo at inclusion to the MPRC. JIA was the commonest condition whereas dermatomyositis was uncommon. Up to 63% patients required some DMARDs during the MPRC follow-up, but only a 37% needs maintained immunosuppressive therapies and three (11%) patients required changing the therapeutic target before transfer. YP adherence to rheumatologist appointments was high. Regarding HEADSS data: most YP were students and living at family home, around 50% gave up sports or other activities due to homework or exams, 29% of YP occasionally drank some alcohol but none used tobacco, and 47% of YP felt sad or down once in a while. Patient's confidence to be transferred was 7.7±2.1 (mean±SD; min-max: 2–10). YP showed high satisfaction with the current transitional process, 9.7±0.4 (min-max: 9–10).

Before transfer, 17 patients with JIA showed a mean±SD value of JADAS10 of 2±5 (min-max, 0–18), clinical remission on/off medication was 23% and 53% respectively. Mostly functional status reported by patient was low, YP-rated CHAQ (mean 0.06; min-max, 0.0–0.75).

Conclusions: To the best of our knowledge, this is the first study evaluating a Spanish transitional care programme. The study reports a positive impact across adolescence of our transitional care model in a real life situation. Implementation of recommendations depended on the local available resources.

THU0528 STING-ASSOCIATED VASCULOPATHY WITH ONSET IN INFANCY (SAVI): A DIFFERENTIAL DIAGNOSIS OF INFLAMMATORY INTERSTITIAL LUNG DISEASE

R. Dagher[1], R. Ghiye[1], G. Nicolas[1], H. Feghali[1], M.C. Fadous Khalife[1], L. Seabra[2], Y.J. Crow[2]. *[1]Pediatrics, Notre Dame de Secours University Hospital, Byblos, Lebanon; [2]Paris-Descartes University, Sorbonne-Paris-Cite, Institut Imagine, INSERM UMR 1163, Paris, France*

Background: STING-Associated Vasculopathy with onset in Infancy (SAVI) is an auto-inflammatory monogenic disease. SAVI is caused by an upregulation of type I interferon signaling due to sporadic or inherited gain-of-function mutations in the STimulator of INterferon Gene (STING)/Transmembrane Protein 173 (*TMEM173).* The first description of this phenotype, and the identification of the mutated gene, was in 2014. SAVI is characterized mainly by cutaneous vasculopathy leading to necrotic lesions, and progressive interstitial lung disease with secondary fibrosis.

Objectives: SAVI is a rare disease with unknown prevalence. To the best of our knowledge, 25 cases have been reported so-far. These patients variably manifest cutaneous lesions and inflammatory lung disease. Here we present a case of SAVI with onset of features at the age of 3 years.

Methods: A now 8 year old boy born to non-consanguineous parents was described to have experienced recurrent fevers, polyarthralgia and polyarthritis, livedo of the limbs, facial telangiectasia, necrotic lesions of auricles and digits and failure to thrive since the age of 3 years. He has normal cognitive development. His familial history is notable for epilepsy in 2 of his siblings and Behcet disease in a paternal cousin.

Laboratory tests at age 6.5 years revealed increased ESR (60mm/h) while CRP varied from 3 to 14 mg/L. ANA titres were positive (1/640), with normal complement level and negative anti-DNA. c-ANCA and p-ANCA were negative. ECA and lysozymes were in the normal range. Although the child had no respiratory symptoms, chest X-ray revealed diffuse interstitial parenchymal infiltrates. Chest angio-CT showed ground-glass lesions with fibrotic bands and mediastinal and para-hilar adenopathies. FVC and DLCO were reduced on pulmonary functional testing. Lung biopsy was not performed.

Empirical treatment with pulse and oral corticosteroids along with azathioprine was started. Over a period of one year, systemic inflammation and skin involvement regressed dramatically, but his lung disease showed no improvement.

Results: Genetic testing identified a previously reported V155M mutation in *TMEM173*.

Conclusions: SAVI is associated with significant morbidity and mortality. The diagnosis should be considered in children with interstitial lung disease after more common causes have been ruled out. Steroids and immunosuppressive therapies apparently show no efficacy in avoiding progression to irreversible lung damage. Promising results with treatment by Janus Kinase inhibitors as a means of blocking signaling downstream of the type I interferon receptor were recently published.

