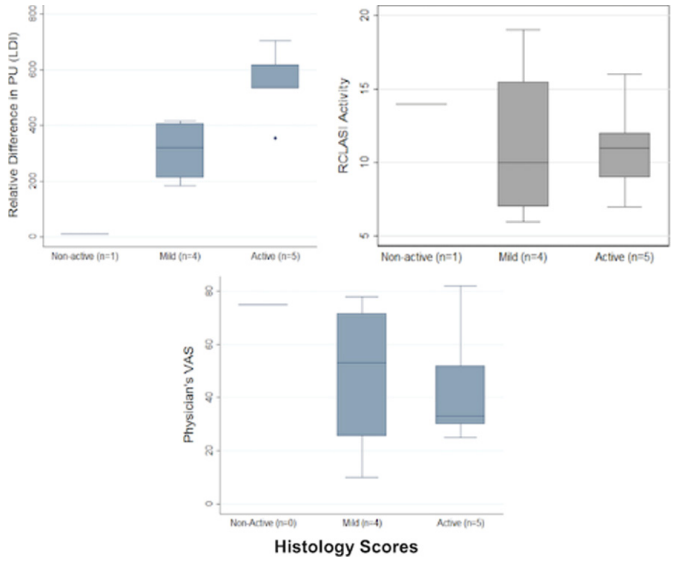
M.Y. Md Yusof[1,2], J. Britton[3], E.M. Hensor[1,4], M. Goodfield[2], M. Wittmann[2], P. Emery[1,2], E.M. Vital[1,2]. *[1]Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit; [3]Medical Physics Department, Leeds Teaching Hospitals NHS Trust; [4]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: Cutaneous lupus erythematosus (CLE) is the most common manifestation of SLE and may occur without systemic features. Skin disease is particularly heterogeneous, rendering assessment of activity difficult. Laser Doppler imaging (LDI) is a non-invasive imaging tool that monitors blood perfusion in dermal tissue. It has been shown to correlate with inflammation in psoriasis but no study has been undertaken in CLE.



Objectives: To evaluate validity of LDI against the gold standard of histology from skin biopsy as well as other clinical tools including the Revised Cutaneous Lupus Erythematosus Disease Area and Severity Index (RCLASI) and Visual Analogue Scale (VAS) scoring of photographs.

Methods: A prospective observational study was conducted in consecutive patients with CLE flare at a single centre. Disease activity was assessed using RCLASI and measured using a high resolution LDI system (Moor Instruments) by JB and YY, both blinded to clinical assessment. Relative difference to the non-lesion area was calculated and expressed in perfusion unit (PU). Skin biopsy was obtained in those who consented and scored as 0=non-active, 1=mild activity and 2=active. Photographs were taken on the same day and were later assessed by a dermatologist and a rheumatologist who were blinded to LDI results using a 100mm VAS. The agreement of VAS between both clinicians was analysed using Bland-Altman limits of agreement (LOA) and the correlation between histology and LDI, RCLASI and VAS were analysed using Kendall's Tau-a.

Results: 20 patients were studied (19 female, median age 47.2 (range 21–62) years, 6 smokers, 2 CLE only, 14 (70%) ANA positive at the time of the scan). The distribution of CLE type were: acute CLE=7, subacute CLE=6 and chronic CLE=7. The agreement between the VAS scores of the two clinicians was fair; mean difference 7.8 (95% CI LOA -26 to 42) mm versus average. In 10 patients with skin biopsy, the correlation with histology was better for LDI (tau-a=0.56) than RCLASI [-0.09; difference (90% CI) 0.64 (0.10, 1.19)] or VAS [-0.16; 0.71 (0.13, 1.29)] (figure 1). One patient who was deemed to have a subacute CLE flare based on clinical assessment indeed had a negative histology and a low PU.

Conclusions: In this preliminary analysis, assessment of blood perfusion to dermal tissue using LDI provides a valid quantitative and objective measure of inflammation in cutaneous lupus. The findings from LDI also had a better correlation with histology from skin biopsy compared to currently used clinical tools. Further validation and longitudinal analysis including assessment of responsiveness to therapy will provide further evidence on the usefulness of LDI in clinical practice and trials.

Acknowledgements: The authors would like to acknowledge Lorraine Green for substantial contribution in the acquisition of data and NIHR for funding the Laser Doppler Imaging.

SAT0648 ULTRASOUND FINDINGS IN SYMPTOMATIC AND ASYMPTOMATIC JOINTS IN PATIENTS WITH GOUT

M.M. Basaric, G. Radunovic, N. Damjanov, M. Radak Perovic. *Institut of rheumatology, Belgrade, Serbia*

Objectives: To determine sensitivity and specificity of ultrasound (US) findings for gout: "double contours" (DC) and hyperechogenic aggregates (HAGs) of symptomatic and asymptomatic joints in patients with gout.
Methods: This prospective study included 69 persons (34 patients with primary gout and 35 healthy subjects). Including criteria for patients with gout were: age ≥18 years; diagnosis of primary gout; absence of acute gout attacks during the study tests; the absence of any other inflammatory and infectious joint disease, and secondary gout. The research included: demography and medical history. Physical and US examination covered following structures: 138 radiocarpal joint, 276 patellar and triceps tendon and 414 articular cartilages (first metatarsal, talar and femoral condyle).
Results: Both groups were compatible for age and gender. In the gout group 124 (30%) symptomatic and 284 (70%) asymptomatic joints were found and in healty group all joints was asymptomatic. The sensitivity of the DC for symptomatic joint was 56 to 84% and specificity also was very high 91 to 94% as well as positive and negative predictive value (69 - 86% and 38 - 71%). Sensitivity of DC finding for the asymptomatic joints was 42 to 73% and specificity was 91 to 94%, with also high positive and negative predictive value (69 - 89% and 44 - 62%). The specificity of the HAGs for both symptomatic and asymptomatic joints was very high 99% but sensitivity of HAGs symptomatic structures was moderate (41 do 56%), while its sensitivity for asymptomatic structures was low (18 to 34%), table 1.

Table 1

Structure		Sensitivity (%)	Specificity (%)	"Cut-off"	PPV (%)	NPV (%)
Symptomatic	DC	56–84	91–94	0.50	69–86	38–71
	HAGs	41–56	98–99	0.50	69–89	44–62
Asymptomatic	DC	42–73	91–94	0.50	58–86	38–71
	HAGs	18–34	98–99	0.50	49–75	31–60

DC - "double contours"; HAGs - hyperechogenic aggregates; PPV - positive predictive values; NPV - negative predictive values.

Conclusions: Ultrasound examination of symptomatic and asymptomatic joints in patients with gout equally observed structural changes characteristic of gout. The finding of "double contours" in the symptomatic and asymptomatic joints has a very high sensitivity and specificity. Consequently, future research should be focused on the ultrasound examination of asymptomatic joints in patients with gout.

SAT0649 CHANGES IN CARTILAGE QUALITY (DGEMRIC) FOLLOWING KNEE JOINT DISTRACTION OR HIGH TIBIAL OSTEOTOMY: A TWO-YEAR FOLLOW-UP

N. Besselink[1], S. Mastbergen[1], K. Vincken[2], L. Bartels[2], A. Concepcion[1], A.K. Marijnissen[1], F. Lafeber[1]. *[1]Rheumatology and Clinical Immunology; [2]Image Sciences Institute, University Medical Centre Utrecht, Utrecht, Netherlands*

Background: Since abnormal loading can cause onset and progression of OA, unloading the affected compartment of an osteoarthritic knee, should slow down OA progression, or even enable joint repair. High tibial osteotomy (HTO) is a well-known unloading approach for treating unilateral compartment osteoarthritis (OA) with mechanical axis deviation. Transient unloading using knee joint distraction (KJD) has demonstrated a progressive decrease in pain, normalization of function, and an increase in cartilage thickness[1]. Although both treatments show indications of joint repair, there is limited information about the actual quality of the regenerated tissue.
Objectives: To evaluate the change in quality of the repaired cartilaginous tissue using dGEMRIC after KJD or HTO treatment.
Methods: 40 patients (20 with KJD, and 20 with HTO), treated for medial tibiofemoral OA, are included in this study. Radiographic changes, clinical changes, and changes in cartilage quality are evaluated after one and two years follow-up. Joint space width (JSW) is evaluated on weight-bearing radiographs. Clinical improvement is evaluated by Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Visual Analogue Scale (VAS) pain score. In order to evaluate the quality of the (newly formed) cartilaginous tissue, quantitative MRI analysis, in the form of Delayed gadolinium enhance Magnetic Resonance Imaging of cartilage (dGEMRIC) is performed.
Results: A significantly increased medial (Δ1.15 mm,p<0.000), minimal (Δ0.93 mm,p<0.000) and mean (Δ0.79 mm,p=0.003) JSW one year after KJD, sustaining up until 2 years, was demonstrated (medial (Δ0.99 mm,p=0.002), minimal (Δ1.04 mm,p<0.000), mean JSW (Δ0.68 mm,p=0.027)). Similarly, medial (Δ0.49 mm,p=0.017) and minimal (Δ0.32 mm,p=0.023) JSW were significantly increased one year after HTO, sustaining up until 2 years (medial: Δ1.03 mm,p<0.000, minimal: Δ0.72 mm,p=0.015), after which mean JSW (Δ0.46 mm,p=0.030) is also significantly increased. Both interventions led to clinical improvement, observed as an increase in WOMAC after one year (KJD: Δ36.89,p<0.000, HTO: Δ33.74,p<0.000) and two years (KJD: Δ32.52,p<0.000, HTO: Δ24.19,p=0.002), and a decrease in VAS Pain, after one year (KJD: Δ-30.79,p=0.001, HTO: Δ-41.89,p<0.000) and two years (KJD: Δ-30.50,p=0.004, HTO: Δ-34.64,p<0.000). However, no statistically significant changes in cartilage quality were found after KJD or HTO, not in the medial and lateral compartments of the tibiofemoral joint, nor in the separate ROIs (see figure 1).

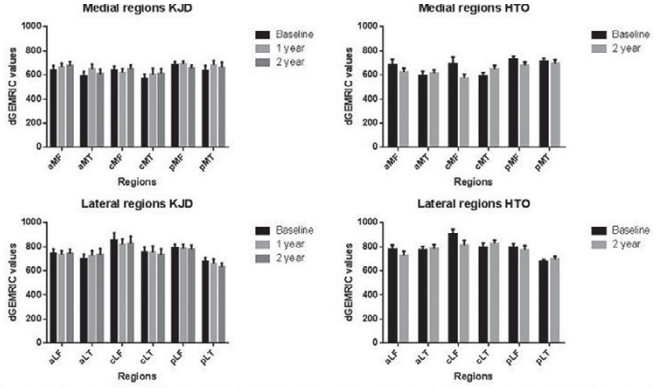

Figure 1: Average dGEMRIC indices (in ms) for the six ROIs of the medial and lateral compartment at baseline and after follow-up.

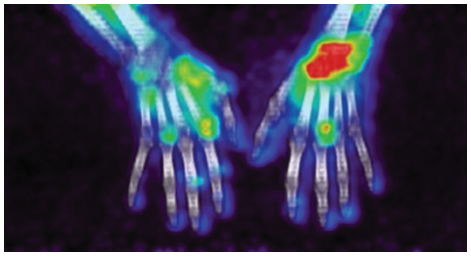

Conclusions: Treatment of medial compartmental OA by either HTO or KJD leads to alleviation of pain and recovery of function, achieved one year after either intervention, and maintained for another year. Within the first year after treatment, KJD shows a statistically significantly higher increase in WOMAC as compared to HTO. Both treatments led to a statistically significant increase in JSW after one and two years, postponing the natural osteoarthritis progression rate. No statistically significant change in the quality of newly formed cartilaginous tissue could be detected by dGEMRIC.

SAT0650 [18F]FLUORO-PEG-FOLATE PET: A NOVEL IMAGING TECHNIQUE TO VISUALIZE RHEUMATOID ARTHRITIS

N. Verweij[1], S. Bruijnen[1], Y. Gent[1], M. Huisman[2], G. Jansen[1], C. Molthoff[2], Q. Chen[3], P. Low[3], A. Windhorst[2], A. Lammertsma[2], O. Hoekstra[2], A. Voskuyl[1], C. van der Laken[1]. *[1]Dept. of Rheumatology, Amsterdam Rheumatology and Immunology Center - location VU University Medical Center; [2]Dept. of Radiology & Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands; [3]Dept. of Chemistry, Purdue University, West Lafayette, United States*

Background: Imaging arthritis activity in rheumatoid arthritis (RA) patients using PET macrophage tracers holds promise for both early diagnostics and monitoring response to therapy (1,2). Previously, (*R*)-[^{11}C]PK11195 has been used, but this macrophage tracer is limited due to high background uptake, especially in bone and bone marrow. Recently, a novel macrophage tracer, [^{18}F]fluoro-PEG-folate,

was developed, which showed excellent targeting of the folate receptor beta on activated macrophages in synovial tissue in a preclinical arthritic rat model (3).
Objectives: To assess the value of [^{18}F]fluoro-PEG-folate PET-CT for imaging inflamed joints in patients with clinically active RA.
Methods: Nine RA patients with at least two clinically inflamed hand joints were included. PET-CT scans of the hands were acquired after intravenous administration of either 185 MBq of [^{18}F]fluoro-PEG-folate (n=6) or 425 MBq of (*R*)-[^{11}C]PK11195 (n=3). Volumes of Interest (VOI) were drawn over joints with visually marked uptake and Standardized Uptake Values (SUVs) were calculated. Background VOIs were drawn on metacarpal bone in order to calculate Target-to-Background (T/B) ratios.
Results: No side effects were observed, establishing the safety of [^{18}F]fluoro-PEG-folate for use in humans. [^{18}F]fluoro-PEG-folate clearly showed uptake in arthritic joints, as shown in Figure 1. In patients scanned with [^{18}F]fluoro-PEG-folate, 25 positive joints were seen, with a minimum of two joints per patient. Clinical arthritis was confirmed in 10 of these 25 joints, and was absent in 15 positive joints, suggesting the presence of subclinical inflammation. Whilst both [^{18}F]fluoro-PEG-folate and (*R*)-[^{11}C]PK11195 accumulated in arthritic joints, [^{18}F]fluoro-PEG-folate showed a significantly lower background uptake than (*R*)-[^{11}C]PK11195 (SUV of 0.18 vs 0.75; $p<0.001$) respectively. T/B-ratios were significantly higher for [^{18}F]fluoro-PEG-folate (3.60vs 1.72, p=0.009).

Conclusions: This first in patient study clearly demonstrates the potential of [^{18}F]fluoro-PEG-folate PET-CT as macrophage tracer to image both clinically and sub-clinically affected joints in RA patients. [^{18}F]fluoro-PEG-folate showed better characteristics for arthritis imaging than the established tracer (*R*)-[^{11}C]PK11195 because of its lower background signal.

SAT0651 QUANTIFICATION OF DYNAMIC MRI EXAMINATIONS IN JUVENILE IDIOPATHIC ARTHRITIS

N. Tzaribachev[1], R. Hagoug[2], P. Louka[2], J. Islam[2], M. Hinton[2], O. Kubassova[2], M. Boesen[3]. *[1]Pri - Pediatric Rheumatology Research Institute, Bad Bramstedt, Germany; [2]Image Analysis Group, London, United Kingdom; [3]Radiology, Copenhagen University Hospital Bispebjerg and Frederiksberg, Bispebjerg, Denmark*

Background: In chronic inflammatory conditions, the need for a more objective measurement of disease activity has been identified. Imaging biomarkers as outcome measurements based on the automated quantification of dynamic contrast enhanced magnetic resonance images (DCE-MRI) have been studied in adult patients with rheumatoid arthritis (RA)[1]. In children with juvenile idiopathic arthritis (JIA) similar knowledge is very limited.
Objectives: To compare treatment related changes of clinical scores in patients with JIA and automated DCE-MRI quantitative parameters analyzed with a dedicated software Dynamika^{tm} also compared to clinical outcomes of the patients.
Methods: In patients with polyarticular JIA with insufficient ($\geq$3 affected joints) response or intolerance to $\geq$3 months Methotrexate, Etanercept was started. Six Slice Axial DCE-MRI of the metacarpophaleangeal (MCP) 2–5 joints in the clinically most affected hand was performed at 3 time points: baseline (BL), month 3 and 6 of treatment using a 0.2 Tesla Esaote C-Scan. Clinical scores included active joint (AJ) counts. Clinical response was considered a state of $\leq$3 AJ. DCE-MRI was analyzed using regions of interest (ROI) covering synovium in slices where MCPs 2–5 were visible. Output parameters included dynamic MRI quantification scores (DEMRIQvol) corresponding to the volume of enhancing voxels within the synovial ROIs alone or multiplied with the mean of the maximum enhancement (ME) or the initial rate of enhancement (IRE). Differences in DEMRIQvol scores between visits were analyzed using t-test ($p<0.05$* = statistically significant, $p<0.25$** = clinically meaningful). Concordance between clinical and DEMRIQvol scores were described.
Results: 18 Caucasian patients (12 girls, median age 12,6 years, median disease duration 1,2 years) were included in the study. Two patients discontinued imaging after BL but continued treatment. In all but 3 of the remaining patients statistically significant and/or clinically meaningful changes were documented for DEMRIQvol ME between visits.
In 4 patients clinical and DEMRIQvol scores showed corresponded changes but these were non-concordant in all others patients.
Based on DEMRIQvol change (irrespective of the clinical scores) the outcome of the patient could be predicted:
- in 5 patients improvement of DEMRIQvol scores predicted response to treatment (within 2–6 months after last MRI examination)
- in 4 patients the increase or the persistence of a high DEMRIQvol predicted non-response to treatment
- in 7 patients increase in DEMRIQvol (after initial decrease) or persistence of a high DEMRIQ vol predicted flare (in 3 of the patients flare occurred after treatment discontinuation)

In all patients subclinical disease could be detected on MRI in clinically unaffected joints.
Conclusions: Dynamika based scores appear to be useful for depicting disease activity in JIA and seem to support clinical examination by detecting subclinical inflammation. More over, in the present study DEMRIQvol scores were predictive for the outcome of the patients and were able to "foresee" response to treatment, flare of disease, non-response to treatment in most patients possibly making DEMRIQvol scores supportive in research and clinical decision taking.

SAT0652 CLINICAL AND IMMUNOLOGICAL SIGNIFICANCE OF RADIOGRAPHIC THYMIC ALTERATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Murata[1], K. Suzuki[1], H. Sugiura[2], Y. Kondo[1], M. Takeshita[1], H. Yasuoka[1], K. Yamaoka[1], K. Koga[3], R. Morita[4], A. Yoshimura[4], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, School of Medicine; [2]Division of Diagnostic Radiology, Department of Radiology, School of Medicine, Keio University, Tokyo; [3]Inflammation Drug Discovery Unit, Pharmaceutical Research Division, Takeda Pharmaceutical Company Limited, Kanagawa; [4]Department of Microbiology and Immunology, School of Medicine, Keio University, Tokyo, Japan*

Background: The thymus, a primary lymphoid organ, plays a crucial role in immune system homeostasis [1,2]. Although several small-scale studies of the association between radiographic thymus alterations and serological features have been reported in systemic autoimmune diseases, information in patients with rheumatoid arthritis (RA) is limited.
Objectives: We conducted a large-scale cross-sectional analysis of radiographic thymus alterations and their association with clinical and immunological features in patients with RA.
Methods: RA patients were randomly selected from all patients who visited our department and underwent chest CT scan between January 2013 and December 2015. Patients with thymoma or thymic cyst and those aged less than 30 years were excluded. Thymic enlargement and thymus attenuation score in axial images of CT scans were quantitatively interpreted. We defined thymic enlargement as a thickness of more than 13 mm and graded the score by a four-point scale (score 0–3) according to previous studies [3,4]. Associations with immunophenotyping data of peripheral blood by flow cytometry and clinical and serological information were statistically analyzed in some available patients.
Results: 387 RA patients were enrolled. 78% were women and mean age was 65.2±12.3 years. Thymic enlargement was found in 76 (19.6%) patients. Thymus attenuation (score $\geq$2) was found in 154 (39.8%) patients. These findings were more frequent than in undiagnosed controls (11.3% (P=0.078) and 22.5% (P=0.017)). Importantly, radiographic thymus alterations in these RA patients, especially thymus attenuation score, were significantly associated with serological features such as serum level of CRP, ESR, IgG, RF-positivity or ACPA-positivity (P=0.0003, 0.001, 0.0009, 0.005, and 0.0009 respectively). When we investigated the association with the proportion of 68 peripheral blood subpopulations in 83 RA patients, thymic enlargement was significantly associated with the proportions of CD45RA+CCR7+ naïve CD4+T cell or CD45RO+CCR7-effector memory CD4+T cell (P=0.04 and 0.009). Furthermore, thymus attenuation score was also significantly associated with the proportions of CD4+ naïve T cell, CD4+effector memory T cell, CXCR5-CXCR3+CXCR6+CD4+Th1/Th17 cell, CD45RO-CCR7+CD95+CD4+ stem cell memory T cell, and CD19+ B cell (P=0.03, 0.02, 0.04, 0.04, and 0.037 respectively).
Conclusions: Radiographic thymus alterations are frequent in RA patients and may reflect immunological features of autoantibody production or T cell differentiation and function.

SAT0653 QUANTITATIVE ASSESSMENT OF INTERSTITIAL LUNG DISEASE IN SJÖGREN SYNDROME: A PILOT STUDY

P. Guisado Vasco[1], M. Silva[2], N. Sverzellati[2], I. Martín Garrido[1], D. Santilli[3], F. Mozzani[3], O. Martin Segarra[1], J.M. Luque Pinilla[1], A. Ariani[4]. *[1]Internal Medicine, Complejo Hospitalario Ruber Juan Bravo, Madrid, Spain; [2]Radiology, University of Parma; [3]Internal Medicine; [4]Internal Medicine and Rheumatology unit, UAzienda Ospedaliero-Universitaria di Parmaniversity of Parma, Parma, Italy*

Background: The interstitial lung disease (ILD) is the most frequent form of lung damage in Sjögren's syndrome (SjS). The diagnosis is still nowadays challenging: there are not specific test -autoantibodies, pulmonary function test- or symptoms. Chest CT is the gold standard. Semiquantitative (SQCT) assessment (such Taouli or Goh visual scores) could estimate ILD severity or burdened by relevant inter-rater variability. Quantitative chest CT (QCT) is a promising method to assess primary or secondary ILD, but there are not studies focused on SjS-ILD.
Objectives: Herein we designed a study to evaluate if QCT indexes might assess differences in SjS-ILD.
Methods: We conducted a multicenter, cross-sectional, and retrospective study, identifying subjects affected of SjS (per modified American-European consensus criteria) and with a thorax CT ordered by local physician by any reason. We enrolled 52 cases, splitted in two cohorts according to the presence/absence of ILD on chest CT. A centralized SQCT assessment was carried out to calculate both Goh and Taouli scores. A DICOM-viewer open-source software (Horos) was used to analyse, blindly and anonymously, all CT images and to calculate QCT indexes (pulmonary (p) and total (t) kurtosis, standard deviation, skewness and mean lung attenuation). QCT indexes and SQCT scores were compared using the Spearman rank and Mann-Whitney tests. ROC curves were calculated to assess the sensibility and specificity of the QCT indexes to detect ILD.
Results: Median age was 70.5 (95% CI 65.47–73.0); 96.2% were female. 9 cases have ILD, and 41 were not affected - two patients not assessable. The disease duration (till CT thorax) have a median of 21 (95% CI -6 – 42.41) months. 42.3% have secondary SjS and 57.7% a primary SjS. All QCT scores, except tSDev, were statistically different in ILD comparing those without ILD; the most relevant were: pKurt 2.05 (IQR 0.389 – 3.78) vs 4.34 (IQR 2.74- 6.0), p=0.008; pSdev (105.6 (IQR 101.4 - 122.95) vs 96.4 (IQR 92.38 to 104.94), p=0.006); pSkew (1.49 (IQR 0,49 -1,94) vs 2.01 (IQR 1.59 – 2.38), p=0.011); tKurt 7.62 (IQR 3.35 – 9.31) vs 10.00 (IQR 8.60 – 11.42),p=0,012 and tSkew 2.52 (1.63 – 2.85) vs 3.04 (2.81- 3.29), p=0.005). ROC analysis showed that tSkew could best discriminate ILD and those without: 0.8 (95% CI 0.66–0.9), cut off point $\leq$2.89; sensitivity 88.89% (95% CI 51.8–99.7), specificity 65.85% (95% CI 49.4–79.9), p$<$0.001. The correlation coefficients for QCT and Goh and Taouli's score ranges around ±0.4.
Conclusions: QCT indexes identified some differences between SjS-ILD and those not. These parameters could be useful both to improve imaging diagnosis and also the decision to treat those cases. This innovative tool migh open up a potential research area to be developed in SjS. Moreover, the operator independence of QCT makes it a time-saving method extremely suitable for multi-centre trials. Our pilot study have some handicaps: small sample, low number of events, different reasons for CT performing, no smoking identification, and biological differences between primary and secondary SjS. However, it could be point out that QTC could be a useful tool to identify and quantify ILD in SjS, and further data are need to ascertain this hypothesis.

SAT0654 THE RECALL SURVEY: DIFFERENCIES OF ULTRASOUND EXAMINATION BETWEEN EARLY VS LONG LASTING RHEUMATOID ARTHRITIS PATIENTS IN CLINICAL REMISSION

P. Macchioni[1], A. Iagnocco[2], M. Canzoni[3], C. Bonali[4], O.M. Epis[5], E. Filippucci[6], A. Delle Sedie[7], S. Tropea[8]. *[1]Rheumatology, Arcispedale S Maria Nuova, Reggio Emilia; [2]2Academic Rheumatology Unit, Università degli Studi di Torino, Turin; [3]Rheumatology, Local Health Unit (ASL)Rome 1, Rome; [4]Rheumatology, Ospedale San Paolo, Bari; [5]Rheumatology, Ospedale Niguarda Milano, Milan; [6]Rheumatology, Università Politecnica delle Marche, Jesi (AN); [7]Rheumatology, Università di Pisa, Pisa; [8]Rheumatology, Busacca Hospital, Ragusa, Italy*

Background: Ultrasound (US) examination is able to show subclinical synovitis and structural changes of joints in patients (pts) with RA in clinical remission (CR).
Objectives: To investigate the differencies of US examination of small joints of hands, feet and wrists in pts with very early (VERA, $<$1y) vs early (ERA, $<$3y duration) vs long lasting RA (LRA, $>$7 y duration) in clinical remission (CR).
Methods: In 2015 an educational event (RECALL survey) focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy. In every center, the local rheumatologists provided RA pts to be examined by US. Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). Bilateral US examinations of wrists, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, using a Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe. All US findings were scored using a 4 degree semiquantitative scoring system.
Results: Eighty-eight pts were classified as VERA, 183 as ERA and 165 as LRA. Drug usage was not different among the three groups of pts. LRA patients were older (p$<$0.001), had longer disease remission before US examination (p$<$0.001) and had an higher prevalence of female sex (p$<$0.01). Table 1 reports the differences of US examination between VRA vs ERA vs LRA patients. LRA patients had more erosions at MTP and wrists with no differences at MCP joints. Synovial hypertrophy and PD signal had the same degree and distribution in the two groups of patients. LRA patients had more MTP joints with effusion with lower degree as compared to patients with ERA and VERA (see table 1).

Table 1

	VERA (A) 88 pts	VERA+ERA 183 pts	LRA (C) 165 pts	p
M/F	25/63	58/125	22/143	A vs C = 0.002 B vs C = $<$0.001
Number of pts aged $<$50y	30/88	58/183	21/165	A vs C = $<$0.001 B vs C = $<$0.001
% of pts with remission $<$12 months	85	80	48	A vs C = $<$0.001 B vs C = $<$0.001
% of pts with $>$1 eroded joint	39	54	62	A vs C = $<$0.001 B vs C = $<$0.001
% of pts with $>$1 joint with synovial hypertrophy	69	71	73	A vs C = ns B vs C = ns
% of pts with synovial hypertrophy $>$1	46	49	51	A vs C = ns B vs C = ns
% of pts with $>$1 joint positive for PD signal	48	50	45	A vs C = ns B vs C = ns
% of joints with PD signal $>$1	32	34	35	A vs C = ns B vs C = ns
% of pts with effusion at MTP joints	45	49	59	A vs C = 0.034 B vs C = 0.044
% of pts with MTP joints effusion $>$1	25	21	12	A vs C = 0.010 B vs C = 0.023

Conclusions: At US examination VERA, ERA and LRA pts in CR have the same degree of synovial hyperplasia and PD signal despite the differences of duration of CR. Higher degree of erosive disease (at wrist and MTP joints), lower degree of MTP effusion and higher prevalence of joint effusion at MTP joints were present among LRA vs ERA and VERA pts.

SAT0655 EARLY ENDOTHELIAL DAMAGE IN PATIENTS WITH RAYNAUD'S PHENOMENON

R. Gualtierotti[1,2], F. Ingegnoli[2,3], T. Schioppo[2], S. Griffini[4,5], E. Grovetti[4,5], M.O. Borghi[6], M. Cugno[4,5], P.L. Meroni[1,2,3,6]. *[1]Lupus Clinic; [2]Division of Rheumatology, ASST G. Pini; [3]Department of Clinical Sciences and Community Health; [4]Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, University of Milan; [5]Medicina Interna, Ospedale Maggiore Policlinico, Fondazione IRCCS Ca' Granda; [6]IRCCS Istituto Auxologico Italiano, Milan, Italy*

Background: Raynaud's phenomenon (RP) can be the first manifestation of systemic sclerosis (SSc) or other connective tissue diseases (CTDs), often preceding an overt disease by years. It is not known if markers of endothelial damage are detectable in those RP patients who subsequently develop a CTD.
Objectives: We studied RP patients at their first evaluation to correlate the levels of endothelial markers with the subsequent development of an overt disease 36 months later.
Methods: Eighty-two patients with RP at their first evaluation were recruited. We measured plasma levels of tissue-type plasminogen activator (t-PA) and von Willebrand factor (vWF), two markers of endothelial damage, and interleukin-6 (IL-6), a pro-inflammatory cytokine. Thirty healthy subjects served as healthy controls.
Results: At baseline, 67 patients showed capillaroscopic normal pattern and 15 patients, of which 11 were very early SSc, had scleroderma pattern. Plasma levels of t-PA, vWF and IL-6 were higher in patients with capillaroscopic normal pattern (p=0.0001) than in normal controls and even much higher in patients with scleroderma pattern (p=0.0001). In patients with capillaroscopic normal pattern and RP of recent onset ($<$18 months), vWF plasma levels were higher when autoantibodies were present (p=0.020). After 36 months, among 48 RP patients with capillaroscopic normal pattern who remained in follow-up, 24 were diagnosed as primary and 24 as secondary RP. In secondary RP, basal levels of t-PA, IL-6 and particularly vWF were higher than in primary RP (p=0.005, p=0.004, p=0.0001 respectively) and normal controls (p=0.0001 for all).
Conclusions: Our findings indicate that markers of endothelial damage are elevated in RP patients who subsequently develop SSc or other CTDs, even in the absence of capillaroscopic abnormalities.

SAT0656 OPTICAL IMAGING OF PHAGOCYTE MIGRATION REPRESENTS A NOVEL METHOD TO DETERMINE DISEASE ACTIVITY IN CIA

S. Gran[1], L. Honold[2], O. Fehler[1], S. Zenker[1], S. Hermann[2], M. Schäfers[2], T. Vogl[1], J. Roth[1]. *[1]Institute of Immunology; [2]European Institute for Molecular Imaging, Münster, Germany*

Background: Recruitment and migration of phagocytes to the site of inflammation are key events in the onset of inflammation. Albeit crucial for pathogen elimination, tissue repair and restoration of tissue homeostasis, dysregulated phagocyte infiltration can also cause severe inflammatory disorders. Therefore, targeting and modulation of phagocyte infiltration represents a promising new approach to fight inflammatory disorders and diseases, such as rheumatoid arthritis. Additionally, non-invasive tracking of phagocyte migration to the site of inflammation could extend both scientific knowledge as well as the repertoire of diagnostic strategies in clinical use.
Objectives: The aim of this study was to establish a fluorescence reflectance imaging (FRI) based system to visualize and analyze migration properties of different cell populations in inflammatory disease models, like experimental arthritis, *in vivo*.
Methods: Immortalized murine myeloid progenitor ER-HoxB8 cells were differentiated to neutrophils or monocytes (1). Cells were labeled with the membrane-selective fluorescent dyes DIR (2) or DID, respectively. We analyzed viability and functionality of stained cells *in vitro* and investigated their ability to migrate to sites of inflammation *in vivo* in several mouse models - particularly in a collagen induced arthritis (CIA) mouse model - via fluorescence reflectance imaging (FRI). Using CRISPR-Cas9 technology we introduced targeted gene deletions for main adhesion molecules.
Results: Differentiated ER-HoxB8 cells could effectively be labeled with DIR or DID. Labeling of monocytes or neutrophils did not affect cellular viability or functionality *in vitro*. Subsequent *in vivo* imaging experiments allowed the visualization of migrated labeled phagocytes in different murine disease models, thereby cells could be detected at sites of inflammation with high sensitivity and specificity. In a CIA mouse model the amount of immigrated cells could even be associated closely to disease score and disease severity. Thus, the detection of immigration of labeled cells might also give hints about new inflammatory spots that are about to settle up before they can be detected macroscopically. Furthermore, differential cell labeling allowed direct quantitative comparison of differences in migration rates of wildtype and CD18 or CD49d knockout cells *in vivo*.
Conclusions: Specific and distinguishable labeling of diverse cell types allows *in vivo* tracking and subsequent quantification of migrated cells within the same animal. Targeted gene deletion allows analysis of molecular mechanisms relevant for leukocyte recruitment during different stages of arthritis. Correlation of the amount of immigrated cells to disease severity offers new opportunities to non-invasively detect and monitor inflammatory sites *in vivo*.

SAT0657 CAN VASCULAR INFLAMMATION IN RA BE DETECTED USING CONTRAST ENHANCED MRI? PRELIMINARY RESULTS

S. Skeoch[1,2], R. Little[3], Y. Watson[4], S. Cheung[3], J. O'Connor[3], Y. Alexander[5], I. Bruce[1,2], G. Parker[3], J. Waterton[3]. *[1]Manchester NIHR Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust; [2]Centre for Epidemiology; [3]Centre for Imaging Sciences; [4]University of Manchester; [5]Health Related Research, Manchester Metropolitan University, Manchester, United Kingdom*

Background: In rheumatoid arthritis (RA) vascular inflammation may contribute to excess cardiovascular (CV) risk. Contrast enhanced MRI has been used to detect vascular inflammation in Takayasu's arteritis. In RA, its utility has not been studied but it may provide a method of identifying and monitoring vascular inflammation and effects of therapy.
Objectives: We sought to compare carotid artery wall enhancement on contrast enhanced MRI in RA patients and controls and evaluate association with circulating markers of inflammation, endothelial activation and CV risk factors.
Methods: Patients and age/sex matched controls underwent clinical and serological assessment (details in Table 1) and a screening carotid ultrasound. Those with wall thickening>2mm had a carotid MRI. T_1-weighted images were acquired before and after gadopentate injection on a 3T scanner. Increase in mean signal intensity (SI) in the carotid vessel wall normalised to adjacent skeletal muscle provided a global enhancement metric (WE_G). Histograms of distribution of SIs on pre-and post- contrast images were generated and bimodal Gaussian distributions fitted to explore patterns of enhancement within the wall. MRI measurements were compared between groups and association with serological markers tested using non-parametric statistics.
Results: 27 patients and 10 controls underwent MR imaging. Key characteristics are seen in Table 1. There was no difference in WE_G between groups and no association with serological markers. However a bimodal distribution of SI in vessel wall was observed (Figure 1) and in exploratory analysis these two components were analysed separately. For the low-signal component enhancement (WE_{low}) correlated with ESR, I-CAM, e-selectin (r=0.39,p=0.03;r=0.44,p=0.01;r=0.37,p=0.04). There was a trend towards correlation with CRP (r=0.30,0.08) and towards higher values in patients (median 0.20 (0.15, 0.33) vs 0.14 (0.11, 0.22),p=0.051). Enhancement in the high-signal component (WE_{high}) was not associated with serological markers or RA status.

Table 1.Key characteristics (median (IQR) or frequency (%) where*)

	Cases	Controls	P value
Age (yrs)	61.0 (56.5, 64.6)	55.4 (54.0, 57.0)	0.07
Female*	22 (81)	5 (50)	0.06
LDL (mmol/L)	2.7 (2.25, 3.23)	3.80 (3.24, 4.53)	0.08
Glucose (mmol/L)	4.8 (4.6, 5.0)	5.8 (5.3, 6.0)	0.01
Hs-CRP (mg/l)	3.34 (2.04, 5.75)	0.81 (0.39, 4.58)	0.047
ESR (mm/hr)	18 (10, 35)	7 (5, 10)	0.01
ICAM (ng/ml)	161.5 (134.8, 213.4)	151.3 (106.9, 220.8)	0.51
V-CAM1 (ng/ml)	398 (352, 473)	376 (353, 390)	0.52
E-selectin (ng/ml)	7.55 (5.79, 21.1)	4.71 (3.01, 7.76)	0.11
WE_G	0.23 (0.23, 0.28)	0.25 (0.18, 0.27)	0.62
WE_{low}	0.20 (0.15, 0.33)	0.14 (0.11, 0.22)	0.05
WE_{high}	0.32 (0.22, 0.50)	0.33 (0.29, 0.38)	0.73

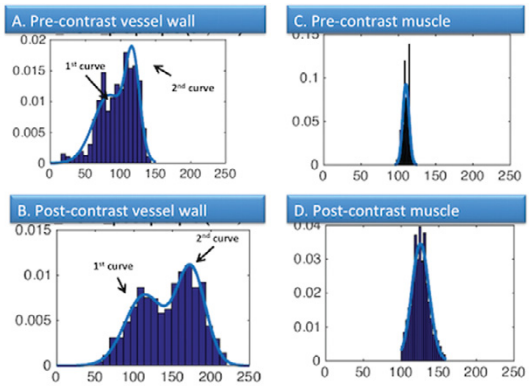

Figure 1. Distribution of signal intensity (SI) within the vessel wall and muscle referent before and after contrast injection (x axis signal intensity (a.u), y axis relative frequency). Gaussian curves were fitted and mean of fit values for each curve were calculated. A bimodal distribution with low and high signal intensity components can be seen in vessel wall (panel A & B) compared with a single curve in muscle (panel C& D). For each curve the difference between pre- and post- contrast mean SI was calculated (with normalisation to muscle signal). This provided a wall enhancement measurement for the 2 separate curves (WE_{low} and WE_{high})

Conclusions: Simple global SI measurement on MRI did not suggest vascular inflammation in RA. However, the bimodal SI distribution may represent different wall components e.g. intima and adventitia. The differential enhancement, and association of WE_{low} with inflammation, endothelial activation and RA status, warrants further investigation.

SAT0658 THE STIFFNESS OF MEDIAN NERVE MEASURED BY ELASTOSONOGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Anno[1], T. Okano[2], Y. Sugioka[3], K. Mamoto[2], T. Koike[3,4], K. Inui[2], H. Nakamura[2]. *[1]Yodogawa Christian Hospital; [2]Department of Orthopedic Surgery, Osaka City University Graduate School of Medicine; [3]Center for Senile Degenerative Disorders (CSDD), Osaka City University Medical School, Osaka; [4]Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan*

Background: Carpal tunnel syndrome (CTS) is the most frequent neuropathy of all entrapment neuropathies in the general population. Rheumatoid arthritis (RA) is one of the disease generate secondary CTS. The pathophysiology of CTS of RA might be different from idiopathic CTS. RA is a disease that has the characteristics to generate inflammatory synovial proliferation of the joint and also tendon. Although inflammation of the wrist joint and synovial tissue of the flexor tendons can cause increased pressure in the carpal tunnel, there is a possibility that even RA patients without symptoms of CTS also have subclinical median nerve damage because of the synovial proliferation and inflammation.
Objectives: The aim of this study was to assess and compare the stiffness of the median nerve measured by quantitative elastosonography between patients with RA without symptom of CTS and controls.
Methods: Four hundred two hands in 201 patients with RA and 222 hands in controls were included. All participants were examined both wrists. Ultrasound (US) examination was performed by using a 5- to 18-MHz linear array transducer (HI VISION Ascendus; HitachiAloka Medical,Tokyo, Japan). As a reference medium, an acoustic coupler (EZUTECPL1; HitachiAloka Medical) with a standardized

elasticity was attached to the transducer during the elastosonography. The inlet of the carpal tunnel at the scaphoidpisiform level and the proximal portion of the carpal tunnel inlet were scanned in a transverse plane. The crosssectional area (CSA) and the elasticity of the median nerve, which was measured as the acoustic coupler/median nerve strain ratio, were evaluated. The measurements were repeated two times, and the average strain ratio was used for analysis.

Results: We analyzed 342 hands in 177 RA patients (139 female, mean age: 63.5±11.6 years) and 158 hands in 81 non-RA (68 female, mean age: 71.5±14 years) finally. There were no significant differences in the cross-sectional area of median nerve (left: 8.9 vs 8.7 mm^2, p=0.91, right: 8.2 vs 8.4 mm^2, p=0.62) or the circumference of median nerve (left: 13.1 vs 13.4 mm, p=0.41, right: 13.7 vs 13.7 mm, p=0.95) within carpal tunnel between RA group and non-RA group. Strain ratio within carpal tunnel in RA group was higher than that of non-RA group (left: 2.6 vs 2.1, p=0.002, right: 2.7 vs 2.2, p=0.003). There were no significant differences in the cross-sectional area of median nerve (left: 7.5 vs 8.1 mm^2, p=0.07, right: 8.8 vs 8.3 mm^2, p=0.6), the circumference of median nerve (left: 13.1 vs 13.5 mm, p=0.3, right: 13.7 vs 13.9 mm, p=0.71) and strain ratio (left: 2.1 vs 2.0, p=0.88, right: 2.3 vs 2.1, p=0.01) at the entrance of the carpal tunnel between RA group and non-RA group.

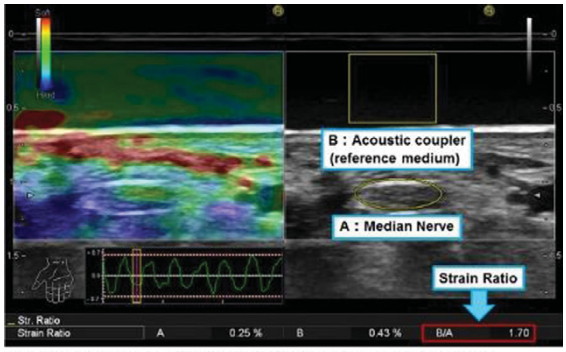

Figure: The images of acoustic coupler /median nerve strain ratio.

Conclusions: Real-time Elastosonography showed the stiffness of the median nerve with RA patients without any symptoms of CTS was higher than controls. It suggests that inflammation of flexor tenosynovitis and wrist joint may generate fibrotic change of median nerve in patients with RA.

SAT0659 COMPARISON BETWEEN EIGHT DIFFERENT ULTRASONOGRAPHIC SCORES FOR HAND ASSESSMENT IN RHEUMATOID ARTHRITIS -A CROSS-SECTIONAL STUDY

S. Hussain[1,2], P. Sivakumaran[1,2], L. Attipoe[2], C. Ciurtin[2]. *[1]University College London Medical School; [2]Department of Rheumatology, University College London Hospitals NHS Foundation Trust, London, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory condition associated with well-recognised inflammatory joint features, which are amenable to ultrasound (US) examination. The implementation of US scoring systems in addition to clinical examination could help standardise the way RA is monitored; however, due to variation in local availability of US and sonographer expertise, different scoring systems have been used in clinical practice (1). Despite significant research progress in supporting the role of US in RA, there is no consensus as to which scoring system is most useful.

Objectives: To assess whether simplified US protocols for hand examination correlate significantly with a 22 hand joint US score in patients with established rheumatoid arthritis, and correlate the US examination with the disease activity score (DAS-28 score).

Methods: This is a cross-sectional study of 224 RA patients stratified based on their DAS-28 scores and assessed using eight preselected US examination protocols including 22, 18, 16, 14, 10, 8 and two different combinations of 4 joints, respectively. Student T, Mann-Whitney U and Kuskal-Wallis tests were employed for analysis of clinical, laboratory and US parameters in the RA patient groups ($P<0.05$ was considered significant). Spearman's coefficients were used to correlate permutations of pairs of US scores, and US and DAS-28 scores.

Results: We found a significant difference between different US hand scores and their ability to detect the presence of active and chronic inflammation in RA patients. The DAS-28 scores correlated very well (R=0.89–1, $P<0.05$) with the total Power Doppler (PD) scores generated by all US protocols irrespective of patients' disease activity. Simplified US scores missed information on presence of erosions ($P<0.05$), but were equivalent to the extensive 22 joint score in appreciating the amount of chronic and active inflammation compared to the extensive 22 joint score (P=0.15, P=0.11, respectively).

Conclusions: This study showed that preselected simplified US scores could be used in clinical practice to appreciate reliably the disease activity in patients with established RA; however they are less reliable in appreciating the disease burden when compared with an extended protocol for US examination of 22 hand joints. All the simplified US scores correlated very well with DAS-28 scores.

SAT0660 SAFETY, FEASIBILITY AND TOLERABILITY OF PERFORMING CONSECUTIVE MINIMAL INVASIVE ULTRASOUND-GUIDED SYNOVIAL BIOPSY PROCEDURES ON THE SAME WRIST IN A PROSPECTIVE RHEUMATOID ARTHRITIS STUDY

S.A. Just[1], C. Nielsen[2], E.K. Hejbøl[3], H.D. Schrøder[3], I.M.J. Hansen[4], T. Barington[2], H.M. Lindegaard[1]. *[1]Rheumatology; [2]Clinical Immunology; [3]Clinical Pathology, Odense University Hospital, Odense; [4]Medicine, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark*

Background: Studies on synovial tissue retrieved using the minimal invasive ultrasound-guided synovial biopsy (USG-SB) method have led to major advances in the understanding of Rheumatoid Arthritis (RA). The method is now used in multicenter RA studies and recommended in the phases of RA drug development. Only to biopsy disease active joints at start and end of a study, can lead to biopsies being retrieved from different joints. This can make interpretation of the changes in the synovial tissue and gene-expression profile difficult, as synovial histology patterns can vary between joints. We here present an approach where we biopsied the wrist with disease activity at presentation and the same wrist after six month of disease duration. We use the wrist, as it is the joint most commonly involved in the upper extremity in RA. The joint is easily accessible for USG-SB and therefore ideal to use to follow disease activity/treatment response/biomarker change in prospective RA studies.

Objectives: To assess the safety, tolerability and feasibility to perform repeated synovial biopsies from the same wrist, using a minimally invasive USG-SB technique in patients suffering from RA.

Methods: Patients with newly diagnosed untreated RA or longstanding (>5 years) RA and at least one clinically swollen wrist, underwent x-ray, magnetic resonance imaging (MRI) and ultrasound examination of the affected wrist and hand on the day of the biopsy. This was repeated 6 months later, where the second biopsy from the same wrist was taken. EULAR guidelines for RA treatment were followed in the 6 months between biopsies. Patient-reported outcomes (PRO) included a standard questionnaire given to all patients on the day of the biopsy as well as 2 weeks after the biopsy. Tolerability and the patient-reported willingness to repeat the procedure was assessed using the 5-point Likert scale.

Results: 38 RA patients (22 early, 16 longstanding) underwent USG-SB procedure at inclusion and after 6 months. One patient was excluded and did not have second biopsy due to diagnosis of CPPD. All patients have undergone first biopsy and at present time and 50% second biopsy. At the EULAR congress complete data will be presented. At present time, at both first and second biopsy no worsening in PRO of the biopsied joints was reported 2w after the biopsy, as compared before the biopsy. No infection, hemorrhage, nerve or tendon damage has currently been observed. One patient developed a tenosynovitis after biopsy (the CPPD patient), successfully treated with glucocorticoid injection. 10% of the patients were somewhat or very unlikely to have another biopsy procedure after the first procedure, and 6% after the second. All included RA patients accepted to have a second biopsy. Detailed data on differences in tolerability between early untreated RA patients versus patients with longstanding RA, will be presented at the conference.

Conclusions: To our knowledge, we are the first, to demonstrate that retrieving synovial tissue using the USG-SB method on the same wrist, at start and end of a prospective RA study, is safe and well tolerated.

SAT0661 FINGER JOINT CARTILAGE THICKNESS EVALUATED BY ULTRASOUND IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

T. Ogura, A. Hirata, N. Hayashi, H. Ito, S. Takenaka, Y. Fujisawa, K. Mizushina, T. Katagiri, R. Kujime, M. Imamura, N. Yamashita, H. Kameda. *Toho University Ohashi Medical Center, Tokyo, Japan*

Background: Joint destruction in RA includes both bone and cartilage lesions. By X-ray examination, cartilage destruction is evaluated as a joint space narrowing (JSN). However, joint space narrowing is not a direct evaluation of cartilage.

Objectives: We aimed to examine the finger joint cartilage thickness (CT) by ultrasound (US) imaging and clarify its clinical significance in patients with RA.

Methods: We enrolled 121 RA patients in low disease activity or clinical remission

(DAS28-CRP <2.7) in this study. The CT of metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints of 2nd to 5th fingers was bilaterally visualized and measured at the middle portion of MCP and PIP joints from a longitudinal dorsal view, with approximately 90 degrees flexion. In addition, JSN of finger were scored by van der Heijde- modified Sharp method for patients who had a hand X-ray within 2 months.

Results: CT in MCP joints ranged from 0.0 to 1.1 mm (median 0.5 mm), and CT in PIP ranged from 0.0 to 0.6mm (median 0.3mm), respectively. The sum of total CT from 8 fingers ranged from 4.0 to 9.4 mm (median 6.9 mm), and there was a significant difference in total CT, but not in JSN score, between male and female patients (7.4 versus 6.7, p=0.006; and 11 versus 10, p=0.899, respectively). CT was well correlated with JSN (ρ=-0.589, p<0.001; ρ=-0.595, p<0.001 for MCP joints andρ=-0.448, p<0.001 for PIP joints), and both CT and JSN were significantly correlated with disease duration (ρ=-0.282, p=0.002, andρ=0.286, p=0.005, respectively). Notably, CT of MCP, but not of PIP, was inversely correlated with disease duration (ρ=-0.328, p<0.001). Height was correlated with CT (ρ=0.244, p=0.008), but not with JSN (ρ=-0.057, p=0.589). CT and JSN were not correlated with age, functional disability, and seropositivity.

Conclusions: A direct visualization and quantification of finger joint CT, especially MCP joints, by US is valid and useful in RA.

SAT0662 EVALUATION OF ANTI-DOUBLE STRANDED DNA ANTIBODIES IN THE MONITORING OF SYSTEMIC LUPUS ERYTHEMATOSUS

T. Dervieux[1], T. O'Malley[1], J. Conklin[1], C. Ibarra[1], C. Bentow[2], M.A. Aure[2], M. Mahler[2]. *[1]Exagen Diagnostics, Vista, CA; [2]Research and Development, Inova Diagnostics, San Diego, CA, United States*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune rheumatic disease characterized by the production of pathogenic autoantibodies. Amongst these antibodies, those directed to dsDNA are routinely used to monitor disease activity and are components of the SELENA-SLEDAI index to score severity of SLE disease. Because the predictive value of anti-dsDNA is dependent on the sensitivity and robustness of the assays used, the choice of anti-dsDNA is crucial in the clinical laboratory and clinical research setting.

Objectives: The objective was to compare four anti-dsDNA assays for their performance characteristics of SLE disease activity.

Methods: A cohort of 36 subjects with active SLE presenting with classical complement activation were enrolled and followed monthly for 1 year. At each study visit blood was collected, serum isolated and frozen until analysis. A total of 371 specimens were collected. Disease activity was scored on the day of each study visit according to the SELENA-SLEDAI method excluding anti-dsDNA or complement components (non-serological [ns] SELENA-SLEDAI). All specimens were tested using four different anti-dsDNA kits; QUANTA Lite, QUANTA Flash, a high Avidity anti-dsDNA ELISA, and the *Crithidia luciliae* indirect immunofluorescence assay (CLIFT) (Inova Diagnostics, San Diego, CA). Study visits presenting with inactive disease (ns-SELENA- SLEDAI score=0) were compared to those presenting with active disease (ns-SELENA- SLEDAI>0). The longitudinal data were analyzed using linear mixed effect modeling with the ns-SELENA-SLEDAI as dependent variable and the anti-dsDNA titers as fixed effect predictors. Marginal R^2 was calculated for each assay.

Results: At enrollment the sensitivity of the QUANTA Lite and High Avidity anti-dsDNA both reached 64%; whereas anti-dsDNA positivity was 83% by QUANTA Flash and reached 96% by CLIFT. Study visits with active disease presented with several fold higher anti-dsDNA titers than those with inactive disease status (Table 1). Linear mixed effect modeling indicated that the decrease in ns-SELENA-SLEDAI scores were associated with significant reduction in titers of all three anti-dsDNA kits (Table 2). QUANTA Flash yielded highest marginal R^2 (0.112) (Table 2).

Table 1. Anti-dsDNA antibody and disease activity

Anti-dsDNA		Inactive Disease 0 (n=141)	Active disease 1+ (n=230)	*p* value
QUANTA Flash	Titers (units)	72 (30–134)	170 (56–813)	<0.001
	Percent positive (>35 Units)	72%	86%	<0.001
High Avidity	Titers (units)	36 (12–170)	129 (47–775)	<0.001
	Percent positive (>30 Units)	56%	77%	<0.001
QUANTA Lite	Titers (units)	343 (106–624)	545 (293–879)	<0.001
	Percent positive (>301 Units)	53%	74%	<0.001
CLIFT	Titers (units)	1:160 (1:80 – 1:320)	1:320 (1:160–1:320)	<0.001
	Percent positive (>1:10)	99%	97%	0.26

Titers are presented as median inter-quartile range.

Table 2. Linear Mixed model effects of anti-dsDNA with ns-SELENA-SLEDAI scores

Assay	Intercept + Estimate SE	*p* value	Marginal R^2
QUANTA Flash	3.3±0.5 + 0.0011±0.001	<0.001	0.112
High Avidity	2.8±0.8 + 0.0023±0.0011	0.001	0.082
QUANTA Lite	2.9±0.6 + 0.0037±0.001	0.022	0.037
CLIFT	3.3±0.8 + 0.0031±0.003	0.28	0.006

Conclusions: These preliminary data indicate that anti-dsDNA antibodies determined by QUANTA Flash have value in monitoring SLE disease activity.

SAT0663 TWO-STEP ALGORITHM FOR EARLY DIAGNOSIS OF OSTEOARTHRITIS BASED ON PLASMA DAMAGED AMINO ACIDS PROVIDES SIMPLE AND LOW COST SCREENING TEST

N. Rabbani, U. Ahmed, P.J. Thornalley. *Warwick Medical School, University of Warwick, Coventry, United Kingdom*

Background: Currently, magnetic resonance imaging techniques have been developed for evaluation of cartilage damage in early-stage osteoarthritis (eOA). These imaging techniques have approximately 70% sensitivity and 90% specificity compared to reference diagnosis by arthroscopy. They require expensive instrumentation, time and facilities. In searching for biomarkers for clinical diagnosis we found that the proteolysis of damaged (oxidised, glycated and nitrated) proteins gives a unique pattern in the plasma of arthritic patients with the severity of the disease – trace level oxidised, glycated and nitrated amino acids. In this study we developed a two-step algorithm using these analytes as features.

Objectives: The objective was to distinguish between the following four groups: healthy control, eOA, early stage rheumatoid arthritis (eRA) and other inflammatory joint disease (non-RA).

Methods: Four algorithm types were tested for performance using random forests, multiclass logistic regression, multi-class sparse logistic regression and support vector machines. In all cases, the diagnostic algorithms were trained on the training data set, before being used to predict the disease class for each sample in the test data set. A two-stage approach was taken: (i) to distinguish between disease and healthy control; and (ii) to distinguish between eOA, eRA and non-RA. The area under the curve of the receiver operating characteristic plot (AUROC) statistic was used as measure of performance

Results: Random forest was the best-performing method. Application of two algorithms consecutively gave the best diagnostic outcome. The AUROC (sensitivity/specificity) values for disease/health were: eOA, 0.99 (0.92/0.91); eRA, 0.96 (0.89/0.90) and non-RA, 0.77 (0.73/0.72) for the training set and test set validations. A random outcome is 0.50. For typing arthritis, eOA, eRA and non-RA, AUROC values were in the range 0.68–0.98, 0.77–0.93 and 0.62–0.91 for training set and test set cross-validations and test set validation, respectively. A random outcome is 0.33.

Conclusions: A two-step algorithm approach based on trace level damaged amino acids gave better diagnostic performance that MRI for detecting and typing eOA. It is low cost and suitable for rollout as a clinical screening test.

SAT0664 IS THERE AN EARLY ULTRASONOGRAPHIC PATTERN IN SALIVARY GLANDS IN BOTH PRIMARY AND SECONDARY SJOGREN SYNDROME?

V.C. Iorgoveanu[1], D. Mazilu[2], I. Saulescu[3], V. Vlad[4], V. Bojinca[3], L. Groseanu[3], D. Opris[3], A. Balanescu[3], C. Constantinescu[3], D. Predeteanu[3], R. Ionescu[3]. *[1]Rheumatology, Carol Davila University of Medicine and Pharmacy; [2]Saint Mary Clinical Hospital, UMF Carol Davila, Bucharest, Romania; [3]Rheumatology, Saint Mary Clinical Hospital, UMF Carol Davila; [4]Rheumatology, Saint Mary Clinical Hospital, Bucharest, Romania*

Background: Sjogren Syndrome (SS) affects mainly exocrine glands. Ultrasonography (US) demonstrates specificity and sensibility in major salivary glands (SG) evaluation. Recent data confirm US might be used as primary evaluation technique for its ability to show structural alterations of parenchyma [1].

Objectives: To assess the gray scale (GS) parenchymal inhomogeneity of major SG in patients with established primary and secondary SS and correlate with clinical and biological data.

Methods: Consecutive patients with SS were recruited and SG US was performed. Inhomogeneity of glandular parenchyma was quantified binary on each gland. ESSDAI and ESSPRI scores were calculated. Statistics was performed with SPSS.

Results: Twenty one (42.85% primary SS, 90.47% female) consecutive patients were included. Mean age was 53.66+/-12.99 years and disease duration 5.33+/-3.74 years. Antibody SSA/SSB presence was found in 85.7% (18/21). ESSDAI mean was 8.67+/-8.9 (0–29), ESSPRI 10.13+/-5.59 (0–20). There were no differences regarding ESSDAI and ESSPRI in the two groups (primary and secondary SS). Right parotid gland showed alterations in 71.4% patients (77%

with primary SS, 66% with secondary SS). Frequently inhomogeneity was found in all major SG (33%, 22% left and right submandibular, 77%, 44.4% left and right parotid glands) in primary SS. Both submandibular glands were symmetrically involved ($p<0.02$). Duration of disease was negatively correlated to inhomogeneity of right parotid gland ($p<0.02$).

Conclusions: Inhomogeneity in major SG in GS US was found in the majority of patients with primary and secondary SS. The symmetrical involvement of submandibular glands was significant. The inhomogeneity appears in the early period of diagnosis. No major differences were found between two groups.

SAT0665 DOES PATIENTS' OPINION OF REMISSION IN RHEUMATOID ARTHRITIS OVERLAP US "TRUE" REMISSION?

V. Vlad[1], F. Berghea[2], M. Popescu[1], V. Iorgoveanu[1], D. Predeteanu[1], R. Ionescu[2]. *[1]Rheumatology, Clinical Hospital Sf Maria Bucharest; [2]Rheumatology, UMF Carol Davila, Bucharest, Romania*

Background: Patients describe RA remission as the absence of any symptoms or return to normality. Ultrasound (US) in RA remission patients did not exactly overlap clinical evaluation of remission in previous studies (residual synovitis frequently described). US tenosynovitis evaluation and scoring seemed to better follow clinical remission scores than synovitis in RA [1].

Objectives: To verify with US/clinical evaluations if patients' reported remission is "true" remission, and if and which clinical and US scores are lowest possible in that cohort.

Methods: Forty-eight RA patients were enrolled in this pilot study between 2015–2017 according to their positive answer to the question "Are you feeling free of symptoms, like before RA started for you?"; the enrollment was regardless of the treatment they were on. Written informed consent was obtained. Clinical evaluation of tender and swollen joints was performed the same day with US evaluation of 24 joints and 26 tendon sites and with lab CRP evaluation, blinded from one another. DAS28 and SDAI were calculated after, counting VAS=1, for both physician and patients.

Results: Mean patients age was 58, 35/48 (72.9%) patients were also in remission per DAS28 criteria. Except for CRP value, no other variables (tender, swollen joints, RF, CCP, remission duration) were significantly different in the group with overlapping DAS28 remission. Considering 1.00 as the "ideal" situation (absolute overlapping of US remission and remission felt by patients), the closest was PD scoring in tenosynovitis of the ankle and feet (100%) and the furthest was GS scoring of synovitis in superior and inferior limbs (mean 17.1%)-table 1. Although residual synovitis and tenosynovitis in remission RA patients did not exhibit a statistically significant difference, PD tenosynovitis in both upper and lower limbs was found in less than 10% of patients. This confirms the results from our previous cohort [1], that tenosynovitis better overlaps RA remission than synovitis.

Table 1. Prevalence of US remission in patients with clinical remission – bootstraping for CI

MSUS Remission	DAS28 remission	SDAI Remission
PD Tenosynovitis	94.3 (5.7–100)	90.9 (77.3–100)
GS Tenosynovitis	57.1 (40.0–74.3)	54.5 (36.4–72.7)
PD Synovitis	62.9 (45.7–80.0)	59.1 (36.4–77.3)
GS Synovitis	17.1 (5.7–31.7)	13.6 (0–31.8)
PD Lower limb tenosynovitis	100 (100)	100 (100)
GS Lower limb tenosynovitis	91.4 (82.9–100)	86.4 (72.7–100)

Conclusions: The way patients perceive their disease activity is not related to either DAS28, SDAI scores or to objective US assessment of joints and tendons (GS or PD). However, PD signal especially in tendons sheaths seems to be absent in patients having a normal life, according to their own opinion. Consequently, patients in remission could benefit from US evaluation on any machine, regardless of its costs and Doppler settings. GSUS synovitis/tenosynovitis can be residual finding and does not imply any dissatisfaction in patients' health. An ongoing cohort of active RA patients is currently conducted to explore the validity of this conclusion in these cases, too.

SAT0666 SAMPLE SIZE FOR RA CLINICAL TRIALS USING ULTRASOUND OUTCOME MEASURES MAY BE REDUCED BY NOVEL JOINT SELECTION METHODS: A PILOT STUDY

J.C. Allen Jr[1], J. Thumboo[2,3,4], W.K. Lye[1], P.G. Conaghan[5,6], L.C. Chew[2,3,4], Y.K. Tan[2,3,4]. *[1]Office of Clinical Sciences, Centre for Quantitative Medicine, Duke-NUS Medical School; [2]Yong Loo Lin School of Medicine, National University of Singapore; [3]Duke-NUS Medical School; [4]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore; [5]NIHR Leeds Musculoskeletal Biomedical Research Unit; [6]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: Novel outcome measures selecting a reduced joint count for ultrasonography can be highly responsive in demonstrating the improvement in joint inflammation seen in rheumatoid arthritis (RA) patients on treatment [1].

Objectives: To determine whether the use of the novel methods can translate into smaller sample sizes for subject recruitment into RA clinical trials. Results from the existing methods are used for comparison.

Methods: 24 RA patients with treatment starts or escalation had clinical and ultrasound joint assessment at baseline and 3 months. The novel methods select joints based on (A) ultrasound joint findings (i.e. Individualized Ultrasound (IUS) method) or (B) a composite of ultrasound and clinical joint findings (i.e. Individualized Composite Ultrasound (ICUS) method). In contrast, the existing methods utilize pre-determined joint sites for ultrasonography. Scores at the relevant joints per patient are summed up to obtain the total inflammatory score (TIS). The effect size (ES) was measured as the mean change of the TIS divided by the standard deviation of the change in the TIS. Sample sizes were calculated from confidence intervals (CIs) on ES that reflect uncertainty in estimating ES. For a given CI on ES, sample sizes are computed as the minimum number of patients required to provide $\geq$80% power at α =0.05 for rejecting the null hypothesis (defined as no difference in the 3-month mean change in TIS comparing novel versus existing methods).

Results: Based on the 95% CI analysis, sample sizes using existing joint assessment methods in conjunction with the 12-joint approach ranged from 10 to 234. The corresponding sample sizes using the ICUS method with the 12-joint approach ranged from 7 to 39, and using the IUS method with the 12-joint approach ranged from 6 to 37. The corresponding sample sizes using the ICUS method with the 7-joint approach ranged from 6 to 24, and using the IUS method with the 7-joint approach ranged from 6 to 35.

Table 1. Summary statistics for novel versus existing methods on 3-month change in scores

Method/Approach	Sample Estimates				95% CI	
	Mean 3-month change in TIS	SD of change in TIS	Effect Size	Post-hoc Sample Size	Effect Size	Sample Size
ICUS/7-joint	0.61	0.54	1.13	9	0.61, 1.64	6, 24
ICUS/12-joint	0.87	0.91	0.96	11	0.46, 1.43	7, 39
IUS/7-joint	0.66	0.67	0.99	11	0.49, 1.47	6, 35
IUS/12-joint	0.91	0.94	0.97	11	0.47, 1.45	6, 37
Existing/7-joint	0.10	0.29	0.34	70	-0.07, 0.75	16, –[1]
Existing/12-joint	0.22	0.35	0.63	68	0.18, 1.06	10, 234

CI: Confidence Interval; SD: Standard Deviation. [1]Interval contains zero which corresponds to the null hypothesis, so upper limit cannot be calculated.

Conclusions: Our findings strongly suggest that novel ultrasound joint selection methods result in smaller sample size requirements compared to existing methods, and provide justification for larger studies to confirm these observations.

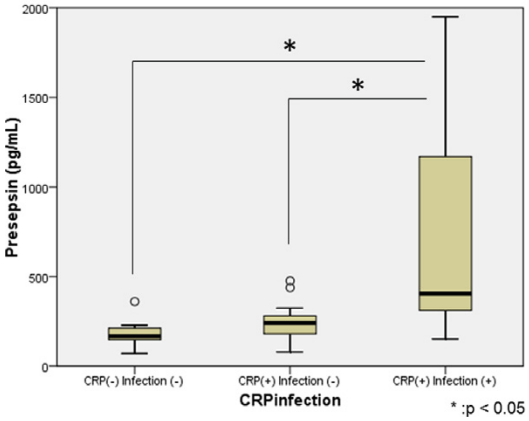
SAT0667 PRESEPSIN AND PROCALCITONIN ARE OF DIAGNOSTIC VALUE FOR BACTERIAL INFECTION IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

Y. Ichimura, Y. Kawaguchi, A. Tochimoto, T. Higuchi, M. Tochihara, Y. Katsumata, H. Yamanaka. *Institute of Rheumatology, Tokyo women's medical university, Tokyo, Japan*



Background: Recently, presepsin (soluble CD14-subtype) and procalcitonin are reported as a good diagnostic markers of bacterial infection, especially sepsis. However, their utility in patients with connective tissue diseases (CTDs) has been unknown.

Objectives: To assess the diagnostic value of presepsin and procalcitonin in patients with CTDs.

Methods: We enrolled the consecutive patients with CTDs, who checked the level of procalcitonin and/or presepsin during January to September, 2016, retrospectively. We divided two groups; the infection group and non-infectious group. Infection was diagnosed by symptoms, micro-bacterial methods and the good response to antibiotics. The data analysis were assessed using IBM SPSS statistics 22.

Results: Eighty-four patients with CTDs were enrolled, including 42 patients with rheumatoid arthritis (RA). The level of procalcitonin was evaluated in all patients, and the level of presepsin was in 48 patients. Thirty-six patients were classified in infection group; 38 patients in the CRP-positive non-infection group; and 10 patients in CRP-negative non-infection group. The level of presepsin was significant higher in infection group than CRP-positive non-infection group (693 +/- 577 pg/mL vs. 250 +/- 101 pg/mL, $p<0.01$) (Fig. 1). Among the patients with RA, the level of presepsin was significant higher in infection group than non-infection group (809 +/- 637 pg/mL vs. 233 +/- 135 pg/mL, $p<0.01$). AUCs of procalcitonin (0.823) and presepsin (0.821) showed similar diagnostic value. The cut-off value of presepsin and procalcitonin were 265 pg/mL and 0.16 ng/mL, respectively (sensitivity: 78.3% and 82.6%, specificity: 76.0% and 76.0%).

【Fig. 1】The level of presepsin in each group

Conclusions: Procalcitonin and presepsin may be of diagnostic value for bacterial infection in patients with CTDs, especially may distinguish bactrial infection from active phase in patients with CTDs.

SAT0668 ASSESSMENT OF INTRACRANIAL VESSELS AND VASCULAR LESIONS IN RHEUMATOID ARTHRITIS. A DETAILED TRANSCRANIAL DOPPLER, CAROTID ULTRASOUND AND BRAIN MRI STUDY

C. Oláh[1], Z. Kardos[2], M. Sepsi[3], A. Sas[4], L. Kostyál[3], H.P. Bhattoa[5], K. Hodosi[6], G. Kerekes[7], L. Tamási[2], A. Valikovics[4], D. Bereczki[8], Z. Szekanecz[6]. *[1]Department of Neurosurgery, Borsod County Teaching Horspital; [2]Department of Rheumatology, Semmelweis Teaching Hospital; [3]Department of Radiology; [4]Department of Neurology, Borsod County Teaching Horspital, Miskolc; [5]Department of Laboratory Medicine; [6]Department of Rheumatology; [7]Department of Angiology, University of Debrecen, Faculty of Medicine, Debrecen; [8]Department of Neurology, Semmelweis University, Budapest, Hungary*

Background: Stroke has been associated with rheumatoid arthritis (RA). Vascular physiology should be assessed in the preclinical vascular state.
Objectives: We assessed RA patients and healthy controls by transcranial Doppler (TCD), carotid ultrasonography and brain MRI. We wished to determine preclinical pathophysiological changes in the cerebral vasculature.
Methods: Altogether 63 female RA patients and 60 age-matched controls underwent TCD assessment of the medium cerebral (MCA), basilar and vertebral arteries. Pulsatility (PI), resistance (RI) indices and circulatory reserve capacity (CRC) were determined. The presence of carotid plaques and intima-media thickness (cIMT) were also determined. Intracerebral vascular lesions were investigated by brain MRI. RA subsets include MTX- and biologic-treated patients.
Results: MCA PI and RI values at rest and after apnea are significantly increased in the total RA population vs controls. MCA PI (r) and RI (r) is also lower in biologic-treated patients. MCA CRC was also impaired and basilar artery PI was higher in RA. More RA patients had carotid plaques and had increased cIMT. Correlation analysis suggested multiple associations between right and left TCD parameters. There may be an association of TCD and carotid features with cerebral atrophy and age. Disease duration, disease activity and anti-CCP may influence left MCA PI and RI, as well as CRC. Lp(a) may also influence the development of carotid plaques.
Conclusions: This may be the first study to show increased distal MCA and basilar artery occlusion in RA as determined by TCD. RA patients also exert CRC defect. We also confirmed increased carotid plaque formation, increased cIMT. Biologics may beneficially influence some parameters in the intracranial vessels.

Epidemiology, risk factors for disease or disease progression

SAT0669 HOW DO WE USE BIOLOGICS IN PATIENTS WITH A HISTORY OF MALIGNANCY? AN ASSESSMENT OF TREATMENT PATTERNS USING SCANDINAVIAN REGISTERS

K. Chatzidionysiou[1], K. Aaltonen[2], D. Nordström[2], B. Gudbjornsson[3], G. Grondal[4], A.J. Geirsson[4], L. Steingrimsdottir[5], T. Frisell[1], J. Askling[1] on behalf of for the Nordic Rheumatology Register Collaboration. *[1]Clinical Epidemiology Unit, Dept of Medicine Solna, Karolinska Institutet, Stockholm, Sweden; [2]Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland; [3]Centre for Rheumatology Research, University Hospital & Faculty of Medicine, University of Iceland; [4]Department of Rheumatology, University Hospital Reykjavik; [5]Icelandic Cancer Registry, Reykjavik, Iceland*

Background: Immune competence is of importance for the occurrence and outcome of malignancies. Robust data on risk of relapse of previous cancer following treatment with biological immune-modulators are scarce. Most treatment guidelines caution about their use in patients with a history of cancer, leaving rheumatologists with the decision whether a potential treatment benefit may offset any potential risk of cancer relapse.
Objectives: To assess the overall use of biologics and the relative use of different biological drugs in RA patients with a history of cancer.
Methods: As part of a Nordic collaboration, and using data from the ARTIS (Sweden), ROB-FIN (Finland), and ICEBIO (Iceland) biologics registers, we identified all patients with RA who initiated a first ever biological treatment 2010 through 2014. Through linkage to the national cancer registers, we identified those patients who had a history of any invasive malignancy (including squamous cell skin cancer) either within the five years preceding start of biological treatment ("recent history of malignancy") or more than five years before start of biological treatment ("non-recent history malignancy).
Results: The age- and gender distributions were similar across countries and drugs. Initiators of non-TNFi biologics were older than TNFI-initiators; the median age at start was the highest for rituximab. Out of a total of 8065 bio-initiations, 6% occurred in individuals with a history of cancer (2% with a cancer within 5 years, and 4% with a cancer more than 5 years before treatment start. Whereas there was little variation (around 5%) across TNFi initiators, the proportion of patients with a history of cancer at treatment start was higher among rituximab initiators, in part explained by age (Table). There were only small variations across country (not shown).
Conclusions: In Sweden, Finland and Iceland, one out of 20 biologics-initiators (and almost one out of five rituximab initiators) have a history of an invasive cancer, underscoring the need for more data on benefit/risks in this treatment context. The higher proportion in rituximab initiators is partly explained by differences in age at treatment start and reflects the preference for rituximab by clinicians for treatment of patients with history of cancer.

SAT0670 THE PREVALENCE OF NEUROPATHIC PAIN-LIKE SYMPTOMS AND ASSOCIATED RISK FACTORS IN THE NOTTINGHAM COMMUNITY: A CROSS-SECTIONAL STUDY

G.S. Fernandes[1,2,3], A. Sarmanova[1,3], S. Warner[1], H. Harvey[1], H. Richardson[1], N. Frowd[1,3], L. Marshall[1,3], J. Stocks[1,3], M. Hall[1,3], A. Valdes[1,2,3], D. Walsh[1,2,3], W. Zhang[1,2,3], M. Doherty[1,2,3]. *[1]Division of Rheumatology, Orthopaedics and Dermatology; [2]Arthritis Research UK Centre for Sports, Exercise and Osteoarthritis; [3]Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom*

Background: Knee pain (KP) affects 1 in 4 adults over the age of 50. Aside from structural joint changes, person-specific factors influence the KP experience. Increased central sensitisation of neural pathways due to localised joint pain or ineffective descending inhibitory mechanisms can cause an enhanced pain response and neuropathic pain-like (NP) symptoms. Understanding these person-specific factors and how they modulate the pain experience might help profile different KP and NP phenotypes.
Objectives: a) To determine the prevalence of NP in a KP community population b) to identify significant risk factors associated with NP and those with both NP and non-NP KP.
Methods: 9,513 men and women, aged 40+ years, were recruited from the East Midlands region (United Kingdom) via postal questionnaire. The questionnaire included sections on KP severity (numerical rating scale) and type (NP versus nociceptive) using the modified PainDETECT Questionnaire (mPDQ); quality of KP using the intermittent and constant osteoarthritis pain (ICOAP) instrument) as well as other risk factors including age, body mass index (BMI), injury, pain catastrophizing scale (PCS) and mental wellness (Hospital Anxiety and Depression Scale). KP participants were those who reported *"knee pain for most days of the past one month"* while likely NP was mPDQ scores of $\geq$13 and definite NP, $\geq$19. Differences between groups were assessed using t-tests for continuous data and chi^2 for categorical data. We used multinomial regression analysis to determine the odds ratios (ORs) of risk factors with 95% confidence intervals (CI) and significance set $p<0.05$.
Results: The prevalence of definite NP in the Nottingham Community was 366 (13.62%). There were more women (p=0.04) and higher BMI (p<0.001) in KP vs. non-KP responders but no age difference (p>0.05). When comparing the neuropathic-like KP to non-neuropathic KP responders, significant risk factors after adjustment for age, BMI, gender and pain severity included: anxiety (OR 3.17 (95% CI 2.38;4.23)); depression (OR 2.99 (95% CI 2.14;4.19)); PCS in highest tertile (OR 5.39 (95% CI 2.94;9.88)); fibromyalgia (OR 4.06 (95% CI 2.48;6.66)) and previous knee injury (OR 1.5 (95% CI 1.12;2.00)). When comparing neuropathic-like KP to non-KP responders, anxiety (1.74 (95% CI 1.31; 2.30), depression (2.05 (95% CI 1.40; 3.01), PCS 3.78 (95% CI 2.57; 5.56)), fibromyalgia (OR 1.94 (95% CI 1.10; 3.40)) and previous injury (OR 1.35 (95% CI 1.05; 1.73)) were significant risk factors after adjustment.
Conclusions: This is the first population based cross-sectional study in the UK to determine prevalence of NP in people with KP. The results suggest that both psychological factors (depression, anxiety, high catastrophising) and peripheral risk factors (injury) associate with NP reporting. These factors can augment pain sensitivity and produce an amplified response via central and peripheral pathways. Phenotypes based on these risk factor profiles may warrant specific management in KP populations.

SAT0671 THE IMPACT OF OBESITY ON TREAT TO TARGET GOALS AND FUNCTIONAL ABILITY IN THE ERAS/ERAN UK PROSPECTIVE COHORTS

E. Nikiphorou[1], S. Norton[1], P. Kiely[2], A. Young[3] on behalf of ERAS/ERAN. *[1]KCL; [2]St George's Hospital, London; [3]St Albans Hospital, St Albans, United Kingdom*

Background: The links between adipose tissue and inflammation on the one hand and obesity and joint dysfunction on the other, are well established. However, how these translate into clinical disease activity and functional disability in rheumatoid arthritis (RA), remains to be clearly defined.
Objectives: To investigate the association between BMI and 1. The achievement of disease remission or low disease activity and 2. Functional ability, in RA.
Methods: Data from two consecutive UK multi-centre RA inception cohorts with similar design were used: the Early RA Study (ERAS) and Early RA Network (ERAN). Recruitment figures/median follow up for ERAS and ERAN were 1465/10 years (maximum 25 years), and 1236/6 years (maximum 10 years) respectively. Standard demographic and clinical variables were recorded at baseline and then annually until loss to follow-up or the end of study follow-up. Multilevel logistic regression analysis was used with either remission (R-DAS) or low disease activity status (L-DAS) and health assessment questionnaire (HAQ, <1 vs $\geq$1) as the dependent categorical variables of interest in models adjusting for patient, disease-related clinical variables and recruitment year. BMI was examined in separate models as both a continuous and categorical predictor variable according to WHO definitions: underweight (BMI less than 18.5), normal (BMI between 18.5 and 25), overweight (BMI between 25 and 30) and obese (BMI greater than 30). BMI was included in the models relating to the same time point as the outcome assessed.
Results: Baseline BMI data from 2420 patients (90%) indicated that 40.0% had BMI scores in the normal range, 1.8% were underweight, 37.2% were overweight and 21.3% were obese. Mean BMI increased slightly over time from 26.5 at baseline to 26.8 at 2 years and then 27.1 at 5 years. In multilevel logistic models adjusting for age, sex, smoking status, antibody status, haemoglobin, erosions and year of recruitment, higher BMI was associated with reduced odds of achieving R-DAS (OR 0.97;95% CI 0.95, 0.99) (table) and L-DAS, although the latter did not reach statistical significance (OR 0.98;95% CI0.96, 1.00). Obesity was related to a significantly lower chance of R-DAS by 29% (OR 0.71;95% CI 0.55, 0.93) and L-DAS by 31% (OR 0.69;95% CI 0.55,0.87). Higher BMI was predictive of higher disability (OR 1.04;95% CI 1.01,1.06). More specifically, obesity increased the odds of higher disability by 63% (OR 1.63;95% CI 1.20,2.23) and in the same models, higher DAS was also strongly predictive of higher disability (OR 3.67;95% CI 3.41,3.95).

Table. Impact of BMI category on disease activity and functional ability in models adjusting for patient demographic, clinical & disease variables.

Independent predictors	MODELS		
	Remission DAS OR (95% CI) (n=1690)	Low DAS OR (95% CI) (n=1690)	HAQ OR (95% CI) (n=1688)
Age at disease onset (years)	0.98(0.97,0.99)	0.98(0.97,0.99)	1.03(1.02,1.05)
Female gender	0.32(0.25,0.41)	0.31(0.24,0.39)	2.47(1.76,3.45)
Past smoking (vs no smoking)	0.58(0.43,0.78)	0.58(0.44,0.77)	1.77(1.20,2.62)
Current smoking (vs no smoking)	0.56(0.42,0.75)	0.66(0.51,0.86)	1.73(1.19,2.51)
Positive rheumatoid factor/anti-CCP	0.83(0.65,1.06)	0.82(0.66,1.02)	1.09(0.79,1.49)
Disease activity score (DAS)	-	-	3.67(3.41,3.95)
Presence of baseline erosions	0.80(0.61,1.04)	0.85(0.67,1.09)	0.63(0.45,0.89)
Haemoglobin (g/dL)	1.03(1.01,1.04)	1.01(1.00,1.03)	1.00(0.98,1.02)
Recruitment year	1.09(1.07,1.11)	1.07(1.06,1.09)	1.09(1.07,1.12)
BMI category* (kg/m^2)			
-Underweight	1.28(0.73,2.26)	1.23(0.75,1.99)	1.83(0.99,3.38)
-Overweight	0.97(0.80,1.18)	0.88(0.74,1.05)	0.97(0.77,1.22)
-Obese	0.71(0.55,0.93)	0.69(0.55,0.87)	1.63(1.20,2.23)

**Reference category = normal BMI*

Conclusions: The findings support a link between higher BMI and worse clinical outcomes, namely disease activity and functional ability. Obesity was associated with lower levels of both remission and low disease activity states, and of higher disability. The findings highlight the importance of monitoring the patients' weight, screening and targeting obesity as part of routine clinical practice, in order to improve disease outcomes. This work provides clinical insights into the role of BMI on disease outcomes in RA.

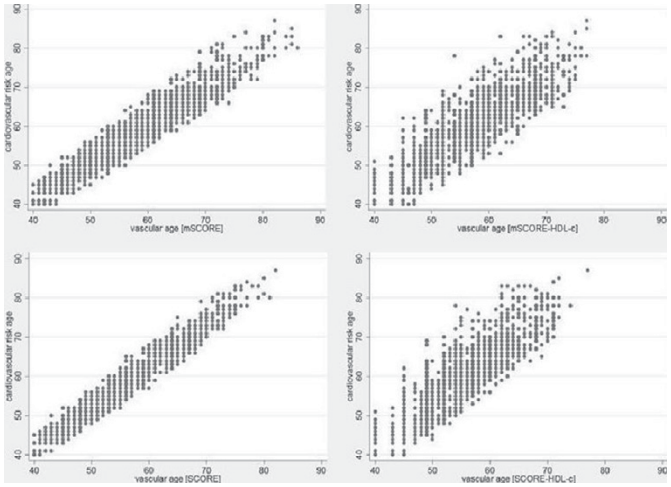
SAT0672 RISK OF FRAGILITY FRACTURE AMONG PATIENTS WITH PSORIASIS: A POPULATION BASED MATCHED COHORT STUDY FROM THE UNITED KINGDOM

Z. Paskins[1,2], R. Whittle[1], A. Abdul Sultan[1], S. Muller[1], M. Blagojevic-Bucknall[1], T. Helliwell[1], S. Hider[1,2], E. Roddy[1,2], C. Mallen[1]. *[1]Research Institute for Primary Care and Health Sciences, Keele University, Keele; [2]Haywood Rheumatology Centre, Haywood Hospital, Burslem, Stoke-on-Trent, United Kingdom*



Background: Psoriasis is a common inflammatory skin disease affecting 2–4% of the population and of these a subset will develop an associated inflammatory arthritis (psoriatic arthritis - PsA). An increased risk of osteoporosis has previously been reported in psoriasis patients but the risk of fracture in patients with both psoriasis and PsA has not been established.
Objectives: To estimate the effect of psoriasis, and PsA, on the risk of fracture using a large electronic primary health care database.
Methods: A matched cohort study was conducted utilizing data from the Clinical Practice Research Datalink, a large UK database of primary care medical records. The exposed population was defined as psoriasis patients aged over 40 years with an incident diagnosis between 1990–2004, who were followed up until 2015. Four unexposed patients were matched to each exposed based on age, sex and general practice. The incidence rate of fracture were calculated as the number of incident diagnoses per 10,000 person-years, stratified by sex. Hazard ratios (HR) and 95% confidence intervals were estimated using a Cox proportional hazards model to compare the hazard rate between the exposed and unexposed, adjusting for BMI, alcohol consumption, smoking status, Charlson comorbidity index and steroid use. Fracture risk was estimated for patients with both psoriasis and PsA, identified as patients with an incident diagnosis of psoriasis and a diagnosis of PsA between 1990–2004.
Results: 24,219 patients with psoriasis and 94,820 controls were included in the study. The mean age was 59 years at study entry and just over half (51%) of the patients were male. The incidence rate of fracture was 58.4 (95% CI:55.6–61.3) and 53.1 (51.7–54.5) per 10,000 person-years for the exposed and unexposed, respectively. After adjusting for confounding factors, patients with psoriasis had 12% increased risk of fracture (HR: 1.12; 95% CI: 1.06–1.19) compared to the matched unexposed group. The risk was slightly higher in males (1.22 (1.09–

1.36)) than females (1.09 (1.03–1.17)). Among those with psoriasis, 4.1% were also diagnosed with PsA. An increased risk of 45% was found in those exposed to both psoriasis and PsA compared to the unexposed group (1.45 (1.09–1.94)).
Conclusions: This study reports for the first time, an increase in fracture risk in patients with psoriasis. A higher risk was found in males than females and the risk was further increased if the patient also had PsA. These findings suggest that fracture risk assessment needs to be considered for individuals with psoriasis and PsA.

SAT0673 RISK AGE AND RELATIVE RISK OF CVD IN INFLAMMATORY JOINT DISEASES

G. Wibetoe[1], E. Ikdahl[1], S. Rollefstad[1], I. Olsen[1], K. Bergsmark[1], T. Kvien[1], A. Salberg[2], D. Soldal[3], G. Bakland[4], Å. Lexberg[5], B.T. Fevang[6], H.C. Gulseth[7], G. Haugeberg[8], A.G. Semb[1]. *[1]Diakonhjemmet Hospital, Oslo; [2]Lillehammer Hospital for Rheumatic Diseases, Lillehammer; [3]Hospital of Southern Norway, Kristiansand; [4]University Hospital of Northern Norway, Tromsø; [5]Vestre Viken Hospital, Drammen; [6]Haukeland University Hospital, Bergen; [7]Betanien Hospital, Skien; [8]Martina Hansens Hospital, Bærum, Norway*

Background: Individuals with inflammatory joint diseases (IJD) [rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA)] have increased risk of cardiovascular disease (CVD). In the European guidelines for CVD prevention, calculation of relative risk and risk age is advised in patients with low absolute risk of fatal CVD events the next 10 years estimated by the systematic coronary risk evaluation [SCORE] algorithm; the rational being that low absolute risk may conceal high relative risk and risk ages far beyond chronological age. Thus, more patients needing intensive CVD prevention may be identified.
Relative risk is a ratio comparing absolute CVD risk in a specific patient to the risk given optimal CVD risk factor levels (CVDRFs). Risk age denotes the age with similar CVD risk and optimal CVDRFs. To this date, no studies have evaluated relative risk and risk age across IJD entities, neither has the agreement between different risk age models been investigated.
Objectives: 1) Estimate relative risk and risk age across IJD entities. 2) Investigate agreement between different risk age models.
Methods: RA/axSpA/PsA patients aged 40≤65 years with low/moderate 10-year risk of fatal CVD were included from a nationwide quality assurance project implementing CVD risk assessment. Relative risk and cardiovascular risk age was calculated in accordance with risk charts published by the European Society of Cardiology (2016) and Cooney et al (2012), respectively. Vascular age was calculated by matching SCORE to estimated risk ages in accordance with Cuende et al (2010). Four different vascular age estimations were calculated, depending on whether the EULAR 1.5 multiplication factor in RA was applied (mSCORE) and if SCORE version with HDL-c (SCORE-HDL-c) was used: SCORE, SCORE-HDL-c, mSCORE and mSCORE-HDL-c. Risk years beyond chronologic age, were calculated. Linear regression models were used to investigate agreement between risk age estimations.
Results: Relative risk was increased in 53% of all patients and 20% had three times the risk or higher compared to individuals with optimal CVDRF levels. In total, 42% and 20% had a risk age ≥5 years higher than their chronologic age, according to the cardiovascular risk age model and the vascular age model derived from SCORE, respectively. There were minor differences between RA, axSpA and PsA patients in terms of relative risk and risk age. Agreement between cardiovascular risk age and various vascular age models varied (Figure). Discrepancies ≥5 years in estimated risk age were observed in 14–43% of estimations. The largest observed difference in calculated risk age was 24 years. Similarly, linear regression models yielded a R^2 of 0.81–0.96. Across all models, median difference between risk age and age increased with advancing relative risk. Moreover, several patients had high relative risk despite a risk age close to their chronologic age.

Conclusions: Relative risk and risk age may identify several patients at high need of intensive CVD preventive efforts despite low estimated absolute risk. However, there are considerable discrepancies between risk age models.

SAT0674 EARLY TREATMENT RESPONSE TO CONVENTIONAL DMARD THERAPY IN RHEUMATOID ARTHRITIS IS A BETTER PREDICTOR OF LOW DISEASE ACTIVITY OR TREATMENT ESCALATION AT 12 AND 24 MONTHS THAN AUTOANTIBODIES OR EROSIONS

A. Richter[1], A. Strangfeld[1], P. Herzer[2], J. Kaufmann[3], T. Klopsch[4], S. Zinke[5], J. Listing[1], A. Zink[1,6]. *[1]German Rheumatism Research Center, Berlin; [2]Scientific Advisory Board, Munich; [3]Rheumatologist, Ludwigsfelde; [4]Rheumatologist, Neubrandenburg; [5]Rheumatologist; [6]Charité University Medicine, Berlin, Germany*

Background: The EULAR guidelines recommend using the presence of seropositivity or erosions to support treatment decisions. The prognostic value of these factors regarding the primary treatment target in rheumatoid arthritis, remission or low disease activity (LDA), is unclear.
Objectives: To investigate biomarkers, csDMARD treatments and response to treatment regarding their usefulness to predict LDA or the need to escalate treatment within 24 month.
Methods: The control group in RABBIT (Rheumatoid Arthritis: Observation of biologic therapy) comprises N=2,228 patients who were enrolled at treatment start with conventional-synthetic (cs)DMARDs after failure of at least one csDMARD therapy, mostly methotrexate (MTX) monotherapy. We excluded patients with a DAS28-ESR<3.2 at enrollment and those with ≥2 csDMARD failures (n=618). 102 patients were excluded due to enrollment less than 12 month prior to closure of the data base (April 30th, 2016). The DAS28-ESR, physical function, age, seropositivity (RF+/ACPA+), comorbidities (≥3 vs. <3) and the presence of erosions at baseline were evaluated as prognostic factors. Concomitant treatment with glucocorticoids (mg/d) and csDMARDs, response to treatment (3–6 month after enrollment) were additionally examined. We applied a multinomial generalized-estimating-equation (GEE) model to investigate: (1) achievement of LDA at month 12/24 or (2) treatment escalation (biologic treatment) in year one and two after enrollment.
Results: More than one third of patients (34.2%) were treated with a combination of MTX and leflunomide (LEF), 23.6% with LEF mono, 20.8% with MTX + hydroxychloroquine (HCQ) or sulfasalazine (SSZ), 16.5% with MTX mono, and 4.9% with SSZ mono. We found no major differences across treatment regimens except for patients treated with MTX+HCQ who had a lower DAS28, better physical function and shorter disease duration at treatment start. Significant predictors for achieving LDA were low DAS28 at baseline, improvement in DAS28 within 3–6 month, better physical function and less than 3 comorbidities (table). Escalation to bDMARD therapy was significantly more frequent in younger patients, those with no improvement in DAS28 or concomitant glucocorticoid treatment, and in patients with less than 3 comorbidities. There were no differences between treatments regarding achievement of LDA. However, switching to bDMARDs was

Table: Results of the multinomial GEE-model in odds-ratios (OR) and 95% confidence interval (CI).

	Achievement of LDA at month 12 or 24	Escalation of Therapy within 12 or 24 month
	OR [95% CI]	OR [95% CI]
Age (per 10 years)	0.97 [0.87; 1.07]	**0.77 [0.70; 0.86]**
DAS28 improvement ≤6 month (per unit)	**1.68 [1.51; 1.87]**	**0.86 [0.76; 0.97]**
Erosions (Yes vs. No)	0.95 [0.75; 1.20]	1.16 [0.86; 1.55]
Seropositivity (Yes vs. No)	0.83 [0.67; 1.02]	0.89 [0.68; 1.17]
DAS at Baseline	**0.67 [0.59; 0.76]**	1.14 [1.00; 1.30]
Physical function	**1.13 [1.07; 1.19]**	1.04 [0.97; 1.11]
≥3 Comorbidities (vs. <3 comorbidities)	**0.73 [0.55; 0.97]**	**0.69 [0.49; 0.98]**
Glucocorticoids (per 5mg/d)	0.96 [0.79; 1.16]	**1.45 [1.23; 1.71]**
MTX monotherapy (Reference)		
LEF	0.81 [0.58; 1.13]	**1.55 [1.01; 2.39]**
MTX + HCQ | SSZ	1.20 [0.86; 1.66]	1.19 [0.74; 1.90]
MTX + LEF	0.81 [0.59; 1.11]	**1.85 [1.24; 2.77]**
SSZ	0.89 [0.50; 1.59]	1.47 [0.74; 2.89]
Year 2 vs. Year 1	1.20 [0.92; 1.56]	**1.47 [1.11; 1.96]**

most frequent in patients treated with LEF mono or with LEF+MTX. The presence of erosions or seropositivity were not associated with any of the outcomes (table).

Conclusions: The highest impact on achieving LDA was found in disease activity at baseline and response to treatment within 3–6 month. The relevance of erosions and/or seropositivity regarding the prediction of a poorer outcome is disputable.

SAT0675 THE ROLE OF EROSIONS TYPICAL OF RHEUMATOID ARTHRITIS IN THE 2010 ACR/EULAR RHEUMATOID CLASSIFICATION CRITERIA: RESULTS FROM A VERY EARLY ARTHRITIS COHORT

G.H. Brinkmann[1,2], E.S. Norli[2,3], P. Bøyesen[2], D. van der Heijde[4], L. Grøvle[1], A.J. Haugen[1], H. Nygaard[5], O. Bjørneboe[3], C. Thunem[2], T.K. Kvien[2], M.D. Mjaavatten[2], E. Lie[2]. *[1]Østfold Hospital Trust, Moss; [2]Diakonhjemmet Hospital, Oslo; [3]Martina Hansens Hospital, Sandvika, Norway; [4]Leiden University Medical Center, Leiden, Netherlands; [5]Lillehammer Hospital of Rheumatic diseases, Lillehammer, Norway*

Background: A EULAR task force has proposed that in addition to the 2010 ACR/EULAR rheumatoid arthritis (RA) classification criteria (2010 RA criteria), patients can still be classified as having RA with less than 6 criteria points on the presence of ≥3 joints with typical erosions on conventional radiographs of hands and feet (erosion criterion) (1).

Objectives: To determine how the EULAR definition of erosive disease contributes to the number of patients classified as RA according to the 2010 RA criteria in an early arthritis cohort.

Methods: Patients with arthritis of ≤16 weeks duration and a clinical diagnosis of RA or undifferentiated arthritis (UA) with available hand and feet radiographs were included from the Norwegian Very Early Arthritis Clinic (NOR-VEAC) study. Erosive disease was defined according to the EULAR definition accompanying the 2010 RA criteria, i.e. ≥3 erosive joints (1). We calculated the additional number of patients being classified as RA based on the erosion criteria at baseline and during follow-up. Other cut-offs and the distribution of erosive joints was also examined.

Results: The current study included 289 patients (mean (SD) age 48 (14.7) years, 54.3% females, median (25, 75 perc) duration of joint swelling 46 (19.5, 79.0) days). At baseline, 120 patients (41.5%) fulfilled the 2010 RA criteria. Of the remaining 169 not fulfilling the 2010 RA criteria, 55 patients had ≥1 erosive joint (40 with hand erosions, 28 with feet erosions and 13 with hand and feet erosions) and 15 (5.2%) patients fulfilled the erosion criterion (Figure 1). The distribution of erosive joints in the 169 patients not fulfilling the 2010 RA criteria at baseline is shown in the table.

	Erosive joints at baseline					
	PIP	MCP	Wrist	CMC + os trapezium	MTP	IP1 feet
≥1 erosive joint (n=55)	23	17	12	8	22	12
≥2 erosive joints (n=27)	11	13	10	8	12	8
≥3 erosive joints (n=15)	6	8	9	6	8	7

118 patients had radiographic follow-up at 2 years, of whom only 1 additional patient solely fulfilled the erosion criterion during follow-up (7 additional patients fulfilled both the 2010 criteria and the erosion criterion). Among patients with no erosions at baseline (N=74), 13 (17.6%) developed erosions during follow-up (PIP joints n=3, MCP n=4, wrist n=3, CMC joint n=1, MTP joints n=9 and IP1 joint in the foot n=3).

Conclusions: Among this cohort of patients with very early arthritis, 5.2% were classified as RA at baseline based solely on the erosion criterion. Of the 118 patients with 2-year follow-up data, only 1 additional patient was classified based on the erosion criterion alone during follow-up, thus, follow-up radiographs in patients with early UA do not seem to provide additional information in classifying patients with RA.

SAT0676 (SERONEGATIVE) MALES SHOW BETTER EULAR TREATMENT RESPONSE THAN FEMALES IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS (RA)

M. Yates[1], J. Galloway[1], A. Rivett[2], S. Norton[1], J.M. Ledingham[3], E.M. Dennison[4], A.J. Macgregor[5], K. Bechman[1], A. Rutherford[1], N. Snowden[6]. *[1]Academic Rheumatology, King's College London; [2]The British Society for Rheumatology, London; [3]Rheumatology Dept, Portsmouth Hospitals NHS Trust, Portsmouth; [4]MRC, Southampton University, Southampton; [5]Rheumatology Dept, Norfolk and Norwich University Hospital, Norwich; [6]Rheumatology Dept, Pennine MSK Partnership, Oldham, United Kingdom*

Background: Gender has been reported to play a role in attainment of RA remission (1), but the data are inconsistent. The impact of gender in early RA therefore warrants further investigation.

Objectives: To assess the impact of gender on early RA outcomes.

Methods: An audit, designed as a national prospective longitudinal observational study, was conducted to assess early RA care. All NHS providers in England and Wales were required to participate. Follow up data were captured over 3 months for subjects with a diagnosis of RA. Logistic regression was used to estimate associations between gender and DAS-28 response. Smoking status, baseline disease activity, age, antibody status, symptom duration, referral times, and treatment were considered in multivariate models.

Results: 136 of 146 eligible trusts submitted data. 11,752 subjects consented, 5,622 were diagnosed with RA. DAS-28 response was available for 2234/5622 (39.7%). Male patients had a similar 3 month improvement in their DAS-28 to females, despite having a lower mean baseline score. Male gender associated with a higher rate of good EULAR response (DAS improvement >1.2, follow up DAS <3.3), with an adjusted odds ratio of 1.42 (CI 1.17–1.72). There were no differences between the genders in their treatment use or in other aspects of care including speed of referral (Table 1).

Table 1

	Male N=786	Female N=1432	P value

*t-test **chi-squared. Social deprivation decile from deprivation rank calculated via super output area.

The male excess in good EULAR response was more pronounced in seronegative compared with seropositive RA (1.98 (CI 1.4–2.8) compared to 1.21 (0.96–1.53)).
Conclusions: The association of male gender with improved outcomes in early RA has not been shown before in a national cohort of this scope. Previous work suggests seronegative individuals achieve greater clinical response (2), here we present this effect amplified in men. To the authors' knowledge this is a new finding. This is likely multifactorial, with biological effect of gender, greater diagnostic uncertainty and higher reporting of global scores in women all potentially playing a role.

SAT0677 THE IMPACT OF DISEASE ACTIVITY DURING PREGNANCY IN WOMEN WITH SLE ON THE OCCURRENCE OF PREECLAMPSIA AND PREMATURE BIRTH

A.C.G. Skorpen[1,2], S. Lydersen[3], I.-M. Gilboe[4], K.Å. Salvesen[5], M. Wallenius[1,2]. *[1]National advisory unit on Pregnancy and Rheumatic Diseases, Trondheim University Hospital; [2]Department of Neuromedicine and Movement Science; [3]Regional Center for Child and Youth Mental health and Child Welfare, Norwegian University of Science and Technology, Trondheim; [4]Department of Rheumatology, Oslo University Hospital Rikshospitalet, Oslo; [5]Department of Laboratory Medicine, Children's and Women's Health, Norwegian University of Science and Technology, Trondheim, Norway*

Background: Pregnancy in women with systemic lupus erythematosus (SLE) is associated with an increased risk of complications such as preeclampsia and premature birth. Active disease is considered one of the risk factors.
Objectives: The aim of this study was to explore the impact of disease activity in pregnant women with SLE on preeclampsia and premature birth, and compare the occurrence with pregnancies from the general obstetric population.
Methods: We linked data from RevNatus with data from the Medical Birth Registry of Norway (MBRN). RevNatus is a Norwegian nationwide prospective observational register including women with an inflammatory rheumatic disease when planning pregnancy or after conception. The register was established in 2006 and is administered by the National advisory unit on pregnancy and rheumatic diseases. Women 18 years or older are recruited and followed-up in each trimester of pregnancy and at 6 weeks, 6 months and 12 months after birth. MBRN is a national birth registry. The population constituted all singleton live births recorded in MBRN in the period 2006 – 2014. The births in women diagnosed with SLE in MBRN and included in RevNatus formed the patient group (n=180). The references were all other births (n=498849). We performed logistic regression, and calculated OR for preeclampsia and premature birth in the patient population compared to the references from the general obstetric population. The target population was then split in two groups according to disease activity assessed in the 2nd trimester, and compared to references.
Results: Women with SLE had a significantly higher risk of preeclampsia and premature birth than references after adjustment for maternal age, parity and smoking (Table 1).
Concerning preeclampsia, there was no significant difference in women with no disease activity compared to references, whereas active disease resulted in a significantly higher odds. We observed a two-fold and eight-fold increase in risk of premature birth in women with quiescent and active disease, respectively (Table 2).

Table 1. Preeclampsia and premature birth in references and in women with SLE

Adverse event, n (%)	References n=498,849	SLE n=180	Adj OR* (95% CI)	p
Preeclampsia	15132 (3.0)	14 (7.8)	2.64 (1.53, 4.58)	0.001
Premature birth	27063 (5.5)	34 (18.9)	4.25 (2.92, 6.19)	<0.001

*Adjusted for maternal age, parity and smoking in pregnancy.

Table 2. Preeclampsia and premature birth in references and in women with SLE according to disease activity status

Adverse event, n (%)	References n=498,849	No disease activity† n=85	Adj OR* (95% CI)	p
Preeclampsia	15132 (3.0)	4 (4.7)	1.60 (0.58, 4.38)	0.36
Premature birth	27063 (5.4)	11 (12.9)	2.78 (1.47, 5.24)	0.002
Adverse event, n (%)	References n=498,849	Disease activity‡ n=63	Adj OR* (95% CI)	p
Preeclampsia	15132 (3.0)	9 (14.3)	5.05 (2.48, 10.30)	<0.001
Premature birth	27063 (5.4)	21 (33.3)	8.63 (5.10, 14.60)	<0.001

†LAI-P=0. ‡LAI-P>0. *Adjusted for maternal age, parity and smoking in pregnancy.

Conclusions: Women with SLE have a higher risk of preeclampsia and premature birth than references from the general obstetric population. Women with active disease in pregnancy are most prone to these complications.

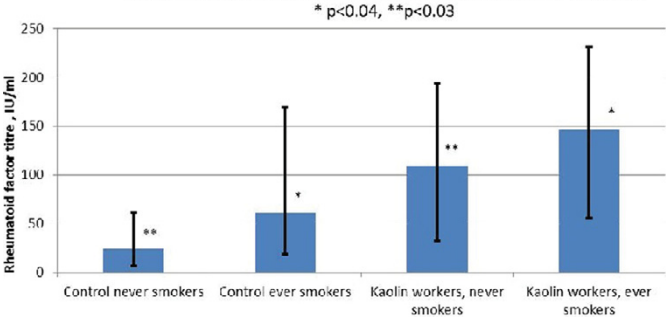
SAT0678 SIGNIFICANTLY INCREASED SEROPOSITIVITY, RHEUMATOID FACTOR TITRES AND RHEUMATOID NODULES IN CORNISH KAOLIN WORKERS



D. Murphy[1,2], E. Fleeming[2], K. Bellis[1], D. Hutchinson[1,2]. *[1]Rheumatology, Royal Cornwall Hospital; [2]University of Exeter Medical School, Cornwall Campus, Truro, United Kingdom*

Background: Kaolin has been mined in Cornwall, UK for over 250 years, with half of the world's production originating from the area at the turn of the 20th century. Mineral kaolinite does not react as free silica, and is used in heavy metal contamination containment due to its adsorption capabilities.[1]
Objectives: To investigate the prevalence of occupational kaolin dust exposure in male rheumatoid arthritis (RA) patients in Cornwall, UK.
Methods: All males diagnosed with RA under follow up at the Royal Cornwall Hospital, UK, during the study period April 2015-January 2017, were invited to complete an occupational questionnaire, detailing current occupation, last occupation (if retired) and other occupations for >1 year.
Results: 39/720 (5%) cases were excluded on non-return of initial questionnaires. 41/720 (6%) cases died during the study period (22 months). 54/640 (8%) remaining cases had occupational kaolin exposure, approximately 12 times higher than expected based on current census employment rates. 30/54 had long term kaolin dust exposure, living in the post code region PL22-PL26 (total male population 33693). These were matched for age ±2 years, sex and index of multiple deprivation (IMD) ±1 decile, to RA patients with no occupational dust or fume exposure. 40/110 potential controls were successfully matched.
Significantly more RA kaolin workers were seropositive for RF and ACPA than non-dust exposed RA controls (Table 1). Of RF seropositive patients, median RF titres were significantly higher in kaolin workers than unexposed controls (p<0.01). No significant differences were seen in ACPA titre. Smoking prevalence rates were not significantly different between kaolin workers and controls. Amongst ever smokers, median pack years smoked showed no difference between cases and controls.

	Kaolin workers (n=30)	Control (n=40)	Significance
RF+	28/30 (93%)	30/40 (75%)	p<0.05
ACPA+	27/30 (90%)	24/40 (60%)	p<0.01
Median seropositive RF titre (IQR)	142 (68–124)	61 (25–162)	p<0.01
Median seropositive ACPA titre (IQR)	375 (169–500)	283 (199–500)	Not sig.
Ever smokers (%)	23/30 (77%)	26/40 (65%)	Not sig.
Median pack years ever smokers (IQR)	18 (15.5–32)	17 (10.75–32.25)	Not sig.

Kaolin exposed never smokers demonstrated significantly higher RF titres than unexposed never smokers (kaolin median RF 109 (IQR 32–193.5), control median RF 24 (IQR 7–61), p<0.04), as did kaolin exposed smokers (kaolin median RF 146.7 (IQR 56–231.5), control median RF 61 (IQR 18.5–170), p<0.03, figure 1). Interestingly, 7/30 (23%) kaolin workers demonstrated nodular disease, compared to 3/40 (7.5%) matched controls, p=0.06, significantly higher than the background nodular rate 79/720 (11%) of male RA patients throughout Cornwall, p<0.04.

Figure 1. Rheumatoid factor titres, RA Kaolin workers vs RA controls.
*** p<0.04, **p<0.03**

Conclusions: Kaolin dust exposure in RA confers higher RF and ACPA seropositivity rates and higher RF titres. Smoking and kaolin dust exposure have an additive effect on RF titres. Higher rates of nodular disease are seen in RA patients exposed to kaolin dust, independent of smoking. We hypothesise that this interaction is due to adsorption of heavy metals from tobacco smoke or other environmental sources by kaolin particles, stimulating autoantibody production.

SAT0679 ARE ADULT TRAJECTORIES OF WEIGHT OVER A LIFETIME LINKED TO FOOT PROBLEMS YEARS LATER?

A.B. Dufour[1], E. Losina[2], H.B. Menz[3], M.P. LaValley[4], M.T. Hannan[1]. *[1]Institute for Aging Research, Hebrew SeniorLife; [2]Brigham and Women's Hospital, Boston, United States; [3]School of Allied Health, la Trobe University, Bundoora, Australia; [4]Biostatistics, Boston University, School of Public Health, Boston, United States*

Background: Obesity and foot problems are common in older adults and associated with many negative health outcomes. Better understanding of the consequences of patterns of weight change may lead to better prediction and dealing with foot pain and foot disorders.
Objectives: This study identified longitudinal trajectories of weight in a population-based study and examined the association of these groups with current foot problems.
Methods: We used 28 measures of weight over 57 years to identify trajectories of weight in 2445 members of the Framingham Foot Study using k-means longitudinal cluster analysis. Foot examinations (2002–2008) recorded presence of foot pain, hallux valgus, claw toes, hammer toes and overlapping toes on each foot. Associations between weight group membership and foot problems at time of foot exam, adjusted for age and sex, were examined using logistic regression with generalized estimating equation correction for two feet per subject. The reference group used for analysis was the group with the lowest weight trajectory ("E").
Results: We found 5 trajectories of weight, representing relatively constant patterns over time, with weight increasing from groups E to A. Those in group "E" were more likely to be older, while the youngest were in group "A" group. "E" had the lowest prevalence of foot pain (14%) while group "A" had the highest (22%). Similarly, group "A" had the lowest prevalence of hallux valgus, while group "E" had the highest (36%) (Table 1).
Compared to group "E", other groups were more likely to have foot pain (ORs 1.57–3.50, Table 2) and less likely to have hallux valgus (ORs 0.73–0.99). For claw toes, all but one group were more likely to have claw toes compared to group "E". Groups "A" and "D" were more likely to have hammer toes (ORs 2.40 and 1.35, respectively) compared to group "E". We found no associations between overlapping toes and group membership.

Table 1. Participant characteristics by weight trajectory group

	A N=201/ 402 feet	B N=644/ 1288 feet	C N=617/ 1233 feet	D N=506/ 1011 feet	E N=477/ 954 feet
Age (years)	63±9.0	69±11.2	68±10.5	66±9.7	71±11.9
Body mass index (kg/m^2)	37±6.3	27±3.3	29±4.0	31±4.3	23±2.9
Female	76 (19%)	1036 (80%)	478 (39%)	230 (23%)	918 (96%)
Foot pain	88 (22%)	240 (19%)	222 (18%)	186 (18%)	135 (14%)
Hallux Valgus	57 (14%)	408 (32%)	267 (22%)	169 (17%)	341 (36%)
Claw Toes	9 (2%)	29 (2%)	29 (2%)	24 (2%)	18 (2%)
Hammer toes	89 (22%)	246 (19%)	197 (16%)	165 (16%)	174 (18%)
Overlapping toes	14 (3%)	99 (8%)	73 (6%)	48 (5%)	90 (9%)

Table 2. Association between weight trajectory group membership and foot problems, adjusted for age and sex

	A vs. E	B vs. E	C vs. E	D vs. E
Foot pain	3.5 (2.49, 4.9)*	1.57 (1.25, 1.98)*	2.16 (1.68, 2.77)*	2.63 (2.00, 3.47)*
Hallux Valgus	0.72 (0.51, 1.02)	0.99 (0.82, 1.18)	0.86 (0.7, 1.06)	0.77 (0.61, 0.99)*
Claw toes	3.97 (1.57, 10)*	1.52 (0.83, 2.79)	2.24 (1.17, 4.29)*	3.1 (1.51, 6.38)*
Hammer toes	2.4 (1.71, 3.38)*	1.2 (0.96, 1.5)	1.12 (0.87, 1.45)	1.35 (1.02, 1.79)*
Overlapping toes	0.78 (0.41, 1.48)	0.93 (0.68, 1.27)	0.87 (0.6, 1.25)	0.85 (0.55, 1.32)

*$p<0.05$.

Conclusions: Trajectories with higher weight over a lifetime had increased odds of foot pain and claw toes, and decreased odds of hallux valgus later in life. These results provide evidence that having lower weight over one's lifetime can reduce the likelihood of foot problems later in life.

SAT0680 THE IMPACT OF DISEASE ACTIVITY DURING PREGNANCY IN WOMEN WITH SLE ON THE BIRTH WEIGHT OF THE CHILD

A.C.G. Skorpen[1,2], S. Lydersen[3], I.-M. Gilboe[4], K.Å. Salvesen[5], M. Wallenius[1,2]. *[1]National advisory unit on Pregnancy and Rheumatic Diseases, Trondheim University Hospital; [2]Department of Neuromedicine and Movement Science; [3]Regional Center for Child and Youth Mental health and Child Welfare, Norwegian University of Science and Technology, Trondheim; [4]Department of Rheumatology, Oslo University Hospital Rikshospitalet, Oslo; [5]Department of Laboratory Medicine, Children's and Women's Health, Norwegian University of Science and Technology, Trondheim, Norway*

Background: Mean birthweight is lower in children of SLE-mothers than in references. Active disease in pregnancy is considered one of the risk factors.
Objectives: The aim of this study was to explore the association of disease activity in women with SLE in pregnancy and the birth weight of the child expressed as mean birth weight and mean z-score for birth weight.
Methods: We linked data from RevNatus with data from the Medical Birth Registry of Norway (MBRN). RevNatus is a Norwegian nationwide prospective observational register including women with an inflammatory rheumatic disease when planning pregnancy or after conception. The register is administered by the National advisory unit on pregnancy and rheumatic diseases. Women 18 years or older are recruited and followed-up in each trimester of pregnancy and at 6 weeks, 6 months and 12 months after birth. MBRN is a national birth registry. The population constituted all singleton live births recorded in MBRN in the period 2006 – 2014. The births in women diagnosed with SLE in MBRN and included in RevNatus formed the patient group (n=180). The references were all other births (n=498849). Mean birth weight in the patient group was compared to mean birth weight in the general obstetric population. We calculated z-score for birth weight adjusted for gestational age and sex. The target population was then split in two groups according to disease activity assessed in the 2nd trimester, and compared to references. One-way ANOVA was performed to compare SLE-women without active disease, SLE-women with active disease and references from the general obstetric population.
Results: The mean birth weight and mean z-score were both significantly lower in women with SLE compared to references.

Table 1. Mean birth weight and z-score in references and in women with SLE

Mean (SD)	References n=497959	SLE n=180	Mean difference (95% CI)	p
Birth weight g	3518 (588)	3091 (691)	426 (325, 528)	<0.001
Z-score	-0.11 (0.98)	-0.59 (0.87)	0.47 (0.33, 0.62)	<0.001

When comparing three groups, a significantly lower mean birth weight and mean z-score remained between women without active disease and references and women with active disease and references. There were no significant differences between the two disease groups.

Table 2. Mean birth weight and z-score in references and in women with SLE according to disease activity status

Mean (SD)	References n=497,959	No disease activity† n=85	Mean difference (95% CI)	p
Birth weight g	3518 (482)	3133 (587)	385 (260, 510)	<0.001
Z-score	-0.11 (0.98)	-0.64 (0.81)	0.53 (0.32, 0.74)	<0.001
Mean (SD)	References n=497,959	Disease activity‡ n=63	Mean difference (95% CI)	p
Birth weight g	3518 (588)	2991 (802)	526 (62- 354)	<0.001
Z-score	-0.11 (0.98)	-0.54 (0.90)	0.43 (0.18, 0.67)	0.001
Mean (SD)	No disease activity n=85	Disease activity n=63	Mean difference (95% CI)	p
Birth weight g	3133 (587)	2991 (802)	141 (-50, 333)	0.15
Z-score	-0.64 (0.81)	-0.54 (0.90)	-0.10 (-0.40, 0.22)	0.53

†LAI-P=0. ‡LAI-P>0.

Conclusions: Mean birth weight and Z-score was significantly lower in women with SLE compared to the general obstetric population. There were no significant differences in diseased women with active as opposed to quiescent disease.

SAT0681 RISK OF ACTIVE TUBERCULOSIS IN PATIENTS WITH INFLAMMATORY ARTHRITIS RECEIVING TNF-INHIBITORS

A.M. Gheorghiu[1,2], A. Garaiman[1,2], A. Radu[1,2], A. Soare[1,2], V. Aramă[2,3], D. Bumbăcea[2,4], R. Dobrotă[1,2], R. Oneata[1,2], S. Pintilie[1,2], M. Milicescu[1,2], I. Ancuta[1,2], A. Martin[1,2], M. Sasu[1], C. Ciofu[1,2], L. Macovei[1,2], V. Stoica[1,2], M. Bojinca[1,2], C. Mihai[1,2]. *[1]Internal Medicine and Rheumatology, Cantacuzino Hospital; [2]Carol Davila University of Medicine and Pharmacy; [3]Infectious Diseases 1, Matei Bals National Institute for Infectious Diseases; [4]Dept. of Pneumology, Elias Emergency University Hospital, Bucharest, Romania*

Background: Tuberculosis (TB) is a major concern in patients receiving TNF inhibitors (TNFi).
Objectives: To assess the incidence of active TB and the efficacy of TB prevention measures in a large, single-center cohort of patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) receiving TNFi.
Methods: Data of all patients in whom treatment with TNFi was initiated in our rheumatology clinic from January 1st 2002 until December 31st 2015 have been retrospectively analysed. The cohort was divided into 2 groups per the mandatory latent TB infection (LTBI) screening method at baseline: tuberculin skin test (group TST), and QuantiFERON®-TB Gold test (group QFT). The incidence of active TB was analysed for each group and compared to TB incidence data in general population.
Results: 653 patients were included (344 RA, 52 PsA, 257 AS); 324 patients belonged to the TST and 329 to the QFT group. The number of active TB cases/ time of exposure to TNFi (person-years, PY) was 17/2002.6 and 7/1041.2 respectively, accounting for an incidence of 848.9 and 672.3 cases per 10^5 PY, about 8 times higher (8.3 and 8.8 for TST, respectively QFT group) than the average TB during the period of exposure to TNFi. LTBI reactivations per total TB cases were only 4/17 and 2/7, respectively, too few to identify statistically significant differences between the 2 LTBI screening protocols. Only 10 patients

Table 1. LTBI screening results and TB occurrence in the 653 TNFi-treated patients (Pearson χ^2 test)

	TST (n=324)	QFT (n=329)	All (n=653)	p value
Positive immuno-diagnostic test at baseline	52 (16.0%)	63 (19.1%)	115 (17.6%)	<0.001*
Active TB	17 (5.2%)	7 (2.1%)	24 (3.7%)	0.185*
Reactivation TB	4 (1.2%)	2 (0.6%)	6 (0.9%)	**
New infection TB	13 (4.0%)	5 (1.5%)	18 (2.8%)	0.052*
Total TB incidence (per 10^5 PY)	848.9	672.3	788.5	–
Maximal period of TNFi exposure in group	2002–2016	2011–2016	2002–2016	–
Mean TB incidence in Romania in the respective time period (per 10^5 PY)	102.3	76.7	102.3	–
TB incidence patients/general population	8.3	8.8	7.7	0.88†

*Pearson χ^2 test comparing TST and QFT. **Reactivation TB cases were too few to perform statistical testing. †Pearson χ^2 test comparing total TB incidence in the TST and QFT groups to the average TB incidence in our region in the respective period of exposure.

had pulmonary TB, whereas the rest were disseminated TB (8 cases), TB pleurisy and/or pericarditis (4 cases), one mediastinal lymph node TB and one isolated hepatic TB. Using Pearson chi-square test, we found no significant differences between LTBI group and active TB (Table 1).

Conclusions: In our cohort, new infection TB exceeds reactivation TB, suggesting the necessity of periodical LTBI re-screening.

SAT0682 PREVALENCE OF SARCOPENIA IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

A. Tournadre[1,2], P. Jaffeux[3], T. Frayssac[1], A. Fan[1], M. Couderc[1], J.J. Dubost[1], S. Malochet-Guinamand[1], S. Mathieu[1], Z. Tatar[1], J.C. Jourdy[3], M. Soubrier[1,2]. *[1]Rheumatology, CHU Clermont Ferrand; [2]UNH, University Clermont Auvergne INRA; [3]Medical Information, CHU Clermont Ferrand, Clermont Ferrand, France*

Background: Evaluation of sarcopenia is of major relevance because of these clinical repercussions on morbidity and mortality. Although the definition should include both low muscle mass and function, a combination of the 2 criteria was not reported in inflammatory rheumatic diseases (IRDs).

Objectives: To determine in a cohort of IRDs the prevalence of sarcopenia using established combined criteria (EWGSOP) (1).

Methods: Sarcopenia defined as both low muscle mass (skeletal muscle index (SMI) <7.26 kg/m^2 for men; <5.45 kg/m^2 for women) and impaired muscular function (handgrip strength or gait speed) (1) was assessed in active rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsoA) patients before initiating first biologic. Body composition (DXA) and related factors were compared using univariate, multivariate and correlation analysis.

Results: 148 patients were included (Table). Sarcopenia with decrease in muscle mass and function was observed in 5 RA (7.8%), one SpA (1.7%) and one PsoA (9.1%). Sarcopenia in terms of reduced SMI only (1) was not more frequent occuring in 5 RA (7.8%), 3 SpA (5.1%) and one PsoA (9.1%). Grip strength was decreased in RA as well as muscle mass compared to SpA and PsoA but the difference was no longer significant when adjusted on age, sex, disease duration (Table). Only fat distribution differed with a trunk/peripheral fat ratio higher in PsoA. In RA, lean mass was negatively correlated with disease duration and sedentary time. In SpA and PsoA, fat mass was correlated with age, disease activity, HAQ. HAQ and CRP level negatively correlated with lean mass. No association between treatments and body composition was observed.

Table 1. Characteristics and body composition of patients with RA, SpA, PsoA [mean±SD; n (%)]

	RA (n=74)	SPA (n=63)	PsoA (n=11)	p/p*
Age, years	59.5±11.7	44.1±12.0	54.6±11.0	<0.0001
Women	54 (73)	27 (43)	6 (55)	0.001
Disease duration, years	9±15.9	6.4±9.4	5.5±6.8	0.4
Body Mass Index	25.8±6.3	26.6±5.8	28.7±5.1	0.3
DAS28	4.37±1.08	2.78±0.91	3.63±1.06	<0.0001
BASDAI		50.8±17.2	49.6±17.7	0.8
HAQ	0.9±0.6	0.7±0.5	1.0±0.7	0.09
CRP, mg/l	16.4±21.3	11.9±14.3	10.7±13.6	0.3
MTX	54 (73.0)	6 (9.5)	6 (54.6)	<0.0001
Steroids	41 (55.4)	1 (1.6)	1 (9.1)	<0.0001
NSAIDs	18 (24.3)	38 (60.3)	7 (63.6)	<0.0001
Total lean mass, kg	46.7±10.8	53.3±11.1	51.1±9.8	**0.004**/0.6
SMI, Kg/m^2	7.2±1.4	8.1±1.6	8.0±1.7	**0.009**/0.5
Total fat mass, kg	21.9±8.1	21.8±10.3	25.5±10.7	0.5/0.1
Fat mass index (FMI), kg/m^2	8.2±3.2	7.8±4.2	9.6±4.3	0.3/0.05
Overfat (Body fat percentage >27% for men and 38% for women)	18 (28)	18 (30.5)	4 (36)	0.8
Trunk/peripheral fat ratio	0.97±0.30	0.99±0.33	1.23±0.26	**0.04**/**0.02**

*Adjusted for age, sex, disease duration.

Conclusions: Sarcopenia with combined criteria (muscle mass and function) occurred in 7.8% of RA corresponding to the values of the general population aged over 70 years-old (2). Reduced muscle mass only was not highly prevalent and lower than that reported in elderly suggesting important cofactors such as functional limitations or muscle quality in sarcopenia associated with rheumatic diseases.

SAT0683 PREVALENCE OF OSTEOPOROSIS IN ALBANIAN POSTMENOPAUSE WOMEN AND THE ROLE OF RISK FACTORS IN OSTEOPOROSIS

A. Kollcaku, J. Kollcaku, V. Duraj. *Rheumatology, University Hospital Center "Nene Tereza", Tirana, Albania*

Background: Menopause is the time in woman's life when production of sex hormones ceases. Sex hormones deficiency leads to increasing bone fragility and, thus, fracture risk. Bone turnover and bone mass could be affected by too many other risk factors. Osteoporosis threatens the health and quality of life of women with postmenopausal osteoporosis.

Objectives: The aims of this study were to assess the prevalence of osteoporosis in Albanian postmenopause women and the role of risk factors in osteoporosis.

Methods: A cross-sectional study was conducted in Tirana city in a period 2009–2013, including a population-based sample of 4,789 women. All subjects enrolled in the study were asked for risk factors for osteoporosis by completing a specific questionnaire. Low bone mineral density (osteopenia defined as a bone mineral density T-score less than -1 and osteoporosis for T-score less than -2.5) was assessed with a bone ultrasound device which is simple and easy to use for screening of bone mineral density in population-based studies. Binary logistic regression was used to determine the relationship of osteoporosis and independent factors in this study population.

Results: The prevalence of osteoporosis in this study population was 6.2% (N=286) and prevalence of osteopenia was 16.6%; 77.1% of osteoporosis women were in postmenopause. In logistic regression models was seen that menopausal women had 69% more chances than no menopausal women to have osteoporosis (OR=1.69, 95% CI=1.45–1.77, P<0.001). Osteoporosis was positively associated with multiparity (P<0.001) and long treatment with glucocorticoids (OR: 1.52; CI95% 1.46–1.94; p=0.02). In multivariable analysis osteoporosis was positively associated with rheumatoid arthritis (OR=1.62, 95% CI=1.47–1.81, P<0.001). In Kendal's correlation coeficient, osteoporosis was negatively associated with level of education (r=-0.101, p<0.001) and body mass index (r=-0.0033, p<0.009) and positively associated with white color of skin (r=0.003, p<0.027) and treatment with diuretics (r=0.007, p<0.001).

Conclusions: This study offers useful evidence about the osteoporosis and osteopenia prevalence among postmenopausal albanian women. Caucasian females with early menopause, multiparous, lower body-weight, suffering from rheumatoid arthritis, long treated with glucocorticoids and diuretics and lower education should be followed-up more carefully for development of osteoporosis.

SAT0684 DETERMINANTS OF 12-MONTHS PERSISTENCE IN RHEUMATOID ARTHRITIS PATIENTS INITIATING SUBCUTANEOUS TNF-ALPHA INHIBITORS

B. Fautrel[1], M. Belhassen[2], C. Hudry[3], M.-C. Woronoff[4], N. Gouyette[5], A. Clément[5], E. Van Ganse[6], F. Tubach[7]. *[1]Sorbonne Universités, UPMC Univ Paris 06; AP-HP, Rheumatology Department, Pitié Salpétrière University Hospital, Paris, France., Paris; [2]Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1; PELyon, Pharmacoepidemiologie Lyon, Lyon; [3]AP-HP Hôpital Cochin, Paris; [4]CHU Besançon, Université Franche-Comté, Comue UBFC, UMR INSERM 1098, Besançon; [5]Merck Sharp & Dohme, Paris; [6]Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1, PELyon, Pharmacoepidemiologie Lyon, Lyon; [7]APHP, Hôpital Pitié-Salpêtrière, Département de Biostatistiques, Santé publique et Information médicale, APHP, Centre de Pharmacoépidémiologie (Cephepi); INSERM, UMR 1123 ECEVE; Université Pierre et Marie Curie Paris 6, Sorbonne Universités, Paris, France*

Background: Biotherapies such as subcutaneous tumor necrosis factor-alpha

inhibitors (SC-TNFis) have transformed the management of inflammatory joint diseases such as rheumatoid arthritis (RA). The assessment of SC- TNFis persistence and its determinants is needed.

Objectives: The objective of this study was to describe treatment persistence in real-world settings, and identify the determinants of persistence among RA patients initiating treatment with an SC-TNFi.

Methods: The French national health insurance scheme database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, RA was diagnosed using Long Term Disease status and hospital admission, based on ICD-10 codes. Patients were then identified through prescription filled for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 2012/07/01 and 2013/12/31. A patient was considered as non-persistent in the event of a prolonged interruption of the therapy lasting 91 days or more. Persistence was estimated with Kaplan Meier analysis. Determinants of persistence in the 12 months before initiation were identified using Cox models.

Results: A total of 7,204 patients with RA were identified. In the descriptive analyses of the 12 months persistence, differences were observed for RA patients, with raw/non-adjusted persistence rates of 51.8% for CZP, 57.4% for ETA, 53.7% for ADA and 56.6% for GLM. Results of the Cox model are presented below, including hazard ratio for biotherapy, adjusted on sex, age, socio-economic status, and criteria on disease severity. The variables biotherapy, sex and socio-economic status did not meet the proportionality hypothesis of risks, and were corrected by the addition of a variable integrating the interaction with time.

Table 1: Determinants of 12-month non-persistence (Cox model)

	Hazard Ratio	IC 95%		P-value
SC-TNFis				
GLM	1.000	–	–	–
CZP	1.642	1.343	2.006	<0.0001
ETA	1.512	1.297	1.763	<0.0001
ADA	1.418	1.258	1.599	<0.0001
Sex				
Male	1.000	–	–	–
Female	1.610	1.367	1.897	**<0.0001**
Age	1.000	0.998	1.003	0.6833
Deprived socio-economic status : Yes vs No	0.901	0.712	1.141	0.3882
Number of comorbid conditions (per additional condition)	1.122	1.086	1.160	**<0.0001**
Biotherapy line (per additional line)	1.364	1.296	1.435	**<0.0001**
DMARD dispensation: Yes vs No	0.952	0.884	1.025	0.1924
Sulfasalazine dispensation : Yes vs No	1.101	0.964	1.258	0.1545
Long term oral steroids : Yes vs No	1.026	0.958	1.099	0.4629
Hospital admission for IRMD	0.932	0.871	0.997	**0.0419**
Visits to rheumatologist				
0	1.000	–	–	–
1–4	0.681	0.578	0.803	**<0.0001**
>4	0.704	0.599	0.828	**<0.0001**
Interaction with time				
Interaction biotherapy * time	1.001	1.000	1.001	**0.0025**
Interaction sex * time	0.999	0.998	0.999	**0.0023**
Interaction socio-economic status * time	1.002	1.000	1.003	**0.0084**

Conclusions: Non-persistent patients were more likely female, with multiple comorbid conditions, and multiple line of biotherapy. Hospital admission for IRMD, visits to rheumatologist and treatment with GLM (compared to CZP, ETA and ADA) decreased the risk of non-persistence. Further analyses are needed to better understand behaviours of patients and to assess the impact of non-persistence on clinical and economics outcomes.

SAT0685 DETERMINANTS OF 12-MONTHS PERSISTENCE IN PSORIATIC ARTHRITIS PATIENTS INITIATING SUBCUTANEOUS TNF-ALPHA INHIBITORS

B. Fautrel[1], M. Belhassen[2], C. Hudry[3], M.-C. Woronoff[4], N. Gouyette[5], A. Clément[5], E. Van Ganse[6], F. Tubach[7]. *[1]Sorbonne Universités, UPMC Univ Paris 06; AP-HP, Rheumatology Department, Pitié Salpétrière University Hospital, Paris, France., Paris; [2]Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1; PELyon, Pharmacoepidemiologie Lyon, Lyon; [3]AP-HP Hôpital Cochin, Paris; [4]CHU Besançon, Université Franche-Comté, Comue Ubfc, UMR INSERM 1098, Besançon; [5]Merck Sharp & Dohme, Paris; [6]Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1, PELyon, Pharmacoepidemiologie Lyon, Lyon; [7]APHP, Hôpital Pitié-Salpêtrière, Département de Biostatistiques, Santé publique et Information médicale, APHP, Centre de Pharmacoépidémiologie (Cephepi); INSERM, UMR 1123 ECEVE; Université Pierre et Marie Curie Paris 6, Sorbonne Universités, Paris, France*

Background: Biotherapies such as subcutaneous tumour necrosis factor-alpha inhibitors (SC-TNFis) have transformed the management of inflammatory joint diseases such as psoriatic arthritis (PsA). The assessment of SC- TNFis persistence and its determinants is needed.

Objectives: The objective of this study was to describe treatment persistence in real-world settings, and identify the determinants of persistence among PsA patients initiating treatment with an SC-TNFi.

Methods: The French national health insurance scheme database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, PsA was diagnosed using Long Term Disease status and hospital admission, based on ICD-10 codes. Patients were then identified through prescription filled for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 2012/07/01 and 2013/12/31. A patient was considered as non-persistent in the event of a prolonged interruption of the therapy lasting 91 days or more. Persistence was estimated with Kaplan Meier analysis. Determinants of persistence in the 12 months before initiation were identified using Cox models.

Results: A total of 2,011 patients with PsA were identified. In the descriptive analyses of the 12 months persistence, differences were observed for PsA patients, with raw/non-adjusted persistence rates of 37.3% for CZP, 51.8% for ETA, 54.7% for ADA and 50.8% for GLM. Results of the Cox model are presented, including hazard ratio for biotherapy, adjusted on sex, age, socio-economic status, and criteria on disease severity. The variables biotherapy, biotherapy line, comorbid conditions and hospital admission for IRMD did not meet the proportionality hypothesis of risks, and were corrected by the addition of a variable integrating the interaction with time.

SAT0686 MAJOR ADVERSE CARDIOVASCULAR EVENTS: RISK FACTORS IN PATIENTS WITH RA TREATED WITH TOFACITINIB

C. Charles-Schoeman[1], H. Valdez[2], K. Soma[3], L. Hwang[2], R. DeMasi[4], M. Boy[3], I.B. McInnes[5]. *[1]University of California, Los Angeles, CA; [2]Pfizer Inc, New York, NY; [3]Pfizer Inc, Groton, CT; [4]Pfizer Inc, Collegeville, PA, United States; [5]Glasgow Biomedical Research Centre, University of Glasgow, Glasgow, United Kingdom*

Background: Patients (pts) with RA have increased risk of myocardial infarction (MI) and stroke that cannot be completely explained by traditional cardiovascular

(CV) risk factors. Tofacitinib is an oral JAK inhibitor for the treatment of RA. Treatment with tofacitinib may increase total cholesterol (TC), low-density lipoprotein-cholesterol (LDL-c) and high-density lipoprotein-cholesterol (HDL-c), without affecting TC/HDL-c ratio.

Objectives: To evaluate major adverse CV event (MACE) risk factors in tofacitinib-treated pts with RA in the clinical development programme.

Methods: Data were pooled from pts with moderately to severely active RA receiving ≥1 tofacitinib dose in 6 Phase 3 and 2 long-term extension (LTE) studies (1 LTE study ongoing, data cut-off: April 2015). MACE was any MI, stroke or CV death (coronary, cerebrovascular, cardiac). Cox regression models evaluated associations between baseline (BL) values and time (BL to first tofacitinib dose) to first MACE. Changes (BL to Week [wk] 24) in MACE predictors and time to future MACE (first occurrence after 24 wks) were evaluated after adjusting for age, BL values and time-varying tofacitinib dose. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated.

Results: 52 MACE cases occurred over 12,873 pt-years (py) of exposure in 4076 pts (incidence rate: 0.4 pts with events/100 py). At BL, compared with pts without MACE, pts with MACE were older (mean age 60.2 vs 52.7 years) with a higher mean BMI (29.2 vs 27.0 kg/m^2) and longer mean RA disease duration (10.1 vs 7.7 years), and were more likely to have a history of diabetes (15.4% vs 7.6%) and hypertension (57.7% vs 33.7%). Pts with MACE had higher mean TC (208.2 vs 198.3 mg/dL), LDL-c (123.3 vs 114.0 mg/dL), TC/HDL-c ratio (4.0 vs 3.5) and triglycerides (152.1 vs 125.3 mg/dL) at BL, and lower HDL-c (55.3 vs 59.4 mg/dL) vs pts without MACE. In univariate analyses, traditional CV risk factors and corticosteroid and statin use at BL were associated with MACE risk (Table). BL disease activity and inflammation measures were not associated with MACE risk (Table). In multivariate analysis, BL age, hypertension and the TC/HDL-c ratio were significantly associated with MACE risk. Increases in HDL-c ($p<0.001$) and decreases in TC/HDL-c ratio ($p<0.05$) after 24 wks of tofacitinib therapy were significantly associated with decreased risk of future MACE (Figure). Increases in erythrocyte sedimentation rate (ESR; p=0.09) may be associated with increased future MACE risk. Changes in TC, LDL-c or other disease activity measures were not associated with future MACE risk.

Conclusions: In pooled analyses of tofacitinib-treated pts (age and BL value adjusted), increases in LDL-c and TC after 24 wks of tofacitinib therapy were not associated with future MACE risk. Increases in HDL-c and decreases in the TC/HDL-c ratio after 24 wks of tofacitinib therapy were associated with reduced future MACE risk. Increases in ESR after 24 wks may be associated with increased future MACE risk. More data are needed to confirm these findings.

Table. Association of baseline risk factors and development of MACE based on univariate Cox analysis

Baseline variable	HR	(95% CI)
Age (years, n=52)	2.02***	(1.53, 2.67)
BMI (kg/m^2, n=52)	1.05**	(1.01, 1.09)
Baseline statin users (Y/N, n=52)	2.77**	(1.45, 5.28)
Baseline corticosteroid users (Y/N, n=52)	0.55*	(0.31, 0.98)
Duration of RA, (years, n=52)	1.03*	(1.00, 1.06)
Triglycerides (mg/dL, n=51)	1.00**	(1.00, 1.01)
TC/HDL-c ratio (n=51)	1.42***	(1.16, 1.74)
Apolipoprotein B (mg/dL, n=48)	1.02**	(1.01, 1.03)
Apolipoprotein B/Apolipoprotein A-1 ratio (n=48)	2.76**	(1.50, 5.09)
SBP (mmHg, n=51)	1.02*	(1.01, 1.04)
DBP (mmHg, n=51)	1.04*	(1.01, 1.07)
History of diabetes (Y/N, n=52)	2.56*	(1.20, 5.43)
History of hypertension (Y/N, n=52)	2.86***	(1.65, 4.96)

*p<0.05; **p<0.01; ***p<0.001
Other BL variables assessed as not being statistically significant were gender, weight, smoking status, DAS28-4(ESR), ESR, CRP, swollen joint count out of 28, tender joint count out of 28, baseline MTX users, baseline MTX dose, TC, HDL-c, LDL-c and history of cardiac disorders
n represents number of patients with MACE (uncensored) analysed for each variable
BL, baseline; BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; DAS28-4, disease activity score in 28 joints; DBP, diastolic blood pressure; ESR, erythrocyte sedimentation rate; HDL-c, high-density lipoprotein-cholesterol; HR, hazard ratio; LDL-c, low-density lipoprotein-cholesterol; MACE, major adverse cardiovascular event; MTX, methotrexate; RA, rheumatoid arthritis; SBP, systolic blood pressure; TC, total cholesterol

Figure. Age-adjusted and baseline parameter-adjusted association of change from baseline to Week 24 in lipid levels, inflammation parameters and RA disease activity measures with future MACE

These data show results from a Cox regression model; age-adjusted and baseline parameter-adjusted association of changes from baseline to Week 24, for future MACE risk
*For each variable listed, a Cox regression model was fitted, with change in variable at Week 24, the variable at baseline, age at baseline and time varying dose as predictors
In this model, only patients with exposure after the tofacitinib-week 24 were considered (ie, patients who had MACE before tofacitinib-week 24 or who had withdrawn or completed the study by tofacitinib-week 24 were excluded). Additionally, patients with missing data for a tofacitinib-week 24 variable were excluded from the analysis of that variable (no imputation method). The HR corresponds to increased risk of MACE per 1-unit increase in the parameter
n is the number of patients with future MACE for each predictor
BMI, body mass index; CI, confidence interval; DAS28-4, disease activity score in 28 joints; DBP, diastolic blood pressure; ESR, erythrocyte sedimentation rate; HDL-c, high-density lipoprotein-cholesterol; HR, hazard ratio; LDL-c, low-density lipoprotein-cholesterol; MACE, major adverse cardiovascular event; PtGA, patient's global assessment; RA, rheumatoid arthritis; SBP, systolic blood pressure; TC, total cholesterol

SAT0687 ADHERENCE OF RHEUMATIC PATIENTS TO INH PROPHYLAXIS PRESCRIBED BEFORE BIOLOGICAL TREATMENT: HUR-BIO SINGLE CENTER REAL LIFE RESULTS

E. Şeyhoğlu[1], O.A. Uyaroğlu[1], A. Erden[2], L. Kılıç[2], B. Armağan[2], A. Sarı[2], M. Baykal[2], S. Ak[2], Ö. Karadağ[2], A. Akdoğan[2], S. Apraş Bilgen[2], S. Kiraz[2], I. Ertenli[2], U. Kalyoncu[2]. *[1]Department of Internal Medicine; [2]Division of Rheumatology, Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Isoniazid (INH) prophylaxis is strongly recommended for the patients who have latent tuberculosis (TB) and who are going to be under anti-TNF treatment. INH is prescribed for 9 months and patient adherence to INH affects the risk of active TB development.

Objectives: In this study we aimed to assess the levels of patient adherence to INH prophylaxis.

Methods: Patients, who are under biological treatment and who have a quantiferon (QFT) test result, were evaluated with a questionnaire between August 2015-August 2016. Questionnaire included the demographic and clinical characteristics. Besides, patients were asked whether they had been prescribed INH. Patients, who were given INH prophylaxis, were asked to answer those questions: i) Did you take INH daily and regularly for 9 months? ii) If not what was the reason? The reasons are classified into three categories: 1) The patient discontinued INH of his/her own volition before 9 months. 2) Continued INH for 9 months but did not take regularly due to forgetfulness. 3) Treatment stopped by physicisan due to an adverse effect (elevation of liver enzymes, neuropathy, etc.)

Results: 1. 710 patients were recruited. INH was prescribed to 169 (23.8%) of 710. Demographic characteristics of INH-prescribed patients: 88 (52.1%) of 169 were female, mean age was 46.2 (SD:11.4), 82 (48.5%) of 169 at least graduated from a high school. Diagnosis were followed; RA 65 (38.4%), SpA 85 (50.3%), PsA 13 (7.7%), others 6 (3.6%). Totally 34 (20.1%) of 169 took INH irregularly. 19 (11.2%) of 169 patients discontinued INH of his/her own volition before 9 months. During follow-up 5 of 19 were prescribed INH again by the physician and they completed the 9-months duration. 9 (5.3%) of 169 patients did not take INH regularly due to forgetting. INH was stopped by a physician due to liver enzyme elevation in 6 (3.5%) of 169 patients. There was not a statistically difference in demographical and clinical characteristics between regular and irregular INH takers.

Conclusions: There is an inadherence to INH treatment approximately in one of five patients. Only 3.5% of INH-recommended patients had a medical reason of inadherence. Among other patients, causes of inadherence were discontinuance of own volition and forgetfulness or perfunctoriness. Physicians should be aware that reminding of INH is one of the question in every outpatient clinic visits. Other reminding methods such as regular calling should be considered in those of high risk population. Further studies were needed for reminding process.

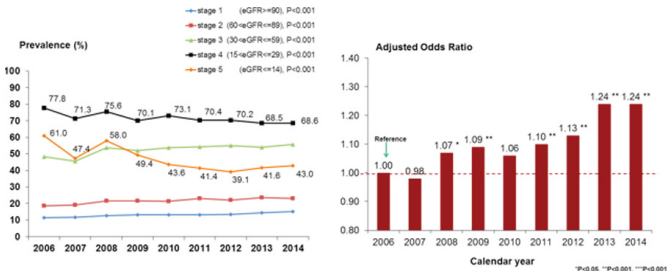
SAT0688 JOINT INVOLVEMENT IN PATIENTS WITH KNEE AND HIP OA SCHEDULED FOR SURGERY: MULTI-JOINT OA, THE RULE NOT THE EXCEPTION?

E.M. Badley[1], C. Yip[1], J.D. Power[2], R. Gandhi[2], N. Mahomed[2], J.R. Davey[2], K. Syed[2], Y.R. Rampersaud[2], C. Veillette[2], A.V. Perruccio[1,2]. *[1]Division of Health Care and Outcomes Research, Krembil Research Institute; [2]The Arthritis Program, Toronto Western Hospital, Toronto, Canada*

Background: Multijoint involvement in osteoarthritis (OA) has long been documented clinically and in the literature. Even so, the vast majority of OA research has focused on OA in individual joints, particularly the knees, hips or hands. In many "joint-specific" studies, the presence of multijoint symptoms are either ignored or peripherally considered in descriptive and analytical work. The implicit assumption is often that OA is OA, irrespective of whether a single joint or several joints are involved.

Objectives: To document the occurrence of multijoint symptoms in a clinical sample of individuals with knee and hip OA scheduled for orthopaedic surgery. To examine the joint sites involved and investigate whether the extent of joint involvement is related to demographic and health characteristics.



Methods: Patients scheduled for total knee or hip replacement for end-stage OA were consecutively recruited from an academic hospital in Toronto, Canada. A health questionnaire completed prior to surgery captured demographic

characteristics (age, sex), symptomatic joints other than the surgical joint (right and left shoulders, elbows, wrists, hands, hips, knees, feet, ankle, neck and back), body mass index (BMI), comorbidities (hypertension, depression, diabetes, migraine headaches, cancer, respiratory disease, heart disease, stomach/bowel disease, stroke) and WOMAC hip- and knee-specific pain and function.
Results: Study questionnaires were completed by 366 hip and 407 knee patients. The mean age of the sample was 65 years (SD=9.2; range 38–89 years), 57% were female. The most frequently reported symptomatic joints among knee patients were the contralateral knee (53.2%), one or both hands (32.1%), and the upper-, mid- or lower-back (31.0%), and among hip patients were one or both knees (49.4%), the back (36.6%), and the contralateral hip (21.3%). The overall mean number of symptomatic joints other than the surgical joint was 3.0 (SD=3.2; range 0–17). Only 19.0% reported the surgical joint as the only symptomatic joint; 23.0% reported 5 or more additional symptomatic joints. Mean hip/knee-specific pain and function scores were significantly worse with increasing symptomatic joint count ($p<0.01$). Additional symptomatic joints were significantly more frequent in women than men; mean count 3.6 vs. 2.3 ($p<0.01$). No significant difference in mean joint count (p=0.64) was observed by age. Similarly, no difference was found by BMI (i.e. overweight/obese vs. normal); p=0.24 for mean count. However, the number of co-occurring conditions increased with increasing joint count: 27.2% reported 2+ co-occurring conditions among those with 1–4 symptomatic joints, and 42.8% among those with 5+ symptomatic joints ($p<0.01$).
Conclusions: In this clinical OA sample, the "average" patient reported multiple symptomatic joints. Increasing age was not associated with increasing frequency of symptomatic joints. Irrespective of age and obesity, multiple symptomatic joints were the rule, not the exception. It was notable that the frequency of co-occurring conditions increased with increasing symptomatic joint count. This may suggest a need to re-examine how OA is characterized and perhaps its underlying etiology as it relates to single vs. multi-joint involvement.

SAT0689 PREVALENCE OF AND TEMPORAL TRENDS IN HYPERURICAEMIA AMONG ADULT PATIENTS WITH CHRONIC KIDNEY DISEASE IN IRELAND

F. Adeeb[1,2], A.A. Udayakumar[2,3], D. Ryan[2], X. Li[2], A.D. Fraser[1,2], A.G. Stack[2,3] on behalf of Health Research Institute, University of Limerick. *[1]Department of Rheumatology, University Hospital Limerick; [2]Graduate Entry Medical School, University of Limerick; [3]Department of Nephrology, University Hospital Limerick, Limerick, Ireland*

Background: An increasing body of evidence links hyperuricaemia with the development of several metabolic disorders and major cardiovascular outcomes. A better understanding of the burden and variation of hyperuricemia within the health system is important in order to identify high-risk groups and facilitate early intervention with effective management strategies.
Objectives: The aim of this study was to describe the prevalence of hyperuricaemia, and period trends within the Irish Health System among patients with chronic kidney disease (CKD).
Methods: 136,325 adult CKD patients aged 18 and above with valid measurements of serum uric acid and creatinine levels were identified between 2006 and 2014 from the laboratory systems within the Irish health system. Hyperuricaemia was defined as serum uric acid $\geq$420μmol/L in men and $\geq$360μmol/L in women. Estimated glomerular filtration rates were determined using the Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) equation and patients were classified by CKD stage according to the Kidney Disease Improving Global Outcomes (KDIGO) staging system. Age- and sex-specific prevalence of hyperuricemia estimates with 95% confidence intervals were determined for each group and across calendar years. Comparisons among groups and across years were conducted using chi-square and multivariate logistic regression was used to explore associations using adjusted odds ratios (AOR) and 95% Confidence Intervals (CI).
Results: Patients with hyperuricaemia were noted to be older [58.2 (18.5) vs. 51.2 (17.4) years]. The prevalence of hyperuricaemia increased progressively between 2006 and 2014 from 20.3% (19.5, 21.0) to 26.5% (25.8, 27.2%) in men and from 17.9% (17.2, 18.6) to 20.4% (19.8, 21.0) in women, $p<0.001$. Age-specific prevalence increased significantly over time for all age groups (18–39, 40–59, 60–79, and $\geq$80 years) for men and women, $p<0.001$. Prevalence was significantly higher with more advanced CKD stage: 15.1% (14.5, 15.6) in Stage 1 CKD compared to 43.0% (34.8, 51.1) in Stage 5 CKD, $p<0.001$. However, rates fell significantly for those Stage 4 and 5 CKD respectively (Figure1). In multi-variable models, the adjusted likelihood of hyperuricaemia increased with each successive year (Figure 2).

Conclusions: The prevalence of hyperuricaemia is substantial in the Irish health system and has increased in frequency over the past decade. Although the burden was highest among patients with more advanced CKD, an encouraging decline in prevalence was observed in recent years. Greater management of gout and hyperuricaemia from increasing utilization of urate-lowering therapies may be responsible for this trend.

SAT0690 RISK OF HOSPITALIZED INFECTION IN CANCER PATIENTS WITH AUTOIMMUNE DISEASES: A SINGLE-CENTER COHORT STUDY

H.-H. Chen[1], D.-Y. Chen[2]. *[1]Department of Medical Research; [2]Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

Background: Whether the risk of hospitalized infection is associated with autoimmune diseases in incident cancer patients is unknown.
Objectives: To examine the risk of hospitalized infection in incident cancer patients with autoimmune diseases compared with those without autoimmune diseases.
Methods: During 2000–2016, we identified 37,027 incident cancer patients from the Cancer Registry database of Taichung Veterans General Hospital. Autoimmune diseases included rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), ankylosing spondylitis (AS), psoriasis (PSO)/psoriatic arthritis (PSA), antiphospholipid syndrome, polymyositis, dermatomyositis, systemic sclerosis, Sjögren's syndrome, mixed connective tissue disease, multiple sclerosis, neuromyelitis optica, palindromic rheumatism, myasthenia gravis, Hashimoto's thyroiditis, immune thrombocytopenic purpura, autoimmune hemolytic anemia, juvenile idiopathic arthritis, adult onset Still's disease, Crohn's disease, ulcerative colitis, Wegner's granulomatosis, and uveitis. Of all subjects, 1,334 had autoimmune diseases. The association between autoimmune diaseases and hospitalized infection risk was shown by calculating hazard ratios (HRs) with 95% confidence intervals (CIs) using cox proportional regression analyses after adjusting for baseline age, sex, cancer stage, hemoglobulin (Hgb), creatinine (CR), log(ALT), log(WBC), and use of biologic agents or tofacitinib.
Results: Among all cancer subjects, the mean ± SD age was 60.2±14.7 years, and the proportion of male gender was 55.7%. Of the 1,334 patients with autoimmune diseases, 338 (25.3%) patients had RA, 221 (16.6%) patients had SLE, 61 (4.6%) patients had AS, 151 (11.4%) patients had PSO/PSA, and 563 (46.8%) had other autoimmune diseases. The incidence rates of hospitalized infection were 143.8 per 10^3 years in patients with autoimmune diseases and 118.9 per 10^3 years in patients without autoimmune diseases. The risk of hospitalized infection was higher in patients with RA and SLE, but not in patients with AS, PSO/PSA, or other autoimmune diseases. Prior use of biologic agents or tofaitinib did not increase hospitalized infection risk. Other risk factors for hospitalized infection included elder age (HR, 1.01; 95% CI, 1.01–1.1), higher cancer stage, CR (HR, 1.04; 95% CI, 1.02–1.06), log(WBC) (HR, 1.21; 95% CI, 1.14–1.28). Female gender (HR, 0.65; 95% CI, 0.62–0.68) and Hgb (HR, 0.89; 95% CI, 0.88–0.90) were associated lower hospitalized infection risk.

Table 1. Univariable and multivariable analyses for the association between autoimmune diseases and hospitalized infection among cancer patients

	Univariate analysis HR (95% CI)	Multivariable analysis* HR (95% CI)
No autoimmune diseases	Reference	Reference
Autoimmune diseases		
RA	1.32 (1.10–1.59)	1.37 (1.13–1.66)
SLE	1.21 (0.95–1.54)	1.41 (1.10–1.80)
AS	0.67 (0.37–1.21)	0.88 (0.46–1.70)
PSO/PSA	1.36 (1.05–1.78)	1.05 (0.80–1.38)
Others	1.17 (1.01–1.36)	1.15 (0.99–1.34)

*Adjusted for age, gender, cancer stage, prior use of biologic agents or tofacitinib, baseline hemoglobulin, creatinine, log (ALT) and log (WBC).

Conclusions: Hospitalized infection was associated with a comorbidity of RA or SLE in incident cancer patients.

SAT0691 INFLUENCE OF SMOKING IN THE EXPRESSION OF CHRONIC PERIODONTITIS AND ANTI-CITRULLINATED PROTEINS ANTIBODIES IN RHEUMATOID ARTHRITIS

J. González Febles[1], J.L. Garnier Rodríguez[2], F. Sánchez Alonso[3], S. Dadlani[2], Y. Barrios[4], S. Bustabad[5], F. Díaz González[5], M. Sanz Alonso[1], B. Rodríguez Lozano[5]. *[1]Periodontology, UCM, Madrid; [2]Odontology/Periodontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife; [3]Research Unit, Sociedad Española de Reumatologia, Madrid; [4]Immunology Section.Central Laboratory; [5]Rheumatology, Hospital Universitario de Canarias, Tenerife, Spain*

Background: Environmental, genetic and epigenetic factors can induce citrullination of structural peptides by the enzyme PAD,which induce anti-citrullinated protein antibodies (ACPA) preceding RA. Among the environmental factors are cigarette smoke, infections, such as *P. gingivalis* in periodontitis (PD) and *Prevotella copri* of intestinal microflora, and silica dust. Given the implication of these two exogenous factors, tobacco and PD,in citrullination, and tobacco enhancer factor in PD, we studied:
Objectives: 1. The risk of smoking for developing advanced PD in patients with RA. 2. Possible influence of smoking on the expression of severe PD and ACPA in RA patients.
Methods: Observational, descriptive, cross-sectional study in RA patients older tan 18y.o.(ACR/EULAR 2010), with ≥4 teeth, without tooth cleaning nor antibiotic intake 6 months previously. Socio-demographic and anthropometric variables included smoking status, social indicators such as Graffar scale, stress level, annual dental prophylaxis, and co-morbidities such as diabetes mellitus, dyslipidemia, ischemic cardiovascular disease. Serum ACPA detection: semiquantification Ab IgG against citrullinated peptides (ELISA) with Immunoscan CCPlus®test kit. Eurodiagnostica: positive >25; ACPA title stratification: Low (25–75), moderate (76–300) and high (>300). Periodontal parameters: plaque index (PI), Bleeding on probing (Bop), probing pocket depth, recession, clinical attachment level (CAL). CAL loss was categorized according to European Workshop 2005 (Tonetti)[1]: T level 0 (abscence), TL1 (mild), TL2 (severe). Statistical analysis: t-student, Kruskal Wallis, Chi-cuadrado by Stata program 13.1.
Results: We studied 187 patients, F/M 78.6%/21.4%, mean age 54.4 y.o. Follow-up time 8.8 y.o. RF+ 74.2%, ACPA positive in 114/168 patients (67.86%). Smoking habit:Current smoker (19.25%), former smoker (24.6%); low socioeconomical status (36.4%)/ relative poverty (33.7%).PD was observed in 97.3%: TL1 52.4%, TL2 44.9%. A "risk gradient" was observed for PD related to smoking habit: former smoker OR 1.62 (95% CI 0.81–3.27),p=0.174; smokers, OR 2.27 (95% CI 1.05–4.91), p=0.037. When analyzing the influence of smoking on PD development according to ACPA profile, a gradient effect of developing severe PD was observed from former smokers OR 2.37 (IC95% 0.52–7.64) to current smokers OR 6.99 (IC95% 1.53–32.07) (p=0.029) in ACPA(-) patients. This relationship was not observed in ACPA (+) patients (p=0.383).
Conclusions: 1.There is a "risk gradient" to develop PD in RA in relation to past or current exposure to tobacco, so that, although not significant, former smokers are at greater risk than non-smokers, and current smokers have a significant risk 2.3 times higher. 2. This risk gradient is shown in ACPA (-) patients, but not in ACPA (+) patients, which suggests an independent relationship between PD and ACPA (+) RA.

SAT0692 PREDICTORS AND PERSISTENCE OF UNACCEPTABLE PAIN DURING THE FIRST YEAR OF RHEUMATOID ARTHRITIS IN SWEDEN

H. Westerlind[1], M.E. Schelin[1], R. Altawil[2], L. Klareskog[3], L. Alfredsson[1], J. Lampa[3]. *[1]Institute of Environmental Medicine; [2]Rheumatology Unit, Department of Medicine, Center for Molecular Medicine (CMM); [3]Rheumatology Unit, Department of Medicine, Center for Molecular Medicine (CMM), Karolinska Institutet, Stockholm, Sweden*

Background: Pain is a dominant symptom in rheumatoid arthritis (RA).
Objectives: Investigate unacceptable pain (VAS-pain ≥40) during the first year of the disease and whether it can be predicted from baseline disease characteristics.
Methods: The cohort included all incident RA cases from the Swedish population-based case-control Epidemiological Investigation of Rheumatoid Arthritis study (EIRA), who also were in the Swedish Rheumatology Register. Unacceptable pain was defined as scoring 40 mm or above on the pain visual analog scale (VAS) (i.e. not reaching the patient acceptable symptom state (PASS) (1)), and the proportion of patients going in and out of PASS was traced over the first year. Association between baseline parameters, divided into quartiles, and unacceptable pain at one year was assessed using modified Poisson regression and expressed as risk ratios with 95% confidence intervals (95% CI), adjusted for sex and age at diagnosis.
Results: A total of 2808 patients were included in the study and 33.8% of the patients presented with PASS (i.e.VAS pain below 40) at inclusion. If a patient had PASS at any given visit, there was over 70% chance that the patient remained in PASS at the following visit. The most common PASS pattern (25.6%), was to present with unacceptable pain, reach PASS at the 3 month visit, and then remain in PASS. However, one year after diagnosis, only two thirds of the patients had PASS. Higher disability (measured as HAQ) at baseline was significantly and independently associated with an increased risk for unacceptable pain at one year (for the highest quartile of HAQ; RR=1.97 [95% CI:1.60–2.42]). Also high tender joint count at baseline was associated with an increased risk for unacceptable pain; RR=1.40 [95% CI: 1.18–1.65] for the highest quartile, whereas high swollen joint count at baseline was associated with a decreased risk; RR=0.79 [95% CI: 0.66–0.95] for the highest quartile.
Conclusions: The results highlight the need for efficient pain treatment strategies early in the disease.

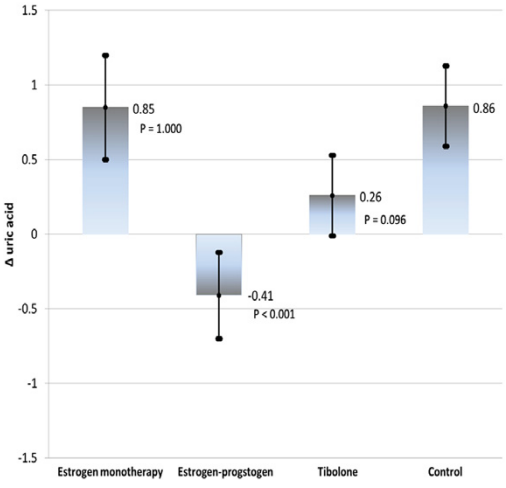
SAT0693 SERUM URIC ACID LEVELS AND HORMONE REPLACEMENT THERAPY TYPE: A RETROSPECTIVE CASE-CONTROL STUDY OF POSTMENOPAUSAL WOMEN



J.H. Jung, J.-H. Kim, Y.H. Lee, G.G. Song, S.J. Choi. *Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

Background: Serum uric acid levels increase in postmenopausal women but decrease when hormone replacement therapy (HRT) is administered. However, no study has evaluated the effects of different types of HRT on serum uric acid levels.
Objectives: We examined whether estrogen monotherapy, estrogen-progestogen combination therapy, and tibolone use affected serum uric acid levels in this population.
Methods: We performed a retrospective case-control study of postmenopausal women. From 2005 to 2015, postmenopausal women measured serum uric acid levels more than twice were included. Patients were grouped according to HRT regimen: estrogen monotherapy, estrogen-progestogen combination therapy, or tibolone. The control group did not receive HRT. Differences in serum uric acid levels were examined in each group. Our analysis was adjusted to accommodate different follow-up intervals for individual patients. Multiple variables were adjusted using the Tukey-Kramer method. Age, body mass index, hypertension, diabetes mellitus, dyslipidemia, alcohol consumption, smoking status, and co-medications were also adjusted.
Results: In the control group, the serum uric acid level increased to 0.86±0.27 mg/dL (least squares mean ± standard error). In comparison, after adjusting for multiple variables, the serum uric levels in the estrogen-progestogen combination

Table 1. Degrees of changes in serum uric acid levels by hormone replacement therapy type

	Estrogen mono		Estrogen-progestogen		Tibolone		Control
	Δ uric acid	P	Δ uric acid	P	Δ uric acid	P	Δ uric acid
Crude	0.64±0.26	1.000	-0.50±0.17	<0.001	0.16±0.18	0.097	0.67±0.13
Model I	0.63±0.26	0.994	-0.51±0.17	<0.001	0.15±0.18	0.059	0.71±0.13
Model II	0.63±0.26	0.994	-0.51±0.17	<0.001	0.14±0.18	0.060	0.71±0.13
Model III	0.67±0.27	0.988	-0.42±0.19	<0.001	0.30±0.21	0.206	0.77±0.14
Model IV	0.64±0.34	0.986	-0.47±0.29	<0.001	0.23±0.26	0.195	0.74±0.26
Model V	0.85±0.35	1.000	-0.41±0.29	<0.001	0.26±0.27	0.096	0.86±0.27

All models that included crude values were adjusted for follow-up intervals. Model I: adjusted age. Model II: adjusted age and BMI. Model III: adjusted age, BMI, HTN, DM, and dyslipidemia. Model IV: adjusted age, BMI, HTN, DM, dyslipidemia, alcohol consumption, and smoking status. Model V: adjusted age, BMI, HTN, DM, dyslipidemia, alcohol consumption, smoking status and co-medications.

therapy group were found to be significantly lower (-0.41±0.29 mg/dL, P<0.001). However, the serum uric acid levels in the estrogen monotherapy and tibolone groups did not differ significantly from the control group level.

Conclusions: Serum uric acid levels decreased in response to estrogen-progestogen combination therapy in postmenopausal women. We attribute our findings to the effects of progesterone, rather than estrogen.

SAT0694 SUBGROUPING OF EARLY RA-PATIENTS IDENTIFIED CLUSTER OF PATIENTS WITH HIGH LEVELS OF PAIN, FATIGUE AND PSYCHOSOCIAL DISTRESS 3 YEARS AFTER DIAGNOSIS

J. Lindqvist[1], H. Westerlind[2], L. Klareskog[1], L. Alfredsson[2], J. Lampa[1]. *[1]Unit of Rheumatology, Department of Medicine Solna; [2]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden*

Background: The wide range of effective treatment alternatives for rheumatoid arthritis (RA) makes treating the disease to inflammatory remission a feasible goal for a majority of patients. However, earlier studies have reported that symptoms other than inflammatory disease activity causes a substantial burden of illness for RA-patients. These unmet needs include persistent pain, fatigue, impaired physical function and mental health status (1).

Objectives: To identify clusters of early RA-patients based on pain, fatigue, sleep, physical function, mental health status and perceptions of quality of life, 3 years after diagnosis. Withal investigate associations between clusters and clinical parameters at the time of diagnosis.

Methods: Data was compiled from the Swedish case-control cohort Epidemiological Investigation of Rheumatoid Arthritis (EIRA) and linked to the Swedish Rheumatology Quality Register (SRQ). All patients were diagnosed with RA according to the 1987 ACR criteria. Early RA-patients with clinical data from diagnosis and 3 year follow-up questionnaire data were included (N=618; 74% women, median age at diagnosis 58 years). Measurements of pain, fatigue, sleep problems, physical and mental functioning and quality of life was entered into a hierarchical agglomerative clustering procedure using Ward's method of squared Euclidian distances. Number of clusters was determined by largest changes in distances at which clusters were formed. Associations between clusters and clinical variables at diagnosis were calculated using contingency analysis. All statistical analysis was performed using jmp statistical software (SAS, US). p<0.05 was considered significant.

Results: The cluster analysis identified three distinct clusters. Cluster 1 consisted of 178 patients (29%) doing significantly worse for all included variables. Cluster 3 consisted of 209 patients (34%) doing very well and cluster 2, consisting of 231 patients (37%), constituted an intermediate group doing fairly well. Cluster 1 was associated with female sex (p=0.0007) and lower education level (p=0.0003) compared to cluster 3. Cluster 1 was also associated to higher HAQ (p<0,0001), higher patient global assessment of health (p<0.0001), higher pain ratings (p<0.0001) and lower swollen/tender joint count ratio (STR) (p=0.0065) at the time of diagnosis compared to cluster 3.

Conclusions: Through cluster analysis, we could identify a subgroup of almost a third of the RA-patients with high levels of pain, fatigue, sleep problems and poor physical and mental health related quality of life 3 years after RA-diagnosis. These symptoms are indicative of a central sensitization syndrome and these findings indicate that other factors than inflammatory disease activity causes a significant burden of illness also at an early stage of RA and that there is a need of additional intervention strategies for these patients.

SAT0695 NO ASSOCIATION BETWEEN VITAMIN D LEVELS AND CARDIOVASCULAR DISEASES IN INFLAMMATORY JOINT DISEASES AND SYSTEMIC AUTOIMMUNE DISEASES – A SYSTEMATIC REVIEW

J.E.S. Ling[1], M. Ter Wee[2], W. Lems[3], M. Nurmohamed[3], H. Raterman[3]. *[1]Newcastle University Medicine Malaysia, Johor Bahru, Malaysia; [2]Epidemiology and Statistics; [3]Amsterdam Rheumatology and Immunology Centre, VU University Medical Centre, Amsterdam, Netherlands*

Background: In recent years, vitamin D deficiency has been linked to disease activity and pathogenesis of systemic autoimmune diseases (SAD) like systemic lupus erythematosus (SLE) and inflammatory joint diseases (IJD) such as rheumatoid arthritis (RA). In the general population, the association between vitamin D with risk for cardiovascular diseases (CVD) is still debatable. While people with IJD and SAD tend to be vitamin D deficient and suffer from an elevated CVD burden, the effect of vitamin D on their cardiometabolic risk factors is of much interest.

Objectives: To provide an overall conclusion on whether vitamin D deficiency contributes to an increased cardiovascular morbidity in these patients, a systematic literature review was done.

Methods: A systematic literature search was done in PubMed/MEDLINE and EMBASE to identify all articles that assessed the association of vitamin D with cardiovascular disease and its risk factors in patients with IJD (rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis) and SAD (systemic lupus erythematosus (SLE), Behcet's disease, vasculitis, Sjogren syndromes, systemic sclerosis). Eligible studies were assessed for quality and risk of bias according to the Cochrane Handbook Chapter 13.5.2.1. (Higgins JPT. GS. Cochrane Handbook for Systematic Review of Interventions The Cochrane Collaboration 2011.)

Results: In total 3273 abstracts were identified. After screening, selection and quality assessment, 16 studies were included (6 case-control and 10 cohort studies), which described only RA and SLE except for one study which focused on PsA. Therefore, this study focused on RA and SLE because they are the most frequent IJD and with highest CVD risk respectively. In RA patients (n=812) vitamin D deficiency was associated with presence of (components)of metabolic syndrome (OR =1.8 (95% CI: 1.3; 2.5), P=0.001) in RA, especially dyslipidemia (OR 1.7; 95% CI:1.1–2.5; P=0.013) and obesity. No studies with prospective design in RA have assessed CVD risk in relation to vitamin D. In SLE patients (n=1850) the only prospective study observed no association between vitamin D deficiency and CVD, although weak associations with dyslipidemia and obesity were observed in some studies.

Conclusions: No clear association between vitamin D deficiency and CVD was found in patients with RA and SLE, probably due to large heterogeneity in terms of sample sizes, designs, analyses and outcome measures. As conclusions were mainly drawn on cross-sectional data, there is an urgent need for adequate prospective studies to assess if vitamin D levels are associated with cardiovascular outcomes.

SAT0696 ENDOTHELIAL NITRIC OXIDE SYNTHASE T-786C GENE PROMOTER POLYMORPHISM IS A POTENTIAL PREDICTOR OF LOW RESPONSE TO THE THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS, UKRAINE POPULATION

K. Zaichko, M. Stanislavhuk, I. Shapoval. *The Internal Medicine, National Pirogov Memorial Medical University, Vinnytsya, Ukraine*

Background: Recently endothelial nitric oxide synthase (eNOS) T-786C gene promoter polymorphism was considered to be a factor of a high severity of RA [1,2]. It is possible that the eNOS T-786C gene promoter polymorphism can modify the efficacy and safety of treatment in patients with RA, but there is no information on the subject.

Objectives: To evaluate efficacy of treatment of patients with RA in accordance to the eNOS T-786C gene promoter polymorphism.

Methods: Patients who were enrolled in the study satisfied follows criteria: MTX 10–15 mg/week during the past 12 weeks, stable oral NSAIDs and corticosteroids (CCS), ≤10 mg/day prednisone or equivalent during the past 2 weeks, DAS28 ≥3.2, >6 tender and swollen joints. We excluded patients with previous biologic agent treatment history. All patients received treatment that included MTX, folic acid, CCS, NSAIDs. We evaluated RA activity (DAS28), number of swollen and tender joints, ESR, CRP, and HAQ before enrollment in the study and at the 12 week. Efficacy of the treatment was assessed by the ACR 20; 50; 70 at the end of the study.

The 12-week study completed 148 patients with RA, 100% female, aged 45.7±8.54 years (mean ± SD), with moderate (DAS28 3.2–5.1; 34.5%) and high disease activity (DAS28 >5.1; 65.5%). Among the patients with RA, seropositive were 81.8% and 84.5% by the RF and the anti-CCP, respectively. Polymorphism of NOS3 T786C gene (rs2070744) was performed by Real-Time PCR. All studied polymorphism satisfied Hardy-Weinberg equilibrium. The study was conducted in accordance with the Declaration of Helsinki of the World Medical Association

"Ethical principles of medical research involving human subjects" (2000), the requirements of GCP, the applicable national legislation.

Results: Among patients with RA frequency of the genotypes was as follows: TT – 37.2%, TC – 42.6%, CC – 20.3%. Age, seropositivity and the duration of the disease were not differing in patients with RA, carriers of the different genotypes of eNOS. Though, CC genotype was associated with high disease activity according to DAS28-ESR >5.2 (OR=9.60; 95% CI 2.18–42.2), HAQ >2 (OR =2.38; 95% CI: 0.94–6.02) and extraarticular manifestations (OR =3.26; 95% CI 1.40–7.56).

After 12 weeks treatment we estimated, that among patients with TT genotype there were 58.3; 16.7; and 8.3% responders ACR20; ACR50; ACR70, and among patients with CC genotype - 20.0; 10.0; 0.0% ($p<0.05$). TC heterozygotes patients had lower (by 22–25%, $p<0.05$) clinical response to the treatment by DAS28 and HAQ than the homozygotes TT.

Conclusions: eNOS T-786C gene promoter polymorphism influence on the efficacy of the treatment, and CC genotype can be considered as a possible predictor of a low response to the treatment in patients with rheumatoid arthritis.

SAT0697 PREVALENCE OF HEPATITIS B AND C INFECTION AND REACTIVATION IN PATIENTS RECEIVING BIOLOGIC IV THERAPIES

K. Arévalo Ruales[1], B. Soler Bas[2], J. Ivorra Cortes[1], E. Grau Garcia[1], E. Vicens Bernabeu[1], E. Labrador Sánchez[1], J.J. Fragio Gil[1], R. González Mazarío[1], C. Alcañiz Escandell[1], I. Cánovas Olmos[1], I. Chalmeta Verdejo[1], C.M. Feced Olmos[1], L. Gonzalez Puig[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J.E. Oller Rodriguez[1], F.M. Ortiz-Sanjuan[1], J.A. Román Ivorra[1,2]. *[1]Rheumatology Department, HUP la Fe; [2]Medical School, UCV, Valencia, Spain*

Background: With the use of biological therapy, cases of reactivation of hepatitis B (HBV) and C (HCV) have been described, consequently its use has to be carefully evaluated. In some cases these therapies have to be administered together with antiviral treatment. Despite the fact that before the beginning of the biological therapy the screening of HBV and HCV virus is done, during the course of treatment serologies are no longer used to detect serovonversions.

Objectives: To analyze the prevalence of HBV and HCV in patients with rheumatic disease at the beginning of biological therapies. To identify the cases of hepatitis reactivation.

Methods: Retrospective observational analysis of the biological treatments administered to patients with rheumatic Disease of the rheumatology department of La Fe hospital, during the period 2000–2015 who had HBV and/or HCV serology at the beginning of treatment. Demographic data and diagnosis of the patient, months of treatment and the results of the serologies performed at the beginning and in the follow-up of the treatment, and the cases of reactivation of hepatitis have been collected.

Results: A total of 388 patients were selected of which 62.4% were female; the mean age at diagnosis of was 38.96±14.36 years. 49.5% of the patients were diagnosed with rheumatoid arthritis (RA), 25.3% of ankylosing spondylitis (AE), 18.6% of psoriatic arthritis (APSO) and 6.7% with other diagnoses. The mean treatment time with patients' biological therapy is 200±118 months (3–464 months), and the mean time between the two serologies is 172±102 months (18–460 months). An incidence of 10% of cases with HBV infection (39 patients) is observed. The serological pattern was 8 cases with Ac-core (+) HBV/Ac-surface (-)/Ag-surface (-) HBV and 31 HBV/Ac- surface (-). The incidence of HCV at the start of treatment was 1.1% (4 patients). A case of reactivation (12.5%) was detected among the 8 patients with Ac-core (+)/Ac-surface (-)/Ag-surface (-) HBV. The patient had infliximab and methotrexate, and reactivation was observed after 12 years of treatment. No reactivation of HCV has been detected.

Conclusions: In our series of patients the incidence of HBV and HCV has been 10% and 1.1%, respectively. One of the 8 patients with Ac-core (+)/Ac-surface (-)/Ag-surface (-) HBV, had reactivation of the virus.

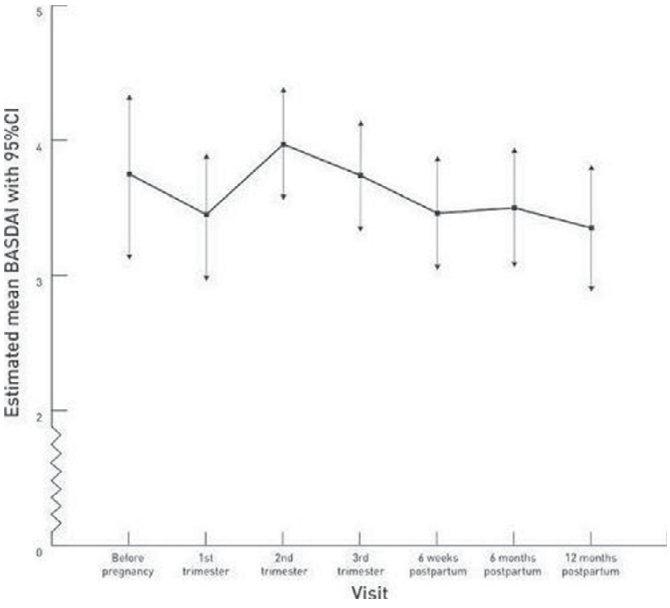
SAT0698 DISEASE ACTIVITY DURING AND AFTER PREGNANCY IN WOMEN WITH AXIAL SPONDYLOARTHRITIS



K. Ursin[1,2], S. Lydersen[3], J. Skomsvoll[1], M. Wallenius[1,2]. *[1]National Advisory Unit on Pregnancy and Rheumatic Diseases, St. Olavs Hospital - Trondheim University Hospital; [2]Department of Neuromedicine and Movement Science; [3]Regional Centre for Child and Youth Mental Health, NTNU, Norwegian University of Science and Technology, Trondheim, Norway*

Background: Studies on disease activity of ankylosing spondylitis in pregnancy have shown diverging results. A large retrospective study from 1998 without validated disease activity scores found no particular pattern of disease course during pregnancy (1). Later two small studies demonstrated a tendency towards lower disease activity in the beginning of pregnancy and deterioration in late pregnancy (2,3). None of these studies included women with non-radiographic axial spondyloarthritis. The only large study was conducted before the widespread use of biological DMARDs.

Objectives: The aim of this project was to prospectively study disease activity in women with axial spondyloarthritis before, during and after pregnancy with BASDAI as disease activity measure.

Methods: RevNatus is a Norwegian nationwide register designed for the follow-up of pregnant women with rheumatic diseases. RevNatus included 181 full term pregnancies in 168 women with axial spondyloarthritis between 2006 and 2016. The women had seven visits at a rheumatology unit; before pregnancy, in each trimester, and six weeks, six months and twelve months postpartum. BASDAI-values from each visit were analyzed in a linear mixed model.

Results: Even though we found a statistically significant relationship between disease activity and time point in the follow-up period, our study demonstrated that women with axial spondyloarthritis had stable, low disease activity during and after pregnancy. Disease activity in second trimester was significantly higher than six weeks after delivery, but the change in estimated mean BASDAI was small (BASDAI 3.97 vs. BASDAI 3.46, p=0.005). The figure below shows changes in disease activity throughout the study period.

Conclusions: Studying women with axial spondyloarthritis, we found that disease activity was highest in second trimester, but altogether stable in the period from planning pregnancy to one year after delivery.

SAT0699 RAPID ASSESSMENT PREDICTS DISEASE ACTIVITY IMPROVEMENT IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS (RA)

M. Yates[1], J. Galloway[1], N. Snowden[2], S. Norton[1], J.M. Ledingham[3], E.M. Dennison[4], A. Rivett[5], A.J. Macgregor[6]. *[1]Academic Rheumatology, King's College London, London; [2]Rheumatology Dept, Pennine MSK Partnership, Oldham; [3]Rheumatology Dept, Portsmouth Hospitals NHS Trust, Portsmouth; [4]MRC, Southampton University, Southampton; [5]BSR, The British Society for Rheumatology, London; [6]Rheumatology Dept, Norfolk and Norwich University Hospital, Norwich, United Kingdom*

Background: Early intervention in RA is associated with improved outcomes in randomised trials. UK guidelines stipulate that those with suspected RA are assessed by a rheumatologist within 3 weeks of referral. However, there are limited real world data confirming the value of early assessment. Previous work suggests social deprivation predicts severe disease at presentation and a worse

clinical course (1). The impact of deprivation in early assessment has yet to be characterised on a national level.
Objectives: To investigate if rapid assessment in secondary care associates with achieving a good treatment response, and if this is modulated by social deprivation.
Methods: An audit, designed as a prospective longitudinal observational study, was conducted to assess early RA care. All NHS providers in England and Wales were required to participate. Follow up data were captured over 3 months for subjects with a diagnosis of RA. Rheumatologist assessment within 3 weeks of referral was the predictor variable. The primary outcome was good EULAR DAS response; the secondary outcome was meaningful improvement in RAID score. Logistic regression was used to estimate for associations. Confounders including age, gender, baseline DAS28 and RAID scores were considered in analyses. The index of multiple deprivation (IMD) rank was calculated for each individual based on super-output geographical areas. The IMD rank was then stratified into quintiles and included as a confounder.
Results: 136 of 146 eligible trusts submitted data. 11,752 subjects consented, 5,622 were diagnosed with RA. 94/5622 (1.7%) had incomplete assessment date data. DAS28 response was available for 2234/5622 (39.7%), and RAID response for 901/5622 (16%). The table shows baseline characteristics and response for subjects with complete data. Assessment within 3 weeks associated with a significantly greater improvement in DAS28 and RAID scores, with an adjusted odds ratio for a good EULAR response 1.38 (1.15–1.66) and meaningful RAID reduction 1.44 (1.03–2.02).

	Seen within 3 weeks	Not seen within 3 weeks	P Value
N	878	1356	
Age (SD)	58.6 (14.8)	59.9 (14.1)	0.046*
Female (%)	65.2	64.4	0.24**
White British (%)	86	88.9	0.015**
Current smoker (%)	21.1	25.4	0.009**
IMD quintile mean	3	3	
DAS28 EULAR good response (%)	43.7	35.8	0.001**
DAS28 EULAR moderate response (%)	31.2	35	
DAS28 EULAR no response (%)	25.1	29.1	
Achieved MCID† RAID (%)	48	40.7	0.026*

*t-test; **chi-squared. †Minimal clinically important difference (reduction by 50% or absolute reduction >3).

Conclusions: These real world data confirm rapid assessment significantly predicts treatment response, in terms of clinical disease activity and patient reported outcomes. Amongst those who were assessed within 3 weeks of referral, an additional 8% achieved a good EULAR response. The association with RAID response was strengthened when social deprivation was included as a confounder. The relationship between IMD and RAID response appears to be non-linear and requires further study.

SAT0700 COMPARATIVE RISK OF RESPIRATORY DEPRESSION IN PATIENTS TREATED WITH OPIOIDS FOR NON-MALIGNANT PAIN

M. Jani[1], K. Kopec-Harding[1], M. Lunt[1], W.G. Dixon[1,2,3]. [1]*Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester;* [2]*Rheumatology department, Salford Royal NHS Foundation Trust, Salford;* [3]*Health eResearch Centre, University of Manchester, Manchester, United Kingdom*

Background: Opioid use for non-cancer pain has increased considerably over the last 30 years. The U.S. Food and Drug Administration announced several boxed warnings in 2016 to highlight serious opioid-related risks (1) in an effort to reduce fatal overdoses, 80% of which are unintentional (2). The most serious opioid related adverse event is respiratory depression (RD), which can be potentially fatal. There are few data on the incidence of RD in opioids users for non-malignant pain and no comparative data between drugs.
Objectives: To assess the comparative risk of RD in new users of opioids for non-malignant pain using routinely collected electronic patient records (EPR).
Methods: Opioid users from Salford hospital EPR were identified between 2014–2016. Patients with prior malignancy were excluded on the basis of ICD-10 codes and health issues. Those with prior history of opioid use were excluded using keyword searches within the medicines reconciliation document. The primary analysis was on drug + 1 day lag window, unless patient switched to another opioid. Exposure was categorised as opioid monotherapy by drug or combination of opioids (so that RD events could be assigned to a single exposure category). Electronic National Early Warning Scores, used to regularly monitor physiological parameters during inpatient visits, were used to classify RD. An RD event was defined as any one of the following: respiratory rate (RR) ≤8/min, RR ≤10/min and oxygen saturations <94%, RR ≤10/min and altered consciousness, or dispensed naloxone use. Crude rates per 1000 person years of follow up were calculated and Cox proportional hazards models were used to examine the comparative risk of dispensed opioids and RD. Patients contributed follow up time for a particular drug from dispensed drug start date until day after discontinuation, first RD event, death or end of last hospital admission (by 31/05/16).
Results: 8007 opioid users were included in the study, 3,976 female (50%) and a mean age (SD) of 53 (21) years. There were 255 RD events observed on treatment, 87 with severe respiratory depression (RR <8/min), 114 requiring naloxone and 3 respiratory arrests. Patients on fentanyl, morphine, oxycodone and combination treatment had the highest crude rates of RD (table). In the age and gender adjusted Cox-model, using codeine as the referent, patients on fentanyl, morphine, oxycodone and combination opioids had the highest risk of RD [(table), adjusted HR (95% CI) for combination opioids: 2.22 (1.56, 3.16)]. Compared to morphine, combination opioids had an adjusted HR of 1.52 (1.09, 2.13).

Opioid (no. of patients)	Codeine (n=4,638)	Fentanyl (n=577)	Morphine (n=3,783)	Oxycodone (n=1,740)	Tramadol (n=189)	Alfentanil (n=372)	Buphrenorphine (n=93)	Combination (n=3,175)
Mean age (years, SD)	51 (20)	62(20)	48 (18)	68 (18)	48 (18)	52 (17)	75 (17)	49 (19)

Age and gender adjusted hazard ratio (95% CI)	0.69 (0.49, 0.95)*	1.40 (0.74, 2.65)	Ref	1.37 (0.91, 2.06)	0.70 (0.17, 2.87)	0.31 (0.08, 1.27)	1.25 (0.17, 9.06)	1.52 (1.09, 2.13)*

* p<0.05

Conclusions: Fentanyl, oxycodone, morphine monotherapy have a significantly higher risk of RD than codeine, but these are not significantly different from each other. Combination opioids confer the highest risk of RD, compared to both codeine and morphine. The strengths of this study include capture of real time physiological parameters to define RD and dispensed medication use (rather than prescribed) to define exposure.

SAT0701 TOWARDS DIAGNOSIS-SPECIFIC LIFETIME RISKS FOR TOTAL HIP ARTHROPLASTY REVISION SURGERY

M. Gademan[1], L.N. van Steenbergen[2], S.C. Cannegieter[3], R.G. Nelissen[4], P.J. Marang-van de Mheen[5]. [1]*Orthopaedics/ Clinical Epidemiology, LUMC, Leiden;* [2]*Dutch Arthroplasty Register (LROI), 's Hertogenbosch;* [3]*Clinical Epidemiology;* [4]*Orthopaedics;* [5]*Medical Decision Making, LUMC, Leiden, Netherlands*

Background: An important aspect regarding optimal timing of primary hip arthroplasty (THA) is to weigh the benefit associated with the primary surgery at a certain point in time against the risk for revision surgery. Revision surgery should be avoided, as outcomes after revision surgery are less favourable than outcomes after primary surgery. Information on lifetime revision risks is needed to guide decision making for individual patients regarding timing of primary surgery.
Objectives: Our aim was to provide the 7 year cumulative percentages for revision surgery stratified for diagnosis, sex, type of fixation and age at which primary THA was performed.
Methods: Data on arthroplasties was available from the Dutch Arthroplasty Register (LROI), a nationwide population-based registry with information on all joint arthroplasties in the Netherlands from 2007 onwards. For the current study, all patients who received a primary THA in the period 2007 to 2015 were included except patients with a metal on metal prosthesis, patients with a hybrid or reversed hybrid fixation type or patients with revision surgery without primary surgery registered. Revision surgery was defined as any change of one or more components of the prosthesis. For the current study age at primary surgery, diagnosis, sex, type of fixation (uncemented, cemented) and survival (alive/dead) and revision of prosthesis (yes/no) were extracted from the LROI database.

Diagnosis was dichotomized into osteoarthritis (OA) and other diagnoses. Annual revision risks were calculated for each subsequent year after primary arthroplasty by dividing the number of revisions by the total number of patients at risk during that year. The risks were stratified according to the underlying diagnosis, sex, age at primary arthroplasty and fixation type. In addition cumulative annual revision percentages were calculated for the full follow-up period. Furthermore we estimated the percentage of avoided OA revisions by assuming that all OA patients received their primary THA 5 years later (in all age groups <85 yrs) and that the revision risks remained the same in all age categories.

Results: In total 134463 primary THA patients were included of whom 68% were female, 89% had OA as underlying indication and 66% of the THAs were uncemented. The 7th year cumulative risk percentage varied between 2.0 and 11.7% (Table 1). Overall cumulative revision percentages were higher in younger age categories (Table 1), with the exception of a 11.7% revision in the group aged 85–90 yrs (uncemented, male, other diagnosis), but this finding is likely due to chance as this group existed of 67 patients. We estimated that by delaying THA for 5 years, a total of 197 revision surgeries (4.4% of all revision surgeries) could be avoided, 48 (14.0%) in the OA male cemented group, 11 (0.9%) in the OA male uncemented group, 69 (3.3%) in the OA female cemented group and 69 (8.6%) in the female uncemented group. This could result in a yearly cost reduction of approximately 4 million euros.

Table 1. Cumulative revision percentages within 7 years after index surgery.

	Osteoarthritis				Other diagnosis			
	Male		Female		Male		Female	
Age-categories	Cemented	Uncemented	Cemented	Uncemented	Cemented	Uncemented	Cemented	Uncemented
50-54	4,10	4,46	3,14	5,27	8,31	6,56	4,44	7,19
55-59	4,55	5,46	6,70	4,63	8,94	5,38	8,02	5,95
60-64	4,72	4,34	3,55	4,24	5,03	5,54	7,23	3,82
65-69	4,23	4,06	2,36	3,63	5,92	7,30	6,86	4,99
70-74	3,71	4,53	2,92	4,50	5,24	7,34	2,46	4,28
75-79	3,00	4,67	2,47	3,78	4,15	7,25	3,87	2,94
80-84	2,69	3,84	2,20	3,59	5,94	3,76	3,48	3,79
85-90	2,02	4,93	2,11	3,73	2,04	11,65	2,47	2,51
Total	3,45	4,50	2,62	4,11	5,53	6,39	4,31	4,54

Conclusions: Cumulative 7th year risk percentages decreased by age in all different categories. By delaying the primary THA surgery, revisions might be avoided thereby resulting in cost reduction.

SAT0702 LOCAL AND SYSTEMIC INFLAMMATION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS WITH CHLAMYDIA TRACHOMATIS INFECTION

M. Natalia, K. Svetlana. *Belorussian State Medical University, minsk, Belarus*

Objectives: We had to study local and systemic inflammation in rheumatoid arthritis patients with persistence Chlamydia trachomatis (Ch tr) in the joint

Methods: 31 patients with early RA; mean age 54,5 (10,6) years, disease duration 21,5 (14,4) weeks witch persistence Ch tr in the joint (mRNP Ch tr had been revealed in synovial fluid by NASBA PCR) were enrolled in this study. The comarison group was patients with RA (n=42) without mRNP in synovial fluid (Ch tr-). Mean age was 51,7 (15,4) years, disease duration 20,8 (13,3) weeks. All the patients had been received only symptomatic treatment (NSAID). Disease activity had been detected by DAS 28. Systemic inflammation was estimated by levels of erythrocyte sedimentation rate (ESR), hsp C-reactive protein (hspCRP), orozomucoid (OR) in the blood samples; local inflammation- by detection hsp CRP, OR in synovial fluid. Also we had been detected level of ACCP in the blood samples and synovial fluid.

Results: We didn't reveal statistically significant differences between levels of ESR, hsp CPR, OR, ACCP in blood samples patients with RA Chtr+ and RA Ch tr-. Level of hsp CPR and OR in synovial fluid of research group (Ch tr+) were significantly higher than comparison group (4,1±0,3 mg/l versus 2,4±0,2 mg/l, $p<0,05$ –hspCRP and 157,4±17,5mg/dl versus 78,5±18,9 mg/dl, $p<0,001$- OR). In the group of research (Ch tr+) level of ACCP in synovial fluid was statistically significant higher than comparison group (Ch.tr -) (195,6±37,3 versus 67,9±15,4; $p<0,001$)

Conclusions: Patients with early RA detected by NASBA PCR in synovial fluid Ch tr+, had been characterized by absence differences compared RA Ch tr- patients in the level of systemic inflammation and had differences in the level of local inflammation. We revealed high level of ACCP in RA patients with Ch tr in the joints, that may be important for understanding some aspects of RA pathogenesis.

SAT0703 INFLUENCE OF PHYSICAL ACTIVITY AND SLEEP ON FUNCTIONAL CAPACITY AND PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS

M. Nuñez[1], E. Nuñez[2], J.M. Segur[3], L. Lozano[3], J. Montañana[3], V. Segura[3], M. Marti[4], A. Garcia-Cardo[4], S. Sastre[3], X. Alemany[3]. *[1]Rheumatology and IDIBAPS Area 1, Hospital Clinic;[2]SAP Suport al Diagnòstic i al Tractament, Institut Català de la Salut;[3]Orthopedic Surgery and IDIBAPS;[4]Rheumatology, Hospital Clinic, Barcelona, Spain*

Background: Knee osteoarthritis (OA) is a degenerative disease in which pain and functional disability progression tend to increase with reducing the health-related quality of life (HRQOL). Factors related to healthy lifestyles, such as physical activity and sleep, are known to have restorative benefits on function and pain in these patients. A previous study found that patients with reparative sleep achieved better WOMAC and SF-36 HRQOL questionnaire dimension scores.

Objectives: To determine the influence of physical activity and sleep on functional capacity and pain in patients with long-term knee OA.

Methods: Cross-sectional study. Sociodemographic and clinical variables, physical activity (PA) (regular physical exercise ≥3 times a week ≥30 minutes per session (PE) and sitting ≤6 hours/day [S]) and sleep quality/reparative sleep (RS) were determined using the question: How do you usually sleep? (1=well [RS], 2=regular, 3=badly, 4 =with medication/treatment [NRS]). Functional capacity and pain were evaluated using the WOMAC (specific) and SF-36 (generic) HRQOL questionnaires. Associations were analysed using multiple regression models.

Results: 453 patients (84.3% female), mean age 69.73 (8.4), BMI 35.27 [SD 6.3], comorbidities 2.43 (SD 1.5), 78.6% with obesity (BMI 33.68 [SD 6.7]), depression/anxiety in 36.4%, PE 60.5%, S 72.2% and PA 48.6%, were included. 22.5% reported RS. Bivariate analysis showed patients with PA and those with RS had better functional capacity and less pain intensity (>10, $p>0.001$, in both WOMAC and SF-36). The four multiple regression showed that patients with PA and SR had better scores, both in functional capacity (dependent variables, WOMAC and SF-36) and pain (dependent variables, WOMAC and SF-36), $p<0.006$. Age, gender, number of comorbidities and obesity were included in the models as potential confounders. Obesity was associated with worse function and more pain in the four models ($p<0.05$). Being female and greater comorbidity were associated with poorer functional capacity and pain assessed by the SF-36.

Conclusions: Physical activity and sleep were associated with less pain and better functional capacity, suggesting these variables should be determined systematically in clinical practice due to their significant relationship with HRQOL. Obesity was negatively associated with function and pain. There was also a negative relationship between female gender and comorbidity according to the SF-36. Differences in generic and specific questionnaires mean they should be used together to provide more detailed information.

SAT0704 THE IMPACT OF AUTOIMMUNE DISEASE IN THE MANAGEMENT AND PROGNOSIS OF ACUTE CORONARY SYNDROME

N. Lozano[1], F.J. Pastor Perez[2], L.F. LInares Ferrando[1], J. Martinez Ferrin[1], J. Ruiz Sara[1], A. Paños Iniesta[1], P. Castillo Dayer[1], A. Bermudez Torrente[1], F.A. Marinez Angosto[1], S. Manzano Fernandez[2]. *[1]Rheumatology;[2]Cardiology, University Hospital Virgen de la Arrixaca, Murcia, Spain*

Background: Patients with autoimmune diseases (AID) have a high burden of cardiovascular disease leading to premature morbidity and mortality. But it is unclear if it is due to a higher prevalence of cardiovascular disease, to a worse case fatality or to a different management after an index event.

Objectives: The primary aim of the study is to assess the prognostic implications of the presence of AID both during the hospitalization and after discharge after an acute coronary syndrome (ACS). The secondary objectives included the assessment of the prevalence of AID in patients with ACS, their clinical profile and the management of this index event

Methods: The study included consecutive patients admitted after ACS from January 2011 to December 2015 at the University Hospital Virgen de la Arrixaca, Murcia (Spain). For AID patients, in-hospital management and ACS presentation was compared to non-AID patients. We also compared in-hospital and major adverse events during follow-up (death, recurrent non-fatal myocardial infarction, stroke and major bleeding, between groups). A multivariate Cox regression model was performed to assess the independent role of the presence of AID in the occurrence of the events of interest.

Results: Of 2236 patients included with ACS, 78 had AID (3.3%): 24 rheumatoid arthritis, 10 inflammatory bowel disease, 7 ankylosing spondylitis, 6 psoriatic arthritis, 5 polymyalgia rheumatica, 2 systemic lupus erythematosus and 20 miscellanea. Mean age of AID patients was 67±13 years and median evolution of the disease was 10 [4–14] years. Seventy percent of AID patients were taking corticosteroids, 50% disease modifying antirheumatic drugs, 22% non-steroidal anti-inflammatory drugs and 8 biological theraphy. No significant differences were found in clinical and demographics characteristics between groups except for a

higher percentage of atrial fibrillation and chronic obstructive pulmonary disease in AID patients. Compared to non-AID patients, AID patients had similar clinical ACS presentation and no differences were found with respect to revascularization strategies or medical treatment at discharge. With respect to prognosis the two groups had comparable rates of adverse events during hospitalization (10% vs 10%, p=0.920) with no statistically significant differences in any single event studied. However after a follow-up of 397 [375–559] years, AID patients had higher rate of combined adverse events (44% vs 28% p<0,001). After multivariate adjustment the presence of AID was associated with increased total mortality (hazard ratio 2.1, 95% CI 1.2 to 3.7, p=0.008) and it was also a borderline risk factor for higher bleeding complications (hazard ratio 2.2, 95% CI 0.9 to 5.5). The presence of AID was not an independent risk factor for neither stroke or recurrent non-fatal myocardial infarction.

Conclusions: The presence of AID did not change ACS presentation and clinical management. Although AID is not associated with worse outcomes during hospitalization it is independently linked to higher total mortality and a trend to an increased risk of major bleeding during follow-up.

SAT0705 DO DIET CHARACTERISTICS IMPACT EFFECT OF A 12-MONTH VITAMIN D SUPPLEMENTATION ON 25OH-VITAMIN D SERUM LEVEL AMONG OVERWEIGHT ELDERLY?

R.M. Baddoura[1], N.A. Yaghi[2], A. Arabi[3], G. Halaby[4], G. El-Hajj-Fuleihan[3].
[1]Rheumatology, Hotel-Dieu de France, St Joseph University; [2]Nutrition, School of Pharmacy, St Joseph University; [3]Calcium Metabolism, American University of Beirut Medical Center; [4]Endocrinology, Hotel-Dieu de France, St Joseph University, Beirut, Lebanon

Background: Achieving desirable 25OHvitamin D serum levels with vitamin D supplementation may be influenced by many confounders including lifestyle patterns and vitamin D receptor genetic polymorphisms.

Objectives: To test the effect of dietary intake confounding variables such total as calories, dietary intake of vitamin D, calcium, proteins, carbohydrates and fats, on the variance in serum 25-hydroxy vitamin D (25OHD) level after vitamin D supplementation.

Methods: Study population: All subjects from one out of three centers who participated in a randomized clinical trial comparing high (3750 IU/day) versus low (600 IU/day) dose of vitamin D supplementation in ambulatory overweight (BMI exceeding 25) elderly subjects (age ≥65 years), with serum 25OHD level between 10 and 30 ng/ml at screening.

Outcome measure: 25OH D serum levels at 12 months of follow-up.

Confounders included gender, body mass index, baseline 25OHD serum level, genetic polymorphism of vitamin D receptor (Fok, BsmI and Taq) and dietary intake of vitamin D, calcium, proteins, carbohydrates, fats and total calories assessed by food frequency and 24h recall questionnaires, administered a year after the termination of the trial.

Statistical analysis: ANOVA for repeated measures and regression using STATA version 13. Numbers expressed as mean (SD).

Results: We studied 117 Participants, 62 females and 55 males, age was 71 (5) years, of who 61 received 3,750 IU of vitamin D, and 55 received 600 IU/day. Vitamin D receptor genetic polymorphisms distribution was comparable in both arms. Daily vitamin D intake excluding provided supplements was 7.59 (1.21) mcg and 8.53 (1.36) mcg from the 24 h recall, and food frequency questionnaires, respectively (p was NS between the two arms). Calories, calcium, protein, carbohydrate and fat mean intake was also similar across both arms. The high-dose group achieved significantly higher 25OH-vitamin D serum levels at twelve months 34.9 (9.3) ng/ml compared to low-dose, 21.9 (6.1) ng/ml (p<0.0001). Difference between arms remained significant adjusting for gender, baseline BMI, Fok, BsmI and Taq genetic polymorphism, baseline serum vitamin D and dietary intake of vitamin D, calcium, calories, proteins, carbohydrates and fats. None of these dietary intake measures was found to have significant contribution to the model variance. Supplementation dose was the only significant predictor of 25OHvitamin D serum levels achieved at 12 months.

Conclusions: Diet composition was not a confounder for the effect of high versus low dose vitamin D 12-month supplementation, on achieved 25OHD vitamin D serum levels.

Objectives: To characterize the main features at presentation of sarcoidosis associated with the development of end-stage organ failure in a large multicenter cohort of patients from Southern Europe.

Methods: In January 2017, the Spanish National Registry of Sarcoidosis (SARCOGEAS-SEMI) included 1082 consecutive patients diagnosed with sarcoidosis according to the ATS/ERS/WASOG 1999 statement and extrathoracic involvement to the 2014 WASOG instrument. The development of end-stage organ failure was assessed at the last visit.

Results: The cohort consisted of 618 (57%) women and 464 (43%) men, with a mean age at diagnosis of 47yrs. After a mean follow-up of 82 months, 90 (8%) patients developed end-stage organ failure, including respiratory failure (n=56), chronic renal failure (n=13), cardiac failure/permanent cardiac device (n=8) and liver cirrhosis (n=3). The following baseline features were associated with end-stage organ failure in the univariate analysis: patients born in Spain (p=0.008), a higher mean age at diagnosis (p<0.001) and a radiological stage III/IV (p<0.001) With respect to extrathoracic involvement, spleen (p=0.015), renal (p=0.001), cardiac (p=0.028) and bone marrow (p=0.003) involvements, hypercalcemia (p=0.018) and use of corticosteroids (p<0.001) were associated with end-stage organ failure, while patients with cutaneous sarcoidosis had a lower risk (p=0.029). Multivariate analysis identified age at diagnosis (OR 1.05), radiological stages III/IV (OR 3.12) and use of corticosteroids (OR 4.55) as independent variables associated with the development of end-stage organ failure.

Conclusions: Nearly 10% of patients with sarcoidosis developed end-stage organ failure. Respiratory failure represented two thirds of cases of sarcoidosis-related organ failure, followed by renal (15% of cases) and cardiac (9%). Older patients, as well as those presenting with advanced radiological stages, had an enhanced risk of developing end-stage organ failure.

SAT0707 EFFICACY AND SAFETY OF PROPHYLACTIC TREATMENT ON ACTIVIATION OF LATENT TUBERCULOSIS DURING GLUCOCORTICOID THERAPY IN PATIENTS WITH RHEUMATIC DISEASES

R. Wu. *Department of Rheumatology, the First Affiliated Hospital of Nanchang University, Nanchang, China*

Background: More than 80% of cases of tuberculosis are the result of reactivated latent infection, and nearly all these cases could be prevented by the administration of a course of antibiotic treatment. Therefore, it is suggested screening and treatment are most beneficial for those patients taking immunosuppressive medications. Although the prevalence of latent tuberculosis infection in China was much higher than the United States on the basis of tuberculin skin testing, In China, so far, no study has been done about prophylactic treatment on prevention of tuberculosis activation during glucocorticoid therapy in patients with rheumatic diseases. Should it been recommended that all patients with rheumatic diseases be screened for the presence of active tuberculosis or LTBI before the use of long term glucocorticoid or immunosuppressive medications in China? It is reported only about 5% of immunocompetent persons with a positive test will have progression from latent infection to disease in their lifetime. and decisions about whether to treat latent tuberculosis should take into account the individual patient's risk for the development of active tuberculosis and the risks of therapy.

Objectives: To evaluate the risk of reactivation of LTBI in patients with rheumatic diseases who were undergoing prednisone use and the efficacy and safety of prophylactic treatment on prevention of tuberculosis reactivation.

Methods: 1000 patients with rheumatic diseases who were treated with prednisone were enrolled since 2012. IGRA test (the T-SPOT.TB test) were performed for all subjects. 50 patients with a IGRA-positive were administrated with rifampin for 4 months. 2-years follow-up was conducted to evaluate the risk factors of reactivation of LTBI and the efficacy and safety of rifampin treatment on prevention of tuberculosis reactivation.

Results: the IGRA-positive rates were 20.6% (206/1000). Forty-eight patients with a IGRA-positive finished the treatment with rifampin for 4 months. 2-years follow-up shows no latent tuberculosis developed into active tuberculosis in the patients with prevention of rifampin, while 3 (0.38%) patients with negative IGRA and 22 (10.7%) patients with positive IGRA without rifampin treatment developed into active tuberculosis. 25 patients had active tuberculosis disease in two years, which 24 patients with SLE and one patient with systemic vasculitis while 20 cases had pulmonary tuberculosis, 3 cases had vertebral tuberculosis and tuberculous peritonitis, tuberculous meningitis was 1 case, respectively. Univariate analysis showed that age, entities of rheumatic disease, dosage of glucocorticoid, DMARDs using, comorbidity with interstitial lung disease and cancer were significantly associated with tuberculosis activation ($P<0.05$), with the ORs of 0.959, 0.592, 4.45, 0.226, A3.51 and 69.9, respectively. Entities of rheumatic diseases, Dosage of glucocorticoid, DMARDs using, comorbidity of cancer entered the final multivariate Logistic model. No severe adverse effects occurred in all subjects.
Conclusions: Medium or high dosage of glucocorticoid treatment appears to increase the risk of activation of latent tuberculosis infection. Latent tuberculosis activation could be safely prevented by 4-months rifampin treatment while starting glucocorticoid and DMARDs therapy.

SAT0708 SYMPTOMS INDICATIVE OF INFLAMMATORY ARTHRITIS ARE COMMON IN THE PRIMARY CARE POPULATION: FINDINGS FROM THE SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS SURVEY

S.L. Hider[1,2], S. Muller[1], J. Prior[1], T. Helliwell[1], D. van Schaardenburg[3], A. van der Helm-van Mil[4], K. Raza[5], C.D. Mallen[1]. *[1]Arthritis Research UK Primary Care Centre, Keele University, Keele; [2]Haywood Academic Rheumatology Centre, Haywood Hospital, Staffordshire, United Kingdom; [3]Reade, Amsterdam; [4]Department Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; [5]Rheumatology Research Group, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom*

Background: Early, accurate diagnosis of RA is critical to improving outcomes. Patients with RA may develop a variety of symptoms including joint pain, swelling and stiffness. The Symptoms in Persons at Risk of Rheumatoid Arthritis (SPARRA) questionnaire was derived to assess the presence, severity and impact of common symptoms in patients at risk of RA (1). However, to date there is little data available on how common these symptoms are in primary care consulters.
Objectives: To describe the prevalence of self-reported inflammatory joint symptoms in primary care patients consulting for both musculoskeletal and non-musculoskeletal complaints.
Methods: Questionnaires were sent to 10161 individuals, of whom 5050 had consulted primary care for musculoskeletal problems. The remainder were matched to this sample by age, gender and general practice and had consulted for any non-musculoskeletal indication. Respondents provided data on presence of common symptoms such as joint pain, stiffness and swelling. The prevalence of these symptoms, their severity and impact was compared between musculoskeletal and non-musculoskeletal consulters.
Results: 4549 people responded to the survey (adjusted response 45.8%) of whom 52.3% were in the musculoskeletal consultation group. The mean (SD) age was 61.6 (14.8) years and 58.9% were female. Symptoms commonly associated with inflammatory arthritis were common in both groups. 89.1% of musculoskeletal consulters reported current joint pain, compared with 74.9% in the non-MSK consulter group, 48.7% of MSK consulters reported joint swelling compared to 37.3% of non-MSK consulters and 77.9% of MSK consulters reported joint stiffness (64.3% in non-MSK group). A similar proportion in each group reported fatigue (59.5% vs 55%). Joint symptoms remained common symptoms in both groups even when severity and impact of symptoms was considered.
Conclusions: Although symptoms such as joint pain, swelling, and stiffness are predictive of inflammatory arthritis, a large proportion of those consulting primary care for non-musculoskeletal reasons routinely report these symptoms when prompted. This compounds the challenges of diagnosing inflammatory arthritis in a non-specialist setting where new approaches are needed to ensure accurate, early diagnosis, facilitating a treat to target approach.

SAT0709 MORTALITY PREDICTION IN MIXED CONNECTIVE TISSUE DISEASE

S. Reiseter[1], R. Gunnarsson[2], T.M. Aaløkken[3], M.B. Lund[4], J. Corander[5], Ø. Molberg[6]. *[1]Institute of Clinical Medicine, University of Oslo, Norway; [2]Dept. of Rheumatology; [3]Dept. of Radiology and Nuclear Medicine; [4]Dept. of Respiratory Medicine, Oslo University Hospital; [5]Institute of Basic Medical Sciences; [6]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*

Background: Mixed Connective Tissue Disease (MCTD) is a chronic, immune-mediated disorder defined by the combined presence of serum anti-ribonucleoprotein (RNP) antibodies and selected clinical features of Systemic Sclerosis, Systemic Lupus Erythematosus, Rheumatoid Arthritis and Polymyositis. Several clinical manifestations and laboratory findings have been found to be associated to increased risk of mortality in univariable analyses (1).
Objectives: Here we present a mortality predicting model in a long-term observational unselected nationwide cohort aiming to enhance the knowledge of long-term prognosis in MCTD.
Methods: 135 patients were included from our nationwide MCTD cohort. Abnormal high resolution computed tomography (CT) findings of ground glass attenuation and reticular patterns were defined as Interstitial Lung Disease (ILD) and expressed as percentage of Total Lung Volume (TLV). Pulmonary function tests and laboratory tests were performed within 2 months of the HRCT examination. Pleuritis was defined as typical pleurisy for more than one day, pleural effusions or pleural rub present at or before baseline. Pericarditis was defined as typical pericardial pain for more than one day, pericardial effusion, pericardial rub or pericarditis by electrocardiography at or before baseline. Myositis was confirmed by muscle biopsy and/or electromyogram and CK elevation at or before baseline. Cox regression analyses were used to find the predictive factors of mortality. Variables at a significant level of $P<.25$ where considered a candidate in the prediction model by manual backward elimination procedure.
Results: 21 patients died after a mean (standard deviation) observation of 9 (2) years. The predictive model is shown in Table 1. According to the Harrell's C index, patient outcomes were accurately predicted by this model 85% of the time.

Table 1

	Univariable			Multivariable		
	HR	95% CI	P value	HR	95% CI	P value
Pericarditis ever	4.0	1.6–9.7	0.003	5.5	1.9–16.0	0.002
Male gender	2.5	1.1–5.9	0.038	5.8	1.9–17.9	0.002
% ILD of TLV	1.1	1.03–1.1	0.001	1.1	1.0–1.1	0.010
DLCO <60%	3.1	1.3–7.5	0.011	3.1	1.0–9.2	0.046
Agegroups* at diagnosis	1.8	1.4–2.4	<0.001	1.9	1.4–2.5	<0.0001
Baseline ESR >30 mm	3.3	1.4–7.7	0.007			
FVC <75%	3.6	1.4–8.8	0.006			
Arthritis present at or before baseline	2.1	0.85–5.2	0.109			
Pleuritis ever	2.2	0.81–6.1	0.121			
Baseline Hb <12 g/dL	2.7	1.0–7.0	0.041			
Myositis	0.22	0.03–1.7	0.144			

*Patients were divided in 6 age groups at diagnosis (<25 years, 26 to 35 years, 36 to 45 years, 46 to 55 years, 56–65 years and above 65 years). FVC = Forced Vital Capacity % of predicted, DLCO = diffusing capacity of the lung for carbon monoxide % of predicted, ESR = erythrocyte sedimentation rate, TLV = total lung volume, Hb = Haemoglobin.

Conclusions: The strongest predicting factors of mortality in MCTD is increasing % ILD of TLV, pericarditis, male gender, DLCO less than 60% of predicted and increasing age at diagnosis.

SAT0710 RENAL FUNCTION CONTRIBUTE TO RISK OF CARDIOVASCULAR DISEASE IN RHEUMATOID ARTHRITIS

S. Hannawi[1], I. Alsalmi[2]. *[1]Rheumatology, Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates; [2]Renal, Royal Hospital, Muscat, Oman*

Background: The excess mortality associated with rheumatoid arthritis (RA) is due largely to cardiovascular disease. This highest risk is not related primarily to traditional cardiovasculr/atherosclerosis risk factors. The presence of RA indepedently, as well as high inflammation associated with RA has been reported as a cardiovascular risk factors. Also, subclinical decreased kidney function has been identified as an independent risk factor for CV events in patients with RA. The potential impact of impaired kidney function on atherosclerosis in RA requires more elucidation.
Objectives: To assess the role of renal parameters, alongside with inflammation and traditional cardiovascular risk factors in predicting cardiovascular disease; as manifested by carotid intima media thickness (cIMT), among RA population.
Methods: cIMT measurement was carried out in 68 RA patients, and correlated with renal function parameters with adjustment for traditional CV risk factors and RA associated inflammation. Glomerular filtration rate (GFR) was estimated with the abbreviated Modification of Diet in Renal Disease formula. Linear regression determined the association between renal parameters and the thickness of cIMT.

Results: Carotid intima media thickness was positively associated with 1-demographic characteristics of the participants such as age of the participants ($p<0.001$), and age at RA sumptoms onset (p=0.001). 2-traditional cardiovascular risk factors such as systolic blood pressure ($p<0.001$), diastolic blood pressure (p=0.016), triglycerid level (p=0.016), and low densilty lipoprotein (LDL) (p=0.001). 3-inflammatory markers such as erythrocytes sedimentation rate (ESR) (p=0.020) and c-reactive protein (CRP) (0.020), and 4-renal function parameters such as uric acid level (p=0.006), urine microalbumin level (p=0.030). cIMT negativlely associated with high density lipoprotein (HDL) (p=0.037), 24 hours urine creatinine level (p=0.020) and glomerular filtration rate (p=0.008).
Conclusions: Subclinical renal function in conjunction with tarditional and non-traditional cardiovascular risk factors work synergistically to accelerate atheroscrlerosis in RA population.

SAT0711 CHECKPOINT INHIBITOR THERAPY IN PATIENTS WITH ADVANCED MALIGNANCIES AND PREEXISTING RHEUMATOLOGIC DISEASE: THE MAYO CLINIC EXPERIENCE

U. Thanarajasingam[1], O. Pinkston[2], L. Kottschade[3], H. Finnes[3], S. Markovic[3].
[1]Rheumatology, Mayo Clinic, Rochester; [2]Rheumatology, Mayo Clinic, Jacksonville; [3]Oncology, Mayo Clinic, Rochester MN, Rochester, United States

Background: Immune checkpoint inhibitors (specifically the anti-CTLA-4 antibody ipilimumab, and the anti-PD-1 antibodies nivolumab and pembrolizumab, have revolutionized the treatment of advanced malignancies. However, by virtue of their mechanism of action – that is, loss of T-cell inhibition and impaired self-tolerance, patients with underlying autoimmune and rheumatologic diseases were typically excluded from the clinical trials leading to the approval of these agents. Limited data, typically of single checkpoint inhibitors, exist for their safety in patients with autoimmune diseases. However, the risk for rheumatologic disease flare in patients exposed to checkpoint inhibitors is unknown.
Objectives: To determine the risk of rheumatologic disease flare in patients receiving checkpoint inhibitor therapy.
Methods: We retrospectively studied all patients who had received a checkpoint inhibitor (i.e. ipilimumab, nivolumab, pembrolizumab, or any combination thereof) for any malignancy on the Mayo Clinic Rochester, Minnesota campus between January 1st, 2011 and May 16th, 2016 (approximately 5,200 patients.) Of these patients, we identified those with preexisting rheumatologic disease according to specific diagnostic codes.
Results: Of the 16 patients identified (13 [81%] female; median [range] age, 68.5 [34–86]y), 6 had inflammatory arthritis, 3 had polymyalgia rheumatica, 2 had lupus, 2 had Sjogren's syndrome, 1 had temporal arteritis, 1 had IBD-associated spondyloarthropathy and 1 had gout. Patients were treated for the following metastatic/advanced malignancies: melanoma (9 [56%]), lung (5 [31%]) and lymphoma (2 [12%]) with; ipilimumab (4 [25%]), nivolumab (7 [44%]), pembrolizumab (5 [31.2%]) and ipilimumab/nivolumab (1 [6%]). Notably, in all cases, checkpoint inhibitor therapy was offered after failure of numerous other chemotherapies. Ten (62.5%) patients were on immunosuppressive therapy (mainly low dose prednisone and methotrexate) at the time of cancer diagnosis, and the majority (10 [62.5%]) were well-controlled/in remission from the standpoint of their rheumatologic disease. Three (19%) patients had flares of their rheumatologic disease after treatment for the following cancers as noted: Patient 1 - temporal arteritis – nivolumab - non-small cell lung cancer, Patient 2 - Sjogren's (severe sicca)– pembrolizumab - melanoma, and Patient 3 - spondylitis-ipilimumab/pembrolizumab combination –melanoma. All flares responded to steroids or supportive therapy. Checkpoint inhibitor therapy was discontinued in all three patients for the following reasons: Patient 1 – flare of temporal arteritis, Patients 2 & 3 – cancer progression.
Conclusions: To our knowledge, we have identified the largest cohort (16) of patients from a single academic with preexisting rheumatologic disease who had been exposed to checkpoint inhibitor therapy for advanced malignancy. Of these patients, only a minority experienced a flare of their disease during cancer treatment, and responded to standard therapies. With close monitoring and in the appropriate clinical context, checkpoint inhibitor therapies should be considered and made available to patients with preexisting rheumatologic disease who develop advanced malignancies.