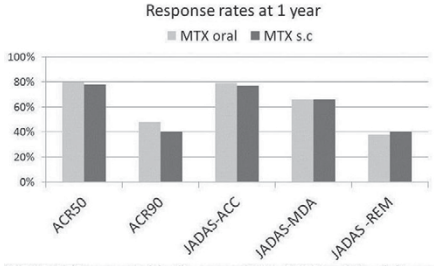
THU0529 METHOTREXATE TREATMENT RESPONSE IN NON-SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

R. Bakry, G. Horneff. *Asklepios, Sankt Augustin, Germany*

Background: Methotrexate is approved and recommend as first line disease modifying antirheumatic drug (DMARD) in polyarticular juvenile idiopathic arthritis (JIA). In can be used orally or via s.c. injection.



Objectives: S.c MTX is thought to be more efficious or act more rapidly than oral MTX. Thus we want to analyse the kinetic of response in JIA patients treated with oral versus s.c. MTX.

Methods: In the German BIKER registry a cohort of biologics naïve JIA patients starting treatment with MTX was built. The data bank was screened for patients treated with MTX orally vs. s.c for the first time. The JIA-ACR 90 and the JADAS10 definition of remission were used as outcome parameters.

Results: 410 JIA patients received treatment with oral MTX and 384 received s.c. MTX. RF negative polyarthritis was the most common JIA category (50%/51%)

followed by by extended oligoarthritis (27%/26%), polyarticular psoriatic arthritis (18%/16%) and RF positive polyarthritis (5%/8%). Disease duration (2.3+/-3.0 vs 1.9+/-2.7 was statistically higher in the oral cohort (p=0.04) but age at onset and baseline were similar. The baseline disease activity was higher in the s.c. cohort (JADAS10 16.5+/-7.2 compared to 14.7+/-8.2; $p<0.001$ and active joint count 9.0+/-10.1 vs. 7.4+/-7.7; p=0,011). The weekly MTX dosages were comparable with 13.6+/-5.4mg and 13.3+/-4.5 mg. Concomitant treatment with NSAIDS (95%/89%), oral steroids (24%/25%) or intraarticular steroids (6%/8%) were comparable.

After 12 months of treatment, 150 (38.3%) reached a JIA ACR90 with oral MTX and 131 (35%) with s.c MTX while 86 (21. 8%) and 72 (19.5%) reached JADAS-remission (JADAS10$\leq$1). By Kaplan-Meyer- analysis no difference in the early kinetic of response was found. Upon total observation for up to 7.5 years in the intention to treat population (patients discontinuing MTX due to inefficacy or intolerance or starting a biologic were calculated as non-responders) more patients in the oral cohort reached a JADAS-remission (162; 41%) than with s.c MTX (126; 34%) which was stastically borderline significant (p=0,05; odd's ratio 1.2 [95CI 1.0–1.8]).

JADAS-ACC= acceptable disease activity, MDA=minimal disease activity, Rem=remission

Conclusions: Data from the BIKER registry out of the clinical practice do show a high rate of JIA patients reaching a significant JIA-ACR response as well as JADAS-remission upon MTX as a sole DMARD. However, on the long term more patients with oral MTX reached JADAS remission. By Kaplan Meyer analyses we did not observe a superiority of s.c. MTX in the kinetic of response. The limitations of our analysis lie the character of a registry study, the lack of randomisation and study protocol leaving all decisions to start or to stop MTX by the responsible rheumatologist. Thus such data are preliminary and should be confirmed by randomized studies.

THU0530 CHARACTERIZATION OF A COHORT OF PSORIATIC JUVENILE IDIOPATHIC ARTHRITIS PATIENTS FROM A PAEDIATRIC UNIVERSITY HOSPITAL IN SPAIN

S. Hernández-Baldizón[1], A. Zacarías-Crovato[2], V. Torrente-Segarra[3], J. Calzada-Hernández[2], J. Sanchez Manubens[2], E. Iglesias[2], R. Bou Torrent[2], J. Anton[2]. *[1]Rheumatology, Juaneda Miramar Hospital, Palma de Mallorca; [2]Paediatric Rheumatology Unit, Sant Joan de Deu University Hospital, (Esplugues)Barcelona; [3]Rheumatology, Moises Broggi General Hospital, Hospitalet de Llobregat, Spain*

Background: Juvenile Psoriatic Arthritis (JPsoA) is a subtype of Juvenile Idiopathic Arthritis (JIA) present in 7% of JIA patients (1). Psoriasis is present in 0.5–1% of children. Diagnosis is often difficult, with the articular manifestations often preceding skin disease by years. Data is scarce in the Spanish population.