SAT0712 SELF-REPORTED SEDENTARY BEHAVIOUR IS ADVERSELY ASSOCIATED WITH MICROVASCULAR ENDOTHELIAL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.A.M. Fenton[1,2], J.J. Veldhuijzen van Zanten[1,2], A. Sandoo[3], J.L. Duda[1], G.S. Metsios[2,4], G.D. Kitas[2]. *[1]School of Sport Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham; [2]Rheumatology, Russells Hall Hospital, Dudley; [3]School of Sport, Health and Exercise Sciences, Bangor University, Gwynedd, Wales; [4]Faculty of Education Health & Wellbeing, University of Wolverhampton, Wolverhampton, United Kingdom*

Background: Patients with Rheumatoid Arthritis (RA) are at increased risk for cardiovascular disease (CVD). Research suggests impaired vascular function contributes to this heightened risk. At present, little is known regarding factors associated with vascular function in RA. Epidemiological evidence demonstrates sedentary behaviour (i.e., waking behaviour $\leq$1.5 metabolic equivalents whilst sitting or lying), to be adversely linked to CVD risk in the general population. Whilst the biological processes underlying this relationship are not understood, vascular dysfunction may play a role (1, 2). However, research is yet to examine the association between sedentary behaviour and vascular function in healthy adults and/or clinical populations. Studies investigating this relationship in RA, will help to determine the extent to which sedentary behaviour may represent a modifiable risk factor for CVD in these patients.
Objectives: To investigate the cross-sectional associations between sedentary behaviour and microvascular and large vessel endothelial function among patients with RA.
Methods: Fifty-three patients with RA participated in the study (*M* age=52.9±12.8, 72% female). Laser Doppler imaging with iontophoresis was used to assess microvascular endothelium-dependent (acetylcholine, ACh) and endothelium-independent (sodium nitroprusside, SNP) function. Large vessel endothelium-dependent and endothelium-independent functions were measured via flow-mediated dilation (FMD) and glyceryl trinitrate dilation (GTN), respectively. Sedentary behaviour was self-reported via the International Physical Activity Questionnaire (hours/week sitting). Data were analysed using multiple linear regressions adjusted for traditional CVD risk factors; age, gender, total cholesterol, smoking status, family history of CVD, hypertension and body-mass-index.
Results: Sitting time (hours/week, M =39.2±17.9) was significantly negatively related to % increase in perfusion in response to ACh (β=–0.30, $p<0.05$) and SNP (β=–0.37, $p<0.01$) after adjustment for traditional CVD risk factors. Sitting time accounted for 8% and 12% of the variance in microvascular endothelium-dependent function (ACh) and endothelium-independent function (SNP), respectively (traditional CVD risk factors, R^2=0.3). No significant associations were observed between self-reported sitting time and large vessel endothelium-dependent vasodilation (FMD, β=0.16, p=0.29) or independent vasodilation (GTN, β=–0.08, p=0.55).
Conclusions: Sedentary behaviour appears to adversely affect microvascular endothelial function, but not large vessel function in patients with RA. It may therefore represent a modifiable risk factor for CVD in this population. Experimental studies employing objective measures of sedentary behaviour are necessary to confirm these findings, and to determine the utility of sedentary behaviour interventions for improving vascular function and reducing CVD risk in RA.

SAT0713 SURVEY ON PREVALENCE OF RHEUMATIC DISORDERS IN BANGLADESHI ADULTS

S. Ahmed[1], S.A. Haq[1], A.Z. Al-qadir[1], M.M. Rahman[2], S. Paul[3].
[1]Rheumatology, Bangabandhu Sheikh Mujib Medical University; [2]Medicine, Dhaka Medical College, Dhaka; [3]Medicine, Chittagong Medical College, Chittagong, Bangladesh

Background: From Community based COPCORD (community oriented program for control of rheumatic diseases) study in Bangladesh about a quarter of people is suffering from musculoskeletal disorders. But the study was conducted over a small number of samples and some specific localities of the country. So further study was required, covering the whole Bangladesh to justify this high prevalence.
Objectives: To determine the prevalence of musculoskeletal symptoms and specific rheumatic disorders in adult population of Bangladesh.
Methods: In this survey, a total of 2000 individuals aged 18 years or older were selected in twenty clusters (primary sample unit) from the seven divisions of the country. Modified COPCORD (Community Oriented Program for Control of Rheumatic Disorders) questionnaire was used to detect positive respondents. Standard criteria were used for diagnosing rheumatic disorders. Clinical judgment was used to solve diagnostic problems.
Results: In total 1843 individuals were interviewed with a response rate of 92.1%. The point prevalence of musculoskeletal pain was 33.7%. It was higher in women (38.7%) than men (28.4%) and higher in rural (34.5%) than that in urban (32.4%) areas. Higher prevalence rates were observed in homemakers (16.0%), laborers

(3.0%), business professionals (2.9%) and cultivators (2.8%). Low back (23.3%), knee (12.7%) and shoulder (6.1%) were the most frequent site of complaint. Non specific low back pain (12.7%) and knee osteoarthritis (7.3%) were the two top ranking disorders. The prevalence of rheumatoid arthritis was 1.6% and spondyloarthritis 1.2%. 5.5% of the respondents had disability from rheumatic problems.
Conclusions: About one third of the Bangladeshi adults suffer from musculoskeletal pain at a given point of time. There are residence and gender variation in the prevalence rates. Low back and knee pain were the principal sites of complaints.

SAT0714 INCREASED RISK OF OPPORTUNISTIC INFECTION IN THE EARLY STAGE OF RHEUMATOID ARTHRITIS

H. Kim[1], S.-K. Cho[1,2], M.J. Kim[1], G.Y. Ahn[1], H.H. Kwon[1], D. Kim[1], J. Lee[2], S.-C. Bae[1,2], Y.-K. Sung[1]. *[1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases; [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, Korea, Republic Of*

Background: The increased risk of opportunistic infections (OIs) in rheumatoid arthritis (RA) patients who started biologic disease modifying anti-rheumatic drugs (DMARDs) has been well known. However, it has not been studied regarding the increased risk of OIs in the early stage of RA.
Objectives: To study the increased risk of incidence rate (IR) of OIs in early RA patients compared with established RA patients, and to evaluate the risk factors for developing the OIs in the early stage of RA.
Methods: Retrospective cohorts of early and established RA patients were conducted independently using the Korean National Healthcare claims database. Early RA patients (n=14,081) were identified in 2010 having disease free period for 1 year before index date, and receiving continuous treatment for over three years. Established RA patients (n=226,838) were recruited between 2010 and 2012 with using the ICD10 code of RA and any DMARD use. Follow-up started on the index date and ended on the data of the development of OIs, at 12 months, or at the time of death. The incidence rates of OIs were compared between two groups by calculating incidence rates ratio (IRR) and standardized incidence ratio (SIR) for overall or each OIs. The multivariable regression model was used to evaluate the risk factors for OIs in the early stage of RA.

Table 1

Type of opportunistic infection	Established RA N=226,838		Early RA N=14,081		SIR comparing early RA patients with established RA patients	
	IR/100PY	95% CI	IR/100PY	95% CI	SIR	95% CI
Total	3.67	3.59–3.74	3.81	3.52–4.11	1.14	1.05–1.23
Tuberculosis	0.71	0.67–0.75	0.70	0.54–0.87	1.06	0.82–1.33
Herpes zoster	2.79	2.72–2.85	2.89	2.64–3.13	1.12	1.03–1.22
Cytomegalovirus	0.02	0.02–0.03	0.03	0.00–0.06	0.98	0.20–2.86
Epstein–Barr virus	0.01	0.00–0.01	0.04	0.00–0.07	3.54	0.96–9.06
Pneumocystis jiroveci pneumonia (PJP)	0.01	0.01 - 0.02	0.02	-0.01–0.04	1.20	0.15–4.34
Candidiasis	0.10	0.08–0.11	0.11	0.07–0.16	2.40	1.55–3.54
Aspergillosis	0.02	0.02–0.03	0.02	0.00–0.05	0.84	0.17–2.47
Cryptococcosis	0.01	0.00–0.01	0.01	-0.01–0.02	1.15	0.03–6.39

RA = rheumatoid arthritis, SIR = standardized incidence ratio, PY = person year, N = number, IR = incidence rate, CI = confidence interval.

Results: The IRs of overall OI in early and established RA patients were 3.81 (95% CI 3.52–4.11)/100PY and 3.67 (95% CI, 3.59–3.74)/100PY, respectively. The SIR for overall OIs in early RA patients was 1.14 (95% CI, 1.05–1.23). The herpes zoster (SIR 1.12, 95% CI 1.03–1.22) and candidiasis (SIR 2.40; 95% CI 1.55–3.54) were commonly affected in the early stage of RA patients. Older age more than 50 years old [50<age≤60 (OR 1.74, 95% CI 1.30–2.33), 60<age≤70 (OR 1.85, 95% CI 1.36–2.52), 70<age (OR 1.89, 95% CI 1.34–2.68)], more comorbidities [one comorbidities (OR 1.53, 95% CI 1.24–1.89), ≥2 of comorbidities (OR 1.84, 95% CI 1.47–2.29)], and corticosteroid ≥5mg per day (OR 1.38, 95% CI 1.13–1.69) were associated with increased risk of OIs in the early stage of RA patients.
Conclusions: The incidence of OIs is increased in early stage of RA patients compared with established RA patients. Old age, comorbidities, high corticosteroid dose were related with the development of OI. Physicians should be aware of the possible occurrence of OIs in early stage of RA treatment.

SAT0715 CLINICAL SIGNIFICANCE OF FIBROMYALGIA SYNDROME IN DIFFERENT RHEUMATIC DISEASES: RELATION TO DISEASE ACTIVITY AND QUALITY OF LIFE

T.A. Gheita, S.M. El-Rabbat, N.K. Mahmoud. *Rheumatology and Clinical Immunology Department, Faculty of Medicine - Kasr Al-Ainy School of Medicine - Cairo University, Cairo, Egypt*

Background: In clinical practice, the co-expression of fibromyalgia syndrome (FMS) and a rheumatologic disease deserves special attention as FMS may go unrecognized especially when it develops after the disease or more commonly when it is misdiagnosed as an autoimmune disorder.
Objectives: The aim of the present work was to compare the frequency of FMS in rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and Behçets disease (BD) patients and to study the relation of FMS to the clinical manifestations, laboratory features, disease activity and/or damage as well as the quality of life (QoL).
Methods: One hundred and sixty patients (50 RA, 50 SLE, 30 SSc and 30 BD) consequently recruited from those attending the Rheumatology outpatient clinic and department, Faculty of Medicine, Cairo University Hospital. and 141 age and sex matched corresponding healthy controls were included. Disease activity was assessed using Disease Activity Score in 28 joints (DAS28) for RA, SLE Disease Activity index (SLEDAI), modified Rodnan skin score for SSc and BD Current Activity Form (BDCAF). The Systemic Lupus International Collaborating Clinics (SLICC)/ACR damage index was assessed in SLE patients. The quality of life (QoL) was also recorded. Severity in FMS cases was estimated using the revised Fibromyalgia Impact Questionnaire (FIQ) score.
Results: In the RA, SLE, SSc and BD patients, FMS was found in 14%, 18%, 6.67% and 3.33% respectively compared to 2.1%, 3%, 3.3% and 0% in their corresponding controls. In RA patients, DAS28 was significantly higher in those with FMS (5.5±0.9) compared to those without (4.3±1.3) (p=0.009); significantly correlated with both Widespread Pain Index (WPI) (p=0.011) and Symptom Severity (SS) scale (p=0.012) and the QoL scale in those with FMS was significantly worse (62.3±7.9) compared to those without (71.7±14.4) (p=0.023). In SLE patients, The WPI and SS both significantly correlated with the presence of thrombosis (r=0.28, p=0.049 and r=0.43, p=0.002 respectively). The SS scale tended to correlate with the SLEDAI (r=0.28, p=0.05). In BD patients, BDCAF and WPI significantly correlated (p=0.03). On comparing the WPI among the rheumatic diseases patients, the mean was significantly higher in the SLE patients (2.3±3.2) compared to that in the RA (1.96±2.6), SSc (1.9±2.2) and BD (0.7±1.1) patients (p=0.047).
Conclusions: Fibromyalgia syndrome is more frequent in rheumatic diseases. The significance of this study is boosted by the fact that it was among the first to investigate the prevalence of FMS in patients with SSc. Also, adds to the limited insights on the relation of FMS to BD. It is novel to present the relative prevalence of FMS in different Egyptian rheumatic diseases patients and to throw light on the association with disease activity in RA and BD as well as thrombosis in SLE. The impact of FMS on the QoL in RA patients requires special attention.

SAT0716 A FIRST TIME HOSPITAL ADMISSION FOR COMORBID CONDITIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IS MORE FREQUENTLY DUE TO CARDIOVASCULAR AND RENAL COMPLICATIONS THAN IN CONTROLS AND SUBSEQUENTLY INCREASES THE RISK FOR DEATH

W.D. Raymond[1], D. Preen[2], C. Inderjeeth[1,3], H. Keen[4,5], J. Nossent[1,6]. *[1]School of Medicine & Pharmacology; [2]School of Population Health, University of Western Australia; [3]Rehabilitation and Aged Care, Sir Charles Gairdner Hospital; [4]Rheumatology, Fiona Stanley Hospital; [5]School of Medicine, Murdoch University; [6]Rheumatology, Sir Charles Gairdner Hospital, Perth, Australia*

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that runs an unpredictable disease course.
Objectives: We aimed to understand the characteristics and outcomes of incident hospitalisation for conditions other than the underlying disease in SLE patients.
Methods: Using whole-population data linkage of hospital admissions and death records in Western Australia (WA) WA between 1980 and 2015, we performed a retrospective analysis for patients where SLE (ICD-9-CM 695.4, 710.0 and ICD-10-AM L93.0 & M32) was a *co-existing* discharge diagnosis. All SLE patients were age- and gender-matched with hospital controls free of rheumatic disease. We investigated the rate and characteristics of the index hospitalisation for comorbidity and the risk of subsequent death by Kaplan-Meier survival and Cox regression.

Table 1: Patient Characteristics (at index hospitalisation) and study outcomes.

	Lupus was secondary to the Admitting Diagnosis	Matched Controls	χ2 or t-test
	MoCT or n(%)	MoCT or n(%)	(p-value)
Age	54.31 ± 18.76	54.32 ± 22.13	0.120
Female	1911 (82.3%)	1755 (82.8%)	0.210
Indigenous Status	82 (3.5%)	26 (1.2%)	<0.001
Length of Stay (days)	5 (IQR 2, 11)	2 (IQR 1, 5)	<0.001
Privately Insured	438 (35.4%)	469 (48.8%)	<0.001
Diagnosed with an Ischaemic Heart Disorder	184 (7.9%)	73 (3.4%)	<0.001
Diagnosed with a Cerebral Ischaemic Disorder	33 (1.4%)	18 (0.8%)	0.074
Diagnosed with a Hypertension Disorder	348 (15.0%)	136 (6.4%)	<0.001
Diagnosed with an Atherosclerotic Disorder	158 (6.8%)	19 (0.9%)	<0.001
Diagnosed with a Kidney Disorder	295 (12.7%)	39 (1.8%)	<0.001
Diagnosed with a Thrombotic Disorder	54 (2.3%)	4 (0.2%)	<0.001
Patient died during the hospital admission	87 (3.7%)	40 (1.9%)	<0.001

MoCT: Measure of Central Tendency, i.e. mean ± standard deviation or median (interquartile range).

Results: Hospitalisation rates for comorbidity were 13.9/million/year in SLE patients. SLE patients were similar to controls for age and gender, but more likely to be Indigenous, have renal failure, cardiovascular and thrombotic conditions (Table 1). Independent predictors of mortality risk following hospitalisation for a comorbid condition included: SLE diagnosis (OR 1.6, CI: 1.3–1.9, $p<0.001$) (Fig. 1), cerebrovascular events (OR 2.0, CI: 1.2–3.7, $p<0.001$), renal disease (OR 1.75, CI: 1.4–2.3 $p<0.001$), thrombotic events (OR 1.8 CI: 1.1–2.8, $p=0.001$) and reliance on Medicare (OR 1.5, CI: 1.3–1.8, $p<0.001$) (Table 2).

Conclusions: SLE patients were more frequently hospitalised than controls for cardiovascular or renal conditions and this increased their mortality risk. These results strengthen the need for close monitoring and interventions to prevent such comorbidity in all SLE patients.

AB0001 FIRST DESCRIPTION AND FUNCTIONAL PROTEOMIC ANALYSIS OF A PROTECTIVE FOR RHEUMATOID ARTHRITIS GENE POLYMORPHISM

A. Sarantopoulos[1], I. Theodorou[2], A. Notopoulos[3], I. Koulas[1], P. Boura[1].
[1]Clinical Immunology Unit, 2nd Dpt of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Laboratoire d' Histocompatibilite et Immunogenetique, Departement d' Immunologie., Groupe Hospitalier Pitie Salpetriere Charles Foix, Paris, France; [3]Department of Nuclear Medicine, Hippokration General Hospital, Thessaloniki, Greece

Background: Rheumatoid Arthritis (RA) is the most common systemic autoimmune disease, with a respective expanded genetic research[1]. Immunogenetic studies have documented the positive correlation of various gene loci with incidence and/or disease profile. However, the description of gene loci negatively related to the incidence of RA is rarely documented. Apart from an early study involving HLA class II, there has been no reference to any genetic locus associated with a protective role against RA incidence.
Objectives: To identify the sequence of the functional areas of the TRAF1 (TNF receptor associated factor 1 - a protein involved in the intracellular signaling pathway of TNF) gene.
Methods: 172 patients and 95 controls were genetically assessed for the sequence of the seven exons of the gene TRAF1.
Results: On the position 9:120905076 of exon 7, the registered polymorphism G/A (rs143265058) was described in the controls group. The same polymorphism was not confirmed in any of the patients. Further functional proteomic study of the polymorphism with computing programs (software), revealed that the presence of this polymorphism leads to a differentiation of the quaternary structure of TRAF1 protein, possibly affecting the cohesion of intracellular TNF signaling pathway[2].
Conclusions: The present reference is one of the extremely rare genetic studies describing a protective gene locus against rheumatoid arthritis, and a pioneer of its kind in the use of Applied Informatics in the depiction of the quaternary structure of the encoded protein. At the same time, it is one of the few immunogenetic studies describing the functional proteomics of the encoded protein, plotting on a molecular level specific interaction modifications affecting the intracellular signaling pathway of TNF.

AB0002 GENETIC STUDY OF THREE-PRIME REPAIR EXONUCLEASE (TREX1) IN THE SUSCEPTIBILITY TO SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AMONG EGYPTIAN PATIENTS

D. El Dessouki[1], M.S. Abdel-Hamid[2], L. Effat[6], M. Niazy[3], N. Kholoussi[4], G. Abdel Moneim[3], G.M. Abdel-Salam[5]. *[1]Rheumatology; [2]Medical Molecular Genetics, National Research Centre; [3]Rheumatology, Faculty of Medicinie, Cairo University; [4]Immunogenetics; [5]Clinial Genetics, National Research Centre, Cairo, Egypt; [6]Affiliation not provided*

Background: Interferon-alpha (IFNα) pathway has a crucial role in the pathogenesis of SLE. Many genes have been encoding with this pathway and their impaired expression have been reported in patients with SLE. *TREX1* is a DNA exonuclease involved in the metabolism and clearance of single stranded DNA from apoptotic cells, which is impaired in SLE[1]. *TREX1* mutations have been reported in SLE[2].
Objectives: Our study was aiming to assess the role of *TREX1* in the genetic susceptibility to systemic lupus erythematosus (SLE) among Egyptian patients.
Methods: Fifty SLE Egyptian patients and 50 age & sex matched healthy controls were included in this study. Based on the clinical history and immunological investigations, the 50 SLE patients were divided into two groups according to the presence of positive family history of autoimmune disease: Group I: 28 patients with positive family history & Group II: 22 patients with no family history. Further, the single exon of *TREX1* and its flanking sequences were amplified by PCR and sequenced in both directions.
Results: Our work showed a recurrent *TREX1* polymorphism rs11797 (c.531C>T) among Egyptian patients (56%) in comparison to control group (36%) (p value of 0.070) especially in cases with NPSLE, seizures and chilblains; with minor allele frequency of 0.28 in cases and 0.18 in controls (p value=0.342). *TREX1* polymorphism was present in 57.1% patients (16/28) of SLE patients in group I versus 54.5% patients (12/22) of SLE cases in, group II. The polymorphism was positively associated with neuropsychiatric manifestations (OR=7.000, 95% CI=0.791–61.975) and chilblains (OR=10.532, 95% CI=0.550–201.679). Furthermore, there was a statistically significant difference in cases with oral ulcers (p value=0.004), photosensitivity (p value=0.047) and seizures (p value=0.029).
Conclusions: We confirm that rs11797 (c.531C>T) could be associated with the susceptibility to neurological manifestations among the studied SLE patients.

Background: Systemic sclerosis (SSc) is a fibrotic immune-mediated disease of unknown etiology. Among its clinical manifestations, pulmonary involvement is the leading cause of mortality in SSc patients. However, the genetic factors involved in lung complication are not well-defined.
Objectives: We aimed to revisit the association of the MIF gene, which encodes a cytokine implicated in idiopathic pulmonary hypertension among other diseases, with the susceptibility and clinical expression of SSc, besides testing the association of this polymorphism with SScrelated pulmonary involvement.
Methods: A total of 4,393SSc patients and 16,591 unaffected controls from six cohorts of European origin were genotyped for the MIF promoter variant rs755622. An inverse variance method was used to meta-analyze the data.
Results: A statistically significant increase of the MIF rs755622*C allele frequency compared to controls was observed in the subgroups of patients with diffuse cutaneous SSc (dcSSc) and with pulmonary arterial hypertension (PAH) indepen-

dently (dcSSc: P=3.20E-2, OR=1.13; PAH: P=2.19E-02, OR=1.32). However, our data revealed a stronger effect size with the subset of SSc patients showing both clinical manifestations (dcSSc with PAH: P=6.91E-3, OR=2.05).
Conclusions: We revisited the association of the MIF rs755622*C allele with SSc and described a phenotype-specific association of this variant with the susceptibility to develop PAH in dSSc patients.

AB0004 PSORIATIC ARTHRITIS. GENES INVOLVED IN THE MESTIZO POPULATION

L.A. Gutierrez-Gonzalez[1], F. Herrera[2], M.T. Fernandez Mestre[2] on behalf of GRUVES (Grupo Venezolano para el Estudio de las Espondiloartritis). *[1]Centro Nacional de Enfermedades Reumaticas (Cner); [2]Laboratorio de Fisiopatología, Instituto Venezolano de Investigaciones Científicas (IVIC), Caracas, Venezuela, Bolivarian Republic Of*

Background: Psoriatic Arthritis (PsA) is not a regular systemic autoimmune disease, many expert define it with autoinflammatory disease, resulting in chronic inflammation of the synovium and consequent cartilage and bone erosion in approximately 10% of patients with skin psoriasis. It is important to identify novel genomic biomarkers associated with disease susceptibility but also able to detect early those patients with negative prognostic factors who may benefit from a more aggressive therapeutic approach. The over-expression of tumor necrosis factor (TNF)-a is a central element in the pathogenesis of psoriasis and psoriatic arthritis (2). The levels of TNF-alpha are under genetic control. An "A" at position *-308* in the *TNFA* promoter has been shown to be associated with increased level of TNF-alpha expression and "A" at position *-238* with a diminished level of TNF-α expression (3,4). Many authors consider that it is a disease only of Europeans descendants or Caucasians, however never be studied in mestizo population
Objectives: We investigate the potential association between the *TNFA*-238 G/A, *TNFA*-308 G/A, *IL10 -1082 G/A,-819C/T, -592C/A* polymorphisms and the Psoriatic Arthritis susceptibility.
Methods: The study included 52 PsA patients diagnosed by CASPAR criteria and 52 controls. The polymorphism of TNFA-308 G/A (rs1800629), TNFA-238 G/A (rs361525), IL10 -1082 G/A (rs1800896), -819C/T (rs1800871) and -592C/A (rs1800872) were genotyped by single specific primers -polymerase chain reaction (SSP-PCR). All subjects were from an unrelated Venezuelan-Mestizo population with a history of ancestors, at least back to the third generation
Results: When comparing allele and genotype frequencies between the groups studied, no significant differences were observed for the TNFA-308 G/A (rs1800629) and IL10 -1082 G/A (rs1800896), -819C/T (rs1800871) and -592C/A (rs1800872). However, our results showed a significant decrease in the frequency of the TNF-*238A* allele among PsA patients compared to healthy individuals (3.8% vs. 10.57%, respectively, OR: 0.31, 95% CI: 0.92 -1.05, p: 0.02), suggesting that *TNFA-238A* allele may have a protective effect (Table 1).

Table 1. Genotypic and allelic frequencies of the 308 G / AG (rs1800629) and -238 G / A (rs36152! variants of the TNFA gene in patients with psoriatic arthritis and healthy controls

TNFA-308 G/A (rs1800629)	PsA n=73	Controls n= 52	OR (IC95%)	*P*
Genotype				
GG	80,7%	84,6% (44)	0,76(0,27-2,12)	0,302
GA	19,3%	15,4% (8)	1,30(0,47-3,63)	0.302
AA	0%	0 % (0)		
Allele				
G	92,3%	90,4% (94)	1,27(0,48-3,37)	0,311
A	7,3 %	9,6% (10)	0,78(0,29-2,07)	0,311
TNFA-238 G/A (rs361525)	PsA n=73	Controls n= 52	OR (IC95%)	*P*
Genotype				
GG	92,3%	78,8% (41)	3,22(0,95-10,8)	*0,025
GA	7,7 %	21,2% (11)	0,31(0,09-1,05)	*0,025
AA	0	0		
Allele				
G	96,2%	89,4%(93)	2,95(0,91-9,61)	*0,0306
A	3,8%	10,6 %(11)	0,39(0,10-1,09)	*0,0306

NOTE: The values shown in parentheses represent the number of individuals carrying the genotype for the polymorphic site studied. The frequency is expressed as a percentage (p> 0.05: not significant, p <0.05: significant) psoriatic arthritis and healthy controls

Conclusions: This is the first genetic study carried out in Venezuelan mestizo patients with Psoriatic Arthritis to establish associations between genetic markers such as the polymorphisms of the promoter region of the TNFA and IL10 genes and the disease. In conclusion the *TNFA*-238 G/A polymorphism might play an important role in the development of Psoriatic Arthritis in Venezuelan mestizos and this association could not only clarify the different factors involved in a multifactorial disease, such as Psoriatic Arthritis, but also establish the relationship of these molecular markers with some clinical manifestations of the disease, which would allow in the future to determine the suitability or not to use some types of treatments, such as the use of anti-TNF therapy, for example.

AB0005 CYTOKINE MRNA GENE EXPRESSION ASSOCIATED WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L. Miteva[1], M. Ivanova Goycheva[2], I. Manolova[1], G. Vasilev[2], R. Stoilov[2], S. Stanilova[1]. *[1]Department of Molecular Biology, Immunology and Medical Genetics, Medical Faculty, Trakia University, Stara Zagora; [2]Clinic of Rheumatology, University Hospital "St. Iv. Rilski", Medical Faculty, Medical University, Sofia, Bulgaria*

Background: Systemic lupus erythematosus (SLE) is a complex polygenic autoimmune disease, characterized by autoantibody production, inflammatory manifestation and imbalanced cytokine production. In accordance with the pivotal role of Th17 cell in autoimmunity and the altered Th17/Tregs balance in response to changes in the cytokine milieu we analyzed mRNA expression of several cytokines in peripheral blood of SLE patients. Quantification of mRNA expression in peripheral blood could be useful to assess the disease activity of SLE patients.
Objectives: The aim of the present study was to investigate the gene expressions at mRNA level of proinflammatory (TNFA, IL18, IL12B); Th17-related (IL23A); immunosuppressive (TGFB1 and IL10) cytokines and Treg-specific transcription factor Foxp3 in peripheral blood of women with SLE.
Methods: Total RNA from peripheral blood was isolated from 28 female patients with SLE and 17 healthy women. Quantitative real-time polymerase chain reaction was performed for 7 genes of interests, using the TaqMan detection system. Relative quantitative evaluation of mRNAs was performed by the comparative ΔΔCt method and results are presented as n-fold mean difference (RQ-relative quantity) of target genes relative to calibrator (healthy controls) after normalization to the reference gene-GAPDH. Disease activity in SLE was determined by SLEDAI and divided into three categories: mild (0–5), moderate (6–10) and high (>10).
Results: The results reveal considerable overexpression of IL23A in SLE patients compared to healthy controls (RQ=5.347; $p<0.001$). According to the level of disease activity we found the highest elevation of IL23A in patients with SLEDAI>10 (RQ=8.54; $p<0.001$) compared to the controls. In inactive to mild (SLEDAI 0–5) and moderate SLE (SLEDAI 6–10), IL23A was also upregulated in approximately equal rate (RQ=4.976; $p<0.001$ and RQ=4.64; $p<0.001$). In addition, immunosuppressive cytokines IL10 and TGFB1 mRNA were elevated significantly in SLE patients than in controls (RQ=1.79; p=0.0077 and RQ=1.78; p=0.02, respectively). We also found that the expression of proinflammatory TNFA and IL12B were significantly downregulated approximately 2-fold. The mRNA level of Foxp3 was downregulated only for patients with SLEDAI>10. A significant good correlation between IL18 and the SLEDAI score was found (r=0.5548; p=0.002). Higher IL18 expression was observed among patients with worsened SLE compared to those with mild (RQ=1.656; p=0.008) and moderate (RQ=1.474; p=0.034) disease activity. We further demonstrated positively correlation between the expression levels of IL23A and TGFB1 (r=0.7276; $p<0.001$) among SLE patients.
Conclusions: These results suggest that upregulation of IL23 and TGFB1 in addition to downregulated Foxp3 expression may contribute to skewing towards Th17 profile in SLE pathogenesis and this was the most markedly manifested at the highest level of disease activity. Our results support indirectly the idea for restoring Th17/Treg balance as a therapeutic target in SLE.

AB0006 MICRORNA-499 IN BEHCET DISEASE AND POSSIBLE ASSOCIATION WITH DISEASE ACTIVITY

M. Eissa[1], M. Al Kaffas[2], S. Abdel Wahab[2], L. Rashed[2]. *[1]Department of rheumatology and rehabilitation; [2]Medical Biochemistry, Cairo University, Cairo, Egypt*

Background: Behçet Disease (BD) is a relapsing inflammatory autoimmune disease. Although the etiology of BD is not yet known, genetic predisposition and immune dysregulation are thought to be critical factors in the pathogenesis of the disease. MicroRNAs (miRNAs) are small RNA fragments that can regulate the gene expression. miRNAs play a critical role in the pathogenesis of autoimmune or auto inflammatory diseases. Sinngle nucleotide polymorphisms (SNPs) may change the property of miRNAs through altering miRNA expression and/or maturation.
Objectives: The aim of this work was to detect miRNA-499 (rs3746444) genotyping and relative expression in BD patients in order to find out the possible association between them and disease activity and severity.
Methods: Relative expression of miRNA-499 was measured by Real-Time PCR and miRNA-499 gene (rs 3746444) genotyping was performed by TaqMan SNP

Genotyping Assay in blood samples obtained from 47 patients BD diagnosed according to 1990 international criteria for behcet disease and 50 matched healthy controls. Disease activity was done using BD current activity form (BDCAF).
Results: Study of miRNA-499 polymorphism, showed that the genotype frequencies of TT, CT, and CC were 21.3%, 63.8%, and 14.9% in BD patients and 18.0%, 52.0%, and 30.0% in the control group respectively. A significant increase in the relative expression of miRNA-499 was found in BD patients compared to control ($P<0.05$). There was no significant relation between relative expression of miRNA-499 and activity of BD patients assessed by BDCAF ($P>0.05$). In addition there was association between genotypes of miRNA-499 and posterior uveitis ($P<0.05$). There was association of the relative expression of miRNA-499 with miRNA-499 (rs3746444) polymorphism and vascular manifestations ($P<0.05$).
Conclusions: Genotyping of miRNA-499 showed higher percentage of TT genotype in BD patients than control and also miRNA relative expession, they may be implicated in pathogenesis of the disease. Genotype TT for miRNA-499 is associated with posterior uveitis. miRNA relative expression is associated with vascular manifestations and aneurysm.

Background: Despite its high prevalence and mortality, little is known about the pathogenesis of RA–associated interstitial lung disease (RA-ILD). Given that familial pulmonary fibrosis (FPF) and RA–ILD frequently share the usual interstitial pneumonia pattern and common environmental risk factors, we hypothesized that the two diseases may share additional risk factors including FPF-linked genes.
Objectives: Our aim was to identify coding mutations of FPF-risk genes associated with RA-ILD.
Methods: We used whole-exome sequencing (WES) followed by restricted analysis of a discrete number of FPF-linked genes and performed a Burden test to assess the excess number of mutations in RA–ILD patients compared to controls.
Results: Among the 101 RA–ILD patients included, 12 (11.9%) had 13 WES-identified heterozygous mutations in the *TERT*, *RTEL1*, *PARN* or *SFTPC* coding regions. The burden test, based on 81 RA–ILD patients and 1010 controls of European ancestry, revealed an excess of *TERT*, *RTEL1*, *PARN* or *SFTPC* mutations for RA–ILD patients ($p=9.45'10^{-4}$, odds ratio [OR] 3.17 95% CI 1.53–6.12). Telomeres were shorter for RA-ILD patients with a *TERT*, *RTEL1* or *PARN* mutation than controls ($p=2.87x10^{-2}$).
Conclusions: Our results support the contribution of FPF-linked genes to RA–ILD susceptibility.

AB0008 THE ASSOCIATION OF THE PTPN22 RS2476601 GENE POLYMORPHISM WITH JUVENILE IDIOPATHIC ARTHRITIS IN CHILDREN FROM RUSSIA

L.S. Nazarova[1], K.V. Danilko[1], V.A. Malievsky[1], T.V. Viktorova[1,2]. *[1]Bashkir State Medical University; [2]Institute of Biochemistry and Genetics, Ufa, Russian Federation*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children. The exact cause of the disease is still unknown, but seems to be related to both genetic and environmental factors [1]. The protein tyrosine phosphatase non-receptor type 22 (*PTPN22*) gene single-nucleotide polymorphism (SNP) rs2476601 was shown to be associated with JIA in different populations, but according to resent reports this association is restricted only to females [2,3].
Objectives: The aim of the study was to determine whether the *PTPN22* rs2476601 SNP is associated with the development of JIA and its subtypes in children from Russia.
Methods: The study included 330 patients with JIA and 346 healthy controls from Russia. Genotyping was performed using real-time PCR method and statistical analysis - using two-tailed Fisher's exact test (p), odds ratio (OR), 95% confidence interval (95% CI).
Results: The frequencies of the genotype AG and the allele A were significantly higher and the frequencies of the genotype GG and the allele G were significantly lower in patients with JIA than in controls (p=0.016, OR=1.65, 95% CI 1.10–2.48; p=0.028, OR=1.48, 95% CI 1.05–2.08; p=0.016, OR=0.62, 95% CI 0.43–0.91; p=0.028, OR=0.68, 95% CI 0.48–0.95, correspondingly). The same analysis was then performed separately for patients with two the most frequent ILAR subtypes: persistent oligoarthritis (n=106) and RF-negative polyarthritis (n=85). Significant associations similar to those in the whole JIA group were found only for persistent oligoarthritis (p=0.018 for the genotype AG; p=0.037 for the allele A; p=0.022 for the genotype GG; p=0.037 for the allele G). No significant differences were found for patients with RF-negative polyarthritis ($p>0.6$). Sex-stratified analysis showed that for the whole JIA group and for persistent oligoarthritis the association with the *PTPN22* rs2476601 SNP is restricted only for girls (for girls with the genotype AG: p=0.024 and p=0.0098; with the allele A: p=0.016 and p=0.0061; with the genotype GG: p=0.015 and p=0.0047; with the allele G: p=0.016 and p=0.0061, correspondingly; for boys: $p>0.2$ for all comparisons).
Conclusions: In this study we revealed the association of the *PTPN22* rs2476601 SNP with the development of JIA and its persistent oligoarticular subtype in girls from Russia.

AB0009 GENOMIC SIGNATURES MAY BE ASSOCIATED WITH VASCULAR PATHOLOGY ASSOCIATED WITH RHEUMATOID ARTHRITIS

S. Poliska[1], E. Végh[2], A. Váncsa[2], S. Szamosi[2], M. Csumita[2], G. Zahuczky[3], G. Szücs[2], S. Szántó[2], L. Nagy[1], Z. Szekanecz[2]. *[1]Clinical Genomics Centre; [2]Department of Rheumatology, University of Debrecen, Faculty of Medicine; [3]UD-Genomed Ltd, Debrecen, Hungary*

Background: Accelerated atherosclerosis and cardiovascular (CV) disease have been associated with rheumatoid arthritis (RA). Many genes have been implicated in atherosclerosis, RA or both. However, most of these studies described SNPs in *CD40, SMAD3, HLADR, CTLA4* and other alleles. Very few studies on genetic signatures have been performed that would link RA and CV pathology. We have previously associated some genomic profiles with pathological carotid atherosclerosis (ccIMT), arterial stiffness (PWV) and brachial artery flow-mediated vasodilation (FMD). In other studies we have also found 165 genes that separated anti-TNF responder patients from non-responders.
Objectives: Here we looked for associations between clinical and "vascular" response to biologics and vascular pathology in RA patients.
Methods: In this study, 19 RA patients were treated with either etanercept (ETN) or certolizumab pegol (CZP) for one year. We separated responders (R) and non-responders (NR) according to EULAR response criteria. Microarray gene expression study was performed (Affymetrix) followed by analysis using the GeneSpring software, hierarchy clustering and principal component analysis (PCA). "Vascular response" (VR) to biologics was defined as an at least 20% improvement in FMD, ccIMT or PWV. Good Vascular Response (GVR) was defined as an at least 20% improvement in two or three of these variables.
Results: Among the 19 patients, 13 were R and 6 were NR. With respect to VR, FMD, ccIMT and PWV responded to anti-TNF treatment in 10, 9 and 8 patients, respectively. GVR was observed in 8 patients and 5 patients had VR in all 3 parameters. When comparing clinical response and VR, 7 out of 8 patients showing GVR also had good clinical response to biologics. Up-regulation of 99 and down-regulation of 67 genes separated clinical R and NR patients. Significant correlation was found between ccIMT improvement upon biological therapy and clinical response (R=0.418, p=0.04).
Conclusions: Genomic signature analysis may be able to separate clinical responders and non-responders to biologics, as well as patients that show or do not show imporvement of vascular pathology.

Adaptive immunity (T cells and B cells) in rheumatic diseases

AB0010 LILRB3 EXPRESSION ON T CELLS CORRELATES WITH DISEASE ACTIVITY IN RA

A. Holz, T. Witte, R.E. Schmidt. *Department of Clinical Immunology and Rheumatology, Hannover Medical School, Hannover, Germany*

Background: Leukocyte immunoglobulin-like receptors (LILR) participate in the generation of immunological tolerance (1,2). LILRB3 can be expressed on T cells and is an inhibiting receptor (3).
Objectives: We wanted to study LILR expression on T cells in RA compared to SLE and controls.
Methods: Heparinised human blood from blood donors was obtained from the Institute of Transfusion Medicine, Medical School Hannover (Germany). Blood samples from RA (DAS28 <3.2 n=11; DAS28>3.2 n=8) and SLE patients (n=9) were obtained from Outpatients' Clinic of the Department of Rheumatology and Immunology after informed consent. PBMCs were stained with LILRA2 (Biolegend, APC), LILRB3 (Biolegend, PE), CD3 (Biolegend, APC-Cy 7), CD4 (BD, PerCP-Cy5.5), CD8 (Biolegend, V500), CD25 (Biolegend, PE/Cy5), CD28 (Biolegend, Pacific Blue). Results were compared to isotype controls.
Statistical analyses and figures were made with GraphPad Prism, ANOVA and the Mann-Whitney Test.
Results: The percentage of both CD4+ and CD8+ T cells expressing LILRB3 was significantly higher in both inactive as well as active RA compared to controls or SLE (See Fig. 1) (p=0.0397 ANOVA: RA all vs. SLE vs. controls). Within the group of RA patients, the percentage of LILRB3 expressing T cells was highest in active compared to inactive (DAS28<3.2) RA (p=0.0287). LILRA2 was not expressed on T cells.

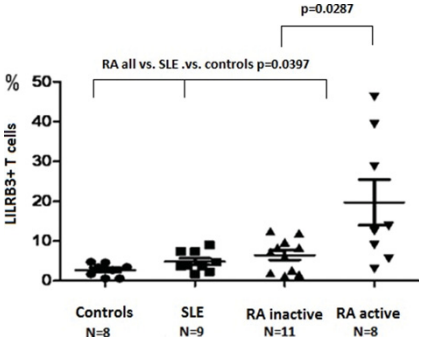

Figure 1

Conclusions: Expression of LILRB3 correlates with disease activity of RA and is decreased after successful treatment with DMARDS or biologicals. Since LILRB3 is an inhibiting receptor the increased expression in active RA may be a counterregulation to reduce disease activity.

AB0011 KLRG1 AS A MARKER OF CD28 NEGATIVITY IN RHEUMATOID ARTHRITIS, COMPARISON WITH CD57 AND CD45RA

C. Rawlings, E. Choy, R. Davies, G. Jones, A. Williams. *Cardiff University, Cardiff, United Kingdom*

Background: Our research has shown that patients with RA have higher proportions of peripheral blood CD3+CD8+CD28- Treg cells compared to healthy individuals. CD3+CD8+CD28- Treg cells in patients with RA have lost their ability to suppress lymphocyte proliferation[1]. Thus CD28 negativity may mark senescent T cells. CD57[2] CD45RA[3,4] and killer-cell lectin like receptor G1 (KLRG1)[5] cell surface molecules have been associated with CD8+ T cell activation and senescence. Defining the phenotypic signature of CD8+CD28- Treg cells will help establish their significance in the immunoregulation of RA.
Objectives: To use immunofluorescence and flow cytometry to define the phenotype of CD3+CD8+CD28+/- cells in relation to early RA progression.
Methods: The effector characteristics of peripheral blood CD8 T cells were evaluated by flow cytometry. RA patients with established (n=21) and early disease (n=20) were recruited, and compared to twenty four healthy controls. The mean age of the subjects was 59 (SD=12.5), 25/38 (66%) were female, 27/38 (71%) were anti-CCP positive and 25/38 (66%) rheumatoid factor positive. The mean age for the controls was 43 (SD=11.6), 14/20 (70%) were female.
Results: Confirming our previous work, a significantly higher proportion of CD3+CD8+CD28- cells was observed in RA patients compared to healthy individuals (P=0.03) (Figure 1).
Flow cytometric evaluation of peripheral blood demonstrated a significantly higher expression of CD57, CD45Ra and KLRG1 in CD28- compared to CD28+ T cells.

Table 1. CD57, CD45Ra, KLRG1 and CD28 on CD3+CD8+ T cells

	CD28–	CD28+	P value
CD57+	40	9	<0.0001
CD45Ra+	38	23	0.0026
KLRG1+	36	20	0.0012

A further evaluation of these markers revealed that 69% of the CD8+CD28- cell pool was KLRG1+, in comparison to 66% being CD57+ and 55% KLRG1+CD57+ double positive. This suggests that KLRG1 is a robust and clinically relevant marker of CD28- T cells in RA. Our current research is investigating the significance of KLRG1 and CD8+CD28- cells as prognostic markers in RA.

CD3+CD8+CD28- cells in Controls (n=24) v.s RA patients (n=41) with median.

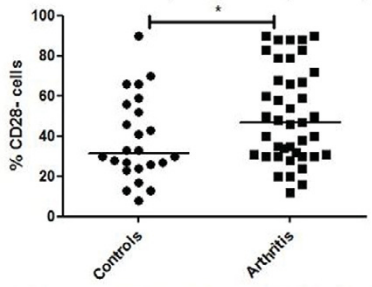

Figure 1: Graph showing the percentage of CD3+CD8+CD28- in RA patients and healthy controls.

Conclusions: CD3+CD8+CD28- cells are enriched in the peripheral blood of RA patients. KLRG1 expression is increased in line with CD57 and CD45Ra in CD8+CD28- cells, and will be used to evaluate the functional significance of these cells in relation to their activation status and potential senescence in the immunoregulation of RA pathogenesis.

Background: Rheumatoid arthritis (RA) consists of two syndromes, one autoantibody-positive and one autoantibody-negative. This multi-cohort study

assessed the age of onset in relation to the presence of autoantibodies. The association with characteristics of the anti-citrullinated protein antibodies (ACPA)-response was also explored.
Objectives: 1) determine the association between age of RA-onset and the presence of ACPA, rheumatoid factor (RF) and anti-carbamylated protein (anti-CarP) antibodies, 2) study if age of onset was associated with characteristics of the ACPA-response, 3) substantiate previously reported associations between age of onset and clinical characteristics.
Methods: 3,321 1987-positive RA-patients included in the Leiden-EAC, BARFOT, ESPOIR, Umeå and Lund cohorts were studied at presentation on age of onset and the presence of ACPA, RF and anti-CarP antibodies. Logistic regression analyses were performed; effect sizes were summarized in inverse-weighted meta-analyses. Within ACPA-positive RA, ACPA-level was studied in all cohorts; ACPA-isotypes, ACPA-fine-specificity and ACPA-avidity index and clinical characteristics were studied in the Leiden-EAC.
Results: From the age of fifty onwards, the proportion of ACPA-negative RA-patients increased in Dutch, Swedish and French cohorts. Similar observations were done for RF and anti-CarP. The composition of the ACPA-response did not change with increasing age of onset with respect to titer, isotype distribution, fine specificity and avidity index. With increasing age of onset RA-patients smoked less often, had higher acute phase reactants and more often a sub(acute) symptom onset.
Conclusions: Data of five cohorts revealed that with higher age of onset ACPA-negative RA is more frequent than ACPA-positive RA, while characteristics of ACPA-positive RA as judged by the composition of the ACPA-response appeared not age-dependent. Although more biologic studies are needed to characterize the pathogenesis of ACPA-negative polyarthritis at older age, the present data can promote personalized treatment decisions in ACPA-negative patients in daily practice.

AB0013 IS THERE IMMUNE DISREGULATION IN NON-SJÖGREN SICCA SYNDROME? A STUDY OF BLOOD LYMPHOCYTE SUBPOPULATIONS

F. Barcelos[1,2,3], C. Martins[3], G. Nunes[3], T. Lopes[3], J. Vaz Patto[1], J. Amaral[4], J.C. Branco[3], L.M. Borrego[3]. *[1]Instituto Português Reumatologia; [2]Hospital CUF Descobertas; [3]Nova Medical School; [4]Faculdade Med Dentária, UL, Lisboa, Portugal*

Background: A large number of patients with sicca syndrome not fulfilling Sjögren's syndrome (SS) classification criteria, present manifestations of autoimmunity, like arthritis, Raynaud's, rash or hematologic disturbances, and have anti-nuclear antibodies, lacking however more specific antibodies. The designation Undifferentiated Connective Tissue Disease was coined to refer to those patients, and some will eventually progress to a definite disease, of which SS would be a likely candidate. Immune cell disturbances could be progression markerr, since diseases like pSS have distinct lymphocyte profiles.
Objectives: We aim to study the circulating lymphocyte subsets in non-Sjögren sicca patients (n-SS), and compare them with pSS and healthy controls.
Methods: We included 65 n-SS patients, 53 pSS patients (2002 AECG criteria) and 22 healthy controls. Lymphocyte subsets were characterized by flow cytometry, including follicular and regulatory T cells and naïve, mature, memory, plasmablasts and regulatory B cells. Statistical analysis was performed with GraphPad, and significance was considered for $p<0.05$
Results: Comparing to controls, n-SS patients had lower counts of T cells (p=0.016), with lower CD4 (p=0.0028), however that difference was not as pronounced as between SS and controls. n-SS patients had higher percentages of CD4 (p=0.0005) and lower CD8 percentages (p=0.0009) than pSS. Additionally, there was a decrease in absolute counts of Tregs (p=0.0028) in n-SS patients compared to controls, which was less pronounced than the comparison between SS and controls (p=0.0008). Th17 cells were decreased in SS compared to controls (p=0.0005), but not in-SS patients. Compared with controls, both n-SS and SS patients presented decreased absolute count (p=0.0001 and p<0,0001, respectively) of $CXCR5^+$ Tfh cells, with no differences between n-SS and SS patients. However, higher levels of $IL21^+CD4$ T cells and Tfh1 cells were found comparing SS patients with both controls (p=0,0209 and p=0,0092 respectively) and n-SS patients (p=0,0051 and 0,0028 respectively).
Absolute counts of memory, unswitched and switched memory cells in n-SS patients present intermediate levels between controls with significantly higher levels, and SS patients with significantly lower levels. Accordingly, using the Bm1–5 classification, we have found decreased Bm1 (p=0.004), eBm5 (Abs, p=0.0273) and Bm5 cells (Abs, p=0.0444) in n-SS patients compared to controls. Though not significant, there was an increase in eBm5 (Abs, p=0.063) and Bm5 cells (Abs, p=0.05) in n-SS compared to SS patients. Again, $CD24^+CD27^+$ Bregs were also decreased in n-SS patients compared to controls (p=0.036), but increased in n-SS compared to SS patients (p=0,0007).
Conclusions: Our data showed that n-SS patients present immune disregulation, represented by alterations in the B cell compartment but also in Tfh subset, known to modulate the humoral immune response. Although less pronounced, these modifications resemble the ones found in SS patients. Wether n-SS is a stage in the evolution to SS remains to be clarified. The identification of a characteristic disregulation of the immune system in n-SS could be usefull for diagnostic and prognostic purposes.

AB0014 DIFFERENTIAL EFFECTS OF A SINGLE DOSE OF CYCLOPHOSPHAMIDE ON CIRCULATING CELL SUBPOPULATIONS IN PATIENTS WITH VASCULITIDES AND AUTOIMMUNE SYSTEMIC DISEASES

G. Gabcova[1], Z. Mikulkova[1], M. Skacelova[2], A. Petrackova[1], A. Smrzova[2], M. Schubertova[2], F. Mrazek[3], P. Horak[2], E. Kriegova[1]. *[1]Department of Immunology, Faculty of Medicine and Dentistry, Palacky University, Olomouc; [2]Department of Internal Medicine III - Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacky University Olomouc, University Hospital, Olomouc; [3]Department of Immunology, University Hospital Olomouc, Olomouc, Czech Republic*

Background: High-dose cyclophosphamide (CFA) is used for treatment of patients with severe manifestations of systemic autoimmune diseases. The knowledge about the effect of CFA on circulating cell populations in these diseases is still limited.
Objectives: To identify the effect of a single dose of CFA on circulating cell populations in patients with vasculitides and autoimmune systemic diseases.
Methods: We immunophenotyped T lymphocytes (CD3, CD4, CD8, CD25, CD127, HLA-DR), B lymphocytes (CD19, CD20, CD27), NK cells (CD3, CD16, CD56, CD69), neutrophils (CD15, CD11b, CD16, CD54, CD62L, CD64), and monocytes (CD11b, CD14, CD16, CD64, HLA-DR) using 6-color cytometer BD FACSCanto II (Becton Dickinson) in peripheral blood of patients with vasculitides (n=6) and systemic disorders of connective tissue (n=6). From each patient, we obtained paired samples before and one month after a single CFA dose. Statistical tests were performed using GraphPad Prism (GraphPad Software, Inc). *P*-value <0.05 was considered as significant.
Results: Single dose of CFA resulted in increase of percentage of CD8+ T lymphocytes (*P*=0.002), leading to marked decrease of CD4+/CD8+ ratio (*P*=0.009). Except three patients, overall percentage of neutrophils decreased after the treatment (*P*=0.01). Although CFA pulse did not influence the percentage of NK cells, the percentage of NK cells carrying stimulatory receptor CD69 increased after CFA (*P*=0.037). Similarly, CFA enhanced the percentage of co-stimulatory molecule CD27 on B lymphocytes (*P*=0.048). Among subsets of monocytes, CFA treatment increased percentage of CD14-CD16+ monocytes (*P*=0.006) and increased expression (MFI) of Fc fragment CD64 (*P*=0.02). Moreover, increase of HLA-DR was observed on CD14-CD16+ monocytes (*P*=0.037). The investigations whether the changes in immune cell subpopulations in treated patients have prognostic potential are ongoing.
Conclusions: Single dose of CFA resulted in increase of CD8+ T lymphocytes, activation of NK, B lymphocytes and monocytes as well as in some patients decrease in neutrophil counts. Further investigation of selected markers may lead to identification of new prognostic markers and predict the effectiveness of the treatment.

AB0015 CAPTURE OF IGA IMMUNE COMPLEXES AND ENRICHMENT IN IGA IG GENE EXPRESSION BOTH SUGGEST A ROLE FOR FCRL4+ B CELLS IN THE LINK BETWEEN MUCOSAL AND JOINT INFLAMMATION

J. Cameron[1], E. Clay[1], K. Amara[2], N. Sippl[2], A. Filer[1], K. Raza[1], V. Malmström[2], D. Scheel-Toellner[1]. *[1]Rheumatology Research Group, RACE AR UK Centre of Excellence in RA Pathogenesis, Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; [2]Rheumatology Unit, Department of Medicine, Karolinska Universitetssjukhuset, Stockholm, Sweden*

Background: Increasing evidence points to the autoimmune process of rheumatoid arthritis (RA) originating at mucosal surfaces. Previous work from our group described a subset of B cells in the synovium and synovial fluid (SF) of RA patients which can be distinguished by their expression of the Fc-like receptor 4 (FcRL4) and elevated expression of RANKL, indicating a unique pathogenic function[1,2]. B cells expressing FcRL4 were originally described as a distinct memory B cell subset in human tonsils where they accumulate in the epithelium[3]. We have recently shown that they are enriched in cells recognizing citrullinated autoantigens (Amara, K. et al. under revision). Recent *in vitro* work suggested that FcRL4 is a low affinity receptor for aggregated IgA[4].
Objectives: 1) To investigate the interaction of RA synovial fluid FCRL4+ B cells with IgA
2) To examine the distribution of Ig classes by flow cytometry and PCR
Methods: SF mononuclear cells were isolated, labelled for FcRL4, IgA and CD19 and analysed by flow cytometry. In experiments identifying IgA B cell receptors, SF mononuclear cells were briefly incubated in an acidic buffer to remove surface receptor bound antibodies before staining. Heat-aggregated purified human IgA

was added to assess IgA binding to FcRL4+ B cells. Single B cells were sorted from SF of RA patients and their constant region genes probed for identification of their Ig subclass by PCR.

Results: *Ex vivo*, FcRL4$^+$ B cells in SF of RA patients have a higher load of IgA bound to their surface compared to their FcRL4- counterparts. After in vitro removal of surface bound IgA, they can bind heat-aggregated IgA (p=0.0313). We also demonstrate that a significantly higher proportion of FcRL4+ B cells use IgA BCRs (p=0.0061) by flow cytometry and further more by probing constant region genes by PCR an enrichment for Ig genes for coding the IgA1 isotype (p=0.009) was found.

Conclusions: Both their ability to capture IgA immune complexes through binding to FcRL4 and their enrichment in IgA Ig gene expression suggest a potential role for synovial fluid FcRL4$^+$ B cells in the mucosal origin of joint inflammation.

AB0016 B-CELL SUBSETS DIFFERENCES IN INFLAMMATORY RHEUMATIC DISEASES

J.L. Gomes[1,2], D. Ligeiro[3], A. Lima[3], A. Sepriano[2,4], C. Teixeira[3], C. Lopes[1], T. Costa[1], S. Ramiro[4], M. Mateus[1], M. Costa[1], J.C. Branco[1,2], F. Pimentel-Santos[1,2]. *[1]Rheumatology, Hospital Egas Moniz - CHLO; [2]CEDOC, NOVA Medical School-Universidade Nova de Lisboa; [3]Centro de Sangue e Transplantação de Lisboa, IPST-IP, Lisboa, Portugal; [4]Rheumatology, LUMC, Leiden, Netherlands*

Background: Targeting humoral immunity has been proved effective in several inflammatory rheumatic diseases (IRD). Though clinical trials have shown some efficacy of B-cell depletion in ankylosing spondylitis (AS), results are less convincing. Other studies have revealed an association between mutations and expression of immune regulatory genes suggesting B-cell dysfunction in the development and progression of AS. Yet, there is still lack of data describing B-cell subsets in AS, how these compare to other IRD and an evaluation of B cell compartment homeostasis in the pathophysiology of this disease.

Mann-Whitney and the Fisher´s exact test were used for comparison between AS and other groups
* p<0.05; **p<0.02; ***p<0.01; †p<0.0001

Objectives: To assess and compare the immature, naive and antigen differentiated subsets of peripheral B-cell compartment in AS with those in healthy controls (HC) and other IRD

Methods: Patients (pts) with AS, RA and SLE according to respective classification criteria were included in this study. Pts under biologic DMARDS were not included. Sociodemographic and clinical variables were recorded. Blood samples were collected for quantification of inflammatory markers (ESR and CRP), immunoglobulin serum levels and assessment of B-cell immature transitional stages and mature subsets by flow cytometry (figure). Mann-Whitney and Fisher's exact test were used for comparison of AS with other groups

Results: Overall, 60 pts and 12 HC were included (Table). All patient groups presented similar and rather low levels of inflammation, as measured by CRP, ESR and immunoglobulins, in addition to a decreased lymphocyte count by comparison with HC. There were no differences in the B-cell counts between AS pts and HC, with both groups having higher B-cell counts than RA and SLE pts. Regarding B-cell subsets, the immature transitional compartment of AS pts was found in normal range, but not in the RA and SLE groups. In fact, the latter presented a significant decrease in all transitional cell maturity stages (T1-T3). The next step in B-cell differentiation is mature naïve cells, also found in normal levels in AS and decreased in RA and in particular in SLE. AS pts presented slightly higher counts of CD27+IgD+ MZ-like and class able to switch memory cells with reference to HC and these cell numbers were found to be low in RA and even lower in SLE pts. Switched memory CD27+IgD- B-cells were reduced in all patient groups, however, only SLE pts presented highly decreased cell levels.

Conclusions: We found that while a severe dysfunction is present in the homeostasis of the B-cell compartment in RA and in particular SLE pts, which are lymphopenic in both immature and mature B-cell compartments, it appears that AS pts are not affected in the same way. At this stage, functional studies appear to be necessary in order to identify differences in key mechanisms of B cell development and differentiation that may play a role in the aetiology and progression of these inflammatory rheumatic diseases. Our first results, however, establish that pathophysiological mechanisms involving B-cells clearly differentiate AS from RA and SLE

AB0017 THERAPEUTIC EFFECT OF UMBILICAL CORD-DERIVED MESENCHYMAL STEM CELLS TRANSPLANTATION IN A MOUSE MODEL OF PRIMARY BILIARY CIRRHOSIS

J. Fan, Q. Wang, R. Feng, G. Yao, X. Tang, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, nanjing, China*

Background: Primary biliary cirrhosis (PBC) is a cholestatic liver disease characterized by slowly progressive non-suppurative cholangitis with immune mediated destruction of intrahepatic bile ducts. Previous studies have shown beneficial effects of mesenchymal stem cells (MSCs) transplantation in many autoimmune diseases. However, few studies have focused on the effects of MSCs on PBC.

Objectives: In our study, we investigated the therapeutic effect of umbilical cord-derived mesenchymal stem cells (UC-MSCs) transplantation in a well-defined mouse model of PBC and explored the potential mechanism.

Methods: After 2OA-BSA-induced autoimmune cholangitis was created in C57BL/6 mice, cultured human UC-MSCs or a vehicle control was administered. Liver injury severity was assessed by clinical and histologic analysis. The immunity suppression effects and mechanism of UC-MSCs were tested.

Results: UC-MSCs administration alleviated bile duct damage and intrahepatic inflammatory cell infiltration in C57BL/6 mice that had undergone 2OA-BSA immunization. Serum levels of ALT and ALP were significantly decreased. Also, UC-MSCs reduced the production of anti-mitochondrial autoantibodies (AMA) in PBC mice. UC-MSCs downregulated inflammatory cytokine, such as IFN-γ, TNF-α, IL-12 and IL-17A production both in peripheral blood and local liver. Notably, Infusion of UC-MSCs resulted in an increase in regulatory T cells (Tregs) in peripheral blood but a decrease of this kind of cells in liver tissues. Furthermore, UC-MSCs significantly suppressed Th1- and Th17-cell responses and these alternations could be detected in spleen, peripheral blood and liver in PBC mice.

Conclusions: In summary, the current study shows that UC-MSCs based therapy has profound inhibitory effects on inflammatory responses and immunoregulatory effects both in local and systemic abnormalities in PBC. These findings also provide further evidence regarding the role of MSCs in the clinical trials of PBC.

AB0018 B CELL DISTURBANCE IN RHEUMATOID ARTHRITIS PATIENTS: COMPARATIVE STUDY BETWEEN TREATED AND NON-TREATED PATIENTS

M.H. Nassr[1], E. Gomaa[2], M.M. Eid[3], A.A. Hamdy[2], A.A. Wegdan[2].
[1]Rheumatology department; [2]Microbiology and Immunology; [3]Clinical Pathology Department, Fayoum University, Fayoum, Egypt

Background: B cells have been shown to play a key role in the pathogenesis of rheumatoid arthritis (RA). Alterations of B cell homeostasis as well as B cell activation markers, such as B-cell activating factor (BAFF) and A Proliferation-Inducing Ligand (APRIL) have been described in RA patients. Up to our knowledge, no data is currently available on differences between treatment naïve patients and those receiving disease modifying anti-rheumatic drugs (DMARDs), regarding B-cell surface expression as well as levels of circulating BAFF/APRIL.
Objectives: The aim of this study is to investigate disturbance of B cell as well as B cell activation markers namely BAFF and APRIL in patients with rheumatoid arthritis comparing treatment naive patients with those receiving disease modifying anti-rheumatic drugs.
Methods: Sixty RA patients and 30 healthy controls were enrolled. Thirty patients receiving non biologic DMARDs and had not received prior biological treatment and 30 treatment naïve patients. Absolute number of blood CD19 B cells was determined by flow cytometry using the CD19-PE Kit (Immunotech, France). BAFF and APRIL blood concentration was measured using commercially available ELISA kits (Bosterbio, USA).
Results: There was statistically significant difference (p-value <0.05) between different study groups as regard B cell count with *low* mean among treated RA patients (137.2±60.5) and *high* mean among controls (243.7±22.5). The B cell count was diminished in the two groups of RA patients, however it is more pronounced in treated patients. Circulating BAFF levels were increased in RA compared to HC (p-value <0.05) with more increase in patients on treatment. Circulating APRIL levels were significantly lower (p-value <0.05) in treatment naïve rheumatoid arthritis patients (343.9±21.7) than the control group (371.5±24.3). However, there was no statistical significant difference (p-value >0.05) between each of treated rheumatoid arthritis group and controls or with non treated rheumatoid arthritis group.

Variables	B cell count		p-value
	Mean	SD	
G1: Treated RA patients	137.2	60.5	**<0.001**
G2: Non treated patients	179.3	59.1	
G3: Controls	243.7	22.5	
Variables	baff Concentration (pg/ml)		p-value
	Mean	SD	
G1: Treated RA patients	1419.4	417.3	**<0.001**
G2: Non treated patients	886.2	258.4	
G3: Controls	444.4	120.1	

Conclusions: More decrease in B cell count and more increase in BAFF level were observed in RA patients receiving non-biologic DMARDs. Conversely, APRIL levels were not affected by treatment.
The contribution of B lymphocyte to RA pathogenesis goes beyond autoantibody production. Disturbances in B cell homeostasis in RA are not only due to disease process itself but closely related to the use of anti-rheumatic drugs.

AB0019 HDL PROMOTES A REGULATORY PHENOTYPE OF THE IMMUNE SYSTEM BY INDUCING THE PROLIFERATION OF HUMAN CD4+ T CELLS WHILE INCREASING THE EXPRESSION OF FOXP3 IN REGULATOR T CELLS

M. Fernandes Das Neves[1,2], J.R. Batuca[2], E.C. Jury[3], J. Delgado Alves[1,2].
[1]Medicine IV, Professor Doutor Fernando Fonseca Hospital, Amadora; [2]CEDOC - Chronic Disease Research Center, NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal; [3]Centre for Rheumatology Research, University College London, London, United Kingdom

Background: High-density lipoproteins (HDL) are the plasma lipoproteins responsible for reverse cholesterol transport. Its protective effect on cardiovascular disease is attributed to the cholesterol efflux capacity as well as to its anti-oxidant and anti-inflammatory properties. HDL low levels are associated with immune diseases, including systemic lupus erythematosus and rheumatoid arthritis, implying a potential link between HDL and immunity.
There is few evidence on the effects of HDL on human T cells. Animal studies suggested that HDL inhibits lymphocyte proliferation[1], but the only study in humans showed that HDL from young and healthy subjects increases the proliferation of lymphocytes[2]. Previous studies also showed that HDL levels are positively correlated with the prevalence of regulator T cells in peripheral blood[3]. Furthermore, it has been shown that one of the main actions of HDL in lymphocytes is the disaggregation of lipid rafts provoked by cholesterol efflux from the membrane, but the final consequences of this effect are not known.
Objectives: To determine the *in vitro* effects of HDL in human T cell proliferation and in the frequency of FoxP3+ regulator T cells.
Methods: Peripheral blood mononuclear cells from six healthy donors were cultured with and without HDL to measure membrane cholesterol and proliferative response to CD3/CD28 stimulation. Membrane cholesterol was measured by filipin binding, assessed by flow cytometry. T cell proliferation was studied by Ki-67 expression and cell trace staining for multiple generations. T cell phenotyping and FoxP3 fluorescence were analyzed by flow cytometry.
Results: HDL significantly reduced the amount of membrane cholesterol in CD4+ T cells, after 24 hours in culture. When added in the absence of stimulation, HDL did not induce any proliferation in CD4+ T cells. When added in conjunction with CD3/CD28 stimulation, HDL significantly increased the proliferation of CD4+ T cells. T cell phenotyping showed a significant increase in CD4+CD25+ FoxP3 fluorescence, after culture with HDL.
Conclusions: This study shows that HDL promotes cholesterol efflux from the membrane of CD4+ T cells *in vitro* and increases CD4+ T cell proliferation. However, the increase in T cell numbers seem to favor the expression of FoxP3 in regulator in T cells, which is associated with suppression of inflammation. With the development of therapies to increase HDL levels, the knowledge of the HDL effects on T cell subsets is very important for the future management of cardiovascular and rheumatic diseases.

AB0020 EXPRESSION LEVELS OF SIGNALING LYMPHOCYTE ACTIVATION MOLECULE FAMILY 6 (SLAMF6) ON CIRCULATING FOLLICULAR HELPER T CELLS ARE ASSOCIATED WITH DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

S.E. Kang[1], S.J. Lee[1,2], D.J. Go[1,2], H.M. Kwon[2], E.Y. Ahn[2], J.K. Park[1,2], E.Y. Lee[2], E.B. Lee[2], Y.W. Song[1,2]. *[1]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University; [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of*

Background: T follicular helper cells (Tfh) are necessary for B-cell maturation and differentiation in the germinal centers (GC). The signaling lymphocyte activation molecule family (SLAMF) receptors on the cell surface mediate T cell:B cell interaction for formation and maintenance of GC. But it remains to be elucidated whether SLAMF is expressed in circulating T follicular helper cells (cTfh).
Objectives: The aim of this study was to investigate the levels of SLAMF3 and SLAMF6 on cTfh and to analyze their association with disease activity in systemic lupus erythematosus (SLE) patients.
Methods: Blood samples were collected from 50 SLE patients, 24 Sjogren's syndrome (SS) patients and 25 age- and sex-matched healthy controls (HCs). In this study, CXCR5, programmed cell death protein 1 (PD-1), and CD4 were used as markers to define cTfh in peripheral blood mononuclear cells (PBMCs). The expression levels of SLMAF3 and SLMAF6 on cTfh were compared to that of circulating B cell subsets by flow cytometry. Clinical features including disease activity and laboratory tests were analyzed according to expression of SLAMF3 and SLAMF6.
Results: Surface expression of SLAMF6 on CD4 T cells was significantly increased in SLE patients compared to SS patients (mean fluorescence intensity [MFI], mean ± SD: 1291±319 vs 1098±147, p=0.015) and HCs (1291±319 vs 1094±243, p=0.011). But there was no difference in expression of SLAMF3 on CD4 T cells between SLE patients and SS patients or HCs. SLAMF6 expressions on cTfh cells, identified as $CD4^+CXCR5^+PD\text{-}1^+$, were significantly increased in SLE patients than in SS patients (1500±270 vs 1296±140, p=0.001) and HCs (1500±270 vs 1295±161, p=0.001). SLAMF6 expressions on cTfh cells had correlation with systemic lupus erythematosus disease activity index (SLEDAI) (Spearman's rho=0.477, p=0.001), proteinuria (rho=0.321, p=0.030) and double strand DNA (rho=0.340, p=0.026) in SLE patients. Moreover, expression levels of SLAMF6 on cTfh cells were correlated with those of several B cell subsets including total B cells ($CD19^+$), naïve B cells ($CD19^+CD27^-IgD^+$) and class-

switched memory B cells ($CD19^+CD27^+IgD^-$). But SLAMF6 expressions of B cell subsets were not correlated with disease activity.
Conclusions: Surface expression of SLAMF6 was increased in cTfh cells in patients of SLE and had correlation with disease activity.

Innate immunity in rheumatic diseases

AB0021 HUMAN T CELL LEUKEMIA VIRUS TYPE 1 (HTLV-1) EXACERBATES RHEUMATOID ARTHRITIS; EXOSOMES AND IFN-GAMMA DERIVED FROM HTLV-1 INFECTED CELLS ENHANCE THE INFLAMMATORY RESPONSE OF RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS VIA PATTERN RECOGNITION RECEPTOR, RIG-I

K. Umekita, S. Miyauchi, K. Kubo, A. Kawano, K. Iwao, M. Komura, M. Matsuda, I. Takajo, H. Nomura, Y. Nagatomo, A. Okayama. *Division of Rheumatology, Infectious Diseases and Laboratory Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan*

Background: Human T cell leukemia type 1 (HTLV-1) positive rheumatoid arthritis (RA) patients show severe inflammatory state and resistance to anti-rheumatic therapy, including biologic agents (1). HTLV-1 infected T cells was increased in the synovial fluid and tissue from an HTLV-1 positive RA patients (2). However the mechanism of worsening RA by HTLV-1 infection remains unclear. We focused on the role of HTLV-1 infected T cells as a key player in the exacerbation of RA.
Objectives: To clarify the role of HTLV-1 infected T cells in the pathogenesis of RA. We investigate inflammatory mediators derived from HTLV-1 infected cells.
Methods: Peripheral blood mononuclear cells (PBMCs) were collected from asymptomatic HTLV-1 carriers (AC) (n=5) and healthy subjects (HS) (n=5). Rheumatoid arthritis synovial fibroblasts (RASFs) were co-cultured with PBMCs for 5 days. Cytokine profiles of supernatants were analyzed by multiplex. Exosomes were isolated and purified from cultured medium of HTLV-1 infected cell line (MT2). RASF was cultured with MT2 derived exosomes with and without IFN-gamma for 24hours. Total RNA was extracted using TRIZOL method. The expression of RIG-I, IL-6, CXCL10, and CCL5 mRNA in RASF was measured using real-time quantitative PCR. The expression of pattern recognition receptor, RIG-I was determined by immune blotting. Silencing of RIG-I in RASF was performed by transfection of siRNA against RIG-I.
Results: The levels of cytokine, including IFN-gamma, IL-2, IL-9, IL-13, IL-6, and CCL20, were higher in supernatants co-cultured with HTLV-1 positive PBMCs than in those of negative PBMC ($p<0.05$). The expression of CXCL10 and IL-6 mRNA was increased in RASF co-cultured with HTLV-1 positive PBMCs compared to those of negative PBMCs. IFN-gamma is well known to be an important cytokine in the pathogenesis of HTLV-1 associated inflammatory diseases. IFN-gamma induced the expression of IL-6, CCL5, and CXCL10 mRNA in RASF. HTLV-1 infected cell line, MT2, autonomously released a large amount of exosomes which contain nucleic acids such as RNA and DNA. MT2 derived exosomes significantly enhanced the expression of CXCL10 mRNA, but not IL-6 and CCL5, in RASF activated by IFN-gamma. Therefore, we hypothesized that exosomes play the role of ligand for pattern recognition receptors. IFN-gamma increased the expression of RIG-I protein in RASF in a dose-dependent manner. The expression of RIG-I protein also increased in RASF co-cultured with HTLV-1 positive PBMCs compared to those of negative PBMCs. Finally, the silencing of RIG-I suppressed the expression of CXCL10 in RASF induced by co-stimulation of both exosomes and IFN-gamma.
Conclusions: It is possible that HTLV-1 infected T cells exacerbate the inflammatory responses of RASFs. Exosomes derived from HTLV-1 infected cells enhance the expression of CXCL10 in RASF induced by IFN-gamma via pattern recognition receptor, RIG-I.

AB0022 CYTOTOXIC PROFILE CHARACTERIZATION OF NK AND NKT CELLS IN PATIENTS WITH BEHÇET DISEASE

M. Bonacini[1], A. Soriano[2], E. Calò[1], A. Zerbini[1], L. Cimino[3], L. Fontana[3], M. Parmeggiani[1], C. Salvarani[2], S. Croci[1]. *[1]Clinical Immunology, Allergy and Advanced Biotechnologies Unit; [2]Rheumatology Unit; [3]Ocular Immunology Unit, Arcispedale Santa Maria Nuova – IRCCS, Reggio Emilia, Italy, Reggio Emilia, Italy*

Background: Behçhet disease (BD) is a rare inflammatory small vessel vasculitis. It is a chronic systemic disorder with multiorgan damage and various clinical manifestations such as oral ulcers, genital ulcers and uveitis. Etiology is still unknown. Some gene polymorphisms have been associated with BD [1]. In addition, a high frequency of circulating Natural Killer T cells (NKT cells) has been found in BD patients respect to patients with other inflammatory uveitis such as Vogt-Koyanagi-Harada disease (VKH) [2].
Objectives: The objective of this study was to characterize the cytotoxic profile of circulating Nautral Killer (NK) and NKT cells in BD patients.
Methods: Peripheral Blood Mononuclear Cells (PBMCs) were collected from 23 BD patients (according to 1990 ISGB criteria), 7 VKH patients (according to 2001 Revised Diagnostic Criteria) and 9 healthy subjects [3,4]. BD activity was evaluated with BD Current Activity Form 2003. Anti-CD56 and anti-CD3 antibodies were used to identify NK ($CD56^+CD3^-$) and NKT ($CD56^+CD3^+$) cells by flow-cytometry. Expression of one inhibiting receptor (NKG2A) and five activating receptors (CD16, CD69, NKG2D, Nkp30 and Nkp46) was determined on the surface of NK and NKT cells. Cytotoxic potential of NK and NKT cells was assessed through incubation of PBMCs with K526 cells in presence or absence of IL-15 followed by flow-cytometry detection of the surface marker CD107a on NK and NKT cells [5].
Results: A higher frequency of NKT cells was detected in peripheral blood of BD patients than VKH patients. Compared to healthy subjects, an increased proportion of CD16 positive NKT cells was found in BD patients. Furthermore it was observed a higher percentage of NKG2D positive cells in both NK and NKT lymphocytes. No difference in the other markers was detected. In BD patients, the incubation of PBMCs with K562 cells in absence of IL-15 induced a higher percentage of NK cells expressing CD107a compared to VKH patients. Frequency of CD107a positive NKT cells was $<1\%$ and similar between groups. Finally, no differences were found between BD patients with active and inactive phase of the disease.
Conclusions: Our study confirms previous reports about an increased level of NKT cells in peripheral blood of BD patients, but we additionally identified a cytotoxic profile of NK and NKT cells characteristic of BD patients when compared to healthy subjects and patients with VKH. Our data revealed for the first time a potential involvement of NKG2D in the pathogenesis of BD. We can speculate that NK and NKT cells of BD patients are more prone to respond to stress/danger signals when exposed on target cells leading to cyclic auto-inflammation.

AB0023 ASSOCIATION BETWEEN MEX-SLEDAI AND INFECTIONS WITH MBL STRUCTURAL AND PROMOTER GENOTYPES IN MEXICAN-MESTIZO PATIENTS

M.A. Villarreal-Alarcón[1], J.A. Esquivel-Valerio[2], D. Vega-Morales[2], R. Ortiz-Lopez[3], A. Rojas-Martínez[3], A.C. Arana-Guajardo[2], M.A. Garza-Elizondo[2]. *[1]Rheumatology Service, Hospital Universitario "Dr. José Eleuterio González", Monterrey, -; [2]Rheumatology Service; [3]Rheumatology, Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico*

Background: The mannose-binding lectin protein (MBL) is a multimeric molecule with a structure that is the analogue to the C1q protein. Deficient and low MBL concentrations in serum are due to the presence of mutations in the structural or promoter region
Objectives: To investigate the role of alleles and haplotypes of MBL2 gene in the clinical expression of systemic lupus erythematosus (SLE) and its association with infections in Mexican-mestizo patients.
Methods: An observational, cross-sectional, retrospective study. We included 74 SLE patients and 75 matched controls. All $\geq$16 years-old who met at least four 1982 or revised 1997 ACR criteria for SLE were included. The association of MBL locus haplotypes with disease activity and past history of infection was studied in those patients. Allele and haplotype determinations in the promoter and structural regions of the MBL2 gene were performed from genomic DNA isolated peripheral blood. Probes were sent to Invitrogen (Carlsbad, California) for synthesis. The disease activity was determined by MEX-SLEDAI. Infections were categorized arbitrarily if patients had $\geq$4 events. The associations between the codons, clinical activity, and having $\geq$4 infection events were by odds ratio.
Results: There were 13/73 (17.8%) SLE patients with $\geq$4 infections. The presence of homozygous C/C codon 57 was observed to be greater risk for SLE activity and

present more than 4 infections. The significance of heterozygous HYLX promoter was observed only for the presence of infection. Table 1.

Table 1. Association between MEX-SLEDAI and Infections with MBL structural and promoter genotypes in SLE patients

	MEX-SLEDAI median (IQR)	p*	Patients with infections events ≥4, n (%)	Total patients with infections events ≥4, n (%)	p**	OR
Codon 52, n=71		0.68		12 (16.9)	0.44	
A/A	3 (6)		10 (17.5)			
A/D	3 (8)		0 (0)			
D/D	1 (7)		2 (25)			
Codon 57, n=73		0.02		13 (17.8)	0.03	8.7 (1.2–58)
A/A	2 (6)		10 (14.7)			
A/C	0 (0)		0 (0)			
C/C	9 (0)		3 (60)			
Promoter, n=74		0.35		13 (17.6)	0.01	
HYHY	3 (7)		2 (18.2)			
LYLY	2 (8)		5 (21.7)			
LXLX	1.5 (6)		1 (4.8)			
LXLY	2.5 (5)		2 (13.3)			
HYLY	5 (0)		1 (50)			
HYLX	0 (0)		2 (100)			

MEX-SLEDAI: Mexican Systemic Lupus Erythematosus Disease Activity Index, IQR: interquartile range, OR: Odds ratio. *Kruskal–Wallis H test, ** Chi-square test.

Conclusions: MBL2 gene polymorphisms of the homozygous C/C in codon 57 of the structural region and heterozygous HYLX of the promoter region are associated with increased risk of a higher number of infections. Also, we observed that homozygous C/C in codon 57 was asociated to a higher MEX-SLEDAI.

AB0024 A NOVEL REAL-TIME IMAGING TECHNIQUE TO CHARACTERIZE MECHANISMS OF CELL DEATH IN NEUTROPHILS

S. Gupta[1], D.W. Chan[1], K.J. Zaal[2], E. Ralston[2], M.J. Kaplan[1]. *[1]Systemic Autoimmunity Branch; [2]Light Imaging Section, NIAMS/NIH, Bethesda, United States*

Background: Neutrophils play a key role in the pathogenesis of autoimmune diseases through various mechanisms including the formation of neutrophil extracellular traps (NETs). NETosis, a recently described distinct form of program neutrophil cell death, is characterized by reactive oxygen species generation, chromatin and nuclear decondensation, membrane rupture and extrusion of a meshwork of chromatin bound to granule peptides.
Objectives: Techniques to assess and quantitate NETosis in an unbiased, reproducible and efficient way are lacking. We developed a new method to automatically quantify the percentage of neutrophils undergoing NETosis using real-time quantitative live-cell analysis with IncuCyte ZOOM™ (Essen BioScience, Inc.) platform and a dual-dye system dependent on membrane integrity to stain DNA, to image neutrophils and characterize their mechanisms of cell death.
Methods: Neutrophils were isolated from healthy controls using density gradient methods and their DNA was stained with a membrane permeable NUCLEAR-ID Red DNA dye. Neutrophils were plated and incubated with various stimuli to induce NETosis (PMA, ionomycin and/or SLE sera), apoptosis (Staurosporin) or necroptosis (TNF with a pan-caspase inhibitor, Z-VAD) and with Sytox, a membrane-impermeable DNA dye. Three 20x magnification images from different areas per well were captured at 10-minute intervals. A processing definition was set and optimized to count all neutrophils (NUCLEAR-ID stained) at baseline and neutrophils undergoing cell death (Sytox stained) at three hours using fluorescence intensity and stained area size (Figure 1).

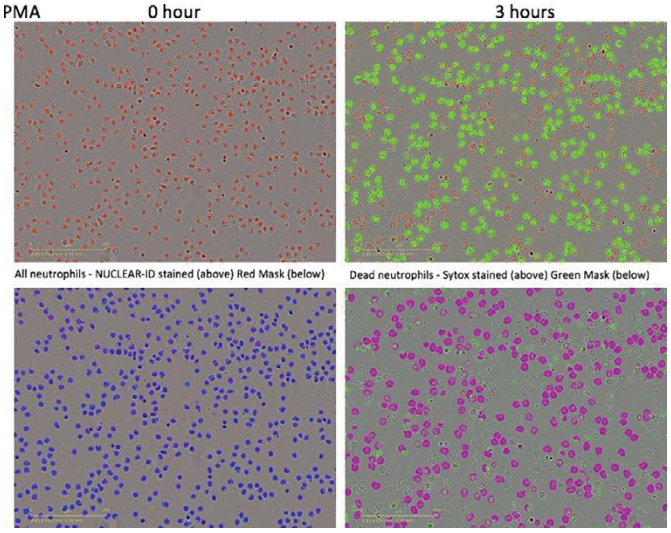

Figure 1

Results: Percentage of neutrophils undergoing cell death using various stimuli was highly reproducible. Characterization of changes in nuclear morphology, quantified by the processing definition, distinguished between NETosis, apoptosis and necroptosis. Findings were confirmed and counts correlated with previously established method using immunofluorescence microscopy.
Conclusions: This novel real time assay distinguishes types of neutrophil cell death and quantifies NETosis in a rapid, accurate and reproducible way. This technique may facilitate studies in neutrophil biology.

AB0025 PREGNANCY RESULTS IN THE SELECTIVE MODULATION OF PLATELET TISSUE FACTOR EXPRESSION INDEPENDENTLY OF THE PRESENCE OF ANTIPHOSPHOLIPID ANTIBODIES OR OF OTHER AUTOIMMUNE FEATURES

V. Canti[1], M.T. Castiglioni[2], M. Angelo A[2], P. Rovere-Querini[2], N. Maugeri[2]. *[1]San Raffaele Scientific Institute, Milano, Italy; [2]via Olgettina 58, San Raffaele Scientific Institute, Milano, Italy*

Background: Neutrophils and platelets are key innate immune cells that productively interact upon activation, generating/releasing moieties that can damage the bystander tissue and prompt vasculogenesis. Successful pregnancy critically depends on a tight regulation of the latter events. Conversely pregnancy complications are associated with alteration/damage of the vasculature associated to the placenta. Blood-born tissue factor (TF) due to the expression of the moiety by platelets and leukocytes has been involved in the pro-thrombotic diathesis associated with sustained human autoimmunity, including that associated with anti-phospholipid syndrome (APS).
Objectives: To test the modulation of parameters related to blood-born TF during normal and pathological pregnancy
Methods: The expression of TF by platelets, monocytes and neutrophils has been studied in 40 women at the 12th week of gestation (wg) including twelve healthy women, 14 patients with insulin-dependent diabetes mellitus (IDDM) and 14 patients with a previous history of pregnancy complications, six of them with APS. 30 healthy age-matched non-pregnant women served as controls. When possible, patients were studied again at least one year after the pregnancy completion. Blood samples were collected and processed as described[1,2]. Other features reflecting cell activation were assessed in parallel[1,2].
Results: The expression of platelet TF was significantly higher in pregnant women compared with age-matched controls. Platelet P-selectin was as well significantly up-regulated. Neutrophils circulating in all pregnant women were mildly degranulated. The content of the neutrophil secondary granules was depleted in particular in subiects with previous pregnancy complications *sine causa*.
Conclusions: Our data support the contention that the activation of the innate immune system is a key feature of pregnancy, regardless of the presence of features of systemic or organ-specific autoimmunity. This implies an important modulation of the machinery involved in the reciprocal activation of platelets and neutrophils and in the pro-thrombotic phenotype of circulating cells. The analysis of the potential modulation of these parameters by ongoing treatment is currently being carried out.

Cytokines and inflammatory mediators

AB0026 CHEMOKINE SIGNALS ARE CRITICAL FOR HOMING AND ENHANCED DIFFERENTIATION OF CIRCULATING OSTEOCLAST PROGENITOR CELLS

A. Sucur[1], Z. Jajic[2], M. Artukovic[3], M. Ikic Matijasevic[3], F. Grubisic[2], B. Anic[4], S. Ivcevic[1], D. Flegar[1], D. Grcevic[1]. *[1]Department of Physiology and Immunology, University of Zagreb School of Medicine; [2]Department of Rheumatology, Physical Medicine and Rehabilitation, Clinical Hospital Center "Sestre Milosrdnice", University of Zagreb School of Medicine; [3]Department of Clinical Immunology and Pulmology, Clinical Hospital "Sveti Duh"; [4]Department of Clinical Immunology and Rheumatology, Clinical Hospital Center "Zagreb", Zagreb, Croatia*

Background: Peripheral blood (PB) monocyte pool contains cells capable of differentiating into osteoclasts (OCs). These osteoclast progenitors (OCPs) contribute to osteoresorption in inflammatory arthritides under influence of the cytokine milieu and chemokine mediated trafficking.

Objectives: Our study aimed to define chemokine receptor profile of peripheral OCPs in rheumatoid arthritis (RA), with comparison to psoriatic arthritis (PSA), as well as their susceptibility to chemotactic signals.
Methods: 129 RA, 53 PSA and 110 control patients were enrolled after Ethical approval. PB samples and synovial fluid (SF) samples, with clinical data of disease activity, inflammation and autoantibody levels were collected. Patients starting anti-TNF therapy were followed up 6 months. TNF-α and CTX serum levels were measured by ELISA. Frequency of OCP-rich subpopulation (CD3-CD19-CD56-CD11b+CD14+), expression of OC differentiation (CD115, RANK) and chemokine (CCR1, CCR2, CCR4, CXCR4) receptors was assessed by flow cytometry. OCPs were sorted using FACS, cultured with M-CSF and RANKL, stained for TRAP enzyme and mature OCs counted. Levels of CCL2, CCL3, CCL4, CCL5, CXCL9 and CXCL10 were measured using cytometric bead array, and of CXCL12 by ELISA. Osteoclastogenic effects of CCL2, CCL5 and CXCL10 were analyzed in cell culture, and chemotactic effects on OCPs were studied by cell migration assay using Transwell, with count of number of migrated cells and subsequently differentiated mature osteoclasts.
Results: OCP population was moderately enlarged in PB, further expanded in SF and correlated with TNF-α and rheumatoid factor (RF) levels in patients with RA. However, sorted OCPs generated similar number of mature OCs as control. RANK+ subpopulation was enlarged in SF vs PB and correlated with number of tender joints. In PSA, the OCP population was not enlarged, but had a higher RANK expression. OCPs in RA and PSA had higher expression of CCR1, CCR2, CCR4, CXCR4, and all except CCR4 showed positive PB-to-SF gradient. RA had higher levels of CCL2, CCL3, CCL4, CCL5, CXCL9 and CXCL10, with a positive PB-to-SF gradient for all except CCL5 and CXCL9. OCP frequency correlated with levels of CCL2 and CCL5. Subset expressing CXCR4 was associated with TNF-α, CTX and RF levels and was lower in patients treated with DMARD, who at the same time had lower osteoresorption (CTX). Subset expressing CCR4 showed significant negative trend during anti-TNF treatment. CCL2, CCL5 and CXCL10 showed significant osteoclastogenic effect. CCL5 showed greatest chemotactic effect, attracting the highest number of cells in the migration assay. At the same time, attracted cells possessed greater osteoclastogenic potential.
Conclusions: Our study provides evidence of the specific importance of certain chemokine signals for stimulation of OCP mobilization, subsequent tissue homing, and maturation, explaining local as well as generalized bone loss seen in RA. Novel insights in regards to migratory behavior and functional properties of PB OCPs in response to chemotactic signals could open way to new therapeutic targets in RA.

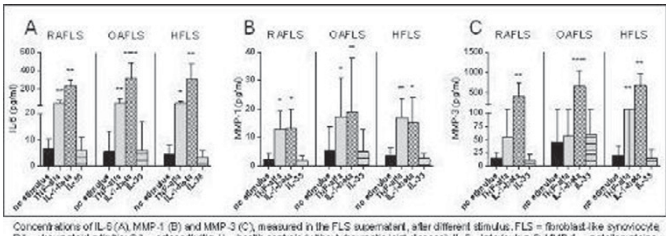
AB0027 EXPRESSION DENSITY OF RECEPTORS TO TNF-ALPHA IS ASSOCIATED WITH DAS-28 SCORE IN RHEUMATOID ARTHRITIS



A.A. Alshevskaya[1], J. Lopatnikova[1], N. Shkaruba[1], O. Chumasova[1], A. Sizikov[1], V. Lukinov[2], A. Moskalev[2,3], S. Sennikov[1]. [1]*Federal State Budgetary Scientific Institution "Research Institute of Fundamental and Clinical Immunology"; [2]EOL Labs Ltd; [3]Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation*

Background: For a number of cytokines and growth factors density of receptors expression has been shown to be important in regulation of action intensity and variation. Although TNF-alpha is actively involved in the development and progression of chronic inflammation in rheumatoid arthritis (RA) role of membrane receptors and their regulatory function in RA remains unclear.
Objectives: To assess associations of membrane-bound receptors expression and soluble receptors and cytokine content with disease activity score in patients with rheumatoid arthritis.
Methods: To reveal linear relationships among integrated score DAS-28 and studied parameters of intact T-cells, B-cells and monocytes (evaluated by flow cytometry) and parameters of mediators soluble content (evaluated by ELISA) building of multiple linear regression model (MLRM) with a standard assessment of the regression coefficients by least squares method were used. To determine receptor number on the cells QuantibritePE Beads (BD) were used.
Results: For the group of patients with acute stage of RA MLRMs with best statistical quality characteristics revealed that for lymphocytes both TNFR1 and TNFR2 number had significant associations with DAS-28; for monocytes only number of TNFR2 was significant. Lower DAS-28 index is associated with higher number of TNFR2 per cell and lower number of TNFR1.
Comparison of models with different combinations of studied TNFR-parameters revealed that percentages of cells expressing receptors for TNFα validated not more than 20% of DAS-28 variation, while the number of receptors indicators on cells validated 40–50% of DAS-28 variation. Full MLRM with all 15 studied parameters validated about 70% of DAS-28 variation.
For the group of patients with acute stage of RA MLRMs with best statistical quality characteristics revealed that for lymphocytes both TNFR1 and TNFR2 number had significant associations with DAS-28; for monocytes only number of TNFR2 was significant. Lower DAS-28 index is associated with higher number of TNFR2 per cell and lower number of TNFR1. Comparison of models with different combinations of studied TNFR-parameters revealed that percentages of cells expressing receptors for TNFα validated not more than 20% of DAS-28 variation, while the number of receptors indicators on cells validated 40–50% of DAS-28 variation. Full MLRM with all 15 studied parameters validated about 70% of DAS-28 variation.
Conclusions: Number of receptors to TNF-alpha is more associated with RA activity score as compared with soluble receptors or cytokine. Number of receptors type 1 and type 2 to TNF-alpha per cell have opposite influence on disease activity score. Our findings indicate the involvement of receptors expression density changes in the pathological process in RA.

AB0028 FIBROBLAST-LIKE SYNOVIOCYTES MAY NOT BE THE TARGET OF IL-33 IN THE JOINT PHISIOPATHOLOGY

C.R.L. Machado[1], G.G. Resende[2], R.B.V. Macedo[2], V.C. Nascimento[2], T.P. Silva[2], A.M. Kakehasi[2], M.V.M. Andrade[2]. [1]*Universidade Federal Minas Gerais; [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

Background: Rheumatoid arthritis (RA) and osteoarthritis (OA) are chronic joint diseases in which fibroblast-like synoviocytes (FLS) actively participate in the synovitis- damage cycle, trough production of cytokines such as IL-6 and metalloproteinases (MMPs)[(1)]. It has already been showed that serum IL-33 levels correlated with disease activity in RA[(2)]. IL-33 is capable to enhance TNF-α effects in FLS[(3)]. In the collagen-induced arthritis (CIA) model, the injection of IL-33 exacerbated the disease[(4)]. Since ST2 receptor is expressed in FLS, it is hypothesized that IL-33 could activate FLS and increase downstream production of inflammatory cytokines.
Objectives: To evaluate the production of IL-6, MMP-1, and MMP-3 by FLS stimulated with IL-33, TNF-α, and IL-1β.
Methods: FLS were cultured from samples of synovial fluid and tissue of OA patients (OAFLS n=8), RA patients (RAFLS n=3), and patients without rheumatic disease (health) (HFLS n=4). FLS were stimulate with TNF-α at concentrations of 1; 5; 10 and 50 ng/ml, IL-1β at concentrations of 0.1; 0.2; 0.3; 0.5 and 1 ng/ml and IL-33 at concentrations of 1; 3; 10; 30; 100 ng/ml, soon after, IL-6, MMP-1, and MMP-3 levels were evaluated by ELISA, in the cell supernatant.
Results: MMP-1, MMP-3 and IL-6 were constitutively expressed by FLS at baseline in all groups. Both TNF-α and IL-1β stimulated the production of IL-6 and MMP-1 with statistical significance in a dose-dependent manner in all three groups. Only IL-1β increased the production of MMP-3. TNF-α stimulated the production of MMP-3 only on HFLS. There was no difference between the concentration of MMP-1, MMP-3 and IL6 in the supernatant of OAFLS, ARFLS and HFLS when IL-33 stimulated and non-stimulated were compared.

Concentrations of IL-6 (A), MMP-1 (B) and MMP-3 (C), measured in the FLS supernatant, after different stimulus. FLS = fibroblast-like synoviocyte; RA = rheumatoid arthritis; OA = osteoarthritis; H = health controls (without rheumatic joint disease); IL-6 = Interleukin-6; MMP-1 = metalloproteinase-1; MMP-3 = metaloproteinase-3; TNF-alpha = Tumor Necrosis Factor-alpha; IL-1-beta = Interleukin-1-beta; IL-33 = Interleukin-33. * p < 0.05; ** p < 0.01; *** p < 0.001; **** p < 0.0001.

Conclusions: This study demonstrated that IL-33 failed to induce the production of IL-6, MMP-1 and MMP-3 by FLS of different diseases sources, suggesting that must be another cell type that plays the role of target to IL-33 in physiopathology of joint inflammation. The absence MMP-3 in response to TNF-α stimulus in RAFLS and OAFLS could be explain by saturation of this cytokine in synovial cells from these diseases.

AB0029 ANTI INFLAMMATORY EFFECT OF PDE5 INHIBITION: SCOPE FOR A NEW POTENTIAL INDICATION IN SSC ASSOCIATED MYOSITIS

C. Corinaldesi[1,2], G. Abignano[1,3], C. Antinozzi[2], V. Riccieri[4], G. Valesini[4], M. Vasile[4], F. Marampon[2], A. Lenzi[4], K. Ballard[5], F. Del Galdo[1,3], C. Crescioli[2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [2]University of Rome Foro Italico, Rome, Italy; [3]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [4]Sapienza University of Rome, Rome, Italy; [5]Myriad RBM, Austin-TX, United States*

Background: Skeletal muscle damage can occur as clinical manifestation of Systemic Sclerosis (SSc) [1], and it is known to be associated to type I IFN pathway activation [2]. The type I IFN-induced chemokine CXCL10 is associated with a more severe SSc prognosis and skeletal muscle disease [3,4], and it has been reported to play a role in inflammatory myopathy (IM) and in diabetic cardiomyopathy (DCM) [5,6]. In DCM the phosphodiesterase type 5 inhibitor (PDE5i) sildenafil significantly decreased CXCL10 systemic and cellular release [7]. In SSc, sildenafil is used to treat pulmonary artery hypertension (PAH) and digital ulcers disease.
Objectives: To determine the serum levels of CXCL10 in SSc patients with or without muscle involvement and treated or not with sildenafil. To determine the role of sildenafil on IFNγ+TNFα-induced CXCL10 release in human skeletal muscle cells (Hfsmc).
Methods: Sera from 109 patients fulfilling ACR/EULAR 2013 classification criteria for SSc and 34 age and gender matched healthy controls (HC) were analysed by multiplexed, bead-based immunoassay. Hfsmc were cultured and analysed as previously described [5].
Results: CXCL10 serum level was significantly higher in SSc vs. HC (602.1±155.1 pg/ml vs 197.5±14.9 pg/ml, $P<0.001$) independently of diffuse or limited clinical subset ($p>0.05$); the presence of sildenafil in therapeutic regimen was associated with lower serum CXCL10 (455.2±211.8 pg/ml vs 633.1±183.02 pg/ml, $P<0.05$). CXCL10 was significantly higher in patients with increased Creatine Kinase (CK) (2703±2172 vs 454±82.51, $P<0.01$) and its concentration strongly correlated with the levels of CK ($r=0.986$, $P<0.001$) and with Medsger muscle Severity score ($r=0.445$, $P<0.001$). *In vitro*, sildenafil suppressed IFNγ+TNFα-induced CXCL10 release by Hfsmc in a dose dependent manner, down to 50% secretion at 1mM ($P<0.05$). The inhibition of CXCL10 secretion was associated with significant reduction in cytokine-induced STAT1, NFKB and JNK phosphorylation ($P<0.01$).
Conclusions: High CXCL10 level is associated with SSc independently from local or diffuse clinical subset and is lower in patients assuming sildenafil independently of other therapies. The strong correlation of CXCL10 and severity of muscle damage as assessed by serum CK and Medsger Muscle severity score, strongly indicate/confirm the involvement of IFN-I pathway activation during myositis in SSc. The direct inhibitory effect of PDE5 inhibitor Sildenafil on proinflammatory induced CXCL10 secretion warrant further research on the potential role of PDE5 inhibitors as disease modifying agents in SSc.

AB0030 THE EFFECT OF SILDENAFIL AND ILOPROST ON CXCL10 LEVEL IN SYSTEMIC SCLEROSIS: IN VIVO AND IN VITRO COMPARISON

C. Antinozzi[1], C. Corinaldesi[2], F. Marampon[1], V. Riccieri[3], G. Valesini[3], M. Vasile[3], A. Lenzi[4], F. Del Galdo[5], C. Crescioli[1]. *[1]University of Rome, Foro Italico, Rome, Italy; [2]University of Leeds, Leeds, United Kingdom; [3]University of Rome, Sapienza; [4]University of Rome Sapienza, Rome, Italy; [5]Univerisity of Leeds, Leeds, United Kingdom*

Background: Th1 cell/cytokine repertoire contributes to systemic sclerosis (SSc) pathogenesis from early autoimmune/vascular stages while Th2 dominance prevails later, when (multi)organ fibrosis occurs [1]. The Th1-type chemokine IFNγ-induced 10 kDa protein (CXCL10), involved in several autoimmune diseases (thyroiditis, rheumatoid arthritis, systemic lupus erythematosus, inflammatory myopathy) exerts detrimental effects at systemic and tissue/cell level; it is reported in association with more severe SSc prognosis [2–4].
Objectives: To compare circulating CXCL10 level in SSc patients starting iloprost (I), prostacyclin analogue with or without sildenafil (S), phosphodiesterase type 5 inhibitor, both vasoactive drugs used in SSc for Raynaud's phenomenon digital ischemic ulcers and/or secondary pulmonary arterial hypertension; SSc subjects under immunosuppressants (DMARDs) or corticosteroids (CCs) - first choice treatments at disease onset - before and after I were also evaluated. Intracellular path activation underlying Th1 cytokine-induced CXCL10 release by human skeletal muscle cells (Hfsmc), endothelial cells (Hfaec), cardiomyocytes (Hfcm) and fibroblasts (hFbs) were compared after iloprost or sildenafil.
Methods: Sera of 27 SSc patients satisfying ACR/EULAR 2013 classification criteria for SSc were analyzed by ELISA before (T0, baseline) and 3 months after I intake (T3) vs. 15 age/gender-matched healthy subjects. Protein extracts from different human cell types were tested by Western blot for IFNγ+TNFα-induced NFkB, Stat1, JNK activation after S or I.
Results: CXCL10 serum level was higher in all SSc under each drug/drug combination (range ~300–500 pg/ml) vs. healthy subjects (~150 pg/ml, $P<0.05$). I intake did not modify baseline CXCL10 in SSc subjects taking only I, DMARDs or CCs, while it significantly decreased CXCL10 in subjects under S (~150 pg/ml, $P<0.05$). In Hfsmc S-induced inhibition of Stat-1/NFkB/JNK phosphorylation was higher vs. I (67/66/66% S vs. 28/30/38% I $P<0.01$). In Hfaec inhibition of Stat1/NFkB phosphorylation was higher and virtually prevented with I (99/92% I vs. 58/66% S $P<0.01$); conversely S-induced inhibition on JNK activation was significantly higher (66% S vs. 20% I $P<0.01$). In Hfcm I-induced inhibition was stronger on Stat1/JNK phosphorylation (67/83% I vs. 33/52% S $P<0.05$/$P<0.01$), while inhibition on NFkB was similar (70% I vs. 71% S). In hFbs, neither S nor I affected IFNγ+TNFα-induced activation of each analyzed path.
Conclusions: Our *in vivo* results show that S and I combination is the more effective in targeting circulating CXCL10 in SSc patients. Our *in vitro* findings show a different inhibitory drug-induced effect onto paths underlying CXCL10 production, depending on cellular/intracellular targets. Thus, we suggest I and S combination as potential pharmacological tool in SSc not limited to treat vascular dysfunction but likely helpful to control different cell/tissue involvement and damage.

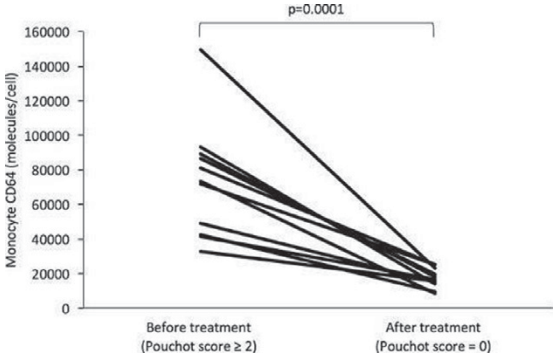
AB0031 IL37 INHIBITS GAG RELEASE FROM HUMAN OA CARTILAGE EXPLANTS

E. Van Geffen, A. van Caam, H. van Beuningen, E. Vitters, C. Dinarello, E. Blaney Davidson, P. van der Kraan. *Radboud Univeristy Medical Center, Nijmegen, Netherlands*



Background: In healthy cartilage, there is a balance between anabolic and catabolic activities of chondrocytes that maintains the functional integrity of the extracellular matrix. However, during osteoarthritis (OA), chondrocytes become more catabolically active and express increased levels of matrix degrading enzymes, such as MMPs and ADAMTSs. Increased MMP and ADAMTS activity results in a net loss of the extracellular matrix and therefore leads to cartilage damage. Previously, we found that the anti-inflammatory cytokine Interleukin 37 (IL37) is able to counter-regulate the catabolic status of chondrocytes by reducing the IL1β-driven expression of pro-inflammatory cytokines and catabolic enzymes.
Objectives: The goal of this study was to investigate, in human OA cartilage explants, the effect of IL37 on sulfated glycosaminoglycans (GAG) content and synthesis of extracellular matrix molecules and cartilage degrading enzymes to investigate its therapeutic potential in OA.
Methods: Human cartilage was obtained from eighteen OA patients undergoing total knee or hip arthroplasty. Biopsy punches of 4 mm in diameter were made to equalize explant size. After culturing overnight, explants were incubated for 48 h with three doses (1, 10 or 100 ng/ml) of recombinant-human IL37 (rhIL37). In the supernatant of the explant cultures, GAG release was measured with the DMB assay and levels of the ARGS neoepitope, which is one of the products of aggrecan degradation by ADAMTS5, were detected using Western Blot. Furthermore, gene and protein expression of extracellular matrix molecules and cartilage degrading enzymes were measured. Nitric oxide (NO), an important effector molecule that may suppress cartilage matrix synthesis, levels were measured in the supernatant of the explants culture using Griess reagens.
Results: Adding rhIL37 (100 ng/ml) to OA cartilage explants caused a highly significant reduction in GAG release to the supernatant of, on average, 32% in eighteen donors (Figure 1). Gene expression of the matrix molecules aggrecan and collagen type II was not affected, indicating that this effect of rhIL37 was not due to a loss of aggrecan synthesis. Another mechanism to prevent GAG release in cartilage is via inhibition of NO synthesis, but NO levels in the supernatant were comparable between rhIL37 treated groups and the control group. In contrast, after addition of rhIL37, ARGS neoeptiope levels, which reflect ADAMTS5 activity, were dose-dependently down regulated in the supernatant. Furthermore, protein analysis of the explants showed that rhIL37 reduced ADAMTS5 levels. These data indicate that IL37 interferes with the amount active matrix degrading enzymes in the cartilage matrix. However, gene expression of ADAMTS5 was not affected by rhIL37, indicating that the effect of IL37 on ADAMTS5 is post translational.
Conclusions: Our data show that rhIL37 reduces GAG release by OA cartilage explants. The mechanism behind this protective effect of IL37 probably runs via a reduction in ADAMTS5 abundance in the cartilage matrix, which is the main aggrecanase involved in OA This effect of IL37 on ADAMTS5 is probably post translational. Our data indicate that IL37 can maintain cartilage matrix integrity

under OA conditions and is able to reduce the severity of cartilage destruction during OA.

AB0032 UPREGULATION OF CD64 EXPRESSION ON MONOCYTES IN PATIENTS WITH ACTIVE ADULT-ONSET STILL'S DISEASE: A POSSIBLE BIOMARKER FOR ASSESSING DISEASE ACTIVITY

E. Oguro[1], T. Shimizu[1], A. Kikuchi-Taura[2], S. Tsuji[1], Y. Okita[1], M. Shigesaka[1], H. Matsuoka[1], T. Nii[1], S. Teshigawara[1], E. Kudo-Tanaka[1], Y. Harada[1], M. Matsushita[1], S. Ohshima[2], Y. Saeki[2]. *[1]Department of Rheumatology and Allergology; [2]Department of Clinical Research, NHO Osaka Minami Medical Center, Osaka, Japan*

Background: Adult-onset Still's disease (AOSD) is a systemic inflammatory disease of unknown etiology. Overproduction of multiple inflammatory cytokines and subsequent hyperactivation of monocytes/macrophages are prominent characteristics of AOSD. However, there are no convenient and precise methods for evaluating monocyte/macrophage activation in AOSD. We previously reported that monocyte CD64 (mCD64) expression could be quantitatively measured by flow cytometry and its expression was tightly correlated with the activity of systemic lupus erythematosus.
Objectives: We examined the association between mCD64 expression and AOSD disease activity.
Methods: This was a prospective, single-center, observational study conducted between January 2013 and December 2016. Eleven active AOSD patients who fulfilled the Yamaguchi's criteria for AOSD and had the modified Pouchot score of $\geq$2 were enrolled. The mCD64 expression levels were quantitatively measured by flow cytometry and individually assessed both before (Pouchot score $\geq$2) and after treatment (score 0). Other disease-related laboratory data, such as C-reactive protein, ferritin, and white blood cell count, were simultaneously measured. As a control, 16 active systemic lupus erythematosus (SLE) patients (SLE disease activity index $\geq$6), 22 active rheumatoid arthritis (RA) patients (disease activity score with 28-joint counts $>$3.2), and 20 healthy controls (HC) (female, 55%; mean age, 38.7±9.1 years) were enrolled. Statistical analysis was performed by the Mann-Whitney and Wilcoxon-paired tests.
Results: The median mCD64 expression levels were 73,339 [interquartile range (IQR), 45,861–88,181] and 16,443 (IQR, 45,891–88,181) molecules/cell before and after treatment, respectively. Thus, mCD64 expression levels were significantly decreased during the inactive phase compared with those in the active phase in AOSD (p=0.0001). The mCD64 expression levels were significantly higher in patients with active AOSD than in those with active SLE [34,648 (IQR, 44,204–24,657) molecules/cell, p=0.001], active RA [25,167 (IQR, 35,778–22,301) molecules/cell, p$<$0.0001], and in HC [14,174 (IQR, 13,413–17,774) molecules/cell, p$<$0.0001].

Conclusions: These results suggest that mCD64 expression levels are highly upregulated in AOSD and tightly correlated with disease activity. The mCD64 expression level may be a useful biomarker for assessing the disease activity of AOSD.

AB0033 THE IDENTIFICATION OF IL-17A+, IL-17RA+ AND IL-17RC+ LYMPHOID AND MYELOID CELLS IN BLOOD OF TREATMENT NAÏVE EARLY AND IN SYNOVIAL FLUID OF ESTABLISHED PSORIATIC ARTHRITIS PATIENTS

X. Xu[1], N. Davelaar[1], A.-M. Otten-Mus[1], P.S. Asmawidjaja[1], H. den Braanker[1], H. Alves[1], J.P. van Hamburg[1], C. Gaillez[2], J.M. Hazes[3], R. Bisoendial[4], M. Vis[3], F. Kolbinger[5], E. Lubberts[1]. *[1]Rheumatology and Immunology, Erasmus Mc, University Medical Center, Rotterdam, Netherlands; [2]Novartis Pharma AG, Basel, Switzerland; [3]Rheumatology, Erasmus Mc, University Medical Center; [4]Rheumatology, Maasstad Hospital, Rotterdam, Netherlands; [5]Novartis, Basel, Switzerland*

Background: Interleukin (IL)-17A is a pro-inflammatory cytokine and is involved in the pathogenesis of psoriatic arthritis (PsA) (1,2). Various cells can produce IL-17A. However, it is not clear which cell types in PsA patients are responsible for the production of IL-17A. In addition, the expression of IL-17RA and IL-17RC on different cell types is not well defined.
Objectives: To identify IL-17A, IL-17RA and IL-17RC positive cells in blood of first diagnosed PsA patients with arthritis and in synovial fluid of established PsA patients with active disease.
Methods: Fresh blood was taken from first diagnosed DMARD and steroid naïve PsA patients (n=10), having arthritis in 1 or more joints (PsA blood). The diagnosis was made by a rheumatologist according to the CASPAR-criteria. In addition, fresh synovial fluid was obtained from established PsA patients (PsA SF) with active disease (n=10) and treated with either methotrexate (n=3) or adalumimab (n=3) or NSAIDs (n=4). Multicolor flow cytometric analysis was performed on PsA blood and PsA SF. For the detection of IL-17A, IL-17RA or IL-17RC the following antibodies were used: IL-17A-PE (eBioscience), IL-17RA or isotype control IgG1k (both Biolegend), IL-17RC or isotype control IgG2b (both R&D systems). The following markers were used to discriminate between different cell populations: T cell subsets (CD3, CD4, CD8, CD45RO, CCR6, TCR$\gamma\delta$), B cells (CD19), NK cells (CD15-CD16+), neutrophils (CD15+CD16+), monocytes (CD33+CD14+CD16+/-), mast cells (CD117+FcER1a+) and eosinophils (CD15+FcER1a+).
Results: Different lymphoid and myeloid cell types were IL-17A positive in PsA blood of first diagnosed PsA patients such as CD3+, TCR$\gamma\delta$+, CD4+, CD8+ lymphoid cells, CD14+ monocytes and eosinophils. In PsA SF of established PsA patients TCR$\gamma\delta$+ T cells, neutrophils, NK cells and eosinophils were IL-17A positive.
In both groups, no difference in expression of IL-17RA and IL-17RC was found on CD4+, CD8+, CD4+CD45RO+CCR6+/-, TCR$\gamma\delta$+ and CD19+ lymphoid cells compared to their isotype control. In contrast, the expression of IL-17RA and IL-17RC was increased compared to their isotype control on neutrophils and monocytes in PsA blood and on neutrophils, monocytes, mast cells and eosinophils in PsA SF.
Conclusions: These preliminary data show that not only lymphoid cells but also specific myeloid cell types may be sources of IL-17A in PsA. Furthermore, not lymphoid cells but IL-17RA/IL-17RC positive myeloid cells such as monocytes, neutrophils, mast cells and eosinophils may be potential target cells for IL-17A.
Together, these data suggest a more broad, but specific IL-17A-IL-17RA/RC signaling network between different cell types important in the IL-17A-driven pathogenesis of PsA.

AB0034 PARAMETERS OF TOTAL BLOOD COUNT; MIGHT THEY BE INDICATORS OF INFLAMMATION IN RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS?

O.G. Illeez, F. Unlu Ozkan, I. Aktas. *PMR, University of Saglık Bilimleri, Fatih Sultan Mehmet Training and Research Hospital, Istanbul, Turkey*

Background: Neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) are launched as recent markers of inflammation in chronic inflammation principally in cancer and cardiovascular diseases (1–2).
Objectives: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are chronic inflammatory disorders marked by variable periods of remissions and relapses.Inflammation is most likely the underlying cause in disability, increased comorbidity therefore need to be closely monitored and kept under control (3).For this reason cost effective, accessible and reliable parameters are needed in daily practice. Our aim is to analyze the relation between inflammation and NLR and PLR which are easily calculated from whole blood count parameters.
Methods: Medical records of 425 subjects were analyzed retrospectively.Mean age of the subjects was 44,64±14,07 years (17–89 years),52.9% was female (n=225) and 47.1% was male (n=200).105 of them had RA, 216 of them had AS and 104 were healthy controls.2010 ACR/EULAR classification criteria and modified New York criteria were used for the diagnosis of RA and AS.Erythrocyte sedimentation rate (ESR), C reactive protein (CRP) and whole blood count were recorded with simultaneous DAS28 scores of patients with RA and BASDAI scores of patients with AS.
Results: Hemoglobin levels of RA patients were significantly (p$<$0.05) lower then the levels of control group (p=0.001).ESR, CRP, NLR and PLR were significantly higher then the control group respectively (p=0.001, p=0.001, p=0.001, p=0.040).In AS group hemoglobin, ESR, CRP and NLR values were significantly higher then the control group respectively (p=0.001, p=0.006, p=0.001, p=0.001). No difference was detected between AS and control groups in terms of PLR (p$>$0.05).When patients with high disease activity and patients in remission were compared for both RA and AS groups ESR (p=0.001, p=0.001)

and CRP scores (p=0.005, p=0.003) were significantly lower respectively. No statistical significance was found in terms of NLR and PLR (p>0.05).Significant positive correlation was found in RA patients with high disease activity between ESR, CRP, NLR and PLR. In AS patients with high disease activity significant positive correlation was found between ESR, NLR and PLR. No correlation was found between disease activity indices, NLR and PLR.

Conclusions: With the advantage of cost effectiveness and easy calculation NLR and PLR in RA patients, and NLR in AS patients might be used as indicators of inflammation together with ESR and CRP or instances when they are not applicable.Although NLR and PLR are useful in the discrimination of healthy and diseased subjects, they are not sufficient to determine disease activity because not only laboratory parameters but clinical findings and self assessment of the patient are also included in activity measurement.

AB0035 ANGIOPOIETINS: THE MISSING LINK IN POEMS SYNDROME?

F. Coutant[1], Z. Tatar[2], P. Rouzaire[1], B. Evrard[1], A. Dosgilbert[1], O. Tournilhac[3], G. Le Guenno[4], R. Lemal[3], M. Soubrier[2]. *[1]Laboratoire d'Immunologie; [2]Rhumatologie et Immunologie Clinique, CHU Gabriel Montpied; [3]Hématologie Clinique; [4]Médecine Interne, CHU Estaing, Clermont-Ferrand, France*

Background: POEMS syndrome (Polyneuropathy, Organomegaly, Endocrinopathy, Monoclonal gammopathy and Skin changes) is a rare multiorgan disease related to plasma cell dyscrasia. The pathogenesis of the POEMS syndrome is currently unknown, but microangiopathy involving neoangiogenesis and increased vascular permeability may explain some of the features of the disorder. Although vascular endothelial growth factor (VEGF) is constantly highly abundant in the serum of patients with POEMS syndrome, therapeutic approaches targeting the VEGF have led to conflicting results, suggesting that other mediators sharing functional similarities with the VEGF contribute to the pathogenesis. Angiopoietins are known to be involved in the development, remodeling and stability of blood vessels. It is thus tempting to speculate that altered expression of angiopoietins might contribute to the pathogenesis.

Objectives: The aim of this study was to evaluate the circulating levels of three major angiogenic cytokines in patients before and after treatment: VEGF, angiopoietin-1, which plays an essential role in the stabilization and the maturation of blood vessels, and angiopoietin-2 that facilitates angiogenesis in the presence of VEGF.

Methods: Circulating levels of VEGF, Angiopoietin-1 and angiopoietin-2 were determined by ELISA in the serum of 3 patients with POEMS syndrome, before and after therapy. All patients had polyneuropathy, organomegaly, a monoclonal gammopathy (2 IgAl, 1 IgGk) and osteosclerotic lesions. Two patients had typical skin lesions, oedema and one patient had a Castleman disease.

Results: As expected, the serum of patients before treatment exhibited high levels of VEGF (2901±920 pg/mL). Strikingly, angiopoietin-1 levels were highly abundant before treatment (67286±20395 pg/mL) and successful treatment led to a strong reduction in both VEGF and angiopoietin-1. Angiopoietin-1 levels strongly correlated with levels of VEGF (r=0.83). By contrast, angiopoietin-2 levels did not differ significantly before and after treatment.

Conclusions: Thus, angiopoietin-1 seems to be a crucial proangiogenic cytokine overproduced in patients with POEMS syndrome that might explain some of the features of the pathology. The overproduction of VEGF and angiopoietin-1 is likely to promote manifestations encountered in POEMS syndrome such as organomegaly, osteosclerotic lesions or glomeruloid hemangioma. Restoring the balance between angiopoitein-1, angiopoietin-2 and VEGF could constitute a very promising therapeutic strategy in this disease.

AB0036 ASSOCIATION BETWEEN SYNOVITIS AND INFLAMMATORY CITOKINES SERUM LEVELS IN A COHORT OF PATIENTS AFFECTED BY PRIMARY KNEE OSTEOARTHRITIS

F. Ceccarelli[1], C. Perricone[1], V.A. Pacucci[2], C. Scirocco[1], C. Alessandri[1], G. Valesini[3], F. Conti[3]. *[1]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma; [2]Reumatologia, Dipartimento Medicina Interna e Specialità Mediche; [3]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza, Università di Roma, Roma, Italy*

Background: Osteoarthritis (OA) is characterized by progressive loss of cartilage, deterioration of subchondral bone and mild synovial inflammation. Classified for a long time as a non-inflammatory arthropathy, a growing number of evidences has suggested that OA course could be driven by systemic and localized inflammation. In particular, serum levels of Interleukin (IL)-6 have been associated with higher prevalence of osteophytes in older adults with knee OA. Furthermore, high levels of other inflammatory cytokines have been identified in serum and synovial fluid of OA patients.

Objectives: In the present cross-sectional study, we aimed at analyzing the correlation between articular inflammatory state, reflected by ultrasonographically-detected synovitis, and the serum levels of 27 cytokines, chemokines and growth factors in a cohort of primary knee OA.

Methods: We consecutively enrolled 47 patients (M/F 16/31, mean age ±SD 63.8±7.8 years, mean onset interval ±SD 70.0±78.6 months) affected by knees OA according to clinical and radiographic ACR criteria. Patients were excluded if they had received non-steroidal anti-inflammatory drugs or other analgesics within the 2 days before enrollment. Pain was assessed with a 100-mm visual analogue scale (VAS), and the Lequesne algo-functional index was used to measure the OA severity. BMI was registered. Each patient underwent ultrasonographic (US) assessment of both knees performed by a single operator. According with OMERACT definitions, we assessed the presence of synovial effusion, synovial hypertrophy and power Doppler. These elementary lesions were scored according to a semi-quantitative scale (0 = absent, 1 = mild, 2 = moderate and 3 = severe), the sum of them allows obtaining a total score of the patient's inflammatory state (0–18). Finally, blood samples for laboratory assays were obtained and commercially available multiplex bead based immunoassay kits (Human 27-plex, Bio-Rad laboratories, Hercules, CA) were used to measure concentrations of IL-1β, IL-1RA, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, FGF-Basic, G-CSF, GM-CSF, interferon-γ, IP-10, MCP-1, MIP-1α, MIP-1β, PDGF, RANTES, TNF, VEGF.

Results: At the study enrollment, OA patients showed a mean±SD US synovitis score of 4.4±2.7, a mean±SD VAS pain rating of 53.3±16.6 mm (range 18–90 mm), a mean±SD Lequesne index of 10.2±4.2 (range 1.5–19), a mean±SD BMI of 26.8±4.2 (range 20–34.7). Positive correlations among US synovitis score and serum levels of IL-6 (r=0.3, p=0.01), IL-2 (r=0.3, p=0.01), IL-5 (r=0.3, p=0.01), IL-7 (r=0.3, p=0.03), MIP-1b (r=0.3, p=0.01), VEGF (r=0.3, p=0.02) were found. Moreover, US synovitis score positively correlated with Lequesne index (r=0.4, p=0.004) and BMI (r=0.4, p=0.04).

Conclusions: The results of the present study confirmed that OA may be associated with systemic inflammatory changes, as demonstrated by the positive correlation between US synovitis and several inflammatory cytokines serum levels.

AB0037 SERUM CYTOKINE SIGNATURE IN MUCOCUTANEOUS AND OCULAR BEHÇET'S DISEASE

G. Lopalco[1], O.M. Lucherini[2], L. Cantarini[2], A. Lopalco[3], V. Venerito[1], M. Fornaro[1], D. Natuzzi[1], M. Galeazzi[2], G. Lapadula[1], F. Iannone[1]. *[1]Department of Emergency and Organ Transplantation, University of Bari, Bari; [2]Research Center of Systemic Autoinflammatory Diseases and Behcet's Disease Clinic, Department of Medical Sciences, Surgery and Neurosciences, University of Siena, Siena, Italy; [3]Department of Pharmaceutical Chemistry, University of Kansas, Lawrence, United States*

Background: Behçet's disease (BD) is a multi-systemic inflammatory disorder consisting of recurrent oral aphthosis, genital ulcers, and chronic relapsing bilateral uveitis. However, many other organs including the vascular, gastrointestinal, neurological, and musculoskeletal systems can be affected. Pathogenetically, both innate and adaptive immunity have shown to play a pivotal role, and several proinflammatory cytokines derived from Th1 and Th17 lymphocytes seem to be involved in different pathogenic pathways leading to development of the clinical manifestations.

Objectives: The primary aim of our study was to compare a core set of proinflammatory cytokines between patients with BD and healthy control (HC). The secondary aim was to evaluate potential correlations between these putative circulating biomarkers, the status of disease activity, and the specific organ involvement at the time of sample collection.

Methods: Fifty-four serum samples were collected from 46 BD patients (17 males, 29 females, mean age 45,5±11,3 years), and 19 HC (10 males, 9 females, mean age 43±8.3 years). Twenty-five serum cytokines (APRIL/TNFS13, BAFF/TNFSF13B, sCD30/TNFRSF8, sCD163, Chitinase3-like1, gp130/sIL-6Rb, IFNb, sIL-6Ra, IL-10, IL-11, IL-19, IL-20, IL-26, IL-27 (p28), IL-28A/IFN-lambda2, IL-29/IFN-lambda1, IL-32, IL-34, IL-35, LIGHT/TNFSF-14, Pentraxin-3, sTNF-R1, sTNF-R2, TSLP and TWEAK/TNFSF-12) were simultaneously quantified using a Bio-Rad cytokine bead arrays.

Results: Serum levels of Chitinase3-like1, gp130/sIL-6Rb, IL-11, IL-26, sTNF-R1, sTNF-R2 were significantly higher in BD patients than in HC. Specifically, serum concentration of sTNF-R1 (p<0.01) and sTNF-R2 (p<0.01) resulted higher in both active- and inactive-BD than HC, whilst Chi-tinase3-like1 (p<0.05) and gp130/sIL-6Rb (p<0.01) serum levels were significantly higher in in-active-BD, and IL-26 (p<0.01) in active-BD than HC. No differences were observed between inactive- and active- BD group. In addition, comparing cytokines levels in patients affected by mucocutenous manifestations with (MO-BD) or without (M-BD) ocular

involvement we observed that gp130/sIL-6Rb, sIL-6Ra, IL-35, and TSLP serum levels were significant enhanced in MO-BD compared to M-BD subgroup.

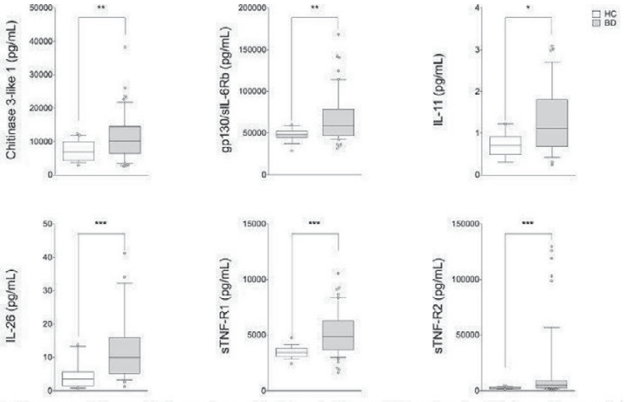

Fig.1. Serum cytokine profile in patients with Behçet's disease. BD patients (n=54) showed up-regulation of serum levels of Chitinase3-like1, gp130/sIL-6Rb, IL-11, IL-26, sTNF-R1 and sTNF-R2 compared with HC (n=19). Mann-Whitney U-test as well as Student's t-test were carried out to check for statistical significance between groups when required (***p<0.001, **p<0.01, *p<0.05). The central line represents the distribution median, boxes span 25th to 75th percentiles, and error bars extend from 10th to 90th percentiles. Dots (°) are outlier values, higher than the 90th percentile. Abbreviations: HC, healthy controls; BD, Behçet's disease.

Conclusions: Our findings showed a signature of IL-6, TNF-α as well as of Th17 response in BD patients due to increased levels of gp130/sIL-6Rb, sTNF-R1, sTNF-R2, IL-26 respectively. This evidence could contribute to improve the knowledge regarding the role of these citokines in the induction of specific BD clinical features

AB0038 INCREASED INTERFERON-ALPHA PRODUCTION BY PLASMACYTOID DENDRITIC CELLS STIMULATED WITH A TLR-7 AGONIST IN SYSTEMIC LUPUS ERYTHEMATOSUS

G. Murayama [1,2], N. Furusawa [2], A. Chiba [2], K. Yamaji [1], N. Tamura [1], S. Miyake [2].
[1] Department of Internal Medicine and Rheumatology; [2] Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan

Background: Type I interferon (IFN) appears to contribute to the development of systemic lupus erythematosus (SLE). IFN-α production is known to be increased in peripheral blood mononuclear cells (PBMCs) from SLE patients. Although plasmacytoid dendritic cells (pDCs) is a major source of IFN-α, previous reports showed that IFN-α production by pDCs stimulated with a TLR-9 agonist was decreased in SLE compared to healthy controls (HC).
Objectives: We set out to investigate an other endosomal TLR-signaling pathway in SLE by using TLR-7 agonist stimulation.
Methods: Blood samples were obtained from 55 HC and 73 SLE patients, diagnosed according to the systemic lupus international collaborating clinics classification criteria for systemic lupus erythematosus (2012). PBMC from SLE patients and HC were stimulated with a TLR-9 agonist, CpG-A oligodeoxynucleotides (CpG-A ODN)-2216, and a TLR-7 agonist, imiquimod. The proportion of pDCs producing IFN-α was investigated by intracellular cytokine staining and flowcytometory. PBMC were pretreated with IFN-α for 24 hours, and then IFN-α production by pDCs was assessed after imiquimod stimulation.
Results: As previously reported, the level of IFN-α production by pDCs stimulated with CpG-A ODN was reduced in SLE compared with HC. However, the proportion of IFN-α producing pDCs stimulated with imiquimod was significantly increased in SLE patients. The percentage of IFN-α producing pDCs stimulated with imiquimod was positively correlated with SLE disease activity index (SLEDAI) score, and that of pDCs stimulated with CpG-A ODN was negatively correlated with SLEDAI. The expression of TLR-7 on pDCs, but not TLR-9, was upregulated in SLE patients compared with HC. Furthermore, pretreatment with IFN-α increased IFN-α production by pDCs upon imiquimod stimulation.
Conclusions: IFN-α production by pDCs form SLE patients was increased when stimulated with a TLR-7 agonist, and this was accompanied with upregulated TLR-7 expression in these cells. In murine lupus-models, TLR7-deletion has been shown to reduce autoimmune disease. The enhanced TLR-7 signaling pathway in pDC may play an important role in lupus pathology.

AB0039 REDUCTION OF TH17+ LYMPHOCYTES IN PART OF SAPHO PATIENTS ON TREATMENT WITH SECUKINUMAB

G. Assmann [1], A. Tajali [2], S. Bamberger [1], M. Pfreundschuh [1], C. Schormann [1], F. Neumann [1]. *[1] Rheumatology and Oncology, University Medical School of Saarland, Homburg; [2] Rheumatology, Püttlingen Hospital, Püttlingen, Germany*

Background: The SAPHO syndrome has to be considered as a rare subtype of the disease entity of the seronegative spondylarthritis. The characteristic defining symptoms are synovitis, acne, palmoplantar pustulosis (PPP), and hyperostosis with osteitis. In general, most of SAPHO patients complete the diagnostic criteria for spondylarthritis and/or psoriatic arthritis. The etiology of SAPHO syndrome remains unclear so far, autoimmune dysregulations potentially triggered by bacterial infection with propionibacterium acnes has been discussed. Firinu D et. al (Ref.) has previously published data of higher Th17+ lymphocytes in the peripheral blood in SAPHO patients compared with psoriatic arthritis patients or healthy controls. Activation of the TH17 pathway leads to pro-inflammatory effects mediated by interleukin 17 with stimulation of osteoblast, macrophages, and fibroblasts with the consequences of secretion f pro-inflammatory cytokines such as interleukin 6 and 1, TNF alpha, and MMPs. The interleukin 17 blocking agent secukinumab has been introduced in the armentarium of antirheumatic drugs against seronegative spondylarthritis including psoriatic arthritis.
Objectives: To evaluate the count of Th17+ lymphocytes in patients with SAPHO syndrome and psoriatic arthritis before and under treatment with secukinumab.
Methods: Peripheral blood was derived from 4 patients with SAPHO syndrome and 4 patients with psoriatic arthritis, respectively before and under 12 week treatment with secukinumab 300mg (dosage: 4 times weekly, then monthly). All patients had received at least one conventional DMARDs and one TNF blocking agent in their medical history. All patients showed active disease with elevated scores of DAS28 and/or HAQ, for SAPHO patients the activity scores of osteitis (from 0 to 6) and PPP (0–6) were estimated by physician. The blood specimen were separated in EDTA containing tubes to separate lymphocytes, which were measured using FACS analysis to evaluate the fraction of Th 17+/CD4+ lymphocytes. The Ethics Committee of Saarland has proven the study, all patients gave their consent to take part in the study.
Results: The Th17+lymphocytes were not detectable in 4 patients with psoriatic arthritis and 2 of 4 SAPHO patients before and under 12 week treatment with secukinumab. In 2 of 4 SAPHO patients the fractions of Th17+ lymphocytes were prominent prior to secukinumab application; after treatment duration of 12 weeks one of both developed a depletion of Th17+ cells (figure), the other SAPHO patient a Th17+ cell reduction. Only the two SAPHO patients with diminishing Th17+ lymphocytes have developed treatment response evaluated by reduction of HAQ score (from 1.75 to 1.25), osteitis score (4.5 to 3.0), and PPP score (5.0 to 4.0). Three of 4 psoriatic arthritis patients showed reduced diseases activity under treatment with secukinumab (DAS28 score from 4.22 to 3.45, HAQ 2.25 to 1.5).

Conclusions: The measurement of Th17+lymphocytes in the peripheral blood of SAPHO patients could be suggested for further evaluation as possible predictor of treatment response by secukinumab.

AB0040 IMMUNE MODULATORY EFFECTS OF MESENCHYMAL STEM CELL TO MONONUCLEAR CELLS FROM PATIENTS WITH ACTIVE ADULT ONSET STILL'S DISEASE

I.W. Sohn[1], H.-J. Jeong[2], G.Y. Ahn[1], M.J. Kim[1], H. Kim[1], S. Kang[1], D.H. Yoo[1]. *[1]Rheumatology, Hanyang University Hospital for Rheumtic diseases, Seoul; [2]Rheumatology, Keimyung University Dongsan Medical Center, Daegu, Korea, Republic Of*

Background: Adult onset Still's disease (AOSD) is an inflammatory disorder of unknown etiology, which is accompanied by increased levels of serum pro-inflammatory cytokine. Mesenchymal stem cells (MSCs) have immunomodulatory capacities and might be a promising therapeutic option in the treatment of refractory autoimmune diseases. Both cell-to-cell contact and the release of soluble factors mediate immune modulatory functions of MSCs.
Objectives: We aimed to determine if MSCs could modulate serum cytokine level in patients with active untreated AOSD, either through paracrine secretion or via direct contacts with the MSCs.
Methods: Human peripheral blood mononuclear cells (hPBMCs) from 6 patients with active AOSD were co-cultured for 72 hours with human MSCs (hMSCs at a ratio of 10 to 1). We compared the cytokine levels before and after direct or indirect (transwell cultures) exposition to activated mononuclear cells (LPS, 10ng/ml) or T cell-inducing conditions (anti-CD3 [5 μg/ml], anti-CD28 [5 μg/ml], recombinant human IL-2 [5 ng/ml]). Cytokine levels were detected by multiplex cytokine detection kit by flow cytometry, or ELISA with culture supernatant. In vitro platform for studying the effects of MSCs on individual cytokines, the Wilcoxon signed-rank test was employed for comparison of serum cytokine levels.
Results: Treatment of mononuclear cells with hMSCs resulted in significant reduction of mean TNF-α level (mean 463.4 pg/ml vs 137.8 pg/ml, $p<0.05$) and IL-1 β (mean 1887.1 pg/ml vs 1127.9 pg/ml, $p<0.05$). When the hMSCs were present during the T-cell differentiation, there was a significant decrease in the mean secreted TNF-α (mean 10953.5 pg/ml vs 454.9 pg/ml, $p<0.05$), IFN-γ (mean 14301.0 pg/ml vs 5090.4 pg/ml, $p<0.05$) and sIL-2 receptor (mean 3550.8 pg/ml vs 2506.4 pg/ml, $p<0.05$). On the contrary, level of TGF-β was significantly increased (mean 4088.8 pg/ml vs 5104.8 pg/ml, $p<0.05$). But, there was a significant increase in the amount of IL-6 (mean 2215.5 pg/ml vs 25130.6 pg/ml, $p<0.05$) and IL-17 α (mean 1357.0 pg/ml vs 2453.6 pg/ml, $p<0.05$). Two chamber experiments also showed similar pattern of cytokine modulation.
Conclusions: This preliminary experiment demonstrated that MSCs can modulate cyokine profiles of AOSD mononuclear cells by decreasing pro-inflammatory cytokines, and increasing anti-inflammatory cytokine such as TGF-β. However, up-regulation of IL-6 and IL-17 might be a hurdle to overvome in the clinical application of MSCs in AOSD patients.

AB0041 LARGE VESSEL VASCULITIS INDUCED BY CANDIDA ALBICAN WATER-SOLUBLE-FRACTION (CAWS) IN THE C57BL/6J MOUSE MODEL IS ASSOCIATED WITH OVEREXPRESSION OF IL-6, TNF-α, AND IL-10 WITH MODEST CHANGE IN SOCS-1

J.M. Springer[1], M. Zhang[2], D. Smith[1], N. Miura[3], N. Ohno[3], O. Tawfik[4], M. Maz[1], K. Dileepan[1]. *[1]Allergy, Immunology and Rheumatology; [2]Department of Orthopedics, Kansas University Medical Center, Kansas City, United States; [3]Department of Pharmacy and Life Sciences, Tokyo University, Hachioji, Japan; [4]Department of Pathology and Laboratory Medicine, Kansas University Medical Center, Kansas City, United States*

Background: We have previously demonstrated that mast cell degranulation acutely downregulates lipopolysaccharide induced aortic expression and serum levels of IL-6 in vivo. This is accompanied by aortic upregulation of suppressor of cytokine signaling-1 (SOCS-1) gene expression[1]. This effect is not seen in histamine H1 receptor-knockout mice suggesting that mast cell-derived histamine is a key mediator involved in IL-6 homoeostasis[2]. Mice injected with *Candida albican* water-soluble-fraction (CAWS) have been shown to develop coronary and aortic vasculitis[3]. Our long-term objective is to determine the pathogenic mechanism of large vessel vasculitis (LVV).
Objectives: The aim of this pilot study was to replicate and develop a working mouse model to determine the regulatory role of mast cells in LVV.
Methods: Eight to ten weeks-old male C57Bl6/J mice were randomly distributed into two groups [CAWS, N=8; and Control, N=8] and were injected i.p. daily for 5 days with either CAWS in normal saline (2 mg/day/mouse) or normal saline alone (controls). All mice were sacrificed 30 days after the 5th injection. We examined serum levels of IL-6 and TNF-α, as well as aortic tissue expressions of IL-6, TNF-a, IL-10 and SOCS-1 mRNA. Heart and aortic sections were evaluated for inflammation and mast cells after staining with H & E and toluidine blue, respectively.
Results: Treatment of mice with CAWS for 5-consecutive days led to overexpression of IL-6, TNF-a and IL-10 genes in the aortic tissue with modest upregulation of SOCS-1. At the root of the aorta, all animals in the CAWS group had intense inflammatory infiltrates composed of mixed acute and chronic inflammatory cells. There is also evidence of vasculitis in the coronary arteries. In contrast, none of the control mice had any evidence of aortic inflammation or vasculitis. Serum IL-6 concentrations were below detectable levels in both controls and CAWS-treated mice whereas TNF-a levels were elevated in 3 out of 8 mice in the CAWS group. There were no signs or increased presence of intact or degranulating mast cells in the area of inflammation.
Conclusions: These results suggest that CAWS-induced LVV involves acute and chronic inflammatory response and vascular tissue expression of both pro- and anti-inflammatory cytokines and SOC-1. Detailed kinetic studies are warranted to determine the optimum windows of peak inflammatory response and the expression of these genes to understand the pathobiology of CAWS-induced LVV.

AB0042 HIGH EXPRESSION OF S100 CALGRANULINS GENES IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF PATIENTS WITH TAKAYASU ARTERITIS

J. Kabeerdoss, R. Goel, H. Mohan, D. Danda. *Department of Rheumatology, CHRistian Medical College, Vellore, India*

Background: Takayasu arteritis (TA) is inflammatory disorder that affects aorta and its branches. Toll-like receptors (TLR) 1 to 4 are highly expressed in aorta (1). Activation of TLR4 causes transmural arteritis in human temporal artery–SCID chimera model (2). Ligand responsible for TLR4 activation is not known in TA.
Objectives: Aim of the study is to examine the expression of TLR4 and its endogenous ligands in peripheral blood mononuclear cells (PBMCs) of patient with TA.
Methods: RNA from PBMCs of 24 TA patients and 19 sex and age matched healthy controls were extracted. The mRNA expression of various endogenous TLR4 ligands, TLR4, RAGE, interleukin-6 (IL-6) and IL-8 were quantified in real time PCR using specific primers and SYBR Green qPCR master mix. Serum S100A8/A9 and S100A12 levels were measured using commercial ELISA kits. S100A8/A9 and S100A12 were measured in cell culture supernatant of un-stimulated and lipopolysaccharides (LPS) stimulated PBMCs, cultured for 4 hours. t-test was used to compare between the groups. $P<0.05$ was considered as statistically significant.
Results: The mRNA of S100A8, S100A9, S100A12 and TLR4 were highly expressed in TA as compared to healthy controls, while RAGE, HSP70 and IL-6 had lower expression in TA. No difference in serum levels of S100A8/A9 and S100A12 was noted between TA and healthy controls. LPS induced high secretion of both S100A8/A9 and S100A12 levels in both TA and healthy controls (Figure-1). However, the stimulatory response in healthy controls [2.88 (1.7–3.53) fold] was significantly higher as compared to TA [1.345 (1–1.82) fold; $p<0.05$] as measured by delta S100A12 (LPS/unstimulated control). Numerically delta S100A8/A9 was also higher in healthy controls [2.04 (1.7–5.6) fold] as compared to TA [1.38 (1.09–3.6) fold; p=0.129].

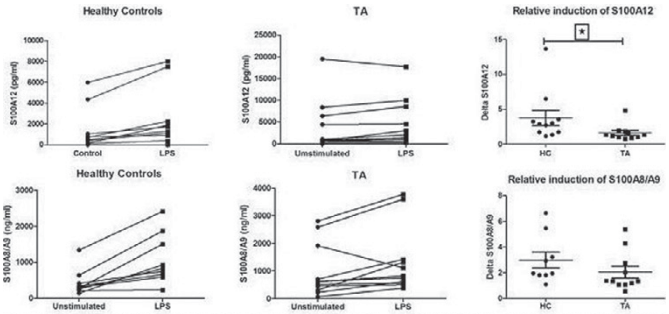

Figure -1. S100A8/A9 and S100A12 secretion by PBMCs cultured with and without LPS (100ng/ml) in RPMI medium for 4 hours for TA (n=10) and Healthy controls (n=10). Each circle represents each subjects and connecting line represents their corresponding S100A8/A9 and S10012 secretion levels in unstimulated control (without LPS) and LPS treatment on PBMCs. *=p<0.05.

Conclusions: mRNA expression of S100A8, S100A9, S100A12 and TLR4 in PBMCs of TA patients were higher as compared to healthy controls. Despite this, S100A12 secretion was lower in TA as compared to healthy controls upon LPS challenge.

AB0043 TLR4 INHIBITION REDUCES MOVEMENT-INDUCED NOCICEPTION AND ATF-3 EXPRESSION IN EXPERIMENTAL OSTEOARTHRITIS

J. Ferreira-Gomes[1,2,3], M.M. Garcia[4], D. Nascimento[1,2,3], L. Almeida[1,2,3], E. Quesada[5], C. Goicoechea[4], J. Castro-Lopes[1,2,3], F. Neto[1,2,3]. *[1]Departamento de Biomedicina – Unidade de Biologia Experimental, Faculdade de Medicina da Universidade do Porto; [2]Instituto de Investigação e Inovação em Saúde, Universidade do Porto; [3]IBMC-Instituto de Biologia Molecular e Celular, Universidade do Porto, Porto, Portugal; [4]Area de Farmacologia, Facultad de Ciencias de la Salud, Universidad Rey Juan Carlos. Unidad Asociada URJC-IQM-CSIC, Alcorcon; [5]Instituto de Química Médica, Consejo Superior de Investigaciones Científicas. Unidad Asociada URJC- IQM-CSIC, Madrid, Spain*

Background: Toll-like receptor 4 (TLR4) is a pattern recognition receptor involved in the initiation of inflammatory responses to control pathogen infections, but is also a "danger-sensing" receptor that recognizes host-derived endogenous molecules called damage-associated molecular patterns (DAMPs). The role of TLR4 in rheumatic diseases is becoming evident, as well as its potential role as a therapeutic option.

Objectives: The aim of this study was to evaluate the effect, both on articular histopathology and pain behaviour, of a TLR4 antagonist (TLR4-A1) on an experimental model of OA. The effect of the TLR4-A1 on the activating transcription factor-3 (ATF-3) signalling pathway was also assessed.

Methods: OA was induced in adult Wistar rats through an intra-articular injection of 2mg of sodium mono-iodoacetate (MIA) into the left knee. Control animals received a similar injection with saline. TLR4-A1 (10 mg/kg), synthesized by Dr. Quesada from a compound previously described by the Peri Laboratory (Piazza et al., 2009), was intraperitoneally administered, daily, from days 14 to 28 after OA induction. Under the same procedure a control group of animals received the vehicle. Movement- and loading- induced nociception was evaluated in all animals, by the Knee-Bend and CatWalk tests, before and after TLR4-A1 or vehicle administration, at several time-points. Animals were sacrificed 28 days after OA induction. L3-L5 Dorsal Root Ganglia (DRG) were used for immunohistochemistry for TLR4 and ATF-3, spinal cords were immunoreacted for TLR4 and knee joints were processed for histopathological evaluation.

Results: Antagonism by TLR4-A1 significantly reduced the nociceptive behavior of OA animals both in the Knee-Bend and Catwalk tests. The effect was immediately observed 1 day after TLR4-A1 administration, but became more evident 4 days later, maintaining thereafter. No improvement in the cartilage histology was observed. The increased ATF-3 expression observed in DRG of OA animals was significantly reduced by TLR4-A1. On the contrary, TLR4 expression slightly increased after antagonist administration both at DRG and superficial dorsal horn levels.

Conclusions: Chronic treatment with TLR4-A1 showed an antinociceptive effect on OA animals, not related to articular histopathological improvement, possibly through an ATF-3 dependent mechanism.

AB0044 THE INHIBITORY EFFECTS OF TACROLIMUS ON GLIOSTATIN PRODUCTION IN RA SYNOVIOCYTES

K. Ikuta[1], Y. Waguri-Nagaya[2], T. Yamagami[3], N. Tatematsu[3], Y. Kawaguchi[3], Y. Oguri[3], T. Terazawa[1], M. Kobayashi[3], K. Asai[4], T. Otsuka[3]. *[1]Orthopaedic Surgery, Daido Hospital; [2]Joint Surgery for Rheumatic Diseases; [3]Orthopaedic Surgery; [4]Molecular Neurobiology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

Background: Gliostatin (GLS) is known to have angiogenic and arthritogenic activities[1]. We also reported a decrease in serum GLS levels in RA patient responders treated with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs)[2]. Tacrolimus (TAC), an orally available calcineurin inhibitor, is a potent immunosuppressant. The efficacy of TAC monotherapy and the combination therapy with TAC and methotrexate in the treatment of RA has been previously described[3]. Although the principal TAC action is thought to be the inhibition of T cell activation, its beneficial effect on RA synoviocytes has not been yet elucidated.

Objectives: To determine the inhibitory effects of TAC on GLS production in RA, we investigated the modulation of serum GLS by TAC therapy and the effect of TAC on the production of GLS in cultured fibroblast-like synoviocytes (FLSs).

Methods: Serum samples were collected from eleven RA patients with active disease at baseline and after 12 weeks of TAC treatment. These RA patients had a history of unsatisfied response with at least one csDMARD or biological DMARD. Serum concentrations of GLS and matrix metalloproteinase (MMP)-3 were measured by enzyme immunoassay (EIA). Synovial specimens were obtained from RA patients at the time of total knee arthroplasty. FLSs were cultured and stimulated by TNF alfa with or without TAC. The expression levels of GLS were determined using RT-PCR and EIA. MMP-3 protein in conditioned media was measured by using EIA.

Results: Six patients fulfilled good and moderate responder and the other five patients fulfilled no responder with EULAR response criteria. DAS28, serum GLS, CRP and MMP-3 were significantly down-regulated in TAC responders. In RA FLSs, GLS mRNA and protein were significantly induced after treatment with TNF alfa alone (GLS mRNA 21.9-fold, protein 1.5-fold compared to control). These inductions were suppressed by TAC in a dose-dependent manner. MMP-3 protein was induced by TNF alfa and was similarly suppressed by TAC in a dose-dependent manner (MMP-3 protein 2.9-fold compared to control).

Conclusions: This study is the first to demonstrate that TAC down-regulates GLS mRNA and protein in FLSs treated by TNF alfa. Our data suggests that the beneficial effect of TAC in RA might be due to, at least in part, to anti-angiogenic and anti-arthritogenic activity following the down-regulation of GLS.

AB0045 IL-17 INDUCED GLUCOCORTICOID INSENSITIVITY MIGHT BE DEPENDENT ON THE REDUCED 11BETA-HSD1 ENZYME ACTIVITY

M. Vitiello[1], V. Kunnathully[1], G. Orsolini[1], O. Viapiana[1], F. Poli[1], A. Mattè[2], L. De Franceschi[2], L. Idolazzi[1], D. Gatti[1], M. Rossini[1]. *[1]Rheumatology Unit; [2]Internal Medicine Section, University of Verona, Verona, Italy*

Background: It has been demonstrated that IL-17A is able to induce GC insensitivity. Although several studies have reported the role of IL-17 in GC insensitivity the mechanism underlying remains still largely unclear.

Objectives: To understand the effects of interleukin-17 (IL-17) on the enzyme 11β-hydroxysteroid dehydrogenases (11β-HSDs) in the two main classes of monocytes, CD14 and CD16.

Methods: Peripheral Blood Mononuclear Cells (PBMCs) were isolated from 5 healthy donors and were sorted into CD14 and CD16 subpopulations using cell sorting. Effect of IL-17 on 11β-HSD1 enzyme activity was measured in terms of conversion of cortisone to cortisol in sorted and unsorted monocytes using Homogeneous Time-Resolved Fluorescence (HTRF). The direct involvement of 11β-HSD1 in the conversion of cortisone to cortisol was confirmed using carbenoxolone, an inhibitor of 11β-HSD1.

Results: Monocytes showed a concentration-dependent decrease in the 11β-HSD1 enzyme activity when incubated with increasing concentrations of IL-17. CD14 and CD16 cells stimulated similarly with IL-17 showed a significant

difference in the enzyme activity between the untreated and stimulated cells in all treatment groups. However, a dose dependent decrease was observed only in case of CD14 cells. Both unsorted monocytes and monocyte sub-populations showed a significant decrease in the concentration of cortisol measured when co-incubated with carbenoxolone, indicative of the direct involvement of 11β-HSD1 enzyme in the conversion of cortisone to cortisol.

Conclusions: The results of this study showed that IL-17 induced GC insensitivity might be dependent on the reduced 11β-HSD1 enzyme activity in inflammatory conditions. We showed that the pro-inflammatory cytokine IL-17 causes a significant decrease in the 11β-HSD1 enzyme activity.

AB0046 METABOLISM AND OSTEOARTHRITIS ARE LINKED BY ADIPOKINES

M.-L. Hülser[1], C. Schreiyäck[1], Y. Luo[2], A. Bozec[2], G. Schett[2], E. Neumann[1], U. Müller-Ladner[1]. *[1]Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Bad Nauheim; [2]Clinic of Medicine 3 - Immunology and Rheumatology, University of Erlangen-Nuremberg, Erlangen, Germany*

Background: Obesity and hyperinsulinemia are of increasing importance in the Western society. Both obesity and insulin resistance lead to changes in expression of adipokines such as adiponectin, visfatin or leptin, which appear to be immunomodulatory factors also in rheumatic diseases.

Objectives: Since osteoarthritis (OA) is often accompanied by hyperinsulinemia and obesity, we combined both mouse models (destabilization of the medial meniscus (DMM) and high-fat diet (HFD)). Here, we evaluated and correlated the systemic and local effects of both models at different states of OA development with special focus on the local/systemic expression of the adipokines adiponectin, visfatin and leptin over time.

Methods: HFD (mainly consisting of saturated fatty acids) to induce obesity and hyperinsulinemia, and ND (normal diet) as control were fed to C57Bl/6 mice for 3 months followed by surgical OA induction (time point 0). Tissues and sera were collected at different time points after DMM-mediated OA induction (4, 6, 8 weeks). Adipocytokine (leptin, visfatin, adiponectin and IL-6) serum levels were measured by ELISA. Histological stainings of the joints (H/E, safranin O, pappenheim and Masson-Goldner's trichrome) were evaluated and arthritis progress was scored. Immunohistochemical stainings of the joints were performed to evaluate the local distribution of adipokines, which were correlated to systemic adipocytokine levels and the respective arthritis score.

Results: Low systemic IL-6 levels confirmed that no acute inflammation due to surgery or infection was present in all animals. OA induction was visible at all time points, which was aggravated in HFD compared to ND mice (OA score: 4 weeks ND 0.87 vs. HFD 0.93, 6 weeks ND 1.44 vs. HFD 3.69, 8 weeks ND 1.78 vs. HFD 2.18). Systemic levels of leptin were significantly induced by HFD confirming the induction of insulin resistance, but DMM decreased leptin levels at all time points (significantly for 3 out of 6 groups, e.g. 4 weeks: HFD healthy vs. HFD DMM 18.4 ng/ml vs. 3.7 ng/ml). Interestingly, the systemic increase of adiponectin by DMM was time dependent (only 8 weeks after surgery: HFD healthy vs. HFD DMM 5176 ng/ml vs. 6149 ng/ml) but independent of diet. However, HFD in combination with DMM did not show significant effects on systemic levels of adiponectin, visfatin or IL-6.

Conclusions: HFD deteriorates OA in the DMM model. Systemic leptin levels were elevated by HFD/insulin resistance but reduced by DMM, which could not be observed for the mainly proinflammatory adipokine visfatin. Of note, systemic inflammation as shown by systemic IL-6 levels was low in all animals. The stage of OA development influences adiponectin levels, which were only increased systemically 8 weeks after surgery. In summary, systemic levels of adipokines are altered by DMM and HFD as well as the combination of both models and the analyzed adipokines show differing reactions to these factors.

AB0047 TYPE I INTERFERON IS HIGHLY EXPRESSED IN RA SYNOVIAL FLUID AND JOINT CARTILAGE CORRELATED WITH SERUM RHEUMATOID FACTOR; A PRELIMINARY EXPERIMENTAL STUDY

M. Nakayama[1], H. Tobimatsu[1], H. Imamura[1], Y. Sakuma[1], K. Yano[1], Y. Niki[2], K. Ikari[1]. *[1]Department of Orthopedic Surgery, Institute of Rheumatology, Tokyo Women's Medical University; [2]Department of Orthopedic Surgery, Keio University, Tokyo, Japan*

Background: It was reported that type I interferon (IFN) is involved in the pathogenesis of rheumatoid arthritis (RA) [1–3], while the relevance of the IFN signature to RA disease activity and progression remains unclear. There were few reports about the expression of IFN in synovial fluid and joint cartilage.

Objectives: The aim of this study is to investigate the role of IFN in the pathogenesis of RA by means of the analysis of joint tissues of RA patients comparing with those of osteoarthritis (OA) patients.

Methods: Synovial fluid, synovia and cartilage were collected from RA and OA patients (n=10 for each) during total knee arthroplasty in our hospital and blood samples were collected just before surgery. As preoperative therapy for RA, Methotrexate (MTX) was administered to 9 patients (dose ranged (4–12mg), DMARDS without MTX to 2, biological DMARDS to 2, Prednisolone (PSL) to 6 (dose 1–5mg). Quantities of IFN alpha or beta of blood and joint fluid were measured with ELISA (PBL Assay Science, USA), and expression of IFN alpha, beta and TNF alpha of synovia and joint cartilage were measured with real time PCR. In RA patients. Serum biomarkers such as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Rheumatoid Factor (RF), hemoglobin and platelet were measured and investigated correlation with the quantities of IFN of blood or joint tissues. Medication for RA were investigated as well.

Results: In blood and synovial fluid of RA patients, IFN alpha and beta were highly detected, while they were not detected in those of OA patients. The expression of IFN alpha and beta of RA cartilage were much higher than those of OA whereas they were not expressed in synovium of both RA and OA. Expression of IFN was not correlated with that of TNF alpha in RA patients. Statistical analysis revealed that RF was related with blood and joint IFN and other markers were not. Medications for RA were not correlated with IFN expression.

Conclusions: IFN was highly expressed in RA synovial fluid, joint cartilage and blood, not in OA. IFN immunotherapy has been reported to induce RA [4–5], therefore abundant IFN might induce RA and inhibit cure of RA. Our results showed that RF was related with blood and joint IFN. It can be speculated that RF might be an index of IFN regulation in RA patient, however, more samples must be investigated to prove this speculation.

AB0048 ANTIPHOSPHOLIPID ANTIBODIES, INTERLEUKIN-6 AND TUMOR NECROSIS FACTOR-α IN ATHEROSCLEROTIC PROCESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

N.A. Bashlakova[1], T.D. Tyabut[2], A.E. Buglova[2]. *[1]Ultrasound Diagnostics Department; [2]Cardiology and Rheumatology Department, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus*

Background: Systemic inflammation has been postulated to be an independent cardiovascular risk factor, particularly in patients with autoimmune rheumatic disorders (ARD), such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), and is associated with accelerated atherosclerosis. There is some evidence to suggest that antiphospholipid antibodies (aPL) may also play a role in the development of atherosclerosis. However, it is few data about the relationship between these autoantibodies and inflammatory mediators in the development of atherosclerosis.

Objectives: To clarify the involvement of inflammatory mediators and aPL in the atherosclerotic process in patients with ARD.

Methods: The study included 87 female patients with ARD (RA (n=47), mean age 45,0 (33,0; 51,0) years old, disease duration 9,0 (3,0; 14,0) years, disease activity (DAS28=5,37 (4,69; 5,86) points); SLE (n=40), mean age 33,5 (27,5; 44,5) years old, disease duration 8,0 (5,0; 14,5) years, disease activity SLEDAI-2K 7,0 (4,0; 11,5) points). Sixty healthy women (mean age 40,5 (36,0; 47,0) years old) formed the control group.

The levels of high sensitive C-reactive protein (hs-CRP), interleukin-6 (IL-6), tumor necrosis factor - α (TNF-α), LA, IgG/IgM antibodies to cardiolipin (aCL), β2-glucoprotein-1(aβ2-GP1), annexin V (aAnV) and prothrombin (aPT)) were determined with ELISA. Intima-media thickness (IMT) of the carotid artery wall and the presence of atherosclerotic plaques were revealed ultrasonographically according to the described ESH/ESC Guidelines.

Results: The levels of hs-CRP, IL-6, TNF-α were significantly higher in ARD patients than in the control group, which indicates the disease activity. Furthermore, the patients with SLE had a significant correlation between IL-6 and SLEDAI-2K (r=0,471, p=0,002), TNF-α and SLEDAI-2K (r=0,499, p=0,001), whereas the patients with RA had only significant correlation between hs-CRP and DAS28 (r=0,355, p=0,031).

The concentration of IgG aCL, IgG and IgM aβ2-GP1, IgM aAnV, IgG aPT, LA were higher in patients with SLE than in the control group, and the levels of IgG and IgM aCL, IgM aβ2-GP1, IgG and IgM aAnV, LA were higher in patients with RA v.s. the control group.

We revealed a correlation between IgG aCL, IgG aβ2-GP1, IgG aAnV and TNF-α, IgG aCL and IL-6 in SLE patients, and only one between IgG aAnV and hs-CRP in RA patients. There wasn't any correlation between aPL and inflammatory mediators in the control group.
Univariate analysis has demonstrated an association of IgG aAnV with IMT (r=0,320, p=0,044) in SLE patients and positive association between TNF-α and IMT (r=0,362, p=0,028) in RA patients. Furthermore, we found an association between IL-6 and IgG aPT (r=0,426, p=0,038), TNF-α and IgG aCL (r=0,419, p=0,042) in SLE patients with carotid atherosclerosis. There wasn't any association between investigated parameters in the control group.
Conclusions: The association between inflammatory mediators and disease activity has been confirmed in ARD patients. Increased autoimmune activity has been verified both in patients with SLE and RA. It has been determined that IgG aAnV had more significance for IMT in patients with SLE, TNF-α - in RA patients. Our data can suggest that inflammatory mediators and antiphospholipid antibodies are involved in the atherosclerotic process in patients with ARD.

AB0049 NF-κB-INDUCING KINASE REGULATES LTβR-DRIVEN NF-κB SIGNALING AND INFLAMMATORY ACTIVATION OF ENDOTHELIUM

P. Kucharzewka[1], C.X. Maracle[2], J.P. van Hamburg[2], K.C. Jeucken[2], H. Olsson[1], S.W. Tas[2]. *[1]Imed Ria, AstraZeneca, Mölndal, Sweden; [2]Department of Clinical Immunology & Rheumatology and Laboratory for Experimental Immunology, AMC, University of Amsterdam, Amsterdam, Netherlands*

Background: Sites of chronic inflammation, such as rheumatoid arthritis synovial tissue, are characterized by neovascularization and often contain tertiary lymphoid structures with characteristic features of lymphoid organs such as endothelial venules (HEV), and sometimes even true germinal centers. Ligation of the lymphotoxin (LT)-β receptor (LTβR) results in activation of both canonical and NF-κB-Inducing Kinase (NIK)-dependent non-canonical NF-κB signaling in endothelial cells (ECs) and plays a crucial role in lymphoid neogenesis. Non-canonical NF-κB signaling in ECs promotes inflammation-induced angiogenesis and triggers the development of the cuboidal HEV appearance. However, the relative contribution of the individual pathways to the acquisition of leukocyte traffic-regulating properties by ECs is less well understood.
Objectives: To identify the molecular pathways by which LTβR drives inflammatory activation of ECs to promote interactions with leukocytes.
Methods: Primary human ECs were treated with LTβ or LIGHT to activate LTβR. Induction of downstream signaling pathways was assessed by western blot analysis and NF-κB transcription factor ELISA. The expression of adhesion molecules, inflammatory cytokines and chemokines, such as CXCL1, CXCL5, CXCL8 and GM-CSF in ECs was measured by RT-qPCR and cytokine antibody arrays. EC interactions with leukocytes were determined by an adhesion assay, and EC barrier integrity was assessed by a permeability assay. To repress canonical NF-κB signaling pathway, a small molecule inhibitor of IKKβ was used, and inactivation of non-canonical NF-κB signaling was achieved with siRNAs targeting NFκB2. The role of NIK in LTβR signaling was investigated using small molecule inhibitors of NIK, siRNAs targeting NIK and adenoviral vectors encoding wild type and kinase-deficient NIK.
Results: LTβR triggering in ECs resulted in activation of both canonical and non-canonical NF-κB signaling pathways and induced the expression of inflammatory cytokines and chemokines (CXCL1, CXCL5, CXCL8, MCP-1, GM-CSF, CCL5). Consistent with inflammatory activation of ECs, LTβR ligation also induced adhesion of immune cells to activated endothelium and increased permeability across EC monolayers. IKKβ inhibition completely repressed LTβR-induced inflammatory activation of ECs, indicating that this process was mediated through canonical NF-κB signaling. Interestingly, inactivation of NIK with small molecule inhibitors and siRNAs significantly decreased LTβR-induced expression of inflammatory cytokines and adhesion of immune cells to endothelium, whereas silencing of NFκB2 had no effect. This suggests that the non-canonical pathway is dispensable for NIK-dependent activation of endothelial cells through the canonical NF-kB pathway. Further analyses, including silencing of NIK and NIK overexpression, demonstrated a role for NIK in activation of the canonical NF-kB pathway by amplifying IKK complex activity.
Conclusions: These findings suggest that in addition to its pivotal role in the non-canonical pathway, NIK can serve as an amplifier of the canonical NF-κB pathway and associated inflammatory responses in ECs mediated by LTβR ligation, which may play a role in development and maintenance of chronic inflammation.

AB0050 IMPAIRED ADIPONECTIN AND LEPTIN LEVELS DURING OSTEOARTHRITIS ONSET AND DEVELOPMENT IN STR/ORT MICE

R. Giambelli, S.K. Bernini, M. Perrella, A. Grotti, R. Cavagnoli, G. Samuelli, P. Garofalo, T. Zanelli, G. Caselli, L.C. Rovati. *Rottapharm Biotech, Monza, Italy*

Background: Obesity is a risk factor for osteoarthritis (OA). In obese subjects OA develops not only in weight-bearing joints but also in non-weight-bearing joints, suggesting that dysregulated metabolism in obese patients may promote OA onset.
As obesity evolves many physiological parameters are dysregulated, including the levels of adipokine hormones such as leptin and adiponectin. For this reason, it has been suggested that adipokine levels in serum and synovial fluid are associated with a worsening of synovial inflammation and OA progression in these patients(1).
In vivo and in vitro studies show that high levels of leptin induce the synthesis of metalloproteases involved in cartilage degradation(2). Conversely, dietary-induced weight loss is associated with increased adiponectin serum levels and reduced loss of tibial and femoral cartilage volume, suggesting a protective role of adiponectin in OA.
STR/ort mice are an animal model of spontaneous OA characterized by early pathology development (at about 20 weeks) and dysregulated metabolism(3). Notably, these mice have adiponectin serum levels lower than those found in control mouse strains(4).
Objectives: To evaluate whether adiponectin and leptin serum levels are associated with OA development and/or progression in STR/ort mice.
Methods: First, we measured the time course of adipokine levels in STR/ort mice before the onset of OA (at 8, 14 and 20 weeks of age), and in age-matched CBA control mice. Then, we calculated the ratio leptin/adiponectin (L/A) in the serum of STR/ort mice during OA progression (at 20, 30 and 40 weeks). Blood samples were collected from caudal vein (time course) or from vena cava at sacrifice, when knee joints were collected, processed for histology and blindly scored according to OARSI and Mankin's methods.
Results: Adiponectin serum levels in STR/ort mice at 8, 14 and 20 weeks were significantly lower than in age-matched CBA mice. Instead, leptin serum levels in STR/ort mice were higher than in CBA strain at 14 and 20 weeks. Consequently, there was a relevant difference in the ratio L/A between the two strains, with greater L/A values in STR/ort mice at 14 and 20 weeks. (Table 1)
In STR/ort mice, the ratio L/A tended to further increase between 30 and 20 weeks (1.73±0.16 from 1.28±0.17, respectively), in parallel with the increase in OARSI scores of knee joints (11.1±1.5 vs 8.4±1.3). The histopathological score increased in STR/ort mice even between 30 and 40 weeks, but without a concomitant increase in the ratio L/A.

Adipokines levels (mean ± SEM)

Age (Weeks)	8	14	20
CBA (n=10)			
Adiponectin (µg/ml)	20.2 ± 0.7	16.0 ± 0.4	14.5 ± 0.3
Leptin (ng/ml)	1.5 ± 0.3	2.5 ± 0.3	3.1 ± 0.4
L/A	0.07 ± 0.02	0.16 ± 0.02	0.21 ± 0.03
STR/ort (n=14)			
Adiponectin (µg/ml)	9.2 ± 0.3**	7.3 ± 0.2**	6.0 ± 0.2**
Leptin (ng/ml)	3.3 ± 0.5	8.7 ± 1.3**	7.9 ± 1.1**
L/A	0.36 ± 0.05	1.15 ± 0.16**	1.28 ± 0.17**

**p<0.001 STR/ort vs CBA

Conclusions: We show for the first time that leptin serum levels and the ratio L/A in STR/ort mice are higher than in CBA mice, and that the ratio L/A in STR/ort mice increases as their histopathological scores worsen. We suggest that dysregulated levels of these adipokines may be associated or even precede OA development in this animal model.

AB0051 INTERLEUKIN-6 BLOCKADE WITH TOCILIZUMAB DECREASES METALLOPROTEINASE-9 ACTIVITY IN SYNOVIAL FIBROBLASTS STIMULATED WITH SYNOVIAL FLUIDS OF PATIENTS WITH RHEUMATOID ARTHRITIS OR SPONDYLOARTHRITIS

R. Blas[1], H. Tamashiro[2], A. Munarriz[3], R. Pardo-Hidalgo[4], M.S. Di Genaro[5,6]. *[1]Centro Médico MEDICI; [2]Clínica Bolivar; [3]Centro Médico CENYR, San Luis; [4]Centro de Rehabilitación Médica CER, San Juan; [5]National University of San Luis; [6]Laboratory of Immunopathology, Multidisciplinary Institute of Biological Investigations - San Luis (IMIBIO-SL), National Council of Scientific and Technical Investigations (CONICET), San Luis, Argentina*

Background: Fibroblast-like synoviocytes (FLS) exhibit a transformed aggressive phenotype characterized by increased secretion of pro-inflammatory cytokines and matrix metalloproteinases (MMPs). Early pathological mechanisms that explain the change to an altered phenotype in FLS of chronic inflammatory arthropathies remain largely unknown. The composition of synovial fluids (SF) is very complex and strongly influences the microenvironment of joints including FLS thus representing an inseparable element of the disease. The MMP-9 is a

gelatinase expressed in three major forms: dimer, monomer and a complex with neutrophil gelatin-associated lipocalin (NGAL). Interleukin-(IL)-6 is a pleiotropic cytokine expressed by a variety of immune and non-immune cells. However, the mechanisms by which IL-6 contributes to the pathogenesis of chronic arthropathies are not fully understood.
Objectives: The purpose of the present work was to perform a comparative study of the IL-6 production and MMP-9 activity in FLS stimulated with SF from patients with osteoarthritis (OA), rheumatoid arthritis (RA) or spondyloarthritis (SpA). In addition, the effect of IL-6 blockade on MMP-9 activity was evaluated.
Methods: Primary FLS were obtained from SF of the RA patients. Furthermore, the SW982 human synovial cell line was used. The SF of patients with OA (n=11), RA (n=11) or SpA (n=9) patients were pooled. The FLS were stimulated with OA, RA or SpA SF pools and supernatants (SN) were collected after 24, 48 and 72 h. The IL-6 levels were assessed in the SN by ELISA. The gelatinase activity of the SN was determined by zymography. The IL-6 function was blocked with the anti-IL-6 receptor antagonist tocilizumab (TCZ) (200μg/ml).
Results: Earlier induction of IL-6 in SW982 cell line was observed by RA and SpA SF stimulation since significant levels were detected at 24 h ($p<0.001$ and $p<0.01$ compared with non-stimulated cells, respectively), whilst OA SF induced significant IL-6 secretion at 72 h ($p<0.01$). Similar results were observed in primary FLS. In contrast to SF of OA patients, SF of patients with RA or SpA induced increased and sustained secretion of active MMP-9. Moreover, the molecular weight band corresponding with NGAL-MMP-9 complex, considered a protected form of MMP-9, was detected with higher intensity in the SN of FLS stimulated with RA or SpA SF compared with OA SF ($p<0.001$). In the presence of TCZ, significant inhibition in the gelatinase activity of all MMP-9 forms was observed at 48h of stimulation with RA or SpA SF ($p<0.001$ for MMP-9 dimer and NGAL-MMP-9 complex; $p<0.01$ for MMP-9 monomer, compared with FLS stimulated in absence of TCZ).
Conclusions: We conclude that SF of patients with inflammatory arthritis recreate a differential microenvironment for FLS that impacts on early phenotypic changes of these cells. The IL-6 provokes augmented and persistent MMP-9 activity in FLS stimulated with RA or SpA SF. This work identifies TCZ as an inhibitor of all forms of MMP-9.

AB0052 INCREASED PERIPHERAL CD8+ T CELL RESPONSES IN SLE BY LOW-DOSE IL-2 TREATMENT

R. Zhang, J. He, X. Sun, Y. Zou, Y. Gan, Z. Li. *Peking University People's Hospital, Beijing, China*

Background: CD8+ T cell responses to viral pathogens is crucial for the prompt resolution of acute infections. SLE patients are more likely to have infections due to suppression of immune system by long-term glucocorticoid and immunosuppressive agent intake. Our previous study showed that low-dose IL-2 is effective in SLE.
Objectives: The present study is to evaluate the potential anti-infection effect of low-dose IL-2 in refractory SLE patients.
Methods: Nine refractory SLE patients and 9 health controls (HCs) were recruited three cycles of 1 million IU recombinant human IL-2 (rhIL-2), administered subcutaneously every other day for 2 weeks, followed by a 2-week break. The disease activitise were evaluated by rheumatologist. The frequencies of T cell subsets were assayed by flow cytometry. Virus-specific CD8 T cells responses were determined based on TNF-a, IFN-g and Grazmy B producing CD8 T cells upon CMV-EBV-Flu (CEF) viral peptide pool stimulation and subsequent intracellular staining.
Results: Most patients showed good clinical responses after three cycles of low-dose IL-2 treatment. Clinical improvement was observed in SIR-4 response, improved complement 3 and 4 serum level and decreased anti-ds-DNA serum level. Functional profiling of CD8 T cells in low-dose IL-2 treated patients revealed an increased in the frequencies of CEF viral peptide specific TNF-a$^+$ and Grazmy-B$^+$ CD8 T cells. Moreover, low-dose IL-2 treated patients showed stronger antigen-specific response demonstrated by an increased stimulated/non-stimulate TNF-a-producing CD 8 T cells proliferation fold. Compared with HCs, SLE patients showed significantly lower frequencies of CEF specific Grazmy-B producing CD8 T cell, and treatment with low-dose IL-2 significantly increased the frequency of these Grazmy-B$^+$ CD8 T cells in SLE patients.
Conclusions: Low-dose IL-2 treatment was effective and safe in refractory SLE patients. Virus-specific antigen-specific CD8 T cell response could be enhanced upon this treatment which might be potentially valuable in anti-infection in SLE.

AB0053 MANGIFERIN MODULATES TNF-ALPHA AND MMP-9 SIGNALING

S. Somani[1,2], K. Modi[3]. *[1]Pharmacology, RK University, Rajkot; [2]Pharmacology, Torrent Pharmaceuticals, Gandhinagar; [3]Pharmacology, B K Mody Government Pharmacy College, Rajkot, India*

Background: Rheumatic manifestation such as arthritis, spondylitis are the most common frequent extra-intestinal manifestations of inflammatory bowel disease (IBD), affecting 6 to 46% of patients. IBD is an umbrella term with two most prevalent entities namely Crohn's disease and Ulcerative colitis, defined as idiopathic chronic, relapsing and remitting inflammatory condition of intestinal tract. MMP-9, a matrixin is involved in the degradation of extracellular matrix promoting inflammation. Studies on MMP-9 knockout mice illustrated protection from collagen induced rheumatoid arthritis (RA) and Dextran sulphate sodium (DSS) induced colitis. Furthermore elevated MMP9 levels can be found in the synovial fluid of RA patients as well as IBD patients signifying that targeting MMP9 may have therapeutic importance. Mangiferin, an active component of Mango has demonstrated anti-inflammatory effects in the treatment of rheumatoid arthritis with low side-effects [1,2]; but its usefulness in chronic remission and relapse phases of human IBD i.e. chronic DSS model have not screened till date.
Objectives: We investigated the therapeutic potential of Mangiferin; in a clinical relevant chronic model of DSS induced colitis in mice.
Methods: Female BALB/c mice (8 to 12 wks) were randomized into four groups. Colitis was induced by cyclical administration of 5% DSS to mice i.e. 3 cycles of DSS with every cycle consisting of 7 days DSS followed by 7 days of autoclaved drinking water (7D DSS + 7D water). Group I (Normal control): free access to autoclaved drinking water. Group II (DSS control): free access to 5% DSS. Group III (DSS + Mangiferin_30mg/kg): free access to 5% DSS + oral Mangiferin at 30mg/kg. Group IV (DSS + Mangiferin_60mg/kg): free access to 5% DSS + oral Mangiferin at 60mg/kg. Mangiferin treatment was initiated following second cycle of DSS (i.e. Day 21); after assuring that colitis relapsed in mice. One fragment of the colon was fixed in 10% neutral buffered formalin for microscopic examination while the remaining tissue was divided into parts and stored at -70℃ for assessment of biochemical markers of oxidative stress and inflammatory cytokines such as TNF-α, IL-1β, MMP-9.
Results: Mangiferin treatment ameliorated the *clinical parameters* (body weight loss, stool consistency, occult blood), reduced *microscopic damage* (re-established mucosal architecture, abridged neutrophil infiltration), restored *epithelial barrier integrity* (diminished goblet cell loss), attenuated biochemical markers of *oxidative stress* (GSH, CAT, SOD, MDA, MPO), crucial *inflammatory cytokines* TNF-α, IL-1β and attenuates *MMP-9* levels implicated in the pathogenesis of arthritis and IBD.
Conclusions: Considering the beneficial effects of Mangiferin in arthritis and IBD, we suggest that it would be valuable to use Mangiferin in IBD patients with arthritis as its extra-intestinal manifestation.

AB0054 CXCL4 POTENTIATES TLR-DRIVEN POLARIZATION OF HUMAN DENDRITIC CELLS TOWARDS CYTOKINE PRODUCTION, ANTIGEN CROSS-PRESENTATION AND INCREASES STIMULATION OF CD8+T-CELLS

S.C. Silva-Cardoso[1,2], A.J. Affandi[1,2], L. Spel[2,3], M. Cossu[1,2], M. Boes[2,3], T.R. Radstake[1,2]. *[1]Depart. of Rheumatology & Clinical Immunology; [2]Laboratory of Translational Immunology; [3]Department of Pediatrics, University Medical Center, Utrecht, Netherlands*

Background: CXCL4 is a chemokine produced by activated platelets and immune cells. Several studies have reported that CXCL4 plays a critical role on physiological processes since it affects the proliferation and maturation of megakaryocytic and hematopoietic progenitor cells, regulates coagulation and wound healing, displays anti-tumoral and angiostatic activity and induces immune cell modulation. Dysregulation of these processes causes the disturbance of the immune system and homeostasis, and might lead to pathological conditions. Indeed, a strong correlation was previously found between elevated CXCL4 levels in the circulation and the clinical features of patients with systemic sclerosis (SSc) (1). Dendritic cells are essential players in innate defence and bridging towards adaptive immune responses, thereby contributing to both immune activation and maintenance of homeostasis.
Objectives: Considering previous observations on the association of dendritic cells and T-cell dysfunction in SSc, we here investigated the effect of CXCL4 on monocyte-derived DC (moDC) differentiation, on Toll-like receptor (TLR)-mediated responses and on activation of polyclonal and antigen-specific CD8$^+$T-cells.

Methods: To this end, we compared the phenotype, TLR-mediated responses and CD8$^+$T-cell activation by moDCs and CXCL4 exposed moDCs.
Results: Already prior to TLR stimulation, CXCL4-moDCs displayed a more matured phenotype. We found that CXCL4 exposure can sensitize moDCs for TLR-ligand responsiveness, as illustrated by a dramatic upregulation of CD83, CD86 and MHC class I, and markedly increased secretion of IL-12 and TNF-α in response to TLR3 and TLR7/8-agonists. Next, we analyzed the effect of CXCL4 in modulating DC-mediated CD8$^+$ T-cell activation. CXCL4-moDCs strongly potentiated proliferation of polyclonal CD8$^+$ T-cells and production of interferon (IFN)-γ and IL-4, in an antigen-independent manner. While the internalization of antigen was comparable to moDCs, antigen processing by CXCL4-moDCs was impaired. Yet, these cells were more potent at stimulating antigen-specific CD8$^+$ T-cell responses.
Conclusions: Together our data supports that increased levels of circulating CXCL4 may contribute to immune dysregulation through the modulation of innate and adaptive responses by dendritic cells.

AB0055 IL-1 BETA AND CASPASE-1 P45 EXPRESSION IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF PATIENTS WITH ADULT-ONSET STILL'S DISEASE

S. Bindoli, F. Fabris, L. Punzi, P. Galozzi, P. Sfriso. *Rheumatology Unit-Department of Medicine, University of Padova, Padova, Italy*

Background: Adult-onset Still's disease (AOSD) is a systemic inflammatory condition characterized by episodes of spiking fever, evanescent rash, arthralgia, leukocytosis and hyperferritinemia. The inflammatory status of AOSD could result from a deregulation of the NLRP3 inflammasome as Interleukin-1 (IL-1) is pivotal in the pathogenesis of AOSD.
Objectives: To evaluate IL-1 beta and caspase-1 p45 expression in AOSD patients.
Methods: 11 AOSD patients with systemic chronic disease (mean age: 44.5±15.6 years; mean disease duration: 3.0±1.7 years) and 5 healthy donors (mean age: 41.8±7.5) were enrolled. Anakinra (in 6 patients) and DMARDs (in 5 patients) adequately controlled the disease. PBMCs (peripheral blood mononuclear cells) obtained by Ficoll centrifugation were stimulated with lipopolysaccharide (LPS) [10 ng/ml] and ATP [1 mM] for 0.5, 1, 6 and 24 hours. IL-1β level was measured in the supernatant by ELISA and the expression of caspase-1 p45 at protein level was detected by Western Blotting.
Results: In unstimulated PBMCs minimal IL-1β production was found both in AOSD patients and controls. After 6 hours stimulation, IL-1β level was increased whereas we observed a reduced processing of caspase-1 p45 particularly in AOSD patients treated with Anakinra.

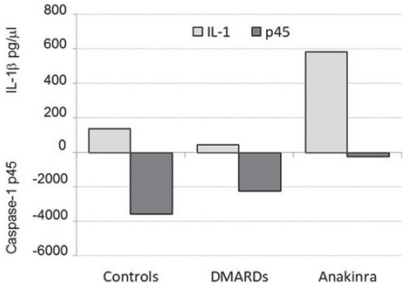

Figure 1. IL-1β secretion and caspase-1 p45 intracellular expression: differences between stimulated and unstimulated PMBCs in anakinra and DMARDs treated AOSD patients and in healthy controls.

Conclusions: Patients with refractory AOSD, who therefore need Anakinra, seem to have an increased production of IL-1β compared to healthy controls and to AOSD patients who respond to standard therapies. Altered processing of caspase-1 p45 in AOSD patients support the involvement of the NLRP3 inflammasome pathway in the pathogenesis of the disease.

AB0056 EMERGING ROLE OF IL-33/ST2 AXIS IN ENDOTHELIAL CELL INJURY OF LUPUS NEPHRITIS

S. Yu, Y. Tao. *Rheumatology, The Second Affiliated Hospital of Guangzhou Medical, Guangzhou, China*

Background: "Alarmins" are prototypic endogenous pro-inflammatory factors as they are released from necotic cells and provoke local damage or systemic inflammation. Evidences are accumulating to support the inclusion of "Alarmins" as targets of autoreactivity as well as inducers in the pathogenesis of Systemic Lupus Erythematosus (SLE). Interleukin (IL)-33 is a novel member of the family of "Alarmins" because of its characteristics and functions in mediating host immune responses. On this background, we sought to determine the role of IL-33/ST2 axis in lupus pathogenesis. The role of IL-33/ST2 axis has not previously been described in lupus nephritis.
Objectives: This project will study the followings: (1) To determine whether IL-33 was present in renal glomerular endothelial cells; (2) To assess the functional and intracellular signal transuction mechanisms regulating the link between IL-33/ST2-mediated innate immunity and inflammation in CD4$^+$ T cells-endothelial cells co-culture system of lupus patients.
Results: Immunofluorescence (IF) for IL-33 in the kidney were performed in both MRL^{lpr} lupus mice and C57BL/6J mice. On double staining for IL-33 and lectin, IL-33 was clearly seen in glomeruli and also in peritubular areas. To determine whether the IL-33 staining in glomeruli and peritubular areas was in endothelium, double IF staining for IL-33 and von Willebrand factor (vWF) was performed. IL-33 co-localized with vWF in glomeruli and in peritubular areas. The increased levels of IL-33 mRNA transcripts were detected in kidney of MRL^{lpr} lupus mice compared with C57BL/6J mice. Expression of cell-surface ST2 was increased on the CD4$^+$ T cells of lupus patients when compared with healthy controls. Serum sST2 level was significantly higher in SLE patients with *flare* than those without *flare* ($p<0.05$).
Conclusions: As a result of external stimuli or infection, renal glomerular endothelial cells undergo cellular death and release the "Alarmin", IL-33, to alert the lupus immune system. Released IL-33 interact with their target cells, CD4$^+$ T cells via their specific receptor ST2 to subsequently induce innate and adaptive responses, activate inflammatory pathways in the pathogenesis of lupus nephritis.

AB0057 THE ROLE OF GROWTH DIFFERENTIATION FACTOR (GDF)-15 AND TRANSFORMING GROWTH FACTOR (TGF)-β IN THE DEVELOPMENT OF PULMONARY FIBROSIS

V. Yazisiz, S. Oygen, M. Çavuşoğlu, M. Kahraman, E.G. Gök, S. Karahan, I. Uçar, M.E. Terzioğlu. *Rheumatology, Akdeniz University, Antalya, Turkey*

Background: The pathogenesis of pulmonary fibrosis is not fully understood and it is thought to develop secondary to inflammation. The main cause of pulmonary fibrosis is considered to be interstitial lung disease (ILD), which can be associted with connective tissue disorders (CTD).
Objectives: The aim of this study was to investigate serum GDF-15 and TGF-β levels in patients with diagnosis of CTD associated with ILD.
Methods: A total of 103 adult patients (19 rheumatoid arthritis, 18 Sjögren's syndrome, 32 systemic sclerosis, 3 systemic lupus erythematosus and 31 healthy controls) were included in the study. Pregnant, acute coronary syndrome, previous myocardial infarction and/or stroke history, heart failure and malignancy were excluded. Serum GDF-15 and TGF-β levels were studied by ELISA method in peripheral blood samples.
Results: There were 44 patients with CTD-ILD, 28 patients without ILD and 31 healthy controls. The age and gender distributions of participants in all three groups were not different. Serum TGF-β and GDF-15 levels in patients with CTD-ILD and CTD without ILD were significantly higher than healthy controls (respectively, 3.05±0.26, 3.05±0.22, 1.39±0.33 pg/ml, $p<0.001$ for TGF-β and 1.17±0.17, 1.12±0.05, 0.95±0.21 pg/ml, $p<0.001$ for GDF-15). There were no statistically different from patients with ILD and without ILD for both TGF-β (p:0.864) and GDF-15 levels (p:0.146) in CTD. Also, GDF-15 and TGF-β levels of patients with systemic sclerosis were not different from other CTD's.

Table 1. Comparison of analysis results of patient and control groups

	Connective tissue disorders		Healty Controls (n: 31)	p
	ILD (+) (n: 44)	ILD (–) (n: 28)		
Gender (Female) (n, %)	35 (79.5%)	22 (78.5%)	23 (74.2%)	0.831
Age (years) (Mean±SD)	53.95±11.9	53.61±9.2	51.68±12.8	0.641
TGF-β(pg/ml) (Mean±SD)	3.05±0.26	3.05±0.22†	1.39±0.33	<0.001
GDF-15 (pg/ml) (Mean±SD)	1.17±0.17	1.12±0.05‡	0.95±0.21	<0.001

†ILD vs non-ILD p=0.864. ‡ILD vs non-ILD p=0.146.

Conclusions: Our findings indicate that TGF-β and GDF-15 are increased in CTD patients but, they are not a specific markers for CTD-ILD

AB0058 LEVEL OF VASCULAR ENDOTHELIAL GROWTH FACTOR A AND INTIMA-MEDIA THICKNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

V.O. Omelchenko, E.A. Letyagina, M.A. Korolev. *FSBSI "Scientific Institute of clinical and experimental lymphology", Novosibirsk, Russian Federation*

Background: Early development of atherosclerosis (AS) with higher mortality risk is observed in patients with rheumatoid arthritis (RA). Actually, this problem hasn't been solved. That's why researches devoted to finding of relationships between RA and AS is still of current interest. In RA pannus formation accompanied by the development of new blood vessels forms main clinical manifestation. Vascular endothelial growth factor A (VEGF-A) is a heparin-binding glycoprotein, that induces the growth of blood vessels and plays a role in differentiation of endothelial cells. The expression of VEGF-A increases when plaque developes.
Objectives: To determine the particular qualities of VEGF-A production in patients with RA and various atherosclerotic damage of vessels.
Methods: 67 Caucasian patients with RA (age - 52 yr., [38;59], DAS28 5,25 [5,5;6,4]) were included in our study. Patients had American College of Rheumatology (ACR)-defined RA (1987 classification criteria). 45 Europeoid patients with OA (56 yr., [50;63]) were in control group. All patients gave written informed consent before enrollment. Level of VEGF-A was determined by ELISA for quantitative detection of human VEGF-A (Bender MedSystem GmbH, Austria). Range of atherosclerotic damage was assessed by ultrasonography with measurement of carotid intima-media thickness (IMT). IMT measured was compared with normal values according to the age and sex classes: younger 40 yr - 0,7 mm, 40–50 yr - 0,8 mm, elder 50 yr - 0,9 mm for men; younger 45 yr - 0,7 mm, 45–60 yr - 0,8 mm, elder 60 yr - 0,9 mm for women. Results is presented as median and 25th/75th percentiles (Me [25th percentile; 75th percentile]. Descriptive statistics, non-parametric Mann-Whitney U-test, Kruskal – Wallis test were used for analysis of the results.
Results: No significant differences of IMT were found between groups with RA and OA. Abnormal IMT were observed in about half of patients (Table 1).

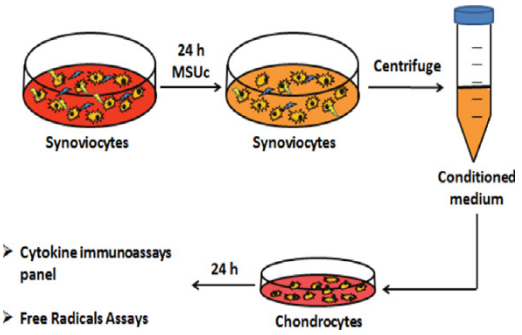
Table 1. IMT in patients with RA and OA

	IMT	IMT>N	Plaque
RA, n (%)	35 (52.2)	20 (29.9)	12 (17.9)
OA, n (%)	18 (40)	12 (26.7)	15 (33.3)

The highest level of VEGF-A was in OA-group with stenosing plaque ($p<0,01$). No significant differences were found between other OA-subgroup. In patients with RA the highest level of VEGF-A was observed in subgroup with abnormal IMT ($p<0,05$), but not with pluques. Generally, VEGF-A production in patients with normal IMT was higher in RA-patients, but not sugnificially.

Table 2. Level of VEGF-A in groups with different values of IMT

	IMT	IMT>N	Plaque without stesosis	Stenosing plaque
VEGF-A in OA-patients, pg/ml	392,30 [225,60;641,33]	396,90 [213,08;519,95]	651,05 [318,58;1041,25]	1148,50 [1041,3;1164,25]
VEGF-A in RA-patients, pg/ml	753,6 [434,4;1301,15]	1013 [595,6;1319,1]	837,25 [677,28;1267,25]	712,75 [505,28;1036,85]



Conclusions: Regulation of VEGF-A production may play a role in earlier onset of atherosclerosis in patients with RA.

AB0059 SYNOVIAL SECRETION OF PRO-INFLAMMATORY AND PRO-OXIDANT MOLECULES TRIGGERED BY MONOSODIUM URATE CRYSTALS INDUCES NGF AND H2O2 PAIN MEDIATORS IN THE CHONDROCYTE

A.G. Lopez-Reyes[1], D. Medina-Luna[2], M. Satamaria-Olmedo[2], K. Martinez-Flores[3], Y. Zamudio-Cuevas[3], J. Fernandez-Torres[3], G. Martinez-Nava[3], D. Clavijo-Cornejo[3], A. Olivos-Meza[4], M. Gutierrez[5], M. Fernandez-Moreno[6], F. Blanco[6], C. Pineda[5]. *[1]Laboratorio de Liquido Sinovial, Instituto Nacional de Rehabilitación "LGII"; [2]Laboratorio de Liquido Sinovial, Instituto Nacional de Rehabilitacion "LGII"; [3]Laboratorio de Liquido Sinovial, Instituto Nacional de Rehabilitacion "LGII"; [4]Arthroscopy Service, Instituto Nacional de Rehabilitación "LGII"; [5]Department of Rheumatic and Musculoskeletal Diseases, Instituto Nacional de Rehabilitacion "LGII", Mexico City, Mexico; [6]Rheumatology Service, INIBIC, CIBER-BBN, A Coruña, Spain*

Background: Gout is the most prevalent inflammatory arthropathy in young men, in which clinical manifestations are triggered by the deposits of monosodium urate (MSU) crystals in and around joints. From a clinical perspective, gouty attacks and tophaceous deposits have been associated to nodal osteoarthritis [1,2].
Objectives: To determine the molecular mechanisms associating MSU crystal deposits with chondrocyte activation and changes in articular cartilage.
Methods: Primary cultures of synoviocytes were activated with MSU crystals for 24 h, the resulting supernatant was used as a supplementary conditioning basal medium (CBM) for 24 h chondrocyte growth. The expression level profile of cytokines (IL-6, IL-8) and nerve growth factor (NGF) in the supernatant was measured. Production of reactive oxygen and nitrogen species, such as $O_2^{\bullet}$, H_2O_2, and $NO^{\bullet}$, was also measured intracellularly.
Results: Upon activation by MSU crystals, synoviocytes increased secretion of IL-6 and IL-8, as well as intracellular production of $O_2^{\bullet}$, H_2O_2, and $NO^{\bullet}$ in comparison to non-stimulated synoviocytes. Additionally, the chondrocytes incubated with CBM for 24 h increased significantly IL-6, IL-8, and NGF levels, as well as $O_2^{\bullet}$, H_2O_2, and $NO^{\bullet}$ levels when compared to non-stimulated chondrocytes. Secretion of these soluble mediators was even higher than the one observed in the synoviocytes and chondrocytes directly stimulated with MSU crystals.

Conclusions: Pro-inflammatory cytokine secretion induced by MSU crystals in synoviocytes triggers chondrocyte activation, intensifying the articular inflammatory state in gouty attacks. Furthermore, the increase in reactive species (particularly $NO^{\bullet}$, which inhibits proteoglycan synthesis) compromises the homeostasis of the extracellular matrix of the cartilage. Finally, overproduction of NGF and H_2O_2 by the chondrocyte functions a pain modulator during gout attacks.

AB0060 MODELLING DELAYED BONE HEALING IN A MOUSE-OSTEOTOMY MODEL TO EVALUATE THERAPEUTIC STRATEGIES FOR AFFECTED PATIENTS WITH RA

A. Lang[1,2,3], S. Fügener[1], P. Hoff[1], K. Schmidt-Bleek[4], T. Gaber[1,3], F. Buttgereit[1,3]. *[1]Department of Rheumatology and Clinical Immunology; [2]Berlin-Brandenburg School for Regenerative Medicine, Charité University Hospital; [3]German Arthritis Research Center; [4]Julius Wolff Institute and Center for Musculoskeletal Surgery, Charité University Hospital, Berlin, Germany*

Background: Anti-inflammatory treatment of rheumatoid arthritis (RA) using non-steroidal anti-inflammatory drugs (NSAID) or glucocorticoids (GC) as well as the disease itself, are supposed to negatively influence bone metabolism and healing. However, *in vivo* models allowing to evaluate therapeutic strategies for patients suffering from delayed bone healing are scarce and mainly created by critical size defects that are not representative for comorbity-induced disorders. In addition, there are no adequate rodent models allowing the analyses of the influence on the bone metabolism by the complete dysregulation of the immune system in RA as well as long-term medications with NSAID or GC. Previously, we have shown that immunologically restricted patients lack an adequate adaptation to hypoxia in the fracture hematoma thus facilitating healing disorders (1). The hypoxic microenvironment during the initial fracture-healing phase is known to be essential for activating the immunological reactions, which induce the regeneration. Furthermore, we performed a single-center retrospective study on fracture healing disorders showing a significant high prevalence for RA patients to be affected by delayed bone healing.
Objectives: In order to evaluate therapeutic strategies for affected patients with RA, we developed a model for delayed bone healing in a mouse-osteotomy model.
Methods: Female C57BL aged 12 weeks underwent osteotomy of the femur (fracture gap 0,7 mm) that was fixated with an external fixator (RIS-System). Lyostypt® (based on bovine Col I; mimicking extracellular bone matrix) was applied in the fracture gap and analysis was performed 2 and 3 weeks after surgery. The ratio of bone volume (BV) per total volume (TV) in the fracture gap was evaluated using *in vitro* μCT. In addition, Movat's pentachrome staining was performed to analyze the cellular and tissue composition within the fracture gap. To investigate the number of cells as well as the vessel formation, we used immunofluorescence to stain for Endomucin, PECAM-1 and DAPI. Quantitative analysis of histological staining was conducted by using ImageJ.
Results: We developed an *in vivo* mouse-osteotomy model showing delayed bone healing by applying Lyostypt® in the fracture gap. The BV, TV as well as the

ratio was significantly higher in the controls (empty gap = normal healing; n=8 per timepoint) as compared to the Lyostypt® group (n=8 per timepoint) 2 weeks after osteotomy and slightly higher after 3 weeks. Histological investigation showed the clear presence of the scaffold on both timepoints without briding cartilaginous tissue. The cell number as well as the vessel formation was significantly reduced within the fracture gap.

Conclusions: The results obtained so far support the hypothesis that we were able to develop a delayed healing or even non-union osteotomy model in mice by avoiding to create a critical size defect. Therefore, this approach represents a promising alternative animal model to evaluate therapeutic strategies to overcome bone healing complications in RA patients and perhaps other immunologically restricted patients.

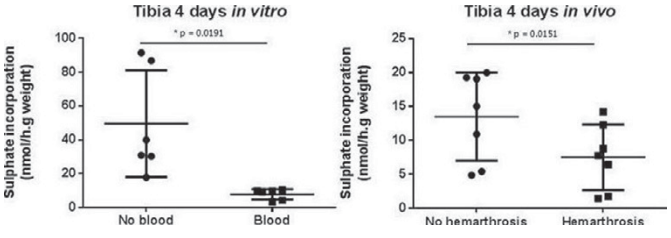
AB0061 35SULPHATE INCORPORATION ASSAY AS A NEW TOOL FOR MEASURING EARLY CARTILAGE DEGRADATION FOLLOWING BLOOD EXPOSURE IN VITRO AND IN VIVO IN F8 KO RATS

A.E. Pulles[1,2], K.R. Christensen[3,4], K. Coeleveld[1], M. Kjelgaard-Hansen[4], R.E. Schutgens[2], F.P. Lafeber[1], K. Roepstorff[4], S.C. Mastbergen[1]. *[1]Department of Rheumatology & Clinical Immunology; [2]Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands; [3]Veterinary Disease Biology, University of Copenhagen, Copenhagen; [4]Global research, Novo Nordisk A/S, Maaloev, Denmark*

Background: Joint damage upon bleeding causes significant morbidity in patients with hemophilia, and adds to joint degeneration after trauma or major joint surgery. To study the pathophysiology, rodent models with histology as primary outcome measure are often used. However, histological changes take time to develop and are subject to interpretation. Determining proteoglycan synthesis rate (PSR) in cartilage, by incorporation of radioactive ^{35}sulphate, is a sensitive method previously applied in human tissue and larger animal models to detect early cartilage changes. Isolating cartilage of small animals can be challenging, so a technique to shave off rat cartilage was developed.

Objectives: To study cartilage degradation following blood exposure, applying the ^{35}sulphate incorporation assay on rat tibial cartilage.



Methods: A total of 13 factor VIII knock out (F8KO) rats were bred and housed at Novo Nordisk A/S, Maaloev, Denmark. After euthanasia, the legs were removed and transported to UMC Utrecht, The Netherlands.

In vitro: within 24 hours after euthanasia the cartilage of 6 healthy F8KO rats was obtained by shaving off cartilage pieces of the tibia plateau by use of a scalpel. All cartilage explants were cultured for four days; in addition to culture medium, half of the cartilage samples were cultured with 50% v/v whole blood. After four days PSR was determined by adding 4uCi $Na_2{}^{35}SO_4$ to the cultures for four hours. $^{35}SO_4^{2-}$ is incorporated into newly synthesized proteoglycans. After digesting the cartilage pieces and precipitating the proteoglycans with cetylpyridinium chloride, the amount of radioactivity was measured by liquid scintillation analysis and normalized to the specific activity of the pulse medium, labeling time and wet cartilage weight.

In vivo: in 7 F8KO rats a unilateral joint bleed was induced by needle puncture and in the following four days until euthanasia, the animals received analgesia. At UMCU, the tibial cartilage was removed and PSR determined as described above.

All animal experiments were performed in accordance with and approved by the Danish Animal Experiments Council, Ministry of Food, Agriculture and Fisheries, Denmark.

Results: On average, a total of 1.6mg (0.8–3.1mg) cartilage per tibia could be obtained. The PSR of healthy cartilage determined after four days of culturing *in vitro* was on average 49.5 nmol/h.g. *In vitro* blood exposure resulted in a diminished synthesis: 7.7 nmol/h.g (p=0.0191), corresponding to an 84% decrease comparable to previously published experiments using human tissue [1]. *In vivo*, an induced joint bleed led to a 44% decrease in PSR (13.5 vs 7.5 nmol/h.g, p=0.0151).

Conclusions: This study demonstrates for the first time that PSR, by use of the ^{35}sulphate incorporation assay, can be determined in rat tibial cartilage and is affected by blood exposure *in vitro* and *in vivo*. As such, this assay can be a valuable tool to detect cartilage changes using joint degenerative rat models.

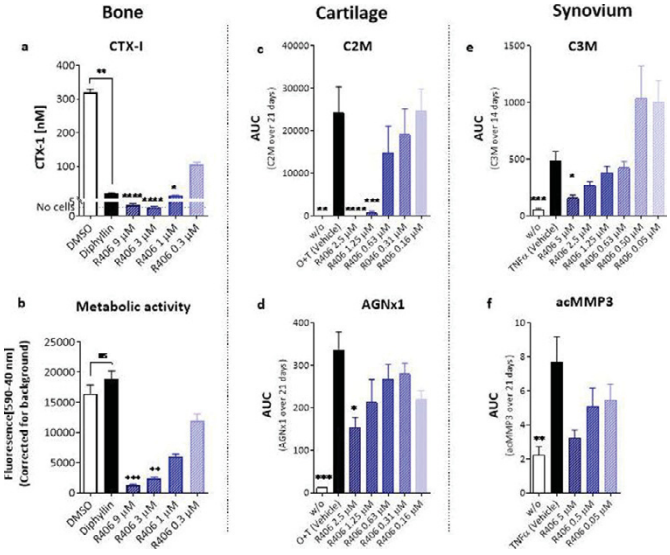
AB0062 EX VIVO BACK-TRANSLATION OF FOSTAMATINIB'S EFFECT ON JOINT ECM TURNOVER SHOWS SIGNIFICANT EFFECT ON BONE BUT NO EFFECT ON THE SYNOVIUM



C.F. Kjelgaard-Petersen[1,2], T.G. Christensen[3], P. Hägglund[2], M.A. Karsdal[4], C.S. Thudium[4], A.-C. Bay-Jensen[4]. *[1]Biomarkers and Reseach, Rheumatology, Nordic Bioscience, Herlev; [2]Bioengineering, Technical University of Denmark, Lyngby; [3]Orthopaedic surgery Unit, Gentofte University Hospital, Gentofte; [4]Biomarkers and Research, Rheumatology, Nordic Bioscience, Herlev, Denmark*

Background: It is important to establish translational methods that aid in pre-clinical go/no-go decision points to increase the success rate of approved DMARDs. The Spleen tyrosine kinase (Syk) inhibitor Fostamatinib (Fosta) was terminated for development for RA, due to insufficient effect on joint structure in phase III.

Objectives: The objective was to use a translational system of *ex vivo* cultures to back-translate the insufficient effect on joint structure described in clinical studies.

Methods: Human mature osteoclasts (HOC) seeded on bone, bovine cartilage explants (BEX) and human synovial explants (SME) were treated with R406 (API of Fosta) at 5μM-0.05μM. Osteoclasts were co-stimulated with 25 ng/ml M-CSF and RANKL, while BEX and SME were co-stimulated with TNFα 2 ng/mL and OSM 10 ng/mL (O+T) or TNFα 10 ng/mL, respectively. CTX-1 and Ca^{2+} were measured in conditioned medium (CM) from HOC. Metabolic activity of HOC was assessed with Alamar Blue. C2M and AGNx1 were measured in CM from BEX, while acMMP3, C1M, and C3M were measured in CM from SME. The biomarkers in BEX and SME CM were measured at 4 time points and the total release were quantified by area under the curve (AUC). CTX-1, C2M, AGNx1, acMMP3, C1M, C2M and C3M were measured with ELISA. $Ca^{2+}$was measured with ADVIA Chemistry system. Statistical differences of metabolic activity was calculated with One-way ANOVA with Dunnett's multiple comparison test. Statistical differences between biomarkers levels or AUC were calculated with Kruskall Wallis test with Dunn's multiple comparision test.

Results: R406 decreased the release of CTX-1 (Fig 1A) and Ca^{2+} in a dose-dependent manner, with a significant decrease at 1μM ($P<0.01$). This might be due to a toxic effect of R406 on HOC (Fig 1B) ($P<0.05$). R406 decreased the total release of C2M and AGNx1 in a dose-dependent manner in BEX. C2M was inhibited a concentrations down to 1.25μM ($P=0.034$), and AGNx1 down to 5μM ($P=0.012$). In SME R406 only decreased the release of C1M and C3M (Fig 1e) significantly at 5 μM (C1M: $P=0.03$, C3M: $P=0.046$), and tended to decrease release of acMMP3 (Fig 1f) at 5μM. The later was however not significant.

Conclusions: Serum-based biomarkers of the joint ECM turnover were measured in CM from HOC, cartilage and synovial explant cultures. R406 decreased bone resorption and HOC metabolic activity in a dose-dependent manner, together with the MMP-mediated degradation of type II (C2M) collagen and aggrecanse degradation of aggrecan (AGNx1) in cartilage. However, R406 had limited effect on the inflammation driven MMP-mediated degradation of type I (C1M) and III (C3M) collagen and activation of MMP-3. CTX-1, C2M, and C3M have previously been measured in OSKIRA-1, with a profile identical to the *ex vivo* measurements here [1].

AB0063 THE PROTECTIVE EFFECT OF PFTα ON ALCOHOL-INDUCED OSTEONECROSIS OF THE FEMORAL HEAD

C. Yixuan. *Orthopedics, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China*

Background: Epidemiologic studies have shown that alcohol plays a pivotal role in the development of osteonecrosis of the femoral head (ONFH). However, few studies have discussed the pathogenesis of or interventions for alcohol-induced ONFH.
Objectives: The aim of this study was to explore the underlying mechanism of alcohol-induced ONFH and the protective effect of pifithrin-α (PFTα).
Results: Through a series of *in vitro* assessments, we found that ethanol treatment significantly activated p53, suppressed Wnt/β-catenin signaling and inhibited osteogenic-related proteins, including runt-related transcription factor 2 (RUNX2), osteocalcin (OCN), osteopontin (OPN) and collagen I (COL1). Furthermore, by separating the cytoplasmic and nuclear proteins, we found that ethanol inhibited osteogenesisby impairing the accumulation of β-cateninin both the cytoplasm and nucleus in human bone mesenchymal stem cells (hBMSCs), which resulted from activating glycogen synthase kinase-3β (GSK-3β). In this *in vivo* study, we established alcohol-induced ONFH in rats and investigated the protective effect of PFTα. Micro-CT, hematoxylin & eosin (H&E) staining, immunohistochemical analyses, immunofluorescence staining, TUNEL staining, and fluorochrome labeling were performed to reveal the PFTα-induced therapeutic effects. H&E findings combined with TUNEL, caspase-3-cleaved immunohistochemical staining, and micro-CT images revealed obvious ONFH in the alcohol-administered rats, whereas significantly less osteonecrosis developed in the rats injected with PFTα. As the initiator of osteogenesis, RUNX2 and its downstream targets OCN, OPN, COL1 were immunostained in the femoral heads. These results indicated that those osteogenic-related proteins were significantly decreased in the alcohol-administered rats, whereas these results were reversed in the PFTα-injected rats. Fluorochrome labeling showed a similar result in that alcohol significantly reduced the osteogenic activity in the rat femoral head, which was blocked by the injection of PFTα.
Conclusions: Pifithrin-α, a p53 inhibitor, was able to block the ethanol-triggered activation of p53 in hBMSCs and alcohol-induced ONFH in a rat model. Its antagonistic effect against ethanol's effect on hBMSCs could be a clinical strategy to prevent the development of alcohol-induced ONFH.

AB0064 ADIPOSE STROMAL CELLS EXERT SPECIFIC EFFECTS ON OSTEOARTHRITIC SYNOVIAL MACROPHAGES

C. Manferdini[1], F. Paolella[1], E. Gabusi[1], L. Gambari[2], A. Piacentini[1], S. Fleury-Cappellesso[3], A. Barbero[4], M. Murphy[5], G. Lisignoli[1]. *[1]Laboratory of Immunorheumatology and tissue regeneration; [2]RAMSES Laboratory, Rizzoli Orthopaedic Institute, Bologna, Italy; [3]4EFS-Pyrénées-Méditerranée, Toulouse, France; [4]Department of Biomedicine, University Hospital Basel, Basel, Switzerland; [5]Regenerative Medicine Institute, Galway, Ireland*

Background: Osteoarthritis (OA) is the most common joint disease and the major cause of pain and disability in the aging population [1]. Adipose stromal cells (ASC) are promising candidate for cell therapy in OA, because they have immunomodulatory, trophic and differentiation capacities [2,3]. Synovial inflammation is accepted as important OA feature for the symptoms and disease progression [4]. Synovial tissue is mainly composed of synovial fibroblasts (SF), macrophages (SM) and a low percentage of other cell types [5].
Objectives: Aim of the study was to analyze the effects of adipose stromal cells in co-culture with SF and SM.
Methods: GMP clinical grade ASC were isolated from subcutaneous adipose tissue. Synoviocytes were isolated from synovial tissue of OA patients undergoing total joint replacement. Synovial cells at passage 1 and 5 were analyzed for: 1. different phenotypical markers by flow cytometric analysis, 2. inflammatory factors by multiplex immunoassay, 3.anabolic and degradative factors by qRT-PCR. Both p.1 (mix of SF and SM) and p.5 (only SF) synovial cells, as different cell models, were co-cultured with adipose stem cells (ASC) to define their effects. Furthermore macrophages type 1 (M1) were isolated and co-cultured with ASC.
Results: Synoviocytes at passage 1 were positive to typical markers of SM (CD14,CD16,CD68, CD80,CD163) and SF (CD55,CD73,CD90,CD105,CD106), whereas at passage 5 were positive only to SF markers and showed a higher percentage of CD55 and CD106. At p.1 synovial cells released a significantly higher amount of all inflammatory (IL6,CXCL8,CCL2,CCL3,CCL5) and anabolic (IL10) factors than those at p.5. Moreover, p.1 synovial cells expressed also higher amount of some degradative factors (MMP13, S100A8, S100A9) than p.5 synovial cells. Co-culture experiments showed that the amount of SM in p.1 synovial cells specifically orchestrate the up or down-modulation of some inflammatory (IL6,CXCL8,CCL2,CCL3,CCL5) and degradative factors (ADAMTS5,MMP13, S100A8,S100A9) analyzed. Interestingly, p.5 synovial cells induced all factors analyzed, except CCL5. Finally, we demonstrated that ASC effects were strictly dependent by M1, that decreased the release of typical macrophages cytokines (IL1β, IL6, TNFα and CCL3/MIP1α) and that ASC effects are responsible for the switching by M1 like inflammatory macrophages to M2 like phenotype mainly due to PGE2 involvement.
Conclusions: These data demonstrate that the GMP-ASC effects on OA synovial inflammation are strictly dependent by macrophages, that orchestrate the switching activated-M1 inflammatory macrophages to a M2-like phenotype, mainly through PGE2

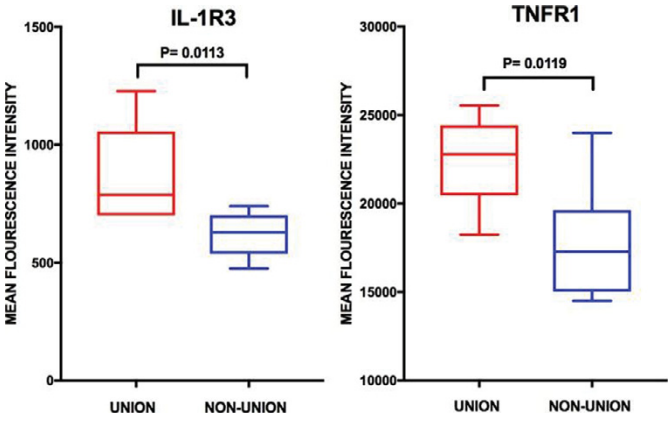
AB0065 2-CARBA-CYCLIC PHOSPHATIDIC ACID SUPPRESSES EXPRESSION OF CARTILAGE DEGRADING ENZYMES SUCH AS MMP-13 IN INFLAMMATORY SYNOVIAL FIBROBLASTS AND ARTICULAR CHONDROCYTES INDUCED BY IL-1 BETA AND/OR TNF ALFA

I. Masuda[1,2], K. Okada[3], H. Yamanaka[1], S. Momohara[1,4]. *[1]Inst. of Rheumatology, Tokyo Women's Medical University, Tokyo; [2]Rheumatology, Inst. for Rheumatic diseases, Jyujyo-Takeda Rehabilitation Hospital, Kyoto; [3]SANSHO, CO., Ltd; [4]Keio University, Tokyo, Japan*



Background: Cyclic phosphatidic acid (cPA) is one of bioactive lipid, has been implicated as a mediator of various biological effects including inhibitory effects of proliferation, invasion and metastasis of cancer cells. cPA is naturally occurring mediator even exists in human serum. 2-carba-cPA (2ccPA) is structurally modified formula of cPA and has shown improved bioactivity. We have previously confirmed that 2ccPA stimulated HAS-2 production on human osteoarthritic chondrocytes and synovial fibroblasts (SFs) in vitro. Furthermore, intra-articular administration of 2ccPA has shown its suppressing effect of pain, swelling, and articular cartilage destruction in rabbit experimental osteoarthritis (OA). We have shown that 2ccPA might had direct inhibitory effect of cartilage degrading enzymes on rheumatoid synovial fibroblasts (SFs) in vitro. Inflammatory arthritis such as rheumatoid arthritis (RA) and early stage of OA involves synovial inflammation and subsequent production of cartilage degrading enzymes also from chondrocytes. 2ccPA may be possible another therapeutic option for degenerative arthritis.
Objectives: The aim of this study was to evaluate the direct effects of 2ccPA on cartilage matrix degrading enzymes using SFs and articular chondrocytes under influence of inflammatory cytokines.
Methods: In vitro studies were performed using SFs and chondrocytes obtained from arthritis patients (RA and OA) at joint replacement surgery. First, 2ccPA 0–25 μM was added to cell cultures and effects of 2ccPA on ADAMTS-4, -5, MMP-3, 9, -13 expression was assessed by real time PCR using specific primers to corresponding genes. Beta-actin was used as endogenous expression control for PCR. As we confirmed that 2ccPA had dose-dependent inhibitory effects on expression of above enzymes, the second experiment was performed. SFs or chondrocytes were pre-cultured with IL-1β (1 ng/ml) and/or TNF-α (10 ng/ml) for 24 hours, then added 10 μM 2ccPA to study attenuated effect of 2ccPA on synthesis of above cartilage matrix degrading enzymes. Newly synthesized MMP-3, -13 from SFs or chondrocytes in cultured media after 24 hours of 2ccPA addition were measured by sandwich ELISA.
Results: 2ccPA itself repressed cartilage degrading enzymes, ADAMTS-4, ADAMTS-5, MMP-3, MMP-9 and MMP-13 expression in both SFs and chondrocytes was all repressed by low dose of 2ccPA. Even after cells had been stimulated by cytokines, 10 μM 2ccPA repressed expression of cartilage degenerating enzymes in SFs or chondrocytes. Expression of MMP-13 were repressed more in chondrocytes by 2ccPA. ELISA results also confirmed the inhibitory effect of 2ccPA on MMP-13 production in RA SFs (n=5) by 52% or in RA chondrocytes (n=3) by 43%. In OA, MMP-13 production was reduced by 31% in OA SFs (n=6) and 34% in OA chondrocytes (n=4). However, not significant reduction of MMP-3 in both SFs or chondrocytes. MMP-9 expression by ELISA was under the detectable limit.

Conclusions: The in vitro results confirmed that 2ccPA had suppressing effect of cartilage degrading enzymes expression on SFs and chondrocytes, supports the hypothesis that 2ccPA might have played direct role to suppress inflammation and also protect articular cartilage in arthritic condition.