Objectives: Describe demographical and clinical caracteristics of our cohort of JPsoA.

Methods: Descriptive, transversal study of patients attended from 1/2012–12/2016. Included were all complyers with ILAR Criteria (2) for JPsoA (Edmonton 2001). We also included the Wallace Criteria for clinical inactive disease (3) as a variable and endpoint. Data were included and analyzed using SPSS MAC 20.

Results: 31 patients were included: 18 (59%) girls, 13 (41%) boys. All Caucasian. They comprised 5% of all our JIA patients in that period.

Mean age at diagnosis was 7.4 years. All were RF-; 9 (29%) ANA+; 4 (12.9%) HLA-B27+; articular onset 17 (55%) and cutaneous onset 14 (45%). 9 (29%) had Temporomandibular Joint (TMJ) symptoms: 5 (16%) had pain and 4 (12.9%) had a positive MRI for TMJ synovitis.

Plaque psoriasis 14 (45%), guttata 3 (9.6%) and 3 (9.6%) had both. Dactylitis 8 (26.6%); enthesitis 6 (19.35%). Joint disease was mainly oligoarticular 15 (48%), monoarticular 14 (45%) and polyarticular 1 (3.2%). Axial disease 4 (12.9%) at follow-up. 7 (22.5%) uveitis; 5 (77%) were ANA +. 3 (9.6%) onicodistrophia and 6 (19.3%) enthesitis.

All patients received NSAIDs; 30 (96%) methotrexate; 6 (19.3%) switched to leflunomide. 16 (51.6%) received biologic treatment and 9 (29%) more than one. Articular debutants 10 (32.2%) received biologic treatment more than the those with cutaneous onset 6 (19.35%). We report 3 (9.6%) anti-TNF/paradoxal psoriasis events.

Wallace Inactivity Criteria were achieved in 25 (80.6%), with no differences between the biologic and DMARDS groups in time up to Achieving Wallace Criteria (TimeWall). TMJ positive MRI did have a negative effect on TimeWall with 2 (66.6%) $\geq$8 yr (8, 11y) to TimeWall.

Conclusions: We describe the clinical features and demographics of a series of spanish JPsoA patients. We found more oligoarticular and monoarticular involvement and an important presence of enthesitis and dactylitis; higher frecuency of uveitis than published data (22.5% vs. 10–15%). Some were ANA-, reinforcing the need for screening. More than half required biologic treatment, and several cases we needed to switch drugs. Almost 60% of the patients were girls. Articular onset was associated with more active, harder to treat disease. TMJ positive RMI was associated with longer TimeWall. However, Wallace Criteria were not achieved globally.

THU0531 USE OF RITUXIMAB IN PAEDIATRIC RHEUMATOLOGY - EXPERIENCES FROM A SINGLE TERTIARY CENTRE

S. Deepak[1], R. Obrien[2], K. Warrier[1], E. Mcdermott[2], S. Rangaraj[1]. *[1]Paediatric rheumatology, Nottingham Childrens hospital; [2]Immunology, Nottingham university Hospitals NHS Trust, Nottingham, United Kingdom*

Background: Rituximab is an anti-CD20 monoclonal antibody therapy used widely in the management of paediatric rheumatological conditions. Studies suggest that Rituximab is safe and effective in rheumatic autoimmune diseases, but data on paediatric use remains limited. Although Rituximab spares plasma cells, hypogammaglobulinaemia can still develop, leading to recurrent infections. Frequency of hypogammaglobulinaemia in children receiving Rituximab for rheumatological conditions is unknown.

Objectives: To analyse the use of Rituximab in a tertiary Paediatric Rheumatology centre over the last 15 years (2001–2015). The primary aims were to identify the number of patients who received Rituximab, the underlying diagnoses and the response to treatment. Our secondary aims were to identify the incidence of hypogammaglobulinemia associated with Rituximab use and the frequency and severity of infections. Frequency of monitoring of immunoglobulin levels, lymphocyte subsets and functional antibodies to pneumococcus were noted.

Methods: Retrospective analysis of case notes, electronic records and laboratory data of patients who received Rituximab in the paediatric rheumatology department from 2001–2015.

Results: A total of 22 patients received Rituximab (total of 1500mg/m^2 per cycle over 2 – 4 divided doses) during the study period. 3 were excluded due to insufficient data. Median time of commencement of Rituximab from diagnosis was 2 years 8 months. Of these, 12 patients achieved remission within 6 to 12 months. Rituximab was discontinued in the non-responders at 12 months.