AB0066 HUMAN MULTIPOTENTIAL STROMAL CELLS EXPRESS LOW SURFACE LEVELS OF PRO-INFLAMMATORY CYTOKINE RECEPTORS IN BONE HEALING DEFECTS

J.J. El-Jawhari[1], G. Kleftouris[1], Y.M. El-sherbiny[1], R. West[2], E. Jones[1], P.V. Giannoudis[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM);* [2]*Leeds Institute of Health Sciences, University of Leeds, Leeds, United Kingdom*

Background: Osteoimmunology is an evolving field where the multipotential stromal cells (MSCs) can be considered as an important player linking immune response with bone generation. A group of pro-inflammatory cytokines including IFN-γ, TNF-α, IL-17 and IL-1, has been proven to have a licensing effect on MSCs promoting the immunomodulatory activities of MSCs (1). Importantly, these cytokines can regulate the osteogenic differentiation capability of MSCs and in particular, IL-1 and IL-17 can enhance the MSC osteogenesis as shown in previous in vitro studies (2,3). However, little is known about the role of these cytokine-MSC interactions in the bone-related diseases in humans.
Objectives: The main focus of this study was to assess if the immune-dependent licensing process of MSCs could be involved in defective bone regeneration.
Methods: We used samples of bone marrow aspirates (n=15) from two groups of traumatic bone fracture patients; normal union and non-union. Bone marrow MSCs were analyzed for the surface expression of the receptors of the pro-inflammatory licensing cytokines using flowcytometry-optimized panels. Additionally, a comparison of the cytokine effect on the proliferation of cultured MSCs was compared between normal union and non-union groups using the cell proliferation XTT test.
Results: Interestingly, there were significant lower expression levels of IL-1 receptors 1 and 3 (IL-1R1 and IL-1R3) on non-union MSCs compared to normal-union MSCs (p=0.0478 and p=0.0113 respectively). Furthermore, the surface levels of TNF-αR1 (CD120a) were significantly lesser on non-union MSCs (p=0.0119). There was a clear trend of reduced expression of IL-17 receptors (CD217) on the surface of non-union MSCs, but it was not statistically significant compared to normal-union (p=0.0726). The XTT data showed a significant less proliferation index for IL-1-treated non-union MSCs compared to normal-union MSCs (p=0.0446). Also, a consistent trend of lower proliferation index of non-union MSCs was detected when these cells were treated by IFN-γ, TNF-α or IL-17.

Conclusions: Together, the lower levels of the pro-inflammatory cytokine receptors indicated a possible mechanism for a defective response of non-union MSCs to the inflammatory signals (particularly IL-1). Further understating of the impact of immune-MSC interactions on human bone healing and regeneration will help to develop new therapies for musculoskeletal diseases involving osteolytic lesions.

AB0067 INFLUENCE OF ADIPOKINES ON DIFFERENTIATION OF SPONGIOSA-DERIVED MESENCHYMAL STROMAL CELLS FROM OSTEOPOROTIC AND OSTEOARTHRITIS PATIENTS

L. Tsiklauri[1], E. Neumann[1], J. Werner[2], K. Frommer[1], R. Engel[1], S. Rehart[3], S. Wenisch[2], U. Müller-Ladner[1]. [1]*Department of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff-Klinik, Bad Nauheim;* [2]*Institute of Veterinary-Anatomy, -Histology and –Embryology, Clinic of Small Animals, Justus-Liebig-University, Giessen;* [3]*Department of Orthopedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt, Germany*

Background: Osteoporosis (OP) and osteoarthritis (OA) are two common age-related disorders leading to chronic pain and disability in elderly people. Age-related bone loss and articular cartilage damage are associated with increased bone marrow adiposity due to a possible shift of osteogenic differentiation towards adipogenic differentiation of bone marrow mesenchymal stem cells (MSC). The differentiation of MSC into adipocytes or osteoblasts is an important determinant of bone structural integrity. Adipose tissue is an metabolically active tissue. Therefore adipocyte-derived factors -adipokines- might influence differentiation of bone marrow-derived MSC.
Objectives: The role of fat-bone interactions in the pathogenesis of OP is poorly understood. Therefore, we analyzed the presence of distinct adipokines (visfatin, resistin and leptin) in the bone marrow cavity and their effects on MSC differentiation.
Methods: Spongiosa from femoral heads was collected (hip replacement surgery of OA patients or after osteoporotic femoral neck fracture). MSC were cultured in adipogenic and osteogenic media with/without adipokines. For the transfer and differentiation of MSC on cancellous bone, bone fragments were purified and sterilized. mRNA expression of adipokines, bone marker genes, TIMPs and MMPs of stimulated MSC and bone samples were evaluated by realtime PCR. Matrix mineralization was assayed using Alizarin red S staining. Proinflammatory factors were measured by ELISA.
Results: Visfatin and leptin levels were increased in OP bone vs. non-osteoporotic bone (n=14). In contrast to leptin and resistin, visfatin induced the secretion of proinflammatory factors (IL-6, IL-8, MCP-1) during both, osteogenic and adipogenic differentiation. Visfatin significantly increased the matrix mineralization and downregulated collagen type 1-expression (e.g. d21: -4.6-fold) in osteogenic differentiated cells. Visfatin also reduced the expression of MMP2, MMP13, RunX2, TIMP1 and TIMP2 (e.g. d21: -2.4-fold/-3.18-fold/-5.85-fold/-3.2-fold/-4.3 fold respectively) during osteogenic differentiation, but not leptin and resistin. In contrast to osteogenesis, visfatin significantly induced MMP13 expression (e.g. d21: 104-fold) during adipogenic differentiation under standard cell culture conditions. However, visfatin-induced MMP13-expression was markedly reduced during differentiation on purified autologous cancellous bone.
Conclusions: Visfatin and leptin levels were elevated in osteoporotic bone tissue. Therefore, the visfatin-mediated increase of matrix mineralization and reduction of collagen type 1 expression might lead to enhanced bone fragility and contribute to the pathogenesis of OP. Visfatin induced release of proinflammatory cytokines and dysregulated expression of MMPs and TIMPs during osteogenic and adipogenic MSC-differentiation might influence bone turnover specifically at the adipose tissue/bone interface.

AB0068 HYPOXIA AND RHEUMATOID PHENOTYPE DECREASE THE CAPACITY OF SYNOVIAL FIBROBLASTS TO SUPPRESS T HELPER CELL PROLIFERATION THROUGH IDO1-MEDIATED TRYPTOPHAN CATABOLISM

L.-O. Tykocinski[1], N.-C. Kaul[1], I. Adam[2], S.R. Mohapatra[2], S. Krienke[1], C.A. Opitz[2], H.-M. Lorenz[1]. [1]*Department of Medicine V, Division of Rheumatology, University of Heidelberg;* [2]*Brain Cancer Metabolism, German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: The pathogenesis of rheumatoid arthritis (RA) is linked to functional changes in synovial fibroblasts (SF) and local infiltration of T lymphocytes. Increased synovial inflammation is also associated with a hypoxic joint microenvironment. Oxygen levels in the joints of RA patients are significantly decreased compared to those of osteoarthritis (OA) patients with values of about 22.5mmHg corresponding to ambient oxygen tensions of 3.2%. So far, little is known about the effects of hypoxia on the interaction between fibroblasts and T lymphocytes and its implications on the pathophysiology of RA.
Objectives: The aim of this study was to compare the influence of SF from RA versus OA patients on T helper (Th) cell responses both under normoxic and hypoxic conditions.
Methods: SF were isolated from synovectomy tissues of OA or RA patients, Th cells were isolated from peripheral blood of RA patients or healthy donors. Cell cultures were performed under normoxic or hypoxic (3% O_2) conditions. Th cell proliferation was determined by PKH26 labelling and flow cytometry. Cytokine secretion was quantified by ELISA. Indoleamine 2,3-dioxygenase 1

(IDO1) expression was analysed by Western Blot and expression of enzymes of the kynurenine pathway by real-time PCR. Tryptophan/ kynurenine levels in culture supernatants were quantified by HPLC.
Results: SF strongly inhibited the proliferation of co-cultured Th cells. Tryptophan was completely depleted within a few days in co-cultures of SF and Th cells, resulting in eukaryotic initiation factor (eIF)2α phosphorylation, TCRζ-chain down-regulation and proliferation arrest. Blocking of IDO1 completely restored Th cell proliferation, indicating that SF suppressed the proliferation of Th cells through IDO1-mediated tryptophan catabolism. Interestingly, RASF showed a significantly lower IDO1 expression, tryptophan metabolism and a weaker Th cell suppressive capacity compared to OASF. Under hypoxic conditions, the secretion of IFNg, the expression of IDO1, the tryptophan metabolism and the Th cell suppressive capacity of both OASF and RASF were significantly reduced.
Conclusions: SF suppressed Th cell growth through IDO1-mediated tryptophan catabolism. This mechanism may play an important role in preventing inappropriate Th cell responses under normal conditions. The reduced tryptophan metabolism under hypoxia together with the inferior efficiency of RASF to restrict T cell proliferation likely supports the development of synovitis in RA.

AB0069 STRONG AGE-DEPENDENT EFFECTS OF DOPAMINE ON JOINT INVASION IN ARTHRITIS

L. Van Nie[1], S. Rehart[2], E. Neumann[1], U. Müller-Ladner[1], S. Capellino[3].
[1]Department of Internal Medicine and Rheumatology, Justus-Liebig-University Gießen, Kerckhoff-Klinik, Bad Nauheim, Bad Nauheim; [2]Department of Orthopedics and Trauma Surgery, Apaglesion Markus Hospital, Frankfurt am Main, Frankfurt am Main; [3]Dept. of Immunology, Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany

Background: Preventing synovial fibroblasts (SF) from migrating into the adjacent cartilage is a desirable therapeutic target in rheumatoid arthritis (RA) in order to avoid joint destruction and disability. In our previous studies we could show that RASF as well as SF from osteoarthritis (OA) patients express all dopamine receptor (DR) subtypes and dopamine stimulation alters pro-inflammatory cytokines (*Capellino S et al, A&R 2014*).
Objectives: Therefore, we aimed to elucidate a potential dopamine-mediated impact on joint invasion and destruction in arthritis.
Methods: SF from RA and OA patients were obtained from patients undergoing knee joint replacement surgery (mean age: 74.3±11.3yrs at OA and 73.7±10.3 yrs at RA patients) to investigate dopamine receptor (DR)-distribution within the RA synovium and in the invasion zone, immunohistochemistry was performed for all five DR-subtypes. Migration and motility assays were performed under D1-like (D1DR and D5DR) and D2-like (D2DR, D3DR and D4DR) receptor stimulation. Dopamine effects on MMP3 and proMMP1 were evaluated using ELISA.
Results: D1DR, D4DR and D5DR were found to be stronger expressed close to the invasion zone and more cells were expressing the respective DR. Migration of RASF and OASF was significantly correlated with patients' age at surgery: younger patients ($\leq$75years) showed an increase in migration up to 78% whereas older patients ($\geq$75years) showed a reduced migration of up to 50% (OA n=8; RA n=7). There was no difference between RA and OA patients and between D1-like and D2-like receptor stimulation. The same effect could be observed in the motility assay (OA n=5; RA n=6). MMP3 levels are altered under DR activation (OA n=6; RA n=6).
Conclusions: The high DR expression close to the invasion zone suggests a direct role of dopamine on RASF aggressiveness and may contribute to cartilage invasion. This was confirmed in the in vitro assays, and supports the idea of a therapeutic potential of the dopamine pathway in RA.

AB0070 CHONDROPROTECTIVE EFFECTS LINKED TO REDUCTION OF ADIPOGENESIS AND REGULATION OF GAP JUNCTION INTERCELLULAR COMMUNICATION: REGENERATIVE POTENTIAL THERAPEUTIC APPROACH FOR OSTEOARTHRITIS

M. Varela Eirin[1], A. Casado-Díaz[2], J. Loureiro[3], J.R. Caeiro[3], J.M. Quesada-Gómez[2], M.D. Mayán[1]. *[1]Translational Research in Cell Communication and Signaling (CellCOM Research Group), Instituto de Investigación Biomédica de A Coruña (INIBIC). Universidad de Córdoba, Córdoba; [3]Department of Orthopaedic Surgery and Traumatology, Complexo Hospitalario Universitario de Santiago de Compostela (CHUS-XXIS). SERGAS, Santiago de Compostela, Spain*

Background: Human bone marrow mesenchymal stem cells (hMSCs) exhibit an age-dependent reduction in osteogenesis and an increased propensity toward adipocyte differentiation. This switch has been associated with different bone disorders characterized by reduced bone formation and increased bone marrow fat accumulation. Connexin43 (Cx43) is an integral membrane protein that forms gap junction channels (GJs) and it is implicated in multiple cellular functions including cellular differentiation and control of bone remodelling and cartilage structure and function.
Objectives: In this study we investigated the effect of oleuropein and other molecules isolated from the *Olea europaea* in cellular differentiation to test if these molecules act as adipogenic suppressors in order to promote bone ad cartilage regeneration through a Cx43-dependent mechanism.
Methods: hMSCs were obtained from bone marrow donors. Human chondrocytes were isolated from cartilage of healthy donors and patients with osteoarthritis (OA). Differentiation assays were carried out in the presence of different concentrations of oleuropein and olive extract (OE). Cellular differentiation was evaluated using histological stains. Scrape loading assays, western-blot, real-time qPCR and immunohistochemistry (IHC) assays were used to study the cellular communication through gap junction (GJs) and the levels and changes in subcellular localization of Cx43 and extracellular matrix (ECM) proteins such as Collagen type II (Col2).
Results: hMSCs treated with olive derived molecules showed a two-fold decrease in adipogenic differentiation, while osteogenesis and chondrogenesis were significantly increased. IHC, RT-qPCR and Western-Bot analysis of hMSCs supplemented with oleuropein/OE showed increased levels of Cx43. On the other hand, OA chondrocytes showed higher levels of Cx43 in comparison with normal chondrocytes; oleuropein and OE treatments significantly decreased Cx43 levels and dye transference through GJ channels. The treatment of OA chondrocytes micromasses with oleuropein and OE increased the levels of proteoglycans and Col2 in the extracellular matrix. These changes in the micromasses were accompanied by a decrease in Cx43 levels improving protein subcellular localization.
Conclusions: Together, our results suggest that the molecules used in this assays, via Cx43 and GJ intercellular communication increase the propensity towards osteogenesis and chondrogenesis, reducing adipocyte differentiation. Our assays indicate that these molecules may represent a potential therapeutic approach for cartilage and bone age-related disorders such as OA in order to promote cartilage regeneration.

AB0071 ANALYSIS OF SYNOVIAL EXPRESSION OF PARVOVIRUS B19 ASSESSED IMMUNOHISTOCHEMICALLY AND CORRELATED TO SYNOVITIS SCORE

M. Tarasovs[1], A. Kadisa[2], A. Mihailova[3], S. Skuja[4], M. Murovska[5], V. Groma[4]. *[1]Riga Stradins University; [2]Department of Internal Diseases, Riga East Hospital Clinic "Gailezers"; [3]Orto Clinic; [4]Institute of Anatomy and Anthropology; [5]A. Kirchenstein Institute of Microbiology and Virology, Riga Stradins University, Riga, Latvia*

Background: Apart from systemic symptoms of viral infection parvovirus B19 (B19) could lead to acute and chronic arthropathy. It has been found in synovial tissue of rheumatoid arthritis (RA) patients, sometimes, being associated with some forms of undifferentiated arthritis. Possibly, it could promote inflammation in various forms of arthritis.
Objectives: To determine the expression of B19 antigens in different compartments of synovial membrane; correlate these findings to the estimated synovitis score.
Methods: 7 RA and 54 osteoarthritis (OA) patients were enrolled in this study. nPCR was used to detect the presence of B19 genomic sequence in 61 samples of synovial tissue. PCR B19 positive tissue samples were immunohistochemically treated with the anti-B19 antibodies detecting B19 capsid proteins' VP1/VP2 expression estimated thereafter semiquantitatively. The intimal and subintimal layers of synovium as well as vasculature were estimated. Synovial inflammation was evaluated using synovitis score.
Results: 3 RA and 3 OA patients were PCR B19 tissue positive. B19 antigens' expression was observed in synovial lining, immune infiltrates and vascular endothelium. Correlation between B19 expression observed in synovial cells and inflammatory infiltrates' lymphocytes and macrophages was r=0.555 ($p<0.0001$) and r=0.793 ($p<0.0001$), respectively. Likewise, correlation between vascular endothelial B19 expression and synovial lymphocytic infiltrates was demonstrated r=0.616 ($p<0.0001$). Determined synovitis score varied from low up to intermediate revealing median value 2. Simultaneously, there was no correlation found between the synovitis score and B19 antigens' expression.
Conclusions: B19 capsid proteins' VP1/VP2 expression is detectable in different structural constituents of synovial membrane. Under conditions studied, the tissue expression of B19 antigens does not correlate with the inflammatory indices scored.

AB0072 RATIONAL DESIGNED GOLD NANOPARTICLE SUPPRESSES RANKL-INDUCED OSTEOCLASTOGENESIS IN RAW264.7 CELLS VIA NF-KAPPA B PATHWAY AND MAPK PATHWAYS

Q. Yuan[1,2], X. Gao[1,2]. [1]*Key Laboratory for Biological Effects of Nanomaterial and Nanosafety, Institute of High Energy Physics, CAS;* [2]*Department of Chemistry and Chemical Engineering, Beijing University of Technology, Beijing, China*

Background: Bone erosion in joint is the most deleterious effect induced by rheumatoid arthritis (RA) and is the major cause of disability. New therapies are urgently required to prevent RA-associated bone destruction. The excessive bone resorption in RA was proved to be mediated by osteoclasts which are derived from the monocyte/macrophage lineage and induced by RANKL. Therefore, RANKL could be a potential target for the preservation of bone mass in RA.
Objectives: Chrysotherapy showed potential effects in reducing of joint destruction but with serious side-effects in RA therapy. A rational designed gold nanoparticle named GN was prepared to provide a choice for suppressing bone loss in RA therapy with more safety.
Methods: Mice macrophage cell line RAW264.7 was activated by RANKL to evaluate the potential osteoclastogenesis suppressing effects of GN. The differentiation, fusion and function of osteoclast were assessed by tartrate-resistant acid (TRAP) staining, actin ring formation assay and osteologic discs detection respectively. Relative expressions of osteoclast-specific genes were evaluated by RT-PCR and the activity of NF-κB pathway as well as MAPK pathways were analyzed by immunoblotting.
Results: Osteoclast differentiation, fusion and bone resorption were activated by RANKL in RAW264.7 cell, while GN significantly attenuates this process in a dose-dependent manner. The expressions of osteoclast-specific genes including TRAP and OSCAR were increased by RANKL stimulation but were effectively suppressed by GN. The activation of NF-kappa B pathway and MAPK pathways induced by RANKL was also suppressed by GN treatment.
Conclusions: Our findings revealed that treatment with GN could prevent RANKL-induced osteoclastogenesis and reduce increased expression of osteoclast-specific genes which may through the suppression of NF-kB and MAPK activation in macrophage. GN may provide a basis for the design of chrysotherapy drugs that effect in progression of RA-associated articular erosions.

AB0073 ACCUMULATION OF ADVANCED GLYCATION END PRODUCTS (AGES) IN OSTEOARTHRITIC CARTILAGE IS RELATED TO AN IMPAIRMENT OF THE ADAPTATIVE MECHANISM OF GLYOXALASE-1

S. Trellu[1], A. Courties[1], S. Jaisson[2], B. Friguet[3], X. Houard[4], F.-P. Ehkirch[5], C. Jacques[4], F. Berenbaum[1], J. Sellam[1]. Background: Advanced glycation end-products (AGEs) that result from a non-enzymatic reaction between a sugar and a protein, are generated during tissular ageing. Accumulation of AGEs could also be part of the osteoarthritis (OA) process by modifying the biomechanic properties of cartilage and by inducing chondrocyte activation. Glyoxalase-1 (Glo-1) is the main enzyme involved in the removal of AGEs precursors, especially the AGE carboxymethyllysine (CML).
Objectives: We aimed to quantify CML in human osteoarthritic cartilage, to investigate Glo-1 expression in chondrocytes and to study chondrocytic Glo-1 regulation in an inflammatory context.
Methods: 1) *Ex vivo:* Osteoarthritic cartilages from patients undergoing knee replacement were collected, dissected and incubated for 24h with or without IL-1β (5ng/ml). We quantified CML in these cartilage explants using liquid chromatography and mass spectrometry, Glo-1 protein expression (Western Blot and immunohistochemistry) and Glo-1 enzymatic activity by measuring the kinetic of formation of the Glo-1 product (S-D lactoylglutathione) using spectrophotometry at 240nm during 10 minutes. 2) *In vitro:* Primary cultured murine chondrocytes (C57B6) were stimulated 72 h with increasing IL-1β doses (0 to 10ng/mL). Glo-1 expression was assessed by quantitative RT-PCR, Western blot and enzymatic activity. To analyze whether oxidative stress is involved in Glo-1 regulation induced by IL-1β, cells were treated with inhibitors of mitochondrial oxidative stress (MitoTEMPO) or of nitric oxide (NO) synthase (L-NAME).
Results: 1) *Ex vivo*, CML was found in all human OA cartilage samples and its level increased according to age (correlation coefficient CML/age: $r=0.78$, $p<0.01$). In parallel to CML increase, Glo-1 protein was expressed in chondrocytes on all layers of cartilage. A positive correlation was found between Glo-1 enzymatic activity and the age of the patients ($r=0.45$, $p<0.05$) but was lost in case of incubation with IL-1β ($r=-0.09$, p non significant). 2) *In vitro*, in murine chondrocytes cultures, we observed a dose-dependent decrease of IL1β-induced Glo-1 mRNA (0.67 fold, $p<0.05$), protein quantity (0.56 fold, $p<0.05$) and enzymatic activity (0.7 fold, $p<0.05$) (n=5). The blockade of NO by L-NAME, and of mitochondrial oxidative stress by MitoTEMPO counteracted the downregulation of IL1β-induced Glo-1 expression and enzymatic activity (n=5).
Conclusions: We show here that the age-dependent accumulation of AGEs in OA cartilage could be due to an impairment of the adaptative mechanism of Glo-1, mediated by oxidative stress. Further studies aiming at targeting Glo-1 restauration as a therapeutical strategy for ageing-related OA are needed.

AB0074 INFLUENCE OF COBALT AND CHROMIUM IONS ON TGF-BETA EXPRESSION AND MINERALIZATION OF BONE FORMING CELLS IN-VITRO

S. Drynda[1,2], A. Drynda[1], J. Kekow[2], C.H. Lohmann[1]. [1]*Department of Orthopaedic Surgery, Magdeburg;* [2]*Clinic of Rheumatology, Vogelsang, Germany*

Background: Bone homeostasis is regulated at different levels. Transforming growth factor-beta (TGF-β) which exists in three isoforms in human and is stored in the latent form in the extracellular matrix is a major player in the regulation of osteoblast and osteoclast maturation, development, and function. The balance of bone formation and resorption is affected by numerous influences, such as hormone status, inflammation, and mechanical load.
In the aging population, supplied increasingly with artificial joint replacements, release of particles or ions from arthroplasty may exert local effects in the periprosthetic tissue. Cobalt and chromium ions are released through corrosion from metal-on-metal arthroplasty and modulate the gene expression level of several cytokines, chemokines and other mediators in bone cells.
Objectives: It was the aim of the study to analyse the effect of Co^{2+} and Cr^{3+} ions on the expression of TGF-β isoforms in bone forming cells and their impact on mineralization.
Methods: The study investigated the effect of Co^{2+} and Cr^{3+} ions on the expression of TGF-β1–3 in the human osteosarcoma cell lines (MG63 and SaOs2) and primary human osteoblasts.
Cells ($3x10^5$) were seeded in 2 ml DMEM (10%FCS) into 12 well plates and stimulated with $CoCl_2$ and $CrCl_3$ in concentrations between 50–250 μM for 24 hours. Total RNA was extracted and changes of expression levels of TGF-β1–3 were analysed by real-time PCR using sequence-specific primers and probes.
For mineralization cells were cultivated for up to 4 weeks in DMEM (10% FCS) supplemented with 0.2mM ascorbic acid, 10nm dexamethasone and 10mM glycerophosphate and Co^{2+} and Cr^{3+}. Calcium deposits were detected by 1% Alizarin Red S (pH 4.1) staining.
Results: The osteosarcoma cell lines as well as primary human osteoblasts isolated from bone explants expressed all three TGF-β isoforms, with TGF-β1 as most abundently expressed isoform. A dose dependent reduction of all TGF-β isoforms by Co^{2+} ions was observed, the strongest effect was found for TGF-β2. In MG63 cells and primary osteoblasts the mRNA levels of TGF-β2 decreased to 15±4% and 17±15% compared to the unstimulated control. The effect was lesser in SaOs2 cells with a reduction to 61±7% compared to control. In contrast to bivalent Co ions, the trivalent Cr ions had no significant effect on the expression of all TGF-β isoforms.
While Co^{2+} in a concentration range of 50–250 μM did not impair the mineralization, Cr^{3+} exerted a strong inhibitory effect on the mineralization in osteosarcoma cells and primary osteoblasts. In a dose dependent fashion mineralization was influenced already at concentrations of 50 μM CrCl3 and showed the strongest effect at 250 μM.
Conclusions: The results of our study show that bivalent cobalt ions and trivalent chromium ions have different effects on bone forming cells. While Cr^{2+} affects the expression of the different TGF-β isoforms in osteoblast-like cells and primary osteoblasts, no inhibitory effect on mineralization in the tested concentrations was seen. Cr^{3+} however, did not influence the expression of TGF-β but strongly inhibited the mineralization in vitro.
Our data implicate that the inhibitory effect of metal ions such as Co and Cr ions on the transcription of the bone regulating cytokines TGF-β1–3 and on bone forming activity may influence bone homeostasis.

AB0075 TARGETING IMMUNE AND NON-IMMUNO SYNOVITIS BY 1,3,5-TRIAZINE-THIAZOLE VIA DUAL INHIBITION OF NF-KB AND EGFR-TKS FOR POSSIBLE BENEFIT IN RHEUMATOID ARTHRITIS

U.P. Singh[1], J.K. Shrivastava[1], A. Verma[1], H.R. Bhat[2]. [1]*Department of Pharmaceutical Sciences, Sam Higginbottom University of Agriculture, Technology & Sciences, Allahabad;* [2]*Department of Pharmaceutical Sciences, Dibrugarh University, Dibrugarh, India*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease which is easily recognised by unrelenting inflammation, joint erosion, joint immobility and severe debilitation. The cause of the disease suggests that, T cells, B cells, macrophages, and dendritic cells gain access to the inflamed synovium causing progression of disease via generation of cytokines and autoantibodies.

The current available therapies to treat RA target the immune response which in turn adversely affects the immunity of the patients.
Objectives: The presents study deals with the discovery of 1,3,5-triazine-thiazoles targeting immune and non-immuno synovitis by via dual inhibition of NF-κB and EGFR-TKs for possible benefit in rheumatoid arthritis.
Methods: The 1,3,5-triazine-thiazole hybrid derivatives were synthesized via cascade of nucleophillic and cyclo-condensation reaction. These inhibitors was screened for NF-kB transcriptional activity in RAW264.7 macrophages, whereas, EGFR-TKs inhibitor activity was assessed via kinase inhibition assay kit. The docking study was carried out with 3D-crystal structure of NF-κB and EGFR-TK to explicate the inhibitory action.
Results: The designed hybrid analogues showed excellent inhibitory activity against both NF-κB and EGFR-TK. Particularly, against NF-κB, methyl (5c) containing molecule showed most significant activity (respectively with relative NF-κB activity: 1.82±1.87). Docking study suggests that, 5c was deeply buried in the DNA binding domain of NF-κB interacting with Tyr57, Val58, Cys59, His141, and Val142. In EGFR-TK inhibitory assay, the synthesized molecules showed IC_{50} ranging from 4.23–39.32μ M via interacting with Leu788, Met766, Lys745, Glu762 with 3D crystal structure of EGFR-TK.
Conclusions: These results demonstrate the feasibility of 1,3,5-triazine-thiazole as dual inhibitior of NF-κB and EGFR-TKs for the treatment of inflammatory disorders such as rheumatoid arthritis in more efficient way.

Rheumatoid arthritis - etiology, pathogenesis and animal models

AB0076 PERIODONTAL MICROBIOTA IN EGYPTIAN RA PATIENTS AND THEIR RELATION TO SERUM AND GINGIVAL ANTI-CITRULLINATED PROTEIN ANTIBODIES AND OTHER DISEASE PARAMETERS

A.A. Abdelati. *Internal Medicine, Rheumatology Unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt*

Background: A possible infectious trigger for RA is suspected at the gingival site. Emerging data implicates the microbiome in RA pathogenesis. Mucosal sites exposed to a high load of bacterial antigens, such as the periodontium, may represent the initial site of autoimmune generation. If validated, these findings could lead to the discovery of potential biomarkers and therapeutic approaches in the pre-clinical and clinical phases of RA[(1)].
Objectives: To determine the organisms causing periodontitis in Egyptian RA patients and their relation to serum and gingival ACPA level and other disease parameters.
Methods: This study was carried out on 100 Egyptian RA patients fulfilling the 2010 ACR/EULAR classification criteria for RA and of less than 5 years disease duration, recruited from Rheumatology Unit, outpatient clinic and Dental clinic at Alexandria Main University Hospital. RA disease activity was assessed by applying DAS28 and functional state of the patients was assessed by applying HAQ score. Dental examination, serum RF, and ACPA in serum and GCF were done for all patients. X-ray of both hands to detect erosions and severity of the disease. Gingival Crevicular Fluid (GCF) culture was performed for all cases with periodontitis for the three micro-organisms most reported in the literature to produce periodontitis (Porphyromonas gingivalis, Aggregatibacter actinomycetemcomitans, and Prevotella intermedia).
Results: Of the 100 patient, 66 patient had periodontitis, for them, GCF culture was performed and Porphyromonas gingivalis, Aggregatibacter actinomycetemcomitans, and Prevotella intermedia were found in 60.6%, 15.2%, and 30.3% of RA patients with periodontitis respectively. Gingival ACPA was detected in the 3 studied organisms, being of significant higher level with P.gingivalis than P.intermedia positive cases (p=0.047). No statistical significant difference detected on comparing P.gingivalis with A.actinomycetemcomitans or A.actinomycetemcomitans with P.intermedia. A. actinomycetemcomitans positive cases were associated with significantly higher level of CRP than P. intermedia positive cases (p=0.029), while no statistical significant difference was detected between P.gingivalis and A. actinomycetemcomitans or P. intermedia positive cases. There was no statistical significant difference between the three studied organisms regarding serum ACPA level, DAS 28, HAQ score, or X-ray findings of hands.
Conclusions: P.gingivalis is the most prevalent periodontal microbiota in Egyptian RA patients with periodontitis, that associated with significant higher level of gingival ACPA. None of the detected organisms correlated with the degree of RA activity or other disease parameters, apart from significantly higher CRP level with A. actinomycetemcomitans.

AB0077 INVESTIGATION OF THE INFLUENCE OF TERIFLUNOMIDE PLASMA CONCENTRATIONS ON DISEASEACTIVITY IN LEFLUNOMIDE-TREATED PATIENTS WITHRHEUMATOIDARTHRITIS

R. Tekaya, A. Ben Tekaya, H. Sahli, O. Saidane, I. Mahmoud, L. Abdelmoula. *Rheumatology charles Nicolle, Tunis, Tunisia*

Background: Leflunomide has become of increasing value for the treatment of rheumatoidarthritis (RA), and leflunomideisused via its active metabolite teriflunomide. The European League Against Rheumatism (EULAR) suggestedthatboth LEF and methotrexatewerefundamentalmedicines for the treatment of RA.
Objectives: To investigate the relationshipbetweenteriflunomideplasma concentrations and diseaseactivity in patients with RA.
Methods: This was a cross-sectional multicenter study (four rheumatology departments) over a four years period.Patients withRA on a stable and dailyleflunomide dose for >2 monthswereincluded.
Socio-demographic data and clinical data were recorded. Respectively, disease status and functional disability were assessed by disease activity score (DAS28) and Health Assessment Questionnaire (HAQ). Treatment response was evaluated according to the EULAR criteria (variation of DAS28).
Quantitative determination of teriflunomide (active metabolite of leflunomide) plasma concentrationswas carried out by high-performance liquid chromatography with ultraviolet detection.
Results: A total of 24 patients were enrolled; sex ratio =1. The mean age of the sample was 51,71 (±15,3) years; the mean disease duration at study baseline was 135,2 (±80,26) months; 70% of patients were RF positive, and 58% ACPA positive.The mean score on VAS pain was 43 mm (±22,92). Respectively, the mean swollen and tender joint counts (SJC-28, TJC-28) were4,3 (±6,1) and 2,8 (±3,09). The mean HAQ was 2,01 (±0,78). At baseline, the mean DAS28 score was 4,17 (±1,12); 56% weregood and moderate EULAR responders.
The mean leflunomide treatment duration was 34,94 months (±32,47). The meanteriflunomide plasma concentrations was 38,34 ug/ml (±24,92).
Residualteriflunomide plasma concentrations was significantly associated SCJ-28 and DAS28 decrease (p=0,0027). However, all these parameters (VAS pain, TJC-28, HAQ, C reactive protein, prescription duration of leflunomide and EULAR response) were not correlated with residualteriflunomide plasma concentrations.
Conclusions: This studyconcludedthatresidualteriflunomide plasma concentration isassociatedwithlow active disease.

AB0078 ROLE OF EXPERIMENTAL RESEARCH IN STUDY OF RHEUMATOID ARTHRITIS ETIOPATHOGENESIS

A.N. Goltsev, E.D. Lutsenko, M.V. Ostankov, N.A. Bondarovich. *Cryopathophysiology and Immunology Dept, Institute for Problems of Cryobiology and Cryomedicine of NAS of Ukraine, Kharkov, Ukraine*

Background: To study the pathogenesis, diagnosis and therapy of rheumatoid arthritis (RA) there are used numerous experimental *in vivo* and *in vitro* models. Topical issue of this problem is to study the causes of disorder and rehabilitation of immune tolerance mechanisms in RA. The concept about the role of different cells in central and peripheral tolerance formation in this pathology is often contradictory and not clear. A tolerogenic activity of products of fetoplacental complex has long been studied at the Cryopathophysiology and Immunology Department of the Institute for Problems of Cryobiology and Cryomedicine of NAS of Ukraine. The presence of a wide range of immunotropic substances in placenta is a premise to use placental cell suspension (PCS) for immunocompetent sphere recovery in autoimmune diseases.
Objectives: The research aim was to determine the possibilities and features of implementation of a tolerogenic activity by native and cryopreserved placental cells in experimental models of RA development: adjuvant arthritis (AA).
Methods: Research was carried out in CBA/H mice. The PCS was obtained via homogenizing the murine placenta to days 18–19 of gestation. The AA was induced by subplantar administration of the complete Freund's adjuvant. The AA development was expressed as the arthritis index. Either native (nPCS) or cryopreserved PCS were administered intravenously to day 7 after pathology induction. The PCS was cryopreserved under protection of either 10% dimethyl sulfoxide solution (suspension CD) or Propandiosakharol (suspension CP). A number of $CD4^+CD25^+$ T reg cells was determined by direct immunofluorescence

using monoclonal antibodies (BD Pharmingen TM) with flow cytometry (FACS Calibur, BD) in AA animal spleen. The *foxp3* gene expression in murine spleen cells was assessed by multiplex reverse transcription polymerase chain reaction (RT-PCR). In PCR we used the primer pairs to *foxp3* gene and that of housekeeping: β-actin. A number of gene transcripts was compared basing on the relative semi-quantitative estimation of amplification products using Agilent Bioanalyzer 2100 (USA).

Results: A disordered $CD4^+CD25^+$ cell accumulation in spleen of experimental animals with AA was established and possible use of PCS for its correction was demonstrated. The *foxp3* expression level in AA animal spleen cells reduced on day 28, suggesting a contribution of this factor into AA pathogenesis within a long-term period of pathology development. During this period a decrease in joint swelling correlated with an increased content of T-reg cells and *foxp3* expression level in spleen of animals after either nPCS or CD administration.

Conclusions: Therapeutic effect of either native or cryopreserved PCS in AA animals is manifested on molecular level, as evidenced by an increased *foxp3* expression in spleen cells after suspension administration. The effect of introduced cryopreserved placental cells as for this gene activation and, consequently, T-reg, was herewith determined by cryopreservation regimen.

AB0079 TRANSDERMAL DELIVERY OF METHOTREXATE IN RHEUMATOID ARTHRITIS: ARE WE DEEP ENOUGH?

B. Sadarani[1], A. Majumdar[1], P. Kamble[1], S. Paradkar[2], A. Mathur[2], S. Sachdev[2], P. Chaudhari[3], B. Mohanty[3]. *[1]Pharmacology, Bombay College of Pharmacy, Mumbai; [2]Radiopharmaceuticals Program, Board of Radiation and Isotope Technology (BRIT); [3]Small Animal Imaging Facility, Advanced Center for Treatment, Research and Education in Cancer (ACTREC), Navi Mumbai, India*

Background: Methotrexate (MTX), at low doses, is the first choice in the management of rheumatoid arthritis (RA). Despite its effectiveness, the probability of its discontinuation remains high due to adverse effects such as gastrointestinal intolerance, bone marrow toxicity as well as hepatotoxicity with conventional oral and parenteral therapy.[1] Transdermal delivery epitomizes an attractive alternative for drugs with systemic toxicities. The physicochemical characteristics of MTX such as high polarity and ionisation at physiologic pH make the development of its topical route of delivery challenging.[2] A new class of liposomes termed deformable or flexible liposomes have been reported to possess the virtue of stress-dependent adaptability that enables them to squeeze through interstices of stratum corneum and increase the depth of skin penetration.[3]

Objectives: This study is intended to explore the transdermal route for the delivery of MTX in ameliorating its systemic toxicity without compromising the therapeutic effect in RA.

Methods: MTX entrapped in deformable liposomes were prepared and characterised for particle size (PS) and entrapment efficiency (EE). They were incorporated into a hydroxyethyl cellulose gel base and evaluated for *ex vivo* skin permeation. Optimized liposomal gel was applied on the back of rats (3x4 cm area) and evaluated for its acute dermal toxicity and pharmacokinetics. Biodistribution was studied by topical application of ^{125}I labelled MTX incorporated liposomal gel in rats. Furthermore the efficacy of optimized gel was determined in collagen induced arthritis (CIA) in rats.

Results: The optimized deformable liposomes exhibited a small PS of 110±20 nm and EE 35–50% while the liposomal gel showed a transdermal flux of 17.37±1.5 $\mu g/cm^2/hr$ in *ex vivo* skin permeation study. Topical application of liposomal gel depicted no clinical abnormalities or pathological changes at the site of application in rats. Pharmacokinetic data indicated sustained systemic delivery of MTX from its liposomal gel up to 48 hours. The gel resulted in lower accumulation of MTX in liver, kidneys and gut in contrast to intravenous administration of plain ^{125}I labelled MTX solution. In the CIA model, topical MTX gel administration demonstrated significant reduction in hind paw swelling and arthritic score, also validated by histological and radiographic examination of ankle joints and lowering of serum levels of cytokines like TNF-α and IL-6 in comparison to disease control group.

Conclusions: The liposomal gel displayed dermal safety, sustained systemic delivery of MTX and its lower distribution to the organs of toxicity which may enable alleviating systemic side effects. Moreover, liposomal gel of MTX showed appreciable therapeutic efficacy in the CIA model.

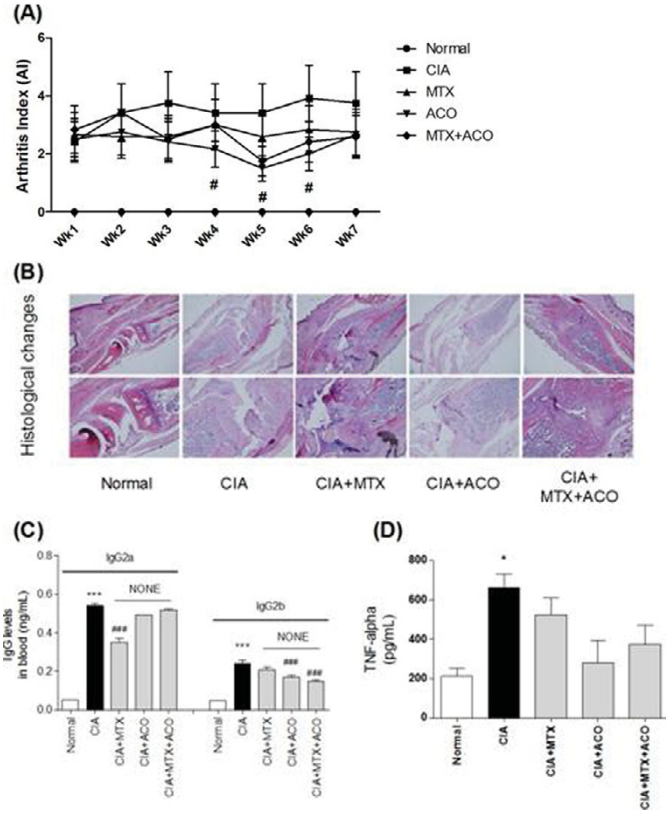
AB0080 MODUALTION OF IMMUNOGLOBULIN G2B BINDING IN COMBINATION OF METHOTREXATE AND ACONITE IN A COLLAGEN-INDUCED ARTHRITIS SETTING



D.-S. Oh, G. Park, S.H. Lee. *The K-herb Research Centre, Korea Institute of Oriental Medicine, Daejeon, Korea, Republic Of*

Background: Our previous study showed synergistic responses in TNF-alpha (TNF-α) and interleukin-6 with the combination of methotrexate (MTX) and aconite. Modulation of those cytokines has not been applied to rheumatoid arthritis (RA)-mimicked in vivo models.

Objectives: To translate in vitro effects of MTX, aconite, and MTX/aconite combination towards anti-arthritic responses in vivo, we investigated arthritis index (AI), histopathologic changes, and levels of TNF-α, immunoglobulin G (IgG) 2a and 2b in a collagen-induced arthritis (CIA) setting.

Methods: CIA was induced in five male DBA/OlaHsd mouse per group by intradermal injection of bovine collagen type II and Complete Freund's Adjuvant. In Day21, a bovine collagen type II and Incomplete Freund's Adjuvant were given for booster infection. The mice of arthritis onset were treated daily throughout Day49 with per oral administration of pre-investigated ratios of three to one; MTX (3 mg/kg), aconite (Aconibal®, 1 mg/kg), and MTX/aconite (3 and 1 mg/kg) combination. The AIs were evaluated every week. Histological changes, levels of TNF-α as well as IgG2a and IgG2b in blood using ELISA kit were evaluated at finals. Repeat measure and one-way ANOVA were analysed using SPSS (ver. 18.0 KO for Windows; SPSS Inc., Chicago, IL, USA) to evaluate inter-period and inter-group differences with Tukey's post-hoc tests.

Results: The CIA phenotypes adequately presented through three groups' AI reductions (CIA vs. MTX, aconite, or MTX/aconite; $p<0.001$, for three). There were differences of AI scores in aconite group from MTX one in week 4, 5, and 6 (MTX vs. aconite; $p=0.038$, $p=0.001$, $p=0.042$, respectively). Synergistic responses of AI were not shown any of three groups. The recoveries of synovial tissues were observed in MTX and MTX/aconite groups. The levels of TNF-α were not changed (aconite vs. MTX/aconite; $p=0.200$ and MTX vs. MTX/aconite; $p=0.700$). MTX group showed IgG2a reduction (CIA vs. MTX; $p<0.001$). Interestingly, MTX/aconite combination and aconite group slightly downregulated IgG2b levels as 80.8±5.6% and 90.5±7.4%, respectively (CIA vs. MTX/aconite; $p=0.001$ and CIA vs. aconite; $p=0.010$).

Conclusions: Synergistic in vitro effects of MTX and aconite combination brought

the partial in vivo phenotypic responses: Aconite showed more AI changes than MTX did in 4, 5, and 6 weeks. However, we found the presence of partial FcγRIIB affinity of binding modulation that MTX/aconite could enhance preventing monocyte/macrophage activation via immune complex in RA pathogenesis, as was other benefits of the combination except direct synergies.

AB0081 REACTIVE OXYGEN SPECIES INHIBIT CATALYTIC ACTIVITY OF PEPTIDYLARGININE DEIMINASE

D. Damgaard[1,2], M.E. Bjørn[1], C.H. Nielsen[1,2]. [1]*Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Institute for Inflammation Research;* [2]*Department of Odontology, Faculty of Health and Medical Sciences, University of Copenhagen, Section for Periodontology, Microbiology and Community Dentistry, Department of Odontology, Faculty of Health and Medical Sciences, University, Copenhagen, Denmark*

Background: Protein citrullination is catalysed by pepdidylarginine deiminase (PAD) and plays an important pathogenic role in anti-citrullinated protein antibody (ACPA)-positive rheumatoid arthritis (RA), and possibly in other inflammatory diseases. PAD activity is dependent on calcium and reducing conditions.

Objectives: To determine the ability of H_2O_2 and reactive oxygen species (ROS) induced by the nicotinamide adenine dinucleotide phosphate (NADPH) oxidase to regulate PAD activity.

Methods: Activity of recombinant human (rh) PAD2, rhPAD4 and PADs released from phorbol 12-myristate 13-acetate (PMA)-stimulated leucocytes was measured using an in-house PAD activity assay detecting citrullination of fibrinogen. PAD2 released from cells was measured using a luminex-based assay. The NADPH oxidase inhibitor diphenyleneiodonium (DPI) was used to inhibit ROS production in cells.

Results: At concentrations above 40 μM, H_2O_2 inhibited the catalytic activity of reduced rhPAD2 and rhPAD4. The inhibitory effect increased with increasing H_2O_2 concentration, reaching complete abrogation at 600 μM. PMA-stimulated leucocytes showed markedly higher PAD activity following inhibition of ROS formation with DPI. At a concentration of 10,000 μM, exogenously added H_2O_2 inhibited the catalytic activity of PAD released from PMA-stimulated leukocytes.

Conclusions: The ROS H_2O_2 directly inhibits enzymatic activity of PAD, and generation of ROS by NADPH oxidase down-regulates the activity of PAD released from stimulated leucocytes. This mechanism may play an important role in preventing hypercitrullination of proteins and thereby generation of self-antigens in RA.

Background: Alkaline phosphatase (AP) functions as a gate-keeper of the innate immune system [1] by detoxifying inflammation triggering moieties (ITMs). As an ectophosphatase, AP thus acts extracellularly by dephosphorylating ITMs that originate and are released from endogenous sources, e.g. by converting ADP and ATP nucleotides into adenosine to establish a key signalling anti-inflammatory effect. Consequently, AP activity prevents the production of pro-inflammatory cytokines by activated leucocytes and their downstream effects. Due to its broad mechanism of action, AP may potentially serve as an attractive therapeutic moiety in chronic inflammatory disorders, including rheumatoid arthritis (RA).

Objectives: To examine the anti-arthritic effects of prophylactic and therapeutic AP interventions in arthritic rats.

Methods: Wistar rats were immunized twice with methylated bovine serum albumin (mBSA), followed by local arthritis induction (intra-articular (i.a.) mBSA injection with 3 repeated injections) in the right knee (arthritic knee) with the contralateral left knee serving as internal control [2]. Interventions were performed using 200 μg human recombinant placental AP, administered subcutaneously, either before i.a. mBSA injections (2x, every 3 days, 2 rats/group; *prophylactic* setting) or after arthritis induction (4x, every 3 days, 4 rats/group; *therapeutic* setting). After *ex vivo* tissue distribution, knees were excised, fixed, decalcified and paraffin-embedded. Knee sections were examined for synovial macrophage infiltration by immunohistochemistry with ED1 (∼CD68) and ED2 (∼CD163) macrophage specific antibodies. Results were compared with untreated arthritic rats and arthritic rats receiving MTX therapy (1 mg/kg, intraperitoneally, 4x, every 3 days, 4 rats/group).

Results: Prophylactic and therapeutic schedules of AP treatment were well tolerated and reduced knee swelling comparable with MTX treatment. Following AP prophylactic intervention, synovial macrophage infiltration in the arthritic knees was reduced 4-fold (ED1) and 6-fold (ED2) when compared with affected knees of untreated arthritic rats, approaching macrophage counts in contralateral (non-arthritic) knees of AP treated rats. Therapeutic AP interventions resulted in 3.5-fold lower synovial infiltration of both ED1 and ED2 macrophages in arthritic knees, comparable with effects of MTX treatment.

Conclusions: AP, both as prophylactic and as therapeutic intervention, demonstrated favourable anti-arthritic efficacy in a rat model of arthritis. These studies warrant further preclinical and clinical evaluation as a putative novel therapeutic entity for arthritis.

Menchaca", Guadalajara, Mexico*

Background: The role of adipose tissue in RA pathogenesis has been acknowledged since the high frequency of dyslipidemia and insulin resistance in these patients. Leptin, a pleiotropic adipokine, has been associated with inflammation markers and articular damage in RA and the anti-citrullinated protein antibodies. Notwithstanding, these findings have not been constant across different populations. These points towards that single nucleotide polymorphism (SNP) in leptin and its receptor might influence the participation of this adipokine in RA pathogenesis.

Objectives: To determine the association of the SNPs *LEP* -2548 G>A and *LEPR* 668 A>G with adiposity, metabolic and inflammation markers in RA patients.

Methods: We enrolled 116 patients with RA (ACR 1987) matched with 133 control subjects by age, gender, and body mass index (BMI). Subjects were evaluated for fat mass and skinfold thickness. Also, serum glucose, insulin, lipid profile, serum leptin (sLep), soluble leptin receptor, TNFa. In patients with RA we evaluated disease activity and anti-CCP. Genotypes of *LEP* -2548 G>A and *LEPR* 668 A>G were determined by PCR-RFPL using *HhaI* and *MspI* restriction enzymes.

Results: There was no difference in genotypes distribution of LEP -2548 G>A and *LEPR* 668 A>G between RA and control. *LEPR* 668 G allele was associated with higher anti-CCP titers and disease activity score compared to *LEPR* 668A/A homozygotes, 4.2±1.7 vs. 3.46±1.2 *P*=0.012. *LEP* -2548A allele was associated with younger age of RA diagnosis vs. G/G homozygotes, 35.9±11.5 vs. 41.8±13.9 years old (*P* =0.045). OR for diagnosis before 40 years old was 2.7 (CI95% 1.04 – 7.45).

Conclusions: *LEP* -2548 G>A is related with a younger age at diagnosis of RA and *LEPR* 668 G/G was associated with increased anti-CCP titers and disease activity. This suggests that there is an additive effect between chronic inflammation of RA and obesity were leptin may favor humoral immune response against citrullinated proteins and influence the severity of RA.

In preobese and obese patients with RA anti-CCP (+) there is an increased sLep production. *LEP* -2548 G>A is related with a younger age at diagnosis of RA and *LEPR* 668 G/G was associated with increased anti-CCP titers and disease activity. These suggests that there is an additive effect between chronic inflammation of RA and obesity were leptin may favors humoral immune response against citrullinated proteins and influence the severity of RA.

AB0084 BREADTH OF BASELINE AUTOANTIBODY PROFILE AND TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

V.F.A.M. Derksen[1], E.C. de Moel[1], L.A. Trouw[1], R.J. Goekoop[2], I. Speyer[3], T.W.J. Huizinga[1], C.F. Allaart[1], R.E.M. Toes[1], D. van der Woude[1].
[1]Rheumatology, Leiden University Medical Center, Leiden; [2]Rheumatology, Haga Hospital; [3]Rheumatology, Haaglanden Medical Center, The Hague, Netherlands

Background: Seropositive and seronegative rheumatoid arthritis (RA) are distinct disease entities with regard to pathophysiological mechanisms and disease outcomes. However, over the past years it has become clear that the autoantibody profile of seropositive RA is very diverse, involving multiple post-translational modifications and isotypes, and it seems unlikely that a single autoantibody will be informative for identifying groups at risk of poor treatment response. Instead of individual autoantibodies, we hypothesized that the breadth of seropositive patients' profile may be the best reflection of the underlying immunopathology, and would be able to identify homogenous treatment response and inform treatment decisions.
Objectives: To investigate whether baseline autoantibody profile is associated with treatment response and the ability to taper off medication in RA patients.
Methods: All RA patients fulfilling the 2010 ACR/EULAR Criteria included in the IMPROVED study[1] that were seropositive for routine clinical testing for anti-cyclic citrullinated peptide-2 (anti-CCP2 IgG), rheumatoid factor (RF IgM), or our in-house assay for anti-carbamylated protein antibodies (anti-CarP IgG) were selected (n=381). In baseline sera of these patients, we measured IgG, IgM, and IgA isotypes for each family (except IgG for RF) and reactivity against 4 citrullinated peptides (cit-vimentin 59–74, cit-fibrinogen β 36–52 and α 27–43, and cit-enolase 5–20). We investigated associations between autoantibody profile and 1) change in disease activity score (DAS)-44 over time and 2) sustained drug-free remission, defined as the ability to taper off medication and remain in remission for ≥1 year after achieving DAS44<1.6.
Results: The initial treatment response (mean ΔDAS 0–4 months) in seropositive patients with a broad autoantibody profile (7–8 isotypes present) was better than in those with fewer isotypes present (ΔDAS 0–4 months of 7–8 isotypes vs 1–2, 3–4, and 5–6 isotypes, respectively: -2.2 vs -1.5 [p<0.001], -1.7 [p=0.04], and -1.8 [p=0.04]). In contrast, the presence of multiple autoantibodies was unfavorable regarding the long-term outcome of sustained drug-free remission. Within seropositive disease, patients with more isotypes and more reactivities to citrullinated peptides significantly less often achieved sustained drug-free remission (SDFR) (Figure).

Conclusions: Seropositive patients with a broader autoantibody profile at baseline initially react better to treatment, but are not able to taper off medication and remain in remission. This may be relevant in individualized decision-making for tapering medication, as these results suggest that disease with a broad autoantibody response, as proxy for an active humoral autoimmunity, is more difficult to control in the long-term without sustained therapy.

AB0085 INTERACTION OF HLA-SHARED EPITOPE (SE) AND SMOKING ON THE DEVELOPMENT OF ANTI-CCP POSITIVE RHEUMATOID ARTHRITIS IN GREEK POPULATION

E.N. Mole[1], K. Tarassi[2], V. Kitsiou[2], T. Athanassiades[2], D. Kouniaki[2], K. Soufleros[2], C. Korkou[1], A. Tsirogianni[2], C. Sfontouris[1]. *[1]Department of Rheumatology; [2]Department of Immunology-Histocompatibility, Evangelismos General Hospital, Athens, Greece*

Background: Rheumatoid Arthritis (RA) is a complex, multifactorial autoimmune disease, whose etiopathogenesis involves genetic and environmental factors.
Objectives: The aim of the study was the assessment of the association of HLA-DRB1*-SE in the presence/absence of anti-CCP autoimmunity in Greek patients with RA (smokers and non-smokers).
Methods: Eighty-three (83) RA patients (41 smokers, 42 have never smoked) were typed for HLA-DRB1* alleles by molecular techniques (PCR-SSOP and -SSP). In 62 out of 83 (74.7%) anti-CCP abs were detected by ELISA.
Results: In RA pts and in comparison to the controls, increased frequency of HLA-DRB1*01:01 (28.9% *vs* 6.8%, OR=4.4), *10:01 (16.9% *vs* 2.4%, OR=8.4), *04:01 (3.6% *vs* 2%, OR=1.8), *04:04 (7.2% *vs* 1%, OR=7.6) and *04:05 (15.7% *vs* 3.7%, OR=4.8), as well as decreased frequency of *04:02 (1.2% *vs* 2%, OR=0.6) and *04:03 (4.8% *vs* 6.8%, OR=0.7) were found. Among the RA patients, 77.1% possess 1SE *vs* 18.9% of controls (OR=14.4), whereas 10.8% possess 2SE *vs* 1% of controls (OR=11.8). In CCP (+) RA patients and in comparison to CCP (-) an increased frequency of HLA-DRB1*01:01 (27.4% *vs* 14.3%, OR=2.3) and *10:01 (21% *vs* 4.8%, OR=5.3) was observed. Furthermore, 88.7% of CCP (+) carry 1SE *vs* 42.9% of CCP (-) patients (OR=10.5). CCP (+) smokers patients in comparison to CCP (+) non-smokers are presented with an increased frequency of DRB1*01:01 (41.9% *vs* 12.9%, OR=4.9). Among the CCP (+) smokers, 96.8% possess 1SE *vs* 80.6% of CCP (+) non-smokers (OR=7.2), whereas 12.9% possess 2SE *vs* 12.9% of CCP (+) non-smokers (OR=1).
Conclusions: a) An increased frequency of HLA-DRB1*01:01, *10:01, *04:05 alleles, as well as the protective role of *04:02, *04:03 alleles in Greek patients with RA were confirmed b) The presence of any SE, particularly *10:01 allele, strongly influences the production of anti-CCP abs and c) Interaction between smoking and any SE, particularly *01:01 allele, is associated with anti-CCP positive RA in Greek patients.

AB0086 PREVENTIVE EFFECTS OF ANGIOTENSIN 1-7 ON NEOANGIOGENESIS AND LEUKOCYTE TRAFFICKING INCREASE IN THE EARLY PHASES OF AN EXPERIMENTAL MODEL OF ANTIGEN INDUCED ARTHRITIS

F. Fischetti, P. Durigutto, D. De Nardo, R. Carretta. *University of Trieste Italy, Trieste, Italy*

Background: Renin Angiotensin System (RAS) might be supposed to be involved in the early and late phases of development of synovitis, since data exist showing that Angiotensin (AT)-II contributes to the development of vascular damage under early inflammatory conditions (1, 2). Little is known about AT 1–7 functions, which is supposed to play counteracting actions vs AT II, under these conditions (2, 3)
Objectives: to evaluate if, in the early phases of an experimental model of arthritis, namely the antigen-induced arthritis (AIA), treatment with AT 1–7 could interfere with the synovial development of capillary vascular growth, and prevent leukocyte trafficking activation, in vivo, either at synovial and at mesentery post-capillary venules.
Methods: in compliance with European (86/609/EEC) and the Italian (D.L.116/92) ethics committees, 2 groups each of 8 male (240–270 gr) Wistar rats were randomly chosen and treated respectively with sterile saline, or with AT 1–7 (576 μg/kg/day), during the time of immunization with methylated serum bovine albumin (mBSA). Arthritis was induced by intraarticular administration of mBSA (0.1mg in 100ml sterile saline) into the right knee of each animal, after previous immunization to mBSA emulsified in complete Freund's adjuvant. The left knee, injected with only saline, served as a control. Two and 5 days after arthritis induction, the count of capillary branches, and the number of fluorescently-labelled leukocytes, showing transient or stable adhesion to the endothelial microvascular layer (EL), were assessed by using an in vivo videomicroscopy technique.
Results: synovial branching vessels with diameter >20μm were not modified after AIA induction, while microvessels having diameter less than 20 μm were significantly increased. After 2 and 5 days, AT 1–7 reduced the number of neo expressed <20μm diameter vessels (Day2: 3.7±3.4 vs 7.7±5.05, p=ns; Day5: 12.7±6.9 vs 21.0±7.3, p<0.05; both significantly greater than control joints). Transient and stable adhesion to EL showed to be partially reduced 2 days after AIA induction and significantly reduced after 5 days (Day5, transient=12.5±6.2 vs 26.0±9.0, p<0.05; stable=27.0±8.3 vs 41.7±10.6, p<0.05; both significantly greater than control joints). Comparable results were found when analysing the number of leukocytes adhering to mesentery EL.
Conclusions: we suggest that AT 1–7 could play an immune modulating role in the early phase of synovitis with possible prevention of further inflammatory and secondary structural tissue alterations. These data further support the hypothesis that mechanisms leading to synovial AT-II activation have a detrimental role in the development of arthritis.

AB0087 SONIC HEDGEHOG PROMOTES FIBROBLAST-LIKE SYNOVIOCYTES PROLIFERATION VIA MODULATING THE MAPK/ERK SIGNALING PATHWAY IN RHEUMATOID ARTHRITIS

F. Liu[1], S.-L. Zhu[2], Y.-F. Pan[1], J.-L. Huang[2]. *[1]Rheumatology, the Third Affiliated Hospital of Sun Yat-Sen University; [2]Rheumatology, the Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: The Sonic hedgehog (Shh) signaling has been reported to be activated in synovium of RA patients and RA-FLS in vitro [1]. Further, Shh signaling plays an important role in RA-FLS proliferation [2]. As for the extracellular signal-regulated kinase (ERK),is a member of mitogen-activated protein kinase (MAPK) [3], which has been reported to be involved in proliferation of RA-FLS [4]. However, the role of MAPK/ERK signaling pathway in the proliferation of RA-FLS modulating by Shh is unclear.
Objectives: To study the effect of MAPK/ERK signaling pathway on cell proliferation modulated by Sonic hedgehog (Shh) signaling in fibroblast-like synoviocytes isolated from patients with active rheumatoid arthritis (RA-FLS).
Methods: The RA-FLS were primarily cultured by the explant culture, and then were treated with Shh agonist Purmorphamine,inhibitor Cyclopamine or MAPK/ERK signaling pathway inhibitor U0126, respectively. Western blots was used to examine the phosphorylation level of ERK 1/2 (p-ERK1/2), which was the critical protein of MAPK/ERK signaling. The cell proliferation activity was detected using cell proliferation and cytotoxicity kit-8 (CCK8),and the cell proliferation rate was detected using a flow cytometry.
Results: Compared with the control group, Purmorphamine transiently increased p-ERK1/2 protein at the concentration of 1 μM, and the peak activations of p-ERK1/2 took place at 15min ($P<0.01$). Cyclopamine and U0126 decreased the expression of p-ERK1/2 protein ($P<0.01$). After the RA-FLS treated with Purmorphmine (1μM) for 48 hours, the cell proliferation activity was 114±4% and the percentage of S phase cells was 8.39±0.60%, significantly higher than those of the control group 100±0% ($P<0.01$) and 3.29±0.69% ($P<0.01$). After treated with Cyclopamine (10μM) for 48 hours, the cell proliferation activity of RA-FLS was 89±1% ($P<0.05$) and the percentage of S phase cells was 1.53±0.22% ($P<0.05$). When co-treated with purmorphamine (1μM) and U0126 (10μM), the cells proliferative activity was 892% ($P<0.05$) and the percentage of S phase cells was 1.07±0.25% ($P<0.05$).
Conclusions: Shh might promote proliferaton of RA-FLS via modulating MAPK/ERK signaling, subsequently contributing to hyperlasia of synovium and ultimately leading to RA disease.

AB0088 THE ROLE OF HIGH MOBILITY GROUP BOX-1 (HMGB1) IN INFLAMMATORY VASCULOPATHY IN COLLAGEN ANTIBODY-INDUCED ARTHRITIS (CAIA)

F. Biscetti[1], A. Flex[2], F. Angelini[2], E. Gremese[1], B. Tolusso[1], G. Ferraccioli[1]. *[1]Rheumatology; [2]Internal Medicine, Catholic University School of Medicine, Rome, Italy*

Background: Rheumatoid arthritis (RA) is associated with vascular disease (1). Recent findings demonstrated that the risk of peripheral arterial occlusive disease is increased in patients with RA compared to the general population (2). However, the pathogenesis is not fully understood. High-mobility group box-1 (HMGB1) is a nuclear protein involved in inflammatory responses (3) and RA-like synovitis (4).
Objectives: Aim of the present study was to analyze the relationship between HMGB1 and peripheral arterial disease in collagen antibody-induced arthritis (CAIA).
Methods: BALB/c mice were injected with monoclonal anti-collagen antibody cocktail followed by lipopolysaccharide to induce arthritis. After the induction of arthritis, we studied ischemia-induced neovascularization in the ischemic hind limb of arthritic and control mice.
Results: We found that the perfusion recovery was significantly attenuated arthritic mice, compared to control mice. The immunohistochemical analysis for the CD31 demonstrated a reduced number of vessel in mice with experimental arthritis. The selective blockade of HMGB1 in arthritic mice resulted in restored blood flow recovery and capillary density in the ischemic muscle. Cytokine enzyme-linked immunosorbent assay (ELISA) analyses performed on peripheral blood demonstrated a significant reduction of interleukin (IL)-1β, IL-6 and tumor necrosis factor (TNF)-α in mice where HMGB1 was blocked. Interestingly, the selective blockade of HMGB1 resulted in an increase of the peripheral IL-17A concentration.
Conclusions: HMGB1 pathway is involved in an experimental vasculopathy induced in a RA-like model. The proangiogenic cytokine IL-17A is increased when HMGB1 is inhibited. Although further data are needed, these findings provide new evidence regarding the pathogenesis of vascular complications observed in patients with RA.

AB0089 ELECTROKINETIC CHARACTERISTICS OF SYNOVIOCYTES (SC) AND THE LEVEL OF ANTIOXIDANT PROTECTION IN RHEUMATOID ARTHRITIS (RA)

G. Kudriavtseva, V.I. Shishkin, V.V. Shishkin, Y.A. Malenkov. *Saint Petersburg State University, Saint Petersburg, Russian Federation*

Background: Known role of SC in the pathogenesis of RA. It is impossible, however, at this level of knowledge to ascertain all the mechanisms for their involvement in the pathological process. Reduced tissue antioxidant protection can affect cellular metabolism, and as might be expected, through the mechanism of autophagy inducing mitochondrial and lysosomal degradation, facilitating cell membrane depolarization.
Objectives: The aim of this work was to study the electrophoretic mobility (EM) of SC of RA patients and its relationship with the activity of antioxidant enzymes: Cu-Zn superoxidismutase (Cu-Zn SOD), Se-glutathione peroxidase (Se-GPO) and catalase (the CAT) in synovial fluid (SF).
Methods: SF has been obtained from the knee of 7 patients with RA and 5 donors. SC isolated by standard methods. EM of SC determined by the automatic microscope. Se level in SF recorded by atomic absorption spectrometry. The activity of the antioxidant enzymes was determined by classical methods of enzymology.
Results: A significant depolarization of the RA SC, resulting in a reduction of their EM as compared to the normal level of the average in 4 times. Activity of antioxidant enzymes is dramatically reduced by a significant decrease of Se concentrations in SF (150 μg/l normally up to 80 μ g/l in RA), which is particularly reflected in the activity of Se GPO (note that SF can be up to 100 Se-containing proteins).

Table 1

	EM of SC (m/v sec)	Cu-Zn SOD (Units/mg of protein)	Se-GPO (Units/mg of protein)	CAT (μmol/min/mg of protein)
Normal SF	$1{,}62\times10^{-8}$	23,4±0,8	1,3±0,3	10,3±0,1
RA SF	$0{,}37\times10^{-8}$	11,7±0,4	0,4±0,1	0,47±0,04

Conclusions: We can assume that aggravated by RA catabolic processes that caused the dysfunction of the lysosomal and mitochondrial structures (autophagy), consistently shoot antioxidant protection of SC and cause depolarization and the decrease in electrophoretic mobility of these cells.

AB0090 N-ACETYL-L-CYSTEINE (NAC) CONTROLS OSTEOCLASTOGENESIS THROUGH REGULATING TH17 DIFFERENTIATION AND RANKL PRODUCTION IN RHEUMATOID ARTHRITIS

H.-R. Kim, K.-A. Lee, S.-H. Lee. *Rheumatology, Konkuk University School of Medicine, Seoul, Korea, Republic Of*

Background: NAC is a thiolic antioxidant produced by the body and serves as a precursor of glutathione synthesis. In rheumatoid arthritis (RA), oxidative stress is an important mechanism causing destructive proliferative synovitis.
Objectives: This study aimed to determine the regulatory role of N-Acetyl-L-cysteine (NAC), an antioxidant, in IL-17-induced osteoclast differentiation in RA.
Methods: After RA synovial fibroblasts were stimulated by IL-17, the expression and production of RANKL was determined by real-time PCR and ELISA. Human peripheral blood monocytes were cultured with M-CSF, IL-17, RANKL, and/or various concentrations of NAC, followed by counting of the cells for tartrate-resistant acid phosphatase activity to determine osteoclast formation. Osteoclastogenesis was also determined after cocultures of IL-17-stimulated RA synovial fibroblasts, Th17 cells and various concentrations of NAC with monocytes. After human peripheral $CD4^+$ T cells were cultured with NAC under Th17 condition, IL-17, IFN-g, IL-4, Foxp3, RANKL and IL-2 expression and production was determined by flow cytometry or ELISA.
Results: When RA synovial fibroblasts were stimulated by IL-17, IL-17 stimulated the production of RANKL, and NAC reduced the IL-17-induced RANKL production in a dose-dependent manner. NAC decreased IL-17-activated phosphorylation of mTOR, JNK and IkB. When human peripheral blood $CD14^+$ monocytes were cultured with M-CSF and IL-17 or RANKL, osteoclasts were differentiated, and NAC reduced the osteoclastogenesis. After human peripheral $CD4^+$ T cells were co-cultured with IL-17-pretreated RA synovial fibroblasts or Th17 cells, NAC reduced their osteoclastogenesis. Under Th17 polarizing condition, NAC decreased Th17 cell differentiation and IL-17 and RANKL production.
Conclusions: NAC inhibits the IL-17-induced RANKL production in RA synovial fibroblasts and IL-17-induced osteoclast differentiation. NAC also reduced Th17 polarization. NAC could be a supplementary therapeutic option for inflammatory and bony destructive processes in RA.

AB0091 SURFACE PHENOTYPE OF CIRCULATING PLATELETS IS ALTERED IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Yasuoka, K. Yoshimoto, K. Yamaoka, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: Rheumatoid arthritis (RA) is a connective tissue disease and characterized with multiple synovitis. However, pathogenesis of RA and systemic characteristic of RA is still under the investigation (1). Platelets distribute systemically through blood circulation and classically contribute to hemostasis physiologically (2). On the other hand, platelets can contribute to disease process by producing humoral factors such as cytokines or growth factors (3). Also, platelets have surface molecules not only associated with hemostasis but with other functional properties. Thus, these molecules can trigger the activation of other cells by cell-to-cell contact (4).
Objectives: To examine the association between characteristics of phenotype of circulating platelets based on the expression of surface molecules and clinical characteristics of RA and to seek the possibility as novel biomarkers.
Methods: Eight patients with RA were involved and 9 with scleroderma and 13 healthy controls were used as controls in this study. Surface expression of CD62P (P-selectin), membrane-bound TGF (transforming growth factor)-beta, CD147 (emmprin), CD142 (tissue factor), CD31 (platelet endothelial cell adhesion molecule (PECAM)-1) on CD41+CD45-CD14- platelets was examined using flow cytometry. Comparison between two groups was by non-parametric Mann-Whitney U-test. Clinical parameters at blood drawing were retrospectively obtained from clinical records, and correlation between proportion of platelet subsets and clinical parameters were examined.
Results: Proportion of CD62P+ activated platelets were higher in both RA and SSc compared to HC ($P<0.0005$, $P<0.0002$, respectively). Interestingly, CD147+ platelets were significantly higher in RA ($P<0.0004$), whereas not only proportion of CD147+ platelets but that of TGF-beta+ platelets were higher in SSc compared to healthy controls ($P<0.0001$, respectively). In patients with RA, proportion of CD62P+ activated platelets was correlated with inflammatory markers such as CRP and ESR and markers for disease activity such as SDAI ($P<0.05$, respectively) and these proportion were decreased after treatment ($P<0.03$).
Conclusions: In patients with RA, proportion of CD62P+ and CD147+ platelets were increased compared to healthy controls. Furthermore, phenotype of platelets of RA was altered compared to SSc. Interestingly, proportion of CD62P+ platelet is associated with the inflammatory markers and disease activity of RA. These results suggest that platelets reflect disease process of RA and could be utilized as novel biomarkers.

AB0092 EFFECT OF METHOTREXATE, LEFLUNOMIDE AND HYDROXYCHLOROQUINE ON THE INSULIN RESISTANCE AND OBESITY ASSOCIATED WITH RHEUMATOID ARTHRITIS: OBESE MOUSE MODELS OF RHEUMATOID ARTHRITIS

I. Arias de la Rosa[1], S. Rodriguez-Cuenca[2], Y. Jimenez-Gomez[1], P. Ruiz-Limon[1], C. Perez-Sanchez[1], M.C. Abalos[1], E. Collantes[1], A. Vidal-Puig[2], A. Escudero-Contreras[1], C. Lopez-Pedrera[1], N. Barbarroja[1]. *[1]Rheumatology Service, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; [2]Metabolic Research Laboratories, Wellcome Trust-MRC Institute of Metabolic Science, Addenbroke's Hospital, Universidad de Cambridge, Cambridge, United Kingdom*

Background: Numerous studies have demonstrated the closely association between rheumatoid arthritis (RA) and metabolic complications such as obesity and insulin resistance. Thus, there is an urgent need for the use of therapies targeting both the activity of the disease and such metabolic disorders. Nowadays, the conventional treatment of RA consists of disease-modifying antirheumatic drugs (DMARDs) in monotherapy or combined. Yet, its beneficial/negative effect on the metabolic complications associated with cardiovascular disease prominent in RA patients is still unravelled.
Objectives: To analyze and compare the effects of methotrexate, leflunomide and hydroxychloroquine on the obesity and insulin resistance in an obese collagen-induced arthritis (CIA) mouse model.
Methods: CIA was developed in obese and lean mice. 55 C57Bl/6 mice (4–5 weeks) were used. Forty-one mice were fed with high fat diet (60%) until reaching 30g (obese) (OB). Groups of study: 5 non-diseased lean mice, 9 CIA lean mice, 5 non-diseased OB mice, 9 OB-CIA mice, 9 OB-CIA mice treated with leflunomide (10 mg/kg daily), 9 OB-CIA mice treated with methotrexate (3mg/kg three times/week) and 9 OB-CIA mice treated with hydroxychloroquine (60 mg/kg daily) for 15 days. Mice were weighted and the number of total inflamed digits was recorded daily. After treatment, before 72 hours of termination, glucose tolerance test (GTT) was performed. Buffy coat, plasma and metabolic tissues (gonadal and inguinal adipose tissue, skeletal muscle and liver) were collected.
Results: CIA obese mice developed the arthritis earlier and more severe (increased number of inflamed digits) compared with CIA lean mice. Regarding the progression of the disease, the three drugs significantly reduced the number of affected joints from the second day of treatment. However, after 15 days of treatment, the therapies more effective inhibiting the generation of inflamed digits were hydroxychloroquine and methotrexate. The development of RA in both obese and lean mice did not have effect on the body weight. Among the therapies used, only the hydroxychloroquine significantly reduced the body weight after 11 days of treatment. Glucose tolerance test revealed that the area under the curve was markedly smaller in OB-CIA mice after treatment with hydroxychloroquine compared to other treatments and OB-CIA mice untreated, suggesting an improvement of insulin sensitivity. Analysis on the metabolic tissues of these mice is currently ongoing in order to completely elucidate the effect of these therapies in the metabolic state.
Conclusions: 1) Obesity accelerates the development and aggravates the outcome of the arthritis in CIA mice. 2) Among the three DMARDs administered, hydroxychloroquine promoted a beneficial effect on the metabolism of CIA obese mice, reducing body weight and improving the insulin sensitivity. These results suggest that hydroxychloroquine could be used as a valuable therapeutic strategy in RA patients to reduce the disease activity and ameliorate the metabolic complications associated.

AB0093 BLYS AND APRIL OVEREXPRESSION IN EARLY RHEUMATOID ARTHRITIS: ASSOCIATION WITH B CELLS AND MYELOID SUBSETS

J. Rodríguez-Carrio[1], M. Alperi-López[2], P. López[1], F.J. Ballina-García[2], A. Suárez[1]. [1]*Area of Immunology, University of Oviedo;* [2]*Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain*

Background: studies on B cell-mediated autoimmune diseases highlight the relevance of the B Lymphocyte Stimulator (BLyS) and A Proliferation-Inducing Ligand (APRIL), but emerging evidence points to an interaction with cell lineages other than B subsets. Although disturbances in the B cell compartment underlie the early stages of rheumatoid arthritis (RA), this phenomenon is poorly understood.
Objectives: to investigate the cellular populations responsible of BLyS expression and their association with the soluble forms of BLyS, APRIL and its receptor TACI (Transmembrane Activator and CALM Interactor) in early RA and to evaluate the changes in these parameters upon TNFα-blockade.
Methods: membrane BLyS (mBLyS) expression was assessed on B cells, monocytes (MØ), myeloid (mDC) and plasmacytoid (pDC) dendritic cells and neutrophils (NØ) by flow cytometry in fresh blood samples from 37 RA patients [DAS28 score (mean±SD): 4.84±1.44, disease duration (mean (range)): 1.26 (0–11) years, 23 (62.1%) RF+, 19 (51.3%) ACPA+, 19 untreated] and 31 healthy controls (HC). A subgroup of 13 biologic-naïve RA patients was prospectively followed for three months upon TNFα-blockade. Serum levels of soluble BLyS (sBLyS), APRIL (sAPRIL) and TACI (sTACI) were quantified by immunoassays.
Results: mBLyS expression was increased on B cells ($p=0.002$), MØ ($p<0.001$), mDC ($p<0.001$) and NØ ($p=0.014$) in RA patients. Higher sBLyS ($p=0.018$) and sAPRIL ($p<0.001$) serum levels were found in RA, whereas those of sTACI were not different compared to HC ($p=0.460$). Serum sAPRIL levels paralleled those of sTACI ($r=0.325$, $p=0.040$), and mBLyS expression on B cells ($r=0.463$, $p=0.009$), MØ ($r=0.521$, $p=0.003$), mDC ($r=0.438$, $p=0.014$) and NØ ($r=0.509$, $p=0.009$) in HC but not in RA patients. Serum levels of sTACI were negatively associated with DAS28 score ($r=-0.272$, $p=0.006$) in RA. However, sAPRIL was associated with mBLyS expression on mDC in patients with longer disease duration (>3 months) ($r=0.779$, $p<0.001$), but not in those recruited at onset ($r=0.245$, $p=0.361$). In the whole RA group, TNFα serum levels were found to be correlated with sAPRIL ($r=0.499$, $p<0.001$) and sBLyS ($r=0.362$, $p=0.013$). Similarly, IFNα and sAPRIL were positively associated ($r=0.423$, $p<0.001$). TNFα-blockade was associated with decreasing mBLyS expression on B cells, MØ, mDC and NØ (all $p<0.050$) and a slight increase in sTACI ($p=0.064$). Higher levels of mBLyS on MØ and mDC at baseline were associated with a poor clinical response upon TNFα-blockade ($n=8$; $p=0.006$ and $p=0.010$ compared to HC, respectively).
Conclusions: a role for B cell-activating factors in the pathogenesis of early RA is supported. B cells and myeloid populations (MØ, mDC and NØ) can account for the BLyS overexpression in RA, although important differences arise in their involvement. TNFα and IFNα are related to sBLyS and sAPRIL levels. An increased production of the soluble forms of BLyS and APRIL in addition to a less efficient feedback from their decoy receptors may delineate its detrimental effect.

AB0094 MIGRATION, COLONIZATION AND DISTRIBUTION OF BONE MARROW MESENCHYMAL STEM CELLS TRANSPLANTED IN CIA RATS WERE TRACED BY GREEN FLUORESCENT PROTEIN

J. Hou, K. Xu, L. Zhang, G. Zhang, J. Gao, D. Ma, J. Fan. *Shanxi Academy of Medical Sciences, Shan xi Da Yi Hospita, Taiyuan, China*

Background: The mechanism of mesenchymal stem cells involved in injury and repair in vivo is not fully understood, so it is difficult to evaluate the effect of stem cells on rheumatoid arthritis.
Objectives: To investigate the migration, colonization and distribution of bone marrow mesenchymal stem cells (BM-MSCs) traced by green fluorescent protein (GFP) in the immune organs and joints of CIA rats, and study the mechanism of MSCs in repairing damage.
Methods: 1.MSCs labeled with GFP was cultured, amplified and identified in vitro.
2.Injected with mixture of II type collagen and complete Freund's adjuvant into Wistar rats space at 14 days: It was randomly divided into five groups, including early intervention group (n=20), late intervention group (n=20), CIA early control group (n=12), late control group (n=12) and normal control group (n=12).(2) MSCs were injected from tail veins according to the number of 1×10^7/kg,and the control groups were given equal volume of normal saline. (3) Observe the changes of arthritis index, arthritis swelling degree,and appearance of imageology and pathology.
3.The spleen, thymus, lymph nodes and joint tissues of the rats were made into pathological sections when transplanted at 3, 11, 30 and 42 days.The migration and distribution of the transplanted cells in the immune organs and the inflammatory joints were detected by immunohistochemistry.
Results: 1.(1)The arthritis index and degree of joint swelling in early and later intervention groups were decreased significantly than that of CIA control groups ($P<0.05$). (2)The early intervention group had lower arthritis index and the degree of joint swelling than the later intervention group ($P<0.05$).
2.The positive results of GFP was successfully detected by immunohistochemical method in the immune organs and joints of CIA rats, and sustainable for at least 42 days.
Conclusions: 1.MSCs transplanted through tail vein can migrate to the spleen, lymph nodes and thymus and joints,and can be long-term (42 days) colonization in these organizations.
2.The intervention of MSCs for CIA rats was effective, and early intervention effect was better than advanced intervention.

AB0095 BY INTRAVENOUS INFUSION MARKED BY GREEN FLUORESCENT PROTEIN TO REVEAL BONE MARROW MESENCHYMAL STEM CELLS' DISTRIBUTION AND DIFFERENTIATION OF COLLAGEN INDUCED ARTHRITIS RATS

J. Gao, L. Zhang. *Rheumatology Department, Shanxi Dayi Hospital, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a autoimmune disease,which is characterized by the osteoclasia or the high deformity rate of cartilage and bone. According to some materials, Mesenchymal stem cells (MSCs) were definited as the cell full of proliferation, differentiation capacity, and potential immune regulation. MSCs transplantation could be a appropriate-designed pattern to the joint damaging from rheumatoid arthritis (RA).However, the repairing mechanism against osteoclasia of cartilage and bone is still unclear.
Objectives: This study used collagen induced arthritis (CIA) rats as animal model to explore MSCs' tissue repairing mechanism.
Methods: We observed the ability of BMSCs differentiating into cartilage cells by toluidine blue staining in vitro;Then,BMSCs were labeled by the green fluorescent protein (GFP), infused into CIA through rats' tail vein infusion. In different point time, the rat's joints were made paraffin section,we observed the differentation of GFP positive cells and the distribution of GFP-positive cells differentiated chondrocytes by immunohistochemicale method.
Results: First,we found BMSCs in vitro can differentiate into cartilage cells under a certain-culture condition. Then, BMSCs were labeled by the green fluorescent protein (GFP), infused into CIA through rats' tail vein infusion. In different point time, the rat's joints were made paraffin section,which the GFP positive cells were observed in synovium and bone marrow tissues after transplantation on the 3th day, and in cartilage tissues on the 11th day, then increased in cartilage tissues on the 30th day,42th day, by laser scanning confocal microscope. Anti-type II collagen, GFP double positive cells were found in articular cartilages (especially damaged part)by Anti-II collagen immunofluorescence technology.

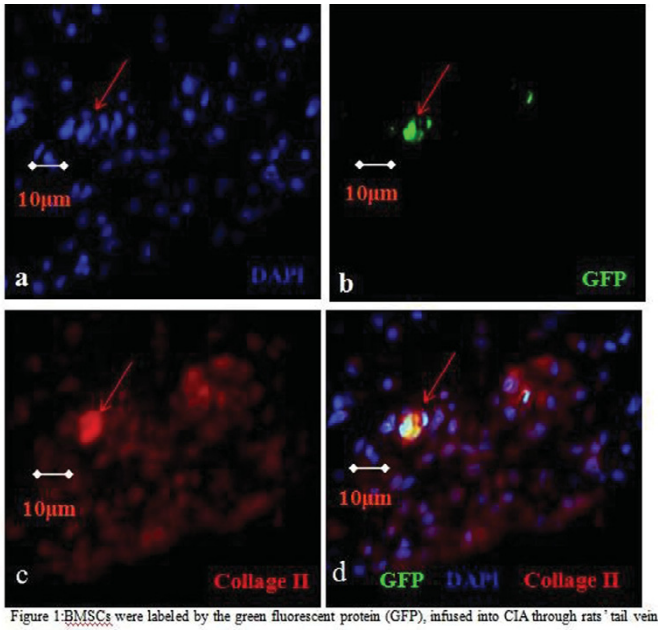

Figure 1:BMSCs were labeled by the green fluorescent protein (GFP), infused into CIA through rats' tail vein infusion. Fluorescence microscopic observation of joint paraffin section. Chondrocyte were stained with an antibody specific to type II collagen and observed by fluorescence microscopy (red fluorescence). Nucles were stained with DAPI (blue fluorescence).GFP-MSCs were observed by fluorescence microscopy (green fluorescence).Anti-type II collagen and GFP double positive cells were found in articular cartilages.

Conclusions: BMSCs were restricted to the joint injury or inflammatory site,differentiated into chondrocytes, and then participated in the cartilage repairing.

AB0096 EFFICACY AND SAFETY OF ORAL ADMINISTRATION OF PURE CELASTROL IN AIA RATS

R. Cascão [1], T. Carvalho [1], J. Goncalves [2], L.F. Moita [3], J.E. Fonseca [4]. *[1] Instituto de Medicina Molecular; [2] iMed – Research Institute of Medicines, Faculdade de Farmácia, Universidade de Lisboa, Lisbon; [3] Instituto Gulbenkian de Ciência, Oeiras; [4] Instituto de Medicina Molecular and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisbon, Portugal*

Background: Celastrol, a pentacyclic-triterpene isolated from *Tripterigium wilfordii* roots, has shown great therapeutic potential for the treatment of several inflammatory diseases, including rheumatoid arthritis (RA). We have previously demonstrated that celastrol has significant anti-inflammatory and bone protective effects in the adjuvant-induced rat model of arthritis (AIA), when administered via intraperitoneal route. For further preclinical evaluation of celastrol as a candidate compound for RA treatment, an effective and safe oral administration is crucial.

Objectives: In this work we aimed to study the dose range for both therapeutic and toxic effects for oral administration of pure celastrol using the AIA rat model.

Methods: Celastrol (1, 2.5, 5, 7.5, 12.5 and 25μg/g/day, N=5/group) was administrated orally in female AIA rats after 8 days of disease induction (therapeutic model) for a period of 14-days. A group of healthy (N=8) and untreated arthritic (vehicle, N=15) gender and age-matched Wistar rats were used as control. During the period of treatment, the inflammatory score, ankle perimeter and body weight were measured. At the end of the treatment, animals were sacrificed, blood was collected for clinical pathology, and necropsy was performed, with collection of internal organs for histopathological analysis and of paw samples for disease scoring.

Results: Oral administration of pure celastrol at 2.5, 5 and 7.5μ g/g/day reduced the inflammatory score and ankle swelling, preserved articular joint structure with a reduction in synovial inflammatory infiltrates and proliferation, halted articular bone destruction, and diminished the number of synovial CD68+ macrophages (a biomarker of response to anti-arthritic treatment). This compound also reduced the number of osteoclasts and osteoblasts present in joints. Bone resorption and turnover was also reduced at both 5 and 7.5μg/g/day, with a significant decrease in serum levels of TRACP-5b, P1NP and CTX-I. Of note, no significant variation in body weight, evidence of nephro-, hepato- or cardiotoxic effects, nor alterations in blood cell counts were observed at these concentrations. However, the dose of 7.5μ g/g/day was already associated with thymic and hepatotoxic changes, and higher doses showed toxicity signs. The lethal dose (LD) and LD_{50} were defined as 25μg/g/day and 12.5μg/g/day, respectively. Of note, oral celastrol at 1μg/g/day had no effect in arthritis progression.

Conclusions: Our results clearly show that 2.5μg/g/day is the lowest and 5μg/g/day is the highest effective and safe oral doses of celastrol in the setting of AIA rat model. These findings suggest that while celastrol is potentially very effective to treat RA, it has a narrow therapeutic window.

AB0097 METHOTREXATE AND LOW DOSE PREDNISOLONE DOWNREGULATE OSTEOCLAST FUNCTION IN MONOCYTES FROM EARLY RHEUMATOID ARTHRITIS PATIENTS

I.P. Perpétuo [1], J. Caetano-Lopes [1], A.M. Rodrigues [1], R. Campanilho-Marques [1,2], C. Ponte [1,2], H. Canhão [3], M. Ainola [4], J.E. Fonseca [1,2]. *[1] Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa; [2] Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria; [3] EpiDoC Unit, CEDOC, NOVA Medical School, Universidade Nova de Lisboa, Lisbon, Portugal; [4] University of Helsinki, Institute of Clinical Medicine, Helsinki, Finland*

Background: Rheumatoid arthritis (RA) is a systemic, immune mediated inflammatory disease that is associated with bone erosions and joint destruction. Methotrexate (MTX) slows bone damage but the mechanism by which it acts is still unknown.

Objectives: In this study we aimed to assess the effect of MTX and low dose prednisolone (MTX+PDN) on circulating osteoclast (OC) precursors and OC differentiation in RA patients.

Methods: RA patients before and at least 6 months after MTX therapy were analyzed and compared with healthy donors. A blood sample was collected in order to assess receptor activator of NF-κB (RANK) ligand (RANKL) surface expression on circulating leukocytes and frequency and phenotype of monocyte subpopulations. Serum quantification of bone turnover markers and cytokines and *in vitro* OC differentiation assays were performed.

Results: The number or $RANKL^+$ neutrophils increased in RA patients when compared to healthy donors (p=0.006) and after treatment with MTX+PDN their count was reduced to healthy control numbers (p=0.0155). Classical activation markers of monocytes such as HLA-DR, CD86, CCR2 and CD11b, and also RANK were increased in RA patients at baseline, comparing to control healthy donors. After MTX+PDN exposure, expression decreased to healthy control levels. Serum RANKL levels were increased at baseline comparing to healthy donors (p=0.0164) and normalized after therapy.

Although the number of OC was not different between groups, resorbed area and resorbed area/pit were elevated when compared to controls (p=0.0436 and 0.0249, respectively) and reduced after treatment ($p<0.0001$).

Conclusions: Our results suggest that MTX+PDN play an important role in downregulating OC function, which we believe occurs through a decrease in RANK surface expression in monocytes.

AB0098 EFFECTS OF TOFACITINIB IN EARLY ARTHRITIS BONE LOSS

B. Vidal [1], R. Cascão [1], M. Finnilä [2,3], I. Lopes [1], S. Saarakkala [2,4,5], P. Zioupos [6], H. Canhão [7], J. Fonseca [1,8]. *[1] Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal; [2] Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulo; [3] Department of Applied Physics, University of Eastern Finland, Kuopio; [4] Medical Research Center, University of Oulu; [5] Department of Diagnostic Radiology, Oulu University Hospital, Oulo, Finland; [6] Biomechanics Labs, Cranfield Forensic Institute, Cranfield University, Swindon, United Kingdom; [7] EpiDoC Unit, CEDOC, NOVA Medical School, NOVA University; [8] Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisboa, Portugal*

Background: Rheumatoid arthritis (RA) causes immune mediated local and systemic bone damage.

Objectives: The main goal of this work was to analyze, how treatment intervention with tofacitinib prevents the early disturbances on bone structure and mechanics in adjuvant induced arthritis rat model. This is the first study to access the impact of tofacitinib on the systemic bone effects of inflammation.

Methods: Fifty Wistar adjuvant-induced arthritis (AIA) rats were randomly housed in experimental groups, as follows: non-arthritic healthy group (N=20), arthritic non-treated (N=20) and 10 animals under tofacitinib treatment. Rats were monitored during 22 days after disease induction for the inflammatory score, ankle perimeter and body weight. Healthy non-arthritic rats were used as controls for comparison. After 22 days of disease progression rats were sacrificed and bone samples were collected for histology, micro-CT, 3-point bending and nanoindentation analysis. Blood samples were also collected for bone turnover markers and systemic cytokine quantification.

Results: At tissue level, measured by nanoindentation, tofacitinib increased bone cortical and trabecular hardness. However, micro-CT and 3-point bending tests revealed that tofacitinib did not revert the effects of arthritis on cortical and trabecular bone structure and on mechanical properties.

Conclusions: Possible reasons for these observations might be related with the mechanism of action of tofacitinib, which leads to direct interactions with bone metabolism, and/or with kinetics of its bone effects that might need longer exposure.

AB0099 TAXOL ALLEVIATES COLLAGEN-INDUCED ARTHRITIS IN MICE BY INHIBITING THE FORMATION OF MICROVESSELS

J. Xu[1], Z. Feng[2], J. Zhu[3], S. Chen[1], X. Chen[4], J. Li[3]. *[1]Department of Internal Medicine of Traditional Chinese Medicine, College of Traditional Chinese Medicine, Southern Medical University, Guangzhou; [2]Department of Traditional Chinese Medicine, Medical College of China Three Gorges University, Yichang; [3]Department of Rheumatology, Nanfang Hospital, Southern Medical University; [4]Department of Pathogen Biology, School of Public Health, Southern Medical University, Guangzhou, China*

Background: Angiogenesis is one of the critical features in rheumatoid arthritis (RA). Uncontrolled neovascularization could help the infiltration of inflammatory cells and lead to synovial hyperplasia and bone destruction further. Precious studies have demonstrated that the medicine taxol (PTX) has anti-angiogenesis effects.
Objectives: To evaluate the inhibitory effects of PTX on angiogenesis in a collagen-induced arthritis (CIA) mouse model.
Methods: A total of 50 mice were used to induce a CIA mouse model with collagen II (CII) and complete Freund's adjuvant (CFA). Twenty-four with obvious arthritis syndrome were randomly divided into four groups: CIA model group, PTX 1.5 mg/kg group, PTX 1.0 mg/kg group, PTX 0.5 mg/kg group. In addition, 6 normal mice was regarded as the control group. PTX was administered by intraperitoneal injection in the PTX treatment groups 8 times every other day. Arthritis index scores, tissue pathology scores after HE staining and synovium microvessel density (MVD) analysis after immunohistochemical (IHC) staining were performed. Immunohistochemistry and ELISA were used to detect the expression of vascular endothelial growth factor (VEGF) and hypoxia-inducible factor-α (HIF-1α). Additionally, the correlation between MVD and pathological scores, level of VEGF and HIF-1α in the synovium were also evaluated.
Results: After PTX treatment, the three intervention group arthritis index scores (1.33±0.52, 2.00±0.63, 3.33±1.03) declined when compared with the CIA group (5.67±1.03, $p<0.001$, $p<0.001$, $p=0.016$). The total histological scores in the three PTX treatment groups (2.50±0.66, 3.89±0.86, 3.89±0.86) were lower than those in the CIA group (7.67±0.79, $p<0.001$, $p<0.001$, $p=0.007$). Similarly, PTX significantly alleviated the scores for synovitis, pannus formation and bone destruction. Compared with the CIA group (110.32±5.06/mm^2), the MVD of the three intervention groups decreased in dose-dependent manner (17.05±1.97/mm^2, 34.73±2.36/mm^2, 57.55±2.72/mm^2; $p<0.001$, respectively). In addition, the expression of VEGF and HIF-1α in synovial tissues and serum also decreased significantly after PTX treatment. Further analysis showed that MVD and pathological scores and levels of VEGF and HIF-1α in the synovium were positively correlated ($r=0.921$, $r=0.944$, $r=0.889$, $r=0.969$, $r=0.933$; $p<0.001$, respectively).
Conclusions: PTX may alleviate CIA by suppressing angiogenesis, providing new insights into the treatment of RA. VEGF and HIF-1α may be the target for PTX suppression of microvessel formation.

AB0100 MTX COMBINED WITH CTX INHIBITED IL-6 INDUCED JAK2-STAT3 ACTIVATION AND THE INDUCTION OF P-GP IN PERIPHERAL BLOOD LYMPHOCYTES OF RHEUMATOID ARTHRITIS PATIENTS

K. Chen[1], Y. Mu[1], K. Qin[1], X. Zhao[1], J. Dong[1], X. Li[1], C. Gao[2], C. Wang[1]. *[1]Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Pathology, Joint Program in Transfusion Medicine, Brigham and Women's Hospital/Children's Hospital Boston, Harvard Medical School, Boston, United States*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by irreversible joint destruction and disability. At present, the biggest challenge in the field of RA treatment is the emergence of multidrug resistance (MDR) in the application of disease-modifying anti-rheumatic drugs (DMARDs).The Multidrug resistance Related Protein and Multi Drug Resistance protein 1, also called P-glycoprotein can decreases the intracellular concentration of different drugs. Moreover, cytokines play an increasingly important role in the expression regulation mechanisms of P-gp, especially inflammatory cytokines IL-6. Previously, We have indicated that Interleukin-6 up-regulates P-gp in peripheral blood lymphocytes via the JAK2-STAT3 pathway in RA patients. Through more than ten-years' clinical research, we observed that the therapeutic cycle alliance of methotrexate (MTX) and cyclophosphamide (CTX) has had better curative effect and lower rate of adverse reaction in treating RA. And we didn't found the emergence of MDR. How can the therapeutic alliance of MTX and CTX overcome MDR in RA patients? This study will give the answer.
Objectives: To Clarify whether the therapeutic alliance of MTX and 4-hydroperoxycyclophosphamide (4-HC) suppress expression and mRNA of P-gp in peripheral blood lymphocytes of RA through JAK2-STAT3 pathway.
Methods: RA patients without any DMARDs and biologic therapy (n=15) were enrolled. P-gp expression level was detected by Flow Cytometry. P-gp mRNA of peripheral blood lymphocytes and the intracellular signaling pathway mediating the effects of MTX and 4-HC on IL-6-stimulated JAK2-STAT3 activation was assessed by RT-PCR.
Results: Compared with blank control group, IL-6 induced P-gp, JAK2 and STAT3 expression levels increased significantly ($P<0.05$). Compared with IL-6 group, P-gp, JAK2 and STAT3 expression levels of 4-HC group and low MTX+4-HC group both decreased ($P<0.05$). the expression levels of P-gp, JAK2 and STAT3 in low MTX group, middle MTX group and high MTX group were lower than IL-6 group, but there were no statistically significant differences ($P>0.05$).
Conclusions: Our data indicated that MTX combined with CTX significantly inhibited IL-6 induced JAK2-STAT3 activation, as well as the induction of P-gp. Inhibition of IL-6-mediated multidrug resistance signaling pathways by the alliance of MTX and CTX may represents a new reversing drug-resistance therapeutic strategy for RA.

AB0101 NEW MUTATED PEPTIDYLARGININE DEIMINASE FROM PORPHYROMONAS GINGIVALIS A TARGET IN EARLY RA CITRULLINATES MAJOR RA-AUTOANTIGENS

M. Jenning[1], B. Marklein[1], J. Yetterberg[2], G. Burmester[1], K. Skriner[1]. *[1]Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin; [2]Department of Rheumatology and Clinical Immunology, Karolinska Institutet, Stockholm, Germany*

Objectives: Previous reports showed that peptidylarginine deiminase (PPAD) form *Porphyromonas gingivalis (P.g.)* is not able to citrullinate proteins internaly. New mutated PPAD (mPPAD) from *P.g.* involved in periodontal disease (PD) cloned out of *P.g.* strain was characterized and analyzed for its reactivity in sera from patients with systemic autoimmune diseases
Methods: We cloned a new enzymatically active recombinant mutated PPAD from *P.g. mPPAD* mutations and citrullination sites were analyzed by DNA sequencing and/or protein mass spectrometry. Autocitrullination activity it's enzymatic-activity and human autoantigen protein citrullination was investigated by 2D-Elektrophoresis, MS, immunoblot analysis and ELISA. Furthermore we tested anti-mPPAD/cit-mPPAD with human sera (n=93) from early RA before and after onset of RA (n=30), established RA (n=32), SLE (n=16) and healthy blood donors (n=15) in ELISA assays. To study a potential impact on the RA mouse model (CAIA), mPPAD-containing vesicles from *P.g.* were injected by intraperitoneal injection (IP).
Results: Recombinant mPPAD lacks 43 amino acids at the N-terminus and exhibits so far two new amino acid mutations (amino acid position 73 (F>L) and 447 (E>V). We were able to demonstrate, mPPAD is enzymatically active over a huge pH-range (3–10) and autocitrullinates at amino acid position 63 the arginine to citrulline. Moreover mPPAd citrullinates major autoantigens in RA (Fibrinogen, Vimentin and hnRNP-A2/B1) which are detectable by RA patient sera and specific anti-citrulline monoclonal antibodies. mPPAD citrullinates HeLa-protein extracts and these specific citrullinated proteins are recognized by RA patient sera. Anti-citrullinated mPPAD antibodies were detected in 41% (n=32) of patients with RA but not in SLE (n=16) and control sera (n=15). In a RA follow-up study (n=30), we detected nearly similar antibody-sensitivities for citrullinated mPPAD before and after onset of RA (13/20%). Only a minority (7%) of RA patients show higher mPPAD antibody levels after RA diagnosis. In the Collagen antibody-induced arthritis (CAIA) RA mouse model mPPAD containing *P.g.* vesicles when injected IP showed a TLR2-dependent protective anti- inflammatory effect like *P.g.* LPS and Lipomannan.
Conclusions: Pg. infection and RA disease diagnosis occurs on different time-points and Pg. infection induces a TLR2-dependent protective anti-inflammatory effect.We show the first time that mPPAD can citrullinate major human autoantigens internally and their immunologically and diagnostic relevance.

AB0102 IMPAIRMENT OF GRANZYME B-PRODUCING REGULATORY B CELLS EXACERBATED RHEUMATOID ARTHRITIS

L. Xu, F. Hu, X. Liu, L. Zhu, L. Ren, H. Liu, H. Zhu, Y. Su. *Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China*

Background: Rheumatoid arthritis (RA) is a common and complex autoimmune disease characterized by chronic inflammation and cartilage/bone damage involving numerous cells, such as T cells, B cells, chondrocytes, fibroblasts [1]. B cells had long been well-demonstrated to participant in the development of RA [2]. Except producing specific antibody and inducing T cell activation, impaired immunosuppressive function of B cells further emphasized their roles in RA recently [3].
Objectives: To investigate whether B cells could produce granzyme B and the potential role in the pathogenesis of Rheumatoid arthritis (RA).
Methods: To reveal the expression of granzyme B in B cells, flow cytometry, PCR and Elispot were performed. The role of IL-21 and anti-BCR stimulation on granzyme B expression was assessed by in vitro stimulation assay. $CD4^+$ T cell-B cell co-culture in the presence of granzyme B neutralizing antibody was performed to demonstrate the function of these cells. Then the levels of granzyme B in B cells between RA patients, OA patients as well as HCs were compared. Next,the correlation analysis between granzyme B-producing B cells and clinical features in RA patients was performed. Finally, the frequencies of granzyme B-producing B cells in RA patients before and after therapy were also evaluated using flow cytometry.
Results: B cells could spontaneously produce granzyme B, which could be perpetuated by IL-21 and anti-BCR stimulation. The frequencies of Th1 and Th17 cells were significantly elevated under the condition of granzyme B blockade when granzyme B was neutralized in $CD4^+$ T cell-B cell co-culture. In RA patients, but not OA patients and HCs, the frequencies of granzyme-B producing Bregs decreased significantly, which was functionally impaired and negatively correlated with disease activity score 28. Moreover, after effective clinical therapy, the frequencies could recover to nomal levels.
Conclusions: B cells could exert the regulatory functions via granzyme B production. Under RA circumstance, these granzyme B-producing Bregs were impaired and contributed to the disease progression.

AB0103 ANTI-INFLAMMATORY AND IMMUNOMODULATORY EFFECTS BY HUMAN UMBILICAL CORD MESENCHYMAL STEM CELL DERIVED MICROVESICLES IN RATS WITH COLLAGEN INDUCED

M. Tian, K. Xu, L. Zhang, J. Gao. *Rheumatology, Shanxi DaYi Hospital, Shanxi Academy of Medical Sciences, Taiyuan, China*

Background: Immunologic deranging and persistent inflammation is closely associated with the arising and developing of rheumatoid arthritis (RA). Increasing investigators demonstrated microvesicles (MVs) derived from mesenchymal stem cell (MSC-MVs) might simulate immune regulation and tissue repair of the parental cells. However,the immunotherapeutic potential of MVs in RA remains unknown.
Objectives: We investigated the therapeutic effects of MSC-MVs in RA model collagen induced arthritis (CIA) rats.
Methods: We tested the therapeutic effects of MSC-MVs on CIA rats,levels of T helper 17(Th17), regulatory T cell,and cytokines related,as well as specific transcriptional regulation factor Foxp3 and ROR-γT analysis was performed.
Results: Here, we show that MSC-MVs administration effectively improve arthritic symptoms, inhibit synovial hyperplasia,thus delaying the progression to inflammatory bone destruction, as effective as their original cells, exerting arthralprotective effects. MSC-MVs treating inhibited the proliferation of T cell,accelerated the apoptosis. MSC-MVs treating reduce proinflammatory cell Th17,cytokines IL-17, while a incline in the level of an-inflammatory cell Treg,ncytokines TGF-β. In the spllen and ankle joint of CIA rats, MSC-MVs treating increased the expression level of Foxp3 and coinciding with the ROR-γT suppressed, which, the enhanced therapeutic effects correlated with the increase of dosage in a certain range.
Conclusions: MSC-MVs showing anti-inflammatory and immunomodulatory activities on CIA rats, suggesting a new and feasible strategy for protection against RA.

AB0104 ALTERATIONS OF SPLICEOSOME COMPONENTS IN LEUKOCYTES FROM PATIENTS WITH RHEUMATOID ARTHRITIS INFLUENCE THEIR AUTOIMMUNE AND INFLAMMATORY PROFILE, AND THE DEVELOPMENT OF CARDIOVASCULAR DISEASE

P. Ruiz-Limon[1], C. Perez-Sanchez[1], R. Ortega-Castro[1], S. Pedraza-Arevalo[2], M. del Rio-Moreno[2], Y. Jimenez-Gomez[1], I. Arias de la Rosa[1], M. Ábalos-Aguilera[1], M. Aguirre[1], P. Segui[1], E. Collantes[1], A. Escudero[1], J. Castaño[2], R.M. Luque[2], N. Barbarroja[1], C. Lopez-Pedrera[1]. *[1]Rheumatology Service; [2]Department of Cell Biology, Physiology, and Immunology, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain*

Background: A significant percentage of genetic and inflammatory diseases derive from splicing alterations. Therefore, the understanding of what modifications in spliceosome determine an alternative splicing and its association with the development of such pathologies is of critical importance.
Objectives: To identify the alterations present in the spliceosome machinery of patients with rheumatoid arthritis (RA),its influence on the development and activity of the disease and their atherothrombotic profile.
Methods: An array of selected components of the major- (n=12) and minor-spliceosome (n=4) and associated splicing factors (n=28) was developed, and their expression levels were evaluated using a Fluidigm methodology, in purified leukocytes from 14 RA patients and 14 healthy donors (HD). In parallel, an extensive clinical/serological evaluation was performed. Carotid intimate media thickness (CIMT) was used as atherosclerosis marker. Endothelial activity was monitored by laser-doppler flowmetry, and pro-inflammatory and oxidative stress markers were quantified. Association of these splicing components with clinical and analytical features were investigated.
Results: A significant alteration in various components of spliceosome and splicing factors was found in all the leukocytes subtypes from RA patients vs HD. Interestingly, we found a specific altered profile of splicing factors and spliceosome components when compared monocytes (CA150, PRP8, SRM160, U2AF1, RNU4atac, PTBB1, RAVER1, RBM17, SRSF4, SRSF10), lymphocytes (RNU12, RNU4, RNU6, PRP8, MAGOH, NOVA1, SRSF3) and neutrophils (RNU11, RNU6, SC35, RBM3).
Altered levels of various spliceosome elements in monocytes were associated with the presence of *atheromatous* plaques, while in neutrophils were found related to radiological involvement. In lymphocytes, the alteration of these components were linked to the positivity for Rheumatoid Factor and anti-CCPs antibodies, indicating that modifications in the spliceosome machinery could contribute to the increase in the production and assembly of autoantigens, inducing autoantibody production.
Correlation studies showed a significant relationship between altered levels of various spliceosome components in different leukocyte subtypes and high disease activity (DAS, HAQ), increased expression of proinflammatory mediators (CRF, TF, TNF, IL-8, TLR4) and oxidative stress markers (peroxides, GPX, SOD)as well as with parameters associated with insulin resistance.
Conclusions: These results reveal that there is a significant alteration of spliceosome components in RA patients that could be associated with the development and activity of this autoimmune condition, and influence mechanisms that drive the development of cardiovascular disease. Studies in progress will help to clarify the physiological implications of these findings, which could constitute new diagnostic biomarkers, as well as new therapeutic tools for the treatment of RA.

AB0105 DOXYCYCLINE AND DEXAMETHASONE-INDUCED REPROGRAMMING OF PERIPHERAL BLOOD MONONUCLEAR CELLS IN A MODEL OF ARTHRITIS WITH THE SYSTEMIC MANIFESTATIONS IN WISTAR RATS

P. Litvitskiy[1], V. Sakharov[1], E. Alexeeva[2], N. Mayansky[2], R. Zakirov[2]. *[1]Pathophysiology, Sechenov First Moscow State Medical University; [2]Scientific Center of Children's Health, Moscow, Russian Federation*

Background: The systemic juvenile idiopathic arthritis (sJIA) is a problem with high social significance all over the world. Targeted cell reprogramming becomes one of the most important lines for modern medicine and can be regarded as

an origin for new highly improved treatment strategy of sJIA. As rat monocytes exhibited CD163 expression in a similar level with that shown for peritoneal macrophages [1], we decided to use CD163 as a key factor indicating cell reprogramming in the study.

Objectives: To investigate the dynamical changes in subpopulations of peripheral blood mononuclear cells (PBMC) and to assess doxycycline and dexamethasone effects in a model of arthritis with the systemic manifestations.

Methods: Animal model [2] was adapted in 24 Wistar rats (males, 6 month old). On the day of the last stimulation all the rats were divided into 3 equal groups and additional subcutaneous (s.c.) injections were performed as follows: DOXY-group – doxycycline (50 mg/kg, Saratov, Russia), DEXA-group – dexamethasone (4 mg/kg, KRKA, Slovenia), control group – 0,9% sodium chloride solution (Belarus). The s.c. injections were repeated on Day 54. Time points were 0, 21, 41, and 55 Days. PBMC were assessed by flow cytometry (BD FACSCanto II, USA) according to manufacturer's instructions. Staining was performed with FITC Anti-Rat CD11b (BD Pharmingen), anti-rat CD68 RPE (Serotec, UK), anti-rat CD163 ALEXA FLUOR 647 (Serotec, UK). CD11b+CD68+ and CD11b-CD68+ cells were regarded as monocytes and circulating dendritic cells consequently. At the termination animal organ masses were measured.

Results: Up to Day 55 proportions of CD163+ in CD11b+CD68+ population changed synchronically in all groups. On Day 55 the proportions (in comparison with the data of Day 41) were significantly higher in DEXA-group ($p<0,05$) but didn't change in DOXY- and control groups ($p>0,05$). Cell reprogramming was also observed in population of CD11b-CD68+. So, on Day 41 the proportions of CD163+ cells in CD11b-CD68+ population were significantly increased (in comparison with the data of Days 0 and 21) in DOXY- and DEXA-groups ($p<0,05$) but not in control group ($p>0,05$). Mentioned changes were subsequent with other parameters of inflammation. We observed significantly lower heart masses in DOXY- and DEXA-groups (median=0,63 and 0,635g consequently) in comparison with control group (median=0,74g) ($p<0,05$), but no difference between DOXY- and DEXA- groups ($p>0,05$).

Conclusions: In a model of arthritis with the systemic manifestations in Wistar rats we demonstrated that subpopulations of PBMC (CD11b-CD68+ and CD11b+CD68+) underwent reprogramming. Doxycycline and dexamethasone modyfied the dynamics of the reprogramming. In DOXY- and DEXA-groups there were lower heart masses than in the control group, the last fact is subsequent with the data by De P. et al. [3]. We can speculate that monocytes and dendritic cells undergo reprogramming (CD163neg and CD163+) in a similar way with M1 and M2 macrophages.

AB0106 EFFECT OF SERUM CYTOKINES ON COLLAGEN INDUCED ARTHRITIS RATS AFTER INTRA-ARTICULAR INIECTION OF OZONE

R. Guo, G. Zhang, L. Zhang, N. Liu. *Department of Rheumatology, Shanxi Dayi Hospital, Taiyuan, taiyuan, China*

Background: Ozone is a new treatment method, study confirmed that the ozone intra-articular injection can reduce the level of TNFR II CIA in rat synovial TNF-a, synovial tissue, the regulation of rat apoptosis inhibiting gene Bcl-2 decreased expression of proapoptotic gene Bax expression increased, thereby promoting apoptosis of synovial cells. However, there are few reports on the effects of ozone on the inflammatory cytokines such as serum TNF-a in the pathogenesis of RA.

Objectives: To observe the effects of intra-articular ozone iniection on the contents of tumor necrosis factor-α(TNF-α),Interleukin-6 (IL-6), IL-17A,and vascular endothelial growth factor (VEGF)in the serum of rats with collagen-induced arthritis (CIA) and explore the therapeutic mechanism of ozone in RA treatment.

Methods: Thrity-two Wistar rats were randomized into 4 groups,including ozone groups receiving intra-articularinjection of 40 μg/ml ozone (O_3 group), Ca blank control group (normal group), a methotrexate group (MTX group) and a collagen-induced arthritismodel (CIA group). All the rats, except for those in the blank control group, were subjected to hypodermic iniection of bovine collagen II and complete Freund'S adiuvant to induce CIA. DOzone treatment was administered once weekly for 3 weeks starting at 14 days after the modeling.MTX group of 0.9 mg/kg, once a week, a total of three weeks.The swelling degree of the foot were observed,the serum contents of TNF-α,IL-6,IL-17A and VEGF were detected. One-way analysis of variance or Kruskal-Wallis test was used to evaluate the experimental data.

Results: At the end of treatment,the foot swelling degree was reduced significantly in rats with O_3 group compared with that in the CIA group [4.21±0.14 ml and 9.12±0.17 ml, t=8.43, P=0.023]. The serum contents of TNF-a, IL-6 and VEGF showed significant difference between the CIA group and O_3 group [93.86±12.49 pg/ml and 14.33±1.85 pg/ml, c^2=6.216, P=0.002; 189.12±164.62 pg/ml and 5.84 (5.47,15.93) pg/ml, c^2=13.136, P=0.00451.56 (46.09,74.10) pg/ml and 37.77±7.88 pg/ml, c^2=3.732, CP=0.002, there was no statistically significant difference between the O_3 group and MTX group [14.33±1.85 pg/ml and 12.45 (11.8,15.6)) pg/ml, c^2=0.243, P>0.05; 5.84 (5.47,15.93 pg/ml, vs 9.59±5.13 pg/ml, c^2=0.058, P>0.05; 37.77±7.88 pg/ml and 41.99±8.78 pg/ml, c^2=0.516, P>0.05]. The serum contents of IL-17A showed no significant difference between the normal group,CIA group,MTX group and the O_3 group (F=1.827, P=0.165).

Comparison of serum levels of inflammatory cytokines in each group rats

	TNF-α (MFI)	IL-6(pg/ml)	IL-17A(pg/ml)	VEGF(pg/ml)
control group	11.21±1.44	10.23±3.18	0.49±0.34	27.65±9.84
CIA group	93.86±12.49[a]	189.12±164.62[a]	0.77±0.18	51.56(46.09,74.10)[a]
MTX group	12.45(11.8,15.6)[b]	9.59±5.13[b]	0.49±0.32	41.99±8.78[a]
O_3 group	14.33±1.85[b]	5.84(5.47,15.93)[b]	0.64±0.27	37.77±7.88[b]
χ^2/F	23.148	17.116	1.827	12.574
P	0.000	0.001	0.165	0.006

Note: [a] indicated that P<0.05 was compared with the control group; [b]indicated that P<0.05 was compared with CIA group;

Conclusions: Intra-articular iniecfion of 40 ug/ml ozone Can attenuate svnovitis in rats with CIA, the mechanism of which may involve the inhibition of TNF-a, IL-6 and VEGF in the serum.

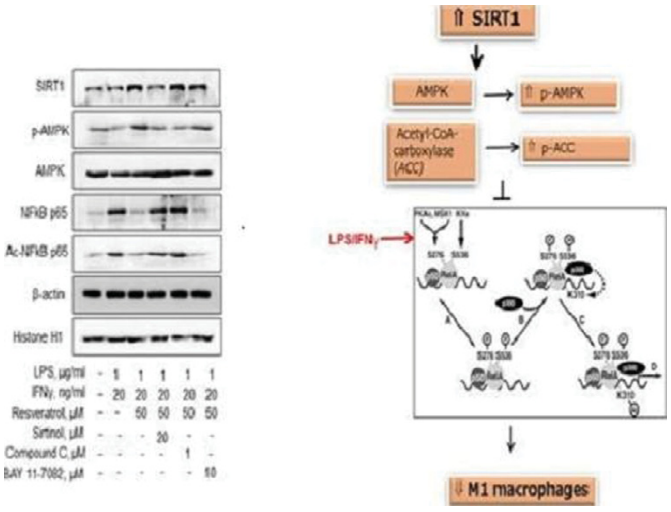
AB0107 THE MODULATION OF MACROPHAGE POLARIZATION BY SIRT1 MAYBE NEW TARGET THERAPY IN RHEUMATOID ARTHRITIS

S.Y. Lee[1], S.W. Lee[1], W.T. Chung[1], S.Y. Park[2], J.H. Bae[3]. *[1]Rheumatology of Internal Medicine, Dong-A University Hospital; [2]Rheumatology of Internal Medicine; [3]Biochemistry, Pusan national university, Pusan, Korea, Republic Of*

Background: The polarization of macrophages was the expressed to M1/M2 phenotype by various stimuli or environment signals. The M1 macrophage was pro-inflammatory phenotype and was key effector cells in the immune response of rheumatoid arthritis (RA). So, M1 macrophage influenced the inflammation of RA synovial membrane and joint destruction in RA, whereas M2 macrophage was anti-inflammatory phenotype and could down-regulate the production of proinflammatory cytokines in RA. The SIRT1 attenuated the RA inflammation via down-regulation of NF-κB signaling. However, the effect of SIRT1 on macrophages polarization remained uncler.

Objectives: We aimed to check out that activated SIRT1 modulated macrophages polarization into M1 phenotype and controlled the inflammation of RA.



Methods: Monocytes from synovial fluid of RA patients, bone marrow–derived monocytes (BMDCs) from mice were studied. monocytes were cultured with M-CSF for 7days to differentiate into M0 macrophages (monocyte-derived mature macrophages M0 phenotype). M0 macrophages were incubated with LPS and IFN-gamma in order to obtain M1 macrophages. M1 macrophage markers were detected by real-time PCR.

Results: Activation of SIRT1 was achieved by Resveratrol, activated SIRT1 attenuated M1 macrophage phenotypes and pro-inflammatory cytokine expression. macrophages obtained from SIRT1-tg mice, which were overexpression of SIRT1, exhibited decreased M1 markers in association with enhanced activation of AMPK/ACC compared with macrophage from control C57BL/6 mice. In addition to SIRT1 activation, M1 polarizing signal, acetylation of NF-κB p65, was suppressed. In SIRT1-deficient macrophages, resveratrol fail to increase AMPK activity and to decrease the expression M1 markers owing to enhanced acetylation of NF-κB p65.

Conclusions: SIRT1 maybe an important modulator of M1 macrophages polarization and increased AMPK activity, which suppressed acetylation of NF-κB p65 during inflammation of RA. so, modulation of SIRT1 maybe a new target in RA treatment.

AB0108 DECREASED EXPRESSION OF PTPN22 GENE IN PATIENTS WITH RHEUMATOID ARTHRITIS CARRYING THE RISK ALLELE OF PTPN22 RS2488457 POLYMORPHISM

S. Remuzgo-Martínez[1], S. Castañeda[2], A. Corrales[1], F. Genre[1], R. López-Mejías[1], P. Moreno-Fresneda[2], B. Ubilla[1], V. Mijares[1], V. Portilla[1], J. González-Vela[1], T. Pina[1], G. Ocejo-Vinyals[3], J. Irure-Ventura[3], R. Blanco[1], J. Martín[4], J. Llorca[5], M.A. González-Gay[1,6]. *[1]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Department, IDIVAL, Santander; [2]Rheumatology Department, Hospital Universitario la Princesa, IIS-IP, Madrid; [3]Immunology Department, Hospital Universitario Marqués de Valdecilla, Santander; [4]Instituto de Parasitología y Biomedicina "López-Neyra", CSIC, PTS Granada, Granada; [5]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL; [6]School of Medicine, University of Cantabria, Santander, Spain*

Background: Mutations in the protein tyrosine phosphatase non-receptor 22 (*PTPN22*) gene are associated with numerous connective tissue and autoimmune diseases [1]. In particular, *PTPN22* has been recognized as the main non-HLA genetic risk factor involved in rheumatoid arthritis (RA) susceptibility [2]. Moreover, it has been suggested that *PTPN22* modulation may influence on inflammatory processes associated with RA [3,4].
Objectives: To determine if *PTPN22* (rs2476601, rs33996649 and rs2488457) polymorphisms, associated with RA, may influence on *PTPN22* expression in RA patients compared to healthy controls. Moreover, the association between *PTPN22* expression in patients with RA and their clinical characteristics was studied.
Methods: *PTPN22* messenger RNA (mRNA) expression was quantified by quantitative real-time PCR in peripheral blood samples from 42 RA patients and 24 healthy controls. *PTPN22* rs2476601 (G>A), *PTPN22* rs3399649 (C>T), and *PTPN22* rs2488457 (C>G) single-nucleotide polymorphisms (SNP) were genotyped by TaqMan SNP genotyping assays. Differences in *PTPN22* expression between patients and controls were analyzed by Student's t test, according to their genotype. Correlation coefficients were also assessed between *PTPN22* expression in RA patients and their clinical characteristics.
Results: A significant down-regulation of *PTPN22* expression in patients with RA carrying *PTPN22* rs2488457 risk allele (G) compared to controls was observed (relative mean values of *PTPN22* mRNA levels ± standard deviation: 2.93±0.76 vs 4.33±0.63, p=0.0004). Furthermore, an inverse relationship between *PTPN22* expression and disease duration (r=-0.38, p=0.03) was found. These results were adjusted by sex, age at time of study and cardiovascular risk factors.
Conclusions: Our study shows for the first time that the risk allele of *PTPN22* rs2488457 polymorphism influences on the down-regulation of *PTPN22* in patients with RA. This result suggests a transcriptional suppression of *PTPN22* gene in RA, which in turn may play an important role in disease diagnosis and progression.

AB0109 AUTOPHAGY INHIBITOR REGULATES APOPTOSIS AND PROLIFERATION OF SYNOVIAL FIBROBLASTS THROUGH THE INHIBITION OF PI3K/AKT PATHWAY IN COLLAGEN-INDUCED ARTHRITIS RAT MODEL

S. Li, F. Li, W.J. Chen, C. Deng. *Department of Rheumatology and Immunology, the Second Xiang Ya Hospital, Central South University, Changsha, Hunan, China, Changsha, China*

Background: Mounting studies have illustrated an important role of autophagy in various diseases, but few studies have reported its contribution to rheumatoid arthritis (RA) and the underlying mechanism is largely unknown.
Objectives: This study aimed to investigate whether autophagy inhibitors could regulate apoptosis and proliferation through PI3K/AKT pathway in RA.
Methods: RA animal model was established by collagen induction. General observations and degree of joint swelling were observed. Inflammatory response, cell survival related factors and apoptosis were also detected in synovial fibroblasts. In addition, cultured rheumatoid arthritis fibroblast-like synoviocytes (RA-FLS) were subjected to TNF-α treatment *in vitro*, and TNF-α induced cell autophagy, synovial cell proliferation and apoptosis were detected. Moreover, cell cycle and cytokine secretion protein, along with the above parameters, were analyzed.
Results: Results from the animal model showed that autophagy inhibitors could attenuate inflammatory reaction and synovial hyperplasia, while promoted synovial fibroblasts apoptosis. Meanwhile, inhibition of autophagy promoted cell apoptosis and reversed cell proliferation *in vitro*, also blocked cell in the G2/M arrest and reduced the S phase cells. Furthermore, inhibition of PI3K/AKT pathway reversed TNF-α mediated autophagy and cytokine secretion.
Conclusions: autophagy inhibitors could mitigate inflammation response, inhibiting RA-FLS cell proliferation while promoting cell apoptosis by PI3K/AKT pathway.

AB0110 EVALUATION OF THE EFFECT OF CHUANTENGTONGBI DECOCTION ON DBA / 1 MICE CIA MODEL

X.-Q. Wang, X.-D. Shen, X.-Y. Zhang, X. Du. *Department of Traditional Chinese Medicine, School of Basic Medical Sciences, Beijing University of Chinese Medicine, Beijing, China*

Background: DBA/1 mouse ($H2^q$ type) CIA model as a mature model of rheumatoid arthritis is widely used in pharmacology and pharmacodynamics research[1]. Chinese medicine treatment of rheumatoid arthritis has accumulated rich experience. The study of Tripterygium glycosides is quite representative, and it has been widely used in the past 30 years. Some Clinical studies showed that tripterygium glycosides treatment of rheumatoid arthritis had good effect[2]. ChuanTengTongBi decoction is also the effective prescription commonly used for the treatment of rheumatoid arthritis.
Objectives: To investigate the pathological damage degree of DBA/1 mouse CIA model and the effects of different doses of ChuanTengTongBi decoction on the CIA model mice.
Methods: The mice were divided into normal group, model group, leflunomide group (3.11mg/kg/d), low-dose of ChuanTengTongBi group (0.44g/ml/d), medium-dose group (0.88g/ml/d) and high-dose group (1.76g/ml/d).
Results: The arthritis index (AI) was evaluated every week to determine whether the model was successful. We defined AI score ≥4 as successful model (AI score

standard:0, No swelling;1, Slight redness and swelling;2, Moderate redness and swelling of ankle; 3, Severe redness and swelling of the entire paw;4, Maximally inflamed limb with involvement of multiple joints [3]). Day 28–42, hind foot redness and swelling of the mouse continued to develop and extended to the forefoot. Compared with the normal group, incidence of CIA model group reached 100%. Day 49, compared with the model group by joint scores, medium-dose group, high-dose group and leflunomide group have Significant differences on CIA model ($p<0.01$). Compared with the Leflunomide group, low-dose group, medium-dose group and high-dose group have no obvious difference ($p>0.05$). Compared with the low-dose group, medium-dose group and high-dose group have no difference ($p>0.05$).

Table 1. Joint scores (mean ± SD)

groups	28d	35d	42d	49d
a	o	o	o	o
b	8.05±1.62	12.40±2.10	14.68±1.77	12.33±1.68
c	8.66±0.14	11.99±0.23	12.10±0.23**	11.30±0.22**
d	7.90±0.34	11.40±0.18	12.80±0.20**	12.00±0.13
e	7.40±0.23	10.90±0.13*	10.40±0.44**	10.60±0.36**
f	8.80±0.24	10.60±0.30*	11.30±0.22**	8.80±0.55**

a. Blank group. b. Model group. c. Leflunomide group. d. Low-dose group. e. Medium-dose group. f. High-dose group. Compared with the model group, *$p<0.05$, **$p<0.01$.

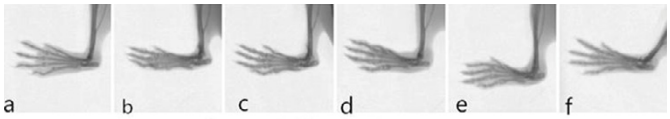

figure 1. Ankle Joint X-ray

a.blank group b.model group c.leflunomide group d.low-dose group e.medium-dose group f.high-dose group

Conclusions: CIA model has a high morbidity, long duration, macroscopic pathological manifestation and irreversible ankle joint deformation, which is consistent with the progress of human RA disease and pathological damage. Medium-dose of ChuanTengTongBi decoction, high-dose and leflunomide group had inhibitory effect on the progress of arthritis, and the effect of high-dose was better than that of leflunomide group.

AB0111 CADMIUM NANOPARTICLES CITRULLINATE INTRACELLULAR CYTOKERATINS: CADMIUM POTENTIALLY LINKS RHEUMATOID ARTHRITIS TO SMOKING AND NUMEROUS WORKING CLASS OCCUPATIONS

D. Hutchinson[1], J. Müller[2], J.E. McCarthy[3], Y. Gun'ko[3], N. Verma[4], X. Bi[5], L. Di Cristo[3], L. Kickham[3], D. Movia[3], A. Prina-Mello[3], Y. Volkov[3]. *[1]Royal Cornwall Hospital Trust, University of Exeter Medical School, Truro, United Kingdom; [2]University of Basel, Switzerland, Basel., Switzerland; [3]Trinity College, Dublin, Ireland; [4]Nanyang Technological University; [5]Bioprocessing Technology Institute, Singapore, Singapore*

Background: Smoking has emerged as a consistent risk factor for ACPA positive RA, although the specific constituents of cigarette smoke that induce citrullination are unknown. It has been hypothesised that cadmium triggers RA as its inhalation links various well established risk factors for RA such as smoking (the most important environmental source of cadmium) and numerous working class occupations [1].

Objectives: To determine whether the cadmium-derived materials induce intracellular citrullination.

Methods: Human A549 lung epithelial cells were exposed to cadmium in ionic and particulate form represented by cadmium chloride and cadmium oxide, respectively, and their combinations with ultrafine carbon black (ufCB) nanoparticles produced following high temperature combustion, imitating cigarette burning. Protein citrullination in cell lysates was analysed by SDS-PAGE electrophoresis with western blotting and verified by immunofluorescence staining and confocal microscopy. Target citrullinated proteins were identified by proteomic analysis.

Results: Cytotoxicity studies demonstrated that cadmium compounds were toxic to the cells. Based on the results of cytotoxicity measurements, all the materials utilised in the experiments were subsequently applied to the cells in sub-toxic concentrations. Cadmium oxide, ufCB and its combination with cadmium chloride and cadmium oxide after high temperature combustion induced citrullination of multiple proteins in cultured human lung epithelial cells of A549 cell line, as demonstrated by SDS-SDS-PAGE electrophoresis and western blotting. This phenomenon develops via a peptidylargininedeiminase-dependent mechanism, as demonstrated in our previous studies [2]. The majority of citrullinated proteins were represented by the bands corresponding to the molecular weights between 55 and 72 kDa, and several less abundant bands at the level of ~25kDa and over 130 kDa. Acidic cytokeratins of type I (9, 10) and basic/neutral cytokeratins type II (1, 2, 5, 6A, 6B and 77) were identified as major intracellular citrullination targets. Immunofluorescent staining demonstrated that the citrullinated proteins were localised both in the cytoplasm and nuclei of cells exposed to cadmium particles, similar to the distribution patterns observed in cells exposed to ufCB.

Conclusions: Cadmium nanoparticle exposure facilitates post-translational citrullination of proteins.

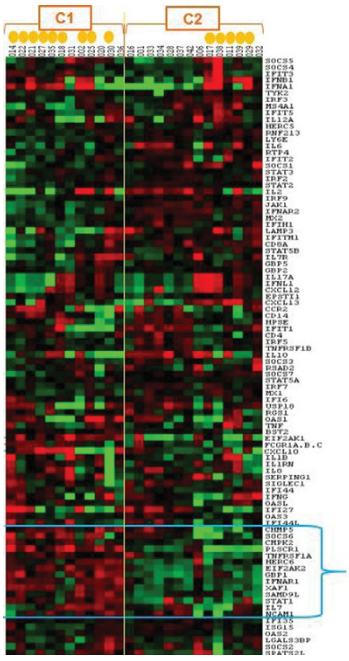
Spondyloarthritis - etiology, pathogenesis and animal models



AB0112 INTERFERON-REGULATED GENES (IRG) SIGNATURES DIFFERENTIATE GROUPS OF AS PATIENTS AND ARE ASSOCIATED WITH ANTI-TNF RESPONSE: PILOT DATA

S.R. Harrison, A.N. Burska, P. Emery, H. Marzo-Ortega, F. Ponchel. *Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Ankylosing Spondylitis (AS) is a chronic inflammatory arthritis characterised by sacroiliac/ lumbar spinal inflammation and extra-articular manifestations. Currently, TNF inhibitors (TNFi) are licensed for treatment-refractory AS; however, many patients do not respond to treatment and there is no way to predict Response/Non-Response (R/NR). The expression of several Interferon (IFN) signalling related genes (IRG) are associated with inflammatory diseases, including AS. Furthermore, an IRG expression signature has been used to predict treatment response in phase-Ia trials in systemic lupus erythematosus (1), demonstrating the feasibility of the use of IRG signatures as biomarkers in routine clinical practice.

Objectives: To explore whether IRG signatures differentiate groups of AS patients, and can be associated with response to TNFi in AS.

Methods: Twenty-six week-0 peripheral blood mononuclear cell (PBMC) samples

Unsupervised Hierarchical Clustering of IRG in AS patients

Red represents higher levels of gene expression and green represents lower levels of gene expression of the corresponding gene following normalisation to the housekeeping gene, GAPDH. Clustering defined two groups (C1 and C2), driven by expression of the 14 IRG (blue box). Patient study numbers are listed at the top of the cluster. An orange dot adjacent to a particular patient indicates that they were an ASDAS NR.

from AS patients participating in a previously reported in-house clinical trial [infliximab (IFX), n=15 vs. placebo (P), n=11] (2) were selected from our tissue bank. R/NR was defined as a ≥1.1 point reduction in AS Disease Activity Score (ASDAS) at week-30, or a reduction in the number of sacroiliac/vertebral MRI lesions. Expression of 96 IRG was quantified from PBMCs using custom TaqMan assays and analysed using unsupervised hierarchical clustering, Chi-Squared, and Mann-Whitney U tests.

Results: A total of 11 patients were clinical responders [IFX=7/15; P=4/11]. At week-0, patients clustered into 2 groups (C1/C2) based on expression of 14 IRG. Clinical/demographic characteristics were not significantly different between C1/C2 and groups were not biased for treatment (C1, IFX=8, P=4; C2, IFX=7, P=7, p=0.735). Improvement in ASDAS was weakly associated with C2 (C2, R=8/14, C1, R=7/12, p=0.098). Looking at IFX treated patients only (n=15), 2 cluster groups were observed (T1/T2) driven by 12 IRG. T2 was associated with a reduction in MRI lesions (T2 R=6/7, T1 R=3/8, p=0.057). Finally, paired week-0 and week-22 samples from 10 IFX-treated patients were analysed and clustered in 2 groups (H1/H2). Changes in IRG signature following treatment were observed towards segregating pre- and post- IFX treatment samples (H1, 6/8 week-0; H2, 8/12 week-22 p=?).

Conclusions: This pilot study suggests a possible association between IRG and response to IFX treatment in AS. These results now require assessment in a larger cohort in order to determine statistical and possible clinical significance, and to refine the signature further to construct potential predictive algorithms.

AB0113 THE RELATIONSHIP OF POLYMORPHISMS OF ANTXR2 GENE WITH ANKYLOSING SPONDYLITIS IN CHINESE HAN

Q. Lv, X. Wu, J. Gu. *Third Affiliated Hospital of Sun Yat-Sen Universit, Guangzhou, China*

Background: ANTXR2 as the protein binding to collagen IV and laminin, may be involved in extracellular matrix adhesion. GWAS study in European had found its SNPs has relationship with ankylosing spondylitis, but these variations were not related to Chinese people.

Objectives: In this study, we would find susceptibility locus in ANTXR2 associated with ankylosing spondylitis.

Methods: After the haplotype analysis from the 1000 Genomes Project data, we chose tags SNPs validated on 254 cases and 170 matched controls through Mass Spectrometry method. The patients were diagnosed accoding to the Modified New York Criteria for Ankylosing Spondylitis (1984).

Results: In 197 Chinese people from the 1000genome database, there are 16 Haplotype blocks of ANTXR2 gene. 5 SNPs were verified (rs78740643, rs11098964, rs28688624, rs4389526 and rs7689197) by mass spectrometry. Case/control association analysis showed rs11098964 having relationship with AS (P=0.01721, OR (95% CI) = 0.4793 (0.2554–0.8621)). Dominant model of rs11098964 were significant difference from controls (P=0.0109).

Conclusions: our study found the rs11098964 also has relationship with AS. rs11098964 was protective against AS. ANTXR2 is related to susceptibility to AS

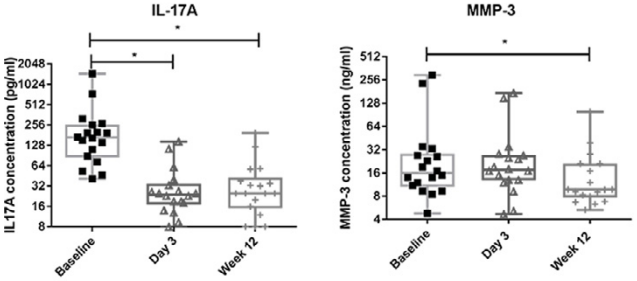
AB0114 EFFECTS OF ANTI-IL17A BLOCKADE WITH SECUKINUMAB ON SYSTEMIC AND LOCAL IMMUNE RESPONSES: A MECHANISM-OF-ACTION STUDY IN PERIPHERAL SPONDYLOARTHRITIS

L.J.J. Van Mens[1], M.G. van de Sande[1], S. Menegatti[2], I.C.J. Blijdorp[1], H.M. de Jong[1], I.A. Fluri[1], T.E. Latuhihin[1], A.W.R. van Kuijk[3], N.G. Yeremenko[1], D.L. Baeten[1,4]. *[1]AMC, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; [2]Immunology, Institut Pasteur, Paris, France; [3]Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; [4]UCB, Brussels, Belgium*



Background: IL-17A blockade is an effective therapy for ankylosing spondylitis (AS) and psoriatic arthritis (PsA), the two prototypical forms of spondyloarthritis (SpA). How IL-17A blockade affects the systemic and local immune responses in SpA remains incompletely understood.

Objectives: To assess the effect of anti-IL17A treatment with secukinumab on the systemic cytokine responses and the synovial immunopathology in SpA patients with peripheral disease (pSpA).

Methods: 20 active SpA patients were included in a 12wk open-label trial followed by 2yrs non-investigational extension. All patients received secukinumab 300mg/wk from baseline to wk4 and then every 4wks. Clinical response was measured 4wkly. TruCulture tubes with SEB and zymosan were drawn at baseline, day3, and wk12. Synovial biopsies were obtained by needle arthroscopy at baseline and wk12, analyzed by immunohistochemistry (IHC) and qPCR.

Results: The 20 pSpA patients consisted of 13 PsA, 3 undifferentiated SpA, 2 AS with peripheral arthritis, 1 reactive arthritis and 1 IBD associated pSpA. There were no SAEs in the 12wk core study. However, two SAEs occurred in the extension of the study: tonsillitis (suspected to be related to study drug) and myocardial infarction (non related), both fully recovered. Secukinumab induced a rapid and highly significant improvement in SJC (Baseline: 2,5 [IQR1–4] vs wk12: 0,5 [IQR0–1]p=0.001), TJC (6 [2–8] vs 0,5 [0–3]p<0.001); VASptglobal (46 [28–65] vs 13 [6–24]p<0.001). 18/20patients reached EULAR DAS response at wk 12 (10 good and 8 moderate responders). This was paralleled by significant improvements in other activity outcomes such as BASDAI (53 [25–63] vs 20 [9–40]p=0.001) and PASI (5,7 [4,5–7,1] vs 0,6 [0,1–1,8]p=0.001). Systemic inflammatory response revealed a decrease in CRP (3,85 [1,35–16,6] vs 2 [1,15–6,3]p=0,001) and ESR (16 [6–35] vs 6 [2,8–16,3]p=0,001), which was associated with decreased production of MMP-3, a validated biomarker of inflammation in pSpA,[1] by peripheral blood cells in the TruCulture system (see figure). With exception of a decrease in IL-17A, the TruCulture system did not reveal any impact of secukinumab on the capacity of peripheral blood cells to produce a broad panel of cytokines and chemokines upon stimulation. In contrast with this preserved systemic immune response, IHC confirmed the positive impact of 12wks of secukinumab on peripheral joint immunopathology as reflected by a significant decrease of infiltration of the synovial sublining with macrophages (2 [1–3] vs 1,5 [1–2]p=0.028) and neutrophils (1 [0,5–3,5] vs 0 [0–1]p=0.004), sensitive synovial biomarkers of treatment response in pSpA.[2] mRNA analysis of synovial biopsies before and after 12wks of secukimumab shows a decrease in IL-17A but not TNF expression.

Figure 1 - Reduction in secretion of IL-17 and MMP-3 in response to SEB in the whole blood TruCulture system after treatment with anti-IL17A.

Significance of the comparisons is determined by a paired T-Test. Concentrations shown are pg/ml (IL-17) and ng/ml MMP-3. P value <0.05 was considered significant and indicated with an (*).

Conclusions: This mechanism-of-action study indicates that IL-17A blockade with secukinumab has a profound beneficial clinical and biological impact on pSpA without compromising systemic immune responses. Further gene expression analysis will delineate which inflammatory pathways are blocked by secukinumab in the diseased target tissue.

AB0115 COMPARISON OF THE BACTERIAL STOOL MICROBIOTA IN ESTABLISHED PSORIATIC ARTHRITIS (PSA) AND PSORIASIS (PSC) - EXPLORATORY ANALYSIS OF PILOT DATA

M. Castelino[1,2], M. Tutino[2], J. Moat[3], U.Z. Ijaz[4], R. Parslew[5], A. Al-Sharqi[5], R.B. Warren[6], C. Quince[7], P. Ho[1], M. Upton[8], S. Eyre[2], A. Barton[1,2]. *[1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester Foundation Trust, Manchester Academic Health Sciences Centre; [2]Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research; [3]Microbiology and Virology Unit, Institute of Inflammation and Repair, University of Manchester, Manchester; [4]School of Engineering, University of Glasgow, Glasgow; [5]Department of Dermatology, Royal Liverpool and Broadgreen Univesrity Hospitals Trust, Liverpool, UK, Liverpool; [6]The Dermatology Centre, Salford Royal NHS Foundation Trust, University of Manchester, Manchester; [7]Warwick Medical School, University of Warwick, Warwick; [8]Faculty of Medicine and Dentistry, University of Plymouth, Plymouth, United Kingdom*

Background: Psoriatic arthritis (PsA) is a complex inflammatory condition with both genetic and environmental risk factors contributing to disease. A potential environmental risk factor, known to modify the immune system, is the intestinal microbiota. In PsA there is evidence of intestinal inflammation [1,2] and recently dysbiosis of the gut microbiota has been reported in treatment naïve PsA patients [3]. However, there is no information on the temporal stability of the microbiota over time in established PsA on treatment compared to matched PsC controls.
Objectives: To explore the temporal stability of gut microbiota composition and reveal associations with PsA compared to PsC while on stable on treatment with methotrexate.
Methods: Patients with PsA and PsC were recruited to the study if they had been on a stable dose of methotrexate for 6 months. Bacterial DNA was extracted and the V3-V4 hypervariable region of the 16S rRNA was amplified and sequenced on MiSeq. The resultant data was analysed using a bespoke bioinformatics pipeline and taxa were assigned using the Ribosomal Database Project classifier according to the SILVA119 database. The Wilcoxon rank sum test was used to assess alpha diversity indices, while permanova testing using Bray Curtis distance and DESeq2 values corrected for false-discovery rate (FDR) were used to compare beta diversity indices after removing low abundance (<0.5%) Operational Taxonomic Units (OTU). The ALDEx2 analysis package was used to assess effect size.
Results: Stool samples were available 9 PsA (n=13) and 6 PsC (n=12) individuals. Second stool samples were also obtained from the PsA (n=5) and PsC (n=4) groups.
No significant difference in the alpha diversity indices was observed between PsA and PsC. The beta diversity index showed no significant difference between the two conditions using permanova test. However, using the DESeq2-FDR analysis,

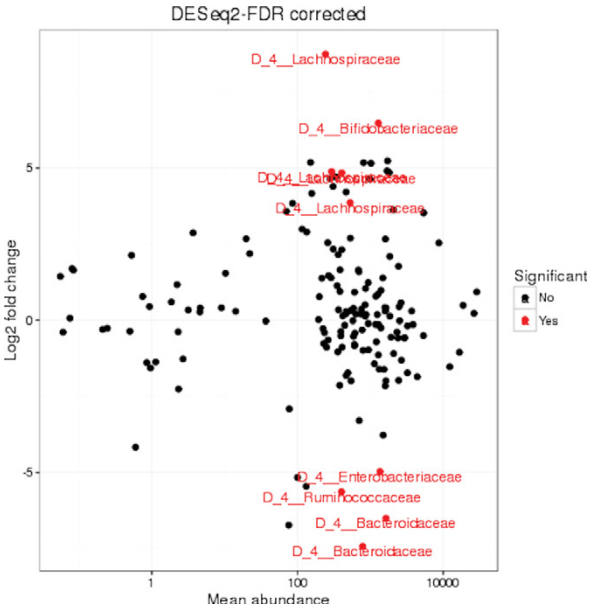

Table 1. Baseline Demographics

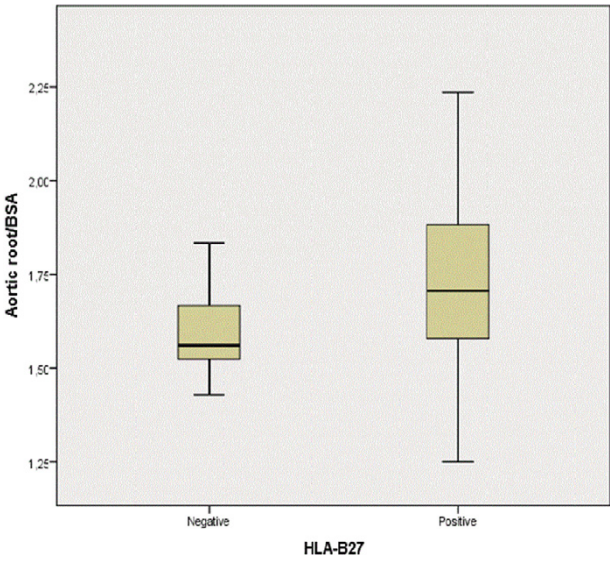

Demographic variables	PsA (n=9)	PsC (n=6)
Age mean (range) yrs	56.8 (40–72)	58.5 (27–79)
Gender Female (%)	2 (22)	4 (67)
Duration of Psoriasis mean (median) yrs	23.7 (26)	26.7 (30)
Type 1 Psorasis (Age at onset <40yrs) (%)	7 (77.8)	3 (50)

8 OTUs were identified which had significantly ($p<0.01$) different abundances in PsA compared to PsC. The taxa (Lachnospiraceae & Ruminococcaceae) predominantly belonged to the Firmicutes phylum, family Lachnospiraceae and Actinobacteria phylum, family Bifidobacteriaceae (Bifidobacteriaceae). The significant OTUs with DESEq2 had an effect size >1 using ALDEx2 but the BH p-value was not significant ($p<0.01$), which may be due to the small sample size. There were no significant differences in the diversity measures over time.
Conclusions: These results suggest that a gut enterotype with predominant Firmicutes/Actinobacteria composition is associated with stable/well controlled disease and is stable over time. This requires replication in a larger cohort.

AB0116 IDENTIFYING THE AS PATIENT AT RISK: IS AORTIC ROOT DILATATION ASSOCIATED WITH HLA-B27?

M. Baniaamam[1], S. Heslinga[2], T. Konings[3], O. Kamp[3], I. van der Horst-Bruinsma[1], M. Nurmohamed[1]. *[1]Rheumatology; [2]Reade/VU medical centre; [3]Cardiology, VU Medical Centre, Amsterdam, Netherlands*

Background: Cardiac involvement is more common in *Ankylosing Spondylitis* (AS) patients with HLA-B27 genotype, especially aortic valvular regurgitation (AVR). AVR in AS is caused by aortic root dilatation and fibrotic thickening of the aortic cusps, both linked to inflammation. Inflammation of the aortic root might lead to a weakening in aortic wall strength and dilatation with AVR. Severe AVR can result in heart failure and is an indication for valve replacement or repair. The prevalence of AVR in AS is estimated at 14–18%, which is significantly higher compared to the general population. Therefore, some advocate regular echocardiographic screening of AS patients [1]. However, the cost-benefit of echocardiographic screening in AS is currently unknown and the precise effect of AS specific cardiac pathology on clinically overt cardiovascular morbidity and mortality remains to be elucidated. Hence, we should aim to identify a specific "at risk" AS population that might benefit from routine echocardiographic monitoring.
Objectives: Primary: To assess the association between the aortic root diameter in HLA-B27 positive versus HLA-B27 negative patients.
Secondary: To assess the association between the aortic root diameter with disease duration and inflammation biomarkers.
Methods: We performed a cross-sectional study in AS patients between 50–75 years who were recruited from a large rheumatology outpatient clinic. Patients underwent echocardiography, with 2D, spectral and colour flow Doppler. The aortic root was measured at sinuses of Valsalva during diastole. The aortic root diameter was corrected for body surface area (BSA). Correlation between aortic root diameter/BSA and disease duration and inflammation biomarkers were assessed.
Results: 132 Consecutive AS patients were included with a mean age of 60.5 years, of whom 110 (83%) were HLA-B27 positive. The median aortic

root diameter/BSA ratio was significantly higher in HLA-B27 positive patients compared to HLA-B27 negative patients: 1.75±0.22 mm vs. 1.61±0.14 mm (p=0.001). Eight AS patients (6%) had aortic root dilatation (>2.1mm corrected for BSA), who were all HLA-B27 positive. Patients with and without aortic root dilatation did not significantly differ in age or disease duration. The median aortic root diameter/BSA ratio was correlated with disease duration (r=0.229, p=0.012), but not with inflammatory biomarkers.

Conclusions: HLA-B27 positive AS patients with a long disease duration have an increased aortic root diameter and a higher risk for aortic root dilatation compared to HLA-B27 negative AS patients. The risk of developing aortic root dilatation in AS patients is comparable to patients with essential hypertension (6%)[2].

Future prospective studies should assess which AS patients phenotype are at the highest risk of this AS specific cardiac disease, thus candidates for regular echocardiographic screening.

AB0117 CADHERIN-11 MRNA EXPRESSION IS INCREASED IN THE PERIPHERAL BLOOD OF PATIENTS WITH ACTIVE SPONDYLARTHROPATHY: A PILOT STUDY

N.I. Vlachogiannis, P.F. Christopoulos, G. Bamias, K. Fragiadaki, M. Tektonidou, P.P. Sfikakis. *Joint Academic Rheumatology Program, National and Kapodistrian University of Athens Medical School, Athens, Greece*

Background: Cadherin-11 is a key regulator of synovial architecture and has a central role in the formation of the rheumatoid pannus. Immunohistochemical studies have shown upregulation of cadherin-11 in the synovium of patients with seronegative spondylarthropathies (SpA), comparable to that in rheumatoid arthritis (RA), as well as in the intestinal tissue of patients with inflammatory bowel disease (IBD). Moreover, cadherin-11 mRNA transcripts have been identified in the peripheral blood of patients with RA and independently associated, among various disease characteristics, with the presence of active inflammation in multiple joints [1].

Objectives: To test the hypothesis that cadherin-11 mRNA transcripts are increased in the peripheral blood of patients with active SpA and search for possible associations with clinical features.

Methods: Fifteen patients with active SpA (BASDAI>4), aged between 21 and 71 years, 11 men, and 30 age- and gender-matched healthy controls were examined. Peripheral whole blood samples (3 ml) were subjected to cDNA synthesis and cadherin-11 mRNA expression was quantified by real-time PCR. Available cDNA from 33 IBD patients without axial or peripheral active arthritis served as disease control and were studied in parallel.

Results: Cadherin-11 mRNA was detected in the peripheral blood of 9/15 (60%) patients with SpA versus 5/30 (17%) healthy controls and 10/33 (30%) patients with IBD (SpA vs healthy controls p: 0.006, SpA vs IBD p: 0.06). Notably, cadherin-11 was not associated with BASDAI or skin/nail psoriasis present in 10 patients, but was detected with increased frequency among SpA patients with clinically active peripheral arthritis at the time of sampling (7 out of 10, 70%) than the remaining patients (2 out of 5, 40%). Moreover, cadherin-11 positivity associated significantly with increased erythrocyte sedimentation rate in SpA but not in IBD.

Conclusions: Cadherin-11 mRNA is upregulated in the peripheral blood of patients with SpA and may correlate with "spreading" of inflammation in peripheral joints. Since an anti-cadherin-11 mAb is in early clinical development for RA, further studies in patients with inflammatory arthritis are warranted.

AB0118 THE LYMPHATIC SYSTEM: A GATEKEEPER FOR MIGRATION OF PATHOGENIC T-CELLS TOWARDS SYNOVIAL JOINTS AND ENTHESES IN PSORIASIS

R. Bisoendial[1], E. Prens[2], A. Mus[3], P. Asmawidjaja[3], N. Davelaar[3], A. Hofman[4], J.-B. Jaquet[4], J. Hazes[3], M. Kok[5], E. Lubberts[3]. *[1]Department of Rheumatology, Maasstad hospital and Erasmus Medical Center; [2]Department of Dermatology; [3]Department of Rheumatology, Erasmus University Medical Center; [4]Department of Plastic surgery; [5]Department of Rheumatology, Maasstad hospital, Rotterdam, Netherlands*

Background: The factors underlying the transition of psoriasis (PsO) to psoriatic arthritis (PsA) are poorly understood. The lymphatic system may control the homing of disease-associated T-cells to skin and extra-cutaneous sites like synovial joints and entheses.

Objectives: To study the capacity of lymphatic endothelial cells (LEC) to regulate T-cell homing capabilities in PsA.

Methods: Human dermal LEC ($0.5x10^4$), and fibroblast-like synoviocytes of a patient with PsA (PsA-FLS; $1.0x10^4$) were pre-incubated for 3 days with PsA synovial fluid (PsA-SF; 0/10/20% v/v) and co-cultured with $2.5x10^4$ allogeneic CD4+CD45RO+CD25- T-cells that were sorted from peripheral blood mononuclear cells of 3 donors (with or without stimulation with αCD3/αCD28). After 72 h, T-cells were analyzed by flow cytometry. The CCR6+ T-helper (Th) subsets Th17.1 (CCR4-/CXCR3+), Th17/Th22 (CCR4+/CXCR3-), Th17 (CCR4+/CXCR3-/CCR10-) and Th22 (CCR4+/CXCR3-/CCR10+), and CCR6- subsets Th1 (CCR4-/CXCR3+), and Th2 (CCR4+/CXCR3-) were identified. We also looked at cutaneous lymphocyte- associated antigen (CLA). IL-17A, IL-22, and TNF protein levels were determined by ELISA. Statistical analysis included unpaired t-test (two-sided) for two-group comparison or one-way ANOVA with the Tukey-Kramer post hoc test for multi-group comparisons.

Results: Stimulation of CD4+CD45RO+ T-cells in co-culture with PsA-FLS skewed towards the CCR6+ subset Th17/Th22, which were predominantly Th17 cells. Th17 differentiation upon stimulation was suppressed in co-culture with LEC, even when LEC were pre-incubated with PsA-SF. T-cell stimulation in co-culture with LEC, as compared to PsA-FLS, promoted the generation of the Th22 subset. Upon co-culture with untreated LEC, stimulated T-cells showed higher expression of the skin homing receptor CLA than those that were co-cultured with PsA-FLS. The proportional reduction in CLA expression on T-cells in the co-cultures with LEC pre-incubated with PsA-SF 20% was comparable to PsA-FLS, however LEC conserved CLA expression on CD4+CD45RO T-cells at a higher level than PsA-FLS; this phenomenon particularly affected the CCR6+ T-cells. In line, a trend towards lower IL-17A and higher IL-22 levels were observed in the co-cultures with LEC that were pretreated with PsA-SF 20%, as compared to the co-culture with PsA-FLS. No differences were seen for TNF protein levels.

Conclusions: LECs are directly involved in T-cell differentiation and homing capabilities, as shown by suppression of Th17 differentiation upon stimulation, as compared to PsA-FLS. Also, LEC promoted Th22 generation, and conserved CLA expression in CCR6+ T-cells, even when LEC were preincubated with PsA-SF. Studies are underway to confirm that LECs from relevant biological tissues (e.g. synovium and lymph nodes) are critical for tissue-restricted T-cell migration to skin and synovial membranes in PsA.

AB0119 ANTI-FIBROTICS TO PREVENT NEW BONE FORMATION IN SPONDYLOARTHRITIS: PROOF OF CONCEPT USING PIRFENIDONE IN CELL CULTURE MODELS

J. Laustsen[1,2], S. Lomholt[3], P. Andersen[3], J. Kelsen[4], T.W. Kragstrup[1]. *[1]Department of Rheumatology, Aarhus University Hospital; [2]Department of Biomedicine; [3]Aarhus University; [4]Aarhus University Hospital, Aarhus C, Denmark*

Background: The pathogenesis of spondyloarthritis (SpA) involves both inflammation and new bone formation in the spine. In line with this, the disease has been characterized as both inflammatory and fibrotic. Current treatment including inhibitors of tumour necrosis factor alpha (TNFα) seem to dampen inflammation while new bone formation can progress. Therefore, there is an unmet therapeutic need for the treatment of new bone formation in SpA. Fibrosis is mediated by myofibroblasts and new bone formation is the result of increased osteoblast mineralization and decreased osteoclast bone degradation. Here, we evaluate the potential effect of the newly approved anti-fibrotic agent pirfenidone (Esbriet, Pirespa) on fibrosis and new bone formation in cell culture models of SpA.

Objectives: We hypothesized that pirfenidone inhibits SpA myofibroblast formation and activity and osteoblast mineralization.

Methods: Synovial fluid mononuclear cells from patients with SpA (n=6) were included for culturing fibroblast-like synovial cells (FLSs) while osteoblasts were purchased. The cells were cultured with pirfenidone in increasing concentrations (0.25, 0.5, and 1.0 mg/ml) with or without stimulation with tumor necrosis factor alpha (TNFα), transforming growth factor beta (TGFβ), or interferon gamma (INFγ). The proliferation of FLSs was analyzed with light microscopy and flow cytometry using the marker Ki67. The differentiation and activation of FLSs was assessed with flow cytometry, a proteome profiler assay and enzyme-linked immunosorbant assays. The mineralization capacity of the osteoblasts was measured as deposition of hydroxyapatite.

Results: Pirfenidone reduced the Ki67 expression 7.1-fold in untreated FLSs (p=0.001) and 11.0-fold in FLSs stimulated with TGFβ, TNFα, and INFγ (p=0.022). PFD further inhibited TGFβ induced upregulation of αSMA (Figure 2A) and INFγ induced upregulation of HLA-DR (Figure 2C) in all cultures. There was no difference between the percentage of ICAM-1 positive FLSs in cultures treated with or without pirfenidone. In supernatants from FLSs stimulated with TGFβ, TNFα, and INFγ a total of 12 cytokines or chemokines had values above the detection limit in the membrane-based antibody array. Pirfenidone decreased the secretion of 3 of these 12 cytokines or chemokines more than 2-fold. The changes in secretion of monocyte chemoattractant protein 1 (MCP-1) and chitinase-3-like

protein 1 (CHI3L1, also known as YKL-40) were validated with ELISA. Further, pirfenidone decreased the secretion of both DKK1 (p=0.006) and OPG (p=0.02) by SpA FLSs stimulated with TGFβ, TNFα, and INFγ, while the concentration of RANKL was below the detection limit of the ELISA assay in all cultures. Finally, pirfenidone inhibited the deposition of hydroxyapatite by osteoblasts in a dose-dependent manner (p=0.0001). This inhibition was partly reversible when removing pirfenidone after the first week of the mineralization assay.
Conclusions: Taken together, pirfenidone inhibited SpA myofibroblast formation and activity and osteoblast mineralization. This encourages further research in anti-fibrotics as treatment of new bone formation in SpA.

AB0120 ACCELERATED OSTEOGENIC DIFFERENTIATION OF HUMAN BONE-DERIVED CELLS IN ANKYLOSING SPONDYLITIS

Y.-S. Park[1], S. Jo[2], I.-H. Sung[3], T.-H. Kim[2]. *[1]Orthopaedic Surgery, Hanyang University Hospital, Guri; [2]Rheumatology, Hanyang University Hospital for Rheumatic Disease; [3]Orthopaedic Surgery, Hanyang University Hospital, Seoul, Korea, Republic Of*

Background: Ankylosing spondylitis (AS) is characterized by excessive bone formation with syndesmophytes, leading to bony ankylosis. The contribution of osteoblasts to the pathogenesis of ankylosis is poorly understood.
Objectives: The aim of this study was to determine molecular differences between disease controls (Ct) and AS bone-derived cells (BdCs) during osteogenic differentiation.
Methods: We confirmed osteoblastic differentiation of Ct and AS BdCs under osteogenic medium by observing morphological changes and measuring osteoblastic differentiation markers. Osteoblast differentiation was detected by alkaline phosphatase (ALP) staining and activity, and alizarin red S and hydroxyapatite staining. Osteoblast-specific markers were analyzed by qRT-PCR, immunoblotting, and immunostaining. To examine the effects of inflammation, we added AS and healthy control serum to Ct and AS BdCs, and then analyzed osteoblast-specific markers.
Results: AS BdCs showed elevated basal intercellular and extracellular ALP activity compared to Ct. When osteoblast differentiation was induced, AS BdCs exhibited higher expression of osteoblast-specific marker genes and faster mineralization than Ct BdCs, indicating that these cells differentiated more rapidly into osteoblasts. ALP activity and mineralization accelerated when serum from AS patients was added to Ct and AS BdCs.
Conclusions: Our results revealed that AS BdCs showed significantly increased osteoblastic activity and differentiation capacity by regulating osteoblast-specific transcription factors and proteins compared to Ct BdCs. Active inflammation caused by adding AS serum accelerated bony ankylosis. Our study could provide useful basic data for understanding the molecular mechanism of ankyloses in AS.

Background: MicroRNAs are small non-coding RNAs that play important regulatory roles in a variety of biological processes. They can regulate the post–transcriptional expression of target genes and play an important role in gene regulation. Specific microRNAs are stably present in serum and changes in their abundance are potentially disease-specific. Considering their important role in regulation of the immune system, we investigated circulating levels of miRNAs in patients with primary Sjögren's syndrome (pSS) and those with non-Sjögren's sicca (nSS) in relation to disease activity.
Objectives: To assess the expression of a large number of miRNAs in the serum of pSS and nSS patients as compared to healthy controls and to investigate their correlation with disease activity.
Methods: Two independent cohorts (discovery and validation) were established, consisting of a total of 37 pSS patients classified according to the 2002 criteria, 20 nSS patients that were not clinically considered to be pSS and did not meet the classification criteria, and 18 healthy controls (HC). Serum miRNAs were isolated and miRNA profiling of 758 miRNA was performed using the OpenArray platform in the discovery cohort. A selection of 10 miRNAs found to be differentially expressed between the groups was measured in the independent validation cohort using single TaqMan microRNA Assays.
Results: miRNA profiling revealed 10 miRNAs to be differentially expressed between the groups; 2 in pSS vs HC, 7 in nSS vs HC and 1 in both pSS and nSS vs HC. One miRNA was excluded from further analysis after technical validation by single TaqMan microRNA Assay. The other 9 miRNAs were measured in the validation cohort. Surprisingly, 2 miRNAs were validated to be increased in the nSS group as compared to HC (snRNA-U6 and miR-661). Using the data from both cohorts combined, the levels of snRNA-U6 and miR-661 was associated with serum Ig and C4 in the nSS group, but also in the pSS group. This prompted us to investigate miRNA expression in subgroups of pSS patients. snRNA-U6 and miR-661 levels are significantly increased compared to HC in pSS patients negative for autoantibodies. In autoantibody positive pSS patients, levels of snRNA-U6 and miR-661 are comparable to those found in HC and both miRNAs are significantly increased in autoantibody negative patients as compared to autoantibody positive pSS patients. In addition, their expression is strongly associated with leukocyte numbers in the autoantibody positive patients, but not in the negative patients.
Conclusions: Increased circulating levels of snRNA-U6 and miR-661 in patients with nSS and autoantibody negative pSS patients are associated with normal B cell activity and normal numbers of circulating leukocytes. Reduced miRNA levels in autoantibody positive pSS patients are associated with B cell hyperactivity and decreased leukocyte counts, which is possibly the result of immune cells migration to the inflammatory sites. Considering the important role of miRNAs in the control of immune cell activation, this work points to a significant role of miRNAs in pSS and nSS patients.

AB0122 DETECTION OF AN INTRIGUING VIRUS-LIKE SEQUENCE IN THE SALIVARY GLAND EPITHELIAL CELLS OF SJÖGREN'S SYNDROME PATIENTS

A.G. Vakrakou[1,2], E. Karamichali[3], O. Georgopoulou[3], M.N. Manoussakis[1,2]. *[1]Pathophysiology, University of Athens; [2]Laboratory of molecular immunology; [3]Molecular Virology Laboratory, Hellenic Pasteur Institute, Athens, Greece*

Background: Several previous studies from our laboratory had indicated that the salivary gland epithelial cells (SGEC) of primary Sjögren's syndrome (SS) patients manifest cell autonomous (intrinsic) activation, which is demonstrated in non-neoplastic cell lines derived from patients (SS-SGEC). As for other autoimmune diseases, it is widely proposed that infectious factors may incite SS. In fact, several viral agents have been proposed to be involved in the development of SS, including EBV, retroviruses (such as HTLV-1 and endogenous retrotransposons) and the Coxsackie virus. Recently, the sequence and antigen of HDV were detected in the salivary gland tissues of approximately half of SS patients studied [Weller et al., 2016], however, in the absence of detectable hepatitis B virus (HBV) surface antigen and antibodies to HBV or HDV. Therefore, we hypothesized that HDV may be causally related with the cell-autonomous aberrations observed in the SS-SGEC lines and may trigger the inflammatory and autoimmune reactions that characterize SS.
Objectives: Herein, using non-neoplastic SGEC lines derived from SS patients, we sought to address directly whether the SGEC of these patients manifest evidence for infection by the HDV virus, despite the fact that patients studied did not display any evidence of infection by HBV or HDV viruses.
Methods: For that purpose, we purified total RNA from SGEC lines from non-SS controls (n=7) and SS patients (n=7). Reverse transcription of RNA isolated from salivary gland epithelial cells (SGEC) was performed using random hexamer primers as per the manufacturer's specifications. We performed PCR for the identification of HDV RNA sequences with three sets of primers from different regions of the viral sequence. RNA extracted from HDV-positive sera was used as positive control in HDV-specific PCR.
Results: All SGEC lines from SS patients and non-SS controls tested were found positive for HDV RNA, as tested by the first two sets of primers (two sets of primers for first and nested PCR with expected PCR products 329bp and 234bp, respectively). Nevertheless, when we selected primers for another region of the HDV genome (set of primers with expected PCR products 375bp) all RNA samples from SGEC lines tested were found negative for HDV RNA, whereas the HDV RNA control specimen was positive.
Conclusions: We conclude that SS-SGEC are not actually infected by the HDV virus, but are probably carriers of an HDV-like sequence. In fact, the putative HDV virus-like sequence has been previously shown be highly homologous to the RNA binding-protein cytoplasmic polyadenylation element-binding protein-3 (CPEB3), which belongs to a family of genes regulating messenger RNA polyadenylation and is structurally and biochemically related to the human HDV ribozymes (Salehi-Ashtiani et al, 2006). We are currently in the process of further analyzing the nature of this HDV-like sequence, through cloning and Sanger sequencing of the RT-PCR products, as well as performing of HDV-specific immunostaining studies in both SGEC lines and salivary gland tissues.

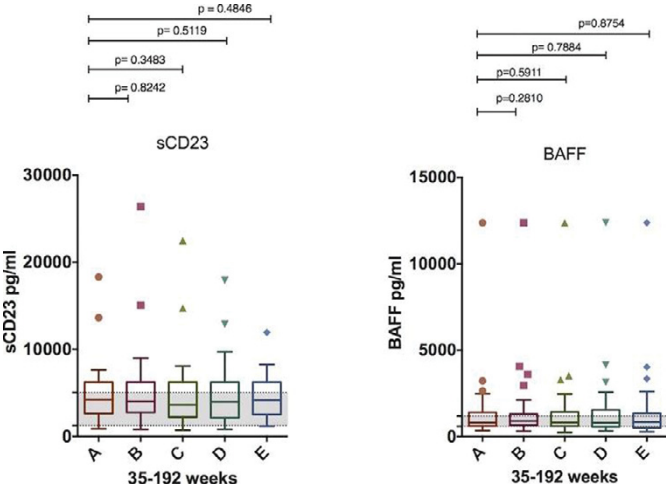
AB0123 T-CELL SURFACE GLYCOSYLATION PATTERN ALTERATIONS IN SLE – A PUTATIVE LINK TO GALECTIN-1-MEDIATED IMMUNOREGULATORY DEFICIENCY



Á. Hornung[1], E. Szabó[2], Á. Czibula[2], É. Monostori[2], L. Kovács[1]. *[1]Department of Rheumatology and Immunology, University of Szeged; [2]Department of Genetics, Hungarian Academy of Sciences, Biological Research Centre, Szeged, Hungary*

Background: We have previously found that activated T-cells from systemic lupus erythematosus (SLE) patients express lower amount of intracellular galectin-1 (icGal-1) than those of healthy controls and are resistant to the apoptotic effect of extracellular galectin-1 (ecGal-1), an endogenous immunoregulatory lectin. We also demonstrated that the *de novo* synthesized icGal-1 level affects apoptosis of T-cells induced by ecGal-1, since low icGal-1 expression resulted in reduced sentsitivity to ecGal-1 (Deák M *et al*). We have therefore proposed the defective icGal-1 production to be an explanation to the insufficient regulatory effects of ecGal-1 in SLE. However, altered binding of ecGal-1 to T-cells due to changes in surface glycosylation may also regulate the apoptotic activity of ecGal-1.
Objectives: We have herein hypothesized that the cell-surface glycosylation pattern, and consequently, lectin-binding ability in SLE T-cells is altered, and that an abnormal expression of glycosylation enzymes may account for these changes.
Methods: In order to analyse the glycosylation pattern of cell surface glycoproteins, lectin-binding assays were performed using 5 different plant lectins and human recombinant Gal-1 on resting and activated T-cells from patients with active SLE (n=8) with multi-colour flow-cytometry, and were compared with 15 healthy controls. mRNA levels of 13 glycosylation enzymes involved in the development of N-glycan structures on T-cells were measured with qPCR, and were correlated with the specific lectin binding data.
Results: As compared with the resting state, the increase in Gal-1 binding during activation was significantly lower in SLE T-cells than in controls, and the level of Gal-1 binding maximum was significantly reduced in SLE activated T-cells than in controls. Binding maximum of plant lectins that recognise high complexity N-glycans also increased less in SLE T-cells than in controls during activation. mRNA level of sialyltransferase ST3GAL6 was increased and neuraminidase Neu1 was decreased in active SLE patients as compared to controls. The ST6GAL1/NEU1 ratio in SLE patients positively correlated with the SLEDAI disease activity index.
Conclusions: SLE T-cells show decreased complexity of N-glycan structures. Increased ST3GAL6 and decreased Neu1 expression result in an increased density of terminal sialic acids, and this may explain the impaired Gal-1 binding. In addition to the previously described deficiency in icGal-1 expression upon activation, our present findings of an attenuated glycan complexity and a shift toward terminal sialylation provide a further mechanism of pathological T-cell activation and regulation of T-cell viability in SLE.

AB0124 SEROLOGICAL MEASURES OF B CELL FUNCTION IN PATIENTS WITH SLE; HOW ROBUST ARE THEY OVER TIME?

A. Hennessey[1,2], R. Marques[3], M. Leandro[1,2], D. Isenberg[1,2], G. Cambridge[2]. *[1]Division of Rheumatology, Department of Medicine, University College London Hospitals; [2]Centre for Rheumatology and Bloomsbury Rheumatology Unit, University College London, London, United Kingdom; [3]Serviço de Medicina Interna B, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*

Background: In SLE the precise mechanisms whereby parent autoreactive B cells are generated and permitted to escape tolerance checkpoints, proliferate, persist and switch to pathogenic autoantibody production remains poorly understood. Hypotheses include defective negative central selection, defective peripheral selection with enhanced germinal center activity as well as positive selection of B cells via autoantigen presentation or T-independent mechanisms. Biomarkers to identify possible breaches in tolerance checkpoints would allow more effective intervention. We have therefore measured relative levels of soluble (s)CD23 (released during B cell differentiation from naive to memory B cell status) and the B cell activation factor, BAFF (survival factor and class-switch/differentiation promoter) in SLE sera to determine if relative levels of sCD23 and BAFF were of use as biomarkers to group patients based on B cell kinetics rather than clinical features. BAFF is often raised in SLE patients and can stimulate the aberrant differentiation of transitional B cells and of plasmablasts in vitro. Combining the 2 biomarkers could therefore indicate whether there was increased expansion of naïve B cells, and whether BAFF was a possible driver/consequence of autoimmunity in different patients.
Objectives: To determine whether relative levels of sCD23 and BAFF reflect disease activity or remain stable over time.
Methods: Stored SLE serum from patients who were Rituximab-naive, had >5 samples available in the biobank over at least 6 months (n=38). Samples were analysed for levels of sCD23 and BAFF via ELISA. Wilcoxon matched-pairs signed rank test were used to compare serial values. Clinical details including BILAG scores were also collected for the available time points. If positive dsDNA at any time during the time period this was deemed positive. The latest BILAG was utilised and reviewed, a patient was deemed not to have system involvement if they had an "E" for that system.
Results: Sera from 38 SLE patients (32 female, 6 male) with mean age of first sample 42 (range: 25–72). Minimum interval between 1st and last sample was 101 weeks (range: 35–192 weeks). Patients were then sorted into clinical groups according to levels of these serum markers. Normal ranges defined as: sCD23 (1235–5023pg/ml), BAFF (584–1186pg/ml). Group I (n=9): – High (H) sCD23, Normal (N) BAFF; Group II (n=11) – H sCD23, H BAFF; Group III (n=17) – N sCD23, N BAFF; Group IV (n=2) – N sCD23, H BAFF. Figure 1 shows the p values generated from the Wilcoxon matched-pairs signed rank test for each time period demonstrating nil significant change over time. Analysis of clinical data showed no differences in terms of organ involvement or anti-dsDNA -Ab status.

Conclusions: Within a cohort of SLE patients, soluble CD23 and BAFF is stable over time despite variation in disease activity. Grouping patients based on sCD23 and BAFF profile may be useful in identifying distinct B cell maturation pathways reflecting underlying autoimmune pathways which vary between patients.

AB0125 BRAIN IMMUNOPATHOLOGY OF LUPUS-PRONE FCΓRIIB-/-YAA MICE - IMPLICATION TO THE INNATE IMMUNE RELATED MECHANISM OF NEUROPSYCHIATRIC SLE

A. Nomura[1], G. Murayama[1,2], A. Chiba[1], S. Miyake[1]. *[1]Immunology; [2]Rheumatology, Juntendo University, Tokyo, Japan*

Background: Neuropsychiatric SLE (NPSLE) is a common manifestation of SLE and problems such as cognitive impairment or depression are elusive. The importance of innate immune related inflammation in the pathomechanism of neurodegenerative or psychiatric diseases has been recognized recently, and the importance of innate immunity in the pathogenesis of NPSLE has also been suggested[1)]. Therefore, we investigated innate immune mechanism of NPSLE by using lupus prone mice.
Objectives: This study is conducted to understand the brain immune pathology of lupus-prone FcγRIIB$^{-/-}$ *Yaa* mice in which innate immune stimulation is potentiated by the duplication of Toll-like receptor 7[2)].
Methods: Immune cell subsets and histopathology of brains were analyzed by flow cytometry and immunohistochemistry in FcγRIIB$^{-/-}$ *Yaa* mice compared with congenic mice at around 16 week-old when glomerulonephritis had developed. For flow cytometric analysis, microglia, myeloid lineage cells and lymphocytes were defined by staining with CD11b and CD45. Subsets of those cells and their activation status were analyzed. For histopathological analysis, microglia, brain macrophages, astrocytes and lymphocytes were immunostained and expression of MHC class I and class II were also analyzed.
Results: Flow cytometric analysis revealed increase in the number of microglial cells (CD11b^{+} CD45^{int}) and myeloid lineage cells (CD11b^{+} CD45^{high}) in the brains of FcγRIIB$^{-/-}$ *Yaa* mice compared with congenic FcγRIIB$^{+/+}$ mice. Mean fluorescence intensity of MHC class I was increased in microglia and myeloid lineage cells in FcγRIIB$^{-/-}$ *Yaa* mice. An increased percentage of CD3 positive cells compared to CD19 positive cells were observed and their expression of CD69, an activation marker, were increased in FcγRIIB$^{-/-}$ *Yaa* mice. In histopathology, number of macrophages and microglia identified by Iba1 (Ionized calcium binding adapter molecule 1) positive cells were increased in FcγRIIB$^{-/-}$ *Yaa* mice. In areas where MHC class I and class II were highly expressed on macrophages,

reaction of astrocytes and patchy increase of lymphocytes were also observed. Furthermore, MHC class I and class II were also highly expressed in the vascular endothelium in FcγRIIB$^{-/-}$ *Yaa* mice.

Conclusions: Activation of myeloid lineage cells and reactive changes of glial cells and endothelial cells were observed in the central nervous system of lupus-prone FcγRIIB$^{-/-}$ *Yaa* mice. These results imply the role of innate immune mechanisms in the pathology of NPSLE.

AB0126 AUTOPHAGY AND SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL SIGNIFICANCE OF ATG14+, FOXP3+, AND CD25+ EXPRESSION ON T REGULATORY CELLS AND NK CELLS

A. Rodríguez[1], E.J. Zurita[1], A.R. Durán[2], R. Bustamante[3], A. Sánchez[3], M.Á. Saavedra[3], C. Arroyo[4], G. Medina[5], L.J. Jara[3]. *[1]Immunology Department, Escuela Nacional de Ciencias Biologicas; [2]Immunology Department, Escuela Nacional de Ciencias Biológicas; [3]Rheumatology Department; [4]Banco de Sangre, Hospital de Especialidades "Dr. Antonio Fraga Mouret", Centro Médico la Raza, IMSS; [5]Rheumatology Department, Hospital de Especialidades "Dr. Antonio Fraga Mouret", CENTRO, Mexico City, Mexico*

Background: Autophagy is a highly conserved protein degradation pathway, essential for removing protein aggregates and misfolded proteins in healthy cells. Autophagy and autophagy-molecules expression have been implicated in autoimmune diseases. Systemic Lupus Erythematosus (SLE) is a prototype of autoimmune disease whose main characteristic is the loss of immune tolerance. Recent evidences suggest that autophagy, and autophagy-related proteins participate in SLE immune regulation. However, little is known about the SLE clinical significance of autophagy-related proteins, T regulatory, and NK cells.

Objectives: To evaluate the expression of ATG14$^+$ (autophagy-related key regulator protein), FOXP3$^+$, CD25$^+$T regulators, CD56$^+$NK cells in active and inactive SLE patients.

Methods: The expression of ATG14$^+$, FOXP3$^+$, CD25$^+$, and CD56$^+$ were measured by flow cytometry, and expressed in percentages in T and NK cells of SLE patients (1997, ACR criteria), and healthy controls. Active SLE was considered by SLEDAI ($\geq$4). The organs affected and treatments were evaluated.

Results: A total of 40 SLE patients and 20 healthy controls were included. The mean expression of autophagy in 20 active SLE patients was 11.19% in comparison with inactive SLE patients, 7.13%, (p=0.04), and in healthy donors, 7.445% (p=0.0281). The FOXP3$^+$ expression in NK cells in active SLE was lower in comparison with inactive patients (0.98% vs 3.82% respectively). In healthy donors was 2.89%.

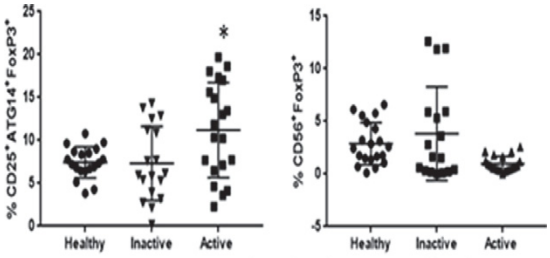

Figure 1: Expression in percentage of CD25$^+$ATG14$^+$FoxP3$^+$ (T reg) and CD56$^+$FoxP3$^+$ (NK cells) in SLE active and inactive patients and healthy controls. *p=0.04 Mann Whitney U test.

Conclusions: We found that in active patients autophagy is higher than in inactive patients. In inactive patients FOXP3 expression in NK cells is normal. These results can be due to the effect of the different treatments given according to clinical manifestations. Autophagy-related key regulator protein may be a new target of SLE treatment

AB0127 ANTI-DS-DNA ANTIBODIES REGULATE ATHEROTHROMBOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS THROUGH THE INDUCTION OF NETOSIS, INFLAMMATION AND ENDOTHELIAL ACTIVATION

C. Perez-Sanchez[1], M.A. Aguirre[1], P. Ruiz-Limon[1], M.C. Abalos-Aguilera[1], I. Arias-de la Rosa[1], N. Barbarroja[1], Y. Jimenez-Gomez[1], P. Segui[1], E. Collantes-Estevez[1], J.A. Gonzalez-Reyes[2], J.M. Villalba[2], M.J. Cuadrado[3], C. Lopez-Pedrera[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba; [2]Department of Cell Biology, Physiology and Immunology, ceiA3, University of Cordoba, Cordoba, Spain; [3]Lupus Research Unit and St. Thomas Hospital, London, United Kingdom*

Background: The role of anti-dsDNA in the pathogenesis of the systemic lupus erythematosus (SLE) has been clearly established. However, the influence of these autoantibodies in the atherothrombotic status of SLE patients has not yet been evaluated

Objectives: 1. To analyse in vivo the involvement of anti-dsDNA antibodies in the development of CVD in SLE patients. 2. To evaluate in vitro the mechanisms underlying the effects of anti-dsDNA antibodies in these processes

Methods: The study was conducted in 50 SLE patients and 38 healthy donors. Endothelial function was assessed by measuring the post-occlusive hyperaemia using Laser-Doppler. Various markers of oxidative stress, inflammatory cytokines, prothrombotic mediators and NETosis, were quantified in purified leukocytes and plasma from SLE patients and controls. Activation of intracellular pathways was analyzed in monocytes using pathscan intracellular signaling array. In vitro, purified neutrophils, monocytes and lymphocytes from healthy donors and endothelial cells (ECs) were treated separately and in a trans-well co-culture system with anti-dsDNA antibodies isolated from the serum of SLE patients. Then, markers of inflammation, thrombosis, oxidative stress and NETosis were evaluated by flow cytometry (protein), RT-PCR (mRNA) and electron microscopy

Results: SLE patients showed impaired micro-vascular endothelial function (reduction of hyperaemia post occlusion area) and altered expression levels of pro-inflammatory proteins (IL6, IL8, MCP-1 and PCR), prothrombotic molecules (TF), oxidative stress markers (peroxides and mitochondrial membrane potential) and netosis-related molecules (NE, MPO and cell free-DNA). Monocytes from anti-dsDNA-positive SLE patients showed activation of various pathways related to inflammation, thrombosis and apoptosis (ErK, STAT-3, p38, JNK, GSK, Bad and Caspase-3). Association studies demonstrated that molecules related to inflammation and thrombosis, endothelial dysfunction, oxidative status and netosis were linked to the occurrence of thrombotic events, as well as to the presence of anti-dsDNA antibodies. In vitro treatment of purified leukocytes with anti-dsDNA antibodies promoted an increase in the production of NETosis, levels of peroxides and percentage of cells with altered mitochondrial membrane potential, as well as enlarged expression of a number of proinflammatory and prothrombotic molecules. In vitro treatment of HUVEC with anti-dsDNA antibodies promoted an increase in endothelial activation molecules (ICAM-1, VCAM-1 and E-selectin).

Conclusions: 1. Positivity for anti-dsDNA antibodies is linked to an increased pro-atherothrombotic status in SLE patients. 2. Anti-dsDNA antibodies, in vitro, promote NETosis on neutrophils, apoptosis on monocytes, modulate the expression of molecules related to inflammation and thrombosis, and induce endothelial activation. Together, that data suggest the involvement of such autoantibodies on atherothrombosis development in SLE

AB0128 ALTERATIONS OF THE SPLICING MACHINERY COMPONENTS IN LEUKOCYTES FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS INFLUENCES ITS DEVELOPMENT AND ATHEROTHROMBOTIC PROFILE AND DRIVES THE THERAPEUTIC RESPONSE

C. Perez-Sanchez[1], M.A. Aguirre[1], S. Pedraza-Arévalo[1], M. del Río-Moreno[1], P. Ruiz-Limón[1], N. Barbarroja[1], Y. Jimenez-Gomez[1], I. Arias-de la Rosa[1], M.C. Abalos-Aguilera[1], P. Segui[1], E. Collantes[1], J. Castaño[1], R.M. Luque[1], M.J. Cuadrado[2], C. Lopez-Pedrera[1]. *[1]IMIBIC/Reina Sofia University Hospital/University of Cordoba, Cordoba, Spain; [2]Lupus Research Unit, St Thomas Hospital, London, United Kingdom*

Background: Recent studies emphasize the relevance of alternative splicing in the development of genetic and autoimmune diseases and suggest therapeutic possibilities based on the modulation of this process.

Objectives: To identify alterations in the leukocyte splicing machinery of patients with systemic lupus erythematosus (SLE) and to evaluate its influence on the development and activity of the disease, its atherothrombotic profile, and the response to specific therapies.

Methods: An array of selected components of the major-(n=12) and minor-spliceosome (n=4) and associated splicing factors (n=28) was developed, and their expression levels were evaluated using a Fluidigm methodology, in purified leukocytes from 36 SLE patients and 29 healthy donors (HD). In parallel, an extensive clinical/serological evaluation was performed. Carotid intimate media thickness (CIMT) was used as atherosclerosis marker. Endothelial activity was

monitored by laser-doppler, and pro-inflammatory and oxidative stress markers were quantified by flow cytometry and RT-PCR. In a parallel cohort of SLE patients (n=12), the effects of in vivo treatment with ubiquinol on spliceosome components was evaluated.

Results: As a general feature, a significant reduction in splicing factors and spliceosome components was found in all the leukocytes of SLE patients. Interestingly, we found a specific altered profile of splicing factors and spliceosome components when compared monocytes (U2AF1, FBP11, SRSF9), lymphocytes (RBM22, PRP8, SRSF5) and neutrophils (RNU4, CA150). The reduced levels of some components of spliceosome in both monocytes and neutrophils were linked to the occurrence of thrombotic events, foetal loss and arterial hypertension. In lymphocytes, those reduced levels were strongly related to the positivity for anti-dsDNA antibodies in SLE patients, thus suggesting that reduced spliceosome machinery would contribute to increase in altered autoantigen assembly, inducing increased autoantibody production. Correlation studies demonstrated an inverse relationship among reduced levels of spliceosome components/splicing factors and high activity of the disease (measured as SLEDAI), endothelial dysfunction, and increased expression levels of peroxides and peroxynitrites, as well as of altered mitochondrial membrane potential in monocytes and neutrophils. In vitro treatment of leukocytes from HDs with anti-dsDNA promoted a reduction in spliceosome components associated with the expression of proinflammatory and oxidative mediators. Finally, in vivo treatment with ubiquinol reversed reduced expression in SLE of spliceosome components related to their proaterothrombotic profile.

Conclusions: These results reveal the existence of SLE- associated spliceosome alterations -promoted by anti-dsDNA antibodies-which could be related to the development and activity of this autoimmune condition and have influence on the induction of mechanisms that drive atherothrombosis as well as the therapeutic response.

AB0129 HMGB1+ MICROPARTICLES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH LUPUS NEPHRITIS

C. Burbano [1], J.A. Gómez-Puerta [1], M. Rojas [1], G. Vasquez [1], J. Orejuela [1], C.H. Muñoz [2], A. Vanegas-García [2], D. Castaño [1]. *[1]Universidad de Antioquia; [2]Hospital Universitario de San Vicente Fundación, Medellín, Colombia*

Background: High mobility group box protein 1 (HMGB1) is a nuclear DNA-binding protein that can function as an alarmin when is released from activated and dying cells. In association with nucleosomes, HMGB1 may contribute to the pathogenesis of systemic lupus erythematosus (SLE). Some previous reports have associated HMGB1 with the pathogenesis of cutaneous lupus and lupus nephritis (LN). HMGB1 may also be contained in microparticles (MPs). These vesicles have a wide spectrum of biological activities in intercellular communication, and they compete with apoptotic cells to bind mononuclear phagocytes.

Objectives: To evaluate the association of MP-HMGB1+ circulating with LN and to correlate them with LN activity.

Methods: Blood samples from 60 SLE patients were used to isolated MPs from platelet-poor plasma by centrifugation and their count, cell source and phenotype were characterized by flow cytometry. Renal pathology was reported using the standardized International Society of Nephrology/Renal Pathological Society classification. Inactive lupus nephritis (LN) was defined by the presence of one or more of the following criteria: 24 hrs proteinuria 500 mg/dl or inactive urine sediments (<5 red cells/HPF) and no red cell casts and no leucocyturia (<5 white cells/HPF) and stable serum creatinine.

Results: Mean age of SLE patients was 31.9±10.8 years, and mean disease duration was 7.8±6.2 years. 73% patients had LN and 89% were female. Patients with LN had significantly higher frequency of MP-HMGB1+, no significant differences were found among patients with active versus inactive LN or among patients with proliferative vs non-proliferative LN; MP-HMGB1+ had a moderate positive correlation with disease activity (SLEDAI, r=0.367, p=0.020), anti-C1q antibodies titers (r=0.42, p=001) and 24 hours proteinuria (r=0,33, p=,032), but no correlation was found with activity or chronicity indexes on renal biopsies. A ROC curve for MP-HMGB1+ and renal involvement showed a good discriminative ability (AUC 0.706). A cutoff of 15.7% of MP-HMGB1+ showed the best discrimination threshold with a sensitivity of 63.3% and specificity of 83.3%.

Conclusions: In our cohort of patients with SLE, MP-HMGB1+ was significantly higher in patients with LN and in patients with active disease. Given the multiple implication of HMGB1 in SLE, including the active kidney recruitment of mononuclear phagocytes, we consider that MP-HMGB1+ could be considered as a potential biomarker for LN in SLE patients.

AB0130 MESENCHYMAL STEM CELLS ALLEVIATE SLE THROUGH PROMOTING TREG CELLS BY HLA-G

C. Chen, J. Liang, G. Yao, Z. Zhang, S. Huang, L. Sun. *The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Background: Soluble human leukocyte antigen-G (sHLA-G) is a non-classical HLA class I molecule, exhibiting strong immunosuppressive properties by inducing the differentiation of T regulatory cells (Treg). Mesenchymal stem cells (MSCs) transplantation alleviates disease progression in systemic lupus erythematosus (SLE) patients. However, the underlying mechanisms are largely unknown.

Objectives: The aim of the present study is to explore whether sHLA-G is involved in upregulating Treg cells by MSCs, which contributes to therapeutic effects of MSCs transplantation in SLE.

Methods: The serum sHLA-G levels of SLE patients and healthy controls were detected by ELISA. The percentages of peripheral blood CD4 + ILT2 +, CD8 + ILT2 +, CD19 + ILT2 + cells and Treg cells were determined by flow cytometry. Ten patients with active SLE, refractory to conventional therapies, were infused with MSCs and serum sHLA-G was measured 24 h after infusion. Peripheral blood mononuclear cells (PBMCs) were isolated from SLE patients and co-cultured with UC-MSCs for 3 days at different ratios (50:1, 10:1, and 2:1) with or without anti-HLA-G antibodies, and the frequencies of CD4 + CD25 + Foxp3 + T cells were then determined by flow cytometry.

Results: The concentrations of serum sHLA-G were comparable between SLE patients and healthy controls. However, there was a negative correlation between sHLA-G levels and SLE disease activity index (SLEDAI) scores in active SLE patients (SLEDAI >4). We found that serum sHLA-G levels were negatively correlated with blood urea nitrogen, serum creatinine and 24-hour urine protein in SLE patients. The sHLA-G levels were significantly lower in SLE patients with renal involvement than those without renal involvement. The expression of ILT2 on CD4 + T cells from SLE patients decreased significantly compared to that of healthy controls. A positive correlation between the frequencies of Treg and CD4 + ILT2 + T cells was found in SLE patients. The levels of sHLA-G increased 24 h after UC-MSC transplantation. The frequencies of Treg cells and the expressions of ILT2 on CD4 + Tcells were significantly increased 24 h after transplantations. *In vitro* studies showed that MSCs increased the frequency of Treg cells in SLE patients in a dose-dependent manner, which was partly abrogated by the anti-HLA-G antibody.

Conclusions: Our results suggested that MSCs might alleviate SLE through upregulating Treg cells, which was partly dependent on sHLA-G.

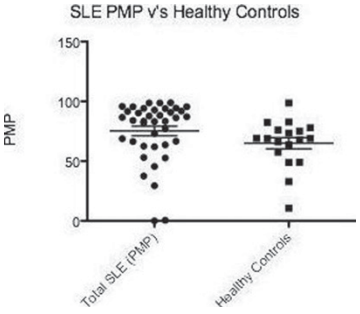
AB0131 PLATELET MICROPARTICLES (PMPS) ARE HIGHER IN PATIENTS WITH SLE COMPARED TO HEALTHY CONTROLS

C.-L.M. Murphy, V. Ripoll-Nunez, C. Periculeous, T. McDonnell, S. Croca, I. Giles, A. Rahman. *Rheumatology, University College London Hospital, London, United Kingdom*



Background: Patients with SLE have an increased risk of cardiovascular disease (CVD) and reasons for this are unknown. Microparticles (MPs) are membrane-bound particles released by many cells, 70–90% are derived from platelets. MPs are a rich source of autoantigens, including DNA and have many functions including thrombosis and inflammation. PMPs can induce foam cell formation and promote adherence of platelets to endothelial lesions. MPs are potentially important in the pathogenesis of autoimmune rheumatic disease and in cardiovascular disease.

Objectives: To determine if EMPs and PMPs are increased in patients with SLE. Our secondary aim was to determine if there was a difference between those with/without subclinical cardiovascular disease and healthy controls.

Methods: Atherosclerotic plaque was previously determined in patients with SLE who had no known history of CVD by carotid and femoral ultrasound scans. Plaque and thickened intima media thickness (IMT) >0.1cm were defined according to the Mannheim Carotid Consensus. Data regarding plaque area, IMT and echolucency were collected. Plasma was stored at -80° at the time of scan. Plasma from n=57; plaque (n=16), no plaque (n=23) and healthy controls (HC) (n=18) were analysed for presence of endothelial and platelet microparticles (EMPs and PMPs), as per protocol. Samples were stained with Annexin V and platelet and endothelial antibodies, CD42a, CD31, CD105 and CD144. MPs were measured using flow cytometry. Statistical analysis was carried out using PRISM.

Results: A total of 57 plasma samples were tested. The average age of those with SLE was 45±12 years. 96% were female. 56% were Caucasian, 18% Asian, 21% Afrocaribbean, 5% other ethnicity. 18% of the SLE patients were smokers. Of the 18 HC, the average age was 37±7 years, 83% were female. 88% were Caucasian and 12% other ethnicity. 11% of the HCs were smokers. PMPs were significantly higher in patients with SLE compared to healthy controls (p=0.025). Patients with SLE without plaque had more PMPs compared to healthy controls

(p=0.037). There was no correlation between age and PMPs. There was no statistical significance between those with SLE with plaque and healthy controls or in EMP levels between the three groups. There was no correlation between EMPs or PMPs with disease activity as measured by BILAG.

Conclusions: PMPs were raised in patients with SLE compared to the healthy controls regardless of whether there was atherosclerotic plaque evident on imaging. Therefore, raised PMPs were associated with SLE itself and did not stratify a subset of patients with subclinical CVD. Further research is required to define whether PMP are important in the pathogenesis of SLE and to clarify the relationship of subclinical CVD in larger cohorts.

AB0132 ANTIPHOSPHOLIPID SYNDROME PATIENTS SHOW AN ALTERED PROFILE OF ENDOTHELIAL PROGENITOR CELLS AND ENDOTHELIAL MICROPARTICLES

C. Barbati, F.R. Spinelli, F. Miranda, F. Ceccarelli, M. Vomero, L. Massaro, T. Colasanti, G. Valesini, C. Alessandri, F. Conti. *Department of Internal Medicine and Medical Specialties, Lupus Clinic, Sapienza University of Rome, Rome, Italy*

Background: Antiphospholipid Syndrome (APS) is an autoimmune disease characterized by recurrent thromboembolic events and pregnancy morbidity associated to the presence of specific serum antibodies directed against membrane phospholipids and proteic co-factors (1). Endothelial dysfunction represents the earlier and reversible stage of subclinical atherosclerosis that characterizes these patients. An altered profile of endothelial progenitor cells (EPCs) and endothelial microparticles (EMPs) could promote endothelial damage (2). Few studies suggested that EMP release is stimulated by circulating anti-phospholipids (aPL). A previous study on EPC reservoir in 7 APS patients showed no difference compared to healthy subjects.

Objectives: Our aim was to evaluate circulating EPCs and EMPs in primary APS patients (PAPS).

Methods: We studied primary APS patients with previous thromboembolic events and sex and age-matched healthy controls (HC). Circulating EPCs was identified by flow cytometry analysis as CD34+/KDR+ positive cells isolated from peripheral blood mononuclear cells (PBMCs); EMPs was obtained by centrifugation of whole blood and quantified by flow cytometry (CD31+/CD41a-). Data were expressed a s mean±standard deviation or median (interquartile range) when appropriate; correlations between EPC and EMP levels with aPL were investigated by Spearman test. P values <0.05 were considered statistically significant.

Results: We enrolled 12 PAPS patients (mean age 44±12 years) and 12 HC. Compared to HC, PAPS patients showed a lower EPC percentage (0.01±0.006% *vs* 0.04±0.003%, p=0.0008) and a higher EMP number (104±80 MPs/microliter *vs* 20±8, $p<0.0001$). EMPs number positively correlated with *anticardiolipin* and *antibeta2 glicoprotein* I, both IgM and IgG ($p<0.05$ and $r>0.7$ for all correlations).

Conclusions: The results of this study suggest that endothelial cells, activated by circulating aPL, release EMPs that can perpetuate the endothelial damage. Moreover, our cohort of APS patients has a reduced number of circulating EPC that could contribute to the impairment of endothelial repair. Both the chronic endothelial damage and the lack of an efficient repair could contribute to the progression of atherosclerosis in PAPS patients.

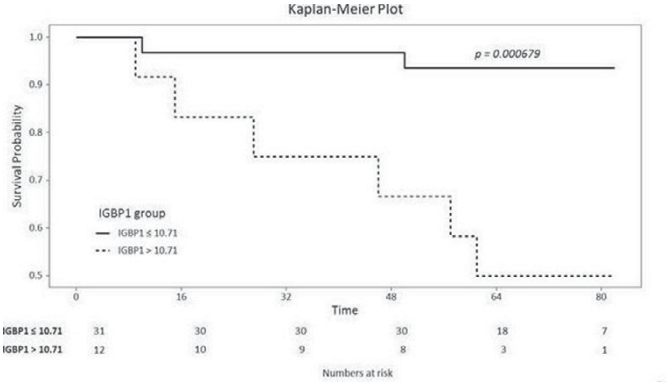
AB0133 BLOOD CONCENTRATION OF IMMUNOGLOBULIN BINDING PROTEIN 1 AS A BIOMARKER TO PREDICT LUPUS NEPHRITIS



D.-H. Lim[1], E.-J. Lee[2], W.-J. Seo[3], O.C. Kwon[2], S. Hong[2], C.-K. Lee[2], B. Yoo[2], Y.-G. Kim[2]. *[1]Division of Allergy and Rheumatology, Ulsan University Hospital, Ulsan; [2]Division of Rheumatology, University of Ulsan College of Medicine, Asan Medical Center; [3]Division of Rheumatology, Seoul Veterans Hospital, Seoul, Korea, Republic Of*

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease of unknown etiology, and renal involvement is an important factor associated with a high morbidity and mortality. Immunoglobulin binding protein 1 (IGBP1) is a phosphoprotein associated with Ig-α of the B cell receptor complex. Intracellular IGBP1 interacts with the catalytic subunit of protein phosphatase (PP2A) and regulates differentiation, proliferation, and apoptosis of B cells. Functional studies reported that high PP2A levels alter the phenotype and function of T cells in SLE patients. Recently, we reported that urinary IGBP1 levels were associated with the pathologic activity in lupus nephritis (LN). However, the role of plasma IGBP1 (pIGBP1) in the clinical features including the development of nephritis has not been identified in SLE.

Objectives: To determine the role of pIGBP1 as a biomarker related with LN.

Methods: Blood samples of SLE patients were collected between Jan 2009 and Dec 2010 in a tertiary hospital. The levels of pIGBP1 were measured in SLE patients with (n=44) or without (n=39) nephritis, and healthy subjects (n=14). Clinical parameters including baseline characteristics, laboratory data, medications and SLE Disease Activity Index (SLEDAI) were collected from electronic medical record. Activity and chronicity index in renal pathology of LN were scored blindly by a renal pathologist. To identify factors related to the development of LN, Cox proportional hazard regression model and Kaplan-Meier curves were used.

Results: The concentrations of pIGBP1 in SLE patient were higher than those in healthy individual (9.6±8.4 ng/mL vs 4.5±2.4 ng/ml) and positively correlated with SLEDAI score. However, the concentrations were not different between LN and non-nephritis SLE and were not associated with activity index score in renal pathology. During follow-up more than 5 years, nephritis was developed in 8 patients (20.5%) among 39 SLE patients who did not have renal involvement at baseline. Interestingly, levels of pIGBP1 (p=0.002), CRP (p=0.009), or anti-dsDNA antibody (p=0.03) were significantly elevated in 8 patients who developed LN compared to who did not. Kaplan-Meier survival curve showed that initial pIGBP1 (>10.71 ng/mL) as well as anti-dsDNA (>30.7 IU/mL) were associated with high probability of LN development in the future.

Conclusions: Based on our results, high concentration of pIGBP1 could be a valuable marker to represent high SLE activity and a predictor for developing nephritis in SLE patients.

AB0134 BLOOD LYMPHOCYTE SUBSETS ACCORDING TO THE CLINICAL PROFILE IN SJÖGREN'S SYNDROME

F. Barcelos[1,2,3], C. Martins[3], G. Nunes[3], T. Lopes[3], J. Vaz Patto[1], J. Amaral[4], J.C. Branco[3], L.M. Borrego[3]. *[1]Instituto Português Reumatologia; [2]Hospital CUF Descobertas; [3]Nova Medical School; [4]Faculdade Med Dentária, UL, Lisboa, Portugal*

Background: It has been recently described the occurrence of disturbances in lymphocyte subsets in Sjögren's syndrome (SS) which may reflect B cell hyper activation and a T cell adjuvant role.
Objectives: We aim to characterize circulating lymphocyte subsets in SS patients, according to disease activity and antibody profile.
Methods: We have included in this study 53 SS patients (2002 AECG criteria) of which 22 with >10 years since diagnosis and 31 with <2 years since diagnosis, and 22 healthy controls. Lymphocyte subsets, including follicular (Tfh) and regulatory T (Treg) cells, maturation subsets, plasmablasts (PB) and regulatory B (Breg) cells, were characterized by flow cytometry. Statistical analysis was performed with GraphPad. Significance was considered for $p<0.05$.
Results: Compared to controls, SS patients had lower absolute counts of B (p=0.0337) and T cells (p=0.0012), lower CD4 (p=0.0002) and higher CD8 percentages (p=0.0006), resulting in an increased CD4/CD8 ratio (p=0.0006). Additionally, there was decrease in absolute counts of Tregs (p=0.0008) and Th17 cells (p=0.0005) in SS patients. Moreover, there was a decreased absolute counts ($p<0.0001$) of Tfh cells, identified by CXCR5 expression, though higher levels of IL21$^+$CD4 T cells (p=0.0209) and Tfh1 cells (p=0.0092). SS patients also presented higher % of naïve B cells (p=0.0412), lower % and absolute counts of memory (%, p=0.0161; abs p=0.0002) and unswitched memory (%, p=0.0106; abs p=0.0005) B cells and lower absolute counts (p=0.0001) of switched memory B cells, with higher naive/memory B cell ratios, compared to healthy subjects (p=0.0219). Accordingly, using the Bm1–5 classification, we have found decreased Bm1 (%, p=0.0087; Abs, p=0.0007), eBm5 (Abs, p=0.0005) and Bm5 cells (Abs, p=0.0015) in SS patients. Similar Bm2+Bm2'/eBm5+Bm5 ratios were observed in patients and controls. CD24$^+$CD27$^+$ Bregs were also decreased ($p\leq0.0012$) in SS patients.
SS patients had also an increase in IL21$^+$CD4 T cells, particularly in patients with extra-glandular manifestations (EGM) (n=12), who also presented less Tfh17 cells (p=0.0409) comparing to patients without EGM. PB were decreased in patients with EGM only when compared to controls (p=0.0434).
SSA$^+$ patients (n=36) had more frequently EGM than SSA$^-$, higher ESSDAI score, γ-globulin levels and lower salivary flow. Compared to SSA$^-$ and controls, increased IL21$^+$CD4 T cells were detected in SSA$^+$patients ($p\leq0.0284$), who also had higher Tfh1 cells than controls ($p\leq0.0065$). Lower Bm1 cells ($p\leq0.0305$) were observed in SSA$^+$patients compared to SSA$^-$ and controls, with an increase % of Bm3+Bm4 cells (p=0.011) compared to SSA$^-$.
Conclusions: The immune profile of SS patients has distinctive features, with decreased memory B cell subsets, including CD24$^+$CD27$^+$ Bregs. Moreover, an increased capacity of IL21 secretion by T cells, together with a more prominent Tfh1 signature seem to be the hallmark of SS, particularly in patients with EGM and autoantibody production, suggesting an immune environment prone to proinflammatory processes, in severe patients. Comprehending the immune dynamics in SS may be valuable for diagnosis, follow-up and future therapeutic decisions.

AB0135 PLASMATIC AND URINARY ENDOTHELIAL MICROPARTICLES ARE INCREASED IN PATIENTS WITH LUPUS NEPHRITIS

F. Miranda, C. Barbati, S. Truglia, F.R. Spinelli, F. Ceccarelli, C. Alessandri, G. Valesini, F. Conti. *Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Rome, Italy*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease presenting with a wide array of clinical manifestations and incompletely understood pathogenesis. SLE is characterized by alterations in both the innate and adaptive immune system ultimately leading to the loss of immunologic tolerance and occurrence of autoantibodies against nuclear material. Lupus nephritis is one of the most severe features of SLE determining an increase in morbidity e mortality rates. Renal biopsy still represent a fundamental diagnostic and prognostic tool for LN. Therefore, non-invasive surrogate biomarkers of active LN are urgently needed. Circulating, heterogeneous subcellular microparticles (MPs) are released from cells and platelets constitutively and upon cellular activation or apoptosis. Such MPs may reflect the state of their parental cells and tissues, and could serve as markers of pathology. Particularly in SLE, MPs are potential biomarkers and triggers of autoimmunity. Recent studies have demonstrated increased levels of plasmatic EMPs in patients with SLE active disease and their reduction after treatment.
Objectives: The aim of this study was to investigate plasmatic and urinary levels of endothelial microparticles in a cohort of SLE patients with and without renal involvement compared to healthy controls.
Methods: Consecutive SLE patients and sex- and age-matched HC were included in the study. MPs were isolated from plasma and urine and characterized by flow cytometry using AnxV (a probe that binds to the exposed phosphatidilserine - PS) and antibodies against surface markers endothelial cells (CD31+CD41-). Mann-Whitney and Spearman correlation tests were used. A p value <0.05 was considered statistically significant.
Results: Sixty SLE patients (55F:5M, age 41,7±9.6 Y disease duration 149±112 months) and 29 healthy controls were studied. Twenty-eight patients had renal involvement.The total number of plasmatic MPs was lower in SLE patients than HC (p=0.001). In contrast there was no significant difference in levels of EMPs between the two groups. When the patients were divided according to renal involvement, the patients with active lupus nephritis (A-LN) showed lower plasmatic level of EMPs in comparison to inactive LN (I-LN) (p=0.01), while the patients with I-LN had higher levels of EMPs than HC (p=0.002). There was no significant difference of total urinary level of MPs between SLE patients and HC. Urinary levels of EMPs were higher in SLE and in lupus nephritis patients than HC.
Conclusions: The results of the present study show increased urinary and plasmatic levels of EMPs in patients with lupus nephritis in remission. Circulating EMPs have been considered as a potential biomarker of endothelial activation and damage in several autoimmune disorders, and higher EMP levels have been detected in patients with vasculitis and associated with disease activation. According to our results, plasmatic EMPs levels are higher in inactive LN patients than in healthy donors. These results may suggest a potential role of EMP as a biomarker of lupus nephritis

AB0136 MICROPARTICLES FROM SLE PATIENTS ARE A SOURCE OF INTERFERON-ALPHA

F. Miranda, C. Barbati, F.R. Spinelli, F. Ceccarelli, S. Truglia, C. Alessandri, G. Valesini, F. Conti. *Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Rome, Italy*

Background: Systemic lupus erythematosus (SLE) is the prototype of systemic autoimmune disorders. In the late 1970s, increased serum levels of interferon (IFN) were shown for the first time to be significantly associated with SLE and to correlate with disease activity. IFNα is a pleiotropic cytokine that can affect multiple cell types involved in lupus.Plasmacytoid dendritic cells have a special role in the production of IFN and are the main sources of serum interferon. IFN has the potential to dramatically influence the development, progression, and pathogenesis of SLE as it can influence the function and activation state of most major immune cell subsets and function as a bridge between innate and adaptive immunity.Lupus-prone mouse models, indicates that the type I interferon system may play a pivotal role in the pathogenesis of several lupus and associated clinical features, such as nephritis, neuropsychiatric and cutaneous lupus.Circulating microparticles (MPs) are ubiquitous in the blood of healthy individuals, These MPs play an active role in coagulation and intercellular communication and assist in activation or suppression of the immune system, depending on their parental cell origin. Changes in the concentration and/or composition of circulating microparticles have been described in various autoimmune diseases, including rheumatoid arthritis (RA) systemic sclerosis (SSc) and systemic lupus erythematosus (SLE). For SLE, the reported microparticle-related changes remain somewhat inconclusive.
Objectives: To better understand the role of MPs in SLE patients, we analyzed the presence of interferon alpha on MPs surface.
Methods: MPs were isolated from citrate-treated plasma; blood cells were removed by two steps of centrifugation process (2500g for 15min at 20 C two time). The resulting platelet-poor-plasma (PPP), was analyzed by flow cytometry with specific antibody against IFN alpha
Results: 20 consecutive SLE patients (10 with active lupus nephritis) and 10 sex- and age-matched healthy control subjects were included in the study. We found that MPs from SLE patients carry on their surface IFN alpha.Moreover, the percentage IFNalpha + MPs was higher in SLE patients and in lupus nephritis patients than in HC, but there was not significant difference between patients with and without renal involvement.
Conclusions: The results of the present study show for the first time the presence of IFN alpha on MPs surface.We may assume that INF+ MPs derive from dendritic cells. In lupus nephritis patients the increased recruitment of dendritic cells was at tubular interstitial level, with subsequent IFN alpha production. Interestingly, MPs (containing RNA and DNA) could stimulate type I IFN production in plasmacytoid dendritic cells and MPs releasing.

AB0137 ALTERATIONS IN MICRORNA EXPRESSION PROFILES IN PRIMARY SJÖGREN'S SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS

G. Papp[1], J.-Q. Chen[1], S. Póliska[2], K. Szabó[1], T. Tarr[1], B.L. Bálint[2], P. Szodoray[3], M. Zeher[1]. *[1]Division of Clinical Immunology; [2]Department of Biochemistry and Molecular Biology, University of Debrecen; [3]Centre for Immune Regulation, University of Oslo, Debrecen, Hungary*

Background: MicroRNAs (miRNAs) are single-stranded, endogenous non-

coding small RNAs, ranging from 18 to 25 nucleotides in length. MiRNAs are essential in regulating gene expression, cell development, differentiation and function. Dysregulation in miRNAs expression may contribute to the development of autoimmunity. However, a given miRNA may have hundreds of different mRNA targets and a target might be regulated by multiple miRNAs, thus the characterisation of dysregulated miRNA expression profiles could give a better insight into the development of immunological disturbances in autoimmune diseases.

Objectives: The aim of our study was to examine the changes in miRNA expression profiles in patients with primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE).

Methods: Eight pSS patients, 8 SLE patients and 7 healthy control subjects were enrolled in the investigation. MiRNAs were isolated from peripheral blood mononuclear cells, and expression patterns were determined with Illumina next-generation sequencing technology. Since the immunopathogenesis of pSS and SLE encompasses pronounced B cell hyperactivity along with specific autoantibody production, we paid a special attention on the association between miRNA expression levels and altered peripheral B cell distribution.

Results: In SLE patients 135, while in pSS patients 26 miRNAs showed altered expression. Interestingly, the 25 miRNAs including miR-146a, miR-16 and miR-21, which were over-expressed in pSS patients, were found to be elevated in SLE group, as well. On the contrary, we observed the down-regulation of miR-150–5p, which is a novel and unique finding in pSS. Levels of several miRNAs over-expressed in SLE, were not changed in pSS, such as miR-148a-3p, miR-152, miR-155, miR-223, miR-224, miR-326 and miR-342. Expression levels of miR-223–5p, miR-150–5p, miR-155–5p and miR-342–3p, which miRNAs are potentially linked to B cell functions, showed associations with the B cell proportions within peripheral blood mononuclear cells.

Conclusions: The observed differences in miRNA expression profiles and the better understanding of immune regulatory mechanisms of miRNAs may help to elucidate the pathogenesis of pSS and SLE.

AB0138 INTERFERON-GAMMA CHALLENGE OF PBMC FROM PATIENTS WITH LUPUS NEPHRITIS IN REMISSION DECREASES SUPPRESSOR OF CYTOKINE SIGNALING 1 (SOCS1) AND REGULATORY T CELLS (TREGS) AND PROMOTES IMMUNE ACTIVATION

G. Gibor[1], U. Arad[1], J. Wallman[1], J. Ablin[1], V. Aloush[1], I. Kaufman[1], S. Jacky[2], D. Caspi[1], O. Elkayam[1], D. Paran[1], A. Sharabi[3]. *[1]Rheumatology; [2]Tel Aviv Medical Center, Tel Aviv, Israel; [3]Harvard BIDMC, Boston MA, United States*

Background: Interferon-gamma (IFN-γ) plays an important role in the development of lupus nephritis (LN). Regulation of IFN-γ signaling that occurs in disease remission and in active LN is herein addressed.

Objectives: To study the impact of IFN-γ on PBMC obtained from patients with LN in remission as compared to active LN.

Methods: Sixteen patients fulfilling the ACR classification criteria for systemic lupus erythematosus were recruited. All patients had a history of LN of whom 10 were in remission (as defined by EULAR criteria) and 6 had active LN (as defined by SLEDAI-2K or BILAG). Healthy subjects (n=10) were included as a control group. Sera and PBMC were obtained from each individual. Flow cytometry, western blots and real time RT-PCR were used in processing and detection of cell subtypes, protein and mRNA levels. Recombinant human IFN-γ (rhIFN-γ) and anti-IFN-γ neutralizing antibody were used in vitro. Mann-Whitney and student t-tests were used for statistical analysis.

Results: In active LN there was a significant 2-fold increase in $CD4^+CD69^+$ activated T cells as compared to healthy subjects and patients in remission. Reactivity to interferon-gamma receptor was determined by the phosphorylation of its predominant transcription factor, signal transducer and activator of transcription 1 (STAT1) in the cells that were incubated with rhIFN-γ or with media alone. In active LN, 3- and 6-fold increase in pSTAT1 occurred with rhIFN-γ incubation during 24h and 48h, respectively, and healthy subjects responded likewise. In patients in remission, pSTAT1 increase was even higher (by 8- and 10-fold at 24h and 48h, respectively). After 24h incubation with rhIFN-g all groups had elevated (mRNA) expression of SOCS1, but at 48h, it significantly decreased in healthy subjects and in patients in remission by 34% and 50%, respectively. Further, at 24h the frequency of $CD4^+CD127^{low}FoxP3^+$ regulatory T cells (e.g. Tregs) increased by 27–30% in active LN and in healthy subjects, and in remission it was minimally changed. At 48h, the frequency of Tregs significantly decreased in healthy subjects (to baseline levels before rhIFN-γ challenge) and in patients in remission (by 24%, p=0.003). A challenge of PBMC from LN patients in remission with sera (at 1% concentration) derived from patients with active LN resulted in 7.5-fold increase in pSTAT1 expression and 20–30% decrease in Tregs, however, combination of sera and anti-IFN-g neutralizing antibody resulted in 5-fold decrease in pSTAT1 expression and significantly diminished the decrease in Tregs.

Conclusions: In LN in remission a challenge with IFN-γ could lead to immune activation and a risk of flare-up, as it results in a decrease in both SOCS1 and Tregs and a robust STAT1 phosphorylation. In active LN, STAT1 phosphorylation is less diminishing, as both SOCS1 and Tregs are saturated, which could affect their suppressive effectiveness.

AB0139 ROLE OF MUCOSAL-ASSOCIATED INVARIANT T (MAIT) CELLS IN A LUPUS MODEL

G. Murayama[1,2], A. Chiba[2], A. Nomura[2], H. Amano[1], K. Yamaji[1], N. Tamura[1], S. Miyake[2]. *[1]Department of Internal Medicine and Rheumatology; [2]Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan*

Background: Mucosal-associated invariant T (MAIT) cells are innate T cells that are restricted by MHC-related molecule-1 (MR1) and express a semi-invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. Previously, we have demonstrated that MAIT cells played a protective role against experimental autoimmune encephalomyelitis, an animal model of human multiple sclerosis. We found that MAIT cells are activated in patients with systemic lupus erythematosus (SLE) and that the activation state of MAIT cells correlated with SLE disease activity index (SLEDAI) score, suggesting their association in lupus pathology.

Objectives: We set out to clarify functions of MAIT cells in a lupus model by using $Fc\gamma RIIB^{-/-}$ Yaa mice.

Methods: $Fc\gamma RIIB^{-/-}$ Yaa mice were crossed to MR1 deficient mice lacking MAIT cells, and disease progression was compared between $MR1^{-/-}$ $Fc\gamma RIIB^{-/-}$ Yaa and $MR1^{+/+}Fc\gamma RIIB^{-/-}$ Yaa mice at 1–4 months of age. Serum anti-dsDNA antibody levels were measured and urinary microalbumin were evaluated. At the time of sacrifice, at 4 months of age, the severity of nephritis and dermatitis were assessed by histologically and IgG deposition in skin and glomeruli was measured.

Results: Survival rate was significantly reduced in $MR1^{-/-}$ $Fc\gamma RIIb^{-/-}$ Yaa mice compared with $MR1^{+/+}$ $Fc\gamma RIIb^{-/-}$ Yaa mice. Anti-dsDNA antibody levels were remarkably higher in $MR1^{+/+}$ than $MR1^{-/-}$ $Fc\gamma RIIb^{-/-}$ Yaa mice at 4 months of age. Even though Glomeruli were significantly enlarged both in $MR1^{+/+}$ and $MR1^{-/-}$ $Fc\gamma RIIb^{-/-}$ Yaa mice due to a marked cellular proliferation in glomeruli, the glomerulonephritis score tended to be lower in $MR1^{-/-}$ $Fc\gamma RIIb^{-/-}$ Yaa mice compared with $MR1^{+/+}$ $Fc\gamma RIIb^{-/-}$ Yaa mice. A larger amount of IgG deposition was observed in mesangial area and along glomerular capillary walls in $MR1^{-/-}$ than $MR1^{+/+}$ $Fc\gamma RIIb^{-/-}$ Yaa mice. However, $MR1^{-/-}$ $Fc\gamma RIIB^{-/-}$ Yaa mice showed exacerbated inflammation in the skin lesions. There was a high degree of inflammatory cells infiltration into the skin and a significant worsening of dermatitis score in $MR1^{-/-}$ $Fc\gamma RIIb^{-/-}$ Yaa mice compared to $MR1^{+/+}Fc\gamma RIIb^{-/-}$ Yaa mice.

Conclusions: These data suggests that MAIT cells exhibit dual roles in lupus pathogenesis. MAIT cells enhance autoantibody production and the disease severity of nephritis, but have a suppressive effect on dermatitis. Further studies are under going to uncover the mechanisms by which MAIT cells are involved in each target tissues.

AB0140 LUPUS-PRONE SLAM HAPLOTYPE EXERTS MONOCYTOSIS AND DEVELOPS SPECIFIC PHENOTYPE OF AUTOIMMUNE DISEASE INTRODUCED BY YAA MUTATION

H. Amano[1], K. Nishikawa[2], Q. Lin[3], S. Kawano[1], K. Yamaji[1], S. Hirose[3], N. Tamura[1]. *[1]Department of Internal Medicine and Rheumatology; [2]Department of Pathology, Juntendo University School of Medicine, Tokyo; [3]Department of Biomedical Engineering, Toin Human Science and Technology Center, Toin University of Yokohama, Yokohama, Japan*

Background: We previously obtained a 129-derive FcγRIIB-deficient C57BL/6 (B6) congenic strain of mice, which spontaneously developed severe rheumatoid arthritis (RA)[1]. The introduction of the *Yaa* (Y-linked autoimmune acceleration) mutation, which is a consequence of a translocation from the telomeric end of the X chromosome containing the *Tlr7* gene onto the Y chromosome, to the FcγRIIB-deficient B6 mice (B6.FcγRIIB-/-. *Yaa*) developed lupus like nephritis but not RA[2].

Objectives: By extensively backcrossing 129-based FcγRIIB-deficient mice to B6 mice, we established wildtype FcγRIIB and 129-derive autoimmune-prone SLAM haplotype ($Slam^{129}$). We examined the phenotype of $Slam^{129}$ mice, and also $Slam^{129}$.*Yaa* mice by introducing *Yaa* mutation to these mice.

Methods: We analyzed peripheral blood monocyte subset and also serum autoantibodies as well as immunohistopathological findings of kidneys and lungs.

Results: $Slam^{129}$ mice showed age-associated monocytosis with marked expan-

sion of Gr-1 negative monocytes, also perivascular inflammatory cell infiltration in lungs. But they did not show any pathogenic autoantibodies. When introducing *Yaa* mutation, *Slam*^{129}.*Yaa* mice showed significant increase the serum levels of anti-RNP antibodies and anti-Sm antibodies. Although they showed significant increase of serum levels of IgM class anti-dsDNA antibodies, they did not show the elevation of IgG class anti-dsDNA antibodies. Also they developed nephritis but the pathological score was significantly lower than B6.FcγRIIB-/-.*Yaa* mice.
Conclusions: Autoimmune-prone SLAM haplotype plays a role for Gr-1 negative monocytosis and *Slam*^{129}.*Yaa* mice developed specific lupus phenotype with elevation of anti-RNP and anti-Sm autoantibodies.

AB0141 LOW DOSE IL-2 CIRCUMVENTED MTOR SIGNALING IN T CELLS IN THE TREATMENT OF SLE

J. He[1], X. Sun[1], J. Li[1], R. Zhang[1], D. Yu[2], Z. Li[1]. *[1]Peking University People's Hospital, Beijing, China; [2]School of Biomedical Sciences, Monash University, Melbourne, Australia*

Background: mTOR signaling is proved to be one of the most important pathway in the pathogenesis in SLE. However, in patients with SLE, whether mTOR pathway can be activated by low-dose IL-2 remained unclear.
Objectives: To clarify the effects of low-dose IL-2 therapy on mTOR signaling in the treatment of SLE.
Methods: Eight patients with active SLE were treated with 1 million IU IL-2. Phophrylation of S6 ribosomal protein (S6RP), AKT and pSTAT5 were measured before and after the first 2 week of low-dose rhIL-2 administration. C57BL/6 mice (male, 8–12 weeks old) were intraperitoneally immunized with SRB and followed by administration of different doses (low:10,000 IU and hight:300,000 IU) of rhIL-2 or PBS from day 3 to day 9. The ratio of Th1, Th2, Tfh, Th17, Tfh and Treg as well as the level of S6RP, AKT and pSTAT5 were assayed by flow cytometry
Results: Low-dose IL-2 was efficient and well tolerated in active SLE, and was associated with expansion of Treg cells ($p<0.001$) and reductions of Tfh and Th17 cells ($p\leq0.001$). No significant change of pS6RP and pAKT was observed. On the other hand, there was a signficiant induction of the activation of STAT5. In mouse studies, low-dose IL-2 inhibited the differentiation of Th17 cells and Tfh cells. Comparing with high dose IL-2 group, there was no significantly increased mTOR activity after low-dose IL-2 administration.
Conclusions: Low-dose IL-2 might circumvent mTOR pathway and play a regulatory role in the T cells in lupus

AB0142 IGM ANTIBODIES AGAINST PHOSPHORYLCHOLINE PROMOTE POLARIZATION OF T REGULATORY CELLS FROM PATIENTS WITH ATHEROSCLEROTIC PLAQUES, SYSTEMIC LUPUS ERYTHEMATOSUS AND HEALTHY DONORS: A NOVEL IMMUNOLOGICAL CONCEPT

J. Sun, S. Lundström, B. Zhang, R. Zubarev, J. Steuer, P. Gillgren, M. Rahman, S. Ajeganova, A. Liu, J. Frostegård. *Karolinska Institutet, Stockholm, Sweden*

Background: IgM antibodies against Phosphorylcholine (anti-PC) are negatively associated with atherosclerosis, cardiovascular disease (CVD) and systemic lupus erythematosus (SLE) where the risk of CVD and atherosclerosis is very high. We here study effects of IgM anti-PC on Th17 and T regulatory cells (Tregs).
Objectives: Immunomodulation in atherosclerosis and SLE could have a huge impact on disease prevention and treatment.
Methods: Mononuclear leukocytes were isolated from peripheral blood (PBMC) obtained from healthy blood donors, from six SLE patients with age- and sex-matched controls and from symptom-giving human atherosclerotic plaques. The proportion of Th17 ($CD4^+CCR6^+$) and Treg ($CD4^+CD25^+CD127^{dim/-}$) cells were determined by flow cytometry in $CD4^+$T cells after 6 days culture with Th17 or Treg-polarizing cytokines, with PMA and Ionomycin stimulation. IgM anti-PC were extracted from total IgM, with flow-through IgM as controls. Dendritic cells (DC) were differentiated from PBMC. Antibody peptide/protein characterization was done by a proteomics de novo sequencing approach.
Results: IgM anti-PC increased significantly the proportion of Tregs from healthy donors, SLE patients and from atherosclerotic plaque cells while control antibodies did not. T cells from SLE patients had a significantly lower proportion of Tregs and higher proportion of Th17 cells as compared to matched controls. IgM anti-PC but not control antibodies significantly reduced production of IL-17 and TNF-alpha in cell culture from SLE patients and from atherosclerotic plaque cells. IgM anti-PC interacted with CD40 and kept DCs in an immature stage potentially being tolerogenic. We identify differences on the IgM peptide expression level in anti-PC compared to control antibodies.
Conclusions: IgM anti-PC increase Tregs and having low levels could contribute to both SLE and atherosclerosis (and CVD) and could thus represent a novel underlying mechanism in these conditions. This finding could also have therapeutic implications.

AB0143 IMMUNOMODULATION FOLLOWED BY QUANTITATIVE TRANSCRIPTIONAL PROFILING TO CHARACTERIZE THE FUNCTIONAL ROLE OF THE SJÖGREN'S-ASSOCIATED NCRNA AC092580.4

J.A. Ice, I. Adrianto, A. Rasmussen, M. Joachims, A. Johnston, C. Montgomery, K. Sivils, C.J. Lessard. *Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, United States*

Background: Despite concerted efforts to characterize dysregulated transcriptional responses observed in Sjögren's syndrome and related autoimmune disorders (both in whole blood and target tissues), the functional roles of non-coding RNAs (ncRNAs), many of which have been identified as critical players in transcriptional regulation of disease, remain poorly defined.
Objectives: In the present study, we describe ongoing efforts to functionally characterize the upregulated ncRNA identified by RNA-seq and *in silico* approaches, *AC092580.4* (FC=2.54), which we hypothesize plays a role in T and NK cell responses.
Methods: To study the immunomodulation of the ncRNA *AC092580.4*, we carried out a time-course experiment (0–36 hrs) using either PMA/I (500x dil) or universal Type I Interferon. Relative gene expression changes were determined using the Livak method by qPCR using optimized primers for *GZMA* and *AC092580.4* normalized to *GAPD*. Healthy PBMCs were subjected to stimulation by PHA (1mg/mL; 3 days), PMA/I (500x dil; 3 days), or anti-CD3/CD28 ($50uL/1x10^6$cells; 1 day). An average 150-bp RNA-seq reads were generated for each sample; alignment was carried out using STAR (hg38) and comparisions of stimulated vs unstimulated cells were done using DEseq. Pearson's correlation (r) was calculated for all 3,748 differentially expressed (DE) transcripts to identify transcripts co-expressed with *AC092580.4*.
Results: Of the transcripts showing DE in our SS RNA-seq study, we identified 8 as having significantly correlated expression with *AC092580.4* in the SS^{Ro-} expression matrix ($r>0.70$ or <-0.65). To understand the possible effects of immunomodulation on relevant cells, we stimulated HSB-2 cells with PMA/I at various time points and assessed *AC092580.4* expression by. We observed downregulation of *AC092580.4* and the co-expressed transcript *GZMA* by PMA/I (trough: 12–16hrs; FC=0.09) followed by slow recovery at 36hrs (FC=0.59). To characterize these transcriptional changes further, we performed RNA-seq using healthy PBMCs exposed to various T cell stimulants. We observed marked upregulation of both *AC092580.4* and *GZMA* at 24/36hrs by all stimulants (FC=4.89–5.98). Other transcripts showed variable responses. *CAV2* is upregulated by PMA/I, but downregulated by CD3/CD28 and PHA. Stimulation by PHA leads to upregulation of *CD3D* (FC=1.56) and *SNRPD1* (FC=3.28) with little change in *RPL36A* (FC=1.09). Stimulation by CD3/CD28 similarly leads to upregulation of *CD3D* (FC=2.85) and *SNRPD1* (FC=10.04), but clear downregulation of *RPL36A (*FC=0.64*)*. We assessed *AC092580.4* expression in HSB-2 cells exposed to I IFN and observed initial upregulation (6hrs, FC=1.46) followed by gradual downregulation (36hrs, FC=0.18).
Conclusions: In the present study, we have initiated stimulation studies with to understand the immune relevance of *AC092580.4* and co-expressed targets. *AC092580.4* shows transcriptional induction by potent inducers of T cell responses (PMA/I, PHA, CD3/CD28) but is downregulated by type I IFN. Transcripts showing co-expressed with *AC092580.4* by whole-blood RNA-seq show divergent expression patterns according to the specific stimulus, suggesting a complex regulatory network governing dysregulated T and NK responses.

AB0144 PREGNANCY OUTCOMES IN IMMUNE-MEDIATED RHEUMATIC DISEASES: A RETROSPECTIVE LONGITUDINAL STUDY IN A TERTIARY HOSPITAL

J. Bernardo[1], I. Brito[1], H. Guimarães[2], M. Guimarães[3], R. Fonseca[1]. *[1]Rheumatology; [2]Pediatrics; [3]Gynecology and Obstetrics, Faculty of Medicine of the University of Porto, Porto, Portugal*

Background: Autoimmune rheumatic diseases such as systemic lupus erythematosus (SLE), antiphospholipid antibody syndrome (APS) and Sjögren's syndrome (SS) are part of a clinical spectrum eligible to affect women in child-bearing ages, increasing pregnancy morbidity and affecting neonatal outcomes. Pregnancy complications include the teratogenic risk from immunosuppressive drugs, pregnancy-related disease flares, recurrent pregnancy loss, premature

delivery, intrauterine growth restriction (IUGR) and preeclampsia. Conceiving in periods of low disease activity helps to reduce these complications.
Objectives: This project aims to describe the occurrence of pregnancy complications among women with immune-mediated rheumatic diseases and to study the associated clinical factors.
Methods: A retrospective longitudinal study was performed including consecutive pregnant women with immune-mediated rheumatic diseases seen in a multidisciplinary group for autoimmune diseases during pregnancy, in a tertiary hospital, between January 2010 and December 2015. Clinical and demographic data, as well as and pregnancy outcomes, were collected through consultation of clinical files. The factors associated with pregnancy manifestations (premature delivery, flares during pregnancy, recurrent pregnancy loss and foetal growth restriction) were studied using Mann-Whitney, qui-square and fisher tests (SPSS 24.0). Significance level was set as <0.05.
Results: We included 151 gestations from a total of 140 women with a mean age of 32,5±4,4 years; 4 gestations were twin pregnancies. Within these 151 gestations, 54 (35,8%) women had SLE, 17 (11,3%) had Sjögren's syndrome, 17 (11,3%) had rheumatoid arthritis, 41 had APS (27,2%), 11 (7,3%) had Behçet's disease, 4 (2,6%) had systemic sclerosis, 8 (5,3%) had mixed connective tissue disease and 16 (10,6%) had other immune-mediated diseases. 35 (23,2%) had anti-SSA/La antibodies, 18 (11,9%) had anti-SSB antibodies, 6 (4,0%) had anti-URNP antibodies and 43 (28,5%) had anti-nuclear antibodies. Seven (4,6%) of the women developed gestational diabetes and 4 (2,6%) developed gestational hypertension. Furthermore, 54 (35,8%) women had had previous miscarriages. Prematurity occurred more frequently among neonates with IUGR (53.8% vs 46.1%; p=0.04), and was associated with gestational diabetes (21.4% vs 2.9%; p=0.018). It also occurred more frequently in multiple pregnancies (75% vs 16.4%; p=0.001), mothers taking glucocorticoids (28.6% vs 9.2%; p=0.003) and active rheumatic disease at conception (23% vs 6.8% p=0.03). No statistically significant differences were observed in the occurrence of different pregnancy complications among different diseases or in presence of different antibodies.
Conclusions: Our study proved a link between immune-mediated rheumatic diseases and specific pregnancy outcomes such as prematurity and IUGR. Outcomes were worse when taking glucocorticoids, when gestational diabetes were developed and when conception occurred in a period of active disease.

AB0145 TLR4 SIGNALING PATHWAY MEDIATES THE SENESCENCE OF BONE MARROW- MESENCHYMAL STEM CELLS FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

J. Ji, Y. Wu, X. Kong, Z. Zhang, Z. Gu. *Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China*

Background: Previous studies of our research group revealed the senescence of bone marrow-mesenchymal stem cells from systemic lupus erythematosus patients,which participated in the development of SLE. "Inflammatory microenvironment" played a very important role in cellular senescence. In the preliminary experiments, we discovered the level of HMGB1 in serum and Peripheral blood mononuclear cells from SLE patients was higher than those of The healthy control group.
Objectives: The aim of this study was to investigate whether HMGB-1 can lead to senescence BM-MSCs from SLE patients and its possible mechanism.
Methods: Tewelve female SLE patients and healthy subjects were enrolled in the study. All patients were females, and their age distribution was similar to that of the cases. All BM-MSCs were Isolated by density gradient centrifugation. Western Blotting and immunofluorescence were used to distinguish the difference of expression and localization of TLR4 signaling pathway between normal group and SLE group. Different concentrations (0.01,0.1,1,10ug/ml) of HMGB-1 (the endogenous ligand of TLR4) stimulated normal BM-MSCs, then detecting expression of TLR4 signal by WB, observing the activity of β-gal of cells, the changes of cytoskeletal structure by F-actin staining and the distribution of cell cycle by flow cytometry. We used small interfering RNA (siRNA) to interfere the expression of TLR4.
Results: BM-MSCs from SLE patients showed prominent features of senescence, characterized by impaired capacities of proliferation, increased SA-β-gal activity, and disordered cytoskeleton distribution, and abnormal activation of TLR4 signaling transduction, high level of phosphorylated p65. IκBα. After stimulation of HMGB1 in normal MSCs,TLR4 signaling was activated. And, the cell volume and the number of SA-β-gal positive in SLE BM-MSCs was increased. The organization of cytoskeleton was neatly disordered. The rate of cell proliferation was decreased. The inhibitors of HMGB-1 and small interfering RNA (siRNA) of TLR4 can significantly reverse the senescence.
Conclusions: HMGB-1 binded to TLR4, and by activating MyD88/IRAK/TRAF pathway, promoted NF-κB signal transduction, thereby affected the expression of cell cycle-related proteins, and then resulted in senescence of MSCs from SLE patients.

AB0146 INVOLVEMENT OF PERIPHERAL CD8 T CELL SUBSETS IN SYSTEMIC LUPUS ERYTHEMATOSUS

J. Kikuchi[1], M. Ushikubo[1,2], S. Saito[1], K. Yamaoka[1], K. Sugahara[3], K. Chiba[3], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]Department of Connective Tissue Diseases, National Tokyo Medical Center, Tokyo; [3]Sohyaku. Innovative Research Division, Mitsubishi Tanabe Pharma Corporation, Kanagawa, Japan*

Background: Although the mainstream of pathogenesis of systemic lupus erythematosus (SLE) is thought to be interactions between antigen-presenting cells like dendritic cells, helper T cells, B cells and cytokines, previous reports suggested CD8 T cells also involve in the pathogenesis of SLE[1,2]. However the associations between subsets of CD8 T cells and clinical manifestations remains unclear.
Objectives: We conducted standard immunophenotyping analysis with peripheral blood from SLE patients and focused on CD8 T cell subsets to elucidate the association with clinical phenotype and serological markers.
Methods: Peripheral blood was obtained from inactive SLE patients and healthy subjects as controls and also from active SLE before and 3 months after treatment. CD8 T cell subsets were measured by flow cytometry with fresh whole blood samples.
Results: Thirty-four active SLE patients and 38 inactive patients and 22 healthy controls (HCs) whose age and sex were matched with those in SLE patients were enrolled. Mean SLE disease activity index (SLEDAI) was 14.2 and 1.8 in active and inactive patients, respectively. Among CD8 T cell subsets, the proportion of HLA-DR+ cells was significantly higher in SLE patients than HCs and positively correlated with SLEDAI (p=0.016, rho =0.283), and was also higher in patients with nephritis than patients without nephritis (p=0.074), though it did not reach statistical significance. The proportion of naive CD8 T cells positively correlated with the titer of anti-dsDNA antibody (p=0.011, rho =0.30) and C1q immune complex levels (p=0.043, rho =0.25), and negatively correlated with serum complement levels (p=0.019, rho = -0.34). The proportion of central memory CD8 T cells (Tcm) negatively correlated with SLEDAI ($p<0.001$, rho = -0.43), the titer of dsDNA antibody ($p<0.001$, rho = -0.51) and C1q immune complex levels ($p<0.001$, rho = -0.44), and positively correlated with serum complement levels ($p<0.001$, rho =0.49), and was lower in the patients with nephritis (p=0.041), skin rash ($p<0.001$), and fever (p=0.002) than the patients without them. The proportion of effector memory CD8 T cells (Tem) was lower in SLE and negatively correlated with the titer of anti-dsDNA antibody (p=0.028, rho = -0.26). Sixteen active patients were treated with prednisolone (PSL) 50mg (mean) with concomitant immunosuppressant; eight were treated with cyclophosphamide. Mean SLEDAI decreased from 15.9 to 3.9 at 3 months after the treatments. The proportion of naïve CD8 T cells significantly decreased (p=0.003), and the proportions of HLA-DR+ cells and Tem increased at 3 months (p=0.011 and p=0.007, respectively). The proportion of Tem increased and negatively correlated with SLEDAI only with those who were treated with cyclophosphamide.
Conclusions: Pathological state of SLE positively correlated with the proportion of naïve CD8 T cells and negatively correlated with the proportion of Tem and these subsets were affected by treatment with PSL and immunosuppressant particularly cyclophosphamide. These results indicate that CD8 T cells are involved in pathophysiology and could potentially become a biomarker or a treatment target in SLE patients.

AB0147 THE EFFECT OF TREATMENT WITH HYDROXYCHLOROQUINE ON SOLUBLE TISSUE FACTOR LEVELS IN PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES AND ANTIPHOSPHOLIPID SYNDROME WITH AND WITHOUT UNDERLYING SYSTEMIC LUPUS ERYTHEMATOSUS

K. Schreiber[1,2], K. Breen[1], K. Parmar[1], B.J. Hunt[1]. *[1]Centre for Thrombosis and Haemostasis, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]Department of Rheumatology, Copenhagen University Hospital, Copenhagen, Denmark*

Background: Antiphospholipid syndrome (APS) is characterized by venous, microvascular and/or arterial and/or obstetric morbidity (obstetric APS) in patients who are persistently positive for antiphospholipid antibodies (aPL)[1]. The mainstay of treatment is based on anticoagulation therapy; however, increasing interest is currently received by the antimalarial hydroxychloroquine (HCQ). The use of HCQ has been associated with a reduced risk of thrombosis but HCQ's antithrombotic mechanism of action is unclear particularly in patients with aPL and APS.
Objectives: The aim of our study was to assess soluble tissue factor (TF) levels in HCQ naïve-patients with persistent aPL or APS at baseline and 12 weeks after commencing HCQ. We hypothesise that HCQ lowers levels of soluble TF.

Methods: Twenty- two individuals with APS with or without other associated autoimmune disease (20 females, two males, median age 55 (range 18–70) years) had blood samples taken before and 12 weeks after starting HCQ 200mg. Plasma was stored at -80°C and thawed to measure TF using Imubind TF kit (Invitech Ltd, Cambridgeshire, UK). The assay was performed according to the manufacturer's instructions. Patient characteristics are outlined in table 1. Statistical analysis was performed using SPSS Version 22. For continuous normally distributed data a two-tailed student's paired t-test was performed. A value of p=0.05 was considered as significant. There are no previous data in this area, so we were unable to do a power calculation to work out study size. Our study is therefore a pilot study.
Results: Soluble TF levels were above our normal range (40–300 pg/ml) prior to the commencement of HCQ and were significantly reduced (pre level mean (SD) 401.8 (152.8) pg/ml versus post 300.9 (108) pg/ml (p=0.010).

Table 1: Demographic data

Variables	APS (N=22)
Age: median (range)	47 (18-69)
Sex (female:male)	20:02
Ethnicity (white:asian:black)	(20:1:1)
aPL subtype	
LA* positive	19
IgG or IgM aCL positive (>99th centile)	5
IgG or IgM anti-Beta2GPI antibody positive (>99th centile)	0
aCL and anti-Beta2GPI antibody positive (>99th centile)	0
aCL antibody and LA* positive (>99th centile)	3
Anti-Beta2GPI antibody and LA* positive (>99th centile)	0
aPL complication	
Thrombosic APS	
Previous arterial thrombosis	10
Previous venous thrombosis	7
Previous arterial and venous thromboses	4
Obstetric APS	
Previous recurrent 1st trimester pregnancy loss	2
Previous pre-eclampsia	1
Previous intrauterine growth restriction	1
Previous stillbirth	3
Treatment	
Warfarin	14
Heparin	0
Aspirin	3
Autoimmune profile	
Antinuclear antibodies (ANA)	10
Extractable nuclear antibodies (ENA)	2
Double stranded DNA antibodies (dsDNA)	1

Key: aCL - anticardiolipin; anti-Beta2GPI - anti-Beta2glycoproteinI; LA - lupus anticoagulant. *LA detected by either DRVVT, dilute aPTT or TSVT

Conclusions: There was a significant reduction in soluble TF levels in this patient cohort of patients with apL and APS after commencing HCQ. Our previous work has shown that HCQ has not affected complement turnover, VEGF levels, thromboelastometry findings or CRP levels. Our findings of a reduction of soluble TF levels in aPL positive patients after the commencement of HCQ maybe a key mechanism by which HCQ reduces thrombotic risk. Further studies of a larger patient cohort are required to confirm our observation.

Background: Systemic lupus erythematous (SLE), is an autoimmune disease characterized by autoantibody synthesis and inflammation. During disease course, up to 70% of SLE patients will develop LN. Emerging evidence has demonstrated that infiltrating monocytes and macrophages are associated with LN pathogenesis. We have previously demonstrated that HO-1, a haem-degrading enzyme with anti-inflammatory properties is decreased in peripheral monocytes of SLE patients. Therefore, we decided to explore the contribution of HO-1 expression to LN pathogenesis.
Objectives: To explore the role of HO-1 in modulating innate immunity through a cytoprotective effect in monocytes of LN nephritis patients. Accordingly, we examined the expression of HO-1 in circulating monocytes, and the effect of HO-1 induction in reactive oxygen species (ROS) production and the phagocytic activity of monocytes from peripheral blood of LN patients and healthy controls (HC).
Methods: SLE patients with proliferative LN confirmed by renal biopsy (Class III, IV or V ISN/RPS) were recruited at Hospital Clinico of PUC. All individuals signed an informed consent form. Monocytes were purified from peripheral blood mononuclear cells (PBMCs) of LN patients and HC using pan-monocytes MACS kit. Subpopulations of monocytes and HO-1 expression were measured by FACS. ROS was determined using CellRox Kit. The phagocytic ability of monocytes was assessed by FACS and the total phagocytosis was calculated as the percentage of cells with engulfed beads.
Results: We found that monocytes from LN patients show significant differences when compared to HC in all the parameters analyzed. The percentage of CD16+ inflammatory monocytes was higher in LN patients (6.72±0.98%) compared to HC (4.07±0.48%) ($p<0.05$). HO-1 protein expression is decreased in circulating LN monocytes (4789±911 vs 1572±481, p=0.005). Baseline levels of ROS are elevated in LN monocytes with similar values that the ones found in monocytes from HC treated with a ROS inducer (HC: 3509±584; HC+TBHP: 8436±1909; LN: 8355±1714). Furthermore, phagocytic activity is increased in LN monocytes (77.97±3.31%) compared to HC (39.63±2.75%). Moreover, our preliminary data indicate that HO-1 induction, using cobalt protoporphyrin (CoPP), leads to downregulation of ROS production in LN (~60%) and HC (~40%) leaving both in similar levels of ROS production. In addition, phagocytic activity is also decreased in LN and HC monocytes in the presence of CoPP (~30%).
Conclusions: Decreased HO-1 expression in circulating monocytes of LN patients leads to higher ROS production and phagocitic activity. ROS level and phagocytosis are reduced when we induce HO-1 expression with CoPP. We propose that HO-1 induction might exert a cytoprotective role in LN by regulating innate immunity. AB0149 PROLACTIN AND AUTOPHAGY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL SIGNIFICANCE OF CORRELATION BETWEEN PRL-R+ (RECEPTOR), CD19+, ATG14+, AND CD25+ EXPRESSION ON B AND T REGULATORY CELLS

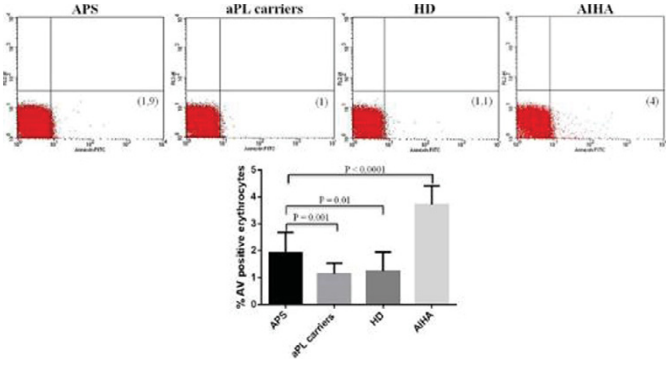
Background: Systemic Lupus Erythematosus (SLE) is a prototype of autoinmune diseases with excessive anti-nuclear autoantibodies production. B cells activation with immune complex formation is the main characteristic of SLE with abnormalities in immune cells, dysregulation of apoptosis, and defects in the clearance of apoptotic materials. Autophagy, a highly conserved protein degradation pathway, is essential for removing protein aggregates and misfolded proteins in cells and its defects contributes to SLE pathogenesis. On the other hand, multiple evidences in humans and experimental models suggest that prolactin (PRL) is associated with active SLE and participates in the immune dysregulation, and one of the mechanisms of PRL action is the inhibition of apoptosis.
Objectives: Analyze the relationship between PRL receptors (PRL-R) on B cells and markers of autophagy on T regulatory cells and the association, if any, with clinical characteristics of SLE.



Expresssion of PRL-R and ATG14 in active SLE patients and healthy controls. *p=0.026 Dunn´s multiple comparisons test.

Methods: The expression of PRL-R on B cells CD19$^+$, and autophagy-related key regulator protein ATG14$^+$, on T regulatory cells CD25$^+$, were measured by flow cytometry, and expressed in percentages of SLE patients (1997, ACR criteria), and healthy controls. Active SLE was considered by SLEDAI ($\geq$4). The organs affected and treatments were evaluated.
Results: A total of 40 SLE patients and 20 healthy controls were included. Mean age of patients and controls was 30.67±4.16. Mean duration of disease was 6±4.6 years. Twenty patients were active (SLEDAI 8.45±1.9) and of these, lupus glomerulonephritis was observed in 13 patients (65%). The expression of PRL-R on B cells of active SLE was higher than in inactive SLE (50.5% vs 26.5%). In active SLE especially in patients with glomerulonephritis, the mean amount of PRL-R on B cells/ml was 6,645/ml (range 3167–6957). In contrast, patients with inactive SLE, had a low amount of PRL-R, 522.5/ml (range 15–895). In the relation of autophagy, the mean expression of ATG14$^+$ in 20 active SLE patients was 11.19% in comparison with inactive SLE patients, 7.13%, (p=0.04), and in healthy donors, 7.445% (p=0.0281).
Conclusions: Our study suggest: In active SLE patients the expression of PRL-R and autophagy-related key regulator protein ATG14+ are very high in B cells and T regulators respectively, in comparison with inactive SLE and healthy donors.
These novel findings suggest the interaction between PRL-R and autophagy in order to promote clinical/immune activation with overproduction of autoantibodies. PRL-R and ATG14$^+$ may be a new target of SLE treatment.

AB0150 INCREASED ERYPTOSIS LEVELS IN PRIMARY ANTIPHOSPHOLIPID SYNDROME PATIENTS

M. Vomero[1], F. Ceccarelli[1], A. Finucci[1], C. Pensa[1], C. Barbati[1], T. Colasanti[1], F.R. Spinelli[1], L. Massaro[1], S. Truglia[1], C. Perricone[1], F. Miranda[1], F.R. Mauro[2], R. Foà[2], F. Conti[1], G. Valesini[1], C. Alessandri[1]. *[1]Department of Internal Medicine and Medical Specialties, Lupus Clinic, Sapienza University of Rome; [2]Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University of Rome, Rome, Italy*

Background: Erythrocytes (RBCs) hold a crucial role in hemostasis and their integrity is influenced by different stimuli including circulating inflammatory mediators. Even though RBCs do not have nuclei and mitochondria, they have developed a process allowing them to undergo a rapid self-destruction named eryptosis. The exact mechanism of erythrocytes cell death is not fully clarified yet but it seems to involve Ca^{2+} and ceramide formation, leading to cell shrinkage and externalization of phosphatidylserine (PS) (1). Interaction between platelets and erythrocytes could participate in an increasing risk of thrombotic episodes typical of several diseases including antiphospholipid syndrome (APS). In fact, not only signals triggering eryptosis are involved in thrombosis activation, but also recent studies have demonstrated how PS-exposing erythrocytes are able to adhere to the vascular wall causing an impairment of circulation (2,3).
Objectives: Enhanced eryptosis is known to contribute to several pathological conditions (1) but the involvement of this process in APS has not been investigated yet. For this reason the aim of the study was to evaluate eryptosis levels in APS, healthy subjects positive for antiphospolipid antibodies without clinical manifestations (aPL carriers), autoimmune haemolytic anaemia (AIHA) and healthy donors (HD).
Methods: 27 patients with primary APS (M/F 5/22, mean age 51.1±7.6 years), 14 aPL carriers (M/F 3/11, mean age 48.9±8.4 years) were recruited after written informed consent. Moreover 10 AIHA patients and 12 HD were also enrolled as positive and negative control group respectively. RBCs were isolated from whole blood after centrifugation and eryptosis levels were analysed by flow cytometry, evaluating the percentage of annexin V-positive cells (PS-exposing cells). Flow cytometry was also use to estimated cellular volume from forward scatter (FSC).
Results: APS patients showed higher levels of eryptosis compared to HD (p=0.01). Interestingly, the percentage of annexin V-positive RBCs was lower in aPL carriers respect to APS patients (p=0.001). Moreover, an inverse correlation between RBCs volume and eryptosis was found in APS patients (r=-0.4, p=0.03). No clinical correlation between eryptosis and clinical manifestations were noticed. As expected, eryptosis was upregulated in AIHA patients compared to all populations studied ($p<0.0001$).
Conclusions: Our study provides for the first time evidence of eryptosis enhancement in APS patients suggesting a possible contribution of RBCs apoptosis in the pathogenesis of the disease.

AB0151 STRESS MODERATION IMPACTING LUPUS WITH EXERCISE (S.M.I.L.E.): INFLUENCE OF DAILY MODERATE EXERCISE AND STRESS MODIFICATION ON AUTOIMMUNE-MEDIATED INFLAMMATION IN MICE AND HUMANS WITH LUPUS

N.A. Young[1], E. Thomas[1], B. Snoad[1], J. Sharma[1], M. Mobeen[1], J. Yedimenko[1], H. Steigelman[1], A. Meara[1], G. Valiente[2], S. Ardoin[1], N. Powell[3], J. Sheridan[3], W. Jarjour[1]. *[1]Rheumatology and Immunology; [2]Medical Oncology; [3]Institute for Behavioral Medicine Research, The Ohio State University Wexner Medical Center, Columbus, United States*

Background: Despite numerous studies indicating the positive effects of exercise and psychological stress reduction in patients with autoimmune disease, these therapeutic modalities are currently underemphasized due to the absence of comprehensive immunological characterization and regimen standardization.
Objectives: In order to examine the influence on the immune system at the cellular and tissue level, disease pathology was analyzed in the NZM2410 mouse model of lupus nephritis. To translate these results and begin to characterize a consensus treatment regimen, a pilot cohort of systemic lupus erythematosus (SLE) patients with active disease was enrolled into a daily Tai Chi program, which emphasized moderate exercise levels with meditative breathing to provide daily physical activity and stress reduction.
Methods: Mice were exercised daily by treadmill walking at moderate intensity. Social disruption stress was induced in mice by disturbing the social order within an established hierarchy. All mice were removed from the study when experimental removal criteria was reached [blood urea nitrogen (BUN)>50 mg/dL; weight loss>20%]. Kidney tissue and serum were collected from mice at experimental endpoint. SLE patients completed daily Tai Chi exercises and data was collected at baseline and throughout the study via questionnaires to access physical activity and stress levels, activity trackers (Fitbit), and serum sample analysis.
Results: Histopathological analysis of NZM2410 mice demonstrated that psychosocial stress induction significantly exacerbated and daily moderate exercise significantly reduced lupus nephritis disease pathology, as measured by BUN levels, complement component 3 and IgG complex deposition in glomeruli, pathological grading of H&E-stained kidney sections, and renal macrophage infiltration. Furthermore, stressors induced levels of IL-6, TNF-α, and IL-1β, while exercise suppressed IL-6, TNF-α, IL-10, and CXCL1 in mice. Compared to baseline data, questionnaires confirmed a significant reduction in perceived social stress and an increase in combined metabolic equivalent of task (MET) and overall physical activity in SLE patients. Moreover, fitness activity tracker data showed a significant increase in steps, distance, and activity calories with no changes in body mass index or vigorous activity levels. Interestingly, this correlated with an increased average time in bed each night. Analysis of pro-inflammatory serum cytokine

expression revealed suppression in the relative fold change of IL-6 by 23%, IL-8 by 30%, TNF-α by 11%, and IFN-γ by 21% with Tai Chi.
Conclusions: These data suggest that moderate exercise and stress management can have potent immunoregulatory effects on the chronic, systemic inflammation associated with SLE and identify daily Tai Chi exercise as a viable adjunct therapy to compliment current pharmacological interventions.

AB0152 DISEASE ACTIVITY AND DAMAGE SCORES CORRELATED DIFFERENTLY WITH THE PATIENT REPORTED OUTCOMES IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME COMPARED TO LUPUS ASSOCIATED WITH SECONDARY SJÖGREN'S SYNDROME

N. Thompson, V. Gupta, A. Gandhi, R. Radmore, S. Cho, D.A. Isenberg, E.C. Jury, C. Ciurtin. *Rheumatology, University College London, London, United Kingdom*

Background: Previous studies showed a poor correlation between EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) in patients with Sjögren's syndrome (SS) (1). There are no previous studies correlating these scores with the SS Disease Damage Index (SSDDI) or assessing comparatively patients with primary (pSS) and secondary SS associated with lupus (SLE/SS).
Objectives: We aimed to assess how well scores assessing disease activity, damage and patient reported outcomes correlate with each other in patients with pSS compared to SLE/SS.
Methods: We conducted a cross-sectional study of 55 patients with pSS and 15 SLE/SS. Detailed clinical and laboratory data, along with patient reported outcomes (ESSPRI) and disease activity and damage scores (ESSDAI, BILAG and SSDDI) were collected. We compared the clinical and laboratory parameters of the two patient groups (pSS and SLE/SS) and assessed the correlations between maximum ESSDAI score since diagnosis and ESSDAI, ESSPRI, SSDDI and BILAG scores at the time of assessment.
Results: The table below shows comparatively the differences between the pSS and SLE/SS patient groups.

Table 1

Demographic	pSS (n=55)	SLE/SS (n=15)	Significance
Sex n (female/male %)	55 (100/0)	15 (100/0)	
Ethnicity n (C/A/MN/O)	43/6/3/3	9/1/5/0	P=0.4571
Age mean (range)	58 (28–84)	56 (25–78)	P=0.5923
Disease duration mean (range)	12 (2–34)	23 (3–40)	P=**0.005
Anti-Ro+ % (n)	76 (42)	73 (11)	P=0.7273
Anti-La+ % (n)	49 (27)	27 (4)	P=0.0565
ESSPRI median [IQR]	5 [3–7]	4 [2– 6]	P=0.3382
ESSDAI median [IQR]	2 [0– 4]	2 [1–4]	P=0.8884
Maximum ESSDAI [IQR]	4 [2–6]	3 [2–6]	P=0.9519
SSDDI median [IQR]	1 [1–2]	1 [0–2]	P=0.1992
Global BILAG median [IQR]		0 [0–2]	
Treatment			
Hydroxychloroquine (%)	65	40	P=0.0775
Methotrexate (%)	5	33	P=**0.0092

Unpaired T test performed; **p<0.01, n = total number, % percentage, IQR = interquartile range, ethnicity: C = Caucasian, A = Asian, MN = African Caribbean, O = Chinese, anti-Ro = anti-Sjögren's-syndrome-related antigen A, anti-La = anti-Sjögren's-syndrome-related antigen B.

We found significant correlations of SSDDI score with disease duration and maximum ESSDAI score in patients with pSS (r=0.27, p=0.05 and r=0.67, p=0.0001, respectively). In SLE/SS patients, ESSPRI scores correlated with both BILAG and maximum ESSDAI score (r=0.55, p=0.03 and r=0.7, p=0.02, respectively). The SSDDI score correlated with the disease duration only in pSS patients (r=0.27, p=0.05).
Conclusions: Our study showed that there was no similar correlation between various disease scores in patients with pSS compared to SLE/SS patients. If the patient reported outcomes correlated with the disease activity (ESSDAI and BILAG) in SLE/SS patients, this correlation was not seen in pSS patients, in which the significant correlations were found only between damage scores, highest disease activity score and disease duration.

AB0153 DELETION OF RECEPTOR FOR ADVANCED GLYCATION END PRODUCTS (RAGE) DOES NEITHER AFFECT AUTO-ANTIBODY PRODUCTION NOR DEVELOPMENT OF RENAL DISEASE IN PRISTANE-INDUCED LUPUS

N. Chevalier, R. Rzepka, R. Voll. *University Freiburg Medical Center, Freiburg, Germany*

Background: Systemic lupus erythematosus (SLE) is characterized by autoantibodies to diverse autoantigens, especially to nuclear components such as double-stranded DNA (dsDNA) or nucleosomes. Still, it remains unclear why poorly immunogenic molecules such as dsDNA and nucleosomes become targets of humoral autoimmunity in SLE. Increased signaling via pattern-recognition receptors (PRRs) through pathogen-associated molecular patterns (PAMPs) or endogenous damage-associated molecular patterns (DAMPs) released from damaged or stressed host cells and tissues, may be critically involved in the break of tolerance against such nuclear antigens. One important PRR in this context may be RAGE. Among many others, RAGE recognizes High mobility group box 1 (HMGB1). HMGB1 is a DNA-binding nuclear protein that has been found at elevated levels in patients with SLE and other autoimmune diseases; likewise perpetuation of RAGE signaling sustains inflammation and leads to the establishment of chronic inflammatory disorders.
Objectives: We therefore examined, using the Pristane-induced SLE model, if increased RAGE signaling may be involved in the break of tolerance against nuclear antigens and contributes to chronic inflammation.
Methods: To that end, WT and RAGE-/- animals were injected intra-peritoneally with a single dose of pristane. Disease manifestations were determined after 7 months and included the determination of proteinuria and renal pathology by evaluating the glomerular cellularity and matrix on H&E stained paraffin-embedded kidney sections and glomerular depositions of IgG and C3c. In addition to that we checked for auto-antibody production at several time points during disease development and immune cell distribution, differentiation and phenotype in inflamed kidneys and spleen.
Results: Apart from a slight decrease in $GL7^{hi}Fas^{hi}$ germinal center B cells and $B220^{+}CD21^{low}CD23^{hi}$ follicular B cells in RAGE-/- animals, we did not detect differences in auto-antibody secretion or disease manifestations between RAGE-/- and WT mice.
Conclusions: Our data contrast with recently published data showing that a deletion of RAGE exacerbated lupus nephritis and lymphoproliferation in a different SLE model (B6-MRL Fas lpr/j). Therefore, we are currently looking into the effects of RAGE deletion in additional models of auto-antibody-mediated immune disease.

AB0154 CIRCULATING CPG DNA PROMOTER FRAGMENTS IN SLE ACTIVATE INTRARENAL TLR9 SIGNALING AND ACCELERATE RENAL INFLAMMATION AND FIBROGENESIS

P. Korsten, B. Tampe. *Department of Nephrology and Rheumatology, Universitätsmedizin Göttingen, Göttingen, Germany*

Background: In systemic lupus erythematosus (SLE), lupus nephritis (LN) is associated with chronic inflammation and perpetuated fibroblast activation, both determined by epigenetic mechanisms involving aberrant CpG DNA promoter methylation. During SLE progression, global methylation patterns are commonly lost. These CpG DNA promoter methylation patterns are not limited to the kidney, circulating CpG-rich DNA is also detectable in the blood allowing for biomonitoring ("liquid biopsy"). However, little is known about its specific contribution to determining disease progression. In the kidney, CpG-rich DNA activates TLR9 signaling mechanisms involved in inflammation and fibrogenesis. Based on these observations, we hypothesized that CpG-rich DNA promoter fragments potentially accelerate renal inflammation and fibrogenesis in SLE-associated LN.
Objectives: To analyze the role of circulating CpG-rich DNA on endothelial TLR9 signalling and the effect of experimental modification of oligodinucleotides on kidney inflammation in the Pristane-induced murine model of SLE.
Methods: We isolated circulating CpG-rich DNA from blood samples in a cohort of SLE patients. Then, we tested how these DNA promoter fragments influenced the LN phenotype in a TMPD ("pristane")-induced mouse model. Further, we investigated how this renal response could be influenced by the administration of either human or synthetic methylated/unmethylated CpG-rich DNA oligodinucleotides. Additionally, the effects of the administration of cicruclating CpG-rich DNA fragments on TLR9-signalling was analyzed in endothelial cell cultures.
Results: We show that circulating CpG-rich DNA promoter fragments are detectable in SLE patients' blood. Furthermore, SLE-associated LN is associated with accumulation of unmethylated CpG-rich DNA promoter fragments, implicating a mechanistic connection. These observations were further corroborated in a rodent model of TMPD-induced SLE where administration of CpG-rich DNA (isolated from LN patients or synthetic unmethylated CpG-rich DNA oligonucleotides) worsened the renal phenotype in terms of inflammation and fibrogenesis.
Causal contribution of TLR9 was further confirmed in *Tlr9*$^{+/-}$-knockout mice with protection from renal inflammation and kidney fibrosis after administration of unmethylated CpG-rich DNA promoter oligonucleotides. TLR9-mediated intrarenal

inflammation can be therapeutically targeted by administration of synthetic methylated CpG-rich DNA oligonucleotides, ultimately associated with suppression of TLR9-mediated signaling responses and renal injury in experimental SLE/LN.
Conclusions: Collectively, our results implicate accumulation of unmethylated CpG-rich promoter DNA fragments in SLE-associated LN. Furthermore. these unmethylated CpG-rich promoter DNA fragments causally contribute to TLR9-mediated inflammation and renal fibrogenesis. Administration of methylated CpG-rich oligonucleotides antagonized intrarenal TLR9-mediated inflammatory signaling responses and fibrogenesis. Therefore, biomonitoring of CpG-rich promoter DNA fragments and modulation of intrarenal TLR9 signaling is a promising therapeutical target in SLE-associated LN.

AB0155 LEARNING SLE PATHOLOGICAL MECHANISMS FROM MULTI 'OMICS PROFILES

S.S. Pfister[1], N. Kelley[2], T. Schlitt[3], A. Fernandez[3], M. Sultan[3], M. Hasan[1], A. Mir[1], J.S. Rush[1]. *[1]Autoimmunity, Transplantation and Inflammation; [2]Analytical Sciences and Imaging; [3]BioMarker Development, Novartis Institutes for BioMedical Research, Basel, Switzerland*

Background: Precision medicine aims at providing intervention based on clinical and molecular stratification of patients, and is an important approach for targeting heterogeneous diseases. A diverse autoimmune disease is systemic lupus erythematosus (SLE), where dysregulation of several immune processes affects multiple organs. Fundamental for targeted treatment of such a heterogeneous disease is the identification of biomarkers predictive for the biological basis of clinical phenotypes.
Objectives: Despite recent progress, few markers for SLE are currently used in the clinic. In order to learn SLE pathological mechanisms and associated biomarkers, we obtained a diverse dataset from a cohort of active SLE patients (SLEDAI >6), including blood transcriptomics, serum proteomics, cytokines, and auto-antibody profiles. Integration of multi-omics data provides a rich dataset to explore associations between molecular and clinical readouts.
Methods: From a machine-learning perspective, biomarker discovery is defined as the process of selecting an optimal subset of variables for the prediction of parameters of interest. However, variable selection approaches are often underpowered for datasets that contain fewer samples than the number of variables. To overcome this problem we present a method based on L1 regularized regression and recursive variable elimination to generate networks of predictive markers across multiple data types.
Results: The proposed method allows us to graphically visualize the relationships among SLE phenotypes, and their molecular fingerprints. Identified networks of markers are validated by mapping to known biological pathways, and when available by comparison to independent patient cohorts. Despite the small number of patients (n=20), we identify known pathological mechanisms, including a type I IFN gene signature, several cell type specific signatures, and potential novel markers of clinically defined SLE subtypes.
Conclusions: Systemic lupus erythematosus is a complex autoimmune disease characterized by a variety of clinical manifestations. While multi-omics profiles from SLE patients pose challenges because of their intrinsic high dimensionality, they also provide a unique insight into the molecular processes of disease. Our integrated analysis gives a novel perspective on the pathological mechanisms of clinical SLE phenotypes.

AB0156 THYMIC STROMAL LYMPHOPOIETIN (TSLP) IN PRIMARY SJÖGREN'S SYNDROME AND RELATED LYMPHOMA: THE POSSIBLE CONTRIBUTION OF A NOVEL GROWTH FACTOR

S. Gandolfo[1,2], C. Fabro[1,2], M. Bulfoni[2,3], S. Russi[4], P. Masolini[1], L. Quartuccio[1,2], D. Cesselli[2,3], S. De Vita[1,2]. *[1]Rheumatology Clinic, Udine University Hospital S. Maria della Misericordia; [2]Department of Medical and Biologic Sciences, University of Udine; [3]Institute of Anatomic Pathology, Udine University Hospital S. Maria della Misericordia, Udine; [4]Department of Biomedical Sciences and Human Oncology, University of Bari, Bari, Italy*

Background: Primary Sjögren's syndrome (pSS) is an autoimmune lymphoproliferative systemic disease with a higher risk of non-Hodgkin B cell lymphoma (NHL) evolution. In SS, salivary gland (SG) epithelium plays a crucial role in initiating and perpetuating the autoimmune response. Thymic stromal lymphopoietin (TSLP) is both an epithelial and lymphopoietic cytokine involved in the maintenance of immune tolerance at interfaces between body and environment and in the regulation of lymphocytes homeostasis.
Objectives: To study TSLP in serum and SG biopsies of pSS patients stratified by the lymphoproliferative histopathologic status, from fully benign lesions (fbSS) to myoepithelial sialoadenitis (MESA) and to NHL, in order to evaluate a possible role of TSLP in SS pathogenesis and in lymphoma evolution.
Methods: Serum TSLP levels were determined by ELISA in pSS patients (n=30: 12 fbSS, 10 MESA, 8 NHL) and in controls (healthy blood donors - HD n=20; non-autoimmune sicca without SS - nSS n=10). TSLP was also studied by immunohistochemistry in SG biopsies of the same patients and nSS controls. Correlations with clinical and histopathologic parameters were performed. Of note, sequential samples were also included from three patients evolving from fbSS to NHL.
Results: TSLP serum levels were significantly higher in pSS compared to nSS (p=0.03) and HD (p=0.0002), with a progressive significant increase from fbSS to MESA (p=0.004) and finally to NHL (NHL vs fbSS p<0.0001; NHL vs MESA p=0.003), where the increase was dramatic. This was observed also in metachronous samples from the three pSS patients evolving to NHL. A positive significant correlation between TSLP serum levels and disease activity assessed by ESSDAI was found (p<0.0001).
Of note, in the affected tissue, TSLP showed an opposite pattern of expression than in the serum. Concerning the salivary epithelium, a declining expression of TSLP was shown from fbSS (expression was similar to nSS) to MESA and finally to NHL. Strikingly, however, the three pSS patients evolving to lymphoma were the only ones showing a low TSLP epithelial expression also at baseline. Concerning the glandular lymphoid infiltrate, the TSLP expression again decreased with progression to NHL. Again, the three pSS patients evolving to lymphoma were the only ones showing a low TSLP inflammatory expression also at baseline.
Conclusions: Serum TSLP increases in pSS and correlates with lymphoma progression. Discrepancies are however observed between serum levels and tissue TSLP expression: while the baseline TSLP tissue expression is evident and similar to controls, tissue TSLP decreases with lymphoma progression. TSLP likely represents an additional growth factor and biomarker for pSS pathogenesis and lymphoproliferation.

AB0157 TREX 1 MUTATION IN THE MEMBERS OF A FAMILY WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

S. Ugurlu[1], I. Karacan[2], H. Ozdogan[1], A. Tolun[3], E. Tahir Turanli[4]. *[1]Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul; [2]Graduate School of Science, Engineering and Technology, Molecular Biology, Biotechnology and Genetics Program, Dr. Orhan Ocalgiray Molecular Biology-Biotechnology and Genetics Research Centre, Istanbul Technical University; [3]Department of Molecular Biology and Genetics, Boğaziçi University; [4]Dr. Orhan Ocalgiray Molecular Biology Biotechnology and Genetics (MOBGAM) Research Centre, Istanbul Technical University, Istanbul, Turkey*

Background: There are reports showing Three Prime Repair Exonuclease 1 (*TREX1*) mutations in atypical Systemic Lupus Erythematosus (SLE) patients.
Objectives: Here we report a family with SLE and Antiphospholipid Syndrome (aPL) who are positive for *TREX1* mutation and complicated with AA amyloidosis
Methods: DNA samples were extracted from peripheral blood samples of two affected (mother and daughter) and two unaffected individuals of the same family. Exome sequencing was performed for the daughter and data was processed according to GATK Best Practices recommendations. Exome variants were used to search for a rare candidate variant causing the disease. Identified variant was screened in four family members using Sanger sequencing.
Results: The index case (mother) was a 63 year-old woman who had developed polyarthritis and recurrent cerebrovascular accident (CVA) at the age of 44. She was positive for ANA, anti-ds-DNA and IgG anti-cardiolipin antibodies. On anticoagulant therapy she still experiences frequent CVAs. The daughter who is 43 years old had experienced depression, non-erosive arthritis and alopecia at the age of 13. She was positive for ANA, dsDNA and ACA and was treated with hydroxychloroquine, prednisolone, and rituximab. She had attacks of deep vein thrombosis despite anticoagulant therapy. A renal biopsy was performed because of an increase in her creatinine level, with no proteinuria and normal urinary sediment, which revealed AA amyloidosis. She was heterozygous for p.R202Q variant in *MEFV* gene. Further genetic testing was performed for the mother and the daughter as well as two other non-affected members of the family.
Candidate variant search in exome data resulted a novel c.2T>A (p.M1?) variant in *TREX1* gene. The variant was in heterozygous state for both affected members. Since the variant disrupts translation initiation codon (ATG/AAG), it is predicted to cause loss of complete protein production.
Conclusions: There is evidence that *TREX1* is involved in the pathogenesis of SLE, especially with neuropsychiatric disease. Here we report a familial SLE and aPL syndrome complicated with AA amyloidosis, with a novel *TREX1* variant. Such cases will increase our ability to understand the genetic spectrum of SLE and may allow the development of more effective therapies.

AB0158 TAUROURSODEOXYCHOLIC ACID DECREASES THE EXPRESSION OF ERAD COMPONENTS AND THE ACCUMULATION OF SALIVARY MUCINS INDUCED BY PRO-INFLAMMATORY CYTOKINES

N. Albornoz[1], S. Aguilera[2], M.-J. Barrera[1], I. Castro[1], P. Carvajal[1], S. González[3], C. Molina[3], U. Urzúa[1], D. Jara[1], C. Leyton[1], M.-J. González[1]. *[1]ICBM, Faculty of Medicine, University of Chile; [2]Reumatología, Clínica Indisa; [3]Patología Oral, Universidad Mayor, Santiago, Chile*

Background: The salivary glands of Sjögren's syndrome patients show endoplasmic reticulum (ER) stress characterized by intracellular accumulation of secretory products such as MUC1[1], dilated ER cisternae[2] and high levels of pro-inflammatory cytokines. Previous results from our laboratory revealed an increase of the ATF6α pathway of the UPR[3] and activation of ER-associated protein degradation (ERAD)[3]. Increased expression of proteins involved in ERAD (SEL1L and EDEM1) has been reproduced *in vitro* in human submandibular gland (HSG) cells treated with TNF-α or IFN-γ[2]. Tauroursodeoxycholic acid (TUDCA) is a chemical chaperone utilized for alleviate ER stress by enhancing the folding of proteins[3].
Objectives: The aim of this study was to evaluate if TUDCA decreases EDEM1, SEL1L, and MUC1 expression induced by pro-inflammatory cytokines in salivary gland epithelial cells.
Methods: HSG-cells were incubated with 10 ng/mL of IFN-γ or TNF-α for 24h. Alternatively, cells were incubated with cytokines for 6h and then co-incubated with TUDCA (150 and 250 μM) up to 24h. EDEM1, SEL1L and MUC1 protein and mRNA levels were determined by Western-blot and RT-qPCR, respectively. EDEM1 and SEL1L localization was determined by immunofluorescence.
Results: HSG cells stimulated with IFN-γ or TNF-α showed a significant increase of EDEM1 and SEL1L protein and mRNA levels. Importantly, TUDCA co-incubation caused a significant decreased expression of both molecules. Treatment with both cytokines induced a cytoplasmic increase of staining intensity of EDEM1 and SEL1L, which was suppressed by TUDCA. HSG cells stimulated with cytokines showed a significant increase of MUC1 protein and mRNA levels, which was also suppressed by TUDCA.
Conclusions: Decreased expression of MUC1, SEL1L and EDEM1 in the presence of TUDCA suggests that this chemical chaperone promotes folding of proteins in the ER, by decreasing ERAD activity and ER stress induced by pro-inflammatory cytokines in HSG cells. These results enable us to propose that TUDCA might alleviate the ER stress of salivary glands from Sjögren's syndrome patients.

AB0159 AUTOIMMUNE REACTIVITY TO MALONDIALDEHYDE ADDUCTS IN SYSTEMIC LUPUS ERYTHEMATOSUS

U. Hardt[1], A. Larsson[2], I. Gunnarsson[1], G.J. Silverman[3], E. Svenungsson[1], C. Grönwall[1]. *[1]Dept. of Medicine, Rheumatology Unit, Karolinska Institute and Karolinska University Hospital, Stockholm, Sweden; [2]Dept. of Medical Sciences, Clinical Chemistry, Uppsala University, Uppsala, Sweden; [3]Dept. of Medicine, NYU School of Medicine, New York, NY, United States*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by recurrent disease activity flares, multiple organ involvement, and often with a presentation of nephritis. Malondialdehyde (MDA) post-translational modification of proteins occurs upon inflammation and oxidative stress. Natural IgM anti-MDA autoreactivity is present from birth and may be beneficial. However, both IgM and IgG anti-MDA can also be increased in autoimmune disease. Yet, the role for potentially pro-inflammatory autoreactive IgG anti-MDA in SLE remains elusive.
Objectives: Here, we study the association between serum IgG anti-MDA and clinical features of SLE.
Methods: This cross-sectional study included 398 SLE patients at the Karolinska University Hospital fulfilling at least four of the 1982 ACR criteria. Data was compared to the previously reported combined US east coast cohorts (1, 2). Disease activity was assessed by SLEDAI-2K. Total IgG and ANA IgGs were assessed in the clinical laboratory and sTNFR by ELISA. IgG anti-MDA was measured by a quantitative ELISA using modified BSA. As a comparison, we measured IgG anti-phosphorylcholine (PC), another oxidation-associated natural IgG. Cutoff for positivity was based on highest control quartile. Specific IgGs were normalized for total IgG levels in the analysis. Means were compared with Mann-Whitney test, correlations with Spearman's analysis, and meta-analysis used Mantel-Haenszel fixed effect model.
Results: Serum IgG anti-MDA significantly correlated with SLE-associated auto-IgG (e.g. anti-dsDNA, n=398 R=0.42 $p<0.0001$). IgG anti-MDA correlated with higher disease activity by SLEDAI in two independent cohorts (Sweden KS, n=397 R=0.33 $p<0.0001$; US east coast, n=219 R=0.34 $p<0.0001$) and was confirmed in meta-analysis of dichotomized data showing an Odds Ratio of 3.9 (CI 2.6–5.8 $p<0.0001$) for IgG anti-MDA positivity in patients with active disease (SLEDAI≥6). Association of anti-MDA with disease activity was supported by an inverse correlation of IgG anti-MDA normalized for total IgG with complement (C2, n=304 R=-0.24 $p<0.0001$, C3 and C4, n=385 R=-0.24 $p<0.0001$). Furthermore, we observed elevated IgG anti-MDA/total IgG reactivity in SLE patients with current or history of nephritis compared to no history of nephritis (n=389 4.5+/-4.0 vs 3.4+/-3.3 $p<0.0001$) and inverse weak correlation of IgG anti-MDA/total IgG with markers of kidney function (serum cystatin C, n=283 R=0.20 p=0.0008, urine albumin, n=373 R=0.23 $p<0.0001$). Anti-MDA IgG/total IgG also directly correlated with serum soluble TNF receptors (sTNFR1, n=286 R=0.21 p=0.0003, sTNFR2, n=287 R=0.35, $p<0.0001$). IgG anti-PC either did not correlate or inversely correlated with disease measurements, consistent with its previously reported more protective properties.
Conclusions: IgG to MDA-modifications correlates with other autoreactivities, disease activity and nephritis in SLE, and should be further evaluated for its potential prognostic utility. Yet, it remains unclear, if IgG anti-MDA directly contributes to pathogenesis in SLE.

AB0160 INTERFERON-Γ-INDUCIBLE KYNURENINES INFLAMMATION PATHWAY: THE MISSING LINK BETWEEN DISEASE ACTIVITY AND SYMPTOMS IN SJÖGREN'S SYNDROME

V. Valim[1], W.M. Sardemberg[1], J.G. Brun[2], E. Zandonade[3], G.M. Balarini[1], L.V. Tanure[4], G.V. Ferreira[4], É.V. Serrano[1], J.F.V. Tonini[1], K.A. Brokstad[5], P.M. Ueland[6], R. Jonsson[5], P.M. Mydel[5]. *[1]Medicine, Federal University of Espírito Santo, Vitória, Brazil; [2]Clinical Science Department, University of Bergen, Bergen, Norway; [3]Statistic Department, Federal University of Espírito Santo; [4]Locomotor System Department, Federal University of Minas Gerais, Vitória, Brazil; [5]Broegelmann Research Laboratory, University of Bergen, Bergen, Norway; [6]Bevital Laboratory A/S, University of Bergen, Vitória, Brazil*

Background: Tryptophan (TRYP) can be converted to kynurenine (KYN) by indoleamine 2,3-dioxygenase (IDO) drived by interferon-γ. Recent studies have suggested that the KYN pathway reflects an important interface between the immune and nervous system modulation.
Objectives: The aim was to study KYN pathway and their correlation to clinical and immunological parameters in primary Sjögren's syndrome (pSS).
Methods: We included 97 pSS (AECG) and 63 healthy controls matched to age, sex, ethnicity, and body mass index (BMI). KYN metabolites and TRYP were analysed by liquid chromatography mass spectrometry.
Results: Patients aged 50±11 years showed anti-SSA-Ro of 63%, anti-SSB-La 31%, anti-nuclear antibody 81%, rheumatoid factor 24%, and systemic manifestations 67%. Most (68%) showed low disease activity measured by Eular Sjögren's Syndrome Disease Activity Index (ESSDAI), 22% moderate and 10% high ESSDAI. The kynurenine:tryptophan ratio (KTR) was (0.031±0.014 vs. 0.024±0.007, p=0.001), KYN (1.890±0.580 vs. 1.652±0.426, p=0.005), quinolinic acid (QA) (477.82±251.55 vs. 382.05±128.06, p=0.018), hydroxikynurenine (3HK) (53.45±52.05 vs. 39.15±9.67, p=0.056), anthranilic acid (AA) (19.86±6.26 vs. 16.78±4.71, p=0.001) were higher while xanthurenic acid (XA) (11.52±7.88 vs.13.00±5.68, p=0.019), and TRYP (64.90±13.43 vs. 71.02±8.88, p=0.012) were lower in pSS compared to controls. Higher KTR was associated with disease duration (r=0.211,p=0.042), CRP (r=0.254,p=0.029), lower hemoglobin (r=-0.219, p=0.34), creatinine (r=0.588, p=0.000), hypergammaglobulinemia (r=0.254, p=0.014), hyper IgG (r=0.354, p=0.004), lower C3 (r=0.262, p=0.011) and C4 (r=-0.294, p=0.004). Higher KTR was observed in those with Biological ESSDAI domain involvement (0.033±0.016 vs. 0.029±0.013, p=0.003), glandular manifestation (0.037±0.014 vs.0.029±0.013, p=0.007), in the other hand lower KTR in those with presence of musculoskeletal pain (0.029±0.011 vs. 0.032±0.015, p=0.003). ESSDAI showed a tendency to correlate with KTR (r=0.177, p=0.091) and ESSPRI inversely correlated with AA (r=-0.233, p=0.071). Either patient with pain showed lower AA (20.66±6.66 vs. 17.22±5.07, p=0.021).
Conclusions: TRYP is decreased and KYN metabolites pathway is increased in pSS. IDO activity expressed like KTR was positively correlated with disease activity and glandular manifestations but negatively with pain. A better understanding of the KYN pathway can clear the dissociation of symptoms and disease activity in pSS.

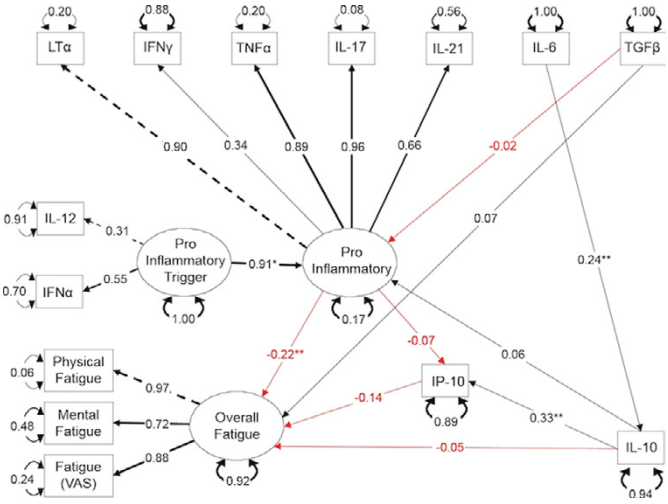
AB0161 ANTIPHOSPHOLIPID ANTIBODIES DIFFERENTIALLY REGULATE THE EXPRESSION & ACTIVITY OF THE LYSOSOMAL PROTEASES WITH EFFECTS UPON MONOCYTE AUTOPHAGY



V.M. Ripoll-Nunez, A. Khawaja, I.P. Giles, A. Rahman. *Division of Medicine, University College London, London, United Kingdom*

Background: Antiphosholipid antibodies (aPLs) are known to activate monocytes in the pathogenesis of antiphospholipid syndrome (APS), although the precise mechanisms by which this activation occurs are not fully understood. We have recently identified several novel protein targets using a comprehensive proteomic analysis of human monocytes treated with IgG from patients with APS. Amongst these novel targets lysosomal proteases, including cathepsin B and cathepsin D were identified. These proteases are important in protein degradation, clearance of autolysosomes, apoptosis and autophagy. Dysregulation of these homeostatic cellular functions may be important in the exposure of autoantigens and pathogenesis of the APS. Therefore, we have now studied the effects of APS IgG upon the expression/activity of different cathepsins and their effects upon autophagy.
Objectives: Determine the effect of pathogenic aPL antibodies on monocyte autophagy and its association with the regulation of lysosomal activity.
Methods: Healthy monocytes were treated with 200 μg/ml of IgG purified from (n=9) patients with APS or (n=9) healthy control (HC) IgG for 6 h. The expression of cathepsin B and cathepsin D were measured by western blotting. Activity assays for lysosomal proteases cathepsin D, cathepsin B and cathepsin L were performed using fluorescence based assays (RayBio®). Intracellular proteolytic activity of monocytes was determined using DQ-BSA (Molecular probes) and flow cytometry analysis. Autophagy was induced by treating monocytes with 50 μg/ml GM-CSF for 14 h.
Results: Consistent with our previous label free quantification mass spectrometry proteomic analysis, western blot analysis confirmed that levels of cathepsin B and cathepsin D were decreased in monocytes treated with APS IgG compared to HC IgG. Similarly, enzymatic assays revealed that cathepsin B and cathepsin D activities were significantly reduced in monocytes treated with IgG from patients with APS compared to HC (p=0.0188, 0.0323). In contrast, levels of enzymatic activity of cathepsin L were increased in monocytes treated with APS IgG compared to HC IgG (p=0.0106). To determine the effect of APS IgG on autophagy, we exposed healthy monocytes to IgG and induced autophagy by treating them with GM-CSF for 14 h. Subsequently we tested the intracellular proteolytic activity with DQ-BSA. Stimulation of monocytes with APS IgG reduced the lysosomal activity of GM-CSF-treated monocytes whereas HC IgG had no effect, indicating that APS IgG disrupts lysosomal degradation during monocyte autophagy.
Conclusions: We found that IgG from patients with APS regulate the expression and activity of lysosomal proteases cathepsins B/D and cathepsin L in opposite directions. Activity of cathepsin B and D was down-regulated by exposure to IgG from patients with APS whereas cathepsin L was up-regulated. Furthermore, we found APS IgG disrupts lysosomal degradation during monocyte autophagy. Additional experiments are now underway to increase our understanding of how modulation of cathepsin activity and autophagy may be important in the pathogenesis of APS and provide new therapeutic targets.

AB0162 SERUM LEVEL OF PROINFLAMMATORY CYTOKINES IS NEGATIVELY ASSOCIATED WITH FATIGUE IN PRIMARY SJÖGREN'S SYNDROME

D. Gardiner[1], W.D. Reid[2], J.R. Tarn[1], D. Lendrem[1], N. Howard-Tripp[1], S. Bowman[3], B. Griffiths[4], S. Rushton[2], W.-F. Ng[1] on behalf of UKPSSR.
[1]Institute of Cellular Medicine & NIHR Newcastle Biomedical Research Centre; [2]School of Biology, Newcastle University, Newcastle upon Tyne; [3]Rheumatology, University Hospital Birmingham, Birmingham; [4]Rheumatology, Freeman Hospital, Newcastle upon Tyne, United Kingdom

Background: We have previously described a model of fatigue in patients with primary Sjogren's syndrome (PSS) based on the levels of serum cytokines, pain and depression scores. Importantly, removal of cytokines from this model substantially reduced the accuracy suggesting that cytokines may have a key role in the biological basis of fatigue [1]. However, interpreting the model is complicated by the complexity of the immune system and the likely multiple interactions between numerous cytokines and other variables [2]. Structural equation modelling (SEM) is a statistical technique that allows for analysis of one or multiple independent variables with one or multiple dependent variables. SEM consists of two components – the structural model, which represents the relationships between the theoretical variables, and the measurement model, which are the relationships between the latent variables and their measures [3].
Objectives: To use SEM to test our hypothesis that the balance between pro-inflammatory and anti-inflammatory cytokines play an important role in determining severity of fatigue in patients with PSS.
Methods: We used Canonical Correpondence Analysis (CCA) to investigate the variation in cytokine expression across our spectrum of fatigue patietns to explore interactions and dependencies between cytokines. We then built a conceptual model based on the literature representing the likely relationships between fatigue and various proinflammatory and anti-inflammatory cytokines and other soluble molecules in the serum. This conceptual model was then challenged using serum data and fatigue scores of 161 PSS patients from the UK primary Sjogren's syndrome registry. Model fit was assessed using the Confirmatory Factor Index, the Root Mean Square Error of Association and the Standardised Root Mean Square Residual. We also analysed changes in fatigue scores over a period between 1–4 years.
Results: CCA revealed the first axis of ordination (CCA1) broadly correlates with fatigue, consists of many pro-inflammatory cytokines including TNFα, LTα and IFNγ, IL17, which were negatively correlated with fatigue while IL-6 and MCP1, which were positively associated with increased fatigue severity. The second axis (CCA2) reflects a trend in cytokines which appear to relate to patients' age. Fatigue scores were largely stable over time and therefore data were not included in the SEM analysis. The main pro-inflammatory SEM model showed fatigue was negatively associated with pro-inflammatory cytokine activity (p=0.019); IL-10 drove IP-10 (p=0.000); and IL-10 was driven by IL-6 (p=0.006) (Fig. 1)

Conclusions: Chronic fatigue in PSS is negatively associated with many pro-inflammatory cytokines. We hypothesize that it reflects adaptive biological processes, which occurs after chronic exposure to inflammation in conditions such as PSS.

AB0163 MESENCHYMAL STEM CELLS INDUCE CD1C+ TOLEROGENIC DENDRITIC CELLS IN HUMAN SYSTEMIC LUPUS ERYTHEMATOSUS VIA UP-REGULATING FLT-3 LIGAND

X. Yuan, D. Wang, Z. Zhang, Q. Wang, W. Li, X. Tang, W. Chen, G. Yao, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower hospital of Nanjing University Medical School, Nanjing, China*

Background: $CD1c^+$ tolerogenic dendritic cells (DCs) play important roles in the induction of peripheral tolerance and control of adaptive immune response. Umbilical cord (UC)-derived mesenchymal stem cells (MSCs) exhibit immunoregulation effects in systemic lupus erythematosus (SLE). However, the underlying immunosuppression mechanism of MSCs via tolerogenic DCs in SLE remains largely unknown.
Objectives: The aim of this study was to examine tolerogenic DCs levels in SLE patients, and to further investigate the mechanism of MSCs in the regulation of tolerogenic DCs.
Methods: Tolerogenic DCs were isolated as Lin $(CD3/19/56/14)^-$ HLA $DR^+CD11c^+CD1c^+$ from peripheral blood mononuclear cells (PBMCs). Levels of tolerogenic DCs were determined by flow cytometry, and serum concentration of Flt-3 ligand (FLT3L) were determined by ELISA from 17 healthy controls and 25 SLE patients. Eight SLE patients were given UC MSCs infusions. We compared the levels of tolerogenic DCs and serum FLT3L before and 24 hours after UC

MSCs transplantation. PBMCs from 8 patients were collected and co-cultured with UC MSCs at ratios of 1:1, 10:1 and 50:1, for 24 hours, 48 hours and 72 hours, respectively, to detect the levels of tolerogenic DCs. The FLT3L in the supernatant solution were determined. FLT3L siRNA was added to the co-culture system, and the level of tolerogenic DCs were detected.
Results: The levels of peripheral $CD1c^+$ DCs and serum FLT3L were significantly decreased in SLE patients compared to healthy controls. After UC MSCs transplantation, the levels of $CD1c^+$ DCs increased, along with an increase in serum FLT3L. In vitro studies showed that UC MSCs time-dependently up-regulated peripheral $CD1c^+$ DCs, but not dose-dependently. The supernatant FLT3L level significantly increased after co-cultured with MSCs. However, the addition of FLT3L siRNA significantly abrogated the up-regulation of $CD1c^+$ DCs by MSCs.
Conclusions: UC MSCs induce $CD1c^+$ tolerogenic DCs through up-regulating FLT3L in lupus patients.

Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models

AB0164 AMYLOIDOSIS IN PROGRESSIVE SYSTEMIC SCLEROSIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 12 PATIENTS

Á. Apáthy[1], M. Bély[2]. *[1]Department of Rheumatology, St. Margaret Clinic Budapest; [2]Department of Pathology, Hospital of the Order of the Brothers of Saint John of God, Budapest, Hungary*

Background: Systemic sclerosis (SSc), like all chronic autoimmune disorders, may be complicated by AA amyloidosis (AAa). An associated B-cell lymphoma my cause amyloid λ or κ light-chain deposition and AL amyloidosis (ALa) in SSc as well.
Objectives: The aim of this study was to determine the prevalence and type of amyloidosis in SSc patients, appraise the extent of amyloid deposits in various organs.
Methods: 12 patients (females 11, age: 54.82 years, range 66–32, onset of SSc: 48.86, disease duration: 6.43 years; one male, age: 65.0 years at death, onset of SSc and disease duration not known) were studied. All patients were autopsied. SSc was diagnosed clinically according to the criteria of the ACR [1].
Amyloid deposits on different tissue structures [arteriole, small artery, medium size artery, venule, small vein, medium size vein, interstitial collagen fiber, reticulin fiber (collagen IV), basal lamina, nerve, renal glomerulus] of 6 organs [heart, lungs, kidney, gastrointestinal tract, skin and brain] were determined histologically. The extent of amyloid A deposits was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [2] ("0": no amyloid deposits, "1": Sporadic, minimal amyloid deposits on different tissue structures, "2": less than five, "3": five or more involved tissue structures per microscopic field at objective magnification of x20)
The prevalence and extent of amyloid deposits in various organs were compared by Student (Welch) t-probe.
Results: Systemic AL-l light-chain amyloidosis was diagnosed in 1 (8.0%) 67 year old female patient (onset of SSc: 66 years, disease duration 1 year), and systemic AAa in 1 (8.0%) 53 year old female patient (onset of SSc: 41 years, disease duration 12 years).
The prevalence (in %) and the average extent of AL-l light-chain and amyloid A deposits (absolute value) in various organs of SSc patients are summarized in Table 1.

Tab;e 1

Organs	SSc-λ Prevalence in %	SSc-AAa Prevalence in %	p<	SSc-λ Average extent	SSc-AAa Average extent	p<
Skin	80.00	0.00	**0.0001**	1.45	0.00	**0.0002**
Heart	72.73	63.64	0.3329	1.45	0.91	0.117
Kidney	63.64	63.64	0.1228	1.09	0.73	0.185
G-I Tract	41.67	66.67	0.1185	1.08	1.00	0.433
Lung	40.00	40.00	0.5000	1.00	0.50	0.077
Brain	0.00	0.00		0.00	0.00	–
Average/Organ	50.79	41.27	**0.052**	1.040	0.556	**0.0036**
Average/Patient	45.56	35.96	0.144	0.965	0.494	**0.0006**

Conclusions: AL-λ deposits were present earlier and were more prominent in the skin, heart and kidney, than in the, G-I tract and the lung. Amyloid A deposits were present earlier and were more prominent in the G-I tract, heart and kidney, than in the, lung and the skin. In the brain AL-λ and amyloid A deposits were absent in both diseases.
Higher prevalence (80.0% versus 0.0%; $p<0.0001$) and massive AL-λ deposition in the skin (1.45 versus 0.0; $p<0.0002$) may be explained by qualitative differences of AL-λ and amyloid A and by a diverse affinity of circulating amyloid precursors to the qualitative changed interstitial collagen and reticulin fibers. In systemic sclerosis patients qualitative change of collagens has been demonstrated [3–5].

AB0165 CXCL4 MAY PLAY A KEY ROLE IN SYSTEMIC SCLEROSIS BY DRIVING CD4 T CELLS TO PRODUCE IL-17

A.J. Affandi[1,2], S.C. Silva Cardoso[1,2], S. Garcia-Perez[1,2], W. Marut[1,2], J.A.G. van Roon[1,2], T.R.D.J. Radstake[1,2]. *[1]Laboratory of Translational Immunology; [2]Dept. of Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: CXCL4 regulates multiple facets of immune response and its level is highly increased in various Th17-associated rheumatic diseases, including systemic sclerosis (SSc)[1–4]. Recently, CXCL4 was shown to induce type I interferon production as well as endothelial activation in SSc patients[1]. Th17 skewing has been demonstrated in SSc[5–6], however, whether CXCL4 plays a role in the induction of IL-17 production by human CD4 T cells is currently unclear.
Objectives: To investigate the effect of CXCL4 on human CD4 T cell phenotype in particular IL-17 production in the absence or presence of antigen presenting cells.
Methods: Blood was obtained from healthy donors and CD4 T cells, monocytes, dendritic cells, were isolated using magnetic-based sorting (n=20). In addition, CD4 T cells from SSc patients were isolated (n=10). CD4 T cells were activated using anti-CD3/CD28, or in co-cultures with antigen presenting cells, stimulated using superantigen Staphylococcal enterotoxin B. Exogenous recombinant human CXCL4 was added during (co-)culture in different concentrations. Cytokine production and proliferation were analyzed using Luminex immunoassays, intracellular cytokine staining, and flow cytometry.
Results: CXCL4 directly induced CD4 T cells secreting both IL-17 and IFN-γ, as well as IL-22, when costimulated with anti-CD3/CD28 ($p<0.05$). In many SSc patients, similar IL-17 increase upon CXCL4 treatment was observed, although this did not reach statistical significance. This might be due to the fact that CD4 T cells from SSc patients had already significant higher levels of IL-17 as compared to healthy donors (2182±722.2 vs 1053±263.6 pg/ml, mean±SEM, $p<0.05$). Furthermore, in co-culture system of CD4 T cells with monocytes or myeloid dendritic cells, CXCL4 treatment induced IL-17 production upon triggering by superantigen ($p<0.05$). Moreover, when monocyte-derived dendritic cells were differentiated in the presence of CXCL4, they orchestrated significantly increased levels of IL-17, IFN-γ, and proliferation by CD4 T cells (all $p<0.05$).
Conclusions: Altogether, we demonstrate that CXCL4 boosts pro-inflammatory cytokine production especially IL-17 by human CD4 T cells, either by acting directly or indirectly via antigen presenting cells. This indicates that targeting CXCL4 may potentially alleviate immune responses in Th17-mediated rheumatic diseases such as systemic sclerosis.

AB0166 INTERLEUKIN-6-POLARISED MACROPHAGES PROMOTE DERMAL MYOFIBROBLAST DIFFERENTIATION

A. Tam, X. Shi Wen, B. Ahmed-Abdi, C. Denton, D. Abraham, V. Ong. *University College London, London, United Kingdom*

Background: Macrophages and fibroblasts are key effector cell types present in scleroderma tissue[1]. While the effect of scleroderma fibroblast conditioned medium on macrophages has been previously studied[2], less is known about the effect of scleroderma macrophages on fibroblasts. Interleukin-6 (IL-6) is an important mediator of fibrosis and is overexpressed in scleroderma sera and cells such as skin fibroblasts, monocytes and endothelial cells[3]. Given the increase in IL-6 levels in scleroderma and presence of the IL-6 receptor on the cell surface of macrophages, we are now investigating the phenotype of macrophages exposed to IL-6. Here we present our work into the paracrine function of IL-6-treated macrophages in stimulating fibroblasts using a media transfer approach.

Objectives: To investigate the effect of macrophage conditioned media on fibroblast activation.
Methods: PBMC-derived macrophages from healthy control (n=3 females, mean age 50.8±21.9 years) and diffuse scleroderma (n=4 females, mean age 54.8±15.7 years, mean disease duration 73.2±90.3 months, 2 with antiScl70 and 2 with antiRNA polymerase antibodies) individuals were cultured in RPMI/10% FBS/M-CSF (4ng/ml)/P/S, quiesced in media with 1% BSA replacing the FBS, and left untreated (M0) or treated with IL-6 (50ng/ml, M (IL-6)) for 24 hours. The cultures were replaced with fresh media and collected after 24 hours. Conditioned media were applied to healthy control skin fibroblasts (24 hours) and fibroblast expression of fibrotic proteins was assessed by Western Blot, using β-tublin and TBP as loading controls. As control, fibroblasts from healthy volunteers were left untreated by culturing in non-conditioned media (fresh RPMI/ 1% BSA/M-CSF (4ng/ml)/P/S).
Results: Fibroblast expression of collagen type I and connective tissue growth factor (CTGF) were not significantly different between untreated and macrophage conditioned medium treatment groups. Baseline levels of collagen type I were high in the fibroblasts cultured in non-conditioned media, and there was a trend towards increased CTGF expression in all conditioned media-treated groups compared to untreated fibroblasts in non-conditioned media. A 2.6-fold increase in α-smooth muscle actin (α-SMA) was observed in the healthy control M (IL-6)-conditioned medium-treated group compared to the group of fibroblasts cultured in non-conditioned media (one-way ANOVA with Sidak multiple comparison, p=0.048).
Conclusions: After 24 hours treatment, control dermal fibroblasts treated with media of IL-6-polarised healthy control macrophages expressed higher levels of α-SMA compared to fibroblasts cultured in non-conditioned medium. A trend towards increased CTGF was also observed. These results suggest that paracrine factors in the IL-6-activated macrophage secretome may promote differentiation of fibroblasts into myofibroblasts, which is a key component of wound healing and scleroderma fibrosis.

AB0167 CALCIUM INFLUX KINETICS AND THE CHARACTERISTICS OF POTASSIUM CHANNELS IN PERIPHERAL T LYMPHOCYTES IN SYSTEMIC SCLEROSIS

N. Legány[1], G. Toldi[2], I. Ocsovszki[3], L. Kovács[1], A. Balog[1]. *[1]Department of Rheumatology and Immunology, Faculty of Medicine, Albert Szent-Györgyi Health Center, University of Szeged, Szeged; [2]First Department of Obstetrics and Gynecology, Semmelweis University, Budapest; [3]Department of Biochemistry, Faculty of Medicine, Albert Szent-Györgyi Health Center, University of Szeged, Szeged, Hungary*

Background: Systemic sclerosis (SSc) is a chronic connective tissue disorder characterized by microvascular injury, fibrosis and autoimmunity that affects the skin and internal organs. The short-term activation of peripheral blood T lymphocytes plays a crucial role in initiating and maintaining the chronic inflammation. The transient increase of the cytoplasmic free calcium level plays a key role in the process of lymphocyte activation. Kv1.3 and IKCa1 potassium channels are important regulators of the maintenance of calcium influx during lymphocyte activation. The influx of calcium is maintained by the function of potassium channels that conserve the electrochemical potential gradient via the efflux of potassium from the cytoplasm. Recent reports raised the notion that the inhibition of lymphocyte potassium channels, especially that of the Kv1.3 channel would be an straightforward solution for specific immunosuppression in autoimmune disorders. Furthermore, our previous studies described an alteration of the short-term activation of peripheral lymphocytes in rheumatoid arthritis and primary Sjögren's syndrome (pSS), and the overexpression of Kv1.3 channels in pSS.
Objectives: Therefore, in this study we aimed to characterize the effects of lymphocyte potassium channel inhibition on short-term peripheral blood T lymphocyte activation in major lymphocyte subsets in SSc.
Methods: We enrolled 12 healthy individuals and 16 SSc patients. We evaluated calcium influx kinetics following activation in CD4, Th1, Th2 and CD8 cells applying a novel kinetic flow cytometry approach. We assessed the sensitivity of the above subsets to specific inhibition of the Kv1.3 and IKCa1 potassium channels. We also assessed the Kv1.3 expression on lymphocytes.
Results: We observed increased parameters of calcium influx in CD8+ lymphocytes' as compared with Th1 cells in SSc. However, the activation of CD8+ cells was lower in SSc compared to healthy controls. Moreover, activation of Th1 lymphocytes was slower in SSc than in healthy controls. The inhibition of IKCa1 potassium channel decreased the activation of CD8+ lymphocytes in healthy controls and the activation of Th1 cells in SSc. The inhibition of Kv1.3 channel modified the dynamics of activation of Th1 and Th2 lymphocytes in SSc.
Conclusions: The altered function of CD8+ cells and the specific inhibition of potassium channels seem to be a consequence of altered calcium influx kinetics in SSc, distinguishing it both from healthy controls and other autoimmune diseases.

AB0168 PROTECTIVE EFFECTS OF EPIGALLOCATECHIN 3 GALLATE ON FIBROSIS IN SCLERODERMA MODEL

A. Kocak[1], D. Harmancı[1], M. Birlik[2], S. Sarioglu[3], G. Guner Akdogan[4]. *[1]Department of Molecular Medicine, Institute of Health Sciences, Dokuz Eylul University; [2]Department of Internal Medicine, Division of Rheumatology & Immunology; [3]Department of Medical Pathology, School of Medicine, Dokuz Eylul University; [4]Department of Biochemistry, School of Medicine, Izmir University of Economics, Izmir, Turkey*

Background: Scleroderma (SSc) is a disease that shows involvement in internal organs or on the skin characterized by fibrosis (1). Dermis thickening and uncontrolled extracellular matrix (ECM) increase are seen in this disease whose pathogenesis is not fully understood. TGF-β/Smad 2&3 pathway is pivotal role in SSc pathogenesis via induction of profibrotic molecules including collagen and by decrease of matrix metalloproteinases (MMPs) synthesis (2,3). The occurrence of the myofibroblast phenotype at fibrosis is thought to be responsible for the contracted regions of the affected tissues (4).
Objectives: The aim of this study with bleomycin (BLM) formed in an experimental model of scleroderma is to investigate the potential effects of epigallocatechin-3-gallate (EGCG) against fibrosis.
Methods: 32 *Balb/c* female mice were randomly selected into four groups.For 21 days: (1) Control group (n: 8) was given 100 μ L *subcutan (sc)* saline (SF) once a day, 100 μL *intraperitoneal (ip)* SF twice a week, (2) BLM group (n: 8) was given 100 μL (100 ug) *sc* BLM once a day, 100 μL *ip* SF twice a week, (3) BLM + EGCG group (n:8) was given 100 μL (100 ug) *sc* BLM once a day, 100 μL (100 μg) *ip* EGCG twice a week, (4) EGCG group (n: 8) was given 100 μL *sc* SF once a day, 100 mL (100 μg) *ip* ECCG twice a week. Hematoxylin&eosin and Masson trichrome staining of dermal areas were performed. Myofibroblast activity was measured using alpha smooth muscle actin antibody (αSMA) by immunohistochemistry.Expression levels of MMP-1, MMP-8, MMP-13 and p-SMAD protein were examined by western blot. Expression levels of TGF-β mRNA were examined by qPCR. All of the statistical analyses were performed using SPSS software and the quantitative data were expressed as the means±SEM.The quantitative variables were compared using the a ANOVA-Sidak. Statistical significance was defined as $p<0.05$

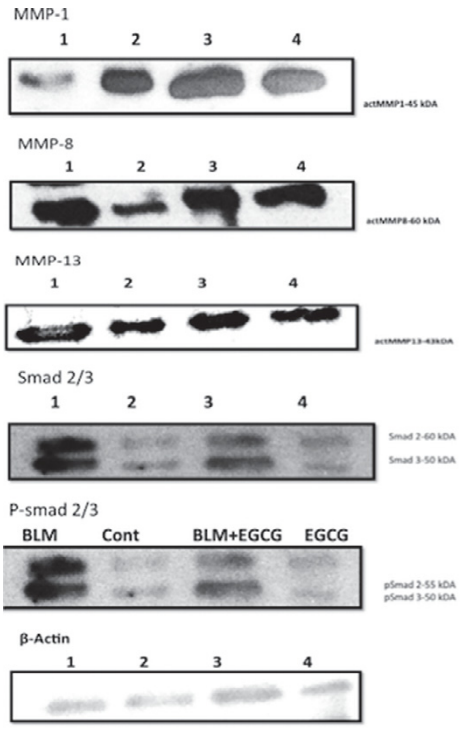

Figure 5. MMP-1, MMP-8, MMP-13, SMAD 2/3 and p-SMAD2/3 expression. β- Actin used for internal control.

Results: When compared to sham,control and experimental groups was observed to have reduced connective tissue fibrosis in dermis area, according to Masson Trichrome results. EGCG group showed a significant reduction in fibrosis at the dermal surface area with respect to hematoxylin measurements. MMP-1, MMP-8, p-SMAD 2/3 protein levels and TGF- β mRNA expression were slightly decreased in EGCG Group compared with the other tested groups ($p<0.05$). Otherwise, MMP-13 wasn't change between groups.
Conclusions: This study contributes to the potential use of EGCG as a treatment for fibrosis in SSc patients. Also, MMP-1&MMP-8 may play an important role in the etiology of SSc.

Background: Systemic sclerosis (SSc) is a chronic fibrosing autoimmune disease which leads to severe musculoskeletal dysfunction, disability and contractures. Little is known on the type and extent of physical therapy (PT) prescribed to SSc patients in daily practice.
Objectives: To determine the type and frequency of PT received by SSc patients.
Methods: The data of 3430 clinically well defined SSc patients registered in the database of the German Network for Systemic Sclerosis were analyzed using SPSS.
Results: 48,5% (1662/3430) of the patients were treated with PT. The most frequently used form of PT was lymphatic drainage (23,6%/876), followed by physical exercise therapy (22%/817) and paraffin wax bath (10,5%/389). About half of the patients (46,9%) received two or three different forms of PT simultaneously. The prescription of PT did not correlate with the SSc subtype, as 49,5% (503/1016) of dcSSc patients, 50,3% (850/1689) of lcSSc patients and 45,7% (143/313) of SSc-Overlap patients received PT. PT was significantly more often prescribed to patients with pulmonary fibrosis in 51,1% (617/1208), synovitis in 61,6% (299/485) and CK elevation in 61,1% (174/285) (p=0,001–0,029). PT did not correlate with the extent of skin fibrosis as measured by mRSS. Interestingly, patients with joint contractures (45,5%) (388/853) or tendon friction rubs (40,6%) (114/281) received significantly less often PT (p=0,006/ 0,045). Comparing the prescription of PT during the initial period 2003–2008 (49,1%; 1937/3942) with the follow up period 2009–2013 (45,3%; 2217/4899), a significant decrease of PT prescription was observed ($p<0,001$). Patterns of PT prescription differed significantly between medical subspecialties ($p<0,005$) i.e. rheumatologists, dermatologists.
Conclusions: Although SSc is characterized by considerable disability and restriction of motion, less than 50% of patients received PT. The significant decrease in PT prescription during recent years may reflect lack of knowledge how to prescribe PT and more restrictive insurance regulations.

AB0170 DIMINISHED PERIPHERAL T-CELL ACTIVATION ALONG WITH MARKED TH17 CIRCULATING PROFILE IN SSC

E. Krasimirova[1], D. Kalinova[2], T. Velikova[1], E. Ivanova-Todorova[1], K. Tumangelova-Yuzeir[1], R. Rashkov[2], D. Kyurkchiev[1]. *[1]Laboratory of Clinical immunology; [2]Clinic of Rheumatology, University Hospital St. Ivan Rilski, Medical University of Sofia, Sofia, Bulgaria*

Background: Systemic sclerosis (SSc) is a rare, debilitating connective tissue disease characterized by immunological alterations, vasculopathy and progressive skin and multiorgan fibrosis. The autoimmune dysregulation in SSc comprises lymphocyte activation that leads to autoantibody production, abnormal production of cytokines and chemokines, and impairment of the innate immunity. Recent research has shown that the T cell activation and especially T helper cells play an important role in the pathogenesis of SSc. Amongst them are the proinflammatory Th17 cells.
Objectives: To investigate T-cell activation, the percentage of Th17 cells and the circulating cytokine profile in SSc.
Methods: We enrolled a total of 24 SSc patients and 16 healthy controls in the study and divided the patients as having diffuse cutaneous SSc (dcSSc, n=13) or limited cutaneous SSc (lcSSc, n=11). Peripheral venous blood samples were collected from all subjects. We examined the percentage of activated T cells (unstimulated and upon stimulation with PHA-M) and of Th17 cells by flow cytometry in both patients and controls. We used ELISA to quantitate the serum levels of human IL-6, TGF-β1, and IL-17A.
Results: We identified a decreased percentage of activated T cells (CD3+CD69+) in PHA-stimulated samples from SSc patients in comparison with healthy controls, $p<0.001$. However, we did not establish a correlation between the down-regulated CD3+CD69+ cells and the SSc phenotype.
With regard to Th17 cells, our patients demonstrated increased percentage as opposed to controls, p=0.031. We detected up-regulated Th17 cells within the lcSSc subset against controls, p=0.025. However, no difference was found between dcSSc and lcSSc patients. Regarding the peripheral cytokine profile, we detected raised levels of IL-6, $p<0.001$, TGF-β1, p=0.02, and IL-17A, $p<0.001$ in patients when compared to controls. Furthermore, we found increased circulating TGF-β, IL-6 and IL-17A in the lcSSc subset versus healthy individuals, as it follows TGF-β1, p=0.031, IL-6, $p<0.001$, and IL-17A, $p<0.001$. Furthermore, circulating IL-17A was higher in lcSSc as opposed to dcSSc subset, p=0.008. Within the dcSSc phenotype, we detected raised levels of IL-17A and IL-6 versus controls: IL-17A, $p<0.001$, IL-6, $p<0.001$.
Conclusions: Our results demonstrate down-regulated T-cell activation upon PHA-stimulation along with pronounced peripheral Th17 profile, and related cytokines in SSc patients, suggesting their implication in the pathogenesis of SSc.

AB0171 ANTI-CARBAMYLATED PROTEIN ANTIBODIES IN PATIENTS WITH SYSTEMIC SCLEROSIS: AN INTRIGUING ASSOCIATION WITH SKIN INVOLVEMENT

E. Favoino[1], M. Prete[1], S. Vettori[2], A. Corrado[3], F.P. Cantatore[3], G. Valentini[2], F. Perosa[1]. *[1]Department of Biomedical Sciences and Human Oncology, Systemic Rheumatic and Autoimmune Disease Unit, University of Bari Medical School, Bari; [2]Department of Clinical and Experimental Internal Medicine, Rheumatology Section, Second University of Naples, Naples; [3]Department of Medical and Surgery Sciences, Rheumatology Unit, University of Foggia, Foggia, Italy*

Background: Systemic sclerosis (SSc), one of the most complex connective tissue disease, is characterized by three pathogenic events namely, vascular damage, autoimmunity and fibroblast activation, leading to a widespread fibrosis of skin and internal organs (1,2). Previous studies showed that 1) carbamylation mainly affects structural proteins undergoing to a low turn-over rate, namely dermal skin and tendons-associated proteins; and that 2) carbamylated proteins accumulate in skin in an age-dependent manner, contributing to tissue alteration (3).
Objectives: As dermis is a disease target and anti-carbamylated protein antibodies (anti-CarP Ab) have been reported in patients with SSc (4), we sought to evaluate any relationship between anti-CarP Ab and clinical parameters reflecting skin involvement in SSc.
Methods: Serum samples and clinical data from 123 patients with SSc were collected. Anti-CarP Ab were detected by indirect ELISA, using carbamylated bovine serum albumin as the antigen. Serum Anti-CarP Ab levels were also measured in 41 healthy aged-matched individuals. Clinical data were retrieved as previously reported (5).
Results: The mean serum levels of anti-CarP Ab did not statistically differ

between healthy and SSc group. In SSc, Spearman analysis showed that anti-CarP inversely correlated with the modified Rodnan skin score (RSS) (R= -0.325, $p<0.001$), independently of patients' age. Receiver operating characteristics (ROC) analysis identified the anti-CarP cutoff that best discriminated dichotomized clinical variables related to skin involvement. This cutoff that was employed to subdivide SSc patients into anti-CarP positive and anti-CarP negative patients. Three SSc skin-related clinical parameters were significantly different between groups: RSS (p=0.001), SI skin (p=0.002), and scleredema ($p<0.001$). A worse skin involvement was associated with low anti-CarP levels.

Conclusions: The study shows that anti-CarP Ab serum level inversely associates to the severity of skin involvement in SSc patients. One possible mechanism to explain the inverse association is that the disease-dependent accumulation of carbamylated proteins in the skin may neutralize circulating anti-CarP Ab, thus contributing to their serum levels decrease. However, further investigation is needed to clarify this issue and to assess whether the levels anti-CarP Ab can be useful in the clinical setting of SSc.

AB0172 PSGL-1 AND ADAM8 ON DENDRITIC CELLS ARE ASSOCIATED WITH SYSTEMIC SCLEROSIS AND COULD ACT AS BIOMARKERS FOR INTERSTITIAL LUNG DISEASE

J. Silván[1], R. González-Tajuelo[1], E. Vicente-Rabaneda[2], A. Pérez-Frías[1], M. Espartero-Santos[1], E. García-Lorenzo[2], I. González-Alvaro[2], S. Castañeda[2], A. Urzainqui[1]. *[1]Immunology; [2]Rheumatology, Hospital Universitario de la Princesa, Madrid, Spain*

Background: Systemic sclerosis (SSc) is a chronic autoimmune disorder with cutaneous, vascular and immune cells abnormalities that lead to extensive cutaneous and visceral fibrosis with high morbidity and mortality. P-Selectin glycoprotein ligand-1 (PSGL-1) is the major ligand for P-selectin. PSGL-1 mediates the initial contacts with endothelial cells during extravasation to inflamed tissues or homing to several tissues in homeostatic conditions. In addition, PSGL-1/P-Selectin interaction contributes to the homeostasis of the immune system by generating regulatory T cells[1]. Importantly, the metalloprotease ADAM8 interacts with PSGL-1 and proteolytically processes it, what could be a regulatory mechanism to control the expression of PSGL-1[2]. Interestingly, mice lacking PSGL-1 develop a progressive SSc-like syndrome[3].

Objectives: To investigate whether PSGL-1 and ADAM8 expression on leukocytes could be implicated in the pathogenesis of SSc.

Methods: PBLs from 47 SSc patients and 35 healthy donors were analyzed by flow cytometry. The percentage of cells expressing PSGL-1, HLA-DR and ADAM8, as well as the membrane (without cell permeabilization) and total (after cell permeabilization) expression were assessed for each leukocyte subset. For cell permeabilization, cells were incubated for 15 min at room temperature with a fixation/permeabilization solution. Positivity was stablished using isotype control antibodies. Comparisons between groups were analyzed with Student t tests or Mann-Whitney U test. For pairwise multiple comparisons one-way ANOVA with Tukey's post hoc test was applied ($p<0.05$, 95% CI). To analyze the possible contribution of PSGL-1, ADAM8 and HLA-DR to SSc pathogenesis, and to explore whether they could be used as biomarkers for SSc, we studied the influence of these molecules using a multivariate logistic regression model.

Results: SSc patients showed increased expression of HLA-DR in antigen presenting cells (B cells, monocytes and dendritic cells), indicating a higher activation of these cells. PSGL-1 expression in B cells was decreased in SSc patients but increased in monocytes, dendritic cells (DC) and T cells. ADAM8 was increased in B and T lymphocytes, monocytes and DC from SSc patients. Overall, we have identified three variables that are associated with SSc: high percentage of ADAM8-expressing pDC, high PSGL-1 expression in cDC and high HLA-DR expression in CD16+ monocytes. Remarkably, highest PSGL-1 expression on conventional DC (cDC) and high levels of ADAM8 on plasmacytoid DC (pDC) associate with interstitial lung disease (ILD), one of the most severe SSc clinical manifestations, suggesting that PSGL-1 and ADAM8 could be prognostic markers of ILD.

Conclusions: This study highlights that PSGL-1 and ADAM8 expression on DC, monocytes and lymphocytes could be implicated in SSc pathogenesis and particularly on DC might act as biomarkers for ILD.

AB0173 MYCOBACTERIAL INFECTION IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL SIGNIFICANCE AND ASSOCIATED FACTORS. DATA FROM THE REGISTRY OF PATIENTS WITH SLE OF THE SPANISH SOCIETY OF RHEUMATOLOGY (RELESSER)

J. Pego-Reigosa[1], V. Campo[2], A. Lois-Iglesias[3], C. Mouriño[2], F. López-Longo[4], M. Galindo[5], J. Calvo[6], J. Ibañez[7], A. Olivé[8], R. Melero[9], A. FdezNebro[10], J. Bernal[11], C. Erausquin[12], E. Tomero[13], L. Horcada[14], E. Uriarte[15], M. Freire[3], I. Rua-Figueroa[12] on behalf of EASSER-RELESSER. *[1]Hospital e IISGS; [2]H, Vigo; [3]H, Coruña; [4]H Gregorio Marañon; [5]H 12Octubre, Madrid; [6]H, Araba; [7]Povisa, Vigo; [8]H, Germans Trias; [9]H, Ourense; [10]H, Carlos Haya; [11]H, Alicante; [12]H, GCanaria; [13]H, la Princesa; [14]H, Navarra; [15]H, Donostia, Spain*

Objectives: To study the prevalence of mycobacterial infection (MI), the associated factors and their clinical significance in patients included in a large SLE cohort.

Methods: Retrospective descriptive study of RELESSER patients with a history of MI and analysis of the factors associated with this infection.

Results: In RELESSER 3,658 patients with ≥4 ACR SLE criteria were included. 90% are women with a mean age of 32.9 years. 93% are Caucasians. The mean follow-up time (± SD) was 120.2 (± 87.6) months. 705 (19.3%) patients had ≥1 severe infection (defined as requiring admission); 1,227 severe infections occurred. MI were diagnosed in 42 patients (1.2% of all RELESSER patients, 3.4% of all severe infections), 85.7% women. The incidence rate of MI was 1 per 1,000 patients/year (95% CI:0.7–1.4).

MI presentation was pulmonary in 18 (42.9%) patients and extrapulmonary in 24 (57.1%) patients [joints in 8 (19.0%) patients, soft tissue in 6 (14.3%) and other sites in 10 (23.8%)]. The extrapulmonary form was associated with immunosuppressants use: 84.6% of the 13 patients treated with immunosuppressive drugs versus 44.4% of the 27 patients without (p=0.01). We did not observe this association with the use of corticosteroids.

To study the factors associated with MI, we performed a bivariate analysis including the variables associated with severe infection in RELESSER (age, sex, ethnicity, corticosteroids, immunosuppressants, antimalarials, previous admission by SLE activity, rituximab and anti-TNF use, Katz severity index, SDI index, SLEDAI index and Charlson comorbidity index). There is a statistically significant association with previous admission by SLE activity (RR:2.9, 95–95%:1.3–6.2, p=0.007), renal impairment (RR:2.0, CI 95%:1,1–3,7, p=0,04), the Katz score (RR:2.1, 95% CI:1.1- 4.0, p=0.04) and the Charlson index (RR: 2.5; 95% CI: 1.3–4.8, p=0.009). Damage (SDI>0) was closely associated with significance:RR: 2.0; 95% CI: 1.0–4.0, p=0.07. Iimmunosuppressants use was associated with an important increase in the risk of MI: RR:4.3; 95% CI:2.2–8.3, p=0.31.

Two patients (4.8%) died (1 respiratory and 1 extrapulmonary). Mean survival after MI diagnosis in these cases was 21 days.

Conclusions: MI in RELESSER affects 1.15% of patients. Its incidence rate is 1 per 1,000 patients/year (95% CI:0.7–1.4). Extrapulmonary localization affects more than half of the patients and is associated with immunosuppressants use. Previous admission by SLE activity, renal involvement, SLE severity and increased number of comorbidities are factors associated with MI.

AB0174 LYMPHOCYTE SUBSETS T, B AND NK CELS IN SYSTEMIC SCLEROSIS

L. Schneider[1], V. Hax[1], N. Marcondes[2], R.M. Xavier[1], R. Chakr[1]. *[1]Rheumatology; [2]HCPA, Porto Alegre, Brazil*

Background: Systemic sclerosis (SSc) is a rare multisystem disease with underlying immune mechanisms, whose pathogenesis remains unclear. Few previous reports have evaluated lymphocyte subpopulations in SSc and your results are conflicting.

Objectives: The present study aimed to analyze the lymphocyte subsets in SSc patients in comparison to healthy individuals.

Methods: Peripheral blood (PB) samples to analyze lymphocyte subsets were obtained from a non-random convenience sample of 20 SSc patients. Twenty healthy individuals recruited from the blood bank were used as sex and age-matched controls. Blood samples were analyzed by flow cytometry for total T cells, CD4+ and CD8+ T cells subsets, CD19+ B cells and total NK cells. Statistical analyses were performed using the IBM Statistical Package for Social Sciences (SPSS 18.0). Data are expressed as mean ± SD and median and range. Non-parametric Mann–Whitney U test was used for analyses of the flow cytometry. A probability $p<0.05$ was considered statistically significant.

Results: The mean (SD) age of SSc patients was 57.9 (14.2) years, 95% were female and 31.6% presented diffuse cutaneous SSc (dcSSc). Patients presented a lower mean total lymphocyte count compared to healthy controls (23.7% vs.

29.6%, p=0.026) (Table 1.). No statistically significant differences were found in the percentages or the absolute numbers of T, B or NK cells.
Conclusions: Our data support previous reports indicating that depletion of lymphocyte in the PB of SSc patients. However, we found no significant difference in relation to lymphocyte subtypes, which differs from the literature data.

AB0175 INHIBITORY EFFECT OF ENDOTHELIN-1 TYPE A RECEPTOR ANTAGONISTS ON MIGRATION OF NEUTROPHILS AND TUMOUR CELLS

L.M. Kappes[1], S. Sommerlatte[1], C. Plattfaut[2], S. Pitann[1], G. Marschner[1], H. Heidecke[3], P. Lamprecht[1], A. Müller[1], F. Gieseler[2], O. Cabral-Marques[1], G. Riemekasten[1]. *[1]Department of Rheumatology; [2]Department of Oncology, University of Lübeck, Lübeck; [3]Celltrend GmbH, Luckenwalde, Germany*

Background: Endothelin-1 type A receptor (ETAR) antagonists (e.g. ambrisentan) are currently approved by the U.S Food and Drug administration, representing a well-tolerated treatment of pulmonary arterial hypertension (PAH)[1] for patients with connective tissue diseases such as systemic sclerosis (SSc). Noteworthy, increased numbers of infiltrating neutrophils have been associated with worse clinical outcome in PAH patients. In another context, several studies have reported that endothelin-1 and its receptor ETAR also play a central role in the development of tumour cell invasion and metastasis. However, the effects of ETAR antagonists on migration of neutrophils and tumour cells remain to be determined.
Objectives: The objective was to analyse the effects of two ETAR antagonists on migration of neutrophils and tumour cell lines.
Methods: The migratory ability of peripheral neutrophils from healthy donors (HD) and different tumour cell lines (myeloid leukaemia HL60 cells and human pancreatic adenocarcinoma COLO357 cells) was analysed in response to N-Formylmethionyl-leucyl-phenylalanine (FMLP) or Protease-activated receptor 2 (Par-2) agonist. Because it has been shown before [2], IgGs from HD and SSc patients were used as additional stimulus for migration. Neutrophils and HL60 cells were preincubated (1h) with sitaxentan or ambrisentan, respectively, before being tested for migration (1h) using the Transwell assay. COLO357 cells were incubated (48h) in the presence of sitaxentan and migration was tested in the Oris Pro Cell assay. Migration was analysed by automatic cell counting or digital photo analysis and a migration index was calculated.
Results: Sitaxentan and/or ambrisentan significantly blocked the migration of neutrophils and tumour cell lines. In more detail, neutrophil migration in response to FMLP, being set to 100%, was completely inhibited by sitaxentan (0,46%). Further, neutrophil migration in response to IgGs from HD and SSc patients was induced equally, again being set to 100%. In the presence of sitaxentan migration was reduced to 60%, respectively. In DMSO-differentiated HL60 cells the migratory capacity in response to FMLP (100%) was reduced to 66% by ambrisentan and to 14% by sitaxentan. Moreover, in the presence of sitaxentan and a Par-2 agonist the migratory ability of COLO357 cells was significantly decreased to 89% compared to Par-2 agonist only, being set to 100%.
Conclusions: Our results suggest a pivotal and non-redundant role of ETAR in cell migration, which needs further clarification in order to repurpose the use of ETAR inhibitors. Therapeutic switching of ETAR antagonists from PAH to cancer therapies is a promising adjuvant therapy.

AB0176 MITOCHONDRIAL DYSFUNCTION IN IDIOPATHIC INFLAMMATORY MYOPATHY DERIVED MYOBLASTS

C. Basualto-Alarcón[1], M.F. Bozán[2], J. Bevilacqua[1,2], F. Urra[1], D. González[1], H. Gatica[2], A. Göecke[2], P. Wurmann[2], M.F. Sabugo[2], S. Saavedra[2], C. Cárdenas[1,3,4]. *[1]Cellular Metabolism and Bioenergetics Laboratory; Anatomy and Developmental Biology Program; ICBM; Faculty of Medicine., Universidad de Chile; [2]Hospital Clínico Universidad de Chile; [3]Geroscience Center for Brain Health and Metabolism, Universidad de Chile, Santiago, Chile; [4]Buck Institute for Research on Aging, Novato, United States*

Background: Idiopathic inflammatory myopathies (IIM) are acquired skeletal muscle diseases, characterized by proximal muscle weakness. This syndrome includes five different (1) diseases, nevertheless, in this work, we included dermatomyositis (DM) and polymyositis (PM) patients. Has been reported that despite treating inflammation, muscle atrophy and weakness persist in some patients, suggesting an inherent muscle cause (2,3). In addition, histological studies show some mitochondrial abnormalities. Our aim was to evaluate a possible role for mitochondrial dysfunction in the pathophysiology of this diseases.
Objectives: To compare the mitochondrial status of myoblast obtained from myositis patients -and healthy control- biopsies.
Methods: Primary cultured myoblasts extracted from the deltoid of IIM patients were used and compared with myoblasts obtained from normal patients subjected to shoulder surgery. Also, a human skeletal muscle cell line (RCMH) was used as control. The bioenergetic profile was analyzed with an Extracellular flux analyzer^{e}96 (Seahorse Biosciences). Also, biopsy tissue was used for Western blot (WB) and immunofluorescence experiments.
Results: Basal oxygen consumption rate, ATP-linked oxygen consumption, maximal oxygen consumption and spare respiratory capacity were lower in IIM myoblasts when compared to RCMH myoblasts, however, when compare to control primary cultured myoblasts we only find differences in ATP-linked oxygen consumption. Expression levels of mitochondrial complexes (I, III, IV and V) were analyzed by WB in tissue samples. No differences were observed between control and IIM patients. Mitochondrial area was estimated by immunofluorescence of the voltage dependent anion channel (VDAC), which show no differences between control and patients.
Conclusions: IIM derived myoblasts present a compromised mitochondrial function, compared to control myoblasts. Specially, oxygen consumption associated with ATP synthesis show decreased levels in patients. Although, expression levels of the mitochondrial complexes as well as mitochondrial area were not different between control and patients. Future experiments should address if IIM mitochondria are consuming less oxygen because of a lower ATP demand or because a primary mitochondrial damage.

AB0177 INCREASED LEVELS OF THE INFLAMMATORY PROTEINS CXCL10, CXCL11, TNFR2 AND YLK-40 TYPIFY THE EARLIEST PHASE OF SYSTEMIC SCLEROSIS (SSC)

M. Cossu[1,2], L. van Bon[1], M. Rossato[1,2], L. Beretta[3], T.R.D.J. Radstake[1,2]. *[1]Rheumatology & Clinical Immunology; [2]Laboratory of Translational Immunology (LTI), UMC Utrecht, Utrecht, Netherlands; [3]Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy*

Background: Definite systemic sclerosis (defSSc) patients yet lacking the prototypical signs of fibrosis stratify in an intermediate severity stage between pre-clinical and fibrotic, limited cutaneous (lcSSc) and diffuse cutaneous (dcSSc) phenotypical subsets[1].
Objectives: We aimed to molecularly position defSSc patients in respect to healthy controls (HC) and early SSc (EaSSc) patients with a broad panel of serum mediators of inflammation and tissue damage in an attempt to increase the knowledge in pathophysiologic mechanisms and biomarkers availability, thereby offering new ground for disease interception before fibrosis develops.
Methods: To this end, an 88-plex immunoassay was performed in sera from an identification cohort composed of 21 EaSSc according to LeRoy and Medsger criteria[2] without other signs and symptoms of evolutive disease, 15 defSSc patients according to the 2013 ACR/EULAR criteria[3] without skin or lung fibrosis and 11 HC. A larger cohort comprising 47 EaSSc, 48 defSSc and 43 HC was used for replication purposes. Fifty-one lcSSc and 35 dcSSc as comparison with established, fibrotic disease were recruited in parallel.
Results: Sixteen mediators differentially expressed in EaSSc and defSSc were selected for replication (one-way ANOVA and/or ANOVA polynomial test for trend with exploratory threshold $p<0.1$). Amongst these, after correction for multiple comparisons, CXCL10/IP-10, CXCL11/I-TAC, TNFR2 and CHI3L1/YKL-40 showed a significant upregulation in defSSc and EaSSc with a linear increase from HC to EaSSc to defSSc. The level of upregulation observed in defSSc individuals was similar (CXCL10/IP-10, CXCL11/I-TAC) or further increased (TNFR2, CHI3L1/YKL-40) in lcSSc and dcSSc patients. A set of 7 ranked markers (Angiopoietin-2, TNFR2, CXCL11/I-TAC, CXCL10/IP-10, sICAM-1, CHI3L1/YKL-40, CXCL9/MIG) provided a good visualization of the gradually increasing pattern from HC to EaSSc to defSSc to lcSSc and dcSSc.
Conclusions: This is the first attempt to validate circulating biomarkers defining the earliest phases of SSc. Despite the need for confirmation in a prospective

setting, our results confirm that defSSc might represent an intermediate entity between pre-clinical stages and the most severe subsets of disease, thereby opening new perspectives on SSc pathophysiology and disease interception.

AB0178 PHENOTYPING OF NATURAL KILLER (NK) RECEPTORS ON NK AND NKT-LIKE CELLS DISCLOSES DEFECTIVE IMMUNE-REGULATORY CAPABILITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Cossu[1,2], L. Beretta[3], E. Trombetta[4], S.T.A. van Bijnen[5,6], M. Rossato[1,2], L. van Bon[1], M. van der Kroef[1,2], E.C. Chouri[1,2], C.G.K. Wichers[1,2], N. Vazirpanah[1,2], M.C. Vonk[7], L. Porretti[4], F. Preijers[6], H. Dolstra[6], T.R.D.J. Radstake[1,2]. *[1]Rheumatology & Clinical Immunology; [2]Laboratory of Translational Immunology (LTI), UMC Utrecht, Utrecht, Netherlands; [3]Referral Center for Systemic Autoimmune Diseases; [4]Flow Cytometry Service, Clinical Chemistry and Microbiology Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [5]Hematology; [6]Laboratory Medicine, Laboratory of Hematology; [7]Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by dysregulation of the immune system, vasculopathy and fibrosis of the skin and internal organs. Natural Killer ($CD56^+CD3^-$, NK) and NKT-like ($CD56^+CD3^+$) cells display receptors (NKR) whose expression pattern determines their cytotoxic and immune-regulatory activity. The role of NK and NKT-like cells in the dysregulation of the immune system in SSc has not been fully elucidated yet.
Objectives: To improve our knowledge on the contribution of NK, NKT-like and a subset of NKT cells expressing invariant TCR (iNKT) in SSc development, we performed a broad phenotyping of NKR in the circulation of SSc patients, including subjects with pre-clinical SSc.
Methods: NKR were assessed by flow cytometry using two 13-color panels on whole blood of 84 SSc patients and 20 healthy controls (HC). In particular, 15 patients with early SSc (EaSSc) without signs or symptoms of evolutive disease (2001 LeRoy and Medsger criteria[1]), 24 patients with definite SSc without skin or lung fibrosis (defSSc), 26 patients with limited (lcSSc) and 19 patients with diffuse cutaneous SSc (dcSSc) (2013 ACR/EULAR classification criteria for SSc[2]) were included. NK degranulation in response to K562 target cells was assessed in lcSSc and dcSSc patients versus HC.
Results: The number of circulating lymphocytes, NKT-like and iNKT cells - but neither $CD3^+$ T nor NK cells - was reduced in dcSSc versus HC. $NKp46^+$ NK cells co-expressing NKG2D and CD16 were decreased in dcSSc versus HC and EaSSc. Consistently with these observations, dcSSc exhibited lower degranulation capability. $(CD57^+)KIR^+$ and activating NKR-expressing NKT-like cells were diminished in both dcSSc and lcSSc versus HC.
Conclusions: dcSSc patients showed a defective NK cytotoxicity potential, possibly due to the decreased $NKp46^+$ fraction. The regulatory, cytolytic KIR^+ NKT-like fraction was also reduced with a parallel decrease of activating receptors expression in both lcSSc and dcSSc. Overall these results point towards an impairment of NK and NKT-like cells as immune check-points in fibrotic SSc.

AB0179 DEGRADATION OF TYPE VII COLLAGEN (C7M) IS ASSOCIATED WITH SYSTEMIC SCLEROSIS – DEVELOPMENT OF A NOVEL NEO-EPITOPE SPECIFIC ASSAY

J. Sand[1], P. Juhl[1], L. Iversen[2], T. Karlsmark[2], M. Karsdal[1], A.-C. Bay-Jensen[1], M. Mogensen[2], A.S. Siebuhr[1], D. Leeming[1]. *[1]Nordic Bioscience, Herlev; [2]Department of dermatology, Bispebjerg Hospital, Copenhagen, Denmark*

Background: Type VII collagen (col7) is the main component of the anchoring fibrils that connects the basement membrane to the underlying interstitial matrix and has mainly been investigated for its role in blistering skin diseases. It has been investigated for its role in dystrophic epidermolysis bullosa, a severe skin disease. Furthermore, increased levels of type VII collagen in skin has been reported for patients with systemic sclerosis (SSc).
Objectives: The objective was to develop and characterize a blood-based marker assessing col7 degradation in patients with SSc.
Methods: We identified a specific fragment of col7 in serum from COPD patients, which was not found in controls, using mass spectrometry. A monoclonal antibody was raised against the first ten amino acids of the neo-epitope (KLH-CGG-GPPGPPGRLV) and employed in a competitive ELISA (C7M). The C7M assay was validated technically and was subsequently evaluated in 2 cohorts including SSc patients. The first cohort (SSc#1; n=35) consisted of early (<2 years of SSc symptoms; n=16) and late (>10 years of disease with stable skin for at least 6 months, n=19) diffuse SSc patients, while the second cohort (SSc#2; n=119) consisted of limited (n=78) and diffuse (n=41) SSc patients. Serum C7M levels were likewise measured in healthy subjects and compared to the levels of SSc patients using the Kruskal-Wallis test with Dunn's multiple comparisons test comparing healthy individuals with the two SSc cohorts.
Results: A technically robust competitive ELISA (C7M), which was highly specific for a col7 fragment was developed. The assay showed acceptable inter- (13%) and intra-assay (9%) variation, linearity (102% dilution recovery), analyte stability (102% recovery after 4 freeze/thaw cycles), and interference.
The C7M marker was evaluated by comparing serum levels in healthy donors with patients with SSc (Figure). Serum C7M levels were not associated with age, gender, BMI, or disease duration. The geometric mean serum C7M level in healthy donors was 4.6 ng/mL (95% CI 3.7–5.6 ng/mL). The geometric mean serum C7M levels were significantly elevated in both cohorts of patients with SSc (SSc#1, 13.6 ng/mL [95% CI 11.1–16.5], $p<0.0001$; SSc#2, 9.2 ng/mL [95% CI 8.3–10.2], $p<0.0001$). Furthermore, a significant difference were observed between the two cohorts (P=0.05).

Conclusions: The C7M ELISA enabled quantification of type VII collagen degradation in serum. Elevated serum C7M levels indicated that the remodeling of type VII collagen was significantly increased in patients with SSc, suggesting a pathological role.

AB0180 BIOMARKERS OF EXTRACELLULAR MATRIX REMODELING ARE ASSOCIATED WITH ACUTE EXACERBATIONS OF IDIOPATHIC INTERSTITIAL PNEUMONIA

J. Sand[1], P. Juhl[1], Y. Tanino[2], T. Nikaido[2], K. Misa[2], Y. Sato[2], R. Togawa[2], X. Wang[2], M. Karsdal[1], A.-C. Bay-Jensen[1], D. Leeming[1], A.S. Siebuhr[1], M. Munakata[2]. *[1]Nordic Bioscience, Herlev, Denmark; [2]Department of Pulmonary Medicine, Fukushima Medical University School of Medicine, Fukushima, Japan*

Background: Idiopathic interstitial pneumonia (IIP) is characterized by an increased rate of extracellular matrix (ECM) turnover resulting in fibrosis. The pathogenic remodeling includes increased levels of protein synthesis and degradation mediated by proteases such as matrix metalloproteinases (MMPs). Acute exacerbations of IIP (AE-IIP) represent periods of increased disease activity. Pulmonary involvement, especially pulmonary fibrosis, is common in patients suffering from systemic sclerosis (SSc) and ankylosing spondylitis (AS)
Objectives: The objective was to investigate if ECM remodeling was altered during AE-IIP by serological neo-epitope biomarkers.
Methods: Serum samples were collected from patients with IIP at clinically stable disease (S-IIP, n=29) and at AE-IIP (n=68). Of these, 11 and 28 patients, respectively, had idiopathic pulmonary fibrosis (IPF). 28 IIP patients had paired samples. Biomarkers released from MMP-mediated degradation of collagen type I (C1M), III (C3M), IV (C4M), and VI (C6M), elastin (ELM7), versican (VCANM), biglycan (BGM), and C-reactive protein (CRPM) were assessed in serum by competitive ELISAs utilizing neo-epitope specific monoclonal antibodies. Data were analysed using Mann-Whitney test, Wilcoxon test, Spearman's rank correlation, and Kaplan-Meier curves as appropriate.
Results: Mean age of patients was 71 (range 54–86) at AE-IIP and 69 (range 55–83) at S-IIP. Mean forced vital capacity in percentage of predicted value (%FVC) was 55.6% (SD 19.5) at AE-IIP and 79.0% (SD 26.5) at S-IIP. Serum

levels of C4M, C6M, and CRPM at AE-IIP were positively correlated with %FVC (r=0.37, p=0.008; r=0.36, p=0.011; r=0.33, p=0.020; respectively). Serum levels of C4M (p=0.002) and C6M (p=0.024) were increased while ELM7 (p=0.024) and VCANM (p<0.0001) were decreased at AE-IIP as compared with S-IIP when analyzing all patients. IPF patients had lower levels of VCANM at AE-IPF (p=0.0001). Patients with paired samples showed significantly elevated serum levels of C4M (p=0.004) and decreased levels of ELM7 and VCANM (p=0.036 and p=0.0001, respectively) at AE-IIP. C1M and C6M levels at AE-IIP were borderline related to mortality outcome for IPF patients (both p=0.059) with levels above median associated with a higher risk of mortality. Analyses of all or paired patients showed no associations with mortality.

Conclusions: Serological levels of neo-epitope biomarkers of ECM degradation were associated with AE-IIP and weakly with mortality outcome. These results indicate that the rate of ECM remodeling in the lungs of patients with IIP is significantly altered during periods of high disease activity such as an acute exacerbation. The difference in degradation profile for the proteins studied is intriguing and indicate activation of different processes contributing to AE-IIP.

Neo-epitope biomarkers of the ECM might be useful in identifying patients diagnosed with rheumatic disease as SSc and AS with pulmonary involvement.

Background: Lung involvement, i.e. interstitial lung disease (ILD) and pulmonary hypertension (PH), is common in patients with systemic sclerosis (SSc), significantly limiting quality of life and survival. Data on clinical correlations between lung function and clinical subsets of SSc are sparse.

Objectives: To investigate the relationship of DLCO and clinical characteristics in patients SSc patients within the registry of the German Network for Systemic Scleroderma.

Methods: Clinical data of the patient registry, currently including DLCO data of 1917 patients were evaluated. In total, these patients were clinically evaluated 5997 times (i.e., at the first visit and during follow-up visits). At the initial visit and during follow-up DLCO levels were correlated with clinical characteristics.

Results: At initial presentation, 64% of the patients had DLCO levels <75% predicted. Impaired DLCO levels were observed in 74% of dcSSc patients, in 64% of SSc-Overlap patients and 57% of lcSSc patients (p<0.0001). Furthermore, male patients (62%), patients with PH (80%), ILD (80%), dyspnea (78%), and those with presence of anti-topoisomerase I antibodies (71%) exhibited significantly more often DLCO levels <75% (p<0.01). Patients suffering from dcSSc had the lowest DLCO levels (mean value, 62%), followed by patients with SSc-Overlap syndromes (mean value, 67%) and lcSSc patients (mean value, 70%) revealing significant differences between subsets. Long-term follow-up evaluation (mean follow up, 6.0 years) revealed that in comparison to lcSSc patients dcSSc patients (OR 2.1; p<0.0001; 95%>CI 1.7–2.5) and SSc-Overlap patients (OR, 1.55; p<0.0001; 95% CI, 1.2–2.0) had a significantly increased risk to a decrease in DLCO levels <75%.

Conclusions: Impairment of pulmonary function as determined by diffusing capacity DLCO is more common and more pronounced in patients with dcSSc and SSc-Overlap Syndrome compared to lcSSc. DLCO may be useful for diagnosing and monitoring pulmonary involvement in SSc.

AB0182 IN VITRO CHARACTERIZATION OF DERMAL FIBROBLASTS FROM SYSTEMIC SCLEROSIS PATIENTS

R. Brizzolara[1], P. Montagna[1], S. Soldano[1], A.C. Trombetta[1], B. Ruaro[1], A. Sulli[1], S. Scabini[2], E. Stratta[2], V. Smith[3], M. Cutolo[4]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, IRCCS San Martino; [2]Oncologic Surgery, Department of Surgery, IRCCS San Martino IST, Genoa, Italy; [3]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; [4]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*

Background: Systemic sclerosis (SSc) is characterized by progressive fibrosis of the skin and/or internal organs. Skin fibrosis is mainly due to the excessive production of extracellular matrix (ECM) proteins from dermal activated fibroblasts. The high amounts of transforming growth factor-beta (TGFbeta) production induce fibroblast proliferation and their transition into profibrotic myofibroblasts. Consequently, the increased presence of alpha-smooth muscle actin (alpha-SMA)-positive myofibroblasts in affected tissues is associated with fibrotic tissue remodelling, that characterize SSc [1–4].

Objectives: To characterize dermal fibroblasts from SSc patients by evaluating the gene expression of specific phenotypic and profibrotic markers: fibrillar collagen type I (COL I), fibronectin (FN), fibroblast-specific protein 1 (S100A4), TGFbeta and alpha-SMA (marker of myofibroblasts).

Methods: Human dermal fibroblasts were obtained by skin biopsy from affected areas of 6 active lcSSc patients after written informed consent and approval of medical ethics committee. SSc patients fulfilled the new EULAR/ACR criteria for SSc and they were treated only with various vasodilators (no severe clinical SSc complications were present at the time of skin sampling). Human SSc dermal fibroblasts were cultured up to 80% of confluence and at the third to fifth subpassages were used for experiments. Total RNA was extracted and quantitative real-time PCR (qRT-PCR) was performed to evaluate the gene expression of relevant fibroblast markers: COL I, FN, S100A4, TGFbeta and alpha-SMA.

Results: In human SSc fibroblasts the gene expression of the relevant markers COL I, FN and S100A4 resulted of 10^7 RNA copies for each gene. Interestingly, in the same tested fibroblasts, the profibrotic alpha-SMA gene expression (marker of myofibroblasts) was similarly found highly expressed, with a result of 10^7 gene copies. On the contrary, TGFbeta showed a much lower gene expression (10^3 copies) compared to the other investigated genes.

Conclusions: In human SSc cultured dermal fibroblasts, the gene expression of ECM proteins (COL I and FN), was found associated with a relevant gene expression of S100A4 and alpha-SMA, confirming their myofibroblast phenotype, as highly differentiated. Interestingly, TGFbeta gene appears to be less expressed. It could be concluded that myofibroblasts from the SSc skin mainly undergo the effects of the tissutal TGFbeta, since it seems that they do not contribute to its further production once differentiated.

AB0183 ISOLATION AND CHARACTERIZATION OF CIRCULATING FIBROCYTES FROM SYSTEMIC SCLEROSIS PATIENTS: AN VITRO INVESTIGATION

R. Brizzolara[1], P. Montagna[1], S. Soldano[1], A.C. Trombetta[1], P. Contini[2], V. Smith[3], B. Ruaro[1], A. Sulli[1], M. Cutolo[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, IRCCS San Martino; [2]Division of Clinical Immunology, Department of Internal Medicine, University of Genoa, Genoa, Italy; [3]Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

Background: In physiological and pathological conditions, such as in tissue repair and in fibrosing diseases (i.e. systemic sclerosis, SSc), the importance of circulating fibrocytes relies on the capacity of such cells to migrate into scleroderma-affected tissues (through CXCR4/CXCL12 interaction) and to differentiate into fibroblasts/myofibroblasts, inducing fibrosis (through matrix protein deposition) (or both) [1–3]. In addition, fibrocytes seem to exert immunomodulatory effects, expressing class II major histocompatability complex molecules (HLA-DP, -DQ, and -DR) [4].

Objectives: To isolate fibrocytes from Circulating Progenitor Cells (CPCs - peripheral blood mononuclear cells PBMCs) of SSc patients and healthy subjects and to identify them by fluorescence-activated cell sorter analysis (FACS), using their specific markers: the leukocyte common antigen CD45, collagen I (COL I), the chemokine receptor CXCR4 and HLA-DR [2].

Methods: Samples were collected, at basal time (t0), from 11 SSc patients, affected by SSc (treated only with different vasodilator drugs) and 5 healthy

subjects (CNTs). PBMCs, isolated from 9 among the SSc patients, were cultured on fibronectin-coated plates [5]. The non-adherent cells were removed and after 8 days (t8) of culture (standardized time), the adherent spindle shaped cells were lifted through incubation in 0.05% EDTA (ice-cold). Fibrocyte identification (at both t0, t8), was performed by FACS, using anti-CD45, anti-COL I, anti-CXCR4 and anti-HLA-DR monoclonal antibodies.

Results: FACS analysis revealed that, at basal time (t0), among the CD45+ cells, the percentage of fibrocytes, identified as triple positive (CD45+, COL I+, CXCR4+) was 1.0±1.2% in SSc patients and 0.4±0.3% in healthy subjects (CNTs). In addition, the HLA-DR expression on fibrocytes in both SSc patients and CNTs showed low values (22.1±21.1% and 7.1±6.1%, respectively).

After 8 days (t8) of culture, fibrocytes presented adherent and spindle shaped morphology. Interestingly, the FACS analysis at t8 of culture, demonstrated that the percentage of SSc fibrocytes CD45+, COL I+, CXCR4+ increased up to 52.8±27.1%, compared to basal time (t0), as well as strongly increasing the HLA-DR+ expression (90.1±22.7%).

Conclusions: Fibrocytes isolated from CPCs of SSc patients were confirmed to express CD45, COL I and CXCR4 molecules, but in very low percentage at the beginning. Already after 8 days of culture in proper conditions, the percentage of differentiated fibrocytes (CD45+, COL I+ and CXCR4+) from SSc patients, increased up to 50 times and the HLA-DR expression increased up to 68%. Additional markers of progressive fibrocyte differentiation are now under test to further characterize the fibrocytes phenotype(s) of SSc patients vs healthy controls.

AB0184 CHROMOSOMAL ABERRATIONS ARE ASSOCIATED WITH DISEASE SEVERITY IN A MOUSE MODEL OF BLEOMYCIN-INDUCED SCLERODERMA

R. Luisetto[1], M. Beggio[2], A. Scanu[2], F. Leite de Oliveira[3], E. Pigatto[2], A. Peruffo[4], E. Zanatta[2], F. Oliviero[2], P. Sfriso[2], L. Punzi[2], F. Cozzi[2]. *[1]Dept of Surgery, Oncology and Gastroenterology; [2]Dept of Medicine- Rheumatology Unit, University of Padova, Padova, Italy; [3]Institute of Biomedical Sciences, Federal University Rio de Janeiro, Rio de Janeiro, Brazil; [4]Dept. of Comparative Biomedicine and Food Science, University of Padova, Padova, Italy*

Background: Scleroderma (SSc) is a connective tissue disease characterized by immunomediated inflammation and fibrosis. The presence of autoantibodies against chromosome associate proteins,such as anti-centromere proteins and anti-topoisomerase I, was observed in SSc patients, however genotoxic events have never been evaluated (2).

Objectives: To assess the presence of aneuploidia, micronuclei (MN) and other chromosomal aberrations in peripheral lymphocytes in a bleomycin (BLM)-induced scleroderma mouse model.

Methods: BALB/c mice (n=20 per condition) were injected subcutaneously daily with BLM 2mg/kg or PBS (control) for 14 days. Urine was collected weekly and proteinuria was measured. At day 15 mice were sacrificed and organs harvested for histological analysis. The MN assay was performed on cultured peripheral lymphocytes isolated from mice spleens. Cells were treated with cytochalasin B (10 μg/ml) for 24 h and a minimum of 1000 binucleated cells/mouse were scored following the criteria of Fenech (1). The antikinetochore (CREST) staining was used to determine the origin of MN observed.

Results: In BLM treated mice was observed huge perivascular lung fibrosis and significant skin involvement. 17 out of 20 mice developed acute renal involvement with mean proteinuria levels of 730±48 mg/dl. In comparison with the control mice, a significant increase in MN number was observed in BLM treated mice (57,8±4,4 vs 6,3±0,6, $p<0.05$). CREST staining was higher in MN derived from BLM treated mice (16,4±1,1 vs 3,7±0,7, $p<0,025$), indicating that in this group lymphocyte MN arised mainly from lagging chromosomes. In addition, an increased frequency of ring chromosome was observed in mice with greater skin fibrosis and renal involvement.A correlation between the presence of CREST stained MN and disease severity parameters as renal failure, lung and skin fibrosis was observed (respectively R=0,4095; R=0,7507 and R=0,9471).

Conclusions: This study provides experimental evidence that significant chromosomal aberrations seem to be related to the severity of disease in a mouse model of SSc. Further investigations on lymphocytes obtained from SSc patients could be matched with results observed in mouse model to confirm the relationship between severity of the disease and chromosomal abnormalities.

AB0185 ENDOTHELIN-1 STIMULATES THE PROFIBROTIC ALTERNATIVE ACTIVATED PHENOTYPE IN CULTURED HUMAN MACROPHAGES ISOLATED FROM SYSTEMIC SCLEROSIS PATIENTS

S. Soldano[1], P. Montagna[1], R. Brizzolara[1], A.C. Trombetta[1], C. Corallo[2], C. Pizzorni[1], S. Paolino[1], A. Sulli[1], M. Ghio[1], V. Smith[3], N. Giordano[2], M. Cutolo[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa; [2]Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy; [3]Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

Background: In the damaged tissue of systemic sclerosis (SSc) patients, the presence of immune inflammatory infiltrate, characterized by T-cells and macrophages, represents an important early pathological event in the fibrotic process (1).

In the macrophage population, the alternatively activated (M2) macrophages were observed in both peripheral blood and damage tissues of SSc patients and they participate in the fibrotic process exerting profibrotic effects, primarily by the production and release of transforming growth factor β1 (TGFβ1) (1,2). These cells are characterized by the expression of specific phenotype markers, such as mannose receptor (CD206) and scavenger receptors (CD204 and CD163), and the production of specific chemokines (i.e. macrophage derived chemokine, CCL-22) (3).

Endothelin-1 (ET1) plays an important role in the fibrotic process of SSc by inducing the profibrotic phenotype in endothelial cells and fibroblasts (4).

Objectives: To evaluate the ability of ET1 to upregulate the profibrotic gene expression profile characterizing the M2 macrophages in cultured monocytes/macrophages isolated from SSc patients.

Methods: Human monocytes were isolated from peripheral blood mononuclear cells of 4 SSc patients (mean age 59±11years, 2 females and 2 males, treated with vasodilator drugs) using a monocyte isolation kit. Cultured cells were maintained in RPMI growth medium for 24hrs and then treated with ET1 (100nM) for 6 days or treated for 1hr with ET receptor antagonist ($ET_{A/B}$RA, bosentan 10μM) before stimulation with ET1. Cultured cells maintained in RPMI growth medium were used as untreated cells.

Gene and protein expression of M2 phenotype markers and TGFβ1 were evaluated by quantitative real-time polymerase chain reaction (qRT-PCR) and Western blotting (WB). Statistical analysis was carried out using a Mann-Whitney non-parametric test.

Results: In cultured SSc macrophages, ET1 induced the upregulation of the gene expression of CD206, CD204, CD163, and CCL22 compared to untreated cells. Moreover, ET1 increased the TGFβ1 gene expression compared to untreated cells. $ET_{A/B}$RA partially contrasted the gene expression of CD204 and CD206. However, $ET_{A/B}$RA antagonized the ET1-mediated increase in the gene expression of CD163, CCL22 and TGFβ1. WB confirmed the results obtained by qRT-PCR.

Conclusions: Preliminary results showed the ability of ET1 to stimulate a profibrotic M2 phenotype in cultured human SSc macrophages characterized by the overexpression of TGFβ1, and this process is partially contrasted by the action of $ET_{A/B}$RA.

AB0186 ASCA (ANTI-SACCHAROMYCES CEREVISAE ANTIBODY) IN SCLERODERMA

A. Fedrigo, T.A.F.G. dos Santos, A. Bortoluzzi, T. Skare, R. Nisihara.
Rheumatology Unit, Hospital Universitário Evangelico de Curitiba, Curitiba, Brazil

Background: The majority of Scleroderma (SSc) patients have gastrointestinal involvement. Motility is usually compromised but few studies address permeability changes in the intestinal wall. ASCA is an antibody direct against mannan in the cell wall of Saccharomyces cerevisiae, the baker's yeast that is found mainly when the small bowel is involved in Chron's disease. Nowadays ASCA is regarded more as a marker of increased gastrointestinal permeability than as a serological autoimmune marker of intestinal inflammatory disease. ASCA levels (anti-Sacharomyces Cerevisae antibodies) are associated with increased intestinal permeability.

Objectives: At present we study the presence of ASCA in the serum of SSc patients aiming to know if there is increased intestinal permeability in this disease and if this is related to any clinical, demographic and treatment data.

Methods: Seventy four SSc patients and 57 healthy controls were studied for ASCA (IgG and IgA) positivity by ELISA. ASCA positivity was associated with demographic, clinical, severity index (Medsger score) and serological data in SSc patients.

Results: ASCA IgG levels were high in 26/74 (43.7%) patients from SSc group and 1/57 (5.2%) of controls ($p<0.001$); IgA ASCA was high in 12/74 (16.2%) from SSc group and 3/57 (1.7%) of controls ($p=0.006$). In univariated analysis IgG ASCA high levels associated positively with African background ($p<0.0001$) and

AB0187 LONG-TERM ADMINISTRATION OF FENSPIRIDE HAS NO NEGATIVE IMPACT ON BONE MINERAL DENSITY AND BONE TURNOVER IN YOUNG GROWING RATS

A. Matuszewska[1], B. Nowak[1], D. Jędrzejuk[2], M. Landwójtowicz[2], M. Bolanowski[2], W. Dziewiszek[1], E. Szelag[3], K. Zduniak[4], J. Kwiatkowska[1], A. Szeląg[1]. *[1]Department of Pharmacology; [2]Department of Endocrinology, Diabetology and Isotopes Therapy; [3]Department of Maxillofacial Orthopaedics and Orthodontics; [4]Department of Pathomorphology, Wroclaw Medical University, Wroclaw, Poland*

Background: In young organisms intensive bone turnover is observed and it allows the skeleton to achieve proper side, shape and weight of bones. It is extremely important to assess the influence on various drugs on growing bones. Fenspiride is registered for therapy of acute and chronic respiratory tract infections in children and adolescence. It decreases the synthesis of proinflammatory cytokines, blocks H1 receptors and has bronchodilatotory properties.

Objectives: The aim of the study was to assess the influence of long-term administration of fenspiride on bone mineral density and selected markers on bone turnover in young growing rats.

Methods: The experiment was carried out on18 young (8-week-old) male Wistar rats receiving standard diet containing 1.2% of calcium ans 0.7% of phosphate. Rats were randomly assigned to one of two groups (9 animals in each group): group F – rats receiving fespiride (15 mg /kg) in saline solution (4ml/kg), and group C (control group) - rats receiving saline solution (4ml/kg). Saline solution and fenspiride were given intragastrically once daily for 90 days (from day 3 to day 92). On day 1 and 93 blood samples for serum isolation were collected. Markers of bone turnover were assessed with commercial ELISA kits according to producers' instruction. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) with Hologic DXA equipment (Hologic Dicovery W 81507) using a small animal software. The experiment was performed with the approval of the First Local Ethics Committee for Experiments on Animals in Wroclaw.

Results: On Day 1 there was no difference in age and body weight between groups. On Day 1 no difference in total body bone mineral density (BMD) (0.160±0.0065 g/cm^2 vs. 0.1608±0.0056 g/cm^2), lower limbs BMD (0.232±0.0267 g/cm^2 vs. 0.2274±0.0314 g/cm^2), serum levels of bone turnover markers (osteocalcin: 1000.921±109.0705 pg/ml vs. 952.5777±178.5306 pg/ml; bCTX: 280.089±54.4298 pg/ml vs. 292.8979±116.0042 pg/ml; osteoprotegerin: 3.5±0.6338 pg/ml vs. 3.7963±0.6894 pg/ml; RANKL: 0.167±0.4099 pg/ml vs. 1.0218±1.2717 pg/ml) was detected.

On Day 93 there was no difference in body weight, total body BMD and lower limbs (0.212±0.0104 g/cm^2 vs. 0.2035±0.0242 g/cm^2; 0.264±0.0159 g/cm^2 vs. 0.2520±0.0271 g/cm^2, respectivelly) between groups. On Day 93 no difference between groups in serum bone turnover markes was detected (OC: 422.758±92.3316 pg/ml vs. 429.2071±83.0520 pg/ml; bCTX: 307.748±77.6733 pg/ml vs. 285.3486±79.16334; OPG: 5.466±0.7815 pg/ml vs. 5.3520±1.6458 pg/ml; RANKL:0.647±0.8457 pg/ml vs. 0.5630±0.8608 pg/ml).

Conclusions: Long-term administration of fenspiride has no negative impact on bone mineral density and bone turnover in young growing rats

AB0188 EFFECT OF MIR-19A AND MIR-21 ON THE JAK/STAT SIGNALING PATHWAY IN THE PERIPHERAL BLOOD MONONUCLEAR CELLS OF PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

H. Li[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]epartment of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Background: Overexpression of the components of the Janus kinase/signal transducer and activator of transcription (JAK/STAT) signaling pathway are key factors of the pathogenic mechanisms underlying systematic juvenile idiopathic arthritis (SJIA).

Objectives: The present study aimed to investigate the association between microRNA (miR)-19a, miR-21 and the JAK/STAT signaling pathway.

Methods: A total of 20 patients with SJIA were included in the study, and peripheral blood mononuclear cells (PBMCs) from 20 normal controls were also collected.RNAiso was used to extract total RNA, and the RNA was then reverse transcribed into cDNA. Primers were designedto detect the mRNA of miR-19a and miR-21, and U6 was set as the internal parameter. In addition, the mRNA of STAT3, suppressor of cytokine signaling 3 (SOCS3), interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) was detected, and β-actin was set as the internal parameter. Reverse transcription-quantitative polymerase chain reaction was performed to detect the expression levels of these proteins in patients with SJIA and control subjects, and non-parametric tests were used to analyze the statistical differences in 2-$\Delta\Delta$Cq between the two groups.

Results: The expression levels of miR-19a and miR-21 were significantly lower in the SJIA group compared with the control group ($P<0.05$). SOCS3, TNF-α and STAT3 were shown to be the target genes of miR-19a and miR-21, as determined by Targetscan. The expression levels of STAT3, SOCS3,TNF-α and IL-6 mRNA were significantly higher compared with those of the control group ($P<0.05$).

Conclusions: In the PBMCs of the patients with SJIA, miR-19a and miR-21 expression levels were lower compared with those of the control group, and the JAK/STAT signaling pathway was activated, which indicated that miR-19a and miR-21 may participate in the activation ofthe JAK/STAT signaling pathway.

Rheumatoid arthritis - prognosis, predictors and outcome

AB0189 RAID COMPOSITE INDEX IN THE EVALUATION OF RA PATIENTS RECEIVING BIOLOGICAL TREATMENT: HUR-BIO REAL-LIFE RESULTS

A. Erden, L. Kilic, B. Armagan, A. Sari, A. Akdogan, S.A. Bilgen, O. Karadag, I. Ertenli, S. Kiraz, U. Kalyoncu. *Department of Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Background: Rheumatoid Arthritis Impact of Disease (RAID) is a composite index. There are seven domains of this index (pain, function, fatigue, sleep disturbance, physical wellbeing, psychological/emotional well-being and coping). Daily activity in last week is evaluated. This score, is reccommended to be used in clinical trials to measure the effect of RA.
Objectives: The aim of this study is to examine the relationship between RAID composite index and other indexes.
Methods: This study was carried out from the HUR-BIO reserved database since August, 2016. In addition to the demographic characteristics of the patients, DAS-28, HAQ-DI, pain, fatigue, Patient global Assesment (PGA), Tender joint counts (TJC), swollen joint counts (SJC), CRP and ESR are recorded. Since 2015, a RAID form is filled for our patients. While this composite scale was being created, Gazi University Turkey carried out Turkish validation, in the original study. RAID composite index includes 7 questions, each scored from 0 to 10, 0 being the best score while 10 points is worst. The relationship between RAID composite index and other indexes were studied with Spearman correlation test.
Results: HUR-BIO database containts 1235 RA patients as of August 2016. A RAID form was filled for 149 of these patients before initiating biological agent. 124 patients (83.2%) were female. Mean age was 49±13 years and mean disease duration was 7.8±7.2 years. Positive ACPA and RF ratios were detected as 48/104 (45.7%) and 78/137 (56.9%) respectively. 77.9% of our patients had education of high school or less. RAID average score was detected as 6.72 (1.98). In female patients RAID disease activity was significantly higher than in men [RAID 6.8 (2.0) vs. 5.9 (1.6), p=0.038]. There was no significant difference among RF, CCP positive patients and auto antibody-negative patients in terms of RAID disease activity. [RAID for RF + vs -; 6.75 (2.05) vs 6.68 (1.86), p=0.82, RAID for CCP + vs -; 6.74 (1.96) vs 6.98 (1.82), p=0.52]. RAID disease activity measurements were correlated moderately acute phase reactants, it was very weak. In table, it is grouped by level of education and re-evaluated. In those with an education higher than college, rising parameters were seen in good level of correlation. [RAID vs Pain, r =0.65, p<0.005; RAID vs PGA, r =0.68, p<0.005].

Table 1. Correlation of RAID composite index according to education level

	RAID Query			
	RAID Total Score n: 149	Lower than High School n: 92	High School and Beyond n: 57	College and Beyond n: 33
DAS-28	0.28*	0.25*	0.42*	0.44*
HAQ-DI	0.49*	0.47*	0.50*	0.54*
Pain	0.51*	0.56*	0.58*	0.65*
Fatigue	0.45*	0.35*	0.52*	0.49*
PGA	0.50*	0.52*	0.59*	0.68*
TJC	0.27*	0.20*	0.30*	0.32
SJC	0.16*	0.06	0.29*	0.25
CRP	0.05	0.09	0.04	0.17
ESR	0.01	-0.01	0.12	0.20

DAS-28: Disease Activity Score, HAQ-DI: The Health assessment questionnaire disability index, PGA: Patient global Assesment, TJC: Tender joint counts, SJC: Swollen joint counts, CRP: C-Reactive Protein, ESR: Sedimentation. *p<0.005.

Conclusions: RAID has low correlation with other composite index such as DAS-28 score. RAID also has moderate correlation with pain, fatigue ad PGA VAS. On the other hand, patient with high education level had better perception for those patient reported composite index. RAID can be used confidently in these selected cases.

AB0190 ASSESSMENT OF PLASMA MICRO-RNA 155 IN RHEUMATOID ARTHRITIS

A.A. Negm[1], S. Al Araby[1], E. Abdulazim[1], H. Raslan[2], K. Mohamed[3], M. Abdelhady[2], M. Hamed[4], S. Ismail[2]. *[1]Rheumatology, Al-Azhar University, Cairo; [2]Internal Medicine; [3]Molecular Biology; [4]Clinical Pathology, National Research Center, Giza, Egypt*

Background: Several observations have indicated that Epigenetics now play a role in the pathogenesis of many diseases including Rheumatological and Immunological disorders such as Rheumatoid Arthritis.(RA). Unlike the genetic code, the epigenome is altered by endogenous (e.g. hormonal) and environmental (e.g. diet, exercise) factors and changes with age. There are three main and interrelated mechanisms: DNA methylation, post-translational modification of histone proteins and non-coding RNA which includes Micro RNA (miR).
Objectives: 1. To determine the level of miR- 155 in plasma of RA patients.
2. To determine the potential value of miR-155 as molecular biomarker for diagnosis, prognosis of disease outcome, and prediction of therapeutic response in RA patients, and to test the relation miR-155 and serum levels of Matrix Metalloproteinase 3.(MMP)
Methods: The study group consisted of 50 female RA patients in active disease and 25 controls of matched age and sex. Disease duration of 1 to 10 years and age range from 20 to 45 years old. They underwent detailed history taking including questionnaire for disability and health assessment scoring, clinical examination, radiological assessment by modified Sharp score. Routine laboratory investigations in addition to assessment of Plasma miR -155 expression levels and serum MMP-3 levels were done for all patients. Ten of the cases were resampled for miR-155 and MMP-3 after receiving treatment and entering disease remission (By DAS 28 score).
Results: Plasma miR–155 expression levels and serum MMP-3 titers were significantly higher in RA patients than in controls (mean 4.071 and 1, $p<0.001$, mean 323.7 and 84.5, $p<0.001$) respectively. MMP-3 titers in serum were significantly higher in erosive than in non-erosive arthritis (mean 366.9 and 163.4, $p<0.001$). There was a significant positive difference between serum MMP-3 levels in disease activity and remission (mean 630 and 380, $p<0.001$). Mean values of the clinical parameters of our study group: STLW score (37.44±15.90), HAQ score (56.86±16.69), ACR disability class (2.224±0.872), DAS 28 score (4.856±1.222), ESR (58.16±29.44), Sharp score (32.36±23.9), There was a significant positive correlation between serum MMP-3 and DAS 28 score and ESR (r=0.022, p_0.022 and r=0.013, p=0.013 respectively). There was a significant positive moderate correlation between Plasma miR-155 and serum MMP-3 ($r=0.596$, $p<0.001$). Correlation between Plasma miR-155 expression levels and HAQ (p=0.612, r=0.0744), with ESR (p=0.13, r=0.219) with DAS 28 score (p=0.187, r=0.192), with Sharp score (p=0.675, r=0.0797).
Conclusions: miR-155 is indeed related to the presence of Rheumatoid arthritis, though not directly related to disease activity like MMP-3. miR-155 significantly but moderately correlates with MMP-3 in blood, but whether it plays a role in the pathogenesis of the disease with or without directly influencing MMP-3 in the joint will require more work on both markers inside the synovial fluid, synovial tissue and the synovial fibroblasts. MMP-3 was re-established in our study as a marker of disease activity and predictor of erosive arthritis.

AB0191 CLINICAL SIGNIFICANCE OF MULTIPLE AUTOANTIBODY SPECIFICITIES IN RHEUMATOID ARTHRITIS: THE ROLE OF ANTI-CITRULLINATED ALPHA ENOLASE AND ANTI-INTERFERON INDUCIBLE PROTEIN 16

A. Alunno[1], O. Bistoni[1], F. Pratesi[2], V. Caneparo[3], G.M.C. La Paglia[1], I. Puxeddu[2], M. De Andrea[4], E. Bartoloni[1], S. Landolfo[4], P. Migliorini[2], R. Gerli[1]. *[1]Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; [2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa; [3]Department of Traslational Medicine, University of Piemonte Orientale Amedeo Avogadro, Novara; [4]Department of Public Health and Pediatric Sciences, University of Turin, Turin, Italy*

Background: Anti-cyclic citrullinated peptide (anti-CCP) auto-antibodies (auto-Abs) represent the current gold standard for the diagnosis of rheumatoid arthritis (RA). However, growing evidence suggests that a variety of other citrullinated or not citrullinated self-proteins may act as autoantigens and lead to the production of auto-Abs. The identification of the diagnostic and/or prognostic value of such novel auto-Abs is under intense investigation. We recently demonstrated that RA patients display a higher prevalence of auto-Abs against the interferon-inducible protein 16 (anti-IFI16) but these auto-Abs do not have a good diagnostic value (1). Recent data showed that auto-Abs against citrullinated alpha-enolase (anti-CEP1) are associated with erosive RA (2).
Objectives: The purpose of this study was to investigate the possible prognostic value of anti-CEP-1 and anti-IFI16 as well as the clinical implication of their association with anti-CCP in a cohort or RA patients.
Methods: Two hundred and fifty two RA patients were enrolled and serum samples were obtained. Auto-Abs were assessed as follows: anti-CCP EDIA 2nd generation ELISA kit (Eurodiagnostica); anti-CEP-1 IgG ELISA kit (Euroimmun). In a subgroup of 113 patients also anti-IFI16 auto-Abs were assessed with an in-house ELISA kit (1). Clinical and serological records of patients were collected and statistical analysis was performed with SPSS 21.0 software.
Results: One hundred and twenty patients (44%) displayed anti-CEP-1 auto-Abs and of these 97 patients (87%) also displayed anti-CCP. Logistic regression analysis revealed an association between both auto-Abs and RA-associated pulmonary disease (odds ratio-OR=2.9; 95% CI=1.06–7.9; p=0.04). We also confirmed that anti-CEP-1 are associated with erosive RA but of interest to a greater extent compared to anti-CCP (anti-CEP-1: OR=4.12; p=0.04; anti-CCP: OR=2.1; p=0.03). The analysis that included anti-IFI16 auto-Abs revealed that a small proportion of patients display all the three auto-Abs (9%) but

the triple positivity was significantly associated with male gender (OR=3.5; p=0.02), the presence of rheumatoid nodules (OR=5,3; p=0.015) and pulmonary involvement (OR=2.6; p=0.007). Anti-IFI16 auto-Abs were associated to male gender independently of the presence of the other two auto-Abs.

Conclusions: Our study demonstrated that anti-CEP-1 auto-Abs may participate to the development of RA-associated pulmonary manifestation together with anti-CCP and that the assessment of multiple auto-Abs in daily practice may help clinician to stratify RA patients at identify those at higher risk to develop extra-articular manifestations.

AB0192 SERUM MEASURES OF TYPE I COLLAGEN DEGRADATION ARE SURROGATE MARKERS OF JOINT DESTRUCTION AND PROGRESSION; FIRST STEPS TOWARDS A PROGNOSTIC SCORE

A.C. Bay-Jensen[1], C. Bager[2], A.S. Siebuhr[1], H. Bay Nielsen[2], M.A. Karsdal[1]. *[1]Rheumatology, Nordic Bioscience Biomarkers and Research; [2]Proscion, Herlev, Denmark*

Background: Monitoring of patients with rheumatoid arthritis (RA) requires assessment of biomarkers reflecting disease activity and its progression. There is a need for non-invasive markers for frequent monitoring of disease severity and progression as well as response to therapy.

Objectives: Serological markers together with clinical parameters was tested in a multi-marker model to assess its ability to objectively predict progression of RA.

Methods: Current post-hoc analysis included RA patients from the biomarker substudy of the phase III clinical study LITHE investigating the safety and efficacy of tocilizumab[1–4]. Patients had moderate/severe, active RA. In addition, only patients of the placebo arm and with total sharp score (SHP) recorded at baseline (BL), week 24 (W24) and W52 were included. Progressors were defined as the delta from BL to W24 and W24 to W52. Biochemical markers reflecting tissue turnover (table) were assessed at BL and W16. Associations with structural progression (deltaSHP) were investigated by spearman's r, least squared multivariate and logistic regression. Covariates were CRP, sex, BMI, age, disease duration, DAS-ESR, no. prior DMARDs/aTNF use and SHP/BL. The data were divided into a training and confirmation set; 1) association between markers/W16 and deltaSHP/W52 (n=31 prog./42 non-prog.), 2) association between markers/BL and deltaSHP/W24 (n=33/48).

Results: *The training set.* Eight markers were correlated (R>0.2) with deltaSHP/W52. Of these C1M, PINP, ICTP and MMP3 were predictive for of progression (deltaSHP/W52>0) with ORs of 3.2 [1.3–8.0], 4.0 [1.4–12], 8.5 [2.4–31], and 2.5 [1.3–5.1]; all p<0.01, respectively. A logistic model for prediction of disease progression incorporating C1M, ICTP, disease duration and BMI demonstrated an AUC of 0.77 [0.66–0.86], p<0.01. The model correctly identified 72% of the progressors. textitThe confirmation set: The results were confirmed in the second dataset with an AUC of 0.75 [0.64–0.81], p<0.01. The model correctly identified 65% of the progressors.

Biochemical marker	Description	Biomarker of	Spearman correlation between DeltaSHP/W52 and baseline biochemical marker R>0.2
C1M	MMP-mediated type I collagen degradation	Connective tissue destruction	**0.377**
C2M	MMP-mediated type II collagen degradation	Cartilage degradation	0.088
C3M	MMP-mediated type III collagen degradation	Connective tissue destruction	**0.277**
C4M	MMP-mediated type IV collagen degradation	Basement membrane destruction	0.157
C6M	MMP-mediated type VI collagen degradation	Connective tissue destruction	0.175
CRP	C-reactive protein	Acute reactant	**0.354**
CRPM	C-reactive degradation	Tissue inflammation	**0.290**
CTX-I/OC	Ratio between cathepsin K-mediated type I collagen degradation and osteocalcin	Bone turnover balance (Bone resporption/formation)	0.063
Gender	-	-	0.090
HAQ	Health assessment questionnaire		-0.032
ICTP	MMP-mediated type I collagen degradation	Connective tissue destruction /bone degradation	**0.334**
MMP3	Matrix metalloproteinase 3	Joint inflammation	**0.226**
Pain (VAS)	-	-	0.073
Patient global score (VAS)	-	-	0.110
Physician global score (VAS)	-	-	0.051
PIIANP	Propeptide of type II collagen	Cartilage formation	-0.077
PINP	Propeptide of type I collagen	Connective tissue and bone formation	**0.217**
VCAM	MMP-mediated Versican degradation	Epithelial turnover	-0.054
VICM	MMP-mediated degradation of citrullinated vimentin	Macrophage activity	**0.232**

Conclusions: We demonstrated that a multi-marker model was able to pint-point, which patients were more likely to be structural progressors. Such first steps to build a progression model, rather than a score reflecting disease activity only, may enrich clinical studies with structurally active diseaese. Importantly, the markers with strongest influence were those associated with MMP-driven bone (ICTP) and connective tissue (C1M) remodelling.

AB0193 MEDICAL ADHERENCE IN PATIENTS WITH TIGHTLY CONTROLLED RHEUMATOID ARTHRITIS

A. Caliskan Uckun, F.G. Yurdakul, H. Bodur. *Physical Medicine and Rehabilitation, Ankara Numune Research and Education Hospital, Ankara, Turkey*

Background: Medication adherence is very important in the treatment of rheumatoid arthritis (RA). However, medication adherence of the patients with RA was not optimal in many of the studies (1–2).

Objectives: The purpose of this study was to investigate the medication adherence in tightly controlled RA patients and reasons of non-adherence.

Methods: A total of 82 RA patients (65 women and 17 men) who followed regularly in our outpatient clinic were included. Socio-demographic features and medical history were collected. The eight-item Morisky scale (MMAS-8) was used to evaluate adherence to medication. Disease activity score (DAS28), health assessment questionnaire (HAQ), mini mental state examination (MMSE) test and Beck depression inventory (BDI) were evaluated.

Results: According to Morisky scale, 34.1%, 15.9% and 50% of our patients were categorized as low, moderate and high adherence, respectively. The most prevalent noticed barriers for adherence were forgetting medication, inadequate information about using instructions, side effects of medications (Table 1). Socio demographic features, duration of disease, type and number of drugs used per day, the route of drug administration, co-morbid diseases, body mass index, smoking and alcohol consumption were not found to be associated with medication adherence, whereas low MMSE and high BDI score were associated with low medication adherence (p=0.009 and p=0.011, respectively). We found that the disease activity was significantly higher in non-adherent cases (p=0.00) (Table 2).

Table 1. Barriers to medication adherence

Barriers	%
Forgetfulness	41.4%
Inadequate information	22%
Side effects of medications	17%
Fears about drug benefit	12.2%
Anxiety about side effects	4.8%
Cost of medications	2.6%

Table 2. Medication adherence and disease activity

DAS 28	Low adherence (Morisky <6)	Moderate adherence (Morisky 6–7)	High adherence (Morisky = 8)	Total
Remission (<2.6)	2 (5.6%)	5 (13.9%)	29 (80.6%)	36
Low disease activity (2.6–<3.2)	7 (36.8%)	3 (15.8%)	9 (47.4%)	19
Moderate disease activity (3.2–<5.1)	17 (68.0%)	5 (20%)	3 (12%)	25
High disease activity (≥5.1)	2 (100%)	0 (0%)	0 (0%)	2
Total	28	13	41	82

DAS: Disease activity score.

Conclusions: Our RA patients who were closely followed had 50% high medication adherence. This rate is quite high compared to other studies using MMAS-8. It should be kept in mind that tight control and adequate communication increase medication adherence but different parameters may also be effective. Assessing cognitive disorders and emotional problems of the patient will be beneficial for improving adherence and controlling disease activity.

AB0194 JOURNEY OF A PATIENT WITH RHEUMATOID ARTHRITIS: DELAY IN DIAGNOSIS AND TREATMENT

A. Luissi, J.E. Rosa, F. Vergara, F.S. Pierini, M. Scolnik, M.V. Garcia, E.R. Soriano. *Rheumatology section, Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*

Background: It has been shown that there is a window of opportunity for treatment in Rheumatoid Arthritis (RA). Several Argentinean studies showed an average of 8 months to arrive to a rheumatology visit and 12 months to receive DMARDs. There aren't recent studies.
Objectives: To establish delay time from onset of rheumatoid arthritis (RA) symptoms to the first rheumatology visit, to diagnosis of the disease and to the beginning of treatment with DMARDs; and to assess impact of such delay on structural damage, in a cohort of RA patients.
Methods: A retrospective study was performed including all patients with RA (fulfilling ACR/EULAR 2010 criteria) seen at a Prepaid Medical Health Plan between 2002–2015. Diagnosis delay and its impact on functional capacity measured by HAQ-A and structural damage by Sharp van der Hejde score (SvdH) was estimated. Demographic and clinical data, and dates ofdiagnosis, onset of symptoms and HAQ-A were extracted from electronic medical records. Svdh score was performed by an experienced rheumatologist.
Results: 246 patients (mean age at diagnosis 67.25±14 years, 199 (81%) female) were included. Clinical presentation was poliarticularin 49% of the cases, oligoarticularin 47% and monoarticular in 3%. 79% had high titers of anti-cyclic citrullinated peptide antibodies, 12% low titers, and 9% were negative. Rheumatoid factor was positive in 82.5%. Mean time of follow up was 7 years (SD: 3.8). At the end of the follow-up,median HAQ-A (n=145) was 0.125 (IRQ: 0–0.87). Hands and feet lastxray available were analized in 171 patients. Median Svdh score was 15 (IQR: 6–33). 242 patients (98.4%) received DMARDs as initial treatment: methotrexate monotherapy (76%) was the most frequent one. 41 patients (17%) received biological agents at some point of their disease. Table 1 shows different delay times in accessing rheumatology consultation, diagnosis and beginning of treatment.
At the end of follow up, 21 patients (12.28%) had noradiological damage (Svdh score =0). In the ROC curve (AUC 0.57,95% CI: 0.45 - 0.69), 5.6 months of diagnosis delay was the best cut off valueto discriminate the presence of erosions (SvdH erosions score>0), with a sensitivity and specificity of 54.17% and 61.90%, respectively. Delay in diagnosis greater than 12 months (n=70) was associated with significantly radiological damage: Svdh mean 30.91 (IC 95% 21.99–39.79) vs 21.32 (IC 95% 16.93–25.72); p=0.0325.

Table 1. different delay times

Variable	Mean (SD)	Median (IQR)
Time from first symptoms to first rheumatology visit (months)	9.21 (20.50)	3 (1–7)
Time from first symptoms to diagnosis (months)	14.2 (24)	4.8 (2.4–13)
Time fromfirst symptoms to DMARDs indication (months)	16.9 (25.4)	7 (3–17)
Time from first symptoms to biological indication (years)	6.2 (4.8)	5.7 (2.4–7.2)

Conclusions: In a Prepaid Medical Health Planwith ease of referral, there is still a significant delay in diagnosis and treatment of RA patients.Delay in diagnosis greater than 12 months was associated with more radiological damage.

AB0195 IS THERE AN ASSOCIATION BETWEEN PERIODONTITIS AND LEVELS OF ANTI-CITRULLINATED PEPTIDES ANTIBODIES IN RHEUMATOID ARTHRITIS?

B. Rodríguez-Lozano[1], J. González Febles[2], F. Sánchez Alonso[3], J.L. Garnier Rodríguez[4], S. Dadlani[4], Y. Barrios[5], M. Sanz Alonso[6], F. Díaz González[1]. *[1]Rheumatology, Hospital Universitario de Canarias, Tenerife; [2]Periodontology, UCM, Madrid; [3]Research Unit, Sociedad Española de Reumatología, Madrid; [4]Odontology/Periodontology, Dental Clinic Dr Garnier, S/C Tenerife; [5]Immunology Unit. Central Laboratory, Hospital Universitario de Canarias, Tenerife; [6]Periodontology, UCM, Madrid, Spain*

Background: Positivity of anti-citrullinated peptides antibodies (ACPA) indicates severity in Rheumatoid Arthritis (RA). There is evidence for chronic periodontitis (PD) in RA autoimmune response by periodontopathogenic bacteria such as *P.gingivalis*, through citrullination of L-arginine.
Objectives: 1.To determine whether there is an association between PD and its severity with ACPA(+).2.To assess relationship between PD and ACPA titres.3.To identify association between certain periodontal parameters and ACPA titres and their possible cutoff points.
Methods: Observational, cross-sectional study RA patients ≥18 with ≥4 teeth, no tooth cleaning, antibiotic intake 6 months before.Socio-demographic and anthropometric variables, annual dental prophylaxis and comorbidities.Serum ACPA detection:Ab IgG against CCP2 (ELISA)Eurodiagnostica:positive≥25; ACPA titres stratification:Low (25–75), moderate (76–300) and high (>300). Periodontal parameters: plaque index (PI), bleeding on probing (Bop), probing pocket depth,clinical attachment level (CAL). CAL loss was categorized according to European Workshop 2005 (Tonetti):T level0 (absence), TL1 (mild), TL2 (severe). Statistical analysis:t-student, Kruskal Wallis, Chi- squared tests by Stata program 13.1.
Results: 187 RA patients included (table 1),ACPA determined in 168 patients: 67.86% (+) with similar titres distribution: low 18%, moderate 26%, high 23%. PD:182 patients (97.3%):TL1 52.4%,TL2 44.9%. Although prevalence of severe PD/ACPA(+) was higher compared to PD/ACPA(-) (69.2% vs 30.7%), there was no association between PD and ACPA positivity/titres. Regarding the association with periodontal parameters, there was tendency of association between ACPA(+) and number of periodontal pockets ≥5mm (NPP),OR 1.02 (95% CI 0.9–1.04) adjusted. There was a gradient effect, where NPP increased as ACPA titles increased, which was significant for high ACPA titres (p≤0.05,OR 1.03 95% CI 1.0–1.05). When ACPA(+) was related to %PI and BoP, a strong association was observed for PI, OR 10.32 (p<0,026), and only a tendency for BoP (p<0.062). With cutoff points of 8% PI and 65% BoP, a risk for ACPA(+) was detected with an OR 2.19 and OR 2.45, respectively.

Table 1

	RA (N)	RA (%)
Female sex	147	78.6
Mean age (SD)	54.4 (10.8)	
Follow up time, median (SD), years	8.88 (7.32)	
Early RA	35	18.7
Rheumatoid factor, seropositive	138	74.2
Disease Activity Ranges		
Remission	39	20.9
Low	45	24.1
Moderate	85	45.4
High	18	9.6
Medication RA		
Without Treatment	10	5.3
DMARDs	99	52.9
≥2 DMARDs	22	11.8
Biologic Drugs	56	29.9

Conclusions: 1.Despite higher prevalence of severe PD in ACPA(+) patients, we found no association between the presence of PD and ACPA positivity nor with serum titres. 2. On analysis of ACPA titres in relation to the severity of the periodontal parameters, there was a "gradient" risk, where NPP increased as ACPA titres increased, which was significant for high ACPA titres.3. Risk cutoff points for ACPA(+) were 8% for PI and 65% for BoP.

AB0196 VASCULAR ENDOTHELIAL GROWTH FACTOR IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Rebrov[1], E. Komarova[1], A. Blagodarenko[1], G. Belkina[2], I. Pokryshka[3]. *[1]Internal Medcine; [2]Medical Chemistry, SI "Lugansk State Medical University"; [3]Rheumatology, Lugansk Clinical Regional Hospital, Lugansk, Ukraine*

Background: The level of vascular endothelial growth factor (VEGF) may reflect the intensity of angiogenesis, which is an important step in the initiation and development of chronic rheumatoid arthritis (RA).
Objectives: to study features of VEGF level changes in the blood of RA patients, depending on the duration of the disease, the degree of activity, the level of antibodies to cyclic citrullinated peptide (anti-CCP)
Methods: 194 patients were examined with a diagnosis of RA (verified according to criteria ACR/EULAR 2010), without concomitant pathology. Among the examined patients with RA women predominated 168 (86.6%), and there were 26 men (13.4%). The age of patients was 22 to 65 years (mean age 47,7±10,22 years), mean duration of the disease was 3,82±3,43 years. Assessment of RA activity was done by DAS 28 index, using blood CRP in the formula. 152 patients were positive for the presence of anti-CCP (≥20 U/ml) (78%) and 42 (22%) - negative. Serum CRP concentrations (Vector-Best, Russia), anti-CCP (Orgentec, Germany), VEGF (BCM Diagnostic, Canada) were determined by ELISA. Statistical processing of the data was performed using non-parametric methods, univariate (ANOVA) variance analysis on a personal computer using a licensed software packages ("Microsoft-Excel" and "Statistica-Stat-Soft", USA)
Results: Analysis of VEGF level changes in the blood depending on the duration of RA revealed that the measure was high in patients with small diseases duration 0–23 months (472.96 (341.1; 582.1) pg/ml) compared with the group 5 years (324.1 (199.2; 556.2) pg/ml) (p<0,04). Analysis of VEGF level in blood depending on the degree of RA activity showed that the VEGF concentration in blood increased with increasing degree of RA activity and it was the greatest - 564.4 (340.1; 758.4) pg/ml in the group with a high degree (DAS28 >5.2) compared to the minimum (DAS28 ≤3,2) - 230,5 (178,1; 385,3) pg/ml, and moderate (DAS28 3,3–5,2) - 356,4 (278 9; 553.1) pg/ml, (p<0,001; p=0,005, respectively). Using ANOVA variance analysis, it was found that the degree of RA activity influenced the VEGF levels in the blood (KW =17,37; p<0,001).
Analysis of the VEGF levels in the blood depending on the level of anti-CCP

showed a significant increase in VEGF level (343.35 (190.62; 561.28) pg/ml) in the group of high positive ACCP (>60 U/ml) compared with the group of low positive ACCP (≤60 U/ml) - 470.23 (324.3, 676.85) pg/ml (p=0,005). Using ANOVA variance analysis, it was found that the level of anti-CCP in the blood of studied RA patients influences the VEGF level in blood (KW =7,88; p=0,005)
Conclusions: In patients with RA duration <2 years VEGF levels in the blood was 30% higher than in patients with a prolonged course of RA. Concentration of VEGF in the blood increased 2-fold with a high degree of RA activity. Levels of VEGF in the blood were 1.5 times higher in the patients with anti-CCP levels>60 U/ml compared to low positive anti-CCP patients. The high level of VEGF may be a marker of severe clinical course of RA, the high rate of disease progression and the development of early joint destruction

AB0197 SUBCLINICAL INTERSTICIAL LUNG DISEASE IN EARLY RHEUMATOID ARTHRITIS

C. Fernández-Díaz [1], M. Calderón-Goerckel [1], J. Martin-Varillas [1], B. Atienza-Mateo [1], A. Corrales-Martinez [1], V. Portilla-Gonzalez [1], V. Calvo-Rio [1], J. Rueda-Gotor [1], N. Palmou-Fontana [1], M. Agudo-Bilbao [1], N. Vegas-revenga [1], L. Domingues-Casas [1], J. Cifrian-Martinez [2], M.A. Gonzalez-Gay [1], R. Blanco [1]. *[1]Rheumatology, Hospital Universitario Marques de Valdecilla, IDIVAL; [2]Pneumology, Hospital Universitario Marques de Valdecilla., Santander, Spain*

Background: Interstitial lung disease (ILD) is a severe extra-articular complication of Rheumatoid Arthritis (RA). The decrease in DLCO diffusion is the most sensitive value for the detection of ILD, DLCO is also a prognostic factor.
Objectives: To study the prevalence of subclinical lung involvement in early RA.
Methods: Cross-sectional study of lung involvement in early RA. The following criteria were used: A) RA according to the EULAR-2010 criteria. B) Early RA if evolution from the onset of symptoms to the diagnosis of RA was less than one year. C) Lung affectation if DLCO diffusion was lower than 80%. In each patient we evaluate: a) presence of dyspnea according to MMRC (Modified British Medical Research Council) scale; B) Respiratory function tests (FVC, FEV1, FEV1/FVC; C) DLCO; classifying the degree in: i) normal>80% (mild decrease 80–60%); ii) Moderate decrease (60–40%) and iii) Severe reduction (<40%); D) Chest x-ray: assessed by radiologist. E) Joint activity of RA (DAS28), F) CRP and ESR. G) RF, CCPA, H) Presence of atheroma plaque on carotid ultrasound. Quantitative variables were expressed as mean±SD or median [IQR] and were compared with the Student t or Mann Whitney U test, respectively. Dichotomous variables were expressed as percentages and compared using the chi-square test. Statistical analysis was performed with the SPSS 15.0 program.
Results: 20 patients (15 women/5 men) with early RA were studied; mean age of 54.1±13.4 years. Some patients were using disease-modifying antirheumatic drugs (DMARDs) prior to performing respiratory function tests (PFR): methotrexate (7) 3 of them with less than 14 days of treatment, hydroxychloroquine (4), sulfasalazine (1). The table shows the main characteristics of patients according to pressence of lung disease. We observed a decrease in DLCO in 15/20 patients (75%) who were mild (DLCO <80%) in 4 (27%); Moderate (DLCO <60%) in 9 (60%) and severe (DLCO <40%) in 2 (13%). Chest x-ray showed these alterations in 3 patients: signs of air trapping, laminar atelectasis and scarring tracts. There were no alterations in FVC in any patient.

Table 1

	With lung involvement (n=15)	Without lung involvement (n=5)	P
Age. mean	56.3±13.11	55.6±15.69	0.55
Sex (W/M)	13/2	3/2	**0.03**
Smokers or ex smokers, n (%)	10 (66.7)	1 (20)	0.06
CCP Antibody, positive n (%)	8 (53.3)	2 (40)	0.60
Titer, median [IQR]	430.5 [165.8–1874.2]	47 [35–59]	0.23
RF Positive, n (%)	8 (53.3)	2 (66)	0.6
RF titer. median [IQR]	213 [67.5–334.75]	135 [74–196]	0.6
ESR mean/ CRP mean	32.1±21.4/ 4.7±7.8	24.6±21.8/ 0.80±0.83	0.84/0.21
DAS28, mean	5.04±1.03	4.48±0.85	0.49
Bone erosions X ray, n (%)	1 (6.7)	1 (20)	0.60
Carotid plaque, n (%)	8 (53.3)	2 (40)	0.60
Extra articular manifestation, n (%)	3 (20)	0	0.16
– Sjögren Syndrome	2		
Abnormalities in thorax Rx. n (%)	3 (20)	0	0.16
Dyspnea, n (%)	1 (6.7)	0	0.60
DMARDs, n (%)	8	4	0.60
Methotrexate,n (%)	5 (55)	2 (50)	
Hydroxichloroquine, n (%)	2 (33)	2 (50)	
Sulfasalazine, n (%)	1 (12)	0	

Conclusions: We find a high frequent of lung involvement in early RA, in most of cases subclinical. Performing Respiratory function tests may help in early detection of lung involvement. These results should be ratified in larger series.

AB0198 DIFFERENTIAL CHARACTERISTICS OF PATIENTS DISCONTINUATING SEVERAL BIOLOGICAL THERAPIES IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS

C. Tornero [1], C. Plasencia [1], D. Pascual-Salcedo [2], B. Hernández [1], M. González [1], M.G. Bonilla [1], L. Nuño [1], A. Villalba [1], D. Peiteado [1], P. Bogas [1], E. Moral [1], A. Balsa [1]. *[1]Rheumatology; [2]Immunology, la Paz University Hospital, Madrid, Spain*

Background: The treatment of Rheumatoid Arthritis (RA) has been transformed in the last decade with the introduction of biologic therapy. Nevertheless, a substantial proportion of patients (pts) are found to be primary or secondary nonresponders and will receive several biologics during the course of the disease. Evidence is lacking on the characterization of patients failing several agents and those who have adequate clinical response to their first biological treatment.
Objectives: To compare demographic, clinical and analytical characteristics in a cohort of RA pts who have failed treatment with at least two biological agents ("switchers") and another cohort of RA patients showing a sustained clinical good response to their first therapy ("maintainers"). As a secondary objective, reasons for therapy discontinuation were also evaluated.
Methods: A total of 186 patients under biological therapy of the RA-PAZ cohort were included in this observational study. In this cohort, 63 pts were switchers and 123, maintainers. Baseline demographic data and clinical disease activity (DAS 28 -ESR), clinical improvement (delta-DAS 28) and serological data (CRP and ESR) were evaluated at baseline and sixth months after starting the first biological treatment.Serum anti-drug antibodies (ADA) were measured by bridging ELISA at the last visit available during the follow-up period under the first treatment. Reasons for discontinuation of the first therapy and the number of biologic treatments received during the course of the disease were also evaluated.
Results: Demographic and clinical characteristics of both groups are shown in Table 1.Mean Age (49,96±10,82 vs 53,77±12,91,p=0,046) and disease duration (6,79±6,19 vs 9,97±8,56,p=0,001) prior to biologic therapy initiation were lower in the switchers.Furthermore, a higher proportion of switchers had extraarticular manifestations in comparison to the maintainers (18/63 (28,6%) vs 16/121 (13,2%),p=0,016). Clinical activity at baseline (DAS28: 5,74±1,26 vs 5,01±1,14,p=0,01) and after 6 months of starting the first biological therapy (DAS28: 4,45±1,6 vs 3,22±1,1,p=0,001) were statistically significant higher in the switchers. At the last visit under the first biologic, there were also more ADA-positive pts in the switchers (6/25 (24%) vs 1/73 (1,4%), p=0,01).Moreover, duration under biologic treatment was higher in this group. In terms of the reason for discontinuation of the first biologic, 22,2% of pts showed primary lack of efficacy;38,1%, secondary loss of efficacy; 33,3%, adverse effects;4,8%interrupted because of other reasons and 1,6% because of

Pts characteristics	Switchers n= 63	Maintainers n= 123	P value
Baseline characteristics at the initiation of the 1st biological therapy (1BT)

Extraarticular manifestations, n/N(%)	18/63 (28,6%)	16/121 (13,2%)	P= 0,011
Monotherapy, n/N (%)	3/ 63 (4,8%)	6 /122 (4,9%)	NS
Baseline activity ± DS - DAS – 28 ± DS - PCR ± DS - VSG ± DS	5,74 ± 1,26 13,82 ± 20,8 33,63 ± 22,03	5,01 ±1,14 10,26 ± 13,6 29.4 ±18,36	P=0,001 NS NS
6 months after the initiation of the 1st biological therapy			
Six months activity ± DS - DAS-28 ± DS - Delta-DAS 28 ± DS	4,44 ± 1,61 1,40 ± 1,6	3,22 ± 1,10 1,77 ±1,2	P= 0,001 NS
Last visit available after the initiation of the 1BT			
ADA+, n/N (%)	6 /25 (24%)	1/ 73 (1,4%)	P= 0,01
At the last visit available after the initiation of the 1st biological therapy			
Age, mean ± DS	61,23 ± 11,8	61,05 ± 12,8	NS
Time of follow-up until the last visit available ± DS, (years)	16,48 ± 7,5	16,71 ± 9,9	NS
Mean time under biologic ± DS, (y)	9,48 ± 4,3	6,72 ± 4,6	P=0,001

remission. There was no association between reasons for discontinuation of the first therapy because of primary or secondary failure and adverse effects (3,4±0,9 vs 3,75±1,11vs 3,86±1,3, p=0,6) with the number of treatments received.
Conclusions: In our biologic therapy RA-PAZ cohort, we found a subgroup of younger pts, with a more systemic phenotype of the disease and a higher disease activity,who required a prompter biological therapy initiation. This subgroup of pts is more susceptible to biological treatment failures. The development of ADA after the first biological agent was also associated with the need to use more biologics.

AB0199 METHOTREXATE RESPONSE IN EARLY RHEUMATOID ARTHRITIS ASSESSED USING A SOMAMER PROTEOMIC ASSAY

C. Hitchon, V. Spicer, X. Meng, A. Gao, H.S. El-Gabalawy, J. Wilkins. *University of Manitoba, Winnipeg, Canada*

Background: Optimizing treatment in early rheumatoid arthritis (ERA) improves clinical outcomes. Developing approaches that would allow for accurate outcome predictions would be useful. We examined the possibility of employing SOMAscan to identify biomarkers that predict treatment response.
Objectives: To define methotrexate (MTX) 6 month treatment associated response protein changes using SOMAscan.
Methods: Sera from 14 Disease Modifying Antirheumatic Drug (DMARD) naive ERA patients at baseline (PRE) and after six months of MTX (POST) were analyzed using SOMAscan, an aptamer based assay that offers simultaneous relative quantitation of 1310 proteins. RA activity was measured by DAS28ESR3var abbrev DAS3; RF and ACPA were measured at baseline. SOMAmer intensity data was log2 transformed and differences (D=POST-PRE) clustered using undirected hierarchical self-organization. Kolmogorov-Smirnov differential analysis determined SOMAmers contributing to these populations at $p<0.05$. Potential processes associated with these SOMAmer regulation groups were identified using an in-house biological enrichment tool.
The potential for SOMAmers to predict treatment response was also explored; for this we defined a fractional clinical response metric dDAS3= (DAS3_POST-DAS3_PRE)/DAS3_PRE. We then selected a population of proteins (n=3 to avoid over-fitting) with PRE expression levels best correlating to dDAS3. These three PRE expression values formed a weighted average, with weighting coefficients optimized by a simple Monte-Carlo method. We included this weighted average with clinical variables in logistic regression models, where 6 month DAS3 was the dependent variable.
Results: Clustering gave two populations of 6 and 8 patients (POP0, POP1) with mean delta DAS3 values of -1.71 and -0.46 respectively. In POP0 compared to POP1, 113 proteins were upregulated and 121 proteins were downregulated. The upregulated proteins were involved in VEGF signalling and platelet activation. The downregulated proteins were involved in regulation of immune response, cellular response to TNF and cytokine –cytokine receptor interactions. The fractional change dDAS3 correlated well with the treatment response panel (R^2=0.8645; p=6.8e-5), with the caution that expression values of the 3 best-correlating proteins exhibited low coefficients of variation (<0.1). However, these proteins did reflect RA responses or inflammation. This weighted sum was also independently associated with treatment response in regression models including baseline DAS3 (or components) and RF/ACPA.
Conclusions: This pilot study suggests that high content proteomic approaches such as SOMAscan may be useful for developing prediction tools of patient responses to treatment. Extension of this work into a larger patient population is ongoing.

AB0200 MUSCULOSKELETAL ULTRASOUND ADDED TO ROUTINE EVALUATIONS OF RHEUMATOID ARTHRITIS PATIENTS HAS A DIFFERENT IMPACT ON THE TREATMENT PROPOSAL DEPENDING ON PHYSICIAN EXPERIENCE

C. Sifuentes[1], I. Contreras-Yáñez[1], M. Gutíerrez[2], V. Pascual[1]. [1]*Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran;* [2]*Instituto Nacional de Rehabilitación y Ortopedia, México, D.F, Mexico*

Background: Disease activity (DA) is the most important factor in the treatment decision/monitoring during rheumatoid arthritis (RA) patient's follow-up. In routine clinical practice, it is recommended to regularly evaluate DA level from patients with RA. Musculoskeletal ultrasound has been suggested to add value to establish the level of DA; evaluations that assess a reduced number of joints, as the German ultrasound score of 7 joints (GUS-7) are easy to incorporate in clinical practice (1).
Objectives: To explore the real impact of GUS-7 in the treatment recommendation to RA outpatients, currently attending an Early Arthritis Clinic (EAC). The primary objective was to determine the proportion of patients in whom treatment recommendation differed after GUS-7 examination. We additionally tested the variations of GUS-7 impact according to the physician's experience (senior rheumatologist [SR] vs. trainee in rheumatology [TR]).
Methods: A sample size of 84 evaluations was calculated to achieve the primary objective. Eighty-seven consecutive and randomly selected RA outpatients were invited to participate; 2 patients denied because of administrative reasons and the 85 patients left underwent 170 assessments (85 each by the SR and the TR). At first, both physicians (blinded to each other evaluations) performed a clinical evaluation that included DAS28 scoring and recommended a RA-treatment. Then, patients underwent GUS-7 by a blinded (to clinical evaluations) rheumatologist that additionally determined the sonographic disease activity. In the final step, the TR and the SR integrated the US findings to their previous evaluation and reviewed their prescription; GUS-7 findings, pre- and post-GUS-7 treatments were recorded on standardized formats. Patients received final recommendation only from the SR. All the patients signed informed consent and were instructed about the process. Descriptive statistics was used.
Results: Patients were primarily middle-aged [(mean±SD) 45.13±12.4 years] female (91.4%), with (mean±SD) disease duration of 7.5±3.9 years. Most of the patients (69.2% according to TR and 71.8% to SR) were in DAS28-ESR-remission, although the four levels of DA were represented. Agreement between both physicians was good (Kappa: 0.82, $p\leq0.001$). Most frequent GUS-7 findings were grey scale synovitis in at least one joint in 98.8% of the patients, among whom 22.6% had Power Doppler activity (PD); one third of the patients had tenosynovitis although few (12%) had PD; erosions were detected in 38.8% of the patients.
In 34 of 170 clinical scenarios (20%), GUS-7 findings modified treatment; treatment changes (after GUS-7 findings were incorporated to clinical findings) consisted of an increase in 24 (70.6%) scenarios, a decrease in 8 (23.5%) and joint injection with corticosteroids in 2 (5.9%). Interestingly, 24 of the 34 clinical scenarios with GUS-7 treatment impact were performed by the TR vs. 10 performed by the SR: 70.5% vs. 29.5%, p=0.01. Treatment changes (increase, decrease and joint injection) were similar among both specialists.
Conclusions: In routine clinical practice of RA patients, GUS-7 assessments impacted treatment decision in 20% of the patients; the impact was stronger among TR than among SR.

Background: There are previous evidence about inflammatory signs related with the intestinal mucosa in spondyloarthritis patients with seronegative arthritis and them relation with articular inflammatory activity. It is uncertain the role of these serological markers on the inflammatory/clinical activity in patients with SpA
Objectives: To establish the relationship among activity variables and indices, and soluble markers associated to mucosal associated lymphoid tissue in a group of SpA patients.
Methods: Patients were selected by rheumatologists with the ESSG criteria. Levels of SIgA, IgA, IgA *Chlamydia trachomatis*, *Shigella spp*, *Yersinia ssp*, *Campilobacter ssp* and *Salmonella ssp*, CRP,ESR,HLA-B27,BASDAI,ASDAS-CRP and ASDAS-ESR were determined. A principal components analysis (PCA), Poisson Regression and multiple correspondence analysis were performed to find relationships between clinical and laboratory variables and SIgA. This study was approved for Ethics Committee.
Results: 46 patients were included (78.2% males with a mean age 34.8±12.3 years). It was reported at least one gastrointestinal sing in 69.2% of patients:abdominal bloating (45%), abdominal pain (43%); all patients showed at least one musculoskeletal symptom, 69.5% enthesitis, 63% inflammatory back pain and 58.6% arthritis, as well as 43.4% previous infection and 47.8% presented HLA-B27.The PCA showed three principal factors which cover a contribution of 82.2% to explain the SIgA variation.The ASDAS-CRP, ASDAS-ESR, BASDAI variables which provide the 47.12%;the regression model shows an inverse association among SIgA and BASDAI (prevalence ratio (PR):0.43, 95% CI:0.26–0.70 p=0.001), ASDAS-CRP (PR:0.72, 95% CI:0.24–0.95 p=0.021) and ASDAS-ESR (PR:0.69, 95% CI:0.39–0.95 p=0.007); however, a risk was demonstrated among BASDAI and Yersinia IgA (PR:1.68 95% CI:1.03–2.74 p=0.036) and between ASDAS-CRP with HLA-B27 (PR:1.62 95% CI:1.18–2.19 p=0.0002). There was a relationship between the absence of clinical activity (ASDAS-CRP, ASDAS-ESR and BASDAI), previous infection, Yersinia IgA with SIgA Q1 (27.8–43.0 ug/mL); the presence of arthritis, Salmonella IgA, and high levels of CRP and ESR were related with SIgA Q2; SIgA levels among (Q3)12.2–18.0 ug/mL were associated with inflammatory back pain, obesity and Salmonella IgA <1/1600. High scores

of BASDAI and ASDAS-CRP, absence of previous infection had a strong relation with low levels of SIgA.
Conclusions: SIgA serum level were the only one serologic maker, which had an inverse correlation with all clinical activity variables of disease, previous infection and some specific antibodies associated with intestinal mucosal infection, suggesting a protective role of this molecular shape of IgA that is characteristic of mucosal immune responses

AB0202 LOW DOSE ACETYLSALICYLIC ACID AS PRIMARY PROPHYLAXIS OF CARDIOVASCULAR EVENTS IN RHEUMATOID ARTHRITIS. A LONGITUDINAL, RETROSPECTIVE STUDY

D. Iacono, S. Fasano, V. D'Abrosca, I. Pantano, R. Chieffo, G. Valentini.
Rheumatology Unit, University of Campania "Luigi Vanvitelli", Naples, Italy

Background: Cardiovascular events (CV) i.e. acute myocardial infarction and stroke are recognized as a leading cause of mortality in patients with Rheumatoid Arthritis (RA) [1,2]. Acetylsalicylic acid (ASA) is known to be associated with a significant decrease in the incidence of CV events in patients at high risk for atherosclerosis like patients with diabetes [3] and has been recently reported to play a primary prophylactic role of CV events in Systemic Lupus Erythematosus by our team [4].
Objectives: To investigate the so far unexplored role of ASA in reducing CV morbidity in RA.
Methods: We analysed patients admitted to our Outpatient clinic from January to December 2015. Out of 199, 155 patients, who had been followed from January 2000 and had not experienced any CV event at the first visit, were enrolled. The incidence of CV morbidity was recorded at December 2016.
Results: The 155 patients had been followed-up for a median of 8 years (range 1–15 years). Out of them, 111 patients had been treated with ASA, that we currently administer to patients undergoing steroid treatment. During the 15-years of follow up, 5 CV events (2 cerebrovascular, 3 acute myocardial infarction) had occurred (Incidence rate 3.93/1000 person/year). Interestingly, only 1 CV event had occurred in ASA treated patients (Incidence rate 1.12/1000 person/year) with respect to 4 in the non-ASA group (44 patients) (Incidence rate 10.48/1000 person/year) (p=0.0146).
Conclusions: Our study has several limitations including the low number of patients and CV events. Nevertheless, it might suggest a primary prophylactic role of ASA in RA, that awaits to be investigated in large controlled prospective studies.

AB0203 EXPRESSION LEVELS OF SELECTED GENES CAN PREDICT THE INDIVIDUAL RHEUMATOID ARTHRITIS PATIENT RESPONSE TO TUMOR NECROSIS FACTOR ALPHA BLOCKER TREATMENT

D. Paran[1], Y. Smith[2], S. Pundak[3], U. Arad[1], D. Levartovsky[1], I. Kaufman[1], J. Wollman[1], V. Furer[1], A. Broyde[1], O. Elalouf[1], D. Caspi[1], S. Pel[4], O. Elkayam[1]. *[1]Rheumatology, Tel Aviv Medical Center and the Sackler school of Medicine, Tel Aviv University, Tel Aviv; [2]Genomic Data analysis, Hadassah Medical School Hebrew University, Jerusalem Israel; [3]Genefron Ltd, Jerusalem; [4]Rheumatology, Tel Aviv Medical Center, Tel Aviv, Israel*

Background: Rheumatoid arthritis (RA) patients have many therapeutic options. However, there are limited tools to predict the individual patient's response to therapy. The Genefron personal diagnostic kit (IFR 300) has been developed based on analysis of large databases to select interferon stimulated gene (ISG) expressions which could predict response to a biologic agent
Objectives: This study aims to evaluate the ability of the Genefron diagnostic kit to predict the individual RA patient response to TNFα blockers.
Methods: Two separate analyses were performed, one retrospective and one prospective analysis. The response of 61 RA patients reported in 2 published data sets was analyzed retrospectively utilizing the Genefron kit. In addition, 18 patients with RA were assessed prospectively, before and 3 months after starting treatment with a TNFα blocker. Clinical assessment included swollen and tender joint counts, patient and physician assessments of disease activity. Patients' blood samples were obtained before administration of the TNFα blocker and were analyzed utilizing the Genefron diagnostic kit which measures expression levels of selected genes by quantitative real time PCR.
Results: Genefron kit analysis of retrospective data correctly predicted the response to a TNFα blocker in 53 of 61 RA patients (accuracy - 86.8%). In the prospective analysis 6 patients achieved a moderate EULAR response, 6 achieved a good EULAR response and 6 did not respond. According to the EULAR moderate response, the Genefron diagnostic kit predicted the response correctly in 16 of 18 patients (accuracy-89%, sensitivity -100%, specificity - 67%). According to the EULAR good response, the kit predicted the response correctly in 15 of 18 patients (accuracy - 83.3%, sensitivity - 100%, specificity - 75%).
Conclusions: The Genefron diagnostic kit predicted the response to TNFα blockers in a high percentage of RA patients assessed either retrospectively or prospectively in a real life setting. This personal diagnostic kit has the ability to guide selection of a suitable biological drug for the individual RA patient

AB0204 DISEASE FACTORS ASSOCIATED TO ABNORMAL INTIMA-MEDIA THICKNESS IN MEXICAN MESTIZO RHEUMATOID ARTHRITIS PATIENTS

D.A. Galarza-Delgado[1], J.R. Azpiri-Lopez[2], I.J. Colunga-Pedraza[1], R.E. Ramos-Cazares[1], F.J. Torres-Quintanilla[2], A. Valdovinos-Bañuelos[1], R.I. Arvizu-Rivera[3], A. Martinez-Moreno[3], J.A. Cardenas-de la Garza[3], R. Vera-Pineda[3], G. Elizondo-Riojas[4], J.I. Garcia-Colunga[4]. *[1]Rheumatology; [2]Cardiology; [3]Internal Medicine; [4]Radiology and Imaging, Hospital Universitario Dr. José Eleuterio Gonzalez, Monterrey, Mexico*

Background: Atherosclerotic cardiovascular disease (ASCVD) is the main mortality cause in patients with rheumatoid arthritis (RA) (1). It has been proven that the carotid intima-media thickness (CIMT) measured with carotid duplex ultrasonography (US) is an important ASCVD predictor with a measurement ≥0.9 mm (2–4).
Objectives: To characterize the disease factors related with abnormal carotid duplex US findings in Mexican mestizo patients with RA.
Methods: In a cross-sectional setting, we enrolled consecutive RA patients. Patients with overlap syndromes, personal history of ASCVD, dyslipidemia and previous use of any statin were excluded. A board-certified radiologist performed a bilateral carotid duplex US to all patients. Abnormal CIMT was defined as ≥0.9 mm (hypertrophy ≥0.9 – 1.2 mm and carotid plaque ≥1.2 mm). A clinical history and blood tests were performed at the time of the patient's visit. Disease activity was measured with Disease Activity Score using 28 joints–C-reactive protein (DAS28-CRP).
Results: We enrolled 57 patients. Demographic characteristics are shown in table 1. A total of 30 (52.2%) patients had an abnormal CIMT. US findings are shown in table 2. A significant correlation between abnormal CIMT and RA disease duration (p=0.04), as well as between the former and anti-cyclic citrullinated peptide antibodies (ACPA) positivity (p=0.033) was found.

Table 1. Demographic and disease characteristics

Variable	Results
Female gender, n (%)	54 (94.7)
Age (years), mean ± SD	56±9.9
Disease duration (years), mean ± SD	12.4±8.3
BMI (kg/m^2), mean ± SD	28.22±4.9
Smoking status, n (%)	5 (8.77)
DAS 28- CRP, mean ± SD	3.33±1.19
Disease Activity, n (%)	
Remission	17 (29.8)
Low	11 (19.3)
Moderate	25 (43.8)
Severe	4 (7.1)
Positive Anti-CCP, n (%)	44 (77.19)
Positive RF, n (%)	51 (89.47)

BMI: Body Mass Index.

Table 2.- *Carotid Doppler ultrasound findings.*

Ultrasound findings, n (%)		Disease duration	Disease Activity	Positive Anti-CCP	Positive RF
				P	
Abnormal CIMT	32 (56.14)	***0.022***	0.57	***0.034***	0.14
Plaque	11 (19.29)	0.33	0.75	0.65	0.67
Hypertrophy	21 (36.84)	0.52	0.59	0.54	0.38

Conclusions: There is a strong relationship between CIMT and the chronic inflammatory process of RA, as well as ACPA positivity. These results might be influenced by the high mean disease duration of our patients. Prospective studies that evaluate CIMT among disease duration intervals are necessary to support these findings.

AB0205 CAROTID INTIMA-MEDIA THICKNESS LINKED TO THE PRESENCE OF CARDIOVASCULAR RISK FACTORS IN MEXICAN MESTIZO PATIENTS WITH RHEUMATOID ARTHRITIS

D.A. Galarza-Delgado[1], J.R. Azpiri-Lopez[2], I.J. Colunga-Pedraza[1], R.E. Ramos-Cazares[1], F.J. Torres-Quintanilla[2], A. Valdovinos-Bañuelos[1], R.I. Arvizu-Rivera[3], A. Martinez-Moreno[3], J.A. Cardenas-de la Garza[3], J.I. Garcia-Colunga[4], G. Elizondo-Riojas[4]. *[1]Rheumatology; [2]Cardiology; [3]Internal Medicine; [4]Radiology and Imaging, Hospital Universitario Dr. José Eleuterio Gonzalez, Monterrey, Mexico*

Background: Rheumatoid Arthritis (RA) is associated to subclinical atherosclerosis. Traditional risk factors for cardiovascular outcomes do not explain completely the higher risk, which could be caused by chronic systemic inflammation.
Objectives: The aim of this study is to relate abnormal carotid intima-media thickness (CIMT) to the presence of cardiovascular risk factors.
Methods: Observational cross-section design. We included patients who fulfilled the 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, 40 to 75 years old, with no personal history of atherosclerotic CV disease. A board-certified radiologist performed carotid duplex ultrasounds. Patients were distributed in two groups according to the absence (Group 1) or presence (Group 2) of traditional risk factors for cardiovascular disease (smoking status, dyslipidemia, high blood pressure and diabetes).
Results: A total of 82 patients were included. Demographic characteristics for each group are shown in Table 1. Ultrasound findings are shown in Table 2. CIMT alterations were more common in Group 2 (66.7%) than in Group 1 (38.7%), with statistical significance (*p=0.013*). Presence of carotid plaque was more common in Group 2 (27.5%) than in Group 1 (16.1%), shown clinical relevance, although did not shown statistical significance (*p=0.18*).

Table 1. Demographic characteristics

Variable	Total	Group 1 (n=31) (CVRF–)	Group 2 (n=51) (CVRF+)	*p*
Patients, n (%)	82 (100)	31 (37.80)	51 (62.20)	–
Female gender, n (%)	77 (93.9)	29 (93.5)	48 (94.1)	0.0917
Age (years), mean ± SD	57±9.96	51.90±8.43	59.82±9.69	**0.001**
Disease duration (years), mean ± SD	12.45±8.39	11.74±8.76	12.89±8.32	0.554

Bilateral, n (%)	12 (14.6)	2 (6.5)	10 (19.6)	0.091

CVRF: Cardiovascular Risk Factors

Conclusions: In this cohort of Mexican patients with RA, we demonstrate relation between the presence of alterations in CIMT (carotid hypertrophy and carotid plaque) and risk factors for cardiovascular disease, which can be enhanced by intrinsic risk of RA. These findings reaffirm the importance of global health assessment in patients with RA to reduce morbidity.

AB0206 INTERLEUKIN-17 AND CC-CHEMOKINE LIGAND 20 ARE NOT USEFUL MARKERS OF RHEUMATOID ARTHRITIS ACTIVITY IN PATIENTS UNDERGOING BIOLOGIC TREATMENT

D. Sikorska[1], R. Rutkowski[2], J. Łuczak[2], W. Samborski[1], J. Witowski[2]. *[1]Department of Rheumatology and Rehabilitation; [2]Department of Pathophysiology, Poznan University of Medical Sciences, Poznan, Poland*

Background: Interleukin-17 (IL-17) and IL-17-induced CC-chemokine ligand 20 (CCL20) are increasingly implicated in the pathogenesis of rheumatoid arthritis (RA). A correlation has been reported to exist between serum levels of IL-17 and CCL20 and the disease activity following biologic treatment [1]. However, such an effect has not been universally demonstrated [2].
Objectives: The aim of the present study was to investigate if serum IL-17 and CCL20 reflect activity of the disease and whether they could be of prognostic value for predicting therapeutic response to biologic therapy in RA.
Methods: Thirty RA patients qualified to receive biologic treatment were prospectively assessed before and 12 weeks of therapy with either TNFα inhibitors or anti-IL-6 receptor antibodies. Serum concentrations of IL-17 and CCL20 were measured with high sensitivity ELISA with estimated detection levels 0.01 pg/ml and 0.47 pg/ml, respectively. Successful response to therapy was defined by the EULAR criteria.
Results: The patient baseline characteristics were summarized in Table 1.

Table 1. Patient characteristics: data presented as the mean ± SD or %

Age (years)	54.3±11.5
Sex (% of male)	4 (13%)
Disease duration (years)	9.6±6.0
Prednisone (<5 mg/24h) (%)	17 (57%)
NSAIDS (%)	22 (73%)
Methotrexate (%)	12 (40%)
Biologic treatment (%)	– TNFα inhibitors (adalimumab, certolizumab, golimumab, infliximab): 22 (73%) – IL-6R blocker (tocilizumab): 8 (27%)

Twelve weeks of biologic treatment resulted in a significant improvement in the majority of the patients with only 2 patients (7%) identified as non-responders. The favorable response to therapy was reflected both by clinical and standard biochemical criteria (Table 2). However, the mean serum concentrations of IL-17 and CCL20 did not change significantly over the course of therapy and they did not correlate with the disease activity, response to therapy, the type of biologic intervention and other medication used.

Table 2. Selected parameters before and after treatment: data presented as the median (interquartile range)

	Before treatment (n=30)	After 12-weeks of treatment (n=30)	P-value (Wilcoxon test)
DAS28 (ESR)	5.53 (5.26–6.08)	3.23 (2.19–3.75)	<0.001
ESR (mm/h)	24.0 (16.0–32.0)	10.0 (4.0–20.0)	<0.001
CRP (mg/l)	7.37 (2.3–15.8)	0.8 (0.1–5.5)	<0.001
WBC (10^3/l)	9.0 (7.6–9.9)	7.8 (6.6–9.6)	0.014
IL-17 (pg/ml)	0.65 (0.00–5.81)	0.53 (0.00–4.45)	0.355
CCL20 (pg/ml)	22.0 (18.0–28.0)	22.5 (20.0–31.0)	0.322

Serum IL-17 and CCL20 levels showed no correlation with DAS28, and standard inflammatory markers.
Conclusions: Serum levels of IL-17 and CCL20 did not parallel changes in the clinical status and standard biochemical parameters in patients undergoing biologic treatment for RA. Thus, the measurement of IL-17 and CCL20 in serum does not seem to provide additional information that would help to monitor the response to biologic treatment in RA more effectively.

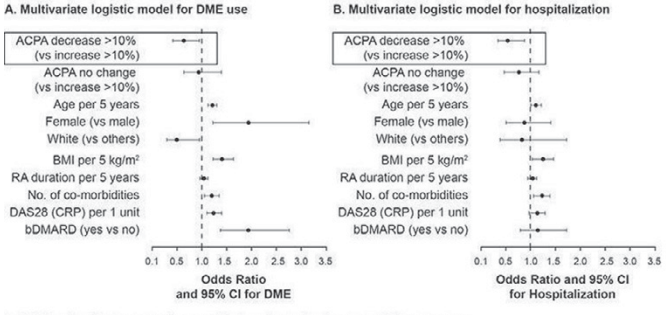
AB0207 CHANGE IN ANTI-CITRULLINATED PROTEIN AUTOANTIBODY LEVELS IN CLINICAL PRACTICE ARE ASSOCIATED WITH RESOURCE USE AND DISEASE ACTIVITY MEASURES

E. Alemao[1], Z. Guo[1], C. Iannaccone[2], M. Frits[2], N. Shadick[2], M. Weinblatt[2]. *[1]Bristol-Myers Squibb, Princeton; [2]Brigham and Women's Hospital, Boston, United States*



Background: High anti-citrullinated protein antibody (ACPA) concentration, beyond ACPA positivity, is indicative of more aggressive radiographic progression in patients (pts) with RA.[1] However, there is limited information on changes in ACPA levels in clinical practice settings, and the association of changes in ACPA with measures of resource use and/or disease activity.

Objectives: To evaluate the association between change in ACPA levels with hospitalizations/durable medical equipment (DME) use and change in disease activity.

Methods: Pts enrolled in a tertiary care centre RA registry, established in 2003, were analysed. The registry mostly comprises pts with established RA who were evaluated semi-annually for multiple clinical patient-reported outcomes as well as resource utilization parameters, and annually for disease activity measures such as DAS28 (CRP), SDAI and CDAI. The current analysis is based on pts enrolled in the registry with ACPA values at the time of baseline (BL) and follow-up visits. BL and follow-up ACPA levels were based on well-documented and validated ELISAs from Euro-Diagnostica (distributed by IBL-America, Minneapolis, MN, USA). Annual mean ACPA change from BL over the first year of enrolment in the registry was calculated. Changes ([follow-up – BL]/BL x 100) in ACPA levels were categorized as decrease (<–10%), no change (–10% to +10%) or increase (>+10%). Use of DME (canes, wheelchairs, walkers and commodes) as well as hospitalizations during 12-month follow-up and annual change in disease activity (DAS28 [CRP], SDAI, CDAI, swollen painful joint counts and pain) were assessed. Multivariate logistic regression analyses for binary outcome variables (DME and hospitalizations) and linear regression for change in disease activity measures were conducted, controlling for BL covariates.

Results: A total of 840 (65%) pts in the registry had BL and follow-up ACPA values and were included in the analysis. Overall, 34.6% (n=291) of pts had a decrease, 31.7% (n=266) had no change and 33.7% (n=283) had an increase in ACPA levels. There were no significant differences in BL characteristics between the three groups except for disease duration. Pts with RA with an increase in ACPA levels had significantly longer disease duration at BL. In univariate analyses, DME use was 23.4%, 30.1% and 28.6%, and hospitalization rate was 13.4%, 16.5% and 20.1% in pts with a decrease, no change or an increase in ACPA levels, respectively. Unadjusted mean (SD) change from BL in DAS28 (CRP), SDAI and CDAI in pts with reductions in ACPA levels was –0.7 (1.4), –6.1 (15.7) and –5.9 (15.1), and –0.5 (1.4), –5.0 (15.7) and –4.7 (14.6) in pts with an increase in ACPA levels. After controlling for BL covariates, the odds ratio (OR) for DME in patients who had a decrease in ACPA levels (vs increase) was 0.62 (95% CI 0.40, 0.94; p=0.026), and the OR for hospitalization was 0.54 (0.33, 0.86; p=0.010). Similarly, reductions in ACPA levels were associated with greater reductions in disease activity measures (Fig).

Figure. Association of Reductions in ACPA Levels With Resource Use (Panel A and B) and Disease Activity (Panel C) in Clinical Practice

C. Multivariate linear regression models for change in disease activity measures

Independent variable of interest*	Outcome modelled	Regression coefficient (p value)
ACPA decrease (vs no change and increase)	Change in DAS28 (CRP)	**–1.97 (0.024)**
	Change in CDAI	–1.68 (0.087)
	Change in SDAI	–1.68 (0.099)
	Change in joint counts	**–2.00 (0.010)**
	Change in pain VAS	**–0.39 (0.026)**

*Other variables in the models included age, sex, race, BMI, RA duration, co-morbidities, biologic use and baseline disease activity. ACPA=anti-citrullinated protein antibody; bDMARD=biologic DMARD; DME=hospitalizations/durable medical equipment; VAS=visual analogue scale

Conclusions: Reductions in ACPA levels were associated with reductions in DME use and hospitalizations as well as reductions in disease activity measures.

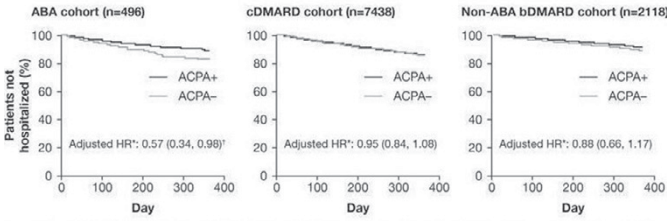
AB0208 HOSPITALIZATION RATES IN PATIENTS WITH RA BY POOR PROGNOSTIC FACTORS: IMPACT OF ABATACEPT AND OTHER DISEASE-MODIFYING ANTIRHEUMATIC THERAPIES

E. Alemao, L. Burns, Z. Guo. *Bristol-Myers Squibb, Princeton, United States*



Background: Studies have reported that poor prognostic factors (PPF) in RA, such as high anti-citrullinated protein antibodies (ACPA), are associated with erosions, rapid radiographic progression and/or extra-articular manifestations.[1,2] Evidence from clinical trials and clinical practice indicate differences in treatment effects of biologic (b)DMARDs by ACPA status and/or level.[3,4] PPF also play an important role in clinical management of patients (pts) with RA, including inpatient admissions.

Objectives: To compare hospitalization rates of ACPA-positive (+) with ACPA-negative (–) pts managed with abatacept (ABA), non-ABA bDMARDs or conventional (c)DMARDs.

Methods: This is a retrospective cohort analysis of Clinformatics Data Mart, a database of administrative health claims including results for outpatient laboratory tests, processed by national laboratory vendors under contract with the managed care organization, for a total of ~53 million unique lives over 13 years. This analysis was restricted to adult pts (aged ≥18 years) who had at least two ICD-9-CM diagnosis codes for RA between Jan 2007 and Dec 2014 (identification period) and 12 months (M) of membership/drug benefit. Pts with ankylosing spondylitis, Crohn's disease, lupus, psoriasis or ulcerative colitis at or before the index date were excluded. ACPA+ was based on >19 or >5 U/mL, depending on the test utlilized. Follow-up for pts initiating ABA was from first day of treatment to first hospitalization, end of enrolment or end of 12M follow-up. The primary outcome was all-cause hospitalization at 12M. Descriptive statistics such as Wilcoxon rank-sum test for continuous variables or Pearson's chi-square test for categorical variables were used. Cox proportional hazard model was used to examine all-cause hospitalization adjusted for age, sex, region and past hospitalization. Additional covariates included co-morbidities that were different between ACPA+/– pts. Similar analyses were performed for pts treated with cDMARDs and non-ABA bDMARDs.

Results: A total of 496 ABA, 7438 cDMARD and 2118 non-ABA bDMARD pts were included, with an overall past hospitalization rate of 35.5, 25.4 and 23.2%, respectively. Overall, 59.5, 41.5 and 51.7% of pts were ACPA+ in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively. ACPA+ pts were older and less likely to have obstructive sleep apnoea, depression and myalgia/myositis across all cohorts. Unadjusted 12M hospitalization rate in ACPA+ vs ACPA– pts was 10.8 vs 16.4%, 13.7 vs 14.3% and 8.5 vs 10.8% in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively. After controlling for baseline covariates, the hazard ratio for hospitalization in the ACPA+ (vs ACPA–) group was 0.57 (95% CI: 0.34, 0.98; p=0.04), 0.95 (95% CI: 0.84, 1.08; p=0.47) and 0.88 (95% CI; 0.66, 1.17; p=0.38) in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively (Figure).

Figure. Kaplan–Meier Plot for 1-Year Hospitalization According to ACPA Status

*HR of hospitalization for ACPA+ vs ACPA– from a Cox model adjusted for age, sex, region, past hospitalization and co-morbidities. †p<0.05. ABA=abatacept; bDMARD=biologic DMARD; cDMARD=conventional DMARD; HR=hazard ratio

Conclusions: ACPA+ pts with RA treated with abatacept have a lower rate of hospitalization than ACPA– pts. This pattern was not observed with cDMARDs or non-abatacept bDMARDs. Further efforts including matching and subgroup analysis should be explored for direct comparisons between the cohorts.