Diagnosis	No of patients		Median No of cycles	Remission achieved
Polyarticular JIA	RF +	2	3.5	2 (100%)
	RF -	4		0
JDM	6		3	5 (83%)
SLE	5		2	4 (80%)
Vasculitis (GPA)	2		2.5	1 (50%)

8 patients (42%) were noted to have hypogammaglobulinaemia at some point. The role of cyclophosphamide contributing to hypogammaglobulinaemia could not be excluded in 2 and a further patient is currently being investigated for an underlying primary immune deficiency. In the remaining 5 (26%) patients, we believe the low IgG levels are secondary to Rituximab, of which two needed long term Ig replacement. Overall 12 patients reported recurrent/severe infections of which 6 had low immunoglobulin levels.

Conclusions: RF+ JIA patients appear to have responded the best to Rituximab and RF- JIA patients the least (0/4), with good results in JDM and SLE subgroups (80–83%). The incidence of hypogammaglobulinaemia secondary to Rituximab in our cohort was 26%, which can be prolonged and worsen with increased number of cycles. Prior treatment with cyclophosphamide may be contributory. We suggest regular monitoring of immunoglobulin levels and lymphocyte markers on all patients prior to commencement of Rituximab and regular intervals subsequently, including further cycles.

THU0532 PAEDIATRIC UVEITIS IN FRENCH REFERRAL OPHTHALMOLOGIC CENTERS: A DESCRIPTIVE ANALYSIS OF 74 CHILDREN

L. Moal[1], A. Rousseau[2], C. Titah[3], M. Labetoulle[4], B. Bodaghi[5], S. Guillaume Czitrom[6]. *[1]Service de Medecine des Adolescents; [2]Service d'Ophtalmologie, CHU Bicetre, le Kremlin Bicetre Cedex; [3]Service d'Ophtalmologie, Fondation Rothschild, Paris; [4]Service d'Ophtalmologie, CHU Bicetre, le Kremlin Bicetre; [5]Service d'Ophtalmologie, CHU Pitie-Salpetriere, APHP, Paris; [6]Service de Medecine des Adolescents, CHU Bicetre, APHP, le Kremlin Bicetre, France*

Background: Uveitis in children is rare. Intensive interactions between ophthalmologists and paediatric rheumatologists are needed in order to choose the best therapeutic strategies for severe uveitis attacks.
Objectives: Describe a cohort of 74 patients with paediatric uveitis.
Methods: Retrospective analysis of children followed for uveitis before 18, by one paediatric rheumatologist (SGC) for systemic treatments' management and members of 3 ophthalmologic departments specialized in uveitis care in children (AR, CT, ML and BB) in Paris, during the 2006–16 period.
Results: There were 74 paediatric uveitis, 42 anterior (57%, group1), 16 intermediate (21%, gr2), 7 posterior (9%, gr3) and 9 pan-uveitis (12%, gr4). Gender was equal in gr2–4, but there were more females in gr1. At presentation, mean ages were 8.6±4.1, 9.8±3.9, 9.1±3.6 and 10±4.2 years old. Mean follow-up was 3.7±3.7 years. JIA was the leading cause of gr1 uveitis (45%); gr2–3 uveitis were idiopathic in 81% and 86%, respectively. In gr4, etiologies were found in 7 out of 9 patients (Behçet-3, JIA-2, BBS-1, TINU-1).

Table 1

Complications	I: Anterior uveitis (42) 51%	II: Intermediate uveitis (16) 71%	III: Posterior uveitis (7) 71%	IV: Panuveitis (9) 100%
Cataracts	25%	21%		44%
Papilledema	19%	21%		56%
HTP/Glaucoma	16%			
Macular edema			29%	33%
Vitreous hemorr.		21%		33%
Retinal detach.		29%		33%
Blindness	6% (n=2Uni)	7% (n=1Uni)	29% (n=2Bi)	33% (n=2Uni+1Bi)

Conclusions: Paediatric uveitis induce a very high-level burden in children, even when anterior and sometimes despite optimal therapeutic management in tertiary care centers. Their early recognition and tight control in specialized units are absolutely required in order to decrease the level of definitive complications.

THU0533 DO JIA CORE OUTCOME VARIABLES AT BASELINE PREDICT CLINICALLY INACTIVE DISEASE STATES AT ONE YEAR?