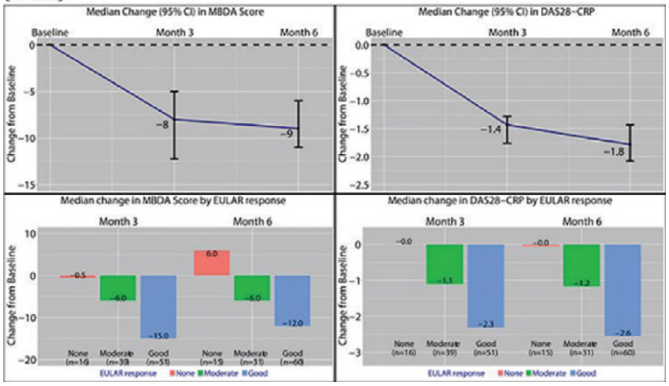
AB0209 THE CHANGES OF SIGNAL PEPTIDE- CUB-EGF DOMAIN-CONTAINING PROTEIN (SCUBE) AND OTHER ANGIOGENESIS PROTEINS DURING DISEASE ACTIVITY AND RELATIONSHIP WITH THE JOINT ULTRASOUND FINDINGS IN RHEUMATOID ARTHRITIS PATIENTS

E. Capkin, N. Cılesızoglu, S. Ozer Yaman, M. Garıpoglu, D. Altay. *Karadeniz Technical University, Trabzon, Turkey*



Background: Rheumatoid arthritis (RA)is a multifactorial, systemic, progressive, inflammatory disease which is characterized with bone and cartilage destruction. Synovial angiogenesis is important at the etiopathology. SCUBE (Signal peptide-CUB-EGF domain-containing protein) is rather a new surface cell protein. Its secretion increases with inflammation and hypoxic conditions. Its relations with inflammation and angiogenesis are shown in preclinical studies.
Objectives: The purpose is to study levels of newly identified plasmaSCUBE 1 and 3 and other angiogenesis markers and analysis of changes after treatment in RA patients. Moreover, to determine whether a correlation with this change in SCUBE proteins after treatment, clinical parameters and with joint ultrasound findings.
Methods: This study covers patients diagnosed with RA associated with 2010 American Collage of Rheumatology (ACR) diagnosis criteria matched with healthy controllers who are equivalent of RA patients in terms of age and gender. Detailed background information and examination of the patients were recorded and disease activity scores (DAS28) were figured out and US7 scores were calculated. The levels of SCUBE 1–3, Vascular Endotedial Groving Factor (VEGF), Matrix metaloproteinaz-9 (MM-9), Interlökin-6 (IL-6), CD40L were evaluated with the method of Enzyme-Linked ImmunoSorbent Assay (ELISA). Clinical and laboratory measurements were re-evaluated at the third month after treatment.
Results: This study covers 56 individuals; 28 of whom were diagnosed with RA and 28 of them were healthy controllers. Significant differences were observed between RA patients and healthy controller groups in terms of MMP-9 levels ($p<0,05$). Levels of SCUBE-1, SCUBE-3, VEGF, İL-6 ve CD-40 were similar ($p>0,05$).After treatment VEGF levels were significantly lower compared to pre-treatment ($p<0,05$), the changes in SCUBE-1, SCUBE-3, İL-6, CD-40 ve MMP-9 levels were not statistically significant ($p>0.05$). After treatment ultrasound scores were significantly lower than before treatment ($p<0.05$).
Conclusions: In our study, significant improvements were observed in clinical, laboratory and ultrasound findings after treatment. MMP-9 and VEGF were associated with disease activity. SCUBE proteins which have been newly identified markers of angiogenesis were shown no relationship with disease activity.

AB0210 THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE FOR ASSESSING RESPONSE TO TREATMENT WITH ADALIMUMAB

D. Pappas[1,2], E.H. Sasso[3], R.J. Bolce[3], X. Liu[3], C.J. Etzel[1,4]. *[1]CORRONA, LLC, Southborough; [2]Columbia University Medical Center, New York; [3]Crescendo Bioscience Inc., South San Francisco; [4]University of Texas MD Anderson Cancer Center, Houston, United States*

Background: The multi-biomarker disease activity (MBDA) score measures 12 serum biomarkers to assess disease activity in patients with rheumatoid arthritis (RA) on a scale of 1–100. The MBDA score was validated in several different cohorts but has not been evaluated in a cohort consisting only of patients initiating TNF inhibitor therapy in clinical practice. We utilized patients enrolled in the Corrona-CERTAIN study to evaluate MBDA scores for patients initiating adalimumab (ADA) in several clinical practices in the US.
Objectives: Evaluate the ability of the MBDA score to assess response to treatment with ADA.
Methods: We studied 106 biologic-naïve RA patients who had been treated with ADA for at least 12 months, had initiated ADA in CERTAIN while in moderate or high disease activity by CDAI, and for whom sera were available at baseline (BL) and Months 3 and 6. Changes (Δ) in MBDA score and DAS28-CRP were evaluated from BL to Months 3 and 6 by the one-sample paired t-test. ΔMBDA scores were evaluated for patients grouped by EULAR response categories, using the Cochran-Armitage test for trend. Receiver Operating Characteristic (ROC) analysis with bootstrap sampling (20,000 iterations) was used to evaluate MBDA score ability to discriminate ΔDAS28-CRP improvement >1.2 units at Month 3, and to determine the optimal MBDA threshold by maximizing the sum of sensitivity and specificity (Youden's index criterion).
Results: At BL, median values were age 54.5 years, disease duration 2 years, BMI 28.2, DAS28-CRP 4.7, CDAI 24, SDAI 25.4; 74.5%/65.4% were RF+/ACPA+. Median MBDA score was 49 with 17 (16%) patients in low (<30), 23 (22%) patients in moderate (30–44), and 66 (62%) patients in high (>44) MBDA categories. The relative magnitude and the direction of median change from BL to Months 3 and 6 were similar for MBDA score (–8, –9) and DAS28-CRP (–1.4, –1.8), with statistically significant changes from BL for each (line graphs in Figure). Similar results were observed for SDAI and CDAI. Pearson's correlations with ΔMBDA score at Months 3 and 6 were 0.58, 0.59, respectively, for ΔDAS28-CRP; 0.48, 0.47 for ΔSDAI; and 0.42, 0.42 for ΔCDAI (all $p<0.0001$). Median reductions in MBDA score were significantly greater for patients with concurrent DAS28-CRP improvement >1.2 units (n=67) vs. ≤ 1.2 units (n=39) at Month 3 (15 vs. 2) and Month 6 (13 vs. 1.5) (both $p<0.0001$); and for patients with EULAR Good vs. Moderate vs. Non-responses (p=0.0002 at Month 3, $p<0.0001$ at Month 6) (bar graphs in Figure). Area under the ROC curve (AUROC) for the ability of ΔMBDA score from BL to Month 3 to discriminate DAS28-CRP improvement >1.2 units at Month 3 was 0.82 (95% CI, 0.74–0.90). The optimal threshold for this discrimination was a reduction in MBDA score >9 units, with sensitivity/specificity=0.63/0.82 and PPV/NPV =0.86/0.56.

Figure. Median changes from baseline in MBDA score and DAS28-CRP at 3 and 6 months: in line graphs with 95% CI (above) and by EULAR response category (below).

Conclusions: This study expands the previous validation of the MBDA score by demonstrating its ability to assess response to treatment with adalimumab in a US clinical practice cohort. The AUROC value of 0.82 for discriminating improvements in DAS28-CRP >1.2 units indicates a significant association between change in MBDA score and clinical improvement.

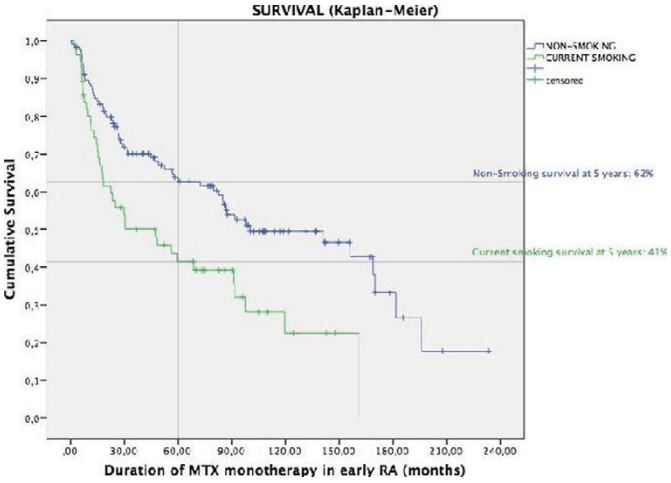
AB0211 THE EFFECT OF SMOKING, ALCOHOL AND CAFFEINE ON EARLY RHEUMATOID ARTHRITIS OUTCOMES

E. Chamizo-Carmona[1], C. Carrasco Cubero[2], J.J. Aznar Sanchez[1], R. Veroz Gonzalez[1], P.J. Cossío Jimenez[1], S.M. Rojas Herrera[1]. *[1]Rheumatology, H. Merida, Merida; [2]Rheumatology, CHU Badajoz, Badajoz, Spain*

Background: The aim of early RA treatment is remission. Intensive treatment with MTX achieve remission in 30–50% patients (pts). Modifiable risk factors, as smoking, alcohol, coffee and tea, may affect response to MTX.
Objectives: To study the influence of tobacco, alcohol, caffeine on the MTX response in early RA pats.
Methods: A case-control study (2010–2015): cases were pts who achieved DAS28<2.6 (remission) and controls were pts who did not. We collected information from pts$>$18years with early RA, treated with MTX, evaluated quarterly in a specialized unit early RA. All the pts underwent a structured interview about their smoking history and others habits. A descriptive and comparative study, was performed (SPSS21).
Results: 182 pts (age 50,96±13,11y, 67,6% female, 81,3% FR+ and 65,7% ACPA+) was treated with MTX and followed 105,03±7,15 months since 1995. More than 95% pts received MTX (in rapid escalation) in the first 24 months of the onset of symptoms. DAS28<2.6 was achieved for 67 (36,8%) pts, who required an lower average dose of MTX (15,07mg/w) than those who did not (18,04mg/w) (p=0,000). Age, DAS28 and physical function at baseline, treatment delay, smoking and adverse events by MTX were related to remission.The univariate and multivariate analysis of the baseline pts characteristics and the relationship of their smoking history with age, RF, ACPA and outcome of MTX monotherapy are shown in table 1and 2, respectively. The median survival of MTX monotherapy was 87,39 months (100.27 non-smokers and 47.70 months for current smokers (Log Rank 10.32, p 0.001) (see graphic).
Conclusions: The treatment of early RA with MTX alone achieved high rates of remission, especially in non-smokers. Smoking cessation could significantly improve the response to MTX and therefore should be an integral part of the treatment of early RA patients.



Abstract AB0211 – Table 1

Baseline Characteristic	Univariate analysis			Multivariate analysis
	DAS28<2.6	No remission	OR (95%IC)	OR (95% CI)
Age, mean (SD), years	55.46 (13.21)	48.34 (12.38)	7.11 (3.26, 10.96)**	0.124

AB0212 CLINICAL AND SOCIODEMOGRAPHIC CHARACTERISTICS ASSOCIATED WITH RESPONSE TO METHOTREXATE (MTX) IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) NAÏVE TO DMARD

E. Chamizo-Carmona[1], C. Carrasco Cubero[2], P.J. Cossio Jimenez[1], S.M. Rojas Herrera[1], T.L. Rodriguez Araya[1], R. Veroz Gonzalez[1], J.J. Aznar Sanchez[1]. *[1]Rheumatology, Hospital de Merida, Merida; [2]Rheumatology, CHU Badajoz, Badajoz, Spain*

Background: RA treatment involves starting early with a DMARD. MTX achieves good sustained response in 30–40% of patients (pts). When MTX response is insufficient add other DMARD by achieve RA remission. Different factors may affect the response to MTX
Objectives: To analyze the clinical and demographic characteristics related to response to MTX in RA pts DMARD-naïve
Methods: We enrolled between 2011 and 2015, pts>18years RA diagnosed (ACR 1987 criteria), treated firs with MTX monotherapy (MTXm). A case-control study (MTXm persistence with CRP-DAS28<3.2 and suspension of MTXm by ineffectiveness or toxicity, respectively) was performed. We collected information that can influence the response to MTXm by medical records review and patient survey. A descriptive and analitical study with SPSS statistics 21 was performed
Results: We included 222 pts (70 men and 152 women). The characteristics of cases (123) and controls (99) are shown in the table. The causes of MTXm suspension were remission (7), intolerance/toxicity (19) and inefficiency (79). MTX was discontinued in 40 (18.2%) pts, 28 (12.7%) of them by intolerance/toxicity. Of 123 (55.4%) responders, 71 (32.0%) were CRP-DAS28<2.6. MTXm response was associated with age at onset ≥60 years (χ2 18.47, p<0.01, OR 3.67), rheumatoid factor (RF) <100 IU (χ2 10.92, p<0.01, OR 3.16) and current smoking (χ2 12.71, p<0.01, OR 2.95). Tobacco was associated with RF+ (χ2 8.9 p<0.01 OR 2.59 (1.37; 4.89) and ACPA+ (χ2 4.49 p<0.05 OR 1.88 (1.04, 3.38). We found no association with gender, education, job, coffee, tea or alcoho drinks, comorbidities, cardiovascular risk, possitivity ACPA or FR, RA presentation, treatment delay, or corticosteroid use. We found no correlation between age of RA-onset and RF or ACPA levels and MTXm duration. MTXm persistence at 5 years was 59% pts and their median survival was 93 months (77.14 to 108.8). We only found significant differences in favor of non-smokers and RF<100

Table 1. Clinical and sociodemographics characterisitics of RA patients

Characteristics	Responders n=125	Nonresponders n=99	Statistic Significancy
Age at onset (y) (mean, SD)	53.48 (13.0)	46.65 (11.5)	t=4.08 p=00006
Female n (%)	80 (65.0)	72 (72.7)	ns
Current Smokers n (%)	23 (18.7)	40 (40.4)	χ^2 12.7 (p<0,01) OR 2.95 (1.6, 5.4)
Alcohol consumers n (%)	35 (28.5)	28 (28.3)	ns
Comorbidity n (%)	92 (74.8)	61 (61.6)	χ^2 4.45 (p<0.05) OR 1.21 (1.0, 1.5)
CV risk factors n (%)	92 (74.8)	81 (81.8)	ns
Polyarticular onset of AR n (%)	61 (49.6)	61 (61.6)	ns
Extraarticular involvement n (%)	17 (13.8)	21 (21.2)	ns
Possitive RF n (%)	89 (72.4)	79 (79.8)	ns
Possitive ACPA n (%)	70 (60.3)	64 (68.1)	ns
Duration of RA (m) (mean (SD)	96.1 (63.1)	96,0 (73.9)	ns
MTX toxicity n (%)	47 (38.2)	59 (59.6)	χ^2 10.0 (p<0.01) OR 2.38 (1.4, 4.1))
MTX dose (mg) (mean, SD)	15.6 (0.32)	17.8 (0.37)	t=-4.52 p=00001

Conclusions: The initial treatment of RA with MTX is an effective and safe option, with a high drug survival. MTX response was not associated with antibody positivity (RF or ACPA), but it was significantly better in non-smokers patients and RF <100. Smoking cessation could significantly improve the response to MTX of RA patients

AB0213 HIGH POWER DOPPLER SIGNALS SEEMS MORE IMPORTANT THAN SYNOVITIS SCORES IN ESTABLISHED RHEUMATOID ARTHRITIS

E.D. Keskin[1], F.G. Yurdakul[2], H. Bodur[2], A. Akıncı Tan[3], L. Özçakar[3]. *[1]Physical Medicine and Rehabilitation, Kırıkkale University Faculty of Medicine, Kırıkkale; [2]Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital; [3]Physical Medicine and Rehabilitation, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease characterized by synovial inflammation, potential cartilage and bone damages. Evaluation with ultrasound (US) has come into prominence due to conventional radiography is relatively insensitive on soft tissue inflammatory changes and early bone erosions (1,2).
Objectives: The value of US has been shown in early arthritis, but is not well known for established RA. The aim of this study is to determine the relation between US signal, disease activity, articular damage and disability in established RA patients.
Methods: Forty-four RA patients (21 women, 23 men) were enrolled to the study. Age and gender, duration of disease, morning stiffness, disease activity score 28 (DAS28), The Rheumatoid Arthritis Articular Damage (RAAD) score, Hand disability Index (HDI), DASH (Disabilities of the Arm, Shoulder and Hand) scale, and grip strength values were recorded. Wrist, I-II- III. metacarpophalangeal and proximal interphalangeal joints of dominant hand were examined by both B mode US (BMOD) and Power Doppler US (PDUS).
Results: All of the 44 patients were established RA. The median of disease

duration was 156 (48–420) months. DAS 28 score was 2.86 (0.68–5.70) and 54.5% of the patients were in remission. BMOD synovitis, erosion and PDUS synovitis total scores were 20 (6–36); 6 (0–17); 1 (0–14) respectively. Although US findings were not correlated with DAS 28 and grip strength; there was poor correlation between US findings and DASH, RAAD and disease duration (Table 1). Signs of synovitis indicated with PDUS in 63.3% of the joints assessed. High-grade PDUS signal (grade 3) was found in 10 (22.7%) of the patients. Duration of morning stiffness, HDI and DASH scores were worse in the patients with high-grade PDUS signals (p=0.01, 0.04, 0.01 respectively)

Table 1. Correlation coefficients between clinical, ultrasound and functional variables

	BMOD synovitis Total		BMOD erosions Total		PDUS synovitis Total	
	r	p	r	p	r	P
DASH	0.37	0.02*	0.19	0.20	0.13	0.38
HDI	0.21	0.17	0.17	0.28	0.21	0.17
RAAD	0.33	0.02*	0.41	0.00*	0.22	0.15
DAS 28	-0.04	0.78	0.01	0.95	-0.05	0.75
MS	0.24	0.12	-0.10	0.51	0.20	0.19
Disease duration	0.13	0.38	0.46	0.00*	-0.31	0.03*
Lateral GS	0.07	0.64	-0.06	0.69	-0.06	0.70
Tip GS	0.11	0.49	-0.27	0.08	0.09	0.56
Three fingered GS	0.21	0.89	-0.17	0.27	0.05	0.76
Mass grasp	-0.08	0.59	-0.078	0.61	-0.12	0.43

BMOD: B mode ultrasound, PDUS: Power Doppler ultrasound, DASH: Disabilities of the Arm, Shoulder and Hand, HDI: Hand disability index, RAAD: Rheumatoid Arthritis Articular Damage, DAS 28: Disease activity score, MS: Morning stiffness, GS: Grip strength. *P<0.05.

Conclusions: US scores in established RA patients are usually high because of synovial hypertrophy. It is considered that the high grade PDUS signals are more appropriate for evaluation of long-standing RA patients. Furthermore in this study, grade 3 PDUS signals were found to be a good indicator of synovial inflammation, morning stiffness, and disability.

AB0214 METHOTREXATE IN EARLY RHEUMATOID ARTHRITIS: A SINGLE-CENTER EVALUATION OF CLINICAL OUTCOME COMPARING TWO STARTING TREATMENT STRATEGIES

F. Benaglio, S. Bugatti, G. Sakellariou, G. Crepaldi, G. Zanframundo, C. Montecucco, R. Caporali. *Early Arthritis Clinic, Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

Background: methotrexate (MTX) is considered the 'anchor drug' in the treatment of rheumatoid arthritis (RA) and it should be part of the first treatment strategy: there are many indications about the correct way to optimize the dosage, depending on clinical response and tolerability, but currently there is no shared evidence about the optimal starting dosage.

Objectives: to compare two different starting treatment strategies with MTX in patients with early RA evaluated at our Early Arthritis Clinic (EAC) in order to assess the rate of patients who reaches the target (remission/low disease activity) at 6 months, according with EULAR guidelines.

Methods: patients with RA (disease duration <12 months) evaluated at our EAC between 2005 and 2016 and treated with MTX parenterally and glucocorticoids (GC) were included. Patients followed a treat-to-target strategy to reach low disease activity with bimonthly tight control. Patients evaluated between 2005 and 2009 were initially treated with MTX 10 mg/week + GC (group A) with increase of MTX to 15 and then 20 mg/week in case of failure to reach the target; patients evaluated between 2010 and 2016 were initially treated with MTX 15 mg/week + GC (group B) with possible increase to 20 and 25 mg/week. The DAS28 response was assessed after 6 months.

Results: 260 patients were analyzed: 123 in group A vs 137 in group B. At baseline patients showed differences in DAS28 (5.2±1.15 vs 4.6±1.16, p<0.0001) and HAQ (1,125 vs 1 IQR IQR 0.75–1.875 0.375–1.5, p=0.006); there were no differences in terms of autoimmunity. After 6 months of therapy there were no differences in clinical response: 32% of patients in the group A reached the DAS28 remission vs 40% of the group B (p= ns), 27% in the group A reached the DAS28 low disease activity vs 24% of the group B (p= ns), 41% of the group A was in moderate disease activity vs 36% in the group B (p= ns). The need to increase the dosage of MTX during the first 6 months was similar: 27.6% of the group A vs 29.9% of the group B (p= ns), conversely, the need to reduce the dosage of MTX due to intolerance and/or adverse event was significantly higher in the group B (group A: 1.6% vs group B: 9.5%, p=0.014).

Conclusions: the use of higher dose of MTX is associated with a higher rate of side effects but does not provide, at short term, a significant improvement in term of clinical outcome. Conversely, the initial use of MTX 10 mg/week, with a quick dose titration in case of persistent disease activity, seems to be an appropriate option for many patients with early RA, as also recently suggested by the Utrecht Arthritis Cohort Study Group; in spite of this, there is an amount of patients who do not achieve the clinical target at short term regardless of the initial dose of MTX. Our experience suggests that in the early phase of RA treatment, in a context based on early diagnosis, tight control and treat to target, the clinical outcome seems to be linked more to the treatment strategy than to the drug dosage used.

AB0215 A LONGER MEAN SURVIVAL OF BIOLOGIC TREATMENTS IS ASSOCIATED WITH DAS28 REMISSION IN RHEUMATOID ARTHRITIS PATIENTS

F. Ometto, C. Botsios, B. Raffeiner, D. Astorri, L. Friso, L. Bernardi, L. Punzi, A. Doria. *Rheumatology Unit, Department of Medicine - Dimed, University of Padova, PADOVA, Italy*

Objectives: To determine factors associated with remission (DAS28<2.6). We specifically considered the association of biologic treatment duration, number of biologic switches and survival of biologic treatment with remission.

Methods: We conducted a retrospective analysis on a monocentric cohort of rheumatoid arthritis patients. We included patients who were on biologic drugs at the time of the analysis (31st December 2016). We considered patients starting the first biologic treatment since January 2000 and with a follow-up ≥12 months. We considered the following variables: demographics, positive rheumatoid factor (RF)/ anti-citrullinated peptides (ACPA), disease duration at the start of the first biologic treatment, number of biologic switches, clinical assessment at the last follow-up, concomitant DMARDs, prednisone dose, current biologic treatment. We also considered the mean survival of biologic treatments, defined as the duration of the biologic treatment of each patient divided by the number of biologics undergone by the patient.

Mann-Whitney test and chi-square test were used to assess the association of continuous and categorical variables with the outcome. Continuous measures are reported as medians and interquartile range. Multivariate regression analysis included all variables reaching a p value <0.2 in univariate analysis

Results: We collected data of 330 patients. All patients had complete data. One hundred thirty-five patients (40.9%) were in DAS28 remission. Characteristics of the patients are reported in Table I. We considered 609 biologic treatments (abatacept n=61; anti-TNF alpha n=445; anakinra n=43; tocilizumab n=56; rituximab n=5). Total biologic treatment duration in all patients was 9.62 years (5.68–12.53), in patients in remission 8.95 (4.70–12.53) and in patients not in remission 10.12 (6.28–12.62) (p=0.248). Median number of previous biologic switches was 1.00 (0–1.00) in patients in remission and not in remission (p=0.436). Survival of biologic treatments was 5.33 years (2.89–7.72) in all patients, 4.57 (2.54–7.28) in patients in remission and 5.81 (3.49–7.93) in patients not in remission (p=0.013).

All clinical assessments at the last follow-up were significantly associated with DAS28 remission. Mean prednisone dose was significantly lower in patients in DAS28 remission but was considered as a consequence of remission rather than a predictor (Table I). The type of current biologic treatment was not significantly associated with DAS28 remission.

Variables included in the multivariate regression analysis were: BMI, age, disease duration, positive RF/ACPA mean survival of each biologic treatment. All variables included in the model were independently associated with DAS28 remission. A higher BMI, older age, longer disease duration and positive RF/ACPA were negatively associated with remission. A longer mean survival of biologic

Table I. Characteristics of the patients according to the achievement of DAS28 remission at the last follow-up: results of univariate and multivariate analysis.

DAS28, median (IQR)	2.82 (2.59-3.44)	3.28 (2.96-3.91)	1.80 (1.52-2.23)	<0.001			

*Continuous variables are presented as medians and the respective interquartile range IQR, and were tested with the Mann-Whitney test. Categorical variables are presented as frequencies and were tested with the chi-square test. † Not included in multivariate analysis. ¶ Not included in multivariate analysis as they are components of the DAS28.

treatments was positively associated with DAS28 remission (OR 1.11 per year increase, 95% C.I. 1.03–1.18, p=0.003).
Conclusions: The duration of biologic treatment and the number of previous biologic switches were not associated with of DAS28 remission. Indeed, a longer survival of biologic treatments was associated with remission. The mean survival of biologic treatments reflects both a smaller number of biologic failures and a prolonged response to each biologic treatment.

AB0216 EFFECTS OF ANTI-CITRULLINATED PROTEIN ANTIBODIES ON SYSTEMIC BONE MASS IN RHEUMATOID ARTHRITIS PATIENTS

G. Orsolini, C. Caimmi, O. Viapiana, L. Idolazzi, E. Fracassi, D. Gatti, G. Adami, M. Rossini. *Rheumatology Unit, University of Verona, Verona, Italy*

Background: Bone loss in rheumatoid arthritis (RA) is a key feature both local and systemic. Anti-citrullinated protein antibodies (ACPA) have recently been found to directly induce differentiation and activation of osteoclasts and therefore contribute to periarticular bone loss.
Objectives: The aim of this study was to analyze the effect of ACPA on systemic bone mineral density (BMD) in patients with established RA.
Methods: This is a cross-sectional study with a single-center RA population. BMD was measured with Dual X-ray absorptiometry at lumbar and femoral sites. ACPA were measured by EIA. Multivariate analysis was performed adjusting for the main confounding variables.
Results: One hundred twenty-seven RA patients were enrolled. In univariate analysis ACPA-positive patients showed lower BMD Z-score (SD below the age- and gendermatched mean reference value) at femoral sites ($p<0.01$). A negative correlation between ACPA titer and BMD Z-score at all sites was observed ($p<0.01$). The multivariate analysis adjusted for the main confounding variables confirmed the negative effect of ACPA at femoral sites ($p<0.05$), but not at lumbar spine BMD. No significant effect of rheumatoid factor has been observed.
Conclusions: ACPA have a negative titer-dependent effect on BMD at femoral sites, mainly constituted by cortical bone. ACPA-positive patients, especially if at high titer, should undergo bone investigations and be treated with bone protecting agents. Disease-modifying anti-rheumatic drugs lowering ACPA titer might have positive effects on systemic bone mass.

AB0217 THE PROGNOSTIC VALUE OF IGA AUTOANTIBODIES (RHEUMATOID FACTOR AND ACPA) FOR PREDICTION OF THERAPEUTIC RESPONSES TO ANTI-TNF THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Steiner[1], D. Sieghart[1], F. Alasti[1], P. Studenic[1], T. Perkmann[2], T. Horn[3], D. Aletaha[1], J.S. Smolen[1]. *[1]Internal Medicine III-Rheumatology; [2]Laboratory Medicine, Medical University Vienna; [3]Phadia Austria GmbH, Thermo Fisher Scientific, Vienna, Austria*

Background: Anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) are important diagnostic markers in rheumatoid arthritis (RA). These antibodies are predominantly of the IgM (RF) or IgG (ACPA) isotype. The added diagnostic and prognostic value of IgA autoantibodies is being debated.
Objectives: To determine the prevalence of IgA-RF and IgA-ACPA in patients with RA and to investigate their potential predictive value regarding response to treatment with methotrexate (MTX) and TNF inhibitors.
Methods: A total of 255 patients were tested for the presence of IgA-RF, IgA-ACPA and IgG-ACPA by EliA® (Thermo Fisher Scientific); IgM-RF was measured by nephelometry. Therapeutic responses to MTX and TNF blocking biologicals were calculated in an inception cohort (n=104) who had started their DMARD therapy at our clinic. To define therapeutic responses simplified disease activity index (SDAI) 50 and American College of Rheumatology (ACR) 20 responses were calculated.
Results: Among the 255 patients tested 125 (49%) had at least one type of IgA autoantibody: 114 (44.7%) were found to be IgA-RF positive and of these 10.5% were negative for IgM-RF and 5.2% were double negative for both IgM-RF and IgG-ACPA; thus, in these patients IgA-RF was the only detectable antibody. IgA-ACPA were detected in 79 (31%) patients and apart from one exception all of them had also IgG-ACPA. Remarkably, the percentage of patients showing a SDAI50 response to TNF inhibitors was significantly lower in patients positive for IgA-RF and/or IgA-ACPA ($p<0.0001$) compared to IgA negative patients. Thus, 58% of IgA negative (but IgM-RF and/or IgG ACPA positive) patients showed a SDAI50 response whereas only 25% of the IgA-RF and/or IgA-ACPA positive ones were responders. Interestingly, while the presence of both IgA specificities did not further change the percentage of responders, patients positive for IgA-ACPA but negative for IgA-RF showed the lowest response rate to anti-TNF treatment. Completely seronegative patients also showed a significantly lower SDAI50 response ($p<0.0001$) to TNF inhibitors compared with the IgA negative (but IgM-RF and/or IgG-ACPA positive) patients. Similar results were obtained when ACR20 was used as response criteria. No differences between the various serological groups were seen with respect to treatment with MTX.
Conclusions: While the added diagnostic value of IgA antibody measurement was moderate, IgA-RF and particularly IgA-ACPA appear to be associated with poorer therapeutic responses to TNF inhibitory biological drugs and therefore may help in further stratification of RA patients and therapeutic decision making.

AB0218 CORRELATION OF GRAY SCALE AND POWER DOPPLER ULTRASONOGRAPHY WITH CLINICAL EVALUATION IN RHEUMATOID ARTHRITIS

I.E. Okatan, M. Torgutalp, M.E. Yayla, A.B. Keleşoğlu Dinçer, E. Uslu Yurteri, A. Ateş, T.M. Turgay, G. Kınıklı. *Department of Internal Medicine, Division of Rheumatology, Ankara University Faculty of Medicine, Ankara, Turkey*

Objectives: Ultrasonography (US) is a useful method for assessing synovial vascularization and proliferation in rheumatoid arthritis (RA). The aim of the study is to compare the tender joint and swollen joint in patients with rheumatoid arthritis (RA) with gray scale (GS) and power doppler (PD) ultrasonography (US).
Methods: Thirty RA patients were included. Median disease duration was 53.7 months. Demographic and clinical data, C reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) were recorded for each patient. Disease activity was evaluated using the Disease Activity Score in 28-joints (DAS28) with a median score 3.8.The joint tenderness and swelling were assessed for 10 joints (wrists, second and third proximal interphalangeal and metacarpophalangeal) in each patient.These joints were evaluated by GS and PD by ultrasonography. US joint effusion, synovitis and PD signals were graded from 1 to 3 for each joints. The 10-joint GS and 10-joint PD scores were then calculated. Correlations were tested using the Spearman coefficient.
Results: GS effusion, synovitis scores ($r=0.565$, $p<0.001$) and PD signals ($r=0.883$, $p<0.001$) correlated highly with the corresponding swollen joints. There was a significant correlation between DAS28 and number of tender joints ($r=0.745$, $p<0.001$) but no correlation was found between the tender joints and ultrasonographycal effusion, synovitis grade ($r=0.073$, $p>0.001$) and the PD signal ($r=0.069$, $p>0.001$). There was moderate correlation between 10 joints GS, 10 joints PD and DAS28, but it was not statistically significant.

Table 1. Demographic and clinical characteristics of the patients (n=30)

Age (years) – mean (SD)	53.7±11.9
Female, n (%)	28 (93.3)
RA duration (months)	42 (67)
Rheumatoid factor positive, n (%)	15 (50)
CCP positive, n (%)	20 (66.7)
Smoking, n (%)	5 (16)
Prednisone, n (%)	11 (36.7)
DAS28 (ESR), (IQR)	3.8 (2.9)
TJC (0–10), (IQR)	2 (5)
SJC (0–10), (IQR)	0 (0)
10 Joint GS score, (IQR)	0 (1)
10 Joint PD score, (IQR)	0 (0)
ESH mm/h (IQR)	23.5 (21)
CRP mg/L (IQR)	4.6 (6.5)

SD: standard deviation, RA: rheumatoid arthritis, CCP: cyclic citrullinated peptide, DAS28: disease activity score in 28 joints, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, GS: gray scale, PD: power doppler, TJC: tender joint count, SJC: swollen joint count.

Conclusions: Evaluating the swollen joints with clinical examination and combining it with US is a sensitive method. As joint tenderness is a more subjective finding than the joint swelling, this may explain the lack of correlation between tender joints and ultrasonography findings. We suggest to use Gray scale US and PD as a complementary method in addition to clinical assessment of joint tenderness in patients with RA.

AB0219 INTENSIVE COMBINATION THERAPY WITH MEDICATION AND ORTHOPEDIC SURGICAL INTERVENTION FOR TREATING RHEUMATOID ARTHRITIS PATIENTS WITH DETERIORATED JOINTS

H. Ishikawa[1], A. Abe[1], Y. Nomura[1], S. Ito[1], T. Kojima[2], M. Kojima[3], N. Ishiguro[2], A. Murasawa[1]. *[1]Rheumatology, Niigata Rheumatic Center, Shibata; [2]Orthopedic Surgery, Nagoya University Hospital; [3]Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

Background: The treatment aim of rheumatoid arthritis (RA) is achieving and maintaining remission (REM) or low disease activity (LDA) via tight medical control. However, despite remarkable advances in medication, progressive deterioration and/or deformity of the joint sometimes occurs, if adequate medication is not administered in the early stage. Surgical reconstruction is still required in the joints with functional loss caused by structural damage. Recently, patients have expressed a desire to achieve functional REM with a higher quality of life (QOL) and improved mental wellness.
Objectives: The objective of this study was to clarify the effectiveness of intensive combination therapy with medication and orthopedic surgical intervention in patients who have already achieved REM or LDA.

Methods: A prospective cohort study was performed on 294 sites in 276 patients with functional loss due to RA scheduled to undergo primary elective surgery between October 2012 and September 2014. There were 99 sites in 96 patients (males: 10, females: 86) whose disease activity was REM or LDA just before surgery. In the REM/LDA group, the average age was 63 (29–82) years, and the average disease duration was 17 (2–60) years. The surgical site was the shoulder in 1 patient, elbow in 7, wrist in 21, hand in 24, hip in 5, knee in 10, ankle in 4, and forefoot in 27. The procedures performed included 38 alloarthroplasties, 41 arthroplasties without prosthesis, 19 arthrodesis, and 9 synovectomies. The patient-reported outcome (PRO) was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), Patient's General Health using visual analogue scale of 100 mm (Pt-GH), and the Disabilities of the Arm, Shoulder and Hand (DASH) for the upper extremity surgery. The Time Up &Go test (TUG) was administered for patients receiving lower extremity surgery. The disease activity was assessed based on the 28-joint Disease Activity Score using C reactive protein (DAS28-CRP). All of these items were investigated just before surgery (baseline) and again at 6 and 12 months after surgery.

Results: On the whole, the physical function (HAQ-DI, DASH, TUG), QOL (HAQ-DI, EQ-5D, Pt-GH), mental wellness (BDI-II, Pt-GH), and disease activity (DAS28-CRP)[1)] were significantly improved at 6 and 12 months after surgery compared to baseline ($p<0.01$). In the REM/LDA group, a significant improvement was noted in the physical function (DASH, TUG) and QOL (EQ-5D) at 6 and 12 months after surgery; however, we did not observe any significant changes in any other items (Table 1).

Table 1: Outcome of combination therapy with medication and orthopedic surgical intervention

		HAQ-DI	EQ-5D	BDI-II	Pt-GH mm	DASH (UE)	TUG (LE) sec	DAS28-CRP
Total n=276 (UE: n=151, LE: n=125)	baseline	1.08 (0.74)	0.69 (0.11)	13.0 (8.7)	39 (25)	43.8 (22.2)	13.0 (9.5)	3.1 (1.0)
	PO# 6mos.	1.00** (0.78)	0.74** (0.14)	11.7** (8.2)	26** (21)	37.3** (29.1)	10.5** (5.4)	2.4** (1.5)
	PO# 12mos	0.98** (0.78)	0.75** (0.14)	11.6** (8.5)	27** (21)	36.2** (23.0)	10.7** (7.0)	2.4** (0.8)
REM+LDA n=96 (UE: n=50, LE: n=46)	baseline	0.84 (0.63)	0.73 (0.13)	11.0 (8.1)	18 (18)	35.2 (20.9)	9.8 (3.2)	2.1 (0.4)
	PO# 6mos.	0.81 (0.67)	0.79** (0.15)	9.9 (7.7)	18 (16)	30.2** (18.9)	9.0** (2.6)	1.9** (0.6)
	PO# 12mos	0.83 (0.70)	0.79** (0.16)	10.1 (8.1)	18 (18)	29.9** (20.3)	9.0** (3.0)	1.9 (0.6)

Mean(SD), **: p<0.01 compared to baseline

Conclusions: Achieving REM or LDA is not the ultimate goal of treatment for patients with functional loss caused by structural damage. Further "wellness" can be achieved by surgical intervention. Intensive combination therapy with medication and orthopedic surgical intervention is effective in improving the QOL and mental health as well as the physical function. Such intervention can also ameliorate the disease activity.

AB0220 THE PROMISE OF ULTRASOUND GUIDED MINIMALLY INVASIVE SYNOVIAL BIOPSIES IN THE UNITED STATES

A.M. Mandelin[1], P. Homan[2], C.M. Cuda[1], S.T. Dominguez[1], S.L. Bridges[3], J.M. Bathon[4], J. Atkinson[5], D. Fox[6], E.L. Matteson[7], C.D. Buckley[8], C. Pitzalis[9], D. Parks[5], L.B. Hughes[3], L. Geraldino-Pardilla[4], R. Ike[10], K. Wright[7], A. Filer[8], S. Kelly[9], E. Bacalao[1], E.M. Ruderman[1], R. Pope[1], H. Perlman[1], D.R. Winter[1]. *[1]Northwestern University, Chicago, United States; [2]Medicine/Rheumatology, Northwestern University, Chicago; [3]UAB, Birmingham; [4]Columbia University, New York; [5]Washington University, St. Louis; [6]Medicine/Rheumatology, University of Michigan, Ann Arbour; [7]Mayo Clinic, Rochester, United States; [8]University of Birmingham Research Laboratories, Birmingham; [9]Queen Mary University of London, London, United Kingdom; [10]University of Michigan, Ann Arbour, United States*

Background: Currently we are in the golden age of therapy for patients with rheumatoid arthritis (RA). However, currently there exists no available assay to predict the response to a particular therapy for an individual patient. Today, rheumatologists do not have information at han for therapeutic decisions. It is clear that the target organ in RA patients, i.e. the synovium, has the potential to unlock the secret for determining therapeutic response. Ideally, a sufficient synovial sample would be obtained from each patient to perform histology, sorting of individual cell populations and transcriptional analyses.

Objectives: Our goal is to establish a minimally invasive ultrasound guided synovial biopsy program in the United States to obtain synovial tissue for determining therapeutic response.

Methods: Rheumatologists from six Universities in the United States were trained in ultrasound guided minimally invasive synovial tissue biopsy procedures. Only patients with a grey scale synovitis score of 2 or greater were selected. A disposable semi-automatic-guillotine type biopsy needle (Quick-Core) was utilized for all patients and 25/26 patients had the biopsy performed on the wrist. Histology was performed on whole tissue. RNA was extracted from whole tissue and from FACS sorted macrophages in order for RNA sequencing (RNA-seq) analysis to be performed.

Results: Our group has already performed over 26 minimally invasive ultrasound guided synovial tissue biopsies on RA patients with active disease. We had minimal adverse effects and patients tolerated the procedure very well. At least 6–12 needle biopsies of synovial tissue were obtained via biopsy per patient. A minimum of 4 needle biopsies were placed in formalin and synovial lining was confirmed via histologic analyses. The remaining pieces were used to prepare libraries for RNA-seq. We observed comparable RNA integrity numbers, a measure of RNA quality, between the whole synovial tissue from RA (biopsy obtained) and OA (surgically-obtained) patients. OA patients segregated together transcriptionally, while RA patients are more heterogeneous as demonstrated via RNAseq analysis. We also optimized a protocol for digestion of synovial tissue biopsies for isolation of macrophages. We identified genes differentially associated with macrophage activity in RA versus OA synovial macrophages that were not evident in the whole tissue transcriptional profile.

Conclusions: Ultrasound guided synovial tissue biopsies are feasible in the United States. Based on our recent success using minimally invasive ultrasound guided synovial biopsies, we believe that this procedure coupled with cutting-edge technologies will provide the critical information to rheumatologists to establish precision based medicine as a reality for RA patients.

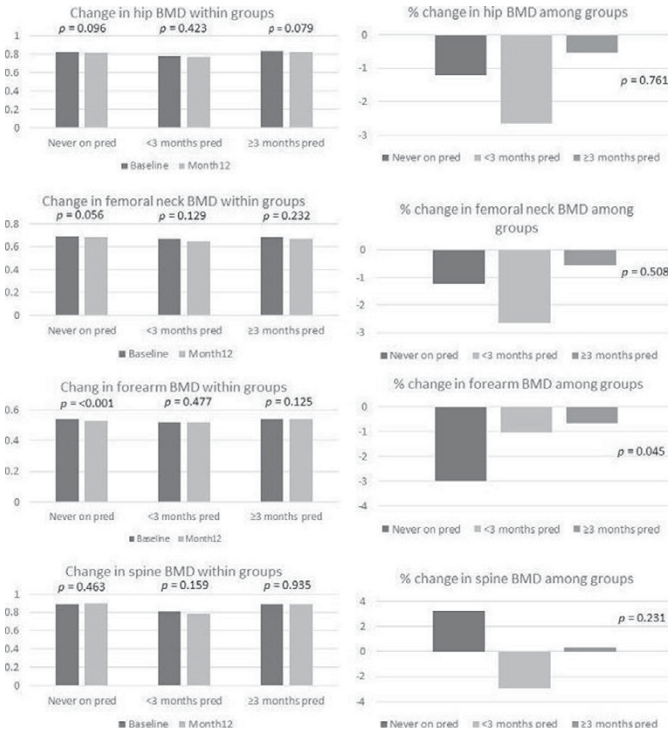
AB0221 IMPACT OF SMALL TO MEDIUM DOSE OF PREDNISOLONE ON BONE MINERAL DENSITY AMONG EARLY RHEUMATOID ARTHRITIS PATIENTS

H.M. Lam[1], M.C. Wan[2], L.S. Tam[1] on behalf of CRYSTAL study group, The Hong Kong Society of Rheumatology. *[1]Dept. of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin; [2]Dept. of Medicine, Ruttonjee Hospital, Wanchai, Hong Kong*

Background: Recent randomized trials in rheumatoid arthritis (RA) using low to medium dose of corticosteroid showed that bone mineral density (BMD) loss over 2 years was not significantly different from that with placebo. Another study in early RA and undifferentiated arthritis even showed a positive correlation between cumulative glucocorticoid (GC) dose with an increase in BMD at the ultradistal forearm. Whether the use of prednisolone (pred) can prevent bone loss in early RA patients remained controversial.

Objectives: The aim of this study was to investigate the impact of small dose pred (≤10mg/day) on BMD in early RA patients.



Methods: Data from 107 patients ((age: 53.3±11.92 years; females: 79 [73.8%], median disease duration at entry: 7-month (IQR, 4–12)) from the Hong Kong early arthritis registry (Clinical Rheumatology Systematic Treat to Target in Asia Leadership [CRYSTAL] project)were analyzed. In this register, clinical and treatment information were recorded systematically, including cumulative GC dose. Hip, spine and forearm BMDs were measured by duel-energy X-ray absorptiometry (DXA) at baseline and month 12. Patients were categorized into three groups according to pred use (never/<3/≥3 months) during the first year of follow-up. Patients who ever took>10mg/day of pred were excluded. The change in BMD was compared between groups and between the two time points.

Results: The baseline characteristics of patients were shown in Table 1. Patients

Table 1. Baseline characteristics

	Duration of pred use			
	Never (n=58)	<3 months (n=8)	≥3 months (n=41)	*p*
Female	46 (79.3%)	5 (62.5%)	28 (68.3%)	0.249
Age (years)	50.66±11.86	48.25±16.4	57.61±10.24	0.004
BMI (kg/m^2)	22.80±3.56	22.27±2.19	23.55±3.84	0.496
RF+ve	46 (79.3%)	6 (75.0%)	32 (80.0%)	0.950
AntiCCP+ve	41 (83.7%)	4 (80.0%)	31 (83.8%)	0.976
Osteoporosis	14 (24.1%)	2 (25.0%)	14 (34.1%)	0.540
Disease duration	10.80±11.41	7.49±3.99	6.73±6.11	0.032
Tender joints	6.77±5.19	6.25±4.17	9.85±7.92	0.218
Swollen joints	4.05±3.70	4.13±2.85	5.98±5.17	0.146
ESR (mm/1st hr)	56.93±35.62	40.75±18.97	62.20±35.72	0.387
CRP (mg/L)	15.18±21.68	14.8619.56	27.31±34.77	0.265
DAS-CRP	4.28±1.20	4.40±1.03	4.95±1.41	0.042
DAS remission	3 (5.3%)	0 (0.0%)	2 (4.9%)	0.436
Pred	0 (0.0%)	5 (62.5%)	25 (61.0%)	<0.001
Osteoporotic drug	0 (0.0%)	0 (0.0%)	2 (5.6%)	0.172
DMARDS	30 (54.5%)	4 (57.1%)	13 (36.1%)	0.332
Biologics	0 (0.00%)	0 (0.00%)	0 (0.00%)	–
NSAID	40 (72.7%)	5 (71.4%)	28 (77.8%)	0.766

who required ≥3 months of pred treatment are older, with a shorter disease duration and a higher disease activity. Significant differences in the percentage change of BMD in forearm was found among the groups (Pred never/Pred<3 months/Pred≥3 months: -2.99±4.21/-1.05±3.10/-0.65±3.45, p=0.045). Post-hoc analysis revealed that the percentage reduction of forearm BMD was significantly less in the Pred ≥3 months group compared to the Pred never group (p=0.043). After adjusting for age, gender, disease duration and baseline DAS-CRP, the changes in forearm BMD was still significantly different among the three groups (p=0.015). No significant differences in the changes of hip and spine BMD were observed. Significant changes in forearm BMD were observed between baseline and month 12 only in the Pred never group (0.54±0.08/0.53±0.0 p<0.001,graph1).

Conclusions: Small to medium dose of prednisolone might protect bone loss in forearm among early RA patients. These results need to be further validated.

AB0222 THE SERUM ANTI-CITRULLINATED PROTEIN/PEPTIDE ANTIBODIES IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

H. Zeng. *Department of Pediatric Allergy, Immunology and Rheumatolog, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: To investigate the diagnostic value and prognostic usefulness of anti-citrullinated protein/peptide antibodies (ACPA) in children with juvenile idiopathic arthritis (JIA).

Methods: The presence of ACPAs in the serum samples from 81 JIA patients were determined using Anti-CCP IgG, CCCP3.1 IgG and IgA ELISA. Citrullinated Protein Antibodies, Anti-MCV, and Aeskulisa RA/CP-Detect which coated various citrullinated antigen substrates: synthetic cyclic peptide, recombinant rat filaggrin, mutated human vimentin, and IgG-derived peptides. 55 children with other joint diseases and 49 healthy donors were control groups. The diagnostic performance of ACPAs was analyzed and correlations between ACPAs and radiological damage were evaluated.

Results: CPAs in 8.8–28.4% of JIA group were detected with specificity of 84.6–98.1%. ACPAs could be seen in all subtypes of JIA, and high levels of ACPAs were particularly found in the RF positive JIA patients No healthy control had increased ACPA tested for CCP, CCP3.1, and CPA, whilst 3and 2 of healthy controls were found positive to MCV and RA/CP, respectively. The presence of ACPAs correlated more frequently with the presence of RF (P<0.05). The ACPA positivities in 18 JIA patients with radiological damage were 27.8–55.6%, which higher than that in patients without damage, and of the ACPA (CCP, CCP3.1, CPA, or MCV) positive JIA patients, 62.5%, 62.5%, 52.9%, 43.5% respectively had radiological damage, which significantly higher than that in JIA patients without ACPA (P<0.05).

Conclusions: This study confirms the main presence of ACPAs in children with polyarticular JIA, especially those with RF positive using ELISA based methods, and ACPAs relate significantly with joint erosions in JIA.

AB0223 PROGNOSTIC FACTORS FOR RADIOGRAPHIC DAMAGE IN PATIENTS WITH SERONEGATIVE RHEUMATOID ARTHRITIS

H.Y. Lee[1], E.-J. Park[2], W.S. Jeong[2], J. Kim[2]. *[1]Department of Medicine; [2]Dvision of Rheumatology, Department of Medicine, Jeju National University Hospital, Jeju-si, Jeju-do, Korea, Republic Of*

Background: Long since it have been suggested that seronegative rheumatoid arthritis (RA) represents a clinical entity quite distinct from that of seropositive RA. However, analytical studies dedicated to clinical outcomes regarding radiographic progression and risk factors for that are scarce[1,2].

Objectives: The aim of this study is to evaluate radiographic outcome and prognostic factors for radiographic damage in patients with seronegative RA.

Methods: RA pateints reportedly seronegative for both rheumatoid factor and anti-cyclic citrullinated peptide antibody who were seen at Jeju National University Hospital in South Korea between August 2003 and December 2016, and followed-up at least 2 years were included. Medical records, laboratory and radiographic data was retrospectively analyzed and multivariate analysis was performed to evaluate prognostic factors for radiographic damage in patients with seronegative RA.

Results: One hundred six patients with seronegative RA were observed and 16 (15.1%) patients demonstrated newly-developed joint damage during follow-up period. Age at diagnosis was 38.9 years and 64 (60.4%) patients were female. Symptom duration at diagnosis was 1.1 years and follow-up duration was 4.4 years. Baseline characteristics including sex, symptom duration, smoking status, number of active joints, acute phase reactant, joint erosion at diagnosis were not significantly different in patients with joint damage compared to those without joint damage. Joint erosion at diagnosis and smoking status were associated with radiographic damage in seronegative RA adjusting age, symptom duration, ESR, CRP values at diagnosis, and follow-up duration, whereas it was not statistically significant (adjusted odds ratio 1.45;p=0.061 and 1.58;p=0.072 respectively).

Conclusions: Our study demonstrated a rate of joint damage in patients with seronegative RA comparable to recent studies. Joint erosion at diagnosis and smoking status showed tendency to correlate with progression of radiographic damage in patients with seronegative RA. A large comparative study dedicated to this issue in seronegative RA is required.

AB0224 SIMULATION FOR CHOICE OF BDMARDS AND TSDMARDS IN ORDER TO SUCCESS FOR THREE-YEAR SURVIVAL IN RHEUMATOID ARTHRITIS TREATMENT

I. Yoshii. *Rheumatology, Yoshii Hospital, Shimanto City, Japan*

Background: In rheumatoid arthritis (RA) treatment, bDMARDs and tsDMARDs (BIO) perform tremendous disease activity control, however, its effectiveness is uncertain and unstable, because their survival ratio is not good enough to tolerate. If more right choice is done in guided by some simulation.

Objectives: This study aims more than 80% of three-year survival ratio (SR@3Y) in simulating risk of BIO by using statistical clinical data and post marketing surveillance (PMS) data with Bayes estimation.

Methods: Infection risk and survival risk were harvested from Japanese PMS data, and our clinical data. All our cases were calculated with last observation carried forward method (LOCF). If BIO was continued for more than three years or discontinued by attaining clinical remission, it was evaluated as success, while other cases were evaluated as failure. Patient's clinical data and general status were calculated for each case, and SR@3Y for success was statistically evaluated with Binary Logistic Analysis for success. Evaluation methods for parameters were divided according to general risk and drug specific possibility. If calculated general risk went above 0.2, selection of BIO was discarded. In other case which had gone below, choice of BIO is done in according to point that had been cumulated by drug specific possibility in choosing what took maximum calculated expectation value.

If chosen drug have matched used BIO, it was evaluated as true, if not, it was evaluated as false, while if true case was in success, it was evaluated as true success, and if in failure, it was evaluated as true failure, while false case was in success, it was evaluated as false success, and if in failure, it was evaluated as true failure. Sensitivity in success cases and specificity in failure cases was evaluated in patients in whom BIO was administered. Statistical evaluation was done with chi-square test.

Results: 188 cases have had enough data for simulating. In these, 108 were success and 80 were failure. In success cases, simulated TNF inhibitor (TNF-i) counted 73, Tocilizumab (TCZ) counted 11, Abatacept (ABT) counted 12, and

Tofacitinib (TOF) counted 2 while real chosen cases were TNF-i counted 65, TCZ counted 11, ABT counted 21, and TOF counted 11. Overall success ratio was 57.4%. In these cases, true choice had been done in 97 cases of 108. In failure cases, simulated TNF-i counted 44, TCZ counted 16, ABT counted 2, and TOF counted 1, while real chosen cases were TNF-i counted 49, TCZ counted 17, ABT counted 10, and TOF counted 4. True success counted 97, and false success counted 11, while false success counted 37 and true failure counted 54. Then, sensitivity was 89.8% and specificity was 67.5% (<0.01).

Conclusions: Drug choice of BIO supported with simulation was superior to real choice. If risk management was adequately performed, SR@3Y is expected more than 85%.

AB0225 CHARACTERISTICS OF MHAQ FOR UPPER AND LOWER EXTREMITY FUNCTION, AND RELATIONSHIP WITH AGE AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENT

I. Yoshii [1], T. Chijiwa [2]. [1] *Rheumatology, Yoshii Hospital, Shimanto City;* [2] *Rheumatology, Kochi Memorial Hospital, Kochi, Japan*

Background: Activity in daily living (ADL) is one of main target to maintain patient's quality of life in rheumatoid arthritis (RA) treatment. Modified Health Assessment Questionnaire (mHAQ) is a most popular index for ADL in routine practice. mHAQ is separated according to function of extremity; namely the first four categories are reflections of upper extremities (mHAQ-UE), while the latter are of lower extremities (mHAQ-LE). If function of each extremity is separately disabled, it should be reflected on each part of mHAQ.

Objectives: mHAQ was separately investigated in order to evaluate characteristics of each part of mHAQ.

Methods: 964 RA patients since January 2010 had been treated. In these, patients who have been treated consecutively for more than five years at December 2016 were recruited in this study. Patient who had been operated musculoskeletal surgery was eliminated. mHAQ, mHAQ-UE and mHAQ-LE, and 28-joint disease activity index with C-reactive protein (DAS28-CRP) were measured every time since first consult. Average value of these parameters including Sharp/van der Heijde Score (SvdHS) were calculated annually. Relationship between each of mHAQ and parameters for each year were evaluated used with multiple linear regression analysis.

Predominant extremity in mHAQ was evaluated as in what upper extremity predominant (G-UE), lower extremity predominant (G-LE), same weight (G-EV), and both of them were zero (G-Z). Changes of the evaluation from first to the last period were evaluated year by year.

Results: One hundred and two male and three hundred and thirty-three female, totally four hundred and thirty five patients were picked up. Their average value of age, SvdHS, DAS28-CRP, mHAQ, mHAQ-UE, and mHAQ-LE were 64.65, 52.1, 2.96, 0.439, 0.386 and 0.491 at first consult, and 71.05, 52.1, 1.72, 0.425, 0.344, and 0.505 at last time follow up, respectively. Both of mHAQ-UE and mHAQ-LE have demonstrated significant regression with both age and SvdHS throughout treatment, while not significant with DAS28-CRP, however, mHAQ-UE correlated with tenderness joint except of knee, and mHAQ-LE have correlated with swelling of the knee joint significantly.

G-UE had counted for 85 patients, G-LE for 136, G-EV for 49, and G-Z for 165 at first consult. Once evaluation had changed, then have continued to the last in all patients. G-UE resulted in G-UE for 83, while G-LE for 2 at last. G-LE resulted in G-LE for 133, G-Z for 2, and G-EV for 1. G-EV resulted in G-LE for24, G-UE for 7, and G-EV for 18. G-Z resulted in G-Z for 137, G-LE for 19, G-UE for 4, and G-EV for 5. G-EV to G-EV demonstrated significant higher DAS28-CRP improvement from first to the last than to G-LE, and to G-UE, and G-EV to G-LE demonstrated significant higher DAS28-CRP improvement than to G-UE, although no significant difference demonstrated for mHAQ improvement among groups. G-UE to G-LE demonstrated significant higher DAS28-CRP improvement than to G-UE, as well as G-UE to G-LE demonstrated significant higher mHAQ improvement than to G-UE.

Conclusions: From these results, it is suggested that mHAQ-UE and mHAQ-LE move under common influence. However, mHAQ-UE change may be reflected by upper exrtremities joint tenderness, while mHAQ-LE can move more sensitively with knee swelling. Tight disease activity control may reduce mHAQ both of them, however, reduces more predominantly with mHAQ-UE than mHAQ-LE.

AB0226 FUNCTIONAL DISABILITY IN RA PATIENTS TREATED WITH BIOLOGICS: HUR-BIO REAL LIFE RESULTS

A. Sari, B. Armagan, A. Erden, L. Kilic, O. Karadag, A. Akdogan, S. Apras Bilgen, S. Kiraz, U. Kalyoncu, I. Ertenli. *Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Rheumatoid arthritis (RA) is a chronic, erozive disorder which may lead to permanent joints damage. Health assessment questionnaire (HAQ) is frequently used for evaluating functional disability in RA patients.

Objectives: The aim of this study is to determine the effect of biologic treatment on functional disability in RA patients.

Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective, monocentric database of biological treatments including 1229 RA patients by August 2016. 523 patients in whom HAQ assessment before biologics was avaliable, were recruited in this retrospective analysis. HAQ score $\geq$1.0 was defined as severe functional disability.[1] HAQ assesment at last follow-up visit were evaluated. Demographic,clinical and serologic data of patients were also collected. Improvement of HAQ score 0,22 points or more was considered as clinically significant response to treatment.[1]

Results: Among 523 patients (80.5% female), mean age was 52.6±12.5 and mean disease duration was 9.4±7.3 years. Seropositivity for RF and/or CCP was present in 67.2% of patients. At baseline visit, HAQ score was $\geq$1.0 in 268 patients (51.2%). Baseline and last follow-up HAQ scores were 1.07±0.62 and 0.64±0.57. Minimal clinically significant improvement of HAQ score was observed in 238/377 patients (63.1%). Clinically significant response was more frequent in patients with baseline HAQ score of $\geq$1 (153/195 (78.4%) vs 85/182 (46.7%), $p<0.001$). Table 1 represents features of patients according to baseline HAQ score. Mean follow-up time was 16.4±16.4 months. Data of at least one visit was available for 377 (72.0%) patients.

Table 1. Comparison of demographic an clinical data of patients according to baseline HAQ score

	HAQ $\geq$1 (n=268)	HAQ<1 (n=255)	p
Age, mean ± SD	55.1±12.3	50.0±12.3	<0.001
Disease duration (years), mean ± SD	10.2±8.0	8.6±6.3	0.01
BMI, mean ± SD	31.3±6.4	28.9±5.9	<0.001
High school or collage graduate n (%)	68 (25.3)	110 (43.1)	<0.001
Smoking (current or previous),n (%)	95 (35.4)	123 (4.,4)	<0.001
Hypertension, n (%)	101 (37.7)	59 (23.1)	<0.001
Patient global assesment VAS, mean±SD	6.8±1.4	5.7±1.8	<0.001
Fatigue VAS, mean ± SD	6.7±2.0	5.0±2.8	<0.001
Pain VAS, mean ± SD	7.1±1.6	6.1±2.1	<0.001
Biologic switch, n (%)	63 (23.5)	41 (16.1)	0.033

Conclusions: Functional disabilty was observed approximately half of patients. Clinically significant improvement was more frequent among patients with higher baseline HAQ scores particularly. Biologic treatment seems to be provide significant functional improvement. However significant functional disability persists in one fourth of patients.

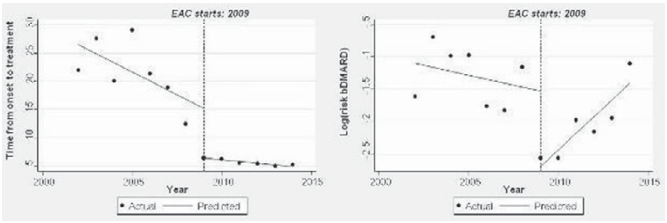
AB0227 IMPACT OF EARLY ARTHRITIS CLINIC ON THE RATE OF TREATMENT WITH BIOLOGICS IN RHEUMATOID ARTHRITIS: INTERRUPTED TIME SERIES ANALYSIS

I. Farina, E. Galuppi, G. Ciancio, C. De Giorgio, C.A. Scire', M. Govoni. *Department of Medical Sciences, UOL Rheumatology, Section of Haematology and Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna, Ferrara, Italy*



Background: Early diagnosis is one of the mainstay of rheumatoid arthritis (RA) management. Early diagnosis reflects on early treatment, better response with reduction of long-term detrimental disease outcomes. Early arthritis clinics (EAC) are the healthcare services devoted to facilitate early diagnosis and optimize treatment of early onset inflammatory arthritis. Despite the a priori beneficial potential of EAC, no strong experimental data support EAC efficacy. Interrupted time series analysis is one of the "next best" approaches for dealing with interventions when randomisation is not possible or clinical trial data are not available.

Objectives: To evaluate the impact of the implementation of an EAC in terms of probability of starting second-line biologic DMARDs, using a quasi-experimental approach.

Methods: RA patients fulfilling 1987 ACR criteria who attended the outpatient rheumatology clinic (RC) between 2002 and 2008 and the Early Arthritis Clinic between 2009 and 2014 were retrospectively analyzed. The EAC was developed as a healthcare service integrating primary care with tertiary rheumatology care to provide early referral of suspected inflammatory arthritis and tight monitoring and standardized therapeutic approach according to "treat to target" (T2T) strategy and EULAR guidelines to early RA. The two sub-cohorts were compared in terms of: 1) lag time from symptoms onset to RA treatment with DMARDs; and 2) risk of treatment with bDMARDs at 24 months. Interrupted time analysis was performed to compare lag time from onset to treatment and log-transformed 24-month risk of biologics periods before the implementation of the EAC with subsequent periods.

Results: A total of 353 RA patients were included: 208 (mean±SD age 58.7±12.6 years, 164 F, baseline DAS28 4.76±1–23) followed in RC and 145 (mean±SD age 58.8±14.9 years, 106 F, DAS28 5.09±1.31) in EAC. Lag time from symptoms onset to treatment resulted significantly lower (median [IQR] months 4 [2–7] vs 12 [5–24]; $p<0.0001$) in patients managed in EAC compared with RC. Within 24 months a biologic therapy was started in 62/208 (29.8%) of patients followed in RC, and 21/145 (14.5%) in EAC group (p=0.001), along with an increased remission rate at 24 months (43% vs 62%, $p<0.001$). Analyzing the time series "interrupted" by the implementation of the EAC, comparing before and after

intervention periods, a significant change in slope was observed for both lag time (coefficient -8.85 [95% CI -17.25, -0.44], p=0.04) and risk of treatment with biologics (coefficient -1.17 [95% CI -2.09, -0.24], p=0.01). As expected in more recent years - according to a T2T approach - a monotonous positive trend in percentage of patients treated with biologics is also observed in EAC (coefficient 0.31 [95% CI 0.05, 0.58]).

Conclusions: The implementation of an EAC that integrates care and applies tight control and standard of care, leads to early diagnosis and treatment and may lower the need – overtime - of second-line biologic drugs, with a significant impact both on individuals and health care systems.

AB0228 IMMUNOLOGICAL APPROACH TO THE DIAGNOSIS OF LESIONS OF THE NERVOUS SYSTEM IN PATIENTS WITH RHEUMATOID ARTHRITIS

I.P. Gontar[1], E.V. Baranov[1], L.A. Maslakova[1], A.S. Trofimenko[1], O.V. Paramonova[2]. *[1]Clinical Immunology Lab, FSBSU Research Institute for Clinical and Experimental Rheumatology; [2] Department of Hospital Therapy, Volgograd State Medical University, Volgograd, Russian Federation*

Background: Although S100 proteins represent 40% of the neutrophil cytoplasmic proteins, their physiological and pathological functions are still unclear. S100 protein concentrations are dramatically enhanced in synovial fluid and synovium of patients suffering from rheumatoid arthritis (RA). Their expression seems to correlate with disease activity and joint damage [1].
Objectives: Improvement of immunological detection of neurological involvement in RA by means of polyacrylamide magnetic beads with immobilized S- 100 protein.
Methods: The research was carried out in agreement with the principles of the World Medical Association Declaration of Helsinki. The informed consent had been signed by all involved persons, another obligate requirement was age 18 years or more. The patients were from the rheumatologic wards in Volgograd Municipal Hospital No. 25 and Volzhsky Municipal Hospital No. 1. Diagnosis of RA was established by ACR-EULAR criteria (2010), RA activity was evaluated using DAS28. Serum anti-S-100 protein antibodies were measured by ELISA, with S-100 protein immobilized on polyacrylamide magnetic beads as an antigen. The antibody concentrations were expressed as optical density units (ODU) and were considered positive if the cutoff value ($M+2\sigma$ of the reference group, 0.050 ODU) was exceeded. The results were expressed as mean$\pm\sigma$, differences were considered significant when $p<0.05$. Pearson correlation coefficient (r) was also used.
Results: 40 healthy persons (29 mans and 11 women), and 95 female patients with RA and the neurological signs, appeared during active phase of the disease, were recruited for this study. Mean age of the healthy controls was 36±7 years, and for the RA group it was equal to 55±11 years. Mean RA duration was 4.2±2.9 years. 13 patients had low, 52 – moderate, and 8 – high disease activity. The most common types of neurological involvement were mononeuropathy (n=29), polyneuropathy (n=65), radiculopathy (n=80); cervicocranialgias (n=51), and trigeminal neuralgias (n=14). The symptoms of central nervous system damage (TIA, seizures, cerebellar ataxia, dysarthria) were found in 21 patients. In RA group, anti-S-100 protein antibodies were detected in 11 (32.4%) cases, with mean concentration 0.078±0.028 ODU. The patients with different neurological signs had mean anti-S-100 protein antibody concentration 0.138±0.046 ODU, the subgroup without any neurological signs had 0.060±0.024 ODU (p=0.022). In all cases analyzed index correlated with the degree of activity of the pathological process. High levels of antibodies to S-100 protein in RA associated with central nervous system (CNS) and peripheral nervous system (PNS).
Conclusions: We found an association between neurological involvement in RA and elevation of anti-S-100 protein antibody concentrations. These findings give us an opportunity to improve the diagnosis of minor neurological damage in RA and thus to make more precise adjustment of the treatment.

AB0229 DOES EXPRESSION LEVEL OF VIP AND ITS RECEPTORS CORRELATED WITH DISEASE SEVERITY IN EARLY ARTHRITIS?

I.V. Seoane[1], A. Lamana[2], M. Carrión[1], Y. Juarranz[1], R. García-Vicuña[2], I. González-Álvaro[2], C. Martínez[3], R.P. Gomariz[1]. *[1]Dpto. Biología Celular, Facultad de Biología, Universidad Complutense de Madrid; [2]Rheumatology Service, Hospital Universitario de la Princesa, Instituto de Investigación Sanitaria Princesa; [3]Dpto. Biología Celular, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain*

Background: Rheumatoid Arthritis (RA) is a heterogeneous disease, not only in the course but also in the response to treatment (1). So, a major challenge is the classification of patients according to the disease severity/mildness to apply customized therapeutic strategies. Low vasoactive intestinal peptide (VIP) serum levels are associated to a worse clinical course in Early Arthritis (EA) (2) and the expression of its receptor VPAC1 is associated with disease activity (3).
Objectives: To identify in an Early Arthritis cohort associations between clinical parameters of severity and serum VIP levels or expression of their receptors VPAC1 and VPAC2.
Methods: We studied 212 patients from the PEARL (Princesa Early Arthritis Registry Longitudinal) study. Follow-up includes five visits (0, 6, 12, 24 and 60 months) in which we collect demographic, clinical, laboratory, therapeutic and radiological data, as well as biological samples. Since there is not a global disease severity variable for RA, we stratified severity as follows: A) remission after two years of follow-up defined as SDAI <3.3 (4). B) Global Disease Assessment by Physician >75th percentile of the population (severe disease) or >25th percentile (mild disease). C) Median value in our population of the Δ erosion score (SvdH method assessed in hands) after two years of follow-up. VIP levels were determined by enzyme immunoassay and mRNA expression levels of VIP receptors in PBMCs by real-time PCR. To analyze the association between severity/mildness and the expression of VIP/VPAC we use several parametric and non-parametric hypothesis testing (t-test, ANOVA and Kruskal-Wallis) using Stata 12 for Windows (StataCorp PL, College Station, TX, USA).
Results: We observed a trend towards higher baseline VIP serum levels in patients who reached remission in terms of SDAI (p=0.1169). Patients no achieving remission showed lower VPAC1 expression (p=0.0494). Severe patients defined by GDAPh displayed a clear trend to lower VIP levels (p=0.081). Those patients also exhibited significant lower VPAC1 expression levels (p=0.0276). Concerning bone erosion score, we did not observe a significant association with VIP levels; interestingly we found that those patients classified as “severe” by erosion score displayed lower VPAC1 expression levels (p=0.0722) and higher levels of VPAC2 (p=0.0253).
Conclusions: VIP serum levels and VPAC1 and 2 receptors expression are associated with a more severe phenotype in EA patients stratified by SDAI, GDAPh and bone erosion.

AB0230 POLYMORPHISM OF CYTOTOXIC T-LYMPHOCYTE 4 +49A/G IS ASSOCIATED WITH EARLY PRESCRIBING THE BIOLOGICAL THERAPY IN ACTIVE EARLY RHEUMATOID ARTHRITIS PATIENTS (ERA PTS) REFRACTORY TO THE PREVIOUS SUBCUTANEOUS METHOTREXATE (SC MTX) MONOTHERAPY

I. Guseva[1], A.S. Avdeeva[1], E.L. Luchikhina[1], D.D. Abramov[2], N.V. Demidova[1], E.N. Alexandrova[1], A.A. Novikov[1], M.Y. Krylov[1], E.Y. Samarkina[1], D.Y. Trofimov[2], D.E. Karateev[1], E.L. Nasonov[1]. *[1]V.A.Nasonova Research Institute of Rheumatology; [2]NRC Institute of Immunology of FMBA of Russia, Moscow, Russian Federation, Moscow, Russian Federation*

Background: Monotherapy with MTX is the first step of RA therapy as recommended by EULAR. According to “Treat to Target” (T2T) strategy principles insufficient response to MTX requires prompt switch to a combination therapy with biological agents.
Objectives: To find out whether polymorphisms of immune response genes are associated with early prescribing the biological treatment in eRA pts, refractory to the SC MTX monotherapy.
Methods: By January 2014, 210 pts with RA were included in the REMARCA study (Russian InvEstigation of MethotrexAte and biologics in eaRly aCtive inflammatory Arthritis), and 88 pts have passed the 12 months control point. All pts started SC MTX monotherapy with rapid up-titration of the dose from 10 to 25–30 mg/week. Therapy was revised every 3 months using DAS28, SDAI and CDAI indices. Combination with biologics (in most cases TNF inhibitors)

was used in 57 (65%) of pts at (median) 3 [3;6] month [1]. Retrospectively, 45 out of 88 active eRA pts (35 woman, mean age 53,5; 46–59,5 years, mean disease duration 7,0; 4,0–11,5 months, mean DAS28 5,8; 4,9–6,4, mean hs-CRP 27,0; 9,7–61,0 mg/l) were selected to evaluate the changes in cytokine profile in MTX-naive pts during SC MTX and SC MTX + adalimumab (SC MTX+ADA) therapy [2]. These 45 pts were genotyped for the following gene polymorphisms (SNPs): PTPN22 (+1858 C/T, rs2476601), CTLA4 (+49A/G, rs231775), TNFAIP3 (rs675520, rs6920220, rs10499194), IL6 (-174G/C, rs1800795), IL6R (+358A/C, rs8192284), TNFA (-308A/G, rs1800629), MCP1/ CCL2 (+2581A/G, rs1024611), IL10 (-592A/C, rs1800872, -1082 A/G, rs1800896), IL1A (-889C/T, rs1800587), IL1B (+3953C/T, rs1143634).

Results: By the end of 3 months of SC MTX therapy, 23 out of 45 eRA pts (51,1%) adequately responded to SC MTX (EULAR criteria) and continued on SC MTX monotherapy. In 22 pts (48,9%) SC MTX monotherapy failed, thus they were switched to SC MTX + ADA combination therapy. CTLA-4 gene polymorphism (+49A/G) was the only predictor for the administration of biological therapy in eRA pts, that was confirmed by a logistic regression analysis [OR=7,7 95% CI 1,4–40,9, p=0,017]. The carriers of at least one G allele (AG/GG genotypes) received the biological therapy more often than subjects with AA genotype (20/22, 90,9% and 13/23, 56,5% respectively). Moreover, the CTLA-4 (+49A/G) genotypes (AG/GG vs AA respectively) were associated with DAS28 (3,6±1,1 and 4,6±1,6, p=0,04), the number of tender joints (3,1±3,1 and 7,1±5,1, p=0,016), the number of swollen joints (2,7±2,5 and 5,3±4,9 p=0,024), SDAI (11,1±7,2 and 20,2±12,1, p=0,018), CDAI (10,6±7,1 and 18,6±10,6, p=0,025) and CRP (6,3±12,1 and 21,8±37,1 p=0,018) values after 3 months of SC MTX monotherapy.

Conclusions: Our data suggest that CTLA-4 (+49A/G) genetic polymorphism is associated with more severe rheumatoid arthritis and may predict the need for early administration of biological therapy.

AB0231 PHYSICIAN VISUAL ANALOG SCALE ESTIMATES FOR DAMAGE ARE HIGHER THAN FOR INFLAMMATION IN PATIENTS WITH OSTEOARTHRITIS AND ALSO IN PATIENTS WITH RHEUMATOID ARTHRITIS AT ALL LEVELS OF CLINICAL SEVERITY ACCORDING TO RAPID3

I. Castrejon, J. Chua, J.A. Block, T. Pincus. *Rheumatology, Rush University Medical Center, Chicago, United States*

Background: A visual analog scale (VAS) to estimate the patient's global status (DOCGL) often is the most efficient of all 7 RA core data set measures to distinguish active from control treatments in clinical trials[1]. DOCGL is designed to assess inflammatory activity, but it may be influenced variably in different doctors by irreversible joint damage and/or distress. Therefore, 3 additional 0–10 VAS have been developed to estimate levels of inflammation, damage, and distress that may impact DOCGL.

Objectives: To analyze 4 estimates for overall global, inflammation, damage and distress according to 4 RAPID3 (routine assessment of patient index data) severity categories in patients with RA or OA.

Methods: Patients seen at one academic clinical setting are assigned 4 0–10 VAS estimates: overall DOCGL, inflammation (reversible), damage (irreversible), and distress (symptoms explained by neither inflammation nor damage, eg, fibromyalgia). All patients complete a self-reported MDHAQ questionnaire as part of routine care. The MDHAQ includes 0–10 scores for physical function (FN), pain (PN), patient global estimate (PATGL), compiled into a 0–30 RAPID3. Patients with a primary diagnosis of RA or OA according to their rheumatologists were included. The percentage of RA and OA patients in each RAPID3 severity category was compared according to mean DOCGL and the 3 subscale estimates using chi-square and ANOVA.

Results: The study included 232 patients with RA and 274 with OA. Patients with OA were older than RA patients (66.5 versus 57.3, $p<0.001$) and had higher scores for RAPID3 (14.4 vs 11.7, $p<0.001$). A higher percentage of patients with OA had high RAPID3 severity compared with RA patients (66% vs 48%, $p<0.001$) (Table). DOCGL and each subscale estimate were higher according to each of 4 RAPID3 categories from remission to high severity in RA and OA (Table). The level of inflammation was higher in RA than in OA, but estimates for damage higher in OA than RA. However, estimates for damage were higher than for inflammation in RA in each RAPID3 category.

Conclusions: Physician VAS for inflammation, damage, and distress may supplement the overall physician global estimate as quantitative physician estimates of reversible findings, irreversible findings, and distress to support clinical management decisions. Estimates of joint damage are higher in OA than in RA, although higher than estimates of inflammation in both RA and OA, in patients in all 4 RAPID3 severity categories.

Table 1. Mean and SD for the four physician estimates according to RAPID3 categories in RA and OA patients

	RAPID3 Severity Categories				P
	Remission (<3)	Low (3–6)	Moderate (6–12)	High (>12)	
Rheumatoid Arthritis	N=45 (19%)	N=19 (8%)	N=57 (25%)	N=111 (48%)	
Overall DOCGL (0–10 scale)	1.7 (1.4)	2.7 (1.5)	3.3 (1.4)	5.1 (1.9)	<0.001
Inflammation (0–10)	1.3 (1.9)	1.4 (1.8)	1.6 (1.3)	3.3 (2.5)	<0.001
Damage (0–10)	1.7 (1.5)	2.9 (2.0)	2.9 (2.0)	3.7 (2.2)	<0.001
Distress (0–10)	0.2 (0.7)	0.3 (0.8)	0.4 (0.9)	1.6 (2.4)	<0.001
Osteoarthritis	N=14 (5%)	N=18 (7%)	N=60 (22%)	N=182 (66%)	
Overall DOCGL (0–10 scale)	1.3 (1.2)	2.5 (0.8)	3.2 (1.4)	4.7 (1.6)	<0.001
Inflammation (0–10)	0.4 (0.6)	0.7 (1.1)	0.8 (1.4)	1.0 (1.4)	0.25
Damage (0–10)	2.5 (1.5)	3.0 (0.9)	3.5 (1.5)	4.5 (1.8)	<0.001

AB0232 MINIMAL CLINICALLY IMPORTANT IMPROVEMENT (MCII) OF RAPID3 (ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3), AN INDEX OF ONLY PATIENT SELF-REPORT SCORES, PERFORMS SIMILARLY TO TRADITIONAL RHEUMATOID ARTHRITIS (RA) INDICES, DAS28 AND CDAI

I. Castrejon[1], M.M. Ward[2], M.J. Bergman[3], L.C. Guthrie[2], M.I. Alba[2], T. Pincus[1]. *[1]Rheumatology, Rush University Medical Center, Chicago; [2]Intramural Research Program, NIAMS/NIH, Bethesda; [3]Rheumatology, Taylor Hospital, Ridley Park, United States*

Background: No single "gold standard" measure is available to assess patients with rheumatoid arthritis (RA) in clinical trials and routine care, as in hypertension, diabetes, and other diseases. Therefore, an index of several measures, such as a DAS28 (Disease Activity Score-28) and CDAI (Clinical Disease Activity Index), based on 7 RA core data set measures; is needed. However, the only quantitative data in many (most) patients in routine rheumatology care are laboratory test results. RAPID3 (routine assessment of patient index data), which includes only patient self-report scores, is considerably more feasible than DAS28 or CDAI for routine care, distinguishes active from control treatments in RA clinical trials similarly and is correlated significantly with these indices. A minimal clinically important improvement (MCII) to interpret changes in clinical trials and clinical care has not been established for RAPID3

Objectives: To estimate MCII of RAPID3, and compare results to MCIIs of DAS28 and CDAI.

Methods: Post hoc analyses were performed of a reported longitudinal study of 250 patients with active RA (1). All 7 RA core data set measures were collected at baseline and after treatment escalation with prednisone 1 month later or with disease modifying medications or biologic agents 4 months later (1). Patient judgment of improvement in arthritis status was obtained as "improved", "the same" or "worsened", and analyzed in relation to changes in RAPID3, DAS28 and CDAI. RAPID3 is the sum of 3 0–10 measures: physical function on a HAQ recalculated from 0–3 to 0–10, pain and patient global estimate on 0–10 VAS (visual analog scales), total=0–30. DAS28-ESR (erythrocyte sedimentation rate) and CDAI were computed as described in the literature. Changes in all indices, standardized response means (SRM), MCIIs as changes that had a specificity of 0.80 for improvement based on receiver-operating characteristic curves, and MCII as a proportion of the maximum score were computed.

Results: Among 250 patients, 167 (66.8%) reported improvement. RA activity and SRMs improved similarly per the 3 indices (Table). ROC curve areas were ≥0.77 (Table). MCIIs with specificity for improvement of 0.80 were -3.5 for RAPID3, -1.17 for DAS28-ESR, and -12.5 for CDAI. MCIIs were in a similar range of 11.6% to 16.8% of maximum score (Table).

Conclusions: MCIIs for RAPID3, DAS28, and CDAI were in a similar range. Knowledge concerning MCII thresholds can improve interpretation of data from clinical trials and routine clinical care.

AB0233 REMISSION ACCORDING TO RAPID3 (ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3) IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY FROM ROUTINE CARE AT 3 USA SITES

I. Castrejon[1], M.J. Bergman[2], K.A. Gibson[3,4,5], Y. Yazici[6], J.A. Block[1], T. Pincus[1]. *[1]Rheumatology, Rush University Medical Center, Chicago; [2]Rheumatology, Taylor Hospital, Ridley Park, United States; [3]Rheumatology, Liverpool Hospital; [4]Ingham Research Institute, Liverpool; [5]University of NSW, Sydney, Australia; [6]Rheumatology, NYU Hospital for Joint Diseases, New York, United States*

Background: RAPID3 remission criteria provide similar results to DAS28 criteria, although less stringent compared to ACR/EULAR Boolean criteria. RAPID3 remission criteria are more feasible in routine care[1] and have been reported at 25% in patients from France[1] and 21% from Norway[2].
Objectives: We examined the proportion of patients in remission and 3 other severity categories according to RAPID3 at 3 sites at which MDHAQ is completed by all patients in routine care.
Methods: All patients seen at each rheumatology site complete an MDHAQ/RAPID3 at all visits in the waiting area as part of their routine care. The MDHAQ includes 0–10 scores for physical function, pain and patient global estimate, compiled into a 0–30 RAPID3, as well as scores for fatigue, RADAI self-report of painful joints, and demographic data. Physicians complete a global assessment (DOCGL) on a 0–10 visual analog scale (VAS). A random visit with complete questionnaire data for each RA patient from each site was included in the analyses. The proportion of patients in 4 RAPID3 categories, high severity (>12/30), moderate severity (6.1–12), low severity (3.1–6), and remission (≤3), was computed. MDHAQ demographic and clinical measures and DOCGL were compared in the 4 RAPID3 severity groups using chi-square and ANOVA tests.
Results: 420 RA patients from the 3 sites were analyzed. Remission rates according to RAPID3 severity ranged from 23% to 26%, similar to reported rates from France and Norway. Low severity ranged from 7–24%, moderate severity from 23–29% and high severity from 21–46%. Age and sex were similar in the disease severity categories at the 3 sites (Table). Patients in the moderate and high severity groups at each site had higher scores for fatigue, RADAI self-reported joint pain, and DOCGL.

Table 1. Mean (SD) for demographic and clinical characteristic of patients in remission versus other disease severity categories according to RAPID3 in each site. *p<0.001

	Remission (≤3)	Low (3.1–6)	Moderate (6.1–12)	High (>12)
Site 1 (N=137)	32 (23.4%)	11 (8%)	31 (22.6%)	63 (46%)
Female, n (%)	27 (84.4%)	9 (81.8%)	26 (83.9%)	59 (93.6%)
Age, yrs	58.5 (16.9)	57.9 (18.8)	56.8 (17.5)	55.6 (14.5)
Fatigue (0–10)	1.1 (1.5)	2.3 (2.0)	3.1 (2.1)	6.6 (2.3)*
Self-report RADAI (0–48)	1.9 (2.9)	5.0 (3.9)	7.5 (5.60	17.0 (9.2)*
DOCGL (0–10)	1.6 (1.2)	3.7 (1.7)	3.2 (1.4)	5.3 (1.9)*
Site 2 (N=144)	37 (25.7%)	35 (24.3%)	42 (29.2%)	30 (20.8%)
Female, n (%)	28 (75.7%)	22 (62.9%)	34 (80.9%)	24 (80%)
Age, yrs	56.6 (16.9)	62.0 (14.6)	62.3 (14.7)	62.5 (15.9)

AB0234 ORAL CONTRACEPTIVES, MENOPAUSE AND RHEUMATOID ARTHRITIS IN KOREAN WOMEN: A NATIONWIDE STUDY

J.H. Jung, H.S. Jeong, J.-H. Kim, G.G. Song, S.J. Choi, Y.H. Seo. *Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease with a multifactorial etiology. Hormonal factors, ethnicity and their interaction may result in the development of RA.
Objectives: We investigated the effects of oral contraceptives (OCs) and menopause on RA in South Korea women using nationwide data.
Methods: Data were collected from the 2008–2012 Korea National Health and Nutrition Examination Surveys. A total of 17,890 eligible participants were included. As there were significant differences in baseline characteristics between the patients on OCs and those not taking OCs, we used propensity score-matching to adjust for such differences. We calculated the odds ratios (ORs) and 95% confidence intervals (95% CIs) of OCs leading to RA development.
Results: The peak incidence of RA was between 50–59 years old. The overall rate of OC usage was 16.5% and mean duration of OC using was 18.41±28.78 (ranged from 0 to 360) months. Before propensity score-matching, using multivariable logistic regression adjusted for traditional risk factors, taking OC was a significantly associated with RA development (OR 1.18, 95% CI 1.18–1.19, p <0.001). After propensity score-matching, taking OCs was not associated with RA (OR 1.05, 95% CI 0.83–1.34, p <0.001). Menopausal status showed strongly significant increase in the risk of RA.
Conclusions: There was an association between menopausal status and RA development in South Korean women. However, usage of OCs did not show significant effects on the development of RA.

AB0235 EFFECT OF BASELINE DISEASE ACTIVITY ON ACHIEVING SUSTAINED LOW DISEASE ACTIVITY IN BARICITINIB PHASE 3 STUDIES

J.R. Curtis[1], A. Kavanaugh[2], D. van der Heijde[3], D. Muram[4], J. Alam[4], J.S. Smolen[5]. *[1]Univ of Alabama at Birmingham, Birmingham; [2]UC San Diego School of Medicine, la Jolla, United States; [3]Leiden University Medical Centre, Leiden, Netherlands; [4]Eli Lilly and Company, Indianapolis, United States; [5]Medical University of Vienna, Vienna, Austria*

Background: In the Phase 3 studies RA-BUILD[1] and RA-BEAM[2], baricitinib (bari) has demonstrated clinical efficacy including reduced disease activity in RA patients (pts) with an inadequate response (IR) to conventional synthetic DMARDs (csDMARDs).
Objectives: To determine whether disease activity at baseline (BL) affects the achievement of sustained low disease activity (LDA) with bari treatment.
Methods: In this post hoc analysis, pts from the placebo (PBO) and bari 4 mg treatment arms of the RA-BUILD and RA-BEAM studies were categorised based on their level of disease activity at BL; either CDAI ≤median or CDAI >median, where median was 34.8 for RA-BUILD and 36.2 for RA-BEAM. Pts who achieved CDAI ≤10 at ≥2 consecutive visits (sustained LDA) within 12 and 24 weeks (wks) were considered as responders. The length of time required by pts to achieve sustained LDA was determined for each group using the incidence rate (percent pts responding per month). In addition, the association between response and dose of bari was explored in csDMARD-IR pts randomised to bari (2 mg or 4 mg) once daily from the RA-BUILD study.
Results: Within the bari 4 mg arm, a greater proportion of pts with CDAI ≤median at BL achieved sustained LDA and within a shorter treatment duration as indicated by higher incidence rates, compared to pts with CDAI >median at BL. In pts with CDAI ≤34.8 at BL, the 2 mg and 4 mg doses showed similar efficacy, but a larger proportion of pts with CDAI >34.8 reached sustained LDA at 24 wks with bari 4 mg than 2 mg (41.4% and 32.4%, respectively).

Table 1. Proportions and Rates of Sustained LDA Achievement with Baricitinib Treatment

Pts achieving CDAI ≤10		BL CDAI ≤ median			BL CDAI > median		
		PBO	Bari 4 mg	Bari 2 mg	PBO	Bari 4 mg	Bari 2 mg
RA-BUILD	N	116	108	114	108	116	111
Wk12	%	19.8	42.6	40.4	7.4	21.6	18.0
	i-rate	4.36	11.78	10.50	1.55	4.69	3.90
Wk24	%	44.8	63.9	63.2	17.6	41.4	32.4
	i-rate	10.63	19.20	17.59	3.80	9.59	7.27

Wk12	%	23.7	39.8		4.3	18.7	
	i-rate	2.71	5.40		0.42	1.98	
Wk24	%	34.5	69.1		14.0	41.9	
	i-rate	4.35	12.97		1.49	5.47	

Pts were defined as responders if they met the response criterion within the stated time frame, prior to any rescue or discontinuation. % = percent of pts meeting response criteria; CDAI median = 34.8 (RA-BUILD) or 36.2 (RA-BEAM); i-rate = exposure-adjusted incidence rate (% pts/month); N = number of randomised and treated pts.

Conclusions: Pts with CDAI ≤35–36 at BL achieved sustained LDA more frequently and more rapidly than pts in the higher disease category at BL. In pts with higher disease activity at BL a more robust response was observed with bari 4 mg treatment.

AB0236 ASSOCIATION OF LYVE-1 PROTEIN IN EXOSOME WITH DISEASE ACTIVITY AS A NEW CANDIDATE BIOMARKER FOR RHEUMATOID ARTHRITIS

J. Yoo[1], S.K. Lee[2], M. Lim[1], D. Sheen[1], E.-H. Choi[2], S.A. Kim[1]. *[1]School of Medicine; [2]Eulji Medi-Bio Research Institute, Eulji University, Daejeon, Korea, Republic Of*

Background: Exosomes, membrane-bound vesicles of 40–100 nm in diameter, have protein and lipid composition that depends on the cell origin, the state of activation, infection and/or transformation of the parent cells. Those proteins and lipid have a role in mediating inflammatory and autoimmune disease as well. Discovery of inflammatory marker to evaluate appropriate response of treatment could give effective timing to adjust treatment for rheumatoid arthritis patients.

Objectives: The aim of the study was to identify protein candidates in exosome being related with other inflammatory parameters.

Methods: The study population consisted of 60 RA patients, in which there were 30 patients of clinical remission (CR) group with DAS28-ESR≦2.6 and 30 patients of non-clinical remission (non-CR) group with DAS28-ESR>2.6. By exosome preparation with ExoQuick™ kit and protein identification with tandem mass tags labeling/mass spectrometry between the groups, potent protein markers were selected. Level of the proteins was measured by ELISA.

Results: We identified 6 proteins by proteomics approach. Amyloid A (AA) and lymphatic vessel endothelial hyaluronic acid receptor-1 (LYVE-1) was identified with different levels in exosome between CR group and non-CR group. AA levels of both serum and exosome were higher in non-CR group than CR group (p value=0.001). Significant positive correlations were found between exosome AA level and CRP as well as between serum AA level and CRP (ρ=0.614, p value=0.001 and ρ=0.624, p value=0.001). Though LYVE-1 level of serum was not different between non-CR group and CR group, LYVE-1 level of exosome was lower in non-CR group than CR group (p value=0.01). We found positive correlations between serum/exosome of LYVE-1 and CRP in only non-CR group (serum ρ=0.376, p value=0.04; exosome ρ=0.545, p value=0.002).

Conclusions: We suggest that LYVE-1 in exosome can be used as an additional marker of disease activity in RA patients and this study provides the evidence about the role of exosome for RA as the carrier of useful marker.

AB0237 PREVALENCE AND CLINICAL CHARACTERISTICS OF MALIGNANCY IN SEROPOSITIVE RHEUMATOID ARTHRITIS PATIENTS

J. Park, C. Lee. *Nhis Ilsan Hospital, Goyang, Korea, Republic Of*

Background: Patients with rheumatoid arthritis (RA) are at an increased risk of malignancies compared with the general population.

Objectives: The aim of this study was to evaluate the prevalence and risk factors of malignancy in National Health Insurance Service Ilsan hospital patients with seropositive RA.

Methods: We found patients with seropositive RA who fulfilled the American College of Rheumatology criteria and American College of Rheumatology criteria/European League Against Rheumatism criteria, from May 2008 to September 2015. Occurrence of malignancy was originally collected by electronic medical record reports and diagnostic code. We consecutively enrolled patients with newly diagnosed malignancy. Control group was selected as five times the number of patients randomized.

Results: Total 12 malignancies in 647 patients were newly identified during the retrospective observation period of 2051 person-years. Malignancy types were 3 lung cancers, 2 colon cancers, gastric cancer, breast cancer, thyroid cancer, cervix cancer, cholangiocarcinoma, lymphoma and parotid gland cancer. In multivariate logistic regression, the variables with independent predictive value were older age (age: odds ratio =1.11, 95% CI =1.01–1.22, p-value =0.02), rheumatoid factor (RF) negativity (RF positivity: odds ratio =0.06. 95% CI =0.01–1.27, p-value 0.07) In cox regression, the variables with independent predictive value were older age (age: hazard ratio =1.12, 95% CI =1.01–1.24, p-value =0.02), negative RF (RF positivity: hazard ratio =0.12. 95% CI =0.02–0.78, p-value 0.02), lower anti-cyclic citrullinated peptide (CCP) antibody titer (anti-CCP antibody titer: hazard ratio =0.98. 95% CI =0.96–0.99, p-value 0.03) and positive antinuclear-antibody (ANA) (ANA positivity: hazard ratio =14.97, 95% CI =0.87–255.05, p-value 0.06).

Table 1. Associations between variables and malignancy event in subjects: longitudinal data

Variables	Univariable			Multivariable		
	Hazard ratio	95% CI	p-value	Hazard ratio	95% CI	p-value
Etiology						
Age	1.14	1.05–1.24	<0.01	1.12	1.01–1.24	0.02
Gender	3.71	0.47–29.08	0.21			
Laboratory results						
RF positivity	0.33	0.09–1.13	0.07	0.12	0.02–0.78	0.02
Anti-CCP Ab titer	0.99	0.98–1.00	0.10	0.98	0.96–0.99	0.03
ANA positivity	5.56	0.69–44.64	0.10	14.97	0.87–255.05	0.06

Conclusions: Age, RF positivity, anti-CCP antibody titer, ANA positivity may be associated with malignancy risk in seropositive rheumatoid arthritis. So, continued vigilance and regular cancer screening are recommended for case of older age, RF negativity, lower anti-CCP antibody titer and ANA positivity.

AB0238 THE INFLUENCE OF FATIGUE IN THE DEFINITION OF REMISSION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

J. Caetano[1], S. Oliveira[1], J. Delgado Alves[1,2]. *[1]Systemic Autoimmune Diseases Unit, Department of Medicine IV, Fernando Fonseca Hospital, Amadora; [2]CEDOC, NOVA Medical School, Lisbon, Portugal*

Background: Achieving disease remission or low disease activity is the therapeutic goal in rheumatoid arthritis' (RA) treatment. Disease activity is defined through established criteria most of them requiring the evaluation of patient global assessment (PGA). PGA is considered a limiting factor for achieving remission definition, as it can be influenced by many factors not RA-related, namely fatigue which is commonly reported in RA and has been correlated with increased levels of interleukin-6 (IL-6).

Objectives: To evaluate the relation between PGA and fatigue, and whether fatigue influences disease remission definition in RA patients treated with tocilizumab (TCZ), an anti-IL-6 receptor monoclonal antibody.

Methods: We prospectively recruited 18 consecutive patients with RA (ACR/EULAR 2010 criteria), on TCZ treatment (≥3 months), from a single referral centre. Disease activity was evaluated by disease activity score for 28-joints (DAS28), and the ACR/EULAR Boolean-based criteria for remission were calculated. Visual Analog Scale for Fatigue (VASF) and Multidimensional Assessment of Fatigue scale (MAF) were used to measure fatigue.

Results: 89% of the patients were female and mean age was 55.5±13.8 years (yrs). Mean disease duration was 8.8±6.8yrs and mean duration of TCZ treatment was 2.3±1.3yrs (50% 1st line). Mean PGA score was 3.3±2.0 (0-best health) and mean DAS28 C-reactive protein (CRP) was 2.27. According to DAS28-CRP 44% of the patients were in remission, 22% had low disease activity and 33% had moderate activity. 3 patients (17%) fullfield the ACR/EULAR Boolean criteria for remission. Considering all the composits of the Boolean criteria, PGA was the only reason for not achieving remission in 10 patients (56%). The mean fatigue scores were: VASF 6.6±2.3 (0-best health), Global Fatigue Index (GFI), calculated through MAF scale, 24.3±14.9 (1-best health). Amongst the 18 patients, PGA correlated with higher fatigue scores on VASF (r=0.50, p=0.00951) and on GFI (r=0.49, p=0.037). In the group of patients not fulfilling Boolean remission, a similar correlation between PGA and higher fatigues scores was found (VASF: r=0.54, p=0.036; GFI: r=0.79, p=0.00041). In the sub-group of patients in which PGA was the only factor for not achieving Boolean remission, there was a significant correlation between PGA and fatigue scores (GFI: r=0.79, p=0.009), that was not present in the other patients (GFI: r=0.24; p=0.49).

Conclusions: We found a positive correlation between higher PGA and fatigue

scores in RA patients treated with TCZ. PGA was the major limiting factor for not achieving ACR/EULAR Boolean remission criteria, and in this sub-group of patients the same positive correlation between higher PGA and fatigue scores was found, not present in the rest of the cohort. These results enhance the influence of fatigue in patients' perspectives of disease and reinforce the limitations of using PGA to define RA activity and remission. Furthermore, considering the influence of TCZ in fatigue mechanisms, by blocking IL-6 receptor, we still found high fatigue scores in this cohort, which can enhance the complex physiopathology of fatigue in chronic inflammatory diseases, and the role of several other cytokines (IL-1, TNF-α). This effect and comparison with RA patients treated with anti-TNF-α can be explored further in larger prospective studies.

AB0239 DKK1 IS NOT ASSOCIATED WITH INFLAMMATORY ACTIVITY INDEXES IN RHEUMATOID ARTHRITIS, BUT WITH FUNCTIONAL DISABILITY RELATED TO THE LONG EVOLUTION OF THE DISEASE

R. Giraldo-Bustos[1], E.L. Saldarriaga[1], A.M. Santos[1], J.I. Angarita[1], J.G. Ballesteros[1], J.C. Rueda-Sanchez[1], A. Vasquez[1], L. Valero[1], S. Arias[2], J. Londono[1] on behalf of Grupo de Espondiloartropatías Universidad de La Sabana – Hospital Militar Central. *[1]Department of Rheumatology; [2]Universidad de la Sabana – Hospital Militar Central., Bogotá, Colombia*

Background: Rheumatoid arthritis (RA) is a systemic chronic inflammatory disease characterized by joint destruction, deformity, lower functional status and decrease in life expectancy. Wnt signaling pathway recently it has been implicated in bone homeostasis. Studies suggest that overexpression of inhibitors of the way, like the Dickkopf 1 protein (DKK1) has been implicated in bone destruction

Objectives: To compare circulating levels of DKK1 in patients with RA to their disease activity and functional status

Methods: 379 consecutive patients with early and established RA were evaluated at the Hospital Militar Central in Bogota-Colombia, between March 2015 and November 2016. A complete medical history related to RA was obtained. Disease activity was evaluated by DAS28-CRP, CDAI, SDAI and RAPID3. functional status was measurement using MDHAQ and the Steinbrocker functional classification. DKK1 levels measured by ELISA using an Abcam® kit

Results: The mean age was 60,7±13,1 years, disease duration 13,1±10,9 years, 80,4% were female. Higher levels of DKK1 were not associated with higher disease activity by CDAI (p=0,70), SDAI (p=0,84), DAS28 with CRP (p=0,80) or RAPID3 (p=0,70). Interestingly Higher levels of DKK1 were significantly associated to greater disability and lower functional status according to the Steinbrocker functional grading (p=0.013) and with severe disability by MDHAQ (p=0.004), Table 1.

Other variables associated with joint destruction were osteoporosis, elevated rheumatoid factor, smoking, and hospitalization

Steinbrocker functional grading	n (%)	DKK1 (pg/mL) M±ds	P
Class I-II	286 (75,2)	4930,9±8061,5	0,013
Class III-IV	93 (24,5)	7930,6±10811,3	
MDHAQ			
Without or low disability	334 (88,0)	3192,0±2729,4	0,004
Moderate or severe disability	45 (12,0)	4445,67±2821,0	

Conclusions: Higher levels of DKK1 were found in patients with lower functional status. This association was not found in patients with greater disease activity according to CDAI, SDAI, DAS28 and RAPID3. This could be explaining by greater structural damage though more studies would be needed to explore this possibility

AB0240 ASSOCIATION BETWEEN LEPTIN CONCENTRATIONS AND CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.A.D.J. Batún Garrido[1], I.E. Juárez Rojop[2], M. Salas Magaña[2], É. Hernández Núñez[1], F. Olán[1]. *[1]Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez; [2]Universidad Juárez Autónoma de Tabasco, Villahermosa, Mexico*

Background: It has been observed that leptin plays a role in the development of cardiovascular risk, independently associated with the development of atherosclerosis, as well as with traditional risk factors such as obesity and arterial hypertension, on the other hand, its participation in carbohydrate and lipid metabolism and in coagulation, makes leptin a promoter of the complications of obesity and therefore increase cardiovascular risk.

Objectives: Identify whether there is a relationship between serum leptin concentrations and cardiovascular risk assessed using the Framingham scale.

Methods: We studied patients with the diagnosis of rheumatoid arthritis (RA) according to the ACR/EULAR 2010 criteria; the leptin determination was through an enzyme immunoassay (ELISA) with the TECO® Test Kit. Cardiovascular risk was calculated using the modified Framingham score, as reported by EULAR, the result obtained was multiplied by 1.5. Were considered as risk values of <1% as low; 1–5% moderate and >5% high. Statistical analysis was performed using the SPSS 22.0 package. A p≤0.05 was considered a significant result. Categorical variables were compared with Chi square test. Continuous variables were compared with either the Student's T test or the Mann-Whitney non-parametric test, according the case.

Results: We studied 77 patients. The traditional CVR factors that presented the highest prevalence were age, hypoalphalipoproteinemia and obesity; With regard to the prevalence of non-traditional factors, hyperleptinemia, glucocorticoid use and positive RF were predominant. More than ¾ parts of the study population consumed methotrexate and hydroxychloroquine, which have been considered as CVR protective factors. Serum leptin concentrations and CVR factors were compared and found that there was a significant difference between higher leptin values and disease activity (p=0.047), obesity (p=0.038), positive rheumatoid factor (p=0.009), Tobacco (0.009) and metabolic syndrome (p=0.001). Likewise, a significant relationship was found between lower leptin concentrations and hydroxychloroquine consumption (p=0.023). Framingahm CVR was calculated and the result obtained was multiplied by 1.5. The 35.2% of the population studied had a low Framingahm RCV, 38.9% moderate and 25.9% presented a high risk. We compared the level of CVR and serum leptin concentrations, finding that the highest CVR were the leptin values.

Conclusions: There is a positive association between CVR and serum leptin concentrations. It is also significantly associated with traditional and non-traditional risk factors

AB0241 RELATIONSHIP BETWEEN LEPTIN AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.A.D.J. Batún Garrido[1], I.E. Juárez Rojop[2], M. Salas Magaña[2], É. Hernández Núñez[3], F. Olán[3]. *[1]Medicina Interna, Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez; [2]Universidad Juárez Autónoma de Tabasco; [3]Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez, Villahermosa, Mexico*

Background: Increased concentrations of leptin have been observed during infectious processes and inflammation, in such a way that it plays a role in the inflammatory and the immune response

Objectives: Determine the association between serum leptin and disease activity measured through DAS-28 PCR.

Methods: Patients with the diagnosis of rheumatoid arthritis (RA) according to the ACR/EULAR 2010 criteria were studied. Leptin was determined by enzyme immunoassay (ELISA) with the TECO® Test Kit, the values higher than 17ng/mL were considered as hyperleptinemia. Disease activity was assessed by the DAS-28 PCR, classifying as remission <2.3, low activity ≥2.3 to <3.8, moderate activity as ≥3.8 to <4.9 and high activity ≥4.9. Statistical analysis was performed using the SPSS 22.0 package. A p≤0.05 was considered a significant result. A multivariate logistic regression model was used to determine the association between significant variables and leptin concentrations.

Results: 77 patients were studied, 93,5% were female. The activity of the disease was determined, finding that 40,3% of patients were in remission, 41,6% had low activity, 11,7% had moderate activity and 6,5% had high activity. The 46,8% had obesity, 32,5% were overweight, 18,2% had normal weight and 2,5% were underweight. The 37,7% of the patients studied had metabolic syndrome, being the main factor the presence of an altered abdominal perimeter. The 63,6% had positive rheumatoid factor. The 71,4% had leptin levels ≥17 ng/ml. A multivariate logistic regression was performed with leptin as dependent variable. The results show an independent association between higher concentrations of leptin and disease activity (OR 1,9; 95% CI 1,3–3,8; p=0,045), obesity (OR 3,63; 95% CI 1,1–11,9; p=0,033), the presence of metabolic syndrome (OR 2,74; 95% CI 1,7–10,4; p=0,038), and positive rheumatoid factor (OR 3,5; 95% IC 1,2–11,3; p=0,033). It was also found that at higher disease activity, there were higher concentrations of serum leptin. Patients with severe activity had higher leptin media than patients in remission

Conclusions: There is a positive relationship between the activity of the disease and the serum leptin concentration, likewise this hormone is related to other inflammatory processes such as metabolic syndrome and rheumatoid factor.

AB0242 EVALUATION OF VARIANTS IN MIR-146A, MIR-196A-2 AND MIR-499 AND THEIR ASSOCIATION WITH SUSCEPTIBILITY FOR RHEUMATOID ARTHRITIS AND ITS EXTRA-ARTICULAR MANIFESTATIONS

J.C. De La Cruz-Castillejos, R.E. Barbosa-Cobos, L.T. Becerril-Mendoza, G.E. Lugo-Zamudio, J. Ramírez-Bello, M. Matias-Carmona, I. Alemán-Ávila. *Hospital Juárez de México, Ciudad de México, Mexico*

Background: The miRNAs, small non-coding RNA, regulate the genetic expression to posttranscriptional level, inhibiting the translation. The role of miRNAs in the evolution of RA is not clear.
Objectives: To evaluate the variants rs 2910164G/C in *miR-146a*, rs11614913C/T in *miR-196a-2* and rs3746444A/G in *miR-499* and their association with susceptibility and severiry to Rheumatoid arthritis (RA) and its extra-articular manifestations (EAM)
Methods: 133 cases with RA were included (ACR/EULAR criteria 2010) and 430 healthy controls. There were evaluated EAM (rheumatoid nodules [RN], Raynaud phenomenon [RP], cutaneous vasculitis (CV), episcleritis, scleritis, peripheral ulcerative keratitis [PUK], multiple mononeuritis [MM] and multiple polyneuritis [MP]) and levels of ESR, CRP, RF and CCP. It was performed genotyping of singe nucleotide polymorphisms (SNPs) rs2910164G/C in *miR-146a*, rs11614913C/T of *miR-196a-2* and rs3746444A/G of *miR-499*. The descriptive and inferential statistical analysis was performed with the software SPSS and Finetti.
Results: Patients with RA, women 126 (94.7%); age Me 48.9 (IQR 40–58); patients with EAM 23 (17.2%; women 22 [95.6%]; RN 14 [60.8%], RP 4 [17.3%], CV 1 [4.3%], episcleritis 1 [4.3%], PUK 1 [4.3%], MM 1 [4.3%], MP 1 [4.3%]); ESR Me 37 (IQR 22–45), CRP Me 0.11 (IQR 0.03–0.27); positive RF 125 patients (93.9%, high positive 106 [79.7%], low positive 19 [14.3%]; EAM with high positive RF, 100%), positive CCP 70 (52.6%, high positive 48.9%, low positive 3.8%; EAM high positive 94.1%, negative 5.9%). The alleles and genotypic frequencies did not show statistically significant difference between cases and the healthy controls ($p>0.05$). It was identified statistical difference between the patients with and without EAM in CPR (p=0.032). The genotypic and allelic frequencies and association analysis of *miRNAs* in patients with and without EAM are shown in table 1

Table 1. Analysis of the genotypic and alleles frequencies of the SNPs rs2010164G-C from *miR-146a*, rs11614913C/T from *miR-196a-2* and rs3746444A/G from *miR-499* in patients with RA with and without EAM

AB0243 SERUM LEVELS OF ANGIOGENIC AND PROINFLAMMATORY CYTOKINES TO DISCRIMINATE BETWEEN 6 SETS OF REMISSION CRITERIA IN RA

J. Ramírez García, A. Cuervo, R. Celis, V. Ruiz-Esquide, M.V. Hernández, R. Sanmartí, J.D. Cañete. *Rheumatology, Hospital Clínic, Barcelona, Spain*

Background: The ideal definition of remission in RA remains to be agreed. Angiogenic factors and proinflammatory cytokines are key in RA pathogenesis.
Objectives: The aim of this study was to analyse serum levels differences of angiogenic and inflammatory biomarkers between SDAI, CDAI, ACR, DAS28 and sonographic remission in patients with (RA).
Methods: We selected patients with RA in clinical remission (DAS28-ESR<2.6 for >6 months). PDUS of knees and hands was performed. Serum levels of biomarkers of inflammation/angiogenesis were determined by Quantibody® Human Array. Patients were classified according to 6 sets of remission criteria: SDAI (<3.3), CDAI (<2.8), ACR, DAS28-ESR (<2.6), Doppler (score Doppler=0) and UdAS (ultrasound defined active synovitis:no joints with SH$\geq$2+PD)
Results: 60 patients with RA were collected. 76% female, aged (mean) 53 years; disease duration 110 months. 47 (76%) csDMARDs, and 27 (45%) biological therapies. At baseline, 67% of patients had PD signal and 48% fulfilled criteria for previously defined UdAS. Although patients in sonographic remission had lower levels of inflammatory biomarkers such as IL-6, IL-17 or IL-23, no significant differences were found between the 6 sets of remission criteria. Angiogenic biomarkers such as CXCL6 (0.039), ENA78 (0.007), SDF1 (0.047) and VEGF-R1 (0.025) were significantly lower in patients fulfilling CDAI remission. Patients with no PD signal (0.009) and no UdAS (0.006) had significantly lower levels of bFGF.
Conclusions: RA patients in CDAI remission had significantly-lower levels of angiogenic cytokines. However, no differences in serum levels of proinflammatory cytokines were found between the 6 sets of remission criteria.

AB0244 MICROWAVE RADIOMETRY-DERIVED THERMAL CHANGES OF SMALL JOINTS AS POTENTIAL ADDITIONAL BIOMARKER IN RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY

K. Laskari[1], G. Pentazos[1], K. Prekas[2], I. Raftakis[3], E. Siores[4], P.P. Sfikakis[1]. *[1]Rheumatology Unit, 1st Dept. of Propaedeutic Internal Medicine and Joint Rheumatology Program, National & Kapodistrian University of Athens Medical School; [2]Technological Education Institute; [3]Department of Rheumatology, Asklepion General Hospital, Athens, Greece; [4]Institute of Materials Research and Innovation, University of Bolton, Bolton, United Kingdom*

Background: Microwave Radiometry (MR) is a rapid, non-invasive method that detects in-depth tissue temperatures. Using joint ultrasound as reference method, in a proof-of-concept study, we have found that an increased temperature at the knee joint detected by MR in the absence of relevant clinical signs reflects the presence of subclinical synovial inflammation in rheumatoid arthritis (RA) (1).
Objectives: To test the hypothesis that temperature of small joints assessed by MR correlates to global disease activity levels in RA, a disease in which small joints are primarily affected.
Methods: Ten patients with active, untreated RA underwent clinical and laboratory assessments, joint ultrasound and MR of hand and foot small joints (RTM 01 RES microwave computer based system, Bolton, UK) at baseline, as well as 15, 30 and 90 days after treatment onset. Twenty aged-matched healthy individuals served as controls.
Results: Using 1248 separate MR-derived recordings from RA patients we created several thermo-scores involving different small joint combinations and compared them with clinical and ultrasound data. The best performing thermo-score involved the sum of temperatures of 16 small joints (2nd-5th metacarpal and proximal inter-phalangeal joints, bilaterally). This thermo-score correlated positively to DAS28 disease activity score (p=0.001), tender joint count (p=0.002), swollen joint count (p=0.001), patient's visual analogue scale ($p<0.001$), CRP

(p=0.040), but not ESR levels, as well as to the standard Ultrasound Score of 7 joints (p≤0.025) (2). The MR-derived thermo-score could also discriminate patients in high [mean (SD) 9.2 (5.6)], moderate [mean (SD) 7.1 (3.5)] and low disease activity/remission [mean (SD) 4.2 (1.8)] (p=0.015), or aged-matched healthy subjects [mean (SD) 5.0 (1.7)] (p=0.002). Moreover, individual changes from baseline to follow-up end mirrored the corresponding DAS28 changes in 7/10 patients.

Conclusions: Increased in-depth temperatures of small joints detected by MR, which are indicative of local inflammation, may serve as an additional biomarker in RA. Optimization of MR equipment and technique may result in an objective measurement of RA disease activity in clinical practice.

AB0245 DISTRICT DIFFERENCES BETWEEN THE SEXES OF PREDICTIVE VALUE OF MATRIX METALLOPROTEINASE-3 AT BASELINE REGARDING CHANGES IN MODIFIED TOTAL SHARP SCORE AT 1 YEAR IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Inui[1], T. Okano[1], K. Orita[2], Y. Sugioka[3], K. Mamoto[1], T. Koike[3,4], M. Tada[5], H. Nakamura[1]. *[1]Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka; [2]Department of Orthopaedic Surgery, Shirahama Hamayu Hospital, Shirahama; [3]Center for Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka; [4]Search Institute for Bone and Arthritis Disease, Shirahama Foundation for Health and Welfare, Shirahama; [5]Department of Orthopaedic Surgery, Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

Background: Matrix metalloproteinase (MMP)-3, also known as stromelysis-1, is expressed in inflamed synovium of patients with rheumatoid arthritis (RA). It degrades components of articular cartilage, such as proteoglycans. In Japan MMP-3 has been used as a clinical biomarker of joint destruction and its predictive value for radiographic progression has been reported.

Objectives: W aimed to confirm a relation between baseline MMP-3 and radiographic progression at 1 year and to examine the association of the MMP-3 level with ultrasonography (US) findings.

Methods: A total of 259 (213 women) consecutive patients with RA were enrolled. We collected baseline data, that included the patient's age, sex, disease duration, use of glucocorticoid or disease modifying antirheumatic drugs, Disease Activity Score-28, and modified total Sharp score (mTSS); MMP-3 and, C reactive protein levels;, rheumatoid factor or anti-citrullinated peptide antibody status,; and the power doppler score (PD) of US assessment of digits and wrists. Baseline MMP-3 level was analyzed in association with the baseline PD value and changes (Δ) in mTSS, erosion score (ΔERN), joint space narrowing (ΔJSN) at 1 year from baseline by Pearson's correlation method. Correlations between ΔMMP-3 and ΔmTSS, or ΔPD were also analyzed. Multiple regression analysis was performed, with ΔmTSS as the outcome for baseline variables. Statistical analysis was performed separately by sex because the upper normal limits of MMP-3 differ between the sexes (men ≤121ng/ml, women ≤59.7 ng/ml).

Results: There was a weak correlation between the baseline MMP-3 level and baseline PD score in men. There was also moderate correlations between baseline MMP-3 level and structural damage at 1 year only in men. There was no predictive value for baseline MMP-3 level in women in terms of structural damage at 1 year. Multiple regression analysis revealed that the baseline MMP-3 level correlated independently with the ΔmTSS only in men (p=0.0031), whereas in the women the baseline PD score was correlated independently with the ΔmTSS (p=0.0003).

Table 1

	Variables	Correlation coefficient	Confidence interval	p
Male patients				
Baseline MMP-3	ΔmTSS	0.501[a]	[0.246, 0.691]	<0.001
	ΔERN	0.336[b]	[0.051, 0.571]	0.022
	ΔJSN	0.542[a]	[0.299, 0.719]	<0.0001
	Baseline-PD	0.228[b]	[-0.074, 0.492]	0.136
ΔMMP-3	ΔmTSS	-0.435[a]	[-0.644, -0.165]	0.003
	ΔERN	-0.325[b]	[-0.562, -0.038]	0.028
	ΔJSN	-0.436[a]	[-0.645, -0.167]	0.002
	ΔPD	0.134	[-0.170, 0.414]	0.387
Female patients				
Baseline MMP-3	ΔmTSS	0.0011	[-0.130, 0.132]	0.987
	ΔERN	0.0188	[-0.113, 0.150]	0.780
	ΔJSN	-0.0148	[-0.146, 0.117]	0.826
	Baseline -PD	0.0985	[-0.040, 0.233]	0.163
ΔMMP-3	ΔmTSS	-0.0344	[-0.165, 0.098]	0.610
	ΔERN	-0.0485	[-0.179, 0.083]	0.472
	ΔJSN	-0.0127	[-0.144, 0.119]	0.851
	ΔPD	0.134	[-0.0058, 0.270]	0.060

[a]Moderate correlation, [b]Weak correlation. Statistical analysis was performed using Pearson's correlation.

Conclusions: The baseline MMP-3 level was a good predictor of deterioration of the mTSS at 1 year in male patients with RA, but not in female patients. On the other hand, the baseline PD score was a useful predictor of joint destruction in female patients with RA.

AB0246 IMPACT OF TREAT TO TARGET STRATEGY WITH COMPLEMENTARY ULTRASOUND ON REAL WORLD RADIOGRAPHIC OUTCOMES IN EARLY RHEUMATOID ARTHRITIS OVER THE PAST DECADE

K. Kobayashi[1], K. Minegishi[1], S. Ohno[1], H. Nakajima[2]. *[1]Center for Rheumatic Diseases, Yokohama City University Medical Center; [2]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan*

Background: Treatment for rheumatoid arthritis (RA) has changed over the past decade. Early diagnosis and prompt agressive treatment based on treat to target strategy, as well as complementary ultrasound have been adopted and proven to improve patient clinical and radiological outcomes in clinical trials.

Objectives: The aim of this study was to compare radiographic progression of early RA patients starting their first DMARD 10 years ago vs more recently in daily clinical practice.

Methods: We reviewed the medical records of consecutive patients with symptom of 3 years duration who fulfilled the 1987 ACR classification criteria or the 2010 ACR/EULAR classification criteria in a single center retrospectively. In the first cohort (2000s), 70 patients (55.3±13.3y.o, Female 77%) who were diagnosed with RA during 2003–2005 were included. in the second cohort (2010s), 71 patients (54.5±17.3y.o,Female90%) who were diagnosed with RA during 2013–2015 were included. Radiographs of hands were assessed at baseline and one year after according to the van der Heijde modified Sharp score (range 0–280) without clinical information and chronological orders of radiographs in the individual patients.

Results: Mean changes in radiographic joint damage for joint space narrowing score, erosion score, total radiographic score were higher in 2000s than 2010s (0.92±2.70 vs 0.28±1.86; p=0.010, 0.54±1.35 vs 0.35±0.99; p=0.390, 1.45±3.54 vs 0.68±2.55; p=0.015, respectively). Radiographic progression defined as total radiographic score >0 and >5 were 31.4% vs 22.5% and 8.6% vs 8.5% between 2000s and 2010s (p=0.230 and p=0.970, respectively). Methotrexate (MTX) was frequently used for initial treatment in 2010s than 2000s (86% vs55%, p≤0.001), and initial dose and maximum dose of MTX were higher in 2010s than 2000s (9.13±2.09 mg/week vs 4.67±1.54 mg/week; p≤0.001 and 12.04±3.73 mg/week vs 8.13±1.88 mg/week; p≤0.001, respectively). The mean duration from symptom onset to diagnosis was earlier in 2010s than 2000s (5.75±5.04 months vs 7.85.±6.85 months, p=0.001). CRP at baseline and 1 year after were lower in 2010s than in 2000s (2.74±1.90 mg/dL vs 3.35±3.94 mg/dl; p=0.001 and 0.60±1.19 mg/dL vs 1.20±1.99 mg/dl; p=0.03 respectively). There were no significant differences in sex, age, positive rate of RF and ACPA, the Sharp score at baseline, steroid use, and biological agents use between two cohorts.

Conclusions: In recent 10 years, early diagnosis with complementary ultrasound and appropriate MTX use based on treat to target strategy led to prevent joint destruction of RA patients in daily clinical practice.

AB0247 EVALUATION OF RHEUMATOID ARTHRITIS CASES WITH HIGH ANTI-CCP ANTIBODY LEVEL

K. Suzuki, M. Minami, Y. Nishio, N. Hara, S. Nakamura. *Hokkaido Orthopedic Memorial Hospital, Sapporo, Japan*

Background: Anti-cyclic citrullinated peptide antibodies (Anti-CCP Ab) are well-established serological markers that show high sensitivity and specificity in diagnosing early rheumatoid arthritis (RA). Furthermore, Anti-CCP Ab is reported to be associated with bone erosions of RA. Therefore, Anti-CCP Ab positive RA patient can be a candidate for intensive treatment.

Objectives: Upper measurement limit of Anti-CCP Ab increased recently up to 1200 units. High level of Anti-CCP Ab may be a predictor of the profound therapy for RA. To understand the importance of Anti-CCP Ab level, we evaluated RA patients with high titer Anti-CCP Ab in relationship to the other activity markers of RA and the intensity of the treatment for RA.

Methods: Total of 186 RA patients with Anti-CCP Ab higher than 30 units was included in this study. Baseline markers such as CRP, MMP-3, RF and anti-CCP Ab were measured at the entry of the study. Relationship among these markers ware evaluated and examined using statistical significance for the single-factor ANOVA and the multiple comparisons. Among those cases 131 cases were treated conservatively with biologics and/or DMARDs and were followed up more than one year. We graded them from I to IV by the intensity of the treatment. Grade I: Biological agent. Grade II: Methotrexate (MTX) more than 12mg or combination with more than 3 DMARDS Grade III: MTX 6–11mg or combination

with two recommended DMARDS Grade IV: single use of DMARDS including MTX less than 5mg.

Results: There was no relationship between titers of Anti-CCP Ab and titers of RF. We found significant statistical correlation between anti-CCP antibody titers and inflammatory markers such as CRP and MMP-3. There was significant statistical correlation between CRP and MMP-3.

In terms of treatment intensity, strong intensity group showed high titer of anti-CCP Ab and CRP. Titer of RF and MMP-3 level did not have any relationship with the treatment intensity. In cases treated with biologics, anti-CCP Ab and CRP were significantly higher compared to non-biologic case group. In 80% of cases treated with biologics titer of anti-CCP was more than 200 units. However, non-biologic treatment was continued in more than 50% of cases with anti-CCP Ab higher than 200 units.

Conclusions: Even though we treated cases based on the severity of the symptoms of the patient and response in laboratory data, high anti-CCP Ab titers and CRP at the base line were most associated with the treatment intensity after 1 year. The results of our study suggest that the titer of anti-CCP Ab can be better a predictor of the treatment intensity than MMP-3 and RF.

AB0248 THE IMPACT OF THERAPY ON ANTI-CARBAMYLATED PROTEIN ANTIBODY ISOTYPES AND SEROSTATUS IN PATIENTS WITH EARLY RA TREATED WITH ABATACEPT AND METHOTREXATE

L. Trouw[1], S. Connolly[2], A. Johnsen[2], J. Ye[2], M. Maldonado[2], R. Toes[1], T. Huizinga[1]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Bristol-Myers Squibb, Princeton, United States*

Background: Maturation of autoantibody responses has been suggested to be a proxy for disease maturation. Autoantibody responses against post-translationally modified antigens are present in autoimmune diseases and antibodies directed against carbamylated proteins (anti-CarP antibodies) are a marker of RA. Anti-CarP antibody analysis in patients with early RA offers the opportunity to estimate whether specific intervention during such early stages of autoantibody development may have an impact on the maturation of the anti-CarP antibody response.

Objectives: We assessed the relationship between changes in anti-CarP isotypes and rates of seroconverson to negative in patients with early RA.

Methods: In the Assessing Very Early Rheumatoid arthritis Treatment study (AVERT; NCT01142726), patients with early RA were treated with abatacept (ABA)+MTX, ABA monotherapy or MTX alone.[1] Patients in AVERT were anti-cyclic citrullinated peptide-2 positive at baseline for study entry.[1] In this *post hoc* analysis, concentrations of anti-CarP isotypes were measured using custom ELISAs. Anti-CarP ELISAs for immunoglobulin (Ig)G, IgM or IgA isotypes were performed in patient serum at baseline, and at Days 85 and 365 on treatment. Baseline levels of each anti-CarP antibody isotype and % seropositivity were comparable across the three treatment arms. Adjusted mean change from baseline was calculated using a longitudinal repeated measures model.

Results: At baseline, 51.3, 42.5 and 29.3% of all patients with serum available in AVERT were positive for IgG, IgM (indicative of an ongoing immunoresponse) and IgA anti-CarP isotypes, respectively. Overall, approximatly 65% of patients were positive for at least one anti-CarP antibody isotype. Median % change from baseline (25%, 75%) for anti-CarP isotypes levels from baseline to Days 85 and 365 are shown (Table). Analysing patients who were positive at baseline for each of the isotypes, we observed that 19/48 (40%), 16/43 (37%) and 11/48 (23%) of the patients positive for the IgG isotype became negative on ABA+MTX, ABA and MTX, respectively, at 1 year. For the IgM isotype, 26/48 (54%), 14/36 (39%) and 15/38 (39%) became negative on ABA+MTX, ABA and MTX, respectively. For the IgA isotype, 12/26 (46%), 10/23 (43%) and 13/31 (42%) became negative on ABA+MTX, ABA and MTX, respectively.

Conclusions: Concentrations of all anti-CarP isotypes (IgM, IgA, IgG) were numerically reduced by abatacept+MTX therapy compared with MTX or abatacept alone. Abatacept+MTX trended towards higher rates of seroconversion to negative for all isotypes over 1 year of treatment. These results indicate that the extent of the anti-CarP antibody response can be modulated by intervention with abatacept on background MTX in anti-citrullinated protein antibody-positive patients with early RA.

AB0249 IDENTIFICATION OF INFLAMMATORY- AND IMMUNE DISORDER- RELATED PROTEINS AS PUTATIVE BIOMARKER CANDIDATES FOR IMPROVING RHEUMATOID ARTHRITIS MONITORING

L. González-Rodríguez[1], V. Calamia[1], L. Lourido[1], P. Fernández-Puente[1], M. Camacho-Encina[1], C. Ruiz-Romero[1], A. Julià[2], A. Fernández-Nebro[3], J. Tornero[4], S. Marsal[2], F.J. Blanco[1]. *[1]Proteomics Group, Rheumatology Division, ProteoRed, PRB2-ISCIII, INIBIC-Hospital Universitario A Coruña, A Coruña; [2]Rheumatology Research Group, Vall d'Hebron Hospital Research Institute, Barcelona; [3]UGC Reumatología, Instituto de Investigación Biomédica (IBIMA), Hospital Regional Universitario de Málaga, Málaga; [4]Hospital Universitario Guadalajara, Guadalajara, Spain*

Background: Rheumatoid arthritis (RA) is a long-lasting inflammatory autoimmune disorder that ultimately leads to the destruction of joint architecture.

Objectives: Using the DAS28 activity index, 80 RA serum samples (40 with low activity and 40 with high activity) were selected in order to be analyzed by mass spectrometry. The aim of this study was to find possible protein biomarkers that could discriminate patients with different RA activity in the daily clinical routine.

Methods: In order to facilitate the complex measurement of these serum samples, a simple, fast and reproducible albumin-specific depletion method using ethanol was optimized and applied to this study. Four independent pools of the 40 high RA activity samples (10 samples per pool) and 4 pools of the 40 low RA activity samples were firstly albumin-depleted, and then the remnant serum proteins were digested and differentially labelled with iTRAQ 8-plex reagents. Subsequently, the 8 labelled pools were combined and cleaned using StageTips-C18. Finally, the pool mixture was fractionated by HPLC (Zorbax-C18) and the resulting fractions were analyzed by nanoLC-MS/MS using two different equipments for validation (MALDI-TOF/TOF and TripleTOF).

Results: The mass spectrometry analysis led to the identification of 186 proteins. Among these, Haptoglobin, Kininogen-1, Alpha-2-HS-glycoprotein, Serum Amyloid A, Afamin and Histidine-rich-glycoprotein, exhibited a differential relative abundance depending on the RA activity of the patients ($p<0.03$) in both analysis. These proteins were also validated by other orthogonal techniques (western blot, ELISA and protein arrays).

Conclusions: In this proteomic study, 9 proteins were found to be modulated between patients with high and low RA activity. Most of these proteins are related with the RA process and the effects caused by this type of disease (inflammation and immune disorder in joints). Therefore, these proteins are possible biomarker candidates for improving RA monitoring. Future validation experiments and prospective studies are needed to facilitate their implementation in the clinical routine.

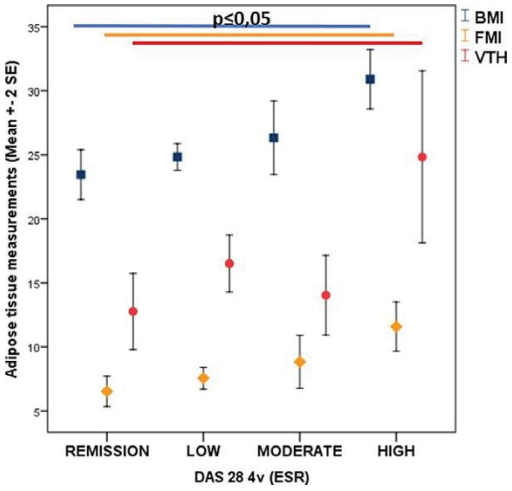
AB0250 THE ADIPOSE TISSUE AS PREDICTIVE FACTOR OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS: EVALUATION OF BODY FAT COMPOSITION BY BIOELECTRICAL IMPEDANCE ANALYSIS AND ULTRASONOGRAPHY

M.G. Anelli[1], C. Rotondo[2], R. Fanizzi[2], O. Magazzino[2], M. Giannotta[2], M. Giannini[2], O. Lorusso[3], E. Praino[2], M.T. Viggiani[3], F. Cacciapaglia[2], M. Barone[3], G. Lapadula[2], F. Iannone[2]. *[1]DIM; [2]DETO, Unit of Rheumatology; [3]DETO, Gastroenterology Unit, Bari, Italy*

Background: Adipose tissue (AT) is an endocrine organ able to secrete the "adipokine" molecules that contribute to the low-grade inflammatory state in obese subjects and to the local inflammation that affects joints and bone (1,2). High-grade inflammation, in course of RA, leads to an altered body composition (3,4), characterized by the increasing of fat mass and the decreasing of lean mass, mostly not associated to body mass index (BMI) variations (3,5). The BMI is not able to differentiate visceral (VTH) and subcutaneous (STH) fat tissue and to distinguish between muscle mass and fat mass body composition (BC) (6,7). Alternative methods proposed for assessment of visceral fat deposition, are bioelectrical impedance analysis (BIA) and ultrasonography (US).

Objectives: The aim of the study is to investigate if BC, assessed by BIA and US,



Abstract AB0248 – Table 1. Median % change from baseline (25%, 75%) for anti-CarP isotypes

	Day 85			Day 365		
	IgG	IgM	IgA	IgG	IgM	IgA
ABA	–17.3 (–55.7, 0.0)	–26.3 (–57.9, 0.0)	–6.8 (–35.1, 0.0)	–31.2 (–67.4, 0.0)	26.0 (-81.2, 0.0)	–26.7 (–72.9, 13.0)
MTX	–19.3 (–53.6, 0.0)	–35.7 (–54.4, –6.9)	–27.2 (–42.4, –3.9)	–17.7 (–65.1, 0.0)	–38.3 (–63.7, 0.0)	–21.9 (–50.3, 0.0)
ABA+ MTX	–38.8 (–62.3, 0.0)	–44.2 (–59.5, –13.8)	–41.3 (–54.9, –28.3)	–55.7 (–76.7, 0.0)	–45.7 (–72.5, –0.2)	–46.4 (–66.7, 0.0)

correlates with disease activity (assessed by the Disease Activity Score using 28 joint counts – DAS28) and affects the response to the therapy (DAS 28 variation from first evaluation).

Methods: 87 consecutive RA patients (pts) (72 women and 15 men; aged 52.4±13.2 years; disease duration of 10.7±8.6 years), treated with DMARDs and/or biologics (bDMARDs), were recruited during their regular visit. The inclusion criteria were the 1987 American College of Rheumatology (ACR) or ACR/EULAR 2010 classification criteria. The pts underwent to anthropometric measures (BMI); abdominal US to assess STH and VTH and derived computing of peritoneal circumference (PC); and BIA to the indices of body composition (fat-free mass index (FFMI) and fat mass index (FMI).

Results: We observed increasing values of BMI, FMI, VTH (fig. 1) and CP with the worsening of disease activity phases, evaluated by DAS 28. In particular, pts with DAS28≥5.1 had highest BMI (30,9±2; p=0,036), FMI (11,5±1,6; p=0,05), CP (92,7±12,5 cm; p=0,035) and VTH (24,8±5,8 mm; p=0,046) than pts in less severe disease activity. By linear regression analysis the predictor of higher DAS28 is the BMI (p=0,028). As regard the drug response, the predictors of DAS 28 improvement are higher FFMI (p=0,044) and lower BMI (p=0,015), independently by bDMARDs or DMARDs treatment. A trend to higher FMI and US AT measures was observed in female with high disease activity, in particular in menopause pts.

Conclusions: An altered fat distribution is observed in active RA phases; in particular, the FMI increasing is attributable just to visceral AT (VTH and CP). An inflammatory hyperactivity of visceral adiposity could be supposed in RA. The body composition, in addition to BMI, seems to predict the disease activity and drug response in RA patients. The evaluation of VTH by US could be useful to not overestimate the disease activity; instead the BIA could be a useful tool to support the clinicians in a more aggressive treatment management.

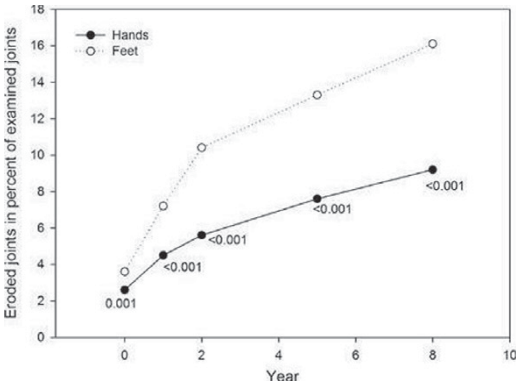
AB0251 IN RHEUMATOID ARTHRITIS EROSIONS ARE MORE FREQUENT IN THE FEET THAN IN THE HANDS

M.L. Andersson, B. Svensson, K. Forslind. *Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund and Helsingborg, Sweden*



Background: Joint destruction in patients with rheumatoid arthritis (RA) is mostly evaluated by scoring radiographs of both hands and feet using the Sharp van der Heijde or Larsen scoring methods. In contrast, DAS28, the most commonly used composite measure of inflammation measure, does not include the feet.

Objectives: To study the distribution of erosions in hand and wrist (hands) and feet in early RA and elucidate if the feet should be included also in composite measures of inflammation

Methods: This study comprises 1 052 patients from the BARFOT study of patients with early RA, recruited 1992–2006. Radiographs of hands and feet were performed at baseline, 1, 2, 5 and 8 years and evaluated by the Sharp van der Heijde scoring (SHS) method (32 joints in the hands and 12 in the feet). Disease activity at baseline was measured by the DAS28.

Results: In the feet there were significantly more eroded joints in percent of examined joints at all time points (p<0.001), and higher erosion scores in percent of maximum erosion score at 5 and 8 years (0.037 and 0.021 respectively), compared with the hands.

There were no differences in mean joint space narrowing (JSN) between hands and feet at any time point. Patients with erosions only in the feet had significantly lower DAS28, mean 4.59, compared with the patients in the other groups, mean 5.03 in the no erosions group p=0.031, mean 5.17 in the group with erosions only in the hands, p=0.013, and mean 5.15 in the group with erosions in both hands and feet, p=0.031.

Conclusions: Joint destruction over time was more pronounced in the feet than in the hands. Baseline erosions limited to the feet were associated with low disease activity, suggesting that inflammation localized to the feet may not be reflected by DAS28. These observations may have relevance to the evaluating of disease activity and progression in the individual patient. Possibly inclusion of the feet to DAS28 might improve the validity of this disease activity measure.

AB0252 THE IMPACT OF THE RHEUMATOID FOOT ON FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS EVALUATED BY FFI AND LFIS

M. Erraoui, B. Amine, L. Tahiri, I. El Binoune, J. Bahha, S. Fellous, Y. Boujenane, F. Allali, R. Bahiri. *Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat, El Ayachi Hospital, SALE, Morocco*

Background: The impairment of function in patients with rheumatoid arthritis (RA) is determined by several factors related to the disease including joint damage. The foot, a location frequently affected during course of the disease, has a major impact on the lower limb and could cause functional disability.

Objectives: The purpose of this study is to evaluate the impact of the rheumatoid foot on function of patients with RA.

Methods: Cross-sectional study was conducted in 33 patients with RA. Patients with static lower limb disorder or foot injury from other origin were excluded. Demographic and clinical characteristics were collected: age, sex, BMI, disease duration, tender joint count, swollen joint count, foot pain evaluated on an VAS, foot squeeze test and various podiatric abnormalities observed clinically (forefoot, midfoot and rearfoot). Biological characteristics also collected: sedimentation rate in the first hour, C reactive protein, rheumatoid factor and anti-CCP. Disease activity was evaluated by DAS28, CDAI, SDAI and DAS44. Functional repercussions were estimated by the French Functional Index (FFI), comprising 23 items, divided into 3 sections: pain, function and limitation of activity. Functional disability was studied by the Leeds Foot Impact Scale (LFIS), which includes 51 items (21 items specific to foot function alteration (LFIS-I) and 30 related to foot disability (LFIS-D)). Statistical analysis was performed using SPSS21 software.

Results: Thirty-three patients followed for RA were included. The mean age of our patients was 49.39±10.52 with a female predominance (87.9%). Mean disease duration was 9.96±7.49 years. In all patients; 21 (95.5%) were seropositive. The mean DAS28 was 5.53±1.38 and the mean HAQ was 1.37±0.83. 93.9% of our patients had bilateral foot pain; 69.7% in the forefoot, 18.2% in the midfoot and 42.4% in the hindfoot. The medial retromalleolar tumefaction was found in 21.2% of the patients and the lateral retromalleolar tumefaction in 45.5% of them. The squeeze test was positive in 23 (69.7%) patients. Prevalences of Podiatric abnormalities were noted in the following ordre: hallux valgus (48.5%), quintus varus (12.1%), hallux rigidus (6.1%), claw toe (15.2%), triangular forefoot (9.1%), rearfoot valgus (27.3%) and rearfoot varus (27.3%).

Mean FFI was 52.35±25.63 (FFI-pain: 58.69±24.41, FFI-function: 53.66±30.48 and FFI- limitation of activity: 39.33±30.58). Mean LFIS-I was 11.48±5.36 and mean LFIS-D was 19.96.

A high FFI was associated with foot pain (p=0.034); in midfoot (p=0.029) and rearfoot (p=0.005) and with high disease activity: DAS28 (P=0.005), CDAI, SDAI and DAS44 (p=0.0001).

LFIS-I and LFIS-D were statistically related to pain in foot (p=0.019) (midfoot (0.042), hindfoot (0.003)), and to a positive squeeze test. The disease activity was positively correlated with high LFIS-I and LFIS-D (p=0.0001). The presence of medial retro-malleolar swelling, posterior gutter filling and calcaneal varus is responsible for a high FFI, LFIS-I and LFIS-D with respectively: p=0.0001, p=0.003, p=0.003.

Conclusions: The rheumatoid foot alters function. It causes disability which is related to foot pain, rearfoot podiatric abnormalities and disease activity.

AB0253 TIPS ON SELECTION OF BIOLOGICS FOR PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON TREATMENT PATTERNS

M. Kamiya[1], S. Soen[1], H. Kikuchi[2], N. Okada[3]. *[1]Department of Orthopaedic Surgery and Rheumatology, Kindai University Nara Hospital, Ikoma-City; [2]Department of Orthopaedic Surgery and Rheumatology, Kindai University Sakai Hospital, Sakai-City; [3]Department of Orthopaedic Surgery, Sumoto Itsuki Hospital, Sumoto-City, Japan*

Background: The emergence of biologics has led to innovation in the treatment of rheumatoid arthritis (RA). In the clinical setting, biologics are administered with careful consideration of complications and medical history in accordance with the treat-to-target recommendations. However, the progression of joint damage, the costs incurred before finding an effective biologic are serious concerns. It is therefore desirable to use biologics with long-term efficacy and less financial burden from the early stage.
Objectives: Participants were RA patients treated with one of three biologics having different mechanisms of action who achieved therapy targets with long-term treatment efficacy and consequently achieved either reduction or withdrawal of therapy. Patients' background characteristics and long-term treatment patterns were evaluated.
Methods: Between November 2004 and October 2016, 196, 57, and 85 RA patients were treated with etanercept (ETN), tocilizumab (TCZ), and abatacept (ABT), respectively, in first- or second-line therapy. These patients were divided into the continuation group, who underwent therapy with the same agent for $\geq$3 years without disease flare (DAS28-ESR $>$3.2) persisting 3 months, and the discontinuation group, who experienced primary failure resulting in discontinuation of the therapy within 3 months. Student's t test or Mann-Whitney's U test were used to compare patients' background characteristics between the two groups for each biologic. Further, log-rank test and Steel-Dwass test, respectively, were used to compare therapy continuation rates and reasons for discontinuation among the three biologics. Finally, relative dose intensity (RDI) was calculated to evaluate the treatment patterns of the individual biologics.
Results: The Kaplan-Meier method showed that the 3-year continuation rates of therapy with ETN, TCZ, and ABT were 54.2%, 23.8%, and 35.8%, respectively: the continuation rate of ETN was significantly higher than that of the other two agents. The numbers of patients treated with ETN, TCZ, and ABT were respectively 46, 9, and 14 in the continuation group and 16, 12, and 11 in the discontinuation group. The proportion of patients treated with ETN plus concomitant MTX was significantly higher in the continuation group than in the discontinuation group (P=0.0057). No significant differences were found in patients' background characteristics (disease duration, rheumatoid or anti-cyclic citrullinated peptide positivity, number of biologics previously used, and DAS28-ESR). Mean RDI values (median value, 95% confidence interval) over a 3-year period were as follows: 0.95 (0.92, 0.83–1.06) for 25 mg/week ETN therapy; 0.78 (0.90, 0.66–0.89) for 50 mg/week ETN therapy; 0.84 (0.84, 0.76–0.89) for TCZ therapy; and 0.87 (0.94, 0.79–0.95) for ABT therapy. The cumulative costs for 3 years of the respective treatments were 19,700, 32,200, 27,300, and 39,000 euros (1 euro =115 Japanese yen). After targets were reached, the dose of ETN was maintained at 25 mg/week or reduced from 50 mg/week, while the TCZ and ABT therapies were continued over the long term with a longer dosing interval.
Conclusions: Treatment with ETN plus concomitant MTX showed high continuation rates, and long-term achievement of therapy targets was maintained at a lower dosage (and thus, lower costs). It is beneficial to choose this method over non-TNF inhibitors.

AB0254 COMPARISON OF DYNAMIC PEDOBAROGRAPHIC FINDINGS BETWEEN RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY INDIVIDUALS

S. Ghadimy, M. Aarabi, N. Abdolahi, N. Nematollahi, M. Aghaei. *Rheumatology Reasearch Center, Gorgan, Iran, Islamic Republic Of*

Background: Foot involvement happens early in RA patients and situation becomes ugly and painful rather very fast. There is a blank gap between starting of foot involvement and the time where patient needs surgical intervention for correcting the damages done by RA. No guideline exists for determining when and what we can do in these patients to detect and prevent the changes or at least reduce their damages.(1)
Objectives: 1. Evaluating foot pressure changes by pedobaroghy:
- comparing maximum force/peak pressure distributed in different regions of foot between RA patients and healthy individuals.
- comparing maximum force/peak pressure distributed in different regions of foot between men and women.
- determining effects of aging on maximum force/peak pressureby comparing them between two age groups.
- determining effects of duration of RA on force/peak pressure in RA patients.

2. Evaluating radiologic findings in symptomatic RA patients and comparing them with pedobarographic findings.
3. Evaluating and comparing quality of life in RA patients and healthy individuals with SF36 questionnaire.
Methods: 90 RA patients and 45 healthy individuals were chosen and entered this research. Patients divided into two groups: 45 patients without any previous foot symptoms, 45 with foot symptoms. All these groups underwent dynamic pedobarography with Novel emed pedobargraphy.
We took foot and ankle X-rays for symptomatic group.
Based on Larsen score, symptomatic patients were divided into individuals with and without radiologic changes.
Results: There was a significant difference in total maximum force between patients and healthy individuals; healthy individuals had lesser amount of maximum force in different parts of their feet compared to RA patients.
Fore foot region endured the most amount of maximum force and pressure in all three groups with no significant difference between groups.
RA patients both symptomatic and asymptomatic had more force and pressure upon their midfoot regions compared to the healthy group p-value:.000.
Since we excluded patients with severe deformities and those who couldn't walk alone from the study, and our cases were relatively in early stages of disease, we didn't find any significant difference in pressure or force between symptomatic patients with and without radiographic findings. This can be explained by the fact that foot pressure alteration detectable in pedobarography is already begun in all patients with foot symptoms but radiologically evident pathologies had not happened yet.
Conclusions: RA has considerable effect on patients' feet along with other physical and mental issues. While conventional radiologic methods has a limited eficacy in predicting and diagnosing the pathologic changes in foot region, pedobarography can easily shows these changes in foot pressure values and can be used to detect RA patients that need simple interventions like using proper insoles to prevent surgical interventions

AB0255 EVALUATION OF KINESIOPHOBIA IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

M. Aykut[1], B. Cakit[2], E. Mert[2], S. Aslan[2], E. Sahingoz[2], H. Genc[2], F.F. Ayhan[2], A. Karagoz[2]. *[1]Physical Medicine and Rehabilitation, Ankara Training and Research Hospital; [2]Physical Medicine and Rehabilitation, Ankara Training and Research Hospital, Ankara, Turkey*

Background: Fear avoidance behavior which is caused by painful injury resulting precision and extreme fear is defined as kinesiophobia. Rheumatoid arthritis (RA) is a chronic, inflammatory and systemic disease with symmetrical arthritis and visceral involvement. Ankylosing spondylitis (AS) is a chronic, inflammatory disease with involvement of the spine or peripheral joints.
Objectives: In our study, we aimed to evaluate the relationships between kinesophobia and disease activity, quality of life (QoL), level of physical activity and emotional status in RA and AS patients.
Methods: We included 42 patients with RA (8 males-M, 34 females-F) (group 1), 49 patients with AS (34 M, 15 F) (group 2) and 29 healthy controls (9 M, 20 F) (group 3) in our study. The QoL was assessed using the health assessment questionnaire (HAQ), kinesiophobia was assesed with Tampa scale of kinesiophobia (TSK), pain was assesed with visual analog scale (VAS), fatigue was assesed with VAS and emotional status was assesed with Beck depression inventory (BDI). Disease activity was assesed with Bath ankylosing spondylitis disease acitivity index (BASDAI) and functional status was assesed with Bath ankylosing spondylitis functional index (BASFI) in patients with AS. Disease activity was assesed with DAS28 in patients with RA.
Results: The mean age was 46.2 in group 1, 43.2 in group 2 and 40.17 in group 3. There was no difference among groups with respect to mean age ($p>0.05$). Kinesiophobia was present in 37 patients in group 1, 22 patients in group 2 and 7 patients in group 3. Statistically significant differences were found among groups

Table 1. Baseline features of the patients of AS and RA and healthy controls

	Group 1	Group 2	Group 3
Age	46,2±11,47	43,2±10,73	40,17±7,77
Gender (F/ M)	34/8	15/34	20/9
VAS*	47,02±24,42	32,44±26,75	1,72±4,68
TKS**	44,73±7,26	36±12,03	29,58±9,37
Fatigue (VAS)†	55,47±24,31	36,93±27,70	37,93±20,59
HAQ‡	0,73±0,83	0,43±0,41	0,06±0,19
BDI§	14,17±9,49	12,23±9,63	5,25±6,13

*p=0.008 between group 1 and 2; p<0.001 between group 2 and 3; p<0.001 between group 1 and 3. **p<0.001between group 1 and 2; p=0.023 between group 2 and 3; p<0.001 between group 1 and 3. †p<0,05 between group 1 and 2; 2 and 3; 1 and 3. ‡p=0.039 between group 1 and 2; p=0.021 betwen group 2 and 3; p<0.001 between group 1 and 3. §p>0.05 between group 1 and 2; p=0.004 betwen group 2 and 3; p<0.001 between group 1 and 3.

with respect to the number of patients with kinesiophobia and to mean scores of pain intensity, fatigue, HAQ and BDI (p<0,05-<0,001). Patients with RA had higher rates of kinesiophobia than patients with AS and healthy controls (p=0.001, p=0,001). Patients with RA had worser scores than patients with AS and healthy controls. Patients with AS had worser scores than healthy controls. In patients with RA and AS, kinesiophobia is associated with pain severity, fatigue, emotional status and QoL.

Conclusions: In our study, patients with RA and AS had higher rates of kinesiophobia. We found that kinesiophobia was related with pain severity, fatigue, depression, disease activity and QoL of the patients. The QoL can be improved through controlling kinesiophobia by reducing pain, depression and fatigue.

AB0256 SERUM AND SYNOVIAL KYNURENIC ACID CONCENTRATION AND ITS CORRELATION WITH DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: CLINICAL AND ULTRASONOGRAPHIC STUDY

F. Elshabacy[1], T. Fathy Mohammed[1], M.A. Mortada[2], H.A. EL-Saadany[3], S.M. Farouk[4], E.R. Amer[4]. *[1]Rheumatology, Benha Teaching Hospital, Benha; [2]Rheumatology & Rehabilitation, Zagazig University, Zagazig; [3]internal medicine and Rheumatology, Military Medical Academy, Cairo; [4]Clinical Pathology, Benha Teaching Hospital, Benha, Egypt*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease. kynurenic acid has anti-inflammatory effects, because it is the most important agonist of the orphan G-protein-coupled receptor (GPR35) which expressed on various types of cells associated with the immune system. Stimulation of these receptors by kynurenic acid lead to reduction in the synthesis of proinflammatory cytokines, nitric oxide, and reactive oxygen species (1).

Objectives: Detection and quantification of kynurenic acid in serum and synovial fluid obtained from the affected joints in patients with rheumatoid arthritis and its relation to different clinical aspects of disease activity and signs of synovitis and synovial hyperplasia detected by musculoskeletal diagnostic ultrasound.

Methods: Thirty RA patients diagnosed according to ACR and EULAR revised criteria and thirty patients of idiopathic knee osteoarthritis as a control group were enrolled in the study. These patients were collected from outpatient clinic of rheumatology department Benha Teaching Hospital. Kynurenic acid was assessed in Serum samples from all patients and controls coupled synovial fluid samples aspirated from knee joint of all RA patients and fourteen OA patients after musculoskeletal ultrasonographic examination of these joints.

Results: Serum and synovial level of kynurenic acid was assessed in the studied groups. Comparison between RA and OA patients as regard serum kynurenic acid showed no differences where it's level was *29.80±13.86 pg/ml in RA versus 30.98±11.03 pg/ml in OA patients)*, while synovial kynurenic acid was significantly lower in RA 16.38±6.45 pg/ml than in OA patients 26.22±2.99 pg/ml ($p<0.001$). kynurenic acid was significantly lower in synovial fluid (16.38±6.45 pg/ml) than in serum (29.80±13.86 pg/ml) in RA group of patients ($p<0.001$). Comparison among different grades of synovitis detected by grey scale U/S and by Doppler signals in RA patients as regard synovial kynurenic acid showed that it was significantly lower in higher grades of synovitis ($P<0.001$). Synovial kynurenic acid level was negatively correlated with grades of synovitis and Doppler signals ($p<0.001$).

Conclusions: The negative correlation between Kynurenic acid concentration in the synovial fluid and both the synovial thickness detected by ultrasonography and the hyperaemia of synovial tissues as represented by the Doppler activity, may support its use as a local marker of the two faces of rheumatoid arthritis (chronicity and activity) at the joint level.

To the best of our knowledge, this is the first study that gives correlation between the serum and synovial levels of kynurenic acid concentrations and the grade of synovitis detected by grey scale and Doppler ultrasonography.

AB0257 SCREENING OF DIFFERENTIALLY EXPRESSED SERUM PROTEINS FOR RHEUMATOID ARTHRITIS BY SURFACE-ENHANCED LASER DESORPTION/INIONATION-TIME OF FLIGHT-MASS SPECTRA

N. Liang, L. Zhang, K. Xu. *Shanxi academy of medical sciences Shanxi dayi hospital, TaiYuan, China*

Background: RA is a chronic inflammatory rheumatic disease, and early diagnosis and treatment can improve prognosis[1].Surface-enhanced laser parsing ionization/time of flight mass spectrometry (SELDI-TOF-MS) combining a protein chip and mass spectrometry technology own the advantages of low dosage of samples, direct point sample detection and high sensitivity.

Objectives: SELDI used to profile and compare the proteomes in serum samples of RA patients including complicated with Sjogren's syndrome (SS), interstitial lung disease (ILD). Using Biomarker Wizard software and Biomarker Pattern Software established diagnostic model, and calculate sensitivity and specificity,which can simplify clinical procedures, save medical costs and explore the pathogenesis.

Methods: Using the Biomarker Wizard and Biomarker Pattern software to establish the diagnosis prediction model to predict RA disease progression between the following groups, including simple RA patients (n=44) and RA-SS patients (n=18), RA patients (n=44) and RA-ILD (n=22), RA patients (n=44) and RA-ONFH (n=6). Also 96 RA patients and 77 healthy control, which were randomly allocated to the training set (83 RA patients and 56 healthy controls) and test set (14 RA patients and 20 healthy controls)to develop and verify a pattern by means of decision treealgorithm.

Using the Biomarker Wizard and Biomarker Pattern software to establish the diagnosis prediction model to predict RA disease progression between the following groups, including simple RA patients (n=44) and RA-SS patients (n=18), RA patients (n=44) and RA-ILD (n=22). Also 96 RA patients and 77 healthy control, which were randomly allocated to the training set (83 RA patients and 56 healthy controls) and test set (14 RA patients and 20 healthy controls)to develop and verify a pattern by means of decision treealgorithm.

Results: 1. Comparison of RA patients and healthy controls: there are 22 up-regulated expression in RA, 36 down-regulated. The diagnostic model of M/Z3448.857,4716.712,8214.285 and 10645. The sensitivity and specificity is 91.566% and 92.857%, the area under the ROC curve was 0.937, to verify the diagnosis model, we get a sensitivity of 100% and a specificity of 95%. 2. Comparison of the simple RA and RA -ILD. The diagnostic model of M/Z10645.1, M/Z12595.86. The sensitivity and specificity is 86.4% and 84.1% and the area under the ROC curve was 0.856.3. Comparison of the simple RA and RA -SS: The diagnostic model of M/Z6635.623, M/Z33897.72. The sensitivity and specificity is 77.8% and 79.5% and the area under the ROC curve was 0.794.

Conclusions: The serum protein fingerprinting by SELDI-TOF-MS could identify new biomarkers in RA. The biomarkers may play an important role in pathogenesis of RA. We could diagnose RA in early stage, predict disease progression and determine disease activity by these biomarkers.

AB0258 AGE AND QUALITY OF LIFE AMONG RHEUMATOID ARTHRITIS PATIENTS TREATED WITH BIOLOGIC AGENTS

N. Oguro, N. Yajima, Y. Miwa. *Rheumatology, Showa University School of Medicine, Nishinakanobu, Shinagawa Ward, Tokyo, Japan*

Background: Rheumatoid arthritis (RA) is a common autoimmune disease of unknown etiology which is characterized by symmetric, chronic inflammatory, peripheral polyarthritis. If it is untreated or unresponsive to therapy, inflammation and joint destruction lead to loss of physical function, inability to carry out daily tasks of living.

In addition to problems related to pain and inflammation, patients with RA are also affected by psychological problems such as anxiety and depression.

It has been a while since, the biologic agents have let RA patients to early remmision, and improved their Quality of life (QOL).

A few studies show relevance between age and QOL among RA patients. Lambert et al. found that age was positively correlated with pain, indicating that increasing age made the situation worse.

Objectives: This study aimed to assess the relationship between age and QOL of RA patients who has been treated with biologic agents.

Methods: 149 RA patients who treated with biologic agents at Showa University Hospital, Showa University Northern Yokohama Hospital and Showa University Koto Toyosu Hospital were recruited from 2005 to 2016. This study design was retrospective cohort study. Loss to follow-up was eliminated. The patients were divided into two groups, whose age was 65 years old and over (elderly) and under 65 (adults). The primary outcome was the change of QOL in 6months'. QOL was measure using SF-36, and we use physical component scale (PCS) and mental component scale (MCS). Logistic regression analysis was performed.

Results: Among 149 RA patients, the mean age was 57 years old and 85.9% was female. 92 out of 149 patients (61.7%) were adult group and 57 (38.3%) were elderly group. Adjusted with sex, disease duration, DAS28-ESR, HAQ, and with or without complications which are interstitial lung disease, diabetes mellitus, and chronic kidney disease, there was no significant difference in change of MCS in 6 months'. But those of PCS was significantly higher in adult's group (regression coefficients -7.25; 95% Confidence Interval (CI) -11.7 to -2.77; $p=0.0018$).

Conclusions: There is a possibility that, younger patient who suffers with RA could achieve better quality of life than those of elderly patients after treatment with biologic agents.

Table1.

		Total (n=149)	Adults (n=92)	Elderly (n=57)
Age	mean(SD)	57(15.4)	47(12.2)	71(5.63)
Female	n(%)	128 (85.9)	77 (83.7)	51 (89.4)

AB0259 PREDICTORS OF HIGH DISEASE ACTIVITY IN A COHORT OF GREEK PATIENTS WITH ACPA POSITIVE EARLY RHEUMATOID ARTHRITIS

N. Papadopoulos[1], A. Gkagkalis[2], E. Konstantinidou[3], L. Mentesidou[1], G. Tzatzagou[4], V. Galanopoulou[1]. *[1]Rheumatology Unit; [2]Gastroenterology Unit, Papageorgiou General Hospital; [3]Molecular Biologist, PRIVATE; [4]1st INTERNAL MEDICINE CLINIC, Papageorgiou General Hospital, Thessaloniki, Greece*

Background: In Early Rheumatoid Arthritis, the presence of ACPA positivity is associated with increased disease activity.
Objectives: To investigate possible predictors, for high disease activity (DAS-28 >5.1), in a cohort of Greek patients with ACPA positive early RA.
Methods: From 2000 until December 2016, 156 patients with ACPA positive early RA, were diagnosed and subsequently followed up as outpatients at the Rheumatology Unit of our hospital. Demographic, clinical, laboratory and therapeutic parameters were evaluated during every follow-up. At the end of the study (last visit during 2016), all the above parameters were re-evaluated, considering the high disase activity (DAS-28 >5.1). The used methods were χ^2, ANOVA, Binary Logistic Regression (BLR) and ROC Curve.
Results: From 156 patients, 25% were males, 37.8% were current smokers, 76.9% were RF positive, 34.6% presenting with extra-articular manifestations and 16% with anemia of chronic disease (ACD). At the time of diagnosis, Univariate analysis revealed that smokers, RF positivity, high levels of CRP, patients with extra-articular manifestations and those with ACD, corellate statstically significant with high disease activity (p=0.011, p=0.006, p=0.03, p=0.001 and p=0.001 respectively). Using the BRL we found that the odds ratio for DAS-28 >5.1, were for smokers 2.95, for RF positivity 3.397 and for CRP 1.066 respectively. Based on the previous results the severity of disease can be predicted with sensitivity 80% (area unedr the curve: p<0.001, CI=0.723–0.878) using the ROC curve.
Conclusions: |High Diseasae Activity in ACPA positive early RA, at diagnosis, is best predicted by smoking, RF positivity and high levels of CRP.

AB0260 THE PREDICTORS OF FRAGILITY FRACTURES IN PATIENTS ON AROMATASE INHIBITORS: AN OBSERVATIONAL STUDY

N. Meah[1], R. Sinha[2], M. Bukhari[2]. *[1]Lancaster Medical School; [2]Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom*

Background: The use of aromatase inhibitors (AIs), given after breast cancer, has been associated with a low bone mineral density (BMD) and as a risk factor for fragility fractures. We have reported on the risk factor for low BMD in a previous abstract and it showed that the use of AIs significantly reduced lumbar spine BMD and femoral neck BMD (1). The FRAX ™ tool uses the femoral neck BMD to predict fractures on a population basis but ignores the lumbar spine. Some patients who have undergone bilateral hip replacements would not be able to estimate their FRAX ™ risk accurately.
Objectives: To determine the predictors of fragility fractures in an observational cohort of female patients on aromatase inhibitors.
Methods: Female patients referred for BMD estimation in a scanner in the North West of England between 2004 and 2014 on aromatase inhibitors were identified from a dual X-ray absorptiometry database. Demographics and other risk factors, as well as fragility fractures, were recorded. Initially, those who had sustained a fracture were compared to those who had not sustained a fracture using chi-squared tests for categorical variables and T-tests for continuous variables. Following that, univariate and multivariate logistic regression models were fitted looking at the predictors of fracture. Variables included age at scan, height, weight, alcohol, smoking, family history, rheumatoid arthritis, secondary osteoporosis as defined by FRAX™, body mass index and steroid exposure, in addition to BMD in the lumbar spine and femoral neck.
Results: 2029 female patients were scanned in the referral period. The mean age at scan was 66 (SD 10.46). 356/2029 (17.55%) had sustained a fracture. Results of the univariate analysis are shown in table 1, significant predictors are indicated with an asterisk (*).

Predictor	All Pts	Pts with Fracture	Pts without Fracture	p-value	Odds ratio (95% CI)
Age at scan (years)	65.85	69.41	65.09	0.00	1.04 (1.03,1.05)*
Height (cm)	160.40	159.60	160.57	0.02	0.98 (0.96,1.00)*
Weight (kg)	72.38	71.35	72.60	0.15	1.00 (0.99,1.00)*
Alcohol	123 (6.06%)	22 (6.18%)	101 (6.04%)	0.92	1.03 (0.64,1.65)
Smoking	698 (34.40%)	132 (37.08%)	566 (33.83%)	0.24	1.15 (0.91, 1.46)
Family Hx	247 (12.17%)	48 (13.48%)	199 (11.89%)	0.41	1.15 (0.82,1.62)
RA	32 (1.58%)	10 (2.81%)	22 (1.32%)	0.04	2.17 (1.02,4.62)*
Secondary op	183 (9.02%)	46 (12.92%)	137 (8.19%)	0.01	1.66 (1.17,2.37)*
Femoral Neck BMD (g/cm^2)	0.87	0.82	0.88	0.00	0.02 (0.01,0.05)*
Lumbar Spine BMD (g/cm^2)	1.10	1.05	1.12	0.00	0.12 (0.06,0.24)*
BMI (kg/m^2)	28.13	28.00	28.16	0.61	0.99 (0.97,1.02)
Steroid	466 (22.97%)	77 (21.63%)	389 (23.25%)	0.51	0.91 (0.69,1.20)

In the multivariate model, the variables that predicted fractures in this cohort were age at scan (OR 1.03 95% CI 1.02,1.05), femoral neck BMD (OR 0.74 95% CI 0.02,0.29) and lumbar spine BMD (OR 0.34 95% CI 0.14,0.80). Using the femoral neck multivariate model resulted in an area under the curve of 0.6720 and using the lumbar spine was 0.6653.
Conclusions: In the univariate analysis, many risk factors are associated with fractures within this cohort of female patients on aromatase inhibitors but both univariate analysis and multivariate analysis showed that lumbar spine BMD is a good predictor of fractures. This is not included in the FRAX ™ tool and would enable fracture risk to be calculated in patients who have undergone hip replacements.

AB0261 CLINICAL AND STRUCTURAL RESPONSES OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS (RA) USING STEP-UP DOSAGES OF TOFACITINIB IN A TREAT TO TARGET APPROACH

N.B. Gaylis[1], J. Sagliani[1], S. Needell[2]. *[1]Arthritis and Rheumatic Disease Specialties, Aventura; [2]Boca Radiology, Boca Raton, United States*

Background: Tofacitinib has been shown to reduce the clinical signs and symptoms of some RA patients at an approved dose of 5 mg bid. Studies report that 10 mg bid is an effective dose. This is the first community practice trial to measure the clinical and structural benefits of stepping up the initial dose of 5 mg bid in non-responders to 10 mg bid in order to achieve a clinical response using a treat to target approach.
Objectives: This study evaluates the optimal dose of tofacitinib (5 mg bid VS 10 mg bid) needed to reach treatment target in a cohort of patients with active RA while comparing the corresponding structural findings measured by low field MRI.
Methods: 20 RA patients who were unresponsive to either methotrexate (10–25 mg weekly) or MTX plus up to 2 prior biologics with synovitis, osteitis or erosions on Baseline MRI (Esaote 0.3T) were treated with 5 mg bid tofacitinib with a treat to target goal of Low Disease Activity (LDA) or remission depending on the Clinical Activity Index (CDAI) score at Baseline. If the target was not met and sustained for 3 months, the dose of tofacitinib was increased to 10 mg bid in an attempt to reach target. MRIs of the hand/wrist were blindly read by a musculoskeletal radiologist using a rheumatoid arthritis MRI scoring system (RAMRIS). A CDAI score of >10 was needed at study entry.
Results: Of the 20 enrolled patients, 6 remained at 5 mg bid and 14 were dose escalated to 10 mg bid most at the 12 week period. Of the 5 mg bid group, 3 completed the trial at target and 3 early termed (ET) for lack of efficacy, relocation and AE. Structurally, there was no change in erosions in all 3 patients; 2 showed regression of synovitis and 1 showed no change; 2 showed regression in osteitis and 1 no change. Of the 14 patients escalated to 10 mg bid, 11 completed the trial with 7 remissions, 2 at LDA, and 1 at MDA. 3 patients ET due to lack of efficacy. In the 10 mg bid group, 9 patients showed no change in erosions, 1 regression and 1 progression. 5 patients showed no change in synovitis and 6 showed regression, and 7 showed no change in osteitis, 3 showed regression and 1 showed progression. The CRP values correlated with the improvement of

the clinical and structural results, in particular, the levels improved after the dose was increased to 10 mg bid.

Patient	CDAI BSL	CDAI 3 Mnth All taking 5 mg bid	CDAI 12 Mnth Remain on 5 mg bid	CDAI 12 Mnth Dose Increased 10 mg bid
001	24.9	0.6	6	
002	56.1	20.9		2.7
003	45.9	27.4		2.3
004	65.2	33.8		0
005	56.1	15.5		3.1
006	34.7	38.9		19.4
007	27.9	56		1.5
008	34.3	18.4		1.8
009	43.6	3.3	2.3	
010	33.5	12.6		ET
011	32.7	5.1	ET	
012	25.3	13		0
013	21.2	2.4	ET	
014	21.6	9.9		2.9
015	21.6	5.2		ET
016	27.7	0.4	ET	
018	31.8	16.9		2.1
019	27.3	0.9		5.2
020	14.5	5.2		ET
021	30.5	2.1	1.9	

Conclusions: Our results suggest that a significant number of patients treated with the standard dose of 5 mg bid may potentially have improved outcomes including LDA or remission when treated at a higher dose (10 mg bid). As is evidenced by the results in this study, 11 of the 14 patients had significant improved response after treatment with the step up dose. It would appear that this improved result occurs by 3 months of therapy. Furthermore, the structural findings correlate in large part to the clinical findings showing stabilization or improvement in the majority of patients. A larger study is needed to validate these clinical and structural responses as well as to evaluate the safety outcomes using 10 mg bid for intervals of more than 12 months.

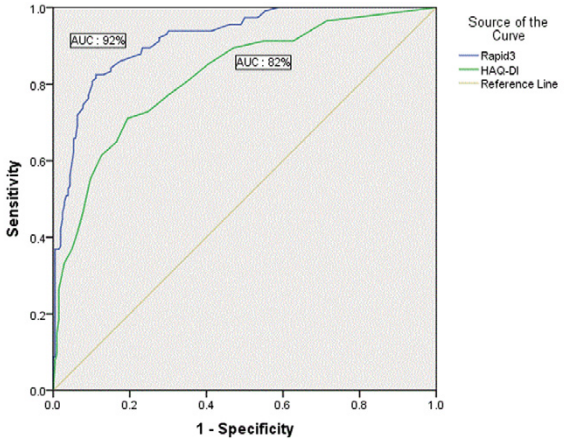
AB0262 EVALUATION OF PATIENT REPORTED OUTCOME USING RAPID3 AND HAQ-DI COMPARED TO DAS28: EXPERIENCE FROM ROUTINE CLINICAL PRACTICE IN MALAYSIA

N. Mohd Jamid[1], B. D'Souza[1], H.C. Hong[1], N. Mohd Noor[1], C.K. Cheah[1], Y.L. Lee[2], S.C. Gun[1]. *[1]Hospital Tuanku Jaafar, Seremban; [2]PFIZER, Kuala Lumpur, Malaysia*

Background: Patient reported outcome (PRO) is an important measure to physician in management of patient with rheumatic diseases. Health assessment questionnaire disability index (HAQ-DI) is the most widely used PRO tool in rheumatoid arthritis (RA) clinical trials. Previous studies have shown that HAQ-DI correlates well with disease activity score of 28-joints (DAS28). However, routine assessment of patient index data 3 (RAPID3) is much simpler and faster questionnaire to score.



Objectives: This study aims to evaluate the correlation between RAPID3 and DAS28 compared to HAQ-DI and DAS28 in our population.

Methods: RA patients who received routine treatment in Hospital Tuanku Ja'afar from March to November 2016 were included in this study. Validated RAPID3 and HAQ-DI questionnaire were made available in other languages; Malay, Chinese and Tamil, for patients who were not English literate. Descriptive analysis were conducted. Pearson correlation was used to measure the correlation between these PRO tools while area under the curve of the receiver operating characteristic (ROC) curves evaluate the sensitivity to detect disease activity. DAS28-ESR and DAS28-CRP were used as the reference variable in ROC analysis to stratified the disease activity into two groups; low (remission and low) and high (moderate and high) disease activity.

Results: A total of 400 patients completed PRO assessments were available for analysis. The median age of our cohort was 57 years old (range 22 to 88) and 87.5% were female. Ethnic distribution in this cohort were as follows; 38.5% Indian, 31.8% Malay and 27.8% Chinese. Both RAPID3 ($r=0.74, p<0.001$) and HAQ-DI ($r=0.57, p<0.001$) were correlated with DAS28-ESR. The area under the curve was significantly higher in RAPID3 (83%) compared to HAQ-DI (75%) which implied greater performance in discriminating low and high disease activity using DAS28-ESR as reference. We observed similar performance trend between RAPID3 (92%) and HAQ-DI (82%) compared to DAS28-CRP.

Conclusions: In conclusion, RAPID3 is an effective quantitative measure of disease activity compared to HAQ-DI in our population. Furthermore, RAPID3 yield similar disease activity categories as DAS28 without the need of joint counts

ROC Curve to discriminate low and high disease activity using DAS28CRP as reference.

and laboratory tests. Hence is an informative assessment of disease activity in busy clinic settings.

AB0263 PREDICTIVE VALUE OF A SINGLE MEASUREMENT OF THE MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) SCORE FOR DISEASE FLARES WITHIN 6 AND 12 MONTHS IN RHEUMATOID ARTHRITIS PATIENTS USING TUMOR NECROSIS FACTOR INHIBITORS AND CONVENTIONAL SYNTHETIC DMARDS

P.M.T. Klooster[1], M. Ghiti-Moghadam[1], F. Lamers-Karnebeek[2], H. Vonkeman[3], E. Sasso[4], P.V. Riel[2], M.V.D. Laar[3], T.L. Jansen[5]. *[1]Rheumatology, University of Twente, Enschede; [2]Rheumatology, Bernhoven hospital, Uden; [3]Rheumatology, Medical Spectrum Twente, Enschede, Netherlands; [4]Medical&Scientific Affairs, Crescendo Bioscience, SanFrancisco, United States; [5]Rheumatology, VieCuri MC, Venlo, Netherlands*

Background: Rheumatoid Arthritis (RA) patients in the maintenance phase should be treated by escalating antirheumatics up to stable low disease activity and then often are treated with tumor necrosis factor inhibitors (TNFi) and conventional synthetic disease modifyers (csDMARD). Once this phase has been reached the risk of flare is an issue once drugs are to be tapered or discontinued.

Objectives: To examine the ability of the multi-biomarker disease activity (MBDA) score as predictor for disease flare in rheumatoid arthritis (RA) patients with stable low disease activity using tumor necrosis factor inhibitors (TNFi) and conventional synthetic disease modifyers (csDMARD).

Methods: Data were used from the continuation control group of the Dutch multicenter, open-label, POET trial, in which patients with stable low disease activity (disease activity score [DAS28] <3.2 for at least 6 months] were randomized to either stop or continue TNFi treatment. Three indicators of disease relapse were assessed: 1) flare based on DAS28 (DAS28 ≥ 3.2 with ΔDAS28 >0.6), 2) flare based on escalation of any DMARD therapy, and 3) flare based on physician-reported disease activity. Associations between baseline MBDA score and meeting the different criteria for disease flare within 6 or 12 months of follow-up were examined using univariate analysis and multivariate logistic regression adjusting for baseline DAS28 score.

Results: For this post-hoc analysis, baseline serum samples to measure MBDA scores were available for 225/286 (78.7%) of the patients randomized to the TNFi continuation group (88.9% also used methotrexate, another 8.0% used another csDMARD and 3.1% used no csDMARD): 86.2% with a first TNFi, 11.6% with second TNFi and 2.2% with a third TNFi. Within 12 months, 19.1% of patients had experienced a DAS28 flare, 12.0% had medication escalation and 8.0% had ≥ 1 physician-reported flare. Median time to DAS28-based flare was 26 weeks (IQR:13–28). Univariately, patients with high baseline MBDA (>44) scores (n=31) were at increased risk of experiencing a DAS28 flare within 6 (OR =4.39, P=0.001) or 12 (OR =2.78, P=0.015) months. MBDA scores were not associated with increased risk of medication escalation or physician-reported flare. After adjustment for baseline DAS28 scores, high MBDA score remained predictive for risk of flare within 6 months (OR =3.15, P=0.017), but not for flare within 12 months (OR =2.05, P=0.107).

Conclusions: MBDA score may be of additional value in predicting DAS28 flares but not in predicting medication escalations or physician-reported flares in RA patients on TNFi in stable low disease activity.

AB0264 THE PERFORIN A91V GENE AND CLINICAL FEATURES ANALYSIS IN CHINESE SO-JIA CASES WITH MACROPHAGE ACTIVATION SYNDROME

P. Wei[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: Macrophage activation syndrome (MAS) is a severe, potentially fatal complication of rheumatoid disease, especially in the systemic onset juvenile idiopathic arthritis (SoJIA). we aimed to investigate the clinical characteristics of 31 SOJIA cases with MAS and the perforin A91V gene were detected in part cases
Methods: gene-specific polymerase chain reaction (PCR) primers were used to analyze the perforin A91Vgene polymorphism.
Results: 31 soJIA cases were associated with MAS.25 out of 31 cases (83%) had infections prior to MAS. Serum ferritin was significantly increased in 27 cases (87.10%). High concentrations of triglycerides (23cases, 74.19%) and lactic dehydrogenase (27cases, 87.10%) are observed. What is more, Creatine Kinase (CK) increased in all cases that had been checked. Well-differentiated macrophages phagocytosing hematopoietic elements were found in all cases (100%).6 cases (19.35%) merged with multiple organ dysfunctions (MODS). The perforin A91V (NCBI: SNP rs35947132) variant gene was detected in twenty cases, but no mutation was found. Corticosteroids, immunosuppressant, cell cycle inhibitors, immunoglobulin, Tumor necrosis factor (TNF) antagonist and plasmapheresis were effective. After treatment, 28cases (90.32%) children were in remission, while 3 out of 31 cases died with mortality of 9.68%.
Conclusions: MAS is a life-threatening complication of systemic onset juvenile idiopathic arthritis. Most cases were preceded by infection. Unremitted fever, progressive hepatosplenomegaly, lymphadenopathy, cytopenias, elevated serum liver enzymes significantly increased serum ferritin are the main feature. Early diagnosis and treatment is the key to improve prognosis. The perforin gene mutations in our patients have not found yet.

AB0265 THE SIGNIFICANCE OF EARLY DIAGNOSIS AND PROGNOSTIC EVALUATION OF FOUR KINDS OF ANTI-CCP ANTIBODIES IN VARIOUS TYPES OF JUVENILE IDIOPATHIC ARTHRITIS

P. Zeng[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: To investigate the relationship between immunological parameters AKA, anti - CCP, the RF- IGG, RF-IGM and the early diagnosis and prognosis in sub- JIA patients.
Methods: Collection of 76 JIA patients in our hospital with system treatment and adhere to the follow-up treatment for at least six months, detect the immunological parameters of AKA, anti- CCP, RF-IGG, RF-IGM in the early diagnosis, compare the Positive rate in different subtypes and prognosis, and make the statistical analysis of sensitivity, specificity and relevant risk, compare to the normal control group of blood of 49 healthy children.
Results: There is a significant difference between polyarticular group and normal control group in positive rate of AKA, anti-CCP, RF-IGG, RF-IGM, there is no significant difference between the type of systemic, oligoarticular, enthesitis and the normal control group in autoantibody-positive detection rate. Polyarticular group's sensitivity AKA > anti-CCP, RF-IGG > RF-IGM and four kinds of joint detection, specificity RF-IGM, four kinds of joint detection > AKA > RFIGG > anti-CCP. There is a significantly different between refractory JIA and general JIA patients in AKA positive rate, relative risk OR is 3.514%.
Conclusions: The effect of AKA, anti-CCP, RF- IGG, RF-IGM in the different subtypes of JIA about early diagnosis are different, it is found that AKA, anti-CCP has good sensitivity and specificity in polyarticular JIA, AKA appears relate with refractory JIA, it is a large sample of the study to be confirmed that whether it can be a serological marker in the early diagnosis and prognosis of Polyarticular JIA.

AB0266 EFFECTS OF PERIODONTAL BASIC TREATMENT ON PERIODONTAL CONDITION,CLINICAL RESPONSE AND SERUM INFLAMMATORY PARAMETERS IN RHEUMATOID ARTHRITIS (RA) PATIENTS WITH MODERATE TO SEVERE PERIODONTITIS

F. Xiao, P. Zhang, X. Li, Y. Mou, H. Chen, Y. Cai. *The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Periodontal disease (PD) shares several clinical and pathogenic characteristics with Rheumatoid Arthritis (RA). Some intervention studies have suggested that periodontal treatment can reduce serum inflammatory biomarkers such as C-reactive protein, or erythrocyte sedimentation rate. Periodontal diseases are not only a threat to dentition, but may also be an aggravating factor in patients with RA, its treatment may improve the RA outcomes.In this study we assessed the effect of periodontal basic therapy in relieving the PD symptoms and the clinical signs of RA in order to evaluate the importance of periodontal treatment in the control of inflammation.
Objectives: To evaluate the effects of periodontal basic treatment on periodontal condition, clinical response and serum inflammatory parameters in RA patients with moderate to severe periodontitis.
Methods: A total of 46 subjects with confirmed diagnosis of RA and moderate to severe periodontitis were included in the study. 18 subjects completing the study received periodontal basic treatment consisting of scaling/root planing and oral hygiene instruction at baseline and at 6 weeks; 28 subjects completing the study received no treatment as control group. Participants continued their usual disease-modifying medications for RA without any changes in DMARD therapy during the study period. Periodontal indices and RA measurements, such as probing depth (Pd), clinical attachment level (CAL), bleeding on probing (BOP), high-sensitivity C-reactive protein (hsCRP), erythrocyte sedimentation rate (ESR), disease activity score in 28 joints (DAS28) and subjective symptom were recorded at baseline, 6 and 12 weeks for each participant.
Results: After periodontal basic treatment,significantly lower Pd, CAL and BOP were observed in the treatment group ($P<0.01$),hsCRP,ESR,DAS28 and patients' subjective symptom improved significantly ($p<0.05$).Besides,the Pd and BOP were statistically significant between treatment subjects after therapy and controls ($P<0.001$).Although hsCRP was significantly lower in the treatment group after therapy than controls ($P<0.01$),there was no significant difference in the DAS 28 level between the two groups after periodontal basic therapy ($P>0.05$). Visual analog scale (VAS)was used to evalue patients' subjective symptom,the results show that the improvement was much better in patients received periodontal therapy than controls ($P<0.001$).
Conclusions: Periodontal basic treatment can effectively improve periodontal status, patients' subjective symptom and circulating inflammatory status.

Background: ACTION is a 2-year, observational study of patients (pts) with moderate-to-severe RA who initiated IV abatacept (ABA) in Canada and Europe (NCT02109666).
Objectives: To determine pt biologic (b)DMARD use prior to initiation and after discontinuation of ABA overall and by treatment line in ACTION.
Methods: Pts with RA initiated IV ABA as first- or second-/further-line therapy. Biologic-naïve and biologic-failure pts were enrolled during three periods between May 2008 and December 2013. Pts could switch administration routes (IV to SC) during treatment. Crude retention rates (Kaplan–Meier) were compared by log-rank test.
Results: Of the 2364 pts enrolled, 2350 were evaluable for analysis: 673 (28.6%) were biologic naïve and 1677 (71.4%) biologic failures. Baseline characteristics differed: biologic-failure pts had longer RA duration, higher CRP levels and prevalence of radiographic erosions, and lower rates of chronic obstructive

pulmonary disease and neoplasms vs biologic-naïve pts. Most biologic-failure pts (96.7%) had previously received ≥1 TNF inhibitor (TNFi): 48.7% had received 1 and 48.0% ≥2 TNFi; 56.6% had received ≥2 bDMARDs. The overall 2-year retention rate was 47.9% and was higher for biologic-naïve vs biologic-failure pts (54.5 vs 45.2%; p<0.001); the most common reasons for ABA discontinuation were inefficacy (61.4 vs 67.7%) and safety (21.3 vs 21.2%). In pts who discontinued ABA, 83.0% started a bDMARD ≤6 months after discontinuation (Table), most commonly ABA IV. Mean (SD) days from stopping ABA to starting a bDMARD was similar for biologic-naïve (93.4 [51.3]) and biologic-failure pts (93.6 [48.0]). Among pts who restarted ABA, 62 (80.5%) biologic-naïve and 158 (85.0%) biologic-failure pts were considered to have discontinued as the time from last dose was >84 (IV) or >28 (SC) days, and thus were no longer temporary discontinuations, as predefined in the protocol. Three pts discontinued for bad compliance, 3 for lack of efficacy, 3 for remission/major improvement, 12 for safety and 15 for surgery. A good/moderate EULAR response was achieved by 76.7% of pts at the last follow-up before ABA discontinuation and 58.3% at ABA restart; mean (SD) DAS28 (CRP) was 3.2 (1.1) and 3.8 (1.4), respectively.

	bDMARD ≤6 months after ABA discontinuation		bDMARD prior to initial ABA treatment in pts who restarted ABA
	Biologic naïve n=186	Biologic failure n=526	Biologic failure n=186
None	35 (18.8)	86 (16.3)	
Abatacept	77 (41.4)	186 (35.4)	–
IV	71 (38.2)	170 (32.3)	
SC	6 (3.2)	16 (3.0)	
TNFi	41 (22.0)	74 (14.1)	181 (97.3)
Adalimumab	10 (5.4)	12 (2.3)	108 (58.1)
Etanercept	13 (7.0)	21 (4.0)	125 (67.2)
Infliximab	7 (3.8)	13 (2.5)	55 (29.6)
Certolizumab	7 (3.8)	17 (3.2)	5 (2.7)
Golimumab	4 (2.2)	11 (2.1)	2 (1.1)
Other bDMARD	33 (17.7)	180 (34.2)	51 (27.4)
Anakinra	1 (0.5)	4 (0.8)	5 (2.7)
Rituximab	6 (3.2)	58 (11.0)	30 (16.1)
Tocilizumab	26 (14.0)	118 (22.4)	21 (11.3)
		Data are n (%)	

Conclusions: Prior to abatacept treatment, over half of biologic-failure pts had received ≥2 bDMARDs and most had received a TNFi. After initial discontinuation (protocol defined), over one-third of pts restarted abatacept.

AB0268 ACPA SEROPOSITIVITY AND PERIPHERAL NATURAL KILLER CELLS AS PREDICTIVE MARKERS OF CLINICAL RESPONSE TO RITUXIMAB IN RHEUMATOID ARTHRITIS PATIENTS

R.M. Ferreira, R. Fonseca, D.R. Gonçalves, F. Aguiar, T.M. Rocha, A. Bernardo, S. Pimenta, M. Bernardes, L. Costa. *São João Hospital Centre, Porto, Portugal*

Background: The efficacy of B cell-depletion therapy confirms the importance of B lymphocytes in rheumatoid arthritis's (RA) pathogenesis. Rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) are prognostic factors for a more severe disease. Others immune elements, namely natural killer (NK) cells, seems to influence RA clinical response to rituximab (RTX), but data are lacking.

Objectives: To analyze the influence of baseline status/levels of RF, ACPA and serum immunoglobulin G (IgG) level in RTX treatment. To study the effect of RTX on NK and CD19+ cells in RA patients and their association with clinical response at 6, 12 and 18 months (M).

Methods: An observational retrospective study was conducted, including all the consecutive patients with diagnosis of RA under rituximab, followed at our Rheumatology department. Demographic and clinical data were obtained by consulting the national database (Reuma.pt) and the analysis was limited until december 2016. RF, ACPA and IgG titres were evaluated at baseline. NK (CD56+CD16+) and B lymphocytes (CD19+) absolute counts were assessed by flow cytometry prior to the first RTX cycle and 6 M after. Clinical responses were assessed by DAS28 and EULAR criteria at 6, 12 and 18 M. Correlations were studied using Spearman coefficient analysis (SPSS 20.0). Significance level was set as 0.05.

Results: We included 63 RA patients (81% of women), with a mean (SD) age of 61 (10) years and a mean disease duration of 19 (10) years, 86% RF-positive and 87% ACPA-positive. Bone erosions were present in 86% of the patients. At baseline, the mean DAS28 was 5.79 (1.55). Combination therapy with methotrexate or with others cDMARDs was used in 48% and 30% of the patients, respectively; RTX monotherapy in 22% of our sample. Thirty three patients were previously exposed to other biologics. The magnitude of response was greater in ACPA-positive vs ACPA-negative patients in terms of DAS28 variation at 6, 12 and 18M (medians of 1.09 vs -0.08; 2.03 vs 0.35 and 2.10 vs 0.19; p=0.029, p=0.039 and p=0.004, respectively), without significant differences between groups in terms of initial DAS28 (5.91 (1.60) vs 5.00 (0.90), p=0.051). The presence of ACPA was also significantly associated with EULAR response at 6, 12 and 18 M (64%, 75% and 85% in ACPA-positive patients vs 25%, 16% and 25% in ACPA-negative patients; p=0.034, p=0.010 and p=0.001, respectively). Outcomes did not differ according FR status. There were no associations between the values of FR, ACPA and IgG at baseline with the clinical response (DAS28 variation). CD19+ cells depletion occurred in all patients (mean of 146.4/mm^3 at baseline vs 10.6/mm^3 at 6M). An increase of peripheral NK cells was seen at 6M (mean 231mm/3 at baseline vs 289/mm^3 at 6 M). We only have found a positive correlation between NK cells number at baseline and DAS28 variation at 6 M (r=0.35, p=0.023). There were no associations between, neither NK cells, nor CD19 cells variations at 6M with clinical response to RTX.

Conclusions: Our data suggest that ACPA seropositivity is associated with a better clinical response to RTX in RA patients. NK cells at baseline may be useful to identify early responders to RTX.

AB0269 RAPID RADIOGRAPHIC PROGRESSION PROGNOSTIC FACTORS IN A LATIN AMERICAN COHORT OF RHEUMATOID ARTHRITIS

R. Gamboa-Cárdenas[1], M. Ugarte-Gil[2], F. Zevallos-Miranda[2], M. Medina-Chinchòn[2], C. Elera-Fitzcarrald[2], V. Pimentel-Quiroz[2], J. Cucho-Venegas[2], O. Sarmiento-Velasquez[2], C. Reàtegui-Solokova[1], J. Alfaro-Lozano[2], Z. Rodriguez Bellido[2], C. Pastor-Asurza[2], R. Perich-Campos[2]. *[1]Rheumatology; [2]HNGAI, Lima, Peru*

Background: Rapid Radiographic Progression (RRP) in Rheumatoid Arthritis (RA) patients predicts long-term disability (1), high related economic costs (2) and loss of working time (3). Detection of RRP predictors as a necessary tool for aggressive therapeutic interventions has been proved, but in Latin-American cohorts, no available data had been reported.

Objectives: To determine independent risk factors associated with RRP in a cohort of RA patients

Methods: A prospective analysis of RA Almenara cohort (January 2015-April 2016), 500 patients followed up with annual evaluations (background clinical/epidemiology, clinimetric, laboratory, health questionnaires and X-rays) who meet ACR 87/ACR-EULAR 2010 criteria's, older than 16 years at diagnosis,sign informed consent. Patients with overlap (except Sjögren), with active infections and/or pregnancy are excluded. Patients with at least two radiographs (baseline/final) were included. The X-rays were taken in a standardized protocol (each hand and foot). Joint damage was measured by Sharp-VDH (erosions, decreased joint space, and total scores). Radiographic Progression (RP) as a annual difference in Sharp-VDH score and RRP (>5 units in RP) were determined. A blinded rheumatologist for the RA condition read all films. Associated factors were analyzed (gender, socioeconomic level, smoking, age at diagnosis, time disease, use of biological and non-biological DMARDs, DAS 28, current steroids, HAQ/functional capacity, RF and basal SharpVDH score). Diagnosis delay and CRP were included to analyze risk factors in the RRP group. Statistical analyzesTweedie regression models with logarithm link. SPSS v. 21.0 was used

Results: 153 patients, 90.8% women, middle low (37.9%) and middle (35.3%) the most prevalent socioeconomic status. Age at diagnosis was 46.06 (12.73) years, time disease 14.25 (10.26) years. DAS28 average: 4.51 (1.33). Basal Sharp VDH:104.53 (90.09), CRP: 9.77 (10.35) UI/L, RF: 352.49 (538.08) UI/L, ACPA: 563.64 (782.2)UI/dL. PR annual rate was 7.64 (2.4 years of follow up),94.8% increased damage and 74 patients (48.36%) had PRR. Most subjects (94.1%) were using DMARDs but only 15 (9.8%) biologicals. The mean dose of prednisone was 4.88 (3.33) mg/d. In the univariate analysis, only DMARDs was associated with RP (B=50.8; CI=40.13–51.48, p<0.001), remaining this association in the multivariate analysis (B=50.56;CI=49.80–51.33,p<0.001). In the multivariate analysis of RRP group, no variables was associated with risk and subjects with steroids use had less radiographic impairment (B=0.859; CI 0.759–0, 893,p=0.017).

Conclusions: In this prospective study of an established RA cohort, a large proportion of patients had RRP and there was few percentage of biologic use. In the RRP subset only steroids use was a protective factor.

AB0270 HOW DOES THE ACTIVITY OF RHEUMATOID ARTHRITIS EVOLVE WITHIN A COHORT OF RECENT ONSET PATIENTS WITH A 5-YEAR FOLLOW-UP?

R. Jiménez Gasco, R. Ortega Castro, J. Calvo Gutierrez, P. Font Ugalde, A. Escudero Contreras, E. Collantes Estevez. *Reumatología, Hospital Universitario Reina Sofia de Córdoba, Cordoba, Spain*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease affecting 0.5% of Spanish population. This disease results in a significant radiological and functional deterioration, decreasing the quality of life and increasing its mortality if an specific treatment is not applied. Although the radiological and functional deterioration progress slowly during the whole course of the disease, it has been proven that early and aggressive approach to the disease is important in order for its control because the final outcome can be improved with a close, intense and early follow-up.
Objectives: To describe the clinical characteristics and evolution during 5 years of disease activity in RA patients derived from a recent arthritis clinic.
Methods: A prospective longitudinal study was carried out of 154 patients diagnosed from 2003 to 2012. They included patients over 18 years old diagnosed with RA (ACR criteria 1987) and with 5 years of follow-up. Socio-demographic and clinical variables such as Rheumatoid factor (FR) and anti-citrullinated peptide antibodies (ACPA) or disease activity (DAS28-VSG) as well as treatment were assessed in those patients. Mean and standard deviation of quantitative variables and frequencies and percentages of qualitative variables were calculated. Proportions were compared using the Cochran Q test statistic in order to compare differences between remission (determined by DAS-28 <2.6) measured at 1 year, 2 years and 5 years from diagnosis. Data were analyzed using SPSS v17 program.
Results: Of the 154 patients, 66.2% were females with a mean age at diagnosis of 52.88±14.64 years. Only 18.8% (29) patients were smokers; 67.5% (104) of patients were RF positive and 57% (88) of them were ACPA positive. Clinical remission measured by means of DAS 28-VSG (<2.6) was achieved in 84 patients (54.5%), 92 patients (59.7%) and 95 patients (61.7%) after 1, 2 and 5 years, respectively. Mean values of DAS 28 were 2.58 (2.02) at first year, 2.56 (1.99) at two years and 2.59 (2.02) at 5 years. Of the 154 patients, 108 (78.8%) started treatment with monotherapy (mostly methotrexate) and after 5 years only 18 (25.7%) patients were on biological treatment. No differences were found when remission was compared at first, second and 5 years of follow-up.
Subsequent comparison of two-to-two ratios among the three groups using χ^2 contrast also indicated that there were no statistically significant differences between groups. However a tendency in data was observed, so that once patients had reached the remission at first year there was no increase in the number of them showing remission in the successive years of follow-up.
Conclusions: These results suggest that achieving an early control of the disease is of importance, since control of the disease becomes more difficult as the delay of the diagnosis increases.

AB0271 T2T ADHERENCE MEASUREMENT TOOL PERFORMANCE IN RHEUMATOID ARTHRITIS

R. Garcia Salinas, M.P. Girard Bosch, M.V. Martire, P. Arturi, S. Magri. *Hospital Italiano de la Plata, la Plata, Buenos Aires, Argentina*

Background: The purpose of the T2T approach in RA is to achieve remission or LDA according to results from objective activity measurements. This strategy has proven clinical benefits, however objective adherence T2T measurement tools are lacked in daily practice.
Objectives: To evaluate the setting, usage of a T2T adherence measure: T2T70 and T2T100, and its association with sustained low disease activity (LDAS) as a measure of outcome.
Methods: Prospective study, consecutive patients with RA diagnosis (ACR/EULAR 2010) and follow-up between 1 and 24 months were included. Data from electronic medical record (EHR) were collected. Demographic variables, characteristics of the disease and treatment were recorded. The following T2T characteristics were defined and collected from each patient: number of visits, visits where treatment was adjusted, CDAI measurements, use of ultrasound to measure disease activity and achievement of LDA. Sustained LDA (LDAS) was defined when the patient had 2 or more records of that consecutive state of activity. Measures of adherence to T2T were defined as follows: T2T-70, when therapeutic decisions were accompanied by the measurement of activity by 70% and the interval between visits did not exceed 6 months; And T2T-100, when 100% of the decisions were accompanied with the activity measurement and the interval between each visit did not exceed 6 months. Statistical analysis: a descriptive analysis of the variables was performed and Chi2 test (categorical) and Student or MannWhitney test (continuous) were applied. For multivariate logistic regression analysis we considered as dependent variable LDAs.
Results: 96 patients were included, with a mean follow-up of 15 months (DS 7.8), equivalent to 120.6 patients/year. Eighty percent of the patients were women, mean age 53.7 years (SD 13), disease duration 36 months (RIC, 12–52), 64% had early diagnosis, 85% and 75% positive For FR and ACPA, respectively. According to T2T characteristics, 526 visits were recorded, 270 were treatment adjustment and 208 (78%) of them were performed according to the CDAI value. The frequency of LDAS was 20% (IC95: 12–30). The frequency of T2T-70 compliance was 62.5% (IC95: 52–72) and T2T-100 was 42% (IC95: 32–52). Compliance with T2T-70 and T2T-100 presented a statistically significant association to the achievement of LDAS in the uni and multivariate analysis (p: 0.000). Compliance with T2T-70 and T2T-100 was associated with a shorter time course of disease; And T2T-70 also showed association with early diagnosis.
Conclusions: T2T-70 and T2T-100 adherence were 62% and 42%, respectively, patients who met these criteria reached more LDAS. The early diagnosis and shorter time to disease evolution at baseline were variables that were variables that were associated with more compliance of these tools.

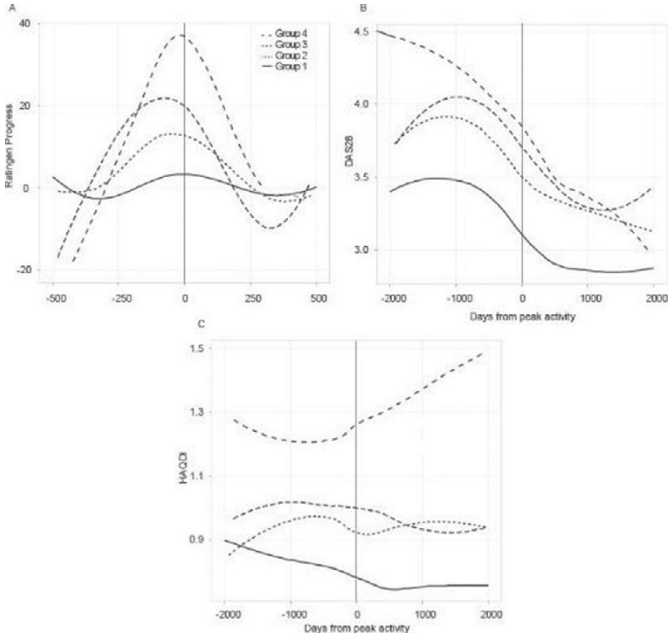
AB0272 THE PERFORMANCE OF A SINGLE CENTRE INTERVENTIONAL CLINIC IN EARLY RHEUMATOID ARTHRITIS

R. Jese, A. Ambrožič, N. Gašperšič, A. Hočevar, K. Perdan Pirkmajer, B. Lestan, M. Pavič Nikolič, M. Plešivčnik Novljan, S. Praprotnik, Ž. Rotar, A. Šipek Dolničar, D. Šuput Skvarča, M. Tomšič. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

Background: In early rheumatoid arthritis (RA), first assessment by a rheumatologist and/or initiation of disease-modifying anti-rheumatic drugs (DMARD) within 12 weeks of symptom onset are associated with a significant benefit in long-term disease outcome.
Objectives: Our objective was to determine the proportion of patients with newly diagnosed RA in whom first rheumatology assessment and/or initiation of DMARD therapy was within the desired time frame.
Methods: A retrospective chart review of adult patients diagnosed with RA during years 2014 and 2015 was performed at the rheumatology department of an integrated secondary/tertiary teaching hospital that provides rheumatology services for a population of more than 500.000 residents. Potential cases were identified by searching the electronic medical records for ICD-10 codes M05.* and M06.* Electronic and paper records of patients were then thoroughly reviewed. In addition to demographic and clinical data, dates were recorded for onset of inflammatory joint symptoms, referral to rheumatologist, initial assessment by a rheumatologist and initiation of DMARD therapy. The percentage of patients assessed by a rheumatologist and/or treated with a DMARD within 12 weeks of symptom onset and the median times for delay were then calculated.
Results: Between January 1st 2014 and December 31st 2015, 243 new cases of RA were identified at our Department of Rheumatology. Of those, 197 (81.1%) were referred to our early interventional clinic. Within 12 weeks of symptom onset, 111 (45.7%) new RA patients were examined by a rheumatologist and 87 (35.8%) were started on DMARD therapy; the median time from symptom onset to consultation was 13.0 (IQR 4.6–27.8) weeks, median time from referral to consultation was 1 (IQR 1–3) days and median DMARD treatment delay was 15.7 (IQR 8.7–31.9) weeks.

Table 1. Demographic data, clinical history, and delays



Gender (female/male) (%)	183/60 (75/25)
Age, years (median)	64.2 (IQR, 52.1–75.9)
Patients fulfilling 2010 ACR/EULAR classification criteria for RA, N (%)	228 (93.8)
DAS28 3v (mean ± SD)	5.3±1.3
Erosive disease (plain radiographs) at first rheumatologist assessment, N (%)	67 (31.5)
Time from symptom onset to first rheumatologist assessment, weeks (median)	13.0 (IQR, 4.6–27.8)
Time from referral to first rheumatologist assessment, weeks (median)	0.14 (IQR, 0.14–0.43)
Time from symptom onset to glucocorticoid initiation, weeks (median)	13.1 (IQR, 5.6–26.9)
Time from symptom onset to DMARD initiation, weeks (median)	15.7 (IQR, 8.7–31.9)

Conclusions: 46% of new RA patients were assessed by a rheumatologist and 36% were treated with a DMARD within the recommended time frame of 12 weeks. Most of the treatment delay was due to the time elapsed between symptom onset and referral to a rheumatologist. These results substantiate the efficacy of our early interventional clinic in diagnosing and treating patients with early RA: despite the heavily protracted nationwide waiting times for first rheumatologist assessment and significantly (40%) lower number of rheumatologists per capita compared to European Union average, the percentage of timely treated patients was comparable to recent reports.

AB0273 VERY HIGH, BUT NOT LOWER, RADIOGRAPHIC PROGRESSION LEADS TO AN INCREASE IN HAQ-DI. RESULTS FROM THE SWISS SCQM RA COHORT

R. Mueller[1], R. Thalmann[1], N. Graf[2], H. Schulze-Koops[3], J. von Kempis[1].
[1]Division of Rheumatology, Kantonsspital St. Gallen, St. Gallen; [2]Graf Biostatistics, Winterthurthur, Switzerland; [3]Rheumaeinheit, Klinikum der Universität München, Campus Innenstadt, Munich, Germany

Background: Numerous predictors of radiographic progression in RA patients have been identified over the last years. In general, analyses of radiographic progression in RA rather focus on radiographic non-progression or repair. High radiographic progression in spite of therapy has, to our knowledge not been analysed in detail in the last years, neither in RCTs nor in cohort studies.
Objectives: To analyse radiographic, demographical and clinical data in RA patients with high radiographic progression before and after the individual peak radiographic progression.
Methods: We included all RA patients from the Swiss registry SCQM with at least two subsequently scored radiographs. Radiographic destruction was scored using the Ratingen erosion score. To analyse high radiographic progression we selected for the highest (peak) radiographic progression in every individual patient for the analysis. The individual peak radiographic progression was analysed in groups as change of Ratingen scores/year: 0-≤10, 10-≤20, 20-≤30, >30 (groups 1–4, follow up 1998 – 2015). The baseline disease characteristics were compared using standard descriptive statistics (Kruskal-Wallis or Chi-square tests). The change of DAS 28 and HAQ-DI scores before and after peak progression was analysed with the Wilcoxon signed rank tests.
Results: 3 patients were included into the analysis. 3'049 patients had a peak radiographic progression between 0 and ≤10/year, 773 between 10 and ≤20, 150 between 20 and ≤30, and 61 of >30. All patient groups were within the same age range (mean: 56.5 – 60.5 years). Rheumatoid factor and ACPA were more frequent in patient groups with higher peak radiographic progression (RF: 73.6, 80.0, 88.9, 90.0; ACPA: 66.8, 73.4, 74.3, 82.1, groups 1–4, respectively). When the rate of radiographic progression before and after peak progression was analysed, 69.7%, 74.7%, 76.9%, and 93.3% of the patients had a radiographic progression of 25% or lower as compared to peak progression before and 76.1%, 81.8%, 91.1%, and 93.8% after this peak progression, respectively for patients in groups 1 to 4 (Figure A).
The disease activity, as assessed by DAS 28, was significantly higher in all patient groups before peak progression and lower thereafter (Figure B, p<0.001). Average HAQ-DI scores increased after peak radiographic progression in group 4 (Figure C, p=0.005) whereas it is stable or even decreases among the patients of the other patient groups.

Conclusions: These data show that higher disease activity precedes radiographic peak progression, which is, if high, overall rare. Radiographic progression before and after the individual peak radiographic progression was far lower as compared to the time of radiographic peak progression. Only the highest individual peak (change of Ratingen score >30/year) radiographic progression was followed by an increase of HAQ-DI scores.

AB0274 THE ASSOCIATION BETWEEN REPEATEDLY INFECTION AND DISEASE OUTCOME IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Zhang[1], J. He[2], C. Li[2], J. Li[2], J. Chen[2], Y. Jin[2], Y. Gan[2], Z. Li[2].
[1]Department of Rheumatology and Immunology; [2]Peking University People's Hospital, Beijing, China

Background: Some publications shows some therapies in rheumatoid arthritis (RA) could cause infections and it also can react the disease prognosis. But there was no report about the relationship between the repeated infections during the disease duration and its outcome.
Objectives: Our study was to evaluate the association between the history of repeated infectious agents that occurred more than three times during the duration of RA and the current disease status of RA, such as disease activity and physical disability.
Methods: 688 pure RA patients were selected from December 2015 to June 2016 in Peking People's hospital and divided into two groups according to their current disease status. Clinical data were collected including DAS28, HAQ, disease duration and therapies. Infectious agents occurred repeatedly during the duration were identified as history repeated infectious agents. T test, ANOVA, chi-squared test and multivariate analysis of covariance were used for analyzing the association between the infections and disease outcome.
Results: 688 RA patients were divided into two groups based on whether their DAS28 reached 3.2 (active or inactive). The HAQ score and the incidence of airway infection has a significant difference among these two groups (P=0.000; P=0.002). Logistic regression analysis shows that smoking, airway infection and age were the risk factor for RA activite (OR=4.844, 95% CI (0.193,1.001); OR=1.326, 95% CI (0.655,2.687); OR=1.013, 95% CI (0.989,1.037)), and the disease duration and the therapy were also effect the disease outcome (OR=0.650;OR=1.560). Than we divided these patients into four groups based on their infectious site such as airway, urinary, intestinal and no-infection. After adjusting for the disease duration, only airway infection incidence has statistically significantly different (P=0.000). DAS 28 has statistical different only among the groups whether they have airway infectious agents after adjusting the smoking and therapy (P=0.002; P=0.002). Compared with infection free group, patients with airway infection has a higher DAS28 because they have more swollen or painful joints, while patients with urinary infection perform a higher scores because they have a high level of ESR.

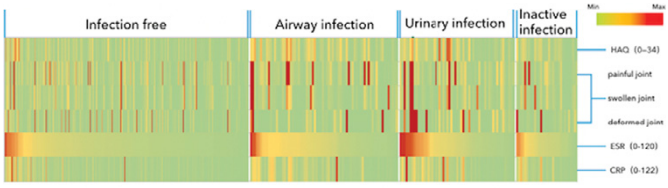

Figure 1. Levels of clinical data include HAQ, abnormal joints number,ESR and CRP were compared among subgroups of infection free(n=469), airway(n=121), urinary(n=75) and inactive infection(n=81).This figure shows which factor contribute to the difference of disease activity between subgroups.

Conclusions: The repeated infectious agents during the disease duration might lead to poor outcome. We should pay more attention to those patients who have repeatedly infectious agents during their disease duration in order to improve their prognosis.

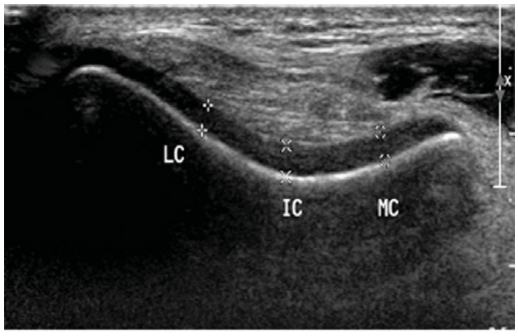
AB0275 THE CORRELATION OF CARTILAGE OLIGOMERIC MATRIX PROTEIN WITH SONOGRAPHIC KNEE CARTILAGE THICKNESS AND DISEASE CHARACTERISTICS IN RHEUMATOID ARTHRITIS

S. Rajalingham[1], S. Rajalingam[2], H. Hussein[2], R. Sridharan[3], A.A. Wahab[4].
[1]Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur; [2]Medicine, Putrajaya Hospital, Putrajaya; [3]Radiology; [4]Microbiology, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia



Background: Cartilage Oligomeric Matrix Protein (COMP) is an extracellular protein which is primarily found in the cartilage and to a lesser extent in ligaments, meniscus, tendons and synovium. Experimental models of rheumatoid arthritis (RA) and osteoarthritis have pointed out that serum COMP levels are reflective of the cartilage turnover rate.

Objectives: To investigate the correlation of serum COMP levels with the articular cartilage damage based on sonographic knee cartilage thickness (KCT) and disease characteristics in RA.
Methods: A total of 61 RA patients and 27 healthy controls were recruited in this study. Serum samples were obtained from all subjects to determine the COMP levels. All subjects had bilateral ultrasound scan of their knees performed by a single radiologist; who was blinded to the details of the subjects. The KCT was based on the mean of measurements at 3 sites; the medial condyle, lateral condyle and intercondylar notch (Figure 1). Besides, the RA patients were assessed for their disease activity based on DAS 28.
Results: Serum COMP concentrations were significantly elevated in the RA patients compared to the controls (p=0.001). The serum COMP levels had an inverse relationship with bilateral KCT in RA subjects and the healthy controls. However, the association was statistically insignificant for bilateral knees in the control arm. COMP correlated significantly with disease activity based on DAS 28 (r =0.299, p=0.010), disease duration (r =0.439,p = <0.05) and mean left KCT (r = -0.285,p=0.014) in RA (Table 1). Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) which are the traditional markers of inflammation; demonstrated a significant positive correlation with the DAS 28 scores (r =0.372, p=0.003 for ESR; r =0.305, p=0.017 for CRP) comparable to the serum COMP. However, neither ESR nor CRP had a significant association with the KCT, as opposed to the serum COMP.

Table 1. Correlation of Serum COMP levels with Clinical Parameters in RA

Parameter	r	p value
Age	0.214	0.094
BMI	0.122	0.259
DAS 28	0.299	0.010
ESR	0.065	0.311
CRP	0.027	0.418
Disease duration	0.439	<0.05
Mean Right KCT	-0.177	0.088
Mean Left KCT	-0.285	0.014

KCT: knee cartilage thickness.

LC: Lateral Condyle, MC : Medial Condyle, IC :Intercondylar notch

Figure 1 : Sites of sonographic knee cartilage thickness measurement

Conclusions: The serum COMP is a promising biomarker in RA which reflects disease activity and damage to the articular cartilage. Serum COMP appeared superior to the traditional markers in RA i.e ESR and CRP in predicting sonographic KCT.

AB0276 EVALUATION OF ADHERENCE TO DRUG TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

A.E.-A.M. Alhefny[1], S.A. Mobasher[2], M.A. Abd El-Rahman[1], N.H. Shedid[1], H.M. Sakr[3], R.M. Hassan[1]. *[1]Ain Shams University Hospitals, Cairo, Egypt; [2]Internal Medicine and Rheumatology; [3]Radiology, Ain Shams University Hospitals, Cairo, Egypt*

Background: the medication adherence is very vital issue nowadays, especially in RA patients.
Objectives: to measure the frequency of the adherence in RA patients, and evaluate the common factors influencing RA patients adherence to drug treatment aiming at improving disease outcome.
Methods: a Prospective cohort study of 100 patients with RA under treatment, fulfilled the American College of Rheumatology/European League Against Rheumatism (ACR/ EULAR) (1) criteria. All patients subjected to Full history taking and clinical examination, (DAS 28 ESR), Health Assesment Questionnaire (HAQ) score, Visual Analouge Scalez (VAS) scale, CBC, ESR, CRP titer, RF titer, ACPA titer and Power Doppler U/S for both hands, patients also respond to specific questionnair containing questions about sociodemographic data, medication, health care system and Compliance Questionnaire of Rheumaology (CQR).
Results: The baseline adherence rate (CQR≥80) was 37%. The nonadherent RA patients to drug treatment were older, living outside Cairo, with low educational level and smokers, they also had higher DAS28ESR score, HAQscore, ESR, CRP titer and more frequent active synovitis in Doppler ultrasound. The cost of medication (61%), non-availability of medication in pharmacy (58%), forgetting the medication (36%), patients' lack of belief in the benefit of treatment (38%), inadequate follow up or discharge planning (23%) and polypharmacy (medication load) (20%) were the most common factors in nonadherent patients table (3). After 9 months of the follow up and trying to correct the causes of nonadherence, the adherence rate increased to (68.75%).Also there was improvement in disease activity, improvement in functional state and improvement in the quality of life.
Conclusions: Low adherence rate was associated with higher disease activity, functional disability. Patient education, financial support, good physician patient relationship, simplification of the prescription, facilitation their communication, using MSUS were found to improve the patient adherence and improve the disease outcome.

AB0277 PATIENT REPORTED OUTCOMES EXPLAIN THE LACK OF AGREEMENT BETWEEN PHYSICIAN AND PATIENT PERCEIVED REMISSION IN EARLY RHEUMATOID ARTHRITIS

S.A. Turk[1], L. Rasch[2], W.F. Lems[1,2], L. van Tuyl[2], D. van Schaardenburg[1,3], M.M. ter Wee[2]. *[1]Amsterdam Rheumatology and Immunology Center| Reade; [2]Amsterdam Rheumatology and Immunology Center| VU University Medical Center; [3]Amsterdam Rheumatology and Immunology Center| Academical Medical Center, Amsterdam, Netherlands*

Background: Rheumatoid arthritis (RA) patients increasingly reach a state of absence of disease activity, or remission. However, the proportion of patients classified as in remission varies substantially between definitions and are often determined by disease activity score (DAS). But, the importance of patients' perspective is increasingly recognized, which often result in discordance between patients and physician assessment.
Objectives: To determine how often patients and physicians agree on a state of remission according to different definitions, as well as the difference in patient reported and clinical outcomes between patients in and not in self-perceived remission.
Methods: In 84 consecutive early RA patients, Boolean remission, EULAR

Table 1

Physician	Remission according to physician		
	PhR	NPhR	T

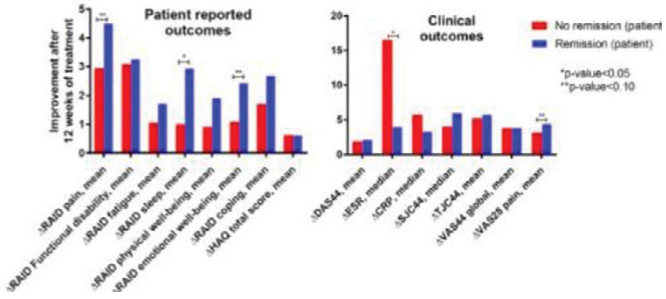
T	23 (100)	0 (0)	23	44 (72)	17 (28)	61

EULAR response	Good			Moderate			None		
	PhR	NPhR	T	PhR	NPhR	T	PhR	NPhR	T
PatR	39 (65)	3 (60)	42 (65)	1 (20)	1 (14)	2 (17)	1 (50)	0 (0)	1 (14)
NPatR	21 (35)	2 (40)	23 (35)	4 (80)	6 (86)	10 (83)	1 (50)	5 (100)	6 (86)
T	60 (92)	5 (8)	65	5 (42)	7 (58)	12	2 (29)	5 (71)	7



ACR	ACR 70			ACR 50 (not 70)			non (not 50)		
	PhR	NPhR	T	PhR	NPhR	T	PhR	NPhR	T
PatR	20 (87)	2 (100)	22 (88)	5 (56)	1 (100)	6 (60)	16 (46)	1 (7)	17 (35)
NPatR	3 (13)	0 (0)	3 (12)	4 (44)	0 (0)	4 (40)	19 (54)	13 (93)	32 (65)
T	23 (92)	2 (8)	25	9 (90)	1 (10)	10	35 (71)	14 (29)	49

Values are expressed as number (%). PhR = physician perceived remission, NPhR = no physician perceived remission, PatR = patient perceived remission, NPatR = no patient perceived remission, T = total.

response and ACR 70 criteria were determined after 12 weeks of treatment with a fixed schedule methotrexate and prednisone. Physician perceived remission (PhR) was defined as a global assessment of ≤20 on a visual analogue scale, phrased: "*How active do you think the RA of your patient is today?*". Patient perceived remission (PatR) was phrased as: "*Would you say that, at this moment, your disease activity is as good as gone? Yes/no*". In patients in PhR, the change in components of the DAS44 and questions of the Rheumatoid Arthritis Impact of Disease (RAID) and Health Assessment Questionnaire (HAQ) were compared between patients in and not in self-perceived remission.

Results: The agreement on remission between patients and physicians was 64% and was dependent of the definition of remission. In Boolean remission, EULAR good response and ACR70 remission agreement was: 86%, 63% and 80% respectively (table). Patients in PhR, the patients in PatR had more improvement on all RAID subdomains. There were no significant differences in clinical outcomes (ESR was significantly different at baseline, but not after 12 weeks; see figure).

Figure. Comparison in improvement in patient reported and clinical outcomes after 12 weeks of treatment, in patients in physician remission, who are and are not in self-perceived remission.

Conclusions: Two-third of the patients agreed with the physician on being in remission. In all different definitions for remission, this discordance between physician and patient on perceived remission remained similar. Patients in self-perceived remission had more improvement in components of the RAID, but not in clinical outcomes. Further research is needed to identify domains of patients perceived remission.

AB0278 ULTRASOUND EXAMINATION IN DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS

W. Hamdi [1], S. Miladi [1], K. Matallah [1], M. Bouaziz [2], D. Kaffel [1], I. Zouch [1], M.M. Kchir [1]. [1]*Rheumatology department;* [2]*Radiology department, Institute Kassab of Orthopedics, Manouba. Tunisia, Tunis, Tunisia*

Background: Fortunately, management of RA at the early stage has become possible thanks to both the emergence of new biotherapies and the strategy treat to target. Musculoskeletal ultrasound (US) is a potent tool for the detection of synovitis, effusion and bone erosion in RA.

Objectives: The aim of this study was to assess the contribution of US in diagnosing RA at the early stage of the disease.

Methods: A cross-sectional study was performed during 2 years. Patients with a history of inflammatory joint pain for ≥6 weeks and ≤2 years with synovitis of at least one joint were enrolled in this study. All patients underwent clinical assessement, laboratory tests and plain radiography of hands and feet.US was assessed within one week of clinical examination. Synovitis and erosion were defined according to the OMERACT.

Results: One hundred patients were included in this study with an average age of 51,8±14,6 years-old. Female outnumbered male with a sex ratio of 3,8. The mean duration of the disease was 10,9±7,4 months. When admitted to our department and after clinical examination it was found that 31% of patients presented polyarthritis, 4% had oligoarthritis and 7% suffered from monoarthritis. *US findings:* US was found to be more sensitive than clinical examination to detect synovitis. Among the 2200 joints assessed by US, a synovitis was detected in 81% patients, an intra-articular effusion in 36% patients and PD signals in 51% patients. Also, flexor tenosynovitis were present in 55% patients and extensor tenosynovitis in 59% patients. Erosions were more detected in plain radiography (70%) than in US (41%). Clinical parameters (VAS, duration of morning stiffness, number of night awakens, TJC) were not correlated with most US findings. Nevertheless, correlation was detected for US effusion (r=0,250, p=0,028) and for US Doppler (r=0,289, p=0,011) with SJC. PDUS examination correlated with CRP results (r=0,302, p=0,023) but not with ESR results. A significant, positive correlation was observed between erosions in X-rays or US assessment (r=0,342, p=0,002). The US detected synovitis in 25% of patients who had no swollen joint at the clinical examination when admitted to our department and had detected erosions in 9% of patients having negative plain X rays.

Conclusions: Ultrasound appears as a sensitive tool to detect subclinical synovitis (25%) and infra- radiological erosions (9%). It helps us to make an early diagnosis and start appropriate treatment before the onset of irreversible joint destruction.

AB0279 HIGH RATE OF DISABILITY PENSION IN CHILEAN RHEUMATOID ARTHRITIS PATIENTS WITHOUT ACCESS TO BIOLOGICS. HOSPITAL PADRE HURTADO EXPERIENCE

S.E. Ibáñez Vodnizza, O. Valenzuela, F. Silva, M.J. Villar. *Rheumatology department, Clínica Alemana de Santiago/Hospital Padre Hurtado, Santiago, Chile*

Background: Until the year 2016, most of the Chilean rheumatoid arthritis patients in the public health system did not have acces to biologic treatment. Now the access is limited to those with high disease activity (DAS 28 >5.1).

Objectives: Our main objective was to evaluate the rate of patients benefited by disability pension within the group of rheumatoid arthritis patients seen in our center, before the introduction of biologic treatment for those with high disease activity. Our secondary objective was to estimate the association between having a disability pension and the characteristics of the patients.

Methods: Consecutive rheumatoid arthritis patients (according to the ACR 2010 criteria), 18 years old or older, that attended to our rheumatology consult between September and December of 2015, were included. Patients with other types of pensions (retirement) were excluded. Information about work status, gender, age, years since diagnosis, medications used, DAS 28 ESR and its variables was collected.

Results: 104 patients were included. 38.5% had a disability pension. We found significant differences between the patients with and without disability pensions for age, years since diagnosis, tramadol use, the number of tender joints, the number of swollen joints and DAS 28 ESR (Table 1). After multivariate logistic regression, age (OR 1, 95% CI 1.02–1.15), tramadol use (OR 0.3, 95% CI 0.08–0.92) and the number of swollen joints (OR 1.4, 95% CI 1–1.96) continued to be significantly associated.

Table 1. Disease characteristics

	All	Without Disability Pension	With Disability Pension	P
Number of patients (%)	104 (100)	64 (61.5)	40 (38.5)	NA
Female (%)	86 (82.7)	53 (82.8)	33 (82.5)	NS
Age (median, IQR)	55.5 (15)	52.5 (18)	58 (15)	0.002
Years since diagnosis (median, IQR)	8.8 (12.2)	5.8 (8.2)	12.3 (19.1)	<0.001
Number of DMARDs used (median, IQR)	2 (2)	1 (2)	2 (2)	NS
Prednisone users (%)	89 (85.6)	52 (81.3)	37 (92.5)	NS
NSAIDs users (%)	75 (72.1)	46 (71.9)	29 (72.9)	NS
Acetaminophen users (%)	68 (65.4)	39 (60.9)	29 (72.5)	NS
Tramadol users (%)	35 (33.7)	13 (20.3)	22 (55)	0.001
Number of tender joints (median, IQR)	4 (6)	3 (5)	6 (11)	0.018
Number of swollen joints (median, IQR)	2 (4)	1 (4)	3 (8)	0.012
ESR (median, IQR)	20.5 (21)	16.5 (18)	25 (31)	NS
VAS pain (median, IQR)	60 (40)	60 (40)	80 (40)	NS
DAS 28 ESR (mean, SD)	4.5 (1.6)	4.1 (1.4)	5 (1.8)	0.026

IQR = interquartile range, DMARDs = Disease-Modifying Antirheumatic Drugs, NSAIDs = Non-steroidal anti-inflammatory drugs, ESR = Erythrocyte Sedimentation Rate, VAS = Visual Analog Scale, DAS = Disease Activity Score, NS = Not significant.

Conclusions: Near forty percent of our rheumatoid arthritis patients, that did not have access to biologic treatment, were being paid a disability pension, and this condition was significatly associated with more years of age, tramadol use, and the number of swollen joints. The mean DAS 28 ESR in the patients with disability pension was 5. The limit of a DAS 28 >5.1 to authorize the use of biologic treatment possibly will not help to reduce the rate of patients with disability pension in our group.

AB0280 INFLUENCE OF HLA CLASS II ANTIGEN (DRB1 AND DQB1) ON THE PRODUCTION OF ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODIES IN A TUNISIAN POPULATION

S. Boussaid [1], S. Kochbati [2]. [1]*Departement of Rheumatologie, la Rabta Hospital;* [2]*Departement of Rheumatologie, Habib Thameur Hspital, tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatism. It's a complex autoimmune disorder. The aim of this study is to focus on the relationship between HLA-DRB1 genes and RA specific antibodies against cyclic citrullinated peptides (anti-CCP antibodies).

Methods: This prospective study was performed on a total of 81 Tunisian patients with rheumatoid arthritis. All patients fulfilled the American College of Rheumatology (ACR 1987) criteria for RA. For each patient we assessed DNA and serum samples. The DNA was extracted from lymphocytes using a commercial kit (Quiagen). The HLA class II (DQB1 and DRB1) was performed by Polymerase Chain Reaction technique Specifying-sequence primers (PCR-SSP). The specific products of PCR were analyzed by 2.5% agarose gel electrophoresis. All tests include positive and negative controls appropriate for each blood sample. The phenotypes of patients were obtained through the Software One Lambda DNA/SOFTWARE (SSP2L-generic DRB/DQB).

Results: The mean age of our population was 49.17±11.21 years (age 24–78). The disease average duration was 7.44±2.12 years (4 months - 29 years), 82.71% of RA were women and 17.29% were men. Seropositive RA were 80.24%, and 71% of RA have anti CCP positive antibody. Univariate analysis of the presence of anti-CCP antibodies in conjunction with HLA DRB1 and DQB1 was performed. Carriership of HLA DR*0301, 0401 and 1501 were significantly associated with the presence of anti-CCP antibodies ($p<0.0001$). Four DRB1 0401 carriers were homozygotes with three out of them having anti-CCP antibodies.
Carriership of HLA DQB1*0201, 0301, 0302,0501 and 0601 was associated with the presence of anti-CCP antibodies and so was HLA-DQB1*0401, but with a less significant association.
Conclusions: Although no formal conclusions on causality can be drawn from this association study, these findings suggest that anti-CCP antibodies are associated with different phenotypes; which suggest that various pathogenetic mechanisms underlie the positivity for anti-CCP in RA.

AB0281 CHARACTERIZATION OF CHANGES IN LYMPHOCYTE SUBSETS IN BARICITINIB-TREATED PATIENTS WITH EARLY, DMARD NAÏVE, RHEUMATOID ARTHRITIS IN A PHASE 3 STUDY

T. Takeuchi[1], R. Fleischmann[2], M. Schiff[3], M. Issa[4], W. Macias[4], T. Rooney[4], S. Zuckerman[4], D. Schlichting[4], I. McInnes[5]. *[1]Keio Univ., Tokyo, Japan; [2]Univ. Texas SW Med Center, Dallas; [3]Univ. Colorado, Denver; [4]Eli Lilly and Company, Indianapolis, United States; [5]Univ. Glasgow, Glasgow, United Kingdom*

Background: In RA-BEGIN (NCT01711359), baricitinib (bari), an oral Janus Kinase (JAK)1/JAK2 inhibitor, improved signs and symptoms of moderately to severely active RA in patients (pts) who had received no or limited prior csDMARD and no prior bDMARD therapy.[1]
Objectives: To analyse changes in absolute lymphocyte count (ALC) and cell subsets (LCS) in RA-BEGIN.
Methods: Pts (N=588) were randomised 4:3:4 (MTX up to 20mg QW, bari 4mg QD, bari 4mg+MTX) for 52 Wks. T and B cells plus subsets and natural killer (NK) cells were quantified by flow cytometry at baseline (BL) and Wks 4, 12, and 32.
Results: At BL, low cell counts were observed in 4.3%, 8.2%, 5.3%, 18.3%, and 19.7% of pts for ALC, CD3+, CD8+, B (CD19+), and NK cells. In the MTX group, slight declines in mean counts were observed for all cell types at post-BL visits (Table). For bari and bari+MTX, cell counts increased for all cell types at Wks 4 and 12, with, except for B cells, a return towards BL, or slightly below, at Wk 32. Changes in other T and B cell subsets generally reflected these patterns (data not shown). Treatment emergent (TE) low NK cell counts occurred in 11.6%, 13.4%, and 20.5% of pts for MTX, bari, and bari+MTX; TE low CD8+ cell counts occurred in 5.2%, 3.2%, and 8.3% of pts. Overall serious infection (SI) rates were 3.8%, 3.8%, and 2.3% for all pts in MTX, bari, and bari+MTX; rates were 6.8% (4 of 59 pts), 4.8% (2 of 42), and 2.8% (2 of 72) for pts with ≥1 low post-BL NK cell count and 15.8% (3 of 19), 25.0% (2 of 8), and 5.3% (1 of 19) for pts with ≥1 low post-BL CD8+ cell count. Herpes zoster (HZ) rates were 1.0% 2.5%, and 2.3% for all pts in MTX, bari, and bari+MTX; rates were 3.4% (2 of 59 pts), 4.8% (2 of 42), and 4.2% (3 of 72) for pts with ≥1 low post-BL NK cell count and 10.5% (2 of 19), 12.5% (1 of 8), and 5.3% (1 of 19) for pts with ≥1 low post-BL CD8+ cell count.

Data are mean (Wk 0) and LSM Δ from BL (Wks 4, 12, 32), last observation carried forward. *p<0.05, **p≤0.01, ***p≤0.001 within grp comparison, LSM Δ from BL. Reference ranges (cells/μL): ALC=800–4280; CD3+=603–2990; CD8+=125–1312; CD19+=107–698; NK=95–64.

Conclusions: Low B and NK cell counts were common at BL, and post-BL changes within normality occurred in all treatment groups. Compared to MTX, bari was not associated with an increase in the % of pts with low NK or CD8+ cell counts while bari+MTX did show an increase in the % of pts with a low NK cell count. Changes appear distinct for LCS suggesting different mechanisms may underscore the effect of JAK inhibition. Whether low NK or CD8+ cell counts predispose to increased risk for SI or HZ was difficult to assess due to few pts with low counts experiencing these events.

AB0282 RHEUMATOID ARTHRITIS PATIENTS ACHIEVED BETTER QUALITY OF LIFE THAN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AT SUSTAINED REMISSION: THE IMPACT OF DISEASE DIAGNOSIS ON HEALTH-RELATED QUALITY OF LIFE OUTCOMES

V. Pascual Ramos, I. Contreras-Yáñez, L. Llorente, K.R. Valencia-Quiñones, J. Romero-Díaz. *Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

Background: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) impact the health related quality of life (HRQoL) of the patients. The 36 item Medical Outcome Study Short-Form survey (SF-36) assesses HRQoL and allows comparison of outcomes among different conditions. Whether remission represents similar status in terms of QoL in RA and SLE patients is unknown. In 2004 and 1999, respectively, recent-onset RA and SLE cohorts were initiated in a referral center for rheumatic diseases in México City; the SF-36 was applied beginning from enrollment.
Objectives: To compare the SF-36v2 scores between patients from both cohorts who achieved for the first time sustained remission (SR) and to define the role of disease diagnosis as associated to SF-36v2 normative data in SR patients.
Methods: First SR was considered when RA and SLE patients achieved at least 12 months of continuous follow-up with either SLE disease activity index 2000 update =0 or Disease Activity Score (28 joints) ≤2.4, respectively. Up to December 2015, updated data from 172 RA patients and 211 SLE patients with at least one year of follow-up were reviewed. In the SLE cohort, SF-36 was incorporated to routine assessments from 2005 onwards, meanwhile in the RA cohort it was applied since the beginning of enrollment. The SF-36v2 licensee re-scored the SF-36 used in the SLE cohort. In all the cases, Spanish versions were used and scoring was adjusted by gender and age. SF-36v2 scores were available for the totality of SR assessments. Logistic regression models were used to investigate factors associated with normative SF-36v2. Written informed consent was obtained from all patients.
Results: Cohorts were integrated primarily by middle-aged females (89%), with recent-onset disease (5.3±3.2 months); at inclusion, RA patients were older and lesser educated; follow-up was longer in SLE patients (10.6±2.9 vs. 7.5±3.2 years, p≤0.001) and a higher number of them died (15% vs. 2%, p≤0.001).
A higher proportion of patients achieved SR sooner in the recent-onset RA cohort than in the SLE cohort: 58% vs. 30.6% of the patients, after 30.8±23.9 vs. 59.4±37.5 months, respectively, p≤0.001. At SR, RA patients achieved better scores in 6 out of 8 SF-36v2 domains and in the physical health component summary (PHCS) compared with SLE patients; also, a greater proportion of RA patients achieved norms in five domains and in the PHCS; SLE patients achieved more frequent roles (physical and emotional) norms and scored higher mental health component summary than their counterpart. Finally, at SR RA patients had greater improvement in the majority of SF-36v2 domains and both summary components, despite having worse SF-36v2 scores at baseline evaluation.
In SR patients from both cohorts, age (β: 1.06, 95% CI: 1.02–1.1, p=0.03) and SLE diagnosis (β: 9.64, 95% CI: 3.61–25.75, p≤0.001) were predictors of not achieving normative PHCS.
Conclusions: RA patients who achieved SR had better HRQoL than their SLE counterparts. Age and SLE diagnosis were associated with not achieving HRQoL norms in SR patients.

AB0283 ONE-YEAR FOLLOW-UP OF QUALITY OF LIFE IN RHEUMATOID ARTHRITIS PATIENTS FROM BULGARIAN POPULATION TREATED WITH CSDMARDS AND BDMARDS

V.V. Boyadzhieva, N.R. Stoilov, M. Ivanova, R. Stoilov. *Rheumatology, University Hospital "St. Iv. Rilski", Medical faculty, Medical University, Sofia, Bulgaria*

Background: Rheumatoid arthritis is a chronic systemic disabling condition associated with pathology mainly of the peripheral joints. Quality of Life (QoL) encompasses the impact of the disease and its treatment on the ability of the patient to fulfill/satisfy his or her needs. Assessing QoL in RA is an attempt to ensure the concern of patients that this important aspect of their daily lives will be measured.
Objectives: To evaluate the change of QoL of Bulgarian patients with RA after 6 months to 1-year of treatment with csDMARDs and bDMARDs by using two

generic questionnaires (HAQ-DI and SF-36) and a disease-specific measurement RAQoL.
Methods: A total of 220 patients with a mean age 55.05±10.63SD meeting the 1987 ACR classification criteria for RA were included in the study. The mean disease duration was 9.97±5.78SD. Patients were stratified according to treatment regimens into 2 age-matched treatment groups: 96 on csDMARDs and 124 on bDMARD therapy. Subjects with significant comorbidity, infectious disease, congestive heart failure (NYHA class III or IV), malignant hypertension, psychiatric illness, a history of lymphoproliferative disease or neoplasia were excluded from the study. All participants completed the HAQ-DI, SF-36v2TM and RAQoL at baseline, at months 6 and 12 thereafter. The scores of the three instruments were calculated via licensed calculator. Comparison was performed by analysis variance ANOVA.
Results: At baseline the mean scores of HAQ-DI and RAQoL did not differ greatly among patients on csDMARDs and bDMARDs (1.29±0.78SD *vs* 1.13±0.54SD, p=0.063; 16.31±8.26SD *vs* 15.03±7.13SD, p=0.219, respectively). However, the mean physical component summary score of SF-36 was significantly higher in bDMARDs compared with csDMARDs (32.98±5.97 *vs* 31.05±7.82, p=0.039), while in the mental component of this scoring system not such a difference was found (p=0.983). After 6 months subjects treated with bDMARD showed a significant decreasing of the means of the HAQ-DI and RAQoL, as opposed to the other treatment group (0.86±0.5SD *vs* 1.17±0.76SD, $p<0.001$; 10.98±6.53SD *vs* 14.55±7.96SD, $p<0.001$ respectively). Similar results were obtained for both physical and mental component summary scores of SF-36 (39.49±6.43SD *vs* 33.48±8.04SD, $p<0.001$; 43.69±7,99SD *vs* 39.66±10.19SD, p=0.001 respectively). At month 12 a significant improvement of QoL, measured by the three assessment tools was registered in patient receiving bDMARDs compared with the csDMARD treatment group ($p<0.001$).
Conclusions: Patient treated with bDMARDs showed better results for QoL than those on therapy with csDMARDs within a period of 12 months of treatment. Current management strategies should focus on improving the symptoms of activity and maintaining physical function in order to increase QoL in patients with RA.

AB0284 ASSESSMENT OF DISEASE ACTIVITY BY DAS28-CRP, CDAI, SDAI AND RESPONSE TO TREATMENT WITH CSDMARDS AND BDMARDS AFTER ONE-YEAR FOLLOW-UP IN RHEUMATOID ARTHRITIS PATIENTS FROM BULGARIAN POPULATION

V.V. Boyadzhieva, N. Stoilov, M. Ivanova, R. Stoilov, R. Rashkov. *Rheumatology, University Hospital "St. Iv. Rilski" Medical Faculty - Medical University, Sofia, Bulgaria*

Background: The assessment of disease activity is an essential component in the selection of therapeutic approach for the prevention of disability of patients with RA.
Objectives: The current study was conducted to evaluate the disease activity in patients on csDMARDs and bDMARDs after 6 months to 1-year of treatment and to determine whether the benefits of different therapies were sustained over time.
Methods: For the purpose of the study were selected 220 patients with a mean age 55.05±10.63SD years, meeting the 1987 ACR classification criteria for RA. Patients were stratified according to treatment regimens into 2 age-matched treatment groups: 96 on csDMARDs and 124 on bDMARD therapy. Patient's assessment of disease related pain, global health and physician assessment of global health was made by visual analogue scale (VAS) – 100mm. Disease activity was the primary outcome domain. Independent joint assessor evaluate 28 joints on baseline, 6th and 12th month of the follow-up period. C-reactive protein (CRP) was used to measure the inflammation process. DAS28-CRP, CDAI and SDAI were calculated according to the standard formulas. Comparison was performed by analysis variance ANOVA.
Results: On baseline, patients on bDMARDs had a significantly higher mean time-averaged 28-joint disease activity score (5.03±0.84SD vs. 4.35±1.20SD, $p<0,001$), CDAI (25.06±7.32SD vs. 20.83±10.53SD, $p<0.001$) and SDAI (28.27±8.74 SD vs. 23.19±11.89 SD, $p<0.001$) compared to those on csDMARDs. On the 6th month in both groups (bDMARDS and csDMARDs) we found significant decrease in mean DAS28 ($p<0.001$, $p<0.001$), although no significant difference in disease activity between the groups was measured by this indicator (3.75±2.49 SD vs 3.90±1.10 SD, p=0.566). Patients on bDMARDs had significantly lower disease activity compared to those on csDMARDs after 6th and 12th month of treatment assessed by CDAI (13.43±4.98 SD vs 16.81±9.94 SD, p=0.001; 8.65±4.53 SD vs 15.86±10.02 SD, $p<0.001$), and SDAI (14.63±5.42 SD vs 18.38±10.49 SD, $p<0.001$; 9.39±4.92 SD vs 16.79±10.5 SD, $p<0.001$). Unlike results reported by DAS28-CRP which showed no change between the 6th and 12th month in patients receiving csDMARDs (3.90±1.10 SD, 3.82±1.12 SD, p=0.156) we observed a statistically significant difference in all three time intervals (0,6th,12th month) of the follow up period regarding to CDAI and SDAI.
Conclusions: After a year prospective follow-up, therapy with biologic DMARDs results in sustained suppression – minimal disease activity assessed by DAS28-CRP, CDAI and SDAI, compared to patients receiving DMARDs who had moderate disease activity according to these tools. The therapy with bDMARDs was superior to csDMARDs therapy for suppressing disease activity (assessed by DAS28-CRP, CDAI and SDAI) of rheumatoid arthritis (RA) on 6th and 12th month of the follow-up period.

AB0285 CLINICAL SIGNIFICANCE OF GLUCOCORTICOID-INDUCED TUMOR NECROSIS FACTOR RECEPTOR RELATED PROTEIN LIGAND (GITRL) IN RHEUMATOID ARTHRITIS: RELATION TO DISEASE ACTIVITY AND TREATMENT OUTCOME

W.A. Hassan[1], A.I. Mansour[2]. [1]*Rheumatology and Rehabilitation;* [2]*Clinical and chemical pathology, Benha university, Benha, Egypt*

Background: Glucocorticoid-induced tumor necrosis factor receptor related protein (GITR) is a member of the tumor necrosis factor receptor superfamily that is activated by its specific ligand (GITRL). GITR is mainly expressed in immature and mature T cells especially regulatory (Treg) cells (CD4+ CD25+) and effector T cells (CD25–) [1]. GITRL is mainly expressed in endothelial cells, dendritic cells, macrophages and B cells but not in T cells. GITR-GITRL system is known to have important regulatory role on inflammatory response and immune reactivity.
Objectives: This study aimed to measure serum and synovial fluid (SF) levels of GITRL in patients with recent onset rheumatoid arthritis (RA) before and after initiation of therapy and to evaluate the relationship between GITRL and RA clinical and laboratory characteristics, disease activity and response to therapy.
Methods: We measured GITRL in the serum (n=48) and SF samples (n=21) from 48 recent onset RA patients and in the serum from 20 healthy control (n=20) at baseline and 6 months after initiation therapy with non-biological disease modifying anti-rheumatic drugs (DMARDS). In the patients Disease activity was calculated by the 28 joint counts (DAS28) and musculoskeletal ultrasound examination (MSUS) was performed at baseline and after 6 months using a 12-joint score (bilateral elbow, wrist, 2nd metacarpophalangeal (MCP), 3rd MCP, knee, ankle) [2]; immunoglobulin-M rheumatoid factor (IgM-RF) titre, anti-cyclic citrullinated peptide (anti-CCP) antibodies titre and C-reactive protein (CRP) levels were measured and the health assessment questionnaire (HAQ) score were recorded.
Results: Serum and SF GITRL levels were highly significantly increased in RA (39.38±16.78 ng/mL and 30.6±16.79 ng/mL respectively) compared to serum level in the healthy controls (10.3±5.46 ng/mL) ($p<0.001$). In RA patients, baseline serum and SF levels of GITRL significantly correlated with DAS28 (r=0.52 and 0.56 respectively, $p<0.05$), anti-CCP titres (r=0.46 and 0.51 respectively, $p<0.05$), grey scale (GS) (r=0.5 and 0.52 respectively, $p<0.05$) and power Doppler (PD) (r=0.65 and 0.68 respectively, $p<0.001$) synovitis scores. Also, serum and SF levels of GITRL at 6 months follow up significantly correlated with the DAS28 (r=0.42 and 0.48 respectively, $p<0.05$), GS score (r=0.46 and 0.51 respectively, $p<0.05$), PD signal (r=0.43 and 0.45 respectively, $p<0.05$). Logistic regression analysis showed that baseline serum levels of GITRL were predictive of follow up DAS 28 and PD synovitis score (p=0.009 and 0.03 respectively).
Conclusions: Rheumatoid arthritis patients have significantly increased serum and synovial levels of GITRL that remarkably correlated with the DAS28 and MSUS parameters of inflammations suggesting that it could be a useful marker to reflect RA disease activity. GITRL could be a useful biomarker to predict treatment outcome in RA patients.

AB0286 14 CASES STUDY OF MACROPHAGE ACTIVATION SYNDROME (MAS) IN SYSTEMIC ONSET JUVENILE IDIOPATHIC ARTHRITIS

X. Chen[1], H. Zeng[2]. [1]*Department of Pediatric Allergy, Immunology and Rheumatolog;* [2]*Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening syndrome.
Objectives: we aim to review the precipitating events,clinical features, treatment, and outcome of macrophage activation syndrome (MAS).Part patients were analysed the Polymorphisms of Perforin A91V (NCBI:SNP rs35947132) using special primers by polymerase chain reaction (PCR).
Methods: Retrospective review of cases of MAS from a prospectively collected database of children with autoimmune diseases from 2003 to 2008.
Results: Fourteen patients (nine boys) were considered to have evidence of MAS.The primary diagnosis was systemic onset juvenile idiopathic arthristis, with age ranged from 5 months to 12 years. No medication was identified as trigger. Eleven had infections prior to MAS,specific infectious agents were identified in four. High grade fever, new onset hepatosplenomegaly, lymphadenopathy, dysfunction

of liver,abnormal fat metabolism and hemophagocytosis were common clinical features.Two cases were with ARDS and MOF in three and three died. The perforin A91V (NCBI:SNP rs35947132) gene was detected in seven systemic onset juvenile idiopathic arthritis compolicated with MAS cases, but no mutation were found. Glucocorticoid, intravenous immunoglobulin, immunoimpressive therapy were effective and HP (Plasmapheresis) used in one serious case was also effective.
Conclusions: MAS is a rare and potentially fatal complication of childhood rheumatoid diseases,especially systemic onset juvenile idiopathic arthritis. Most of our patients were male, and most cases were preceded by infection. Bone marrow studies support the diagnosis. MOF may be a poor prognostic sign.Aggressive early therapy is essential.

AB0287 MUTUAL ASSENT TOWARDS COMPREHENSIVE DISEASE CONTROL: THE RELATIONSHIP BETWEEN US MEASURES AND PATIENT REPORTED OUTCOMES IN EARLY RHEUMATOID ARTHRITIS

Y. El Miedany[1], M. El Gaafary[2], N. El Arousi[3], S.S. Youssef[3], A. Nasr[4].
[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Community and Public health; [3]Rheumatology and Rehabilitation; [4]Radiology, Ain Shams University, Cairo, Egypt

Objectives: Assessment of the relationship between US measures of joint inflammation/damage and patient reported outcomes (PROs): HAQ, pain and patient global assessment in early rheumatoid arthritis (early RA) patients over 5-years follow up period.
Methods: This longitudinal cohort of 261 patients with early RA was derived from the US monitoring study [1]. Adopting OMERACT definitions; correlations between total US scores (synovial hypertrophy, synovial fluid, Power Doppler, bone erosion and tenosynovitis) and PROs [2] namely functional disability (HAQ), pain and patient global scores were determined at 0, 1, and 5years. Radiological damage was assessed using modified Total Sharp score (mTSS). Univariate correlations as well as correlations between interval changes were assessed. Multivariable regression models were used to evaluate the associations over all time-points and their relationship to clinical disease activity measures.
Results: There were significant correlations ($p<0.01$) between total US score and HAQ (r=0.71), pain (r=0.69) and patient global scores (r=0.66) at all timepoints. The association tends to be stronger with increase disease duration (Spearman correlation 0.12 at baseline, 0.22 at 1-year and 0.41 at 5-years). Change in mTSS score at 5-years was not associated with changes in PROs. Improvements in US scores were also associated with improvements in PROs. Multivariate models revealed that synovial hypertrophy and Power Doppler scores were associated ($p<0.01$) with functional disability, pain and patient global assessment, controlling for clinical disease activity measures. Studying the pattern of joint involvement, it was associated significantly ($p<0.01$) with the US score of the affected joints. US total score at 1-year predicted subsequent 5-year HAQ score (R2=0.17). At 0, 1- and 5-years, total US scores were higher in patients whose HAQ score was >1 (9.26) compared to those below 1 (4.16, $p<0.01$).
Conclusions: the link between joint inflammation/structural damage and PROs is of critical importance to the care of patients with inflammatory arthritis. US measures of inflammation and structural damage correlated independently with physical function, pain and patient global assessments. A clear relationship between radiographic structure damage and the patient's perceived remission/flare provide the basis for comprehensive disease assessment and management.

AB0288 LABORATORY MARKERS OF INFLAMMATION AND SERUM NICOTINAMIDE PHOSPHORIBOSYLTRANSFERASE LEVEL IN RHEUMATOID ARTHRITIS PATIENTS

Y. Akhverdyan[1], B. Zavodovsky[1], J. Polyakova[1], L. Seewordova[1], I. Zborovskaya[1], T. Rogatkina[2]. *[1]Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology" Under the Russion Academy of Medical Sciences; [2]Volgograd State Medical University, Volgograd, Russian Federation*

Objectives: To study relationship between serum levels of nicotinamide phosphoribosyltransferase and laboratory markers of inflammation in patients with rheumatoid arthritis (RA).
Methods: We determined nicotinamide phosphoribosyltransferase level in sera of 140 patients with RA (96 women and 44 men) by indirect enzyme-linked immunosorbent assay (RaiBiotech, cat No. EIA-VIS-1). The control group consisted of 20 women and 10 men aged 22 to 55 years without complaints of pain in the joints throughout life. The mean duration of disease was 5.94±0.37 years.
Results: We divided all RA patients into 2 groups: one group (118 patients) with elevated levels of nicotinamide phosphoribosyltransferase serum (more than 3.9 ng/ml) and second group (22 patients) - with normal range.
In each of the two groups, the levels of CRP and ESR were determined.
Patients with elevated levels of Nampt had the following laboratory parameters (M±m): ESR – 37.83±1,57, CRP – 56.09±3,73 (rate - less than 5.0 mg/l). The second group had following data: ESR 22.46±0,56, CRP 21,65±1.38. Thus, patients with elevated levels of nicotinamide phosphoribosyltransferase had significantly higher concentrations of ESR and CRP ($p<0,001$).
Conclusions: There is the relationship between the level of nicotinamide phosphoribosyltransferase serum and laboratory markers of inflammation in RA (CRP and ESR). The data indirectly confirm the hypothesis that increased levels of nicotinamide phosphoribosyltransferase in RA patients is associated with disease activity.

AB0289 PREDICTOR OF THE SIMPLIFIED DISEASE ACTIVITY INDEX 50 (SDAI 50) AT MONTH 6 DURING BDMARDS TREATMENT IN PATIENTS WITH LONG-ESTABLISHED RHEUMATOID ARTHRITIS: A SINGLE-CENTER, RETROSPECTIVE STUDY

Y. Miwa, A. Nishimi, S. Nishimi, T. Tokunaga, S. Ishii, T. Kasama on behalf of ASHURA Registry Group. *Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan*

Background: The simplified disease activity index (SDAI) 50 has good agreement with the EULAR response measures for early rheumatoid arthritis (RA). Although there are reports on early RA, there have been no reports on long-established RA.
Objectives: In this study, we analyzed the relationships between various baseline factors and SDAI 50 after six months of biological disease-modifying antirheumatic drugs (bDMARDs) treatment to determine the prognostic factors for long-established RA.
Methods: The subjects were 332 RA patients who had been treated with bDMARDs for 6 months. The following characteristics were investigated: age, gender, disease duration, smoking history, body mass index, steroid and methotrexate dosage, previous bDMARDs use, combined csDMARDs use, ESR, CRP, serum matrix metalloproteinase-3 levels, SDAI score, health assessment questionnaire disability index score (for daily living activities) and short form-36 score (for quality of life). As a primary outcome index, SDAI response was defined as a 50% reduction in SDAI score between baseline and 6 months (SDAI 50).
Results: The group of RA patients who achieved SDAI 50 (Group A: 204 patients) had a higher tender joint count (p=0.041), swollen joint count (p=0.001), evaluator's global assessment (p=0.027) and SDAI (p=0.006) than did those who did not achieve SDAI 50 (Group B: 152 patients). Before the start of the treatment, steroid dosage (p=0.0187, odds ratio: 1.119, 95% CI: 1.029–1.229) and SDAI (p=0.0003, odds ratio: 0.953, 95% CI: 0.928–0.978) were determined based on logistic regression analysis. Comparisons were performed between Groups A and B and between before treatment and after 6 months of SDAI. Group A showed a significant improvement compared to Group B by repeated measure analysis of variance (ANOVA) (Interaction: p=0.000, Group A vs. Group B: p=0.000, before vs. after treatment: p=0.000).
Conclusions: Our study demonstrated that RA patients with a lower steroid dosage and higher SDAI baseline are more likely to achieve SDAI 50 with bDMARD treatment.

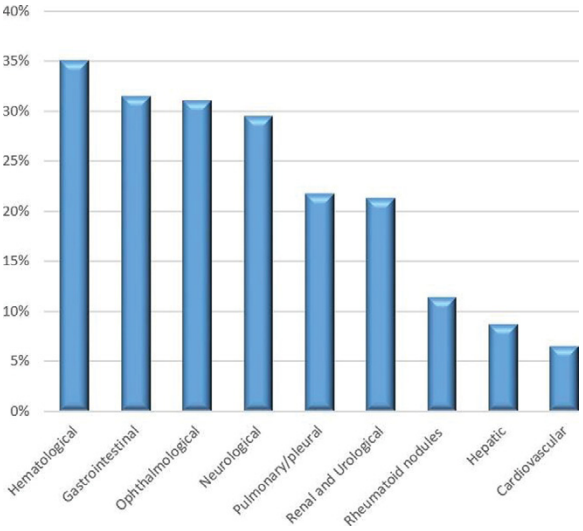
Rheumatoid arthritis - comorbidity and clinical aspects

AB0290 PULMONARY AMYLOIDOSIS IN RHEUMATOID ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 PATIENTS

Á. Apáthy[1], M. Bély[2]. *[1]Department of Rheumatology, St. Margaret Clinic Budapest; [2]Department of Pathology, Hospital of the Order of the Brothers of Saint John of God, Budapest, Hungary*

Background: AA amyloidosis (AAa) is one of the most insidious systemic complications of rheumatoid arthritis (RA), which furtively may lead to death [1].
Objectives: The aim of this study was to determine the prevalence and location of amyloid A deposition in the lungs of RA patients at the time of death.
Methods: A randomized autopsy population of 161 in-patients with RA was studied. AAa complicated RA in 34 (21.1%) cases [1].

At least four tissue samples of lungs (from apical and basal regions of both lungs) were available for histologic evaluation in 33 of these 34 patients.
RA was confirmed clinically according to the criteria of the ACR.
The presence of amyloid A deposits in various structures of the lungs was determined histologically by amyloid specific Congo red staining, according to Romhányi [2].
The extent of amyloid A deposition was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [1]. ("0": no amyloid deposits, "1": Sporadic, minimal amyloid deposits on different tissue structures, "2": less than five, "3": five or more involved tissue structures per microscopic field at objective magnification of x20)
Results: Amyloid A deposition in the lungs was detected in 24 of 33 (72.2%) patients.
Amyloid deposition in various structures does not begin at the same time.
In the early stage of systemic amyloidosis there were histologically detectable amyloid deposits only in a few structures (arterioles, interstitial collagen fibers, peribronchial and perilobular basement membranes). In other structures (small and medium size arteries, panlobular basement membranes, small veins, collagen IV reticulin fibres, venules, medium size veins and nerves) deposits were seen only in late stages of amyloidosis (with massive involvement of the mentioned structures).



Conclusions: Amyloidosis is a progressive, cumulative process, involving in its early stage only a few structures in some organs, and increasingly more in the later stages of the disease [1]. Amyloid A deposition starts in the most frequently involved structures of the most frequently involved organ [1].
In the lungs amyloid A deposition starts in the wall of arterioles and in interstitial collagen fibers. As time progresses, basement membranes of peribronchial and peripheral regions of lobules, small and medium sizes arteries become involved. Still later panlobular deposition of basement membranes, small veins, reticulin fibers (collagen IV) of subpleural fat tissue, venules and medium size veins become involved. The involvement of nerves indicates advanced stages of amyloid deposition in the lung.
This chronology of amyloid A deposition allows an indirect assessment of the stage of amyloidosis. Based on the involvement of structures in lung biopsy specimens the pathologist may be able to estimate involvement of the other structures, even if not present in the sections. Involvement of arterioles alone (without involvement of small arteries) indicates an early stage of amyloidosis, whereas amyloid A deposits in veins or peripheral nerves suggests an advanced stage with massive involvement of other pulmonary structures.

AB0291 EPIDEMIOLOGY AND COMORBIDITY OF RHEUMATOID ARTHRITIS IN UPPER EGYPT, A HOSPITAL BASED STUDY

A.M. Elsaman, A.R. Radwan, M.H. Abou Dahab, A.M. Sherif, E.M. Abu Al-Fadl.
Rheumatology, Sohag University Faculty of Medicine, Egypt, Egypt

Background: Rheumatoid arthritis (RA) is one of the commonest autoimmune diseases. It affects about 1% of the population worldwide (1). The prevalence of RA varies widely between different countries (2). Not only the prevalence of the disease which differs among different continents, races, ages and socioeconomic levels but also the disease pattern. Studies explaining the epidemiology of RA in Egypt in general and in upper-Egypt, in particular, are very limited (3).
Objectives: To estimate the comorbidity of rheumatoid arthritis and its relation to disease activity, duration, disease pattern and demographic features of RA patients in upper Egypt.
Methods: This study was carried out on 923 patients who fulfilled ACR/EULAR criteria 2010. All of them live in Sohag governorate and aged 18 years or older DAS28-ESR score, first involved joint, joint distribution, disease pattern, extra-articular comorbidities including gastrointestinal, urinary, cardiac, haematological and neurological were estimated. The activity of daily living was valued by Erlangen score (E-ADL).
Results: The mean age of the participants was 45±10.9 years, with a range (19–70). The median of the disease duration was 5 years, with a range (0.5–40 years). Most of the participants were female (691, 74.9%). Disease onset was gradual or insidious in 94.3% of cases and acute in 5.7% of them. First joint group affected were the small joints of the hands (MCPs and PIPs), recorded in 48.9% of cases, Followed by wrist joints (29.3% of cases), then knees (9%), ankles and small joints of the foot (6%) and lastly other joints collectively recorded in only 6.8%. The commonest extra-articular comorbidities were haematological, seen in 323 cases; 35%, followed by gastrointestinal in 290 cases (31.4%), then ophthalmological in 31%, entrapment syndromes in 29.4%, pulmonary in 21.7%, urological in 12.4%, rheumatoid nodules in 11.4%, liver cirrhosis in 8.7%, renal impairment in 8.5% and Cardiovascular diseases in 6.5%. The activity of daily living (E-ADL) showed that most of the cases fell in score 4 (58.2%). Regarding DMARDs treatment of the study population, Methotrexate (MTX) was used regularly by 78.3% of cases, hydroxychloroquine (HCQ) by 78.1%, followed by Leflunomide (LEF) by 26.4% and sulfasalazine (SSZ) by 13.1%. The majority of cases used combination therapy of either MTX+HCQ, MTX+SSZ, MTX+HCQ+SSZ or MTX+LEF. Regarding other drugs, 99% of cases used NSAIDs (regularly in 30.2% and on demand in 68.8%). Steroids were regularly used by 28.8% of cases.

Conclusions: The commonest comorbidities were haematological, gastrointestinal, ophthalmological and neurological ones; respectively. Erosion, deformity and Das28-ESR score have a great impact on E-ADL score.

AB0292 CLINICAL FEATURES OF RHEUMATOID ARTHRITIS AT 75 YEARS OF AGE AND OLDER IN JAPAN – COMPARISON WITH POLYMYALGIA RHEUMATICA IN THE SAME AGE GROUP

A. Aoki[1], H. Oka[1], I. Aoki[2]. *[1]Dept. of Rheumatology, Tokyo Medical University Hachioji Medical Center, Tokyo; [2]Dept. of Pathology, Kanagawa Prefectural Ashigarakami Hospital, Kanagawa, Japan*

Background: As Japan is a super-aged society, we have many chances to care for elderly patients in our hospital. Elderly-onset rheumatoid arthritis (RA) (onset age >60 years) may present similar symptoms to those of polymyalgia rheumatica (PMR). We consider that differential diagnosis of RA and PMR is more difficult in patients over 75 than those under 74 in clinical practice.
Anti-cyclic citrullinated peptide antibody (ACPA) was reported to be a helpful tool in the differential diagnosis of EORA from PMR. However, when elderly patients with negative ACPA complained of bilateral shoulder and/or girdle pain, it was difficult to differentiate PMR from RA.
Objectives: The study aimed to explore clinical features of RA and PMR at onset age 75 years. For the present investigation, we used a novel diagnostic

tool to distinguish ACPA-negative elderly RA patients from PMR patients at initial presentation.

Methods: From April 2011 to December 2016, 21 RA patients and 24 PMR patients in our hospital, whose onset age was over 75 years, were recruited for this study. PMR patients did not have any evidence of giant cell arteritis. The diagnosis of RA was made based on 2010 ACR/EULAR RA classification criteria. The diagnosis of PMR was made based on 2012 EULAR/ACR classification criteria or Bird's criteria. Data were obtained from medical records under informed consent. Statistical analysis was performed using the Mann-Whitney U-test to compare median values and Fisher's exact test to compare frequencies (IBM SPSS version 24). $P<0.05$ indicated statistical significance.

Results: RA patients (6 men and 15 women) consisted of fifteen ACPA+ (11 RF+, 4 RF–), six ACPA– (1 RF+, 5 RF–). PMR patients consisted of 12 men and 12 women. All of them were ACPA–/RF– and did not meet 2010 RA criteria. Twenty patients met 2012 PMR classification criteria, and 4 patients without bilateral shoulder pain met Bird's criteria. Clinical features and statistical results are shown in the Table. Sixty-seven percent of RA patients and 13% of PMR patients had left-right differences in joint pain.

Scoring was performed based on clinical findings. Tenderness and/or swelling joint counts among wrists, fingers, ankles, and knees = each 1 point, left-right difference =1 point, no bilateral shoulder pain =1 point, no girdle pain =1 point, no fever =1 point; the maximum score was 8. The mean score in RA patients was 4.8 (SD =1.44), whereas that in PMR patients was significantly lower at 1.5 (0.98) ($P<0.001$). Receiver operating characteristic (ROC) curve analysis was used to determine the most suitable cut-off level to find RA. A score over 3 was 100% sensitivity and 87.5% specificity. All 6 ACPA-negative RA patients showed a score over 4.

Table Clinical features in patients with rheumatoid arthritis (RA) and polymyalgia rheumatica (PMR)

			RA≧75 (n=21)	PMR≧75 (n=24)	*P*-value
Age at onset (years)		mean (SD)	81.5 (4.18)	80.5 (3.95)	0.4
Male		n (%)	6 (33)	12 (50)	0.1
Time from onset to start of treatment (months)		median (IQR)	2.0 (1.5)	1.5 (1.4)	0.09
Joint/muscle pain at onset	Bilateral shoulder	n (%)	10 (48)	20 (83)	0.03
	Girdle	n (%)	0 (0)	12 (50)	<0.001
	Wrist	n (%)	19 (91)	7 (30)	<0.001
	Finger	n (%)	4 (19)	0 (0)	0.04
	Foot	n (%)	6 (29)	0 (0)	0.007
	Knee	n (%)	13 (62)	2 (8)	<0.001
Systemic symptoms	Fever	n (%)	3 (14)	14 (58)	0.002
	Body weight loss	n (%)	6 (29)	14 (58)	0.07
Rheumatoid factor positive		n (%)	12 (57)	0	<0.001
Anti-CCP antibody positive		n (%)	15 (71)	0	<0.001
C-reactive protein (mg/dL) at onset		mean (SD)	6.1 (5.66)	8.4 (4.61)	0.1
Matrix metalloproteinase 3 (ng/mL) at onset		mean (SD)	431 (373.6)	421 (342.0)	0.9

SD, standard deviation; IQR, interquantile range; CCP, cyclic citrullinated peptide

Conclusions: Pease et al studied RA at onset 60 years and over and PMR, and reported that arthritis of wrists and fingers was suggestive of RA[1]. However, in our study, small joint swelling was rare in RA patients 75 years and older. The scoring system we made might be useful for the differential diagnosis of ACPA-negative RA and PMR in elderly patients 75 years and older.

AB0293 METABOLIC SYNDROME AND INSULIN RESISTANCE IN ADULT EGYPTIAN FEMALES WITH RHEUMATOID ARTHRITIS

A.A.-R. Youssef[1,1], N.O. Neseem[1], M.A.-B. Omar[2], O.M. El-Siri[1].
[1]Rheumatology & Rehabilitation; [2]Clinical Pathology, Mansoura University, Mansoura, Egypt

Background: Patients with Rheumatoid Arthritis (RA) have an increased risk for cardiovascular disease (CVD) due to higher prevalence of traditional risk factors (1), Insulin resistance (IR) is implicated in inflammatory diseases such as RA (2). The prevalence of Met.Syn and IR in Egyptian female RA patients has not been studied before.

Objectives: To find out the prevalence of Met.Syn and IR in a cohort of Egyptian females with RA and in controls and to study the associated risk factors

Methods: 60 female RA patients and 30 healthy females matched for age were included according to the ACR/EULAR 2010 classification criteria. Disease activity was assessed using DAS- 28. IR using HOMA- index (HOMA- IR) (3) Met.Syn was defined according to the updated third report of the National Cholesterol Education Program's Adult Treatment Panel (NCEP-ATP III) criteria (4).

Results: Prevalence of Met.Syn in female RA patients is significantly (sig.) higher (56.7%) than that of controls (33.3%, P=0.04). IR is prevalent in RA patients (63.4%), Patients with Met.Syn exhibited sig. higher serum levels of TG ($P<0.001$,) FBG (P=0.02), CRP (P=0.02), Fasting insulin (P=0.01) and IR (P=0.03) than those without. Median CRP (24) and mean DAS- 28 (5.6±1.5) in RA patients with increased IR are sig. higher than those of RA Patients with normal IR (6.5, $P<0.01$) & (4.7±1.5 $P<0.04$) respectively. Significant positive correlation was found between DAS-28 and IR (Rs =0.3, P=0.03). Using logistic regression, high systolic blood presser (OR =1.2, 95% CI: 1.02 – 1.39, P=0.03) and elevated CRP (OR =1.07, 95% CI: 1.01 – 1.14, P=0.04) have shown to be the significant independent predictors for the development of Met.Syn

Conclusions: Met.Syn. and IR are prevalent in female Egyptian RA patients adding to the CV risk of the disease and both are related to increased disease activity. Rheumatologists should pay an attention to control RA disease activity in addition to screen patients for components of the Met.Syn and introduce appropriate treatment strategies. Further studies are warranted to get more conclusive results.

AB0294 PREGNANCY IN RHEUMATOID ARTHRITIS – A ROMANIAN COHORT

A. Bobirca[1], F. Bobirca[2], I. Ancuta[1], C. Mihai[1], C. Tataru[1], C. Comsa[1], M. Bojinca[1], M. Micu[3], A. Musetescu[4], C. Ancuta[5], V. Stoica[1]. *[1]Internal Medicine and Rheumatology; [2]General Surgery, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest; [3]Division of Rheumatology, Department of Rehabilitation II, Clinical Rehabilitation Hospital, Cluj-Napoca; [4]Rheumatology Department, University of Medicine and Pharmacy, Craiova; [5]Clinical Hospital of Rehabilitation, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania*

Background: Planning a pregnancy in rheumatoid arthritis (RA) meets several issues, mostly concerning potential drug toxicity and disease flares

Objectives: The purpose of this study is to evaluate pregnancy planning, RA activity during pregnancy and postpartum, pregnancy and fetal outcomes in a Romanian cohort of female patients diagnosed with RA.

Methods: This is an observational, ambispective study, including 58 RA Caucasian females with obstetric history after the onset of RA (20 females - prospective, 38 - retrospective). The cases were obtained from several Clinics of Rheumatology from Romania

Results: The mean age at inclusion was 37.1 years, age at RA diagnosis 3.9 years and mean age at conception 32.2 years. We recorded a total number of 96 pregnancies: 48 deliveries at term, 4 premature births, 15 elective abortions, 24 spontaneous abortions, and 5 ongoing. 34/96 (35.4%) had at least one unplanned pregnancy, while being on treatment.

Concerning the exposure to synthetic DMARDs during the pregnancy: 6 patients received Leflunomide and 4 received Methotrexate during the first trimester, the pregnancy outcomes being: 3 spontaneous and 3 elective abortions, 3 normal birth (1- Cholestiramine wash-out), 1 premature twin pregnancy.

Regarding biologic DMARDs: 5 were exposed to Etanercept - 3 less than 3 weeks, (2 normal births and one elective abortion- due to Methotrexate use), 2 treated in second trimester: 1 only in the 15th and 16th weeks due to relapse - normal birth, and the other one until week 20, pregnancy still ongoing.

One patient was treated with Certolizumab until week 12, the pregnancy is ongoing, and one with Adalimumab until week 4, the fetus had intrauterine growth restriction, premature birth.

6 patients treated with Rituximab were included, last infusions were: 4 weeks before conception (1- spontaneous abortion and 1 normal birth), 48 weeks (2 normal births and 1 premature), and one at 4 weeks after conception - normal birth.

In 4 cases the patients stopped the biological DMARD before conception: Etanercept 6 months and 2 years, Adalimu-mab,6 months with normal outcome, and for Tocilizumab 9 months (growth restriction)

81.25% of our patients were in Remission or Low Disease Activity (by DAS28CRP) at conception and generally this status was maintained, excepting several situations.

The average pregnancy length was 36.36 weeks and the mean birthweight was 2878.90 grams.2 growth restriction was identified and several atopic dermatitis, no teratogenic effect.
13 patients never had a new flare postpartum and in the others the mean time of postpartum flare was 12.1 weeks
Conclusions: Patients with RA can have successful pregnancies. More than 60% of pregnancies have been planned. Pregnancy decreases disease activity, but many deliveries are followed by RA flares. No fetal abnormalities were diagnosed.

AB0295 THE RECALL SURVEY: DATA FROM A MULTICENTER EDUCATIONAL EVENT ON PATIENTS WITH RA

A. Delle Sedie[1], E. Filippucci[2], O. Epis[3], P. Macchioni[4], S. Tropea[5], C. Bonali[6], M. Canzoni[7], A. Iagnocco[8]. *[1]Rheumatology Unit, University of Pisa, PISA; [2]Rheumatology Department, Università Politecnica delle Marche, Jesi; [3]Rheumatology Unit, Ospedale Niguarda Milano, Milano; [4]Rheumatology Unit, Reggio Emilia Hospital, Reggio Emilia; [5]5ASP7 Busacca Hospital, Ragusa; [6]Rheumatology Unit, Ospedale San Paolo, Bari; [7]Local Health Unit (ASL) Rome 1, Rome; [8]Academic Rheumatology Unit, Università degli Studi di Torino, Torino, Italy*

Background: Ultrasound (US) is able to show subclinical synovitis in patients (pts) with rheumatoid arthritis (RA) who are in clinical remission (CR); this has been proposed as a predictive factor for both clinical flares and progression of the structural damage in CR pts.
Objectives: To investigate the US characteristics of RA pts presenting either CR or low disease activity (LDA).
Methods: In 2015 an educational event focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy. After a brief presentation on the evidence of US added value for the clinician given by expert sonographers (rheumatologists with a special interest in US that were performing US as their usual activity for many years), in every center, the local rheumatologists provided RA pts to be examined by US. All the US machines were identical both for type (Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe) and settings (both for grey-scale and power Doppler (PD)). Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). The US examination was performed bilaterally on wrists, MCP and MTP joints, looking for synovitis (effusion, synovial proliferation and PD signal) and bone erosions. The positive findings were scored according to a 0–3 score for synovitis components and presence/absence for erosions; the number and size of the largest erosion was also registered.
Results: Demographic and descriptive data of the 433 pts examined are reported in Table I. Pts were divided on the basis of the DAS28 result. Statistically significant differences in age and disease duration were registered between the group in CR and the group with DAS28≥3.2 (p=0,019 and p=0,012, respectively), while no differences were found for HAQ or MTX use. Higher positivity of findings, regardless which was the score, was present in LDA group for effusion, synovial proliferation and PD signal. Significant differences were seen between CR and LDA group for effusion (general, MCP and MTP joints; p=0,011, p=0,026, p=0,017 and p=0,013, respectively), PD positivity (general, wrist, MCP and MTP joints; p=0,006, p=0,023 and p=0,05, respectively) and erosions (p=0,002), with higher positivity for pts in LDA.

Table 1. demographic data

	DAS28 <2.6	DAS28 2.6–3.2	DAS28≥3.2
N (M:F)	155 (34:121)	170 (39:131)	108 (20:88)
Age (mean±SD; yy)	56.1±14.3	59.2±12.2	60.5±11.4
Disease duration (mean±SD; dd)	2368.49±2565.39	3274.16±2948.36	1966.53±1884.58

Conclusions: The US assessment in this large cohort of RA pts showed frequent positive findings both in the CR and in the LDA group, confirming the results from previous studies. US is a useful imaging tool for the detection of subclinical joint abnormalities in RA.

AB0296 HMG-COA REDUCTASE INHIBITOR DRUGS (STATINS) BENEFIT IN CARDIOVASCULAR RISK PREVENTION AND AMELIORATE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Hon, M. Sultanova. *Cardiorheumatology, Tashkent Medical Academy, Tashkent, Uzbekistan*

Background: Patients with active rheumatoid arthritis (RA) are frequently diagnosed with an atherogenic lipid profile and supra-aortic vessel ultrasound signs of atheromatous plaques, which have been linked to the inflammatory activity of RA. Recent experimental and clinical evidences suggest that the beneficial effects of statins are pleiotropic and have been proposed to have anti-inflammatory and immunomodulatory effects, inhibiting proinflammatory cytokines (IL-1β, 6, 8, TNF-α), adhesion molecules (sICAM 1, E-, P-selectin), osteoprotegerin, which are implicated in RA pathogenesis. However, the beneficial role of statin therapy in clinical improvement and their benefit-risk profile are still debatable.
Objectives: To evaluate the effect of medium-term rosuvastatin therapy on lipid profile, endothelial dysfunction and RA activity in patients with rheumatoid arthritis (RA) in comparison with conventional disease modifying antirheumatic drugs (DMARD) therapy.
Methods: The study included 82 patients in the Specialized Course Outpatient Therapy Department of the 1st Clinic of Tashkent Medical Academy of age group between 44 and 65 years (mean 52±8.4), predominantly female gender (n=57, 69.5%), with early RA (mean disease duration 9.2±2.4 months), and divided into 2 groups. Group 1 (n=40) received methotrexate (MTX; 7.5 mg/week; plus prednisolone (10 mg/day). Group 2 (n=42) received MTX and prednisolone with the same previous doses plus rosuvastatin (40 mg/day). Lipid profile assessment comprised triglycerides, total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C). Disease activity was assessed by the disease activity score of 28 joints (DAS28), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and visual analog scale (VAS). Disease activity, lipid profile and intima-media thickness (IMT) of common carotid arteries were measured before and after 85 days (6 months) of treatment.
Results: 4 patients receiving rosuvastatin were excluded due to abnormal liver function test parameters (De Ritis ratio <0.9), further assessment was thus performed on 78 (Group 2, n=38) early RA patients. Overall ESR (Group 1: 24.4±7.26; Group 2: 37.4±12.3) and CRP (Group 1: 5.56±0.58; Group 2: 3.71±1.23) declined significantly during the treatment. The mean DAS28, unconditionally considered as the most important index of clinical disease activity in RA, was found to be lower ($p<0.05$) in the adjunct statin-treated group (Group 2: 3.68±0.77) than that of the conventional DMARD treated group (Group 1: 4.45±1.08). Statin significantly reduced LDL-C (3.9±1.2 mmol/l to 3.3±0.8 mmol/l; p=0.08) and increased HDL-C (1.3±0.6 mmol/l to 2.0±0.4 mmol/l; p=0.06) after 6 months of treatment. However, rosuvastatin therapy showed no significant improvement in VAS score (6.7±1.5 to 6.9±0.6; p=0.41) and IMT (1.04±0.09 to 1.08±0.07; p=0.05).
Conclusions: Statins ameliorate RA activity, reduce potential cardiovascular risk in the context of atherosclerosis and mediate clinically apparent anti-inflammatory effects, but long-term effects and benefit-risk profile should be addressed in the management of elevated risk of cardiovascular events in RA patients.

AB0297 TREATMENT WITH LOW-DOSE PREDNISONE DOES NOT INFLUENCE BODY COMPOSITION DURING THE FIRST YEAR OF RHEUMATOID ARTHRITIS- A PILOT STUDY

A. Raczkiewicz, O. Bujakowska, A. Juszkiewicz, B. Kisiel, J. Kur-Zalewska, M. Tłustochowicz, W. Tłustochowicz. *Internal Medicine and Rheumatology, Military Institute of Medicine, Warsaw, Warsaw, Poland*

Background: Early change in body composition is one of the risk factors of CVD in rheumatoid arthritis (RA). These changes have been atributed to inflammation and decreased physical activity. Glucocorticosteroids (GCS) reduces inflammation but may influence body composition. There is limited information about the effects of low-dose GCS on body composition in early RA.
Objectives: The aim of the study was to assess the presence of altered body composition in patients with early rheumatoid arthritis (eRA) and to determine whether low-dose prednisone affects body composition.
Methods: 65 consecutive eRA patients (49 women) aged 61±14 years were assessed at the time of diagnosis and after 12 months of treatment. All the patients had been treated with methotrexate (target dose 25–30mg/week) and tapered doses of prednisone (mean dose 4.8±3.4 mg/day). Disease activity score (DAS28), Health Assesment Questionnaire (HAQ), body mass index (BMI), waist/hip ratio, comorbidities, physical activity and smoking were recorded. Total and regional lean mass and fat mass were measured with dual energy X-ray absorptiometry (DXA). DXA measures were repeated after 12 months in 34 patients (24 women) and compared with baseline data.
Results: At baseline fat free mass index (FFMI; kg/m^2) was below the 10th percentile of a reference population in 32% of the women and 25% of the men. Reduced FFMI correlated with baseline ESR. Fat mass index (FMI) was above 90th percentile in 28% of the women and 42% of the men. Fat mass index (FMI;kg/m^2) correlated with HAQ, age and femoral BMD in women. After 12 months FFMI and FMI did not change significantly. There was no correlation between prednisone doses and the duration of prednisone treatment and changes in regional lean mass and fat mass. The decrase of FFMI (in 16 patients) was associated with higher mean ESR and lower vitamin D3 serum concentration.
Conclusions: Low FFMI was common in patients with eRA. The treatment with

low-dose glucocorticosteroids did not influence altered body composition during the first year of eRA therapy.

AB0298 ANTIBODIES TO CYCLIC CITRULLINATED PEPTIDE AND MODIFIED CITRULLINATED VIMENTIN: A ROLE IN RHEUMATOID ARTHRITIS ASSOCIATED WITH AUTOIMMUNE THYROIDITIS

A. Dvorovkin[1], V. Odin[1], O. Inamova[2], V. Tyrenko[1], M. Toporkov[1]. *[1]Faculty therapy, Military Medical Academy Named After S.M. Kirov; [2]Clinical Rheumatic Hospital No. 25, St. Petersburg, Russian Federation*

Background: Specific antibodies, including antibodies to cyclic citrullinated peptide (ACCP) and modified citrullinated vimentin (AMCV) are markers of severe course of rheumatoid arthritis (RA). At the same time, rheumatoid arthritis often associated with autoimmune thyroiditis (Hashimoto's thyroiditis (HT)).
Objectives: Evaluate the role of antibodies to ACCP and AMCV on the clinical and laboratory features of rheumatoid arthritis in association with autoimmune thyroiditis.
Methods: The study included two groups of patients. The first group of patients included 16 patients (14 men and 2 women, mean age - 62.37±2.12 years) with RA in combination with HT and detection in the blood only ACCP (group 1). The second group also included 16 patients (14 women and 2 men, mean age – 52.31±4.94 years) with RA in combination with HT and detection of ACCP and AMCV in the blood (group 2). In the first group of patients 10 patients had euthyreose, from 5 - hypothyroidism, compensated intake of L - thyroxine, 1 patient - thyrotoxicosis underway medikal euthyreose. In the second group of patients was observed in 14 patients euthyreose, from 2 - hypothyroidism, compensated reception L-thyroxine.
Results: Both groups of patients differed on the following parameters studied: erosion detected in 68% in group 1 and 50% in group 2 ($p<0,05$), in the first group of patients predominated (62%) the high degree of activity of RA by DAS-28, in while in group 2 - the average (56%, $p<0,05$).
By using correlation analysis Spearman correlation relationships among the studied attracted attention significant ($R=0,62$, $p<0,05$) relationship between erosions and detection in the blood of antibodies to ACCP in the second group of patients (a combination of RA and HT and identifying in blood ACCP and AMCV), which was repeatedly weakened and unreliable in group 1 (combination of RA and HT and only detect of ACCP) in the blood.
Conclusions: Second group patients (a combination of RA with HT and detection in blood ACCP and AMCV) are closer correlations with indicators of joint destruction than group 1 patients, that in the future may use as a prognostic marker of a more severe course of RA in combination with HT.

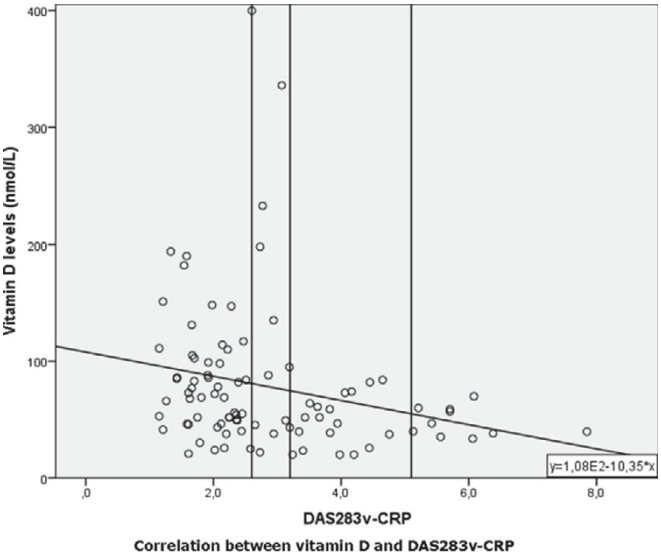
AB0299 ATLANTOAXIAL SUBLUXATION AS A PROBLEM IN PATIENTS WITH RHEUMATOID ARTHRITIS



S. Misevska Percinkova[1], A.A. Kuchi[2]. *[1]Dept. for Inflamatory Rheumatic Disease, University Rheumatology Clinic; [2]Dept. for Internal Medicine, PHO City Health Centre Skopje 1, Skopje, Macedonia, The Former Yugoslav Republic Of*

Background: Atlantoaxial subluxation (AAS) is important and potentially life threatening complication of Rheumatoid arthritis (RA). It is defined when the space between odontoid process from C2 and arch of the atlas exceeds more than 3 mm. Instability in atlantoaxial joint may result with numerous neurological symptoms, compression of spinal cord and ultimately quadriparesis or quadriplegia.
Objectives: Aim of the study was to determine the frequency and the characteristics of atlantoaxial instability among our patients with RA and its dependence on the nature of the disease.
Methods: 92 outpatients from University Rheumatology Clinic in Skopje, with classical RA (ACR criteria 1988) were examined for the AAS. In all cases were analysed the duration of the disease, haematological and serological tests, disease activity (DAS 28), visual analogue scale (VAS) for the degree of articular pain and verbal rating scale (VRS).for cervical-occipital pain. All patients underwent native and functional x-ray, CT scan and MRI of cervical spine. A complete neurological examination was obtained, with SEP of the n. medianus et n. tibialis.
Results: Atlantoaxial instability, with expressed cervical-occipital symptomatology, occurred in 54 from 92 (58,69%) patients with RA. AAS appeared significantly more often in patients with longer duration of the disease ($p<0,0001$), in cases with significant cervical-occipital pain (VRS $p<0,0001$), with stronger joint pains (VAS), with higher values of SR ($p=0,002$), CRP ($p=0,023$), RF ($p=0,000005$), anti CCP ($p=0,00003$), and DAS 28 ($p<0,0001$). Anaemia and thrombocytosis ($p=0,0008$) appeared significantly more in cases with AAS. Anterior AAS, (mostly combined with other types) was the most frequent type, presented in 41 participants (75,92%). In one case posterior AAS was detected, what is very rare finding. Positive SEP was significantly higher in the group with AAS
Conclusions: AAS is serious extra-articular manifestation of RA. Cervical subluxation may be a general anesthetic risk and risk for a neck injury. Routine cervical radiographs with the head in flexed position should be recommended in need of general anaesthesia and in situations with risk for a neck injury.
Acknowledgements: Rheumatoid arthritis, atlantoaxial subluxation.

AB0300 ASSOCIATION OF VITAMIN D STATUS WITH RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND UV INDEX

C. Lopes[1], J.L. Gomes[1,2], T. Costa[1], M. Mateus[1], F. Pimentel-Santos[1,2], J.C. Branco[1,2]. *[1]Rheumatology Department, Hospital de Egas Moniz | CHLO; [2]CEDOC, NOVA Medical School | Faculdade de Ciências Médicas - NOVA University of Lisbon, Lisbon, Portugal*

Background: Lower serum vitamin D levels have been shown to be associated with various autoimmune disorders, including Rheumatoid Arthritis (RA). Vitamin D deficiency is common in RA patients, despite profiting from a sunny country.
Objectives: The aim of the study is to evaluate (1) – the association between vitamin D serum levels and disease activity in patients with RA; (2) – seasonal distribution of vitamin D levels.
Methods: Patients fulfilling the 2010 EULAR/ACR Rheumatoid Arthritis Classification Criteria, which had serum vitamin D [25(OH)D3] levels measured between January 2013 and December of 2016 were included. Demographic data, disease activity scores, including DAS283v-CRP and DAS283v-ESR, vitamin D supplementation with cholecalciferol and other therapeutic approaches were recorded. Vitamin D insufficiency was considered between 25–75 nmol/L and deficiency if <25 nmol/L. According to the national agency for the study of sea and atmosphere, UV Index levels were grouped into low UV Index 3–6 (October to April) and high UV Index 9–10 (May to September). Correlation between variables was analyzed using Spearman's rho.
Results: A sample composed by 95 patients, 79 females (83.16%), with an average age (SD) of 68.57 (11.92) years within 40–88 years range were included. Average disease duration was 13.46 (11.41) years. The average age at diagnosis was 57.10 (14.25) years. The average vitamin D levels were 78.13 (60.98) nmol/L in a range between 20–400 nmol/L. Vitamin D levels were not significantly different in male *vs.* females patients. The prevalence of vitamin D insufficiency and deficiency was 53.68% and 8.42% respectively, despite 57.89% of the patients taking supplementation (average 6141 (4800) UI/week). The univariable analysis showed that albeit vitamin D levels presented a negative poor correlation with DAS283v-CRP (rho=-0.348, p-value<0.001) and DAS283v-ESR (rho=-0.271, p-value<0.01), there was a direct reduction in dispersion of the vitamin D values for increasing values of DAS283v-CRP and ESR. It was observed that vitamin D levels increase with patient age and decrease with disease duration. Sazonality and supplementation didn't affect vitamin D levels in our population.

Correlation between vitamin D and DAS283v-CRP

Conclusions: Vitamin D insufficiency/deficiency was frequent among RA patients (62.1%), independently of seasonality or supplementation. An interesting pattern

behavior was observed in this study, which indicates that the likelihood of encountering a very narrowband of vitamin D values for patients with high disease activity is very high, and thus, the forecast capability of vitamin D values for patients with increasingly active disease is quite good. Future research will aim at strengthening the statistical parameters of relevance, identifying and characterizing the more specific behaviours of this global pattern.

AB0301 CARDIOVASCULAR RISK AND END ORGAN DAMAGE IN AN ITALIAN GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS

C.A. Valena[1], S. Barbarossa[1], G. Erba[1], R. Facchetti[2], A. Maloberti[1], P. Villa[1], I. Boggioni[1], M. Riva[1], G. Grassi[1], M.R. Pozzi[1]. *[1]Clinica Medica Università Milano Bicocca; [2]Dipartimento di Medicina Clinica e Prevenzione, Università Milano Bicocca, Monza, Italy*

Background: The elevated cardiovascular burden of rheumatoid arthritis is well known and the recent update of EULAR recommendations for cardiovascular disease management (1) establish as overarching principle that the rheumatologist is responsible for CVD risk management in patients with RA. They highlight the need of optimal disease activity control, regular CVD risk assessment, lifestyle counseling, appropriate prescription of NSAIDS,corticosteroids,antihypertensives and statins. Screening for asymptomatic atherosclerotic plaques by use of carotid ultrasound is also suggested: the presence of carotid plaques is associated with poor CVD-free survival and is strongly linked to future acute coronary syndrome in RA patients.
Objectives: We performed an overall cardiovascular assessment to evaluate the presence of end-organ damage in a group of RA patients.
Methods: We carried out non-invasive 24 hours ambulatory blood pressure monitoring, echocardiography, carotid doppler ultrasound and pulse wave velocity (PWV) in a group of RA patients to optimize non-DMARDs therapy and to evaluate end organ damage.
Results: 55 RA patients, 76.4% female, mean age 62.8±9 yrs were examined. The median disease duration was 12 yrs. 84% were RF +, 80% ACPA + and 51% had erosions. Mean DAS 28 CRP was 2.82±1.23 and HAQ 0.54±0.6. All pts were treated with cDMARDs and/or bDMARDs (54%) and Pd mean dosage was $\leq$5 mg/day. Only 3 patients had previous CV event. 49% were hypertensive, 25% had high cholesterol, 13% diabetes and 16% were smokers: median BMI was 25. MAP monitoring revealed that 43/55 (78%) pts were hypertensive: 13 of them had unknown or not/under treated hypertension: 63% had dipper profile and only 12% were reverse dipper. We did not find increased left ventricular mass and wall thickness, but left ventricular diastolic dysfunction grade I-II was found in 26/55 pts, not related to hypertension nor to RA activity. The IMT median value was 655 mm; only in 3 pts was $>$900 mm: no relation with disease activity was found. In 11 pts carotid plaques were present and related with age, BMI and ambulatory mean pressure values, but not with RA activity or duration. In one patient the plaque required carotid endarterectomy. The PWV median value was $>$10m/s in 16 pts, all hypertensive.
Conclusions: The accurate evaluation of cardiovascular involvement of this small group of RA patients shows that hypertension is frequent and often not appropriately treated and seems to be the main cause of the increased PWV. Low grade LV diastolic dysfunction was found in half of patients, with no relation with hypertension or RA features, except for CCP presence, but the small numbers do not allow any speculation. Carotid artery involvement was present in 20% of pts, but only in 1 was clinically significant. Once again no relation with RA features was found: the small number of patients, the low disease activity and the tight and overall clinical control could be partial explanations. The clinical tight control of patients with RA is an unique opportunity to fulfill EULAR reccomendations.

AB0302 WORKABILITY IN PATIENTS WITH SEROPOSITIVE RHEUMATOID ARTHRITIS

C. Berner[1], T. Lamprecht[2], K.H. Fenzl[2], L. Erlacher[1], T.E. Dorner[3]. *[1]2nd Medical Division, Rheumatology, Kaiser Franz Josef Hospital, SMZ-Süd; [2]Karl Landsteiner Society, Institute for Autoimmune Illnesses and Rheumatology; [3]Institute of Social Medicine, Centre for Public Health, Medical University of Vienna, Vienna, Austria*

Background: Rheumatoid arthritis (RA) and other rheumatic conditions can lead to work disability, and temporary or permanent exit from the labour market. The indirect costs related to work disability, are higher than direct treatment costs, and pose an economic burden on patients and society. Workability in RA is influenced by many factors, including symptoms, such as pain, swelling and stiffness, muscle strength, or physical or mental exhaustion, which are components of the frailty syndrome.
Objectives: This study aimed to determine the association of workability with disease activity, pain, functional disability and frailty in patients with seropositive rheumatoid arthritis.
Methods: We conducted a monocentric cross-sectional study at a rheumatologic outpatient clinic and day hospital including 100 seropositive RA patients (according to 2010 EULAR classification) in the working age ($<$65 years). Workability was assessed with the self-administered Work Ability Index questionnaire. For disease activity, we used the Clinical Disease Activity Index (CDAI), a Visual analogue scale for pain assessment, for functional disability the self-administered Health Assessment Questionnaire Disability Index (HAQ-DI) and for the degree of frailty the SHARE Frailty Instrument (SHARE-FI). After testing for normal distribution, bivariate correlations between workability and associated variables were calculated using Spearman's correlation coefficients.
Results: Of 100 patients for 58 the workability index could be assessed. The remaining 42 were either unemployed, on disability pension, or employed but currently not working. These 58 patients, 37 women and 21 men, had an average age of 64.8 years (min-max=22–59, SD=9.3) and an average disease duration of 93.9 months (min-max=3–360, SD=86.7). 8 patients reported excellent workability, 27 good workability, 16 moderate workability and 7 poor workability. The workability was weakly correlated with age (r_s= -0.37, p$<$0.004), and moderately correlated with pain intensity (r_s=0.42, p$<$0.001), disease activity (r_s=0.40, p$<$0.002), functional disability (r_s=0.64, p$<$0.000) and frailty (r_s=0.623, p$<$0.000).
Conclusions: A considerable portion of employed RA patients reported poor or moderate workability, which is significantly associated with disease activity but also with the other parameters assessed. An adequate therapy may therefore not only improve well-being and state of health in RA patients but also provide socioeconomically advantage by maintaining patients' workability.

AB0303 DOES COMORBIDITY ADVERSELY IMPACT ON TREATMENT RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

C.D. Hughes, N. Gullick. *Rheumatology, King's College Hospital, London, United Kingdom*

Background: The burden of comorbid illness in Rheumatoid Arthritis is high. Whilst there can be coincidental existence of comorbidity, it can be attributed to the disease process itself or therapeutic agents. Recent EULAR guidelines recommend reporting, screening and prevention of six common co-morbidities (cardiovascular, malignancy, infections, gastrointestinal, osteoporosis, depression). Limited research is available evaluating the impact of comorbidity on disease response following biologic treatment.
Objectives: To analyse retrospective data from the King's College Hospital (KCH) Virtual Biologic Clinic (VBC) to assess the impact of comorbidity on disease response following treatment with biologics.
Methods: Retrospective patient note review data was collected for patients referred to the VBC from May 2013 to July 2016. The following data was recorded: age, sex, disease duration, smoking status, BMI, presence or absence of Anti CCP antibody +/-Rheumatoid factor and the six specified comorbidities. Disease Activity Score in 28 joints (DAS28) at time of referral for biologic and within 6 months of commencing treatment was also recorded in order to calculate treatment response.
The impact of comorbidity and disease variables on 6 month EULAR response were analysed using logistic regression (SPSS version 23).
Results: The database contained 150 patients. 18 patients were excluded due to no follow-up DAS28, leaving 132 for analysis. Mean age and disease duration were 58 years and 10.45 years respectively. Comorbidity was present in 70% of patients. 70% of patients achieved a EULAR moderate response (improvement of $>$1.2 of DAS28) and 36% of this group achieved EULAR good response (DAS28$<$3.2). The most prevalent comorbidities were infection, cardiovascular disease and depression.
Logistic regression analysis was run analysing EULAR moderate response against presence of comorbidity and dataset variables (age, gender, serostatus, baseline DAS, HAQ and polypharmacy). The resulting model was not statistically significant (p=0.975).
Logistic regression analysis looking at EULAR good response against presence of comorbidity was also not statistically signifiicant (p=0.149). Analysis looking at EULAR good response against three variables (HAQ, baseline DAS and serostatus) was found to be statistically significant (p$<$0.001)

Characteristics	All N=132	No EULAR moderate response N=40	EULAR moderate response N=92	EULAR good response N=34
Age years (SD)	58 (13)	56 (10)	59 (14)	57 (11)
Gender (%F)	79%	72.5%	81.5%	76%
Positive serostatus	77%	65%	82%	74%
RA Disease duration (years) (SD)	10.45 (10.81)	10.70 (11.47)	10.34 (10.52)	10.54 (10.74)
Prior biologic use	55%	60%	52.2%	32%
Comorbidity	70%	80%	82%	62%
Baseline DAS28 (SD)	6.27 (0.93)	6.27 (0.93)	6.28 (0.93)	6.26 (0.93)
Mean DAS improvement (SD)	1.97 (1.57)	1.97 (1.57)	1.99 (1.58)	1.95 (1.58)

Conclusions: Comorbidities were present in the majority of patients assessed

(70%). Results show no significant relationship between EULAR moderate response or EULAR good response and the presence of comorbidity. Lower HAQ, lower baseline DAS28 and seronegativity contribute towards good treatment response.The limitations of this study include gaps in clinical records, absence of patient reported questionnaires, and small size of database.

AB0304 SERUM LEVELS OF SCLEROSTIN AND DICKKOPF-1, AND THEIR CORRELATION WITH BONE MINERAL DENSITY AND BONE MARKERS IN RHEUMATOID ARTHRITIS

C.A. Nava-Valdivia[1], E. Corona-Sanchez[2], J. Ponce-Guarneros[3], A. Saldaña-Cruz[2], J. Murillo-Vazquez[2], E. Perez-Guerrero[2], P. Hernandez-Cuervo[2], M. Salazar-Paramo[3], D. Cardona-Müller[2], E. Cardona-Muñoz[2], L. Gonzalez-Lopez[3], J. Gamez-Nava[1]. *[1]Unidad Biomédica 02, IMSS; [2]Universidad de Guadalajara; [3]IMSS, Guadalajara, Mexico*

Background: Sclerostin (SOST) and dickkopf-1 (DKK1) are involved in the development of primary osteoporosis. Although to date, it is controverted does exist about if serum levels of these molecules may reflex adequately a subgroup of patients with decrement of Bone Mineral Density (BMD) being useful as clinical biomarkers. Some non-conclusive observations made in postmenopausal osteoporosis have shown abnormalities in serum levels. To date, there is a lack of information about if these serum molecules are associated with a decrease of BMD in RA. This information is relevant for to know if the measurement of these serum molecules could be useful in the clinical care to identify a subgroup of patients with low BMD.
Objectives: To evaluate if serum levels of SOST and DKK1 correlate with bone mineral density and other bone markers in RA.
Methods: In this Cross-sectional study, we included 115 women with RA >40 years old. All patients were assessed for clinical characteristics disease activity (DAS28) and functioning (HAQ-Di). BMD was measured in lumbar spine, hip and forearm using DXA. According to their results, osteoporosis was identified if the BMD in a patient had a T-score with a decrement of ≤-2.5 standard deviation (SD). According to their results we classified these patients in two groups: a) low BMD (T-score≤-1SD on lumbar spine or total hip) and b)normal BMD (T-score>-1SD). Serum SOST, DKK1, including serum Receptor Activator of NF-κB Ligand (sRANKL) and osteoprotegerin (OPG) were quantified by ELISA. We compared serum levels between the groups using Student t-tests. For comparisons between proportions we performed Chi-square test (or Fisher exact test if required). Correlations between serum levels of SOST, DKK1, with BMD, clinical variables, sRANKL and OPG we performed Pearson correlation tests.
Results: From the 115 women with RA, 58 patients had low BMD (50.4%), from them 44 patients (38.3%) had osteoporosis. Patients in the group with low BMD had higher age (63±8 vs 53±9,p<0.0001), DAS28 (4.1±1.5 vs 3.3±1.4, p=0.011), and HAQ-Di score (0.69±0.53 vs 0.36±0.47, p=0.001) compared with normal BMD; whereas lower serum levels of sclerostin was observed in the low BMD group (128.5±75.0 vs 178.2±103.3, p=0.004). SOST levels were correlated with BMD in lumbar spine (r=0.393, p<0.0001), hip (r=0.388,p<0.0001) and forearm (r=0.319, p=0.001). sRANKL serum levels had a negative correlation with BMD in hip (r=-0.17, p=0.03). No correlations were observed between serum DKK1 and OPG with BMD in hip or lumbar spine.
Conclusions: These results indicate that SOST, and RANKL are biomarkers may associated with abnormal BMD in RA. Further long-term follow-up studies should evaluate if high levels of these serum biomarkers could be useful as tests to predict the future development of osteoporotic fractures.

AB0305 FACTORS CONSIDERED BY RHEUMATOLOGISTS TO DECIDE TREATMENT DURING RHEUMATOID ARTHRITIS PATIENT'S FOLLOW-UP

C. Sifuentes-Cantu[1], I. Contreras-Yañez[1], M. Gutierrez[2], V. Pascual-Ramos[1]. *[1]Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran; [2]Division of musculoskeletal and rheumatic diseases, Instituto Nacional de Rehabilitación, México, D.F, Mexico*

Background: Disease activity (DA) is the most important factor in the treatment decision during rheumatoid arthritis (RA) patient's follow-up. In routine clinical practice, it is recommended to regularly evaluate DA and musculoskeletal ultrasound has been suggested to add value to establish the level of DA. Nevertheless, the final treatment proposal also requires considering additional factors. In a previous clinical study performed in the setting of an early arthritis clinic, we found that in 20% of the clinical scenarios evaluated, the German ultrasound score of 7 joints (GUS-7) (1) findings impacted the rheumatologist 's treatment proposal; the impact was more frequent among the trainee in rheumatology (TR) than among the senior rheumatologist (SR).
Objectives: To determine and rate, which among the following factors were determinant to recommend a treatment in the same population of RA patients above described: the clinical assessment, the GUS-7, comorbidities, treatment-related adverse events, DMARDs costs/availability, patient's preference and DMARD maximum dose. We also compared if factors differed between both physicians.
Methods: Eighty-seven consecutive and randomly selected RA outpatients were invited to participate; 2 patients denied and 85 patients underwent 170 assessments (85 each by the SR and the TR); at first, both physicians (blinded to each other) performed a clinical evaluation that included DAS28 scoring and recommended a RA-treatment. Then, patients underwent GUS-7 by a blinded (to clinical evaluations) rheumatologist. In the final step, the TR and the SR integrated the US findings to their previous evaluation and reviewed their prescription; also, both physicians recorded and rated on a standardized format which of the factors above described were determinant in the final treatment proposal. Patients signed informed consent and were instructed about the process. Only the SR met each patient for the final recommendation. Descriptive statistics was used.
Results: Patients were primarily middle-aged female (91.4%) and had (mean±SD) follow-up of 7.5±3.9 years. The majority of them were in DAS28-remission (72%). Clinical assessment (DAS28) was rated as determinant in the totality of the clinical scenarios (100%), followed by GUS-7 in 84.7%, DMARD maximum dose in 41.2%, comorbidities in 23.5%, DMARD cost/availability in 21.2%, treatment-related adverse events in 20% and patient's preference in 14.1% of them. The SR and the TR differed in their selection: GUS-7 and treatment-related adverse events were more frequently considered determinant for the TR (45.9% vs. 38.8%, p=0.01 and 12.9% vs. 7.1%, p=0.08), meanwhile the opposite figure was true for DMARD cost/availability (4.7% vs. 16.5%, p≤0.001) and DMARDs maximum doses (17.1% vs. 24.1%, p=0.08).
Conclusions: in a real clinical setting, DA assessed by DAS28 and by musculoskeletal ultrasound were the most important factors to determine the treatment of RA outpatients; additional factors were considered and differently rated by TR and SR.

AB0306 CAPLAN'S SYNDROME, CADMIUM AND CHINA CLAY: COULD OCCUPATIONAL KAOLIN INHALATION ENHANCE CADMIUM EXPOSURE TO EXPLAIN THE SIXTY YEAR CONUNDRUM OF CAPLAN'S SYNDROME FIRST REPORTED IN COAL MINERS?

D. Murphy[1,2], K. Bellis[1], D. Hutchinson[1,2]. *[1]Rheumatology, Royal Cornwall Hospital; [2]University of Exeter Medical School, Cornwall Campus, Truro, United Kingdom*

Background: Caplan's syndrome was first described in the coal miners of South Wales (UK). The specific cause for rheumatoid pulmonary nodules associated with coal dust exposure remains unknown. Coal dust exposure alone does not appear to explain Caplan's syndrome as almost all of these men were also smokers. Cigarette smoke is the most important environmental cause of cadmium exposure. We describe Caplan's syndrome in an ex-smoking kaolin worker associated with a significantly raised urinary cadmium level.
Objectives: A 65 year old Cornish kaolin worker and ex-smoker of 20 pack years with life limiting nodular erosive rheumatoid arthritis (RA), developed extra-articular manifestations including pulmonary nodules suggestive of Caplan's syndrome. We review the literature on kaolin, with respect to inhalation and mechanism of action for heavy metal adsorption and nodular disease development.
Methods: Pubmed searches were undertaken using the keywords "kaolinosis", "kaolin", "cadmium" "nodules", "adsorption", "coal". First pass mid-stream urine was analysed for cadmium using inductively coupled plasma–mass spectrometry (ICP-MS).[1]
Results: Urinary cadmium was significantly raised at 0.66 μmol/mol creatinine (non-occupationally exposed UK male median 0.17μmol/mol creatinine[1]), 20 years post-industrial exposure and 35 years post-smoking cessation. Contemporary serology levels demonstrated a rheumatoid factor of 481.7 iu/ml (0–10 normal range) and an anti-cyclic citrullinated peptide of >500 u/ml (0–17 normal range). CT scan of the chest demonstrated multiple pulmonary nodules consistent with Caplan's syndrome.
The prevalence of Caplan's syndrome in kaolin workers is the highest of any occupation ever reported.[2] Elevated cadmium levels of 11.2–15.9 mg/kg have been observed in kaolin,[3] fifty- fold higher than those reported in coal.[4] Coal contains variable amounts of clays and minerals such as kaolinite. Cadmium content in coal is strongly associated with levels of kaolinite contamination.[4] Cadmium

nanoparticles have been observed to cause lung parenchyma inflammation and granuloma formation in an animal model.[5]
Conclusions: Kaolinite mineral capacity for adsorption of heavy metals, in particular cadmium, could explain the scale and pattern of Caplan's syndrome incidence seen in Welsh coal miners and Cornish kaolin workers, and further explains the interactive risk seen in sequential dust and cigarette smoke exposure.

AB0307 DIFFERENTIAL ASSOCIATION OF AGE AND DISEASE ACTIVITY WITH CAROTID INTIMA-MEDIA THICKNESS IN MEN AND WOMEN WITH RHEUMATOID ARTHRITIS

D. Taverner[1], S. Paredes[1], R. Ferre[2], L. Masana[2], A. Castro[2], J.C. Vallve[3].
[1]Rheumatology; [2]Internal Medicine; [3]Biologyst, Hospital Sant Joan de Reus, Reus, Spain

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory condition and is characterized by an increase risk in cardiovascular (CV) disease. Carotid intima-media thickness (cIMT) is a surrogate marker of CV disease and many studies have evaluated the relationship between cIMT and RA disease activity with contradictory results.
Objectives: To evaluate in RA patients the association between both cIMT and carotid plaque presence and clinical RA features and analytical measurements.
Methods: We selected 214 RA patients according to the American College of Rheumatology criteria. Conventional clinical evaluation and analytical measurements were performed, including a standard lipid profile. We used My Lab 50 X-Vision sonograph to measure cIMT and atherosclerotic plaque presence
Results: No differences between men and women regarding age, body mass index, glycaemia, LDL-C and TG were observed. However, men had a significantly higher waist circumference, systolic and diastolic BP and lower levels of HDLc. On the other hand, women had significantly higher values of DAS28 (3.7 vs 2.99), HAQ, and VSG with no differences in other inflammatory variables (rheumatoid factor, ACPA, CRP or fibrinogen). Moreover, 74% of patients had pathological cIMT without gender differences and 43% had plaque presence in the carotid artery with a significant higher percentage in men (57%) than women (36%). Overall, men had significantly higher cIMT (0.678 vs 0.627 mm) but when disease activity (DAS28) was considered, we observed that such difference was due to patients that were in remission or in low activity. Men and women with moderate and high disease activity had no statistical differences in cIMT. Furthermore, across women cIMT was significantly higher in those with high disease activity compared with remission. This effect was not observed in men. Multivariate linear regression with cIMT showed a significant interaction between age and gender, so that the effect of age on cIMT was significantly more pronounced in men than in women.
Conclusions: We have described that in our RA cohort, disease activity measured with DAS28 and age are differentially associated with cIMT in men and women. Our results could explain the contradictory results published in the literature and it can be justified by a higher incidence of RA in women and by the hormonal-genetic status.

AB0308 DISEASE ACTIVITY, GRIP STRENGTHS AND HAND DEXTERITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Palamar[1], G. Er[1], R. Terlemez[1], U. Isil[2], G. Can[3], M. Saridogan[1].
[1]Department of Physical Medicine and Rehabilitation, Istanbul University Cerrahpasa Medical Faculty; [2]Physical Medicine and Rehabilitation Clinic, Bagcilar Training Hospital; [3]Department of Public Health, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease affecting hand joints, and leading impairment in hand functions. To date many scientific studies assessed the disease activity of patients with RA, but little attention has been carried out to assess hand functions, and dexterity (1–2).
Objectives: The purpose of this study was to determine the clinical relevance of the Quick Disabilities of Arm, Shoulder and Hand (QuickDASH), hand dexterity with the Purdue Pegboard Test (PPT), and grip and pinch strengths of RA patients.
Methods: Eighty-two women with a diagnosis of RA according to the 2010 American College of Rheumatology/the European League Against Rheumatism (ACR/EULAR) criterion were recruited to the study. The disease activity scores were determined by using Disease activity score-28 (DAS-28). Grip strengths was measured with a Jamar dynamometer, and pinch strengths were measured by pinchmeter. Hand functions were evaluated with the PPT, and functional outcomes were assessed with the QuickDASH questionnaire.
Results: The mean age of the study group was 49.27±10.69 years. Average values of DAS-28, the QuickDASH values were found to be 4.22±1.28, 38.33±19.78, consecutively. High correlation was observed between DAS-28 and the QuickDASH values ($p<0.001$). The mean grip strengths were significantly correlated with the QuickDASH and DAS-28 values ($p<0.01$) (Table 1). The mean lateral pinch strengths were correlated significantly with DAS-28 and the QuickDASH scores ($p<0.001$). DAS-28 was correlated with PPT performance just on the dominant hand ($p<0.05$). The QuickDASH values were not correlated with all PPT performances ($p>0.05$). Grip strengths were positively correlated with the PPT performances ($p<0.05$).

Table 1. Showing the correlation coefficients of DAS 28 and QuickDASH scores between other parameters

	Correlation coefficients (r)	
	DAS 28	QuickDASH
QuickDASH	0.616***	
Grip strength (dominant hand)	-0.412***	-0.409***
Grip strength (nondominant hand)	-0.329**	-0.404***
Lateral pinch strength (dominant hand)	-0.320***	-0.327***
Lateral pinch strength (nondominant hand)	-0.276*	-0.310**
Palmar pinch strength (dominant hand)	-0.215	-0.157
Palmar pinch strength (nondominant hand)	-0.190	-0.165
Tip pinch strength (dominant hand)	-0.248*	-0.237*
Tip pinch strength (nondominant hand)	-0.227*	-0.201
Dexterity (dominant hand)	-0.277*	-0.033
Dexterity (nondominant hand)	-0.128	-0.098
Dexterity (both hands)	0.004	0.059
Dexterity (assembly)	-0.084	0.047

Spearman correlation analysis used for all parameters. *$p<0.05$, **$p<0.01$, ***$p<0.001$.

Conclusions: In conclusion, we determined that grip strengths were significantly related to disability and disease activity in RA patients in our study. The clinical significance of QuickDASH is high, and the questionnaire can be used effectively.

AB0309 LIPID-LOWERING INTERVENTION OF A PREVENTIVE CARDIO-RHEUMA CLINIC IN MEXICAN MESTIZO PATIENTS WITH RHEUMATOID ARTHRITIS

D.Á. Galarza-Delgado[1], J.R. Azpiri-López[2], I.J. Colunga-Pedraza[1], R.E. Ramos-Cázares[1], F.J. Torres-Quintanilla[2], A. Valdovinos-Bañuelos[1], R.I. Arvizu-Rivera[3], A. Martínez-Moreno[3], J.A. Cárdenas-de la Garza[3], R. Vera-Pineda[3], J. García-Colunga[4], M.A. Garza-Elizondo[1], G. Elizondo-Riojas[4]. *[1]Rheumatology; [2]Cardiology; [3]Internal Medicine; [4]Radiology, Universidad Autónoma de Nuevo León, Monterrey, Mexico*

Background: Patients with rheumatoid arthritis (RA) have a significantly increased risk for cardiovascular (CV) morbidity and mortality when compared to general population (1). Preventive cardio-rheuma clinics have been created in recent years and proven to be effective to manage CV risk in patients with inflammatory joint diseases around the world (2).
Objectives: To evaluate the need for lipid-lowering intervention in Mexican mestizo patients with RA.
Methods: We initiated a preventive cardio-rheuma clinic for appropriate CV disease prevention in patients with RA in our population. A complete evaluation and CV risk stratification was performed to our patients, including blood tests and ultrasound examination of both carotid arteries. Each patient was classified to lifestyle changes only, a lifestyle intervention plus lipid-lowering treatment, or to have a low risk with no need for intervention, in accordance to the 2012 European Guidelines on cardiovascular disease prevention in clinical practice and the 2016 ESC/EAS Guidelines for the Management of Dyslipidemias.
Results: A total of 100 patients were evaluated, patient characteristics and intervention group distribution are shown in Table 1. Among these patients, 49 were found not to need any lipid-lowering intervention. The remaining 51 were classified into lifestyle change (n=18, 35.3%) or lipid-lowering drug regimens (n=33, 64.7%). A significant difference between intervention groups was only found regarding age ($p<0.001$). A multiple regression analysis was performed to predict the kind of intervention needed from age, disease duration, disease

Table 1 Patient characteristics and group distribution

	General n = 100	Group 1 (No intervention) n = 49	Group 2 (Lifestyle changes) n = 18	Group 3 (LLD) n = 33	p
Female gender, n (%)	96 (96)	47 (95.9)	18 (100)	31 (93.9)	0.58
Age (years), mean ± SD	56.7 ± 9.7	52.2 ± 8.8	62.4 ± 9.9	60.2 ± 7.6	< 0.001
Disease duration (years), median (IQR)	10.3 (4.2 – 17.9)	10.1 (3.8 – 16.2)	13.8 (9.3 – 21.5)	9 (3 – 19.7)	0.181
Disease activity (DAS28-CRP), median (IQR)	3.2 (1.9 – 4.1)	2.9 (1.9 – 4.1)	3.7 (2.2 – 4.2)	3.4 (1.8 – 4.2)	0.639
RF IgG (IU/ml), median (IQR)	8.8 (4.1 – 22.9)	8.4 (4.1 – 24.7)	7.25 (4 – 15)	11.5 (4.8 – 31.7)	0.381
RF IgM (IU/ml), median (IQR)	145.9 (52 – 200)	160.1 (35.4 – 200)	160.7 (57.8 – 200)	100 (48.9 – 200)	0.933
RF IgA (IU/ml), median (IQR)	44.3 (14.3 – 148.6)	41 (13.1 – 144.9)	38.3 (15.3 – 187.2)	67.1 (16.4 – 116.7)	0.935
ACPA (IU/ml), median (IQR)	99.2 (4.5 – 198.4)	100 (4.1 – 196.6)	18.4 (5.2 – 199.1)	114.4 (5 – 198.6)	0.970

SD: Standard deviation, IQR: Interquatrile range, DAS28-CRP: Disease activity scale using 28 joints – C-reactive protein, RF: Rheumatoid factor, ACPA: Anti-cyclic citrullinated peptide antibodies. LLD: Lipid-lowering drug.

activity and autoantibody levels, only age added statistically significantly to the prediction ($p<0.001$).

Conclusions: There was indication for preventive intervention in more than half of our patients. Age is a determinant factor that increases CV risk in RA patients independently from disease-specific factors. Treatment to lipid targets is essential to reduce their risk of CV morbidity and mortality (3). A prospective study evaluating treatment success rate is needed to further evaluate the intervention of the clinic.

AB0310 PREVALENCE OF COMORBIDITIES OF RHEUMATOID ARTHRITIS IN A MEXICAN MESTIZO POPULATION

D.Á. Galarza-Delgado[1], J.R. Azpiri-López[2], I.J. Colunga-Pedraza[1], R.E. Ramos-Cázares[1], F.J. Torres-Quintanilla[2], A. Valdovinos-Bañuelos[1], R.I. Arvizu-Rivera[3], A. Martínez-Moreno[3], J.A. Cárdenas-de la Garza[3], R. Vera-Pineda[3]. *[1]Rheumatology; [2]Cardiology; [3]Internal Medicine, Universidad Autónoma de Nuevo León, Monterrey, Mexico*

Background: Patients with rheumatoid arthritis (RA) have an increased risk of developing comorbid conditions which are associated to increased mortality, hospital admissions, higher costs of care and inability to work (1, 2).

Objectives: To evaluate the prevalence of comorbidities in a Mexican mestizo population of RA patients.

Methods: We performed a cross-sectional study in which RA patients who were admitted to our outpatient clinic between August 2014 and December 2016 were consecutively enrolled. We collected data regarding demographics, disease characteristics (activity, severity, treatment), comorbidities (cardiovascular, infections, cancer, and osteoporosis), and performed blood tests at the time of the patient's visit to the clinic.

Results: We analyzed 225 patients. Their characteristics are shown in Table 1. Age, 55.7±8.3 years (mean ± SD); disease duration, 9.5 (4 – 15.5) (median (IQR)); female gender, 93.7%; Disease Activity Score using 28 joints–C-reactive protein (DAS28-CRP), 3 (2 – 4) (median (IQR)); past or current methotrexate use, 84.9%; past or current use of any other conventional disease modifying anti-rheumatic drug (cDMARD), 52.4%; past or current use of biological agents, 8%. The most frequently associated diseases were: hypertension, 29.8%; dyslipidemia, 27.1%; osteoporosis, 19.1%; diabetes, 12.4%; hypothyroidism, 6.2%; solid malignancies (excluding basal cell carcinoma), 4.4%. Risk factors were also evaluated, the most prevalent was overweight (BMI $\geq$25 <30) present in 101 (44.9%) of our patients. A total of 71 (31.6%) had obesity (BMI $\geq$30). The systematic evaluation of our patients allowed us to detect abnormalities in vital signs, such as elevated blood pressure in 12.4%, and to identify conditions that manifest as laboratory test abnormalities, such as hyperglycemia in 27.1% and hyperlipidemia in 49.8%.

Conclusions: This study confirms the high prevalence of comorbidities in RA patients. Among our cohort, 63.5% had at least one comorbidity, being those associated with cardiovascular disease the most common. With a systematic assessment (3) including a thorough physical examination, vital signs and laboratory tests, it is possible to detect comorbid conditions that would otherwise remain unrecognized.

Table 1 Demographic characteristics

Variable	Result
Women, n (%)	211 (93.8)
Age (Years), mean ± SD	55.71 ± 8.38
Disease duration (years), median (IQR)	9.57 (4 – 15.58)
BMI (kg/m2), median (IQR)	27.41 (25.16 – 31.62)
Normal, n (%)	53 (23.6)
Overweight, n (%)	101 (44.9)
Obese, n (%)	71 (31.6)
Smoking, n (%)	20 (8.9)
DAS28-CRP, median (IQR)	3.01 (2.04 – 4.08)
Joint surgery due to RA, n (%)	25 (11.1)
Medication, n (%)	
Prednisone	135 (60)
Methotrexate	191 (84.9)
Other non-biologic DMARDs	118 (52.4)
Biologic DMARDs	18 (8)

AB0311 RESULTS OF SCREENING FOR TUBERCULOSIS INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE AND ON TREATMENT WITH BIOLOGICAL DMARDS

D. Karateev[1], S. Borisov[2], T. Fomina[2], G. Loukina[3], E. Luchikhina[4], L. Guntupova[2], A. Satybaldyev[4]. *[1]Nasonova Research Institute of Rheumatology; [2]Moscow Centre against tuberculosis; [3]Moscow clinical scientific center; [4]Early arthritis department, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: The prevalence of tuberculosis infection in Russia is much higher than in Western Europe. Therefore, screening for TB infection in patients with RA before therapy with biological agents is of particular importance. At the same time, reliable information on the results of screening are very few.

Objectives: Explore the results of the application of different methods of diagnosis of tuberculosis infection in RA patients before and during treatment with biological agents.

Methods: We used the data from the Russian register "Observational REgister of arthritis in cLinical practice" (OREL). 1471 RA patients were screened for TB infection before prescribing biologics, of whom 829 patients were exposed to TB infection monitoring on therapy by biologics. The group included 21.1% men, 78.9% women; at the time of initial screening age was 50,0±0,4 years, the duration of the disease 8,5±3,8 yrs, 68,3% RF +, 85.1% anti-CCP +, DAS28-ESR 5,7±1,1, 95,7% used synthetic DMARDs, 60,1% used systemic steroids. We used PPD (Mantoux) test, Diaskin test (intradermal test with tuberculosis recombinant allergens CFP10-ESAT6) and QuantiFERON-TB Gold (QFT) test (in some patients), chest X-ray, chest CT scan (if needed), all the patients were consulted by phthisiatrician. PPD and Diaskin test results were considered positive if the papule was $\geq$5 mm. Duration of treatment with biologics (anti-TNFs and others) varied widely (2–154 months), making a total of 2552,4 patient-years.

Results: At screening, we got 40,3% positive results of PPD test (significantly more in younger patients and patients who did not receive steroids), 16,5% positive results of Diaskin test (with no significant correlations with age and steroids). Positive results matched in 19.9% of cases, negative - in 51.9%. Discordant results in 217 patients were in 92,2% cases related to negative results of Diaskin in PPD-positive persons. Active TB was found after additional examination in 3 (0,2%) patients, inactive TB-related changes were revealed in 124 (8,8%) patients. Positive PPD and Diaskin results, but not QFT, correlated with signs of inactive TB lesions. Positive results of PPD and QFT tests matched in 36.5% of cases, negative - in 18.7%, Diaskin and QFT – in 33,6% and 41,1% of cases resp. As a result of screening, 224 pts were treated by isoniazid or combination of anti-TB drugs before initiation of biologics. On treatment with biologics, 114 (13,7%) pts became PPD-positive and 56 (6,8%) Diaskin positive, active TB was diagnosed in 8 (0,97%) pts.

Conclusions: In carrying out TB screening before prescribing biologics in high-

risk population of TB infection it is reasonable to use both PPD and Diaskin tests, and repeat them every 6 months on treatment.

AB0312 US7 SCORING SYSTEMS FOLLOW-UP 48 WEEKS TNF-A ANTAGONISTS PLUS MTX TREATMENT FOR HIGH DISEASE ACTIVITY REFRACTORY RHEUMATOID ARTHRITIS

D.F. Lin[1], X. Gu[1], J. Cao[1], Y. Pan[2], J. Gu[1]. [1]*Rheumatology department;* [2]*Ultrasound department, the 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: US7 score is the ultrasound scoring system for rheumatic arthritis (RA) with the most clinical evidence so far. Several reports accessed its inter-, intra-observer agreement, its specificity, sensitivity and practical possibility compared to more complex scoring systems such as 72-joints scoring systems, which showed it is an convenient tool for clinical use.
Objectives: Our goal is to employ US7 to investigate the ultrasonic changes during biological agents plus MTX Treatment in high disease activity refractory RA patients in Yellow people.
Methods: All cases were diagnosed as RA fulfilling 2009 ACR/EULAR classification criteria and evaluated as high disease activity for DAS28>5.1 with MTX+HCQ+SASP or MTX+LEF invalid therapy for more than 3 months before baseline. Biological agents including TNF-a antagonist or IL-6 antagonist plus with MTX 10mg qw were then given and ultrasound was performed by 2 observers blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to assess disease activity.
Results: 1) 26 subjects were enrolled in the program up to now. 22 were given TNF-a antagonists and 4 were given IL-6 antagonists. 17 finished 24 weeks follow-up. 1 withdrew for TB infection at 12 week and 1 withdrew for fungi pneumonia at 8 weeks. Mean age of 17 was 44.3±11.8 years old, female-male ratio was 15:2, and disease duration was 71 months. All were RF and ACPA postIve.
2) DAS28-CRP, DAS28-ESR had prominent decrease from 0 to 24 week (DAS28-CRP: 0w: 4w: 12w: 24w = 6.76, 5.98, 5.09, 4.48, DAS28-ESR: 0w: 4w: 12w: 24w = 6.36, 4.94, 3.99, 3.35, paired Wilcoxon test, all sig<0.05)
3) The same prominent improvement also well reflected by the ultrasonic scores: average sum scores (0w:4w:12w:24w = 22.9:15.6:13:9.3, all sig <0.05 except 4w: 12w, sig=0.126), synovitis grey scale scores (0w:4w:12w:24w = 11.6:9.3:8.1:6.0, all sig <0.05, except 0w:4w, sig=0.068), synovitis Power Doppler scores (0w:4w:12w:24w = 8.5:4.9:3.8:2.7, all sig <0.05, except 4w:12w,4w:24w, 12w:24w, sig = 0.361,0.227, 0.235), tenosynovitis grey scale scores (0w:4w:12w:24w = 0.63:0.25:0.25:0.07, all sig <0.05, except 4w:12w,4w:24w, 12w:24w, sig = 1.0 , 0.26, 0.26), tenosynovitis Power Doppler scores (0w:4w:12w:24w = 1.00:0.19:0:0 all sig <0.05, except 4w:12w,4w:24w, 12w:24w, sig = 0.18, 0.18, 1.0), bone erosion scores (0w:4w:12w:24w = 1.2:1.0:0.94:0.53, all sig <0.05 except 0w:4w, 4w: 12w, 4w:24w, 12w:24w, sig = 0.083, 0.317, 0.102, 0.102). The above data showed the sum scores found biological agents improved thorough the whole course as Das28 did. Synovitis seemed to be eliminiated faster than tenosynovitis and the repair of bone erosion was the latest event compared to decreased synovitis and tenosynovitis.
Conclusions: It is recommended US7 used in clinic for US7 scoring system could reflect more exquisitely than DAS28 in more refined aspects including the changes of tendon, joint, bone at different phrases during biological agent treatment for RA. However, more samples should be included in our study to illuminate above conclusion with sufficient evidence.

AB0313 CARDIOVASCULAR RISK, BIOLOGICS AND ANTI-CYCLIC CITRULLINATED PEPTIDE POSITIVITY IN RHEUMATOID ARTHRITIS

E.A. Jauregui, C.A. Agudelo, C. Aldana, Y.A. Muñoz. *Rheumatology, Riesgo de fractura S.A-CAYRE, Bogotá, Colombia*

Background: Co-factors and traditional cardiovascular disease (CVD) risk factors contribute to atherosclerosis in rheumatoid arthritis (RA). Several records since 1953 have reported an increase of up to 4 times the CVD risk and mortality in RA patients. Physicians who evaluate these patients forget to perform or record this assessments in medical records. Since 1948, the Framingham Heart Study became an ambitious project in health research, to identify the general causes of heart disease and stroke, they proposed a new risk estimator of general cardiovascular risk defined as CVD.This estimator was calibrated for Colombia and should be multiplied by a factor of 0.7
Objectives: To describe whether the request and registration of CV risk factors is performed. Also to estimate 10-year risk of CVD in RA patients and to compare the CVD risk among patients receiving or not biological therapy and those with positive and negative anti-cyclic citrullinated peptide (anti-CCP)
Methods: We conducted an observational descriptive study of patients who attended a specialized rheumatology clinic in Bogotá, Colombia from 2010 to 2015. Patients with RA were enrolled who had completed at least 5 year of follow-up. The information required to estimate CVD risk was obtained from medical records. Other variables included were biological therapy and test result of anti-CCP. For the calculation of CVD risk, the Framingham estimator was used and adjusted for the Colombian population. Additionally, patients who had 2 or more of these criteria: More than 10 years of evolution of RA, positive rheumatoid factor and/or extra-articular compromise, the risk was adjusted by multiplying by 1.5. Nonparametric statistics (Mann-Whitney U test) was used.
Results: We identified 273 eligible patients with RA with mean age 61, 66% women. Only 117 (42.8%) had recorded in their charts all variables to calculate CVD risk. We found that 32% had high blood pressure, 7% type II DM, 11% Obesity and 13% smoking. For the population evaluated, 10-year CVD risk median was 12.42% and for Colombia was 8.69%, adjusting this risk according to the disease in Colombia, increased to 13.03%. When we compare the 10-year CVD risk in anti-CCP positive patients (median: 11.15) and anti-CCP negative (median: 8.22) we did not find difference (p: 0.614). However, we found differences in the 10-year CVD risk median 9.04 vs. 23.25, 10-year CVD risk adjusted to Colombia median 6.32 vs. 16.31 and 10-year CVD risk adjusted to Colombia and RA median 6.81 vs. 13.39 between patients using biological therapy versus patients without receiving respectively (p: <0.001)
Conclusions: Only 42.8% of the sample had all CV risk factors requested and registered in the clinical record, so should promote improvement in the health team to increase this. The average 10-year CVD risk in all people with RA was 12.42%, and in patients who met the criteria to be multiplied by the factor 1.5 increased to 13.03%, which means that these patients should be reported this and applied risk prevention guidelines regarding obesity and cholesterol levels. Despite population receiving biologics are younger, they had lower CV risk. We need more research to confirm this results

AB0314 HIGH INFLAMMATORY ACTIVITY AS A PREDICTOR OF INCREASED ARTERIAL STIFFNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Troitskaya, S. Velmakin, S. Villevalde, Z. Kobalava. *Propaedeutics of internal disease, RUDN University, Moscow, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) have a high risk of cardiovascular (CV) morbidity and mortality. Arterial stiffness (AS) is a known predictor of CVD. Relationships between inflammation and arterial stiffness in patients with RA are not well understood.
Objectives: The aim of the study was to evaluate parameters of (AS) and their associations with inflammatory activity in patients with RA.
Methods: 62 patients with RA (EULAR 2010) without known CVD were examined (73% females,age 58,5±15,4 (M±SD) years, 13% smokers, 61% with AH, 34% with dyslipidemia). Median duration of RA was 8 years (IQR 3–17). Seropositive RA was diagnosed in 69% of patients. Median hsCRP was 12,1 mg/dl (IQR 2,2;23,4 mg/dl), median rheumatoid factor (RF) was 32,5 IU/ml (IQR 8,3;173 IU/ml). Mean DAS-28 (ESR) was 4,7±1,2. All patients received disease-modifying antirheumatic drugs, 22 (38%) - biological treatment. Parameters of AS were assessed by applanation tonometry (SphygmoCor, AtCor). Cardio-ankle vascular index (CAVI), ankle-brachial index (ABI) and vascular age were measured by VaSera 1500. Carotid intima-media thickness (CIMT) was evaluated by ultrasound. Pulse wave velocity>10,0 m/s and CAVI>9,0 were considered as AS increase. ABI<0,9 and CIMT>0,9 were considered as markers of subclinical atherosclerosis. p<0.05 was significant.
Results: Mean PWV was 9,3±3,2 m/s. PWV>10m/s was observed in 32,3% patients, CAVI>9,0 - in 25,8%, ABI<0,9 – in 6,5% and CIMT>0,9 – in 21%. Patients with PWV>10m/s were older (69,8±8,5 vs 53,2±15,1 years), had higher BMI (29,3±6,5 vs 24,7±4,8 kg/m^2), longer duration of AH (median 11,5 [IQR 5,5;17] vs 0 [IQR 0;5] years), higher BP levels (144±20/85±9 vs 123±14/77±10 mmHg), lower level of GFR (64±17 vs 89±19 ml/min/1,73m^2), higher levels of LDL-C (3,7±0,9 vs 3,2±1,0 mmol/l), plasma glucose (5,6±0,9 vs 4,8±0,7 mmol/l), hs-CRP (median 22 [IQR 13,3;60] vs 6,7 [IQR 1,6;17,2] mg/dl), higher CAVI (9,5±1,1 vs 7,6±1,4), vascular age (71±8,4 vs 53,4±17,5 years) and CIMT (1,01±0,3 vs 0,7±0,2 mm), p<0,05 for trend. Spearmen analysis revealed significant positive correlations between PWV and age (r=0,7), BMI (r=0,4), duration of AH (r=0,6), SBP (r=0,6), DBP (r=0,4), plasma glucose (r=0,3), hs-CRP (r=0,3), vascular age (r=0,6), CIMT (r=0,7), CAVI (r=0,6) and negative correlations with eGFR (r=-0,6). hsCRP correlated with PWV, aortic pulse pressure (r=0,3), CAVI (r=0,5), vascular age (r=0,5) and ABI (r=-0,5). Multiple regression analysis confirmed that AH duration (β=0,2, p=0.03), SBP (β=0,6, p<0.0001), GFR (β=-0,3, p=0,005) and hs-CRP-level (β=0,3, p=0.000009) were independent predictors of AS increase.
Conclusions: High prevalence of AS increase is observed in patients with RA without known CVD. Elevation of hsCRP as well as other traditional risk factors is an independent predictor of PWV increase in patients with RA.

AB0315 THE POTENTIAL ASSOCIATION BETWEEN RHEUMATOID ARTHRITIS AND TRADITIONAL CARDIOVASCULAR RISK FACTORS: A META-ANALYSIS OF CONTROLLED STUDIES

E. Filhol[1], C. Gaujoux-Viala[2], B. Combe[1], J. Morel[1], C. Hua[1], A. Nutz[2], C. Lukas[1], F. Flaisler[2]. *[1]Lapeyronie Hospital, Montpellier; [2]Nimes Hospital, Nimes, France*

Background: Systemic inflammation is the cornerstone of both rheumatoid arthritis (RA) and atherosclerosis. RA is currently considered as a cardiovascular risk factor.
Objectives: The aim of this systematic review was to assess the association between RA and the traditional cardiovascular risk factors (hypertension, dyslipidemia, diabete mellitus, and atherosclerosis) in RA patients in comparison to the general population.
Methods: We systematically searched literature (via Pubmed, Cochrane and abstracts from recent ACR and EULAR congresses) up to March 2016 for observational studies providing data concerning the presence of a traditional cardiovascular risk factor (among hypertension, dyslipidemia, diabetes mellitus, atherosclerosis) in patients with RA and in a control group. A meta-analysis of the relative risk (RR) concerning patients with RA in relation to the control group was performed for each cardiovascular risk factor.
Results: Out of 5714 screened references, 13 studies were included. Due to lack of data, atherosclerosis studies could not be included in this meta-analysis. For hypertension and diabetes, an increased risk was observed: RR =1.15 [95% CI 1.07–1.24], p=0.0003 and RR=1.11 [1.04–1.19], p=0.001, respectively. On the contrary, not any association was found with the dyslipidemia (RR=0.93 [0.77–1.12], p=0.43).
Conclusions: This meta-analysis highlights a moderate excess risk of hypertension and diabetes among patients with RA relative to the general population. A comprehensive identification of cardiovascular risk profile of RA is an opportunity to improve health management of these patients. Future research is crucial in order to establish to what extent the control of modifiable risk factors can improve cardiovascular outcome of these patients.

AB0316 HOSPITAL ADMISSIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DMARD

E.C. Cervantes Pérez, J.R. Maneiro, A. Souto Vilas, J.A. Mera Varela, J.J. Gómez-Reino. *Ramón Domínguez Foundation, University Hospital Complex of Santiago de Compostela, Santiago de Compostela, Spain*

Objectives: To describe hospital admissions and contributing factors in patients with rheumatoid arthritis (RA) treated biological DMARD (b-DMAR) and conventional synthetic DMARD (cs-DMAR).
Methods: Retrospective observational study of RA patients admitted to the hospital for any cause from 2010 to 2015. Demographic, clinical and therapeutic characteristics were collected from the medical charts. Multivariate and univariate models were used to identify variables associated with admissions for any cause, major adverse cardiovascular events (MACE), and infection. The statistical program Stata 14.0 was used for the analysis.
Results: In the period 2010–2015, 26% of all RA patients were treated with b-DMARD. There were a total of 1251 hospital admissions for any cause in 600 patients; 1055 admissions in 477 patients treated with cs-DMAR and 196 admissions in 123 patients treated with b-DMAR. Of the 1251 admissions, 251 were due to infections and 60 to MACE. Demographic characteristics, comorbidities and treatment are disclosed in table. In the multivariate analysis, diabetes mellitus (p<0.001), and hypertension (p=0.029) were associated with admission for infections, and hypertension (p 0.011), and dyslipidemia (p=0.02) with admissions for MACE.
Conclusions: infections and MACE are a significant cause of hospital admission in patients with rheumatoid arthritis. Comorbidities as diabetes, hypertension and dyslipidemia but not b-DMARD are significantly associated with admission for infection or MACE.

Table. Demographic characteristics, comorbidities and treatment in 600 patients admitted to an university hospital.

	AR patients admitted (600)	Patients b-DMAR treated (123)	Patients cs-DMAR treated (477)	p*
Age > 65 years	428	59 (47.97%)	369 (77.36%)	0.03
Female	412	88 (71.54%)	324 (67.93%)	0.269
COPD[1]	59	8 (6.96%)	51 (10.81%)	0.062
Diabetes mellitus	109	10 (8.70%)	99 (20.97%)	0.364
Dyslipemia	161	23 (20.00%)	138 (29.30%)	0.025
Arterial hypertension	295	41(35.65%)	254 (53.93%)	<0.001

AB0317 RHEUMATIC DISEASES AND PREGNANCY: PRACTICE PATTERNS AMONG RHEUMATOLOGISTS AND OBSTETRICIANS IN LEBANON

F. Fayad[1,2], N. Ziade[1,2], G. Abi Karam[1,2], W. Ghaname[3,4]. *[1]Saint Joseph University; [2]Hotel Dieu de France University Hospital, Beirut; [3]Holy Spirit University, Kaslik; [4]Notre Dame de Secours University Hospital, Jbeil, Lebanon*

Background: For years, women with potentially serious systemic diseases, such as rheumatic diseases (RD), have been advised against getting pregnant. However, with careful clinical management, most of these women can have successful pregnancies. The use of RD drugs before or during pregnancy is problematic due to the lack of knowledge about their compatibility with pregnancy. Recently, the British Society of Rheumatology (BSR) and the European League Against Rheumatism (EULAR) published guidelines on prescribing drugs in pregnancy and breastfeeding.
Objectives: To evaluate the perceptions and clinical practices of rheumatologists and obstetricians in Lebanon regarding the use of medications prior and during pregnancy and breastfeeding. The secondary objective was to assess the variables that are significantly associated with the physicians' adherence to guidelines.
Methods: A national, observational, cross-sectional physician survey was conducted among a representative sample of rheumatologists and obstetricians throughout Lebanon. Collected data included physicians' information (age, gen-

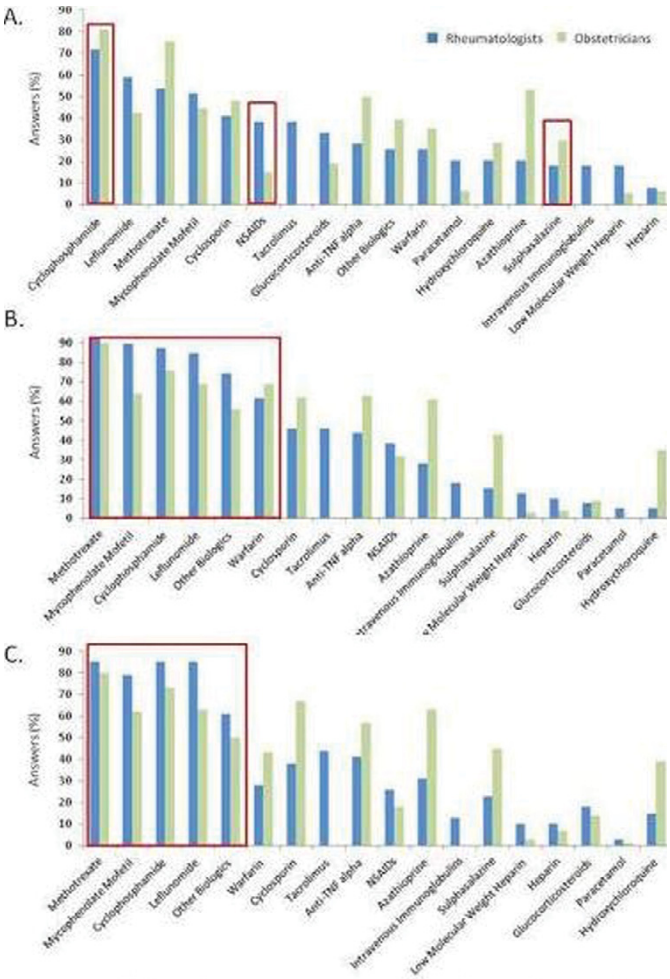

Figure 1. Percentage of rheumatologists and obstetricians who consider RD medications detrimental to fertility (A), pregnancy (B) and breastfeeding (C). Red squares indicate answers in accordance with EULAR/BSR guidelines.

der, years of experience, practice setting and number of pregnant patients with RD seen per month), their opinion on pregnancy in RD patients (pre-conception status of RD and counseling, remission length before allowing pregnancy) and compatible RD drugs with pregnancy and lactation. Qualitative variables were analyzed using Chi-square or Fisher's exact tests, while quantitative variables were analyzed using Wilcoxon or Student t tests. A total score of answers per physician in accordance with EULAR/BSR guidelines was calculated. Univariate and multivariate analysis assessed the variables significantly associated with this score. P value <0.05 indicated statistical significance.

Results: Thirty-nine (90.7%) rheumatologists participated in this survey. They had 22.2±11.6 years of practice. Ninety-four (41.4%) obstetricians participated in this survey. They had 26.0±12.8 years of practice. Figure 1 displays the percentage of physicians who consider the selected RD medications detrimental to/not compatible with fertility, pregnancy and breastfeeding.

Average score of answers in accordance with EULAR/BSR guidelines was 0.654±0.154 and results were significantly different between specialties ($p<0.001$): rheumatologists scored between 0.41 and 1, with an average of 0.777±0.152 and obstetricians scored between 0.36 and 1 with an average of 0.603±0.124. Multivariable analysis showed that the scores reflecting adherence to recommendations were significantly associated with type of specialty (rheumatology v/s obstetrics) and number of pregnant patients with RD seen per month.

Conclusions: Advices given to RD patients who plan on becoming pregnant in Lebanon vary largely, especially among the physicians' specialty and experience in RD, which highlights the urgency of disseminating the EULAR/BSR guidelines among rheumatologists and obstetricians alike.

AB0318 CLINICAL AND SEROLOGIC CHARACTERISTICS OF A COHORT OF ECUADORIAN MEN WITH RHEUMATOID ARTHRITIS

G. Maldonado[1], C. Ferro[2], R. Guerrero[3], C. Paredes[3], C. Rios[4]. *[1]Universidad Espiritu Santo, Universidad Espíritu Santo; [2]Universidad Católica Santiago de Guayaquil; [3]Universidad Espíritu Santo; [4]Centro de Reumatología y Rehabilitación, Guayaquil, Ecuador*

Background: Rheumatoid arthritis (RA) is an inflammatory and disabling disease whose expression and clinical course is influenced by gender. In developed countries the prevalence of RA is 0.5–1%, with a ratio 3:1 female:male. Comparative gender studies have shown that women have greater functional disability, disease activity and pain than men1.

Objectives: The purpose of this study is to describe and compare the clinical and serological characteristics of a cohort of men with RA.

Methods: A cross-sectional study was conducted in patients with established diagnosis of RA (American College of Rheumatology criteria 1988) from the Luis Vernaza Hospital and a private rheumatology center (CERER). The data included clinical manifestations, demographic data, comorbidities, habits, treatment, activity index DAS28-CRP, HAQ-DI disability index and the PHQ-9 questionnaire. The statistical program SPSS V. 22 was used to analyze the data and calculate frequencies, percentages, means, ranges, Spearman correlation and ANOVA coefficient. Statistical significance used was 0.05, with a 95% reliability.

Results: A cohort of 50 men was compared with a control group of 50 women. Most men worked while women stayed at home (72% and 66%, respectively, p=0.000). Tobacco and alcohol were more common in men (34% vs 8% p=0.001 and 38% vs. 0% p=0.000 respectively). The delay in the first visit to the specialist was shorter in men than in women (24 vs 32 months) and they had a longer follow-up (55 vs 41 months). In clinical manifestations, women had greater fatigue (60% vs 30% p=0.003), weight loss (44% vs 20% p=0.010), loss of appetite (54% vs 12% p=0.000) and depression (60% vs 22% p=0.000). There was no significant difference in comorbidities and treatment between the groups. Men had lower disease activity: VSG (23 vs 47 p=0.046), DAS 28 (2.5 vs 3.4 p=0.011), HAQ DI (0.37 vs 1.12 p=0.000), functional disability (12% vs 36% p=0.005), severe disability (2% vs 22% p=0.002), painful joints (2 vs 8 p=0.000), swollen joints (2 vs 6 p=0.000) and VAS of doctor (2 vs 3 p=0.047).

Conclusions: This is the first cohort study of men with RA in Ecuador. As shown in other international studies2–3, our results confirm that men have a less aggressive disease.

AB0319 COMORBIDITIES IN ECUADORIAN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Maldonado[1], C. Rios[2], C. Ferro[3], R. Guerrero[4], C. Paredes[4], M. Moreno[5], C. Vallejo[6]. *[1]Universidad Espiritu Santo, Universidad Espíritu Santo; [2]Centro de Reumatología y Rehabilitación; [3]Universidad Católica Santiago de Guayaquil; [4]Universidad Espíritu Santo; [5]Hospital Luis Vernaza; [6]Sociedad Ecuatoriana de Reumatología, Guayaquil, Ecuador*

Background: Rheumatoid arthritis (RA) is associated with several comorbidities that reduce life expectancy. These comorbidities may be due to the rheumatic process itself, treatment or be independent, and include: anemia, osteoporosis, fractures, infections, gastric ulcers, myocardial infarction, depression, lymphoma and other malignancies.

Objectives: The aim of this study is to determine the comorbidities in patients with an establish diagnosis of rheumatoid arthritis.

Methods: A cross-sectional descriptive study was conducted in patients with an established diagnosis of RA according to the ACR 1987 criteria, from public and private rheumatology clinics in Guayaquil, Ecuador. The database included; demographics, comorbidities, habits, treatments, laboratory exams, number of swollen and tender joints, Visual Analog Scale (VAS), activity and disability index (DAS28 and HAQ-DI) and PHQ-9 for depression. The statistical program SPSS V. 22 was used to analyze the data and calculate frequencies, percentages, means, ranges, Spearman correlation and ANOVA coefficient. Statistical significance used was 0.05, with a 95% reliability.

Results: 402 patients with a mean age of 50 years were included, 87.8% (353) women and 12.2% (49) men. 93.8% (377) were mestizos, 3.5% (14) White, 1.5% (6) Indigenous and 1.2% (5) Afro-Ecuadorians. As for the marital status 55.5% (223) were married, 15.4% (62) cohabiting, 12.4% (50) divorced, 8.5% (34) singles and 8.2% (33) widowers. 9.7% (39) of the patients smoked, 7.5% (30) ingested alcohol and 0.5% (2) drugs. The average age of onset of the disease was 41 years, with a median time from onset of symptoms and the first rheumatology visit of 28.7 months, median follow-up time of 51.8 months and average disease duration of 11 years. For comorbidities, 54.8% (147/268) had dyslipidemia, 28.4% (114) gastric disease, 23.6% (95) hypertension, 20.1% (81) obesity, 19.6% (79) depression, 15.2% (61) thyroid disease, 12.4% (50) of the sexual involvement, 10.7% (43) allergies, 10.4% (32/307) hypertransaminasemia, 9.3% (21/225) anemia, and 6.7% (27) diabetes mellitus. 32.3% (114) of women have had at least one abortion. The PHQ-9 medium was 5.3; according to this 11.2% (45) corresponded to mild depression, 4.5% (18) moderate depression, 3.2% (13) moderately severe depression and 0.7% (3) severe depression. As for the other indicators of disease activity, the average for the number of painful joints was 5 (0–28), swollen joints 4 (0–26), patient VAS 3.9 (0–10) and doctor VAS 3.4 (0–10). In laboratory data, 67.4% (215/319) had positive ESR, 64.8% (149/230) PCR, 90.5% (182/201) anti CCP positive, and 94.4% (286/303) RF.

Conclusions: This is the first study of comorbidities in patients with RA in Ecuador. Patients with RA have a high prevalence of comorbidities and risk factors, which is why physicians should be prepared to prevent them and offer an early treatment.

AB0320 RHEUMATOID ARTHRITIS IN BRAZIL – THE "REAL" STUDY: A NATIONWIDE PROSPECTIVE STUDY

G. Castelar-Pinheiro[1], A.B. Vargas-Santos[1], C. Albuquerque[2], R. Amorim[1], R. Giorgi[3], S. Radominski[4], I. Pereira[5], M.F. Guimarães[6], M. Bértolo[7], P. Louzada Jr.[8], M.F. Cunha[9], K. Bonfiglioli[10], C. Brenol[11], L.M.H. Mota[2]. *[1]Internal Medicine, Rheumatology Unit, Universidade do Estado do Rio de Janeiro, Rio de Janeiro; [2]Universidade de Brasília, Brasília; [3]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo; [4]Universidade Federal do Paraná, Curitiba; [5]Universidade Federal de Santa Catarina, Florianópolis; [6]Universidade Federal de Minas Gerais, Belo Horizonte; [7]Universidade Estadual de Campinas, Campinas; [8]Universidade de São Paulo - Ribeirão Preto, Ribeirão Preto; [9]Universidade Federal do Pará, Belém; [10]Universidade de São Paulo, São Paulo; [11]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil*

Background: Early diagnosis and immediate treatment are critical in achieving optimal outcomes in rheumatoid arthritis (RA). However, anecdotal evidence suggests that in Brazil there is still a significant delay in patient referral, RA diagnosis and DMARD initiation. The lack of national data hinders effective advocacy for proper public health policies, which led the RA commission of the Brazilian Society of Rheumatology to create a nationally-representative multicenter RA cohort to provide the necessary data.

Objectives: To describe the development process and baseline characteristics of a large, nationally-representative multicenter cohort of RA patients in Brazil.

Methods: Eleven public rheumatology centers from all of the 5 regions of Brazil enrolled ~100 consecutive RA patients each (1987 ARA or 2010 ACR-EULAR). This cohort is being followed prospectively for 1 year, with systematic data collection at time 0, 6±1 months and 12±1 months, and registration of all other visits during this 1-year period. Data collection began in 08–2015, using a single online electronic medical record, and included demographic, socioeconomic, clinical, lab, radiographic and therapeutic characteristics, along with functional status, quality of life and adherence to treatment information.
Results: 1125 patients were enrolled (Table), ~90% were female, with a mean age of 56 years and median disease duration of 13 years. Median BMI was 27 kg/m^2, with 64% of the patients classified as overweight or obese. The interval between symptoms and diagnosis varied from 1 to 457 months (median 12 months). Almost half of the patients were on glucocorticoids, 96% on DMARDs, with 36% on biologics. Only 7% were seronegative for both rheumatoid factor and ACPA. Median HAQ-DI was 0.875 and median DAS28-ESR was 3.5, with 58.6% of patients presenting moderate or high disease activity.

Table 1. Patients baseline characteristics

	N	
Age, years*	1125	56.7 (22.1–88.8)
Female	1125	89.5%
Current or former smoker	1125	39.6%
BMI, kg/m^2*	1055	26.6 (15.8–56.2)
Disease duration, years*	1124	12.7 (0.7–56.7)
Rheumatoid factor+	1105	78.7%
ACPA+	479	76.8%
Erosive disease	1105	55.2%
Extra-articular manifestation ≥1	1118	23.3%
Drugs in use:		%
– Glucocorticoids	1125	47.0
– NSAIDs	1125	9.0
– Synthetic DMARDs	1125	90.8
– Methotrexate	1125	66.5
– Biologic DMARDs	1125	36.1
Erythrocyte sedimentation rate (ESR), mm/1st hour*	933	21 (1–140)
C-reactive protein, mg/dL*	954	0.7 (0–76.1)
DAS28-ESR*	932	3.5 (0.3–8.2)
HAQ-DI*	1121	0.875 (0–3)

*Results in median (range).

Conclusions: The delay in diagnosis may explain the high percentage of patients with moderate or high disease activity and erosive disease. The low level of physical dysfunction observed in this established, predominantly seropositive RA population may be explained by the large proportion of patients on glucocorticoid and biologic therapy. Our findings suggest that, despite current treatment concepts being well known and accepted by Brazilian rheumatologists, there is still a gap in early diagnosis and management of RA.

AB0321 RELATIONSHIP OF CAROTID FEMORAL PULSE WAVE VELOCITY WITH AGE AND TIME OF EVOLUTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Ramos[1], G. Alanis[1], D. Cardona[2], S. Totsuka[1], E. Cardona[1], F. Pérez[1], A. Coldivar[1], J. Gómez[1], M. Vázquez del Mercado[1]. *[1]Physiology, University of Guadalajara; [2]Physiology, University of Gudalajara, Guadalajara, Mexico*

Background: Early vascular aging occurring in Rheumatoid Arthritis (RA) may be a consequence of chronic inflammation. The measurement of Carotid-femoral pulse wave velocity (cfPWV) is the gold standard to evaluate arterial stiffness. Vascular aging is a result of a change in the biomechanical properties of the vascular wall. This process can be accelerated by the accumulated damage of high mechanical stress (high blood pressure), chronic inflammation and comorbidities such as smoking, Diabetes Mellitus and dyslipidemia[1]
Objectives: The aim of this study was to evaluate variations in the Carotid-Femoral Pulse Wave Velocity (cfPWV) and it's association to age and time of disease evolution in patients with rheumatoid arthritis.
Methods: RA patients were matched for age and sex with healthy controls. Subjects with a history of smoking, cardiovascular disease, hypertension, diabetes mellitus, cancer, liver disease, thyroid disease and kidney disease were excluded. The cfPWV was calculated using the Pulse Pen ® (Diatechne, Italy) device.
Results: We included 76 women with RA and 28 healthy women, mean age (44.3±10.92 vs. 43.0±16.26, P=0.654). cfPWV demonstrated good correlation with age (r=0.459, P<0.01), disease evolution time (r=0.311, P=0.008), triglycerides (r=0.289, P=0.03), total cholesterol (r=0.421, P<0.01) and atherogenic index (r=0.320, P=0.02). No association with disease activity was found. cfPWV was higher in those patients with RA >10 years evolution compared to patients with <10 years of disease evolution and to controls (P<0.05).
Conclusions: A significant association between cfPWV was seen in patients with RA, and was also correlated to age and to a disease evolution >10 years long without finding a significant association with increased disease activity.

AB0322 THE ROLE OF HOMA-IR AND HOMA-ISLET INDICES IN DIFFERENT CARBOHYDRATE METABOLISM DISORDERS DURING GLUCOCORTICOID THERAPY

G. Nurullina. *Kazan Medical State University, KAZAN, Russian Federation*

Background: Diabetogenic effect limits the use of glucocorticoids (GC), especially in patients with diabetes risk factors. At present HOMA index is widely used for the evaluation of insulin resistance (IR) and β-cell function. HOMA-IR index increase is an indirect measure of IR progression and cardiovascular risk elevation.
Objectives: To evaluate the role of modified HOMA-IR and HOMA-islet indices in different carbohydrate metabolism disorders (CMD) during oral (OGCT) and PULSE (GCPT) glucocorticoid therapy (GCT).
Methods: A prospective study including 118 patients with systemic lupus erythematosus (SLE) (n=63) and systemic vasculitis (SV) (n=55) was performed. Seventy one patients received GCPT (i.v. infusion of 10–15 mg/kg of prednisolone with 250 ml of normal saline per day, for 3 consecutive days (1 course of 3 sessions); course dose was 1800–3000 mg; 47 patients received oral GC 15–30 mg/day. HOMA-IR index and β-cell function (HOMA-islet index) were calculated as follows: Homa-IR =1.5 + fasting blood glucose (mmol/l) x fasting C-peptide level (pmol/l) /2800. HOMA-islet =0.27 x fasting C-peptide level (pmol/l)/(fasting blood glucose (mmol/l) – 3,5).
Results: GCPT was associated with less CMD compared to OGCT. Impaired fasting glucose (IFG) was observed in 7 (9.9%) and 9 (19.1%), impaired glucose tolerance (IGT) – in 9 (12.7%) and 14 (29.8%) and diabetes mellitus (DM) – in 9 (12.7%) and 13 (27.7%) patients in GCPT and OGCT groups, respectively. There was a significant decrease of HOMA-islet during glycemic peak in DM patients from 13.96 to 6.17 after GCPT (p<0.05), compared to insignificant changes in other groups. Decrease of HOMA-islet index reflects a disturbance of overall functional activity of β-cells in DM patients. After a course of GCPT HOMA-islet index was significantly lower in DM patients compared to patients with no CMD (11.8 vs. 15.4), as GCPT is associated with a decrease of β-cell function which does not return to baseline as a consequence of β-cell reserve depletion. No rapid decrease of β–cell function was observed in OGCT group, instead there was a compensatory increase, which was insufficient to maintain normoglycia because of high insulin resistance. C-peptide, HOMA-IR and HOMA-islet levels in OGCT patients demonstrated the same trend as in GCPT patients. Significant differences were observed in patients with IGT and DM before and after oral glucose tolerance test (OGTT) on C-peptide (1042 pmol/l vs. 1978 pmol/l in IGT; 1306 pmol/l vs. 2286 pmol/l in DM) and HOMA-IR (4.53 vs. 9.81 in IGT; 5.6 vs. 11.27 in DM patients), whereas in patients without CMD and in patients with IFG, C-peptide before OGTT was 489 pmol/l vs. 743 pmol/l, after - 1295 pmol/l vs. 1488 pmol/l, HOMA-IR – 2.59 vs. 2.88 before OGTT and 2.88 vs. 5.85 after the test in the absence of CMD and in IFG patients, respectively. A significant decrease of β–cell function was observed in DM patients, reflected by a decrease of HOMA-islet index after OGTT compared to baseline (147 vs. 78.4).
Conclusions: Evaluation of blood glucose level, which was normal in all included patients, and isolated C-peptide evaluation are insufficient for the evaluation of carbohydrate metabolism before GCPT and long-term OGCT. The evaluation of modified HOMAA-IR and HOMA-islet indices before the start of intensive GC treatment and during OGCT may improve early detection of risk groups for serious CMDs – IGT and DM.

AB0323 CARBOHYDRATE METABOLISM AND GLUCOCORTICOID THERAPY IN PATIENTS WITH SYSTEMIC INFLAMMATORY DISEASES

G. Nurullina. *Kazan Medical State University, Kazan, Russian Federation*

Background: Glucocorticoid therapy (GCT) is one of the risk factors of carbohydrate metabolism disorders (CMD) in patents with systemic inflammatory diseases. CMD development is a concern not only with long-term therapy, but also during intensive short-term GC administration, which can lead to different CMDs, including impaired glucose tolerance (IGT) and diabetes mellitus (DM).
Objectives: to evaluate the prevalence of CMD after long-term and intensive GC treatment (GCT) in patients with systemic lupus erythematosus (SLE), systemic vasculitis (SV) and chronic glomerulonephritis (CGN).
Methods: Ninety eight patients with systemic inflammatory diseases were included (SLE - 53, SV – 35), among them 68 received GC pulse-therapy (GCPT) (1 series of 3 sessions), and 30 – oral GCT (OGCT). All patients underwent standard clinical and laboratory evaluation, oral glucose tolerance test (OGTT), evaluation of C-peptide, HOMA-IR and HOMA-islet indices.
Results: CMDs developed less often in patients receiving GCPT compared to long-term OGCT (p=0.035). In patients receiving OGCT the most prevalent CMDs were IGT and DM – in 9 (30.0%) and 8 (26.7%) patients respectively, which

was significantly higher compared to patients in GCPT group – 7 (10.3%) and 6 (8.8%) respectively (p=0.038 and p=0.049). Baseline C-peptide was elevated in patients who developed IGT after a course of GCPT (850 pmol/l before GCPT, 4099 pmol/l 4–6 hours after GCPT and 1904 pmol/l after a 3-days course of GCPT) or DM (1050 pmol/l, 3170 pmol/l and 1796 pmol/l before GCPT, at peak blood glucose level and after a 3-days course of GCPT, respectively) ($p<0.05$). C-peptide remained normal in the absence of CMD and in IGT patients.
Baseline HOMA-IR index was elevated in patients with IGT (4.52, 17.47, 9.67 before GCPT, at peak blood glucose level and after a 3-days course of GCPT, respectively) and DM (5.04, 15.2, 10.4 respectively) ($p<0.05$), and normal in patients without CMD (2.2, 5.84 and 4.01 respectively) and patients with impaired fasting glucose (IFG) (2.46, 7.08 and 5.46).
HOMA-islet index analysis revealed that in the absence of CMD and at earlier stages of CMDs (IFG, IGT) insulin resistance is compensated via an increase of β-cell secretory activity. In DM patients there is a trend towards decreased β-cell secretory activity, which is associated with a significant decrease of HOMA-islet index to 64,6 at peak blood glucose levels after GCPT compared to baseline level (170) ($p<0.05$). C-peptide, HOMA-IR and HOMA-islet index levels in OGCT patients demonstrated same trend as in GCPT patients. Significant differences were observed in patients with IGT and DM before and after oral glucose tolerance test (OGTT) on C-peptide (1042 pmol/l vs. 1978 pmol/l in IGT; 1306 pmol/l vs. 2286 pmol/l in DM) and HOMA-IR (4.53 vs. 9.81 in IGT; 5.6 vs. 11.27 in DM patients), whereas in patients without CMD and in patients with IFG, C-peptide before OGTT was 489 pmol/l vs. 743 pmol/l, after - 1295 pmol/l vs. 1488 pmol/l, HOMA-IR – 2.59 vs. 2.88 before OGTT and 2.88 vs. 5.85 after the test in the absence of CMD and in IFG patients, respectively. A significant decrease of β–cell function was observed in DM patients, reflected by a decrease of HOMA-islet after OGTT compared to baseline (147 vs. 78.4).
Conclusions: GCT leads to IGT and DM in patients with increased IR both during GCPT and long-term OGCT. Long-term OGCT is associated with more CMDs compared to GCPT.

AB0324 IS LOW SERUM VITAMIN D LEVEL ASSOCIATED WITH INCREASED NEUROPATHIC PAIN IN RHEUMATOID ARTHRITIS PATIENTS? A CROSS-SECTIONAL STUDY

H. Yesil[1], U. Sungur[2], S. Akdeniz[3], G. Gurer[3], B. Yalcın[4], U. Dundar[1]. *[1]Physical Medicine and Rehabilitation, Afyon Kocatepe University, Afyonkarahisar; [2]Physical Medicine and Rehabilitation, Ege University, Faculty of Medicine, Izmir; [3]Physical Medicine and Rehabilitation, Adnan Menderes University, Faculty of Medicine, Aydın; [4]Afyon Kocatepe University, Afyonkarahisar, Turkey*

Background: Rheumatoid arthritis (RA) is a systemic, autoimmune, progressive condition characterised by progressive synovitis with resultant joint destruction, functional disability and significant pain. Recent experimental data indicates that there may be a neuropathic component of pain perception in RA.
Objectives: The aim of this study was to examine the development of neuropathic pain (NP) in patients with RA and its relationship with vitamin D.
Methods: We used the Leeds assessment of neuropathic symptoms and signs (LANSS) questionnaire to evaluate NP in 93 patients with RA. Clinical parameters included general demographics, and disease activity scores were evaluated. The patients also completed Short form-36 survey, and Health Assessment Questionnaire.
Results: Of all the patients who were eligible for the study, 75 were female (80.6%). Mean serum vitamin D level of the participants was calculated to be 22.8±11.9 ng/mL. According to the LANSS questionnaire 31 patients (33.3%) were classified as having NP. There was a negative correlation between vitamin D levels and LANSS value (p=0.001). We have determined that patients with vitamin D serum levels below 20 ng/mL have significantly higher NP positivity rate (p=0.012), besides they have 5.8 times more risk of developing NP when compared to patients with vitamin D serum levels ≥30 ng/mL.
Conclusions: We conclude that Vitamin D deficiency is prevalent in RA patients with NP. Once it is the right diagnosis, Vitamin D deficiency treatment is relatively easy, safe, inexpensive and with satisfactory outcomes; therefore, an underlying vitamin D deficiency should be explored in the etiology of NP in patients with RA.

AB0325 TREAT TO TARGET AND THE REAL LIFE EXPERIENCE – DATA FROM A COHORT OF RHEUMATOID ARTHRTIS PATIENTS IN SOUTH EAST ROMANIA (CONSTANTA COUNTY)

V.C. Suta[1,2], I.-T. Andronache[1], M. Suta[2]. *[1]Rheumatology Department, IInd Internal Medicine Clinic, "Sf. Apostol Andrei" Emergency Clinical County Hospital Constanta; [2]Faculty of Medicine, "OVIDIUS" University Constanta, Constanta, Romania*

Background: Treatment target in rheumatoid arthritis (RA) is remission or low disease activity. Considering that there is no quantitative "gold standard " for measuring the disease activity, monitoring and evaluation of RA patients is made through composite scores, which have an important subjective component. Moreover, the laboratory investigations used (ESR and CRP) are commonly discordant with the clinical findings
Objectives: To evaluate disease activity and establish relations between disease activity scores and their components in RA patients
Methods: We performed a transversal study which included 447 RA patients (aged 18 to 86-years-old) admitted to our Rheumatology Department between January 2014 and December 2015. Patients' evaluation was performed by the rheumatologist. All the data obtained from the medical history, clinical examination, laboratory tests and imaging studies was recorded at the same date. All patients signed a dated informed consent at the time of admission.
Results: The study included 447 patients, mean age 62.13±11.44, 85% women, accounting for a female:male ratio (F:M) of almost 6:1 (5.7:1) with an average disease duration of 10,75±8,85 years. 48% of our patients presented with normal CRP values (≤0.5mg/dl) and values of ≤1mg/dl for CRP, compatible with Boolean remission, were present in 66.6% of the patients. A significant percentage of our sample population (194 patients: 43.4%) registered normal ESR values (≤28 mm/h)
Remission and LDA were registered in 18.1% up to 29.8%.of the patients, depanding on the score used. The lowest rate of remission and low activity is registered through the DAS28 ESR evaluation (18.1%). The other three scores outline similar percentages for T2T group of patients: 27.1% (SDAI), 28.7% (CDAI), and 29.7% (DAS28 CRP). The LDA group is characterized in our study by a small number of swollen joints (<1), medium-normal ESR values (<30mm/h) and CRP values <1mg/dl (with the exception of SDAI). Consequently, patients with low activity based on the afore mentioned scores meet remission according to Boolean definition.
Conclusions: The disease activity and implicitly the remission rate are appreciated differently depending on the scale used. The limit between remission and low disease activity is fragile, influenced mainly by the purely subjective components of the assessment instruments. The important differences between the subjective and objective components of the evaluation scales recommend the supplementation of methods used in order to emphasize the real degree of joint inflammation.

AB0326 INFLUENCE OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS ON ARTERIAL STIFFNESS IN PATIENTS WITH RHEUMATIC DISEASES

J.N. Kim, J.-Y. Choe, S.-K. Kim, S.-H. Park, H. Lee, C.U. Lee, J.-W. Kim. *Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of*

Background: The association with adverse cardiovascular (CV) events and NSAIDs has been the topic of much debate.
Objectives: The aim of the present study was to investigate the effects of continuing NSAIDs therapy on predictable parameters for CV events.
Methods: We enrolled 155 patients with variable rheumatic diseases (95 rheumatoid arthritis, 49 systemic lupus erythematosus, 3 behçet's disease, 3 gout, 5others.) who were free from established CV diseases and had taken cardiovascular function tests from June 2015 to June 2016. They were divided into two groups depending on whether or not to have taken NSAIDs therapy for at least 5 years: NSAIDs taking group (91 patients) vs. non NSAIDs taking group (64 patients). For evaluating heart function, transthoracic echocardiography was used. Arterial stiffness was assessed using brachial-ankle pulse wave analysis.
Results: There were no significant differences in blood pressure, serum creatinine, serum hemoglobin, total cholesterol, erythrocyte sediment rate, C-reactive protein, disease duration, age, and smoking history between the groups. The NSAIDs

taking group had a higher median (95% CI) baPWV (brachial-ankle pulse wave velocity) and median (95% CI) mean pulmonary artery pressure (mPAP) than non-NSAIDs taking group: baPWV 13.72 (12.77–15.62) vs. 15.29 (13.93–17.63) m/s, p=0.005; mPAP 26.5 (22.8–30.5) vs. 30.5 (27.3–32.3) mmHg, p=0.011. But baPWV and mPAP were not significantly different between selective cyclooxygenase-2 inhibitor (22 patients) and nonselective NSAIDs (69patients): baPWV 15.33 (13.98–17.63) vs. 14.83 (13.82–17.39) m/s, p=0.191; mPAP 29.0 (24.5–34.5) vs. 30.0 (26.0–33.0) mmHg, p=0.960.

Conclusions: Our study suggests that continuing NSAIDs therapy is associated with increased arterial stiffness in patients with rheumatic diseases, independently noted to increase the incidence of cardiovascular disease.

AB0327 FEAR OF FALLING AND FOOT PAIN, IMPAIRMENT AND DISABILITY IN RHEUMATOID ARTHRITIS

J. Bahha, B. Amine, M. Erraoui, Y. Boujenane, S. Fellous, I. El Binoune, R. Bahiri. *Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat, El Ayachi Hospital, sale, Morocco*

Background: Fear of falling, foot pain and functional disability are commonly reported in rheumatoid arthritis. Moreover, the relationship between the fear of falling and foot pain, impairment and disability has rarely been studied.

Objectives: To evaluate the relationship between fear of falling and foot pain, impairment and disability in patients with established RA.

Methods: A cross-sectional study that included patients with rheumatoid arthritis. We collected the following data: age, sex, duration of disease, foot pain assessed by the Visual Analogue Scale (VAS), Disease activity assessed by DAS 28, HAQ disability index (HAQ-DI). Fear of falling was assessed by Falls Efficacy Scale-International (FES-I) which consists of 16 different activities, scored using a four point scale (1=not at all concerned, 2=somewhat concerned, 3=fairly concerned and 4=very concerned). The summed scores for the 16 activities for each participant were calculated. Scores of ≥23 indicated a significant fear of falling. Foot disability and impairment were measured using the Leeds Foot Impact Scale (LFIS), Foot disability was represented by the total score (LFIST; range 0 to 51) of the LFIS and foot impairment by the first subscale (LFISIF; range 0 to 21). Correlations were used to assess the relationship between fear of falling and foot pain, impairment and disability.

Results: Thirty-three patients were included. The mean age was 49.3±10.5 years with female predominance (n=29 (87.9%)). The mean disease duration was 9.9±7.5 years. The mean HAQ-DI was 1.3±0.8. The mean DAS28 score was 5.5±1.3 and the mean EVA foot pain was 5.5±2.4. The mean FES-I score was 37.4±15.1 and 69.7% (n=23) of patients had a significant fear of falling. Positive correlations were found between fear of falling and foot impairment (r=0.66; p<0.0001) and disability (r=0.80; p<0.0001). No correlation was found between fear of falling and foot pain (r =0.29, p=0.07).

Conclusions: The results of this study have demonstrated the importance of the relationship between fear of falling and foot impairment and disability.

AB0328 RHEUMATOID ARTHRITIS AND FEAR OF FALLING: THE INFLUENCE OF DISEASE ACTIVITY

J. Bahha, B. Amine, M. Erraoui, Y. Boujenane, S. Fellous, I. El Binoune, R. Bahiri. *Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat, El Ayachi Hospital, sale, Morocco*

Objectives: The objective of this study was to evaluate fear of falling in patients with established RA and its relation to disease activity.

Methods: A cross-sectional study that included patients with rheumatoid arthritis. We collected the following data: age, sex, duration of disease, body mass index (BMI). Fear of falling was evaluated by the Falls Efficacy Scale-International score (FES-I) which consists of 16 different activities, scored using a four point scale (1=not at all concerned, 2=somewhat concerned, 3=fairly concerned and 4=very concerned). The summed scores for the 16 activities for each participant were calculated. Scores of ≥23 indicated a significant fear of falling. Disease activity was measured with swollen and tender joint count (SJC28, TJC28), pain on a visual analogue scale (VAS pain), patient and evaluator global assessment of disease activity (PGA, EGA), HAQ disability index (HAQ-DI), 28-joint DAS (DAS-28) and the clinical and simple disease activity indexes (CDAI, SDAI). Correlations were used to assess the relationship between fear of falling and disease activity.

Results: Thirty-three patients were included. The mean age was 49.3±10.5 years with female predominance (n=29 (87.9%)). The mean disease duration was 9.9±7.5 years.

The mean FES-I score was 37.4±15.1 and 69.7% (n=23) of patients had significant fear of falling. The mean VAS pain was 5.3±2.5, the PGA was 6.2±2.1 and the EGA was 5.7±1.7. The mean HAQ-DI was 1.3±0.8. The mean DAS28 score was 5.5±1.3. The mean CDAI was 29.9±13.6 and the SDAI was 31.6±13.7.

FES-I was significantly correlated with TJC28 (r =0.52, p=0.02), PGA (r=0,56, p=0,01), EGA (r=0,39, p=0,025), HAQ-DI (r =0.70, p=0001), DAS28 (r =0, 38, p=0.029), CDAI (r =0.48, p=0.005) and SDAI (r =0.52, p=0.002).

Conclusions: This study suggests that fear of falling is frequent in patients with rheumatoid arthritis and demonstrated that fear of falling is significantly correlated with disease activity.

AB0329 DO ANXIOUS OR DEPRESSIVE RHEUMATOID ARTHRITIS PATIENTS ON BIOTECHNOLOGIC THERAPY HAVE WORSE DISEASE ACTIVITY, FUNCTION AND QUALITY OF LIFE?

J. Borges[1], N. Madeira[1], A. Cardoso[2], L. Cunha-Miranda[1], F. Barcelos[1], C. Miguel[1], C. Silva[1], S. Fernandes[1], R. Trinca[3], D. Medeiros[1], R. Campanilho-Marques[1], H. Santos[1], R. Leitão[1], A. Faustino[1]. *[1]Rheumatology; [2]Nutrition; [3]Nursing, Instituto Portugues de Reumatologia, Lisboa, Portugal*

Background: Depression, anxiety and fatigue are common symptoms in rheumatoid arthritis (RA) patients, and seem to influence disease activity, pain, quality of life (QoL) and treatment response.

Objectives: To assess disease activity, function and QoL in RA patients with symptoms of anxiety/depression.

Methods: Observational, cross-sectional study including RA patients on bDMARD followed at our centre, registered at Reuma.pt with ≥1 evaluation from 2015/11 to 2016/07. Clinical data including DAS28, CDAI, SDAI, TJC, SJC, patients' and physicians' pain/global assessments (VAS), ESR, CRP, HAQ, EQ5D, HADS score (anxiety and depression domains, cutoff ≥8) and FACIT-F were collected. Data were analyzed using Mann-Whitney, Qui-Squared and Spearman correlation, p<0.05.

Results: 182 patients enrolled, 84.6% female, mean: age at 1st bDMARD 53.8±11.1; time since diagnosis 16.2±9.3 years; DAS28 3.54±1.3; CDAI 10.2±9.6; SDAI 11.2±10.4; HAQ 0.97±0.6; HADS-Anxiety 7.13±4.5; HADS-Depression 6.62±4.54, FACIT-F 35.1±9.2, EQ-5D 0.36±0.2. 77 (44.5%) patients scored ≥8 in the HADS-Anxiety domain and 71 (41.0%) scored ≥8 in the HADS-Depression domain. Comparison of depressive *vs* non-depressive and anxious *vs* non-anxious groups appears on table 1. There was a correlation of *HADS-Anxiety* with DAS28 (r=0.391, p<0.001), CDAI (r=0.441, p<0.001), SDAI (r=0.426, p<0.001), HAQ (r=0.509, p<0.001), FACIT-F (r=-0.669, p<0.001) and EQ5D (r=-0.592, p<0.001). There was a correlation of *HADS-Depression* with DAS28 (r=0.389, p<0.001), CDAI (r=0.455, p<0.001), SDAI (r=0.439, p<0.001), HAQ (0.596, p<0.001), FACIT-F (r=-0.679, p<0.001) and EQ5D (r=-0.659, p<0.001).

Abstract AB0329 – Table 1. Comparison of anxious vs non-anxious and depressive vs non-depressive patients

	HADS-A <8	HADS-A ≥8	p	HADS-D<8	HADS-D ≥8	p

28 SJC, mean ± SD	1.02±1.7	1.86±2.7	0.042	0.97±1.5	2.00±2.9	0.020
PGA (VAS), mean ± SD	28.46±23.2	46.3±24.1	<0.001	28.9±23.03	47.3±24.2	<0.001
Patients' pain assessment (VAS), mean ± SD	28.4±22.5	46.4±26.2	<0.001	28.8±22.4	47.3±26.5	<0.001
PhGA (VAS), mean ± SD	15.9±13.9	23.8±20.6	0.022	14.4±12.7	26.5±20.8	<0.001
ESR (mm/H), mean ± SD	26.42±19.6	28.43±21.2	0.513	25.3±18.4	30.2±22.6	0.190
CRP (mg/L), mean ± SD	6.9±10.9	9.3±23.5	0.771	6.1±8.9	10.6±25.3	0.808
CDAI, mean ± SD	7.3±7.1	13.8±11.2	<0.001	7.2±6.4	14.5±11.7	<0.001
SDAI, mean ± SD	8.2±7.4	14.96±12.4	<0.001	7.97±6.7	15.8±12.97	<0.001
FACIT-F, mean ± SD	39.8±7.5	29.3±7.7	<0.001	39.1±7.8	29.4±8.2	<0.001
EQ5D, mean ± SD	0.43±0.17	0.28±0.20	<0.001	0.44±0.17	0.26±0.19	<0.001

Conclusions: Anxious or depressive patients showed higher disease activity, especially in measures with some subjectivity (such as TJC and PGA) but not regarding ESR or CRP and worse function and QoL. This fact must be taken into account when evaluating therapeutic efficacy.

AB0330 RHEUMATOID FACTOR AND RO52KDA ANTIBODIES ARE INDEPENDENT PREDICTORS OF INSULIN RESISTANCE IN RHEUMATOID ARTHRITIS

J. Aguilar-Arreola[1], F.D.J. Perez-Vazquez[2], E. Gomez-Bañuelos[2], G.-I. Diaz-Rubio[2], S. Duran-Barragan[2], F.-I. Corona-Meraz[2], A. Saldaña-Millan[2], R.-E. Navarro-Hernández[2], M. Vázquez-Del Mercado[2]. *[1]Servicio de Reumatología, División de Medicina Interna, Pnpc 004086, CONACyT, Hospital Civil, "Juan I. Menchaca"; [2]Instituto de Invesgitación en Reumatología y del Sistema Musculoesquelético, Universidad de Guadalajara, Guadalajara, Mexico*

Background: The rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) autoantibodies in rheumatoid arthritis (RA), have been used as diagnostic and prognostic tools [1]. However, this traditional perspective has changed toward a major role in RA pathogenesis. Several studies have demonstrated that FR and ACPA autoantibodies positivity beyond its level, might influence disease activity, bone erosions and development of comorbidities. Anti-Ro52kDa antibodies have also been associated with disease severity in RA and might influence the development of comorbidities such as insulin resistance (IR) in RA.
Objectives: To evaluate the association between RF, ACPA and anti-Ro52 kDa and IR in RA patients.
Methods: We included 83 RA patients classified according to ACR 1987 and ACR/EULAR 2010 criteria and 90 controls matched for age, gender and body mass index (BMI). Homeostasis Model Assessment-Insulin Resistance (HOMA-IR), anthropometric parameters and antibody positivity (RF, ACPA, Ro52 kDa) were evaluated. Multivariate regressión analysis was used to assess the contribution of autoantibodies, adiposity and disease activity to insulin resistance in RA.
Results: Patients positive for RF or anti-Ro52 kDa showed higher levels of basal insulin (P=0.009, P=0.006) and HOMA-IR. DAS-28 ESR was correlated with basal insulin (r=0.31, P=0.01) and HOMA-IR (r=0.29, P=0.02). We also observed positive correlations between serum triglycerides (r=0.47, P=0.01) and HDL-c (r=-0.38, P=0.02) and basal insulin. Multivariate analysis showed that Triglycerides, HDL-c, DAS-28, RF and anti-Ro52 kDa were independent predictors of basal insulin and HOMA-IR in patients with RA.
Conclusions: In RA, RF or anti-Ro52 kDa are independent predictors of IR. This phenomenon might be linked to the network of inflammation, adipokine secretion, since disease activity was also precitive of higher basal insulin. Both RF and anti Ro52 kDa, along with disease activity are independent predictors of IR in RA patients without comorbidities.

AB0331 BEHAVIOR OF THE VALUE OF RED CELL DISTRIBUTION WIDTH IN PATIENTS WITH RHEUMATOID ARTHRITIS IN TREATMENT WITH DAILY DOSE OF METOTREXATE

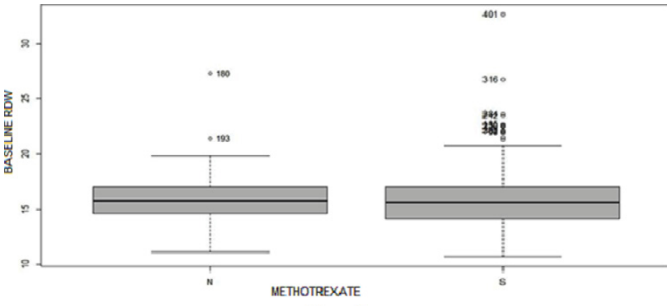
J.E. Espinoza Martinez, M.U. Martinez MArtinez, C. Abud-Mendoza. *Unidad de Reumatología y Osteoporosis, Hospital Central Dr. Ignacio Morones Prieto, San Luis Potosí, Mexico*

Background: Recently the relationship between inflammatory biomarkers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) has been found, with the increase in the percentage of red cell distribution width (RDW), events related to increase in cardiovascular risk in patients with rheumatoid arthritis (RA). RDW is a parameter that represents the heterogeneity of erythrocyte size and is calculated by an automatic blood analyzer, translates anisocytosis and in turn is related to atherosclerosis, is a predictor of mortality in patients with cardiovascular diseases such as acute myocardial infarction (AMI) and Congestive Heart Failure (CHF) plus it has the advantage of being very cheap. In patients with RA who receive treatment with methotrexate (MTX), particularly those with good therapeutic response with decreased disease activity, the values of ESR and CRP decrease.
Objectives: The aim of this study is to verify if there is a decrease, increase or neither change in the value of RDW in the patients receiving or not MTX comparing the value prior to the start of treatment and the last value measured during their therapy.
Methods: In this descriptive, non-experimental cross-sectional study, men and women older than 18 years of age with a diagnosis of rheumatoid arthritis according to ACR criteria (Aletaha et al., 2010) who were or not treated with methotrexate and other DMARDs. We excluded patients with less than two visits in this unit and the elimination criteria were patients who did not have baseline or last RDW test. The records of all patients included name, age, sex, date of diagnosis of RA, comorbidities, baseline and final laboratory exams during follow-up that included tests with RDW and medications.
Results: A total of 403 all with a diagnosis of RA and an average of 4.62 years of evolution, of which 51 they do not take methotrexate in daily dose and 352 receive treatment and only 4.2% suffered from a cardiovascular event. The comparison was made grouping the patients in whom they received and not treatment with methotrexate and correlated with the value of baseline and final RDW as shown in Table 1.

Table 1

	Methotrexate			
	Receive		Do not Receive	
	Baseline RDW	Final RDW	Baseline RDW	Final RDW
Minimum	10.70	10.40	11.10	12.20
Median	15.70	15.70	15.85	15.35
Mean	15.97	16.01	15.97	15.93
Maximum	32.60	26.60	27.30	21.80

The results shown in Table 1, do not appear to reveal a significant change in RDW values between the different subgroups; in the figures we compared the median of RDW for each group of patients who take methotrexate from all patients included in this study.



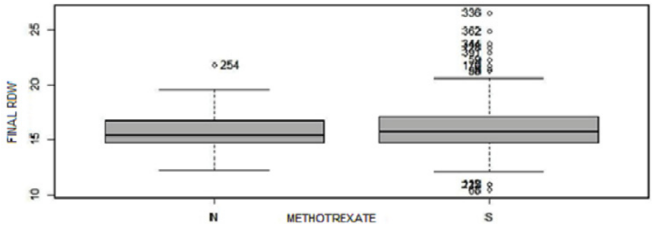


Figure. 2.

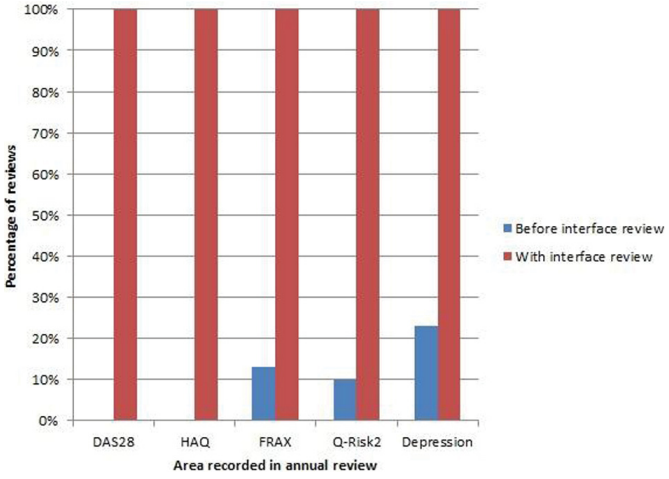

Conclusions: The value of RDW does not appear to significantly change its value when taking methotrexate at a daily dose in RA patients. The value of RDW may have weight in the assessment of the risk of suffering a cardiovascular event in patients with rheumatoid arthritis.

AB0332 DOES A COMMUNITY INTERFACE RHEUMATOID ARTHRITIS ANNUAL REVIEW IMPROVE PATIENT CARE?

J. Mcdonald, R. Haigh, D. Murphy. *Rheumatology, Royal Devon and Exeter Hospital, Exeter, United Kingdom*

Background: Patients with rheumatoid arthritis are known to have a long term disability and increased risk of extra-articular comorbidities. EULAR guidelines suggest annual review of cardiovascular risk in patients with rheumatoid arthritis [1] whilst UK national (NICE) guidelines suggest a more holistic annual review to look at the impact of the disease on quality of life as well as co-morbidities [2].

Objectives: Our aim was to look at the annual reviews currently taking place in primary care to see how frequently patient co-morbidities were assessed and documented. We then implemented a formal community rheumatology interface review to assess whether this improved patient care.
Methods: A large primary care practice (16,000 patients) was offered a community rheumatology interface review by a secondary care clinician. A search was undertaken for patients with rheumatoid arthritis who had attended for an annual primary care review between December 2015–2016. Of these 30 reviews were selected and we assessed how frequently the following were recorded; DAS28, HAQ score, FRAX score, Q-Risk2 (CV risk assessment tool) and screening for depression. Once we had analysed these results we implemented a community rheumatology interface review and assessed compliance with the above outcomes had improved compared to standard primary care management.
Results: In patients assessed prior to implementation of interface review, we found that a DAS28 score was recorded in 0%, HAQ score in 0%, FRAX in 13%, Q-Risk2 in 10% and depression screening in 23%.
In comparison, patients assessed by a community rheumatology interface clinician recorded DAS28 in 100%, HAQ score in 100%, FRAX in 100%, Q-Risk2 in 100% and depression screening was recorded in 100%. Based on improved interface review 7 patients (23%) were sent for DEXA scanning or started on a bisphosphonate, we discussed cardiovascular risk and starting a statin in 8 patients (26%) and 7 patients (23%) required follow-up for mental health. Of the 30 patients in this cohort all patients reported full adherence to their anti-rheumatic regime.

Conclusions: 1. An annual review with a rheumatology interface practitioner is of benefit in holistic patient care and improved compliance with all domains of the annual review.
2. Management of metabolic bone, cardiovascular and mental health issues was improved, according to current national guidelines.

AB0333 USE OF BIOLOGICAL DMARDS, BUT NOT OF CONVENTIONAL SYNTHETIC DMARDS OR STEROIDS, MAY BE RELEVANT TO INCREASED ENERGY INTAKE IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Masuko[1,2], Y. Mizukami[3], S. Tohma[4], T. Matsui[5]. *[1]Clinical Research Center for Medicine, International University of Health and Welfare; [2]Health Evaluation and Promotion Center, Sanno Medical Center, Tokyo; [3]Graduate School of Nutritional Science, Sagami Women's University; [4]Clinical Research Center for Allergy and Rheumatology, National Hospital Organization Sagamihara National Hospital, Kanagawa; [5]Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan*

Background: Dietary and nutritional factors may modulate the onset and/or outcome and comorbidities including cardiovascular diseases in rheumatoid arthritis (RA)[1]. For instance, a potential contribution of sodium intake and the occurrence of autoimmunity has been suggested, however the role of sodium in disease activity of RA is unclear.
Objectives: To investigate the potential relationship between dietary intake and current medications and the disease activity of RA.
Methods: Patients with RA in outpatient clinic of National Hospital Organization, Sagamihara National Hospital (n=89, M/F=18/71, age 65.0±12.8 yo, mean disease duration 16.8±13.2 y) were enrolled to the study. A questionnaire regarding dietary habit and the brief-type self-administered diet history questionnaire (BDHQ) were used to assess the relationship between clinical activity, status of medication and intake of each foodstuff and nutritional factors. The results were analyzed using IBM SPSS software using Pearson's correlation test and Levene test.
Results: The number of current medication was found to weakly correlate with DAS-28 (r=0.386), and negatively with intake of ethanol (r=-0.277). When users of biological disease modulating anti-rheumatic drugs (bDMARDs) were compared with non-users, the biologics-taking patients tended to have higher intake of total energy and carbohydrates than non-users. Use of oral corticosteroids, nor other anti-rheumatic DMARDs, did not significantly impact the total energy or carbo intake in RA patients. Sodium intake did not correlate with the disease status or the number of medications.
Conclusions: Although salt intake has been suggested to evoke autoimmunity, the amount of dairy intake of salt does not significantly modulate the current disease activity of RA. Use of biologics, but not of corticosteroids, may lead to increased energy and carbohydrate intake in RA patients.

AB0334 KNEE FUNCTION AFTER TOTAL KNEE ARTHROPLASTY IS INFLUENCED BY DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Harigane[1,2], K. Kumagai[2], Y. Mochida[1], K. Ishii[1], Y. Miyamae[1], H. Choe[2], A. Nagaoka[2], Y. Inaba[2], N. Mitsugi[3], T. Saito[2]. *[1]Center for Rheumatic Diseases, Yokohama City University Medical Center; [2]Department of Orthopaedic Surgery, Yokohama City University; [3]Department of Orthopaedic Surgery, Yokohama City University Medical Center, Yokohama, Japan*

Background: Several studies reported that development of phaemacological treatment for rheumatoid arthritis (RA) contributed to decreased number of orthopaedic surgery. [1–3] Surgical treatment is, however, still required in many cases, and the impact of orthopaedic surgery on disease activity remain unclear.
Objectives: The aims of current study was to evaluate the effect of total knee arthroplasty (TKA) with capsulosynovectomy on changes of disease activity and knee function after TKA in patients with RA.
Methods: Seventy-seven serial patients with RA (61 female and 16 male) who underwent primary TKA with more than one year of follow-up were retrospectively reviewed to assess postoperative disease activity and knee function. The mean age at the time of surgery was 68.3 years old. The disease activity of RA was measured using Disease Activity Score in 28 Joints (DAS28). Clinical outcome was measured by treatment score for RA knee of the Japanese Orthopaedic Association (JOA) score. To evaluate the effects of disease activity on knee function, outcomes at before and one year after surgery were separately investigated following two groups; patients who had remission or low disease activity in DAS28-CRP (good controlled group), and patients who had moderate or high disease activity (poor controlled group) one year after surgery.
Results: The disease activity of RA was significantly decreased in DAS28-CRP one year after surgery. (3.9 vs. 2.7, $p<0.01$) Postoperative knee function was significantly improved in JOA scores one year after surgery. (48.9 vs. 86.0, $p<0.01$) As for differences of knee function between good and poor controlled group, the mean JOA score in good controlled group was significantly better than in poor controlled group. (90.4 vs. 82.1, $p<0.01$) Postoperative knee function was negatively correlated with RA disease activity. ($R^2=0.21$, $p<0.01$)
Conclusions: TKA with capsulosynovectomy improves both knee function and disease activity in patients with RA. Based on the results, knee function after TKA is influenced with disease activity.

AB0335 EFFECT OF TOTAL KNEE ARTHROPLASTY ON MEDICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Harigane[1,2], Y. Mochida[1], K. Kumagai[2], K. Ishii[1], Y. Miyamae[1], N. Mitsugi[3], H. Choe[2], A. Nagaoka[2], Y. Inaba[2], T. Saito[2]. *[1]Center for Rheumatic Diseases, Yokohama City University Medical Center; [2]Orthopaedic Surgery, Yokohama City University; [3]Orthopaedic Surgery, Yokohama City University Medical Center, Yokohama, Japan*

Background: Several studies reported that development of phaemacological treatment for rheumatoid arthritis (RA) contributed to decreased number of orthopaedic surgery. [1–3] Surgical treatment is, however, still required in many cases, and the impact of orthopaedic surgery on disease activity remain unclear.
Objectives: This study evaluated the effect of total knee arthroplasty (TKA) with capsulosynovectomy on chenges of disease activity and medication in patients with RA.
Methods: Seventy-seven serial patients with RA (61 female and 16 male) who underwent primary TKA with more than one year of follow-up were retrospectively reviewed to assess postoperative disease activity and drug administration. The mean age at the time of surgery was 68.3 years old. The disease activity of RA was measured using Disease Activity Score in 28 Joints (DAS28). To evaluate the effects of medication on preoperative and postoperative disease activity, outcomes at before surgery and one year after surgery were separately investigated following two groups; patients who were treated with the same or reduced medication (same group) and patients who were administered with additional or altered medication (change group).
Results: Seventy-two patients (97.3%) were administered with at least one DMRDs before or after surgery. The mean dose of methotrexate (MTX) was 7.7mg/week before surgery and 8.0mg/week after surgery respectively. The number of patients who were treated with biological DMARDs was increased after surgery (17 patients vs.21 patients), however there was not significant differences. RA disease activity was significantly decreased in DAS28-CRP one year after surgery. (3.9 vs. 2.7, $p<0.01$) As for difference of the disease activity in same and change groups, DAS28-CRP was significantly decreased after surgery. (same group; 3.7 vs. 2.5, $p<0.01$, change group; 4.5 vs. 3.2, $p<0.01$) DAS28-CRP in change group was significantly higher both before and after surgery compared with those in same group. ($p<0.01$)
Conclusions: TKA with capsulosynovectomy improves disease activity after surgery in patients with RA. Based on the results, patients with higher disease activity before surgery required further medication after surgery.

AB0336 MAGNETIC RESONANCE IMAGING-ASSESSED SYNOVIAL AND BONE CHANGES IN HAND AND WRIST JOINTS OF RHEUMATOID ARTHRITIS PATIENTS

K.A. Lee, S.-H. Min, T.-H. Kim, S.-H. Lee, H.-R. Kim. *Internal Medicine, Konkuk University Medical Center, Seoul, Korea, Republic Of*

Background: Magnetic resonance imaging (MRI) is a sensitive and useful method for the detection of synovitis and joint destruction in rheumatoid arthritis (RA) patients. However, the patterns of MRI-detected bone erosion, bone marrow edema (BME), synovitis, and tenosynovitis have received insufficient attention.
Objectives: Therefore, this study evaluated the patterns of bone erosion, BME, synovitis, and tenosynovitis, and calculated the RA-MRI score (RAMRIS) of patients with RA at the carpal and metacarpophalangeal (MCP) joints using MRI.
Methods: MRI datasets from 43 RA patients were analyzed. All patients had undergone MRI of one wrist. In addition, 36 patients had MCP joint images taken, and 3 had also received MRI of the contralateral wrist and MCP joints. The MR images were evaluated for bone erosion, BME, and synovitis in consensus by 2 blinded readers according to the OMERACT RA-MRI score (RAMRIS). The MRI-detected tenosynovitis was evaluated based on Haavardsholm's tenosynovitis score.
Results: The capitate, lunate, triquetrum, and hamate bones were the most common sites of erosion and BME and showed the highest RAMRIS erosion and BME scores. Moreover, MRI-detected tenosynovitis was present in 78.3% of all patients with RA, and the extensor compartment 4 and flexor digitorum profundus and superficialis were frequently affected.
Conclusions: This study identified the distribution and prevalence of MRI-detected bone erosion, BME, synovitis, and tenosynovitis of the wrist and MCP joints in RA patients. The patterns of the MRI-detected abnormalities may help to select sites for the application of MRI protocols in clinical trials and practice.

AB0337 BIOLOGIC THERAPY IN SEVERE PERIPHERAL ULCERATIVE KERATITIS (PUK). MULTICENTER STUDY OF 27 PATIENTS

L. Domínguez-Casas[1], V. Calvo-Río[1], O. Maíz[2], A. Blanco[2], E. Beltrán[3], L. Martínez-Costa[4], M. Alvarez del Buergo[5], E. Rubio-Romero[6], D. Díaz-Valle[7], R. López-González[8], A. García Aparicio[9], A. Juan Mas[10], N. Palmou[1], M. González-Gay[1], R. Blanco[1]. *[1]HUMV, Santander; [2]H, Donostia; [3]H; [4]H Peset, Valencia; [5]H; [6]H Río Carrión, Palencia; [7]H San Carlos, Madrid; [8]C Hospitalario, Zamora; [9]H, Toledo; [10]H S Llàtzer, P Mallorca, Spain*

Background: Peripheric Ulcerative Keratitis (PUK) is a severe inflammation that may lead to ocular perforation. PUK may be primary or associated with systemic conditions. Treatment is based on corticosteroids and conventional systemic immunosuppressive drugs.
Objectives: To evaluate biologic therapy in cases with severe and refractory PUK.
Methods: Multicenter study from 9 hospitals. Patients presented inadequate response or intolerance to conventional therapy with corticosteroids and at least 1 systemic traditional immunosuppressive drug.
The main outcome measures were visual acuity, signs of inflammation, progression to corneal thinning, central keratolysis and ocular perforation. Comparisons were made between baseline and 1st week, 1st month, 6th month and 1st year. Statistical analysis was performed using the software STATISTICA (StatSoft). Results were expressed as mean±SD for variables with a normal distribution, or as median [IQR] when they were not normally distributed. The comparison of continuous variables was performed using the Wilcoxon test and categorical variables with chi-square test.
Results: We studied 27 patients/35 affected eyes (7 men/20 women), mean age, 57.2±16.3 years (range 28–89). PUK was primary in 1 case whereas in the 26 remaining cases, the underlying diseases were Rheumatoid Arthritis (RA) (n=19), Psoriasic Arthritis (n=2), RA+Felty syndrome+common variable immunodeficiency (n=1), Behçet Disease (n=1), Type I diabetes mellitus (n=1), granulomatous polyangiitis (n=1) and microscopic polyangiitis (n=1). They received the following topical therapy: corticosteroids (n=18), antibiotics (n=17), lubricants (n=18), autologous serum (n=11), topical cyclosporin 2% (n=11) and topical tacrolimus 0.03% (n=1). Besides oral corticosteroids and before the onset of the biologic therapy they had received iv pulses of methylprednisolone (n=8), methotrexate (16), oral doxycycline (9), azathioprine (3) and ascorbic acid (2). Moreover, 10 patients required surgery: amniotic membrane (n=7), penetrating keratoplasty (n=4), conjunctival resection (n=3), tissue adhesives (n=2), conjunctival flap (n=1) and lamellar keratoplasty (n=1).
Anti-TNFα drugs were the most common biologic agents used in these cases (n=19): Adalimumab (ADA) (n=10; 37%), Infliximab (IFX) (n=8; 29.6%) and etanercept (n=1; 3.7%). In the remaining 8 cases the biologic agents were rituximab (n=7; 25.9%) and tocilizumab (n=1; 3.7%). The main outcome measures are summarized in the Table.
After a mean follow-up of 23.7±20 months, all objective outcomes had improved with a reduction of the median prednisone dose from 33.7 [17.5–52.5] mg at baseline to 0 [0–2.5] mg (p=0.028). The main observed adverse effects were supraventricular tachycardia (n=1) and pulmonary Tuberculosis (n=1).

	Basal	1 week	1 month	6 months	1 year
Visual acuity, mean±SD	0.54±0.37	0.55±0.35	0.58±0.33	0.67±0.3*	0.69±0.27*
Peripheral thinning #	85.7	80*	57.1*	40*	34.3*
Central keratolysis #*	17.1	8.6*	0*	8.6*	5.7*
Ocular perforation #	11.4	14.3*	0*	0*	2.8*
Scleritis #	34.3	22.8*	8.6*	0*	0*
Episcleritis #	22.8	11.4*	5.7*	2.8*	2.8*
Uveitis #	14.3	14.3	8.6*	2.8*	2.8*

Data expressed as % of the active eyes
*$p < 0.05$ compared with basal data

Conclusions: In our series, biological therapy, especially IFX and ADA, is effective and relatively safe in patients with PUK refractory to standard systemic treatment.

AB0338 HEADS-UP! SARCOIDOSIS AND RHEUMATOID ARTHRITIS CO-EXIST

L. Zickuhr, R. Hajj-Ali. *Rheumatology, Cleveland Clinic Foundation, Cleveland, United States*

Background: Sarcoidosis and rheumatoid arthritis (RA) uncommonly co-occur. How dual diagnosis affects these patients' clinical phenotype is unknown.
Objectives: To characterize the clinical and laboratory phenotype and to increase awareness of the coexistence of sarcoidosis and RA.
Methods: We searched PubMed from 1980–2016 for relevant articles using key words "sarcoidosis" and "rheumatoid arthritis," excluding cases with tumor necrosis factor inhibitors. We found 12 cases, omitted 5 lacking clinical detail, and added 2 from our experience at the Cleveland Clinic. Clinical features, laboratory and imaging findings were reviewed and summarized.
Results: Females comprised 7/9 cases (77%). Our cases are the first to describe men with dual diagnosis. Of the 8 cases reporting ethnicity, 4 (50%) were white. The mean age at time of diagnosis was 35.3 years for RA and 51.0 years for sarcoidosis. In 5/9 cases (55%), RA preceded sarcoidosis. RA affected the hands in 8/9 patients (88.9%). Of the 8 cases reporting symptoms of sarcoidosis, 5 (62.5%) had dyspnea. All cases (100%) had elevated rheumatoid factor (RF) and, when checked, anti-citrullinated peptide (anti-CCP) antibodies. Angiotensin converting enzyme (ACE) was elevated in 6/9 patients (66.6%). Of the 5 patients with joint imaging, 4 (80%) had inflammatory changes. All sarcoidosis (100%) was biopsy-proven. One case (11.1%) demonstrated concomitant pulmonary RA and sarcoidosis.
Conclusions: Sarcoidosis and RA coexist in seropositive patients, most commonly in women in their fourth through sixth decades of life. RA preceded sarcoidosis about half the time. Hand arthritis and dyspnea were the most common symptoms for RA and sarcoidosis, respectively. Awareness of this dual diagnosis may help identify RA and sarcoidosis earlier and prevent treatment delay.

AB0339 COMORBIDITIES AND RISK FACTORS OF CARDIOVASCULAR DISEASES IN RHEUMATOID ARTHRITIS PATIENTS

L.V. Khimion[1], I.V. Klymas[1], I.M. Naishtetik[2]. *[1]Department of Family Medicine, Shupyk National Medical Academy of Postgraduate Education; [2]Kyiv Regional Clinical Hospital, Kyiv, Ukraine*

Background: It is well known, that atherosclerosis associated cardiovascular diseases in many cases determine the life expectancy in RA patients. At the same time, risk factors which promote the development of premature atherosclerosis, including comorbidities, remain uncertain.
Objectives: to analyze comorbid conditions in RA patients under age of 50 years and assess their impact on the vascular wall (evaluated by ultrasound investigation of the carotid arteries).
Methods: The study was conducted at the Department of Family Medicine, Shupyk NMAPE at the Kyiv Regional Clinical Hospital. The study included 126 RA patients, aged from 18 to 49 years (women - 102 (81%), men - 24 (19%), average age 43.82±8.8 years, who provided written consent to participate in research. As a control group 30 persons without any autoimmune diseases (women - 25 (83.3%) men - 5 (16.7%), average age 42.4±8.6 years) were examined.
All RA patients and control group underwent comprehensive clinical, laboratory and instrumental examination to identify comorbid conditions including evaluation of atherogenesis by use of ultrasound examination of the carotid arteries with intima-media thickness (IMT) measurement and atherosclerosis plagues (AP) assessment.
Results: The frequency of identified comorbid conditions and diseases in RA patients and control group are presented in Table 1.
The average number of comorbid diseases/conditions per RA patient significantly exceeded its number in controls (4.13 and 1.67 respectively, $p<0.05$); most frequently among RA patients was determined: dyslipidemia (60.32%), nonalcoholic fatty liver disease (61.11%), chronic cholecystitis (36.51%), cholesterosis of the gallbladder (30.16%), hypertension (37.30%), autoimmune thyroiditis (27.77%), spinal osteoarthritis (33.33%).

Table 1. The frequency of comorbidities in RA patients and control group

Diseases and conditions	RA (n=126)		Control (n=30)	
	n	%	n	%
Coronary heart disease	12	9.52*	0	0
Arterial hypertension	47	37.30*	0	0
Neurocirculatory asthenia	2	1.58*	1	3.3
Dyslipidemia	76	60.32*	2	6.67
Peptic ulcer	6	4.76*	1	3.30
Chronic gastritis	29	23.00	3	10.0
Chronic pancreatitis	19	15.08	5	16.67
Nonalcohol fatty liver disease	77	61.11*	2	6.67
Cholesterosis of the gallbladder	38	30.16*	1	3.33
Chronic cholecystitis	46	36.51*	3	10.00
Gall stones	8	8.25*	0	0
Diabetes mellitus type 2	3	2.38*	0	0
Diffuse goiter	5	3.97*	0	0
Autoimmune thyroiditis	35	27.77*	1	3.33
Chronic obstructive pulmonary disease	5	3.97	4	13.33
Osteoarthritis of the spine	42	33.33	9	30.00
Chronic kidney disease	5	3.97	1	3.33
Abdominal obesity	21	16.67	4	13.33

*The difference between groups is significant, $p<0.05$.

Results of the carotid ultrasonography and assessment of atherosclerosis surrogate markers (IMT, AP) showed higher severity of atherosclerotic process in patients with RA compared to controls; the most important risk factors for increasing IMT and atherosclerotic plaques in carotid arteries were dyslipidemia, autoimmune thyroiditis with hypothyroidism and nonalcoholic fatty liver disease.
Conclusions: Patients with RA have a higher frequency of comorbid conditions and diseases than controls without RA; some of comorbidities have significant influence on atherogenesis; RA patients require a multidisciplinary and holistic approach for effective management of their health related problems.

AB0340 CLINICAL EFFICACY OF STATINS IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Mikulets, T. Ilashchuk. *Department of Propedeutics of Internal Diseases, Higher State Educational Establishment of Ukraine "Bukovinian State Medical University", Chernivtsi, Ukraine*

Background: Cardiovascular disease (CVD) is a major cause of mortality in patients with rheumatoid arthritis (RA). In the literature there are conflicting data on the use of statins in patients with RA, indicating a lack of attention to the issue of prevention of CVD in this category of patients.
Objectives: The aim of the study was to improve the efficiency of the treatment of rheumatoid arthritis by including to the basic treatment rosuvastatin.
Methods: The study included 43 patients with RA. A survey conducted by the protocol patients (DAS28 index, visual analog scale (VAS), morning stiffness). The study of lipid metabolism included: determining the level of total cholesterol (total cholesterol), HDL cholesterol (HDL) and low density (LDL), atherogenic index (AI), triglycerides (TG). Total cardiovascular risk assessment was performed using a table SCORE. Surveyed patients divided into groups: primary (n=20) (basic therapy and rosuvastatin, 10 mg 1 time per day) and comparison (n=23) (basic therapy that included methotrexate, non-steroidal anti-inflammatory drugs, glucocorticoids in medium therapeutic doses).
Results: As a result of the treatment found that patients with a primary and group comparison, there was a positive dynamics of clinical indicators of inflammatory activity (DAS28, VAS, morning stiffness). In the study group experienced a significant decrease ($p<0.05$) at the same time as in the comparison group had a tendency to decrease. Noted a reduction parameters: CRP ($\Delta_1$37% main group and the comparison group $\Delta_2$21%), ESR ($\Delta_1$39% and $\Delta_2$26% respectively). Also noted the changes in the lipid profile. Significantly decreased in the study group performance total cholesterol ($\Delta_1$31% versus $\Delta_2$15%), LDL cholesterol ($\Delta_1$19% against $\Delta_2$8%) and AI ($\Delta_1$29% and $\Delta_2$16% respectively).
Conclusions: Inclusion in the complex therapy of patients with RA statins contributes to a significant reduction in total cholesterol, LDL cholesterol, and positively affects the activity of the process, reducing the levels of acute phase proteins. Additional indications for the purpose of statins have high activity process and late onset. The use of statins in RA, given their lipid-lowering and anti-inflammatory effects, may be an effective means for the successful prevention of cardiovascular complications.

AB0341 HOW COMMON IS DISCORDANCE IN DAS COMPONENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Shaikh. *Rheumatology, Addenbrooke's Hospital, Cambridge, United Kingdom*

Background: Chronic pain remains a significant problem for patients with rheumatoid arthritis (RA) despite advances in the management of joint inflammation (1–3). Pain that persists in the absence of significant inflammatory disease activity is thought to arise from sensitisation of the central nervous system. Composite scores such as DAS28, combine both objective and subjective aspects of disease. This may overestimate inflammatory disease in patients in whom pain occurs independently and has implications for treatment. However, the proportions of patients with such discordance is not clear.
Objectives: 1. To assess the degree of discordance between objective and subjective components of the DAS28 score in patients attending rheumatology clinics in a teaching hospital in Cambridge.
2. To assess the association between such discordance and the DAS28-P measure
Methods: A retrospective review of clinic notes was conducted of patients attending the rheumatology department at Addenbrooke's Hospital, Cambridge. Patients attending the early arthritis clinic, nurse practitioner follow up clinic and biologics clinic were included. Demographic information was collected including age, gender, current use of synthetic and biologic DMARDs. DAS28 scores and the individual components were retrieved and analysed. DAS28P was calculated as well as the difference between tender and swollen joint count (TJC-SJC) which has also been noted to be a measure of discordance between subjective and objective symptoms.
Results: 120 patients with RA were studied. The mean age was 59.4 years (range 27–86). 74% (89) were female. 88% (106) were on synthetic DMARDs: MTX 48% (58), HCQ 37% (45), SSZ 12% (15), LEF 3% (4), Gold 0.8% (1). 30% (36) were on biologic DMARDs: RTX 30% (11), ETA 30% (11), TOCI 17% (6), ADA 14% (5), ABA 6% (2).
Mean DAS28 was 3.42, SD 1.39. Mean TJC 4, mean SJC 2. Mean PGA 43, SD 24. DAS28-P was calculated as per previous studies (3). Mean TJC-SJC was 2, median 1. PGA and TJC-SJC (r=0.33) and TJC-SJC and DAS28P were correlated (r=0.44).
Conclusions: Discordance between subjective and objective components of DAS scores is relatively frequent in patients with RA. This can lead to confounding of DAS scores. There is currently no formal system of assessing the degree of such discordance which can have implications for treatment of inflammatory disease as compared to pain management strategies.

AB0342 POOR SLEEP QUALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS RELATED TO SUBCLINICAL CERVICAL SPINE AFFECTION MEASURED BY MRI

M. Hassanien[1], A. Al-johi[2], A. Al-awamy[3], N. Abas[4], R. Abdel-Razek[2]. *[1]Rheumatology Department; [2]Rheumatology Department; [3]Anathesia pain subdivision; [4]Radiology, Assuit University, assuit, Egypt*

Background: Rheumatoid arthritis is a chronic systemic inflammatory disease that often affects the cervical spine. Cervical disorders in rheumatoid arthritis (RA) patients have been an important problem for a long time
Objectives: investigate association between poor sleep complaints in rheumatoid arthritis patients and subclinical cervical spine involvement measured by MRI and its relation to disease activity in a population-based cross-sectional study.
Methods: 200 Egyptian RA patients fullfilling the American college of Rheumatology Criteria 2010 who were under follow up in the rheumatology and pain clinic, Assuit university hospital, Egypt. All patients underwent a complete history and physical examination with a focus on the cervical spine to assess disease duration, age of disease onset, swollen and tender joint counts. ESR, Hb, CRP, RF levels and disease activity was measured using the disease activity score 28 (DAS28). Oswestry-Neck-Pain-Questionnaire were completed. All patients filled out the Pittsburgh sleep quality index to evaluate their sleep quality, anxiety and depression scale. Symptomatic patients and previously diagnosed cervical subluxation were excluded. Radiographs of the cervical spine included lateral views taken in flexion, extension, neutral position of neck and antero-posteriorly and odontoid projection view.Patients suspicious for atlantoaxial affection underwent Magnetic Resonance Imaging to evaluate the cervicomedullary angle, dens erosion, amount of hypervascular –active pannus, atlantoaxial impaction, vertebral plate erosion, subaxial subluxation, apophyseal joints and disc material
Results: Asymptomatic cervical spine subluxation was found in 46 of the 200 RA patients (23%). The prevalence among involved patients of, anterior atlanto-axial subluxation, atlantoaxial impaction and subaxial subluxation was 25 (54.3%), 8 (17.4%) and 13 (28.2%), respectively. Posterior subluxation was not detected. There is significant relationship with cervical spine subluxation and sleep disturbance (interruption pattern) (P=0.006). The main baseline risk factor for difficulty falling asleep was anterior atlanto-axial subluxation, whereas for cervical spine subluxation it was higher patient age. Logistic regression confirmed early final awakening and short sleep respectively (HR 1.109, 95% CI 1.120–1.260, p=0.05) and (HR 1.095, 95% CI 0.991–0.998, p=0.005) as independent predictors of anterior atlanto-axial subluxation. The main risk factors for incident hypervascular atlantoaxial joint active pannus was disease activity score and older age. The frequency of early final awakening and short sleep were higher in relation to cervical spine involvement. Male sex, CRP positivity, and older age were risk factors for incident anterior atlantoaxial subluxation.
Conclusions: Cervical spine involvement is common and may be asymptomatic indicating routine cervical spine imaging is needed in patients with RA specially patients with sleep disturbances and high disease activity

AB0343 THE RHEUMATOID FOREFOOT: WHICH FREQUENT INJURY? WHAT IMPACT ON WALK?

M. Erraoui, B. Amine, L. Tahiri, I. El Binoune, J. Bahha, S. Fellous, Y. Boujenane, F. Allali, R. Bahiri. *Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat, El Ayachi Hospital, SALE, Morocco*

Background: Foot involvement is the most common cause of disability in patients with rheumatoid arthritis (RA). The forefoot remains the most affected location.
Objectives: Investigate the forefoot injuries in patients with RA and evaluate its impact on walking.
Methods: Cross-sectional study of 33 patients with rheumatoid arthritis. Patients with static lower limb disorder or foot injury from other origin were excluded.Demographic and clinico-biological characteristics were collected: age, sex, BMI, disease duration, tender joint count, swollen joint count, foot pain evaluated on an VAS, squeeze test in foot, various podiatric abnormalities, sedimentation rate in the first hour, C reactive protein, rheumatoid factor and anti-CCP. Disease activity was evaluated by DAS28, CDAI, SDAI and DAS44. The effect on walking was studied by the HAQ (specific item of walking) and the French version of FFI (Foot Functional Index) which consists on 23 items, divided into 3 sections: pain, function and limitation of activity. Statistical analysis was performed using SPSS21 software.
Results: 33 patients followed for RA were included. The mean age of our patients was 49.39±10.52 with a female predominance (87.9%). Mean duration of the disease was 9.96±7.49 years. 21 (95.5%) of patients were seropositive. Mean DAS28 was 5.53 (4.58–6.50) and mean HAQ was 1.37 (0.70–2.10). 54.5% of our patients reported right forfoot pain and 57.6% of them reported left forefoot pain; with predominant metatarsalgia (right 54.5% and left 57.6%). 33.3% had forfoot pain in the day of the examination and 69.7% (23) had a positive squeeze test. 18 (54.5%) patients had a foot podiatric abnormalities. They are represented by: right hallux valgus (39.4%), left hallux valgus (39.4%), right quintus varus (12.1%), left quintus varus (9.1%), right claw toe (9.1%), left claw toe (12.1%), right triangular foot (6.1%) and left triangular foot (6.1%).
Mean FFI was 52.35 (34.73–71.43), and mean FFI-function was 53.66 (34.44–74.99). 27.3% (9) of patients had walking difficulty according to item 4 of HAQ. A statistically significant association was found between a high FFI-function and metatarso-phalangeal pain (p=0.029), anterior plantar pain (p=0.018) and a positive squeeze test (p=0.01). Impairment of walking assessed by FFI-function was positively correlated with pain (r=0.58,p=0.0001) and discomfort in forfoot (r=0.452,p=0.008), VAS pain (r=0.48,p=0.005) and global gene VAS (r=0.70,p=0.001) associated with disease. Disease activity was positively correlated with FFI-function (DAS28 (r=0.48,p=0.005), CDAI (r=0.6-p=0.0001), SDAI (r=0.60,P=0.0001) and DAS44 (r=0.55, p=0.001)). The difficulty of walking assessed by item 4 of HAQ was associated with metatarso-phalangeal pain (p=0.01), and was not influenced by adaptation of the footwear (p=0.015). Also, item 4 was statistically associated with disease activity (DAS28 (p=0.028) and SDAI (p=0.049)) and impaired function evaluated by FFI (p=0.001) and particularly FFI-Function (p=0.0001). Podological abnormalities were not statistically associated with either functional FFI or the item 4 of HAQ.
Conclusions: Forefoot involvement is frequent during RA, particularly podiatric abnormalities. It generates a functional repercussion on walking which would be rather related to pain and disease activity than to podiatric abnormalities.

AB0344 SUBCLINICAL VASCULAR DAMAGE AND ITS ASSOCIATION WITH ACPA AND RF IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Aguilar-Zamora, M. Robustillo-Villarino, C. Vergara-Dangond, L. Montolio-Chiva, E. Valls-Pascual, A. Martínez-Ferrer, D. Ybañez-Garcia, V. Nuñez-Monje, J.J. Alegre-Sancho. *Rheumatology, Hospital Universitario Dr. Peset, Valencia, Spain*

Background: Accelerated atherosclerosis (AE) and increased arterial stiffness

are comorbidities of rheumatoid arthritis (RA) and are related to the inflammatory burden of the disease, as well as to certain clinical and genetic characteristics of the disease. There is controversy about the role of ACPA in the development of AE in these patients.
Objectives: To explore the relation between ACPA and RF titres and subclinical vascular damage in RA patients.
Methods: Descriptive cross-sectional study with analytical components. A total of 244 RA patients were recruited consecutively over a period of 18 months (2013–2014) in a rheumatology department of a tertiary hospital. Patients with high vascular risk (vascular ischemic events, renal failure and diabetes mellitus) were excluded. Demographics, clinical data (ACPA and RF titres, duration of disease, hypertension and dyslipidemia) and vascular damage (atheroma plaque, carotid intima thickness [IMTc] and pulse wave velocity [PWV]) were collected. The atheroma plaque and IMTc measurement was performed by ultrasonography of the carotid arterial tree using an Esaote® MyLab70XVG with a 7–12 MHz linear transducer and an automated program measuring intima-media thickness (IMT) through radiofrequency (Quality intima media Thickness in real time, QIMT). PWV was obtained by analysis of brachial pulse waves with an automated and validated system (Mobil O Graph®). Statistical analysis was performed with the SPSS 17.0 program.
Results: We included 181 patients, 141 (77.9%) women and 40 (22.1%) men, with a mean age of 60.4 years (SD 13.2) and a mean duration of the disease of 13.1 years (SD 10.5); 107 patients (59.1%) were smokers or ex-smokers, 56 (30.9%) hypertensive and 77 (42.5%) dyslipemic. 118 patients (65.2%) had positive ACPA, with a mean value of 330 (SD 621.5), and 107 (59.1%) had a positive value of RF with a mean of 114 (SD 164.5).
No association was found between the positivity of ACPA and RF and the presence of atheroma plaques or with the values of IMTc and/or PWV. In patients with positive ACPA, a positive correlation was observed between ACPA titers and PWV values ($p<0.05$). In particular, ACPA titers over 1600 were the ones that discriminated the highest values of PWV in our population ($p<0.009$). The ACPA and RF values, on the other hand, were not related to the presence of plaques or to IMTc.
Conclusions: No relation was found between the positivity of RF and ACPA titers and the presence of pathological carotid ultrasound in our RA patient population. However, higher arterial stiffness was observed in patients with high ACPA titers.

AB0345 PSYCHIATRIC DISORDERS RELATED TO HYPERLEPTINEMIA AND RHEUMATOID ARTHRITIS CLINICAL ACTIVITY MEASURED BY DAS28

M. Vázquez-Del Mercado[1,2], A.-M. Rodrígez-Ramírez[2], E. Chavarria-Avila[2], F. Sandoval-García[2], B.-T. Martin-Marquez[2], R.-E. Navarro-Hernandez[2], F. Corona-Meraz[2], E. Gomez-Bañuelos[2]. *[1]Servicio de Reumatología, División de Medicina Interna, Pnpc 004086, CONACYT, Hospital Civil Juan I. Menchaca; [2]Instituto de Invesgitación en Reumatología y del Sistema Musculoesquelético, Universidad de Guadalajara, Guadalajara, Mexico*

Background: Leptin is an adipose-derived hormone with a role in depression related to chronic stress, anxiety and pain disorders, disturbs with a high prevalence in RA patients. In previous studies, it has been demonstrated the role of leptin in the pathogenesis of RA, in particular, its association with anti-CCP. The purpose of this study was to evaluate the psychiatric disorders risk related to serum soluble leptin (sLep) levels with clinical activity in RA patients.
Objectives: To evaluate the association between psychiatric disorders and serum leptin (sLep) levels and RA disease activity
Methods: 76 outpatients diagnosed with RA (ACR1987/ ACR/ EULAR2010) were evaluated with clinical, laboratory and image assessment. Disease activity was measured using DAS28 CRP, the Mini International Neuropsychiatric Interview Plus (M. I. N. I. Plus) was used for the psychiatric evaluation. sLep levels were measured by ELISA method.
Results: sLep levels were significantly higher in RA patients M.I.N.I. plus (+) ($P<0.001$). DAS28 CRP score was significantly higher in patients with a present psychiatric disorder ($P=0.006$) with an odds ratio of 1.6 ([1.04–2.46] $P=0.03$) for present psychiatric comorbidity. After adjustment with age and years of RA diagnosis, the odds ratio increased to 1.72 ([1.08–2.73] $P=0.02$). Also, DAS28 CRP had a moderate correlation with the number of psychiatric diagnosis present, past and for lifetime ($r=0.485$, $P<0.001$, IC95% [0.99–0.636]).
Conclusions: sLep levels and DAS28-CRP were associated with symptoms of depression, such as anxiety and pain disorder in RA patients.

AB0346 MOOD DISORDERS (ANXIETY AND DEPRESSION) IN RHEUMATOID ARTHRITIS

M. Brahem[1], M. Maraoui[1], H. Hachfi[1], S. Ben Hammouda[1], I. Haddada[1], M. Jguirim[2], M. Younes[1]. *[1]Rheumatology, Taher Sfar Hospital Mahdia, mahdia; [2]Rheumatology, Fattouma Bourguiba Hospital Monastir, Monastir, Tunisia*

Background: In addition to recurrent pain, fatigue, and increased rates of physical disability, individuals with rheumatoid arthritis (RA) have an increased prevalence of some mental health disorders, particularly those involving affective or mood disturbances.Many researchers have shown that mood disturbance and disability may serve as important pathways through which disease burden contributes to poor health functioning in RA.
Objectives: Our aim is to estimate the mood disorders (anxiety and depression) in patients with RA and to evaluate the associated factors.
Methods: This is a cross-sectional and descriptive study during a period of the year 2016, including 37 patients followed in the department of Rheumatology in Mahdia Tunisia. All patients were diagnosed with RA based in ACR 1987/EULAR2010.We evaluated for each patient the parameters of activity of the disease, the quality of life by the HAQ questionnaire and the mood disorders using the Hospital Anxiety and Depression Scale (HAD).
Results: The age of the RA patients (32 females/5 males) ranged from 21 to 76 years. The mean age was 53.1±12 years. The mean duration of the disease was 11±10 years [1–34]. The mean number of tender joints was 13.2±9.6 and swollen joint was 5.9±7. The mean DAS28 was 5.5±1.5 [2.9–8.2] and HAQ was 1.6±0.9 [0–2.8]. 51.3% of patients had specific joint deformations, 83.8% had radiologic involvement and 29.7% had osteoporosis.
The biologic analysis showed that the mean ESR was 45±27.1 and the CRP was 13.7±25.3. Rheumatoid factors were positive in 37.8% of cases, the ACPA were positive in 32.4% of cases. 81.1% of RA patients were treated by methotrexate and 13.5% were treated by biologic treatments.
The average score of depression was 9±2.6 [1–14]. Basing on this score, 12 patients (32.4% of cases) didn't have depression (score <8), 14 patients (37.8% of cases) suffered probably from depression (score between 8 and 10) and 11 patients (29.7%) had a certain depression (score$\geq$10). Our study didn't found any correlation between the score of depression and the age, the score and clinical parameters of RA (duration of disease, DAS28, number of tender and swollen joints and deformations), the score and biologic parameters (ESR, CRP, Rheumatoid factor, ACPA).
The average score of anxiety was 9.2±4.2 [0–20]. 12 patients (32.4%) didn't have signs of anxiety (score <8), 12 patients (32.4%) had probably an anxiety (score between 8 and 10) and 13 patients (35.2%) presented a certain anxiety (score$\geq$10). We found a significant correlation between the score of anxiety and the number of tender joints, the anxiety score and the HAQ (Health Assessment Quality).
Conclusions: Our study showed that the majority of our RA patients suffered from mood disorders; 67.5% had signs of depression and 65.6% had signs of anxiety.So, it's important to evaluate the mood disturbances in RA patients to ameliorate their quality of life.

AB0347 EVALUATION OF THE IMPACT OF RHEUMATOID ARTHRITIS ON SEXUAL FUNCTION

M. Brahem[1], H. Hachfi[1], S. Ben Hammouda[1], I. Haddada[1], M. Maraoui[1], M. Jguirim[2], M. Younes[1]. *[1]Rheumatology, Taher Sfar Hospital Mahdia, mahdia; [2]Rheumatology, Fattouma Bourguiba Hospital Monastir, Monastir, Tunisia*

Background: Rheumatoid arthritis (RA) may affect all aspects of life including sexual functioning.The percentage of arthritic patients who experience sexual problems ranged in various studies from 31% to 76%.The reasons for disturbing sexual functioning are multi-factorial and comprise disease-related factors as well as therapy.It can occur before, during and after sexual activities, and can affect sexual health in different perspectives.
Objectives: The aim of our study is to evaluate the impact of the RA in sexual function and its associated factors.
Methods: This is a cross-sectional and descriptive study during a period of the year 2016, including 37 patients followed in the department of Rheumatology in Mahdia Tunisia. All patients were diagnosed with RA based in ACR 1987/EULAR 2010. We evaluated for each patient the sexual quotient (QS). It is a validated scale which estimates the degree of satisfaction of the sex life.
Results: The age of the RA patients (32 females/5 males) ranged from 21 to 76 years. The mean age was 53.1±12 years. The mean duration of the disease was 11±10 years [1–34]. The mean number of tender joints was 13.2±9.6 and swollen joint was 5.9±7. The mean DAS28 was 5.5±1.5 [2.9–8.2] and HAQ was 1.6±0.9 [0–2.8]. 51.3% of patients had specific joint deformations, 83.8% had radiologic involvement and 29.7% had osteoporosis.
The biologic analysis showed that the mean ESR was 45±27.1 and the CRP was 13.7±25.3. Rheumatoid factors were positive in 37.8% of cases, the ACPA were positive in 32.4% of cases. 81.1% of RA patients were treated by methotrexate and 13.5% were treated by biologic treatments.
The mean sexual quotient was 50.25±20.8 [6–87.5]; only 8.1% of patients had a great sexual life (QS between 80 and 100), 16.2% expressed some sexual satisfaction (QS between 60 and 80), 21.6% had a mild sexual life (QS between

40 and 60), 18.9% presented a disappointing sexual life (QS between 20 and 40) and 35.4% didn't have any partner.
Our study showed a significant correlation between the duration of the disease and the alteration of the sexual quotient, but no correlation with the clinical and biological parameters of RA.
Conclusions: We conclude that only 24.3% of our RA patients had satisfaction in their sexual life. This alteration of the sexual quotient was found to be correlated with the duration of the disease.
This fact may be explicated by the disability, fatigue and pain caused by this chronic inflammatory disease. This relation should be confirmed by future studies.

AB0348 SLEEP DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Brahem[1], S. Ben Hammouda[1], H. Hachfi[1], M. Maraoui[1], I. Haddada[1], M. Jguirim[2], M. Younes[1]. *[1]Rheumatology, Taher Sfar Hospital Mahdia, mahdia; [2]Rheumatology, Fattouma Bourguiba Hospital, Monastir, Tunisia*

Background: Rheumatoid arthritis (RA)as one of the most common autoimmune diseases is known to be one of the leading causes of disability.Sleep disorders have direct influence on patient's life. But the exact nature of relationship between sleep disorders and Rheumatoid arthritis is not completely understood.
Objectives: The aim of our study is to evaluate the impact of RA in sleep quality and to establish associated factors.
Methods: This is a cross-sectional and descriptive study during a period of the year 2016, including 37 patients followed in the department of Rheumatology in Mahdia Tunisia. All patients were diagnosed with RA based on ACR 1987/EULAR2010. We evaluated for each patient the parameters of activity of the disease, the quality of life by the HAQ questionnaire and the quality of sleep using two scales: Epworth (ESS) and Pittsburg scale (PSQI) which is composed from 7 components rated each one from 0 to 3.
Results: The age of the RA patients (32 females/5 males) ranged from 21 to 76 years. The mean age was 53.1±12 years. The mean duration of the disease was 11±10 years [1–34]. The mean number of tender joints was 13.2±9.6 and swollen joint was 5.9±7. The mean DAS28 was 5.5±1.5 [2.9–8.2] and HAQ was 1.6±0.9 [0–2.8]. 51.3% of patients had specific joint deformations, 83.8% had radiologic involvement and 29.7% had osteoporosis.
The biologic analysis showed that the mean ESR was 45±27.1 and the CRP was 13.7±25.3. Rheumatoid factors were positive in 37.8% of cases, the ACPA were positive in 32.4% of cases. 81.1% of RA patients were treated by methotrexate and 13.5% were treated by biologic treatments.
The mean Epworth score was 9±5.7 (0–23). 56.8% of patients had no sleep debt, 32.4% had a sleep deficit and only 10.8% had signs of somnolence. Our study confirmed a significant correlation between the Epwoeth score and the number of tender joints, the ESR, the Health assessment quality (HAQ) score.
Regarding the overall score of Pitsburg, the average was 8.4±4.1 (1–16). The average of the "subjective sleep quality" was 1.35, "latency to sleep" was 1.81, "sleep duration" was 1.24, "habitual sleep efficiency" was 1.08, "sleep disorders" was 1.62, "the use of a sleep medicine" was 0.27 and finally the average of the 7th component about "poor form during the day" was 1.11 out of 3. So the latency to sleep and sleep disorders were the most affected components. We had a significant correlation between PSQI and the number of swollen joints, the HAQ score. The value of the ACPA was found to be associated with high score of PSQI.
Conclusions: Our study showed that the sleep disruption wasn't rare in patients with RA. This can be related to the disability and pain caused by this disease. Further studies with large sample size, as well as more careful tools of sleep disorders, would help to generalize results and suggestions. By providing adequate health care, and recognition of the patients' pain conditions we would ameliorate sleep quality and increase the QOL of RA patients.

AB0349 THE SERUM LEVEL OF IRISIN IS DECREASED IN THE PATIENTS WITH RHEUMATOID ARTHRITIS

A.T. Kalkan[1], M. Ozmen[2], B. Birlik[3], D. Kozaci[4], I. Turkmen[5], D. Solmaz[2], O. Gercik[2], S. Gucenmez[2], S. Akar[2]. *[1]Department of Internal Medicine; [2]Department of Internal Medicine, Division of Rheumatology; [3]Department of Radyology, Izmir Katip Celebi University, School of Medicine; [4]Department of Medical Biochemistry; [5]Department of Musculoskeletal System and Regenerative Medicine, Ankara Yıldırım Beyazıt University, School of Medicine, Izmir, Turkey*

Background: *Adipomyokines* are proteins that are synthesized by and secreted from both skeletal muscle and adipose tissue, and show their effects through autocrine, paracrine or endocrine pathways (1). *Irisin*, a novel adipomyokine, is secreted in association with exercise from the skeletal muscle, and from the white fat tissue to help the brown fat tissue gain the energy expenditure phenotype (2). There is evidence that the irisin is associated with metabolic syndrome (MetS) and cardiovascular risk (3,4).
Objectives: Rheumatoid arthritis (RA) is associated with an increased risk of cardiovascular disease (CVD) and MetS compared with the general population (5,6). The aims of this study were to assess the serum level of irisin, and the possible relationships of irisin with disease activity in patients with RA.
Methods: Eighty four consecutive RA patients fulfilling the 2010 ACR/EULAR RA Classification Criteria were included in the study. Fifty age- and sex-matched healthy volunteers were enrolled as the control group. Disease duration, medications, history of traditional risk factors of CVD and demographic data of patients were noted. Body Mass Index (BMI) was calculated as "weight (kg)/height (m)^2". HbA1c, lipid profile, insulin were measured. Insulin resistance was assessed with the Homeostasis Model Assessment (HOMA) Index. RA disease activity was assessed by disease activity score based on evaluation of 28 joints (DAS28). Serum irisin level was assessed by ELISA. Measurement of carotid intima media thickness by carotid doppler ultrasonography was performed by a radiologist for cardiovascular risk assessment.
Results: There was no significant difference between the groups in terms of BMI (p=0,20), HbA1c (p=0,15), lipid profiles ($p<0.05$), insulin resistance (p=0.72) and carotid intima-media thickness (p=0.216).
Serum irisin levels were found to be significantly lower in RA patients (20,65 (minimum:16,94- maximum:99,35) ng/mL) than healthy controls (37,56 (18,37–84,70) ng/mL) ($p<0.001$). There was no relationship between RA disease activity and irisin levels.
Conclusions: This study showed that irisin was significantly lower than controls. Irisin may be responsible for increased cardiovascular risk in RA patients. But before a definite judgment; prospective studies with a larger sample size assessing the exercise behaviour of patients and the presence of CVD are necessary.

AB0350 FUNCTIONAL DISABILITY MEASURED BY HEALTH ASSESSMENT QUESTIONNAIRE (HAQ) CORRELATES WITH DISEASE ACTIVITY IN ELDERLY RHEUMATOID ARTHRITIS PATIENTS

N. Alpay-Kanıtez[1], Ö. Pehlivan[2], A. Omma[3], S. Can-Sandıkçı[3], S. Yılmaz-Öner[1], C. Bes[1], S. Çelik[1]. *[1]Bakırköy Dr. Sadi Konuk Research and Training Hospital; [2]Umraniye Research and Training Hospital, Istanbil; [3]Ankara Numune Research and Training Hospital, Ankara, Turkey*

Background: Rheumatoid arthritis (RA)'s prevalence increases with age and the recognition of functional disability related to RA could be challenging in elderly patients (1).
Objectives: In this study, we aimed to look at the correlation between disease activity and the functional disability by using HAQ score in elderly RA patients.
Methods: Elderly RA patients, $\geq$65 years old at their routine visits were included to the study. The composite "disease activity score" in 28 joints (DAS-28) and "Physician Global Assessment" (PhGA) were used to determine disease activity. Health assessment questionnaire (HAQ) scores were calculated to describe the functional disability and compared across the disease activity groups according to DAS-28.
Results: Two hundred and fifty eight RA patients with the mean age of 71±5

(65–90) were included. Seropositivity rate was 71% and 47% of the patients had erosive disease. Joint deformity was seen in 72 (28%) of patients and 28 (11%) patients had undergone total arthroplasty. Lung involvement (8.5%) and Sjogren's syndrome (7.4%) were found as the most frequent extra-articular manifestations. Hypertension (66%) and osteoporosis (36%) were the common co-morbidities. The proportion of patients with high and moderate disease activity was found as 70%. HAQ and PhGA scores were significantly correlated with the disease activity (Figure).

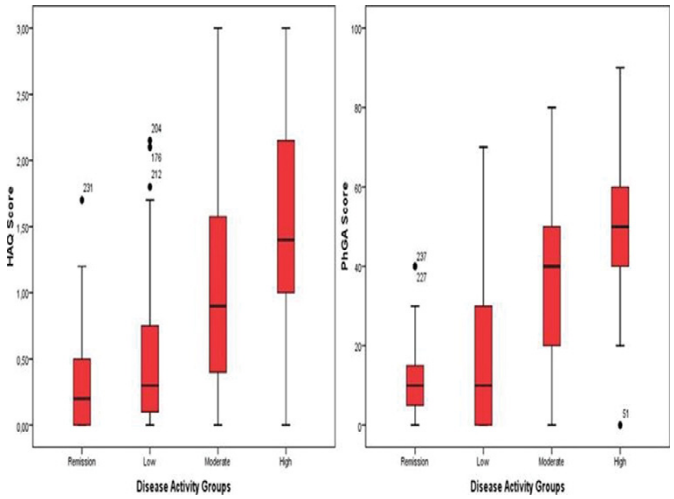

Figure 1. HAQ and PhGA distribution in disease activity subgroups. Both of them were found correlated with disease activity (p: 0.000).

Conclusions: We provided a novel data concerning the usefulness of HAQ for prediction of disease activity in RA patients who are elderly as well. In the future, our report will be supported by the studies which suggest that HAQ score improve with effective treatment in elderly RA patients.

AB0351 CORRELATION BETWEEN SERUM ANTI-CITRULLINATED PROTEIN ANTIBODIES AND SUBCLINICAL CARDIC AFFECTION IN RHEUMATOID ARTHRITIS PATIENTS

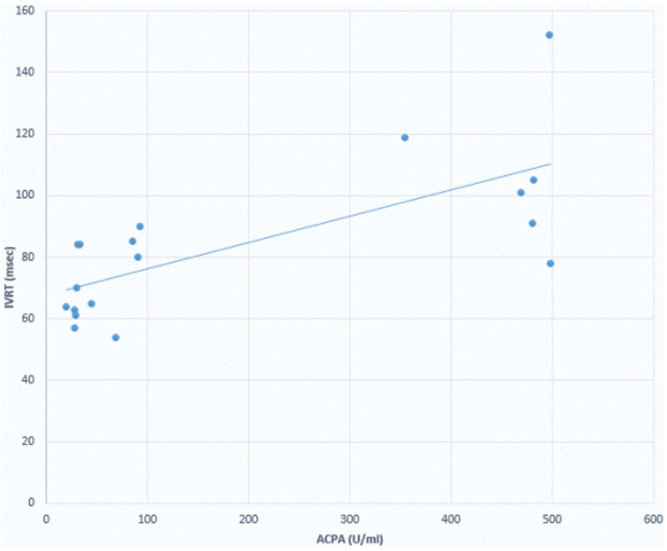
A. Helal[1], G. Younis[1], N. Hussein[1], E. Elsharkawy[2], N. Abdelhady Abdelsadek[1]. *[1]Physical Medicine, Rheumatology and Rehabilitation, Alexandria University Hospital; [2]Cardiology and Angiology, Faculty of Medicine, Alexandria, Egypt*

Background: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in rheumatoid arthritis (RA) patients. It has been postulated that chronic inflammatory activity is important for the development of CVD in RA even after adjustment for traditional cardiovascular risk factors.(1) One of the changes occurring in the context of inflammation is citrullination. Development of anti-citrullinated protein antibodies (ACPA) is implicated in higher frequency of extra-articular manifestations including cardiovascular complications.(2)

Objectives: To assess the relation of ACPA to subclinical cardiac affection in RA patients.

Methods: Thirty RA patients fulfilling the 2010 ACR-EULAR classification criteria for RA with no clinically evident CVD were subjected to full history taking and clinical examination. Disease activity was assessed by 28-joint disease activity score based on C-reactive protein (DAS28-CRP) (4 variables). The levels of ACPA, CRP, total cholesterol, triglycerides, high density lipoprotein cholesterol and low density lipoprotein cholesterol were measured. The patients were subjected to M-mode and colour Doppler echocardiographic examination.

Patients were subdivided into two subgroups according to ACPA positivity (ACPA positive patients represented "group A" and ACPA negative patients represented "group B").



Results: The frequency of subclinical cardiac affection by echocardiographic examination was significantly higher among group A patients (4 patients had valvular lesion and 9 patients had diastolic dysfunction) than in group B patients (3 patients had diastolic dysfunction), (p=0.011). ACPA level showed significant positive correlation with isovolumic relaxation time (IVRT) in group A patients (prolongation of IVRT is a sign of diastolic dysfunction), (p=<0.001).

Conclusions: The presence of ACPA is related to development of subclinical cardiac involvement in RA patients and all RA patients with high level of ACPA should be routinely evaluated with echocardiography to assess their cardiovascular status.

Comparison between the two studied groups according to subclinical cardiac affection

	Group A (n=18)		Group B (n=12)		Test of sig.	p
	No.	%	No.	%		
Subclinical cardiac affection						
Present	13	72.2	3	25.0	$^{FE}\chi^2$=6.451	0.011*
Absent	5	27.8	9	75.0		

FE: Fisher Exact for Chi square test, χ^2: Chi square test. *Statistically significant at p≤0.05.

AB0352 RISK FACTORS AND SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS FEMALES COMORBID WITH HYPERTENSION

O. Kuryta, T. Lusynets, O. Sirenko. *State Establishment "Dnipropetrovsk medical academy of Health Ministry of Ukraine", Dnipropetrovsk, Ukraine*

Background: Rheumatoid arthritis (RA) associates with accelerated atherosclerosis and high cardiovascular mortality. Cardiovascular risk management in RA comorbid with HT pts is do not fully reflected by traditional risk scales, thus additional factors searching is required.

Objectives: We aimed to estimate the subclinical manifestations of atherosclerosis in RA females comorbid with HT and its relationship with traditional, additional risk factors.

Methods: The study included 112 *RA* females with comorbid *HT* (mean age of 54 [50,3; 61,5] years) and 105 *RA* females without *HT* (control group). All pts received stable therapy of RA more than 6 months. Pts with coronary artery disease were excluded. The risk of fatal cardiovascular disease was calculated using m SCORE (EULAR 2010). RA disese activity was measured using DAS28 scale. Carotid ultrasound with stiffness indexes detection and endothelial-dependent flow mediated vasodilatation (EDVD) by Celermajer method were performed. The levels of adiponectin, insulin were measured using ELISA kit test, insulin resistance was estimated using HOMA2 index.

Results: Subclinical manifestations of atherosclerosis were established in 88 (78.6%) RA females with HT and 55 (52,4%) control group pts. The majority of main group pts have atherosclerotic plaques - 62 (55.4%), unstable plaques had 26 (23.2%) pts. While only 33 (29,5%) patients were high and very high cardiovascular risk assessed by mSCORE. In compare, 35 (33,3%) control group pts have atherosclerotic plaques, unstable plaques had only 14 (13.3%) control pts (p<0.05). The presence of atherosclerotic plaques in RA females with HT was associated with age, RA disease activity, endothelial dysfunction, carotid stiffness, LDL cholesterol level, insulin resistance, adiponectin level, duration of steroid therapy. AUROC index for adiponectin and HOMA2 were 0.83 (95% CI 0.74–0.95; p<0.05 and 0.75 (95% CI 0.68–0.91; p<0.05 respectively, that indicate a good quality of diagnostic models.

Conclusions: RA females with comorbid HT are characterized by higher frequency of subclinical atherosclerosis with unstable atherosclerotic plaques in compare with controls. Endothelial function, insulin resistance, adiponectin level,

carotid stiffness determining may be useful additional tools for cardiovascular risk evaluating in this pts.

AB0353 ASSOCIATED FACTORS FOR FALLS AND FEAR OF FALLING IN AMBULATORY PATIENTS WITH RHEUMATOID ARTHRITIS: A COMPARATIVE STUDY WITH HEALTHY SUBJECTS

A. Yesim[1], Y. Ulus[1], T. Berna[1], L. Tomak[2], Y. Zahiroglu[1], A. Bilgici[1], O. Kuru[1]. *[1]Department of Physical Therapy and Rehabilitation, Faculty of Medicine; [2]Department of Biostatistics, Faculty of Medicine, Ondokuzmayıs University, Samsun, Turkey*

Background: Rheumatoid arthritis (RA) is a chronic disease that affects the bone and joints. Patients with RA migth be considered to be at increased risk of falls and FOF for a variety of reasons, including the presence of muscle weakness and stiff or painful joints of the lower extremities resulting in impaired physical activity, mobility, balance, and postural stability (1,2).
Objectives: The aim of the present study was to compare fall history and fear of falling (FOF) in patients with RA with healthy controls, and to investigate their relationships between the demographic features, severity of pain, disability, disease activity, walking velocity, balance and emotional status in patients with RA.
Methods: One hundred-twenty patients with RA and 60 healthy volunteers were included in the study. Their fall history (yes, no) and the number of falls within the last year were questioned. FOF by presence of FOF (yes/no) and by Falls Efficacy Scale-International-I (FES-I), walking time by 10 Meter Walk Test (10MWT), balance by One-Leg Stand Test (OLST) and Berg Balance Scale (BBS), emotional status by Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI) were performed in both groups. Pain severity and patient global assessment (PGA) by Visual Analogue Scale (VAS), disability by the Health Assessment Questionnaire (HAQ), disease activity by Disease Activity Score-28 (DAS-28) were evaluated in patients with RA.
Results: There was no statistically difference between the RA patients and controls in terms of presence of fall history while presence of FOF and FES-I scores were significantly high in patients. PGA, 10MWT, pain VAS, HAQ, FES-I, BAI and BDI scores were significantly high, BBS score and OLST were significantly low fallers when compared to the non-fallers in the patients ($p<0.05$). In the patient group, FES-I score was significantly correlated with pain VAS, PGA, DAS-28, HAQ, BAI, BDI, 10MWT positively, and BBS, OLST negatively ($p<0.05$). In regression analysis; the number of falls, HAQ, BBS and BDI scores were detected to be the apparent independent risk factors affecting variations in FES-I scores ($p<0.001$).
Conclusions: According to the results of our study, ambulatory patients with RA have increased FOF, disturbed balance, increased walking time and impaired emotional status compared with controls. On the other hand; walking time, pain severity, disability, scores of emotional status and PGA were higher, while the balance scores were lower in the RA patients with fallers. There were relationships between FOF and increased pain, high disease activity and anxiety level, impaired PGA, increased walking time but the most important factors associated with FOF were impaired balance, increased disability and depression, and number of falls in RA patients. Strategies for preventing falls, maintaining balance, improving emotional status and againts FOF are of the utmost importance in patients with RA.

AB0354 PREVALENCE OF SIGNS OF CONNECTIVE TISSUE DYSPLASIA IN PATIENTS WITH RHEUMATOID ARTHRITIS AND CHARACTERISTICS OF THE COURSE OF COMBINED PATHOLOGY

R. Demidov, S. Lapshina, L. Myasoutova. *Kazan State Medical University, Kazan, Russian Federation*

Background: Connective tissue dysplasia (CTD) has a common pathogenesis with rheumatoid arthritis (RA). Question of peculiarities in such combination remains little known.
Objectives: To analyze the peculiarities of RA in patients with signs of CTD.
Methods: Among the 107 patients with RA, seen in the rheumatology departments in Kazan city, 18 (16.8%) patients (15 women and 3 men, mean age 47,9±12,89 years) with reliable signs of CTD were selected, identified clinically and the analysis of their documentation was performed. By DAS28 low RA activity was detected in 1 (5.6%) patients, average - 13 (72.2%), high - 4 (22.2%). The clinical-laboratory and instrumental methods of diagnosis, standardized and independently developed questionnaire for the presence of CTD in selected group of patientswere used
Results: The most frequently following signs of CTD syndrome - vegetative-vascular dystonia - 14 (77.7%), myopia - in 9 (50%), mitral valve prolapse- in 6 (33.3%), small heart abnormalities - in 8 (44.4%), flat feet - 6 (33.3%), scoliosis - in 5 (27.7%), hyperkyphosis - in 2 (11.1%), hypermobility of joints - in 2 (11 1%), anomaly of kidney structure- in 2 (11.1%), rhythm and conduction disturbances- in 7 (38.8%). Osteoporosis was observed in 11 (61.1%) patients.
We select two group of patients: the first (n=9) from 1 to 5 CTD signes and the second (n=9) – from 6 to 9 dysplasia symptoms. In the second group RA activity by DAS28 was significantly ($p\leq0.05$) higher (4.52±1,20) than in the first (DAS28 =3.95±0.81). Obtained differences in RA activity, depending on the availability of myopia (DAS28 =4,68±0,87) or its absence (DAS28 =3,78±1,06); flatfoot (DAS28 =4,53±1,05) or its absence (DAS28 =4,04±1,02) were evaluated. A significant ($p\leq0.05$) difference was found in patients with osteoporosis, the availability for activity (DAS28 =4.68±0.97), pain intensity VAS (1,44sm ± 6.90), compared with normal bone density tissue (DAS28 =3,36±0,36, pain VAS =5,83±2,22 cm).
Conclusions: Among patients with RA CTD signes occur more frequently than in the population (16.8% versus 10%). The most frequently detected are myopia, vegetative-vascular dystonia, cardiac diseases, osteoporosis. Patients with signs of dysplasia had a trend towards a higher activity of RA.

AB0355 MUSCLE POWER AND FALL RISK IN RHEUMATOID ARTHRITIS

R. Dietzel, D. Felsenberg, G. Armbrecht. *Centre of Muscle and Bone Research, Charite, Berlin, Germany*

Background: One of the serious consequences of aging is the gradual loss of muscle function, a phenomenon called sarcopenia. Skeletal muscle power refers to the ability to generate high-velocity movements and current evidence suggests that it declines earlier with advancing age [1] and is more strongly related to functional status than muscle force [2]. A decreased capacity for high-velocity movements in the legs has been linked to delayed responses in maintaining postural stability and thus with age-associated fall risk [3]. People with rheumatoid arthritis (RA) may be at high risk of falling due to disease-related impairments such as pain, joint deformity, muscle weakness, altered gait and decline in postural stability.
Objectives: As role of muscle power in fall-risk assessment of RA patients has not been investigated, so far, the aim of the present study was to determine the association between muscle power, muscle force, functional performance and falls in the last 12 months in RA patients.
Methods: 98 subjects with RA older than 60 years from a cross-sectional study on the prevalence of corticoid-induced osteoporosis in Germany (PSIO-D Berlin) and 98 age-matched controls without inflammatory disease, randomly chosen from a cross-sectional study collecting reference values for body composition, were analyzed in this case-control study. Muscle function was determined by muscle power per body mass in vertical countermovement jumps ($2LJP_{rel}$) on a force plate, the chair rise test (CRT), gait speed, grip strength and the Short Physical Performance Battery. Differences in muscle function measures between the RA group and the healthy reference were derived separately by sex with Student-T-test or Mann-Whitney-U-test. Using logistic regression adjusted for age and sex the association between muscle function and falls was determined.
Results: In bivariate analysis RA patients showed significantly weaker performance in all muscle function tests compared to controls in both sexes. Applying logistic regression, age (OR 1.10, 95%>CI 1.00–1.24) and female sex (OR 5.99, 95%>CI 1.25–28.57) were significantly associated with retrospective falls in RA subjects but not in controls. Gait speed (OR 0.09, 95%>CI 0.01–0.88) remained a significant correlate for falls independent of age and sex in RA patients. In controls only the CRT (OR 1.13, 95%>CI 1.02–1.26) could differentiate individuals who had past fall events in the age and sex adjusted model. No association was found for the $2LJP_{rel}$ and retrospective falls.
Conclusions: The results of the present study could not confirm an association between fall risk and muscle power in RA patients, but they highlight the importance of monitoring neuromuscular function such as gait speed, in order to prevent falls and consequently to prevent fractures, contributing to a better prognosis of rheumatic disease.

AB0356 ASSOCIATION BETWEEN CARDIOVASCULAR RISK FACTORS AND CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. González Mazarío[1], J.J. Fragio Gil[1], J. Ivorra Cortes[1], C.M. Feced Olmos[1], F.M. Ortiz-Sanjuan[1], E. Grau Garcia[1], E. Labrador Sánchez[1], S. Huerta Barberá[2], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], I. Martínez Cordellat[1], I. Chalmeta Verdejo[1], L. Gonzalez Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Vicens Bernabeu[1], J.E. Oller Rodriguez[1], V. Fornés Ferrer[3], J.A. Román Ivorra[1,2]. *[1]Rheumatology Department, HUP la Fe; [2]Medical School, UCV; [3]Biostatistic Unit, IIS la Fe, Valencia, Spain*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease which affects 0.5% of adults, especially women. This disorder is associated with increased morbidity and mortality due to atherosclerotic cardiovascular diseases. In addition to classical cardiovascular risk factors, inflammation plays a key role in this fact. Intima-media thickness (IMT) measured by carotid ultrasound is currently used to detect the presence of atherosclerotic disease and its value could be a predictor of subclinical cardiovascular disease.
Objectives: To study cardiovascular risk factors, disease activity and carotid IMT in a RA patients series.
Methods: Cross-sectional observational study of patients diagnosed with RA according to ACR/EULAR 2010 criteria. Patients with age under 75 years old and up of 5 years of disease evolution were included. Cardiovascular established disease patients were excluded. During a unique visit, patients underwent anamnesis, physical examination, laboratory test, electrocardiogram, chest X-ray and carotid ultrasound with *Esaote-MyLabClassC* equipment. Statistical analyses were performed using software R (version 3.3.2).
Results: A total of 31 patients (57.1±9.7 years, 83.6% female, with 19.2±11.2 years of average disease course) were included. In relation to the classic cardiovascular risk factors, 19.4% were active smokers, 41.9% hypertensives and 45.2% had hypolipidemic treatment (85.7% with a statin), three of the patients were diabetic (9.7%). All patients were treated with monotherapy or combination therapy and 41.9% were also given glucocorticoid at low doses during the last 6 months. The median DAS28-VSG was 2.49 (1ºQ=1.6; 3ºQ=3.9), with an average HAQ of 0.88±0.68. As for extra-articular manifestations, 45.2% had xerophthalmia, 29% xerostomia, and 19.4% had rheumatoid nodules. The median total cholesterol was 195 mg/dL (174–221), and LDL of 116 mg/dL (96.5–138). The mean of the right carotid IMT was 576.13±118.78 mm and the carotid left IMT was 616.32±134.31 mm, resulting in 12 determinations higher values than expected to their age and sex provided by the ultrasound developer (38.7%). Using the SCORE table (modified by EULAR), only 5 patients (16.1%) had moderate-to -high cardiovascular risk. Statistical analysis showed a significative association between an increased IMT with tobacco consumption (classic cardiovascular risk factor) (p=0.028) and the modified SCORE (p=0.04). Neither years of evolution of disease nor the analytical biomarkers showed a significant association.
Conclusions: Our study shows that in patients with good disease control data, classic cardiovascular risk factors are related to increased carotid intima-media thickness. However, these factors may underestimate overall cardiovascular risk over other measures of subclinical cardiovascular disease, such as carotid IMT.

AB0357 SEXUALITY IN WOMEN WITH RHEUMATOID ARTHRITIS - RESULTS OF A SURVEY

R. Puchner[1], J. Sautner[2], J. Gruber[3], A. Trenkler[4], E. Bragagna[5], G. Eberl[6], A. Alkin[7], H. Pieringer[8]. *[1]Rheumatologist in private practice Wels, Wels; [2]Lower Austrian State Hospital, Stockerau, Stockerau; [3]Medical University of Innsbruck, Innsbruck; [4]Elisabethinen Hospital Linz, Linz; [5]Specialist in Sexual Medicine in private practice Vienna, Vienna; [6]Klinikum Malcherhof Baden, Baden bei Wien; [7]Centre of Excellence in Medicine Linz; [8]2nd Department of Medicine, General Hospital Linz and Faculty of Medicine, Johannes Kepler University Linz, Linz, Austria*

Background: Diseases such as rheumatoid arthritis (RA) are distinguished by their chronic and progressive characteristics; they may lead to premature loss of joint function and constitute major social, economic and health burdens. Rheumatic diseases may affect all aspects of life including patients' sexuality.
Objectives: The objective of the study was to evaluate the impact of RA on women's sexuality regarding sexual motivation, activity, and satisfaction and to assess the correlation of disease related physical impairment within sexual functioning.
Methods: A group of rheumatologists, a sociologist and a specialist in sexual medicine initiated a substantial survey, including standardised questionnaires. The items asked were assessments of disease activity with the Clinical Disease Activity Index (CDAI) and measurements of illness and medically induced changes in sexual functioning with the Changes in Sexual Functioning Questionnaire-short form (CSFQ-14). Levels of depression were evaluated with the Beck Depression Inventory FastScreen (BDI FastScreen) and to establish disability the Health assessment questionnaire (HAQ) was used. Further questions were concerning demographic and health related data such as comorbidities, medication, alcohol and smoking habits.
Results: 319 questionnaires were distributed to RA-patients and 319 to healthy controls (HCOs). 235 questionnaires from patients (73, 7%) and 180 HCO-questionnaires (58, 8%) were sent back.
Women with RA had a significantly lower CSRQ Score than HCOs. 48% of the patients had a total CSFQ score of $\leq$41, which is defined as an indicator of sexual dysfunction. However, only 14% of the healthy respondents scored similarly.
29.3% of the surveyed patients were in remission, 45.1% in low disease activity, 18.9% in a moderate disease activity and 6.8% in high disease activity. There was no relationship between CDAI and CSFQ.
Age and level of education were the most important demographic parameters connected with sexual dysfunction. There was also a moderate and significant relationship between depression and sexual dysfunction.
A significant correlation between the HAQ index and the level of sexual dysfunction was to be observed.
Conclusions: Due to the lack of substantive surveys in this field, we tried to undertake a comprehensive study covering sexual dysfunction in women with RA. The study shows that RA has a significant effect on the sexuality of women, compared to healthy individuals.

AB0358 PATIENTS WITH EARLY RHEUMATOID ARTHRITIS HAVE INCREASED CARDIOVASCULAR RISK AT THE TIME OF DIAGNOSIS

R. Davies[1], C.R. Thompson[1], H.S. Jin[1], E.A. Ellins[2], J.P. Halcox[2], A.S. Williams[1], E.H.S. Choy[1]. *[1]CREATE centre, Institute of Infection and Immunity, Cardiff University, Cardiff; [2]Institute of Life Sciences, Swansea University Medical School, Swansea, United Kingdom*

Background: Cardiovascular (CV) mortality in patients with rheumatoid arthritis (RA) is up to 50% higher than the general population. Whilst traditional CV risk factors such as smoking, diabetes and hypertension contribute to this increased mortality in RA, they do not fully explain the increase in risk. The British Society for Rheumatology, National Institute for Health and Clinical Excellence and European League Against Rheumatism (EULAR) recommend annual assessment of CV risk in RA patients. Furthermore, EULAR recommends multiplying such traditional CV risk scores by 1.5 for RA patients who meet two of three criteria consisting of (1) disease duration >10 years, (2) positive rheumatoid factor or anti-cyclic citrullinated peptide (anti-CCP) serology, (3) presence of severe extra-articular manifestation, to account for the unexplained increased CV risk in RA.
Objectives: This study assessed CV risk by QRISK2 score and used carotid ultrasound to determine cardiovascular risk and prevalence of subclinical atherosclerosis at the time of diagnosis of RA.
Methods: Patients $\geq$18 years-old with early RA, defined by ACR/EULAR 2010 criteria and diagnosis of RA <6 months were recruited from The University Hospital of Wales, Cardiff. Exclusion criteria included definite other autoimmune or inflammatory rheumatic disease, ACR Classification of Functional Status stage IV, previous history of CV disease and diabetes mellitus. Demographic details were collected, blood pressure, body mass index, ESR, CRP and lipid profile were measured and QRISK2 was calculated. Carotid ultrasound was performed and mean carotid intima media thickness (CIMT) and presence of plaque were measured. The study was approved by Research Ethics Committee for Wales (11/WA/0326).
Results: 40 patients, 10 males and 30 females with early RA were recruited. Mean age was 55.7±14.8 years. Rheumatoid factor and anti-CCP antibodies were positive in 62% and 80% of patients respectively. Mean BMI was 27.2±5.9. Twenty-nine percent were current smokers. Mean DAS28 was 3.8±1.3. According to the QRISK2, 54% of patients had >10% risk of CV disease over 10 years. Carotid ultrasound was conducted in 35 patients. Mean CIMT was 0.71±0.19 mm. 10 patients (29%) had carotid plaques. Fourteen patients (40%) had either plaque or CIMT >0.9mm, both considered markers of high CV risk. These patients were termed "ultrasound positive" patients. The sensitivity and specificity of the QRISK2 to predict US positive patients was 82% and 56% respectively. The positive predictive value of the QRISK2 was 63% and the negative predictive value of the QRISK2 was 88%. No patients met >1 criteria for EULAR adjustment of risk as all patients had early RA and none had severe extra-articular manifestations.
Conclusions: Many patients with early RA have significant CV disease at the time of diagnosis. This suggests subclinical CV disease may be developing before patients become symptomatic. More than half of the patients with early RA fulfil current NICE guidelines for starting lipid-lowering therapy, although of these, over one-third had no subclinical disease on carotid ultrasound. There is scope to improve the sensitivity and specificity of the QRISK2 calculation in RA patients, perhaps with a biomarker.

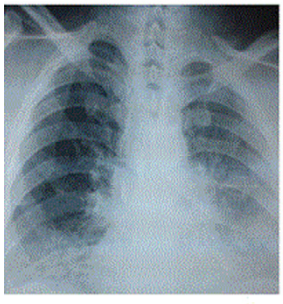
AB0359 ASSESSING DEPRESSION IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS-HOW DO DIFFERENT APPROACHES COMPARE?

S.L. Hider[1,2], S. Ryan[1], N. Dale[1], N. Stanyer[1], A. Machin[2], C.A. Chew-Graham[2,3]. *[1]Haywood Academic Rheumatology Group, Haywood Hospital, Staffordshire; [2]Research Institute Primary Care and Health Sciences, Keele University, Keele; [3]Collaboration for Leadership in Applied Health Research and Care (CLARHC), West Midlands, United Kingdom*



Background: Depression is common in patients with rheumatoid arthritis and negatively impacts on their quality of life and disease outcomes, including disease activity and treatment response. Several case-finding tools for depression are available, including the PHQ2, which is both valid (1) and easy to use.
Objectives: The aim of this study was to compare the prevalence of depression using case finding tools and self-report measures in patients with established RA.
Methods: Patients with established RA, attending a nurse-led annual review clinic, which aimed to offer patients a holistic review, were asked to complete a short questionnaire including demographics and self-reported comorbidity. The presence of depression was assessed in 3 ways a) PHQ2 score $\geq$3 b) Self recorded "ever" depression using the self-administered report comorbidity questionnaire (2) and c) Self report health status using the EQ5D - which includes a statement regarding current anxiety/depression (dichotomised into no anxiety/depression vs. slight/moderate/severe/extremely anxious or depressed. Ethical approval was obtained (15-WS-0063).
Results: 179 RA patients provided data. Of these 119 (66%) were female and the mean (sd) age was 67.1 (11.7) years. 59 patients (33%) reported they had ever had depression using the self-report comorbidity questionnaire and 25 (14%) indicated they were currently receiving treatment. 68 (38%) indicated they were currently slightly (or more) anxious or depressed when assessed with the EQ5D. 37 (21%) scored positively on the PHQ2. There was good concordance between the PHQ2 and EQ5D at higher levels of depression, in that all those with severe or extreme anxiety or depression on EQ5D also scored positively on the PHQ2. However, of those with moderate anxiety/depression on EQ5D, 4/14 patients scored less than 3 using the PHQ2 score.
Conclusions: Depression is common in patients with established RA. Use of the PHQ2 case-finding questions in patients with established RA, may help clinicians identify patients who may benefit from more detailed assessment of mood and interventions to improve their outcomes. Reliance should not be placed on a single tool, and exploration of mood should be part of routine assessment of a patient with RA.

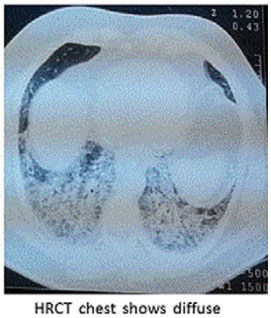
AB0360 CLINICAL AND HIGH RESOLUTION CT STUDY OF THE LUNGS IN 96 EGYPTIAN PATIENTS WITH RHEUMATOID ARTHRITIS



S. Tharwat, D. Shahin, A. Abdesalam, A.F. Barakat. *Internal Medicine (Rheumatology &Immunology), Mansoura University Hospital, Mansoura, Egypt*

Background: Lung involvement is a common extra-articular manifestation of rheumatoid arthritis (RA) that confers significant morbidity and mortality. However, this issue has not been sufficiently studied in Egyptian patients.
Objectives: To assess the prevalence of pulmonary abnormalities by high resolution computed tomography (HRCT) chest in RA patients and their association with clinical variables.
Methods: Ninty-six patients with RA were assessed regarding their age, gender, duration of RA disease, sicca symptoms, presence of subcutaneous rheumatoid nodules, rheumatoid factor, respiratory symptoms, use of medications, disease activity of RA using Disease Activity Score 28 (DAS28), basic laboratory investigations and pulmonary abnormalities in plain x-ray and HRCT.
Results: HRCT abnormalities were identified in 25% of the patients; 58.3% had respiratory symptoms while 41.7% were subclinical. Dyspnea and cough were the most frequent symptoms. HRCT abnormalities were interstitial lung disease (ILD) in 11 patients (11.5%), pleural involvement in 8 patients (8.3%), consolidation in 4 patients (4.2%), diffuse alveolar hemorrhage in 3 patients (3.1%), bronchiectasis in 2 patients (2.1%), and apical fibrosis with cavitation in only 1 patient (1%). Patients with dyspnea, cough, chest rales, cutaneous rheumatoid nodules, and who received disease modifying antirheumatic drugs (DMARDs) combination were more likely to have HRCT abnormalities.
Conclusions: Pulmonary involvement is not uncommon in RA patients, and HRCT is a sensitive tool in pulmonary evaluation.
Disclosure of Interest: None declared

44 year old male RA patient diagnosed as RA 5 years ago

Chest x-ray shows reduced lung volumes with bilateral reticular opacities

HRCT chest shows diffuse reticulo-nodular shadows suggestive of interstitial lung disease

AB0361 BODY COMPOSITION AND PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS (AR)

S. Manrique-Arija, N. Mena-Vazquez, M. Rojas-Giménez, C. Fuego, S. Abad-Sanchez, I. Ureña-Garnica, C. Domic, F.G. Jiménez-Núñez, M.C. Ordoñez-Cañizares, R. Caparros-Ruiz, L. Cano-Garcia, A. Belmonte, B. Panero-Lamothe, A. Fernandez-Nebro. *Department of Rheumatology at the University Regional Hospital of Malaga (HRUM). Institute for Biomedical Research in Malaga (IBIMA). Malaga University., Malaga, Spain*

Objectives: To describe the body composition and physical activity of patients with RA
Methods: *Design:* Observational case-control study. *Population:* 31 consecutive RA-patients (ACR/EULAR 2010 criteria) selected from a prospective inception cohort (diagnosis of RA between 2005 and 2012),and 31 sex and age-matched voluntary controls.*Protocol:* We included 62 subjects who were assessed using dual-body X-ray absorptiometry (DEXA) for the assessment of body composition at study entry. Data on clinical activity were also collected from the onset of the disease.The level of physical activity was assessed according to the abbreviated protocol of the International Physical Activity Questionnaire (IPAQ). *Main outcome:* Fat mass index (FMI) and fat free mass index (FFMI).FMI was defined as fat mass (kg)/ height (m^2) and FFMI as lean mass (kg)/height (m^2).*Secondary outcome:* description of the anthropometric parameters:BMI (body mass index),waist-hip index. *Variables:* Demographic, treatment, clinical-analytical variables: Disease Activity Score of 28 joints (DAS28-ESR), Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI);Anti–cyclic citrullinated peptide (ACPA), Rheumatoid factor (RF),Health Assessment Questionnaire (HAQ)and erosions.BMI was categorized according to the OMS classification. Waist- hip index (central obesity>1 for men and>0.8 for women). *Statistical analysis:* Descriptive and paired T-test or ranks test and Wilcoxon signed rank,as required
Results: We included 62 subjects,31 RA (50%) and 31 controls (50%).The mean duration of the disease of RA patients was 84.4 months. With a DAS28 mean of 3.04 (0.8), mean HAQ of 0.77 (0.6). The majority presented erosions (64.5%) RF (83.9%) and ACPA (77.4%) positive. Differences in clinical and densitometric anthropometric parameters between cases and controls are shown in Table 1. Significant differences were observed in the proportion of overweight subjects between cases and controls (p=0.03). A higher percentage of controls had moderate to high physical activity compared with the patients (65.5% vs 34.8%). The majority of patients with RApatients had low physical activity (74.2%).These had a mean (SD) of HAQ higher than patients with moderate-high physical activity [1.2 (0.9) vs 0.66 (0.6); p=0.09].Finally, patients performing moderate-high physical activity had less inflammatory activity than those performing low physical activity,with a DAS28 mean of 2.69 (0.7) vs 3.08 (0.9) ;p=0.308, respectively

Variable	Cases (n=31)	Controls (n=31)	P
Age (years), mean (SD)	53.6 (12.1)	53.6 (12.3)	0.999
Sex (Female), n (%)	27 (87)	27 (87)	1
Body mass index (BMI), mean (SD)>25 n (%)	25 (80.6)	17 (54.8)	0.03
Waist perimeter (cm), mean (SD)	88.7 (13.2)	89.1 (14.4)	0.891
Hip perimeter (cm), mean (SD)	103.9 (9.5)	106.8 (15.8)	0.395
Waist-hip index, mean (SD)	0.85 (0.1)	0.84 (0.1)	0.653
– Total fat (kg), mean (SD)	28.2 (9.3)	29.1 (10.9)	0.737
– Total lean (kg), mean (SD)	39.5 (7.6)	38.2 (9.6)	0.555
– Total mass (kg), mean (SD)	70.08 (13.8)	69.2 (15.5)	0.817
FMI (%) median (p25-p75)	10.44 (8.3–12.4)	9.51 (8.2–13.8)	0.882
FFMI (%) median (p25-p75)	14.27 (13.1–15.8)	13.83 (13.1- 15.7)	0.522

Conclusions: Patients with RA compared to controls show more overweight and less physical activity
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6056

AB0362 ANALYSIS OF INSULIN RESISTANCE IN A RHEUMATOID ARTHRITIS INCEPTION COHORT: CASE-CONTROL STUDY

S. Manrique-Arija[1], N. Mena-Vázquez[1], I. Ureña[1], S. Abad[2], M. Rojas-Gimenez[1], L. Ginel[2], L. Cano-Garcia[1], C. Fuego[1], C. Domic[1], M.C. Ordoñez-Cañizares[1], F.G. Jimenez-Nuñez[1], G. Diaz-Cordoves[1], A. Belmonte[1], V. Coret[1], M.V. Irigoyen[1], A. Fernandez-Nebro[1]. *[1]Department of Reumatology at the University Regional Hospital of Malaga (HRUM). Institute for Biomedical Research in Málaga (IBIMA). Malaga University; [2]Ciudad Jardín (Guadalmedina) Health center. Hospital Regional de Málaga., Málaga, Spain*

Objectives: To describe insulin resistance (IR) in patients with rheumatoid arthritis (RA) and compare it with healthy controls and to analyze the association between the accumulated inflammatory burden in patients with RA and IR.
Methods: *Design:* Observational case-control study. *Population:* consecutive RA-patients (ACR/EULAR 2010 criteria), >16 years, selected from a prospective inception cohort (diagnosis of RA between 2007 and 2011). Patients with Diabetes Mellitus (according to ADA 2010 criteria) were excluded. *Controls:* sex- age and BMI -matched controls were collected from a health center in our hospital area. *Protocol:* Cases and controls were evaluated by a rheumatologist. Clinical data of disease activity (RA patients), analytical values and oral glucose tolerance test (OGTT) were determined. All participants signed informed consent. *Main outcome:* IR measured by the homeostasis model for insulin resistance (HOMA-IR) (IR>2.29 μU * mmol/ml). *Secondary outcome:* IR measured by quantitative insulin sensitivity check index (QUICKI) (<0.337μU * mmol/ml) and by the homeostatic model assessment of β-cell function (HOMAβ). *Variables:* Demographic, clinical-analytical variables, Disease Activity Score of 28 joints (DAS28-ESR), Health Assessment Questionnaire (HAQ), BMI (according to OMS classification) and glucose and insulin before and after OGTT values. *Statistical analysis:* Descriptive and paired T-test or Chi-square test followed by binary logistic regression in RA patients (Dependent variable: Insulin Resistance).
Results: Sixty-two subjects were studied, 8 of them were excluded after OGTT (4 diabetic patients and their respective controls). Finally, 54 subjects were included; 27 RA and 27 healthy controls. The mean age of patients with RA was 52.2 (12.1) years. Most of them were women (88.9%), with seropositive (FR 81.5% and ACPA 74.1%) and erosive (63%) RA. The mean duration of the disease was 85.6 months (27.1) and mean DAS 28 index since the onset of the disease of 2.98 (0.9).
Differences between clinical characteristics and in relation to IR between cases and controls are shown in Table 1. No significant differences in the proportion of subjects with IR in cases and controls were observed. 33.3% of patients with RA had IR. In multivariate analysis, the only independent variable associated with IR in RA patients was disease activity score (DAS28) (OR [95% CI] = 3.6 [1.0–12.9], p=0.045).

Table 1

VARIABLE	CASES n=27	CONTROLS n=27	P - VALUE
Age, years; mean(±SD)	52.2(12.0)	52.3(12.3)	0.979
Sex, women; n(%)	24(88.9)	24(88.9)	1
Comorbidities			
BMI > 30 (obesity) n(%)	5(18.5)	4(14.8)	0.715
BMI, mean(±SD)	26.7(4.6)	26.3(5.4)	0.776
Waist perimeter(cm), mean(±SD)	88.7(13.2)	89.1(14.4)	0.891
Hip perimeter (cm), mean(±SD)	103.9(9.5)	106.8(15.8)	0.395
Dyslipemia, n(%)	5(18.5)	7(25.9)	0.513
Hypertension, n(%)	3(11.1)	6(22.2)	0.273
Insulin Resistance Indexes			
HOMA-IR>2,25, n(%)	9(33.3)	7(25.9)	0.551
HOMA-IR, mean(±SD)	1.9(10)	1.7(1.1)	0.514
HOMA-β, mean(±SD)	41.03(22.3)	37.7(25.26)	0.630
QUICKI, mean(±SD)	0.35(0.0)	0.36(0.0)	0.255

Conclusions: The only predictor of IR in RA patients was the inflammatory activity measured by DAS28. We did not find a higher IR in RA patients than in healthy controls, it could be because the patients were well treated and the inflammatory activity was controlled in the most of them.
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6469

AB0363 RESULTS OF SCREENING FOR VIRAL HEPATITIS IN RA PATIENTS TREATED WITH BIOLOGICS: HUR-BIO REAL LIFE RESULTS

A. Sari, B. Armagan, A. Erden, L. Kilic, A. Akdogan, S. Apras Bilgen, I. Ertenli, U. Kalyoncu, S. Kiraz. *Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Turkish Society of Rheumatology (TSR) proposed a guideline of recommendations for viral hepatitis screening before biological therapy in 2015.[1]
Objectives: The aim of this study was to assess results of viral hepatitis serological tests performed before biologics in RA patients.
Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective,single center database of biological treatments including 1229 RA patients by August 2016. Results of serological tests for HBV of 468 RA patients were evaluated. The guideline includes 5 groups according to hepatitis B virus (HBV) serology; group 1 –HBV seronegative [HbsAg (-),anti HbS (-), anti-Hbc total (-)], group 2-vaccinated [HBsAg (-), anti-HBs (+), anti-HBc total (-)], group 3-previous HBV infection [HBsAg (-), anti-HBs (-), anti-HBc total (+)], group 4-Chronic HBV infection [HBsAg (+), anti-HBs (-), anti-HBc total (+)], group 5-secondary immunity [HBsAg (-), anti-HBs (+), anti-HBc total (+)]. Patients were also classified according to risk for HBV reactivation as very high risk (Group 4 patients receiving rituximab), high risk (group 3 patients receiving rituximab) and medium risk (Group3 or Group 4 patients receiving TNFi or T-cell blockers,IL12/23 pathway inhibitor). Screening results for hepatitis C virus (HCV) were also evaluated.
Results: Among 1229 patients (79.7% female), mean age was 54.9±11.7 and mean disease duration was 12.3±8.2 years. In total, 104 (22.2%) of patients had received rituximab. Serology for HbsAg, anti-Hbs and anti-HbC were avaliable in 468 patients. There were 273 (58.3%) patients in group 1, 81 (17.3%) in group 2, 19 (4.1%) in group 3, 9 (1.9%) in group 4 and 86 (18.3%) in group 5. Table 1 represents distribution of patients according to HBV reactivation risk. Anti-HCV was positive in 21 (2.5%) of patients.

Table 1. Distribution of patients according to HBV reactivation risk

HBV reactivation risk (%)	N (%)
Very high risk (>%20)	2 (%0.4)
High risk (%11–20)	22 (%4.7)
Medium risk (%1–10)	81 (%17.3)
No risk	363 (%77.6)

Conclusions: Among patients registered in HUR-BIO, 1.9% had chronic HBV infection and 2.5% anti-HCV positivity. 5.0% of them were under high and/or very high risk for HBV reactivation. Medium risk group which includes 17.0% of patients, seems to deserve most of the attention. Screening for viral hepatitis must be performed before biologics and TSR guideline may be useful in this matter.

AB0364 CHARACTERISTICS OF BLOOD PRESSURE PHEHOTYPES IN PATIENTS WITH RHEUMATOID ARTHRITIS - EULAR

S. Velmakin, E. Troitskaya, S. Villevalde, Z. Kobalava. *Propaedeutics of Internal Diseases, Rudn University, Moscow, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) have increased cardio-vascular risk. Arterial hypertension (AH) is highly prevalent, and seems to be under-diagnosed and under-treated among patients with RA. Data on ABPM profile in patients with rheumatoid arthritis are lacking.
Objectives: The aim of the study was to evaluate ABPM parameters and characterize phenotypes of blood pressure (BP) in patients with RA.
Methods: 62 patients with RA (EULAR 2010) without known cardio-vascular disease were examined (73% females, age 58,5±15,4 (M±SD) years, 13% smokers, 61% with AH, 34% with dyslipidemia). Median duration of RA was 8 years (IQR 3–17). Seropositive RA was diagnosed in 69% of patients. Median CRP was 12,1 mg/dl (IQR 2,2–23,4 mg/dl), median rheumatoid factor (RF) was 32,5 IU/ml (IQR 8,3–173 IU/ml). All patients received disease-modifying antirheumatic drugs (DMARDs), 22 (38%) - biological treatment. Median duration of AH was 6,1 years (IQR 0–10 years). All patients with AH received antihypertensive treatment. 24-h peripheral and central BP monitoring was performed (BPLab Vasotens, “Petr Telegin”). P<0.05 was considered significant.
Results: Mean office BP was 130±15/80±10 mmHg (peripheral) and 123±21/80±10 mmHg (central). 10 (17%) patients had elevated office BP (>140/90 mmHg). Mean BP values for peripheral and central BP were as follows: 125±15/73±9 and 116±14/75±9 mmHg for 24-h BP; 127±15/74±9 and 117±14/77±9 mmHg for daytime BP; 119±15/69±10 and 112±15/70±10 mmHg for nighttime BP. AH according to daytime BP was found in 15 (24,2%) pts, nighttime BP – in 29 (46,8%) pts, 24-h BP - in 19 (30,6%) pts. Phenotypes of BP were as follows: sustained normotension – in 38 (61,2%), masked hypertension in 12 (19,4%), sustained AH – in 10 (16,1%), white-coat hypertension in 2 (3,2%) patients. Isolated nocturnal AH was observed in 12 (19,4%) pts. 10 (16,1%) patients had isolated elevated central BP. 20 (32,3%) pts had elevated central SBP according to individual reference values; all patients with high office BP had elevated central BP.
Conclusions: Patients with RA free of CVD are characterized by high prevalence of with the satisfactory control of office BP in the majority of patients. Relatively high prevalence of masked and isolated nocturnal hypertension despite antihy-pertensive treatment is observed in this population. These findings may help to optimize hypertension treatment in patients with RA.

AB0365 HENOCH-SCHÖNLEIN PURPURA IN TUNISIAN ADULTS: MONOCENTRIC STUDY

S. Hammami, M. Nasr, N. Sassi, R. Klii, M. Kechida, I. Kochtali. *Internal medicine, University Hospital F Bourguiba Monastir, Monastir, Tunisia*

Background: Henoch-Schonlein purpura (HSP) is a non thrombopenic leucocytoclasic acute systemic vasculitis of the small vessels with IgA-immun complex deposits, most commonly affecting the skin, joints, gastro-intestinal tract and the kidneys. It commonly affects the children aged between 4 to 10 years. The occurrence of HSP in adults is significantly less frequent with atypical profile, and more serious complications.
Objectives: Analysis of the clinical presentations, biological characteristics, treatment and evolutions of HSP in this population, compared with other tunisian and international studies.
Methods: This is a monocentric retrospective study using an operating record data from 30 adult patients aged 16 to 82 years hospitalized for HSP in Internal Medicine Department in Monastir university hospital between May 2005 to July 2015. Inclusion criteria's where those defined in 2006 by the European League Against Rheumatism (ELAR) and the Pediatric Rheumatology European Society (PRES) for the diagnosis of HSP.
Results: Thirty patients with Henoch-Schönlein purpura (18 women and 12 men) were included in the study. The mean age at onset of the disease was 48.80±18.77 years (16 -82 years). The vascular purpura was the most frequent inaugural clinical manifestation (90%). It was diffuse and necrotic in 3.3% of cases. Cutaneous biopsy practiced in 26 cases (86.6%), found leukocytoclastic vasculitis in 21 cases (80.7%). Joint involvement was present in 80%: Inflammatory arthralgia in 56.6% and arthritis in 23,3%. Sixteen patients (53.3%) had gastro-intestinal involvement: Gastric and duodenal ulcers, occlusive syndrome, gastrointestinal bleeding and pancreatitis in 26,6%, 16,6%, 10% and 3,3% respectively. Eighteen patients (60%) had renal involvement. Nephritic syndrome was observed in thirteen patients (43,33%). Hematuria was objectified in 11 patients. Four patients had renal failure (13,33%). The renal biopsy practiced in 4 cases, objectified IgA nephropathy in 3 patients and glomerulonephritis extra-capillary in 1 case. Interstitial lung disease with bilateral pleurisy was observed in a patient. A woman had a cerebral vasculitis. Corticosteroids were prescribed in 8 patients for gastrointestinal and renal impairment. Two patients received cyclophosphamide cures for cerebral vasculitis and severe digestive impairment. Anti-inflammatory drugs were prescribed in 9 cases. A favorable spontaneous development was observed in 9 patients. A recurrence was reported in 2 cases. One patient dead by severe sepsis.
Conclusions: HSP manifests in adult patients as a more severe and atypical disease with more relapses and more frequent and severe gastro-intestinal and renal disease. HSP in adults requires a sustainable monitoring and more aggressive treatment

AB0366 "I JUST WANT MY LIFE BACK": PHYSICAL FUNCTION AND FATIGUE ARE CRITICAL TARGETS FOR IMPROVING PARTICIPATION AND HRQL IN RHEUMATOID ARTHRITIS

S.J. Bartlett[1,1], A. Sirois[2], N. Chiarlitti[2], M. Inceer[2], M. Jones[3], C.O. Bingham[3]. *[1]Medicine; [2]Mcgill University, Montreal, Canada; [3]Johns Hopkins, Baltimore, USA*

Background: The primary goal of treatment for rheumatoid arthritis (RA) is to maximize health-related quality of life (HRQL) through symptom and damage control, and normalize function and participation in social and life activities. Although fatigue is recognized as one of the most debilitating symptoms of RA, little is known about how fatigue impacts participation.
Objectives: We hypothesized that fatigue, along with pain, mood, disease activity, and disability would be associated with reduced participation.
Methods: RA patients enrolled in an observational study at an academic center completed PROMIS measures assessing fatigue, physical function, mood (depression and anxiety), pain interference, sleep disturbance, and participation. RA clinical indicators were also collected at the visit. Variance inflation factors were examined to evaluate collinearity among variables. Covariates/confounders independently associated with participation included pain, mood (depression, anxiety), sleep, disease activity (CDAI), and physical function. Multiple regression models that did and did not include pain were compared using likelihood ratio tests with SPSS and R.
Results: Participants were mostly female (82%) and white (83%) with mean (SD) age of 56 (13) years; 24% had $\leq$ high school, 29% had RA $\leq$5 years with 13% $\leq$2 years, and 22% were disabled. Mean CDAI was 7.9 (7.8). Most were in CDAI remission (n=56; 32%) or LDA (n=67; 38%); 39 (22%) were in MDA and 14 (8%) in HDA. Mean PROMIS fatigue was 53.9 (10.0); fatigue increased across CDAI levels from 46.2 (8.6) in remission to 64.0 (9.6). Only those with HDA had mean sleep, depression or anxiety scores $>$55 (i.e., above population norms).
In the full model, fatigue, depression, CDAI, and physical function were significant independent predictors of reduced participation in social roles and activities ($F(2, 162) = 29.75$, $p < .001$, adjusted $r^2 = .55$). Contrary to our hypothesis, pain was not associated with participation in univariate or multivariate models.
Conclusions: Our results suggest that in RA patients, high levels or fatigue are common; conversely, depression, anxiety, and sleep disturbance were elevated only in people with HDA. Disability and fatigue appear to have the greatest impact on participation in social roles and activities. RA treatments and interventions that attenuate fatigue and improve mood in people with active RA may improve their ability to participate in social and life situations restoring a sense of normalcy and improving HRQL.

AB0367 THE PROPHYLACTIC EFFECT OF SULFASALAZINE AGAINST PNEUMOCYSTIS PNEUMONIA: AN ANALYSIS OF INCIDENCE FOR PNEUMOCYSTIS PNEUMONIA IN PATIENTS WITH RHEUMATOID ARTHRITIS IN JAPAN

T. Nunokawa, N. Yokogawa, K. Shimada, S. Sugii. *Department of Rheumatic Diseases, Tokyo Metropolitan Tama Medical Center, Fuchu-shi, Japan*

Background: Cases with *Pneumocystis* pneumonia (PCP) have been reported in patients with rheumatoid arthritis, mainly treated with biologics. An experimental study in the mouse revealed that sulfasalazine enhances the clearance of the *Pneumocystis* organism from the lung (1). Furthermore, a case-control study with small sample size indicated possible preventive effect of sulfasalazine against PCP (2).
Objectives: The aim of this study is to clarify the prophylactic effect of sulfasalazine against PCP in patients with rheumatoid arthritis with a large sample size.
Methods: This retrospective study focused on all patients with rheumatoid arthritis seen between April, 2011 and October, 2016. at department of rheumatology, Tokyo Metropolitan Tama Medical Center. We investigated their demographics and medication, including corticosteroids, disease-modifying antirheumatic drugs and prophylactic drugs against PCP. The person-time at risk was calculated from prescription records. We compared the incidence during the period of follow-up in which the patients received sulfasalazine with that in which they did not received sulfasalazine. The incidents were assumed to follow a Poisson distribution and statistical analysis was performed using z-test.
Results: In the study period, 2,394 patients with rheumatoid arthritis were treated at our hospital. Among them, 24 patients received the treatment for PCP because the infection was diagnosed or was strongly suspected. All the cases developed the condition while they were not taking sulfasalazine. The incidence rate of PCP was significantly lower in the treatment period with sulfasalazine than that without sulfasalazine ($p < 0.001$).
Conclusions: Our study confirmed that sulfasalazine has a preventive effect against PCP in patients with rheumatoid arthritis.

AB0368 PREDICTORS OF NEUROPATHIC PAIN IN RHEUMATOID ARTHRITIS

T. Martins Rocha[1], S. Pimenta[1], M. Bernardes[1], A. Bernardo[1], M. Barbosa[2], R. Lucas[3], L. Costa[1]. *[1]Rheumatology; [2]Pain Unit, Centro Hospitalar de São João; [3]Clinical Epidemiology, Faculty of Medicine University of Porto (FMUP), Porto, Portugal*

Background: Significant pain persists in a substantial proportion of Rheumatoid Arthritis (RA) patients in spite of disease remission. Recent evidence indicates that features suggestive of neuropathic pain (NP) are present in RA patients with a prevalence range of 33–38% using the painDETECT questionnaire (PDQ).
Objectives: To estimate the clinical predictors of NP in a cohort of RA patients.
Methods: Observational, cross-sectional study was performed with RA patients followed at our Rheumatology department with unchanged DMARD treatment during the last 3 months. Patients with diagnosed neuropathy or non-RA risk factors for NP were excluded. Selected patients were evaluated in a medical visit. Demographic, clinical and laboratorial data were collected and disease activity and functional measures were evaluated. Two questionnaires were applied to assess NP: the Leeds Assessment of Neuropathic Symptoms (LANSS) and the PDQ. Univariate and multivariate logistic regression were performed to identify the predictors of NP. Significance level was set as <0.05.
Results: 112 RA patients were included. 86 (77%) were females, with a mean (SD) age of 55.1 (10.8) years and median disease duration of 13 years (range: 2–41). 84% patients were seropositive for Rheumatoid Factor and/or ACPA. 102 (91%) were treated with DMARDs and 42% with a biologic DMARD, whom 8% in monotherapy. The mean (SD) DAS28 4V was 3.61 (1.01) and 12% were in remission. 45 (40%) patients had NP by the LANSS ($\geq$12), 28% had a possible/likely NP in the PDQ ($>$12) and 21% were positive in the both tests. Female sex was predictive of LANSS and PDQ NP (OR: 3.44, p=0.02 and OR: 3.70; p=0.05, respectively) and disease duration was a predictor of LANSS (OR: 0.92 per year, p=0.004). After adjusting for these variables, pain VAS, patient global activity and the tender joint count were positive predictors of NP by both tests. Swollen joint count, ESR or CRP levels were not significantly associated with NP. DAS28 CRP and HAQ scores were both significant positive predictors of PDQ NP (OR: 1.77 and OR: 3.61, $p<0.01$, respectively). DAS28 CRP, dichotomized as remission/non-remission, and the HAQ score were also significantly positive predictors of LANSS NP (OR: 5.55, p=0.01 (DAS28 CRP$\geq$2.6); OR: 2.15, p=0.03). Positivity for ACPA was a negative predictor of LANSS NP (OR: 0.23, p=0.009), remaining significant after adjusting for DAS28 CRP, HAQ and current methotrexate (MTX). Number of analgesics and current NSAIDs treatment were associated with PDQ NP (OR: 2.72 and OR: 3.40, respectively, $p<0.05$). Current MTX and previous/current Hydroxychloroquine (HCQ) treatment were both negative predictors for PDQ NP (OR: 0.41 and OR: 0.20, respectively, $p<0.05$). No other significant associations were found. In a subgroup with dosed TSH levels (n=18), there was a positive though non-significant association with LANSS and PDQ (OR: 3.12, OR: 14.98, p=0.09).
Conclusions: NP was present in sizable proportion of RA patients. Consistently with previous data, our study supports the association between NP and disease activity/functional scores but not with objective inflammatory measures. This study newly points to a possible protective role of ACPA positivity, MTX and HCQ treatment in NP risk.

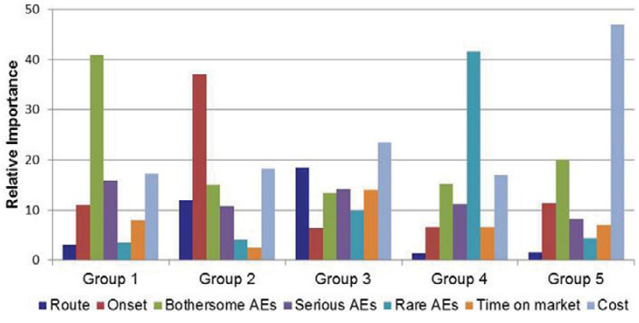
AB0369 VITAMIN D STATUS AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. Povoroznyuk[1], O. Synenky[2], N. Balatska[1]. *[1]D.F. Chebotarev Institute of Gerontology Nams Ukraine, Kyiv; [2]Lviv Regional Clinical Hospital, Lviv, Ukraine*



Background: The purpose of the study was to define the associations between serum level of 25-hydroxyvitamin D (25(OH)D) and disease activity in patients with rheumatoid arthritis (RA).
Objectives: The study group comprised 93 patients aged 27–80 years suffering from RA (74.2% women) and 93 controls.
Methods: The levels of rheumatoid factor (RF) and C-reactive protein (CRP) were measured by immunoturbidimetric assay. Erythrocyte sedimentation rate (ESR) was measured by Westergren method. Serum $25(OH)D_{total}$ level was determined by electrochemiluminescence (ECL) method. The optimal vitamin D status was defined when serum 25(OH)D level was 30–50 ng/ml.
Results: In general, 54.8% of RA patients revealed vitamin D deficiency, and 37.6% - vitamin D insufficiency. No significant difference was found when mean serum 25(OH)D levels in RA patients and healthy controls where compared. 25(OH)D levels appeared markedly lower in patients with the highest activity of RA compared to values noted in patients with the minimal RA activity (16.55±9.26 vs 22.59±9.74 ng/ml, $p<0.05$). In RA patients 25(OH)D levels were significantly and negatively associated with markers of disease activity (DAS28-ESR (β = -0.33; 95% CI =0.05, -0.01), CRP (β = -0.23; 95% CI = -0.72; 0.00), and ESR (β = -0.26; 95% CI = -0.78; -0.10). All these associations remained statistically significant after adjustment for gender, age and BMI.
Conclusions: Vitamin D deficiency should be considered as an important predictor of the high RA activity (AUROC =0.67; 95% CI =0.513–0.83, P=0.05).
Disclosure of Interest: None declared

AB0370 DEVELOPMENT OF PATIENT PREFERENCE PHENOTYPES FOR RHEUMATOID ARTHRITIS

W.B. Nowell[1], C. Wiedmeyer[1], G. Herath[2], G. Michel[3], L. Fraenkel[2]. *[1]Global Healthy Living Foundation, Upper Nyack; [2]Yale University School of Medicine; [3]Yale University, New Haven, CT, United States*

Background: Many important treatment decisions for patients with rheumatoid arthritis (RA) are conditional on patient preferences and, according to the U.S. National Academy of Medicine, mandate a shared decision making approach (SDM). Furthermore, SDM is being increasingly recognized as an important quality measure. One of the most common preference sensitive decisions in RA is how to escalate care when response to methotrexate monotherapy is inadequate. However, the number of RA medications currently approved makes it challenging for patients to weigh the pros and cons related to each of the treatment options in order to develop a preference.
Objectives: The objective of this study was to develop representative patient preference phenotypes to enable patient-physician dyads to effectively incorporate patient preferences at the point-of-care.
Methods: People living with RA were invited to complete a Choice-Based Conjoint analysis survey including seven attributes (route of administration, time to onset of action, bothersome adverse events (AEs), serious AEs, extremely rare AEs, duration of time on the market and affordability) developed iteratively based on patient feedback. Each attribute was described across three or four levels using plain language. Preference phenotypes were identified by applying latent class analysis to the conjoint data. Class solutions were replicated five times from random starting seeds. A five-group solution was chosen based on Akaike's information criterion. We calculated the percentage of importance assigned to each attribute and performed simulations to estimate preferences for triple therapy, SC and IV biologics, or tofacitinib.
Results: 1100 U.S. subjects recruited via the CreakyJoints online patient community completed the survey. Of these, 49 were eliminated because they completed the survey in less than 10 minutes and an additional 45 people were excluded because they did not respond correctly to a dominant choice task. The mean age was 51.7 (11.2). The majority were female; (92%) and Caucasian (93%). Preferences (assuming low cost across options), and the reasons underlying each respondent's preference, clustered into five groups (Figure 1). There were no differences in the distribution of demographic or clinical characteristics across the five groups. Phenotypes were created based on the stated preference data.

Figure 1. Relative Importances

Conclusions: RA patients' preferences vary and can be classified into distinct phenotypes. Ongoing research is evaluating whether enabling patients to identify with a preference phenotype facilitates SDM at the point-of-care.

AB0371 THE QUALITY OF LIFE CAN BE IMPROVED BY FOREFOOT RECONSTRUCTION EVEN IN PATIENTS WITH WELL-CONTROLLED RHEUMATOID ARTHRITIS

Y. Nomura[1], H. Ishikawa[1], A. Abe[1], S. Ito[1], T. Kojima[2], M. Kojima[3], N. Ishiguro[2], A. Murasawa[1]. *[1]Rheumatology, Niigata Rheumtic Center, Shibata; [2]Orthopedic Surgery, Nagoya University Hospital; [3]Medical Education, Nagoya City University Hospital Graduate School of Medicine, Nagoya, Japan*

Background: The treatment aim of rheumatoid arthritis (RA) is achieving and

maintaining remission (REM) or low disease activity (LDA) via tight medical control[1)]. However, despite remarkable advances in medication, progressive deterioration and deformity of the forefoot sometimes occur if adequate medication is not administered in the early stage. Surgical reconstruction is still required in patients with painful callosity and footwear problems caused by typical forefoot deformity. Recently, patients have expressed a desire to achieve functional REM with a higher quality of life (QOL) and improved mental wellness.

Objectives: The objective of this study was to clarify the systemic effects of forefoot reconstruction on the impaired foot, even in patients who have achieved REM or LDA.

Methods: A prospective cohort study was performed for 63 feet of 50 patients (males: 6, females: 44) with RA who underwent primary elective surgery between October 2012 and September 2014. Both feet underwent surgery on the same day in 13 patients. The average (range) age was 64 (42–89) years, and the average (range) disease duration was 20 (2–36) years. The procedures performed included shortening oblique osteotomy at the metatarsal neck of the lessor toes in 47 feet, first metatarsophalangeal joint arthroplasty (Swanson) in 44 feet, correction shortening osteotomy (modified Mitchell) at the first metatarsal in 4 feet, and fusion at the first interphalangeal joint in 7 feet, among others. A total of 30 feet in 27 patients (males: 5, females: 22) had a disease activity of REM or LDA just before surgery. The patient-reported outcomes (PROs) were assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), and Patient's General Health using a visual analogue scale of 100 mm (Pt-GH). The 28-joint Disease Activity Score using C reactive protein (DAS28-CRP), the Japanese Society of Surgery of the Foot (JSSF) standard rating system (JSSF) for the RA foot and ankle scale[2)], and the Time Up&Go test (TUG) were also evaluated. All of these items were investigated just before surgery (baseline) and again at 6 and 12 months after surgery.

Results: Overall, the physical function (JSSF, TUG), QOL (EQ-5D), and mental wellness (depression) (BDI-II) were significantly improved at 6 and 12 months after surgery compared to the baseline values ($p<0.05$). In the REM/LDA group, significant improvement was noted in the physical function (JSSF), QOL (EQ-5D) both at 6 and 12 months after surgery; however, we did not observe any significant changes in the Pt-GH or DAS28-CRP (Table 1).

Table 1: Outcome of surgical intervention in the deformed forefoot for the patients with rheumatoid arthritis

		HAQ-DI	EQ-5D	BDI-II	Pt-GH (mm)	DAS28-CRP	JSSF	TUG (sec)
Total n=50	baseline	0.98 (0.77)	0.71 (0.11)	11.7 (8.2)	30.4 (22.9)	2.63 (1.1)	61.9 (16.4)	10.0 (4.0)
	PO# 6mos.	1.01 (0.8)	0.75* (0.13)	9.9* (7.0)	25 (20.9)	2.43 (0.92)	78.7** (14.7)	9.2* (3.0)
	PO# 12mos	1.04 (0.71)	0.76* (0.15)	9.7* (6.9)	25.4 (19.7)	2.40 (0.89)	78.2** (14.3)	9.3* (3.0)
REM+LDA n=27	baseline	0.78 (0.66)	0.73 (0.13)	10.3 (7.8)	18.9 (18.6)	1.85 (0.49)	68.0** (15.4)	8.6 (2.4)
	PO# 6mos.	0.81 (0.65)	0.80* (0.13)	8.1* (6.3)	19.5 (16.7)	2.0 (0.60)	82.8** (11.5)	8.4* (2.0)
	PO# 12mos	0.89 (0.66)	0.80* (0.16)	8.7 (7.6)	19.4 (16.1)	2.0 (0.57)	81.4** (11.8)	8.4 (2.5)

Mean(SD) *: p<0.05 compared to baseline, **: p<0.01 compared to baseline

Conclusions: Achieving REM or LDA is not the ultimate goal of treatment for patients with painful callosity and footwear problem functional loss. A higher QOL and improved function can be achieved by surgical intervention in the deformed forefoot.

AB0372 ASSOCIATED FACTORS OF CERVICAL AND LUMBAR SPINAL INSTABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Sugimura[1], N. Miyakoshi[2], T. Kashiwagura[3], M. Kobayashi[4], T. Aizawa[5], H. Aonuma[6], Y. Shimada[2]. *[1]Orthopedic Surgery, Nakadori General Hospital; [2]Orthopedic Surgery, Akita University Graduate School of Medicine; [3]Orthopedic Surgery, Akita City Hospital, Akita; [4]Orthopedic Surgery, Hiraka General Hospital, Yokote; [5]Orthopedic Surgery, Kita Akita Municipal Hospital, Kitaakita; [6]Orthopedic Surgery, Kakunodate Municipal Hospital, Senboku, Japan*

Background: Few studies have compared rheumatoid arthritis (RA)-related disorders of the cervical and lumbar spine.

Objectives: The objectives of this study were to examine the prevalence of and risk factors for cervical and lumbar spinal instability in patients with RA.

Methods: From a total of 1,843 patients registered in the Akita Orthopedic Group on Rheumatoid Arthritis (AORA), 135 patients [118 women, 17 men; mean age, 66 (41–84) years; mean disease duration, 14 (1–63) years] who underwent a radiographic examination were enrolled in this study. In the cervical spine, we defined instability as one of the following characteristics: (1) atlantodental interval (ADI) >3 mm, (2) Ranawat value <13 mm on a neutral plain radiograph, or (3) anteroposterior translation >3 mm at the subaxial cervical spine on an anteroposterior bending plain radiograph. In the lumbar spine, instability was defined as anteroposterior translation >3 mm on a neutral plain radiograph.

At the time of radiographs evaluation, demographic characteristics, clinical variables, medical history and current medications were investigated.

The patients were classified into two groups: with both cervical and lumbar spinal instabilities and without. The independent risk factors for both cervical and lumbar spinal instabilities were then determined using multivariate logistic regression analysis.

Results: Forty-six (34.1%) patients exhibited cervical spinal instability, and 50 (37.0%) patients exhibited lumbar spinal instability. Twenty-four patients (17.8%) exhibited both cervical and lumbar spinal instability. The presence of both cervical and lumbar spinal instability was significantly and independently associated with disease duration (OR: 1.06; 95% CI: 1.01–1.12).

Conclusions: The prevalence of both cervical and lumbar spinal instability in patients with RA was 17.8%. Disease duration was independent risk factor for presence of both cervical and lumbar spinal instability in this study.

AB0373 ANALYSIS OF RISK FACTOR FOR LOCOMOTIVE SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM CHIKARA STUDY

Y. Yamada, M. Tada, K. Mandai, N. Hidaka. *Department of orthopedics surgery, Osaka City General Hospital, Osaka City, Japan*

Background: Patients with rheumatoid arthritis (RA) are at a higher risk for sarcopenia due to joint destruction and chronic inflammation*1, which can lead to locomotive syndrome (LS), i.e., being restricted in the ability to walk or lead a normal life owing to a dysfunction in one or more of the parts of the musculoskeletal system*2. The prospective observational CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease activity in rheumatoid arthritis; registration number UMIN000023744) was begun in 2016 to investigate the correlation between RA disease activity and sarcopenia and LS.

Objectives: We investigated the relationship between LS and disease activity at baseline in patients with RA.

Methods: One hundred patients (78% women; average age, 66y) enrolled in the CHIKARA study were examined for body weight, muscle mass, fat mass, predicted bone mass, basal metabolic rate (BMR), leg muscle score, etc., using a body composition analyzer. Laboratory data, disease activity, Health Assessment Questionnaire (HAQ) and treatment were also investigated. LS was diagnosed using a questionnaire called Locomo-5. We investigated the correlation between LS and each status using univariate and multivariate analyses.

Results: Fifty-two percent of the patients with RA that we examined had LS. Mean disease duration was 5.5 years and mean DAS28-ESR was 3.55. Table 1 shows the risk factors for LS. Univariate analysis showed that age, percent body fat, body weight, visceral fat rating, leg muscles score, rheumatoid factor status and HAQ had significant associations to LS. Leg muscle score and HAQ were detected as significant factors by multivariate analysis. Patients whose leg muscle score was less than 90 had a significantly higher prevalence of LS by ROC curve analysis (Odds ratio 3.77, p=0.001). Disease activity and use of glucocorticoids or biological agents showed no significant relationship.

Table 1. Risk factors for locomotive syndrome in patients with rheumatoid arthritis

	Univariate		Multivariate		
	R	p value	Odds ratio	95% Confidence Interval	P value
Age, y	0.255	0.01	–	–	–
% body fat	0.244	0.014	–	–	–
% body water	-0.215	0.032	–	–	–
Visceral fat rating	0.205	0.041	–	–	–
Leg muscle score	-0.359	<0.001	0.91	0.84–0.97	0.005
Rheumatoid factor	0.221	0.027	–	–	–
Health Assessment Questionnaire	0.460	<0.001	8.78	2.66–29.0	0.001

Conclusions: Lower leg muscle score and higher HAQ score are independent risk factors for LS among patients with RA.

Rheumatoid arthritis - anti-TNF therapy

AB0374 FLARE INCIDENCE AND PREDICTIVE FACTORS IN A POPULATION OF PATIENTS WITH RHEUMATOID ARTHRITIS UNDER OPTIMISED TREATMENT WITH ADALIMUMAB AND INFLIXIMAB

A. Pieren[1], C. Plasencia[1], D. Pascual-Salcedo[2], M.B. Paredes[1], A. Balsa[1].
[1]Rheumatology; [2]Immunology, Hospital la Paz, Madrid, Spain

Background: Anti-TNF are nowadays widely used for the treatment of Rheumatoid Arthritis (RA),which has drastically changed the prognostic of the disease,carrying an important healthcare expense.This is why,optimisation seems a successful strategy that should not be linked to a worse become of our patients' clinical evolution.
Objectives: Describe a population of patients with RA under optimised treatment with Adalimumab (Ada) and Infliximab (Ifx).Study the incidence of flares and establish predictive factors of flares at baseline and pre-optimization.
Methods: Observational study of the prospective cohort RA-Paz. All the patients diagnosed of RA under treatment with Ifx and Ada between Jan.2000 and Dec.2016 of the day-care unit of La Paz Hospital,were included.Demographic data,clinical activity and blood sample results were collected at baseline, pre-optimization (pre-op)and at 3,6,9,12,18 and 24 months.Drug serum trough levels were measured under ELISA in each visit.Optimal range for Ifx was described as drug concentration between 1000- 4000 ng/ml and 1500- 5000 ng/ml for Ada.Optimisation was defined as drug use below standard dose.Flares were collected from the pre-op visit.Flare was described as clinical worsening which led to a therapeutic change or a DAS28>3.2 and DeltaDAS28>0,6.Predictive factors of flare at baseline and pre-op were evaluated with a uni and multivariate analysis. Statistical study was performed with the statistical program SPSS.
Results: Of the 271 patients diagnosed of RA, 74 patients were optimised (44 under Ada and 30 under Ifx). Baseline demographic caracteristics are shown in the table below.During the 24 months after the pre-op visit, 55,4% (41)of the patients presented at least one flare,with an average of 1,38 flares [1–5]. Most of the patients (53.7%,22/41),were controlled with the adjustment of non biological treatment.Only 39,0% (16) of the patients,had to go back to the previous optimised dose and 7,3% (3)to the standard dose.88% (39/41)were controlled after the dose modification.104 flares were collected,33% (34) happened at the 3rd month and 20% (21) at 24th. In the population who presented flares, we observed a persistent higher DAS Vs the patients who never presented flares (DAS pre-op 3,20±1,16 Vs 2,26±0,59;DAS 24month 3,61±1,13Vs2,10±0,65;p=0,007). A least proportion of patients with flares were in supra-optimal range (13,3% with flares vs 26% without, p=0,007). At baseline, no clinical factors were predictive of flare. Nor were blood sample results. In contrast, a higher disease activity, measured by DAS pre-op (p=0,004),a worst EULAR answer (p=0,027) and not being in supra-optimal range (p=0,032),were statistically correlated with flares development at the univariate analysis. Time to the optimisation tended to the significance (OR=1,152; p=0.08). In the multivariate analysis, only a higher DAS pre-op (OR:2,00,[1,08–3,73])and being in optimal (OR:5,90, [1,38–25,2])and sub-optimal range (OR=6,05 [1,28–28,7]), were independently correlated.

	N Total= 74
Sex	Women 83,8 % (62) Men 16,2 % (12)
Age	64,1 (+/-12,6)
Age at diagnosis	41,6 (+/-14,0)
bDMARD	Ada 59,5% (44) IFX 40,5% (30)
Time to the beginning of bDMARD (years)	10,7 (+/- 7,50)
Time to optimisation (years)	4,70 (+/-3,12)
Treatment duration (years)	8,80 (+/-4,00)
RF +	75,7% (56)
ACPA +	73,0% (54)
Smoking	No smokers 68.9% (51) Smokers 17,6% (13) Ex smokers 12,2% (9)
BMI	25,6 (+/-4,61)
Methotrexate (MTX)	74,3% (55)
Average dose MTX (mg/sem)	12,3 (+/-8,60)
Other sDMARD	54,1% (40)
sDMARD	Leflunomide 62,5% (25) Salazopyrine 15% (6) Hydroxychloquine 10% (4) Leflunomide+SZP 5% (2) Leflunomida+HCQ 5% (2) SZP+HCQ 2,5% (1)
Prednisone	37,8% (28)
Prednisone dose (mg/día)	1,89 (+/-2,62)
DAS baseline	5,03 (+/-1,35)
VSG baseline	34,7 (+/-18,9)
PCR baseline	10,2 (+/-12,5)

Conclusions: In our cohort of optimised patients, we noted a high proportion of flares. However, flares were controlled with dosage readjustment without needing a treatment change. Independently correlated predictive factors for flares were a higher disease activity measured by DAS and not being in therapeutic range in the pre-optimisation visit.

AB0375 THE EFFECT OF CONCOMITANT USE OF METHOTREXATE ON THE CLINICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS UNDER ANTI-TNFTHERAPY

A. Martinez-Feito[1], C. Plasencia[2], B. Hernandez-Breijo[1], A. Jochems[1], C. Diego[3], A. Villalba[2], D. Peiteado[2], L. Nuño[2], P. Nozal[3], A. Balsa[2], D. Pascual-Salcedo[1]. *[1]Immuno-Rheumatology research group; [2]Rheumatology; [3]Immunology, University Hospital la Paz, madrid, Spain*

Background: Several publications in rheumatoid arthritis (RA) have demonstrated a beneficial effect of concomitant methotrexate (MTX) use with TNF inhibitors (TNFi), mainly because of the MTX effect in reducing immunogenicity. In a previous work in the RA-La Paz cohort, we found that the concomitant use of MTX had a positive effect on the pharmacokinetics of serum TNFi levels, decreasing the immunogenicity of these drugs. Furthermore, the MTX effect was dose-dependent, being greater at high MTX dose. Currently, we investigate the effect of concomitant MTX use on the clinical response.
Objectives: To investigate the MTX influence on the clinical response in the RA-La Paz cohort treated with Infliximab (Ifx), Adalimumab (Ada) or Etanercept (Etn) at one year of treatment.
Methods: This is an observational study from a prospective cohort from the Biological Unit of the University Hospital La Paz, Madrid, Spain that analysed a total of 293 RA patients treated with Ifx (112 patients), Ada (71 patients) and Etn (110 patients). Patients were grouped according to the MTX dose: no MTX, low dose (LD: ≤12.5 mg/week), intermediate dose (ID: 15–17.5 mg/week) and high dose (HD: ≥20 mg/week). For this study, the clinical response was evaluated by DAS28-ESR and the clinical improvement by∆DAS28. Data were collected at baseline, 0.5 and 1 year of TNFi treatment. Statistical analysis was performed using GraphPad Prism 6.0 software.
Results: Out of 293 RA patients (pts) under TNFi treatment, 184 (71 with Ifx, 40 with Ada and 73 with Etn) were included. In this cohort, 128 (70%) pts used concomitantly MTX (91% oral administration) and 56 (30%) pts were in monotherapy. No differences in DAS28 were found at baseline between patients with or without MTX (p=0.8).
After one year of treatment, pts with TNFi +MTX have a significantly lower DAS28 than patients without MTX (3.3±1.3 vs 3.9±1.1; p=0.004). When analyzing the DAS28 values in relationship to the MTX dose, statistical differences are observed with use of HD (≥20 mg/week) (3.1±1.3 with HD vs 3.9±1.1 without MTX; p=0.001) but not with intermediate (3.4±1.2 with ID vs3.9±1.1 without MTX; p=0.06) or low MTX dose (3.8±1.6 with LD vs 3.9±1.1 without MTX; p=0.4) at 1 year of therapy.
Clinical improvement by∆DAS28 was higher in patients with TNFi +MTX than in patients without MTX (1.7±1.4 vs 1±1.3p=0.007). This effect was observed with all MTX doses (1.7±1.5 with HD vs 1±1.3 without MTX, p=0.01; 1.6±1.3 vs with ID 1±1.3without MTX, p=0.03; 1.8±1.3 with LD vs 1±1.3 without MTX, p=0.01).
Conclusions: In the RA-La Paz cohort under TNFi treatment, the concomitant use of MTX has a positive effect on the clinical activity, mainly when high dose of MTX is used. Moreover, we demonstrate a positive effect of any MTX dose on the clinical improvement at one year of treatment.

AB0376 CARTILAGE OLIGOMERIC MATRIX PROTEIN, A BIOMARKER OF ARTHRITIS, COULD BE USEFUL FOR PREDICTING THE RESPONSE TO BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS?

B.I. Gavrila[1], C. Ciofu[1], C. Mihai[1], G. Udrea[1], M. Bojinca[1], V. Stoica[1], E. Panaitescu[2]. *[1]Department of Internal Medicine and Rheumatology Cantacuzino Hospital; [2]Medical Informatics and Biostatistics, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Background: introduction of biologic therapy has revolutionized the treatment of Rheumatoid Arthritis (RA). Despite these advances, 20–40% of the patients are declared nonresponders to at least one of the therapies (1).High costs and patient exposure to severe adverse reactions (ex. infections) determined the need to identify biomarkers that can distinguish pretreatment responders versus nonresponder patients.
Objectives: evaluating the predictive role for the response to anti tumor necrosis factor therapy (anti-TNF) of cartilage oligomeric matrix protein (COMP), a specific serological marker, which evaluates the articular cartilage degradation and its turnover.(2)
Methods: prospective and observational study including 64 patients followed 12 months with active RA, uncontrolled by conventional synthetic DMARDs.Clinical assessment was performed at 0, 6 and 12 months according to ACR criteria approved by OMERACT and evaluation of treatment response according to EULAR criteria (good /moderate /nonresponder).

Results: of the 64 patients included in the study, 59 (92.2%) were women and 5 (7.8%) men, mean age 57.55±9.42 years. After 6 months, 7 patients were declared nonresponders, 38 achieved a moderate response and 19 good response.
Following baseline COMP titres and the EULAR response at 6 months, general tests identified significant differences between groups. Lower baseline titres had predictive value for achieving a good response (746.04±130.095 ng/ml) comparing with moderate responders (1032.8±188.671ng/ml) and nonresponders (1042.2±181.717 ng/ml, p=0.0000).
After 12 months 11 patients achieved moderate response, 44 a good response and just 1 patient was declared nonresponder. At this visit, even if we didn't find significant differences between baseline COMP titres and the EULAR response (p=0.1430), we observed lower baseline titres for good responders (917.8±219.943 ng/ml) versus moderate responders (1042.7±193.117 ng/ml).
Grouping patients in 2 categories (responders/nonresponders) there were no differences between groups at 6 months (937.27±218.106 ng/ml versus 1042.2±181.717 ng/ml, p=0.227) or 12 months (942.82±219.025 ng/ml versus 896.5±0.000 ng/ml, p=0.9753).
Following the status pretreatment of COMP and EULAR response at 6 months, we identified differences between groups (p=0,0001), all 7 patients declared nonresponders were COMP positive and only 13/19 (68.4%) of good responders were tested positive. At 12 months there were no differences between pretreatment status of COMP and response to treatment (p=0.2805).
Regarding the evolution of serum levels, we noticed a decrease statistically significant from baseline (948.75±215.683 ng/ml) to 12 months (740.88±227.04 ng/ml, p=0.0000).
Conclusions: COMP could be one of the biomarkers for identifying pretreatment the patients who will respond to biologic therapy in Rheumatoid Arthritis.

AB0377 SWITCHING FROM BIO-ORIGINAL ETANERCEPT TO BIOSIMILAR ETANERCEPT SB4: PATIENT ACCEPTABILITY AND OUTCOMES IN THE REAL WORLD

C. Holroyd[1], D. Wallis[1], S. Bennett[1], P. Clayton[1], C.J. Edwards[2].
[1]Rheumatology; [2]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton, Southampton, United Kingdom

Background: A number of studies have demonstrated the efficacy of biosimilar therapies including SB4 (a biosimilar-etanercept). However, real world data of the process of switching, acceptability to patients, efficacy and safety is lacking.
Objectives: To obtain real world data of the acceptability and outcomes of patients with severe (eligible for TNFi therapy as defined by UK NICE) rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) who switch from bio-original etanercept (boDMARD-ETN) to the bsDMARD etanercept SB4 (bsDMARD-ETN).
Methods: Adult patients, with RA, PsA & AS, currently enrolled in the SMaRT study and switching from boDMARD-ETN to bsDMARD-ETN were followed for 6 months. Primary outcome was change in DAS28, PsARC response or BASDAI following switching. Additional outcomes included; % change of remission rate, HAQ-DI, CRP or ESR levels, patient satisfaction, PDUS and SAEs leading to discontinuation. All patients had severe disease and were receiving boDMARD-ETN as per local guidelines of UK NICE. Analysis was performed in a similar way to a cross-over RCT trial design where patients act as their own control with the experience in the 6 and 12 months prior to switching used as the control for experience after switching.
Patient education and support during the switch included: rheumatologist face to face discussion, letter giving details of the switch and bsDMARD-ETN information sheet, patients invited to discuss switch in clinic, helpline number with patients advised to call for further information or to report adverse events (AEs), routine review in clinic 3 months after switching, and then 6 monthly thereafter or more often if clinically necessary.
Results: Following the education and support programme 99% of patients agreed to switch to bsDMARD-ETN (one declined due to concerns about allergic reactions to previous therapies). To date 92 patients have switched from boDMARD-ETN to bsDMARD-ETN and been followed up for more than 6 months (58 RA, 15, AS, 16 PSA and 4 enteropathic arthritis; mean age 55.9 (14.9) yrs, (56 female, 36 male), mean disease duration 16.8 (10.9) yrs, duration on boDMARD-ETN before switch mean 4.85 (3.92) yrs and duration since switch 204.1 (51.4) days. After 6 months following the switch 91% of patients using bsDMARD-ETN have continued with mean last DAS28 – 2.67 (1.32) for RA patients and mean last BASDAI – 4.58 (2.47). Following the switch 8 patients stopped bsDMARD-ETN after mean of 93.6 (56.4) days, the reasons for this were 7/8 clinician/patient determined inefficacy (6 returned to boDMARD-ETN, 1 switched to certolizumab), 1/8 switched after reporting palpitations and poor concentration. In the control period 6 months before switching 17/110 patients stopped boDMARD-ETN (85% continued) including 7 due to primary failure, 7 due to secondary failure, 1 adverse event (AE), 1 patient choice, 1 death (Lung cancer in male ex-smoker with longstanding RA who had received boDMARD-ETN for 10 yrs).
Conclusions: An education programme prior to switching to a biosimilar TNFi leads to a high uptake by patients. In follow-up of 6 months after switching from boDMARD-ETN to a bsDMARD-ETN there appears to be a low rate of discontinuation due to inefficacy or AEs.

AB0378 IMPROVED CLINICAL OUTCOMES AND PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ADALIMUMAB IN CENTRAL AND EASTERN EUROPE

D. Karateev[1], C. Codreanu[2], B. Rojkovich[3], M. Hojnik[4], E. Smirnova[5].
[1]Nasonova Research Institute of rheumatology, Moscow, Russian Federation; [2]"Dr. Stoia" Center for Rheumatic Diseases, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania; [3]Hospital of Hospitaller Brothers of St. John of God, Budapest, Hungary; [4]AbbVie, Ljubljana, Slovenia; [5]AbbVie, Moscow, Russian Federation

Background: Although physical activity has known positive impacts upon pain, disease activity and functional status in patients with rheumatoid arthritis (RA), very little is known about physical activity in patients with RA on biologic therapy.
Objectives: To evaluate the effect of adalimumab treatment on physical activity and relationship with improvements in disease activity and physical function in patients with RA in routine clinical practice.
Methods: This was a 52-week multi-center, post-marketing observational study conducted in 7 countries in Central and Eastern Europe (CEE). Eligible RA patients were prescribed originator adalimumab according to the local practice; visits were performed approximately 3 months apart. Physical activity was assessed by validated Short QUestionnaire to ASsess Health-enhancing physical activity (SQUASH)[1,2], which measures habitual physical activity across four domains: commuting, leisure time and sport, household, work and school. RA disease activity was assessed by DAS28 and physical function by HAQ-DI; clinical remission (REM) and low disease activity (LDA) were defined as DAS28<2.6 and <3.2, respectively. Descriptive statistical analyses were performed, observed data are presented.
Results: 462 patients were enrolled and 255 patients completed the study. Mean age was 53.9 (±12.1) yrs; 82.2% of enrolled patients were female; average disease duration was 7.8 (±7.5) yrs. DAS28 decreased from 6.1 (±1.1) at baseline to 2.9 (±1.0) at study end, whereas the mean HAQ-DI from 1.6 (±0.6) to 0.7 (±0.5). The proportion of patients in LDA and REM at study end was 56.0% and 31.1%, respectively. Total SQUASH score increased from 4772 (±4132) to 6104 (±4921), representing 28% improvement in overall physical activity. The largest score improvements were seen in the SQUASH domains of leisure time and sport (by 43%), followed by household activities and activities at work and school (each by 19%). The correlations between the total SQUASH score and its subscores with DAS28 were weak both at baseline and study end. A significant correlation between the total SQUASH and HAQ-DI scores was seen at baseline (r -0.30), but not at the study end (r -0.22). Correlations between SQUASH subscores and HAQ-DI were not significant. The percentage of work disabled subjects decreased from 22% to 17%. According to linear regression analysis, sociodemographic factors did not substantially influence habitual physical activity.
Conclusions: Treatment with adalimumab in clinical practice in CEE resulted in clinically meaningful improvements in disease activity and physical function as well as improvements in physical activity. The correlation between the scores for disease activity, physical function and physical activity were however poor and there was no clear influence of the standard sociodemographic factors on physical activity.

AB0379 EFFICACY OUTCOMES FOR ORIGINATOR TNF INHIBITORS AND BIOSIMILARS IN RHEUMATOID ARTHRITIS AND PSORIASIS TRIALS: A SYSTEMATIC LITERATURE REVIEW

R. Moots[1], C. Curiale[2], D. Petersel[2], C. Rolland[3], H. Jones[2], E. Singh[2], E. Mysler[4]. *[1]University of Liverpool, Liverpool, United Kingdom; [2]Pfizer, Collegeville, United States; [3]Envision Pharma Group, London, United Kingdom; [4]Organización Médica de Investigación, Buenos Aires, Argentina*

Background: Regulatory approval of biosimilar versions of innovator biotherapeutics requires that new biological products be highly similar to innovator products, with no clinically meaningful differences in safety, purity, and potency.[1,2] Pre-specified margins for equivalence in efficacy have been met in comparative trials of biosimilars of tumour necrosis factor inhibitors (TNFis) in rheumatoid arthritis (RA)[3] and plaque psoriasis (PsO),[4] supporting biosimilarity, but differences in treatment responses between originator pivotal trials and biosimilar trials have posed some interesting questions.
Objectives: To compare American College of Rheumatology 20% response (ACR20) and Psoriasis Area Severity Index 75% (PASI75) responses to originator TNFis in pivotal trials with those to originator TNFis and TNFi biosimilars in biosimilar trials in RA and PsO.
Methods: Historical data from originator pivotal trials (averaged across trials) were obtained from published systematic literature reviews. Searches were conducted to identify comparative randomized clinical trials of approved or proposed biosimilars of adalimumab (ADA), etanercept (ETN), and infliximab (INF) using Embase®, MEDLINE®, the Cochrane Central Trials Register and Database of Systematic Reviews, and other Cochrane Library databases, and 2015/16 congress abstracts. To reduce variability, only studies conducted in disease-modifying antirheumatic drug-experienced patients treated with the same biologic dosages and assessed at the same time points were selected for analysis.
Results: Of 83 publications initially identified, 16 publications were included for analysis (RA: originators, n=4; biosimilars, n=6; PsO: originators, n=3; biosimilars, n=3). Higher proportions of ACR20 responders were found among RA patients receiving the originator biologics and biosimilars in biosimilar trials, than among patients receiving the originator biologics in pivotal trials (Table). Insufficient data were available from ADA and INF biosimilar studies in PsO; in ETN studies in PsO, a difference was also observed in the proportions of PASI75 responders between biosimilar and pivotal trials.

Table: ACR20 and PASI75 responders in pivotal vs biosimilar trials and differences in response rates

Product	RA trial type	Time point (wk)	ACR20 responders, %	Difference, pivotal vs biosim, %
ADA	Pivotal[5,6]	24	65	—
ADA	Biosim[7]	24	72	10

Conclusions: Differences were observed in treatment response rates between originator pivotal trials and more recent trials of originator biologics and their respective biosimilars. Such differences in outcomes may be attributable to fundamental differences in study design and/or baseline patient characteristics, which require further analysis. Additional research is also needed to explore the clinical relevance of these differences.

AB0380 RESULTS FROM A RANDOMIZED, SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS DEMONSTRATING PHARMACOKINETIC SIMILARITY BETWEEN ABP 710 AND INFLIXIMAB

E. Krishnan, V. Chow, N. Zhang, A. Kaliyaperumal, P. Kaur. *Amgen, Thousand Oaks, United States*

Background: ABP 710 is being developed as a biosimilar with the same amino acid sequence as infliximab, an anti-tumor necrosis factor therapy. Analytical and functional comparisons between ABP 710 and infliximab have been conducted and completed.
Objectives: This report describes the results of analyses comparing the pharmacokinetics (PK), safety, and immunogenicity of ABP 710 and infliximab sourced from the European Union (EU).
Methods: This was a single-blind, single-dose, parallel-group study among healthy adults, 18 to 45 years of age and with a body mass index of 18 to 30 kg/m^2. Subjects were randomized to receive a 5 mg/kg intravenous infusion of either ABP 710 or infliximab. The primary objective of this analysis was demonstration of PK similarity of ABP 710 to infliximab based on area under the serum concentration-time curve from time 0 extrapolated to infinity (AUC_{inf}; primary endpoint). PK equivalence was deemed achieved if the geometric mean (GM) ratio and its 90% confidence interval (CI) for AUC_{inf} was within the range of 0.80 and 1.25. Secondary endpoints included maximum observed serum concentration (C_{max}), area under the serum concentration-time curve from time 0 to last quantifiable concentration (AUC_{last}), safety, and immunogenicity.
Results: *Pharmacokinetics:* A total of 49 subjects received ABP 710 and 49 subjects received infliximab. Following a single dose, the adjusted least square (LS) GM of AUC_{inf}, AUC_{last}, and C_{max} for ABP 710 was 33559 μg·h/mL, 31789 μg·h/mL, and 123 μg/mL, respectively. The adjusted LS GM of AUC_{inf}, AUC_{last}, and C_{max} for infliximab was 33706 μg·h/mL, 31847 μg·h/mL, and121 μg/mL, respectively. Ratios of adjusted LS GMs (90% CIs) between ABP 710 and infliximab for AUC_{inf}, AUC_{last}, and C_{max} were 0.996 (0.904, 1.096), 0.998 (0.918, 1.086), and 1.021 (0.962, 1.083), respectively.
Safety: There was one subject in the infliximab group who developed polyarthritis that resolved with treatment and the subject completed the study. There were no deaths, other serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study. The incidence of TEAEs was similar in the two treatment groups (ABP 710: 83.7%; infliximab: 83.7%); the majority of TEAEs were mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy.
Immunogenicity: All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of study (Day 57), 40% of subjects in the ABP 710 group and 27% in the infliximab group were positive for binding ADAs, and 13% of subjects in the ABP 710 group and 19% in the infliximab group were positive for neutralizing ADAs.
Conclusions: Results of this phase 1 study demonstrate PK similarity between ABP 710 and infliximab sourced from the EU among healthy subjects. The safety and immunogenicity profile were comparable between the treatment groups.

AB0381 CHANGE IS GOOD, BUT WHAT IS BETTER? RETROSPECTIVE STUDY IN CLINICAL PRACTICE FIRST SWITCH WITH DIFFERENT BIOLOGICAL THERAPIES IN RHEUMATOID ARTHRITIS

F.A. Ojeda, C. Pérez-García, E. Beltran, A. Pros, T. Salman-Monte, F. Castro, L. Polino, P. Corzo, I. Carrión, S. Castell, P. Benito. *Rheumatology, Hospital del Mar, Barcelona, Spain*

Background: The effectiveness of the switch when the first anti-TNF failure in patients with rheumatoid arthritis has been demonstrated in multiple studies. But what is more effective, if you make the switch to another anti-TNF or another molecule, is not clearly defined.
Objectives: A retrospective study was performed in clinical practice to determine if there is a response to DAS 28 at 6 months of change and whether there is a difference in response if the switch is performed on another anti-TNF or another biological.
Methods: From a total of 254 that met ACR 2010 criteria for RA, which have been biologically treated at Rheumatology of the Parc Salut Mar from 2000 to 2016, 61 (24%) were the first switch and the DAS 28 response at 3 and 6 months of follow-up. The following variables were analyzed: age, sex, years of evolution RA, erosions, FR, ACPA, type of biological treatment, DAS 28 at the start of the switch, 3 months and 6 months,% of patients presenting DAS 28 <2, 6 at 6 months.The statistical study was performed with SPSS 20 for paired and independent quantitative variables with Student's T and chi2 for qualitative variables
Results: Of the total of 61 first treatment changes, 27 (44.3%) were to another anti-TNF alpha, 23 (37.7) to tocilizumab (TCZ), 7 to abatacept (11.5%) and 4

to RTX (6,6). The demographic and response data DAS 28 are shown in Table 1. There are no differences in the years of evolution,% of women, FR or ACPA positive, erosions and disease activity, as measured by DAS 28, before the switch, between The two groups (anti-TNF vs non-anti-TNF). Patients in the anti-TNF group were slightly younger than non-anti-TNF.When the DAS 28 response is evaluated at 3 and 6 months, modifying the treatment is effective (DAS 28 beginning 4,40 vs DAS 28 6 months 2.8 $p<0.001$). When assessing the response to change, there is no difference in the DAS 28 response at 3 months or 6 months, if you switched to anti-TNF or non-anti-TNF (3.18 vs 2.52 p=0.122).
When comparing the patients with anti TNF alpha vs TCZ, 62.5% of the patients with TCZ are in remission compared to 38, 5% (p=0.047).

Table 1

	Total n=61	Swich anti-TNF alpha n=26	Swich No anti-TNF alpha n=35	p
Age (years)	60.08±11,5	56.19±8,4	62.97±12,8	0.023
Sex (% M)	80.3	84.6	77.1	0.532
Years evolution (years)	17.44±9,4	18.92±11,6	16.34±7,4	0.298
Erosion (%)	90.2	92.3	88.6	1.000
FR+ (%)	77.0	76.9	77.1	1.000
ACPA+ (%)	91.8	88.5	94.3	0.642

Table 2

	Total n=61	Swich anti-TNF alpha n=26	Swich No anti-TNF alpha n=35	p
DAS 28 Swich	4.40±1,38	4.61±1,5	4.21±1,3	0.216
DAS 28 3 months	3.18±1,52	3.52±1,09	2.96±1,7	0.167
DAS 28 6 months	2.8±1,54	3.18±1,74	2.52±1,3	0.122
DAS 28 <2.6 6 m (%)	52.5	38.5	62.5	0.047

Conclusions: In this retrospective study in daily clinical practice, it is evident that the change in treatment after failure of the first biological one, without differences if the change is to an anti TNF or another treatment. The percentage of patients who are remission at 6 months is higher if the change is at TCZ. Given the small number of patients, larger studies would be needed to confirm the results.

AB0382 OUTCOMES OF ETANERCEPT THERAPY IN ELDERLY RHEUMATOID ARTHRITIS PATIENTS: AN INVESTIGATION OF THE AKITA ORTHOPEDIC GROUP ON RHEUMATOID ARTHRITIS REGISTRY

H. Aonuma[1], T. Kashiwagura[2], M. Urayama[3], M. Kobayashi[4], T. Aizawa[5], Y. Sugimura[6], N. Miyakoshi[7], Y. Shimada[7]. *[1]Orthopedic Surgery, Kakunodate Municipal Hospital, Senboku; [2]Orthopedic Surgery, Akita City Hospital, Akita; [3]Orthopedic Surgery, Ogachi Central Hospital, Yuzawa; [4]Orthopedic Surgery, Hiraka General Hospital, Yokote; [5]Orthopedic Surgery, Kita Akita Municipal Hospital, Kita Akita; [6]Orthopedic Surgery, Nakadori General Hospital; [7]Orthopedic Surgery, Akita University Graduate School of Medicine, Akita, Japan*

Background: The Akita Orthopedic Group on Rheumatoid Arthritis (AORA) encompasses 32 physicians and 28 clinics providing medical care to rheumatoid arthritis (RA) patients in Akita Prefecture, Japan. The patient registry for this group (the AORA registry) reflects actual clinical data on RA therapy in Akita, where the proportion of elderly (age ≥65 years) residents in the population is the highest in Japan. Etanercept (ETN) is a tumor necrosis factor inhibitor reportedly associated with fewer adverse event-related treatment discontinuations than other drugs of this class. However, few evaluations of the efficacy and safety of ETN have been reported for elderly populations.
Objectives: Based on data from the AORA registry, we aimed to investigate the continuation rate for ETN therapy, reasons for discontinuation, and therapeutic effects among elderly RA patients living in Akita.
Methods: Among 204 AORA-registered patients starting ETN therapy between January 2009 and August 2014, data for the 73 patients (35.8%) who were ≥65 years old at the initiation of therapy were evaluated. Mean age was 72.4±4.7 years (range 65–83 years), and 79.5% were women. Mean disease duration was 15.1±12.6 years (range 9 months-55 years), 13.7% of patients were switching from another biologic agent, 49.3% could perform activities of daily living (ADL) independently, and 65.8% had at least one of the following comorbidities: hypertension, diabetes, respiratory disorder, cardiovascular disease, and cerebrovascular disease. We evaluated the 1-year cumulative continuation rate for ETN therapy using the Kaplan–Meier method, and investigated the characteristics of patients who discontinued treatment because of adverse events (AE cohort) or lack of efficacy (LOE cohort). We evaluated efficacy in 55 patients for whom Disease Activity Score – C-reactive protein assessments were possible, based on European League Against Rheumatism (EULAR) criteria.
Results: The 1-year cumulative continuation rate for ETN therapy was 87.2%, and 24 patients discontinued treatment. The AE and LOE cohorts contained 12 and 7 patients, respectively. The AE cohort had a mean age of 75.5 years at the start of treatment, with a mean disease duration of 20.7 years, 8.3% of patients switching from another biologic agent, 16.7% performing ADL independently, and a comorbidity rate of 100%. Corresponding values for the LOE cohort were: mean age, 71.4 years; disease duration, 12.7 years; switching from another biologic agent, 42.9%; performing ADL independently, 57.1%; and comorbidity rate, 28.6%. Efficacy was noted for 81.8% of all patients with 52 weeks of ETN therapy, achieving good efficacy in 21 cases and moderate efficacy in 24 cases.
Conclusions: Retention rate and efficacy were considered satisfactory in elderly RA patients receiving ETN therapy. The risk of adverse events was suggested to increase with increasing age, declining ADL, and presence of comorbidities. These factors require attention when prescribing ETN therapy.

AB0383 SUBCLINICAL BRAIN DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS RELATIONSHIP TO TNF BLOCKER THERAPY

S. Sağ, I. Tekeoğlu, M.S. Sağ, A. Kamanlı, K. Nas. *Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya, Turkey, sakarya, Turkey*

Background: RA is a chronic disease with a yet unclarified etiology, which causes the activation of pro-inflammatory pathways that bring about joint and systemic inflammations (1).In recent years, the pathophysiology of brain damage that can occur in RA has drawn attention. Emphasis is being put on the possibility that brain damage occurs due to blood-brain barrier (BBB) damage that is linked to chronic inflammation
Objectives: In this study, we aimed to investigate the peripheral blood levels of brain-specific proteins such as S100 beta and GFAP (glial fibrillary acidic protein), the differences in these proteins in patients who did and did not undergo TNF blocker therapy and their relationship with cranial MR lesions, disease activity and cognitive functions with the purpose of determining CNS (central nervous system) damage in patients with rheumatoid arthritis (RA).
Methods: 58 RA patients (47 (81.0%) females, 11 (19.0%) males) and 34 healthy controls (24 (70.6%) females, 10 (29.4%) males) were included in the study. All RA patients were on synthetic DMARD therapy at the beginning. While 30 patients continued sDMARD therapy, 28 patients with high disease activity were started on TNF blocker therapy. All demographic characteristics of the patients were recorded. Disease activity was evaluated using DAS28. The Mini-Mental State Examination (MMSE) was used to evaluate cognitive functions, and the Fazekas Scale was used to assess the cranial MRI lesions. The peripheral blood S100 beta, GFAP, claudin, IL-17, IL-1 beta levels of the patients were measured at the beginning and on the 6th month.
Results: Demographic characteristics were similar between the two groups and no statistical difference was detected between the patient group and the control group in terms of sex, age, and BMI. ($p>0.05$) S100 beta and GFAP levels were higher to a significant degree compared to the control group. ($p<0.05$) In the group that was started on TNF blocker therapy, S100 beta and GFAP levels were detected to have decreased significantly 6 months after treatment compared to the start of treatment. ($p<0.05$) No difference was found between the RA and control groups in terms of hyperintense lesions seen in the cranial MRI. ($p>0.05$) As the lesions in the deep white matter seen in the cranial MRI of RA patients increased, their S100 beta levels were also seen to increase. ($p<0.05$)
Conclusions: In conclusion, next to decreasing disease activity and joint erosions by suppressing inflammation, anti-TNF therapy in RA can also suppress potential brain damage linked to subclinical BBB (blood-brain-barrier) dysfunction. Further studies with broader participation and longer patient follow-up are needed to reinforce this hypothesis.

AB0384 CLINICAL AND RADIOLOGICAL EVOLUTION IN RHEUMATOID ARTHRITIS (RA) PATIENTS AFTER DEINTESIFICATE BIOLOGICS

J. Uceda, R. Hernandez, J.L. Marenco. *Rheumatology, Valme University Hospital, Seville, Spain*

Background: RA is the most common chronic inflammatory arthritis. About 30% of patients are treated with biological therapy (BT). Deintensification of BT for patients in clinical remission, is a strategy used in clinical practice to reduce side effects and burden.
Objectives: The primary endpoint was evaluate clinical and radiological behavior of the RA in patients receiving BT at reduced doses.

The secondary endpoint was to analyze the characteristics of patients who remain for a longer period of time in an optimized dose regimen.
Methods: In our Rheumatology Unit we are treating 271 RA patients with BT, the dose was deintensificated for 62 (23%) patients in remission or low disease activity for at least 6 months. We have selected 32 patients with BT reduced for at least 6 years in an observational, descriptive, longitudinal and retrospective study. Disease activity was measured by the DAS 28 index. Structural damage was evaluated by SENS method.
Results: We analyze 32, 20 female, 12 male, mean age at diagnosis 42.6 years old; BT was started after RA evolution of 98.63 months. Drug reduction was performed after full BT for 62 months, mean DAS 28 was 2,47.
Patients were 75% FR positive and 56.7% ACPA positive. Etanercept was the BT more commonly reduced 59.4%, followed by adalimumab 21.9%, infliximab 12.5% and certolizumab 6.3%.
BT dose returned to normal for 11 patients because of disease activity worsening after an average time of 15.90 months.
For 21 patients remaining on reduced doses, the mean DAS28 at time for analysis was 2.67.
BT reduction as different drugs: none infliximab reduced dose patients required return to normal dose. All certolizumab reduced (2 patients) patients needed to back to normal dose. Etanercept in 36,8% and adalimumab 28,6%.
The mean of SENS score before the optimization was 8.78 and at time for analysis 10.67 for both kind of patients, who continued reduced and those who needed to increase BT dose.
For the secondary endpoint 10 out of 12 male continue with deintensificated BT (83%) in the other hand only 11 out of 20 female (55%) maintained reduced dose.More negative for FR (69,2%) and ACPA (75%) patients keep on reduced dose regimen.
Conclusions: We have deintensificated 62 out of 271 RA patients on BT (23%). All patients were in clinical remission at the beginning of BT dose reduction for more than 6 months.
Most patients (65%) analyzed remain long time with reduced BT in clinical remission.
We have not observed significant X-ray progression for reduced patients, even if they increase disease activity and need to back to the original BT dose.
The increase in disease activity was the main reason to interrupt the optimization regime.
Infliximab was the drug that remained more time optimized.
According to the results of our study, male patients negative for ACPA and FR remain longer with reduced doses

AB0385 STRATEGIES FOR THE OPTIMIZATION OF BIOLOGICAL THERAPY IN PATIENTS WITH JOINT INFLAMMATORY DISEASE: ANALYSIS OF CLINICAL RESULTS AT 4 YEARS

M.J. Rodriguez Valls, M.D. Toledo Coello, Y. Cabello Fernandez, M.V. Perez Romera, J.J. Perez Venegas. *Reumatologia, Hospital de Jerez, Jerez de la Frontera, Spain*

Background: Biological therapies optimization in joint inflammatory diseases is indicated in patients who have more than six months in clinical remission. The main objective is to limit the occurrence of adverse effects, which are dosage-dependent. In addition, the cost savings suppose a better access of new patients to these treatments. Given the increasing importance of this topic in recent years, we present the optimization experience in our center at the last 4 years
Objectives: 1.To analyze the clinical evolution evaluated by DAS28 in patients with rheumatoid arthritis (RA) and polyarticular psoriatic arthritis (PPSA) in biological therapy (BT) followed in a university hospital in the south of Spain which are performed in optimization of BT. 2.To analyze the optimization strategies used with the different BT
Methods: Observational, longitudinal, retrospective and descriptive study by the review of clinical records, between January 2013 and January 2017, of patients with RA and PPSA who underwent BT optimization for more than 6 months at follow-up (DAS28 $<$2.6) or minimal activity (DAS28 2.6–3.2). We analyze demographic data, time of evolution of illness before the use of BT, time of TB until optimization, clinical evaluation by DAS28 and therapeutic strategies. Statistical analysis was performed with the IBM SPSS Statistics program
Results: From 294 patients in BT (174 RA and 120 PPsA), 95 (32.3%) were submitted to optimization treatment: 58 in RA group and 37 in PPSA group. 57 were women and 38 men, with 56±12 years mean age. The mean treatment time at optimized doses was 32±17 months. At the optimization time, 85 (89.5%) patients presented DAS28 remission and 10 (10.5%) had low activity; at the study cut time, 67 (70.5%) of them continue at clinical remission,14 (14.7%) low activity, 11 (11.6%) moderate and 3 (3.2%)high activity according to DAS28. A 69.5% (66) of the patients continued with optimized doses at the end of the study. From the 58 patients included in the RA group, 14 (5 with adalimumab 40 mg/21 days, 8 with etanercept 25 mg/7–10 days or 50 mg/10 days and 1 with certolizumab 200 mg/month) need the standard dose of the drug for disease control; a patient receiving etanercept discontinued the treatment after the diagnosis of breast cancer, as well as three other patients treated with adalimumab who were diagnosed of pancreatic cancer, septic arthritis and cognitive impairment respectively. On the other hand, 9 patients from of the PPSA group needed to restart the treatment at standard doses, either for articular (4) or cutaneous (5) worsening, 3 of them being treated with adalimumab and 6 with etanercept. In addition, a patient had to be discontinued due to the diagnosis of decompensated liver cirrhosis; another patient suspended it voluntarily
Conclusions: After 4 years, we can conclude that in our cohort of patients with inflammatory joint disease in BT that have been submitted to dose optimization because they were in remission or low disease activity, a high percentage (69.5%) remain in the same clinical situation for an average of 32 months. The response rate obtained for optimization in the RA group and in the PPSA group are comparable. The most frequent optimization strategies employed were adalimumab 40mg/21 days, etanercept 25mg/7 days and etanercept 50mg/10 days.

AB0386 A STUDY OF RETENTION AND SWITCHING RATES OF 1ST LINE BIOLOGICS FOR RHEUMATOID ARTHRITIS

M. Sato, T. Tani, T. Ohashi. *Rheumatology, Ohashi and Tani Orthopedics, Gifu, Japan*

Background: Since the introduction of biologics for rheumatoid arthritis (RA) treatment, significant improvements in joint inflammation control, prevention of bone/joint destruction, activities of daily living (ADL), and quality of life (QOL) have been observed. Tumor necrosis factor (TNF) inhibitors, such as anti-TNF drugs and TNF receptor drugs, accounted for the majority of biologics. However, the use of non-TNF inhibitors, including interleukin (IL)-6 receptor antibodies and selective modulators of T-cell co-stimulation, has been approved, and their efficacy has been demonstrated.
Objectives: This study aimed to analyze the effective usage retention rate of TNF inhibitors and non-TNF inhibitors in RA patients.
Methods: Among 475 RA patients who were administered biologics up to the end of 2015, 329 patients who had been treated for more than 5 years (treatment initiated before the end of December 2010) since the first introduction of biologics (1st line) were included in this study. These patients were divided into TNF inhibitor (infliximab: IFX, etanercept: ETN, and adalimumab: ADA) and non-TNF inhibitor groups (tocilizumab: TCZ, and abatacept: ABT) to investigate the number of patients who progressed to 2nd or 3rd line therapy by 5 years after introduction, and which biologic was administered as the 2nd or 3rd line therapy in each group.
Results: Of 329 patients, 67 were men and 262 were women. Patient age ranged between 22 and 83 years with a mean of 58.7±13.5 years. RA disease duration ranged between 1 and 50 years with a mean of 9.6±8.1 years. TNF inhibitors and non-TNF inhibitors were used as 1st line therapy in 278 and 51 patients respectively. In the TNF inhibitor group, IFX, ETN, and ADA were administered to 145, 87, and 46 patients respectively. In the non-TNF inhibitor group, TCZ and ABT were administered to 48 and 3 patients respectively. In the TNF inhibitor group, 94 of 278 patients (33.8%) progressed to 2nd line therapy owing to efficacy attenuation and adverse events. Thirty-four of these patients were switched to TNF inhibitors and 60 to non-TNF inhibitors. Conversely, 6 of 51 patients in the non-TNF inhibitor group (11.8%) advanced to 2nd line therapy, with 2 switching to TNF inhibitors and 4 to non-TNF inhibitors. Additionally, 25 and 3 patients advanced to 3rd line therapy in the TNF inhibitor and non-TNF inhibitor groups respectively. Throughout the 5 years, 154 (55.4%) patients in the TNF inhibitor group did not change their treatment agent while 69 (24.8%), 24 (8.6%), and 1 (0.4%) switched once, twice, or 3 times or more, respectively. Thirty (10.8%) patients discontinued biologic usage. In the non-TNF inhibitor group, 3 (5.9%), 2 (3.9%), and 1 (2.0%) patients switched once, twice, or 3 times, respectively. Six (11.8%) patients discontinued biologic usage, and no change in treatment occurred in 39 (76.5%) patients. The mean number of biologic agent switches per patient in each group over 5 years was 0.43 times in the TNF inhibitor group and 0.20 times in the non-TNF inhibitor group, indicating that the number was significantly lower in the non-TNF inhibitor group (p=0.0032).
Conclusions: While the sample size was small and patient characteristics varied, it appears that non-TNF inhibitors are not inferior to TNF inhibitors as 1st line therapy biologics in terms of retention rate and number of switches to TNF inhibitors.

AB0387 COMPARISON OF ETANERCEPT IN MONOTHERAPY AND COMBINATION WITH SYNTHETIC DMARDS: DATA FROM ATTRA REGISTRY

P. Horák[1], M. Skácelová[1], L. Szczuková[2], A. Smržová[1], J. Vencovský[3], J. Závada[3], K. Pavelka[3] on behalf of ATTRA registry Czech Republic. *[1]III Department of internal Medicine, Faculty of Medicine and Dentistry, University Olomouc, Olomouc; [2]Institute of Biostatistics And analysis, Masaryk University Brno, Brno; [3]Institute of Rheumatolgy, Charles University of Prague, Prague, Czech Republic*

Background: Etanercept (ETN) is an established bDMARDs for therapy of rheumatoid arthritis and some other inflammatory diseases. In rheumatoid arthritis patients ETN could be given in combination therapy with sDMARDs as well as in monotherapy.

Objectives: To investigate and compare etanercept monotherapy versus combination with sDMARDs in RA patients regarding survival on drug, efficacy, quality of life and reason for discontinuation.
Methods: Observational, open, long-term study of patients from the ATTRA registry starting the ETN therapy since 2010 either on monotherapy or in combination with sDMARDs (n=605). 461 patients (80.7%) were females, rheumatoid factor was positive in 429 (76.6%), anti CCP antibodies in 412 (74.5%) patients. The following groups of patients were assessed: Etanercept monotherapy (ETN-mono, n=83), combination with methotrexate (Combo-MTX, n=378), combination with other sDMARDs (Combo-other sDMARDs, n=110).
Mean ± SD and absolute/relative frequencies were used to describe continuous and categorical variables, respectively. P-value of Pearson Chi-square test and Kruskal-Wallis test is given when assessing differences between groups in categorical and continuous variables. Results are presented as hazard ratio (HR) with corresponding p-value. Statistical evaluation was processed by IBM SPSS Statistics ver. 24.
Results: In the first measurement of activity after 3 months, there were significantly lower disease activity in both Combo groups compared to ETN mono (3.2±0.1 resp. 2.9±0.1 versus 3.7±0.2, $p<0.001$). However since the month 6 the differences lost their significance and the disease activity were comparable in all groups up to the month 24.
The HAQ value was significantly higher already at the time of ETN onset at month 0 in the ETN-mono group (1.7 versus 1.4 resp. 1.5, $p<0.001$) and stayed significantly higher at the month 3 and 12.
The hazard ratio (HR) for ETN discontinuation was higher in ETN mono group compared to Combo-MTX (HR=1.330) and also compared to Combo-other sDMARDs (HR=1.098), even if the differences did not reach statistical significance (p=0.131, resp. 0.671). Similar trend was evident, if the etanercept was given in the first and any subsequent line of biological therapy. The HR for ETN discontinuation was also numerically higher in Combo-other sDMARDs than in Combo MTX group (HR=1.211, p=0.244).
The patients on ETN mono have higher risk of discontinuation due to inefficacy compared to Combo-MTX (HR=1.415) and also to Combo-other sDMARDs (HR=1.670). The patients of combo-other sDMARDs group had lower risk of discontinuation due to inefficacy also in comparison with combo-MTX (HR=0.847). None of the differences reach statistical significance.
The patients on ETN mono have higher risk of discontinuation due to adverse event compared to Combo-MTX and also to Combo-other sDMARDs. This trend is higher, if ETN is given in the subsequent line of biological therapy, but not in first line. Nevertheless like in other situations, the differences showed some trend, but were not statistically significant.
Conclusions: Results support the evidence of advantages of ETN combination with methotrexate – quicker onset of efficacy and give some evidence of better survival on etanercept therapy in combination with methotrexate.

AB0388 RESULTS AT 3 YEARS OF AN OPTIMIZATION GUIDELINE OF BIOLOGICAL THERAPIES IN RHEUMATOID ARTHRITIS. CREATE RECORD RESULTS

P. Font[1], M.C. Castro[2], M. Romero[2], R. Ortega[2], J. Calvo[2], D. Ruiz[2], M. Cardenas[2], R. Alejandre[2], P. Carreto[3], E. Collantes[2]. *[1]Hospital Reina Sofia - Imibic-Universidad de Córdoba; [2]Hospital Reina Sofia - Imibic-Universidad de Córdoba, Cordoba; [3]MFyC de Valladolid, Area Este, Valladolid, Spain*

Background: Dose optimization, such as dose reduction or dose spacing, is nowadays presented as a therapeutic strategy to be followed in patients with rheumatoid arthritis (RA) who have managed to reach and maintain clinical remission for a while. This strategy reduces the frequency of adverse effects and promotes cost savings
Methods: Patients with RA (Criteria ACR 1987) of the CREATE registry (patients who was treated in real life conditions) who had clinical remission (DAS28 <2.6) of at least 6 months of duration on November 1, 2013, constituted the cohort of patients who were optimized for the dose received. According to the consensus of the Spanish Societies of Rheumatology and Hospital Pharmacy, the optimization of doses meant the reduction of between 20 and 50% of the same.
A multidisciplinary team of rheumatologists and clinical pharmacists in a third-level hospital was involved in decision-making on treatment and dose reduction, which involved the application of protocols and the follow-up of patients at least every two months.
Results: A prospective follow-up of 70 patients with RA who had received optimized doses of biological therapy for 3 years, with a mean age of 56.9 (13.7) years, of which 78.6% were women, 68.8% were positive rheumatoid factor and 66.7% ACPA +.
The relapse occurred in 41.8% (at first year), 56.7% (at second year) and 62.7% (at third year). There were no statistical differences between these last 2 percentages. The median survival time of the optimization regimen was 15.24 (4.65) months (95% CI: 4.66–25.83). No statistically significant differences were found when comparing patients according to the optimized drug (antiTNF versus non-anti-TNF) (test log.rank: 0.239, p: 0.625).
When relapse occurs, the patient returns to normal doses prior to optimization of the drug. Our data show that 62.7% of the patients in whom the relapse occurs at 3 years, maintains DAS28 <2,6 ($P<0.05$) when dose was returned to the manufacturer recommended dose.
The 37.3% (95% CI: 26.72%, 49.28%) patients maintained the optimization pattern throughout the follow-up without relapse, with an average DAS28 of 1.99 (1.07) at 3 years. Comparing these patients with those who relapse, they achieved significantly lower DAS28 values at both (p: 0.028) and at three years (p: 0.025)
Conclusions:
- The strategy of dose reduction of biological therapies in patients with established RA that achieve sustained remission is possible in 37.3% of cases in real clinical practice (CREATE Registry) and it was maintained for 3 years.
- The probability of occurrence of relapse decreases after 2 years of treatment with an optimized regimen in those patients who have not relapsed before.
- This strategy is possible in patients with persistently controlled disease and in view of our results, it is independent of the drug administered (antiTNF versus non-antiTNF).
- After 3 years of follow-up, all patients maintained clinical remission (DAS 28 <2.6) despite relapses, and after resumption of the usual dose, all of them reached the therapeutic goal again.
- Patients who maintain clinical remission for 3 years achieve DAS28 values statistically lower than those who did not after 2 years.

AB0389 THE IMMUNOGENICITY OF BRANDED AND BIOSIMILAR INFLIXIMAB IN RHEUMATOID ARTHRITIS ACCORDING TO TH9-RELATED RESPONSES

R. Talotta[1], A. Berzi[2], A. Doria[3], A. Batticciotto[1], M.C. Ditto[1], D. Trabattoni[1], P. Sarzi Puttini[1]. *[1]Rheumatology Unit; [2]Department of Biomedical and Clinical Sciences, University Hospital "Luigi Sacco", Milan; [3]Rheumatology Unit, University Hospital, Padua, Italy*

Background: There are many evidences that Th9 lymphocytes take part to the pathogenesis of rheumatoid arthritis (RA), however it is unclear whether these cells are implicated in the immunogenicity of biologic agents.
Objectives: We aimed to evaluate the immunogenicity of branded and biosimilar infliximab by detecting changes in Th9 percentages following an *"in vitro"* stimulation test.
Methods: PBMCs from 55 consecutive RA outpatients (15 drug-free, 20 successfully treated with branded infliximab and 20 failing branded infliximab) and from 10 healthy controls were collected. PBMCs were cultured with/without 50 μg/mL infliximab originator (Remicade®) or 50 μg/mL infliximab biosimilar (Remsima®), 50 μg/mL Human IgG1kappa and 50 μg/mL recombinant Human IgG Fc for 18 hours. Th9 lymphocytes were identified by means of flow cytometry as PU.1+, IRF4+, IL9+ CD4+ cells. Furthermore, the markers CCR7 and CD45RA were used to distinguish naive from memory IL-9-producer cells.
Results: In unstimulated condition, RA patients showed the highest percentages of Th9 lymphocytes. Following stimulation with branded infliximab, the percentage of PU.1+, IRF4+ Th9 cells, CCR7+, CD45RA- central memory and CCR7-, CD45RA- effector memory IL-9 producer cells significantly increased in the group of infliximab non responder RA patients. On the contrary, no significant variation was observed after biosimilar exposure. Figures 1,2,3,4 resume the results.

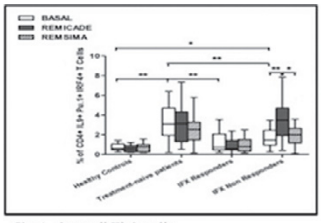

Fig.1 Overall Th9 cells

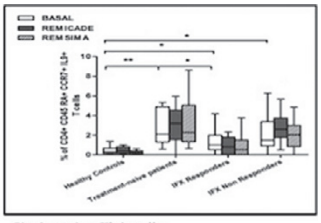

Fig.2 Naive Th9 cells

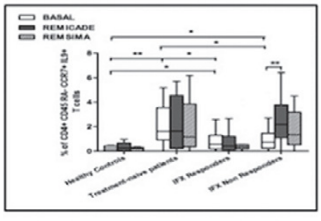

Fig.3 Central memory Th9 cells

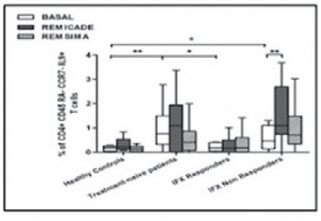

Fig.4 Effector memory Th9 cells

Conclusions: According to our results, Th9 cells seem to be involved in the immune response against the epitopes of branded but not biosimilar infliximab and this condition could rely on the recall and the stimulation of both central and effector memory cells. Further studies are indeed needed to confirm these data.

AB0390 EFFICACY AND SAFETY OF YISAIPU, A RECOMBINANT HUMAN TUMOR NECROSIS FACTOR-α RECEPTOR II IGG FC FUSION PROTEIN IN CHINESE PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

R. Wu. *Department of rheumatology, the First Affiliated Hospital of Nanchang University, Nanchang, China*

Background: Rheumatoid arthritis (RA) is characterized by chronic autoimmune diseases of progressive synovitis and joint destruction, which can eventually lead to joint deformation and disability. A number of clinical studies showed the effectiveness of tumor necrosis factor antagonist combined with methotrexate in the treatment of RA. Yisaipu used in this study is produced by CPGC Company (Shanghai, China), which was approved to treat RA by Chinese Food and Drug Administration, in 2005, which is biosimilar of etanercept (a soluble recombinant human receptor antibody fusion protein, an immunoglobulin molecule which connects two TNF receptors (p75) to the human IgG1 FC division). Etanercept had been confirmed the effectiveness in rheumatoid arthritis already in many clinical trial.[5–8] However, there is rare randomized control study published regarding Yisaipu in international journals. We conducted an open-label, randomized controlled study for 24 weeks to evaluate the efficacy and safety of Yisaipu in combination with DMARDs in comparison with low or medium dose of glucocorticoid in patients with moderate to severe RA.

Objectives: to evaluate the efficacy and safety of Yisaipu in combination with DMARDs in comparison with low or medium dose of glucocorticoid in patients with moderate to severe RA.

Methods: Eighty four patients with moderate to severe rheumatoid arthritis were randomly assigned into 4 groups: group 1: methotrexate plus Yisaipu; group 2: methotrexate plus medium-dose prednisone (30mg/d, reduced to 15 mg/d after 2 weeks); group 3: methotrexate plus low-dose prednisone (prednisone 7.5mg/d); group 4: methotrexate alone. Each group was treated with MTX (12.5mg once weekly, the next day with folic acid 10mg) and hydroxychloroquine sulfate (200 mg twice a day) concomitantly. The primary endpoint was ACR20 response rate at week 24. Secondary efficacy endpoints were ACR20, ACR50, ACR70, DAS-28, Health Assessment Questionnaire (HAQ) and EULAR remission rate at week 4, 12 and 24.

Results: At week 24, a higher proportion of patients in the group 1and group 2 than the other two groups met the ACR20 response criteria (85.7% in group 1 and 71.4% in group 2 vs. group 3 and group 4, $P<0.05$). The reductions of HAQ at week 24 showed significant improvement in group 1 and group 2 compared to group 3 and 4 (-2.96 and -2.69 respectively, $P<0.05$). Reduction of DAS-28 in group 1 and group 2 were significantly higher than the other two groups ($P<0.05$). The percentage of EULAR remission rate of group 1 and group 2 is significantly higher than group 3 and group 4 at week 24 (47.6% in group 1, 33.3% in group 2, 23.8% in group 3 and 14.3% in group 4, $P<0.05$). There were no significant differences of adverse event among four groups.

Conclusions: Yisaipu plus MTX or GCs plus MTX in Chinese patients with moderate to severe RA is safe and effective in our study. More studies are needed to compare the long-term safety and cost-effectiveness between Yisaipu and GCs in treatment with RA.

AB0391 SIMILAR PHARMACOKINETICS, SAFETY AND TOLERABILITY OF THE ADALIMUMAB BIOSIMILAR CANDIDATE BI 695501 ADMINISTERED SUBCUTANEOUSLY VIA PREFILLED SYRINGE (PFS) OR AUTOINJECTOR (AI) (VOLTAIRE®-AI)

S. Ramael[1], V. Moschetti[2], N. Peter[2], I. Sonderegger[2], S. Wiebe[2], B. Liedert[2]. *[1]SGS Life Science Services, CPU, Antwerp, Belgium; [2]Boehringer Ingelheim, Ingelheim a.R., Germany*

Background: PK bioequivalence of BI 695501, an adalimumab biosimilar candidate, and the adalimumab originator was demonstrated previously (VOLTAIRE®-PK: Wynne et al., Expert Opin Investig Drugs 2016;25:1361–70). Administration in chronic inflammatory diseases benefits from patient-friendly PFSs or AIs, the development of which requires assessment of PK, safety, immunogenicity, and local tolerability.

Objectives: To compare PK, safety, immunogenicity, and tolerability of BI 695501 after subcutaneous (SC) injection using either a PFS or an AI.

Methods: In this 16-week randomised, single-dose, open-label, parallel-group study (NCT02606903), 40mg BI 695501 was administered either via PFS or AI in healthy, Caucasian, male, non-athletic volunteers aged 18–65 years with body mass index (BMI) of ≥18 to ≤30 kg/m^2. The study end points included AUC_{0-1032}, C_{max}, and $AUC_{0-\infty}$, analysed using an ANOVA model with fixed effects for treatment and BMI group. Safety assessment included the proportion of subjects with drug-related adverse events (AEs). Immunogenicity parameters were: proportion of subjects with binding/neutralising anti-drug antibodies (ADAs), and ADA titers.

Results: Seventy-one volunteers were randomised: PFS, n=36; AI, n=35. Key demographic and baseline characteristics were well balanced between the treatment groups. PK end point results are shown in Table 1. Estimates for AI/PFS geometric mean (gMean) ratios were within the standard bioequivalence acceptance range (80–125%). Mean plasma concentration-time profiles and total exposure for BI 695501 administered via PFS or AI were similar over the observation period; treatment-emergent AEs (TEAEs) and administration site conditions (ASC) are shown in Table 2.

Table 1. PK Parameters over All Subjects for BI 695501 via PFS or AI

Parameter	PFS		AI		Adjusted gMean ratio (AI/PFS)*	2-sided 90% CI*
	n	Adjusted gMean*	n	Adjusted gMean*		
$AUC_{0-\infty}$† [μg·h/mL]	35‡	2270	35	2280	100.22	82.13, 122.29
AUC_{0-1032} [μg·h/mL]	35‡	1960	35	1960	100.14	85.15, 117.76
C_{max} [μg/mL]	36	3.76	35	4.14	110.19	96.80, 125.44

*Adjusted for treatment and BMI group as fixed effects; †Based on observed last concentration values; ‡AUC values could not be calculated for one subject (Subject 1001-0110), due to the lack of appropriate terminal phase (only one non-BLQ [below the limit of quantification] value in the elimination phase).

Table 2. TEAEs and ASC

n (%)	PFS (n=36)	AI (n=35)
≥1 TEAE	29 (80.6)	29 (82.9)
≥1 TEAE related to trial drug	16 (44.4)	20 (57.1)
≥1 non-serious TEAE	29 (80.6)	29 (82.9)
≥1 serious TEAE	0	0
ASC*	14 (38.9)	20 (57.1)
Injection site erythema	13 (36.1)	18 (51.4)
Injection site swelling	3 (8.3)	7 (20.0)
Injection site induration	1 (2.8)	4 (11.4)

*Injection-site reactions are those events recorded within the electronic case report form "Administration site reactions" (narrow) list.

Similar frequencies of patients tested positive for ADAs (57.6% in the PFS group and 51.5% in the AI group), and for neutralising antibodies (33.3%% in the PFS group and 30.3% in the AI group) at the end of the study.

Conclusions: PK, safety, tolerability, and immunogenicity of BI 695501 after SC injection with a PFS or an AI were comparable.

Kim[12], J.Y. Choe[13], H.I. Yang[14], M.K. Lim[15], S.J. Hong[16], Y.S. Kim[17], J.H. Lee[18], J. Suh[19], S. Lee[19]. *[1]The Catholic University of Korea Seoul St.Mary's Hospital, Seoul; [2]Soonchunhyang University Cheonan Hospital, Cheonan; [3]The Catholic University of Korea St. Vincent's Hospital, Suwon; [4]Chonnam National University Hospital, Gwangju; [5]Inha University Hospital, Incheon; [6]Gyeongsang National University School of Medicine, Jinju; [7]Ajou University School of Medicine, Suwon; [8]Keimyung University Dongsan Medial Center, Daegu; [9]Bucheon St.Mary's Hospital, Bucheon; [10]Konkuk University School of Medicine, Seoul; [11]Gachon University Gil Medical Center, Incheon; [12]The Soonchunhyang University Seoul Hospital, Seoul; [13]Daegu Catholic University Medical Center, Daegu; [14]Kyung Hee University Hospital at Gang Dong, Seoul; [15]Eulji University School of Medicine, Daejeon; [16]Kyung Hee University Medical Center, Seoul; [17]Chosun University Hospital, Gwangju; [18]Inje University Ilsan Paik Hospital, Goyang; [19]Celltrion, Inc, Incheon, Korea, Republic Of*

Background: CT-P13 is approved in both European Union and United States, and licensed for use in 79 countries around the world as a biosimilar to innovator infliximab (INX). The independent registries of CT-P13 have been conducted in a number of European countries and Korea [1].

Objectives: To evaluate safety and effectiveness of CT-P13 when administered in a real-life setting in active RA patients.

Methods: This study collected data of patients who were treated with CT-P13 from 2013 December to 2016 June. Efficacy was assessed at baseline and every 6 months thereafter using DAS28 (ESR) and/or DAS28 (CRP) and collection of adverse events (AEs) was performed. Immunogenicity was assessed at baseline, Week 30 and every year during CT-P13 treatment period.

Results: Total 125 patients were enrolled; 104 patients started treatment with CT-P13 (Naïve group) and 21 patients (8 from INX, 13 from other anti-TNFs) switched treatment to CT-P13 (Switching group). The mean (SD) duration since RA diagnosis was 6.5 (±6.85) years for all patients.

Of all patients treated with CT-P13, only 4.8% (6/125) of patients changed to other anti-TNFs. Two of six patients changed treatment within 8 month after starting CT-P13.

The proportion of patients achieving clinical remission by DAS28 (ESR/CRP) increased gradually (Figure 1). DAS28 (ESR/CRP) value decreased from baseline at 6 months and it maintained thereafter (Table 1). Switching group also showed similar results that remission rate by DAS28 (CRP) was 42.9% (3/7) and mean actual value was 2.85 at 12 months.

For Naïve group, 50% (52/104) of patients had at least one positive anti-drug antibody result and it is consistent to other published study [2].
Overall safety summarized as the percentage of patients with at least one treatment emergent AE (TEAE) was similar or lower after switching to CT-P13 (Table 2). No cases of active tuberculosis were reported.

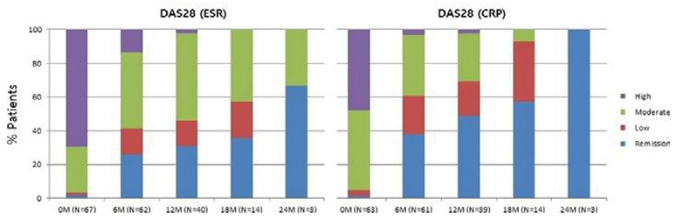

Table 1. DAS28 in CT-P13 Naïve group over 24 months

		Baseline	6 months	12 months	18 months	24 months
DAS28 (ESR)	n	67	62	40	14	3
	Mean	5.78	3.61	3.30	3.01	2.42
	SD	1.14	1.40	1.22	1.03	0.74
DAS28 (CRP)	n	63	61	39	14	3
	Mean	5.06	2.97	2.59	2.35	1.81
	SD	1.19	1.21	1.06	0.69	0.63

Table 2. Safety results in CT-P13 Naïve and Switching group

	Naïve group	Switching group
TEAEs	80.8% (84/104)	66.7% (14/21)
Related TEAEs	31.7% (33/104)	28.6% (6/21)
Infection and Infestation	42.3% (44/104)	33.3% (7/21)

Figure 1. Disease Activity by DAS28 in CT-P13 Naïve group

Conclusions: The overall safety profile revealed that CT-P13 is well-tolerated in patients with RA and remission rate for 24 months also showed that CT-P13 is efficacious under real world practice.

AB0393 ADVERSE SKIN REACTIONS IN RHEUMATOID ARTHRITIS PATIENTS RECIEVING TUMOR NECROSIS FACTOR ALPHA INHIBITOR – AN ANALYSIS OF DATA FROM THE SLOVENIAN BIOLOGICAL REGISTRY

S. Drljača[1], A. Podovšovnik[1], Ž. Rotar[2], A. Hočevar[2], S. Praprotnik[2], M. Tomšič[2] on behalf of rheumatologist participating in BioRx.si registry.
[1]Department of Internal medicine, Izola General Hospital, Izola; [2]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background: Paradoxical skin reactions (PSR) are defined as a new onset or worsening of skin conditions during treatment with tumour necrosis factor alpha (TNF-α) inhibitors that generally improve or respond to this therapy. The list of PSR is growing. The most commonly reported are psoriasiform skin eruptions.
Objectives: To evaluate the frequency of PSR in the group of rheumatoid arthritis (RA) patients treated with TNF-α inhibitor at the time of development of skin eruption.
Methods: We conducted the analysis of the data from the mandatory Slovenian national registry of patients treated with bDMARDs (BioRx.si) which includes spontaneous adverse reaction reports between 01.01.2008–31.05.2016. The analyses were limited to patients with RA.
Results: During the observation period, 1,046 RA (82% female; median (IQR) age at initiation of TNF-α inhibitors 56 (49–63) years) patients treated with TNF-α inhibitors for 3,140 person years. We identified 14 cases with PSR (71% female, median age (IQR) 45 (53–62)). There were 6 PSR cases on adalimumab, 4 on etanercept, 3 on certolizumab – pegol, and 1 on infliximab. 10 patients developed psoriatic/psoriasiform eruptions, 2 patient leucocytoclastic vasculitis, one had lichen planus, and one undifferentiated skin changes. The incidence rate of new onset of psoriasis in RA patients treated with TNF-α inhibitors was estimated at 3.2 cases/1000 patient-years (95% CI 2.58 to 3.82). The incidence rate of leucocytolastic vasculitis was 0.64/1000 person-years (95% CI 0.36 to 0.92), and of lichen planus 0.32/1000 person-years (95% CI 0.12 to 0.52).
Conclusions: The most commonly reported PSR in RA patients treated with TNF-α inhibitor was psoriasiorm PSR, which is in line with published data.

AB0394 TAPERING TNF INHIBITORS IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE STUDY

A. Hacioglu, G. Hatemi, S.N. Esatoglu, Y. Ozguler, S. Ugurlu, E. Seyahi, M. Melikoglu, I. Fresko, H. Ozdogan, S. Yurdakul, V. Hamuryudan. *Division Rheumatology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey*

Background: Increasing evidence suggests the feasibility of biologic DMARD tapering in RA patients after achieving and maintaining good control of disease activity. Current guidelines on RA treatment also recommend tapering of biologic and non-biologic DMARDs for patients in remission. Data on biologic DMARD tapering reflecting real life settings are limited.
Objectives: To collect information on biologic DMARD tapering and its outcome in RA patients who are followed-up in a rheumatology outpatient clinic.
Methods: In this retrospective study we used the hospital administrative database to identify patients with a diagnosis of RA and a first time prescription of a biologic DMARD that was specifically limited to one of the 3 TNF inhibitors (etanercept, adalimumab, infliximab) between January 2012 and the end of December 2013. Demographics and information regarding treatment and outcome were taken from the medical charts.
Results: Of the 125 patients identified at the database search, 104 were belonging to our clinic and had available follow-up data until June 2016. Seventy-nine of them were women and 25 were men. Their mean age was 47.7±13 SD years and their mean disease duration was 7.4±6.9 SD years. 60% were prescribed etanercept, 23% adalimumab and 17% infliximab. After a mean duration of 14.0±7.6 SD months a dose reduction of TNF inhibitors was made in 44 patients (42%). This was in the form of spacing in 39 patients (Etanercept =16, Infliximab =14, Adalimumab =9) and dose tapering in 5 (all Etanercept). All of these were due to good clinical response except for 1 patient's own request for fear from adverse effects. Following dose reduction increased disease activity was seen in 16 patients (36%) mandating restoration to original dose within a mean of 8.8±9.7 SD months with good response. Twenty-eight patients (64%) preserved their good clinical response during a mean follow-up of 46.1±6.3 SD months which enabled further dose reductions in 20 patients. There was also reductions in the mean number of synthetic DMARD's (1.4±0.8 SD at the initiation of TNF inhibitors and 0.7±0.8 SD at the end of follow-up) and in the percentage of patients using steroids (78% to 33%). At the end of the follow-up, among the whole group of 104 patients, only 73 (70%) were using biologics (TNF inhibitors =49, non-TNF biologics =24). The reasons for stopping biologics in the remaining 31 patients were ongoing remission (16 patients), pregnancy (1 patient), non-compliance (4 patients), injection site reactions (3 patients), fear from adverse events (1 patient), deciding to try complementary medicine (1 patient) and other issues such as losing insurance and family issues (5 patients).
Conclusions: Tapering of TNF inhibitors was possible in 40% of RA patients during their routine follow-up. Half of the patients maintained good clinical response after tapering allowing further dose reductions in one third.

Rheumatoid arthritis - other biologic treatment

AB0395 SUBCUTANEOUS TOCILIZUMAB AS MONOTHERAPY OR IN COMBINATION WITH A CSDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS: 24 WEEKS RESULTS OF THE FRENCH PHASE IIIB STUDY, "TOSCA"

B. Fautrel[1], E. Senbel[2], O. Vittecoq[3], S. Rist[4], B. Combe[5], T. Schaeverbeke[6], F. Lioté[7], R.-M. Flipo[8], C. Baffie[9], D. Pau[10], E. Condé Da Silva Fraga[10], A. Pinta[11], P. Gaudin[12]. *[1]Rheumatology, Hôpital Pitié-Salpêtrière, Paris; [2]Rheumatology, Cabinet médical, Marseille; [3]Rheumatology, CIC/CRB 1404 CHU de Rouen, Rouen; [4]Rheumatology, CHG Orléans, Orleans; [5]Rheumatology, CHU Montpellier, Montpellier; [6]Rheumatology, CHU Bordeaux, Bordeaux; [7]Rheumatology, CHU Lariboisière, Paris; [8]Rheumatology, CHRU Lille, Lille; [9]Opérations cliniques, Altizem on behalf of Roche; [10]Clinical operations; [11]Medical department, Roche, Boulogne-Billancourt; [12]Rheumatology, CHU Grenoble, Grenoble, France*

Background: After the two global pivotal studies, which evaluated the safety and efficacy of subcutaneous tocilizumab (TCZ-SC) in combination (combo) with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), it was important to understand the efficacy and safety profile of TCZ-SC both as monotherapy (mono) and in combo with csDMARDs in patients (pts) managed in conditions less strict than those of pivotal clinical trials.
Objectives: To evaluate the efficacy and safety of TCZ-SC 162 mg once weekly (qw) as mono and in combo with csDMARDs over 24 weeks in adult pts with moderate to severe RA. The primary efficacy criterion was the change in DAS28-ESR from baseline to week 24 (W24).
Methods: TOSCA is a national, multicenter, open-label phase IIIb study, part of the international umbrella study (TOZURA). It aimed to enroll TCZ-naïve pts who were csdMARDs inadequate responders (IR) and/or biological DMARD-IR. Pts received TCZ-SC 162 mg qw for 24 weeks, administered at the investigator's discretion as mono or in combo with a csDMARD. Stable oral corticosteroids (CCS), ≤10 mg/day prednisone or equivalent (eq.pred), were allowed.

Results: The baseline characteristics of the 139 included patients were: mean age 57.3 years (±13.8), 74.1% female, mean RA disease duration 10.8 years (±9.2), immunopositivity 85.5%, structural joint damage 65.6%, mean DAS28 5.8 (±1.1). 52.5% of patients were bDMARD-IR. TCZ-SC was initiated in mono TCZ in 30.9% of pts and in combo in 69.1% (79.1% MTX). Oral CCS were used by 56.8% of pts (mean 7.4 mg/d/eq.pred.±2.7). In comparison with combo pts, the mono pts were older (58.7 vs 56.7 years), with a higher mean DAS28 (6.1 vs 5.7), a longer disease duration (11.5 vs 10.6 years), and a higher CCS mean dose (8.3 vs 6.9 mg/d/eq.pred.). At W24, the mean DAS28 score variation vs baseline was -3.1 overall ($p<0.0001$); -3.0 in mono TCZ vs -3.1 in combo TCZ ($p=0.76$) (Fig.). The proportion of pts who achieved DAS28 remission was 51.1% (41.9% in mono vs 55.2% in combo ($p=0.14$)). CDAI remission, which does not include acute phase reactants, was achieved in 17% pts, 16% in mono vs 17% in combo ($p=0.95$). At W24, 27.9% of pts receiving >5 mg CCS at baseline decreased the daily dose ≤5 mg/d/eq.pred. (30.1% in mono TCZ and 26.7% in combo). Out of the 23 pts (16.5%) who withdrew, 13.0% did so for lack of efficacy and 52.1% for safety reasons; one death occurred following a septic shock after surgery for gastric volvulus, not related to TCZ. At W24 95.7% of patients had experienced at least one adverse event (AE) and 10.1% at least one serious AE with similar rates between groups.

Conclusions: TCZ-SC demonstrated at 6 months comparable efficacy, safety and steroid sparing results in mono- and combo therapy consistent with the known profile of TCZ-IV.

AB0396 TOCILIZUMAB I.V. EFFECTIVENESS IN RA PATIENTS IS INDEPENDENT OF SMOKING STATUS

C. Specker[1], H. Kellner[2], P. Kästner[3], C. Volberg[4], V. Braunewell[5], I. Schwarze[6], M. Aringer[7], M. Sieburg[8], M.W. Hofmann[9], J.P. Flacke[10], H.-P. Tony[11], G. Fliedner[12]. *[1]Kliniken Essen Süd, Essen; [2]Schwerpunktpraxis für Rheumatologie und Gastroenterologie, München; [3]MVZ Ambulantes Rheumazentrum Erfurt, Erfurt; [4]Rheumazentrum Neuss, Neuss; [5]Schwerpunktpraxis Rheumatologie, Mönchengladbach; [6]Praxis für Internistische Rheumatologie, Leipzig; [7]Medizinische Klinik III, Rheumatologie, Technischen Universität Dresden, Dresden; [8]Rheumatologische Gemeinschaftspraxis, Magdeburg; [9]Rheumatologie, Chugai Pharma Europe Ltd., Frankfurt; [10]Rheumatologie, Roche Pharma AG, Grenzach-Wyhlen; [11]Rheumatologie/Immunologie der Medizinischen Klinik und Poliklinik II, Universitätsklinikum Wuerzburg, Wuerzburg; [12]Rheumapraxis, Osnabrueck, Germany*

Background: Cigarette smoking is considered an established risk factor for the development of rheumatoid arthritis (RA) and for poor response in RA patients to treatment with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and with anti-tumor necrosis factor (anti-TNF) agents [1,2].

Objectives: This interim analysis of the German non-interventional study ICHIBAN (NCT01194401) assessed the effectiveness and safety of intravenously administered Tocilizumab (TCZ i.v.) with respect to patients' smoking status (smoker, ex-smoker, non-smoker).

Methods: Since 2010 the ICHIBAN study collects clinical data of the routine use of TCZ i.v. in RA patients. The observation period for each patient is up to two years. At the due date of the current interim analysis (Dec 10, 2015) 2999 patients were enrolled. 902 patients have completed the maximal 104 weeks observation period (Group W104). Patients were subgrouped according to their smoking status at baseline (BL).

Results: At BL the subgroups showed the following distribution: smokers 19.0%, non-smokers 52.5%, and ex-smokers 17.0%. The mean TCZ i.v. treatment duration was 1.7, 1.8, and 1.6 years, respectively, for the three groups.

In comparison to non-smokers and ex-smokers, smokers comprised a higher percentage of male patients, were younger, and showed shorter disease duration. Smokers showed slightly lower overall comorbidity rates, while COPD was observed almost three times more among smokers (3.5%) and ex-smokers (3.9%) than in non-smokers (1.3%). Concomitant use of csDMARDs and glucocorticoids (GC) was more frequent among smokers.

DAS28-ESR disease activity at BL was similar between the 3 subgroups. After 2 years TCZ i.v. therapy, disease activity was comparably decreased in all 3 groups. The mean reduction from BL in DAS28-ESR was 2.6 (smokers), 2.8 (non-smokers), and 2.5 (ex-smokers). At last visit, DAS28-ESR remission (<2.6) was reached by 48.0%, 52.3%, and 51.6% of patients, respectively The similar effectiveness of TCZ i.v. was also shown by patient reported outcomes via visual analogue scales (VAS).

Regarding safety, smokers showed higher event rates of adverse events (AE), serious adverse events (SAE), infections, and serious infections [Tab. 1]

Table 1 Effectiveness and safety of TCZ i.v. in RA patients

		W104 (Total)	Smokers	Non-smokers	Ex-smokers
Baseline characteristics, % (n)		100.0 (902)	19.0 (171)*	52.5 (474)*	17.0 (153)*

Age [years], mean ± SD		55.7 ± 12.4	51.8 ± 10.1	56.8 ± 13.6	56.6 ± 11.4
Duration of RA [years], median		8.0	6.0	8.0	8.0
Comedication, % (n)					
• DMARDs		42.6 (384)	49.7 (85)	41.4 (196)	37.9 (58)
• GC		61.5 (555)	68.4 (117)	59.7 (283)	56.2 (86)
Comorbidities, % (n)		72.5 (654)	68.4 (117)	72.4 (343)	78.4 (120)
Effectiveness					
DAS28-ESR					
• Week 0 (Baseline), mean ± SD		5.5 ± 1.1	5.5 ± 1.1	5.5 ± 1.1	5.3 ± 1.0
• Last visit under TCZ, mean ± SD		2.7 ± 1.5	2.9 ± 1.7	2.7 ± 1.5	2.8 ± 1.5
• Change from BL, mean ± SD		-2.7 ± 1.6	-2.6 ± 1.7	-2.8 ± 1.7	-2.5 ± 1.5
• Remission (< 2.6), % (n)		51.9 (468)	48.0 (82)	52.3 (248)	51.6 (79)
VAS [mm], median (Q1, Q3)					
• Exhaustion/Tiredness	(Baseline)	60.0 (36, 79)	62.0 (31, 80)	59.0 (40, 78)	55.0 (34, 75)
•	(Last visit)	37.0 (14, 60)	39.0 (13, 62)	35.0 (15, 60)	40.5 (12, 57)
• Intensity of pain	(Baseline)	65.0 (45, 79)	67.0 (42, 80)	63.0 (45, 77)	62.0 (46, 78)
•	(Last visit)	30.0 (13, 56)	32.0 (16, 58)	30.0 (11, 53)	38.5 (15, 60)
• Sleep disturbances	(Baseline)	50.0 (21, 74)	48.0 (15, 80)	45.0 (21, 72)	50.0 (25, 72)
•	(Last visit)	30.0 (10, 60)	27.0 (5, 57)	28.0 (10, 59)	35.0 (12, 62)
Safety (event rate per 100 patient years)					
Adverse events (AEs)		80.1	99.0	74.6	97.9
Serious adverse events (SAEs)		19.4	30.4	15.7	22.2
Infections (AEs) **		21.8	29.4	20.5	26.3
Infections (SAEs) **		2.9	5.2	2.0	2.4
Discontinuations due to AEs		2.9	3.5	2.2	5.7

SD: Standard deviation; VAS: Visual Analogue Scale; Q1, Q3 = 1st / 3rd quartile

* Please note, that for 104 patients (11.5%) the smoking status is unknown

** Infections: All AEs/SAEs with a MedDRA Preferred Term indicating an infection

Conclusions: TCZ i.v. treatment over two years resulted in improvements of all disease activity parameters. Contrary to csDMARDs and TNF-blockers, the results show that smokers benefit from TCZ i.v. to the same extent as non-smokers and ex-smokers. The similar effectiveness of TCZ i.v. was confirmed by distinctly improved patient reported outcomes (PROs) in all subgroups. On the other hand, smoking seems to coincide with a higher rate of adverse events and an increased risk of infections. However, due to differences in baseline characteristics between the subgroups, this has to be interpreted with caution.

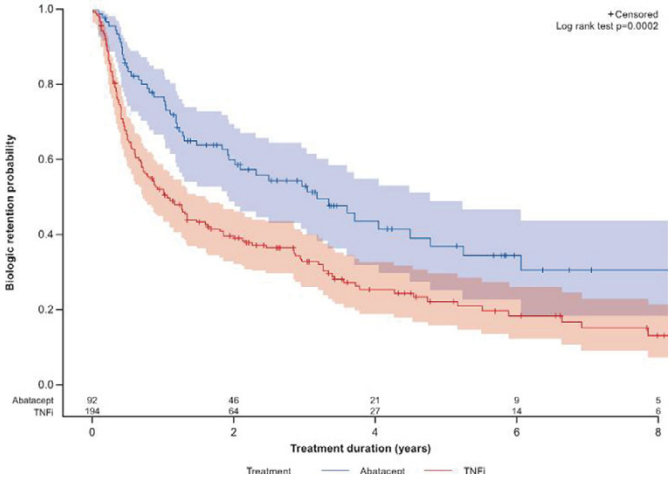
AB0397 ABATACEPT SHOWS BETTER SUSTAINABILITY THAN TNF INHIBITORS WHEN USED FOLLOWING INITIAL BIOLOGIC DMARD FAILURE IN THE TREATMENT OF RHEUMATOID ARTHRITIS: 8 YEARS OF REAL-WORLD OBSERVATIONS FROM THE RHUMADATA® CLINICAL DATABASE AND REGISTRY

D. Choquette[1], L. Bessette[2], E. Alemao[3], B. Haraoui[1], F. Massicotte[1], M. Mtibaa[4], E. Muratti[4], J.-P. Pelletier[1], R. Postema[5], J.-P. Raynauld[1], M.-A. Rémillard[1], D. Sauvageau[1], A. Turcotte[2], É. Villeneuve[1], L. Coupal[1]. *[1]Rheumatology, Institut de recherche en rhumatologie de Montréal (IRRM), Montréal; [2]Rheumatology, Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, Canada; [3]Bristol-Myers Squibb, Princeton, United States; [4]Bristol-Myers Squibb, Montréal, Canada; [5]Bristol-Myers Squibb, Uxbridge, United Kingdom*



Background: In the absence of biomarkers predicting response to a specific therapy, the choice of second biologic is based mostly on habit and availability of an alternative agent. Traditionally, a second anti-TNF was the preferred option, but recent registry data point to better responses and retention if a drug with a different mode of action is prescribed.
Objectives: Assess the long-term retention of abatacept (ABA) and TNFi following first biologic (b)DMARD inadequate response in RHUMADATA® registry patients (pts) with RA.
Methods: Data from RHUMADATA® pts with RA prescribed either ABA or TNFi as the second bDMARD after 1 January 2006 were analysed. Pts were followed until treatment discontinuation or 9 January 2017 cut-off. Pt characteristics were compared using descriptive statistics, bDMARD discontinuation rates using Kaplan-Meier methods, and proportional hazard models were used to identify predictors of treatment discontinuation.
Results: Data for 92 and 194 pts prescribed ABA or a TNFi, respectively, as second-line treatment were extracted. No clinically significant differences in baseline characteristics were noted between treatment groups. Most pts were women (76.2%), average age (SD) was 45.1 (13.3) years at diagnosis and disease duration 10.8 (9.0) years. Most pts were stopping an anti-TNF agent: 97% of those who were switched to ABA and 83% of those who were prescribed a second anti-TNF. Overall, 77.6% of pts stopped their first bDMARD after >6 months of treatment (secondary failure). Significant differences in retention between ABA and TNFi groups (log-rank p=0.0002) were observed (Table, Figure). Results remained unchanged for pts treated with TNFi only in first line, and primary/secondary failure of the first bDMARD did not affect sustainability of the second agent. Lack of efficacy (57.7%) and AEs (16.5%) were the most commonly cited reasons for treatment discontinuation.
Conclusions: Abatacept has better sustainability over a second line TNFi in RA patients having failed one prior bDMARD.

AB0398 IMPACT OF BODY COMPOSITION ON RESPONSE TO BIOTHERAPY IN RHEUMATOID ARTHRITIS

S. Bouden, D. Kaffel, W. Hamdi[1,1], M.M. Kchir. *Rheumatology, Institut kassab, tunis, Tunisia*

Background: Biological therapies had greatly improved the treatment of rheumatoid arthritis (RA). The response to biologics may be influenced by many factors. Little is known about the impact of body composition inRA biologics.
Objectives: We aimed to investigate the impact of obesity (BMI≥30) andbody composition (lean mass/ fat mass)on response to biotherapy in RA.
Methods: A retrospective study was performed over a period of 11 years (2006–2016). Patients diagnosed RA (according to the ACR 1987 criteria) and treated by biologics were enrolled. Body composition (lean mass/ fat mass) was measured by X-ray biphotonic absorption (DXA). The threshold of signification was set for a value of $p<0.05$.
Results: Fifty patients were enrolled, including 5 men and 45 women (sex ratio=0.11). The mean age was 66 years [38–79]. The mean duration of RA was 5 years [1–30]. The mean duration of treatment with biologics was 38 months [6–120]. Thirty nine patients were treated by TNF alpha inhibitors (25 etanercept, 7 adalimumab, 6 infliximab and 1 certolizumabpegol), 6 rituximab and 5 tocilizumab. Nine patients had a normal weight (18%), 17 had overweight (34%) and 24 had obesity (49%). The average percentage of fat mass was 44.8 [23–54], with a median of 46. While comparing obese patients with others, we did not notice a significant difference in the mean variation of the DAS28 at 6 months for TNF alpha inhibitors nor for all biotherapies combined (respectively p=0.6 and p=0.9). The same result was observed while comparing the DAS28 according to the body composition (relative to the median of the percentage of the fat mass: for TNF alpha inhibitors (p=0,6) and for all biotherapies combined (p=0,09)).
Conclusions: In our study, there was no change in response to biologics in patients with RA. Further prospective studies with a larger size will be required to confirm or reverse these results.

AB0399 RITUXIMAB TREATMENT AND IMMUNOGLOBULIN LEVELS MONITORING

G. Kasavkar, S. Kamath. *Rheumatology, Haywood hospital, Stoke on Trent, United Kingdom*

Background: Rheumatoid arthritis is a well-known inflammatory condition with a prevalence around 1% in females and 0.5% in males in UK (as per NOAR study). In the past decade use of biologic therapy has helped clinicians to treat rheumatoid arthritis more effectively. Rituximab is one of the biologics which is used commonly for treating rheumatoid arthritis. Rituximab is chimeric monoclonal antibody targeting CD20 molecule of B cells. First trial of rituximab in treating rheumatoid arthritis was published in 2004 and since then it has shown promising results in trials. In order to guide clinicians British society of rheumatology proposed recommendations in March 2010. An audit is required to ensure adherence to clinical guidelines at Haywood hospital.
Objectives: To assess whether patients receiving Rituximab are appropriately monitored with pretherapy evaluation of immunoglobulin levels

To assess the effects of rituximab on immunoglobulin levels and incidence of infection among patients on rituximab
Methods: Data was collected of all (N=105) patients who received Rituximab between May 2014 until April 2015 at the Haywood Hospital where patients attend for Rituximab injections.
Data was collected retrospectively from the Diamond System, Medisec system and Clinical Information System and entered onto an excel spread sheet which included following details
- Start date of Rituximab
- IgG levels prior to Rituximab and current IgG levels
- Total doses of rituximab and frequency of IgG monitoring
- Intermittent infections and type of infections.

Results: We observed that 82 out of 105 patients were started on rituximab after February 2011 when the BSR guidance was published and 53 out of 105 patients had their immunoglobulin levels checked prior to commencing rituximab
35/76 (46%) patients had 1 or more episodes of infections whilst on Rituximab which required treatment. Of these, 16 (46%) had recurrent infections.
39 patients had dropped their IgG levels after starting rituximab 18 (46%) of these suffered from infections.
17 patients had a drop in IgG ≥20% and 6 of these (36%) had recurrent infections and 1 patient had 1 episode of infection.
None of the patients had dropped their IgG levels below 5
Conclusions: A significant number of patients (35/76 =46%) had 1 or more episodes of infections despite IgG levels being above lower normal limit
Among patients who dropped their IgG levels had increased number infections. Also they had more than 1 episodes of infection
Patients who dropped IgG levels ≥20% suffered with recurrent infections

AB0400 EFFICACY AND SAFETY OF INTRAVENOUS AND SUBCUTANEOUS TOCILIZUMAB IN A COHORT OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS IN REAL-LIFE

G. Pomponio, C. Tontini, A. Angeletti, D. Olivari, D. Benfaremo, L. Manfredi, M.G. Danieli, P. Fraticelli, M.M. Luchetti, G. Moroncini, A. Gabrielli. *Department of Internal Medicine, Azienda Ospedaliero-universitaria 'Ospedali Riuniti', Ancona, Italy*

Background: Tocilizumab (TCZ) is a humanized monoclonal anti-interleukin-6 receptor antibody, used for the treatment of moderate to severe rheumatoid arthritis (RA). Although TCZ has been proved to be highly effective and safe in RA patients in large clinical trials, few data are available from real-life practice [1].
Objectives: To evaluate efficacy, safety and retention rate of intravenous (IV) and subcutaneous (SC) TCZ in a real-world setting.
Methods: We evaluated patients affected by moderate-to-severe RA and treated with TCZ from April 2010 to January 2017. Data of patients treated with IV-TCZ until January 2017 were collected retrospectively, while patients treated with either IV or SC-TCZ from January 2015 were included in a prospective cohort and assessed for disease activity, treatment discontinuation and/or onset of adverse events (AEs). DAS28-CRP, CDAI and SDAI scores were used for disease activity assessment and paired t test was used for statistical analysis. Treatment retention rate was estimated by Kaplan-Meier method.
Results: We evaluated 100 patients, 58 treated with IV-TCZ (8 mg/kg every 4w), 16 with SC-TCZ (162 mg every week), 26 switched from IV to SC during followup and 6 of these returned to IV-TCZ for cutaneous intolerance (80 females, median age 63 y, median duration of disease 11 y, median follow-up 16 months). Seventy-eight patients (78%) were treated with monotherapy and twenty-two (22%) in combination with methotrexate. At baseline, disease activity was severe in 87% of patients, moderate in 6% and mild or inactive in 7%; at the latest follow-up 60% of patients are in clinical remission. The mean DAS28-CRP in IV-TCZ and SW-TCZ groups considered as a whole was 4.34 at baseline and 2.71 at the latest follow-up available ($p<0.0001$). In the SC-TCZ group, mean basal DAS28-CRP was 3.70 vs 1.89 measured at the latest follow-up ($p<0.0001$). Fifty-three patients (53%) discontinued TCZ because of inefficacy (19), AEs (13) or other reasons (21, mostly lost to follow-up). Infections were the most frequent AE (45.1/100 person-years), 3 cases of severe pneumonia, one required treatment discontinuation. Infusion reactions were reported in 6/58 IV-TCZ patients, while injection site reactions in 14/42 SC-TCZ patients. Six of these intolerant patients were subsequently treated with i.v. tocilizumab without reactions. We observed an overall high retention rate of IV-TCZ and SW-TCZ (91.1%, 81.2%, 70.6%, 61.3%, 57.1% and 50% at 1, 2, 3, 4, 5, and 6 years respectively). The retention rate of SC-TCZ patients at 3 years was about 77%. The difference between IV/SW-TCZ and SC-TCZ groups was not significant (Fig. 2).
Conclusions: TCZ is effective, well tolerated and safe in a population of RA patients followed in a real-life setting.
No unexpected AE was observed in this large population followed for a long period. Interestingly retention rate was not affected by the administration route and in real life many patients can safely shift across different administration modalities.

AB0401 THE EFFICENT REGULATION OF TOCILIZUMAB FOR THE EXPRESSION OF CD4+/CD8+ T/CD19 + B CELLS AND THE IMMUNOGLOBULIN IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

H. Li[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: To study the influence of tocilizumab on lymphocyte subsets, immunoglobulin and biochemical indicators of Systemic juvenile idiopathic arthritis.
Methods: DMARDs poor efficacy in children with severe SJIA 18 patients were divided into two groups, of which eight patients tocilizumab + DMARDs group (in cluding a case of refractory MAS), 10 patients in the placebo + DMARDs control group, according to the weight>30kg, 8mg/kg, <30kg, 12mg/kg, injected once every two weeks in hospital.Symptoms and CD3 +, CD4 +, CD8 + T, CD19 + B, CD16 + 56-NK cell ratio in two groups were observed by the flow cytometry before or after 12 weeks treatment. Comparing immunoglobulin IgG, IgM, IgA, IgE with baseline after the therepy in two group, and continuous observe inflammatory markers (CRP, ESR, FER, WBC) and ALT/AST changes, adverse reactions and reduce stopping hormone case inductive analysis in following 12 weeks.
Results: After 12 weeks, tocilizumab + DMARDs group, CRP, ESR, FER were significantly decreased, the most frequently occurring adverse reaction was infection, mostly upper respiratory tract infection, followed by elevated transaminase, cholesterol, low-density lipoprotein High-density lipoprotein and triglyceride levels increased; two groups no serious adverse events (three-line reduction, severe infections, etc.). the proportion of CD4 + T, CD19 + B cells in Tocilizumab group were lower than baseline ($P<0.05$), CD8, CD3 + T cells were increased in comparing with baseline, however,no significant change with CD16 + 56-NK cells ($P>0.05$), and immunoglobulins IgG, IgM, IgA lower than baseline ($P<0.05$). The control group had no significant difference ($P>0.05$).
Conclusions: Tocilizumab can significantly reduce inflammatory markers (CRP, ESR, FER), but affect lipid metabolism and ALT/AST.Blocking IL-6 can be adjusted hyperthyroidism humoral and regulate CD4 + T, CD19 + B cells, reduce joint destruction. Tocilizumab can effectively control the development of DMARDs poor efficacy SJIA.

AB0402 RITUXIMAB MAY DELAY THE MOVEMENT OF RHEUMATOID ARTHRITIS PATIENTS ON CARDIORENAL CONTINUUM: RESULTS FROM A PROSPECTIVE OBSERVATIONAL SINGLE-CENTRE COHORT STUDY

I.R. Gaisin[1], L.V. Ivanova[2], A.A. Trukchina[2], A.A. Tukmacheva[2], Y.A. Volkova[1], A.A. Tebenkova[1], N.I. Maximov[1]. *[1]Izhevsk State Medical Academy; [2]Clinical Diagnostic Centre of the Udmurt Republic, Izhevsk, Russian Federation*

Background: Similarities in risk factors, initial stages, progression and final stage of both atherosclerotic cardiovascular disease (CVD) and chronic kidney disease (CKD) allowed formulating a concept of cardiorenal continuum.[1] CVD and CKD remain the main causes of mortality in rheumatoid arthritis (RA) patients.[2,3]
Objectives: We aimed to evaluate the effects of rituximab biologic therapy on cardiorenal continuum of RA patients.
Methods: Biologics-naïve RA patients (n=50; age 55.1±10.3) were followed up for 72 months after commencing and continuing rituximab therapy (1–10 standard courses) compared with 30 control RA patients (age 53.2±9.8).
Results: At year 6, rituximab patients have fewer incidences of hypertension, anxiety/depression, atherosclerosis and diastolic dysfunction than control patients (Table).
There were no significant differences in frequencies of other risk factors, signs of asymptomatic multiorgan damage and cases of established heart, cerebrovascular and renal diseases/complications.
Conclusions: Rituximab may be effective in delay of the movement of RA patients on cardiorenal continuum. The clinical implications of rituximab for cardiorenal correlations in RA patients need to be confirmed in large-scale clinical outcome trials.

AB0403 ADHERENCE AND ACCESS TO BIOLOGICAL THERAPY AND TOFACITINIB IN A COHORT OF COLOMBIAN PATIENTS WITH RHEUMATOLOGICAL DISEASES

J.E. Machado-Alba, M.E. Machado-Duque, S. Granada on behalf of Grupo de Investigación en Farmacoepidemiología y Farmacovigilancia, Universidad Tecnológica de Pereira-Audifarma S.A, Pereira, Colombia. *Grupo de Investigación en Farmacoepidemiología y Farmacovigilancia, Universidad Tecnológica de Pereira-Audifarma S.A, Pereira, Colombia*

Background: Biological disease-modifying antirheumatic drug (bDMARD) and tofacitinib are highly effective, but with different pharmaceutical forms, adverse reactions and cost that could affect adherence therapy and drug access.
Objectives: To determine patient adherence and administrative access to the treatment with bDMARDs and tofacitnib in patients with rheumatological diseases in Colombia.
Methods: A retrospective cohort study, which included all patients in management with bDMARD and tofactinib initiated between July 1, 2015 and June 30, 2016. A monthly follow-up of the administrative adherence were evaluated by holding or applying the medication, as well as the application of Morisky-Green test in self-administered oral and subcutaneous therapies (non-adherent patient was considered when at least one doses is lost), other variables such as sociodemographic, comorbidities, and co-prescriptions were evaluated. A descriptive analysis, χ^2 for comparison and multivariate logistic regression were performed.
Results: A total of 1102 patients were evaluated, with a mean age of 52.8±15.4 years and a female predominance (72.8%). The most frequent comorbidities were hypertension (22.6%) and dyslipidemia (15.9%). The most prescribed drugs studied were adalimumab (31.9%), etanercept (22.2%) and tofacitinib (12.5%). 52.8% use conventional DMARDs and 42.2% use glucocorticoids. Global adherence was 66.3% as measured by Morisky-Green test. Adherence was better with self-administered subcutaneous drugs every week or longer, compared to daily dosing of oral drug; these data are detailed in table 1. In 42.4% of the patients, at least one delay per year in the application or dispensation occurred, leading to 36.1% of patients experiencing dose losses due to difficulties in access. The main reason (23%) for delays and dose losses is the failures by health-insurance companies to allow timely access to the therapy. In the multivariate analysis treatment with adalimumab or tofacitinib was associated with a greater probability of presenting delays in access after adjustment of variables.

Drug	(n)	(%)	Drug administration route and interval	Morisky-Green test adherence (%)	At least one dose application delay in the year of follow up (%)	Missed dose (%)
Adalimumab	351	31.9	SC – Every two weeks	74.8	62.7	51.3
Etanercept	245	22.2	SC – weekly	72	27.3	22.4
Tofacitinib	138	12.5	OA – every 12 hours	48.8	52.2	52.2
Golimumab	82	7.4	SC - monthly	64.7	32.9	28
Rituximab	66	6.0	IV - biannual and annual	Not apply	3.0	1.5
Certolizumab	58	5.3	SC - monthly	83.3	32.8	32.8
Infliximab	40	3.6	IV - monthly and every two months	Not apply	35.0	27.5
Abatacept	62	5.6	IV y SC - monthly and weekly	42.9 - (SC route)	38.7	27.4
Tocilizumab	60	5.4	IV y SC - monthly	50.0 - (SC route)	36.7	33.3

Conclusions: Subcutaneous self-applications of bDMARD have better adherence rates compared to oral drug. However, the limitations in access to treatment decrease the adherence. On the other hand the impact of the adherence could be major in the case of self-administered DMARD when weekly or longer intervals doses are lost, compared with the loss of one daily dose of tofacitinib.

AB0404 SIMILAR REMISSION RATES AMONG RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ANTI TNF AND NON-ANTI TNF THERAPIES: REAL-LIFE DATA

J.A. Gómez-Puerta [1,2], N. Duque [1], M. Saldarriaga [1], L.A. González [1,2], C. Cerón [1], L. Uribe Botero [1], O.J. Felipe-Díaz [1]. *[1]Medicarte IPS; [2]Grupo de Reumatología, Universidad de Antioquia, Medellín, Colombia*

Background: Several biological DMARD (bDMARD) therapies have been approved for use in rheumatoid arthritis (RA) and are classified according to their respective therapeutic target: Anti TNF therapies and non-Anti TNF therapies. They are very effective in most of patients but their comparative efficacy in daily clinical is less well known.
Objectives: Our aim was to compare the efficacy of anti-TNF therapies vs non-Anti TNF therapies in a cohort of Colombian RA patients followed in different arthritis clinics under daily clinical practice conditions.
Methods: We conducted a cross-sectional study including with RA patients treated at Medicarte IPS from March 2009 to December 2016. Medicarte is a referral center for the integral medical care and pharmaco-surveillance of patients under biologic therapies in 13 cities in Colombia for inflammatory arthropathies, mainly RA, psoriatic arthritis and spondyloartropathies. Clinical information was obtained from electronic clinical records and medical claims. Only those patients with disease activity scores (DAS-28) at baseline and at the last visit were included. Remission was defined as DAS-28 <2.6 on the last visit. Patients treated only with conventional DMARD and/or tofacitinib were excluded.
Results: A total of 1,020 patients with RA were identified. 844 patients (88% female) were included in the final analysis, 416 patients with anti TNF and 428 with non-anti TNF therapies (Rituximab 199, Tocilizumab 125 and Abatacept in 104 patients). The mean age was 55.2±11.8 years, with a mean disease duration

Table 1. General Characteristics of patients with RA under bDMARD therapy

	Total N=844	Anti TNF N=416	Non-Anti TNF N=428	p value
Gender (female) %	88.0	88.7	87.6	NS
Age (years, SD)	55.2±11.8	55.0±11.8	55.4±11.8	NS
Disease duration (years, SD)	15.2±9.5	15.0±9.9	15.5±9.0	NS
bDMARD therapy duration (years)	3.2±2.5	3.2±2.5	3.2±2.4	NS
First line bDMARD therapy,%	64.0	75.2	53.2	p<0.001
Combined therapy, %	83.0	90.9	75.0	p<0.001
Seropositive (either CCP and/or RF) %	80.1	82.0	78.3	NS
DAS-28 at baseline (± SD)	4.3±1.1	4.20±1.14	4.4±1.21	NS
HAQ at baseline (± SD)	1.13±0.77	1.09±0.78	1.16±0.77	NS

of 15.2±9.5 years. bDMARD therapy was used for a mean time period of 3.2±2.5 years. Eighty three percent of patients were treated in combination therapy and 80% of patients were seropositive (CCP and/or RF). Both groups did not differ significantly on baseline clinical characteristics (see Table), with 2 exceptions: patients who received Anti-TNF therapies were treated more frequently as first line therapy (75.2% vs 53.2%, $p<0.001$) and received in a higher proportion combined therapy (90.9% vs 75.0%, $p<0.001$). A total of 59% of patient achieved remission at the last visit. Three year remission rates were slightly higher but not significant in patients treated with non-anti TNF therapies vs anti-TNF therapies (59.6% vs 53.3%, p=NS). We did not find significant differences in remission rates according serological status.

Conclusions: In real-life setting, a meaningful proportion of RA patients achieved remission on the last visit. Patients treated with anti-TNF and non-anti TNF therapies had similar baseline characteristics and after a mean time period of treatment of 3 years, achieved similar remission rates.

AB0405 SAFETY OF RITUXIMAB THERAPY IN AUTOIMMUNE DISEASES:SYSTEMATIC REVIEW AND META-ANALYSIS

K. Kobayashi[1], K.M. Minegishi[1], N. Horita[2], S. Ohno[1], H.N. Nakajima[3]. *[1]Center for Rheumatic Diseases, Yokohama City University Medical Center; [2]Department of Pulmonology; [3]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan*

Background: Treatment with rituximab (RTX), a chimeric CD20 monoclonal antibody, has demonstrated efficacy for patients with several autoimmune diseases. There is a growing concern, however, safety evidence of RTX is still lacking.

Objectives: We conducted to evaluate the safety of rituximab (RTX) for autoimmune diseases.

Methods: A literature review was performed based on the randomized clinical trials (RCTs) that assessed adverse events by comparing RTX and placebo or no treatment for autoimmune diseases. The same add-on treatment for both arms were allowed. Study selection and data extraction were independently conducted in duplicate. Meta-analyses were performed for each outcome separately using fixed model and generic inverse variance method.

Results: In the primary analysis, 16 eligible RCTs, with a total of 4147 patients for five autoimmune diseases (n=8: rheumatoid arthritis, n=3: Sjogren syndrome, n=1: systemic lupus erythematosus, multiple sclerosis, ulcerative colitis, Graves orbitopathy, immune thrombocytopenia) were analyzed. The incidence of infusion related reactions and the human antichimeric antibody (HACA) were higher in RTX group than placebo/no treatment group (OR 1.49, 95% CI 1.25–1.77 and OR 2.25, 95% CI 1.35–3.76, respectively). However, there were no significant differences the odds of total adverse events, serious adverse events, withdrawal for adverse events, infections, serious infections, malignancy, and all-cause death between two groups.

Conclusions: Our meta-analysis revealed that RTX was not associated with an increased risk of adverse events except for infusion related reactions and the incidence of HACA compared with placebo.

AB0406 STABLE EFFICACY AND SAFETY AFTER SWITCHING FROM TOCILIZUMAB INTRAVENOUS TO SUBCUTANEOUS IN RHEUMATOID ARTHRITIS: RESULTS OF A COHORT OF 200 PATIENTS

L. Joffres[1], E. Ricard[2], C. Pereira Gillion[3], M. Herbette[4], C. Lucas[5], J.B. Cren[6], E. Bergeal[7], Y. Maugars[8], C. Saillot[2], P. Goupille[3], A. Saraux[4], A. Perdriger[5], B. Bouvard[6], E. Solau Gervais[1,9]. *[1]Rheumatology, University Hospital, Poitiers; [2]Rheumatology, General Hospital, Orleans; [3]Rheumatology, University Hospital, Tours; [4]Rheumatology, University Hospital, Brest; [5]Rheumatology, University Hospital, Rennes; [6]Rheumatology, University Hospital, Angers; [7]Medical information, General Hospital, la Rochelle; [8]Rheumatology, University Hospital, Nantes; [9]LITEC, Immunology Laboratory, Poitiers, France*

Background: Intravenous tocilizumab has been used since 2009 in Europe for the treatment of active rheumatoid arthritis. Since 2015, a subcutaneous formulation is available. The switch from a monthly, intravenous, with dose adjusted for bodyweight treatment to a weekly, subcutaneous, fixed dose, leads to various questions about efficacy and toxicity.

Objectives: The objectives were to evaluate the efficacy maintenance (maintenance rate and DAS28 variation), the safety, the dose variation after the switch and the characteristics of patients switching to the subcutaneous form respect to those following with the intravenous tocilizumab.

Methods: Multicenter and retrospective study was performed from a cohort of 203 patients undergoing intravenous tocilizumab from the rheumatology unit of 7 university hospitals between September 2015 and May 2016. Assessment has been done on the records, effectiveness was assessed using the DAS28, adverse events and reasons for staying on IV form were reported.

Results: On the 203 records analyzed, 3 were secondarily excluded. Of the 200 patients, 77 have switched for the subcutaneous form. Mean age of the 200 patients was 58 years (+/- 13.3) with 155 women (78%) and the mean duration of rheumatoid arthritis was 14 years (+/- 10.4). 72% of patients received a standard intravenous dose (8mg/kg/month) at baseline.

At the first visit after the prescription of the subcutaneous treatment, 58 patients on 65 (89%) maintained the treatment. The mean DAS28 was 1.53 (+/-1.00) at baseline and 1.19 (+/-0.78) at T1 (45 patients). Three patients received a reduced subcutaneous dose of 162mg/2 weeks following a reduced IV dose (<8 mg/kg/month) and maintained the subcutaneous treatment.

About safety, there was no new case of neutropenia $<1000/mm^3$. One severe adverse effect occurred (gastro intestinal perforation).

Regard to the dose variation, for the 77 patients switching, the mean difference between intravenous and subcutaneous dose was + 29mg/week (+/-35mg) with the subcutaneous tocilizumab.

Reasons for staying on IV form were essentially: the subcutaneous tocilizumab was not proposed in 55% of the cases and 17% of patients refused the subcutaneous form.

Conclusions: 89% of patients maintained the subcutaneous treatment after 4 months; efficacy was maintained in patients who received a reduced subcutaneous dose. Despite the higher dose after the switch (+29mg/week), there was no new case of neutropenia.

AB0407 COMPARATIVE EFFECTIVENESS OF TOCILIZUMAB (TCZ) MONOTHERAPY WITH TUMOR NECROSIS FACTOR INHIBITORS (TNFI) IN COMBINATION WITH VARYING DOSES OF METHOTREXATE (MTX) IN PATIENTS WITH RHEUMATOID ARTHRITIS

L.R. Harrold[1,2], G.W. Reed[1,2], J. Best[3], S. Zlotnick[3], G. Persuitte[2], J.M. Kremer[2,4]. *[1]University of Massachusetts Medical School, Worcester; [2]Corrona, LLC, Southborough; [3]Genentech, Inc, South San Francisco; [4]Albany Medical College and The Center for Rheumatology, Albany, United States*

Background: Clinical studies have shown that the efficacy of TCZ monotherapy (TCZ mono) is superior to that of TNFi monotherapy and comparable to that of TCZ in combination with MTX.

Objectives: To compare the effectiveness of TCZ mono vs TNFi plus varying doses of MTX in patients with rheumatoid arthritis (RA) and prior exposure to TNFi in routine clinical practice.

Methods: Eligible participants were TCZ-naïve patients from the Corrona RA registry who had prior exposure to ≥1 TNFi, initiated TCZ mono or a TNFi + MTX between 2010 and 2016 and had a 6-month follow-up visit. The primary outcome was mean change from baseline in Clinical Disease Activity Index (CDAI) at 6 months. Secondary outcomes included achievement of low disease activity (LDA; CDAI ≤10) at 6 months. Patients initiating a TNFi + MTX were grouped by MTX dose (≤10 mg; >10 to ≤15 mg; >15 to ≤20 mg; >20 mg); outcomes in each group were compared with those initiating TCZ mono using trimmed populations, excluding patients outside the propensity score (PS) distribution overlap (not on common support). The PS included age, sex, race, body mass index, smoking status, work status, disease duration, concomitant prednisone use/dose, prior biologic use, American College of Rheumatology functional class and baseline modified Health Assessment Questionnaire, CDAI and patient pain scores. As a sensitivity analysis, stratified-matched populations were created (stratified by 1 vs ≥2 prior biologics, then matched on PS). Linear and logistic regression models were estimated in the trimmed populations, adjusting for the same covariates as in the PS.

Results: Baseline demographics were generally comparable between the TNFi + MTX groups and their matched TCZ mono groups. Overall, the mean age was 54 to 59 years, and the mean disease duration was 10.5 to 15 years. A higher proportion of patients initiating TCZ mono had received ≥3 prior biologics compared with those initiating TNFi + MTX. Patients initiating TCZ mono had significantly longer mean disease duration than those initiating TNFi + MTX >15 to ≤20 mg (13.0 vs 10.5 years) or TNFi + MTX >20 mg (12.3 vs 9.3 years) and a higher mean baseline CDAI than those initiating TNFi + MTX ≤10 mg (28.1 vs 25.4). Patients in all groups had improvement in CDAI scores at 6 months. In adjusted models, improvement in CDAI and the likelihood of achieving LDA were similar between the TCZ mono group and all TNFi + MTX groups (Table). Similar results were observed in the PS-matched cohorts.

Conclusions: TCZ mono was as effective as TNFi + MTX, regardless of MTX dose, for improving disease activity in patients with prior TNFi exposure. These data suggest that TCZ mono is an effective treatment option for patients with RA who cannot tolerate or prefer not to use MTX.

AB0408 COMPARATIVE EFFECTIVENESS OF ABATACEPT VERSUS TNFI IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO ARE CCP+ IN THE UNITED STATES CORRONA REGISTRY

L. Harrold[1], H. Litman[2], S. Connolly[3], E. Alemao[3], K. Price[3], S. Kelly[3], S. Rebello[2], W. Hua[2], J. Kremer[4]. *[1]University of Massachusetts, Worcester; [2]Corrona, LLC, Southborough; [3]Bristol-Myers Squibb, Princeton; [4]Albany Medical College and The Center for Rheumatology, Albany, United States*

Background: Anti-cyclic citrullinated peptide positivity (CCP+) is associated with a better response to abatacept (ABA) than anti-CCP negativity in patients (pts) with RA[1,2]; however, there are no head-to-head or comparative effectiveness research studies available evaluating responses to biologics in CCP+ pts in a real-world setting.
Objectives: To compare the effectiveness of ABA vs a TNF inhibitor (TNFi) in pts with RA who are CCP+.
Methods: We identified adult pts with RA from a large observational US cohort (1 Dec 2005–31 Aug 2016) who initiated ABA or a TNFi and who were CCP+ (≥20 U/mL) at or prior to initiation. Both groups had to have no prior exposure to other non-TNFi biologics or targeted synthetic DMARDs. TNFi initiators were excluded if they had prior use of ABA. Using propensity score matching (1:1) stratified by prior TNFi use (0, 1 and 2+), effectiveness at 6 months after initiation was evaluated. Mean change in CDAI over 6 months following initiation was the primary outcome, and secondary outcomes were: achievement of remission (CDAI ≤2.8), modified (m)ACR20, 50 and 70 responses and achievement of LDA/remission (CDAI ≤10) in those with moderate/high disease activity at initiation. A subset analysis was performed to consider separately pts who were biologic naïve and those who were biologic experienced at initiation.
Results: The 330 pairs of propensity score-matched ABA and TNFi initiators had no substantial differences in baseline characteristics. Both treatment groups had similar mean change in CDAI at 6 months as well as achievement of LDA, remission and mACR20/50/70 responses (Table). Among the 97 matched biologic-naïve pairs, there was no significant difference in change in CDAI for ABA initiators vs TNFi initiators (p=0.19). However, in the 233 matched biologic-experienced pairs, those initiating ABA had a greater improvement in mean change in CDAI (p=0.033) and were more likely to achieve an mACR50 response (p=0.014).
Conclusions: Pts with RA who were CCP+ and received either ABA or TNFi had a substantial improvement in clinical disease activity. In the overall propensity score-matched sample, similar outcomes were observed for both treatment groups. However, analysis of the biologic-experienced cohort found that ABA initiators had a greater improvement in disease activity than TNFi initiators.

AB0409 CORTICOSTEROID-SPARING IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TOCILIZUMAB: FIRST EXPERIENCE OF BAB -EL- OUED HOSPITAL

M.A. Ifticene, H. Hafirassou, R. Benaziez, F. Mechid, F. Hanni, C. Dahou Makhloufi. *Hospital, algiers, Algeria*

Background: Tocilizumab (TCZ) is a monoclonal antibody directed against the IL-6 receptors. This treatment (TRT) allows for the cortisone weaning in preventing of its complications.
Objectives: The goal of this study is to evaluate the corticosteroid sparing in patients with RA treated with TCZ.
Methods: Prospective, descriptive study of patients hospitalized between 2012 and 2016, the diagnosis was made according to the ACR 1987 ACR/EULAR 2010 criteria. Included, are the patients treated with TCZ for at least 3 months associated with corticosteroids.
We have studied the following: the epidemiology, the associated DMARDs, the average DAS28VS, the average dosage of prednisone-equivalent and the percentage of patients with decreased or interrupted corticosteroids at M0, M3, M6 and M12.
Results: 26 patients (sex ratio: 0.7) treated with TCZ and corticosteroids, average age is 43.4 years (range 30–62). Average duration of the development of RA: 9.1±6.4 years. DMARDs was associated in 15 patient.
At baseline, 46.2% of patients were on 10 mg/day of cortisone, the average dose of prednisone-equivalent was at 7.7±3.6mg at M0, 5.3±3.2 mg at M3, 4.6±2.3 mg at M6, 2.6±2.6 mg at M12 with a statistically significant difference (p=0.000003). The average DASVS28 activity index was 5.6±0.9 at M0, 3.5±1.3 at M3, 3.04±1.2 at M6 and 2.6 ± M6 at M12 with a statistically significant difference (p<0.000001). Corticosteroid treatment was stopped in 12 patients after 1 year of treatment.
Conclusions: Through this study we note that the TRT using TCZ has enabled a significant reduction in the dose of corticosteroids. Stopping prednisone was possible in 50% of patients after 1 year of biotherapy.
Disclosure of Interest: None declared

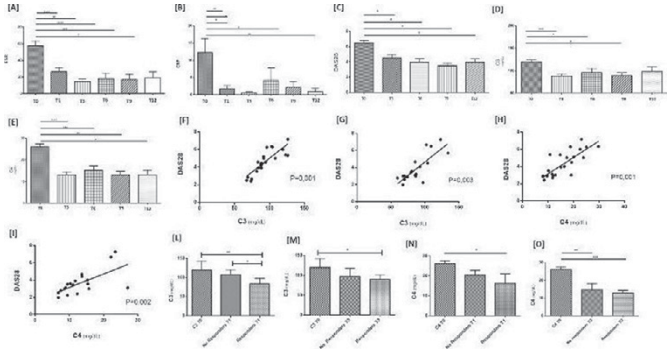
AB0410 THE INTERPLAY BETWEEN C3 AND C4 AND DISEASE ACTIVITY IN PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS DURING TREATMENT WITH ANTI-IL6 RECEPTOR



P. Conigliaro[1], P. Triggianese[1], M.S. Chimenti[1], I. Duca[2], B. Kroegler[1], R. Perricone[1]. *[1]Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata; [2]Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Rome, Italy*

Background: The complement system (CS) is involved in the pathogenesis of rheumatoid arthritis (RA). Evidence reported that high C3 levels C3 in RA patients might reflect a pro-inflammatory status and represent a negative prognostic factor for TNF-inhibitors therapy.
Objectives: We evaluated CS in a cohort of RA patients treated with tocilizumab (TCZ) to explore whether there was any correlation between CS and both disease activity and response to therapy.
Methods: Consecutive outpatients affected by RA who started TCZ treatment i.v. at the Rheumatology Unit of "Policlinico Tor Vergata" in Rome (Italy) were enrolled (n=25) (Table I). We included 25 healthy subjects as controls. Disease activity was assessed by using DAS28 ESR-based while clinical response to therapy by EULAR response criteria. Peripheral blood samples were obtained from all patients at the time of each infusion. Laboratory assessment included ESR, CRP, RF, ACPA, C3, C4, CH50 assay. Clinical and laboratory data were registered at baseline (T0), after 1 (T1), 3 (T3), 6 (T6), 9 (T9), and 12 (T12) months from the beginning of the TCZ treatment.
Results: At baseline, both C3 and C4 were significantly higher in RA than in controls (Table 1).

Table 1

	RA (N=25)	Controls (N=25)	P value
Female (N/%)	23/92	23/92	N.S.
Age (years)	65.4±11.5	60.1±9.3	N.S.
Disease duration (years)	13±8.2	N.A.	N.A.
DAS28	6.5±1.3	N.A.	N.A.
HAQ	1.9±0.8	N.A.	N.A.
Positivity of RF (N/%)	17/68	N.A.	N.A.
Positivity of ACPA (N/%)	20/80	N.A.	N.A.
ESR (mm/h)	58±28	N.A.	N.A.
CRP (mg/l)	8.5±7.6	N.A.	N.A.
C3 (mg/dl)	119.4±22.4	104±18	0.04
C4 (mg/dl)	26±6.7	22±4	0.013
CH50 (%)	108±24	100±18	N.S.
Therapy:		N.A.	
PDN ≤7.5 mg/die (N/%)	9/36		
At least one DMARD (N/%)	13/52		
– MTX (N/%)	9/69.2		
– HCQ (N/%)	4/30.7		
– SSZ (N/%)	2/15.4		
– LEF (N/%)	2/15.4		
I line TCZ (N/%)	3/12		
II line TCZ (N/%)	3/12		
III line TCZ (N/%)	9/36		
IV line TCZ (N/%)	7/28		
V line TCZ (N/%)	3/12		

No difference in C3 and C4 resulted between ACPA positive and ACPA negative patients during the follow up. ESR, CRP and DAS28 levels were significanlty reduced at T1, T3, T6, T9, and T12 with the respect to T0 (Figure 1A-C). C3 levels were significantly reduced at T3, T6, and T9 with the respect to T0 while C4 levels were significantly reduced at T3, T6, T9, and T12 with the respect to T0 (Figure 1D-E). Positive correlations resulted between DAS28 and both C3 and C4 at T1 and T3 (Figure 1F-I). C3 and C4 were directly related with ESR at T1 (C3: P 0.002; C4: P 0.005), T3 (C3: P 0.04; C4: P 0.03), and T6 (C3: P<0.0001; C4: P 0.002) and with CRP at T1 (C3: P 0.03; C4: P 0.01) and T6 (C3: P<0.0001; C4: P 0.03). When stratifying patients in accordance with the EULAR response to therapy, C3 decreased significantly in responders than in no-responders at T1; moreover, responders showed lower levels of both C3 and C4 at T1 and T3 with the respect to T0 (Figure 1L-O).

Conclusions: In RA patients, treatment with TCZ is able to reduce C3 and C4 levels in an early and substained way. The disease activity is directly related with the reduction of C3 and C4 serum levels. RA patients with a good/moderate clinical response show significantly lower C3 and C4 levels than no-responder patients. Our preliminary data suggest that C3 and C4 can be a reliable marker of both the disease activity and the response to therapy in RA patients treated with TCZ.

AB0411 COMPARISON OF TUBERCULIN SKIN TEST AND INTERFERON-GAMMA RELEASE ASSAY SCREENING IN PATIENTS WITH RHEUMATOID ARTHRITIS STARTING ANTI-TUMOR NECROSIS FACTOR THERAPY

D.T. Archimandriti[1], C. Iliou[1], A.T. Tzallas[2], E. Pelechas[1], A.A. Drosos[1], P.V. Voulgari[1]. *[1]Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina; [2]Department of Computer Engineering, Technological Educational Institute of Epirus, Greece, School of Applied Technology, Ioannina, Greece*

Background: Biologic agents provide clinical benefits in patients with Rheumatoid Arthritis (RA) but they are associated with an increased risk of tuberculosis (TB) infection.
Objectives: We investigated the accordance between the tuberculin skin test (TST) and the interferon-gamma (IFN-γ) release assay (IGRA) for the diagnosis of latent tuberculosis infection (LTBI) in patients with RA. The objective of our study was a direct comparison between the IGRA and the TST regarding LTBI diagnosis in RA patients before starting anti-TNF agents and at least one year after the initiation of treatment.
Methods: RA consecutive patients have been included in the study both before and after 1 year of the initiation of TNF-α antagonist therapy. A standard questionnaire was completed for each patient, including basic demographic data and concurrent immunosuppressive therapy (corticosteroids, disease-modifying anti-rheumatic drugs [DMARDs], synthetic and biologics). The patients were screened for LTBI using IGRA and TST methods.
All analyses were performed with IBM-SPSS Statistics for Windows (version 21). The kappa coefficient (κ) was calculated to determine the concordance between the two tests: TST and IGRA. The strength of the agreement was considered "poor" for $\kappa \leq 0.20$, "low-moderate" for $0.20 < \kappa \leq 0.40$, moderate for $0.40 < \kappa \leq 0.60$, "substantial" for $0.60 < \kappa \leq 0.80$, and "optimal" for $0.80 < \kappa \leq 1$.
Results: 78 patients (67 female, 11 male) have been screened with TST and IGRA. The accordance between TST and IGRA was 89.7% (κ 0.514, $\kappa<0.001$). A κ value of 0.514 represents a moderate accordance between the two tests. 6 female patients converted TST (4 became positive, and 2 became negative). No patient developed active tuberculosis.
Conclusions: A moderate accordance between the two methods (TST and IGRA) was obtained. In the absence of a diagnostic gold standard for LTBI, different issues should be taken into consideration regarding the two methods (cost, laboratory expertise and equipment etc). More studies are needed in the field in order to elucidate the cost-effectiveness but also the appropriateness of both methods.

AB0412 LESS THAN 5% OF REAL-LIFE PATIENTS WHO SWITCH FROM IV TO SC ABATACEPT IN REAL-WORLD CLINICAL PRACTICE SUBSEQUENTLY SWITCH BACK TO THE IV FORMULATION

R. Alten[1], H.-M. Lorenz[2], X. Mariette[3], H. Nüßlein[4], M. Galeazzi[5], F. Navarro[6], M. Chartier[7], J. Heitzmann[8], C. Rauch[9], M. Le Bars[7]. *[1]Schlosspark-Klinik University Medicine, Berlin; [2]University Hospital, Heidelberg, Germany; [3]Université Paris-Sud, Paris, France; [4]University of Erlangen-Nuremberg, Nuremberg, Germany; [5]University of Siena, Siena, Italy; [6]Hospital Univesitario Virgen Macarena, Seville, Spain; [7]Bristol-Myers Squibb, Rueil-Malmaison; [8]Excelya, Boulogne-Billancourt, France; [9]Bristol-Myers Squibb, Munich, Germany*

Background: Patients (pts) with RA may be able to switch from IV to SC abatacept with no loss of efficacy or safety concerns, but data are inconclusive.[1–4] In the ACTION (AbataCepTIn rOutiNe clinical practice; NCT02109666) study, a 1-year interim analysis showed that switching had no adverse clinical effect.[5]
Objectives: To examine treatment patterns and explore abatacept formulation switching over 2 years in ACTION.
Methods: ACTION is a 2-year, prospective, observational study of pts with moderate-to-severe RA who initiated IV abatacept in Europe and Canada between May 2008 and December 2013. Assessments in biologic-naïve and biologic-failure pts were: baseline characteristics, rates of and reasons for switching (IV to SC), and re-switching to IV over 2 years. Descriptive data were generated: mean (SD) for continuous variables and n (%) for categorical variables. Rates of switching were estimated by Kaplan–Meier analysis. Cohorts were pooled to analyse further pts who switched owing to low numbers.
Results: In the ACTION cohort, 2350/2364 pts (99.4%) were evaluable for this analysis (673 [28.6%] biologic naïve, 1677 [71.4%] biologic failure). A total of 729

(43.4%) biologic-failure pts had received 1, and 948 (56.6%) had received ≥2 previous biologics. Baseline characteristics in biologic-naïve and biologic-failure pts, respectively, were: mean (SD) age 59.9 (12.7) and 56.9 (12.5) years; RA duration 7.2 (8.22) and 12.1 (9.13) years; 496 (73.7%) and 1379 (82.2%) were women; 621 (92.3%) and 1552 (92.5%) had received prior MTX; and 533 (79.2%) and 1386 (82.6%) had received corticosteroids. Over 2 years, 195 pts switched from IV to SC abatacept (57 biologic naïve, 138 biologic failure; Fig.). Reasons for switching were available for 172 pts (51 biologic naïve, 121 biologic failure; some had >1 reason); biologic naïve/biologic failure: pt wish 54.9%/62.0%, physician choice 31.4%/19.8%, safety 5.9%/9.9%, remission/major improvement 3.9%/5.0%, poor compliance 0%/4.1%, lack of efficacy 2.0%/3.3%, surgery 2.0%/0.8%, weight adjustment 2.0%/0%, other 49.0%/36.4%. Only eight pts (2.6%) re-switched to IV abatacept (2 biologic naïve, 6 biologic failure). Reasons for re-switching were: pt wish (n=4), lack of efficacy (n=4), safety issue (n=1) and other (n=2).

Figure. Patients Who Switched From IV to SC Abatacept Over 2 Years (Kaplan–Meier Analysis)

Conclusions: Less than 5% of pts who switched formulation from IV to SC abatacept in real-world clinical practice re-switched to the IV formulation, suggesting that switching has no adverse clinical impact. A change in formulation was mainly due to pt wish, reflecting their involvement in decision-making.

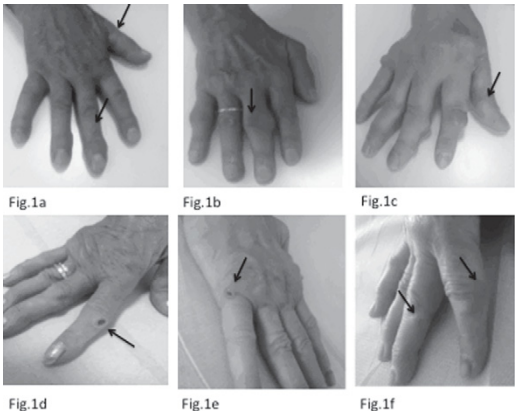
AB0413 INDUCTION AND PROGRESSION OF SUBCUTANEOUS NODULOSIS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB



R. Talotta, A. Batticciotto, M.C. Ditto, M.C. Gerardi, D. Ventura, P. Sarzi Puttini.
Rheumatology Unit, University Hospital "Luigi Sacco", Milan, Italy

Background: Tocilizumab (TCZ) is a monoclonal antibody (moAb) directed against the IL-6 receptor approved for moderate-to severe rheumatoid arthritis (RA) treatment. Some authors have reported a beneficial effect of TCZ in preventing lung and subcutaneous nodulosis in RA patients. On the contrary, to our knowledge no data concerning the acceleration of subcutaneous nodulosis under TCZ therapy are currently available.

Objectives: We report a small case series of 5 RA patients experimenting an evident worsening of subcutaneous nodulosis during the treatment with intravenous tocilizumab.

Methods: Our cohort included 5 patients (1 male and 4 females, mean age ± Standard Deviation (SD) 64±10.6 years, mean disease duration ± SD 21.8±10.9 years). Four patients were rheumatoid factor and anti-citrullinated peptide antibodies positive. Each patient had been previously treated with several conventional and biologic drugs. At the time of observation, three subjects were practicing methotrexate (MTX), two patients were taking hydroxychloroquine (HCQ) and one patient was taking prednisone. Intravenous tocilizumab 8 mg/kg every 4 weeks was administered for a mean ± SD of 43.4±32.4 months, with a good disease control in 3 cases. All the patients had a previous history of subcutaneous nodulosis that considerably worsened during the treatment with tocilizumab. Patients experimented the development of new subcutaneous nodules localized at the fingers, elbows or the inframammary fold, tending to ulceration. The management of this medical event included the tapering of MTX, the administration of steroids, the addition of HCQ, the use of antibiotics and surgery. However, neither pharmacological nor surgical treatment was completely effective, as nodules tended to recur and to increase in number and dimensions.

Results: To our knowledge this is the first report describing an accelerated subcutaneous nodulosis in a small cohort of RA patients treated with tocilizumab.

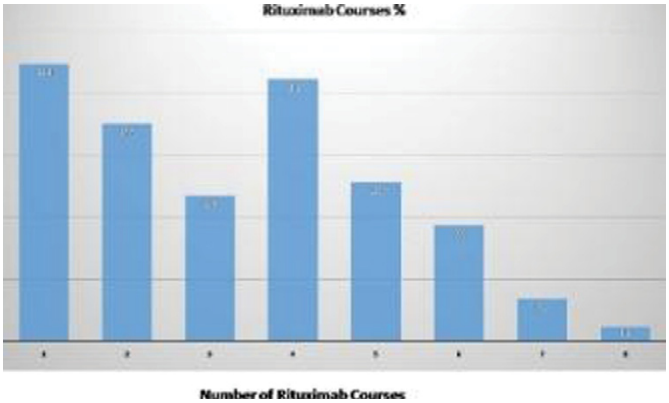
AB0414 THE USE OF RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: IN WHICH INFUSION INTERVALS WERE GIVEN AND HOW DID THEY RESPOND? HUR-BIO REAL LIFE RESULTS



B. Armagan, A. Sari, A. Erden, L. Kilic, O. Karadag, A. Akdogan, S. Apras Bilgen, U. Kalyoncu, I. Ertenli, S. Kiraz. *Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Rituximab is one of the treatment options in rheumatoid arthritis (RA) patients and officially recommended as a maintanance treatment given every 6 months after the initial loading of first course.

Objectives: In this real life study, it was aimed to investigate the infusion frequency of rituximab maintanance treatment and possible effects on disease activity.

Methods: The HUR-BIO is a single-center biologic registry of Hacettepe University which is established in Ankara and in which patients have been prospectively recorded since 2012. This database has 1235 RA patient records as of August 2016. Rituximab was prescribed at least once in 273 (22.1%) patients. The residence address of 85 those patients was within the boundaries of center city (Ankara) and they were included in to the study. In our clinic, the dates and the DAS-28 scores at the time of rituximab courses were recorded. Rituximab infusion compliance was classified as; "regular " if there is less than one month delay, "slightly irregular" if less than 3 months delay and "irregular" if more than 3 months delay.

Results: The mean age of the 85 patients (80% female) was 59.1 (10.1), the mean disease duration was 12.9 (8.6) years and 74.1% of patients were seropositive. 39/85 (46%) patients previously used at least one biological agent (46 (54%) patients were biologic naive before Rituximab therapy). Median rituximab course number was 3 (1–8). A total of 211 rituximab courses were given to 85 patients. Rituximab course number and percentage is shown in figure. The mean interval time between rituximab courses was 7.9 (2.8) months. Total of 102 (52.6%)

courses were admistred at normal times regularly, 60 (30.9%) were slightly irregular and 32 (16.5%) were irregular. There was no significant difference between the mean DAS-28 responses in the time of the courses and the rituximab infusion compliances [in regular group mean DAS-28 was 3.31 (1,19), in slightly irregular group mean DAS-28 was 3.26 (1.35) and irregular group mean DAS-28 was 3,57 (1.34), $p>0.05$]. Before rituximab courses, 33.7% of patients had remission, 19.1% had low disease activity, 36.3% had moderate disease activity and 10.9% had high disease activity.

Conclusions: Rituximab administration was approximately 2 months delayed in RA patients who were living in center-city boundaries. The pre-treatment mean disease activity scores were similar, even if there was a delay in rituximab administration. In our center, about 85% of patients were taking RTX courses regular and/or slightly irregular and about half of the patients before treatment were in remission and/or low disease activity.

AB0415 TENDENCY TO CHOOSE FIRST BIOLOGIC AGENT THERAPY OF RHEUMATOID ARTHRITIS IN THE ELDERLY: RESULTS FROM JAPANESE MULTICENTER REGISTRY

T. Watanabe, T. Kojima, N. Takahashi, S. Asai, N. Asai, T. Matsumoto, Y. Sobue, N. Ishiguro. *Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine Department of Orthopaedic Surgery, Nagoya, Japan*

Background: Of the treatment of rheumatoid arthritis (RA), biologic agent therapies are chosen, if disease activity remains moderate or high despite csDMARDs therapy. In the elderly, with comorbidity and their less spare ability, safety is often concerned in the choice of biologic agent.

Objectives: We investigated the tendency to choose biologic agent and drug continuation rates in elderly in last decade.

Methods: Records of relevant patients with RA were collected from the Tsurumai Biologic Communication Registry, wherein the department of Nagoya University and 20 affiliated hospitals in Japan are enrolled. A total of 873 biologics-naïve and age 65 and older patients were recruited from January 2004 to December 2014. We studied the choice of the biologic agent year by, and baseline disease activity and concomitant methotrexate (MTX) among TNF inhibiters, tocilizumab (TCZ), and abatacept (ABT) groups. Drug continuation rates were compared among TNF inhibiters, TCZ, and ABT groups.

Results: From 2005 to 2010, etanercept (ETN) was used the most (2007; 73.5%, 2009; 65.9%). After the advent of ABT, ABT was used the most (2011; 44.3%, 2014; 38.8%).

Baseline disease activity slightly decreased as a whole (DAS28-CRP; 4.88 to 4.44). Despite baseline disease activity of TNF inhibitors group decreased (DAS28-CRP; 4.88 to 4.37), that of TCZ group increased (DAS28-CRP; 4.94 to 6.24).

In 2011–2014, baseline disease activity of TCZ group (5.85) was higher than that of TNF inhibiters group (5.11) ($p<0.05$). Concomitant MTX rate and dose were lower in ABT group (40.2%, 7.6mg) than that of TNF inhibiters group (79.0%, 8.9mg). 2 years drug continuation rate due to all unfavorable causes; ABT group was 92.4%, better than that of TNF inhibitors 87.1% and TCZ 69.2% ($p<0.05$). 2 years drug continuation rate due to adverse events; TCZ group was 80. 8%, lower than that of TNF inhibitors 94.6% and ABT 96.2% ($p<0.05$).

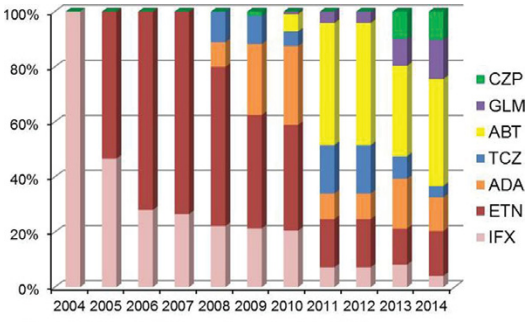

Figure 1. Changes of biologic agent from 2004 to 2014 (IFX:infliximab, ETN: etanercept ,ADA: adalimumab, TCZ:tocilizumab, ABT:abatacept,GLM: golimumab, CZP:certolizumab pegol)

Conclusions: ETN was used most before the advent of ABT. After the advent of ABT, ABT was used most and ETN decreased. This selection was made for speculation that ABT is lower risk than other biological agents. Baseline disease activity slightly decreased showing that tight control management became also popular among elderly. In 2011–2014, concomitant MTX rate and dose were lower in ABT group, but 2 years drug continuation rate was the highest.

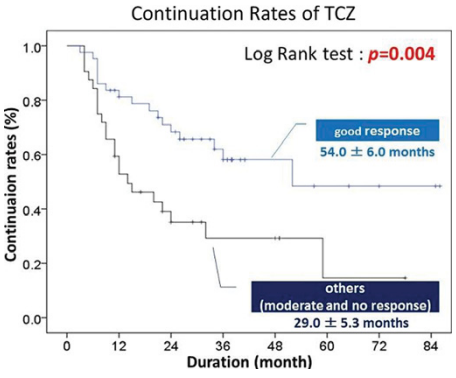
AB0416 WHICH FACTORS PREDICT THE RESPONSIVENESS TO TOCILIZUMAB IN RHEUMATOID ARTHRITIS? THE DIFFERENCE BETWEEN THE USAGE AS THE FIRST BIOLOGIC AND AS THE SECOND BIOLOGIC



Y. Kunishita, R. Yoshimi, H. Nagai, N. Hamada, Y. Soejima, Y. Sugiyama, N. Tsuchida, H. Nakano, D. Kishimoto, R. Kamiyama, Y. Asami, Y. Kirino, H. Nakajima. *Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan*

Background: Although recent development of a variety of biologics has dramatically improved treatment for rheumatoid arthritis (RA), it is still unclear which biologics is better for use in each patient. Some previous studies have shown the predictive factors for good response (GR) to tocilizumab (TCZ), including low HAQ, high DAS28[1], low levels of serum soluble IL-6 receptor[2], and low numbers of previous use of other biologics[3]. However, the consensus is not immediately available.

Objectives: To compare continuation rates (CR) of TCZ by the responsiveness to the therapy and to identify predictive factors for GR to TCZ in RA.

Methods: Patient with RA who newly started receiving TCZ after April 2008 in our hospital, were included in the study. We collected patient records, medication histories, laboratory data, and clinical parameters longitudinally after starting TCZ. Statistical analyses were performed using the chi-square test, binomial *logistic regression* analysis, Kaplan-Meier method, and the log-rank test.

Results: Ninety-two patients were included in the study. The mean age and disease duration at baseline were 60.0±13.5 years and 8.7±8.0 years, respectively. The seroprevalence of the anti-cyclic citrullinated peptide antibody and the rheumatoid factor were 95.4% and 95.7%, respectively. The rate of methotrexate and prednisolone at baseline were 45.7% and 64.1%, respectively. TCZ was administered as the first biologic in 42 patients, and as the second biologic in 33. DAS28(ESR) and CDAI revealed high disease activity at baseline (5.2±1.5 and 25.4±14.1, respectively). The mean CR of all patients was 42.1±4.0 months. The CR was significantly higher in patients who achieved GR in EULAR response criteria at 6 months after starting TCZ than those who did not achieve GR (54.0±6.0 months vs 29.0±5.3 months, p=0.004). Multivariate statistical analysis revealed two predictive factors for achieving GR at 6 months after starting TCZ, the low number of previous use of other biologics and the low CDAI at baseline (p=0.018, odds ratio (OR) =0.386, and p=0.011, OR=0.944, respectively). We divided the patients into two groups, patients using TCZ as the first biologic and patients using it as the second biologic. Univariate statistical analyses revealed low usage rate and dose of prednisolone (PSL) and low serum creatinine level at baseline as the predictive factors for achieving GR in patients using TCZ as the first biologic, and low DAS28(ESR), CDAI and HAQ-DI in the patients using TCZ as the second biologic. By multivariate statistical analysis, we identified the low CDAI as a predictive factor in the patients using TCZ as the second biologic.

Conclusions: RA patients who achieved GR at 6 months after starting TCZ showed higher CR than the others. This study also suggests that low number of biologics usage and low CDAI at baseline are the predictive factors for GR. The history of biologics usage may be important to identify the predictive factors for GR to TCZ.

Rheumatoid arthritis - non biologic treatment

AB0417 EFFICACY AND SAFETY OF METHOTREXATE AND LEFLUNOMIDE AS A COMBINATION THERAPY IN RHEUMATOID ARTHRITIS PATIENTS WITH HIGH DISEASE ACTIVITY PRESENTING AT A TERTIARY CARE SETTING IN PAKISTAN

B. Salim, S. Samreen, A. Nasim, H. Gul, A. Masood. *Rheumatology, Rawalpindi, Pakistan*

Background: In the management of rheumatoid arthritis (RA), the goal is remission. However it is not easy to attain this goal in all patients. Its not only the high disease activity, but rather other factors like availability and cost of biologics in developing countries. Therefore various combination therapies of conventional DMARDs are in vogue in such scenarios. Methotrexate (MTX) and Leflunomide (LEF) in combination is an effective option which can be fairly utilized in resource constraint settings to induce remission.
Objectives: To study the efficacy and safety profile of MTX+LEF combination in patients with active RA at 24 weeks.
Methods: This is a quasi-experimental study conducted at Rheumatology department, Fauji Foundation Hospital, Rawalpindi. 95 patients with active RA despite optimal dose (20–25 mg/week) of MTX. Leflunomide 20mg/day was added. Patients underwent clinical and laboratory review at 0, 4, 12 and 24 weeks to note down primary efficacy end points and adverse effects.
Results: Ninety five patients were enrolled with a mean age (years) ± SD of 51.7±8.9 and a mean duration of disease (years) of 8.6±7.1.Patients had active disease at baseline with a mean disease activity score (DAS28) of 5.99±0.6. At 24 weeks the mean change in tender joint count (TJ), swollen joint count (SJ), patients pain score on visual analogue scale (VAS) and DAS 28 were all statistically significant (p-value 0.000).The mean change in m HAQ was also statistically significant (p-value 0.000).
At 6 months the most frequent side effects (though mostly mild); were abdominal pain and nausea. 78 patients (79.1%) continued with the combination therapy. Only 3 patients stopped the treatment temporarily (due to raised ALT and vomiting).14 patients discontinued treatment mainly due to diarrhea, severe oral ulcers and markedly raised ALT.

Table 1. Baseline clinical and demographic feature of patients enrolled for MTX+LEF combination therapy

Total patients	95 (100%)
Age mean ± SD (years)	51.7±8.9
Gender m/f	2/93
Duration of diseasemean± SD (years)	8.6±7.1
RA factor (positive)	72 (75.8%)
Anti CCP (positive)	61 (64.2%)
Premorbids	
Diabetic (DM)	10 (10.5%)
Hypertensive (HTN)	16 (16.2%)
DM+HTN	3 (3.2%)

Table 2. Outcome/efficacy measure of MTX+LEF (n=95)

	Baseline (0 week)	24 weeks	p-value
Mean Tj	14.92±6.44	3.38±2.38	0.000
Mean Sj	4.29±2.30	0.90±1.28	0.000
Mean pain VAS (Patient)	7.19±1.86	2.91±1.85	0.000
Mean ESR	33.3±9.10	16.78±5.99	0.000
Mean DAS 28	5.99±0.64	3.52±0.86	0.000
Mhaq	1.75±0.64	0.59±0.42	0.000

Conclusions: MTX+LEF combination is an effective and safe option in RA patients failing MTX monotherapy provided regular clinical and laboratory monitoring is done.

AB0418 COMPARISON OF ANTI-INFLAMMATORY DRUGS WITH GLUCOCORTICOIDS IN TREATMENT OF RHEUMATOID ARTHRITIS

B.N. Coskun[1], F. Ulutaş[2], S. Ermurat[1], E. Dalkılıc[1]. *[1]Rheumatology; [2]Internal Medicine, Uludag University, Bursa, Turkey*

Background: Rheumatoid arthritis (RA) is a chronical autoimmune disease that commonly presented with symmetrical polyarthritis of hands and feet. Pharmacological treatment options are non-steroid anti-inflammatory drugs (NSAIDs), glucocorticoids (GK) and disease modifying anti rheumatoid drugs (DMARDs) ([csDMARDs] or [tsDMARDs or [bDMARD].
Objectives: In this study we aimed to review the use of NSAID and GK in our patients.
Methods: The patients who diagnosed as RA at our office were included in the study. Patients were classified with EULAR 2010 RA criteria. The demographics and medications of the patients were recorded. All patients we examined pain with visual analog scale (VAS), global assessment of patient and doctor, number of tender and swollen joints (28 joints), health assessment questionnaire (HAQ), C – reactive protein (CRP), eritrocyte sedimentation rate (ESR), rheumatoid factor (RF) and anti – CCP. We assessed activity of disease by using disease activity score DAS28.
Results: A total of 686 patients were enrolled in the study (580 female [84.5%], 106 male [15.5%]). Mean age was 53.23±12.21 and mean length of diagnosis was 10.74±7.59 months. The rate of extra-articular disease was 17.9% and the deformity rate was 31.3%. In all patients, activity of disease was mild in 55%, moderate in 37.8% and severe in 7.3% with regard to DAS28 score. The disease activity was mild in 54.6%, moderate in 43.11% and severe in 2.3% in patients who were using only NSAIDS. These rates of diseases activity was 57.2%, 40.7% and 2.1% in mild, moderate and severe disease respectively for the patients using only GK. In patients using both NSAIDs and GK, the disease activity was mild in 55%, moderate in 44% and severe in 1%. Comparison of the disease activity with medications revealed statistically significant difference in patients that using only NSAID and using both, but not in that using only steroid (respectively p: 0.022, p: 0.025, p: 0.46).

DAS 28	Mild <3,2	Moderate ≥3,2-<5,1	Severe ≥5,1
All patients %	55	37,8	7,3
Only NSAIDS %	54,6	43,11	2,3
Only GK %	57,2	40,7	2,1
Both NSAIDs and GK %	55	44	1,0
p	**0,022**	**0,025**	0,46

Conclusions: In our study we found that patients has mild activity of disease use highly rates of NSAID and GC. It is important for providing remission using NSAIDs and GC along with DMARD. Our results demonstrate use of both GK and NSAIDS results in better outcomes.

AB0419 REAL WORLD USE OF TOFACITINIB IN RHEUMATOID ARTHRITIS: DATA FROM LATIN AMERICA

E.E. Schneeberger[1], A. Salas[2], L.F. Medina[3], J.B. Zacariaz[4], R.D. Mantilla[5], J.C. Sarmiento-Monroy[5], L.J. Elizondo[6], B. Garro[7], H. Madariaga[8], L. Górriz[9], R.D.N. Giorgi[10], M. Pinheiro[11], D. Ponce de Leon[12]. *[1]Servicio de Reumatología, Instituto de Rehabilitación Psicofísica; [2]Servicio de Reumatología, HIGA San Martin de la Plata, Buenos Aires, Argentina; [3]Servicio de Reumatología, Hospital Universitario del Valle, Cali, Colombia; [4]Servicio de Reumatología, Hospital Italiano, Buenos Aires, Argentina; [5]Epidemiólogo, Centro de Dermatología y Reumatología FUNINDERMA, Bogotá, Colombia; [6]Reumatólogo, Centro de Investigación Clínica de Ciudad Obregón, Sonora, Mexico; [7]Reumatólogo, Centro de Excelencia en Reumatología, Lima; [8]Reumatólogo, Clínica del Sur, Arequipa, Peru; [9]Servicio de Reumatología, Hospital Santo Tomas, Panamá, Panama; [10]Servicio de Reumatología, Hospital do Servidor Público Estadual; [11]Pfizer Inc, São Paulo, Brazil; [12]Pfizer Inc, Lima, Peru*

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. Tofacitinib can be given as monotherapy or with csDMARDs. Published data on real world (RW) tofacitinib use in Latin America (LA) are limited. We characterise the patient (pt) population starting tofacitinib and gain insights into the safety profile in the RW LA setting.
Methods: Initial tofacitinib therapies in adult RA pts from 10 private/public centres in 6 countries (Argentina, Brazil, Colombia, México, Panamá, Perú) were considered. Data were retrospectively obtained via a standardised format, focusing on demographics, drug history, adverse events (AEs), safety events of special interest, latent tuberculosis (TB) screening, selected confirmed laboratory abnormalities and discontinuation rates. Tofacitinib use as monotherapy or with csDMARDs was at the rheumatologist's discretion.
Results: 288 pts with severe active RA were included; most were female (n=263; 91%), mean (SD) age was 51.3 (6.36) years (yrs) and mean (SD) disease duration was 10.4 (4.0) yrs. 89% of pts were RF+ or ACPA+. The max (range) follow-up period was 22 (10–34) months. Tofacitinib was given as 2nd-line therapy (post-csDMARD) in 44% of pts, after one biologic DMARD (bDMARD) in 18% of pts and after ≥2 bDMARDs in 38% of pts. Tofacitinib was given as monotherapy in 117/283 (41%) pts and with csDMARDs in 171/283 (59%) pts. Tofacitinib usage corresponds to 13% of advanced therapies (JAK inhibitors, bDMARDs and biosimilars). Thirty-eight AEs were observed; upper respiratory infections (n=11), skin infection (n=5), herpes zoster (HZ; n=4) and urinary infections (n=4) were most common. Gastrointestinal intolerance was seen in 2 pts. Three (1%) pts had serious infection events (SIEs); no opportunistic infections (OIs), including TB, occurred. All HZ cases (n=4; 1.4%) were monomeric, non-serious and resolved without complication after antiviral therapy. Before starting tofacitinib, 5 pts (1.7%) were vaccinated against HZ and 5.6% were diagnosed with latent TB. No active

TB cases occurred with tofacitinib treatment. One malignancy (thyroid cancer) was reported. Severe (>3 ULN) elevation of liver enzymes or increases of CPK above normal were infrequent (<1%); no severe cytopenias were reported. Lipid increases occurred in 10% of pts. Tofacitinib was withdrawn in 40 pts (13.9%) due to lack of efficacy (n=20; 7%), AEs (n=11; 3.8%) or other reasons (n=9; 3.1%), such as loss of follow-up, pregnancy, access issues or travel. Limitations include limited pt numbers and follow-up of exposure.

Conclusions: In the RW LA setting, tofacitinib was used mostly as 2nd-line therapy; no new safety signals emerged vs clinical trials. SIEs and HZ were uncommon; no cases of TB/other OIs occurred, but were seen in the clinical program.

AB0420 THE SAME TREATMENT RESPONSE OF MONO- AND COMBINED-MTX TREATMENT IN DMARDS-NAÏVE TURKISH PATIENTS WITH SEROPOSITIVE RHEUMATOID ARTHRITIS AND THE IMPORTANCE OF PULMONARY TOXICITY

F.F. Ayhan[1,2], A. Gümüştepe[1], B. Nacır[1], A. Karagöz[1]. *[1]Physical medicine & rehabilitation, Ankara Training and Research Hospital, Ankara; [2]Physical therapy & rehabilitation, Uşak University, School of Health Sciences, Uşak, Turkey*

Background: Methotrexate (MTX) is the anchor drug for the treatment of rheumatoid arthritis (RA). There are important guidelines suggesting mono-MTX treatment at first for pharmacologic treatment of RA (1,2). We thought that these recommendations should be evaluated in different geographic regions and ethnic groups because of genetic factors.

Objectives: Therefore, we aimed to compare the efficacy and adverse effect profile of mono-MTX and combined-MTX treatments in patients with DMARDs-naïve Turkish patients with seropositive RA.

Methods: Hundred patients with seropositive RA (mean age: 47.4±12.0 years, 63 females and 37 males) were included. Patients were excluded the past history of using for synthetic or biologic DMARDs or moderate-high dose steroid (>10mg/day), viral hepatitis, transaminase elevations, and other contra-indications for MTX. Then they were divided as mono-MTX (n=57) and combined-MTX (n=43) groups.

Results: There was no difference between groups in age (p=0.34), sex (p=0.104), age of onset (p=0.10), MTX-weekly dose (p=0.228), the score of DAS28 (p=0.783), RF level (p=0.473), and CCP level (p=0.592) at the beginning. Patients of combined-DMARDs group used higher dose of prednisolone than patients of mono-MTX group (p=0.011). The change of DAS28 scores was not different between groups. CRP levels of combined-MTX group were higher than mono-MTX group both beginning and at 6th month. The frequencies of adverse events were not different between groups. GI adverse events are the first line in both groups (28% vs.16.3%). The frequencies of dose decrease (7% vs. 14%) or stop (7% vs. 4.7%) for MTX were also not different between groups (p=0.288, p=0.257). The frequencies of other adverse effects were less than 5%. MTX dose decrease or stop have been moderately correlated with pulmonary involvement (r=0.4, p=0.02).

Conclusions: Both mono-MTX and combined-MTX treatment had similar efficacy and safety profile in Turkish patients with seropositive RA as reported in studies of other countries suggesting no any advantage of combined MTX compared to mono-MTX (3). The frequency of MTX-stopping in our study was similar to this systematic review (9%). As a conclusion, MTX should also be the first choice of the treatment of RA in our country. Pulmonary adverse events should not be ignored.

AB0421 RAPAMYCIN REDUCES DISEASE ACTIVITY THROUGH RESTORING REGULATORY T CELL NUMBERS IN PATIENTS WITH ACTIVE REFRACTORY RHEUMATOID ARTHRITIS

H. Niu[1], Z. Li[1], J. He[1], R. Jia[1], J. Luo[1], C. Gao[2], C. Wang[1], X. Li[1]. *[1]Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, United States*

Background: $CD4^+CD25^+Foxp3^+$ T regulatory (Treg) cells play a key role in peripheral tolerance. Rapamycin was approved by the FDA to preserve renal allografts and to be efficacious in patients with several autoimmune diseases [1].

Objectives: To investigate the status of Treg cells in active refractory rheumatoid arthritis (RA) and the effects of rapamycin on patients with RA.

Methods: Forty-five active refractory RA patients were enrolled. Rapamycin was used at a dose of 0.5 mg every 2 days [the preliminary, open-label clinical trial of rapamycin (Clinical Trials.gov number: ChiCTR-IPR-17010307)]. Clinical improvement and immunological assessments were performed before 1st rapamycin dose and 12 weeks post treatment. Blood samples were obtained from RA patients and 75 healthy volunteers for estimation of $CD4^+$ T cell subsets.

Results: Two patients dropped out due to non-compliance. As compared to healthy controls (median of Treg cells: 33.32 cell/ul), the absolute counts of circulating Treg cells were significantly decreased in patients with active refractory RA (median: 27.17 cell/ul; P=0.046). While the median ratios of Th17/Treg cells in patients with active refractory RA (median: 0.26) were significantly higher than those of healthy volunteers (median: 0.19; P=0.029). No difference in the absolute counts of circulating Th17 cells and Th1 cells was observed between patients with active refractory RA and healthy subjects. Rapamycin treatment led to clinical improvement with the median post-treatment DAS28-ESR decreasing when compared to baseline (from 4.19 to 3.78) in active refractory RA patients. Sixteen patients (16/43 patients, 37.21%) achieved an EULAR moderate response and 6 patients (6/43 patients, 13.95%) reached good response at week 12. Rapamycin administration resulted in an increase in the absolute counts of Treg cells in active refractory RA patients, from a median of 27.17 cell/ul (at week 0) to 37.57 cell/ul (at week 12) (P=0.041). The ratios of Th17/Treg cells shows a reduction from a median of 0.26 at baseline to 0.20 at week 12, but the difference is not significant (P =0.376). No significant difference was observed in the absolute counts of circulating Th17 and Th1 cells after rapamycin treatment. Interestingly, we observed that Treg cells increased before the complete remission of the disease (DAS28 score <2.6) in patients with active refractory RA. At week 12, the mean dose of prednisone which refractory RA patients were receiving decreased from 11.98 mg/d to 8.31 mg/d, with a dose reduced by ≥30% than that at baseline. The categories of DMARDs use were also reduced (P<0.05). No serious adverse events was observed during the 12-week period of rapamycin treatment.

Conclusions: Reduced absolute number of Treg cells was found in the patients with active refractory RA, indicating an imbalance between Th17 and Treg cells. Rapamycin elicits rapid improvement of disease activity via restoring circulating Treg cells numbers in patients with active refractory RA.

AB0422 1,25-DIHYDROXYVITAMIN D3 MODULATES T CELLS DIFFERENTIATION AND IMPACTS ON THE PRODUCTION OF ASSOCIATED-CYTOKINES FROM CHINESE HAN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

H. Wen[1], X. Li[2]. *[1]Rheumatology; [2]the Second Hospital of Shanxi Medical University, Taiyuan, China*

Background: Recent studies have suggested that vitamin D may play a role in select inflammatory diseases including rheumatoid arthritis (RA). Epidemiological studies suggest that there is an association between vitamin D deficiency and susceptibility to RA.

The present study sought to investigate effects of 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) on T cells differentiation and associated cytokines in Chinese Han patients with early rheumatoid arthritis (RA). The results reported that 1,25(OH)2D3 inhibits the synthesis of Th1 cytokines IFN-γ, Th17 cytokines IL-17, IL-22, IL-6, TNF-α, and up-regulates Th2 cytokine IL-4, which indicated that the possible immunoregulatory role and bone-sparing effects of 1,25(OH)2D3 in RA through modulation of the Th1/Th17 and Th2 cytokine balance.

Objectives: To study effects of 1,25-dihydroxyvitamin D3 ($1,25(OH)_2D_3$) on T cells differentiation and associated cytokines in patients with early rheumatoid arthritis (RA).

Methods: The level of Th1, Th2, Th17 and Treg cell were detected with BDFACS Calibur flow cytometer. IFN-γ, TNF-α, IL-2, IL-4, IL-6, IL-10, IL-17 and IL-22 were examined in 54 patients with incipient RA using a cytometric bead array (CBA).

Results: After 72 hours of incubation of peripheral blood mononuclear cells (PBMCs) with $1,25(OH)_2D_3$ in RA patients, the levels of IFN-γ, TNF-α, IL-2, IL-6 and IL-17 significantly decreased compared to those of the control. $1,25(OH)_2D_3$ had no significantly impact on the levels of IL-4, IL-10 and IL-22. The levels of Th17 and the ratio of Th17/Treg significantly decreased in $1,25(OH)_2D_3$ treated

groups compared to those of the control. 1,25$(OH)_2D_3$ had no significantly impact on the level of Th1, Th2, Treg and the ratio of Th1/Th2.
Conclusions: The present study demonstrated that 1,25$(OH)_2D_3$ inhibits the synthesis of Th1 cytokines IFN-γ, Th17 cytokines IL-17, IL-22, IL-6, TNF-α, and up-regulates Th2 cytokine IL-4, which indicated that the possible immunoregulatory role and bone-sparing effects of 1,25$(OH)_2D_3$ in RA through modulation of the Th1/Th17 and Th2 cytokine balance.

AB0423 MINIMALLY INVASIVE SURGICAL TREATMENT OF TEMPOROMANDIBULAR JOINT IN PATIENTS WITH VARIOUS RHEUMATIC DISORDERS

I. Zaslavskiy[1], A. Drobyshev[1], T. Dubinina[2], S. Erdes[2], A. Kuznetsov[1]. *[1]A.I. Yevdokimov Moscow State University of Medicine and Dentistry; [2]"Va Nasonova Research Institute of Rheumatology, RUSSIA, MOSCOW, Moscow, Russian Federation*

Background: Currently, maxillofacial surgery to actively develop and improve minimally invasive surgical methods for the treatment of patients with diseases of temporomandibular joint (TMJ). These types of surgical treatments like arthroscopy and artrolavazh TMJ are less traumatic and therefore can be effective in patients with rheumatic pathology.
Objectives: To evaluate the efficacy of minimally invasive surgical treatment of TMJ in patients with rheumatic diseases (RD).
Methods: In the study were included 64 pts aged from 18 to 65 years with various rheumatic disorders and lesions of the TMJ. Of these, rheumatoid arthritis (RA) - 43 (67.2%), psoriatic arthritis (PsA) 11 (17.2%), systemic lupus erythematosus - 8 (12.5%) and ankylosing spondylitis (AS) - 2 (3.1%). Before and after 14 days, a month and 6 months after surgery were assessed the following parameters: the level of pain in the TMJ (VAS), the aperture of mouth opening. All the patients at baseline and at 6 months after treatment was performed MRI of the TMJ. Interpretation of the TMJ MRI studies performed by the presence of signs of pathological changes in the joint, which were scored according to the number of pathological signs (from 0 to 8 points). As a preparatory stage before surgery all patients – splint therapy during 1 month was performed. Surgery included arthrolavage and arthroscopy TMJ followed by the introduction of hyaluronic acid.
Results: Before treatment all patients had severe involvement of the TMJ by Wilkes international classification: III of St is 62.5%, IV – by 21.9%, V – 15,6%. 6 months after surgical treatment the level of pain in the TMJ decreased 9.8 times (from 4.9 to 0.5, $p<0,0001$). Mouth opening increased 2.3 times (from 17.5 mm to 40.9 mm, $p<0,0001$), was reached from 96.7% of patients normal value. In the control MRI study of the TMJ at 6 months after surgery, the quantity of signs of pathological changes in the joints were reduced by 2.7 times in comparison with the initial level. The best results were achieved in patients with RA and PsA. The lowest result was achieved in the group of patients with AS.
Conclusions: Minimally invasive methods of surgical treatment of TMJ (arthrolavage and arthroscopy), the most effective and appropriate for the treatment of patients with RD lesion of the temporomandibular joint.

AB0424 THE EFFECT OF HIGH LEVEL OF ANTI-CITRULLINATED PROTEIN ANTIBODIES AND RHEUMATOID FACTOR ON BONE EROSIONS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS– A CROSS-SECTIONAL AND LONGITUDINAL ANALYSIS

J. Yue[1], J. Griffith[2], J. Xu[3], L. Shi[1], D. Wang[4], P. Wong[1], E.K. Li[1], M. Li[1], T.K. Li[1], T.Y. Zhu[5], L. Qin[5], L.-S. Tam[1]. *[1]Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong; [2]Department of Imaging and Interventional Radiology, The Prince of Wales Hospital, The Chinese University of Hong Kong;[3]Department of Orthopedics & Traumatology; [4]Department of Imaging and Interventional Radiology; [5]Bone Quality and Health Center of the Department of Orthopedics & Traumatology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hongkong, Hong Kong*

Background: Bone erosions are a key feature of rheumatoid arthritis (RA) reflecting both disease severity and disease progression. Recent studies using HR-pQCT demonstrated impairment in the bone microstructure of the metacarpophalangeal (MCP) joints of ACPAs-positive healthy individuals despite no signs of arthritis. In patients with established RA, ACPAs and rheumatoid factor (RF) showed an additive effect on erosion number and erosion size. Furthermore, RF influences erosion size only in ACPAs-positive but not in ACPAs-negative patients.
Objectives: To determine the effect of high titre of anticitrullinated protein antibodies (ACPAs) and rheumatoid factor (RF) on the number and size of bone erosions in patients with early rheumatoid arthritis (ERA) by high-resolution peripheral quantitative computed tomography (HR-pQCT) at baseline and whether these antibodies are associated with the progression of erosion after one year of follow-up.
Methods: In the cross-sectional study, HR-pQCT of the second metacarpophalangeal joint (MCP2) was performed in 124 patients with ERA at baseline, images were analysable in 117 patients. Erosions were visualized in 72 patients and parameters of bone erosions were assessed. In the prospective study, 63 ERA patients who had completed one year of follow-up with repeat HR-pQCT scan were also analysed. The number and volume of the erosions as well as bone mineral density (BMD) surrounding erosion were quantified. Data on demographic and disease-specific parameters including ESR, CRP, DAS 28, ACPAs and RF levels and treatment were recorded.
Results: At baseline, 90/117 patients were both ACPAs and RF positive (ACPAs+/RF+ group), 7/117 were only RF (RF+), 13/117 were only ACPAs (ACPAs+) and 7/117 were antibody negative (non-ACPAs+/RF+ group, n=27). Erosion depth and volume were increased in the ACPAs+/RF+ group compared with the non-ACPAs+/RF+ group (both $P<0.05$) (Table 1). Independent explanatory variables associated with a larger erosion volume included RF>16U (P=0.012), older age (P=0.003) and a higher damage joint count (P=0.028). Images from 63 patients who completed 12 months follow-up were analysed. Erosion volume were significantly lower in patients who achieved simplified disease activity score (SDAI) remission at 12 months compared to those who did not (P=0.045). Linear regression analysis indicated that independent predictors for an increase in erosion volume included RF>16U (P=0.032) and a higher damage joint count (P=0.009) at baseline and failure to achieve SDAI remission at 1 year (P=0. 043).

AB0425 TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS IN POLAND - ESTIMATE THE FREQUENCY OF USE OF METHOTREXATE DURING A RANDOM APPOINTMENT WITH A RHEUMATOLOGIST

K. Sikorska-Siudek[1], M. Przygodzka[1], R. Radomski[2], S. Bojanowski[2]. *[1]Mazovian Centre of Rheumatology and Osteoporosis; [2]iEHR.eu, Warsaw, Poland*

Background: In accordance with the EULAR/ACR reomendations disease-modifying antirheumatic drugs (DMARDs), particulary metotrexate (Mtx) should be applied after diagnosis of rheumatoid arthritis (RA). The goal of the treatment is to get remission/low disease activity
Objectives: The aim of this study was evaluation of the RA treatment, the frequency of use of Mtx and its dose application during control visits to rheumatologist in Poland. The disease activity was evaluated by using disease activity 28 joint score (DAS-28).
Results: There were analysed 301 case records of patients diagnosed with RA on the basis of the ACR 1997 and/or ACR/EULAR 2010 criteria. Patients recently diagnosed were excluded from analysis. In the examined group were 226 women and 75 men, median age 58.0, disease duration 5.0 Patients were divided in groups depending on the type of applied therapy 215 (71%) patients were treated with Mtx monotherapy or combined with other DMARDs. 161 patients (53%) took glucocorticosteroids simultaneously. Average DAS28 – 5.09, disease duration 6.2 At 18 patients (6%) contraindications against the Mtx were stated. 127 patients (59%) took high dosage of Mtx (20–30 mg/week), 84 (39%) low dosage (7.5–15 mg /week) 31 patients (10%) were treated other than Mtx DMARDs in monotherapy or in combined therapy 14 (45%) took glucocorticosteroids simultaneously, average DAS 28 – 4.82, disease duration 5.0 55 (18%) patients didn't undergo treatment of DMARDs in the moment of analysis, 11 (20%) patients underwent treatment with glucocorticosteroids. Duration of disease 2.1 average DAS 28 5,43.
Conclusions: In patients treated with DMARDs in it also with Mtx a remission and/or a low activity of illness weren't being observed what is indicating for the ineffective treatment with RA.
Mtx wasn't applied in recommended doses in spite of the moderate or high activity of illness
There were patients who never had been treated with DMARDs. Causes of this occurrence require further research

AB0426 THE EFFICACY OF THE TRIPLE COMBINATION THERAPY WITH METHOTREXATE, LEFLUNOMIDE AND METHYLPREDNISOLONE IN RHEUMATOID ARTHRITIS

L. Groppa[1], E. Russu[1], L. Chislari[1], O. Bujor[2]. *[1]Rheumatology and Nephrology, State University of Medicine and Pharmacy "Nicolae Testemitanu"; [2]Arthrology, Republican Clinical Hospital, Chisinau, Moldova, Republic of*

Background: The RA modern treatment approaches are based on "aggressive therapy", which aims at suppressing autoimmune inflammation and prevent joint destructionsat the early stages of the disease.
Objectives: To evaluate the effectiveness and tolerability of the triple combination therapy with methotrexate, leflunomide and methylprednisolone in patients with rheumatoid arthritis.
Methods: The study included 150 patients with rheumatoid arthritis. As a result of randomization, 50 patients received triple combination therapy (methotrexate +methylprednisolone+leflunomide), 50 patients with monotherapy with methotrexate, leflunomide 50 others. As a result all patient groups were comparable after all clinical and demographic indices.
Results: Our results showed that triple therapy is very effective in treating patients with RA. A significant improvement on the criteria of the AAR (ACR>50) at the end of the study was observed in most patients receiving methotrexate, leflunomide and methylprednisolone. This is confirmed statistically and clinically positive dynamics significantly in almost all indicators used of efficacy (pain, stiffness, number of tender and swollen joints, the activity of AR, the value VSH index functional HAQ) In addition, the use of triple therapy decreased average dose simultaneous use of glucocorticosteroids daily (from 5.0 to 2.5 mg) and 76% of patients canceled anti-inflammatory non-steroid drugs.
Conclusions: After randomized trial data lasting 24 months based triple therapy (methotrexate, leflunomide and methylprednisolone) was highly effective in patients with high RA activity. A significant improvement according to the criteria of ACR (ACR>50) was obtained in 31 of 39 patients (79.48%), including the nine patients (23.07%) had developed clinical remission.
Administration of the basic triple therapy was characterized by a significant clinical effect ACR stability of>50. It was maintained during not less than 15 months of research in 28 (90.32%) of patients who received this treatment and only 3 of 11 (27.27%) patients who received methotrexate alone group and 8 in 10 (80%) who administered LF (p=0.039). Evidence recovery (ACR>50), as well as clinical remission was kept stable in all 28 patients that triple therapy was extended after the ending of basic research.

AB0427 EFFICACY OF HYPNOTIC ANALGESIA FOR THE REDUCTION OF PAIN AND NEGATIVE EMOTIONAL STATES IN PATIENTS WITH RHEUMATOID ARTHRITIS OF THE "HOSPITAL CIVIL DE GUADALAJARA "FRAY ANTONIO ALCALDE"

F. Bolaños-Chamorro[1], L.A. Hernandez-Palma[2], G. Vazquez-Murillo[1], S. Cerpa-Cruz[3], J.F. Muñoz-Valle[2], R.M. Meda-Lara[1]. *[1]Basic Psychology; [2]Research Institute in Biomedical Sciences, University of Guadalajara; [3]Division of Rheumatology, Guadalajara Civil Hospital Fray Antonio Alcalde, Guadalajara, Mexico*

Background: Rheumatoid arthritis is a autoimmune and multisystemic disease. However, the negative emotions of anxiety and depression are the ones that have been most addressed, and there is a close relationship between pain associated with pain. Hypnosis is one of the best documented behavioral interventions in the management of acute and chronic pain in adults.
Objectives: To evaluate the efficacy of hypnotic analgesia for pain reduction and negative emotional states in patients with Rheumatoid Arthritis of the Guadalajara Civil Hospital Fray Antonio Alcalde
Methods: The method was developed through a quasi-experimental study, in which had two groups: a control group (CG) of 11 patients and an experimental group (EG) of 17, the women's age group were developed between 18 and 65 years old diagnosed with arthritis. The medition of Pain was realized through an instrument called EVA, and for the case of the Anxiety and depression were through HAD, achieving the baseline of each one of the variables. The EG group attended three psychological sessions of Hypnosis, with intervals of one month each. In these sessions, the perception of pain with an EVA was measured at the beginning and at the end. After a month, the subsequent evaluation was performed, measuring the same initial variables, in order to make the comparison of the pre and pos.
Results: The U of MANN Whitney was applied and it was identified that in the pre-test measurement, there were no statistically significant differences in the variables. However, in the pos measurement, differences were found in the patient's pain perception ($z=-2.84$, $p<0.05$), anxiety ($z=-2.36$, $p<0.05$) and The depression ($z=-2.68$, $p<0.05$). In addition, a Wilcoxon test was developed to determine differences between the pre-test score and the pos-test score in the EVA of each session. Statistically significant differences were found in the first session ($Z=-3.65$, $p=0.001$), second session ($Z=-3.67$, $p=0.001$) and third session ($Z=-3.56$, $p=0.001$).
Conclusions: Hypnosis, as a behavioral technique, has shown efficacy in patients with chronic pain. In this research, a significant decrease in patients' perception of pain has been demonstrated.

AB0428 A SYSTEMATIC REVIEW ON EFFICACY AND SAFETY OF SELECTIVE GLUCOCORTICOID RECEPTOR MODULATORS IN COMPARISON TO GLUCOCORTICOIDS IN ARTHRITIS

M. Safy[1], M.J. De Hair[1], J.W. Jacobs[1], F. Buttgereit[2], M.C. Kraan[3], J.M. van Laar[1]. *[1]Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; [2]Rheumatology and Clinical Immunology, Charité - Universitätsmedizin, Berlin, Germany; [3]Department of Rheumatology and Inflammation Research, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden*

Background: Glucocorticoids (GCs) can cause unwanted effects. Both rheumatologists and patients classify osteoporosis, hyperglycemia/diabetes mellitus, cardiovascular diseases, and infections as the most worrisome adverse effects of GCs. Alternatives with less adverse effects but with good efficacy are needed, thus with a better efficacy/safety ratio. Selective GC receptor modulators (SGMRs) are designed to engage the receptor with dissociative characteristics: less transactivation of genes, mainly responsible for unwanted effects, while trans-repression of genes, inducing anti-inflammation, is maintained. Hereby, SGRMs are expected to have a better efficacy/safety ratio. A systematic review providing an overview of the efficacy and safety data of SGRMs is lacking.
Objectives: To systematically review the current literature on efficacy and safety of SGRMs in arthritis, compared to those of GCs.
Methods: A search was performed in Medline, Embase and the Cochrane Library, from inception dates of databases to October 5th, 2016. Experimental studies involving animal arthritis models or human material of arthritis patients, as well as clinical studies in patients of arthritis were included, if they reported original data. All types of arthritis were included. Data was extracted on the SGRM studied and on the GC as reference standard, design or setting of the study and whether or not safety and efficacy parameters had been reported.
Results: A total of 437 articles was retrieved of which 15 articles were eligible for our analysis. The following SGRMs were investigated: Compound A[1–6], PF-04171327[7], LGD-5552[8–9], Compounds 4[10], 5[10], and 14[11], (R)-16[12], (R)-18[13],

(R)-21[13], (R)-35[14], (R)-37[12], Ginsenoside Rg1[15] and Org 214007–0[16]. Results are shown in Table 1. (R)-16 showed better efficacy and safety compared to prednisone. Compound A, Ginsenoside Rg 1, Compounds 14, (R)-18, and (R)-21 had better safety profiles than a GC, but with similar efficacy. (R)-35 and (R)-37 showed better efficacy than a GC, but safety data was lacking. Org 214007–0, LGD-5552, Compounds 4 and 5 and PF-04171327 showed similar efficacy as a GC, but no safety data was provided.

Author, year	SGRM tested	Reference compound	Clinical trial	Pre-clinical human	Pre-clinical animal	Efficacy	Safety	Conclusion on efficacy and safety in comparison to reference compound
Dewint et al., 2008	Compound A	Dex		X	X	X	X	Similar efficacy. Better safety of Compound A.
Gossye et al., 2009	Compound A	Dex		x				Similar efficacy. No safety data
Gossye et al., 2010	Compound A	Dex		X	X			Less efficacy of Compound A. No safety data.
Rauch et al., 2011	Compound A	Dex		X		X	X	Similar efficacy. Better safety of Compound A.
Rauner et al., 2013	Compound A	Dex			X	X	X	Less efficacy of Compound A. Better safety of Compound A.
Malaise et al., 2015	Compound A	Pred		X		X	X	Similar efficacy. Better safety of Compound A.
Yang et al., 2015	Compound 4 and 5	Pred			X	X		Similar efficacy of compound 4, better efficacy of compound 5. No safety data.
Razavi et al., 2014	Compound 14	Pred			X	X	X	Similar efficacy. Better safety of Compound 14.
Riether et al., 2010	Compound (R)-16 and (R)-37	Pred			X	X	X	Better efficacy of (R)-16. Better safety of (R)-16 and (R)-37.
Harcken et al., 2014	Compound (R)-18 and (R)-21	Pred			X	X	X	Similar efficacy. Better safety of R)-18 and (R)-21.
Weinstein et al., 2011	Compound 35 and 37	Pred, dex			X	X		Better efficacy of compounds 35 and 37. No safety data.
Miner et al., 2007	LGD-5552	Pred			X	X		Similar efficacy. No safety data.
Lopez et al., 2008	LGD-5552	Pred			X	X		Similar efficacy. No safety data.
Du et al., 2011	Ginsenoside Rg1	Dex			X	X		Similar efficacy. Better safety of Ginsenoside Rg1.
Van Lierop et al., 2012	Org 214007-0	Pred			X	X	X	Similar efficacy of Org-214007-0.No safety data.
Conrado et al., 2015	PF-04171327	Pred	X			X		Similar efficacy. No safety data.

Table 1. Efficacy and safety results of selective glucocorticoid receptor modulators (SGRMs).

Conclusions: Studies both assessing efficacy and safety parameters of SGRMs are scarce. Currently, there is insufficient evidence for the presumed superior efficacy/toxicity balance of SGRMs compared to that of GCs.

AB0429 SHORT-TERM EFFECTS OF LOW DOSE GLUCOCORTICOIDS ON BONE METABOLISM IN EARLY RHEUMATOID ARTHRITIS

M. Vitiello[1], O. Viapiana[1], N. Malavolta[2], G. Saviola[3], R. Bortolotti[4], L. Idolazzi[1], F. Bertoldo[1], G. Orsolini[1], M. Risoli[1], D. Gatti[1], M. Rossini[1].

Background: Glucocorticoids (GCs) are frequently used in the treatment of Rheumatoid Arthritis (RA). Studies in humans about the effects on bone turnover markers and modulators are poor, and results are discordant and controverse, probably because conducted with different doses and underlying diseases.
Objectives: To evaluate changes in serum bone turnover markers and Wnt inhibitors at 7- and 30-days after initiation of low dose GCs treatment of early RA.
Methods: 27 adult patients suffering from early RA were prospectively enrolled. Blood tests including C-Reactive Protein (CRP), amino-terminal propeptide of type 1 procollagen (P1NP, marker of bone formation), carboxy-terminal telopeptide of type 1 collagen (CTX, marker of bone resorption), Sclerostin, and Dickkopf-related protein 1 (DKK1) were detected at baseline and 7 and 30 days after starting low dose of GC (methylprednisolone 4 mg/day).
Results: At baseline we observed a significant positive correlation between CRP and DKK1 serum levels ($r=0,63$; $p<0,05$) and between DKK1 and CTX serum levels ($r=0,38$; $p<0,05$). A significant decrease in serum levels of CRP, P1NP, and Sclerostin was observed after 7 and 30 days of GC treatment ($p<0,05$). About DKK1, it has been detected a not significant tendency to decrease after starting GC. CTX serum levels showed no significant changes.
Conclusions: This study has shown that a low dose GC treatment might have complex and conflicting short-term effects on bone metabolism in early RA (a reduction of bone formation, without increase of bone resorption), different from those observed with higher dose, in other diseases or in healthy subjects. The observed decrease in P1NP and Sclerostin serum levels might mean that also low dose of GC could acutely suppress bone formation and induce loss of function and/or number of osteocytes.

AB0430 LEFLUNOMIDE AS A SECOND LINE DMARD AFTER METHOTREXATE HAS LIMITED IMPACT ON RHEUMATOID ARTHRITIS IN REAL LIFE

G. Weigt, A. Erler, M. Aringer. *Medicine III, University Medical Center TU Dresden, Dresden, Germany*

Background: If rheumatoid arthritis (RA) is not in remission or at least low disease under methotrexate (MTX), leflunomide is an approved conventional synthetic DMARD, which is commonly used in some countries.
Objectives: To investigate in a real life situation whether patients with RA benefit from instituting leflunomide after methotrexate.
Methods: The clinical data of all RA patients who had at least once received leflunomide, and who agreed to the pseudonymized analysis of their data (approved by the local ethics committee), were analyzed from the time of leflunomide initiation on to the time of stopping leflunomide or the last visit in 2015, which ever came first.
Results: In total, 145 RA patients treated with leflunomide were identified. Of these, 87 received leflunomide after MTX had failed as a first line DMARD, and 8 received leflunomide as a first line DMARD. 50 patients had another first line therapy. Of the first line leflunomide patients 3 (38%) were still on leflunomide at the last visit, as compared to 7 of the 44 patients (16%) who were switched from MTX to leflunomide, and 0 of the 27 patients in whom leflunomide was added to MTX ($p<0.01$ vs 1st line leflunomide). For leflunomide monotherapy, 29% and 19% were still on the drug after 24 and 48 months, respectively, as compared to 14 and 0% under the combination with MTX. Of all patients who started leflunomide, remission (at least low disease activity) as per CDAI ($\leq$2.8 ($\leq$10)) was reached by 23% (57%) 3 months, 20% (40%) 6 months, and 16% (34%) one year after initiating leflunomide monotherapy, with corresponding percentages of patients of 39% switched to other approaches at six months and of 60% switched at one year. Under the combination of leflunomide and MTX, remission (at least low disease activity) was seen in 18% (53%) at 3 months, 20% (37%) at 6 months, and 8% (20%) at one year, and 55% and 71% had switched to other modes of action at six months and one year, respectively. Gastrointestinal and mucocutaneous adverse events and hypertension were common, and 4 our patients experienced serious bacterial infections.
Conclusions: Leflunomide constitutes a longer term option for a subgroup of RA patients with contraindications to MTX or after MTX failure. After one year, leflunomide had led to sustained acceptable disease control in approximately one third of the patients, but only in one in five under leflunomide combined with MTX. These results are supportive of the EULAR recommendations that patients should be switched to a second conventional DMARD in the absence of predictors of bad outcome only. If leflunomide is initiated, the patients need to be followed closely for potential secondary loss of efficacy.

AB0431 POST-MARKETING SURVEILLANCE OF TOFACITINIB IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: AN INTERIM REPORT OF SAFETY DATA

T. Mimori[1], M. Harigai[2], T. Atsumi[3], M. Kuwana[4], S. Takei[5], N. Tamura[6], T. Fujii[7], H. Matsuno[8], S. Momohara[9], K. Yamamoto[10], T. Kokubo[11], Y. Endo[11], N. Sugiyama[11], T. Hirose[11], Y. Morishima[11], N. Yoshii[11]. *[1]Kyoto University, Kyoto; [2]Tokyo Women's Medical University, Tokyo; [3]Hokkaido University, Sapporo; [4]Nippon Medical School, Tokyo; [5]Kagoshima University, Kagoshima; [6]Juntendo University, Tokyo; [7]Wakayama Medical University, Wakayama; [8]Matsuno Clinic for Rheumatic Diseases, Toyama; [9]Hakkeikai Inc Medical Institution, Shizuoka; [10]The University of Tokyo; [11]Pfizer Japan Inc, Tokyo, Japan*

Background: Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy and safety of tofacitinib have been shown in RA patients in global Phase 2, Phase 3 (one study included Japanese patients) and long-term extension (LTE) studies and in two Phase 2 and one LTE study in Japanese patients.

Objectives: We evaluated the safety of tofacitinib following drug approval in Japanese patients with RA using all-case post-marketing surveillance (PMS) data.
Methods: A 6-month interim analysis of safety data from an ongoing 3-year PMS study was conducted (5 Nov 2016 data-cut). All Japanese patients with RA who were treated with tofacitinib were consecutively and prospectively registered in the PMS study and were monitored for all adverse events (AEs) for 3 years. Baseline and follow-up data were collected from booklet-type survey forms. Follow-up surveillance after discontinuation of tofacitinib treatment was implemented: 12 months for serious infections and 3 years for malignancy or AEs leading to death from the date of treatment initiation with tofacitinib. AEs were coded using MedDRA/J.
Results: Overall, 2387 tofacitinib-treated patients were enrolled (1020.0 patient-years [pt-yrs] of exposure); of these, 594 patients (24.9%) discontinued treatment, mainly due to AEs (n=236; 9.9%) or lack of effectiveness (n=225; 9.4%). In total, 1793 (75.1%) patients continued treatment for 6 months. At least one AE was observed in 815 patients (34.1%), the most frequent of which was herpes zoster (n=78; 3.3%), including 12 serious cases. Serious AEs occurred in 190 patients (8.0%); the most frequent were pneumonia (n=20; 0.8%), interstitial lung disease (n=14; 0.6%) and condition aggravated (n=13; 0.5%). Infections (n=304; 12.7%) were serious in 88 patients (3.7%). Thirteen patients (0.5%) reported malignancy, including ovarian cancer (n=2; 0.1%), diffuse large B-cell lymphoma (n=2; 0.1%) and lymphoproliferative disorder (n=1, 0.04%). Sixteen (0.7%) deaths were reported.
Conclusions: Interim analyses of AEs during the initial 6-month treatment period from PMS reports of tofacitinib in Japanese patients did not reveal any new or unexpected safety signals vs the tofacitinib RA clinical programme. The target sample size for the final PMS analysis is 6000 patients (4000 tofactinib-treated, 2000 control patients).

AB0432 ABT-494 HAS NO EFFECT ON THE QT INTERVAL AT THE DOSES BEING EVALUATED IN RHEUMATOID ARTHRITIS PHASE 3 TRIALS

M.-E.F. Mohamed, J. Zeng, P. Jiang, B. Hosmane, A.A. Othman. *Clinical Pharmacology and Pharmacometrics, AbbVie, North Chicago, United States*

Background: ABT-494 is a selective Janus Kinase 1 inhibitor currently being evaluated in Phase 3 trials for treatment of rheumatoid arthritis (RA) at doses of 15 mg and 30 mg once daily using the extended-release tablet formulation. Exposure-response analysis of ECG data collected at early stage clinical trials has been recently adopted in regulatory guidelines as a tool to assess the proarrhythmic risk of investigational new drugs.
Objectives: The objective of this work was to evaluate ABT-494 QT prolongation potential using exposure-response analysis of data collected in early Phase 1 studies.
Methods: Doses of ABT-494 or placebo were administered to healthy subjects in two Phase 1 studies. Evaluated ABT-494 immediate-release regimens ranged from 1 mg to 48 mg single doses under fasting conditions and 3 mg to 24 mg twice daily under non-fasting conditions. Serial triplicate electrocardiograms and pharmacokinetic assessments were conducted. The relationship between change from baseline in Fridericia-corrected QT interval (QTcF) and ABT-494 plasma concentrations was characterized using linear mixed-effects modeling. To evaluate the ECG assay sensitivity, the change in QTcF from baseline to 2 hours post-dose was compared for subjects who received placebo under fasting and non-fasting conditions.
Results: There was no statistically significant relationship between the change from baseline in the QTcF interval and ABT-494 plasma concentrations. The point estimate of the effect on QTcF for the highest concentration observed in the evaluated studies, which is approximately 4-fold higher than the mean C_{max} of the highest RA Phase 3 dose, is –1.77 msec (with upper bound of the 95% one-sided confidence interval of 3.33 msec; lower than the regulatory threshold of concern of 10 msec). Food shortened the QTcF interval by 5.9 msec (2-sided 90% confidence interval of -9.6 to -2.1 msec), indicating that the ECG assay used in the studies had adequate sensitivity to detect the small change in QTcF caused by food.
Conclusions: ABT-494 showed no potential for QT prolongation at the expected therapeutic and supra-therapeutic plasma exposures for the doses being used in Phase 3 RA trials.

AB0433 CORRECTION OF LIPID AND ENDOTHELIAL DYSFUNCTION BY USING NO DONATORS (4,2% SOLUTION OF ARGININE HYDROCHLORIDE AND L-ARGININE ASPARTATE) IN PATIENT WITH RHEUMATOID ARTHRITIS IN COMBINATION WITH THE RAYNAUD'S SYNDROME

O. Shtefiuk, R. Yatsyshyn. *Internal Medicine #1, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*

Background: Lesion of the cardiovascular system is associated with uncontrolled inflammation and immune defects in patients with Rheumatoid Arthritis (RA). There is an evidence of the close pathogenetic connection between rheumatoid inflammation and accelerated development of atherosclerosis. The first sing of atherosclerosis is endothelial dysfunction (ED).
Objectives: Evaluate the effectiveness of NO donators (4,2% solution of arginine hydrochloride and L-arginine aspartate) in the correction of lipid and ED in patients with RA and secondary Raynaud's syndrome (RS).
Methods: 68 patients with RA were examined. All patients were divided into 2 groups: (37 people with RA in combination with secondary RS) received basic therapy of RA (methotrexate 10–15 mg/wk.), antiplatelet and vasodilatory drugs; II group (31 people – RA in combination with secondary RS) got similar therapy plus NO donators (4,2% solution of arginine hydrochloride and L-arginine aspartate). The examination was carried out at the patient's admission to the hospital and the hospital and 3 months after the beginning of treatment. Endothelial function was assessed by determining the flow-mediated vasodilation of brachial artery (FMD), levels of endothelin-1, rheumatoid factor (RF), C-reactive protein (CRP), lipid profile (total cholesterol – TC, low density lipoprotein – LDL, high-densitylipoprotein – HDL and triglycerides – TG), index of intima/media (IM) and atherogenic index (AI).
Results: Levels of TC, LDL, AI and MI indexes were significantly higher than the norm in 2 compared groups before the treatment and 3 months after its start ($p<0,05$). There were significant decreases in levels of lipid profile, IA and MI index in II group 3 months after treatment in comparison to benchmarks (TC by 13,3%, LDL by 16,1%, TG by 14,7%, AI index by 13,8% MI index by 12,7%,$p<0,05$) and they were significantly unchanged in I group ($p<0,05$). It was elucidated a direct reliable strong correlation in patients of II group between the level of FMD and endothelin-1 before treatment ($r=0,73$, $p<0,05$) and after treatment ($r=0,69$, $p<0,05$). Symptoms of ED, levels of endothelin-1, RF, CRP were decreased in patients of both groups after the conducted therapy. It was established a proportionately reliable correction between CRP and LDL levels after treatment in II group of patient ($r=0,63$, $p<0,05$).
Conclusions: 1.There is a lack of flow-mediated vasodilation of brachial artery in patients with RA and secondary RS, which can indicate a dysregulation of endothelial function.
2. The level of CRP is increased in patients with RA and secondary RS and is associated with the risk of hyperlipemia and atherosclerosis. 3. The usage of NO donators (4,2% solution of arginine hydrochloride and L-arginine aspartate) in the treatment of RA with secondary RS significantly reduces the levels of IA and IM index, the level of atherogenic lipoprotein fractions (TC, LDL and TG) and decreases the severity of ED, which leads to minimizing the risk of atherogenesis and its complications.

AB0434 TOFACITINIB IN RHEUMATOID ARTHRITIS: REAL LIFE EXPERIENCE

P. Sansinanea[1], A.C. Costi[1], A. Vulcano[2], A.P. Salas[2], J. Marcos[3], M.A. Belini[4], M.A. García[2]. *[1]Rheumatology Unit, Sanatorio Ipensa, HIGA San Martín la Plata; [2]Rheumatology Unit, HIGA San Martín la Plata; [3]Rheumatology Unit, Sanatorio IPENSA, Pfizer Inc., la Plata; [4]Medical Affairs, Pfizer Inc, CABA, Argentina*

Background: Tofacitinib is a new small molecule, Janus kinase 1 and 3 inhibitor, interfering with the JAK-STAT signaling pathway. The JAK-STAT transmits the extracellular information in the cell nucleus, influencing DNA transcription. Its efficacy and safety in Rheumatoid Arthritis (RA) has been demonstrated in different phase II, III and long-term clinical studies. It has been approved in Argentina for the treatment of patients with moderate to severe rheumatoid arthritis RA with failure to conventional DMARDs.
Objectives: To communicate real world safety data from patients with RA under treatment with Tofacitinib.
Methods: A retrospective, descriptive study from patients with RA (ACR/EULAR2010) under treatment with Tofacitinib from September 2014 to December 2016 was conducted. Medical records from patients being treated with Tofacitinib were reviewed and demographic data were recorded. Comorbidities, concomitant treatments, and reported adverse effects were documented.
Results: 62 patients were treated with Tofacitinib. 53 were female and 9 were male, with a mean age of 57.91±14.72 years and average disease duration of 140.09±130.83 months. 18 patients (29%) had at least one comorbidity, the most frequent being hypertension (77%).
Of the 62 patients studied, 54 (87%) had established RA (duration of illness greater than 24 months) and 8 patients (13%) with early RA (less than 24 months). In 54 patients Tofacitinib was indicated in combination with another DMARD (87%), and only 6 patients received treatment as monotherapy.
The most commonly used DMARD in combination therapy was methotrexate (MTX) in 92.5%
Treatments were indicated by failure to MTX or other conventional DMARDs, 12/62 treatments were indicated by failure to treatment with 1 biological DMARD and 13/62 treatments were indicated by failure to two or more biological DMARDs. The maximum exposure time was 21 months.
During the time of exposure to Tofacitinib the following adverse events were observed: Herpes Zoster infection 2 cases (monometameric, no visceral involvement in unvaccinated patients), upper airway infection 1 case, transient increase in liver enzymes 1 case, peripheral facial paralysis 1 case, tachycardia 1 case. There were no cases of serious infections, opportunistic infections, cytopenias, dyslipidemia, or increased CPK.
Three patients discontinued Tofacitinib: one due to tachycardia, another case peripheral facial paralysis and another case due inefficacy.
Conclusions: Most patients received combined treatment with DMARDs being the most commonly used Methotrexate. There were no cases of serious infections, opportunistic infections, cytopenias or dyslipidemia. The use of Tofacitinib in RA patients in our cohort showed a comparable safety profile with long-term extension studies in the treatment of patients with RA diagnosed with failure of conventional or biological DMARDs.

AB0435 COMBINATION THERAPY IN EARLY STAGE OF RHEUMATOID ARTHRITIS

S.X. Matchanov. *Internal disease, Tashkent Medical Academy, Tashkent, Uzbekistan*

Background: It is known that the early period of rheumatoid arthritis (RA) has a critical role in the development and progression of immune inflammation. Allocation of early RA is due to the need for timely appointment of basic anti-inflammatory drugs to prevent the development of destructive changes in the joints and improve its current forecast. We have proposed a combination of two basic drugs for the treatment of RA, methotrexate (MTX) and leflunomide (LF). While this combination, we proceeded from the basic principles of combination therapy: each of the drugs has an independent clinical effect in early RA, the drugs have different mechanisms of action and different spectrum of side effects.
Objectives: Investigating of clinical efficacy of combination therapy with MT and LF in patients with RA in its early stages
Methods: We observed 80 patients with early RA, 50 patients of them were women and 30 patients were male. The age of patients ranged from 24 up to 42 years old (31,7±7,6), the duration of illness was 6 months. Activity of RA was corresponded to the II degree (DAS 28 <4.7) in 48 patients, III degree (DAS28>5,1) was in 32 patients. 1st group consisted of 40 patients and the 2nd group involved 40 patients. Patients in 1st group received combination therapy with LF in doses 20 mg/day and MT in doses 7.5 mg/week. 2nd group received just MT as a single basic anti-inflammatory drug in doses 7.5 mg/week. In order to improve portability of MT was administered to all patients folic acid in doses 1.2 mg/day, 5 days in a week. The efficiency of the intervention was evaluated after 6 months by reducing of the final value of the indicator of inflammatory activity.
Results: The results of observation of patients for 6 months were showed that, combination therapy with MT and LF provides a quick and pronounced clinical effect in patients in the early stages of RA. Patients of 1st group according to criteria ACR 50- 70% improvement was achieved in 50% of patients, while figure of all indicators of patients in 2nd group was 33.4%. During the treatment was indicated improvement of laboratory parameters of disease activity of RA in both groups, features of activity of 1st group were decreased up to (DAS28 =2,9), signs of 2nd group were (DAS28 =3,6). However, there were 26% of cases of clinical remission of the disease in patients of 1st group than patients of 2nd group. Known side effects of combination therapy with MT and LF in most cases have not been severe, reversible and demanded the abolition of drugs in rare (11.2%) cases.
Conclusions: Combined basic therapy of patients in the early stages of RA with LF and MT has more efficiency than mono therapy.

AB0436 COMPARISON OF TOFACITINIB EFFICACY IN PATIENTS WITH MODERATE VS SEVERE RHEUMATOID ARTHRITIS: POOLED ANALYSIS OF PHASE 3 STUDIES

S. Schwartzman[1], P. Sunkureddi[2], L. Takiya[3], M. Snyder[3], H. Fan[4], T. Lukic[5], J. Roberts[6], W.F.C. Rigby[7]. *[1]Hospital for Special Surgery, New York, NY; [2]Clear Lake Rheumatology, Nassau Bay, TX; [3]Pfizer Inc, Collegeville, PA; [4]Pfizer Inc, Groton, CT; [5]Pfizer Inc, New York, NY, United States; [6]Pfizer Inc, Tadworth, United Kingdom; [7]Geisel School of Medicine at Dartmouth, Lebanon, NH, United States*

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA.
Objectives: To evaluate tofacitinib 5 and 10 mg twice daily (BID) efficacy in patients (pts) with moderate vs severe RA.
Methods: Tofacitinib 5 and 10 mg BID efficacy data were obtained from 6 randomised double-blind Phase 3 studies of 6–24 months' duration. Tofacitinib was administered as monotherapy (NCT00814307 ORAL Solo; NCT01039688 ORAL Start) or with csDMARDs, mainly MTX (NCT00960440 ORAL Step; NCT00847613 ORAL Scan; NCT00856544 ORAL Sync; NCT00853385 ORAL Standard). Pts receiving MTX monotherapy (ORAL Start), or placebo (±csDMARDs) were combined as a single "placebo" group. Baseline (BL) disease severity was classified as moderate or severe using Disease Activity Score in 28 joints with erythrocyte sedimentation rate (DAS28: moderate 3.2 to ≤5.1; severe >5.1) and Clinical Disease Activity Index (CDAI: moderate 10 to ≤22; severe >22). Month 3 (M3) efficacy outcomes included: pts (%) achieving low disease activity (LDA; DAS28 ≤3.2, CDAI ≤10), remission (DAS28 <2.6, CDAI ≤2.8), HAQ-DI <0.5 (normal physical functioning), HAQ-DI improvement >0.22 and mean change from BL (Δ) in DAS28, CDAI and HAQ-DI. This post hoc analysis had no multiplicity adjustments.
Results: Overall, more pts had severe BL disease by DAS28 (91.0%) and CDAI (89.5%). The table shows BL disease characteristics and M3 efficacy outcomes for pts classified by BL DAS28 disease severity; CDAI classification demonstrated similar trends.

Table. Baseline disease characteristics (A) and Month 3 efficacy outcomes (B) by baseline disease severity assessment using DAS28

*p<0.05, **p<0.001, ***p<0.0001 vs placebo
BID, twice daily; CDAI, clinical disease activity index; CI, 95% confidence interval; DAS28, Disease Activity Score in 28 joints with erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDA, low disease activity; LS, least squares; SD, standard deviation

BL characteristics were balanced between treatment groups in each disease severity category. M3 efficacy was significantly greater with tofacitinib 5 and 10 mg BID vs placebo, regardless of BL disease severity. As expected, larger proportions of tofacitinib-treated pts with moderate vs severe BL RA achieved LDA by either DAS28 (32.3–36.7% vs 13.8–19.1%) or CDAI (49.2–55.0% vs 26.0–31.7%). Similarly, a higher proportion of pts achieved remission in the moderate vs severe BL groups by DAS28 (20.0–22.8% vs 6.2–9.0%) or CDAI (11.5–12.1% vs 5.1–6.7%). A greater proportion of pts achieved HAQ-DI <0.5 with moderate vs severe RA classified by BL DAS28 (45.0–60.6% vs 24.5–30.0%) or BL CDAI (40.8–52.4% vs 24.7–30.4%). Greater improvements from BL in disease activity and HAQ-DI were seen for pts with severe vs moderate RA classified by BL DAS28 (Table), and by BL CDAI (Tofacitinib 5/10 mg BID ΔCDAI: -21.1/-23.0 vs -8.1/-9.4; ΔHAQ DI: -0.5/-0.6 vs -0.3/-0.4).

Conclusions: Tofacitinib 5 and 10 mg BID demonstrated efficacy in treating pts with moderate and severe RA with >7 years' mean disease duration. By M3, pts with severe vs moderate BL disease activity had greater improvements in disease activity and physical functioning; higher proportions of pts with moderate vs severe BL disease activity achieved remission, LDA or normal physical functioning. Interpretation of this post hoc analysis may be limited by the smaller sample size of the moderate disease group and the combining of mono- and combination-therapy results.

AB0437 EFFICACY AND SAFETY OF LONG-TERM ANALGESIC THERAPY WITH ETORICOXIB FOR PATIENTS WITH RHEUMATIC DISEASES

S. Lapshina, L. Myasoutova. *Kazan State Medical University, Kazan, Russian Federation*

Background: There are some data in literature on decompensation of arterial hypertension and other chronic diseases during the treatment with coxibs which in practice unfortunately limits their administration for patients with comorbidities.

Objectives: To evaluate the efficacy of analgesic effect of etoricoxib and frequency of comorbidities exacerbation on such treatment.

Methods: 58 patients with rheumatoid arthritis (34,4%), osteoarthritis (29,2%), ankylosing spondylitis (19%), gout (14%), psoriatic arthritis (3,4%) at the age of 25 to 75 years (the average age, 52,9±13,03 years) were included. 79,3% patients had comorbidities (diseases of digestive system – 37,9%, arterial hypertension – 53,4% (including 3,2% with decompensated hypertension), bronchial asthma – 1,7%). All the patients before the appointment had taken NSAIDs (diclofenac, nimesulid, ketoprofen, meloxicam, aceclofenac, ibuprofen) with lack of effect (84,4%) or minimal effect (15,6%). Etoricoxib was administered in 100% cases. Pain severity according to visual analogue scale (VAS), comorbidities exacerbation and blood pressure were assessed at the beginning and during the first month of treatment.

Results: The average time period between 2 appointments was 20,72±9,3 days. By the second appointment 98,2% patients were taking etoricoxib regularly, and good tolerability of the medication was noted (63,8% excellent, 36,2% good). The average VAS score at the first appointment was 7,27±1,04, at the second appointment – 2,75±1,12, in the meantime VAS score improvement was noted mostly in the group of patients with long disease duration (more than 3 years). At the time of second examination total relief of back pain was revealed in 16,7%, in knee joint – 35,5%, in hip joint – 68,1%, in the neck – 61,9%, in small joints – 30,8%, of shoulder blade pain – 82,4%. No comorbidities exacerbation was noted. There were also no cases of sudden blood pressure increase on the administered therapy, including patients with arterial hypertension.

Conclusions: Etoricoxib administration leads to significant decrease of pain syndrome and its relief without increasing blood pressure and exacerbations of chronic comorbidities.

AB0438 RHEUMATOID ARTHRITIS DRUG THERAPY IN THE PERIOPERATIVE PERIOD OF LARGE JOINTS ARTHROPLASTY, ITS IMPACT ON THE LONG-TERM RESULTS OF SURGERY

S. Lapshina[1], I. Akhtyamov[1,2], I. Gilmutdinov[2], L. Myasoutova[1]. *[1]Kazan State Medical University; [2]Republic Clinical Hospital, Kazan, Russian Federation*

Objectives: To analyze the results of large joints arthroplasty depending on the received rheumatoid arthritis (RA) drug therapy

Methods: Knee and hip joints arthroplasty was performed for 54 RA patients (48 women, 6 men), mean age 51,4±12,8 years. At the time of the operation disease duration was 11,8±3,8 years, high activity (DAS28) - in 26%, moderate - in 55.5%, the low - at 18.5% patients. At the time of surgery 39 (72.2%) pts continued to take basic anti-rheumatic drugs (DMARDs) (methotrexate at a dose of 10–20 mg per week - 32, leflunomide (20 mg daily) -5). Corticosteroids (prednisone at a dose of 5–15 mg, an average of 7.1 mg per day) - 25 (46.2%) patients, of which in combination with DMARDs - 10 (18.6%). Before the operation, and after the 6 months joint pain (VAS), disease activity - DAS28, functional ability HAQ index were evaluated. In 32 patients, these same indexes were estimated after 12 months.

Results: The reduction of pain intensity VAS was observed in the first month after a joint arthroplasty, after 6 months VAS fell almost to 31.8 mm ($p<0.05$). Activity of the disease decreased (high - 11.2%, moderate - 44.4%, low - 44.4%), HAQ - from 1,61±0,41 to 1,09±0,26 ($p<0$, 05). After 12 months HAQ - 1,01±0,28.

The analysis showed that in patients not receiving corticosteroids (n=29) arthroplasty was conducted in 13,6±3,2 years after RA onset, and receiving long-term steroids (n=25) significantly earlier ($p<0,05$) - through 9,9±3,5 years. The functional capacity of patients in the group receiving DMARDs without corticosteroids (n=29) (the HAQ 6 months - 0,9±0,24, 12 months - 0 81±0,16) was significantly ($p<0.05$) higher compared with patients receiving corticosteroids (n=25) without the basic treatment (HAQ 6 months -1.13±0.21, over 12 months-1,24±0,19)

Conclusions: Large joints arthroplasty is an effective method to improve the functional capacity of patients with RA. For patients receiving corticosteroids need of arthroplasty arises a few years earlier. The function of the joints after surgery and in the remote period is better when patients continuously receive DMARDs compared to steroid therapy, the dose should be reduced to a reasonable minimum for the time of surgical treatment.

AB0439 EFFICACY AT THREE YEARS OF DAILY CLINICAL USE OF IGURATIMOD IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Suto[1], Y. Yonemoto[1], K. Okamura[1], M. Tachibana[1], C. Okura[1], M. Matsushita[2], K. Takeuchi[2], K. Otsuka[2], K. Ayabe[3], T. Kaneko[4], Y. Tamura[4], M. Inoue[5], H. Inoue[4], H. Chikuda[1]. *[1]Department of Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashishi; [2]Department of Orthopaedic Surgery, Isesaki Fukushima Hospital, Isesakishi; [3]Department of Orthopaedic Surgery, Keiyu Hospital, Tatebayashishi; [4]Department of Orthopaedic Surgery, Inoue Hospital; [5]Department of Medicine, Inoue Hospital, Takasaki, Gunma, Japan*

Background: Iguratimod (IGU) is a small-molecule antirheumatic drug that was developed in Japan and is currently only approved for treatment of rheumatoid arthritis (RA) in Japan and China. IGU suppresses tumor necrosis factor-alpha-induced production of interleukin (IL)-6, IL-8 and monocyte chemoattractant protein 1 via the inhibition of nuclear factor-kappa B activation in cultured human synovial cells and human acute monocytic leukemia cells. There are some reports about the efficacy and safety of IGU in patients with RA. However, the assessment about efficacy of the clinical use of IGU has mainly been restricted to short-term (within one year) outcome.

Objectives: The purpose of this study was to assess the efficacy of IGU in 3 years

Methods: Sixty-nine RA patients (14 males and 55 females, mean age of 63.9 years, mean disease duration of 14.9 years) were enrolled in this study. The clinical course of RA was evaluated during 3 years. The patients who discontinued the IGU therapy were analyzed by the last observation carried forward method.

Results: The survival rate at 3 years was 49.3%, and 8 patients discontinued the IGU therapies due to insufficient response, 12 patients due to adverse events such as exanthema, pneumonitis or hepatic disorder, and other patients based on their requests. The DAS28-CRP, DAS28-ESR, SDAI and CDAI significantly decreased at 6 months, 1, 2, 3 years compared with baseline. The low DAS28-CRP at 3 months and younger age were associated to the continuation of IGU. Furthermore, 27 patients (39.1%) were in remission at 3 years. In the remission achievement group, the DAS28-CRP and the usage rate of prednisolone at baseline were significantly lower and patients' age was younger. A logistic regression analysis revealed the low DAS28-CRP and low usage rate of prednisolone at baseline were significant factors contributing to the achievement of a clinical remission at 3 years.

Conclusions: We assessed middle-term outcome of the clinical use of iguratimod therapy in RA patients. The low DAS28-CRP and low usage rate of prednisolone at the initiation of IGU were significant factors of clinical remission achievement at 3 years.

AB0440 IMPACT OF VITAMIN D DEFICIENCY UPON DISEASE ACTIVITY AND IMMUNE DISORDER IN RHEUMATOID ARTHRITIS PATIENTS

Y. Liu, H.Y. Wen. *Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China*

Background: Emerging evidence suggests that vitamin D plays an important role in immune regulation.
Objectives: The objective of this work was to determine if patients with rheumatoid arthritis (RA) are at risk for vitamin D deficiency and whether vitamin D levels correlate with disease activity or immune disorders.
Methods: This study was a retrospective research. RA patients who had vitamin D levels and immune function indexes of each other were included. Patients receiving or have received vitamin D, corticosteroids, disease-modifying anti-rheumatic drugs or a tumor necrosis factor antagonist and those who had hepatic or renal insufficiency were excluded. Multivariate analysis was performed to examine correlations and control for confounding factors.
Results: As suggested threshold (≤25 ng/ml), the overall prevalence of vitamin D insufficiency was 265 of 280 (94.8%). Mean serum vitamin D insufficiency levels of 11.15±4.74 ng/ml for RA patients were significantly lower compared to controls (31.62±6.46) (p=0.001). Among all the subjects, 208 (72.7%) were females. Vitamin D levels in high disease activity group were lower compared to vitamin D level in patients with low and moderate disease activity (DAS-28 score >5.1, 3.2–5.1, <3.2, respectively, p<0.001) and vitamin D levels had an inverse correlation with DAS28 score (β-coefficient-0.164, p=0.018, per 1 ng/ml). In patients with RA, the levels of vitamin D were moderately and inversely associated with Th 17 (β-coefficient-0.158, p=0.019, per 1 ng/ml). However, no significant relationship was found between vitamin D and these variables (T cell, B cell, NK cell, Treg, Th1, Th2, Th17/Treg) in patients.
Conclusions: Lower levels of vitamin D are associated with worse DAS28 and higher levels of Th17 with RA, especially in female patients. The levels of 1,25-dihydroxycholecalciferol (1,25$(OH)_2D_3$) could be a marker to monitor the disease activity in RA patients and vitamin D may be an alternative supplementary treatment for RA.

AB0441 USING OF SUBCUTANEOUS METHOTREXATE IN AGED PATIENTS WITH SEROPOSITIVE RA

Y. Muraviev, G. Gridneva, E. Luchikhina, N. Demidova, V. Lebedeva, D. Karateev. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Background: Increasing life expectancy is a global process involving multiple nations, thus deeper insights into methotrexate (MTX) therapeutic potential in aged people is of paramount importance, as MTX still remains an anchor DMARD in RA management.
Objectives: To assess the results of 12-months therapy with subcutaneous MTX (SC MTX) injections in RA patients aged more than 60 years.
Methods: The 12 months open study included pts with active RA (DAS28 >3,2), meeting ACR/EULAR (or ACR 1987) criteria, with RA lasting up to 3 years, and naïve to SC MTX. All pts were RF and/or ACPA-positive, 68% had increased BMI, 31% - obesity, 8% were smokers, 25% were taking oral GCS (≤10 mg/day equivalent to *prednisolone*).All pts were administered SC MTX monotherapy once a week as a DMARD, starting at 10–15 mg/week, with subsequent 5 mg up-titration each 1–2 weeks (to max 30 mg/week) up to achieving the target (remission or minimum disease activity) or up to emergence of an adverse drug reaction (ADR). Folic acid (min 5 mg/week) was administered at any day(s) except for the day of SC MTX injection for ADR prophylaxis. Disease activity was scored using DAS28. GEBA were administered in pts with insufficient SC MTX clinical effect. Pts were monitored within universal institutional REMARKA program, envisaging physical examination, blood analysis and biochemistry panel (including liver enzymes and creatinine). STATISTICA 10 software was used for data processing.
Results: 32 RA pts (28 females, 4 males) were included (mean disease duration 12±10 months, mean age - 65,7±4,7 years, mean DAS28 score -5,6±0,9. Cumulative SCMT dose by the end of the study reached 264±180 mg). The therapeutic target (remission or minimum disease activity based on DAS28 score) was achieved in 20 pts receiving SCMT monotherpay, 12 pts required administration of GEBAs. Adverse drug reactions (ADRs) were documented in 10 pts, including cases of more than one ADR at a time: breast abscess (1), alopecia (2), diarrhea (2), skin rash (1), a metallic aftertaste (1), local post-injection reactions (1), nausea (2), elevation of liver enzymes (3), leucopenia (1), pneumonia (1). There were 5 cases of SC MTX monotherpay discontinuation (2 - temporary, and 3 - permanent). The majority of pts (88%) could manage self-injection without additional training or assistance from medical staff.
Conclusions: 62,5% of aged RA pts participating in the study managed to achieve the therapeutic target after 12 months of SC MT monotherapy, although 31% ADRs rate required temporary (2)/permanent (3) SCMT discontinuation.

SLE, Sjögren's and APS - treatment

AB0442 REAL-LIFE EXPERIENCE WITH BELIMUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): CONTROL OF DISEASE ACTIVITY AND FLARES IN A MULTICENTER COHORT

A. Fanouriakis[1], C. Adamichou[2], S. Koutsoviti[3], A. Klagou[4], C. Tsalapaki[5], S. Konsta[6], D. Dimopoulou[7], S. Ntali[8], D. Vassilopoulos[5], P. Konstantopoulou[9], A. Elezoglou[3], P. Sidiropoulos[2], A. Erden[10], G. Bertsias[2], D. Boumpas[1]. *[1]Rheumatology and Clinical Immunology, "Attikon" University Hospital, Athens; [2]Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Heraklion; [3]Dept of Rheumatology, "Asklipieion" General Hospital; [4]Dept of Rheumatology, "G. Gennimatas" General Hospital; [5]2nd Dept of Internal Medicine, "Ippokrateion" General Hospital; [6]Dept of Rheumatology, "Evangelismos" General Hospital, Athens; [7]Dept of Rheumatology, "Ippokrateion" General Hospital; [8]Private rheumatologist, Thessaloniki; [9]Dept. of Rheumatology, "G. Gennimatas" General Hospital, Athens, Greece; [10]Dept. of Rheumatology, Hacettepe University, Faculty of Medicine, Ankara, Turkey*

Background: Data on the efficacy of belimumab in SLE mainly originate from large randomized clinical trials, whereas reports from real-life clinical practice are lacking.
Objectives: To describe the clinical experience from the use of belimumab in Greece since the approval of the drug.
Methods: Multicentre observational study of patients receiving belimumab, with documentation of disease activity (SLEDAI-2K index), achievement of low disease

activity states [remission (SLEDAI-2K=0) and lupus low disease activity state (LLDAS)], accrual of irreversible damage (SLICC damage index, SDI), number and severity of flares, and side-effects. Analyses were performed at quarterly intervals and only patients with at least 3 months of follow-up were included in the study.

Results: A total of 56 patients were included [53 women (94.6%), mean (SD) age 46.3 (12.7) years]. Evidence of serologic activity (low C3/C4 and/or high anti-ds DNA) was evident in 30 patients (53.5%). Most frequent manifestations were arthritis (82.1%), inflammatory rash (73.2%), active hair loss (57.1%), mucosal ulcers (26.8%) and leukopenia (10.7%).

Median (range) duration of follow-up was 9.1 (2.9 - 34.6) months. We observed a significant decrease in the SLEDAI-2K, physician global assessment (PGA) and daily prednisone dose over time, starting as early as 3 months after belimumab initiation (Table 1). This effect was significantly more pronounced in patients who were serologically active (SA) at baseline, even after exclusion of the serologic component of the SLEDAI [median (range) *clinical* SLEDAI-2K for SA patients: 7 (1–24) at baseline vs. 2 (0–16) at 6 months and 2 (0–16) at 12 months, $p<0.0001$ and p=0.013, respectively; for serologically inactive patients: 6 (2–23) at baseline vs. 6 (0–14) at 6 months and 5 (0–18) at 12 months, p=0.017 and p=0.024, respectively]. For patients with $\geq$12 months of follow-up (n=20), belimumab treatment resulted in a significant decrease in flare rate [median (range) total number of flares for the 12 months before and after belimumab treatment, 3 (0–7) and 0 (0–2), respectively, $p<0.0001$). 10 patients (17.8%) discontinued belimumab due to inefficacy after a median (range) 7.1 (5.5 - 20.4) months of therapy and 5 patients discontinued due to planned pregnancy. There were no drug discontinuations due to side-effects.

Table 1. Changes in disease activity and daily prednisone dose during treatment with belimumab

	Baseline (reference) n=56	3 months n=56	6 months n=47	9 months n=26	12 months n=22	18 months n=10	p value
SLEDAI, median (range)	8 (2-28)	6 (0-24)*	4 (0-20)*	4 (0-18)*	4 (0-18)*	3 (0-14)**	*p<0.001 **p=0.01
	Baseline (reference)	3 months	6 months	9 months	12 months	18 months	p value
PGA, median (range)	1.9 (1-3)	1.5 (0.3-3)*	1.5 (0.5-3)*	1.5 (0-2.2)*	1.15 (0-3)*	1 (0-2)***	*p<0.001 **p=0.18 ***p=0.01
	Baseline (reference)	3 months	6 months	9 months	12 months	18 months	p value
Pr dose, median (range)	7.5 (0-40)	7.5 (0-30)*	5 (0-25)*	5 (0-10)*	5 (0-30)**	4.3 (0-7.5)***	*p<0.001 **p=0.001 ***p=0.021
Low disease activity states, n(%)	Baseline	3 months	6 months	9 months	12 months	18 months	
LLDAS	0 (0)	10 (17.9)	15 (31.9)	10 (34.5)	5 (21.7)	4 (40)	
Remission	0 (0)	3 (5.4)	4 (7.1)	3 (5.4)	4 (7.1)	2 (3.6)	

Conclusions: In real-life clinical settings, belimumab is efficacious in controlling disease activity of SLE and permitting tapering of glucocorticoid dose. Similar to data from RCTs, this effect seems to be more pronounced in serologically active patients.

AB0443 INFUSION REACTIONS TO RITUXIMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE ANALYSIS

A. Hennessey[1,2], J. Lukawska[3], G. Cambridge[1], D. Isenberg[1,2], M. Leandro[1,2]. *[1]Centre for Rheumatology and Bloomsbury Rheumatology Unit, University College London; [2]Division of Rheumatology, Department of Medicine; [3]Allergy Medicine, University College London Hospitals, London, United Kingdom*

Background: B-cell depletion with Rituximab (RTX) has been used since since 2000 in the treatment of Systemic Lupus Erythematosus (SLE). An issue with the use of RTX is the attrition rate due reactions during of following infusions. This can prevent re-treatment with RTX in patients with a good initial response to RTX and in whom other treatments had failed, this is especially important in SLE patients with limited biologic options.

Objectives: To identify the rates and patient characteristics of infusion reactions to RTX in patients with SLE.

Methods: A retrospective analysis of the SLE patient cohort receiving RTX at University College London Hospitals via examination of patient records was used to determine if there was a clinically significant reaction (from clinic letters or discharge summary) for each RTX infusion. One cycle of RTX refers to 2 infusions given 2 weeks apart. A descriptive analysis of the reaction was recorded as was the decision making surrounding the infusions.

Results: Records from 151 RTX-treated patients were reviewed with 13 excluded due to missing data. 138 remaining patients (130 females and 8 males, mean age (1st infusion) =33 years; range: 16–73) received a total of 478 individual RTX infusions (between 1–9 cycles). Prior to 2007, standard of care was to receive Cyclophosphamide (CYC) with each cycle. The total rate of infusion reactions was 5.85% (23 patients had 28 reactions). Of these 4 (50%) were males, 19 females (14.6%; *p*=0.009, Chi square). Average number of cycles in those without, compared to with a reaction was 1.61 vs 1.64. With 1st dose, 7 patients (25%) had reactions, 19 with 2nd (67.9%). 3 patients were retreated (1 twice); 2/3 had further reactions and the 3rd two further cycles without issues. Most were not retreated. Reactions ranged from mild to severe (Table 1). A total of 24 RTX reactions were categorized into: Immediate- unlikely immune mediated 4; likely cytokine release 7; IgE mediated 5; and bone pain reactions 2. Delayed-early (24–48hours) 1; and late (>48hours) 5; by a Clinical Allergist. 4 reactions were excluded from this analysis; 1 death as likely CYC induced (but occurred within 24 hours of RTX) and 3 due to lack of data.

Table 1. Severity of Infusion Reactions

Severity of reaction	Number of patients	% of total infusion reactions	Retreated?
Death	1	3.6%	N
Severe	3	10.7%	Y – 1 (had further reaction)
Moderate	7	25.0%	Y – 1 (2 further cycles)
Mild	8	28.6%	Y – 1 (2 further cycles)
Delayed	5	17.9%	Y – 1 (1 further cycle)
Unclassified	4	14.3%	N

Mild (infusion resumed/completed), Moderate (had to cease infusion reaction), Severe (hospital admission), Delayed/serum sickness.

Conclusions: The number of previous cycles was similar in patients who reacted versus those who did not. Patients were most likely to experience a clinically significant reaction with the second infusion. Males had higher incidence of reactions. Most (19%) were immediate and the majority (79%) of immediate and delayed reactions occurred during 1st (10) and 2nd (9) cycles. The total rate of infusion reactions in this cohort was lower than previously reported however this is likely contributed to by the limitations of a retrospective review. However 64% of reactions (11/17) in this cohort were significant, necessitating cessation of infusion or hospital admission.

AB0444 EFFECT OF RITUXIMAB ON A SALIVARY GLAND ULTRASOUND SCORE IN PRIMARY SJÖGREN'S SYNDROME: RESULTS OF THE TRACTISS MULTICENTRE RANDOMISED TRIAL SUB-STUDY

B.A. Fisher[1], C.C. Everett[2], J. Rout[3], J.L. O'Dywer[4], P. Emery[5], C. Pitzalis[6], W.-F. Ng[7], A. Carr[8], C.T. Pease[5], E.J. Price[9], N. Sutcliffe[10], J. Makdissi[10], N.S. Gendi[11], F.C. Hall[12], S.P. Ruddock[2], C. Fernandez[2], C.T. Hulme[4], K.A. Davies[13], C.J. Edwards[14], P.C. Lanyon[15], R.J. Moots[16], E. Roussou[17], L.D. Sharples[18], M. Bombardieri[6], S.J. Bowman[1]. *[1]Rheumatology, University of Birmingham, Birmingham; [2]Leeds Institute for Clinical Trials Research, Leeds; [3]Dental Hospital, Birmingham; [4]Health Economics; [5]LMBRU, University of Leeds, Leeds; [6]Barts and the London School of Medicine, London; [7]Musculoskeletal Research Group, University of Newcastle; [8]Newcastle University, Newcastle; [9]Great Western Hospital, Swindon; [10]Royal London Hospital, London; [11]Basildon and Thurrock University Hospital, Basildon; [12]University of Cambridge, Cambridge; [13]Brighton and Sussex Medical School, Brighton; [14]University Hospital Southampton, Southampton; [15]University of Nottingham, Nottingham; [16]University of Liverpool, Liverpool; [17]BHRUT, Goodmayes; [18]London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: B lymphocytes are important in the pathogenesis of primary Sjögren's syndrome (PSS), but two phase III trials (TEARS and TRACTISS) of the B cell depleting agent rituximab (RTX) failed to show an effect on their primary endpoints in PSS. Whilst RTX may lack efficacy in a non-stratified PSS population, other possible explanations for these negative results include the choice and timing of primary outcome. In a small single-site salivary gland ultrasound (SGUS) substudy in TEARS, more subjects in the RTX arm demonstrated improvement in parotid gland echostructure. Importantly, SGUS is an operator-dependent technique.

Objectives: To compare the effects of RTX versus placebo on SGUS in PSS, in a multicentre, multiobserver substudy of TRACTISS.

Methods: Subjects consenting to SGUS were randomised to 1000mg RTX or placebo given at weeks 0, 2, 24 and 26, and scanned at baseline and weeks 16 and 48. Sonographers completed a 0–11 total ultrasound score (TUS) comprising domains of echogenicity, homogeneity, glandular definition, glands involved, and size of hypoechoic foci. Baseline-adjusted values of TUS were analysed over time, modelling change from baseline at each time point. For each TUS domain we fitted a repeated measures logistic regression model to model the odds of a response in the RTX arm (defined as a 1 point improvement) as a function of the baseline score, age category, disease duration and time point.

Results: 66 patients (49.6% of the total study population) consented to SGUS, and 52 (39.1%; n=26 RTX and n=26 placebo) completed the baseline and at least one follow-up visit. Estimated baseline-adjusted TUS at week 16 was 6.2 (95% CI 5.4–7.0) for placebo and 5.0 (95% CI 4.4–5.6) for RTX, and at week 48, 6.1 (95% CI 5.5–6.6) and 4.8 (95% CI 4.2–5.4) respectively. Estimated between group differences (RTX-placebo) in baseline adjusted TUS were -1.2 (95% CI -2.1 to -0.3; p=0.0099) and -1.2 (95% CI -2.0 to –0.5; p=0.0023) at weeks 16 and 48. Glandular definition was the only domain to show statistically significant improvement with an OR of 6.8 (95% CI 1.1–43.0; p=0.043) at week 16 and 10.3 (95% CI 1.0–105.9; p=0.050) at week 48. Improvement of $\geq$1 point in TUS was associated with improvement in oral dryness VAS at week 16 (diff=15.9; CI 1.5 to 30.3; p=0.030) but not week 48 in the RTX arm.

Conclusions: TUS differed between study arms, favouring RTX. This encourages further research into SGUS as an imaging biomarker in PSS clinical trials.

AB0445 HYDROXYCHLOROQUINE'S IMPACT IN RENAL BIOPSY AND OUTCOMES OF LUPUS NEPHRITIS

D. Navarro, A.C. Ferreira, H. Viana, F. Carvalho, F. Nolasco. *Nephrology Department, Hospital Curry Cabral, Lisboa, Portugal*

Background: Given its immunomodulatory effects, hydroxychloroquine use is recommended in systemic lupus erythematosus (SLE). It is associated with a lower rate of appearance and of relapse of lupus nephritis (LN). LN is classically classified using ISN/RPS classification, but others indexes, such as the ones described by Austin and Hill, allow for the quantification of SLE activity in the kidney tissue.
Objectives: To analyze the association between the use of hydroxychloroquine and the activity of LN in the kidney biopsy.
Methods: Retrospective single center study of consecutive SLE and biopsy proven LN patients, diagnosed from 2010 to 2016. We evaluated the following outcomes: clinical remission, renal function and proteinuria at end of follow-up (g/24h). Complete remission was defined as a reduction of proteinuria to <0,5g/24h, inactive urinary sediment and serum creatinine <115% of baseline; partial remission same parameters, except proteinuria <1g/24h if initial value <3h/24h, or reduction to <3g/24h if initial value >3g/24h. Kidney biopsies were evaluated by the INS/RPS LN classification and the morphological indexes described by Austin and Hill, obtained after histomorphological review of renal biopsies. The studied predictor was the use of hydroxychloroquine. Statistical analysis was performed with STATA software, using one-way ANOVA, Qui2 and Pearson/Sperman test were appropriate.
Results: During 6 years, there were 46 biopsy-proven LN cases, 84,8% (n=39) woman, median 35 years old (27–42,5) and 57,6% (n=19) caucasian. 39 patients were already known to have SLE, 7,44 (1,13–12,3) years previously. Of those 39 patients, 46% were under hydroxychloroquine and 77% under other immunosuppression.
The median follow-up was 31,9 (13,2–45,6) months. Based on biopsy findings, 35 patients were started on immunosuppression – induction in 50% of cases with MMF and in 50% with cyclophosphamide; maintenance in 81% with MMF, the rest with azathioprine. Complete remission was achieved in 58% of patients, 27% achieving partial remission. We observed 4 LN relapses. At the end of FUP, we saw a 96% (n=44) patient survival, with a median serum creatinine of 0,8 mg/dl (0,7–0,99), eGFR 99,8 ml/min (71,2–116,8) and proteinuria of 0,6 g/24h (0,2–1,6). From those 46 patients, 30 were under immunosuppressive therapy at time of LN presentation, and 60% (n=18) were also under hydroxychloroquine. Table 1 summarizes the clinical findings:
With the use of hydroxychloroquine, we observed a lower histomorphological activity, as represented by a lower Hill biopsy index, and tendency towards lower Activity index. We also saw a tendency towards lower proteinuria.
Conclusions: Our data reinforces the recommendations of using hydroxychloroquine for its adjuvant role in SLE patients, as we saw a lower histomorphological activity in kidney biopsy, and a trend towards lower proteinuria.

AB0446 ADDITIVE INHIBITION OF INTERFERONS, B AND T CELL ACTIVATION AND TFH-RELATED CYTOKINE CXCL13 BY LEFLUNOMIDE AND HYDROXYCHLOROQUINE SUPPORTS RATIONALE FOR COMBINATION THERAPY IN PSS PATIENTS

E.H. van der Heijden[1,2], S.A. Hartgring[1,2], A.A. Kruize[2], T.R. Radstake[1,2], J.A. van Roon[1,2]. *[1]Laboratory of Translational Immunology; [2]Dept. of Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: T and B cell-driven immunity is critically involved in immunopathology of pSS. Recently we demonstrated synergistic T and B-cell activation upon T cell triggering and TLR7/9-driven B cell activation in pSS patients, accompanied by synergistic induction of immunoglobulins and IFN-γ- and IL-17-producing T cells[1]. In addition, TLR7/9-expressing activated pDCs associated with increased type I IFNs and IFN-inducible genes are increased pSS patients. Several studies have shown that the DMARDs leflunomide and hydroxycholoroquine inhibit immune activation in pSS but only show moderate efficacy. However, LEF and HCQ target different pathways with overlapping, but also potentially additive mechanisms, where LEF primarily targets T and B cells and HCQ TLR7/9-driven B cell and pDC activation.
Objectives: To assess the additive effects of LEF and HCQ on CD4 T- and B-cell activation and production of interferons IFN-α and IFN-γ, Tfh-related cytokine CXCL13, as well as IgG and IgM *in vitro* employing SEB/TLR9-triggered PBMC.
Methods: PBMCs of healthy individuals (n=9) and of pSS patients (n=8) were cultured with antigen (SEB), TLR9 and their combination, in presence or absence of LEF, HCQ and their combination in clinical relevant concentrations. Proliferation of T and B cells and release of IFN-α, IFN-γ, CXCL13, IgG and IgM were measured.
Results: In line with robust T and B cell activation, IFN-γ, IFNα, CXCL13, IgG and IgM production was achieved by a combination of SEB and TLR9 (all at least $p<0.001$). LEF dose dependently inhibited B and T cell proliferation, Interferon, CXCL13 and immunoglobulin production. HCQ dose dependently inhibited B cell proliferation, IFN-α, CXCL13, and immunoglobulin production. T cell proliferation and IFN-γ production were inhibited by HCQ only at higher concentrations. At several suboptimal concentrations LEF and HCQ additively inhibited T cell proliferation both in healthy individuals and in pSS patients. (Figure 1). Significant additive effects were seen for all outcome measures except IFN-α. Since IFNa was already robustly inhibited by HCQ alone (eg.for pSS 90% at 3.3 μM, $p<0.001$), only trends towards additive effects were observed.

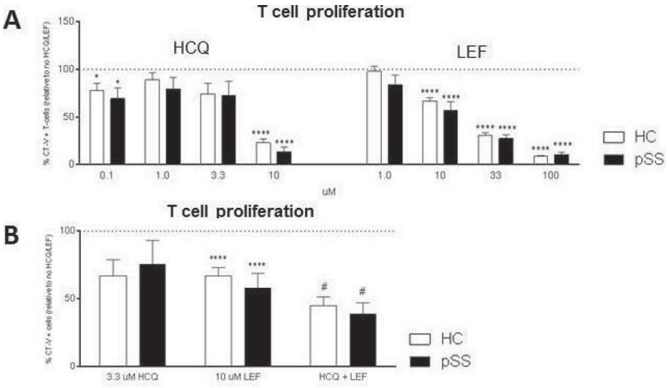

Figure 1. HCQ and LEF additively inhibit T cell activation. T cell proliferation is dose dependently inhibited by LEF and by HCQ at 0.1 and 10 μM **(A).** Significant additive inhibition of T cell proliferation is achieved by combination of suboptimal concentrations of LEF and HCQ both in HC and pSS patients **(B).** *and **** indicates statistical significance of p<0.05 and p<0.0001 resp. vs control, # indicates statistical significance of p<0.05 of the combination vs each of the single drugs.

Conclusions: LEF and HCQ robustly inhibited proliferation of T and B cells, cytokine production and immunoglobulin production with clear additive efficacy in both healthy individuals as in pSS patients. These data support the potential surplus value of combination therapy with LEF and HCQ for patients with pSS.

Background: Nowadays the importance of antimalarials, especially hydroxychloroquine (HCQ) and chloroquine (CQ), in treatment of systemic lupus erythematosus (SLE) has been demonstrated. However, few have examined the efficacy of HCQ and CQ on eastern Chinese SLE patients.
Methods: The analysis is based on 1372 patients who were enrolled in a retrospective study of 26 centers from January 1st, 1999 through December 31st, 2009, during which time is their first hospitalization. Baseline and follow-up clinical, laboratory and therapeutic data and survival status before April 30th, 2015 were recorded. Statistical analysis consist of Chi-square test, *t*-test, Kaplan-Meier curves and logrank test.
Results: Compared with 562 patients without HCQ or CQ treatment, the hazard ratio (HR) of deaths in 810 patients taking those was reduced (HR 0.52, 95% CI 0.38–0.70, $p<0.001$). 376 of these 1372 patients experienced their second hospitalization, during which treating group (165 of 376) showed lower blood level of total cholesterol (TG), compared to control group (4.47 (0.13) vs 5.03 (0.21), p=0.027), while no statistical difference of TG exists between the two groups' first hospitalization ($p>0.05$). Other metabolic data, such as systolic and diastolic blood pressure, fasting blood sugar, Triglyceride and uric acid were similar between the two groups in two times of hospitalization. On second inpatient visit, disease activity (SLEDAI, blood sedimentation rate, complement) and organ involvements (SLICC) of those who took antimalarials and no users have no significant differences.

Conclusions: Use of HCQ or CQ lower the risk of mortality and TG levels of eastern Chinese SLE patients.

AB0448 USE OF DENOSUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A REAL LIFE MULTI-CENTRIC EXPERIENCE

F. Crisafulli[1], M. Fredi[2], A. Bortoluzzi[3], I. Cavazzana[2], F. Furini[3], M. Govoni[3], A. Tincani[1], F. Franceschini[2]. *[1]Rheumatology Unit and University of Brescia; [2]Rheumatology Unit, Brescia; [3]Department of Medical Sciences, Rheumatology Unit and University of Ferrara, Ferrara, Italy*

Background: The occurrence of osteoporosis (OP) and fragility fractures (FF) is a frequent comorbidity in patients with systemic lupus erythematosus (SLE), mainly due to the concomitant presence of many risks factors for secondary osteoporosis (drugs, gender, concomitant diseases). The use of corticosteroids (CS) increases the risk of osteoporosis induced by corticosteroid (GIOP) and FF [1]. Denosumab is monoclonal antibody that binds to RANKL, inhibiting osteoclast formation and activation, used for both male and women OP to prevent FFx [2,3]. Previous RCT [2] reported a numerically higher serious adverse events of infections in the denosumab users. In particular severe skin infections were significantly more frequent [4]. The possible increase in infection risk might be a concern in subjects treated with CS. The use of denosumab in SLE with GIOP patients is recently reported in 17 cases within a RCT [5]. Anyway, no data regarding the tolerability and disease activity during therapy were reported
Objectives: Our aim was to analyze the prevalence, the tolerability, and relevant changes in disease activity or damage in a cohort of SLE patients treated with denosumab
Methods: among all SLE patients currently followed in two referral Center we selected the ones that received at least one dose of denosumab. Clinical, serological manifestations, concomitant diseases and therapies were collected from clinical charts. Damage index (SDI), activity index (SLEDAI-2K) were calculated when denosumab was introduced (first cycle) and at the last evaluation (last cycle). For statistical analysis Chi-squared test or Fisher exact test was used
Results: Among 793 patients in our cohorts, 21 (2.6%) were treated with denosumab. Demographic data reported a female prevalence (19 cases,90%), mean age at onset of 38±12years, mean duration of disease of 28±10years and mean follow-up of 21±7.8years; most frequent manifestations were arthritis (90%), cutaneous (67%) and neurological (67%). All patients were still treated with CS (mean duration of 25±6.8 years) with a daily dose of 8.5±3.5mg/day. Other risk factors for OP were present in the majority of them: drugs (anticoagulants in 6pts, cyclosporin in 3 and antiepileptic in 2), chronic kidney disease (CKD) (4pts), hypovitaminosis D (15pts), anorexia, celiac disease and hemochromatosis (1pt, each). Indication for denosumab was OP with FFx in 17 cases: denosumab was used for a new FF during biphosphonates or after teriparatide. In the other 4 the indication was primary prevention with contraindications at the use of biphosphonates for concomitant severe CKD. Mean duration therapy was 4 cycles (range 1–8): data regarding disease activity, damage and adverse events are reported in table 1. No new FFx developed in any of the included patients at the last evaluation available.

Efficacy/adverse events	First cycle (N=21 pts)	Last cycle (N=21 pts)	P value
New fracture	Not applicable	0 (0%)	na
Mean dose of GC, mg/day (mean±DS)	6.9±3.4	5.8±3.1	ns
T score hip*	-2.6±1.4	-2±1	ns
T score lumbar spine *	-2.61±1.1	-2.3±0.8	ns
Hypovitaminosis D **	15 (71%)	13 (62%)	ns
SLEDAI-2k (mean±DS)	3.5±3.3	2.36±2.65	ns
SDI (mean±DS)	4 ±1.18	4.1±1.21	ns
Any adverse event	1	1	ns
Infective episodes	1 (not requiring antibiotic	1 (not requiring antibiotic)	
Skin infection	0	0	ns
Flare SLE	0	1 (arthritis)	ns
Therapy withdrawal	na	0	ns

*available for 18 patients at first cycle and 13 at last evaluation; **=all patients received vitamin D supplementation; na=not applicable; ns=not significant

Conclusions: In our cohorts denosumab is still used in few selected patients. However it could be considered as a valid option in GIOP patients because it was globally well tolerated and in our cohort it's efficacy in the prevention of new fragility fractures was confirmed

AB0449 OFF LABEL OF BIOLOLOGICS IN CONNECTIVE TISSUE DISEASES. A SINGLE CENTER EXPERIENCE

G. Orsolini[1], C. Crowson[2], O. Viapiana[1], M. Rossini[1], K.G. Moder[2]. *[1]Rheumatology, University of Verona, Verona, Italy; [2]Rheumatology, Mayo Clinic, Rochester, United States*

Background: Connective tissue diseases (CTDs) are a broad spectrum of autoimmune conditions including different entities such as systemic sclerosis (SSc), Sjogren syndrome (SSj), systemic lupus erythematosus (SLE) and autoimmune myositis. There are many patients that do not meet the classification or diagnostic criteria and they fall under the diagnosis of Undifferentiated connective tissue disease (UCTD). Treatment of refractory forms of these could be challenging and clinicians sometimes are forced to try off label drugs such as biologics on the basis of scarce literature support and the experience on different rheumatic disease.
Objectives: To evaluate duration of biologic drug administered off label for the treatment of CTD and investigate variables possibly associated to drug suspension.
Methods: We used ACE program to search among Mayo Clinic clinical records all the patients that had in their records the words "undifferentiated connective tissue disease" or "lupus" or "myositis" or "Sjogren" or "systemic sclerosis" or "scleroderma"(and acronyms) AND "infliximab" or "etanercept" or "golimumab" or "certolizumab" or "tocilizumab" or "abatacept" or "adalimumab" (and their brand names).
All records were checked for definite diagnosis and patients with uncertain ones where excluded. Also medications were checked, patients without any information about treatments where excluded. All the records of the selected patients were used to collect information about the off label biologic treatment but also clinical, serological and demographic variables.
Results: We collected data on 122 patients with connective tissue diseases, some of them had other concomitant autoimmune diseases with indication for biologic treatment (e.g. rheumatoid arthritis, etc). We analyze the group with some CTD alone (n=72) considering SLE (n=18 – 25%), inflammatory myositis (n=22 – 31%) and UCTD (n=32 – 44%). In this group the first biologic was etanercept in 55%, adalimumab in 18%, infliximab in 17%, golimumab in 1% and abatacept in 8%. The 22% tried also a second biologic and 4% a third. We consider for analysis the first treatment.
Mean treatment duration was 0.8 (±1.1)years. In our population 12,5% experienced a flare of CTD, 12,5% had infections, 18% had allergic reactions (of any type). The 44% experienced primary failure, 11% loss of efficacy, 31% had minor adverse events, 14% major ones (possible more than one reason for interruption).
Analysis showed no definite factors correlated with treatment duration or failure or adverse events, No difference due to type of CTD.
Conclusions: The study is retrospective and this limits the conclusions to be taken from it, however is one of largest population of off label treatments in CTDs

so far. Due to retrospective data we choose as outcome only treatment duration and adverse events, direct outcomes of efficacy were impossible to evaluate. Our results indicates a poor treatment duration of biologics given off label in CTDs with a relevant prevalence of adverse events and failures. It has to be underlined that our population was mainly on TNF blockers.
These data discourage the use of biologics, mainly of TNF blockers in CTDs, even if they still can be considered with caution in very selected cases after failure of the other on label medications.
Disclosure of Interest: None declared

AB0450 THE DARK SIDE OF GLUCOCORTICOID THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CAN WE DO SOMETHING ABOUT THAT?

I. Saulescu, T. Gudu, A. Neagu, D. Opris, A. Borangiu, S. Daia-Iliescu, L. Groseanu, A. Balanescu, V. Bojinca, R. Ionescu. *Internal Medicine and Rheumatology, Umf Carol Davila, Sf. Maria Hospital, Bucharest, Bucharest, Romania*

Background: Corticosteroids are still one of the main treatment in Systemic Lupus Erythematosus (SLE). Beside the effect on controlling disease activity, they are also implicated in damage accrual. Both patients and physicians are some time afraid to adopt a steroid free regimen when possible.
Objectives: To evaluate the knowledge and perception of patients with SLE upon glucocorticoids.
Methods: 84 patients with SLE were evaluated and data about demographic, clinical, serological characteristics or treatment were collected. Presence of steroids related side effects like hypertension, osteoporosis, cataracts or diabetes mellitus were also assessed. All patients completed a questionnaire in order to evaluate patient's knowledge about steroids. They were asked if they had a discussion with the doctors about corticotherapy and side effects related to them, if they consider that this treatment could be stopped with specialist approval. Statistics was performed with SPSS program.
Results: All patients had treatment with corticosteroids during disease evolution. 57.14% of them experienced at least one steroids related side effect. This patients were significant older: mean age at evaluation 49.50 versus 36.47 ($p<0.0001$), had a longer disease duration: mean SLE duration 9.27 versus 4.69 (p0.016), a higher mean Prednisone equivalent dose: 8.86 versus 4.71 (p 0.031), a higher mean SLICC Damage Index: 1.53 versus 0.44 (p 0.001) than patients without steroids related side effects. This complications were significantly more rare in patients that were on a steroid free regimen at the moment of evaluation versus those on a continuum steroid regimen (7.14% versus 50%, $p<0.0001$).
When patients were asked if they will stop steroids according to medical advice, almost 1/3 of patients - 28.57% - responded "no- to afraid to do that". Patients willingness to adhere to a steroid free regimen in the future according to a physician recommendation was significant more frequent in younger patients (p 0.031, r -0.235), in those with steroids initiated in less than 1 year (p 0.016, r -0.297) and in those with less damage accrual (p 0.017, r-0.267). Flare at the moment of evaluation significantly reduced this possibility, at least from the patient perspective (p0.041, r 0.224). The likelihood of a future steroid free regimen was increased by a previous discussion patient-doctor about steroids (p0.002).
Conclusions: This study clearly shows that an open discussion with our SLE patients about corticosteroids is mandatory from the beginning. Patients should be informed about possibility of a steroid free regimen when disease status permits. This will increase patient willingness to get free of steroids when possible, helping physician to limit the continuum damage accrual of SLE patients.

AB0451 RIVAROXABAN VERSUS WARFARIN AS SECONDARY THROMBOPROPHYLAXIS IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME PROTOCOL: A RANDOMIZED, MULTICENTRE, OPEN-LABEL, CLINICAL TRIAL

J. Cortés-Hernández[1], L. Saez-Comet[2], M. Perez-Conesa[2], A. Riera Mestre[3], A. Castro-Salomo[4], S. Parra[4], J. Cuquet-Pedragosa[5], V. Ortiz-Santamaria[6], M. Mauri-Plana[7], P. Suñe[8], J. Ordi-Ros[9]. *[1]Vall Hebron Institute Research (Vhir), Barcelona; [2]Autoimmune Unit. Internal Medicine Department, Miguel Servet Hospital, Zaragoza; [3]VTE Unit. Internal Medicine Department, Bellvitge University Hospital, Barcelona; [4]Internal Medicine Department, Sant Joan de Reus University Hospital, Reus; [5]Internal Medicine Department; [6]Rheumatology Unit, Granollers University Hospital, Granollers; [7]Internal Medicine Department., Mataró Hospital, Mataró; [8]Pharmacy Department, Vall d'Hebron Hospital; [9]Autoimmune Unit. Internal Medicine Department, Vall Hebron Institute Research (Vhir), Barcelona, Spain*

Background: Long-term anticoagulation is widely used for secondary thromboprophylaxis in the antiphospholipid syndrome (APS) due to the high risk of recurrent events. Currently anticoagulation with vitamin K antagonists (VKAs) is the standard of care but have unpredictable pharmacodynamic properties that requiere monitoring for dose adjustment. Rivaroxaban, an orally active direct factor Xa inhibitor, has been shown to be effective and safe compared with warfarin for the treatment of venous thromboembolism and non valvular atrial fibrillation in major RCTs. No studies had been published in APS.
Objectives: To investigate the efficacy and safety of rivaroxaban in preventing recurrent thrombosis in patients with APS compared with warfarin.
Methods: This is a phase 3 randomized, multicenter, non-inferiority open-label RCT. 190 eligible APS patients with arterial or venous thrombotic history receiving warfarin will be stratified according the presence of SLE and venous/arterial thrombotic history and randomized (1:1) either to continue warfarin (standard of care, normalized ratio (INR) 2–3 or 2.5 to 3.5 in those with recurrent thrombotic episodes) or to switch to rivaroxaban (20 mg/day). The primary efficacy outcome is the development of any thrombotic event during the study period. Secondary efficacy outcomes include time to thrombosis, type of thrombosis (arterial or venous), overall causes of death, evaluation of a prognostic biomarker panel of recurrent thrombosis. The primary safety outcome will be major bleeding. Secondary safety outcomes include any adverse event and minor bleeding. The study has 3 years follow-up. First patient was included in March 2013 (EUDRA-CT:2010–019764–36).
Conclusions: If the study demonstrates a non-inferior anticoagulant effect compared with warfarin, this would provide sufficient supporting evidence to make rivaroxaban a standard of care for the treatment of patients with APS with previous thrombotic history.

AB0452 CASE REPORT OF ALLOGENEIC UNRELATED-DONOR MESENCHYMAL STEM CELLS (MSC) INFUSION IN SJOGREN SYNDROME (SS) WITH REFRACTORY THROMBOCYTOPENIA

J. Qi, M. Qiu, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Intravenous MSC infusion has been reported occasionally in SS treatmen and Immune Thrombocytopenia ttreament. To our knowledge,there is rare report of allogeneic unrelated-donor intravenous MSC infusion in SS with thrombocytopenia without immunosuppresive induction of MSC transplantation.
Objectives: To report the case of a Sjogren syndrome with refractory thrombocytopenia treated with MSC infusion. To review the current literature on intravenous MSC infusion for SS.
Methods: Literature review and multidisciplinary discussion were thoroughly performed before treatment protocol was approved by institutional ethics committee and patient and family signed informed consent form.
Results: A 48 year-old female with a 2-year history of SS, manifested by severe thrombocytopenia (PLT 14–30*10E9/L, after each injection of recombinant human interleukin 11, platelets can be transiently recovered.) refractory to Methylprednisolone, methotrexate, azathioprine and cyclophosphamide received Four infusions (Once a month) of allogeneic unrelated-donor $2x10^6$/Kg MSC. After two infusiong of MSC, the PLT increased gradually to greater than 100*10E9/L. After 1 year of follow-up, Platelet counts remained normal.
Conclusions: These results suggest that mesenchymal stem cells may be a therapeutic strategy for Sjogren syndrome with Refractory thrombocytopenia patients. Larger studies are needed to validate clinical efficacy and safety and to standardize treatment protocol of MSC infusion in SS.

AB0453 OFF-LABEL USE OF MYCOPHENOLATE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN A RHEUMATOLOGY CENTER IN COLOMBIA

K. Mendez[1], D. Buitrago-Garcia[2], P. Santos-Moreno[3], J. Urrego[4]. *[1]Pharmaceutical chemist; [2]Epidemiology; [3]Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota; [4]Pharmaceutical chemist, UDCA University, Bogota, Colombia*

Background: Immunosuppressants such as mycophenolate are widely used in people with systemic lupus erythematosus (SLE), but not all are specifically licensed by FDA, EMA (1) and in the case of Colombia the Regulatory Agency for Food and Drugs (INVIMA) has not approved it for this indication, only for the

prevention of the rejection of some transplants. Mycophenolate mofetil was found to be associated with a lower risk of toxic adverse events such as ovarian failure, alopecia and leucopenia, compared with cyclophosphamide (1).
Objectives: To describe the population of patients with SLE receiving mycophenolate during a five year period.
Methods: We conducted a retrospective observational study, extracting information from a database in our rheumatic diseases center; we reviewed the clinical record of each patient with diagnosis of SLE and receiving mycophenolate. Descriptive epidemiology was performed for each variable presented.
Results: 1989 patients were diagnosed with Systemic Lupus Erythematosus (SLE) during 2011 and 2016 and 287 were receiving mycophenolate. Regarding demographic characteristics 94% were woman and 6% men, mean age was 49 years ± 15. 41% of patients were employed, 40% were housekeepers, 11% students and 8% retired. The indication for mycophenolate was mainly for lupus nephritis 62%, SLE in overlapping with systemic sclerosis 30% and only for SLE in 8% of cases. 36% of patients received a daily dose of 2000 mg, 30% 1500 mg, 20% 1000 mg, 8% 3000 mg, 3.5% 4000 mg and 1.5% 6000 mg and 1% 500mg. The mean value for 24 hour urine protein was 792 mg/dl ± 140 and for creatinine was 0.84 mg/dl ± 0.36. In our population patients were taking mycophenolate during a median of 24 months with a minimum of 6 and a maximum of 132. In combination with mycophenolate 28% of the patients were taking corticoids, 21% hydroxichloroquine, 20% chloroquine, 17% antihypertensive drugs, 7% other medications and only 4% were taking the mycophenolate alone.
Conclusions: Despite of the absence of a license for mycophenolate for the management of Systemic Lupus Erythematosus, the use off-label of this drug continues to be frequently as an alternative and effective treatment in patients with lupus nephritis and other conditions associated to SLE.

AB0454 CLINICAL AND IMMUNOLOGICAL ACTIVITY IN POLISH COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH GLUCOCORTICOIDS

K. Pawlak-Bus, P. Leszczynski. *Department of Rheumatology and Rehabilitation, University of Medical Sciences, Poznan, Poland*

Background: Nowadays the lupus treatment strategy is based on background therapy, immunosuppressive drugs and glucocorticoids (GC). Using minimal effective dose of GC only in flares is a recomandation for preventing complications which increase mortality.
Objectives: To evaluate SLE clinical and immunological activity in lupus patients during the standard clinical care and analyze GC treatment
Methods: We observed Polish cohort of patients with SLE 127 patients (118 female and 9 male) with average age 43±6 years, average disease duration 7,8±5,6 years. All of them were treated with oral and pulse GC and standard immunosuppressive therapies (CTX, MMF, AZT,MTX, CsA). As a background therapy 77% of these patients were on chloroquine or hydroksychloroquine. All patients were assessed according to Systemic Lupus Erythematosus Disease Activity Index assessed by SLEDAI (version 2000) and divided into 5 groups: no GC, low dose, medium dose, high dose and puls GC therapy group. Immunological activity was assessed by anti-dsDNA and C3 and C4 complements levels.
Results: In analyzed group 28 of patients wihout GC the average SLEDAI score was 7 and 50% of this pts not revealed any immunological activity. Low dose of GC was used in 50 pts with average SLEDAI score 13 and in 24 pts of this group anti-dsDNA and C3 or C4 levels upper limit were not observed. Medium dose of GC was used in 20 pts with average SLEDAI score 19 and it was contained with high immunological activity in 55% (n=11) of pts. In 27 of pts, high doses of GC including puls therapy were needed, the average SLEDAI score was very high 30 and most of pts from this group 70% were immunologicaly active.
Conclusions: In this Polish cohort lupus patients GC doses depended on lupus activity. Minimazing glucocorticoid exposure is an important part of appropriate management of lupus patients. Proper assessment of clinical and immunolgical lupus activity is critically for treatment decisions, especially for long-term GC use.

AB0455 SURVIVAL OF PREDNISONE-FREE REMISSION IN SLE PATIENTS WITH SEROLOGICALLY ACTIVE CLINICAL QUIESCENT DISEASE

L. Nalotto, F. Ometto, M. Zen, L. Iaccarino, M. Gatto, M. Larosa, A. Doria. *Department of Medicine, Rheumatology Unit, University of Padova (Italy), Padova, Italy*

Objectives: To evaluate survival of prednisone (PDN) – free remission in systemic lupus erythematosus (SLE) patients and to investigate the potential predictors of disease flares.
Methods: Inclusion criteria were: (1) Diagnosis of SLE according to American College of Rheumatology (ACR) Classification Criteria of SLE; (2) Caucasian ethnicity; (3) Clinical remission (clinical SLEDAI-2K=0) at the time of PDN-withdrawal; (4) Stop of PDN treatment between 2010 and 2016; (5) At least two visits per year between January 2010 and April 2016.
Disease activity was assessed according to SLE Disease Activity Index-2000 (SLEDAI-2K). Damage was measured by the SLICC/American College of Rheumatology Damage Index (SDI). Flares were defined according to Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI criteria.
We evaluated whether gender, age, age at PDN-stop, disease duration, duration of corticosteroid therapy, duration of remission before PDN withdrawal, time to flare, SLICC/American College of Rheumatology Damage Index (SDI) – score >3, positive anti-dsDNA antibodies (abs) and-or low C3/C4, type of SLE-involvement and concomitant immunosuppressive treatment could be predictors of flare. Multivariate logistic regression analysis was run to investigate the predictors of flare. Covariates included in the analysis were all variables reaching $p<0.20$ in the univariate analyses.
Results: Among 400 patients evaluated, 104 (26%) fulfilled inclusion criteria. Baseline characteristics are reported in table 1. Twenty-two (21.2%) patients flared. Mean time to flare was 19.91±13.14 months. Types of flare were 7 renal, 7 articular, 4 cutaneous, 2 haematological, 1 serositic and 1 neurological. Variables included in the multivariate logistic regression analysis were: positive anti-dsDNA abs and-or low C3/C4, skin, articular and haematological involvement. Skin involvement resulted predictive of flare (OR 3.07, 95% CI 1.11–8.53, P 0.031) as reported in table 2.

Demographic and clinical variables in all patients and according to survival of prednisone-free remission

	All patients	Patients maintaining PDN-free remission	Patients who flared	p Value
Patients, N	104	82	22	-
Female, N (%)	91 (87.5%)	69 (84.1%)	22(100.0%)	0.046
Age in 2016, years, mean±SD	41.25±10.95	41.46±11.13	40.45±10.46	0.723
Age at PDN-stop, years, mean±SD	39.08±11.2	39.32±11.27	38.18±10.68	0.644
Disease duration, months, mean±SD	188.54±101.57	187.61±97.96	192.0±116.52	0.817
Duration of corticosteroid therapy, months, mean±SD	131.77±89.74	128.34±88.3	140.73±96.16	0.607
Duration of remission before PDN-withdrawal, months, mean±SD	36.80±33.01	38.24±34.95	31.91±23.51	0.765
Time to flare, months, mean±SD	-	-	19.91±13.14	-
SDI >3, N (%)	10 (9.6%)	8 (9.8%)	2 (9.1%)	0.925
Positive anti-ds-DNA abs and-or low C3/C4, N (%)	89 (85.6%)	68 (82.9%)	21 (95.5%)	0.138
Skin rashes, N (%)	35 (37.7%)	22 (26.8%)	13 (59.1)	0.004
Arthritis, N (%)	69 (66.3%)	51 (62.2%)	18 (81.8%)	0.084
Serositis, N (%)	16 (15.4%)	13 (15.9%)	3 (13.6%)	0.798
Glomerulonephritis, N (%)	65 (62.5%)	53 (64.6%)	12 (54.5%)	0.385
Neuropsychiatric manifestations, N (%)	10 (9.6%)	8 (9.8%)	2 (9.1%)	0.925
Vasculitis, N (%)	6 (5.8%)	4 (4.9%)	2 (9.1%)	0.452
Haematological involvement, N (%)	25 (24.0%)	17 (20.7%)	8 (36.4%)	0.128
Concomitant immunosuppressive treatment, N (%)	41 (39.4%)	32 (39.0%)	9 (40.9%)	0.872

PDN: prednisone; SD: standard deviation; SDI: SLICC/American College of Rheumatology Damage Index

Risk of flare in prednisone-free remission. Logistic regression analysis

	OR (95% C.I.)	p Value
Skin involvement	3.07 (1.11;8.53)	0.031
Articular involvement	2.75 (0.80;9.44)	0.106
Haematological involvement	1.89 (0.62;5.73)	0.261
Positive anti-ds-DNA abs and-or low C3/C4	3.17 (0.37;27.05)	0.292

OR: Odds Ratio; C.I.: Confidence Interval

Conclusions: In SLE patients who stopped corticosteroid therapy, previous skin involvement resulted to be a predictor of disease flare.
Disclosure of Interest: None declared

AB0456 SAFETY AND RETENTION RATE OF BELIMUMAB: DATA FROM A MULTICENTRIC ITALIAN STUDY

L. Iaccarino[1], M. Larosa[1], L. Andreoli[2], E. Bartoloni-Bocci[3], A. Bortoluzzi[4], F. Ceccarelli[5], F. Conti[5], R. De Angelis[6], G. De Marchi[7], S. De Vita[7], A. Di Matteo[6], G. Emmi[8], L. Emmi[8], R. Gerli[3], M. Gerosa[9], M. Govoni[4], M. Mosca[10], P.L. Meroni[9], G. Pazzola[11], R. Reggia[2], C. Salvarani[11], C. Tani[10], M. Zen[1], A. Tincani[2], A. Doria[1]. *[1]University of Padova, PADOVA; [2]University of Brescia, BRESCIA; [3]University of Perugia, PERUGIA; [4]University of Ferrara, FERRARA; [5]University la Sapienza, ROMA; [6]University of Ancona, ANCONA; [7]University of Udine, UDINE; [8]University of Firenze, Firenze; [9]University of Milano, MILANO; [10]University of Pisa, PISA; [11]University of Reggio Emilia, Reggio Emilia, Italy*

Background: Belimumab is used in the treatment of systemic lupus erithematosus (SLE), but few data on its safety in daily clinical practice are available to date.
Objectives: To investigate safety, retention rate (RR), reasons and predictors of belimumab discontinuation in a prospective multicentric Italian study.
Methods: A total of 188 active SLE patients refractory to standard therapy were treated with belimumab as add-on-therapy in 11 Italian centers. Adverse events (AEs) were defined as “any untoward medical occurrence in a patient

treated with a pharmaceutical product which does not necessarily have a causal relationship with this treatment". AEs were subdivided in non-infectious, infectious, infusion and hypersensitivity reactions. Infusion and hypersensitivity reactions were defined as transient AEs related to belimumab occurring within 6 hours and 6–48 hours after drug administration, respectively. AEs was defined as severe (SAE) in case of hospitalization and/or death and/or life-threatening manifestations. Infections were considered severe in case of hospitalization and/or intravenous antibiotic use and/or death. Infusion and hypersensitivity reactions were considered severe when intensive care unit support was required. As baseline predictors of discontinuation the following variables were analyzed: gender, age, age at SLE onset, disease duration, disease activity pattern (relapsing remitting or chronic active), SLEDAI-2K $\geq$10, prednisone $>$7.5 mg/day, concomitant immunosuppressant, antimalarial drug use, number and type of comorbidities, number of previous organ involvement, type of major involvement and number of flares in the 12 months before belimumab initiation. Data were analyzed using the SPSS (version 23.0, Chicago, IL) software.

Results: A total of 453 EAs were recorded in 132 patients after a mean follow-up period of 17.5±10.6 months (range 3–36): 443 (97.8%) were non severe and 10 (2.2%) SAEs (Table 1). No deaths and severe infusion/hypersensitivity reactions occurred. Belimumab discontinuation was observed in 58 patients (30.8%) after 10.4±7.5 months of follow-up (Table 2). RR was 91.5% at 6 months, 81.4% at 12 months, 72.9% at 18 months, 72.4% at 24 months, 69.7% at 30 months and 69.2% at 36 months. No associations were found between baseline variables and drug discontinuation.

Table 1. AEs observed in 188 patients with refractory SLE treated with belimumab

	Pts with AEs (N)	Pts with AEs (%)	AEs (N)	AEs (%
Non severe AEs	*129*	*68.6*	*443*	*97.8*
Infectious AEs	101	53.7	273	60.3
Non infectious AEs	57	30.3	84	18.5
Hypersensitivity reactions	26	13.8	81	17.9
Infusion reactions	4	2.1	5	1.1
SAEs	*9*	*4.8*	*10*	*2.2*
Infectious SAEs	1	0.5	1	0.2
Non infectious SEAs	8	4.3	9	2.0
Total	**132**	**70.2**	**453**	**100.0**

Pts: patients; AEs: adverse events; SAEs: severe adverse events.

Table 2. Reasons of discontinuation of belimumab

	Pts (N)	Pts (%)
AEs	22	37.9
Non-responder (articular/renal/cutaneous/haematological)	16	27.6
Pregnancy	8	13.8
Flare (renal/articular)	6	10.3
Lost of follow-up	4	6.9
Remission	2	3.4
Total	**58**	**100.0**

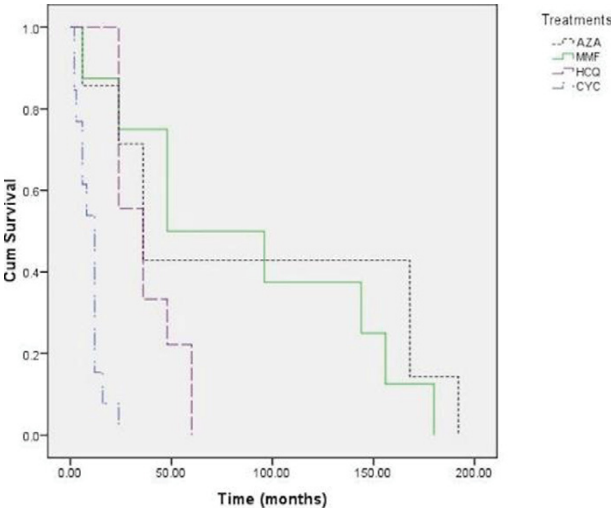
Pts: patients.

Conclusions: Belimumab demonstrated a good safety profile with a low rate of SAEs. Discontinuation occurred in less than 1/3 of subjects with a low rate of discontinuation due to AEs.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6088

AB0457 LONG-TERM EFFECTIVENESS OF TREATMENTS FOR NEUROPSYCHIATRIC MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS



L.D. Fajardo Hermosillo. *Rheumatology, IMSS, Guadalajara, Mexico*

Background: Neuropsychiatric involvement of systemic lupus erythematosus (NPSLE) is one of the most deleterious complications of the disease, leading to great decrease of quality of life and poor prognosis [1]. Factors such as activity of disease have been associated NPSLE [1,2]. The current treatment of NPSLE remains mostly empiric, requiring high-dose corticosteroids and extensive immunosuppressive therapy [3,4]. Short-term efficacy of treatments in NPSLE have been evaluated by several studies, however few studies have been performed to evaluate long-term efficacy of these drugs [4].

Objectives: To compare the long-term effectiveness among drugs and associated factors in the treatment of NPSLE.

Methods: 209 patients ($\geq$14 years) from a Mexican cohort from 2011 to 2017 were examined. SLE and NPSLE cases fulfilled 1997 ACR and 1999 ACR criteria respectively. Demographic factors, comorbidities and pharmacologic treatments were reviewed for patients with NPSLE. Variables were studied by bivariate, multivariate and survival analyses.

Results: Of 209 SLE patients, 37 (17.7%) had NPSLE; of them 32 were women. The mean age [standard deviation (SD)] was 38.8 (14.6) years. The mean of time at onset of SLE (SD) was 6.2 (5.4) years. SLEDAI and SLICC mean (SD) were 22.1 (10.2) and 1.83 (1.2) separately. Diffuse and focal manifestations of NPSLE were presented in 20 and 17 cases. Central and peripheral nervous system events of NPSLE were described in 34 and 3 of patients. The NPSLE manifestations more prevalent were cerebrovascular disease (n=15), psychosis (n=8) and seizure disorders (n=5). A total of 112 cycles of treatment were analyzed [prednisone (PDN) n=30, intravenous (iv) methylprednisolone (MTP) n=23, iv cyclophosphamide (CYC) n=13, azathioprine (AZA) n=12, mycophenolate mofetil (MMF) n=11, rituximab (RTX) n=10, hydroxichloroquine (HCQ) n=9, plasmapheresis (PPH) n=2 and iv immunoglobulin (IVIg) n=2]. Cognitive dysfunction was more associated to higher SLE activity, damage and mortality. Also, psychosis was more associated to receive higher doses of oral PDN or iv MTP, to employ iv CYC and to be linked with renal SLE disease activity. On the other hand, cerebral vascular disease was more associated to receive HCQ and to have antiphospholipid antibodies. The main cause to therapy discontinuation was inefficacy and was more common in patients treated with iv CYC. Corticosteroids survival in months was higher in-group PDN $<$15 mg/d (97.89±16.4; IC95% 65.8–130). AZA survival in months (90±30.8; IC95% 29.6–150) was higher than others treatments for NPSLE and was more associated to use IVIg (OR 10.8, 95% CI 1.04–111, p=0.04). When the first therapy was failed, the drug as second therapy used with higher survival in months was MMF (100±60.5; IC95% 1.6–218).

Conclusions: This study suggests that patients with diffuse manifestations and central nervous system involvement in NPSLE presented more activity, damage and mortality and therefore used more PDN, MTP and CYC. Among the treatments as first therapy for NPSLE with the better long-term efficacy was AZA and when it failed, MMF remained as better second therapy.

AB0458 B CELLS DEPLETION FOR THE TREATMENT OF SYSTEMIC AUTOIMMUNE DISEASES

M.L. Velloso Feijoo, S. Rodriguez Montero, N. Plaza Aulestia, J.L. Marenco de la Fuente. *Rheumatology Unit, Valme University Hospital, Seville, Spain*

Background: Systemic autoimmune diseases (SAD) have traditionally been treated with steroids and immunosuppressants, but not all patients respond to these measures.

Rituximab (RTX) has been used in several SAD with favorable results, but there are only a few reports of isolated clinical experiences, with a very small number of patients.

Data about use of this drug under conditions of daily clinical practice may be relevant.

Objectives: To describe the characteristics of patients with SAD who are candidates for treatment with RTX.

To evaluate the response to this drug in the different SAD.

Methods: Demographic data and disease, treatment and response variables were included.

We use the EULAR definitions of partial response (improvement of at least 50% of the main manifestations of the disease) and complete response (disappearance of the manifestations of the disease), because of the heterogeneity of the SAD and their multiple manifestations.

Results: We included 53 patients, 90.6% were women. The mean age at diagnosis was 31.42±14.33 years; and the median duration of disease at the onset of RTX 1.99 (0–7.5) years. Patients received a median of 2 cycles (1–3 min

-1, max 12); and the median interval between cycles was 14.81 months (6–15.75, min 6, max 120).
The EAS included SLE with 23 (43.4%) cases, systemic sclerosis with 7 (13.2%) cases, Sjögren's syndrome with 6 (11.3%) cases, vasculitis with 5 (9.4%) cases, Still disease with 3 (5.7%) cases, autoinmune cytopenias with 3 (5.7%) cases, dermatomyositis with 2 (3.8%) cases, Behçet's disease with 2 (3.8%) cases, IgG4 disease with 1 (1.9%) case and sarcoidosis with 1 case (1.9%).
A partial response was observed in 27 patients (50.9%) and complete in 20 patients (37.7%). There was no response in 6 of the 53 patients (11.3%). The response by disease groups is detailed in Table 1.

SAD	Partial response	Complete response	No response
SLE (n=23)	9 (39,1%)	12 (52,2%)	2 (8,7%)
Systemic Sclerosis (n=7)	5 (71,4%)	2 (28,6%)	0
Vasculitis (n=5)	5 (100%)	0	0
Sjögren (n=6)	3 (50%)	3 (50%)	0
AI cytopenias (n=3)	1 (33,3%)	1 (33,3%)	1 (33,3%)
Dermatomyositis (n=2)	1 (50%)	1 (50%)	0
Behçet's disease (n=2)	0	0	2 (100%)
IgG4 related disease (n=1)	0	1 (100%)	0
Sarcoidosis (n=1)	1 (100%)	0	0

Conclusions: In our study, patients treated with RTX achieved response in 88.7%; similar than some experiences of RTX off-label use.
Remision of the disease occurs in 50% of the patients.
The best results are observed in SLE, especially in lupus nephritis, and Sjögren disease.
The results in SS are promising due to the limited therapeutic resources for this disease.

AB0459 TREATMENT OF SYSTEMIC AUTOIMMUNE DISEASES WITH RITUXIMAB: SAFETY DATA

M.L. Velloso Feijoo, N. Plaza Aulestia, S. Rodriguez Montero, J.L. Marenco de la Fuente. *Rheumatology Unit, Valme University Hospital, Seville, Spain*

Background: Systemic autoimmune diseases (SAD) have traditionally been treated with steroids and immunosuppressants, but not all patients respond to this strategy. Rituximab (RTX) has been used in several SAD with favorable efficacy and safety results; there are only reports of isolated clinical experiences of small series of patients. The description of this drug safety data in daily clinical practice may be relevant.
Objectives: To describe the adverse events and the hospital admissions during the treatment of a series of patients with SAD with RTX.
Methods: Demographic data, related to disease and treatment, response and safety variables were included. We use the EULAR definitions of partial response (improvement of at least 50% of the main manifestations) and complete response (disappearance of the manifestations), because of the heterogeneity of the SAD.
Results: We included 53 patients, 90.6% were women; the mean age at diagnosis was 31.42±14.33 years; and the median duration of disease at the onset of RTX 1.99 (0–7.5) years. Patients received a median of 2 cycles (1–3; min -1, max 12); and the median interval between cycles was 14.81 months (6–15.75;min 6, max 120).
The SAD were SLE with 23 cases (43.4%), systemic sclerosis with 7 cases (13.2%), Sjögren's syndrome with 6 cases (11.3%), vasculitis with 5 cases (9.4%), Still disease with 3 cases (5.7%), autoinmune cytopenias with 3 cases (5.7%), dermatomyositis with 2 cases (3.8%), Behçet's disease with 2 cases (3.8%), IgG4 disease with 1 case (1.9%) and sarcoidosis with 1 case (1.9%).
A partial response was observed in 27 patients (50.9%) and complete in 20 patients (37.7%). There was no response in 6 of the 53 patients (11.3%).
Adverse events were detected in 15 of the 53 patients (28.3%) and 20 were hospitalized (37.7%) during the treatment with RTX (Table 1).

Infecctions (9)	Disease activity (8)	Others (3)
Respiratory: 7	LES: 8	Acute coronary syndrome: 1
Pyelonephritis: 1		Vertebral fracture: 1
Stomach flu: 1		Metrorrhagia: 1

Three patients developed hypogammaglobulinemia, only one of them was associated with recurrent respiratory infections and even hospitalized in one occasion. Febrile neutropenia was detected in 2 patients, and one of them required admission. Three patients were diagnosed with pneumonia and admitted for supportive and antibiotic treatment. Three other patients suffered gastroenteritis requiring admission in one of them. In two cases, low respiratory infections were repeated requiring admission on 7 occasions. There was also recurrent otitis and a severe hypersensitivity reaction.
Conclusions: The most frequent adverse event were the infectious, mainly respiratory tract infections followed by an infusion reaction. No patient developed opportunistic diseases. This findings are similar than observed in other studies on patients with SAD treated with RTX. Infusion reactions are becoming less frequent, due in part to premedication.
We are dealing with a large number of patients with refractory EAS treated with RTX, so the data obtained from this study show an acceptable safety profile.

AB0460 USE OF INTRAVENOUS IMMUNOGLOBULIN (IVIG) IN AUTOIMMUNE RHEUMATIC DISEASES: EXPERIENCE IN A THIRD LEVEL MEDICAL CENTER

M. Pérez Cristóbal[1,2], R. Ricaño Rocha[2], G. Horta Baas[2], L. Barile Fabris[2], M. Portela Hernández[2]. *[1]Rheumatology; [2]Imss, Mexico City, Mexico*

Background: IGIV therapy in rheumatology has been used as an alternative treatment for patients with refractory, severe disease, or with contraindication to the use of conventional immunosuppressive therapy as serious infections; it has recently been increased its use to treat multiple autoimmune diseases, however with a limited number of precise indications as there are not enough studies to increase the level of evidence for the administration of IVIG
Objectives: To describe the experience gained with the use of IVIG in autoimmune rheumatic diseases in a third level medical center
Methods: This is an observational, descriptive and retrospective study. We report the use of IVIG in our clinical practice, efficacy and adverse effects. We included consecutive patients with autoimmune rheumatic diseases that received IVIG between 2012 and 2015. The information was extracted from clinical records
Results: We included 35 patients: 19 women, 16 men, 18 with systemic lupus erythematosus (SLE), 15 with autoimmune inflammatory myopathy, 1 with primary Sjögren's syndrome (SSp) and 1 with polyarteritis nodosa (PAN).
The most common indication was active disease associated with severe infection that contraindicated the use of immunosuppressants in 24 patients and in 11 patients refractory activity disease to conventional therapy. The most frequent indications in patients with SLE were: 6 thrombocytopenias, 5 lupus nephritis, 4 pulmonary hemorrhage and 3 neurolupus; of the group of inflammatory myopathy the indications were: 6 dysphagia, 5 respiratory insufficiency and 4 refractory myopathy. In patients with SSp and PAN the indication was peripheral neuropathy.
The mean number of IVIG applications was 3.3 (range 1–15). Activity scales were decreased in all patients with IVIG: mean SLEDAI at baseline 15.6 and in the follow up 4.5; in inflammatory myopathies remission was reached in 86% of the cases.
The steroid dose was significantly reduced in most patients in the follow up.
Four patients had adverse effects associated with IGIV: 2 with tachycardia and hypertension, one with acute pulmonary edema and one with hemolytic anemia.
Conclusions: In our experience, IGIV administration was effective in controlling the activity of the autoimmune rheumatic disease, mainly in patients with concomitant infection, and with a good safety profile.
Discussion: IGIV was an effective alternative treatment in patients with contraindication of conventional treatment or in refractory disease, however it is a high cost treatment and should be used in well selected cases

AB0461 BENEFITS OF VITAMIN D IN SLE DEPEND ON THE ORGAN SYSTEM

M. Petri[1], L.S. Magder[2]. *[1]Johns Hopkins University School of Medicine; [2]Biostatistics, University of Maryland, Baltimore, United States*

Background: Low 25-OH Vitamin D is associated with SLE. Both a randomized clinical trial and a longitudinal cohort study proved that supplementation reduced SLE disease activity.
Objectives: We examined whether Vitamin D benefits in SLE are dependent on the organ system.
Methods: Vitamin D and SLEDAI components were measured at each cohort visit starting in 2010 and 16,519 visits of 1,345 different patients were included. The patients were 92% female, 50% Caucasian, 41% African American.
Organ-specific disease activity was defined as a set of binary variables based on SLEDAI. If the patient received any score for any component, then the patient was defined as having that type of activity.
Interestingly, after adjustment for repeated measures and covariates, the relationship between vitamin D and immunologic disease activity totally disappeared.

Table 1. Estimated association between vitamin D levels and odds of organ-specific lupus disease activity, adjusting for age, race, sex, calendar year, prednisone use and plaquenil use

Vitamin D Level (ng/mL)	Immunologic Disease Activity		Skin Disease Activity		Renal Disease Activity	
	OR (95% CI)	P-value	OR (95% CI)	P-value	OR (95% CI)	P-value
<10 (n=163)	1.0 (0.7, 1.5)	0.88	1.4 (1.0, 2.1)	0.049	3.1 (2.0, 4.9)	<0.0001
10–20 (n=1039)	1.0 (0.9, 1.1)	0.93	0.9 (0.8, 1.1)	0.41	2.2 (1.5, 3.1)	<0.0001
20–30 (n=2760)	1.0 (0.9, 1.1)	0.97	1.0 (0.9, 1.2)	0.53	1.6 (1.2, 2.0)	0.0008
30–40 (n=3959)	1.0 (0.9, 1.1)	0.78	1.1 (1.0, 1.2)	0.13	1.2 (0.9, 1.5)	0.23
40–50 (n=3578)	1.0 (Ref Grp)		1.0 (Ref Grp)		1.0 (Ref Grp)	
50–60 (n=2308)	1.0 (0.9, 1.1)	0.78	1.1 (0.9, 1.3)	0.19	1.0 (0.7, 1.3)	0.91
60–70 (n=929)	1.0 (0.9, 1.2)	0.98	1.0 (0.8, 1.3)	0.74	0.8 (0.5, 1.3)	0.33
70–80 (n=504)	1.1 (0.8, 1.2)	0.92	1.3 (1.0, 1.7)	0.072	0.8 (0.4, 1.4)	0.41
80+ (n=356)	(1.1 (0.9, 1.4)	0.42	1.4 (1.0, 1.9)	0.072	0.6 (0.3, 1.6)	0.32

However, for skin activity, there was a significantly elevated risk among those in the very extreme levels of vitamin D. For Renal Disease Activity, there was a significantly higher rate of renal disease activity among those with low levels of vitamin D. In addition, there was a clear trend such that the higher the vitamin D, the lower the risk of renal disease activity.

We then conducted a "within person" analysis. In this analysis, each person serves as his own control, and the question is: "When a person has a vitamin D level lower than his/her average, are they more likely to have renal disease activity". Note, this analysis implicitly adjusts for race, sex, and all variables (measured and unmeasured) that are invariant within a person. The results are shown in Table 2.

Table 2. Within-person analysis of the relationship between vitamin D levels and renal activity adjusting for prednisone use, plaquenil use, and implicitly for all time-invariant characteristics

Vitamin D Level	Odds Ratio	P-value
10 ng/mL or more lower than personal average	1.5 (1.3, 1.8)	<0.0001
Within 10 ng/mL of the personal average	1.0 (Ref Grp)	
10 ng/mL or more higher than personal average	0.8 (0.7, 1.0)	0.080

For Renal, it appears (based on the within-person analysis), that increasing vitamin D results in a reduction in renal activity. Based on other analyses, it is clear this drop was mostly among those in the vitamin D deficiency range.

Conclusions: Low vitamin D is associated with cutaneous and renal SLE activity, but not with immunologic (low C3 or high anti-DNA) activity, in adjusted analyses.

AB0462 VITAMIN D SUPPLEMENTATION SIGNIFICANTLY REDUCES CHOLESTEROL IN SLE

M. Petri[1], L.S. Magder[2]. [1]*Johns Hopkins University School of Medicine;* [2]*University of Maryland, Baltimore, United States*

Background: The benefit of vitamin D on SLE global and renal activity have now been proven by both cohort studies and a clinical trial. The benefits on cardiovascular risk factors, however, are less well understood.

Objectives: We present the first longitudinal study on hyperlipidemia.

Methods: A within-person aanalysis addressed the question of whether a person tends to have higher cholesterol when her vitamin D is lower than her average vitamin D. To assess this, for each visit, we calculated the difference between the vitamin D level at that visit and the person's average of vitamin D. Differences in the range of vitamin D <50 ng/mL were distinguished from differences in the range above 50 ng/mL. Then we modelled the relationship between these differences in vitamin D and the difference between the person's cholesterol at each visit and the person's average cholesterol.

Results:

Table 1. Difference in Cholesterol at each visit per 10 ng/mL difference in between the patient's vitamin D at that visit and the patient's average vitamin D

Range of Vitamin D	Estimated difference in cholesterol (relative to a patient's average cholesterol) as a function of differences in a patient's Vitamin D levels (relative to her average Vitamin D levels)			
	Unadjusted	P-value	Adjusted[1]	P-value
0–50 ng/mL	-3.4 (-3.9, -2.9)	<0.0001	-3.1 (-3.6, -2.6)	<0.0001
50+ ng/mL	-1.1 (-1.7, -0.5)	0.0003	-1.0 (-1.7, -0.4)	0.0016

[1]Adjusted for age, age-squared, sex, race, proportion of time on Plaquenil, mean prednisone dose, mean BM and systolic blood pressure.

Table 2. Difference in Cholesterol per 10 ng/mL Difference in Vitamin D

Range of mean Vitamin D	Estimated difference in cholesterol per 10 ng/mL difference in Vitamin D (95% CI)			
	Unadjusted	P-value	Adjusted[1]	P-value
0–50 ng/mL	-3.7 (-4.2, -3.2)	<0.0001	-3.0 (-3.5, -2.4)	<0.0001
50+ ng/mL	-0.9 (-1.5, -0.2)	0.014	-1.1 (-1.8, -0.3)	0.0037

[1]Adjusted for age, age-squared, sex, race, proportion of time on Plaquenil, mean prednisone dose, mean BMI and SBP.

This means that at a particular clinic visit, if a person's vitamin D is higher than the person's mean vitamin D by 10 ng/mL and the person has vitamin D below 40 ng/mL, then the expected cholesterol will decrease by 3.4 mg/dL. There is no significant effect of higher vitamin D among those whose mean vitamin D exceeds 50.

Conclusions: Vitamin D supplementation (in those whose level is below 40 ng/mL) has a significant benefit on total cholesterol that is independent of age, sex, ethnicity, Plaquenil, prednisone and body mass index. Vitamin D supplementation - as it also helps systolic blood pressure - is both important for SLE activity and for reduction of cardiovascular disease.

AB0463 THERAPEUTIC PLASMA EXCHANGE (TPE) FOR REFRACTORY SLE: A COMPARISON OF OUTCOMES BETWEEN DIFFERENT SUB-PHENOTYPES?

A. Soyuoz[1], O. Karadag[2], L. Kilic[2], T. Karaagac Akyol[3], S. Apras Bilgen[2], O.I. Ozcebe[4]. [1]*Department of Internal Medicine;* [2]*Department of Internal Medicine, Division of Rheumatology, Hacettepe University Faculty of Medicine;* [3]*Blood and Apheresis Unit, Hacettepe University Hospitals;* [4]*Department of Internal Medicine, Division of Haematology, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Background: Therapeutic plasma exchange (TPE) offers an alternative therapeutic modality for patients with systemic lupus erythematosus (SLE) and primary antiphospholipid syndrome (APS). However, there is conflicting evidence regarding its efficacy in different sub-phenotypes.

Objectives: This study aims to investigate the main clinical characteristics and outcomes of patients with different phenotypes of SLE and APS treated with TPE at a tertiary care centre.

Methods: Database of Blood and Apheresis Unit between 2001–2013 was screened for patients with SLE and primary APS. SLE disease activity index (SELENA-SLEDAI), the indications for treatment, complications and outcomes were obtained from review of medical records and phone calls. A total of 24 patients (SLE: 20, APS: 4) were recruited for the study.

Results: Mean ages of SLE (M/F: 1/19) and primary APS (PAPS) patients (M/F: 2/2) were 32.4±12.89 and 52.0±10.7, respectively. The main indications for TPE were haematologic, neurologic, pulmonary involvement and APS-related. TPE was preferred in 8 patients because of leukopenia, and co-infection. SLEDAI was significantly decreased after TPE (16.7±8.3 vs. 8.8±3.1, p=0.001). Both primary APS and SLE related CAPS patients had completely responded to TPE. Success rate of TPE in patients with thrombocytopenia were lower than patients with haemolytic anaemia. Median (IQR 25%>75%) TPE sessions were 6.5 (5–10.5).

Table 1. Clinical, disease activity, treatment findings and TPE outcomes of SLE patients

Patient number	Major TPE Indication	Age/ Sex	H/o Nephr itis	Pre-TPE Drugs	preTPE SLEDAI	Concomitant problem, synchronous treatment/ procedures	PostTPE SLEDAI	Outcome	Follow-up
1	TTP	29	no	MP, CYC	13		13	CR	144 months

17	APS-widespread thrombosis	60	no	MP, CYC, MG	11		8	CR	4 months
18	Evans syndrome	33	no		9		8	CR	36 months
19	Hemolytic anemia	47-M	yes	MP, CYC, MG	28	MP, CYC	NA	Give up TPE	12 months
20	Hemolytic anemia	34	no	MP, CYC	8		3	CR	73 months

Abbreviations: L, leukopenia, PN: Pneumonia, MP: Pulse methyl prednisolone, CYC: Cyclophosphamide, AZA: Azathioprine, RTX:Rituximab, HD: Hemodialysis, MV: Mechanical Ventilation, CR: complete Response, PR: partial response, TF: Treatment Failure

Conclusions: This study suggests catastrophic antiphospholipid syndrome (CAPS) and other APS related problems respond well to the TPE treatment. TPE should be kept in mind for the treatment of patients with other features of SLE, especially those resistant to other agents and in the presence of leukopenia and psychosis

AB0464 AZATHIOPRIONE METABOLITES IN CONNECTIVE TISSUE DISEASE

P. Pentony, T.Y.-E. Tsai. *Rheumatology, the Canberra Hospital, Canberra, Australia*

Background: Azathioprine (AZA) is a common treatment for connective tissue diseases (CTD). AZA is a pro-drug which is metabolised to active moieties of

6-thioguanine (6-TGN) and 6-methylmercaptopurine (6-MMP). These metabolites, rather than the absolute dose of AZA, are associated with clinical efficacy and toxicity. An idiosyncratic skewed metabolism towards 6-MMP in some patients ("shunters") increases the risk of hepatotoxicity and treatment failure. Allopurinol can correct such shunts[1]. Therapeutic protocols using metabolite concentrations have been shown to be cost effective, improve efficacy, and decrease treatment morbidity in IBD[1]. Only one small study estimated a therapeutic 6-TGN level for SLE patients[2]. There are scant data on AZA shunters in connective tissue disease[3].

Objectives: Explore the proportion of AZA therapeutic failure, toxicity, and shunters in CTD patients.

Methods: Retrospective, multicentre audit of AZA metabolite levels in CTD patients from 2012–2016. Patient demographics, treatments, disease activity and drug toxicity were also extracted.

Results: 61 testing episodes occurred in 34 patients whose mean age was 55 (32–79) years; predominantly female (N=26, 77%), with SLE (N=19, 56%). Active disease was present in 15/61 (25%) episodes. 20/34 (60%) patients were on HCQ + AZA. 25/34 (76%) of patients were either on no or <10mg/day of prednisone. 22/61 (36%) episodes had bone marrow suppression, and 8/61 (13%) had moderate liver function derangement. 12/35 (34%) patients were AZA shunters.

Based on AZA metabolite levels, patients were classified into four categories:

Classification[3]	6-TGN	6-MMP	Prevalence in Study (N)
Underdosed/ noncompliant	Low	≤ Normal	9
Appropriately dosed	Therapeutic	≥ Normal	23
Overdosed	High	≥ Normal	16
6-MMP Shunter	Low	> Normal	13

SLE patients were over-represented in the underdosed/non-compliant category (7/9). Patients in underdosed and 6-MMP shunter categories had more active disease (44% & 31%), compared with appropriate and overdosed (17% and 19% p=0.24). Surprisingly, patients who were overdosed by 6TGN levels had the lowest mean AZA dose. 6-MMP shunters had significantly lower median 6TGN levels (147pmol/8x10^8 RBC), yet toxic MMP levels (9630pmol/8x10^8 RBC) that was associated with worst LFT derangement prevalence (4/13, 31% vs <13%, p=0.16).

Conclusions: AZA dose is poorly predictive of 6-TGN and 6-MMP levels. Overall, one third of CTD patients were shunters, with lower 6-TGN levels and more hepatotoxicity. Only 40% of test episodes were appropriately dosed. Patients with low disease activity are more likely to have adequate 6TGN levels, however, 40% of patients with CTD won't have adequate disease control despite therapeutic 6-TGN levels. AZA metabolites can identify the multiple causes for therapeutic failure (under dosing, shunter, or true non-response), and enable early detection of shunters to avoid liver toxicity.

AB0465 ASSOCIATION BETWEEN SAFETY, EFFICACY AND HYDROXYCHLOROQUINE DOSAGE IN THE TREATMENT OF CUTANEOUS LUPUS ERYTHEMATOSUS AND SYSTEMIC LUPUS ERYTHEMATOSUS

R. Wakiya, T. Kameda, M. Izumikawa, S. Nakashima, H. Shimada, H. Ozaki, A. Kondo, N. Kadowaki, H. Dobashi. *Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa University, Kagawa, Japan*

Background: Hydroxychloroquine (HCQ) are considered to be effective against cutaneous lupus erythematosus (CLE) and symptoms associated with systemic lupus erythematosus (SLE) such as rashes, joint pain, and fatigue. In a randomized controlled trial in stable active patients with SLE on HCQ treatment, those who achieved blood HCQ levels greater than or equal to 1000ng/ml had a tendency for reduced SLE flares during a 7 month period [1]. To prevent ocular toxicity, HCQ should be maintained at a dose of 6.5mg/kg or less for ideal body weight [2], however, optimal HCQ dosage is unclear.

Objectives: To extract the problem of the dosage based on ideal body weight and identify safer and more effective HCQ dosage.

Methods: We enrolled patients who took HCQ for SLE or CLE more than 3 months in our institute and 2 related facilities from September 2015. We used Cutaneous Lupus Erythematous Disease Area and Severity Index (CLASI) to evaluate cutaneous symptoms and evaluated effect at start of administration and 3 months of that. The attending doctors assessed the adverse events (AEs). We investigated the change of serum biomarker, such as the value of serum complement and anti-ds-DNA body, the number of white blood cells, lymphocytes and platelets.

Results: We enrolled the 30 patients with administration of HCQ more than 3 months and in CLE were 2 cases, in SLE were 28 cases. In 21 cases HCQ dosage were based on ideal weight. The AEs were in 13/30 cases (43.3%). The AEs were the new cutaneous symptoms in 5 cases, eye manifestation in 3 cases (abnormal visual field in 2 cases, color anomaly in 1 case), diarrhea in 2 cases, fever in 2 cases, feeling of fatigue in 2 cases, renal dysfunction in 1 case, muscular pain in 1 case, and pericarditis in 1 case. The eye manifestation in the 3 cases disappeared for a few days by stopping or reducing HCQ dosage. Although we needed glucocorticoid treatment for pericarditis, the other AEs improved by reducing HCQ dosage or stopping. The AEs of taking HCQ 200mg/day were in 6 cases, 200mg and 400mg alternatively on every other day in 6 cases, and 400mg/day in 1 case. The AEs of taking HCQ dosage based on ideal body weight were in 10/21 cases (47.6%) and by minimal dosage in 3/9 cases (33.3%). 22/28 cases (78.6%) significant improved cutaneous symptoms (amount of mean change of CLASI -4.57, p=0.024). There is no difference in the efficacy of cutaneous symptoms between group received HCQ based on ideal body weight (80.0%) and the others (92.3%). 5/21 cases of HCQ based on ideal body weight were made to reduce HCQ dosage due to AEs, but all 5 cases improved cutaneous symptoms. 53.3% (16/30) cases increased complement, but other biomarkers didn't change.

Conclusions: HCQ was effective for the treatment of CLE even when HCQ dosage was reduced due to AEs. These findings suggest that low-dose HCQ is also effective and safe, and HCQ initial dosage wasn't the need to adjust for ideal body weight.

AB0466 THE EFFECT OF OMEGA-3 FATTY ACIDS ON DISEASE ACTIVITY, ENDOTHELIAL FUNCTION, INFLAMMATORY MARKERS, AND LIPID PROFILE IN SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED, CONTROLLED TRIALS

R. Castillo[1], P.P. Uy[1], D.M. Francisco[1], S. Lakshminarayanan[2]. *[1]Internal Medicine; [2]Rheumatology, University of Connecticut, Farmington, United States*

Background: Omega-3 fatty acids have been shown to have potentially beneficial immunomodulatory activity in autoimmune conditions such as rheumatoid arthritis and Sjogren's syndrome. Whether this extends to systemic lupus erythematosus (SLE) remains unclear.

Objectives: We undertook this study to summarize the body of evidence available from published clinical trials on the effectiveness of omega-3 fatty acids on clinical and laboratory outcomes in SLE.

Methods: Two independent reviewers systematically searched PubMed, MEDLINE, Scopus, and the reference lists of related articles for studies published from inception to November 2016 using relevant keywords. Randomized, controlled trials (RCTs) on SLE patients comparing omega-3 fatty acids with placebo were included in the analysis. The quality of the included RCTs was assessed in accordance with the Cochrane Handbook. A random effects model was used to pool extracted data. Heterogeneity was evaluated with Chi^2 test and I^2, with *p*-values <0.05 considered significant. Data presented in median and interquartile range were converted to mean and standard deviation using the method described by Wan et al.

Results: A total of seven clinical trials consisting of 303 subjects with a duration of treatment ranging from 12 to 52 weeks were included. In studies using SLAM-R as the measurement of disease activity (n=82), there was a statistically significant mean score reduction in the omega-3 fatty acid group vs. the placebo group at 24 weeks. However, in studies that used mean change in SELENA-SLEDAI (n=117, WMD: -0.87, 95% CI: -3.9, 2.17, I^2=0%, p=0.58) and PGA (n=117, WMD -0.46, 95% CI: -1.16, 0.24, I^2=85%, p=0.20) scores, there was no significant effect (Figure 1). Mean brachial artery diameter after 12 weeks likewise did not reveal

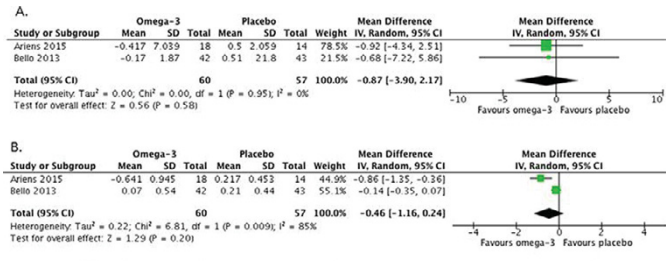

Figure 1. Effect of omega-3 fatty acids on SLE disease activity as measured by mean change in SELENA-SLEDAI (A) and PGA (B) scores.

any difference between the two groups (n=141, WMD: -0.01, 95% CI: -0.03, 0.01, I^2=0%, p=0.26). The data on percent increase in flow-mediated dilation was conflicting. In terms of inflammatory markers, there were likewise no clear associations, with some studies reporting significant changes in ESR, CRP, IL-12, and IL-13 levels which were not observed in others. With regards to lipid profile, treatment with omega-3 fatty acids was associated with a non-significant trend toward increase in all lipid profile parameters at 12 weeks including HDL (WMD 6.83, 95% CI: -4.37, 18.02, I^2=12, p=0.23), LDL (WMD 5.41, 95% CI: -1.27, 12.10, I^2=0%, p=0.11), and total cholesterol (WMD 8.48, 95% CI: -0.38, 17.33, I^2=0, p=0.06).

Conclusions: The limited data on the use of omega-3 fatty acids has not shown clear benefit in improving disease activity, endothelial function, inflammatory markers, or lipid profile in patients with SLE. Larger studies for longer durations using standardized scales for measuring outcomes are needed.

AB0467 EFFICACY AND SAFETY OF ASSISTED REPRODUCTIVE TECHNOLOGIES (ART) IN RHEUMATIC PATIENTS: A MULTICENTER STUDY

R. Reggia[1], H. Sebbar[1], L. Andreoli[1], A. Hoxha[2], M. Larosa[3], F. Ceccarelli[4], V. Canti[5], V. Ramoni[6], A. Inversetti[7], A. Ruffatti[2], A. Doria[3], F. Conti[4], G. Valesini[4], P. Rovere Querini[5], C. Montecucco[6], A. Lojacono[8], L. Fallo[8], A. Tincani[1]. *[1]Rheumatology and Clinical Immunology, ASST Spedali Civili di Brescia, BRESCIA; [2]Rheumatology Unit, Department of Medicine - DIMED; [3]Rheumatology Unit, Hospital and University of Padua, Padua; [4]Internal Medicine and Medical Specialties Department, Policlinico Umberto I, "La Sapienza" University of Rome, Rome; [5]Allergology and Clinical Immunology, U.O. Internal medicine, Ospedale San Raffaele, Milan; [6]Rheumatology Unit, IRCCS Policlinico San Matteo and University of Pavia, Pavia; [7]Department of Obstetrics and Gynaecology, Ospedale San Raffaele, Milan; [8]Maternal-Fetal Medicine, ASST Spedali Civili di Brescia, BRESCIA, Italy*

Background: Always more frequently rheumatic patients (pts) ask for Assisted Reproductive Technologies (ART) for infertility problems. The main concern is determined by the ovarian stimulation, associated with an increased risk of disease flare and thrombosis.

Objectives: To describe a case series of ART cycles in pts affected by rheumatic diseases, analyzing pregnacy rate and outcome, fetal-maternal complications and disease flares.

Methods: We included all the consecutive pts evaluated in the Pregnancy Clinic of 5 Italian Rheumatology Units after having performed ≥1 ART cycle from 1997 to 2016.

Results: We included 60 pts: infertility was primary (no previous spontaneous conception) in 68% of cases, idiopathic in 76.5%, of male origin in 8.3%, of female origin in 15%, mixed in 0.2%. One hundred and eleven ART cycles were performed: 13IUI, 44FIVET (3eterologous), 53ICSI (14eterologous), 1embryodonation. Antiphospholipid antibodies were positive in 23 (38.3%) pts and in 45 (40.5%) cycles. Procedures were unstimulated in 14 (12.6%) stimulated in 97 (59.5%) cases: with GnRH-Antagonist in 26 (26.8%), GnRH-agonist in 60 (61.8%), gonadotropins only in 7 (7.3%) and with clomiphene in 4 (4.1%) cases. We registered 3 (3%) cases of Ovarian Hyperstimulation Syndrome, all after Agonist protocol. Overall we observed 46 pregnancies, with a *pregnancy rate* of 38.7% for omologous procedures and of 55.5% for eterologous. No miscarriages were reported. Pregnancies ended with 35 single and 5 twin birth, 6 are still ongoing: we recorded 4 (8.9%) perinatal deaths: 1 baby died at birth for multiple malformations and 3 died in the first days of life for extreme prematurity. One or more fetal complications were reported in 11 (27.5%) pregnancies: 3PROM, 3IUGR, 3oligohydramnios, 4fetal malformation (2 severe, 1multiple and fatal). The mean age of the women suffering from fetal complications was significantly lower (p:0.03). One or more maternal complications were reported in 13 (32.5%) pregnancies: 4gestational diabetis, 2thrombocytopenia, 2pre-eclampsia, 2placenta previa, 1hypothyroidism, 1gestational hypertension, 1cholestasis of pregnancy. Disease Flares were reported in 5 (12.5%) pregnancies: 4 articular (2 in RA patients, 2 in SLE patients), 1haematological (in SLE patient, after spontaneous therapy discontinuation). No cases of thrombosis were reported.During puerperium: 1 (2.5%) post-partum hemorrage (no LMWH ongoing), 1 articular flare (2.5%). Additional informations are available in Table 1.

Mean age at procedure; [median]; range	36.4; [37]; 19-45	
Diagnosis	22 SLE (2+APS), 12 UCTD, 5 PAPS, 8 RA, 5 AS, 2 SjS, 1 DM, 1PA, 1 Takayasu Arteritis, 1 Churg-Strauss Vasculitis, 1 Behcet Disease, 1SSc.	
Mean disease duration at procedure; [median]; range	6.9 years; [6]; 1-22	
Prophylactic therapy during ovarian stimulation (data available in 109 cycles) Mean n' of embryos transferred in utero; [median]; range	yes in 71 (65.1%)	LDA only n:23 (32.4%)
		LMWH only n:25 (35.2%) Prophylactic dose in 25(100%)
		LDA+LMWH n:23 (32.4%)

Tab.1 Main features of patients, procedures and newborns

SLE: Systemic Lupus Erythematosus; PAPS: Primary Antiphospholipid Syndrome; UCTD: Undifferentiated Connective Tissue Disease; SjS: Sjögren Syndrome; SSc: Systemic Sclerosis; PA: Psoriasic Arthritis; AS: Ankylosing Spondylitis.

Conclusions: We didn't found any good reasons to discourage ART performance in rheumatic pts: the safety seems to be high and the *complications rate* is in line with that reported in general population. An adequate prophylaxis during stimulation, pregnancy and puerperium seems to provide a good protection from thrombotic complications.

AB0468 POSSIBLE EFFECTS OF BELIMUMAB THERAPY ON T- AND B-CELL PHENOTYPE IN A COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Piantoni[1], F. Regola[1], M. Scarsi[2], F. Dall'Ara[1], L. Andreoli[1], A. Tincani[1], P. Airò[1]. *[1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia; [2]Internal Medicine Unit, Esine-Vallecamonica Hospital, Esine, Italy*

Background: B- and T-cell activation are one of the pathogenic mechanisms of systemic lupus erythematosus (SLE). After repeated antigenic stimulation, T-cells undergo different modifications, leading to the differentiation into effector memory T-cells (CCR7-CD45RA-) and highly experienced memory T-cells (CCR7-CD45RA+). Similarly, down-modulation of CD28 may lead to the expansion of the CD28neg T-cells, a subpopulation with peculiar effector activities (1).

Recent studies showed that memory CD4+ T-cells are increased in the peripheral blood of SLE patients, whereas contradictory data are reported on CD28 neg T-cells (2).

Peripheral transitional B-cells (38high24high) are immature B-cells transiting to secondary lymphoid organs, where their maturation into follicular or marginal zone B-cells is driven by a stimulating factor called BLyS. This population is expanded in patients with SLE (3). The anti-BLyS therapy agent belimumab is approved for treatment of SLE.

Objectives: The aims of this study were to characterize B- and T-cell phenotype in a cohort of patients with SLE, according with disease activity, and to analyse their modifications therapy with belimumab.

Methods: Phenotypic analysis of peripheral blood B and T lymphocytes was made by flow-cytometry. First, a cross-sectional study on 51 consecutive SLE patients (F/M: 48/51; median age: 35 years; anti-dsDNA: 16 UI/ml; C3: 79 mg/dl; C4: 10 mg/dl) was performed.

Second, 18 patients treated with belimumab were longitudinally followed.

Disease activity was evaluated by SLEDAI-2K score.

Results: SLE patients were divided in two groups according disease activity: patients with SLEDAI-2K ≥6 (n:13) had a higher percentage of circulating CD4+T-cells with CD28neg phenotype: median value (25th-75th percentile)=13 (5–19) vs 3 (1–5) % of CD4+ T-cells, p<0.01), as well as of those with an effector memory (37 (29–40) vs 18 (12–27) % of CD4+ T-cells, p<0.01), highly experienced memory phenotype (9 (7–12) vs 1 (1–3) % of CD4+ T-cells, p<0.01), and of B-cells with a transitional phenotype (3 (0.5–5) vs 0.2 (0–0.4) % of CD19+ cells, p=0.02), in comparison with patients with low disease activity (n:38).

After 6 months of treatment with belimumab, no significant variation in the T-cell subset was observed, but there was a reduction in the number of circulating naïve B-cells (from 49 (30–71) to 21 (11–36) % of CD19+ cells; p<0.01). Among these patients, the proportion of transitional B-cells, was raised (as compared with normal controls) at baseline in 3/11 patients with SLEDAI-2K ≥6, and 0/7 with low disease activity. After 6 month of therapy, their number normalized in 2 of these 3 patients.

Conclusions: CD4+ T-cells subpopulations displaying phenotype characteristics of effector lymphocytes, and transitional B-cells are expanded in peripheral blood of patients with active SLE. Therapy with belimumab may inhibit the production of transitional and naïve B-cells.

AB0469 **EVALUATION OF PILOCARPINE TREATMENT IN XEROSTOMIA BY PULSED DOPPLER COLOR ULTRASONOGRAPHY: ECHOPILO STUDY**

T. Depinoy[1], A. Saraux[1], S. Boisrame[2], D. Cornec[1], J.O. Pers[3], T. Marhadour[1], D. Guellec[1], V. Devauchelle-Pensec[1], S. Jousse-Joulin[1]. *[1]Rheumatology, Cavale Blanche Hospital; [2]Odontology Department; [3]Immunology Department, Morvan Hospital, Brest, France*

Background: The ultrasonography of salivary glands (USSG) has proved its utility in diagnosing and following primary Sjögren patient's (pSS) (1,2). The evaluation of disease activity is still of interest and can be studied by assessing the inflammatory status of SG using US Doppler.
Objectives: To evaluate the vascularization of salivary glands, and particularly the parotid gland (PG) using Pulsed Doppler color ultrasonography (USSGPD) in patients complaining of xerostomia before and after treatment by pilocarpine.
Methods: We prospectively included patients with objective dry mouth syndrome (using salivary flow rate) at Brest University Hospital (DiapSS cohort). The vascularization was assessed by the resistive index (RI) at the left parotid. Only patients with pathological RI (<0.8) were included in order to observe evolution after pilocarpine. USSGPD was carried out by the same operator. A dental consultation with measure of salivary flows before and after stimulation was performed. These examinations were performed at baseline and after 3 months of treatment with pilocarpine at 4 mg 3 times daily.
Results: Among the 19 patients included, 11 received pilocarpine treatment for the whole 3 months period, 6 of the 8 remaining patients stopped the pilocarpine due to side effects. Among the 11 patients with a follow-up evaluation at 3 months, 5 had pSS according to AECG criteria. The differences of RI before and after lemon stimulation were on average of -0.04 at baseline and -0.04 at M3. The sum of ultrasound's grades average of the four glands was 3.47 at M0 and 4.18 at M3. The non-simulated salivary flow was on average of 1.96 mL/mn at M0 and 5.23 mL/mn at M3, whereas the average of stimulated salivary flow was 2.84 mL/mn at M0 and 8.51 mL/mn at M3. None of these observed differences were statistically significant before and after 3 months of treatment by Pilocarpine: RI before and after lemon stimulation (p=0.953), the sum of the four glands' grades (p=0.858), the non-stimulated (p=0.26) and stimulated salivary flow (p=0.139). Concerning the 3 patients with Sjögren's syndrome, there was no differences using RI before and after treatment but the RI was lower in this subgroup compared to the xerostomia patients.The study was marked by a large number of pilocarpine's discontinuation (31%) due to adverse effects.
Conclusions: Preliminary results showed no significant differences between the 4 gland's grade, ultrasound's RI and salivary non and stimulated flow before and after three months of pilocarpine's treatment. The vascularisation of salivary glands could be an opportunity to follow our treated patients with Sjögren's syndrome or with xerostomia but more studies are needed to prove the interest of this procedure.

AB0470 **RESPONSIVENESS OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AFTER RITUXIMAB TREATMENT: A SINGLE CENTER EXPERIENCE**

Y.P. Tsao, C.Y. Tsai. *Medicine, Taipei Veterans General Hospital, Division of Allergy, Immunology, Rheumatology (Air), Taipei, Taiwan, Province of China*

Background: Systemic lupus erythematosus (SLE) is a complex disease with multi-organ presentations. Lupus nephritis, which results from autoantibody deposition at glomerulus, induces inflammation and damage. Lupus nephritis is also the leading cause of comorbidity in SLE patient and associated with poor prognosis.
Objectives: To evaluate the treatment responsiveness of rituximab in patients with SLE.
Methods: Patients should fulfill the criteria of 1997 American College of Rheumatology classification criteria for SLE. Patients underwent chemotherapy, with severe infection, under hemodialysis or after kidney transplantation were excluded. Total 37 patients were evaluated receiving rituximab infusion from 2009 to 2013. Clinical parameters were measured before and after rituximab usage.
Results: Among the 37 patients, the female patient was 89.2%. Mean age was 39.53 years old. The mean creatinine level remained similar during the 36 months of follow-up. In the beginning of the treatment, the mean creatinine level was 1.40mg/dl (SD 0.84). After 12, 24, 36 months of follow-up, the mean creatinine levels were 1.73mg/dl, 2.16mg/dl, and 2.40mg/dl, respectively (p=0.431, 0.148, 0.328). The mean proteinuria level was 3.51g/day initially (SD 2.52), but it rapidly decreased to 1.60g/dl after 6 months of follow-up (p<0.001), and further decreased to 1.40g/day, 1.12g/day, and 0.90g/day after 12, 24, 36 months of follow-up (p=0.001, 0.002, 0.012). The mean ds-DNA level was 216IU/ml in the starting of the treatment, and it decreased to 97.04IU/ml, 88.28IU/ml, 94.6IU/ml after 12, 24, 36 months of follow-up (p=0.002, 0.003, 0.05). The C3 level revealed elevation after 36 months of follow-up. The mean C3 level was 70.63mg/dl initially, and increased to 88.60mg/dl, 90.65mg/dl, and 96.20mg/dl after 12, 24, 36 months of follow-up (p<0.001, 0.002, 0.011). The platelet level remained similar from the beginning of the study to 36 months of follow-up (269.97K/cumm to 253.5K/cumm, p=0.929). The improvement of proteinuria was significant and could be detected in 6 months, which had significant correlations with the reduction level in 24 months (p<0.001). This suggested that early improvement of proteinuria may predict the further responsiveness.
Conclusions: Although the role of rituximab still remained controversial in the treatment of systemic lupus erythematosus, it showed positive effects in our single center's experience. Early response to rituximab was an important predictor of further sustained responsiveness and reduction of proteinuria and other clinical parameters.

SLE, Sjögren's and APS - clinical aspects (other than treatment)

AB0471 **WIDE HETEROGENEITY IN TREATMENT PROTOCOLS AND INAPPROPIATE USE OF PREDNISOLONE FOR ANTI-RO/LA ASSOCIATED-CONGENITAL HEART BLOCK: A SYSTEMATIC REVIEW OF 492 CASES**

A. Erden[1], L. Kilic[1], E. Bilgin[2], A. Fanouriakis[3], S. Ceylan[2], B. Hymabaccus[2], Y.Z. Sener[2], F. Gurler[2], A. Sari[1], B. Armagan[1], O. Karadag[1], S. Kiraz[1], D. Boumpas[3], U. Kalyoncu[1]. *[1]Department of Rheumatology; [2]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey; [3]Rheumatology and Clinical Immunology, 4th Department of Internal Medicine, "Attikon" University Hospital, Athens, Greece*

Background: Congenital heart block (CHB) risk is 1–2% in case of maternal anti SSA/Ro and/or anti SSB/La antibody positivity. CHB have significant mortality (20–30%) and available therapeutic options' efficacy is contradictory.

Table. Treatments after diagnosis of CHB

General treatment, n(%)			
Only glucocorticoids	92 (39.3)		
Glucocorticoids and IVIG	10 (4.2)		
Only IVIG	2 (0.8)		
Glucocorticoids and hydroxychloroquine (HCQ)	2 (0.8)		
Glucocorticoids, HCQ and IVIG	2 (0.8)		
Only HCQ	1 (0.4)		
No treatment	134 (57.2)		
Glucocorticoid type, n(%)			
Dexamethasone	54 (50.9)		
Prednisolone	27 (25.4)		
Betamethazone	11 (10.3)		
Not known	14 (13.2)		
Dosing regimen of glucocorticoids, n(%)			
Dexamethasone 4 mg/day, until birth	25 (30.4)		
Prednisolone 40-60 mg/day, until birth	11 (13.4)		
Dexamethasone but not know dosage or time period	9 (10.9)		
Dexamethasone or Betamethasone cumulative dose over 100 mg's'	7 (8.5)		
Dexamethasone 8 mg/day until birth	5 (6.0)		
Dexamethasone or Betamethasone cumulative dose over 100 mg's'	3 (3.6)		
Dexamethasone 2 mg/day, until birth	3 (3.6)		
Prednisolone until birth, dosage not specified	3 (3.6)		
Prednisolone 10 mg/day, until birth	2 (2.4)		
Dexamethasone 12 mg/week, until birth	2 (2.4)		
Dexamethasone or Betamethasone 12 mg/day, until birth	2 (2.4)		
Dexamethasone or Betamethasone 25 mg/ twice a week, until birth	1 (1.2)		
Dexamethasone 10 mg/day, until birth	1 (1.2)		
Dexamethasone 6 mg/day, until birth	1 (1.2)		
Prednisolone 2 mg/kg/day, no time period	1 (1.2)		
Use of betamimetics, n(%)			
Yes	17 (12.4)		
No	120 (87.6)		
Dosing regimen of IVIG, n(%)			
0.4gr/kg/day for 5 days, then one per month or 1 g/kg 2 consequent day in a month	4 (28.6)		
1gr/kg per week	3 (21.4)		
0.4 gr/ kg per 3 weeks	3 (21.4)		
1 gr/kg per 3 weeks	2 (14.3)		
1 gr/kg per 15 days until birth	1 (7.1)

Total	62 (21)	234 (79)	
Plasma exchange schedule n(%)			
Two consequtive days, then weekly	13 (61.9)		
Totally 3 plasma exchanges in 48 hours, 1 cycle	2 (9.5)		
Totally 3 plasma exchanges in 48 hours, 2 cycles	1 (4.7)		
Totally 3 plasma exchanges in 48 hours, one per 4 weeks	2 (9.5)		
Totally 3 plasma exchanges in 48 hours, one per 3 weeks	1 (4.7)		
Unknown time period	2 (9.5)		

Objectives: To review the literature regarding different treatment modalities for CHB.
Methods: We performed a systematic review (August 2015) on Pubmed, using the following MeSH terms: "neonatal lupus", "congenital heart block"; results were restricted to human studies and English language. 1125 articles were assessed in abstract form and, after employing exclusion criteria, 267 original articles/case reports were evaluated in full text. Finally, 199 studies were included, reporting on a total of 492 CHB patients. All administered treatments were assessed on a patient-by-patient basis.
Results: A total of 243 cases reported data for CHB treatment: glucocorticoids (GCs) in 106 (43.6%) cases, intravenous immunoglobulin (IVIG) in 14 (5.7%) cases, and hydroxychloroquine in 5 (2.0%) cases. 21 patients received plasmapheresis treatment. 134 (55.1%) cases received no treatment. Both GCs and IVIG were mostly used in cases with complete atrioventricular (AV) block (74.1% and 61.5% of cases, respectively). Different types of GCs were used: Dexamethasone in 54 (58.6%) patients, prednisolone in 27 (29.3%) and betamethasone in 11 (11.9%) patients (total 92 patients with available data). Dosing schemes and regimens were also widely heterogeneous, with fifteen different regimens used by different centres (Table). Regarding IVIG treatment, six different algorithms were used. Similarly, five different plasmapheresis protocols were used.
Conclusions: There is no consensus in the treatment of CHB. Drug selection and dosing regimens have wide heterogeneity. More than half cases received no treatment. Of note, prednisolone has often been used, despite its inability to cross the placenta.

AB0472 IMPACT OF DISEASE ON FAMILY AND SOCIAL LIFE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

H. Babaoglu[1], Ö. Varan[1], S.C. Guven[2], D. Tecer[2], H. Küçük[1], A. Tufan[1], S. Haznedaroglu[1], M.A. Öztürk[1], B. Goker[1]. *[1]Department of Internal Medicine, Division of Rheumatology; [2]Department of Physical and Rehabilitation Medicine, Division of Rheumatology, Gazi University Faculty of Medicine, Ankara, Turkey*

Background: Systemic lupus erythematosus (SLE) is a chronic connective tissue disease with involvement of various organ systems and characteristically has a higher incidence in women than men[1]. The disease, as well as its treatment, could have significant effects on the quality of life of lupus patients.
Objectives: Here, we aimed to investigate the impact of SLE on quality of the social and family life of women.
Methods: One hundred and twenty women diagnosed with SLE were included in the study. A questionnaire including questions about family and social relations were applied and demographic information, educational status, marital status, organ involvement and treatment data were obtained. The results of this study are preliminary and the study is still ongoing.
Results: One hundred and twenty patients were studied. The average age was 37 (± 10). 77 patients were married, 29 patients were single, 12 patients were divorced and 2 patients were widows. 29% of the patients were employed. 10,8% of the patients declared having difficulty in accepting their illnesses. 94,8% of the married patients had nuclear families. Relationship with partners and family members detoriated in 15,5% of the married patients after the diagnosis of SLE. 10,7% of single patients ended their serious relationships and 28,6% developed negative thoughts about marriage after the diagnosis of SLE.
17,6% of the married patients were exposed to verbal or physical violence by their partners. 33% of the patients declared having worse social life compared to prior to diagnosis and 20,7% declared having poor relations with their friends due to their disease. 34.5% of the patients stated that they received psychological counseling after their diagnosis. No significant relationship was found between family problems, social activities, age and educational level.
Conclusions: Systemic lupus erythematosus is a connective tissue disease affecting various organ systems and leading to various comorbidities. Our results suggest that family and social relations detoriate in lupus patients due to their illness independent of their age and educational level. Over one third of the patients received psychological counseling after diagnosis. Moreover, results of this study suggest that having a diagnosis of lupus has substantial impact on the marital considerations.

AB0473 ANTI CCP AND ANTI MCV ANTIBODIES ARE MARKER OF ARTHRITIS IN SYSTEMIC LUPUS ERYTHEMATOUS & SCLERODERMA

A.M. Elsayed[1], S.A. ElBakry[1], N.O. El-Azizi[1], S.I. Ibrahim[1], A. Abdelzaher[1], N.M. Lotfy[2], F.M. Badr[1]. *[1]Internal Medicine & Rheumatology; [2]Clinical pathology, Facilty of Medicine- Ain Shams University, Cairo, Egypt*

Background: Anti-citrullinated protein antibodies (ACPA) have been reported as more specific serological markers of rheumatoid arthritis (RA). They provide a superior alternative to the rheumatoid factor (RF) test in laboratory diagnostics of RA (1). Different studies suggest that the enzymatic citrullination and the production of ACPAs may also be associated with other inflammatory arthritis-associated autoimmune diseases (2).
Objectives: Is to detect the presence of anti CCP and anti CMV antibodies in SLE & SSc and its correlation to radiological findings and disease activity.
Methods: Our study was included 70 SLE patients and 30 systemic sclerosis (SSc) patients diagnosed according to ACR classification criteria. After informed consent, all patients were subjected to detailed history taking, full clinical examination including rheumatological examination, laboratory investigations: included CBC, ESR, CRP with titer, urine analysis, renal & liver function, serum uric acid, Anti CCP antibodies & Anti MCV antibodies by ELISA. X- ray and U/S on both hands and knees and disease activity score using SLEDAI score for SLE patients and SSc disease activity score (Medsgar score) for SSc patients.
Results: In our study, anti CCP antibodies were found in 8 (11.4%) of SLE patients and 4 (13.3%) SSc patients, while anti MCV antibodies were found in 14 (20%) SLE patients and 8 (26.7%) of SSc patients.There is association between presence of anti CCP Abs and anti MCV Abs and a clinically evident arthritis in both SLE and SSc. Strong relationship between high CRP level and a severe arthritis and joint erosions was noticed in SLE patients. A significant radiological evident in the form of synovial hypertrophy and bony erosions were found using ultrasonography and plain X-ray with seropositive anti CCP and anti MCV Abs in both SLE and SSc patients.In our study, cut off value of anti CCP which was >12, with sensitivity of 70.42%, specificity of 60% positive predictive value of 80.6%, negative predictive value of 46.2% with diagnostic accuracy of 61.7%, and best cut off value of Anti MCV which was >11, with sensitivity of 98.46%, specificity of 30%, positive predictive value of 75.3%, negative predictive value of 90% with diagnostic accuracy of 60.2% in SLE & SSc.
Conclusions: There is a significant association between presence of anti CCP antibodies and anti MCV antibodies and the presence of evident arthritis either clinical or radiologically by using both x-ray and U/S on both hands and knees in SLE and SSc patients.

AB0474 THYROID DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS: ITS IMPACT AS A CARDIOVASCULAR RISK FACTOR

A. Mabrook, M.I. Abd elkareem, M.M. Rayan. *Rheumatology, Alazhr University, Assuit, Egypt*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease caused by immune system–mediated tissue damage Thyroid function abnormalities and thyroid autoantibodies have been frequently described in patients with rheumatologic autoimmune diseases, such as SLE
Objectives: The aim of the study Was to assess thyroid function and anti-thyroid antibodies in SLE patients and evaulate the effects of the thyroid dysfunction on the clinical parameters, disease activity and assess its impact as a cardiovascular risk factor.
Methods: A total number of Fifty SLE female patients were selected, Triglycerides (TG), total cholesterol (TC), LDL and high density lipoprotein (HDL).Thyroid Stimulating Hormone (TSH),serum freeT3 (FT3), freeT4 (FT4).Serum thyroid peroxidase antibodies (TPOab) and serum thyroglobulin antibodies (TGab) erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), IMT (intima-media thickness) of the carotid arteries and Echocardiography was done for all patients
Results: There is a statistically significant correlation between SLE and thyroid disorder p. value<0.05.clinical hypothyroidism was the most common abnormality presented followed by subclinical hypothyrodism.There is a statistically significant correlation between IMT and thyroid disorder p. value<0.05.There is a statistically significant correlation between cardiac valves disorder and thyroid disorderT, we found a statistically significant correlation between pericardial effusion and thyroid disorder p. value<0.05.
Conclusions: we conclude that thyroid disorder is more common in lupus patients especially those in exacerbation and +ve for antithyroid Ab and Those with thyroid dysfunction had increased cardiovascular risk. These patients should be investigated for Lipid profile echocardiography and neck US for detection of early atherosclerosis and other CVD Those with thyroid dysfunction had increased cardiovascular risk.

AB0475 CHANGES IN HEART RATE VARIABILITY REFLECT CHANGES IN CLINICAL STATUS AND PATIENT REPORTED OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL ANALYSIS

A. Thanou[1], S. Stavrakis[2], J.C. Reynolds[2], S. Kamp[1], P. Kamp[1], J.A. James[1,2], J.T. Merrill[1]. *[1]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation; [2]University of Oklahoma Health Sciences Center, Oklahoma City, United States*

Background: We previously observed an association between systemic lupus erythematosus (SLE) disease activity and heart rate variability (HRV) with a preliminary observation of consistency between these two measures when disease activity changed between two timepoints (1).
Objectives: To prospectively test the hypothesis that HRV reflect longitudinal changes in clinical status and patient reported outcomes.
Methods: The current project evaluated HRV measurements using a 5 min ECG in SLE patients who completed a minimum of 2 visits in an ongoing clinical trial. HRV parameters were calculated in the time domain (RMSSD and pNN50) and the frequency domain [high frequency (HF) as well as low frequency to high frequency (LF/HF) ratio]. A mixed effects linear model, with generalized estimating equations to account for clustering of visits for each patient, was used to compare changes in HRV between paired visits and to examine linear associations between HRV parameters and clinical scores. All models were adjusted for baseline values of each HRV parameter.
Results: Forty nine patients (age 44.9±11.7, 46 female), followed in a total of 413 paired visits (median time between visits 1 month), were included. Global BILAG score was inversely associated with RMSSD (regression coefficient β=-1.39±0.01; $p<0.0001$). BILAG, SLEDAI and PGA were directly associated with the LF/HF ratio (β=0.96±0.02; $p<0.0001$, 0.42±0.10; $p<0.0001$ and 0.83±0.09; $p<0.0001$, respectively). Changes in BILAG were inversely associated with changes in RMSSD and pNN50 (β=-7.0±1.9; p=0.003 and -1.6±0.04; $p<0.0001$, respectively). BILAG changes were also directly associated with changes in the LF/HF ratio (β=0.78±0.05; $p<0.0001$). Categorical improvement, defined as $\geq$1 letter grade improvement in BILAG and no new BILAG A or B scores, occurred in 77 (19%) visit pairs (group 1) and either no improvement or worsening in 335 (81%) group 2. RMSSD and HF increased in group 1 compared to group 2 (group difference=-33.3±10.1; p=0.001 and -30.9±4.1; $p<0.0001$, respectively), and the LF/HF ratio decreased in group 1 compared to group 2 (group difference=3.1±0.8; p=0.002). Changes in Physical Component Summary (PCS) of SF36v2 were inversely related to changes in SLEDAI and PGA (β=-0.39±0.14; p=0.006 and -0.19±0.02; $p<0.0001$, respectively). Changes in Mental Component Summary (MCS) were inversely related to changes in BILAG, SLEDAI and PGA (β=-0.23±0.07; p=0.0001, -0.31±0.10; p=0.002 and -0.08±0.03; p=0.008, respectively). PCS was related to HF (β=0.67±0.28, p=0.01) whereas MCS was inversely related to the LF/HF ratio (β=-0.11±0.03, p=0.0001). Changes in PCS were related to changes in pNN50 (β=0.21±0.05, p=0.0001) and changes in MCS were related to changes in HF (β=1.57±0.18; $p<0.0001$).
Conclusions: Changes in HRV reflect changes in clinical status and patient reported outcomes in patients with SLE. These data suggest that HRV may be a simple non-invasive tool used to gage or predict clinical improvement in SLE. Further studies are warranted.

AB0476 INNER EAR INVOLVEMENT IN SYSTEMIC RHEUMATIC DISEASES

G. Tsirves[1], P.V. Voulgari[2], D. Archimandriti[2], E. Pelechas[2], D. Asimakopoulos[1], A.A. Drosos[2]. *[1]Otorhinolaryngology Clinic; [2]Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece*

Background: Patients with systemic rheumatic diseases have increased prevalence of sensorineural hearing loss (SNHL). Detection of cochlin specific antibodies has been reported in patients with idiopatic sensorineural hearing loss. Interestingly, cochlin has been shown a stronger link to autoimmune hearing loss.
Objectives: Objective of this cross-sectional study was to calculate the prevalence of SNHL in patients with systemic rheumatic diseases and to detect human cochlin antibodies in their sera.
Methods: This was a prospective study. Patients older that 18 year old who gave informed consent and fulfilled the criteria of American College of Rheumatology for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), Sjogren's syndrome (SS) and systemic sclerosis (SSc) were included. Complete head and neck clinical examination was performed, including otoscopy, nasendoscopy and hearing investigation with pure tone audiometry (250Hz -8000Hz). All medical treatments as well as Disease activity score (DAS) 28 for RA and SLE disease activity index (SLEDAI) for SLE were documented. An average tone loss was calculated, taking as a starting point the loss in dB at various frequencies according the American Committee on Hearing and Equilibrium Guidelines for Meniere's disease and also recommendation 02/1 of "Bureau International d' Audiophonologie" (BIAP). Blood samples of the patients were tested for the presence of IgG anti-cochline antibodies (COCH-IgG). The results were compared with those of sex and age-matched healthy subjects.
Results: We studied 133 patients (60 with RA, 41 with SLE, 24 with SS and 8 with SSc) and 133 healthy subjects.61.4% of patients reported vertigo, 41% hyperacousis, 39% hearing loss, 38% tinnitus, 37.9% headache and 2.1% sensation of ear pressure with unremarkable otoscopy. The prevalence of SNL was increased in patients affected by RA, SLE, SS and SSc in comparison to healthy controls (66.6%, 31.71%, 54.17% and 75% respectively). The average hearing thresholds (AHT) calculated using BIAP recommendation 02/1 were significantly increased in RA compared to SLE. AHT were also increased in patients with RA and secondary SS but without statistical significance compared to RA patients. There was a statistically significant correlation between AHT and DAS28 in RA. No correlation observed between AHT and SLEDAI. COCH-IgG were detected in two samples (one patient with RA and one with RA and SS).
Conclusions: Cochlin has been shown to have a stronger link to autoimmune hearing loss, but our study concluded no correlation of hearing loss with human cochlin IgG (COCH). Additional prospective studies are needed to elucidate its pathogenesis.

AB0477 VITAMIN D STATUS, SYSTEMIC LUPUS ERYTHEMATOSUS ACTIVITY AND ENDOTHELIAL DYSFUNCTION

A. Caraba, V. Crisan. *Internal Medicine-Rheumatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania*

Background: Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease, in which cardiovascular complications due to premature and accelerated atherosclerosis represent a serious problem. Endothelial dysfunction is the first step in the atherosclerosis development. Low levels of vitamin D have a high prevalence in lupus patients, correlating with high prevalence of cardiovascular diseases in these patients.
Objectives: The aim of this study was represented by the assessment of endothelial dysfunction in patients with active systemic lupus erythematosus, and correlations of this with SLE activity and vitamin D status.
Methods: The study was performed on a group of 35 female patients with active systemic lupus erythematosus. In all the patients were assessed: SLE activity using SLEDAI (SLE Disease Activity Index), vitamin D status and endothelial dysfunction by means of flow-mediated dilation (FMD). Data were presented as mean ± standard deviation. The statistically analysis was performed using Pearson's test, $p<0.05$ was considered statistically significant.
Results: The mean age of the studied patients was 33.68±8.55 years, and the average duration of SLE was 8.91±5.29 years. The assessed parameters had the values: SLEDAI 9.02±4.51, vitamin D 12.79±2.45 μg/l (4 patients had vitamin D deficiency, and 31 patients had vitamin D insufficiency), and FMD 9.26±2.34%. There were significant correlations between vitamin D levels and FMD (r =0.4517, p=0.003), and between vitamin D levels and SLEDAI (r = -0.6297, p=0.00025).
Conclusions: Low values of vitamin D levels were present in all the studied patients, correlating with the systemic lupus erythematosus activity, and endothelial dysfunction.

AB0478 COMPARATIVE STUDY BETWEEN PATIENTS WITH NORMAL AND OVERWEIGHT IN A COHORT OF SYSTEMIC LUPUS ERITEMATHOSUS FROM ARGENTINA

A.M. Beron, S. Sapag Duran, M. Garcia Carrasco, A.M. Sapag Duran, G. Medina, G. Nasswetter, D. Dubinsky. *Rheumatology, Clinical Hospital "Jose de San Martin", University of Buenos Aires., CABA, Argentina*

Background: Systemic lupus erythematous (SLE) have an increase cardiovascular risk, worsened by overweight and obesity. Increased BMI is associated with other severe complications and comorbidities as lupus nephritis, hypertension, insulin resistance and dyslipemia. Body weight is a modifiable risk factor.
Objectives: To determine the frequency of overweight and obesity in patients with SLE and their impact on this disease

Methods: Descriptive, cross-sectional study. We reviewed the medical records of outpatients with SLE (ACR 1997) who were seen since 2014 to 2016 in the Clinical Hospital of Buenos Aires, Argentina.
We evaluated sex, age, disease duration, obstetric history, use and doses of oral corticosteroids, BMI, 25 OH vitamin D and educational level. Disease activity was scored by SLEDAI. Scores ≥4 were classified as active.
The patients were classified into 2 groups, according to BMI: normal weight (NW) (19–25), overweight and obesity (≥25).
Results: One hundred and sixty two of 230 were evaluated. Sixty-eight patients were excluded due to lack of data. 157 (97%) were women. Mean age for both sexes was 40.6±14.3 years (p 0.70). Means of: SLEDAI 4.3±4.47 (54.9% had SLEDAI ≥4), IMC: 27.04±5.22 (56% had a BMI ≥25) and 25-hidroxivitamin D was 25.15±9.0.
Relation between 2 groups, according to BMI: 84.5% whom were in NW group have received steroids at some point vs 95.6% in BMI≥25 group (p 0.02). Mean steroids doses: BMI ≥25: 9.53±10.98 vs 5.0±7.2 in NW group (p 0.04). Multivariate analysis showed that BMI ≥25 continued significantly associated with SLE duration, independently of the steroids use and other variables.
25 OH vitamin D tended to be lower in BMI ≥25 vs NW, but no significant differences (24.53±9.91 vs 25.50±9.85) (p=0.071)

Table 1. In the multivariate analysis, Number of pregnancies was the only one variable remained significant (OR: 0.78, IC 95%: 0.63–0.98) (p=0.03)

Variable	IMC ? 25 (n: 71)	IMC ≥25 (n: 91)	P
Duration (months) Median (rank)	60 (1–384)	84 (2–480)	0,02
Pregnancies mean (SD)	1,20±1,62	2,64±2,84	0,0
Menopause (%)	27 (38,5)	51 (58,6)	0,009
Abdominal perimeter mean (SD)	88±8,3	99±11,9	0,0
Depression (%)	9 (12,5)	24 (26,6)	0,02
Chronic renal failure (%)	2 (2,7)	9 (10)	0,03
SLEDAI ≥4 (%)	33 (45,8)	56 (62,2)	0,02
SLICC mean (SD)	0,30±0.55	1,3±1,3	0,0
SLICC ≥1 (%)	18 (25)	64 (71,1)	0,0
Arterial hypertension (%)	12 (16,6)	32 (35,5)	0,003
Grade and University Studies (%)	32 (45)	19 (20)	0,004

Conclusions: Over a half of our cohort had BMI ≥25 and was characterized by older age, more frequent menopause, longer course of the disease, increased steroid use and lower educational level. Depression and hypertension were the statistically more frequent comorbidities found. Obesity was associated with more activity and accrual damage including chronic renal disease.

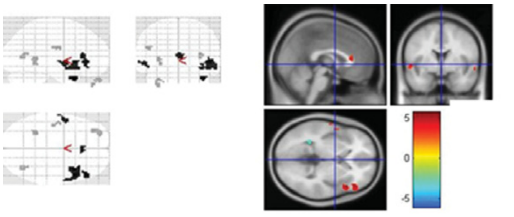
AB0479 THE ROLE OF ANTIBODIES TO XANTHINE OXIDASE AND ADENOSINE DEAMINASE IN THE DEVELOPMENT OF ANTI-PHOSPHOLIPID SYNDROME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS



A.V. Aleksandrov, I.Y. Alekhina, N.V. Aleksandrova, N.V. Nenasheva, V.A. Aleksandrov. *Federal State Budgetary Science Institution Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation*

Objectives: The aim of the research was to study the processes of formation of antibodies to the enzyme purine metabolism (PM) - xanthine oxidase (XO) and adenosine deaminase (ADA) - in patients with systemic lupus erythematosus (SLE) with laboratory indicants of secondary antiphospholipid syndrome (APS).
Methods: 30 healthy people and 60 SLE patients with different clinical manifestations were included in this research. Antibodies to the investigated enzymes were determined in the procedure of an indirect ELISA-test using immobilized form of the corresponding enzyme as antigen array (We have developed this technique). The results of the detection of antibodies to the XO (anti-XO), antibodies to ADA (anti-ADA) and antibodies to the ADC (anti-ADC) were recorded on a spectrophotometer at a wavelength of 450 nm. b_2-glycoprotein-I-dependent (b_2GP-I) to the phospholipid antibodies (aPL) class IgM and IgG were determined by using a commercial test kit “Anti-Phospholipid Screen IgG/IgM” (Orgentec). The levels of IgG aPL/IgM did not exceed 10 GPL/MPL-U/ml in the group of healthy individuals.
Results: According to the survey the number of SLE patients with elevated levels of anti-ADA was 51.6%, the anti-XO - 53.3%. There has been a number of statistically significant correlations between the presence of anti-XO with clinical and laboratory parameters: the level of circulating immune complexes (r=0.297, p=0.024), with a hemoglobin level (r= -0.286, p=0.042), the number of lymphocytes (r= -0.29, p=0.033), and platelets (r= -0,308, p=0.028). In 25 (41.7%) patients with SLE aPL IgG class were detected, in 19 (31.7%) - aPL IgM were detected. As a result of multivariate dispersive analysis leading role of aPL in the development of APS has been established (F=52,5, p<0,001).
In positive for the presence of anti-ADA patients with SLE aPL IgG class (but not aPL class IgM) were detected more frequently and at higher titer than in SLE patients, without this type of antibodies (p=0.029). Joint detection of anti-ADA and aPL in patients with SLE manifestations was associated with cytopenia (p=0.019, Fisher’s exact test). It was also noted that elevated levels of anti-XO were significantly more frequently detected in patients which were also positive for the presence of aPL IgG class (p=0.036) and aPL IgM class (p=0.044). Comparison of the groups of patients with SLE, the positive and negative for the presence of anti-XO, demonstrated a statistically significant increase in the frequency of signs of vasculopathy (chi-square=4.4, p=0.042).
Considering a direct link between the level of anti-XO and the level of the CIC we can assume that the anti-XO in the composition of the CIC have some impact on the transformation of “xanthine oxidase ↔ xanthine dehydrogenase” in the direction of increasing the formation of XO and, as a consequence, a significant increase of generation of superoxide radicals, release of calcium ions into the extracellular space, and, in addition, platelet aggregation and increased blood viscosity.
Conclusions: Antibodies to enzymes PM may be a factor in the development and maintenance of vascular disorders in patients with SLE, and their detection can be used as an additional test in the complex diagnosis of SLE with symptoms of APS.

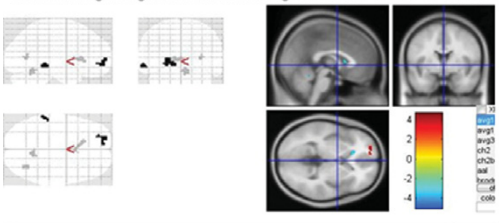
AB0480 A FUNCTIONAL MAGNETIC RESONANCE IMAGING STUDY ON THE PSYCHOPATHOLOGY OF PATIENTS WITH PRIMARY SJOGREN’S SYNDROME AND ANXIETY DISORDER



B. Cui, Y. Liu. *West China Hospital, Chengdu, China*

Background: Sjogren syndrome (SS) is a chronic systemic autoimmune disease characterized by exocrine gland inflammation and symptoms of oral and ocular dryness. Anxiety affects as many as 50–70% of persons living with SS. While anxiety is commonly experienced, very little is known concerning the mechanisms of cognitive dysfuction in SS.
Objectives: To reveal the psychopathology of patients with Sjogren’s syndrome and anxiety disorder.
Methods: 12 patients with pSS and anxiety disorder (SAS≥50), 11 patients with pSS, and 10 healthy controls were recruited. (1) Self-rating Anxiety Scale (SAS) were used to assess anxiety level of participations. All the subjects went through functional magnetic resonance imaging (fMRI) while listening actively to neutral words, negative words and negative words alternating with neutral ones.
Results: When subjects listened to neutral words alternating with no words, prefrontal cortex and BA21 were active in patients with pSS and anxiety disorder. When subjects listened to negative words alternating with no words, patients showed increased activity in prefrontal cortex, BA21, anterior cingulate and fusiform. Furthermore, when subjects listen to negative words alternating with neutral words, patients with pSS and anxiety disorder showed more increased

10	40	3.78	0.004	-24	51	-3
	39	3.72	0.004	-9	18	6
47	15	4.39	0.004	-31	27	0

Fig.2 The results of comparison between pSS with anxiety group and health controls, while listening to negative words alternating with neutral words. （P<0.005）

activity in prefrontal cortex, anterior cingulate, and caudate nucleus than that of other two groups.

Conclusions: Anxiety disorder commonly exists in patients with pSS. The pathology of this psychological symptom is poorly understood, which may be one of manifestation of nervous system involvement. fMRI may provide a novel insight into the pathological process accompanying subtle psychiatric disorders commonly experienced by patients with pSS.

AB0481 SUBCLINICAL NEUROPSYCHIATRIC DYSFUNCTIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS -A HOSPITAL BASED STUDY

C.S. Morad[1], H.E. Mansour[1], K.A. Ahmed[2], S.G. Arafa[1]. *[1]Internal medicine and Rheumatology; [2]Radiodiagnosis, Faculty of Medicine, Ain Shams University, Cairo, Egypt*

Background: Up to 50% of systemic lupus erythematosus (SLE) patients experience neuropsychiatric manifestations (NP) during the disease course but many might have subclinical neuropsychiatric lupus (NPL), causing significant increase in morbidity and mortality. The pathogenesis of NPL is multifactorial and involves various inflammatory cytokines, autoantibodies and immune complexes[1].

Objectives: To examine for the presence of subclinical NPL, cerebral atherosclerosis and their correlation - if any to brain magnetic resonance imaging (MRI/MRA) findings and SLE disease activity.

Methods: This is a cross sectional observational study that included thirty adult female SLE patients fulfilling the updated ACR classification criteria for SLE[2]. All were subjected to: detailed history taking, thorough clinical examination, assessment of SLE disease activity using Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score, psychometric evaluations using the Modified Mini-Mental State Examination (MMSE) to assess for cognitive dysfunction, Hamilton Depression Rating Scale (HAM-D) and Hamilton Anxiety Scale (HAM-A) to assess for the presence of depression and anxiety respectively. CBC, ESR, full blood chemistry, urine analysis, protein/creatinine ratio, brain MRI/MRA.

Results: The mean age was 31.7 years (22 to 40 years). 12 patients (40%) had positive antiphospholipid (APL) antibodies with or without clinically evident antiphospholipid syndrome (APS). 22/30 (73.33%) had different NP manifestations, 13 had depression (43.3%), 15 had anxiety (50%) and 16 had cognitive impairment (53.3%). All patients with depression and anxiety, 87.5% of patients with dementia had MRI abnormalities. All SLE patients with positive aPL were found to have MRI abnormalities, while MRI abnormalities were found in only 8 SLE patients with negative aPL (100% vs. 44.4%) ($p<0.001$). There was a statistically significant correlation between SLE disease activity and both NP manifestations and MRI/MRA abnormalities. aPL antibodies also had a significant correlation with NP manifestations. MRI abnormalities included discrete white matter lesions (60%), cortical atrophy (25%) and gross infarctions (15%). MRA revealed atherosclerotic changes of one or more of the large intracranial vessels in (27.27%) of NPSL patients.

Conclusions: Significant number of SLE patients without overt neuropsychiatric manifestations were found to have subclinical cerebrovascular and cognitive dysfunctions, depression and anxiety by simple bedside questionnaires. SLE disease activity positively correlates with neuropsychiatric manifestations. The presence of APL antibodies is a strong risk factor for developing NPSL. Several distinct brain MRI patterns were observed in patients with active NPSL, suggestive of different pathogenetic mechanisms.

AB0482 ELEVATION OF SERUM PROPROTEIN CONVERTASE SUBTILISIN/KEXIN TYPE 9 (PCSK9) CONCENTRATIONS AND ITS CORRELATION WITH C-REACTIVE PROTEIN, BUT NOT ATHEROGENIC LIPIDS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Fang[1], L. Huang[2], T. Luo[3], X. Chen[1], L. Lin[1]. *[1]Rheumatism Department; [2]Nuclear Medicine Department; [3]Ultrasonic Cardiogram Department, Second affiliated hosptial of Fujian Medical University, Quanzhou, China*

Background: Patients with systemic lupus erythematosus (SLE) have a tendency of accelerated atherosclerosis with controversial benefits from statin. This phenomenon can only partly be explained by traditional risk factors for cardiovascular disease. Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a serine protease associated with cardiovascular risk that not only regulates cholesterol metabolism, but acts as a critical regulator of inflammatory reaction. PCSK9 inhibitors were also highly promising drugs bringing added cardiovascular benefit when administered with statin [1] [2].

Objectives: The present study firstly aimed to compare serum PCSK9 levels in SLE patients and healthy controls. The association between PCSK9 concentrations with atherogenic lipids and C-reactive protein (CRP) in SLE patients was also analyzed.

Methods: 77 individuals encompassed; 47 patients with SLE and 30 age- and sex-matched controls. Serum PCSK9, lipoproteins concentrations and CRP levels were assessed in patients and controls. Individuals with history of smoking, diabetes, infection, tumor and statin use were excluded.

Results: Serum PCSK9 levels were significantly elevated in patients with SLE, compared with healthy controls ($p=0.034$). PCSK9 positively correlated with serum levels of CRP ($r_s=0.351$, $p=0.016$); The tendency seemed more significant in female patients ($r_s=0.487$, $p=0.001$); No correlation with statistical significance between PCSK9 levels with disease activity (SLEDAI) or serum lipids parameter was found ($p>0.05$, all) (Table 1).

Table 1. Characteristics of patients and controls and correlational analysis of PCSK9 levels and disease parameters in SLE patients. Data are shown as number or median (interquartile range), respectively

Variables	Healthy controls	SLE	r_s, p-value
Number	30	47	NA
Female/Male	24/6	42/5	NA
Age (years)	30.5 (26–39.5)	33 (28–42)	-0.014, 0.927
PCSK9 (ng/ml)	292.44 (199.87–499.93)	390.53 (305.37–525.92)	NA
SLEDAI	NA	6 (4–8)	0.092, 0.539
Cholesterol (mmol/l)	NA	4.50 (3.90–5.40)	-0.012, 0.935
LDL cholesterol (mmol/l)	NA	2.38 (1.74–3.19)	0.002, 0.989
ApoA1 (g/l)	NA	1.30 (0.97–1.59)	0.011, 0.943
ApoB (g/l)	NA	0.79 (0.63–0.94)	0.181, 0.223
Triglycerides (mmol/l)	NA	1.26 (0.79–1.64)	-0.020, 0.896
HDL cholesterol (mmol/l)	NA	1.49 (1.22–1.86)	-0.112, 0.453
CRP (mg/l)	NA	1.31 (0.50–3.60)	0.351, 0.016
CRP (mg/l) in female patients	NA	1.195 (0.500–3.568)	0.487, 0.001

Conclusions: Elevation of PCSK9 was observed in patients with SLE and correlated with CRP but not atherogenic lipids, particularly in female patients. The result was indicative of pathogenic role of PCSK9 in the low-grade inflammation which promotes the atherogenic process in SLE patients.

AB0483 RESPONSIVENESS OF LUPUS IMPACT TRACKER AMONG CHINESE PATIENTS WITH LUPUS

C.C. Mok[1], J. Block[2], M. Jolly[2]. *[1]Medicine, Tuen Mun Hospital, HK, Hong Kong; [2]Medicine and Behavioral Sciences, Rush University Medical Center, Chicago, United States*

Background: Lupus Impact Tracker (LIT), a 10 item, patient reported outcome tool for patients with systemic lupus erythematosus (SLE) has undergone psychometric validation and responsiveness studies in the US and Europe.

Objectives: To report results on responsiveness of Lupus Impact Tracker among Chinese patients with SLE.

Methods: 430 patients with SLE meeting the ACR classification criteria were recruited in Hong Kong, China at a single center. LIT scores from two visits one year apart were analyzed for responsiveness and Minimal Clinically Important

Difference (MCID) against patient report and physician assessed anchors of changes in health. Two patient reported anchors were used (Global change in health and item 2 of Short Form 36 form). Physician assessed anchors of change in health were disease activity (Physician global assessment-PGA, SELENA-SLEDAI) and damage (SLICC-SDI/ACR). Change in PGA of ≥0.3 and SELENA-SLEDAI of ≥4 in either direction was used to define worsening in disease activity. Analysis of variance was used to compare changes in LIT score against the anchors.

Results: Mean (SD) age of participants was 42 (14) years. Ninety five percent were women. Mean (SD) PGA, SELENA-SLEDAI and SDI at baseline were 0.5 (0.5), 2.9 (3.0) and 0.7 (1.2) respectively. Mean (SD) LIT score at baseline was 27.8 (18.2). Mean changes in LIT scores in response to worsening, no change or improvement based on patient report and physician assessments are shown in Table 1. MCID for "some worsening" were -4.0 and -3.9 on patient reported health question and SF36 question 2 respectively.

Table 1: Responsiveness of LIT to patient and physician based anchors in SLE.

Anchor	Change	N	Mean Change In LIT	p-value
Patient Reported Change				
SF36-Q2	Worse	118	-4.7	<0.001
	No Change	155	0.3	
	Much Better	157	2.5	
Global Change In Health Status	Worse	118	-4.7	<0.001
	No Change	155	0.3	
	Better	157	2.5	
Patient Assessed Change				
PGA	Increase of ≥0.3	72	-2.8	0.02
	Stable	251	-1.0	
	Decrease of ≥0.3	104	2.7	
SELENA- SLEDAI	Increase of ≥4	49	-3.5	0.005
	Stable	340	-0.6	
	Decrease of ≥4	41	6.0	
SDI	Unchanged	405	0.1	0.005
	Increase of ≥ 1.0	21	-8.7	

Conclusions: LIT shows responsiveness to changes in both patient-reported and physician assessed changes in health status among Chinese SLE patients.

AB0484 LUPUS NEHRITIS AND PREGNANCY: MATERNAL AND FETAL OUTCOME

P.B. Alba [1], C. Otaduy [1], C.A. Gobbi [1], A. Alvarez [2], A. Albiero [3], E.H. Albiero [1], M.L. Propato [2], M.A. Yorio [1]. *[1] Rheumatology, Córdoba State University; [2] Rheumatology, Hospital Materno Neonatal; [3] Rheumatology, Hospital Córdoba, Córdoba, Argentina*

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that primarily affects women during their reproductive years. The presence of Lupus nephritis (LN) may result in an increased risk of disease flare and adverse maternal and fetal outcomes, such as preeclampsia, fetal loss, and preterm delivery

Objectives: The purpose of this work is to evaluate pregnancy outcome in SLE patients with previous diagnosis of LN.

Methods: We retrospectively studied SLE patients according 1997 ACR criteria with previous diagnosis of LN by renal biopsy who attended to Materno Neonatal Hospital during the last 5 years. We evaluated demographic, clinical, laboratory and obstetric data. Renal biopsies were classified according ISN/RNP 2004. Lupus activity was evaluated by modified pregnancy SELENA SLEDAI score at the conception and during pregnancy. Maternal complications were evaluated: Preeclampsia, HELLP, Gestational Diabetes, Premature Rupture of the membranes, arterial and venous thrombosis, and others. Fetal outcome was evaluated as live birth, gestational age and weight at birth.

Results: 44 pregnancies in 32 patients were included. Maternal mean age was 22,68 years old, mean duration SLE was 7.8 years and 22% had antiphospholipid syndrome (APS), 62.5% were from Córdoba city, 84.3% did not have health insurance, and they have mean previous pregnancies of 2 with 1 live birth. Maternal complications were: Pre eclampsia in 22.7% of patients, Preterm delivery in 20.45% of patients, Premature rupture of the membranes in 6.8%, Gestational Diabetes in 2.27% of patients. 14 patients had normal labour, 29 cesarean section and 1 abortion. 97% (n=42) of patiens have live birth with mean gestational age of 36 weeks with mean weight at birth of 2.399 g. and there was no maternal mortality.

Table 1. Maternal Complications

Preeclampsia	10 (22,7%)
Pre term delivery	9 (20,4%)
Premature rupture of the membranes	3 (6,8%)
Gestacional diabetes	1 (2,3%)
Mortality	0
Renal relapse	8 (18,1)
Renal Insufficiency	2 (4,5%)

Conclusions: SLE patients with previous LN had a good maternal and fetal outcome in this study.

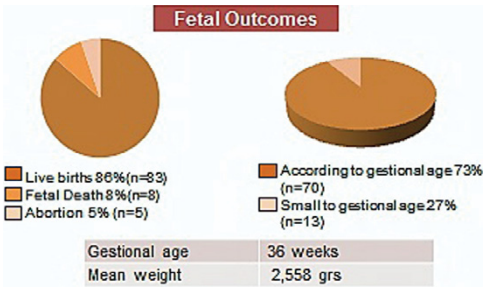
AB0485 PRIMARY ANTIPHOSPHOLIPID SYNDROME: MATERNAL AND FETAL OUTCOME

C. Otaduy [1], P.B. Alba [1], C.A. Gobbi [1], A. Alvarez [2], A. Albiero [3], E.H. Albiero [1], M.L. Propato [2], M.A. Yorio [1]. *[1] Rheumatology, Córdoba State University; [2] Rheumatology, Hospital Materno Neonatal; [3] Rheumatology, Hospital Córdoba, Córdoba, Argentina*

Background: Antiphospholipid antibodies (APLAs) have been associated with pregnancy loss and other obstetric complications, such as pre-eclampsia, fetal growth restriction and preterm delivery.



Objectives: The purpose of this work is to evaluate maternal and fetal pregnancy outcome in Primary Antiphospholipid Syndrome (PAPS).

Methods: We retrospectively studied PAPS patients according to Sydney Criteria who are attended to Materno Neonatal Hospital during the last 8 years. We evaluated demographic, obstetric and thrombotic clinical data. Maternal complications were evaluated: Preeclampsia, HELLP, Gestational Diabetes, Premature rupture of fetal membranes, arterial and venous thrombosis, mortality, the way of end of pregnancy, and others. Fetal outcome was evaluated as live birth, gestational age and weight at birth.

Results: 96 pregnancies in 68 patients were included. Maternal mean age was 30,75 years old, 84% were from Córdoba city, 70.5% did not have health insurance, and they have mean previous pregnancies of 4 with 1 live birth. Maternal complications were: Pre eclampsia in 12 patients (12.5%), Preterm delivery in 6 patients (6.25%), Premature rupture of fetal membranes in 8 (8.33%), Gestational Diabetes in 7 (7.29%), Arterial Thrombosis in 2 (2.08%), Venous thrombosis in 3 (3.12%). 33,69% have normal labour and 66,33% cesarean section. 86% of patients have live birth with mean gestational age of 36 weeks with mean weight at birth of 2.558 g and 73% of patients according to gestational age.

Table 1. Maternal Complications

Pre Eclampsia	12 (12,5%)
Pre term delivery	6 (6,2%)
Premature rupture of fetal membranes	8 (8,2%)
Gestacional Diabetes	7 (7,3%)
Arterial Thrombosis	2 (2%)
Venous Thrombosis	3 (3,1%)
Notch	10 (10%)
Mortality	0

Conclusions: PAPS pregnancies patients had a good maternal and fetal outcome in this study.

AB0486 INCIDENCE OF VERTEBRAL FRACTURES: 8 YEARS FOLLOW-UP STUDY IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Mendoza Pinto [1,2], M.D.L.L. Leon Vazquez [3], A. Montiel Jarquin [4], H. Sandoval-Cruz [5], M.A. Buendía Luca [1], M. García-Carrasco [1,6]. *[1]Medicine School, BUAP; [2]Systemic Autoimmune Diseases Research, Hgr36-Cibior, IMSS; [3]Systemic Autoimmune Diseases Research, Hgr-36 Imss; [4]Hospital de Traumatología y Ortopedia, IMSS; [5]Radiology Unit, Hgr-36 Imss; [6]Systemic Autoimmune Disease Research Unit, Hgr36-Cibior, IMSS, Puebla, Mexico*

Background: Vertebral fractures (VF) are the hallmark of bone fragility. Patients with systemic lupus erythematosus (SLE) are at high risk of developing prevalent VF. Although several risk factors for VF in patients with SLE have been suggested, there is limited longitudinal supporting data in the literature.
Objectives: The aims of this study are to determine the incidence of VF and to evaluate possible associations between potential risk factors and the occurrence of VF in women with SLE.
Methods: Consecutive patients with SLE were enrolled in a prospective, observational study from 2006 to 2015. Information on potential risk factors, including demographics, clinical data and bone mineral density (BMD) at the lumbar spine and hip on dual-energy X-ray absorptiometry was collected at baseline and follow-up. Semi-quantitative analysis was used to determine incident VF on lateral thoracic and lumbar radiographs, defined as any vertebral body graded normal at baseline and at least mildly deformed (20–25% reduction or more in any vertebral height) during follow-up. Differences in baseline characteristics were assessed in patients with and without radiographic VF.
Statistical analysis: The Chi-square or Fisher's exact test, independent samples t-test, and Mann-Whitney U-test were used as appropriate to compare baseline characteristics of patients with and without prevalent or incident VF. Possible risk factors for incident VF were assessed by multivariate logistic regression analysis.
Results: Of 110 SLE patients included, with a median follow-up of 8 (IQR 8–9) years, 22 (20%) had radiographic VF at baseline; 35 (32%) patients had a new VF. The annual incidence rate of new morphometric VF was 3.5 (95% CI 2.4–4.91) per 100 patient/years. Most fractures were located in the mid-thoracic and thoracolumbar region of the spine. Table 1 shows sociodemographic and clinical differences between patients with and without VF. In the multivariable analysis, VF were significantly associated with baseline BMD at the total hip and longer disease duration. Cumulative glucocorticoid dose, postmenopausal status and previous prevalent VF were not associated with VF.

	Vertebral fractures		
	Yes (n= 35)	No (n=105)	p
Age, years, mean (SD)	44.1 ± 11.0	41.4 ± 11.8	0.272
BMI, kg/m^2, mean (SD)	27.1 ± 5.3	27.3 ± 3.9	0.871
Postmenopausal at baseline, n (%)	**22 (63)**	**30 (40)**	**0.021**
Disease duration, years, median (IQR)	**9.0 (5-14)**	**5.0 (3-12)**	**0.005**
Vertebral deformity at baseline, n (%)	9 (26)	13 (17)	0.317
25OHvitD levels, ng/mL, mean (SD)	20.8 ± 6.6	19.1 ± 7.0	0.407
SLICC/ACR DI, ≥1 n (%)	**21 (60)**	**29 (39)**	**0.042**
Cumulative dose of GCT, gram, median (IQR)	**16.2 (7-41)**	**9.9 (6-24)**	**0.037**
BMD lumbar spine, g/cm^2, mean (SD)	0.981 ± 0.222	1.039 ± 0.217	0.205
BMD total hip, g/cm^2, median (IQR)	**0.884 (0.844-1.025)**	**0.981 (0.914-1.055)**	**0.011**
Use of bisphosphonates during follow-up,	15 (43)	24 (32)	0.185

Conclusions: In this SLE cohort in daily clinical practice, radiographic VF were frequently present in SLE patients, especially those with longer disease duration and low hip BMD.

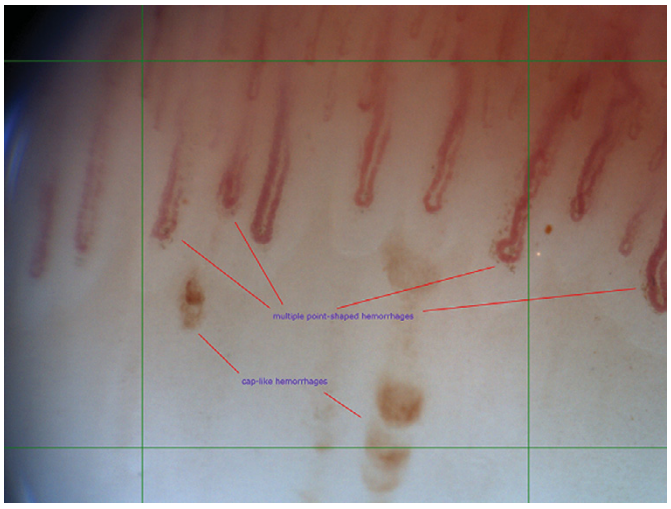
AB0487 NEUROLOGIC MANIFESTATIONS AND THEIR IMPACT ON CHRONIC DAMAGE IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: RESULT FROM A MONOCENTRIC COHORT

D. Mazilu [1], D. Potarniche [2], I. Saulescu [1], A. Borangiu [1], L. Groseanu [1], C. Constantinescu [1], V. Vlad [2], F. Berghea [1], V. Bojinca [1], D. Opris-Belinski [1], A. Balanescu [1], D. Predeteanu [1], R. Ionescu [1]. *[1]"Sfanta Maria" Clinical Hospital, "Carol Davila" University of Medicine, Bucharest, Romania; [2]"Sfanta Maria" Clinical Hospital, Bucharest, Romania*



Background: Antiphospholipid syndrome (APS) is an autoimmune disease with wide clinical features and cumulative damage. The nervous system involvement is very broad and severe.
Objectives: The aim of this study is to analyze the impact of neurologic manifestations on Damage Index in Patients with APS (DIAPS).
Methods: All consecutive patients known with APS were included in our monocentric cohort. Data on medical history, clinical manifestations, aPL profile and medication were collected. DIAPS score was used to measure damage in each patient.
Results: Seventy six patients with APS were included: 11 patients with primary APS and 65 patients with secondary APS, with mean disease duration of 9.59±7.39years. Overall,35 patients (46.1%) had neurologic manifestations. Their mean disease duration was 9.2±5.76 years. Seven patients had primary APS and 28 patients had secondary APS. Six patients were on chronic oral anticoagulant therapy and low dose aspirin, 12 patients on oral anticoagulant alone and 15 patients on low dose aspirin. Transient ischemic attack was the first manifestation of APS in 4 patients (11.42%) at mean age of 29.5±10.96 years. Their mean DIAPS value was 7.75±4.19. Ischemic stroke was the first APS manifestation in 12 patients (34.28%) at mean age of 40.08±16.31years, with DIAPS mean value of 7.41±3.67. All of these patients have neurological sequelaes. The DIAPS value was higher in patients with neurologic manifestations (3±2.9 vs 5.71±3.62, p=0.001) and DIAPS value correlated significantly to neurologic manifestations (R=0.416, p<0.000) reflecting it's impact on cumulative damage in APS patients.
Conclusions: Neurologic manifestations in APS patients have a great impact on cumulative damage especially in patients presenting with ischemic stroke or transient ischemic attack as the first manifestation of APS.

AB0488 CAPILLAROSCOPY FINDINGS IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS, A DUTCH EXPERIENCE OF 20 CHILDREN AND ADOLESCENTS

D. Schonenberg-Meinema [1], M. vd Berg [1], A. Nassar-Sheikh-Rashid [1], G. de Bree [2], L. Hak [3], M. van Onna [3], K. Melsens [4,5], M. Cutolo [6], T. Kuijpers [1], V. Smith [4,5]. *[1]Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Diseases; [2]Department of Infectious Diseases; [3]Department of Clinical Immunology and Rheumatology, AMC Amsterdam, Amsterdam, Netherlands; [4]Department of Rheumatology; [5]Department of Internal Medicine, Ghent University Hospital, Ghent, Belgium; [6]Research Laboratory and Academic Unit of Clinical Rheumatology, University of Genova, Genova, Italy*

Background: Capillaroscopy findings can be qualitatively described as: normal, microangiopathy (non-specific abnormalities) or scleroderma pattern (1). Capillary abnormalities, described in varying prevalence in patients with systemic lupus erythematosus (SLE), are mainly described as microangiopathy (2–4)
Objectives: To describe capillary characteristics in a cross-sectional cohort of patients with childhood-onset SLE (cSLE) by quantitative and qualitative assessment
Methods: Nailfold videocapillaroscopy (NVC) was performed in cSLE-patients (onset <18 years) with a x200 magnification lens (Optilia). The following capillaroscopic characteristics were evaluated per millimeter: density (compared to mean density known for age, sex and ethnicity) (5), number of abnormal shapes (as defined by the EULAR study group on microcirculation in Rheumatic Diseases (6)), giant capillaries (defined as apical diameter >50 mcm), maximum apical diameter (dilatations defined as apical diameter 20–50mcm) and microbleedings (large hemorrhages and small multiple point-shaped hemorrhages surrounding the capillary loop [image])
Results: 4063 capillaries from 20 patients with cSLE, were analyzed. All patients showed capillary abnormalities, 15% (n=3) showed a scleroderma-pattern. A lower mean density (mean 6.7, range 1.9–9.5) was seen in 55% (n=11), multiple

(>8 per patient) abnormal shapes in 60% (n=12), apical dilatations in 90% (n=18). Total count of large/small point shaped hemorrhages was 109/855, with a mean of 0.2/1.6 per analyzed image/per patient. These were detected in 85/85% of patients (n=17)

Conclusions: In this pilot (n=20) of cSLE patients, all showed capillary abnormalities. The most striking finding was the point-shaped bleeding surrounding the capillary, observed in 85% (n=17) of our patients. Prospective longitudinal cohort studies in children through the EULAR study group on microcirculation in Rheumatic diseases will elucidate whether specific findings can be found in child rheumatic diseases

AB0489 THE SLE-KEY® RULE-OUT TEST PERFORMS WELL AS AN AID IN CLINICAL PRACTICE

D. Massenburg, J. Oldenberg, A. Sell, T. Krause, A.F. Wells. *Rheumatology and Immunotherapy Center, Franklin, WI, United States*

Background: The SLE-key® test was developed by ImmunArray and was validated to rule out SLE with 94% sensitivity, 75% specificity and a negative predictive value (NPV) of 93%[1]. We reported earlier that the SLE-key® RuleOut test could aid in the diagnosis and disposition of a cohort of 55 patients in our clinical practice[2].
Objectives: We have now expanded this cohort and report here the usefulness of the SLE-key® test in aiding the management of a cohort of challenging and suspected SLE patients in a large clinical practice.
Methods: In patients referred to the Rheumatology and Immunotherapy Center, in Franklin, WI, results from the SLE-key® RuleOut test were included as part of the clinical evaluation. Serum samples were collected from individual subjects with informed consent and tested at VERACIS (Richmond, VA), using the SLE-Key® iCHIP®[1].
